Results: 41 patients were started on urgent PD during the study period. 12 patients (29%) were started as an inpatient and 29 patients (71%) as an outpatient. Median time from catheter placement to initiation of dialysis was 5 days. Major complications including peri-catheter leaks occurred in 3 patients (7.3%), catheter malfunction in 7 patients (17.1%), peritonitis within the first 4 weeks occurred in 3 patients (7.3%) and 2 patients (4.8%) developed an exit site infection. There was 1 patient that had a major bleeding event after catheter placement. 11 patients (27%) were admitted to the hospital within the first 30 days after urgent start PD. During the follow-up period, the median time patients were on PD after urgent start was 15.9 months, 16 patients (39.02%) transitioned to another form of RRT.

Conclusions: As has been demonstrated in previous studies urgent start PD remains a viable option for initiation of RRT and ensures increased access to home dialysis.

PO1269

Megaloblastic Anemia in a Patient on Peritoneal Dialysis Returning from Kenya

Marie-Laure Cambier,[1] Tom Robberechts,[1] Simon Planken,[2] Rembert A. Mertens,[2] Veerle Beckers,[3] Karlien Francois.[1] *[1]Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Division of Nephrology and Hypertension, Brussels, Belgium; [2]Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Division of Internal Medicine, Brussels, Belgium; [3]Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Division of Hematology, Brussels, Belgium*.

Introduction: We describe a case of atovaquone-proguanil (A-P)-related toxicity in a patient treated with peritoneal dialysis (PD).

Case Description: A 40-year old man treated with PD presented 48 hours after return from Kenya with a diffuse erythematous rash, dysphagia, fever and weight loss. Clinical evaluation showed a maintained general status, diffuse non-palpable purpura and tonsillopharyngitis. Laboratory testing revealed an elevated c-reactive protein and pancytopenia. Malaria prophylaxis (A-P) had been prescribed by his general practitioner and accurately taken. Malaria infection was ruled out through blood smear analysis. Broad serologic testing was negative. Empiric antibiotics were administered for tonsillopharyngitis. Bone marrow examination showed a megaloblastic anemia. Besides, he developed a diffuse nonscarring hair loss within weeks.

Discussion: DNA synthesis requires the presence of thymidylate, a nucleotide present in cells in rate-limiting amounts. Both folate and vitamin B12 are crucial cofactors in the thymidylate metabolism. Vitamin B12/folate deficiency or drugs affecting the vitamin B12/folate metabolism will slow down DNA synthesis. Proguanil is a folate analogue and its metabolites inhibit dihydrofolate reductase (DHFR), disrupting the thymidylate synthesis. The use of a fixed dose combination of A-P for malaria prophylaxis is contra-indicated in chronic kidney disease (CKD) because of proguanil accumulation in patients with kidney disease. Inhibited DNA synthesis manifests as megaloblastic anemia or as hair loss because of altered regulation of hair follicle growth cycle. DHFR inhibition was corrected by discontinuing A-P and by stimulating thymidylate synthesis through the administration of folinic acid. Supportive care included administration of Granulocyte–Colony Stimulating Factors, platelet and red blood cells transfusion. PD was continued. There was no indication in switching the patient to hemodialysis since extracorporeal clearance of proguanil is limited due to high protein binding (75%) and very high distribution volume (42L/kg).

Key message: The use of A-P is contra-indicated in CKD, due to the risk of proguanil accumulation and consecutive hematologic toxicity. Treatment is based on discontinuing the drug, administration of folinic acid and supportive care. Data suggest proguanil is poorly dialyzable.

PO1270

Serum Uric Acid, Mortality, and Decline of Residual Kidney Function in Patients Undergoing Chronic Peritoneal Dialysis

Inês D. Coelho,[2] Catuxa Rodriguez,[1] Ana Rodriguez-carmona,[1] Miguel Perez Fontan.[1] *[1]Complexo Hospitalario Universitario A Coruna, A Coruna, Spain; [2]Hospital Amato Lusitano, Castelo Branco, Portugal*.

Background: Hyperuricemia is known to be associated with cardiovascular (CV) events and mortality in patients with chronic kidney disease (CKD). However, in the particular case of patients on chronic dialysis, the relationship between serum uric acid (UA) levels and adverse outcomes is less consistent. The aim of this study was to identify the correlation between UA, on one side, and all-cause mortality (primary endpoint) and the rate of decline of residual kidney function (RKF) (secondary endpoint), on the other, among patients undergoing chronic peritoneal dialysis (PD).

Methods: We conducted a single centre, retrospective, observational cohort study of 682 patients who started PD between 1990 and 2019. We recorded essential demographic, clinical and laboratory data at baseline, 6, 12 and 24 months. We categorized the study population according to the median of mean UA levels during the first 3 months on PD (hyperuricemic/nonhyperuricemic) and, on the other side, according to any of: mean UA above/below median and treatment with UA lowering agents (gouty/nongouty). Cox proportional hazard model was applied to investigate the primary endpoint, and logistic regression analysis was used to assess the secondary endpoint.

Results: The study population included 407 males and 275 females, with a mean age of 60.2±14.6 years. Diabetes was present in 30.9% (n=211) of the patients. Mean follow-up on PD was 31,4±25,6 months. In univariate analysis, hyperuricemic patients presented higher levels of albumin (p=0.001), phosphate (p=0.003) and haemoglobin (p=0.002), and lower levels of cholesterol (p<0.001) and ferritin (p=0.039). In multivariate analysis, hyperuricemia was not an independent predictor of the rate of decline of RKF (HR 1.069; 95% CI:0.695 -1.644; p=0.761) or mortality (HR 0.997; 95% CI:0.738 -1.345; p=0.983), after controlling for age, diabetes, comorbidity and baseline RKF. The same applied when the study population was categorized as gouty/nongouty patients.

Conclusions: Higher UA levels were not independent predictors of mortality or the rate of decline of RKF, in our patients on PD. Patients presenting higher UA levels display a better nutritional and inflammatory profile than those with lower UA levels, which may suggest a component of reverse epidemiology.

PO1271

Phase Angle and Extracellular Mass to Body Cell Mass Ratio in Peritoneal Dialysis

Ana T. Domingos, Roberto C. Marques, Anabela M. Guedes, Céu Laranjo, Idalécio Bernardo, Pedro L. Neves. *Centro Hospitalar do Algarve EPE, Faro, Portugal*.

Background: Extracellular mass to body cell mass ratio (ECM/BCMr) is an important marker of malnutrition and a described independent predictor of long-term survival in Peritoneal Dialysis (PD). Its potential as dual index of wasting-fluid overload has been explored in Hemodialysis (HD). Phase angle (PA) – a predictor of long-term survival in dialysis – also appears as a potential nutritional-evaluation tool, with some authors defining protein-energy wasting as PA <4.5°. Higher ECM/BCMr would indicate either lower muscle mass and/or fluid overload. Its adequate cut-off point in PD remains unclear. Reports in CKD/HD-patients suggest a cut-off point ≥1.20, which added to a PA value <6, would work as markers of poor cardiovascular prognosis. But, how could these markers work in our population?

Methods: A prospective study included patients' first simultaneous acquisition of bioelectrical impedance analysis (BIA) and peritoneal equilibration test (PET). Phase angle at 50 kHz was recorded. Spearman correlation and T-student analysis were used.

Results: Were included 67 patients, with a mean age of 54.1±17.3 years, 59.7% men, 95.5% Caucasian, 84.4% hypertensive and 31.3% diabetic. Mean ECM/BCMr was 0.57±0.03 and mean PA was 5.12±0.3°. ECM/BCMr is positively correlated with age (r=0.293, p=0.017), pulse pressure (r=0.334, p=0.006=), ECW/TBW (r=0.948, p<0.01) and TBW/FFM (r=0.678, p<0.01), and inversely with albumin (r=-0.477, p=<0.01), uric acid (r=-0.287, p=0.027) and GFR (r=-0.308, p=0.012). A higher ECM/BCMr was observed among diabetics (0.59 vs. 0.56, p=0.011). PA is directly correlated with albumin (r=0.364, p=0.013) and GFR (r=0.291, p=0.049). Inverse correlations are described with ECW/TBW (r=-0.888, p<0.01), TBW/FFM (r=-0.674, p<0.01), ECM/BCMr (r=-0.909, p<0.01), age (r=-0.323, p=0.029) and diabetes (r=-0.312, p=0.035).

Conclusions: ECM/BCM and PA correlate with several volume and nutrition markers and work "contrariwise". Our population is prone to a poorer cardiovascular prognosis and eventually malnutrition, considering these cut-offs. Since BIA is a non-invasive, easily and periodically applied method, we believe that approval of these markers as dual index could be applied to PD, although admitting that this population would probably require new cut-offs.

PO1272

Association of Ambulatory Blood Pressure with All-Cause Mortality and Cardiovascular Outcomes in Peritoneal Dialysis Patients

Shuqi Dai, Yun Chen, Da Shang, Chuan-Ming Hao, Tongying Zhu. *Huashan Hospital Fudan University, Shanghai, China*.

Background: Ambulatory blood pressure monitoring (ABPM) is the gold standard for the diagnosis of hypertension, but its effects on all-cause mortality and cardiovascular outcomes in peritoneal dialysis (PD) patients remain uncertain. We aimed to investigate the association of ambulatory blood pressure and clinical outcomes in PD patients and to explain the underlying cause of the association.

Methods: A prospective, observational cohort study was conducted in PD patients enrolled from March 2001 to July 2018 and followed until October 2019. Blood pressure was evaluated using 24-hour ambulatory blood pressure monitoring. The endpoints included all-cause mortality, cardiovascular mortality and cardiovascular events. Multivariable Cox regression was used to identify the associations between ambulatory blood pressure and endpoints. Subsequently, multivariable logistic regression was conducted to identify factors associated with elevated pulse pressure.

Results: A total of 260 PD patients (154men, 59.2%) were recruited. The median follow-up duration was 40.7 months. Our studies revealed that pulse pressure was an independent predictor for all-cause mortality (HR, 1.018; 95%CI, 1.001-1.034; P=0.032), cardiovascular mortality (HR, 1.039; 95%CI, 1.017-1.061; P<0.001) and cardiovascular events (HR, 1.028; 95%CI, 1.011-1.046; P=0.001). Systolic blood pressure was an independent predictor of cardiovascular mortality (HR, 1.023; 95%CI, 1.007-1.040; P=0.005) and cardiovascular events (HR, 1.018; 95%CI, 1.006-1.030; P=0.003). The presence of vascular calcification (OR, 3.069; 95%CI, 1.632-5.772; P=0.001) and NT-proBNP (OR, 1.074; 95%CI, 1.026-1.124; P=0.002) were significantly associated with elevated pulse pressure.

Conclusions: 24-hour ambulatory pulse pressure is the most significant predictor of all blood pressure indicators for clinical outcomes in PD patients, and systolic blood pressure is an independent predictor for cardiovascular outcomes. Meanwhile, it suggests that the associations can be explained by vascular calcification and volume status in PD patients.

Differences in Protein Energy Wasting Indicators by Peritoneal Transport Type: A Cross-Sectional Study with Automated Peritoneal Dialysis Patients

Gabriela Leal,[1] Enzo C. Vasquez jiménez,[1] Ivan A. Osuna Padilla,[2] Bernardo Moguel,[1] Karla B. Cano Escobar.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico*.

Background: In chronic kidney disease (CKD) population protein energy wasting syndrome (PEW) is a prevalent problem with a multifactorial etiology (uremia, low energy and protein intake, basal energy expenditure increased, inflammation, metabolic acidosis, nutrient loss during renal replacement therapy (RRT). In peritoneal dialysis, patients with high peritoneal transport tend to have enhanced clearance of small solutes and shows low ultrafiltration capacity and higher inflammatory state, that impacts negatively in nutritional status. We evaluate the differences in nutritional status indicators and the association of high type transporter peritoneal with protein energy wasting (PEW) syndrome.

Methods: Cross-sectional study of a cohort of 36 patients with CKD on automated peritoneal dialysis (APD) [18 men, 18 women; age, 35.1 ± 13.3 years; dialysis duration, 7 (2-24) months]. Peritoneal transport characteristics were classified after a peritoneal equilibration test (PET). The PET study reasons were: baseline study, low ultrafiltration, underdialysis and after an event of peritonitis. Patients were classified according to peritoneal characteristics as a low transporter (LT) [low/low average] and as high transporter (HT) [high/high average transporters]. Weight and height were measured using standard procedures and body composition was assessed by multifrequency bioelectrical impedance analysis.

Results: HT individuals have lower albumin concentrations than LT (3.3 ± 0.42 vs 3.7 ± 0.39, p=0.026). Higher glucose absorption from dialysis solution (p=0.036) and a trend toward in higher c reactive protein plasma concentrations (p=0.089) was observed in the HT group. Higher prevalence of PEW condition (50 vs 23%) was observed in HT group without statistical significance (p=0.144). Higher malnutrition status using malnutrition inflammation score and PEW criteria was observed in HT-PET, without statistical significance.

Conclusions: HT peritoneal membrane confers a risk for hypoalbuminemia and inflammatory state in CKD patients on automated peritoneal dialysis. HT patients are at an increased risk of PEW. Intervention studies to elucidate the best nutritional approach should be designed to improve nutritional status in this population.

PO1274

Monitoring for Early Signs of Peritonitis in Patients Undergoing Peritoneal Dialysis

Michael A. Fischman,[3] Benjamin Briggs,[1] Glenn M. Chertow.[2] *[1]University of California San Francisco, San Francisco, CA; [2]Stanford University, Stanford, CA; [3]Southland Renal Medical Group, Long Beach, CA.*

Background: In 2019 the U.S. Department of Health and Human Services (HHS) established the "*Advancing American Kidney Health*" initiative, with a goal of increasing home-based dialysis from 12% to over 50% by 2025. To meet this goal, healthcare providers must address the common complications of peritoneal dialysis (PD) that contribute to modality failure and reluctance to opt for PD when starting dialysis. A sharp increase in PD utilization will require new approaches to reducing peritonitis and infection-related hospitalization.

Methods: Current strategies to detect peritonitis rely on crude signs and symptoms – predominantly cloudy spent dialysate and abdominal pain – an insensitive and non-specific approach. With the CloudCath monitoring system, the intent is to automatically and quantitively monitor the turbidity of the effluent fluid. We evaluated the CloudCath monitoring device which includes a cloud-based algorithmic solution for early detection of the patient condition associated with peritonitis.

Results: The device and algorithm were tested in a proof of concept clinical study where we found a discernable change in monitoring status in 99% of samples from patients with peritonitis, while changes in monitoring status were present in only 2% of samples from dialysis sessions of otherwise healthy PD patients. In some cases, the device was able to provide indicators of impending peritonitis, before standard laboratory values met accepted diagnostic criteria peritonitis. The device (CloudCath, San Francisco, CA) remotely monitors the patient's effluent dialysis fluid and sends alerts via the cloud to healthcare providers as soon as abnormal fluid characteristics are detected.

Conclusions: Early detection of peritonitis can lead to earlier clinical intervention and a better clinical response, relative to the current standard of care. Studies are ongoing to test the ability of the device to reduce morbidity, reduce infection-driven hospitalizations, and maintain PD as the patient's preferred dialysis modality.

Patient-Reported Factors and Peritonitis Risk: Results from the Optimizing Prevention of Peritoneal Dialysis-Associated Peritonitis in the US Study (OPPUS)

Keith McCullough,[1] Jeffrey Perl,[2] Muthana Al sahlawi,[2] Neil Boudville,[6] Yasuhiko Ito,[8] Talerngsak Kanjanabuch,[3] Beth M. Piraino,[4] Douglas E. Schaubel,[10] Martin J. Schreiber,[9] Isaac Teitelbaum,[5] Graham Woodrow,[7] Junhui Zhao,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Chulalongkorn University, Bangkok, Thailand; [4]University of Pittsburgh, Pittsburgh, PA; [5]University of Colorado, Denver, CO; [6]University of Western Australia, Perth, NSW, Australia; [7]St. James's University, Leeds, United Kingdom; [8]Aichi Medical University, Nagakute, Japan; [9]DaVita Inc, Denver, CO; [10]University of Pennsylvania, Philadelphia, PA.*

Background: Peritoneal dialysis (PD)-associated peritonitis has been found to be associated with depression in a single-center study (Troidle 2003). Using international multicenter PDOPPS data, we investigated the association of peritonitis with reported symptoms of depression via the Center for Epidemiologic Studies Depression Scale (CES-D) and quality of life (QoL) measures.

Methods: We used Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2018) data from Australia and New Zealand (A/NZ), Canada (CA), Japan (JP), Thailand (TH), the UK and US in cause-specific recurring-event survival models on peritonitis outcomes, stratified by previous episodes. Patient QoL) was estimated using the SF-12 Physical and Mental Health Composite Scores (PCS, MCS), and CES-D. Analyses were adjusted for age, years on PD, serum albumin level, residual urine, black race, sex, heart disease, diabetes, GI bleed, country, and prior peritonitis events.

Results: Peritonitis risk was associated with higher CES-D scores (p=.05). Patients who reported CES-D scores ≧ 15 had 27% higher peritonitis risk compared to patients who reported scores < 10. While associations were weaker for MCS (p=.69) and PCS (p=.40), scores that indicated the lowest tertile of QoL in these areas were associated with 6-7% higher peritonitis risk than scores in the highest tertile (table).

Conclusions: While the association between poorer QoL and peritonitis risk was weak and non-significant, the association between having greater symptoms of depression (per CES-D) and future peritonitis risk warrants further investigation, as depression may be a modifiable risk factor.

Image-Guided Percutaneous Peritoneal Dialysis Catheters: Greater Than the Sum of Their Parts

Anubha Mutneja,[1] Shilpa Arora,[2] Frank J. O Brien,[1] Daniel W. Coyne,[1] Daniel Picus.[1] *[1]Washington University in Saint Louis, Saint Louis, MO; [2]Rush University Medical Center, Chicago, IL.*

Background: Peritoneal Dialysis (PD) is a favored treatment modality for patients with end stage kidney disease. PD initiation depends on adequate and timely insertion of PD catheter. Most centers rely on laparoscopic insertion of PD catheters for PD initiation. Small studies indicate that image guided percutaneous (IGP) PD catheter insertion by interventional radiology (IR) may be non-inferior to laparoscopic catheters. However, there are limited data to compare IGP PD catheters to those inserted with laparoscopic technique. Hence, there are no definitive evidence based recommendations to support which technique may be superior. We conducted a retrospective analysis to compare complication rates and catheter survival in laparoscopic versus IGP PD catheter insertions.

Methods: Patients who underwent laparoscopic or IGP PD catheter placement from Jan 2014 to Aug 2019 were included in the analysis. IGP catheter placement employed

both fluoroscopic and ultrasound guidance. Primary outcome was rate of mechanical complications. Secondary outcome was death and transplant censored complication free catheter survival at 1 year.

Results: 244 PD catheters were placed at our institution during the study time period - 56 by laparoscopic surgical technique and 188 by IGP technique. Baseline characters including age, gender, race and BMI were similar in both groups. Surgical group consisted of 60% of patients with prior abdominal surgery as compared to 24% in the IR group OR 4.62 (2.35 – 9.09), P <0.0001. Mechanical complication rates were higher in the surgical group 29.6 % (18.0 – 43.6) versus 13.4 % (8.9 – 19.2) in the IR group (p 0.02). Death and transplant censored complication free catheter survival rate at one year was 87.8% (79.6 – 93.5) in the IR group and 73.3% (54.1 – 87.7) in the surgical group, P 0.063. In the surgical group, patients with higher BMI (> 35) had higher rate of complications 83.3% versus 22.9% in the low BMI (<35) group, OR 16.82 (1.77 – 159.58) P 0.014. In the IR group, catheter complication rates were not different in high versus low BMI groups, 5.0% vs 14.6% respectively, OR 0.31 (0.04- 2.4) P 0.26.

Conclusions: Our findings suggest IGP PD catheter is an effective option for PD initiation even in patients with high BMI and offers several advantages including ease of placement and lower recovery time.

PO1277

Repeat Peritonitis: A New Reality After *Staphylococcus aureus* Carriage Surveillance Implementation

Marina Reis, Ana Marta Gomes, Daniela Lopes, Clara Santos, João C. Fernandes. *Centro Hospitalar Vila Nova De Gaia/Espinho, Vila Nova de Gaia, Portugal.*

Background: Peritonitis is one of the major peritoneal dialysis complications and an important cause of technique failure. Notably, repeat peritonitis (RP) have substantial risk of developing further infection episodes that perpetuate peritoneal membrane damage. As S*taphylococcus aureus* (SA) is a major causative of RP, strategies such as *staphylococcus aureus* carriage surveillance (SACS) were implemented to decolonization of carriers in order to decrease SA PD infections. This study aims to describe repeat peritonitis clinical behavior and SACS influence on repeat peritonitis.

Methods: We developed one center retrospective study from 1998 to 2019 that compared RP episodes with a control group in terms of causative microorganisms, cure rate, catheter removal and permanent and temporary transfer to hemodialysis. We also compared the same data in RP episodes before and after SACS.

Results: Overall, RP were caused by gram positive microorganisms and had a significantly higher cure rate (97,1% *versus 67,3%*, $p<0.001$) and lower rate of hospitalization (11,4% versus 30,8%) than control group. After SACS, global peritonitis rate decreased (0,54 versus 0,35 episodes per patient-year), and RP rate increased (37,5% versus 7,4% p<0,001) as *Streptococci* became more frequent (56,7% versus 0,0% p 0,007) and *SA* less frequent (3,3% versus 60,0% p=0,001). Also, RP cure rate increased (100 % versus 80,0%, p 0,013) and permanent transfer to hemodialysis decreased (6,7%, versus 40,0%, p=0,03).

Conclusions: RP Group have more favorable results than control group that presented higher gram-negative peritonitis rate. After *SACS, Streptococci* became more frequent than *SA* in repeat group, peritonitis outcomes became more favorable but repeat peritonitis rate increased. We believe that as measures to prevent *SA* infections are implemented more programs will face this reality.

Repeat Peritonitis Causative Micoorganisms

	Before SACS (n=5)	After SACS (n=30)	Univariate Analysis p value
Streptococci spp	0	17, 56,7%	0,007
Coagulase-negative Staphylococcus	2, 40,0%	7, 23,3%	0,48
Staphylococcus aureus	3, 60,0%	1, 3,3%	0,001
Gram negative	0	1, 3,3%	0,55

PO1278

Strategies to Prevent Infection-Related Losses in US Peritoneal Dialysis Programs by More Actionable Predictive Data Reporting

Martin J. Schreiber, Michelle Cassin, Bram Van hout, Meredith L. Zywno, Tanvi Rane. *DaVita Inc, Denver, CO.*

Background: Peritoneal dialysis (PD)–associated peritonitis (PTN) accounts for a significant percentage of patients who transition to hemodialysis due to infection-related technique failure. Data reporting to individual PD home programs on PTN rates is designed to drive a proactive approach for optimizing infection rates in PD programs.

Methods: Between 2016 and 2020, a standardized reporting of PD-related PTN was carried out for 1487 affiliated PD programs across the United States (66,687 patients). Currently, PTN is reported on a 3-month rolling average for each program, with a current average PTN rate of 1 event/66 patient-months; 32% of PTN events fall into the hospitalization criterion bucket, with 3% already having cultures drawn prior to admission. Among all episodes with an associated hospitalization, 90% have an associated culture. For non-hospitalization events, 64% had an associated culture among other criteria for event diagnosis. Beginning in 2020, an effort to advance PTN preventive strategies with a more in-depth characterization of PTN events was implemented. These additional data included reporting rates as episodes/patient-year; PD catheter removal rate post PTN/infection; culture-negative PTN rate; organism-specific PTN reporting, with patient loss by organism; percentage of patients PTN-free (cumulative patient-months without an infection); percentage of patients with >1 episode/year; percentage of events occurring at <30 days or 30 to 90 days; PTN-associated hospitalization rates and length of stay; time at risk calculation (>day 1 training); and PTN-associated mortality rates.

Results: The table displays PTN from 2019 and preliminary results of the PTN additional data report from January through March 2020.

Conclusions: Reporting on PTN events with these additional metrics, on a program-by-program basis, could assist in aligning specific action steps critical to reducing infection related PD failure. These data could be incorporated into an early warning system to predict PD loss.

	2019	2020 (Jan - Mar)
Female, n (%)	1067 (41.9)	484 (42.5)
Observed PTN Events	3992	1140
PTN Rate Overall Annualized	1 per 5.9 patient years 0.17 per-patient per year	1 per 5.5 patient-years 0.18 per-patient per year
Patients with Culture-Negative PTN, n(%)	678 (17.0)	191 (16.8)
Gram-Positive PTN, n (%)	1448 (36.7)	450 (39.5)
PTN-Free Patients, n (%)	32,554 (90.8)	27,471 (96.3)
Fungal PTN, n (%)	79 (2.0)	25 (2.2)
Patients with Any Infection who Experience PD Failure within 30 Days, n (%)	905 (22.7)	200 (17.5)
Patients with Gram-Positive Infection who Experience PD Failure within 30 Days, n (%)	214 (14.8)	54 (12.0)

PO1279

Smoking Is a Risk Factor for Endogenous Peritonitis in Peritoneal Dialysis Patients

Kohsuke Terada, Akio Hirama, Yukinao Sakai. *Department of Nephrology, Graduate School of Medicine, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: Peritonitis is one of the most common complications observed in patients who are undergoing peritoneal dialysis (PD). PD-related peritonitis is associated with total mortality and transfer from PD to hemodialysis. Therefore, the prediction and prevention of peritonitis are important in PD patients. Exit-site infection (ESI) is an important risk factor for peritonitis. Whereas, there exists peritonitis without ESI and technical failure such as endogenous peritonitis in patients on PD. However, it is unclear that the prevention and prediction of endogenous peritonitis. Therefore, we investigated the risk of endogenous peritonitis in PD patients in this study.

Methods: We investigated the patients who were undergoing PD at our hospital and attended our hospital regularly from April 2015 to March 2020. We treated 22 cases of peritonitis in these patients; there were 18 cases of endogenous peritonitis without ESI and technical failure. We considered older age, female sex, obesity, diabetes mellitus, diverticulosis, and constipation as the important risk factors for endogenous peritonitis in patients undergoing PD. Therefore, we added these six factors as confounding factors with current and previous smoking history in the univariate logistic regression models. P values < 0.05 were considered statistically significant.

Results: We used univariate logistic regression models for the above-mentioned seven factors. Then, we defined age > 65 years as older age and body mass index > 25 as obesity. We defined patients who received purgative medication as having constipation. We found that diabetes mellitus ($p = 0.0106$), former or current smoking ($p = 0.0065$), and constipation ($p = 0.0065$) were statistically significant risk factors of endogenous peritonitis. Moreover, smoking and constipation were the most significant independent risk factors for endogenous peritonitis ($p = 0.0036$) in our multivariate logistic regression model.

Conclusions: In conclusion, smoking and constipation are significant independent risk factors of endogenous peritonitis in PD patients. The management of constipation and discontinuation of smoking may lower the risk of endogenous peritonitis in PD patients.

PO1280

Impact of Performing Cultures of Peritoneal Fluid Correctly on the Reduction of False-Positive and False-Negative Culture Rates in Patients on Peritoneal Dialysis (PD) Presenting with Peritonitis

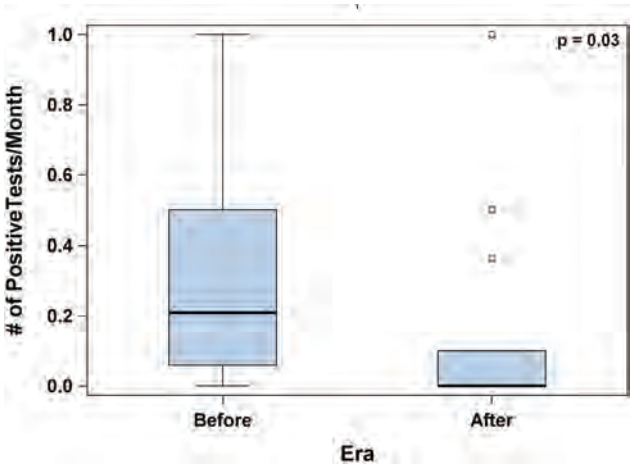
Sunil Sherchan, Jie Ouyang, Angelika C. Gruessner, Subodh J. Saggi. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: Peritonitis is feared complication of PD and reason for loss of peritoneal membrane function. It negatively impacts the Quality metrics of home program performance. Preliminary observations in 2013 showed a high failure rate for treating culture negative peritonitis. Intervention based on our root cause analysis from 07/30/2013 to 12/31/2019 done to address disparities in performing proper culture techniques within hospital systems and outpatient home dialysis ambulatory clinics

Methods: Prior to 07/30/2013 (5-10 ml) of a cloudy PD fluid was injected into an aerobic and an anaerobic blood culture bottle. After 07/30/2013 we implemented a policy whereby 50 ml of PD effluent was used for centrifugation and the pellet was injected into culture bottles to preferentially concentrate the inoculum. We queried our EMR after 7 years as rates of peritonitis are low across programs. Data was extracted using diagnostic codes and laboratory request. Data was analyzed using student's 2 sample t test, Kruswall-Wallis and Wilcoxian analysis

Results: Total of 41 observations met our inclusion criteria for retrospective analysis. We had 26 observations before and 15 observations after the policy implementation. Mean number of tests ordered after 07/30/2013 declined. Number of false positive tests declined and number of true negative tests and true positive tests increased (p=0.02), indicating increasing specificity and a more targeted antibiotic regimen rescuing peritoneal membrane function early. No direct impact on survival nor any impact on technique failure was observed

Conclusions: A gap in proper collection of PD fluid was identified. We educated all residents, renal fellows, nursing staff and microbiology laboratory staff across the entire health care systems, and created an order sets within EMR systems to close this gap



PO1281

A Rare Cause of Peritoneal Dialysis-Associated Peritonitis

Anup S. Jheeta, Jayakeerthi Rangaiah, John Clark, David Makanjuola, Subash Somalanka. *St Helier Hospital, Carshalton, United Kingdom*.

Introduction: Peritoneal dialysis (PD)-associated peritonitis (PDaP) caused by the non-tuberculous mycobacterium (***M)*** species *Mycobacterium abscessus* (***MA***) is emerging as a severe infective complication of PD. ***MA*** causes disseminated infection in immunocompromised individuals and is resistant to classical anti-tuberculous drugs and antibiotics. Diagnosis of ***MA*** PDaP is often delayed, as it presents as a culture –ve peritonitis. Successful treatment requires a PD catheter (PDC) removal in addition to multiple anti-microbial therapies and results in a permanent switch to haemodiafiltration (HDF).

Case Description: A 50-yr-old ♂, presented with fever, abdominal pain and cloudy PD fluid (PF) after returning from a holiday. He was systemically well apart from a tender abdomen. PD exit site and tunnel appeared normal. CRP was 80.7 mg/L (0-5 mg/L) and WCC was 6.0 x 10^9/L. Empirical treatment for PDaP was commenced with intra-peritoneal Vancomycin + Gentamicin. Microscopy of the PF showed a WCC of 155/µL and –ve Gram stain. ***MA*** was cultured and confirmed by whole-genome sequencing. Clarithromycin, Amikacin, Imipenem + Cilastatin and Tigecycline were commenced. Emergency PDC removal with a peritoneal washout was performed. He was switched to HDF. Day16, Clarithromycin was stopped due to a prolonged QTc interval. Day26, he developed hepatopathy that resolved after cessation of Tigecycline. Amikacin + Imipenem was continued for 5 months and switched to Amikacin + Linezolid. He developed Amikacin-induced tinnitus despite therapeutic dose monitoring. He completed 20 weeks of therapy and remains free of infection.

Discussion: ***MA*** is an environmental ***M*** that is found in water, soil, dust and is related to ***M*** causing tuberculosis and leprosy. It is known to contaminate devices and medical products. It causes lung infections in the immunocompromised. Our patient had no such history. The duration between PDC insertion and this episode was 2 yrs, making this an unlikely cause. The history did not reveal any reason for contracting this organism. The optimum treatment duration and selection of anti-microbial therapy in the management of ***MA*** PDaP is unclear, primarily due to the paucity of confirmed cases and variability of the treatment regimens. PDC removal and peritoneal washout remain the mainstay of treatment. Our case highlights ***MA*** as an emerging organism in PDaP and physicians should be aware of it.

PO1282

A Unique Case of Encapsulated Peritoneal Sclerosis

Sumanth Kacharam, Jie Tang. *Brown University, Providence, RI*.

Introduction: Encapsulating peritoneal sclerosis (EPS) is a rare but devastating sequela of chronic inflammation in patients on peritoneal dialysis (PD). EPS is classically associated with filtration failure and can lead to recurrent abdominal pain and obstruction due to encasement of small and large bowel

Case Description: A 45 year-old Cambodian male with a past medical history of ESRD secondary to IgA nephropathy on PD for 10 years presented with loose stools and hypotension after dialysis. His medical history included CML complicated by spinal chloroma, paraplegia, neurogenic bladder and PVD with osteomyelitis resulting in bilateral AKA. He was previously admitted 14 days prior for culture negative (including fungal) peritonitis treated with intraperitoneal cefepime and C. difficile colitis treated with oral Vancomycin. Despite completing a course of antibiotics, he had persistent abdominal pain and inability to tolerate PO intake. Repeat diagnostic paracentesis on this presentation revealed a total cell count of 2519 with 98% PMN. But culture remained negative. CT of abdomen showed global thickening and calcification of his peritoneal membranes. Ex laparotomy was performed with biopsies confirming EPS. At the time of diagnosis, he did not exhibit signs or symptoms of dialysis failure with excellent ultrafiltration. Repeat microbiology studies showed fungal elements in the PD fluid, later identified as penicillium species mold. Patient was not started on Steroids and Tamoxifen due to underlying fungal peritonitis. He was transitioned to hemodialysis and treated with a prolonged course of amphotericin. Subsequent peritoneal studies showed increasing burden of mold despite intraperitoneal drains. His course was further complicated by recurrent upper GI bleed and inability to tolerate hemodialysis due to hypotension. Patient was eventually transitioned to comfort measures.

Discussion: The pathogenesis stilof EPS is poorly understood. Some of the risk factors include use of PD for > 5 yrs, high dialysate glucose concentrations, repeated episodes of peritonitis, which can cause structural and functional damage to the peritoneal membrane. Development of EPS is related to dialysis vintage and "second hits" like infection as demonstrated in this case. However, the case is unique in that he had no difficulty with his PD ultrafiltration, and we believe the fungal peritonitis was a late sequala of his EPS.

PO1283

Spontaneous Peritoneal Dialysis Catheter Expulsion: Our Experience

Eva Lopez Melero, Haridian Sosa Barrios, Victor Burguera, Sofia Ortego, Marta Álvarez nadal, Milagros Fernandez-Lucas, Maite Rivera. *Hospital Ramon y Cajal, Hospital Universitario Ramon y Cajal, Madrid, Spain*.

Introduction: Mechanical complications of PD are a significant cause of technique failure. Amongst them, complete expulsion of the peritoneal catheter (PC) is rare.

Case Description: CASE1: 62-year-old woman with chronic kidney disease (CKD) secondary to unknown glomerulonephritis. PD was started after a failed transplant. She had two episodes of exit site infection (ESI) secondary to *Corynebacterium spp,* recovered. In 2001 she presented with pericatheter leak, solved after transient switch to hemodialysis for 2 months. In 2002 she was admitted with complete spontaneous PC extrusion (straight Tenckhoff PC 2 cuffs). She had no signs of ESI and denied using any topical medication. A contralateral PC was inserted with no complications. CASE2: 61-year-old woman with CKD due to anti-glomerular basement membrane disease. She received induction treatment with high-dose steroid therapy, with no response, so a straight Tenckhoff PC (2 cuffs) was placed and she started PD. 2 months later she presented a spontaneous PC expulsion with evidence of ESI with *Candida parapsylosis* that was adequately treated. After infection resolved, a contralateral PC was placed with no complications. CASE3: 68-year-old woman with CKD secondary to type 2 cardiorenal syndrome. She started on PD because of diuretic-resistant heart failure (straight Tenckhoff PC, 2 cuffs). She presented Pseudomonas aeruginosa relapsing peritonitis in 4 occasions, requiring taudolidine-urokinase PD catheter lock with good outcome. In 2018 she had an episode of ESI, again by *Pseudomonas aeruginosa* solved after a course of topical antibiotics as well as external cuff shaving. In 2019 she developed again ESI with *Pseudomonas areuginosa,* and despite topic treatment as per antibiogram exit site cultures remained positive. One month later she presented a spontaneous expulsion of the PC. A contralateral PC was placed without further infectious complications.

Discussion: We present an atypical complication in PD. Triggers for PC extrusion in our cases appear to be related to peritoneal leak in the first case, and to ESI in the remaining two cases. Steroids are likely disrupting exit site healing and fibrosis formation around the cuff, contributing to this infrequent complication. These risk factors should be identified and kept in mind to prevent the catheter extrusion.

PO1284

Polymicrobial Peritoneal Dialysis Peritonitis due to Eggerthella lenta, Parabacteroides Species, and Bacteroides distasonis

Supriya Gerardine,[1] Vesh Srivatana.[2] *[1]New York Presbyterian -Weil Cornell, New York, NY; [2]Rogosin Institute, New York, NY*.

Introduction: Peritionitis is a severe and common infectious complication among patients on peritoneal dialysis (PD). Most cases are due to Coagulase negative staphylococcus. Anaerobic bacteria constitute < 0.5% of the peritonitis in PD patients. This is a case of anaerobic polymicrobial PD peritonitis of rare pathogens without a clear intrabdominal source.

Case Description: 92 year old man with end stage renal disease who had a failed deceased donor renal transplant and was started on peritoneal dialysis 6 months ago was admitted for abdominal pain with cloudy peritoneal fluid for 3 days. Peritoneal fluid had cell count of 22,000 cells/ul. He was treated with intraperitoneal (IP) vancomycin and ceftazidime with improvement in abdominal pain and cell count downtrended to 2700/ul on Day four he was discharged with continued IP antibiotic administration. He was re-admitted in two days for worsening abdominal pain with a cell count of 14,000/ul. Patient had been correctly administering IP antibiotics with the assistance from his family members. CT abdomen pelvis with intravenous and oral contrast showed small bowel ileus likely due to the peritonitis. At this time the peritoneal dialysis catheter was removed and he was converted to hemodialysis. The peritoneal fluid cultures on Day 7 resulted Eggerthela Lenta and on Day 10 grew Parabacteroides species. Upon review his initial PD fluid culture prior to transfer from outside hospital was positive for Bacteroides Distastonis. Sensitivities were reported for only Eggerthela Lenta and Parabateroides species and they were both sensitive to metronidazole. Antibiotics were broadened to intravenous vancomycin, ceftazidime and metronidazole with clinical improvement in patient.

Discussion: To our knowledge, this is the first case of bacterial peritonitis from Parabacteroides species and Bacteroides Distastonis. There is only one case report of Eggerthela Lenta reported by Goupil et al. causing PD peritonitis. The PD fluid culture was slow growing and this highlights the potential need for anaerobic coverage in PD peritonitis without early pathogen isolation and/or failure of initial empiric treatment.

PO1285

A Rare Case of Trichoderma-Related Peritonitis in a Patient on Peritoneal Dialysis

Ramya Bachu, Stefan C. Hemmings, Suman Siddamreddy. *Baptist Health - UAMS Medical Education Program, North Little Rock, AR.*

Introduction: Trichoderma spp are saprophytic fungi commonly found in the soil, decaying wood and humid environments. They are known to cause infections in immunocompromised hosts but rarely in peritoneal dialysis (PD) patients. Cases are infrequently reported in the literature and are associated with high morbidity and mortality.

Case Description: A 65yo white male with DM, HTN, HLD, ESRD on PD, was admitted with worsening abdominal pain for 4 weeks with low grade fever, chills, nausea and vomiting. His vitals were stable. Significant findings were a diffusely tender abdomen without guarding, rigidity or rebound tenderness. His PD effluent was cloudy. Labs were unremarkable. CT abdomen was negative for acute pathology. He was started on intraperitoneal vancomycin and ceftazidime as an outpatient as he had two earlier bacterial peritonitis episodes in the year. However, preliminary cultures from his clinic grew fungal elements. This prompted urgent PD catheter removal and conversion to hemodialysis. The fungus indentified was Trichoderma and he was started on IV Anidulafungin. Repeat PD cultures were negative and he was discharged on oral Voriconazole with follow up in ID clinic. Over the course of 2 weeks, he was readmitted twice with worsening abdominal pain. On the third admission, he had exploratory laparoscopy and found to have diffuse thrush like plaques all over the peritoneum. IV amphotericin B was added to inpatient antifungal regimen. However, he continued to deteriorate and elected to go home on hospice and passed away soon after.

Discussion: Diagnosis of fungal peritonitis in PD is challenging and oftentimes delayed. Occurrences usually follow treatment of bacterial peritonitis and mimics its clinical features. Most isolates of Trichoderma spp have shown resistance to fluconazole and 5- Fluorocytosine but show intermediate susceptibility to Amphotericin B, Itraconazole, Ketoconazole and Miconazole. Therefore, it is important to perform antifungal susceptibility tests and then adjust the final treatment. In conclusion, Physicians who treat patients on PD should be aware of the possibility of this opportunistic infection. Prompt antifungal treatment should be considered in cases of recurring peritonitis in the appropriate patients. More research is needed to guide early diagnosis and guide effective treatment of this rare fungal disease with high mortality.

PO1286

Streptococcus oralis Peritonitis in Peritoneal Dialysis

Swe Zin Mar Winhtutoo, Jayesh B. Patel, Lama A. Noureddine. *The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Peritonitis is the most common complication seen in peritoneal dialysis (PD). Although staphylococcal infections are most common, Streptococci are rare causes of ambulatory peritoneal dialysis (APD) peritonitis. We report a case of APD peritonitis due to Streptococcus oralis (also known as mitis) in a patient who habitually engages in nail-biting.

Case Description: A 57-year-old male with end-stage renal disease due to biopsy proven focal segmental glomerulosclerosis on PD since 2018 presented with 1 day of severe diffuse abdominal cramps. He has no known history of peritonitis. Vital signs were stable, and examination was notable for diffuse abdominal pain without rebound tenderness. PD catheter site was clean and dry. Abdominal CT scan did not reveal any acute intra-abdominal pathology. PD fluid was sent for cell count and culture. PD fluid was cloudy in appearance and amber in color. Due to concern for peritonitis, he was started on intraperitoneal vancomycin and tobramycin. Final fluid cell count was 20,900 WBCs/mm3 and final fluid culture was positive for Streptococcus mitis. He was successfully treated with 2 weeks of vancomycin, as he had an allergy to penicillin. He admitted that he is a habitual nail-biter. We educated him on the importance of hand hygiene and continuously adhering to a sterile dialysis technique.

Discussion: Streptococcus oralis is the most virulent of the streptococci viridians comprising normal human oral flora. It is primarily associated with dental caries but can have opportunistic pathogenicity in immunocompromised patients and can cause subacute infective endocarditis and septicemia if left untreated. Because the peritoneal cavity lacks robust innate immune response, it is a favored site for infection. Cefazolin is the antibiotic of choice for gram-positive cocci. Our patient denied breaking sterile technique but admitted that he is a nail-biter. He had no evidence of dental caries and didn't seed through hematogenous spread. The only possible route of transmission was direct contamination from biting of his nails. We recommended the use of a bitter flavored nail biting deterrent nail polish at the time of discharge that could help him break his habit.

PO1287

Effect of N-Acetylcysteine on Nontraditional Cardiovascular Risk Factors and Carotid Intimal Medial Thickness in Chronic Peritoneal Dialysis Patients

Sandeep Mahajan. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Accelerated atherosclerosis increases morbidity and mortality among PD patients. Various non-traditional risk factors (NTRFs) like oxidative stress (OS), impaired endothelial function (EF), micro-inflammation and increased homocysteine (HCS) have been implicated. N-acetyl cysteine (NAC) is an antioxidant, reduces HCS and has shown to improve EF and cardiovascular endpoints in HD patients. No study has looked at its effect on NTRFs in PD patients & its effect on structural atherosclerosis

Methods: Stable consenting patients on chronic PD (PD duration >3 months) were given oral NAC (600 mg twice daily) for 3 months. No changes were made in PD prescription. Demographic data, clinical, biochemical profile, EF, OS, HCS, highly-sensitive C-Reactive protein (Hs-CRP) and Carotid intimal medial thickness (CIMT, marker of structural atherosclerosis) were noted before and after 3 months. OS was measured by total anti-oxidant capacity (TAC) and thiobarbituric acid reactive substances (TBRAS). EF was assessed by brachial artery flow-mediated dilatation (FMD) subsequent to occlusion. CIMT of both carotids at 8 sites was assessed by high-resolution ultrasonography

Results: Of 80 patients approached by convenience sampling, 73 who completed study were analysed (2 refused consent, 5 did not follow-up at desired time). None of the patients reported any adverse events or discontinued the drug. In these patients, 28 were diabetics, 50 were males. Mean age, duration of PD and urine output: were 51.6±11.1 years, 11.6±3.2 months and 448.7±341.9 ml/day respectively. Table shows study parameters before and after NAC

Conclusions: In our open-label study NAC effectively reduced multiple NTRFs and atherosclerotic burden in PD patients. T

Parameter	Pre NAC	Post NAC	P-Value
HCS (µmol/L)	23.6±4.5	14.7±3.1	<0.001
HsCRP (mg/dl)	3.8±1.1	2.2±0.5	<0.001
FMD (%)	7.6±2.4	11.2±3.5	<0.001
TBARS (nmol/ml)	18.4±11.1	14.4±6.6	<0.01
TAC (Mmol/L)	1.01±0.2	1.14±0.3	0.03
CIMT (mm)	0.59±0.2	0.48±0.1	<0.001

NAC-N-acetyl cysteine ; HCS-homocysteine; HsCRP-highly-sensitive C-Reactive protein; FMD-brachial artery flow-mediated dilatation; TBARS-thiobarbituric acid reactive substances; TAC-total anti-oxidant capacity; CIMT-Carotid intimal medial thickness

PO1288

Outcomes of Cardiac Surgery in ESKD Patients on Hemodialysis (HD) vs. Peritoneal Dialysis (PD)

Elias Bassil,[1] Aimen Liaqat,[1] Milad Matta,[1] Ronak J. Shah,[1] Jonathan J. Taliercio,[1] Remy Daou,[2] Susana Arrigain,[1] Victoria Konig,[1] Jesse D. Schold,[1] Serge C. Harb,[1] Per Wierup,[1] Georges Nakhoul,[1] Ali Mehdi.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Universite Saint-Joseph, Beirut, Lebanon.*

Background: Patients with ESKD have worse outcomes following major cardiac surgery compared to those without ESKD. However, the outcomes of cardiac surgery in PD patients vs. HD patients are not well studied.

Methods: Using our EHR-based Cardio-Thoracic Surgery (CTS) registry, we compared the outcomes of 590 patients with ESKD on HD and PD undergoing Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery. We compared baseline demographics and comorbidities between patients on PD and HD using Chi-square and t-tests for categorical and continuous variables respectively. We compared Length of Stay (LOS), days in the ICU, number of transfusions, and post surgical complications: (pericardial effusion, gastro-intestinal (GI) bleed, cardiac arrest, and in-hospital death) using Kruskal-Wallis test, Chi-square and Fisher's exact tests.

Results: Among 590 patients undergoing cardiac surgery, 62 (11%) were on PD, and 528 (89%) were on IHD. PD patients had a lower proportion of heart failure (50% vs. 72%), lower median Cardio-Pulmonary Bypass (CPB) time (106 vs. 122 minutes), and a higher proportion of dyslipidemia (92% vs. 79%) at baseline. HD and PD patients had no significant differences in post-operative length of stay, number of ICU days, and postoperative complications including GI bleed, pericardial effusion, and cardiac arrest (table 1). There was also no difference in mortality between the two groups. Out of 62 PD patients, 15 (24%) were converted to HD.

Conclusions: There were no significant differences in the measured outcomes between patients on HD vs. patients on PD post cardiac surgery and or valvular surgery.

Post-operative outcomes of HD vs. PD

Factor	N missing	Overall (N=590)	HD (N=528)	PD (N=62)	p-value
Intraoperative RBC Units	2	2.0[0.00,3.0]	2.0[0.00,3.0]	2.0[1.00,3.0]	0.84b
Post-op Length of Stay	0	11.0[8.0,18.0]	11.0[8.0,19.0]	10.0[7.0,17.0]	0.21b
ICU Total hours	2	95.7[52.2,188.8]	96.1[52.1,194.1]	93.3[57.6,164.9]	0.52b
Pericardial effusion	10	36(6.2)	32(6.2)	4(6.5)	0.99d
Gastrointestinal Event	0	48(8.1)	42(8.0)	6(9.7)	0.64c
Cardiac Arrest	0	29(4.9)	29(5.5)	0(0.0)	0.06d
In-Hospital Death	0	26(4.4)	25(4.7)	1(1.6)	0.51d

PO1289

HAS2 Expression as a Novel Mechanism of TGF-β-Induced Phenotype Transition of Human Peritoneal Mesothelial Cells

Hyun-Jung Kang, Dal-ah Kim, Cheongran Je, Duk-Hee Kang. *Ewha Womans University, Seoul, Republic of Korea.*

Background: Epithelial-to-mesenchymal transition (EMT) of human peritoneal mesothelial cells is one of the key mechanisms of peritoneal fibrosis in peritoneal dialysis (PD), which can be reversible at early stage of phenotype transition. Therefore,

the identification of novel molecular biomarkers of peritoneal EMT may facilitate the diagnosis of peritoneal damage allowing early initiation of treatment targeting peritoneal fibrosis. Hyaluronan (HA) is a glycosaminoglycan component of the extracellular matrix, produced by three members of HA synthase (HAS1, HAS2 and HAS3). HAS are known to be involved in EMT of cancer cells, however there is no information on the association of HAS and peritoneal EMT.

Methods: Peritoneal MCs isolated from overnight dwell dialysates from 16 PD patients (PD_MC) at 2 [baseline peritoneal equilibration test (PET)] and 6 (follow-up PET) months of the PD initiation. We divided PD patients into two groups based on the alteration of baseline and follow-up PD_MC morphology (Group 1 epithelial-epithelial and Group 2 epithelial-mesenchymal). RNA-seq analysis (Ebiogen, Korea) was performed in order to detect baseline molecular markers predicting mesenchymal phenotype in follow-up. Based on RNA-seq analysis, the expressions of HAS isoform were evaluated in MCs isolated from omentum (OM_MC) with an exploration of the role of HAS on TGFβ-induced EMT.

Results: RNA-seq analysis demonstrated the difference of gene expression related to EMT (27.6%), angiogenesis (30.2 %), cell migration (27.4%), and extracellular matrix remodeling (26.3%). Among them, HAS2 expression in baseline analysis showed the highest fold difference (28.5-folds) between group 1 and 2. In OM-MC, HAS1, HAS2 and HAS3 were constitutively expressed whereas only HAS1 and HAS2 were upregulated by TGFβ. TGFβ-induced changes in cell morphology and the expression of E-cadherin, α-SMA, and fibronectin were ameliorated by siHAS2, but not by siHAS1. HAS inhibitor (4-methylumbelliferone; 4-MU) also alleviated TGFβ-induced EMT.

Conclusions: This data suggest HAS2 plays a role in TGFβ-induced EMT of peritoneal mesothelial cells and modulation of HAS2 can protect the peritoneal fibrosis in PD patients. Both HA or HAS2 in peritoneal effluent of baseline PET also can be the markers predicting peritoneal EMT and fibrosis.

PO1290

Am80, a Synthetic Retinoic Acid Receptor α-Specific Agonist, Suppresses Peritoneal Fibrosis via Inhibition of Krüppel-Like Transcription Factor 5 in Mice

Kumiko Muta,[1] Yuka Nakazawa,[2] Yoko Obata,[1] Hiro Inoue,[1] Kenta Torigoe,[1] Kazuo Yamamoto,[3] Tomoya Nishino.[1] *[1]Nagasaki University Hospital, Nagasaki, Japan; [2]Hokusyo Central Hospital, Nagasaki, Japan; [3]Nagasaki University School of Medicine, Nagasaki, Japan.*

Background: We presented previously that Am80, a synthetic retinoic acid receptor a specific agonist, inhibited the expression of Krüppel-like transcription factor 5 (KLF5) and reduced peritoneal fibrosis in mice. Now, we examined further detail about the mechanism to inhibit peritoneal fibrosis.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of chlorhexidine gluconate (CG) into peritoneal cavity of ICR mice. Am80 was administered orally for every day from the start of CG injection. After 3 weeks of treatment, peritoneal tissues were examined using serial sections by immunohistochemistry to identify what kind of cells expressed KLF5. Am80 was given in mouse fibroblasts stimulated by transforming growth factor β1 (TGF-β1) and the expression of KLF5 was assessed by Western blotting.

Results: While KLF5 was expressed in the thickened submesothelial area of CG injected mice, Am80 treatment reduced KLF5 expression and remarkably attenuated peritoneal thickening. The numbers of TGFβ positive cells, a-smooth muscle actin (aSMA) or F4/80 positive cells were significantly decreased in Am80 treated group. KLF5 was expressed in aSMA, F4/80 or CD31 positive cells. Western blotting for KLF5 showed the tendency that KLF5 expression was decreased in higher concentration of Am80 in mouse fibroblasts stimulated by TGF-β1 in vitro.

Conclusions: These results indicate the KLF5 might not only associate phenotypical differentiation from fibroblasts to myofibroblasts but also regulate inflammatory responses and angiogenesis in peritoneal fibrosis model. Am80 can suppress peritoneal fibrosis through inhibiting these mechanisms.

PO1291

Peritoneal Protein Clearance and Lean Body Mass Index: Relationship in Peritoneal Dialysis Patients

Roberto C. Marques,[1] Ana T. Domingos,[1] Eduarda C. Carias,[1] Anabela M. Guedes,[1,2] Idalécio Bernardo,[1] Pedro L. Neves.[1,2] *[1]Centro Hospitalar Universitário do Algarve, Faro, Portugal; [2]Universidade do Algarve, Faro, Portugal.*

Background: An important feature of Peritoneal Dialysis (PD) is peritoneal protein loss (PPL) during dialysis. Peritoneal Protein Clearance (PPCl) is considered a better index as it reflects the individual differences of PPL and membrane function of both small and large pores. Higher PPCl has been reported to be associated with hypoalbuminemia and malnutrition, with some authors stating higher overall mortality. However, new studies failed to draw similar conclusions, arousing new insights on the peritoneal protein metabolism. Lean body mass index (LBMI) has been used as a useful marker of nutritional status in PD patients. The aim of this study was to evaluate the relationship between PPCl and LBMI.

Methods: Prevalent PD patients with peritoneal equilibration test and multi-frequency bioelectrical impedance analysis (BIA) were enrolled in the cross-sectional study in a single tertiary centre from January 2014 to December 2019. PPCl was calculated dividing 24h dialysate protein loss by serum total protein. LBM was assessed by BIA and LBMI was calculated dividing LBM by body height square. Spearman correlation test was performed to examine the association between body indexes and PPCl. Multiple regression linear model was used for exploring the associated factors of PPCl.

Results: We included 67 PD patients (54.1±17.3 years, 59.7% male, 31.3% diabetic). The mean evaluated parameters were: total Kt/V 2.52±0.8, nGFR 6.7±4.1 ml/min/1.73m2 and D/P creatinine ratio 0.63±0.01. The median PPL and PPCl were 5.2(3.8-6.7) g/day and 78.35(54.81-97.19) ml/day, respectively. PPCl was significantly positively associated with LBMI (r=0.401, P 0.001) and BSA (r=0.327, P 0.007), but not with BMI (r=0.109, P 0.381). Compared with conventional body indexes, LBMI had better performance in predicting higher PPCl. Multiple linear regression model, when adjusted for gender, nGFR, kt/V and diabetes, showed that older age (β=0.288, P 0.018), higher D/P creatinine ratio (β=0.232, P 0.050) and higher LBMI (β=0.334, P 0.014) were independent predictors of PPCl.

Conclusions: Higher LBMI is a marker of better nutritional state, which is associated with better survival in PD patients. In this study, higher LBMI was independently associated with higher PPCl, potentially explaining conflicting results on the impact of higher PPCl on mortality.

PO1292

Burden of Dialysis, Health-Related Quality of Life, and Employment Comparisons Between Peritoneal Dialysis and In-Center Hemodialysis: Findings from the DOPPS Program

Edwina A. Brown,[1] Junhui Zhao,[2] Keith McCullough,[2] Douglas S. Fuller,[2] Ana E. Figueiredo,[3] Brian Bieber,[2] Fredric O. Finkelstein,[4] Jenny I. Shen,[5] Talerngsak Kanjanabuch,[6] Hideki Kawanishi,[7] Ronald L. Pisoni,[2] Jeffrey Perl.[8] PDOPPS patient support working group *[1]Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]School of Health Sciences and Life, Nursing School, Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil; [4]Yale University, New Haven, CT; [5]Division of Nephrology and Hypertension, LaBiomed at Harbor–UCLA Medical Center, Torrance, CA; [6]Deparment of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [7]Tsuchiya General Hospital, Nakaku, Japan; [8]St. Michael's Hospital, University of Toronto, Toronto, ON, Canada.*

Background: The Dialysis Outcomes and Practice Patterns Study (DOPPS) and the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) collect information annually about quality of life, including employment and functional status. Differences in these domains by dialysis modality (PD vs. centre-based hemodialysis) may inform individuals in choosing a dialysis modality.

Methods: PD and HD patients with comparable characteristics were analyzed. For baseline patient questionnaire, we used logistic regression to analyze binary outcomes employment (full- or part-time versus unemployed), depression (CES-D ≥10 vs. <10), and functional status (≥11 vs. <11), and used linear mixed models to analyze continuous outcomes (PCS, MCS, and burden of kidney disease score). Change of outcomes were described descriptively.

Results: There were 3227 PD and 4544 HD patients at baseline. Burden of kidney disease scores were better for PD compared to HD (overall 9-point adjusted difference, [95%CI: 7-11]) with a higher proportion of patients on PD in the lowest burden range (10%-37%) compared to 8%-24% on HD, depending on country. PD patients also had better PCS and MCS, though these were less marked (overall adjusted difference of 0.9 [0.2-1.6] for PCS, 1.0 [0.2-1.9] for MCS). HD patients had worse functional status scores (adjusted OR HD vs. PD 0.6, [0.5, 0.8] for score ≥ 11); were less likely employed (OR=0.6, [0.5, 0.8]); and had worse CES-D scores (OR=0.8, [0.7, 1.0] for CES-D < 10). In Australia/New Zealand, HD patients had better MCS and CES-D scores and a higher proportion being employed than PD patients. 174 PD patients and 254 HD patients died within one year; 614 PD patients and 535 HD patients left the study between questionnaires. Changes over time in the continuous measures were small. Trends in employment, CES-D score, and functional status were small and not statistically significant.

Conclusions: Compared to HD patients, PD patients reported a lower burden of kidney disease score and among survivors, remains stable on either PD or HD over 12 months. This information, when shared with patients choosing a dialysis modality, could result in an increased uptake of PD.

PO1293

H2S May Inhibit Peritoneal Dialysis-Related Fibrosis Through the Sulfhydrylation Regulation of PSMA7

Xujiao Chen, Ying Hu. *Department of Nephrology, Second Affiliated hospital of Zhejiang University, Hangzhou, China.*

Background: Peritoneal dialysis (PD) is one of the first treatment methods for patients with end-stage renal disease, which has advantages on cardiovascular system protection, large toxin clearance and patients' life quality improvement. But statistics shows that the 5-year withdrawal rate of PD patients was around 50%, and ultrafiltration failure caused by peritoneal fibrosis is the main reason, and there is no effective clinical prevention and treatment. In our previous study, we found that the flora of PD patients was obviously maladjusted, and the production of H2S in the intestine was significantly reduced. Some evidences showed that H2S may alleviate PD-related fibrosis, suggesting that H2S may affect the fibrosis by regulating the level of sulfhydrylation, but the mechanism is not clear.

Methods: Rat peritoneal mesothelial cells were randomly assigned into different groups, 4.5% peritoneal dialysate group (PD group), PD+H2S supplement GYY4137 group and PD+H2S inhibitor PAG group. The expression of pyroptosis associated proteis, inflammatory factors and fibrosis related pathways in different groups were compared. The changes of protein sulfhydryl sulfhydrylation level were analyzed by HPLC/MS/ MS. The target protein and related pathway protein were up/down regulated by SiRNA and the downstream pathways expression were observed by PCR and Western blot.

Results: GYY4137 significantly reduced the expression of pyroptosis proteins (NLRP3, ccas-1, gsdmd-n), inflammatory factors (IL-6, IL-8, TNF - α) and fibrosis related proteins (p-smad3, Smad, TGF-β, VEGF) response to high glucose PD fluid. We found that the level of PSAM-7 sulfhydrylation in the PD group decreased significantly, but in GYY4137 group, the level of PSMA7 ulfhydrylation increased significantly. The expression of pyroptosis proteins, inflammatory factors and fibrosis related proteins were significantly increased after PSMA7 sulfhydrylation was interfered by mutant plasmids. The expression level of NLRP3 was up/down regulated by siRNA. The expression of downstream inflammatory factors and fibrosis-related proteins were significantly increased/decreased.

Conclusions: H2S has a protective effect on PD-related fibrosis through the PSMA7 sulfhydryl sulfhydrylation regulation, and further break the pathological changes of "pyroptosis- inflammation-fibrosis" axis and avoid the occurrence of inflammatory cascade reaction.

PO1294

Fatigue Predicts Higher Risk of Mortality in Peritoneal Dialysis Patients: A BRAZPD Analysis

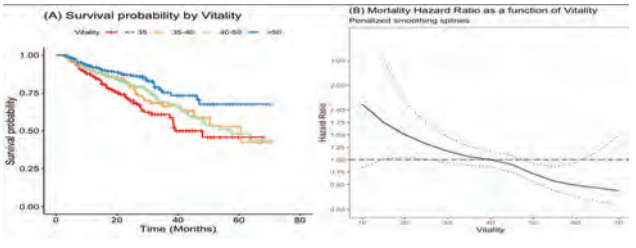
Murilo H. Guedes,[1] Liz R. Wallim,[1] Camila R. Guetter,[2] John W. Larkin,[3] Chance Mysayphonh,[3] Yue Jiao,[3] Len A. Usvyat,[3] Peter Kotanko,[4] Roberto Pecoits-Filho,[1,5] Thyago P. Moraes.[1] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Universidade Federal do Parana, Curitiba, Brazil; [3]Fresenius Medical Care North America, Waltham, MA; [4]Renal Research Institute, New York, NY; [5]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: End-stage kidney disease (ESKD) patients are often burdened by fatigue. Fatigue is a core outcome to peritoneal dialysis (PD) patients and providers, but its associations with clinical outcomes are unknown. We analyzed a nationally representative cohort of PD patients to test the hypothesis that higher fatigue independently associates with higher mortality risk.

Methods: We analyzed data from adult patients in BRAZPD, a nationwide Brazilian cohort across 122 PD centers. Patients incident to PD with complete KDQOL-SF survey in the first 90 days of dialysis were included. Fatigue was defined by the vitality subscale in four subgroups: >50 (high vitality), ≥40 to ≤50 (moderate vitality), >35 to <40 (moderate fatigue), ≤35 (high fatigue). We built four distinct models to estimate the association between fatigue and 12-month mortality: (i) Cox-proportional hazard model; (ii) competitive risk model accounting for technique failure events; (iii) multilevel survival analysis modeling clinic-level clusters; (iv) Cox regression with smoothing splines treating vitality as a continuous measure. Analyses were adjusted for age, comorbidities, residual kidney function (RKF), daily prescribed PD volume, and PD modality.

Results: We included data from 1,388 PD patients (mean age 58.5±15.47 years, 64% had RKF). Proportions of patients with high vitality, moderate vitality, moderate fatigue and high fatigue were 21%, 38%, 15% and 26%, respectively. Hazard-ratios (95%CI) for mortality estimated for the high vitality group (compared to high fatigue) were 0.39 (0.23-0.65), 0.41 (0.24-0.68) and 0.39 (0.22-0.68) for Cox, competitive risk and multilevel models, respectively. Results from the smoothing spline regression are shown in the Figure (B).

Conclusions: Higher fatigue in the initial months of PD was independently associated with 12-month mortality risk. Potential interventions targeting ESKD fatigue in PD patients may not only yield benefits in patient-reported outcomes but possibly also improve survival.



PO1295

Urgent-Start Peritoneal Dialysis: Experience in Mechanically Ventilated Prone Patients

Qandeel H. Soomro, Nina J. Caplin. *NYU Langone Health, New York, NY.*

Background: Patients with respiratory failure who require prone positioning are not considered good candidates for PD due to the concerns for increased intra-abdominal pressure, impaired diaphragmatic movement, and leaking of peritoneal fluid. We addressed the COVID-related AKI (CRAKI) surge for renal replacement therapy (RRT) by initiating an acute PD program at Bellevue Hospital including prone patients.

Methods: All patients were in the ICU with COVID related hypoxic respiratory failure and acute kidney injury (AKI). 6/35 patients who received PD were treated for 16 hours per day in the prone position to improve oxygenation. The mean age was 54.6. The average BMI was 35.5. Patients were on mechanical ventilation 12-33 days. 3/6 patients were on CVVH however, switched to PD due to clotting. Patients were on PD for an average of 9.3 days. All PD catheters were placed at the bedside using an open cut down technique. PD was started the same day using manual exchanges. Dwell volume was gradually increased to 2 L. Exchanges were performed q1h while supine and q2h while prone, a total of 4-6 exchanges/day. The PD team coordinated timing with the prone team and ICU nurses to allow the continuation of the PD treatment. Patients were monitored clinically for abdominal distention and changes in respiratory mechanics.

Results: All 6 patients remained on PD for the duration of the hospitalization. There were no incidences of bowel injury, hemorrhage, exit-site infections, or peritonitis. None of the patients had any catheter malfunction. Leaking was addressed with temporarily reducing the dwell volume. Patients experienced slow draining which was due to kinking of the tubing during prone positioning. All patients were able to continue receiving PD without interruptions. Either no change or improvement in ABG and ventilator settings was noted after prone positioning and PD.

Conclusions: Due to COVID related surge, we saw a significant number of patients in the ICU with severe acute respiratory failure requiring prone positioning who also developed AKI requiring RRT. We were able to successfully provide acute PD in ventilator-dependent prone patients suffering from CRAKI. This required a team effort and some modifications in the conventional PD prescription.

PO1296

Inline Turbidity Measurement Using an Optical Sensor for Early Detection of Peritonitis

Mia Garbaccio,[1] Nadja Grobe,[1] Xia Tao,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Peritonitis, a serious bacterial infection, can occur in patients undergoing peritoneal dialysis (PD). Timely treatment is critical for peritonitis since delay in the initiation of antimicrobial therapy is linked with an increased risk of technical failure and death. Peritonitis was oftentimes presented with turbid PD spent dialysate induced by increased white blood cells (WBC) concentration. This can be detected by the change of light intensity transmitted through PD fluid onto an optical sensor. We have developed a low cost (<$10), reusable in-line optical sensor that can adapt to automated PD cycler tubing sets to detect turbidity in PD fluid.

Methods: A optical sensor system with white-light LED light source was designed to clamp on the visualization chamber of Liberty cycler tubing set. Spent PD dialysate and fresh dialysate were tested through a drain line recirculation circuit by the optical sensor system at 50 and 100 ml/min flow rate. To mimic peritonitis, isolated white blood cells, ranging from 50-300 cell/ μl, were added to fresh dialysate and analyzed with the optical sensor.

Results: 12 deidentified peritonitis-negative (WBC <100 cells/μl) spent dialysate samples from stable PD patients were tested. Fresh dialysate had a similar signal magnitude compared with spent dialysate. A change of flow rate from 50 ml/min to 100ml/min did not affect the signal from the optical sensor at baseline. A linear relationship (R2=0.99) between increased concentration of WBC and decreased transmitted light intensity was captured by the optical sensor.

Conclusions: Change of WBC induced-turbidity in PD dialysate can be detected with a low cost optical sensor without alternation of an existing PD drain line.

PO1297

Peritoneal Dialysis (PD) Technique Training: What Features Influence Learning Time?

Haridian Sosa Barrios,[1,2] Victor Burguera,[1] Cristina Campillo,[1] Sofia Ortego,[1] Eva Lopez Melero,[1] Marta Álvarez nadal,[1] Daniel E. Villa,[1] Milagros Fernandez-Lucas,[1,2] Maite Rivera.[1,2] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Universidad de Alcala de Henares, Madrid, Spain.*

Background: The adequate training of patients started on PD is an essential issue for technique success and basic to avoid and/or reduce complications. However, features affecting training duration have not been sufficiently studied so far. AIM: Identify features influencing PD training duration and their relation to first peritonitis episode timing and permanence on PD.

Methods: We retrospectively analysed all training sessions done with first time PD starters in our Unit (January 2001-December 2018). Demographic data on age, gender, end ESRD cause, Charlson morbidity index (CCI), number of training sessions, type of PD start, employment and education status, derivation and PD technique were recorded.

Results: 188 patients were trained, 72% male. Median age 55.49±15 yr. 25% were diabetic. Mean CCI: 4.9. Our patients required a median of 10 sessions (range 2-28) to gain sufficient skills performing the PD technique and feel confident, with a median of 19 days. Number of training sessions required increased with higher age ($p< 0.05$), higher CCI ($p< 0.05$) and diabetics ($p< 0.05$). Neither gender, cohabitation, type of PD start, education level, derivation type nor employment status were statistically significant factors affecting PD training. Assisted PD patients were older (54 vs 71 yo, p=0.00) and they required a higher number of training sessions (10 vs 15.7 sessions). Patients requiring longer training (>23 days) had more peritonitis episodes ($p< 0.05$), the first peritonitis episode happened sooner (15.7 vs 17.4 months, p=NS) and they remained less time on PD (32.57 vs 27.7 months, $p< 0.01$).

Conclusions: The PD training time needed depends on patient's age, diabetic status and comorbidities but does not relate to social, educational nor employment status. Patient's requiring less training sessions have less peritonitis episodes and it happens later, remaining longer on PD technique.

Clinical Outcomes of Infection-Related Hospitalization in Incident Peritoneal Dialysis Patients

Yong Kyun Kim,[2] Jin Kim.[1] *[1]Ajou University School of Medicine and Graduate School of Medicine, Suwon, Gyeonggi-do, Republic of Korea; [2]Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea.*

Background: Infection is the second leading cause of death in patients undergoing long-term dialysis. Peritoneal dialysis (PD) is associated with an increased risk of infection-related hospitalization (IRH) when compared with hemodialysis. However, the effects of IRH on clinical outcomes in PD patients have not been established. In this study, we investigated the influence of IRH on clinical outcomes in incident PD patients.

Methods: In total, 583 incident PD patients were selected from the Clinical Research Center Registry for End-Stage Renal Disease, a nationwide multicenter prospective observational cohort study in Korea. Incident PD patients who had been hospitalized for infection-related diseases were categorized as the IRH group. The primary outcome was all-cause mortality and the secondary outcome was technical failure. The median follow-up period was 29 months.

Results: Seventy-three PD patients (13%) were categorized as the IRH group. Multivariate logistic regression analysis showed that diabetes mellitus was a significant independent predictor for IRH (odds ratio: 2.43, 95% confidence interval [CI]: 1.12–5.29, p=0.007). The most common causes of IRH were peritonitis (64.9%) and respiratory tract infection (11.9%). Multivariate Cox proportional hazard model analysis showed that IRH was a significant independent risk factor for all-cause mortality (hazard ratio [HR]: 2.51, 95% CI: 1.12–5.62, p=0.026) and for the technical failure of PD (HR: 3.23, 95% CI: 1.90–5.51, p<0.001).

Conclusions: Our data showed that after initiation of PD, IRH was significantly associated with higher risk of all-cause mortality and technical failure. Careful consideration of infection-related disease is needed in incident PD patients.

PO1299

Fluoroscopic-Guided Peritoneal Catheter Insertion: Radiology Anthropometric Analysis for Determining Optimal Catheter Position

David Clark,[1] Meherzad Kutky,[3] Karthik K. Tennankore,[1] Arsh Jain.[2] *[1]Dalhousie University Faculty of Medicine, Halifax, NS, Canada; [2]Western University, London, ON, Canada; [3]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

Background: Placement of a functioning peritoneal catheter requires optimal catheter positioning. Traditionally the pubis symphysis has been used as a landmark for the true pelvis and referenced for catheter-tip positioning. This practice is based on physical-exam methods without the benefit of fluoroscopic imaging.

Methods: Retrospective cohort of adult, peritoneal dialysis patients in London, Ontario, who underwent percutaneous peritoneal catheter insertion using fluoroscopy spanning Feb 1, 2013 - Aug 1, 2017. Pre-specified anthropometric measures: 1) distance between deep pelvic space (outlined by caudal border of pooled radiocontrast injected intra-procedure) and cranial border of pubis symphysis; 2) distance between catheter-tip and cranial border of pubis symphysis - were measured using Citrix software of stored images. Anthropometric measures were contrasted according to sex via t-tests ($p<0.05$) and multivariable regression analyses, assessing relationships of potential predictors (age, BMI, prior abdominal surgery).

Results: 295 patients (69% male) underwent fluoroscopic catheter insertion during the study period. Average age was 60 ± 16 years (std. dev.), BMI 28 ± 5 kg/m^2. 52% of patients had no prior surgical history, 30% had 1 prior abdominal surgery, 18% had ≥2 prior surgeries. Average distance between deep pelvic space and pubis symphysis was 2.9 ± 1.5 cm, with females having a larger distance (3.4 ± 1.7 cm) compared to males (2.8 ± 1.4 cm; P=0.001); Female sex being associated with a 0.6 ± 0.2 cm, (P=0.03) increase in distance between the pubis symphysis and deep pelvic space as compared to males, adjusted for age, BMI, and number of prior abdominal surgeries. Stratified by sex: age, BMI, number of prior abdominal surgeries was not associated with distance between the pubic symphysis and deep pelvic space. Catheter-tip to pubis symphysis distance was 3.8 ± 1.7 cm and similar across sexes.

Conclusions: Fluoroscopic methods of outlining the deep pelvic space for peritoneal catheter positioning approximate traditional methods. Differences observed in the distance between the pubic symphysis and deep pelvic space according to sex may reflect the impact of anatomical differences and/or type of abdominal surgeries. However, catheter tip positioning remained unaffected.

PO1300

Blood Pressure Telemonitoring in a Large US Peritoneal Dialysis Population

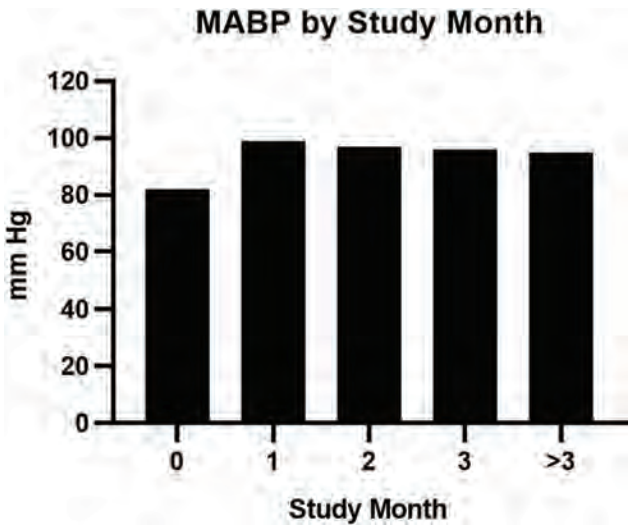
Martin J. Schreiber, Mike Gonzales, Bram Van hout, Brooke Bowlby, Michelle Cassin, Jodi Holly-Kestel. *DaVita Inc, Denver, CO.*

Background: Home remote monitoring (HRM) is a telehealth strategy that utilizes cellular technology to transmit patients' biometric data collected at home to the electronic health record of their dialysis provider. In April 2017, a HRM program was launched nationwide for peritoneal dialysis (PD) patients at a US large dialysis organization (LDO). Here, we report longitudinal trends in blood pressure (BP) control among PD patients participating in the HRM program.

Methods: Data for this analysis were abstracted from LDO electronic medical records. Patients included were dialyzing with PD and participating in the HRM program from Apr 2017-Jan 2020. The following outcomes were tracked monthly for all patients: mean BP, mean arterial BP (MAPB), number of transmitted BP measurements, number of BP alerts, and number of antihypertensive (anti-HTN) medications prescribed. BP alert thresholds were determined on a patient-by-patient basis by the treating physician.

Results: We identified 21,081 eligible patients (average age 59 years old; 57% male) from which >3.5 million individual BP measurements were transmitted. On average, there were 170 readings transmitted per-patient over the monitoring period of 43 months; in total, 764,658 total BP alerts occurred (36 BP alerts/patient). Only 34% of patients achieved the target BP of <130/80 mm Hg. We observed 30%, 23%, and 47%, of patients were prescribed 0, 1-3, and >3 anti-HTN medications, respectively. The most common action responding to BP alerts included changes in medications and in prescribed ultrafiltration volume. However, a significant percentage of PD patients did not see an improvement in MABP [Figure].

Conclusions: HRM identified a significant percentage of PD patients with uncontrolled BP. HRM could be a useful component of clinical programs designed to improve BP control and cardiovascular outcomes.



PO1301

Plasmatic Magnesium as a Marker of Nutrition and Inflammation in Peritoneal Dialysis?

Ana T. Domingos, Roberto C. Marques, Anabela M. Guedes, Céu Laranjo, Idalécio Bernardo, Pedro L. Neves. *Centro Hospitalar do Algarve EPE, Faro, Portugal*.

Background: There's an important prevalence of hypomagnesemia (hypoMg) in Peritoneal Dialysis (PD), namely due to magnesium (Mg^{2+}) losses in the dialysate. HypoMg has recently been associated with increased mortality in PD, a clearer fact in Hemodialysis. Processes involved seem to include alterations in body composition (BC) and inflammation, known as predictors of mortality in PD, beyond the risks immediately associated with hypoMg such as cardiac arrythmias. The aim of this study was to evaluate the correlations between plasmatic Mg^{2+} (pMg), BC, inflammation and nutrition in PD.

Methods: A prospective study included patients admitted at our Unit between 2010 and 2019, with simultaneous acquisition of bioelectrical impedance analysis (BIA) and pMg levels. Clinical and biochemical data were collected from clinical records. Spearman rank-correlation coefficient was used to report correlations.

Results: 54 patients were enrolled (mean age of 54.2±17.6 years, 61% men, 86.3% hypertensive and 33.3% diabetic). Mean pMg was 2.1±0.37 mg/dL and high-sensitivity C-reactive protein (hs-CRP) 10.8±20 mg/L. Inverse correlations were found between pMg and fat mass (rs=-0.356, p=0.009), body mass index (BMI) (rs=-0.414, p=0.002) and hs-CRP (rs=-0.334, p=0.014). Regarding serum markers of nutrition, a correlation with pre-albumin (rs=0.297, p= 0.036) was found. No correlations with phase angle, ratio of extracellular mass to body cell mass, lean body mass index, serum albumin, creatinine, total protein, total cholesterol or transferrin were found. Hs-CRP in turn correlates with BMI (rs=0.309, p=0.023), inversely with pre-albumin (rs=-0.353, p=0.012) and has a tendency to correlation with fat mass (rs=0.254, p=0.052) and albumin (rs=-0.267, p=0.051).

Conclusions: Lower pMg is associated with increased fat mass and higher BMI. No correlations were found with other nutrition markers. The obesity paradox is still controversial in PD and some authors defend that an elevated BMI is associated with neutral to deleterious impact on PD outcomes, fact explained by fat mass. Proinflammatory effects are also well described in relation to obesity in PD. In conclusion, hypoMg seems associated with poorer nutrition, increased fat mass and inflammation. Dietary interventions with Mg^{2+} supplementation could address this problem and should be a target of interventional studies.

PO1302

Feasibility of Using Platelet PGDprime® Rapid Assay as a Peritonitis Screen for Peritoneal Dialysis Patients

Lisa A. Shinefeld, Nancy B. Best, Remo P. Vallejo. *Verax Biomedical Incorporated, Marlborough, MA.*

Background: Peritoneal Dialysis (PD) patients carry the risk of bacterial infection via the catheter access site and the exit site. Peritonitis is suspected based on patient symptoms and the visual quality of effluent, but may not be confirmed until a sample of the effluent is tested at a central lab via culture. A result may take several days to generate. The Platelet PGD*prime* rapid test is a multiplexed immunoassay used to detect Gram-positive (GP) and Gram-negative (GN) bacteria in platelet units prior to transfusion. The utility of this rapid test for detection of bacteria in PD effluent was evaluated.

Methods: A sample (600 mL) of PD effluent from an asymptomatic patient was obtained and confirmed to be negative for bacteria by aerobic and anaerobic cell culture. Eight bacteria (5 GN & 3 GP) were grown in RPMI media and individually spiked at initially high levels into aliquots of the PD effluent, then serially diluted with the unspiked effluent in tenfold series. The CFU/mL of each starting spiking stock was quantified by OD at 620 nm. Each dilution was tested with PGD*prime* to determine the observed lowest detectable level of bacterial contamination by ten-fold dilution.

Results: The lowest detectable concentrations of bacteria are summarized in Table 1. The true Limit of Detection (LoD) for each species is between the lowest detectable concentration shown and the next lower logfold dilution level. Total test time was 25-35 minutes.

Conclusions: The PGD*prime* rapid test for bacteria in platelets can detect bacteria in PD effluent and may be useful for early detection of peritonitis in PD patients. Additional optimization to further adapt the test for PD effluent testing is underway.

Funding: Commercial Support - Verax Biomedical Incorporated

Table 1. Detection of Bacteria in PD Effluent by the PGDprime Rapid Test

Species	*Lowest Concentration Detected by PGDprime (CFU/mL)*
Klebsiella pneumoniae	*9.6E+04*
Serratia marcescens	*2.0E+04*
Pseudomonas aeruginosa	*2.7E+04*
Escherichia coli	*1.0E+04*
Klebsiella aerogenes	*2.5E+04*
Staphylococcus aureus	*3.5E+06*
Staphylococcus epidermidis	*2.3E+05*
Bacillus cereus	*1.0E+05*

PO1303

Omentectomy Reduces the Need for Peritoneal Dialysis Catheter Revision in Children: A Study from the Pediatric Nephrology Research Consortium

Meredith P. Schuh,[1] Edward Nehus,[1] Abdulla Ehlayel,[7] Stephanie L. Clark,[7] Aftab S. Chishti,[2] Alcia D. Edwards- Richards,[8] Stephanie M. Jernigan,[9] Margret Kamel,[4] Kera E. Luckritz,[3] Bliss Magella,[1] Asif Mansuri,[6] Amy C. Wilson,[5] Donna J. Claes.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Kentucky Medical Center, Lexington, KY; [3]University of Michigan, Ann Arbor, MI; [4]Emory University, Atlanta, GA; [5]Indiana University Health, Indianapolis, IN; [6]Augusta University, Augusta, GA; [7]The Children's Hospital of Philadelphia, Philadelphia, PA; [8]Wake Forest Baptist Health, Winston-Salem, NC; [9]Children's Healthcare of Atlanta Inc, Atlanta, GA.*

Background: There are no recommended guidelines for performing omentectomy at the time of peritoneal dialysis (PD) catheter placement in the pediatric population. There are no multi-center studies investigating omentectomy and PD catheter revision in the pediatric dialysis population.

Methods: A multi-center, retrospective study was performed through the Pediatric Nephrology Research Consortium (PNRC). Data review included all incident tunneled PD catheters placed between 1/1/2011 – 12/31/2016 for first-time PD patients (ages 0-20). The primary outcome was the need for catheter revision and/or replacement following initial placement. Multivariable logistic regression was used to determine the independent association of omentectomy with catheter revision/replacement.

Results: Data from 184 patients (62.5 % male; 35.4 % glomerulonephritis) from 8 centers were analyzed. Median age at PD catheter insertion was 7.4 years. Omentectomy was performed in 67 children at the time of catheter placement (36.4%). Revision or replacement was required in 63 children (34.2%); median time to revision/replacement was 38.5 days (IQR 20.5, 109) after catheter insertion. Revision/replacement of the catheter occurred in 23.9% who had an omentectomy, compared to 52.2% without omentectomy (p=0.0005). Compared to younger children, those ≥ 6 years of age at the time of PD catheter placement had decreased risk of catheter revision/replacement (18.2% age ≥ 6 vs 56.5% age < 6, p <0.001). After adjusting for all clinical and surgical covariates, omentectomy reduced need for revision by almost 70%, and revision was 4x more likely in those < 6 years of age.

Conclusions: This multi-center study is the first to show that omentectomy at the time of PD catheter placement in pediatric patients is associated with decreased PD catheter revisions. Omentectomy should be strongly considered at the time of PD catheter placement, especially in children < 6 years of age who are at high risk for PD catheter malfunction.

PO1304

Quality Improvement Initiative: Suboptimal Utilization of Loop Diuretics in Peritoneal Dialysis Patients

Zeyana Al hadhrami, Omar M. Ghadieh, Eduard A. Iliescu. *Queen's University, Kingston, ON, Canada*.

Background: The prescription of high dose loop diuretics is safe and beneficial for PD patients to increase urine output, control of volume status, and decrease the need for high PD fluid glucose concentrations. The aim of this study is to assess the current state and develop an algorithm for rational diuretic use in PD pts to optimize dose, frequency, and reduce pill count in patients with urine output while reducing diuretics in anuric patients.

Methods: This was a prospective cohort QI initiative in prevalent PD pts. The algorithm considered PD fluid glucose > 1.5 % used, the volume status, current and historical urine volume trend, and clinical assessment. The dosing of loop diuretics was increased in pts with residual urine output > 200 ml/24 hrs when increased ultrafiltration was needed, while diuretics were stopped in anuric pts. The outcomes were the proportion of pts on loop diuretic in those with and without urine, the dose (median total daily,

frequency) and the pill count before and 3 months after the intervention. In the algorithm, Furosemide prescriptions of 40 mg tablets were converted to 500 mg tablets divided as needed where possible.

Results: The study included 91 pts, mean age 63 yrs, 45% female, 75% Caucasian, 64% with DM, median time on PD of 1.58 yrs. Furosemide was the only loop diuretic used. At base line median total daily dose was 120 mg, BID 27 %, OD 73 %, and mean pill count was 3.6 pills/day. The proportions of patients prescribed diuretics among those with and without urine output were 54/84 (63%) and 8/17 (47%) respectively. Three months after the intervention the median total daily dose was 240 mg, BID 53 % and OD 47%, mean pill count was 2.96 pills/day, and the proportions of pts on Furosemide for those with and without urine output improved to 85% and 27% respectively (all changes $p < 0.05$).

Conclusions: This short-term study suggests that QI intervention using an algorithm aimed at optimizing loop diuretic use in PD patients based on PD fluid glucose concentration used, and urine volume can increase the prevalence of diuretic use, increase the single and total daily dose, improve dosing frequency, and reduce pill burden in patients with urine output while reducing unnecessary use in anuric pts. This study is ongoing to examine outcomes of urine volume, glucose load of PD fluid, and electrolytes with the intervention.

PO1305

Assessing Fluid Status of Peritoneal Dialysis Patients with Assistance of Lung Ultrasound (Fluid-PLUS)

Michael Ajuria,[1,2] Wael F. Hussein,[2,1] Graham E. Abra,[2,1] Vladimir Glinskii,[1] Brigitte Schiller.[2,1] *[1]Stanford University School of Medicine, Stanford, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Fluid overload (FO) is common in patients on dialysis, and is associated with increased cardiovascular morbidity and mortality. Clinical examination is limited in detecting FO. Lung ultrasound (US) is a portable and relatively inexpensive objective measure of FO. In this study, we aimed to evaluate the potential utility of lung US for evaluation of FO in patients on peritoneal dialysis (PD) in the ambulatory setting.

Methods: This is a cross-sectional, observational study at 4 home dialysis clinics in Northern California. Adult patients on PD attending routine outpatient visits were asked to participate. Patients on PD for less than 3 months or endorsing new or worsening shortness of breath were excluded. Participants underwent lung US examination. Based on the total number of B-lines, patients were classified as no US-fluid overload (< 16 lines), or US FO (>= 16 lines). Independently, nurses clinically evaluated patients' fluid status and determined if a patient had clinical FO or no clinical FO.

Results: 43 patients underwent full evaluation. Mean age was 55 +/- 15, 28% were female, 51% of patients had diabetes mellitus, and median PD vintage was 19 (IQR 10-37) months. Clinically, 13 (30%) of patients had FO. Lung US identified 15 patients (35%) as having FO. Clinical and US findings were congruent in 35 (81%) patients, but discordant in 8 (19%) of patients. Of the 30 patients without clinical FO, 5 (17%) were identified with US FO. On the other hand, of the 13 patients with clinical FO, 3 (23%) had no US FO. – Figure (1). Agreement between clinical examination and lung US was moderate (kappa 0.58, 95% CI 0.32 to 0.84).

Conclusions: Lung US may identify a subset of patients with FO missed by clinical examination. Further studies are required to evaluate the impact of managing patients according to lung US findings on clinical outcomes.

Use of Incremental Peritoneal Dialysis: Impact on Clinical Outcomes and Quality-of-Life Measures

Mihran V. Naljayan,[1,2] Francesca Tentori,[3,4] Abigail Hunt,[3,4] Katherine L. Mckeon,[3,4] Martin J. Schreiber,[1] Steven M. Brunelli.[3,4] *[1]DaVita Inc, Denver, CO; [2]LSU School of Medicine, New Orleans, LA; [3]Davita Clinical Research, Minneapolis, MN; [4]DaVita Patient Safety Organization, Denver, CO.*

Background: Incremental peritoneal dialysis (PD), defined as a PD prescription that is less than the standard, full-dose prescription, has been suggested as a means of preserving residual kidney function and offering better quality of life; however, published evidence is limited.

Methods: We considered adult patients initiating PD between 31 Jul 2015 and 31 May 2019. Patients with body weight <40 kg, limb amputation, or estimated glomerular filtration rate (eGFR) >20 mL/min during first 4 weeks on PD were excluded. Exposure group was ascribed (incremental vs full PD) based on PD prescription during dialysis weeks 5 to 8. Incremental PD was defined by treatment frequency, exchanges/day, and exchange volume (for continuous ambulatory PD [CAPD] patients) or by treatment frequency and presence/absence of last fill (for automated PD [APD] patients). Analyses were performed separately for CAPD and APD patients: for each, incremental PD patients were propensity score matched to eligible full PD patients. Patients were followed for up to 12 months until censoring for loss to follow-up or study end. Outcomes were compared using Poisson models (mortality, hospitalization, PD failure), linear mixed models (eGFR), and paired t-tests (Kidney Disease Quality of Life [KDQOL] domain scores).

Results: Among CAPD patients, compared to those on full PD, incremental PD use was associated with better KDQOL scores on 3 domains: physical composite score (42.5 vs 37.7, P=0.03), burden of kidney disease (60.2 vs 45.6, P=0.003), and effects of kidney disease (79.4 vs 72.3, P=0.05). Hospitalization and mortality rates were numerically lower (0.77 vs 1.12 admits/patient-year, P=0.09 and 5.0 vs 10.2 deaths/100 patient-years, P=0.22); there was no association with residual eGFR or PD failure rate. Use of incremental PD was not differentially associated with any outcome among APD patients.

Conclusions: These results suggest that it may be beneficial to use incremental PD in the context of CAPD, particularly with respect to quality of life. No significant benefits were detected among patients initiating APD. No detrimental effects of using incremental PD were observed for either PD type.

PO1307

Combination of Hypertension and Preexisting Cardiovascular Disease and Mortality in Patients on Continuous Ambulatory Peritoneal Dialysis

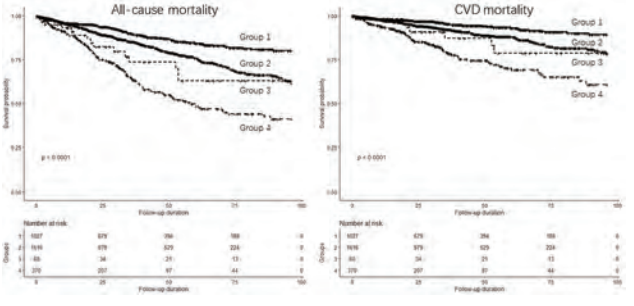
Xianfeng Wu, Niansong Wang, Junnan Wu. *Affiliated Sixth People's Hospital, Shanghai Jiao Tong University, Shanghai, China, Shanghai, China.*

Background: Little is known about whether combination of hypertension and pre-existing cardiovascular disease (CVD) is more strongly associated with outcomes compared with either comorbidity alone in patients on continuous ambulatory peritoneal dialysis (CAPD).

Methods: We conducted a retrospective study of 3073 incident Chinese patients on CAPD from five dialysis centers between January 1, 2005 and December 31, 2018 in a real-world setting. All patients were divided four groups: group 1 (patients without either hypertension or pre-existing CVD); group 2 (patients with only hypertension); group 3 (patients with only pre-existing CVD); group 4 (patients with both hypertension and pre-existing CVD). The association between interesting comorbidities and mortality was analyzed using Cox regression models.

Results: Over a median of 33.7 months of follow-up, 581 (18.6%) patients died, with 286 (9.3%) CVD mortality. The incidence of all-cause mortality was 32.2, 56.1, 74.4, and 131.0/1000 patient-years, and the incidence of CVD mortality was 15.0, 28.2, 34.7, and 69.6/1000 patient-years in group 1, 2, 3, and 4, respectively. Cumulative survival and CVD mortality-free survival were lowest in those with both hypertension and pre-existing CVD (Figure 1). After adjusting for the demographic characteristics and laboratory parameters, group 4, 3, and 2 had 3.07 (95% CI 2.23 to 4.22), 2.05 (95% CI 1.11 to 3.80), and 1.38 (95% CI 1.08 to 1.77) of hazard ratios for all-cause mortality, and 3.20 (95% CI 2.04 to 5.03), 2.09 (95% CI 0.85 to 5.15), and 1.56 (95% CI 1.09 to 2.23) of hazard ratios for CVD mortality, respectively, compared to the group 1.

Conclusions: Combination of hypertension and pre-existing CVD was more strongly associated with mortality compared to either comorbidity alone in CAPD patients.



PO1308

Returning to Peritoneal Dialysis After Kidney Transplant Failure Is a Valuable Option

Ana Gabriela J. T. Melo, Rayra G. Ribeiro, Daniela Via Reque Cortes, Géssica S. Braga Barbosa, Carolina S. Martins, Luiza K. Araujo, Benedito J. Pereira, Hugo Abensur, Rosa M. Moyses, Rosilene M. Elias. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: The prognosis for patients returning to peritoneal dialysis (PD) after a failed transplant is poor and associated with peritonitis and transfer to hemodialysis. PD has an advantage over hemodialysis in preserving residual renal function, which is associated with better outcomes, including survival. Maintaining immunosuppression after starting PD can preserve transplant function but can also increase the risk for infection, and therefore is still arguable.

Methods: We have reviewed electronic charts of patients on PD in the last 8 years in a tertiary academic hospital. We compared survival, residual diuresis and reasons to discontinue PD in 2 groups: patients with graft failure that returned to PD (PD-Ktx, N=17) and other clinical conditions (PD-other, N=153). Reasons for stopping PD therapy included: dialysis inadequacy, kidney transplant, death, transfer to another center, and peritonitis.

Results: The median follow-up was 36 (12,71) months, which was similar between groups [45 (18,96) in PD-Ktx vs. 35 (12,70) months in PD-other, p=0.403]. Patients from PD-Ktx group were lighter than those from PD-other (57.2 ± 14.7 vs. 66.1 ± 16.1kg, p=0.032). Initial and final diuresis volumes were similar among groups (p=0.879 and p=0.698, respectively). Reasons for stopping PD therapy in PD-Ktx and PD-other groups were dialysis inadequacy (17.6% and 20.9%, respectively), kidney transplant (17.6% and 15.7%), death (5.9% and 12.4%), transfer to another center (17.6% and 20.9%), and peritonitis (17.6% and 14.4%). These outcomes were not significantly different between groups (p=0.921). Four out of 17 patients from PD-Ktx maintained immunosuppression and none of those had peritonitis. Kaplan Meier survival comparing PD-Ktx and PD-other showed there is no difference in stopping PD due to peritonitis (log-rank 0.543), which was confirmed in a Cox regression adjusted for weight, diabetes, residual diuresis and age (p=0.493).

Conclusions: Clinicians should leverage the risk of peritonitis versus extend PD technique by preserving residual diuresis in patients with allograft failure returning to PD. We have found similar outcomes in the current study. However, whether withdrawal immunosuppression is needed for these patients requires further investigation.

PO1309

Five-Year, Prospective, Observational, International Study on the Impact of Decision-Making Tools for Choice of Renal Replacement Therapy Modality

Belen Marron,[1] Suzanne H. Pearce,[1] Janusz Ostrowski,[4] Dan Munteanu,[3] Marietta Török,[1] Jaime Garcia-Marron,[2] Carlos Lucas,[1] Israel P. Silva,[1] Filiz Akdeniz,[1] Charlotta Wollheim,[1] Fernando Macario.[1] *[1]Diaverum Renal Services Group. Medical Office, Hyllie, Mälmo, Sweden; [2]ESIC, Madrid, Spain; [3]Diaverum Renal Services, Bucharest, Romania; [4]Diaverum Renal Services, Wloclawek, Poland.*

Background: Decision-Making Tools (DMTs) are still not widely used but are considered the Gold Standard to ensure patients are well informed to choose renal replacement therapy (RRT) modality. OBJECTIVE: To analyze the impact of a structured modality information program (via DMTs) on RRT modality choice and start.

Methods: All 2014-2017 predialysis patients (pts) with CKD G4-G5 and those starting unplanned dialysis without a prior information process underwent a DMTs process for RRT choice and were followed up to Dec.31st, 2018. DMTs included values evaluation, RRT information with different tools, staff deliberation support and patient modality choice. Results shown as percentage of pts who reached a certain stage over the total number of pts under evaluation.

Results: 2012 pts (mean age 61 y.) from 48 clinics (cl.) in Poland (PL, 19 cl., 980 pts), Romania (RO, 12 cl., 351 pts), Hungary (HU, 10 cl., 341 pts), Germany (DE, 6 cl., 292 pts) and Argentina (AR, 1 cl., 48 pts) underwent DMTs. Staff considered PD contraindicated in 29% of pts, hence optimal candidates for HD/PD were 1408 pts. (mean age 60y. and 46% prone for a home therapy). Early referral (≥3 m. in clinic before DMT started): 51%. Aids used included written information (97% of pts), DVD in 27% and HD/PD utility visits in 49%. Relatives' participation in the process was 82%. Most pts (91%) considered the program useful whilst 64% of staff felt that this program was better than the prior one. PD choice (35%) varied among countries: 15% (RO), 30% (PL), 36% (HU), 62% (DE) and 98% (AR). For pts who had started dialysis by study closure (n=948), PD as chronic RRT was 31% (9% after an unplanned HD start); 13% (RO), 27% (PL), 34% (HU), 54% (GE) and 83% (AR).

Conclusions: Use of DMTs at the time of RRT modality choice complies with patient empowerment and decision sharing (patients-relatives-staff). PD choice and take-on varied among countries. Most patients who chose PD were chronically ascribed to PD representing at least one third of the suitable patients for both dialysis modalities.

PO1310

Peritoneal Dialysis or Haemodialysis for Polycystic Kidney Disease? Ten Years' Experience in a Single Centre

Zi Chan, Ka Lok Chan, Chi Kwan Lam, Wai ping Law, Wai lun will Pak, Patrick Y. Wong, Sunny S. Wong. *United Christian Hospital, Hong Kong, Hong Kong.*

Background: When polycystic kidney disease (PKD) progresses into end-stage renal disease (ESRD), the choice of dialysis modality is not straight forward. PKD may increase risk of complication and technique failure (TF) in peritoneal dialysis (PD). We looked at the long-term outcomes of PKD patients put on either PD or haemodialysis (HD).

Methods: New cases of ESRD due to PKD entered into dialysis program of a regional hospital in Hong Kong from December 2009 to November 2019 were identified. Their baseline demographics, mean kidney size and clinical outcomes were recorded. Hong Kong has a 'PD first' policy. But for PKD patients, the decision to start PD or HD is by the nephrologists' clinical judgment. For statistical analysis, chi-square test and t-test were used for categorical and continuous variables respectively. Kaplan-Meier curve was used to analyse survival.

Results: A total of 45 patients were identified, 31 were put on PD, 14 were put on HD. Their baseline characteristics were shown in Table 1. HD patients had higher mean kidney size to body weight ratio compared to PD patients. The median survival of those on PD (7.1 years) and HD (7.2 years) were not significantly different. For patients on PD, the 5 year TF rate was 0.22, which was similar to overall PD patients in our centre. Four patients had early TF (mean time 1.6 years). Two of them had significant pressure symptoms, the other two had inadequate dialysis. Further analysis showed that for those with TF, both mean kidney size and mean kidney size to body weight ratio were significantly higher than those without TF (Table 2).

Conclusions: This study showed that for PKD patients with moderate enlarged kidneys, PD could be a reasonable choice. However, for patients with very large kidneys, early TF rate with PD was high, HD would be a better choice for these patients.

Table 1

	PD	HD	p-value
Patient number	31	14	
Age	54.9 ± 8.5	53.0 ± 10.0	0.513
Gender (male)	45.2%	35.7%	0.553

PO1311

Peritoneal Dialysis in the Setting of Acute Brain Injury, an Underappreciated Modality

Elaina J. Wang,[1] Ankur Shah.[2,1] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Division of Nephrology, Rhode Island Hospital, Providence, RI.*

Introduction: Dialysis is complicated in the setting of acute brain injury due to a number of factors including acute shifts of solute, acute acid base shifts, need for anticoagulation, and changes in intracranial pressure. For these reasons, CRRT is the modality of choice when renal replacement therapy is needed. PD is less discussed but shares many of the benefits often attributed to CRRT. We describe a case successfully managed with PD.

Case Description: A 25-year-old male with history of ESRD secondary to FSGS on CCPD for 5 years presented to the hospital with headache and altered mental status. He was in his usual state of health until the day prior to admission. Initial imaging revealed a large intraventricular hemorrhage extending to the 4th ventricle. He underwent an emergent right depressive hemicraniectomy and clot evacuation. Patient was admitted to NCCU. Post-operative imaging revealed worsening cerebral edema, intraventricular hemorrhage, and hydrocephalus. As the patient had a functioning tenkhoff catheter, the decision was made to continue peritoneal dialysis, which he tolerated well until the need for a percutaneous gastrostomy tube arose. He was transitioned to hemodialysis transiently but returned to peritoneal dialysis once he was able to tolerate oral food. He has now continued on PD for 1 year.

Discussion: In the dialytic management of patients with acute brain injury, a number of considerations must be undertaken including the avoidance of hypotension to minimize ischemia reperfusion injury and maintain cerebral perfusion pressure, avoidance of anticoagulants that can precipitate or worsen bleeding, the potential for the precipitation of cerebral edema by rapid solute clearance and osmotic dissipation of therapeutic hypernatremia, and the mitigation of intracellular acidosis from bicarbonate delivery. Peritoneal dialysis is an ideal but underreported modality as evidenced by the case presented.

PO1312

Peritoneal Ultrafiltration Is Associated with Improvement of Functional Class in Patients with Congestive Heart Failure

Gajapathiraju Chamarthi, Amardeep Singh, Harini Bejjanki, Amir Kazory. *University of Florida College of Medicine, Gainesville, FL.*

Background: Congestion is considered an integral component of heart failure syndrome and is a key driver of adverse outcomes. Peritoneal ultrafiltration (PUF) has emerged as an efficient therapeutic modality for management of fluid overload in patients with congestive heart failure (CHF) without end-stage kidney disease (ESKD). The efficacy of therapies of CHF are conventionally assessed through their effect on New York Heart Association (NYHA) classification. We sought to explore the reported impact of PUF on functional class of these patients.

Methods: Articles cited in PubMed database using keywords "heart failure", "peritoneal ultrafiltration", and "peritoneal dialysis" were searched. Available data from contemporary clinical trials of PUF in patients with CHF (without ESKD) that were performed between January 2010 and August 2019, and included more than 20 patients were selected and reviewed. Those trials evaluating the impact of PUF on NYHA functional class were included. Pertinent data were extracted and recorded.

Results: Out of 10 clinical studies meeting the criteria, 4 did not have the needed data on NYHA class; 6 studies (3 retrospective and 3 prospective) with a total of 408 participants and a mean age of 71.9 were included. The pre-PUF mean left ventricular ejection fraction and weight were 34.4% and 78.6 Kg respectively. The median follow up was 13.7 months. There was substantial variation in the reporting of time point for various endpoints. These studies unanimously reported improvement in NYHA functional class, which was close to -1 class for those that assessed the entire study population.

Conclusions: Available data based on contemporary clinical trials suggests that PUF, when used for management of patients with CHF, is associated with improvement of functional class. This finding is in keeping with our previous report on the salutary impact of PUF on volume status of these patients. Future controlled studies are needed to explore whether these benefits would translate into improved survival.

PO1313

Blood Urea Nitrogen/Creatinine Ratio and Mortality in Patients on Continuous Ambulatory Peritoneal Dialysis

Xianfeng Wu, Junnan Wu, Niansong Wang. *Affiliated Sixth People's Hospital, Shanghai Jiao Tong University, Shanghai, China.*

Background: Little is known about the association between the Nitrogen/Creatinine (BUN/Cr) ratio and mortality in continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: We conducted a retrospective study of eligible 2837 patients on CAPD from five dialysis centers in Chinese between January 1, 2005 and December 31, 2018. We calculated baseline BUN/Cr ratio, and then estimated the hazard ratio (HR) of BUN/Cr ratio for all-cause mortality using Cox hazard regression models, and used the restricted cubic spline curve to evaluate the association between the BUN/Cr ratio and mortality, with adjusting for confoundering factors.

Results: The median age of at baseline was 50.0 years (39.0-61.0) and the baseline median BUN/Cr ratio was 7.02 (5.43-9.13). The median observational period was 35.3 (18.3-61.9) months. During this period, 509 (17.9%, 95% CI 16.5 to 19.4%) of 2837 patients died, with 253 (8.9%, 95% CI 7.9% to 9.9%) CVD mortality. The incidence of all-cause mortality was 39.8, 48.9, 50.2 and 70.7/patient-years, and CVD mortality incidence was 19.0, 26.0, 28.1, 30.9/1000 patient-years among quartile 1, quartile 2, quartile 3, and quartile 4, respectively. When using BUN/Cr ratio of ≤5.43 as a reference, those with BUN/Cr ratio ≥9.14 had 1.72 (95% confidence interval, 1.34 to 2.22) of HR for all-cause mortality and 1.66 (95% confidence interval, 1.15 to 2.40) of HR for CVD mortality, after adjusting for baseline characteristics and laboratory variables. Cubic spline showed there was a linear association between the baseline BUN/Cr ratio and the risk of all-cause and CVD mortality, with a higher risk of mortality at a higher BUN/Cr ratio (Figure 1).

Conclusions: In conclusion, the BUN/Cr ration at the start of dialysis therapy was independently associated with all-cause and CVD mortality among CAPD patients, with a higher risk of mortality at a higher BUN/Cr ratio.

PO1315

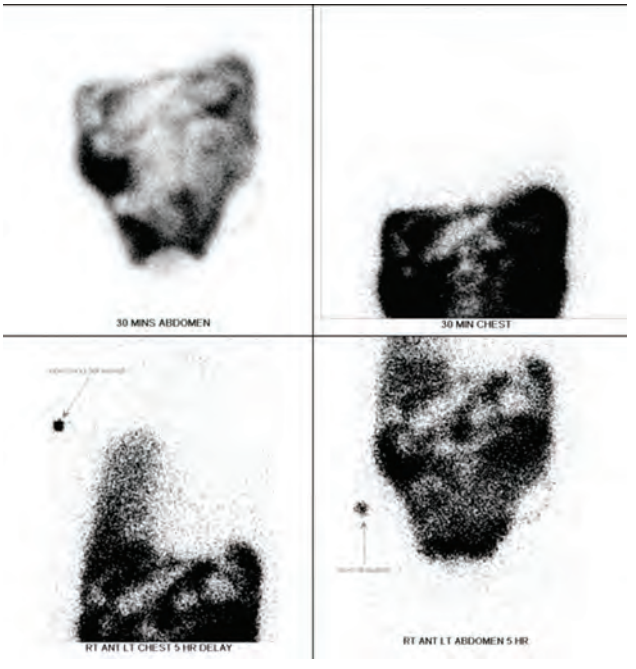
Between Gradients and Ratios

Nidrit Bohra, Abigayle Sullivan, Haseeb Chaudhary. *Reading Hospital, Reading, PA.*

Introduction: Hydrothorax due to peritoneal dialysis is a rare but known outcome from dialysis mainly in continous ambulatory peritoneal dialysis [CAPD]. Around 80% cases are due to a pleuroperitoneal fistula (PPF), an abnormal communication between the pleural and peritoneal space allowing leak of dialysate. A pleural fluid glucose to serum glucose gradient of >50 mg/dl is 100 % specific for detecting the leak of glucose rich dialysate via the fistula.

Case Description: A 63-year-old man with history of heart failure with reduced ejection fraction and end stage renal disease [ESRD] on continuous cyclic peritoneal dialysis [CCPD] for 3 months, presented with recurrent hydrothorax. CXR showed worsening right sided hydrothorax despite a recent paracentesis. He continued CCPD as his initial pleural to serum [PF-S] glucose gradient was normal at 21 mg/dl. However, PF-S glucose ratio was >1 raising the clinical suspicion. For confirmation, a peritoneal scintigraphy with nuclear technetium 99 scan was performed that revealed a pleuroperitoneal fistula as the source of the recurrent hydrothorax.

Discussion: Peritoneal dialysis can be complicated by development of a hydrothorax in both CAPD and CPPD. Hydrothorax development is often attributed to a pleuroperitoneal leak which can be congenital or acquired. Initial diagnosis can be supported by increased PF-S glucose gradient >50mg/dl, but in our case, this did not prove to be a reliable indicator. Literature suggests that the pleural effusion is unlikely to be due to a pleuroperitoneal communication with a low PF-S glucose gradient of <50 mg/dL. However, there is also evidence that supports that peritoneal leak as the only cause for pleural glucose to be higher than the serum, i.e. a PF-S glucose ratio >1.0. The PF-S glucose > 1.0 in our case also supports the higher sensitivity of this approach.



PO1316

Impact of Obesity on Success of Peritoneal Dialysis in ESRD Patients

Irene Nunuk, Frank J. O Brien. *Washington University in Saint Louis, Saint Louis, MO.*

Background: Obesity rate is rising in the US and 1 in 4 adults are projected to have severe obesity by 2030. Prevalence of obesity in ESRD patients is also rising. Higher BMI has been shown to be associated with better survival in HD patients. However, data is inconsistent for PD patients. We examine the impact of different BMI classes on PD outcomes

Methods: This is a single center retrospective cohort study. Inclusion criteria includes patients >18 yrs, > 3 month PD vintage and patients who received PD from 2014-2018. Exclusion criteria includes patients with BMI <20, patients with no Kt/V data or missing BMI. SAS statistical software was used for data analysis

Results: 181 total patients are divided into 4 groups. Baseline characteristics were similar in all groups (fig 1). Outcomes include transition from PD to HD, transplantation rate, mortality rate, number of hospitalizations, PD vintage and catheter related infections. Our data showed that there is no difference in outcomes among different BMI groups (tab1, fig 2)

Conclusions: Our single study shows that obesity is not associated with poor peritoneal dialysis outcomes. People with high BMI should still be offered PD as a modality

Outcomes	BMI 20-24.9 kg/m2	BMI 25-29.9 kg/m2	BMI 30-34.9 kg/m2	BMI >35 kg/m2	P value
Transition from PD to HD	26.2%	26.2%	30.4%	50%	0.092

PO1317

Late Onset of Sweet Hydrothorax: A Rare Complication of Peritoneal Dialysis

Amel L. Tobaa, Tyler Andrea, Swati Arora, Harry K. Williams, Bhavna Chopra. *Allegheny General Hospital, Pittsburgh, PA.*

Introduction: Peritoneal dialysis (PD) has a variety of complications, with diaphragmatic leak causing pleural effusions occurring in 1.6% of cases within 30 days of initiation of PD. We present a case of late-onset right sided pleural effusion, 14 months after initiation of PD, due to spontaneous pleuro-peritoneal leak and the course leading to this rare diagnosis.

Case Description: A 34-year-old female with polycystic kidney disease, bilateral native nephrectomies, and failed kidney transplant receiving PD presented with three days of right sided chest tightness and shortness of breath associated with ultrafiltration failure on PD. Chest x-ray on admission showed a large right-sided pleural effusion (Figure1A). The patient received PD using 2.5% dextrose dianeal; 2 hours after thoracentesis was performed with placement of a chest tube. Fluid analysis revealed a transudative effusion, with glucose of 322 mg/dL with corresponding plasma glucose of 147 mg/dL, consistent with dianeal solution in pleural space. Figure 1B demonstrates passage of the radiotracer from the peritoneal cavity (B) to the pleural space (A), suggestive of right-sided pleuro-peritoneal fistula (C). PD was discontinued and the patient was transitioned to hemodialysis (HD).

Discussion: This case demonstrates a rare complication of PD. Hydrothorax can occur due to increased intra-abdominal pressure causing migration of dialysis fluid from the peritoneal cavity into the pleural space by opening of defects in the diaphragm communicating the two cavities; negative intrathoracic pressure and transiently increased hydrostatic pressure of the dialysate may cause dialysate leak. This phenomenon typically occurs more frequently in women with polycystic kidney disease due to reduced abdominal capacity. Increased glucose in pleural fluid, CT peritoneography and NM scintigraphy are methods of confirming diagnosis. Transition to HD with monitoring for spontaneous closure of the pleuro-peritoneal leak is first line conservative treatment. If the leak persists, surgical repair of the diaphragmatic defect is definitive treatment to resume PD.

PO1318

Ochrobactrum Peritonitis in Peritoneal Dialysis: A Rare Case and Literature Review

Edward G. Medeiros,[1] Lubin Juarez,[1] Susie L. Hu,[1] Ankur Shah.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Providence VA Medical Center, Providence, RI.*

Introduction: Ochrobactrum are glucose-non-fermentative, non-fastidious, motile gram-negative bacilli typically isolated in aqueous environments. Reported infections by this pathogen primarily occur in immunocompromised hosts from environmental exposure, nosocomial contamination of sterile fluids and/or indwelling catheter use. Due to impaired immunity and exposure to exogenous microbes, peritonitis is a common and feared complication of peritoneal dialysis. We present a case of *Ochrobactrum Anthropi* peritonitis and review the literature of similar case.

Case Description: A 67-year-old male with history of ESRD secondary to IgA nephropathy on CCPD for 4 years presented to the hospital with fevers, nausea, abdominal pain and generalized weakness. He experienced an episode of acute bacterial peritonitis 1-month prior to this hospitalization secondary to Pseudomonas aeruginosa treated with ciprofloxacin and no other previous PD complications. A peritoneal effluent sample showed 347 nucleated white blood cells. He was empirically initiated on intraperitoneal cefepime and vancomycin, as well as oral fluconazole for fungal prophylaxis. Peritoneal effluent culture grew Orchrobactrum anthropi, sensitive to fluoroquinolones and carbapenems but resistant to cefepime. Antimicrobials were subsequently transitioned to ciprofloxacin and fluconazole, and he completed the antibiotic course with resolution of symptoms and peritoneal leukocytosis.

Discussion: We present the 8th case of *Ochrobactrum Anthropi* peritonitis in a peritoneal dialysis patient. Zero of the published cases were associated with bacteremia. Attempted treatments have typically included carbapenems, aminoglycosides, and fluoroquinolones. Three of eight cases required removal of the tenkhoff catheter. Peritonitis related mortality was zero percent. This case and review of the literature can serve to inform future occurrences.

PO1319

The Utility of Point-of-Care Reagent Strips for Rapid Rule out of Peritonitis in Patients on Peritoneal Dialysis

Madhuri Ramakrishnan, Andy Chuu, Frank J. O Brien. *Washington University in Saint Louis, Saint Louis, MO.*

Background: 10% of all end stage renal disease (ESRD) patients in the United States use peritoneal dialysis (PD). An important complication in this population is PD-related peritonitis, which is a risk factor for hospitalizations, mortality and is the most common cause of transition to hemodialysis. The diagnosis of PD-related peritonitis requires the presence of white blood cell count of > 100/μL or positive culture from the effluent dialysate in the setting of abdominal pain and cloudy effluent dialysate. This method requires time and access to a diagnostic facility, which may not be easily available to all patients on PD. Point-of-care strips that utilize colorimetric changes in leukocyte esterase reagent can be used to provide a quick, presumptive diagnosis of peritonitis. We evaluate the specificity or true negative rate of two reagent strips – PeriScreen and Multistix 10 SG.

Methods: We are conducting a diagnostic test study in a prospective cohort at the home dialysis clinic at Washington University in Saint Louis. We plan to include 100 patients to achieve a power of 80% to be able to obtain a 95% specificity. We are including

patients who are asymptomatic i.e. without abdominal pain or cloudy dialysate effluent. We will be obtaining four 20 mL aliquots of their effluent dialysate, taken at the time when their dialysis kinetics are being measured. Two samples will be sent to the laboratory to obtain white blood cell count, and bacterial culture. PeriScreen and Multistix 10 SG reagent strips will then be dipped in the remaining two samples. The results from all four tests are reported as positive or negative, and the results of the reagent strips will be compared to the gold standard of white blood cell count and culture. Specificity will then be calculated.

Results: Data from 10 patients has been obtained to-date. The average age of these patients was 60.1 (± 14.7) years, with 50% of them being females, and 50% of them were Caucasians. In these patients, the Periscreen was found to have specificity of 100% and the Multistix 10 SG was found to have specificity of 100%.

Conclusions: Based on preliminary results, both PeriScreen and Multistix 10 SG reagent strips appear to have specificity >95%. Using this data, we aim to create a protocol for patients to use these strips at home to help rule out PD-related peritonitis in a more efficient manner.

PO1320

Acyclovir for Herpes Zoster Encephalitis: Panacea or Problem?

Adil Ghaffar, Laura J. Maursetter, Neetika Garg. *University of Wisconsin System, Madison, WI.*

Introduction: Herpes zoster, which is the reactivation of varicella-zoster virus (VZV), is more common in immunocompromised patients, with a higher incidence of encephalitis. The treatment of choice is intravenous acyclovir, with one of its adverse effects being neurotoxicity. We present a case where the disease effects and the medication side effects were difficult to distinguish.

Case Description: A 59-year-old man with ESKD and a history of failed allograft on peritoneal dialysis (PD) presented with one day of acute onset headache, confusion and ataxia. Two days prior, he was diagnosed with dermatomal zoster and was treated with valacyclovir 1000 mg thrice daily. Lumbar puncture showed no pleocytosis, but protein elevation at 90 mg/dL. EEG showed no epileptiform activity and MRI and MRA brain were normal. Because his symptoms started after the initiation of overdosed valacyclovir, medication toxicity was considered more likely than VZV encephalitis. PD was continued, but he deteriorated with worsening mental and pulmonary status after aspiration, requiring intubation. Subsequently, he underwent 3 daily hemodialysis (HD) treatments without improvement. On the 3rd day post-intubation, the CSF VZV PCR returned positive prompting intravenous acyclovir at 5mg/kg/day. Over the next day, he showed marked mental status improvement and got extubated. The serum VZV PCR also resulted positive which was diagnostic of disseminated herpes zoster with encephalitis. After 6 days of intravenous acyclovir therapy, he was discharged on valacyclovir 500mg twice daily to complete 21 days of therapy.

Discussion: Herpes zoster encephalitis and valacyclovir neurotoxicity can lead to similar presentations and pose a diagnostic challenge. Due to low volume of distribution and low protein binding, valacyclovir is highly dialyzable. Hemodialysis can be helpful diagnostically. Our patient's neurologic symptoms started after an inappropriately high dose of valacyclovir was prescribed. He did not improve with hemodialysis, pointing away from valacyclovir overdose and more toward VZV encephalitis. This case underscores the need for dosing adjustments in patients with renal insufficiency and the need for clinical awareness to keep both diagnoses in mind.

PO1321

Pittsburgh Sleep Quality Index Score Predicts All-Cause Mortality Independently in Chinese Dialysis Patients

Bo Liu,[1] Qianqian Han,[1] Sha Fu,[1] Peifen Liang,[1] Bin Li,[2] Qiongqiong Yang.[1] *[1]Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]Clinical Trials Unit, the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Poor sleep quality (SQ) is common in dialysis patients. The Pittsburgh Sleep Quality Index (PSQI) is a standard tool for evaluating SQ with high validity and reliability. The relationship of PSQI score to survival in dialysis patients has not been well studied. Less was reported in China. The aim of this study was to explore the association between PSQI score and all-cause mortality in Chinese dialysis patients.

Methods: Dialysis patients who were treated for more than 3 months in Sun Yat-sen Memorial Hospital of Sun Yat-sen University between April 1, 2006 and Aug 1, 2017 and completed questionnaires on SQ were enrolled in this retrospective study. The PSQI was used to evaluate SQ. PSQI score >5 or ≤5 were considered to indicate "poor sleepers" or "good sleepers" respectively. The primary outcomes was all-cause mortality. Restrictive cubic spline (RCS) regression models were used to examine the dose-response relationship between PSQI score and all-cause mortality. Cox proportional hazards regression analysis was performed.

Results: 109 patients were included, composed of 51 hemodialysis and 58 peritoneal dialysis patients. Mean follow-up time was 69.1 ± 29.9 months, during which 21 deaths occurred. 67 (61.5%) patients had poor SQ. Compared with poor sleepers, good sleepers had significantly higher levels of hemoglobin [78.0 (68.0, 97.0) vs. 74.0 (61.0, 85.0), $P = 0.030$] and carbondioxide combining power (20.0 ± 3.7 vs. 18.0 ± 4.5, $P = 0.022$). RCS analysis showed that 7 was the cutoff value at which the effect of PSQI score on mortality changed. More than 7 of PSQI score increased the risk on all-cause mortality. When PSQI score was analyzed as a continuous variable in the multivariate Cox proportional hazards model, it was associated significantly with all-cause mortality (hazard ratio [HR] = 1.20, 95% confidence interval [95% CI] 1.05, 1.36, $P = 0.007$). While a threshold of 7 on the PSQI score was used in an additional adjusted model, a PSQI score > 7 was associated with a 2.96 times increase in the hazard for all-cause mortality (HR = 2.96, 95% CI 1.15, 7.61, $P = 0.025$).

Conclusions: PSQI score > 7 predicted all-cause mortality independently in Chinese dialysis patients. Further studies are needed to confirm decreasing PSQI score less than 7 in Chinese dialysis patients will improve survival.

PO1322

Patient Characteristics and Frequency of Prescription (Rx) Alterations in Automated Peritoneal Dialysis (APD)

Harold E. Giles,[1,2] Vidhya Parameswaran,[3] Linda Ficociello,[3] Claudy Mullon,[3] Dinesh K. Chatoth,[4] Michael S. Anger,[3] Robert J. Kossmann.[4] *[1]Nephrology Associates PC, Birmingham, AL; [2]Fresenius Medical Care Birmingham Home Clinic, Birmingham, AL; [3]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: APD provides the flexibility to adapt PD Rx to the needs, lifestyle, and health status of a patient (e.g. residual renal function [Kru], volume and transport status). The alterations may include changes in dwell volumes, dwell times, or number of exchanges. The current analysis aims to describe frequency of APD Rx alterations and patient (pt) characteristics associated with these alterations

Methods: All de-identified demographic, lab, and Rx data were extracted from Fresenius Kidney Care clinical data warehouse. Adults who were incident to APD from 01/01/2015 to 12/31/2019, completed APD training and ≥1 treatments, and had no change in PD modality or data quality issues with their records were included. Any change in dwell volumes, dwell times, or number of exchanges was considered an alteration. Characteristics of the pts in the month leading up to their most recent alteration were described and stratified by the number of Rx alterations they received at followup.

Results: 15,237 pts were eligible for inclusion. The majority (72.7%) of pts had ≥1 PD Rx alterations during a mean follow-up time of 418 days (compared to 201-day follow-up for pts with 0 alterations). Most pts (53%) had dwell volumes adjusted, with 52%, 4%, and 44% having increases, decreases, or both increases and decreases in dwell volume, respectively. The table details pt characteristics prior to alteration by frequency of Rx alterations.

Conclusions: Compared to pts with no Rx alterations, pts with more Rx alterations were heavier, had higher serum phosphorus, lower PD Kt/V, and lower Kru. The number of alterations along with the timing and direction of these changes need to be further studied to help determine if a pattern of changes is associated with risk of PD technique failure and switch to HD.

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group

Mitochonic Acid 5 Alleviates Chlorhexidine Gluconate-Induced Peritoneal Fibrosis in Mice

Hiro Inoue,[1] Yoko Obata,[1] Takehiro Suzuki,[2] Miki Torigoe,[1] Kenta Torigoe,[1] Kumiko Muta,[1] Chitose Suzuki,[2] Takaaki Abe,[2] Takehiko Koji,[3] Tomoya Nishino.[1] *[1]Department of Nephrology, Nasasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; [2]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; [3]Department of Histology and Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: Peritoneal fibrosis is one of important complications induced by long-term peritoneal dialysis. Mitochondrial dysfunction causes an increase of oxidative stress and depletion of ATP. Thus, it may be associated with fibrosis and other diseases in several organs. Recently, mitochonic acid 5 (MA-5), which is a derivative of the plant hormone indole-3-acetic acid, was synthesized and its therapeutic potential for mitochondrial dysfunction in kidney disease models has been reported. In this study, we investigated the effect of MA-5 for peritoneal fibrosis in mice.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of chlorhexidine gluconate (CG) every other day for 3 weeks in C57BL/6 mice. MA-5 was administered at 2 mg/kg by gavage every day. Control mice received only a vehicle

(distilled water). After 3 weeks of treatment, the animals were sacrificed and the peritoneal tissues were collected. The peritoneal sections were stained with Masson's trichrome for light microscopic examination and the fibrotic thickening of parietal peritoneum was measured on the randomly selected different regions on each section. The expressions of F4/80, which is a marker of macrophages, monocyte chemotactic protein-1 (MCP-1), transforming growth factor-β (TGF-β) and α-smooth muscle actin (α-SMA) were examined by immunohistochemistry.

Results: Compared with control mice, the fibrotic thickening of parietal peritoneum was significantly attenuated in MA-5 treated mice (the thickness of submesothelial area: 100.24 ± 13.67 vs 54.78 ± 7.43 μm ($p<0.05$)) with the lower number of TGF-β positive cells and α-SMA positive myofibroblasts. The infiltration of macrophages was markedly reduced with the decreased expression of MCP-1 in MA-5 treated mice than those in control mice.

Conclusions: Our results suggest that MA-5 alleviates peritoneal fibrosis with the reduction of macrophages infiltration. Thus, MA-5 may have a therapeutic potential in the progression of peritoneal fibrosis as well as kidney disease models.

PO1324

Longitudinal Changes in the Use of Peritoneal Dialysis Assistance for Patients Maintained on Peritoneal Dialysis

Jorge I. Fonseca-Correa,[1,4] Janine F. Farragher,[2] Matthew J. Oliver,[5] Arsh Jain,[3] Sarbjit V. Jassal.[4] *[1]University of Toronto, Toronto, ON, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]University Health Network, Toronto, ON, Canada; [5]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: Home dialysis therapies such as peritoneal dialysis (PD) offer flexibility and improved wellbeing for older individuals. However, a substantial proportion require assistance with personal care and health self-management. The study objective was to assess whether the nature of, and need for, assistance with PD management tasks changes over time. We hypothesized that patients and families would require less assistance as they became more familiar with PD management.

Methods: Using a multicentred, prospective observational study design, we recruited patients aged ≥50 years initiating PD. Patients underwent formal evaluation at baseline using validated components of a Comprehensive Geriatric Assessment. They then completed a monthly questionnaire for 6 months about their need for assistance with PD management tasks.

Results: 111 patients (age 69 ± 10 years, 68% male, 56% diabetic) were followed for a total of 609 patient-months. Assistance for PD management tasks remained generally stable throughout follow-up, and did not vary according to age, frailty, functional dependence or cognitive impairment. The proportion of patients needing assistance varied widely across the 13 different PD management tasks, but the proportion of patients needing help for each task remained relatively stable across time (Figure 1). Of those who needed assistance, 40% had help from a family member and 33% were helped by nurses. The family/nurse caregiver ratio for the different tasks did not change over time.

Conclusions: Older patients initiating PD, in the outpatient setting, have a high need for assistance with PD-related tasks which appears to persist over the initial 6-month period. It emphasizes the importance of starting discussions early, and addressing advance care plans, goals and most importantly expectations, as patients approach dialysis initiation.

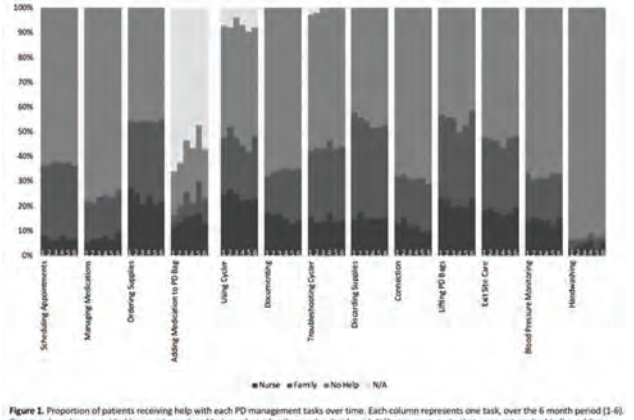

Figure 1. Proportion of patients receiving help with each PD management tasks over time. Each column represents one task, over the 6 month period (1-6). Care may have been provided by a paid caregiver (dark grey) or a family member (mid grey). N/A represents tasks that were not applicable (i.e. adding medication to PD bags or using a cycler). Sample sizes for months one through six were 109, 104, 101, 93, and 91 subjects, respectively.

PO1325

Vascular Access Type and Risk of Mortality and Hospitalization Among Elderly Hemodialysis Patients: A Target Trial Emulation Approach

Beini Lyu, Micah R. Chan, Brad C. Astor. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: Evidence is mixed regarding optimal choices of incident vascular access type for elderly patients on hemodialysis (HD). Prior studies have primarily compared functioning arteriovenous fistula (AVF) to arteriovenous graft (AVG) and been limited to survival outcome. We used a target trial emulation approach and intention to treat (ITT) analyses to compare AVF versus AVG placement among elderly patients on HD.

Methods: Patients eligible for the target trial were those ≥67 years old at HD initiation, with no AVF/AVG placed before HD initiation, referred for AVF/AVG placement, and had AVF/AVG within 1 year after HD initiation. Patients would be randomly assigned to AVF or AVG and be followed right after AVF/AVG placement for 5 years. Outcomes including mortality, all-cause hospitalization, and cause-specific hospitalization (infection, cardiovascular disease (CVD), and vascular access (VA) related) within 6 months, 1 year, 3 years, and 5 years would be assessed. ITT analysis based on patients' first AVF or AVG placed would be applied. We used USRDS data from 2010-2016 to emulate the target trial and propensity score (PS) matching to balance the groups' characteristics.

Results: A total of 37,890 (out of 47,912) patients who had AVF/AVG placed within 1 year after HD initiation were included after PS matching. Among them, 28,847 (76.1%) had AVF placed and 9,043 (23.9%) had AVG placed. AVF was associated with lower risk of mortality over follow-up. Within 6 months after AVF/AVG placement, incidence of all-cause and VA-related hospitalization was significantly lower in the AVF group (RR 0.85 (95% CI: 0.78-0.93) for all-cause hospitalization; RR 0.68 (0.62-.74) for VA hospitalization), but not infection- or CVD-related hospitalization. AVF was associated with significantly lower incidence of all-cause and VA-, infection-, and CVD-related hospitalizations in longer follow-up time (RR 0.84 (0.82-0.87) for all-cause hospitalization within 3 years; RR 0.63 (0.59-0.67) for VA-related hospitalization within 3 years).

Conclusions: Our primary analyses found elderly patients on HD may benefit from getting an AVF compared to an AVG. We will further test whether these results hold true in patients within strata of age group, comorbidities, probabilities of AVF maturation, and life expectancy.

PO1326

Implementing Multidisciplinary Pre-ESRD Program to Improve Vascular Access in New-Start Dialysis Patients

Nathan K. Jobalia,[1] Tammy L. Sirich,[2,3] Vy D. Nguyen,[1] Nhat M. Pham.[1,2] *[1]Santa Clara Valley Medical Center, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]US Department of Veterans Affairs, Palo Alto, CA.*

Background: Tunneled dialysis catheters (TDC's) are associated with morbidity and mortality in dialysis patients. In the U.S., more than 80% of patients start dialysis with a TDC and even higher rates for ethnic minorities. As part of the Santa Clara County healthcare system, we care for an underserved population, predominately of ethnic minorities. To reduce our TDC rates, we implemented a Pre-ESRD program that encompasses a multidisciplinary team, EMR tracking, access referral guidelines, and culturally relevant patient education. We assessed whether this program reduced the proportion of patients starting dialysis with a TDC and no other vascular access (TDC-Only).

Methods: We performed a retrospective chart review of new start dialysis patients in 2014 (before program implementation) and in 2017 (after program implementation). Patients must have been seen in renal clinic for at least 3 months before starting dialysis. We compared the proportion of TDC-Only between the two groups using the Chi-Square Test. We also compared the type of vascular access placed between the two groups.

Results: 87 patients started dialysis in 2014 and in 2017. There was no difference in age (58 vs 56 years) or diabetes (61% vs 70%) between the two groups. The two groups consisted mostly of minorities (Hispanic: 52% vs 55%, Asian: 31% vs 26%, Black: 7% vs 3%, and White: 10% vs 14%) and non-English speakers (44% vs 46%). The type of access at dialysis start is summarized in the table. The proportion of TDC-Only reduced by 21% after program implementation but did not reach statistical significance: 62% of patients started with TDC-Only in 2014 compared to 49% in 2017 ($p=0.09$). In addition, AVF placement more than doubled after program implementation (19% vs 42%, $p=0.001$).

Conclusions: Implementation of a multidisciplinary Pre-ESRD program reduced the number of TDC-Only and increased the number of AVF's in new dialysis start patients. Our study is unique due to our patient population of predominantly minorities and non-English speakers.

Initial Vascular Access

	2014 (n=87)		2017 (n=87)	
TDC-Only	54	62%	43	49%
TDC w/Other Access	3	3%	11	13%
AVF	15	17%	25	29%
AVG	5	6%	2	2%
PD	10	11%	6	7%

PO1327

Conversion to Arteriovenous Fistula but Not Arteriovenous Graft Is Associated with Improved Hemodialysis Efficacy Markers in Children: Pediatric Nephrology Research Consortium Study

Ali Mirza Onder,[1] Joseph T. Flynn,[2] Md Abu Yusuf Anasri,[1] Craig B. Langman,[5] Chryso P. Katsoufis,[4] Marissa J. Defreitas,[4] Ellen G. Wood.[3] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Seattle Children's Hospital, Seattle, WA; [3]SSM Health Cardinal Glennon Children's Hospital, Saint Louis, MO; [4]University of Miami School of Medicine, Miami, FL; [5]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Arteriovenous fistulae (AVF) and arteriovenous grafts (AVG) are preferred vascular access for chronic hemodialysis (HD) patients. Our objective was to investigate the impact of switching from tunneled cuffed catheters (TCC) to AVF or AVG on HD efficacy markers in pediatric HD patients.

Methods: Retrospective chart reviews were completed on individual patients from 20 pediatric HD centers. All the patients used TCC prior to AVF/ AVG and each patient acted as his/her own control. Data on dialysis efficacy markers were collected at creation of AVF/AVG and for two years follow-up, along with patient demographics and clinical information. Statistical methods used included hypothesis testing and statistical modeling after adjusting for relevant demographic variables.

Results: First PVA was created in 98 individual children: 87 (89%) were AVF and 11 (11%) were AVG. The mean TCC vintage prior to AVF/AVG was 10.4± 17.3 months. At one-year follow-up, AVF patients improved the Kt/V by 0.23 (p=0.008) and URR by 5.4% (P<0.001). At second year follow-up, both Kt/V and URR remained higher than values at creation (p=0.02, p<0.0001, respectively), being similar to first year's values (p=0.57, p=0.36, respectively). Furthermore, AVF patients improved serum albumin by 0.33 gram/dl (p<0.0001) and serum hematocrit by 2.94% (p<0.0001) at one-year and maintained similar improved values at second year follow-up (p=0.001, p=0.003, respectively). These observations were further supported by the adjusted models. Children with AVG did not demonstrate any statistically significant change in Kt/V, URR, serum albumin or hematocrit at either one-year or second year follow-ups.

Conclusions: Switching to AVF was associated with improved HD efficacy markers (Kt/V, URR, serum albumin and hematocrit). Surprisingly, conversion to AVG was not associated with a similar positive impact for the above markers.

PO1328

Study of Impact of Preoperative Venogram as an Adjunct to Doppler Imaging in Difficult Vascular Access

Viswanath Moturu. *Narayana Medical College and Hospital, Nellore, India.*

Background: As the number and complexity of patients on dialysis increases, this presents an increasing challenge for vascular access. Successful renal access surgery requires both careful planning and technical skill. Venography offers direct imaging of both peripheral and central veins in the upper limb.

Methods: Venography was done at our institute prospectively for difficult vascular access cases between Oct 2019 & Mar 2020. All patients who had prior 2 failed AVF surgeries were included in study and were evaluated with physical examination, Doppler imaging and Venography. We prospectively analysed venograms and also compared the outcomes before and after venography based on historic control before venogram with same inclusion criteria. Both groups were compared with respect to vascular access type, patency, complications.

Results: During the study period, venography prior to surgery was performed in **30 patients**. Venography of one upper limb (right/left: 6/30) was performed in **6 patients(20%)**. The **remaining 80%** patients underwent bilateral venography, resulting in a total of 54 upper limb venograms. **9 patients**(30%) were considered unsuitable for native AVF creation based on the venograms. **3** underwent a haemodialysis AV-graft (AVG) creation (2 autologous saphenous vein AVG grafts, 1 synthetic graft), two opted for CAPD, **remaining 4** surgery was not done.

Conclusions: Venography is a useful imaging modality in preoperative venous mapping prior to difficult vascular access surgery along with preoperative Doppler imaging, resulting in increased patency rates. In our study, preoperative venous imaging in adjunct with color Doppler imaging helped in choice of AVF site planning and avoiding complications and ruling out central venous obstruction and a better patency rates although limited by shorter follow up and small size.

Analysis of Vascular Distensibility Measured by Ultrasound Speckle Tracking

William Weitzel,[1,2] Nirmala Rajaram,[1,2] Lenar T. Yessayan,[2] Yihao Zheng,[3] Brian Thelen,[1,4] Timothy Morgan,[1] James Hamilton,[1] Miguel A. Funes-Lora.[2] *[1]Veterans Affairs Ann Arbor Health System, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Worcester Polytechnic Institute, Worcester, MA; [4]Michigan Technical Research Institute, Ann Arbor, MI.*

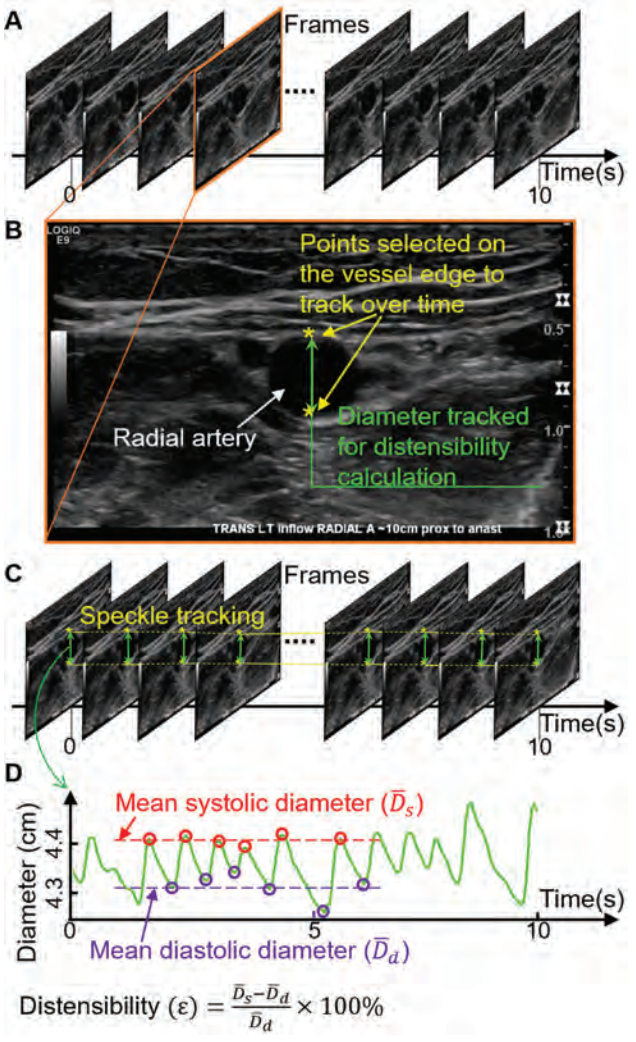
Background: We have developed a novel open source ultrasound software program that measures vascular strain and distensibility using conventional ultrasound Digital Imaging and Communications in Medicine (DICOM) data for use in the dialysis vascular access setting. In this study, we evaluated the variation in measurement from operator point selection and physiologic beat to beat variation of the arterial wall.

Methods: Ten subjects scheduled for arteriovenous fistula (AVF) creation were enrolled in the study. Ultrasound scanning of the brachial/radial arteries was performed. Ten users were prompted to select two points of interest at the top and bottom of the arterial vessel wall in each of the ten subjects. These points were tracked using the Kanade-Lucas-Tomasi (KLT) tracking algorithm.

Results: Sub-millimeter resolution (less than 100 micron) measurements were obtained. We found variation point selection by the users for the ten cine loops to be up to 120 pixels for the top and up to 140 pixels for the bottom of the vessel wall. The range in measured variation attributable to user point selection was 5.79 to 47.29% and inter-cardiac (physiologic) variation was 6.41 to 17.68%.

Conclusions: Despite the low resolution of conventional DICOM images, we are able to measure sub-millimeter distensibility. In order to better understand the physiologic variation in vascular wall compliance, a formalized approach to point selection is needed. We are evaluating algorithms and statistical ensemble methods for use in studies to predict AVF maturation.

Funding: Veterans Affairs Support



From image cine loop (A), a single frame (B) is used to select vessel wall edge points, for image tracking (C), to determine sub-millimeter resolution wall strain and distensiblity (D) showing beat to beat variation.

PO1330

Relationship of Vascular Access Flow and Stenosis Detected by Frequency Domain Analysis of Videos Taken with a Smartphone

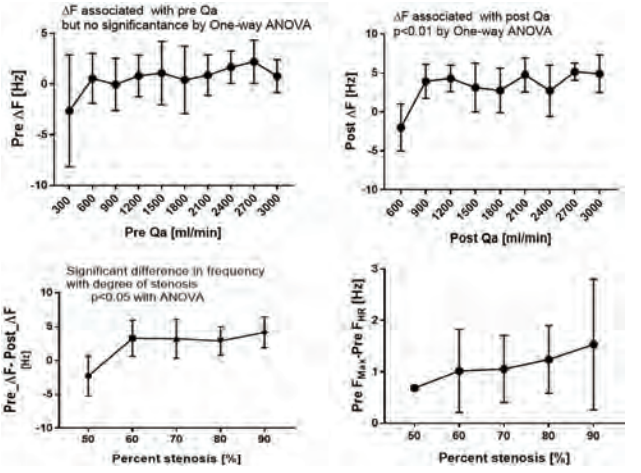
Fansan Zhu,[1] Lin-Chun Wang,[1] Alhaji Cherif,[1] Vaibhav Maheshwari,[1] Ohnmar Thwin,[1] Lela Tisdale,[1] Xia Tao,[1] Paulo Paneque Galuzio,[1] Norbert Shtaynberg,[2] Dean C. Preddie,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]AzuraVascular Care, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We developed a video image processing (VIP) technique with frequency domain analysis to assess arteriovenous fistula (AVF) blood flow. This study aimed to investigate the relationship of heart rate and access blood flow rate (Qa) represented by the frequency signals at maximum (F_{Max}, Hz) and minimum (F_{Min}, Hz) of magnitude in frequency domain analysis.

Methods: We employed VIP pre- and post-endovascular interventions in 90 hemodialysis patients (age 63.3 ± 14.3, 41 females, weight 78.6 ± 21.5 kg). F_{Max} and F_{Min} pre- and post-intervention were recorded. ΔF was defined as F_{Min} - F_{Max} for each video. Qa was measured pre- and post-intervention by HVT100 endovascular flowmeter (Transonic Systems Inc., Ithaca, NY, USA). The degree of stenosis (%) was quantitated by angiography. Heart rate (HR, beats/min) was expressed as a frequency (F_{HR}, Hz).

Results: The pre- and post-intervention differences between F_{Max} and F_{HR} were 1.14±0.74 Hz and 1.38±1.44 Hz, respectively. ΔF was associated with Qa pre- (Fig 1(a)) and post-intervention (Fig1(b)). ΔF increased most when Qa increased from pre-intervention range of 300 to 600 ml/min to post-intervention 600 to 900 ml/min. Fig 1(c) shows the relationship between % stenosis and the change in ΔF between pre- and post-intervention. The difference between F_{Max} and F_{HR} was associated with % stenosis pre-intervention (Fig. 1(d)).

Conclusions: The relationship between F_{Max} and F_{HR} suggests that the signal of F_{Max} represents an important hemodynamic component of Qa. ΔF may be used as an index to predict low levels of stenosis. The use of frequency domain analysis from video image data provides a contact-free method to ascertain Qa and to indirectly indicate the degree of stenosis. Further study is needed to standardize the quality of video and streamline the methodology.



PO1331

Impact of Ultrasound Guidance in Assessment of the Maturity and Cannulation of New Arteriovenous Fistula (AVF): A Quality Improvement Initiative

Niraj Karki, Vandana D. Niyyar. *Emory University, Atlanta, GA.*

Background: A common complication during cannulation, particularly in new AVF, is needle infiltration. AVF infiltration is associated with major morbidity, including additional interventions, prolongation of catheter dependence and access failure. Judicious use of ultrasound guidance has been successfully used in difficult peripheral as well as central venous access to reduce iatrogenic injury. We hypothesized that the use of portable ultrasound for cannulation of hemodialysis (HD) access would minimize infiltration during cannulation of new AVF in HD patients at Emory Dialysis over a 6-month period as compared to a control period without the use of ultrasound guidance for cannulation.

Methods: We implemented an educational protocol to train 18 members of our dialysis staff in the use of portable ultrasound for evaluation of dialysis access. 2 dedicated vascular access coordinators were trained as "access champions" and led the initiative. Each of the 4 HD units were equipped with a portable ultrasound machine. All new AVF were evaluated by ultrasound 4-6 weeks post-operatively. Immature AVF were sent for further evaluation/interventions. Mature AVF were cannulated under real-time ultrasound guidance. All data, including AVF infiltrations, were recorded prospectively.

Results: Infiltration data of new AVF for the control period was obtained from a retrospective database. The infiltration rate was 14% in our dialysis (calculated by dividing the number of new AVF infiltrations by the total number of new AVF cannulated). During the study period (8/15/2019 to 2/14/2020), 39 new AVF were evaluated for cannulation using a combination of physical examination and ultrasound guidance. There were only 4 infiltrations of new AVF. The rate of infiltration was thus 10.2% in our patients, a decrease of 3.8% from baseline.

Conclusions: The use of portable US devices for assessment of maturity and cannulation guidance is feasible even in busy HD units. We were able to reduce the infiltration rate with the use of US guidance for cannulation in combination with physical examination. We plan to expand ultrasound education to include all members of the dialysis staff involved with cannulation within our dialysis units. Regular competency checks are essential to identify and supplement gaps in knowledge.

PO1332

The Effect of Nitrate as a Vasodilator to Vascular Access Patency in Patients Undergoing Hemodialysis

Kyu Sang Yun,[1] Juhee Kim,[1] Hayne C. Park,[1] Ajin Cho,[1] Youngki Lee,[1] Sun Ryoung Choi,[3] Jung-woo Noh,[2] Do Hyoung Kim.[1] *[1]Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; [2]Chun & Cho's Medical Clinic & Dialysis Center, Seoul, Republic of Korea; [3]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea.*

Background: Maintaining the patency of vascular access (VA) is very important to achieve adequate hemodialysis (HD) dose in HD patients. Failure of vascular access is associated with morbidity and mortality. Thus, maintaining the patency of VA is challenging. In this study, we investigated the effects of nitrate as a vasodilator on VA patency in HD patients.

Methods: We investigated study on the Korean insurance claims data of the HD patients between January 2012 and December 2017. All patients divided into nitrate therapy group and no therapy group depending on whether nitrate was administered. The nitrate therapy group included only patients who received the drug for 30 days or more. The primary outcome was the primary patency of VA. Effect of nitrate treatment was examined using Kaplan Meier analysis and Cox proportional hazard, after adjusting for covariates.

Results: A total 7,428 participants were included in this study, and nitrate therapy was noted in 7.7% of total patients. 1,178 patients underwent the angioplasty. In Kaplan-Meier analysis, nitrate therapy was lower probability of angioplasty than non-user (log-rank, P<0.001). The risk of angioplasty was low in patients receiving mononitrate and nicorandil (hazard ratio (HR) 0.18, [95% confidence interval 0.07-0.45]; HR 0.15, [0.06-0.41]). But, dinitrate and molsidomine were not associated with the risk of angioplasty. Multivariate Cox proportional analysis revealed that nitrate therapy with mononitrate and nicorandil had a decreased risk of angioplasty after adjustment for age, sex, hypertension, and diabetes (HR 0.17, [0.05-0.53]; HR 0.14, [0.04-0.45]).

Conclusions: In this large national database, we showed that nitrates such as mononitrate and nocorandil were associated with improved primary patency in HD patients. Nitrate treatment may have a beneficial effect for maintaining vascular access patency in patients undergoing HD, and further research is needed to relate nitrate therapy to VA patency.

PO1333

Influence of CKD on In Situ Tissue Formation in Biodegradable Vascular Grafts

Paul J. Besseling,[1] Merle M. Krebber,[1] Joost O. Fledderus,[1] Martin Teraa,[1] Carlijn V. Bouten,[2] Martijn Cox,[3] Marianne C. Verhaar.[1] InSiTeVx *[1]University Medical Centre Utrecht, Utrecht, Netherlands; [2]Eindhoven University of Technology, Eindhoven, Netherlands; [3]Xeltis bv, Eindhoven, Netherlands.*

Background: Vascular access is considered the Achilles' heel of hemodialysis, requiring frequent interventions to maintain patency. One proposed solution is a self-healing *in situ* tissue engineered vascular access graft. This requires the presence of a functional wound healing response capable of initiating tissue formation. However, it is unknown whether tissue formation is negatively affected by chronic kidney disease(CKD). In this study, we aim to investigate the effect of CKD on *in situ* tissue formation in vascular grafts in a rat model.

Methods: To mimic the effect of CKD in humans, a rat 5/6th nephrectomy model was created. Control animals underwent a sham operation. When CKD animals reached a threshold of 50mg/24h proteinuria an electrospun biodegradable vascular graft, made from supramolecular polymers, was implanted in the abdominal aorta. Explantation was performed at 2, 4, 8 and 12 weeks, to follow the different phases of wound healing and early tissue formation. Explants were examined for cell infiltration and proliferation, presence of immune, endothelial, smooth muscle cells, and extracellular matrix components.

Results: Cytometry of circulating immune cells shows an increase in monocytes($CD11b^+$) and macrophages($CD68^+$) in CKD animals. Histological analysis indicates that all implanted grafts contain infiltrated cells throughout the material with a non-significant increase over time in both groups. Both groups show a peak in proliferating cells at week 8, with virtually no proliferating cells at 12 weeks. Infiltrated macrophages ($CD68^+$ & $CD163^+$) show no significant difference between sham and CKD and peak at week 8 followed by a decline. Masson trichrome and Sirius red stains show an increase in ECM formation over time with no significant difference between groups. Mature vascular cells such as smooth muscle cells and endothelial cells are found from week 8 onward, indicating a shift from a proliferative phase to a remodeling stage.

Conclusions: The found difference in circulating immune cells this did not translate in a significant difference in tissue build up, cell type, ECM production, scaffold breakdown and patency between sham and CKD animals. Our data suggests that uremic conditions have a limited effect on tissue formation in creating *in situ* tissue engineered vascular grafts.

PO1334

Use of Ticagrelor to Preserve Hemodialysis Vascular Access

Dennis Hu, Genevieve R. Lyons, Jennie Z. Ma, Emaad M. Abdel-Rahman. *University of Virginia Health System, Charlottesville, VA.*

Background: Hemodialysis (HD) is the main renal replacement therapy for end stage renal disease (ESRD) patients in the USA. Arteriovenous fistulas (AVF) remain the access of choice due to their superior patency and infection risk when compared to other access forms. The main complications of AVF are stenosis and thrombosis which lead to increased morbidity and hospitalizations in HD patients. There is currently no consensus as to whether thrombo-prophylaxis is warranted. Multiple studies have looked at various antiplatelet agents; however, none have looked at Ticagrelor, a newer antiplatelet that has been shown to inhibit platelet aggregation more effectively than Clopidogrel and is hepatically eliminated.

Methods: We underwent a randomized placebo-controlled single blind pilot study to evaluate the efficacy and safety of Ticagrelor in HD patients with AVF. 33 HD patients aged 18 to 35 years old with AVF were randomized to receive either Ticagrelor 90 mg orally twice a day (n=17) or placebo (n=16) for 6 months. Patients were seen twice a month while on therapy and monthly for 6 months post therapy. The number of vascular interventions and bleeding complications pre-treatment, during treatment, and for 6 months after treatment were recorded to determine efficacy and safety of Ticagrelor, respectively.

Results: No statistically significant difference was noted between Ticagrelor and placebo in terms of number of vascular interventions pre-study, while on therapy, or 6 months post therapy. When adjusting for access vintage, age, and race there was no statistically significant difference between both groups. There was also no statistically significant difference in bleeding complications between both groups.

Conclusions: We conclude that while using Ticagrelor in patients with ESRD on HD is safe, we could not demonstrate a therapeutic superiority in preserving the patency of AVF using this drug compared to placebo. This study is limited by the number of patients and more studies may be warranted in the future.

Funding: Commercial Support - AstraZeneca

Outcomes

Endpoint		Placebo	Ticagrelor	p-value (Fisher's exact test)
Intervention month 0-6	None	14 (87.5%)	13 (76.5%)	0.66
	1+	2 (12.5%)	4 (23.5%)	
Intervention month 7-12	None	13 (81.3%)	15 (88.2%)	0.66
	1+	3 (18.8%)	2 (11.8%)	
Bleeding complication	None	13 (81.3%)	16 (94.1%)	0.34
	1+	3 (18.8%)	1 (5.9%)

The Integrated Program of Needle Dislodgement Bleeding Alarm System Is Associated with a Decreased Incident of Venous Needle Dislodgement or Bleeding

Chi yang Hsin,[1] Hsuan Ming Lin,[1] Hsiang Wei Hu.[2,3] *[1]An Nan Hospital, China Medical University, Tainan, Taiwan, Tainan City, Taiwan; [2]National Cheng Kung University, Tainan City, Taiwan; [3]Acusense Biomedical Corp., Tainan City, Taiwan.*

Background: A puncture of vascular access is commonly used in clinical treatment, such as hemodialysis or central venous catheters. There are some devices for detecting the presence of needle dislodgement in the market. Still, there are no large-scale reports for the integrated program for nursing training and device implantation. This study aims to conduct a program for an integrated training course and the VND device. We hope to reduce the incidence of needle removal and blood leakage.

Methods: This study was divided into two phases, the control period, and the study period. In the control period, the abnormal events of venous needle dislodgement and blood leakage was recorded in the hemodialysis unit room during the first three months. Before the study period, we introduced an integrated program, including the standard process of fistula puncture, care during hemodialysis, an inspection of the venous puncture site and an alarm system. In the study period, we also conducted the standard program and collected the data of the events of venous dislodgement or bleeding.

Results: The control period was conducted from July 2019 to September 2019, and the study period was performed in November 2019. A total of 62 patients completed the study. During the control period, there were a total of 2087 dialysis treatments, of which 30 patients had venous needle dislodgement or bleeding. There were a total of 71 events of venous needle dislodgement or bleeding, and the incidence rate was 3.3 events per 100 sessions. There were a total of 682 dialysis sessions and 15 events of venous needle dislodgement or bleeding during the study period. The incidence rate was 2.1 events per 100 sessions. The incidence rate of moderate and severe cases were 1.1 events per 100 sessions in the control period and 0.3 events per 100 sessions in the study period.

Conclusions: This study introduced venous needle dislodgement or bleeding alarm system and training program in the hemodialysis unit. The incidence of venous needle dislodgement or bleeding was lower after the program The incidence rate in the moderate and severe groups was also decreased. This program can improve the quality of patient care.

PO1336

Evaluation of Stable Permanent Hemodialysis Access Bleeding Time After Dialysis Needle Removal

Samshita Yalamanchili,[2] Paul J. Der Mesropian,[1,2] Gulvahid G. Shaikh,[1,2] Loay H. Salman,[2] Elvira O. Gosmanova.[1,2] *[1]Albany Stratton VA Medical Center, Albany, NY; [2]Albany Medical College, Albany, NY.*

Background: Prolonged bleeding time (BT) after dialysis needle removal may signify permanent hemodialysis access (PHA) dysfunction but "normal" BT is not well defined.

Methods: This was an observational study examining 35 patients receiving chronic hemodialysis with PHA using 15-g needles for ≥3m at Stratton VAMC, Albany NY. BT was determined as no bleeding at dialysis needle removal site after manual pressure applied for at least 10min with additional 1-5 minutes increments, if needed. The mean BT for arterial and venous sites were calculated for each patient over 1-month period. Associations between BT and baseline characteristics were evaluated using adjusted regression analysis.

Results: The mean age of patients was 73 yrs, 97% were males, 63 and 31% were Whites and Blacks, respectively. The mean (SD) hemoglobin concentration and platelet count were 10.4 (1.0)g/dL and 184 (77)x10^9/L, respectively. Sixty and 74% of patients were on oral antiplatelet agents and intradialytic heparin. The mean (SD) BT after arterial and venous needle removal were 12.7 (2.1) and 12.9 (2.2) minutes. In the adjusted analyses, there was strong correlation between arterial and venous BT (r^2=0.98, p<0.016), however, no correlations were seen between arterial and venous BT and any baseline variables (Table).

Conclusions: In this study, BT after dialysis needle removal was between 10 and 15 min in patients with stable PHA. Future studies are needed to understand what changes in BT may predict PHA dysfunction.

Natural Vascular Scaffolding Therapy for Arteriovenous Fistula Development in Rats

Yan-Ting E. Shiu,[1,2] Blake Anderson,[3] Yuxia He,[1] CS Jason Tey,[1] Katalin Kauser.[3] *[1]University of Utah, Salt Lake City, UT; [2]VASLCHSC, Salt Lake City, UT; [3]Alucent Biomedical Inc., Salt Lake City, UT.*

Background: Arteriovenous fistula (AVF) maturation failure results from insufficient lumen dilation and progressive inward neointimal hyperplasia (NH). Vascular wall distention is likely affected by the integrity of vascular extracellular matrix (ECM). We hypothesized that preserving ECM integrity at the time of AVF creation surgery could improve AVF maturation. Natural Vascular Scaffolding (NVS) Therapy is known to interlink collagen and elastin, the most abundant vascular ECM components, by covalently linking these proteins via photoactivation. We investigated the effect of NVS treatment on AVF development in a rat model.

Methods: Femoral AVFs were created in young Wistar male rats as an end-to-side anastomosis. Immediately after the blood flow was restored to dilate the femoral vein by arterial pressure, a 10 µl-drop of the NVS compound (2 mg/ml in phosphate buffered saline (PBS)) was placed at the anastomosis perivascularly and incubated for 5 minutes to allow full vessel wall penetration, followed with 1-min illumination of the anastomosis area by 450-nm light. The control group received a 10 µl-drop of PBS and the same light activation. The skin was closed immediately after light activation. Each group had 10 rats. Rats were euthanized 4 weeks post-AVF creation for histology, morphometry, immunohistochemistry of interleukin-6 (IL-6, an inflammation marker), and second-harmonic-generation evaluation by multiphoton microscopy of collagen fibers.

Results: Rats tolerated the NVS treatment well. The NH area was similar in both groups. The AVF vein's open lumen area and % open lumen area in treated rats were significantly larger than in control rats (4.18-fold p=0.014 and 1.98-fold p=0.009, respectively). IL-6 intensity was significantly smaller in the NVS group than the PBS group (p=0.027). Collagen fibers in the NVS-treated AVFs trended towards perpendicular alignment with respect to the lumen circumference, with greater roundness, roughness, and eccentricity than in the PBS-treated AVF vessels.

Conclusions: Our studies showed that the NVS treatment significantly increased the AVF open lumen area, without significantly affecting the NH area. This suggests that NVS treatment may have therapeutic potential by facilitating lumen expansion while allowing a concomitant outward remodeling of the veins potentially leading to enhanced AVF maturation in patients.

Geometry and Interuser Variability of Arteriovenous Fistulas in Mice and Rats

Hannah M. Northrup,[1] Isabelle D. Falzon,[1] Savanna Cahoon,[1] Yan-Ting E. Shiu,[1,2] Maheshika S. Somarathna,[3] Timmy C. Lee.[3,4] *[1]University of Utah, Salt Lake City, UT; [2]VASLCHCS, VA Salt Lake City Health Care System, Salt Lake City, UT; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Veterans Affairs Medical Center, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) maturation failure is a significant and unresolved clinical issue. Although rodent models have been used extensively to investigate the pathobiology and treatment of AVF maturation failure, the literature has largely relied on histology to analyze rodent AVF remodeling. Information regarding three-dimensional (3D) AVF lumen geometry in live animals is lacking. Our group has developed a magnetic resonance imaging (MRI)-based protocol to quantitively characterize 3D AVF lumen geometry in mouse and rat AVFs. Inter-user variabilities were also determined.

Methods: Carotid-jugular AVFs were created in C57BL/6 mice (n=21). Femoral AVFs were created in Sprague Dawley rats (n=7). Both had the arterial-side-to-venous-end configuration. Black blood MRIs were taken at 7 or 21 days post-AVF creation. Two users reconstructed the AVF lumens and computed the cross-sectional lumen area, anastomosis angle, nonplanarity angle magnitude, and tortuosity, using a centerline-based approach.

Results: Mice had a greater anastomosis angle (94.29° vs. 38.75°) and tortuosity (0.42 vs. 0.035) than rats (p<0.05). The nonplanarity angle magnitude was similar for mice and rats (~8.5°). Geometries of mouse and rat AVFs from the two users are overlaid in Figure 1. Inter-user variabilities were predominately small, indicating the reliability and reproducibility of our protocol.

Conclusions: Our work is the first detailed study of luminal changes in rodent AVFs using MRI. The anastomosis angles of mouse and rat AVFs are similar to human brachiocephalic AVFs (~70-90°) and radiocephalic AVFs (~30-60°) in the literature, respectively. These data suggest the clinical relevance of our rodent AVF models and set the stage for future studies on how these geometrical parameters affect AVF maturation and the mechanisms leading to geometrical changes.

PO1339

Longitudinal Geometry of Pig Arteriovenous Fistulas (AVFs)

Savanna Cahoon,[1] Isabelle D. Falzon,[1] Yan-Ting E. Shiu,[1,2] Alfred K. Cheung.[1,2] *[1]University of Utah, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Hemodynamics has been postulated to be an important factor contributing to successful versus failed AVF maturation. Pigs, in general, have hemodynamic features that are similar to those in humans, and thus are an attractive animal model for investigating the mechanisms underlying and the interventions for promoting AVF maturation. A few earlier small clinical studies found associations between AVF geometry and maturation. Since geometry is a critical determinant of hemodynamics, we investigated the geometry of pig AVFs using magnetic resonance imaging (MRI) technology.

Methods: Carotid (side)-jugular (end) AVFs were created in female Yorkshire cross domestic pigs. Non-contrast black-blood MRIs were obtained at 1, 2, and 6-10 weeks (wks) post-AVF creation (n=3 per time point) and used to reconstruct AVF lumen geometries. Lumen area, anastomosis angle, venous tortuosity, and nonplanarity angle magnitude were quantified.

Results: The non-surgery lumen area of the external jugular vein was ~7 mm^2. The AVF vein lumen area (mean ± standard deviation) significantly (p=0.0370) increased from 25.3 +/- 11.1 mm^2 in wk 1, to 32.3 +/- 4.3 mm^2 in wk 2, then to 62.7 +/- 21.3 mm^2 in wks 6-10 suggesting that our pig AVF is a model for successful AVF maturation. Importantly, we also observed an increasing trend in the lumen areas from wk 1 to wks 6-10 of the proximal artery (24.0 +/- 17.3 mm^2 vs. 28.0 +/- 8.60 mm^2) and the distal artery (24.5 +/- 16.1 mm^2 vs. 34.8 +/- 13.9 mm^2). The anastomosis angles were similar in wk 1 and 2 (51.6 +/- 23.2° vs 50.2 +/- 21.0°) then decreased to 25.8 +/- 17.3° in wks 6-10. Venous tortuosity slightly increased from 0.13 +/- 0.05 in wk 1 to 0.15 +/- 0.05 in wk 2 then to 0.17 +/- 0.06 in wks 6-10. Non-planarity angle magnitude was 14.9 +/- 8.9° in wk 1 then decreased to 10.7 +/- 8.5 in wk 2 then increased to 24.6 +/- 9.4° in wks 6-10.

Conclusions: This is the first serial and detailed study of pig AVF geometric parameters. The anastomosis angles of our pig AVFs were in line with human radiocephalic AVFs in the literature (~30-60°). Our study sets the stage for examining the role of geometry in alterations in hemodynamic forces and in AVF maturation processes.

Funding: NIDDK Support, Other NIH Support - NHLBI

PO1340

To Study Real-World Effectiveness of Paclitaxel Drug-Coated Balloon Angioplasty in Hemodialysis Patients

Pye Oo, Sayee Sundar Alagusundaramoorthy, Muhammad Sohaib Karim, Micah R. Chan, Brad C. Astor, Ali I. Gardezi. *University of Wisconsin-Madison, Madison, WI.*

Background: A large, multicenter randomized study has shown that use of drug coated balloon (DCB) in angioplasty improves vascular access patency trend over control at 9-month during 2-year study period. We have conducted a retrospective study to see if there is a real-world effectiveness of DCB angioplasty in maintaining vascular access patency in hemodialysis patients.

Methods: We retrospectively reviewed 83 drug coated balloon angioplasties performed in our hospital from April 2018 to April 2020 and compared them with a control group of 83 angioplasties done by non-drug coated balloon matched by the date

of procedure. Target lesions were categorized as central, peripheral, anastomotic and in-stent for both arteriovenous fistulae (AVF) and arteriovenous grafts (AVG). Patient demographics (Age, Sex) and risk factors (Hypertension, Hyperlipidemia, Vascular Disease, Diabetes Mellitus) were also compared. The duration of target lesion patency (in days) before and after the DCB interventions were compared with date matched non-DCB interventions (control group).

Results: There are 83 angioplasties in each group (DCB versus control group). The average duration of target lesion patency (in days) before intervention in DCB and control group were 152 versus 137 (P value = 0.57) for AVF and 163.3 versus 191.3 (P value = 0.70) for AVG respectively. The average duration of target lesion patency (in days) after intervention in DCB group and control group were 114.8 versus 161.7 (P value = 0.03) for AVF and 177.9 versus 221.5 (P value = 0.5) for AVG respectively.

Conclusions: As opposed to the randomized controlled trial, our study shows that the average duration of target lesion patency of AVF after drug coated balloon angioplasty was significantly shorter than non-drug coated balloon. Greater severity of lesions in the DCB group could be the reason for this observation.

Target Lesion Patency Outcomes

Type of Access	Duration of Patency (Days)	Drug Coated Balloon N=83	Non Drug Coated Balloon N=83	P-Value
AVF	Pre-intervention	152.5	137.9	0.57
	Post-intervention	114.8	161.7	0.03
AVG	Pre-intervention	163.3	191.3	0.70
	Post-intervention	177.9	221.5	0.50

PO1341

Estimated Upper-Body Blood Flow and Central-Venous Oxygen Saturation Before and After Percutaneous Transluminal Angioplasty in Newly Created Vascular Access

Laura Rosales, Hanjie Zhang, Marilou Mateo, Brenda K. Chan, Seth Johnson, Stephan Thijssen, Peter Kotanko. *Renal Research Institute, New York, NY.*

Background: Arterio-venous fistula (AVF) is the most effective vascular access in hemodialysis (HD) patients and, assessing AVF maturation is critical to initiate its timely use. Previously we have demonstrated that central-venous oxygen saturation (ScvO2) and estimated upper-body blood flow (eUBBF) increase during AVF maturation. We assessed ScvO2 and eUBBF before and after percutaneous transluminal angioplasty (PTA).

Methods: We studied HD patients from an ongoing AVF quality improvement project. ScvO2 and hematocrit were measured with Crit-Line (FMC, Waltham, MA) between minutes 5 and 20 into HD. eUBBF was computed and described previously (Rosales, Blood Purif, 2019). Five out of 19 patients underwent PTA during AVF maturation and subsequent successful cannulation.

Results: Three of five patients (mean age 71±11) were males two were incident patients. Four interventions were due to venous stenosis and one was due to arterial anastomosis stenosis. Two patients underwent PTA 2.2 ± 0.3 weeks after AVF creation and the remaining 3 patients within 11.2 ± 4 weeks. Following PTA ScvO2 increased in all, except in patient #1, eUBBF increased in every patient (Table 1).

Conclusions: Our preliminary results indicate that ScvO2 and eUBBF provide functional information that can be obtained non-invasively. These point-of-care bio-signals reflect hemodynamic cardiovascular adaptation following successful PTA. Future studies are warranted if knowledge of ScvO2 and of eUBBF shorten catheter residence time.

Table 1. $ScvO_2$ and eUBBF before and after percutaneous transluminal angioplasty

N=5		Before Intervention		After Intervention	
	Time to Intervention [Weeks]	$ScvO^2$ [%]	eUBBF [L/min]	$ScvO^2$ [%]	eUBB F [L/min]
Patient 1	2.0	68.4 ± 1.5 [67.3; 69.5]	1.2 ± 0.0 [1.2; 1.3]	64.4 ± 1.7 [63.3; 65.6]	1.3 ± 0.0 [1.3; 1.3]
Patient 2*	2.4	63.5	1.3	68.3 ± 3.1 [66.2; 70.7]	1.7 ± 0.2 [1.5; 1.8]
Patient 3	7.0	71.8 ± 0.4 [71.5; 72.1]	1.8 ± 0.1 [1.8; 1.9]	73.1 ± 2 [71.7; 74.6]	2.1 ± 0.5 [1.7; 2.5]
Patient 4	13.0	66.8 ± 0.8 [66.3; 67.3]	1.4 ± 0.0 [1.4; 1.4]	71.2 ± 0.8 [70.7; 71.7]	1.8 ± 0.1 [1.7; 1.9]
Patient 5	13.7	64.6 ± 4.6 [61.4; 67.9]	1.0 ± 0.2 [0.9; 1.2]	67.4 ± 0.2 [67.4; 67.5]	1.3 ± 0.0 [1.3; 1.3]

*Patient # 2 had only the average of 1-week measurements prior intervention. Data are expressed as mean, standard deviation, minimum and maximum values.

PO1342

Association Between FGF-23 Serum Levels with the Maturation Process of a Native Arteriovenous Fistula in Patients with End-Stage CKD

Juan Reyna-Blanco, L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: The process of maturation of an arteriovenous fistula (AVF) is complex and difficult to predict. It is known that high levels of fibroblast growth factor 23 (FGF-23) could be related to endothelial dysfunction, which could also influence the maturation of an AVF. Our goal is to know the association between serum levels of FGF-23 and the maturation of an AVF

Methods: This is a prospective cohort study with patients who underwent an AVF. The primary outcome was ultrasonic maturation at 6 weeks defined by the Birmingham criteria (diameter >0.4 cm and blood flow more than 500 ml/min).

Results: Forty-nine patients with a mean age of 48 ±14 years were included and 24% were women. The most common cause of CKD was diabetic nephropathy (55%). 49%, 25%, 10% and 16% were brachycephalic, brachyimedian, brachybasylic and other AVF respectively. thirty nine percentage of AVFs did not mature at 6 weeks. No significant differences were identified when comparing the agreement with maturation or not of the AVF in age, comorbidities, BMI, previous number of hemodialysis catheters, history of thrombosed catheter or catheter infection, hemodialysis vintage, residual diuresis, surgical time, hemoglobin, creatinine and serum calcium or phosphorus. However, the length of the arteriotomy was greater in the fistulas that do not mature with respect to the mature fistulas (7 mm vs. 6 mm p = 0.03). Likewise, the use of loop diuretics was more prevalent in AVF that did not mature (without maturation: 74% vs. maturation: 43%, p = 0.03). None of the distal radiocephalic AVF reached maturity. There were no association between serum levels of cFGF-23 and maturation of AVF, nor was the correlation between serum levels of cFGF-23 and the diameter or flow of the fistulas at six weeks.

Conclusions: The prevalence of maturation failure in AVFs was 39% according to Birminghams criteria. There is no correlation between serum levels of cFGF-23 and the flow or diameter of the AVF at six weeks. A larger population is required to corroborate these results.

PO1343

Effect of Hemodialysis Vascular Access Type on Serum Interleukin-6 (IL-6) Levels in ESRD

Monika Aggarwal (Gupta),[1] George M. Feldman,[1] Naveen Samuel,[1] Reuben P. Retnam,[2] Dipankar Bandyopadhyay,[2] Shobha Ghosh.[1,2] *[1]Hunter Holmes McGuire VA Medical Center, Richmond, VA; [2]Virginia Commonwealth University, Richmond, VA.*

Background: Chronic inflammation is prevalent and associated with poor outcomes in end stage renal disease(ESRD), and may be related to underlying comorbid conditions like diabetes mellitus. It is unclear if dialysis vascular access type may affect inflammation. We evaluated the effect of hemodialysis vascular access type on serum IL-6 level.

Methods: 15 patients with ESRD on chronic maintenance hemodialysis at McGuire Hunter Holmes VAMC were enrolled. Blood samples were drawn at 0, 30, 60, 90, 120, 180, and 240 minutes after starting dialysis. Serum IL-6 was measured using ELISA. Data were analyzed using t-test and is presented as Mean±SD.

Results: 6 patients had catheter (mean age 71.3±3.3 years), and 9 (mean age 64.5±4 years) had AV access. All were male. 5 patients in each group were African-American. 2 patients with catheter and 7 patients with AV access had diabetes. IL-6 level was higher at all time points(statistically significant) in patients with catheter compared to patients with AV access (Fig 1. and Table 1.)

Conclusions: ESRD patients with catheters had higher serum IL-6 levels compared to AV access inspite of lower proportion of diabetics. Catheters may contribute to inflammation, which may partly explain worse outcomes seen with catheters.

Funding: Veterans Affairs Support

Table 1.IL-6 Level at different time points (Mean+/-SD)

Time Point (Minutes)	AV access	Catheter	P value
0	2.87+/-1.53	11.96+/-9.47	0.009
30	2.1+/-1.14	11.29+/-10.29	0.011
60	2.73+/-1.53	11.6+/-8.92	0.004
90	3.15+/-1.51	12.32+/-9.42	0.006
120	3.14+/-1.65	13.11+/-9.53	0.003
180	3.32+/-1.57	13.76+/-9.75	0.003
240	3.27+/-1.26	14.8+/-11.08	0.003

Assessment of Arteriovenous Fistula Dysfunction with Access Stenosis in Hemodialysis Patients Using Smartphone Videos

Lin-Chun Wang,[1] Fansan Zhu,[1] Ohnmar Thwin,[1] Lela Tisdale,[1] Xia Tao,[1] Vaibhav Maheshwari,[1] Alhaji Cherif,[1] Norbert Shtaynberg,[2] Dean C. Preddie,[2] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Azura Vascular Care, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Hemodynamically relevant stenoses in arteriovenous fistulas (AVF) lead to a reduction in access flow rate (Q_a). We hypothesized that these changes in blood flow patterns may be detectable in video recordings done with commercially available smartphones.

Methods: We studied HD patients with AVF dysfunction requiring balloon angioplasty. One-minute video recordings of the skin above the AVF and Q_a measurements were conducted before and after the intervention by an iPhone 6S. Q_a was measured by HVT100 Transonic flowmeter. Degree of stenosis was assessed by angiography. Frame-to-frame pixel changes in video images were amplified; time-domain data were transformed into the frequency-domain signals. Fifty random 10-second segments were sampled per one-minute video, and the frequency with the lowest magnitude (F_{min}) was determined in each sample (Fig. 1). The average F_{min} was assessed for its association with the degree of stenosis.

Results: Ninety subjects were studied (63±14 years, HD vintage 4.1±3.5 years). Post-intervention Q_a (1638±714 ml/min) was on average 1.23-fold higher than pre-intervention Q_a (1373±684 ml/min; P<0.01, paired t-test). Subjects were grouped by degree of stenosis, and the number of subjects in each category is shown in Fig. 1B. Higher degrees of stenosis were associated with greater increases in Q_a from before to after the intervention (Fig. 1C). Interestingly, the degree of AVF stenosis was also positively related with the change in F_{min} from before to after the intervention (Fig. 1D).

Conclusions: Smartphone video recordings of AVF appear to contain frequency-domain information that correlates with hemodynamic changes caused by AVF stenoses. While the F_{min} metric employed in our analysis is not ideal, these results should encourage the quest for other parameters that exhibit higher correlations with vascular access dysfunction, allowing timely referrals and avoidance of emergency interventions.

PO1345

Surgical or Endovascular Intervention for Dialysis Access Thrombosis?

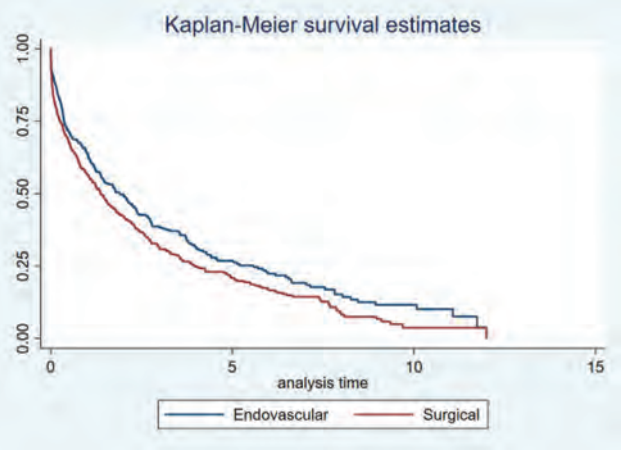
Ulrika Hahn Lundström,[1] Gunilla Welander,[4] Juan J. Carrero,[2] Ulf Hedin,[3] Marie Evans.[1] *[1]Karolinska institutet Department of Clinical Sciences Intervention and Technology, Stockholm, Sweden; [2]Karolinska Institutet Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden; [3]Karolinska Institutet Department of Molecular Medicine and Surgery, Stockholm, Sweden; [4]Uppsala University Department of Medical Sciences, Uppsala, Sweden.*

Background: Thrombosis is the most common cause of arterio-venous (AV) access failure in patients on hemodialysis. It is unknown if this complication is best treated by surgical or endovascular intervention. We compared the influence of surgical or endovascular intervention for AV access thrombosis on access survival using real-life data from a national AV access registry.

Methods: Patients from the Swedish Renal Access Registry (SRR-Access) with a prevalent and functional AV access who underwent surgical or endovascular intervention for their first thrombosis between Jan 1, 2008 and April 20, 2020 were included. The primary outcome was access survival. Secondary outcomes were time to next intervention and 30-day mortality. Access characteristics (date for access creation, upper or forearm access, graft or fistulae, first cannulation, date of thrombosis and time to next intervention) were obtained from SRR-Access. Patient characteristics were collected from SRR (age, sex, primary renal disease, comorbidities and start date of dialysis). The outcomes were assessed with Cox proportional hazard regression models adjusted for demographics, clinical, and access variables (previous interventions and time to first thrombosis). Analyses were stratified by age, sex, type of access and comorbidities.

Results: In total, 904 patients with access thrombosis were included. The mean age was 62 years, 60% were women. A large proportion (75%) had hypertension, 33% had diabetes, 54% were fistulas and 35% upper arm accesses. The median follow-up time was 1.1 year (0.2-2.9). The adjusted total risk of access abandonment was increased if the thrombosis was treated with surgical thrombectomy, HR 1.22 (1.04-1.44). There was no significant difference in time to next intervention or mortality. The results were consistent within subgroups.

Conclusions: Endovascular intervention was associated with better long-term access survival in hemodialysis patients with AV access thrombosis.



PO1346

Efficacy and Long-Term Patency of Kissing Stent Technique for Endovascular Reconstruction of the Axillary Vein: A Case Report with Long-Term Follow-Up

Sami M. Akram, Khurram Saleem, Mohamed A. Rahman. *Nephrology Associates of Northern Illinois and Indiana, Oak Brook, IL.*

Background: Purpose: to report the endovascular reconstruction (EVR) of axillary vein (AXV) with kissing stent technique (KST) following AXV obstruction due to proximal stent migration (PSM) from the cephalic arch (CA). We suggest a strategy to minimize this problem. PSM in venous system is rare but dreadful complication of EVR. Increasing venous sizes towards the heart predisposes to PSM. We report a case of AXV obstruction due to stent migration into subclavian vein (SCV). We describe the successful use of kissing stent technique (KST) to reconstruct the AXV.

Methods: Case report and review of literature.

Results: Case report: MS is an 81-yr-old female with right brachiocephalic arteriovenous fistula (R BCAVF) for chronic hemodialysis. She has recurrent cephalic arch stenosis (RCAS) (Fig1). A Viabhan 11 x 5 stent was placed which, partially migrated into the SCV, blocking the AXV (Fig2 & Fig3). The Basilic vein (BV) was cannulated and a straight glide wire introduced. A Luminex 10 x 6 stent was delivered next to Viabhan stent in the AXV. Both stents were expanded with 10 x 4 angioplasty balloon restoring the forward flow in the AXV (Fig4). At 5-year follow up both stents were patent (Fig5) except for pre and post stent stenosis, successfully treated with angioplasty. **Discussion:** EVR is employed to treat RCAS[1,2]. However, there is risk of PSM. A strategy we implement to reduce PSM is to avoid complete dilatation of lesion prior to stenting which, in this case prevented full migration of the stent. KST for EVR of superior vena cava[3] and common iliac veins[4] has been reported but not for EVR of AXV. We report the first case of utilizing KST for EVR of the AXV with 5-year follow up.

Conclusions: KST for EVR of the Axillary vein is technically feasible and has long term efficacy.

PO1347

Understanding the Transition to Standardized Fistula Rate (SFR) and Long-Term Catheter Rate (LTCR) Measures in the Medicare ESRD Quality Incentive Program (QIP)

Dongyu Wang,[1] Alissa Kapke,[1] Jeffrey Pearson,[1] Adebola O. Adeleye,[2] Delia Houseal,[2] Eric W. Young.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: In ESRD QIP Payment Year (PY) 2021, vascular access measures change to the SFR and LTCR measures. The changes involve transition of the data source from Medicare claims (CLM) to CROWNWeb (CW), expansion from Medicare fee-for-service (M-FFS) to all ESRD patients, revised numerator criteria (e.g. multiple access types), expanded patient exclusions (e.g. limited life expectancy), and case-mix adjustment for SFR.

Methods: The degree of concordance in reporting vascular access type reported in CLM and CW was assessed and trends in arteriovenous fistula use (AVF) and long-term catheter use (LTC) with the CLM-based and CW-based methods were evaluated from calendar year (CY) 2012-2019. Facilities' performance rates for the CW-based measures were calculated using PY20 data and compared to their PY20 performance for the CLM-based measures.

Results: The degree of reporting concordance between CLM and CW was high for fistula use (κ=0.95; p<0.01) and slightly lower for catheter use (κ=0.76; p<0.01). The agreement of all access types increased from 90% in CY12 to 97% in CY18. National trends in vascular access were consistently worse for CW-based measures, although this gap narrowed over time (Figure). PY20 data indicate facilities achieved a lower median SFR by 0.8% (vs. CLM-based AVF rate) and higher median LTCR by 1.4% (vs. CLM-based LTCR); however, accompanying changes to performance standards (using baseline data) result in simulated ESRD QIP measure scores increasing by approximately 0.5 points.

Conclusions: Vascular access reporting concordance in CLM and CW improved considerably in CY 2018, which corresponds to the first year of use in the ESRD QIP. The CW-based vascular access performance rates were worse than CLM-based rates; these differences are primarily attributed to the poorer performance of non-FFS patients included in the CW-based measures. While the new vascular access measures have worse performance rates, average ESRD QIP measure scores increase slightly.

Hemodialysis Access Surveillance Evaluation (HASE) Study

Loay H. Salman,[1] Abid A. Rizvi,[4] Gabriel Contreras,[2] Christina E. Manning,[1] Paul J. Feustel,[1] Ivy Machado,[2] Patricia L. Briones,[3] Aamir Z. Jamal,[4] Nicolle Bateman,[5] Laisel Martinez,[2] Roberto I. Vazquez-Padron,[2] Arif Asif.[6] *[1]Albany Medical College, Albany, NY; [2]University of Miami School of Medicine, Miami, FL; [3]University of Miami School of Nursing and Health Studies, Coral Gables, FL; [4]California Kidney Specialists, San Dimas, CA; [5]Dialysis Clinic Inc, Nashville, TN; [6]Jersey Shore University Medical Center, Neptune City, NJ.*

Background: Arteriovenous (AV) access thrombosis remains one of the most troubling AV access related complication affecting hemodialysis patients. It necessitates an urgent and occasionally complicated thrombectomy procedure and increases the risk AV access loss. The routine use of AV access surveillance for early detection and management of stenosis to reduce thrombosis remains controversial.

Methods: We conducted a multicenter, prospective, randomized clinical trial comparing standard of care with monthly Ultrasound Dilution Technique (UDT) flow surveillance using a Transonic flow measurement device (Transonic Systems Inc., 34 Dutch Mill Road, Ithaca, NY 14850, USA) to standard of care alone.

Results: We prospectively randomized 436 patients with end stage renal disease (ESRD) on hemodialysis with arteriovenous fistula (AVF) or graft (AVG) using cluster (i.e. dialysis shift) randomization to either standard of care with monthly blood flow surveillance or standard of care alone. There were no statistically significant differences in the baseline demographic data between the two groups except for ethnicity (p=0.017). Patients were followed on average for 15.2 months. There were significantly less per patient thrombotic events (Poisson rate) in the surveillance group (0.12/patient) as compared to the control group (0.23/patient) (p=0.012). There was no significant difference in total number of procedures between the two groups, irrespective of whether thrombectomy procedures were included or excluded. There was no statistically significant difference between the two groups in the rate of or the time to a first thrombotic event or number of catheters placed due to thrombosis.

Conclusions: The use of monthly AV access surveillance with UDT flow measurement in this multicenter randomized control trial reduced the per patient thrombotic events without significantly increasing the total number of angiographic procedures. Even though there is a trend, surveillance did not reduce the first thrombotic event rate. **Funding** Transonic Systems Inc., 34 Dutch Mill Road, Ithaca, NY 14850, USA

PO1349

Right Heart Dysfunction in Hemodialysis Patients

Richard E. Wing, Michael R. Gagnier, Ajay K. Thakur, Peihsuan R. Tsai, Eugene Storozynsky, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Despite emerging evidence that right ventricular dysfunction (RVD) is a major determinant of outcome, previous studies have largely neglected the RV in ESRD patients.

Methods: We conducted a cross-sectional study on patients who received maintenance hemodialysis (HD) between Jan 1 - Dec 31, 2010 and were cared for by URMC nephrology faculty. For this cohort, all ambulatory trans-thoracic echocardiograms (TTEs) between Jan 1 2010 and Dec 31, 2018 were identified. Only TTEs with images of sufficient quality to assess the RV were included. Those with pre-existing congenital heart disease, atrial fibrillation, or prior valve surgery were excluded. Subjects might have more than one included TTE. Data from subject's charts were extracted.

Results: We identified 425 individuals on HD. Of these, there were 141 ambulatory TTEs, of which 64 TTEs met all inclusion criteria. RVD is defined as abnormality in any of the following echocardiographic parameters: S' (< 9.5 cm/sec), TAPSE (< 17 mm), Free Wall Right Heart Strain (> - 20%), or RV Fractional Area Change (< 35%). Of the 64 TTEs, 19 had one or more parameters indicating RVD. Select findings with bivariate analysis are summarized in the Table 1. Continuous variables are expressed as means (S.D.) and analyzed by ANOVA. By multivariate logistic regression, dialysis vintage < 10 years, history of vascular disease, and absence of AVS were associated with RVD. There was a trend with OSA. Limitations include retrospective analysis, small numbers, and heterogeneity in patients with respect to history of dialysis access type prior to undergoing TTE.

Conclusions: RVD is common finding on TTEs in HD patients, but is under recognized. A larger prospective study is needed to identify factors that are associated with development of RVD that could potentially be modifiable.

Table 1

	Whole Group N=64	Normal N=45	RVD N=19	P Value
Male Sex	35.9%	37.8%	31.6%	0.637
Age in years	50.2 (11.8)	48.6 (11.9)	53.8 (10.8)	0.109
African American	53.1%	53.3%	52.6%	0.959
Vintage in years	9.88 (5.8)	10.9 (6.3)	7.5 (3.8)	0.032

PO1350

Catheter Care in a Hemodialysis Unit: "Do It Daily," a Multimodal Patient Education Approach

Miten Dhruve. *Michael Garron Hospital Foundation, Toronto, ON, Canada.*

Background: Central venous catheters or CVLs are the leading cause of mortality and morbidity in the dialysis population. The HDU personnel wanted to empower the patients to manage and care for their catheters. We developed a standardized educational framework in collaboration with **healthcare professionals** and the **Patient Experience Panel. Objectives:** Our ultimate goal was to reduce the rates of catheter infections in our hemodialysis unit by improving patient's knowledge, confidence, and skills related to catheter self-care. Our immediate goal was to improve patients' catheter care knowledge and skills and to standardize and optimize nursing skills and knowledge

Methods: The patients were given a pre-education survey to establish baseline knowledge, attitudes and skill levels. Educational materials were developed based on the patients' feedback, knowledge and needs, and also on practice guidelines and best practice recommendations from **CDC, KDIGO, and ORN**. Nursing education involved updating nursing policies, and a nursing catheter care certification program. Educational materials included a video, posters, pamphlets and fridge magnets using the catchphrase **"Do it Daily".** The acronym **"DAILY"** represents the following: **D** for "dressing, soiled wet or damaged", **A** for "any rash, itching or broken skin, **I** for "increased pain at catheter site, **L** for "length of catheter changed" and **Y** for "you have redness, pus, fever". Post education surveys were conducted to assess the patients' knowledge and skill levels.

Results: Thirty-three patients completed baseline surveys, education programs and post education surveys. No significant difference in proportion of patients answering yes to Knowledge or Skill assessment pre- and post-education survey. Although, there was a trend of patients stating they had received enough teaching about catheter care, knew how to keep catheter clean and dry, recognize complications and not adjust catheter by themselves. Eighty-nine percent of patients found the education/training easy to understand.

Conclusions: Use of Multi-Modal patient education material is an easy to understand and feasible tool to help patients understand proper care of their dialysis catheters.

PO1351

A Retrospective Study of Tunneled Dialysis Catheters with Exposed Cuff and Risk of Subsequent Catheter-Related Bloodstream Infection

Zachary J. Bauer, Aeman Hana, Christopher Kassab, Amulya Rajagopal, Lalathaksha Murthy Kumbar. *Henry Ford Hospital, Detroit, MI.*

Background: Tunneled dialysis catheters (TDC) are prevalent in patients with end stage renal disease (ESRD) on hemodialysis (HD). Exposure of catheter cuff leads to replacement of TDC over guidewire (TDCEx). It is unclear if exposed catheter cuff increases the risk of infection if exchanged over guidewire.

Methods: This single center retrospective study reviewed TDCEx procedures in patients with ESRD on HD using a TDC for at least 14 days. The primary endpoint was catheter related bloodstream infections within 30 days or within 90 days of catheter exchange. Infection rate (IR) were reported as total infections per 1000 catheter days.

Results: 1030 procedures were reviewed; 537 were included. TDCEx for mechanical dysfunction (n=305) and exposed cuff (n=130) were compared to TDC with infection (n=102). Catheters with infection were mainly treated with removal and delayed insertion. IR based on indications were, 0.78 (95% confidence interval (CI), 0.38-1.38) for infections, 0.64 (95% CI, 0.24-1.14) for exposed cuffs, 0.46 (95% CI, 0.25-0.76) for mechanical dysfunction. When comparing all TDCEx due to non-infectious reason to the catheters with infection, no significant difference was found for IR within 30 days [hazard ratio (HR), 0.78; 95% confidence interval (CI), 0.21-2.82; p-value 0.700] or within 90 days (HR, 0.51; 95% CI, 0.24-1.07; P=0.075). Comparing TDCEx due to exposed cuff with TDCEx for a mechanical dysfunction, insignificant difference in IR was noted at 30 days [HR, 1.59; 95% CI, 0.45-5.63; P=0.474] and at 90 days (HR, 1.65; 95% CI, 0.71-3.87; P=0.246). No significant difference was seen in IR between catheters with infection and TDCEx for exposed cuffs at 30 days [HR, 0.95; 95% CI, 0.21-4.25; P=0.948] or at 90 days (HR, 1.42; 95% CI, 0.58-3.51; P=0.442). Catheters with infection compared to TDCEx for mechanical dysfunction had a significantly increased IR at 90 (HR, 2.36; 95% CI, 1.03-5.37; P=0.042) with no significant difference at 30 days [HR, 1.52; 95% CI, 0.38-6.06; P=0.556].

Conclusions: TDCEx for catheters with exposed cuff do not increase the risk for catheter related bloodstream infections at 30 or 90 days. Infected catheters continue to have a higher risk for CRBSI at 90 days even with removal and delayed insertion.

PO1352

Meta-Analysis of Antibiotic and Non-Antibiotic Lock Solutions for Prevention of Hemodialysis Catheter-Related Infections

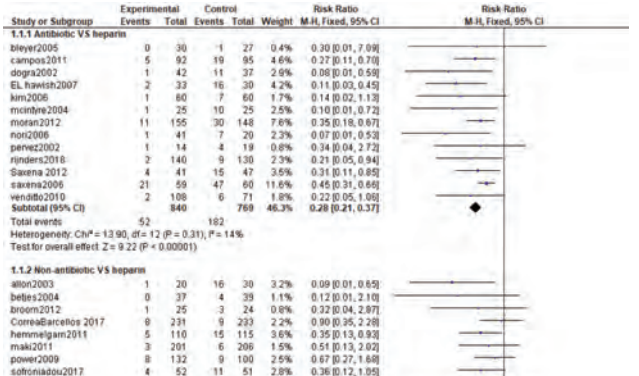
Sohail Abdul Salim,[1] Wisit Cheungpasitporn,[1] Charat Thongprayoon,[4] Karim M. Soliman,[5] Mihaly B. Tapolyai,[3] Lajos Zsom,[2] Tibor Fulop.[5] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Cegléd Hemodialysis Units, Cegled, Hungary; [3]Hatvan Hemodialysis Units, Hatvan, Hungary; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Medical University of South Carolina, Charleston, SC.*

Background: Catheter-related bloodstream infection (CRBSI) associated with hemodialysis catheters are associated with increased mortality and morbidity whilst posing a significant financial burden on health care. The effects of antibiotic and antimicrobial locking solutions on the risk of CRBSI are unclear.

Methods: From inception to April 2020, we looked for relevant clinical controlled trials in the following databases: EBSCO, PubMed, Cochrane CENTRAL, MEDLINE, EMBASE, clinicaltrial.gov, Google Scholar and performed a meta-analysis of the identified studies.

Results: 26 studies with 4,967 patients reported on the incidence of catheter-related bacteremia (CRBSI). The overall pooled Risk Ratio (RR) was lower in the intervention group signaling a 70% lower incidence of CRBSI compared with the heparin group (RR= 0.30, 95% CI [0.25, 0.36], p<0.001). Subgroup analysis showed that the administration of antibiotic regimens led to a 72% decrease in the risk of CRBSI episodes (RR=0.28, 95% CI [0.21, 0.37], p<0.0001), whereas non-antibiotic antimicrobial solutions reduced the risk of CRBSI by 68% (RR= 0.32, 95% CI [0.25, 0.41], p<0.0001). A test for subgroup differences revealed no significant difference favoring either of the two interventions.

Conclusions: Both antibiotic and antimicrobial solutions are effective in reducing CRBSI.



PO1353

The Catheter Tip Position as the Main Non-Infectious Cause of Catheter Replacement Survival

Joana G. Navarro gallardo, Pablo Maggiani, Noe Martinez murillo, Jorge J. Font, Jonathan Chavez, Jose A. Torres, Christian P. Flores. *Universidad de Guadalajara, Guadalajara, Mexico.*

Background: Identify the risk factors associated with catheter (Cath) replacement **(CR)**. Novel anatomic variables analyzed

Methods: Our objectives: Identify risk factors associated with **CR**. The Cath were placed guided by ultrasound (US). We analyze age, gender, height, previous number of Cath and placement, lab tests, blood pressure, anatomic position, extrasystoles, # punctures, Jugular Vein (JV) collapsibility, Cath TUG, TIP and TOP, tunneled or not, Heparin, complications, Skin-JV Distance, Neck circumference, cath insertion to clavicula distance (CICD), JV and Carotid diameter and distance between JV and Carotid.

Kaplan Meier survival analysis. Multivariable logistic regression model was performed. $P < 0.05$ which is significant

Results: From Feb-Dec 2019 with a 180 days follow-up, 147 vascular Cath placements were analyzed. The **CR** was presented in 21 patients (14.2%) with a survival of 85.5% (95% CI 0.80 to 0.91) (figure 1). The correct position of the Cath TIP decreases risk of **CR** (OR 0.81, 95% CI 0.73-0.90, p <0.001). Cath-related bloodstream infection (CRBI) increases the risk of **CR** (OR 2.52, 95% CI 2.13-2.98, $P < 0.001$). **CICD** >3.4 cm decrease risk of **CR** due to CRBI. (OR 0.89, 95% CI 0.81-0.97, $P < 0.01$)

Conclusions: Only the correct position of the Cath TIP protects vs **CR** while CRBI increases the risk. The shorter the CICD the less **CR** due to CRBI.

NitriCap Hemodialysis Catheter Insert to Prevent Catheter-Related Bloodstream Infection

Alexander S. Yevzlin,[1] Karthik Ramani,[1] Maria Kim,[2] Joshua Doverspike,[1,2] Faroug Suliman,[1] Marie Cornell,[1] Alvaro Rojas-Pena.[1] *[1]University of Michigan, Ann Arbor, MI; [2]NOTA Labs, Ann Arbor, MI.*

Background: Tunneled dialysis catheters (TDCs) are associated with blood stream infections. We developed a novel nitric oxide (NO) eluting catheter insert and tested its effects *in vitro* and in sheep for two weeksto assess itsbacteriocidal activity.

Methods: Two cm long inserts using S-nitrosoglutathione (GSNO) as the NO donor and various other components were prepared and tested for their real-time NO release. *In vitro* studies were done to test the insert's bactericidal effects in a real catheter hub antimicrobial model with *S. aureus* and *P. aeuruginosa*. NO releasing inserts (NitriCap) were compared to a control (without NO releasing). After 72 h of incubation at 24°C, the amount of viable bacteria in the fluid was quantified for each sample. Subsequently, the antimicrobial/anti-biofilm efficacy of NitriCap was tested in a 14-day ovine model of microbe rich natural environment and compared to controls (without NO).

Results: A formulation was devised with an initial burst of NO (>100 flux), followed by sustained NO flux for 72 h duration (>20 flux). This formulation lead to a 6.6 log reduction of *S. aureus* and 6.7 for *P. aeruginosa* using NitriCap compared to a control of no insert. The *in vivo* 14-day sheep studies showed a log reduction of 3.9 by Day 4 and 5.4 by the end of the study (Day 14) in the NitriCap group when compared to controls, **(Fig. 1)**. After the 14 day sheep study was completed, the amount of bacteria/biofilm adhered to the inner lumen walls in four different regions of each catheter showed a 1.9 log reduction of bacteria even at the proximal tip for NitriCap vs. controls. Fluorescent microscopic images of bacteria/biofilm were taken of the inner lumen wall of each sample to qualitatively show the difference in bacterial/biofilm growth at four different regions of the catheter for NitriCap vs. control **(Fig. 2)**.

Conclusions: This data strongly suggests that the NitriCap displays significant antimicrobial/anti-biofilm effects during *in vitro* and large animal *in vivo* studies, demonstrating that its implementation could minimize catheter related blood stream infections.

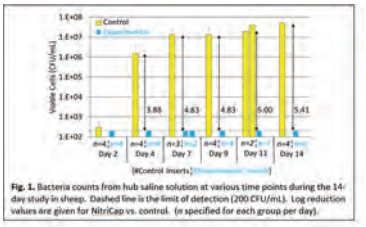

Fig. 1. Bacteria counts from hub saline solution at various time points during the 14-day study in sheep. Dashed line is the limit of detection (200 CFU/mL). Log reduction values are given for NitriCap vs. control. (n specified for each group per day).

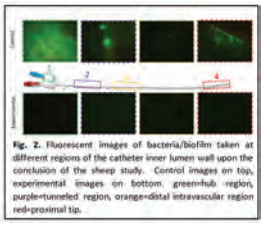

Fig. 2. Fluorescent images of bacteria/biofilm taken at different regions of the catheter inner lumen wall upon the conclusion of the sheep study. Control images on top, experimental images on bottom. green=hub region, purple=tunneled region, orange=distal intravascular region red=proximal tip.

PO1355

Catheter Dependency After Vascular Access Placement Among Elderly Patients on Hemodialysis: An Intention-to-Treat Analysis

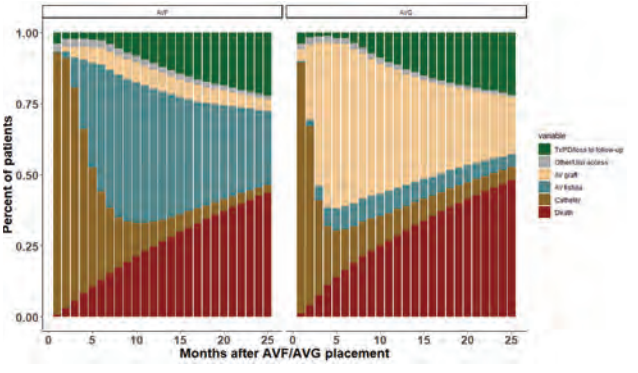
Beini Lyu, Micah R. Chan, Brad C. Astor. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: Evidence is mixed regarding optimal choices of incident vascular access type for elderly patients on hemodialysis (HD). Arteriovenous fistula (AVF) may be desirable given its better long-term outcomes. However, many elderly patients have a lower probability of AVF maturation and limited life expectancy that may limit the potential long-term benefit of AVF. We aimed to use an intention-to-treat (ITT) analysis to assess catheter dependency after incident AVF/arteriovenous graft (AVG) placement among elderly patients on HD

Methods: Patients who were ≥67 years old at HD initiation, with no AVF/AVG placed before HD initiation, and had a first AVF/AVG placed within 1 year after HD initiation between May 2012 and May 2017 in the USRDS were included. Patients were followed from the first AVF/AVG placement using ITT analysis principles. Vascular access in use for HD was assessed using CrownWeb data. Catheter dependency was defined as using catheter only or using AVF/AVG combined with a catheter for HD.

Results: A total of 39,036 patients were included. Among them, 31,190 (79.9%) had AVF and 7846 (21.1%) had AVG placed. A substantially lower proportion of patients in the AVG group relied on catheter for HD early after VA placement (88.2% vs 91.9% in AVG and AVF, respectively, at 1m after placement; 23.3% vs 64.3% at 3m; 16.4% vs 28.9% at 6m, Fig1). In longer follow-up, proportion of catheter dependency was similar among patients remaining on HD in both groups, with slightly higher proportion in the AVG group observed at 1 year and beyond (14.8% vs 12.3% at 12m; 14.6% vs 9.6% at 24 m). Risk of mortality was high in both group (24.8% in AVF vs 28.7% in AVG by 12m; 42.4% in AVF vs 46.7% in AVG by 24m after VA placement).

Conclusions: AVG is associated with substantially less catheter dependency than AVF in the short-term and only slightly higher catheter dependency at one year and beyond. AVG placement may be beneficial in selected elderly patients to minimize catheter use.



PO1356

Detecting the Prevalence of Bacterial Colonization on Tunneled Hemodialysis Catheters Using 16S rRNA Gene Sequencing and Scanning Electron Microscopy: Lack of Evidence for Universal Colonization

Ali Mirza Onder,[1] Christopher F. Cuff,[3] Anthony A. Billings,[3] Songul Onder,[2] Judy A. King.[4] *[1]University of Mississippi Medical Center, Jackson, MS; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]West Virginia University Health Sciences Center, Morgantown, WV; [4]Louisiana State University Health Sciences Center Shreveport, Shreveport, LA.*

Background: Tunneled cuffed hemodialysis catheters (TCC) are claimed to be colonized by microorganisms early after placement, increasing risk for catheter related bacteremia (CRB). Our objective was to detect the prevalence of bacterial colonization of TCC by using 16S rRNA gene sequencing (qPCR) and investigate its association with intraluminal biofilm coverage.

Methods: 45 TCC were investigated; 10 were removed due to CRB and 35 were removed for non-infectious reasons. 16S rRNA qPCR technique was used to detect intraluminal bacterial colonization after scraping the intraluminal biologic material. Proximal, middle and distal TCC were evaluated by scanning electron microscopy to

determine the percentage (%) of intraluminal biofilm surface area coverage (BSA). All catheters were cultured for bacterial growth following sonication.

Results: Twenty-seven catheters were 16S rRNA qPCR (+) (60%). Eight of these catheters were removed due to CRB. 16S rRNA qPCR (-) results were associated with the absence of bacteremia (negative predictive value of 89% and Odds Ratio = 8.0). 16S rRNA qPCR (-) results were not predicted by catheter vintage or dialysis vintage. All catheter segments were covered by biofilm with a mean % BSA of 68.4 ± 26.1%. There was statistically significant difference between the % BSA of the three catheter segments (p=0.0344). The proximal catheter segments had larger % BSA compared to distal segments. The intraluminal % BSA was inversely correlated with dialysis vintage (p<0.01). There was no statistical difference for % BSA when catheters were compared according to their 16S rRNA qPCR, catheter culture, or blood culture results.

Conclusions: For this cohort, biofilm accumulation on TCCs was universal but bacterial colonization was not, as measured by three different methods, suggesting that biofilm may precede colonization of TCC by microorganisms. This piece of evidence may help to improve prophylactic strategies against CRB.

PO1357

Are Rescue Maneuvers More Efficient for Tunneled Catheter Late Dysfunction Than Wire Guide Catheter Replacement?

Daniel Murillo brambila,[1,2] Monica C. Jimenez Cornejo,[1,2] Gabriela J. Abundis Mora,[1,2] Karina Renoirte.[1,2] *[1]PISA SANEFRO, Guadalajara, Mexico; [2]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.*

Background: Late catheter dysfunction is a common complication in HD patients. Complications associated with vascular accesses account for approximately 30% of hospital admissions for chronic HD patients. It also increases mortality. It is diagnosed when a catheter has been used successfully and later becomes dysfunctional. Thrombotic occlusion is the main cause. It is traditionally managed by placing a new catheter, wich may later lead to vascular access exhaustion. The purpose of this study was to assess the efficacy and safety of rescue maneuvers to treat late dysfuntional tunneled catheters versus catheter replacement.

Methods: Prospective, observational study. 195 procedures were performed between 2018 and 2019 in patients with late tunneled catheter dysfunction. Patients were ramdomly assigned to one group: group A, high pressure saline solution infusion into both lumens until obtaining good patency (permeabilization); B, catheter tip mobilization to reposition catheter tip until obtaining good patency; C, wire guide catheter replacement. Variables analyzed: age, gender, CKD etiology, vascular access site at the time of dysfunction, patency after rescue maneuvers (days). Percentages, means, Kruskal Wallis and Kaplan Meir and chi-square test were used.

Results: 118 were male (60.5%), with mean age of 51.2 years (17.3). CKD etiology was of unknown origin in 90 patients (46.2 %) and 52(26.7%) had diabetes mellitus. The right jugular vein was the most common anatomical site at the time of dysfunction (n=87, 44.8%). Catheter patency: group A, 119 days (99.3); group B, 175.4 days (175.5) and group C 217.6 days(157). Kruskal-Wallis test in the comparison between groups: group A vs B, p=0.8; C vs A, P=0.001; C vs B, p=0.057. The Kaplan Meir curve showed that group B and C had a longer catheter survival than A group (p=<0.001). Complications: six patients (3.1%) had bleeding from the catheter exit site in group C (p=0.015).

Conclusions: In late vascular catheter dysfunction, catheter tip mobilization is a rescue maneuver as effective as wire guide replacement tunneled catheter and with fewer complications.

PO1358

Use of Diphenhydramine as Adjuvant to Conscious Sedation in Patients Undergoing Interventional Nephrology Procedures

Ravi V. Patel, Sayee Sundar Alagusundaramoorthy, Muhammad Sohaib Karim, Micah R. Chan, Brad C. Astor, Ali I. Gardezi. *University of Wisconsin-Madison, Madison, WI.*

Background: Benzodiazepine and opioids are commonly used for conscious sedation during interventional nephrology procedures but are associated with adverse events such as bradycardia and respiratory depression. We are proposing to use Diphenhydramine as adjuvant medication to decrease the required dose of benzodiazepine and opioid.

Methods: We compared patients who received conscious sedation with IV midazolam and IV fentanyl as per standard practices to patients who received IV diphenhydramine prior to receiving IV midazolam and IV fentanyl. Level of sedation was managed as per guidelines of moderate sedations. Data collected included baseline patient characteristics, dose of midazolam and fentanyl used, duration of the procedure, type of the procedure and incidence of bradycardia and hypoxia during procedure. We also looked at if sedation was administered by physician vs nurse.

Results: Out of total 407 patients included in the study, 225 patient received Diphenhydramine as adjuvant to conscious sedation. Diphenhydramine use significantly reduced midazolam (2.2 mg vs 2.88 mg, p valuve <0.001) and fentanyl (88.2 mcg vs 102.07 mcg p value 0.005) dose requirements during procedures. It was not associated with increased rates of bradycardia and hypoxia. When comparing who administered sedation, physician administered sedation was associated with lower midazolam (2.18 mg vs 3.37 mg, p value < 0.001) and fentanyl (99.29 mcg vs 105.97 mcg, p value 0.04) dose without any difference in the rate of side effects, as compare to nurse administered sedation.

Conclusions: Our study indicates that the use of IV diphenhydramine is safe and effective as conscious sedation for patient undergoing Interventional Nephrology procedures and associated with reduction in benzodiazepine and opioid dose requirements.

PO1359

Perforation of Superior Vena Cava: A Rare Complication of Tunneled Hemodialysis Catheter Placement

Mukesh K. Sharma.[1,2] *[1]Sierra Nevada Nephrology, Reno, NV; [2]University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Placement of tunneled hemodialysis catheter (TDC) is a fairly common procedure performed in hospitals and outpatient vascular centers. It is considered a fairly simple and risk free procedure for most part. Perforation of SVC while passing guide wires or dilating the tract is very rare and has been reported only in a very few case reports in the literature. We report a case that highlights this rare but frightful complication. This case also highlights the risk of deep central vein thrombosis associated with dialysis catheters.

Case Description: A 40-year-old female had a left subclavian vein temporary HD catheter placed in ER for emergent HD for ethylene glycol poisoning related complications. After one week, the temporary HD catheter was exchanged for a TDC under fluoroscopy. Shortly after the procedure the patient became dyspneic, tachycardic, and hypotensive. Imaging revealed perforation of SVC by the catheter tip resulting in a large Rt hemothorax. Immediate chest tube was placed followed by Thoracotomy and repair of SVC perforation and removal of TDC. One week later she developed left arm swelling and was diagnosed with deep vein thrombosis of the left subclavian vein, left internal jugular vein and the left axillary vein. The patient continued HD through a femoral HD catheter. She was started on heparin drip and systemically anticoagulated. The renal functions eventually recovered and arm swelling resolved and she was able to be discharged from hospital.

Discussion: Teaching Points: This case highlights rare but frightful complications of placement of a tunneled hemodialysis catheter, especially involving the left side neck veins. SVC perforation is a potentially fatal complication that can occur during placement of HD catheters. Immediate recognition, chest tube insertion for drainage, and/or pericardiocentesis along with emergent SVC repair are the key factors to management. Given the high frequency of HD catheter placements, providers should be aware and know how to treat and manage these complications in a timely manner.

PO1360

Unusual Dialysis Catheter Location in a Transplant Patient

Daniela Via Reque Cortes, Pablo A. Vale, Paulo R. Lins. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Introduction: Persistent left superior vena cava (PLSVC) is the most common thoracic venous malformation, despite its low incidence. PLSVC is generally discovered fortuitously without clinical signs. Serious hemodynamic complications may occur during the implantation and the permanency of a hemodialysis vascular access on this vessel.

Case Description: A 56-year-old woman, kidney transplant recipient 8 years ago, was admitted to the Intensive Care Unit with septic shock secondary to disseminated shingles after immunosuppressive therapy for acute cellular rejection. The patient developed acute kidney injury requiring renal replacement therapy. Due to history of right internal jugular vein thrombosis, the left internal jugular vein was catheterized with a non-tunneled double lumen hemodialysis catheter (12 French, 20 cm) without any complications. Routine post-procedure chest radiograph showed that the catheter was descending straight into the left border of the mediastinum (Image 1A). CT angiography (CTA) of the neck and thorax revealed the catheter localized on the PLSVC (Image 1B). The patient was placed on hemodialysis through this access uneventfully throughout the hospitalization period.

Discussion: PLSVC is a congenital malformation reported in 0.4-0.5% of the general population. Patients are mostly asymptomatic and the anomaly is frequently underdiagnosed or only noticed incidentally during imaging studies. Some patients can present with arrhythmias and sudden death. Screening diagnostic studies include chest radiograph and echocardiography, confirmed by CTA, magnetic resonance and cardiac catheterization. The possibility of catheterization of PLSVC is uncertain. Some authors argue that this vessel is too thin to keep a long-term catheter, but others suggest that if an accurate assessment of inner diameter of the vein can be performed before catheterization, it could be used as a site for conventional vascular access. However, there are reports of serious complications during catheterization such as pneumothorax, hemothorax, arrhythmias and cardiac arrest.

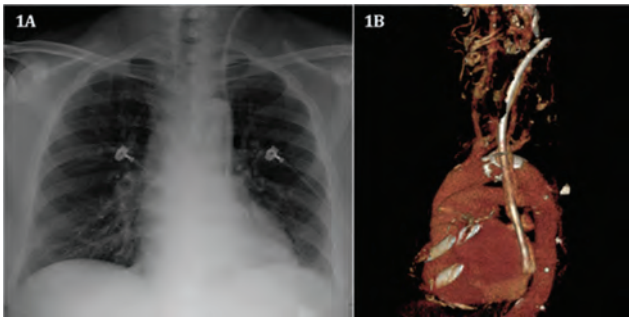

Image 1A/1B.

PO1361

Percutaneous Thrombectomy of an Ipsilateral Arteriovenous Dialysis Graft in a Patient with Dextrocardia

Alexander Hlepas, Anna M. Zemke, Monnie Wasse. Interventional Nephrology
Rush University Medical Center, Chicago, IL.

Introduction: Dextrocardia with situs solitus (DSS) and associated duplicated left superior vena cava (DLSVC) is a rare condition. In affected patients with end-stage kidney disease (ESKD) the preferred dialysis access type and site are unclear, however anatomical variations may impact feasibility and success of dialysis access related procedures. In the setting of the altered anatomy, drainage of an access to the right atrium takes an altered pathway with differing technical concerns for stent deployment and avoidance of thrombus propagation in a clotted AVG.

Case Description: We report a rare case of covered stent placement during thrombectomy of a clotted ipsilateral right forearm loop AVG in the setting of DSS in an ESRD female. Given a severe venous anastomotic lesion and severe draining brachial vein stenosis, a covered stent was placed across the length of the stenosis. However, a guidewire could not be parked in the IVC to safeguard against potential stent migration to the heart, given the presence of dextrocardia, and the procedure was associated with a high risk of thrombus migration. An associated DLSVC draining into the CS (Coronary Sinus) was present, thus creating a direct path from the AVG through the central veins and the CS down to the heart. A right brachiocephalic vein was not present, and the right subclavian vein drained directly into the persistent right SVC (right part of duplicated left). After repeating the angiogram, measuring the length and marking it on the imager, a 6.10 cm Viabahn stent graft was passed to the level of the stenosis bridging the lesion with 2 cm maintained in the Acuseal 6 mm AVG and deployed. Thrombus was cleared with a 4 French Fogarthy catheter and after installation of TPA and excellent flow return achieved.

Discussion: DSS is a rare malformation which may impact the preference of dialysis access site and type in ERSD patients. Possible complications due to the altered anatomy need to be further evaluated. Appropriate precautions to prevent thrombus migration from a clotted ipsilateral graft in the setting of dextrocardia need to be further discussed. This case shows the feasibility of stent placement in a clotted AVG despite the inability of placing a guidewire down the IVC due to dextrocardia.

PO1362

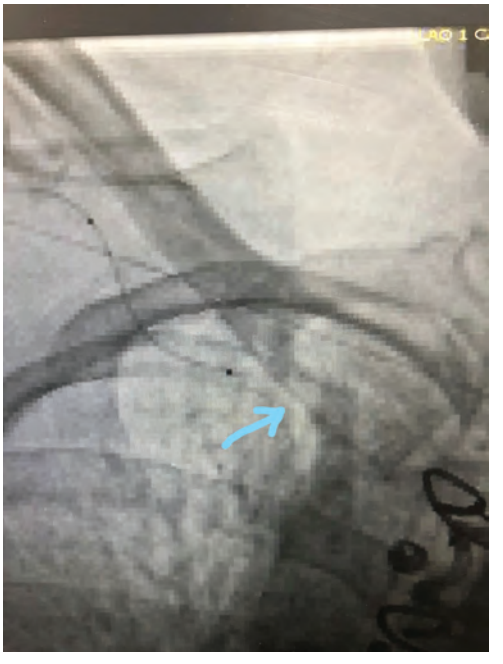
Missed Central Venous Stenosis Causing Unilateral Arm Swelling

Sylvester Barnes.[1,2] *[1]Loyola University Health System, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL.*

Introduction: The patient is a 67YOM with a history of ESRD, right mandible SCC treated with resection, chemotherapy, and radiation with a right sided PowerPort placed for chemo, removed after roughly 1 year. Prior to initiation of dialysis the patient had a right upper extremity brachiocephalic fistula created leading to unilateral right arm swelling shortly afterwards.

Case Description: Fistulogram was performed showing no significant stenosis. Persistent arm swelling continued. CT venogram showed no areas of central stenosis nor any external mass compression (figure 1). Repeat fistulogram showed similar findings; however, pressure wire measurement was obtained showing a gradient of 20 mmHg at the right innominate/SVC junction. Catheter directed injection revealed a near complete stenosis (figure 2). Angioplasty was performed with an 8 mm balloon. Repeat pressure measurements showed a decrease to 10 mmHg with angiogram demonstrating significant improvement in the lesion.

Discussion: Over two weeks he had swelling resolution. This case highlights physical exam findings of central vein stenosis. Despite being absent on multiple imaging modalities persistent physical exam findings necessitated continued evaluation. The validity of pressure wire measurements to help guide further imaging and treatment options is also highlighted.



PO1363

Arterial Emboli in the Setting of Prolonged Dialysis Access Thrombosis

Alian Albalas, Sloan Almehmi. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Thrombosis of the dialysis access is a frequent complication that is encountered in dialysis patients and is associated with poor access outcomes. Delaying dialysis access thrombectomy decreases the chances of re-establishing the flow within the access circuit. However, it is unclear whether this delay would be associated with emboli of the arterial tree. Here we report on two patients in which the access declotting was delayed resulting in arterial emboli.

Case Description: Patient 1: A 32-year-old male with a history of end stage renal disease (ESRD) on hemodialysis via right upper arm HeRO graft who presented with clotted access and volume overload. Due to the severe respiratory distress, he underwent a temporary catheter insertion and urgent dialysis. He came back after 4 days for access declotting. Initial arteriogram revealed right axillary and brachial artery emboli that was removed successfully using tissue plasminogen activator (tPA) catheter infusion followed by and Fogarty balloon. Patient 2: A 65 yr. old male with ESRD on hemodialysis via right upper extremity AV graft who presented with clotted access for one week. The angiogram revealed total occlusion of the venous anastomosis that was treated with angioplasty. The arteriogram demonstrated an embolus within the brachial artery distal to the anastomosis and another embolus in the distal radial artery. Both emboli were treated successfully with selective tPA infusion using Kumpe catheter.

Discussion: These two cases showed that prolonged dialysis access thrombosis can be complicated with arterial embolic events that require high suspicion and immediate treatment.

PO1364

Associations Between Length of Dialysis Facility Ownership and Vascular Access

David T. Gilbertson,[1,2] Yi Peng,[1,2] William Eggert,[1,2] Mahesh Krishnan.[3] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Hennepin Healthcare Research Institute, Minneapolis, MN; [3]DaVita HealthCare Partners, Denver, CO.*

Background: Length of dialysis facility ownership may be associated with facility performance in achieving guideline-recommended clinical indicators and outcomes measures. Using publicly available dialysis facility-level data, we sought to assess dialysis facility performance on 2 clinical indicators prior to and after facilities were acquired by a large dialysis organization (LDO).

Methods: Using data from Dialysis Facility Compare, we compared units that the LDO acquired during 2013 through 2016 to existing units by looking at 3 time frames: change from the year prior to acquisition, the year of acquisition, and the year following acquisition. These were compared to facilities under LDO ownership for at least 3 years and facilities not owned by the LDO. The measures assessed were percentage of patients with a catheter in use for more than 90 days and percentage of patients with an arteriovenous (AV) fistula in use.

Results: Sixty-seven units were acquired by the LDO during 2013 through 2016. Units acquired by the LDO had a higher percentage of patients with catheter use ≥90 days in the year prior to acquisition than units owned by the LDO for at least 3 years and units not owned by the LDO and improved during the year acquired and the year following acquisition (14.1%, 12.8%, 11.4%, respectively). Similar improvements were observed for AV fistula use (see Table).

Conclusions: Prior research has posited both positive and negative effects of acquisition on quality of patient care. The current results do not find negative effects and suggest possible improvements in care over the course of 1 to 2 years following acquisition, which suggests that implementation of LDO patient care protocols in newly acquired facilities may take time to unfold.

Funding: Commercial Support - DaVita

% of Patients With a Catheter ≥90 Days	Year Prior	Year Acquired	Year After
Acquired by LDO	14.1%	12.8%	11.4%
Owned by LDO for at least 3 years	8.5%	8.5%	9.0%
Not owned by LDO	12.0%	11.8%	12.0%
% of Patients With AV Fistula in Use			
Acquired by LDO	63.4%	63.1%	64.7%
Owned by LDO for at least 3 years	65.8%	67.3%	67.3%
Not owned by LDO	63.0%	64.5%	64.8%

PO1365

Data-Backed Multidisciplinary Care Substantially Improves Renal Replacement Therapy Outcomes

Xiaoyan Wang,[1] Ollie Fielding,[1] Jung Hoon Son,[1] Edward M. Lee,[1] Andrew Bohmart,[2] Frank Liu,[2] Jeffrey I. Silberzweig.[2] The PEAK team *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: The Rogosin Institute created the Program for Education in Advanced Kidney Disease (PEAK), a multidisciplinary care team that assists patients in making a smooth transition to renal replacement therapy (RRT) in 2015. In October 2018 the PEAK team transitioned to using a machine learning (ML) algorithm and care platform devised by pulseData to identify their highest risk patients and increase the rate of optimal RRT starts and increase support for patients in choosing a home dialysis modality.

Methods: The ML model continually surveys the Electronic Health Record (EHR) to identify patients at risk of progression to an eGFR <10 or RRT start in the next six months for referral into the PEAK program. The patient review platform presents a longitudinal view of the patient's data, allows for the documentation of the RRT care plan and is used to review the high risk patients at a weekly care planning session. The care team updates patient progress and the platform highlights patients who have had no recent care actions.

Results: Home dialysis rates increased 50% after the ML/platform deployment (30% vs 20%). Home dialysis rates among graduates of the PEAK program are now 10x the NYC average (27% since January 1, 2019 vs 2.5%). Patients who spend more time in the PEAK program are more likely to receive an optimal dialysis start (as an outpatient and with venous access) ($p<0.00002$, unequal variances t-test); the mean PEAK duration for an optimal start is 316 days vs. 196 for non-optimal starts. Optimal starts are also associated with a greater number of PEAK appointments, (4.9 appointments vs 3.7; $p<0.0004$, unequal variances t-test). Further, of patients starting dialysis using a central venous catheter (CVC), PEAK program graduates remove them significantly sooner (mean 88.57 days for non-PEAK vs. 54.71 mean days for PEAK ($p<0.02$, unequal variances t-test).

Conclusions: The PEAK MDC-pulseData partnership has dramatically improved care coordination resulting in a substantial increase in home dialysis modality and optimal dialysis starts and reduced the amount of time dialysis patients spend using a CVC.

Funding: Commercial Support - pulseData

PO1366

Education and Experience Gained Through Nephrology Business Leadership University (NBLU) Provide Valuable Benefits to Graduating Nephrology Fellows: A Survey-Based Study

Diana Mahbod,[1] Manasi Bapat,[3] Samir Nangia.[1,2] *[1]Dallas Renal Group, Dallas, TX; [2]Texas Christian University, Fort Worth, TX; [3]East Bay Nephrology, Berkeley, CA.*

Background: Nephrology fellowship programs provide excellent clinical training but education regarding the economic, business, and leadership aspects of practicing as a nephrologist are lacking. Nephrology Business Leadership University (NBLU) addresses these needs in order to provide graduating fellows with practical tools for navigating their early private practice or academic careers.

Methods: We surveyed attendees of NBLU from each of the four years since the conference was created. An anonymous survey was sent to alumni electronically and focused on how the experiences and knowledge gained at NBLU have impacted their early careers.

Results: Seventy-one percent of fellows who were contacted responded to the survey. Respondents represented all four years of NBLU and all geographic areas of the U.S. All fellows indicated that they would recommend NBLU to other fellows, with 91% indicating that they would highly recommend it. Respondents reported that NBLU increased their knowledge about the nephrology job market, the economics of nephrology practice, and the various ways to engage in leadership opportunities in nephrology, including by using social media platforms for education and networking. Fellows reported enhanced knowledge regarding both private and academic nephrology careers and most established lasting relationships with colleagues from across the country which they intend to maintain throughout their careers.

Conclusions: Nephrology fellows report a significant need for business and leadership education which is currently lacking from fellowship programs. NBLU provides a week-long curriculum which has a lasting positive impact on graduating nephrology fellows. Empowering nephrology trainees on the verge of entering the workforce has the power to strengthen the field as these early career nephrologists inspire other trainees to join this challenging yet fulfilling field.

PO1367

Medicine Residents' Perception of the Nephrology Specialty

Georges Nakhoul,[1,2] Ali Mehdi,[1,2] Jonathan J. Taliercio,[1,2] Patricia F. Kao,[3] Grace Mcnutt,[1] Jessica Greenfield,[1] Abby L. Spencer,[1,2] John F. O'Toole,[1,2] Joseph V. Nally,[1,2] John R. Sedor,[1,2] S. beth Bierer.[1,2] *[1]Cleveland Clinic, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Washington University in Saint Louis, Saint Louis, MO.*

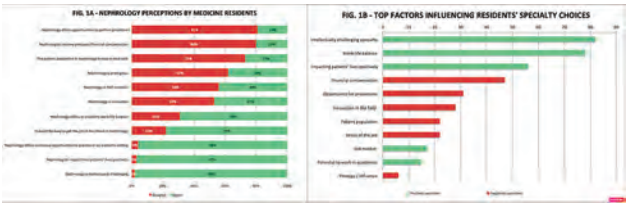
Background: Interest in nephrology as a specialty has been declining among residents. As a result, more than half of the programs remain unfilled. The residents' perceptions of the nephrology field that might account for this loss of interest are unknown. We aimed to identify factors influencing residents' views on pursuing a career in nephrology.

Methods: We used the results of our previously published qualitative analysis on residents' perception of nephrology to inform and design a survey of 60 questions. The survey was delivered using the secure we application "REDCap to 680 residents across eight medicine residency programs in different regions nationally.

Results: 184 residents (27%) responded to the survey. 56% (103) were male, 77% (142) were American graduates and 21% (42) were international graduates. Major positive perceptions of nephrology were: intellectually challenging, positively impacts patients' lives, opportunity to obtain the job of choice with possibility to practice in an academic setting, and a good work-life balance (Fig. 1A). Those aligned well with the top factors influencing residents' choice of specialty (Fig. 1B). The major negative perceptions included: inability to perform procedures, financial compensation, and patient population (Fig. 1A). Those aligned poorly with many of the key factors influencing residents' choice of specialty (Fig. 1B).

Conclusions: Nephrology is well perceived in the top three categories of factors that influence residents' specialty choices. This suggests that negative factors such as inadequate financial compensation, inability to perform procedures, lack of innovation, and a difficult patient population largely outweigh the positives. In order to attract more candidates, the nephrology community should highlight the innovations and policy initiatives such as the Kidney Precision Medicine Project, the Kidney Innovation Accelerator, and the Advancing American Kidney Health initiative. Nephrologists should also consider creating/expanding interventional nephrology programs and increasing resident exposure to outpatient nephrology.

Funding: Private Foundation Support



PO1368

Clinical Practice Guideline Adoption and Nephrologist Demand

Joseph Lunyera,[3] Kurtis Pivert,[1] Stephen M. Sozio.[2] *[1]American Society of Nephrology, Washington, DC; [2]Johns Hopkins University, Baltimore, MD; [3]Duke University, Durham, NC.*

Background: It is unknown how clinical practice guidelines (CPGs) can affect subspecialty consult (and subspecialist) demand. This study sought to quantify how nationwide adoption of a CKD evaluation and management CPG could influence consult volume, nephrologist demand, and existing geographic maldistribution of nephrologists.

Methods: We projected the volume of nephrology consults based on KDIGO's *2012 Clinical Practice Guideline for the Evaluation and Management of Chronic Kidney Disease* recommendations for nephrology consultation. KDIGO's CPG recommends a nephrology consult for patients with either a) eGFR <30 ml/min/1.73 m^2; b) urine ACR ≥300 mg/g; or c) eGFR <60 ml/min/1.73 m^2 and/or ACR >30 mg/g and refractory hypertension (BP ≥140/90 mmHg despite ≥4 antihypertensives). We used data from the National Health and Nutrition Examination Survey (NHANES) from 2011–2016 weighted equally across three survey periods, and disaggregated data at the Census Division level to capture geographic variation in potential demand. We calculated eGFR using the CKD-EPI formula and projected KDIGO-recommended nephrology consults as number of weighted individuals per Census Division meeting KDIGO criteria. We quantified nephrologist demand as a ratio of consult volume per nephrologist at the Census Division level using data from the 2014 American Medical Association Masterfile.

Results: Projected nephrologist demand varied geographically, from 1.67% in the Middle Atlantic to 2.33% in the South Atlantic (Table 1), translating to 330–1553 consults/nephrologist if KDIGO's CPG were implemented nationwide. Maldistribution in the Mountain (2.19 nephrologists/100K population) and West North Central (2.44) exacerbated consult demand.

Conclusions: Implementing a CKD CPG could lead to increased demand for nephrologists, which may exacerbate the suboptimal geographic distribution of kidney health specialists.

Results

Census Division	NHANES 2011–2016 Weighted Population	Meet KDIGO Criteria (Weighted Total)	Meet KDIGO Criteria (%)	Nephrologists (2014 AMA)	Nephrologist/100K Population (2014 Census Estimate)	Additional Consults Per Nephrologist
New England	29,970,615	564,870.2	1.88%	509	3.46	1,109.76
Middle Atlantic	14,304,792	239,159.2	1.67%	1,596	3.86	149.85
South Atlantic	39,132,703	913,497.4	2.33%	1,854	2.97	492.72

PO1369

Association Between Different Payment Models, Workload, and Job Satisfaction of Nephrologists in Lebanon and Jordan

Mabel Aoun,[1,2] Nour Breiteh,[2] Kassem M. Kassak.[2] *[1]Saint-Joseph University, Beirut, Lebanon; [2]American University of Beirut, Beirut, Lebanon.*

Background: The main challenges that nephrologists are facing worldwide are lower income, dissatisfactory payment models, long work hours and burnout. This study aimed to identify factors associated with nephrologists' satisfaction in Lebanon and Jordan.

Methods: An online survey was sent to all 250 Lebanese and Jordanian nephrologists, including data on demographics, education, academic activities, job satisfaction, burnout, workload and reimbursement.

Results: A total of 59 nephrologists responded. Mean age was 46.9 ±12.5 years, 39% women. Respondents reported low rates of satisfaction in job opportunities (20%), income (25%) and administrative support (32%). On the other hand, 68% reported that nephrology is stressful. High satisfaction rates were found in relationship with patients (78%) and colleagues (73%). Income was significantly higher among males than females ($p < 0.001$). Satisfaction towards income was significantly lower in females, mean score difference 0.71 ± 0.30 (95%CI: 0.10,1.32; p=0.024). A greater proportion of male over female practitioners wanted to follow above the 40-dialysis-patient regulation ($p<0.001$) and preferred pay-for-performance over fee for service. Satisfaction with income and work-life balance was positively correlated with age and young nephrologists had significantly lower satisfaction with job opportunities (11%). Driving over 1 hour daily to work was significantly associated with dissatisfaction in work-life balance (p=0.029), stress and burnout (p=0.016). Using regression analysis, longer delay in payment predicted worse work-life balance among Lebanese nephrologists (p=0.04). Compared to male practitioners, female practitioners spent more time on teaching ($p < 0.001$), and more female had academic rank and publications ($p < 0.001$). Gender discrimination was perceived significantly among women.

Conclusions: Unfair and delayed reimbursement is associated with dissatisfaction among the surveyed nephrologists. Gender differences are very significant with lower income and satisfaction rates among women. Similarly, it seems that the younger generation perceives low job potentials. Decision makers need urgently to empower women, address payment delays conduct market analysis and accordingly regulate nephrologists' entry to avoid oversupply or unemployment.

PO1370

Assessing Nephrology Competency in General Pediatrics

Amrit Kirpalani,[1,2] Natasha Jawa,[1] Charushree Prasad,[3] Adelle R. Atkinson,[1] Mark E. Feldman,[1] Justin M. Jeffers,[4] Damien G. Noone.[1] *[1]Hospital for Sick Children, Toronto, ON, Canada; [2]London Health Sciences Centre Children's Hospital, London, ON, Canada; [3]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [4]Johns Hopkins University, Baltimore, MD.*

Background: General pediatricians may be the first-line providers to care for children with kidney disease, however studies suggest they find nephrology to be a difficult subject. This study aimed to identify areas of lowest perceived competency and importance within nephrology for general pediatricians.

Methods: A web-based survey was distributed to general pediatricians through the Paediatricians of Ontario network, to all Pediatrics Residency Program Directors in Canada and to Pediatric Nephrologists in the Canadian Association of Paediatric Nephrologists. Pediatricians were asked to rate nephrology objectives of training on a 5-point Likert scale for perceived competence and importance. Program Directors and Nephrologists were asked for perceived importance of each objective for general pediatricians. Scores were analyzed using Student's t-test and mean scores were calculated. Knowledge Gap scores were calculated as the difference between perceived importance and competence scores.

Results: ***General Paediatricians.*** 60/350 (17%) responded to the survey. Domains scoring significantly below the mean in terms of competency (2.9/5) and importance (3.2/5), respectively, were kidney stones (2.5 and 2.6), AKI (2.5 and 2.4), CKD (1.9 and 2.1), Tubular disorders (1.8 and 2.0), and kidney transplant (1.6 and 1.7). Hypertension had the most significant knowledge gap score (0.8/5, 16%, $p<0.05$). ***Program Directors.***

9/17 (53%) responded to the survey. ***Nephrologists.*** 20/80 (25%) responded to the survey Program Directors and Nephrologists agreed that Stones, CKD, Tubular disorders, and Transplant were of lower importance. AKI was the domain with the largest discrepancy in perceived importance rated between nephrologists (4.2) and Program Directors (4.2) compared to general pediatricians (2.4) (1.8/5, 36%, p<0.05).

Conclusions: General pediatricians do not feel comfortable with AKI and do not find this topic important to their practice, contrary to Program Directors' and Nephrologists' opinions, and despite growing evidence in recent years of the under-recognition, poor follow-up, and significant long-term implications of AKI. Hypertension is the area with the largest knowledge gap, which also raises concerns due to its rising prevalence in pediatrics. Educational interventions are needed to address deficits in these crucial domains of renal health in general pediatrics.

PO1371

Assessment of Faculty Developed e-Curriculum in Hemodialysis

Namrata Krishnan.[1,2] Yale teaching and learning center *[1]Yale University School of Medicine, New Haven, CT; [2]Veterans Affairs Medical Center, West haven, CT.*

Background: E-learning is gaining popularity in medical education and offers several advatages. We have developed a comprehensive, hands-on online E-curriculum in hemodialysis based on ACGME competency requirements. The curriculum includes two online modules on Hemodialysis kinetics/adequacy; and Hemodialysis access. In this study we describe the experience among nephrology trainees, of using this E-curriculum, and assess its effectiveness as a teaching tool.

Methods: This pilot study sample included 11 nephrology fellows (8 from Yale and 3 from other US nephrology programs). **Design**: A mixed methods approach using a triangulation model. **Data collection**: A Qualtrics survey was distributed to the participants after curriculum completion. This was followed by a 15 minute zoom interview of each individual participant. This study was approved by our local IRB.

Results: The study sample had an even distribution of participants across all levels of training. 6/11 identified themselves as visual learners. Irrespective of the learner type, animated videos were the most desired feature of the E-modules and helped visualization of abstract concepts. Concepts of flux vs. efficiency; convection vs. diffusion, Kt/V, physical examination of an AV fistula, and access recirculation were topics reviewed repetitively. Based on survey data, there was 100 % agreement among the learners that the websites were easy to navigate; the content represented common clinical scenarios and the interactive knowledge testing helped in concept retention and improving student engagement. Statistical analysis (paired t-tests) showed that there was significant improvement in perceived knowledge by the learner in 6 core competencies after module completion (p<0.01). The advantages of an E-curriculum were reported to be simplified visualization of key concepts; excellent clinical application, time flexibility;repetitive review, standardization of content, learner centric approach; and a flipped classroom model. The disadvantages were the lack of community learning and the inability to ask questions immediately.

Conclusions: In conclusion, the hemodialysis E-curriculum was an effective educational platform for nephrology fellows. Although an E-curriculum allows standardized learning with a learner-centric approach, it can cause social isolation and requires a self-motivated learner. A blended learnng approach, combining E-learning and traditonal methods may be ideal.

PO1372

Implementation and Assessment of Virtual Standardized Patient Sessions to Teach Communication Skills to Nephrology Fellows During COVID-19

Racquel J. Holmes,[1] Jonathan Fischer,[1] Jared Lowe,[1] Jane O. Schell,[2] Samira S. Farouk,[3] Matthew A. Sparks.[1] Duke Nephrology *[1]Duke University, Durham, NC; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Standardized patients (SP) are routinely used in medical education teaching learners how to communicate in traditionally challenging environments like end-of-life discussions or delivery of a difficult diagnosis. Adherence to the need for social distancing during COVID-19 has eliminated in-person SP encounters and necessitated virtual sessions using a video conferencing software. We assessed the impact of virtual, SP-based communication skills workshops on a cohort of nephrology fellows.

Methods: Over two weeks, nephrology fellows were invited to participate in two 90-minute communications workshops with a SP conducted over Zoom. Workshops included a didactic portion and SP interviews simulating difficult conversations. Fellows observed each other and provided feedback during the interviews. A 10-question survey was then distributed to the participants to evaluate the training sessions and compare them to analogous in-person communication workshops.

Results: All invited fellows participated in at least one session and completed the survey (100%, 12/12). Five first-year fellows (42%, 5/12), 5 second-year fellows (42%, 5/12), and 2 third-year fellows (17%, 2/12) participated. 67% (8/12) of participants reported that they found the sessions useful. Of the fellows who had attended a prior in person simulation-based workshop (67%, 8/12) with standardized patients, 88% (7/8) rated the virtual session as good as or better than in-person role-playing. 83% (10/12) of respondents reported that skills learned during the virtual session would be used in their clinical practice. 83% (10/12) felt observing their co-fellows was useful. Write-in comments indicated a barrier to using virtual role playing was a challenge in recognizing emotion and empathy.

Conclusions: Virtual training sessions with SP actors were rated highly by the fellows and provided an opportunity for them to practice communication skills to incorporate into current practice. The virtual workshops were easily implemented, well-received, and should be considered as an alternative training format, especially when in-person workshops cannot be conducted. Future trainings can incorporate communication challenges that arise during telemedicine video or telephone encounters.

PO1373

Dose Adjustment of Rheumatologic and Allergic Medications in CKD: Awareness and Knowledge Among Internal Medicine House Staff

Jessica M. Loiodice,[1,2] Joshua Fogel,[3] Sofia Rubinstein.[2] *[1]New York Institute of Technology College of Osteopathic Medicine, Old Westbury, NY; [2]Nassau University Medical Center, East Meadow, NY; [3]Brooklyn College Department of Business Managment, Brooklyn, NY.*

Background: Patients with chronic kidney disease (CKD) are at increased risk for adverse drug events due to medication dosing errors. We study the awareness and knowledge among Internal Medicine house-staff (IMHS) of proper dose adjustment of commonly used rheumatology and allergy/immunology medications for patients with CKD.

Methods: We surveyed 353 IMHS to evaluate their awareness of medication dose needs adjustment for patients with CKD and knowledge for medication adjustment by level of glomerular filtration rate for common rheumatology and allergy/immunology medications.

Results: There was lack of awareness and knowledge for both rheumatology and allergy/immunology medications. Not correct awareness and knowledge were: allopurinol (21.2%, 73.4%), colchicine (19.0%, 75.9%), diphenhydramine (34.0%, 34.0%), loratadine (82.2%, 93.2%), and montelukast (34.0%, 34.0%). Exploratory logistic regression analyses showed PGY1 residents had higher odds for lack of awareness for allopurinol (OR:24.57, 95% CI:4.69, 99.13, p<0.001), colchicine (OR:3.98, 95% CI:1.50, 10.51, p<0.01), diphenhydramine (OR:2.24, 95% CI:1.10, 4.54, p<0.04), and montelukast (OR:2.45, 95%CI:1.20, 5.00, p<0.05) than PGY3 residents. Nephrology rotation in medical school was associated with lower odds for incorrect knowledge for allopurinol (OR:0.46, 95%CI:0.25, 0.87, p<0.05) and montelukast (OR:0.50, 95%CI:0.27, 0.92, p<0.05).

Conclusions: Overall, awareness and knowledge was poor among IMHS for dose adjustments of rheumatology and allergy/immunology medications in patients with CKD. Proper education and exposure to nephrology during training may improve quality and safety of care for patients with CKD.

PO1374

Emerging Therapies for Managing Patients with Alport Syndrome: Online Medical Education Improves Knowledge and Confidence of Nephrologists

Amy Larkin,[1] Donald Blatherwick,[1] George Boutsalis,[1] Ellie Kelepouris.[2] *[1]Medscape Education, New York, NY; [2]Drexel University College of Medicine, Philadelphia, PA.*

Background: As new therapies for Alport syndrome continue to progress through development, nephrologists need an increased understanding of these drugs. We sought to determine if online education for nephrologists could improve clinical knowledge and confidence in managing patients with Alport syndrome with current and emerging treatment strategies.

Methods: The continuing medical education (CME) activity was an online video panel discussion among 3 faculty on current and emerging strategies for the management of Alport syndrome. Three multiple-choice knowledge questions and 1 self-reported confidence question were presented both before and immediately after the CME activity. A repeated pairs pre-/post-assessment study design was used and a chi-square test (P <.05 is considered significant) assessed educational effect for each activity. Cramer's V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched online on March 1, 2019, and data were collected through April 2, 2019.

Results: Overall, knowledge and confidence improved among nephrologists (n = 71, V=.348, P<.001) from pre- to post-assessment: 24% demonstrated improved understanding of important factors when prescribing renin-angiotensin-aldosterone system (RAAS) inhibitors in patients with Alport syndrome (V=.216 (considerable educational impact), P<.05) 32% demonstrated improved recognition of efficacy data for bardoxolone methyl in Alport syndrome increase in the number of nephrologists (V=.297 (extensive educational impact), P<.001) 63% demonstrated improved identification of adverse effects for emerging treatments for Alport syndrome (V=.581 (extensive educational impact), P<.001) 38% reported increased confidence in understanding of role that chronic renal inflammation plays in AS Continued educational gaps: 41% failed to recognize impact of bardoxolone methyl on Alport syndrome 20% did not recognize important factors when prescribing RAAS inhibitors in patients with Alport syndrome

Conclusions: The online video panel discussion CME activity demonstrated success in improving knowledge and confidence of nephrologists related to current and emerging therapies for the management of Alport syndrome. Continued knowledge gaps were identified for future educational targets.

Funding: Commercial Support - Reata

PO1375

Online CME Effectively Improves Nephrologists' Knowledge, Competence, and Confidence Related to Hyperkalemia Management

Amy Larkin, David R. Anderson, George Boutsalis. *Medscape LLC, New York, NY.*

Background: To improve outcomes for patients, clinicians must be able to implement evolving standards of care and apply relevant data on hyperkalemia management. We sought to determine if a series of online continuing medical education (CME) activities could improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The curriculum consisted of 2 online, 30-minute activities related to new data and case-based application of data in common patient cases. The educational effects were assessed using a repeated pairs preassessment/postassessment study design. For all questions combined, the McNemar's chi-squared test assessed differences pre to post. P values <.05 are statistically significant. Cramer's V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activities launched in March and June 2019, and data were collected for 4 weeks for each activity.

Results: Improved knowledge and competence was demonstrated among nephrologists (N= 371): 17% increase in selecting a treatment strategy when a patient becomes euvolemic but still shows slightly elevated potassium levels (N=188; V=.191; $P < .001$) 24% increase in recognition of long-term data for newer potassium binders (N=183; V=.193; $P < .001$) 26% (N=183) had a measurable increase in confidence in using a potassium binder to treat a patient hyperkalemia 34% (N=188) had a measurable increase in confidence in applying team-based strategies to better manage patients with HF who present with hyperkalemia Persistent knowledge/competence gaps remain: 56% of nephrologists (N=183) incorrectly identified incidence of hyperkalemia in patients with heart failure treated with renin-angiotensin-aldosterone system (RAAS) inhibitors 49% of nephrologists (N=183) could not recognize long-term efficacy data for newer potassium binders 74% of nephrologists (N=188) made an incorrect clinical-decision in a patient who was euvolemic but had elevated potassium levels

Conclusions: This study demonstrates the success of an online curriculum with multiple educational components at improving knowledge, competence, and confidence of nephrologists related to hyperkalemia management. Persistent gaps were identified for future educational targets.

Funding: Commercial Support - independent educational grant from Astrazeneca

PO1376

Case-Based, Interactive Medical Education Significantly Improves Management of Chronic Hyperkalemia in Complex Patients

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape LLC, New York, NY.*

Background: We sought to determine if interactive, case-based online continuing medical education (CME) for nephrologists could improve clinical knowledge, competence, and performance in the area of chronic hyperkalemia management in complex patients.

Methods: The instructional method consisted of an online, case-based, interactive text activity. Clinicians were presented with 2 patient cases that included multiple-choice knowledge or competence questions allowing them to make clinical decisions about treatment. Educational effect was assessed using a 4-question repeated pairs pre-/post-assessment and McNemar's chi-squared test. *P* values are shown as a measure of significance; *P* values <.05 are statistically significant. Cramer's V determined the effect size (<0.05 no effect; 0.06-0.15 small effect; 0.16-0.30 medium effect; >0.30 large effect). The activity launched May 15, 2019; data were collected through June 24, 2019.

Results: Significant overall improvements were seen (n = 59; *P* =.003; V= 0.156) as a result of participation in the CME activity. Specific areas of improvements include: 8% of nephrologists (*P*=.05; V=.179) improved at using a loop diuretic when a low-potassium diet was unsuccessful at lowering potassium levels 25% of nephrologists (*P*=.008; V=.241) demonstrated improvement at prescribing a newer potassium binder in a patient with consistently elevated potassium despite a low potassium diet and loop diuretic 10% of nephrologists (*P*=.4; V=.076) improved at using a newer potassium binder in a patient on dialysis with hyperkalemia 36% of nephrologists reported increased confidence using potassium binders in patients on RAAS inhibitors Continued educational gaps: 29% of nephrologists did not initiate a newer potassium binder in an appropriate patient

Conclusions: This study demonstrates the success of an online, highly interactive, case-based educational intervention on improving knowledge, competence, and performance of nephrologists regarding complex management of chronic hyperkalemia.

Funding: Commercial Support - Relypsa, a Vifor Company

PO1377

Curriculum-Based Online Education Effectively Improves Nephrologists' Ability to Manage Hyperkalemia in Practice

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape LLC, New York, NY.*

Background: The goal of continuing medical education (CME) is professional growth and improved patient care. We sought to determine if a series of online continuing medical education (CME) activities could improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The online CME curriculum consisted of 6 activities. Of these, 5 were video-based and used repeated pairs pre-/post-assessment study design and McNemar's test (P <.05 is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions. The activities launched in 2019 and data were collected for up to 12 weeks.

Results: The education reached over 14,000 physicians, including over 3,200 nephrologists. Overall, knowledge improved by 29%, competence by 14% and performance by 150% (all relative improvements, P<.001) by nephrologists. Specific improvements: 22% relative increase in knowledge related to rationale for optimizing RAAS inhibitors in patients with chronic hyperkalemia (P<.001) 15% relative increase in competence related to effective use of pharmacotherapy for hyperkalemia (P<.001) 441% and 231% relative increases in performance (2 patient simulation cases) related to effective use of pharmacotherapy for hyperkalemia (P<.001) Of the nephrologists who were included, 36% reported increased confidence in managing hyperkalemia, with the largest confidence gains being related to effective use of potassium binders.

Conclusions: This curriculum demonstrates that by increasing knowledge and competence related to hyperkalemia management in a curriculum approach, large improvements in performance can be achieved (over 90% were effectively using pharmacotherapy post-CG). Learners, on average, knew 70% of the information assessed and still require more education in optimizing RAAS inhibitors in patients with chronic hyperkalemia and use of diet to manage hyperkalemia. Among the learners, 36% gained confidence regarding hyperkalemia management in practice, but are still not fully confident. As such, further education is needed in these areas.

PO1378

An Analysis of Scientometrics and Social Media in Nephrology

Nilan G. Vaghjiani,[2] Nishi Shah,[2] Vatsal Lal,[2] Tejas Desai,[3] Anna K. Vinnikova.[1] *[1]Virginia Commonwealth University, Richmond, VA; [2]Virginia Commonwealth University School of Medicine, Richmond, VA; [3]NOD Analytics, Charlotte, NC.*

Background: In the past decade, the use of social media to disseminate scientific literature, particularly in the Nephrology community, has exponentially increased to educate, network, mentor. The hallmark of scientometrics has traditionally been based on Journal Impact Factor (JIF), calculated from the citations of each article. It has been previously demonstrated that twitter mentions of published works, correlate with citations, and therefore JIF, in the fields of Urology, Biomedical Science, and Ecology. However, this relationship has yet to be established in the field of Nephrology.

Methods: The top 5 journals in Nephrology, based on impact factor (Kidney International, Nature Reviews Nephrology, AJKD, JASN and CJASN), published 76 articles in January of 2018 in print. Altmetrics bookmarklet was used to collect twitter demographics on each article (number of tweets, by whom, and number of followers). Citation data was sourced from Web of Science's InCites Journal Citation Reports. Articles were categorized as 'highly cited or tweeted' when they were ≥ 75th percentile of citations or tweets, and 'less cited or tweeted' at ≤ 25th percentile.

Results: Of the article cohort, the most common article types were clinical investigations (42%), followed by basic research (20%), and reviews (10%). The citation mean was 18.29 ± 15.87 citations per article, while the twitter mentions mean was 28.38 ± 68.97 tweets. The Spearman correlation coefficient for Twitter mentions and citations was 0.25 (p = 0.026). The odds ratio of an article being both highly cited and highly tweeted was 3.6 (CI: 0.71 to 18.25). The relative risk showed that highly tweeted articles were 1.87 (CI: 0.83 to 4.19) times more likely to be highly cited than less cited. Finally, the peak tweets (279) occurred in October of 2017 while the peak in citations occurred in 2019.

Conclusions: The preliminary analysis showed a significant but weak correlation of twitter mentions and citations. This suggests that twitter increases an article's reach, its likelihood of becoming cited, and therefore the JIF. Future directions will include exploring a larger sample size and confounding factors such as word count, number of authors, and number of citations.

PO1379

Qualitative Interview Study on Advanced Care Planning for Patients with Advanced CKD and Their Families: The Impact of the MY WAY Advance Care Planning Intervention

Tinsley Grimes Webster,[1] Elise M. Pearson,[2] Natalie C. Ernecoff,[1] Jane O. Schell.[2] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Despite recommendations for shared decision-making approaches to advance care planning (ACP) for people with chronic kidney disease (CKD), doctor-patient conversations about ACP are infrequent. The MY WAY educational and patient-coaching intervention aims to elicit patient values to increase rates of ACP. This qualitative sub-study sought to: (1) gain understanding of participant responses to MY WAY ACP materials, and (2) learn about participant wishes for kidney care within ACP.

Methods: We conducted semi-structured interviews with participants from the intervention arm of the MY WAY study. Fifteen people with CKD were queried about their experiences of the MY WAY print materials and coaching session. Interviews were recorded and transcribed for simultaneous coding by two researchers. Data were analyzed using thematic analysis.

Results: Fifteen intervention participants ages 59-87 were interviewed (10 women, 5 men). Five major themes emerged: participant advice for interventionists; experience with ACP before and after the intervention; participant experience of printed materials; participant response to coaching session; and chronic kidney disease thoughts and communication. Differences between participant experiences of general and CKD-specific ACP emerged, including willingness to discuss care wishes with family members and clinicians.

Conclusions: Participants perceived the coaching session to have high utility in facilitating ACP, but expressed less engagement with CKD-specific care plans. Findings suggest that characteristics of the coach, including empathy and problem-solving, play a key role in participant comfort with ACP conversations, and that engagement with ACP may not correlate with engagement with CKD-specific care wishes. Notably, even participants who engaged actively with general ACP expressed that kidney-specific care would be addressed with their nephrologists if or when the need arose. Future studies should further explore the interrelation of general ACP and CKD-specific care planning.

Funding: Private Foundation Support

PO1380

Enhancing Patient Care by Partnering with Patients in Kidney Health Research

Leah Getchell, Mary Beaucage, David Hillier, Anne Macphee, Arris H. Vorster, Graham J. Pollock. *Can-SOLVE CKD Network, Vancouver, BC, Canada.*

Background: Canada's Strategy for Patient-Oriented Research (SPOR) has raised awareness of the need to generate knowledge that is more relevant to patients and to accelerate the translation of evidence into clinical care. Members of the Canadian nephrology community have come together to develop a national patient-oriented research network, Can-SOLVE CKD, that is partnering with patients to close existing gaps in kidney disease knowledge in order to deliver better health outcomes. The Can-SOLVE CKD Network brings together patients and nephrology researchers to transform treatment and care for Canadians living with or at risk for chronic kidney disease.

Methods: The network's 18 research projects are informed by two national priority-setting exercises conducted with patients, their families and care providers. As the network executes the projects, patients have been integrated into research teams, bringing an enhanced "patient lens" to bear on all aspects of the research life cycle: design, development, recruitment, implementation, and dissemination. Patients are also at the centre of the network's governance model, which incorporates a Patient Governance Circle and an Indigenous Peoples' Engagement and Research Council.

Results: Can-SOLVE CKD researchers have reported the positive impact of partnering with patients. "My research is better" is often cited as an outcome of patient engagement within the network. Patient partner involvement on the network's Research Operations Committee has enriched the annual review of projects, resulting in valuable, real-world feedback to project teams. Respondents to the network's patient engagement survey report feeling better informed about and having greater trust in kidney research as a result of their participation.

Conclusions: We have witnessed a shift in the culture of nephrology research in Canada paralleling the broader movement toward patient-oriented research. The traditional role of patients as research subjects has evolved to include patients as valuable and equal members of Can-SOLVE CKD's research projects.

PO1381

Online Patient/Caregiver Education on Hyperkalemia Can Improve Knowledge and Confidence as Well as Prompt Real-Life Changes

Amy Larkin, Donald Blatherwick. *Medscape LLC, New York, NY.*

Background: Managing hyperkalemia with a strict diet is limiting and difficult for patients. We sought to measure the impact of online education for patients/caregivers on knowledge and confidence as well as prompting change in daily life.

Methods: The patient/caregiver education was designed as 2 online, interactive activities. Both were comprised of text and integrated visuals, the second also included a patient commentary video. Demographic questions were asked prior to starting the education. A knowledge question was asked both before and after the activity to assess learning gains, as well as intent to change and confidence questions at the end. The activities launched in March and May of 2019, and data collected through September 2019.

Results: To date, 72,440 learners have participated in the patient/caregiver activity. Activity 1: Do You Have High Potassium? Here are Some Tips for Managing Potassium in Your Diet Participants: 35, 889 Completers of all questions (included in outcomes analysis): 4,305 Demographics: 65% female; 63% white, non-Hispanic; 67% over the age of 54; 45% have hyperkalemia, 42% were interested in learning more about the condition Knowledge changes: 24% improvement in recognizing foods high in potassium (50% pre to 74% post) Intent-to-act: 81% plan to identify and avoid foods high in potassium Confidence changes: 79% reported increased confidence talking to their doctor about ways to lower their potassium levels Activity 2: Are Medicines That Lower Potassium Right for You? Participants: 36, 551 Completers of all questions (included in outcomes analysis): 2, 917 Demographics: 59% female; 70% white, non-Hispanic; 82% over the age of 54; 58% were interested in learning more about the condition and 29% have this condition Knowledge changes: 23% improvement in recognizing how potassium binders work to treat hyperkalemia (42% pre to 65% post) Intent-to-act: 69% plan to talk to their healthcare provider about medicines that can treat hyperkalemia Confidence changes: 73% reported increased confidence talking to their doctor about medicines that can treat hyperkalemia

Conclusions: The metrics and outcomes gathered in this assessment are a strong indicator that these patient/caregiver-focused online educational activities improved knowledge and confidence, and prompted intent to act by patients/caregivers related to hyperkalemia.

PO1382

Rethinking Renal Caregiving in Anthropological Terms: An Interdisciplinary Methodological Approach

Insa M. Schmidt. *Boston University Medical Center, Boston, MA.*

Background: Rethinking caregiving in nephrology through an anthropological lens may bring a new perspective to a holistic understanding of renal care by encouraging health professionals to reflect critically on the complex webs of care, culture, and ethics in which renal medicine is enmeshed.

Methods: This study draws on anthropological methodology and ethnographic research to develop a framework for reconceptualizing renal care. An extensive review of the anthropological literature on renal care is used to illustrate some of the multifaceted challenges of caregiving in nephrology and to develop a framework for use in the clinical encounter to better understand patients' illness-related beliefs and their relevance for clinical practice.

Results: The key domains in renal care are framed by diverse cultural, societal, and individual beliefs regarding the organ's function and the causes of kidney disease. Ethnographic data from dialysis and renal transplant patients in the United States, Europe, Mexico, and China show that diverse and controversial disease and treatment beliefs pose a different kind of challenge to the communication between health professionals and their patients. Based on these findings, a framework has been developed that can be integrated in medical education programs and provides a guide for health professionals to think through the complex psychological, ideological, and ethical underpinnings of nephrology's central therapeutic modalities such as transplantation and dialysis.

Conclusions: Bringing an anthropological sensibility to the clinical gaze may help to understand the cultural and moral world in which the caregiver-patient relationship needs to be formed. The integration of the medical humanities into the educational programs of renal caregivers can be used to develop a better understanding of patients' diverse disease and treatment beliefs which will ultimately improve the caregiver-patient relationship.

WeChat Platform and Specialty Nursing Outpatient Clinics to Improve the Compliance of a High-Quality Low-Protein Diet in Patients with CKD Stage 3-5

Haixia Xiong,[1] Hui-qun Li,[1] Fangfei Ren,[1] Yin Zhou,[1] Chunlin Hu.[2] *[1]the third affiliated hospital of Sun Yat-sen University, Guang zhou, China; [2]THE First Affiliated hospital of sun-yat sen university, Guang zhou, China.*

Background: Low protein diet (LPD) has become one of the important means to treat chronic kidney disease (CKD) patients. At present, the low protein diet compliance of CKD patients in China is not ideal, the compliance rate is only 48.3% - 54.5%. The dietary compliance of CKD patients is based on the knowledge of diet, and the survey shows that CKD patients and their families have a low level of knowledge of diet of kidney disease. Therefore, in order to improve the low protein diet compliance of ckd3-5 patients and reduce the incidence of malnutrition, we set up a wechat group through the network platform to guide the low protein diet of ckd3-5 patients. The nutrition team regularly issues the low protein diet knowledge, and makes an appointment for the follow-up of patients to the specialized nursing clinic every 1-3 months to provide one-to-one guidance services. To explore the effect of continuous care based on We-Chat platform and Specialist Nursing Outpatient Clinics on the compliance of high-quality low-protein diet in patients with Chronic Kidney Disease (CKD) stage 3-5.

Methods: 46 cases of diagnosed CKD 3-5 patients were randomly divided into a control group (22 cases) and an observation group (24 cases). The control group conducted routine nursing and high-quality low-protein diet nursing guidance, and the observation group implemented a high-quality low-protein diet nursing strategy based on We-Chat platform and Specialist Nursing Outpatient Clinics on a routine basis. Compare the performance and effect of high-quality low-protein diet between the two groups.

Results: In the observation group, there were 10 men and 12 women with an average age of 42.6 ± 2.3 years; in the control group, there were 12 men and 12 women with an average age of 40.2 ± 2.1 years. There was no significant difference between the two groups in height, weight, education level, and basic diseases ($P > 0.05$). The observation group's preparation of CKD high-quality low-protein diet,three-day diet diary,and daily protein intake were better than the control group ($P < 0.05$).

Conclusions: The continuous nursing strategy based on We-Chat platform and Specialist Nursing Outpatient Clinics can effectively improve the compliance of CKD3-5 patients with high-quality low-protein diet.

PO1384

A Kidney Education Program Integrated into Middle School Science Classes Increases Student Kidney Knowledge, Improves Health Behaviors, and Increases Kidney Health Literacy

Julie A. Wright Nunes, Panduranga S. Rao, Ben Ransier, Jean DuRussel-Weston, Brad Newman, Julie Ma, Kenneth A. Resnicow, Kim Eagle. *University of Michigan, Ann Arbor, MI.*

Background: Chronic kidney disease (CKD) is a serious and growing public health problem. Literature shows primary disease prevention is successful when incorporated early in life. There are few reports about CKD prevention efforts in youth.

Methods: A 3-lesson kidney program was designed by health and wellness staff, school teachers and researchers, and aligned with U.S. school science standards. It was integrated into two middle school science classes, located in high-risk areas of renal failure. The 3-lesson program covered kidney physiology, epidemiology and environmental and genetic risk factors. Students were tested before and after the kidney program. We used linear regression to examine bivariate and multivariate associations between demographics and test responses comparing pre- and post-tests.

Results: Two-hundred and nine 6th and 7th grade students received the 3-lesson kidney program. One-hundred and eighteen (57%) were male, 44 (23%) non-Hispanic Caucasian, 26 (12%) non-Hispanic African American, 26 (12%) other races, and 98 (48%) were Hispanic. Post-tests increased significantly for health literacy (from mean SD 3.1 (0.05) to 3.4 (0.05) p=0.02), kidney general knowledge (2.3 (1.1) to 3.9 (1.6) p<0.01), kidney physiology (3.9 (1.1) to 4.6 (1.0) p<0.01) and student ratings of kidney importance (4.0 (0.9) to 4.3 (0.7) p<0.01). Students also reported increases in daily activity and reduced consumption of fruit juices. In analyses adjusted for school, race, gender, ethnicity and age, health literacy, kidney general knowledge, kidney physiology, kidney importance and behaviors remained significantly improved.

Conclusions: A 3-lesson kidney program seamlessly delivered by teachers during science classes at two middle schools in high-risk areas for renal failure improved student health literacy, knowledge and behaviors. Next steps will be to examine impact in larger cohorts and clinical indices over time.

PO1385

Nephrology Exposure and Quality of Education in Residency and Medical School

Georges Nakhoul,[1,2] Ali Mehdi,[1,2] Jonathan J. Taliercio,[1,2] Patricia F. Kao,[3] Grace Mcnutt,[1] Jessica Greenfield,[1] Abby L. Spencer,[1,2] John F. O'Toole,[1,2] Joseph V. Nally,[1,2] John R. Sedor,[1,2] S. beth Bierer.[1,2] *[1]Cleveland Clinic, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Washington University in Saint Louis, Saint Louis, MO.*

Background: Interest in nephrology as a specialty has been declining among residents. Lack of exposure to nephrology has been identified as one of the factors possibly accounting for this loss of interest.

Methods: We used the results of our previously published qualitative analysis on residents' perception of nephrology to inform and design a survey of 60 questions. The survey was delivered using the secure we application "REDCap to 680 residents across eight medicine residency programs in different regions nationally.

Results: 184 residents (27%) responded to the survey. 56% (103) were male and 77% (142) were American graduates. During medical school, 82% of respondents were taught nephrology as a unique discipline, while 33.5% rotated on a nephrology service. During residency, 75% of respondents rotated in nephrology and the rotation took place during PGY1 for 68% of the respondents. On a scale of 1 (poorest) to 100 (best), the quality of nephrology education was rated favorably during residency and during the pre-clinical years of medical school, and less favorably during the clinical year of years of medical school (Fig. 1). Out of 134 residents (73%) who expressed interest in pursuing fellowship training, only 5.8% selected nephrology. Only 6.3% of residents identified a mentor in nephrology vs. 29.7% in general medicine and 26.6% in cardiology (Table 1).

Conclusions: We observed a "dip" in the quantity and quality of nephrology exposure during the clinical years of medical school. More work is needed to characterize the significance of this dip and to understand whether or not this may represent an opportunity to improve the visibility and impact of nephrology on trainees.

Internal Medicine Residents' Perceptions of Nephrology as a Career: A Focus Group Study

Natalie Beck, Seth B. Furgeson, Michel Chonchol, Jessica B. Kendrick. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: The interest in nephrology as a career has declined dramatically over the past several years. Only 62% of nephrology fellowship positions are filled for the upcoming 2020 appointment year. The purpose of this study was to identify perceptions, attitudes, motivators and barriers to a career in nephrology among internal medicine residents.

Methods: Focus groups of internal medicine residents (N=25) from the University of Colorado were performed. Questions were aimed at exploring perceptions, attitudes, and barriers to a career in nephrology and ways to increase interest in nephrology. All focus groups were conducted on the University of Colorado Denver Anschutz Medical Campus. Focus groups were recorded and transcribed. Thematic analysis was used to identify key concepts and themes.

Results: Residents' described many barriers to a career in nephrology including lack of exposure, lack of advances in the field, low monetary compensation, too complex, lack of role models/mentors and low prestige/non-competitive. Most residents had no exposure to outpatient nephrology. Lack of new therapeutics was a significant deterrent to nephrology. Nephrology teaching in medical school was described as not clinically relevant and too complicated. Several residents felt they were not smart enough for nephrology. Only 3 residents had a role model within nephrology. Residents used the word "stigmatized" to describe nephrology and discussed how low prestige decreases their interest in a field. Participants expressed suggestions to increase interest in nephrology through earlier and more outpatient nephrology exposure, enhanced interactions with nephrologists and research and advancements in the field.

Conclusions: Residents' identified several modifiable barriers to a career in nephrology. Changing how nephrology is taught in medical school, enhancing interactions with nephrologists through increased exposure and highlighting research and advancements in nephrology may change the perception of nephrology and increase the number of residents entering the field.

PO1387

Changes in the Demographics and Research Focus of Renal Physician-Scientists in the United States

Delaney C. Abood, Susan M. Wall. *Emory University School of Medicine, Atlanta, GA.*

Background: The enormous strides in biomedical research made over the past 50 years are in large part due to the contributions of physician-scientists. However, while the renal physician-scientist workforce has been thought to be falling, these changes have not been quantified. The purpose of this study was to compare changes in the demographics and the research focus of established physician and non-physician principal investigators

(PIs) with active kidney-focused RO1s in 2005 and in 2020. We also compared changes in the demographics and research focus of more junior physician PIs by examining the K series grants over the same period that have focused on the kidney.

Methods: We mined NIH RePORTER for NIDDK-funded, kidney-focused RO1s and K series grants to determine the PI demographics, the terminal degree(s) of the PIs (physician versus non-physician) and to determine the relative number of clinical and basic science proposals. As an age-surrogate, we compared the year at which the respective RO1 PIs received either their M.D. (physicians) or their Ph.D. (non-physicians) degrees. Taking these values, along with published data as to the median age at which students received their M.D. or Ph.D. in the U.S. in both 2005 and 2020, we estimated the ages of the NIDDK RO1-funded physician and non-physician workforce doing kidney research in the U.S.

Results: Amongst grants focused on kidney, the apparent median age of non-physician, RO1-funded PIs was similar in 2005 and in 2020. However, the apparent median age of physician, RO1-funded PIs is approximately 6 years older in now in 2020 than that in 2005. While the number of basic science grants was similar for physician PIs in 2005 and 2020, the number of clinically-focused RO1s increased. The number of NIDDK K series-funded physicians peaked in 2010 and then declined. However, the percent of physician-scientist RO1s held by women has risen from 15% in 2005 to 25% in 2020, while physician-scientist K series awards held by women has risen from 35% to 48% over that time period.

Conclusions: The representation of women in the physician-scientist workforce doing kidney research has increased. However, this physician-scientist workforce is older and relatively fewer are engaged in basic science research.

PO1388

"I Hear and I Forget. I See and I Remember. I Do and I Understand." Incorporating Emergency Room-Based, High-Fidelity Medical Simulation into the Undergraduate Nephrology Course

Ewa Pawlowicz, Michelle Kulesza, Aleksandra Szymanska, Anna Masajtis-Zagajewska, Maria K. Bartczak, Michal P. Nowicki. *Medical University of Lodz, Uniwersytet Medyczny w Lodzi, Lodz, Poland.*

Background: Medical simulation develops clinical skills by implementing scenario in a true-to-life environment, but without exposing patient to any risk. There has been no information on use of high-fidelity simulation in undergraduate nephrology teaching. Scenarios are provided in Fig. 1. Aim of this study was to analyze students' opinions and reactions to the simulation module in nephrology.

Methods: The survey consisting of the Satisfaction with Simulation Experience scale (SSES) and open-ended question concerning the overall impression of classes was conducted among 103 5-year medical students, who took part in the simulation training in nephrology. SSES consisted of three parts (debriefing, reasoning, education). Statements from the open-ended question were interpreted by means of the *Atlas.ti* software for qualitative data analysis.

Results: The overall score for simulation classes was 4.39±0.69 points. Students rated debriefing, reasoning and education at 4.43±0.78, 4.32±0.7 and 4.39±0.73 points, respectively. 87.4% and 84.5% of participants agreed that simulation developed their clinical reasoning and decision-making skills in nephrology, respectively. Thematic analysis revealed that students evaluated the module as 'interesting', 'useful' and 'informative', but they found number of classes significantly insufficient. Students pointed out that due to the small emphasis placed on practical aspects in the existing curriculum e.g. routes of drug administration and conversion of doses, they could not fully benefit from simulation.

Conclusions: Medical simulation is a valuable constituent of the nephrology course. Putting greater emphasis on practical aspects from the beginning of training may enable students to benefit more from simulation modules.

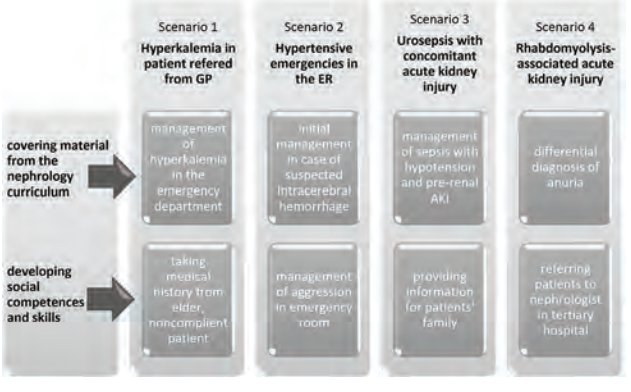

Figure 1. Medical simulation scenarios conducted as a part of undergraduate nephrology course.

PO1389

The Skeleton Key Group: The Impact of Fellow-Led Education

Amy Yau,[1] Joel M. Topf,[2] Sayna Norouzi.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Oakland University William Beaumont School of Medicine, Rochester, MI; [3]Baylor College of Medicine, Houston, TX.*

Background: The Skeleton Key Group (SKG) is an online collective of trainees working to generate free, open-access medical education focusing on the pathophysiology, presentation, and management electrolyte disorders. The final product is a monthly case report published at Renal Fellow Network. Trainee created and edited visual abstracts, tweetorials, and Twitter polls supplement the report. All content is reviewed by senior fellows and an experienced attending nephrologist.

Methods: The SKG formed in September 2019, and group members were continually added. An anonymous survey was sent to the 32 members from May 3-20, 2020. Data here was censored May 2020.

Results: Response rate was 62.5% (n=20). 65% were nephrology fellows with 3 independently practicing nephrologists and 4 residents. The impact of involvement in the SKG on members' medical education was positive (Fig 1). 85% of respondents felt the experience improved their medical knowledge, and 70-80% noted improved manuscript construction (Fig 1). Secondarily, 50-55% noted improved ability to edit, review, and write a peer reviewed publication. Over 75% of respondents stated an improved ability to educate and mentor trainees and increased desire to continue/pursue nephrology training. Surveyees' primary goal was to learn (90%, Fig 2). 60% met all and 30% met some of their goals. Among low-engagement members (n=10), defined as < 25% involvement, a busy work/life schedule was the largest barrier, yet still 50% met some and 30% met all of their goals.

Conclusions: Members felt participation in the SKG added to their medical education regarding knowledge and manuscript construction. Involvement provides the skills needed to continue scholarly activities, and it may help familiarize and motivate trainees to pursue nephrology and subspecialty nephrology training. Even low level involvement in our educational fellow led forum enhanced the education of future nephrologists.

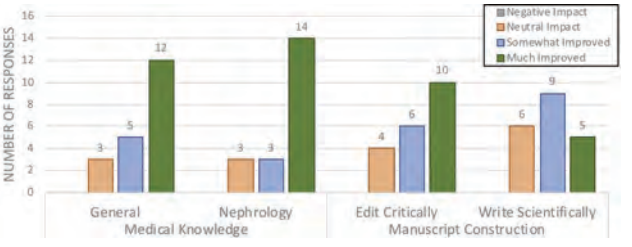

Fig 1. Impact of Involvement in the SKG on Medical Education

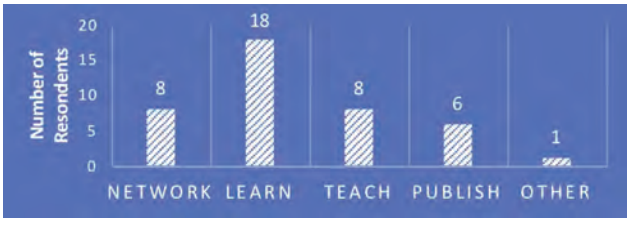

Fig 2. Goals of Members

PO1390

The Skeleton Key Group: Teaching Electrolyte Disorders Using Social Media Tools and Spaced Learning

Sayna Norouzi,[1] Joel M. Topf,[2] Amy Yau.[3] *[1]Baylor College of Medicine, Houston, TX; [2]Oakland University William Beaumont School of Medicine, Rochester, MI; [3]Mount Sinai Hospital, New York, NY.*

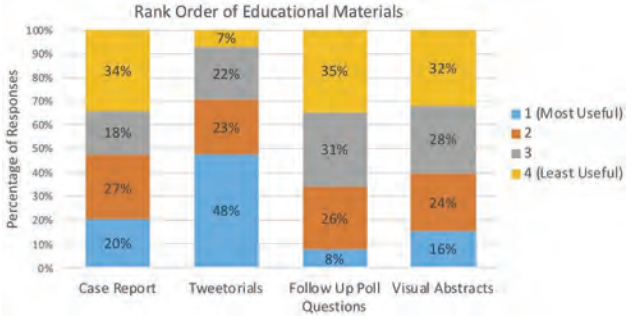
Background: Social media is being adopted by healthcare professionals as a platform for education. It's ability to close geographic gaps and flex to busy schedules is increasing the demand for online educational platforms. The Skeleton Key Group (SKG) is a free open access medical education (FOAMed) platform focusing on electrolyte physiology and management. Group members collaborate to publish a monthly case report with learning objectives on the Renal Fellow Network (RFN) website. Content is supplemented by a visual abstract, tweetorials and follow up quizzes to ensure effective long-term learning and reach multiple learning styles.

Methods: An anonymous survey was conducted and disseminated on Twitter to gather information from users to evaluate if SKG teaching methods added to their education. Questions were designed as multiple-choice answers or qualitative responses on a 0-100 scale.

Results: There were a total of 130 responses from 32 different countries. The majority were nephrology fellows (33%), followed by internal medicine residents/interns (29%), attending physicians (23%), other specialty trainees (10%) and medical students (5%). On a scale of 1-100 (100 is considered highest quality), the mean score was 91±15.5 for the quality of our case reports. Overall, 95% of surveyors found our educational materials useful with tweetorials ranked highest (Fig 1). As training level progresses, a

larger percentage of readers found the tweetorial more useful compared to the case report. Around 80% confirmed their educational experience was affected during the pandemic, and 90.4% found the SKG an effective educational experience during this time period.

Conclusions: Innovative teaching methods provided by the SKG was found to be beneficial in teaching complicated electrolyte concepts. Our data reinforces the ability of FOAMed to cater to different learning styles and to complement traditional medical education specifically during periods of social distancing such as COVID19 pandemic.



PO1391

Glomerular Disease Education Experience Across Nephrology Fellowship Programs

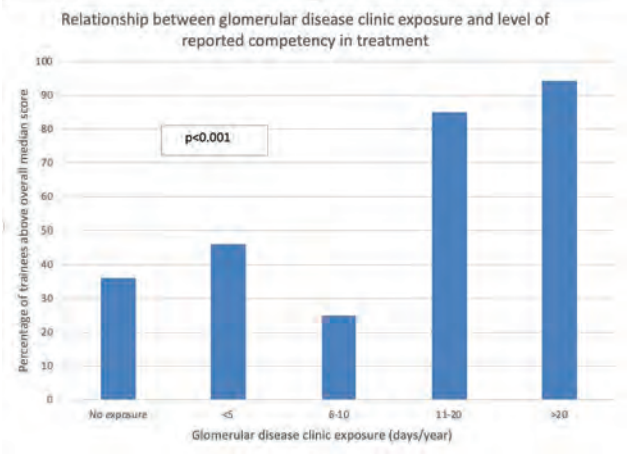
Sayna Norouzi,[1] Harish Shanthanu Seethapathy,[3] Ali Poyan-Mehr.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Kaiser Permanente, San Franciso, CA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Glomerular disease (GN) education is an important, albeit a challenging component of nephrology fellowship training. We hypothesized that trainee experience varies widely across programs, leading to differences in self-reported competency levels in the diagnosis and managing of GN.

Methods: The Glomerular Disease Study & Trial Consortium (GlomCon) conducted an anonymous online survey to evaluate the educational experience of nephrology trainees. We used multiple-choice questions to obtain data about a) curriculum-based education, b) dedicated specialty clinic, and c) exposure to pathology. We leveraged a visual analogue scale of 1-100 (higher number indicating a higher comfort level) to assess self-reported levels of clinical competency. The survey was disseminated via email, the GlomCon website, and Twitter.

Results: There were 107 responses across all years of fellowship training – first-year (25%), second-year (34%), third-year (22%), and fourth-year (19%). A total of 44% reported no GN clinic at their institutions. The presence of an onsite nephropathologist was reported by 63% of responders and 37% reported no onsite nephropathologist or limited exposure. In a visual analogue, the mean competency for GN diagnosis and treatment were 59±26 and 52±25, respectively. Trainees with no onsite nephropathologist and those with limited exposure scored significantly lower in diagnosing GN as compared to those with an onsite nephropathologist (51±25 vs. 64±26, $p<0.05$). Trainees with more exposure to GN specialty clinic had a higher comfort level in treating GN (Fig). Figure demonstrates frequency of trainees in each group with a comfort level above the overall median score (51).

Conclusions: Trainees report a wide variation in GN education across fellowship programs. A lack of exposure to onsite nephropathologist and a dedicated GN curriculum were associated with lower scores in self-reported clinical competency in caring for patients with glomerular disease.



PO1392

Frequency and Severity of Moral Distress in Nephrology Fellows: A National Survey

Fahad Saeed,[1] Paul Duberstein,[2] Ronald M. Epstein,[1] Valerie J. Lang,[1] Scott E. Liebman.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Rutgers School of Public Health, Piscataway, NJ.*

Background: Moral distress is a negative affective response to a situation that conflicts with an individual's values. Health care practitioners who care for chronically ill patients frequently experience moral distress. Little is known about the frequency and severity of moral distress in nephrology fellows.

Methods: We used the modified Moral Distress Scale-Revised to assess the frequency and severity of moral distress in nephrology fellows. Using a 5-point (0-4) scale, fellows rated both the frequency (never to very frequently) and severity (not at all disturbing to very disturbing) of scenarios commonly encountered in training. Responses of ≥ 3 were used to define "frequent" and "moderate-to-severe" moral distress. We identified scenarios most commonly associated with moderate-to-severe moral distress. The survey was sent to 148 program directors with a request to forward to their fellows.

Results: The survey was forwarded by 64 fellowship directors to 386 fellows, 142 of whom (40%) responded. Their mean age was 33 ± 3.6 years; 43% were female; and 55% were international medical graduates. The most common scenarios causing moderate to severe moral distress include: Other providers giving overly optimistic descriptions of the benefits of acute (54% seeing frequently, 64% rating the distress as moderate to severe) or chronic dialysis (43%; 64%), initiating dialysis in patients when they deemed it futile (50%; 77%), continuing dialysis in a hopelessly ill patient (45%; 81%) and carrying a high patient census (43%, 75%). Approximately 27% considered quitting fellowship during training, including 9% at the time of survey completion.

Conclusions: Moral distress is frequently encountered by nephrology trainees and is often moderate to severe in intensity. To address this issue, organizational changes (e.g., reduced workload, ethics guidelines), curricular changes (emphasizing primary palliative care, communication, and ethical decision-making skills) as well as opportunities for reflection and self-care (e.g., Balint groups, Schwartz rounds) may be helpful.

PO1393

The Sustainable Pediatric Nephrology Workforce Project (SUPER-POWER): A Pilot Study of Burnout and Resilience

Susan M. Halbach,[1] Kartik Pillutla,[3] Alan Schwartz,[4] Patricia Seo-Mayer,[5] Darcy K. Weidemann,[6] John D. Mahan.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]Nationwide Children's Hospital, Columbus, OH; [3]Dell Children's Medical Center of Central Texas, Austin, TX; [4]University of Illinois at Chicago, Chicago, IL; [5]Inova Fairfax Hospital, Falls Church, VA; [6]Children's Mercy Hospitals and Clinics, Kansas City, MO.*

Background: Physician well-being is an important contributor to both job satisfaction and patient outcomes. Rates of burnout among physicians vary by specialty, ranging from 35-70%. Among pediatric residents, longitudinal data demonstrates consistent rates of burnout around 50-60%, although little is known about burnout among pediatric subspecialty fellows. The degree of burnout among pediatric nephrologists specifically remains unknown. We sought to evaluate prevalence and predictors of burnout among U.S. pediatric nephrology fellows and faculty, and their interactions.

Methods: A multi-center pilot survey of United States pediatric nephrology training programs from February – April 2020. Burnout was assessed through abbreviated Maslach Burnout Inventory and predictors included demographic, job-related and career satisfaction questions. Other validated assessments included: quality of life, perceived stress, resilience and sleep.

Results: A total of 30/34 available fellows and 86/102 faculty from 11 institutions (of 42 programs nationally) completed the survey. The prevalence of burnout was 13% among fellows and 16% among faculty. Demographic (age, gender, year of training, faculty rank, marital status) and program factors (fellowship size, faculty size, current block/rotation, vacation or weekend off timing) were not significantly associated with burnout. Faculty and fellows with burnout reported significantly lower quality of life (5.3 vs 7.9), higher perceived stress (2.4 vs. 1.4) and lower satisfaction with career choice (66% vs. 22%) and work life balance (28% vs. 0%), compared to those without burnout ($p<0.05$ for all). Other important factors associated with burnout included lower institutional support for wellness programs and lower satisfaction with both colleague and faculty support.

Conclusions: Larger studies are needed to explore if burnout is truly less prevalent among pediatric nephrology fellows and faculty than pediatric residents and graduate physicians. Future studies should explore how to promote well-being through addressing key factors such as overall learning/working environment, stress reduction, and building resilience.

PO1394

Protein Kinase A Catalytic-α and Catalytic-β Proteins Have Non-Redundant Functions

Viswanathan Raghuram, Chin-Rang Yang, Euijung Park, Mark A. Knepper. *National Institutes of Health, Bethesda, MD.*

Background: Vasopressin regulates osmotic water transport in the renal collecting duct by PKA-mediated control of the water channel aquaporin-2 (AQP2). Collecting duct principal cells express two seemingly redundant PKA catalytic subunits, PKA catalytic α

(PKA-Cα, Gene symbol: *Prkaca*) and PKA catalytic β (PKA-Cβ, Gene symbol: *Prkacb*). At an amino-acid level, the two are 91 percent identical and the catalytic domains are virtually identical. However, whether the two PKA catalytic subunits have redundant functions, as is implicitly assumed in many studies involving PKA-mediated regulation, has not been tested.

Methods: To identify the roles of these two protein kinases in in kidney collecting duct cells, either PKA-Cα or PKA-Cβ was deleted using CRISPR-Cas9-based genome editing. Controls were cells carried through the genome editing procedure, but without deletion of either PKA catalytic subunit. Protein mass spectrometry-based quantitative proteomics and phosphoproteomics was carried out in both PKA catalytic-α and PKA catalytic-β single knockouts cells. TMT mass tagging was used for protein mass spectrometric quantification.

Results: Of the 4635 phosphopeptides that were quantified 67 were significantly altered in abundance with PKA-Cα deletion, while 21 were significantly altered in abundance with PKA-Cβ deletion. However, only four sites were changed in both. The target proteins identified in PKA-Cα-null cells were largely associated with cell membranes and membrane vesicles, while target proteins in the PKA-Cβ-null cells were largely associated with the actin cytoskeleton and cell junctions. In contrast, in vitro incubation of mpkCCD proteins with recombinant PKA-Cα and PKA-Cβ resulted in virtually identical phosphorylation changes. In addition, analysis of total protein abundances in the in vivo samples showed that PKA-Cα deletion resulted in a near disappearance of AQP2 protein, while PKA-Cβ deletion did not decrease AQP2 abundance.

Conclusions: We conclude that PKA-Cα and PKA-Cβ serve substantially different functions in renal collecting duct cells and that differences in phosphorylation targets may be due to differences in protein interactions, e.g. mediated by AKAP, C-KAP or PDZ binding.

Single-Cell RNA Sequencing Reveals Transcriptomes of DCT1, DCT2, Macula Densa, and Two Subtypes of Cortical Thick Ascending Limb Cells

Lihe Chen, Chung-Lin Chou, Mark A. Knepper. *National Heart Lung and Blood Institute, Bethesda, MD.*

Background: Several distinct epithelial cell types have been proposed to form the transition region from the cortical thick ascending limb of Henle (CTAL) to the distal convoluted tubule (DCT) to the connecting tubule (CNT). However, a complete understanding of the cellular composition and transcriptional profiles of the cells in this region is lacking.

Methods: We developed a FACS protocol to enrich cells from the mouse CTAL-DCT-CNT region and carried out single-cell RNA-seq analysis (scRNA-seq) of 9099 such cells. We also used small-sample RNA-Seq to determine transcriptomes of microdissected tubules corresponding to 14 distinct mouse renal tubule segments.

Results: Unbiased clustering and UMAP visualization revealed a single cluster of cells showing *Slc12a3* expression without *Pvalb*, which we identified as DCT2 cells. These cells express ENaC subunits but little or no *Hsd11b2* or *Aqp2* mRNA. These DCT2 cells also express *Calb1, Slc8a1, S100g, Ptges,* and *Trpv5*. In contrast, there were 6 tightly arranged clusters of cells expressing both *Slc12a3* and *Pvalb,* which we identify as DCT1 cells. DCT1 heterogeneity appears to be associated with variable expression of *Slc8a1, Calb1,* and *Ckb* among other mRNAs. An additional DCT1 (*Slc12a3*$^{+}$*Pvalb*$^{+}$) cluster showed marked enrichment of cell cycle and cell proliferation associated mRNAs (e.g. *Pcna, Mki67, Cdk1,* and *Top2a*), which fits with the known plasticity of DCT cells. In addition, scRNA-seq identified three distinct CTAL (*Slc12a1*$^{+}$) cell subtypes. One of these expressed *Nos1, Avpr1a,* and *Pappa2,* consistent with macula densa cells. The other two CTAL clusters were distinguished by *Cldn10* and *Ptger3* in one and *Cldn16* and *Foxq1* in the other. These two CTAL types were also distinguished by alternative expression of Iroquois homeobox transcription factors, with *Irx1* and *Irx2* in the *Cldn10*$^{+}$ CTAL cells and *Irx3* in the *Cldn16*$^{+}$ CTAL cells.

Conclusions: This work identifies unexpected diversity among cell types populating the CTAL and DCT. The new data have allowed the creation of a publicly accessible web resource for the support of future studies.

Dietary Potassium Restriction Induces Nephrogenic Diabetes Insipidus

Lama Al-Qusairi, Paul R. Grimm, Paul A. Welling, Ava Zapf. *Johns Hopkins University, Baltimore, MD.*

Background: Dietary potassium deficiency is well-appreciated to induce diabetes insipidus (DI) but the underlying mechanisms have not been established.

Methods: C57BL6J mice were randomized to control or diets with graded reductions in dietary K^+ for 8 days. Kindey function tests were performed in metabolic cages, and tissues were harvested for western blotting and immunocytochemistry at the end of the experiment.

Results: We found that C57BL6J mice rapidly develop DI when potassium is eliminated from the diet, coincidence with the development of hypokalemia. Loss of free-water reabsorption, polyuria and polydipsia was observed within four days, despite increased plasma copeptin, a vasopressin surrogate. In contrast to control mice, desmopressin treatment failed to increase urine osmolality and urine volume after potassium deprivation. Altogether, these observations indicate dietary potassium restriction induces nephrogenic DI (NDI). Characterization of responses to graded reductions in dietary K^+ diet revealed NDI was dependent on the development of hypokalemia. Females were more prone to develop hypokalemia, even in response to modest changes in dietary potassium, and displayed more severe DI than males. Females also exhibited a much greater decrease in AQP2 and phosphorylated s256AQP2 in response to dietary potassium deprivation.

Conclusions: This data together indicate that i) hypokalemia-induced DI is nephrogenic, ii) a tight relationship links hypokalemia to renal concentrating ability, ii) females are more prone to develop hypokalemia and as a consequence, more prone to NDI.

Tfap2a Integrates Cellular Patterning and Barrier Formation in the Renal Collecting Duct

Janna Leiz,[1,2] Christian Hinze,[1,2] Kai M. Schmidt-Ott.[1,2] *[1]Department of Nephrology and Intensive Care, Charite - Universitatsmedizin Berlin, Berlin, Germany; [2]Max-Delbruck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.*

Background: The renal collecting duct plays important roles in fine-tuning urinary composition, electrolyte and water balance, blood pressure, as well as acid-base regulation. The patterning and molecular signatures of principal cells (PCs) and intercalated cells (ICs) of the collecting duct are tightly controlled by transcriptional processes and determine collecting duct physiological function and related clinical abnormalities. The transcription factor Tfap2a has previously been implicated in epithelial differentiation, in pronephros development in zebrafish, and in human congenital kidney defects. Using an integrated bioinformatics approach, we predicted that Tfap2a may critically control collecting duct functions. We tested our hypothesis using experimental model systems.

Methods: A collecting duct-specific knockout of Tfap2a was generated in mice. Additionally, mouse inner medullary collecting duct (IMCD3) cells were engineered to harbor CRISPR/Cas9-induced knockouts (KO) of Tfap2a. Deregulated genes were identified by mRNA sequencing. Patterns of principal and intercalated cells in mouse kidneys were analyzed by microscopy. Additionally, the in vivo model was used in metabolic studies to analyze urinary concentration ability.

Results: Mice lacking Tfap2a in the collecting duct were viable and fertile but showed a defect of urinary concentrating ability. mRNA sequencing of Tfap2a-deficient kidneys and cells and subsequent gene ontology analysis indicated an impact of Tfap2a on molecular processes including Notch signaling, focal adhesion formation and tight junction formation. Further experiments indicated abnormalities of PC/IC patterning in Tfap2a-deficient collecting ducts.

Conclusions: Our data suggest that Tfap2a controls transcriptional processes that integrate patterning and barrier formation in the collecting duct.

PO1398

The Phosphorylated States of Human Aquaporin 2 Revealed by Liquid Chromatography Coupled to Tandem Mass Spectrometry Phosphoproteomic Analysis of Urinary Exosomes

Kenichi Ishibashi,[1] Sei Sasaki,[1,2] Tadashi Yamamoto,[3] Keiko Yamamoto,[3] Yasuko Tanaka.[1] *[1]Meiji Pharmceutical university, Kiyose, Japan; [2]Dept Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [3]Biofluid Biomarker Center, Niigata University, Niigata, Japan.*

Background: Aquaporin-2 (AQP2) is a key water channel to enhance water permeability of collecting ducts. Multiple phosphorylation sites at the C-terminal of AQP2 have been identified including S256 (serine at the 256 residue), S261, S264 and S/T269. Moreover, the phosphorylation profile induced by vasopressin (VP) seems to affect AQP2 trafficking to and from the plasma membrane in rodent AQP2, with limited studies in human AQP2 whose residue at 269 is T instead of S. As AQP2 is abundantly excreted in urinary exosomes, they will be useful to examine the phosphoprotein profile of human AQP2 modulated by VP.

Methods: We examined the phosphorylation profile of urinary exosomal human AQP2 to obtain the insight into the mechanism of AQP2 trafficking by VP. Human urinary exosomes were digested with trypsin or glutamyl endopeptidase (Glu-C) to apply for the liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) phosphoproteomic analysis, in parallel with immunoblots by commercially available phosphoryation-site specific anti-human AQP2 antibodies.

Results: The most dominant phosphorylated AQP2 peptide was phosphorylated at S256 (pS256), followed by pS261, less pS264 and much less pT269. The results were confirmed by the western blot analysis using antibodies specific to each phosphorylated AQP2. To document the time-course of urinary exosomal AQP2 phosphorylation by VP, a VP analogue was administered to a patient with central diabetes insipidus. It induced total exosomal AQP2 urinary excretion plateauing at 60 min with a transient increase (peaking at 30~60 min) of pS261 and a progressive increase of pS256. All four corresponding phosphorylation sites of human AQP2 including T269 were phosphorylated and the phosphorylation sites at S256 and S261 were tightly linked to toal exosomal AQP2 urinary excretion.

Conclusions: We conclude that human AQP2 is predominantly phosphorylated at S256 and moderately at S261 in urinary exosomes. T269-phosphorylation may not be needed for exosomal AQP2 excretion in human urine.

Bayesian Identification of Transcription Factors That Regulate Aqp2 Transcription

Hiroaki Kikuchi,[1] Hyun Jun Jung,[2] Euijung Park,[1] Lihe Chen,[1] Viswanathan Raghuram,[1] Mark A. Knepper.[1] *[1]National Institutes of Health, Bethesda, MD; [2]Johns Hopkins University, Baltimore, MD.*

Background: Renal collecting duct and connecting tubule cells selectively express the water channel aquaporin-2 (AQP2) and *Aqp2* gene transcription is strongly regulated by vasopressin. However, the transcription factors (TFs) responsible for regulation of expression of AQP2 remain largely unknown. Here, we used Bayesian data integration techniques to identify these TFs.

Methods: The general strategy is to use Bayes' Rule to integrate several -omic datasets to stratify a curated list of 1344 TFs present in the mouse genome with regard to probability of regulating *Aqp2* gene transcription. First, existing proteomic and transcriptomic data were used to select the TFs most strongly expressed in mpkCCD cells. Then, we used our existing ATAC-Seq, histone H3K27-acetylation ChIP-Seq, and RNA-polymerase II ChIP-Seq data to identify enhancer regions in the CTCF loop surrounding the *Aqp2* gene. The sequences within these enhancers were analyzed to identify recognized TF binding motifs within them; and these motifs were matched to TFs on the Bayesian list to identify the TFs most likely to bind *Aqp2* regulatory regions.

Results: The analysis showed that the TFs most likely involved in regulation of *Aqp2* gene expression are associated with six enhancer regions in the CTCF loop surrounding the *Aqp2* gene. Of the six enhancers, of particular interest is a 517 bp region identified 5.0 kb upstream from the *Aqp2* transcription start site (TSS) that is predicted to bind Tcf7l2 (Wnt signaling), Tead2 (Hippo signaling) and Gli3 (Hedgehog signaling). Also within this enhancer region are high probability binding sites for TFs previously identified to regulate *Aqp2* gene transcription, viz. Nfat5/NfatC3, Nfkb1/Rela, and Grhl2. Another enhancer is 5.8 kb downstream from the *Aqp2* TSS and contains binding sites for three TFs already implicated in *Aqp2* transcriptional regulation, namely Cebpb, AP-1 (Jun/Fosl2) and Elf1/Elf3, as well as sites for several TFs that are so far unstudied with respect to *Aqp2* regulation.

Conclusions: The Bayesian analysis has defined the enhancer regions within the CTCF loop surrounding the *Aqp2* gene and identified the TFs most likely to bind to these regions, providing a roadmap for future studies to understand regulation of *Aqp2* gene expression.

Kidney Osmoregulation Is Regulated by RNA Polymerase Pausing

Jason A. Watts,[1,3] Winny Soerianto,[3] Joshua T. Burdick,[2,3] Vivian G. Cheung.[2,3] *[1]Department of Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, Chevy Chase, MD; [3]Life Sciences Institute, University of Michigan, Ann Arbor, MI.*

Background: Osmoregulation is a complex but critical component of renal physiology that relies on the regulation of gene expression. While many genes and some transcription factors that are involved in osmoregulation have been identified, the initiating regulatory step that triggers the gene expression response to changes in osmolarity remains unknown. To address this knowledge gap, we identified the pausing of RNA polymerase II as a key regulatory step.

Methods: We used the Precision nuclear Run-On and Sequencing assay (PRO-seq), to identify locations of nascent RNA bound to actively transcribing RNA polymerases in inner medulla collecting duct cells (IMCD).

Results: We began by studying *Akr1b3*, the gene that encodes aldose reductase which is the enzyme that reduces glucose to sorbitol and is essential for osmoregulation in the kidney. We exposed IMCD cells to increasing concentrations of sodium chloride and confirmed that the transcript expression of *Akr1b3* increased in a dose-dependent manner. Then we asked how *Akr1b3* is regulated transcriptionally. The PRO-seq assay was used to trace the first steps in the synthesis of RNA transcripts for aldose reductase. In IMCD cells at baseline, there is an accumulation of RNA Pol II in the promoter of *Akr1b3* consistent with RNA polymerase pausing. Under hypertonic conditions, the paused polymerase is released resulting in the synthesis of aldose reductase transcripts, and subsequent increase in *Akr1b3* gene expression level. We confirmed this result by treating IMCD cells with flavopiridol, a drug that increases the stability of proteins in the pausing complex, and *Akr1b3* was no longer induced in hypertonic conditions. Next by RNA-sequencing, we found that in addition to *Akr1b3*, there are over 500 osmotically-induced genes that are regulated by RNA polymerase pausing. These include membrane transporter proteins such as the sodium/myo-inositol cotransporter (*Slc5a3*) as well as protein chaperones like heat shock protein H1 (*Hsph1*).

Conclusions: These results indicate RNA Pol II pausing plays a key role in the regulation of gene expression during osmoregulation. In this presentation, I will present data from this study and discuss the tight coupling of gene regulation with renal physiology.

Flow Regulation of WNK1 in the Cortical Collecting Duct (CCD)

Rolando Carrisoza-Gaytan,[1] Daniel Flores,[1] Arohan R. Subramanya,[2] Evan C. Ray,[2] Thomas R. Kleyman,[2] Lisa M. Satlin.[1] *[1]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Department of Medicine, University of Pittsburgh, Pittsburgh, PA.*

Background: A high K diet (HKD) x 10 d increases (i) luminal flow rate in the distal nephron and (ii) expression of apical immunodetectable L-WNK1 in CCD intercalated cells (IC), which we propose enhances apical BK channel activity measured as flow-induced K+ secretion (FIKS) (Webb et al, 2015). We previously demonstrated that fluid shear stress (FSS) x 30 min induces expression of ERK and p-38, both BK channel modulators, in a CCD principal cell (PC) model (Carrisoza-Gaytan et al, 2014). The objective of this study was to test the hypothesis that an increase in tubular fluid flow rate rapidly induces apical localization of L-WNK1 in the CCD.

Methods: CCDs isolated from NZW rabbits fed a HKD x 10 d were microperfused at slow (n=4) or fast (n=4) luminal flow rates x 1 hr, fixed on the rig, immunoperfused with antibodies (Abs) directed against L-WNK1 (+ A488-fluorescent 2o Abs) and rhodamine-conjugated peanut lectin (PNA) or Dolichus biflorus lectin (DBA), which bind to apical surfaces of IC and PC, respectively, and examined by confocal microscopy. MDCK cells were subject to no (static), low or high FSS x 1 hr (n=3 each condition) and fixed for immunodetection of L-WNK1 and BKα in situ or harvested for semi quantitative immunoblotting of isolated plasma membranes.

Results: Expression of IC apical L-WNK1 relative to that in the total cell was 40.0±1.1 % greater in CCDs perfused at fast flow compared to those perfused at slow flow rates ($p<0.001$). In plasma membrane preparations of MDCK cells subject to low and high FSS, L-WNK1 abundance was 5.4±0.3 and 10.6±1.7 fold greater, respectively, to that measured in the absence of flow ($p<0.001$). In static MDCK cells, BKα did not colocalize with L-WNK1 at the apical membrane; however, colocalization of the two proteins was detected in cells subject to low or high FSS.

Conclusions: In conclusion, (i) apical expression of L-WNK1 in ICs in microperfused CCDs is rapidly stimulated by increases in luminal flow rate, and (ii) FSS favors apical colocalization of L-WNK1 with BKα, responses that may facilitate BK channel-mediated FIKS in the CCD.

Inhibition of Actin-Related Protein 2/3 Complex Blocks Vasopressin-Induced AQP2 Membrane Accumulation

Chen-Chung Liu, Pui Susan W. Cheung, Richard Bouley, Dennis Brown. MGH Program in Membrane Biology *Massachusetts General Hospital, Boston, MA.*

Background: Aquaporin 2 (AQP2) is a water channel protein located primarily on principal cells of the kidney collecting ducts and is crucial for regulating body water homeostasis. Regulation of AQP2 trafficking is subject to hormonal control, mainly via the canonical vasopressin (VP) signaling pathway which stimulates AQP2 membrane accumulation. Active actin cytoskeleton remodeling has been known to also play an important role in AQP2 trafficking, however, the mechanism is incompletely understood.

Methods: We applied CK-666, a pharmacological inhibitor of actin nucleator actin-related protein (Arp) 2/3 complex on our AQP2-transfected cells and animal (rat) models. Results were observed by using immunohistochemistry and confocal microscopy. VP signaling pathway and phosphorylation of AQP2 on various serine residues were studied with Western blotting.

Results: Using CK-666, an Arp2/3 complex inhibitor, we found that VP induced AQP2 membrane accumulation was inhibited both in rat kidneys and LLC-AQP2 cells in vitro. Instead of distributing throughout the cytoplasm, AQP2 in cells treated with CK-666 was concentrated in vesicles forming a perinuclear patch, which was also positive for Rab-11 (a recycling endosome marker) and clathrin (a trans-Golgi Network (TGN) marker). Similar perinuclear AQP2 patches appear in cells incubated at 20°C (cold block), which allows endocytosis to continue, but prevents protein exit from the TGN. By rewarming the cells to 37°C, these perinuclear patches dissipate, and AQP2 quickly redistributes throughout the cytoplasm (cold block release). However, we found that in cells exposed to a 20°C cold block and treated with CK-666, AQP2 patches failed to dissipate upon rewarming, suggesting that CK-666 blocked the release of AQP2 from the TGN in the exocytotic pathway. This effect of CK-666 was independent of VP signaling and did not alter the VP-induced phosphorylation state of AQP2 at residues serine-256, S269, and S261.

Conclusions: Inhibition of the Arp2/3 complex blocks VP-induced AQP2 plasma membrane accumulation by blocking AQP2 exocytosis at the level of the TGN and the recycling endosome but did not affect VP signaling pathway. This result suggests that actin filament nucleation and growth via Arp2/3 activity is essential for AQP2 recycling and trafficking.

PO1403

STCH Regulates NKCC2 Biogenesis by Both the Endoplasmic Reticulum-Associated Degradation and the Endoplasmic Reticulum-to-Lysosome-Associated Degradation Pathways

Dalal Bakhos Al Douaihy,[1,2] Elie Seaayfan,[3] Sylvie Demaretz,[1,2] Mehdi Hamdani,[1,2] Martin Kömhoff,[3] Kamel Laghmani.[1,2] Team 3 *[1]Sorbonne Universite, Paris, France; [2]Centre de Recherche des Cordeliers, Paris, France; [3]Philipps Univ Marburgersity, Marburg, Germany.*

Background: Mutations in the apically located Na-K-2Cl co-transporter NKCC2 lead to type I Bartter syndrome, a life-threatening kidney disease. We previously showed that export from the ER constitutes the limiting step in the maturation and cell surface expression of NKCC2. Yet very little is known about the molecular components of NKCC2 ER quality control. Using the yeast two hybrid system and co-immunoprecipitation assays, we identified chaperone stress 70 protein (STCH), as a binding partner of the immature form of NKCC2. STCH is supposed to function as an ER chaperone but the precise molecular role of STCH remains obscure.

Methods: Protein expression was monitored in transiently transfected HEK cells, using immunoblot and confocal imaging. Protein maturation and stability were assessed by Endo-H digestion and cycloheximide chase (CHX) assay.

Results: Co-immunolocalization experiments revealed that NKCC2 interacts with STCH mainly at the ER. However, CHX assay together with Endo-H digestion revealed that STCH is initially synthesized in the ER as a core-glycosylated protein before being gradually converted to a hybrid N-glycosylated form. These data are in an agreement with a previous study showing that STCH contains a mannose-6-phosphorylation site, suggesting therefore that STCH expression is not restricted to the ER. STCH knock-down increased NKCC2 protein abundance in a dose-depend manner, whereas STCH over-expression had the opposite effect. CHX assay showed that in cells over-expressing STCH, NKCC2 stability and maturation are heavily impaired. STCH induced reduction in NKCC2 expression were offset partially by the proteasome inhibitor MG132. Interestingly, leupeptin and chloroquine, two potent inhibitors of the lysosome, mimicked MG132 effect on NKCC2 regulation. Accordingly, the simultaneous presence of proteasome and lysosome inhibitors, completely abolished STCH-induced down-regulation of NKCC2.

Conclusions: Our data demonstrate the presence of an STCH mediated ER quality control of NKCC2 in renal cells. They suggest a model whereby, in addition to the proteasome-dependent ERAD, the ER quality control of NKCC2 mediated by STCH, involves also the ER-to-lysosome-associated degradation pathway, revealing therefore a new regulatory mechanism governing the co-transporter biogenesis.

$P2Y_2$ Receptor Directly Mediates Collecting Duct Remodeling Induced by Acid Loading in Mice

Marshall R. Roedel,[1,2] Kalani L. Raphael,[1,2] Audrey Izuhara,[3] Bellamkonda K. Kishore,[1,2] Janos Peti-Peterdi.[3] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]University of Southern California, Los Angeles, CA.*

Background: Previously we reported that genetic deletion of $P2Y_2$-R suppresses lithium(Li)-induced collecting duct (CD) remodeling. Since genetic deletion of $P2Y_2$-R has a generalized ameliorating effect on Li-induced diabetes insipidus, here we evaluated the direct effect of $P2Y_2$-R in CD remodeling using a model of acid loading.

Methods: Groups of WT or $P2Y_2$-R knockout (KO) mice (B6D2; N = 3 or 4/group) were fed standard rodent chow and given tap water with/without addition of 0.28 M NH_4Cl for 9 days and humanely euthanized. AQP2 and $[H^+]$-ATPase double immunolabeling was used to identity the principal (PC) and intercalated (IC) cells of the medullary CD, respectively.

Results: As reported previously, KO mice developed more severe metabolic acidosis than WT after NH_4Cl loading (not shown here). Furthermore, as shown in the pie charts, statistical analysis of the numbers of cells found a marked increase in the number of medullary ICs in NH_4Cl-treated vs. untreated control (CT) mice in WT (28 ± 2 vs. 6 ± 1), but only a blunted response in $P2Y_2$ KO mice (10 ± 1 vs. 4 ± 1, $P < 0.001$ *WT vs. KO*). These increases in ICs were associated with significant decreases in the proportion of PC cells in NH_4Cl-treated vs. untreated CT mice in WT (72 ± 2 vs. 94 ± 1), and again a blunted response in $P2Y_2$ KO mice (90 ± 1 vs. 96 ± 1, $P < 0.001$ *WT vs. KO*).

Conclusions: The data clearly show that $P2Y_2$ receptor has a "direct effect" on CD remodeling in the kidney following acid-loading.

Funding: NIDDK Support, Veterans Affairs Support

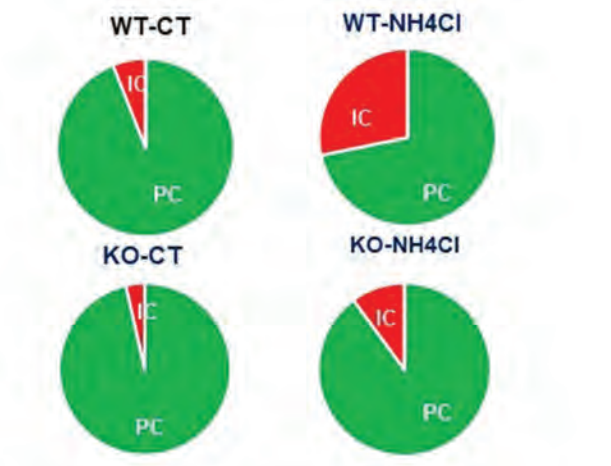

Figure 1. Pie charts of data from immunofluorescence analysis of NH_4Cl-induced changes in medullary CD cell composition in wild type WT or KO mice. AQP2 (green) and $[H^+]$ATPase (red) double-immunolabeling was used to identify the principal (PC) and intercalated (IC) cells of the collecting duct, respectively. CT – control group.

PO1405

Resolving the Kidney's Reaction to Acute Dehydration on the Single-Cell Level

Christian Hinze,[1,2] Felix Boivin,[2] Janna Leiz,[2,1] Nikos Karaiskos,[3] Anastasiya Boltengagen,[3] Christine Kocks,[2] Nikolaus Rajewsky,[3] Kai M. Schmidt-Ott.[1] *[1]Charité-Universtitätsmedizin, Berlin, Germany; [2]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [3]Berlin Institue for Medical Systems Biology MDC, Berlin, Germany.*

Background: Dehydration is a common clinical finding and frequent among the elderly or patients with chronic diarrhea. Acute kidney injury frequently develops as a result of a fluid deficit. There is growing evidence that recurrent dehydration can cause chronic kidney disease. The kidney's response to fluid deprivation is incompletely understood. Having a gene expression atlas of the kidney's reaction to fluid deprivation at single cell resolution might help to understand biological mechanisms but also to identify biomarkers and therapeutic targets.

Methods: We performed single-cell RNA sequencing of dissociated mouse kidneys after 24 hours of water restriction (n=2) and control kidney (n=2). We assigned cell type information based on known marker genes, and systematically analyzed gene expression differences between baseline and water-restricted animals within different cell types. We furthermore applied a computational approach to spatially sort cells based on gene expression similarities to investigate corticomedullary gene expression profiles.

Results: Our data show cell type-specific differential gene expression in all kidney tubule cells with the most prominent response in collecting duct principal cells (CD-PC). Pathways dysregulated in CD-PC included sodium and water reabsorption, immune system modulation and endoplasmatic reticulum (ER) stress. Pathway activation displayed regional cortico-medullary differences.

Conclusions: Fluid deprivation induces regional and cell type-specific responses in kidney cells. Genes and pathways identified by single cell transcriptomics comprise biomarkers and therapeutic targets for dehydration-associated pathologies.

PO1406

Angiotensin II Receptor Blockade Alleviates Calcineurin Inhibitor Nephrotoxicity by Restoring p38 MAPK/NF-kB/COX-2 Signaling in Kidney Cortex

Junda Hu,[1] Yan Xu,[1] Sebastian Bachmann,[1] Kerim Mutig.[1,2] *[1]Charité-Universitätsmedizin Berlin, Berlin, Germany; [2]Sechenov First Moscow State Medical University, Moscow, Russian Federation.*

Background: Immunosuppression based on calcineurin inhibitors (CNI) such as cyclosporine A (CsA) is the current standard for patients undergoing organ transplantation. Nephrotoxic side effects of CNI include reduction of renal cortical cyclooxygenase 2 (COX-2) expression along with pathophysiological alterations of glomerular filtration rate and sodium balance. The underlying molecular mechanisms are poorly understood. Since CNI stimulate the renin-angiotensin system (RAS), we hypothesized that the suppression of COX-2 is related to enhanced RAS activity.

Methods: To test this hypothesis, short- (3 days) and long-term effects (3 weeks) of CsA (25mg/kg*d), candesartan (5mg/kg*d), celecoxib (50 mg/kg*d) or their combinations

were evaluated in Wistar rats to monitor COX-2 and RAS, as well as kidney physiology, morphology and biochemistry. Cultured macula densa (MD) cells were treated with CsA, angiotensin II (Ang II), p38 MAPK inhibitor or NF-kB inhibitor in various combinations to reveal molecular pathways mediating effects of RAS on COX-2.

Results: Inhibition of calcineurin in cultured MD cells using CsA or siRNA increased COX-2 activity via stimulation of p38 MAPK and NF-kB. Concomitant application of Ang II abolished these effects suggesting a dominant role for RAS. In rats, 3 days and 3 weeks CsA treatments led to increased renin biosynthesis, decreased cortical COX-2 expression, reduced creatinine clearance, and sodium retention due to activation of major distal salt transporters, NKCC2 and NCC. These deteriorations were partially or completely normalized by simultaneous administration of a RAS inhibitor candesartan for 3 days or 3 weeks, respectively. In contrast, administration of a selective COX-2 inhibitor, celecoxib, largely recapitulated effects of CsA and significantly reduced the beneficial effects of candesartan by concomitant drug application. Therefore, COX-2 suppression is a major factor contributing to CNI nephrotoxicity.

Conclusions: In summary, the present study established calcineurin as an endogenous COX-2 inhibitor, acting via suppression of p38 MAPK and NF-kB activity in MD cells. CNI-induced RAS activation critically reduces cortical COX-2 activity, thus overriding local stimulatory effects of calcineurin inhibition. Our data support the use of RAS inhibitors for alleviation of CNI nephrotoxicity.

A Novel Mouse Model for Familial Hypomagnesemia with Hypercalciuria and Nephrocalcinosis (FHHNC) Bearing the Most Frequent Human CLDN16 Mutation

Caroline Prot-Bertoye,[1,2] Camille Griveau,[1] Lydie Cheval,[1] Honoré A. Langlais,[1] Gaëlle Brideau,[1] Pascal Houillier.[1,2] *[1]Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Université de Paris, CNRS, ERL8228, Paris, France; [2]Service de Physiologie, Hôpital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, France.*

Background: Mutations of claudin (CLDN) 16 and CLDN19 cause FHHNC, characterized by a urinary loss of calcium (Ca) and magnesium (Mg), hypomagnesemia, nephrocalcinosis and renal failure. Cldn16 and Cldn 19 are co-expressed at the tight junction (TJ) of the thick ascending limb (TAL) of Henle's loop and play a key role in paracellular reabsorption of Ca and Mg. Here, 25% of filtered Ca and 70% of filtered Mg are reabsorbed. Cldn16 knock-out mouse model failed to faithfully recapitulate the human disease, as it was complicated by neither nephrocalcinosis nor renal failure. Cldn 16 knock-down mice have a renal loss of NaCl and hyperaldosteronism. We hypothesized that a knock-in model bearing the most frequent human CLDN 16 mutation (p.L151F) would be helpful to delineate the abnormalities caused by mutated Cldn16.

Methods: Cldn $16^{L151F/\ L151F}$ mice were generated by CRISPR Cas9-based mutagenesis. Cldn $16^{+/+}$ and Cldn $16^{L151F/\ L151F}$ female mice were housed in metabolic cages at 3 months of age. Daily food and water intake, body weight were recorded. Blood and urine composition were analyzed. Nephrocalcinosis and Cldn expression in TAL were studied on kidney sections by alizarin red coloration and immunofluorescence.

Results: At 3 months, weight, food and water intake, blood parameters (Na, Cl, Ca, Mg, Pi, creatinine) did not differ between Cldn $16^{+/+}$ and Cldn $16^{L151F/\ L151F}$ mice. Cldn $16^{L151F/\ L151F}$ mice had significantly higher urinary excretions of Ca, Mg and Pi and a lower urinary pH; urine volume, osmolality, Na, K and aldosterone were unaltered. At 6 months calcitriol was significantly increased in Cldn $16^{L151F/\ L151F}$ mice. No nephrocalcinosis was seen at 12 months. Cldn 16 was almost never seen at TJ and Cldn 19 seems to be less expressed at TJ in Cldn $16^{L151F/\ L151F}$ mice suggesting that Cldn 16^{L151F} has a negative effect on Cldn19 expression.

Conclusions: Cldn $16^{L151F/\ L151F}$ mice have a urinary loss of Ca and Mg, as typically observed in patients with FHHNC. No evidence of NaCl wasting was found. Further studies are ongoing on male mice, renal function and PTH, bone and dental phenotypes. This model will help to better understand the link between an altered CLDN 16 and defective Ca and Mg handling.

Sex Differences in Expression of Renal Urate Transporters

Victoria L. Halperin Kuhns, Owen M. Woodward. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Elevated urate (UA) levels in the serum (hyperuricemia, HUA) can contribute to the development of diseases, including kidney stones, chronic kidney disease, cardiovascular disease, metabolic syndrome, and gout. Men are 5x more likely to have HUA than women, yet this risk increases in women 4x after menopause. This suggests premenopausal women are protected against developing HUA, but the mechanisms have yet to be elucidated. These differences are echoed in our HUA mouse model, where insertion of an orthologous human pathological UA transporter ABCG2 variant Q141K (Q140K in mice) causes significant HUA in the male but not female mice. Paradoxically, we found female mice had lower fractional UA excretion than males, suggesting complex differences in the renal UA handling between the sexes. We hypothesized that these differences were likely due to either UA transporter expression or regulation.

Methods: RNA-Seq was performed on male and female wild type (WT) and Q140K mice, followed by DESeq2 analysis to determine differentially expressed genes between both sexes of each genotype.

Results: Targets of interest included 12 transporter and 3 transcription factor (TF) genes that associated with serum UA levels in humans in recent genome wide association studies. We found small (0.49–2.1-fold) but statistically significant changes in many of these transporter genes. Specifically, female mice had lower expression of UA transporters *SLC22A12, SLC22A6, SLC17A1,SLC17A3,* and *ABCA1*. These genes have variants that associated with lower UA levels in human populations, consistent with female mice potentially more efficiently excreting surplus UA. Females also had significantly lower levels of the 3 key UA associated TFs, *HNF1A, HNF4A,* and *HNF4G,* providing a possible mechanism of differentiation. The Q140K mice DESeq2 analysis reveals 273 alterations in male Q140K kidney gene expression as compared to WT, including 5 potentially compensatory SLC transporters. None of these changes were observed in female Q140K mice, indicating that changes are the result of the elevation in SUA and not due to mutant ABCG2 protein.

Conclusions: Female sex may confer protection from developing HUA and related conditions. Further understanding this mechanism should lead to improved understanding of UA homeostasis and new insights into HUA treatment.

SPAK Signaling Stimulates the Activity and Protein Expression of Large Conductance Ca^{2+} Activated Potassium (BK) Channels

Ye Bi,[1] Chunmei Li,[1,3] Xiaonan H. Wang,[1] Eric J. Delpire,[4] Robert S. Hoover,[1,2] Douglas C. Eaton,[1] Hui Cai.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Atlanta VA Medical Center, Decatur, GA; [3]Qingdao University Affiliated Hospital, Qingdao, China; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Ste20-like proline alanine rich kinase (SPAK) plays important roles in regulating the function of numerous ion channels and transporters. With-no-lysine (WNK) kinase phosphorylates SPAK kinase to active the SPAK signaling pathway. Our previous studies indicated that WNK kinases regulate the activity of the large-conductance Ca^{2+}-activated K^+ (BK) channel and its protein expression via the ERK1/2 signaling pathway. It remains largely unknown whether SPAK kinase directly modulates the BK activity and protein expression in kidney.

Methods: Electrophysiology, cell culture, western blot, siRNA knockdown, and SPAK knockout (KO) mice were used in the study.

Results: We first determined the effects of SPAK gene depletion using SPAK KO mice on BK channel activity in the isolated, split-opened renal collecting ducts (CD) from WT and SPAK KO mice. We found that there is no BK channel activity in principal cells (PCs) of cortical CD (CCD) in SPAK KO mice, whereas there is BK channel activity in PCs from WT mice. We further investigated the effects of overexpression and siRNA knockdown of SPAK expression on BK in HEK293 cells. Overexpression of SPAK significantly increased BK protein expression with decreasing ERK 1/2 phosphorylation, whereas knockdown of SPAK expression using siRNA significantly reduced BK protein expression associated with increased ERK1/2 phosphorylation, both in a dose-dependent manner. Knockdown of ERK1/2 prevented SPAK siRNA-mediated inhibition of BK protein expression. Similarly, pretreatment of HEK293 cells with either the lysosomal inhibitor bafilomycin A1 or proteasomal inhibitor MG132, reversed the inhibitory effects of SPAK knockdown on BK protein expressions. In addition, we found that BK protein abundance in the renal cortex of SPAK KO mice was significantly decreased and ERK1/2 phosphorylation was significantly enhanced. A high potassium diet significantly increased BK protein abundance and SPAK phosphorylation levels in WT mice, while reducing ERK1/2 phosphorylation levels.

Conclusions: These findings suggest that SPAK stimulates BK channel activity and protein expression by reducing ERK1/2 signaling-mediated lysosomal and proteasomal degradations of the BK channel.

High Dietary K^+ Attenuates Salt-Induced NCC and mTORC1 Activity in Dahl Salt-Sensitive Rats

Mohammed Z. Ferdaus, Jesse D. Moreira, Kiyoung Kim, Franco J. Puleo, Richard D. Wainford. *Pharmacology & Experimental Therapeutics, Boston University School of Medicine, Boston, MA.*

Background: Na^+ reabsorption by renal Na^+-Cl^- cotransporter (NCC) plays a key role in blood pressure (BP) regulation. Dahl Salt-Sensitive (DSS) rats exhibit aberrant NCC activity and salt-sensitive hypertension (HTN) when fed a high-salt diet. The renal mammalian target of rapamycin complex 1 (mTORC1) is also implicated in the pathogenesis of DSS HTN. Studies in normotensive mice suggested an inverse relationship between blood [K^+] and NCC activity; however, the effect of dietary K^+ on NCC activity in DSS rats is still controversial. Moreover, the impact of dietary K^+ on mTORC1 activity is unknown. **Hypothesis:** Dietary K^+ supplement downregulates salt-induced NCC and mTORC1 activity in DSS rats.

Methods: 3 month old male DSS rats were randomly placed on high salt (4% NaCl, HS, n=3) or HS + high K^+ (5% K^+, HS+HK, n=4) diet for 28 days. Another group of DSS rats, maintained on HS diet for 14 days, were placed on HS+HK for another 14 days (HS→HS+HK, n=4). NCC activity was assessed by Hydrochlorothiazide (HCTZ, NCC antagonist) injection (20 mg/kg, intraperitoneal) induced natriuretic response. Protein abundance was determined by western blotting. The ratio of phosphorylated ribosomal protein - $S6^{Ser235/236}$ to total S6, was used as mTORC1 activity marker.

Results: In response to HCTZ, urinary Na^+ excretion was trending lower in HS+HK and HS→HS+HK than HS group, while the baseline excretion was unaltered. Total NCC (tNCC) and phosphorylated NCC (pNCC) abundance, a surrogate for NCC activity,

were trending lower in HS→HS+HK compared with HS group. Interestingly, mTORC1 activity was significantly reduced in HS→HS+HK.

Conclusions: Trending lower response in HS+HK and HS→HS+HK to HCTZ suggests that dietary K^+ may counteract and reduce salt-induced NCC activation. Downregulation of mTORC1 reveals that dietary K^+ can reverse salt-induced mTORC1 activation. Critically, our data suggest that compared with the initial phase, K^+ is more effective in reducing salt-induced NCC and mTORC1 activity when added later to the diet, which may attenuate established HTN in DSS rats.

Four Weeks of Dietary Potassium Restriction Causes Distal Convoluted Tubule Remodeling

Xiao-Tong Su,[1] Turgay Saritas,[2] Chao-Ling Yang,[1] Paul A. Welling,[3] David H. Ellison.[1] *[1]Oregon Health & Science University, Portland, OR; [2]University Hospital RWTH Aachen, Aachen, Germany; [3]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Previous studies have described a 'renal potassium switch' within the distal nephron that turns on the thiazide-sensitive Na-Cl cotransporter (NCC) in the distal convoluted tubule (DCT) in response to low potassium intake and off in response to high potassium intake. Studies using genetically modified mice indicate that decreased NCC activity is associated with decreased DCT length and mass; increased NCC activity is associated with increased, DCT length and mass. The aim of our study was to test whether dietary potassium intake causes the DCT remodeling physiologically.

Methods: Male C57Bl/6 mice were provided either control potassium diet or low potassium diet for four weeks and blood and kidneys were harvested. To determine the length of the DCT in three dimensions, we used Ethyl-cinnamate-based optical clearing, combined with whole-mount immunolabeling, confocal microscopy and three-dimensional morphometric analysis.

Results: Mice on low potassium diet for four weeks were severely hypokalemic (plasma potassium <2 mM) compared with mice on control diet (4.2 mM). Western-blot analysis of the whole kidney confirmed that total and phosphorylated NCC were higher in mice on low potassium diet, compared to mice on control diet. By immunolabeling with pThr53-NCC antibody, we visualized the DCTs in optically cleared kidney slices. Three-dimensional morphometric analysis suggested that four-weeks of low potassium diet (465±14 µm, n=6) increased DCT length by 13% compared to NK diet (412±9 µm, n=5).

Conclusions: Our results indicate that the DCT remodels physiologically to maintain potassium homeostasis. Additional animals are currently being studied.

Pendrin Null Mice Develop Hypokalemia During Dietary Na^+ Restriction Through an Epithelial Sodium Channel-Dependent Mechanism

Truyen D Pham,[1] Jill W. Verlander,[3] Chao Chen,[3] Spencer A. King,[1] Anthony J. Elengickal,[1] Paul A. Welling,[2] Susan M. Wall.[1] *[1]Emory University, Atlanta, GA; [2]Johns Hopkins University, Baltimore, MD; [3]University of Florida, Gainesville, FL.*

Background: Pendrin is an electroneutral Cl^-/HCO_3^- exchanger expressed in the apical regions of intercalated cells. It is thought to modulate NaCl absorption, while mitigating urinary K^+ loss. However, the effect of pendrin gene ablation on K^+ homeostasis has not been examined directly. The purpose of this study was to determine if pendrin gene ablation reduces serum K^+ concentration, the conditions under which this occurs and the mechanism(s) responsible.

Methods: Pendrin null and wild type mice were given a diet deficient in Na^+, K^+ and Cl^- or diet supplemented with Na^+, K^+, Cl^- and/or water. We measured urine and serum electrolytes as well as K^+ channel and Cl^- transporter abundance by immunoblot and immunohistochemistry.

Results: Serum K^+ was ~1 mEq lower in pendrin null than in wild type mice after 7 days of the Na^+, K^+, Cl^--deficient diet. This difference was attenuated, but not eliminated, with moderate dietary K^+ supplementation. Differences were eliminated with either dietary Na^+ supplementation or with ENaC blockade, while differences were enhanced when ENaC was constitutively upregulated. Further studies determined whether the lower serum K^+ observed in the pendrin null mice occurs from greater urinary K^+ excretion. Over the first 3 days of the Na^+, K^+, Cl^--deficient diet, pendrin null mice develop a lower serum K^+ and a higher arterial pH and HCO_3^- concentration, likely from greater intravascular volume contraction from their enhanced urinary Na^+ excretion, although urinary K^+ excretion was similar in both groups over this time period. However, starting at day 4 of the diet, the pendrin null mice excrete more K^+ than the wild type mice. At day 8 of the ion-deficient diet, pendrin null mice have marked hypokalemia, likely due to both the metabolic alkalosis as well as greater urinary K^+ excretion, in part, from inappropriately high Maxi-K^+ channel abundance.

Conclusions: Pendrin null mice develop marked hypokalemia during dietary Na^+ restriction in part due to a contraction alkalosis as well as increased urinary K^+ excretion that occurs in part from relatively high Maxi K channel abundance.

Architecture of the Distal Nephron Mineralocorticoid Receptor-Dependent Transcriptome Defined

Hyun Jun Jung,[1] Xiao-Tong Su,[2] Lama Al-Qusairi,[1] David H. Ellison,[2] Paul A. Welling.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Oregon Health and Science University, Portland, OR.*

Background: The mineralocorticoid receptor (MR, *Nr3c2*) is responsible for aldosterone-regulation of Na^+ and K^+ balance and blood pressure. Although a handful of aldosterone/MR-dependent genes have been identified, their regulation cannot fully explain how aldosterone activates electrogenic Na^+- K^+ exchange in the aldosterone sensitive distal nephron (ASDN). Here, we apply RNA-Seq and bioinformatic approaches in isolated tubule segments of MR KO vs. Control mice to define a more complete inventory of MR-dependent genes.

Methods: $MR^{fl/fl}$/Pax8-rtTA/LC1 mice were used as a doxycycline (DOX)-inducible *Nr3c2* gene KO model. After DOX treatment, four groups were prepared to distinguish between K^+ and MR effects: 1) control mice on normal K^+ diet (CT-NK) or 2) high K^+ diet (CT-HK) and 3) MR knockout mice on normal K^+ diet (KO-NK) or 4) low K^+ diet (KO-LK). RNA-Seq analysis was carried out in the micro-dissected connecting tubule and cortical collecting duct tubule segments (5-6 mice per group and ~10 fresh ASDN tubules per mouse). Differential expression (DE) genes were identified (FDR < 0.05) and used for further bioinformatic analyses.

Results: 927 and 2010 DE genes were identified from comparisons of MR KO-NK vs. CT-NK and MR KO-LK vs. CT-HK, respectively. Diet effects were not detected. Absence of transcripts on the third exon of *Nr3c2* gene confirmed complete disruption of *Nr3c2* gene in the MR KO. All known aldosterone-response genes, including *Sgk1*, *Scnn1a*, *Ndrg2*, *Per3*, *Tsc22d3*, *Zbtb16*, *Mlph* and *Atp1a1* were significantly decreased in MR KO-LK compared to CT-HK. In addition, 5 DE genes (*Sgk1*, *Scnn1a*, *Nedd4l*, *Fxyd4* and *Atp1a1*) were mapped on small known "Aldosterone-regulated sodium reabsorption" profile. However, genome-wide identification of GR and MR binding sites revealed that 526 of the significantly down-regulated genes in MR KO mice are potential MR-regulated genes. Pathway enrichment analysis of 2010 DE genes showed that DE genes were highly enriched in mitochondria-associated metabolic processes.

Conclusions: The inventory of MR-regulated genes in the ASDN is much larger than previously imagined. In addition to pathways that directly up-regulate epithelial sodium channel (ENaC) and the Na^+-K^+ ATPase, the data suggest that aldosterone-MR may directly influence metabolism to make energy-consuming transport highly efficient.

Effect of Patiromer and Sodium Zirconium Cyclosilicate on Blood Pressure in a Rat CKD Model Induced by 5/6th Nephrectomy

Lingyun Li,[1] Ansgar Conrad,[1] Alain Romero,[1] David A. Bushinsky.[2] *[1]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [2]University of Rochester School of Medicine, Rochester, NY.*

Background: Patiromer (PAT) is a sodium-free, non-absorbed polymer drug approved for treatment of hyperkalemia (HK) in adults. In clinical studies of patients with CKD and HK, decreases in BP were observed during PAT treatment. The objective of this study was to evaluate effect of PAT and another K^+ binder, sodium zirconium cyclosilicate (SZC), on BP in a CKD rat model.

Methods: 36 Sprague Dawley (SD) rats underwent 5/6 nephrectomy (Nx) and each had a telemetry device implanted. Animals were randomized into 3 groups of 12. PAT (4 g/kg), SZC (4 g/kg), or vehicle was administered daily via oral gavage for 8 wks. Telemetry data was collected for at least 24 hrs once weekly from baseline (BL). Blood and urine samples were collected weekly. All values are mean ± SD.

Results: Systolic BP from BL to Wk 8 increased in vehicle-treated rats (136 ± 4.0 mmHg to 154 ± 4.8 mmHg), PAT-treated rats (132 ± 3.7 mmHg to 140 ± 3.6 mmHg), and SZC-treated rats (135 ± 4.1 mmHg to 158 ± 5.3 mmHg). PAT-treated rats had significantly lower systolic BP at Wk 8 compared to rats in vehicle and SZC-treated groups (P<0.001) (**Figure**). Mean BP change from BL in PAT-treated rats (8 ± 3.2 mmHg) was significantly lower vs vehicle group (18 ± 2.9 mmHg, P<0.001) and vs SZC-treated group (23 ± 4.2 mmHg, P<0.001), while mean BP change from BL in SZC-treated rats was significantly higher vs vehicle group (P<0.005). Serum K^+ levels were in range of normokalemia (4.0-6.2 mEq/L in normal SD rats) from BL to Wk 8 in all groups (5.6 ± 0.26 mEq/L to 5.5 ± 0.22 mEq/L in vehicle-treated rats, 5.6 ± 0.43 mEq/L to 5.5 ± 0.25 mEq/L in PAT-treated rats, and 5.3 ± 0.36 mEq/L to 4.9 ± 0.35 mEq/L [P=0.02] in SZC-treated rats). There was no difference in serum creatinine levels among the 3 groups during the study.

Conclusions: With 8 wks of PAT treatment, SD rats with 5/6 Nx exhibited significantly lower BP compared to vehicle-treated and SZC-treated rats. Additional analyses are warranted to determine mechanism of PAT's effect on BP in this model of CKD.

Funding: Commercial Support - Relypsa, Inc., a Vifor Pharma Group Company

Figure. Mean BP in Vehicle-, Patiromer-, and SZC-treated Groups (n=12/group)

PF-06869206 Is a Selective Inhibitor of Phosphate Transport: Evidence from In Vitro and In Vivo Studies

Linto Thomas, Jianxiang Xue, Jessica Dominguez Rieg, Timo Rieg. *USF Health Morsani College of Medicine, Tampa, FL.*

Background: The kidneys are key players in maintaining the body's phosphate (P_i) homeostasis, and patients with chronic kidney disease (CKD) develop hyperphosphatemia. Two renal transporters mediate the majority of P_i reabsorption, the Na^+-phosphate cotransporters Npt2a and Npt2c, with Npt2a accounting for ~80% of P_i reabsorption. The aim of the current study was to determine the *in vitro* effects of a Npt2a-I (PF-06869206) in opossum kidney (OK) cells as well as its *in vivo* effects in Npt2a knockout ($Npt2a^{-/-}$) mice.

Methods: To study the *in vitro* effects of Npt2a-I (0.1-100 μmol/L) on P_i uptake, ^{32}P radiotracer was used in OK cells. *In vivo*, Npt2a-I dose-response (3-300 mg/kg, 1% bw by oral gavage) effects on urinary P_i excretion were assessed in metabolic cages for 3 hours in wild-type (WT) and $Npt2a^{-/-}$ mice. Effects on plasma P_i were studied before (baseline) and 2 hours after application of Npt2a-I (30 mg/kg, 1% bw by oral gavage).

Results: *In vitro* Npt2a inhibition caused a dose-dependent decrease in P_i uptake, showing a half-maximal inhibitory concentration of ~1.4 μmol/L. Kinetics of Npt2a uptake inhibition showed an increased Michaelis-Menten constant in response to Npt2a-I compared to vehicle (~2.4 fold); in contrast, V_{max} was unaffected, indicating competitive inhibition. No differences were observed in live or dead cell populations after 24-hours treatment between vehicle or Npt2a-I. Parathyroid hormone (PTH) caused a dose-dependent decrease in P_i uptake, with 10 nmol/L being equivalent to the maximal inhibitory effect of Npt2a-I. No additional inhibitory effect was observed by co-incubation of PTH and Npt2a-I. *In vivo*, Npt2a inhibition caused a dose-dependent increase in urinary P_i excretion in WT mice with an EC_{50} of ~23 $mg*kg^{-1}$. No effect on urinary P_i excretion was observed in $Npt2a^{-/-}$ mice. In WT mice, Npt2a-I caused a ~31% ($P<0.05$) decrease in plasma P_i levels; in contrast, plasma P_i levels were unchanged in $Npt2a^{-/-}$ mice.

Conclusions: Our studies show that PF-06869206 is a competitive inhibitor of P_i transport in OK cells and the effect on urinary P_i excretion and plasma P_i levels are mediated by Npt2a. Human studies are needed to identify if Npt2a inhibition is a useful treatment for hyperphosphatemia.

PO1416

Critical Role of Threonine Residue in PDZ-1 Binding Motif of Type 2a Sodium-Phosphate Cotransporter (Npt2a)

Kenneth Gagnon,[1] Michelle T. Barati,[1] Kathleen Kitterman,[1] Adrienne M. Bushau-Sprinkle,[1] Barbara Clark,[1] Eleanor D. Lederer.[2] *[1]University of Louisville Health Sciences Center, Louisville, KY; [2]University of Texas Southwestern Department of Internal Medicine, Dallas, TX.*

Background: Npt2a brush border membrane (BBM) expression is the major determinant of proximal tubule phosphate reabsorption. Binding of the Npt2a carboxy terminus Class I PDZ binding motif (S/T-x-Φ-COOH) to NHERF1 (sodium-hydrogen exchange regulatory factor 1), a PDZ protein, is critical for Npt2a BBM expression. We have shown that NHERF1 deficiency results in increased binding of Npt2a to 14-3-3 epsilon, a chaperone protein with a Class III PDZ-binding domain. Phosphorylation of the Class I PDZ binding motif Thr residue converts it into a Class III binding motif (pT-x-x-COOH). We hypothesize that phosphorylation of the Thr residue prevents NHERF1 interaction, promotes 14-3-3 epsilon interaction, and inhibits BBM expression of Npt2a.

Methods: We generated cDNA constructs modifying the Thr residue at position -2 (T635) in the Npt2a PDZ binding motif to phosphomimic (T635E) or phosphonull (T635A) status. We sub-cloned WT and mutant Npt2a cDNAs alone, with NHERF1, or with 14-3-3 epsilon in an IRES-containing bicistronic mammalian expression vector. We transiently transfected these cDNA constructs in NHERF1-deficient opossum kidney cells, assessed membrane expression by confocal microscopy, and Npt2a function by (^{32}P) phosphate uptake.

Results: Npt2a (T635), Npt2a (E635), or Npt2a (A635) alone showed dense cytosolic expression and negligible ^{32}P uptake. Npt2a (T635) with NHERF1 colocalized at the plasma membrane and increased ^{32}P uptake seven-fold. Npt2a (E635) and Npt2a (A635) appeared at the plasma membrane, but neither co-localized with NHERF1 nor showed ^{32}P uptake. Each Npt2a plus14-3-3 cDNA construct exhibited apparent membrane localization, but none co-localized with 14-3-3 epsilon or exhibited significant ^{32}P uptake.

Conclusions: We conclude that the -2 Thr of the Class I PDZ binding motif of Npt2a is essential for interaction with NHERF1 and functional activity of the cotransporter. 14-3-3 promotes Npt2a membrane localization but not function in NHERF1 deficient states and may not be dependent on the phosphorylation status of the -2 Thr.

Metabolic Acidosis Exacerbates Pyelonephritis in Mice Prone to Vesicoureteral Reflux

Jeffrey M. Purkerson, Janine L. Corley, George J. Schwartz. *University of Rochester Medical Center, Rochester, NY.*

Background: Acute pyelonephritis is a serious bacterial infection in children. The prevalence of acute pyelonephritis is due at least in part to vesicoureteral reflux (VUR). Although an association between pyelonephritis and abnormalities in acid-base balance is common in young children, the impact of metabolic acidosis (MA) on progression of acute pyelonephritis is not fully understood. In the current study the effect of metabolic acidosis on pyelonephritis was studied in C3H mouse strains prone to VUR.

Methods: MA was induced in female C3H mice via NH_4Cl (2% w/w) supplementation of food. Acid-base state was assessed by blood /gas analysis using an iSTAT® G3+ and urine pH. UPEC-UTI: Urinary Tract Infection of mice (6-8 wks) with Uropathogenic E. Coli (UPEC strain CFT073) 0.5-$1X10^7$ cfu/50 μl was performed via the transurethral inoculation. Bacteria burden (cfu/g) in bladder and kidney was determined by culture of tissue homogenates. Collecting duct (CD) fragments and neutrophils were enriched from collagenase-digested kidney by magnetic-sorting utilizing DBA-lectin and monoclonal anti-Ly6G (1A8). Cytokine (IL-1β, TNFα, IL-6) and chemokine (CXCL1, CXCL2, CXCL5) RNA in CD cells was quantitated by qRT-PCR. Ly6G$^+$ cells were enumerated by imaging utilizing a Cellometer K2 Image Cytometer. Statistics: T-test or two-tailed Mann-Whitney U-Test $p<0.05$ or $P \leq 0.02$ for Bonferroni correction.

Results: NH_4Cl fed-mice were acidotic (s[HCO_3^-]: 17±0.6*, Ur pH: 5.8±0.02*) compared to normal (s[HCO3-]: 22.2±0.68; Ur pH: 6.8±0.01, N≥4; *p<0.05). MA concurrent with UPEC-UTI markedly increased kidney UPEC burden in innate immune competent HeN mice (HeN = 4E2±2E2 versus MA HeN= 1E6±1E6; $p<0.02$ MW U-TEST), but not Tlr4-deficient HeJ mice (HeJ = 2E6 ±1E6 versus MA HeJ = 5E5±1E5). MA markedly increased CD inflammation in infected HeN mice characterized by an 18-124 fold increase in chemokine/cytokine mRNA abundance and a 4.5±0.6 fold increase in Ly6G+ neutrophil infiltrates over normal-infected mice, N=3; $p<0.01$ versus normal, TTEST.

Conclusions: Concurrent metabolic acidosis exacerbates pyelonephritis in innate immune competent mice that is characterized by an elevated cytokine and chemokine expression and kidney neutrophil infiltrates.

PO1418

Oxidized Alkyl Phospholipids Stimulate Proximal Tubule Sodium Transport via PPARγ/ERK Pathway

Tomohito Mizuno,[1] Motonobu Nakamura,[1] Nobuhiko Satoh,[1] Hiroyuki Tsukada,[1] Yusuke Sato,[2] Shoko Horita,[1] Haruki Kume,[2] Masashi Suzuki,[3] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, The University of Tokyo, Tokyo, Japan; [2]Department of Urology, The University of Tokyo, Tokyo, Japan; [3]Tokyo Yamate Medical Center, Tokyo, Japan.*

Background: We previously reported thiazolidinediones stimulated proximal tubule (PT) sodium transport via non-genomic PPARγ/ERK pathway. However, the contribution of endogenous PPARγ ligands to PT transport has been unknown. In this study, we investigated effects of 1-O-hexadecyl-2-azelaoyl-*sn*-glycero-3-phosphocholine (azPC), an endogenous lipid oxidation product (LOP) acting as a potent PPARγ agonist, on PT sodium transport.

Methods: We measured basolateral Na^+/HCO_3^- cotransporter 1 (NBCe1) activity in lumen-collapsed PTs and luminal Na^+/H^+ exchanger (NHE) activity in freshly-isolated rat and human PTs obtained during surgery for renal cell carcinoma by using a pH-sensitive dye BCECF. NBCe1 activity in lumen-collapsed PTs was measured by the rate of pH_i decrease in response to HCO_3^- reduction. Luminal NHE activity in lumen-opened PTs was measured by the rate of pH_i decrease caused by Na^+ removal in the presence of VATPase inhibitor, Bafilomycin A_1. To examine the signaling pathway of azPC, we used a PPARγ antagonist (GW9662) and a MEK inhibitor (PD98059) and siRNA against PPARγ. The expression of PPARγ mRNA was determined by quantitative PCR. ERK phosphorylation was analyzed by western blotting.

Results: In freshly-isolated human and rat PTs, 0.3 μM azPC stimulated NBCe1 and NHE activity. The stimulatory effects were completely suppressed by GW9662 or PD98059 without affecting the basal activities. siRNA against PPARγ completely suppressed the stimulation of both NBCe1 and NHE activities by azPC in rat PTs. We

found that azPC enhanced ERK phosphorylation in human and rat renal cortex tissue. This phosphorylation was also completely suppressed by GW9662 or PD98059.

Conclusions: These results indicated azPC stimulated both NBCe1 and NHE activities through PPARγ/ERK pathway in PTs. The stimulatory effect of azPC, one of the LOPs on PT sodium reabsorption, could be a novel mechanism of volume expansion and hypertension induced by atherosclerosis.

PO1419

A Novel Distal Convoluted Tubule-Specific Tamoxifen-Inducible Cre-Recombinase Driven by the NaCl Cotransporter Gene

Ryan J. Cornelius,[1] Avika Sharma,[1] Xiao-Tong Su,[1] David H. Ellison,[1,2] Andrew P. McMahon,[3] James A. McCormick.[1] *[1]Oregon Health & Science University, Portland, OR; [2]VA Portland Health Care System, Portland, OR; [3]Keck School of Medicine of the University of Southern California, Los Angeles, CA.*

Background: The use of knockout and transgenic mouse models coupled with Cre-lox technologies has revolutionized research in kidney transport physiology by allowing site-specific genetic recombination in individual nephron segments. Although several groups have tried to generate a distal convoluted tubule (DCT)-specific mouse Cre-recombinase driven by the thiazide-sensitive NaCl cotransporter (NCC) promoter, this goal has remained elusive. The only previously recognized mouse model available allowing targeted gene modification in the DCT is the DCT1-specific mouse with Cre-recombinase under control of the *Pvalb* gene encoding parvalbumin. The model, however, has limitations including activity in neurons that prevent comprehensive characterization of transport pathways in the DCT.

Methods: CRISPR/Cas9 was used to introduce Cre-ERT2 into the 3′ UTR near the stop codon of the *Slc12a3* gene encoding NCC (*Slc12a3*-Cre-ERT2 mice). Here, we crossed *Slc12a3*-Cre-ERT2 mice with YFP floxed mice to test whether the Cre expression would mimic that of NCC, and to determine whether the construct is 'leaky'.

Results: Without tamoxifen, approximately 6% of NCC positive cells expressed YFP, indicating minimal leakiness. After five days of tamoxifen injection, mice showed YFP expression in almost all NCC positive cells and there was complete overlap of YFP expression in NCC positive cells. Crossing to TdTomato mice revealed higher leakiness (64.5%), suggesting differential sensitivity of the floxed site. Western blotting revealed no differences in abundances of total or the active-phosphorylated form of NCC in *Slc12a3*-Cre-ERT2 mice of either sex compared to controls. Furthermore, functional analysis of NCC showed no effects on NCC activity in *Slc12a3*-Cre-ERT2 mice. Plasma K^+ and Mg^{2+} concentrations, and thiazide-sensitive Na^+ and K^+ excretion did not differ in *Slc12a3*-Cre-ERT2 mice compared to controls.

Conclusions: Thus, the *Slc12a3*-Cre-ERT2 mice have high recombination efficiency and complete fidelity in cell-specificity. Our data show that Cre expression is entirely localized to the DCT and the genetic modification has no effect on NCC expression and renal function. The *Slc12a3*-Cre-ERT2 mice are the first mice generated with Cre recombinase activity along the entire DCT, and will be a powerful tool to study DCT function.

PO1428

A Case of Central Diabetes Insipidus due to Pituitary Adenoma Complicated by Amphotericin-Induced Nephrogenic Diabetes Insipidus

Meenakshi Sambharia, Lama A. Noureddine. *University of Iowa, Iowa City, IA.*

Introduction: Amphotericin B (Amph B) is an anti-fungal agent that exhibits its action by binding to ergosterol, the main component of the fungal cell wall and shares a similar structure to the human cell membrane. Its main site of action is the principal cell where it causes an increase in membrane permeability by insertion of pores into the membrane, causing leaking of potassium into tubular lumen leading to hypokalemia. It also causes nephrogenic diabetes insipidus (NDI) by preventing insertion of vasopressin-induced aquaporin 2 (AQP-2). Reports in the literature have suggested that liposomal formulations might be less nephrotoxic than conventional ones.

Case Description: A 37-year-old male with history of pituitary adenoma s/p trans-sphenoidal resection of pituitary tumor with subsequent central diabetes insipidus (CDI) on maintenance desmopressin DDAVP 1mcg BID presented to hospital for suspected meningitis. He was started on liposomal Amph B 5mg/kg (550mg) for empiric fungal coverage. Lumbar drain cultures returned positive for Candida albicans on Hospital Day (HD) 1 and Amph B was continued. Renal was consulted for evaluation of worsening polyuria. Increased dose of DDAVP was recommended. He continued to be polyuric despite this dose adjustment. Amph B induced NDI was suspected secondary to refractory polyuria and hypokalemia. Amph B was discontinued on HD 7, after which his polyuria improved gradually. He was switched to fluconazole to complete the remainder of the treatment duration.

Discussion: Our patient with h/o CDI developed worsening polyuria on Amph B treatment, unresponsive to escalating DDAVP. Improvement with cessation of Amph B supports causality of concurrent drug-induced NDI. Amph B renal toxicity frequently presents with AKI with potassium wasting. NDI induced by Amph B is rare. A high index of suspicion is required for diagnosis of NDI occuring on top of CDI. Early discontinuation of Amph B usually leads to resolution of symptoms.

Water Load Test in the Diagnosis of Syndrome of Inappropriate Antidiuresis (SIAD): Results from the Waterline Study

Raphael R. Cohen,[1] Elise Bouderlique,[4] Côme Bureau,[1] Riyad N. Seervai,[5] Anne Blanchard,[1] Pascal Houillier,[1] Laurence Vrigneaud,[3] Jean-philippe Bertocchio.[1,2] Waterline study investigators *[1]Hopital Europeen Georges-Pompidou Pole Cardio-vasculaire Renal Metabolique, Paris, France; [2]University of Texas MD Anderson Cancer Center, Houston, TX; [3]Hopital Prive La Louviere, Lille, France; [4]U1155 Inserm, Tenon Hospital, Paris, France; [5]Center for Precision Environmental Health, Baylor College of Medicine, Houston, TX.*

Background: SIAD is caused by an inadequate kidney reabsorption of water, mainly under the action of antidiuretic hormone. The latest international recommendations stated the diagnosis of SIAD relies on hypotonic hyponatremia with inadequate urine osmolality. Blood volume has to be normal, with adrenal, thyroid, and renal insufficiency excluded. These guidelines ruled out the usefulness of abnormal response to water load test (WLT) due to the lack of published evidence.

Methods: In the Waterline study (NCT04256499), we retrospectively analyzed data from patients who underwent a WLT (oral administration of 20 mL/kg of water) in our department.

Results: From 02/2001 to 10/2019, 173 adults were included. Out of them, 80(46%) had a SIAD and 21(12%) were considered 'normal', 72(42%) had hyponatremia of other origin. Among the SIAD patients, 33(41%) had a fasting plasma sodium (PNa) ≥135mM ('normonatremic SIAD'), 47(59%) had 'hyponatremic SIAD': We found no differences in demographic data or medical history between these two groups. During WLT, 'normonatremic SIAD' patients behaved specifically by exerting hyponatremia (while normal individuals did not), resembling 'hyponatremic SIAD' patients (**Figure 1**). While their fasting urine osmolality (U-Osm) was initially higher, 'normonatremic SIAD' and 'hyponatremic SIAD' patients reached the same minimum U-Osm (389±257 *vs.* 350±202mOsm/kgH_2O, p=0.76). Additionally, they reached a higher minimum value of PNa than 'hyponatremic SIAD' patients (132±2 *vs.* 127±3mM, p<0.0001). These results were confirmed in an independent cohort of 38 WLT where 24 (63%) were 'normonatremic SIAD'.

Conclusions: We conclude that, without WLT, a diagnosis of SIAD could be missed in 40 to 63% of SIAD patients.

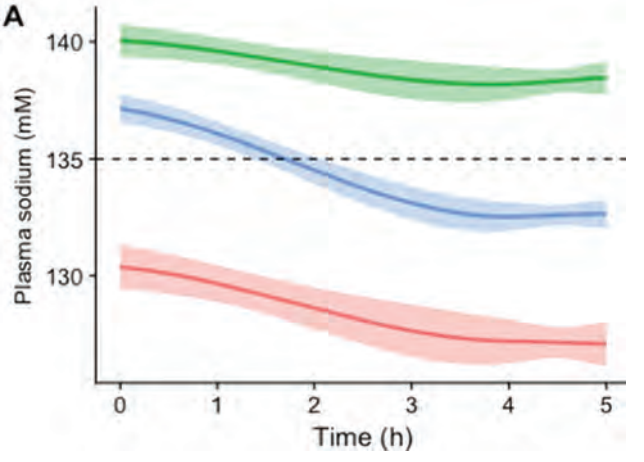

Figure 1. Evolution of PNa during WLT in normal (green), 'hyponatremic SIAD' (red), and 'normonatremic SIAD' (blue) patients.

PO1430

Reconsidering the Edelman Equation: Impact of Individual Total Body Cation Content and Body Weight

Mart D. Vuurboom, Eliane Wenstedt, Liffert Vogt, Rik H. Olde Engberink. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Treatment of hypo- and hypernatremia is guided by formulas that are based on the Edelman equation, including Adrogue-Madias' and others. This equation is the result of a unique study in which serum sodium concentration ($[Na^+]$), total body exchangeable Na^+ and potassium (K^+) and total body water (TBW) were measured in a highly heterogeneous population. However, the Edelman equation does not account for the recently uncovered body compartment where Na^+ can be temporarily stored and released without affecting TBW.

Methods: We performed a post-hoc analysis of original data from the Edelman study. In a linear regression model, the effects of important clinical characteristics on the relation between (Na_e+K_e)/TBW and serum [Na^+] were examined: sex, age, body weight and presence of edema. Using piecewise regression, we analyzed differences in slope and y-intercept for increasing values of (Na_e+K_e)/TBW. Serum [Na^+] was calculated by multiplying serum water [Na^+] by 0.93.

Results: Data was available for 85 measurements in 82 patients; 57 males, 25 females, with a mean age of 57±15 years. Serum [Na^+] ranged from 103 to 150 mmol/L. The association between serum [Na^+] and (Na_e+K_e)/TBW was different for high and low weight categories (table). Sex, age or presence of edema did not alter the association. In piecewise regression, a significant change in slope was found at 149 mmol/L (Na_e+K_e)/TBW (figure; 1.12 vs 0.56, p = 0.01).

Conclusions: The coefficients of the Edelman equation are significantly affected by weight and total body cation content. The less steep slope for the higher (Na_e+K_e)/TBW and high weight groups may reflect an increase in osmotically inactive Na^+ storage. This may explain the inaccuracy of Edelman based formulas in daily clinical practice.

PO1431

Hyponatremia: It's in the Eye of the Beholder

Muhammad Y. Jan, Richard N. Hellman. *Indiana University School of Medicine, Division of Nephrology and Hypertension, Indianapolis, IN.*

Introduction: An 85 year old Asian American female presented with 2 days history of worsening right eye pain, headache, scalp tenderness, and hypertensive urgency. Medical history was notable for keratoconjunctivitis sicca, osteoarthritis, and central retinal occlusion of the left eye. Initial labs showed erythrocyte sedimentation rate of 75 mm/hr. and C reactive protein of 3 mg/dL. A presumptive diagnosis of Giant Cell Arteritis (GCA) was made. She was started on high dose oral prednisone. Hypertension was treated with labetalol, amlodipine, and pain with opioids. Over the course of the next 36 hours she began to have somnolence. Initial sodium (Na) on admission was 131 mmol/L, with prior normonatremia. She was given a normal saline bolus followed by infusion due to concern for hypovolemia and reduced oral intake. This resulted in a consistent drop in her serum sodium acutely to 116 mmol/L and a nephrology consultation was sought.

Case Description: Our evaluation showed euvolemia with confusion and obtundation. Labs showed serum osmolality of 252 mosm/kg, urine osmolality of 626 osm/kg and Urine Na consistently around 90-129 mEq/L. A diagnosis of SIADH with desalination was made. She was treated with free water restriction, 3% saline, salt tablets, and furosemide. Na improved to 120 mmol/L however it dropped again next day to 117mmol/L requiring repeated doses of 3% Saline. Daily urine osmolality continued to decrease to 500s osm/kg and later to 360 mosm/kg as did urinary sodium 48 hours after these interventions. Peri-ocular swelling and a herpes zoster rash appeared on her eye 48 hours later. PCR for herpes was positive.

Discussion: Acyclovir was started and corticosteroids stopped. Over 8 days the hyponatremia resolved with Herpes Zoster Opthalmicus (HZO) treatment. HZO is a rare cause of SIADH thought to be due to dysregulation of stimulating signals from nucleus tractus solitarious to the supraoptic and paraventricular nuclei in the brainstem. In our case pain and opioids may have also been factors. Desalination needs to be considered in the correction of hyponatremia in SIADH, hyponatremia correction in HZO takes an average of 7 days although up to 4 months has been reported in 1 case series[1]. HZO should be considered in the differential diagnosis of SIADH.

PO1432

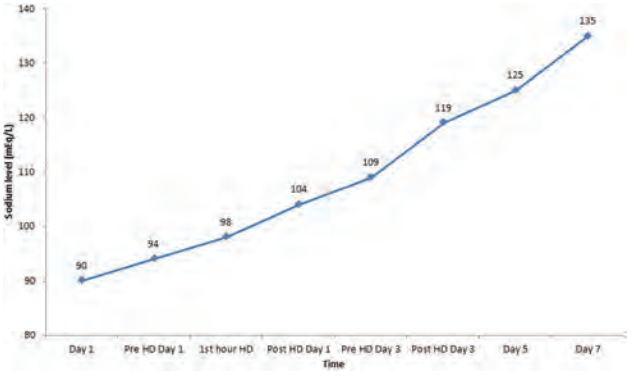
Acute Hemodialysis Prescription in Severe Hyponatremia Patient

Yasmine Wardoyo,[1,2] Donnie L. Gaol,[1,3] Parlindungan Siregar.[1] *[1]Rumah Sakit Dr Cipto Mangunkusumo, Central Jakarta, Indonesia; [2]Rumah Sakit Umum Pusat Fatmawati, Jakarta, Indonesia; [3]Fakultas Kedokteran Universitas Kristen Indonesia, Jakarta, Indonesia.*

Introduction: Severe hyponatremia in end-stage renal disease with fluid overload give rise to clinical dilemma. Dialysis and ultrafiltration are needed to reduce uremic toxins and fluid overload, yet there is a danger of osmotic demyelination syndrome if blood sodium level rapidly increase above the permissible range.

Case Description: 60 years old male patient was admitted with acute pulmonary oedema due to chronic kidney disease. He came with ureum 140 mg/dl, creatinin 20.3 mg/dl and had severe hyponatremia 94 mEq/L. He underwent hemodialysis with low blood flow rate (50 ml/min) and low dialysate sodium (130 mEq/L). Second hemodialysis was done with blood flow rate 100 ml/min and dialysate sodium 130 mEq/L. With this approach, we succeeded in increasing sodium gradually, not exceeding the limit of 10 mEq/day.

Discussion: In order to avoid rapid increment of serum sodium level, the sodium in dialysate can be set as low as possible to 130 mEq/L. We aim to limit the increment of serum Na to 10 mEq/day. Since the patient's total body water is approximately 36 L, an increase of 3 mEq/L/hour during 3-hour dialysis session would require a transfer of 108 mEq of Na per hour or total 324 mEq. We set a very slow blood flow rate, set dialysate rate to 800 ml/min and we assume that there is a 100% equilibration of Na between the patient's blood and the dialysate, resulting in net transfer of 36 mEq Na ($Na_{dialysate}$ - Na_{serum}) to each liter of blood that flow through the dialyzer. As the desired total Na transfer was 324 mEq, and 36 mEq would be added for every litre of blood dialyzed, we estimated that 9000 ml of blood needed to be dialyzed. The amount of blood divided by 3 hour hemodialysis treatment time leads to a blood flow rate 50 ml/min. With this approach, post dialysis sodium level increase 10 mEq/L. Similar approach gave similar finding in second hemodialysis. In conclusion, hemodialysis in severe hyponatremia patient needs several modifications in order to limit the increment of sodium within safe and permissible range.



Serum sodium level increment

PO1433

Urea as a Newer Therapy for Hyponatremia

Sangeeta Mutnuri,[1] Aswin Srinivasan,[4,5] Shabbir Safri,[6] Mahendra L. Agraharkar.[2,3] *[1]Creighton University, Omaha, NE; [2]UTMB, University of Texas Medical Branch at Galveston, Galveston, TX; [3]Baylor College of Medicine, Houston, TX; [4]University of Houston, Houston, TX; [5]HCA Gulf Coast Division, Houston, TX; [6]Montefiore Medical Center, Bronx, NY.*

Introduction: Hyponatremia is the most common electrolyte disorder observed in hospitalized patients and is associated with increased mortality, length of stay and readmission rates. Treatment includes fluid restriction, salt tablets, intravenous (IV) hypertonic saline and Antidiuretic Hormone (ADH) antagonists. Urea is a known therapy option for SIADH, but has been an infrequent choice.

Case Description: We present five cases of hyponatremia. The ages of the first four patients who had good response to urea were all older than 50 years. They included three SIADH patients and one hypervolemic hyponatremia. The hypervolemic patient had a reduced ejection fraction and had no improvement with diuresis and salt tablets and responded to urea. Of the other three, one required hypertonic saline and transition to urea, the other had been treated with tolvaptan and switched to urea due to cost concerns and the third patient had a component of low solute intake which responded well to urea. The fourth patient had SIADH secondary to malignancy and needed a combination of salt tablets and urea to achieve goal sodium. Addition of urea to salt tablets lowered the dose of salt tablets needed to maintain goal sodium. The last and youngest patient did not respond well to urea and needed tolvaptan to maintain sodium levels at goal.

Discussion: The treatment of hyponatremia is challenging as the correction has to be controlled to avoid osmotic demyelination syndrome from rapid fluid shifts. While hypertonic saline is a reliable treatment in hospitalized patients, it can prolong hospital stays. Tolvaptan helps with sodium correction, but is limited by its cost and liver toxicity. Urea increased serum sodium levels reliably in our older patients and reduced dose of salt tablets needed. In comparison to Tolvaptan, urea is a cost-effective alternative. Salt tablets are more affordable but cause volume overload. Hence, we think urea is a newer, well-tolerated and safer option in the treatment of hyponatremia either alone or in combination with other therapies.

Case Description

Patient	Age/Sex	Admission Na+ (meq/L)	Discharge Na+ (mEq/L) and treatment	Duration of admission (days)	Urine Osmolality (mOsm/kg)	urine Na+ (mEq/L)
1	61 yo Female	118	135 Salt tablets/diuresis/tolvaptan Lastly urea with good response	26	211	34
2	77 yo Male	117	131 Hypertonic saline and tolvaptan Switched to urea due to cost	13	427	27
3	70 yo Male	123	128 0.9% NS and then urea	5	561	49
4	59 yo Male	127	129 0.9% NS and urea with salt tablets	16	629	181
5	39 yo Male	115	135 Hypertonic saline, urea with variable response Tolvaptan worked well	14	735	53

PO1434

Should Sodium Monitoring Be Included in Routine Prenatal Care?

Talar Kharadjian, Mitra Jamshidian, Cynthia Miracle. *University of California San Diego, La Jolla, CA.*

Introduction: The American College of Obstetricians and Gynecologists does not recommend serum chemistries as part of routine prenatal care. Our case demonstrates the clinical utility in diagnosing hyponatremia prior to symptom development in mother or newborn.

Case Description: A 39-year-old pregnant female with no known prenatal issues underwent a spontaneous vaginal delivery; the infant was initially apneic and had a witnessed seizure. His initial serum sodium was 120mEq/L, and he was treated with phenobarbital and hypertonic saline. Serum sodium corrected by 4mEq/L during the first 7 hours, and increased from 120 to 133mEq/L over the first 24 hours. Brain MRI performed on day 4 demonstrated no abnormal findings. The mother's baseline sodium level was unavailable. She received 1L of D5LR and 1L of LR during labor. She had urinary retention following delivery and a foley catheter immediately drained 2L of urine. Her initial postpartum sodium level was 123mEq/L without associated symptoms. Urine osmolality was 64 mOsm/kg on admission. History revealed typical daily fluid consumption of 6L. Two days prior to admission, she had abruptly increased fluid intake to 13L per day in response to contractions. Twelve hours into admission, serum sodium corrected from 123 to 134 mEq/L in the setting of a relative reduction in fluid intake to 5L. Due to concern for a chronic component of hyponatremia, free water and DDAVP were given to slow the rate of correction. With the effect of DDAVP, urine concentrated to 695 mOsm/kg, illustrating the regeneration of an osmotic gradient within 30 hours.

Discussion: Primary polydipsia served as the leading driver of acute hyponatremia in this mother and infant, appropriately associated with ADH suppression. Although well-known drivers of increased ADH secretion were present, such as urinary retention and labor pain, their effects were less significant, as evidenced by very dilute urine on presentation. She was not exposed to the antidiuretic effects of oxytocin, which is an additional consideration in the peripartum period. Higher plasma volume during pregnancy and chronic polydipsia increased the mother's propensity to develop clinically significant hyponatremia in this case. This may have been detected earlier had serum sodium testing been included in routine prenatal care.

PO1435

Hyponatremia: A Real Headache

Jordan R. Evans,[1,2] Matthew Rodrigues,[1] David N. Dado.[1] *[1]US Army Brooke Army Medical Center, Fort Sam Houston, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Pituitary apoplexy is a condition characterized by pituitary gland injury via either infarction or hemorrhage. This can result in endocrinological dyscrasias. We describe a case of SIADH secondary to pituitary apoplexy.

Case Description: A 70 year old female with a past medical history of atrial fibrillation on rivaroxaban presented to the hospital with nausea, vomiting, and new onset headache for 1 week. She received 1 L of saline in the emergency room and her nausea resolved. Basic chemistry was significant for a serum sodium of 124 mEq/L. A physical exam including neurological assessment was unremarkable as was a CT scan of the head. The patient was admitted and placed on a 1.5 L fluid restriction. By the next morning, she had a serum sodium of 112mEq/L, serum osmolality at 238 mOsm/kg, urine osmolality at 434 mOsmol/kg, urine sodium at 143 mmol/L, and urine potassium at 45 mmol/L. The patient was immediately transferred to the ICU and nephrology was consulted for severe hyponatremia due to SIADH. Given the acute drop from 124 mEq/L to 112 mEq/L over a 20-hour period, the patient was aggressively treated with hypertonic saline boluses as well as continuous infusion. Fluid restriction was tightened to 500 ml daily. SIADH was initially thought to be due to hypovolemia and vomiting, however, the differential was revisited when the severe hyponatremia persisted despite resolution of her nausea and hypovolemia. Given the new onset headache in an older adult, a MRI of the brain was obtained which revealed a convexity in the sella that was identified as a 1 cm pituitary hemorrhage. Rivaroxaban was discontinued. Further evaluation of pituitary hormones were all within normal limits. The hyponatremia corrected over 3 days and the patient was discharged home with a sodium of 132 mEq/L.

Discussion: SIADH is a rare finding in pituitary apoplexy that can be seen transiently 3-11 days after a pituitary surgery or injury. The mechanism is not known but is suspected to be due to the release of intracellular ADH stores from injured posterior pituitary cells. Pituitary apoplexy should be considered in the differential diagnoses for SIADH in the setting of recent brain surgery or new red flag neurological symptoms.

PO1436

Dysnatremias and Mortality in CKD: Analysis of the Chronic Renal Insufficiency Cohort (CRIC) Study

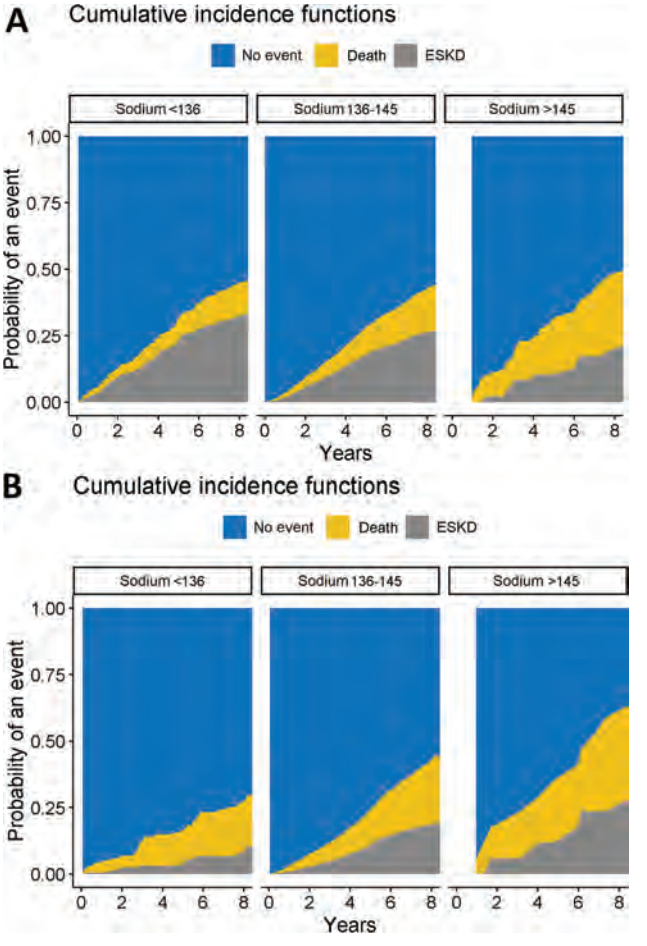
Mohamed Hassanein, Susana Arrigain, Jesse D. Schold, Georges Nakhoul, Jonathan J. Taliercio. *Cleveland Clinic, Cleveland, OH.*

Background: Dysnatremias have been associated with increased mortality in patients with chronic kidney disease (CKD). We studied the association of dysnatremias with mortality and end-stage kidney disease (ESKD) in patients with CKD.

Methods: We included 5,444 patients from the Chronic Renal Insufficiency Cohort (CRIC) over a median time of 8.8 years. We analyzed baseline and time-dependent hyponatremia (<136 mmol/L) and hypernatremia (>145 mmol/L) with all-cause mortality and risk of ESKD using Cox proportional hazard models and competing risks models.

Results: Hyponatremia and hypernatremia were found in 9% and 1% of patients, respectively. In adjusted Cox models, time-dependent hyponatremia and hypernatremia were significantly associated with mortality (hyponatremia HR 1.37, 95% CI: 1.15, 1.63, and hypernatremia HR 1.60, 95% CI: 1.08, 2.39). Among age <65, baseline and time-dependent hyponatremia were associated with increased risk of ESKD (baseline hyponatremia HR 1.27, 95% CI: 1.008, 1.61, time-dependent hyponatremia HR 1.38, 95% CI: 1.10, 1.72). Time-dependent hypernatremia was associated with increased risk of ESKD regardless of age (HR 1.58, 95% CI: 1.02, 2.45).

Conclusions: In the CRIC, time-dependent hyponatremia and hypernatremia were significantly associated with mortality suggesting frequent measurements is predictive of prognosis. Time-dependent hypernatremia was associated with increased risk of ESKD at all ages. Baseline and time-dependent hyponatremia were associated with increased risk of ESKD in patients <65. Subjects ≥ 65 may have competing risk factors or progression of underlying comorbidities that supersede the detrimental effects of hyponatremia.



Cumulative incidence of death and ESKD across sodium groups – Graph A: Age <65, B: Age ≥ 65

PO1437

The Prognostic Importance of Serum Sodium Levels at Hospital Discharge and 1-Year Mortality Among Hospitalized Patients

Charat Thongprayoon,[1] Wisit Cheungpasitporn,[2] Ranine Ghamrawi,[1] Sorkko Thirunavukkarasu,[1] Api Chewcharat,[1] Kianoush Kashani.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University of Mississippi Medical Center, Jackson, MS.*

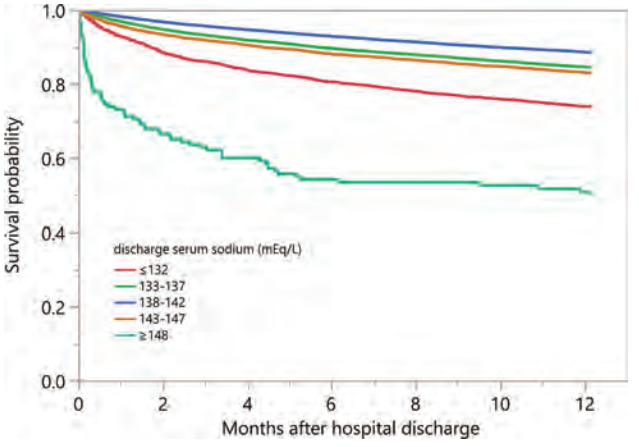
Background: The optimal range of serum sodium at hospital discharge is unclear. Our objective was to assess the one-year mortality based on discharge serum sodium in hospitalized patients.

Methods: We analyzed a cohort of hospitalized adult patients between 2011 and 2013 who survived hospital admission at a tertiary referral hospital. We categorized discharge serum sodium into five groups; ≤132, 133-137, 138-142, 143-147, and ≥148 mEq/L. We assessed one-year mortality risk after hospital discharge based on discharge serum sodium, using discharge sodium of 138-142 mEq/L as the reference group.

Results: Of 55,901 eligible patients, 4.9%, 29.8%, 56.1%, 8.9%, 0.3% had serum sodium of ≤132, 133-137, 138-142, 143-147, and ≥148 mEq/L, respectively. We observed a U-shaped association between discharge serum sodium and one-year mortality, with nadir mortality in discharge serum sodium of 138-142 mEq/L. When adjusting for potential confounders, including admission serum sodium, one-year mortality was significantly higher in both discharge serum sodium ≤137 and ≥143 mEq/L, compared

with discharge serum sodium of 138-142 mEq/L. The mortality risk was the most prominent in elevated discharge serum sodium of ≥148 mEq/L (HR 3.86; 95% CI 3.05-4.88), exceeding the risk associated with low discharge serum sodium of ≤132 mEq/L (HR 1.43; 95% CI 1.30-1.57).

Conclusions: The optimal range of serum sodium at discharge was 138-142 mEq/L. Both hypernatremia and hyponatremia at discharge were associated with higher one-year mortality. The impact on higher one-year mortality was more prominent in hypernatremia than hyponatremia.



PO1438

Peripheral Administration of 3% Sodium Chloride Is Not Associated with Local Infusion Reactions

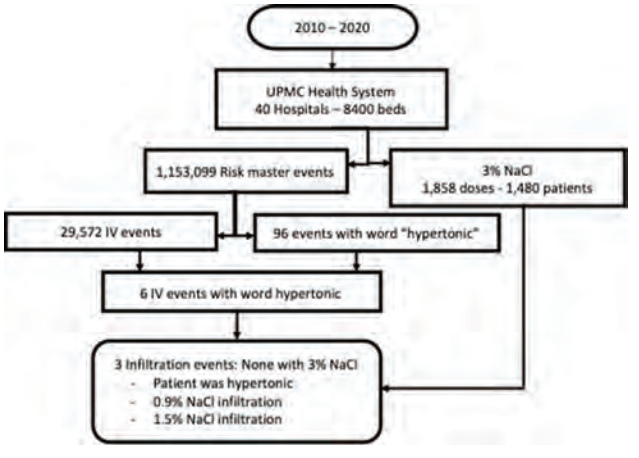
Michael L. Moritz,[1,2] Juan Carlos Ayus,[3,4] Joel B. Nelson.[1,2] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Renal Consultants of Houston, Houston, TX; [4]University of California Irvine, Irvine, CA.*

Background: Three-percent sodium chloride (3% NaCl) is a hyperosmolar agent indicated for the treatment of hyponatremic encephalopathy or to raise the serum osmolality in other cases of increased intracranial pressure. A barrier to the use of 3% NaCl is the perceived risk of a local infusion reactions when administered through a peripheral vein (Front Med. 2019 Mar 15;6:47), even though it has not been reported in large case series of 3% NaCl (AJKD. 2015 Mar;65(3):435-42). We sought to evaluate reports of local infusion reactions associated with 3% NaCl over a 10-year-period throughout a large healthcare system.

Methods: A query was conducted through Risk Master database to determine if there were any local infusion reactions associated with peripheral 3% NaCl administration throughout the entire UPMC health system over a 10-year time period from May 14, 2010 to May 14, 2020. Search terms included infiltrations, extravasations, phlebitis, IV site issues and IV solutions.

Results: In over 1.1 million events (figure), there were 23,714 intravenous events which were non-chemotherapeutic or non-contrast of which 4,648 (19.7%) were in children. 617 (2.59%) of these events were deemed serious by a patient safety officer. There were no reported local infusion reactions with 3% NaCl.

Conclusions: There were no reported local infusion reactions events associated with 3% NaCl in a large healthcare system despite widespread use of 3% NaCl and numerous intravenous events reported. This suggests that 3% NaCl can be safely administered through a peripheral IV.



Local Intravenous Infusion Reactions

PO1439

Hyponatremia: Mind the (Osmolar) Gap

Joy Ayyoub, Shahrzad Zonoozi, Pooneh Alborzi. *Penn Medicine, Philadelphia, PA.*

Introduction: Hyponatremia, one of the most commonly encountered electrolyte abnormalities, is associated with considerable mortality and morbidity. It is important to rule out pseudohyponatremia by determining serum tonicity.

Case Description: 65-year-old female with history of hypertension presented with worsening painless jaundice. Initial investigation was notable for an obstructive liver injury; total bilirubin of 28.4 mg/dL (direct 19.5 mg/dL and indirect 8.9 mg/dL), ALP 1225 U/L, AST 237 U/L, ALT 384 U/L and GGT 2274 U/L. She was also found to have a sodium of 126 mmol/L and potassium of 2.5 mmol/L. With fluids and potassium repletion, her sodium plateaued at 131 mmol/L. Further investigation revealed a measured serum osmolality of 301 mOsm/kg with an osmolar gap of 33 mOsm/kg, and a urine osmolality of 589 mOsm/kg. Sodium analysis using ion-selective electrode (ISE) showed a correction in the sodium from 131 mmol/dL to 139 mmol/L on the same specimen, confirming the diagnosis of pseudohyponatremia. Lipid panel showed severe hypercholesterolemia (total cholesterol 1016 mg/dL, LDL 868 mg/dL, HDL 31 mg/dL and triglycerides at 604 mg/dL). Patient underwent endoscopic retrograde cholangiopancreatography and biliary sphincterotomy with biopsy consistent with adenocarcinoma of the pancreas. Following sphincterotomy, lipid panel and serum sodium normalized without further intervention.

Discussion: Serum cholesterol is elevated in cholestasis because its metabolic degredation and excretion are impaired. Much of the cholesterol is in the form of lipoprotein-X, an abnormal lipoprotein observed only in patients with cholestasis. Standard methods of sodium analysis, indirect ISE, calculates electrolyte concentration on the assumption that the non-aqueous portion of serum, predominantly proteins and lipids, comprises approximately 7% of a patient's plasma volume. In our patient with significant hyperlipidemia, this led to falsely low indirect ISE values. Direct potentiometric measurements use undiluted samples and are not subjected to this artifact, a method also used in blood gas analysis. This case demonstrates a rare presentation of pseudohyponatremia and highlights the importance of its consideration in cases where the serum osmolarity is normal or when an osmolar gap is present suggesting reduced plasma water content or the presence of ineffective osmoles.

PO1440

Development of Hyponatremia and Overcorrection in a Patient with COVID-19 and Vasopressin Exposure

Meghana Eswarappa, Niralee Patel, Samira S. Farouk. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Hyponatremia in the setting of elevated antidiuretic hormone (ADH) is a common phenomenon. However, exogenous ADH from vasopressin administration for hemodynamic support does not cause clinically relevant hyponatremia, despite its widespread use. Further, discontinuing vasopressin may lead to rapid rises in sodium that may be missed. Here, we present a case of a critically ill patient who developed hyponatremia in the setting of vasopressin use, with subsequent rapid overcorrection that required re-lowering of serum sodium after discontinuing vasopressin.

Case Description: A 40-year-old male with no known history was admitted to the ICU for respiratory failure due to COVID-19 pneumonia. Initial labs showed normal renal function and electrolytes. He received azithromycin, hydroxychloroquine, and glucocorticoids and required extracorporeal membrane oxygenation. During the first 45 days of hospitalization, he had persistent hypernatremia(sodium as high as 154 mEq/L) despite free water flushes(FWF) and intermittent IV 5% dextrose in water(D5W). On day 45, vasopressin and norepinephrine were initiated for hypotension. Over the next 72 hours, serum sodium decreased from 148 to 128 mEq/L (Figure 1). Urine osmolality(UOsm) and sodium were 684 mOsm/Kg and 145 mEq/L, respectively. During this 72-hour period, the patient received about 1L/day FWF. On day 55, vasopressin was discontinued for 11 hours, during which time the sodium rose from 126 to 138 mEq/L and UOsm decreased from 705 to 82 mOsm/kg. He received D5W to re-lower the sodium. Vasopressin was also restarted, and the sodium stabilized near 132mEq/L.

Discussion: Although pneumonia may have contributed to high ADH release in this patient, the timing of vasopressin administration prior to the development of hyponatremia and the acute rise in sodium after vasopressin discontinuation suggests an important role for exogenous ADH. Clinicians should pay close attention to fluctuations in sodium levels in patients receiving IV vasopressin, particularly when therapy is discontinued, given the risk of rapid overcorrection and development of osmotic demyelination syndrome.

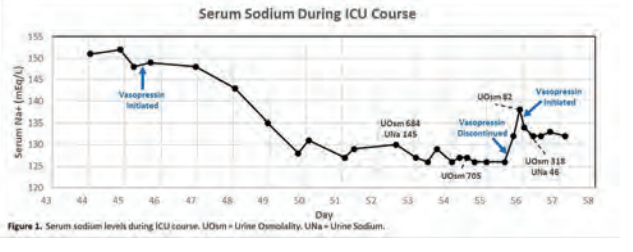


Figure 1. Serum sodium levels during ICU course. UOsm = Urine Osmolality. UNa = Urine Sodium.

PO1441

Continuous Renal Replacement Therapy (CRRT) for Overcorrection of Hyponatremia After Left Ventricular Assistance Device (LVAD) Placement

Abdulhadi T. Gelaidan, Pooja D. Amarapurkar, Jonathan J. Suarez. *Emory University School of Medicine, Atlanta, GA.*

Introduction: Rapid correction of severe hyponatremia can result in osmotic demyelination syndrome, central pontine myelinolysis and locked-in syndrome. Rapid correction is defined as an increase in serum sodium (Na) by 10-12 mEq/L in the first 24 hours and 18 mEq/L in the first 48 hours. Rapid lowering serum Na in a short period after rapid correction of hyponatremia could prevent these complications. Conventional strategies use hypotonic intravenous fluids and desmopressin to lower overcorrected hyponatremia. However, CRRT can correct serum sodium in a very predictable and controlled manner.

Case Description: A 35-years old woman with a history of non-ischemic cardiomyopathy with an ejection fraction of 5-10% was admitted with an acute CHF exacerbation. Her hospitalization was complicated by AKI and hyponatremia. She underwent LVAD placement and her sodium increased from 111 to 137 mEq/L within 18 hours of surgery. She was started on CRRT using continuous venovenous hemodiafiltration (CVVHDF) with post-filter 5% dextrose in water to lower her sodium level to close to 120 meq/L. The patient tolerated the treatment very well with no immediate central nervous system complications or even delayed neurological complications at the two month follow up.

Discussion: To our knowledge, this is the first case report describing the use of CRRT for overcorrection of hyponatremia after LVAD placement. The overcorrection of hyponatremia after LVAD placement was likely due to the kidney's restored ability to excrete diluted urine from improved renal perfusion. Given the total fluid volume of hypotonic intravenous fluids and unpredictability of desmopressin we recommend considering early initiation of CRRT to treat overcorrection of hyponatremia after LVAD placement. Another consideration should be made for Initiation of CRRT prior to LVAD placement in patients with severe hyponatremia to prevent the rapid correction from occurring in the intraoperative setting.

PO1442

Neuroprotective Hypernatremia in Acute Liver Failure Using CRRT: A Challenging Scenario

Jean Maxime Cote.[1,2] [1]*Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada;* [2]*University College Dublin, Dublin, Ireland.*

Introduction: Acute liver failure is associated with severe complications, including encephalopathy. Cerebral edema may occur, leading to increased intracranial pressure. Urgent medical management sometimes includes neuroprotective hyperosmolality and ammonia control using convective techniques. We describe a patient where high-volume CVVHDF was used to increase ammonia clearance while maintaining therapeutic hypernatremia.

Case Description: A 64-year-old female with severe bipolar disorder presented into the ED ~24hours after voluntary ingestion of ~150 tablets (75g) of acetaminophen. She was initially confused with normal blood pressure. Laboratory work showed severe metabolic acidosis with the following values: lactate 9.1 mmol/L, pH 6.99, ammonia 409 mmol/L, ALT 6398 U/L, creatinine 44 μmol/L, INR 9.1 and acetaminophen 250.2 mg/L. NAC and IV bicarbonate were quickly initiated, and a short plasmapheresis treatment was started 12hours later, inducing moderate hypercalcemia, hypernatremia (153 mmol/L) and normalising INR temporarily. Encephalopathy, oliguria and hemodynamic instability progressed. High-volume CVVHDF (90 mL/kg/h) was started at day 3 to optimise ammonia clearance and electrolytes. Hypertonic NaCl 23.4% (50 mmol) was added to a low-calcium 5L dialysate preparation (PrismOcal22) to obtain [Na] of 150 mmol/L. Over the next 3 days, additional hypertonic NaCl was required (until 80 mmol) (dialysate [Na] 156 mmol/L) to reach the ~150 mmol/L serum sodium targeted. However, after numerous medical complications, the patient was declared ineligible to liver transplantation and palliative care was initiated. She died 3 weeks after initial admission.

Discussion: Usage of high-volume CRRT in severe hepatic encephalopathy increases despite the paucity of evidence. Commercial standard solutions of dialysate used for CRRT usually have fixed sodium concentration (140 mmol/L). Adding sterile hypertonic NaCl into the dialysate bag allows us to modify its tonicity to obtain neuroprotective hypernatremia. However, as shown in our case, complete sodium equilibration between dialysate and patient, even when using high-volume CVVHDF, is unlikely because of residual kidney function and concomitant hypo- and isotonic IV medications. To obtain and maintain therapeutic hypernatremia in these conditions, the CRRT dialysate tonicity should be slightly higher than the targeted serum sodium.

PO1443

Unraveling the Role of Serum Chloride Level as a Strong Predictor of Outcomes in Patients with Heart Failure: A Systematic Review and Meta-Analysis

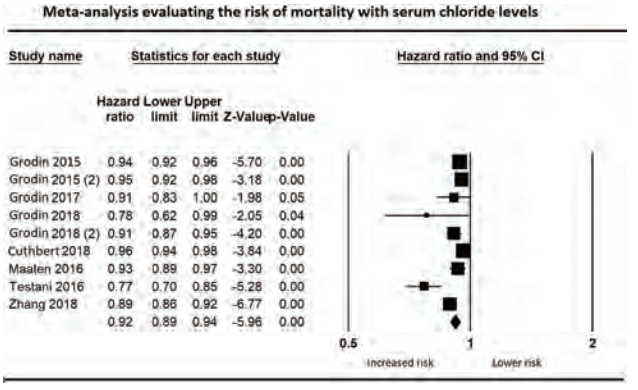
Ankur Jain,[1] Shriharsha Kallahalli Jayaramu,[1] Abhilash Koratala,[2] Amir Kazory.[1] [1]*University of Florida, Gainesville, FL;* [2]*Medical College of Wisconsin, Milwaukee, WI.*

Background: The field of heart failure (HF) is conventionally sodium-centric. Low serum sodium concentration has long been recognized as an established marker of adverse outcomes and is commonly included in HF risk prediction models. Not only could the mechanisms leading to hyponatremia result in concurrent hypochloremia, but chloride also has distinct biological roles (e.g. modulating renin secretion) that are relevant in HF. We sought to explore the impact of hypochloremia on the outcomes of patients with a HF.

Methods: This is a PRISMA-guided systematic literature review and meta-analysis (registered in PROSPERO). We searched PubMed, Cochrane, and Embase databases from January 2010 to March 2020 for clinical trials exploring relationship between serum chloride and the outcomes of HF patients. A cumulative analysis of Hazard Ratios (HR) with 95% confidence intervals (CIs) was done using comprehensive meta-analysis software.

Results: A total of 9 studies with 15,979 patients were eligible for analysis; 5 had patients with systolic HF, 3 with both systolic and diastolic HF, and 1 with diastolic HF only. These studies reported HR for risk of mortality with change in serum chloride levels stratified by unit, standard deviation, or predefined groups, and adjusted for serum sodium and a variety of potential confounders. On cumulative analysis we found that serum chloride levels are inversely associated with risk of long-term mortality HR 0.92 (95% CI 0.77 - 0.96; p<0.01).

Conclusions: Based on the data from currently available studies, we identified low serum chloride level as a strong independent predictor of mortality in various phenotypes of HF. While it remains to be elucidated whether it represents a marker of disease severity or reflects an actual pathogenetic mechanism, our results suggest that inclusion of serum chloride in HF risk models is likely to improve their predictive value.



PO1444

Patiromer vs. Kayexalate: Comparison of Potassium Binding Efficacy and Impact on Other Electrolytes in Infant Milk Formula Similac PM 60:40

Vimal Chadha, Leah Oladitan, Jessica Tower, Tyson Moore, Valerie F. Smith, Uttam Garg, Uri S. Alon. *Children's Mercy, Kansas City, MO.*

Background: Hyperkalemia is one of the common metabolic abnormalities seen in patients with renal failure. Management includes combination of low-potassium diet with additional potassium-binding medications if necessary. However, these measures are impractical in infants whose dietary intake is predominantly milk based and both breast as well as the renal milk formula, Similac PM 60:40, have high potassium content. Low-potassium milk formulas such as Renastart® and Renalcal® are not readily available. Pretreatement of milk with Kayexalate has been utilized as an effective means of reducing the milk potassium content. As Kayexalate exchanges sodium for potassium, it results in extra sodium load that is undesirable in patients with hypertension; moreover, Kayexalate also binds calcium thus decreasing calcium intake. Patiromer (Veltassa®), a recently introduced sodium-free potassium-binder exchanges calcium for potassium thus avoiding both hypernatremia and hypocalcemia.

Methods: Potassium binding effectiveness of Patiromer was comapred with Kayexalate by pretreating Similac® PM 60:40 milk formula. Three different concentrations of Kayexalate (3.4, 6.8, and 13.6 g/L) and Patiromer (8.4, 16.8, and 33.6 g/L) were used. Supernatant samples were collected at 30, 60, and 120 minutes respectively. Samples were analyzed for sodium, potassium, calcium, and magnesium. The experiment was conducted in duplicate.

Results: Results are shown in Table.

Conclusions: Both Kayexalate and Patiromer were effective in lowering the potassium concentration. While Kayexalate increased the sodium content of the formula by almost 100 to 300%, and reduced the calcium concentration by 40%, Patiromer did not affect the sodium concentration and increased the calcium concentration by 40%. Both Kayexalate and Patiromer decreased the magnesium concentration with the decrease being more pronounced with Kayexalate. Knowledge of these electrolyte changes is crucially important in the care of infants with renal disease as they are vulnerable to negative consequences of electrolyte imbalance.

Funding: Commercial Support - Relypsa, Inc

Table: Percentage changes in electrolyte concentrations at the end of 30 minutes with three different doses of Kayexalate and Patiromer

Medication	Kayexalate			Patiromer		
Electrolytes	3.4 g/L	6.8 g/L	13.6 g/L	8.4 g/L	16.8 g/L	33.6 g/L
Potassium	↓15%	↓33%	↓61%	↓7%	↓15%	↓22%
Sodium	↑87%	↑239%	↑300%	↓3%	↓6%	↓9%
Calcium	↓13%	↓19%	↓41%	↑19%	↑37%	↑43%
Magnesium	↓31%	↓46%	↓69%	↓15%	↓30%	↓38%

PO1445

Post-Discharge Outcomes Among Hyperkalemic Patients Treated with and Without Sodium Polystyrene Sulfonate in the Inpatient Setting

Jill Davis,[1] Rubeen K. Israni,[1] Erin Cook,[2] Fan Mu,[2] Keith Betts,[2] Deborah A. Anzalone,[1] Emma Billmyer,[2] Esteban J. Lemus Wirtz,[2] Lei Yin,[2] Harold M. Szerlip,[3] Gabriel I. Uwaifo,[4] Vivian A. Fonseca.[5] *[1]AstraZeneca, Wilmington, DE; [2]Analysis Group, Boston, MA; [3]Baylor University Medical Center, Dallas, TX; [4]Oschner Medical Center, New Orleans, LA; [5]Tulane University Medical Center; Tulane University School of Medicine, New Orleans, LA.*

Background: Sodium polystyrene sulfonate (SPS) is a common treatment option for hyperkalemia (HK) in the inpatient (IP) setting. However, the post-discharge outcomes of patients with HK treated with and without SPS in the IP setting are not well characterized.

Methods: Adult patients with ≥1 IP stay with HK (≥1 potassium [K] lab >5.0 mEq/L) were identified using electronic medical record data from the Research Action for Health Network (2012-2018). Patients treated with SPS during the IP stay were matched 1:1 to patients not treated with SPS on discharge status (dead/alive) and HK severity (most severe K lab during IP stay). Patient characteristics, K levels, HK treatments, length of stay (LOS) and death during IP stay were described. All-cause and HK-related IP readmission, and HK recurrence (in any setting) within 30, 60 and 90 days post-discharge were described and compared using conditional logistic regressions.

Results: A total of 4,847 SPS users were matched to non-SPS users (23.2% K>5.0-5.5, 36.8% >5.5-6.0, 40.0% >6.0 mEq/L). During the stay, 11.7% of patients died in both cohorts. Mean age was 65.7 and 62.1 years for the SPS and non-SPS users. SPS users had a higher burden of comorbidities than non-SPS users, including CKD (79.1% v 57.2%) and heart failure (49.8% v 37.7%; both p<0.001). The average LOS was similar for SPS and non-SPS users (9.0 v 9.1 days) and most patients had their last K level normalized (≤5.0 mEq/L) during the stay (83.0% v 86.2%, p<0.001). Use of temporizing agents was common for SPS and non-SPS users (58.2% v 43.5%, p<0.001); however, very few SPS users received SPS at discharge (0.4%). The 30-day all-cause and HK-related IP readmission rates were 27.0% and 13.6% for SPS users and 19.3% and 5.4% for non-SPS users, respectively. HK recurred within 30 days in 23.0% of SPS users and 7.1% of non-SPS users. The differences remained after adjusting for baseline and IP stay characteristics (odds ratio [95% CI]: all-cause readmission=1.4 [1.2, 1.6]; HK readmission=2.4 [2.0, 2.9]; HK recurrence=3.1 [2.7, 3.6]). The adjusted results were similar for 60 and 90 days post-discharge.

Conclusions: Despite treatment with SPS in the IP setting there was a high burden of readmission and HK recurrence among patients with HK.

PO1446

Serum Potassium Levels at Hospital Discharge and 1-Year Mortality Among Hospitalized Patients

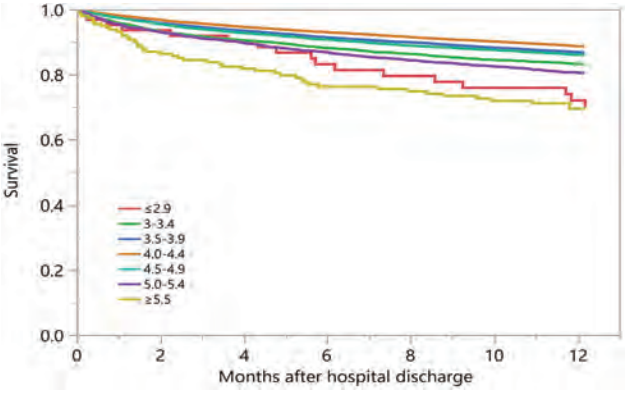
Michael A. Mao,[1] Charat Thongprayoon,[2] Wisit Cheungpasitporn,[2] Sorkko Thirunavukkarasu,[2] Api Chewcharat,[2] Stephen B. Erickson.[2] *[1]Mayo Clinic's Campus in Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: The aim was to assess the relationship between discharge serum potassium levels and one-year mortality in hospitalized patients.

Methods: All adult hospital survivors between years 2011 and 2013 at a tertiary referral hospital who had available admission and discharge serum potassium levels were enrolled. End-stage kidney disease patients were excluded. Discharge potassium was defined as the last potassium measured within 48 hours prior to hospital discharge and categorized into ≤2.9, 3.0-3.4, 3.5-3.9, 4.0-4.4, 4.5-4.9, 5.0-5.4 and ≥5.5 mEq/L. Cox proportional hazard analysis was performed to assess the independent association between discharge potassium and one-year mortality after hospital discharge, using discharge potassium of 4.0-4.4 mEq/L as the reference group.

Results: Of 57,874 eligible patients, with a mean discharge serum potassium of 4.1±0.4 mEq/L, the estimated one-year mortality rate after discharge was 13.2%. A U-shaped association was observed between discharge potassium and one-year mortality, with nadir mortality in the discharge potassium of 4.0-4.4 mEq/L. After adjustment for clinical characteristics, including admission potassium, both discharge potassium of ≤3.9 mEq/L and ≥4.5 mEq/L were significantly associated with increased one-year mortality, compared with the discharge potassium of 4.0-4.4 mEq/L. Stratified analysis based on admission serum potassium showed similar results except that there was no increased risk of one-year mortality if discharge potassium group was ≤3.9 mEq/L in patients with an admission potassium of ≥5.0 mEq/L.

Conclusions: The association between discharge serum potassium and one-year mortality after hospital discharge had a U-shaped distribution and was independent of admission potassium. Favorable survival outcomes occurred when discharge potassium was within the range of 4.0-4.4 mEq/L.



The Kaplan-Meier plot of one-year mortality based on discharge serum potassium levels

PO1447

Mitragyna speciosa (Kratom)-Induced Hyperkalemia

Aldo E. Torres Ortiz, Muhannad Alqudsi. Ochsner Nephrology *Ochsner Health System, New Orleans, LA.*

Introduction: Kratom is a non-controlled herbal supplement that has been used for its opioid-like effects. Case reports of different organ toxicities from Kratom have been reported in the literature. However, little is known regarding its effects on potassium (K) homeostasis. We present here the first case-report of kratom-induced hyperkalemia.

Case Description: A 61 yo male with a history of degenerative disc disease and hyperlipidemia, referred to nephrology clinic for unexplained hyperkalemia for the past 2 months. He was asymptomatic. His only home medication was rosuvastatin. Serum (K) was elevated in four different occasions with 5.8 mmol/L being the highest (non-hemolyzed samples). He denied NSAID or antibiotic use, smoking, alcohol intake, illicit drug abuse, sickness, or high (K) diet intake. No family history of renal diseases. Physical exam was unremarkable with a blood pressure of 124/76 mm Hg without orthostatic changes. Serum creatinine (Cr) was 0.8 mg/dL, eGFR >60 mL/min, plasma aldosterone was 3.6 ng/dL, rennin activity was 0.88, urine (K) was 14 mmol/L and urine Cr was 16 mg/dL, (K) fractional excretion was 15%, sodium of 141 mmol/L, CO2 33 mmol/L and the rest of the electrolytes were normal. TSH, CPK, AM cortisol, and WBC were within normal limits and he had no hematuria or proteinuria. Kidney ultrasound was normal. Upon re-interrogation, patient admitted taking daily Kratom for recreational purposes for the past 4 months as herbal supplement. A repeat blood chemistry 4 weeks after patient confirmed abstinence from Kratom, revealed normalization of (K) down to 4.6 mmol/L.

Discussion: *Mitragyna speciose (Kratom)* is a herbal supplement with potential abuse due to its opioid-like properties. Our patient had hyperkalemia unexplained by low renal clearance, adrenal insufficiency, medication use, or other etiologies. A study in cultured heart cells revealed a blocking effect of the cardiac (K) inward rectifier channels (Kir 2.1) by Mitragynine causing prolonged QT interval arrhythmia. Kir family does exist along the nephron with little known about Kir 2.1. Whether Kratom has effect on renal Kir 2.1, or other Kir channels is yet to be further studied. This case-report serves to highlight the importance of the identification of lesser-known supplements with potential abuse that can cause life-threatening side-effects.

PO1448

The Relationship Between Comorbidities and Hyperkalaemia in Patients with CKD

Eskinder Tafesse,[2] Glen James,[3] Daniel Sugrue,[1] Michael A. Hurst,[1] Louise Hoskin,[1] Karolina Badora,[1] Philip McEwan.[1] *[1]Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; [2]Global Health Economics, AstraZeneca, Gaithersburg, MD; [3]Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom.*

Background: Hyperkalaemia (HK) is common in patients with chronic kidney disease (CKD) due to the role the kidneys play in maintaining normal potassium (K^+) homeostasis. The presence of comorbidities in patients with CKD may further increase HK risk. Therefore, this study explored the incidence of HK in CKD patients with different comorbidities.

Methods: A retrospective cohort study was conducted using primary and secondary care data from the UK Clinical Practice Research Datalink and linked Hospital Episode Statistics, respectively. Eligible patients had non-dialysis dependent CKD, with or without resistant hypertension (RHTN); heart failure (HF) or diabetes (type 1 or type 2) recorded between January 2003 – June 2018. Patients were grouped according to CKD severity (stage 3a, 3b, 4 and 5) and follow-up time was partitioned based on their current status. Crude rates of HK per 1,000 patient-years were analysed for each group and the data was further categorised according to HK-defining serum K^+ thresholds: ≥5.0, ≥5.5 and ≥6 mmol/L.

Results: In total, 229,350 patients with CKD stage 3+ contributed to follow-up, including 514, 250, 114 and 39 thousand patient years in the CKD only, RHTN, diabetes and HF cohorts, respectively. Declining renal function was consistently associated with increasing incidence of HK at all K^+ thresholds. Additionally, within the same CKD stage, comorbidities were also consistently associated with an increase in HK incidence. Patients in the diabetes cohort were consistently at the greatest risk of HK, with a significant ($\alpha = 0.05$) increase in risk of HK (defined at ≥5.0 mmol/L) compared with other comorbid groups. Conversely, patients without any comorbidities were at the lowest risk of HK, regardless of CKD stage and HK threshold.

Conclusions: In patients with CKD, comorbidities – specifically HF, diabetes, and RHTN – increase the risk of HK. This risk increases as renal function declines. As such, CKD patients, particularly those with comorbidities, may benefit from additional monitoring for HK.

PO1449

Hyperkalemia Secondary to Carbapenem Use

Sabine Karam. *Saint George Hospital University Medical Center, Beirut, Lebanon.*

Introduction: Hyperkalemia can be a life-threatening complication and can often occur in the hospital setting as the result of the use of certain medications. In particular, hyperkalemia has already been described as a rare complication of ertapenem use.

Case Description: A 24 year-old gentleman with no past medical or surgical history presented with a one week history of abdominal pain and nausea. He underwent a CT scan that showed a perforated appendix with small abscesses. Upon admission, his creatinine level was 1.28 mg/dL and his potassium level was 4.24 mEq/L. He was initiated on intravenous fluids and ertapenem 1g IV once daily. His renal function improved and his creatinine level decreased to 0.83 mg/dL however he developped hyperkalemia with a potassium level that peaked at 5.9 mEq/L. He was switched to meropenem, however the hyperkalemia persisted and resolved only when he was switched to ciprofloxacin.

Discussion: Carbapenem use is associated with severe hyperkalemia and this complication seems to stem from a class-effect rather than the effect of a specific drug.

PO1450

Relationships Between CKD Duration, Serum Potassium Level, and Adverse Outcomes

Eskinder Tafesse,[2] Glen James,[3] Michael A. Hurst,[1] Louise Hoskin,[1] Karolina Badora,[1] Daniel Sugrue,[1] Philip McEwan.[1] *[1]Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; [2]Global Health Economics, AstraZeneca, Gaithersburg, MD; [3]Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom.*

Background: Patients with chronic kidney disease (CKD) are at increased risk of hyperkalaemia as the kidneys are important in maintaining potassium homeostasis. This study examined the relationships between CKD duration, serum potassium level (K^+) and rates of adverse clinical outcomes.

Methods: This retrospective cohort study used linked primary and secondary care data from that UK Clinical Practice Research Datalink (CPRD) GOLD and Hospital Episode Statistics (HES), respectively. Eligible patients were aged ≥18 years with new or existing CKD stage 3+ (READ code or estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2 without prior dialysis) between January 2008 and June 2018, or during lookback (2003 to 2007). Index date was 01 January 2008 (prevalent cases) or CKD diagnosis date (incident cases); whichever occurred later. Adverse outcomes were all-cause mortality (ACM) and major adverse cardiovascular events (MACE), a composite of arrhythmia, heart failure, myocardial infarction, and stroke. Crude incidence rates of ACM and MACE were estimated over follow-up from index date to event or end of follow-up (earliest of death, loss to follow-up or study end) based on 1,000 patient years. Published risk equations for ACM and MACE were refitted with adapted coefficient values to include CKD duration (≤5 and >5 years). Reference category for incidence rate ratios was K^+ level 4.5 to <5.0 mmol/L.

Results: Among 297,702 CKD patients, 58.6% were female and mean age was 74.7 years (standard deviation, SD 11.3) at index, with mean follow up of 5.6 years (SD 3.20). Mean eGFR at index was 49.7 mL/min/1.73m^2 (SD 11.6). Crude rates of ACM and MACE in patients with CKD duration ≤5 years were 60.8 per 1,000 patient years (95% confidence interval (CI) 60.3-61.3) and 102.6 (95% CI 102.0-103.3). Rates in patients with CKD duration >5 years were 76.3 (95% CI 75.4-77.2) and 127.4 (95% CI 126.2-128.5), respectively. Irrespective of duration of CKD, K^+ <4.5 or ≥5.0 mmol/L were associated with increased risk of MACE/ACM in comparison with 4.5 to <5.0 mmol/L.

Conclusions: CKD patients with K^+ outside the normal range are at increased risk of ACM and MACE, irrespective of CKD duration. Improved management of K^+ may reduce adverse clinical outcomes in these patients.

Can Potassium Be a Predictor of Cardiovascular Mortality?

Catarina Mateus,[1] Carolina Ormonde,[2] Catarina Brízido,[1] Ana Rita M. Martins,[1] Patricia Q. Branco.[1] *[1]Centro Hospitalar Lisboa Ocidental - Hospital de Santa Cruz, Lisbon, Portugal; [2]Hospital do Divino Espirito Santo de Ponta Delgada EPE, Ponta Delgada, Portugal.*

Background: Epidemiologic data demonstrates association between hyperkalaemia and mortality. Patients with ST-segment elevation myocardial infarction (STEMI) often have comorbidities that are associated with hyperkalaemia, such as Chronic Kidney Disease (CKD) and Diabetes Mellitus (DM). The aim of our study was to analyse hyperkalaemia as a prognostic factor in patients with STEMI.

Methods: Retrospective single-center analysis of all patients admitted for STEMI and undergoing primary percutaneous coronary intervention in a two-year period (January 2009 to December 2010). Demographic aspects, comorbidities, potassium level at admission and outcomes were evaluated. Hyperkalaemia was defined as potassium level superior to 5 mmol/l.

Results: Overall, 276 patients were included (mean age 62 ± 14 years, 75% males), 55% had hypertension, 20% diabetes mellitus and 14% previous myocardial infarction. Only 14% were pretreated with renin–angiotensin–aldosterone system inhibitors (RAASi). The median potassium at admission was 4 mmol/l (IQR 3.7 - 4.4mmol/l), and the median creatinine level at admission was 0.88 mg/dl (IQR 0.74 - 1.1mg/dl). 5-year all-cause mortality was 23%. Univariable analysis revealed that age (p <0.001), previous myocardial infarction (p 0.038) and hyperkalaemia at admission (p 0.039) were associated with 5-year all-cause mortality. After adjustment for therapy with RAASi, higher potassium level at admission was associated with 5-year all-cause mortality (adjusted HR 1.55, 95%CI 1,01-2,38; p 0. 045).

Conclusions: In our study, potassium at admission was a predictor of 5-year all-cause mortality. Potassium measurement is an easy tool to help in risk stratification in this population. Further studies are needed to access if pharmacological control of potassium levels will change prognosis.

PO1452

Epidemiology of Hyperkalemia Among Patients Presenting at the Emergency Department in China

Jianming Bian, Li Zuo, Houyu Zhao, Xu Han. *Department of Pharmacology, Chinese People's Liberation Army General Hospital, Beijing, China.*

Background: In China, the clinical burden of hyperkalemia (HK) among patients presenting emergency department (ED) is not well described.

Methods: Data containing hospital information system (HIS) records of 157 hospitals, covering 30 provinces in China were extracted from Beijing Data Center for Rational Use of Drugs. Patients presenting ED (aged >=18 years old) with record(s) of serum potassium (S-K) from 2015.1.1 to 2017.12.31 were included. Hyperkalemia were defined as S-K > 5.0 mmol/L. The proportion of patients experience at least one hyperkalemia and the severity of hyperkalemia were calculated among overall outpatients and patients with chronic kidney disease (CKD), heart failure (HF), hypertension (HTN), and diabetes mellitus (DM). The geographic and seasonal distribution of the proportion among overall patients were calculated.

Results: A total of 1,039,245 patients with at least one S-K record each were analysed, in which 36615 (3.52%) patients experienced HK (S-K >5.0 mmol/L), 15059 (1.45%) patients experienced S-K ≥5.5mmol/L. Analysing the index S-K in HK patients, the composition of patients with S-K levels of 5.0-5.5, ≥5.5-6.0, ≥6.0-6.5, ≥6.5-7.0 and ≥7.0 mmol/L were 57.5%, 22.8%, 10.1%, 4.7% and 4.9%, respectively. In patients with CKD, HF, DM and HTN, the proportions of patients who experienced HK were 47.7%, 29.1%, 21.7% and 10.2%, respectively. Analysing the severity of HK in HK patients with CKD, HF, DM and HTN, the proportions of patients with S-K levels ≥5.5 were higher than that in overall ED patients. (Table). Geographic analysis showed that provinces with higher proportions of HK were Tianjin (6.2%), Jiangsu (6.1%) and Jilin (5.7%). Higher proportion of HK were observed in winter (4.1%) than in summer (2.9%).

Conclusions: The proportions of HK in ED patients with CKD, HF, HTN or DM were higher than that in overall ED patients, and the severity of HK increased in patients with CKD, HF, DM and HTN.

The composition of patients at different S-K intervals in hyperkalemia patients with/without CKD, HF, HTN, or DM in ED

S-K (mmol/L)	CKD, N (%)	HF, N (%)	DM, N (%)	HTN, N (%)	Patients without CKD, HF, DM or HTN, N (%)
5.0≤ K <5.5	1165 (38.6)	1786 (49.9)	1832 (49.4)	2018 (54.1)	14755 (65.3)
5.5≤ K <6.0	822 (27.2)	910 (25.4)	955 (25.7)	916 (24.6)	4554 (20.2)
6.0≤ K <6.5	457 (15.1)	471 (13.2)	458 (12.4)	393 (10.5)	1775 (7.9)
6.5≤ K <7.0	257 (8.5)	205 (5.7)	230 (6.2)	196 (5.3)	703 (3.1)

PO1453

Machine Learning Models for Risk Prediction of Adverse Events in Hyperkalemic Patients

Eiichiro Kanda,[1] Shun Kohsaka,[2] Suguru Okami,[3] Masafumi Okada,[4] Xiaojun Ma,[4] Toshitaka Yajima.[3] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Keio University, Tokyo, Japan; [3]AstraZeneca K.K., Osaka, Japan; [4]IQVIA Solution Japan K.K., Tokyo, Japan.*

Background: Hyperkalemia is a common electrolyte abnormality in heart failure (HF) and chronic kidney disease (CKD) patients. Although increased risks of adverse events in hyperkalemic patients have been well reported, there is limited information on causality of adverse events. Considering multifactorial conditions of hyperkalemic patients, we aimed to develop predictive models using novel machine learning algorithms.

Methods: We utilized a Japanese hospital claims registry, Medical Data Vision. We extracted hyperkalemic patients with either CKD and/or HF aged ≥18 years, defined as patients with ≥2 serum potassium values ≥5.1 mmol/L; from April 2008 to September 2018. Extracted dataset was split into 80:20 for training and validation. The risk of adverse clinical events including all-cause death, hospitalization for cardiac events, hospitalization for HF, and renal replacement therapy (RRT) introduction over 3 years after hyperkalemic episodes was modeled using gradient boosted tree (XG), neural network (NN), and logistic regression (LR) based on 81 clinical variables collected in 12 months before hyperkalemic episodes.

Results: Of 74,974 hyperkalemic patients, 8,480 patients were included. Mean age was 75.6 years and 53.7% were male. The ROC curve and calibration analyses showed excellent performance for death (AUC=0.841 [XG], 0.815 [NN], 0.838 [LR]), hospitalization for cardiac events (AUC=0.782 [XG], 0.718 [NN], 0.743 [LR]), HF (AUC=0.875 [XG], 0.850 [NN], 0.855 [LR]), and RRT (AUC=0.958 [XG], 0.917 [NN], 0.946 [LR]) (Table). Clinical variables with high importance were identified (Figure).

Conclusions: The machine learning model successfully identified high-risk hyperkalemic patients for adverse events. Despite the need for model validation, these results support the use of predictive models to select high-risk hyperkalemic patients.

PO1454

Extracellular Volume and Plasma Potassium Determine Urinary Prostaglandin E2 Excretion in Kidney Disease

Frank Geurts,[1] Dominique M. Bovee,[1] Martin Gritter,[1] Erik J. van Bommel,[3] Catherina A. Cuevas,[1] Daniël H. van Raalte,[3] Robert A. Fenton,[2] Ewout J. Hoorn.[1] *[1]Erasmus MC, Rotterdam, Netherlands; [2]Aarhus Universitet, Aarhus, Denmark; [3]Amsterdam Universitair Medische Centra, Amsterdam, Netherlands.*

Background: Prostaglandin E2 (PGE2) is the most abundantly produced prostaglandin in the kidney where it plays a key role in renin secretion and electrolyte handling. It is unknown whether urinary PGE2 excretion is a reflection of these functions in patients with kidney disease. Here, our aims were to (1) analyze the changes in urinary PGE2 excretion during interventions modulating extracellular volume (ECV) or electrolyte homeostasis and (2) identify the determinants of urinary PGE2 excretion.

Methods: Urinary PGE2 and PGE2 metabolite (PGEM) excretions were measured in two studies in chronic kidney disease patients: 1) a randomized cross-over trial comparing a low sodium (Na^+) diet (60 mmol/day) with amiloride/hydrochlorothiazide (n=26, each intervention 2 weeks), 2) a 2-week intervention with potassium chloride supplementation (40 mmol day, n=28), and in patients with diabetic kidney disease from a 12-week randomized trial comparing dapagliflozin (n=23) with gliclazide (n=19). The baseline data of these studies were combined (n=96) to identify determinants of urinary PGE2 using multivariable linear regression with correction for age, sex, eGFR, and study.

Results: A low Na^+ diet, amiloride/hydrochlorothiazide, and dapagliflozin reduced ECV and increased plasma renin. Amiloride/hydrochlorothiazide and dapagliflozin increased total urinary PGE2 excretion by 5.3% (95% CI 1.9-8.7%) and 5.8% (95% CI 0.9-10.8%), respectively, while a low Na^+ diet increased PGEM excretion by 5.9% (95% CI 1.2-10.6%). Potassium supplementation had no effect on ECV, plasma renin, or urinary PGE2 excretion. On multivariable linear regression total urinary PGE2 excretion was associated with plasma renin (β 0.3, 95% CI 0.2-0.4), urinary Na^+ excretion (β 0.003, 95% CI 0.0007-0.006), and plasma potassium (β 0.7, 95% CI 0.3-1.0).

Conclusions: Interventions that decrease extracellular volume increase urinary PGE2 excretion. In addition, plasma renin, urinary Na^+ excretion, and plasma potassium are independently associated with urinary PGE2 excretion. Our data suggest that in patients with kidney disease urinary PGE2 excretion not only reflects the kidney's response to changes in extracellular volume but also plasma potassium.

Patient and Clinician Preferences for Hyperkalemia Treatment: A Qualitative Study

Rubeen K. Israni,[1] Anne B. Brooks,[2] Tommi Tervonen,[2,3] Joanna C. Huang,[1] Harold M. Szerlip.[4] *[1]AstraZeneca, Wilmington, DE; [2]Evidera, London, United Kingdom; [3]University Medical Center Groningen, Groningen, Netherlands; [4]Baylor University Medical Center, Dallas, TX.*

Background: Treatment options for chronic hyperkalemia include the potassium binders Kayexalate®, Veltassa®, and since 2018, Lokelma®. In a qualitative research study, we explored which treatment characteristics are important to patients with hyperkalemia and treating clinicians.

Methods: Adult patients in the US who had received treatment for chronic hyperkalemia in the past 12 months and US clinicians who had treated ≥10 patients with chronic hyperkalemia with potassium binders in the last 3 months participated in focus group discussions consisting of concept elicitation and a ranking exercise, guided by a semi-structured discussion guide, with potential attributes identified through review of product labels.

Results: Twenty-five patients (52.4 ± 14.8 years; 56% male; 32% on dialysis; 20% kidney transplant recipients) and eight clinicians (n=4 nephrologists, n=2 cardiologists, n=2 hospitalists) participated. For patients, the most commonly reported medication side effect was diarrhea (64%), followed by abdominal pain and cramping (56%), nausea and/or vomiting, bloating/flatulence, and cramping in hands and legs (all 36%). The most disliked treatment characteristic was the medication's taste/texture; 58% of patients ranked it among three most important treatment characteristics. Although most patients reported gastrointestinal-related side effects, 54% did not rank diarrhea and 46% did not rank abdominal cramping in the top three characteristics. For clinicians, the most commonly encountered medication side effect was diarrhea (50%), followed by abdominal cramping (25%) and constipation (25%), and the most commonly considered treatment characteristic when prescribing a binder was taste/texture (50%), followed by time before/after taking medications (38%), time to onset (38%) and adherence (38%). Sustained efficacy followed by time to onset were ranked by 88% of clinicians as the two most important characteristics. Medication preparation, medication storage, and constipation were ranked low by both patients and clinicians.

Conclusions: Different potassium binder characteristics are most important to patients (taste/texture and abdominal cramping) and clinicians (sustained efficacy and time to onset). Clinicians should therefore take patient preference into consideration when prescribing a potassium binder.

PO1456

Patient Palatability and Preference Study of Three Potassium Binders in Patients with CKD and Hyperkalemia: Rationale and Design of the APPETIZE Study

Glen James,[1] Henning Søndergaard,[2] Carol P. Moreno Quinn,[1] Katarina Hedman,[3] Niklas Karlsson,[3] Jonatan Hedberg,[3] Eric T. Wittbrodt,[4] Ian Sabir,[1] Eskinder Tafesse,[4] Jennifer Kim,[4] Robin L. Allgren,[4] Gunilla Stjernlöf,[3] Mats Någård,[4] Hui-Lan Chung,[6] Jon D. Morris,[7] Lars Fransson,[3] Annika I. Rutgersson,[3] David C. Wheeler.[5] *[1]AstraZeneca PLC, Cambridge, United Kingdom; [2]Danish Kidney Association, Copenhagen, Denmark; [3]AstraZeneca, Gothenburg, Sweden; [4]AstraZeneca, Gaithersburg, MD; [5]University College London, London, United Kingdom; [6]AstraZeneca, Taipei, Taiwan; [7]AdSAM, Gainesville, FL.*

Background: Patients with CKD are at risk of hyperkalemia (HK) which has been associated with a higher risk of cardiovascular events and mortality. Recently approved K^+ binders provide new treatment options to fulfil the unmet need for HK treatment beyond traditional K^+ binders, which are poorly tolerated by patients and are associated with GI side effects.

Methods: APPETIZE is a cross-sectional, randomised cross-over study with the aim to evaluate the palatability of and patient preference for 3 currently available K^+ binders: Sodium Polystyrene Sulphonate (SPS) or Calcium Polystyrene Sulphonate (CPS), Sodium Zirconium Cyclosilicate (Lokelma®) and Calcium Patiromer Sorbitex (Veltassa®). A single (patient) blind side-by-side, sip and spit taste-test approach will be utilised where patients will be presented with a single full, per label dose of each product to replicate the real-world patient experience. Patient ratings, assessed on a 0-10 scale and emotional response using the AdSAM tool® to evaluate feelings (Appeal, Engagement and Empowerment) will be used to assess patient centric attributes: taste (primary outcome), texture, smell, mouthfeel and likelihood of adherence (secondary outcomes) of each product. Preferential ranking will be performed after all 3 products have been tested. Sixty CKD patients (both dialysis and non-dialysis) with HK per country (480 overall) from US, Canada, Spain, Italy, Germany, France, Sweden and Norway will be included, with equal proportions of patients ever-treated and never-treated with K+ binders.

Results: APPETIZE will describe, compare and rank palatability and preference of 3 currently available K^+ binders by country. Initial results are anticipated towards end of 2020.

Conclusions: Utilizing innovative methodology, APPETIZE will generate evidence intended for patients and physicians (including nephrologists and cardiologists) regarding patient palatability, patient preference and predicted likelihood of adherence for currently available K+ binders.

PO1457

Fixing the Kidneys to Fix the Heart: BRASH Syndrome, a Case Report

Man Kit Michael Siu, Muhammad Naveed, Mohammad-ehsan Owrangi, Ammar Rasul. *MedStar Health, Baltimore, MD.*

Introduction: BRASH (bradycardia, renal failure, AV-nodal blockade, shock, and hyperkalemia) is a multi-system syndrome. Immediate potassium removal is necessary and will result in resolution of cardiac arrhythmia.

Case Description: A 69 y/o male presented with generalized weakness, oliguric for 2 weeks and subsequence anuric. Lab was significant for hyperkalemia (6.2). EKG showed sinus bradycardia (HR 30), but without pathognomonic features of hyperkalemia. (Fig 1) Medical history significant for nephrectomy from an MVA injury, and IgA nephropathy s/p right renal transplant, hepatitis C, diabetes on insulin, and heart failure on Carvedilol 25mg BID. The patient was admitted to ICU and treated with calcium gluconate and insulin. Cardiology team was consulted for temporary pacers with eventual pacemaker insertion planned. However, upon discussion with the nephrology team, suspicion of BRASH syndrome was raised. Urgent CRRT was started. Rapid correction of potassium resulted in normalization of heart rate immediately. The patient received CRRT for 24 hours, and discharged on scheduled hemodialysis.

Discussion: BRASH syndrome is an uncommon presentation of a vicious cycle in the setting of hyperkalemia from acute kidney leading to the accumulation of AV node blockade medications. This synergizes bradycardia and hypoperfusion. Hypoperfusion, in turn, worsens renal failure leading to a cycle that continues until the patient deteriorates into lethargy, shock, and potentially death. Nowadays, despite commonplace to see patients with chronic kidney injury and cardiac diseases requiring AV nodal blocking medication, BRASH is still an underrecognized syndrome with only a handful of reported cases. Mild hyperkalemia without EKG changes make this diagnosis difficult, as such it is vital to recognize this syndrome from a multi-organ perspective - treatment with immediate correction of potassium via CRRT or hemodialysis can result in resolution without unnecessary transvenous pacing or pacemaker insertion.

Figure 1: Initial EKG on presentation.

PO1458

Laxative Use and Plasma Potassium Trajectory in Patients with Advanced CKD Transitioning to Dialysis

Keiichi Sumida,[1] Ankur A. Dashputre,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Yoshitsugu Obi,[1] Miklos Z. Molnar,[1] Elani Streja,[2] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA.*

Background: Intestinal potassium excretion is increased in patients with advanced CKD. This compensatory mechanism may be enhanced by laxative use; however, little is known about the association of laxative use with longitudinal potassium (K^+) balance in advanced CKD.

Methods: In 34,697 US veterans who transitioned to ESRD from 2007-2015 and with ≥2 K^+ measurements during the last 1-year period before ESRD transition, we examined the association of time-varying laxative use with change in K^+ (slope) over the 1-year pre-ESRD period, using multivariable linear mixed-effects models. The difference in K^+ slope by laxative use status was tested by the interaction of laxative use with time for K^+ slope in the mixed-effects models.

Results: Overall, the mean age was 68 years; 98% were male; 32% were African American; and 76% were diabetic. In the crude model, there was a significant difference in K^+ slope between laxative use and non-use, with declining K^+ slope observed only for laxative use (median, -0.010 vs. 0.008 mEq/L/year, P=0.02; **Table**). Although the magnitude of K^+ slopes was clinically negligible, the between-group difference remained significant even after multivariable adjustment, with laxative use being associated with decline in K^+ (median, -0.013 vs. 0.003 mEq/L/year, P=0.02; **Table**).

Conclusions: Laxative use was modestly and independently associated with decline in K^+ over the last 1-year pre-ESRD period, suggesting enhanced intestinal potassium excretion by laxatives. Further studies are warranted to test whether active interventions with laxatives can improve potassium management in advanced CKD beyond their traditional indication.

Funding: NIDDK Support

Changes in plasma potassium concentration associated with time-varying laxative use status during the last 1-year pre-ESRD period (n=34,697)

	Change in K^+ (median [IQI], mEq/L per year)		P[†]
	Laxative use	Non-laxative use	
Crude model	-0.010 (-0.21, 0.19)	+0.008 (-0.20, 0.20)	0.022
Multivariable-adjusted model[‡]	-0.013 (-0.19, 0.16)	+0.003 (-0.17, 0.18)	0.022

[†]*P* values were for the difference in K^+ slope by time-varying laxative use status.

[‡]Model was adjusted for demographics, smoking status, BMI, comorbidities, length of hospital stay, in-hospital AKI, number of K^+ measurements, last K^+ value, and time-varying medication use and eGFR

PO1459

Effect of Lactated Ringer Solution Use on Serum Potassium in Advanced Kidney Disease

Arun Rajasekaran, Naveen K. Bade, Abolfazl Zarjou. *UAB, The University of Alabama at Birmingham, Birmingham, AL.*

Background: Lactated Ringer's (LR) solution is a balanced crystalloid containing 4 mEq/L of potassium (K). Its use is restricted in hyperkalemia and in those with advanced kidney disease given potential concerns of exacerbating hyperkalemia. We assessed the effect of LR on serum K levels in patients with advanced kidney disease.

Methods: Retrospective evaluation of 191 patient encounters with advanced kidney disease [defined by estimated glomerular filtration rate (eGFR) of < 30 ml/min/1.73m^2 - including patients with acute kidney injury (AKI), chronic kidney disease (CKD), AKI on CKD, and end-stage kidney disease (ESKD) either on dialysis or post renal-transplantation] admitted at the University of Alabama at Birmingham Hospital between 9/1/2017 to 9/1/2018 who received LR for resuscitation and its effect on serum K levels. We stratified patients based on renal function; accounted for concomitant medication use that frequently potentiate hyperkalemia, use of K supplements, blood transfusions immediately prior to LR use, presence of sepsis, and administration of tube feeds.

Results: Average age of patients was 59 years. 19 patients had AKI, 60 patients had AKI on CKD, 20 patients had known CKD, and 61 had ESKD (including 11 who had renal transplantation). Average LR use was 1.9L per patient. Hyperkalemia [defined by serum K ≥ 5.2 mEq/L] was seen in 27 patient encounters (14.1% of the study population). However, 16 of these patients had average K of 5.8 mEq/L prior to LR use. 11 among them were managed with medications alone and 4 patients needed dialysis. Average and highest K levels among all patients within 24-hour post LR use were 4.2 mEq/L and 4.4 mEq/L respectively. 131 patient encounters had sepsis. There was 1 death attributable to hyperkalemia.

Conclusions: 27 out of 191 patient encounters (14.1%) with advanced kidney disease in our cohort had hyperkalemia within 24 hours post-LR administration, and 16 had known hyperkalemia prior to LR use. Our study demonstrates that LR use is not independently associated with hyperkalemia in advanced kidney disease, a population subset who frequently cannot renally excrete K adequately. Further large scale clinical studies are warranted to confirm our findings.

PO1460

Association Between Dyskalemias and Short-Term Hospital/Emergency Department Visits in Patients with Advanced CKD Transitioning to Dialysis

Ankur A. Dashputre,[1] Keiichi Sumida,[1] Justin Gatwood,[1] Fridtjof Thomas,[1] Oguz Akbilgic,[2] Praveen Kumar Potukuchi,[1] Yoshitsugu Obi,[1] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]Loyola University Chicago, Chicago, IL; [3]University of California Irvine, Irvine, CA; [4]Memphis VA Medical Center, Memphis, TN.*

Background: Patients with advanced CKD may experience immediate hospital/emergency department (ED) visit due to dyskalemia-associated adverse events (e.g. arrhythmias). The association of dyskalemias with short-term hospital/ED visits is understudied amongst those with advanced CKD transitioning to dialysis.

Methods: From among 102,477 US Veterans transitioning to dialysis between 2007-2015, we identified 21,150 patients with pre-dialysis eGFR <30 ml/min/1.73m^2 and a concurrent plasma potassium (K) measurement. We examined the association of hypokalemia [K <3.5], hyperkalemia [K >5.5] and normokalemia [3.5-5.5, reference] with hospital/ED visits within 2 days of plasma K measurement using logistic regressions adjusted for sociodemographics, smoking status, comorbidities, BMI, healthcare encounters, SBP, medications and eGFR.

Results: The mean age of the cohort was 67.3 years; 98% were male; 32% were African American. The mean eGFR and K were 22.3 ml/min/1.73m^2 and 4.6 mEq/L, respectively, and 7% and 3.5% of patients were hyper- and hypokalemic, respectively.

Three % of patients experienced a hospital/ED visit. Both hyper- and hypokalemia were significantly associated with higher risk of a hospital/ED visit in the crude (ORs [95% CIs] 2.73 [2.22-3.37] and 2.28 [1.68-3.09], respectively) and multivariable-adjusted models (2.47 [1.98-3.09] and 1.88 [1.37-2.58], respectively) (Figure).

Conclusions: Hyper- and hypokalemia are associated with higher short-term risk of hospital/ED visits in patients with advanced CKD. Preventing dyskalemias may help in reducing the incidence of short-term hospital/ED visit.

Association between dyskalemias and short-term hospital/emergency department visits in patients with advanced CKD

PO1461

Characteristics of CKD Patients with Hyperkalemia: A Report from the DISCOVER CKD Retrospective Cohort

Glen James,[1] Juan J. Carrero,[2] Supriya R. Kumar,[3] Steven Fishbane,[4] Carol P. Moreno Quinn,[1] Eric T. Wittbrodt,[3] Eiichiro Kanda,[5] Katarina Hedman,[6] Naoki Kashihara,[5] Mikhail Kosiborod,[7] Lam S. Carolyn,[13,14] Carol A. Pollock,[8] Peter Stenvinkel,[9] David C. Wheeler,[10] Roberto Pecoits-Filho.[11,12] *[1]AstraZeneca UK Ltd, Cambridge, United Kingdom; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Northwell, Manhasset, NY; [5]Kawasaki Medical School, Kurashiki, Japan; [6]AstraZeneca, Gothenburg, Sweden; [7]Saint Luke's Mid America Heart Institute, Kansas City, MO; [8]University of Sydney, Sydney, NSW, Australia; [9]Karolinska Universitetssjukhuset, Stockholm, Sweden; [10]University College London, London, United Kingdom; [11]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [12]Arbor Research Collaborative for Health, Ann Arbor, MI; [13]National Heart Centre Singapore, Singapore, Singapore; [14]Duke-NUS Medical School, Singapore, Singapore*.

Background: Hyperkalemia (HK), defined as serum potassium (sK^+) >5.0 mmol/L, is a potentially fatal condition most often observed in patients with chronic kidney disease (CKD), heart failure (HF) or diabetes and exacerbated by medications that inhibit the renin-angiotensin aldosterone system (RAASi). This real-world study describes characteristics of patients with HK in a large observational international study of CKD patients.

Methods: The DISCOVER CKD retrospective cohort was extracted using the US TriNetX hospital-EMR and Japan Medical Data Vision (JMDV) databases. The study included patients aged >18 years (>20 JMDV) with a diagnostic CKD code (stage 3A to Stage 5 including renal replacement therapy [RRT]) or 2 estimated glomerular filtration rate (eGFR) measures <75 mL/min/1.73m^2 at least 90 days apart between January 2008 and March 2020. The index date was 2nd sK^+ measurement >5.0 mmol/L. Descriptive analyses were used.

Results: Preliminarily, 16436 CKD patients with HK (43% female, mean±SD age 72.2±13.7 years) were identified. Common comorbidities included HF, hypertension and type 2 diabetes, which increased in prevalence with increasing HK severity, Table 1. Mean eGFR was 43.3±24 mL/min/1.73m^2 and mean sK^+ was 5.4±0.5 mmol/L. HK severity, RAASi and diuretic use increased as mean eGFR decreased.

Conclusions: HK was more common in patients with significant comorbidities where RAAS inhibitors have evidence-based indications. Future analyses will determine whether HK limits appropriate management of these comorbidities.

Table 1: Baseline characteristics of CKD patients with HK by severity.

PO1462

Ambulatory Treatments for RAAS Inhibitor-Related Hyperkalemia and the 1-Year Risk of Recurrence

Gregory L. Hundemer,[1] Navdeep Tangri,[2] Silvia J. Leon mantilla,[2] Manish M. Sood.[1] *[1]Ottawa Hospital, Ottawa, ON, Canada; [2]University of Manitoba, Winnipeg, MB, Canada*.

Background: Hyperkalemia commonly occurs with RAAS inhibitor (RAASi) use. The effectiveness of common outpatient interventions in preventing recurrent hyperkalemia has never been directly compared.

Methods: Population-based, retrospective cohort study of Ontario (Canada) residents ≥66 years old on RAASi therapy with ≥1 outpatient hyperkalemia (≥5.3 mmol/L) measurements between 2007-16. RAASi included ACE inhibitors, ARBs, MR antagonists, and ENaC inhibitors. Patients were included if they had one of the following interventions performed within 30 days of the hyperkalemia measurement: a) RAASi discontinuation, b) RAASi dose decrease, c) new K^+ wasting diuretic prescription, d) K^+ wasting diuretic dose increase, or e) sodium polystyrene sulfonate [SPS] prescription. The primary outcome was recurrence of hyperkalemia within 1 year. Secondary outcomes included major adverse cardiovascular events (MACE) and all-cause mortality within 1 year. Multivariable Fine and Gray sub-distribution models accounting for the competing risk of death were used for recurrent hyperkalemia and MACE outcomes. Multivariable Cox proportional hazards models were used for the all-cause mortality outcome.

Results: A total of 21,723 patients were included: RAASi discontinuation (N=13,539), RAASi decrease (N=5,075), new diuretic (N=1,010), diuretic increase (N=1,245), and SPS (N=854). RAASi discontinuation was associated with a lower risk for recurrent hyperkalemia and MACE over 1 year compared with other common hyperkalemia interventions (see **Figure**). However, there was no clear difference in 1-year all-cause mortality among these interventions.

Conclusions: RAASi discontinuation is associated with a lower 1-year risk for recurrent hyperkalemia and MACE compared with other common ambulatory interventions for hyperkalemia.

Lethal Refractory Hyperkalemia and Metabolic Acidosis in a Patient with Secondary Hemophagocytic Lymphohistiocytosis (HLH)

David Grand,[2] Mina Sourial,[1,2] Maureen E. Brogan,[1,2] Jyotsana Thakkar.[1,2]
[1]Montefiore Medical Center, Bronx, NY; [2]Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

Introduction: Renal replacement therapy (RRT) is used as an adjuvant therapy to treat severe electrolyte and acid-base abnormalities. We describe a case of severe metabolic acidosis (lactic acidosis) and hyperkalemia which was refractory to treatment with simultaneous continuous renal replacement therapy (CRRT) and hemodialysis (HD) in a patient with HLH.

Case Description: A 63-year-old female with a history of diabetes mellitus, warm antibody autoimmune hemolytic anemia was admitted to the hospital with hyponatremia and hyperglycemia diagnosed on outpatient labs. Her hospital course was complicated with fevers, severe lactic acidosis, worsening thrombocytopenia and anemia. Infectious and rheumatologic workup was negative. Presumed diagnosis of secondary HLH was made with elevated serum ferritin (100,000 ng/ml), elevated triglyceride levels (346 mg/dl), low fibrinogen levels (70 mg/dl), fevers, bicytopenia and elevated soluble IL-2 receptor levels (34177 units/ml). She was treated with etoposide and dexamethasone for secondary HLH. Nephrology was consulted for hyperkalemia, metabolic acidosis and elevated lactate in our patient with normal renal function. Hyperkalemia was thought to be due to ongoing hemolysis. Despite medical management with intravenous bicarbonate, albuterol and insulin, the hyperkalemia persisted so RRT was initiated. Her potassium levels did not improve despite her serum pH increasing to 7.33. Serum lactate remained persistently elevated to 21 mmol/L. Neither high dialysate flow rates (DFR) up to 7.5 liters per hour with a 2 meq/ dl potassium bath nor hemodialysis which followed, using a zero potassium dialysate bath, lowered the potassium level. The patient continued to have a wide complex QRS interval on her ECG and episodes of ventricular tachycardia and suffered from a cardiac arrest when her potassium was 6.9 meq/dl. Suspected malignancy associated secondary HLH was thought to be the possible etiology of her refractory lethal metabolic problems.

Discussion: HLH has been associated with severe type B lactic acidosis from excessive cytokine overproduction. Often, CRRT with higher DFR than recommended have been used in the past to achieve solute clearance. Our case was unique as the patient continued to have refractory hyperkalemia and elevated lactate despite receiving CRRT and HD and had poor outcomes.

PO1464

Laxative Use and Incidence of Dyskalemia in Patients with Advanced CKD Transitioning to Dialysis

Keiichi Sumida,[1] Ankur A. Dashputre,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1,2] Yoshitsugu Obi,[1] Miklos Z. Molnar,[1] Elani Streja,[2] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA.*

Background: Intestinal potassium excretion is increased in patients with advanced CKD. This compensatory mechanism may be enhanced by laxative use; however, little is known about the association of laxative use with dyskalemias in advanced CKD.

Methods: In 34,697 US veterans who transitioned to ESRD from 2007-2015 and with ≥2 plasma potassium (K^+) measurements during the last 1-year period before ESRD transition, we examined the association of time-varying laxative use with incidence of dyskalemia over the 1-year pre-ESRD period, using generalized estimating equations with adjustment for potential confounders. K^+ levels were categorized as <3.5, 3.5-≤5.5 (reference), and >5.5 mEq/L at each K^+ measurement and treated as a repeated multinomial outcome.

Results: The mean (SD) age of the cohort was 68 (11) years; 98% were male; 32% were African American; and 76% were diabetic. In the crude model, laxative use (vs. non-use) was significantly associated with higher risk of hypokalemia (OR [95% CI], 1.19 [1.13-12.5]) and lower risk of hyperkalemia (0.74 [0.71-0.78]) (**Table**). The associations of laxative use with dyskalemias remained statistically significant even after multivariable adjustment (adjusted ORs [95% CI] for hypo- and hyperkalemia, 1.08 [1.02-1.13] and 0.79 [0.76-0.83], respectively; **Table**).

Conclusions: Laxative use was independently associated with higher and lower risk of hypo- and hyperkalemia, respectively, during the last 1-year pre-ESRD period. Our findings suggest the putative role of constipation in potassium disarrays and the need for careful consideration for the risk-benefit profiles of laxatives in potassium management in advanced CKD.

Funding: NIDDK Support

Adjusted odds ratios (95% CI) for dyskalemia associated with time-varying laxative use (vs. non-use) during the last 1-year pre-ESRD period (n=34,697)

	Time-varying plasma potassium concentration (mEq/L)		
	<3.5 (hypokalemia)	3.5 to ≤5.5 (normokalemia)	>5.5 (hyperkalemia)
% of all repeated values	5.9%	88.6%	5.5%
Crude model	1.19 (1.13-12.5)	1 [reference]	0.74 (0.71-0.78)

†Model was adjusted for demographics, smoking status, BMI, comorbidities, length of hospital stay, in-hospital AKI, number of outpatient medical visits, and time-varying medication use and eGFR

PO1465

Acquired Bartter-Like Syndrome: An Unusual Presentation of Disseminated Tuberculosis

Isabelle Dominique V. Tomacruz, Anthony Russell Villanueva. *Philippine General Hospital, Manila, Philippines.*

Introduction: Acquired Bartter-like syndrome is a rare renal tubular disorder described to occur in granulomatous disorders such as sarcoidosis; but, its propensity to occur in tuberculosis (TB) is less known.

Case Description: We report the case of a 33-year-old Filipino woman with a 2-week history of lower extremity weakness. She had normal blood pressure and mild weakness on manual muscle testing. Abdominal examination revealed an incidental left lower quadrant mass. Workup revealed hypokalemia with urinary potassium wasting, hypercalciuria, hypomagnesemia, hypochloremia, and metabolic alkalosis, all consistent with Bartter-like syndrome. Abdominal CT scan findings were suggestive of disseminated TB. Ultrasound guided aspiration of the psoas abscess and pigtail insertion were done. Abscess aerobic, anaerobic, and fungal cultures did not isolate any organisms. Histopathology did not reveal any malignant cells. Detection of acid fast bacilli by Ziehl-Neelsen stain and culture confirmed the diagnosis. The patient was started on anti-TB therapy and was maintained on spironolactone, potassium and magnesium supplementation upon discharge. On follow up, electrolyte abnormalities resolved after four months of anti-TB therapy.

Discussion: TB may be a rare acquired cause of Bartter-like syndrome. Management involves treatment of the underlying cause, spironolactone and electrolyte supplementation.

Curious Case of Bartter Syndrome-Like Phenotype Unmasked by Diuretics

Prathima Gopinath, Krishna S. Ravipati, Pramodh Chanumolu, Siddhartha Kattamanchi. *Marshfield Clinic Health System, Marshfield, WI.*

Introduction: SLC12 A1 mutations have been associated with Bartter syndrome type 1. Here we present a case of severe hypokalemia with diuretics which when investigated led to discovery of a novel SLC12A1 mutation which might have predisposed the patient to Bartter syndrome like phenotype.

Case Description: 68 y/o f with no history of hypokalemia developed heart failure with preserved ejection fraction and was started on low dose loope diuretics which was gradually increased to1-1.5 mg po daily Bumetanide. She developed severe hypokalemia with diuretics which worsened with increasing diuretic doses, needing enormous amounts of potassium supplements. She continued to have persistent hypokalemia (serum potassium 3.0- 3.5 mmol/L) with significant urinary potassium excretion despite being on 260 mEq of oral potassium supplement/day, which improved mildly with addition of Amiloride. She also was hypotensive and was alkalotic secondary to diuresis. Given the significant kaliuresis leading to severe hypokalemia which was out of proportion to the dose of diuretics we did Genetic testing for presence of Bartter's mutation. Genetic testing revealed a novel heterozygous variant mutation in SLC12A1 gene. It showed 1972 C>T transition in exon 16 of SLC12A1 gene. This change converts a codon for leucine (CTT) to a codon for phenylalanine (TTT).

Discussion: Bartter syndrome (BS) type 1 is an autosomal recessive disorder caused by loss of function mutations. Mutations in SLC12A1 gene leading to dysfunction of NKCC2 co-transporter is one of the known mutations associated with Bartter's syndrome. There have been cases of heterozygous mutations of SLC12A1 gene which presented as Bartter syndrome. Our patient is unique as she has a novel heterozygous variant mutation in SLC12A1 gene and this mutation has not been reported to be associated with bartter syndrome. We believe this mutation might cause mild bartter phenotype. Our patient probably has a mild sublicnical Bartter like phenotype secondary to heterozygous variant of the mutation and developed severe hypokalemia when exposed to loop diuretics. Pursuing genetic testing for inappropriately severe hypokalemia needing exorbitant amount of potassium supplementation in a patient due to loop diuretic is a worthy consideration. Further research into this variant is needed to confirm it's pathogenicity.

PO1467

A Case of the Cons: How Contraception Confused Congenital Adrenal Hyperplasia for Conn

Linda-Marie U. Lavenburg, Sanjeev R. Shah, Sandeep Aggarwal. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Drospirenone is a synthetic progestin oral contraception (OCP) with anti-androgen and anti-mineralocorticoid properties. We present a case of hypokalemic alkalosis and hypertension masked by drospirenone use.

Case Description: A 21-year old female with presumed polycystic ovarian syndrome (PCOS) was referred for hematuria, facial rash, and positive ANA concerning for lupus nephritis. Her only medication was drospirenone-ethinyl estradiol for oligomenorrhea, acne and hirsutism. Blood pressure (BP) was 98/67mmhg and heart rate 88 bpm with orthostasis. She had male pattern hair loss and dense comedones on her cheeks. Labs were significant for normal renal function, 2+ hematuria with isomorphic RBCs, negative BHCG and ANA titer 1:64. Glomerulonephritis and rheumatology work-ups were negative. Hematuria was attributed to breakthrough uterine bleeding. Gynecology held her OCP to allow for withdrawal bleeding. At 6-week follow-up, she reported muscle cramps and increased facial hair. BP was 176/98 mmhg. Hypertension was confirmed with ambulatory BP monitoring. Labs were significant for potassium 2.8 meq/L, bicarbonate 37 meq/L, urine sodium 14 meq/L, potassium 54 meq/L, chloride 38 meq/L. Mineralocorticoid excess due to primary hyperaldosteronism (Conn's syndrome) was suspected but plasma renin activity was <1 and aldosterone was <1. Syndrome of apparent mineralocorticoid excess was considered but the presence of hirsutism prompted investigation of congenital adrenal hyperplasia (CAH). Work-up found elevated levels of ACTH (146 pg/ml), DHEA-S (694 mcg/dl), 11-deoxycortisone (452 ng/dl), and testosterone (92 ng/dl), but normal 17-OH progesterone, LH and FSH. Ultrasound showed bilateral adrenal enlargement, normal right and left ovaries with two dominant follicles. She declined genetic testing for 11-beta hydroxylase deficiency (11BHD). Clinical and lab findings were consistent with non-classical CAH due to 11BHD. She started hydrocortisone with suppression of ACTH, decrease in 11-deoxycortisone, and normalization of BP and electrolyte abnormalities.

Discussion: 11BHD is rare form of CAH, which can be confused with PCOS and other syndromes of mineralocorticoid excess. In this case, drospirenone use controlled symptoms but potentially delayed diagnosis of 11BHD. Clinical trials should assess drospirenone in treatment of endocrinopathies.

PO1468

Posaconazole-Induced Hypokalemia in a Hemodialysis Patient

Mital Patel, Minhtri K. Nguyen. *Ronald Reagan UCLA Medical Center, Los Angeles, CA.*

Introduction: Posaconazole is a commonly used antifungal agent that is used for prophylaxis in many transplant recipients. Its side effect profile can vary from cardiovascular effects to metabolic derangements, such as hypokalemia. A prior case report of apparent mineralocorticoid excess (AME) secondary to Posaconazole therapy has been reported in 2017; however, this has not previously been reported in the ESRD patient population.

Case Description: A 68-year-old male with past medical history of idiopathic pulmonary fibrosis who underwent left lung transplant in December 2019 was consulted for acute kidney injury (AKI). Etiology of AKI was attributed to Tacrolimus induced thrombotic microangiopathy that ultimately required initiation of hemodialysis. Posaconazole 200mg PO daily was used for anti-fungal prophylaxis. Throughout the hospitalization, persistent hypokalemia was observed despite dialyzing the patient against a 4K bath. Further hypokalemia evaluation revealed plasma renin level at lower limit of normal (0.5ng/mL/hr), and low plasma aldosterone level at <3.0 ng/dL. 24 hr urinary cortisol-to-cortisone ratio was non-diagnostic likely due to an inadequate collection (creatinine 160 mg/24 hr).

Discussion: We identified a case that mimics apparent mineralocorticoid excess syndrome, where patients receiving Posaconazole behave as if they have increased serum aldosterone levels; however, when serum levels are measured, aldosterone levels are in fact low. Patients are unable to metabolize cortisol to cortisone due to a defect in 11β-hydroxysteroid dehydrogenase. This leads to an accumulation of cortisol, allowing it to bind to the aldosterone receptor and increase sodium entry intracellularly via the epithelial sodium channel (ENaC). Stimulation of the ENaC then leads to potassium secretion and subsequent hypokalemia. Common lab findings include: hypokalemia, low serum renin and aldosterone levels, and elevated urine cortisol/cortisone ratio. Similar presentations can be seen with licorice ingestion, hereditary AME, and carbenoxolone use. This case illustrates the unique presentation of Posaconazole-induced hypokalemia in an ESRD patient (a population that typically experiences hyperkalemia and poor clearance of potassium), who was dialyzed against a 4K bath but persistently remained hypokalemic.

PO1469

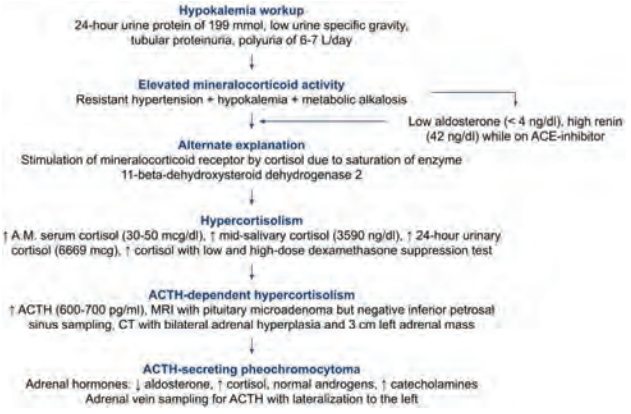
Hypokalemia from ACTH-Secreting Pheochromocytoma

Sana J. Shaikh,[1,2] Anitha Vijayan,[2] Anubha Mutneja.[2] *[1]Barnes-Jewish Hospital, Saint Louis, MO; [2]Washington University in Saint Louis, Saint Louis, MO.*

Introduction: The kidney is the critical effector organ in potassium homeostasis and mineralocorticoids (MC, usually aldosterone), distal sodium delivery and urine flow impact its response. Hypokalemia with HTN and metabolic alkalosis points to high MC activity. This can be classified as (a) ↑renin ↑aldosterone (b) ↑aldosterone despite ↓renin or (c) ↓renin ↓aldosterone. Here we describe an unusual case of hypokalemia due to ACTH-secreting pheochromocytoma.

Case Description: 62-year-old man with resistant HTN, DM, multiple sclerosis was admitted for persistent hypokalemia. Medications were KCL 360 mEq/day, amlodipine, carvedilol, doxazosin, hydralazine and lisinopril. Labs showed hypokalemia (2.4 mmol/L) and metabolic alkalosis (HCO_3 31 mmol/L). Urinary potassium losses were significant. After aldosterone level returned low, focus shifted towards hypercortisolism as a cause of MC activity. Studies confirmed raised cortisol and high ACTH. Pituitary gland workup was negative. Investigation for ectopic ACTH production revealed bilateral adrenal hyperplasia and discrete left adrenal mass. Adrenal hormone workup detected raised catecholamines. Adrenal vein sampling for ACTH showed laterization to the left. After alpha and beta-blockade, laparoscopic left adrenalectomy was done. Intraoperative biochemistry and pathology confirmed ACTH-secreting pheochromocytoma.

Discussion: In the distal nephron, cortisol is inactivated to cortisone by 11-beta-dehydroxysteroid dehydrogenase 2 (11βHSD2). Hypercortisolism causes relative deficiency of 11βHSD2 due to enzyme saturation. Cortisol then stimulates non-selective MC receptor. Systematic workup led to diagnosis of ACTH-secreting pheochromocytoma. After resection of ectopic ACTH source, patient became normokalemic and was discharged with steroid replacement.



Laparoscopic left adrenalectomy

	Left Adrenal	Right Adrenal	Peripheral Blood
Norepinephrine	297607	4423	2528
Epinephrine	160582	23397	1052
Dopamine	4632	150	50
ACTH	> 2000	489	725
Aldosterone	6.2	20	<4
Cortisol	288	800	47

Intraoperative chemistry as noted above.
Biopsy showing adrenal cortical hyperplasia, and a 4.3 centimeter pheochromocytoma confined to the gland and with uninvolved resection margins.

PO1470

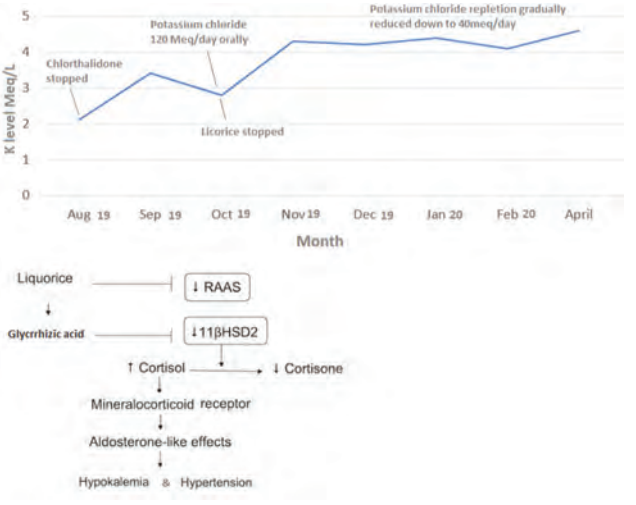
An Interesting Case of Hypokalemia

Adil Ghaffar, Tripti Singh. *University of Wisconsin System, Madison, WI.*

Introduction: Hypokalemia (serum potassium <3.5 meq/L) is one of the most common abnormalities encountered in nephrology practice. With careful history and laboratory investigations, the cause can usually be found.

Case Description: A 68-year-old caucasian male with Hypertension was referred for hypokalemia with level of 2.1 meq/L, serum bicarbonate was 27 meq/L and serum magnesium was 1.7meq/L. His antihypertensives were lisinopril 40mg and chlorthalidone 25mg daily. Despite discontinuation of chlorthalidone, he still required 120 meq of potassium chloride ER tablets daily with potassium levels at 2.8 to 3 meq/L. 24 hr urine potassium was 51 meq/L, denoting renal potassium wasting. Serum cortisol and ACTH levels were normal. Serum aldosterone level was <3 ng/dl and renin activity was 0.1 ng/ml/hr. Upon further exploration, he reported use of licorice for few months. He was advised to stop its use with subsequent improvement of potassium levels to above 4 meq/L and a reduction in potassium repletion.

Discussion: The causes for hypokalemia with hypertension and renal potassium wasting can be differentiated with serum aldosterone, renin activity and cortisol levels. In primary hyperaldosteronism, serum aldosterone is elevated and renin activity suppressed whereas in secondary form, both are elevated. When both are suppressed, it denotes either apparent mineralocorticoid excess, Liddle syndrome, cortisol excess or licorice use. Our patient had normal cortisol level, presented late in adulthood excluding Liddle syndrome and apparent mineralocorticoid excess, and making licorice as a likely cause. He had been chewing black licorice for its taste. Licorice was used in the past for gastric ulcers but it is rarely used nowadays. It inhibits the conversion of cortisol into inactive cortisone, allowing cortisol to act on the mineralocorticoid receptor. The use of licorice should be explored, whenever one encounters renal potassium wasting with suppressed renin and aldosterone.



PO1471

Thyrotoxic Periodic Paralysis: A Stunning Diagnosis

Piotr Starakiewicz, Syed A. Husain. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Thyrotoxic periodic paralysis (TPP), acute hypokalemia and proximal muscle weakness in the setting of thyrotoxicosis, is primarily seen in Asian men with undiagnosed hyperthyroidism in the 2nd-4th decade, often with family history of paralysis and thyroid disease. We describe a case of a young male presenting with acute TPP.

Case Description: A 28year-old white male with no medical history presented with acute onset diffuse weakness with inability to get out of bed, preceded the night prior by leg stiffness. He exercised 2 days prior. He reported marijuana use and a balanced diet. He denied recent travel, medication or supplements. His father had Hashimoto's thyroiditis. Exam showed tachcyardia (106 bpm) and hypertension (132/74 mmHg), and EKG revealed sinus tachycardia with QTc 629. Labs showed: K+ 1.7 mEq/L, HCO3- 22 mmol/L, Cr 0.7 mg/dL, TSH <0.01, fT4 >6ng/dL, and T3 320ng/dL. Fractional excretion of K+ was 3.2%. He was treated with 120mEq KCl with repeat K+ 5.6 mEq/L in 4 hours and symptom resolution. Elevated TSH receptor, anti-thyroglobulin, and thyroid stimulating antibodies with a homogenous radioactive iodine uptake scan [Fig 1] confirmed Grave's disease. He was started on metoprolol and methimazole and discharged home without further episodes.

Discussion: TPP results from acute intracellular K+ shift due to Na/K-ATPase activation in myocytes from a hyperadrenergic state (increased number and sensitivity of β-receptors) and thyroid hormone stimulation. Muscle hyperpolarization and loss of excitability required for contraction results. Body K+ stores remain unchanged. Episodes are associated with high insulin or epinephrine states (eg. mornings, exercise, high-carbohydrate meal). Paralysis, lasting minutes to days, is ascending, symmetrical, and proximal, chiefly affecting legs (bulbar or respiratory involvement is rare). Usually painless, it can be preceded by muscle aches or cramps. Sinus tachycardia is common and life-threatening arrhythmias can occur. Labs demonstrate normal acid-base status and low urinary K. CPK can be elevated. Low TSH, elevated free T4 and T3 confirm the diagnosis. Treatment involves cautious K replacement (due to risk of rebound hyperkalemia), non-selective β-blockers, and therapy for hyperthyroid state

PO1472

CYP24A1-Hypercalcemia in Pregnancy

Sana J. Shaikh,[2,1] Anitha Vijayan.[1] *[1]Washington University in Saint Louis, Saint Louis, MO; [2]Barnes-Jewish Hospital, Saint Louis, MO.*

Introduction: Hypercalcemia due to primary hyperparathyroidism and malignancy is common. However, rare genetic mutations in VitD metabolism (CYP24A1 & SLC34A1) are often culprits.

Case Description: 33-year-old woman with chronic hypercalcemia, nephrocalcinosis, CKD 3, HTN was admitted at 34-weeks of gestation for symptomatic hypercalcemia (13.2 mg/dL). Labs showed ↓PTH (9 pg/mL), ↓/↔25-VitD (35 ng/mL) & ↑/↔1,25-VitD (65 pg/mL). Defect in VitD pathway was suspected. 25-VitD:24,25-VitD ratio returned raised (178). Genetic testing confirmed compound heterozygous CYP24A1 mutation.

Discussion: CYP24A1 gene encodes 24-hydroxylase which inactivates 25-VitD and 1,25-VitD to 24,25-VitD and 1,24,25-Vit D. Biochemical profile includes ↑ serum & urinary calcium, ↓PTH, ↑25-VitD:24,25-VitD ratio +/- ↑ 1,25-VitD & 25-VitD. 25-VitD:24,25-VitD > 80 warrants genetic analysis. Azoles inhibit 1-hydroxylase and ↓1,25-VitD, and can be utilized. Steroids ↓1,25-VitD production by activated macrophages, inhibit intestinal calcium absorption and induce CYP24A1, but this cohort is often resistant. Pregnancy upregulates 1-hydroxylase, rendering patients with CYP24A1 mutations sensitive to hypercalcemia. Antepartum therapy options are limited. To limit adverse impact on maternal and fetal health, delivery may be required.

PO1473

A Case of Medication-Induced Hypercalcemia: But It Is Not What You Think

Harsha Aramada, Ashish Sharma, Khaled Nashar. *Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.*

Introduction: Hyperkalemia is a life-threatening complication of CKD. Patients with diabetes mellitus, congestive heart failure, and those receiving renin angiotensin aldosterone inhibitors are at particularly high risk of developing hyperkalemia. We present a case of hypercalcemia, possibly related to patiromer.

Case Description: A 71-year-old man with past medical history of hypertension, right nephrectomy for renal cell cancer and chronic kidney disease stage GIIIb-IV A3. Serum Cr levels range was 3.5-3.9 mg/dl. Patient was placed on losartan 100 mg to slow the progression of his CKD, and as a result he developed mild to moderate hyperkalemia (5-6.2 mEq/dl). His hyperkalemia persisted despite dietary modification. Patiromer was begun at a dose of 8.4 g/day. Dose was uptitrated to 25.2 g/day to maintain potassium levels < 5.5 mEq/dL. A few months later he developed mild hypercalcemia with serum calcium levels ranging between 10.4- 11.5 mg/dL. The patient was not receiving any oral calcium or vitamin D supplements. His work up included 25 hydroxy Vit D and 1-25 dihydroxy vitamin D levels which were normal at 28 ng/mL and 40 pg/mL respectively. Magnesium levels were normal 1.8-2.0 mg/dL. His PTH level was suppressed for his level of kidney function at 13pg/mL. TSH level was normal at 4 mIU/L. PTH-rp was 13 (normal: 14-27). Urine and serum protein electrophoresis did not reveal paraprotenemia. Given the absence of a clear explanation for his non-PTH mediated hypercalcemia, patiromer was considered as a possible cause. Patiromer was stopped and zirconium cyclosilicate was started. Serum Ca levels began to decline and returned to normal at 9.8 mg/dl two months after the discontinuation of patiromer.

Discussion: Patiromer is a cation exchange resin approved by the FDA in 2015 for the treatment of hyperkalemia. It binds to potassium in exchange for calcium predominantly in distal colon, facilitating increased fecal potassium excretion. Clinical trials that led to the approval of patiromer did not find any increase in serum calcium levels. However, hypomagnesemia was noted. This prompted the recommendation for the need to monitor magnesium levels while receiving the drug. There are only two other reports in the literature of hypercalcemia attributed to patiromer. Our findings call for further investigation and the need for monitoring serum calcium following the initiation of this treatment.

PO1474

An Unusual Source of Hypercalcemia

JoBeth McCoy. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Hypercalcemia is a common electrolyte abnormality seen in daily practice. This case describes elevated serum calcium from a common cause, but an unexpected source.

Case Description: A 62-year-old female presented with complaints of fatigue, weight loss, and weakness. She was found to have a calcium level of 14mg/dL, acute kidney injury with a creatinine of 2.9 mg/dL from a baseline of 1.6mg/dL, and severe weight loss of 60lbs in the past 6 months. She had been evaluated for malignancy with no concerning findings. Initial workup included: parathyroid hormone (PTH) 8pg/mL, 25, vitamin D 22ng/mL, and creatinine phosphokinase 75u/L. There was concern for occult malignancy so further workup included a serum and urine protein electrophoresis that was negative, parathyroid hormone-related protein (PTHrp), 1,25 dihydroxy vitamin D, and Histoplasma antigen. She had a full-body computed tomography (CT) scan without contrast to look for occult malignancy which was negative for any granulomas, masses, adenopathy, or bony lesions. 1,25 vitamin D was elevated at 238 pg/mL. PTHrp was

elevated at 5.4 pmol/L. It was thought that Positron Emission Testing (PET) was needed and showed extensive skeletal muscle uptake that was nonspecific. With this result, she underwent a biopsy of the quadriceps muscle. She then had electromyography consistent with myositis with a nonspecific pattern. The muscle biopsy showed non-necrotizing intramuscular granulomas consistent with sarcoid-like myositis. She was started on prednisone 60mg daily. Within three days, her serum calcium had decreased to normal.

Discussion: Sarcoidosis is a multisystem disorder of unknown etiology, which is characterized by the accumulation of noncaseating granulomas in involved tissues. The pathogenesis is unclear, but the histopathologic findings of sarcoidosis in the muscles appear as granulomatous inflammation in muscle that leads to muscle fibrosis and tissue injury. The most common is a chronic myopathy with insidious onset of proximal muscle weakness. In our case, the elevated serum calcium and calcitriol guided the diagnosis. Hypercalcemia in granulomatous disease has been described to be secondary to high levels of calcitriol that increase intestinal reabsorption of calcium. Sarcoidosis, though a common entity, can declare itself through extrapulmonary sources and must remain in the differential for all hypercalcemia cases.

PO1475

Amiloride Effects on Urine Calcium in the Setting of Urolithiasis

Kian Ahmadieh,[1] Jonathan Moore,[1] Maya Patel,[2] Mira T. Keddis,[1] Karen L. Stern.[1] *[1]Mayo Clinic Arizona, Scottsdale, AZ; [2]The University of Arizona College of Medicine Phoenix, Phoenix, AZ.*

Background: Medical management of urolithiasis often targets the biochemical properties of urine to prevent further development of stone burden. Thiazide diuretics are commonly used for recurrent stone formation in patients with hypercalciuria. However, data related to the use of potassium-sparing diuretic amiloride is relatively scarce and the aim of this study is to investigate amiloride's effects on urinary calcium and other properties of urine in prevention of urolithiasis.

Methods: All nephrolithiasis patients who were prescribed amiloride for treatment of hypercalciuria between the years 2011 and 2019 at a single tertiary care center were retrospectively reviewed. Patients met criteria if they had a pre and post treatment 24 hour urine collections. Pre and post urinary calcium levels were compared. Other comparative measures include levels of other stone risk factors measured on urine collections, stone events on treatment and adverse reaction to medication.

Results: A total of 31 patients were started on amiloride. Of those, 15 patients tolerated the medication and completed follow-up urine testing. Amiloride was given due to intolerance of thiazide (11, 73%), persistent hypercalciuria on thiazide (3, 20%), or as combination with thiazide (1, 7%). Maximum treatment dose ranged from 2.5 mg daily to 5 mg BID. Mean duration on treatment was 57.2 months (SD 32.5;9-96). Three (20%) patients stopped due to delayed intolerance and 2 (13%) due to elevated urinary calcium. In the overall cohort, there was no significant difference in urine parameters (Table 1) including urinary calcium (286.3 mg/day pre vs 310.0 mg/day post, p=0.552). Three (20%) had a stone event at a mean of 23.3 months on treatment with 1 surgery, and 2 passage of stones. Six (40%) patients showed metabolic activity with new or growing stones.

Conclusions: In patients that have failed thiazides for treatment of hypercalciuria, switching to or adding amiloride did not result in lower urinary calcium levels.

24 Hour Urine Parameters before and after amiloride treatment

24 urine Parameter	Pre-amiloride (SD)	Post-amiloride (SD)	P-value
Volume (L)	2.37 (0.93)	2.69 (0.86)	0.316
SS Calcium Oxalate	7.15 (3.74)	6.22 (2.8)	0.078
Calcium mg/day	286.3 (103.8)	310.0 (175.6)	0.552
Oxalate (mg/d)	42.5 (16.6)	37.5 (7.94)	0.316
SS Calcium Phosphate	1.52 (1.16)	1.09 (0.80)	0.193

PO1476

Hospital-Acquired Phosphate Derangements and Associated In-Hospital Mortality

Michael A. Mao,[1] Charat Thongprayoon,[2] Wisit Cheungpasitporn,[3] Api Chewcharat,[2] Kianoush Kashani.[2] *[1]Mayo Clinic's Campus in Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of Mississippi Medical Center, Jackson, MS.*

Background: We aimed to report the incidence of hospital-acquired hypophosphatemia and hyperphosphatemia along with their associated in-hospital mortality.

Methods: We included 15,869 adult patients hospitalized at a tertiary medical referral center from January 2009 to December 2013 that had normal serum phosphate levels at admission and at least two serum phosphate measurements during their hospitalization. The normal range of serum phosphate was defined as 2.5-4.2 mg/dL. In-hospital serum phosphate levels were categorized based on the occurrence of hospital-acquired hypophosphatemia and hyperphosphatemia. We analyzed the association of hospital-acquired hypophosphatemia and hyperphosphatemia with in-hospital mortality using multivariable logistic regression.

Results: Fifty-four percent of patients developed new serum phosphate derangements during their hospitalization. The incidence of hospital-acquired hypophosphatemia and hyperphosphatemia was 35% and 27%, respectively. Hospital-acquired hypophosphatemia and hyperphosphatemia were associated with odds of 1.56 and 2.60 for in-hospital mortality, respectively (P-value<0.001 for both). Compared with patients with persistently normal in-hospital phosphate levels, patients with hospital-acquired hypophosphatemia only (OR 1.64), hospital-acquired hyperphosphatemia only (OR 2.74), and both hospital-acquired hypophosphatemia and hyperphosphatemia (i.e., phosphate fluctuations; OR 4.00) were significantly associated with increased in-hospital mortality (all p-value<0.001).

Conclusions: Hospital-acquired serum phosphate derangements affect approximately half of hospitalized patients and are associated with increased in-hospital mortality rate.

Table 2 Association between hospital-acquired serum phosphate derangements and in-hospital mortality

Serum phosphate during hospitalization	N (%)	In-hospital mortality (%)	Univariable analysis		Multivariable analysis	
			OR (95% CI)	p	Adjusted OR (95 % CI)	P
Hospital-acquired hypophosphatemia

Adjusted for age, sex, race, principal diagnosis, Charlson comorbidity score, coronary artery disease, congestive heart failure, peripheral vascular disease, stroke, diabetes mellitus, chronic obstructive pulmonary disease, cirrhosis, end-stage renal disease, eGFR, acute kidney injury, number of serum phosphate measurements, length of hospital stay, and admission serum phosphate level.

Association between hospital-acquired serum phosphate derangements and in-hospital mortality

PO1477

Pseudohypophosphatemia Caused by Severe Leukocytosis in a Patient with Chronic Lymphocytic Leukemia (CLL) and Tumor Lysis Syndrome (TLS)

Mehrian Jafarizade, Grace Y. Chong, Joseph C. Guzzo, Nelson P. Kopyt, Margaret Duffy. *Lehigh Valley Health Network, Allentown, PA.*

Introduction: TLS is an oncologic emergency, which can cause life-threatening electrolyte derangements. Classic laboratory abnormalities in TLS include hyperphosphatemia, hyperkalemia, hypocalcemia, and hyperuricemia. In cases of severe hyperleukocytosis, false laboratory abnormalities can occur, and can lead to apply inaccurate, potentially harmful treatments.

Case Description: A 71-year-old man with a history of CLL was admitted for dyspnea and volume overload. He had recently started venetoclax one week prior to presentation. Labs revealed a WBC of 79,300/cm^2 (33% blasts), creatinine 1.49 mg/dL (baseline 0.80 mg/dL), serum potassium 7.2 mmol/L, CO_2 8 mmol/L, calcium <5.0 mg/dL, phosphorus 0.5 mg/dL, and uric acid 8.9 mg/dL. He was diagnosed with TLS and treated with rasburicase. Despite aggressive phosphorus repletion, the patient remained severely hypophosphatemic, though he was never symptomatic. Given the incongruence between lab values and clinical status, we suspected a lab error. We ordered STAT labs, sent on ice, which revealed normal serum phosphorus (4.5 mg/dL) on the same day that labs processed by standard protocol revealed a low level (0.9 mg/dL). Other discordant results noted were hyperkalemia (>9.5 mmol/L but 3.7 on a point-of-care arterial blood sample), hypoxemia (pO2 <48 mmHg on ABG but 98% on pulse oximetry room air), and hypoglycemia (serum blood glucose 9 mg/dL but 86 on point-of-care finger testing).

Discussion: This abstract reports the first case of reported pseudohypophosphatemia in a patient with CLL. The pathophysiology of pseudohypophosphatemia is thought to involve a sodium-phosphate co-transporter, though the exact underlying pathophysiology is unknown. Pseudohypoxemia and pseudohypoglycemia, also described in hematologic disorders, are thought to be due to increased metabolic demands by blasts, which decrease oxygen tension and glucose levels in vitro. Increased leukocyte fragility in CLL patients can lead to pseudohyperkalemia. In conclusion, it is crucial to verify lab abnormalities in patients with hyperleukocytosis with point-of-care or deliberate (i.e. arterial blood sample on ice or STAT) sample collection. Failure to recognize psuedohypophosphatemia may result in unnecessary phosphorus repletion, leading to potential harm for the patient.

PO1478

A Deadly Treatment for Opioid-Induced Constipation

Maria T. Story, Mony Fraer. *The University of Iowa Hospitals and Clinics Department of Internal Medicine, Iowa City, IA.*

Introduction: Hypermagnesemia is a rare but serious complication of exogenous magnesium (Mg) administration that can occur when GFR is reduced. We describe a case of Mg citrate ingestion for opioid-induced constipation (OIC) and the deadly consequences.

Case Description: A 68-year-old female with history of lumbar spinal stenosis, chronic kidney disease stage IIIA, and hypertension was admitted to our ICU with distributive shock. Over the last month, she had seen physicians 7 times for severe low back pain and was prescribed high quantities of oxycodone and NSAID's. She developed constipation and her rheumatologist instructed she take a bottle of OTC Mg citrate. The next day, she presented to the ED for shortness of breath. Exam: BP 76/52, HR 118, Oxygen sat 86% on room air. She was ill appearing and tachypneic, with a firm/distended abdomen. CT abdomen/pelvis revealed a severe ileus. Labs: acute kidney injury (Creatinine 2 weeks prior 1.1, up to 3.3 mg/dL) and severe hypermagnesemia of 7.5 mg/dL. She was admitted to the ICU, started on pressor support and intubated. Twelve hours later, CVVHD was initiated for severe hypermagnesemia and oliguric AKI; however, her pressor requirements progressively increased until she was on 3 drugs. Eventually, her family decided to withdraw care.

Discussion: Hypermagnesemia is a rare event and occurs in the context of high dose Mg administration (ie. eclampsia treatment) or Mg ingestion in acute or chronic kidney disease. Mg acts as a calcium channel blocker, causing hypotension, bradycardia, muscle paralysis, somnolence, hypocalcemia, respiratory failure, and eventually cardiac arrest. The severity of manifestations is concentration dependent. Management includes IV fluids, loop diuretics, and IV calcium (if the patient is making urine). Hemodialysis is often required for those with severe AKI or ESRD. This case illustrates the challenges of care coordination and duplicate medication prescribing among multiple physicians/practices. OIC was preventable with a bowel regimen. She received 3 different NSAIDs which led to AKI on CKD IIIA. Magnesium citrate was rapidly absorbed systemically in the context of ileus and Mg toxicity developed in the setting of low GFR. Nephrology consultation was delayed, resulting in prolonged severe hypotension, late hemodialysis initiation and ultimately death. These complications were entirely avoidable with a more thoughtful approach to medication prescribing.

PO1479

Constipation to Neuromuscular Deficits: A Case of Hypermagnesemia

Mal P. Homan, Tyler Boozel, Stacey J. Smith. *Lehigh Valley Health Network, Allentown, PA.*

Introduction: Magnesium is a relatively safe over-the-counter cathartic and antacid, but may have dangerous side effects. Hypermagnesemia can be precipitated by renal insufficiency, active gastrointestinal illness, or excessive intake of magnesium. Symptoms, which include neuromuscular and cardiovascular effects, can start when levels exceed 4.8mg/dL.

Case Description: A 60-year-old female with a medical history of bipolar affective disorder, seizures, migraines, type 2 diabetes, and past subarachnoid hemorrhage presented with slurred speech and weakness leading to a fall. She complained of chronic constipation and had taken an unknown amount of milk of magnesia with her docusate. Neurologic exam revealed slowed speech and symmetric muscle weakness. Labs revealed sodium 121mEq/L, creatinine 1.01(baseline 0.5) mg/dL, magnesium 10.0mg/dL, calcium 8.0mg/dL, and phosphate 6.5mg/dL. After imaging ruled out any intracranial pathology, the patient was diagnosed with hypermagnesemia, then started on IV fluids and loop diuretics. Her electrolytes and kidney function continued to correct with hydration, diuretic therapy, and stopping all magnesium-containing medications. It was discovered that she had ingested 52 grams of magnesium by drinking two 26oz bottles. Her weakness improved throughout the second day and returned to full muscle strength by the third. She was discharged with a magnesium level of 2.3mg/dL.

Discussion: This case demonstrates the importance of physician awareness regarding the effects of hypermagnesemia. Although hypermagnesemia is multiple symptoms, "few clinicians associate these symptoms with high levels of serum magnesium, due to an overall unfamiliarity with this condition." An article reported that more than 86% of patients with hypermagnesemia are clinically unrecognized, and in most hospitals, the measurement of magnesium is based on the physician's judgement. Treatment consists of magnesium removal (IV fluids, loop diuretics, or dialysis), stopping magnesium use, and gastrointestinal decontamination. Calcium can also be used as an antagonist by competitively inhibiting magnesium. Prompt recognition is necessary because when magnesium levels are greater than 7.2mg/dL, patients can develop hemodynamic changes (bradycardia, hypotension) and once levels exceed 12mg/dL, symptoms could become fatal (respiratory failure, heart block, cardiac arrest, and flaccid quadriplegia).

PO1480

Clinicopathological Characteristics and Long-Term Prognosis of Monoclonal Immunoglobulin Light Chain-Associated Fanconi Syndrome

Jiaying Li, Xiaoxiao Shi, Peng Xia, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Monoclonal immunoglobulin light chain associated Fanconi syndrome (LC-FS) is a rare disease which involved the proximal tubules. As most of the cases came from western countries, we aimed to analyze the clinicopathological characteristics of Asian LC-FS and its long-term prognosis.

Methods: From January 1998 to February 2019, 26 patients who were diagnosed with both FS and monoclonal gammopathy in Peking Union Medical College Hospital were enrolled. Their clinicopathological and follow-up records were retrospectively reviewed.

Results: At diagnosis, the mean age of the 26 Asian LC-FS patients was 54.7±14.7 years, with females accounting for 57.7 %. The underlying malignancies included monoclonal gammopathy of renal significance (MGRS, n=14, 53.8%), multiple myeloma (MM, n=10, 38.5%), Waldenstrom macroglobulinemia (WM, n=1) and primary plasma cell leukemia (PPCL, n=1). The most common symptoms were fatigue (95.7%), ostealgia (88.5%) and nocturia (61.1%). Their mean eGFR was (68.0 ± 26.4) ml/min/1.73m^2, with different degrees of proximal tubular dysfunctions, including normoglycemic glycosuria (88.0%), hyperphosphaturia (84.2%), aminoaciduria (84.0%), hypouricemia (80.8%), hypophosphatemia (80.8%), RTA (73.1%), and hypokalemia (42.3%). For kidney pathology, some specific features of LC-FS were observed in proximal tubular cells, including k deposition, intracellular crystalline formation and increased lysosomes. A total of 13 patients received chemotherapy, which mainly included bortezomib-based (n=6) and melphalan-based (n=2) regimens. Renal response was achieved in 58.3% cases which was accompanied by the hematological response, and tubular response was acquired in 66.7% cases. The k-LC FS patients presented with more common hypophosphatemia and hyperphosphaturia than the λ-LC group, and no differences were shown in treatment responses between these two groups. Compared to the primary Sjogren's syndrome associated FS patients with increased immunoglobulin G, LC-FS patients had more severe proteinuria, a higher prevalence of ostealgia, and less hypokalemia.

Conclusions: Asian LC-FS patients had mild renal function disorder, with more common hypophosphatemia and hyperphosphaturia in κ-LC patients than in λ-LC patients. The chemotherapy could improve renal function, which was related well to the hematological response.

PO1481

Metabolic Acidosis in CKD: Time for a New Approach?

Jennifer Robinson, Tucker B. Hurtado. Spherix Global Insights Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: Metabolic acidosis in chronic kidney disease (CKD) is relatively common and increases as renal function declines. More recently, metabolic acidosis has been identified as a key risk factor for the progression of CKD in addition to being linked to increased risk of renal osteodystrophy and muscle wasting. Presently, there are no FDA indicated therapies for the treatment of chronic metabolic acidosis, though sodium bicarbonate is commonly used to try to maintain serum bicarbonate levels in the normal range (22 – 29mEq/L). We sought to understand how prevalent metabolic acidosis is in a real world setting.

Methods: Patient level data was collected online via a HIPAA-compliant form in November 2019 as part of an independent chart audit. A total of 1,008 patient records were submitted by 201 nephrologists. Records were selected based on the most recently seen non-dialysis patients in the outpatient setting with an eGFR<60ml/min/1.73m^2.

Results: At the time of first referral to a nephrologist, 92% of patients had a bicarbonate measure in the chart and 29% initially presented with a level <22mEq/L. At the most recent visit, 14% of the CKD Stage 3 patients, 37% of the CKD Stage 4 patients, and 57% of the CKD Stage 5 (non-dialysis) patients had low levels of serum bicarbonate. Among the patients being treated with sodium bicarbonate, 58% were below 22mEq/L, suggesting that treatment may not be entirely effective. The co-morbidity burden for CKD patients is extremely high. Many patients with serum bicarbonate levels below target have hypertension (80%, 28% classified as uncontrolled), diabetes (46%), heart failure (13%), and coronary artery disease (24%) – conditions that could be aggravated by sodium-containing medications. Furthermore, among those with low serum bicarbonate levels, 33% were notable for edema at the most recent visit. Indeed, overall the rate of edema across all stages of CKD was 22%, but this symptom was significantly higher among patients on sodium bicarbonate.

Conclusions: Metabolic acidosis is highly prevalent in CKD patients. Additionally, the vast majority of patients with metabolic acidosis have co-morbidities that make them not ideally suited for sodium-containing products. New agents that can address metabolic acidosis without a sodium load may provide a better options for these patients.

PO1482

Metformin-Associated Lactic Acidosis and Blindness

Pooja Kalantri, Robert Mark Black, Kristin M. Corapi. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Metformin, a first line medication in the treatment of diabetes mellitus, can rarely cause lactic acidosis, usually in patients with acute or chronic kidney disease stage III onwards. We report a case of blindness associated with severe lactic acidosis in a patient with diabetes on metformin and show that the ophthalmologic symptoms may not be a direct result of the severe lactic acidemia alone.

Case Description: A 77 year old female with CKD stage III and type 2 diabetes on 1250 mg of metformin twice daily developed confusion, hypoglycemia and sudden visual loss. Over the prior 3 days, she had nausea, vomiting and diarrhea as well as a reduced urine output. On admission to the hospital, her vitals were stable. She had no other focal neurological deficits. Her creatinine was 4.4 mg/dL(with a baseline of 1.4), potassium 5.9 meq/L, bicarbonate 3 meq/L and blood lactate 23.8 mmol/L. Her arterial blood pH was 6.7. She underwent emergent hemodialysis and mid-way through her 4 hour session, she had complete resolution of her visual loss. By the end of her dialysis, her bicarbonate rose to 18. Ultimately, in a few months, she recovered her renal function back to a serum creatinine of 1.8-1.9, a little higher than her baseline.

Discussion: Some publications suggest vision loss (due to effect on retinal horizontal cell function) and optic nerve ischemia are associated with metformin induced lactic acidosis (MALA) at pH <7.09. It improves after correction of acidosis. But, in our case, the vision improved even before the acidemia corrected. We suggest that, since acute reversible blindness has been described with MALA, but not in patients with hypotension- or sepsis-induced lactic acidosis, this neurologic symptom may be a direct result of abnormal retinal horizontal cell function induced by metformin at a low pH, or the metabolic effects of metformin, rather than due to the acidemia alone. Hemodialysis helps correct electrolyte abnormalities and lactic acidosis. Also, metformin has a large volume of distribution. Its removal by dialysis is uncertain. But there are some case reports suggesting its clearance by HD. Further studies are thus warranted.

PO1483

Metabolic Acidosis Is a Predictive Factor for All-Cause Mortality in Patients with CKD

Navdeep Tangri,[1] Nancy L. Reaven,[2] Susan E. Funk,[2] Vandana S. Mathur.[3] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]Strategic Health Resources, La Canada, CA; [3]MathurConsulting, Woodside, CA.*

Background: The consequences of metabolic acidosis are wide-ranging, consistent with the fact that many critical cell functions require physiologic pH (Salameh AI, *Am J Physiol Regul Integr Comp Physiol*. 2014). The extent to which metabolic acidosis contributes to mortality in patients with chronic kidney disease (CKD) is unknown.

Methods: Optum® de-identified Electronic Health Records dataset 2007 to 2017 was queried to identify patients with non-dialysis CKD Stages 3-5 with ≥2 consistent serum bicarbonate tests 28–365 days apart, ≥3 eGFR values <60 mL/min/1.73 m^2 and ≥2 years of post-index data or who died during that period. Cohorts with metabolic acidosis and normal serum bicarbonate were established based on the baseline serum bicarbonate (12 to < 22 mEq/L or 22 - 29 mEq/L). All-cause mortality was measured at 2 years in patients with metabolic acidosis vs. normal serum bicarbonate at baseline. The impact of baseline serum bicarbonate on 2-year mortality, adjusted for age, sex, race, diabetes, hypertension, heart failure, Charlson Comorbidity Score (index of comorbidity burden), and baseline eGFR and log albumin-to-creatinine ratio (ACR) was evaluated using logistic regression models.

Results: 51,558 patients qualified for analysis; 17,350 with metabolic acidosis, 34,208 with normal serum bicarbonate at baseline. Unadjusted rates of mortality within 2 years were higher among patients with metabolic acidosis vs. normal serum bicarbonate (30.9% vs. 10.2%, respectively, $P< 0.0001$) and within all CKD stages ($P< 0.001$). Each 1 mEq/L lower serum bicarbonate value was independently associated with a 15% higher risk of all-cause mortality, OR: 0.853, 95% CI: 0.846-0.861. These findings were consistent in subgroup and sensitivity analyses.

Conclusions: The presence of metabolic acidosis was associated with a high 2-year risk of all-cause death in patients with CKD. This finding was independent of age, sex, race, pre-existing comorbidities, and baseline eGFR and ACR.

SGLT2-Mediated Changes in Urinary Handling of Ketones in Type 1 Diabetes

Daniel Scarr,[1] Leif E. Lovblom,[1] Daniel Montemayor,[3] Hongping Ye,[3] Hongyan Liu,[2] Yuliya Lytvyn,[2] Kumar Sharma,[3] David Cherney,[2] Bruce A. Perkins.[1,4] *[1]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; [2]Division of Nephrology, Department of Medicine, University Health Network, University of Toronto, Toronto, ON, Canada; [3]Center for Renal Precision Medicine (CRPM), Division of Nephrology, Department of Medicine, University of Texas Health San Antonio, San Antonio, TX; [4]Division of Endocrinology and Metabolism, Department of Medicine, University of Toronto, Toronto, ON, Canada.*

Background: Adjunctive therapy with sodium glucose co-transporter 2 (SGLT2) inhibitors have demonstrated clinically meaningful metabolic benefits in type 1 diabetes (T1D), but also represent a component cause of diabetic ketoacidosis. In this *post-hoc* analysis we examined SGLT2-mediated changes in ketone concentrations during clamped euglycemia and hyperglycemia in people with T1D.

Methods: T1D participants enrolled in the ATIRMA trial (NCT01392560) underwent measurement of plasma and urine beta-hydroxybutrate (BHB) and acetoacetate (AA) at baseline and after 8 weeks of empagliflozin 25 mg QD using a novel ZipChip Method developed at the CRPM, during both clamped euglycemia (4-6 mmol/L) and hyperglycemia (9-11 mmol/L).

Results: Forty participants (50% female), aged 24±5 years, HbA1c 8.0±0.9% with diabetes duration of 17.5±7 years, were enrolled. Median [IQR] plasma BHB at baseline was 0.05 [0.02-0.16] mmol/L during euglycemia and 0.06 [0.02-0.17] mmol/L during hyperglycemia. Plasma BHB significantly increased after treatment during both euglycemia (0.20 [0.09-0.40] mmol/L) and hyperglycemia (0.21[0.05-0.40] mmol/L), p<0.05 for both comparisons. Urine BHB at baseline was 1.9 [1.2-4.3] µmol/mmol creatinine during euglycemia and was 3.7 [1.7-10.0] µmol/mmol creatinine during hyperglycemia. Urine BHB significantly increased after treatment during euglycemia (4.1 [1.8-9.7] umol/mmol creatinine), p<0.01. Results were similar for AA.

Conclusions: In people with T1D, ketones were detectable in plasma and urine at baseline during clamped euglycemia and hyperglycemia and ketone concentrations significantly increased after 8 weeks of SGLT2 inhibition under the same study conditions. Further work is needed to establish factors associated with SGLT2-mediated changes in urinary handling of ketones and ketogenesis in people with T1D, which may assist in ketoacidosis prevention strategies.

PO1485

Lactate Gap as Initial Indicator for Ethylene Glycol Toxicity

Varun Madireddy, Mark A. Finger. *Zucker School of Medicine at Hofstra/ Northwell, Great Neck, NY, Hempstead, NY.*

Introduction: Ethylene glycol poisoning is a medical emergency which on initial presentation can be missed if the clinician does not have a high index of suspicion. Treatment of ethylene glycol toxicity is time dependent in preventing morbidity and mortality, thus early recognition and intervention is of critical value. In this case report we aim to focus on the lactate gap as the first indicator of ingestion.

Case Description: 50-year-old female was brought in by EMS after being found unresponsive and covered in vomitus. Vital signs were stable. The patient was thought to have had a seizure causing the lactic acidosis and was post ictal. Labs are shown below. Ethylene glycol toxicity was made the presumptive diagnosis. The patient was transferred to the medical ICU and given a loading dose of fomepizole while hemodialysis was being arranged. The patient then had one session of hemodialysis in the medical ICU and repeat blood gas is displayed below.

Discussion: The diagnosis of ethylene glycol poisoning remains challenging due to non-specific signs and symptoms on presentation. Presentation and lab values may differ depending on the time and amount since ingestion. Access to real-time ethylene glycol serum concentration is uncommon in many health facilities, so the diagnosis relies upon a high index of suspicion. Laboratory studies, specifically the "lactate gap", can be used in aiding the diagnosis. The "lactate gap" is a lab artefact due to a chemical cross reaction. Most POC whole blood analyzers use the enzyme lactate oxidase which cross reacts with the breakdown products of ethylene glycol, specifically glycolate. The lab instrument cannot differentiate between lactate and glycolate because of their structural similarity. Laboratory serum analyzers which are used for routine venous blood samples have less cross-reactivity and thus show a minimal elevation of lactate in comparison. In addition to securing the diagnosis, the lactate gap can be used to monitor clearance of the glycol metabolites.

Laboratory Values

Measurement	On arrival	2 hours later	Post Hemodialysis	Ref Values
pH	7.33	7.22	7.43	7.35-7.45
pCO2	25	40	40	35-45 mmHg
Bicarbonate	12	9	23	23-30 mEq/L
Lactate (POCT)	27	23	2.4	0.5-2.2 mmol/L
Lactate, blood	N/A	8.1	2.1	0.5-2 mmol/L
"Lactate gap"	N/A	14.9	0.3	
Osmolar gap	99	N/A	9	<10 mOsms

PO1486

Anion Gap (AG) and Negative Osmotic Gap (OG) due to Remdesivir's (R) Excipient

Sameer Alqassimi,[1,2] Octavio Chavez,[1] Claude Bassil,[1] Pranjal Jain,[3] Jacques A. Durr.[1] USF Nephrology and Hypertension *[1]USF Health Morsani College of Medicine, Tampa, FL; [2]Jazan University Faculty of Medicine, Jazan, Saudi Arabia; [3]Florida Kidney Physicians, Tampa, FL.*

Introduction: The FDA authorized R for COVID-19. Excess Na sulfobutylether (SBE) substituted β-cyclodextrin (CD) solubilizes R (PMID: 32376442). Minute accumulation of SBECD can cause an AG as *n*, its substitution in SBE is 6.5 (Captisol). The FDA advises against using R in adults with eGFR ≤30 mL/min *unless the potential benefit outweighs the potential risks* because SBECB accumulates. We report 2 cases of AG with the FDA protocol.

Case Description: Case A: 77 obese ♀ with bilateral AKA, and initial serum creatinine (Scr) of 1 mg/dL, currently decreasing (0.6 mg/dL). On day 5 R was initiated while a mild ketosis resolved (β OH-butyrate 0.6→0.3→0.1 mmol/L). An AG as high as 16 mmol/L (Alb ~2 g/dL) ensued, wherein the AG of the 1st blood sample after each R infusion correlated inversely with the time elapsed after the infusion. Like ketones, lactate was low throughout R therapy. By the time R started, Scr had risen and plateaued at 1.8 mg/dL and the AG mirrored the subsequent increase and decrease in Scr, and vanished by day 9, when her Scr was < 1.7, after peaking at 2.6 mg/dL, in spite of continuing R, consistent with SBECD cleared by GFR, like cr. Her initial *normal* Scr already meant AKI in this elderly sedentary, bilateral AKA patient. Her OG, only 7 on day 2 of R, further decreased by 11, to a negative OG of –4 mOsm/Kg H_2O the next day, suggesting polyanion accumulation. The calculated osmolarity of a Na_nSBECD solution is $((n + 1)/n)$*[Na] = 1.15*[Na], not 2*[Na] since $n \approx 6.5$, which explains the negative OG. **Case B:** 42 ♀, with morbid obesity and initial Scr of 1 mg/dL. R started on day 2, as Scr rose fast but her AG was 10 mmol/L. Again, the AG rapidly rose to 16 mmol/L (Alb. ~2.5 g/dL), and paralleled the rise and drop in Scr. CRRT was started when Scr was 6 mg/dL. Here again, prior to CRRT the AGs of the 1st samples following each R infusion were inversely related with the time from R infusion. While R was continued, CRRT caused parallel decreases in AG and Scr, since it clears cr and SBECD equally. The R loading dose contains 6 g and the 9 subsequent daily doses 3 g SBECD. Since the mass of $SBE_{6.5}CD$ is 2163.3 D, the initial anion load is ~18 mmol, followed by 9 daily loads of ~ 9-10 mmol.

Discussion: Depending on plasma volume, rate of escape from plasma, GFR, and timing after the infusion, SBECD can cause an AG, and negative OG, when the GFR is low.

PO1487

Anion Gap and Cardiovascular Mortality

Ashish Verma,[1] Sonu Subudhi,[2] Ankit B. Patel,[1] Maria Clarissa Tio,[1] Sushrut S. Waikar.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Boston University Medical Campus, Boston, MA.*

Background: Anion gap has been shown to be independently associated with hypertension, but the association of anion gap and cardiovascular mortality has been unexplored.

Methods: We conducted a prospective cohort study using the National Health and Nutrition Examination Survey (NHANES), a nationally representative cross-sectional survey of the US non-institutionalized population. Anion gap (mEq/L) was calculated as serum sodium (mmol/L) – (serum chloride (mmol/L) + serum bicarbonate (mmol/L). We used weighted Cox proportional hazards models to assess the associations between anion gap with cardiovascular specific mortality, as recorded by the National Death Index. Multivariable models were adjusted for demographics data, BMI, smoking status, diabetes, systolic blood pressure, cardiovascular disease history, ACEi/ARB, diuretics, serum albumin, total cholesterol, total protein, total calorie intake, hemoglobin, cancer diagnosis, eGFR and urine albumin and creatinine ratio.

Results: This study was performed on 39,189 participants [mean (SD) age, 46.86 (19.25) years; 20,194 (51.5%) female. During 875 (4436210 weighted) person-years of follow-up, 936 participants (3169889 weighted participants) died of cardiovascular disease. A history of cardiovascular disease at the time of enrollment was reported in 3875 (9.8%). Figure 1 shows the associations between anion gap in tertiles with cardiovascular related mortality. In analyses restricted to those with a history of cardiovascular disease, results were 116% increased risk for cardiovascular mortality [HR 2.16;95% CI (1.37,3.4)].

Conclusions: Higher anion gap may be a risk factor for cardiovascular-related mortality in adults.

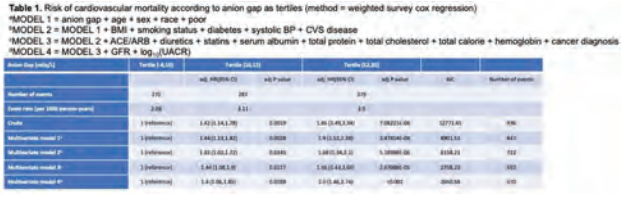

Figure 1. Risk of cardiovascular mortality according to anion gap as tertiles (method = weighted survey cox regression)

PO1488

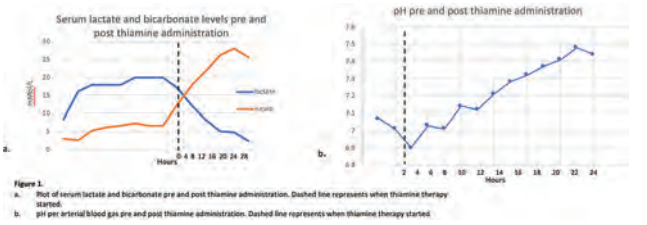
Profound Lactic Acidosis due to Dextrose Infusion and the Role of Thiamine

Kristen R. Lile, Sarah Faubel. *University of Colorado, Denver, CO.*

Introduction: Severe metabolic acidosis due to dextrose infusion is a rare but life-threatening complication for which treatment options are poorly described. Normally dextrose is metabolized to pyruvate during glycolysis. Pyruvate is converted to acetyl-CoA via pyruvate dehydrogenase (PDH); this requires abundant oxygen. Thiamine is an essential cofactor for PDH. During anerobic conditions, pyruvate is converted to lactate during a process known as anerobic glycolysis, producing a type A lactate. Pyruvate may also be converted to lactate when oxygen levels are normal via aerobic glycolysis. Aerobic glycolysis produces type B lactate and occurs due to a number of conditions, including thiamine deficiency.

Case Description: A 54-year-old woman with malignant insulinoma was admitted for severe hypoglycemia. The patient was given continuous 20% dextrose infusion; she developed severe lactic acidosis on day seven. Serum bicarbonate was undetectable on blood gas at the time of renal consult; serum lactate was >20. The patient decompensated due to the acidosis, became obtunded, was intubated, and was placed on continuous renal replacement therapy (CRRT). The acidosis failed to improve for 36 hours. Thiamine therapy was begun in an attempt to restore function of the PDH complex and restart the metabolism of pyruvate through the citric acid cycle, halting further type B lactate production. Within hours, lactate levels fell with parallel rise in serum pH. The patient was extubated, alert, and taken off CRRT within 24 hours of beginning thiamine therapy.

Discussion: This patient developed a profound metabolic acidosis secondary to type B lactic acidosis via accelerated glycolysis from dextrose infusion. This case highlights the intricate regulation of dextrose metabolism as well as thiamine as a vital therapy in type B lactic acidosis. Thiamine therapy was key, presumably reinstituting aerobic respiration through the PDH complex and ultimately leading to cessation of lactate production. Given the critical role of thiamine in this case, it is plausible that thiamine could be crucial for other cases of metabolic acidosis, particularly those secondary to type B lactic acidosis.



PO1489

Persistent Lactic Acidosis due to Thiamine Deficiency

Mita Zahra E. Co,[1] Zhiwei Zhang.[2] *[1]Loma Linda University Medical Center, Loma Linda, CA; [2]VA Loma Linda Healthcare System, Loma Linda, CA.*

Introduction: Lactic acidosis is one of the most common causes of metabolic acidosis in hospitalized patients. Clinically it is usually associated with obviously impaired tissue oxygenation, but also occurs in situation where systemic impairment in oxygenation does not exist or is not readily apparent. Here we present a case of persistent lactic acidosis found to be due to thiamine deficiency and resolved rapidly after thiamine supplementation.

Case Description: A 38-year old woman presented with 4-day history of abdominal pain, vomiting, diarrhea, and not able to eat. She has a history of alcoholism in remission, vitamin B12 deficiency, PTSD and bipolar disorder. Her medications included cyanocobalamin, disulfiram, lithium, trazodone, and ziprasidone. Vital signs were normal except for mild sinus tachycardia, and the rest of her examination was unremarkable. Laboratory results indicated normal CBC, glucose, BUN, Cr, LFT, and urine analysis. Serum Na, K, Mg, Ca, and PO4 were all low. Serum ethanol and salicylate were not detected, and urine drug screen was negative. Serum HCO3 was low at 14 mmol/L with anion gap of 26. Serum ketone was negative, but serum lactic acid was severely elevated at 9 mmol/L. ABG was consistent with compensated metabolic acidosis. Cardiac echo and other imaging studies did not reveal significant abnormalities. The patient received intravenous fluid replacement and supplementation for various electrolyte abnormalities. While her symptoms of gastroenteritis had improved, the serum lactic acid continued to remain high (7-9s). Since most of the apparent causes of lactic acidosis were excluded in this patient, thiamine deficiency was suspected and thiamine level was confirmed to be low at 59 nmol/L (normal 78-185). Supplementation was initiated with rapid normalization of lactic acidosis.

Discussion: Thiamine is essential for normal aerobic metabolism, and its deficiency may lead to accumulation of pyruvate and conversion to lactic acid. Because thiamine is water soluble, its stores are limited. Thiamine deficiency can occur readily if intake is suboptimal in people who have risk factors, such as long-term heavy alcohol ingestion in this patient. **Teaching points** Thiamine deficiency is a potential cause of lactic acidosis that is reversible with supplementation. A high index of suspicion is necessary for diagnosis in patients with risk factors but no other apparent cause of lactic acidosis.

PO1490

Methanol Intoxication Secondary to Adulterated Cane Alcohol "El Chorrito"

Jorge J. Font, Jonathan Chavez, Joana G. Navarro gallardo, Christian P. Flores, Sergio J. Sánchez Villaseca, Ekatherina Yanowsky ortega. *Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.*

Introduction: Methanol intoxication is a rare and lethal form of poisoning that may cause severe anion gap and osmolar metabolic acidosis (MA), visual disturbances, neurological dysfunction and death. We present a group of seven unrelated cases with methanol intoxication from cities in southern Mexico of a total of 106 intoxicated patients and 43 deaths reported.

Case Description: Upon arrival to Hospital Civil of Guadalajara a group of seven patients presented with severe MA, high anion and osmolar gap, neurologic and visual deterioration, respiratory failure requiring mechanical ventilation and hemodynamically unstable requiring vasopressor. Intake of methanol was accidental, since a batch of adulterated alcoholic bottles was identified and distributed by "El Chorrito" store. Methanol concentrations is not available in our hospital. CT Scan revealed hemorrhage in basal ganglia and white matter involvement in all of them. Fomepizole is not available in Mexico so an ethanol infusion with vodka was started. All patients initiated hemodialysis (HD) as soon as possible and all underwent at least two sessions. Acid base balance was restored but five (71%) of the seven patients died. The remaining two patients persist in critical conditions requiring mechanical ventilation, no neurologic response and vasopressor dependent.

Discussion: This case series illustrates the poor clinical outcomes suffered by patients with methanol poisoning and the limitations of our public health system. Unfortunately the time lapse upon arrival was prolonged and organ damage irreversible leading to mortality in the majority of the cases.

Table 2.2

Individual values (First-Last)	pH	HCO3	Lactate	Anion Gap	Creatinine
#1	7.24 - 7.29	6.4 - 15.4	7.9 - 4.8	33.2 - 18.57	1.76-1.16

PO1491

Starvation Ketoacidosis in a Patient with Muscular Dystrophy

Khaled Srour, Bilal Shahzad Azam Khan, James E. Novak. *Henry Ford Hospital, Detroit, MI.*

Introduction: Patients with muscular dystrophy have low muscle mass; thus, they have lower glycogen stores and are more prone to develop ketoacidosis with minimal stress or decreased oral intake. Here we present a rare presentation of ketoacidosis in a patient with muscular dystrophy with concurrent ketoacidosis and hyperchloremic metabolic acidosis who was treated successfully with lactated Ringer's (LR) and dextrose (D5W).

Case Description: A 48 year old woman with a history of muscular dystrophy and chronic, ventilator dependent respiratory failure was referred to our hospital for evaluation of granulation tissue in her trachea. Body mass index was 18 kg/m 2. Laboratory data on admission were significant for sodium of 132 meq /L, potassium of 4.5 meq /L chloride 114 mEq/L, bicarbonate 12 mEq/L, creatinine < 0.1 mg/d, and pH 7.23 (venous blood gas) consistent with non anion gap metabolic acidosis. The following day, laboratory data showed sodium 137 mEq/L, chloride 113 mEq/L, bicarbonate 8 mEq/L, and pH 7.29. The calculated anion gap was 16 mEq/L with albumin 4.2 g/ dL. The urine anion gap was 30 mmol/L. Serum β hydroxybutyrate (BHB) was elevated at 6.6 mmol/L. Because of muscular dystrophy with decreased oral intake, the patient's anion gap metabolic acidosis was attributed to starvation ketoacidosis. The non anion gap metabolic acidosis was attributed to renal tubular acidosis. LR and D5W solutions were administered to treat non anion gap and anion gap metabolic acidosis (starvation ketoacidosis), respectively. After 1-2 days, BHB decreased and electrolytes normalized.

Discussion: Few cases have been reported regarding ketoacidosis in patients with muscular dystrophy, and all of these were treated with dextrose and 0.9% saline. In our case, we used LR and D5W due to concurrent non anion gap and anion gap metabolic acidosis, as 0.9% saline administration was projected to worsen the hyperchloremic acidosis. Anion gap metabolic acidosis in patients with muscular dystrophy and without diabetes should raise suspicion for starvation ketoacidosis requiring D5W. LR should be substituted for 0.9% saline in patients with concurrent hyperchloremic acidosis.

PO1492

Metabolic Acidosis Associated with Linezolid Toxicity

Carmen E. Cervantes,[1] Steven Menez,[1] Jose M. Monroy-Trujillo,[1] Mohamad A. Hanouneh.[1,2] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Nephrology Center of Maryland, Baltimore, MD.*

Introduction: Linezolid is an oxazolidinone antibiotic that inhibits bacterial protein synthesis. It can impair mitochondrial ribosomal function leading to severe lactic acidosis, liver toxicity and myelosuppression.

Case Description: A 65-year-old Caucasian woman with PMH of compensated NASH cirrhosis, osteomyelitis diagnosed 4 weeks prior to presentation and now on linezolid, was admitted with abdominal pain. Her vital signs and cardiopulmonary exam were unremarkable. Her abdomen was distended with mild epigastric tenderness. Figure 1 outlines the initial laboratories. Urinalysis was benign and blood cultures were negative. CT abdomen revealed moderate ascites. The anion gap metabolic acidosis (AGMA) were likely explained by Linezolid toxicity. The respiratory alkalosis is related to liver cirrhosis which is associated with increased level of progesterone leading to hyperventilation. Linezolid was stopped and repeat laboratories at 72 hours demonstrated normalization of bicarbonate and lactate values.

Discussion: Our patient has a primary AGMA (Corrected AG = 31) with mild respiratory alkalosis (calculated PaCO2 by Winter's formula = 23). She had an osmolar gap of 5 (The calculated osmolality = 282 mOsm/kg). The AGMA is likely secondary to lactic acidosis (figure 2). The patient does not have signs of hypovolemia. Ethylene glycol (EG) can lead to a false elevation in L-lactate. However, the normal OG makes EG and methanol toxicity less likely. Normal beta hydroxybutyrate level excludes ketoacidosis. Major risk factors for linezolid toxicity include prolonged exposure, administration of relatively higher doses, and baseline chronic liver or kidney disease. Lactic acidosis often resolves rapidly following discontinuation of Linezolid.

Tests	Results	Normal range
Hemoglobin	6.9 g/dL	12-16 g/dL
White Blood cell count	2.5 k/uL	3.70 - 11.00 k/uL
Platelet count	24 k/uL	150-400 k/uL
Sodium	131 mmol/L	132-148 mmol/L
Potassium	5.5 mmol/L	3.5-5 mmol/L
Chloride	94 mmol/L	98-111 mmol/L
Bicarbonate	10 mmol/L	23-32 mmol/L
Blood Urea Nitrogen	29 mg/dL	10-25 mg/dL
Creatinine	0.69 mg/dL	0.7-1.4 mg/dL
Calcium	7.9 mg/dL	8.4-10.5 mg/dL
Albumin	2.3 g/dL	3.5-5.0 g/dL
Glucose	170 mg/dL	65-100 mg/dL
Alanine aminotransferase	7 U/L	0-45 U/L
Aspartate aminotransferase	16 U/L	7-40 U/L
Alkaline phosphatase	256 U/L	40-150 U/L
Bilirubin, total	0.3 mg/dL	0-1.5 mg/dL
PTT	50 seconds	22-32 seconds
INR	1.2	
LDH	125 U/L	0-249 U/L
Lactate	11.5 mmol/L	0.4-1.9 mmol/L
Beta-hydroxybutyrate	0.3 mg/dL	0 – 3 mg/dL
Serum osmolality	287 mOsm/K	275-295 mOsm/K
Serum acetaminophen	< 5.0 mcg/mL	
Serum salicylate	< 0.3 mg/dL	< 20 mg/dL
Serum Ethanol	2 mg/dL	Non-detected
Arterial Blood Gas		
pH	7.34	7.35-7.45
PCO2	19 mm Hg	35-45 mm Hg
PO2	116 mm Hg	75-100 mm Hg
HCO3	10 mmol/L	18-23 mmol/L

Tissue hypoperfusion (Type A)
- Hypovolemia
- Septic shock
- Cardiogenic shock

Decrease Utilization (Type B)- Usually toxin-induced impairment of cellular metabolism
- Diabetic ketoacidosis
- Metformin
- Alcoholism
- Mitochondrial dysfunction (nucleoside reverse transcriptase inhibitors, propofol, linezolid)
- Malignancy
- HIV infection
- Beta-adrenergic agonists (IV epinephrine)

D-Lactate acidosis
- short bowel syndrome
- Propylene glycol

PO1493

The Real Life of Oral Alkalinization by Urologists and Nephrologists on Extracellular Volume: The AlcalUN Study

Jean-philippe Bertocchio,[1,2] Julie Moriniere beaume,[2,3] Lucile Figueres,[2,4] Mickaël Bobot,[2,19] Olivier Aubert,[2,5] Louis De laforcade,[2,6] Hamza Ayari,[7] Thibault Dolley-Hitze,[2,8] Victor Gueutin,[9,11] Antoine Braconnier,[2,15] Leonard Golbin,[2,10] Salvatore Citarda,[2,17] Guillaume Seret,[16] Lisa Belaid,[8] Raphael R. Cohen,[7] Yosu Luque,[2,12] Riyad N. Seervai,[18] Camille Overs.[13,14] AlcalUN study investigators *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]Club des Jeunes Néphrologues, Paris, France; [3]Association Varoise pour l'Organisation de la Dialyse a Domicile, Toulon, France; [4]Centre de Recherche en Transplantation et Immunologie, Nantes, France; [5]Paris Centre de Recherche Cardiovasculaire, Paris, France; [6]Centre Hospitalier Pierre Oudot de Bourgoin-Jallieu, Bourgoin-Jallieu, France; [7]Hopital Europeen Georges Pompidou, Paris, France; [8]AUB Santé, Saint-Malo, France, Saint-Malo, France; [9]AURA Paris Plaisance, Paris, France; [10]University Hospital of Rennes, Rennes, France, Rennes, France; [11]Hopital Universitaire Pitie Salpetriere, Paris, France; [12]Tenon University Hospital, Paris, France, France, France; [13]Association des Urologues en Formation, Paris, France; [14]University hospital of Grenoble, Grenoble, France; [15]University hospital of Reims, Reims, France; [16]ECHO Santé, Pôle Santé Sud, Le Mans, France; [17]CALYDIAL, Irigny, France; [18]Center for Precision Envrionmental Health, Baylor College of Medicine, Houston, TX; [19]Hopital de la Conception Centre de nephrologie et de transplantation renale, Marseille, France.*

Background: Oral alkalinization with sodium bicarbonate ($NaHCO_3$) or citrate is prescribed to treat conditions ranging from metabolic acidosis to nephrolithiasis. While most nephrologists/urologists use these treatments regularly, extracellular volume (ECV) increase is a main feared adverse event for $NaHCO_3$ use. To date, no clinical trial has specifically addressed this aspect in clinical routine.

Methods: AlcalUN (NCT03035812) is a multi-center, prospective, open-label study aiming to assess the impact of a chronic oral alkalinization on ECV. Patients receiving oral alkalinization without $NaHCO_3$ (citrate) comprised the control group. Increased ECV (primary outcome) was assessed based on body weight (BW), blood pressure (BP), and edema at first follow-up visit.

Results: From 02/2017 to 02/2020, 156 patients were enrolled (129 received $NaHCO_3$, 27 citrate). Out of them, 127 (80%) participants had at least one follow-up visit. Normalizing for demographics, patients in the $NaHCO_3$ group had higher incidence of chronic kidney disease (68 *vs.* 30%, p=0.002) and hypertension (75 *vs.* 35%, p=0.001), while patients in the No-$NaHCO_3$ group (citrate) had more nephrolithiasis (95 *vs.* 28%, p<0.001). At baseline, BW, BP, and presence of edema were similar in both groups. After a median of 90 days of treatment, 91 (72%) patients reached the primary outcome, with similar distribution in both groups (71 *vs.* 75%, p=0.79). We found similar results after after propensity score matching.

Conclusions: Chronic oral alkalinization with $NaHCO_3$ does not increase ECV more than citrate, even though it is used in a higher-risk population. These results confirm secondary outcomes from other trials, potentially highlighting the role of chloride load instead of sodium load.

PO1494

Effect of Sodium Bicarbonate on Kidney Injury: A Secondary Analysis of the BASE Pilot Trial

Kalani L. Raphael,[1] Brett Larive,[2] Tamara Isakova,[3] Joachim H. Ix,[4] Myles Wolf,[5] Dominic S. Raj,[6] Susan R. Mendley,[7] Linda F. Fried,[8] Cynthia A. Kendrick,[2] Jennifer J. Gassman,[2] Donald E. Wesson,[9] Alfred K. Cheung.[1] CKD Pilot Studies Consortium *[1]University of Utah Health, Salt Lake City, UT; [2]Cleveland Clinic, Cleveland, OH; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]University of California San Diego, La Jolla, CA; [5]Duke University School of Medicine, Durham, NC; [6]George Washington University Medical Faculty Associates, Washington, DC; [7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [8]University of Pittsburgh Medical Center, Pittsburgh, PA; [9]Baylor Scott and White Health, Dallas, TX.*

Background: $NaHCO_3$ is used to treat metabolic acidosis in CKD. In the Bicarbonate Administration to Stabilize eGFR (BASE) Pilot Trial, a dose-dependent increase in albuminuria was observed with $NaHCO_3$ over 28 weeks, suggesting that $NaHCO_3$ may promote kidney injury. We investigated the effect of $NaHCO_3$ on kidney tubule injury markers (KIM-1 and NGAL) in BASE participants.

Methods: Urinary KIM-1 and NGAL were measured in 176 BASE participants at baseline, week 12, and week 28. Change in urinary KIM-1/Cr and NGAL/Cr was compared within and between the three treatment groups (Placebo, n=49; Lower-Dose [0.5 meq/kg/d] $NaHCO_3$, n=48; and Higher-Dose [0.8 meq/kg/d] $NaHCO_3$, n=79) using linear mixed models.

Results: Mean±SD baseline values were: age 67±12 years, systolic BP 126±13 mm Hg, eGFR 36±9 ml/min/1.73m^2, serum tCO_2 24±2 meq/L. Median (IQR) urinary values at baseline were: ACR 185 (24, 767) mg/g, KIM-1/Cr 0.88 (0.43, 1.36) ng/mg, and NGAL/Cr 14.3 (6.44, 34.0) ng/mg. At week 12, urinary KIM-1/Cr levels were not different from baseline in any group. However, at week 28, KIM-1/Cr levels were significantly lower in all three groups. NGAL/Cr was significantly higher in the Higher-Dose $NaHCO_3$ group at week 12; however, there were no other significant within group differences at week 12 or 28. In the between group comparisons, there were no significant differences in KIM-1/Cr ($p\geq0.16$) or NGAL/Cr ($p\geq0.07$) at either week 12 or 28.

Conclusions: Among BASE Pilot Trial participants, $NaHCO_3$ had no significant effect on urinary KIM-1/Cr or NGAL/Cr levels over 28 weeks.

Re-Evaluation of Renal Bicarbonate Compensation in the Setting of Extreme Chronic Respiratory Acidosis

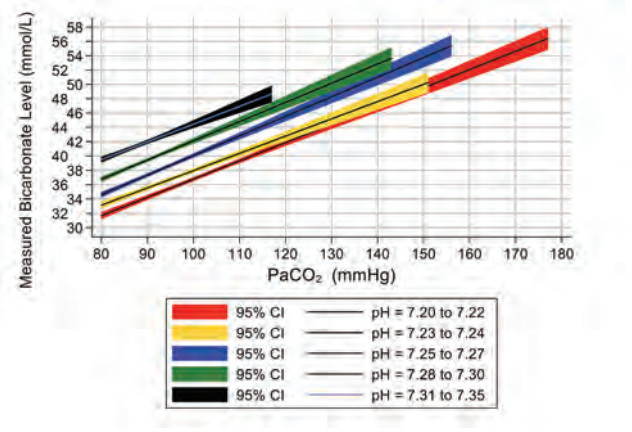
Asad H. Khan,[1] Brian H. Nathanson,[1,2] Daniel L. Landry,[1] Bill Mcgee,[1] Gregory L. Braden.[1] *[1]University of Massachusetts Medical School-Baystate, Springfield, MA; [2]OptiStatim LLC, Longmeadow, MA.*

Background: In chronic respiratory acidosis (CRA), the expected renal compensatory increase in serum bicarbonate (HCO3) is 0.35-0.4 mEq/L for every 1 mmHg PaCO2 over 40 mmHg. However, at extreme hypercarbia, at PaCO2 >80 mmHg, limited research dating from the 1960s suggests the HCO3/PaCO2 relationship flattens at a PaCO2 >70 mmHg.

Methods: We analyzed 2840 arterial blood gas (ABG) observations from 761 patients with extreme chronic hypercarbia with PaCO2 > 80 mmHg from 7/2015-7/2017 from a single, US teaching hospital. We included all patients with a pH ranging from 7.20 to 7.35 who had serum bicarbonate levels measured by the main lab autoanalyzer, within 12 hours of the ABG. To reduce the bias of acute respiratory acidosis (RA), we performed a sensitivity analysis on 101 patients who had 603 ABGs 4-10 days apart to assure chronicity of RA. Generalized linear regression models were developed to predict HCO3.

Results: For the 2840 ABGs, the mean (SD) was: pH: 7.27 (0.05), PaCO2: 92.51 (10.95) mmHg (range 80-177), and HCO3 : 37.9 (4.5) mEq/L. In Figure 1. the increase in serum HCO3 was 0.26; 95% CI (0.25, 0.28) for each value of PaCO2 above 80 mmHg after adjusting for pH. The regression equation yielded: HCO3= 88.64*pH +0.34 *PaCO2 - 637.2. The sensitivity analysis produced very similar findings.

Conclusions: At extreme hypercarbia, defined as PaCO2 >80 mmHg, the kidneys have limited ability to retain bicarbonate compared to established formulae for lesser increases in PaCO2. Our new equation predicts this response is a 0.26 mEq/L increase in HCO3 for each 1 mmHg of PaCO2 increase over 80 mmHg.



Measured bicarbonate (Y axis) plotted against measured PaCO2 (X axis) showing an increase of 0.26 mmol/L of bicarbonate for each value of PaCO2 above 80 mmHg, with adjustments for different values of pH (colored lines).

PO1496

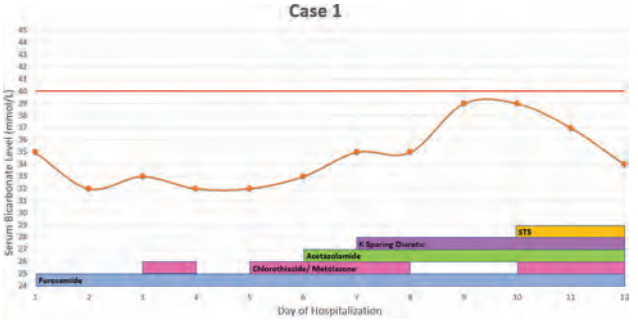
It's Not a Bad Trip with This Acid: Sodium Thiosulfate Use in Refractory Metabolic Alkalosis

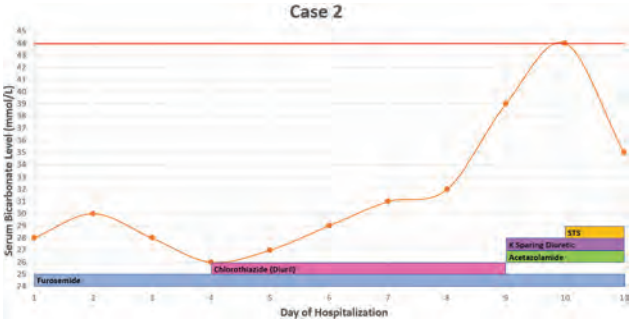
Melby Philip, Kamalanathan K. Sambandam. *University of Texas Southwestern Department of Nephrology, Dallas, TX.*

Introduction: Metabolic alkalosis is often a complication of loop diuretic use. It may at times become rate limiting. Serum bicarbonate (HCO3) levels upwards of 30 mmol/L can make even the most eager clinician stop dead in their tracks in the quest for optimal volume control.

Case Description: Here we highlight two patients, a 63 year old female and an 81 year old gentleman, who while on diuretic therapy developed severe metabolic alkalosis, with peak serum bicarbonate levels of 39 and 44 mmol/L respectively. Several strategies were attempted to mitigate the alkalosis. Potassium was aggressively repleted to maintain a normal serum level of 4.5 and 3.6 mmol/L respectively, however, this was unsuccessful. Acetazolamide was employed but ineffective due to its limited efficacy in the setting of low effective circulating volume and renal insufficiency. Advanced measures such as hydrochloric acid and ammonium chloride were not readily available nor feasible to administer. Ultimately, given the known side effect of sodium thiosulfate (STS) to cause metabolic acidosis, STS was administered, resulting in a decrease in the serum HCO3 level and an ability to resume diuresis.

Discussion: When continued diuresis is necessary and correction of metabolic alkalosis cannot be facilitated by potassium repletion or carbonic anhydrase inhibitors, a novel option is to utilize STS and its known ability to generate an acid load to treat the alkalosis. While the mechanism is unclear, a metabolite of STS, hydrogen sulfide, is proposed to be the source of acid. This strategy for correcting metabolic alkalosis has never been reported in the literature before.





PO1497

A Case of Extreme Alkalosis: A Perfect Combination of Perpetuators

Patrícia Valerio,[1] Hugo Ferreira,[2] Teresa Chuva,[2] Ana M. Paiva,[2] Inês Neves,[2] Filomena Faria,[2] José M. Costa.[2] *[1]Centro Hospitalar de Setubal EPE, Setubal, Portugal; [2]Instituto Portugues de Oncologia do Porto Francisco Gentil EPE, Porto, Portugal.*

Introduction: Metabolic alkalosis results from retention of alkali excess. Normally, a physiological response leads to hypoventilation with a secondary increase of $PaCO_2$. The most common cause is H^+ loss, through kidney or gastrointestinal tract, usually with concurrent loss of Cl^- and K^+.

Case Description: 70 y/o caucasian man was admitted for a scheduled surgery due to a stage II urothelial carcinoma. The immediate postoperative period occurred without complications. The patient presented with abdominal distention and gastric stasis. He remained fasting, with gastric tube draining freely. Surgical team performed an exploratory laparotomy with correction of a small bowl internal hernia. In the postoperative period Nephrology collaboration was requested due to acute kidney injury (AKI), with a creatinine (Cr) of 3,39 mg/dL (baseline 1,5 mg/dL) and urea 89,5 mg/dL. On examination the patient was prostrate, severely dehydrated and bradypneic, with oxygen supply FiO_2 28%. He maintained gastric passive drainage for 3 days, around 3 to 3,5 L/day. Blood work showed Cr 4,15 mg/dL, urea 103,9 mg/dL, hypernatremia 147 mEq/L, hypochloremia 78 mEq/L, hypokalemia 3,2 mEq/L, uric acid 16,8 mg/dL, albumin 3,2 g/dL and a total corrected calcium 9,5 mg/dL. Urinalysis revealed a pH of 9,0 and arterial blood gas analysis presented severe metabolic alkalosis (pH 7,63, PaO_2 90 mm Hg, $PaCO_2$ 99 mm Hg, bicarbonate 104,1 mmol/L), low ionized calcium 0,86 mmol/L and lactate 1,9 mg/dL. The patient was immediately admitted in ICU, starting aggressive IV hydration with NaCl 0,9%, IV potassium supplementation and parenteral nutrition.

Discussion: This is an extreme case of metabolic alkalosis where a myriad of contributors gathered in a perfect storm to achieve a bicarbonate concentration above 100 mmol/L, thought to be incompatible with life and, to our knowledge, never reported in the literature. However, the pH value was maintained in life-compatible values by an extreme respiratory compensation which may have saved the patient before treatment initiation. An approach correcting the cause and, at the same time, the perpetuators are the key factors to successfully treat a metabolic alkalosis. Due to severe AKI and alkalosis, dialysis with low bicarbonate dialysate may be indicated.

PO1498

A New Insight into Hyperchloremic Metabolic Acidosis in Kidney Transplant Recipients: Increased Postglomerular Blood Flow Is a Key Condition for Calcineurin Inhibitor-Induced Renal Tubular Acidosis

Shuzo Kaneko, Joichi Usui, Kazuhiro Takahashi, Tomokazu Kimura, Akio Hoshi, Kunihiro Yamagata. *Tsukuba Daigaku Igaku Iryokei, Tsukuba, Japan.*

Background: Hyperchloremic metabolic acidosis (HCMA) due to renal tubular acidosis(RTA) is a common in kidney transplant recipients(KTR). Calcineurin inhibitor (CNI) have been identified as a cause but have not been fully proven, and whether HCMA is a determinant of poor graft prognosis is controversial.

Methods: HCMA was defined as having a Na-CL (simple strong ion difference) value of 34 or less. All the cases of having diarrhea were excluded. The study group consisted of 26 KTRs who received the renal hemodynamic studies based on urinary clearance of inulin and para-aminohippuric acid 1year post-KT. And glomerular filtration rate (GFR), renal plasma flow (RPF), filtration fraction(FF) (GFR/RPF) and pre-/post-glomerular vascular resistance (pre-/postVR) were calculated.

Results: The incidence of HCMA was 31%(8/26). The univariate analysis of HCMA compared with non-HCMA significantly showed an increase in RPF(P=0.016), a decrease in post-VR(P=0.003), and a decrease in FF(P=0.0001), suggesting an increase in post-glomerular peritubular blood flow. In addition, the aah lesion score, an indicator of CNI vasculopathy, was significantly higher in the HCMA(P=0.015). All cases with HCMA were classified into low post-VR (Fig.1). Furthermore, in low post-VR alone, the tacrolimus trough level was significantly higher in the HCMA(P=0.002) (Fig.2).

Conclusions: In KTRs, increased postglomerular peritubular blood flow is a key condition for CNI-induced RTA. The presence of HCMA is probably not a serious condition, but rather a desirable hemodynamic state, however, more attention should be paid not to elevate CNI concentration levels in such condition.

Renal Negative Pressure Treatment as a Novel Therapy for Cardiorenal Syndrome

Jennifer L. Asher, Christopher D. Maulion, Olyvia Gleason, Grace Meegan, Juan B. Ivey-Miranda, James H. Fleming, Veena Rao, Jeffrey M. Testani. *Yale University School of Medicine, New Haven, CT.*

Background: Decongestion is the primary therapeutic objective in acute decompensated heart failure (ADHF). However, congestion itself can worsen renal function and limit diuresis. Renal pelvis negative pressure treatment (rNPT) should reduce tubular pressure, allowing improved kidney function and diuresis. We hypothesized that rNPT would improve diuresis, natriuresis & renal function in a congestion predominate heart failure (HF) model.

Methods: Ten ~80 kg pigs underwent thoracotomy with implantation of a pericardial, Swan Ganz, & bilateral ureteral JuxtaFlow® catheters. High dose furosemide (400mg bolus, then 80mg/hr) was administered since HF clinical use of rNPT will be in conjunction with loop diuretics. Each animal served as its own control with randomization of L vs. R kidney to -30 mmHg rNPT or no rNPT. HF was induced via cardiac tamponade (~200 ml of pericardial 6% hydroxyethyl starch) and IV normal saline. Pericardial pressure was maintained at 20-22.5 mmHg.

Results: Prior to HF induction, rNPT increased urine output (UOP) & creatinine clearance (CrCl) compared to the control kidney during furosemide diuresis ($p<0.001$ for all, Figure). HF induction achieved the target hemodynamic profile with stable cardiac output & elevated filling pressures (Figure). UOP, sodium excretion, & CrCl decreased during HF ($p<0.001$ for all, Figure), but were higher consistently in rNPT kidney vs. control ($p<0.05$ for all, Figure). UOP ($p=0.38$) was the same in rNPT during HF as control prior to HF (Figure).

Conclusions: rNPT increased UO and CrCl, with & without HF. Notably, rNPT rescued the congested cardio-renal phenotype with equivalent diuresis & natriuresis during HF with rNPT compared to the non-HF period without rNPT.

Accurate Estimation of Individual Sodium Intake with Repeated Spot Urine Sampling

Bigina N. Ginos,[1] Liffert Vogt,[1] Petra Frings-Meuthen,[3] Martina D. Heer,[2] Rik H. Olde Engberink.[1] *[1]Amsterdam University Medical Centres, location Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands; [2]Institute of Nutritional and Food Sciences, University of Bonn, Bonn, Germany; [3]German Aerospace Center (DLR), Institute of Aerospace Medicine, Cologne, Germany.*

Background: In clinical practice, individual sodium (Na^+) intake is estimated by measuring Na^+ excretion in one 24-h urine collection (UC), whereas long-term Na^+ balance studies indicate that 7 consecutive 24-h UCs may be needed. To reduce the burden of 24-h UC, single spot urine based alternatives have been suggested, but this approach has been shown to be very inaccurate. Whether the use of repeated spot UCs is an appropriate alternative for (multiple) 24-h UCs to estimate Na^+ intake is unknown.

Methods: We performed a post-hoc analysis of a metabolic ward study in 8 healthy male adults who consumed a 7-d diet with a fixed amount of 200 mmol/d Na^+. Urine was collected in 4 daily intervals (7-13h, 13-19h, 19-23h and 23-7h). After reaching steady state, we estimated Na^+ intake by single and repeated 24-h UCs and repeated spot UCs, using the Kawasaki formula with measured 24-h urine creatinine excretion.

Results: After day 5, mean 24-h Na^+ excretion matched intake, indicating that steady state was achieved (Fig 1A). Mean absolute differences (Δ) between measured Na^+ intake and 3-d spot UC estimates were 18.8 (SD 14.6), 32.3 (SD 18.7), 74.6 (SD 30.0) and 28.2 (SD 19.8) mmol for interval 7-13h, 13-19h, 19-23h and 23-7h, respectively (Fig 1B). With the exception of samples collected between 19-23h, Na^+ intake estimates by 3-d spot UCs did not significantly differ from Na^+ intake estimates by single (Δ 29.8 mmol; SD 23.9) and three 24-h UCs (Δ 22.9 mmol; SD 11.4).

Conclusions: Bias in Na^+ intake estimation did not significantly differ between repeated spot UCs and single and repeated 24-h UCs. Adequately powered studies need to confirm whether repeated spot UCs are an accurate and low burden alternative to 24-h UCs.

Funding: Private Foundation Support

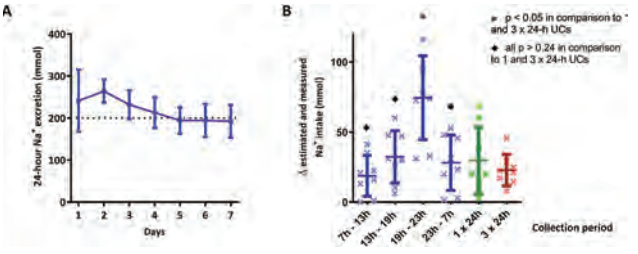

Figure 1. (A) Mean 24-h Na^+ excretion during 7-d diet. (B) Comparison of the performance of three consecutive spot UCs (blue), single 24-h UC (green) and three consecutive 24-h UCs (red) for estimating Na^+ intake (200 mmol/d). Absolute differences between estimated and measured Na^+ intake. Data are mean and SD.

PO1501

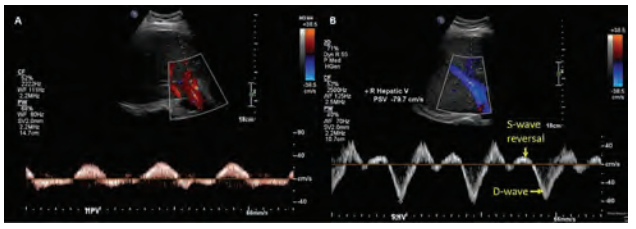
Utility of Doppler Ultrasound-Derived Hepatic and Portal Venous Waveforms in the Management of Heart Failure Exacerbation

Shashank S. Singh,[1] Mir tariq Ali,[1] Abhilash Koratala.[2] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Medical College of Wisconsin, Milwaukee, WI.*

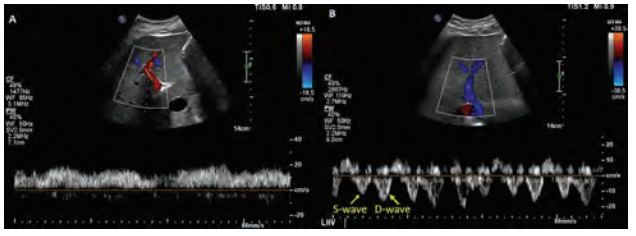
Introduction: Careful evaluation of the fluid volume status and systemic hemodynamics is of paramount importance in patients with heart failure. With growing interest in point of care ultrasonography, non-invasive parameters such as hepatic and portal vein waveforms are assuming importance as markers of systemic venous congestion.

Case Description: 43 year old male was admitted for right lower extremity necrotizing fasciitis requiring below the knee amputation. Postoperatively, he subsequently developed volume overload with pulmonary edema and acute renal injury. Given the patient's sensitive hemodynamic state, volume depletion was driven by doppler ultrasound, specifically portal vein and hepatic vein doppler. After a few days of therapy, the patient had improvement of his renal function, leading to a cessation of dialysis and return of renal function to near baseline.

Discussion: In patients with acute decompensated heart failure, residual clinical congestion at hospital discharge is associated with worse outcomes. A standard assessment of congestion is the measurement of right atrial pressure (RAP) and pulmonary capillary wedge pressures using pulmonary artery catheterization, though its invasive nature precludes routine use. Estimating beside RAP using inferior vena cava (IVC) ultrasound is now common, though it is not without numerous pitfalls limiting its utility. For example, the changes in size of the IVC depend on variations in intrathoracic pressure and lung compliance. Using portal and hepatic vein waveforms can add another piece of information for volume assessment. As shown in our images, the changes initially seen on doppler with hypervolemia can direct management for diuresis/volume removal. These changes seen on doppler waveform aids in management for decongestive therapy.



Portal (A) and Hepatic (B) vein waveforms before decongestive therapy



Portal (A) and Hepatic (B) vein waveforms after decongestive therapy

PO1502

Multiple Spot Urine Sampling Is More Precise and Accurate Than 24-Hour Urine Collection for Estimating Urinary Sodium Excretion

Gianluigi Ardissino,[3] Antonio Vergori,[3] Cesare Vergori,[3] Laura Martelli,[3] Silvia A. Ghiglia,[2] Antenore Giussani,[1] Alice Monzani,[4] Giovanni R. Pieri,[3] Marta Brambilla,[3] Patrizia Salice,[2] Annalisa Bosco,[3] Maria Cristina Mancuso,[3] Martino Marsciani,[5] Roberto Romano,[3] Michela Perrone,[3] Valentina Capone.[3] *[1]Renal Transplant Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Cardiology Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [3]Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [4]Dept. of Pediatrics, Novara, Italy; [5]UO Pediatria e Terapia Intensiva Pediatrica-Neonatale - Ospedale Bufalini, Cesena, Italy.*

Background: The estimate of sodium excretion (NaE) is important for the management of hypertension, but 24 hours urinary collection (24-hrsUC), the current standard of care, can be inaccurate, unpractical and poorly representative of the usual Na intake. Multiple spot urine sampling is not affected by any of these errors, so we hypotesized that it can be equally or more precise than 24-hrsUC for estimating NaE.

Methods: 4/subject 24-hrsUC and the related 439 urine samples (1/voiding), were analyzed for uNa and uCr. uNaE (in mEq/Kg/day) of each 24-hrsUC and uNa/uCrR of each voiding were calculated. Individual uNa excretion from 24-hrsUC were compared with all the means of uNa/uCrR derived from 2, 3 and 4 random samples from different days for both precision and accuracy using the mean of all the 24-hrsUC as individual "gold standard". Precision in estimating the gold standard of the 2 methods was measured by comparing the respective coefficient of variations (CV). Accuracy was measured by comparing the P30 and P20 of the 2 methods after transforming uNa/uCrR into uNaE in (mEq/kg/day) by means of the equations (one for children and one for adults) derived from the study data set.

Results: CV of 24-hrs-UCs was 25.7% and that of uNa-to-uCrR as derived from the mean of 2, 3 and 4 samples were respectively 37.1, 28.2 and 22.5%. The CVs were significantly higher in children. Accuracy: P30 and P20 of the 24-hrs-UC were 62.5% and 78.7%, respectively. The corresponding figures obtained from all the 20,258 possible means of 4 samples randomly taken from different days were 73.1% and 94.5%. The internal validation performed by the same subjects 1 year after and the external validation in 8 subjects confirmed the superiority of multiple spot urine sampling.

Conclusions: In real life, with various sources of error systematically affecting 24-hrs-UCs, uNa-to-uCrR will have an even higher precision and accuracy and should be preferred for estimating uNaE.

PO1503

Abnormal Circadian Rhythm of Urinary Sodium Excretion Correlates Closely with Hypertension and Target Organ Damage in Chinese Patients with CKD

Jun Zhang. *Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Whether the abnormal circadian rhythm of urinary sodium excretion is associated with hypertension in chronic kidney disease (CKD) is poorly understood. In this study, we assessed the relationship between the circadian rhythm of urinary sodium excretion and hypertension.

Methods: Urinary samples were collected during both the day (07:00 to 22:00) and night (22:00 to 07:00) to estimate night/day urinary sodium excretion ratios. Blood pressure (BP) and clinical data were also measured.

Results: A total of 1,099 Chinese CKD patients were recruited, 308 patients were excluded, and 791 patients were final enrolled in this study. Among them, 291 patients were normotensive and 500 were hypertensive CKD patients. A 1:1 propensity score matching (PSM) analysis was performed with age and estimated glomerular filtration rate (eGFR) matched between 190 normotensive and hypertensive patients. In the full cohort and PSM cohort, multivariate regression analysis showed that the night/day urinary sodium excretion ratio was an independent risk factor for clinical hypertension, whereas 24 h urinary sodium excretion, diurnal and nocturnal urinary sodium excretion were not. When the night/day urinary sodium excretion ratios were further divided into tertiles (tertile 1 < 0.47, tertile 2, 0.47–0.84 and tertile 3 > 0.84), multivariate analysis showed that tertile 3 was independently associated with hypertension in the full and PSM cohorts. In addition, tertile 3 was also independently associated with eGFR ≤ 60 mL/min/1.73 m2 and left ventricular hypertrophy.

Conclusions: These data suggested that an abnormal circadian rhythm of urinary sodium excretion was independently associated with hypertension and target-organ damage. Individualized salt intake and therapeutic strategies should be used to normalize the natriuretic dipping profile in CKD patients.

Mirabilite External Application for the Treatment of Nephrotic Edema: A Randomized Controlled Study

Haitao Tu, Siying Chen, Liangliang Wang, Huan Lu, Shuifu Tang. *The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.*

Background: Lower limb edema is the main symptom of nephrotic syndrome (NS). In addition to well established treatment for edema, external mirabilite application (EMA) around swollen areas could potentially benefit patients with NS. Mirabilite is hydrous sodium sulfate mineral that quickly turns into thenardite which is known for its ability to highly absorb water.

Methods: A randomized, single-blinded study included 52 patiennts with NS who were randomly assigned to the experimental group (EMA+diurethic therapy, n=26) and the control group (diurethic therapy, n=26). The study was approved by IRB of the 1st Affiliated Hospital of Guangzhou University of Chinese Medicine. Mirabilite treatment was applied via special cloth bag placed around swollen area on legs, 6 hours per day for 10 days. The primary outcome was the change in leg circumference (LC) and biochemical characteristics of patients. The secondary outcome included body weight and urine output.

Results: Patients from experimental group had significant decrease in LC compared to controls (P=0.000), yet small changes in urine volume output (P=0.436). However, significant correlation of LC with weight gain of mirabilite was observed (r=-0.586, P=0.002). Concentration of electrolytes did not change significantly in the groups. Similar effect was observed regarding liver function markers. However, albumin concentration increased significantly in both experimental and control group. After EMA+diurethic treatment patients had significantly lower body weight (P=0.000). Moreover, weight loss was significantly positively correlated with decrease in LC (r=0.612, P=0.000).

Conclusions: This study suggests that MEA is effective in relieving the symptoms of lower extremity edema in NS patients, but it does not help much in the state of water and sodium storage.

PO1505

Reappraisal of Urinary Sodium Excretion as a Predictor of Clinical Outcomes in Heart Failure

Harini Bejjanki,[2] Eddy J. De Jesus,[2] Vijay Damarla,[1] Amir Kazory.[2] *[1]Decatur Memorial Hospital, Decatur, IL; [2]University of Florida, Gainesville, FL.*

Background: Congestion is established as the driver of adverse outcomes in heart failure (HF). Since removal of excess fluid and sodium is often the primary therapeutic objective in this setting, accurate monitoring of the progress of diuretic therapy is of critical importance. While weight change and fluid balance have conventionally been used for this purpose, inconsistent collection, inherent delay in data availability, and lack of distinction between water and sodium balance are among their limitations. We sought to explore the contemporary data on the use of urinary sodium (UNa) as a predictor of outcomes in these patients.

Methods: Articles cited in the PubMed database using keywords "heart failure" and "urine sodium" were searched. Available data from clinical trials published between June 2015 and May 2020 were included. The studies were selected if they prognosticated outcomes in the HF population through use of UNa. Pertinent data on clinical and laboratory parameters (e.g. dose and timing of diuretic therapy, eGFR, serum sodium, and UNa) were extracted and reviewed.

Results: A total of 14 studies with 2,350 participants were included, of which 11 were prospective. The study populations consisted of 12 acute HF cohorts, 1 chronic, and 1 with both. The mean age was 67 years (64% men) with an ejection fraction of 35% and an eGFR of 50 ml/min. Most studies (12 out of 14) used UNa concentration, 2 used fractional excretion and clearance of sodium. Surprisingly, while there was substantial variation across studies in the timing of the applied metric, those exploring clinical endpoints unanimously reported a correlation between low UNa excretion and various adverse outcomes (e.g. worsening renal function, HF readmission, and mortality).

Conclusions: Over the past few years, UNa has been the focus of much investigation as a tool for monitoring of therapy and prognostication in patients with HF. The findings of our study are two folds: 1) Regardless of the applied metric and its timing, contemporary data supports the use of UNa as a potent predictor of clinical outcomes in HF that lacks the limitations of conventional methods. 2) There is no consensus on the optimal cut off and time points for measurement of UNa in this setting. In order for UNa to be applied widely as a consistent and reliable tool, this knowledge gap needs to be addressed in future studies.

PO1506

Defective NAD$^+$ Homeostasis in ADPKD and the Effects of PC1CTT on Redox Modulation and Disease Progression

Laura Onuchic,[1] Valeria Padovano,[2] Nikolay P. Gresko,[1] Giorgia Schena,[1] Vanathy Rajendran,[1] Michael J. Caplan.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Broad Institute, Cambridge, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in the genes encoding polycystin-1 or 2 (PC1 or PC2). Defective metabolism is a hallmark of ADPKD. The C-terminal cleavage product of PC1 (PC1CTT) can translocate to mitochondria and its expression in Pkd1 KO cells may rescue defective mitochondrial phenotypes. Altered oxidoreductase activity is detected in an ADPKD *in vitro* model. Here we assess the degree of redox imbalance between NAD/NADH in *in vitro* and animal ADPKD models. Moreover, we use an *in vitro* model to express variations of PC1CTT that localize to different subcellular compartments and reveal an association between PC1CTT localization and Redox modulation. Finally, we show that expression of a PC1CTT variant with predominant nuclear as opposed to mitochondrial localization exacerbates the cystic phenotype in a PKD1 KO mouse model.

Methods: We quantified the ratio between NAD+ and NADH in lysates from Pkd1$^{+/-}$ and Pkd1$^{-/-}$ mouse renal epithelial cells. We also assessed the NAD/NADH ratio in kidney lysates from ADPKD mouse models and WT controls. We generated 3 variations of PC1CTT with either an N-terminal HA-tag (2HA-PC1CTT), a C-terminal HA-tag (PC1CTT-HA) or no additional tag, and applied the assay to lysates from HEK cells transfected with these constructs. Finally, we expressed 2HA-PC1CTT in a PKD1 KO mouse model and observed phenotypic differences.

Results: The NAD/NADH ratio was 80% higher in Pkd1$^{+/-}$ cells in comparison to Pkd1$^{-/-}$ cells. Kidney lysates from WT mice had double the NAD/NADH ratio compared to that observed in cystic and pre-cystic animals. Transfection of HEK cells with the PC1CTT constructs revealed distinct patterns: 2HA-PC1CTT localized to nuclei, PC1CTT-HA localized to mitochondria and PC1CTT was found in both. PC1CTT and PC1CTT-HA expressing HEK cells exhibited 40% and 60% higher NAD/NADH ratios than those measured in 2HA-PC1CTT-expressing cells. ADPKD mice expressing 2HA-PC1CTT exhibited a 3-fold increase in kidney-weight/body-weight in comparison to control ADPKD mice.

Conclusions: ADPKD is characterized by defective NAD+ homeostasis. Mitochondrial localization of PC1CTT can potentially rescue this redox imbalance, while nuclear localization of PC1CTT appears to aggravate this imbalance and exacerbate the cystic phenotype in animal models.

PO1507

Cleavage Fragments of Polycystin 1 Respond to Oxidative Stress and Alter Mitochondrial Dynamics and Function

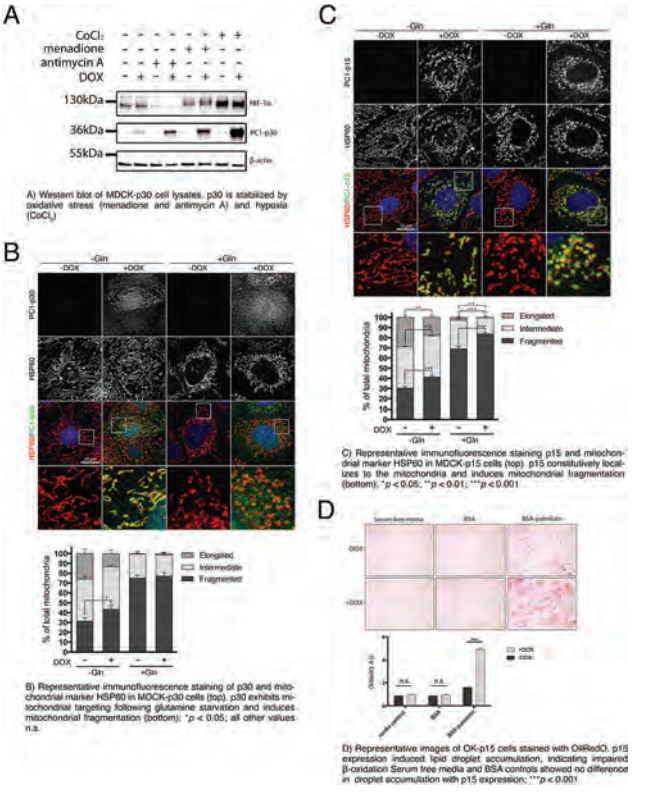
Hannah Pellegrini, Elizabeth H. Sharpe, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

Background: The PKD1 gene, which is mutated in ADPKD, encodes for the PC1 transmembrane protein containing a cytoplasmic C-terminal tail that undergoes cleavage at multiple sites. Two of these C-terminal fragments, a ~30 kDa fragment (p30), and a ~15 kDa fragment (p15) corresponding to the entire soluble C-terminal tail and the extreme end respectively, are overexpressed in patient kidneys. Metabolic reprogramming is a hallmark of ADPKD. We demonstrate that the C-terminal fragments of PC1 respond to oxidative stress and contribute to metabolic reprogramming by altering mitochondrial dynamics.

Methods: MDCK and OK cell lines were generated stably expressing myc-tagged p30 or p15 under a doxycycline-inducible promoter Protein levels of p30 were determined by western blot and localization by immunocytochemistry. Mitochondrial morphology was classified performing immunocytochemistry combined with image analysis. Fatty acid oxidation was assessed performing OilRedO staining and quantified by measuring the number of lipid droplets

Results: p30 normally undergoes rapid degradation and is stabilized in response to oxidative stress. Following glutamine starvation, p30 targets mitochondria and results in fragmentation. p15 does not undergo degradation and constitutively targets to the mitochondria where it induces mitochondrial fragmentation. Further, expressing p15 results in accumulation of lipid droplets indicative of impaired mitochondrial β-oxidation.

Conclusions: Our data unmasks p30 as a sensor of metabolic stress. We speculate that p30 stabilization and subsequent p15 cleavage are involved in metabolic reprogramming in ADPKD by altering mitochondrial morphology and function. Elucidating the exact underlying mechanisms is of major importance to understanding disease progression in ADPKD.



PO1508

Cardiac Dysfunction in Pkd1-Deficient Mice Is Associated with Metabolic Rewiring

Andressa G. Amaral,[1] Camille C. Silva,[1] Kinulpe H. Sampaio,[3] Amaro N. Duarte-Neto,[1] Antonio C. Bloise,[1] Laura Cassina,[2] Alessandra Boletta,[2] Adriano B. Chaves-Filho,[1] Marcos Y. Yoshinaga,[1] Sayuri Miyamoto,[1] Silvana A. Bordin,[1] Alicia J. Kowaltowski,[1] Luiz F. Onuchic.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]IRCCS Ospedale San Raffaele, Milano, Italy; [3]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brazil.*

Background: Myocardial abnormalities are associated with significant clinical burden in ADPKD but the underlying pathogenesis is still largely unclear.

Methods: We investigated the metabolic basis of the ADPKD-associated cardiac phenotype using a mouse homozygous for a *Pkd1* hypomorphic allele that prevents PC1 cleavage (VV) with early cardiac dysfunction.

Results: VV hearts displayed metabolome and lipidome signatures associated with lower levels of glucose and amino acids (aa) and higher levels of lipid species than wild-type (WT) hearts. This VV profile also included decreased *Cpt1b* (-28±12%, p<0.05, *Pparα* (-26±12%, p<0.05), PGC1α (-22±8.4%, p<0.05), phospho-AMPK (-46±12%, p<0.01) and phospho-ACCβ (-35±15%, p<0.05) expression, indicating downregulation of fatty acid oxidation and lipotoxicity. Mitochondrial density was higher in VV than WT hearts (49.5±1.8% *vs* 41.3±3.0%, p<0.01) and size was smaller, but shape descriptors and MFN2 and DRP1 expression did not differ. Structural changes were followed by increased cardiac oxygen consumption in response to glucose (928±157 *vs* 762±104pmolO_2/min/mg, p<0.05). Notably, VV neonate cardiomyocytes showed higher mitochondrial maximal respiration than WTs (327±24 *vs* 216±64pmolO_2/min, p<0.01) and a trend of increased basal respiration (p=0.09). These data suggest that glucose and aa may be preferably used as energy substrate in VV hearts. Cardiac expression of fetal genes *Nppa* and *Acta1* were also increased (3.35±1.54 *vs* 1.10±0.54 AU, p<0.01 and 2.26±0.94 *vs* 1.07±0.38 AU, p<0.01, respectively), revealing inappropriate transcriptional transition to the mature state. Unlike *Pkd1*-deficient kidneys, phospho-RPS6 is downregulated in VV hearts (-58±15%, p<0.01) and glucose is not targeted for aerobic glycolysis, since lactate levels were reduced. These metabolic changes correlated with increased cardiac apoptosis and inflammation but not with hypertrophic remodeling.

Conclusions: Our findings uncover a cardiac metabolic rewiring associated with *Pkd1* deficiency, revealing a pattern only partially similar to the metabolic profile observed in the cystic kidney phenotype. These data conceptually expand the understanding of heart dysfunction associated with *Pkd1* deficiency and likely ADPKD.

PO1509

Elevated Expression of CaMK4 Contributes to mTOR-dependent Cell Proliferation and Cyst Growth of ADPKD Cells

Yan Zhang, Emily A. Daniel, Gail Reif, Darren P. Wallace. *University of Kansas Medical Center, Kansas City, KS.*

Background: Mammalian target of rapamycin (mTOR), a central integration site for pathways involved in cell growth, is abnormally activated in renal cyst-lining cells in human ADPKD and PKD mice. mTOR inhibition reduces cell proliferation and cyst growth in PKD mice. A better understanding of the pathways responsible for elevated mTOR activation is important for the development of new therapies. Calcium/calmodulin-dependent kinase type IV (CaMK4) was recently identified as an important upstream regulator for mTOR activation in multiple cells. CaMK4 is fully activated by binding of Ca^{2+}/Calmodulin(CaM) and phosphorylation by Ca^{2+}/CaM-dependent kinase kinases β (CaMKKβ). However, the role of CaMK4 on mTOR signaling and cyst growth in ADPKD remains unclear.

Methods: We stained tissue sections of human ADPKD kidneys and normal human kidneys (NHKs) with an antibody to CaMK4. We also analyzed levels of CaMK4 in primary human ADPKD and NHK cells, 30-weeks old *Pkd1*$^{RC/RC}$ (BALB/c background) and *Pkd1*$^{RC/+}$ (normal) mouse kidneys. We determined the effects of W7, a calmodulin inhibitor, STO-609, a CaMKKβ inhibitor, and KN-93, a CaMK4 inhibitor, on mTOR signaling, cell proliferation, and *in vitro* cyst growth of ADPKD cells. To confirm a role of CaMK4 on mTOR regulation, we knocked down CaMK4 using a lentiviral shRNA approach in human ADPKD cells.

Results: We found moderate levels of CaMK4 in nuclei of tubule cells in NHK; by contrast, there were elevated levels of CaMK4 in the cytosol and nuclei of cystic epithelial cells of human ADPKD kidneys. CaMK4 level was 2.5-fold higher in human ADPKD cells compared to NHK cells. We also found a 2.8-fold increase of CaMK4 expression in *Pkd1*$^{RC/RC}$ kidneys compared to normal kidneys. Inhibition of CaMK4 using KN-93 caused a remarkably decreased in levels of P-S6K and P-S6 in a dose-dependent and time-dependent manner. Inhibition of CaMK4 activation using W7 and STO-609 reduced P-S6 in ADPKD cells. CaMK4 knock down decreased levels of mTOR, P-S6K and P-S6 confirming regulation of CaMK4 on mTOR signaling in ADPKD cells. W7, STO-609, and KN-93 significantly inhibited cell proliferation and *in vitro* cyst growth of ADPKD cells within a collagen matrix.

Conclusions: The aberrant expression of CaMK4 appears to contribute to elevated mTOR-dependent proliferation of cystic cells and may be a potential target to slow cyst growth in PKD.

Mechanisms of Tethered-Ligand Mediated Polycystin 1 GPCR Signaling

Shristi Pawnikar,[1] Brenda S. Magenheimer,[2] Robin L. Maser,[2] Yinglong Miao.[1] *[1]University of Kansas, Lawrence, KS; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Polycystin-1 (PC1) is the most commonly mutated protein in autosomal dominant polycystic kidney disease (ADPKD) thought to function as an atypical GPCR. *In vivo* studies have demonstrated PC1-regulated G protein signaling is a critical function for preventing renal cystogenesis. Like the Adhesion class of GPCRs, PC1 undergoes auto-catalyzed cleavage at a GPS motif which generates an extracellular N-terminal fragment and a membrane-embedded C-terminal fragment (CTF) composed of 11 transmembrane domains preceded by an N-terminal extracellular stalk of 25 residues. We previously reported that CTF-mediated signaling to an NFAT promoter-luciferase reporter is dependent on the presence of the stalk, is reduced by ADPKD-associated missense mutations within the stalk, and can be rescued by synthetic, stalk-derived peptides, supporting a tethered ligand mechanism of PC1-G protein signaling. In this study, we have utilized a combination of computational molecular dynamics (MD) simulations and mutation-function analyses to investigate the mechanism of PC1 signaling.

Methods: A computer model of the human PC1 CTF was generated using the cryo-EM structure of the PC1-PC2 complex (Su et al, 2019) and the I-TASSER protein structure prediction tool. All-atom enhanced simulations (> 900 ns) using a robust Gaussian accelerated molecular dynamics (GaMD) technique were performed followed by calculation of residue correlation matrices and free energy profiles for residue-residue interactions.

Results: All-atom simulations with the wildtype, ADPKD mutant and stalk-less versions of the PC1 CTF model were consistent with the previous functional signaling data. Key residue interactions between different domains of the CTF predicted from the GaMD simulations suggest an allosteric mechanism for PC1-G protein activation for which mutagenesis and functional signaling and expression assays are underway.

Conclusions: Complementary experiments and simulations have provided important insights into a mechanism of PC1 GPCR signaling at an atomic level and support an important role of the stalk region as a tethered ligand. This in-depth knowledge is expected to facilitate future drug design efforts targeting this function of PC1 for more effective treatments of ADPKD.

Role of Polycystin 2 in Endoplasmic Reticulum Calcium Release and Pathogenesis of Polycystic Kidney Disease

Biswajit Padhy, Jian Xie, Chou-Long Huang. *University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: The prevailing view is that PKD is a ciliopathy. Yet, polycystin-2 contains an ER retention signal, is most abundantly expressed in ER. Early studies showed that PC2 is involved in agonist-induced ER Ca2+ release. Decrease in ER Ca2+ release in PC2-deficient cells is believed to contribute to cAMP overproduction and cystogenesis, the foundation for treatment by tolvaptan. Recent patch-clamp recordings reveal that PC2 conducts predominantly monovalent cation with ~40X more selective to K+ than Ca2+. The low selectivity for Ca^{2+} raises the question regarding the role of PC2 in Ca2+ release in ER and thus the role of ER-localized PC2 in PKD pathogenesis. Cation exchange and/or parallel anion movement across ER membrane is imperative for Ca2+ release. TRIC-B (trimeric intracellular cation-B) is a known ER resident K+ channel mediates counterion exchange for IP3R and RyR-mediated Ca2+ release.

Methods: For in vitro studies PC2-deleted renal epithelial cell line and HEK cells with CRISPR-Cas9-mediated gene knockout of TRICB channel are used. ER Ca2+ release stimulated by carbachol or ATP is assayed by increases in the intracellular Ca2+ measured by using Fura-2 calcium imaging. Zebrafish is used as in vivo PKD model. Gene specific antisense morpholinos are used for targeted knockdown of PC2 and TRICB in zebrafish embryos. Dorsal curvature and pronephric cystic phenotypes are analyzed.

Results: Agonist-stimulated ER Ca2+ release is blunted in PC2-null epithelial cells. Expression of WT PC2 restores ER Ca2+ release. Expressing WT TRIC-B channel, but not LOF mutant, rescues ER Ca2+ release in PC2-null cells. Similarly, ER Ca2+ release is blunted in cells deleted of TRIC-B, and expression of WT PC2 partially rescues defective ER Ca2+ release in TRIC-B-null cells. Zebrafish embryos injected with PC2 antisense morpholino develops dorsal curvature and enlarged pronephric cyst, which can be rescued by co-injecting WT, but not LOF mutant, PC2 RNA. Co-injecting WT, but not LOF, TRIC-B RNA rescues defects in PC2-morphant fish.

Conclusions: PC2 is a monovalent cation channel facilitates ion exchange for IP3R-mediated Ca2+ release. Loss of this function of PC2 in ER plays a critical role in the cystogenesis of PKD.

Ca^{2+}-Permeable TRPV4 Channel Modulates Cystogenesis in ARPKD PCK453 Rats

Victor N. Tomilin, Naghmeh Hassanzadeh Khayyat, Oleg L. Zaika, Oleh Pochynyuk. *University of Texas John P and Katherine G McGovern Medical School, Houston, TX.*

Background: PKD is a cohort of monogenic disorders that result in the development of renal cysts filled with fluid. Deficient flow-mediated $[Ca^{2+}]_i$ responses have been linked to the development of PKD. We showed that mechanosensitive TRPV4 channel is preferentially expressed in the distal nephron where its activity is imperative for flow-dependent $[Ca^{2+}]_i$ elevations. We also found that TRPV4 activity was dramatically decreased in primary cells cultured from ADPKD patients thus contributing to their impaired $[Ca^{2+}]_i$ dynamics.

Methods: We tested how manipulation of TRPV4 activity with pharmacological or dietary means affects cystogenesis in PCK453 rats, a model of ARPKD using a combination of metabolic studies, biochemistry, and $[Ca^{2+}]_i$ imaging in freshly isolated cyst monolayers.

Results: Treatment with TRPV4 activator, GSK1016790A for 1 and 2 months attenuated ARPKD progression manifested as a significant decrease in kidney to total body weight ratio, reduced cyst numbers and area when compared to the control. TRPV4 blocker, GSK2193874 exacerbated ARPKD progression leading to a larger kidney volume and more pronounced cystogenesis. We showed that high K^+ intake increased renal TRPV4 expression and activity. Consistently, high K^+ diet (10% KCl) had similar to GSK1016790A beneficial actions on ARPKD progression. GSK2193874 reversed these effects suggesting their TRPV4-dependent nature. Unexpectedly, high K^+ high alkali diet

(10% K Bicarbonate/Citrate) dramatically accelerated cystogenesis despite augmented renal TRPV4 expression. TRPV4 activity (estimated as a GSK1016790A-dependent rise in $[Ca^{2+}]_i$ in freshly isolated cyst monolayers from PCK453 rat kidneys) was approximately 2 fold larger in cyst cells from high K^+ diet treated compared to control. Basal $[Ca^{2+}]_i$ and flow-induced $[Ca^{2+}]_i$ levels were also larger on this condition. In contrast, TRPV4 activity was more than 2 fold lower in rats on high K^+ high alkali diet.

Conclusions: We show a positive correlation between TRPV4 functional status and the time course of ARPKD progression in PCK 453 rats. Chronic alkali load renders TRPV4 to an inactive state, which contributes to exacerbated cystogenesis in PCK453 rats. We also posit that stimulation of TRPV4 with GSK1016790A or high K^+ but not high K^+ high alkali diet will be instrumental to attenuate the rate of PKD progression in clinic.

Somatic Tubular Epithelial Cell Model of Type II Polycystic Kidney Disease Reveals Phenotypes of Altered Ciliary Length and Polycystin-Intraflagellar Complex Degradation

Ankita Roy,[1,2] Courtney E. Vishy,[1,2] Louisa Helms,[1,2] Ivan G. Gomez,[1,2] Jonathan Himmelfarb,[2] Benjamin S. Freedman.[1,2] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA.*

Background: Autosomal dominant polycystic kidney disease (PKD) is a life-threatening monogenic disorder affecting 12 million people worldwide, commonly due to loss-of-function mutations in *PKD1* or (type II) *PKD2*, encoding polycystin-1 (PC1) and polycystin-2 (PC2), respectively. These form a receptor-channel complex in the primary cilium whose molecular function remain uncertain, making it difficult to develop targeted therapeutics. Mice and organoids can express PKD phenotypes, but are slow and complex, posing challenges for mechanistic analysis.

Methods: To establish a somatic cell model of PKD, we generated five clones of porcine proximal tubule cell line (LLCPK1) completely lacking PC2 using the CRISPR-Cas system, alongside five isogenic control lines. Mutations were verified for each allele by TOPO cloning and clones were derived from a single subclone to minimize heterogeneity. Cells were evaluated for PC1 steady-state levels, ciliary defects, and cyst formation in low adhesion plates in the presence of cyst activators. Forskolin, 8-Br-cAMP and the myosin inhibitor blebbistatin promoted cystogenesis. Transcript analysis indicated that the effects of altered PC1 steady-state levels was post-transcriptional. Exogeneous *myc*-PC2 rescued PC1 in the PC2 null cells.

Results: In the absence of PC2, PC1 was thoroughly degraded, similar to findings in human and distinct from mouse. Notably, intraflagellar transport components including ARL13B and IFT88 were also reduced. Cilia in 2D cultures appeared short while in the cystic cells was lengthened. Pharmacologic agents that inhibit the proteasome and the lysosome stabilize PC1 in these cells and rescues the ciliary phenotype. Additionally, the drugs reduce cyst size in human PKD organoids lacking *PKD2*.

Conclusions: We have established a somatic tubular epithelial cell model for PKD, which can be rapidly assessed for molecular and cellular phenotypes. This reveals the necessity of PC2 for proper ciliary structure and to prevent the degradation of a protein complex containing PC1 and intraflagellar transport components. Overall the porcine lineage appears more similar to human cells compared to mouse. Targeting degradation pathways rescues this novel complex and may represent a useful therapeutic approach for PKD.

Heterozygous Loss of Pkd2 Accelerates Cystogenesis in Pkd1$^{RC/RC}$ Mice

Emily A. Daniel, July P. Metcalf, Yuqiao Dai, Yan Zhang, Darren P. Wallace. *University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in *PKD1* (~85% of cases) or *PKD2* (~10% of cases), which encode polycystin-1 (PC-1) and polycystin-2 (PC-2), respectively. The sporadic nature of cyst formation led to the hypothesis that cystogenesis requires a two-hit mechanism, involving a germline mutation (first hit) and somatic mutation (second hit) in the PKD gene. More recent evidence indicates that reducing normal PC-1 expression below a critical threshold is sufficient to initiate cyst formation. To further investigate the role of gene dosing, we evaluated the effect of knocking out one allele of *Pkd2* on the onset and progression of cystogenesis in the *Pkd1$^{RC/RC}$* (R3277C) hypomorphic mouse model that develops mild cystic disease over several months (Hopp, *et al.* J CIin Invest., 2012).

Methods: *Pkd2$^{+/-}$* mice (Wu *et al*. Cell, 1998), which have normal kidneys, were crossed with *Pkd1$^{RC/RC}$* mice to generate *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* mice. Body weight (BW), two kidney weight (KW), KW/BW, and cystic index were compared between *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* and *Pkd1$^{RC/RC}$* littermates from 1 week to 9 months. Cystic index and blood urea nitrogen (BUN) were also measured.

Results: There was no difference in BW between the *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* and *Pkd1$^{RC/RC}$* mice. We found that *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* mice developed early cystogenesis with rapid increases in KW and cystic index up to 8 weeks of age. The KW/BW of *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* mice was twice that of *Pkd1$^{RC/RC}$* mice at 8 weeks (3.0 ± 0.2 *vs.* 1.5 ± 0.1%) and cystic index was also significantly higher (32.0 ± 3.8 *vs.* 5.6 ± 3.7%). At 9 months, KW/BW of the *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* mice remained elevated compared to *Pkd1$^{RC/RC}$*mice (3.2 ± 0.2 *vs.* 1.7 ± 0.1%). Cystic index was 21.0 ± 0.7 and 6.4 ± 2.1% for the *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* and *Pkd1$^{RC/RC}$* kidneys, respectively. *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* mice also had elevated renal fibrosis and BUN levels at 9 months, consistent with a decline in renal function.

Conclusions: This study demonstrates that heterozygous loss of *Pkd2* accelerated the onset of cystogenesis in *Pkd1$^{RC/RC}$* mice, supporting the hypothesis that PC-1 and PC-2 function in a common pathway and that lowering the expression of the polycystins is sufficient to initiate cystogenesis. We think that the increased progression of cystic disease in *Pkd1$^{RC/RC}$*; *Pkd2$^{+/-}$* mouse makes it a promising model for evaluating therapeutic interventions.

FPC, TFAP2B, and MCM3 Function in a Species-Specific Regulome That Modulates Myc/MYC Expression: Implications for ARPKD

Naoe Harafuji,[1] Chaozhe Yang,[1] Maryanne Odinakachukwu,[1] Maoqing Wu,[1] Ljubica Caldovic,[2] Lisa M. Guay-Woodford.[1] *[1]Center for Translational Research, Children's National Medical Center, Washington, DC; [2]Center for Genetic Medicine Research, Children's National Medical Center, Washington, DC.*

Background: Mutations in *PKHD1* cause human ARPKD (MIM 263200), but mouse *Pkhd1* mutants have limited or no renal cystic disease. We previously showed that MYC is overexpressed in human ARPKD kidneys but not in mouse *Pkhd1* mutant kidneys, and that mouse FPC C-terminal domain (FPC-CTD) activates *Myc* (ASN 2018). Trudel (2019) has reported that Myc is a central driver in *Pkd1*-induced pathogenesis. Relevant to the current study, mice express three TFAP2B isoforms while humans express only one, which is most similar to mouse isoform TFAP2B1. Here, we describe a species-specific regulatory framework (regulome) in which FPC-CTD, TFAP2B, and MCM3 regulate *Myc/MYC* in renal collecting duct (CD) cells.

Methods: Human and mouse CD cell lines, *Myc*-tagged *TFAP2B*, *Tfap2b1*, and *Tfap2b2*, V5-tagged human and mouse FPC-CTD constructs, and *Cys1*, *Pkhd1* and *Myc/MYC* promoter constructs were used to perform dual luciferase and co-IP assays.

Results: In mouse cells, TFAP2B1 & 2 positively regulated expression of *Pkhd1* and *Cys1* while *Myc* was positively regulated by TFAP2B2 but negatively regulated by TFAP2B1. TFAP2B1 negative regulation of *Myc* was epistatic over FPC-CTD activation. MCM3, previously identified as a FPC-CTD binding partner, positively regulated *Myc* promoter activity. Human *MYC* was activated by FPC-CTD and negatively regulated by TFAP2B.

Conclusions: We show that in both mouse and human, FPC-CTD and TFAP2B regulate *Myc/MYC* expression. Notably, mouse TFAP2B isoforms differentially regulate *Myc* expression, while humans lack a *MYC* activating isoform. Based on our data, we propose a model in which a regulome that includes FPC-CTD, TFAP2B, and MCM3 modulates *Myc/MYC* expression in CD cells in a species-specific fashion. Species-specific renal phenotypes could be attributable to differences in constituent proteins, isoform diversity, and epistatic interactions within the proposed regulome. We speculate that this model may explain the differential effects of *PKHD1*/*Pkhd1* deficiency on renal cystogenesis and provide initial clues for putative renoprotective mechanisms in *Pkhd1* mutant mice.

Characterization of Porcine Models of Autosomal Recessive Polycystic Kidney Disease

Jessica M. Smith,[1] Alexander W. Coutts,[2] Barbara R. Tschida,[2] Harrison H. Wells,[1] Daniel F. Carlson,[2] Peter C. Harris.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Recombinetics, St Paul, MN.*

Background: Autosomal recessive polycystic kidney disease (ARPKD), a relatively common form of mainly infantile PKD, is caused by biallelic mutations to *PKHD1*. The missense change, p.T36M, is the most common pathogenic allele (~15% of the total) and associated with severe disease. Mouse and rat models do not display the classical ARPKD presentation of early onset, enlarged, echogenic kidneys. Therefore, to better understand the pathomechanism, we developed and characterized porcine ARPKD models. The pig has a similar anatomy (multi-papillary structure) and physiology to humans, and thus it makes an ideal model system to study disease progression and test treatment options in this disorder.

Methods: Using the CRISPR/Cas9 methods and homology directed repair (HDR), we genetically engineered pigs with the p.T36M or null *PKHD1*alleles. The following genotypes were breed (WT, T36M/T36M, T36M/KO, KO/KO) and characterized longitudinally to 5-months old (where possible) using MRI and a blood chemistry panel, and analyzed histologically.

Results: Two KO/KO pigs were sacrificed at one and two days of age with a phenotype of greatly enlarged cystic kidneys with severe functional loss as well as fibrotic, cystic livers, matching classical human ARPKD. Four T36M/KO pigs were imaged monthly to five months but they only developed a few kidney cysts that did not grow significantly during follow up, and without a decline in function. Similar analysis of two T36M/T36M pigs revealed only occasional kidney cysts.

Conclusions: Through gene editing, an authentic porcine model of early onset ARPKD kidney and liver disease was developed that will be valuable for understanding the pathomechanism of neonatal ARPKD. MRI and biochemical assays enabled detailed

evaluation of functional and morphological changes in the kidneys, liver, and heart of the milder genotypes. Analysis of the p.T36M allele indicates it more functional in pigs, and so associated with a milder phenotype than in humans.

PO1518

Cystin Deficiency in Cys1$^{cpk/cpk}$ Cells Leads to Marked Reduction in Fibrocystin/Polyductin (FPC)

Yiming Zhang,[3] Chaozhe Yang,[4] Phillip D. Bell,[2] Lisa M. Guay-Woodford,[1,4] Zsuzsanna M. Bebok.[3] *[1]The George Washington University, Washington, DC; [2]The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; [3]University of Alabama at Birmingham, Department of Cell Developmental and Integrative Biology, Birmingham, AL; [4]Children's National Health System, Washington, DC.*

Background: Human ARPKD (MIM 263200) is caused by mutations in *PKHD1* (which encodes FPC), yet mouse *Pkhd1* mutations cause minimal renal cystic disease. By contrast, *Cys1$^{cpk/cpk}$ (cpk) mice* exhibit an ARPKD-like renal phenotype. The function of cystin (encoded by *Cys1*) is not fully understood, but the protein is found in the cytoplasm, primary cilium, and nucleus. Its N-terminal myristoylation enables membrane-association, and the AxEGG motif is necessary for ciliary targeting, suggesting a function for cystin in vesicular trafficking. To examine whether cystin is a trafficking adaptor for transmembrane ciliary proteins, like FPC, we evaluated FPC expression in *wild-type (WT)* and *cpk* mouse kidney cell lines.

Methods: Cell lines: Wild-type (WT) and *cpk* mouse kidney cortical collecting duct cells were developed using mTERT immortalization. We used qRT-PCR, western blotting, morphometry (ImageJ), and protein colocalization with fluorescent confocal microscopy.

Results: While *Pkhd1* mRNA levels were similar, FPC protein levels were reduced by 75% in *cpk* cells relative to WT. In contrast, PC2 protein levels were only reduced by 25% and no differences in acetylated tubulin or other ciliary proteins, e.g. Ift88 or Arl13b, were observed. In *cpk* cells, both cystin and FPC were absent from primary cilia, but the percentage of *cpk* cells with primary cilia, ciliary length and thickness were identical to *WT* cells. These observations suggested that cystin deficiency specifically influenced FPC protein expression and localization. Elevated levels of p62/*SQSTM1* expression suggest that enhanced, selective autophagy could explain reduced FPC levels in *cpk* cells. In support of this proposed mechanism, we observed that proteasome inhibition, which activates autophagy, reduces FPC levels in both *WT* and *cpk* cells.

Conclusions: Our studies reveal a patho-mechanistic connection between renal phenotypes in human ARPKD and *cpk* mice, wherein cystin deficiency is linked to reduction in FPC. Current studies are focused on elucidating mechanisms by which cystin deficiency induces autophagy and loss of FPC. The recent identification of an ARPKD patient with a homozygous *CYS1* mutation (bioRxiv 2020 doi.org/10.1101/2020.02.18.946285) highlights the significance of these studies for human disease.

Tsc2 Mutation Induces Renal Tubular Cell Nonautonomous Disease

John J. Bissler,[1,2] Prashant Kumar,[1] Ying Yao,[1] Fahad Al-Zadjali.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]St. Jude Children's Research Hospital, Memphis, TN.*

Background: Tuberous sclerosis complex is associated with both renal tumors and cysts in most affected patients. The renal cystic disease is poorly understood and has no approved treatment. Using a new principal cell-targeted murine model of the Tsc cystic disease, we found that the renal cystic epithelium was mostly composed of type A intercalated cells with an intact *Tsc2* gene by sequencing, though they exhibited a *Tsc*-mutant disease phenotype. We posited that extracellular vesicles were involved in promoting the intercalated cell phenotype and disease expression.

Methods: We used lineage tracing experiments to understand the tubular cell fate, and dynamic light scattering, tunable resistive pulse sensing, transition electron microscopy and western blot analysis to characterize the extracellular vesicles. We used microarray analysis to characterize the effects of the extracellular vesicles on target tubule cells.

Results: Using lineage tracing experiments, we find that while principal cells are involved and undergo clonal expansion, they contribute a surprisingly small number of cells to the cyst. We identify that cystic kidneys contain more interstitial extracellular vesicles than noncystic kidneys, excrete fewer extracellular vesicles in the urine, and contain extracellular vesicles in the cyst fluid. We demonstrate that the loss of the *Tsc2* gene in the cells producing the extracellular vesicles greatly changes the effect of extracellular vesicles on renal tubular epithelium, such that they develop increased secretory and proliferative pathway activity. mTORC1 activity is not the only controller of extracellular vesicles production, but mTORC1 inhibition does reduce the extracellular vesicle production and greatly changes the effect of extracellular vesicles from treated cells. This may be, at least in part, why mTORC1 inhibitors have a beneficial effect in patients.

Conclusions: Taken together, these results contribute to the mechanistic understanding of how genetically intact cells contribute to the disease phenotype.

PO1520

Tsc Gene Locus Disruption and Differences in Renal Epithelial Extracellular Vesicles

Prashant Kumar,[1] Fahad Al-Zadjali,[1] Ying Yao,[1] John J. Bissler.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]St. Jude Children's Research Hospital, Memphis, TN.*

Background: The severity of tuberous sclerosis complex (TSC) manifestations seem to be different depending which TSC locus is affected. This is a puzzling finding, given that the gene product of both loci heterodimerize to regulate mTORC1 activity, so loss of either one releases the repression and results in constitutive mTORC1 activation.

Methods: To begin to understand possible mechanisms for this difference, we have used mouse inner medullary collecting duct (mIMCD) cells with either the *Tsc1* or the *Tsc2* gene disrupted by a CRISP/CAS9 strategy. We have previously characterized the *Tsc2*-mutant cell line derived EVs, and present here intriguing differences between the extracellular vesicles (EVs) derived from cells with mutant *Tsc1* or *Tsc2* genes. To characterize the EVs, we used tunable resistive pulse sensing, dynamic light scattering, transition electron microscopy and mmunoblot analysis.

Results: To characterize the size of the EVs, we used tunable resistive pulse sensing and dynamic light scattering. The parental cell line had an average size of 123.5 ± 5.7 nm and mutant *Tsc1*-derived EVs had an average size 131.5 ± 8.3 nm. The surface charge for the two cell lines were -16.3 ± 2.1mV and -19.8 ± 2.7mV respectively. The isolated nanosized vesicle had excellent purity as assayed using transmission electron microscope. Both cell lines had a heterogenous population of EVs based on size, and more than 90% of the EVs were smaller than 150nm. Immunoblot analysis revealed by the presence of the cilial Hedgehog signaling protein Arl13b and the intercellular proteins TSG101 and Alix, as well as the transmembrane proteins CD63, CD9, and CD81. *Tsc1* deletion resulted in less EVs production and synthesis rate compared to *Tsc2* deletion. RNA and protein transfection studies were done to evaluate the role of EVs in disease pathology. Quantitative PCR analysis showed the downregulation of miR-212a-3p and miR-99a-5p in EVs derived from *Tsc2* which are sought to contribute the more TS severity as compared to TSC1. In addition, miR-212-3p/mTORC1 and mIR-99a-5p/mTORC1 axis are could be a novel therapeutic and biomarker strategy for TSC disease.

Conclusions: We have found that the intercellular communication of EVs has significant differences depending upon which TSC locus is affected, and this difference may be involved in the different phenotypes expressed.

Rapamycin and Dexamethasone in Pregnancy Prevents Tuberous Sclerosis Complex-Associated Cystic Kidney Disease

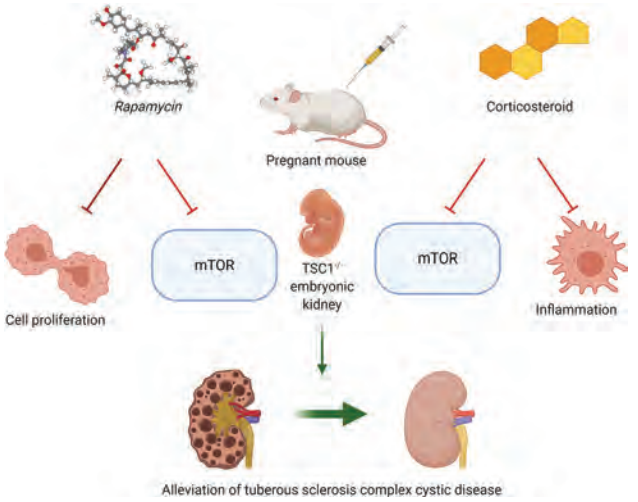
Morris Nechama,[1] Yaniv Makayes,[1] Elad Resnick,[1] Karen Meir,[2] Oded Volovelsky.[1] *[1]Pediatric Nephrology Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Division of Pathology, Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Background: Renal cysts appear in the majority of tuberous sclerosis complex (TSC) patients and lead to a gradual loss of renal parenchyma. Chronic kidney disease is the leading cause of morbidity and mortality in adult TSC patients. The molecular pathways responsible for cyst formation and progression are not known and medical therapy is not available.

Methods: Homozygous deletion of *TSC1* in Six2+ nephron progenitor cells was generated by mating *TSC1$^{f/f}$* females with Six2 Cre$^{tg/+}$ males. Kidneys were harvested at different embryonic ages for histopathology and western blotting for phosphorylated S6, F4/80, P65, c-Myc, and Ki-67. Proximal tubular cells were FACS-sorted using CD133 antibody for RNA sequencing and immunological phenotyping by F4/80. Rapamycin or dexamethasone was injected intraperitoneally during pregnancy.

Results: *TSC1* deletion in nephron progenitor cells induced proximal tubule cell damage and cyst formation, starting as early as E15.5. mTORC1 hyperactivation, as well as macrophage infiltration in TSC null proximal tubules, led to tubular cell damage and cyst formation. Rapamycin prolonged survival by inhibiting mTORC1 and c-Myc activity in the embryonic kidneys and reducing the proliferation rate of PTCs. Administration of steroids during pregnancy prevented cyst formation in TSC offspring, not only by hindering the inflammatory process but also by downregulating mTORC1 activity.

Conclusions: TSC cystic kidney disease can be ameliorated during pregnancy by inhibiting mTOR activity and inflammation.



PO1522

Description of a Multidisciplinary Model of Care in a French Cohort of Tuberous Sclerosis Complex Adult Patients

Pierre Pfirmann,[1,2] Christian Combe,[1,2] Claire Rigothier.[1,2] *[1]Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France; [2]Inserm U1026, Biotis, Bordeaux, France*.

Background: Tuberous sclerosis complex (TSC) is a rare autosomal dominant genetic disorder. Due to the various manifestations of TSC and their potential complications, a multidisciplinary care approach is recommended by consensus guidelines. Our study aimed to give a complete description of our TSC adult cohort and to evaluate the multidisciplinary and interdisciplinary management model.

Methods: Data on each adult patient diagnosed with TSC, including disease manifestations, interventions and outcomes, were collected at baseline and updated annually. A multidisciplinary TSC approach with all the recommended explorations was carried out annually. Quality of life was evaluated by SF36 score.

Results: 90 patients were enrolled in a french hospital, between January 2000 and September 2018. Median age of patients at inclusion was 37 years (range, 27-47). Regarding the occurrence of TSC manifestations, 97% of the patients had cutaneous lesions, 89% had neurological manifestations, 83% had renal manifestations and 100% had dental lesions with pits. More than half the patients had sclerotic bone lesions (68%), TAND (64%) and lymphangioleiomyomatosis (LAM) (59%). A TSC multidisciplinary approachin day hospital was developed including a global follow-up and an evaluation of TSC targeting organs, according to the recommendations. A satisfaction survey revealed global and entire TSC patient satisfaction (100%). The assessment of physical health and mental health indicated considerable deterioration (47.52% and 43.46%, respectively). The patient's family's quality of life was evaluated and the results were similar to those found for patients, for each variable (figure).

Conclusions: We obtained an accurate description of a cohort of adult patients with TSC. Our multidisciplinary approach model allowed us to provide optimal management of TSC patients with a high level of patient satisfaction.

Whole-Exome Sequencing in 97 Families with Renal Ciliopathies Reveals a Causative Mutation in a Known Kidney Disease Gene in 62% and Identifies Potential Novel Causative Genes

Konstantin Deutsch,[1] Verena Klambt,[1] Thomas M. Kitzler,[1] Tilman Jobst-Schwan,[1] Shirlee Shril,[1] Shrikant M. Mane,[2] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Department of Medicine, Boston, MA; [2]Yale University School of Medicine, New Haven, CT*.

Background: Nephronophthisis-related ciliopathies (NPHP-RC) represent the most frequent genetic cause of end-stage renal disease in the first three decades of life. Affected children present with increased echogenicity and/or cysts on renal ultrasound. As mutations in 96 recessive genes have been identified as disease-causing (*Kidney Int* 95:914, 2019), whole exome sequencing (WES) represents the best approach for the identification of the causative mutation (*Nephrol Dial Transplant* 31:1802, 2016). In a previous study of consanguineous or familial cases of NPHP, we identified causative mutations in 63% of all patients (*Kidney Int* 89:468, 2016) by WES.

Methods: To reveal the percentage of causative mutations in NPHP-RC and to identify potential novel disease genes, we evaluated WES data from 97 families with childhood-onset NPHP-RC for causative mutations in 178 monogenic chronic kidney disease genes. Clinical inclusion criteria were increased renal echogenicity or identification of ≥ 2 renal cysts on renal ultrasound.

Results: In 60 out of 97 families (62%), we identified a mutation in a known monogenic kidney disease gene as causative for the phenotype. Out of these, 47 families harboured mutations in one of the known ciliopathy genes. 13 families were diagnosed for a disease that phenocopies NPHP-RC. Amongst these, CAKUT represented the most frequent phenocopy disease (7/13 families), followed by Alport syndrome, metabolic diseases and nephrocalcinosis (2/13 families each). In 10 families, in which a mutation in known disease genes was excluded, we identified a biallelic mutation in a potential novel causative gene candidate.

Conclusions: By whole exome sequencing we identified a disease-causing mutation in 62% of families with a diagnosis of NPHP based on renal ultrasound and identified 10 potential novel causative gene candidates.

PO1524

Using Whole-Exome Sequencing to Identify PKD1 and PKD2 in 50,000 UK Biobank Participants

Kittiya Sukcharoen,[1] Coralie Bingham,[1] Daniel P. Gale,[2] Michael Weedon,[3] Richard A. Oram.[3] *[1]Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom; [2]University College London, London, United Kingdom; [3]University of Exeter, Exeter, United Kingdom*.

Background: Studies have demonstrated that genetic testing using whole-exome sequencing (WES) detects undiagnosed monogenic kidney disease in up to 2% patients with predefined clinical phenotypes and/or strong family histories of kidney disease. We aimed to take advantage of newly available datasets with WES and medical information on 50,000 people from UK Biobank (UKBB) to identify *PKD1* and *PKD2* variants in a sample not selected for kidney disease, to compare their phenotypic features to people with ICD 10 codes for *PKD* in UKBB.

Methods: We analysed data from the subset of 50,000 individuals from UK Biobank (n=500,000) who have had WES data released. We looked for mutations in *PKD1* and *PKD2*. Our primary analysis involved looking for a subset of mutations, protein-truncating variants, that had a very high likelihood of being disease-causing. We performed standard quality control which included visual inspection and assessing individual mutation on genome databases.

Results: We found 53 protein truncating variants (44 in *PKD1* and 9 in *PKD2*). The Average age for those with mutations was 57, the same as the UKBB population. We excluded 33 variants on the basis that they were either very common in GNOMAD therefore unlikely to be pathogenic or did not pass visual inspection on IGV plot. This left 20 likely pathogenic mutations (13 *PKD1* and 7 *PKD2*). An ICD 10 code for PKD on hospital records was found in 8 of those with mutations. The 8 individuals with mutations and a PKD ICD 10 code had a more severe phenotype; 7/8 (88%) were hypertensive compared with 6/12 (50%) in those with mutations but without a PKD ICD10 code. Their renal function was worse (63% v 15% had CKD, eGFR 53 v 80, p=0.01) and 1 individual received a renal transplant.

Conclusions: We were able to find disease causing mutations in *PKD1* and *PKD2* and link this to phenotype in UKBB. People with protein truncating mutations and hospital codes for *PKD* had independent evidence of kidney disease however those without an ICD 10 code of *PKD* could either have milder undiagnosed *PKD*, or non-pathogenic mutations. The genetic complexity of *PKD1* and 2, and the difficulty of ascertaining mutations with exome sequencing means that further work needs to be done to see if prevalence of *PKD*, and in particular undiagnosed mutations, could be assessed using WES from the complete UKBB dataset when available.

PO1525

PKD1 Compared with PKD2 Genotype and Cardiac Hospitalizations in the HALT-PKD Studies

Cortney Steele,[1] Zhiying You,[1] Berenice Y. Gitomer,[1] Godela M. Brosnahan,[1] Peter C. Harris,[2] Vicente E. Torres,[2] Kaleab Abebe,[3] Theodore I. Steinman,[4] Alan S. Yu,[5] Ronald D. Perrone,[6] William E. Braun,[7] Arlene B. Chapman,[8] Michel Chonchol,[1] Kristen L. Nowak.[1] *[1]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]University of Kansas Medical Center, Kansas City, KS; [6]Tufts Medical Center, Boston, MA; [7]Cleveland Clinic, Cleveland, OH; [8]University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Polycystin 1 and 2 are expressed in vascular endothelial and vascular smooth muscle cells. While the hallmark of autosomal dominant polycystic kidney disease (ADPKD) is the development and continued growth of multiple renal cysts that ultimately result in loss of kidney function, cardiovascular complications are the leading cause of death. Although hypertension occurs earlier and more frequently in *PKD1* vs. *PKD2*, both genotypes seem to confer equal risk of developing intracranial aneurysms. It is currently unknown if *PKD1* vs. *PKD2* confers a different risk of cardiovascular events.

Methods: 864 individuals with ADPKD who participated in the 5-yr HALT-PKD study A or B and had genotype data with either a *PKD1* or *PKD2* mutation were included in this analysis. Since the number of cardiac events in the HALT-PKD studies was limited, we determined the association of genotype with the adverse cardiac event with the highest frequency (cardiac hospitalization; defined according to the Common Terminology Criteria for Adverse Events v.4.0 of the National Cancer Institution and adjudicated by an endpoints committee). The association of genotype with cardiac hospitalization was determined using logistic regression.

Results: Among the 864 included participants, individuals with the *PKD1* genotype (84%) were slightly younger (42±10 vs. 46±10 yrs, p<0.0001) and had a slightly lower baseline estimated glomerular filtration rate (eGFR; 70±26 vs. 75±26 ml/min/1.73m^2, p=0.06) vs. *PKD2*. Cardiac hospitalization (n=43) was more common in individuals with a *PKD2* genotype (9.2%) compared to a *PKD1* genotype (4.1%; p=0.01). After adjustment for age, sex, race, and study randomization, *PKD2* was associated with an increased odds of cardiac hospitalization (OR; 2.14, 95% CI: 1.04-4.41 vs. *PKD1*). This association was slightly attenuated after further adjustment for cardiac history, systolic blood pressure, body mass index, and baseline estimated glomerular filtration rate (OR: 2.12, CI: 0.99-4.52).

Conclusions: In early- and late-stage participants in the HALT-PKD studies, *PKD2* genotype was independently associated with increased odds of cardiac hospitalization.

PO1526

A Novel Case of Turner Syndrome and Autosomal Dominant Polycystic Kidney

Rachel Styer,[1] Faris Q. Hashim.[2] *[1]Departments of Pediatrics, Texas A&M Health Science Center, Baylor Scott & White McLane Children Medical Center, Temple, TX; [2]Division of Pediatric Nephrology, Texas A&M Health Science Center, Baylor Scott & White McLane Children Medical Center, Temple, TX.*

Introduction: Turner Syndrome (TS) is a sex chromosome disorder resulting from the complete or partial loss of one of the X chromosomes. Short stature is common feature of TS and is commonly treated with growth hormone (GH). Autosomal dominant polycystic kidney disease (ADPKD) is a multisystem disease that has bilateral renal cysts and is an important cause of end stage renal disease (ESRD).

Case Description: A 5-y/o girl with TS with 45 XO, treated with GH since the age 2 yr with good clinical response. She presented to nephrology clinic for evaluation of bilateral large kidneys for age (RK 10.0 cm, LK 9.7 cm) per recent renal ultrasound (US). No hypertension was found on her exam. Family History was negative for polycystic kidney disease (PKD), hypertension, renal disease, hemodialysis, renal transplant or intracranial aneurysms. On follow up US 1 year later, a few small bilateral cysts measuring < 1cm and persistent renal enlargement was noted. Due to concerning findings of progressive renal cysts with further growth of the kidneys potentially secondary to GH treatment, her GH treatments was stopped. After 6 months off GH therapy, renal enlargement was unchanged with more enlargment of her cysts. Patient got genetic studies for PKD and was found to be heterozygous for pathogenic variant in the *PKD1* gene consistent with the diagnosis of ADPKD. Parents both tested negative for *PKD1* mutation suggestive of de novo mutation.

Discussion: Patients with TS often have short stature requiring GH treatment in order to achieve improved adult height. TS has multi-organ system manifestations including an increased risk for renal anomalies like simple renal cyst, horseshoe, duplicated, or absent kidney. This case highlights the potential increased risk for patients with TS who are on GH treatment to develop kidney disease. To the best of our knowledge, the association of TS and ADPKD has not been described yet. The current clinical practice guidelines state that patients with known TS should receive a renal US at time of diagnosis with no further follow up renal imaging has been recommended at this time. Given the potential role of GH in cyst proliferation and frequency of GH therapy in this patient population, we recommend reevaluation of current renal screening guidelines for patient with TS. Early diagnosis and treatment could potentially reduce morbidity associated with renal disease and growth hormone.

PO1527

CYP24A1 Mutations Are Associated with Renal Cystic Disease

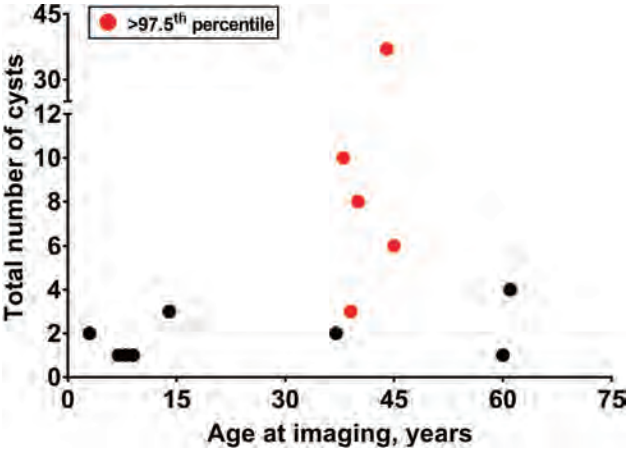
Christian Hanna, Theodora A. Potretzke, Peter Tebben, Vicente E. Torres, Peter C. Harris, John C. Lieske, David J. Sas, Dawn S. Milliner, Fouad T. Chebib. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Loss-of-function mutations in the *CYP24A1* gene cause a rare hereditary disease leading to reduced 24-hydroxylase enzyme activity, characterized by increased serum 1,25-dihydroxyvitamin D_3 levels, hypercalcemia, hypercalciuria, nephrocalcinosis, and/or nephrolithiasis. Renal cysts in *CYP24A1* mutations were first reported in a single case study from our institution. However, to date a possible association between *CYP24A1* mutations and renal cysts has not been examined.

Methods: Retrospective review of all patients with confirmed *CYP24A1* mutations and complete renal imaging studies at a tertiary academic center between 2010 and 2020. Cyst location, number, and diameter were measured by contrast-enhanced computed tomography (CT), non-contrast CT, ultrasound or magnetic resonance imaging.

Results: Among the 13 patients with *CYP24A1* mutation, 46% were male and 38% children. The mean age at diagnosis was 24.7 ± 18.8 years (range 1-60). Medullary and/or corticomedullary junction renal cysts were present in all 13 cases (5 with unilateral and 8 with bilateral cysts). The mean age at imaging with first detected cyst was 31.1 ± 20.5 years (range 3-61). The median number of cysts per patient was 3 (IQR 1.5-7). The mean size of the smallest and largest cyst were 3.6 ± 2.2 mm (range 2-8) and 11.9 ± 6.9 mm (range 2-30) respectively. All 13 had normal age-adjusted renal size and none had a family history of polycystic kidney disease. The number of cysts (≥ 5 mm in size) in 63% of adult patients was above the 97.5th percentile of an age- and sex-matched control population (Figure 1).

Conclusions: This study suggests an association between *CYP24A1* mutations and cystic kidney disease. Further studies are needed to evaluate the role of *CYP24A1* and vitamin D metabolism in renal cyst formation, and whether cysts enhance CKD risk in patients with *CYP24A1* deficiency, or modify nephrocalcinosis/urinary stone risk.



PO1528

Collagen Changes Suggestive of a Primary Defect in pkd2$^{+/-}$ Adult Zebrafish Kidney

Mohamed A. Addani, Deema A. Anaam, Diana Alzamareh, Abdalla A. Modawi, Nicole Ho, Kevin L. Webb, Heather L. Holmes, Michael F. Romero, Slobodan Macura, Timothy L. Kline, Vicente E. Torres, Caroline R. Sussman. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Zebrafish are a valuable model for studies of PKD, with conservation of pathways and phenotypes including renal cysts. *Pkd2* mutant zebrafish develop dorsal tail curvature (*pkd2*$^{-/-}$), which prevents survival. No phenotype has been described in *pkd2*$^{+/-}$ zebrafish embryos or adults. MRI is useful for analysis of PKD kidney and collagen changes characterize PKD. In this study, we examined collagen changes in *pkd2*$^{+/-}$ adult zebrafish kidney and MRI *in vivo*.

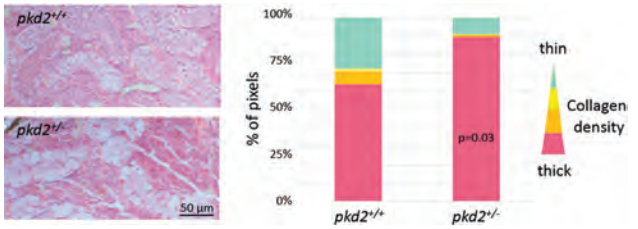
Methods: Zebrafish *hi4166 pkd2*$^{+/-}$ were compared to sibling *pkd2*$^{+/+}$ (males). Total kidney volume and texture were quantified from MRI *in vivo* (16mo, n=3). Collagen density was quantified from picrosirius red (PSR) stained sections using polarized light microscopy and ImageJ for color thresholding (19m, n=3). Integrity of the collagen triple helix was assessed in kidney frozen sections labeled with collagen hybridizing peptide in zebrafish (18m, n=4) and mouse *Pkd1*$^{RC/RC}$ (10m).

Results: Kidney volumes were not different; however, texture analysis showed *pkd2*$^{+/-}$ kidney was more heterogeneous. This was not explained by cysts, as none were visible by H&E staining, nor were tubule diameters different. PSA staining showed significantly

more dense collagen, and collagen hybridizing peptide labeling showed more denatured collagen in *pkd2*$^{+/-}$ zebrafish kidney. Preliminary data from *Pkd1*$^{RC/RC}$ mice show similar patterns of collagen density and denaturation.

Conclusions: To our knowledge, this is the first report of any phenotype in *pkd2*$^{+/-}$ zebrafish (adult or embryo). The presence of a dominant phenotype and a collagen defect suggests conservation of disease etiology. A collagen defect in the absence of cysts indicates independence of collagen changes from cyst formation, suggesting collagen changes may be a primary defect in PKD pathophysiology.

Funding: NIDDK Support



Increased collagen density in kidney of *pkd2* mutant zebrafish visualized by staining with picrosirius red and imaging using polarized light (left) quantified using image thresholding in ImageJ (right). Pixels are binned by color indicating density as shown.

PO1529

Cystic Kidney Disease in Patients with Thin Basement Membrane Disease (TBMD)

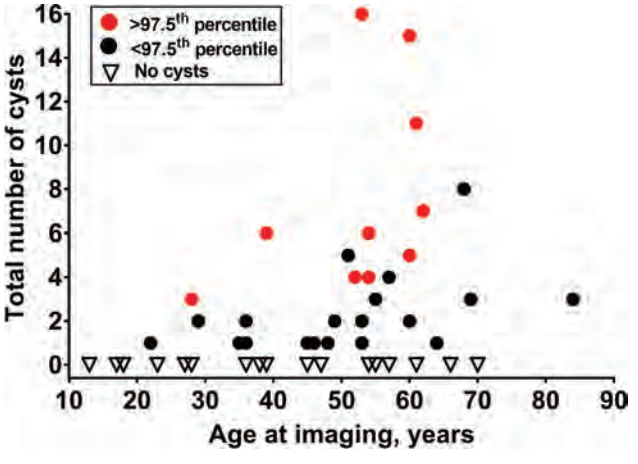
Janina Paula T. Sy-Go, Samar M. Said, Jing Miao, Theodora A. Potretzke, Prince Singh, Reem M. Neal, Peter C. Harris, Vicente E. Torres, Samih H. Nasr, Fouad T. Chebib. *Mayo Clinic Minnesota, Rochester, MN.*

Background: TBMD is a benign glomerular disease typically manifesting as microscopic hematuria with/without minimal proteinuria and with preserved kidney function. A few reports described the finding of kidney cysts in TBMD patients, but this association remains uncertain.

Methods: A retrospective study of patients seen at a tertiary academic center (2009-2019) and had a kidney biopsy with reported diffuse glomerular basement (GBM) thinning was done. The diagnosis of TBMD was confirmed by a careful review of the biopsy findings, including EM images. Patients with clinical and/or pathologic features of Alport disease or with unavailable abdominal imaging were excluded. Cyst number and size were recorded on the first available imaging.

Results: Among 49 TBMD patients, 29 (59%) had kidney cysts (cystic), and 20 had no cysts (noncystic). Both cystic and noncystic groups were mostly females (69% vs. 80%). Cystic patients were older at time of biopsy (51 vs. 38 yrs) and imaging (51 vs 39 yrs). Hematuria was the major indication for biopsy. Hematuria and dysmorphic RBCs were found in 72% and 41% of cystic patients respectively vs. 80% and 10% in noncystic patients. Cystic patients had lower mean eGFR at time of biopsy (69 vs. 93 mL/min/1.73 m^2), higher mean 24-h proteinuria (968 vs. 172 mg/d), and comparable mean GBM thickness (193 vs. 206 nm). 18 (62%) patients had bilateral cysts. Median number of cysts was 3 (IQR 1-5.5). Average sizes of the smallest and largest cysts were 5.1 (± 4) and 19.6 (± 24) mm respectively. The number of cysts (≥5 mm) in 34% of cystic patients was above the 97.5th percentile of an age-/sex-matched control population (Figure 1).

Conclusions: Bilateral kidney cysts were found in a large percentage of biopsy-proven TBMD patients. COL4A mutations could be a potential etiology of mild cystic kidney disease with hematuria or mild proteinuria.



No. of cysts at imaging.

PO1530

COL4A3/COL4A4 as a Cause of Multicystic Kidney Disease

Teresa Bada Bosch, Sara Afonso Ramos, Angel M. Sevillano, Eduardo Gutierrez-martinez, Teresa Cavero escribano, Elena Gutierrez-solis, Florencio García, Enrique Morales, Paula J. Caro espada, Manuel Praga. *Department of Nephrology, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Thin basement membrane nephropathy (TBMN), the most common cause of persistent microhaematuria (mH), is due to mutations in genes codifying alfa-3 and alfa-4 collagen IV chains *(COL4A4/COL4A3*). Initially considered as a benign condition, subsequent studies have shown that an important number of patients develop proteinuria and CKD. We reported in a previous small study the presence of multicystic kidney disease (MCD) in some TBMD patients. In this study we aimed to evaluate the presence of MCD in a larger cohort of TBMD patients and analyze its association with renal outcomes.

Methods: We collected 50 patients with a diagnosis of TBMD based on the presence of persistent mH (>5 erythocytes per high power field in more than 90% of urinary sediments and radiological examinations to exclude other causes of mH) and at least one first-degree relative with persistent mH. TBMD diagnosis was confirmed by renal biopsy (glomerular basement membrane thickness less than 150nm) in 18 patients and by genetic test (pathogenic mutations in *COL4A3/COL4A4*) in 6 patients. MCD was diagnosed by the presence of uncountable cysts on renal ultrasonography.

Results: Mean age at diagnosis was 43.7 years, 34% were males and 18% had hypertension. At baseline, serum creatinine (SCr) was 0.9 mg/dL, proteinuria 0.48 gr/24h and 9 patients (18%) had CKD (estimated glomerular filtration rate -eGFR- lower than <60 mL/min/1.73m^2). 7 patients (14%) had CKD G3 and 2 (4%) CKD G4. Kidney cysts were found in 34 patients (68%) and 19 (38%) met MCD criteria. After a mean follow-up of 14.7±11.5 years, 23 patients (46%) had CKD. Among them, 17 patients (34%) had CKD G3, 2 (4%) CKD G4, and 4 (8%) CKD G5. Hypertension was more frequent among CKD patients as compared with no-CKD patients (39 vs 0%, p 0.00), proteinuria was higher (0.58±0.68 vs 0.39±0.58 g/24h, p 0.05) and MCD more frequent (65.2% vs 14.8%, p 0.00). Patients with MCD had higher SCr (2.1 vs 1.1 mg/dL, p 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m^2, p 0.00) at the end of follow-up, and MCD was the only risk factor for the occurrence of CKD (OR 6.49, 95% CI 1.3-31.6) by multivariable analysis that included age, hypertension and proteinuria.

Conclusions: MCD is frequently observed in TBMD patients and is a risk factor for the progression of CKD.

PO1531

Genotype-Phenotype Correlations in Pediatric Patients with HNF1B Mutations

Seonhee Lim,[1] Ji hyun Kim,[2] Hee Gyung Kang,[1] IL-Soo Ha,[1] Hae Il Cheong.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Bundang Seoul National University Hospital Department of Internal Medicine, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: *HNF1B* is one of the most common disease-causing genes of CAKUT, especially renal cysts. *HNF1B* mutations also manifest various renal and extra-renal phenotypes. Faguer S, et al. proposed *HNF1B* scoring system in 2014 to screen patients with *HNF1B* mutations clinically.

Methods: A total of 14 patients, who were diagnosed as having *HNF1B* mutations in the Department of Pediatrics, Seoul National University Children's Hospital during the period from 1990 to 2019, were recruited in this study, and the phenotypes of the patients were analyzed retrospectively.

Results: All 14 patients were male. Initial symptoms of patients revealed incidental azotemia(36%), abnormal prenatal USG(29%), etc. The median ages at the onset, at the genetic diagnosis, and at the last follow-up were 0.1 years, 12.8 years, and 20.3 years, respectively. *HNF1B* genotyping revealed total heterozygous mutation in 43%, truncating mutations in 36%, and missense mutations in 21% patients. The renal image studies revealed multiple renal cysts in 93% patients, renal parenchymal hyperchogenecity in 79%, and unilateral/bilateral renal hypoplasia in 50%. The other renal or extra-renal phenotypes included hyperuricemia in 79% patients and hypokalemia in 57%. During follow-up, 86% patients progressed to CKD, including 36% patients to ESRD. The mean *HNF1B* score at the time of diagnosis was 14.4±5.8, and all patients except one had a score higher than 8. The score at the last follow-up in ten patients except for 4 patients with transplantation was highest in patients with missense mutations (22.5±3.5) and lowest in those with truncating mutations (14.0±2.9, *P*=0.040). Hypokalemia was most common in patients with total deletion mutations (83%) and least common in those with missense mutations (0%, *P*=0.027).

Conclusions: *HNF1B* mutations manifest various renal and extra-renal phenotypes. Most patients (86%) progressed to CKD or ESRD during follow up. The *HNF1B* scoring system showed high sensitivity, although specificity was not evaluated.

PO1532

Identifying and Assessing the Phenotypic Features of HNF1B Deletions and Duplications in UK Biobank

Kittiya Sukcharoen,[1] Coralie Bingham,[1] Michael Weedon,[2] Richard A. Oram.[2] University of Exeter *[1]Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom; [2]University of Exeter Medical School, Exeter, United Kingdom.*

Background: Heterozygous mutations of hepatocyte nuclear factor 1β (*HNF1B*) are the most common known monogenic cause of developmental kidney disease. Renal cysts are the most frequently detected feature. Other features include early-onset diabetes and abnormal liver function. It is thought that duplications of *HNF1B* do not result in strong phenotypic features. The true pathogenicity and penetrance of many rare putative disease-causing copy number variants (CNVs) is uncertain and may be over-estimated by clinical ascertainment. We aimed to assess the pathogenicity and penetrance of *HNF1B* deletions and duplications in UK Biobank (UKBB) and to describe any associated phenotype.

Methods: We used data from 388,714 UKBB participants to assess CNVs of HNF1B in a population-based setting using SNP chip intensity data. We tested the association of these CNVs with diabetes and other clinically-relevant traits. We assessed the UKBB phenotype and biomarker information and correlated these with the deletions and duplications.

Results: We identified 11 individuals with large deletions relating to *HNF1B* and 106 with duplications. There were no significant difference in the average ages of deletion (53), duplication (56) and UKBB population (57). Of the 11, 3 were reported to have glomerular disease, 1 had haematuria, 1 had a renal transplant, and 6 had diabetes (55% vs. 5% amongst the rest of UKBB; P=2x10-6). The penetrance of diabetes was 30% and average eGFR was 71 (45% with eGFR<60) compared to average GFR 91(p<0.0001) in UKBB population. Their liver function is comparatively different. Gamma GT 110 v 37.4 (p<0.0001) and ALP 186.5 v 83.5 (p<0.0001) in UKBB population. Average eGFR was lower in people with a duplication (80 v 91 in UKBB population, p<0.0001). We found no association between *HNF1B* duplication and diabetes (4.4% vs. 5.3%; P=0.8) or liver function.

Conclusions: *HNF1B* deletions and duplications can be detected in a large unselected dataset. Deletions are more pathogenic than duplications. However, *HHF1B* duplications do appear to affect renal function, which has not been previously described. The frequency of both *HNF1B* deletions and duplications may be higher than previously estimated.

PO1533

Late-Onset Hepatocyte Nuclear Factor 1β-Associated Kidney Disease

Emad Alahiri, Molly Fisher. *Montefiore Medical Center, Bronx, NY.*

Introduction: Hepatocyte Nuclear Factor 1β (HNF1β) is an important transcription factor for kidney development. HNF1β mutations are rare, associated with multisystemic disease and heterogeneous kidney involvement. HNF1β-associated kidney disease may not manifest until adulthood. We present a case of an older female with chronic hypomagnesemia and kidney cysts due to a heterozygous deletion in the HNF1β gene.

Case Description: 66 y/o Puerto Rican female with a history of recurrent urinary tract infections, pre-diabetes, hypertension, arthritis, congenital absence of left ovary and baseline SCr 0.9 mg/dL was referred for evaluation of bilateral kidney cysts and chronic hypomagnesemia. Review of magnetic resonance imaging and ultrasound going back to 2003 showed normal sized kidneys and presence of more than 4 cysts in each kidney, some of which were mildly complex. No extrarenal cysts were noted and she denied family history of kidney cysts. Chronic symptomatic hypomagnesemia was present since at least 2015 with serum magnesium ranging from 1.1-1.6 meq/L, resulting in emergency room visits and hospitalizations. Fractional excretion of magnesium was 29%, consistent with renal magnesium wasting. Serum potassium and bicarbonate were normal. Intact parathyroid hormone ranged from 83-112 pg/mL but serum calcium, phosphorus, 25 dihydroxyvitamin D were normal. Urinalysis was bland. She was sent for genetic testing and underwent whole exome sequencing. Results demonstrated a heterozygous deletion in the HNF1β gene consistent with HNF1β nephropathy. She was started on amiloride and slow release magnesium supplementation with near normalization of her serum magnesium.

Discussion: HNF1β-associated kidney disease is a challenging diagnosis given extreme variability in phenotypes. De novo mutations occur in up to half of patients leading to diagnosis later in life. Our patient's constellation of medical problems including glucose intolerance, mild hyperparathyroidism, hypomagnesemia, unilateral ovary agenesis and genitourinary (GU) tract abnormalities are all features of HNF1β-associated kidney disease. This diagnosis should not be overlooked in patients with GU abnormalities, electrolytes disturbances and/or signs of tubulointerstitial kidney disease. Additionally, these patients should be monitored for progressive kidney disease and undergo periodic screening for renal cell carcinoma.

PO1534

A Post Hoc Analysis of Tolvaptan (TOL) Efficacy and Safety in Slowing Rate of Renal Function Decline in Subjects with Very Late-Stage Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Vicente E. Torres,[1] Ron T. Gansevoort,[2] Arlene B. Chapman,[3] Ronald D. Perrone,[4] John Ouyang,[5] Jennifer Lee,[5] Hina Japes,[5] Tao Wang.[5] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Rijksuniversiteit Groningen, Groningen, Netherlands; [3]University of Chicago, Chicago, IL; [4]Tufts Medical Center, Boston, MA; [5]Otsuka Pharmaceutical Development and Commercialization Inc, Rockville, MD.*

Background: ADPKD is a progressive disease that causes end-stage renal disease in ~50% of the affected individuals by age 60. TOL, a selective vasopressin V2-receptor antagonist, has been shown to slow the progression of renal function decline in ADPKD subjects with an eGFR of 25 mL/min/1.73m^2 or higher. The efficacy and safety of TOL in subjects with lower eGFR remain understudied. This post-hoc analysis evaluated the efficacy and safety of TOL in subjects with stage 4 CKD (eGFR of <30 mL/min/1.73m^2).

Methods: This is a retrospective analysis of a subgroup of ADPKD subjects who enrolled in the TOL open-label extension (OLE) trial (NCT02251275). Included subjects had a baseline eGFR of <30 mL/min/1.73m^2, received ≥ 1 TOL dose, and were randomized to the placebo group in the REPRISE trial (NCT02160145). Two subgroups of subjects were analyzed, one with baseline eGFR of 25-30 (Subgroup 1) and one <25 (Subgroup 2). The variables evaluated included demographics, adverse event (AE) profile, and intra-subject comparison of change in annualized eGFR decline during the OLE trial to that during placebo use in the REPRISE trial. Annualized eGFR change slopes in the treatment period were calculated using eGFR values between Month 1 and 12 visits to compensate for the acute hemodynamic effect of tolvaptan. Comparison was made by linear mixed model.

Results: Of 1,803 subjects enrolled, 159 (8.8%; 76 in Subgroup 1 and 83 in Subgroup 2) met the selection criteria. Annualized eGFR change slopes for all subjects (n=148) were -5.28 in the REPRISE trial and -3.16 in the OLE trial with a treatment effect of 2.11 (95% CI 1.56, 2.66), p<0.0001). The treatment effects were 1.99 and 2.17 for Subgroups 1 and 2, respectively (p<0.0001 for both subgroups). The 5 most common AEs were thirst (32%), polyuria (30%), renal pain (25%), blood creatinine increase (23%) and nocturia (22%); the rates were similar between the 2 subgroups. One incidence of hepatic enzyme increase, one of hemodialysis and one death (unrelated to TOL) was only observed in Subgroup 2.

Conclusions: This post-hoc analysis demonstrated that TOL significantly decreases the rate of eGFR decline in ADPKD subjects with stage 4 CKD, including those with an eGFR of <25 mL/min/1.73m^2.

PO1535

Tolvaptan and Renal Function in Autosomal Dominant Polycystic Disease: A Two-Center Experience of 186 Cases

Yasuhiro Oda, Daisuke Ikuma, Hiroki Mizuno, Akinari Sekine, Masayuki Yamanouchi, Tatsuya Suwabe, Junichi Hoshino, Yoshifumi Ubara. *Toranomon Hospital Kajigaya, Kawasaki, Japan.*

Background: TEMPO and REPRISE trials demonstrated that tolvaptan slows the decline in the estimated glomerular filtration rate (eGFR) in patients with autosomal dominant polycystic kidney disease (ADPKD). However, the real-world data of the change in eGFR in patients with ADPKD taking tolvaptan is lacking. Also, comparison of the slopes of the change in eGFR before and after starting taking tolvaptan in a same patient has not been reported.

Methods: Patients who started taking tolvaptan for ADPKD between June 2014 and June 2019 at Toranomon Hospital and Toranomon Hospital Kajigaya were retrospectively analysed for the change in eGFR before and after starting taking tolvaptan. Note that approved indication of tolvaptan for ADPKD patients in Japan includes total kidney volume larger than 750 mL and eGFR greater than 15 mL/min/1.73 m^2. The eGFR at 1, 2, 3, 4, 5 years before and after starting tolvaptan were collected from the medical record. Patients with none of these values were excluded from the study.

Results: 186 patients were included in the study. 43% were men. Average age was 50.2 ± 10.2 (mean ± standard deviation). Total kidney volume was as follows when stratified by chronic kidney disease (CKD) stages: stage 1, 1119 ± 266; stage 2, 1521 ± 600; stage 3a, 1659 ± 787; stage 3b, 2106 ± 1330; stage 4, 2847 ± 1976 mL. 139 patients had eGFR data before and after starting tolvaptan, whereas 24 patients only had data before and 23 patients only had data after starting tolvaptan. The eGFR slope after starting taking tolvaptan was -3.7 ± 2.3 mL/min/1.73 m^2 (n=162), and was as follows when stratified by CKD stages: stage 1, -5.9 ± 4.3 (n=4); stage 2, -4.5 ± 2.8 (n=47); stage 3a, -3.1 ± 2.1 (n=38); stage 3b, -3.5 ± 1.8 (n=40); stage 4, -3.3 ± 1.8 mL/min/1.73 m^2/year (n=33). The change in eGFR slope after starting tolvaptan was -1.2 ± 5.4 in stage 1-3a patients (n=76) and +0.8 ± 2.3 mL/min/1.73 m^2/year in stage 3b-4 patients (n=63), which showed statistically significant difference (p=0.003).

Conclusions: Real-world data from our institution observed the eGFR slope of -3.7 ± 2.3 mL/min/1.73 m^2 after starting taking tolvaptan. The eGFR slope in patients with CKD stage 3b-4 improved on average after taking tolvaptan. The same was not observed in patients with CKD stage 1-3a.

PO1536

Impact of Long-Term Tolvaptan Treatment for Autosomal Dominant Polycystic Kidney Disease: A Single-Centre Retrospective Japanese Cohort Study

Junya Yamamoto, Saori Nishio, Daigo Nakazawa, Tatsuya Atsumi. *Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan.*

Background: Several clinical trials have revealed the efficacy of the tolvaptan for autosomal dominant polycystic kidney disease (ADPKD) in recent years. Our objective is to verify the impact of tolvaptan in our Japanese ADPKD cohort.

Methods: We retrospectively investigated the efficacy of tolvaptan for ADPKD patients who initiated tolvaptan from June 2014 to March 2020 in Hokkaido University Hospital. Patients treated with tolvaptan for more than 1 year were included for analyses. Patients never treated by tolvaptan were set as control. Patients in CKD stage 5 or 5D at baseline or postkidney transplantation were excluded from analyses. We stratified patients by Mayo classification (Class 1A-1E). Analyses included the comparison of the annual changes of eGFR(ΔeGFR (mL/min/1.73m^2/year)) and total kidney volume (ΔTKV (%/year)) between pre and post-treatment, and ΔeGFR or ΔTKV between tolvaptan-treated and control.

Results: 109 tolvaptan-treated and 139 control patients were included. 24 patients in each group were excluded. About 40% of tolvaptan-treated patients belonged to advanced CKD stage (CKD3b-4). Duration of tolvaptan treatment was 3.3±1.3 years. eGFR of tolvaptan group were lower and htTKV of tolvaptan group were higher compared to those of control group at baseline (eGFR: 53.7±22.8 vs 65.7±30.0, p=0.16. htTKV: 1193.9±649.6 vs 829.5±799.5 mL/m, p<0.0001). There was no significant difference in ΔeGFR between (tolvaptan -2.95±2.86 vs control -3.09±3.31, p=0.33), however in tolvaptan group ΔeGFR improved compared to pre-treatment (-2.95±2.86 vs -4.33±5.72, p=0.027) and this improvement lasted at least for 36 months in 50 patients. ΔTKV of tolvaptan group was lower than that of control (2.19, 95%CI(0.33-4.05) vs 5.10(4.00-6.19), p<0.01) and this trend was also found in Mayo class 1B-1D. ΔTKV also decreased compared to pre-treatment (2.19(0.33-4.06) vs 4.67(2.57-6.76), p<0.01).

Conclusions: Tolvaptan dramatically reduced ΔTKV, while there was no beneficial effect for ΔeGFR compared to control. However tolvaptan improved ΔeGFR compared to that of pre-treatment. The discrepancy between our results and previous reports might arise from the fact that our cohort mainly comprised advanced CKD stage patients or limited sample size. Further long-term observation is required to validate the effect of tolvaptan.

PO1537

Canadian Real-World Assessment of Tolvaptan in ADPKD: C-MAJOR Study and Safety Monitoring and Distribution Program

Philip McFarlane,[2] Patrick S. Parfrey,[3] Daniel G. Bichet,[4] Luc Bergeron,[1] Annick Laplante.[1] *[1]Otsuka Canada Pharmaceutical Inc., Montreal, QC, Canada; [2]St Michael's Hospital, Toronto, ON, Canada; [3]Memorial University of Newfoundland, St. John's, NL, Canada; [4]Universite de Montreal, Montreal, QC, Canada.*

Background: Tolvaptan is the only approved treatment in Canada for slowing renal function decline and kidney enlargement in ADPKD patients. As per Health Canada requirement, a patient registry evaluating long-term clinical outcomes (C-MAJOR study) and a hepatic safety monitoring and distribution program (HSMDP) to mitigate risk of liver injury were implemented and have been ongoing for 5 years. The aim of this interim analysis is to describe baseline characteristics of patients at initiation of tolvaptan through the C-MAJOR study and to report on treatment persistence and liver transaminases elevation rate through the HSMDP.

Methods: C-MAJOR is a non-interventional, multi-centre study of ADPKD patients treated with tolvaptan. HSMDP ensures tolvaptan is dispensed under controlled liver function monitoring.

Results: As of April 2020, 398 patients, 51% female, were enrolled in C-MAJOR. At baseline, mean (SD) age was 45.1 (11.5) years, BP was 129.4 (13.4)/83.1 (10.0) mmHg and eGFR was 63.6 (27.8) mL/min/1.73 m^2. Total kidney volume was 1949 (1562) mL, 80.7% of patients had a family history of ADPKD and 39.4% had a family history of early end-stage renal disease. As per Mayo classification, 90.2% were at high risk of disease progression (1C-D-E). The most common ADPKD clinical manifestations were hypertension (83.2%), hepatic cysts (69.6%) and kidney pain (24.1%). Over a mean (SD) follow-up of 2.0 (1.0) years, adverse events were reported in 82.7% of patients, most common being polyuria (19.6%), fatigue (18.6%), and nocturia (15.1%). Over a mean (SD) follow-up of 23.0 (17.6) months in the HSMDP, 2.4% (39) of the 1,600 patients who received at least one shipment of tolvaptan reported an elevation of transaminases >3x ULN. There were 0.3% (5) of patients meeting the guidelines for permanent discontinuation. No cases of drug-induced liver injury were reported. Treatment discontinuation rates at 12, 24 and 36 months were 14%, 21% and 26%, respectively.

Conclusions: This analysis provides Canadian real-world evidence of high-risk disease progression at tolvaptan initiation, 3-y persistence data similar to phase III study and the HSMDP showing tolvaptan was permanently discontinued in 0.3% of patients because of hepatic effects.

PO1538

Early Findings of Patients with Autosomal Dominant Polycystic Kidney Disease Initiating Tolvaptan in the United States: A Claims-Based Analysis

Irene Cosmatos,[1] Sunning Tao,[1] Gretchen S. Dieck,[1] Michele L. Julian,[1] Timothy Wilt,[2] Kristin Pareja,[2] Myrlene Sanon.[2] *[1]United BioSource LLC, Blue Bell, PA; [2]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease. Tolvaptan (Jynarque®), the first and only approved treatment for ADPKD in the United States (US), has been shown to slow kidney function decline in clinical trials. An understanding of characteristics of the real-world patients initiating treatment with tolvaptan in the US is needed.

Methods: An observational, retrospective analysis assessing baseline measures was conducted among patients with ADPKD who had initiated treatment with tolvaptan from 14 May 2018 through 9 January 2020 in the US. Data were obtained by linking the Symphony Health Integrated Dataverse (IDV), a nationally representative billing database, with Specialty Pharmacy (SP) data from the tolvaptan Risk Evaluation and Mitigation Strategy (REMS), which is a mandatory program for patients prescribed tolvaptan to treat ADPKD. The study index date was the date of first shipment of tolvaptan. Descriptive analyses were conducted on the following baseline measures: demographics, comorbidities, and disease characteristics. All measures were identified within the 6-month period prior to the index date in the Symphony Health IDV. For patients with more than 1 CKD stage diagnosis during the baseline period, the CKD stage closest to the index date was captured.

Results: The study sample included 4,355 patients. The mean age at tolvaptan initiation was 48.8 years (Standard Deviation: 12.3), with 51.7% (n=2,251) female. Hypertension was the most commonly observed comorbidity (n=3,520, 80.8%), followed by diabetes (n=273, 6.3%). The distribution of CKD stage, available for 1,566 (36.0%) patients during their baseline period, was: 6.2% (n=97) in CKD Stage I, 13.4% (n=210) in CKD Stage II, 55.2% (n=864) in CKD Stage III, 22.9% (n=359) in CKD Stage IV, and 2.3% (n=36) in CKD stage V.

Conclusions: This is one of the first real-world studies to describe comorbidities and disease characteristics in patients with ADPKD initiating tolvaptan in the US. Stage III was the most commonly reported CKD stage among patients with a known CKD stage during their baseline period. Additional analyses evaluating the real-life impact of tolvaptan on clinical outcomes, healthcare utilization, and quality of life are needed.

PO1539

Early Real-World Descriptive Findings on Tolvaptan-Treated Patients with Autosomal Dominant Polycystic Kidney Disease in the United States

Myrlene Sanon,[2] Sunning Tao,[1] Irene Cosmatos,[1] Gretchen S. Dieck,[1] Michele L. Julian,[1] Timothy Wilt,[2] Kristin Pareja,[2] Alvin Estilo,[2] Carol I. Matthews.[1] *[1]United BioSource LLC, Blue Bell, PA; [2]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ.*

Background: Tolvaptan is the first and only treatment for autosomal dominant polycystic kidney disease (ADPKD) approved in the United States (US). The Food and Drug Administration (FDA) required a Risk Evaluation and Mitigation Strategy (REMS) to mitigate the risk of severe liver injury potentially associated with tolvaptan. This study aims to characterize patient demographics and treatment patterns among patients enrolled in the REMS in the US.

Methods: A descriptive analysis of patients with ADPKD enrolled in the tolvaptan REMS from 14 May 2018 through 3 February 2020 was conducted. Only patients enrolled in the REMS with at least 1 tolvaptan prescription dispensed were included in the analysis. The observational period began from a patient's first shipment date of tolvaptan (index date) and ended on 3 February 2020 or patient death, whichever occurred earlier. Descriptive analyses provided baseline patient characteristics and follow-up measures on a subset of patients eligible for treatment pattern assessment. Additionally, medication possession ratio (MPR) (number of days supplied over a 1-year period) and persistency (length of time taking tolvaptan allowing for ≤59 days between refills) were measured.

Results: A total of 5,366 patients who initiated tolvaptan in the REMS comprised the study population. Mean age at tolvaptan initiation was 46.8 years (standard deviation [SD]: 11.6); 2,751 (51.3%) were female. Of the patients with a known race (n=2,705, 50.4%), the majority were white (n=2,153, 79.6%). Of those with known ethnicity (n=2,682, 50.0%), 2,352 (87.7%) were non-Hispanic or non-Latino. Overall, 2,366 (44.1%) tolvaptan initiators had at least 1 year of follow-up after the index date and were included in the treatment pattern analysis. The most frequent dose of tolvaptan was 45/15 milligrams daily (47.5%). The mean MPR was 0.74 (SD: 0.32); mean persistency was 325.9 days (SD: 173.2).

Conclusions: This is the first descriptive demographic report of real-world ADPKD patients in the US initiating tolvaptan. Based on the data currently available, most patients were between 35-55 years, equally male or female, and were non-Hispanic or non-Latino whites. The patients included in the treatment pattern analysis remained on tolvaptan close to 1 year.

PO1540

Benefit of Tolvaptan on Time to ESRD for Patients with Rapidly Progressing Autosomal Dominant Polycystic Kidney Disease (ADPKD): A Disease Progression Model

Gregory Mader,[1] Molly F. Purser,[1] Deirdre M. Mladsi,[1] Myrlene Sanon,[2] Dorothee Oberdhan,[2] Terry J. Watnick,[3] Stephen L. Seliger.[3] *[1]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC; [2]Otsuka America Pharmaceutical Inc, Rockville, MD; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: The efficacy and safety of tolvaptan in adults with ADPKD was initially established in a 3-year phase 3 clinical trial (TEMPO 3:4; NCT00428948). Tolvaptan was approved in the United States in 2018 for patients with ADPKD at high risk of progression. A published ADPKD progression model predicted longer-term outcomes including eGFR decline and time to ESRD. The model incorporated an equation used to predict eGFR based on Mayo subclasses 1C, 1D, and 1E as indicators of rapid progression. To estimate treatment benefit, long-term outcomes were modelled for patients treated with and without tolvaptan based on the TEMPO 3:4 cohort.

Methods: In the base case, the annual absolute reduction in eGFR decline for tolvaptan versus placebo of 1.2 ml/min/1.73m^2 was applied to the predicted rates of eGFR decline in the absence of treatment. Additionally, in a sensitivity analysis based on a post-hoc analysis of TEMPO 3:4, the effect on eGFR decline by subclass 1C, 1D, and 1E was applied. CKD progression and time to ESRD were estimated for both cohorts.

Results: The predicted time to ESRD was longer for all patients in CKD stages 1-3 treated with tolvaptan, with greater estimated absolute benefit when treatment was initiated for patients in early CKD stages (Image).

Conclusions: The model estimates that patients treated with tolvaptan versus no treatment spend more time in earlier CKD stages and later onset of ESRD. Results were consistent across CKD stages and Mayo subclasses. Findings highlight the potential long-term value of early intervention with tolvaptan in patients at risk of rapid ADPKD progression.

PO1541

Global Real-World Evidence of Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Brett A. Maiese,[1] Jennifer A. Colby,[1] Kristin Pareja,[4] Annick Laplante,[2] Xinyu Wang,[3] Linda Mccormick,[4] Ali Nourbakhsh,[4] Tao Wang,[4] Myrlene Sanon.[4] *[1]Xcenda LLC, Palm Harbor, FL; [2]Otsuka Canada Pharmaceutical Inc, Saint Laurent, QC, Canada; [3]Otsuka Pharmaceutical Europe Ltd, Wexham, United Kingdom; [4]Otsuka Pharmaceuticals Development & Commercialization, Princeton, NJ.*

Background: ADPKD is a rare, hereditary, systemic kidney disease characterized by progressive renal damage. Patients frequently develop end stage kidney disease, requiring renal replacement therapy. Tolvaptan is the first and only treatment shown to slow kidney function decline in adults who are at risk of rapidly progressing ADPKD. The goal of this literature review was to understand real-world effectiveness and safety data currently available on tolvaptan treatment.

Methods: A review of the literature was conducted in January 2020 in Embase (including Medline) with no language, timeframe, or geography restrictions. Observational studies of ADPKD patients receiving tolvaptan were identified; outcomes of interest included clinical effectiveness and safety, healthcare resource utilization and costs, and quality of life (QoL).

Results: A total of 43 relevant publications were identified. Studies were conducted in Canada, Japan, and across Europe with sample sizes ranging from a single case report to registry analyses of more than 1,000 patients. Clinical results from 6 studies reported a slowing of total kidney volume (TKV) growth and no significant changes in annual decline of estimated glomerular filtration rate (eGFR) over a range of 3 months to 2 years following tolvaptan initiation. Commonly reported adverse events included polyuria (~10%) and liver function-related events (~9%). Reported in 6 studies, 15.6% of patients discontinued tolvaptan treatment, primarily for aquaretic symptoms. Two studies reported that tolvaptan treatment did not appear, over a 1-year period, to negatively impact QoL, with more than 75% of patients reporting little impact on daily activities. No eligible economic studies were identified.

Conclusions: Patients with ADPKD receiving tolvaptan in the real-world experienced improved clinical outcomes without negative impact on QoL. Additional studies assessing real-world evidence supporting tolvaptan treatment in this population are needed.

Funding: Commercial Support - Otsuka Pharmaceuticals Development & Commercialization, Inc.

PO1542

Urinary Lithogenic Risk Profile in ADPKD Patients Treated with Tolvaptan

Matteo Bargagli,[1] Nasser Dhayat,[3] Pietro Manuel Ferraro,[1,2] Daniel G. Fuster.[3] *[1]Università Cattolica del Sacro Cuore, Roma, Italy; [2]U.O.C. Nefrologia, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Roma, Italy; [3]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland.*

Background: Nephrolithiasis is a common health problem in autosomal dominant polycystic kidney disease (ADPKD) and significantly contributes to patient morbidity. Recently, Tolvaptan has been introduced for the treatment of ADPKD, but if it is associated with alterations of the urinary lithogenic risk profile remains unknown.

Methods: We conducted an analysis of participants enrolled in the Bern ADPKD registry, a prospective observational cohort study. 24 hour urine analyses were performed at baseline and then at yearly follow-ups. Relative supersaturation ratios for calcium oxalate, brushite and uric acid were calculated with the program EQUIL2. Unadjusted and multivariable mixed-effects linear regression models, adjusted for age, sex, body mass index, estimated glomerular filtration rate, net acid excretion and height-adjusted total kidney volume were used to assess the association of Tolvaptan with urinary parameters relevant for kidney stone formation. Maximum individual follow-up time was 3 years, median follow-up time 1.9 years and cumulative follow-up time was 169 years.

Results: 125 participants (38 with and 87 without Tolvaptan treatment) were included in the analysis. In multivariable analysis, Tolvaptan treatment was associated (adjusted estimate of the difference Tolvaptan vs. no Tolvaptan; 95% CI) with lower urine relative supersaturation ratios for calcium oxalate (-0.56; -0.82 to -0.3, $p < 0.001$), brushite (-0.33; -0.54 to -0.11, $p = 0.004$) and uric acid (-0.62; -0.88 to -0.37, $p < 0.001$) and with increased urine citrate in mmol/mmol creatinine per day (0.25; 0.050-0.46, $p = 0.02$) and calcium in mmol/mmol creatinine per day (0.31; 0.090-0.53, $p = 0.006$) excretion. In addition, Tolvaptan treatment was associated with decreased net acid excretion in mEq/mmol creatinine per day (-0.54; -0.90 to -0.17, $p = 0.004$) and increased net gastrointestinal alkali absorption in mEq/mmol creatinine per day (0.57, 0.26-0.88; $p < 0.001$).

Conclusions: Tolvaptan treatment is associated with a significantly improved urinary lithogenic risk profile in ADPKD patients.

PO1543

The Effect of Trichlormethiazide in Patients with Autosomal Dominant Polycystic Kidney Disease Using Tolvaptan: A Randomized Cross-Over Controlled Trial

Kiyotaka Uchiyama,[1] Yoshitaka Ishibashi.[2] *[1]Keio University School of Medicine, Shinjuku-ku, Japan; [2]Japanese Red Cross Medical Center, Shibuya-ku, Japan.*

Background: The vasopressin V2 receptor antagonist tolvaptan has been shown to slow the progression of autosomal dominant polycystic kidney disease (ADPKD). However, some patients discontinue tolvaptan due to severe adverse aquaretic events. This open-label, randomized, controlled, counterbalanced, crossover trial investigated the effects of trichloromethiazide, a thiazide diuretic, on reducing urinary volume and improving tolvaptan tolerability in patients with ADPKD on high-dose tolvaptan, based on the effects of thiazides in patients with nephrogenic diabetes insipidus.

Methods: A total of 10 patients with ADPKD on high-dose tolvaptan (median age, 49 years; 4 males) received antihypertensive therapy with or without trichloromethiazide in random order for 12 weeks. The starting doses for trichloromethiazide were 2 and 4 mg in patients with estimated glomerular filtration rates of ≥30 and <30 mL/min/1.73 m^2, respectively. Target blood pressure range was 110/70–130/80 during the study period. Primary outcomes were 24-h urine volume and urine osmolarity. Secondary outcomes were health-related quality of life (HRQOL) assessed by the Kidney Disease Quality of Life-Short Form questionnaire, rate of decline in renal function, serum/urinary electrolytes, serum/urinary biomarkers associated with chronic kidney disease and ADPKD progression, and office blood pressure.

Results: The urine volume was significantly reduced (3324 ± 614 vs. 4169 ± 729 mL; $P < 0.001$) along with an increase in urinary osmolarity (179.0 ± 26.6 vs. 139.1 ± 39.6 mOsm; $P = 0.001$) in patients on antihypertensive therapy with trichloromethiazide. Moreover, trichloromethiazide improved several HRQOL subscales including effects of kidney disease, sleep, emotional role functioning, social functioning, and role/social component summary. There were no significant differences in the slope of estimated glomerular filtration rate assessed by creatinine and cystatin C or serum/urinary biomarkers between the patients on antihypertensive therapy with and without trichloromethiazide. Office blood pressure was not significantly different between the treatment groups.

Conclusions: In patients with ADPKD treated with high-dose tolvaptan, trichloromethiazide may improve tolvaptan tolerability and HRQOL by reducing urinary volume without affecting ADPKD-related parameters.

PO1544

Predictors for Suppressing Polycystic Liver Progression of ADPKD by Tolvaptan

Hiroki Mizuno, Yoshifumi Ubara, Junichi Hoshino. *Toranomon Byoin, Minato-ku, Japan.*

Background: Polycystic liver disease (PLD) is one of the fatal complications of ADPKD, which leads to abdominal compression, cyst infection, and liver failure. Although PLD progresses after reaching ESKD, few drugs can effectively inhibit its growth. Tolvaptan (TVP), V2 receptor antagonist, has been known to suppress the growing rate of polycystic kidney disease, but the effect on PLD has not been studied yet. In order to evaluate the tolvaptan's effect on PLD, an observational cohort study was conducted.

Methods: ADPKD patients with PLD taking tolvaptan were enrolled in this study. Total liver volume (TLV) was measured by CT and calculated by automated calculated application, VINCENT®. Annual change of TLV (ΔTLV) was defined by the approximate slope estimated from more than two points. If the patients had some interventions including cyst drainage, surgical fenestration, and transcatheter trans-arterial embolization, the observational period was excluded for one year after such interventions. We compared ΔTLVs before and after TVP initiation, and defined "responder" as patients whose post-ΔTLV were smaller than pre-ΔTLV. Factors associated with "responder" were analyzed by the logistic regression model, adjusting sex, age, BMI, blood pressure, height adjust total kidney volume(htTKV) and ΔTLV before taking TVP(preΔTLV), by using R version 3.4.3.

Results: 85 patients were eligible to this study. Median observational periods were 1.98 and 2.19 year in pre-prescription period and post-prescription period respectively. Median age was 53 years old and 31 cases were female. Median htTLV and htTKV before taking TVP was 1747[557-7432] (ml/m) and 909[226-4152] (ml/m), respectively. The reduction of ΔTLV were observed in 46 cases, who were significantly older, had higher preΔTLV and had higher rate of taking ursodeoxycholic acid. Logistic regression analysis showed older age (OR 2.60[1.36-5.72],$p<0.01$) and higher preΔTLV (OR 1.25[1.12-1.46], $p<0.01$) were the predictors of the reduction of ΔTLV.

Conclusions: In this study, more than half of ADPKD patients experienced reduction of ΔTLV after taking TVP. Our study suggests that elder age and higher pre-ΔTLV would predict the reduction of the progression of PLD after TVP use, though it was reported younger female tend to have larger PLD.

PO1545

Use of Lixivaptan in a Patient with Autosomal Dominant Polycystic Kidney Disease (ADPKD) Who Previously Experienced Liver Toxicity with Tolvaptan

Neil H. Shusterman,[1] Lorenzo Pellegrini,[1] Elaine R. Richardson,[1] Marie C. Hogan.[2] *[1]Palladio Biosciences, Horsham, PA; [2]Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Blockade of the vasopressin V2 receptor has beneficial effects on the renal manifestations of ADPKD, the most prevalent inherited renal cystic disease in humans. Tolvaptan, a vasopressin V2 receptor antagonist, is the only approved pharmacologic therapy for the treatment of ADPKD patients; however, it is associated with potentially serious idiosyncratic liver toxicity. Lixivaptan is a novel, potent antagonist of the V2 receptor in Phase 3 development for the treatment of ADPKD. Evidence from non-clinical and in silico studies predicts that lixivaptan will have a safer liver toxicity profile in patients with ADPKD. Here we provide the first clinical evidence of lixivaptan's superior liver safety compared to tolvaptan.

Case Description: A female patient with ADPKD presented with severe bilateral, intractable flank and abdominal pain. The patient had been treated with tolvaptan previously in an attempt to improve her pain; however, tolvaptan therapy had to be permanently discontinued after the patient developed clinically-meaningful alanine aminotransferase (ALT) elevations on each of three sequential attempts to treat her. The patient was screened and enrolled in an open-label study of lixivaptan under a US IND expanded-access protocol (PA-103). After treatment with therapeutic doses of lixivaptan for 12 months, there have been no elevations of ALT or other liver chemistry tests. Improved pain control has allowed resumption of more normal daily activities and the cessation of use of opioid pain medications. Pharmacodynamic effects including decreases in total kidney volume and liver volume were demonstrated as well as expected changes in eGFR with a vasopressin antagonist. Treatment with lixivaptan continues.

Discussion: This is the first report of successful treatment with lixivaptan of a patient who had previously experienced liver toxicity on tolvaptan. These clinical data highlight the potential for improved liver safety with lixivaptan in a patient at high risk for developing liver toxicity. A larger study (PA-ADPKD-303: The ALERT Study) is starting up to treat ADPKD patients with lixivaptan who previously discontinued tolvaptan because of liver chemistry test elevations.

PO1546

Generation of Collecting Duct Kidney Organoids from Human Induced Pluripotent Stem Cell

Sergii Kyrychenko, Eva Fast, Alyssa Fanelli, Henrietta W. Bennett, Peter H. Mundel, John F. Reilly, Amy D. Westerling-Bui. *Goldfinch Bio Inc, Cambridge, MA.*

Background: Polycystic kidney disease (PKD) is one of the most common human genetic disorders without effective therapy. During its progression, fluid-filled cysts displace normal collecting duct (CD) tubules causing end-stage renal failure. The lack of disease-relevant in vitro models of PKD has hampered early drug discovery and needs more efficient and robust tools.

Methods: Here we modified a previously published protocol [1] and established a high-throughput and highly efficient method for the generation of CD kidney organoids from human induced pluripotent stem cells (hiPSC). We employed a dynamic modulation of cell signaling pathways in combination with 3D extracellular matrix support to induce CXCR4+/cKit+ ureteric bud (UB) cell progenitors and further UB branching.

Results: The UB gives rise to renal collecting ducts and the lower urinary tract. We observed the development of UB-like cytoarchitecture including, bifurcated ureteric tip expressing specific markers (RET, WNT9B, HOXB7). Using single-cell RNA sequencing (scRNAseq) we identified two major cell populations in differentiated CD organoids – collecting duct cells and stromal cells. CD cells express typical markers of UB trunk (CK19), the ureteric epithelium (CDH1, CK8), as well as mature markers (AQP2, CALB1, MUC1) including principal (AQP3) and intercalated cells (AQP5). Moreover, we identified cilia formation on the inner surface of the luminal cavity of CD tubules which mimics normal kidney development. Using pharmacological approaches, we were able to induce cysts formation in response to forskolin and cholera toxin treatment, thus, simulating the abnormal CD response to excess cAMP in PKD or normal rodent embryonic kidneys [2].

Conclusions: In conclusion, we provide a robust and highly efficient method for collecting duct marker expressing organoids that may contribute to elucidating the mechanisms of kidney development, disease modeling of the lower urinary tract (polycystic kidney disease), and drug discovery. 1. PO1547

A Fluidic Model of ARPKD Using Vascularized Kidney Organoids Identifies HIF-1 as a Potential Therapeutic Target

Ken Hiratsuka,[1,2] Tomoya Miyoshi,[1] Katharina T. Kroll,[2] Navin R. Gupta,[1] M. Todd Valerius,[4,3] Takuya Matsumoto,[1,2] Jennifer A. Lewis,[2,3] Ryuji Morizane.[1,3] *[1]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [2]Wyss Institute/Harvard University, Boston, MA; [3]Harvard Stem Cell Institute, Cambridge, MA; [4]Brigham and Women's Hospital/Harvard Medical School, Boston, MA.*

Background: We have recently reported a method to generate vascularized kidney organoids using fluidic chips. Vascularized kidney organoids derived from PKHD1 mutants demonstrated clinically relevant phenotypes that recapitulate cystogenesis in distal nephrons unlike static models with forskolin which induces cysts in proximal tubules. Here, we utilized this new PKD model to elucidate pathomechanisms and identified potential therapeutic targets for ARPKD patients.

Methods: PKHD1-mutant hPSCs were generated by CRISPR/Cas9 genome editing and differentiated into kidney organoids by following our reported protocol. Cystogenesis was stimulated by either fluidic flow on fluidic chips or forskolin in static culture. Cystic phenotypes were quantitatively determined by immunostaining. Gene expression was evaluated by 3D-gene microarray, and signal pathways were assessed by Metacore. Based on signal pathway results, candidate compounds were tested, and phenotypic improvement was evaluated by measuring tubular/cyst diameters using whole-mount immunostaining.

Results: Fluidic flow altered 407 signal pathways in PKHD1-/- organoids when compared to PKHD1+/- organoids while 63 pathways were changed by forskolin treatment in conventional static culture. In those pathways, 32 were involved in both flow- and forskolin-induced signal changes. In the common 32 pathways, HIF-1 pathway was top ranked with lowest p value of 3.71×10^{-14}, suggested as a potential pathomechanism of ARPKD. To validate the result, we treated vascularized kidney organoids with HIF-1 inhibitor from day 16, the earliest stage of nephron differentiation. The distal nephron diameter was increased from 36.2 ± 7.7 μm (n=96) to 54.4 ± 21.8 μm (n=59) by fluidic flow ($p=8.65\times10^{-12}$), which was decreased to 46.1 ± 16.8 μm (n=158) by a HIF-1 inhibitor ($p=0.004$).

Conclusions: We identified HIF-1 as a potential therapeutic target for ARPKD patients. PKD organoids using an organ-on-a-chip platform might serve as a better model to elucidate disease developing mechanism and discover disease-specific new therapeutic targets *in vitro*.

The Effect of Trehalose on Autophagy-Related Proteins and Cyst Growth in a Hypomorphic Pkd1 Mouse Model of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Daniel Atwood, Deepak Pokhrel, Carolyn N. Brown, Katharina Hopp, Charles L. Edelstein. *Univ Colorado, Aurora, CO.*

Background: There is growing attention on understanding the role of impaired autophagy in ADPKD. Trehalose (TRE) is a natural sugar that is used as a food additive. TRE increases protein stability, aggregate clearance and autophagy in neurodegenerative diseases. TRE treatment in wild type (WT) mice resulted in increased expression in the kidney of Atg12-5 complex and Rab9a (Table), autophagy-related proteins that play a role in the formation of autophagosomes. Thus, the aim of the study was to determine the effect of TRE on cyst growth and autophagy-related proteins, in the Pkd1$^{RC/RC}$ (RC) mouse model.

Methods: Autophagy proteins determined by immunoblot analysis. Male RC mice were treated with TRE from 50-120 days of age.

Results: In RC kidneys, expression of the Atg12-5 complex was inhibited by TRE resulting in increased free Atg12. TRE was unable to rescue the deficiency of the Atg12-5 complex. Rab9a was decreased in RC and unaffected by TRE. The TRE-induced increase in p62, a marker of autophagic cargo, that was seen in WT was blocked in RC kidneys. In RC kidneys, there were decreases in autophagy-related proteins (Atg12-5 complex, Atg5, Atg16L1), decreased Rab9a and increased mTORC1 (pS6, p-mTOR) proteins. 2 kidney/body weight ratio (2K/BW), cyst index/count, BUN were not different in TRE vs. Veh treated RC kidneys.

Conclusions: The autophagy phenotype in RC kidneys was characterized by decreases in essential autophagy related proteins. TRE increased Atg12-5 complex, Rab9a and p62 in WT kidneys, but was unable to rescue the deficiency in autophagy proteins or suppress mTORC1 in RC kidneys and did not protect against cyst growth.

Suppressed Autophagic Flux in the Heart in a Hypomorphic Pkd1 Mouse Model of ADPKD

Daniel Atwood, Carolyn N. Brown, Katharina Hopp, Charles L. Edelstein. *Univ Colorado, Aurora, CO.*

Background: Heart disease is largely unexplored in mouse models of ADPKD. The aim of the study was to determine mTOR signaling and autophagy in the heart in Pkd1$^{RC/RC}$ (RC) mice

Methods: Proteins were determined by immunoblot analysis. Mice were treated with autophagy inducers 2-deoxyglucose (2-DG) or Tat-Beclin1 peptide (Tat).

Results: There was increased heart weight/body weight ratio (HW/BW) in 180 d old RC mice. In 70 day old RC hearts, there was no increase in mTOR but a large increase in p-AMPK^{Thr172}, a known autophagy inducer. In 150 day old RC hearts, there was an increase in p-S6, p-Akt^{Thr308}, p-GSK3β, p-AMPK, p-Beclin, an autophagy regulator and activating molecule in Beclin-1-regulated autophagy (AMBRA1). There was suppressed autophagic flux (lack of an increase in LC3-II, a marker of autophagosomes, with the lysosomal inhibitor bafilomycin-Baf), in 70 and 150 d old RC hearts compared to an increase in wild type (WT) hearts. In 120 d old RC hearts there was no increase in proliferation (PCNA) or apoptosis (TUNEL). Both 2-DG and Tat treatment increased heart weight and had no effect on kidney weight

Conclusions: There was a large increase in p-AMPK and suppressed autophagy in RC hearts. Unexpectedly, autophagy inducers increased heart weight

Ferroptosis Promotes Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Xiaoqin Zhang, Hao Ding, Xiaoyan Li, Peter C. Harris, Xiaogang Li. *Mayo Clinic, Rochester, MN.*

Background: Ferroptosis is a newly discovered form of non-apoptotic cell death which is dependent on accumulation of lipid reactive oxygen species (ROS). Recent studies have shown that ferroptosis is involved in the pathophysiological processes of many diseases, such as cancer. However, the roles of ferroptosis in ADPKD remain unknown.

Methods: To evaluate whether ferroptosis occurs in ADPKD, we detected the levels of ROS with C11-BODIPY and 4-HNE staining, and the expression of glutathione peroxidase 4 (GPX4), a key protein in the ferroptotic pathway, by western blot and qRT-PCR in cystic cells and kidneys. To understand the role of ferroptosis in ADPKD, we treated *Pkd1* mutant mice with erastin, a ferroptosis inducer, and Ferrostain-1, a ferroptosis inhibitor.

Results: We found that the levels of free radical-induced oxidation and 4-HNE, a biproduct of lipid peroxidation, were increased in *Pkd1* mutant renal epithelial cells and tissues as examined by C11-BODIPY and 4HNE staining. Erastin treatment resulted in smaller-than-normal mitochondria with increased density, a morphological feature of ferroptotic cells, in *Pkd1* mutant renal epithelial cells under electronic microscopy. We further found that treatment with erastin promotes cyst growth as seen by increased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and lipid peroxidation in *Pkd1*$^{RC/RC}$ mice (all $p < 0.01$). In contrast, treatment with Ferrostain-1 delayed cyst growth in early stage *Pkd1*$^{flox/flox}$;*Pkhd1*-Cre mice and *Pkd1*$^{RC/RC}$ mice as seen by decreases in all the parameters observed in erastin treated mice. Treatment with erastin increased the activation of ERK, Stat3, Akt and Rb in *Pkd1* mutant renal epithelial cells and tissues. Activation of Stat3 increased the expression of DNA methyltransferase 1 (DNMT1), leading to the binding of DNMT1 to the *GPX4* promoter and decreased expression, resulting in the accumulation of ROS species to promote cystic renal epithelial cell ferroptosis. Treatment with Ferrostain-1 reversed all these processes in *Pkd1* mutant renal epithelial cells and tissues.

Conclusions: *Pkd1* mutation induced the downregulation of GPX4 via Stat3-DNMT1, resulted in accumulation of ROS species, and the induction of ferroptosis to promote renal cyst growth. Inhibition of ferroptosis may be a viable new therapy for ADPKD.

Cux1 Regulates Cilia Length in Polycystic Kidney Disease

Greg Vanden heuvel,[1] Zhi Nee Wee,[2] Conner L. Holthaus.[1] [1]*Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI;* [2]*Kalamazoo College, Kalamazoo, MI.*

Background: Renal cyst development in ADPKD results from mutations in the PKD1 or PKD2 genes, which encode the proteins polycstin1 (PC1) and polycystin2 (PC2). PC1 and PC2 proteins are localized to primary cilia where they are proposed to form a receptor channel complex that detects flow transmitting a calcium-mediated signal. Primary cilia are critical to the pathogenesis of ADPKD, which is one of many ciliopathies that exhibit renal cystic disease. Cux1, a murine homolog of the Drosophila gene Cut, is a cell cycle dependent transcriptional repressor that regulates the cyclin kinase inhibitor p27. Cux1 is highly and ectopically expressed in mice carrying a collecting duct (CD) specific mutation of Pkd1 (Pkd1 knockout) and in human ADPKD cells. Mice carrying mutations in both Cux1 and Pkd1 have reduced cystic disease and an increased life span. A role for Cux1 in regulating genes involved in cilia assembly and function has recently been identified in the Galapagos cormorant, however the role of Cux1 in cilia in the mammalian kidney is not known.

Methods: To begin to determine whether Cux1 regulates ciliogenesis we evaluated cilia morphology and the expression of the ciliary protein, OFD1 (oral-facial-digital-1),

identified as a Cux1 target in the Galapagos cormorant. Cilia analysis was performed on kidneys isolated from wild type, Cux1 transgenic, Pkd1 knockout, and Pkd1/Cux1 double knock out mice. Cilia morphology was assessed by immunofluorescence labeling of alpha-tubulin, a major component of cilia, and the collecting duct marker dolichos biflorus agglutinin (DBA) to identify cells in which Pkd1 was deleted.

Results: Cilia in Pkd1/Cux1 double knockout kidneys were significantly shorter than cilia in the Pkd1 knockout kidneys alone, consistent with previous studies showing that decreased cilia length corresponds to decreased cystic disease. OFD1 is an inhibitor of ciliogenesis and OFD1 expression in the various mouse models demonstrate that OFD1 expression corresponds to Cux1 expression. OFD1 protein levels were the lowest in the kidneys of mice constitutively expressing Cux1 and were highest in mice with deletions of Cux1.

Conclusions: Taken together, our results suggest a novel role for Cux1 in regulating ciliogenesis in the kidney and that reduced cystic disease in the Pkd1/Cux1 double mutant mice results from reduced cilia length.

PO1552

Low-Dose Repeated Cisplatin-Induced Renal Injury Promotes Cyst Formation in Both Cilia Mutant and PC2 Mutant Mouse Models

Zhang Li, Courtney J. Haycraft, E.j. Aloria, Bradley K. Yoder. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Multiple renal cystic diseases, including PKD, are caused by dysfunction of the primary cilium on the tubule epithelium. Links between cilia dysfunction, cyst formation, and renal injuries have been reported. In animal models, injury (e.g. ischemia reperfusion) exacerbated the rate of cyst formation. Cisplatin is an antitumor drug used widely in treatment of varieties of malignancies that also has severe nephrotoxicity side effects. Here we evaluate whether a second form of renal injury induced by a low dose of Cisplatin also leads to mal-repair of the kidney and to increased cyst formation in mouse models with cilia function perturbation.

Methods: To test the effects of cisplatin-induced renal injury on cyst formation, we utilized a low-dose repeated cisplatin protocol (5.0mg/kg BW; IP once a week for 4 weeks) on adult-induced conditional Ift88 and PC2 mutant mice. We preformed IF staining for the injury marker kim1 and flow cytometry analysis of immune cells from WT and cilia dysfunctional kidneys 3 days after 2° cisplatin treatment to evaluate renal injury. Cyst index were analyzed at 5 weeks in PC2 mutant and at 9 weeks in Ift88 mutant after the final dose.

Results: Low-dose repeated cisplatin treatment resulted in increased kim1 expression, mainly in the cortex, compared to vehicle treatment group in both Ift88 mutant and PC2 mutant mice compared to control. Analysis of flow cytometry data showed that there was minimal immune cell accumulation, including macrophages, NK, B or T cells, at 3 days after 2° cisplatin injection, similar to that in controls. Additional time points are currently being evaluated. While we did not observe major changes in immune cell response at the earlier time point prior to cyst formation, in both PC2 and Ift88 mutants there was a marked increase in cyst severity, accompanied with massive immune cell accumulation compared to vehicle treated mutants at 5 and 9 weeks after the final cisplatin injection, respectively.

Conclusions: These data indicate cilia function is important in regulating repair processes following injury, defects in which contribute to more aggressive rates of cystogenesis. Additionally, it suggests multiple forms of injury induce cyst formation and that the cisplatin protocol could be used as an alternative approach to IRI to accelerate cyst formation in PKD animal models.

Primary Cilia Defects Reflect Specific Bone Cell Activity in Human ADPKD Osteoblast Cells

Renata C. Pereira,[1] Berenice Y. Gitomer,[2] Peter C. Harris,[3] Isidro B. Salusky,[1] Lauren V. Albrecht.[1] *[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]University of Colorado Denver School of Medicine, Aurora, CO; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is predominately caused by mutations in primary cilium genes polycystic kidney disease *PKD1* and *PKD2*. Recent studies show that ADPKD is associated with abnormal bone health with decreased bone formation and low bone serum alkaline phosphatase, even when kidney function is preserved. Knowledge of the regulatory links between ADPKD, cilia, and human bone health is lacking.

Methods: We assessed primary cilia in cultured pre-osteoblasts derived from ADPKD patients with *PKD1* or *PKD2* mutations, relative to healthy controls and non-ADPKD chronic kidney disease (CKD) patients. Cilia were quantified by immunofluorescence staining of pericentrin and acetylated-α-tubulin. Cilia responsiveness was examined following treatment with lithium chloride (LiCl), an activator of the canonical Wnt signaling pathway that is known to induce cilia elongation. Biochemical osteoblast analyses included bone turnover by alkaline phosphatase (ALP) activity and mineralization assays.

Results: Compared to healthy control cells, ADPKD osteoblasts displayed longer cilia at baseline and were significantly more responsive to elongation with LiCl. In contrast, non-ADPKD CKD osteoblasts had shorter cilia and lacked LiCl responsiveness. Despite similar histological features and adynamic bone characteristics, ADPKD osteoblasts mineralized faster than osteoblasts from non-ADPKD CKD. The ALP activity levels were decreased in ADPKD osteoblast cells, which is consistent with the lowered circulating bone ALP levels.

Conclusions: Together, these data support a model whereby altered cilia responsiveness in ADPKD osteoblasts is linked to bone cell activity and mineralization defects that are distinct from adynamic bone of non-ADPKD CKD patients.

Pathobiology of Cyst Progression in Nbce1A and Pkd1 (RC/RC) Mouse Models

Deema A. Anaam,[1] Heather L. Holmes,[2] Adriana Gregory,[1] Ka Thao,[3] Alison Stiller,[2] Peter C. Harris,[3,4] Timothy L. Kline,[1,2] Michael F. Romero.[2,3] *[1]Radiology, Mayo Clinic Minnesota, Rochester, MN, Rochester, MN; [2]Physiology & Biomedical Engineering, Mayo Clinic Minnesota, Rochester, MN, Rochester, MN; [3]Nephrology & Hypertension, Mayo Clinic Minnesota, Rochester, MN, Rochester, MN; [4]Biochemistry & Molecular Biology, Mayo Clinic Minnesota, Rochester, MN, Rochester, MN.*

Background: The *Pkd1(RC/RC)* mouse is a hypomorphic model of autosomal polycystic kidney disease (ADPKD) characterized by renal cortical and medullary cysts which increase in size and number with age. The nature of these cysts and how this epithelium differs from normal collecting duct epithelia is currently unknown. Moreover, as the phenotype is variable, the disease progression of any individual mouse is unknown. We also generated an isoform specific Na^+ bicarbonate cotransporter knockout (*Nbce1A*-KO) mouse using TALENs. As with the whole gene knockout, these mice are severely acidotic but also present with cortical renal cysts. The nature of these cysts and their connection to NBCe1A protein expression is currently unknown.

Methods: We measure mouse (Bk6J) total kidney volume (TKV) using MRI (7T/16T) and ultrasound (US; SonoVol Vega). The Vega system allows 3D renal imaging and cardiac analysis (e.g., heart rate, ejection fraction, cardiac output). We follow renal function using transdermal GFR measurements. Lastly, kidneys are harvested, fixed, followed by immunofluorescence (IF) of cryosections with nephron segment specific markers or picrosirius red (collagen stain) of paraffin sections.

Results: A longitudinal study of *Nbce1A-KO* and *RC/RC* mice shows both models increased TKV (Fig A) measured by MRI or US (Fig B,C). Both show lower GFR [WT: 558±40, *nbce1A-KO*: 420±144, RC/RC: 276±63 μL/min/(100g-bw)]. Ejection fraction and stroke volume were preserved, while heart rate and cardiac output decreased in *Nbce1A-KO* and *RC/RC* mice (Fig A). Both *Nbce1A-KO* (Fig E) and *RC/RC* mice (Fig F) have collecting duct cysts, positive for AQP2 and cKit. Picrosirius red staining shows that these cystic structures have increased collagen thickening.

Conclusions: Taken together these data imply that cystogenesis in the *RC/RC* and *nbce1A-KO* models have similar pathobiology. Potentially this means that understanding how and why cysts develop in nbce1A-KOs may provide additional mechanistic information in ADPKD.

Funding: NIDDK Support, Private Foundation Support

Characterization of the Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) Response in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Jared J. Lutsic, Yahya Alsawaf, Peter C. Harris, Vicente E. Torres, Maria V. Irazabal. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive development and enlargement of bilateral renal cysts. Abnormal epithelial cell proliferation, along with the inability to maintain planar cell polarity, underlies cyst formation and enlargement. Therefore, processes that stimulate renal cell proliferation have the potential to generate the cystic phenotype. Interestingly, an increased nuclear factor erythroid 2-related factor 2 (Nrf2) response has been shown to direct cancer cells into an anabolic mode that favors cellular proliferation, and has been associated with renal cyst formation in experimental and human fumarate hydratase deficiency. However, the Nrf2 response has not been described in ADPKD. We hypothesized that early ADPKD presents with an elevation in the Nrf2 response that favors cellular proliferation and contributes to cystogenesis.

Methods: We sought to longitudinally characterize the Nrf2 response and association with cystogenesis and fibrosis in a slow progressive mouse model of ADPKD (*Pkd1*$^{RC/RC}$) and its wildtype controls (n=6 males, 6 females per group). Urine and plasma samples were collected at 30, 60, 120, and 180 days for chemistries and metabolic profiles, and cystic index (CI), and total kidney volume (TKV) were determined from abdominal MRI. Nrf2 levels and related response enzymes, as well as cell proliferation and fibrosis were analyzed using western-blots, immunofluorescence, and assay kits.

Results: At 30 days, *Pkd1*$^{RC/RC}$ mice presented increased CI and TKV/BW. However, serum creatinine and fibrotic markers were not different compared to controls. *Pkd1*$^{RC/RC}$ mice exhibited elevated Nrf2 expression and immunoreactivity early on that declined as ADPKD progressed from 30 to 180 days and correlated directly with cell proliferation (R^2=0.693, $p<0.05$) and inversely with fibrotic markers (R^2=0.672, $p<0.05$).

Conclusions: Our study shows longitudinal changes in the Nrf2 response in *Pkd1*$^{RC/RC}$ mice that are associated with cystogenesis early on and renal fibrosis at later stages of the disease. These findings have significant implications for the treatment of human ADPKD, and suggest that Nrf2 modulators might represent an advantageous intervention for the disease.

Dietary Protein Load Increases Kidney Macrophage and Accelerates Polycystic Kidney Disease

Jifeng Huang, Jung-Shan Hsu, Takamitsu Saigusa. *Department of Medicine, Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Background: The disease severity for autosomal dominant polycystic kidney disease (PKD) is highly variable even among families with the same gene mutation, suggesting factors other than genetics may affect cystogenesis. One factor that accelerates cyst growth in PKD mouse is compensatory renal hypertrophy triggered by unilateral nephrectomy or a high protein diet. We recently reported that unilateral nephrectomy increases kidney macrophages, cytokines and accelerates cystogenesis in *Pkd1*-knockout mice. We hypothesize that *Pkd1*-knockout mice fed a high protein diet, similarly increases kidney macrophages and accelerates cyst growth.

Methods: We used adult tamoxifen inducible *Pkd1*$^{flox/flox}$ mice with or without CAGG-cre. After cre induction, mice were fed either a high protein (HP: 60%), a normal protein (NP: 18%) or a low protein (LP: 6%) diet for a total of 1 or 6 weeks. Some mice fed a HP diet were treated with liposomal clodronate (to deplete macrophage) or phosphate buffer saline (intraperitoneally twice a week) for a total of 6 weeks. Mice were euthanized at the end of the experiment for kidney histology, measurements of cytokine and macrophages by FACS.

Results: *Pkd1*-knockout mice fed a HP diet for 6 weeks resulted in increased number of kidney resident macrophage (CD11b^{lo}, F4/80 ^{hi}) and infiltrating macrophages (CD11b^{hi}, F4/80^{lo}) compared to *Pkd1*-knockout mice fed a NP or LP diet. HP diet fed mice resulted in increased kidney pro-inflammatory cytokines, chemokines and severe kidney cysts growth compared to NP or LP diet fed mice. Early after dietary protein modification (1 week), *Pkd1*-knockout mice fed a HP diet had larger kidneys, higher cystic index and kidney mTOR level compared to LP diet fed *Pkd1*-knockout mice but there were no differences in the number of macrophages, chemokine and cytokine levels in the kidney. HP diet fed *Pkd1*-knockout mice treated with liposomal clodronate, resulted in decreased number of macrophages, cytokine and fewer cysts compared to PBS treated *Pkd1*-knockout mice.

Conclusions: Dietary protein load increases kidney macrophages, inflammatory cytokine production and accelerates cyst growth in adult *Pkd1*-knockout mice. HP diet stimulates kidney cyst expansion prior to the recruitment of macrophages early on, but subsequent macrophage depletion therapy slowed the acceleration of cyst growth.

Cyst-Lumen Renal Stones in Mice Compound Heterozygous for Hypomorphic Pkd1^{V} and Pkd1^{RC} Alleles

Stephen C. Parnell,[1,4] Heather A. Riddle,[1,4] Shiqin Zhang,[1,4] Feng Qian,[2] James C. Williams,[3] Jason R. Stubbs,[1,4] Peter S. Rowe.[1,4] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Maryland School of Medicine, Baltimore, MD; [3]Indiana Uniersity School of Medicine, Indianapolis, IN; [4]Jared Grantham Kidney Institute, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) patients exhibit a ~2.5-fold higher propensity for renal stone formation compared to that of the general population. However, there are no good mouse models for the analysis of stone formation in ADPKD. We previously reported the presence of cortical renal stones in cystic mice compound heterozygous for hypomorphic alleles *Pkd1*^{V} and *Pkd1*^{RC} (Parnell *et al.* 2018 J Am Soc Nephrol 29:295). In this present study, the composition and location of the renal stones in this PKD model were determined.

Methods: *Pkd1*^{V} and *Pkd1*^{RC} mice on a C57 background were crossed to produce cystic *Pkd1*$^{V/RC}$ mice. Mice were sacrificed at 3-26 weeks and their kidneys analyzed by Alizarin Red and von Kossa staining. Individual stones were microdissected from cysts and analyzed by μCT and infrared spectroscopic analysis to determine their composition.

Results: Although *Pkd1*$^{V/RC}$ mice were noticeably cystic by 3-weeks of age, stone formation was not obvious until ~13-weeks. Histological sections from 13- and 26-week old mice had regions that stained positive by Alizarin Red and von Kossa in a generally overlapping pattern. In contrast, there were no obvious staining patterns by Alizarin Red or von Kossa in kidneys from 3-week old mice. When kidneys were dissected it became evident that the stones were found almost exclusively within the lumens of cysts (see microdissected cyst with internal stone in Figure 1). μCT and infrared spectroscopic analysis confirmed that dissected stones were comprised of calcium phosphate in the mineral form of apatite, and also rich in protein.

Conclusions: *Pkd1*$^{V/RC}$ mice develop mineralized stone deposits comprised of apatite and protein within the renal cystic lumen. To our knowledge this is the first known instance of renal stones in a mouse model of ADPKD.

Small-Molecule Allosteric Activators of Long-Form PDE4 Enzymes Suppress Cystogenesis in Models of ADPKD

David J. Henderson,[1,2] Xiaofang Wang,[3] Faisa Omar,[1] Gemma Carfray,[1] Li Jiang,[3] Julia M. Adam,[1] Adele Rowley,[1] David R. Adams,[1,4] Vicente E. Torres,[3] Miles D. Houslay.[1] *[1]Mironid Ltd, Glasgow, United Kingdom; [2]University of Strathclyde, Glasgow, United Kingdom; [3]Mayo Foundation for Medical Education and Research, Rochester, MN; [4]Heriot-Watt University, Edinburgh, United Kingdom.*

Background: In ADPKD, mutations in either *PKD1* or *PKD2* perturb intracellular calcium signalling and drive a chronic elevation of intracellular cAMP through de-suppression of calcium inhibited adenylyl cyclase 5/6. This elevation of cAMP signalling underpins the molecular pathology of ADPKD, promoting widespread cyst formation within the nephron epithelium, ultimately leading to renal failure. Phosphodiesterase 4 (PDE4) enzymes degrade intracellular cAMP in a localised manner, and their activity contributes to the compartmentalisation of sub-cellular cAMP dynamics. By modulating or terminating cAMP mediated signalling events, PDE4 isoforms are placed as a central regulator of many cAMP mediated biological processes. We have previously described the discovery and characterization of novel small-molecule compounds which allosterically activate long isoforms of PDE4, and here we further describe their therapeutic potential in suppressing the core cAMP drive behind the pathogenesis of ADPKD.

Methods: Biochemical assay, gene expression profiling and genetic manipulation of cell models were undertaken alongside primary human cell 3D-culture experiments and

Mouse *Pkd1*$^{RC/RC}$ metanephric organ culture to investigate the effects of pharmacological long-form PDE4 activation on intracellular cAMP and cyst dynamics.

Results: Our data show that within murine kidney epithelial cells PDE4 long-form variants from Pde4c and Pde4d predominate and that allosteric pharmacological activation of long-form Pde4 enzymes suppresses intracellular cAMP. We show that the PDE4 mediated suppression of cAMP signalling results in the suppression of cystogenesis in translational models of ADPKD, such as in *Pkd1*$^{RC/RC}$ metanephric organ culture and primary human ADPKD cyst culture. This further supports the potential therapeutic benefit of allosteric activation of PDE4 in treating ADPKD.

Conclusions: Small-molecule activators of long-form PDE4 enzymes suppress aberrantly elevated cAMP signalling and exhibit potential utility as therapeutics in ADPKD.

Probenecid Inhibits Cyst Development in Pkd1$^{RC/RC}$ Mice

Sergey N. Arkhipov,[1] Regina F. Sultanova,[2] Daria Ilatovskaya,[2] Tengis S. Pavlov.[1] *[1]Henry Ford Health System, Detroit, MI; [2]Medical University of South Carolina, Charleston, SC.*

Background: ADPKD cysts contain high levels of ATP that contribute to cyst enlargement. Among other effects, ATP excess leads to a reduced reabsorption in cyst-lining cells and cyst fluid accumulation. We demonstrated that Pkd1$^{RC/RC}$ mice, a model of ADPKD, exhibit increased expression of pannexin-1, a membrane channel capable of ATP release. Probenecid, a uricosuric agent, is also used as a pannexin-1 blocker reducing ATP release. We studied therapeutic potential of probenecid in Pkd1$^{RC/RC}$ mice and its effect on sodium reabsorption.

Methods: Pkd1$^{RC/RC}$ mice, a hypomorphic model of ADPKD, were aged till 10.5 months and osmotic minipumps were implanted to deliver probenecid for 42 days. After treatment, 1 year old conscious mice were subjected to glomerular filtration rate (GFR) measurements and kidneys were collected for histomorphological studies. Effect of probenecid on Na^+ reabsorption was tested on mpkCCD cells seeded onto permeable supports with open-circuit current measurements.

Results: In vivo inulin clearance study demonstrates that Pkd1$^{RC/RC}$ mice have normal GFR 1.05±0.09 ml/min/100g at the 6 months old age (n=15) whereas GFR in C57BL/6 mice - 0.94±0.1 ml/min/100g (n=8). With disease progression GFR in Pkd1$^{RC/RC}$ mice reduces to 0.36±0.08 ml/min/100g at 12 months age. 42 days long probenecid treatment (15.9 mg/kg/day) significantly improves GFR to 1.43±0.11 ml/min/100g ($p<0.001$). Probenecid treatment also reduced kidney hypertrophy: kidney/TBW ratio in vehicle group was 2.54±0.17% vs 1.76±0.05% probenecid ($p<0.05$). Histological study on sectioned kidneys revealed that probenecid significantly reduces cyst size. Cyst to total slice area ratio was 13.9±2.7% (vehicle) vs 3.4±0.8% (probenecid) (n=5 each group). Earlier we have shown that probenecid decreases luminal ATP release in immortalized CD cell culture. As ATP is cable of downregulating Na^+ reabsorption via the epithelial sodium channel we tested if probenecid increases ENaC activity. We applied probenecid to mpkCCD cell monolayer and found that the drug causes a bell-shaped dose-dependent increase of amiloride-sensitive transepithelial flux with maximal effect at 50 μM.

Conclusions: Probenecid demonstrates therapeutic potential against ADPKD cyst progression in a Pkd1$^{RC/RC}$ mouse model by reducing cyst size, renal hypertrophy and supporting GFR and reabsorption from the cyst space. Support: ASN Carl W. Gottschalk Award

Pharmacological Inhibition of β-Catenin-Activated Transcription Slows Cystogenesis in a Postnatal Mouse Model of ADPKD

Valerie A. Schumacher,[1,2] Yun Joon Jung,[1,2] Jordan A. Kreidberg.[1,2] *[1]Boston Children's Hospital, Department of Urology, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: The Wnt signaling pathway has an important role in nephron development and elevated expression of β-catenin, master regulator of the Wnt signaling pathway, has been shown to correlate with cystogenesis in autosomal dominant polycystic kidney disease (ADPKD). Here we provide evidence that pharmacological inhibition of β-catenin-activated transcription slows cystogenesis in a postnatal model of ADPKD.

Methods: To understand the pathological contribution of Wnt signaling to ADPKD, we measured expression of Wnt genes and β-catenin *in vivo* using a postnatal murine model of ADPKD. We also tested the effect of a selective β-catenin-CBP inhibitor on cyst formation.

Results: We observed both increased expression of *Wnt 7a* and higher levels of β-catenin in cystic kidneys of *CAGG-CreER^{T2};Pkd1$^{flox/flox}$* mice. In addition, fibronectin, a known transcriptional target of β-catenin was significantly overexpressed in murine cystic kidneys and also in kidneys from humans with ADPKD. To test whether increased β-catenin transcriptional activity was required for cystogenesis, we treated *CAGG-CreER^{T2};Pkd1$^{flox/flox}$* mice with a small molecule, ICG-001, that blocks the interaction of β-catenin with CBP. We detected significant reduced cyst formation as measured by the kidney/body weight ratio (0.047g ±0.004 vs 0.022g ±0.001) and the cyst area per kidney area (37.8% ±3.1 vs 13.7% ±3.1) and also observed a significant reduction in fibronectin after ICG-001 treatment. Interestingly, cysts that may have formed prior to the start of the treatment remained large suggesting that ICG-001 may primarily act on inhibiting cyst initiation, rather than inhibiting the enlargement of pre-existing cysts. Importantly, ICG-001 treatment did not affect the growth of the mice.

Conclusions: Our study demonstrates that increased β-catenin transcriptional activity has an important role in cystogenesis and inhibition of the β-catenin-CBP complex by ICG-001 may serve as a new therapeutic modality to decrease cyst formation.

Glucosylceramide Synthase Inhibition Preserves Mitochondrial Function and Reduces Reactive Oxygen Damage in the Jck Mouse Model of Polycystic Kidney Disease

Tyler Picariello, Kelly A. Rogers, Laurie A. Smith, Christina M. Bracken, Nikolay O. Bukanov, Oxana Beskrovnaya, Thomas A. Natoli. *Rare and Neurological Disease Research, Framingham, MA.*

Background: Glucosylceramide synthase inhibitor (GCSi) treatment blocks disease progression in PKD mouse models. Defective mitochondrial morphology and function are observed in kidneys of ADPKD patients and murine models. We assessed the impact of GCSi treatment on mitochondrial function in the *jck* mouse model of PKD and *jck* derived kidney epithelial cells.

Methods: Twenty-six-day old WT or *jck* mice were treated with vehicle or 60 mg/kg GCSi (Genz667161) in feed for 38 days prior to tissue harvest. mRNA expression was measured using RT-PCR. protein levels were measured by western blot. Mitochondrial DNA content was measured using real-time PCR. Oxidized DNA was detected using anti-8OHdG antibodies. Oxidized proteins were measured using the Oxyblot system (Millipore).

Results: Reductions in electron transport chain and mitochondrial membrane proteins, as well as mitochondrial DNA were observed in control *jck* mouse and ADPKD patient samples. Decreased antioxidant gene expression was also observed in *jck* kidneys as were increased levels of oxidized DNA and protein; these changes were mirrored in ADPKD samples. Reduced cystic burden following treatment of *jck* mice with GCSi was associated with increased levels of mitochondrial DNA, mitochondrial proteins, and induction of mitochondrial biogenesis pathways. GCSi treatment partially reversed antioxidant gene downregulation and normalized oxidized DNA and protein levels in *jck* tissues. *Jck* cells exhibited decreased mitochondrial number, defective mitochondrial function, and increased protein oxidation consistent with *in vivo* and ADPKD patient data. GCSi treatment alleviates these defects. This suggests that reduced mitochondrial function and increased oxidative stress are primary cellular defects and not a result of cystogenesis.

Conclusions: Mitochondrial dysfunction and increased oxidative stress were observed in *jck* mouse tissues, *jck* cell lines, and ADPKD patient samples. GCSi treatment inhibited disease progression in *jck* mice, reducing oxidative stress and correcting mitochondrial dysfunction. Reduced kidney cyst growth following GCSi treatment correlates with preserved mitochondrial function.

Oral Delivery of Nanoparticles for Renal Disease

Jonathan Wang, Kenneth R. Hallows, Eun ji Chung. *University of Southern California, Los Angeles, CA.*

Background: Nanomaterials are promising for drug delivery, but few have been successful for oral delivery, the optimal route for chronic diseases like polycystic kidney disease (PKD). Drug candidates that slow cyst growth require high dosages leading to side effects like hepatoxicity. To limit this, we previously developed kidney targeting micelles (KM) and found they accumulated in the kidneys. To augment this system for oral delivery, herein, we load KMs and metformin (met), a diabetes drug with PKD promise, into chitosan nanocapsules (CS-NC) to overcome the barriers of the gastrointestinal (GI) tract. We hypothesize that CS-NC will deliver met across the GI tract and show efficacy in PKD mice models. Furthermore, we characterize KMs loaded into CS-NC to serve as a platform for future oral delivery of targeted therapeutics.

Methods: CS-NC were synthesized via ionic gelation. To confirm KM loading into CS-NC, dynamic light scattering (DLS) was performed for the following: KMs loaded into CS-NC, KMs mixed with CS-NC, CS-NC, or KM. To assess the oral delivery performance, we orally gavaged 300 mg/kg met loaded in CS-NC or free met to Pkd1$^{fl/fl}$; Pax8 rtTA;Tet-O cre mice. On P22, kidneys were excised to assess kidney morphology.

Results: DLS of CS-NC showed diameters of 148.5 ± 0.3 nm, while KMs are 14.9 ± 1.5 nm (Fig. 1 Ai, ii). DLS results of the mixed conditions show both populations of particles (Fig. 1 Aiii), whereas loading KMs within CS-NCs removes free KMs (Fig. 1 Aiv), demonstrating encapsulation within CS-NCs. TEM of KMs (Fig. 1 B) and CS-NC (Fig. 1 C) show spherical morphology. Upon oral gavage of CS-NC met, a lower kidney to body weight ratio (10.3 ± 1.1 vs. 13.1 ± 1.0) and (b) cystic index (57.6 ± 1.2 vs. 66.5 ± 0.8) was seen in the CS-NC met group vs. free met (Fig. 1 E,F) ($N \geq 4$, $^{**}p \leq 0.01$, $^{****}p \leq 0.0001$).

Conclusions: These initial studies show promise that KMs can be loaded within CS-NCs and can function as an orally delivered targeted nanotherapeutic. To our knowledge, our studies represent the first nanomedicine strategy for PKD therapy.

Long-Term Effect of Novel Morphometric 3D Capsule Device to Constrain Growth in Polycystic Kidney: Comparison Between Wild-Type, Cy/+, and PCK Rat Models

Kyongtae T. Bae,[1] Aya Yoshimura,[2] Kanako Kumamoto,[2] Masanori Kugita,[2] Tamio Yamaguchi,[3] Shigeo Horie,[4] Junu Bae,[5] Shizuko Nagao.[2] *[1]University of Pittsburgh, Department of Radiology, Pittsburgh, PA; [2]Fujita Health University, Education and Research Center of Animal Models for Human Diseases, Toyoake, Japan; [3]Suzuka University of Medical Science Faculty of Health Science, Department of Clinical Nutrition, Suzuka, Japan; [4]Juntendo University, Faculty of Medicine, Department of Urology, Tokyo, Japan; [5]Ohio State University College of Medicine, Columbus, OH.*

Background: As a potential therapeutic method to halt the progression of polycystic kidney disease, we developed and implanted a computed tomography (CT) image-derived morphometric 3D capsule device to encase a kidney. In this study, the long-term effect of the capsule device on size, function, and histology of polycystic kidneys were assessed using wild-type, Cy/+ and PCK rat models.

Methods: Kidney capsule devices were designed from CT images of rats and surgically implanted on left kidneys, while sham operations performed as controls, in wild-type (n=2), Cy/+ (n=2) and PCK (n=3) rats. After operation, rats were followed to grow. Monthly CT scans were performed and used to measure kidney volume. At the final follow-up, rats were sacrificed and kidney weight, serum BUN and creatinine (Cre) were measured. Histological analyses including cystic area measurement and immunohistochemistry were performed.

Results: In wild-type rats, kidney weights in sham and encapsulated (Enc) rats were similar (Right [R]: 2.2g, Left [L]: 2.1g sham vs. R 2.3g, L 2.2g Enc). In Cy/+ rats survived over 6 months, kidney weights, BUN, and Cre were all lower in Enc rats than those in sham rats (Weight: R 4.7g, L 4.6g sham vs. R 3.6g, L 2.9g Enc (Figure); BUN mg/dL: 113.8 sham vs. 44.9 Enc; Cre mg/dL: 2.06 sham vs. 0.71 Enc). In PCK rats survived over 3 months, kidney weights, BUN, and Cre were all lower in Enc rats than those in sham rats (Weight: R 5.6g, L 6.0g sham vs. R 4.5g, L 3.8g Enc; BUN: 30.6 sham vs. 22.9 Enc; Cre: 0.43 sham vs. 0.36 Enc). Encapsulated kidneys of polycystic rats showed smaller histologic cystic area with reduced cell proliferation and macrophages than unencapsulated kidneys.

Conclusions: Both Cy/+ and PCK rats in long-term follow-ups showed considerable reductions in size of the kidneys that were encapsulated with morphometric 3D capsule devices as well as reduction in BUN and creatinine, demonstrating proof of concept toward a novel potential therapeutic avenue for halting progression of polycystic kidney disease.

Quantifying Murine Total Kidney Volume with Robotic 3D Ultrasound

Tomasz J. Czernuszewicz,[1,3] Nathan Beaumont,[1] Heather L. Holmes,[2] Juan D. Rojas,[1] Ryan Gessner,[1] Paul Dayton,[3] Timothy L. Kline,[2] Michael F. Romero.[2] *[1]SonoVol, Inc., Durham, NC; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Polycystic kidney disease (PKD) is a genetic disorder characterized by renal cyst formation and kidney enlargement. Noninvasive staging of PKD can be accomplished by measuring total kidney volume (TKV). While TKV has been readily implemented in the clinic, its adoption in preclinical research with small animals has lagged. In this study, a new high-throughput imaging device, based on robotic ultrasound (US), was evaluated as a complementary approach for measuring TKV in murine models and validated against *in vivo* and *ex vivo* gold standards (MRI and Vernier calipers).

Methods: Two cohorts of mice were evaluated in a cross-sectional study. Cohort 1 included a range of mature *Pkd1* mice (N = 14 kidneys) that were imaged in 3D with both US and MRI. Cohort 2 included healthy mice (N = 16 kidneys) spanning both sexes and two ages (4&16 wks). Mice from Cohort 2 were imaged with 3D US *in vivo*, euthanized, and TKV measured *ex vivo* with Vernier calipers (length/width). Agreement was assessed with correlation and Bland-Altman (BA) analysis. US images were segmented by 4 independent readers and inter-reader reliability was assessed via intraclass correlation coefficient (ICC).

Results: US-TKV correlated strongly with both MRI and caliper measurements (r^2 = 0.97 and 0.93, respectively). Against MRI, BA-analysis demonstrated no significant bias and a limit of agreement (LOA) of 70 mm^3 between the techniques. Against calipers, a small but statistically significant overestimation was detected of kidney length/width by *in vivo* US imaging (0.87 mm). Inter-reader agreement for TKV was strong with an ICC of 0.93 (95%CI: 0.83–0.97).

Conclusions: These results show that robotic 3D US, performed by a novice operator, can produce rapid, accurate, and consistent *in vivo* measurements of TKV in murine models. Future studies will include larger cohort sizes and additional models of kidney disease (e.g. fibrosis) making this approach ideal for therapeutic screening.

Rapid, Quantitative Measures of ARPKD Kidney Disease with Novel Magnetic Resonance Fingerprinting

Christina J. Macaskill,[1] Dan Ma,[1] Yong Chen,[1] Chris Flask,[1] Katherine M. Dell.[1,2] *[1]Case Western Reserve University, Cleveland, OH; [2]Cleveland Clinic Children's Hospital, Cleveland, OH.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a rare but potentially lethal genetic disorder characterized by diffuse collecting tubule microcysts. There are currently no disease-specific treatments, although several therapies have shown promise in ARPKD animal models. Clinical trials for ARPKD patients have not been possible due to the lack of sensitive measures of ARPKD kidney disease progression. We previously identified renal T1 and T2 relaxometry as potential imaging biomarkers of ARPKD. The goal of this study was to evaluate a novel, rapid magnetic resonance imaging (MRI) technique, magnetic resonance fingerprinting (MRF), in kidneys of healthy volunteers and pediatric ARPKD patients.

Methods: MRF is a quantitative MRI technique that simultaneously generates maps of multiple MRI parameters (e.g., T_1,T_2), while also showing resistance to motion artifact, allowing for more rapid and comprehensive assessment of tissue composition and pathology. We developed a kidney MRF acquisition protocol to generate T_1 and T_2 maps in a single breath-hold (~15 seconds/slice). This MRF method was first validated *in vitro* using standardized T_1 and T_2 phantoms. *In vivo* kidney T_1 and T_2 maps were then obtained from 10 healthy volunteers and 3 ARPKD patients.

Results: MRF-based T_1 and T_2 maps demonstrated good agreement with reference values in standardized phantoms. MRF experiments in healthy volunteers further showed repeatable assessments of the renal cortex (T_1:1318±91 ms; T_2:71±6 ms) and medulla (T_1:1592±63 ms; T_2:73±5 ms), consistent with literature values. Repeated kidney MRF scans for 3 ARPKD patients (age 7-13 yrs, estimated glomerular filtration rates 52-97 ml/min/1.73m^2) on 2 successive days demonstrated good reproducibility (< 3% differences for T_1 and T_2). Significant differences were seen between the volunteer and ARPKD patient populations for both mean kidney T_1 ($p<0.007$) and T_2 ($p<0.04$).

Conclusions: This novel kidney MRF acquisition provides fast, accurate, and repeatable kidney T_1 and T_2 maps in pediatric ARPKD patients. The short acquisition times, coupled with resistance to motion artifact, suggest that MRF could allow rapid, quantifiable imaging assessments of ARPKD kidney disease even in younger children, which could be used to identify high risk patients and/or to assess therapeutic efficacy in clinical trials.

Automated Instance Cyst Segmentation of Polycystic Kidneys in MRIs

Adriana Gregory,[1] Deema A. Anaam,[2] Andrew Vercnocke,[2] Marie E. Edwards,[2] Fouad T. Chebib,[1] Vicente E. Torres,[1] Peter C. Harris,[1] Bradley J. Erickson,[2] Timothy L. Kline.[2] *[1]Mayo Clinic, Department of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic, Department of Radiology, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the development of multiple cysts in the kidneys. Currently, total kidney volume (TKV) is used as the only imaging biomarker to monitor disease progression. However, the ADPKD phenotype can vary widely among patients presenting with similar TKVs. In this study, we developed an MR image analysis method that automatically segments and differentiates individual cysts (i.e. instance-based segmentation) within the kidneys of patients affected by ADPKD.

Methods: A total of 60 T2-weighted MR images representative of different ADPKD stages and phenotypes were identified from our database (TKV range: 296mL-9690mL). The automated 3D instance cyst segmentation model was developed using a convolutional neural network. We reformulated the instance segmentation task by training the model to learn cyst edges and cores separately. The instance labeling was later generated by a combination of connected components and the watershed algorithm. The network was trained on 30 images and validated on 10 images using a 4-fold cross validation technique. The remaining 20 images were used for testing and were compared to manual tracings from two independent readers.

Results: An example of the automated method performance is shown in figure 1A. Quantification of the automatically generated cysts (Fig. 1B.) showed strong correlation with the number of cysts detected by readers 1 and 2 with an R^2 of 0.96 and 0.88, respectively. The cystic index showed high correlation with an R^2 of 0.92 and 0.90 for the comparisons between the automated method and readers 1 and 2, respectively.

Conclusions: We developed and tested the first fully automated instance cyst segmentation method for patients affected by ADPKD. The results demonstrate the feasibility and high accuracy of performing cyst counting and measuring total cyst volume and cystic index automatically.

Human Factors Impact on the Development of Software as a Medical Device (SaMD): A Case Study Using the System Usability Scale (SUS)

Mosaddeq Hossain,[2] Mary Dixon,[1] Annie Lutz,[1] Jeff Horvath.[3] *[1]Innovenn, Inc., Madison, WI; [2]Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; [3]Balanced Experience, LLC, Madison, WI.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is an inherited, progressive, cystic kidney disease and is the fourth leading cause of end-stage renal disease (ESRD). Total kidney volume (TKV) is the most relevant imaging biomarker for tracking and predicting the natural course of ADPKD. Accurate prognostic tools may help predict outcomes and optimize clinical management to slow the loss of renal function. The ADPKD Progression Management (APM) System is a web-based, clinical-decision support software that offers a consistent method for estimating TKV and aids in the prediction of likely risk of progression. The system helps health care providers (HCPs) automatically calculate TKV, project likely TKV growth, and track eGFR and TKV changes over time. The APM System was evaluated for perceived ease-of-use and user satisfaction utilizing the industry standard System Usability Scale (SUS). The SUS is a simple, reliable tool consisting of 10-items with five response options, anchored by "Strongly Disagree" and "Strongly Agree"; the calculated score ranges from 0-100.

Methods: The SUS was used in 4 human factors studies of the APM System. Participants included nephrologists and radiologists who completed test cases using mock data. Participants had no prior experience with the software and received no training on the system. Participants entered clinical information, utilized the automated image measurement to calculate TKV, and generated the automated statistical calculation of predicted growth of TKV, a marker of disease progression. Participants then completed a SUS questionnaire. In each study, a global SUS score was calculated; a total of 79 participants contributed to the global SUS scores: 37 nephrologists, 28 radiologist and 14 nephrologist/radiologist support staff.

Results: APM System received the following SUS scores in studies one through four: 72, 77, 70*, and 80. The SUS score showed an 8 point increase from the first study to the fourth study. *New functions (e.g. Consultation workflow) introduced.

Conclusions: The SUS results demonstrate the impact of iterative improvements in the design and usability of the APM System. The SUS global scores provide evidence that the perceived usability is above average and comparable to the average SUS score for the top 10 apps across iPhone, Android and tablets.

PO1568

Correlation of Baseline Urinary Metabolic Biomarkers with ADPKD Severity in the TAME-PKD Study Participants

Kenneth R. Hallows,[1] Andrew D. Althouse,[2] Hui Li,[1] Biagio Saitta,[1] Kaleab Abebe,[2] Kyongtae T. Bae,[2] Dana Miskulin,[3] Ronald D. Perrone,[3] Stephen L. Seliger,[4] Terry J. Watnick.[4] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]University of Pittsburgh, Pittsburgh, PA; [3]Tufts Medical Center, Boston, MA; [4]University of Maryland School of Medicine, Baltimore, MD.*

Background: Recent work suggests that dysregulated cellular metabolism plays a key role in autosomal dominant polycystic kidney disease (ADPKD) pathogenesis, with increased glycolytic metabolism (Warburg effect) and impaired oxidative metabolism. The TAME-PKD double-blind, placebo-controlled RCT is underway, testing the safety, tolerability and efficacy of metformin, a regulator of cell metabolism and activator of AMP-activated kinase, in ADPKD patients. The purpose of this study was to analyze the degree to which various baseline urinary biomarker values of key metabolites and metabolic enzymes correlate with ADPKD disease severity parameters in this study population.

Methods: Concentrations of total protein, key metabolites (creatinine, lactate, pyruvate, succinate, and cAMP), and key glycolytic enzymes (pyruvate kinase M2 (PKM2), lactate dehydrogenase A (LDHA), and pyruvate dehydrogenase kinase 1 (PDK1)) were measured by ELISA, enzymatic assays and immunoblotting in baseline urine specimens of 95 TAME-PKD participants. These analytes normalized by creatinine were correlated with patients' baseline height-adjusted total kidney volumes (htTKV) by MRI and estimated GFR (eGFR) by CKD-EPI in unadjusted analyses. Additional analyses were performed adjusting for participants' age and sex.

Results: As expected, a very significant negative correlation was found between htTKV and eGFR ($r = -0.385$; $p = 0.0001$) in this population, with a modest positive correlation between urinary total protein excretion and htTKV ($r = 0.201$; $p = 0.052$). None of the metabolites correlated with htTKV or eGFR. Among metabolic enzymes, PKM2 and LDHA both positively correlated with htTKV ($r = 0.286$; $p = 0.005$ and $r = 0.233$; $p = 0.025$, respectively). All of these correlations remained generally consistent in multivariable regression models adjusting for patient age and sex.

Conclusions: To varying degrees, proteinuria, lactate, PKM2, and PDK1 urinary concentrations correlated with ADPKD severity at baseline in the TAME-PKD study population, consistent with the idea that upregulated glycolytic flux is a feature of ADPKD severity. Future analysis will reveal how treatment with metformin may affect both disease progression and the various urinary metabolic biomarkers in patients throughout the study.

PO1569

Urine NAG Is an Effective Clinical Parameter to Presume Disease Activity of Autosomal Dominant Polycystic Kidney Disease

Yuta Kogure, Kaori Takayanagi, Mai Aoyagi, Minoru Hatano, Takatsugu Iwashita, Tomonari Ogawa, Hajime Hasegawa. *School of Medicine, Saitama Medical University, Kawagoe, Japan.*

Background: Patients with ADPKD are mixed with those who progress to ESRD and those who maintains stably, and should be assessed separately from disease activity shown in rate of kidney volume progression (RKVP), disease progression shown in total kidney volume (TKV), and also renal function shown in eGFR. This is also crucial in considering indication of tolvaptan. However, the evaluation of RKVP requires multiple imaging studies, and problems with costs and complexities. Considering that ADPKD is a disorider primarily affecting tubulo-interstitium, we aimed to examine the clinical potential of urine NAG to evaluate RKVP by retrospective obseration.

Methods: Among ADPKD patients treated in our hospital between January 2010 and June 2019, 62 patients who met the conditions of no tolvaptan use, GFR≧30, duration of treatment in our hospital≧1 year, and multiple TKV measurement by CT scanning were included in the analysis.

Results: The mean age was 46.3 years, 62.9% men, the mean baseline eGFR was 60.1±18.5 ml/min/L, the median TKV was 1137 mL, and the median urine NAG index (NAG-to-Cr ratio) was 4.64 U/mg Cr. In the reduced renal function group (30≤eGFR< 60 mL/min, n=32), we observed a correlation between NAG index and RKVP in single-regression analyses ($R^2 = 0.330$, $p = 0.003$), but not with eGFR, TKV. However, there was no significant correlations between all parameter and RKVP, including NAG index, in the normal renal function group (eGFR≥60 mL/min, n=30). Multiple regression analysis showed that NAG index was a predictor of RKVP in the reduced renal function group ($p = 0.005$). Based on the approximate equation in the single-regression analyses of NAG index and RKVP (RKVP=1.511 X NAG index-2.869), the 95% confidence interval for NAG index (5.98-9.40 U/mgCr) in the reduced renal function group, and the corresponding RKVP values (6.16-11.33%/year), reasonable cut-off value of NAG index to predict RKVP≥5% per year might be considered to be 6.0 U/mgCr.

Conclusions: In ADPKD patients with renal dysfunction (CKD stage≤3), it was considered that NAG index may be useful as a predictor of the disease activity shown by RKVP and, if it is 6.0 U/mgCr or greater, may be presumed to be associated with higher disease activity.

PO1570

Overweight and Obesity Are Predictors of Pain in the HALT-PKD Studies

Wei Wang,[1] Zhiying You,[1] Berenice Y. Gitomer,[1] Godela M. Brosnahan,[1] Peter C. Harris,[2] Dana Miskulin,[3] Vicente E. Torres,[2] Kaleab Abebe,[4] Theodore I. Steinman,[5] Alan S. Yu,[6] Ronald D. Perrone,[3] William E. Braun,[7] Arlene B. Chapman,[8] Michel Chonchol,[1] Kristen L. Nowak.[1] HALT-PKD Study *[1]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Tufts Medical Center, Boston, MA; [4]University of Pittsburgh Medical Center, Pittsburgh, PA; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]University of Kansas Medical Center, Kansas City, KS; [7]Cleveland Clinic, Cleveland, OH; [8]UChicago Medicine, Chicago, IL.*

Background: Pain is a frequent complication of autosomal dominant polycystic kidney disease (ADPKD) and includes back and abdominal pain. Level of pain was previously found to be unrelated to kidney size in participants in the 5-yr HALT-PKD studies. We hypothesized that overweight and obesity would be independently associated with greater self-reported back, abdominal, and radicular pain at baseline and that weight loss would be associated with reduced pain over the follow-up period.

Methods: 835 individuals with ADPKD who participated in the 5-yr HALT-PKD study A or B were included in a cross-sectional analysis. The association of baseline BMI with pain was evaluated using multivariable ordinal logistic regression (likert-scale responses). In a longitudinal analysis, the association of annual change in BMI as a time-varying predictor with annual change in pain was evaluated using a generalized estimating equation analysis.

Results: Participants were 43±10 years old and baseline estimated glomerular filtration rate (eGFR) was 71±26 ml/min/1.73m^2. Back, abdominal, and radicular pain were reported more frequently in individuals with overweight/obesity ($p<0.05$). After adjustment for demographics, exercise, pain medications, eGFR, and mutation class, overweight/obesity were associated with increased odds of greater back pain and radicular pain, but not abdominal pain. Associations remained similar after further adjustment for baseline height-adjusted kidney and liver volume (Study A only; n=436); back pain: overweight OR: 1.66 [1.02, 2.68], obese OR: 1.77 [1.03, 3.03]; radicular pain: overweight: 2.28 [1.13, 4.60], obese OR: 2.68 [1.25, 5.76]. Longitudinally (n=823), weight loss (annual BMI decrease >3%) was associated with decreased odds of worsening back pain (OR: 0.87 [0.76, 1.00]) over time vs. weight gain (annual BMI increase >3%).

Conclusions: In early- and late-stage participants in the HALT-PKD studies, overweight and obesity were associated with greater back and radicular pain, independent of total kidney/liver volume. Weight loss was associated with reduced risk of worsening back pain, thus may be an effective strategy to reduce pain symptoms in individuals with ADPKD.

PO1571

Asymptomatic Pyuria as a Prognostic Factor in Autosomal Dominate Polycystic Kidney Disease

Brian E. Jones,[2] Yaman G. Mkhaimer,[1] Reem M. Neal,[1] Amarjyot K. Randhawa,[1] Vicente E. Torres,[1] Fouad T. Chebib.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Department of Internal Medicine, Rochester, MN.*

Background: Urinary tract infection (UTI) in patients with autosomal dominant polycystic kidney disease (ADPKD) is linked to faster disease progression. The effect of asymptomatic pyuria on ADPKD disease progression is not known.

Methods: Retrospective study of ADPKD patients seen at a tertiary academic center with available urinalysis (UA) and abdominal CT/MR imaging, and without infection or other cause of pyuria. Clinical characteristics of patients with asymptomatic pyuria (AP) (> 10 urinary WBC/hpf without UTI) were compared to the group with no pyuria (NP) (WBC 0-3/hpf). First and last available eGFR and height-adjusted total kidney volume (HtTKV) were obtained to calculate the rate of eGFR and HtTKV change with time.

Results: Female and male patients with AP had similar mean age at UA and baseline eGFR as compared to their counterpart with NP (Table 1). Median baseline HtTKV was similar in NP and AP females (596 vs 550 ml/m, respectively) but higher in AP males as compared to NP males (1132 vs 898 ml/m, respectively). There was no difference between females NP and AP in the median rate of eGFR decline (-2.2 vs -2.0 ml/min/1.73m^2/yr) or HtTKV growth (4.4 vs 4.0 %/yr). Compared to males NP, males AP had a higher median rate of eGFR decline (-3.8 vs -2.6 ml/min/1.73m^2/yr, p= 0.04) and a faster median rate of Ht-TKV growth (12.9 vs 6.7 %/yr, p= 0.03).

Conclusions: Asymptomatic pyuria is associated with a faster decline in kidney function and growth of kidney volume in male patients with ADPKD. This could be used as an additional negative prognostic marker.

Table 1: Kidney Function and Height-adjusted Total Kidney Volume by Subgroup

	Females No pyuria (N=317)	Females Asymptomatic pyuria (N=189)	Males No pyuria (N=259)	Males Asymptomatic pyuria (N=67)
Age at UA, years, mean + SD	46.5 ± 13.7	49.5 ± 16.1	50.1 ± 16.1	47.3 ± 16.3
eGFR1, ml/min/1.73m2, mean + SD	66.5 ± 29.3	65.2 ± 29.7	59.9 ± 32.8	58.3 ± 35.5
Age at eGFR1, years, mean + SD	44.3 ± 13.0	45.7 ± 15.4	46.8 ± 15.4	43.3 ± 16.6
eGFR2, ml/min/1.73m2, mean + SD	51.7 ± 32.1	47.5 ± 32.7	42.3 ± 32.1	32.3 ± 25.8
Age at eGFR2, years, mean + SD	51.0 ± 13.4	54.9 ± 15.3	54.4 ± 16.0	51.0 ± 15.7
Time between eGFR1 and eGFR2, years, mean + SD	6.6 ± 6.9	9.2 ± 7.6	7.5 ± 7.3	7.6 ± 7.3
Ht-TKV1, ml/m, median (IQR)	595.7 (343.1 – 1029.9)	550.2 (319.5 – 974.0)	898.0 (475.5 – 1621.2)	1132.2 (6509.4 — 2507.7)
Age at Ht-TKV1, years, mean + SD	45.2 ± 13.2	47.3 ± 15.5	48.6 ± 15.9	44.0 ± 20.1
Ht-TKV2, ml/m, median (IQR)	692.4 (400.9 – 1295.0)	705.0 (349.8 – 1172.6)	1060.2 (572.2 – 2090.5)	1850.5 (819.6 – 2865.6)
Age at Ht-TKV2, years, mean + SD	49.1 ± 13.0	51.9 ± 15.1	52.0 ± 15.5	49.4 ± 15.4
Time between HtTKV1 and HtTKV2, years, mean + SD	3.8 ± 4.7	4.5 ± 5.2	3.4 ± 5.1	5.3 ± 12.6
eGFR rate of decline, ml/min/1.73m2 per year median (IQR)	-2.2 (-4.1 — -0.7)	-2.0 (-3.3 – -0.8)	-2.6 (-4.3 — -1.1)	-3.8 (-5.7 — -2.2)
HtTKV rate of growth, % per year, median (IQR)	4.4 (0.7 – 8.4)	4.0 (1.2 – 8.0)	6.7 (3.1 – 13.1)	12.9 (1.7 – 15.4)

PO1572

Volume Progression and Imaging Classification of Polycystic Liver in ADPKD

Kyongtae T. Bae,[1] Cheng Tao,[1] Robert Feldman,[1] Alan S. Yu,[2] Vicente E. Torres,[3] Arlene B. Chapman,[4] Ronald D. Perrone,[5] Godela M. Brosnahan,[6] Theodore I. Steinman,[7] William E. Braun,[8] Michal Mrug,[9] William M. Bennett,[10] Peter C. Harris,[3] Doug Landsittel,[1] Kaleab Abebe.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Kansas Medical Center, Kansas City, KS; [3]Mayo Clinic Department of Internal Medicine, Rochester, MN; [4]University of Chicago, Chicago, IL; [5]Tufts Medical Center, Boston, MA; [6]University of Colorado, Denver, CO; [7]Beth Israel Deaconess Medical Center, Boston, MA; [8]Cleveland Clinic, Cleveland, OH; [9]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [10]Legacy Health System, Portland, OR.*

Background: While polycystic liver in ADPKD is common and affects significantly the quality of life, volume progression of liver cysts is not well understood. This is in part because previous longitudinal studies focused on the progression of liver volume not liver cyst volume. Thus, the purpose of the study is to evaluate and classify polycystic liver progression in patients with ADPKD based on patient's age, sex, height-adjusted liver cystic volume (htLCV) and height-adjusted liver volume (htLV) measurements.

Methods: Longitudinal MRI data (CRISP and HALT studies) from 695 patients with ADPKD over a maximum follow-up of 14.23 years were evaluated to measure LCV and LV. Among them, 258 patients with LCV > 50mL and at least 2 time-points were included in the analysis. Linear mixed models on log-transformed htLCV and htLV were fitted as a function of participant's age and study as well as a random intercept and slope. The slope coefficient was used to approximate the mean annual rate of change (MAROC) for each outcome. Using the age of 15 years as the hypothetical initial age for LCV=0, differential growth trajectories were plotted to categorize the participants according to their LCV growth rate and age.

Results: Overall, the MAROC was 10.8% for htLCV and 1.8% for htLV ($P<0.0001$). 232 participants had net-increases (last measurement > first) on htLCV, while 26 participants had net-decreases (or values remained the same) on htLCV. For the net-increase group, MAROC was 12.7% for htLCV and 2.2% for htLV ($P<0.0001$). For the net-decrease group, MAROC was -7.3% for htLCV ($P=0.0168$) and -2.1% for htLV ($P=0.1116$). According to the annual growth rate, 5 classes (A <5%, B 5-<10%, C 10-<15%, D 15-<20%, E ≥20%) were defined. The numbers for female and male participants in each class were (F,M): A (31,7); B(48,15); C (49,51); D (27,16); E (9,5).

Conclusions: The mean volume growth rate of the liver cyst was 6 times greater than that of the liver. Similar to the kidney imaging classification, the severity of polycystic liver may be categorized on the basis of patient's age and liver cyst volume.

PO1573

Baseline Characteristics and Associations with Renal Function in a Greek Cohort of Polycystic Kidney Disease

George I. Tsirpanlis,[2] Myrto Kostopoulou,[2] Michaela Louka,[2] Konstantina Kanellopoulou,[2] Vasiliki Gkika,[2] Stavros Fokas,[2] Anastasia Karolina Koutsogianni,[1] Konstantinos Lymperopoulos.[1] *[1]Magnetic Resonance Department, General Hospital of Athens, "G. Gennimatas", Athens, Greece; [2]Nephrology Department of General Hospital of Athens "G. Gennimatas", Athens, Greece.*

Background: Recent advances in the treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD) highlight the interplay between the clinical and the laboratory profile of the disease. This study aims to present the baseline characteristics of patients followed in a large ADPKD cohort from a single center in Greece, and explore possible associations between demographic, clinical and laboratory parameters

Methods: Patients followed in a specialized outpatient PKD clinic from December 2018 up to December 2019 were recruited in this study. At enrollment, demographics, medical and family history and laboratory data were recorded using a standardized form. Estimated glomerular filtration rate (eGFR) was calculated and Magnetic Resonance Imagining for total kidney volume (TKV) measurement was performed

Results: One-hundred three females and 83 males with a mean age±SD of 41.4 ± 13 years (18.8 % < 30 years) were enrolled. Overall, 60.8% of them were classified as Chronic Kidney Disease, (CKD) stage 1 and 2. The ADPKD was diagnosed at a mean age±SD of 26.5±12.5 years. Thirty four percent out of 186 patients were diagnosed before the age of 20 and 9% of them before the age of 10. A positive family history was present in 89% of patients. In this subgroup, the median age of the affected parent that reached end stage renal disease (ESRD) was 55 (range 28-87) years. Hypertension was diagnosed in 89% at a mean± SD age of 37.2 ± 10.5 years. Hepatic cysts were present in 79.3% of patients, urinary tract infections, nephrolithiasis, macroscopic hematuria and pain in 44.3%, 42.5%, 24.8% and 54.4% respectively. A history of intracranial bleeding in family was positive in 21.5%. In multivariable analysis, lower eGFR was associated with younger age at the time of APKD diagnosis ($p < 0.002$), younger age at hypertension diagnosis ($p < 0.08$) and greater values of TKV ($p < 0.001$), height adjusted TKV ($p < 0.001$) and Body Mass Index (BMI) ($p = 0.02$)

Conclusions: In this study, patients with ADPKD were diagnosed at a young age and hypertension developed early on the course of the disease. Both these factors together with higher values of BMI and TKV were independently associated with low eGFR

PO1574

Identification of Factors Associated with Progression, Prognosis, and Tolvaptan Indication in Polycystic Kidney Disease Patients

George I. Tsirpanlis,[1] Myrto Kostopoulou,[1] Michaela Louka,[1] Stavros Fokas,[1] Eirini Tigka,[1] Angelos Drakopoulos,[1] Vasiliki Gkika,[1] Niki Markou,[1] Konstantina Kanellopoulou,[1] Michail Tsagkatakis.[2] *[1]Department of Nephrology, General Hospital of Athens "G. Gennimatas", Athens, Greece; [2]"Geniki Apikonistiki", Medical Imagining, Athens, Greece.*

Background: The identification of risk factors for the progression of Autosomal Dominant Polycystic Kidney Disease (ADPKD) is an emerging field. The present study explores the associations between epidemiological, clinical and imagining data in a large cohort of ADPKD patients

Methods: All patients included in the study had a Magnetic Resonance Imaging (MRI) for measurement of Total Kidney Volume (TKV). For all patients, the Mayo Clinic Imaging Category (MCIC) and the respective prediction for End Stage Renal Disease (ESRD) were calculated. Patients eligible for tolvaptan treatment (MCIC 1C,1D,1E, age <55 years old and estimated-GFR (e-GFR) ≥25ml/min) were identified. Individual medical history, clinical and laboratory data were examined for associations with renal and imaging parameters using linear regression models

Results: 158 patients in total were included. Based on measurements of height-adjusted TKV (ht-TKV) and age, 5% of the patients were classified as 1A, 20% as 1B, 34% 1C, 25% 1D and 16% 1E, MCIC. In multivariable analysis, patients' age ($p=0.01$), male sex ($p<0.001$), parent's age at time of ESRD ($p<0.001$) and proteinuria ($p=0.04$) were associated with ht-TKV. Parent's age at ESRD differed significantly between the MCICs of the offspring (mean±(SD)), 70.83 (12.90) in 1A, 63.79 (11.39) in 1B, 57.32 (10.42) in 1C, 51.42 (9.18) in 1D and 47.94 (5.73) years old in 1E, ($p<0.001$). Similarly, there were differences in the presence and age of hypertension onset ($p=0.004$ and $p=0.003$, respectively). In 104 patients eligible for tolvaptan treatment, age at ADPKD diagnosis, age at hypertension onset and parent's age reaching at ESRD were all significantly lower ($p<0.001$ for all) when compared to non-eligible patients. Finally, factors associated with the prediction score of ESRD (e-GFR 10ml/min) were hypertension, uric acid and the age at ESRD of the affected parent ($p=0.001$, 0.02, 0.01, respectively)

Conclusions: The age at which an affected parent had reached ESRD, as heritability estimator, was significantly associated with a worst phenotype, prognosis and tolvaptan indication. Early diagnosis of the disease, hypertension and its early onset, proteinuria and male sex are also possible risk factors for the progression of ADPKD

PO1575

Design and Basic Characteristics of a National Patient Registry in ADPKD

Elise Hoover,[1] David Baron,[1] Beverly A. Benson,[1] Berenice Y. Gitomer,[4] Klee R. Kleber,[1] Amy Manelli,[1] Michal Mrug,[6] Meyeon Park,[5] Chris Rusconi,[1] Stephen L. Seliger,[2] Ronald D. Perrone,[3] Terry J. Watnick.[2] *[1]PKD Foundation, Kansas City, MO; [2]University of Maryland Baltimore, Baltimore, MD; [3]Tufts Medical Center, Boston, MA; [4]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; [5]University of California San Francisco, San Francisco, CA; [6]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Most patients with autosomal dominant polycystic kidney disease (ADPKD) do not participate in clinical research. To empower ADPKD patients in the US to participate in research and to encourage the development of optimal prognostic and treatment strategies, the PKD Foundation designed a national ADPKD Registry of patient-reported data.

Methods: The ADPKD Registry is hosted on a secure, online platform (IQVIA, oc-meridian.com/pkdcure). Participants are registered and consented through the online system and asked to complete a series of modules quarterly. The Core Questionnaire asks about diagnosis, latest kidney function lab values, current symptoms, and comorbidities. Participants are also asked about family history, diet and lifestyle, and quality of life.

Results: The ADPKD Registry was launched on September 4, 2019. As of May 2020, 1023 ADPKD patients across the US have registered and completed the Core Questionnaire. Participants have a median age of 52 years, and are 72% female, 94% Caucasian, 4% self-identifying as Hispanic/Latino and 2.4% as African American. 76% have not reached end stage renal disease, 4% are treated with dialysis, and 21% received a renal transplant. A family history of the disease was reported in 79% of participants, 12% have had a genetic test for PKD, with a vast majority (94%) reporting diagnosis by imaging. At the time of entering the registry, 78% reported having hypertension and 62% had liver cysts (although only 28% reported a diagnosis of polycystic liver disease(PLD)).

Conclusions: The ADPKD Registry is a longitudinal research tool intended to capture patient-reported data with respect to ADPKD and is designed to impact research in multiple ways. All participants have consented to be contacted about future clinical trials for which they will likely qualify and a process has been established to enable researchers to submit content for new outcome modules. Thus far modules addressing extra renal complications such as PLD and vascular aneurysms have been developed. In addition, the variety of disease stages reported by participants will allow for a range of research questions related to the clinical management of ADPKD from early stage disease through dialysis outcomes and post-transplant complications.

PO1576

First in Canada: A Comprehensive Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patient Registry in British Columbia (BC)

Sharon Gradin,[2] Janet L. Williams,[2] Adeera Levin,[1,2] Ognjenka Djurdjev,[2] Sanford Kong,[2] Karin Jackson,[2] Micheli U. Bevilacqua.[1,2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Early identification, assessment of renal progression and implementation of appropriate treatments are key components of modern ADPKD care. Existing BC Renal programs focus on patients in later disease stages when they access chronic kidney disease clinics, renal replacement modalities, or renal formulary drugs, but data capture of early stage ADPKD patients is limited. A comprehensive ADPKD patient registry was created to enhance identification and understanding of ADPKD in BC.

Methods: The registry was created within PROMIS, the dedicated BC Renal database. A specific focus was registration of patients seen in nephrologists' private offices, prior to enrollment in other BC Renal administered services. Minimum registry data set included basic patient name, date of birth, provincial healthcare number and diagnosis. Laboratory and outcome data are captured via existing PROMIS infrastructure. A streamlined registration process was developed with stakeholder feedback. Time-limited reimbursement was provided to nephrologists' office to support the new workflow of identifying and registering patients.

Results: With the ADPKD registry, the number of ADPKD patients registered in PROMIS has increased from 545 to 1065 between January 2015 to January 2020. The increase in patient registration has been most prominent in early stage patients not on dialysis or transplant (increased from 237 to 703). In those not on dialysis or transplant increase in patients registered was most pronounced in those at earlier CKD stages; from 2015 to 2020, in those with eGFR<15ml/min, registration increased from 27 to 34 patients, with eGFR 15-30ml/min registration increased from 97 to 98, with eGFR 30-45ml/min registration increased from 43 to 117, with eGFR 45 to 60ml/min registration increased from 19 to 109, and in those with eGFR >60ml/min, registration increased from 32 to 237 patients.

Conclusions: Through creation of a comprehensive ADPKD registry, greater numbers of ADPKD patients have been identified in BC, particularly patients earlier in their disease course. The registry will continue to build on this with next steps including enhancements to clinical data, patterns of treatment use, quality metrics for care delivery, and clinical outcomes.

Funding: Commercial Support - Creation of the registry was assisted via an unrestricted grant from Otsuka Canada Pharmaceuticals Inc.

PO1577

STAGED-PKD: An Enriched, Seamless, Two-Stage Study for Venglustat Assessment in ADPKD

Ronald D. Perrone,[1] Ali Hariri,[2] Pascal Minini,[3] Curie Ahn,[4] Arlene B. Chapman,[5] Shigeo Horie,[6] Bertrand Knebelmann,[7] Michal Mrug,[8] Albert C. Ong,[9] York P. Pei,[10] Vicente E. Torres,[11] Vijay Modur,[2] Ron T. Gansevoort.[12] *[1]Division of Nephrology, Tufts Medical Center, Tufts University School of Medicine, Boston, MA; [2]Sanofi Genzyme, Cambridge, MA; [3]Sanofi, Chilly Mazarin, France; [4]Department of Internal Medicine, Seoul National University, Seoul, Seoul, Republic of Korea; [5]Department of Medicine, University of Chicago, Chicago, IL; [6]Department of Urology, Juntendo University Graduate School of Medicine, Tokyo, Japan; [7]Université Paris-Descartes, Faculté de Médecine, AP-HP, Service de Néphrologie, Hôpital Necker-Enfants Malades, Paris, France; [8]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; [9]Department of Infection Immunity & Cardiovascular Disease, University of Sheffield, Sheffield, United Kingdom; [10]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [11]Mayo Translational Polycystic Kidney Disease Center, Mayo Clinic, Rochester, MN; [12]Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) occurs due to cyst formation and growth, resulting in increased total kidney volume (TKV) preceding kidney function decline by decades. The natural history of ADPKD complicates testing of new therapies. Venglustat, a glucosylceramide synthase inhibitor, inhibits cyst growth and reduces kidney failure in PKD mouse models. STAGED-PKD determines venglustat safety and efficacy and was designed using enrichment for progression to ESRD and extensive modeling from prior ADPKD trials.

Methods: STAGED-PKD is a two-stage (Phase 2/3), international, double-blind, randomized controlled trial in adults with ADPKD with increased TKV (Mayo Imaging Class 1C–1E) and eGFR 45–90 mL/min/1.73 m^2. Target enrollment in Stages 1 and 2 is 240 and 320 patients, respectively. Stage 1 randomizes patients 1:1:1 to venglustat dose 1, dose 2 or placebo. Stage 2 randomizes patients 1:1 to placebo or venglustat preferred dose based on Stage 1 safety data. Primary endpoints are TKV growth rate over 18 months in Stage 1 and $eGFR_{CKD-EPI}$ slope over 24 months in Stages 1 and 2 (n=560).

Results: Baseline characteristics for Stage 1 are shown (Table; n=225). Mean patient age is 42.7 years; mean $eGFR_{CKD-EPI}$ is 65.5 mL/min/1.73 m^2. Overall, 55.1%, 30.7% and 14.2% are of Mayo Imaging Class 1C, 1D and 1E, respectively.

Conclusions: STAGED-PKD enables optimal dose selection and evaluation of venglustat safety and impact on TKV growth and eGFR slope in ADPKD. Stage 1 TKV assessment via a nested approach allows early efficacy evaluation, increasing trial design efficiency.

STAGED-PKD: Patient Enrichment and Modeling-Driven Efficient ADPKD Trial Design

Ronald D. Perrone,[1] Ali Hariri,[2] Pascal Minini,[3] Arlene B. Chapman,[4] Shigeo Horie,[5] Bertrand Knebelmann,[6] Michal Mrug,[7] Albert C. Ong,[8] York P. Pei,[9] Vicente E. Torres,[10] Vijay Modur,[2] Ron T. Gansevoort.[11] *[1]Division of Nephrology, Tufts Medical Center, Tufts University School of Medicine, Boston, MA; [2]Sanofi Genzyme, Cambridge, MA; [3]Sanofi, Chilly Mazarin, France; [4]Department of Medicine, University of Chicago, Chicago, IL; [5]Department of Urology, Juntendo University Graduate School of Medicine, Tokyo, Japan; [6]Université Paris-Descartes, Faculté de Médecine, AP-HP, Service de Néphrologie, Hôpital Necker-Enfants Malades, Paris, France; [7]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; [8]Department of Infection Immunity & Cardiovascular Disease, University of Sheffield, Sheffield, United Kingdom; [9]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [10]Mayo Translational Polycystic Kidney Disease Center, Mayo Clinic, Rochester, MN; [11]Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Total kidney volume (TKV) and eGFR slope are key endpoints in autosomal dominant polycystic kidney disease (ADPKD) trials, indicative of cyst growth and kidney function decline. To date, unequivocal demonstration of drug effect on these endpoints required two trials. STAGED-PKD assesses the effect of glucosylceramide synthase inhibition with venglustat on both endpoints in one efficient, short-duration trial.

Methods: Retrospective analysis of TKV and eGFR slope data from CRISP (3-yr) and HALT-A combined identified rapidly progressing patients for enrichment. A statistical relationship between TKV growth vs eGFR slope was derived by modeling. Meta-analysis was conducted of randomized clinical trials assessing treatment impact on both TKV and eGFR. These analyses enabled study powering for both endpoints. Comparison of design efficiency was performed vs prior trials.

Results: Retrospective analysis of CRISP and HALT-A confirmed a significant correlation between TKV growth and eGFR slope (correlation 0.346, p<0.0001; Figure). Different statistical approaches showed that in rapidly progressing ADPKD patients, 50% reduction in TKV growth is associated with a ~30% reduction in eGFR slope. Thus, STAGED-PKD is powered to detect 50% reduction in TKV growth and 30% reduction in eGFR slope. STAGED-PKD is highly efficient vs HALT-A and -B, TEMPO 3:4, and REPRISE.

Conclusions: Modeling allowed the design and powering of a two-stage study to assess venglustat impact on TKV growth and eGFR slope. STAGED-PKD improves study efficiency via modeling and patient enrichment to reduce patient number and trial duration.

Modeling of the Relationship Between TKV Growth Rate and eGFR Decline

PO1579

Biological Efficacy and Safety of Niacinamide in Patients with Autosomal Dominant Polycystic Kidney Disease

Mireille El Ters,[1] Xia Zhou,[2] Rebecca J. Lepping,[2] Pengcheng Lu,[2] Jonathan D. Mahnken,[2] William M. Brooks,[2] Franz Winklhofer,[2] Xiaogang Li,[1] Alan S. Yu.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive cyst enlargement, leading to kidney failure. Sirtuin-1 is upregulated in ADPKD and accelerates disease progression by deacetylating p53. Niacinamide is a dietary supplement that inhibits sirtuins at high doses.

Methods: We conducted an open-label, single arm intervention trial (Study 1, N=10), and a randomized, double blinded, placebo-controlled trial (Study 2, N=36) to assess the biological activity and safety of niacinamide. Patients with ADPKD were given 30 mg/kg oral niacinamide or placebo, for 12 months. Primary endpoint was ratio of acetylated p53 to total p53 protein in peripheral blood mononuclear cells. Secondary outcomes were change in height-adjusted total kidney volume (ht-TKV) and overall pain and quality of life scores. Other biomarkers of efficacy included serum creatinine, CRP, urine protein/creatinine and urine MCP1/creatinine ratios.

Results: There were no statistically significant differences in the baseline characteristics between treatment arms. There was no sustained effect of niacinamide on acetylated/total p53 ratio in either study. In study 1, the ratio was higher at 1 month (p= 0.003) but not at 6 and 12 months and no difference was noted between placebo and niacinamide arms in study 2 (p=0.51). There was no difference in the change of ht-TKV from baseline to 12 months between niacinamide and placebo. Ht-TKV increased slightly from 1049 to 1082 ml/m (p=0.71) with small eGFR decline from 83.6 to 81 ml/min/1.73 m^2 (p=0.84) in niacinamide treated patients (combined study 1+2). Furthermore, there was no statistical difference in urine MCP1/creatinine, urine protein/creatinine and quality of life scores over time. Niacinamide was generally well-tolerated. Most common adverse effects were nausea, diarrhea, gastroesophageal reflux (combined GI symptoms:70% in study 1,78% in study 2 niacinamide treatment arm and 58% placebo), headache and acneiform rash with no difference in their incidence between niacinamide and placebo.

Conclusions: Niacinamide is safe and well-tolerated in ADPKD patients. However, we were unable to detect a sustained inhibition of sirtuin activity over 12 months of treatment, and there was no signal to suggest a beneficial effect on any efficacy measure.

Curcumin Therapy to Treat Vascular Dysfunction in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Design and Baseline Characteristics of Participants

Heather Farmer-Bailey,[1] Melissa A. Cadnapaphornchai,[2] Zhiying You,[1] Diana George,[1] Wei Wang,[1] Anna Jovanovich,[1,3] Danielle Soranno,[4] Berenice Y. Gitomer,[1] Michel Chonchol,[1] Kristen L. Nowak.[1] *[1]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; [2]Rocky Mountain Pediatric Kidney Center, Rocky Mountain Hospital for Children at Presbyterian St. Luke's Medical Center, Denver, CO; [3]Rocky Mountain Regional VA Medical Center, Aurora, CO; [4]Children's Hospital Colorado, Aurora, CO.*

Background: Complications of ADPKD begin in childhood. While the hallmark of the disease is the development and continued growth of multiple renal cysts that ultimately result in loss of kidney function, cardiovascular complications are the leading cause of death. Vascular dysfunction (endothelial dysfunction and large elastic artery stiffness) is evident from a very young age and appears to involve increased oxidative stress and inflammation. Treatment options to prevent cardiovascular disease in adults with ADPKD are limited; thus, childhood may represent a key therapeutic window.

Methods: Curcumin is a safe, naturally occurring polyphenol found in the Indian spice turmeric, with a unique ability to activate transcription of key antioxidants, suppress inflammation, and reduce proliferation. We are conducting an ongoing randomized, placebo-controlled, double-blind clinical trial to assess the effect of curcumin therapy (25 mg/kg/d) on vascular function (brachial artery flow-mediated dilation [FMD_{BA}] and aortic pulse-wave velocity [aPWV]; co-primary outcomes) and kidney growth (change in height-adjusted total kidney volume [htTKV]) in children/young adults 6–25 yrs with ADPKD.

Results: The study is fully enrolled. Of the 68 screened participants, all 68 were randomized to receive either the curcumin or placebo. Participants ranged in age from 6-25 yrs, n=25 (37%) were children <18 yrs, and mean±S.D.estimated glomerular filtration rate was 117±16 ml/min/1.73m^2. FMD_{BA} was 9.3±0.5%, aPWV was 510±95 cm/sec, and median (IQR) htTKV was 333 (234, 475) ml/min. In the sub-group of young adults who received a supraphysiological infusion of ascorbic acid to inhibit vascular oxidative stress (n=24), FMD_{BA} improved vs. isovolumetric saline (13.6±5.2% vs. 11.3±4.3%), indicating baseline vascular oxidative stress. Greater baseline aPWV was independently associated with larger baseline htTKV.

Conclusions: The trial will be completed in December of 2020. This study has the potential to establish a novel, safe, and facile therapy for the treatment of arterial dysfunction, and possibly renal cystic disease, in an understudied population of children and young adults with ADPKD.

PO1581

End-of-Study Results from ACQUIRE: A Study Measuring Quality of Life, Treatment Preference, and Treatment Satisfaction of Autosomal Dominant Polycystic Kidney Disease Patients in Europe

Dominique Joly,[1] Helen Doll,[2] Anne De Jong-Laird,[3] Madhusudan Kabra.[3] *[1]Nephrology Department, Necker Hospital, Paris, France; [2]Clinical Outcomes Solutions Ltd, Folkestone, United Kingdom; [3]Otsuka Pharmaceutical Europe Ltd, Wexham, United Kingdom.*

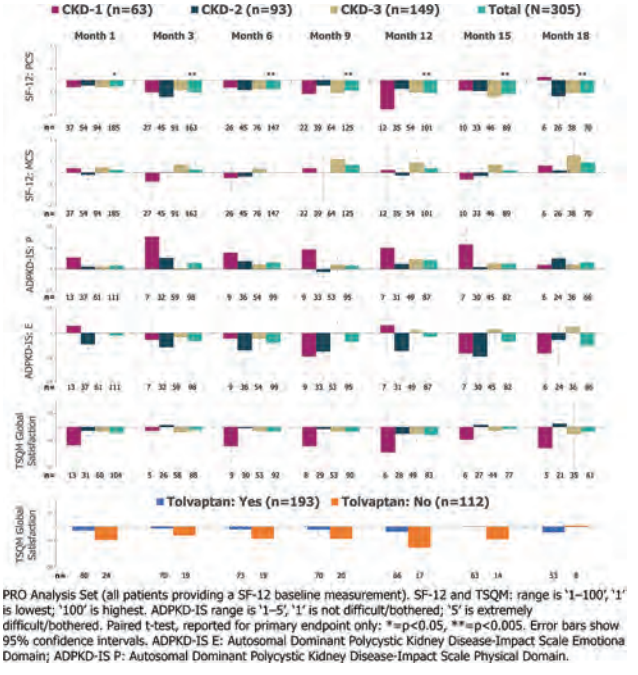
Background: Little is known about health-related quality of life (HRQoL) and patient (pt) reported outcome (PRO) measures in early autosomal dominant polycystic kidney disease (ADPKD), and longitudinal studies are lacking.

Methods: ACQUIRE (NCT02848521) was a prospective, non-interventional, real-world observational study in pts with early and rapidly progressing ADPKD (chronic kidney disease [CKD] stages 1–3) across 7 European countries. The primary objective was to measure changes in Physical Health Composite Scale (PCS) scores of the 12-item Short Form Health Survey (SF-12) over 18 months. Other objectives included changes in SF-12 Mental Health Composite Scale (MCS) scores, ADPKD-specific PROs including the ADPKD-Impact Scale (IS), -Urinary Impact Scale (UIS) and -Pain & Discomfort Scale (PDS), and treatment satisfaction questionnaire (TSQM-9).

Results: Patient demographics were previously reported. Overall 305/403 (75.7%) were included in the PRO analysis set. Changes from baseline in SF-12 (PCS and MCS), ADPKD-IS (Physical and Emotional domains) and TSQM-9 (Global Satisfaction) through Month 18 are presented in **Figure 1.** CKD-1 pts and pts not receiving tolvaptan reported the lowest treatment satisfaction. No consistent changes were observed for ADPKD-UIS and ADPKD-PDS (not shown).

Conclusions: Over an 18-month timeframe, pts reported reduced scores in the PCS component of SF-12, deterioration in the physical components of ADPKD-IS and reduced treatment satisfaction. These data suggest that continued disease progression negatively impacts the HRQoL of pts with early stages of ADPKD and implies there may be current unmet treatment needs in this pt population.

Funding: Commercial Support - Otsuka Pharmaceutical Europe Ltd.



PRO Analysis Set (all patients providing a SF-12 baseline measurement). SF-12 and TSQM: range is '1–100', '1' is lowest; '100' is highest. ADPKD-IS range is '1–5', '1' is not difficult/bothered; '5' is extremely difficult/bothered. Paired t-test, reported for primary endpoint only: *=p<0.05, **=p<0.005. Error bars show 95% confidence intervals. ADPKD-IS E: Autosomal Dominant Polycystic Kidney Disease-Impact Scale Emotiona Domain; ADPKD-IS P: Autosomal Dominant Polycystic Kidney Disease-Impact Scale Physical Domain.

Mortality Risk in Elderly ESRD Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Study Findings Using Data from the United States Renal Data System

Gregory Mader,[1] Deirdre M. Mladsi,[1] Xiaolei Zhou,[1] Myrlene Sanon,[2] Jinyi Wang,[1] Cynthia J. Willey,[4] Stephen L. Seliger.[3] *[1]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC; [2]Otsuka America Pharmaceutical Inc, Rockville, MD; [3]University of Maryland School of Medicine, Baltimore, MD; [4]University of Rhode Island, Kingston, RI.*

Background: Mortality rates may be different for patients in end-stage renal disease (ESRD) with ADPKD compared with patients with other etiologies of ESRD. While mortality estimates have been published by USRDS (2018) for elderly ESRD patients in general (220 per 1,000 patient-years using data from 2012) little has been published reporting national estimates for patients with ADPKD specifically. This analysis sought to estimate ADPKD-specific mortality rates among ESRD patients aged 65 years or older.

Methods: ESRD patients treated with dialysis or transplant with at least one ADPKD diagnosis code and a reported ESRD service date from January 1, 2014, to December 31, 2016, in the US Renal Data System (USRDS) were included. Mortality rates were estimated overall, by sex, by race, and by age group (with a patient's follow-up potentially spanning two age groups). Both unadjusted mortality and adjusted mortality by 2016 US population age distributions for 65 years and older were estimated.

Results: Of 3,208,884 ESRD patients in the USRDS database, 76,428 patients (2.4%) had ADPKD and of those 14,756 were aged 65 years and older in the study period. Among elderly ADPKD patients, mean age was 70.8 years and overall mortality was 99.8 per 1,000 patient-years (129.6 age-adjusted).

Conclusions: These findings fill an important gap in the literature on ADPKD mortality in the US.

Funding: Commercial Support - Otsuka Pharmaceutical Development & Commercialization, Inc.

Mortality (Deaths per 1,000 Patient-Years) Among Elderly Patients with ADPKD in ESRD

Population	Number of Patients (%)*	Mortality (95% CI)	Age-adjusted Mortality
Overall	14,756 (100%)	99.8 (96.4, 103.3)	129.6
Overall, by sex	7,433 (50.4%)		
Male	7,323 (49.6%)	104.4 (99.5, 109.6)	134.4
Female	11,413 (77.3%)	95.3 (90.6, 100.2)	124.8
Overall, by race			
White	11,413 (77.3%)	101.7 (97.8, 105.8)	136.1
Black	1,610 (10.9%)	104.7 (94.2, 116.0)	123.3
Hispanic	1,186 (8.0%)	80.0 (69.6, 91.5)	100.3
Asian	422 (2.9%)	91.4 (73.1, 112.9)	102.9
Other or unknown	125 (0.8%)	86.1 (55.1, 128.1)	94.2
Overall, by age group			
65 to 74 years	11,183 (75.8%)	68.8 (65.5, 72.2)	
75 to 84 years	3,060 (20.7%)	158.9 (150.1, 168.2)	
85 years and older	513 (3.5%)	340.6 (307.6, 376.2)

PO1583

Risk of Severe Herpes Zoster Infection in Patients with Polycystic Kidney Disease: A Nationwide Cohort Study with Propensity Score-Matching Analysis

Tung-Min Yu. *Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Polycystic kidney disease (PKD) should be considered as a systemic disorder rather than only a kidney disease. Significantly lower lymphocyte cell counts, including B and T lymphocyte counts, is noted in patients with PKD. This lymphopenia poses a risk of viral infection. Data to elucidate the herpes virus infection risk in patients with PKD are lacking; therefore, we conducted a national-wide population-based cohort study to investigate the herpes virus risk in PKD patients.

Methods: Patients who were hospitalized at least once with a diagnosis of autosomal dominant PKD were defined as PKD patients; patients without any diagnosis of PKD during the study period were grouped into the non-PKD cohort. The index date was set as the date when the patients were newly diagnosed with PKD. All study patients were followed up until the occurrence of herpes zoster infection, herpes simplex infection, death, withdrawal from the National Health Insurance Research Database for other reasons, or until December 31, 2013.

Results: We included 4358 PKD patients and 4358 non-PKD patients. The incidence rate and the risk of developing herpes zoster and herpes simplex were estimated using multivariate stratified analyses. PKD patients had an overall 2.43-fold risk of herpesvirus infection (aHR = 2.43, 95% CI 1.47–4.04) and 2.36-fold risk of herpes zoster (aHR = 2.36, 95% CI 1.34–4.13) in subgroup analysis compared with the non-PKD cohort. PKD patients without any comorbidities had a significantly higher risk of herpes zoster or herpes simplex (aHR = 3.38, 95% CI 1.51–7.56).

Conclusions: This is the first study to reveal the severe risk of herpes zoster infection in patients with PKD. High index suspicion of severe herpes zoster infection should be maintained in clinical professionals. Whether patients with PKD should be prophylactic universally with anti-varicella-zoster virus vaccine needs to be investigated in the future.

PO1584

The Use of a Visual Four-Score Scale Improves the Yield of ^{18}F-FDG PET-CT Imaging in the Diagnosis of Cyst Infection in Patients with Autosomal Dominant Polycystic Kidney Disease

Francois Jouret, Marie Neuville, Pierre Lovinfosse, Alexandre Jadoul, Marie Thys, Laurence Seidel, Roland Hustinx. *Universite de Liege, Liege, Belgium.*

Background: [^{18}F]FDG PET/CT proved useful in the diagnosis of renal and hepatic cyst infection (CyI) in patients with autosomal dominant polycystic kidney disease (ADPKD). However, the definition of CyI by [^{18}F]FDG PET/CT is subjective. Here, we infer a diagnostic threshold of [^{18}F]FDG uptake in case of CyI based on a visual 4-point scale.

Methods: All ADPKD patients who were hospitalized between January 2007 and March 2019 for suspected CyI and who underwent an [^{18}F]FDG PET/CT were retrospectively identified. CyI was defined upon 5 concomitant criteria: (i) fever ≥38°C; (ii) abdominal pain; (iii) peak plasma C-reactive protein levels ≥70 mg/L; (iv) no other cause of inflammation; and (v) favorable outcomes after antibiotics for ≥21 days. First, all [^{18}F]FDG PET/CT images were qualitatively interpreted by 2 blinded board-certified physicians in nuclear medicine. CyI was diagnosed in case of (i) homogeneous or (ii) heterogeneous [^{18}F]FDG accumulation in cyst wall, or (iii) diffuse [^{18}F]FDG accumulation within the cyst. Next, the uptake of [^{18}F]FDG of the suspected CyI was scored in comparison to blood pool and liver activities. An accumulation of [^{18}F]FDG around the cyst equivalent or inferior to the blood pool was scored as 1. If it was superior to the blood pool but inferior or equal to the hepatic [^{18}F]FDG background, it was scored as 2. If it was slightly superior to the liver, it was scored as 3. If it was largely superior to the hepatic [^{18}F]FDG activity, it was scored as 4.

Results: Sixty [^{18}F]FDG PET/CT (man/woman ratio of 54.1%) were performed for suspected CyI in 38 ADPKD patients: 29 episodes met the gold-standard criteria for CyI. The visual assessment of PET/CT images reached a sensitivity of 73.1% and a specificity of 70.6%. The pattern of [^{18}F]FDG accumulation around or within the suspect cyst was not discriminant. By contrast, the 4-point scale improved the diagnostic yield (specificity of 85.3%), with a diagnostic threshold of [^{18}F]FDG uptake ≥3, i.e. higher than the hepatic background.

Conclusions: [^{18}F]FDG PET-CT imaging helps in the diagnosis of CyI in ADPKD patients, and the use of a 4-point scoring of [^{18}F]FDG uptake improves its yield, with positive and negative predictive values of 78.3% and 78.4% respectively.

PO1585

Liver Cyst Infection After Hepatic Transcatheter Arterial Embolization in Patients with Autosomal Dominant Polycystic Kidney Disease

Yasuhiro Oda, Daisuke Ikuma, Hiroki Mizuno, Akinari Sekine, Masayuki Yamanouchi, Tatsuya Suwabe, Junichi Hoshino, Yoshifumi Ubara. *Toranomon Hospital Kajigaya, Kawasaki, Japan.*

Background: Hepatic transcatheter arterial embolization (TAE) is a non-surgical treatment to reduce the volume of enlarged liver in patients with autosomal dominant polycystic kidney disease (ADPKD). The incidence of liver cyst infection after hepatic TAE is not known.

Methods: Patients with ADPKD who underwent hepatic TAE between January 2014 and July 2019 in Toranomon Hospital Kajigaya to reduce the volume of enlarged liver were retrospectively analyzed for their history of liver cyst infection before and after hepatic TAE.

Results: 107 patients were included in the study. The mean ± standard deviation (SD) of age and height-adjusted total liver volume was 53.9 ± 9.6 years and 5,048 ± 2,124 mL, respectively. 26 patients (24%) were men, and 36 patients (34%) were on renal replacement therapy. Seven patients (7%) had a history of liver cyst infection before hepatic TAE. During the follow-up period, 16 patients (15%) experienced 20 liver cyst infections in total after hepatic TAE, and only one of them had a history of liver cyst infection before hepatic TAE. The mean ± SD of the follow-up period was 714 ± 601 days, while median [interquartile range] was 467 [225-1,078] days. 10 out of 16 patients were on renal replacement therapy, which were all hemodialysis. Four out of 20 liver cyst infections occurred within three months of hepatic TAE. The incidence rate of liver cyst infection after hepatic TAE was 96 cases per 1,000 person-years.

Conclusions: This is the first report on the incidence of liver cyst infection after hepatic TAE. Although comparison with a control group without hepatic TAE is necessary to evaluate the risk of liver cyst infection caused by hepatic TAE, setting a control group with a similar background is difficult and remains a research question.

PO1586

3D Facial Gestalt Analysis of Individuals with Mutated PKD1 and PKD2 Genes in Polycystic Kidney Disease: Results of a Czech Pilot Study

Michaela Zelinova,[1,3] Veronika Moslerová,[1,2] Martin Schwarz,[1,2] Marek Turnovec,[1,2] Dana Thomasova.[1,2] *[1]University Hospital Motol, Prague, Czechia; [2]Univerzita Karlova, Prague, Czechia; [3]Univerzita Karlova, Praha, Czechia.*

Background: Pathogenic variants in *PKD1* and *PKD2* genes cause autosomal dominant polycystic kidney disease (ADPKD) that can also manifest in the liver, pancreas or cardiovascular system. Nonetheless, association of ADPKD with 3D facial gestalt has not been studied SO far. Here we present our first results of 3D facial morphometry in a Czech ADPKD patients.

Methods: Thirty ADPKD cases were enrolled and analyzed by the 3dMD Face System. Morphometric analyses were performed using the Morphome3cs software by comparing cases versus age and sex matched controls.

Results: We observed that 3D facial gestalt in ADPKD patients differs from controls. ADPKD patients have more prominent nasal region, most significantly in the area of the tip of the nose. In addition, there is retrusion of the eyebrows area, midface-zygomatic prominence and retrusion of the lateral buccal region. Most of the ADPKD cases have thin upper lip (red part of lip) in opposition to a prominent lower lip.

Conclusions: The preliminary results of this pilot study suggest that there could be a distinct 3D facial gestalt in ADPKD. ADPKD is an ideal candidate for "phenotype-driven variant prioritization", where molecular genetic analysis could be linked to 3D morphometry. In ADPKD families, where molecular genetics failed to identify a causative variant, 3D morphometry could be used as a predictive marker of the risk of disease in presymptomatic patients. Supported by Charles University Grant Agency, project number 44120.

Background: Genetic mutations in ACTN4 have been linked to focal segmental glomerulosclerosis (FSGS) in humans through cytoskeletal disruption and impairment in podocyte response to mechanical stress. ACTN4 is phosphorylated at S159 in podocytes, but the effect of this post-translational modification on podocyte and kidney function is not known.

Methods: We used phosphomimetic ACTN4 to investigate the effects of this phosphorylation *in vitro* and *in vivo*. The effect of phosphorylation on the interaction between ACTN4 and F-actin was assessed through F-actin bundling assays, and the effect on F-actin alignment was assessed by immunofluorescence staining and quantified using autocorrelation analysis. Microfluidic organ-on-a-chip technology was used to measure the rate of podocyte detachment when simultaneously exposed to fluid flow and cyclic strain. A phosphomimetic mouse model was generated, subjected to subtotal nephrectomy (to simulate glomerular hyperfiltration), and assessed for renal injury. Targeted mass spectrometry was used to determine whether injurious stimuli to podocytes increased ACTN4 phosphorylation.

Results: Compared to wild type (WT) ACTN4, phosphomimetic ACTN4 led to increased F-actin bundling activity and higher spatial correlation of F-actin alignment in podocytes. When subjected to mechanical stress in organ-on-a-chip culture devices, phosphomimetic podocytes demonstrated nearly a 3-fold higher rate of detachment (28/154 podocytes, 18.2%) in comparison with WT (12/170 podocytes, 7.1%, $p<0.05$). Phosphomimetic Actn4 mice developed proteinuria and glomerulosclerosis after subtotal nephrectomy. Finally, phosphorylation of ACTN4 at S159 in podocytes was stimulated by high extracellular glucose and TGF-b.

Conclusions: Increased phosphorylation of ACTN4 at S159 leads to biochemical, cellular, and renal pathology that is similar to pathology resulting from human disease-causing mutations in ACTN4. Stimulation of this phosphorylation by glucose and TGF-B suggests potential mechanisms of ACTN4-mediated kidney disease that extend beyond its original genetic etiology.

PO1588

Toward a Molecular Mechanism for Low-Molecular-Weight Proteinuria in Dent Disease

Katherine E. Shipman, Kimberly R. Long, Youssef Rbaibi, Catherine J. Baty, Ora A. Weisz. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Dent disease is a progressive X-linked disorder caused by loss of function of the Cl^-/H^+ exchanger CLC-5. Early symptoms include low molecular weight (LMW) proteinuria resulting from inefficient recovery of filtered proteins by megalin and cubilin receptors in the proximal tubule (PT). Knockout of Clc-5 in mice recapitulates the LMW proteinuria observed in human disease and decreases protein (but not mRNA) levels of megalin and cubilin. How loss of CLC-5 leads to reduced receptor expression remains unknown. Previous gene expression studies in *Clcn5* KO mice suggest there are alterations in cholesterol and lipid metabolism. Elevated cholesterol levels have been demonstrated to alter the organization of the endocytic pathway and impair receptor recycling in cultured cells. We hypothesize that altered cholesterol metabolism impairs megalin traffic through the recycling pathway and promotes its degradation.

Methods: We used siRNA knockdown (KD) and CRISPR/Cas9 knockout (KO) and rescue approaches in an opossum kidney (OK) cell culture model that recapitulates morphologic and functional features of the PT *in vivo* to study the role of Clc-5 in the endocytic pathway. Additionally, we assessed PT function, megalin/cubilin expression, and cholesterol distribution in newly generated CRISPR/Cas9 Clc-5 KO mice.

Results: KD or KO of Clc-5 resulted in significantly decreased endocytic uptake of fluorescently labeled albumin that was fully rescued by heterologous expression of wild-type human CLC-5. Additionally, the half-life of megalin was reduced in Clc-5 depleted cells. We confirmed LMW proteinuria in the KO mice. Heterozygous females also have reduced PT albumin uptake and megalin expression. We observed an accumulation and a redistribution of cholesterol in PTs of heterozygous mice and in Clc-5 KD OK cells.

Conclusions: Our new cellular models for Dent disease should enable us to identify the molecular mechanism that results in reduced megalin/cubilin expression and determine whether altered cholesterol metabolism contributes to the LMW proteinuria observed in Dent disease.

Super-Resolution Imaging of the Filtration Barrier Suggests a Role for Podocin R229Q in Genetic Predisposition to Glomerular Disease

Linus Butt,[1] David Unnersjö-Jess,[1] Martin Höhne,[1] Robert Hahnfeldt,[1] Dervla Reilly,[1] Markus M. Rinschen,[2] Ingo Plagmann,[1] Paul T. Brinkkoetter,[1] Hjalmar Brismar,[3] Hans Blom,[3] Bernhard Schermer,[1,4] Thomas Benzing.[1,4] *[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; [2]Center for Mass Spectrometry and Metabolomics, The Scripps Research Institute, La Jolla, CA; [3]Royal Institute of Technology, Stockholm, Sweden; [4]CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.*

Background: Breakdown of the three-layered glomerular filtration barrier is a leading cause of end-stage kidney disease. Whereas extensive research led to a growing understanding of hereditary glomerular diseases in children, most adult patients lack a genetic diagnosis. p.R229Q is a common missense variant in *NPHS2*, the gene encoding podocin, and it is associated with albuminuria in the general population. However, epidemiological studies suggest that p.R229Q is only disease causing in trans-association to additional genetic alterations.

Methods: We assessed the predisposition of p.R229Q to glomerular disease by introducing the equivalent point mutation in mice using CRISPR/Cas9-mediated genome editing. By applying super-resolution STED microscopy and functional measurements, we characterized the phenotype of Pod^{R231Q} mice. Additionally, we evaluated the $podocin^{R231Q}$ protein stability in human cultured podocytes.

Results: Although $Pod^{R231Q/wildtype}$ mice do not develop overt glomerular disease, super-resolution microscopy and morphometric analyses revealed ultrastructural alterations that have recently been linked to disease predisposition. Ultrastructural alterations were even more prominent in homozygous $Pod^{R231Q/R2321Q}$ mice eventually resulting in microalbuminuria in aged mice. Consistent with a recently published study, the slit diaphragm length correlated significantly with levels of albuminuria. $Podocin^{R231Q}$ protein levels were decreased in $Pod^{R231Q/R231Q}$ mice and human cultured podocytes expressing the variant. Mechanistically, increased proteasomal degradation resulted in a decreased protein stability of $podocin^{R231Q}$ in human cultured podocytes.

Conclusions: Collectively, our data suggest that podocin R231Q may contribute to genetic predisposition in adult patients.

PO1590

Reduced Glomerular and Nephron Injury due to Albumin Knockout in the Heavily Nephrotic, Polymerization-Defective GBM Laminin B2-Del44 Mutant Mice

Steven D. Funk, Jeffrey H. Miner. *Washington University Department of Medicine, Division of Nephrology, Saint Louis, MO.*

Background: Increased proteinuria is associated with adverse outcomes in chronic renal disease. Much evidence indicates that increased albumin filtration through the glomerular filtration barrier exacerbates nephron injury, but in vivo evidence is conflicting. Although it was previously shown that Nagase analbuminemic rats exhibit little or no increase in renal injury following multiple insults, Alport mice lacking albumin were previously shown to have dramatically increased lifespan with delayed injury to glomeruli and nephron epithelium.

Methods: We mated CRISPR-mediated, albumin-knockout mice with laminin B2-Del44 mice, which exhibit heavy albuminuria, but delayed foot process effacement and fibrosis. Mice were monitored until their natural deaths or euthanized at 9, 3, or 10 months for analyses. Plasma was analyzed for BUN. Glomeruli were analyzed by electron microscopy to determine foot process effacement. Nephron epithelium was analyzed by immunofluorescent microscopy to determine status of injury markers.

Results: Albumin-Del44 double mutant mice exhibited a significantly increased lifespan (6-month vs 9-month average), with significantly reduced BUN at all ages. Similar to Alport mice, foot process effacement in albumin-Del44 double mutant mice

was decreased at yonger ages. Nephron tubule epithelium exhibited reduced KIM-1 expression at early ages, indicating delayed injury.

Conclusions: Similar to Alport mice, the absence of albumin in *Lamb2*-Del44 mice resulted in increased lifespan with delayed renal injury. These data support a significant role of albumin in nephron injury in murine models of nephrotic syndrome.

Klotho Improves Renal Function in Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD-UMOD)

Jing T. Zhang,[1] Mingzhu Nie,[1] Jyothsna Gattineni,[1] Elisabeth Kemter,[2] Thomas Froehlich,[2] Matthias T. Wolf.[1] *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [2]Ludwig-Maximilians-Universitat Munchen, Munchen, Germany.*

Background: Heterozygous Uromodulin (UMOD) mutations cause ADTKD but no therapies are available. We tested if Klotho improves renal function in a murine model for ADTKD-*UMOD*.

Methods: To generate a stronger phenotype we crossed homozygous mutant Umod ($Umod^{C93F/C93F}$) mice with Klotho-overexpressing (TgKl) mice. We studied wild-type (WT), TgKl, $Umod^{C93F/C93F}$ and TgKl/$Umod^{C93F/C93F}$ mice at 6 and 13 months. For quantitative proteome analysis (LC-MS/MS) we harvested kidneys at 3 months.

Results: 1. Compared to $Umod^{C93F/C93F}$ mice, TgKl/$Umod^{C93F/C93F}$ animals had significantly lower serum BUN, creatinine, cystatin C (see Figure 1), PTH, FGF23 values, and less renal fibrosis. 2. Mutant UMOD is retained in the endoplasmic reticulum but relative urinary UMOD secretion was higher in TgKl/$Umod^{C93F/C93F}$ vs. $Umod^{C93F/C93F}$ (relative UMOD protein expression 0.27±0.15 vs 0.13±0.06, p<0.05). 3. Compared to $Umod^{C93F/C93F}$, TgKl/$Umod^{C93F/C93F}$ animals had significantly lower systolic (mean 118±5 vs. 137±5 mmHg, p<0.05) and diastolic blood pressures (56±4 vs. 83±7 mmHg, p<0.01), and lower mRNA expression of markers of cardiac hypertrophy. 4. To identify the mechanism for better renal outcome in TgKl/$Umod^{C93F/C93F}$, we performed an unbiased proteomics approach. We identified downregulation of Transforming growth factor-beta-induced protein (TGFBI) together with multiple collagens, prolargin, biglycan, and osteoglycin/mimecan in TgKl/$Umod^{C93F/C93F}$ vs. $Umod^{C93F/C93F}$ animals. We confirmed lower mRNA expression of TGFBI and collagens.

Conclusions: Klotho improves renal outcome in ADTKD-*UMOD* mice by increasing urinary UMOD secretion and ameliorating renal fibrosis by downregulation of TGFBI and collagens.

Spectrum of Mutations in 106 Chinese Patients with Gitelman Syndrome

Lijun Mou, Xujiao Chen, Ying Hu. *Nephrology Department. Zhejiang University School of Medicine, Zhejiang University School of Medicine, Hangzhou, China.*

Background: Gitelman's syndrome (GS) is an rare, autosomal recessively inherited salt-losing tubulopathy(SLT) characterized by hypokalemic metabolic alkalosis. GS is caused by the mutations in *SLC12A3* gene encoding for the thiazide-sensitive NaCl cotransporter (NCC). However, the sensitivity of genetic sequencing was low. No large genomic rearrangements in Chinese patients with GS was previously identified.

Methods: Targeted gene sequencing (TES) by next generation sequencing associated with SLTs was performed for patients suspected of GS. Then, a search for large genomic rearrangements by ligation-dependent probe amplification(MLPA) assay was performed in patients with heterozygous for point mutations and patients with homozygous mutations without consanguinity history.

Results: Fifty-nine patients(55.67%) were female, the age was (34.87±15.36)years, serum potassium level was (2.68±0.36)mmol/L, serum magnesium level was (0.58±0.13)mmol/L, ninty-four patients(88.68%) had hypomagnesemia, seventy-nine patients(81.44%,79/97) had hypocalciuria. Eighty-three different mutations in *SLC12A3* were identified within these 106 GS patients, including 32 novel mutations and 4 recurrent ones,5 large genomic rearrangements. Recurrent mutations were p.T60M (22.86%),c.965-1_976delGCGGA CATTTTTGinsACCGAAAATTTT(6.19%),p.D486N(4.76%), p.N359K(4.76%). Triple mutations was identified in 8 patients, compound heterozygous mutations were identified in 70 patients, homozygous mutations were identified in 18 patients, whereas 10 patients had only one heterozygous mutation. The 5 large genomic rearrangements were exon deletion, including E7,E8 deletion, E8,E23 deletion, E20-E24 deletion, E8 deletion,E4-E6 deletion. The sensitivity of genetic testing sequencing was 90.57%.

Conclusions: We identified 83 mutations related to GS, containing 32 novel variants and 4 high-frequency ones, 5 large genomic rearrangements. TES combined with MLPA significantly increased the sensitivity of genetic sequencing and facilitate more accurate diagnosis of GS.

Glucosylceramide Synthase Inhibition with Venglustat in Classic Fabry Disease Patients Leads to Progressive Reduction of Endothelial Cell Globotriaosylceramide Inclusion Volume

Behzad Najafian,[1] William Wilcox,[2] Robert Hopkin,[3] Elena Lukina,[4] Patrick B. Deegan,[5] Charlotte Sensinger,[6] Eric Hailman,[6] Vijay Modur,[6] Michael Mauer.[7] *[1]Department of Pathology, University of Washington, Seattle, WA; [2]Emory University School of Medicine, Atlanta, GA; [3]Division of Human Genetics, Cincinnati Children's Hospital Medical Center, University of Cincinnati College Medicine, Cincinnati, OH; [4]National Research Center for Hematology, Moscow, Russian Federation; [5]Lysosomal Disorders Unit, Addenbrooke's Hospital, Cambridge, United Kingdom; [6]Sanofi Genzyme, Cambridge, MA; [7]Departments of Pediatrics and Medicine, University of Minnesota, Minneapolis, MN.*

Background: Fabry disease (FD) is a rare disorder caused by mutations in the gene for the lysosomal enzyme alpha-galactosidase A (αGal-A). Progressive accumulation of globotriaosylceramide (GL-3) in vascular endothelial and other cell types leads over decades to renal, cardiovascular, and other severe clinical manifestations. In a phase 2 study, glucosylceramide synthase inhibition with venglustat led to reduction in microscopic (LM) scores of lysosomal GL-3 inclusions in skin capillary endothelial cells (EC) after 3 years, although not after 6 months. We applied quantitative unbiased stereological methods to better characterize the effect of venglustat on skin EC GL-3 inclusions.

Methods: Skin biopsies were obtained from classic male Fabry disease patients (N = 11) at baseline and during daily treatment with venglustat (NCT02228460, NCT02489344). Images from at least 50 randomly selected superficial skin capillaries per biopsy were obtained using transmission electron microscopy (EM) at 7,500 X magnification. The fraction of the volume (Vv) of EC cytoplasm occupied by GL-3 inclusions [Vv(Inc/Endo)] was estimated using point counting by a masked reader. Two-sided paired t tests were used to evaluate changes from baseline to post-treatment values at each time point.

Results: Venglustat therapy led to a significant reduction from baseline in Vv(Inc/Endo) of 0.062 (21.1%; p=0.001) after 6 months and 0.119 (38.7%; p=0.001) after 3 years of treatment.

Conclusions: Treatment with venglustat led to reduction in skin capillary GL-3 inclusion fractional volume which was detectable after 6 months using precise quantitative EM methods, but not by LM scoring. This was followed by further reduction over the next 2 1/2 years. We posit that, in the absence of αGal-A activity, inhibition of GL-3 production with venglustat allowed other enzymatic or non-enzymatic mechanisms to progressively reduce EC lysosomal GL-3 content. Long-term venglustat therapy may therefore prevent or reverse progressive tissue injury in Fabry disease.

The Role of Claudin Variants in the Formation of Kidney Stones

Yuan Zhuang,[1] Jasmine El andalousi,[2] Sero Andonian,[1] Bertrand J. Jean-Claude,[1] Aimee K. Ryan,[1] Indra R. Gupta.[1] *[1]McGill University Faculty of Medicine, Montreal, QC, Canada; [2]Research institute of McGill university, Montreal, QC, Canada.*

Background: Genetic risk factors contribute to the formation of calcium-based kidney stones. The majority of calcium is reabsorbed via paracellular transport through tight junctions along the human nephron epithelium where Claudin proteins are expressed. Claudins determine the selectivity and permeability of different nephron segments. Studies have shown that *CLDN* gene sequence variants are associated with kidney stones. I hypothesize that sequence variants in Claudin genes that regulate paracellular renal transport of calcium. will be associated with the formation of kidney stones.

Methods: Patient DNA was analyzed by Fluidigm Next Generation Sequencing and confirmed by sanger sequencing. Rare variants (MAF<1%) were compared to the gnomAD database. *In silico* prediction software was used to predict the impact of the amino acid change. Human claudin variants were generated by site-directed mutagenesis and cloned into a mammalian expression vector, pEGFP. Immunofluorescence was performed on HEK293 cells that were transiently transfected with both variant and WT sequences.

Results: Ninety adult patients (45 females, 45 males) with recurrent calcium-based kidney stones were recruited from one urologist's kidney stone clinic. Seventy-two percent (65/90) of the patients self-defined as Canadian-European. Sixty-two percent (56/90) of the patients presented with the first kidney stone less than 40 years of age. Four novel heterozygous missense variants were identified in the following: *CLDN11* S157F, *CLDN16* K29E, *CLDN17* A94V, and *CLDN18* H212D. Nine rare variants include *CLDN*4 A82T, *CLDN*4 A113T, *CLDN7* V55I, *CLDN*8 A94V, *CLDN*8 M97T, *CLDN*12 M98V, *CLDN*23 A90T, and *CLDN*24 V97I. *CLDN4* A82T, *CLDN8* A94V, *CLDN11* S157F, and *CLDN17* A94V are predicted to be deleterious. HEK293 cells were transiently transfected with *CLDN4* A82T and the mutant protein was unable to localize to the tight junction, unlike the WT *CLDN4* protein which did co-localize with ZO-1 by immunofluorescence as expected (n=3 independent experiments). Other claudin variants are under evaluation.

Conclusions: The rare heterozygous variant, *CLDN4* A82T is located at the second transmembrane domain and predicted to be deleterious. Functional analysis showed that *CLDN4* A82T has an impact on the localization of the protein to the tight junction.

Elucidation of Molecular Pathogenesis of Lowe Syndrome and Dent Disease Type 2

Nana Sakakibara, Kandai Nozu, Shinya Ishiko, Yuya Aoto, China Nagano, Tomoko Horinouchi, Tomohiko Yamamura, Takeshi Ninchoji, Kazumoto Iijima. *Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Lowe syndrome and Dent disease-2(Dent-2) are both X-linked kidney diseases caused by *OCRL* gene abnormalities. However, the severity of these diseases are quite different. Genetic studies have shown that patients with truncating mutation in exon 1-7 of *OCRL* gene were diagnosed with Dent-2, and those with truncating mutations in exon 8-24 were diagnosed with Lowe syndrome. OCRL protein encodes a 5-phosphatase that acts on phosphatidylinositol 4,5-bisphosphate (PI(4,5)P2) and is related to cellular functions by the regulation of inositol phospholipids. The molecular mechanism by which different phenotypes of Dent-2 and Lowe syndrome are caused by the same gene variant has not been clarified until now, but it is suspected that an isoform consisting of exon 8-24 exists and it works partially as a 5-phosphatase. However, such isoform has not been identified yet.

Methods: We extracted mRNA from cultured urine derived cells of healthy controls and Dent-2 patient with truncating mutation in Exon4 of *OCRL* gene and then examined 5 'end of mRNA of these cells by using rapid amplification of cDNA ends (5' RACE) method. We also prepared three types of OCRL protein expression vector: wild type model, Dent-2 models harboring truncating mutation in exon 4 and exon 7, and Lowe syndrome models harboring truncating mutation in exon 16 and exon 22. These vectors were transfected into Hela cells and analyzed the protein expression and 5-phosphatase activity.

Results: As a result of 5' RACE, the 5' end starting from Exon 6 was detected in both cells of healthy control and Dent-2 patient. In fluorescent immunostaining of transfected Hela cells, strong protein expression was observed in the wild type model, relatively weak expression was observed in Dent-2 models and no expression was observed in Lowe syndrome models. Western blot analysis detected two bands of 105kDa and 80kDa in the wild type model, single band of 80kDa in Dent-2 models, and no band in Lowe syndrome models. 5-phosphatase activity of Dent-2 models was 50-85% of that of wild type model, whereas that of Lowe syndrome models was less than 20% of that of wild type model.

Conclusions: An isoform OCRL protein with 5-phosphatase activity is synthesized by alternative transcription of *OCRL* gene. This isoform contributes to the mild clinical phenotype in Dent-2.

Atypical Histological Abnormalities in Patients with Nephronophthisis Diagnosed with NPHP1 Deletion

Maiko Akira,[1] Hitoshi Suzuki,[1] Arisa Ikeda,[2] Masako Iwasaki,[1] Daisuke Honda,[1] Hisatsugu Takahara,[1] Shigeki Tomita,[1] Hisaki Rinno,[1] Yusuke Suzuki.[2] *[1]Juntendo University Urayasu Hospital, Urayasu, Japan; [2]Juntendo University Faculty of Medicine, Tokyo, Japan.*

Introduction: Nephronophthisis (NPHP) is a chronic tubular interstitial disorder that exhibits autosomal recessive genetic forms, causing progressive renal failure in children. It is rare to show urinary abnormalities, edema and hypertension in patients with NPHP. Thus, it is often detected only when the renal failure becomes advanced. NPHP is divided into three types leading to the age of end-stage renal failure, *i.e.*, infant type (around five years old), juvenile type (around 13-14 years old), and adolescent type (around 19 years old). In present study, we report a case of NPHP diagnosed at twenty-six years old who was detected renal dysfunction by annual medical check-up.

Case Description: A 26-year-old woman has not been recognized any growth disorder, and has never been pointed out any urinary abnormality in a school checkup. She was detected renal dysfunction (sCr 2.2mg/dL) by annual medical check-up at 26 years old. Urine test indicated low specific gravity urine, but not proteinuria and microscopic hematuria. However, urinary β2-MG was high (805μg/L), and renal biopsy was performed for definitive diagnosis. Histological findings showed no significant findings in glomeruli. However, moderate fibrosis was observed in the interstitial area, and moderate atrophy was observed in the tubules. There was no significant finding in the immunofluorescence analysis, and no electron dense deposits was detected by electron microscopy. Although cyst-like expansion of the tubules was not clear, tubular atrophy was dominantly found in the distal tubules by CK7 staining. Then, we performed genetic analysis of *NPHP1* gene, and found complete deficiency of *NPHP1* gene, leading to definitive diagnosis of juvenile NPHP.

Discussion: NPHP is often progress to ESRD at an average age of 13-14 years old. Thus, it is exceedingly rare to find NPHP in adult. Although present case did not show the typical histological abnormalities, such as cyst-like expansion of the tubular lesion, we could diagnose by genetic analysis of NPHP1 gene. In patients with renal failure with tubular interstitial disease dominantly in distal tubule, it is necessary to discriminate NPHP even in the adult case.

PO1597

Biobank of Urinary Cells and Human Kidney Organoids Reveals Nephropathic Cystinosis Phenotypes and Gene Therapy Strategy

Louisa Helms,[1] Ivan G. Gomez,[1] Dries David,[2] Nelly M. Cruz,[1] Elena N. Levtchenko,[2] Rik Gijsbers,[2] Benjamin S. Freedman.[1] *[1]University of Washington, Seattle, WA; [2]Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium.*

Background: Cystinosis is a rare disorder caused by mutations in *CTNS* encoding a cystine transporter, leading to renal Fanconi syndrome and kidney failure. Cysteamine treatment slows, but does not prevent these outcomes and animal models fail to exhibit Fanconi syndrome. Stem cell derived kidney organoids exhibit structures with segmented, nephron-like segments, providing an *in vitro* platform to study nephropathic cystinosis. As a monogenic disorder, gene therapy is an attractive therapeutic approach which can be optimized in kidney organoids. However, cystinosis patients are rare, and iPS cells representing this population are needed.

Methods: Cells from the urine of 16 patients with cystinosis and control subjects were reprogrammed into iPS cells via Sendai virus. CRISPR gene editing was applied to non-cystinotic iPS cells generating 8 *CTNS*$^{-/-}$ lines with isogenic controls. Patient-derived and CRISPR-derived *CTNS* mutant and control iPS cell cohorts were differentiated into kidney organoids and propagated in suspension culture to assess cystinotic phenotype. Organoids were transduced at different stages of differentiation with lenti and adeno-associated viruses with fluorescent reporters to assess efficacy of gene transfer.

Results: Patient-derived and CRISPR-derived stem cells exhibited >100 fold increased intracellular cystine content and vacuole-like structures, compared to controls. Both patient and CRISPR iPSCs differentiated into kidney organoids with proximal and distal tubules and podocyte segments. However, cystinotic organoids developed lobular cyst-like structures in suspension culture over multiple weeks, which were reduced with cysteamine treatment. Lentiviral and AAV transduction successfully entered kidney organoid structures and co-localized with nephron markers when transduced at early stages of differentiation.

Conclusions: We have established a biobank of urinary and iPS cells representing over 20 cystinotic genotypes, with phenotypes in both patient- and CRISPR-derived *CTNS* mutant lines that show improvement with cysteamine. Viral transduction of kidney organoids can be timed to produce high levels of entry. This biobank provides a comprehensive resource for patient-specific development of more efficacious therapeutics for cystinotic nephropathy, including gene therapy.

Clinical and Genetic Features of Autosomal Dominant Alport Syndrome

Monica Furlano,[1,2] Víctor Martinez Jimenez,[3] Marc Pybus,[1,2] Andrea Domingo Gallego,[1,2] Nadia Ayasreh,[1,2] Silvia Benito García,[1,2] Rosa Arlandis Gallego,[4] Elisabet Ars,[1,2] Roser Torra.[1,2] *[1]Fundacio Puigvert, Barcelona, Spain; [2]Universitat Autonoma de Barcelona, Barcelona, Spain; [3]Hospital Clinico Universitario Virgen de la Arrixaca, El Palmar, Spain; [4]Hospital General de Castellon, Castellon de la Plana, Spain.*

Background: Alport Syndrome is the second most frequent genetic kidney disease, accounting for around 2% of patients with end-stage kidney disease. It is caused by pathogenic variants in *COL4A3*, *COL4A4* and *COL4A5* genes. The aim of this study was to evaluate the clinical and genetic spectrum of patients with autosomal dominant Alport syndrome.

Methods: Retrospective cohort study of 82 families (252 patients) with autosomal dominant Alport Syndrome. Clinical, genetic, laboratory and pathological data were collected. Renal survival, estimated glomerular filtration rate (eGFR) decline, genotype-phenotype correlation and extrarenal features were analyzed.

Results: A pathogenic DNA variant in *COL4A3* was identified in 106 patients (34 families) while 134 harbored a pathogenic variant in *COL4A4* (44 families). Complex/digenic inheritance was observed in 12 patients without clear genotype–phenotype correlation. Overall median renal survival was 67 years [95% CI, 58–73], without significant differences related to gender, causative gene or type of variant ($p = 0.85$, $p = 0.28$ *and* $p = 0.81$ *respectively*). Microhematuria was the most common renal manifestation (93%) while extrarenal features were rare. The results of kidney biopsies ranged from normal to focal segmental glomerulosclerosis. Hypertension was common and the age at its diagnosis correlated with age at end-stage kidney disease ($p < 0.01$). The slope of eGFR decline was -1.66 mL/min/1.73m^2 per year (-1.9 to -1.42) for the overall group, with no significant differences between *COL4A3* and *COL4A4* genes (P=0.60).

Conclusions: This study shows that autosomal dominant Alport Syndrome patients present a wide spectrum of symptoms ranging from asymptomatic to end-stage kidney disease, regardless of the affected gene or type of variant. This broad phenotype contributes to underdiagnosis in clinical practice and makes autosomal dominant Alport Syndrome diagnosis very challenging.

Beneficial Effect of Oxalobacter formigenes Treatment on Nephrocalcinosis in a Rat Model of Primary Hyperoxaluria

Anja Verhulst,[1] Bastian Dehmel,[2] Elisabeth Lindner,[2] Maria E. Akerman,[2] Patrick C. D'Haese.[1] *[1]Universiteit Antwerpen, Antwerpen, Belgium; [2]Oxthera, Stockholm, Sweden.*

Background: Hyperoxaluria leads to urinary calcium-oxalate supersaturation and crystal retention in renal tissue (nephrocalcinosis). In case of primary hyperoxaluria (PH), increased hepatic oxalate production because of a rare genetic defect often leads to severe nephrocalcinosis and early ESRD. Secondary hyperoxaluria is generally less severe, however more common and often related to intestinal oxalate hyperabsorption. Current therapy is often unsatisfactory. Oral administration of *Oxalobacter formigenes* (OxF), an oxalate-degrading bacteria, is thought to reduce intestinal oxalate absorption and to derive oxalate from systemic sources by inducing enteric oxalate secretion. Here, the ability of OxF treatment to prevent or reduce PH induced nephrocalcinosis, by using an ethylene glycol (EG) rat model to mimic increased hepatic oxalate production, was investigated.

Methods: Eighteen rats were administered EG (0.75% in drinking water) for 6 weeks, of which 9 were treated by oral gavage with OxF and 9 received vehicle. Five control rats did not receive EG/OxF. Plasma and urinary oxalate levels, calcium-oxalate crystalluria, urinary volume, fluid intake, and serum creatinine were monitored during the study period. At sacrifice, nephrocalcinosis was quantified.

Results: Vehicle treated EG animals showed clear hyperoxalemia, hyperoxaluria, calcium-oxalate crystalluria and nephrocalcinosis. In OxF treated EG animals the plasma oxalate levels were lower compared to vehicle-treated ones (significant at week 4: 47.6±20.9 vs 20.8±8.9 μM). Nephrocalcinosis was completely absent in the EG/OxF group. Urinary output of oxalate (crystals) was similar in OxF and vehicle treated EG animals which indicates that, taking into account the absence of crystals in renal tissue of OxF treated EG animals, the amount of oxalate offered to the kidney for excretion was higher in the EG/vehicle group. EG administration significantly increased urinary volume, renal mass and fluid intake, most probably due to osmotic diuresis and partially reversed by OxF. Serum creatinine levels of EG animals (both vehicle/OxF) stayed at baseline levels throughout the study.

Conclusions: This study shows a beneficial effect of OxF treatment on the development of PH-induced hyperoxalemia and nephrocalcinosis, pointing to OxF induced enteric oxalate elimination.

The Knockdown of RPL36A Downregulates GLA Expression Associated with Fabry Disease In Vitro Model

Mohammed A. Al-Obaide. *Texas Tech University Health Sciences Center, School of Medicine, Amarillo, TX.*

Background: Mutations in the galactosidase alpha (*GLA*) locus can cause Fabry disease. The *GLA* locus is mapped in the reverse strand of *the RPL36A-HNRNPH2* readthrough locus. The study aimed to show the influence of the siRNA downregulation of the *RPL36A* expression (the first gene in the *RPL36A-HNRNPH2* locus*)* on the *GLA* expression.

Methods: The siRNA method was used to downregulate the expression of *RPL36A* in HEK293 cells. The expression of the two genes *RPL36A* and *GLA in vitro* was analyzed by RT qPCR. The protein products of the two genes were analyzed by ELISA and Western blot.

Results: The RT qPCR results of the *RPL36A* knockdown by siRNA showed a significant decrease not only for *RPL36A* expression but also for *GLA* expression ($p<0.05$) compared with the results of the untreated HEK293 cells. ELISA and Western blot assays showed a decrease in the GLA protein following knockdown of *the RPL36A* gene, but the two assays did not show a decrease in the expression for RPL36A protein. Alignment analysis by EMBOSS Matcher showed RPL36A protein amino acid sequence (Length: 106, Mass (Da): 12,441) is 99.1% like RPL36AL protein amino acid sequence (Length: 106, Mass (Da):12,469). Intriguingly, the sequence of mRNA transcripts of both genes showed an 85.3% similarity. The designed siRNA was specific to *RPL36A* transcript NM_021029.6 and not to *RPL36AL* transcript NM_001001.5, which may explain the RT qPCR results.

Conclusions: The data provided evidence that malfunction in the expression of *the RPL36A* locus located at the start of the *RPL36A-HNRNPH2* readthrough locus can cause an error in the expression of *GLA*. These findings revealed the importance of the *RPL36A-HNRNPH2* readthrough region in Fabry disease. The work was supported by Sanofi-Genzyme Project GZ-2017-11708.

Focal Segmental Glomerulosclerosis with Glomerular Basement Membrane Abnormalities Caused by Compound Heterozygous Myosin 1E Gene Mutations

Claudia Aiello, Dhruti P. Chen, J. Charles Jennette, Keisha L. Gibson. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Nephrotic syndrome due to focal segmental glomerulosclerosis (FSGS) in children is often associated with genetic mutations in podocyte structural proteins. This clinical case report highlights a pediatric patient with nephrotic syndrome and FSGS found to have two genetic mutations in myosin 1E gene (MYO1E) encoding the motor domain of the protein. While both of these mutations have previously been identified as variants of unknown significance individually, we report a case of compound heterozygous mutations resulting in FSGS.

Case Description: An 11-year old white male presented with proteinuria and hematuria. Family history of kidney disease included a paternal cousin with hematuria that spontaneously resolved. The patient had no history of recurrent urinary tract infections, kidney stones or excessive NSAID usage. Kidney biopsy revealed FSGS with basket-weaving, splitting and segmental thickening of glomerular basement membranes (GBM) on electron microscopy. Genetic testing was negative for Alport mutations but identified two variants in MYO1E gene (Table). Parental testing revealed each had one variant inherited by the patient, resulting in compound heterozygous mutation in the patient.

Discussion: Both missense mutations in this patient encode the motor domain of myosin 1e protein (residue 19-692), essential for podocyte motility and structural integrity. Hereditary mutations at other locations encoding the motor domain of MYO1E have been described and associated with FSGS. Functional studies showed that MYO1E motor domain variants led to protein mis-localization and disruption to the podocyte structural integrity (Mele et al. NEJM, 2011). MYO1E depletion in mice causes GBM abnormalities similar to lesions in this patient (Chase et al. Am J Physiol Renal Physiol, 2012). While each individual mutation inherited by the patient is not known to be pathogenic, we hypothesize that the combination of non-conservative mutations in the patient resulted in abnormal myosin-1e protein function that caused GBM abnormalities and FSGS.

Genetic diagnostic testing results for proband and parents

	Gene	Variant Location	Allelic Inheritance	Encoded location of myosin-1e
Mother	MYO1E	1684 G>A (Gly562Arg)	Heterozygous	Motor domain, missense mutation
Father	MYO1E	275 C>A (Ala92Glu)	Heterozygous	Motor domain, missense mutation
Patient	MYO1E	275 C>A (Ala92Glu) and 1684 G>A (Gly562Arg)	Double heterozygous	2 Motor domain mutations

PO1602

Metabolic State Modeling of Kidney Single Nuclei Data Reveals Cell-Specific Signatures at Baseline and in Disease

Eriene-Heidi Sidhom,[1,2] Anna Greka.[1,2] *[1]Harvard Medical School, Boston, MA; [2]Broad Institute, Cambridge, MA.*

Background: The kidney is a metabolically active and cellularly diverse organ. Perturbations in metabolic pathways, such as lipid metabolism, is a well-established sequelae of chronic kidney diseases, such as diabetic nephropathy. Single cell RNA sequencing has allowed for an unprecedented understanding of the kidney's transcriptomic complexity. However, until now, understanding the diverse metabolic states of the kidney has been limited to either expression analysis of single metabolic enzymes or bulk metabolomics experiments. Given the highly interconnected nature of metabolic networks and the kidney's cellular complexity, integrating a systems-level understanding of metabolic perturbations with single cell sequencing has the potential to reveal previously unappreciated metabolic cell states and disease perturbations.

Methods: We have applied the newly developed Flux Balance Analysis (FBA) algorithm for single cell sequencing data, Compass (doi: 10.1101/2020.01.23.912717), to a dataset of 36,560 single nucleus transcriptomes from mouse kidney comprised of three healthy mice and three mice with CoQ-deficiency proteinuric kidney disease.

Results: First, Compass correctly predicted well-established cell-specific kidney transport processes. Next, when comparing proximal tubule clusters, corresponding to S1, S2 and S3 segments, the S3 segment was found to have both high activity of branched chain amino acid (BCAA) metabolism and high activity of fatty acid oxidation (FAO). This previously unknown link between BCAAs and FAO in the kidney is of particular interest, given the known relationship between BCAA metabolism, FAO and metabolic disease. Finally, when comparing transcriptomes between disease and healthy mice, podocyte-specific changes in FAO and steroid metabolism were observed which correlated with podocyte cytoskeletal regulation, a hallmark of podocyte injury.

Conclusions: In summary, the combination of an enhanced resolution of single nucleus transcriptomics with a systems-level analysis of metabolic networks in the kidney have revealed cell-specific metabolic states at baseline and in disease. Future application of this analysis to human data will provide important validation for the generalizability of these findings and further insight into metabolic perturbations in human disease.

Metabolic Dysfunction of Glomerular Endothelial Cells in Alport Syndrome

Hasmik Soloyan,[1] Matthew E. Thornton,[2] Valentina Villani,[1] Patrick Khatchadourian,[1] Paolo Cravedi,[3] Andrea Angeletti,[4] Brendan Grubbs,[2] Roger E. De Filippo,[1,2] Laura Perin,[1,2] Sargis Sedrakyan.[1,2] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Mount Sinai Health System, New York, NY; [4]Orsola University, Bologna, Italy.*

Background: Glomerular endothelial dysfunction plays a key role in the development of chronic kidney disease (CKD), but its impact on Alport syndrome (AS, characterized by mutations in collagen IVα3α4α5) is unknown. We have previously shown that glomerular endothelial cells (GEC) are damaged in AS mice, manifested by enlarged fenestrations and alteration of the glycocalix in the early stage of disease. In the present study we report the early transcriptional changes in AS GEC as an indication of endothelial dysfunction and a contributing factor to Alport progression.

Methods: We generated endothelial *td*Tomato reporter AS mice and isolated GEC at 4 month of age by FACS. We studied *tdT* specificity in GEC by flow cytometry, WB, and by multiphoton and confocal microscopy, and their transcriptome by RNA-seq analysis. Data were analyzed and AS-GEC were compared to WT-GEC in terms of their morphology and differential gene expression. Tissue samples from patients with AS were used to confirm out findings from mice to that of in human by immunohistochemistry.

Results: Comparative transcriptomics showed high enrichment of differentially expressed genes associated with cellular metabolism, with lipid metabolism being among the top five most highly enriched biological processes in GEC. In particular, genes associated with fatty acid uptake, synthesis and oxidation were significantly downregulated. Among the differentially regulated genes, PGC-1α, which acts as a master regulator of cellular metabolism, was the most highly downregulated. Downstream of PGC-1α, genes associated with fatty acid transport, (CD36, FATP-1, FATP-2, Fabp3), fatty acid synthesis (fatty acid synthase), fatty acid oxidation (Acox1, Bdh2, Eci3, Abcd2), and antioxidant enzymatic scavenger proteins (Gpx3, Gpx6, Gsta3, sod2) were also downregulated. We observed similar findings in human biopsy samples from AS patients by histology.

Conclusions: In sum, we report for the first time a lipid metabolic dysfunction in Alport glomerular endothelial cells. Therefore, better understanding of the functional role of the glomerular endothelium in AS could lead to the development of targeted new therapies for the treatment of this and other forms of CKD.

NPHS1 Variants Can Cause Persistent Asymptomatic Proteinuria: Genetic and Clinical Characteristics of Patients with NPHS1 Variants in Japan

Tomohiko Yamamura,[1] Tomoko Horinouchi,[1] Shinya Ishiko,[1] Yuya Aoto,[1] Nana Sakakibara,[1] China Nagano,[1] Takeshi Ninchoji,[1] Yuko Shima,[2] Koichi Nakanishi,[3] Kandai Nozu,[1] Kazumoto Iijima.[1] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Department of Pediatrics, Wakayama Medical University, Wakayama, Japan; [3]Department of Child Health and Welfare (Pediatrics), Graduate School of Medicine, University of the Ryukyus, Nishihara, Japan.*

Background: *NPHS1* gene, which encodes nephrin, is known as a causative gene of congenital nephrotic syndrome (CNS). In addition, recently, it had been recognized that *NPHS1* variants present with childhood steroid resistant nephrotic syndrome (SRNS) or focal segmental glomerular sclerosis (FSGS). However, it is not well known that this gene variants account for more milder phenotypes such as asymptomatic proteinuria.

Methods: 347 unrelated patients with CNS, infantile nephrotic syndrome, FSGS and asymptomatic proteinuria were screened for podocyte related genes including *NPHS1* by using targeted exome sequencing. A retrospective review of clinical information was conducted for the cases with pathogenic variants in *NPHS1*.

Results: We identified 15 *NPHS1* autosomal recessive pathogenic variants in 15 cases including 2 siblings. Regarding clinical manifestation, 6 cases showed CNS, 5 cases showed SRNS and 4 cases showed only asymptomatic mild to moderate proteinuria. The median age developing proteinuria in cases with SRNS and asymptomatic proteinuria was 6 years old. Pathological evaluation for 12 cases revealed that 11 cases showed minor glomerular abnormality and 1 case showed findings resemble membranous nephropathy. Genetic analysis revealed the variants c.2464G>A p.(V822M) and c.2515del were variantal hot spots in the Japanese population and all 6 cases having V822M showed milder phonotypes such as SRNS (n=2) or asymptomatic proteinuria (n=4) and no one showed CNS.

Conclusions: In this study, *NPHS1* variants were detected not only in cases with CNS and SRNS, but also in cases with asymptomatic proteinuria. Shono et al. have previously reported that V822M was a causative variant in cases with familial nephrotic syndrome who showed complete remission and functional analysis revealed that this variant leads to milder phenotype through mechanisms of (1)mild reduction of cell surface expression, (2)motion and trafficking restriction on surface and (3)interfering with assembly of microdomain on surface (Hum Mol Genet. 2009). Our study confirmed this variant leads to very mild phenotypes of SRNS or even the asymptomatic proteinuria and broadened the understanding of clinical manifestations of cases with *NPHS1* variants.

PO1605

Ckd. Qld fabRy Epidemiology (aCQuiRE) Study: Fabry Disease Prevalence Among Patients with CKD

Andrew J. Mallett,[1,2] Phoebe J. Kearey,[2] Anne Cameron (Salisbury),[1,2] Helen G. Healy,[1,2] Charles P. Denaro,[1,2] Mark A. Thomas,[3] Vincent W. Lee,[4] Maria Fuller,[5] Wendy E. Hoy.[2] aCQuiRE Study Team *[1]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [2]The University of Queensland Faculty of Medicine, Herston, QLD, Australia; [3]Royal Perth Hospital, Perth, WA, Australia; [4]Westmead Hospital, Westmead, NSW, Australia; [5]Genetics and Molecular Pathology Laboratory, SA Pathology, Adelaide, SA, Australia.*

Background: Fabry disease (FD) is a rare, genetic disorder resulting in absence or deficiency of alpha-galactosidase A (α-Gal A), leading to accumulation of globotriaosylceramide (GB3) in cells and tissues. Associated mortality and morbidity are due to renal, cardiac, and cerebrovascular manifestations. General population prevalence is ~0.0025%. Dialysis population prevalence is estimated at 0.12-0.36%. Little is known about the prevalence of FD amongst wider chronic kidney disease (CKD) populations. Although FD is X-linked, affected females can have variable disease manifestations. Prevalence amongst women is unclear.

Methods: A prospective cross-sectional study of FD prevalence amongst CKD patients in public Queensland nephrology services was undertaken across 7 sites Oct 2017-Aug 2019. Patients with all stages of CKD including Stage 5D/5T were eligible to participate, irrespective of prior CKD aetiology or diagnosis.3,000 CKD patients were screened using dried blood spot (DBS) testing. Repeat DBS and/or Lyso-GB3 testing was employed where results were inconclusive. FD was confirmed through diagnostic *GLA* genetic sequencing. All biochemical and genetic testing was undertaken in an accredited clinical laboratory.

Results: 6 unrelated cases (0.20%) of FD were identified. 3 were patients with a previously identified diagnosis of FD (100% sensitivity). 3 were patients with a new diagnosis of FD as a result of study participation. Of these 6 identified cases, 5/6 were male and 1/6 was female. This represented 0.3% and 0.08% of all male and female participants respectively. All newly diagnosed cases were male with two being CKD Stage 5T, and one being CKD Stage 5D. One case was in a participant who identified as Indigenous, the first known case in this population. In total, an additional 28 at-risk family members were identified who may benefit from family screening. No readily identifiable pattern of symptoms was identified.

Conclusions: Our results support the potential feasibility and utility of a cascade testing strategy principally using DBS, as a primary screening method for FD in adult patients with CKD. Further, we confirm that a significant proportion of prevalent cases of FD amongst those with CKD remains undiagnosed.

Systems Analyses of Renal Fabry Transcriptome and Response to Enzyme Replacement Therapy (ERT) Identifies a Cross-Validated and Druggable ERT-Resistant Module

Oystein Eikrem,[1,2] Nicolas Delaleu,[3,4] Philipp Strauss,[1] Miroslav Sekulic,[5] Camilla Tøndel,[2,1] Sabine Leh,[2,1] Einar Svarstad,[1] Rannveig Skrunes,[2] Albina Nowak,[6] Elena-Emanuela Rusu,[7,8] Tarig A. Osman,[1] Hans-Peter Marti.[1,2] Renal Research Group Bergen *[1]University of Bergen, Bergen, Norway; [2]Haukeland University Hospital, Bergen, Norway; [3]2C SysBioMed, Contra, Switzerland; [4]Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; [5]UH Cleveland Medical Center, Cleveland, OH; [6]University Hospital of Zurich, Zurich, Switzerland; [7]Fundeni Clinical Institute, Bucharest, Romania; [8]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*.

Background: Fabry nephropathy (FN) is caused by mutations in the α-galactosidase A gene and can be managed with ERT. Via understanding the molecular basis of FN and long-term ERT impact, we aim at a framework for selection of biomarkers/drug-targets.

Methods: Obtained from normal controls and two independent FN-cohorts, mRNA-isolates from archival kidney biopsies (n=41) taken prior and up to 10 years of ERT were subjected to RNAseq and partly IHC. Combining pathway-centered analyses with network-science allowed computation of transcriptional landscapes from glomeruli, proximal/distal tubuli & arteries and integration with existing proteome and drug::target data.

Results: Despite inter-cohort heterogeneity, FN seemed well controlled, esp. via early introduced ERT. Pathways consistently altered in both FN-cohorts pre-ERT vs. controls were limited to glomeruli and arteries and commonly pertained to same biological themes. While glomerular keratinization-related processes were ERT sensitive, a majority of alterations, such as transporter activity and responses to stimuli, remained dysregulated or remerged despite ERT. Inferring an ERT-resistant genetic module on this basis identified targets suitable for drug repurposing **(Figure 1)**.

Conclusions: Transcriptional landscapes of kidney compartments reflected differences in FN-cohorts. ERT can revert FN molecular state to closely match controls. We identified and cross-validated ERT-resistant modules, when leveraged with external data, allowed estimating their suitability as biomarkers and targets for adjunct treatment.

Circular RNA-Based Biomarker Profile of Patients with Fabry Disease

Albina Nowak,[1] George Haddad,[2] Andreas D. Kistler,[3] Stellor Nlandu khodo,[4] Rudolf P. Wuthrich,[2] Johan M. Lorenzen,[2] Malte Kölling.[2] *[1]University Hospital Zurich - Department of Endocrinology, Zurich, Switzerland; [2]University Hospital Zurich - Department of Nephrology, Zurich, Switzerland; [3]Cantonal Hospital Frauenfeld - Department of Medicine, Frauenfeld, Switzerland; [4]University of Zurich - Institute of Physiology, Zurich, Switzerland*.

Background: Fabry disease is a rare X-linked lysosomal storage disease, caused by mutations in the galactosidase α gene. Deficient activity of α-galactosidase A leads to glycosphingolipid accumulations in multiple organs. Circular RNAs represent strong regulators of gene expression. Their circular structure ensures high stability in blood. We hypothesized, that blood-based circular RNA profiles improve phenotypic assignment and therapeutic monitoring of Fabry Disease.

Methods: A genome-wide circular RNA expression analysis was performed in blood of 58 genetically diagnosed patients with Fabry Disease and 14 age- and sex matched healthy controls. Most highly increased circular RNAs were validated by quantitative real-time PCR. A disease control cohort of 109 patients with acute kidney injury was included. Linear regression analyses were performed for validated circular RNAs and clinical patient characteristics.

Results: A distinct circular RNA transcriptome signature identified patients with Fabry Disease. Circular RNAs *hsa_circ_0006853, hsa_circ_0083766* and *hsa_circ_0002397* distinguished patients with Fabry Disease from healthy controls and patients with acute kidney injury. *Hsa_circ_0002397* demonstrated, furthermore, a female-specific circular RNA expression pattern. Circular RNA level were significantly related to galactosidase α gene mutations, early symptoms, phenotypes, disease severities, specific therapies and long-term complications of Fabry Disease.

Conclusions: The discovery of circular RNA-based and Fabry Disease specific biomarker may advance future diagnosis and therapeutic monitoring to diminish long-term complications of Fabry Disease.

Outcome of Primary Hyperoxaluria Type 3: Clinics, Diagnostics, and Follow-Up

Cristina Martin Higueras,[1] Sander F. Garrelfs,[2] Bodo B. Beck,[3] Marcin Zaniew,[4] Przemyslaw Sikora,[5] Bernd Hoppe.[6] *[1]Dept. Ciencias Médicas Básicas, Fac. Medicina, Universidad de la Laguna, Tenerife, Spain; [2]Amsterdam Medical Center, Amsterdam, Netherlands; [3]Institute of Human Genetics, University Hospital Cologne, Cologne, Germany; [4]University of Zielona Gora, Zielona Gora, Poland; [5]Department of Pediatric Nephrology, Medical University of Lublin, Lublin, Poland; [6]German Hyperoxaluria Center, Bonn, Germany*.

Background: Primary hyperoxaluria type 3 (PH3) is said to be the most benign form of PH and the risk of chronic kidney disease (CKD) and even end stage renal disease (ESRD) is reported to be low. We collected clinical, diagnostic and follow up data from our PH3 patients to evaluate the true disease characteristics.

Methods: We retrospectively screened the OxalEurope Registry for data of PH3 patients known to the German Hyperoxaluria Center and analyzed them for clinical and laboratory parameters.

Results: From the 90 PH3 patients enrolled in the OxalEurope Registry, 45 had all laboratory analysis done at the Hyperoxaluria Center (3-45 years of age, 23 males). Genetically confirmed diagnosis revealed 21 different biallelic mutations in *HOGA1*. The main symptom was recurrent urolithiasis, most prominently found in the first 3 years of life (>25% of patients). Nephrocalcinosis was seen in 7 patients. Mean follow up for all patients was 7.76 (0.25-34) years, median age at first symptom was 0.96 (0.17-10) and median age at diagnosis (based on genetics) was 4.57 (0.25-16.86) years. Not all patients experienced clinical remission: 3/6 patients > 20 years of age have ongoing kidney stone development. A high amount of stone removal procedures during the first years of life, but also later in life was observed. Urinary oxalate (Uox) excretion was significantly and continuously elevated over time. There was no significant difference in Uox between PH1 (1.37 mmol/1.73m^2/24h), PH2 (1.4 mmol/1.73m^2/24h) and PH3 (1.13 mmol/1.73m^2/24h) with the exception of a lower Uox in PH1 patients sensitive to B6 medication (0.94 mmol/1.73m^2/24h, $p<0.05$). A decline in kidney function was observed, which was related to a decreased clearance of oxalate. Nine patients had CKD stages 2 or 3. One patient showed a significant decline in eGFR over a period of 15 years (134 to 68.1 ml/min/1.73m^2), which we would relate several lithotripsy procedures (n=16), but also ongoing hyperoxaluria.

Conclusions: Our analysis from a subgroup of European PH3 patients provides additional information on clinical outcome. PH3 patients seem to have the highest kidney stone burden during the first years of life, but they do not stop producing stones. Some PH3 patients progress to CKD and to loss of kidney function over time. Uox is comparable to non B6 responsive PH1 and also to PH2 patients.

PO1609

Patient Journey in Alport Syndrome

Mariah Lopshire,[1] Dhaivat Joshi,[1] Rebecca Gould,[2] Emily Wu,[2] Daniel Day,[2] Ali Hariri.[1] *[1]Sanofi Genzyme, Cambridge, MA; [2]Fulcrum Research Group, Waltham, MA*.

Background: Patients with Alport Syndrome(AS) experience difficulties in diagnosis. Misdiagnosis remains frequent even after detailed clinical and pathological assessment. Qualitative interviews were conducted with patients diagnosed with AS and caregivers, to better understand the patient experience.

Methods: Thirty-nine Interviews (16 male and 23 females >18 years) from the United States, United Kingdom, France, Japan, and Germany were conducted with patients and caregivers. Respondents were recruited by each country's Alport advocacy groups. Responses were summarized and presented quantitatively and qualitatively.

Results: Thirty-nine participants (20 patients, 4 caregivers, 15 respondents being patients themselves and caregivers) completed the interview; and shared their experience as patients, or that of the patients they care for (interviews reflect 32 firsthand patient experiences, and 7 patient experiences from caregivers; mean age=34). Thirty-four patients experienced their first symptoms as children (mean=9 yrs). Seventy-nine percent experienced hematuria before diagnosis. Despite early signs, diagnosis was delayed.

Males recorded hearing loss more than females (2/3 vs. 1/3 respectively) and at earlier ages (adolescent for males vs. females in 20-30s). Males consulted a nephrologist earlier than females (median age: 12 vs. 28) and were diagnosed ~15 years earlier than females (median age=16, female=31). The median delay in diagnosis from first symptom onset was 15 years (males=11, females=26). Two-thirds of patients were diagnosed with genetic testing and/or renal biopsy. The remainder were diagnosed by an array of treatment criteria (16 genetic, 16 biopsies, 9 others). Patients on delayed diagnosis sometimes receive inconclusive or no biopsy results. Based on current standard of care, dialysis or transplant is seen as inevitable future outcome. The same population included patients with dialysis (n=7) and transplant (n=5) experience. Participants perceived transplant as an improvement of renal symptoms compared to dialysis.

Conclusions: Diagnosis can take years. Initial symptoms such as hematuria alone would not raise the suspicion for AS. Delays in diagnosis have significant psychosocial impact on patients and caregivers. While dialysis and transplant are considered inevitable outcomes of the disease, patients and caregivers recognize the unmet need for future disease specific treatments.

PO1610

Multidisciplinary Renal Genetics Clinics: Family Perspectives and Preferences

Ella J. Wilkins,[1,2] Catherine Quinlan,[3] Andrew J. Mallett,[4] Zornitza Stark.[1,2] *[1]Victorian Clinical Genetics Services Ltd, Parkville, VIC, Australia; [2]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [3]The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; [4]Royal Brisbane and Women's Hospital, Herston, QLD, Australia.*

Background: Multidisciplinary renal genetics clinics (RGC) comprising nephrologists, clinical geneticists, and genetic counsellors operate in 15 public hospitals across Australia with the goal of providing family-centred care and definitive molecular diagnoses to patients. However, little is known about family perspectives of multidisciplinary clinics or of undergoing genomic testing in this context.

Methods: Patients having genomic testing were surveyed following initial RGC attendance and after results disclosure. We explored patient experiences of the clinic, perceived impact of the disease on the family and reproductive planning, understanding of the test, and hopes and expectations relating to testing. Surveys included the Decision Regret, and Genetic Counselling Outcome scales.

Results: Of 221 respondents to the baseline survey (RR=72%), most preferred the multidisciplinary clinic model to seeing specialists in separate clinics (n=145, 70%). A better understanding of the condition and implications for relatives were most commonly ranked as the most important advantages of the multidisciplinary clinic (n=27, 47%). Respondents agreed they received enough information during pre-test counselling (n=180, 92%) and had the opportunity to ask questions (n=181, 94%). The majority of respondents understood that the test analyses many genes (n=115, 59%), causative variant(s) may not be identified (n=143, 73%), and results may be of uncertain significance (n=142, 73%). Despite this, 44% of respondents thought the test was likely / highly likely to identify the cause of the condition (n=85).

Conclusions: Understanding patient and family experiences and opinions, and the short- and long-term impacts on families will guide the design and delivery of RGCs and associated genomic testing programs. A full author list is available online at www.kidgen.org.au.

PO1611

Autosomal Recessive Renal Tubular Dysgenesis Caused by a Founder Mutation of Angiotensinogen (AGT)

Min-hua Tseng,[1] Shih-Hua P. Lin.[2] *[1]Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Tri-Service General Hospital, Taipei, Taiwan.*

Background: Autosomal recessive renal tubular dysgenesis (ARRTD) caused by inactivation mutations in *AGT, REN, ACE*, and *AGTR* is a very rare but fatal disorder with incomplete knowledge about pathogenesis and a lack of therapeutic options.

Methods: We report six Taiwanese with ARRTD from six unrelated families diagnosed by renal histology. Clinical features, prevalence of carrier heterozygosity, pathogenesis, and potential rescue therapy were examined.

Results: All patients exhibited antenatal oligohydramnios, postnatal anuria, pulmonary hypoplasia, and profound hypotension refractory to interventions. AGT (Angiotensinogen) protein levels were diminished in the liver along with reduced serum AGT, angiotensin I (Ang I) and II (Ang II) levels. Neonatal demise occurred in all but one. All carried the same homozygous E3_E4 del:2870bp deletion+9bp insertion in *AGT*. The allelic frequency of this heterozygous *AGT* mutation was approximately 1.2% (6/500), suggesting that ARRTD may not be exceedingly rare in Taiwan. This mutation results in skipping of exons encoding the serpin domain of AGT, which is important for renin interaction and the generation of truncated protein (1-295 amino acids). *In silico* modeling revealed a diminished interaction between mutant AGT and renin, and proximity ligation assay demonstrated a significant decrease in the amount of this truncated protein.

Conclusions: This *AGT* mutation leads to the diminished interaction with renin and decreased Ang I and II generation. Hydrocortisone may potentially rescue the cases of ARRTD caused by this truncated AGT.

PO1612

KIDNEYCODE: A Genetic Testing Program for Patients with CKD

Prasad Devarajan,[1] Gerald B. Appel,[2] Geoffrey A. Block,[3] Kenneth V. Lieberman,[5] Stephen McCalley,[6] Jim McKay,[6] Colin J. Meyer,[6] Bradley A. Warady,[4] Alex R. Chang,[7] Kristina A. Robinson.[8] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Columbia University Irving Medical Center, New York, NY; [3]US Renal Care Inc., Plano, TX; [4]University of Missouri Kansas City, Kansas City, MO; [5]Hackensack University Medical Center, Hackensack, NJ; [6]Reata Pharmaceuticals Inc, Irving, TX; [7]Kidney Health Research Institute, Geisinger Medical Center, Danville, PA; [8]Invitae Corporation, San Francisco, CA.*

Background: The International Society of Nephrology recommends the adoption of genetic testing with a goal of providing precision medicine based on individual risk. A recent whole-exome sequencing study showed that genetic inheritance may be responsible for up to 10% of CKD diagnoses. We designed a gene panel to prospectively provide genetic testing in a subset of patients with CKD.

Methods: Reata Pharmaceuticals is partnering with Invitae on KIDNEYCODE, a US program that provides no-charge genetic testing using next generation sequencing (NGS) to enable diagnosis of a subset of rare monogenic causes of CKD: Alport syndrome (AS), autosomal dominant polycystic kidney disease (ADPKD) due to *PKD2* variants, focal segmental glomerulosclerosis (FSGS), and autosomal recessive PKD due to *PKHD1* variants. Invitae's renal disease panel includes 17 genes (*ACTN4, ANLN, CD2AP, COL4A3, COL4A4, COL4A5, CRB2, HNF1A, INF2, LMX1B, MYO1E, NPHS1, NPHS2, PAX2, PKD2, PKHD1*, and *TRPC6)*. Patients at risk for hereditary CKD (eGFR ≤ 90 mL/min/1.73m^2 plus hematuria or a family history of CKD) or known or suspected AS or FSGS are eligible. Family members of those with known or suspected AS or FSGS are also eligible.

Results: Of 455 test results, a genetic variant was reported in 278 patients. Of those, 206 patients had 219 variants in *COL4A3, 4, or 5* genes [112 Pathogenic/ Likely Pathogenic (P/LP), 107 Variants of Uncertain Significance (VUS)], 87 patients had 95 variants in genes associated with FSGS (22 P/LP, 73 VUS), 40 patients had 44 variants in *PKHD1* (5 P/LP, 39 VUS), and 8 patients had variants in *PKD2* (4 P/LP, 4 VUS). Of the 109 patients with P/LP *COL4A* variants, 51 reported a previous diagnosis of Alport syndrome. Other diagnoses in patients with P/LP *COL4A* variants included FSGS, thin basement membrane disease, familial hematuria, hereditary nephritis, IgAN, diabetic CKD, hypertensive CKD, and ADPKD. Hearing loss was reported in 34, and eye disease was reported in 2 of the 109 patients with P/LP *COL4A* variants.

Conclusions: Initial results with the KIDNEYCODE panel demonstrate the utility of NGS. Combining genetic testing with clinical presentation and medical history can improve the accuracy of diagnosis of hereditary CKD.

PO1613

Very Rare Mutation Identified in Female Patient with Multisystemic Fabry Disease in the United States

Sam Kant, Steven Menez, Mohamad A. Hanouneh, Mohamed G. Atta. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Introduction: Fabry disease is an X-linked lysosomal storage disorder characterized primarily by kidney, cardiac and central nervous system dysfunction. Over a 1000 mutations have been identified to be associated with disease. We describe a patient with biopsy confirmed Fabry disease identified to have very rare mutation not listed in genetic databases.

Case Description: A 48 year old female with past medical history of chronic kidney disease G4A3 (previously biopsy proven Fabry disease), dilated cardiomyopathy, atrial fibrillation, previously treated breast cancer, was referred to our clinic by a nephrology group given progressive worsening of kidney function and consideration for migalastat. Patient was diagnosed with Fabry disease at the age of 32 (normal renal function at the time), and subsequently received agalsidase beta for a period of 3 years thereafter. However, therapy was ceased due to insurance issues. In the interim, patient has progressive decline in renal function (creatinine 2.5 mg/dL on referral), worsening proteinuria, along with development of dilated cardiomyopathy and neuropathy. We proceeded with genetic testing to identify mutation of galactoside A (GLA) gene and kidney biopsy(image 1). Genetic testing revealed a novel mutation variant c.820G>C(p.Gly274Arg) deemed to be heterozygous and of unknown significance by the laboratory. Kidney biopsy revealed classic finding of glomerular inclusions (podocyte and mesangium) with diffuse renal parechymal scarring. Patient was eventually prescribed agalsidase beta, given non amenability to migalastat.

Discussion: This case highlights identification of a very rare mutation of the GLA gene that appears to have late onset manifestations. Pursuing genetic testing in patients with Fabry disease has become more important with the introduction of novel therapy migalastat, which may not be compatible with numerous pathogenic mutations.

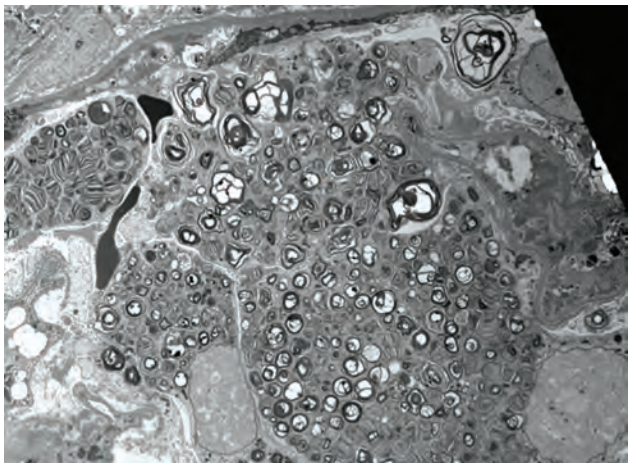

Image 1

PO1614

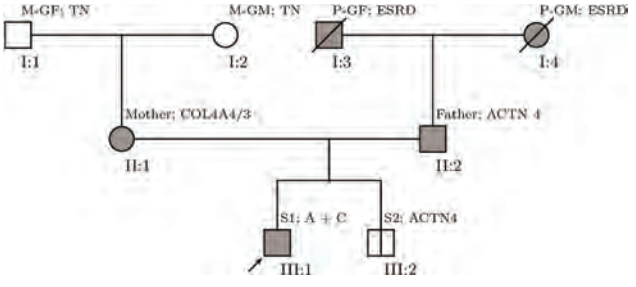
A Unique Case of COL4A3/4 and ACTN4 Mutations Combined

Estibhaliz L. Perez Leal,[2] Joshua T. Kuehne,[3] Pablo E. Pergola.[1] *[1]Renal Associates PA, San Antonio, TX; [2]Universidad Autonoma de Guadalajara, San Antonio, TX; [3]University of the Incarnate Word School of Osteopathic Medicine, San Antonio, TX.*

Introduction: Alport syndrome is due to mutations of the COL4A gene. Males with COL4A5 mutations present with proteinuria and CKD, hearing impairment and anterior lenticonus. Disease in women ranges from mild hematuria and proteinuria to a syndrome similar to that of X-linked males. Patients in families with mutations of the Alpha-actinin-4 gene (ACTN4; autosomal dominant inheritance) present histologically and clinically with focal segmental glomerulosclerosis. We present the first ever-reported case of a patient with both COLA4 and ACTN4 mutations

Case Description: Family pedigree is shown in the figure. Subject II:1 is a female with Alport's syndrome diagnosed by kidney biopsy, CKD3 (in her 50's) had genetic testing showing a COL4A3 mutation. Her husband (II:2, in his 50's), had ESRD presumed to be secondary to diabetes (DKD). Given concerns for possible disease in their 2 sons, genetic testing was performed. The oldest son (III:1; in his 30's) showed the same COL4A3 mutation as II:1 but an additional ACTN4 mutation. He has microalbuminuria (90mg/g) and GFR >90 ml/min. The younger son (III:2; in his 20's) showed the ACTN4 mutation but no COL4A mutation (clinical tests are pending). Given the ACTN4 mutations in the sons, subject II:2 was tested, showing an ACTN4 mutation (suggesting DKD was not the single etiology of his ESRD). Family history showed both paternal grandparents had ESRD, unknown etiology for I:4 (died in her 50's) and presumed to be due to DKD for I:3 (died in his 80's)

Discussion: ACTN4 and COL4A mutations have not been reported in a single patient before. The identification of 2 mutations known to be associated with CKD will allow for early intervention with management of comorbid conditions like hypertension, obesity and diabetes and use of RAAS inhibitors. Distinct disease patterns may emerge associated with specific genetic abnormalties allowing a more personalized treatment. Genetic testing should be considered for all patients presenting with proteinuria as findings may dictate changes in management



PO1615

Kidney Tubuloids Model Cystinosis and Allow Drug Screening

Fjodor Yousef Yengej,[1,2] Amer A. Jamalpoor,[3] Maarten B. Rookmaaker,[1] Carola Ammerlaan,[1,2] Esther A. Zaal,[4] Celia Berkers,[4,5] Rosalinde Masereeuw,[3] Manoe J. Janssen,[3] Hans Clevers,[2] Marianne C. Verhaar.[1] *[1]Department of Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Hubrecht Institute – Royal Netherlands Academy of Arts and Sciences and University Medical Center Utrecht, Utrecht, Netherlands; [3]Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands; [4]Division of Cell Biology, Metabolism and Cancer, Department of Biomolecular Health Sciences, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands; [5]Biomolecular Mass Spectrometry and Proteomics, Bijvoet Center for Biomolecular Research, Utrecht University, Utrecht, Netherlands.*

Background: Cystinosis causes progressive damage to the kidney and other organs. In cystinosis, a *CTNS* mutation causes lysosomal cystine accumulation and other metabolic abnormalities including alfa-ketoglutarate (aKG) accumulation in patient cells and serum. Excess KG associates with aggravated apoptosis, abnormal autophagy and proximal tubule dysfunction, suggesting a key role in cystinosis pathology (*Jamalpoor et al. BioRXiv 2020*). Current treatment with cysteamine reduces cystine and delays, but does not stop, progression of renal insufficiency nor restores tubular dysfunction. Therefore, new therapies are needed. Here, we use patient kidney tubuloids to model cystinosis and to test the efficacy of a novel drug combination.

Methods: Tubuloids were grown from primary renal cells from the urine of two cystinosis patients and compared with two healthy controls. Tubuloid origin and composition were assessed by qPCR and stainings. The effect of cysteamine and/or bicalutamide treatment was studied by a large-scale metabolic screen using LC-MS. Potential toxicity of bicalutamide was tested by measuring ATP levels as proxy for tubuloid viability at increasing doses.

Results: Urine-derived tubuloids consisted of kidney cells (PAX8+p63-) and not urothelium (PAX8-p63+). Tubuloids contained proximal tubule, loop of Henle, distal tubule and collecting duct epithelium. Patient tubuloids showed hallmark cystine accumulation (1.25 ± 0.12 *vs.* 0.16 ± 0.01 nmol/mg protein in controls, $p<0.05$). Although cysteamine normalized cystine levels, it failed to restore aKG accumulation. The novel combination of cysteamine with bicalutamide more potently lowered cystine and reduced aKG in tubuloids (aKG peak area reduction of 16-28% with bicalutamide and 21-37% with the combination, both $p<0.05$). Finally, the used bicalutamide dose did not compromise the viability of cystinotic tubuloids.

Conclusions: Tubuloids model cystinosis *in vitro* and allow personalized drug screening. Moreover, tubuloids show that the combination of cysteamine and bicalutamide is more effective in normalizing the metabolic abnormalities in cystinosis than cysteamine alone. **Acknowledgements** This work is supported by the partners of RegMedXB, powered by Health Holland, Top Sector Life Sciences & Health and the Dutch Kidney Foundation (grant 150KG19).

PO1616

Case Report: Familial FSGS Associated with a Novel Variant of WT1

Alexandra Stewart, John S. Thurlow. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: The underlying causes of Familial FSGS are currently being elucidated by exome sequencing. WT1 has been reported in association with Frasier Syndrome, Denys-Drash syndrome and isolated nephrotic syndrome. WT1 variants have emerged as a common cause of autosomal dominant FSGS.

Case Description: We report a case of a 22 year old male who presented at age 17 with nephrotic range proteinuria progressing to ESRD over 4.5 years. His renal biopsy at that time revealed FSGS andExome sequencing (Next Generation Sequencing) demonstrated a WT1 variant of uncertain significance. Family history was significant for the following: mother with microalbuminuria (229mg/24hr on spot protein) and hypertension (onset 2 years prior to proteinuria); maternal uncle with congenital unilateral renal agenesis and later End Stage Kidney Disease requiring transplant at age 29 years; and maternal grandfather who died in his 60s on dialysis for unknown reasons. Genetic analysis in the patient and mother revealed the same heterozygous variant in WT1 (c.1078G>T, p.Gly360Cys).

Discussion: WT1-related renal disease is associated with autosomal dominant inheritance. We strongly suspect the WT1 variant described was pathogenic, as evidenced by a family history of both FSGS and genitourinary tract malformations. We review the association of WT1 with nephrin and postulate a potential interaction with XY karyotype, similar to other WT-1 associated disease. Disclosure: The views expressed are those of the authors and do not reflect the Department of Army or U.S. Government.

PO1617

Positive Identification of Genetic Causes of FSGS Increases with Proper Patient Selection

Jing Miao,[3] Ladan Zand,[3] Filippo Vairo,[2] Marie C. Hogan,[3] Stephen B. Erickson,[3] Carri Prochnow,[4] Mireille El Ters,[3] Andrew J. Bentall,[3] Aleksandra Kukla,[3] Eddie L. Greene,[3] Loren P. Herrera hernandez,[1] Sanjeev Sethi,[1] Fernando C. Fervenza.[3] *[1]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [2]Department of Clinical Genomics and Center for Individualized Medicine, Mayo Clinic, Rochester, MN; [3]Department of Internal Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [4]Center for Individualized Medicine, Mayo Clinic, Rochester, MN.*

Background: FSGS is a histological lesion with diverse pathogenesis, commonly divided into primary, secondary (maladaptive, virus or drugs), and genetic forms. Differentiation of these forms is challenging but important for management and prognosis. We aimed to identify clinicopathologic factors that could be predictive of finding a genetic diagnosis in individuals with unknown forms of FSGS.

Methods: Cohort study included 51 FSGS patients with either a "secondary" form of FSGS without an identifiable cause or with presumed "primary" FSGS who failed to respond to immunosuppressive therapy (IS). Seven patients with primary FSGS in remission following IS served as negative control. Patients were classified as having pathogenic/likely pathogenic variants (Group 1a), relevant variants of uncertain significance (relevant VUS; Group 1b), and no relevant variants (Group 2). Clinicopathologic characteristics are presented in Table 1.

Results: A pathogenic/likely pathogenic genetic variant or relevant VUS was found in 41.2% (n=21/51) and in 11.8% (n=6/51) of the patients, respectively. 55.6% were in *COL4A* (*A3/A4/A5/A1*), 33.3% in podocyte genes (*INF2/NPHS2/TRPC6/NPHS1*), and 11.1% in other genes (*DLC1/SMARCAL1/UMOD*). Family history of kidney disease was present in 75% (n=15/20) of the patients in Group 1a, 16.7% (n=1/6) in Group 1b, 20.8% (n=5/24) in Group 2 and 0% (n=0/7) in the negative control. There was a negative correlation between proteinuria and the probability of finding a genetic variant. Severe foot process effacement on EM and nephrotic syndrome were significantly more common in the negative control group compared to Group 1a.

Conclusions: Over 50% of adult patients with FSGS who could not be categorized into primary or known secondary forms were found to have a genetic diagnosis. Positive family history and absence of nephrotic syndrome increased the likelihood of identifying a pathogenic/likely pathogenic variant. Genetic testing is therefore highly recommended in such population.

Table 1 Clinicopathologic characteristics of the patients

	Negative control (NC; n=7)	Group 1a (n=21)	Group 1b (n=6)	Group 2 (n=24)	*P value (NC vs. Group 1a)*

PO1618

A Rare Case of Nephrotic Syndrome Associated with Dent Disease

Shinichi Makino, Maulana A. Empitu, Masayoshi Ishii, Masashi Aizawa, Katsuhiko Asanuma. *Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan.*

Introduction: Dent's disease is a rare X-linked condition caused by a mutation in *CLCN5* and *OCRL* gene, which impair the megalin-cubilin receptor-mediated endocytosis in kidney's proximal tubules. Thus, it may manifest as nephrotic-range low-molecular-weight proteinuria (LMWP). On the other hand, glomerular proteinuria, hypoalbuminemia and edema formation are the key features of nephrotic syndrome (NS) that rarely found in Dent's disease.

Case Description: A man in his 30s with Dent's disease presented with leg edema for five days. The laboratory results revealed hypoalbuminemia and a decreased of urine β2-microglobulin/urine protein ratio (Uβ2/UP), indicating that the primary origin of proteinuria shifted from LMWP to glomerular proteins. The kidney biopsy revealed no glomerular abnormality, and calcium deposition in the renal medulla. Electron microscopy indicated extensive foot-process effacement of the glomerular podocytes. After a combination of treatment with prednisolone and cyclosporine, the nephrotic syndrome was remitted.

Discussion: This report describes a first case of adult-onset NS in Dent's disease. Given the atypical clinical presentation and the shift of LMWP to glomerular proteinuria in this patient, glomerulopathy and the Dent's disease existed separately in this patient. In such a case of combind LMWP and glomerular proteinuria, the Uβ2/UP can be used to monitor the relapse of NS. We should perform renal biopsy in patients with sudden onset of edema and hypoalbuminemia even those who have a congenital proteinuria.

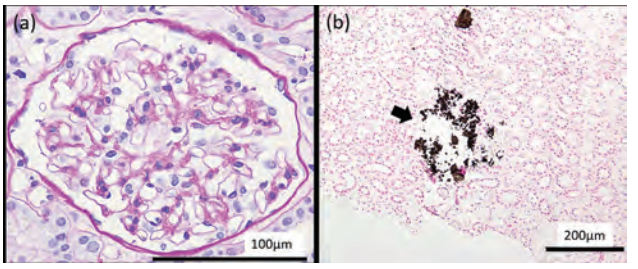

Figure1(Left)A glomerulus in PAS staining showed there were no cellular crescents and no proliferation of mesangial cells. (Right) Von Kossa staining showed renal medulla with calcifications (arrows) was observed in the medullary interstitium.

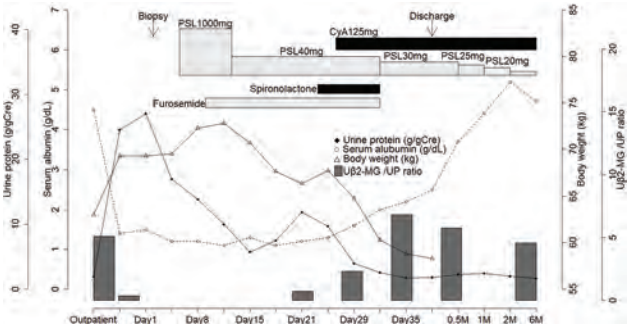

Figure 2 The patient treatment course

PO1619

Mitochondriopathy Manifesting as Inherited Tubulointerstitial Nephropathy Without Symptomatic Other Organ Involvement

Alessia Buglioni,[1] Linda Hasadsri,[1] Samih H. Nasr,[1] Marie C. Hogan,[1] Ann M. Moyer,[1] Mariam P. Alexander,[1] Khurrum Siddique.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]DHR Health, McAllen, TX.*

Introduction: Mitochondrial dysfunction has been previously described in cases of human chronic kidney disease (CKD), and subjects affected by primary systemic mitochondrial disease develop CKD. Importantly, examples of mitochondrially inherited tubulointerstitial kidney disease in subjects with no other symptomatic organ involvement have been recently reported, suggesting the possibility of a single-organ mitochondrial disease.

Case Description: A 12-year-old boy presented with short stature, low body weight, increased serum creatinine (1.9 mg/dL) and increased blood urea nitrogen (30 mg/dL). Blood analysis showed anemia, vitamin D deficiency, hyperparathyroidism and negative antinuclear antibodies (ANA) and antineutrophil cytoplasmic antibodies (ANCA). Ultrasound showed small kidneys (< 5th percentile). A kidney biopsy showed mild, non-specific, chronic tubulointerstitial nephropathy on light microscopy. Immunofluorescence was negative. Electron microscopy showed markedly enlarged and dysmorphic mitochondria. Given this striking histopathologic finding, genetic testing was performed. Next generation sequencing of mitochondrial DNA from the tissue biopsy showed the presence of a homoplasmic, single, missense mutation in position 616 (m.616T>C) of the mitochondrially encoded transfer RNA phenylalanine (*MTTF*) gene. Analysis of blood derived mtDNA from mother and maternal uncle, who were on dialysis since their 30s, confirmed the same homoplasmic mitochondrial mutation, supporting our hypothesis. The renal biopsy findings, genetic findings, and pattern of inheritance were strongly suggestive of a diagnosis of mitochondrially inherited tubulointerstitial kidney disease. Notably, no additional symptomatic organ involvement was present in these subjects.

Discussion: Our case supports and reinforces the possibility of a single organ-limited mitochondrial disease, regardless of the systemic mitochondrial DNA mutation status, potentially radically changing management and prognosis of these patients. Careful analysis of mitochondria by electron microscopy should be performed in patients with tubulointerstitial nephropathy and family history of kidney failure.

PO1620

Discovery of CHK-336: A First-in-Class, Liver-Targeted, Small Molecule Inhibitor of Lactate Dehydrogenase for the Treatment of Primary Hyperoxaluria

Jennifer H. Cox,[1] Marc-Olivier Boily,[1] Alex Caron,[1] Amandine Chefson,[1] Oliver Chong,[1] Jim Ding,[1] Valerie Dumais,[1] Samuel Gaudreault,[1] Robert Gomez,[1] James Guthrie,[1] Ross P. Holmes,[2] Andrew J. King,[1] John Knight,[2] Jeff Lester,[1] W. T. Lowther,[3] Renata Oballa,[1] Michael D. Percival,[1] Tao Sheng,[1] Jayakumar Surendradoss,[1] Joyce Wu,[1] David A. Powell.[1] *[1]Chinook Therapeutics Inc., Vancouver, BC, Canada; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Wake Forest University, Winston-Salem, NC.*

Background: Primary hyperoxalurias (PH) 1-3 are autosomal recessive disorders involving excess hepatic oxalate production resulting in frequent kidney stones, progressive CKD and ESRD. Few therapeutic options currently exist for these patients. Lactate dehydrogenase (LDH) catalyzes the final and only committed step in hepatic oxalate synthesis and represents a potential therapeutic target for all forms of PH. Herein we describe the profile of a potent and selective LDH inhibitor.

Methods: CHK-336 was evaluated in LDH activity assays and in an AGXT knockout PH1 mouse model. Additional characterization of drug properties was performed.

Results: CHK-336 demonstrates potent and selective inhibition of LDH in enzyme assays (IC_{50} = 0.4 nM) and hepatocyte assays (IC_{50} = 80-142 nM). To minimize the potential for extra-hepatic LDH inhibition, a liver-targeted tissue distribution profile was engineered into the molecule. CHK-336 demonstrates exceptional liver-targeting across species mediated by OATP-uptake into hepatocytes and tight binding to LDH resulting in a long liver half-life that supports once-daily oral dosing. In a PH1 mouse model, CHK-336 produced significant and dose-dependent reductions in urinary oxalate to levels observed in wild-type mice. Wide safety margins were established in rodent toxicity studies to support continued development of CHK-336.

Conclusions: By potently blocking LDH, the terminal step in hepatic oxalate synthesis, along with engineering of liver-targeted tissue distribution, CHK-336 is a promising oral small molecule development candidate with the potential to treat patients with hyperoxaluria.

CHK-336 reduces UOx in AGXT-KO mice

PO1621

Disease Manifestations, Treatment, and Healthcare Resource Use (HRU) in Primary Hyperoxaluria Type 1 (PH1): An International Online Chart Review Study

Xiangling Wang,[4] David S. Danese,[1] Thomas A. Brown,[1] Jessica Baldwin,[1] Gautam Sajeev,[2] Erin Cook,[2] Yao Wang,[2] Chunyi Xu,[2] Hongbo Yang,[2] Michael L. Moritz.[3] *[1]Alnylam Pharmaceuticals Inc, Cambridge, MA; [2]Analysis Group Inc, Los Angeles, CA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Cleveland Clinic Department of Nephrology and Hypertension, Cleveland, OH.*

Background: Few multinational studies have examined the clinical burden of PH1. This online retrospective chart review evaluated disease manifestations, treatments, and HRU in a large international sample of PH1 patients.

Methods: Nephrologists in the US, Canada, UK, France, Germany, and Italy provided data from PH1 patients in their care via an online platform. Eligible patients had PH1 confirmed by genetic testing or liver biopsy and ≥2 office visits from 2016-2019. Data on disease manifestations, treatment and HRU were collected.

Results: Overall, 86 patients (56% from North America; 63% female) from 41 unique providers were analyzed. Mean age at diagnosis was 21.2±11.6 yrs, with a mean of 6.7±9 yrs to diagnosis from first symptoms. Mean age at index (first office visit in past 3 yrs) was 25.3 yrs; 71% had stage ≥3 CKD at index (median eGFR: 44mL/min/1.73m^2). Mean follow-up was 1.6±1 yrs. The most common PH1 manifestations during follow-up were uro-/nephrolithiasis (57.1%) and urinary tract infection (UTI; 56.0%). Additionally, 29.8% of patients had ≥1 acute renal decline episode, of which 53% resulted in lasting renal function loss. In total, 11.6% of patients had ESKD at or before index, and 8.1% developed ESKD post-index; 2.3% had ESKD with timing not noted. Dialysis and transplant (liver and/or kidney) at any time were reported in 22.2% and 17.1%, respectively. In terms of HRU during follow-up, 51% of patients required ≥1 stone removal procedure (lithotripsy: 38%; ureteroscopy: 28%; percutaneous nephrolithotomy: 9%). Hospitalization and ER visits were required by 85.9% and 84.6% of patients, respectively, where data was reported (n=73).

Conclusions: There is significant delay between PH1 presentation and diagnosis. Patients with PH1 suffer progressive renal function decline, with many progressing to ESKD. During follow-up, almost all patients required ER visits and hospitalization, and most had stone episodes and UTIs and required stone removal procedures. These findings highlight an ever-present risk of acute events that contribute to ongoing morbidity, HRU and impaired quality of life, underscoring the need for early intervention with effective PH1 treatment.

PO1622

Recurrent SLC12A3 Mutations in Taiwanese Families with Gitelman Syndrome: A Rapid Detection for the Higher Prevalence

Shih-Hua P. Lin,[1] Sung-Sen Yang,[1] Chih-Chien Sung,[1] Min-hua Tseng.[2] *[1]Division of Nephrology, Tri-Service General Hospital, Taipei, Taiwan; [2]Division of Pediatrics, Tao-yang, Taiwan.*

Background: Recurrent mutations in *SLC12A3* gene responsible for autosomal recessive Gitelman syndrome (GS) are reported to be common with uncertain prevalence. Rapid detection of the recurrent hotspots may help early diagnosis of GS but remain challenging. We aim to investigate the prevalence of recurrent *SLC12A3* mutations in a large Taiwan cohort of GS families and develop a simple, novel, and rapid method to detect recurrent *SLC12A3* hotspots.

Methods: One hundred and thirty independent families with genetically-confirmed GS referred from different regions of Taiwan were consecutively enrolled to define recurrent *SLC12A3* hotspots and determine their prevalence. Using Taqman MGB probe-based real time primer chain reaction (RT-PCR), hotspots-based mutational detection plate was designed and optimized to recognize all hotspots. We validated this mutation detection plate and also tested the feasibility in 12 newly-diagnosed GS patients.

Results: A total of 57 mutations in *SLC12A3* gene were identified from our cohort and 22 different mutations including two deep intronic mutations were found in at least two unrelated families, comprising 85.7% of all allelic mutations including biallelic triple mutations. These 22 hotspots-based detetion plate was fully validated with excellent sensitivity and specificity in GS patients carrying biallelic *SLC12A3* mutations and healthy subjects. In the clinical validation, recurrent mutations were recognized in 87.5% of allelic mutations of 12 newly-diagnosed GS patients within 4 hours and all confirmed by direct sequencing.

Conclusions: Recurrent *SLC12A3* mutations are very common in Taiwanese GS patients. This novel hotspots-based detection plate may be time, cost, and labor saving to rapidly identify the recurrent hotspots and provide an early molecular diagnosis of GS in patients with chronic hypokalemia.

PO1623

AVR-RD-01, an Investigational Lentiviral Gene Therapy for Fabry Disease, Reduces Gb3 Substrate in Endothelial Cells of Renal Peritubular Capillaries

Mark A. Thomas,[1] Mirjam Trame,[2] Chris Mason,[2] Birgitte Volck.[2] *[1]Royal Perth Hospital, Perth, WA, Australia; [2]AVROBIO, Cambridge, MA.*

Background: Lysosomal disorders are attractive candidates for *ex vivo* gene therapy based on the potential to transform a patient's own cells into a drug product to deliver sustained functional protein/enzyme after a single treatment. Fabry disease (FD) is caused by mutations in the *GLA* gene that result in functional deficiency of the lysosomal enzyme, alpha-galactosidase A (AGA), which leads to pathological accumulation of substrates and metabolites, including globotriaosylceramide (Gb3) and globotriaosylsphingosine (lyso-Gb3). Significant morbidity and early mortality result from damage to kidneys, heart, and brain.

Methods: AVR-RD-01 is an investigational *ex vivo* gene therapy that involves transplantation of autologous stem cells genetically modified with a lentiviral vector which inserts into the human genome a complementary deoxyribonucleic acid (cDNA) sequence that encodes for functional human AGA.

Results: In a Phase 1 trial of AVR-RD-01, 5 patients, previously on enzyme replacement therapy (ERT), after gene therapy demonstrated increases in plasma and leukocyte AGA activity and decreases in substrate (Gb3) and metabolite (lyso-Gb3) in plasma, now sustained up to 32 months. A Phase 2 clinical trial in 8-12 treatment-naïve males (16-50 years) with classic FD investigates the safety, tolerability, and efficacy of AVR-RD-01, including its effect on substrate accumulation in the kidney after 48 weeks. Kidney biopsy results for the first patient in the Phase 2 clinical trial demonstrated reduction in renal peritubular capillary (PTC) Gb3 inclusions, quantitatively assessed by the BLISS methodology. At 48 weeks, Gb3 inclusions were reduced from an average of 3.55 to 0.47 per PTC corresponding to an 87% reduction versus baseline (BL). Leukocyte and plasma AGA activity increased, associated with declines in plasma and urine Gb3 and lyso-Gb3, including an 87% reduction in plasma lyso-Gb3 at 48 weeks versus BL. Adverse events were as expected with the particular conditioning regimens

(i.e. mild/moderate and quickly resolving), underlying FD and pre-existing conditions, with no serious adverse events related to AVR-RD-01 drug product. Low-titer anti-AGA antibodies were transiently detected at week 24.

Conclusions: The latest results from this ongoing open label Phase 2 study will be shared.

Funding: Commercial Support - AVROBIO

PO1624

ILLUMINATE-B, a Phase 3 Open-Label Study to Evaluate Lumasiran, an RNAi Therapeutic, in Young Children with Primary Hyperoxaluria Type 1 (PH1)

Mini Michael,[5] Georges Deschênes,[1] Pierre Cochat,[2] Daniella Magen,[3] William van't Hoff,[4] David J. Sas,[6] Gesa Schalk,[7] Hadas Shasha-Lavsky,[8] Wesley N. Hayes,[4] Kyounghwa Bae,[9] Ali Seddighzadeh,[9] Pushkal Garg,[9] Akshay Vaishnaw,[9] Tracy McGregor,[9] Kenji Fujita,[9] Yaacov Frishberg.[10] *[1]Hospital Robert Debré, Paris, France; [2]Centre for Rare Renal Diseases & Inserm Pediatric Clinical Investigation Centre – Hospices Civils de Lyon and Université de Lyon, Lyon, France; [3]Rambam Health Care Campus, Haifa, Israel; [4]Great Ormond Street Hospital for Children, Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; [5]Department of Pediatrics, Texas Children's Hospital, and Baylor College of Medicine, Houston, TX; [6]Mayo Clinic, Rochester, MN; [7]University of Bonn, Rheinische Friedrich-Wilhelms-Universitat Bonn, Bonn, Nordrhein-Westfalen, Bonn, Germany; [8]Galilee Medical Center, Nahariya, Israel, Nahariya, Israel; [9]Alnylam Pharmaceuticals Inc, Cambridge, MA; [10]Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: PH1 is a rare genetic disorder that often presents in young children. It is caused by hepatic oxalate overproduction leading to recurrent kidney stones, nephrocalcinosis, progressive kidney failure, and multiorgan damage from systemic oxalosis. There are no approved pharmacologic therapies for PH1. Lumasiran is a subcutaneously-administered investigational RNAi therapeutic that reduces hepatic oxalate production by targeting glycolate oxidase. In ILLUMINATE-A, a randomized, placebo-controlled Phase 3 study in patients with PH1 ≥6 years, lumasiran demonstrated an acceptable safety profile. The study met its primary efficacy endpoint [percent change from baseline, relative to placebo, in 24hr urinary oxalate (UOx) excretion averaged across months 3 to 6, P<0.001] and all tested secondary endpoints. Here, we present results from ILLUMINATE-B, an ongoing open-label Phase 3 study to evaluate efficacy and safety of lumasiran in young children with PH1.

Methods: Key inclusion criteria: <6 years, confirmed PH1 diagnosis, eGFR >45 mL/min/1.73m^2 if ≥12 months or normal serum creatinine for age if <12 months. Patients received lumasiran 3×monthly, then monthly or quarterly. Primary endpoint: percent change in UOx excretion from baseline to month 6.

Results: Eighteen patients enrolled, including 4 patients <2 years; median age at first dose 4.3 years (range: 0.3-6). The baseline mean spot urinary oxalate:creatinine (UOx:Cr) was 0.63 mmol/mmol (range: 0.17-1.71), equivalent to 5.8×ULN for age. As of March 2020, there were no lumasiran-related serious adverse events; no deaths, severe adverse events, or treatment discontinuations. The most common adverse events related to lumasiran were mild, transient injection site reactions in 3/18 patients. Results from the complete primary analysis period (primary and secondary endpoints) will be presented.

Conclusions: Lumasiran demonstrated an acceptable safety profile in this interim analysis of ILLUMINATE-B. These results are consistent with those observed in ILLUMINATE-A in older children and adults and support the continued development of lumasiran for PH1.

PO1625

PHYOX3: A Long-Term, Open-Label Extension Trial of Nedosiran in Patients with Primary Hyperoxaluria Type 1, 2, or 3

Martin Coenen,[1] Gesa Schalk,[1] Pierre Cochat,[2] Graham Lipkin,[3] John C. Lieske,[4] Jaap Groothoff,[5] Michelle A. Baum,[6] Bernd Hoppe,[7] Ralf Rosskamp.[7] *[1]University Hospital Bonn, Bonn, Germany; [2]Hôpital Femme Mere Enfant HCL, Bron, France; [3]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Amsterdam UMC (Academic Medical Center), Amsterdam, Netherlands; [6]Boston Children's Hospital, Boston, MA; [7]Dicerna Pharmaceuticals, Inc., Lexington, MA.*

Background: Primary hyperoxaluria (PH) is an ultra-rare, autosomal recessive genetic disorder characterized by overproduction of oxalate in the liver. Clinical manifestations can include nephrocalcinosis, recurrent kidney stones, progressive renal impairment, and systemic oxalosis. Nedosiran (formerly DCR-PHXC) is an investigational RNAi therapy administered monthly by subcutaneous injection. It is designed to reduce hepatic LDHA protein thereby inhibiting the final step responsible for overproduction of oxalate in PH1, PH2, and PH3.

Methods: This is an interim analysis of multidose data from the ongoing open-label, rollover extension PHYOX3 trial (NCT04042402) to evaluate long-term safety and efficacy of nedosiran in patients with genetically confirmed PH1, PH2 or PH3. Patients aged 6 years or more who have completed a previous nedosiran trial and their siblings with genetically confirmed PH are eligible.

Results: As of May 2020, 16 participants were enrolled (13 PH1, 3 PH2) in this study. Total exposure (based on 15 participants) to monthly dosing of nedosiran has exceeded 3 years based on the cumulative duration of patient participation in the trial. Seven participants have had exposure to at least 3 monthly doses of nedosiran. Treatment-emergent adverse events (AEs) were observed in 11 participants. Seven participants experienced 33 AEs considered related to study drug: administration-site events (18), blood chemistry findings (6), pain (2), dysuria (1), nasal congestion (1), edema (1), and erectile dysfunction (1). Three AEs were uncoded at this time. None of the participants experienced injection-site reactions (defined as occurring 4 hr or more after injection). All drug-related AEs were mild. There were no drug-related serious AEs. Six out of the 7 participants who have had exposure to at least 3 monthly doses of nedosiran showed normalization or near-normalization of urinary oxalate excretion (defined as < 0.46 mmol/24 hr/1.73 m^2 and ≥ 0.46-0.60 mmol/24 hr/1.73 m^2, respectively) on at least 2 visits after the first dose.

Conclusions: Nedosiran has shown an acceptable safety profile in the interim analysis. This and the sustained reduction of urinary oxalate excretion are encouraging signs of potential long-term safety and clinical benefit of a multidose regimen of nedosiran.

A Case of De Novo X-Linked Alport Syndrome Treated by Kidney Transplantation from the Patient's Healthy Mother

Atsuya Hane, Mika Fujimoto, Ryosuke Saiki, Keiko Oda, Yosuke Hirabayashi, Ayumi Haruki, Tomohiro Murata, Kan Katayama. *Mie Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Tsu, Japan.*

Introduction: X-linked Alport syndrome is a hereditary nephritis that leads to end-stage kidney failure by 40 years of age in most affected males. Although kidney transplantation is well tolerated in X-linked Alport syndrome, donors should be carefully selected since the proband's mother is usually the gene carrier.

Case Description: The patient was a 38-year-old man. Microhematuria had been pointed out during his early childhood and had been diagnosed with Alport syndrome based on the results of a kidney biopsy at five years of age. He developed bilateral sensory deafness at 20 years of age and started hemodialysis due to end-stage kidney failure at 28 years of age. Although an X-linked mode of inheritance was suspected, none of the patient's relatives, including his mother, had kidney disease. Since his mother had normal urinalysis results, living kidney transplantation from his mother was performed when he was 34 years of age. A genetic diagnosis at a later date revealed a splicing variant at c.3107-2A>G in COL4A5 of the patient. However, there was no apparent genetic mutation in COL4A5 of his mother, suggesting that the patient had a *de novo*mutation. The kidney function of both the patient and his mother was stable at 4 years after kidney transplantation.

Discussion: For transplantation in cases of hereditary nephritis, it is preferable to avoid transplantation from an affected individual or the gene carrier. The kidney prognosis of female X-linked gene carriers is reported to be worse than expected. Although there was no genetic mutation in the donor in the present family case, if an X-linked form is suspected, a genetic diagnosis of the donor candidate should be performed before kidney transplantation is considered.

PO1627

Clinical and Economic Impact of Primary Hyperoxaluria: A Retrospective Claims Analysis

Bernd Hoppe,[2] Abigail Silber,[1] Gavin Miyasato,[1] Tom Koenig,[2] Jeffrey R. Skaar,[1] Craig B. Langman.[3] *[1]Trinity Life Sciences, Waltham, MA; [2]Dicerna Pharmaceuticals Inc, Cambridge, MA; [3]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Primary hyperoxalurias (PH; types 1, 2, and 3) are rare genetic disorders resulting in the overproduction of oxalate in the liver and that manifest in renal complications. This study sought to quantify the healthcare resource utilization (HCRU), costs, and clinical characteristics of PH patients.

Methods: This retrospective study analyzed claims from IQVIA PharMetrics® Plus (1/2014-12/2019). PH cohort inclusion was an ICD-10 code for PH (E72.53) and no evidence of secondary hyperoxaluria (SH). A random 5% sample from the same database of patients without PH or SH served as a control cohort (non-PH). Clinical outcomes, including kidney stones, costs, and HCRU were compared between the cohorts for a 12-month period. The Charlson Comorbidity Index (CCI) was used to characterize comorbidities.

Results: The annualized median and mean costs per patient for the PH cohort (n=325; median $10,385; mean $21,541) were significantly higher (p<0.001) than the non-PH cohort (n=2,579,352; median $1,079; mean $5,041). Costs were significantly higher for PH patients across age groups (see table) and care settings, including inpatient/outpatient settings (p<0.001). The majority of PH patient cost (62%) was associated with outpatient visits. The PH cohort saw significantly higher use of specialists compared to non-PH patients (p<0.001), including nephrologists (19% vs 1%) and urologists (66% vs 3%). Over one year, 80% of the PH cohort had at least one kidney stone. The CCI scores for the PH and non-PH cohorts were 0.79 and 0.22, respectively.

Conclusions: The median cost of care for the PH cohort was 10 times higher than the non-PH cohort over all age groups annually, and the PH cohort showed substantially greater HCRU compared to the non-PH cohort. Additional research is required to better understand these costs in an effort to enable more efficient healthcare utilization and improve care delivery to these at-risk patients.

PO1628

Identification of Genetic Drivers of Age-Related Renal Histopathology

Susan M. Sheehan, Ron Korstanje. *The Jackson Laboratory, Bar Harbor, ME.*

Background: Studies to understand age-related changes in the human kidney have been performed by measuring kidney function and damage markers in the urine. These studies have provided valuable information, including clear genetic components underlying kidney disease. However, due to the highly invasive nature of kidney biopsies, it is not possible to identify early causal changes in humans by histological analyses that are hypothesized to precede changes in function and renal damage. However, mouse models provide access to kidneys at specific time points enabling us to conduct histological analyses across lifespan. We established the Aged Mouse Kidney Resource, which consists of kidneys from 600 genetically diverse mice (males and females) at three ages (6, 12, and 18 months). Scanned PAS slides for all mice are publically available at korstanjelab.jax.org, as well as gene expression, protein expression, and DNA methylation data for a subset of kidneys

Methods: Renal histology has been mostly a qualitative or semi-quantitative discipline. We leverage new approaches in image analysis and machine learning and demonstrate the feasibility of quantification on entire sections of mouse kidneys (pathomics) from a large number of animals. We have developed a pipeline that uses machine learning on scanned slides, which allows us to automatically segment glomeruli and quantify mesangial matrix expansion (MME) in a high-throughput fashion.

Results: Applying our pipeline on the 12-month kidneys from our Resource shows an estimated heritability (h^2) of 0.76 for MME and genetic analysis identifies three significant loci with *Abca13* and *Cfl2* as strong candidate genes for two of these loci. On the other hand, we find that the heritability drops to 0.61 and no significant loci were found in the 18-month old kidneys. We hypothesize that this is caused by the increasing effect of environmental variation with age and death before 18 months of animals with fast age-related renal functional decline that reduces the genetic variability and mapping power in the population.

Conclusions: Our results demonstrate the importance of genetic factors contributing to histological phenotypes and the power of combining pathomics and genetics to identify genes involved in age-related histological changes.

Epigenome-wide Association Study of Kidney Function

Nora Franceschini,[1] Charles E. Breeze,[3] Josyf Mychaleckyj.[2] COGENT-KIDNEY Consortium *[1]University of North Carolina System, Chapel Hill, NC; [2]University of Virginia, Charlottesville, VA; [3]UCL Cancer Institute, University College London, London, United Kingdom.*

Background: DNA methylation regulates gene regulation and may influence estimated glomerular filtration rate (eGFR).

Methods: The study included over 13,000 participants from multi-ethnic studies for discovery and replication. We tested the associations between whole blood DNA methylation and eGFR using normalized beta values from Illumina 450K or EPIC arrays. Analyses were performed in study- and race-stratified samples using linear mixed models and adjusting for age, sex, and study-specific and technical variables. Study-specific results were meta-analyzed, and findings were assessed using integrative epigenomics methods and pathway analyses.

Results: The study identified 93 DMPs genome-wide significantly associated with eGFR, of which 35 replicated in independent samples. We also replicated 6 previously published DMPs including the *ZNF20-ZNF788* locus. Identified DMPs showed significant overlap enrichment with DNase I hypersensitive sites in kidney tissue, sites associated with the expression of genes in *cis*, and transcription factor motifs, in addition to pathways associated with kidney development. Among main findings, we identified a DMP at the *KANK1* gene, which has been previously associated with podocyte dysfunction and nephrotic syndrome.

Conclusions: We identified DMPs associated with eGFR and uncovered associations with genomic regions related to regulatory function in kidney tissue. These findings shed light on epigenetic mechanisms associated with kidney function, bridging the gap between eGFR-associated DNA methylation and tissue-specific chromatin context.

Generation of Monogenic Candidate Genes of Human Nephrotic Syndrome via Three Independent Approaches

Ana C. Onuchic-Whitford,[1,2] Verena Klambt,[1] Youying Mao,[1] Ronen Schneider,[1] Florian Buerger,[1] Hanan E. Shamseldin,[3] Konstantin Deutsch,[1] Thomas M. Kitzler,[1] Makiko Nakayama,[1] Amar J. Majmundar,[1] Nina Mann,[1] Heidi L. Rehm,[4,5] Shrikant M. Mane,[6] Fowzan S. Alkuraya,[3,7] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [4]Broad Institute, Cambridge, MA; [5]Massachusetts General Hospital, Boston, MA; [6]Yale University School of Medicine, New Haven, CT; [7]Alfaisal University College of Medicine, Riyadh, Saudi Arabia.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is a frequent cause of chronic kidney disease in childhood. The finding of >60 single-gene causes of SRNS, mainly through whole-exome sequencing (WES), has contributed to the understanding of its disease mechanisms. Whereas in ~12-30% of cases with onset <25yo, a monogenic cause is detected, most cases remain molecularly unsolved. This indicates that additional monogenic causes of SRNS may exist.

Methods: We generated 3 independent lists of candidate genes: **1)** 63 published monogenic mouse models of nephrotic syndrome (NS) or proteinuria, obtained from stringent review of published databases and literature; **2)** 64 genes, whose podocytic expression is regulated by WT1 (Lefebvre *Kidney Int* 88:321, 2015); and **3)** a discovery set of 120 candidate genes that we generated by WES analysis of 1,382 NS families over 12 years. We first validated candidate lists **1)** and **2)** for overlap with 63 known human SRNS genes. We then overlapped candidate lists **1)** (mouse models) and **2)** (WT1-regulated genes) with our 120 WES-derived candidate genes **(3)**, in order to identify potential novel genes that may cause monogenic NS.

Results: Twelve of the 63 NS mouse models **(1)** and 5 of the 64 WT1-regulated genes **(2)** overlapped with the control set of 63 known human SRNS genes, indicating relevance of the 2 candidate gene lists. When we evaluated for overlap with our 120 WES-derived candidate genes, 6 overlapped with the mouse candidate list **(1)**, and 4 with the WT1-regulated candidate list **(2)**. Of note, 3 genes (*SYNPO*, *SEMA3G*, *ITGB8*) were shared by all 3 lists. We found a homozygous *SYNPO* mutation (c.2540C>T, p.P847L) in a 4yo patient with NS. We show that loss-of-function of *SYNPO* decreases CDC42 activity and reduces podocyte migration rate, both rescued by overexpression of wild type cDNA, but not by cDNA representing the patient mutation.

Conclusions: By overlapping 2 candidate gene sets with a set of 120 genes resulting from WES analysis in 1,382 families with NS, we identified *SYNPO* as a potential novel monogenic cause of NS.

An International Cohort Study of Mutations in RENIN Causing Autosomal Dominant Tubulointerstitial Kidney Disease

Anthony J. Bleyer,[1,2] Martina Zivna,[2] Kendrah O. Kidd,[1,2] Gregory Papagregoriou,[7] Luca Rampoldi,[3] Mayssa Abdelwahed,[5] Matthew R. Sinclair,[6] Howard Trachtman,[8] Tal H. Kopel,[4] Marisa Santostefano,[3] Claudia Izzi,[3] Agnieszka Laszkiewicz,[10] Anna Jakubowska,[9] Mohamad Zaidan,[11] Katerina Hodanova,[2] Bertrand Knebelmann,[11] Stanislav Kmoch.[2,1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; [3]IRCCS Ospedale San Raffaele, Milano, Italy; [4]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [5]Universite de Sfax, Sfax, Tunisia; [6]Duke University School of Medicine, Durham, NC; [7]University of Cyprus, Nicosia, Cyprus, Nicosia, Cyprus; [8]NYU School of Medicine, NY, NY; [9]Wroclaw Medical University Department and Clinic of Paediatric Nephrology, Wroclaw, Poland; [10]Laboratory of Molecular and Cellular Immunology, Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland; [11]Necker Hospital; APHP; Universite de Paris, Paris, France.*

Background: There have been few clinical reports of Autosomal Dominant Tubulo-interstitial Kidney Disease due to *REN* Mutations (ADTKD-*REN*), limiting clinical characterization.

Methods: We formed an international collaboration that identified and characterized 111 individuals from 30 families with heterozygous *REN* mutations.

Results: Sixty-nine (62%) individuals had a *REN* mutation in the signal peptide region (signal group), 27 (24%) in the prosegment (prosegment group), and 15 (14%) in the mature renin peptide (mature group). Laboratory investigations revealed that *REN* signal peptide mutations prevented recognition and translocation of preprorenin into the endoplasmic reticulum (ER), prosegment mutations led to abnormal deposition of prorenin and renin in the ER Golgi intermediate compartment (ERGIC), and mutations in mature renin led to deposition of prorenin and renin in the ER. Signal and prosegment patients were most severely affected, often presenting at <10 years (see Table 1) with anemia, hyperkalemia, and acute and chronic kidney disease. While eGFR was approximately 50 ml/min in children < 10 years, eGFR remained stable until age 20, with mean age of end-stage kidney disease (ESKD) >50 in this cohort. The mean hemoglobin level in children <10 y not receiving erythropoietin was 9.6±1.04 g/dL (7.4-13.8 g/dl), which improved with erythropoietin administration. The serum potassium values decreased and

bicarbonate values increased in 9 patients taking fludrocortisone (4.77±0.55 mEq/L vs. 4.37±0.54 mEq/L, p< 0.01 and 23.7±3.5 mEq/L vs. 25.9±2.3 mEq/L, p=0.003). Patients with mutations in mature renin presented ⟩20y with gout and chronic kidney disease.

Conclusions: There are 3 subtypes of heterozygous *REN* mutations that are pathophysiologically and clinically distinct.

PO1632

Clinical Manifestations and Mutation Analysis of Idiopathic Renal Hypouricemia

Lijun Mou, Xujiao Chen, Ying Hu. *Nephrology Department. Zhejiang University School of Medicine, Hangzhou, China.*

Background: Idiopathic renal hypouricemia (RHUC), was thougt an autosomal recessive inheritancea disorder, characterized by impaired uric acid (UA) reabsorption in the proximal tubule and subsequent profound hypouricemia, caused by mutations in *SLC22A12* or *SLC2A9*. Most cases of RHUC were reported in Japan, only a few have been detected in China. A retrospective analysis was performed in this study to report the clinical manifestations and genetic mutation profiles of RHUC patients in China.

Methods: The medical history, clinical manifestations, biochemical and genetic data, clinical outcomes of Chinese patients with RHUC were collected in this study.

Results: Seven male and two female patients were diagnosed with idiopathic RHUC according to the criteria: serum uric acid(S_{UA}) level of ≤120μmol/L, fractional excretion of uric acid (FE_{UA}) and exclusion of other diseases that present hypouricemia as a symptom. The median age of onset were 30 (11~48) years old. The median levels of S_{UA} was 83(5~95)μmol/L, the median FE_{UA} was 29%(26.6%~346.83%). Homozygous *SLC2A9* mutations were identified in two male patients, homozygous mutations in *SLC22A12* in two patients, compound heterozygous mutations in *SLC22A12* in one patient, heterozygous mutations in *SLC22A12* in four patients. Exercise-induced acute kidney injury(EIAKI) developed in six patients, including the two patients with mutations in *SLC2A9*, the patient with compound heterozygous mutations in *SLC22A12*, one patient with homozygous mutations in *SLC22A12*, two patients with heterozygous mutations in *SLC22A12*. The two female patients were asymptomatic and the patients with EIAKI were all male. Two patients with heterozygous mutations in *SLC22A12* had nephrolithiasis. Two patients had recurrent EIAKI whereas the renal function of all patients with EIAKI returned to normal. Strenuous exercise was strictly prohibited. Over the median 40 (7~233) months follow-up, no patient developed EIAKI again.

Conclusions: *SLC22A12* mutations were more common than *SLC2A9* mutations in Chinese patients with RHUC, EIAKI only developed in male patients. Heterozygous mutations in *SLC22A12* also resulted in hypouricemia, EIAKI and nephrolithiasis. The prognosis of RHUC was favorable.

PO1633

RhoA-Rac1-CDC42 Regulators as Candidates for Monogenic Nephrotic Syndrome

Abdul A. Halawi,[1] Konstantin Deutsch,[1] Ronen Schneider,[1] Verena Klambt,[1] Florian Buerger,[1] Ana C. Onuchic-Whitford,[1,2] Muhammad Y. Zahoor,[1] Detlef Bockenhauer,[3] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Department of Pediatrics, Boston Children's Hospital, HMS, Boston, MA; [2]Department of Nephrology, Brigham and Women's Hospital, HMS, Boston, MA; [3]Department of Renal Medicine, University College London and Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK, London, United Kingdom.*

Background: Steroid resistant nephrotic syndrome (SRNS) frequently causes chronic kidney disease in children. 58 monogenic SRNS genes are known to cause 11%-29.5% of SRNS in children. These genes map to 12 distinct pathogenic pathways, including RhoA-Rac1-CDC42 regulators (RRCR). Genetic data indicate that many additional monogenic SRNS genes exist.

Methods: To search for additional monogenic SRNS genes, we generated two lists of independent functional candidate genes: i) 123 genes involved in the RRCR pathway, which has been implicated in the pathogenesis of nephrotic syndrome (*Nat Commun* 9:1960, 2018), and ii) 30 genes from a single-cell RNA sequencing (scRNA-seq) dataset (*JASN* 29:2060, 2018).

Results: First, we validated the candidate status of both candidate lists by overlapping them with the 58 known SRNS genes. 12 of the 123 RRCR candidates from list i) (9.7%) overlapped with the 58 known SRNS gene lists (20.6%). Likewise, of the 30 genes from list ii) that were most strongly expressed in podocytes (scRNA-seq), 9 overlapped (30%) with the 58 known SRNS genes (15.5%), thereby validating both functional candidate lists as relevant for SRNS pathogenesis. We then evaluated for overlap of both candidate gene lists [list i) RRCR and list ii) scRNA-seq] with 114 candidate genes that we identified by whole exome sequencing (WES) in 1,382 families. We found that 10 RRCR candidates (8.1%) overlapped with the 114 WES candidates (8.7%). Interestingly, 2 genes (*ARHGEF17* and *MYO9A*) overlapped with all three candidate gene lists, i.e. the 123 RRCR candidates, the 30 scRNA-seq candidates, and the 114 WES candidates. Within the 8 (of 10) remaining candidates the strongest mutation was detected in the *NEK3* gene (*NIMA Related Kinase 3*). By WES we had identified a homozygous truncating mutation, p.N209Kfs*21, in a family of two siblings. We present data on the cell biological role of *NEK3* in podocytes.

Conclusions: Utilizing two independent non-overlapping candidate lists, we established 10 potential novel candidate genes for human SRNS.

PO1634

Generating Monogenic CAKUT Candidate Genes from Existing Single-Cell Transcriptomics Data of Human Fetal Kidney

Luca M. Schierbaum, Sophia Schneider, Florian Buerger, Steve Seltzsam, Chunyan Wang, Bixia Zheng, Chen-Han W. Wu, Makiko Nakayama, Shirlee Shril, Friedhelm Hildebrandt. *Department of Pediatrics, Boston Children's Hospital, Boston, MA.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most frequent birth defect and the most frequent cause of chronic kidney disease in the first 3 decades of life. Discovery of >34 monogenic causes of human CAKUT has helped mapping pathogenic pathways of CAKUT in humans (*JASN* 29:36, 2018). We hypothesized that genes specific to pathogenic pathways of CAKUT may show a temporo-spatial single-cell mRNA expression pattern in human fetal kidney tissue, and that highly expressed genes may represent novel CAKUT candidate genes.

Methods: First, we evaluated 34 monogenic human genes involved in CAKUT pathways for clustering in a temporo-spatial mRNA expression pattern by using the single-cell mRNA sequencing derived dataset of human fetal kidney at developmental week 17 (Hochane, *PLoS Biol* 21:17, 2019) and week 16 (Lindstrom, *Dev Cell* 45:651, 2018). 86 novel CAKUT candidate genes were generated by Whole Exome Sequencing (WES).

Results: The evaluation of the 34 known CAKUT pathway genes showed that genes involved in the FRAS/FREM, RA signaling and BMP signaling pathways did not cluster in either mRNA dataset. However, genes involved in the pathogenesis of branchiootorenal (BOR) syndrome (*EYA1, SIX1, SIX2*, SIX5) clustered in nephron progenitor cells (NPCs) in both datasets. We therefore concluded that NPCs are relevant for CAKUT pathogenesis. Based on the outcome of this first step, to prioritize potential novel CAKUT genes, we then generated and overlapped two lists of independent candidate genes: i) 86 novel single CAKUT candidate genes derived from WES in 1,380 patients and ii) the 100 highest expressed genes in each NPC type a, b, c and d according to Hochane (*PLoS Biol* 21:17, 2019). This overlap of lists i) and ii) resulted in one gene KIF19 (*Kinesin Family Member 19*), which is therefore considered as a novel candidate gene for human CAKUT.

Conclusions: Genes of the BOR pathway are co-expressed in a temporo-spatial way and expressed in a time-specific and cell-type-specific manner throughout human renal development. Single-cell mRNA expression data from human fetal kidney can be used to prioritize WES-derived CAKUT candidate genes.

CHRM5 Mutations as a Potential Cause of Neurogenic Bladder

Sophia Schneider, Luca M. Schierbaum, Steve Seltzsam, Chunyan Wang, Bixia Zheng, Chen-Han W. Wu, Makiko Nakayama, Shirlee Shril, Friedhelm Hildebrandt. *Department of Pediatrics, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston, MA.*

Background: Neurogenic bladder is caused by disruption of neuronal pathways that regulate bladder relaxation and contraction. In severe cases, neurogenic bladder can lead to vesicoureteral reflux, recurrent urinary tract infections, and even chronic kidney disease and renal failure. These symptoms overlap with the manifestations of congenital anomalies of the kidneys and urinary tract (CAKUT). Animal models of bladder dysfunction suggest that neurogenic bladder can be caused by single gene mutations (*PNAS* 96:5746, 1999).

Methods: To identify novel monogenic causes of neurogenic bladder we applied whole exome sequencing (WES) to our worldwide cohort of families with CAKUT.

Results: By WES, we discovered a homozygous missense variant (p.Gln184Arg) in the gene *CHRM5 (cholinergic receptor, muscarinic, 5)* in a patient from a non-consanguineous family with CKD stage 4 secondary to neurogenic bladder with small trabeculated bladder, severe right-sided vesicoureteral reflux (VUR) and bilateral hydronephrosis. Evaluation of WES data of 703 additional patients with CAKUT did not identify further families with mutations in *CHRM5*. *CHRM5* codes for a seven transmembrane-spanning G-protein coupled muscarinic acetylcholine receptor. Crystal structure modeling shows the mutation p.Gln184Arg affecting the second extra-cellular loop between the transmembrane spanning alpha helices 4 and 5. The receptor *CHRM5* is shown to be expressed in murine and human bladder wall. We propose *CHRM5* to be involved in bladder tone regulation and that the molecular defect of our patient causes neurogenic bladder with secondary symptoms as CAKUT. This is similar to *CHRNA3*, which we published as the first gene to cause neurogenic bladder (*AJHG* 105:186, 2019). Deckmann et al (*FASIB* J. 32:2903, 2018) demonstrate that *Chrm5* knockout mice show symptoms of bladder overactivity. Functional studies testing the effect of the variant p.Gln184Arg on *CHRM5*'s receptor function are pending.

Conclusions: We identified a recessive mutation in *CHRM5* as a potential cause of neurogenic bladder in humans.

Whole-Exome Sequencing Reveals a Monogenic Cause of Disease in 23.1% of 276 Families with Steroid-Resistant Nephrotic Syndrome

Ronen Schneider,[1] Ana C. Onuchic-Whitford,[1,2] Konstantin Deutsch,[1] Abdul A. Halawi,[1] Youying Mao,[1] Florian Buerger,[1] Verena Klambt,[1] Amar J. Majmundar,[1] Thomas M. Kitzler,[1] Shrikant M. Mane,[3] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Yale University School of Medicine, New Haven, CT.*

Background: Steroid-resistant nephrotic syndrome (SRNS) overwhelmingly progresses to end-stage renal disease. To date, more than 59 monogenic genes have been identified to cause SRNS. We previously detected causative mutations in 25% using whole exome sequencing (Warejko *CJASN* 13:53, 2018) and in 29.5% of patients with SRNS using targeted panel sequencing (Sadowski *JASN* 26:1279, 2015). However, whole exome sequencing (WES) has become more accessible, with the advantage of detecting not only known monogenic causes of SRNS, but also novel candidate NS-causing genes.

Methods: We employed whole exome sequencing (WES) to detect monogenic causes of SRNS in a large international cohort of 276 families with nephrotic syndrome (NS).

Results: Samples were recruited from April, 1998 to December, 2018 (21 years). WES was performed at the Yale Center of Mendelian Genomics. First, we examined the WES data for mutations in 59 genes known to cause SRNS. In 64/276 families (23.1%), we identified mutations in 22 of the known genes. There were also 7 genes that were identified as phenocopies of SRNS, e.g. *COL4A3*. In 42 families (15.2%), we have identified mutations in a potential novel candidate gene for SRNS. We found a 39.5% solve rate in consanguineous individuals and 10.8% solve rate in non-consanguineous individuals, recapitulating similar solve fractions to what has been previously published (Sadowski 2015; Warejko 2017).

Conclusions: This study confirms that in ~23% of families in our cohort, NS is due to monogenic causes. WES is a viable way to diagnose the underlying cause of NS in children and young adults, and to suggest novel monogenic candidate genes of NS.

Recovery from Dialysis in Responsive Primary Hyperoxaluria Type 1 (PH1) Patients After Initiation of Pyridoxine

Elizabeth C. Lorenz, John C. Lieske, Barbara M. Seide, Julie B. Olson, Ramila A. Mehta, Dawn S. Milliner. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: PH1 is a genetic disorder characterized by hepatic overproduction of oxalate and eventual end-stage kidney disease (ESKD). The only established treatment to reduce hepatic oxalate production is the use of pharmacologic doses of pyridoxine in responsive patients including those with G170R mutations, though emerging therapies to block specific hepatic enzymes are under clinical trial and appear promising. However, whether reducing oxalate production can result in recovery of kidney in a subset of patients with advanced chronic kidney disease (CKD) is unknown. Here we report a series of three G170R homozygous patients with ESKD who experienced recovery of kidney function that allowed dialysis discontinuation following treatment with pyridoxine.

Case Description: Data from the Rare Kidney Stone Consortium PH Registry was reviewed. Among the 41 G170R homozygous patients, 23 progressed to ESKD, including those who are the subject of this report. Median age at initiation or resumption of pyridoxine treatment following ESKD among these three patients was 37 years (range 20-53), and pyridoxine dose was 8.8 mg/kg/d (range 6.8-14.0 mg/kg/d). Median duration of dialysis prior to renal recovery was 10 months (range 5-19). Plasma oxalate (POx) improved after recovery of renal function even while still on dialysis. At a median of 3 months (range 2-46) following discontinuation of dialysis, estimated glomerular filtration rate was 34 ml/min/1.73 m^2 (range 23-52), POx was 8.8 µmol/L (4.6-11.3), and UOx was 0.93 mmol/24 hours (0.47-1.03). Kidney function was maintained during a median of 3.2 yrs (range 1.3-3.8) of follow-up.

Discussion: Our findings challenge the conventional wisdom that ESKD in PH1 is always irreversible. Rather, in selected PH cases advanced CKD could potentially be reversed if hepatic oxalate production is reduced promptly after dialysis initiation. Thus new or emerging treatments may prevent the need for kidney transplantation in a subset of PH1 patients, even after ESKD ensues.

Baseline characteristics of G170R homozygous PH1 patients who recovered renal function after treatment with pyridoxine

Patient	Age at PH1 symptom1 onset (years)	Age at dialysis initiation (years)	Pyridoxine initiation or resumption	Initial POx (µmol/L)	UOx before pyridoxine (mmol/24 hrs)
1	25	37	3 months after dialysis initiation	47.2 on dialysis, prior to pyridoxine initiation	0.95
2	2.5	20	At time of dialysis initiation	26.6 on dialysis, 6 weeks after pyridoxine initiation	2.34
3	33	53	Within 1 week after dialysis initiation	67.9 on dialysis, 6 weeks after pyridoxine resumption	1.87

The Distribution of APOL1 Risk Variants and Their Association with CKD in Rural East Africa: The SEARCH-CKD Study

Anthony N. Muiru,[1] Assurah W. Elly,[2] Jane Kabami,[3] Mucunguzi Atukunda,[3] Wendy Chan,[1] Jennifer Puck,[1] Edwin Charlebois,[1] Diane Havlir,[1] Moses Kamya,[3] Michelle M. Estrella,[1] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Kenya Medical Research Institute, Nairobi, Kenya; [3]Infectious Diseases Research Collaboration, Kampala, Uganda.*

Background: Apolipoprotein L1 (APOL1) high-risk genotypes (G1/G1, G1/G2 or G2/G2) are well-known CKD risk factors that arose in sub-Saharan Africa. The G1 and G2 allele frequencies may be as high as 45% and 24%, respectively in some West African countries, but few studies have examined the association of high-risk genotypes and CKD in Eastern Africa.

Methods: We conducted a study of CKD prevalence among a population-based sample of 3,686 participants (PMC7055898) nested within an HIV trial in rural Uganda and Kenya. We collected dried blood spots (DBS) on filter cards for subsequent genetic studies. After DNA extraction, we genotyped *APOL1* risk variants and used multivariable logistic regression models to assess the association of *APOL1* high-risk genotypes with prevalent CKD defined as a serum creatinine-based eGFR <60 mL/min/1.73m^2 or proteinuria (urine dipstick ≥1+).

Results: We successfully obtained DBS from 90% of all individuals approached for the study. We have extracted DNA and genotyped 492 (~10%) samples (convenient selection). Un-weighted CKD prevalence among these individuals was 7.7% (95% CI: 5.2-11%). The overall allele frequencies for *APOL1* G1 and G2 variants were 6.1% and 5.8%, respectively and varied by region (**Figure 1**). Only 2.2% of individuals had *APOL1* high-risk genotypes. The adjusted odd ratio for association of *APOL1* high-risk genotypes with CKD was 1.5 (95% CI 0.15-15) in this limited sample.

Conclusions: Our study is one of the largest studies to define the prevalence of *APOL1* risk variant frequencies and evaluate the association of *APOL1* high risk genotype with CKD in rural East Africa. Our preliminary results show a relatively low prevalence of APOL1 risk variants—supporting the distinctive west-east Africa cline in APOL1 distribution previously reported. Further genotyping will permit more precise estimation of the association of APOL1 and CKD.

APOL1 Cytoxicity Is Variant and Dose Dependent

Opeyemi A. Olabisi,[4,1] Somenath Datta,[4,1] Jiayue Zhang,[2,3] Savannah Moore,[5] Kaitlyn M. Petitpas,[5] Adam Mohamed,[5] Nathan Zahler,[6] Martin R. Pollak.[2,3] *[1]Duke University, Durham, NC; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Duke University School of Medicine, Durham, NC; [5]Massachusetts General Hospital, Boston, MA; [6]Icagen Inc, Durham, NC.*

Background: Two coding renal risk variants (RRVs) of *APOL1* gene (G1 and G2), are associated with large increases in chronic kidney disease (CKD) rates among populations of recent African descent, but the underlying molecular mechanisms are unknown. *In vitro* mammalian cell cultures models are widely used to study cytotoxicity of RRVs, but results have been contradictory. It remains unclear whether cytotoxicity is RRVs-dependent or driven solely by variant-independent overexpression. It is also unknown whether the reference APOL1 allele, G0 could prevent cytotoxicity of RRVs.

Methods: We generated tetracycline-inducible APOL1 expression in HEK293 cells and examined the effects of increased expression of APOL1 (G0,G1,G2,G0G0,G0G1,or G0G2) on known cytotoxicity phenotypes including reduced cell viability, increased cell swelling, cellular potassium loss, aberrant protein phosphorylation, and dysregulated energy metabolism. Furthermore, whole genome transcriptome analysis was performed to discover deregulated canonical pathways.

Results: At moderate expression, RRVs but not G0 caused cytotoxicity. RRVs-induced cytotoxicity is dose-dependent and is not reduced by co-expression of G0. RRVs also have dominant effects on canonical pathways relevant for cellular stress response.

Conclusions: In HEK293 cells, RRVs have dominant gain-of-toxic function that worsens with increasing expression. These observations suggest that high steady state levels of RRVs may underlie cellular injury in APOL1 nephropathy, and that interventions that reduce RRVs expression in kidney compartments may be effective for mitigating APOL1 nephropathy.

Mapping the Genetic Susceptibility of HIV-Associated Nephropathy in a Mouse Model

Nicholas J. Steers,[1] Yask Gupta,[1] Tze Yin Lim,[1] Anna Mo,[1] Judy Liang,[1] Kelsey O. Stevens,[1] Vivette D. D'Agati,[2] Simone Sanna-Cherchi,[1] Ali G. Gharavi.[1] [1]*Columbia University Irving Medical Center, New York, NY;* [2]*Columbia University Vagelos College of Physicians and Surgeons, New York, NY.*

Background: We studied the genetic determinants of nephropathy in HIV-1 transgenic (Tg) mice, a model that displays all the clinical and molecular signatures of collapsing FSGS. On the FVB/NJ background over 80% of the Tg-FVB mice develop significant glomerulosclerosis, however F1 hybrids with other inbred strains of mice demonstrate variable penetrance from completely resistant to highly sensitive.

Methods: Tg-FVB mice were crossed with 20 different inbred strains of mice to generate F1 hybrids. At 8 weeks of age, we evaluated the severity of nephropathy by histology, BUN, and proteinuria, hematuria and NGAL was analyzed in the urine. To map loci predisposing to HIVAN, we performed a GWAS using a mixed linear model method.

Results: Six strains (A/J, C3H/HeJ, DBA/1J, KK/HlJ, WSB/EiJ, and LP/J) were highly sensitive to the Tg resulting in severe glomerulosclerosis, 9 strains (129S1/SvImJ, Balb/CJ, C57BL/6J, C57BL/6NJ, C57BL/10J, C57L/J, C58/J, CAST/EiJ and NZB/BINJ) were resistant to the Tg resulting in limited to no glomerulosclerosis, and 5 strains were (CBA/J, DBA/2J, NOD/ShiLtJ, NZO/HlLtJ and FVB/NJ) had intermediate glomerulosclerosis. The glomerulosclerosis score correlated with the presence of casts, interstitial fibrosis and tubular atrophy, interstitial inflammation, proteinuria, elevated plasma BUN, and the detection of urine NGAL. A GWAS searching for haplotype distribution patterns that matched the high/low strain susceptibility pattern identified a genome-wide signal on Chr 13 within a previously known QTL for HIVAN. The interval contains *Ssbp2*, encoding a DNA binding protein that stabilizes transcriptional complexes by prevent proteasomal degradation. *Ssbp2* is highly expressed in podocytes.

Conclusions: Our data demonstrates differences in the susceptibility of inbred strains to the HIV-1 transgene and suggest *Ssbp2* as culprit in producing susceptibility to HIVAN in the mouse. Future studies will evaluate the role of *Ssbp2 in vitro* and in *Ssbp2* null mice.

One Disease Cannot Exclude the Other: The Coexistence of IgA Nephropathy and Alport Syndrome

Jayesh B. Patel, Sreedevi koppisetti Jenigiri, Prerna Rastogi, Christie P. Thomas. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Alport syndrome and IgA nephropathy (IgAN) have shared clinical characteristics such as persistent hematuria, proteinuria, and progressive renal failure. We describe a case that histologically was diagnosed as IgAN, genetic testing and segregation analysis confirmed the coexistence of Alport. The additional diagnosis came to light when the daughter, a kidney donor candidate presented with persistent microscopic hematuria (MH).

Case Description: A 61-year-old female with diabetes, hypertension and ESRD presented for evaluation of transplant candidacy. The patient was diagnosed with IgAN after a biopsy at age 50. A second biopsy at the age of 61 years, showed granular mesangial and para-mesangial IgA staining, foot process effacement and irregular thickening of the glomerular basement membrane (GBM). Her daughter presented for evaluation as a live kidney donor and reported MH. She had normal renal function and imaging. Cystoscopy and urine cytology were negative. To evaluate the hematuria further, her mother was first screened with a renal genetic panel, KidneySeq™ which demonstrated a likely pathogenic variant in the COL4A3 gene, c.361 G>A, p. Gly121Ser. The donor underwent focused screening and was positive for this familial variant. Subsequently obtained FH revealed that a maternal aunt had early onset deafness, and another had CKD. The donor's daughter was found to have MH. The results suggested that both the transplant candidate and her daughter had a genetic diagnosis consistent with Alport type nephropathy.

Discussion: Pathogenic or likely pathogenic variants in COL4A3 and COL4A4 cause FSGS and AR and AD Alport syndrome. Up to 50% of causal variants are a substitution of glycine in the Gly-X-Y repeat sequence disrupting the triple helical structure of the collagen fiber and causing anomalies in the GBM. Heterozygous carriers of these variants may also manifest with thin basement membrane disease. In this transplant candidate with IgAN and GBM abnormalities, the relative contribution of the COL4A3 variant to her CKD cannot be ascertained. Consequently, the daughter's long-term renal outcome cannot be predicted. The co-existence of both IgAN and Alport syndrome is rarely described in the literature and the importance of the consideration of genetic renal disease is emphasized here in the context of living donor safety.

PO1642

Discovery of Genetic Modifiers in Thin Basement Membrane Nephropathy (TBMN) Using Pedigree-Based Whole-Exome Sequencing

Laith Al-Rabadi, Edwin Lin, Bushra Gorsi, Lydia Sauer, Paul Bernstein, Marcus G. Pezzolesi, Martin C. Gregory. *University of Utah Health, Salt Lake City, UT.*

Background: TBMN is caused by heterozygosity in COL4A3 or COL4A4, and is the carrier state of autosomal recessive Alport syndrome (ARAS). TBMN is less severe than ARAS, but its phenotype can range from asymptomatic microscopic hematuria and/or low-grade proteinuria, focal segmental glomerulosclerosis, to end-stage renal disease (13-25% in patients >60 years). The cause of phenotypic heterogeneity in TBMN is unknown. Previously, we found an autosomal dominant pattern of transmission of isolated microscopic hematuria and low-grade proteinuria in two large pedigrees in Utah with ARAS, which led us to hypothesize that genetic modifiers may affect the severity of TBMN.

Methods: Based on pedigree analysis, 64 participants from two large families with characterized COL4A3 mutation were recruited for WES. In order to identify candidate disease-modifying genes, we used Pedigree-VAAST (pVAAST), a probabilistic algorithm for disease gene prioritization that uses pedigree information to perform linkage analysis. Candidate modifying genes were analyzed using Phevor, an algorithm that performs reprioritization based on information about phenotype, gene function, and disease.

Results: We found 17 candidate modifier genes that co-segregated with hematuria, proteinuria and renal dysfunction (Figure). Of note, GRIP1 co-segregated with the Alport allele, hematuria, proteinuria, renal dysfunction (P=9.4E-04), and had a high biologic correlation score (Phevor score=4.1).

Conclusions: GRIP1 is involved in cell adhesion to extracellular matrix proteins, crucial for kidney morphogenesis, and compound heterozygosity in GRIP1 causes renal agenesis and Fraser syndrome. Whole-exome sequencing in large pedigrees reveal 17 candidate disease-modifying genes in TBMN. Validation studies will be needed to ascertain their role in TBMN.

In the Presence of Genetic Heterogeneity of CAKUT, Whole-Exome Sequencing Establishes a Molecular Genetic Diagnosis in 14% of Cases

Steve Seltzsam,[1] Chunyan Wang,[1] Bixia Zheng,[1] Chen-Han W. Wu,[1] Sophia Schneider,[1] Luca M. Schierbaum,[1] Dervla M. Connaughton,[1] Amelie Van der ven,[1] Nina Mann,[1] Makiko Nakayama,[1] Rufeng Dai,[1] Franziska Kause,[1] Caroline M. Kolvenbach,[1] Shrikant M. Mane,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] [1]*Division of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA;* [2]*Department of Human Genetics, Yale University School of Medicine, New Haven, CT.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most common cause of chronic kidney disease in children and young adults. More than 44 monogenic causes of CAKUT have been discovered so far (*NDT* 35:390, 2020). The high number of unsolved consanguineous families with CAKUT strongly suggests the existence of additional monogenic causes of CAKUT.

Methods: We conducted whole exome sequencing (WES) and homozygosity mapping in an international cohort of patients with CAKUT from 211 unrelated families. We evaluated WES data for mutations in the 44 known genes that cause isolated CAKUT in humans and the 179 genes that cause syndromic CAKUT in humans. We then evaluated unsolved cases for potential novel genetic causes of CAKUT using our established criteria for variant identification (*JASN* 29:2348, 2018).

Results: In 30 of 211 (14%) families, we detected mutations in one of the 44 genes for isolated CAKUT or in one of the 179 syndromic CAKUT genes. In particular syndromic cases, reverse phenotyping was helpful to increase certainty of the deleteriousness of a genetic variant. In the remainder, we performed a targeted analysis for novel candidate genes. In 40 families of this subset, we identified likely deleterious mutations in 36 genes not previously reported to cause CAKUT.

Conclusions: In a large, international cohort we detected causative mutations in 14% of families with a diagnosis of CAKUT. We show that when combined with homozygosity mapping and segregation analysis, WES is useful in identifying potential candidate genes in consanguineous families or families with multiple affecteds.

PO1644

Extremely Rare Variants in Four Complement Genes Contribute to Genetic Susceptibility to Atypical Hemolytic and Uremic Syndrome

Armance Marchal,[1] Julien Zuber,[1] Sophie Limou,[2] Paula Vieira-Martins,[1] Alice Le Clech,[2] Claire Leman,[2] Eric Rondeau,[1] Fadi Fakhouri,[3] Veronique Fremeaux-Bacchi.[1] *[1]Assistance Publique - Hopitaux de Paris, Paris, France; [2]Centre Hospitalier Universitaire de Nantes, Nantes, France; [3]Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland.*

Background: The study of complement genetics has dramatically changed the landscape of atypical hemolytic uremic syndrome (aHUS) and has paved the way for highly tailored therapy. However, the assessment of the contribution of each identified variant to aHUS pathogenesis still remains a challenge. In this study we aimed to analyze the enrichment of rare variants in 6 aHUS-associated genes, including *C3, CFH, CFI, CD46/MCP, CFB* and *THBD*, in comparison with a reference population.

Methods: We analyzed the distribution of rare variants in 433 adult patients with a clinical diagnosis of aHUS, without coexisting disease. As a control group, we used European individuals from the 1000 Genomes project (N=503), focusing on the 6 genes of interest. We analyzed the enrichment of genetic variants in the aHUS cohort compared to the reference population.

Results: A total of 168 variants in complement genes, with a minor allele frequency (MAF) <1%, involving 247 alleles, were identified in 224 patients (51.7%). 115 of the identified variants were not reported in the population database gnomAD, including 75 variants detected in *CFH* gene (65%). Variants with a MAF of <0.01% in the *C3 and MCP* genes and variants with a MAF <0.1% in the CFH and CFI genes were enriched in the aHUS population as compared to controls. In contrast, rare variants in *CFB* and *THBD* genes were not significantly enriched in the aHUS population. We identified 18 variants overrepresented in patients, including the CFH/CFHR1 hybrid genes. Among these variants resulting with functional deficiency in the encoded protein the C3 variant p.Lys155Gln associated with risk of advanced age-related macular degeneration was not significantly increased in the aHUS population. Finally, multiple rare variants in a single individual were more frequently present in aHUS patients compared to controls.

Conclusions: We showed the enrichment of extremely rare variants limited to *CFH, CFI, CD46/MCP* and *C3*, genes. The study confirms that a variant with a MAF>0.1% should not be considered at risk for developing aHUS. Our study indicates that targeting the MAF provide reasonable diagnostic tools as a guide to variant classification.

PO1645

Whole-Exome Sequencing Identifies Likely Causative Variants in Four Candidate Genes in 16 Families with Spina Bifida

Chunyan Wang, Chen-Han W. Wu, Steve Seltzsam, Bixia Zheng, Sophia Schneider, Luca M. Schierbaum, Nina Mann, Makiko Nakayama, Shirlee Shril, Stuart B. Bauer, Michelle A. Baum, Carlos R. Estrada, Friedhelm Hildebrandt. Boston Children's Hospital *Boston Children's Hospital, Boston, MA.*

Background: Spina bifida (SB) is the most common central nervous system malformation compatible with life and the second leading cause of birth defects. The following lines of evidence support the hypothesis that SB may be caused by multiple monogenic genes: i) congenital nature, ii) familial occurrence, and iii) existence of monogenic mouse models. However, only few monogenic genes have been described so far and the majority of the candidate genes derived from mouse models have not been studied in human SB.

Methods: We evaluated the literature and generated a list of 95 candidate genes from four categories: i) 7 known genes from human isolated SB, ii) 11 genes from human syndromic SB, iii) 35 genes considered risk factors for human SB, and iv) 42 genes from monogenic mouse models for SB. We evaluated whole exome sequencing (WES) data obtained from 16 individuals with SB who were enrolled at Boston Children's Hospital from 06/2019 to 11/2019.

Results: In 4 of 16 families (25%), we identified 4 likely deleterious heterozygous (het) mutations in each one potential SB candidate gene. All variants are very rare with a frequency of less than 0.01% in a control database of 125,000 healthy control individuals (gnomAD). Specifically, in family B4103 with myelomeningocele, we identified a CELSR1 het missense mutation (c.2296G>A; p.Asp766Asn). In family B4197 with myelomeningocele, we identified a TBXT het missense mutation (c.301C>T; p.Arg101Cys). In family B4125 with meningocele, we found a het missense mutation in the human risk SB gene PCYT1A (c.194A>G; p.Glu65Gly). Finally, in the family B4197 with SB, we identified a het missense mutation in the mouse SB gene TULP3 (c.703C>T; p.Asp766Asn). TULP3 variants have not been reported yet in human SB patients.

Conclusions: Through whole exome sequencing, we detected likely deleterious mutations in 4 of 16 cases with a diagnosis of SB. We show that composing a list of 95 candidate genes based on established mouse models and genes known to be related to SB in human facilitates the detection of monogenic causes for SB. We are expanding this study to a larger cohort.

PO1646

APOL1 by Second-Gene Interaction on eGFR Among African Americans Without Diabetes: The Million Veteran Program

Cassianne Robinson-Cohen,[1,5] Bryce Rowan,[1,5] Katalin Susztak,[2] Ran Tao,[1] Loren Lipworth,[1] Talat Alp Ikizler,[1] Christopher J. O'Donnell,[3,4] Adriana Hung.[5,1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]VA Boston Health Care System Jamaica Plain Campus, Boston, MA; [4]Boston University, Boston, MA; [5]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Two high-risk variants in the Apolipoprotein L1 (*APOL1*) gene are associated with eGFR and a substantial increase in risk of end-stage renal disease (ESRD) among African Americans without diabetes. Not all individuals with high-risk variants develop kidney disease, suggesting that unidentified genetic factors may modify the effects of *APOL1*.

Methods: We tested interactions between the *APOL1* haplotype and single nucleotide polymorphisms (SNPs) from 22 independent loci associated with eGFR among 55,004 African Americans without diabetes in the Million Veteran Program. We used linear regression to investigate multiplicative *APOL1**SNP interactions on eGFR at enrollment, adjusting for age, sex, body mass index and the first 5 principal components of ancestry, with Bonferroni-correction for multiple testing (alpha=0.05/22=0.002).

Results: We detected significant interactions between *APOL1* high-risk variants and SNPs at two loci (*GATM/SPATA5L1* (rs62025168, p-interaction= 0.0012) and *UBE2Q2* (rs74024005, p-interaction = 0.0014) (**Table**). *SPATA5L1* is a protein-coding gene with elevated expression in the kidney and previous associations with familial juvenile hyperuricemic nephropathy. *UBE2Q2* is also a protein-coding gene with gene expression in the distal kidney tubule of a murine model.

Conclusions: Our results identify two novel *APOL1*-gene interactions, highlighting that secondary genes may modify the effect of *APOL1* on kidney function, which may uncover underlying biological mechanisms and be useful for prevention.

Funding: NIDDK Support, Veterans Affairs Support

Results from the Ongoing Phase 2 Open-Label Extension Study of Lumasiran, an Investigational RNAi Therapeutic, in Patients with Primary Hyperoxaluria Type 1 (PH1)

Yaacov Frishberg,[1] Sally Hulton,[2] Pierre Cochat,[3] Jaap Groothoff,[4] Daniella Magen,[5] Jerome Harambat,[6] Gesa Schalk,[7] William van't Hoff,[8] Dayna Lesueur,[9] Tracy McGregor,[9] Georges Deschênes.[10] *[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]Birmingham Women's and Children's Hospital, Birmingham, United Kingdom; [3]Centre for Rare Renal Diseases & Inserm Pediatric Clinical Investigation Centre – Hospices Civils de Lyon and Université de Lyon, Lyon, France; [4]University of Amsterdam, Amsterdam, Netherlands; [5]Rambam Health Care Campus, Haifa, Israel; [6]Bordeaux University Hospital, Bordeaux, France; [7]University of Bonn, Bonn, Germany; [8]Great Ormond Street Hospital For Children, London, United Kingdom; [9]Alnylam Pharmaceuticals, Cambridge, MA; [10]Hospital Robert Debré, Paris, France.*

Background: PH1 is a rare genetic disorder characterized by hepatic overproduction of oxalate, leading to recurrent kidney stones, nephrocalcinosis, progressive renal failure, and multiorgan damage from systemic oxalosis. There are no approved pharmacologic therapies for PH1. Lumasiran is a subcutaneously-administered investigational RNAi therapeutic that decreases hepatic oxalate production by targeting glycolate oxidase. We present long-term safety and efficacy data of up to 22 months exposure from the ongoing Phase 2 open-label extension (OLE) study of lumasiran.

Methods: Phase 2 OLE includes patients with PH1, ≥6 years old, urinary oxalate (UOx) ≥0.7mmol/1.73m^2/day, and eGFR >45mL/min/1.73m^2 who completed the Phase 1/2 study. Patients initially received lumasiran 1mg/kg monthly, 3mg/kg monthly or 3mg/kg quarterly, and all transitioned to 3mg/kg quarterly. Endpoints include safety and change in 24h UOx excretion.

Results: This trial enrolled all 20 patients from the Phase 1/2 study. At baseline of the parent study, patients had a mean age 14.9 years (range: 6-43), mean baseline UOx

2.24 mmol/1.73m^2/day (range: 0.94, 5.18). As of January 2020, patients were dosed in OLE for a median of 15 months (range: 11–22). Adverse events were reported in 19/20 (95%) patients; all were mild or moderate and the majority were assessed as unrelated to study drug. There were no discontinuations or drug-related serious adverse events. The mean max reduction in 24h UOx relative to Phase 1/2 baseline was 74.5% (N=17) and 17/18 patients achieved normal or near normal levels of UOx. Plasma oxalate levels also decreased (mean max reduction 55.2%, N=19). Plasma and urinary glycolate increased and later stabilized, consistent with the effect of lumasiran on glycolate oxidase.

Conclusions: Lumasiran had an acceptable safety profile. Continued therapy with lumasiran maintained reduction of UOx to levels near or below the upper limit of normal, consistent with the Phase 1/2 study. These data further enable ongoing Phase 3 studies to evaluate lumasiran in patients with PH1 of all ages and at all stages of renal impairment.

Genome-wide Association Study of Lupus Nephritis in Chinese Han Population

Kangkang Song,[1] Xiaodong Zheng,[2] Xiaomin Liu,[1] Xuejun Zhang,[3,2] Xiangmei Chen.[1] *[1]Department of Nephrology, the First Medical Centre, Chinese PLA General Hospital, Medical School of Chinese PLA, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing Key Laboratory of Kidney Diseases., Beijing, China; [2]Institute of Dermatology and Department of Dermatology at No.1 Hospital, Anhui Medical University, Hefei, China; [3]Institute of Dermatology and Department of Dermatology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Lupus nephritis (LN) is one of the most common and serious complications of systemic lupus erythematosus (SLE). The genetic factors play a vital role in the pathogenesis of LN. The purpose of this study was to screen for susceptible variants of LN in Chinese Han populations in whole genome.

Methods: A genome-wide association study (GWAS) was performed in 592 LN patients and 453 SLE patients without LN. Fifty-six single nucleotide polymorphisms (SNPs) in 34 loci were selected for replication in independent cohort of 188 LN and 171 SLE without LN patients. Besides, gene-based analysis of selected loci was performed in the enlarged population (2336 LN and 2466 SLE without LN patients) based on exome Asian array data.

Results: We identified 9 SNPs suggesting a correlation with LN ($P<10^{-4}$). The most significant SNP was rs12606116 (18p11.32) with $P=6.75\times10^{-6}$. The rest SNPs were rs11826924 (11p15.2, INSC), rs10151371 and rs17124022 (14q31.3, GPR65), rs10435744 (9p24.1, CD274), rs203339 and rs433091 (12q24.23, CIT), rs7157731 (14q32.2, WDR25), rs2372192 (3p14.1, MAGI1). Gene-based analysis results showed 11 suggestive LN related genes in 11 loci ($P<0.05$): GPR139 (16p12.3), TH (11p15.5), SEMA6D (15q21.1), EPHA5 (4q13.1), ADAM8 (10q26.3), BDKRB2 (14q32.2), SLC26A7 (8q21.3), AQPEP (5q23.1), C15orf55 (15q14), TGM1 (14q12), GRIP1 (12q14.3). The relation of 14q32.2 and LN was showed in both replication stages.

Conclusions: Association Analysis of LN was performed in Chinese Han SLE patients for the first time. Multiple susceptible genes were identified moderately associated with LN which may advance our understanding of the genetic basis of LN.

Funding: Government Support - Non-U.S.

Copy Number Variation Analysis Increases Diagnostic Yield of Exome Sequencing and Facilitates the Identification of Genetic Causation for Congenital Anomalies of the Kidneys and Urinary Tract (CAKUT)

Chen-Han W. Wu,[1] Tze Yin Lim,[2] Chunyan Wang,[1] Steve Seltzsam,[1] Bixia Zheng,[1] Luca M. Schierbaum,[1] Sophia Schneider,[1] Nina Mann,[1] Dervla M. Connaughton,[1] Stuart B. Bauer,[1] Simone Sanna-Cherchi,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital/Harvard Medical School, Boston, MA; [2]Columbia University, New York, NY.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most common cause of chronic kidney disease in children and adults under the age of 30 years. In a previous study, we detected by whole exome sequencing (WES) a causative mutation in a known gene for isolated or syndromic CAKUT in 13% of 232 families with CAKUT (JASN 29:2348, 2018). However, WES will not detect the presence of causative copy number variations (CNV), and CNVs have been detected in up to 16% of CAKUT (AJHG 9:987, 2012).

Methods: We performed a genome-wide single nucleotide polymorphism (SNP)-based CNV analysis on the same cohort of 232 families with CAKUT in which we previously conducted WES analysis (JASN 29:2348, 2018). We evaluated the CNVs with the published predefined criteria (Nat Genet 51:957, 2019).

Results: In a subcohort of 170 families of the 232 family CAKUT cohort (JASN 29:2348, 2018) in whom sufficient DNA was available, we detected in 9 families (5.29%) a pathogenic CNV known to cause CAKUT. There was no competing variant by genome-wide CNV analysis, and there was no conflicting variant by WES analysis. In addition, we identified likely pathogenic CNVs in 1.76% of cases, potentially increasing the CNV diagnostic rate to 7.05%.

Conclusions: CNV analysis in this subcohort of 170 CAKUT families increased the diagnosis rate for genetic causes of CAKUT from 13% to 18% - 20%. We also identified three candidate loci that may cause CAKUT.

PO1650

Genotyping of Renal Transplant Patients

Susan L. Murray,[1,3] Katherine A. Benson,[1] Claire Kennedy,[1,3] Sarah Cormican,[3] Kendrah O. Kidd,[4] Anthony J. Bleyer,[4] Mark A. Little,[2] Gianpiero Cavalleri,[1] Peter J. Conlon.[1,3] *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]University of Dublin Trinity College, Dublin, Ireland; [3]Beaumont Hospital, Dublin, Ireland; [4]Wake Forest University, Winston-Salem, NC.*

Background: There is an increasing recognition that though individual inherited kidney diseases are rare, when considered as a single cohort inherited forms of kidney disease may account for up to 10% of CKD. This can have implications for potential living kidney donors who are often related to the recipient and at higher lifetime risk of kidney failure. We sequenced patients undergoing renal transplantation to assess what proportion of kidney failure was caused by monogenic kidney disease.

Methods: We identified adult patients undergoing living or deceased renal transplantation. We excluded those with pauci-immune vasculitis, systemic lupus erythematosus, drug-induced causes and those with renovascular kidney disease over the age of 50. Patients underwent targeted next generation sequencing using a custom panel of 127 genes known to cause renal disease. All suspected disease-causing variants were classified by American College of Medical Genetics guidelines and discussed by a multidisciplinary team[KB1].

Results: We sequenced 99 patients who presented for renal transplantation. We were able to detect an ACMG-classified pathogenic/ likely pathogenic variant in 27 (26%) patients. The most common disease-causing variant identified was in *PKD1*, which was identified in 14 patients (14%), accounting for 52% of all individuals with a disease-causing gene identified. Four others (16%) had pathogenic variants in *COL4A4* or *COL4A5* genes. No other disease-causing variant was present in more than one individual.

Conclusions: It is possible to identify monogenic causes of kidney disease in a carefully selected population with ESRD, and this may be useful in stratifying risk in potential living renal donors.

PO1651

21%-51% of a Single-Center, 15-Year Cohort of All Patients with ESKD Prior to the Age of 50 Have Monogenic Kidney Disease

Rozemarijn Snoek,[1] Richard H. van Jaarsveld,[1] Tri Q. Nguyen,[2] Edith Peters,[1] Martin Elferink,[1] Robert F. Ernst,[1] Maarten B. Rookmaaker,[3] Marc Lilien,[4] Eric Spierings,[6] Roel Goldschmeding,[2] Nine V. Knoers,[5] Bert Van der zwaag,[1] Arjan D. Van Zuilen,[3] Albertien M. van Eerde.[1] Nephrogenetics @ UMCU
[1]Department of Genetics, UMC Utrecht, Utrecht, Netherlands; [2]Department of Pathology, UMC Utrecht, Utrecht, Netherlands; [3]Department of Nephrology, UMC Utrecht, Utrecht, Netherlands; [4]Pediatric Nephrology, Wilhelminas Children Hospital, UMC Utrecht, Utrecht, Netherlands; [5]Department of Genetics, UMC Groningen, Groningen, Netherlands; [6]Department of Immunology, UMC Utrecht, Utrecht, Netherlands.

Background: Often only CKD patients with high likelihood of genetic disease are offered genetic testing. Early genetic testing could obviate the need for kidney biopsies, allowing for adequate prognostication and treatment. To test the viability of a 'genetics first' approach for CKD, we performed genetic testing in a group of renal transplant recipients <50 years, irrespective of cause of transplant.

Methods: From a cohort of 273 transplant patients, we selected 110 that were in care in the UMC Utrecht, had DNA available and were without clear-cut non-genetic disease. Forty patients had been diagnosed with a genetic disease prior to enrollment, in 70 patients we performed a whole exome sequencing based 379 gene panel analysis.

Results: Genetic analysis yielded a diagnosis in 51%. Extrapolated to the 273 patient cohort, who did not all fit the inclusion criteria, the diagnostic yield was still 21%. Retrospectively, in 43% of biopsied patients the kidney biopsy would not have had added diagnostic value if genetic testing had been performed as a first tier diagnostic.

Conclusions: The burden of monogenic disease in transplant patients with ESKD of any cause prior to the age of 50 is 21-51%. Early genetic testing can provide a non-invasive diagnostic, impacting prognostication and treatment and obviating the need for an invasive biopsy. We conclude that in patients who one expects to develop ESKD prior to the age of 50, genetic testing should be considered as first mode of diagnostics.

PO1652

Genome-Wide Analyses Provide Insights into the Genetic Architecture of Kidney Function and CKD Among Hispanics in the Million Veteran Program

Elvis A. Akwo,[2,1] Cassianne Robinson-Cohen,[2,1] Bryce Rowan,[2,1] Edward D. Siew,[1,2] Ran Tao,[2,1] Christopher J. O'Donnell,[3,4] Adriana Hung.[1,2]
[1]Nashville VAMC, Nashville, TN; [2]VUMC, Nashville, TN; [3]VA Boston Health Care System Jamaica Plain Campus, Boston, MA; [4]Brigham and Women's Hospital Department of Medicine, Boston, MA.

Background: Hispanics (HAs) have a higher risk of progressing to end-stage renal disease (ESRD) than non-Hispanic European Americans. Genetic variants influencing kidney function have been identified through genome-wide association studies (GWAS) of CKD and ESRD, as well as estimated glomerular filtration rate (eGFR), however, small sample sizes have stalled discovery in the Hispanic population.

Methods: We performed a GWAS of eGFR in 32,821 Hispanics from the Million Veteran Program (MVP); eGFR was estimated using the CKD EPI equation with IDMS calibrated creatinine. Patients on dialysis, transplant recipients, or with BMI <18 kg/m^2 were excluded. eGFR was regressed on to common genetic variants (minor allele frequency > 1%) imputed to the 1000 Genomes reference panel adjusted for age, sex, BMI, and the top ten principal components. Analyses were performed by strata of diabetes, estimates from which were aggregated with fixed-effects meta-analysis.

Results: A total of 397 SNPs representing 8 loci exceeded genome-wide significance. The most significant association was at a previously known locus, *SPATA5L/GATM* on chromosome 15 (p-value =3.78Ex10 $^{-21}$). Two novel loci were detected. One in *SLC30A4* (rs2643718 p-value= 4.51x10^{-15}) a protein-coding gene for zinc transmembrane transporter, and another one on *LNC00972* (rs62489732 p-value= 2.64x10-8). Other previously reported signals in the European American population for kidney phenotypes were also found with genome-wide significance : *UMOD/PDILT* (rs71149135 p-value =1.18 x $^{-9}$), *PRKAG2* (rs10224210 p-value 1.99= x10 $^{-12}$), *UNCX* (rs12702509 p-value =2.22 x10 $^{-9}$), *SLC34A1* (rs3812036 p-value = 1.29x10^{-9}) and *ALMS1P1* (rs12713788 p-value =4.14 10^{-8}). Several additional important CKD loci were associated with kidney function at p-values below the genome-wide threshold including: APOL1 (rs6029573 p=2.98 10^{-6}), *TPRKB* (rs35805651 5.49 10^{-7}), *SHROOM3* (rs60529470 p=1.36 10^{-6}). Five of the variants that reached genome-wide significance were exonic variants.

Conclusions: Our study results emphasize the transethnic nature of genetic variation contributing to kidney function. Overall, this is the largest GWAS of eGFR in Hispanics to date, which replicates previously identified loci in tranethnic analysis and detects two novel loci in Hispanics.

PO1653

Assessing Alport Syndrome and Thin Basement Membrane Nephropathy (TBMN) by Optical Coherence Tomography (OCT)

Laith Al-Rabadi, Lydia Sauer, Alex Vitale, Edwin Lin, Ragheed Aldulaimi, Alun Thomas, Paul Bernstein, Martin C. Gregory. *University of Utah Health, Salt Lake City, UT.*

Background: Using OCT to identify temporal macular thinning has diagnostic importance in patients with X-linked Alport syndrome (XLAS) but little prior research has been done to evaluate temporal macular thinning in COL4A3 and COL4A4 compound heterozygotes (ARAS) and simple heterozygotes. (TBMN) Individuals with heterozygous COL4A3 or COL4A4 mutations usually have TBMN, which is considered the carrier state of autosomal recessive Alport syndrome (ARAS). The aim of this study is to assess ophthalmologic findings in simple and compound heterozygotes and to compare them to normal control and XLAS.

Methods: Genotyping was done to detect COL4A3 and Col4A4 mutations and to classify family members as ARAS, TBMN or normal. Temporal thinning index (TTI) was calculated from OCT measurements of the more severely affected eye by comparing the ratio of the retinal thickness of the temporal (T) to the nasal (N) subfields with a published normative database. (Figure, y axis) Student's T-test and ANOVA were used to identify binary and multiple groups' differences. In addition, multivariate linear regression was also performed controlling for age, gender and interaction terms between different variables.

Results: We report results from 12 normal controls, 16 COL4A3 or COL4A4 simple heterozygotes, 7 compound heterozygotes and 18 hemizygous males with XLAS. Mean TTI was 5.75, 7.4, 9.45 and 9.37 in these four groups, respectively. TTI in each group (simple heterozygotes, compound heterozygous, and XLAS) was significantly greater than normal controls (P < 0.01). TTI was not significantly different between simple and compound COL4A3/4 heterozygotes (P= 0.13). Age, gender, and GFR were not associated with significant differences in the regression analysis.

Conclusions: This is the largest study that systematically assessed ophthalmologic findings in XLAS, ARAS and TBMN. OCT may guide our evaluation of family members who are potential donors.

LAMA5 Gene Mutations in Japanese Cases with Infantile Nephrotic Syndrome

China Nagano, Kandai Nozu, Shinya Ishiko, Yuya Aoto, Nana Sakakibara, Tomoko Horinouchi, Tomohiko Yamamura, Takeshi Ninchoji, Kazumoto Iijima. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Steroid resistant nephrotic syndrome (SRNS) have high risks to progress to end stage renal disease. Mutations in genes encoding podocyte-associated proteins have been implicated in about 30% of SRNS cases in children. Recently, *LAMA5* gene mutation have been identified in patients with nephrotic syndrome. The *LAMA5* gene encodes laminin α5, an essential component of the glomerular basement membrane. Here, we report the three cases with *LAMA5* gene mutations.

Methods: We conducted comprehensive gene screening of Japanese patients with severe proteinuria. Using targeted next-generation sequencing, 60 podocyte-related genes were screened in 326 unrelated patients with proteinuria.

Results: *LAMA5* gene variants were detected in two families. The patient 1 and 2 were siblings. They presented with proteinuria at ages three months and four months, respectively. They were subsequently found to have compound heterozygous mutation for *LAMA5* gene (NM_005560). One was nonsense mutation (c.9232C>T, p.Arg3078Ter), and the other was splice site mutation (c.1282+1G>A). The patient 3 presented with proteinuria at 6 months old. She had congenital cataract and hypoplastic kidney. Her renal pathology showed remarkable irregular form of glomerular basement membrane. She was subsequently found to have compound heterozygous mutation for *LAMA5* gene: c.8185C>T (p.Arg2720Ter), c.1282+1G>A. We performed immunofluorescence analysis of laminin α5 and her renal pathology showed completely negative staining pattern.

Conclusions: Our cases show clinical and pathological findings in a very rare disease of *LAMA5* related nephropathy. Patient 3 showed more severe phenotype compare to patient 1 and 2. We speculate the reason for this difference is the position of the variants, i.e. Patient 3 lacks laminin G-like domains that is the major cell-adhesive sites of laminin. *LAMA5* gene mutation screening should be performed in congenital/infantile nephrotic syndrome cases. Further investigation for this disease entity should be notified to all pediatricians.

PO1655

Variation in Phenotype in Utah Families with Autosomal Recessive Alport Syndrome

Laith Al-Rabadi, Edwin Lin, Lydia Sauer, Alex Vitale, Paul Bernstein, Martin C. Gregory. *University of Utah Health, Salt Lake City, UT.*

Background: Individuals with heterozygous COL4A3 or COL4A4 mutations usually have thin basement membrane nephropathy (TBMN), which is often considered the carrier state of autosomal recessive Alport syndrome (ARAS). Patients with ARAS usually progress to end-stage renal disease (ESRD) by the fourth decade of life. While ocular abnormalities, hearing loss and renal impairment are classically absent with TBMN, a subset of patients develop focal segmental glomerulosclerosis (FSGS) and 13-25% of patients progress to ESRD. It is unclear why some individuals with heterozygous COL4A3 mutations follow a mild course with isolated microscopic hematuria or low-grade proteinuria while others with the same mutations develop progressive renal dysfunction. It is also unclear why some family members show hematuria while others with the same mutation do not.

Methods: This study was designed to address these clinical questions using unbiased Whole Exome Sequencing (WES) in a population of patients harboring a limited number of pathogenic heterozygous COL4A3 mutations. Our work has focused on detailed examinations of patients carrying the same mutation to assess carefully the inter and intrafamilial variability and assess the impact of mutation on pathology.

Results: Two Utah families (figure) with a unique combination of two pathogenic mutations were identified. These pathogenic mutations have been reported before. However, the compound heterozygous status in each family is unique and has not been reported before. The probands are compound heterozygotes sharing one mutation (c.2083G>A, p.Gly695Arg) but differ in the second mutation (c.4981C>G, p.Arg1661Cys vs c.4421T>C, p.Leu1474Pro).

Conclusions: This study expanded the phenotypic spectrum of COL4A3 mutation carriers. Our findings showed the significant overlap between phenotypes induced by COL4A3 variants and the considerable intra and inter-familial variability and renal disease progression in patients with COL4A3 mutations.

PO1656

Whole-Exome Sequencing as a Predictive Tool for Severe CAKUT

Meredith Harris, Elif Erkan, Kenneth Kaufman. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) represent about 1% of births, with about 20% secondary to genetic causes. The Cincinnati Fetal Center is one of the few centers worldwide offering fetal interventions including amnioinfusion and for infants with oligo/anhydramnios. As these infants are phenotypically severe, we predict they will be genetically enriched. We hypothesize that identifying novel genetic variants in infants with CAKUT will aid in determination of clinical course and improve parental counseling.

Methods: We collected blood from infants whose mothers underwent fetal interventions for oligo/anhydramnios for the purpose of Whole Exome Sequencing as well as blood samples from parents for trios testing.

Results: We completed variant calling for 2 singletons and 1 maternal sample. Both patients' mothers underwent multiple amnioinfusions, and the patients required initiation of RRT within week 1 of life. In both patients, we identified a nonsynonymous SNV of HSPG2 on chromosome 1. HSPG2 encodes for perlecan, which has a role in renal embryogenesis, specifically the maturation of the epithelial and mesenchymal tissues of the kidney. We identified a rare heterozygous variant found in 0.28% of the population in 1 patient. In the other patient, we identified 2 variants, which form a state of compound heterozygosity. We found a rare heterozygous nonsynonymous SNV mutation in T-Box Transcription Factor-18 (TBX18) in 1 sample. TBX18 is imperative for the development of ureteric mesenchyme and is expressed in the renal capsule and glomerular mesangial cells. This patient had bilateral VUR and dysplastic kidneys. The other patient had a rare heterozygous nonsynonymous SNV in the transcriptional repressor GLI3 which is implicated in renal morphogenesis. Variants in GLI3 have been described in renal dysplasia and aplasia. This patient was born with bilateral multicystic dysplastic kidneys.

Conclusions: In our pilot data of WES of 2 singletons and 1 maternal sample, we report 3 candidate genes, HSPG2, TBX18, and GLI3, all of which are necessary for renal and urinary tract development, specifically glomerular and ureteric development and transcriptional regulation. In a small cohort, we demonstrate that WES of a severely affected population provides insight into the molecular mechanisms underlying CAKUT, which can aid in prognosis and parental counseling in the future.

Perceived Clinical Utility and Barriers to Genetic Testing in the Adult CKD Population: A Survey of General Nephrologists

Trudy McKanna, Philippe M. Gauthier, Christine Seto, Christin Chong, Monica L. Johnson. *Natera, Inc, San Carlos, CA.*

Background: Genetic testing for chronic kidney disease (CKD) can lead to personalized medicine, family planning opportunities, and living kidney donor screening.[1] Comprehensive genetic testing in CKD patients with a suspected genetic cause or predisposition is important for accurate diagnosis.[2] However, the uptake of genetic testing in the general nephrology setting lags behind other specialties.[3] There exists a lack of information on barriers perceived by nephrologists on genetic testing. This survey aims to understand the current barriers and perceptions to performing genetic testing for kidney disease in a general nephrology setting. We describe here in brief the survey design and preliminary results

Methods: An online, multiple choice survey was sent to 400 general nephrologists in clinical practice to elicit feedback on the use of genetic testing in clinical nephrology care. The questions focused on perceived clinical utility and potential barriers to ordering genetic testing.

Results: Early findings suggest that while clinical utility is acknowledged in many situations, there are opportunities to provide physician education regarding test results and insurance coverage that may increase test adoption. The perceived lack of genetic counseling resources and ethical concerns may inhibit the ordering of genetic testing in patients with CKD. We will present results from the complete dataset of responses to this survey of practicing general nephrologists and provide insights into their concerns about ordering genetic testing.

Conclusions: The survey results will assess current opinions on the utility of genetic testing in an adult CKD population, and identify barriers to ordering this test. Second, survey results will aid in development of targeted strategies to increase utilization of genetic testing. 1. Is There a Contribution of Genes Involved in Hereditary Nephropathies to AKI?

Sol M. Carriazo,[1,2] Maria Dolores Sanchez-Nino,[1] Laura J. Castañeda Infante,[1] Alberto Ortiz.[1] *[1]Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; [2]Universidad Autonoma de Madrid, Madrid, Spain.*

Background: The diagnosis of hereditary kidney disease has been improving with the use of novel diagnostic tools in the last decades. More than 600 genes have been detected using techniques such as whole exome sequencing. However, it is not clear if those genes causing hereditary nephropaties have any independent contribution in the pathogenesis of acquired nephropaties.

Methods: We analyzed the kidney transcriptomic after 24 hours of acute kidney injury (AKI) induced by folic acid in a murine model. In this database we evaluated if 625 genes described as responsible for hereditary nephropathies were expressed significantly. Later, using transcriptomic databeses of human nephropathies (Nephroseq), we evaluated the correlation between those differentially expressed genes and glomerular filtration. Using the software Gorilla, a functional enrichment analysis was done. Some of those were validated in our laboratory using RT-PCR.

Results: Among 25051 genes, 7443 (29.7%) were found to have a significant modification in their expression in AKI ($p<0.05$). When analyzing 625 responsible for familiar nephropaties, we identified 615 in our database. 260 (41,6%) of those genes were differentially expressed in our model. An association between 241 of those 260 differentially expressed genes and glomerular filtration rate in human nephropaties was identified. The most enriched GO process were "complement activation", "protein activation cascade", "activation of immune response" and "RNA processing". 7 of the 241 mentioned genes, showed changes greater than twofold. On the other hand, 18 of the 241 showed more than a half-fold change. We have validated the expression of 2 of the genes in acute kidney injury (SLC34A3, FN1), which supports the relevance of the transcriptomic results.

Conclusions: Several genes responsible for familiar nephropathies are differentially expressed in acquired nephropathies, suggesting that they could play a role in its

pathogenesis, through complement activation, protein activation of immune response and the regulation of the RNA processing. The identification of those genes showing a more significant change will allow us to select candidates for further studies and new possible therapeutic targets in kidney damage.

Features of Hereditary Nephropathy with COQ8B Mutation

Jiwon M. Lee.[1,2] *[1]Chungnam National University, Daejeon, Daejeon, Republic of Korea; [2]Chungnam National University Hospital, Daejeon, Daejeon, Republic of Korea.*

Background: Mutations in the genes related to biosynthesis of Coenzyme Q 10 (CoQ_{10}, ubiquinone) cause primary CoQ_{10} deficiency resulting in various clinical phenotypes. *COQ8B* (also known as *ADCK4*) has been first reported in association with nephropathy in 2013, and previously a Korean cohort has reported six patients, notably accompanied by medullary nephrocalcinosis in all the six cases. Because these patients can benefit from CoQ_{10} replacement, early differential diagnosis is essential. This study systematically reviewed clinical features and genotypes of patients with *COQ8B*-associated nephropathy.

Methods: Electronic databases were searched using related terms (till March 30, 2020). This report adhered to the Preferred Reporting Items for Systematic Reviews and Meta-analyses guidelines.

Results: From 126 articles searched, there were 11 eligible studies with 49 patients with *COQ8B*-associated nephropathy. Of them, 26 patients were Caucasian and 21 were Asian (the rest had no data regarding ethnicity). Female to male ratio was 2:1. Median age at diagnosis was 14.6 years. Proteinuria was reported in 100% of the patients with median serum albumin level of 3.7 g/dL and creatinine level of 1.45 mg/dL. Twenty two patients (43%) had chronic kidney disease and twelve patients had end-stage renal disease (25%)/ Transplantation was performed in 6 cases out of which 5 had no recurrence. Of 33 patients available for pathology reports, most (32/33, 97%) patients showed histology compatible with focal segmental glomerulosclerosis (FSGS) and seven (14%) patients had abnormal mitochondrial aggregation in the podocyte cytoplasm visualized by electon microscopy. Seven (14%) patients presented with medullary nephrocalcinosis who were notably all Koreans. Outcomes related to CoQ_{10} replacement was reported in 14 cases and half of them reported partial or complement remission. Effect of calcineurin inhibitors were reported in 7 cases which showed partial remission in 4 cases.

Conclusions: *COQ8B*-associated FSGS is a rare hereditary nephropathy which can greatly benefit from early diagnosis and CoQ_{10} supplement. Aberrant mitochondrial accumulation in the cytoplasm of the podocytes and increased medullary echogenicity may add to diagnostic suspicion. So far, all patients with *COQ8B* mutation reported in South Korea had medullary nephrocalcinosis.

PO1660

CKD in Patients with Primary Hyperoxaluria Type 3: A Meta-Analysis from Literature

Cristina Martin Higueras,[1] Kelly Barrios,[2] Bernd Hoppe.[3,2] *[1]Dept. Ciencias Médicas Básicas, Fac. Medicina, Universidad de la Laguna, Tenerife, Spain; [2]Dicerna Pharmaceuticals, Inc., Lexington, MA; [3]German Hyperoxaluria Center, Bonn, Germany.*

Background: Primary hyperoxaluria type 3 (PH3) is considered the most benign phenotype of all forms of primary hyperoxaluria. Being it typical that patients with PH type 1 and 2 develop chronic kidney disease (CKD) or end-stage renal disease (ESRD), it appears to be more or less uncommon that patients with PH3 are on risk of CKD and even do not develop ESRD. We now aimed to determine the number of PH3 patients reported to have any kind of CKD.

Methods: We performed a literature meta-analysis, searching in PubMed and Embase with the following keywords: primary hyperoxaluria, PH, primary hyperoxaluria type III, PH III or PH3.

Results: We found 151 patients in 18 relevant papers published between 2010-2019. Age of diagnosis/disease onset ranged from 1 month to 48 years of life. Most of the patients suffered recurrent urolithiasis, most often during the first years of life, but recurrent kidney stone episodes were also found later in life. The most common mutations found were the c.700+5G>T splice site mutation (37%) and the p.E315del mutation (22%). In 77 patients any information was provided with regard to renal function, in 22 of those kidney function was said to be normal, but no eGFR or CKD stage was mentioned. In 25 patients kidney function was found to be normal based on eGFR levels. CKD stage 1 was reported in 21 patients, CKD stage 2 in 5 patients, CKD-3 in 2 patients and 1 patient each had CKD stage 4 or ESRD, respectively. In 10 patients, follow-up measures were available, as their data were included in two papers (5 years apart from each other). Here, in 1 patient eGFR significantly declined from 134 to 68.1 ml/min/1.73 m^2, while 2 patients remained in CKD-1 and in 5 kidney function remained normal over time. In 1 patient kidney function ameliorated under standard treatment of care from CKD 1 to normal.

Conclusions: There is a massive bias in the data published, as data on kidney function is mostly not completely reported. Kidney function was normal only in 22 of the 54 patients (41%) with complete information. CKD-2 or worse was observed in 16.7% of PH3 patients, and even one patient with ESRD was described. Also, one PH3 patient had died at age 4 months because of respiratory failure and not because of PH. Thus, as true long-term follow-up data is still missing, we nevertheless suspect PH3 not being as benign as currently being reported.

Segmental Expression of Nephrin in the Slit Diaphragm of a Patient with a Nonsense Mutation in NPHS1

David Unnersjö-Jess,[1,2] Linus Butt,[1,2] Lina Hieronymi,[1,2] Martin Höhne,[1,2] Hans Blom,[4] Peter Hoyer,[3] Bernhard Schermer,[1,2] Thomas Benzing.[1,2] *[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [3]Pediatric Nephrology, Pediatrics II, Univeristy of Duisburg-Essen, Cologne, Germany; [4]Science for life Laboratory, Dept. of Applied Physics, Royal Institute of Technology, Solna, Sweden.*

Background: Nephrotic syndrome due to nonsense mutations in the *NPHS1* gene typically presents with a severe congenital proteinuria. However, patients harboring nonsense mutations close to the carboxyl terminus of the *NPHS1* encoded nephrin protein can present with a milder phenotype. In this study, we use high-resolution microscopy to investigate the expression pattern of nephrin p.1160X in a patient with such a mutation.

Methods: We used confocal and stimulated emission depletion (STED) microscopy to visualize the distribution of nephrin p.1160X at the glomerular filtration barrier and to study the correlation between nephrin expression and foot process morphology.

Results: Confocal microscopy revealed a highly heterogeneous expression pattern of nephrin p.1160X. While most glomerular capillaries showed absence of nephrin, there were sharply defined patches with almost normal levels (see figure). To clarify whether this unexpected pattern was due to sporadic re-expression of a wild-type nephrin, we used antibodies raised against the carboxyl terminus of nephrin which is lacking in the mutant protein. These data confirmed expression of nephrin p.1160X. Moreover, qPCR and cell culture experiments indicated normal levels of nephrin mRNA, but a decreased stability of p.1160X nephrin which could partly be rescued by inhibition of proteasomes.

Conclusions: We here show, that mutations in *NPHS1* may result in heterogeneous expression patterns of the truncated protein. We also found a directly observable link between insertion of nephrin in the slit diaphragm and normal foot process morphology. Taken together, these data suggest potential therapeutic interventions targeting proteasomal degradation of nephrin as a novel treatment strategy in selected patients with congenital nephrotic syndrome.

Funding: Government Support - Non-U.S.

PO1662

A Delayed Diagnosis of Gordon Syndrome: Better Late Than Never!

Meenakshi Sambharia, Christie P. Thomas, Lama A. Noureddine. *University of Iowa, Iowa City, IA.*

Introduction: Gordon syndrome, also known as Pseudohypoaldosteronism Type II (PHA-II) or Familial Hyperkalemic Hypertension (FHH), is a rare Mendelian syndrome causing hypertension(HTN), hyperkalemia and non-anion gap metabolic acidosis. Genes responsible are the with- no-lysine kinase 1 and 4 (WNK1/WNK4), kelch-like 3 (KLHL3) and cullin 3 (CUL3). WNK1/WNK4 are expressed in the DCT, connecting tubule and collecting duct. WNK4 reduces cell surface expression of the thiazide sensitive Na-Cl co-transporter (NCCT) and the potassium channel, ROMK. WNK1 prevents WNK4 from interacting with NCCT. KLHL3 and CUL3 are part of a ubiquitin ligase complex that targets WNK4 for degradation. While FHH from WNK1, WNK4 and CUL3 have an autosomal dominant (AD) mode of inheritance, disease from KLHL3 can be autosomal recessive (AR) or AD. AR disease presents at an earlier age with severe hypertension and hyperkalemia.

Case Description: A 56-year-old Caucasian male with history of recurrent atrial fibrillation with multiple cardioversions was referred to renal clinic for evaluation of chronic hyperkalemia. Upon presentation, he had been on furosemide 40mg and sodium polystyrene sulfonate (SPS) 30mg daily for the last 6 years for K^+ values as high as 7 mEq/L

with normal renal function. Initially the hyperkalemia was attributed to Type IV RTA from heavy NSAID use. Renin and aldosterone levels were low at 0.1ng/ml/hr and 6.1ng/dl respectively. He was suspected to have Gordon syndrome and was referred for genetic counseling and testing. He had a family history of HTN in his mother, father and multiple brothers. His daughter, in her 30s, also had a history of long-standing hyperkalemia. Genetic testing identified a heterozygous likely pathogenic missense variant in KLHL3: ***NM_001257194:c.1487G>A,p.Arg496His.*** Based on prior reports and within this clinical context, this variant confirmed a diagnosis of AD FHH. Furosemide was switched to low hydrochlorothiazide, SPS was discontinued and hyperkalemia resolved.

Discussion: Hypertension with hyperkalemia should prompt evaluation for Gordon syndrome. Thiazides are the treatment of choice. When suspected, genetic testing confirms diagnosis, prompting disease-guided therapy and preventing life-threatening consequences.

PO1663

Burden of Alport Syndrome in the United States: A Retrospective Observational Cohort Study Using Optum Humedica Data

Amanda Wilson, Ali Hariri, Pronabesh Dasmahapatra. *Sanofi Genzyme, Cambridge, MA.*

Background: To understand patient characteristics, treatment patterns and natural history of patients diagnosed with Alport syndrome (AS) in the US.

Methods: The study was a retrospective, observational cohort study of electronic health records (EHRs) in the Optum Humedica database. Patients were identified from January 1, 2008 to March 31, 2018, with 1+ inpatient or 2+ outpatient encounters (at least 30 days apart) by ICD-10 code, or by ICD-9 code with at least 2 non-negative mentions of AS in the physician notes within 90 days of diagnosis. Controls were matched to cases on age, sex, and Elixhauser Comorbidity Index (excluding kidney-related comorbidities). All patients had 12 months of activity prior to the AS diagnosis.

Results: A total of 628 patients met the AS criteria; 624 were matched with 2,496 non-AS controls. Median age was 38 years (47.6% were 40 years or older) and 43% were female. At baseline, 27.4% of the AS cohort recieved ACE inhibitors and 11.7% with ARBs, as compared with 15.8% and 6.8% of the controls, respectively ($p<0.0001$ for both); 25 (4%) of the AS cohort and 2 (0.1%) of the matched non-AS cohort had a kidney transplant ($p<0.001$). Baseline eGFR was significantly lower in the AS cohort (mean [sd] 54.4 [42.5] mL/min/1,73 m^2) compared with the matched non-AS cohort (mean [sd] 96.7 [32.8] mL/min/1,73 m2; $p<0.001$). Median time to ESRD was 504 days, to kidney transplant 786.5 days, and to death 807 days.

Conclusions: Alport syndrome has a significant unmet medical need due to the burden of kidney disease and short time to onset ESRD.

A Case with Somatic and Germline Mosaicism in *COL4A5* Detected by Multiplex Ligation-Dependent Probe Amplification in X-Linked Alport Syndrome

Yuya Aoto,[1] Koichi Nakanishi,[2] China Nagano,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Shinya Ishiko,[1] Nana Sakakibara,[1] Yuko Shima,[3] Kazumoto Iijima,[1] Kandai Nozu.[1] Department of Pediatrics, Kobe University Graduate School of Medicine *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Department of Child Health and Welfare (Pediatrics), Faculty of Medicine, University of the Ryukyu, Nishihara, Japan; [3]Department of Pediatrics, Wakayama Medical University, Wakayama, Japan.*

Introduction: X-linked Alport syndrome (XLAS) is a progressive hereditary kidney disease caused by mutations in *COL4A5* gene encoding the type IV collagen α5 chain. To date, 11 cases with somatic mosaicism in *COL4A5* have been reported; however, all of them involved single-nucleotide variations (SNVs). Copy number variations (CNVs) in *COL4A5* have also been reported, and pathogenic CNVs are relatively rare. Here, we report a female XLAS patient with somatic mosaicism identified by CNVs in *COL4A5*.

Case Description: The case was a 35-year-old female, the mother of the proband, whose only clinical symptom was hematuria. The proband was the son of this patient. His hematuria was detected at 3 months of age, and gross hematuria was occasionally exhibited. At the age of 2, proteinuria was persisted, so kidney biopsy was performed. The pathological findings showed diffuse thin basement membrane and partial basket-weave change. Then he was conducted a gene test at the age of 4. He exhibited moderate proteinuria (0.68 g/g creatinine) and hematuria, and his serum albumin was slightly low (3.5 g/dl). He had bilateral hyperopia but no deafness or kidney dysfunction. There was no familial history of ESRD. He diagnosed with XLAS by gene testing, which showed a large hemizygous deletion from exon 3 to 51 in *COL4A5* detected by *next-generation sequencing* and then confirmed by *multiplex ligation-dependent probe amplification* (MLPA). Then, MLPA analysis revealed that the female patient had the same deletion with only a 20% copy number reduction compared with a normal female control; she was thus diagnosed with XLAS with somatic mosaicism.

Discussion: Previous XLAS cases with somatic mosaicism in *COL4A5* had SNVs, and these changes could be detected by sequencing analysis. In contrast, our case had somatic mosaicism of CNVs in *COL4A5*. CNVs in *COL4A5* are relatively rare (5%) and, CNVs were usually detected by the absence of PCR products or MLPA. This case clearly featured a germline variant because the patient's son exhibited XLAS. In conclusion, this is the first case report with somatic and germline mosaicism caused by CNVs in an XLAS patient detected by MLPA. This information was important for the genetic counseling of this affected family.

PO1665

Phenotype Characteristics of Patients with Novel and Described COL4A5 Mutations Causing X-Linked Alport Syndrome in Croatian Population

Danica G. Ljubanovic,[1,2] Matija Horacek,[2] Petar Senjug,[1] Tamara Nikuseva-Martic,[2] Marija Senjug Perica,[4] Maja Oroz,[2] Dragan Klaric,[5] Ivica Horvatic,[1] Danko Milosevic,[3,2] Danica Batinic,[4,2] Kresimir Galesic.[1,2] *[1]University Hospital Dubrava, Zagreb, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia; [3]University Hospital Centre Zagreb, Zagreb, Croatia; [4]Children's Hospital Srebrnjak, Zagreb, Croatia; [5]Zadar General Hospital, Zadar, Croatia.*

Background: Alport syndrome (AS) is an inherited renal disorder caused by mutations in collagen IV genes. The most common type is X-linked AS caused by COL4A5 mutations which presents as a progressive nephritis with hematuria, ultrastructural changes of glomerular basement membrane, sensorineural hearing loss and ocular lesions. Males are usually more severely affected.

Methods: We are presenting genotype-phenotype correlation for Croatian patients with X-linked AS. Next generation sequencing for COL4A3, COL4A4 and COL4A5 was performed as part of the nationwide project "Genotype-phenotype correlation in Alport syndrome and thin basement membrane nephropathy (TBMN)". There were 24 male and 26 female patients from 36 unrelated families. Probands were selected based on the kidney biopsy findings.

Results: We have identified 23 mutations, 13 being novel and 10 previously reported. In two patients additional COL4A4 mutations were found. Male patients, median age 27 years, presented with hematuria (96%), proteinuria (54%), sensorineural hearing loss (27%) and ocular changes (4.5%). Most patients (62%) had normal, 17% mildly and 21% moderately reduced kidney function. No one had severe renal insufficiency or ESRD. Kidney biopsy was performed in 18 male patients and AS was the most common diagnosis (67%) followed by TBMN with FSGS (17%) and isolated TBMN (11%). In one patient (5%) the diagnosis was inconclusive for AS or TBMN. Female patients, median age 16 years, presented with hematuria (89%) and proteinuria (19 %). There were no ocular abnormalities and the hearing loss was present in 5% of patients. Most females (73%) had normal kidney function while 8% had mild, 12% moderate, 3.5% severe reduction of renal function and 3.5% had ESRD. The kidney biopsy was performed in 14 female patients. The most common diagnosis was AS (65%) followed by isolated TBMN (21%) and TBMN with FSGS (7%). Only 1 specimen (7%) was signed out as inconclusive for AS or TBMN.

Conclusions: We have presented characteristics of 50 Croatian patients with X-linked AS. In our cohort 56% of mutations were novel. While renal biopsy provides information about degree and the type of renal parenchyma damage, genetic analysis is crucial for diagnosis.

Clinomics Implementation in the Mayo Clinic Nephrology Practice

Marie C. Hogan,[1] Filippo Vairo,[4] John C. Lieske,[1] Fernando C. Fervenza,[1] Stephen B. Erickson,[1] Mireille El Ters,[1] Linnea Baudhuin,[5] Ann M. Moyer,[5] Emily C. Lisi,[6] Jennifer L. Kemppainen,[7] Carri Prochnow,[4] Konstantinos N. Lazaridis,[4] Sam Albadri,[2] Lynn D. Cornell,[2] Peter C. Harris.[3] *[1]Mayo Clinic MN Div of Neph & HTN, Rochester, MN; [2]Mayo Clinic Dpt of Renal Pathology, Rochester, MN; [3]Mayo Clinic Dpt of Neph & HTN Research, Rochester, MN; [4]Mayo Clinic Ctr for Individualized Medicine, Rochester, MN; [5]Mayo Clinic Personalized Genomics Laboratory, Rochester, MN; [6]Wake Forest University, Winston-Salem, NC; [7]Mayo Clinic Dpt of Clinical Genomics, Rochester, MN.*

Background: Next generation sequencing has been increasingly used to diagnose monogenic kidney diseases. In 2018, we launched the Nephrology Genetics Clinic (NGC) with a primary focus to identify the etiology of unexplained nephrotic syndrome, chronic kidney disease, or stone disease/nephrocalcinosis. An essential component of the NGC is the Genomic Odyssey Board (GOB) which consists of nephrologists, geneticists, genetic counselors, pathologists, translational 'omics scientists, and trainees who meet at least monthly to interpret the genetic findings in the context of the patient's clinical data. Clinical and research follow-up recommendations are made after this careful multidisciplinary review and discussion.

Methods: In 2018 and 2019, the GOB reviewed 118 cases (9 cystic, 79 glomerular, 4 CAKUT, 10 stones, 7 tubulo-interstitial (TI), and 9 other; **Table 1**). Genetic testing was performed with a targeted analysis of 344 kidney disease-related genes (with *MUC1* variant analysis in subset of TI cases).

Results: A definite genetic diagnosis was achieved for 34 families (29%). After a multidisciplinary evaluation of variants of uncertain significance (VUS), another 16 (13.6%) were deemed to have variants likely related to the phenotype. The highest diagnostic yield was achieved in individuals with TI diseases (50%), followed by cysts (33.3%), glomerular (28.7%), CAKUT (25%), stones (20%), and others (11%). Of the unresolved/partially resolved cases, the GOB decided to pursue research activities such as trio whole exome sequencing or transcriptome sequencing for 22 (31%) families.

Conclusions: Implementation of genomic testing and analysis by a multidisciplinary team in a nephrology cohort with clinically suspected monogenic disease has provided a firm diagnosis in 29% of families, often resulting in changes in management/treatment. Ongoing research screening is likely to increase this yield.

CD11b Activation Suppresses Pro-Inflammatory suPAR in Myeloid Cells and Reduces Lupus Nephritis in Mice

Veronica Villanueva,[2] Xiaobo Li,[2] Samia Q. Khan,[2] Sanja Sever,[1] Jochen Reiser,[2] Vineet Gupta.[2] *[1]Harvard Medical School, Boston, MA; [2]Rush University Medical Center, Chicago, IL.*

Background: Lupus nephritis (LN) is a debilitating glomerular disease and a comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin CD11b/CD18, plays a critical role in cell signaling. Several mutations in the gene ITGAM, encoding CD11b, are associated with SLE and LN, these mutations are reported to reduce integrin function. suPAR is produced by myeloid cells upon pro-inflammatory activation and is a circulating risk factor for glomerular diseases. suPAR is downstream of Toll-like receptor signaling, where TLR-activation increases suPAR levels. We previously showed that activation of CD11b suppresses TLR-dependent pro-inflammatory signaling. Here, we investigate if this mechanism includes control of suPAR levels, which may provide novel therapeutic options for LN.

Methods: To investigate TLR-dependent signaling affected by CD11b activation, we utilized in vitro assays using primary macrophages and genetically engineered K562 cells expressing CD11b and CD18. K562 cells were developed to express either wild type CD11b or CD11b carrying mutations commonly found in LN patients. These cells were treated with TLR agonists or LN patient sera and level of suPAR in cell supernatants was assessed by ELISA. For complementary in vivo studies, we utilized our newly generated mouse model, where we incorporated a constitutively active CD11b point mutation (I332G) globally in mice to generate a model for CD11b activation – CD11b knock-in model. C57BL/6 wild type mice, the CD11b knock-out and the CD11b knock-in mice were used in models of SLE and LN to determine the effect of CD11b activation on circulating suPAR levels and course of the disease.

Results: TLR-stimulation increased suPAR levels in vitro and in vivo. Importantly, CD11b activation resulted in significantly reduced suPAR levels in both systems, suggesting a novel mechanism for controlling glomerular diseases. Additional mechanistic studies are on-going to define the exact molecular mechanism of action.

Conclusions: Using these models, we have identified a possible link between CD11b activation and suPAR levels in myeloid cells. These studies will provide understanding of the influence CD11b has on signaling pathways and inflammation associated with LN.

Drug-Induced Thrombotic Microangiopathy as a "Second-Hit" Phenomenon

Aimen Liaqat, Ali Mehdi, Mohamed Hassanein, Tushar J. Vachharajani. *Cleveland Clinic, Cleveland, OH.*

Introduction: Thrombotic Microangiopathy (TMA) syndrome is a diverse group of inherited or acquired diseases characterized by microvascular thrombosis and endothelial damage. Etiologies include drugs, thrombotic thrombocytopenic purpura, shiga toxin mediated hemolytic uremic syndrome (HUS), and complement mediated HUS. Environmental triggers are proposed as a second hit precipitating the disease process in some cases of atypical HUS (aHUS). We hereby present a case of drug induced TMA in a patient with an underlying pathogenic mutation for aHUS.

Case Description: 41-year-old male with presented to an outside hospital with AKI requiring dialysis and uncontrolled hypertension. He had a positive urine toxicology and admitted to marijuana, amphetamines (crystal meth), and heroin use. Labs revealed severe anemia and thrombocytopenia along with low haptoglobin, elevated LDH, and schistocytes on blood smear. Shiga toxin assay was negative with normal ADAMS-TS 13 and coagulation profile. C3 was notably low at 63 mg/dL. As such, he was diagnosed with presumed aHUS and treated with steroids, eculizumab, and plasmapheresis. He was then transferred to our facility where a kidney biopsy confirmed TMA. The etiology was presumed to be drug induced, however genetic evaluation showed heterozygosity for a pathogenic variant in the Complement Factor H (CFH) gene region. Notably, his sister also carried the diagnosis of aHUS. The patient was restarted on eculizumab and remained dialysis dependent on discharge. Unfortunately, he was then lost to follow up.

Discussion: Atypical HUS is associated with a myriad of genetic mutations involving the alternate complement pathway. Pathogenic variants of CFH gene have been implicated in autosomal dominant and recessive forms of the disease. While drug use might have triggered the TMA in our patient, it is likely that his underlying mutation was the first hit creating a disease predisposition. It remains unclear how frequently a culprit mutation is present in patients with presumed drug induced TMA. However, in patients with persistent TMA and a suggestive family history, clinical suspicion for aHUS should be maintained. This distinction is important as drug discontinuation alone would be ineffective for aHUS whereas complement-blocking therapies could be potentially curative.

PO1669

In Silico Prediction Performance for Type IV Collagen Variants

Cole Shulman,[3] Emerald Liang,[3] Misato Kamura,[1] Khalil Udwan,[3] Tony Yao,[3] Daniel C. Cattran,[3] Heather N. Reich,[3] Michelle A. Hladunewich,[2] York P. Pei,[3] Judith A. Savige,[5] Andrew Paterson,[4] Mary Ann Suico,[1] Hirofumi Kai,[1] Moumita Barua.[3] *[1]Kumamoto Daigaku, Kumamoto, Japan; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada; [4]Hospital for Sick Children, Toronto, ON, Canada; [5]The University of Melbourne, Melbourne, VIC, Australia.*

Background: Advances in genomics technology and knowledge has led to increased sequencing for diagnosis, including in kidney disease. However, sequencing can reveal rare missense variants for which the relationship to disease is unclear. To address this need, *in silico* programs have been developed to assign variant categorization. Recently, pathogenic variants in *COL4A3/A4/A5* have been reported to account for a significant minority of chronic kidney disease. Here we evaluate the performance of *in silico* programs for type IV collagen variants.

Methods: Rare *COL4A3/A4/A5* missense variants were identified in an FSGS cohort, unscreened controls (gnomAD) and disease databases (ClinVAR, ARUP, LOVD). Comparisons between *in silico* predictions, disease database classifications and functional characterization were performed.

Results: *In silico* predictions and functional characterization classified all 9 definitely pathogenic *COL4A3/A4/A5* variants in the FSGS cohort correctly. *In silico* predictions correctly classified the majority (93-97%) of definitely pathogenic *COL4A3/A4/A5* variants in ClinVAR, ARUP and LOVD. However, a significant proportion of benign variants were predicted as pathogenic. Thirty-five percent of *COL4A3/A4/A5* missense variants obtained from gnomAD were also predicted deleterious. *In silico* predictions tended to overestimate the effects of *COL4A* variants of uncertain significance (VUS) when compared to functional characterization.

Conclusions: Our results demonstrate that *in silico* programs are sensitive but not specific to assign *COL4A3/A4/A5* variant pathogenicity, with misclassification of benign variants. Limitations of our computational work include overestimation of *in silico* program sensitivity given that they have likely been used in the categorization of variants labelled as pathogenic in disease databases; and the lack of clinical data to correlate rare variants in gnomAD controls.

Genetic Studies of the Etiology and Complications of Nephrotic Syndrome by Large-Scale Exome Sequencing

Dina Ahram,[1] Adele Mitrotti,[1] Avinash V. Dharmadhikari,[1] Gina Ying Jin,[1] Byum hee Kil,[1] Enrico Cocchi,[8] Francesco Scolari,[2] Marijan Saraga,[3] Danko Milosevic,[4] Gianluigi Zaza,[15] Domenico Santoro,[9] Giovanni Montini,[10] Landino Allegri,[11] Pasquale Esposito,[12] Sandro Feriozzi,[13] Patricia L. Weng,[14] Loreto Gesualdo,[5] Vimla Aggarwal,[1] Gerald B. Appel,[1] Enrico Fiaccadori,[16] Ali G. Gharavi,[1] Yasar Caliskan,[6] Gian Marco Ghiggeri,[7] David B. Goldstein,[1] Simone Sanna-Cherchi.[1] Sanna Cherchi Lab *[1]Columbia University Irving Medical Center, New York, NY; [2]Divisione di Nefrologia, Ospedale di Montichiari, Brescia, Italy; [3]Department of Pediatrics, University Hospital of Split, Split, Croatia; [4]Department of Pediatric Nephrology, Dialysis and Transplantation, University Hospital Center Zagreb, Zagreb, Croatia; [5]Department of Medicine, University of Bari Aldo Moro, Bari, Italy; [6]Saint Louis University School of Medicine, Saint Louis, MO; [7]Division of Nephrology, Dialysis, Transplantation, and Laboratory on Pathophysiology of Uremia, Genova, Italy; [8]Department of Public Health and Paedriatric Sciences, University of Torino, Torino, Italy; [9]Division of Nephrology, University of Messina, Messina, Italy; [10]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [11]Department of Internal Medicine and Nephrology, University of Parma, Parma, Italy; [12]Department of Nephrology, Dialysis and Transplantation, University of Genoa, Genoa, Italy; [13]Nephrology and Dialysis, Belcolle Hospital, Viterbo, Italy; [14]Pediatci Nephrology, University of California Los Angeles., LA, CA; [15]Renal Unit, Department of Medicine, University Hospital of Verona, Verona, Italy; [16]Clinical and Experimental Medicine Dept, University Hospital of Parma, Parma, Italy*.

Background: Idiopathic nephrotic syndrome (NS) is a major cause of renal failure. NS and its complications, including venous thrombosis, hypercholesterolemia and cancer display strong genetic predisposition. We hypothesize that the utility of exome sequencing (ES) will optimize precision medicine for clinical management of NS and its risk factors.

Methods: ES was performed in 2007 NS patients with variable onset age and steroid responsiveness. ACMG guidelines for clinical variant interpretation were used to classify monogenic causes and risk predisposition for a) NS in curated gene lists (glomerulopathies, N=127; expanded nephropathies, N=679); b) Incidental variants in 59 ACMG actionable-genes; c) Genetic risk for NS complications (Coagulation, N=100; lipid metabolism/cardiovascular risk, N=35); d) Germline cancer predisposition (N=77).

Results: We identified a monogenic cause for NS in 13% of cases, with *COL4A3* (2.2%), *COL4A5* (1.8%) and *WT1* (1.3%) representing the lead causes. Monogenic causes were enriched in FSGS and steroid resistant nephrotic syndrome cases. Analysis of the expanded nephropathy gene panel revealed an additional diagnostic rate of ~1%, representing coincidental diagnoses or phenocopies. *APOL1* associated FSGS risk genotypes were identified in 5% of cases. Variants of actionable potential were noted in 2.9% of patients, led by *BRCA2* (3.9%), *MYBPC3* (3.5%) and *LDLR* (0.25%). Variants predisposing to coagulation defects, lipid metabolism and cancer risk were found in ~11% of cases. Overall, we identified a monogenic cause or predisposing risk factor to NS or its complications in 27%, corresponding to 1 per 4 cases.

Conclusions: Our results reveal the importance of ES in the diagnosis of NS and its complications, with implications in risk stratification and clinical management. We showed that one every 4 cases carried a genetic variant that has potential to help clinicians optimize precision medicine approaches at the single-patient level. Our results enable designing cost-effective panels to maximize yield in routine clinical practice.

Additional Mutations in NRIP1 in Families with Congenital Anomalies of the Kidneys and Urinary Tract (CAKUT)

Bixia Zheng, Sophia Schneider, Konstantin Deutsch, Chunyan Wang, Steve Seltzsam, Makiko Nakayama, Chen-Han W. Wu, Shirlee Shril, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most common cause of chronic kidney disease in the first three decades of life. In a previous study, we identified a dominant mutation in nuclear receptor interacting protein 1 (*NRIP1*) as causing urinary tract malformations via dysregulation of retinoic acid signaling (*JASN* 28:2364, 2017), which remains the only family with *NRIP1* mutation reported so far.

Methods: To identify additional families with *NRIP1* mutations, we performed whole exome sequencing (WES) in 232 families with CAKUT. We also screened for mutations in *NRIP1* in a cohort of 59 affected individuals with small kidneys and a suspected diagnosis of nephronophthisis (NPHP).

Results: By WES analyses, we discovered three heterozygous mutations (one frameshift and two missense) in three unrelated CAKUT families. In particular, individual B3864 with bilateral hydroureteronephrosis and right grade 5 vesicoureteral reflux (VUR) carried a heterozygous frameshift variant (c.2028_2031del; p.Asn676Lysfs*27). Individual A3460 with left renal agenesis harbored a heterozygous missense variant (c.970C>T; p.His324Tyr). In individual A782 with right renal agenesis, we identified a heterozygous missense variant (c.1343G>A; p.Arg448Gln). Family B3977 with an NPHP diagnosis, showing bilaterally increased echogenicity and corticomedullary cysts, carried a heterozygous missense variant (c.2252T>G; p.Leu751Arg). The four variants occurred 2, 0, 2, and 17 times, respectively as heterozygous in the gnomAD database of 125,000 healthy control individuals. All affected individuals exhibited an isolated CAKUT phenotype.

Conclusions: This study confirms that germline mutations in the transcription co-factor *NRIP1* gene are a novel genetic cause of human autosomal dominant CAKUT and strengthens the association between retinoic acid and renal malformations.

PO1672

Recessive Mutations in SEMA3G as a Potential Novel Cause of Nephrotic Syndrome

Florian Buerger,[1] Verena Klambt,[1] Ana C. Onuchic-Whitford,[1,2] Ronen Schneider,[1] Konstantin Deutsch,[1] Amar J. Majmundar,[1] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. The identification of monogenic causes of SRNS has revealed ~60 single-gene etiologies. While in 12-30% of patients with SRNS a causative mutation may be detected, many remain without a molecular diagnosis (Sadowski *JASN* 26:1279, 2015). These genes are predominantly expressed in glomerular podocytes and the encoded proteins merge onto molecular complexes and pathways that are essential to podocyte development or homeostasis.

Methods: To identify novel monogenic causes of NS, we performed whole exome sequencing (WES) in an international cohort of 1,382 NS patients.

Results: We identified homozygous mutations in *SEMA3G* in 3 unrelated children with nephrotic syndrome, 1 nonsense mutation (c.1078C>T, p.Arg360*), 1 essential splice site mutation (c.460-2A>G, predicted to lead to skipping of exon 5 and thus causing a frame-shift and truncation of the protein) and 1 missense mutation (c.2225G>A, p.Arg742Gln). SEMA3G is a secreted protein that has been implicated in cell migration and axon guidance, and shown to protect podocytes from inflammatory kidney disease in a mouse model (Ishibashi *Sci Rep* 6:25955, 2016). We evaluated publicly available kidney single-cell RNA sequencing datasets and found *SEMA3G* to be predominantly expressed in podocytes (Karaiskos *JASN* 29:2060, 2018). We then performed co-immunofluorescence staining in adult rat kidney sections for Sema3g and established markers of podocytes (nephrin), endothelial cells (CD31), and mesangial cells (αSMA). The Sema3g signal was strongest in podocyte foot processes as indicated by partial overlap with nephrin but lack of overlap with CD31, or αSMA signal.

Conclusions: We, here, identified recessive mutations in *SEMA3G* as a potential novel cause of nephrotic syndrome in children.

Gaslini, Genoa, Italy, Genoa, Italy.*

Background: Several focal segmental glomerulosclerosis (FSGS) genes have been discovered through family studies. Rare-variant case-control studies, however, have been largely underpowered and/or restricted to a single ancestry.

Methods: We performed exome sequencing of 1,989 cases with FSGS and compared them to 18,835 controls. Using gene-based collapsing, we looked for genes with an excess of rare qualifying variants (QVs) in cases or controls. Standard collapsing was complicated by the diverse ancestry of our cases that not only included African, Asian, and Hispanic samples, but also Caucasian subpopulations not well represented in public databases or our controls. Therefore, we extended our collapsing workflow by a clustering step based on principal components reflecting ancestry. We performed coverage harmonization and frequency filtering within the clusters to capture population-specific differences. We used the Cochran-Mantel-Haenszel test to test for an association between disease status and QV status while controlling for cluster membership.

Results: Collapsing analyses were conducted on all cases together and on pediatric, adult, steroid-resistant, and steroid-sensitive subgroups. We detected a significant enrichment of QVs in known FSGS genes *WT1*, *INF2*, and *NPHS2*; additional signals in other FSGS genes (e.g. *PAX2*, *COL4A3*, *COL4A5*, *CD2AP*); and two novel ones that did not reach study-wide significance due to the limited sample size and phenotype heterogeneity. In several models and subgroups, the majority of the top 10 genes was formed by known FSGS genes, confirming the robustness of our novel approach.

Conclusions: We show that our new collapsing approach decreases inflation when samples with different ancestries are analyzed together, while preserving the underlying disease signals. We are currently more than doubling our case cohort, which should increase the power to detect significant signals in known FSGS genes, clarify the suggestive signal in two new genes, and allow well-powered sub-phenotype analyses.

eNOS/NO Signaling Attenuates Progression of Age-Related Kidney Diseases via Suppression of Inflammasome

Hajime Nagasu, Yoshihisa Wada, Hiroyuki Kadoya, Megumi Kondo, Kengo Kidokoro, Eiichiro Kanda, Seiji Kishi, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Medical School, Kurashiki, Japan.*

Background: Ageing affects the function of the immune system and leads to immunosenescence, which is characterized by defective immune responses and increased systemic inflammation (also termed inflammageing). Inflammageing is maladaptive and results from multiple mechanisms, including aberrant inflammasome activation. The ASC is an essential component of inflammasome. Endothelial dysfunction is also a common pathophysiologic mechanism of age-related organ damage. Nitric oxide (NO) produced by endothelial nitric oxide synthase (eNOS) is an important mediator in the maintenance of vascular homeostasis. We've reported that the eNOS-NO pathway attenuates the progression of kidney injury via suppression of inflammasomes. However, the relationship between the eNOS-NO pathway and inflammageing in the kidney remains unclear. To determine if the eNOS-NO pathway attenuates kidney damage via the regulation of inflammasome in ageing kidney, we used eNOS-deficient mice (eNOSKO) and eNOS-ASC double-knockout mice (eNOS-ASC-DKO).

Methods: Wild-type mice (WT) and eNOSKO were used to determine the role of the eNOS-NO pathway in ageing kidneys. WT and eNOSKO were sacrificed at 18 months of age to harvest kidney tissue. The localization of inflammasome activation in the kidney was evaluated with immunohistochemical analyses. To determine the role of inflammasomes in ageing kidneys, we generated eNOS-ASC-DKO. The mRNA expression of inflammasome components were determined in isolated glomeruli.

Results: The glomerular injury was more exacerbated in eNOSKO-18M than in WT-18M. In the immunohistochemical, the expression of ASC coexisted with the macrophages detected by F4/80 staining in eNOSKO-18M. These data suggested that the inflammasome activation was located in the macrophages. In the isolated glomeruli, mRNA of inflammasome components were higher in eNOSKO-18M than in WT-18M. The glomerular damage were ameliorated in eNOS-ASC-DKO-18M compared to eNOSKO-18M. In summary, in eNOSKO, inflammasomes were activated in macrophages, and interstitial fibrosis was exacerbated. However, in eNOS-ASC-DKO-18M mice, the tubulointerstitial damage was attenuated.

Conclusions: Endothelial NOS/NO signaling ameliorates kidney damage in the aging process via the modulation of inflammageing associated with inflammasome-activation.

PO1675

Alpha Lipoic Acid Supplementation Prevents the Age-Related Decrease in Nuclear Reduced Glutathione Levels in Kidneys from Old Female Lewis Rats

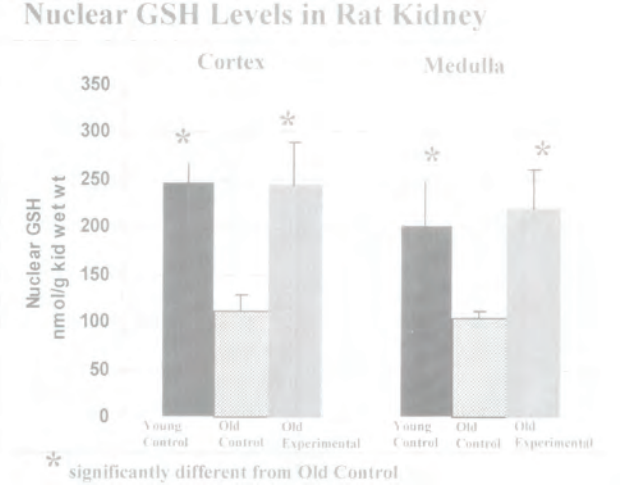
Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

Background: The purpose of the present study was to investigate whether supplementation with alpha lipoic acid reverses the decrease in nuclear reduced glutathione (GSH) levels in kidneys from old rats. GSH is the major antioxidant inside cells, and a decrease in GSH levels is associated with increased oxidative damage caused by free radicals.

Methods: There were three groups of female Lewis rats used in the study. The Young Control rats (n=4) were 3 months of age, the Old Control rats (n= 4) were 22 months of age, and the Old Experimental rats (n=4) were 22 months of age. Only the Old Experimental rats received alpha lipoic acid (100 mg/Kg body wt) by i.p. injection for one week. The kidneys were harvested from anesthetized rats, and the cortex and medulla were separated and homogenized. The nuclear fractions were isolated using differential centrifugation. The GSH levels were measured with a spectrophotometric assay. Comparisons between groups were done using ANOVA followed by the Fisher's LSD post hoc test. All data are shown as X ± SEM. Statistical significance was determined at $p \leq 0.05$.

Results: Supplementation with alpha lipoic acid reversed the age-related decrease in nuclear GSH levels in the kidney cortex and medulla from old rats. The GSH levels were not different from the levels observed in young rats.

Conclusions: The findings suggest that dietary supplementation is beneficial to cell nuclei in rat kidney by preventing the decrease in GSH levels observed with age.



PO1676

SIRT3 Confers Protection and Mediates Sex Differences in Aging-Related Kidney Injury

Huiyun Shen,[1] Michael Holliday,[1,2] Qingtian Li,[1] Li Tan,[1,3] David Sheikh-Hamad,[1,2] Jenny S. Pan.[1,2] *[1]Baylor College of Medicine Department of Medicine - Nephrology, Houston, TX; [2]Michael E. DeBakey VA Medical Center, Renal Section, Houston, TX; [3]West China Hospital, Chengdu, China.*

Background: Fibrosis and mitochondrial dysfunction are hallmarks of most progressive CKD. Studies suggest women have slower progression of CKD and lower ESKD incidence before menopause vs. men. SIRT3, a major mitochondrial acetyltransferase, is critical in maintaining mitochondrial homeostasis and anti-oxidative defense. We observe higher kidney mitochondrial SIRT3 (mtSIRT3) in females vs. males; mtSIRT3 declines with age but sex differences persist. We hypothesize that SIRT3 protects from and mediates sex differences in aging-related kidney injury and fibrosis.

Methods: Male and female WT, SIRT3 transgenic (Tg), inducible kidney tubule-specific SIRT3 knockout (iKO) or global SIRT3 KO mice were aged under physiologic conditions. Kidney fibrosis was detected by trichrome staining and expression of fibrosis markers (α-SMA; fibronectin). 6-month (mo) old male or female WT mice were treated with S.C. implantation of a 200 mg, 21-day-release testosterone pellet for 3 wks.

Results: In male mice, we observed that lower kidney mtSIRT3 expression vs. age-matched females is associated with higher baseline ROS generation, and development of tubular cytoplasmic vacuoles by 6-mo and fibrosis by 14-mo. Aging-related changes are attenuated in SIRT3 Tg males. Conversely, 6-mo iKO male mice display higher ROS, tubular injury and fibrosis vs. age-matched control males. In contrast to male mice, WT females display minimal tubular vacuolization or fibrosis at 14-mo. SIRT3 knockdown aggravates tubular injury and fibrosis in aged 14-mo iKO females; outcomes similar to WT males. Furthermore, young (2-3 mo) male and female global SIRT3 KO mice display baseline kidney injury characterized by: increased urinary albumin excretion, ROS and tubular injury vs. WT. Mechanistic studies show that testosterone (T) administration to WT males increased serum T ~4-fold, decreased kidney mtSIRT3, and caused kidney injury (decreased CrCl and increased tubular vacuolization). T increased kidney mtSIRT3 and caused no measurable kidney injury in WT females, possibly due to an associated increase in serum estradiol.

Conclusions: 1) SIRT3 is critical for kidney tubular epithelial cell survival under physiologic conditions, and inhibits development of tubular injury and fibrosis in aged kidneys; 2) sex-dependent differences in kidney SIRT3 expression may mediate sexual dimorphism in CKD outcomes.

PO1677

Percutaneous Renal Biopsy in Frail and High-Risk Patients

Dario Roccatello, Savino Sciascia, Roberta Fenoglio. *Nephrology and Dialysis Unit & CMID (Center of Research of Immunopathology and Rare Diseases), Coordinating Center of the Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital of Turin, and Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, Turin, Italy.*

Background: Many patients (pts) with End Stage Kidney Disease (ESKD) do not undergo percutaneous kidney biopsy (KB) and do lack a definite diagnosis. Whether KB is beneficial in the extreme patients' categories, remains controversial. Aim: To analyse the benefit/risk balance in terms of therapeutic options and general outcome of KB procedure in these borderline categories.

Methods: Files for all biopsies performed in our Centre between 2013 and 2019 (# 903 inpatients' native kidney) were retrospectively analysed with special focus on histological diagnosis, biopsy complications, and post-biopsy patient's outcome. Two groups of high risk patients were identified 1. >75 years old patients, and 2. patients requiring dialysis at the first clinical evaluation. A rigorous protocol of screening of the bleeding risks was adopted.

Results: Of the 903 biopsies, 217 cases had group 1, and 92 group 2 criteria. Group 1: mean age 80 years, main histological diagnoses: ANCA associated vasculitis (AAV); membranous nephropathy (MN), diabetic nephropathy, IgA glomerulonephritis (IgAGN), cast nephropathy, renal amyloidosis, focal segmental glomerulosclerosis (FSGS). Group 2: mean age 60 years, most frequent histological diagnosis: AAV; cast nephropathy, nephroangiosclerosis, IgAGN, diabetic nephropathy, renal amyloidosis; FSGS. Five major complications (2,3%), including AV fistula with spontaneous resolution in 4 pts and 1 case of severe bleeding requiring arterial embolization, and 14 minor complications (6,5%), including post biopsy haematomas <2cm in 12 pts and haematuria in 2 pts were observed in group 1. Only 1 major complication (AV fistula) and 4 minor complications, including post biopsy <2cm haematomas in group 2 were identified in group 2. Histological diagnosis conditioned or changed treatment strategy in 71% of elderly pts (group 1), and 63% of pts in dialysis (group 2). Dialysis discontinuation was achieved in 30 out of 92 pts (36,6%) with a sparing of over 1 million euro/year.

Conclusions: Given its high diagnostic value (especially in patients who are willing to be transplanted), the prognostic significance, and the potential impact on the treatment policy, indications to percutaneous KB in elderly and dialysis pts should be probably revised.

PO1678

CKD Is an Independent Risk Factor for Mortality in Elderly Patients Affected by COVID-19

Venceslau A. Coelho, Marlon J. Aliberti, Thiago Silva, Felipe V. Moreira, Otavio Fortes, Rosa M. Moyses, Wilson Jacob Filho, Rosilene M. Elias. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: COVID-19 infection, an acute respiratory syndrome caused by coronavirus, has recently emerged as a lethal pandemic. Many elderly patients have chronic kidney disease and several other comorbidities that are associated with worse outcomes. We hypothesized chronic kidney disease (CKD) in elderly patients is an independent risk of mortality and more severe COVID-19, even after adjustment for comorbidities.

Methods: This is a retrospective study, which enrolled 120 patients attended in a tertiary academic hospital divided into 2 groups, CKD (N=58) and non-CKD (N=62), according to eGFG < or ≥ 45ml/min/1.73m^2. Charlson Comorbidity Index was used to evaluate comorbidities.

Results: Patients with CKD have a significantly (all p values <0.05) higher leucocytes count, C-reactive protein, troponin, and lactate dehydrogenase; they also presented lower albumin. There was no difference in body mass index (BMI), lymphocytes, hemoglobin, age, gender, Charlson Comorbidity Index, or duration of symptoms between groups. Patients with CKD presented more severe COVID-19, as evidenced by a higher inspiratory oxygen fraction (p=0.001), major radiological findings in computed tomography, ground-glass opacity (25% non-CKD and 53.1% CKD group presented lesion in >75% lung, p=0.042), and higher mortality (40.3% non-CKD vs. 75.9% CKD, p=0.0001). Logistic linear regression has revealed that CKD (RR 5.4, p=0.0001) was independent associated with mortality after adjustment for Charlson comorbidity Index (RR 1.2, p=0.034), age (p=0.551), gender (p=0.820) and BMI (p=0.941).

Conclusions: Elderly patients with CKD have a higher and independent risk for mortality after COVID-19. These patients should be closely monitored during this pandemic situation in order to avoid further damage.

PO1679

Efficient Follow-Up and Its Effects on Questionnaire Responses in the EQUAL Study in the United Kingdom

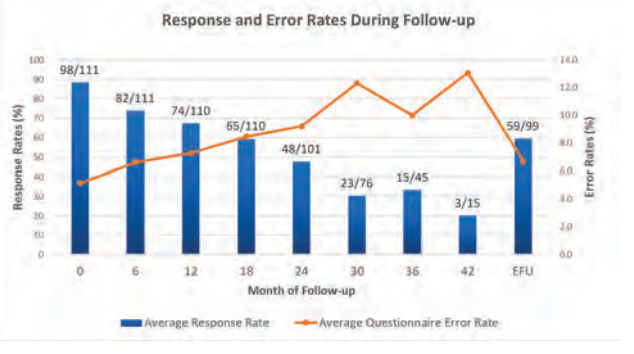
Emer R. Gates,[1] Barnaby D. Hole,[2,1] Samantha J. Hayward,[1,2] Fergus J. Caskey.[2,1] EQUAL Investigators *[1]North Bristol NHS Trust, Westbury on Trym, United Kingdom; [2]University of Bristol, Bristol, United Kingdom.*

Background: Minimising patient contact is more important amidst the COVID-19 pandemic; yet altering follow-up data collection methods may introduce unintentional bias. We describe our findings from the European Quality (EQUAL) study in which UK patients switched from 'traditional' clinic follow-up (TFU) to 'efficient' postal follow-up (EFU).

Methods: EQUAL is a prospective study on treatment in people aged ≥65 with advanced chronic kidney disease (eGFR ≤20mL/min/1.73m^2). UK patients were recruited to EQUAL from 2013-2017. During TFU, patients were invited to complete a questionnaire (SF-36, Dialysis Symptom Index and Renal Treatment Satisfaction Questionnaire) at research clinics every 3-6 months. In 2018, all alive patients were invited to switch to EFU, which used an abbreviated questionnaire administered centrally by post. Questionnaire response and error rates for six-monthly TFU and the first EFU are presented for UK patients who consented to EFU.

Results: In total, 506 UK patients were recruited. In 2018, 236 of these patients were alive and almost half (n=111) consented to the change in follow-up. Of those consenting to EFU, response rates fell from 88.2% (98/111) to 59.0% (65/110) for patients who completed 1.5 years of TFU. Of those who were recruited earlier and had completed 3.5 years of TFU, response rates fell again to 20% (3/15). The response rate for the first EFU questionnaire was 59.6% (59/99) of those alive. Errors almost trebled throughout TFU, before falling to baseline at the first EFU.

Conclusions: In this prospective study of older people with advanced CKD, response rates fell and error rates rose during TFU. On introducing a shorter postal questionnaire, response and error rates improved to levels resembling early TFU. This suggests that even in older people with advanced CKD, returning questionnaires by post is acceptable and may provide more complete data than costly TFU. This is acutely relevant in this period of limited contact in the COVID-19 pandemic.



Response and error rates across follow-up, from those consenting to EFU.

PO1680

CKD in the Very Elderly: When Is It Only Aging?

Marina Reis, Ana Marta Gomes, João C. Fernandes. *Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal.*

Background: Chronic kidney disease (CKD) diagnosis is increasingly common in the elderly and is associated with increased morbidity and mortality. As life expectancy increases, so does the prevalence of risk factors for CKD such as hypertension and diabetes. On the other hand, it is known that after 30 years, glomerular filtration rates decrease progressively, in a process called renal senescence. This study aims to identify risk factors for progressive CKD *versus* renal senescence in patients over 80 years.

Methods: We developed a single center retrospective study with 101 patients over 80 years followed by a nephrologist with CKD (estimated glomerular filtration rate (GFR) < 60 mL/min/ 1.73 m²) diagnosed for at least for 5 years. Progressive disease was defined as GFR decline greater than 5 mL/min/1.73 m²/year.

Results: Of 101 patients, 55.4% (n = 56) were male. Thirty eight percent presented CKD of undetermined etiology. Average GFR progression rate was 2.0 ± 4.4 ml/min/1.73m² /year and in about 66% GFR decline rate was less than 5 ml / min / 1.73m². Regarding CKD complications, 37.6% had anemia and 18.7% needed erythropoiesis-stimulating agents. No patient was under phosphate binders and 4% needed vitamin D analogues. About 20.9% presented metabolic acidosis requiring supplementation. In the progressive CKD group, there was a higher prevalence of obesity (OR 4.1, p = 0.04) and metabolic acidosis (OR 6.1, p = 0.01). Nephrologist follow-up time was also statistically different between the groups (6.1 years in progressive CKD vs 4.1 years in non-progressive CKD, p = 0.04). In the multivariate analysis, only the presence of metabolic acidosis (1.07, 95% CI [1.1-7.5]) was associated with the development of progressive CKD.

Conclusions: In patients over 80 years, average rate of progression of CKD was 2.0 mL / min / 1.73 m2 / year, which, associated with the reduced life expectancy of patients in this age group, allows us to state that the vast majority will not reach CKD stage 5. According to this resuts, only patients with metabolic acidosis are at risk of developing progressive CKD. Nephrology consultation does not seem to have an impact on CKD progression, since the group with progressive disease had the longest follow-up.

PO1681

Using the Difference in Estimated Glomerular Filtration Rate by Cystatin C vs. by Serum Creatinine (eGFRDiff) to Assess Muscle Mass and Frailty in Older Adults

O. Alison Potok,[1] Joachim H. Ix,[1,6] Michael Shlipak,[4,5] Nisha Bansal,[2] Ronit Katz,[2] Stephen B. Kritchevsky,[3] Dena E. Rifkin.[1,6] *[1]University of California San Diego, La Jolla, CA; [2]University of Washington, Seattle, WA; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]San Francisco VA Medical Center, San Francisco, CA; [5]University of California San Francisco, San Francisco, CA; [6]VA San Diego Healthcare System, San Diego, CA.*

Background: Preliminary work has shown that the difference in estimated glomerular filtration rate by cystatin C vs by creatinine (eGFRDiff) is associated with frailty and mortality. As creatinine is influenced by muscle mass, more so than cystatin, we aim to determine whether muscle mass explains the relationship between eGFRDiff and frailty.

Methods: In the Health Aging Body Composition study, 2980 (97% of HABC) had baseline serum creatinine, cystatin C, and muscle mass measures on imaging. eGFRs were calculated using CKD-EPI equations (cystatin-based [$eGFR_{Cys}$] and creatinine-based [$eGFR_{Cr}$] respectively), and eGFRDiff was $eGFR_{Cys} - eGFR_{Cr}$. Total thigh muscle area was evaluated on computed tomography. Frailty was scored on a continuous scale including standing and walking tasks; the lowest quartile of scores were defined as frail.

Results: Mean age was 74 (±3) years, $eGFR_{Cys}$ was 72 (±19), $eGFR_{Cr}$ was 68 (±15), and eGFRDiff was 4 (±14) mL/min/1.73m². Compared to participants with minimal difference in eGFR (within 10 mL/min/1.73m²), those in the positive eGFRDiff group (>10 mL/min/1.73m²) were less likely to have fallen in the past year (19% vs. 21%), had stronger grip strength (31 vs. 30kg) and walked faster (1.22 vs. 1.17m/s). Higher eGFRDiff was significantly associated with larger thigh muscle area. In cross-sectional analyses, each 1 SD increment in eGFRDiff was associated with 30% lower odds of frailty in models adjusted for demographics, cardiovascular risk factors, and chronic kidney disease category (**Table**). This relationship was attenuated when adjusting for measures of muscle mass and strength but remained statistically significant.

Conclusions: The difference $eGFR_{Cys}$ - $eGFR_{Cr}$ provides information on older adults' functional status which is only partially explained by muscle quantity and quality.

Cross-sectional association of eGFRDiff with frailty in HABC participants

Outcome: Frail	eGFRDiff (per SD =14 increase)	
n=2980	OR (95%CI)	p value
unadjusted	0.69 (0.63; 0.76)	<0.0001
Model 1*	0.70 (0.64; 0.78)	<0.0001
Model 2**	0.79 (0.71; 0.89)	<0.0001

*adjusted for age gender race education BMI serum albumin CRP

smoking HTN, antiHTN meds, diabetes CKD category by eGFRCr

**further adjusted for total thigh muscle area & grip strength

PO1682

The Difference in eGFR by Cystatin C vs. Creatinine Is Strongly Associated with Mortality Independent of Measured GFR

O. Alison Potok,[1] Dena E. Rifkin,[1,4] Joachim H. Ix,[1,4] Michael Shlipak,[2,5] Alice Schneider,[3] Nina Mielke,[3] Elke Schaeffner,[3] Natalie Ebert.[3] *[1]University of California San Diego, La Jolla, CA; [2]San Francisco VA Medical Center, San Francisco, CA; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]VA San Diego Healthcare System, San Diego, CA; [5]University of California San Francisco, San Francisco, CA.*

Background: In preliminary work, we have shown that the difference in glomerular filtration rate (eGFR) estimated by cystatin C [$eGFR_{Cys}$] and creatinine [$eGFR_{Cr}$], was associated with risk of frailty, hospitalization, cardiovascular events and mortality. Prior studies lacked directly measured GFR so it remained uncertain if associations were influenced by kidney function.

Methods: 567 participants of the Berlin Initiative Study (BIS) had baseline GFR measured by iohexol clearance (mGFR), as well as serum creatinine and cystatin C levels. $eGFR_{Cr}$ and $eGFR_{Cys}$ were calculated using CKD-EPI equations, and eGFRDiff was defined as $eGFR_{Cys}$ - $eGFR_{Cr}$. Mortality was recorded during up to 8 years follow-up. The association between eGFRDiff and mortality was assessed using Cox regression.

Results: Average (SD) age was 79 (±6) years, $eGFR_{Cys}$ 63 (±21), and $eGFR_{Cr}$ 69 (±17) for an eGFRDiff of -6 (±12) mL/min/1.73m². Compared to participants with minimal differences in eGFR, those with a substantially positive difference eGFRDiff (≥10 mL/min/1.73m²) were younger (76 vs. 78 years), less were diabetic (17% vs. 24%) and fewer took antihypertensives (59% vs 76%). Those with a substantially negative eGFRDiff (≤ -10 mL/min/1.73m²) were at much higher death risk which was minimally influenced with or without adjustment for measured GFR, age, sex, and urine albumin/ creatinine ratio (**Table**).

Conclusions: In BIS, an $eGFR_{Cys}$ estimate that was substantially less than an $eGFR_{Cr}$ estimate was associated with significantly higher risk of death. This association remained after adjusting for mGFR. Important clinical information beyond kidney function is embedded in eGFRDiff.

Funding: Private Foundation Support

Table. Association of eGFRDiff with Mortality in Older Adults in the Berlin Initiative Study

All cause mortality	eGFRDiff= eGFRCys-eGFRCr	eGFRDiffGroups		
		Negative (eGFRCys-eGFRCr ≤ -10)	Reference (-10< eGFRCys-eGFRCr ≤+10)	Positive (eGFRCys-eGFRCr > +10)
	n=567 # events=154	n = 200 # events =74	n = 308 # events=73	n = 59 # events=7
Age mean (SD), years	79 (6)	79 (6)	78 (6)	76 (5)
Female N (%)	243 (43)	76 (38)	140 (45)	27 (46)
mGFR mean (SD) mL/min/1.73m2	60 (16)	57 (14)	60 (17)	72 (14)
	Hazard Ratio (95% CI) Per 1SD=12 point increment	Hazard Ratio (95% CI)	Hazard Ratio (95% CI)	Hazard Ratio (95% CI)
Unadjusted	0.64 (0.55; 0.76)	1.73 (1.25; 2.39)	1 (ref)	0.51 (0.23; 1.10)

Outcomes of Haemodialysis in Incident Elderly Haemodialysis Patients: Single-Centre Experience

Rouvick Gama, Jocelyn Heins, David Makanjuola, Subash Somalanka. *St Helier Hospital, Carshalton, United Kingdom.*

Background: In the UK, elderly patients represent the most rapidly expanding group of the dialysis population. However, there remains little evidence to suggest improved quality of life or increased life expectancy, particularly in those over 80 years old.

Methods: We retrospectively reviewed patients who were initiated on haemodialysis (HD) between January and October 2019 in a tertiary renal centre in the United Kingdom. Data were collected using an electronic database. Baseline characteristics, 3 and 12-month mortality were recorded. Data were presented as counts with percentages and mean +/- SD.

Results: There were 263 patients initiated on HD, of which 120 (45.6%) were over 70 years; 67 were aged 70-79 years (group A) and 53 were aged 80-90 years (group B). Mean age was 78.1 ± 5.3 years and 74% were of white ethnicity. Baseline characteristics are summarized in table 1. Sixty patients remained on HD, 14 recovered, 6 moved to other modalities and 40 died. The 90-day mortality was 21% (18% in group A, 25% in group B); 6-month mortality was 27% in group A and 34% in group B; 1-year mortality was in 36% in group A and 35% in group B. In those established on HD (>90 days), 1-year mortality was 12% (17% in group A, 4% in group B).

Conclusions: We report a high 1-year mortality of 35% in the elderly population. However, the majority occurred during the 1st 90 days. For those established on HD, mortality is 12%; this is substantially lower than the UK renal registry data for over 75s which was 23% in 2017. Mortality was comparable between age groups, although we were limited by small sample size. A key question is whether there is a difference in quality of life and life expectancy in this cohort.

	70-79 years (n=67)	80 + years (n=53)
Male gender	40 (60%)	35 (66%)
Female gender	27 (40%)	18 (34%)
White ethnicity	51 (76%)	38 (72%)
Black ethnicity	1 (2%)	3 (6%)
Other ethnicity	15 (22%)	12 (23%)
90-day mortality	18%	25%
12-month mortality	36%	35%
>90 days on HD, 12-month mortality	17%	4%

Baseline characteristics and mortality in elderly incident haemodialysis patients.

Cost Effectiveness Study of Hyperkalemia Management

Nihar Desai,[1] Christopher G. Rowan,[2] Paula J. Alvarez,[3] Jeanene Fogli,[3] Steven G. Coca.[4] *[1]Yale University, Center for Outcomes Research and Evaluation, New Haven, CT; [2]COHRDATA, Santa Monica, CA; [3]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Patiromer (PAT) is a sodium-free, non-absorbed potassium (K^+) binder approved for the treatment of hyperkalemia (HK). There is limited real-world evidence on the cost implications associated with PAT treatment of HK. The objective of this study was to assess the cost-effectiveness of treating HK with PAT vs. no K^+ binder in a Medicare Advantage population.

Methods: This retrospective, matched cohort study was conducted using the de-identified Optum Clinformatics® Data Mart Database from 1/1/16–12/31/18. Two HK cohorts were identified: PAT exposed and unexposed (NoPAT). Patient inclusion criteria included pre-index serum K^+ ≥5.0 mEq/L and HK diagnosis (ICD-10 code) and ≥6 months insurance enrollment post-index. Propensity score matching and coarsened exact matching with baseline variables were used to identify the complete set of matching unexposed and exposed HK episodes. Follow-up began on index date and ended at the first censoring event (insurance disenrollment, death, 12/31/18, sodium polystyrene sulfonate or sodium zirconium cyclosilicate initiation, PAT discontinuation [exposed only], PAT initiation [unexposed only]). Cost outcomes measured at 6 months post-index: total, inpatient, emergency department (ED), outpatient services and outpatient pharmacy (mean US$ [CI 95%]).

Results: The study population was 2004 patients (1002 matched pairs). Overall, mean age was 74 years and 60% were male. Patients had a mean of 5 comorbidities. Comorbidities included: DM (73%), CHF (35%), and ESRD (10%). At 6 months post-index, 300 (150 matched pairs) PAT and NoPAT patients remained uncensored. Total PAT mean cost difference (savings) of $7220 ($2211,$9584) was observed at 6 months post-index ($P<0.01$). This cost difference included a pharmacy increase of $3094 ($3964,$2224) and a decrease in medical costs, specifically, inpatient $4718 ($2222,$7215), outpatient $4781 ($2274,$7288), and ED $815 ($488,$1142).

Conclusions: At 6 months post-index, PAT cohort observed a 27% reduction in cost compared with the unexposed cohort for HK management. Further study is warranted to replicate these findings in a large cohort.

PO1685

Effects of Veverimer on Serum Bicarbonate and Physical Function in Elderly Patients with Metabolic Acidosis in CKD

Donald E. Wesson,[1] Vandana S. Mathur,[2] Navdeep Tangri,[3] Yuri Stasiv,[4] Dawn Parsell,[4] Elizabeth Li,[5] Gerrit Klaerner,[4] David A. Bushinsky.[6] *[1]Baylor Scott & White Health and Wellness Center, Dallas, TX; [2]MathurConsulting, Woodside, CA; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Tricida, Inc., South San Francisco, CA; [5]PharmaStat LLC, Fremont, CA; [6]University of Rochester Medical Center, Rochester, NY.*

Background: Use of $NaHCO_3$ to treat acidotic pts with CKD increases daily Na load which may be particularly detrimental to elderly pts who may have hypertension and congestive heart failure. Veverimer is a non-absorbed polymer that treats metabolic acidosis (MA) by binding and removing HCl from the GI tract. It is not an exchange resin and does not introduce unwanted cations such as Na or K. In Phase 3 randomized, blinded, placebo-controlled trials, veverimer significantly increased serum bicarbonate and improved subjective and objective measures of physical function in pts with MA in CKD (Wesson et al. *Lancet*, 2019). Here we report data from pts aged ≥65 yrs from these studies.

Methods: Patients were treated for up to 1 yr with veverimer or placebo with frequent determinations of blood bicarbonate. Physical function was assessed at Baseline and Weeks 12, 40, and 52 using the KDQOL-PFD which quantifies limitations on daily activities and by performance on the repeated chair stand (RCS) test.

Results: Of the 217 pts randomized, 113 (52%) were ≥65 yrs (mean 72 yrs). Select comorbidities included HTN (98%), diabetes (70%), and CHF (40%). At Baseline, the mean eGFR was 30.7 mL/min/1.73m² and the mean serum bicarbonate was 17.2 mEq/L. In this elderly cohort, more pts receiving veverimer met the primary study endpoint, had a significant increase in serum bicarbonate, and improved both KDQOL-PFD scores and RCS time (**Table**) compared with placebo. These effects of veverimer exceeded the minimal clinically important difference for both the KDQOL-PFD (+3 to +5 points) and RCS (-1.7 seconds). Safety was similar in both treatment groups.

Conclusions: In older adults with CKD, treatment with veverimer significantly increased serum bicarbonate levels and improved how pts felt and functioned. The safety of veverimer was not different from placebo.

Funding: Commercial Support - Tricida, Inc.

Efficacy Endpoints	Placebo (N = 48)	Veverimer (N = 65)
Primary Endpoint: proportion increasing serum bicarbonate by > 4 mEq/L or achieving normalization at Week 12	25%	76% P<0.0001
Change from baseline in Serum Bicarbonate (LS mean, mEq/L) at Week 12	+2.1	+5.4 P< 0.0001
Patient-Reported Physical Function (Change from baseline in mean [SD] KDQOL-PFD total score at Week 52)*	-0.13 (20.84)	+10.95 (21.57) P = 0.003
Objective Measurement of Physical Function	-2.46	-2.59 (7.55)

P-values are vs. placebo; An ANCOVA rank-based method was used for physical function endpoints

*Based on evaluable patients enrolled in controlled extension study (placebo, n=38; veverimer, n=58)

PO1686

Design of a Consensus-Based Geriatric Assessment Tailored for Older Patients Approaching ESKD

Carlijn G. Voorend,[1] Noeleen C. Berkhout-Byrne,[1] Adry Diepenbroek,[2] Casper F. Franssen,[2] Willem Jan W. Bos,[1,3] Simon Mooijaart,[1] Marjolyn Van Buren.[1] on behalf of principal investigators of the POLDER study *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Sint Antonius Ziekenhuis, Nieuwegein, Netherlands.*

Background: Routine geriatric evaluation in older patients approaching end stage kidney disease (ESKD), benefits disclosure of highly prevalent unidentified functional and cognitive impairments. Although recommended in guidelines, a suitable standardized geriatric test set is lacking. We aim to propose a consensus-based test set for geriatric assessment useful in both routine care and research in older (≥ 65 year) patients approaching ESKD.

Methods: A multidisciplinary expert panel of physicians, nurses and supportive disciplines with clinical and/or scientific experience in geriatric nephrology was assembled. Preconditions and selection-criteria for the selection of potential measures resulted from general geriatric principles, critical appraisal of literature, inventory of conventional instruments, and focus group meetings with patients, carers and health professionals. Older patients (aged ≥65 years) approaching end-stage kidney disease (eGFR < 20 ml/min/1.73M2) were selected as the target population. An expert panel meeting and subsequent round of comments by email led to agreement on the best suitable test set.

Results: The final consensus set contains instruments in functional, cognitive, phycological, and somatic domains, and patient preferences, nutritional status and fall risk. The set comprises a patient questionnaire (six instruments) and a professional-administered test set (including ten instruments). Estimated time for administration in pilot testing was 20 and 40 minutes respectively.

Conclusions: We propose a consensus-based nephrology-tailored geriatric assessment, to benefit clinical care for older (pre-)ESKD patients and enhance research comparability. Future research should investigate effectiveness, feasibility of implementation, patients satisfaction and the value for treatment decision making and outcome improvement.

PO1687

Correlation Between Patient-Reported Physical Limitation and Objective Physical Performance on the Repeated Chair Stand Test Among Patients with Non-Dialysis Dependent CKD and Metabolic Acidosis

Vandana S. Mathur,[1] Michael Walker,[2] Gerrit Klaerner.[3] *[1]MathurConsulting, Woodside, CA; [2]Walker Biosciences, Carlsbad, CA; [3]Tricida, Inc., South San Francisco, CA.*

Background: CKD accelerates the loss of physical function, in part due to the development of sarcopenia caused by metabolic acidosis (MA). Decline in the ability to rise from a seated position is consequential as it can lead to loss of independence. However, physical performance is not routinely measured in CKD clinical practice.

Methods: We evaluated the correlation between patient-reported limitation on daily activities on the Kidney Disease and Quality of Life Physical Function Domain (KDQOL-PFD, a 10-item survey in which possible responses are "not limited at all", "limited a little", and "limited a lot") and the standardized 5-times repeat chair stand time (RCS) using data from a 1 year randomized trial of pts (N = 196) with MA in CKD (Wesson et al. *The Lancet*, 2019). These measures showed an ability to detect change - pts in the veverimer group improved significantly on both.

Results: There was a significant, direct correlation between improvement (i.e., higher score) over 1 yr on the KDQOL-PFD total score and improvement on the RCS (i.e., faster time), (Pearson's product-moment correlation, 0.33, $P < 0.001$). Additionally, 5 of the 10 individual KDQOL-PFD activity limitations correlated significantly with RCS time: "lifting or carrying groceries"; "bending, kneeling, or stooping"; "walking one block", "walking several blocks", and "bathing or dressing yourself" (P-value < 0.05 for

the correlation for all questions). Using a linear model, we found that each category of decline in the KDQOL-PFD for these individual questions was associated with significant deterioration of RCS time in the range of 3.29 to 3.80 seconds, exceeding the minimally clinically important difference of 1.7 seconds (Jones et al. *Thorax*, 2013).

Conclusions: Our findings suggest that asking pts if they are limited in their ability to do daily activities such as walking 1 block or lifting or carrying groceries may be a practical way to screen for significant physical performance declines known to have important health, social, and economic consequences. Routine identification of pts with physical functional decline might allow for earlier implementation of interventions to forestall further impairment.

PO1688

Mobility in Older Hemodialysis Patients: A Mixed Methods Study

Christine Liu,[1,2] Janet J. Seo,[5] Kristen A. Wright,[1] Dayeun Lee,[1] Jennifer Moye,[3,4] Jonathan Bean,[3,4] Daniel E. Weiner.[2] *[1]Boston University, Boston, MA; [2]Tufts University, Medford, MA; [3]VA Boston Health Care System Boston Vet Center, Boston, MA; [4]Harvard University, Cambridge, MA; [5]Mount Sinai Health System, New York, NY.*

Background: Mobility, or the ability to move reliably and safely, impacts quality of life and predicts future disability and mortality. This is especially relevant for older adults, who comprise a large part of the hemodialysis (HD) population. For older hemodialysis patients, factors that limit mobility and which specific components of mobility are involved are not well-defined. Using a mixed methods approach, we investigated these factors and components in older HD patients.

Methods: Eligibility criteria were age ≥60 years and receipt of maintenance HD. Participants had a single in-person assessment that occurred in their home when feasible. We administered the Short Physical Performance Battery (SPPB) to assess balance, walking speed, and lower leg strength (range 0-12 for full SPPB, range 0-4 for individual domains). We conducted semi-structured key informant interviews, using an interview guide based on the literature. Interview transcripts were descriptively coded and major themes were extracted using both deductive and inductive approaches.

Results: A total of 31 persons enrolled, with a mean age of 72.5±8.1(S.D.) years and mean vintage of 4.6±3.5 years; 42% were female and 68% African-American. Mean overall SPPB was 4.4±2.3 points; mean scores for balance, walking and lower leg strength were 2.3±1.1, 1.8±1, and 1.3±0.7 points, respectively. Mean gait speed was 0.46±0.22 meters/second. Coding inter-rater reliability > 0.8. Three major themes emerged: 1) losses in balance and walking are the most debilitating, 2) fluctuations in mobility are frequent, and 3) post-HD procedure fatigue and the presence of amputations limit mobility (Table).

Conclusions: In a diverse sample of older HD patients, mobility is significantly limited with multiple domains affected. Patients identified balance and walking as the most problematic, and cope with frequent changes in mobility. Future studies should focus on improving balance and walking, and include strategies to mitigate fluctuations in mobility.

Funding: Other NIH Support - K23AG057813, Government Support - Non-U.S.

Key themes regarding mobility in older hemodialys patients

Theme	Quote
Specific domains of mobility that are limited: balance and walking	"Oh, give me more balance so my back don't hurt when I try to walk around." -Female, age in 70s
Frequent changes in mobility	"I get off the machine, crawl around the corner to the car. 'Cause I have my good days and my bad days on dialysis… It seems like it's miles and miles and miles down the road when it's only right around the corner." -Male, age in 60s
Impact of post-HD procedure fatigue on mobility	"'Cause you're on dialysis three days a week for hours, and then you're tired when you come home…After I came on, my walking got considerably worse. That's why I had to go to the walker. I'm hoping that's where it ends at." -Female, age in 70s

PO1689

Rehabilitation in CKD

Clemens Grupp,[1,2] Thomas Tuemena,[3] Jens Troegner,[4] Walter Swoboda,[5] Karl-Guenter Gassmann.[6] *[1]Academic Teaching Hospital Bamberg, Bamberg, Germany; [2]Georg-August University, Department of Nephrology and Rheumatology, Goettingen, Germany; [3]GiB-DAT Head Office, Nuernberg, Germany; [4]Academic Teaching Hospital St. Marien, Amberg, Germany; [5]Klinikum Main-Spessart, Marktheidenfed, Germany; [6]Waldkrankenhaus St. Marien, Erlangen, Germany.*

Background: Older patients with impaired renal function (renal patients: RP) often show the criteria of a geriatric patient with increasing stages of CKD. Geriatric phenomena such as frailty are considered a predictor of poor outcomes particularly during acute illness in these patients. These consequences can be alleviated in patients without renal insufficiency (HP) by rehabilitative measures both in acute geriatrics units (AG) and in inpatient geriatric rehabilitation facilities (RG). So far it is largely unknown whether RP benefit from this type of rehabilitation to the same extent as HP. We have now examined this question by evaluating a large geriatric database.

Methods: The Geriatrics in Bavaria-Database (GiB-DAT) was established with the support of the Ministry of Health as a quality assurance project. It comprises the vast majority of anonymized records of cases treated in Bavarian AG and RG. In this study all data records for the years 2012-2019 from AG and RG were evaluated. The following parameters were examined: At admission: age, gender, cognition (Minimal Status Examination: MMSE), emotion (Geriatric Depression Scale: GDS), degree of care (DC); at discharge: number of diagnoses and medication; at admission and discharge: self-help ability (Barthel Score: BS), mobility (Timed Up and Go-Test: TUG) and place of residence.

Results: Both in AG and RG, HP (AG/RG n=116513/248831) and RP (AG/RG n=27294/45984) did not relevantly differ in age, gender, MMSE, GDS and DC. The number of diagnoses (AG: 10.7 vs. 9.3; RG 10.3 vs. 8.3) and drugs (AG 10.1 vs. 9.3; RG 9.9 vs. 9.0) was slightly higher in RP compared to HP. No major differences between RP and HP were observed at the beginning of the rehabilitation in BS, TUG and place of residence. In RP/HP, BS improved during rehabilitation by +14.4/14.5 (AG) and +21.1/21.9 (RG) points and the number of patients "able to walk" in the TUG by +22.1/20.6% (AG) and +14.3/14.5% (RG) respectively. Domestic living could be maintained in 66.0/68.9% (AG) and 81.6/81.5% (RG). Subgroup analysis of CKD-stages 3-5 showed no relevant difference for any of the examined parameters both in AG and RG.

Conclusions: RP benefit to a similar extent as HP from rehabilitative measures both in AG and RG with respect to improvement of self-help ability, mobility as well as the preservation of private residency. This was observed regardless of the stage of renal insufficiency.

PO1690

Predictors of Functional Status Change in Patients with CKD Between Two Hip Fracture Events: A 6-Year Prospective Study

Henry Wu,[1,2] Rene Van Mierlo,[1] Ajay P. Dhaygude,[1,2] Sandip Mitra,[2,3] Andrew C. Nixon.[1,2] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom; [3]Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: Patients with chronic kidney disease (CKD) are susceptible to recurrent hip fractures (Hip#). Functional status decline after Hip# is transient, exacerbated by frailty, sarcopenia and co-morbidities. We studied the prognostic value of clinical and laboratory parameters for functional status change in CKD after recurrent Hip#.

Methods: Patients with CKD G3b-5 admitted with 2 separate Hip# events between June 2013 and Dec 2019 in a North West UK tertiary care hospital were included. Difference in Karnovsky Performance Status (KPS) Scale between 1st and 2nd Hip# admission determined functional status change. KPS is a linear scale between 0 (dead) and 100 (normally active). Parameters assessed include Clinical Frailty Scale (CFS), Hopkins Frailty Score (HFS), CKD FI-LAB, Sernbo Score, Charlson's Co-morbidity Index, Nottingham Hip Fracture Score, ASA Score and Abbreviated Mental Test Score. Differences in each parameter score between 1st and 2nd Hip# admission were recorded. ROC curve analyses was performed to assess discriminative ability between individual scoring tools.

Results: 37 patients met inclusion criteria (F:M 1.8:1; mean age 84.5±10.2 yrs). 10 were receiving long-term dialysis, whilst non-dialysis CKD patients had a mean eGFR 33±15 mL/min/1.73m^2. Mean age difference between Hip# is 1.4 yrs (p=0.032). Mean KPS difference between Hip# is -10.6 (p=0.028). AUC values from ROC analyses are shown in Table 1.

Conclusions: There was a significant decline in functional status between Hip#. Frailty assessment tools (CFS, HFS and CKD FI-LAB) had the best predictive performance for functional status change. Frailty measures may be utilized as risk prediction tools of functional status change from first Hip# admission. Further Research is needed on post-Hip# interventions that aim to maintain functional status and reduce subsequent fracture risk.

Table 1

Predictors	AUC Value (95%CI)
Clinical Frailty Scale	0.96 (0.90-1.00)
Hopkins Frailty Score	0.95 (0.89-1.00)
CKD FI-LAB	0.91 (0.83-0.99)
Sernbo Score	0.85 (0.77-0.93)
Charlson's Co-morbidity Index	0.78 (0.69-0.88)
Nottingham Hip Fracture Score	0.74 (0.66-0.82)
ASA Score	0.67 (0.59-0.75)
Abbreviated Mental Test Score	0.56 (0.51-0.61)

PO1691

Which Parameters Best Predict Mortality After Hip Fracture for Patients with CKD? Insights from a 6-Year Prospective Analysis

Henry Wu,[1,2] Rene Van Mierlo,[1] Ajay P. Dhaygude,[1,2] Sandip Mitra,[2,3] Andrew C. Nixon.[1,2] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom; [3]Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: Hip fracture is more prevalent in patients with CKD and has associated worse clinical outcomes than those without CKD. Uncertainties remain on which clinical or laboratory parameters best predict mortality outcomes following hip fracture for patients with CKD.

Methods: Patients with CKD G3b-5 admitted to a tertiary hospital in North West UK with hip fracture between June 2013 and Dec 2019 were included. Mortality outcomes

at 1st year, 3rd year and 6th year after hip fracture were assessed. Parameters assessed on hospital admission included Clinical Frailty Scale (CFS), Hopkins Frailty Score (HFS), CKD FI-LAB, Sernbo Score, Charlson's Co-morbidity Index, Nottingham Hip Fracture Score, ASA Score and Abbreviated Mental Test Score. ROC curve analyses were performed to evaluate ability of individual scoring tools to predict mortality outcomes after hip fracture.

Results: A total of 397 patients met study inclusion criteria of which 42 were receiving long-term dialysis. Mean age was 83.5±9.2 yrs. Non-dialysis patient mean eGFR was 37.4±14.9 mL/min/1.73m^2. Mortality at 1, 3 and 6 years were 38% (n=151), 60% (n=239) and 77% (n=305) respectively. AUC values from ROC curve analyses are presented in Table 1.

Conclusions: Frailty assessment tools (CFS, HFS and CKD FI-LAB) had the best predictive value for short- and long-term mortality after hip fracture for patients living with CKD. A comprehensive frailty assessment should be performed on patients with CKD admitted after a hip fracture to identify those at greatest risk of adverse outcomes. Further research is needed to evaluate interventions that aim to reduce mortality risk after hip fracture for patients living with CKD.

Funding: Government Support - Non-U.S.

Table 1: AUC values of tools used to predict mortality following hip fracture

Predictor	AUC Value (1 year mortality)	95%CI	AUC Value (3 year mortality)	95%CI	AUC Value (6 year mortality)	95%CI

PO1692

Mortality Outcomes of Dialysis Patients Who Sustained Neck of Femur Fractures in a Tertiary London Renal Centre

Eleanor I. Reeve, Diya Kapila, Nivi Singh, Bhrigu Raj Sood. *St Helier Hospital, Carshalton, United Kingdom.*

Background: Patients with end stage renal disease have an increased risk of fractures, including neck of femur (NOF) fractures, partly due to bone mineral disorders. Studies show higher post-operative mortality rates in this group, attributed to abnormal vitamin D metabolism, challenges with fluid status, and dialysis sessions impeding physical therapy rehabilitation. St Helier hospital has an onsite tertiary renal centre and the Hip Fracture Unit has been ranked as one of the best performing in the country. We sought to establish if this on-site standardised local practice translated to reduced mortality outcomes in dialysis patients who sustained NOF fractures.

Methods: We performed a retrospective analysis of the 30 day mortality of dialysis patients sustaining NOF fractures between April 2011 and July 2018. Patients with NOF fractures were identified from the National Hip Fracture Database and dialysis patients from the renal unit database. We reviewed demographics, pre and post-surgical parameters and 30-day unadjusted mortality.

Results: We identified 3164 NOF patients and 46 of these patients were on dialysis (n=46). 43 were on haemodialysis and 3 were on peritoneal dialysis. The dialysis cohort included 20 females and 26 males and average age was 77 years (53-95). ASA grades were 3 in 23 patients, 4 in 22 patients, and 5 in 1 patient. 29 operations were conducted under general anaesthesia, 16 under spinal anaesthesia and 1 patient had non-operative management of a subcapital fracture. All patients had a pre-operative review by an orthogeriatrician and remained under joint care of the orthopaedic, orthogeriatric and renal teams. 30-day unadjusted mortality for the dialysis cohort was 8.70% (4 deaths), compared to 7.60% for the general cohort (RR 1.144, CI 0.445-2.942, P = 0.7801). Average length of stay for the dialysis cohort was 26 days (5-87). Average length of survival for the dialysis cohort was 801 days following admission.

Conclusions: Previous studies have demonstrated 2 to 4 fold increased mortality in dialysis patients with NOF fractures. Our data shows that patients on renal replacement therapy did not have higher 30-day mortality compared to the general cohort. A multidisciplinary service with close collaboration between specialities can lead to good outcomes in this high risk population.

PO1693

Intensive Blood Pressure Control and Fall Injuries in Older Adults: A Systematic Review and Meta-Analysis

Mako Wakabayashi,[1] Takayuki Yamada.[2,3] *[1]Nihon Ika Daigaku Fuzoku Byoin, Bunkyo-ku, Japan; [2]Mount Sinai Beth Israel, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Yokohama City University Graduate School of Medicine, Yokohama, Japan.*

Background: Hypertension is the leading preventable risk factor for cardiovascular disease (CVD), and its prevalence increases with age. While prior studies suggested that intensive blood pressure (BP) control achieved a reduction in CVD, antihypertensive treatments can cause adverse events such as falls. Falls are one of the leading causes of hip fractures and traumatic brain injuries. However, it remains unclear if intensive BP control could lead to an increased risk of falls.

Methods: We performed a systematic literature search up to April 2020. We selected randomized control trials (RCTs) and cohort studies which compared the risk of falls in the intensive BP control group with that in the less intensive control group the elderly. Risk ratios (RRs) with corresponding 95% confidence interval (CI) were synthesized.

Results: Five studies (three RCTs and two cohort studies) were included, with 11,245 patients. The characteristics were shown in Table. Intensive BP control was no associated with significantly increased risk of falls, but the results showed high heterogeneity. (RR [95% CI]; 1.10 [0.87-1.39], I2= 73%)

Conclusions: In older patients, intensive BP control was not associated with an increased risk of falls, but with high heterogeneity. The proportion of frail patients might be a source of heterogeneity. Further studies that stratify patients with risk of frail are needed.

Characteristics of the studies included in the Meta-analysis

Study	Design	Definition of intensive BP control	Age (years)	Follow up (years)	Total number of patients	Male (%)	Smoker (%)	Obesity (%)	Diabetes Mellitus (%)	Myocardial infarction (%)	Heart failure (%)	Cognitive impairment (%)	Prior falls (%)
Callisaya 2014	Prospective cohort	0 or >3 medications	>60	1.0	237	57.4	53.6	N/A	11.8	11.0	N/A	N/A	18.1
SHEP	RCT	active treatment or placebo	>60	4.5	4736	43.2	49.8	N/A	10.1	4.9	N/A	1.7	N/A

Potentially Inappropriate Antihypertensive Medications and Mortality in Older Adults on Hemodialysis

Rasheeda K. Hall,[1,2] Sarah N. Morton,[1] Jonathan A. Wilson,[1] Patti Ephraim,[4] L. Ebony Boulware,[1] Wendy L. St. Peter,[5] Cathleen Colon-emeric,[1,2] Jane F. Pendergast,[1] Julia J. Scialla.[3] *[1]Duke University School of Medicine, Durham, NC; [2]Durham VA Medical Center, Durham, NC; [3]University of Virginia, Charlottesville, VA; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]University of Minnesota System, Minneapolis, MN.*

Background: Older patients on hemodialysis often have difficult to control hypertension, but also suffer from orthostatic or post-dialysis hypotension. Some orthostasis-causing antihypertensives (i.e., central alpha agonists (CAA) and alpha blockers (AB)), are considered potentially inappropriate medications (PIMs) for older adults because they carry more risk than benefit. We sought to determine if these PIMs are associated with mortality risk among older adults on hemodialysis.

Methods: Using USRDS analytic files, we studied adults aged ≥66 years initiating in-center hemodialysis (ICHD) from 2013-2014 with a Medicare Part D prescription for CAA or AB at initiation. All had Medicare Parts A, B, and D ≥1 year prior to initiation, no hospice care within prior 6 months, and continued ICHD for ≥120 days. We classified patients as continuing or discontinuing CAA/AB at 120 days and examined risk of death over 2 years using Cox models adjusted for demographics, dual Medicare and Medicaid eligibility, comorbidity index, diabetes, ESRD cause, hospitalization count in prior 12 months, pre-dialysis nephrology care, facility for-profit status/region, nursing home residence, and functional limitation (CMS form 2728). We tested interaction between CAA/AB continuation and functional limitation. We censored models for discontinued dialysis, hospice, loss to follow up, modality change, and transplant.

Results: Of 5,981 patients, mean age 75.6±6.5, 51.4% women, and 24.6% black. Most [65.5% (n=3,920)] continued CAA/AB prescription at 120 days. Compared to those who discontinued, those who continued were more likely to be black (26.3 vs. 21.3%), dual eligible (31.5 vs. 27.3%), and have no functional limitations (84.1 vs. 79.8%). With a smaller proportion of deaths compared to discontinuers (17.3 vs. 20.9%), continuation of CAA/AB was associated with a lower hazard of death (unadjusted HR 0.78, 95% CI: 0.68-0.90). After adjustment, this was attenuated and not significant (aHR 0.88, 95% CI: 0.76-1.01). The association was not modified by functional limitations (p=0.54).

Conclusions: We did not find increased mortality among older adults on ICHD who continue CAA or AB prescriptions after 120 days, providing some reassurance on their use in all older adults on ICHD.

PO1695

Tailoring the Beers Criteria for Mortality Risk Stratification Among Older Adults Initiating Hemodialysis

Rasheeda K. Hall,[1,2] Abimereki Muzaale,[3] Dorry L. Segev,[3] Mara McAdams-DeMarco.[3] *[1]Durham VA Medical Center, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]Johns Hopkins University, Baltimore, MD.*

Background: American Geriatrics Society's Beers Criteria lists potentially inappropriate medications (PIMs) that carry more risk of harm than benefit in older adults, but PIM risks may differ in kidney failure. To tailor the Beers Criteria, we developed a novel mortality risk score for older patients initiating hemodialysis.

Methods: We assembled a USRDS cohort of 39,098 adults aged ≥65 initiating hemodialysis (2013-2014) and enrolled in Medicare Part D by 90 days post-initiation. We used Part D claims days' supply to quantify prescription length of Beers Criteria PIMs. In a training cohort (60% sample), we identified which of 38 PIM classes were associated with mortality using Cox modeling; censoring for loss of Medicare coverage, modality change, or 9/1/2015. Models were adjusted for demographics, initiation year, comorbidities, drug dependence, smoking status, inability to ambulate, and institutionalization. PIMs classes that were associated with mortality were summed to create a PIM count risk score. We used Cox models to estimate the association of PIM count risk score (time-varying) with mortality in training and validation cohorts.

Results: The training cohort (n=23,521) had mean age 75 years, 43% women, 21% black, and 75% (n=17,706) had ≥2 PIM fills/month. We identified 15 PIMs (HR >1) to include in the risk score (Figure). Patients with ≥2 fills/month (vs. no fills) were more likely institutionalized (13.8 vs. 10.1%), non-ambulatory (20.8 vs. 17.2%), and have cardiovascular disease (62.4 vs. 50.7%). Compared to those with no fills, there was increased mortality risk among those with 1 fill (aHR=1.32;1.25-1.39) and ≥2 fills (aHR=1.66;1.56-1.75).

Conclusions: We identified 15 of 38 PIM classes associated with mortality to yield a novel PIM count risk score. This score facilitates tailoring the Beers Criteria to promote age-appropriate prescribing in older adults initiating hemodialysis.

PIM Classes and Mortality Risk

PO1696

Symptoms and Suffering at the End of Life in ICU Patients Receiving Dialysis

Sarah Ramer, Martin Viola, Holly G. Prigerson. *Weill Cornell Medicine, New York, NY.*

Background: Patients with end-stage kidney disease (ESKD) on dialysis suffer from a significant burden of physical symptoms. Little is known, however, about the symptoms that intensive care unit (ICU) patients receiving dialysis experience at the end of life.

Methods: This is a cohort study conducted at NewYork-Presbyterian Hospital / Weill Cornell Medical Center and Brigham and Women's Hospital from September 2015 to March 2017. Nurses who cared for deceased ICU patients were interviewed within 3 weeks of the deaths about patients' physical and psychological symptoms in their last week of life. On a 1-10 scale, nurses rated 16 different symptoms on how much they contributed to a patient's suffering and rated the patient's overall suffering in the last week of life. Study staff abstracted demographic and clinical data from patient charts.

Results: One-hundred nurses completed interviews on 200 deceased patients, 67 of whom underwent dialysis in the last week of life (for ESKD or acute kidney injury). Mean dialysis patient age was 63 years; 39% were female; 32% were non-white; 12% were Hispanic. The nurses rated patients who underwent dialysis in the last week of life as having significantly more suffering from painful, broken skin than non-dialysis patients (mean 4.6 vs. 3.5 out of 10, P=0.045) but significantly less suffering from hunger (mean 2.4 vs. 3.6 out of 10, P=0.012) or thirst (mean 3.2 vs. 4.8 out of 10, P=0.005). There was also a trend towards more suffering from swelling in the dialysis patients (mean 6.2 vs. 5.3 out of 10, P=0.083). An unadjusted linear regression model revealed that receipt of dialysis in the last week of life was significantly associated with perceived overall suffering (β=1.35, P=0.006); however, after adjustment for painful, broken skin (β=0.19, P=0.013) and swelling (β=0.20, P=0.007) in the model, the relationship between dialysis and overall suffering was attenuated (β=0.84, P=0.074).

Conclusions: Nurses rated ICU patients who received dialysis in the last week of life as suffering from more painful, broken skin but less hunger or thirst than non-dialysis patients. The relationship between dialysis and perceived overall suffering was attenuated by painful, broken skin and swelling, suggesting that attention to these problems might reduce suffering at the end of life in ICU dialysis patients.

PO1697

Want to Reduce Regret with Dialysis Initiation? Implement Shared Decision-Making

Fahad Saeed, Basil S. Kazi, Nicole L. Mayo, Spencer Dahl. *University of Rochester Medical Center, Rochester, NY.*

Background: The American Society of Nephrology's "Choosing Wisely Campaign" recommends that nephrologists should not initiate chronic dialysis without implementing a shared decision-making (SDM) process. The current literature lacks details on the relationship of SDM with outcomes such as quality of life and decisional regret.

Methods: We surveyed 223/380 (response rate 59%) hospitalized patients receiving maintenance dialysis in the Upstate, NY, and asked them about their experience with dialysis decision-making using the SDM-9 Questionnaire. Quality of life and decisional regret were assessed by KDQ0L-36 and Decisional Regret Scale, respectively. Candidate predictors in the final linear regression model included age, sex, time on dialysis, race, marital status, income level, education level, quality of life, fear of death, and decisional regret.

Results: Nearly 41% of patients were <65 years old, 47% were women, and 41% were White. The mean scores for SDM were 25.9 ± 12.2. In the bivariate analyses, patients who were married or in a relationship had greater mean SDM scores ($p<0.01$) than those who were single. Patients with higher scores on SDM had less anxiety over death and less decisional regret. (R = -0.17 and -0.29, respectively). The candidate predictors in the final model together explained 21.4% of the variance in SDM ($p = 0.02$). SDM decreased for every 0.15 unit increase in decisional regret score (CI: -0.25, -0.07) when controlling for all other predictors in the model.

Conclusions: We found that patients with higher scores on the SDM-9 Questionnaire had less decisional regret regarding their decision to initiate dialysis. Future interventions to implement SDM in clinical settings are a top research priority.

PO1698

Attitudes Towards Physician-Assisted Death in Patients Receiving Maintenance Dialysis

Fahad Saeed,[1] Basil S. Kazi,[1] Nicole L. Mayo.[2] *[1]University of Rochester Medical Center, Rochester, NY; [2]University of Rochester, Rochester, NY.*

Background: During recent years, the debate about the legalization of physician-assisted death (PAD) has intensified at both public and policy levels. Surveys and polls on this issue have included seriously ill patients such as those with cancer; however, voices of patients receiving maintenance dialysis are not represented in the current literature.

Methods: We surveyed 223/380 (response rate 59%) hospitalized patients receiving chronic dialysis in Upstate, NY. We asked patients about their views on PAD using the following two questions: (1) Which of the following best describes your views about whether a physician should ever be allowed to take the final action in response to a patient's request for assisted death? (2) In case you had a great degree of pain and suffering and if physician-assisted death were legally available, do you think you might request it for yourself? Response options for the first and second questions included: (a) support/yes (b) oppose/no (c) uncertain. Candidate predictors in the final logistic regression model included age, time on dialysis, race, marital status, income level, education level, spirituality, social support, symptom burden, sense of burdensomeness, fear of death, and fear of the dying process.

Results: Nearly 41% of patients were <65 years old, 47% were women, and 41% were White. Fifty-five percent supported PAD, 20% expressed uncertainty, and 22% opposed it with missing data on 3% of patients. In response to the question, if patients would choose PAD for themselves, in case of pain and suffering, and if PAD was legally available: 37% said yes, 44% no, and 17% chose the unsure option. In the bivariate analyses, those who supported PAD had lower mean spirituality, higher anxiety about the dying process, and had spent more time on dialysis compared to those who opposed or were uncertain ($p<0.05$) about it. In the final model, none of the candidate predictors were significant for support or opposition/uncertainty about PAD.

Conclusions: More than half of hospitalized dialysis patients supported PAD, while fewer would actually use this option in case of pain and suffering. In the absence of the legalization of PAD in the NY state, the promotion of palliative care and hospice services and high-quality end-of-life care for dialysis patients are high priority policy issues.

PO1699

Perspectives on Conservative Management of Advanced Kidney Disease: A Qualitative Study of US Patients and Family Members

Susan P. Wong,[1,2] Taryn Oestreich,[1,2] George G. Sayre,[1,2] Ann M. O'Hare,[1,2] J. Randall Curtis.[1,3] *[1]University of Washington, Seattle, WA; [2]VA Puget Sound Health Care System, Seattle, WA; [3]Cambia Palliative Care Center of Excellence, Seattle, WA.*

Background: Growing recognition of the limits of maintenance dialysis for some groups of patients has led to the emergence of conservative care models for advanced kidney disease in several countries outside the US. There is strong interest in replicating similar models in the US, however little is known about how these models are perceived by US patients and family members.

Methods: We conducted a qualitative study using cognitive interviews with 14 patients aged ≥75 years with advanced kidney disease and 6 of their family members about their perception of conservative care approaches in other countries as described in available patient decision aids on treatment of advanced kidney disease. We performed an inductive thematic analysis of interviews to identify themes reflecting participants' understanding and receptivity to conservative care.

Results: Subjects were mostly white (n=15) and had at least some college education (n=16). 4 prominent themes emerged from analysis of interviews: 1) *Core elements of conservative care*: aspects of conservative care that were appealing to participants included a whole-person, multidisciplinary approach to care that focused on symptom management, maintaining current lifestyle and managing health setbacks; 2) *Importance of how conservative care is framed*: participants were more receptive to conservative care when this was framed as an active rather than passive treatment approach and were accepting of uncertainty in disease prognosis; 3) *An explicit approach to shared decision-making*: participants believed decisions about conservative care or dialysis address considerations about risk and benefits of treatment options, family and clinician perspectives and personal goals, values and preferences; and, 4) *Relationship between conservative care and dialysis*: although conservative care models outside the US are generally intended to serve as an alternative to dialysis, participants' comments implied that they did not view conservative care and dialysis as mutually exclusive

Conclusions: Although participants in this study found many aspects of conservative care models developed in other countries to be appealing, models will likely require adaptation to meet the needs and preferences of US patients and their families.

PO1700

Feasibility and Acceptability of Telepalliative Care in Rural Dialysis Units

Katharine L. Cheung,[1] Manjula Kurella Tamura,[2] Michael A. Lamantia,[1] Terry Rabinowitz,[1] Renee Stapleton,[1] Bob Gramling.[1] *[1]University of Vermont College of Medicine, Burlington, VT; [2]Stanford University School of Medicine, Stanford, CA.*

Background: Limited access to palliative care is a key barrier to its integration in routine dialysis care. We evaluated the feasibility and acceptability of telepalliative care while patients received dialysis in rural units.

Methods: The target population included any patients with end-stage kidney disease receiving dialysis. Palliative care physicians and APPs conducted consultations as per their usual practice and used a large wall mounted screen with centrally positioned camera. Patients used an iPad attached to an IV pole positioned next to the dialysis chair. Patients were provided the option of having family present, receiving the consult on dialysis or off dialysis in a private room. Feasibility was measured by 1-month completion rate. Acceptability was measured using an adapted telemedicine questionnaire.

Results: We recruited 40 patients to undergo a telepalliative care consultation while receiving dialysis. Four specialty palliative care clinicians (3 physicians and 1 nurse practitioner) conducted the visits. The recruitment rate was 35% (40/113), scheduling rate was 97.5% (39/40) and completion rate was 85% (33/39). Thirty-six patient participants (15 women, 21 men) completed the baseline survey. One patient requested family to be present during the conversation. No patients requested to have the conversation off dialysis in a private room. Audiovisual aspects of the conversation were rated highly. More than 3/4 reported the visit being at least as good as an in-person visit and 40% felt the televisit was better. Patients felt the appointment was relevant to them, but they were less certain that they learned new things about their condition, and they were mixed about whether the appointment changed the way they think about dialysis.

Conclusions: Telepalliative care is acceptable to patients receiving dialysis and is a feasible approach to integrating palliative care in rural dialysis units.

Funding: Private Foundation Support

Acceptability of Telepalliative care in dialysis

Acceptability score, (Likert score 1-5, 1=strongly agree/very helpful)	1.75	
Telepalliative was better than in-person visit	41%	
Telepalliative was no better or worse than in-person	38%	
Telepalliative was worse than in-person visit	21%	
Requested to meet again with palliative care	Yes	56%
	Maybe	34%
	No	9%

Abstract Withdrawn

PO1702

Modestly Low eGFR Is Not Associated with Cognitive Decline in the Elderly

Michael Grasing,[1] Kevin Kennedy,[2] Jeffrey M. Burns,[3] Mark J. Sarnak,[4] Aditi Gupta.[3] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]Kansas City VA Medical Center, Kansas City, MO; [3]University of Kansas Medical Center, Kansas City, KS; [4]Tufts Medical Center, Boston, MA.*

Background: Kidney disease is associated with cognitive impairment. Whether mild to moderate CKD is associated with cognitive decline in older adults is not clear. We evaluated changes in cognition in relation to baseline eGFR in the elderly Alzheimer's Disease Neuroimaging Initiative (ADNI) participants.

Methods: ADNI is an NIH funded, multicenter study, which includes participants with normal and impaired cognition who were administered a comprehensive battery of neuropsychological tests every six months. We related the CKD-epi eGFR with previously validated composite scores for memory (ADNI-Mem) and executive function (ADNI-EF) in multivariable linear regression analysis.

Results: 1127 participants with a mean age of 73.8±7.1 years, 57% men, 97% Caucasian, and mean follow up for 6±2.6 years were included. Mean baseline eGFR was 76.4±19 ml/min/1.73 m^2. ADNI-Mem and ADNI-EF scores declined across all eGFR categories (figure). Older age and lower education were associated with declines in both ADNI-Mem and ADNI-EF scores. Baseline eGFR was not associated with declines in either ADNI-Mem or ADNI-EF scores (table).

Conclusions: There is no association between baseline eGFR and cognitive decline in elderly persons with mild-moderate impairment in kidney function.

Funding: Other NIH Support - K23-AG055666

PO1703

Post-Operative Delirium and Cognitive Decline in Kidney Transplantation

Nadia M. Chu, Xiaomeng Chen, Dorry L. Segev, Mara McAdams-DeMarco. *Johns Hopkins University, Baltimore, MD.*

Background: Post-operative delirium may be a marker for greater cognitive vulnerability to stressors. As such, those with post-operative delirium may experience steeper decline in cognitive performance following stressors of surgery post-KT.

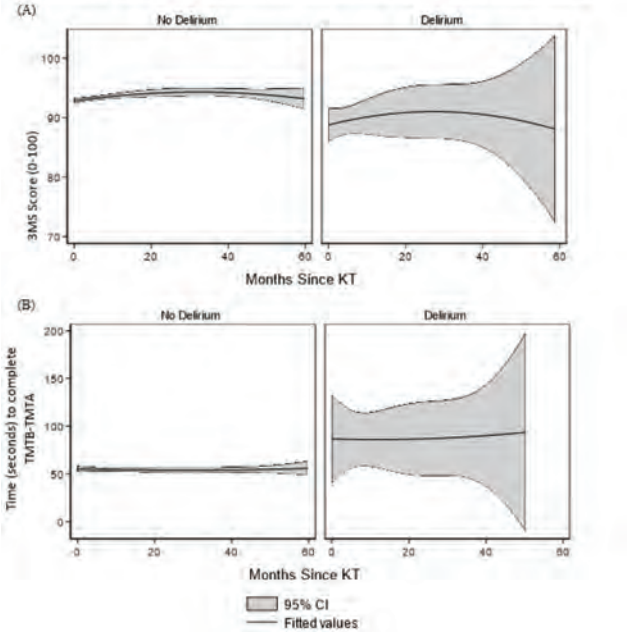
Methods: We used a single center cohort of 912 adult KT recipients with delirium assessments abstracted from medical records and global (3MS) and domain-specific (executive function: time to complete TMT-B minus TMT-A) cognitive performance measured at KT, 1-month, 3-months, 6-months, 1-year, and annually thereafter post-KT. We used mixed effects models to describe repeated measures of cognitive performance and compare trajectories by post-operative delirium.

Results: Among 912 KT recipients, 44 (4.8%) had post-operative delirium. Delirium was associated with higher levels of cognitive impairment at KT (18.2% vs 8.0%), and was associated with lower 3MS component scores including memory, identification/association, and orientation. After adjustment, those with delirium had 3MS scores that were on average 3.6 points lower than those without delirium (95%CI: -6.9, 0.3) at time of KT; delirium was not associated with differing global cognitive trajectories post-KT (difference=0.04 points/month, 95%CI:-0.1, 0.2) (Figure1A). However, delirium was associated with lower executive function at KT (difference=44.0s, 95%CI: 17.4, 70.6) and steeper decline in executive function post-KT (difference=-1.1s/month, 95%CI:-2.1,-0.05) (Figure1B).

Conclusions: KT recipients with delirium experience greater decline in executive function, indicating greater cognitive vulnerability with potential vascular etiologies. Nephrologists and transplant centers should be aware of cognitive risks associated with post-KT delirium and implement available preventative interventions to reduce risk of delirium.

Funding: NIDDK Support, Other NIH Support - National Institute on Aging (NIA)

Figure1. Unadjusted cognitive trajectories by post-operation delirium status among kidney transplant (KT) recipients (n=912). (A) Global cognitive function: 3MS Scores ranging from 0-100, where lower scores equate to poorer cognitive function, and (B) Executive function: time to complete Trail Making Test Part B (TMTB) minus time to complete Trail Making Test Part A (TMTA), where longer time equates to poorer executive function.



PO1704

A Comparison of Frailty Measures Among Patients Referred for Kidney Transplantation

George L. Worthen,[1] Rita Suri,[6] Lakshman Gunaratnam,[2] Seychelle Yohanna,[5] Michael Walsh,[5] Bhanu Prasad,[3] Navdeep Tangri,[4] Steve Doucette,[7] Kenneth J. Rockwood,[1] Amanda J. Vinson,[1] Kenneth A. West,[1] Karthik K. Tennankore.[1] *[1]Dalhousie University, Halifax, NS, Canada; [2]Western University, London, ON, Canada; [3]University of Saskatchewan, Saskatoon, SK, Canada; [4]University of Manitoba, Winnipeg, MB, Canada; [5]McMaster University, Hamilton, ON, Canada; [6]McGill University, Montreal, QC, Canada; [7]Nova Scotia Health Authority, Halifax, NS, Canada.*

Background: Frailty is highly prevalent in patients referred for kidney transplantation. While the Fried Frailty Phenotype (FP) is widely used, less is known about other frailty assessment tools. We assessed and compared the prevalence of frailty using three tools in kidney transplant waitlist candidates.

Methods: Kidney transplant waitlist candidates were prospectively enrolled from five centers from June 2016-Feb 2020. Frailty was primarily defined using the FP as three or more of slowness (using walk time), weakness (using grip strength), weight loss, low activity or exhaustion (the latter three using questionnaires). Secondary tools included a Frailty Index (FI) consisting of 37 variables across the domains of social function/cognition, function, mobility and comorbidity, and the Clinical Frailty Scale (CFS), a frailty screen based on clinician gestalt that ranges from 1 (very fit) to 8 (very severely frail). We used adjusted logistic regression to identify factors associated with frailty measured by the FP. Area under the receiver-operator characteristics (ROC) curves were calculated to compare the FP to the FI and CFS.

Results: Of 542 enrolled patients, 64% were male, 80% were white, and the mean age was 54±14. The prevalence of frailty by the FP was 16%; it was 27% for those >65 years old. Of the FP components, low grip strength (41%), and exhaustion (36%) were the most prevalent. Using an established cut point of 0.25 yielded a prevalence of 38% by the FI (46% for those >65). Using a cut-off of 5 on the CFS (mildly frail), frailty prevalence was 4% (7% for those >65). The mean FI score was 0.23±0.14 (max 0.70) and median CFS score was 3 (IQR 2,3) or "managing well". Diabetes (adjusted odds ratio; aOR 2.0, 95% CI 1.0, 3.8), and cerebrovascular disease (aOR 3.3 95% CI 1.3, 8.5) were associated with frailty defined by the FP. Area under the ROC curve for the FP and FI/CFS were 0.86 (good) and 0.69 (poor) respectively.

Conclusions: The prevalence of frailty varies using different measurement tools and there are differences in perceived (CFS) versus measured (FP/FI) frailty among patients referred for transplantation. Determining which tool is most associated with outcomes for waitlisted patients is a future objective of this study.

PO1705

DNA Double-Strand Breaks of Human Glomerular Endothelial Cell-Induced Collagen Type VI Excretion and Nodular Lesions in Various Kidney Diseases

Ai Fujii,[1] Yumi Sunatani,[2] Kengo Furuichi,[1] Keiji Fujimoto,[1] Hiroki Adachi,[1] Kuniyoshi Iwabuchi,[2] Hitoshi Yokoyama.[1] *[1]Kanazawa Medical University School of Medicine, Department of Nephrology, Kahokugun, Japan; [2]Kanazawa Medical University School of Medicine, Department of Biochemistry, Kahokugun, Japan.*

Background: Collagen deposition is the common histological end-point of progressive chronic kidney diseases (CKDs). We focused on collagen type VI (COL6) which is known as components of nodular lesions. This study was performed to test the hypothesis that glomerular endothelial cells with DNA double-strand breaks (DSBs) induce the accumulation of COL6 in various kidney disease and evaluated the mechanism of COL6 accumulation after DSBs.

Methods: We examined various kidney diseases (n:180) in which DSBs and glomerular fibrosis were detected by phospho-histone H2AX (γ-H2AX) expression and COL6 accumulation. In *vitro* study, we investigated the relationship between DSBs and COL6 excretion and the intracellular signal pathways in human glomerular endothelial cells (HRGECs) using mitomycin C (MMc)-induced DNA damage, and other two agents; Neocarzinostatin (NCS) and camptothecin (CPT). We examined the effect of DSBs response signal pathways, i.e. ATM, ATR and DNA-PK using their specific kinase inhibitors (KU55933, VE-821, Nu7441).

Results: COL6 and γ-H2AX were detected in glomeruli in which the γ-H2AX-positive area was identified as the independent factor for the % COL6-positive area (β: 0.553, t = 2.842, p = 0.009). Furthermore, COL6 was a component of the nodular lesions found in various kidney diseases. In *vitro* study of MMc-induced DNA damage, COL6 excretion detected by the decrease of COL6 positive cells was suppressed in the ATR-inhibited group (p <0.01 for 2 h, p <0.001 for 24 h). Moreover, CPT treated cells induced the COL6 excretion as well as MMc treated cells (p <0.001 for MMc, p=0.002 for CPT).

Conclusions: This study showed that DNA damage-sensing kinase of ATR was activated in response to DSBs and induced COL6 secretion of human glomerular endothelial cells. Furthermore, DNA damage may induce the nodular glomerulosclerosis in various kidney diseases.

Funding: Government Support - Non-U.S.

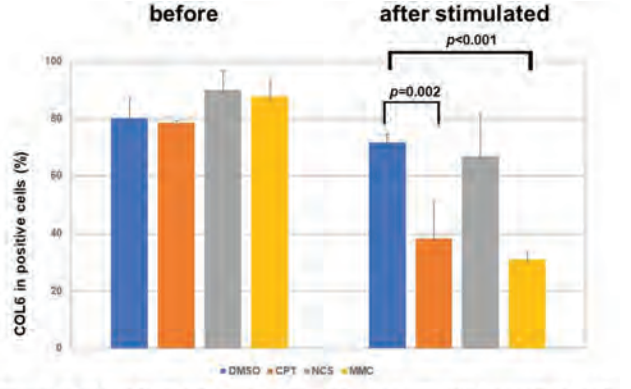


Figure. ATM and Rad3-related (ATR) is associated with COL6 secretion (n=3).

Clinical Course of a Patient with FSGS and a Basement Membrane Defect

Frank A. Portugal, Steve I. Khalil. *Robert Wood Johnson University Hospital, New Brunswick, NJ.*

Introduction: We present a case of a patient with a familial basement membrane abnormality who developed nephrotic syndrome and worsening CKD due to FSGS and outline her response to immunosuppressive therapy over 15 months. Our case suggests that immunosuppressive therapy may benefit such patients and delay progression to ESRD.

Case Description: A 38-year-old woman with microscopic hematuria was found to have a urine Pr/Cr ratio of 2.4 during pregnancy. Her s.Cr was 1.4-1.6 mg/dL and she had over 13g of proteinuria during pregnancy. After delivery, the serum creatinine stabilized between 1.1-1.3 mg/dL and her urine Pr/Cr ratio was 8.0 with an unrevealing serologic workup. She has no family history of renal insufficiency, but her father and 14-year-old daughter have microscopic hematuria. A renal biopsy revealed FSGS with ultrastructural GBM alterations including thinning and lamellation as well as nearly complete foot process effacement. Collagen IV staining demonstrated a normal IF pattern for α2 and α5 chains. She was started on prednisone, however, her glycemic control deteriorated and therapy was stopped after 1 week. She was then treated with Losartan and Cyclosporine and her Pr/Cr ratio improved to 1.3-1.5 mg/dL but her serum creatinine gradually rose to 2.0 mg/dL. Losartan was changed to Diltiazem and CsA was changed to MMF. Her s.Cr has trended down to 1.4 mg/dL with a urine Pr/Cr of 1.9 fifteen months after diagnosis. She was referred for genetic testing and was found to be heterozygous for a mutation of COL4A4 (Exon 39, c.3679G>A, p.Gly1227Arg).

Discussion: Prior case series have demonstrated the coexistence of familial FSGS and hereditary GBM abnormalities. However, it has not been fully elucidated whether FSGS occurs as a primary process or secondary to the GBM abnormalities nor is it known whether such patients benefit from immunosuppression. Our case details the course of a patient with nephrotic syndrome due to FSGS and thin basement membrane changes with normal collagen IV staining found to have a genetic COL4A mutation which is not known to be a pathogenic variant. She demonstrated a partial response to immunosuppression with greater than 75% improvement in proteinuria and stabilization of the serum creatinine with treatment with MMF suggesting that immunosuppressive therapy may alter the course of disease in patients with a dual diagnosis of FSGS and thin basement membrane abnormalities.

PO1707

VEGFA-Angpt-Tie2 Participates in the Interaction Between Mesangial Cells and Glomerular Endothelial Cells in Rat Anti-Thy-1 Nephritis

Lingling Wu, Yinghua Zhao, Jie Wu, Xiangmei Chen. *Chinese PLA General Hospital and Military Medical Postgraduate College, Beijing, China.*

Background: Mesangial cells and glomerular endothelial cells, as the renal intrinsic cells,are involved in the occurrence and development of various kidney diseases. In mesangial proliferative glomerulonephritis, the endothelial cells are affected by the signals from mesangial cells and show pathological changes such as diffuse capillary proliferation. But the specific signaling pathway mechanism is still unclear.

Methods: By establishing the rat model of anti-Thy-1 nephritis,and co-culturing mesangial cells and endothelial cells in the transwell system.

Results: By establishing the rat model of anti-Thy-1 nephritis, we found that the damage of mesangial cells in the glomeruli was accompanied by the proliferation of diffuse endothelial cells on the 7th day. Furthermore, we found that activated mesangial cells can promote endothelial cell proliferation and migration through co-culturing mesangial cells and endothelial cells in the transwell system, and vice versa. VEGFA expression was increased in activated mesangial cells, which promoted the expression of Angpt2 in endothelial cells. Angpt2 binds to Tie2, the endothelial cell surface receptor, and inhibits the phosphorylation of Tie2, thereby causing endothelial cell proliferation. When VEGFA neutralizing antibody was added into the co-culture system, the expression level of Angpt2 in endothelial cells decreased, the phosphorylation level of Tie2 increased, and cell proliferation was inhibited. If Angpt1 was added into the co-culture system and combined with Tie2, the effect of Angpt2 could be competitively inhibited, and the endothelial cell proliferation could be alleviated. In addition, after we injected Angpt1 into rats of anti-Thy-1 nephritis, the expression of Angpt2 in glomeruli decreased, the phosphorylation level of Tie2 increased, and the proliferation of endothelial cells decreased significantly.

Conclusions: The above results suggest that VEGFA-Angpt-Tie2 signaling pathway is involved in the interaction between mesangial cells and endothelial cells in mesangial proliferative glomerulonephritis. Angpt1 can be used as a new method to treat mesangial proliferative glomerulonephritis.

PO1708

GBM Deposition of Collagen 3α1 in Alport Glomeruli by Mesangial Filopodia Injure Podocytes via Aberrant Signaling Through DDR1 and Integrin α2β1

Dominic E. Cosgrove, Kevin Wilhelm, Jacob D. Madison, Daniel T. Meehan, Duane C. Delimont. *Boys Town National Research Hospital, Omaha, NE.*

Background: We have previously shown in In Alport mice that ET_AR activation in mesangial cells results in sub-endothelial invasion of glomerular capillaries by mesangial filopodia. The filopodia deposit mesangial matrix in the GBM, including laminin 211 which activates NF-kB, resulting in induction of inflammatory cytokines culminating in tubulointerstitial fibrosis. Here we show that collagen 3α1 is also deposited in the GBM, where it contributes to podocyte injury through activation of DDR1 and integrin α2β1 receptor signaling.

Methods: Wild type and Alport kidneys from mice were dual immunostained with anti- collagen 3α1 and anti-laminin 211 antibodies and analyzed by confocal microscopy. Dual staining with anti-DDR1 and anti-collagen 3α1 was analyzed by super resolution microscopy (SR-SIM). Cultured murine Alport podocytes were overlaid with recombinant collagen 3α1 or not for 24 hours and RNA analyzed by RNA-seq. These same cells were subjected to Si-RNA knockdown for integrin α2 or DDR1 and the RNA analyzed by RNA-seq. Results from this study were compared with RNAseq from RNA isolated from 7-week-old wild type and Alport mouse glomeruli.

Results: Collagen 3α1 localized to the mesangium in wild type mice and was found in both the mesangium and in the GBM in Alport mice where it co-localized with laminin 211. SR-SIM showed that collagen 3α1 staining was juxtaposed to DDR1 staining on podocytes and thus available for binding podocyte receptors. Numerous genes associated with podocyte injury are up-regulated in both Alport glomeruli and GECs treated with collagen 3α1, including osteopontin, TGF-β1/2, and collagen 1α1 among many others. Knockdown of α2β1 integrin or DDR1 ameliorated induction of selective profibrotic genes in GECs treated with collagen 3α1.

Conclusions: Collagen 3α1 is deposited in the GBM by mesangial filopodia where it activates DDR1 and α2β1 receptors resulting in podocyte injury and likely contributing significantly to glomerular damage. This may explain why deletion of either DDR1 or α2β1 integrin in Alport mice ameliorates renal pathology.

Protection of the Remnant Rat Glomeruli from Mechanical Stress Through Structural Adaptation and Pharmacological Intervention After 5/6-Nephrectomy: A Modeling Study

Owen Richfield,[1] Ricardo Cortez,[2] L. Gabriel Navar.[3] *[1]Tulane University Bioinnovation PhD Program, New Orleans, LA; [2]Tulane University Department of Mathematics, New Orleans, LA; [3]Tulane University Department of Physiology, New Orleans, LA.*

Background: 5/6-nephrectomy leads to increased blood flow and pressure in the remaining glomeruli, ultimately resulting in sclerosis. It is hypothesized that these hemodynamic alterations increase mechanical stresses, including shear stress on the glomerular endothelial cells and circumferential hoop stress on podocytes, however these mechanical stresses have not been rigorously quantified. In renoprival conditions glomerular capillary diameters increase, and it is unclear how these structural adaptations affect the mechanical stress magnitudes.

Methods: A mathematical microvascular hemodynamic model was developed to simulate blood flow and plasma filtration on each capillary segment of an anatomically-accurate rat glomerular capillary network. Model parameters were adjusted to match glomerular hemodynamic data for control and 5/6-nephrectomized conditions with and without the presence of the ACE inhibitor, enalapril (Meyer TW et al. *Kidney Int.* 1987;31(3):752-759). Glomerular capillary diameters were increased according to experimental imaging data (Ferrell, Nicholas, et al. *AJP-Renal* 308.6 (2015): F588-F593) to simulate glomerular structural adaptations post-5/6-nephrectomy.

Results: Post-5/6-nephrectomy, glomerular capillary structural adaptations reduced mean network shear stress from 156.5 to 92.8 dynes/cm^2. Without structural adaptations enalapril reduced mean shear stress to 136.1 dynes/cm^2. The increase in glomerular capillary diameter reduced shear stress while the increased diameters combined with glomerular hypertension increased mean hoop stress from 90.9 to 104.3 kPa. The combination of enalapril and structural adaptations resulted in a mean network shear stress of 81.1 dynes/cm^2 and hoop stress of 69.7 kPa.

Conclusions: Our results indicate that glomerular structural adaptations protect the glomerular endothelial cells from increased levels of shear stress, thus preserving kidney function. However, these structural adaptations in turn lead to increased hoop stresses. The combination of enalapril with structural adaptations reduces mechanical stress, providing protection and maintaining function for longer periods.

Major Vault Protein Contributes to Increased Interstitial Fibrosis in a Murine Model of CKD

Cheuk Yin Wong, Susan Yung, Caleb C. Chan, Tak Mao D. Chan. *The University of Hong Kong, Hong Kong, Hong Kong.*

Background: Chronic kidney disease (CKD) is a global health issue characterized by interstitial fibrosis and tubular atrophy, and progressive CKD results in kidney failure. There is currently no effective intervention for interstitial fibrosis. We previously showed that major vault protein (MVP), a key component of the vault complex, contributed to increased matrix protein deposition in murine unilateral ureteral obstruction (UUO) animal model. We extended our investigations to a murine model of CKD.

Methods: CKD was induced in MVP wild-type (WT) and knockout (KO) mice by feeding with standard chow containing 0.2% adenine for 8 weeks, after which time mice were sacrificed and kidneys were harvested and examined. Spot urine albumin-to-creatinine ratio was also measured. MVP WT and KO mice fed with standard chow served as controls.

Results: MVP WT mice with CKD showed increased MVP expression, predominantly in proximal tubular epithelial cells, compared to MVP WT control mice, and this was accompanied by development of proteinuria, tubular atrophy, tubulo-interstitial macrophage infiltration, and increased interstitial α-smooth muscle actin, fibronectin and collagen III expression. MVP KO mice with CKD showed less proteinuria ($P<0.05$) and less severe kidney histopathological features with reduced immune cell infiltration, and also reduced expression of fibrosis mediators compared to WT CKD mice. Exogenous TNF-α, IL-6, or MCP-1 increased MVP expression in cultured renal proximal tubular epithelial cells.

Conclusions: The data suggest that progressive CKD in this murine model is accompanied by increased renal tubular epithelial MVP expression, and MVP may contribute to the pathogenesis of tubulo-interstitial injury and damage.

Signaling at the Mesangial Cell (MC) Membrane in Light Chain Deposition Disease (LCDD) and AL-Amyloidosis (AL-Am) Involves Sortilin-Related Receptor (SORL1), Caveolins, and C-Fos

Jiamin Teng,[1] Chun Zeng,[1] Elba A. Turbat-Herrera,[1] Takahito Moriyama,[2] Luis Del Pozo-Yauner,[1] Bing Liu,[1] Xinggui Shen,[3] Guillermo A. Herrera.[1] Department of Pathology, University of South Alabama *[1]University of South Alabama, Mobile, AL; [2]Tokyo Joshi Ika Daigaku Fuzoku Kogenbyo Ryumachi Tsufu Center, Shinjuku-ku, Japan; [3]Louisiana State University Health Sciences Center Shreveport, Shreveport, LA.*

Background: AL-Am and LCDD are two diametrically opposed glomerulopathies in terms of mesangial alterations produced by glomerulopathic light chains (GLCs). Their pathogenesis involves surface MC interactions resulting in cytoskeletal changes, c-fos translocation, phenotypic transformations, lysosomal activation (AL-Am), rough endoplasmic reticulum expansion (LCDD), and ultimately, mesangial matrix alterations. The present study addressed signaling pathways involved.

Methods: Human (H) MCs (both caveolin 1- wild type / knock-out) were incubated with monoclonal LCs purified from the urine of renal biopsy-proven AL-Am, LCDD, myeloma cast nephropathy (MCN) patients or albumin for up to 96 hours at different time frames. The samples were analyzed using light, immunofluorescence and electron microscopy, including immunolabeling for c-fos, kappa / lambda light LCs, caveolin-1 and SORL1.

Results: Co-localizations in cup-shaped MC membrane indentations (caveolae) of GLCs with caveolin-1, and SORL1 were documented using double immunofluorescence and immunogold labeling ultrastructural techniques. Upon interactions with GLC (but not MCNLCs or albumin) caveolae on the surface of MCs increased dramatically, SORL1 was activated and c-fos translocated from cytoplasm to nuclei.

Conclusions: SORL1 is a key component of GLCs signal transduction in MCs. Co-localization supported the notion that Interactions of GLCs with MCs occurred in caveolae activating SORL1. Caveolin-1 knock out HMCs abolished c-fos translocation from cytoplasm to nuclei and the downstream mesangial alterations (i.e. mesangial expansion / increased protein production) in LCDD group. In ALLC group, c-fos translocation and amyloid production were decreased but not totally abolished, suggesting that other mechanism may be involved in amyloidogenesis. C-fos plays a crucial role following SORL1 activation to promote mesangial cell phenotypic transformation essential for amyloidogenesis and extracellular matrix over production, in AL-amyloidosis and LCDD, respectively.

Compartmental Differences Within the COL3A1 Network in Proteinuric Kidney Disease: Informing Drug Activity Using the Jaccard-Tanimoto Index

Prakash Narayan, Sony Dalapati, Ping Zhou, Natalia Prakash, Anthony Pellicano, Itzhak D. Goldberg. Angion Biomedica Corp. *Angion Biomedica Corp, Uniondale, NY.*

Background: In proteinuric kidney disease, type III collagen (COL III) participates in mesangial expansion, crescent organization, and glomerulosclerosis. Matrix deposition within the tubulointerstitium is associated with worse prognosis. A semi-quantitative analysis was conducted to understand compartmental differences within the *COL3A1* transcriptomic network, and to inform therapeutic potential of drugs that mitigate COL III deposition.

Methods: Proteinuria and renal *COL3A1* (day 21) mRNA were measured in adult male Wistar rats administered PAN (~100 mg/kg, intraperitoneal). HumanBase was used to build glomerular (G) and tubular (T) *COL3A1* transcriptomic networks. Network analysis was restricted to 51 elements each, inclusive of *COL3A1*, with a minimum interaction confidence of 0.01. The Jaccard-Tanimoto similarity index was used to calculate common elements within the two compartments.

Results: The rat PAN model was associated with increased proteinuria (*, $p<0.01$ vs. sham) which correlated directly and significantly with renal *COL3A1* mRNA expression level. Network analysis revealed a relative strong glomerular *COL3A1* interactome with an average strength of 0.8±0.08 and a relatively weaker tubular *COL3A1* interactome with an average strength of 0.56±0.01. The Jaccard-Tannimoto similarity index between the glomerular and tubular COL3A1 signaling elements was 5.1%.

Conclusions: Glomerulosclerosis in proteinuric kidney disease may result from a relatively strong *COL3A1* transcriptomic network within that compartment. Tubulointerstitial matrix deposition is rare in proteinuric kidney disease, possibly due to a weaker *COL3A1* transcriptomic network in that compartment. Drugs designed to specifically mitigate COL III deposition might be most effective against glomerulosclerosis.

The Correlation Between Urinary MicroRNA-21 and Renal Parameters in Patients with IgA Nephropathy

Akira Araumi, Tsukasa Osaki, Kazunobu Ichikawa, Masafumi Watanabe, Tsuneo Konta. *Yamagata University Faculty of Medicine, Yamagata, Japan.*

Background: The expression of microRNA-21 (miR-21) in renal tissue is reported to be related to tubulointerstitial fibrosis and renal outcome in IgA nephropathy. In this study, we examined whether the urinary concentration of miR-21 is related to clinicopathological parameters and short-term changes in renal function in patients with IgA nephropathy.

Methods: We extracted and quantified microRNAs in morning spot urine in 88 patients with IgA nephropathy at biopsy and five control subjects, and examined the relationship between clinical and histological parameters, one-year changes in eGFR and urinary miR-21. The concentrations of microRNAs and proteins were corrected to the concentration of urinary creatinine and were log-transformed for simple correlation analysis.

Results: The urinary excretion of miR-21 was detected in all subjects, and the urinary concentration of miR-21 in patients with IgA nephropathy was significantly higher than those in controls. Among 88 patients with IgA nephropathy, urinary miR-21 levels showed a significantly positive correlation with the urinary concentration of total microRNA (r=0.65), total protein (r=0.40), beta2-microglobulin (r=0.62), and N-acetyl-beta-D-glucosaminidase (NAG) (r=0.37), but not with baseline GFR, and urinary red blood cells. In contrast, the urinary miR-21 levels did not show a significant correlation with histological changes, including glomerular proliferation/sclerosis and tubulointerstitial fibrosis. The one-year changes in eGFR after biopsy showed a significant inverse correlation with the urinary concentration of miR-21 (r=-0.31) and total protein (r=-0.37), but not total microRNA, beta2-microglobulin, and NAG. The correlation between urinary miR-21 and one-year eGFR change was similar in the subjects with and without steroid treatment.

Conclusions: In this study, the urinary excretion of miR-21 was associated with clinical parameters and one-year changes in renal function in patients with IgA nephropathy, suggesting that urinary miR-21 might be used as a biomarker of IgA nephropathy.

Diagnostic Delay and the Clinical Prodrome in US Adults with Systemic Light Chain (AL) Amyloidosis with Renal Involvement

Laura Hester,[1] Dina Gifkins,[1] Kevin Bellew,[2] Jessica Vermeulen,[3] Jordan Schecter,[4] Victor Dishy,[4] Brendan Weiss.[2] *[1]Janssen Research & Development LLC, Titusville, NJ; [2]Janssen Research & Development LLC, Spring House, PA; [3]Janssen Research & Development LLC, Leiden, Netherlands; [4]Janssen Research & Development, LLC, Raritan, NJ.*

Background: Early therapy for AL can reverse renal impairment, but AL diagnosis (dx) is often delayed. We report the first population-level study of the diagnostic delay and prodrome in systemic AL patients (pts) with prior signs/symptoms (S/Sx) of renal impairment.

Methods: Pts with renal S/Sx at AL dx were identified in the US Optum Clinformatics® claims data since June 2001. AL was defined as ≥1 inpatient or ≥2 outpatient AL codes, followed by ≥1 anti-plasma cell therapy in 2 yrs. Renal S/Sx were defined as ≥1 prior dx code for stage 1-3 chronic kidney disease (CKD), renal failure/ESRD, nephrotic syndrome, acute kidney injury, or proteinuria. We described prevalence and overlap of S/Sx and time from first S/Sx to AL dx in renal AL pts. Kaplan-Meier estimates and log-rank tests compared time to AL diagnosis by prior monoclonal gammopathy (MG).

Results: Of 870 renal AL pts (67% of AL pts), 70% had CKD, 46% had renal failure, 58% had acute renal failure, 29% had nephrotic syndrome, and 61% had proteinuria by AL dx. Median time since first renal S/Sx and AL dx was 196 days, with a median of 205 days since CKD dx and 23 days from first nephrotic syndrome dx (**Figure**). Among renal AL pts, 89% had cardiac S/Sx, 67% had neurologic S/Sx, and 57% had ≥3 systems involved. Median time from first nephrology visit for renal S/Sx and AL dx was 67 days (6 visits). AL dx was earlier for pts with prior MG than without (median 83 vs 210 days, *P*=0.002).

Conclusions: The median time to AL dx after the first renal S/Sx was 196 days and 67 days after the first nephrology visit. The presence of a prior MG shortened the time to AL dx.

Case of Leukocyte Cell-Derived Chemotaxin 2-Associated Renal Amyloidosis

Anita Kamarzarian, Masood Mahmood, Golriz Jafari. *Olive View Medical Center, Sylmar, CA.*

Introduction: Amyloidosis is a disorder characterized by the abnormal deposition of insoluble protein fibrils in tissues. The most recently described form of amyloidosis is derived from leukocyte cell-derived chemotaxin 2 (LECT2).

Case Description: 60 yo with history of HTN and COPD referred for evlauation of CKD. Creatinine of 1.29 (6/2017) and 1.65 (09/2017). urinalysis no protein and 1 RBC. 24 hour urine protein showed 190 mg of protein. Renal Ultrasound was normal and all other serolgic labs were normal. She had a Renal Biopsy that showed Cango red positive amyloid deposits and Mass Spectromety based proteomic analysis showed peptide profile consistent with ALECT-2 type Amyloid deposition.

Discussion: Ever since the first case of ALECT2 was discovered in 2008, several cases have been reported. ALECT2 affects patients mainly of Hispanic origin, especially Mexican Americans. It is less common in African Americans and Caucasians. The pathogenesis of this disease is related to accumulation of a protein called LECT2 which was first isolated in 1998. LECT2 protein is a multifunctional factor involved in chemotaxis, inflammation, immunomodulation, and the damage/repair proces. Most patients with ALECT2 present with minimal proteinuria, bland urine sediment and impaired renal function, and the diagnosis of ALECT2 is usually incidental following biopsies for unrelated conditions or uncertain diagnoses. ALECT2 is a slowly progressive disease likely due to the selective involvement of the interstitium. A full nephrotic syndrome is uncommon in renal ALECT2. Neither the renal function nor the proteinuria correlates with the amyloid load in the renal biopsy. There is no specific therapy for ALECT2. Transplantation remains the only effective treatment. But there is a high risk of recurrence in view of ongoing synthesis of the abnormal protein by the liver. In addition to the renal biopsy findings, confirmation of ALECT2 diagnosis requires immunohistochemistry or chemical analysis by tandem mass spectrometry.

PO1716

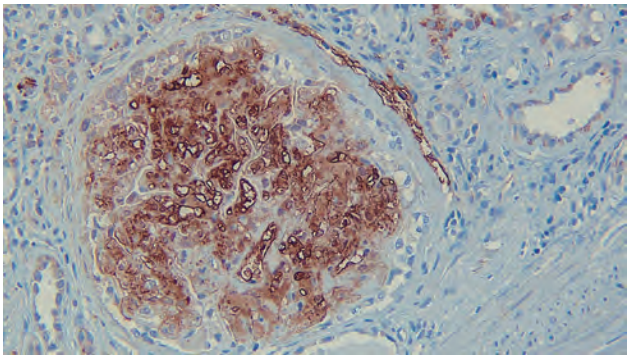
Idiopathic Fibrillary Glomerulonephritis: A Report of Two Cases

Gargi Sharma Priamvada,[1] Aneesh S. Kallapur,[2] Josue A. Lozano,[3] Pankaj Jawa,[1] Koyal Jain.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; [3]Department of Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Fibrillary glomerulonephritis(FGN) is a rare glomerular disease characterized by the presence of fibrillar deposits in glomeruli and is associated with poor prognosis, often leading to end stage renal disease(ESRD). Previously considered to be idiopathic, new data suggests there is a secondary association in 30-50% of cases with underlying hepatitis C infection, malignancy, dysproteinemia and autoimmune disease. Immunohistochemical staining for DNA-J heat shock protein B9(DNAJB9) is emerging as a marker for rapid diagnosis of FGN.

Case Description: We report two patients with FGN who initially presented with monoclonal gammopathy(MG), but varied clinical courses. First patient, 60 year-old female presented with MG(IgG4 subclass), acanthocyturia and nephrotic syndrome. Renal biopsy showed PAS positive deposits in capillary loops and mesangium; Immunofluorescence microscopy showed IgG, C3, κ and λ light chains. Electron microscopy showed 20nm non-branching randomly arranged fibrils. Five years later, she is still in remission after treatment with bortezomib, cyclophosphamide and dexamethasone. Another 63 years old female presented with renal failure, positive pANCA and MG. Biopsy showed DNAJB9-positive sclerosing and proliferative FGN with 10% cellular crescents and severe interstitial fibrosis and tubular atrophy. She was treated with corticosteroids and rituximab for idiopathic FGN mimicking type III RPGN. However, she became dialysis dependent.

Discussion: FGN has broad presentation and course despite aggressive therapy. A study determined the strongest predictor of outcome to be initial serum creatinine. Other predictors were age, degree of glomerulosclerosis and proteinuria. Knowledge of pathogenesis along with renal pathology can help differentiate this from other fibril deposition diseases like amyloidosis and immunotactoid glomerulopathy. It is imperative to promptly identify FGN as it often progresses to ESRD and has limited data on optimal therapy.



Immunohistochemistry stain for DNAJB9. Glomerulus show diffuse extracellular smudgy staining. mag x200.

PO1717

A Case of Secondary Focal Segmental Glomerulosclerosis and Thrombotic Microangiopathy in a Heart Transplant Patient

Neha Deval, Hay Me Me, Jennifer Griffiths, Aromma Kapoor, Savneek S. Chugh. *Westchester Medical Center, Valhalla, NY.*

Introduction: A few case reports have shown that focal segmental glomerulosclerosis (FSGS) can lead to thrombotic microangiopathy (TMA) in chronic kidney disease patients with severe hypertension. One case report presented the development of FSGS and TMA in liver transplant patient on Tyrosine kinase inhibitor. We present a case of FSGS without vascular injury despite clinically diagnosed TMA in heart transplant patient.

Case Description: A 42-year old female with history of postpartum cardiomyopathy with implantable cardioverter defibrillator since 2005 was admitted for heart transplant evaluation. Patient developed rapid progressive worsening of renal failure requiring hemodialysis after the heart transplant. Urinalysis showed proteinuria, hematuria; blood work showed hemolytic anemia, thrombocytopenia and schistocytes. TMA was diagnosed and eculizumab was started while continuing with hemodialysis. Heart biopsy showed no rejection, but kidney biopsy revealed the pathological diagnosis of secondary FSGS of not otherwise specified type without vasculitis under both light and electron microscopy. No significant glomerular staining seen on immunofluorescence microscopy as well. Patient was maintained on immunosuppressive regime with mycophenolate, tacrolimus and prednisone, receiving eculizumab weekly for 3 months, and subsequently recovered from hemodialysis.

Discussion: It is very rare to have FSGS without microangiopathy in hematologically confirmed TMA. Calcineurin induced inhibitors (CIN) are known to cause various forms of acute kidney injury including FSGS. In our case, presumed calcinuerin induced nephrotoxicity presented as secondary FSGS without angiopathy. This case reflects the unpredictability of the etiology of kidney disease based solely on clinical features and blood tests. No improvement in kidney function necessitated the renal biopsy. It also raises the challenging points in treatment regime in transplant patient populations.

PO1718

D-Penicillamine-Induced ANA(+)ANCA(+) Crescentic Glomerulonephritis in Wilson Disease

Shinichiro Koga. *Section for Nephrology and Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo 1868541, Japan.*

Introduction: Wilson's disease is an inherited autosomal recessive disorder caused by loss of function of a copper exchanger adenosinetriposphate encoded by ATP7B, which results in impaired biliary copper excretion and accumulation of copper in plasma and tissues. In the kidney, copper accumulation may affect tubular cells, but was never associated with glomelular lesions. Some patients have been reported as crescentic glomerulonephritis with Wilson's disease treated with D-penicillamine[1)2)].

Case Description: A 45 years old female was consulted to adult nephrology clinic on worsening chronic kidney disease. She had prescribed 800mg metalcaptase for 3

years on compound heterogenous Wilson's disease diagnosed by liver biopsy, Western blotting and gene sequence on ATP7B[3]. Serum creatinine(Cr) was around 4.5 mg/dl, antimyeloperoxidase(MPO)-ANCA 350 U/ml, antinuclear factors titer 1/640. Both anti-proteinase(PR3) antibody and anti-glomelular basement membrane(GBM) antibody were negative. Renal biopsy specimen show pauci-immune crescentic glomerulonephritis with 7/9 fibrous or fibrocellular crescents, and 2/9 global collaptic sclerosis. Also, mild diffuse interstitial fibrosis was found with lymphoid and other chronic inflammatory cells. No pathological finding was detected on vasculitis. Diagnosed as ANCA-associated glomerulonephritis, methyl-prednisolone(PSL) pulse therapy was given and preceded to oral PSL[4]. PSL was gradually reduced and terminated after seven years, along with getting MPO-ANCA<3.5 U/ml.Cr was improved to 1.5mg/dl in spite of presence of mild diffuse interstitial fibrosis. Hereafter 15 years, no medication except metalcaptase was given, but regretfully Cr has been deteriorated to 4.5mg/dl,MPO-ANCA~15-25 U/ml. Other paraproteinemia or malignant diseases including multiple myeloma was excluded. Taken together for these 25 years, D-penicillamine-associated interstitial nephritis[1)2)] has suspected. Oral zinc acetate was once truncated due to gastroenterological side effect, then planned to change to trientene.

Discussion: The pathogenesis of drug-induced ANCA-associated vasculitis has not been proven. There is a hypothesis that MPO binds to drug metabolites and alters the MPO antigenic property[2]. Treatment of AAV is usually with mPSL pulse, cyclophosphamide, and/or rituximab. **References**:1)Am J Kidney Dis 2007;**50**:821.2) Clin Nephrol 2016;**85**:296.3)Kanzo-Hepatology(Tokyo)1996;**37Suppl2**:116.4)Japan J Nephrol 1998;**40**:518.

In Silico Prediction of Potential New Biomarkers of IgA Nephropathy Interstitial Lesion

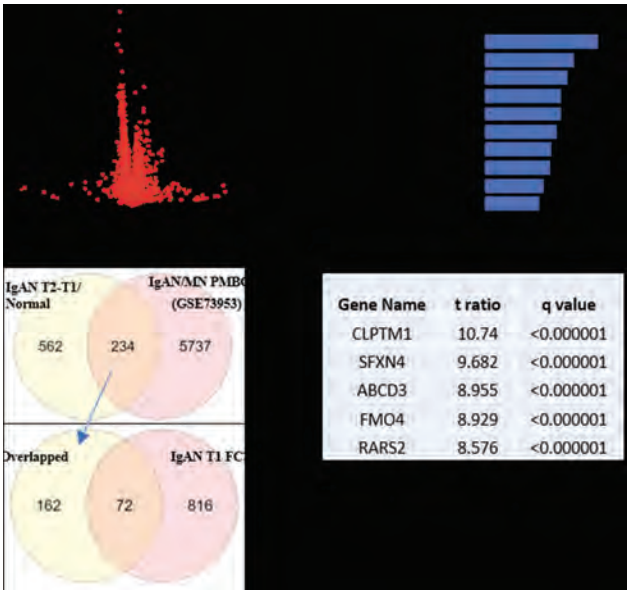
Fengge Zhu,[1] Guangyan Cai,[1] Yujing Ke,[2] Xiangmei Chen.[1] *[1]Department of Nephrology, Chinese PLA General Hospital, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China; [2]Guangdong Pharmaceutical University, Guangzhou, China.*

Background: IgA nephropathy remains one of the major causes of end stage renal diseases globally. Interstitial lesion in IgA nephropathy is correlated with unfavorable prognosis. This study aims to find new potential biomarkers in IgA nephropathy patients with interstitial lesion based on an *in silico* method.

Methods: Proteomics matrix data from IgA nephropathy patients are obtained from a local renal biopsy patient cohort. Discovery is determined using the Two-stage linear step-up procedure of Benjamini, Krieger and Yekutieli, with Q = 1%. Transcriptomic data from peripheral mononuclear blood cell of IgA nephropathy patients are obtained from GEO (GSE73953). Detection of transcriptomic difference genes are made with limma method in GEO2R.

Results: Multiple t test indicates 887 differentially expressed genes between IgA nephropathy interstitial lesion (T1 or T2) and control renal tissues. KEGG pathway annotation reveals that cytochrome p450 related drug metabolism pathway and oxidative phosphorylation pathway are significantly clustered in IgA nephropathy patients with interstitial lesion. No herbal medicine or drug use (apart from ACEI or ARB) were recorded. Differential gene analysis reveals a total of 250 genes with positive discoveries in peripheral mononuclear blood cells of IgA nephropathy compared with membranous nephropathy (GSE73953). Further screening of overlapping genes demonstrates that ABCD3, CLPTM1, FMO4, RARS2, SFXN2 are the most significantly enriched proteins in IgA patients with interstitial lesion.

Conclusions: Preliminary results from this *in silico* study of proteomics and transcriptomics data in IgA nephropathy patients using a T score specific and overlapping screening approach provide a new possibility of noninvasive detection of interstitial lesion in IgA nephropathy patients.



PO1720

Pacemaker Macula Densa Cells Form a Nephron-Level Autonomous Somatosensory Neuronal Network

Georgina Gyarmati, Anne Riquier-brison, Urvi Nikhil Shroff, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: The autonomous nervous system in several organs performs local control of organ functions. Macula densa (MD) cells that are specialized renal epithelial cells capable of sensing the local tissue environment and releasing various chemical messengers to control nearby cells have well-known neuronal features. This study addressed the hypothesis that MD cells perform neuron-like functions that play important roles in maintaining key organ functions.

Methods: MD-GT mice with MD-specific inducible expression of the Ca^{2+} sensitive fluorescence reporter GCaMP5 and the calcium insensitive tdTomato were developed to visualize the Ca^{2+} homeostasis of MD cells with multiphoton microscopy (MPM). Whole transcriptome RNA seq was performed to establish the gene profile of MD cells providing molecular detail of their function.

Results: MD cell imaging in vivo revealed regularly oscillating, propagating Ca^{2+}-firing pacemaker activity with peaks showing ~4-fold elevations and average frequency of 0.03/s. This phenomenon was preserved in freshly isolated MD-GT cells in vitro indicating autonomous pacemaker function. Several divergent stimuli altered steady-state Ca^{2+} and/or firing frequency, including mechanical (tubule flow), altered tubular fluid composition (low salt diet), local autacoids (angiotensin II), systemic hormones (AVP, CaSR mimetic), and metabolic states (diabetic hyperglycemia). Bolus injection of the β-agonist Isoproterenol caused the most robust changes in firing frequency as compared to control (frequency fold change 3.4±0.6 and 0.9±0.1, respectively). Diabetic hyperglycemia was associated with the greatest increase in steady-state MD cell Ca^{2+} level compared to control (2.4±0.2 and 1.1±0.1, respectively). RNA seq analysis revealed enrichment of numerous genes involved in membrane depolarization and pacemaker activity, such as voltage-dependent sodium, potassium, and calcium channels (Scn4b, Scn2b, Kcnd3, Kcnc2, Cacna1d), in afterhyperpolarization (Kcnn2), in the initiation of pacemaker activity (Itpr1), and in synapse formation and transmission (Nsg2, Tmem158, Syt5-13, Sv2a).

Conclusions: This study uncovered new neuron-like functional and molecular features of MD cells and established them as chief sensory neuroepithelial cells that form a nephron-level autonomous neuronal network to control key organ and somatosensory functions.

A New View of Macula Densa Cell Protein Synthesis

Urvi Nikhil Shroff, Georgina Gyarmati, Anne Riquier-brison, Audrey Izuhara, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Macula densa (MD) cells, a chief regulatory cell type in the kidney, have prominent protein synthetic organelles. mRNA translation and protein synthesis are tightly regulated processes and the mTOR and Wnt signaling pathways play a central role in regulating this activity. The present study aimed to examine the role of Wnt/mTOR in regulating MD protein synthesis.

Methods: Changes in bulk protein synthesis activity were quantitatively visualized using an OPP-incorporation based fluorescence assay in a new mouse MD cell line (mMD^{Geo}) treated with low salt medium or the GSK3b inhibitor lithium to activate MD cells. For studies *in vivo*, MD-Wnt^{gof} and MD-$mTOR^{gof}$ mice were developed using a nNOS-Cre inducible system with Wnt and mTOR gain-of-function, respectively, to

upregulate signaling specifically in MD cells. MD gene profiling validated by data from Human Protein Atlas (HPA) was used to confirm the expression of various pathways and regulators of protein synthesis and vesicular exocytosis.

Results: OPP experiments in mMD^{Geo} cells *in vitro* showed that low salt (5.98 ± 1.15) and lithium (5.67 ± 0.24) treated cells had significantly higher protein synthetic activity as compared to control (3.13 ± 0.15). Similarly, MD cells *in vivo* in wildtype mice on a low salt (2.59 ± 0.26) or lithium diet (2.00 ± 0.26) had significantly higher OPP fluorescence as compared to control diet (1.16 ± 0.18). Upregulation of MD-Wnt signaling in MD-Wnt^{gof} mice (1.36 ± 0.04) also resulted in a significant increase in MD protein synthesis as compared to control (1.16 ± 0.06). The expression of MD-enriched secreted proteins (Ccn1, Pappa2, Nov, Cxcl14) was enhanced in activated MD cells. Finally, results from MD gene profile analysis with HPA validation showed high and MD-specific expression of several pathways involved in mRNA translation (p70S6K, eIF3C, eEF2), chaperones (HSP90AB1) along with certain elements of regulated vesicular exocytosis.

Conclusions: In summary, the unique MD microanatomy and cell-specific protein synthetic machinery support the robust synthesis and secretion of a diverse array of tissue remodeling and angiogenic proteins which are regulated by mTOR and Wnt signaling in these cells. The regulatory pathways MD protein synthesis and secretome may be targeted to enhance endogenous glomerular and vascular tissue remodeling and repair.

Kidney Transcriptome-Wide Association Study Analysis Identifies Dach1 as a Kidney Disease Risk Gene

Tomohito Doke,[1] Shizheng Huang,[1] Chengxiang Qiu,[1] Xin Sheng,[1] Hongbo Liu,[1] Jianfu Zhou,[1] Aili Cao,[2,3] Jianhua Li,[2] Lewis Kaufman,[2] Richard G. Pestell,[4] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Shanghai University of Traditional Chinese Medicine, Shanghai, China; [4]Pennsylvania Cancer and Regenerative Medicine Research Center, Doylestown, PA.*

Background: Genome-wide association studies (GWAS) has identified more than 300 loci where genetic variants are associated with kidney function, however, the causal variants, genes, cell types and the disease mechanism remain mostly unknown. Transcriptome-wide association studies (TWAS) is a method to prioritize GWAS-identified variants by linking gene expression data to phenotypic and genetic variation.

Methods: We obtained genotype and gene expression data for 121 microdissected human kidney tubule and glomerular samples. We applied a variety of TWAS models, such as Mendelian Randomization, TWAS Fusion, Metaxcan. Bulk kidney epigenome maps and single cell ATAC-Seq data were used for fine-mapping. We generated tubule specific Dach1 knock-out (KspCre/Dach1flox/flox) and transgenic (Pax8-TREDach1) mice to define the functional role of Dach1 in kidney disease development. Murine cultured tubule cells and single cell RNA sequencing were used for functional studies.

Results: Integration of the 3 TWAS methods with CKD GWAS datasets highlighted only 5 genes those levels were consistently influenced by the GWAS variants. Expression of DACH1; a transcription factor, was lower in tubules of patients with CKD risk variant. Immunofluorescence analysis indicated that DACH1 was mainly expressed in podocytes and in distal convoluted tubule (DCT) in the kidney. Bulk and single cell ATAC denoted that disease risk variants localized to a regulatory region in the DCT. Mice with tubule specific Dach1 deletion developed more severe renal fibrosis when challenged with folic acid (FA) compared to controls. Mice with tubule specific Dach1 overexpression were protected from FAN-induced kidney fibrosis. Single cell RNA sequencing and cultured primary renal tubule cells indicated that Dach1 plays role in controlling cell proliferation and inflammatory gene expression contributing to fibrosis development.

Conclusions: Integration of GWAS, TWAS, single cell expression, epigenome analysis, mouse models and cultured cell systems identified Dach1 as a causal gene for CKD.

PO1723

Role of Plin5 Deficiency in Podocyte Lipotoxicity and the Progression of Alport Syndrome

Jin Ju Kim,[1] Sydney S. Wilbon,[1] Judith T. Molina David,[1] Sandra M. Merscher,[1] Flavia Fontanesi,[1] Jeffrey H. Miner,[2] Alessia Fornoni.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Washington University in Saint Louis School of Medicine, Saint Louis, MO.*

Background: Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. We and others have demonstrated pathogenic renal lipid accumulation in experimental AS (Col4a3KO mice). Excess lipids stored in lipid droplets (LD) as cholesterol ester and triglyceride (TG) are known to cause lipotoxicity. Excessive FFA catabolism resulting from excessive lipolysis of TG is a major contributor to cell lipotoxicity in obesity and diabetes. Perilipin 5 (PLIN5) is a LD-related protein that plays a critical role in the regulation of triglyceride lipase activity and in the interactions between LD and mitochondria, where it protects mitochondria from excessive exposure to FFA. Here we test the hypothesis that PLIN5 is express in podocytes and that excessive TG breakdown occur in AS podocytes as a consequence of PLIN5 deficiency.

Methods: Immortalized AS podocytes (AS podocyte) and WT podocytes were established and characterized in our laboratory by breeding the Col4a3KO mice (Jackson Laboratory) to Immorto mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in podocytes from Col4a3KO mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. Mitochondrial function was determined by utilizing Seahorse XF cell mito stress kit. To determine ATP linked respiration and proton leak, 1.5uM Oligomycin was injected to cells and analyzed by Seahorse XF96 Analyzer (Agilent).

Results: We demonstrate that PLIN5 is expressed in podocytes and the expression of PLIN5 is significantly decreased in AS podocytes when compared to WT podocytes ($p<0.01$). AS podocytes also showed significantly increased rates of TG lipolysis ($p<0.05$), intracellular free fatty acids ($p<0.05$) and apoptosis ($p<0.01$) when compared to WT podocytes. AS podocytes had increased proton leak, implying that the FFA may uncouple the mitochondria, leading to mitochondrial dysfunction and apoptosis. Moreover, ezetimibe, which *in vivo* improved kidney function, was found to *in vitro* restorePLIN5 expression in a dose-dependent manner.

Conclusions: Our study suggests that podocyte PLIN5 deficiency may cause podocyte injury in AS through excessive TG lipolysis and mitochondrial dysfunction.

PO1724

The Mesenchymal Stem Cell Marker Meflin Defines a Novel Subset of Renal Fibroblasts and Counteracts the Action of TGF-β

Shun Minatoguchi, Shoji Saito, Shoichi Maruyama. *Nagoya university graduate school of Medicine, Department of Nepgrology, Nagoya, Japan.*

Background: Fibroblasts proliferation is the hallmark of renal fibrosis and is important for the progression of CKD. Recently developed single-cell sequencing technology has revealed the substantial heterogeneity of cells that constitute the kidney in health and disease. The heterogeneity of renal fibroblasts, however, has not been completely understood. We recently reported that a fibroblast subset marked by Meflin, a marker of undifferentiated mesenchymal stem cells, has a role to suppress fibrosis in cardiac disease conditions and pancreatic cancer. In the present study, we examined the role of Meflin and the distribution of Meflin-positive fibroblasts in kidney by using cultured fibroblasts and mouse models.

Methods: We evaluated the expression of Meflin in normal and fibrotic kidney by in situ hybridization(ISH). To assess the expression of Meflin at a cellular level, we used the rat renal fibroblast cell line NRK49f.

Results: ISH revealed that Meflin was expressed by some rare stromal cells found in the interstitial and peri-glomerular areas in the normal kidney. Meflin-positive cells were also detected in the wall of middle-sized vessels in the medulla of the kidney. Induction of renal fibrosis by obstructive nephropathy(UUO model) led to a significant proliferation of Meflin-positive cells, which seemed to be distinct from αSMA positive myofibroblasts. Consistent with this, the analysis of single-cell transcriptomic databases showed Meflin and αSMA are expressed in distinct subsets of fibroblasts in the kidney. The expression pattern of Meflin was also confirmed by lineage tracing assay. In the UUO model, some of Meflin-lineage cells were positive for αSMA, suggesting that they give rise to myofibroblasts in the progression of fibrosis. Finally, we assessed the function of Meflin using NRK49f. Meflin expression was significantly downregulated by TGFβ stimulation, and exogenous Meflin overexpression led to the suppression of TGFβ induced αSMA and vimentin expression.

Conclusions: Our present study identified a new subset of renal fibroblasts, which is positive for Meflin but negative or weakly positive for α-SMA. Consistent with our previous studies, Meflin has a role to counteract the action of TGF-β, implying that Meflin-positive fibroblasts have a role to suppress or alleviate renal fibrosis.

CD14 Contributes to Increased Inflammation and Fibrogenesis in Lupus Nephritis

Jing Yu, Chi pang Tai, Susan Yung, Tak Mao D. Chan. *University of Hong Kong, Hong Kong, Hong Kong.*

Background: CD14 is a GPI-anchored membrane protein that serves as a pattern recognition receptor in the clinical setting of sepsis. CD14 transfers lipopolysaccharide (LPS) from the acute phase protein LPS-binding protein (LBP) to TLR-4/MD-2 complex, to initiate signal transduction and cytokines release. Serum CD14 level is increased in SLE patients, but little is known about its clinical significance or pathogenic role in lupus nephritis (LN).

Methods: Serum LPS and CD14 levels were determined in LN patients and healthy subjects using commercially available assays. CD14 expression in LN kidney biopsies was examined with cytochemical staining. CD14-overexpressing HK-2 cells were generated and the role of CD14 in inflammatory and fibrotic processes investigated.

Results: Serum LPS and CD14 levels were significantly higher in LN patients compared to healthy subjects ($P<0.05$, for both). Kidney biopsies from active LN patients showed increased CD14 expression, predominantly in proximal tubular epithelial cells, compared with normal kidney tissue. CD14 overexpression did not affect cell proliferation in HK-2 cells, but was associated with increased IL-6 secretion and fibronectin expression, by 26.73±4.63 fold and 3.19±2.28 fold respectively. Upon stimulation with either LPS or endotoxin-free TGF-β1, CD14-overexpressing HK-2 cells showed further augmentation of IL-6 secretion and fibronectin expression ($P<0.05$, for all). In contrast, HK-2 cells deficient in CD14 showed attenuated fibronectin expression upon LPS or TGF-β1 stimulation.

Conclusions: Our data show that active LN is accompanied by increased serum and renal tubular epithelial CD14 expression, and CD14 may contribute to LPS- or cytokine-dependent inflammatory and fibrotic processes in the setting of LN.

CircZNF609 Participates in the Pathogenesis of Focal Segmental Glomerulosclerosis by Sponging miR-615-5p

Junjun Luan, Hua Zhou. *Department of Nephrology, Shengjing Hospital of China Medical University, Shenyang, China*.

Background: Focal segmental glomerulosclerosis (FSGS) is the most common cause of adult nephrotic syndrome, but its mechanism remains unclear. We recently identified and validated that circZNF609 increased in renal biopsies of lupus nephritis patients. We aim to verify whether circZNF609 participates in the pathogenesis of FSGS and the underlying mechanisms.

Methods: FSGS was induced by adramycin (ADR) injection to mice. Proteinuria and serum albumin were examined six weeks after ADR administration. Glomerulosclerosis and tubulointerstitial fibrosis were verified on PAS and Masson staining. Podocyte injury indicated with Wilms tumor 1(WT1) and Podocin, pro-fibrotic proteins including collagen 1 (COL1) and transforming growth factor-beta1 (TGF-β1) were analized by western blotting. Further, renal circZNF609 and miR-615 were measured by qPCR and fluorescence in situ hybridization (FISH). The correlation between renal circZNF609 and above indices were analyzed. In vitro study, circZNF609 in bovine serum albumin (BSA) stimulated HK2 cells for 24 h, which mimic the toxicity of proteinuria from FSGS to tubules. CircZNF609, miR-615, COL1 and TGF-β1 were analyzed by qPCR. Lastly, The renal localization of circZNF609 in FSGS patients was stained by FISH.

Results: In vivo study, proteinuria and hypoalbuminemia were found six weeks after FSGS onset by ADR injection. Glomerulosclerosis and tubulointerstitial fibrosis showed on PAS and Masson staining. CircZNF609 was upregulated while miR-615-5p was downregulated in FSGS mice analyzed by qPCR and FISH. Podocyte proteins WT1 and Podocin were decreased; pro-fibrotic proteins COL-1 and TGF-β1 were increased on western blotting. Renal circZNF609 positively correlated and miR-615-5p negatively correlated with podocyte injury and renal fibrosis. Importantly, circZNF609 and miR-615-5p co-localized on glomeruli and tubules on FISH. Perfect match seeds were found between circZNF609 and miR-615-5p and COL-1. In vitro study, circZNF609 increased and miR-615-5p decreased after BSA stimulation and negatively correlated between each other. COL-1 and TGF-β1 were upregulated and negatively correlated with miR-615-5p. Lastly, circZNF609 was confirmed to increase in glomeruli and tubules in renal biopsies from FSGS patients.

Conclusions: We conclude that circZNF609 may play an important role in FSGS by sponging miR-615-5p and may be a novel therapeutic target.

PO1727

The Role of Proteoglycans in Glomerular Physiology and Pathophysiology

Kerstin Ebefors, Alina Khramova, Jenny C. Nystrom. *Goteborgs universitet Sahlgrenska Akademin, Goteborg, Sweden*.

Background: Diabetic kidney disease (DKD) is the leading cause of renal failure in the world. Diabetes is associated with damage to the endothelial glycocalyx (eGCX), the layer of negatively charge molecules, such as proteoglycans (PGs) that cover the cells. The negatively charge restrain the flow of charged molecules, as albumin, over the filtration barrier. Loss of the glomerular eGCX leads to proteinuria without other visible damage to the barrier, but the composition of this structure is still largely unknown. The aim of this study was to gain new knowledge about the composition and role of the eGCX in health and DKD.

Methods: The negatively charged PGs in the eGCX was eluted from rats using 1 M NaCl solution (high salt, HS). 1 M mannitol was used as osmotic control (HO) and 0.15 M NaCl as physiological salt (NS). Solutions were introduced intra-arterially to rat kidneys under anesthesia *in vivo*. Venous effluent was analyzed using mass spectrometry. Fractional clearance of albumin and GFR was measured. Electron microscopy (EM) was used to investigate morphology. Expression of PGs and PG related genes in glomeruli from patients with DKD was investigated using deep sequencing data from the Swedish DKD cohort (DKD n=19, controls n=20).

Results: We identified 17 PGs in the eluates from rats. PGs were found in in the highest yields in the HS samples. EM demonstrated that the eGCX thickness was significantly reduced in the HS rats compared to NS. Rats perfused with HS had significantly increased fractional clearance of albumin and reduced GFR, compared to NS and HO, 10 minutes after perfusion. In glomeruli from patients with DKD 12 PGs were found to be significantly regulated, and 4 of these PGs were also identified in the eGCX eluates from rats. There was an overall decrease in expression of enzymes responsible for PG side chain synthesis and an increase in proteins involved in PG degradation.

Conclusions: In our study, we identified several PGs novel to the glomerular eGCX. We show that loss of eGCX leads to proteinuria and reduced GFR, strongly suggesting that the eGCX is important for preventing proteinuria. In glomeruli from patients with DKD we found significant changes in the gene expression of PGs, indicating a changed composition of the matrixes in the glomeruli. Further investigation is needed to clarify how these changes are involved in development of DKD, and especially the eGCX.

Low- vs. Standard-Dose Rituximab for Induction and Maintenance Treatment of ANCA-Associated Vasculitis in Elderly Patients: A Single-Centre Observational Study

Shams Ur Rehman, Elhakem Metraiah, Dana Kidder. *Aberdeen Royal Infirmary, Aberdeen, United Kingdom*.

Background: ANCA associated vasculitis (AAV) affects more than 20 per million population per year, with a peak age of 65-74 years. Elderly patients (Age > 65 years) with AAV tend to have higher rates of mortality and treatment-related adverse events. However, outcomes are better for those treated with immunosuppressive regimens. Rituximab is now widely used in the treatment of AAV based on the results of randomized controlled trials. Elderly patients were relatively under-represented in these trials. We aimed to examine the outcome of elderly patients who received either low dose Rituximab (LDR) or standard-dose (SDR) for remission induction and maintenance.

Methods: We investigated the outcome of three treatment strategies in the elderly patients who presented with AAV to our Vasculitis clinic from July 1, 2007 to July 9, 2017. These strategies included: LDR (17 patients), SDR (14 patients) and Cyclophosphamide/ Azathioprine (Cyc/A) 26 patients. LDR patients received two doses of 500mg Rituximab fortnightly followed by six monthly 500mg doses for 2 years. SDR patients received 1g Rituximab fortnightly followed by six monthly 1g doses for 2 years. Cyc/A patients received 1.5mg/kg oral Cyclophosphamide for 3 months followed by 18 months of Azathioprine.

Results: Among 57 AAV patients, 17 received LDR, 14 received SDR and 26 were treated with Cyc/A. 56% were females, mean age of 79.6 +/- 4 (LDR), 72.4 +/- 7.2 (SDR), and 71.1 +/- 5 (Cyc/A) (p=0.001). The distribution of MPA and GPA was 11:6 in LDR, 7:7 in SDR and 18:8 in Cyc/A, respectively. Relapsing AAV was significantly higher in SDR 12 of 14 compared to LDR 3 of 17, and Cyc/A none (p=0.0001). There were no significant differences in serum creatinine, BVAS scores or CRP between groups. Patients survival at 24 months was 88% (LDR), 92% (SDR), and 77% (Cyc), p=0.3. The mean corticosteroids dose at 3 months from onset of treatment was significantly lower in the LDR (7.6 +/- 1.7) and SDR (8.6 +/- 3.1) compared with Cyc/A (12.5 +/- 3.6), p=0.001. One patient relapsed in the SDR group and 4 in the Cyc/A group. Hospitalization for infections were significantly lower in the LDR (3 episodes) compared to Cyc/A (17 episodes), p=0.004.

Conclusions: Low dose Rituximab for remission induction and maintenance was associated with similar patient outcome compared to SDR.

PO1729

Efficacy of Rituximab and Plasma Exchange in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis with Severe Renal Disease

Marta I. Casal Moura, Maria V. Irazabal, Alfonso Eirin, Ladan Zand, Sanjeev Sethi, Alvise Berti, Misbah Baqir, Jeffrey L. Winters, Rodrigo Cartinceba, Gwen Thompson, Ashima Makol, Kenneth Warrington, Bijan J. Borah, Viengneesee Thao, Ulrich Specks, Fernando C. Fervenza. *Mayo Foundation for Medical Education and Research, Rochester, MN*.

Background: Treatment of patients with ANCA-associated vasculitis (AAV) and severe renal involvement is not established. We describe outcomes in response to rituximab (RTX) versus cyclophosphamide (CYC) and plasma exchange (PLEX).

Methods: A retrospective cohort study on MPO- or PR3-ANCA positive patients with AAV (MPA and GPA) and severe renal disease (eGFR<30mL/min/1.73m^2). Remission, relapse, end-stage renal disease (ESRD) and death after remission-induction with CYC or RTX, with or without the use of PLEX were compared.

Results: Of 467 patients with active renal involvement, 251 had severe renal disease. Patients received CYC (n=161) or RTX (n=64) for remission-induction, and 51 were also treated with PLEX. Predictors for ESRD and/or death at 18 months were eGFR<15mL/min/1.73m^2 at diagnosis (HR 3.092, [95%CI 1.493-6.401], p=0.002), renal recovery (HR 0.274, [95%CI 0.118-0.637],p=0.003) and renal remission at 6 months (HR 0.402, [95%CI 0.179-0.902],p=0.027). RTX was comparable to CYC in remission-induction (BVAS/WG=0) at 6 months (HR 1.374, [95%CI 0.909-2.076];p=0.132). Addition of PLEX showed no benefit on remission-induction at 6 months (HR 0.732, [95%CI 0.440-1.219],p=0.230), in the rate of ESRD and/or death at 18 months (HR 1.052,[95%CI 0.508-2.180], p=0.891), in progression to ESRD (HR 1.056, [95%CI 0.496–2.247], p=0.887), or survival at 24 months (HR 0.542, [95%CI 0.159–1.853], p=0.330).

Conclusions: The apparent benefits and risks of using CYC or RTX for the treatment of patients with AAV and severe renal disease are balanced. The addition of PLEX to standard remission-induction therapy showed no benefit in our cohort.

PO1730

Time to CD20 B-Cell Return After Rituximab in Patients with Antineutrophil Cytoplasmic Antibody Vasculitis

Noah Huizenga, Karen A. Laliberte, Reza Zonozi, Jillian Rosenthal, Anushya Jeyabalan, Frank B. Cortazar, John Niles. *Massachusetts General Hospital, Boston, MA*.

Background: Rituximab (RTX) has been shown to be an effective maintenance treatment for ANCA vasculitis. However, the optimal dosing regimen is not well-defined. We analyzed data from the MAINTANCAVAS trial (NCT02749292) to determine time to CD20 B cell return in patients who were treated with ≥ 2 years of continuous B cell depletion and subsequently randomized into the trial and dosed for B cell return or a rising ANCA titer.

Methods: All patients in the MAINTANCAVAS trial were included. Patients were enrolled after ≥ 2 years of continuous B cell depletion. B cells were measured at 3-month intervals with a ± 2 week window. Days to B cell return were calculated as the time from the last rituximab dose (1000 mg) to date of first detectable CD20 B cells by flow cytometry. Kaplan Meier curves were produced for each round of B cell depletion.

Results: We analyzed data from 109 patients. Median (IQR) duration of B cell depletion was 280.0 (272.0 – 363.0) days until first episode of recovery (Table 1). >80% of subjects had B cell return by 1 year and <10% had B cell return prior to 6 months (Figure 1). Median (IQR) duration of B cell depletion was 265.0 (247.0 – 354.5) days for patients who received a second round of rituximab (Table 1).

Conclusions: This data suggests that after 2 years, maintenance RTX dosing can be extended beyond 6 months for many patients. Further analysis is needed to determine optimal dosing based on B cell return vs ANCA titer and the associated adverse event profiles and RTX utilization.

Table 1. Demographics and B cell depletion duration (median (IQR)).

# of subjects	109

PO1731

Predictive Significance of Urinary CD11b and CD163 for the Renal Outcomes in ANCA-Associated Glomerulonephritis

Naotake Tsuboi,[1] Yuki Yokoe,[1] Takahiro Imaizumi,[2] Akimitsu Kitagawa,[1] Shoichi Maruyama.[2] *[1]Department of Nephrology, Fujita Health University Graduate School of Medicine, Toyoake, Japan; [2]Department of Nephrology, Internal Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: We hypothesized that the detection of leukocyte-derived CD11b (α subunit of integrin Mac-1) and CD163 (scavenger receptor) in urine may reflect renal inflammation and predict the renal outcomes in anti-neutrophil cytoplasmic antibody-associated glomerulonephritis (ANCA-GN). The aim of this study was to evaluate the clinical significance of urinary CD11b (U-CD11b) and CD163 (U-CD163) as alternative noninvasive tests for ANCA-GN.

Methods: U-CD11b and U-CD163 levels were examined using ELISA in ANCA-GN urine samples from institutional cohort (n = 88) and a nationwide cohort (n = 138), and their association with renal histology were analyzed. Logistic regression analyses were performed on a nationwide ANCA cohort to determine the associations of the two urinary molecules with renal remission failure at 6 months or with yearly eGFR slope over a 24-month observation period.

Results: The significant elevations of U-CD11b and U-CD163 were observed in ANCA-GN patients histologically classified to the crescentic category. Histological analyses focusing on the distributions of $CD11b^+$ or $CD163^+$ leukocyte subsets in diseased glomeruli demonstrated dominant distribution of $CD11b^+$ cells in undisrupted area than in glomerular crescent as contrasted with global distribution of $CD163^+$ cells in diseased glomerulus. In addition, levels of U-CD11b and U-CD163 significantly correlated with crescent formation rate, respectively with $CD11b^+$ cell and $CD163^+$ cell number in glomerular crescents. Association analyses of both urinary molecules with post-treatment renal outcomes at 6 months after the treatment demonstrated that U-CD163 levels were significantly reduced and those at the time of diagnosis were already increased in patients who failed to remission or progressed renal insuficiency. Although these associations were not found in U-CD11b, analyses to determine the associations of the two urinary molecules and other clinical parameters with yearly impairment of renal function over a 24-month observation period demonstrated U-CD11b, but not U-CD163, at diagnosis as an independent factor predicting renal recovery.

Conclusions: Although both U-CD11b and U-CD163 reflect renal leukocyte accumulation, U-CD11b at diagnosis predicts the recovery rate after the treatment of ANCA-GN.

Urinary Biomarkers as a Tool for Monitoring Remissions and Predicting Relapses in Autoimmune Glomerulonephritis

Suzanne Dominique Genest,[2,1] Myriam Khalili,[2,1] Jean-Philippe Rioux,[2,1] Jérémy Quadri,[3,1] Arnaud Bonnefoy,[3,1] Stephan Troyanov.[2,1] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [3]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.*

Background: Complement-mediated injury, inflammation and fibrosis play central roles in the pathogenesis of autoimmune glomerulonephritis. The use of urinary biomarkers as a surrogate of these pathways of injury could assist clinicians during the clinical follow-up. We investigated the value of urinary biomarkers of complement activation, inflammation and fibrosis during periods of sustained remission among patients with autoimmune glomerulonephritis.

Methods: We prospectively examined 100 patients with ANCA-associated vasculitis, focal segmental glomerulosclerosis, IgA nephropathy, lupus nephritis, membranoproliferative glomerulonephritis and membranous nephropathy. Proteinuria, urinary sC5b-9, monocyte chemoattractant protein-1 (MCP-1) and transforming growth factor-β1 (TGF-β1), expressed as creatinine ratios, were measured at presentation and during follow-up visits. We used standard definitions of remission and relapse for each type of glomerulonephritis. Wilcoxon signed-rank test was used to compare changes in urinary biomarkers during remissions and relapses.

Results: We identified 95 periods of active disease and 82 episodes of sustained remission. Inactive periods lasted a median of 22 (11-32) months. Eighty percent (n=66) of these were not followed by a relapse. During these episodes of remission, urinary biomarkers continued to steadily decrease, achieving a reduction of 40% for proteinuria, 40% for urinary sC5b-9, 38% for MCP-1 and 40% for TGF-β1 (all $p < 0.05$). Twenty percent (n=16) of inactive periods reflected remissions with subsequent relapses. Biomarker levels during the inactive period preceding relapses did not significantly change for proteinuria (+8%), urinary sC5b-9 (+15%) and MCP-1 (4%), while they decreased for TGF-β1 (-30%, p=0.02). During relapses, we observed a 3.2-fold (1.9-8.3) increase in proteinuria and a significantly greater 8.5-fold (4.2-56.9) increase in urinary sC5b-9 (p=0.001). By contrast, urinary MCP-1 and TGF-β1 increased significantly less than proteinuria.

Conclusions: Failure to achieve a sustained reduction in urinary biomarkers during remission was associated with a subsequent risk of relapse of autoimmune glomerulonephritis. Urinary sC5b-9 appears to be a more discerning marker of immunological relapse.

Clinical Impact of PRTN3 Polymorphism in Antineutrophil Cytoplasmic Antibody (ANCA) and Similar Vasculitides

Dhruti P. Chen, Candace D. Henderson, Claudia Aiello, Yichun Hu, Susan L. Hogan, Lauren N. Blazek, Dominic J. Ciavatta, Ronald J. Falk. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Genetic variants associated with ANCA vasculitis include a single-nucleotide polymorphism (SNP) at the proteinase 3 (*PRTN3*) locus, however the impact of this risk variant on demographics and disease characteristics has not been fully described.

Methods: 401 patients with ANCA and similar vasculitidies from the Glomerular Disease Collaborative Network were genotyped for the *PRTN3* SNP (rs62132293): myeloperoxidase (MPO) (n= 197), proteinase3 (PR3) (n = 170), dual positive (n=9), and seronegative (n=25). SNP homozygous ("GG") were compared to heterozygotes ("CG") and homozygous ("CC"). *PRTN3* expression was measured by quantitative polymerase

chain reaction amplification of cDNA from patient peripheral blood polymorphonuclear leukocytes during active disease. Comparisons were done using Fisher exact and Wilcoxon tests or ANOVA. Bonferroni correction and Tukey test used for multiple comparisons Cox regression was used for multivariable time to relapse and end stage kidney disease (ESKD), with hazards ratios (HR), 95% confidence intervals (CI) reported.

Results: 179 CC, 181 CG and 41 GG patients with median follow-up of 4.8 years were studied. GG patients were significantly younger at disease-onset than others (FIGURE, A). There were no statistical differences in race/sex categories, ANCA seropositivity, organ involvement, or estimated glomerular filtration rate between groups. In a subset of the cohort (n=298) GG had significantly higher peak expression of *PRTN3* (FIGURE, B). In the entire group, renal disease was predominant (CC 78%, CG 83%, GG 76%, p = 0.34) and the majority of the treated patients reached remission (91% CC, 88% CG and 90% GG, p=0.79). Upon remission there was no difference in time to first relapse in GG vs. others (HR 1.02, CI 0.62,1.68, p=0.94) and time to ESKD (HR 0.62, CI 0.15, 2.67, p=0.52) adjusted for age and seropositivity.

Conclusions: Disease starts at an earlier age among GG patients, with no clear impact on outcomes. Higher *PRTN3*expression may explain earlier disease onset.

PO1734

The Compositional and Functional Changes of Gut Microbiota in Crescentic Glomerulonephritis

Huanhuan Yin, Xiaoxiao Shi, Peng Xia, Limeng Chen. Department of Nephrology, Chinese Academy of Medical Sciences & Peking Union Medical College Hospital, Beijing, China *Peking Union Medical College Hospital, Beijing, China*.

Background: Crescent glomerulonephritis(CreGN) is the most dangerous glomerulonephritis, but the specific mechanism remains unclear. Recent evidences suggested that gut microbiota was associated with kidney injury. This study aimed to observe the role of gut microbiota in CreGN.

Methods: A comparative analysis of the gut microbiota was performed in 10 CreGN patients and 10 matched healthy controls by 16S rDNA amplicon sequencing, and half of each group were also analyzed by metagenomics for further function analysis.

Results: The mean age of the 10 CreGN patients was 54.8±17.1 years, with 70.0% were female. The median eGFR was 5.4(interquartile range:3.6-9.5)ml/min/1.73m2. Compared to controls, CreGNs showed a significant lower richness(683.2±113.4 vs.800.1±73.5, *P*= 0.015) despite a similar level of Shannon index(diversity)(5.4±0.6 vs.5.6±0.5,*P*=0.579). PCoA showed a different pattern of clustering in CreGN(*P*=0.036, Fig.1a). There were 66 differentially enriched bacteria genera, with a significant($q<0.05$) lower relative abundance of *Agathobacter, Prevotellaceae, Faecalibacterium, Dialister, Megamonas,* and *Alloprevotella* genera, and a higher relative abundance of *Faecalitalea, Anaerostipes, Paraprevotella,* and *Streptococcus* genera(top 10)in CreGN. All the genera above showed significant correlations with renal injury indicators. For example, *Agathobacter* was significantly correlated with creatinine(r =−0.77),24h urine protein(r =−0.86), and eGFR(r=0.73)(Fig.1b). Besides, *Agathobacter, Prevotellaceae, Faecalibacterium,* and *Dialister* were also confirmed as significant biomarkers by LEfSe(Fig.1c). Metagenomics showed 21 significant differentially enriched functional categories, with a decreased proportion of genes involved in"digestive system"(q=0.022) and an increased risk of"infectious diseases: bacterial"(q= 0.011) in CreGN.

Conclusions: Gut microbiota in CreGN differed at compositional and functional levels compared with healthy controls, and correlated well with renal injuries.

Funding: Government Support - Non-U.S.

Role of Repeated Renal Biopsy in ANCA Vasculitis

Maroua Baaziz, Eric Thervet, Alexandre Karras. *Hopital Europeen Georges Pompidou, Paris, France.*

Background: Pauci-immune necrotizing crescentic glomerulonephritis is a severe renal complication of AAV. Despite immunosuppressive therapy, relapses are frequent during the course of the disease. Kidney biopsy is routinely used to diagnose AAV at initial presentation. Although the activity of renal AAV is not easily evaluated by plasma or urine biomarkers, kidney biopsy is rarely performed when relapse is suspected. We herein analyze the clinical, laboratory and renal pathology data from patients who underwent repeated kidney biopsies during the course of AAV.

Methods: We retrospectively reviewed data from 37 patients who underwent at least 2 kidney biopsies in our centre, between 2002 and 2018. The first renal biopsy (B1) was constantly performed at diagnosis. A follow-up biopsy (B2) was performed for purpose, either for suspicion of refractory disease or confirmation of renal relapse. Modifications of renal pathology between B1 and B2 were studied, by comparing presence of active and chronic lesions.

Results: The median delay between B1 and B2 was 3,3 [0,9-5,8] years. B2 was done for suspicion of refractory disease (n=8) or of renal relapse (n=29). Causes of B2 were : persistence or reappearance of haematuria in 78% of cases, increase of creatinine in 43%, increase of ANCA titer in 67%. Systemic AAV activity was more important at B1 vs B2 (median BVAS 18 vs 9), as well as renal dysfunction (median sCreat 200 vs 156 µmol/l). Active glomerulonephritis was constantly found at B1 but was present in only 35% of B2. Presence of cellular crescents decreased from 71,4 to 29,7% (p = 0,002), whereas fibrinoid necrosis decreased from 80,6 to 35,1% (p = 0.0003). Five factors were significantly associated with the presence of active lesions : presence of at least one extra-renal AAV manifestation (p = 0.0006), increase of ANCA titer (p = 0.0022), CRP>30mg/l (p = 0.001), absence of IF/TA (p=0,02) and high percentage of normal glomeruli (p=0,014) at B1. Interestingly, level of proteinuria and persistence of hematuria were not associated with histological activity at B2 (p =0,64 and 0,22 respectively). In contrast, chronic lesions were more severe at B2 compared to B1 (p <0,0001 and 0,014 respectively).

Conclusions: Despite several clinical and laboratory signs suggesting active renal AAV, B2 revealed no relapse in 2/3 of cases, allowing avoidance of a new immunosuppressive induction treatment.

PO1736

Single-Center Experience of Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis in a Region of Central Appalachia

Muhammad M. Aljuhani, Devan Makati, Abigail Hoff, Vishy Chaudhary, Bethany S. Pellegrino, Rebecca J. Schmidt, Dinesh Kannabhiran. *West Virginia University Health Sciences Center, Morgantown, WV.*

Background: Antineutrophil cytoplasmic autoantibody-associated vasculitis (AAV) is a rare disease with significant morbidity and mortality. Suspicions that our caseload of AAV might exceed the estimated 3 in 100,000 incidence estimates prompted us to investigate the characteristics of our patients with AAV.

Methods: A retrospective study of all patients diagnosed with AAV at our center prior to December 31, 2019 was performed. Patients were identified based on ICD10 (349),

ICD 9 (1846) codes or diagnosis of a positive ANCA lab test (589). Charts were reviewed for demographic and clinical information. Incidence was estimated for the 10-year period being January 1, 2009 using population estimate.

Results: A total of 225 patients had a confirmed diagnosis of AAV of whom 114 were males (50.6%) and 111 females (49.4%). 94.7% were Caucasian, 2.2% African American and 2.2% Hispanics, reflective of our population. Most were older (50.2% >60 years). The kidneys(67.6%), lungs (42.7%) and ENT organs(30.2%) were most commonly involved. The predominant ANCA subtype was p-ANCA(52.3%), followed by c-ANCA (43%) and ANCA-negative (4.7%). p-ANCA was most common in patients with renal involvement (58.8%) and c-ANCA was most common in patients with ENT involvement (60%); p <0.01. Of those with renal involvement, 51 needed dialysis (33.6%), 47 of whom became dialysis-dependent (30.9%). Mortality was high in patients with kidney (32.2%) and lung involvement (30.2%) compared to those with ENT involvement (16.2%); p=0.04. Preliminary estimates suggest a regional incidence that may exceed that of other states.

Conclusions: In our population, p-ANCA was the predominant subtype and incidence estimates did not mirror those of other areas. These findings suggest that AAV may differ in subtype predominance and incidence by geographic setting.

Organ Involvement

Organ involved (N of patients)	c-ANCA N (%)	p-ANCA N (%)	Neg ANCA N (%)
Renal (152)	59 (39.9%)	87 (58.8%)	2 (1.4%)
Lung (96)	44 (46.8%)	47 (50%)	3 (3.2%)
Eyes (15)	9 (60%)	5 (33.3%)	1 (9.1%)
ENT (68)	45 (68.2%)	15 (22.7%)	6 (9.1%)
Skin (21)	8 (38.1%)	9 (42.9%)	4 (19%)
Brain (19)	10 (52.6%)	7 (36.8%)	2 (10.5%)
Heart (3)	2 (66.7%)	1 (33.3%)	0 (0%)
GI (2)	0 (0%)	2 (100%)	0 (0%)

PO1737

Exploring the Role of Type I Interferons in ANCA-Associated Vasculitis

Isabella Batten,[5] Mark W. Robinson,[3] Arthur White,[2] Barbara Fazekas,[6] Cathal D. Walsh,[4] Jason Wyse,[2] Suzanne D'Arcy,[1] Antonia Buettner,[1] Mark A. Little,[1] Nollaig M. Bourke.[5] *[1]Trinity Health Kidney Centre, Trinity Translational Medicine Institute, Trinity College Dublin, Ireland, Dublin, Ireland; [2]School of Computer Science and Statistics, Trinity College Dublin, Dublin, Ireland, Dublin, Ireland; [3]Department of Biology, Human Health Institute, Maynooth University, Kildare, Ireland, Maynooth, Ireland; [4]Department of Mathematics and Statistics, University of Limerick, Limerick, Ireland; [5]Centre for Medical Gerontology, School of Medicine, Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland, Dublin, Ireland; [6]Regenerative Medicine Institute, School of Medicine, National University of Ireland Galway, Galway, Ireland, Galway, Ireland.*

Background: ANCA-associated vasculitis (AAV) is a group of autoimmune diseases characterised by inflammation of small blood vessels. Type I interferons (IFNs) are cytokine mediators of the innate immune response, most known for their anti-viral properties. Dysregulation of type I IFNs is a major factor in the development of several autoimmune diseases, now termed type I interferonopathies, and thought to be the pathogenic link with chronic inflammation in these conditions. Despite evidence of type I IFNs driving autoimmunity, they have not been comprehensively studied in AAV. We hypothesised that type I IFN responses are systemically dysregulated in AAV, indicative of a type I interferonopathy.

Methods: Matched whole blood and serum samples collected from healthy individuals (n=67), disease control patients (n=32) and AAV patients (n=71) were obtained from the Rare Kidney Disease Biobank of Ireland. qPCR was used to measure gene expression in blood of seven type I IFN stimulated genes (ISGs) characteristic of type I interferonopathies: *IFI27*, *IFI44L*, *IFIT1*, *ISG15*, *RSAD2*, *SIGLEC1* and *STAT1*. Serum type I IFN regulated proteins (CXCL10, MCP-1 and CCL19) were assessed by ELISA.

Results: No significant difference in ISG gene expression was observed between control samples and AAV patients for any ISG analysed, irrespective of treatment received, age or sex. No significant differences in MCP-1, CCL19 and CXCL10 expression were observed between each cohort. CXCL10 levels were significantly lower in AAV patients on immunosuppressive treatment. Markers of Type I IFN responses did not correlate with clinical measurements of disease severity in AAV patients.

Conclusions: Systemic type I IFN responses are not dysregulated in AAV and are unlikely to contribute towards AAV pathogenesis; therefore AAV should not be considered as a type I interferonopathy

Angiotensin Converting Enzyme-Overexpressing Neutrophils Suppress Glomerular Injury in Crescentic Glomerulonephritis

Narihito Tatsumoto,[2] Suguru Saito,[3] Hiroshi Nishi,[1] Kenneth E. Bernstein,[3,2] Michifumi Yamashita.[2] *[1]Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Department of Pathology and Laboratory Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; [3]Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Angiotensin Converting Enzyme (ACE) is well known as the responsible enzyme to regulate blood pressure by producing angiotensin II in renin-angiotensin system, while recent studies have revealed that ACE has a novel function in immune cells. We previously found that ACE overexpressed myeloid lineage cells promoted an inflammatory response resulting in increasing resistance to bacterial infection and tumor growth. These results prompt us to investigate the effect of overexpressed ACE in myeloid lineage cells on immune complex (IC)-mediated crescentic glomerulonephritis (GN).

Methods: We induced the nephrotoxic serum nephritis (NTN) in C57Bl/6 (WT), and NeuACE mice that overexpressing ACE in neutrophils. In addition, IC uptake and IC-mediated responses were investigated in both WT and NeuACE neutrophils by *ex vivo* experiments.

Results: Seven days after induction of NTN, NeuACE mice showed less severe proteinuria, histological glomerular injury, and less number of macrophages infiltration into the glomeruli than those in WT mice. While production and serum level of autologous antibody titer were comparable, IC deposits in glomeruli were reduced in NeuACE mice compared to WT mice. In *ex vivo* experiments, IC uptaking was significantly promoted in NeuACE neutrophils as compared to WT cells. As an underlying mechanism of the promoted IC uptaking in neutrophils, we found that serum level of complement C3b and expression of complement receptor CR1/2 on neutrophils were significantly elevated in NeuACE mice. Furthermore, we confirmed that anti-CR1/2 blocking antibody abolished the uptaking of IC in neutrophils and the NeuACE serum enhanced IC uptake in both normal and ACE overexpressing neutrophils. These results suggest that ACE in neutrophils directly or indirectly pre-activate C3, and that both the elevated CR1/2 expression and the increased serum C3b play the pivotal role in IC uptake by neutrophils. Despite the increase in IC uptaking, neutrophils from NeuACE mice showed better cell survival after IC stimulation compared to those from WT mice.

Conclusions: Overexpressed ACE in neutrophils contributes to the effective elimination and suppression of IC deposits in glomeruli via C3b-CR1/2 axis, ameliorating glomerular injury in crescentic GN. These results indicate a novel immunological aspect of ACE in GN.

Recurrence of Anti-GBM Disease: An Epiphenomenon?

Sri Vibhavari Guntupalli, Robert Mark Black. *Saint Vincent Hospital, Worcester, MA.*

Introduction: The simultaneous presentation of anti-GBM antibodies with ANCA-associated glomerulonephritis occurs in about 40% of individuals with anti-GBM disease. However, recurrence of anti-GBM disease is rare. We report a case of relapsing disease where the recurrent anti-GBM may have been caused by the ANCA-induced glomerular injury.

Case Description: A 62-year-old woman presented with generalized weakness and arthralgia. Creatinine was elevated to 1.7 mg/dL from 0.8 mg/dL, urinalysis showed 3+ blood and 1+ protein with dysmorphic RBCs. Her serologies showed an elevated anti-MPO and a moderately high anti-GBM titre. Her renal biopsy revealed crescentic glomerulonephritis with segmental linear IgG staining of the glomerular basement membrane on immunofluorescence. In 2015, at the time of her presentation, she was treated with plasmapheresis, cyclophosphamide and maintained on tapering doses of azathioprine and prednisone. In 2017, as her immunosuppression was tapered, her Pcr rose, her urine showed RBCs and her anti-GBM titer, which had been undetectable each month, again became positive. She was retreated with a similar regimen. In 2019, she had another relapse with a higher ANCA titer, a mild rise in creatinine and hematuria. Her anti-GBM, by comparison, remained negative. Her repeat renal biopsy was consistent with vasculitis, but the immunofluorescence at this time was negative. She was treated with an escalated steroid dose and with rituximab. She appears to be in clinical and laboratory remission at this time with a persistently negative anti-GBM, but with continued anti-MPO positivity. A re-review of her initial biopsy showed that there was linear staining, but it was discontinuous and segmental.

Discussion: On initial presentation, this patient appeared to have anti-GBM disease with concomitant ANCA positivity, a not uncommon combination. Both titers rose with her first relapse. However, during her second recurrence she was noted to have an elevated ANCA with necrotizing vasculitis and was promptly treated. At that time, her anti-GBM remained negative. We suggest that this patient has an ANCA-positive vasculitis and that the anti-GBM may have been a secondary or epiphenomenon due to release of GBM antigens as a result of glomerular damage by anti-MPO antibodies [1]. We believe that this might explain the unusual recurrence of anti-GBM serology in this patient.

PO1740

Activation of the cGAS-STING Signaling Pathway Is Associated with Glomerular Diseases

Antonio M. Fontanella, Shamroop Kumar Mallela, Judith T. Molina David, Jin Ju Kim, George W. Burke, Sandra M. Merscher, Alessia Fornoni, Alla Mitrofanova. Katz Family Division of Nephrology and Hypertension *University of Miami School of Medicine, Miami, FL.*

Background: Podocytes express elements of the innate immune system which may be involved in the local immune response and contribute to chronic inflammation and glomerular damage. The cGAS-STING pathway is activated as part of the innate immune response to pathogens or host cytosolic DNA and has been shown to regulate inflammation and energy homeostasis under obesity conditions, kidney fibrosis and acute kidney injury. Whether cGAS-STING pathway contributes to development and progression of glomerular diseases remains largely unknown. This study aimed at filling this gap.

Methods: Immortalized human podocytes were cultured in RPMI medium and differentiated for 14 days. c-diAMP treatment (10 μM) was performed for 24h. Real-time PCR and Western blot analysis were used to evaluate mRNA and protein expression. Male and female, 8-week-old C57BL/6J mice were randomly divided into two groups: control (n=7) and I.P. injected with a single dose of c-diAMP, 25 mg/kg (n=9). The animals were sacrificed 72 h after injection, blood and kidneys were harvested and processed for in-depth phenotypical analysis, including urinary albumin-to-creatinine ratio, histological analysis, transmission electron microscopy analysis (foot process effacement quantification), immunohistochemistry, glomeruli isolation and serum analysis.

Results: *In vitro*, podocytes showed expression all of the cGAS-STING components at the mRNA and protein level under physiological conditions and treatment with c-diAMP, an antagonist of STING, lead to activation of the cGAS-STING pathway. *In vivo*, treatment of mice with c-diAMP resulted in an increased expression of all components along the cGAS-STING pathway at both the mRNA and protein levels. Histology data show that c-diAMP-treated mice have a lower number of podocytes per glomerulus and a lower podocyte density, showing an increase in foot process effacement. This is further confirmed by increase in blood urine nitrogen and serum creatinine levels and in the urine albumin-to-creatinine ratio.

Conclusions: Genes of the cGAS-STING pathway are expressed in human podocytes and the pathway can be activated both *in vitro* and *in vivo*. Activation of the cGAS-STING pathway in mouse models *in vivo* is associated with increased podocyte injury and contributes to the glomerular diseases.

PO1741

C5a Enhanced the Recruitment of CD16^{+} Monocytes by CX3CL1-CX3CR1 Axis in ANCA-Associated Vasculitis

Jiale Tang, Zhonghua Liao, Xiaozhao Li. *Xiangya Hospital Central South University, Changsha, China.*

Background: Monocytes play a major role in ANCA-associated glomerulonephritis. The mechanism is not well understood. Additionally, it is a consensus that C5a participates ANCA-associated vasculitis (AVV) pathogenesis. The relevance of C5a in terms of monocytes recruitment, as well as the nature and function of monocytes has not been well studied in AAV.

Methods: Monocytes in blood was counted and its phenotypic characteristics were analyzed by Flow cytometry. C5a and monocyte - related cytokines and chemokines was detected in AAV. The phenotype of monocytes in Kidney tissues from MPO-AVV patients was studied by immunohistochemistry and immunofluorescence. The chemoattractant activity of chemokines produced by human renal glomerular endothelial cells(HRGEC) for monocytes was observed.

Results: Monocytes were higher in activated MPO-AAV patients. The proportion of CD16+ monocytes in the peripheral blood of the patients was significantly reduced and CX3CR1 was highly expressed in CD16+ monocytes. C5a, IL-6, TNF-α, and chemokine CX3CL1 were significantly increased in serum of activated MPO-AAV patients. CD16+ monocytes were clearly seen in the glomeruli of MPO- AVV patients. Chemokine CX3CL1 was expressed in glomerular endothelial cells. Consistently, we demonstrated C5a enhance recruitment of CD16+ monocyte via CX3CL1 produced by TNF-αinduced HRGEC in vitro.

Conclusions: We report an altered distribution of monocyte subsets in MPO-AAV patients; CD16+ monocytes may be recruited to kidney through CX3CL1-CX3CR1 axis to aggravate ANCA-associated GN.

PO1742

Melanocortin 5 Receptor (MC5R) Deficiency Aggravates Glomerular Injury and Proteinuria in the Autologous Phase of Nephrotoxic Serum (NTS) Nephritis

Bohan Chen, Lance D. Dworkin, Rujun Gong. *University of Toledo Medical Center, Toledo, OH.*

Background: The successful use of corticotropin in steroid-resistant nephrotic glomerulopathies suggests a unique proteinuria-reducing activity of adrenocorticotropic hormone that is steroidogenic-independent and may be attributable to its melanocortinergic activity. It remains uncertain which melanocortin receptor conveys this beneficial effect. Emerging evidence implicates MC5R signaling in the regulation of immune response. However, the role of MC5R in glomerular disease is unknown.

Methods: NTS nephritis was induced in MC5R knockout (MC5R$^{-/-}$) and wild-type (WT) mice. Kidney function, proteinuria and renal pathology were evaluated in the autologous phase.

Results: On 14 days after NTS injection in the autologous phase, MC5R$^{-/-}$ as compared with WT mice exhibited an exacerbated kidney dysfunction and injury, as evidenced by higher serum creatinine levels, heavier proteinuria and aggravated renal pathology, featured by crescent formation, glomerular hypercellularity, mesangial expansion, protein casts in renal tubules, inflammatory infiltration in both glomeruli and tubulointerstitium and renal fibrosis. Consistent with the worsened proteinuria, MC5R$^{-/-}$ mice displayed more severe podocyte injury and loss, as evidenced by diminished WT-1 staining and loss of homeostatic podocyte markers, like synaptopodin and podocin, as determined by immunohistochemistry staining and immunoblot analysis of isolated glomeruli. Mechanistically, although glomerular basement membrane-reactive rabbit IgG was found to deposit in glomeruli in both MC5R$^{-/-}$ and WT mice to a comparable magnitude, MC5R$^{-/-}$ mice demonstrated much more glomerular deposition of autologous anti-rabbit IgG together with enhanced fixation of the terminal complement complex C5b-9 along glomerular capillary loops in the autologous phase, suggesting that a potentiated humoral immune response to NTS antigen resulting from MC5R deficiency may contribute to the aggravated NTS nephritis.

Conclusions: MC5R signaling is essential for protection against glomerular injury and proteinuria in murine NTS nephritis via, at least in part, a regulatory effect on humoral immunity.

Glomerular Complement Proteins in Thrombotic Microangiopathy

Lilian M. Palma,[1] Meera Sridharan,[2] Kenneth L. Johnson,[2] Benjamin J. Madden,[2] Cristine Charlesworth,[2] Sanjeev Sethi.[2] *[1]Universidade Estadual de Campinas, Campinas, Brazil; [2]Mayo Clinic, Rochester, MN.*

Background: Thrombotic Microangiopathy (TMA) is a clinicopathological entity resulting from complement abnormalities (atypical hemolytic uremic syndrome, aHUS) and a number of secondary causes including malignant hypertension, autoimmune diseases and drugs. Distinguishing aHUS from secondary TMA is a challenge. A comprehensive evaluation of complement burden in TMA has not been done.

Methods: Glomeruli were laser microdissected and mass spectrometry (MS) was performed. The glomerular complement protein profile was analyzed in aHUS (n=12) and secondary TMA (n=12). The spectral counts obtained from MS are semiquantitative with regards to abundance of the protein.

Results: C3 was the most the abundant complement protein in all cases (Figure). The remaining complement proteins were grouped into classical (C1/C4A/C4B), terminal pathway (C5/6/7/8A/8B/9), and complement regulatory proteins (CRP=CFH/CFHR1-2-3-5/CFB/CFD). MS studies show accumulation of C3, and complement proteins of classical and terminal pathways in all cases. Overall, there was greater accumulation of complement proteins in secondary TMA compared to aHUS (248.3 vs. 192.5). Importantly, even though C3 was higher in aHUS, both classical pathway and terminal pathway protein accumulation were higher in secondary TMA compared to aHUS. Among the secondary TMA, drug-induced TMA showed the highest accumulation of complement proteins compared to autoimmune and hypertension-induced TMA (306.9 vs. 217 vs. 219.9, respectively). Finally, CRP were present in all TMA, of which CFH was the most abundant protein.

Conclusions: Complement proteins of all pathways were identified in TMA. C3 followed by C4A/C4B and C9 were most abundant proteins. Higher counts of C3 in aHUS versus higher counts of C4A/C4B in secondary TMA, suggests a greater role of alternative pathway in aHUS and a greater role of classical pathway in secondary TMA.

Protein category	Proteins	aHUS (n=12)	Secondary TMA (n=12)
C3	C3	63.75	53
Terminal	C5/6/7/8A/8B/9	32.9	50.1
CRP	CFH/CFHR1-2-3-5/CFB/CFD	32.9	48.25
Classical	C1QB/C1QC/C1R/C1S/CR1/C4A/C4B	63	97
Total		192.55	248.35

Protein category	Hypertension (n=5)	Autoimmune (n=3)	Drug (n=4)
C3	42.6	52	67
Terminal	56	46	46
CRP	36.1	47.6	63.75
Classical	85.2	72.3	130.2
Total	219.9	217	306.9

MS: Total spectral counts in TMA.

PO1744

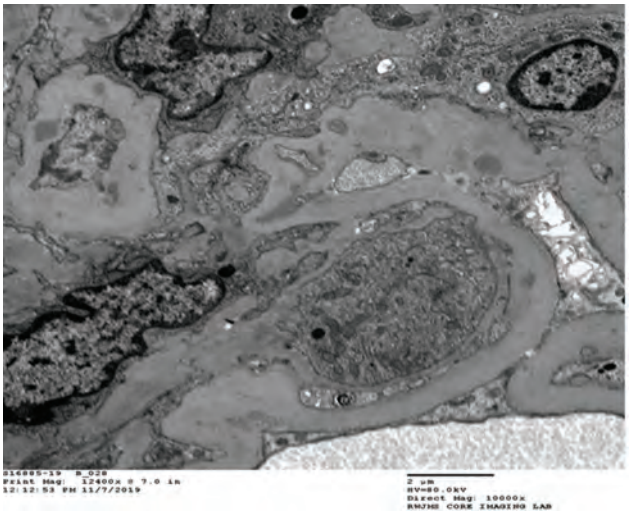
Complement 3 Glomerulonephritis in a Patient with Microscopic Polyangiitis

Hammad Siddiqui, Ayesha Ahmed, Bushra Z. Saleem. *Robert Wood Johnson University Hospital, New Brunswick, NJ.*

Introduction: C3GN is a rare disorder of excess alternative complement pathway activation, with renal biopsy characteristic of glomerular C3 deposits. We present a unique case, where patient has H/O MPA, admitted for AKI and hematuria, found to have C3GN on renal biopsy.

Case Description: 69 yo M with H/O CKD stage 4 due to microscopic polyangitis (baseline Cr 2.6 - 2.9), spinal stenosis, HTN and BPH presented with complaint of painless hematuria, epistaxis, decrease UOP and weight gain x 4 days. He was diagnosed with MPA in 2005 after a renal biopsy, recieved treatment with steroids, Cyclophosphamide for 18 months, switched to MMF for 2 years and then to Azathioprine which was discontinued due to intolerance (off all immunosuppressant's since 2012.). On admission labs; BUN/Cr 90/6.5, K 5.6, ESR 39, C-RP 1.24, P-ANCA and MPO positive. UA +3 protein, +3 blood, > 182 RBCs and 16 WBCs. Random urine protein > 600 mg per dl. C3 was low (44.1), C4 normal. AH50 was low (36.1%). Hepatitis panel, C-ANCA, PR-3 and anti-GBM were negative. Pt was admitted with preliminary diagnosis of AKI on CKD 2/2 MPA flare and was started on pulse dose of steroid. He was also started on HD and plasmapheresis. Renal biopsy showed active crescents with strong C3 global glomerular staining in the mesangium and the capillary wall and trace to no staining of IgG, IgA, IgM, C1q, kappa, lambda. S. EM showed measnagial and sub endothelial deposit suggestive of active crescentic C3 GN.

Discussion: C3 GN is rare in clinical practice. Incidence is estimated to be 2–3 cases per 1,000,000 in the United States. MPA, like other ANCA-associated vasculitis, is typically associated with a pauci-immune GN. We presented a case with signs, symptoms, labs and histopathology consistent with both C3GN and MPA. It is unclear whether this patient truly had both diseases, which are typically caused by different immunologic pathways. Depressed C3 levels and normal C4 levels, diffuse glomerular C3 deposits on immunohistochemistry, and subendothelial deposits on electron microscopy strongly supports the diagnosis of C3GN in our patient with MPA.



PO1745

Eculizumab Use in Scleroderma Renal Crisis with Thrombotic Microangiopathy

Claire Avillach, Aala Jaberi, Laurence H. Beck, Jean M. Francis. Boston Medical Center *Boston Medical Center, Boston, MA.*

Introduction: Scleroderma renal crisis is a life-threatening condition with increased mortality and morbidity leading to end-stage renal disease in about 25% of cases. Here we report a case of newly diagnosed scleroderma renal crisis with thrombotic microangiopathy (TMA) successfully treated with eculizumab.

Case Description: A 44-year-old African American female with no significant past medical history, presented with acute pulmonary edema in the setting of malignant hypertension and severe accelerated acute kidney injury (AKI) with rapidly declining GFR and clinical features of systemic sclerosis sine scleroderma. Patient was commenced on renin-angiotensin system blockade (ACEI). Despite good blood pressure control on ACEI, her creatinine continued to rise with persistent hemolysis. The kidney biopsy revealed severe features of scleroderma renal crisis with active thrombotic microangiopathy (TMA), and the decision was made to treat the patient with Eculizumab in addition to ACEI. Kidney function rapidely improved on treatment from a peak creatinine of 9.5mg/dl to 2.5mg/dl over few weeks without requiring dialysis, combined to resolution of all TMA features. Eculizumab was stopped after 3 months, without sign of relapse 2 months after discontinuation.

Discussion: TMA is a common feature of SRC, reported in about 50% of cases. The positive C4d staining on the kidney biopsy in our patient supports complement activation through the classical or mannan-binding lectin (MBL) pathway. Several studies identified the presence of auto-antibodies directed against endothelial cells that could lead to complement activation. Presence of autoantibodies against vascular receptor (against angiotensin II type 1 receptor and endothelin-1 type A receptor) have been associated with pulmonary hypertension, pulmonary fibrosis and digital ulcers but no association with SRC and TMA has been reported yet. On the other hand, hemodynamic shear stress itself has been shown to activate the classical pathway, and trigger secondary TMA. In addition, an increased FBb/FB ratio has been reported in a SRC with TMA, suggestive of subsequent recruitment of the alternative pathway through the C3b feedback cycle leading to further endothelial injury. These data support the potential role of complement blockade for the treatment of SRC with TMA.

PO1746

Thrombotic Microangiopathy and AKI Induced After Intravitreal Injection of Vascular Endothelial Growth Factor Inhibitors

Ramy M. Hanna,[1] Sapna S. Patel,[4] Ngoc G. Tran,[4] Kenar D. Jhaveri,[2] Kamyar Kalantar-Zadeh,[3] Ira Kurtz.[3] *[1]University of California Irvine, Orange, CA; [2]Northwell Health, Great Neck, NY; [3]University of California Los Angeles, Los Angeles, CA; [4]Long Beach Medical Center, Long Beach, CA.*

Introduction: Vascular Endothelial Growth Factor (VEGF) inhibition can cause worsening hypertension, proteinuria, acute and chronic kidney injury, as well as glomerular disease from Thrombotic Microangiopathy (TMA) and other nephrotic disorders when given systemically. These same agents are given intravitreally for age related macular degeneration (AMD) and Diabetic Retinopathy (DR) among other ophthalmologic conditions, albeit at lower doses than those given for systemic indications. Systemic absorption of anti-VEGF agents when given intravitreally has been shown consistently along with evidence of significant intravascular VEGF suppression. While worsening hypertension has only been seen in some large-scale studies, case reports show worsening proteinuria and diverse glomerular diseases. These include TMA-associated lesions like Focal and Segmental Glomerulosclerosis with Collapsing Features (cFSGS).

Case Description: In this paper, we report 3 cases of TMA likely associated with use of intravitreal anti VEGF therapy. These patients developed the signature lesion of VEGF blockade in a 6 month – 11-month time frame after starting intravitreal VEGF inhibitors.

Discussion: The literature is reviewed showing similar cases. Intravitreal VEGF blockade may cause these adverse events in a hitherto unidentified subgroup of patients. Further studies are needed to determine the event rate and identify which patients are at increased risk for hypertension, proteinuria worsening, renal injury, and glomerular diseases from intravitreal VEGF blockade.

Table 1 TMA and CFSGS observed with Intravitreal VEGF blockade

Reference	N	Age	Gender	Agent	Pathology on biopsy
Nobakht (4)	1	96	F	Luc→Bev→Aflib	CFSGS

PO1747

Bintrafusp α-Associated Thrombotic Microangiopathy

Jacob Ninan, Swetha Reddy, Musab S. Hommos. *Mayo Clinic, Phoenix, AZ.*

Introduction: Immune check point inhibitors (ICPIs) have been reported to cause acute kidney injury. Acute tubulointerstitial nephritis is the most common finding on renal biopsy. This has resulted in recommendations to forgo renal biopsy in some patients and therapy with empiric steroids. Here we present a different renal pathology related to use of Bintrafusp-α, a novel therapy targeting TGF-beta and PD-L1.

Case Description: A 41 year old man with metastatic cholangiocarcinoma was admitted for hypertension urgency and acute kidney injury following 2 cycles of Bintrafusp-α in 6 weeks. Exam was remarkable for BP 204/101 mmHg, pulse 62/min, muscle wasting and anasarca. His labs revealed hemoglobin 8.9 g/dL, platelets 109 × 10^9/L, occasional schistocytes, lactate dehydrogenase 626 U/L(112–222 U/L), undetectable haptoglobin, serum creatinine 2.8 mg/dL, microscopic hematuria and protein creatinine ratio 2.79g/g. ADAMTS13 activity 72% (≥70%), antiphospholipid antibody was negative, complement levels normal. The renal biopsy demonstrated acute and subacute thrombotic microangiopathy(TMA). The patient received a dose of Soliris empirically, pending workup for atypical HUS. Further doses of Soliris were held as TMA was attributed to immunotherapy and atypical HUS genetic testing panel returned negative.

Discussion: TMA is characterized by microangiopathic hemolytic anemia and thrombocytopenia. The most studied secondary cause of TMA is drugs. The pathogenesis of drug-mediated TMA is either the generation of an immunologic reaction or its direct dose- and time-dependent toxicity. ICPI monotherapy has a nephrotoxicity incidence of 2-5%. In the largest retrospective study of 1016 patients treated with ICPI therapy, 17% developed AKI, 2% experienced stage 3 AKI and 0.4% required dialysis. TMA was documented in 1 patient receiving Ipilimumab and was HD-dependent. The National Comprehensive Cancer Network guidelines recommend empirically treating AKI in some

patients with steroids. We believe renal biopsy is essential, if safe, to rule out causes of AKI that are not remediable with steroids. Renal biopsy would expand our knowledge on the pathology of AKI post-ICPI treatment. We report the first case of TMA associated with the new bifunctional immunotherapy for solid cancers.

PO1748

Atypical Hemolytic Uremic Syndrome Attributed to Complement Dysregulation in Setting of Metastatic Prostate Cancer Patient

Matthew Van Norman,[1,2] Omar Mamlouk,[2] Biruh Workeneh.[2] *[1]University of Texas Health Science Center at Houston, Houston, TX; [2]University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Thrombotic microangiopathy (TMA) is a collection of syndromes, with the most frequent types encountered being hemolytic uremic syndrome (HUS), thrombotic thrombocytopenic purpura (TTP), and atypical HUS. Atypical HUS (aHUS) may be attributed to inherited or acquired complement abnormalities, or secondary causes such as pregnancy, malignancy, transplantation, drugs. Malignancy-associated aHUS is caused by a two-hit event with complement activation playing minor role while in primary aHUS, the primary hit is complement dysregulation. We describe an unusual case of aHUS in a metastatic cancer patient attributed primarily to complement dysregulation.

Case Description: A 64-year old male with history of metastatic prostate adenocarcinoma with spinal involvement presented with a chief complaint of new onset hypertension. He reported dark "coke-colored" urine for one day with intermittent episodes of hematuria. Patient last received chemotherapy with cabazitaxel five months prior. Rest of history and physical exam was unremarkable. Laboratory findings were significant for thrombocytopenia, anemia, and peripheral smear demonstrating schistocytes. Cr peaked at 6.58 mg/dL, ADAMTS13 activity was 100%, and stool PCR was negative for shigella. Complements C3 and C4 were within normal limits. Patient became oliguric with worsening acidosis and was initiated on renal replacement therapy. He underwent a bone marrow biopsy showing no evidence of infiltration of malignancy into the bone marrow. He then had a renal biopsy with pathology showing acute TMA with fibrin thrombi in approximately 50% of the glomeruli. sC5b9 levels were elevated. He was initiated on Eculizumab 900mg once weekly and began to show signs of renal recovery. Within two weeks, he was transitioned off renal replacement therapy.

Discussion: Primary aHUS as a result of complement dysregulation can occur in patients with malignancy. This patient had elevated sC5b9 complex levels with increased alternative pathway activation. He responded to eculuzimab, monoclonal antibody inhibiting activation of C5, with full recovery of his renal function. In cases of aHUS presenting in patients with malignancy, physicians should be aware that aHUS may still occur secondary to the primary hit of complement dysregulation and should consider treatments targeting this complement pathway.

PO1749

An Unusual Case of Complement-Mediated Thrombotic Microangiopathy

Sobia N. Khan, Wilfred Lieberthal. *Stony Brook University, Stony Brook, NY.*

Introduction: Thrombotic microangiopathy is a specific pathologic lesion in which abnormalities in the vessel wall of arterioles and capillaries lead to microvascular thrombosis. Diagnosis is made by tissue biopsy Complement mediated TMA is hereditary deficiency of regulatory proteins that restrict activation of alternative pathway or hereditary abnormality of proteins that accelerate activation of this pathway. Deficiency of complement factor H or I can also be acquired

Case Description: 19-year-old female with ulcerative colitis presented with bloody diarrhea and decreased oral intake for one week. She endorsed not taking mesalamine and use of naproxen daily for two weeks. Laboratory data, leukocytosis 22k with 84% neutrophils, 5% bands and schistocytosis, hemoglobin 6.1g/dL, thrombocytopenia, BUN 77 mg/dL, creatinine 7.16 mg/dL, Lactate dehydrogenase 1042IU/L and haptoglobin undetectable. Coomb's test negative The patient was admitted for presumed Colitis flare given methylprednisolone. Renal biopsy obtained for acute kidney injury showed glomerular basement membrane duplication, multi layering and arterioles showed focal obliterative changes and onion skinning. 5% global sclerosis and 18% of glomeruli showed segmental sclerosis. Electron microscopy showed active endothelial injury, including subendothelial expansion. Microangiopathic anemia, thrombocytopenia and acute kidney injury raised concern for TMA. Shiga toxin negative and ADAMTS13 activity ~ 71%. Complement factors and autoantibodies to H, I, and B and membrane cofactor were sent out Patient started treatment for TTP, presumably aHUS. She received solumedrol 500mg/day IV x 3 and then prednisone 60mg/day. Plasma exchange was initiated. She was noted to have persistent high LDH and undetectable haptoglobin indicating ongoing MAHA. After 2 weeks of meningococcal vaccine, she was started on Eculizumab. Prednisone, Eculizumab and PEX were continued. In the interim, labs showed CFH level~ 105 mcg/mL (normal range 160-142). A genetic renal panel, which tested for CFH, CFI, CFI, MCP, and several other genes, confirmed she had a heterozygous deletion of a CFH related gene, CFHR1/CFHR3, as well as autoantibodies to CFH

Discussion: In our case, aHUS was likely predisposed by her heterozygous deletion of CFHR1/CFHR3 genes. What makes this case unusual is she did not have a homozygous deletion, but developed autoantibodies to CFH, to our knowledge has not been previously reported.

PO1750

A Case of "Immunofluorescence-Negative" Lambda Light Chain Deposition Disease

Kunal B. Buch, Satyanarayana R. Vaidya, Sheryl C. Caberto, Alton B. Farris. *Emory University, Atlanta, GA.*

Introduction: Light chain deposition disease (LCDD) is the most common form of monoclonal immunoglobulin deposition disease (MIDD). Pathologically, glomeruli develop nodular expansion of mesangial regions and deposits of monoclonal light chain (LC) positive, electron dense deposits within glomerular and tubular Basement menbrane. (1,2) The majority of monoclonal LC in LCDD are of kappa type. (3) We report a case of lambda LCDD with negative immunofluorescence microscopy (IF), but with characteristic granular, basement membrane, electron dense deposits on ultrastructural examination.

Case Description: A 42-year-old Caucasian female with no PMHx, no NSAID, Chinese herbal or PPI use presented with fatigue, malaise and dark urine for 2 weeks. She had a normal BP and no edema. Labs: Scr was 2.4 mg/dL with unknown baseline levels, BUN 26 mg/dL, Hb level 9.0 gm/dL with MCV of 90 fl, with a negative autoimmune panel. Urine microscopy showed 10 RBC/HPF and 24-hour protein excretion was 460 mg. SPEP and immunofixation detected a Lambda LC monoclonal paraprotein. Serum free Lamba LC level was 1044 mg/L with free kappa/lambda LC levels ratio of 0.03. A kidney biopsy revealed nodular expansion of glomerular mesangial regions, modest amount of IFTA. RBCs and red cell casts were present in tubules. Direct IF microscopy with FITC-conj. anti-human IgG, IgM and IgA heavy chains and Kappa/lambda light chains was negative with testing performed in duplicate. Ultrastructural examination revealed powdery, granular electron dense deposits diffusely along tubular and glomerular basement membranes with focal areas of podocyte foot process effacement. Bone marrow biopsy revealed plasma cell neoplasm.

Discussion: Our patient underwent autologous SCT after pretreatment with Melphalan. Renal function has been stable at stage III CKD. She never developed HTN or significant proteinuria, which usually are some of the presenting features of LCDD. She had lambda LC paraproteinemia, which is a more common feature of heavy chain deposition disease than LCDD. Direct IF microscopy was negative, which could be due to abnormal LCs being truncated in the tissue deposits, and commercially available, FITC-conj., anti-human Abs might not have been able to detect them. (4) This case emphasizes the fact that negative staining by routine, direct IF microscopy methods does not exclude the presence of MIDD.

PO1751

Hydralazine-Induced Vasculitis and Pulmonary-Renal Syndrome

Siddharth Mehta,[2,1] Frank S. Santana Martinez,[2,1] Shantanu Solanki,[3] Jagmeet Singh.[3] *[1]Trumbull Regional Medical Center, Warren, OH; [2]Western Reserve Health Education/ NEOMED, Warren, OH; [3]Geisinger Commonwealth School of Medicine, Scranton, PA.*

Introduction: Hydralazine, an arterial vasodilator, is a commonly used medication for the management of hypertension, heart failure with reduced ejection fraction (HFrEF), and hypertensive emergency in pregnancy. Hydralazine-induced antinuclear cytoplasmic antibody (ANCA) vasculitis leading to pulmonary-renal syndrome (PRS) is a very rare and fatal condition. A high degree of clinical suspicion, thorough history, early diagnosis, and prompt treatment is associated with a good clinical outcome.

Case Description: A 79-year-old woman with past medical history of type 2 diabetes mellitus, hypertension, lung mass, coronary artery, cerebrovascular accident, and chronic anemia presented with lethargy. Her home medications included aspirin, hydralazine, metoprolol tartrate, amlodipine, atorvastatin, and baclofen. On admission, serum creatinine was 2.5 mg/dl and erythrocyte sediment rate was more than 140 ml/min. Urinalysis showed positive urine RBC and leukocyte esterase. Chest radiograph and CT chest without contrast showed bilateral posterior opacities. Bronchoscopy showed thick mucus secretion and inflamed erythematous mucosa on left lung. Bronchoalveolar lavage showed positive bronchial fluid RBCs. Serology work-up was positive for antinuclear, antineutrophil cytoplasmic, anti-histone, anti-myeloperoxidase, and anti-proteinase 3 antibodies. Complement C3 level was low. Hydralazine was empirically held early at admission and the patient was started on intravenous corticosteroids. Consequently, patient's supplemental oxygen requirement decreased. However, serum creatinine up trended to 3.9 mg/dl requiring a need for renal replacement therapy. Patient decided not to undergo hemodialysis and opted for hospice care.

Discussion: Pathogenesis of hydralazine induced vasculitis is not well understood. It has multifactorial involvement with dose dependent relationship. A higher incidence is seen in females, patients with HLA DR4 genotype, slow hepatic acetylators, and those with a history of thyroid disease. Diagnosis is mainly based on constitutional and system-specific symptoms, thorough medication history, serology workup, and a strong clinical suspicion. In the setting of prolonged hydralazine use, clinicians should consider this rare condition which requires prompt diagnosis, early discontinuation of offending drug, and treatment with immunosuppressive therapy.

PO1752

A Case of Granulomatosis with Polyangiitis Complicated by Renal Mass-Like Lesion

Daichi Kaikoi, Koichi Sato, Hisayuki Ogura, Taro Miyagawa, Tadashi Toyama, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan.*

Introduction: Granulomatosis with polyangiitis (GPA) is a multiorgan systemic disease. Some cases of GPA may mimic IgG4-related disease (IgG4-RD) on histologic examination. Here we report a case of GPA complicated by renal mass-like lesion with infiltration of IgG4-positive plasma cells.

Case Description: A 76-year-old woman was diagnosed with otitis media with effusion 6 years before admission, and scleritis 3 years before admission. She developed nasal leaks and nasal bleeding a year before admission, and high fever and general malaise a month before admission. She visited nearby hospital and was detected a mass-like lesion in the right nasal cavity. Contrast-enhanced computed tomography (CT) of the head revealed an enhanced soft-tissue from the right middle meatus to the nasal septum and cervical lymphadenopathy. Serum proteinase 3-antineutrophil cytoplasmic antibody (PR3-ANCA) was positive (271.7 U/mL) with high C-reactive protein (CRP) level (29.7 mg/dL). Urinalysis findings showed minor proteinuria (0.1 g/gCr), but elevated tubular injury markers such as urinary beta 2-microglobulin. So, she admitted to our department. Contrast-enhanced CT of the abdomen revealed a 47-mm large mass-like lesion in the right kidney, and CT-guided renal biopsy was performed. Cellular to fibro-cellular crescent and fibrinoid necrosis were observed in the glomerulus. In the interstitium, granulomas with multinucleated giant cells and infiltration of IgG4-positive (IgG4+) plasma cells were observed. In addition, cell infiltration into the arteriolar wall and the rupture of lamina elastica were observed. From these findings with small vessel vasculitis, we diagnosed her as GPA with infiltration of IgG4+ plasma cells. After two courses of methylprednisolone pulse therapy, we added two courses of cyclophosphamide pulse therapy. With improved symptoms and serum data (PR3-ANCA level reduced from 266.8 to 39.0 U/mL), mass-like lesions in nasal turbinate and right kidney diminished.

Discussion: We experienced a case of GPA complicated by renal mass-like lesion. Renal biopsy revealed a coexistence of microvasculitis and infiltration of IgG4+ plasma cells. Further investigation will be required to clarify the role of IgG4+ cells in the pathogenesis of GPA.

PO1753

Granulomatosis with Polyangiitis and Acute Tubulointerstitial Nephritis in the Absence of Glomerulonephritis

Weiwen Guo, Cynthia C. Lim, Jason Choo Chon Jun. *Singapore General Hospital, Singapore, Singapore.*

Introduction: Isolated TIN in the absence of glomerular involvement is uncommon in ANCA-associated vasculitis(AAV).

Case Description: 77 year old female with normal renal function presented with acute kidney injury (AKI) with peak SCr 482 μmol/L and required dialysis. She received antibiotics for sinusitis and pneumonia 2 weeks prior. Urinalysis noted iso-morphic RBCs and proteinuria of 2g/24hours. Anti-proteinase3(PR3) antibody was positive at 114U/ml. Anti-nuclear, anti-dsDNA and anti-GBM antibodies were negative. Bronchoalveolar lavage was negative for alveolar hemorrhage. Kidney biopsy revealed minor glomerular abnormalities and acute TIN with interstitial non-necrotising granuloma and multinucleated giant cells. Ziehl-Neelsen stain was negative. Immunofluorescence, electron microscopy were non-contributory. She was treated for possible drug-induced interstitial nephritis with oral prednisolone 0.6mg/kg and therapy was rapidly tapered due to cytomegalovirus infection. She was on prednisolone 5mg daily by 3 months. SCr improved to 174μmol/L and anti-PR3 was 4.4U/ml. A year later, she presented with episcleritis, fever, weight loss and AKI. SCr was 399μmol/L with glomerular hematuria and proteinuria. Patient refused a repeat biopsy but in view of AKI with concurrent rise in the anti-PR3 antibody at 95.1U/ml, she was diagnosed with PR3-ANCA granulomatosis with polyangiitis (GPA) and treated with cyclophosphamide, prednisolone and dialysis.

Discussion: Our patient had PR3-ANCA GPA that presented with isolated granulomatous TIN without glomerulonephritis. Rapid improvement in renal function after low-dose prednisolone monotherapy was consistent with treatment response for TIN. In AAV, isolated TIN may be caused by vasculitis of the peritubular capillaries. Most cases of AAV with isolated acute TIN improved with no treatment or prednisolone monotherapy. Thus, it is important to recognize that isolated acute TIN is an unusual presentation for AAV.

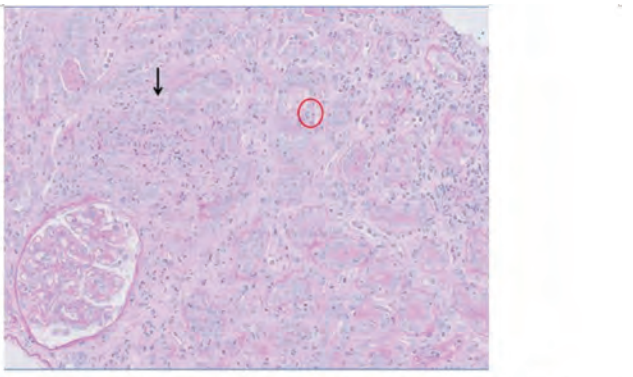

Figure 1.Acute tubulointerstitial nephritis is present, with polymorphs and lymphocytes within oedematous interstitium, including lymphocytes seen within tubular profiles. A vague granuloma is present (black arrow) where epithelioid histiocytes are observed together with other inflammatory cells. Acute tubular damage with a tubular mitosis (red circle) is also noted. A glomerulus with slightly wrinkled capillary walls is seen. (PAS stain)

PO1754

Coexisting Proteinase 3 Antineutrophil Cytoplasmic Antibody-Associated Crescentic Glomerulonephritis, Immunoglobulin A Nephropathy, and Lambda Light Chains

Arjun L. Kalaria, Amoghavarsha Puli, Sheldon Bastacky. *UPMC, University of Pittsburgh Medical Center, Pittsburgh, PA.*

Introduction: Rapidly progressive glomerulonephritis (RPGN) is a clinical syndrome that develops within weeks and is manifested by glomerular disease that is histologically delineated by crescent formation and progressively worsening renal function. The most common causes of RPGN include anti-neutrophil cytoplasmic antibody (ANCA) vasculitis, immune complex-mediated injury, and anti-glomerular basement membrane disease. We report a case of proteinase-3 (PR-3) ANCA associated crescentic glomerulonephritis with concurrent immunoglobulin A (IgA) nephropathy and lambda light chain. The co-existence of ANCA associated crescentic GN, IgA nephropathy and lambda light chain is rare.

Case Description: A previously healthy 53-year-old Caucasian woman with newly diagnosed Granulomatosis with Polyangiitis (PR-3 ANCA positive) presented with tachycardia, cough and congestion over the past 2 months. Physical examination was notable for sinus tachycardia and tenderness to palpation over maxillary sinuses. Urinalysis revealed active sediment with dysmorphic red blood cells. Initial workup was significant for serum creatinine of 1.35 mg/dl (baseline of 0.7 mg/dl), positive C-ANCA 1:160, anti-Proteinase-3 antibody 28.4 (normal <1) and 24-hour urine protein of 576 mg. Preliminary native kidney biopsy light microscopy showed active and organizing crescentic glomerulonephritis involving 15 of 34 (44%) non-globally sclerotic glomeruli. Immunofluorescence and electron microscopy were significant for granular mesangial staining for IgA and lambda light chain and presence of few mesangial electron-dense deposits. The patient was empirically pulsed with intravenous steroids for three days. She was given one dose of Rituximab with a planned second dose two weeks after discharge.

Discussion: Rapidly progressive ANCA associated crescentic GN along with mesangial staining for IgA and lambda light chain is extremely uncommon with limited literature. By presenting this case, we highlight the significance of a renal biopsy as an essential tool for diagnostic purposes and the need to have a low threshold to biopsy in otherwise clinically straight forward cases given unexpected histologic and immunologic findings that could affect therapy and consequently patient's morbidity and mortality.

PO1755

A Case of Microscopic Polyangiitis Accompanied by Refractory Immune Thrombocytopenic Purpura

Masahiro Muto,[1,2] Hitoshi Suzuki,[1] Yasuhiko Kanaguchi,[1] Hiroyuki Yanagawa,[1] Masao Kihara,[1] Seiji Ueda,[1] Tomohito Gohda,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan.*

Introduction: Microscopic polyangiitis (MPA) is an idiopathic autoimmune disease characterized by systemic vasculitis that predominantly affects the small blood vessels and is mediated by the presence of antineutrophil cytoplasmic autoantibodies (ANCA). Immune thrombocytopenic purpura (ITP) is also an autoimmune disease characterized by autoantibody induced platelet destruction and reduced platelet production, leading to low blood platelet count. Secondary ITP is defined as an ITP induced by other diseases including autoimmune disorders. Here we present a rare case of a patient who developed ITP just after treatment with steroids for MPA with rapidly progressive glomerulonephritis (RPGN).

Case Description: 66-year-old female was hospitalized due to microscopic hematuria, proteinuria, elevated serum creatinine (2.8mg/dL) and high Myeloperoxidase-ANCA (MPO-ANCA) titres (94.1U/ml). We performed a renal biopsy that revealed pauci immune crescentic glomerulonephritis. After the definitive diagnosis of MPA, the patient was treated with intravenous corticosteroids and oral prednisone (0.8mg/kg). Although serum creatinine subsequently improved to 1.6mg/dl, the peripheral platelet count was

rapidly reduced from 20×10^9/L to 2×10^9/L after a week treatment with steroids. She was frequently treated with platelet transfusion. Bone marrow examination revealed normal morphology of all the cell lines, with increased megakaryocytes. Based on the clinical findings, we diagnosed as ITP. Then, the patient received rituximab followed by thrombopoietin-receptor agonists eltrombopag. After a week of treatment with oral eltrombopag at 25mg daily, the platelet count increased from 0.5×10^9/L to 4×10^9/L. After six weeks from initiation of eltrombopag, her platelet count remains $>3\times10^9$/L, and she has not shown any signs of bleeding or hemorrhage. MPO-ANCA titres reduced to 1.3U/ml.

Discussion: It is a novel case of MPA with RPGN accompanied by ITP. It was recently recognized that diversity existed in both pathogenesis and clinical characteristics in patients with ITP. Present case showed the possibility for an association of pathological mediator for both diseases. Although further studies are needed to confirm this idea, present findings provide clues for our understanding of this association for a better management of these diseases.

PO1756

Rituximab Rescue in Anti-GBM Nephritis

Shikha Shailly, Lorin Berman, Sofia Rubinstein. *Nassau University Medical Center, East Meadow, NY.*

Introduction: Anti-GBM nephritis is a rare, severe autoimmune disease. If left untreated or in patients requiring dialysis at presentation, it has a renal survival of 8% at 1 year. Conventional therapy includes corticosteroid, cyclophosphamide and plasmapheresis. An anti-B cell agent, rituximab is more recently being used in refractory cases (defined as no response after 4 weeks of standard therapy).

Case Description: 59-year-old female with hypertension presented with 1 month of fever, generalized malaise, and cough following recent travel to Iraq. Laboratory evaluation showed serum creatinine 1.3 mg/dL with hematuria and proteinuria (0.8g/day). ANA, ANCA, RF, Hepatitis B/C, HIV, RPR, and streptozyme panel were negative. Renal and pulmonary imaging were unremarkable. With creatinine rising rapidly, renal biopsy was performed revealing acute focal segmental necrotizing and crescentic glomerulonephritis involving 50% of glomeruli. Anti-GBM antibody level was 8U. Plasmapheresis daily, cyclophosphamide and steroids were initiated. She remained non-oliguric, but developed edema requiring intermittent diuresis. On day 15, plasmapheresis was reduced to every 48 hours. Anti-GBM antibody failed to decline, therefore 1 gr of rituximab infusion was initiated 3 weeks later. Standard therapy was continued until the second dose of 1gr of rituximab 2 weeks later. Patient was discharged with creatinine stable at 4 mg/dL, anti-GBM antibody level at 1.4U and on prednisone taper. On follow up day 75, antibody levels were undetectable and on day 147 she remained dialysis free.

Discussion: Our patient presentated with favorable prognostic markers including non-oliguria, low creatinine and anti-GBM antibody levels, negative ANCA, involvement of 50% of glomeruli, and no dialysis requirement. Despite these factors, she did not respond to standard therapy alone. Our patient was initiated on rituximab earlier than reported refractory cases while continuing standard therapy until the 2nd dose of rituximab, with a favorable outcome of remaining dialysis free. We suggest early use of rituximab with overlapping of the standard regimen is safe and effective in older age group.

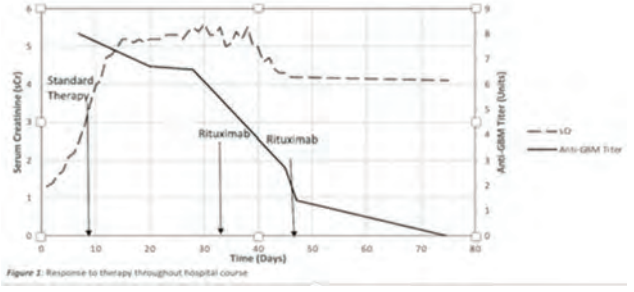

Figure 1: Response to therapy throughout hospital course

PO1757

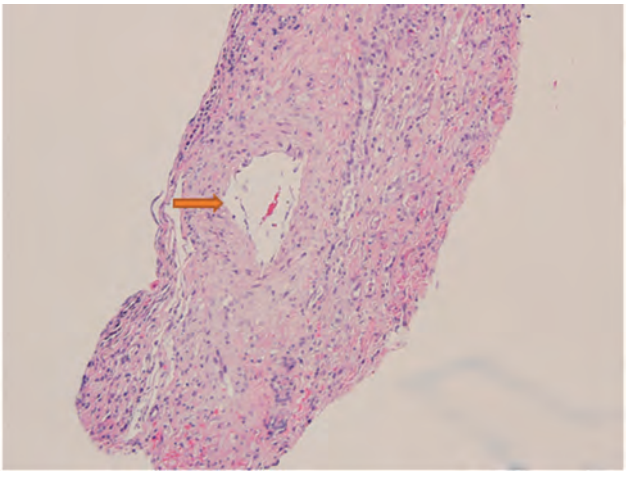
Rare Case of Myeloperoxidase-ANCA-Positive Polyarteritis Nodosa

Bhaktidevi Makadia,[1] Sandeep K. Mallipattu,[1] Monica P. Revelo Penafiel.[2] *[1]Stony Brook University Hospital, Stony Brook, NY; [2]University of Utah Health, Salt Lake City, UT.*

Introduction: Polyarteritis Nodosa (PAN) is systemic necrotizing vasculitis involving medium-size vessels. PAN is typically not associated with positive antineutrophil cytoplasmic antibodies (ANCA) titter. Here, we report a patient who presented with abdominal pain, hematuria, sub-nephrotic range proteinuria, acute kidney injury (AKI) with high MPO ANCA titer who was diagnosed with PAN.

Case Description: 40-year-old male with asthma presented with abdominal pain, generalized weakness and myalgia, weight loss of 25 pounds over the last 2 months. Two weeks prior to presentation, patient was diagnosed with eosinophilic granulomatosis with polyangiitis (EGPA) and started on prednisone at the outpatient clinic. Physical exam was significant for hypertension, abdominal tenderness and petechial rash in the lower extremities. Laboratory findings were significant for serum creatinine 1.6 mg/dl, ESR 93 mm/hr, CRP 25 mg/dl, ANCA titer 1:160 with MPO – 46 units. Urinalysis revealed 28 RBC/hpf with urine protein/creatine - 1.4 g/g. Esophagogastroduodenoscopy and skin biopsy of petechial rash were negative for vasculitis. Kidney biopsy reveled focal arterial fibrinoid necrosis with mixed interstitial inflammatory infiltrate consistent with necrotizing arteritis involving predominantly medium size arteries, leading to a diagnosis of PAN (fig 1). Patient was treated with pulse dose methylprednisolone and cyclophosphamide for PAN with maintenance prednisone.

Discussion: PAN is a rare disease involving multiple organ systems, including the kidney, and is typically not associated with a positive ANCA titer observed in small-vessel vasculitis. In the largest database of biopsy-proven PAN (n=348), French Vasculitis Study Group, 253 patients had ANCA titer done at the time of diagnosis with PAN, and all were negative. Kidney biopsy revealed a rare diagnosis of MPO-ANCA+ PAN which was critical to determining the management in this patient.



Arrow Shows necrotizing arteritis of medium size arteries

PO1758

Complement-Mediated Thrombotic Microangiopathy in a Patient with Anti-GBM Disease: A Case Report

Yuliya Sharakova, Mohamed Hassanein, Rhyan Maditz, Leal C. Herlitz, John F. O'Toole. *Cleveland Clinic, Cleveland, OH.*

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is a rapidly progressive glomerulonephritis, caused by pathogenic antibodies directed against the α3NC1 epitope of type IV collagen, and accompanied by pulmonary hemorrhage in about 50% of cases. Here we present a case of anti-GBM disease in combination with hemolysis, a rare and poorly understood association.

Case Description: A 22 y/o male with a history of tobacco use was admitted for oliguric acute kidney failure requiring initiation of dialysis. Kidney biopsy showed linear GBM staining for IgG, κ and λ, supporting the diagnosis of anti-GBM nephritis with crescentic involvement of all glomeruli and positive serum anti-GBM antibody. High dose corticosteroids were given but additional immunosuppression was held due to low probability of benefit in the setting of severe renal limited disease. One week after biopsy, the patient developed fever, and his Hb decreased to 6 g/dL due to microangiopathic hemolytic anemia with low haptoglobin, elevated LDH, mild platelet decline, and negative Coombs test. Additional workup was negative for malignancy, cobalamin deficiency, malignant hypertension, or infection including shiga-toxin, showed normal ADAMTS13 activity, C3, C4, factor H, I, B, and no CFH autoantibody, but an elevated sC5b9 level demonstrating terminal complement activity. Repeat kidney biopsy revealed an acute thrombotic microangiopathy (TMA) along with previously diagnosed anti-GBM disease. Treatment with Eculizumab was started, but diffuse alveolar hemorrhage (DAH) developed 19 days after admission and thus plasmapheresis and cyclophosphamide were initiated with reduction of anti-GBM titers and hemolysis and resolution of DAH.

Discussion: Anti-GBM disease and complement-mediated TMA are both exceedingly rare clinical entities. While hemolysis has been reported in the literature, this is the first report of complement-mediated TMA driving hemolysis in the setting of anti-GBM. Dysregulated activation of the alternative pathway in complement-mediated TMA and literature reports supporting a role for both classical and alternative pathways in anti-GBM disease suggests a possible link between the two diseases and a previously unrecognized role for complement dysregulation in cases of hemolysis observed in the setting of anti-GBM.

PO1759

IgG4-Related Kidney Disease Associated with an Unusual Vasculitic Peripheral Neuropathy

Muhammad T. Baig, Anjali A. Satoskar, Benjamin Jiang, Miriam L. Freimer, Isabelle Ayoub. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: IgG4-related disease is a systemic autoimmune fibro-inflammatory disorder showing lymphoplasmacytic infiltrates with predominance of IgG4+ plasma cells and variable amounts of storiform fibrosis in the affected tissues. When kidneys are the only organs involved it is called IgG4-related kidney disease (IgG4-RKD). Neurologic involvement is less common and known to manifest as hypophysitis and pachymeningitis.

Peripheral neuropathy is rare. Our case illustrates an unusual presentation of IgG4-RKD with vasculitic peripheral neuropathy, which has never been reported before

Case Description: A 55-year-old Southeast Asian woman with allergic rhinitis presented to her PCP with burning and tingling from the knees down and difficulty with gait for about 6 months. Neurological examination was notable for weakness of ankle dorsiflexion and plantarflexion and loss of pinprick and vibration sense distal to ankles. This was attributed to iron deficiency anemia and a compressed nerve. However, her symptoms worsened on iron supplements and gabapentin and were accompanied by weight loss. CT scan of abdomen showed heterogeneous masses of the kidneys with few enlarged retroperitoneal lymph nodes. Kidney biopsy was performed and showed storiform fibrosis and plasma cell rich interstitial inflammation (>30 IgG4+ plasma cells/HPF) suggesting IgG4-RKD. Further work up was significant for serum IgE 1309 IU/ml (1.5-165), IgG4 177 mg/dl (2.4-121), ANA >1:1280, positive MPO-ANCA, RF 38 IU/ml (<14), ESR 77 mm/hr. CRP, complement levels and kidney function were normal. Prior to initiating therapy for IgG4 RKD she was referred for sural nerve biopsy for concern of associated vasculitis. Nerve biopsy showed severe myelinated and unmyelinated fiber loss in all fascicles, a recanalized epineural blood vessel, and dense perineural mononuclear cell infiltrates consistent with vasculitic neuropathy. Additionally, immunostaining showed IgG4 plasma cells up to 10/HPF. Her symptoms resolved with steroids, IVIG and rituximab. Serum IgG4 level improved to 26 mg/dl.

Discussion: IgG4-RD can have varied systemic manifestations. Although neurologic disease is less commonly seen in IgG4-RD, we report for the first time an associated vasculitic neuropathy that should be considered and worked up in symptomatic patients

PO1760

Differential Expression of Interferon-Stimulated Genes in ANCA-Associated Vasculitis

Prasanti Kotagiri, Eoin F. McKinney, Paul A. Lyons, Kenneth G. Smith. Smith Laboratory *University of Cambridge, Cambridge, United Kingdom.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a multi-systemic, necrotising vasculitis, causing severe morbidity and mortality. It is characterised by the presence of auto-reactive antibodies against neutrophil granule components, myeloperoxidase (MPO) and proteinase 3 (PR3). The disease course remains variable, and patients suffer substantial morbidity and mortality. Therapeutic advances are hampered by a lack of understanding of the mechanisms driving both initial disease susceptibility and long-term clinical outcome. To increase our understanding of disease mechanism and to uncover untargeted pathways for treatment, we studied the transcriptomes and serum proteomes of patients with active AAV.

Methods: The transcriptional profiles and protein expression of patients with AAV (31 PR3-AAV, 15 MPO-AAV, 1 dual ANCA positivity, 4 ANCA-negative) were studied at the time of diagnosis or during an active flare, whilst on minimal immunosuppression, along with healthy controls. AAV patients were profiled longitudinally at 3 and 12months. Separated leucocyte transcriptomes were profiled, using Affymetrix HuGene ST1.1 gene expression microarray. Transcriptional profiles were available on peripheral blood mononuclear cells (PBMCs), neutrophils, monocytes and CD4 and CD8 T cells. Protein expression was assessed on the SOMAscan platform. Analytical techniques included differential gene-expression, weighted gene co-expression network, gene set enrichment and multi-omics factor analyses.

Results: Here we identify, a module of interferon stimulated genes (ISG) that distinguishes the serological subtypes of AAV, MPO- and PR3-ANCA. This module of ISG was upregulated in MPO- compared with PR3-AAV during the time of active disease and at 3 months post treatment. The signature was present in the neutrophil, monocyte and PBMC transcriptome but was absent in T cells. Multi-omic factor analysis revealed a parallel upregulation of interferon like proteins in serum, coinciding with the increase in gene expression.

Conclusions: AAV causes severe morbidity and mortality. The differential expression of ISG in MPO compared with PR3-AAV highlights potential differences in pathogenesis. The presence of an interferon response in MPO-AAV opens new avenues for targeted treatment with agents such as Jak inhibitors and monoclonal anti-IFN-α antibodies.

PO1761

IL233-Induced Remission from Lupus Glomerulonephritis Involves Regulation of Mitochondrial Function and Canonical WNT Signaling

Rajkumar Venkatadri, Vikram Sabapathy, Murat Dogan, Saleh Mohammad, Shu man Fu, Rahul Sharma. *University of Virginia, Charlottesville, VA.*

Background: We recently showed the efficacy of a hybrid cytokine IL233 to protect mice from lupus glomerulonephritis (GN). We have now investigated the status of mitochondrial function, canonical Wnt signaling and metabolic fitness of regulatory T cells (Tregs), risk factors known to be associated with lupus GN to further delineate the mechanisms of protection offered by IL233.

Methods: We made use of the recombinant hybrid cytokine (IL233) bearing activities of IL-2 and IL-33 and tested its efficacy to prevent glomerular nephritis in the adenovirus (Ad)IFNa accelerated lupus GN NZM2328 model. Kidney lysates were screened for transcripts of mitochondrial and Wnt inhibitor genes by real time PCR and Western blotting. Mitochondrial membrane potential and metbolic fitness in IL233 treated mouse glomerular endothelial cells (MGECs) was investigated by flow cytometry and Seahorse assay. Metabolic fitness of Tregs with and without IL233 treatments were investigated by Seahorse assay by employing *ex vivo and in vivo* approaches.

Results: Analysis of transcript levels of mitochondrial function and biogenesis related genes (Pgc1α, Nrf1, Nrf2, Tfam, Drp1 and Mfn1) confirmed that IL233 treated kidneys displayed an elevated status. *In vitro*, changes in Pgc1α and its downstream target Nrf2 were recapitulated in treated MGEC cells. IL233 treated Tregs (*ex vivo and in vivo*) and MGECs (*in vitro*) also exhibited better mitochondrial metabolic fitness and displayed elevated levels of basal respiration, maximal respiration and ATP production investigated by the Seahorse assay. Wnt activators LRP6, Dvl3 and Wnt mediators - Axin1, GSK3a and GSK3b were significantly reduced in IL233 protected kidney. Levels of Axin2 was significantly upregulated with IL233 treatment indicating activation of a negative feedback loop for Wnt inhibition.

Conclusions: We present in depth mechanistic evidence of the observed remission from lupus GN with IL233 treatment. IL233 treated kidneys exhibit better mitochondrial dynamics and function. We show *in vitro, in vivo* and *ex vivo* evidence of IL233 treatment leading to betterment of mitochondrial function and metabolic fitness. Canonical Wnt signaling was attenuated. The data presented confirms the therapeutic efficacy of IL233 as a promising therapeutic agent for lupus nephritis and kidney injury.

Prediction of Histologic Class Using Deep Learning on Renal Biopsies from a Trial of Obinutuzumab for Proliferative Lupus Nephritis

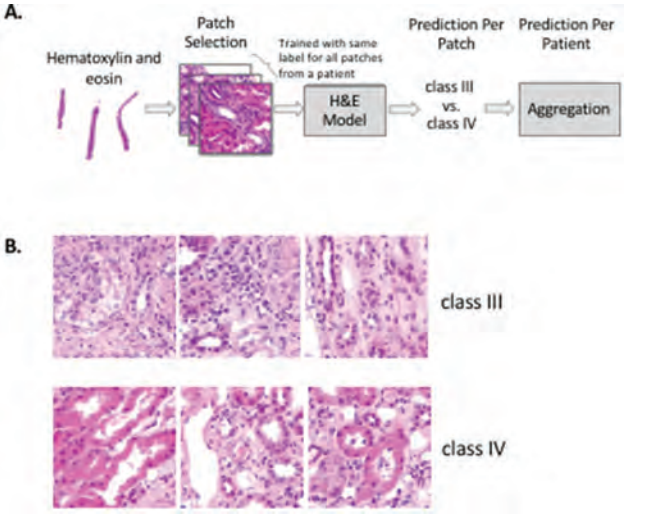
Bryan D. He,[1] Matthew Cascino,[2] Thomas Schindler,[3] Cary D. Austin,[2] Wei Tew,[2] Jay P. Garg,[2] James Zou,[1] Marco Prunotto.[3,4] *[1]Stanford University, Palo Alto, CA; [2]Genentech Inc, South San Francisco, CA; [3]F Hoffmann-La Roche AG, Basel, Switzerland; [4]University of Geneva, Geneva, Switzerland.*

Background: Glomerular lesions in lupus nephritis (LN) are classified according to the International Society of Nephrology and the Renal Pathology Society classification system and significant disagreement between pathologists can occur on histopathologic lesions. The aim of this study was to assess if deep learning on renal biopsy whole-slide images could be used to predict class III vs. IV status among patients enrolled in a randomized trial of obinutuzumab for the treatment of proliferative LN (NCT02550652).

Methods: Baseline biopsies from 84 of the 126 patients randomized were available for analysis. From each hematoxylin and eosin (H&E) slide, patches of 512x512 pixels were extracted resulting in an average of 500 patches per slide. An Inception v3 neural network (NN) with weights pretrained on the ImageNet dataset was used to make a prediction for each patch, which were then combined to make a prediction for the patient (Fig. A). From the initial weights, all slide's layers were further fine-tuned using the cross-entropy loss between the model's prediction and the patient's true class. To evaluate the trained model, 25% of patients were held-out as a test set.

Results: The NN was able to classify the held-out patients with an area under the receiver operating characteristic of 0.82 (95% CI 0.60 - 1.00). Patches associated with class III vs. IV prediction could be extracted from each patient to provide interpretation (Fig. B).

Conclusions: These preliminary results showed that deep learning on renal biopsies can predict LN histologic class. The predictive patches provided additional interpretation. Such objective classification method has potential value to help minimize reading variability between pathologists.



(**A**) Computational pipeline for predicting the lupus nephritis histologic class of a patient from a whole-slide image. Examples of whole-slide image and patches were shown. (**B**) Examples of patches identified by the model as being most indicative of class III or IV.

PO1763

A Prospective Randomized Study on Preemptive Immunosuppressive Therapy in Lupus Nephritis Patients with Asymptomatic Serological Reactivation

Desmond Y. Yap, Paul Lee, Irene Yam, Tak Mao D. Chan. *University of Hong Kong, Hong Kong, Hong Kong.*

Background: The optimal management for asymptomatic serological reactivation (ASR) in lupus nephritis (LN) patients remains undefined. Our previous retrospective study suggested that pre-emptive moderate increase in immunosuppression may prevent subsequent clinical relapses.

Methods: We prospectively randomized LN patients with ASR (defined as ≥2-fold increase of anti-dsDNA to >100 IU/mL, with or without change in complement level, and absence of clinical lupus exacerbation) to receive pre-emptive treatment or unchanged management ('Control' group). Pre-emptive treatment included increasing prednisolone to 0.5 mg/kg/D, and the dose of mycophenolate to 1g/D or azathioprine to 75 mg/D, then tapered over 12-16 weeks back to the original dosages.

Results: Eighteen patients pre-emptive group and 17 in control group respectively). Pre-emptive group showed lower anti-dsDNA and higher C3 levels after 12 weeks compared with Controls ($p<0.001$, for both) (Figure 1). Pre-emptive group showed significantly lower incidence rates of all clinical relapses and renal relapse during subsequent 9 months follow-up compared with Controls (11.1% vs 41.2%, $p=0.02$; and 0% vs 17.6%, $p=0.03$; respectively). The pre-emptive group showed lower serum miR-148a compared with baseline value and also the Controls ($p<0.001$, for both). There was no clinically significant adverse event.

Conclusions: Our results suggest that pre-emptive moderate increase of immunosuppressive treatment reduces the risk of disease flare in LN patients with ASR and is well tolerated.

Funding: Government Support - Non-U.S.

Kidney Thrombotic Microangiopathy Associated to Lupus Nephritis Is Mediated by the Activation of the Alternative Complement Pathway

Juan M. Mejia, Ismael A. Gómez Ruiz, Rossa A. Méndez, Cristinoc Cruz, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter. *Department of Nephrology and Mineral Metabolism. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran., Mexico City, Mexico.*

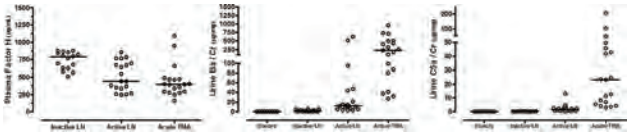
Background: Thrombotic microangiopathy (TMA) in the context of lupus nephritis is a rare disease whose pathogenesis has been linked to complement activation. This study aimed to evaluate complement pathway activation products in plasma and urine from patients with LN associated TMA (LN-TMA) and to compare its levels to patients with active LN (aLN), patients with inactive lupus (iSLE) and kidney donors (KD).

Methods: Plasma and urine samples were obtained from 19 patients with acute LN-TMA and 19 patients with biopsy-proven aLN matched by histologic activity index. Patients with iSLE (n=16) and kidney donors (n=10) were included as controls. Complement activation fragments C3a, C4a, C5a, Ba, C5bC9, and factor H were assessed by ELISA. Kidney C4d deposition was detected by immunohistochemistry. After 12 months, complement activation products were re-assessed after treatment.

Results: Both, the acute LN-TMA and aLN patients had increased plasma Ba and C5bC9 along with decreased plasma C3, C4, C4a, and factor H. Urine C5a, Ba, and C5bC9 were higher in patients with acute LN-TMA than in aLN. The levels of the urine complement fragment correlated with the degree of interstitial inflammation, interstitial fibrosis, and tubular atrophy in the kidney biopsy. After treatment, the levels of circulating C3, C4, and factor H increased, and the levels of urine C5bC9 decreased. In two patients with repeated LN-TMA episodes, factor H and urine C5a levels decreased, while urine Ba and C5bC9 increased after treatment in each episode. There was no difference in C4d fragment deposition in glomerular capillaries, tubular basement membrane, peritubular capillaries, and arterioles, between patients with aLN and those with acute LN-TMA.

Conclusions: The levels of plasma and urine complement activation products suggest that the pathogenesis of acute LN-TMA is mediated through activation of the complement alternative pathway.

Funding: Government Support - Non-U.S.



Levels of plasma factor H (A), urine complement fragment Ba (B) and urine complement fragment C5a (C) in the studied groups.

Glycol Chitosan-Based Tacrolimus-Loaded Nanomicelle Therapy Ameliorates Lupus Nephritis

Chang Seong Kim, Tae ryom Oh, Hong sang Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Chonnam National University, Gwangju, Jeollanam-do, Republic of Korea.*

Background: Hydrophobically modified glycol chitosan (HGC) nanomicelles loaded with tacrolimus (HGC-TAC) enhance the renal delivery of tacrolimus. Here, we determined whether the administration of HGC-TAC nanomicelles decreases kidney injury in a model of lupus nephritis.

Methods: Lupus-prone female MRL/lpr mice were randomly divided into 2 groups and given either intravenous vehicle or HGC-TAC (0.5 mg/kg tacrolimus) weekly for 8 weeks. Age-matched MRL/MpJ mice without *Fas^{lpr}* mutation were treated with a vehicle and used as healthy controls.

Results: Weekly treatment with intravenous HGC-TAC remarkably reduced genetically attributable lupus activity, blood urea nitrogen, and proteinuria in lupus nephritis-positive mice. In addition, HGC-TAC treatment mitigated renal dysfunction and histological injury, including glomerular proliferative lesions and tubulointerstitial infiltration. Furthermore, HGC-TAC treatment reduced renal inflammation and inflammatory gene expression, as well as ameliorated the increased glomerular fibrosis. Moreover, the administration of HGC-TAC appeared to regulate renal injury via the TGF-β1/p38MAPK/NF-κB signaling pathway.

Conclusions: Our study clearly indicates that weekly treatment with HGC-TAC nanomicelles reduces kidney injury resulting from lupus nephritis by preventing inflammation and fibrosis. This advantage of HGC-TAC nanocarriers may improve drug adherence and treatment efficacy in lupus nephritis patients.

Funding: Government Support - Non-U.S.

Renal Activity Index for Lupus Nephritis Distinguishes Active Renal Disease Among Lupus Patients

Najla F. Aljaberi,[3] Arjun Mathur,[3] Steffy Jose,[1,2] Theresa Hennard,[3] Angela Merritt,[3] Qing Ma,[3] James Rose,[3] Rashmi Sahay,[3] Chunyan Liu,[3] Hermine Brunner,[3] Scott E. Wenderfer.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Conventional tools to identify active nephritis in SLE (LN) fail to supersede invasive kidney biopsy. The renal activity index in lupus (RAIL) was developed using 6 urinary biomarkers to reflect disease activity (Brunner, *et al*. 2016). Our objective was to test RAIL for identifying active LN in childhood-onset SLE.

Methods: Urine samples obtained from cross-sectional sampling of 2 cSLE cohorts, classified as active LN, inactive LN or non-LN SLE. RAIL scores were calculated from ELISA or nephelometry data for six urine markers (NGAL-1, ceruloplasmin, MCP-1, adiponectin, hemopexin, kidney injury molecule-1). Data collected included ISN/RPS histologic classification and extra-renal component of SLE disease activity index (SLEDAI) score.

Results: Among 117 cSLE patients, 37 had active LN; 30, inactive LN; 50, no-LN. RAIL scores of inactive LN and no-LN group largely overlapped, so they were combined (Group 2) and compared to active LN (Group 1, Table). Group 1 had higher RAIL score (0.7 vs. -1.1). After adjusting for age and extra-renal SLEDAI score, RAIL score odds ratio was 2.16 (95%CI 1.4-3.3, p=0.001) for active LN. A receiver operating curve (ROC) for an adjusted RAIL cut-off score of 0.35 produced an AUC=0.9 (sensitivity 86%, specificity 84%) for active LN. Adjustment for urinary protein and creatinine did not influence results.

Conclusions: The RAIL score is highly accurate in distinguishing active from inactive LN and non-LN SLE. Scores >0.35 identify cSLE patients who very likely have active LN.

Clinical characteristics and distribution of RAIL scores among Group 1 (active LN) and Group 2 (inactive LN + active non-LN SLE) patients

	Group 1 Active LN N = 37	Group 2 Inactive LN + Non-LN SLE N = 80	p-value
Age (y), median (IQR)	15 (13-17)	18 (16-21)	< 0.0001
Extra-renal SLEDAI, median (IQR)	9 (6-13)	2 (0-4)	< 0.0001
GFR, median (IQR)	91 (60-129)	108 (98-126)	0.05
Urinary creatinine, median (IQR)	92 (61-191)	134 (73-184)	0.32
Urinary protein, median (IQR)	254 (98-404)	21 (11-50)	< 0.0001
Urinary microalbumin, median (IQR)	254 (189-316)	15 (9-43)	< 0.0001
RAIL Score, median (IQR)	0.7 (-0.1-1.6)	-1.1 (-2.5-0.3)	< 0.0001
NIH-AI, median (IQR)[¥]	9 (4-13)	0 (0-0)	< 0.0001
NIH-CI, median (IQR)[¥]	1 (0-2.75)	0 (0-0)	0.11

[¥] Includes only active (N=24) and inactive LN (N=4) patients with sampling performed within 30 days of kidney biopsy

A Novel Inflammatory Dendritic Cell in Lupus Nephritis

Latha Prabha Ganesan,[1] Ana Malvar,[2] John P. Shapiro,[1] James M. Turman,[1] Huijuan Song,[1] Valeria G. Alberton,[2] Bruno J. Lococo,[2] Sethu M. Madhavan,[1] Anjali A. Satoskar,[1] Daniel J. Birmingham,[1] Wael Jarjour,[1] Brad H. Rovin,[1] Samir V. Parikh.[1] OSU Nephrology *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Hospital Fernandez, Buenos Aires, Argentina.*

Background: Progress in Lupus Nephritis (LN) management has been limited and treatment outcomes remain sub-optimal. Knowledge on intra-renal changes during LN flare and the major immune cells that drive local inflammatory damage will lead to improved outcomes in LN.

Methods: We performed transcriptomic analysis on serial kidney biopsies of proliferative LN (n=58). Glomeruli and Tubulointerstitium (TI) were isolated using LCM, and 580 immune transcripts were analyzed using Nanostring human immunology panel. Guided by transcriptomic analysis, multi-color, high-resolution confocal immunofluorescence (IF) analysis using antibodies against various immune cell markers, was performed on LN flare kidney biopsies (n=5) and healthy nephrectomy controls (n=5), to identify the dominant intra-renal immune cell phenotypes present during LN flare.

Results: Transcriptomic analysis identified Fc receptor gamma chain (FcRγ), to be the most significantly overexpressed glomerular immune transcript (Fold change (FC): 3.5, P=1E-10) and also overexpressed in the TI (FC: 1.7, P=0.001) compared to controls. Confocal IF analysis found FcRγ to be abundantly present in the peri-glomerular (PG) region and to a lesser extent in the TI during LN flare. FcRγ was weakly expressed in controls. Further IF analysis identified the phenotype of FcRγ expressing cells to be CD11c+,DC-SIGN+,MHC II+,CD64+,CD14+, CD16+,CD206-,CD68-,CD123-,CD3-,CD11b-. This signature aligns with a dendritic cell (DC) phenotype but distinct from plasmacytoid and conventional DC. It is most consistent with an inflammatory dendritic cell (infDC) phenotype. Importantly, confocal IF identified CD3+ T cells present in close proximity to PG infDC.

Conclusions: In this study, we identified a novel population of InfDC not previously described in LN. During LN flare, InfDC are present in abundance in the PG region. Their presence next to T cells suggests infDC dictate the nature of the T cell response during LN flare. Targeting infDC or their associated T cell phenotype may attenuate renal inflammation and improve outcomes in LN.

Burden of Illness of Lupus Nephritis in Patients with Systemic Lupus Erythematosus

Christopher F. Bell,[1] Benjamin Wu,[1] Bin Xie,[2] Shirley Huang,[1] Benjamin Chastek,[2] Bernie Rubin,[3] Joan Von Feldt,[3,4] Gary Bryant.[3] *[1]GlaxoSmithKline, Research Triangle, NC; [2]Optum, Eden Prairie, MN; [3]GlaxoSmithKline, Philadelphia, PA; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Approximately 35% of adults with systemic lupus erythematosus (SLE) develop lupus nephritis (LN). LN is associated with an increased risk of renal failure, cardiovascular disease, and death. Little is known about healthcare resource utilization (HRU) or costs of care for patients with LN versus those without SLE.

Methods: This retrospective cohort study used Optum Research Database administrative claims data (GSK Study 213062). Patients with LN had ≥2 renal diagnosis codes during 08/01/2017–07/31/2018 and ≥1 inpatient or ≥2 outpatient SLE diagnosis codes >30 days apart in the 12 months prior to index; index date was the date of first renal diagnosis code. The control cohort had plan members with no diagnosis codes for SLE or LN during 08/01/2016–7/31/2018. Control patients were matched 1:1 to patients with LN based on baseline demographics. Inclusion criteria: ≥18 years of age at index, and continuous medical and pharmacy coverage in the 12 months pre and post index. HRU in the 12 months post index captured ambulatory visits, emergency department (ED) visits, and hospitalizations. Total healthcare costs in the 12 months post-index were quantified combining health plan– and patient-paid amounts and adjusted using the Consumer Price Index.

Results: Across the LN and control cohorts, 2326 patients met study criteria; 38.5% were 45–64 years of age, 44.1% were ≥65 years of age, 85.6% were female, 58.1% were located in Southern USA states, and 66.3% were covered by Medicare. The LN cohort had a significantly higher mean (standard deviation [SD]) number of ambulatory visits (53.93 [55.34] vs 18.27 [21.61]), ED visits (2.87 [7.91] vs 0.86 [2.31]), and hospitalizations (0.86 [1.48] vs 0.12 [0.51]) versus the control cohort, respectively. Mean (SD) total costs were $50,958 ($86,100) for the LN cohort, which were significantly higher than $10,737 ($21,741) in the control cohort. Differences in cost were largely driven by mean (SD) medical expenses for the LN cohort versus the control cohort ($40,648 [$78,134] vs $6,781 [$14,773] respectively). All p-values were <0.001.

Conclusions: All-cause HRU and costs were higher for patients with LN than patients without SLE. This study quantifies the economic burden associated with LN.

Clinico-Pathological Associations with Serum Thrombomodulin Level in Patients with Lupus Nephritis

Tak Mao D. Chan, Kelvin Y. Yu, Desmond Y. Yap, Susan Yung. *The University of Hong Kong, Hong Kong, Hong Kong.*

Background: Conventional serological markers do not always correlate with clinical activity or histolopathology in lupus nephritis (LN). There is evidence of endothelial activation and injury in LN pathogenesis. Thrombomodulin (TM), a component of endothelial glycocalyx, is shed into the circulation in endothelial cell injury. We investigated clinico-pathological associations of circulating TM level.

Methods: TM level was measured by ELISA in sera collected serially every 3-4 months over ≥2 years (n=482) from 31 patients with biopsy-proven Class III/IV LN. Patients with non-renal SLE or non-lupus kidney diseases (CKD) and healthy subjects were included as Controls.

Results: Patients with active LN had the highest serum TM level, compared with LN patients in remission, patients with active non-renal SLE, CKD patients, or healthy subjects (P<0.01, for all). Serum TM level correlated with anti-dsDNA antibody titre, proteinuria, serum creatinine, SLEDAI-2K and renal SLEDAI-2K score; and inversely correlated with eGFR and C3 (P<0.05, for all). 8 patients had blood samples collected before disease flare, and 6 showed increased TM level (3.65±2.16 months before clinical flare). All episodes of LN flare were accompanied by elevated TM level, which decreased after treatment. A temporal relationship was noted between TM level and anti-dsDNA titre and C3 levels, proteinuria, SLEDAI-2K and renal SLEDAI-2K scores. TM level also correlated with renal interstitial inflammation score (r=0.54, P=0.0081). ROC analysis showed that serum TM level distinguished active LN from healthy subjects (sensitivity 100.00%, specificity 100.00%), from LN in remission (sensitivity 89.66%, specificity 68.97%), from active non-renal SLE (sensitivity 90.91%, specificity 100.00%), and from CKD (sensitivity 89.66%, specificity 56.52%) (P<0.001, for all).

Conclusions: Determination of serum TM level may facilitate early diagnosis of active LN, and may be useful in monitoring the response to treatment.

Enhanced Na-K-ATPase Expression Mediates B-Cell Survival in Lupus Kidneys

Irene Chernova, Joseph Craft. *Yale University School of Medicine, New Haven, CT.*

Background: Systemic lupus erythematosus (SLE, lupus) is a multi-organ autoimmune disease characterized by antibody deposition in target organs, including the kidney. Kidneys of affected patients are characterized by lymphocytic infiltrates that correlate with tissue damage and disease severity. The kidneys are also characterized by a high salt environment not found elsewhere in the body. Thus, infiltrating lymphocytes are presented with the unique challenge of surviving in a high salinity environment which may define their phenotype and function. We now describe the molecular mechanisms utilized by immune cells when faced with this hypertonic microenvironment.

Methods: We utilized lupus-prone (MRL^{lpr}) and wildtype (C57BL/6) mice and renal biopsy samples from lupus nephritis patients for this study. B cells from mice were cultured *in vitro*under standard versus high salt conditions. Kidney immune cell subsets were identified using flow cytometry and immunofluorescence techniques.

Results: B cells from lupus-prone (MRL^{lpr}) mice have enhanced survival when exposed *in vitro* to a high salt environment, compared to cells from control, non-autoimmune mice. The salt transporter Na-K-ATPase, and specifically its gamma subunit Fxyd2, is upregulated in the kidney and is necessary for kidney epithelial (tubular) cell survival under high salt conditions. We hypothesized that infiltrating lymphocytes also utilize Na-K-ATPase upregulation to survive in the hypertonic environment of the kidney. We found high expression of Na-K-ATPase alpha and gamma subunits on kidney-localized B cells of lupus-prone mice and high gamma subunit expression in B cells from human lupus kidney biopsies. Inhibition of Na-K-ATPase activity with a small molecule inhibitor ouabain led to increased cell death when lupus-prone B cells, but not control B cells, were cultured in high salt conditions, suggesting a role for Na-K-ATPase in the enhanced survival of MRL^{lpr} B cells in high salt. *In vivo* treatment of MRL^{lpr} mice with ouabain depleted renal-infiltrating B cells, but not T cells. MRL^{lpr} mice lacking the gamma subunit of Na-K-ATPase appear to phenocopy the ouabain-treated mice in preliminary analyses.

Conclusions: These studies identify a novel role for Na-K-ATPase in B cell survival in the hypertonic renal microenvironment and suggest it is a potential therapeutic target in lupus nephritis.

TNIP1/ABIN1 Mutation Contributes to Lupus Nephritis via Chemokine IP-10 Induction

David W. Powell, Makayla Brady, Michelle T. Barati, Dawn J. Caster. *University of Louisville School of Medicine, Louisville, KY.*

Background: We previously reported TNIP1 gene variants as risks for lupus nephritis (LN). TNIP1 encodes the protein ABIN1, which is a polyubiquitin binding protein that negatively regulates the prominent immune regulatory transcription factor NF-κB. We reported that transgenic mice with impaired ABIN1 ubiquitin binding function (ABIN1[D485N]) spontaneously develop SLE-associated autoimmunity and LN and that ABIN1 determines the severity of LN via activation of kidney and immune cell inflammation. Interferon gamma-inducible protein -10 (IP-10) is a pro-inflammatory chemokine and NF-κB target that has been implicated in the pathogenesis and as a diagnostic marker of LN. The current project tested a hypothesis that LN development is mediated by induction of IP-10 expression due to loss of cellular ABIN1 activity.

Methods: In order to test our hypothesis, we measured urine and serum IP10 in ABIN1[D485N] mice using ELISA and utilyzed IHC techniques to measure kidney IP10 expression. Additionally, we used ELISA to measure urinary IP10 levels in human subjects with LN (with and without TNIP variant rs4958881) and in healthy controls.

Results: We found that serum, urine, and kidney cell IP-10 expression is enhanced in ABIN1[D485N] mice. We also found that urinary IP-10 levels are higher in LN patients with TINIP1/ABIN1 variant rs4958881 when compare to LN patients without the TNIP1 variant and healthy controls. The rs4958881 variant also correlated with disease severity.

Conclusions: Our findings indicate that TNIIP/ABIN1 mutation contributes to the pathogenesis of LN via kidney and immune cell induction of IP-10 secretion and that serum and urinary IP-10 are promising diagnostic markers for LN especially in patients with TNIP1 variants. Further, successful Phase 2 clinical trials with IP-10 mAb for ulcerative colitis indicate its potential for effective LN treatment.

Comparative Cross-Tissue and Cross-Species Transcriptome Analyses Predict Lupus Nephritis in Human Systemic Lupus Erythematosus and Guide Therapy in a Tissue-Specific Manner

Eleni A. Frangou,[1,2] Panayiotis Garantziotis,[2] Maria Grigoriou,[2] Aggelos Banos,[2] George Bertsias,[4] Anastasia Filia,[2] Dimitrios Boumpas.[2,3] *[1]Geniko Nosokomeio Lemesou, Lemesos, Cyprus; [2]Idryma Iatrobiologikon Ereunon tes Akademias Athenon, Athens, Greece; [3]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [4]Panepistemio Kretes Iatrike Schole, Heraklion, Greece.*

Background: Despite advances, morbidity and mortality in systemic lupus erythematosus (SLE) and lupus nephritis (LN) remain increased. Most clinical trials on novel therapies failed to meet their primary end-points, highlighting the need for therapeutic interventions targeting pathways enriched within individual tissues.

Methods: We applied RNA-sequencing to spleen, kidneys and brain from NZB/W-F1 lupus-prone mice at three stages: the pre-puberty, pre-autoimmunity and nephritic stage. Differentially expressed genes (DEGs) were analyzed with DESeq and functionally annotated with gProfiler. ChEA and Genes2Network were used to infer transcription factors and identify proteins that physically interact with them, respectively. KEA was used to link kinases predicted to regulate DEGs. Implications for human disease were explored in our whole-blood RNA-sequencing dataset of 120 SLE patients [55 LN and 65 non-LN SLE patients and 58 healthy individuals (HI)]. The L1000CDS^2 engine was used to identify drugs/small molecules predicted to reverse DEGs. Human orthologs of DEGs were compared to human DEGs. Using machine learning, orthologs from the mouse dataset were used to predict LN in the human dataset, which was split in training and validation sets.

Results: We define lupus-susceptibility and lupus-progression signatures that reveal pathways and gene hubs, and a common cross-tissue signature that depicts transcription factors as putative upstream regulators and kinases as potential targets. Tissue-specific signatures uncovers distinct tissue response and repair mechanisms in end-organ injury and distinct targets. 7 small molecules/drugs are predicted to reverse gene signatures in both murine and human SLE.193 orthologs accurately predict LN patients from HI (accuracy=0.86, sensitivity=0.82, specificity=0.91 in the validation set) and 30 orthologs with age and gender best predict LN from non-LN SLE patients (accuracy=0.71, sensitivity=0.73, specificity=0.69 in the validation set).

Conclusions: A murine cross-tissue transcriptome analysis uncovers gene signatures, pathways and tissue-specific targets. The cross-species transcriptome analysis predicts LN in human SLE and guides therapy in a tissue-specific manner.

PO1773

An Inducible Model of Early Lupus Nephritis

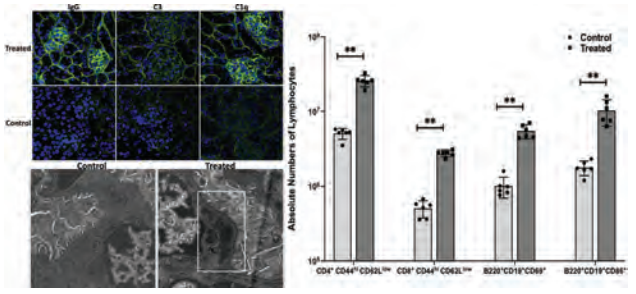
Aneesha Bhandari, Katherine R. Bull, Richard J. Cornall, Maria F. Soares, Ian Roberts. *University of Oxford, Oxford, United Kingdom.*

Background: Lupus nephritis (LN) is characterised by polyreactive antibodies targeting 'planted' glomerular autoantigens. But how these deposits recruit inflammatory mediators and the roles of resident and recruited cells is unclear. Distinguishing damaging pathways from protective tissue responses is a major challenge. With disease progression, non-specific signals of fibrosis become dominant and human tissue comparisons are confounded by genetic and environmental heterogeneity. A way to separate these early and late pathological events is to use murine models of nephritis. Topical treatment with toll like receptor-7(TLR7) agonist Imiquimod(IMQ) for 8 weeks has been shown to induce glomerulonephritis(GN), significant weight loss and mortality. Using detailed renal and immune phenotyping we explored the suitability of this model to study the very early, active stages of LN.

Methods: 6-week female BALB/c mice were treated 3 times weekly for 5 weeks with topical IMQ or Vaseline control(n=6/group). Immune profiling of spleen, bone marrow and mesenteric lymph node was by flow cytometry. Kidneys were fixed and processed for Period Acid Schiff, immunofluorescence and TEM. Serum was assayed for creatinine, urea and albumin.

Results: Treated mice had increased numbers of activated splenic CD4 and CD8 T cells($CD44^{hi}CD62L^{low}$,$P<0.001$), Tregs($CD4^+CD25^+FOXP3^+$,$P<0.01$) and activated B cells($B220^+CD19^+CD86^+CD69^+$,$P<0.001$). IMQ did not result in weight loss, mortality or significant changes in serum creatinine or urinary protein creatinine ratio but kidney histology showed mild mesangial hypercellularity with strong glomerular positivity for IgG, C1q and C3. TEM showed early basement membrane duplication, focal subendothelial and mesangial deposits and mild podocyte effacement.

Conclusions: This study characterises the IMQ model of LN revealing $CD44^{hi}$ T cell activation and TEM evidence of immune deposits reminiscent of human class II lupus. Treatment for 5 weeks is well tolerated without overt renal failure and creates a model for studying the early pathways involved in immune complex GN and associated therapeutic targets.



PO1774

Efficacy and Safety of Non-Mitogenic Anti-CD3 in the Treatment of Lupus-Prone Mice

Masashi Morita, Masayuki Mizui, Satoshi Masuyama, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Armenian hamster anti-mouse CD3ε monoclonal antibody (145-2C11) is known to suppress T cell function in vivo by reducing T-cell receptor (TCR) expression and inducing T cell depletion. However, it has also mitogenic potentials through the functional Fc portion. Although in vivo administration of Fc-deleted 145-2C11 F(ab')2 was reported to ameliorate lupus in mice, the detailed mechanisms are still unclear. Recently developed Fc-modified 145-2C11 (2C11 silent; 2C11S), which lacks the ability to bind complement or Fc receptor, is expected to be stable and safe in vivo as compared with native 145-2C11 (2C11N). Whether 2C11S has therapeutic potential in lupus remains to be elucidated.

Methods: Twenty micrograms of Armenian hamster anti-CD3ε (hamster 2C11N), mouse anti-CD3ε (mouse 2C11N), mouse anti-CD3ε Fc-silent (2C11S), or isotype control IgG1κ (IC) were injected intraperitoneally to C57BL6 mice. Lymphocyte number, TCR expression and plasma cytokines from peripheral blood were checked in time series. Next, 2C11S, 2C11N, and IC were administered (100 μg / week, 4 times, intraperitoneally) to NZB/W F1 mice at the age of 10 (early phase) and 20 (active phase) weeks, respectively. Renal histology, immune cell infiltration, and gene expression of cytokines/chemokines were evaluated.

Results: As compared with 2C11N, 2C11S reduced TCR expression on T cells in vivo for longer period (more than 96 hours) without inducing cytokine release. In early phase of lupus, the rate of change in anti-dsDNA IgG titers (day28 / day0) were significantly reduced in 2C11S group (IC; 2.9±2.0, 2C11S; 2.1±3.0, 2C11N; 2.0±1.8, IC vs 2C11S; p=0.03), which was associated with the decreased number of both follicular helper-T cells and germinal center B-cells in spleen. In active phase, glomerular hypercellularity was diminished in 2C11S group (glomerular cell number: IC; 53±18, 2C11S; 44±6.1, 2C11N; 47±6.6, IC vs 2C11S; p=0.03) and lymphocyte infiltration into kidney was significantly reduced in 2C11S group. In addition, reduction of inflammation-related genes such as IFNγ and IL-2 in kidney indicated improvement of lupus nephritis by 2C11S.

Conclusions: 2C11S, but not 2C11N, suppressed autoantibody production and ameliorated lupus nephritis, possibly through stable down-regulation of TCR. Targeting CD3 to modulate TCR expression could be a novel therapeutic approach in lupus.

PO1775

Suboptimal Serological and Clinical Remission on Supportive Therapy in Phospholipase A2 Receptor Membranous Nephropathy

Jennifer A. Pham, Juan Carlos Q. Velez. Ochsner Nephrology *Ochsner Health System, New Orleans, LA.*

Background: A traditional notion is that one third of patients with primary membranous nephropathy (MN) are expected to achieve spontaneous clinical remission without immunosuppressive therapy (IST). Thus, Kidney Disease Improving Global Outcomes (KDIGO) recommends at least 6 months of supportive therapy (SUPPT) without IST in patients with primary MN with low risk for developing end-stage renal disease. Recently, phospholipase A2 receptor (anti-PLA2R) antibody titers have been added to decision-making algorithms. Our objective was to examine and contrast the rates of serological and clinical remission in patients with PLA2R-MN managed by either SUPPT or IST.

Methods: We retrospectively reviewed records of adult patients diagnosed with PLA2R-MN in native kidneys over the last 5 years at our single medical center. Trajectories of anti-PLA2R titers were extracted. Rates of partial remission (PR) (reduction in urine protein-to-creatinine ratio (UPCR) to 0.5 to 3.0 g/g) and complete remission (CR) (UPCR < 0.5 g/g) were assessed at varying time points within a 24 month interval and compared between patients managed by either SUPPT or IST.

Results: We included 25 patients, median age 59 years, 44% women, 60% black. Positive PLA2R antigen in kidney biopsy was verified in 18/27 (72%). Eight patients were managed by SUPPT and 17 by IST. The median serum creatinine at the time of biopsy was 1.0 mg/dL for both groups (p=0.58), whereas the median UPCR were 5.6 g/g in the SUPPT arm and 10.5 g/g for IST (p=0.004). Median anti-PLA2R titer at baseline were 49 (17-76) and 258 (35 - >1500) RU/mL for the SUPPT and IST arms, respectively, p=0.0058. By the 18-month time mark, 9/17 (53%) in the IST group achieved serologic remission (negative anti-PLA2R titer) vs 0/6 (0%) in the SUPPT arm (p=0.02) (missing follow up anti-PLA2R titer in 2 SUPPT patients). At 24 months, CR and PR was achieved in 1/8 (12.5%) and 3/8 (37.5%) of patients under SUPPT and in 3/17 (17.6%) and 8/17 (47%) of those under IST (p=0.75 and p=0.66, respectively).

Conclusions: Despite baseline characteristics denoting less aggressive disease, patients with PLA2R-MN under SUPPT therapy did not achieve greater rates of clinical remission and exhibited a lower rate of serological remission. Current algorithms dictating choice of SUPPT as initial treatment in low-risk PLA2R-MN should be revisited.

PO1776

Glomerular Proteomics Reveal Shared Pathways Across Several Disease

Salem Almaani,[1] Isabelle Ayoub,[1] John P. Shapiro,[1] Sethu M. Madhavan,[1] Anjali A. Satoskar,[1] Michael Merchant,[2] Jon B. Klein,[2] Brad H. Rovin,[1] Samir V. Parikh.[1] *[1]The Ohio State University, Columbus, OH; [2]University of Louisville, Louisville, KY.*

Background: Glomerular diseases are caused by a variety of immunologic and metabolic disturbances. While there is considerable disease heterogeneity, morphologic patterns of injury are limited and clinical phenotypes are similar across diseases. This suggests that mechanisms of inflammation and the glomerular response to injury is similar across disease states. Characterizing these mechanisms may provide insights into the common pathways of glomerular injury and lead to new insights in pathogenesis and treatment. As a first step, we used an agnostic proteomics approach to identify common regulated pathways across a variety of glomerular disorders.

Methods: Kidney biopsies from 36 patients across several glomerular diseases and 21 controls (transplant donor biopsies) were used. Glomeruli were isolated using laser-capture microdissection, processed, and submitted for LC-MS/MS. Peptides were analyzed for spectral count quantitation. Spectral counts of each disease were compared to control samples that were analyzed in the same batch. Only peptides with a spectral count coefficient of variation <1 were included in expression ratio calculations. Disease-to-control expression ratios >2 or <0.5 were used for pathway analysis using Reactome. The top 10 pathways were grouped into domains and are depicted in figure 1.

Results: Pathways involved in complement regulation and activation, fibrin clot formation, and platelet aggregation were upregulated in most disease categories. On the other hand, pathways of carbohydrate, protein, amino acid metabolism, and cell cycle pathways were downregulated in most disease categories.

Conclusions: Proteomic analysis of a heterogeneous population of glomerular diseases identified several shared dysregulated pathways that may reflect common final pathways associated with glomerular injury. These pathways reflect important immunologic and metabolic changes that have the potential to be leveraged therapeutically across a variety of glomerular diseases in a manner similar to RAAS blockade.

Glucocorticoid Toxicity in the Ponticelli Regimen

Abby L. Huckle, Ajay P. Dhaygude. *Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.*

Background: Idiopathic membranous nephropathy (IMN) is a immune complex mediated renal disease and the leading cause nephrotic syndrome in non-diabetic adults. Long term relapse data for modern drugs like Calcineurin inhibitors and B-cell therapy are lacking. Modified Ponticelli regime offers 70% relapse free survival for 10 years however toxicity of cyclophosphamide and glucocorticoids(GC) remains major concern. Assessment of GC toxicity has not been assessed in this cohort. This study looked at the GC toxicity of patients in the year following treatment completion[1,2]

Methods: The glucocorticoid toxicity index (GTI)was calculated for 15 IMN patients treated with modified Ponticelli regime at time of treatment completion(0) and then 6 and 12 months post treatment completion, and compared to a pre-treatment baseline. The total dose of steroids received during treatment was also calculated.

Results: Mean cumulative prednisolone dose was 11.05g. The results at 0,6 and 12 months post completion of the Ponticelli regime for individual patients is shown on the graph. At completion 12/15 patients demonstrated GC toxicity, 7 at 6 months improving to 6/15 at 12 months. Effect on blood pressure (BP) was the most common indicator of GC toxicity at 12 months: 4/15 patients. 6 patients were in negative points at 12 months, due to improvement in weight, BP and lipid levels

Conclusions: Overall apart from BP, only 2/15 patients had evidence of damage due to GC exposure at 12 months in spite of very high cumulative GC doses. This lower level incidence of GC toxicity could be due to less impact on hypothalamo-pitutary axis due to unusual dosing regime of alternating months. Limitations: Relatively small cohort and

Experimental Membranous Nephropathy in a Novel Transgenic Rat Model of Decay-Accelerating Factor Deficiency Generated by CRISPR-Associated Protein 9 (Cas9) Genome Editing

Maria Detsika,[1,2] Harikleia Gakiopoulou,[3] Eirini Grapsa,[2] Elias Lianos.[4,5]
[1]National and Kapodistrian Univeristy of Athens, School of Medicine, 1st Department of Critical Care Medicine and Pulmonary Services, GP Livanos and M Simou Laboratories, Evangelismos Hospital, Athens, Greece; [2]National and Kapodistrian University of Athens - Nephrology Clinic, Aretaieio Hospital, Athens, Greece; [3]National and Kapodistrian University of Athens, Pathology Department, Athens, Greece; [4]Thorax Research Center of Intensive and Emergency Thoracic Medicine, Athens, Greece; [5]Salem VA Medical Center and Virginia Tech Carilion School of Medicine, Salem, VA.

Background: Decay accelerating factor (DAF), controls extent of formation of C3 and C5 convertases. Using clustered regularly-interspaced short palindromic repeats, CRISPR/ associated protein 9 (Cas9) genome editing a DAF deficient (*daf*$^{-/-}$) rat model was generated. The present study describes the renal and extrarenal phenotype of this model and responses to podocyte injury in experimental membranous nephropathy (MN).

Methods: daf+/- rats were produced by injecting multiple CRISPRs targeting Cd55 exon 2 into Sprague-Dawley rat embryos. A founder harboring a net 4-bp deletion in exon 2 was backcrossed to the parental strain and litters were genotyped. 1 ml of anti-Fx1A serum was injected in daf+/+ and daf-/- rats to induce MN. Control rats received a single dose (1ml) of normal rabbit serum. DAF protein and mRNA levels were determined by western blotting and Real time PCR Renal function assessment involved measurement of serum urea and creatinine levels and urine albumin/creatinine ratio. C3 deposition was confirmed by immunofluorescence (IF) and western blot (WB) analysis.

Results: daf-/- rats were healthy, viable and able to reproduce normally. DAF was completely absent in renal and extrarenal tissues (lung, heart) at protein and mRNA level. There was no effect on glomerular Crry and CD59 protein expression. There were no glomerular or tubulointerstitial lesions in daf-/- rats compared to daf+/+ and no change in serum urea and creatinine or in urine protein excretion. There was a significant increase in proteinuria 14 days following anti-Fx1A injection in daf-/- rats accompanied by increased glomerular C3 deposition.

Conclusions: In experimental MN, DAF attenuates proteinuria. The daf-/- rat model provides a valuable tool to assess role of DAF in regulating complement activation in glomerular diseases, such as MN, which is best characterized in this species.

PO1779

T-Cell Epitopes of M-Type Transmembrane Phospholipase A2 Receptor in Primary Membranous Nephropathy

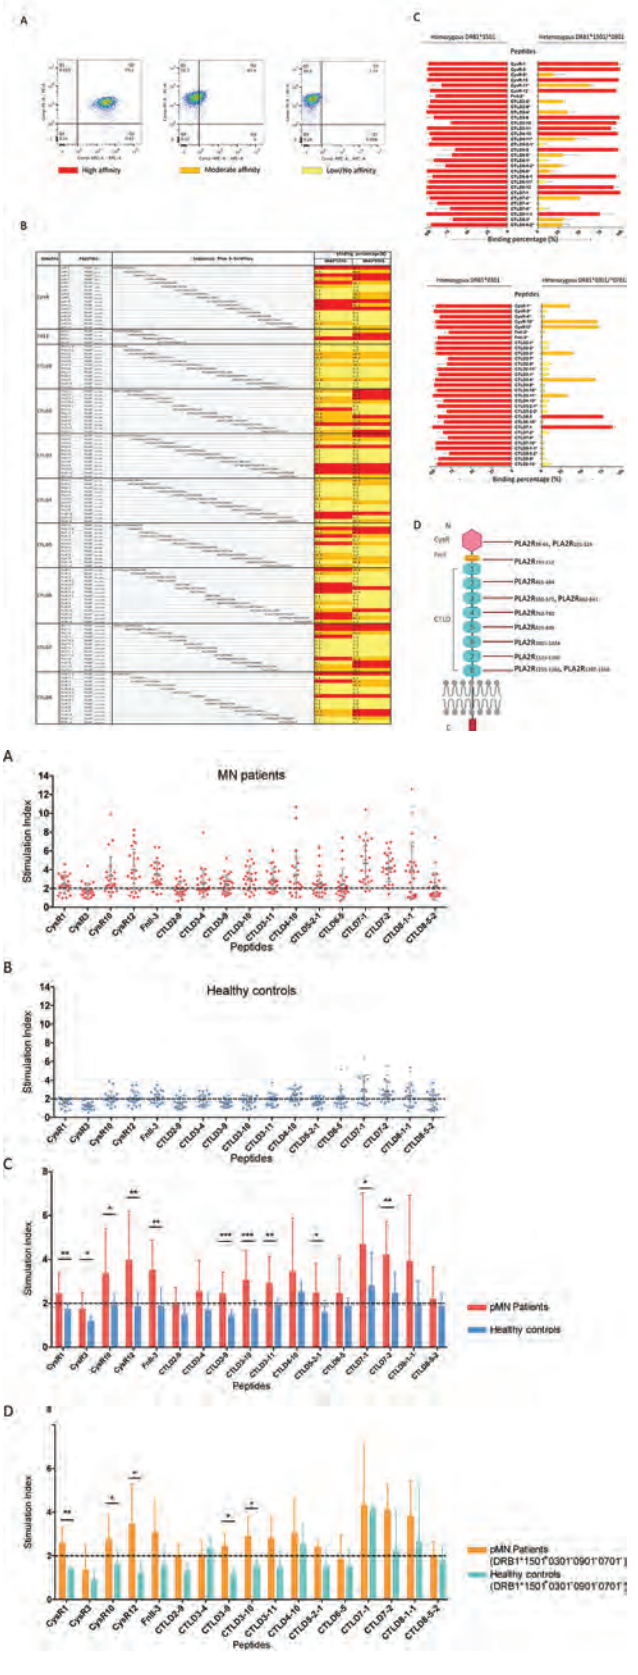
Xiao-dan Zhang, Cui Zhao. *Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: PLA2R is the major autoantigen of pMN. There is no information on T cell epitopes. We previously identified the risk HLA molecules DRB1*1501 and DRB1*0301.

Methods: 123 linear peptides, each consisting of 15-22 amino acids and overlapping by 8-12 amino acids, were synthesized across PLA2R. Their binding capacity to DRB1*1501 and DRB1*0301 were assessed by flow cytometry. Proliferation of CD4$^+$ T cells from patients with anti-PLA2R positive pMN was analyzed after peptide stimulation using CFSE dilution assay. Cytokines produced by activated PBMC were measured by cytometric beads array.

Results: We found 17 peptides that bound to both DRB1*1501 and DRB1*0301 molecules with high capacity. Among them, 11 peptides induced significant proliferations of CD4$^+$ T cells from patients with anti-PLA2R positive pMN: $PLA2R_{38-52}$(CysR1), $PLA2R_{52-66}$(CysR3), $PLA2R_{101-120}$(CysR10), $PLA2R_{113-129}$(CysR12), $PLA2R_{193-212}$(FnII-3), $PLA2R_{602-621}$(CTLD3-9), $PLA2R_{612-631}$(CTLD3-10), $PLA2R_{622-641}$(CTLD3-11), $PLA2R_{829-838}$(CTLD5-2-1), $PLA2R_{1121-1140}$(CTLD7-1) and $PLA2R_{1129-1150}$(CTLD7-2). Upon activation, PBMCs had similar pro-inflammatory cytokine profiles, predominantly IL-6, TNF-α and IL-10, and to a lesser extent IL-4/5/13 and IL-17.

Conclusions: Thus, we identified 11 potential T-cell epitopes on PLA2R.



PO1780

Investigating the Role of Complement in Membranous Nephropathy Using a Novel Ex Vivo Podocyte Model

Sarah M. Moran,[4] Carolina Ortiz,[1] Moin Saleem,[3] Daniel C. Cattran,[2] Christoph Licht.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Bristol Royal Hospital for Children, Bristol, United Kingdom; [4]Queen's University Faculty of Health Sciences, Kingston, ON, Canada.*

Background: Membranous nephropathy (MN) is an immune-mediated glomerular disease and is the commonest cause of nephrotic syndrome in adults. Progressive loss of kidney function leading to end-stage kidney disease occurs in up to one third of patients. We aimed to explore the potential functional link between antibody positive primary MN and the innate immune complement system using an ex vivo model of human podocytes.

Methods: Using a human podocyte ex vivo model, we evaluated complement activation via immunofluorescence staining for deposition of C3b and C5b-9, and functional alterations (demonstrated by cytoskeletal rearrangement) via IF staining for ActinGreen. Activation of complement via the classical pathway was used as positive control (incubation of podocytes with anti-CD59 and 50% NHS for 30 min), whereas NHS-only treated cells were used as negative control. Four patients with biopsy proven primary membranous nephropathy and detailed clinical phenotype were recruited from the Toronto GN Registry. To determine the role of complement in MN pathogenesis, podocytes were incubated with patient serum for 30 min.

Results: 2/4 patients who were nephrotic, antibody (aPLA2R or THSD7A) positive with no current immunosuppression demonstrated (1) positive C3b and C5b-9 staining confirming complement activation (Fig. 1A), and (2) reduced actin staining confirming impaired cytoskeletal organization (Fig. 1B). The remaining 2 patients with negative findings were Ab positive and treated with rituximab at the time of sample collection.

Conclusions: We successfully applied a new ex vivo model using podocytes to demonstrate complement activation in non-immunosuppressed MN patients. Further studies are needed to elucidate the detailed structural and functional consequences of complement activation in MN.

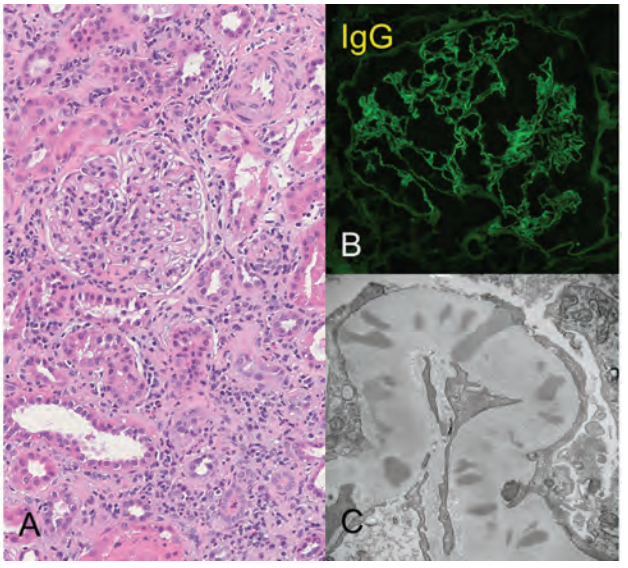
Red Herrings: Delayed Immune Checkpoint Inhibitor-Associated Interstitial Nephritis with Membranous Glomerulonephritis and Myeloperoxidase-ANCA Antibodies

Orhan Efe,[1,2] Ivy Rosales,[1] Veronica E. Klepeis,[1] Robert B. Colvin,[1] Andrew S. Allegretti.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Immune checkpoint inhibitor (ICI) indications are expanding. The most common renal pathology is interstitial nephritis. Here, we report a late presentation of ICI-induced interstitial nephritis with concurrent membranous glomerulonephritis (MGN) and MPO-ANCA antibodies.

Case Description: A 52-year-old woman with stage IV small cell lung cancer and prior gastric sleeve surgery on PPI therapy presented with diarrhea and AKI 5 months after discontinuing nivolumab. Her serum creatinine (SCr) was 5.5 mg/dL on presentation, from a baseline of 0.8 mg/dL, along with 0.69 g/g proteinuria and an MPO-ANCA titer of 19 units. Her PPI was discontinued and her AKI rapidly improved with hydration to a SCr of 1.5 mg/dL. Three weeks later, and four days after resuming her PPI, her SCr increased to 7.6 mg/dL. Repeat MPO-ANCA titer was 7 units. Renal biopsy showed diffuse interstitial nephritis and glomerular capillary wall thickening **(Figure 1A)**. Immunofluorescence showed capillary wall and mesangial IgG4-dominant depositions which did not colocalize with PLA2R **(Figure 1B)**. Penetrating subepithelial and intramembranous deposits along with thickened membrane were suggesting a late stage MGN **(Figure 1C)**. The patient was diagnosed with ICI-associated interstitial nephritis, likely provoked by PPI. Following a steroid taper, her SCr improved to 1.2 mg/dL.

Discussion: We reported a late-manifestation of ICI-associated interstitial nephritis (6 months after last exposure) in the setting of PPI use. This case is unique because of its late presentation (>90% of cases present within 3 months from the last dose), and findings of MPO-ANCA antibodies and MGN. Given her mild proteinuria and downtrending ANCA titer, we hypothesized that these were not the cause of AKI, but both were likely ICI-associated nonetheless. Nephrologists should be aware of these rare ICI-associated autoimmune conditions.



PO1782

A Case of Membranous Nephropathy After Nivolumab Administration

Maki Okamoto, Yuta Kogure, Momoko Sekiguchi, Takayuki Hamada, Mariko Sato, Yumiko Nakamura, Takatsugu Iwashita, Hajime Hasegawa. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Introduction: Nivolumab is one of the molecularly targeted drugs and is an anti-human PD-1 monoclonal antibody. We report a case of nephrotic syndrome caused by Nivolumab for treatment-resistant gastric cancer.

Case Description: The patient is a 61-year-old man. In June of -4 years before admission, total gastrectomy was performed for gastric cancer, and postoperative chemotherapy was administered as a second-line treatment, but peritoneal dissemination occurred. Nivolumab therapy was started in June of -2 years as a third-line treatment. She developed secondary adrenal insufficiency, which was considered an immune-related adverse event (irAE) with Nivolumab after the first dose, and oral hydrocortisone was initiated. In March of -1 year, mediastinal and hilar lymphadenopathy and skin pruritus, which were considered to be immune-related adverse events, were observed again, so Nivolumab was once discontinued, but it was resumed in April after improvement of the skin symptoms. However, proteinuria with hypoalbuminemia was appeared in June, Nivolumab was stopped again and the patient was finally consulted to our department in July. His serum albumin was 2.8 g/dL and urine protein was 5.9 g/gCr. Since the right kidney was atrophic, the open kidney biopsy was carried out in September. Light microscopy did not reveal thickening of the basement membrane, spike formation or bubbling appearance, however, immunofluorescence staining showed granular staining of IgG, C3, C1q and all of IgG subclasses although PLA2R staining was negative. Electron microscopy revealed electron-dense deposits under the epithelium, suggesting secondary membranous nephropathy. Though the urine protein tended to decrease after the discontinuation of Nivolumab, Prednisolone 40 mg/day was started and resulted in the complete remission in the 19th hospital day.

Discussion: There are several reports of interstitial nephritis by Nivolumab, however, the report of nephrotic syndrome is rare. Particularly, no case of membranous nephropathy by Nivolumab has ever been reported and this case is considered to be valuable.

PO1783

Evolution of Resolving Clinical and Histological Changes in Kidney Grafts from a Donor with Primary Membranous Nephropathy

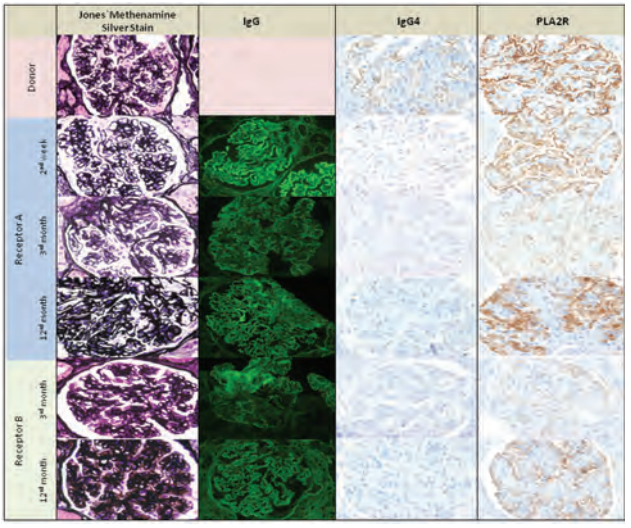
Evelyn Hermida Lama, Adriana Garcia, Diana Rodriguez-Espinosa, Enrique Montagud-Marrahi, Luis F. Quintana, Alicia M. Andújar. *Hospital Clinic de Barcelona, Barcelona, Spain.*

Introduction: Primary membranous nephropathy (PMN) is an autoimmune disease limited to the kidney that is characterized by the presence of circulating PLAR2 antibodies in 70% of the cases and usually positivity for PLA2R and IgG4 by immunohistochemistry (IHC) staining. We report the clinical and histopathological evolution of two recipients from a donor after circulatory death (DCD) with PMN.

Case Description: DCD Maastricht III was a 63-year-old male, died from respiratory failure. His serum creatinine was 0.9 mg/dL, no urinalysis was performed. The Remuzzi-score preimplant-biopsy was 1 point for the right kidney (recipient A) and 2 points for the left kidney (recipient B). Thymoglobulin as induction therapy, with tacrolimus,

mycophenolate mofetil, and prednisone as a maintenance immunosuppressive regimen for both recipients. A kidney biopsy was performed two weeks after in recipient A due to delayed graft function. It was compatible with MN with both PLA2R and IgG4 subepithelial deposits. The donor's kidneys biopsies were reexamined, revealing MN, with high intensity for PLA2R and IgG4 in IHC. Recipient B 3rd-month protocol allograft biopsy revealed histology compatible with MN, without the presence of PLA2R and IgG4 in IHC. At one year follow-up, both recipients maintain graft function and the protocol biopsies showed a negativization of IgG4 but the persistence of PLA2R in IHC, this positivity was attributed to the variability inherent to the technique.

Discussion: Given the reversal of PMN changes in the grafts, it is probably safe to transplant a patient from an asymptomatic donor with PMN as long as he maintains unaltered renal function. Observation of IgG4 immune complexes is more accurate to assess histological remission.



PO1784

Coexistence of Bullous Pemphigoid and Membranous Nephropathy

Brigette Thomas, Dhishna Chaudhary, Anika Bethel, Enoemem M. Okpokpo. *Florida Atlantic University Charles E Schmidt College of Medicine, Boca Raton, FL.*

Introduction: Bullous pemphigoid (BP) is an autoimmune disease with linear deposition of IgG and C3 in the skin basement membrane. BP is rarely associated with renal abnormalities like membranous glomerulonephropathy (MN). We describe a rare case of MN in a patient with BP.

Case Description: 75-year-old male, intermittently treated with prednisone for upper extremity (UE) skin lesions, presents with bilateral UE pruritic bullae, bilateral lower extremity (LE) and scrotal edema. He was previously treated for LE edema. Renal indices confirmed nephrotic range proteinuria. Kidney biopsy showed subepithelial immune deposits consistent with primary MN (immunostain negative for PLA2R). He was treated with furosemide and lisinopril. Skin biopsies of his bullae were inconclusive. His LE edema and UE bullae progressed due to lack of follow up, leading to this hospitalization. Labs revealed eosinophilia, hypoalbuminemia and nephrotic range proteinuria. HIV, hepatitis panel, ANA, SPEP and UPEP were negative. Malignancy was ruled out. Diagnosis of BP was finally confirmed via positive indirect immunofluorescence and ELISA testing. Treatment was limited to ethacrynic acid since ACEi/ARBs and furosemide are known to induce BP. Initiation of prednisone and rituximab resulted in cessation of new bullae and decrease in proteinuria.

Discussion: Both BP and MN are immune complex diseases involving two different basement membranes, so their occurrence together is not coincidence. Although our patient's kidney biopsy had negative immunostaining, the electron microscopy identified only subepithelial deposits, characteristic of primary, not secondary MN. This coincides with few cases in literature identifying BP occurring exclusively with primary MN. Our patient developed BP manifestations prior to MN and received intermittent prednisone without formal diagnosis of BP. Perhaps corticosteroids suppressed his MN symptoms leading to delay in diagnosis. Improper treatment of MN with known BP inducing medications led to persistent bullae formation. As the severity of skin lesions decreased, so did the proteinuria, suggesting that progression of bullae may be a sign of worsening MN. This case highlights the importance of thorough history taking, detail review of medications and appropriate outpatient follow up.

PO1785

Phospholipase A2 Receptor (PLA2R) Positive Membranous Nephropathy (MN) in Celiac Disease

Luba Muaddi. AGH Nephrology Fellowship *Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.*

Introduction: In a 2011 study, PLA2R antibody (Ab) was detected in lupus MN, HBV MN, and solid tumor associated MN, with IgG4 stained glomeruli. PLA2R+ patients did not achieve remission with HBV treatment and tumor resection, suggesting a coincidental occurrence of primary membranous nephropathy (PMN). PLA2R Ab levels in cases of PMN were higher (87.5%) than non-membrane nephropathy (0%) in a 2018 study. PLA2R was positive in 40 cases of secondary membranous nephropathy SMN (25%), including lupus MN, HBV MN, and atypical MN. In 2014, a case of celiac disease (CD) and H. Pylori infection with PLA2R+ MN was reported. Remission was achieved by H Pylori eradication without immunosuppression. In 2002, 2007 and 2009, three cases of renal failure due to MN in CD patients were reported raising the possibility of a link between the two conditions. We report the fourth case on the association of CD and MN to date.

Case Description: 40-year-old male with iron deficiency anemia and small bowel biopsy proven CD presented with pleural effusions, hypoxia, and generalized anasarca. Infectious and rheumatologic work up was negative. Lung biopsy showed hemosiderosis reaching diagnosis of Lane-Hamilton Syndrome (LHS) (idiopathic pulmonary hemosiderosis (IPH), CD, chronic anemia). Three years prior, he was diagnosed with PMN by PLA2R+ renal biopsy and had nephrotic range proteinuria >9g. He was treated with losartan and diuretics with improvement in his symptoms and decrease in proteinuria to 6g. Serum creatinine rose from baseline of 1 to 1.9 mg/dL. He was then started on high dose prednisone for IPH and cyclosporine for MN with further improvement in proteinuria to 2.6g and creatinine to 1.3 mg/dL. Anti-thrombospondin type I domain-containing 7A Ab was negative arguing against PMN. He had been trying to adhere to gluten free diet but was not consistent.

Discussion: CD is known to cause IPH and chronic anemia. It was hypothesized that chronic gastrointestinal inflammation triggers auto antibody formation against PLA2R1, which is present in duodenal and gastric cells in addition to glomerular cells. This would favor a causal relationship rather than coincidence of two idiopathic processes. Gluten free diet and steroids are the mainstay of therapy for LHS. We hope to prove that adherence to strict gluten free diet in our patient in addition to sustained low dose prednisone would lead to remission of MN without need for cyclosporine.

PO1786

Hydralazine-Induced Membranous Nephropathy

Tudor Gradinariu, Bruce A. Jones, Sandeep S. Soman. *Henry Ford Hospital, Detroit, MI.*

Introduction: Hydralazine is associated with a variety of rare renal diseases including drug-induced lupus, ANCA vasculitis and membranous nephropathy (MN) with associated crescentic GN. We present a case of a patient with features of hydralazine-induced MN with some FSGS but no features of vasculitis. This would be the first such reported case to the best of our knowledge.

Case Description: This 67-year-old female with a medical history of HTN, DMT2, and CKD stage 3 initially presented to our clinic for evaluation of her renal function. Patient had increasing Cr up to 1.9 mg/dL over the course of 2 years. Her work up demonstrated modest albuminuria with several UACR results between 37.9 and 196.7 mg/g. UA demonstrated unremarkable chemistry and only 2 RBC and 1 WBC /plf. Serology showed positive ANCA 1:640 homogenous; dsDNA resulted negative; anti-histone Ab returned positive at 3.2 units (normal <1) as did her anti-MPO of 85 units (normal is <20). Of note, C3 and C4 returned normal. Patient remained asymptomatic but had rapidly worsening Cr rising from 1.9 to 2.69 mg/dL over 1 month, prompting a renal biopsy and stopping hydralazine therapy. The biopsy showed areas of scarring and FSGS on light microscopy and membranous nephropathy on EM but demonstrated none of the classic necrotizing or crescentic lesions associated with drug-induced vasculitis or any of the typical findings of lupus nephritis. Follow-up PLA2R, thrombospondin, and Hep returned negative. Age appropriate cancer screening was negative. Repeat blood work showed Cr returning to prior baseline after 1 month off hydralazine. We decided together with the patient to continue to monitor and forgo more aggressive therapy. Renal function remained baseline for the next 6 months.

Discussion: This case represents an up-to-now unreported case of hydralazine-induced MN without associated vasculitic lesions. Patient fit the classic serological findings for a drug-induced vasculitis and her renal function stabilized upon cessation of exposure to hydralazine, giving us a high suspicion for causality. Given renal decline during workup, re-exposure was not attempted. This patient never demonstrated any clinical or lab findings of MN disease: no severe proteinuria, no sequalae of nephrotic syndrome, and no associated diseases. Additionally, no lupus-like findings were appreciated on biopsy. We believe we have identified a novel association of hydralazine-induced MN.

PO1787

An Atypical Presentation of Lupus Nephritis

Gaurav Kiri,[1] Jaideep U. Hingorani.[2] *[1]USF Health Morsani College of Medicine, Tampa, FL; [2]Charlotte Nephrology Associates, P.A., Port Charlotte, FL.*

Introduction: Lupus nephritis in the absence of ANA and dsDNA, and normal C4 levels is a rare, atypical presentation. To arrive at the diagnosis requires EM examination of renal biopsies and is responsive to immunosuppressive therapy. We present a report of such a case.

Case Description: A 49-year-old female was referred for asymptomatic hematuria and nephrotic-range proteinuria (4.9 g/g) in March 2014. Her creatinine (0.77 mg/dL), C4, ANA, dsDNA, and Rheumatoid factor were normal with low C3. Labs were normal for Hepatitis B, C, HIV, ANCA, RNP, and Sm antibodies. She was started on lisinopril, and initially the proteinuria improved (2.3 g/g) and renal functions were stable. Hematuria was initially suspected to be secondary to MPGN. Renal biopsy immunofluorescence showed IgG, C3, IgM, kappa/lamda, and C1q (in lesser quantitiy). EM showed deposits in subendothelial, subepithelial and mesangium. She was diagnosed with immune complex glomerulonephritis without evidence of systemic lupus. Over the next 2 years, proteinuria worsened from 1.9 to 5.7 g/g despite increasing lisinopril to maximum dosage (40 mg/day). Hematuria and low C3 levels persisted. In February 2017, creatinine worsened (1.33 mg/dL). Cellcept (1000 mg/day) was started in March; by June, there was no response. Lisinopril was stopped in May due to low BP. A second renal biopsy (November 2017) showed a lupus picture with a full house pattern (3+ IgG, 1+ IgM, 2+ C3, 3+ C1q, 2+ kappa/lambda, IgA+ tubular casts). EM showed subendothelial and scattered subepithelial deposits, and GBM duplication. She was diagnosed with Class IV Lupus Nephritis. She was started on Cytoxan (500 mg q 2 weeks x6 weeks) and prednisone (60 mg/day). She showed improvement and was started on Imuran in May 2018 for maintenance. Her proteinuria (400mg/g) and creatinine (0.93mg/dL) improved, C3 normalized, and hematuria resolved.

Discussion: Diagnosis of lupus nephritis can be missed on the basis of atypical labs and requires a high degree of suspicion and a biopsy. This case represents such an atypical presentation without systemic lupus. Initially, thought to have C3 nephritis; but later, the diagnosis was confirmed by renal biopsy and electron microscopy. The Full House immunofluorescence pattern seen in this patient is characteristically indicative of lupus nephritis, and she was responsive to immunosuppressive therapy.

PO1788

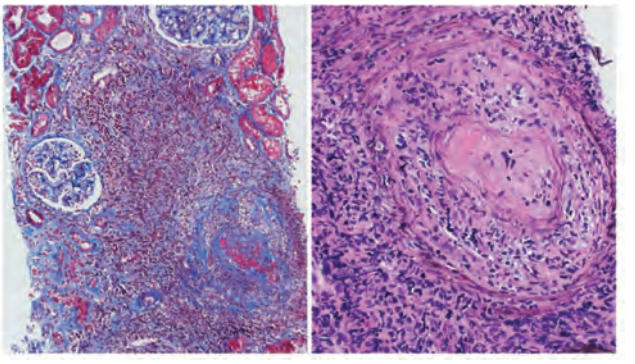
Lupus Nephritis Classification Should Consider Lupus Arteritis in the Activity Score

Nora M. Alzahrani,[1] Ismail K. Almokyad,[1] Scott D. Cohen,[1] Renu Regunathan-Shenk,[1] Sanjeev Sethi.[2] *[1]The George Washington University School of Medicine and Health Sciences, Washington, DC; [2]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN.*

Introduction: Lupus nephritis (LN) complicates 20-49% of systemic lupus erythematosus (SLE) patients. Vascular lesions are not considered in the activity index of LN pathology classification. We report a case of LN with severe necrotizing arteritis without proliferative glomerular lesions, prompting a more aggressive intervention.

Case Description: A 36-year-old woman with known SLE with Class II LN, as well as vasculitis, resulting in multiple digital amputations presented with eight days of abdominal pain, vomiting, fever, and tea-colored urine. Labs showed creatinine of 1.4 mg/dL, microscopic hematuria, urine protein/creatinine of 5 g/g, low complements, positive anti-double-stranded DNA of 14, an elevated antinuclear antibody of 1:320, elevated Myeloperoxidase (MPO)–Antineutrophil Cytoplasmic Antibody (ANCA) of 59. She received induction therapy with intravenous (IV) methylprednisolone 1g daily x3, followed by prednisone 60 mg daily and mycophenolate mofetil (MMF) 500 mg twice daily. A repeat kidney biopsy was performed, and 12 glomeruli showed only mesangial proliferation. She was classified as International Society of Nephrology and the Renal Pathology Society (ISN/RPS) class IIIA LN based on two arteries revealing severe arteritis with transmural necrosis causing occlusion, inflammation, and rupture of the vessel walls. Consequently, we switched MMF to IV cyclophosphamide 1g/m2 monthly. Creatinine improved to 1 mg/dl on discharge and 0.9 mg/dl two months later.

Discussion: There is limited attention to non-glomerular vascular lesions among patients with LN. Prior case reports show that LN patients with vascular involvement have worse outcomes and may require more aggressive treatment. The vasculitis in this case was attributed to the MPO Antibody. Given the potential prognostic and therapeutic implications of vascular involvement in LN patients, we suggest that lupus arteritis be considered in the LN pathology classification.



PO1789

Hepatitis B-Associated Lupus-Like Nephritis

Anita Vincent-Johnson, Mohammed Y. Al Mulhim, Helen P. Cathro, Tushar Chopra, Negiin Pourafshar. *University of Virginia, Charlottesville, VA.*

Introduction: The spectrum of renal disease with hepatitis B virus (HBV) is broad including different glomerular lesions related to the presence of viral antigens. HBV-associated lupus-like nephritis (HBLN) is characterized by immune deposits of polyclonal immunoglobulins linked to polytypic complements in glomeruli, structures reminiscent of lupus nephritis (LN). There is a dearth of literature regarding differentiation of HBLN and LN along with differing management and outcomes.

Case Description: We report a 46-year-old male with known HBV infection with 3 weeks of progressive dyspnea and edema. The serum creatinine (SCr) rose from a baseline of 0.8 mg/dl to 5.2 mg/dl with proteinuria of 1.7 g/g and microscopic hematuria. Serology showed transiently positive ANA, negative anti ds-DNA, and low levels of C3. Hepatitis B e Ag and hepatitis B surface Ag were positive, and the viral load was 2483 IU/mL with normal liver enzymes. A renal biopsy revealed severe diffuse endocapillary hypercellularity, a "full house" immunofluorescent pattern, and numerous subendothelial and mesangial immune deposits ultrastrurally, findings consistent with a diagnosis of HBLN. The patient was started on Entecavir for treatment of hepatitis B. After 2 months of treatment, the Scr improved to 1.97 mg/dL with improvement in initial symptoms.

Discussion: Our case highlights the inherent difficulty in recognition of renal failure secondary to HBLN with associated pathology findings consistent with LN in the presence of hepatitis B infection. Although the full-house immunofluorescent pattern generally implies a diagnosis of LN, renal biopsy findings have to be interpreted in the clinical context. All the findings in renal biopsies of LN can also be seen in HBLN. Renal manifestations in both groups, including proteinuria and Scr, can be similar. Although considerably lower C3 levels in patients with lupus may suggest more widespread extrarenal disease, low C3 levels have also been reported in HBLN. The distinguishing feature between HBLN and LN is the presence of HBeAg and hepatitis B DNA. Our case is an unusual presentation of hepatitis B with renal involvement with effective diagnosis and management. While there is limited data for the treatment of HBLN with most studies excluding patients with an elevated SCr, small studies suggest first-line treatment with antiviral agents to achieve viral clearance.

PO1790

A Unique Case of Autoimmune-Mediated Cryoglobulinemic Glomerulonephritis

Monika Sadlak, Sumayya Muneer, Amit K. Rajput. *TriHealth, Cincinnati, OH.*

Introduction: Cryoglobulinemic syndrome is a disease in which immunoglobulin components are deposited within tissues, resulting in various end-organ damage. Subtypes Type II and III contain mixed monoclonal and polyclonal immunoglobulins, thereby referred to as Mixed Cryoglobulin Syndrome (MC). MC is often associated with infections such as Hepatitis C; however, it can also be secondary to autoimmune diseases. While the most common associations are with Systemic Lupus Erythematosus and Sjogren's disease, occasionally, MC can be seen with other rheumatologic conditions. We examine a rare case of Overlap Syndrome (OS) induced cryoglobulinemic glomerulonephritis (CG).

Case Description: A 44-year-old woman with a history of OS, presented with symptoms of fatigue, generalized edema, weight gain of 20lbs, and found to have an acute kidney injury (AKI). She was admitted to the hospital with a diagnosis of decompensated heart failure. The diagnosis of OS was confirmed with elevated ANA, SSA, RNP antibodies, as well as negative dsDNA and anti-smith antibodies. Previously, she was unsuccessfully treated with methotrexate and hydroxychloroquine. She was on hydroxychloroquine monotherapy at the time of admission. During the investigation for her AKI, she was found to have hematuria and non-nephrotic range proteinuria (UPCR 2.65g/dL), raising concerns for glomerulonephritis. Subsequent renal biopsy showed autoimmune-mediated cryoglobulinemic glomerulonephritis. She was treated with a combination of methylprednisolone/prednisone and rituximab, which resulted in normalization of renal function.

Discussion: This case illustrates a patient with a history of OS with biopsy proven autoimmune mediated CG. The patient's underlying diagnosis of OS is likely the leading risk factor for renal impairment secondary to immunoglobulin deposits. Treatment

is focused on immunosuppression, including steroids, rituximab, or mycophenolate mofetil. Combination therapy with a non-steroid immunosuppressant is preferred over monotherapy with steroids. The patient was treated with steroids and rituximab, with recovery of renal function. Given the varying presentation of CG, physicians should be mindful of keeping a broad differential, particularly in patients with rheumatological history presenting with proteinuria, hematuria, and signs of renal dysfunction.

PO1791

Bartonella Buried in the Aortic Valve

Niraj K. Yadav, Janame J. Kottey, Josephine Abraham, Laith Al-Rabadi. *University of Utah Health, Salt Lake City, UT.*

Introduction: Bartonella species are the most common cause of culture negative endocarditis in the United States. We report a case with culture negative Bartonella endocarditis masquerading as Antineutrophil cytoplasmic antibody (ANCA) associated vasculitis.

Case Description: A 46 year old male presented with leg rash and swelling. Physical exam was notable for diastolic murmur in aortic area and a systolic murmur in the mitral area and non blanching purpura on the lower extremities. Labs showed BUN 18mg/dL, creatinine 1.54 mg/dL. Urinalysis showed non nephrotic range proteinuria and urine microscopy showed dysmorphic hematuria. ANA was 1:160, RF was 541 IU/mL, complement C3 and C4 levels were low and serum cryoglobulin was positive. ANCA titer was elevated with myeloperoxidase ANCA of 38 AU/mL and serine proteinase 3 ANCA of 580 AU/ml. Anti-Smith antibodies were 68AU/ml. Echocardiography showed severe mitral and aortic regurgitation with mitral and aortic vegetations. Ceftriaxone and vancomycin were started after blood cultures were obtained which remained negative. The aortic valve was replaced with mitral and tricuspid valve repair. Bartonella Quintana IgG titer was positive at 1:1024. Valve tissue cultures were negative and tissue PCR was positive for B. Quintana. He was eventually started on gentamycin and oral doxycycline. Creatinine 1 month later was 1.2 mg/dl.

Discussion: *Bartonella* is the most common cause of culture-negative endocarditis in the United States with a reported association with pauci- immune glomerulonephritis. In our case serological testing and valve PCR were helpful in establishing the diagnosis. In conclusion, SBE induced glomerulonephritis with false positive serology for ANCA can mimic the clinical features of ANCA associated glomerulonephritis. Intense immunosuppressive therapy can have catastrophic consequences. We recommend considering the possibility of SBE in all patient with dual positive ANCA with hypocomplementemia, positive ANA and a positive RF.

Purpuric rash present on admission.

PO1792

Clinicopathological Analysis of Renal Dysfunction due to Idiopathic Multicentric Castleman Disease in Japan

Hiroki Mizuno, Junichi Hoshino, Yoshifumi Ubara. *Toranomon Hospital, Minato Ward, Japan.*

Background: Renal dysfunction is a fatal complication of idiopathic multicentric Castleman disease. Although AA amyloidosis and glomerular endotheliopathy with severe proteinuria were reported due to this disease, human immunodeficiency virus (HIV) were positive in these previously reported cases. On the other hand, HIV-negative cases are common in Japan, and the precise renal involvement of Japanese cases has not been studied yet.

Methods: Case-series was designed for analyzing the clinicopathological features of renal dysfunction accompanied with Castleman disease. Inclusion criteria of the object is renal biopsy performed between 1990 and 2019 and the patients who were diagnosed as Castleman disease. Clinical and pathological data was collected from the electrical medical record.

Results: Eight patients were eligible to the study. Seven out of eight cases were plasma cell type, while anti-HIV antigen/antibody was negative in all cases. Laboratory data at the time of renal biopsy showed; median serum creatinine was 0.75(0.6-5.0) mg/dL, urine protein was 1.28(0.04-8.9) mg/dL. In glomerular lesion, following involvement were found: two cases of AA amyloidosis and membranous nephropathy respectively, while IgA deposition and nephrosclerosis in one case each. Nephrotic range proteinuria was found in two cases of AA amyloidosis as well as one case of membranous nephropathy. Among two cases diagnosed as membranous nephropathy, immunofluorescent analysis about IgG subclass showed that IgG1 was dominant in one case and IgG2 was in the other. IgG4 was negative in both cases. In interstitial lesion, chronic tubulointerstitial nephritis was diagnosed in one case.

Conclusions: Heterogenous glomerular lesions were found in our cohort. Previous cohort study showed that membranous nephropathy was rare, but in this study, two out of eight cases turned out to be membranous nephropathy. In addition, analysis of IgG subclass suggests that either IgG1 or IgG2 was dominant in secondary membranous nephropathy due to Castleman disease and that deposition of immunoglobulin complex could be associated to the onset of proteinuria of Castleman disease.

PO1793

Is It Systemic Lupus Erythematosus Nephritis or Not?

Alexander Pennekamp,[1] Karl B. Pembaur.[2] *[1]The Christ Hospital, Cincinnati, OH; [2]The Kidney and Hypertension Center, Cincinnati, OH.*

Introduction: IC-MPGN (immune complex-mediated glomerulonephritis) is a histopathological finding that is associated with infection, immune-complex deposition, monoclonal gammopathies as well as autoimmune disorders such as lupus, Sjögren's, and rheumatoid arthritis. MPGN traditionally has been classified as I-III depending on the pathology findings. More recently, an alternative classification system based on the pathological process has been developed (immune complex-mediated vs complement-mediated). In cases of IF showing IgG +/- C3, a tentative diagnosis of immune-complex mediated MPGN can be made. MPGN treatment is aimed first at treating the underlying cause. In the case where a cause cannot be found, as in our case of biopsy-proven IC-MPGN with negative serologies, the underlying mechanism is not clear.

Case Description: 71-year-old female with PMHx aortic valve replacement, HTN, CKD-I presented with constitutional symptoms, and AKI on CKD with proteinuria. She was found to have biopsy-proven immune complex mediated MPGN, but the etiology was unclear due to negative: ANA, anti-Smith, anti-Ro/SS, anti-La/SSB, Hep B/C, cryoglobulins, CCP, CRP, ESR, K/L. The biopsy pattern was consistent with Lupus Type IV/V, with EM findings showing scattered sub endothelial dense deposits and full house IF staining pattern. CT abdomen/pelvis was negative. Further testing and workup for malignancy were negative. She was started on high-dose steroids for initial treatment of presumptive seronegative lupus nephritis. Serologies were repeated and all were negative. Patient showed improvement with initiation of mycophenolate + steroids; proteinuria and creatinine improved on follow-up.

Discussion: The optimal initial treatment of idiopathic/seronegative immune complex-mediated MPGN has not been established. In this case, the patient improved with aggressive steroid treatment with a tapering dose after starting mycophenolate. Proteinuria which was initially nephrotic at 14 g/g is now near 0.2 g/g.

PO1794

Role of the IgA Immune Complexes Bound to FcαRI/CD89 in IgA Nephropathy

Xue Zhang,[1] Jing Jin,[2] Jicheng Lv,[1] Manliu Wang,[1] Hong Zhang.[1] *[1]Peking University First Hospital, Beijing, China; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Studies have demonstrated the pathogenic role of circulating polymers IgA immune complexes (poly-IgA ICs) in IgA nephropathy (IgAN). In this study we aim to evaluate the role of poly-IgA ICs specifically bound to FcαRI/CD89 in the kidney development of IgAN.

Methods: rCD89 protein was produced from a HEK293 cell expression system. A novel ELISA method that using rCD89 as the 'capturing' probe was established for detecting poly-IgA ICs. The plasma levels of poly-IgA ICs were measured in 181 IgAN patients and 35 patients with glomerular diseases of unrelated etiologies. Another 85 age-, gender-, and geographically-matched healthy individuals were enrolled as controls. rCD89-bound poly-IgA ICs were analyzed by mass spectrometry.

Results: rCD89-mounted plates specifically captured plasma poly-IgA. The levels of poly-IgA ICs in IgAN (26.67, 17.06 to 42.61 units/ml) were significantly higher than healthy controls (15.46, 10.73 to 20.04 units/ml; P<0.001) or disease controls (13.99, 10.35 to 24.22 units/ml; P<0.001). Patients with higher levels of poly-IgA ICs had lower eGFR, higher proteinuria and higher Oxford scores in E and T lesions. Accuracy parameters and concordant statistics showed good discrimination between IgAN and healthy controls for poly-IgA ICs levels (AUC, 0.777; 95% CI, 0.722–0.832; P<0.001), significantly better than IgA1 levels (AUC, 0.710; P=0.015) and galactose deficient-IgA1 levels (AUC, 0.702; P=0.048). A total of 268 proteins were identified in mass spectrometry analysis. The protein abundance of fibrinogen alpha chain, protein AMBP and C4B were higher in IgAN group.

Conclusions: Higher level of rCD89-bound poly-IgA ICs was a potential useful diagnostic biomarker in patients with IgAN which was also associated with the severity of the disease. The findings suggest that the role of CD89 in eliminating IgA ICs and it may be a new approach to improve the clinical progress of patients with IgAN.

The baseline clinical and pathological characteristics of IgA nephropathy patients

	Total	CD89-bound poly-IgA ICs low-level	CD89-bound poly-IgA ICs high-level	P value
Patients(n)	181	85	96	-

Racial Heterogeneity of IgA_1 Hinge Region O-Glycoforms in Patients with IgA Nephropathy

Yukako Ohyama,[1] Samantha Chiurlia,[2] Sharon N. Cox,[2] Nikoletta-Maria Kouri,[3] Maria J. Stangou,[3] Hisateru Yamaguchi,[1] Kazuki Nakajima,[1] Daijo Inaguma,[1] Midori Hasegawa,[1] Yukio Yuzawa,[1] Naotake Tsuboi,[1] Aikaterini A. Papagianni,[3] Francesco P. Schena,[2] Kazuo Takahashi.[1] *[1]Fujita Health University, Toyoake, Japan; [2]University of Bari and Schena Foundation, Valenzano, Italy; [3]Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Background: IgA1 with galactose (Gal)-deficient hinge region (HR) *O*-glycans (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). The microRNAs, named let7b and miR-148b, which affect IgA1 HR *O*-glycosylation, showed differences in serum levels between Caucasians and Asians, suggesting a racial difference in HR *O*-glycosylation. To understand race-specific IgA1 HR *O*-glycoform heterogeneity at the molecular level, we compared Greek and Japanese profiles of IgA1 HR *O*-glycoforms in patients with IgAN.

Methods: IgA1 from sera of 10 Japanese healthy controls (J-HC), 36 Japanese IgAN patients (J-IgAN), 16 Greek HCs (G-HC), and 23 Greek IgAN patients (G-IgAN) were purified through affinity chromatography. After neuraminidase and trypsin digestion, samples underwent liquid chromatography-high-resolution mass spectrometry, and individual profiles of IgA1 HR *O*-glycoform were quantitatively analyzed. The amounts of *N*-acetylglucosamine (GalNAc) and Gal were shown as the median number of sugar moieties per HR.

Results: Twelve variants of the IgA1 HR *O*-glycopeptide were detected in both HCs and IgAN patients. The disease-specific IgA1 HR *O*-glycoforms were 3GalNAc3Gal in Japanese ($P < 0.001$) and 3GalNAc2Gal ($P = 0.007$) and 5GalNAc3Gal ($P = 0.043$) in Greek individuals. The amount of GalNAc per HR showed a common tendency to decrease in patients from both racial groups, compared with healthy subjects, and was more prominent in G-IgAN than in J-IgAN ($P = 0.027$). The amount of Gal per HR decreased in the following order: J-IgAN, G-HC, J-HC, and G-IgAN, and was significantly lower in G-IgAN than in J-IgAN ($P = 0.001$).

Conclusions: The amount of GalNAc per HR decreased in patients of both races and was prominent in G-IgAN. The difference in GalNAc levels between G-IgAN and J-IgAN showed correspondence with previously reported serum let-7b racial differences, which were associated with the regulation of the initial glycosylation of HR. Further studies regarding upstream factors and changes downstream of GalNAc glycosylation are required to understand the pathogenesis of IgAN.

IgA Nephropathy Complicated with Crohn Disease: A Clinical and Pathological Study of Kidney Biopsied Cases

Minako Akiyama,[1,2] Shimomura Kousuke,[2] Shaho Yoshimoto,[2] Minako Sako,[2] Makoto Kodama,[2] Keiko Abe,[2] Mariko Sano,[1] Dedong Kang,[1] Takashi Takaki,[1] Yukihiro Wada,[3] Masayuki Iyoda,[4] Kazuho Honda.[1] *[1]Department of Anatomy, Showa University School of Medicine, Shinagawa-ku, Japan; [2]Tokyo Yamate Medical Center, Shinjuku-ku, Japan; [3]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Shinagawa-ku, Japan; [4]Department of Microbiology and Immunology, Showa University School of Medicine, Shinagawa-ku, Japan.*

Background: Intestinal immunity is closely related with the pathogenesis and progression of renal diseases, called as "entero-renal linkage". To figure out the association between IgA nephropathy (IgAN) and Crohn's disease (CD), we performed the clinico-pathological study of IgAN patients with (CD-IgAN) and without CD (NOS-IgAN).

Methods: We enrolled 29 patients diagnosed with IgAN by renal biopsy in Tokyo Yamate Medical Center from 2009 to 2017. The patients were divided into CD-IgAN (n=18) and NOS-IgAN (n=11) and investigated their clinical and pathological findings. IgA subclasses and galactose-deficient IgA1 (Gd-IgA1) on glomerulus were examined by immunohistochemistry.

Results: No significant difference in the grades of urinary protein and hematuria was observed between CD-IgAN and NOS-IgAN, but CD-IgAN had elevated serum creatinine (sCr) and lower rate in clinical remission after steroid treatment as compared to NOS-IgAN. Pathologically, CD-IgAN had remarkably higher levels of global glomerulosclerosis (%), grades of interstitial fibrosis and tubular atrophy (IF/TA) than NOS-IgAN. Immunohistochemically, IgA1 was a dominant subclass and Gd-IgA1 was frequently detected in glomerular mesangium in both groups. No difference was noted in the extents of IgA1, IgA2 and Gd-IgA1 deposition, depending on the presence or absence of CD.

Conclusions: From the results of the subclasses and galactose-deficiency of the IgA molecules, no difference was suggested in the etiology and pathogenesis between CD-IgAN and NOS-IgAN. However, advanced glomerular sclerosis and tubulointerstitial fibrosis in renal pathology and highly resistant clinical features to medical treatments in CD-IgAN suggest that the intestinal immunity and other clinical factors associated with CD may promote and activate the inflammatory process of IgAN.

PO1797

Antibody Sequencing Analysis After Flu Vaccine Response in IgA Nephropathy Patients Reveals Enhanced IgA Variable Regions of the Heavy Chains Lineage Diversity

Colin Reily, Barbora Knoppova, Christopher Fucile, Alex Rosenberg, Dana Rizk, Bruce A. Julian, Jan Novak, Rodney G. King. *University of Alabama at Birmingham, Departments of Medicine and Microbiology, Birmingham, AL.*

Background: IgA nephropathy (IgAN), the most common primary glomerulonephritis in the world, is characterized by mesangial immunodeposits consisting of galactose-deficient IgA1 (Gd-IgA1) and Gd-IgA1-specific IgG autoantibodies. IgG autoantibodies in IgAN patients have variable regions of the heavy chains (VH) with long complementarity-determining region 3 (CDR3) that contains a key amino-acid residue important for binding Gd-IgA1. This CDR3 modification is not due to a genetic variant of a *VH*gene in IgAN patients but it is thought to originate from somatic mutations. To determine whether IgAN patients have generally enhanced rates of *VH*somatic mutations, we have assessed responses to influenza-vaccine antigens in IgAN patients vs. healthy controls.

Methods: Peripheral blood (PB) from 4 IgAN patients and 4 healthy controls (HC) was collected 7 d after flu vaccination (i.m.), the peak of plasmablasts in PB. Plasmablasts were isolated after enrichment with CD138-coated beads. cDNA from plasmablasts was used for *VH*gene amplification with *VH*- and isotype-specific primers, and sequenced on an Illumina MiSeq. Sequences were filtered, aligned, and grouped using an in-house workflow, with further analyses performed in Matlab.

Results: Isotype-specific nucleotide mutation rates were similar in IgAN and HC plasmablasts, except for *IGHV3-7*with a higher rate in HC for IgM (p=0.01). Average nucleotide mutation rate for CDR3 was 1.6% higher in HC compared to IgAN, almost reaching significance (p=0.06). Further analysis revealed that number clonotype-specific*VH*sequences was increased for IgA in plasmablasts from HC vs. IgAN for *IGHV2-5*(p=0.02), *IGHV3-7*(p=0.04), *IGHV3-15*(p=0.02), *IGHV3-21*(p=0.01), *IGHV3-30* (p=0.01),*IGHV3-48*(p=0.03), *IGHV4-38-2*(p=0.05), *IGHV4-59*(p=0.04), and *IGHV4-61* (p=0.02).

Conclusions: Analysis of influenza-vaccine-specific immune responses showed that IgAN patients and HC exhibit similar *VH*nucleotide mutation rates. Unexpectedly, we also observed thatIgAN patients produced fewer IgA *VH*sequences than healthy controls after flu vaccination, indicating a possible disparity of IgA responses in IgAN.

Identification of Proteins Associated with IgA_1-Containing Circulating Immune Complexes in Patients with IgA Nephropathy

Mary A. Bunten,[1] Amanda Holloway,[1] Audra A. Hargett,[1] Stacy D. Hall,[1] Zhi qiang Huang,[1] Nicolas Maillard,[2] Bruce A. Julian,[1] Jan Novak,[1] Matthew B. Renfrow.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.*

Background: IgA1-containing immune complexes (IgA1-ICs), consisting of galactose-deficient IgA1 (Gd-IgA1) bound by IgG specific for Gd-IgA1, are central to the pathogenesis of IgA nephropathy (IgAN). We have shown that Gd-IgA1 alone is not sufficient to induce mesangial-cell proliferation and that additional serum proteins are required for IgA1-ICs to become nephritogenic. To elucidate the composition of IgA1-ICs, we have developed a novel proteomic-bioinformatic workflow to identify proteins in IgA1-ICs in patients with IgAN.

Methods: IgA1-ICs from sera of 20 patients and 20 healthy controls were isolated by lectin affinity chromatography followed by size-exclusion chromatography (SEC). Quality-control test confirmed that most IgA1-ICs and free IgA1 were captured by affinity chromatography. IgA1-ICs were separated by SEC from monomeric and polymeric IgA1. After IgA-specific protease and LC-MS sequence-grade trypsin digestion, each IgA1-IC sample was analyzed by liquid chromatography coupled on line with mass spectrometry (LC-MS). After standard proteomic database searches, LC-MS results were extensively curated by use of *Scaffold perSPECtives* to identify proteins enriched in IgA1-ICs of IgAN patients vs. healthy controls. Additional comparisons included polymeric and monomeric IgA1.

Results: Seventy-nine proteins were identified in IgA1-ICs samples from IgAN patients, with a false discovery rate of 1%. After proteomic-bioinformatic curation, we generated a list of 38 proteins with high-confidence identification that were uniquely enriched in the IgA1-ICs from patients with IgAN. Using Principle Component Analysis, we confirmed that protein content differentiated the three molecular forms of IgA1, monomeric, polymeric, and IgA1-IC. Pathway analysis indicated that proteins in IgA1-ICs were part of the complement cascade, with seemingly more enrichment in the regulation of complement, and the plasma lipoprotein pathway.

Conclusions: Our new workflow enabled targeted identification and evaluation of proteins associated with IgA1-ICs in IgAN. These proteins represent new targets to be evaluated for their roles in the formation and activity of the nephritogenic IgA1-ICs in IgAN.

PO1799

Low Serum IgG4: A Remarkable Diagnostic Biomarker for IgA Nephropathy

Xinyu Tian, Song Wang, Zhenling Deng, Yue Wang. *Peking University Third Hospital, Beijing, China.*

Background: Reports regarding IgG subclasses in IgA nephropathy (IgAN) were scarce. Low serum IgG4 levels in IgAN were noticed in our preliminary experiment. We aim to verify the low IgG4 levels in IgAN and investigate the related immune mechanism.

Methods: Three groups of IgAN patients were enrolled, including the newly diagnosed IgAN-N (n = 58), IgAN-F (n = 28) with a follow-up interval of (19 ± 11) months, and IgAN-10 patients (n = 27) who have been diagnosed over 10 years. Healthy individuals (n = 56) and patients with idiopathic membranous nephropathy (IMN, n = 30) were enrolled as controls. Serum IgG4, IgG, galactose-deficient IgA1 (Gd-IgA1), and urine IgG4 levels were detected by ELISA. The $IgG4^+B$, Th1, and Th2 cells were measured by flow cytometry. Receiver operating characteristic curves and logistic regression analyses were performed to evaluate the diagnostic and predictive abilities of IgG4.

Results: The serum IgG4 levels in IgAN patients with different courses, severity, and outcomes were all significantly lower than those of healthy controls and IMN (all $P < 0.001$). The cutoff value of IgG4 in differentiating IgAN from healthy individuals and IMN was respectively 0.26mg/ml (sensitivity 98.3%, specificity 82.1%, AUC 0.938, $P < 0.0001$) and 0.24mg/ml (sensitivity 96.6%, specificity 73.3%, AUC 0.869, $P < 0.0001$). The risk of IgAN in subjects with low IgG4 levels was 281 times higher than those with normal IgG4 (OR 281.11, 95%*CI* 34.33 - 2301.97, $P < 0.001$), and a negative correlation between serum Gd-IgA1 and IgG4 levels was observed in healthy controls (r = -0.240, P = 0.077) instead of IgAN-N patients (r = -0.066, P = 0.629). Similar results were obtained when IgG4/IgG was analyzed in the same patients and controls. The urine IgG4 levels [μg/(g.Cr)] in IgAN-N [798.16 (308.75, 1533.56)] were higher than healthy controls [72.87 (31.51, 201.89), $P < 0.001$], but were similar to IMN [1153.39 (378.83, 2108.40), P = 0.341]. The $IgG4^+B$/B cells (0.29 ± 0.17 vs. 0.61 ± 0.56, P = 0.017) and Th2/Th (0.54 ± 0.27 vs. 0.87 ± 0.44, P = 0.037) of IgAN were significantly lower than those of healthy controls.

Conclusions: Serum IgG4 levels of IgAN patients are generally low, and the low IgG4 level may be a risk factor for IgAN. Serum IgG4 may be a remarkable diagnostic biomarker for IgAN. Decreased $IgG4^+B$ and Th2 cells may contribute to the low IgG4 levels.

PO1800

Comparing the Lectin and Mass Spectrometry-Based Approaches to Quantify Galactose-Deficient IgA_1 in IgA Nephropathy

Olivier Lardinois,[2] Patrick H. Nachman,[1] Jason G. Williams,[2] Leesa Deterding.[2] *[1]University of Minnesota, Division of Renal Diseases and Hypertension, Minneapolis, MN; [2]NIEHS, Mass Spectrometry Research and Support Group, Research Triangle Park, NC.*

Background: Abnormalities in *O*-glycosylation of circulating IgA_1 are implicated in the pathogenesis of IgAN. This was initially demonstrated by the altered binding of lectins with specificity for *O*-linked glycans and confirmed later by mass spectrometry. Nevertheless, combining and interpreting the results from these two orthogonal techniques is difficult, due to their different levels of complexity. We applied the two approaches to quantify galactose-deficient IgA_1 (Gd-IgA_1) in plasma samples of IgAN patients and matched controls. We aim to identify potential sources of discrepancy between the two analytical methods.

Methods: IgAs were affinity purified from plasma samples from 23 patients with IgAN and 36 controls. We used enzyme-linked lectin assay and the lectin from *Vicia villosa* (VVL) to measure defective galactosylation of *O*-linked oligosaccharides. Monomeric (mIgA) and polymeric (pIgA) forms of IgA_1 were size-separated by gel electrophoresis. IgA_1-containing bands were in-gel digested with trypsin, the released glycopeptides were analyzed by electrospray ionization liquid mass spectrometry.

Results: A significantly larger fraction of IgA_1 molecules in the circulation of IgAN patients exist as high molecular mass complexes, as compared with the control group (48.8 *vs* 42.8%, p=4.25E-02). The reactivity of VVL lectin with unfractionated IgA_1 was higher in the IgAN group compared with healthy controls (10.9 *vs* 9.1 A.U., p=8.60E-02). In both groups, IgA_1 binding to VVL was much stronger for pIgA than mIgA. Mass spectrometry showed that the level of Gal was higher in pIgA than in mIgA (3.66 *vs* 3.54 Gal/Heavy Chain, p=7.63E-05). However, no significant differences in glycan composition was detected between patients and controls. In all the experiments, the inter-individual differences in glycan composition were large, which may have obscured the signals from the disease-related galactose-deficient IgA_1.

Conclusions: Our results suggest that the apparent increased abundance of Gd-IgA_1 in circulation of patients with IgAN is, at least in part, attributable to a greater abundance of polymeric IgA_1 compared with controls. However, the glycosylation profile of each form of IgA_1 appeared indistinguishable in the IgAN group when compared to the corresponding form in the control group.

PO1801

Developing Molecular-Specific Biomarker Assays for IgA Nephropathy and IgA Vasculitis with Nephritis

Alyssa L. Hansen, Ellenore P. Craine, Audra A. Hargett, Stacy D. Hall, Dana Rizk, Bruce A. Julian, Jan Novak, Matthew B. Renfrow. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with IgA nephropathy (IgAN) develop characteristic glomerular immunodeposits containing IgA that is enriched for IgA1 glycoforms with galactose-deficient hinge-region *O*-glycans (Gd-IgA1). Blood levels of Gd-IgA1 are elevated in patients with IgAN and those with IgA vasculitis with nephritis (IgAV-N), suggesting a key role of Gd-IgA1 in pathogenesis of these diseases. In contrast, patients with IgA vasculitis (IgAV) without renal involvement do not have elevated blood levels of Gd-IgA1. These observations suggest a potential prognostic role for a minimally invasive biomarker based on profiling serum/plasma IgA1 *O*-glycoforms. Here, we describe a novel workflow to qualitatively and quantitatively assess molecular IgA1 phenotype(s) in IgAN by profiling serum IgA1. This validated approach can be extended to IgAV-N patients.

Methods: Isolation of IgA1 from sera is based on lectin-affinity chromatography followed by size-exclusion chromatography to separate IgA1 monomeric and polymeric forms and IgA1 bound in immune complexes. IgA1 *O*-glycosylation was analyzed by liquid chromatography-high-resolution mass spectrometry (LC-MS). In a pilot study, we used monomeric IgA1 from sera of 10 healthy controls and 10 IgAN patients. LC-MS runs were standardized using internal and external calibration methods.

Results: Quantitative LC-MS analysis revealed variations in the abundance of individual IgA1 *O*-glycoforms in the tested samples. We used quantitative data for 10-15 IgA1 glycoforms, expressed as relative ratios, to distinguish IgA1 from patients with IgAN vs. healthy controls. Furthermore, the LC-MS assay was standardized with internal and external calibration methods, an approach that will enable sample normalization, longitudinal studies, as well as evaluation of IgA1 from patients with IgAV-N.

Conclusions: Quantitative profiling of IgA1 clustered *O*-glycosylation can determine molecular IgA1 phenotype(s) and identify IgA1 glycoforms as biomarkers related to disease pathogenesis. These approaches are applicable to differential profiling of IgA1 from patients with IgAV-N vs. IgAV vs. healthy controls to identify pathogenic IgA1 glycoforms involved in the formation of nephritogenic immune complexes in IgAV-N.

PO1802

Mass Spectrometric Analysis of IgA_1 O-Glycoforms Reveals the Basis of IgA_1 Galactose Deficiency Detected by Quantitative Lectin ELISA

Ellenore P. Craine,[1] Hiroyuki Ueda,[1,2] Yoshimi Ueda,[1,2] Colin Reily,[1] Zina Moldoveanu,[1] Stacy D. Hall,[1] Takashi Yokoo,[2] Dana Rizk,[1] Krzysztof Kiryluk,[3] Ali G. Gharavi,[3] Bruce A. Julian,[1] Jan Novak,[1] Matthew B. Renfrow.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]The Jikei University School of Medicine, Tokyo, Japan; [3]Columbia University College of Physicians and Surgeons, New York, NY.*

Background: Patients with IgA nephropathy (IgAN) have elevated serum levels of IgA1 with some hinge-region (HR) *O*-glycansdeficient in galactose (Gal; Gd-IgA1). Gd-IgA1 is recognized by IgG autoantibodies, resulting in the formation of pathogenic immune complexes. Our group has established a quantitative ELISA for Gd-IgA1 using GalNAc-specific lectins (e.g., from *Helix pomatia*; HPA). This test enabled determination of genetic basis of IgA1 Gal deficiency and provided a better understanding of IgAN pathogenesis. However, understanding of IgA1 *O*-glycosylation at a molecular-level is needed.

Methods: We used liquid chromatography with high-resolution mass spectrometry (LC-MS) to analyze and quantify *O*-glycoforms of monomeric (m) and polymeric (p) IgA1 in sera of IgAN patients (n=31) and healthy controls (HC; n=10). Total serum IgA1 was isolated by lectin affinity chromatography and m and p forms were separated by size-exclusion chromatography. Gd-IgA1 was measured by lectin ELISA. HR glycopeptides, generated by an IgA-specific protease and trypsin, were analyzed by LC-MS using LTQ Orbitrap Velos MS. LC-MS data were analyzed with the Pinnacle software.

Results: Quantitative LC-MS *O*-glycosylation profiling of IgA1 HR was performed, and results calculated as relative abundance of individual glycoforms and as ratios of Gal-containing *vs.* Gal-deficient glycoforms. Both LC-MS data and lectin ELISA confirmed that pIgA1 exhibited higher degree of Gal deficiency than mIgA1. LC-MS data provided additional insight into the molecular basis of the variability of Gd-IgA1 serum levels in IgAN patients. For example, IgA1 HR glycoform GalNAc4Gal3 was more abundant for the pIgA1 in the patients with high vs. low serum levels of Gd-IgA1 ($p<0.005$). LC-MS analysis enabled identification and quantification of individual HR glycoforms and defined the Gd-IgA1 glycoforms detected by lectin ELISA.

Conclusions: High-resolution LC-MS IgA1 glycoprofiling confirmed pIgA1 as the main form of IgA1 detected by Gd-IgA1 lectin ELISA. Furthermore, we identified several different Gal-deficient glycoforms in pIgA1, an observation that enables quantitative molecular-level assessment of Gd-IgA1 glycophenotype.

SeqStain: A Multiplex Staining Method for Deep Profiling of Human Kidney Tissues

Anugraha R. Rajagopalan,[1] Ishwarya Venkatesh,[1] Rabail Aslam,[1] Vineet Gupta.[1,2] *[1]Drug Discovery Center, Department of Internal Medicine, Rush University Medical Center, Chicago, IL; [2]Division of Hematology, Oncology and Cellar Therapies, Department of Internal Medicine, Rush University Medical Center, Chicago, IL.*

Background: Chronic Kidney Disease (CKD) is an emerging global health challenge, affecting 10-15% of the population. Lack of reliable biomarkers precludes the early diagnosis of CKD. The progression of CKD is known to be dictated by renal tissue changes. For example, in the case of Diabetic Nephropathy, disease progression is accompanied by considerable changes to the glomeruli including the thickening of the glomerular basement membrane and mesangial expansion, extracellular matrix accumulation, reduced podocyte number, inflammation of the renal tissue, the influx of immune cells which ultimately lead to tissue damage and progression to CKD. Understanding these tissue-centered events on a deeper level is imperative to reduce morbidity associated with CKD and for early diagnosis.

Methods: To aid high-level multiplex staining of these tissues by immunofluorescence, we developed a novel multiplex staining method called SeqStain. The SeqStain multiplex platform uses DNA tagged antibodies and Fab fragments to stain while endonucleases are used to achieve gentle de-staining after each round. We designed a SeqStain multiplex panel with antibodies to probe different histological regions relevant to the kidney. Antibodies or Fab fragments were tagged with DNA oligonucleotide duplex which carries multiple fluorophores. Labeled Fab fragments were pre-complexed with primary antibodies for staining.

Results: SeqStain modified antibodies and Fab fragments efficiently labeled multiple markers in tissue sections. Kidney tissues were stained with the SeqStain reagents and de-stained using endonucleases and provided a simple, gentle, and rapid technique for multiplex imaging of the tissues. The method was implemented using a custom flow chamber and allowed the labeling of tens of antigens on a single tissue section. Image alignment and analyses provided spatialomic data on multiple cell types in the tissue.

Conclusions: SeqStain method offers a robust yet gentle multiplex staining method to profile the CKD kidney tissues and comprehend the tissue-centered events that could play a role in the disease progression. Currently, we are profiling the CKD tissues in multiplex staining experiments and comparing it to healthy human kidney tissues to generate the spatial maps.

PO1804

TLR9 Signaling Pathways in Nasal-Associated Lymphoid Tissue Have a Crucial Role in the Pathogenesis of IgA Nephropathy

Toshiki Kano,[2] Hitoshi Suzuki,[2,1] Yuko Makita,[2] Yusuke Fukao,[2] Yusuke Suzuki.[2] *[1]Juntendo Daigaku Igakubu Fuzoku Urayasu Byoin, Urayasu, Japan; [2]Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Background: The pathogenesis of IgA nephropathy (IgAN) is closely associated with dysregulation of mucosal immune system. However, it is unclear which nasal-associated lymphoid tissue (NALT) or gut-associated lymphatic tissue (GALT) is more involved in the pathogenesis of IgAN. In present study, we examined whether NALT or GALT is the major responsible site for the nephritogenic immune complexes in murine IgA nephropathy.

Methods: We examined the effect of broad-spectrum antibiotics in the IgAN onset ddY mice. In addition, we assessed disease phenotypes of the IgAN onset ddY mice housed in germ free condition (GF-ddY) and transferred to specific pathogen free (SPF) condition. The levels of aberrantly glycosylated IgA and IgG-IgA immune complexes (IC) in serum and supernatant of cultured cells purified from NALT and mesenteric lymph node (MLN) were measured using the IgAN onset and the quiescent ddY mice (each n=15). To identify dysregulation of mucosal immune response site in IgAN, NALT and GALT were immunized separately in GF-ddY mice, *i.e.*, nasally challenged with TLR9 ligand (CpG-ODN) stimulation and fecal transplantation.

Results: Broad-spectrum antibiotics depleted microbiota efficiently, resulted in ameliorating clinicopathological changes in IgAN onset ddY mice. Moreover, the GF-ddY mice did not develop IgAN, meanwhile, the GF-ddY mice showed an aggravation of renal injury with mesangial IgA deposition after transferred to SPF condition. In the IgAN onset ddY mice, the levels of aberrantly glycosylated IgA and IgG-IgA IC in serum and supernatant of cultured cells purified from NALT are significantly higher than those in the quiescent ddY mice. However, the levels of supernatant aberrantly glycosylated IgA and IgG-IgA IC produced by cultured cells purified from MLN showed no significant difference between the IgAN onset and the quiescent ddY mice. Although the GF-ddY mice nasally immunized with CpG-ODN also showed an aggravation of renal injury with mesangial IgA deposition, the GF-ddY mice which received fecal transplant did not develop IgAN.

Conclusions: Present study indicated that the dysregulation of mucosal immune response due to exogenous antigen exacerbated the pathogenesis of IgAN. TLR9 signaling pathways in NALT may be mainly involved in the pathogenesis of IgAN.

PO1805

Functional Studies of IgG Autoantibodies in IgA Nephropathy

Barbora Knoppova, Alyssa L. Hansen, Zina Moldoveanu, Stacy D. Hall, Zhi qiang Huang, Lea Novak, Bruce A. Julian, Matthew B. Renfrow, Jan Novak, Todd J. Green. *University of Alabama at Birmingham, Birmingham, AL.*

Background: IgA nephropathy (IgAN) is an autoimmune disease wherein galactose-deficient IgA1 (Gd-IgA1) is recognized by IgG autoantibodies (autoAbs), resulting in the formation of immune complexes (ICs), some of which deposit in the kidneys and induce glomerular injury. We have shown that a recombinant IgG (rIgG) autoAb derived from an IgAN patient can bind to Gd-IgA1, form ICs, and induce pathologic mesangioproliferative changes in a passive mouse model of IgAN. However, the interaction between the key elements, Gd-IgA1 and IgG autoAbs, has not been fully clarified. After solving the Fab 3-D structure, we focused on functional characterization of this rIgG autoAb.

Methods: Based on solved 3-D structure of the Fab of rIgG autoAb, we used site-directed mutagenesis to replace specific amino-acid (aa) residues in the rIgG autoAb. rIgGs were expressed in Expi293F cells and purified by affinity chromatography. ELISA was used to assess the binding of rIgGs to Gd-IgA1. Fab fragments of two selected mutants of rIgG were purified and used for hanging-drop crystallization. Liquid chromatography coupled with mass spectrometry (LC-MS) analysis was used to identify Gd-IgA1 *O*-glycoforms recognized by rIgG autoAb.

Results: We generated rIgG variants with aa replacements in several heavy-chain segments: junction of framework 1 (FR1) and complementarity-determining region 1 (CDR1) and in the CDR3. The FR1-CDR1 mutations reduced or disabled rIgGs binding to Gd-IgA1, depending on the specific aa residue used for replacement. Mutations in CDR3 completely impaired the binding of rIgG to Gd-IgA1. LC-MS analyses indicated that rIgG autoAb preferentially binds to a subset of IgA1 molecules, resulting in enrichment of hinge-region (HR) glycoforms with 4 *O*-glycans, including HR glycoform GalNAc4Gal3.

Conclusions: Our study identified specific aa residues in the FR1-CDR1 and CDR3 regions of the rIgG autoAb that are critical for Gd-IgA1 binding. The ongoing structural studies of different variants of this rIgG will elucidate the nature of autoantigen recognition by IgG autoAbs. This knowledge, together with the understanding what are the main targeted HR glycoforms, will enable the design of future therapeutic approaches based on blockade of these pathogenic IgG autoAbs in IgAN.

Can the Cross-Talk Between PDGF Receptor and Axl in Mesangial Cells Represent a Possible Therapeutic Target in IgA Nephropathy?

Qi Bian,[1] Zhi qiang Huang,[2] Joshua C. Anderson,[2] Xianwen Zhang,[3] Kerstin Ebefors,[4] Jenny C. Nystrom,[4] Stacy D. Hall,[2] Lea Novak,[2] Bruce A. Julian,[2] Christopher D. Willey,[2] Jan Novak.[2] *[1]Changhai Hospital, Changhai Hospital, Second Military Medical University/Naval Medical University, Shanghai, China; [2]University of alabama at Birmingham, Birmingham, AL; [3]Long Hua Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China; [4]University of Gothenburg, Gothenburg, Sweden.*

Background: PDGF is involved in the pathogenesis of IgA nephropathy, namely in the activation of mesangial cells (MC). Our kinomic profiling revealed that receptor tyrosine kinase Axl and non-receptor tyrosine kinase ABL were the top upregulated protein-tyrosine kinases in MC stimulated by PDGF-AB. In this study, we describe crosstalk between Axl and a PDGF receptor (PDGFR-β) in human MC stimulated with PDGF.

Methods: Quiescent primary human MC were stimulated with PDGF-AB for 15 min. Cell lysates were analyzed with SDS-PAGE/Western blotting to probe for phospho-PDGFR-β, phospho-Axl, and down-stream signaling. Immunoprecipitation with antibodies specific for PDGFR-β or Axl was used to assess association of Axl and PDGFR-β. To test the role of Axl in crosstalk with PDGFR-β, the Axl/ABL inhibitor R428 and an Axl-specific siRNA knock-down (k/d) were used. Cellular proliferation was measured by BrdU incorporation ~20-h after PDGF-AB stimulation.

Results: PDGF-AB stimulated cellular proliferation of MC. PDGF-AB induced phosphorylation of multiple kinases, including Axl, PDGFR-β, Akt1, and ERK1/2 in MC. Immunoprecipitation experiments revealed association of Axl with PDGFR-β. The Axl/ABL inhibitor R428 inhibited PDGF-AB-induced phosphorylation of Axl, PDGFR-β, AKT1, and ERK1/2, and partially reduced PDGF-AB-induced MC proliferation. siRNA k/d of Axl reduced expression of Axl, but did not prevent PDGF-AB-induced phosphorylation of AKT1, ERK1/2 and PDGFR-β, and did not reduce proliferation of MC.

Conclusions: In summary, PDGF-AB induced multiple signaling events in cultured human MC that included crosstalk between PDGFR-β and Axl. MC cellular signaling induced by PDGF-AB was blocked by the Axl/ABL inhibitor R428 but not by Axl siRNA k/d. These findings suggest a role for the non-receptor tyrosine kinase ABL in a crosstalk between the two receptors. We postulate that the PDGFR-β/Axl/ABL pathway may represent a possible therapeutic target in the treatment of IgA nephropathy.

Galactose-Deficient IgA_1-Containing Immune Complexes Deposit with Complementary Activity in Mesangium Through Endothelial Cell Injuries

Yuko Makita,[1] Hitoshi Suzuki,[2] Daisuke Nakano,[3] Toshiki Kano,[1] Akira Nishiyama,[3] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; [3]Department of Pharmacology, Kagawa University, Kagawa, Japan.*

Background: IgAN is defined by the presence of dominant mesangial IgA1 immune deposits, accompanied by C3 deposits, and deposition of IgA1 includes galactose-deficient IgA1 (Gd-IgA1). However, the pathogenic role of Gd-IgA1-containing IC with regard to mesangial immune deposits are still unclear. The endothelial surface glycocalyx modulates microvascular function. Loss of the glomerular endothelial glycocalyx is involved in albuminuria. In present study, we hypothesized that Gd-IgA1-containing IC deposit in mesangium through glomerular endothelial cell injuries.

Methods: Gd-IgA1 and recombinant anti-glycan IgG were used to form IC (Gd-IgA1-IgG IC) to inject *i.v* into nude mice. After various time intervals, mice were sacrificed and kidney was harvested to determine mesangial deposition and kidney injuries. To investigate that Gd-IgA1-IgG IC stimulation increases permeability of glomerular microvascular resulted in renal injuries, the renal microvascular endothelial glycocalyx removal was estimated by real-time glycocalyx imaging. Furthermore, human renal glomerular endothelial cells (HRGEC) were co-cultured with Gd-IgA1 alone or Gd-IgA1-IgG IC for 72 h to assess the potential capacity of these IC to activate endothelial cells.

Results: After injection of Gd-IgA1-IgG IC, but not Gd-IgA1 only induced proteinuria and hematuria in nude mice. Gd-IgA1-IgG IC deposited with murine C3 in the mesangium as well as subendothelial area of the glomerular capillaries. Furthermore, electron microscopic examination showed that injection of Gd-IgA1-IgG IC induced endothelial injuries. In fact, real-time glycocalyx imaging showed that renal microvascular glycocalyx were reduced after injection of Gd-IgA1-IgG IC in nude mice. After co-culture of Gd-IgA1-IgG IC with HRGEC, transcript levels of endothelial adhesion factors such as ICAM-1, VCAM-1 and E-selectin were significantly upregulated ($P<0.01$). Transcript levels of TNFα and IL-6, proinflammatory mediators which are able to induce the expression of adhesion factors on endothelial cells, were also increased ($P<0.01$).

Conclusions: Present data suggested that Gd-IgA1-containg IC deposition and subsequent complement activation may induce endothelial damage and overexpression of pathogenic cytokines and adhesion molecules resulting in glomerular injuries in IgAN.

PO1808

Sparsentan Protects Against Development of Albuminuria and Glomerulosclerosis in the gddY Mouse Model of IgA Nephropathy

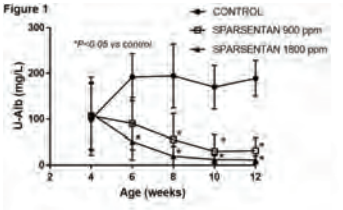
Hajime Nagasawa,[1] Hitoshi Suzuki,[1,2] Celia P. Jenkinson,[3] Seiji Ueda,[1] Yusuke Fukao,[1] Maiko Nakayama,[1] Tomoyuki Otsuka,[1] Kai Liu,[3] Radko Komers,[3] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrogy, Juntendo University Facility of Medicine, Chiba, Japan; [3]Retrophin Inc, San Diego, CA.*

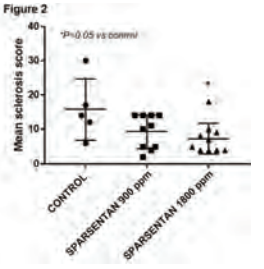
Background: gddY mice are an IgA nephropathy (IgAN) model that develops albuminuria by 8 weeks (W) of age with glomerular IgA, IgG, and C3 deposits and progressive mesangioproliferative glomerulonephritis. A previous study in the ddY mouse model (the predecessor to gddY mice) using the endothelin type A receptor (ET_AR) antagonist FR139317 resulted in amelioration of proteinuria and preservation of kidney function. Treatment of ddY mice with the angiotensin II type 1 receptor (AT_1R) blocker valsartan resulted in significant protection from glomerulosclerosis (GS) without a significant prevention in proteinuria. We examined the effect of sparsentan (SP), a dual ET_AR and AT_1R blocker, on development of albuminuria and GS in gddY mice.

Methods: 4 W old gddY mice were fed with control (C) chow (n=5) or chow containing 900 ppm (n=10) or 1800 ppm (n=10) SP (180 and 360 mg/kg/day) for 8 W. Albuminuria (U-Alb) was assessed at 4, 6, 8, and 12 W of age and plasma levels of SP were determined at 8 am and 4 pm at 6, 8, and 12 W. Kidney biopsies were taken at the end of the study at 12 W of age and 30 glomeruli/animal were scored for the percentage of GS. Serum IgA and glycosylation of IgA was measured using ELISAs.

Results: gddY mice fed SP for 8 W from 4 W of age demonstrated significantly ($P<0.05$) decreased U-Alb vs mice fed C diet (Fig 1). Development of GS in SP-fed mice was significantly ($P<0.05$) attenuated vs C diet (Fig 2). Plasma levels of SP taken at 8 am and 4 pm after 8 W of treatment were (mean±SD) 281±107 and 105±62 ng/ml respectively for 900 ppm SP and 774±674 and 304±176 ng/ml respectively for 1800 ppm SP. Weight gain in mice fed SP was not different from mice receiving C diet. There was no difference in serum levels of IgA or aberrantly glycosylated IgA.

Conclusions: 8 weeks of treatment with SP significantly attenuated increases in albuminuria and GS associated with the development of IgAN in gddY mice. If translated to the clinic, these data support SP as a new approach to the treatment of IgAN.





PO1809

Dysregulation of B-Cell Differentiation in IgA Nephropathy Model Mice

Yoshihito Nihei,[1] Hitoshi Suzuki,[1,2] Yusuke Fukao,[1] Maiko Nakayama,[1] Mingfeng Lee,[1] Rina Kato,[1] Toshiki Kano,[1] Yuko Makita,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Faculty of Medicine, Chiba, Japan.*

Background: Several novel drugs targeting B cells are reported to be effective in the treatment of IgA nephropathy (IgAN). On the other hand, we have reported that the abnormal B cells expressing APRIL (A proliferation-inducing ligand) are present in tonsils of human IgAN. Given these reports, dysregulation of B cells may be involved in the pathogenesis of IgAN. To elucidate the abnormality in B cells of IgAN, we analyzed characteristics of B cells by using IgAN prone mice with (O-ddY) or without (NO-ddY) full onset of this disease. Furthermore, we recently developed a novel culture system mimicking germinal center in mucosa, by which nearly 50 % of B cells undergo class switch (CS) to IgA. Here, we aim to evaluate characteristics of B cells in O-ddY mice using this novel B cell culture system.

Methods: Splenic B cells from O-ddY or NO-ddY mice were stimulated with membrane-bound IgM and CD40 for 48h and then proliferation of B cells was evaluated by Thymidine-uptake analysis. To examine CS to IgA, naïve splenic B cells from O-ddY or NO-ddY mice were cultured for seven days under the newly developed culture system. The frequency of IgA CS was evaluated by flow cytometry.

Results: We found that naïve B cells of O-ddY proliferated more than those of NO-ddY mice in response to stimuli through CD40 and membrane-bound IgM. There was no significant difference in the frequency of class switch to IgA between splenic B cells from O-ddY mice and those from NO-ddY mice.

Conclusions: These data indicate that B cells in O-ddY mice are hyper-sensitive to stimuli by antigen and T-cell help without increasing the frequency of IgA class switch and suggest that such dysregulation of B cells may be involved in the pathogenesis of IgAN

PO1810

Novel Model for IgA Nephropathy Using Synthetic Polymeric IgA

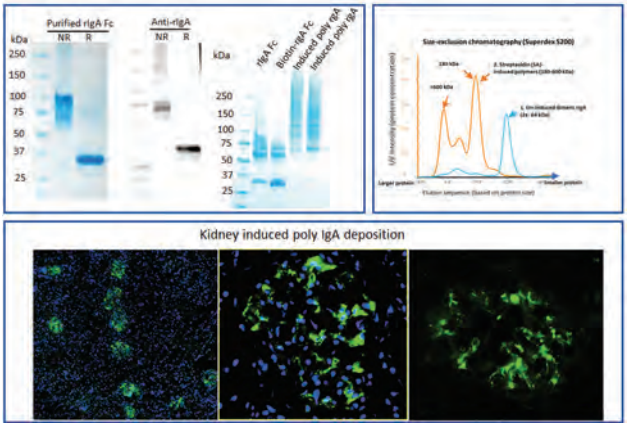
Xinfang Xie,[1,2] Pan Liu,[1] Jing Jin.[1] 1. Division of Nephrology and Hypertension, Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA; and Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA 2. Department of Nephrology, The First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an, China *[1]Division of Nephrology and Hypertension, Northwestern University Feinberg School of Medicine, Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Department of Nephrology, The First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an, China*.

Background: IgA nephropathy (IgAN) is characterized by polymeric IgA deposition in the glomerulus. The mechanism for IgA deposition remains elusive. We constructed a recombinant IgA polymerized by streptavidin to model the initiation and development of IgAN.

Methods: To model IgA complex, we produced recombinant rat and human IgA CH2-CH3 segments. By fusing them with Avi-tag, adding biotin and tetrameric streptavidin to form 4-8-unit multimers. Both dimeric IgA and polymeric IgA constructs were IV injected in rats. Renal deposition of the IgA was detected by immunofluorescence. Polymer IgA was used to stimulate mesangial cells and IL-6 production was measured by ELISA.

Results: Through BirA enzymatic reaction, single biotin was added to the Avi-Tag at the N-terminus of IgA. The total molecular sizes of IgA with and without streptavidin were measured by size-exclusion chromatograph. As expected, uninduced IgA was a standard dimer of 65 kDa, whereas streptavidin-induced IgA formed multimers of 4-8 units, resembling poly-IgA in IgAN. These dimeric and polymeric IgA at 2 mg/kg. BW were injected in 5 week-old Wister rats. 1h, 3 hrs and 24 hrs after injection, the kidney and the liver were harvested for detection of rIgA. Exclusive IgA deposition in the glomerulus mesangial areas was found(Figure). In general, the staining intensity gradually diminished over 24 hrs period. However, rats received daily doses of the induced IgA for 2 and 5 days showed enhanced intensity of IgA deposition. In contrast, the dimeric IgA was not detectable in kidney. Furthermore, EM and PAS staining of the renal sections showed mesangial proliferation. Ex vivo stimulation of human mesangial cells also showed increased levels of IL-6 in the medium.

Conclusions: The findings indicate streptavidin-induced poly-rIgA causes specific renal mesangial deposition and mesangial cells proliferation, which can be used to study the kinetics of mesangial accumulation and clearance of IgA deposition, as a new model for investigating IgAN pathogenesis.



PO1811

Nephritic Factor Function Over Time

Christopher Culek,[1,2] Monica D. Hall,[1,2] Yuzhou Zhang,[1,2] Richard J. Smith,[1,2] Carla M. Nester.[1,2] *[1]Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; [2]University of Iowa, Iowa City, IA.*

Background: Nephritic factors (Nef) are autoantibodies that stabilize and dysregulate the function of the C3 convertase, the cornerstone of complement amplification. Their association with renal inflammation central to the C3 Glomerulopathies (C3G) is well reported, however it is unknown whether Nefs 1) change over time, 2) correlate with serologic biomarker assessments, and/or 3) are useful for predicting risk for relapse of C3G. We aimed to create a novel assay that allows comparison of Nef properties over time. We further sought to correlate these results with an array of serologic biomarkers. We hypothesized that when Nef activity remains high, this abnormality is associated with ongoing serologic biomarker abnormalities.

Methods: The test subject was a C3G patient with disease recurrence 7 months after renal transplant. Reagent C3 convertase was formed by injecting factor B, factor D, and patient-derived IgG (versus normal pooled human IgG as a control) over a C3b-immobilized CM5 chip (Biacore X100) followed by injection of Decay Accelerating Factor (DAF) to remove unstabilized convertase. Nef-stabilized convertases were allowed to dissociate for 3600 minutes. Kinetic data were collected at five time points during dissociation. Data for each clinical time point were normalized to the amount of stabilized convertase at t=0. Serologic biomarker assays were performed as previously described.

Results: Qualitatively, test subject Nef stabilized the convertase 1.32 to 1.44 fold longer than unstabilized convertase. Between sample time point variability at 800s was less than 13%. Nef function correlated with serologic biomarker abnormalities at all 4 samples.

Conclusions: Using a novel assay, we show that Nefs isolated from a test subject remained remarkably stable over a 28-month period. In addition, the stabilizing effect of Nefs on C3 convertase consistently correlated with serologic biomarker abnormalities. We are extending this approach to additional C3G patients with and without recurrence of disease in transplant in order to provide a method for comparing Nefs over time, thereby defining the role of Nef-stabilizing function as an at-risk biomarker for C3G recurrence in transplant.

Funding: NIDDK Support

PO1812

C3 Glomerulopathy Recurrence After Kidney Transplant: A Systematic Review

Oumayma Taroua.[1,2] *[1]Universite Internationale Abulcasis des Sciences de la Sante, Rabat, Morocco; [2]Hopital Universitaire International Cheikh Zaid, Rabat, Morocco*.

Background: C3 glomerulopathy (C3G) is a recently defined entity, characterized by the dysregulation of the complement pathway, leading to deposition of C3 complement in the glomeruli, with no or few immunoglobulin deposits. While it is known that membranoproliferative glomerulopathies carry a risk of recurrence after transplant, no large-scale meta-analysis was done after 2015 to assess the precise recurrence risk and remission duration for C3 glomerulopathies. The goal of this work is to determine if there is currently enough literature specific for C3G to conduct such a metanalysis.

Methods: Our research protocol was guided by the PRISMA protocol, and the Joanna Briggs Institute Critical Appraisal Tools. A search was conducted in 3 databases using a specific search string, at the conclusion of which, 230 papers were found. The identified papers were subsequently screened by the 2 authors independently using precise inclusion and exclusion criteria. The screening resulted in the final inclusion of 6 papers, on which a qualitative synthesis was performed. The information extracted was organized on the basis of demographics, time of transplantation, disease recurrence, and disease-free period post-transplantation.

Results: Among the 6 papers selected, 2 were case series and 4 were case reports. In total, 25 patients were reported as having a recurrence of C3G. The age of the patients ranged between 7 and 60 years of age. Among the 25 patients, 11 of them were male, while 6 of them were females. The C3G subtype was determined for 25 patients, with 16 were classified as having C3GN. and 8 having DDD. The age of transplant was reported for 14 patients, ranging from 11 to 64 years old. The disease-free period between the kidney transplant and the recurrence of the disease ranged from 14 days to 91 months, with 1 case series paper only reported the median time to recurrence in months (59[27-91] for C3GN patients and 41[0-71] for DDD patients).

Conclusions: While C3G, with its 2 subtypes, have been well-defined entities for a decade, our review reveals that little research about the post-transplant evolution and recurrence of these diseases has been done. While extensive research can be found on the recurrence risks of Membranoproliferative Glomerulonephritis, we believe that with the new classification, more data on the new subtypes is necessary to guide the decision-making of clinicians and their patients.

PO1813

C3 Glomerulonephritis: A Rare Complication of Chronic Lymphocytic Leukemia

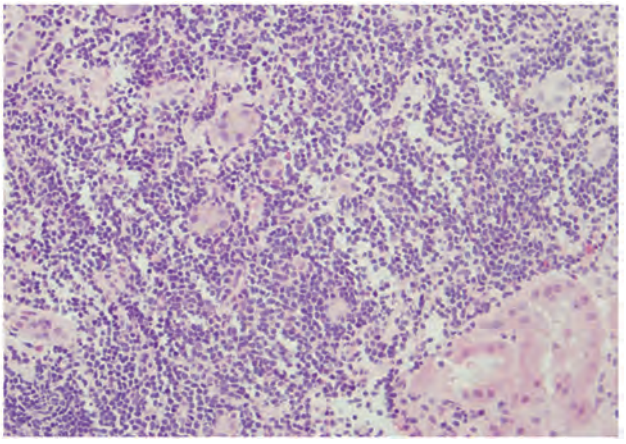
Khaled Srour, Jayanth Lakshmikanth, Chandrika Chitturi, Mark D. Faber. *Henry Ford Hospital, Detroit, MI*.

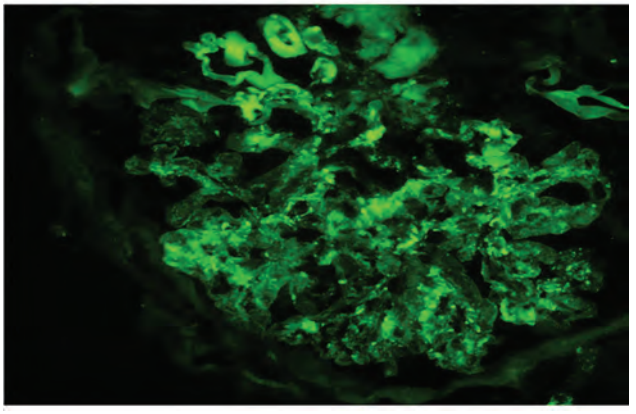
Introduction: Kidney disease develops in chronic lymphocytic leukemia (CLL) patients via multiple mechanisms including infiltration, obstruction, tumor lysis syndrome, and glomerular disease. We present a rare case of C3 glomerulonephritis (C3GN) associated with pulmonary renal syndrome that we believe was an autoimmune manifestation of CLL.

Case Description: A 76 year old male with a 15 year history of SLL/CLL, DVT, HTN, DM and Stage 3 CKD developed SOB and dry cough. At ED presentation he was in respiratory distress with BIPAP resistant hypoxia requiring intubation. Labs included Cr 7.1 mg/dL, K 5.7 mEq/L and uric acid 12.2 mg/dL CXR showed vascular congestion. Prior to developing anuria urine sediment showed RBC casts. Bronchoscopy DAH, consistent with a pulmonary renal syndrome. Patient was started on plasmapheresis, high dose steroids and CRRT. Autoimmune workup including ANA, anti GBM and ANCA was negative. Kidney biopsy showed diffuse proliferative and sclerosing glomerulonephritis with lymphocytic infiltrates consistent with involvement by patient's known CD5+, CD23+ B cell lymphoproliferative disorder. IF showed diffuse C3 staining. Steroids and

plasmapheresis were continued. Renal function improved and dialysis discontinued, with Cr at last follow up 1.9. Chemotherapy for CLL has been ordered. Lymphocytes were negative for CD3, CD10, Bcl6, and cyclin D1; with a MIB1 nuclear proliferation rate within the lymphoid infiltrates less than 5%.

Discussion: We present a case of C3GN and DAH secondary to CLL autoimmune etiology, a rare complication of CLL which usually affects the kidney by infiltration and by toxicity of the CLL treatment. Recent case reports suggest improved outcomes of CLL associated C3GN when CLL is treated.





PO1814

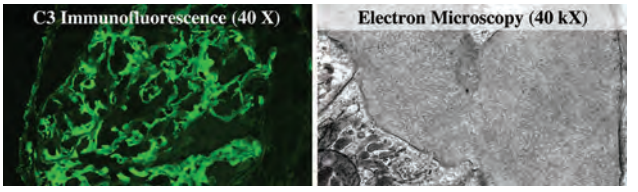
Fibrillary Glomerulonephritis or Complement 3 Glomerulopathy: A Rare Case of Crescentic Glomerulonephritis with C3 Dominant Glomerular Deposition and Positive DNAJB9

Lyle W. Baker,[1] Mahnoor M. Khan,[1] Cherise M. Cortese,[2] Nabeel Aslam.[1]
[1]Mayo Clinic Florida, Department of Nephrology and Hypertension, Jacksonville, FL; [2]Mayo Clinic Florida, Department of Pathology, Jacksonville, FL.

Introduction: Fibrillary glomerulonephritis (FGN) and complement 3 glomerulopathy (C3G) are two rare forms of GN. FGN is diagnosed by electron microscopy (EM) showing randomly oriented fibrils ranging in diameter from 15-25 nm. Immunofluorescence (IF) in FGN typically is IgG-predominant. C3G is diagnosed by isolated C3 (>3+ intensity) or dominant C3 (≥2 orders of intensity from other deposits) on IF. We present a rare case of crescentic GN with dominant C3 glomerular staining–consistent with C3G–but EM findings suggestive of FGN.

Case Description: A 57-year-old female with history of HTN, type 2 DM, questionable SLE (not on therapy), presented with gross hematuria & lower extremity edema. BP 113/71, pulse 88. Creatinine 1.82mg/dL (0.75 two months prior). Urinalysis with 132RBC/hpf & 51WBC/hpf. Urine Prot/Cr 24. Cultures grew mixed flora in urine & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dL, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, hepatitis B & C, and HIV were negative. Kidney biopsy was performed. LM: diffuse necrotizing crescentic (15 of 15) GN, focal areas of double contours. IF: dominant 3+ C3 granular stain of capillary loops, lesser 1+ IgG. Remaining IF stains negative. Testing for alternative complement dysregulation was negative. EM showed fibrillary structures within basement membranes & mesangium (mean diameter 14 nm). DNAJB9 staining was positive. Patient was treated with steroids & cyclophosphamide but became dialysis dependent.

Discussion: FGN is associated with autoimmune disease, dysproteinemia, hepatitis C, & malignancy. Our patient's EM findings & positive DNAJB9 strongly support a diagnosis of FGN likely due to an autoimmune etiology given her prior history and positive ANA, SS-A. However, the patient's IF findings of dominant C3 deposits is atypical for FGN, but rather characteristic of C3G which is caused by complement dysregulation. To the best of our knowledge, this is the first reported case of FGN to show dominant C3 glomerular deposits. Further studies are needed to determine the significance of this finding.



PO1815

A Case with Immunotactoid Glomerulonephritis with Masked Monoclonal Light-Chain Deposition Disease

Merve Postalcioglu.[1,2] *[1]Kent Hospital, Warwick, RI; [2]Brown University Department of Medicine, Providence, RI.*

Introduction: The immunotactoid glomerulonephritis (ITG) is a rare disorder that is characterized by proteinuria, hematuria, hypertension, and kidney failure. Its diagnosis and timely treatment are important in order to decrease morbidity, conserve kidney function, and improve survival.

Case Description: An 82-year old man with a past medical history of uncontrolled hypertension and cerebrovascular disease presented with myalgia, profound weakness and persistent vomiting for 9 days. In the emergency department, his vital signs were significant for blood pressure 220/109 mmHg. BMP revealed creatinine as 3.48 mg/dl, which was 0.9 mg/dl at baseline. The patient was diagnosed with hypertensive urgency and acute kidney injury. Urinalysis showed 107/HPF red blood cells and protein >500 mg/dl. Spot urine albumin/creatinine ratio was 869.9 mg/g. Serum C3 decreased to 29.5 mg/dl (reference: 88-201) and C4 decreased to 2.5 mg/dl (reference: 16-47). Hepatitis B and C were non-reactive. Kidney biopsy was planned and pulse dose steroid, 500 mg IV daily, was prescribed for 3 days. The patient's kidney function continued to worsen and he required hemodialysis. His serum free kappa level elevated to 4.54 mg/dl (reference 0.33-1.54), lambda level was normal 2.54 mg/dl (reference 0.57-2.63), free kappa/lambda ratio elevated to 1.80 (normal 0.26-1.65). Serum immunofixation study showed IgG kappa monoclonal ab without M-spike; urine protein electrophoresis showed elevated protein level with no apparent M-spike. Initially, kidney biopsy suggested proliferative glomerulonephritis with C3 deposits with light-microscopy. However, repeat immunofluorescence was consistent with diffuse proliferative immunotactoid glomerulonephritis with "masked" monoclonal IgG1-kappa deposits. Congo red stain was negative, ruling out amyloidosis. The patient was continued on daily high-dose steroid treatment. He was referred to Hematology/Oncology for bone marrow biopsy for concern of plasma cell neoplasm or lymphoproliferative disorder. Dialysis was discontinued at the time of discharge as patient's kidney function improved with steroid treatment.

Discussion: It is important to keep ITG in the differential diagnosis as high-dose steroid or cyclophosphamide might prevent rapid glomerulonephritis progression. Treatment of underlying disease such as light-chain deposition disease might have some benefit on renal disease.

PO1816

Rare Association of Monoclonal Gammopathy of Renal Significance with Acquired Angiodema

Sasmit Roy,[1,2] Subhasish Bose.[1,2] *[1]Lynchburg General Hospital, Lynchburg, VA; [2]Lynchburg Nephrology Physicians, Lynchburg, VA.*

Introduction: Acquired angioedema(AA) due to deficiency of C1 esterase inhibitor is also abbreviated as C1INH-AAE. This rare syndrome presents with recurrent angioedema episodes, without urticaria, and sometimes is associated with B-cell lymphoproliferative disorders. Kidney involvement is rare with AA. The monoclonal immunoglobulins are secreted by a nonmalignant B-cell or plasma cell clone, causing renal damage representing a group of disorders called monoclonal gammopathy of renal significance (MGRS). We present a rare association of these two entities.

Case Description: 64 year old female patient came to the emergency department with complaints of 2 week duration waxing, waning maculopapular rashes in all extremities, chills, hoarseness of voice and lower extremity swelling. She had no family history of angiodema. Positive examination findings were rashes and bilateral pedal edema. With a normal baseline creatine, admission serum creatine was high at 2.4 mg/dl. Positive laboratory findings were very low complements level (C4> C3), low C1q level, high C1 esterase inhibitor level. Other immunological workup including serum, urine immunoelectrophoresis, kappa lambda ratio, serum immunofixation were normal. Kidney biopsy undertaken revealed monoclonal gammopathy–associated diffuse proliferative glomerulopathy. She responded well to steroids only and is in clinical remission with normal renal function.

Discussion: Paraproteinemia is characterized by clonal proliferation of B-cells and/or plasma cells resulting in overproduction of monoclonal proteins and can cause significant renal dysfunction. Paraprotein-induced renal disease can occur without malignancy, now termed as monoclonal gammopathy of renal significance. MGRS includes a wide spectrum of disorders like light/heavy chain deposition disease, C3 glomerulopathy, proliferative glomerulonephritis with monoclonal immunoglobulin deposition(PGNMID), and primary amyloidosis. MGRS necessitates strict monitoring,

early interventions to prevent renal damage. Acquired angioedema generally presents with head and neck symptoms, mainly swollen upper airways, cheeks, and tongue. AA has low C1q levels unlike hereditary angiodema. Systemic manifestations are far common with AA than hereditary angioedema. No literature has shown an association of MGRS/PGNMID with AA and low complement levels. Further case studies needs to be done to discover any large-scale association of MGRS with AA.

Clinical Biomarker Trend in C3 Glomerulopathy

Monica D. Hall,[1,2] Christopher Culek,[1,2] Yuzhou Zhang,[1] Richard J. Smith,[1,2] Carla M. Nester.[1,2] *[1]Molecular Otolaryngology and Renal Resesarch Laboratories, Iowa City, IA; [2]University of Iowa, Iowa City, IA.*

Background: There is a paucity of data defining the natural history of the clinical and complement biomarker characteristics of C3 Glomerulopathy (C3G) patients. Whether there are disease defining trends and/or relationships between the markers of disease is unknown. In a series of C3G patients, we sought to describe the trend in three commonly available markers of disease: complement C3, urine protein-to-creatinine ratio (UPCR), and GFR. We hypothesized that lower C3 levels, as a reflection of ongoing complement activity would be associated with progressive renal disease as represented by changes in UPCR and/or GFR.

Methods: All patients met the consensus, renal biopsy definition of C3G. Thirty-two native kidney disease subjects with an age ≥ 12 years and GFR ≥ 30 ml/min were included. Trends in C3, UPCR and GFR were monitored in 1-year spans. Ninety spans with matched C3, UPCR and GFR data were identified. Mean and median statistics across all spans were reported as percent change per year and standard regression analyses were used to define the relationship between variables.

Results: 54% of patients retained a C3 within 10 mg/dL of their span entry C3; 86% had a C3 within 25 mg/dL of their entry C3. In only three 1-year spans did a patient start with a low C3 and finish with a normal C3. Mean and median change in GFR per year were a decrease of 4.5% and 2.9% respectively, with the greatest GFR decreases in those spans with the lowest C3. Mean and median change in UPCR per year was a decrease of 8.3% and 10.9%. When considering baseline GFR, baseline UPCR, baseline C3 and change in UPCR, loss of GFR most closely correlated with baseline C3 (Figure, p <0.01).

Conclusions: These data indicate that C3 levels vary little from baseline over a 1 year period and that loss of GFR correlates with baseline C3. These results suggest that treatment approaches that effect an improvement in C3 may have a beneficial effect on GFR.

A Case Series of Proliferative Glomerulonephritis with Monoclonal Immune Deposits

Deepa A. Koshti, Ramesh Saxena. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) comprises B-cell and plasma-cell clonal proliferative disorders that do not require treatment for the clonal disease but produce nephrotoxic monoclonal immunoglobulins (mIg) that elicit a variety of kidney manifestations. One such presentation is proliferative glomerulonephritis associated with monoclonal immune deposits (PGNMID), typically presenting as membranoproliferative glomerulonephritis (MPGN) and non-organized glomerular mIg deposits. We describe 3 unique cases of PGNMID from our institution.

Case Description: Case-1: A 16-year old female presented with abdominal pain, gross hematuria, nephrotic proteinuria, edema and normal renal function. Protein electrophoreses and bone marrow (BM) biopsy were unremarkable. Kidney biopsy showed MPGN with monoclonal IgG3 lambda deposits. She had inadequate response to B or plasma cell targeted therapies but responded very well to multitargeted therapy (mycophenolate+tacrolimus) achieving complete response. Case-2: A 39-year old woman with history of antiphospholipid syndrome and 2 miscarriages developed persistent nephrotic proteinuria after uncomplicated third pregnancy. Kidney biopsy showed membranous glomerulopathy with mesangial hypercellularity and monoclonal IgG3 lambda deposits. BM biopsy and protein electrophoresis were unremarkable. She had partial response to rituximab. She is currently being treated with plasma cell targeted therapy with good response. Case-3: A 28-year old male with nephrotic proteinuria found on routine examination. Further evaluation showed unremarkable BM biopsy and protein immunofixation. Kidney biopsy showed mesangial hypercellularity and monoclonal-IgG1 kappa deposits. He is currently being treated with rituximab.

Discussion: PGNMID is a subset of MGRS with variable histologic pattern and histological features of immune complex glomerulonephritis; however, the immune deposits are monoclonal and are seldom associated with serum M-spike. Our patients were younger than those reported in literature and had variable histologic patterns. None had M spike or clonal B or plasma cells. The response to treatment was variable. Two patients showed no response to B-cell depleting therapy. One patient did not respond to plasma-cell directed therapy, but the other did. The third patient is currently receiving B-cell depleting therapy.

PO1819

Role of SIRT1 in HIV-Associated Kidney Disease

Xuan Wang,[1,2] Weijia Zhang,[1] Paul E. Klotman,[3] Kyung Lee,[1] John C. He.[1,4] *[1]Department of Medicine, Division of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Division of Nephrology, Shanghai General Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [3]Division of Nephrology, Department of Medicine, Baylor College of Medicine, Houston, TX; [4]Renal Section, James J Peter VAMC, Bronx, NY.*

Background: HIV infection of kidney cells can lead to HIV-associated nephropathy (HIVAN) and aggravate the progression of other chronic kidney diseases. Thus, a better understanding of the mechanisms of HIV induced kidney cell injury is needed for effective therapy against HIV-induced kidney disease progression. We previously showed that the acetylation and activation of key inflammatory regulators, NF-κB p65 and STAT3 were increased in HIVAN kidneys. Here, we examined the key role of SIRT1 deacetylase in regulation of NF-κB and STAT3 in HIVAN.

Methods: We analyzed expression of SIRT1 in glomeruli of human and mouse HIVAN kidneys, and then we explore the role of SIRT1 on acetylation of NF-κB p65 and STAT3 and expression of HIV genes by overexpression or knock-down of SIRT1 or using SIRT1 agonist, BF175 in cultured podocytes. In vivo, we examined the effects of SIRT1 on HIVAN progression by administration of BF175 for four weeks and inducible podocyte-specific SIRT1 overexpression in Tg26. We also assessed whether miR34a was associated with SIRT1 expression.

Results: SIRT1 expression was reduced in the glomeruli of human and mouse HIVAN kidneys and that HIV-1 gene expression was associated with reduced SIRT1 expression and increased acetylation of NF-κB p65 and STAT3 in cultured podocytes. Interestingly, SIRT1 overexpression in turn reduced the expression of Nef in podocytes stably expressing the HIV-1 proviral genes, which was associated with the inactivation of NF-κB p65 and reduction in the HIV-1 LTR promoter activity. In vivo, the administration of small molecule SIRT1 agonist BF175 or inducible overexpression of SIRT1 specifically in podocytes markedly attenuated albuminuria and kidney lesions in Tg26 mice. Finally, the reduction in SIRT1 expression by HIV-1 is in part mediated through miR-34a expression.

Conclusions: These findings provide a new mechanism of SIRT1 regulation and its downstream effects in HIV-1 infected kidney cells and indicate that SIRT1/miR-34a are potential drug targets to treat HIV-related kidney disease.

Protein Kinase R Inhibition Ameliorates Tg26 HIV-Associated Nephropathy Mouse Model

Teruhiko Yoshida, Koji Okamoto, Shashi Shrivastav, Jurgen Heymann, Jeffrey B. Kopp. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: HIV-associated nephropathy (HIVAN) has become less common with widespread use of antiretroviral therapy but has not yet disappeared. Double-stranded RNA (dsRNA)-activated protein kinase (PKR) is a sensor for dsRNA in response to viral infection such caused by HIV. We previously reported that APOL1 risk alleles damages podocytes through double-stranded RNA-activated protein kinase (PKR) activation. Thus, we hypothesized that PKR activation could be an activated pathway shared in the pathology of HIV- and APOL1-mediated nephropathies. We tested this hypothesis by investigating whether PKR inhibition would ameliorate HIVAN using the well-established Tg26 mouse model.

Methods: We evaluated the kidney phenotype of Tg26 mice and wild type mice treated with or without the PKR inhibitor (C16) from 6 to 12 weeks of age. We quantified albuminuria after treatment and evaluated kidney pathology after 6-week treatment.

Results: We confirmed the activation of PKR in Tg26 mice kidney by Western blot. We saw a significant decrease in kidney disease development in the PKR inhibitor (C16) treatment group compared to the vehicle control group. Urine albumin/creatinine ratio (mg/gCr; mean [IQR]) was 668 [60-1064] in the treatment Tg26 group and 2564 [1786-5646) in the vehicle control Tg26 group (P=0.026). Kidney pathology showed fewer sclerotic glomeruli and tubular microcystic lesions in the treated Tg26 group than in the vehicle control Tg26 group.

Conclusions: PKR inhibition ameliorated HIVAN phenotype of Tg26 mouse, suggesting that PKR activation contributes to the pathophysiology of HIVAN in this model.

Interleukin 22 Attenuates Renal Tubular Cells Inflammation and Fibrosis Induced by TGF-β1 Through Notch1 Signaling Pathway

Rong Tang. *Xiangya Hospital Central South University, Changsha, China.*

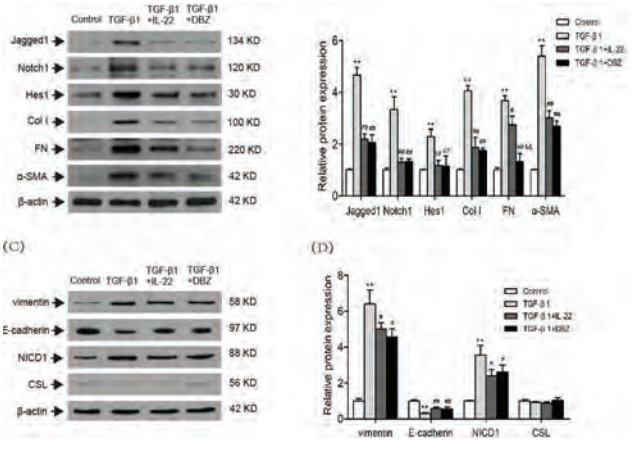
Background: Transforming growth factor-β1 (TGF-β1) is a crucial factor implicated in the development of renal inflammation and tubulointerstitial fibrosis. The cytokine interleukin 22 (IL-22) was previously reported to involve in the pathogenesis of chronic inflammatory diseases In the present study, we aim to investigate the role and mechanisms of IL-22 in renal tubular cells inflammation and fibrosis induced by TGF-β1.

Methods: HK-2 cells were treated with TGF-β1 in the presence of IL-22 or the Notch pathway inhibitor dibenzazepine (DBZ) for 48 h. Cell proliferation was determined by MTT assay, Cytotoxicity was assessed by LDH assay. Collagen I (Col I), fibronectin (FN), α-smooth muscle actin (α-SMA), vimentin and E-Cadherin were detected by western blot, proinflammatory factors (TNF-α, IL-6) and chemokines (MCP-1, RANTES) in the supernatant of cell cultures were evaluated by ELISA. Jagged1, Notch1, NICD1, and Hes1 were also detected by western blot.

Results: In our study, IL-22 (10–40 ng/ml) did not affect cell proliferation and cytotoxicity. Then IL-22 (20 ng/ml) incubation for 48 h was chosen for subsequent experiment. We found TGF-β1 increased the levels of Col I, FN, α-SMA and vimentin in HK-2 cells compared with control, and decreased E-Cadherin level, however, IL-22 restored their expressions partly. IL-22 reduced over expression of proinflammatory factors (TNF-α, IL-6) and chemokines (MCP-1, RANTES) levels induced by TGF-β1, along with down-regulation of Jagged1, Notch, NICD1 and Hes1. Fibrosis and inflammation in renal tubular cells induced by TGF-β1 could be attenuated by IL-22, and the effects were similar to DBZ treatment.

Conclusions: Collectively, our study shows that IL-22 exerts a protective role in renal fibrotic and inflammatory responses induced by TGF-β1 in vitro, which may be through inhibiting Jagged1/Notch1 signaling pathway activation.

Funding: Government Support - Non-U.S.



IL-22 reduced Notch1 pathway activation and fibrosis in HK-2 cells induced by TGF-β1.

Urine Single-Cell RNA Sequencing in Focal Segmental Glomerulosclerosis Reveals Inflammatory Signatures in Immune Cells and Podocytes

Khun Zaw Latt,[1] Jurgen Heymann,[1] Joseph H. Jessee,[1] Avi Z. Rosenberg,[2] Sean Eddy,[3] Teruhiko Yoshida,[1] Yongmei Zhao,[4] Vicky Chen,[4] George W. Nelson,[4] Margaret Cam,[4] Parimal Kumar,[4] Monika Mehta,[4] Michael C. Kelly,[4] Matthias Kretzler,[3] Cheryl A. Winkler,[4] Jeffrey B. Kopp.[1]
[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Johns Hopkins Medicine School of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [3]University of Michigan, Ann Arbor, MI; [4]Frederick National Laboratory for Cancer Research, Frederick, MD.

Background: Individuals with focal segmental glomerulosclerosis (FSGS) typically undergo kidney biopsy only once, which limits the ability to characterize cell populations within kidney over time.

Methods: We used single cell RNA-sequencing (scRNA-seq) to explore disease-related molecular signatures in urine cells of FSGS subjects. We collected 23 urine samples from 12 FSGS subjects, and captured the urine cells using Chromium Single Cell 3' Library & Gel Bead Kit v2 (10x Genomics, Pleasanton, CA). We used Seurat package (v2) for single cell analysis, Harmony for batch correction and SingleR for annotation of cell clusters using Encode and Blueprint data. We also used Monocle2 to characterize the pseudotime trajectory of differentiation of FSGS urine monocytes from healthy peripheral blood monocytes.

Results: Using single cell transcriptomic analysis of 23 urine samples from 12 FSGS subjects, we identified immune cells, predominantly monocytes, and renal epithelial cells, including podocytes. Further analysis revealed two subtypes consistent with M1 monocytes (produce pro-inflammatory cytokines, initiate immune response) and M2 monocytes (participate in tissue repair). Shed podocytes in urine showed high expression of marker genes for epithelial-to-mesenchymal transition (EMT). We selected the 16 most highly expressed genes from urine immune cells and 10 most highly expressed EMT genes from urine podocytes as immune and EMT signatures, respectively. Using transcriptomic data from kidney biopsies from the Nephrotic Syndrome Study Network (NEPTUNE), we found that urine cell immune- and EMT-signature genes were more highly expressed in FSGS biopsies compared to minimal change disease biopsies.

Conclusions: The identification of monocyte subsets and podocyte expression signatures in FSGS subjects' urine samples suggests that urine cell profiling might serve as a diagnostic and prognostic tool in the context of nephrotic syndrome. Further, this approach may aid in the development of novel biomarkers for FSGS and for identifying personalized therapies targeting particular molecular pathways in immune cells and podocytes.

PO1823

Retinal Drusen and Atrophy in Focal and Segmental Glomerulosclerosis: A Complement-Mediated Disease?

Philip A. Harraka,[1] Heather G. Mack,[2,3] Deb J. Colville,[1] David Barit,[1] David Langsford,[1] Timothy J. Pianta,[1] Judith A. Savige.[1] *[1]The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; [2]The University of Melbourne Department of Sugery (Ophthalmology), Melbourne, VIC, Australia; [3]Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia.*

Background: Retinal drusen are small yellow-white deposits typically found in age-related macular degeneration but also with dense deposit disease, lupus nephritis, IgA disease, and membranous and post-streptococcal glomerulonephritis. Drusen and glomerular immune deposits result from complement activation, are similar in composition and share a subepithelial location. Focal and segmental glomerulosclerosis (FSGS) is a heterogeneous clinicopathological entity in which immune deposits comprising IgM and C3 may be seen. This study investigated a cohort of individuals with FSGS for retinal drusen.

Methods: This was a cross-sectional observational case-control study of individuals with FSGS recruited from a general renal clinic in an Australian tertiary-care metropolitan hospital. Previous structural renal disease and glomerulonephritis were noted. Two-field colour fundus images were assessed by two trained graders for drusen count, location and size using the Wisconsin Age-Related Maculopathy Grading Grid. Central drusen counts ≥10 were considered abnormal. Retinal atrophy and pigmentation were recorded by a retinal expert.

Results: Forty-nine individuals with FSGS were compared with 49 matched controls. Mean age was 55 ± 14 years and 29 (59%) were male. One (2%) with FSGS had co-existent structural renal disease, two (4%) had thin basement membrane nephropathy and three (6%) had syndromic FSGS. Twenty-five (51%) had reached end-stage kidney failure, and 16 (33%) had transplants. Central drusen count was 9 ± 25 in FSGS and 3 ± 8 in controls with normal renal function (**p=0.02**). Central drusen counts ≥10 were present in nine patients with FSGS (18%) and four controls (8%) (p=0.23). Seven of these nine (78%) were younger than 60 years which excluded age-related macular degeneration. Medium-sized drusen (>63μm) were more common in FSGS (20, 41%) than controls (10, 20%) (**p=0.048**). Retinal atrophy was present in 9 with FSGS (18%) and no controls (**p=0.003**).

Conclusions: Drusen are more abundant and larger in FSGS than controls. Drusen reflect complement activation and their similarities in composition and subepithelial location with glomerular immune deposits suggests that some of the mechanisms underlying drusen are also relevant to FSGS. Retinal atrophy occurs more often in FSGS and may reflect podocyte loss.

PO1824

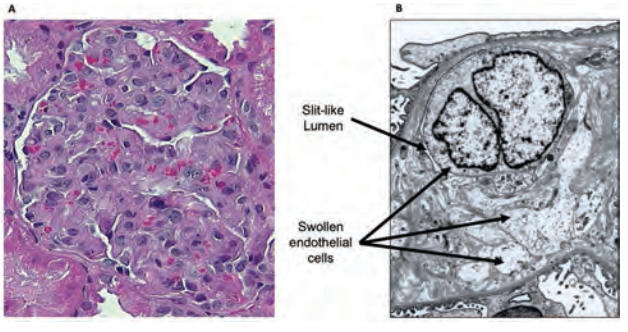
Idiopathic Glomerular Endotheliosis

Sheikh B. Khalid, J. Charles Jennette, Vimal K. Derebail. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Introduction: Glomerular endotheliosis is a form of thrombotic microangiopathy (TMA) seen with preeclampsia, anti-vascular endothelial growth factor (VEGF) therapy for cancer, and some forms of Castleman's disease. We present a case without these usual conditions.

Case Description: A 31-year-old female with rheumatoid arthritis, ulcerative colitis (UC), and hypothyroidism presented with abdominal pain and emesis. Medications included adalimumab and levothyroxine. Abdominal imaging and upper endoscopy were unremarkable. Serum chemistries were initially normal. Pregnancy testing was negative. Abdominal computed tomography showed mild cecal inflammation. Fecal calprotectin was elevated. Oral budesonide was given for suspected UC flare. Symptoms worsened and she was given intravenous methylprednisolone. She developed proteinuria (up to 3.5 gm/day by 24hr urine) and worsening renal function. Serum complement was only mildy reduced - C3 (72) and C4 (10). C-reactive protein and erythrocyte sedimentation rate were elevated. Autoimmune serologies were unremarkable. Serum creatinine peaked at 5 mg/dl prompting hemodialysis. Kidney biopsy demonstrated severe glomerular endotheliosis but no other features of TMA (Figure). Pulse dose steroids were given and then daily prednisone; she had 2 sessions of plasmapheresis (PLEX). Renal function improved, attributed to steroids, and PLEX was held. At 4 weeks, she had only modest proteinuria (1.4 g/24hr) and improved renal function (serum creatinine (0.9 mg/dl).

Discussion: Glomerular endotheliosis is thought to occur due to VEGF inhibition in podocytes (by VEGF-inhibitors or by soluble fms-like tyrosine kinase in preeclampsia). Patients with endotheliosis of unknown cause have been reported to respond to immunosuppression (steroids, cyclophosphamide). Endotheliosis occurs in Castleman's disease and may improve with IL-6 inhibitors. The etiology in our patient remains unknown but she has demonstrated improvement with corticosteroids.



Hematoxylin and eosin (H&E) stain (A) and electron microscopy (B) demonstrating glomerular endothelial cell swelling and loss of capillary lumens.

PO1825

Minimal Change Disease Relapse Following Administration of an Anti-IgE Monoclonal Antibody, Omalizumab

Cliona Cowhig, Vicki K. Sandys, Sinead Stoneman, Colm Magee. *Beaumont Hospital, Dublin, Ireland.*

Introduction: Minimal Change Disease (MCD) is incompletely understood with immune cells, circulating factors, and glomerular basement membrane all considered potential precipitants. We present the first reported case of reactivation of MCD following administration of omalizumab.

Case Description: A 59-year-old lady presented with lower limb oedema two days following a second dose of Omalizumab for treatment of severe eosinophilic asthma. Her background was significant for two previous episodes of biopsy-proven MCD. Exam was significant for bilateral lower limb pitting oedema, a blood pressure of 174/86 mmHg, and proteinuria on urine dipstick. Urine PCR was 473 mg/mmol on presentation with preserved GFR. Treatment for a presumed MCD relapse was commenced with prednisolone and diuresis and omalizumab was discontinued indefinitely. Clinical and biochemical remission was achieved at 2-weeks and maintained at 6-month follow-up.

Discussion: Omalizumab is indicated as add-on therapy in patients with severe persistent allergic asthma, the primary mechanism of which is the binding of the active drug to IgE. The clinical effects of omalizumab are not accounted for solely by IgE antagonism with further immune regulatory effects hypothesised. Notably reduction in IL4, IL13, and IL8 have been described post-treatment. Immune system dysregulation, a hypothesized circulating factor, medications, and atopy are all considered to play a role in development of MCD. Studies have supported an imbalance of T-cell subpopulations and cytokines in MCD. Of note, Th2 cytokines IL4 and IL13 can interact directly with the glomerular basement membrane and are acted upon by omalizumab. In particular IL13 has been described as being related to a nephrotic syndrome in animal studies, and high levels are seen in paediatric nephrotic syndromes, with IL13 levels increasing further in remission. This is the first reported case of MCD in the context of omalizumab administration. IL13 and IL4 appear key to the hypothesised pathophysiology of MCD and mechanism of action of omalizumab. This case provides an insight into the interactions between MCD, atopy, and biologic medications, presenting MCD as a novel complication of omalizumab.

PO1826

Neurorenal Syndrome: Two Cases of Tip-Variant Focal Segmental Glomerulosclerosis Associated with Guillain-Barré Syndrome

Drew Hager, James M. Zacharias, Ian W. Gibson, Jay P. Hingwala. *University of Manitoba College of Medicine, Winnipeg, MB, Canada.*

Introduction: Glomerular disorders have been associated with immune-mediated polyneuropathies in previous case reports. We present two cases of tip-variant focal segmental glomerulosclerosis (FSGS) associated with a variant of Guillain-Barré syndrome (GBS) in Winnipeg, Manitoba.

Case Description: Two previously healthy males aged 62- and 55-years old presented to our hospital with extremity weakness and paresthesias. They each progressed to flaccid paralysis and respiratory failure despite IV immunoglobulin (IVIG) and plasma exchange therapy (PLEX). Initial investigations were consistent with Acute Motor-Sensory Axonal Polyneuropathy (AMSAN), a variant of GBS. Nephrotic syndrome was identified after four months in case one and immediately in case two. Each patient had 20 g/day of proteinuria, preserved renal function, and histologic diagnosis of tip-variant FSGS on renal biopsy. Both cases responded to high-dose corticosteroids initially. Case one relapsed during his taper requiring re-initiation of steroids and addition of mycophenolate mofetil (MMF). He was discharged following thirteen months in hospital with complete remission of proteinuria and ongoing neurologic recovery. Case two achieved complete remission of proteinuria and was discharged after six months with ongoing neurologic recovery.

Discussion: Our cases have similar presentations and responses to therapy suggesting they may share a common circulating autoantibody reacting against shared neural and glomerular podocyte antigens. Circulating autoantibodies including anti-contactin-1 and neurofascin have previously been implicated in chronic inflammatory demyelinating polyneuropathy (CIDP), a chronic variant of GBS. Identifying the culprit immune target in primary FSGS is limited due to the absence of immune complex deposition. The timing of podocytopathy development compared to GBS is highly variable in cases reported throughout the literature. The onset and diagnosis of FSGS in Case 1 was either delayed or unrecognized illustrating the importance of educating clinicians about this neuro-renal syndrome. Although not routinely used in GBS, corticosteroids have led to favorable outcomes in our cases and those reported throughout the literature. Recognition of a co-existing nephrotic syndrome with GBS could significantly change management and impact treatment outcomes.

PO1827

Hemophagocytic Lymphohistiocytosis Presenting as Nephrotic Syndrome

Ghazal Z. Quinn,[1] Michael Triebwasser,[2] David T. Teachey,[2] Matthew Palmer,[1] Abdallah Sassine Geara.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Introduction: Minimal change disease (MCD) is a podocytopathy resulting from systemic T cell dysfunction. Although frequently a primary disease, MCD can be secondary to immune dysregulation in malignancy or autoimmune disease. Hemophagocytic

lymphohistiocytosis (HLH) is a rare syndrome of excess immune activation with poorly understood renal sequelae. Here, we report a rare case of HLH-induced podocyte injury resulting in MCD.

Case Description: A 25-year-old African American male with nine-month history of progressive edema presented with tachycardia, fever and anasarca. Initial evaluation confirmed the diagnosis of nephrotic syndrome with hypoalbuminemia (1.6 g/dl) and proteinuria (15 g/24-hour). Echocardiography showed a pericardial effusion with tamponade treated with pericardiocentesis. Additional testing showed sCr 0.8 mg/dl, hypertriglyceridemia (735 mg/dl), ferritin (817 ng/dl) and EBV viral load of 43,006 copies/ml. Renal biopsy showed normal glomeruli by light microscopy with extensive foot process effacement on electron microscopy. A diagnosis of MCD was made. The patient was treated with steroids and cyclosporine. The patient was readmitted six months later with intermittent fevers, edema, pancytopenia, ferritin >3000 ng/d, hypofibrinogenemia, hepatosplenomegaly and elevated soluble IL-2R. Bone marrow biopsy showed hemophagocytosis. EBV viremia persisted (362,318 copies/ml) and he was diagnosed with chronic active EBV infection with associated HLH. Genetic testing of 15 known HLH associated genes did not identify a pathogenic mutation. HLH was treated with dexamethasone; rituximab was given once but stopped due to lack of CD19+ cells. HLH flared again during dexamethasone wean, prompting treatment with etoposide, then anakinra, without success. He achieved sufficient remission with IFN-gamma blockade with emapalumab-lzsg to undergo stem cell transplant. Three months after transplant, UPCR decreased from 20 g/g at HLH diagnosis to 1 g/g. His eGFR by cystatin C recovered to 46 ml/min/BSA from 10 ml/min/BSA prior to transplant.

Discussion: Virus-induced HLH can result in podocytopathy manifesting as MCD which can have serious sequelae including irreversible renal damage leading to chronic kidney disease, hypertriglyceridemia and pericardial effusion. This nephrotic syndrome can improve with treatment of HLH with immunosuppression or stem cell transplant.

PO1828

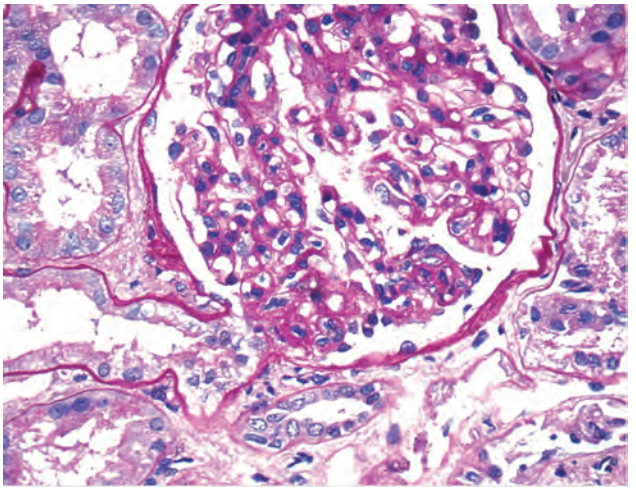
Case of FSGS in a Patient on Pembrolizumab

Shoaib Mansoor,[1] Sharon E. Maynard,[1] Glen S. Markowitz,[2] Henry L. Schairer.[1] *[1]Lehigh Valley Health Network, Allentown, PA; [2]Columbia University, New York, NY.*

Introduction: Pembrolizumab, a humanized antibody directed against human cell surface receptor PD-1 with immune check point inhibitory and antineoplastic activities, has been reported to cause minimal change disease (MCD). Here we report a case of focal segmental glomerulosclerosis (FSGS) glomerular tip lesion (GTL) in a patient on pembrolizumab.

Case Description: A 55 year old man with a history of HTN, ex-smoker, and bladder cancer in 2014, presented with leg edema and raised creatinine. His bladder cancer was treated with cystoprostatectomy. Chemotherapy included methotrexate, vinblastine, doxorubicin, and cisplatin (2015), pembrolizumab and epacadostat (7/2016-5/2018) and guadecitabine and atezolizumab (6/2018-12/2018). Pembrolizumab was given again Dec 2018-July 2019. On physical examination he had 3+ edema up to his knees. Labs showed creatinine 1.4 mg/dl (baseline 1.0 mg/dl). Urinalysis showed proteinuria without hematuria. Urine protein excretion was 19.5 g/day. Kidney biopsy showed 8 out of 24 glomeruli were globally sclerotic. Of the remaining 16 glomeruli, 4 displayed cellular lesions of FSGS and one glomerular tip lesion (GTL). There was GBM duplication and focal endothelial swelling, suggestive of mild endothelial injury (i.e. thrombotic microangiopathy).

Discussion: Glomerular tip lesion (GTL) is a prognostically favorable variant of FSGS with presenting features intermediate between FSGS and MCD. There are reports of MCD with pembrolizumab but no reports of GTL. Given the clinical presentation and similarities between MCD and GTL, it is likely that pembrolizumab contributed to the development of GTL in this case. His FSGS was treated with steroids and pembrolizumab was withheld. His proteinuria started to improve and renal function stabilized.



Glomerular Tip Lesion of FSGS

PO1829

Collapsing Glomerulopathy in Mixed Connective Tissue Disease: Case Report

Mohammad Atari,[1] Josephine M. Ambruzs,[2] Talal Nakkar,[1] Moh'd Sharshir,[1] Osaid Saqqa,[1] Eric E. Simon.[1] *[1]Tulane University School of Medicine, New Orleans, LA; [2]arkana laboratory, Little Rock, AR.*

Introduction: Collapsing glomerulopathy (CG) is a form of podocytopathy with segmental or global wrinkling and collapse of capillary walls and overlying epithelial cell proliferation but may be distinct from other forms of focal and segmental glomerular sclerosis (FSGS). CG may be idiopathic or associated with infections, autoimmune diseases, malignancies, genetic diseases, certain drugs and in post-transplant setting. Although CG has been reported in lupus nephritis, it was rarely reported in the setting of mixed connective tissue disease (MCTD).

Case Description: A 30 y/o African American male with a history of muscle aches, nontraumatic rhabdomyolysis, evanescent skin rashes and weight loss was found to have a creatinine of 5.1 mg/dl (1.4 1 year earlier) with urine protein/creatinine ratio (uPCR) of 10,136 mg/g. CPK was 1697 U, erythrocytes sedimentation rate > 120, a positive speckled ANA of 1:640, positive anti-SSA 5.9, anti-chromatin >8, anti-sm 7.2, anti-sm RNP >8, anti-RNP >8. Kidney biopsy showed mesangial immune complex deposition, collapsing glomerulopathy and diffuse podocytopathy, immunofluorescence showed global mesangial IgG staining (3+), IgM (1+), C3 (2+), and kappa (2-3+) and lambda (3+) light chains. Electron microscopy revealed several mesangial electron-dense deposits with mild increase in mesangial matrix and hypercellularity and severe epithelial foot processes effacement without glomerular or tubular basement membrane deposits. Muscle biopsy confirmed the diagnosis of dermatomyositis. The patient was treated with pulse methylprednisolone 1 gm IV for three days followed by prolonged prednisone taper. Later, MMF was started at 500 mg bid, lisinopril 40 mg daily, hydroxychloroquine 200 mg bid and bumetanide 2 mg bid. By 4 months creatinine had stabilized at 2.6 mg/dl, uPCR was 1,824 mg/g, and CPK was 55 U.

Discussion: Here we describe a case of collapsing glomerulopathy in the setting of MCTD (SLE and dermatomyositis), with at least partial response to high dose prednisone for 16 weeks, hydroxychloroquine and late initiation of MMF. CG can present in association with autoimmune diseases including but not limited to SLE. This case represents the second such as this case of CG in the setting of MCTD and is notable for its response to immunosuppressive therapy.

PO1830

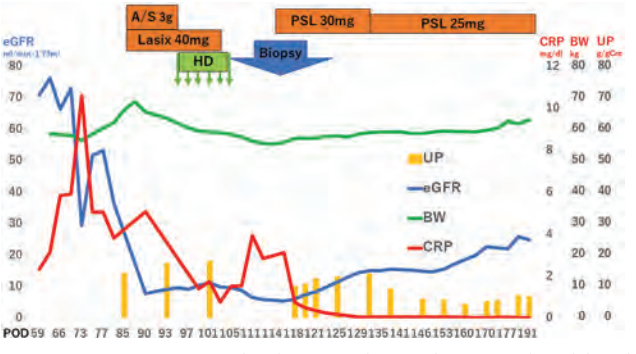
A Case of AKI with Nephrotic Syndrome After Intraperitoneal Infection with Methicillin-Sensitive *Staphylococcus aureus* (MSSA)

Issei Okunaga, Shinichi Makino, Masashi Aizawa, Katsuhiko Asanuma. *Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan.*

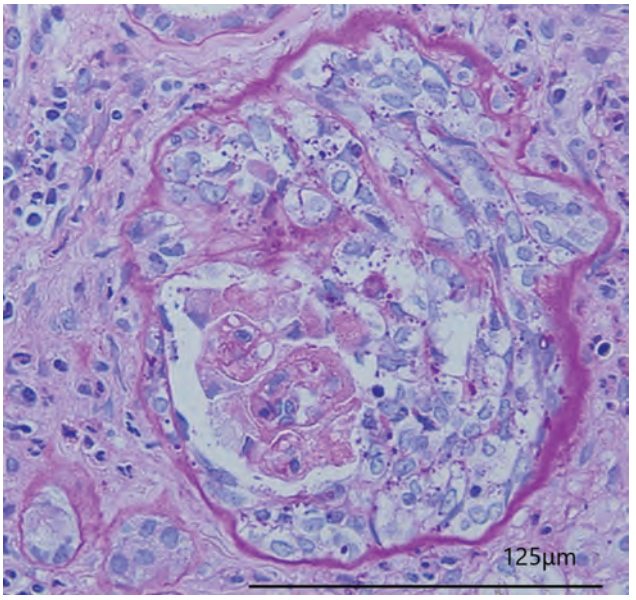
Introduction: Postinfectious glomerulonephritis (PIGN) causes acute nephritic syndrome complicated with urinary protein and hematuria after infection but rarely leads to nephrotic syndrome. The effectiveness of steroid for PIGN has been reported, but still controversial. We report a case of refractory nephrotic syndrome caused by PIGN treated with steroid.

Case Description: A 78-year-old man presenting with nausea and dizziness was admitted. He had pancreatectomy for intraductal papillary mucinous tumor two months before. He was diagnosed as postoperative pancreatic fistula with intraperitoneal infection caused by MSSA. During treatment for the infection, he presented acute kidney injury with nephrotic range proteinuria and hematuria, and required hemodialysis. Renal biopsy revealed diffuse endocapillary proliferative glomerulonephritis with cellular crescents. He was diagnosed as nephrotic syndrome caused by PIGN after intraperitoneal infection with MSSA. Since renal failure was persistent despite infection resolution, he started steroid treatment, lead to improve kidney injury.

Discussion: Antibacterial treatment is important for treatment of PIGN, but if the improvement is still poor, steroid treatment may be effective.



Treatment coursePOD: Postoperative day, UP: Urine protein, BW: Body waight, A/S: Ampicillin sulbactam, HD: Hemodialysis, PSL : Prednisolone



PAS stain: Diffuse endocapillary proliferative glomerulonephritis with cellular crescents

PO1831

Mitochondrial Injury May Be a Ubiquitous Finding in the Pathogenesis of Various Glomerulonephritis

Byung chul Yu, Moo Yong Park, Soo Jeong Choi, Jin kuk Kim, Seung D. Hwang. *Division of Nephrology, Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Gyeonggi-do, Republic of Korea.*

Background: Previous study showed that mitochondrial injury is associated with IgA nephropathy (IgAN). It is not clear whether mitochondrial injury is a unique finding in IgAN or a ubiquitous finding in various glomerulonephtiris (GN). To clarify this, we analyzed urinary mitochondrial DNA (mtDNA) levels and expression of the stimulator of interferon genes (STING) pathway activated by mtDNA leakage in various GN.

Methods: We prospectively enrolled age-sex matched healthy volunteers (HV) and biopsy-proven IgAN, minimal change disease (MCD), acute tubulointerstitial nephritis (ATIN), and minor glomerular abnormalities (MGA) (n=30, 8, 10, and 7 each, respectively). Urinary copy number of the mtDNA genes cytochrome-c oxidase-3 (COX3) and nicotinamide adenine dinucleotide dehydrogenase subunit-1 (ND1) were measured by quantitative polymerase chain reaction. We analyzed STING expression in prostatic cancer specimen as control and kidney tissues obtained from each GN patients by immunohistochemistry staining.

Results: $\log_{10}$ND1/nDNA and $\log_{10}$COX3/nDNA were significantly higher in IgAN ($p<0.001$, $p=0.002$), MCD ($p<0.001$, both), ATIN ($p<0.001$, both), and MGA ($p<0.001$, both) compared with HV (Figure 1). Although there was a difference in signal intensity and site of kidney structures, positive staining for STING was observed in the kidney tissue of each GN patients. Characteristically, STING was strongly stained in the tubulointerstitium for ATIN and in the distal tubule for MGA (Figure 2).

Conclusions: Elevated urinary mtDNA copy numbers and STING activation were observed in various GN. These results suggest that mitochondrial injury would be a ubiquitous finding in the pathogenesis of various GN.

Funding: Government Support - Non-U.S.

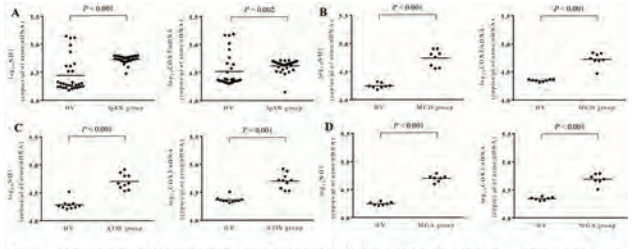


Figure 1. Urinary mitochondrial DNA copy number of patients with IgAN (A), MCD (B), ATIN (C), MGA (D), and HV. Data were analyzed by Mann-Whitney test. ATIN, acute tubulointerstitial nephritis; COX3, cytochrome-c oxidase-3; HV, healthy volunteers; IgAN, IgA nephropathy; MCD, minimal change disease; MGA, minor glomerular nephritis; ND1, nicotinamide adenine dinucleotide dehydrogenase subunit-1.

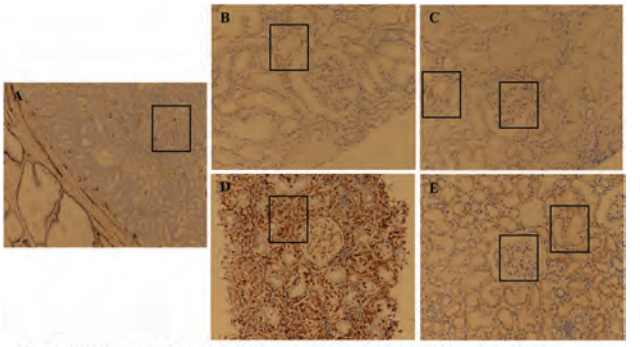

Figure 2. STING expression in prostatic cancer tumor specimen as control and kidney tissues in various glomerulonephritis. All images were captured at 40x magnification. Prostatic cancer tumor (A) and kidney tissues in patient with IgA nephropathy (B), minimal change disease (C), acute tubulointerstitial nephritis (D), and minor glomerular abnormalities (E) were stained for STING expression by immunohistochemistry staining.

Single-Cell Transcriptomic Profiling Reveals Aberrant Signaling Responses to Tfh Cytokines in IgA_1-Secreting Cells from IgA Nephropathy Patients

Colin Reily,[1] Shigeaki Nakazawa,[2] Masakazu Kamata,[1] David K. Crossman,[1] Dana Rizk,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Departments of Medicine, Microbiology and Genetics, Birmingham, AL; [2]Osaka University Graduate School of Medicine, Department of Urology, Osaka, Japan.*

Background: IgA nephropathy (IgAN), a common primary glomerulonephritis, is characterized by glomerular IgA1 immunodeposits enriched for galactose-deficient IgA1 (Gd-IgA1). These immunodeposits are likely derived from Gd-IgA1-containing immune complexes that are elevated in the circulation of IgAN patients. Gd-IgA1 is produced by IgA1-secreting cells due to abnormal expression of several glycosyltransferases in IgAN. Furthermore, some cytokines can enhance production of Gd-IgA1 by IgA1-secreting cells from IgAN patients but not those from healthy controls. We hypothesize that pro-inflammatory factors, such as those identified by GWAS or produced during episodes of synpharyngitic hematuria in IgAN patients, may further dysregulate IgA1-secreting cells and lead to enhanced Gd-IgA1 production.

Methods: As an experimental model, we used T-follicular helper (Tfh) cell-derived cytokines (IL-4, IL-6, IL-21, CD40L) to stimulate for 30 min immortalized Ig-producing cells derived from peripheral blood of IgAN patients and healthy controls. Then, single-cell transcriptomic analysis was performed. IgA1 splice variants were integrated into the hg38 reference genome to identify IgA1-secreting cells and the data analyzed using Seurat and Alteryx workflow. siRNA knock-down (k/d) was used to confirm involvement of candidate regulatory elements in cytokine-mediated overproduction of Gd-IgA1. Production of Gd-IgA1 was assessed after 72 h.

Results: Single-cell transcriptomics identified discrete populations of IgA1-secreting cells with differential*C1GALT1*expression after Tfh-cytokine stimulation. Furthermore, these subpopulations exhibited reduced expression of cytokine-signaling regulatory elements, *SOCS3*,*SOCS1*, *PTPN2*, and *PTPN11*($p = 0.07, 0.04, 0.02, 0.07$), indicating dysregulation of cytokine-signaling JAK/STAT pathways in IgAN-derived cells. Involvement of SOCS3 in Gd-IgA1 production was further supported by the observation that *SOCS3*siRNA k/d increased Gd-IgA1 production in healthy-control cells ($p = 0.01$).

Conclusions: Single-cell transcriptomics with stratification of IgA1-secreting cells based on *C1GALT1*expression and siRNA k/d experiments revealed that aberrant regulation of Tfh cytokine signaling was associated with enhanced Gd-IgA1 production in IgAN.

The NefIgArd trial: The Effect of Nefecon® (Budesonide) in Patients with Primary IgA Nephropathy at Risk of Developing ESRD

Jonathan Barratt,[1] Jens Kristensen,[2] Andrew M. Stone.[2] *[1]Mayer IgA Nephropathy Laboratory, University of Leicester, UK, Leicester, United Kingdom; [2]Calliditas Therapeutics AB, Stockholm, Sweden.*

Background: The gut-associated lymphoid tissue (GALT) has been identified as the potential source of poorly *O*-galactosylated immunoglobulin A (IgA) 1 that triggers the formation of nephritogenic immune complexes in IgA nephropathy (IgAN). The NEFIGAN trial (NCT01738035), which assessed the safety and efficacy of a novel targeted-release formulation of budesonide (NEFECON®), highlighted the potential of selectively targeting GALT in patients with IgAN. After 9 months' treatment, urine protein–creatinine ratio (UPCR) was reduced by 29.3% in the NEFECON® 16 mg/day group vs placebo. Estimated glomerular filtration rate (eGFR) decreased by 4.7 ml/min/1.73 m^2 in the placebo group, but with no deterioration seen with NEFECON® 16 mg/day. The incidence of patient-reported adverse events was similar in all groups. Based on these data, the phase 3 NefIgArd study was designed to assess the efficacy and safety of NEFECON® 16 mg/day in patients with IgAN at risk of end-stage renal disease.

Methods: NefIgArd is a randomized, double-blind, placebo-controlled trial with two parts, recruiting a total of 360 patients across 150 nephrology clinics in 20 countries. Patients must be aged ≥18 years with biopsy-confirmed primary IgAN, proteinuria >1 g/24 h and eGFR 35–90 ml/min/1.73 m² (CKD-EPI) despite optimized renin–angiotensin system blockade. Part A of the study, comprising the first 200 dosed patients, will form the basis for submission for accelerated/conditional regulatory approval to the FDA and EMA. The primary outcome will assess the effect of NEFECON® 16 mg/day on UPCR at 9 months vs placebo, consistent with the 2019 Kidney Health Initiative White Paper "Proteinuria Reduction as a Surrogate End Point in Trials of IgA Nephropathy". Part B is a post-approval confirmatory trial to validate the surrogacy of the Part A UPCR endpoint. For this purpose, and based on the 2018 NKF/FDA/EMA workshop supporting eGFR slope as an endpoint for full approval, the primary outcome will assess the effect of NEFECON® on a 2-year eGFR-based endpoint vs placebo.

Results: In 2019 the 200 patients needed for Part A were randomized, with top-line data expected in Q4 2020.

Conclusions: Randomization will continue until 360 patients are reached for Part B, which is expected to report in 2022.

Effect of Hydroxychloroquine in Patients with IgA Nephropathy with Insufficient Responses to Immunosuppressive Therapy: A Retrospective Case-Control Study

Chen Tang, Jicheng Lv, Sufang Shi, Yuqing Chen, Lijun Liu, Hong Zhang. *Peking University First Hospital, Beijing, China.*

Background: Hydroxychloroquine, a well-known immunomodulator, has recently been used in IgA nephropathy (IgAN) due to its antiproteinuric effects. We aimed to verify the effect of HCQ in patients with IgAN whose proteinuria remained above 1 g/d after conventional immunosuppressive (IS) therapy

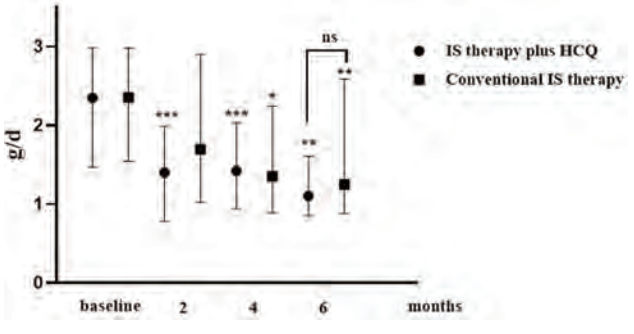
Methods: This was a retrospective case-control study. Twenty-six patients with IgAN who received HCQ and had insufficient responses to IS therapy (corticosteroid (CS) therapy with/without IS agents) were included. 26 matched historical controls who received conventional IS therapy were selected by propensity score matching. The clinical data from 6 months were compared

Results: Proteinuria at baseline was comparable between the "IS therapy plus HCQ" and "conventional IS therapy" groups (2.35 [interquartile range (IQR), 1.47, 2.98] vs. 2.35 [IQR, 1.54, 2.98] g/d, p=0.920). There was a significant reduction in proteinuria in patients with IgAN with HCQ treatment (2.35 [IQR, 1.47, 2.98] vs. 1.10 [IQR, 0.85, 1.61] g/d, p=0.002). The percent reduction in proteinuria at 6 months was similar between the two groups (-39.81% [-66.26, -12.37] vs. -31.99% [-67.08, -9.14], p = 0.968). The cumulative frequency of patients with a 50% reduction in proteinuria during the study was also comparable between the two groups (53.8% vs. 57.7%, p= 0.780). No serious adverse events were observed during the study

Conclusions: HCQ could further reduce proteinuria in patients with IgAN who had insufficient responses to conventional IS therapy

Proteinuria of enrolled patients

	IS therapy plus HCQ N=26	Conventional IS therapy N=26	P-value
Proteinuria level before IS therapy (g/d)	2.52(1.66,5.60)	2.27(1.54,4.36)	0.727
Baseline Proteinuria (g/d)	2.35(1.47,2.98)	2.35(1.54,2.98)	0.920
Proteinuria at months 6(g/d)	1.10(0.85,1.61)	1.24(0.87,2.58)	0.312



Proteinuria of patients during the follow-up. The dots represent the median value, the bars represent the 25th and 75th percentiles. Each Month's was compared with "Baseline" respectively. * p < 0.05; ** p < 0.01; *** p < 0.001

IgA Nephropathy Study: A Multicentric Study in Portugal

Sofia Santos,[1] Jorge Malheiro,[1] Ana Marta Gomes.[2] Grupo de Estudo da Nefropatia de IgA e Nefropatia Membranosa em Portugal (ENIGAM), Sociedade Portuguesa de Nefrologia, Portugal *[1]Centro Hospitalar Universitario do Porto EPE, Porto, Portugal; [2]Centro Hospitalar de Gaia / Espinho, Gaia, Portugal.*

Background: In the last decade, an attempt to correlate the histopathological lesions with renal prognosis in IgA Nephropathy (IgAN) was developed in order to identify patients that benefit from IS therapy.

Methods: A multicentric, longitudinal and retrospective (2007-2019) study was developed in Portugal: adult patients with histological diagnosis of IgAN. Biopsy date defined study entrance and data was collected.

Results: 167 patients were analyzed. The coorte was divided in 2, according the use of steroid therapy: 105 in group of no steroids (noCST) and 62 in the group with steroids (wCST). Endocapillary hypercellularity (29% vs 16%, p=0.049) and crescents 34% vs 10%, p<0.001), were significantly more frequent is wCST group. Median time until the beginning of steroids was 55 days (IQR 7-251), and tmedian duration was 195 days (IQR 96-239). Follow up time was 39 months (IQR 15.1-65.8), significantly superior in wCST group (56.6 vs 29.8 months, p=0.004). No difference between groups considering infections, AKI, CV disease or death. Renal survival at 7 years was 70% at noCST group and 85% at wCST group, p=0.184. Multivariable analysis identified HT (OR 3.81), proteinuria (OR 2.80) and crescents (OR 2.72) as significant factors associated with steroids use. Table 1 defines the independent predictors for ESRD (Cox regression analysis). When we analyze the steroids effect on renal survival, we saw that the average time until renal replacement therapy (RRT) was 47.7 months (IQR 34.6-60.7) in noCST group and 81.6 months (IQR 63.8-99.3) in wCST group. The average treatment effect with steroids was 33.9 months (11.9-55.9, p=0.002), that means that if we treat all, this was the time that we could delay beginning of RRT.

Conclusions: In this group of patients, use of steroids was an independent predictor for delaying CKD progression and the beginning of RRT. HT, degree of proteinuria and crescents presence were significant predictors for its use. In spite of the controversy about the use of steroids therapy in IgAN, this study showed their effectiveness without risk increase.

	HR (95% CI)	P
Steroids	0.318 (0.120-0.842)	0.021

PO1836

Corticosteroid Therapy Improves Renal Prognosis in IgAN Patients with Crescent

Keiichi Matsuzaki,[1,2] Hitoshi Suzuki,[2,3] Takumi Imai,[4] Rei Aida,[5] Sean Barbour,[7] Daniel C. Cattran,[6] Ritsuko Katafuchi,[8] Yusuke Suzuki.[2] *[1]Kyoto University Health Service, Kyoto, Japan; [2]Juntendo University Faculty of Medicine, Tokyo, Japan; [3]Juntendo University Urayasu Hospital, Urayasu, Japan; [4]Osaka City University Graduate School of Medicine, Osaka, Japan; [5]Graduate school of medicine Kyoto University, Kyoto, Japan; [6]Toronto General Hospital, Toronto, ON, Canada; [7]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [8]National Hospital Organization Fukuoka HIgashi Medical Center, Fukuoka, Japan.*

Background: IgA nephropathy (IgAN) has been identified as having an inflammatory basis leading to the biological rationale of immunosuppressive therapy. However, little is known about the clinical indication of immunosuppressive therapy related to each histological finding. Recently, Haas et al reported that the crescent lesion is an independent predictor for renal survival in IgAN especially with no immunosuppressive therapy. We assessed the effect of corticosteroid therapy on renal survival of IgAN with crescent based on the Japanese dataset used in the recently published IgAN prediction tool from multinational multi-ethnic cohort (Barbour SJ, JAMA Intern Med. 2019), given it was almost all corticosteroids.

Methods: We extracted the 566 Japanese adults with biopsy-proven IgAN patients (male 45.9%, median age 34.7) from original cohort. Baseline characteristics were evaluated at the biopsy, and clinical data including serum creatinine, urinary findings, use of RAS blockers (RASB) and corticosteroid therapy and tonsillectomy were collected at every visit. The outcome was defined as 50% decline in eGFR or end-stage kidney disease. Cox proportional hazard models were used to investigate the association between corticosteroid therapy and renal survival with adjustments of confounders including the Oxford classification. Treatment options were included in the model as time-dependent covariates.

Results: At biopsy, median eGFR and proteinuria and proportions of the patients with crescent were 73.2ml/min/1.73m², 0.67g/day, and 59.9%, respectively. During a median follow-up of 3.79 years, 57 patients (10.1%) reached the outcome. RASB and corticosteroid were used in 377 patients (66.6%) and 368 patients (65.0%), respectively. 241 (42.6%) patients were performed tonsillectomy. Hazard ratio (HR) of corticosteroid

therapy was reversed by presence of crescent (no crescent: HR 1.75 95% confidence interval [CI] 0.72-4.23, presence of crescent: HR 0.26 95%CI 0.11-0.61), indicating the interaction between corticosteroid therapy and presence of crescent (p<0.001). Tonsillectomy had also a favorable effect on renal survival (HR 0.43 95%CI 0.20-0.91).

Conclusions: Present findings revealed that corticosteroid therapy improved renal survival in Japanese IgAN patients with crescent and are thus suggestive for the indication of this therapy.

PO1837

Vitamin D Deficiency and Outcome of IgA Nephropathy in North Indian Patients

Naba Farooqui, Soumita Bagchi, Arunkumar Subbiah, Pradeep Chaturvedi, Hem Sati, Dipankar M. Bhowmik, Sanjay K. Agarwal. *All India Institute of Medical Sciences, New Delhi, India*.

Background: Vitamin D has been shown to be beneficial in reducing proteinuria in patients with chronic kidney disease (CKD). IgA Nephropathy (IgAN) is one of the leading causes of CKD in India and worldwide. Asians, especially Indians develop more severe IgAN. We conducted this study to evaluate 25-hydroxy vitamin D (25(OH)D) level as a prognostic marker for disease progression and outcomes in a cohort of Indian patients with IgAN.

Methods: In this retrospective cohort study, demographic and clinical data of Indian adult patients with biopsy proven IgAN, diagnosed between 2015 and 2019, was obtained. Patients with a minimum follow-up of 6 months were included for analysis. A 25-(OH)-vitamin D assay was performed on serum samples collected at the time of kidney biopsy. 25-(OH) D levels <10 ng/mL were considered as deficient.

Results: Of the 105 patients included in the study, 69.5% were males. The mean age was 34.0±10.6 yrs. The mean baseline creatinine and 24 hr proteinuria was 1.37±0.51mg/dL and 3.12±2.45 g/day, respectively. The mean baseline vitamin D levels were 15.88±11.85 ng/mL. 39% patients were 25(OH)D deficient. The median duration of follow up was 23.5 months (range: 6 – 56 mon). Eleven patients (10.5%) progressed to end stage renal disease (ESRD) during follow-up. Vitamin D deficiency was not significantly associated with progression to ESRD (p=0.61) or proteinuria remission (0.83). Risk for ESRD was reduced in patients with lower baseline creatinine levels (p=0.00) and patients on ACE inhibitors (p=0.03). Remission of proteinuria was more common in patients with lower baseline creatinine levels (p=0.006) and normotensive patients (p=0.03). Baseline creatinine (HR = 14.40; 95% CI, 1.02 – 202.15), 24 hr proteinuria (HR = 0.03; 95% CI, 0.00–0.85) and disease remission (HR = 0.01; 95% CI, 0.00–0.32) were predictors of risk for ESRD.

Conclusions: Vitamin D deficiency is common in Indian patients with IgAN. Baseline vitamin D deficiency did not affect outcomes of IgAN.

PO1838

Long-Term Beneficial Effects of Tonsillectomy on Patients with Immunoglobulin A Nephropathy

Takahito Moriyama, Kazunori Karasawa, Yoei Miyabe, Kenichi Akiyama, Norio Hanafusa, Kosaku Nitta. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan*.

Background: Tonsillectomy may treat immunoglobulin (Ig) A nephropathy (IgAN) by reducing the levels of galactose-deficient IgA1. Hence, we aimed to analyze the long-term effects of tonsillectomy as an initial treatment and a treatment at any time in their lives on patients with IgAN.

Methods: In this retrospective cohort analysis, 1147 patients with IgAN were grouped according to whether or not they had undergone tonsillectomy at any time in their lives (Study 1) or within 1 year after renal biopsy (Study 2). The patients who underwent tonsillectomy (T1) and who did not undergo tonsillectomy (T0) were propensity score matched, and the 20-year renal survival rates were evaluated until the serum creatinine level doubled (primary endpoint) and end-stage renal disease was reached (secondary endpoint).

Results: In both studies, the groups' clinical data, histological data according to Oxford classification, and treatments such as immunosuppressants and inhibitors of renin-angiotensin systems were similar after propensity score matching (Study 1, n=179/each group (T1 vs. T0); median age: 31.0 vs. 30.0 years, p=0.53; mean arterial pressure: 90.0 vs. 88.0 mmHg, p=0.72; median eGFR: 76.1 and 79.1 mL/min/1.73m^2, p=0.46; median proteinuria: 0.72 vs. 0.82 g/day, p=0.71) (Study 2: n=143/each group (T1 vs. T0); median age: 30.0 vs. 30.0 years, p=0.414; mean arterial pressure: 86.3 vs. 88.7 mmHg, p=0.56; median eGFR: 81.0 vs. 81.5 mL/min/1.73m^2, p=0.98; median proteinuria: 0.77 vs. 0.62 g/day, p=0.48). In Study 1, the renal survival rates at the primary and secondary endpoints were significantly higher in T1 than in T0 (primary endpoint: 82.1 vs. 63.3%; p=0.002) (secondary endpoint: 98.1 vs. 76.3%; p= 0.002). In Study 2, the renal survival rate at the primary endpoint tended to be higher and the renal survival rate at the secondary endpoint was significantly higher in T1 compared with T0 (primary endpoint: 97.5 vs. 81.5%; p=0.063; secondary endpoint: 98.9 vs. 88.7%; p=0.04). Multivariate Cox regression analyses showed that immunosuppressants and tonsillectomy prevented disease progression (hazard ratio, 0.27; p=0.04). Complications associated with tonsillectomy occurred in 7.8% of the patients.

Conclusions: Among patients with IgAN, tonsillectomy at any time of life or soon after renal biopsy prevents disease progression, and it is relatively safe.

PO1839

Rituximab in IgA Vasculitis with Aggressive Glomerulonephritis: A Real-Life Experience

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *Nephrology and Dialysis Unit & CMID (Center of Research of Immunopathology and Rare Diseases), Coordinating Center of the Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital of Turin, and Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, Turin, Italy*.

Background: IgA-vasculitis (IgAV) is a systemic small vessels vasculitis characterized by deposition of underglycosylated IgA1 immune complexes. Presently, no treatment is specifically recommended in IgAV Glucocorticoids (GC) have been traditionally thought to be effective in tempering systemic symptoms, but did not show long-term benefits either in reducing flares or progression of kidney disease. Recently Rituximab (RTX) has been proved to be effective in a few case series of adults with IgAV. Aim of the study: to evaluate the effectiveness of RTX as first line therapy in induction and maintenance of remission of adults with IgAV with biopsy-proven crescentic glomerulonephritis.

Methods: We reviewed the clinical records of patients (pts) with adult-onset IgAV treated with RTX at our Center. Patients included 8 males and 4 females, mean age 45 years with mean follow-up duration of 31 months. All pts had a biopsy proven IgAV- severe nephritis. Pts received 4 weekly doses of RTX given alone (8 pts) or in combination with CS (4 pts). Disease activity was evaluated by BVAS version 3 at the onset and at 1, 6 and 12 months and at the end of follow up. Complete remission (CR) was defined as BVAS of 0.

Results: Eleven pts (91.7%) achieved a clinical response at 6 months. 10 pts had a CR while 1 pt had a partial response and was given an additional dose of RTX after 12 months from induction due to persistent proteinuria (1gr/24 hrs), despite systemic remission. He achieved a CR 6 months later. One patient did not respond to RTX and was switched to MMF. Among the 10 pts with CR, 1 patient needed maintenance doses of RTX every 6 months due to relapse of palpable purpura; 1 relapsed after 15 months and received a new induction course showing a CR again. Significant decrease in 24-hour proteinuria, BVAS, and CRP level was detected. RTX was generally well tolerated. One patient, who had a CR with RTX alone died after 6 months of follow-up for cardiovascular cause.

Conclusions: This extended experience confirms our initial results supporting the use of RTX in the treatment of IgAV with severe renal involvement. Indeed, RTX proved to be effective and safe for induction and maintenance of long-lasting remission. Present data also suggest that RTX is not only effective for severe and refractory IgAV, but can be also proposed as a first line therapy.

PO1840

External Validation of International IgA Nephropathy Prediction Tool in a Singapore Cohort (EXIST Study)

Ru Sin Lim, Su mein Goh, See Cheng Yeo. *Tan Tock Seng Hospital, Singapore, Singapore*.

Background: IgA Nephropathy (IgAN) is the most common cause of glomerulonephritis worldwide, including in Singapore. Although IgAN may lead to end-stage kidney disease (ESKD), the risk of progressive kidney function decline is extremely heterogeneous; a reliable risk prediction model is important to inform both patients and physicians of renal prognosis and to guide clinical treatment decisions. A newly validated International IgAN prediction tool has been published recently and we aim to externally validate this model in our Singapore cohort.

Methods: We validated the predictive performance of the two full models (with or without race) derived from the International IgAN Prediction Tool study in our IgAN patient dataset over 11 years (Jul 2009 to Oct 2020) using external validation of survival prediction models (Royston and Altman). The discrimination and calibration of the models were tested using the R^2_D measure, C statistics, Akaike Information Criterion (AIC), and calibration plot.

Results: The study included 119 patients; mean age of 43.3 (± 16.66) years; 62 (52.1%) were male; 90 (75.6%) Chinese, 12 (10.1%) Malay, 7 (5.9%) Indian and 10 (8.4%) other ethnicity. Complete case analysis was done with 93 patients. The 5-year risk of the primary outcome (50% reduction in estimated glomerular filtration rate or ESKD) was 15.0%. Oxford T2 histologic score was removed from the full model analysis as the number of observations is low (n=2). The original study reported AIC of 6338 for full model with race, 6379 for full model without race, vs 107.35, and 111.90 respectively in our study. The R^2_D for the full models with and without race when applied to our validation cohort were 39% and 32% respectively, both were similar or better than the R^2_D for the same models applied to the original derivation and validation cohorts (26.3%, 25.3%, and 35.3%, respectively). The C statistics for the full model with race was 0.858 (95% CI, 0.687-1.000), without race was 0.811 (95% CI, 0.599-1.000), comparable to the C statistics from the original derivation and validation analysis. Both full models were well-calibrated in our cohort, with good agreement between predicted and observed risk of the primary outcome at 5 years post-biopsy.

Conclusions: The 2 full models with or without race were shown to be validated in our multi-ethnic Singapore IgAN cohort for predicting disease progression.

PO1841

Associations of Genetic Variants Contributing to Gut Microbiota Composition in IgAN

Jiawei He, Xujie Zhou, Yanna Wang, Lijun Liu, Sufang Shi, Jicheng Lv, Hong Zhang. *Peking University First Hospital, Beijing, China.*

Background: Gut microbiota is observed to be associated with IgAN, as immune response in the gut is assumed to be one of the triggers of its development. And because the microbial composition is heritable, we hypothesize that genetic variants controlling gut microbiota composition may associate with susceptibility to IgAN or clinical phenotypes.

Methods: 175 gut-microbiome-associated genetic variants were retrieved from GWAS Catalog. Genetic associations were examined in 1511 patients with IgAN and 4469 controls. Sub-phenotype associations and microbiome annotations were undertaken for better understanding how genes shaped phenotypes. Likely candidate microbes suggested in genetic associations were validated using 16s rDNA sequencing in 29 patients with IgAN and 20 controls.

Results: Nine genetic variants associated with susceptibility to IgAN (*P* values from 4.13×10^{-2} to 1.39×10^{-3}). The rs1889714-AA/AG risk genotypes associated with higher serum levels of Gd-IgA1 (**A**). Other significant findings included the associations between rs148330122-CC risk genotype and early age of onset (**B**), rs6065904-AA/AG risk genotypes and worse kidney function (**C**), rs9363741-GG/GA risk genotypes and severer hematuria (**D**). Besides, rs1889714-AA/AG risk genotypes associated with decreased abundance of beneficial *Dialister*; whereas rs6065904-AA/AG and rs9363741-GG/GA risk genotypes associated with increased abundance of detrimental *Erysipelotrichaceae* and *Lachnobacterium*, respectively. 16S rDNA sequencing data validated the decreased *Dialister* (**E**), and a tendency of increased *Erysipelotrichaceae* and *Lachnospiraceae* abundance in faeces from IgAN (**F/G**).

Conclusions: Our results provided supporting evidence that gut microbiota in IgAN was affected by host genetics and shed light on candidate bacteria for future pathogenesis studies.

IgA Nephropathy: Quantifying Remission Duration on Clinical Outcome

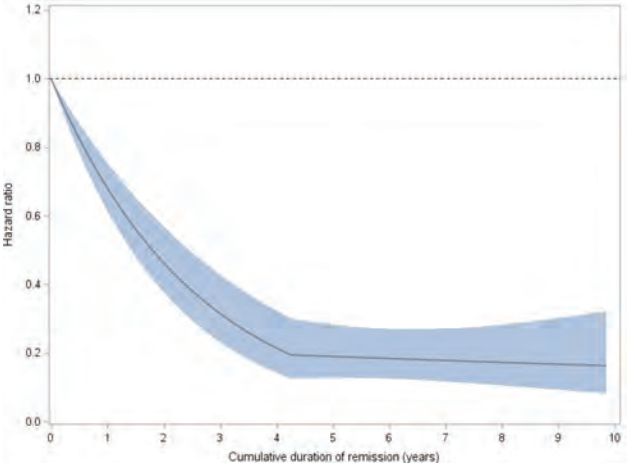
Mark Canney,[1] Sean Barbour,[1] Yuyan Zheng,[2] Rosanna Coppo,[3] Hong Zhang,[4] Zhihong Liu,[5] Keiichi Matsuzaki,[6] Yusuke Suzuki,[6] Ritsuko Katafuchi,[7] Heather N. Reich,[8] Daniel C. Cattran.[8] The International IgA Nephropathy Network *[1]The University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]Fondazione Ricerca Molinette, Torino, Italy; [4]Peking University, Beijing, China; [5]Nanjing University, Nanjing, China; [6]Juntendo University, Bunkyo-ku, Japan; [7]Fukuoka Higashi Medical Center, Koga, Japan; [8]Toronto General Hospital, Toronto, ON, Canada.*

Background: A relative reduction in proteinuria has been proposed as a surrogate outcome for therapeutic trials in IgA nephropathy (IgAN). We sought to quantify the association between duration of proteinuria remission and the risk of disease progression in IgAN.

Methods: In this retrospective international cohort of adult patients with biopsy-proven IgAN, we defined remission based on: (i) a ≥25% reduction in proteinuria from the peak value after biopsy; (ii) an absolute reduction in proteinuria to <1g/day; (iii) peak proteinuria prior to remission ≥1g/day. The total duration of first remission was treated as a time-varying exposure using longitudinal proteinuria measurements. Time-dependent Cox proportional hazards models were used to quantify the association between duration of remission and the primary outcome (ESKD or 50% reduction in eGFR).

Results: Of 1864 patients who entered a first remission, 274 (14.7%) experienced the outcome during median follow-up of 3.9 years. The relationship between duration of proteinuria remission and the primary outcome was non-linear (Figure). Each 3 months in sustained remission up to 51 months was associated with an additional 9% reduction in the risk of disease progression (HR 0.91, 95% CI 0.89-0.93). Each additional 3 months in remission beyond 51 months was associated with a non-significant risk reduction (HR 0.99, 95% CI 0.96-1.03). Results were robust to multivariable adjustment and consistent across subgroups including immunosuppression exposure.

Conclusions: We observed a non-linear dose-response relationship between the duration of proteinuria remission and the risk of disease progression in IgAN. When considering proteinuria as a surrogate outcome, our findings illustrate the need to consider the duration of remission in addition to the magnitude of proteinuria reduction when evaluating the anticipated impact on long-term clinical endpoints.



PO1843

Results of a Phase 1 Trial to Investigate the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of BION-1301 in Healthy Volunteers

Jeannette Lo,[1] Sharon Yavrom,[1] Jessy Fan,[1] Aaron N. Endsley,[2] Tamara Schroeder,[1] Jonathan Barratt,[4] David M. Essayan.[3] *[1]Aduro BioTech Inc, Berkeley, CA; [2]Certara LP, Princeton, NJ; [3]ONCORD, Inc., Westlake Village, CA; [4]University of Leicester, Leicester, United Kingdom.*

Background: IgA nephropathy (IgAN) is an autoimmune disease with no approved treatments[1]. Key steps in IgAN pathogenesis are the production of galactose-deficient IgA1 (Gd-IgA1), the generation of anti-Gd-IgA1 autoantibodies and the formation of immune complexes resulting in kidney inflammation and damage[2]. Patients with IgAN have elevated levels of A proliferation-inducing ligand (APRIL) which regulates B cell differentiation and proliferation[3]. In a study of patients with IgAN, those with high plasma APRIL levels had elevated levels of Gd-IgA1 and proteinuria and lower eGFR[3]. BION-1301, a first-in-class humanized anti-APRIL antibody, was well-tolerated with no dose-limiting toxicities in a Phase 1/2 first-in-human study in multiple myeloma[4]. This 3-part Phase 1 trial characterizes the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of BION-1301 in healthy volunteers (HV) and patients with IgAN.

Methods: (NCT03945318) Parts 1 and 2 are double-blind, randomized, placebo-controlled single and multiple ascending dose studies, respectively. Part 1 enrolled 36 HV in 5 dose cohorts, randomized in a 3:1 ratio to receive a single dose of BION-1301 or placebo delivered by IV infusion. Part 2 enrolled 27 HV in 3 dose cohorts, randomized in a 2:1 ratio to receive 3 doses of BION-1301 or placebo delivered by IV infusion every two weeks. Part 3 assesses a multiple dose regimen in patients with IgAN and is currently enrolling.

Results: BION-1301 was well-tolerated with low incidence of non-neutralizing ADAs in HVs. The PK profile was well behaved with a half-life supporting monthly dosing. Durable target engagement, suppression of IgA and IgM, and to a lesser extent IgG were observed following BION-1301 administration. IgG values remained in normal ranges with no increase of infections post-treatment. Updated data will be presented including B cell immunophenotyping of HVs and results from patients with IgAN, if available.

Conclusions: BION-1301, an anti-APRIL antibody, offers a pharmacodynamic window to exploit IgA suppression while tempering impact to IgG. BION-1301 may provide a novel approach to address the pathophysiology of IgAN.

PO1844

Clinical Significance of Intensity of Galactose-Deficient IgA1 Deposition in Patients with IgA Nephropathy

Maiko Nakayama,[1] Hitoshi Suzuki,[1,2] Yusuke Fukao,[1] Mingfeng Lee,[1] Toshiki Kano,[1] Yuko Makita,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) have a crucial role in the pathogenesis of IgA nephropathy (IgAN). It was reported that Gd-IgA1 specifically deposit on glomeruli of primary IgAN using Gd-IgA1-specific monoclonal antibody (KM55 mAb). However, the association between intensity of Gd-IgA1 deposition and histological severity and clinical parameters are not clear.

Methods: We performed immunostaining with anti-IgA and KM55 mAbs in 74 patients who were diagnosed as IgAN at Juntendo University Hospital. We quantified the intensity of glomerular Gd-IgA1 by Image J software, and analyzed its association with histological findings. We also analyzed the association of intensity of glomerular Gd-IgA1 with serum levels of Gd-IgA1 and creatinine, urinary Gd-IgA1 and proteinuria.

Results: Glomerular Gd-IgA1 was positive in all 74 primary IgAN cases, we divided into high-intensity (n=45) and low-intensity groups (n=29) by Image J software. In the Gd-IgA1 high-intensity group, acute lesions such as cellular crescents are dominant compared with low-intensity group ($P=0.01$). Moreover, the levels of proteinuria and urinary Gd-IgA1 were significantly high compared with Gd-IgA1 low-intensity group ($P<0.05$). Next, we analyzed the pathogenic significance of merge ratio of glomerular IgA and Gd-IgA1. Interestingly, levels of proteinuria and urinary Gd-IgA1 were correlated with high merge ratio of glomerular IgA and Gd-IgA1.

Conclusions: Present study suggested that high intensity of glomerular Gd-IgA1 deposition is associated with histological severity, especially acute lesions. Moreover, levels of proteinuria were correlated with high merge ratio of glomerular IgA and Gd-IgA1. Thus, glomerular Gd-IgA1 staining may be considerable index for therapeutic intervention.

PO1845

Glomerular Galactose-Deficient IgA_1 Expression Analysis in Pediatric Patients with Glomerular Diseases

Shinya Ishiko,[1] Kandai Nozu,[1] Rika Fujimaru,[5] Yuko Shima,[2] Hiroshi Kaito,[6] Ryojiro Tanaka,[6] Shingo Ishimori,[4] Yuya Aoto,[1] Nana Sakakibara,[1] China Nagano,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Takeshi Ninchoji,[1] Koichi Nakanishi,[3] Norishige Yoshikawa,[4] Kazumoto Iijima.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Wakayama Medical University, Wakayama, Japan; [3]University of Ryukyus, Nishihara, Japan; [4]Takatsuki General Hospital, Takatsuki, Japan; [5]Osaka City General Hospital, Osaka, Japan; [6]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) has been identified as a key molecule in the pathogenesis of IgA nephropathy (IgAN). Using a Gd-IgA1-specific monoclonal antibody (KM55), glomerular Gd-IgA1 deposition has been detected in patients with IgAN and IgA vasculitis with nephritis (IgAV-N), but not other glomerular diseases. However, this specificity is controversial and there are currently no studies in pediatric cases.

Methods: We conducted a retrospective, multicenter study to examine double-immunofluorescence staining of IgA and Gd-IgA1 (KM55) in 60 pediatric patients with various glomerular diseases.

Results: Glomerular Gd-IgA1 deposition was detected in all cases of IgAN (n=17/17) and IgAV-N (n=6/6), and in patients with immunocomplex-mediated glomerulonephritis, including lupus nephritis (n=9/9), membranoproliferative glomerulonephritis (n=3/4), and membranous nephropathy (n=1/1). However, Gd-IgA1 was negative in patients with non-immune related glomerular diseases with IgA deposition, including idiopathic nephrotic syndrome (n=6/6), oligomeganephronia (n=2/2), Alport syndrome (n=1/1), dense deposit disease (n=1/1), and crescentic glomerulonephritis (n=1/1). Both IgA and Gd-IgA1 were negative in patients with idiopathic nephrotic syndrome (n=5/5), membranoproliferative glomerulonephritis, membranous nephropathy, oligomeganephronia, Alport syndrome, C3 glomerulonephritis, poststreptococcal acute glomerulonephritis, and hemolytic uremic syndrome (n=1/1 each).

Conclusions: Gd-IgA1-positivity in patients with IgAN and IgAV-N was consistent with previous reports. However, Gd-IgA1 was also positive in patients with IgA-positive immunocomplex-mediated glomerulonephritis. KM55 may have the potential to distinguish incidental IgA deposition in pediatric cases. We speculate that Gd-IgA1 may be involved in the pathogenesis of these immune-related diseases, or KM55 may recognize IgA-related immunocomplex nonspecifically.

PO1846

Urinary Exosomal MicroRNAs Are Potential Diagnostic and Prognostic Biomarkers in IgA Nephropathy Patients

Kyung hwan Jeong, Jin sug Kim, Hyeon Seok Hwang, Ji Yoon Kong, Shinyeong Kang, Ri Ra, Yang gyun Kim, Ju young Moon, Sangho Lee. *Division of Nephrology, Department of Internal Medicine, College of Medicine, Kyung Hee University, Seoul, Republic of Korea.*

Background: Micro-RNAs (miRNAs) are small non-coding RNA molecules which regulate disease pathophysiology by modulating target gene expression. miRNAs are derived from tissues and biofluids such as serum, saliva, and urine. Recently, emerging evidence suggests urinary exosomal miRNAs as non-invasive biomarkers of various kidney diseases. However, few studies investigated clinical relevance of miRNA in IgA nephropathy (IgAN). In this study, we evaluated urinary exosomal miRNA expression and analyzed its clinical significance in patients with IgAN.

Methods: Urine samples were collected from 93 patients with biopsy-proven IgAN and 14 normal controls. We identified mRNA differential expression of renal tissue between IgAN and normal subjects in the gene expression omnibus dataset, and selected 884 glomerular and 67 tubulointerstitial genes through meta-analysis. We then used the miRTarBase, TargetScan, micorRNA database to predict potential miRNA targets. Finally, 11 urinary exosomal miRNAs were selected. We observed urinary exosomal expression of miRNAs and analyzed their diagnostic and prognostic accuracy for IgAN.

Results: The expression of miR-16-5p, miR-26b-3p, miR-29a-3p, miR-29c-3p, miR-126-3p, miR-199a-3p, miR-615-3p, and miR-29b-3p were significantly upregulated in IgAN patients as compared with normal controls. miR-16-5p, miR-26b-3p, miR-29a-3p, miR-29c-3p, miR-126-3p, miR-199a-3p, and miR-29b-3p have good diagnostic accuracy of IgAN (area under curve of the receiver operating characteristic curve > 0.8). Baseline renal function significantly correlated with miR-16-5p, miR-29a-3p, miR-199a-3p, miR-199b-5p, miR-335-3p, and miR-615-3p. During follow-up period, 43 (46.2%) IgAN patients experienced adverse renal outcomes defined as a greater than 25% reduction in estimated glomerular filtration rate (eGFR), decline in eGFR category from the value determined at the time of renal biopsy, or start renal replacement therapy. miR-16-5p, miR-29a-3p, miR-199a-3p, and miR-335-3p were independently associated with increased risk of adverse renal outcomes.

Conclusions: Urinary exosomal miRNAs might be potential non-invasive biomarkers for diagnosis and prediction of disease progression of IgAN. Further studies are needed to clarify our results and ascertain the underlying mechanisms.

PO1847

Urinary Sediments Could Differentiate the Endocapillary Proliferative Lupus Nephritis and Endocapillary Proliferative IgA Nephrology

Mo Yuan, Ying Tan. *nstitute of Nephrology, Peking University, Beijing, China.*

Background: The role of manual urine sediment examination in the diagnosis and prognostication of endocapillary proliferative glomerulonephritis remains to be elucidated. This study aims to investigated the differences of urinary sediment findings between lupus nephritis and IgA nephropathy with endocapillary proliferative glomerulonephritis and further evaluated associations of leukocyturia with disease activity, pathological features and prognosis.

Methods: The urinary sediment of 126 patients, including 92 patients with lupus nephritis and 34 patients with IgA nephropathy, with a renal biopsy-proven endocapillary proliferative glomerulonephritis were examined in the morning before renal biopsy according to a standardized method. The urinary elements investigated including various cells, casts and crystals. The associations of the level of leukocyturia and disease activity, pathological features and prognosis were further analyzed.

Results: In the patients with endocapillary proliferative glomerulonephritis, normal to mild leukocyturia (≤12/HPF), and moderate to severe leukocyturia (>12/HPF) were found in 52(41.27%) and 74 (58.73%) patients, respectively. The proportion of moderate to severe leukocyturia, the frequency of urinary white blood cells casts and waxy casts were significantly higher in endocapillary proliferative lupus nephritis patients compared with endocapillary proliferative IgA nephropathy patients ($P<0.001$, $P=0.020$, $P=0.010$, respectively). In the proliferative lupus nephritis group, the levels of leukocyturia was significantly correlated with serum creatinine (r=0.288, $P=0.005$), eGFR (r=-0.284, $P= 0.006$), serum C3 (r=-0.275, $P= 0.009$), SLEDAI scores (r=0.383, $P=<0.001$) and glomerular leukocyte infiltration (r=0.285, $P= 0.002$). A multivariate analysis showed that leukocyturia was identified as an independent risk factor for renal outcome in proliferative lupus nephritis (HR: 1.456, 95% CI: 1.083-1.957, $P=0.013$) but not in IgA nephropathy (HR: 1.069, 95% CI: 0.494-2.312, $P=0.866$).

Conclusions: Urinary sediments of the endocapillary proliferative lupus nephritis and endocapillary proliferative IgA nephrology differed in many aspects. Leukocyturia could reflect the disease activity and prognosis of endocapillary proliferative glomerulonephritis, especially in lupus nephritis.

PO1848

A Single-Center Retrospective Study of Thrombotic Microangiopathy

Aulio E. Bustos, Savneek S. Chugh, Sanjeev Gupta, Neha Deval, Firas Jafri, Jagjit Khosla, Vrunda Mangaroliya, Shruti Kore. *Westchester Medical Center Health Network, Valhalla, NY.*

Background: Thrombotic microangiopathies (TMAs) are a rare group of clotting disorders of various origin, including infectious, idiopathic, autoimmune or drug-induced. This group shares common clinical manifestations that include low red blood cell and platelet counts. Although the disease is rare but treatable if clinician is aware about its manifestations. To increase the awareness and understand the disease better we conducted a retrospective study to characterize and assess TMAs in our institution

Methods: An observational retrospective study of patients with a diagnosis of TMA at Westchester Medical Center in the past 5 years was conducted. Data was collected from electronic medical records. Demographic, clinical and therapeutic variables were extracted, tabulated and analyzed

Results: A total of 43 patients with a diagnosis of TMA were identified and included in the study. The cohort had a mean age of 39.9 years; 20 were male and 23 females. As shown in **Table 1**. Thrombotic thrombocytopenia purpura (TTP) (n=14, 32%), systemic lupus erythematosus (SLE) (n=5, 11.6%), and hemolytic uremic syndrome (HUS) (n=5, 11.6%) are the most common etiologies. Other identifiable etiologies were atypical HUS (9%), use of calcineurin inhibitors (9%), acute myeloid leukemia (4.6%). About 6.9% cases didn't have any identifiable cause (6.9%). Patients with TTP had a mean age of 48 years, mean platelet count of 17 k/mm3, and most were female (71%). Fifty-seven percent had hematuria, 21% proteinuria and 85% had schistocytes in the blood smear

Conclusions: Most common cause of thrombotic Microangiopathies is TTP which is what we found in our institution. It is essential to aware about the manifestation of this disease since early recognition and prompt treatment is the key for better outcome

Table 1

Etiology	TTP	SLE	HUS
Number of cases	14	5	5
Mean age, years	48	30	16
Mean platelets count (k/mm3)	17	105.4	53.8
Hematuria, %	57	80	100
Proteinuria, %	21	80	100
Schistocytes, %	85	60	100

TTP, thrombotic thrombocytopenia purpura; SLE, systemic lupus erythematosus; HUS, hemolytic uremic syndrome

PO1849

Changing Prognostic Factors and Sustainability in Thrombotic Microangiopathy Patients: A Need for a Multidisciplinary Team

Miguel Uriol Rivera, Aina Obrador, Joan M. Gasco, Jose Luis Garcia Villa. *Hospital Universitari Son Espases, Palma de Mallorca, Spain.*

Background: Thrombotic microangiopathy (TMA) is associated with a higher risk of dead and chronic renal replacement therapy (CRRT). Eculizumab is highly effective but also expensive. We evaluate the economic burden of the TMA, the cost of CRRT, Eculizumab, and the impact of a multidisciplinary team (MDT) after two years of its implementation.

Methods: It is a retrospective study. We evaluate the risk of i) dead and ii) CRRT need. The cost (euros) for hospitalization at the floor and intensive care unit admission, CRRT and Eculizumab at the pre-MDT implementation (from January 2008 to May 2016) in comparison with the post-MDT period (from May 2018 to Dec 2018). Clinical outcomes: i) risk of death and ii) risk of CRRT need. To determine the cost per patient-year, we calculated the total number of days of hospitalization, the entire months on dialysis or in kidney transplant program (KTx) and the milligrams of Eculizumab used at any period. The total amount divided by the whole years of observation and finally and by the mean number of patients per year diagnosed at any period. The number of patients-year we determined considering the incidence density (ID: cases/1,000,000 person-year). Patients with ADAMTS-13 deficiency were excluded.

Results: Forty-two patients were included. ID increased from 2.3 cases/1,000,000 person-years (n=20) to 11.7 cases/1,000,000 person-year (n=22). Comparing with the pre-MDT period, the number of patients who died increased from 3(15%) to 7(32%), P=0.20; while the risk for CRRT decreased from 9(45%) to 0, P<0.01 [relative risk (95%CI) for no CRRT requirements: 0.55 (0.37 to 0.81)]. One (5%) and three (14%) patients died under futility consideration at the pre- and post-MDT period, respectively (P=0.60). From all the patients who died, only one was in acute dialysis program while 7 showed neurologic damage. The mean cost per patient-year changed from 319,931 to 150,878 euros from the pre- to post-MDT period.

Conclusions: The implementation of an MDT shows a change in the natural history of the disease, where neurological damage emerges as a risk factor associated with mortality instead of CRRT needs. TMA patients represent a remarkable economic burden, representing an essential challenge for the health system sustainability that could be improved by an MDT.

PO1850

Does Kidney Histology Predict Renal Response or Complement Status in Atypical Hemolytic Uremic Syndrome?

Jessamyn S. Carter, Senthil Sukumar, Vedat O. Yildiz, Clarissa A. Cassol, Sergey V. Brodsky, Tibor Nadasdy, Spero R. Cataland, Samir V. Parikh. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Atypical Hemolytic Uremic Syndrome (aHUS) is diagnosed based on clinical evidence of microangiopathic hemolytic anemia, thrombocytopenia and renal failure and histologic evidence of thrombotic microangiopathy (TMA). However, these characteristics are not specific and cannot differentiate aHUS from other causes. Whether specific histologic lesions of TMA can predict complement mutation status (CM +/-), guide treatment, or predict renal outcomes has not been explored. Here, we evaluate the potential of using kidney histology to predict CM status and renal response in aHUS.

Methods: A retrospective analysis of aHUS patients (N=35) who achieved a hematologic response after treatment with anti-C5 therapy was conducted. Clinical and demographic data were recorded and two blinded Nephropathologists scored native kidney biopsy findings independently. Seventeen histologic lesions of TMA were scored. Statistical analysis was performed using SAS version 9.4 (SAS Institute Inc., Cary, NC, USA). Association between morphology scores and CM status (n=29), renal response (n=27) and other categorical characteristics were tested using chi-squared or Fisher's exact test as appropriate. Unpaired t-test was used for continuous variables. Significance level was set at $\alpha \leq 0.05$.

Results: In this cohort, 13/29 (45%) were CM+. Of the 17 histologic variables studied, only glomerular intracapillary fibrin differentiated CM+ from CM- (0% vs 30%, P=0.04). Histologic features were also similar between patients who achieved renal response (RR) and non-responders (NR). Although not statistically significant, NR had a higher percentage of global glomerulosclerosis (38 vs 16%, P=0.07) and concentric fibrous intimal thickening (onion skinning) (70% vs 29%, p=0.08) compared to RR.

Conclusions: Glomerular intracapillary fibrin was the only histologic variable different in CM+ versus CM- TMA. When present, this variable may suggest patients with TMA will be CM-. Percentage of glomerulosclerosis and presence of fibrous intimal thickening was higher in NR compared to RR but this did not reach statistical significance. A larger study is needed to determine the value of these features in predicting complement mutation status and renal response in aHUS.

PO1851

Comparative Efficacy of Ravulizumab and Eculizumab in the Treatment of Atypical Hemolytic Uremic Syndrome: An Indirect Comparison Using Clinical Trial Data

Eric Rondeau,[1] Anthony J. Hatswell,[2] Spero R. Cataland,[3] Peter Chen,[4] Nicholas Freemantle,[5] Karl-Johan Myren,[4] Asa Lommele,[4] Yan Wang,[4] Kevin Deighton,[2] Emma Knowles,[2] Neil S. Sheerin,[6] Ioannis Tomazos.[4] *[1]Hôpital Tenon, APHP and Sorbonne Université, Paris, France; [2]Delta Hat Limited, Nottingham, United Kingdom; [3]Ohio State University, Columbus, OH; [4]Alexion Pharmaceuticals Inc., Boston, MA; [5]University College London, London, United Kingdom; [6]Newcastle University, Newcastle, United Kingdom.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease that can cause organ damage or death if not suitably treated. Eculizumab (ECU), a C5 inhibitor, was approved to treat aHUS in 2011. Ravulizumab (RAV), approved in 2019, was engineered from ECU to reduce dosing frequency (every 8 weeks [for patients weighing ≥20 kg] vs 2 weeks, respectively) and minimise treatment burden. Both drugs have established safety and efficacy via pivotal single armed studies. We indirectly compared the efficacy of RAV vs ECU using clinical trial data.

Methods: Patient-level data from a pivotal RAV trial (NCT02949128) and pivotal ECU trials (NCT00844428, NCT01194973) for adults with aHUS without kidney transplant were used. Propensity scores were calculated based on baseline characteristics (dialysis status, estimated glomerular filtration rate [eGFR], platelet count and serum lactate dehydrogenase), with stabilized inverse probability weighting used to balance groups while preserving sample size. Outcomes were changes in clinical characteristics at 26 weeks, and evaluated between groups using appropriate statistical tests at a 5% significance level.

Results: In all, 85 patients (46 RAV, 39 ECU) were included for analysis. Baseline characteristics were balanced after weighting, with no significant difference between groups in any clinical or patient-reported characteristics. At 26 weeks, outcomes were improved from baseline in both groups, including reduced prevalence of dialysis, and increased mean eGFR and mean platelet count, with no significant differences between groups (**Table**).

Conclusions: After balancing patient characteristics between study groups, no significant differences were seen between outcomes for ECU and RAV at 26 weeks.

Funding: Commercial Support - This study was sponsored by Alexion Pharmaceuticals, Inc.

Representative clinical characteristics at baseline and 26 weeks.

Clinical characteristic	Patients receiving ravulizumab (n=46)*	Patients receiving eculizumab (n=39)	*P* value	Differences between groups (95% confidence interval)
Patients receiving dialysis (%) At baseline At 26 weeks	52 22	53 8	0.998 0.070	0 (-21 to 21) -15 (-30 to 1)
eGFR (mL/min/1.73m^2; mean [SD])† At baseline At 26 weeks	16.7 (16.6) 55.4 (40.8)	16.6 (12.4) 51.4 (30.8)	0.986 0.619	0.0 (-6.3 to 6.3) -4.0 (-19.8 to 11.8)
Patients experiencing an improvement of ≥15 mL/min/1.73m^2 in eGFR from baseline at 26 weeks (%)	59	64	0.662	5 (-16 to 26)
Platelet count (x10^9/L; mean [SD]) At baseline At 26 weeks	118 (85) 243 (81)	118 (65) 244 (65)	0.979 0.953	0 (-33 to 32) 1 (-31 to 33)

*For eGFR and platelet count, n=43 at 26 weeks.

† eGFR defined as 10 mL/min/1.73m² for those on dialysis.

C3 Inhibition with Pegcetacoplan Targets the Underlying Disease Process of C3 Glomerulopathy (C3G) and Improves Proteinuria

Bradley P. Dixon,[1] Larry A. Greenbaum,[2] Liwei Huang,[3] Sandeep K. Rajan,[4] Derrick Robinson,[5] Marvin R. Garovoy,[6] Wyatt Gilmore,[7] Natasha Picazio,[7] Nick Robertson,[7] Temitayo Ajayi,[7] Carl Di casoli,[7] Pascal Deschatelets,[7] Cedric G. Francois,[7] Hetal S. Kocinsky,[7] Federico Grossi.[7] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Emory University, Atlanta, GA; [3]Tidewater Kidney Specialists, Inc., Chesapeake, VA; [4]University of Tennessee Health Science Center, Memphis, TN; [5]Eastern Nephrology Associates, Wilmington, NC; [6]Ex-Equals, LLC, Sausalito, CA; [7]Apellis Pharmaceuticals, Inc, Waltham, MA.*

Background: C3G is a rare renal disease in which C3 overactivation leads to the accumulation of C3 breakdown products in the glomeruli. Progression to end-stage renal disease occurs in up to 50% of patients (pts) within 10 years of diagnosis; no therapies target the underlying pathophysiology of C3 activation. The study aims to assess whether pegcetacoplan (APL-2; Apellis Pharmaceuticals, Waltham, MA), a C3 inhibitor, targets C3G complement dysregulation and reduces proteinuria.

Methods: This phase 2 open-label study was designed to evaluate preliminary efficacy and safety of pegcetacoplan in pts with complement-mediated glomerulopathies. Pts with C3G who were ≥16 years old, with proteinuria >750 mg protein/g creatinine, and eGFR ≥30 mL/min/1.73 m² were eligible for inclusion. Pegcetacoplan was administered as 360 mg daily subcutaneous infusions with transition to 1080 mg twice weekly from Week 24. The primary endpoint was change in proteinuria from baseline to Week 48, measured by 24-hour urine protein-to-creatinine ratios (uPCR). Serum C3, albumin, and creatinine as well as safety were also evaluated.

Results: Eight C3G pts were enrolled in the study. Three pts were excluded from efficacy analyses for self-reported non-compliance or interrupted study drug administration. Data showed a greater than 65% reduction in 24-hour uPCR from baseline to Week 48. Serum albumin and C3 increased, and serum creatinine was stable (Table). No serious or severe adverse events were reported and no TEAEs led to discontinuation.

Conclusions: These data suggest that pegcetacoplan targets the underlying pathophysiology of C3G, resulting in proteinuria reduction with stable renal function. Pegcetacoplan also appeared to be well-tolerated. Further studies are warranted to investigate the therapeutic potential of pegcetacoplan in the treatment of C3G.

C3 Glomerulonephritis Associated with Monoclonal Gammopathy: A Retrospective Case Series Study from a Single Institute in China

Xin Zhang, Yu Xiaojuan, Dan Y. Li, Su-xia Wang, Fu De Zhou, Ming Hui Zhao. *Peking University First Hospital, Beijing, China.*

Background: To analysis the demographic and clinicopathological features and renal outcomes of Chinese patients with C3GN in the setting of monoclonal gammopathy.

Methods: Patients with renal biopsy-proven C3 glomerulonephritis and detectable serum and/or urine monoclonal Ig from 2006 to 2018 in Peking University First Hospital were included, clinical data, renal pathology type, treatment and prognosis were collected.

Results: Nineteen patients were enrolled, accounting for contemporaneous 26.7% of C3GN patients. The mean age was 55 years old, and average eGFR at biopsy 48.42ml/min/1.73m². The IgG was the most common isotype of monoclonal Ig on immunofixation electrophoresis. Eleven patients had nephrotic ranged proteinuria and hypoalbuminemia. Kidney biopsies revealed a relative prominent MPGN pattern. Two patients had concurrent TMA-like renal injuries. The median renal survival was 24 months. Median renal survival was 12, 12, and 34 months, respectively in patients receiving conservative therapy, immunosuppressant therapy, and clone-targeted chemotherapy, without statistical significance. Plasma exchange therapy only improved one patient's renal outcome.

Conclusions: The clinicopathological features of Chinese patients with C3GN combined with monoclonal gammopathy are consistent with the previously reported population. Renal prognosis of these patients is poor, and immunosuppressant therapies show no advantage over supportive therapy in renal prognosis, while the benefit of clone-targeted chemotherapy is still requiring investigation.

Funding: Government Support - Non-U.S.

The Prognostic Value of Chronic Histopathological Lesions in Monoclonal Immunoglobulin Deposition Disease: A Clinicopathological Analysis of Patients from a Single Institution

Zixuan Zhu, Wenling Ye, Xuemei Li. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Kidney is the most common involved organ in monoclonal immunoglobulin deposition disease (MIDD), which could lead to end stage renal disease (ESRD). Few studies have evaluated the association between the irreversible chronic histopathologic lesions and clinical features, and its prognostic value in renal outcomes in MIDD.

Methods: A series of 20 patients with MIDD and 20 patients with renal AL amyloidosis proven by renal biopsy between January 2001 and December 2018 were reviewed retrospectively. The degree of chronic changes including glomerulosclerosis, interstitial fibrosis, and arteriosclerosis were semiquantitatively scored and the overall chronic lesions were also graded based on the grading system proposed in 2017. The association between histopathologic lesion and clinical manifestations, and the correlation with risk of progression to ESRD were investigated.

Results: MIDD patients presented more significantely overt ischemia-related global glomerulosclerosis and a more severe tendency of interstitial fibrosis(Figure 1). The significantly higher extent of overall chronic changes was also seen in MIDD compared with AL amyloidosis, which was independently correlated with worse baseline estimated glomerular filtration rate (β coefficient (95% CI): -4.618(-8.238-0.999), *P*=0.017). And the overt interstitial fibrosis predicted the increased risk of developing ESRD in MIDD.

Conclusions: The extent of overall chronic changes and the overt interstitial fibrosis provide information both about baseline manifestation and renal survival. Carefully grading and evaluating the chronic changes in MIDD may help guiding the treatment and accessing the renal outcomes.

Figure1.Comparison of overt histopathological lesions between AL and MIDD at kidney biopsy

Histopathological score	MIDD	AL	P-value

PO1855

Development of Atypical Hemolytic Uremic Syndrome in a Patient with Complement 3 Glomerulonephritis

Ravi V. Patel, Gauri Bhutani, Tripti Singh. *University of Wisconsin-Madison, Madison, WI.*

Introduction: Uncontrolled hyperactivity of alternative complement pathway has been implicated in development of two distinct pathological processes, namely C3 glomerulonephritis (C3GN) and atypical hemolytic uremic syndrome (aHUS). Here we present a unique case which initially started as C3GN on kidney biopsy and progressed to aHUS.

Case Description: 68-year-old female presented with progressive weakness and palpitations over a month. She denied any fever, chills, dysuria, chest pain, dyspnea or abdominal pain. Her past medical history was significant for hypertension and coronary artery disease, with no family history of end stage renal disease. On admission, her medications included amlodipine for hypertension, levothyroxine for hypothyroidism and intermittent steroids for gouty arthritis. On exam, her vital signs revealed tachycardia with heart rate 119 beats/min and hypotension with blood pressure 97/59 mmHg. Exam was significant for dry mucosa and irregular heart rate. Initial laboratory evaluation was significant for acute kidney injury (AKI), with creatinine (Cr) of 2.6 (baseline Cr of 1.2). Urinalysis demonstrated 21-50 RBC/hpf and urine protein/Cr of 12.5 g/g. A renal biopsy was performed which showed endocapillary proliferation with dominant staining for C3 in the mesangium and along the capillary wall, consistent with C3GN. The patient was started on prednisone 60 mg daily.

Hemodialysis was initiated for uremic symptoms. Complement function test was consistent with ongoing complement dysregulation at C3 convertase level and C5 convertase level without the presence of autoantibodies towards complement proteins. 2 months after her kidney biopsy, she developed worsening anemia and thrombocytopenia, elevated lactate dehydrogenase and undetectable haptoglobin. Direct coombs test was negative, peripheral smear showed schistocytes, ADAMTS13 level was 65%, consistent with diagnosis of atypical hemolytic uremic syndrome. Patient was started on Eculizumab therapy with stabilization of hemoglobin and platelets but remains dialysis dependant.

Discussion: In our growing understanding of alternative complement pathway, it is thought that dysregulation at fluid state is associated with C3GN, while solid state dysregulation is associated with widespread endothelial injury leading to aHUS. Our patient developed both pathologies, suggests further research is needed in understanding the details of complement system.

PO1856

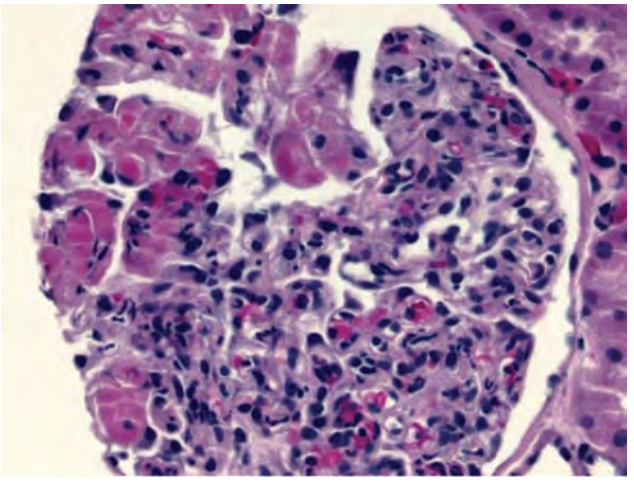
Acute Renal Failure from Thrombotic Microangiopathy: Is IgA Vasculitis to Blame?

Dipal Patel. *Yale University School of Medicine, New Haven, CT.*

Introduction: Thrombotic microangiopathy (TMA) has been associated with several cases of IgA nephropathy. In most cases the clinical significance of the TMA is uncertain. We describe a case of acute renal failure in a patient with systemic IgA vasculitis, who was found to have severe renal-limited TMA treated with eculizumab for the possibility of underlying complement dysregulation.

Case Description: A 34 year old male presented with abdominal pain and bloody bowel movements, and was found to have extensive duodenitis. Infectious testing of stools was negative, though he later tested positive for H. pylori. While hospitalized he developed acute kidney failure, with creatinine rising from 1.5 to 11.7 within four days. Urine sediment demonstrated granular casts consistent with acute tubular injury, though he also had white cell casts for which acute interstitial nephritis was considered. Blood counts were normal on admission, but he developed anemia and thrombocytopenia with mildly positive markers of hemolysis (haptoglobin 25, LDH 269, no schistocytes). Serum complements were profoundly low (C3 33, C4 9). A kidney biopsy revealed severe TMA. Given the rapidity of progression to renal failure requiring dialysis, he was started on eculizumab for a presumed atypical hemolytic uremic syndrome (aHUS). Since he did not have evidence of active hemolysis, he was not started on plasmapharesis. Kidney biopsy demonstrated proliferation and expansion of the mesangium with IgA deposition. Endoscopy was later performed with biopsy consistent with systemic IgA vasculitis, for which he was started on steroids. Abdominal symptoms improved and he was discharged home. He continues on eculizumab with normalization in complements, but without improvement in renal function.

Discussion: There have been case reports of complement factor dysregulation resulting in both IgA vasculitis and TMA. Given the extent and acuity of renal failure in this case, we treated our patient with eculizumab for presumed aHUS.



PO1857

Proliferative Glomerulonephritis with Monoclonal IgG Deposits (PGNMID): A Report of Two Cases Managed with Renin-Angiotensin-Aldosterone System (RAAS) Inhibition Alone

Marianna Vynnyk, Maria V. DeVita, Jordan L. Rosenstock. *Lenox Hill Hospital, New York, NY.*

Introduction: PGNMID is a relatively rare disorder with monoclonal immunoglobulins (Ig) deposition in glomeruli that resembles immune complex glomerulonephritis (GN), after exclusion of other related disorders such as amyloidosis and cryoglobulinemia. The pathogenesis and management of PGNMID remains uncertain, especially if no systemic clonal disorder is found, which is frequently the case. Some groups have recommended anti-plasma cell or anti-B cell therapy in most if not all cases, even if a clone is not identified. We present two cases of PGNMID that were managed with RAAS blockade alone and whose renal disease remained stable over 6 and 10 years of follow up.

Case Description: Two cases were identified who had prolonged follow up with PGNMID and no immunosuppressive treatment. Charts were reviewed retrospectively and data collected from time of biopsy until most recent follow up. Case 1 is a 25 year old obese black woman with recent onset of hypertension who presented with serum creatinine (sCr) 1.4mg/dl. Urinalysis (UA) showed 1+ protein and no blood. 24hr urine protein was 296mg. Renal biopsy (done as she had positive antiphospholipid antibodies) revealed PGNMID (IgG kappa) with diffuse mesangial proliferation and focal sclerosing GN with focal fibrous crescents. There was no evidence of thrombotic microangiopathy. Serum and urine immunofixation (IF) were negative for monoclonal protein. Bone marrow biopsy was unremarkable. The patient was treated with angiotensin-receptor blocker (ARB) without immunosuppressive therapy. Six years later the most recent sCr was 1.5mg/dl and urine protein-creatinine ratio (PCR) was 1100mg/g. Case 2 is a 41 year old white woman who presented with sCr 0.6mg/dl. UA had 3+ protein and no blood. 24hr urine protein was 2.3g. Renal biopsy showed PGNMID (IgG kappa) with mesangial and endocapillary proliferation. Serum and urine IF were negative for monoclonal proteins. Bone marrow biopsy was not done. The patient was treated with an angiotensin-converting enzyme inhibitor (ACEI) alone. After ten years of follow up, her sCr was 0.7mg/dl, and urine PCR was 632mg/g.

Discussion: We report 2 cases of PGNMID with stable renal function and proteinuria after 6 and 10 years of RAAS therapy alone. This suggests that not all patients with PGNMID may require immunosuppression.

PO1858

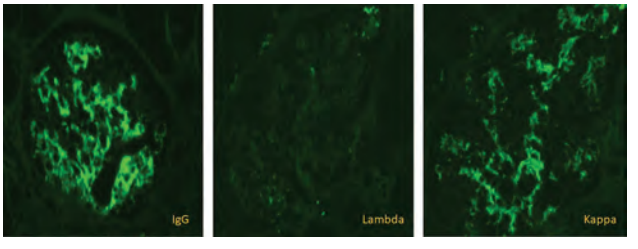
Use of Pronase-Treated Paraffin Immunofluorescence to Unmask a Reclusive Glomerular Disease

Phuong Truong,[1] Amna Ilahe,[1] Rama Nadella,[1] Diana Mahbod,[1] Christopher P. Larsen,[2] Irfan Agha.[1] *[1]Dallas Renal Group, Dallas, TX; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Interpretation of renal biopsy depends on light, IF and electron microscopy. Direct IF on unfixed frozen tissue sometimes fails to pick up immunoglobulins. Treatment of paraffin embedded formalin-fixed tissue with pronase renders such Igs more amenable to detection. We present a case of a young woman where use of this "unmasking" technique allowed the correct diagnosis to be made.

Case Description: A 24 YO WF presented to our GN Clinic with intermittent edema, proteinuria and hematuria noticed about a year ago. Her creatinine was 1.5 mg/dl. Urine Pr/Cr ratio was 1.8 g/g. Her ANA was 1:320 but the rest of the antibody panel was negative. C3 and C4 were normal. Lupus Anticoagulant, beta 2 GPI, anticardiolipin IgG and IgM were positive. Screens for paraproteins and relevant viruses were negative. Renal Biopsy: 20/31 glomeruli were globally sclerotic. Intact glomeruli showed mesangial proliferation and hypercellularity. IF showed C3+ but all other stains were negative. IF on pronase digested, paraffin embedded tissue stained IgG, C3 and kappa with no lambda. Stain for SAP was positive. EM showed numerous mesangial deposits, some sub-epithelial but no sub-endothelial deposits. Based on above, she was diagnosed with Membranous like glomerulopathy with masked IgG-kappa deposits. Her age, race, gender, Ab profile as well as biopsy findings all supported the diagnosis. She was started on immunosuppression therapy to attempt salvage of renal function and delay progression.

Discussion: Refinement in IF techniques has expanded our diagnostic ability and mechanistic understanding of glomerular disease. Use of paraffin embedded tissue for IF after pronase treatment helps discover Ig deposits not picked up by traditional IF. This can prove critical in correctly diagnosing glomerular disease, as exemplified in this case. This patient could have been misdiagnosed as C3 glomerulopathy based on traditional IF. Unmasking IgG-kappa deposits allowed us to correctly diagnose her with a rare disease, MGMID. This technique expands our ability to correctly diagnose glomerular disease and should be applied routinely.



IF on Paraffin Embedded Tissue

PO1859

Fibrillary Glomerulonephritis: A Case Series with Clinical Features and Outcomes

Reza Zonozi,[1] Karen A. Laliberte,[1] Jillian Rosenthal,[1] Noah Huizenga,[1] Sarah Dowst,[1] Anushya Jeyabalan,[1] Frank B. Cortazar,[2] John Niles.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]New York Nephrology Vasculitis and Glomerular Center, Albany, NY.*

Background: Fibrillary glomerulonephritis (FGN) is a rare cause of chronic glomerulonephritis with a poor prognosis. We evaluated a series of patients with FGN, most of whom were treated with rituximab, low-dose cyclophsophamide, and prednisone (RCP).

Methods: Patients were included if they had FGN treated at Massachusetts General Hospital between 2008 – 2020 with a minimum of six months of follow up. The primary outcome was achievement of remission, defined as serum creatinine that remained stable, improved or increased <25% of the original value after treatment, and a 50% reduction in proteinuria at the end of follow up.

Results: We identified 11 consecutive patients with FGN. ANCA-associated vasculitis (n = 3), rheumatoid arthritis (n = 1), chronic hepatitis C (n = 1), and monoclonal B lymphocytosis (n = 1) were concurrently present. At the start of therapy, the median (IQR) serum creatinine, eGFR, and protienuria was 2.31 mg/dL (1.25 – 4.69), 30 mL/min/1.73 m^2 (11 – 68), and 6.6 g/g (1.5 – 8.4), respectively. Of the 11 patients, 10 were treated with RCP, and one patient with rituximab monotherapy. The median (IQR) follow-up was 2.6 years (2.0 – 3.9). Seven of 11 patients achieved remission. Of the 4 patients who did not achieve remission, one received pre-emptive transplantation, two initiated hemodialysis, and one had > 25% rise in serum creatinine not reaching ESRD. Five serious adverse events occurred over 33 patient years.

Conclusions: Remission was achieved in most patients with FGN treated with rituximab, low-dose cyclophosphamide, and prednisone. Larger studies evaluating this regimen are warranted.

Patient	Age	Gender	Race	Cr (mg/dL)		eGFR		Proteinuria (g/g)		Albumin (g/dL)		Additional Diagnosis	Treatment	# of RTX doses	Years of CBCD	Outcome

Abbreviations: AAV anti-neutrophil cytoplasmic antibody-associated vasculitis, AA African-American, CBCD continuous B cell depletion, Cr creatinine, DM diabetes mellitus, eGFR estimated glomerular filtration rate, ESRD end-stage renal disease, F/u follow-up, HCV hepatitis C virus, HIV human immunodeficiency virus, MBL monoclonal B lymphocytosis, RA rheumatoid arthritis, RCP rituximab-cyclophosphamide-prednisone, RTX rituximab, W white

Table 1. Baseline characteristics

[a]Calculated by CKD-EPI Creatinine Equation (2009); reported as mL/min/1.73m^2
[b]Patient 1 had an undetectable HIV viral load with antiretroviral therapy; however, he had treatment-naive chronic HCV with viremia.
[c]Continuous B cell depletion is defined as scheduled rituximab infusions to maintain B cell depletion (total B cell count <5 cells/µL).
[d]RCP is defined as rituximab-induced continuous B cell depletion, low-dose oral cyclophosphamide for 8 weeks, and a rapid prednisone taper.

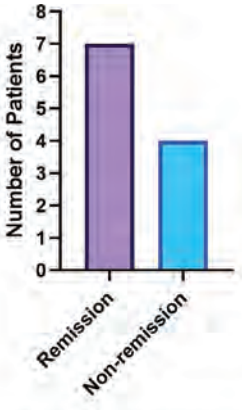

Figure 1. Primary outcome of renal disease. The primary outcome was achievement of remission, defined as serum creatinine that remained stable, improved or increased <25% of the original value after treatment, and a 50% reduction in proteinuria at the end of follow up. Non-remission was defined as serum creatinine increased >25% of the original value after treatment, failure to achieve a 50% reduction in proteinuria, or development of ESRD (dialysis initiation or transplantation).

PO1860

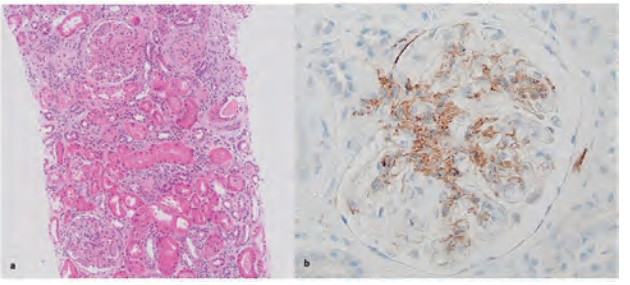
An Atypical Case of Fibrillary Glomerulonephritis

Jessica M. Greco,[2] Asish Thakkar,[3] Clarissa A. Cassol,[1] Anjali A. Satoskar,[2] Salem Almaani.[2] *[1]Arkana Laboratories, Little Rock, AR; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]Veterans Health Administration, Columbus, OH.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease with multiple disease associations such as hepatitis C, malignancy, and dysproteinemia. Despite these known associations, little is known about the interaction between FGN and other comorbidities. We present a case of FGN that presented years after successful treatment of hepatitis C infection (HCV).

Case Description: The patient is a 72 year old male with history of HCV. He was treated with ledipasvir/sofosbuvir and achieved a sustained virologic response however developed liver cirrhosis and underwent a liver transplant 2 years later. Histological examination of his liver explant was positive for hepatocellular carcinoma however he did not demonstrate any systemic involvement. 1 year after his transplant, he was noted to have a progressively worsening serum creatinine (1.37mg/dl from 0.97mg/dl) and new nephrotic range proteinuria (5.7 gram protein/gram creatinine). Autoimmune serology including ANCA, ANA, and monoclonal protein testing was negative. Complement levels were normal. He underwent a kidney biopsy which demonstrated focal endocapillary hypercellularity (figure 1a), segmental glomerular sclerosis, and mild mesangial and capillary wall staining for IgG, kappa, and lambda, with less C3. Electron microscopy demonstrated mesangial, subendothelial and few isolated subepithelial and intramembranous deposits with a vague fibrillar appearance. DNAJB9 staining was later performed and was positive, confirming a diagnosis of FGN (Figure 1b). After diagnosis of FGN, he underwent extensive malignancy screening which was unrevealing.

Discussion: FGN has a known association with HCV infection. Case series reported positive HCV serology in around 15% of patients with FGN, but none reported FGN after HCV eradication. DNAJB9 staining is specific for FGN and helps establish the diagnosis especially when histology does not demonstrate the classical membranoproliferative or mesangioproliferative patterns of glomerular injury.



PO1861

Fibrillary Glomerulonephritis Treated with Rituximab: A Case Report

Serah Kae L. Laquindanum, Eladio Miguel M. Penaranda. *Makati Medical Center, Makati City, Philippines.*

Introduction: Fibrillary Glomerulonephritis (FGN) is a rare primary glomerular disease first described by Rosenmann and Eliakim in 1977 present in 0.5 to 1% of native kidney biopsies defined by haphazardly arranged fibrils 10 to 30 nm in thickness deposited in the mesangium, glomerular basement membranes or both. Initially, FGN was considered to be idiopathic. However, approximately one-third have a history of malignancy, monoclonal gammopathy, autoimmune disease, hepatitis C infection or an IgM glomerular deposit disease. Prognosis is generally poor with 50% of patients developing ESRD within 6 years of presentation. The most common form of treatment is steroids with or without a second agent usually Cyclophosphamide or Rituximab. To date, there is no convincingly effective treatment but published case series reports clinical response referred to as "nonprogression" defined by stable renal function in those treated with Rituximab.

Case Description: Our patient is a 49-year old Filipino female, hypertensive, diagnosed case of Immune Complex-Mediated Glomerulonephritis presenting with elevated blood pressure and nephrotic-range proteinuria. Initial adjustment of her anti-hypertensive regimen controlled her blood pressure. Subsequently, she developed resistant hypertension and increasing proteinuria. Creatinine increased to 2.1 mg/dL from a baseline of 1 mg/dL in 12 months. A second renal biopsy was done showing fairly widespread podocyte foot process effacement and mesangial fibrillary deposits measuring 13 nm in mean diameter suggestive of Fibirillary Glomerulonephritis. Patient was worked up for an underlying malignancy, autoimmune disease and infectious causes but none turned out positive. At this time, proteinuria has increased to 7596.05 grams from 1622.08 grams with a creatinine clearance of 39.80 ml/min/1.73 m^2. After discussing with the patient, she was given Rituximab as four weekly doses of 375 mg/m^2 intravenously. After five months, there was significant reduction in proteinuria at 1734.32 grams with stable creatinine clearance of 31.99 ml/min/1.73 m^2.

Discussion: In general, FGN prognosis is poor and majority of patients progress to ESRD. Treatment options are currently limited and conclusions regarding immunosuppressive therapy cannot be drawn from limited published data. Rituximab may offer benefit particularly in patients with relatively normal baseline renal function.

PO1862

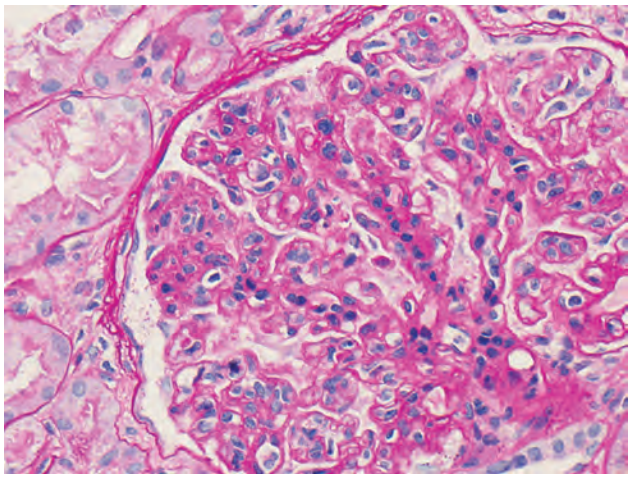
Cryoglobulinemia After Hepatitis C Virus Eradication

Andy L. Silva Santisteban, Yiqin Zuo, Efren A. Chavez Morales. *University of Miami School of Medicine, Miami, FL.*

Introduction: Mixed cryoglobulinemia (cryo) is often caused by HCV infection. Major clinical manifestations are arthralgias, myalgias, palpable purpura, peripheral neuropathy and glomerulonephritis (GN). Diagnostic evaluation may reveal the presence of serum cryoglobulins, rheumatoid factor (RF) and hypocomplementemia. If diagnosis is uncertain tissue biopsy with histologic confirmation may be useful. The treatment of patients with HCV-related cryo GN involves eradication of HCV infection with direct-acting antiviral agents (DAAs) and immunosuppression for more severe systemic disease. Some patients develop persistent or relapsing disease despite a sustained virologic response (SVR) with DAAs rarely leading to life-threatening manifestations.

Case Description: We report a case of a 76-year-old female with chronic HCV infection treated with DAAs with SVR for years referred to nephrology clinic for evaluation of CKD and nephritic syndrome. She also reported pain and a purpuric papular rash on her legs. Labs showed hypocomplementemia and high levels of RF. Cryo was suspected, but repeated testing of serum cryoglobulins was negative. Renal biopsy showed membranoproliferative GN with endocapillary hypercellularity and intracapillary "cryo-plugs" by LM, and IgM dominant with kappa greater than lambda capillary loop and mesangial staining by IF, and subendothelial and mesangial deposits by EM. These findings suggest cryo GN. Patient was treated with a prednisone taper and rituximab. She had a rapid improvement in renal function, complete remission of proteinuria and normalization of complement levels.

Discussion: Mixed cryo should be considered in the differential diagnosis in the appropriate clinical setting in patients with HCV infection even after treatment and prolonged SVR. To detect serum cryoglobulins blood should be collected in a prewarmed tube without anticoagulant. Inadequate technique may lead to false-negative results.



Renal Biopsy. Cryoglobulinemic Glomerulonephritis

PO1863

Clinico-Biological Characteristics and Treatment of Hepatitis B Virus-Related Mixed Cryoglobulinemia: Current Clinical Evidence

Wenbin Tang, Xiufen Wang, Huipeng Ge, Tianci Deng, Xiangcheng Xiao. *Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.*

Background: Hepatitis B virus(HBV)-related mixed cryoglobulinemia (MC) was considered to be a rare disease, presented as mild clinical symptoms just like purpura to severe organ damage such as glomerulonephritis. We aimed to clarify the clinico-biological characteristics and treatment of HBV-related MC.

Methods: We reported a case of HBV-related MC, enrolled 41 HBV-related MC cases from literature, and summarized demographic, clinical, laboratory, treatment and outcome data of the 42 HBV-related MC cases. Meanwhile, the Asian and European group, patients in remission and refractory were compared. Kidney involvement, death and time to death were included for survival analysis.

Results: Of the 42 HBV-related MC, Mean age was 53±14 years, and 47.6% patients were male. Extrahepatic clinical manifestations mainly included cutaneous lesions, kidney involvement, peripheral neuropathy, articular involvement, which accounted for 78.6%, 54.8%, 35.7%, 19.0%, respectively. 87.1% (27/31) patients had low serum C4, and 92.6% (25/27) patients' rheumatoid factors(RF) were positive. Renal pathology showed membranous proliferative glomerulonephritis, the capillary lumen disclosed hyaline thrombi and electron microscope found microtubular substructure. 36 (85.7%) patients received antiviral therapy. Corticosteroids were used in 22 (52.4%) patients, immunosuppressive agents were given to 13 (31.0%) patients, and plasma exchange (PE) were used in 9 (21.4%) patients. At the end of follow-up, 52.4% (22/42) patients were in remission, 47.6% (20/42) patients had refractory disease, and 11.9% (5/42) patients died. The patients who had cutaneous necrosis, peripheral neuropathy and kidney involvement were more likely to have refractory disease but without statistical difference. The Asian group showed more kidney involvement than the European group (P=0.001), but the European group had more peripheral neuropathy (P=0.037). The Asian group showed a higher mortality than the European group(P=0.048). Univariate analysis showed kidney involvement had correlation with overall survival (log rank P=0.034).

Conclusions: Extrahepatic clinical manifestations of HBV-related MC were varied. Anti-HBV treatment, corticosteroids, immunosuppressive agents and PE were useful for some patients. The patients with kidney involvement may be related to poor prognosis.

PO1864

Membranoproliferative Glomerulonephritis (MPGN) Associated with Epstein Barr Virus (EBV)

Faris Al faris, Sheikh Raza Shahzad, Mauricio Monrroy, Krishnakumar D. Hongalgi, Swati Mehta, Loay H. Salman, Kelly H. Beers. *Albany Medical Center, Albany, NY.*

Introduction: Immune complex-mediated MPGN has been commonly associated with viral infections including Hepatitis B, C, HIV and Hantavirus. We present a rare case of EBV associated MPGN successfully treated conservatively.

Case Description: A 19-year old female, previously healthy, presented with fatigue, sore throat and periorbital swelling for 3 weeks. Vitals were stable on presentation. Her EBV IgM and IgG serologies were positive while CMV was negative. UA showed proteinuria (>300mg/dL) and microscopic hematuria. Albumin was 2.9 g/dL. Spot urine protein to creatinine ratio was 2.6g/g. Urine sediment was bland. SCr was 0.72 mg/dL. Extensive serological work up was negative. Renal biopsy showed mesangial hypercellularity, double contours of capillary loops with intramembranous, subendothelial and subepithelial immune type electron dense deposits. Immunofluorescence revealed segmental globular to coarsely granular staining in the glomerular capillary walls for IgG (3+), IgA (1+), IgM (3+), kappa (2+), lambda (3+), C3 (1-2+), C1q (3+), and C4 (1+). Mesangial regions showed segmental granular staining for IgG (1+), kappa (1+), lambda (1+) and C4 (1+). She was treated with furosemide 20mg daily as needed for swelling and lisinopril 5mg daily. Her symptoms resolved within 2 weeks of initiating treatment. She self-discontinued her medications after 4 months. On 6 month follow up, she remained asymptomatic and urine protein was undetectable.

Discussion: Infectious Mononucleosis (IM) is caused by EBV. EBV primarily infects human B cells via the CD21 receptor and may infect renal tissue since the CD21 molecule has been detected in proximal tubular cells of kidneys. Further, acute EBV infection may cause immune-mediated response with deposition of immune complexes and subsequent glomerulopathy. Renal involvement is reported with 3-16% cases of acute IM. Common renal lesions include acute tubulointerstitial nephritis, membranous nephropathy, minimal change disease and vasculitic lesions. MPGN is a rare presentation of EBV and should be considered in patients with IM and proteinuria. Previous case reports have suggested that nephrotic syndrome in patients with an acute EBV infection is usually self-limiting. Our case report also suggests that MPGN associated with EBV may have a relatively benign course.

PO1865

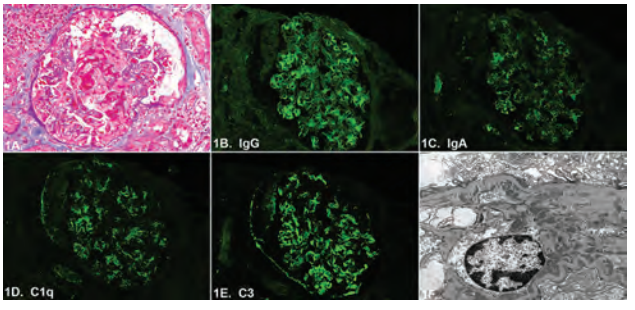
Infection-Related Glomerulonephritis Mimicking Lupus Nephritis

Rasha Alawieh, Anjali A. Satoskar, Isabelle Ayoub. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Differentiating infection vs auto-immune related GN is crucial in order to avoid inadvertent immunosuppressive therapy that can be harmful and even lead to fatal consequences. This case illustrates the dilemma of medical management in lupus like-GN

Case Description: A 66 year old man with mitral valve prolapse, was found to have elevated creatinine of 3.59 mg/dl from a baseline of 1 mg/dL. He complained of leg rash and dark urine. His rash was symmetric and non blanchable petechiae. Urine sediment showed 20 dysmorphic RBC per high-power field and RBC casts. Urine protein/creatinine ratio was 1.35 g/g. Serum creatinine peaked at 10.4 mg/dl. Hemodialysis was begun. Further testing was significant for pancytopenia, low complements (C3 was 40 mg/dl, C4 10 mg/dl) and positive MPO-ANCA. Kidney biopsy was performed (Fig 1). On light microscopy 2 glomeruli were globally sclerotic. One glomerulus showed crescentic and necrotizing lesion. There was diffuse ATN. Some tubules showed red blood cell casts. Interstitial inflammation was mild. Direct IF showed a full house pattern with bright IgG, IgM, kappa, lambda, C1q, C3 and mild to moderate IgA staining. EM identified few mesangial and subendothelial deposits with a single subepithelial hump. During his hospitalization, streptococcus bacteremia was documented. Echo showed mitral valve vegetation. In setting of bacterial endocarditis, the Biopsy is consistent with infection related glomerulonephritis (IRGN).

Discussion: Crescents as well as ANCA positivity have been described in IRGN. However a full-house immunostaining pattern is not typical of IRGN and has never been reported in IRGN. Instead, this is typical of lupus- like GN. The patient didn't have positive ANA, however he developed pancytopenia and hypocomplementemia which can be manifestations of both SLE even at an old age as well as infection. The dilemma is that auto-immune mediated GN warrants immunosuppressive therapy which is contraindicated in IRGN. Our patient received penicillin and underwent mitral valve replacement His kidney function gradually improved and dialysis was discontinued after 4 months.



PO1866

Hypocomplementemic Urticarial Vasculitis: Interstitial Nephritis with New Microtubular Deposits and Successful Response to Rituximab

Adam Dossaji, Spencer Hodgins, Daniel L. Landry, Giovanna M. Crisi, Sara A. Pawlak, Gregory L. Braden. *Baystate Medical Center, Springfield, MA.*

Introduction: HUV is caused by antibodies to C1q complement and has many features of systemic lupus and cryoglobulinemia. Different patterns of GN often occur such as the mesangial GN, MPGN or membranous GN but interstitial nephritis has never been described.

Case Description: A 57 year old female in 2007 developed recurrent hives, angioedema, leucocytoclastic vasculitis on skin biopsy & 5 g proteinuria with RBC casts. C1q complement was 2 mg/dL, C3 20 mg/dL, C4 6 mg/dL & C1q antibody was 35 mg/mL (NL<10). All other serology and cryos were negative. Serum creatinine was 0.6mg/dL.

Her 1st renal biopsy showed mesangial proliferative GN with +3 IF for IgG, IgA, C1q & EM deposits in the mesangial, subendothelial, subepithelial locations & interstitial inflammation. Parallel microtubular structures, 25 nm wide with hollow cores, were present in interstitial capillaries and hilar arterioles but not in the glomeruli. Tubular basement membranes & peritubular capillaries were +3 positive for IgG & C1q with granular deposits on EM. She failed prednisone, mycophenolate & cyclosporin, but after 4 weekly doses of Rituximab 375 mg/m^2 she rapidly went into remission within 2 months which was sustained for 6 years. HUV flared in 2016 with new onset nephrotic syndrome, hives, angioedema, COPD & AKI. Serum creatinine was 2.2 mg/dL & urine total protein/creatinine ratio was 8.7 with RBC casts. C1q was 4 mg/dL, C3 38 mg/dL, C4 4 mg/dL & C1q antibody > 100 mg/ml. A 2nd renal biopsy showed diffuse endocapillary proliferation with membranous GN similar to lupus Class IV & V and interstitial inflammation. IF was +3 for IgG, IgA, C1q and kappa and lambda in the same locations as biopsy 1. Tubules & peritubular capillaries were positive for IgG & C1q, peritubular capillaries had 25 nm hollow microtubule structures as before. Rituximab was initiated at 375 mg/m^2 for 4 doses. It induced a complete renal remission after 3 months with a serum creatinine of 0.6 mg/dL & urine total protein of 210 mg.

Discussion: We conclude: In addition to glomerulonephritis HUV can cause interstitial nephritis with +IF for IgG & C1q. HUV causes unique microtubular structures in the interstitium but not the glomeruli. Rituximab rapidly induces clinical renal remission in HUV.

PO1867

Unusual Aggregation of Different Glomerulopathies in a Family Resolved by Genetic Testing

Vahakn S. Keskinyan, Reeti Kumar, Rasheed A. Gbadegesin. *Duke University, Durham, NC.*

Introduction: Glomerulonephritis (GN) is a major cause of chronic kidney disease (CKD) in children. The conventional approach to diagnosis of GN includes clinical evaluation and in most cases kidney biopsy to make a definitive diagnosis. However, in many cases, clinical presentations of different GNs can overlap leading to uncertainty in diagnosis and management even after renal biopsy. In this report we identify a family with clinical diagnoses of post infectious glomerulonephritis (PIGN) and IgA nephropathy in a parent and two children. Renal biopsies were inconclusive and we were only able to make final diagnoses in each of the family members after genetic testing and reverse phenotyping.

Case Description: A previously healthy 7 year old male presented to the emergency department with hematuria, fever, and sore throat. Apart from being obese, his physical examination was unremarkable. Laboratory data was remarkable for microscopic hematuria and non-nephrotic range proteinuria. C3/C4 complements, ASO, anti-DNase b, anti-dsDNA, ANCA, and anti-GBM titers were all normal. A presumptive diagnosis of PIGN was made. However, he had persistent hematuria and proteinuria over the next 10 months. Further history at follow up revealed a history of IgA nephropathy in his mother and CKD of unclear etiology in his maternal grandfather. Renal biopsy was initially reported to be consistent with IgA nephropathy. However, because of the family history we carried out genetic testing and identified a rare hemizygous variant [c.3437G>A (p.Gly1146Glu)] in the gene *COL4A5*. COL4A staining was performed on the prior biopsy and staining pattern was consistent with COL4A5 disease. We confirmed that his mother also carried the same variant and she also has a history of hearing loss. Incidentally, his older brother presented a few weeks later with AKI and classical features of PIGN. His renal biopsy was consistent with PIGN and genetic testing in him was negative for the *COL4A5* variant found in his brother and mother.

Discussion: This case highlights the utility of genetic testing and reverse phenotyping in resolving clinical diagnosis in families with unusual constellations of different glomerulopathies. We propose that clustering of different glomerular disease phenotypes in a family should be an indication for genetic testing.

PO1868

Unusual Case of Histiocytic Glomerulopathy in the Setting of Sarcomatoid Malignancy

Faris Al faris, Majd Al-Ahmad, Llewellyn A. Foulke, Mauricio Monrroy, Kelly H. Beers. *Albany Medical Center, Albany, NY.*

Introduction: We present a case of histiocytic glomerulopathy and pauci-immune ANCA negative glomerulonephritis (GN) in the setting of sarcomatoid malignancy.

Case Description: An 83-year-old female presented to our hospital for evaluation of abdominal pain. Her vital signs were normal and her physical exam was only significant for mid-abdominal tenderness on palpation. Aortic angiography revealed occlusion of the superior mesenteric artery, celiac artery and left renal artery, in addition to a mass engulfing the celiac artery. She later developed acute kidney injury (AKI) with creatinine rising to 1.5mg/dl from baseline of 1.2mg/dl. Work up reveled bland urine sediment and 24-hour urine protein of 3.4g/day. Further laboratory studies revealed anti myeloperoxidase of 19.4u/ml, anti-proteinase 3 of 10.3u/ml, negative C-ANCA and P-ANCA, and normal complement levels. Renal biopsy showed focal crescentic and endocapillary proliferative GN comprised of mostly of CD68-positive foamy histiocytes, pauci-immune, with segmental C3 staining, as well as severe arterial fibrointimal hyperplasia with scattered intimal histiocytes and lymphocytes, consistent with arteritis and acute tubular injury with foci of prominent tubular vacuolization. Contrast induced nephropathy was thought to be the cause of AKI. Celiac mass biopsy showed sarcomatoid malignancy.

Discussion: Histiocytic glomerulopathy poses a diagnostic challenge as it has many possible underlying causes with different pathophysiology. Kaur and Sethi described 5 entities with histiocytic/foamy glomerular change on the kidney biopsy: crystal-storing histiocytosis, histiocytic glomerulopathy associated with macrophage-activating syndrome, thrombotic microangiopathy, lecithin-cholesterol acyltransferase deficiency and lipoprotein glomerulopathy. Our patient does not fulfill criteria for either of these entities. Small and large vessel vasculitis is well described as neoplastic and paraneoplastic phenomena, including both immune complex–mediated and ANCA-associated (pauci-immune). Pauci-immune GN is a rare and aggressive cause of AKI with 10% of the cases being ANCA-negative. Few case reports linked ANCA-negative pauci-immune GN to non-small cell lung cancer. To our knowledge this is the first case of histiocytic glomerulopathy, ANCA-negative pauci-immune GN and arteritis in the setting of sarcomatoid malignancy.

PO1869

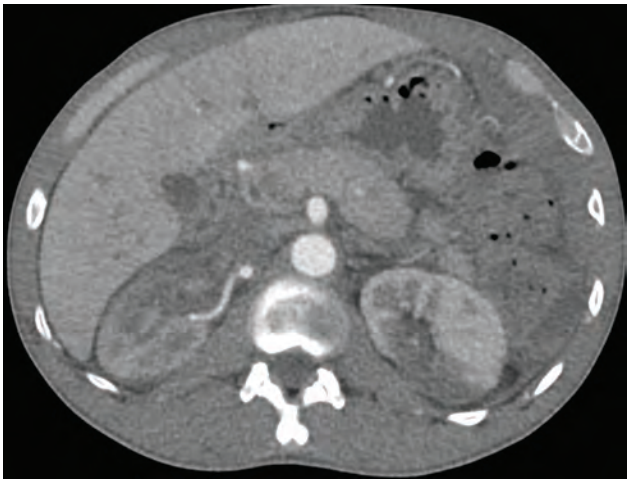
Bilateral Renal Infarctions: A Perplexing Presentation of Polyarteritis Nodosa

Alissa Ice, Matthew Foy. *Louisiana State University Health Sciences Center, Baton Rouge, LA.*

Introduction: Classic polyartertis nodosa (c-PAN) is an autoimmune necrotizing vasculitis with predilection for medium-sized vessels. Although c-PAN can be associated with renal involvement, acute renal failure or extensive renal infarctions are exceedingly uncommon. We report a rare case of c-PAN manifested by bilateral renal infarctions on initial clinical presentation.

Case Description: A 40 year old man with no known medical issues presented to the emergency department with encephalopathy in the setting of one month of reported myalgia, fevers, chills, night sweats, and unintentional ten lb. weight loss. Upon physical examination, his vitals were 95.1°F, 101 beats/min, 145/101 mmHg, with no evidence of trauma or skin abnormalities. His lab results were notable for Cr 1.83 mg/dL, AST 247 U/L, ALT 136 U/L, Hbg 12.6 g/dL, WBC 24.1x10^9/L, and UA with hematuria and proteinuria. An extensive workup was completed, and his HIV, Hepatitis B and C, ANCA, Cardiolipin Ab, DRVVT, and ANA results were negative. TEE was normal. His ESR was 116 mm/hr, and he had transient worsening of his Cr (2.96 mg/dL) and Hbg (6.7 g/dL). CT/CTA revealed bilateral renal infarctions with perinephric and retroperitoneal hematomas, right renal artery aneurysm, thrombosis of one of three left renal arteries, and splenic hematoma, while MRI demonstrated a small parietal hematoma and thoracic intrathecal/epidural hemorrhage. He was initiated on monthly cyclophosphamide and prednisone. One month later, he had symptomatic resolution and a Cr of 1.89 mg/dL.

Discussion: Given his fulfillment of five American College of Rheumatology (ACR) criteria, he was diagnosed with c-PAN as a constellation of clinical findings can be used, and biopsy results are not always necessary, especially given the risk of hemorrhage. Although it is a rare condition, it is important to remain cognizant and consider c-PAN in the differential due to its significant implications and the importance of timely treatment.



Right Renal Artery Aneurysm and Renal Infarctions

PO1870

Clinical Predictors of Response to Rituximab in the Nephrotic Syndrome Study Network (NEPTUNE) Cohort

Daniella Levy Erez,[1,2] Kevin E. Meyers,[1,2] Jarcy Zee,[3] Abigail R. Smith.[3] *[1]Division of Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Rituximab, an anti CD20 monoclonal antibody, is one of the alternative medications offered to children and adults with Nephrotic syndrome. Despite the growing knowledge regarding this medication, there are still concerns regarding long-term safety that need to be considered prior to initiation of therapy. Given these risks there is a need to identify characteristics of patients who will respond best to rituximab therapy.

Methods: We identified all patients who received rituximab within NEPTUNE, a prospective study of adults and children with glomerular disease enrolled at the time of first biopsy or at initial presentation. Remission was defined as UPCR<0.3 mg/mg

after rituximab initiation. Kaplan-Meier plots and log-rank tests were used to compare the probability of response among various levels of demographic and clinical variables.

Results: Of 734 patients enrolled in NEPTUNE, 57 (34 adult, 23 pediatric) received rituximab after enrollment and were eligible for analysis. In the adult cohort, average age at initiation was 45.8 (SD=15.4), majority were male (79%) and white (88%) and diagnosed with membranous nephropathy (MN) (74%). In the pediatric cohort, most had Minimal change disease (MCD) disease on biopsy or nephrotic syndrome not specified (not biopsied) (NSNS) (83%), mean age was 6.96 yrs (SD=4.25), 57% were male, and 74% were white. Remission was achieved in 18 (53%) adults and children 19 (83%) respectively, with median time to remission of 25.4 months and 4.8 months respectively. Probability of achieving remission was higher in patients with MCD/NSNS compared to MN (p<0.001, Figure). Among patients with MCD/NSNS, probability of remission was higher in <6 yrs. vs. ≥6 yrs. and adults (p=0.036).

Conclusions: Rituximab response rate in patients with MCD/NSNS were higher and quicker than in those with MN. Young children with MCD/MSNS had the highest rates of response. Future work is now targeted at identifying additional biomarkers (specifically lymphocyte profile) to predict response to rituximab.

PO1871

Tobacco Exposure in the Nephrotic Syndrome Study Network (NEPTUNE)

Linda Wang,[2] Kevin E. Meyers,[1] Christine B. Sethna.[2] NEPTUNE Cardiovascular Working Group *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Cohen Children's Medical Center, Queens, NY.*

Background: Tobacco exposure is associated with cardiovascular disease (CVD) risk and chronic kidney disease (CKD) progression. Risks of tobacco exposure in proteinuric glomerulopathies are not known. The objectives were to describe the prevalence of tobacco exposure and determine the longitudinal associations between tobacco exposure and CVD risk factors and kidney outcomes in adults and children with proteinuric glomerulopathies in NEPTUNE.

Methods: Tobacco exposure was self-reported at study enrollment as non-smoker, active smoker, past smoker and passive smoker. Baseline characteristics were compared by t-test, ANOVA and chi square. Using adjusted generalized estimating equations and time-varying Cox survival analysis, tobacco exposure was analyzed for association with blood pressure (BP), lipids, urine protein:creatinine ratio (UPCR), glomerular filtration rate (eGFR), complete remission (UPCR <0.3), kidney failure (eGFR <15 or Kidney Replacement Therapy [KRT]) and CKD progression (40% eGFR decline and eGFR <90, or KRT).

Results: Included were 371 adults (45.9±16.0 yrs.; 60.6% M; 23.0% black, eGFR 66.4 [IQR 42, 91]) and 192 children (9.8±5.0 yrs; 57.3% M; 39.4% black, eGFR 93.1 [IQR 78,114]) with median 45 (IQR 27,55) months of follow up. Among adults, there were 14.6% active smokers, 29.1% past smokers and 4.9% passive smokers. In children, percentages were 0.5%, 1.6%, and 16.7%, respectively. In adults, there were significant differences in age, sex, race, and employment among groups. In children, non-smokers were significantly older than passive smokers (10.1±4.9 vs 8.0±4.9, p<0.01). Tobacco exposure was associated with greater total cholesterol in adults and UPCR in children in adjusted models (Table).

Conclusions: In NEPTUNE, tobacco exposure was associated with higher levels of cholesterol in adults and proteinuria in children.

Funding: NIDDK Support

Table. Association of Tobacco Exposure with Cardiovascular Risk Factors and Kidney Outcomes in Adjusted Regression Models*

Reference Non-Smokers	Adult Active Smokers			Pediatric Passive Smokers		
	OR (95% CI)		p value	OR (95% CI)		p value

Kidney failure	N=30	0.82 (0.51, 1.32)	0.41	N=2	-	-

* Models were adjusted for age, sex, weight status, black race, glomerular diagnosis, UPC, log eGFR and steroids. Exceptions: UPC model did not include UPC, eGFR model did not include eGFR. Kidney Failure adjusted only for age and sex due to N of outcome in adults. Kidney failure not performed in children due to small N. CKD progression in children adjusted for age and sex due to N.

PO1872

Validating a Computable Phenotype for Nephrotic Syndrome in Children and Adults Using PCORnet Data

Andrea L. Oliverio,[1] Dorota Marchel,[1] Cheryl L. Tran,[4] Isabelle Ayoub,[2] Salem Almaani,[2] Jessica M. Greco,[2] Michelle Denburg,[3] Debbie S. Gipson,[1] Laura H. Mariani.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Mayo Clinic Minnesota, Rochester, MN.*

Background: Primary nephrotic syndromes (pNS) are rare diseases which can be a barrier to adequate sample size for observational patient-oriented research. A computable phenotype may be powerful in identifying patients with these diseases for research while leveraging data from millions of patients in the PCORNet Common Data Model (CDM).

Methods: A comprehensive algorithm of ICD-9 and ICD-10 codes indicative of pNS was developed based on prior work in the University of Michigan Health System. Cases of pNS were defined as subjects that were seen for at least one encounter with more than 1 NS code, and did not have codes for diabetes mellitus, systemic lupus erythematosus, or amyloidosis. Non-cases were individuals not meeting case criteria who were seen in the same calendar year and within 2 years of age of a case. The algorithm was executed against the PCORNet CDM at 3 institutions from Jan 1, 2009 to Jan 1, 2018, where a random selection of 50 cases and 50 non-cases were reviewed by a nephrologist, for a total of 150 cases and 150 non-cases reviewed. The classification accuracy (sensitivity, specificity, positive and negative predictive value, F1 score) of the computable phenotype was determined.

Results: The algorithm identified a total of 2,708 patients with NS from 4,305,092 distinct patients in the CDM at all sites. For all sites, the sensitivity, specificity, PPV, and NPV of the algorithm were 99.1%, 81.0%, 76.7%, and 99.3%, respectively. The accuracy of the algorithm was 88.0% with an F1 score of 86.5%. The most common cause of false positive classification was secondary FSGS (17/35), followed by class V lupus nephritis (9/35).

Conclusions: While prior computable phenotypes for glomerular diseases have used IMO and SNOMed codes, this computable phenotype had good classification in identifying both children and adults with pNS utilizing only ICD-9 and ICD-10 codes, which are universally available. This may facilitate future screening and enrollment for research, however further refinements to the algorithm or addition of natural language processing may help better distinguish primary and secondary FSGS.

Family History of Diabetes Is Associated with Progression of Kidney Disease: The CureGN and CRIC studies

Francesca Zanoni,[1] Miguel Verbitsky,[1] Maddalena Marasa,[1] Joshua D. Bundy,[3] Afshin Parsa,[2] Krzysztof Kiryluk,[1] Harold I. Feldman,[4] Ali G. Gharavi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [3]Tulane University, New Orleans, LA; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Family history (FHx) of complex traits may reflect shared genetic/environmental risk. We studied associations of FHx with presentation patterns, comorbidities and renal disease progression in a prospective cohort of primary GN and one of non-GN chronic kidney disease(CKD).

Methods: The Cure Glomerulopathy Network(CureGN) is a prospective multi-center study of patients(N=2474-median age 29 years)with biopsy-proven GN. Associations of self-reported FHx of diabetes(DM), cancer(C), clotting disorders(CD), and autoimmune diseases(AD) with eGFR and comorbidities prevalence were studied with multivariable regression models. We investigated associations of FHx and end-stage renal disease/50%eGFR decline(ESRD/50%eGFR) with multivariate Cox models. The Chronic Renal Insufficiency Cohort (CRIC) Study, a multi-center prospective study of 3939 adult(median age 59 years)CKD patients, was used for replication.

Results: FHx of DM predicted lower eGFR at diagnosis(p=0.002) in CureGN. Figure 1 summarizes associations of FHx of complex traits with comorbidities in CureGN. FHx of DM was associated with higher odds of DM(OR 1.56, 95%CI 1.16-2.09, p=0.003)in the subgroup of CRIC with no DM at baseline. After adjustment for relevant covariates, FHx of DM was associated with higher risk of the composite outcome of ESRD/50%eGFR reduction in both CureGN (HR 1.43, 95%CI 1.06-1.94, p=0.02) and CRIC (HR 1.15, 95%CI 1.01-1.31, p=0.038).

Conclusions: FHx of complex traits are associated with specific comorbidities. FHx of DM identifies patients with lower eGFR and disease progression. In conclusion, FHx could be an additional parameter for risk stratification and management of CKD.

PO1874

Proteinuria Selectivity Index as a Predictor for Response to Therapy in Nephrotic Syndrome

Maiko Nakayama,[1] Hitoshi Suzuki,[1,2] Masao Kihara,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan.*

Background: Minimal change disease (MCD) is the most frequent cause of primary nephrotic syndrome (NS) in Japan. The response to steroid therapy is highly sensitive, and remission rates are over 90% in patients with MCD. However, recurrence rates are also high. Selectivity index (S.I.) of proteinuria using clearance ratio of IgG to transferrin is commonly used for initial examination to differentiate MCD. Whereas, there is no useful index of predictor for response to therapy in nephrotic syndrome. In present study, we evaluated clinical markers to predict the treatment response.

Methods: Of the 94 patients with NS who were performed renal biopsy in our hospital from 2013 to 2019, 60 patients with primary nephrotic syndrome were divided into complete remission group and incomplete remission group by initial treatment response. We examined whether clinical markers including eGFR, serum albumin and S.I. can predict initial treatment response. We further examined the association between S.I. and risk of relapse in patients with MCD.

Results: Forty-five of sixty patients with primary NS were complete remission group. In complete remission group, the incidence of MCD, idiopathic membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS) and membranoproliferative glomerulonephritis (MPGN) were 75%, 16%, 7%, and 2%, respectively. The S.I. was significantly lower in the complete remission group than in the incomplete remission group (P<0.01). And, the S.I. in the complete remission group was less than 0.2 in any underlying diseases. Thus, regardless of the primary underlying disease, NS patients with low S.I. may have high remission rate after initial prednisolone (PSL) therapy. In patients with MCD, the relapse group showed the higher level of urine IgG and transferrin compared with the remission maintenance group (P<0.05), although the level of S.I. was the same degree. The remission rate and recurrence rate were not correlated with age, levels of serum albumin, creatinine, eGFR, IgG or urinary protein.

Conclusions: Regardless of the causal diseases of NS, the patients with S.I. less than 0.2 have good response to PSL treatment. Moreover, it is suggested that S.I. as well as levels of urinary IgG and transferrin may be useful to assess the risk of recurrence in patients with MCD.

PO1875

Fractional Excretion of Total Protein in Nephrotic Syndrome

Hideaki Kuno, Go Kanzaki, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. *The jikei university school of medicine, Minato-ku, Japan.*

Background: Lower estimated glomerular filtration rate (eGFR) and higher proteinuria are the most sensitive predictor of the development of progressive renal insufficiency in various glomerular diseases. Fractional excretion of total protein (FETP) calculated by dividing the total protein clearance by the creatinine clearance is tightly associated with both proteinuria and GFR. However, few studies have analyzed in glomerular diseases the FETP to evaluate their relationship with renal function and histologic lesions. This study aimed to evaluate the relationship between FETP and the clinical features and histologic lesions and to assess whether FETP predicts outcome in nephrotic syndrome (NS).

Methods: Subjects who exhibited NS with a histological diagnosis were retrospectively analyzed at the Jikei University School of Medicine Hospital, Tokyo, Japan, during biopsy performed between 2002 and 2018. We analyzed 24-h urinary protein excretion, FETP, and other clinicopathological findings at kidney biopsy. The FETP was determined by the standard clearance technique based on 24-h urine collection: FETP = (urinary total protein / serum total protein) / (urinary creatinine / serum creatinine) × 100.

Results: A total of 113 subjects with NS were identified (Age 53.7 ± 17.3 [mean ± SD] years old; Male 71.7%, eGFR 57.6 ± 27.7 mL/min/1.73m^2; urinary protein excretion 7.02 ± 3.67 g/day; minimal change nephrotic syndrome [n = 41]; focal segmental glomerular sclerosis [n = 10]; membranous nephropathy [n = 36]; diabetic nephropathy [n = 26]). FETP was significantly associated with eGFR (ρ = -0.65, P <0.01), urinary protein excretion (ρ = 0.58, P <0.01), interstitial fibrosis and tubular atrophy (ρ = 0.24, P <0.05), and glomerulosclerosis (ρ = 0.24, P <0.05). Interestingly, patients with diabetic nephropathy showed the highest level of FETP with the poor renal outcome, while membranous nephropathy revealed the lowest level of FETP.

Conclusions: These results suggest that FETP would be a useful marker combining the two predictors of the decline of renal function in NS showing increased glomerular protein permeability and decreased glomerular filtration function.

PO1876

Prediction of Morphological Lesions Using Various Glomerular Filtration Rate Equations in Patients with Primary Glomerulonephritis

Elena Saganova, Olga Galkina, Vasiliy Sipovskii, Ivan Kayukov, Alexey Smirnov. *Pervyj Sankt-Peterburgskij gosudarstvennyj medicinskij universitet imeni akademika I P Pavlova, Sankt Peterburg, Russian Federation.*

Background: Glomerular filtration rate (GFR) is generally accepted best overall index of kidney function. However, it remains controversial to use GFR as a marker of morphological lesions. **Aim.** To assess GFR equations as a predictor of chronic morphological lesions in patients with glomerulonephritis (GN).

Methods: 100 patients [48 female, age Me 39 (27; 54) years] with biopsy proven primary GN were included in the study (9%–minimal change disease, 28%–focal segmental glomerulosclerosis, 26%–membranous nephropathy, 37%–IgA-nephropathy). Serum creatinine was measured by enzymatic, serum cystatin C - immunoturbidimetric methods. GFR was estimated using creatinine clearance (CCr), MDRD, CKD-EPICr, CKD-EPICysC, CKD-EPICrCysC, full age spectrum (FASsCr) equations. Glomerulosclerosis (GS) was assessed quantitatively, tubulo-interstitial fibrosis (TIF), tubular atrophy (TA) - semi-quantitatively (0-lesions absent; 1-mild focal lesions; 2-moderate lesions; 3-diffuse lesions). All patients were separated consistently in two groups according to the degree of each morphological lesion: “mild” (GS<25% or TIF/TA=0-1), “severe” (GS≥25% or TIF/TA=2-3).

Results: Independently of estimating equation, GFR positively correlated (p<0,001) with GS, TIF, TA and was higher in patients with “mild” GS, TIF and TA (p<0,001). Based on the results of ROC-analysis patients were separated (p<0.001) in two groups using all equations according to the degree of morphological lesions (“mild” or “severe” GS, TIF and TA). Using comparison of AUC we found the significant difference between CCr and CKD-EPICr, CKD-EPICysC, CKD-EPICrCysC, between MDRD and CKD-EPICr, CKD-EPICrCysC equations in prediction of TIF, between CKD-EPICrCysC and FASsCr - in prediction of GS and no difference for all equations in prediction of TA (Fig. 1).

Conclusions: Independently of estimating equation, GFR is a good marker of morphological lesions in patients with primary GN. Our data shows that CKD-EPI equations, especially CKD-EPICrCysC, provide the highest diagnostic value in prediction GS and TIF.

Funding: Government Support - Non-U.S.

PO1877

Fluid Overload and Markers of Cardiovascular Damage in Severe Nephrotic Syndrome

Aleksandra Rymarz, Anna Matyjek, Stanislaw Niemczyk. *Military Institute of Medicine, Warsaw, Poland, Warsaw, Poland.*

Background: The purpose of the study was to evaluate the dimension of body water compartments and markers of cardiovascular damage in patients with severe nephrotic syndrome (SNS) defined as nephrotic range proteinuria and hypalbuminaemia ≤ 2.5 g/dl.

Methods: 40 patients with SNS and eGFR >30 ml/min/1.73m² formed the study group (SNSG) and 40 healthy volunteers without SNS matched according to age, sex, height, body mass, kidney function formed the control group (CG). Body water compartments were assessed using Body Composition Monitor, Fresenius Medical Care. For statistical analysis Spearman's correlation coefficients, chi² or Mann-Whitney U tests were used (Statistica v 13.1).

Results: SNSG included 28 males and 12 females, the mean daily proteinuria was 10.5±5.0 g. The groups are described in the table. In SNSG significantly higher hsTnT, NT-proBNP and extracellular water(ECW) were observed in comparison to CG. Intracellular water (ICW) was significantly lower in comparison to CG. Total body water (TBW) did not differ between the groups. Overhydration (OH) was higher in SNSG than in CG. Significant, positive correlation was observed between OH and NT-proBNP (R=0.56, p<0.0001) as well as hsTnT (R=0.60, p<0.0001). We did not observed significant correlation between ECW and NT-proBNP or hsTnT.

Conclusions: In SNSG fluid retention was associated with the increase in ECW and the decrease in ICW whereas TBW was the same in both groups. Such constellation can indicate for intracellular underhydration which was not describe so far. OH, which is a derivative of ECW, correlated with markers of cardiovascular damage and can be important for patients with resistant SNS and influence their prognosis.

Clinical characteristic of the study groups

Glomerular Filtration Barrier Dysfunction in an RNA Virus-Induced Glomerulopathy Resembles Findings of Common Nephrotic Syndromes

Christian Nusshag,[1] Alisa Stütz,[1] Stefan Hägele,[1] Claudius Speer,[1] Florian Kälble,[1] Christoph Eckert,[1] Christian Morath,[1] Jochen Reiser,[2] Martin G. Zeier,[1] Ellen Krautkrämer.[1] *[1]Heidelberg University Hospital, Heidelberg, Germany; [2]Rush University Medical Center, Chicago, IL.*

Background: Virally induced kidney dysfunction is highlighted by the alarming incidence of SARS-CoV-2 associated acute renal disease including nephrotic syndrome (NS). Plasma levels of soluble urokinase plasminogen activator receptor (suPAR) are elevated in COVID patients and provide prognostic insights. SuPAR is also involved in proteinuric kidney diseases such as focal segmental glomerulosclerosis in which podocytes effacement/injury is a common feature. Hantavirus-induced hemorrhagic fever with renal syndrome (HFRS) represents another RNA virus-induced disease with acute kidney injury and NS. The exact pathophysiology of proteinuria is, however, unclear. We hypothesized that hantavirus infection results in podocyte injury and a dysfunctional glomerular filtration barrier (GFB), similar to findings in common NS.

Methods: Renal biopsy specimens were analyzed by light and electron microscopy. Urinary nephrin and serum suPAR were measured over time in 26 patients with HFRS and 18 healthy controls.

Results: Hantavirus patients showed significantly increased urinary nephrin, immunoglobulin G (IgG), a1-microglobulin (a1-MG) and serum suPAR concentrations compared to healthy controls. Furthermore, nephrin and IgG levels were significantly higher in patients with severe than with mild proteinuria. Differences in a1-MG levels, however, disappeared after normalization to urinary creatinine. Urinary nephrin levels as a marker for podocyte damage correlated strongly with biomarkers of non-selective glomerular proteinuria. Interestingly, suPAR correlated significantly with urinary nephrin, IgG and albumin levels, suggesting suPAR as a potential pathophysiological mediator in GFB dysfunction in response to RNA virus infection. The main finding in microscopy analyses was a focal foot process effacement. Proteinuria and kidney dysfunction recovered autonomously in all patients.

Conclusions: Hantavirus infection causes a podocyte injury leading to GFB dysfunction. A better understanding of transient virally induced proteinuria syndromes and their often self-limiting disease character may generate new therapeutic approaches for NS.

PO1879

Nephrotic Syndrome from the Age of 65 Years: Epidemiological, Clinical, and Renal Biopsy Data

Luana R. Soares, Jose Mariano S. Pantoja, Lectícia Jorge, Viktoria Woronik, Cristiane B. Dias. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: This study aims to evaluate epidemiological, clinical, and renal biopsy data of patients aged 65 or over with nephrotic syndrome, admitted in a University Hospital.

Methods: Retrospective cohort study of renal biopsies performed from 2012 to 2017, considering the age 65 years or over, with diagnosis of nephrotic syndrome, under follow-up at the Nephrology Department of the Hospital das Clínicas of the University of São Paulo.

Results: In these period 103 renal biopsies were performed in patients aged 65 or over, 45 (43.68%) of them were indicated by the diagnosis of nephrotic syndrome. These 45 patients had mean age of 70.60±5.24 years old, 60% male, laboratory data at diagnosis were median serum creatinine of 2.02±1.53 mg/dl, hemoglobin of 11.34±1.41 g/dl, serum albumin of 2.23±0.83 g/dl and proteinuria of 6.95±4.64 g/day. Only minor complications of renal biopsy were observed and occurred in 6.6% of cases. The most frequent histological lesion was Membranous Nephropathy in 13 cases (28.88%), followed by Renal Amyloidosis AL in 9 cases (20%), Focal Segmental Glomerulosclerosis (FSGS) in 8 (17.77%) highlighting that 4 patients had the Collapsing Form, Minimal Change Disease (MCD) occurred in 7 cases (15,55%) and the remaining 8 had others glomerular diseases. In Table 1 has the comparison between patients data according the glomerular disease. [Table]

Conclusions: Renal biopsy was a safe procedure and provided confirmation that Membranous Nephropathy was the most common histological lesion followed by Amyloidosis AL in aged 65 or over. Highlights the Collapsing glomerulopathy founded in 8.88% of the patients none of them associated with HIV or other disease. Minimal Change Disease was the only cause of nephrotic syndrome with acute tubular necrosis in this population, while FSGS had less vascular lesions at renal biopsy.

Clinical Characteristics, Treatment Patterns, and Outcomes of Children and Adults with Biopsy-Proven Minimal Change Disease from the Cure Glomerulonephropathy Network Study (CureGN)

Dhruti P. Chen,[1] Margaret Helmuth,[2] Rasheed A. Gbadegesin,[3] Amy K. Mottl,[1] Debbie S. Gipson,[4] Katherine Twombley.[5] The Cure Glomerulonephropathy Network Study (CureGN) *[1]University of North Carolina, Chapel Hill, NC; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Duke University Hospital, Durham, NC; [4]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [5]Medical University of South Carolina, Charleston, SC.*

Background: The age of Minimal Change Disease (MCD) onset spans all ages. We analyzed the CureGN multi-center observational cohort study to elucidate differences in natural history and treatment patterns by age of MCD onset.

Methods: 567 participants enrolled within 5 years from kidney biopsy were available. Continuous variables are described as median [25,75 percentile] or n[%]. Univariate comparisons were performed using chi-square tests and Wilcoxon rank-sum tests for categorical and continuous variables, respectively. eGFR was winsorized to 120 ml/min in repeated measures models used to assess eGFR over time.

Results: Comparisons by age group are shown in the Table. There were modest differences in the racial/ethnic composition and weight. Severity of proteinuria was similar at disease onset [6.1 vs 6.5, p-value=0.5] but higher in adults at biopsy (6.6 vs. 3.4, p-value=<0.001). At biopsy, eGFR was higher in children than adults (127.7 vs 88.6, p-value<0.001), and were more likely to have received immunosuppression prior to biopsy (58% vs. 18%, p-value<0.001). Compared to children, adults were more likely to report a history of HTN (29% vs 43%, p-value<0.001). Children were more likely to have frequently relapsing/steroid dependent disease than adults (51% vs. 29%, p-value <0.0001) and higher steroid resistant disease than adults (17% vs. 12%, p-value <0.0001). Over a median of 29.1 months follow up, ESKD occurred in 13 (2%) participants (8 children; 5 adults) and deaths occurred in 3 (1%) (1 child, 2 adult).

Conclusions: Significant sociodemographic and clinical differences exist between adult-onset versus pediatric onset MCD at the time of biopsy. These differences are most likely due to differences in treatment and biopsy practices relative to symptom onset.

Funding: NIDDK Support

****Fishers exact test. GFR estimated using CKiD bedside (pediatric) and CKD-Epi (adults) equations, GFR's from both equations were averaged for participants between ages 18-26. UPCR collected from either a 24 hour, a 1st morning or a spot urine, depending on availability.

PO1881

Clinical Characteristics of Acute Glomerulonephritis with Presentation of Nephrotic Syndrome at Onset in Children

Huipeng Ge, Qiongjing Yuan, Xiangcheng Xiao. *Xiangya Hospital Central South University, Changsha, China.*

Background: Acute glomerulonephritis (AGN) is a common disease in children, which placed a huge burden on developing countries. Prognosis of it may not always good. However, the clinical characteristics of AGN with nephrotic syndrome (NS) at onset were not fully clarified.

Methods: 113 cases were analyzed retrospectively. Clinical data, pathological results and prognosis between AGN with NS (AGN-NS) and AGN without NS (AGN-no-NS) were compared.

Results: 20 (17.7%) of 113 patients were AGN-NS. The patients with AGN-NS were more likely to have hypertension (55.0% vs. 25.8%) and acute kidney injury (AKI) (50% vs. 17.2%). The AKI was significantly related to the manifestation of AGN-NS in children (OR=3.812, *P*=0.040). Compared with the AGN-no-NS, the immunosuppressive treatments were more common in AGN-NS. A severer pathological grade was significantly related to the lower C3 fraction, estimated glomerular filtration rate (eGFR) and AKI, but not the performance of AGN-NS. There was no difference in prognosis between two groups.

Conclusions: The AKI was significantly associated with AGN-NS. The prognosis of AGN-NS and AGN-no-NS in our study was almost good. Given the fact that AGN-NS patients more likely to use the immunosuppressive therapy, the long-term outcome of AGN-NS is worth a further research.

Estimation of Childhood Nephrotic Syndrome Incidence: Data from the Atlanta Metropolitan Statistical Area and Meta-Analysis of Worldwide Cases

Jackson Londeree,[1,2] Larry A. Greenbaum,[1,2] Evan Anderson,[1,2] Laura Plantinga,[1,3] Courtney Mccracken,[1,2] Scott Gillespie,[1,2] Chia- Shi Wang.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Children's Healthcare of Atlanta Inc, Atlanta, GA; [3]Emory University School of Public Health, Atlanta, GA.*

Background: There is limited epidemiological data on childhood idiopathic nephrotic syndrome (NS) in the United States. We estimated contemporary childhood NS incidence estimates in a racially and ethnically diverse U.S. population, and performed a meta-analysis of published reports to examine differences by race and ethnicity and changes over time.

Methods: Children 1-17 years-old diagnosed with NS in the Atlanta MSA between 1/1/2013 and 12/31/2018 were identified by chart review using practice data from the only pediatric nephrology practice in the region. Annual incidence rates were calculated by dividing the number of cases by population data provided by the Georgia Department of Public Health. We also performed a literature review for published childhood NS incidence and calculated pooled incidence estimates using random-effects regression models. Incidence estimates by race and ethnicity were compared by computing pooled estimates within each subgroup and testing for significant heterogeneity between subgroup estimates. We also reviewed U.S. incidence over time comparing pooled incidence estimates before and after 1984.

Results: 175 children aged 1-17y were diagnosed with NS between 2013-2018 in the Atlanta MSA. Incidence by race and ethnicity from the Atlanta MSA and meta-analysis demonstrated highest incidence in Asian children, followed by those of African descent, Hispanics and Caucasians (Table 1). Incidence in the U.S. was stable over time.

Conclusions: Risk for childhood NS development differs by race and ethnicity without changes over time. Future studies need to evaluate the underlying genetic and environmental factors associated with NS incidence.

Table 1. Incidence of childhood idiopathic nephrotic syndrome

Steroid Treatment for the First Episode of Childhood Nephrotic Syndrome: Comparison of the 8- and 12-Week Regimen Using an Individual Patient Data Meta-Analysis

Anne M. Schijvens,[1] Nynke Teeninga,[5] Eiske Dorresteijn,[2] Nicholas Webb,[3,4] Michiel F. Schreuder.[1] *[1]Radboudumc, Nijmegen, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands; [3]Royal Manchester Children's Hospital, Manchester, United Kingdom; [4]Health Innovation Manchester, Manchester, United Kingdom; [5]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: Steroids are the cornerstone of the treatment of childhood nephrotic syndrome. The optimal duration for the first episode remains a matter of debate. The aim of this study is to determine whether the 8 weeks ISKDC regimen (prednisolone 4 weeks 60mg/m^2 daily, 4 weeks 40mg/m^2 on alternate days) is equally effective as the 12 weeks APN regimen (prednisolone 6 weeks 60mg/m^2 daily, 6 weeks 40mg/m^2 on alternate days).

Methods: An individual patient data (IPD) meta-analysis of randomized controlled trials reporting on prednisolone treatment for a first episode of childhood nephrotic syndrome was conducted. European trials aimed at investigating the ISKDC and/or APN steroid regimen were selected. Statistical models were adjusted for relevant covariates.

Results: Four trials included European patient cohorts treated according to the ISKDC and/or APN steroid regimen. IPD of two trials were available (PREDNOS, UK, 2019, n=109 and Nephrotic Syndrome trial, the Netherlands, 2013, n=62). Baseline characteristics did not significantly differ between the two treatment groups, with the exception of ethnicity. A significant difference was found in the time to first relapse after cessation of steroid treatment between the 8 and 12 weeks treatment group (p 0.04). The incidence of frequent relapsing nephrotic syndrome (FRNS) was similar in the two groups (p 0.75). Interestingly, a significant difference was found in the incidence of steroid dependent nephrotic syndrome (44% [8 weeks] vs 24% [12 weeks], p 0.01). Overall, relapse rate ratios were 51% higher in the 8 weeks group compared to the 12 weeks group (p 0.01). Finally, children below 4 years of age seem to have a significantly lower survival time (time to first relapse and time to FRNS) compared to children of 4 years and older (p 0.02 and p 0.003).

Conclusions: The results of this IPD meta-analysis suggest that the 8 weeks regimen for a first episode of nephrotic syndrome is not equally effective as the 12 weeks steroid regimen. Although less steroids for the first episode would be beneficial in terms of steroid toxicity in the short term, these results suggest patients treated with a 12 week steroid regimen may have a less complicated disease course.

PO1884

Targeted B-Cell Depletion with Rituximab in Adult Relapsing Minimal Change Disease

Rakesh Dattani, Tom Cairns, Marie B. Condon, Jeremy B. Levy, Liz Lightstone, Stephen P. McAdoo, Frederick W. Tam, Megan Griffith. *Imperial College NHS Healthcare Trust, London, United Kingdom.*

Background: Case series suggest use of rituximab is effective in treating adults with relapsing Minimal Change Disease (MCD). We previously reported rituximab to increase time in remission, however, the majority of patients did have further relapses. We thus studied the efficacy of retreatment with rituximab on B cell repletion for 2 years to prevent relapse.

Methods: Adult patients with recurrent MCD relapses were identified and treated with rituximab and monitored for lymphocyte depletion (total B-lymphocyte <10) with pre-emptive re-dosing after reconstitution was observed.

Results: 16 patients (8 female, 8 male) started B cell targeted maintenance rituximab for up to 2 years. At start of the maintenance period, 14/16 were on immunosuppression, tacrolimus (7) steroids (3), or both (4), stopped at a mean of 6.4 months (range 2-16 months). 15/16 patients re-dosed after reconstitution was observed. 1/16 received 6 monthly rituximab, without waiting for lymphocyte reconstitution, due to a history of rapidly relapsing disease. 16/16 achieved lymphocyte depletion post rituximab. 3/16 relapsed during the 2 year treatment period, 1/3 was B cell deplete at relapse, 2/3 were B cell replete at relapse having been deplete on their previous blood test. As of May 2020, 10/16, have completed 2 years treatment, with a mean follow up post treatment of 6.6 months (range 1 to 13.). Of these 3/10 have subsequently relapsed at mean time of

3.3 months (range 1-5), 2/3 were B cell replete at relapse. Rituximab was generally well tolerated, with no significant hypogammaglobinaemia or hospital admissions observed.

Conclusions: Targeting B cell depletion with rituximab is effective in maintaining remission of MCD. However, relapse can occur rapidly post repletion of lymphocytes, so frequent monitoring of lymphocyte subsets is required to ensure early retreatment upon reconstitution. An alternative strategy maybe pre-emptive rituximab dosing at fixed intervals. Even after 2 years of maintenance therapy, B cell repletion is still associated with relapse. Further work is needed to compare maintenance strategies and to determine the optimal length of time of maintenance rituximab.

PO1885

Belimumab for the Treatment of Frequently Relapsing Nephrotic Syndrome: The BELNEPH Study

Marina Vivarelli, Manuela Colucci, Antonio Gargiulo, Chiara Bettini, Francesco Emma. *Ospedale Pediatrico Bambino Gesù – IRCCS, Rome, Italy*.

Background: A pathogenic role of B cells in pediatric idiopathic nephrotic syndrome (INS) has been suggested by the therapeutic efficacy of B-cell depletion, which however can impair immune memory. Belimumab treatment affects B-cell survival and differentiation but preserves the established immune memory. Its efficacy has been proven in other immune-mediated diseases, such as systemic lupus erythematosus and membranous nephropathy.

Methods: In this open-label, prospective, single-arm study, 5 children with frequently-relapsing INS who were on alternate-day prednisone only were enrolled. Belimumab was administered at 10 mg/kg i.v. on day 0, 14, 28 and then every 4 weeks for up to 12 months. Concomitant prednisone treatment was gradually tapered up to recurrence of NS if it occurred. Safety, efficacy and laboratory blood and urine parameters were monitored for the duration of the study.

Results: Four patients completed the primary endpoint (6 months) and 2 patients completed the study. Infusions were well tolerated. One patient experienced a pulmonary infection which required hospitalization 2.3 months after the first infusion. Four patients experienced a first relapse within 6 months (1.9, 2.5, 2.6, 3.3 months after starting treatment) and 1 patient 8.1 months from first infusion. Three patients discontinued the study due to the frequency of relapses (≥2) after 5.2, 9.2, 9.6 months, respectively, and were started on another steroid-sparing agent. The study was discontinued due to apparent lack of effectiveness. $CD19^+$ B cells decreased during the follow-up, with a nadir at 6 months (8.6% of lymphocytes vs 19.1% at baseline, $p<0.01$). Naïve B cells started to significantly decrease after 1 month (7.7% vs 12.4% at baseline, $p<0.05$) and continued to decline during the follow-up. In contrast, no significant impact was observed on memory B cells, which became the most representative B-cell subset already at 1 month (43.5% of B cells vs 27.3% at baseline, $p<0.01$), with an initial shift toward a switched subset (57.4% and 59.0% of memory B cells at 3 and 6 months, respectively, vs 48.3% at baseline, $p<0.01$). Serum IgG, IgA and IgM levels were not significantly modified.

Conclusions: Belimumab treatment in children with frequently-relapsing INS failed to modify disease course. Persistence of circulating memory B cells supports their pathogenic role in INS.

PO1886

GFB-887, a TRPC5 Inhibitor, Is Safe and Well Tolerated and Engages the TRPC5 Target, Leading to Reductions in Urinary Rac1 in Healthy Subjects

Liron Walsh, Chris Lynam, Leslie Johnson, Tingting Ge, Xin-Ru Pan-Zhou, Frank S. Czerwiec, Yossi Dagon, Hari Raghu, John F. Reilly. *Goldfinch Bio Inc, Cambridge, MA*.

Background: Activation of the TRPC5-Rac1 pathway is a key driver of podocyte injury in focal segmental glomerulosclerosis (FSGS), minimal change disease (MCD), and diabetic nephropathy (DN). Inhibition of the TRPC5 ion channel may be a potential therapeutic target for these disorders. GFB-887 is a sub-type selective, small molecule TRPC5 ion channel inhibitor that has been shown in preclinical models to prevent podocyte damage mediated by Rac1 activation. This is a first-in-human study to evaluate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of single ascending doses (SAD) of GFB-887 in healthy subjects.

Methods: This is a phase 1, double-blinded, randomized, placebo-controlled, study in healthy subjects. The objectives were to characterize safety, tolerability, PK profile, and effects on urinary Rac1 after single oral doses of GFB-887. Subjects were randomized to either GFB-887 or placebo (8:2) in 5, 20, 40, 80,160, 320, and 900 mg SAD cohorts. Each subject received a single dose, had 24-hour urine collection pre and post-dose, and followed for 28 days post-dose.

Results: 70 healthy subjects (median age 43 years, 86% male, 56% Caucasians, 42% African Americans) were dosed with GFB-887. The most common adverse event (AE) was headache. All AEs were mild and non-serious. There were no clinically significant changes in ECGs, vital signs or laboratory results. Blood pressure was modestly and asymptomatically reduced at the highest doses. C_{max} and AUC of GFB-887 increased with higher doses in a less than dose proportionally manner through 900mg. Urinary Rac1 was significantly reduced from baseline with increasing doses of GFB-887.

Conclusions: Single doses of GFB-887 were well tolerated with a favorable PK profile in healthy subjects. GFB-887 exhibits dose-dependent reduction in urinary Rac1, a regulator of podocyte cytoskeletal structure and motility, indicating that GFB-887 engages and inhibits the TRPC5-Rac1 pathway. The safety and efficacy of GFB-887 is currently being evaluated in patients with FSGS, MCD, and DN (NCT04387448).

PO1887

Phase 1 Study of N-Acetylmannosamine (ManNAc) for Glomerular Disease

Jodi Blake, Federico Fuentes, Marjan Huizing, William Gahl, Jeffrey B. Kopp, Petcharat Leoyklang, Kenneth J. Wilkins. *National Institutes of Health, Bethesda, MD*.

Background: ManNAc is an uncharged monosaccharide and precursor of N-acetylneuraminic acid (NeuAc, sialic acid). It provides anionic charges to proteins, including those constituting the glomerular filtration barrier. Glomerular hyposialylation is common in nephrotic diseases and may contribute to podocyte foot process effacement and increased protein permeability. ManNAc showed benefit in nephrotic mouse models.

Methods: We performed a phase 1 study to evaluate the safety, tolerability, and pharmacokinetics of single and multiple doses of ManNAc in nephrotic subjects (NCT02639260). Seven subjects were enrolled, 6 with focal segmental glomerulosclerosis and 1 with membranous nephropathy. Urine protein/creatinine ratio was 1.3 to 9.9 l g/g and estimated glomerular filtration rates were 29 to 89 ml/min/1.73m2. Six subjects completed a 11-day inpatient stay, receiving a 3 g single ManNAc dose, followed by 5 days 1.5 g twice daily. One subject received a single dose of 6 g ManNAc.

Results: ManNAc administration was well-tolerated. There were no serious adverse events. Most subjects (5 of 6) that received ManNAc twice daily showed a marked reduction in urine PCR (26-54%), which correlated with the degree of glomerular hyposialylation. Baseline plasma ManNAc levels in nephrotic subjects with normal eGFR were similar to those in subjects with normal renal function, but baseline plasma free NeuAc levels were elevated in nephrotic subjects with lower eGFR. This is consistent with NeuAc having high glomerular permeability and little tubular reabsorption. Plasma ManNAc levels peaked 2-4 h after dosing and returned to baseline after ~12h. Plasma free NeuAc levels peaked ~10h after dosing, remained elevated beyond 48h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. There appeared to be no adverse effects with increased free sialic acid levels, but confirmation is needed. These data support twice daily dosing, with reduced doses for subjects with low eGFR.

Conclusions: Oral ManNAc was safe and well tolerated in glomerular disease subjects. ManNAc supplementation showed a trend towards proteinuria reduction, possibly linked to the degree of glomerular hyposialyation. A phase 2 study is planned, to include assessment of longer-term pharmacokinetics, efficacy and safety.

PO1888

Efficacy and Safety of ACE Inhibitor and ARB Therapies in Primary FSGS Treatment: A Systematic Review and Meta-Analysis

Kirk N. Campbell,[1] Natali Pennese,[2] Andrea Zaffalon,[2] Barbara Magalhaes,[2] Marina Faiella,[2] Dawn J. Caster,[3] Jai Radhakrishnan,[4] Vladimir Tesar,[5] Howard Trachtman.[6] *[1]Mt Sinai School of Medicine, New York, NY; [2]LatticePoint Consulting, Geneva, Switzerland; [3]University of Louisville School of Medicine, Louisville, KY; [4]Columbia University Medical Center, New York, NY; [5]Charles University, General University Hospital, Prague, Czechia; [6]NYU School of Medicine, NYU Langone Medical Center, New York, NY*.

Background: Use of ACEi and/or ARB (RASi) as conservative management to control proteinuria in primary and genetic focal segmental glomerulosclerosis (FSGS) follows guideline recommendations based on other proteinuria-related kidney diseases. There is lack of consensus about the efficacy and safety of RASi therapies in primary and genetic FSGS, thus this systematic review aims to assess the benefits and risks of RASi therapies on renal outcomes in these patients.

Methods: English-language studies were searched in MEDLINE, Embase and Cochrane Central Register of Controlled Trials, from inception to April 2019. Cohort studies assessing efficacy (response to treatment and indicators of renal function) and safety outcomes in primary and genetic FSGS were selected. Study results were summarized as Ratio of Means (ROM) between baseline and follow-up measurements, or as Hazard Ratio (HR) using random effects models.

Results: We selected 30 studies of which only 5 were controlled trials. Only 8 assessed RASi as monotherapy while the rest studied them in combination with other drugs, mainly immunosuppressants (IS). On average, a 32% reduction on proteinuria (ROM=0.68; 95% CI: 0.47-0.98) and no change on CrCl (ROM=0.95; 95% CI: 0.77-1.16) from baseline to variable follow-up periods was observed in patients treated with RASi therapy alone. A reduction of 72% in proteinuria was observed when RASi were combined with other drugs, mainly IS (ROM=0.24, 95% CI: 0.08-0.75). Published data did not allow to evaluate the eGFR ROM between follow-up and baseline and the

effect on the risk of reaching ESRD of RASi therapy alone. Only one controlled study reported adverse effects of RASi as monotherapy. Overall, the available evidence exhibits considerable heterogeneity in cohort baseline characteristics and study design.

Conclusions: This review supports the tendency to observe a reduction of proteinuria in patients treated with RASi, and demonstrates the lack of strong evidence to quantify their effect on eGFR and their long-term impact on renal survival. The current lack of properly controlled studies in primary FSGS stresses the need for larger and better designed clinical trials to better understand the effect of RASi.

Efficacy and Safety of Immunosuppressive Therapy in Primary FSGS: A Systematic Review and Meta-Analysis

Dawn J. Caster,[1] Barbara Magalhaes,[2] Natali Pennese,[2] Andrea Zaffalon,[2] Marina Faiella,[2] Kirk N. Campbell,[3] Jai Radhakrishnan,[4] Vladimir Tesar,[5] Howard Trachtman.[6] *[1]University of Louisville School of Medicine, Louisville, KY; [2]LatticePoint Consulting, Geneva, Switzerland; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Columbia University Medical Center, New York, NY; [5]Charles University, General University Hospital, Prague, Czechia; [6]NYU School of Medicine, NYU Langone Medical Center, New York, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) is a rare condition which can lead to decline in renal function and progression to ESRD. Immunosuppressants (IS) are often used to treat primary FSGS. However, their efficacy and safety is not clearly established. The objective of this work was to assess the current knowledge on the clinical effectiveness and safety of IS in the treatment of primary FSGS.

Methods: MEDLINE, EMBASE and Cochrane Central Register of Controlled Trials were searched for English-language studies on primary FSGS from inception to 2019. Clinical outcomes of interest were changes from baseline in proteinuria, and renal function (eGFR or CrCl) and survival (ESRD, renal failure, doubling of creatinine, or author reported). When possible, study results were summarized using random effects models as Ratio of Means (ROM) between follow-up and baseline measurements or as Hazard Ratio (HR).

Results: We included 100 articles. Substantial heterogeneity was observed in patient baseline characteristics and study design. Most studies assessed treatment with corticosteroids alone or combined with other drugs, mainly other IS. On average, patients treated with IS showed a reduction of proteinuria (14 studies, ROM=0.34; 95% CI 0.25-0.46). Pooled studies showed a lower CrCl at the end of the follow-up compared to baseline (ROM=0.77; 95% CI 0.71-0.83). In contrast, eGFR measurements suggested no change from baseline to follow-up (16 studies, ROM=0.92; 95% CI 0.84-1.01). IS therapy had uncertain effect on reducing the risk of reaching ESRD (HR=0.79; 95% CI 0.47-1.32). Hypertension and infections were the most commonly reported AEs.

Conclusions: This systematic literature review supports that patients treated with IS have on average, a reduction in proteinuria between baseline and varying follow-up periods. Reported changes from baseline to follow-up in CrCl and eGFR are contrasting and effect of IS on renal survival is uncertain. However, due to lack of properly controlled studies, it is hard to attribute how much of these outcome are due to IS treatment effect, stressing the low certainty evidence currently available in the literature and the need for better designed studies to reliably assess the effect of IS on primary FSGS patients.

PO1890

The Epidemiological Comparison Between North American and Japanese FSGS/Minimal Change Disease Patients

Takaya Ozeki,[1,2] Maria Larkina,[1] Shoichi Maruyama,[2] Matthias Kretzler,[1] Laura H. Mariani.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Few studies directly compared the presentation and treatment response of nephrotic syndrome (NS) considering the racial and ethnic differences of different countries.

Methods: NEPTUNE is a prospective cohort study of NS across 23 North American centers. Nagoya Kidney Disease Registry (N-KDR) is a Japanese retrospective cohort in Nagoya area. Nephrotic FSGS/MCD adults who received immunosuppressive therapy (IST) were included. Demographics and laboratory data of the patents were compared. Time to complete remission (CR: UPCR<0.3) from the start of IST were evaluated using Kaplan-Meier method. The common predictors for CR among both cohorts were evaluated by Cox proportional hazard model and selected using a backward stepwise method.

Results: Eighty-eight NEPTUNE and 302 N-KDR cases were eligible. The median of follow-up was 35 and 47 months in NEPTUNE and N-KDR, respectively. In NEPTUNE, 20.7% were African Americans and 26.1% were Hispanic. NEPTUNE had higher proportion of FSGS (55.7 vs. 16.2%, p<0.001). N-KDR cases were older (55 vs. 43 years, p<0.001) and showed more rapid NS onset (0.8 vs. 1.5 months, p=0.004). NEPTUNE cases demonstrated lower level of UPCR (4.20 vs. 8.00, p<0.001) and hypoalbuminemia (2.6 vs. 1.8 mg/dL, p<0.001). In both cohorts, >85% started on steroid monotherapy. In NEPTUNE, only 1% of patients changed within first 28 days as compared to 10% of N-KDR patients. N-KDR cases showed higher proportion of CR in overall sample (89.7 vs. 62.5%, p<0.001), FSGS (67.4 vs. 42.9%, p=0.015) and MCD (94.1 vs. 87.2%, p=0.113). Multivariate analysis showed associations of FSGS (HR=0.65, 95%CI: 0.52-0.81), hypertension (HR=0.64, 95%CI: 0.45-0.90), serum albumin (HR=0.62, 95%CI: 0.45-0.85) and eGFR (HR=1.24, 95%CI: 1.17-1.32, for 10 mL/min/1.73m^2) with time to CR. There were significant interactions between the cohort and hypertension (p=0.008), albumin (p=0.030) and eGFR (p<0.001).

Conclusions: Adult nephrotic FSGS/MCD in the North American cohort showed diverse ethnical background and less severe NS. Japanese patients had a higher rate of response to the IST. FSGS, hypertension, higher albumin, and lower eGFR were considered as shared predictors of poor treatment response between both cohorts.

Long-Term Renal Outcomes in Focal Segmental Glomerulosclerosis

Benjamin M. Forster, Robert Nee, Stephen W. Olson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is a glomerular disease defined by pathognomonic histopathology but is caused by multiple mechanisms of disease, not all of which have been fully elucidated. Therefore, the reported renal prognosis, treatment strategies, and treatment response has varied significantly in previous small case series. We sought to analyze long term renal survival and associated risk factors in the largest cohort over the longest period of follow up described to date.

Methods: We performed a retrospective cohort study on all previous and current active duty military with biopsy proven FSGS. Potential cases were identified through query of the military electronic medical record for International Classification of Diseases 9 and 10 codes (581.1, 582.1, and N04) and then confirmed by comprehensive chart review. Extensive data collection was performed and then analyzed using STATA 16.

Results: We identified 348 patients with biopsy proven FSGS with a mean follow up of 9.5 years. The majority were black, male, and under 40 years old. Progression to end stage kidney disease (ESKD) was 14%, 25%, and 35% at 5 years, 10 years, and 15 years after diagnosis, respectively. More patients with nephrotic range proteinuria progressed to ESKD (20%, 31%, and 49% at 5, 10, and 15 year follow up, respectively) than non-nephrotic range proteinuria (13%, 20%, and 31% at 5, 10, and 15 year follow up, respectively), and no significant proteinuria (6%, 14%, and 23% at 5, 10, and 15 year follow up, respectively); p=0.04. Overall progression to stage 3 chronic kidney disease (CKD3) was 32%, 40% and 50% at 5, 10, and 15 years after diagnosis, respectively. Full remission from initial treatment was associated with a substantial reduction in progression to ESKD (2%, 4%, and 7% at 5,10, and 15 years follow up, respectively) compared to partial remission (12%, 21%, and 30%) and no remission (27%, 45%, 63%), p<0.001.

Conclusions: We present the largest cohort of biopsy proven FSGS cases over the longest follow up period to date. Approximately one third of all FSGS patients develop ESKD and one half developed CKD3 within 15 years. Proteinuria significantly increased the risk of progression to ESKD. Achieving a full or partial remission after initial treatment significantly decreased the risk of progression to ESKD.

PO1892

Cellular Senescence Is Associated with Faster Progression of Renal Disease in Adults with Focal Segmental Glomerulosclerosis: A 6-Year Prospective Cohort Study

Daniela Verzola,[1] Michela Saio,[1] Daniela Picciotto,[1] Francesca Viazzi,[1] Elisa Russo,[1] Leda Cipriani,[1] Annalisa Carta,[1] Francesca Costigliolo,[1] Gabriele Gaggero,[2] Pasquale Esposito,[1] Giacomo Garibotto,[1] Laura Poggi.[1] *[1]Division of Nephrology, Dialysis and Transplantation, Department of Internal Medicine, University of Genova and IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Division of Pathology IRCCS Ospedale Policlinico San Martino, Genova, Italy.*

Background: A current hypothesis is that an acceleration of cellular senescence, a state of irreversible cell cycle arrest mediated by cyclin-dependent kinase inhibitors, is involved in impaired renal repair and in the progression of renal diseases. The functional role of the senescent changes observed in patients with glomerular diseases are unknown and if senescence is really associated with more disease progression is still not understood.

Methods: The hypothesis that cell senescence represents a proximate mechanism by which the kidney is damaged in focal segmental glomerulosclerosis (FSGS) was investigated in 26 consecutive kidney biopsies from FSGS patients (Age 50 ± 3, M/F 12/14, eGFR 72 ± 3.7, proteinuria 2.3 ± 0.6) who were incident in a Northern Italy Nephrology Centre. All biopsies were classified as the not otherwise specified (NOS) FSGS subtype.

Results: Cell senescence (p16INK4A, SA-b-galattosidase stains) was upregulated both in glomeruli (mainly in podocytes) and tubule cells in FSGS as compared to controls (p<=.05-0.01). Tubular p16INK4A correlated with tubulointerstitial fibrosis. Baseline proteinuria, eGFR, interstitial fibrosis and p16INK4A expression in the tubular compartment were associated with eGFR loss at follow up (6.5 ± 2 years). In multiple regression analysis, loss of renal function was predicted by interstitial fibrosis and tubular p16INK4A only. No association with faster eGFR decline was observed for SA-b-galattosidase stain.

Conclusions: These results indicate that an elevated cell senescence rate at the time of initial biopsy represents an independent predictor of progression to ESRD in adult patients at an early stage FSGS.

PO1893

Clinicopathologic Characterization of Focal and Segmental Glomerulosclerosis in a Dominican Republic Sample

Eliana Dina-Batlle,[1] Limber I. Rojas,[2] Mirtha C. Almanzar,[1] Hector A. Pantaleon,[1] José J. Sánchez.[3] *[1]Hospital Metropolitano de Santiago, Santiago, Dominican Republic; [2]Hospital General de la Plaza de la Salud, Santo Domingo, Dominican Republic; [3]Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.*

Background: There are limited recent epidemiological and clinicopathological behavior reports on FSGS in the Caribbean population. The aim is to identify clinical characteristic, epidemiological trend and treatment response of patients with diagnosed FSGS and their different variants in a Dominican Republic sample

Methods: Cross-sectional study of performed transcutaneous native kidney biopsy taken in an interval date from years 2018-2019 of two separate nephrology consult from Dominican Republic. Diagnosed FSGS biopsy reports availability and biochemical laboratories (creatinine, BUN, 24h Proteinuria, cholesterol, triglycerides, hematuria) within the date of biopsy were analyzed. Histopathological analysis of foot process effacement (FPE) degree reported and nephrotic syndrome (NS) presentation was correlated to primary or secondary cause of FSGS. Also, description of FSGS variants response to the different treatments implemented at the time of data collection, overlapping comorbidities and serology were taken in notice

Results: 49 biopsies were analyzed with FSGS. NOS variant was the most common (72%), tip lesion (6%) and collapsing (6%), with no reported perihilar or cellular variants and (16%) reported as unsampled biopsy of FSGS. Biopsy with diffuse FPE (>80%) 24 presented with nephrotic syndrome and 8 did not (p= 0.010). Remission in biopsy with described diffuse foot process effacement (DFPE) with unidentified cause 32% had complete remission (CR) (serum albumin >3.5g/dl or <300 mg/24h protein), 16% had partial remission (PR) (≥50% reduction basal proteinuria, subnephrotic proteinuria), and 20% did not remitted at a ≥ 6 month period (p=0.921). Steroids and calcineurin inhibitors treatment were significantly associated with CR in FSGS with DFPE with unidentified cause (p=0.029, p=0.014 respectively)

Conclusions: Biopsies analyzed in a 2 year period presented NOS as the most common variant while perihilar or cellular variants were not reported. In the sample studied the degree of FPE was associated to NS presentation. The use of steroids and calcineurin inhibitors in suitable patients is significantly associated with remission of disease. The FPE degree on biopsy, clinical manifestations of patients and history represent the best tools for correct diagnose and treatment

PO1894

Differentiating Focal and Segmental Glomerulosclerosis

Afonso Santos,[1] Anna Lima,[1] Ana Gaspar,[1] Ana C. Brás,[1] Pedro Pereira Campos,[1] Rita Theias Manso,[2] Karina Soto.[1] *[1]Nephrology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal; [2]Pathology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal.*

Background: FSGS is a histological pattern of kidney injury associated to broad causes and pathogenesis. FSGS can be primary, genetic or secondary to other conditions. Differentiating these subclasses is crucial for management and prognosis, but there is no biomarker for it and genetic testing is not suitable for all patients. Herein, we present a series of patients with FSGS classification based on clinical and histological criteria comparing outcomes.

Methods: In a retrospective analysis of 359 kidney biopsies were identified patients with FSGS histological diagnosis. Primary and secondary FSGS were identified based on clinical and histological data. Genetic FSGS was considered if they present at least one of the following:a)nephrotic syndrome (NS) resistant to corticosteroids;b)NS with normal serum albumin;c)NS with focal foot process effacement or d)non-nephrotic proteinuria with diffuse foot process effacement. Each group was divided in immunosuppression treatment (IST) or only supportive treatment (ST) groups. Renal and survival outcomes were assessed.

Results: Among 66 FSGS patients, 65% were males, 71% non-black, 74% had HTN, 26% diabetes; median eGFR 26.5mL/min/1.73m^2 (IQR 15.3-48.8), 24h-UProt 4.4g (IQR 2.5-7.6). Globally, 38% (n=25) progressed to ESKD and mean time to RRT was longer in IST group (p=0.37). According to the applied criteria 52% (n=34) were classified as having secondary FSGS, 23% (n=15) primary and 25% (n=17) as genetic FSGS. Among primary FSGS patients 40% received IST. In ST group 25% progressed to ESKD in a median time to RRT of 24 months (SD±31.7) *vs* 13% in 66mo (SD±93.3) in IST group. Among secondary FSGS, 17.6% received IST. Of them, 50% developed ESKD in 31.7mo (IQR SD±28.6) *vs* ST group with 46% progression to ESKD in 12mo (SD±28.7). From the genetic group 59% were in IST group and 30% progressed to ESKD in 12mo (SD±27.1) *vs* ST group with 29% ESKD in 42mo (SD±27.1).

Conclusions: FSGS etiology is not straightforward in most patients. Since IST can be inappropriate and potentially harmful in some FSGS subclasses, it is crucial to identify patients who are likely to benefit from such therapies, in order to obtain better outcomes. Most of genetic forms of FSGS do not respond to IST and have a rapid progression to ESKD. Therefore, in a suspicion of a genetic cause a genetic screening should be performed for appropriate management.

PO1895

APOL1 High-Risk Genotype Is Highly Prevalent Among Brazilian Patients with Collapsing Glomerulopathy, an Association That Manifests from Adolescence to Early Middle Adulthood

Precil D. Neves,[1] Andreia Watanabe,[1] Elieser H. Watanabe,[1] Livia B. Cavalcante,[1] Denise M. Malheiros,[1] Lectícia Jorge,[1] Matt G. Sampson,[2] Luiz F. Onuchic.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Boston Children's Hospital, Boston, MA.*

Background: Collapsing glomerulopathy (CG) is associated with fast progression to ESKD. CG has been linked to specific infections, drugs and immune disorders, the *APOL1* high-risk genotype (HRG) and monogenic pathogenic variants.

Methods: 70 Brazilian patients of all ages with the diagnosis of idiopathic CG were submitted to *APOL1* genotyping and 51 of them to broad genetic evaluation through whole exome sequencing, a 62-gene panel directed to glomerulopathies or Sanger sequencing. Based on retrospective analyses of medical records, the frequency and clinical impact of HRG were analyzed.

Results: Thirty-three (47.1%) patients harbored an HRG. Monogenic pathogenic or likely pathogenic variants were identified in 5 *APOL1* low-risk genotype (LRG) individuals, affecting the *COL4A5* (2 cases), *COQ2*, *MYH9*, and *PLCE1* genes. Gender distribution did not differ between the HRG and LRG groups. Patients with HRG were less often self-declared Caucasian than LRG individuals (36.4% vs 89.2%, p<0.001). While the age of disease onset was not significantly different between the HRG and LRG groups [21 (17-33) vs 25 (18-31) years, p=0.755], patients harboring HRG manifested the disease from adolescence to early middle adulthood (10-44 years) more frequently than LRG individuals (97% vs 70.3%; OR=13.54, CI 2.01-150.00; p=0.004). HRG patients reported more often family history of renal disease than individuals with LRG (36.4% vs 10.8%, p=0.01). HRG patients, however, did not differ from individuals with LRG or with monogenic/likely monogenic etiologies with respect to hematuria, hypertension and eGFR decline. The transplant rate did not differ between patients with HRG and individuals with LRG without identified Mendelian disease, whereas the rate of disease relapse in the graft was significantly lower in the first group (0 vs 33.3%, p=0.02).

Conclusions: *APOL1* HRG is highly prevalent among Brazilian patients with CG, suggesting a common role of second hits in genetic-environmental interaction in the pathogenesis of this glomerulopathy. Our findings strongly suggest that HRG-associated CG is a disease that manifests primarily from adolescence to early middle adulthood.

PO1896

Collapsing Glomerulopathy and Vascular Lesions

Mateus J. Luvizotto, Precil D. Neves, Cristiane B. Dias, Luis Yu, Leonardo Testagrossa, Denise M. Malheiros, Viktoria Woronik, Lectícia Jorge. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Collapsing Glomerulopathy (CG) has usually been associated with rapidly progressive renal failure. Some authors have found that vascular injury could be associated with poor outcomes. The goal of the study was to compare patients with and without vascular lesion on renal biopsy

Methods: A retrospective analysis was performed on all CG cases diagnosed by kidney biopsy between 1996 and 2019 at the University of Sao Paulo. Clinical and laboratory data were collected at baseline and at the end of follow up. We excluded cases of chronic viral infection(8 HIV, 4 HCV, 2 HBV) drugs, any suspected immune-mediated disease(4 SLE) and diabetes(3). We analyzed histological, clinical and follow-up data and compared patientes with and without vascular lesions in biopsy.

Results: Clinical features of the groups with and without vascular lesions are summarized in Table 1. There was no significant difference in gender, albumin, proteinuria, among the two groups. Moreover, the immunofluorescence of the renal biopsies showed no difference in IgM and C3 deposits in glomeruli. Patients with vascular lesions were older and presented with worse renal function.

Conclusions: Vascular lesion in CG is associated with worse renal function and it is more prevalant in older adults.

Clinical Features of the groups with and without vascular lesions

	With Vascular Lesion(32)	Without Vascular Lesion (47)	P value
Age(years)	37.0±3.0	27.4±1.53	0.002
Male(n,%)	13(38)	25(48)	0.37
Creatinine (mg/dL)	3.2±0.39	1.8± 0.17	0.001
CKD-EPI baseline	45.0±6.9	64.5± 6.5	0.050
Proteinuria g/day	6.7±0.97	7.9±0.98	0.369
Albumin (g/dL)	2.4 ±0.17	2.0 ± 0.13	0.06
IgM positive (%)	27(55)	38(68)	0.296
C3 positive (%)	19(67)	27(71)	0.784
Interstitial fibrosis (n, %)	33(93)	52(80)	0.091
Creatinine at the end mg(dL)	5.1±1.0	5.9±1.6	0.64
Follow up (months)	28±10	61±11	0.04

The Dual Endothelin/Angiotensin II Receptor (ET_AR/AT_1R) Antagonist Sparsentan Slows Renal Disease, Improves Lifespan, and Attenuates Hearing Loss in Alport Mice: Comparison with Losartan and Atrasentan

Dominic E. Cosgrove,[1] Brianna M. Dufek,[1] Duane C. Delimont,[1] Daniel T. Meehan,[1] Gina C. Samuelson,[1] Jared Hartsock,[2] Grady Phillips,[2] Ruth Gill,[2] James Hasson,[3] Celia P. Jenkinson,[3] Radko Komers,[3] MichaelAnne Gratton.[3] *[1]Boys Town National Research Hospital, Omaha, NE; [2]Washington University, St. Louis, MO; [3]Retrophin, Inc., San Diego, CA.*

Background: In Alport syndrome (AS), ET_AR activation is important in renal and inner ear pathologies. Previously, sparsentan (SP) was shown to prevent increases in proteinuria, glomerulosclerosis, and glomerular basement membrane dysmorphology in AS mice. Here we compare the effect of SP, the AT_1R antagonist losartan (LS), and the ET_AR antagonist atrasentan (ATR) on lifespan and proteinuria, and of SP and LS on hearing loss and inner ear pathology.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (V), 60 or 120 mg/kg of SP (SP60, SP120), LS (20 mg/kg; 3-4 W) or LS (10 mg/kg from 4 W), or ATR (7.5 mg/kg females or 10 mg/kg males) in the drinking water. Two studies were conducted: early intervention for hearing from 3-8.75 W (V, SP120 and LS), and for lifespan with treatment from 3 W (V) or from 4 W (SP60, SP120, LS or ATR). Urinary protein/creatinine ratio (UP/C) was assessed weekly. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8-8.75 W. The cochleae were preserved and strial pathology determined by transmission electron microscopy.

Results: SP120 significantly ($P<0.05$) increased median lifespan compared to any other group (Figure 1). At 8 W, only SP120 significantly ($P<0.05$) attenuated the increase in UP/C compared to V (UP/C mg/mg mean±SD: 47±16 V; 31±6 LS; 42±18 ATR, 61±44 SP60; 20±3 SP120). UP/C at 11 W in SP120 mice was significantly attenuated ($P<0.05$) vs. LS mice. SP120 significantly improved post-noise ABR thresholds at 16 kHz vs. V mice ($P<0.05$), LS had no effect. Dysmorphology of the stria vascularis was noted in LS but not SP120-treated mice.

Conclusions: SP120 in AS mice extended lifespan beyond that of mice treated with SP60, LS, or ATR and attenuated noise-induced hearing loss compared to LS. Sparsentan may therefore offer a novel, dual-therapeutic approach in AS by reducing both renal injury and hearing loss.

Long-Term Outcomes of Tacrolimus Treatment for Idiopathic Membranous Nephropathy

Aikaterini K. Nikolopoulou,[1] Sarah Gleeson,[1] Rakesh Dattani,[1] Marie B. Condon,[1] Tom Cairns,[1] Jeremy B. Levy,[1] Liz Lightstone,[2] Stephen P. McAdoo,[1] Frederick W. Tam,[2] Charles D. Pusey,[2] Megan Griffith.[1] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London Faculty of Medicine, London, United Kingdom.*

Background: Tacrolimus (TAC) is effective for the treatment of membranous nephropathy (MN).

Methods: Retrospective study of longterm outcomes of 111 patients (pts) with MN treated with TAC from January 2000 to June 2018.

Results: Demographics:table 1. Treatment: 91/111 TAC monotherapy, 20/111 dual therapy with mycophenolate + TAC. All pretreated with ACEi/ARB. Median follow up (FU) 68 months (IQR 33-115). 93/111 pts (84%) reached Partial Remission (uPCR reduction by 50% and <300mg/mmol) at 5.1 months (median, IQR 2-11). 76/111 (69%) also reached Complete Remission (uPCR<50mg/mmol) at 15.2 months (9.3-24). 18/111(16%) did not respond to initial treatment with TAC.3/18 progressed to ESRD rapidly, 9/18 were treated with Rituximab (RTX), 4/18 with cyclophosphamide (CYP) and steroids. Only 4 achieved remission, all in the RTX group. 2 lost to FU. 48/93 (51%) of pts that achieved remission relapsed after 22 months (14-34) (Figure 1) following withdrawal or reduction of immunosuppresion. 28/48 were retreated with TAC and all achieved remission, 15/48 treated with RTX, remission in 11/15. 3/48 treated with CYP and steroids (2/3 remission, 1 lost to FU). No treatment in 2. 11/28 cases retreated with tacrolimus had a second relapse. At 3 months on TAC there was a reduction of eGFR from baseline (90ml/min) to 78 ml/min (48-99, p<0.001),(Figure 2). Renal function stabilised thereafter during the follow up period to 10 years. 10(9%) pts reached ESRD and 5/10 within 12 months from diagnosis;these pts had a lower baseline eGFR 48ml/min (23-61).

Conclusions: TAC can be an effective treatment for MN with a relatively rapid response. Lack of response to TAC and low eGFR at presentation are associated with non-response to alternative immunosuppression and ESRD. Relapse is common often necessitating repeat immunosuppression. Most pts maintain eGFR in the longterm.

PO1899

Etiology, Histology, and Prognosis of Primary and Secondary Membranous Nephropathy in Young Patients Under 50 Years Old: A 35-Year, Two-Center Experience

Yasuhiro Oda, Masayuki Yamanouchi, Tatsuya Suwabe, Junichi Hoshino, Yoshifumi Ubara. *Toranomon Hospital Kajigaya, Kawasaki, Japan.*

Background: Membranous nephropathy (MN) is often diagnosed in older age group; its mean age of onset is 50-60 years old. Although retrospective analyses on young patients with primary MN have been published, clinicopathologic characteristics of primary MN and secondary MN combined in young patients have not been reported.

Methods: All patients diagnosed with MN in the age under 50 years old by a kidney biopsy performed between January 1985 and December 2019 at Toranomon Hospital and Toranomon Hospital Kajigaya were retrospectively analyzed. All patients with glomerular membranous changes presumed to be due to subepithelial deposits were included except for cases with classic membranoproliferative glomerulonephritis.

Results: 37 patients met the criteria. 19 of them (51%) had nephrotic syndrome, 17 (46%) had urinary protein excretion less than 3.5 grams per day, and one (3%) had no proteinuria. To evaluate renal biopsy specimens, light microscopy was performed in all cases, fluorescence microscopy in 36 cases and electron microscopy (EM) in 28 cases. 14 patients (38%) were diagnosed with primary MN, 22 patients (59%) with secondary MN, and one patient (3%) with de novo MN post-transplantation. Secondary MN were due to lupus erythematosus (27%), mixed connective tissue disease (14%), Sjögren's syndrome (3%), hepatitis B (11%), bucillamine use (3%), and graft versus host disease (GVHD) after peripheral blood stem cell transplantation (3%). Mean and median follow-up period was 14.9 and 12.0 years, respectively. At the end of follow-up, only two patients out of the 37 patients reached end-stage renal disease, and 33 patients (89%) observed serum creatinine level lower than 1.5 mg/dL. 21 patients achieved complete remission (CR). Among 27 cases who underwent EM, cases with subendothelial deposits had smaller CR rate (3/11 cases) than those without subendothelial deposits (12/16 cases), which was statistically significant ($\chi2=6.01$, $p=0.014$). The CR rates of cases with mesangial deposits (12/21 cases) and those without mesangial deposits (3/6) was not significantly different ($\chi2=0.096$, $p=0.76$).

Conclusions: The prognosis of renal function was fairly good in patients with MN in the age under 50 years old. Cases with coexisting subendothelial deposits showed lower CR rate than the rest.

PO1900

A Target Antigen-Based Approach to the Classification of Membranous Nephropathy

Shane A. Bobart,[1] Shahrzad Tehranian,[1] Sanjeev Sethi,[1] Mariam P. Alexander,[1] Samih H. Nasr,[1] Julie A. Vrana,[1] Samar M. Said,[1] Callen D. Giesen,[1] John C. Lieske,[1] Fernando C. Fervenza,[1] An S. De Vriese.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]AZ Sint-Jan Brugge-Oostende AV, Brugge, Belgium.*

Background: Primary membranous nephropathy (MN) is caused by circulating auto-antibodies against podocyte surface antigens, identified as M-type-phospholipase–A2-receptor (PLA2R) in 70-80% and thrombospondin-type-1-domain-containing-7A (THSD7A) in 2-5% of patients. Secondary MN occurs in the context of malignancy, autoimmune disease, infection, paraproteinemia or medication. Some patients with PLA2R-associated MN have a current or previously diagnosed associated condition, but it remains unclear whether it is causally related or coincidental. A few THSD7A-associated MN cases have a strong etiologic link with active malignancy, while in others malignancy appears coincidental. Exostosin 1/exostosin 2 (EXT1/EXT2) are recently discovered target antigens in patients with MN, the majority of whom have auto-immune disease. These recent findings blur the traditional distinction between primary and secondary MN.

Methods: To describe the phenotypes of PLA2R-, THSD7A- and EXT1/EXT2-associated MN, 201 adult patients with biopsy-proven MN were classified using serology, immunostaining and mass spectrometry. Clinical, biochemical and follow-up data were examined for associated disease and its relationship with MN.

Results: PLA2R-associated MN (n=161) occurred predominantly in middle-aged white males, with 72% presenting without associated disease. Only 1 case of THSD7A-associated MN was identified, with a concomitant malignancy. EXT1/EXT2-associated MN (n=8) was identified in younger females and was strongly linked with active auto-immunity. The majority of patients who were negative for all three target antigens (n=27/31, 87%) presented with associated disease, mainly malignancy and auto-immunity.

Conclusions: In conclusion, the historical primary-secondary dichotomy has substantial limitations when applied to MN. We propose a terminology combining the target antigen involved in pathogenesis and the associated clinical diseases in order to classify MN and guide clinical decision making.

PO1901

Noninvasive Diagnosis of Primary Membranous Nephropathy Using Anti-Phospholipase A2 Receptor (PLA2R) Antibodies: A Validation Study

Shane A. Bobart,[1] Shahrzad Tehranian,[1] Cristina Andrades Gómez,[2] Sanjeev Sethi,[1] Callen D. Giesen,[1] John C. Lieske,[1] An S. De Vriese,[3] Fernando C. Fervenza.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [3]AZ Sint-Jan Brugge-Oostende AV, Brugge, Belgium.*

Background: Kidney biopsy is the current gold standard to diagnose membranous nephropathy (MN). Approximately 70-80% of patients with primary MN have circulating anti-PLA2R antibodies. We sought to validate our previous work showing that in a proteinuric patient with preserved renal function (eGFR >60ml/min/1.73m^2) and no associated conditions (e.g. autoimmunity, malignancy, infection, drugs, paraproteinemia) a positive anti-PLA2R antibody test by simultaneous ELISA and IFA, is a valid strategy to make a non-invasive diagnosis of primary MN (Bobart et al. KI 2019; 95: 429-438).

Methods: The medical records of all Mayo Clinic patients with positive serum anti-PLA2R antibody tests by both ELISA and IFA between July 2018 and April 2020 were reviewed.

Results: A total of 1522 anti-PLA2R antibody tests were ordered in 1112 unique patients, yielding 128 positive results. We excluded previously reported patients (n=33), renal transplant recipients (n=5), no biopsy available (n=18), and pediatric cases (n=2). In all 70 remaining patients, the primary biopsy diagnosis was MN. Associated disease was identified in 28 cases (autoimmunity = 10, malignancy = 6, NSAID = 4, Hepatitis = 3, monoclonal protein = 5). Of the 42 patients with negative work up for secondary causes, 32 (76%) had preserved renal function. One patient had fibrin thrombi and neutrophils in the capillary loops, and one patient had 1 glomerulus with focal glomeruar basement membrane duplication. Neither of these findings altered diagnosis or management. Among the 10 patients with eGFR <60 ml/min/1.73m^2, additional findings that altered the treatment plan included acute interstitial nephritis (n=1) and superimposed diabetic nephropathy (n=1).

Conclusions: The study extends our previous observations that in patients with preserved renal function and no evidence of secondary causes or diabetes, a positive PLA2R test by simultaneous ELISA and IFA confirms the diagnosis of MN.

PO1902

Association Between Anti-Complement Factor H Antibodies and Renal Outcome in Primary Membranous Nephropathy

Yu Kagaya, Norifumi Hayashi, Keiji Fujimoto, Hiroki Adachi, Kengo Furuichi, Hitoshi Yokoyama. *Department of Nephrology, School of Medicine, Kanazawa Medical University, Uchinada, Japan.*

Background: The complement factor H (CFH) regulates activation of the alternative complement pathway. Autoantibodies against CFH have been involved in progressive renal dysfunction in a case with primary membranous nephropathy (MN) (Ronco P. et al. N Eng J Med 2018;379: 2479-81). However, the prevalence and the roles of anti-CFH antibodies in the clinical outcome of MN remains unclear.

Methods: We investigated retrospectively 36 Japanese patients with primary MN (23 males, 13 females; age 64.5 [59-72] years old) and 18 healthy normal controls (8 males, 10 females, age 31 [27-38] years old). Serum anti-CFH antibody titers were measured by enzyme-linked immunosorbent assay (Vidia Vestec, Czech Republic) to evaluate the association between anti-CFH antibody titers and the clinical outcome of MN patients.

Results: Anti-CFH antibody titers were significantly higher in MN patients as compared with normal controls [4.69 (3.69-6.38) RU/mL vs. 0.0 (0.0-0.0) RU/mL, p <0.001]. Twenty-eight patients were classified into the anti-CFH antibody positive group. The other 8 patients were classified into negative group. According to the Kaplan-Meier method, no significant difference was observed in the complete or incomplete remission rate of proteinuria, the incidence of renal dysfunction judged by the 30% reduction of estimated glomerular filtration rate (eGFR) and 50% elevation of serum creatinine (s-Cr) levels between the anti-CFH antibody positive group and the negative group of MN patients, however. In MN patients, anti-CFH antibody titer was selected an independent unfavorable predictor of renal dysfunction in Cox proportional hazards analysis adjusted by age, gender, sCr levels, proteinuria (g/gCr), anti-CFH antibody titer and immunosuppressive therapy (adjusted hazard ratio (HR) 1.344, 95% confidence intervals (CI) 1.038 to 1.741, p=0.025 for 30% reduction of eGFR; adjusted HR 1.930, 95% CI 1.108 to 3.363, p=0.020 for 50% elevation of sCr).

Conclusions: These data suggested that anti-CFH antibodies may be involved in the deterioration of renal function in primary membranous nephropathy.

PO1903

Concurrent Anti-Glomerular Basement Membrane Nephritis and Membranous Nephropathy

Syeda B. Ahmad, Dominick Santoriello, Pietro A. Canetta, Andrew S. Bomback, Vivette D. D'Agati, Glen S. Markowitz, Wooin Ahn, Jai Radhakrishnan, Gerald B. Appel. *Columbia University Irving Medical Center, New York, NY.*

Background: Anti-GBM nephritis is an uncommon entity with a rapidly progressive course. The concurrence of anti-GBM nephritis with membranous nephropathy (MN) is rare and poorly understood. We report a single center case series of this dual glomerulopathy with emphasis on presenting features, course, and outcome.

Methods: A total of 12 cases of combined anti-GBM nephritis and MN were identified from the archives of the Columbia Renal Pathology Laboratory over the past 18 years. Presenting clinical, histopathologic and laboratory data with follow up were obtained by chart review.

Results: The cohort of 12 cases included 7 men and 5 women with age range 18-81 years. The most common presenting feature was AKI (mean creatinine 9.3 mg/dL), with one patient having pulmonary symptoms. Positive anti-GBM serology was available at presentation for 11 cases, 5 with titers > 100 au/mL, and all were ANCA negative. Of those tested the majority were PLA2r negative. Patients were predominantly Caucasian (N = 9). All patients required hemodialysis (HD) at presentation, and two patients, a 20-year-old woman and an 81-year-old woman had renal recovery with the later having a stable creatinine of 2.0 mg/dL 11 months later. Treatment regimens included the following: cyclophosphamide, plasmapheresis, and prednisone (N=9); cyclophosphamide and prednisone (N=1), prednisone and plasmapheresis (N=1) and rituximab alone (N=1). Two patients died, both on HD, one 16 years later from unknown cause and one 3 months after presentation from sepsis. Analysis of the 12 renal biopsies showed combined linear and granular staining of GBMs for IgG, with crescents involving 23-100% of glomeruli, and fibrinoid necrosis involving 15-100%. The two patients who recovered renal function had fewer total crescents (82% crescents, and 23%, respectively) and less fibrinoid necrosis (15% and 31%) compared to the subgroup without recovery respectively, on kidney biopsy.

Conclusions: Combined anti-GBM and MN is a rare entity presenting with severe AKI requiring dialysis. Renal recovery is uncommon. High percentage of crescents are consistent with poor outcomes. Treatment and course are dominated by anti-GBM nephritis. The MN component is predominantly PLA2R negative, and further studies into pathogenesis are needed.

PO1904

Recurrent Membranous Post Transplantation: Histopathology, Treatment, and Outcomes

Sarah Gleeson,[1] Aikaterini K. Nikolopoulou,[1,2] Megan Griffith,[1,2] Marina Loucaidou,[1] Michelle Willicombe,[1,2] Candice A. Roufosse.[1,2] *[1]Imperial NHS Healthcare Trust, London, United Kingdom; [2]Imperial College London Faculty of Medicine, London, United Kingdom.*

Background: Membranous nephropathy(MN) recurs in 30-45% of transplants. Reported recurrence rates are higher in centres that perform surveillance biopsies. Optimal treatment is unknown. We examined recurrent MN in our cohort in terms of their histopathology, treatment and outcomes.

Methods: Patients with MN as the cause of their ESRF who were later transplanted were identified from an in-house database. Further data was collected from the electronic health record.

Results: 36 patients with a diagnosis of MN were transplanted. Mean follow up was 6.4 ± 4.2 years. 41.6% had a rejection episode (mean time from transplant 0.42±0.15 years). Overall there was 22% graft loss (mean time 6.5± 3.7 years), 11% deaths (8.6± 2.3 years from transplant) and 6% deaths with functioning grafts (mean time 6.9± 2.3 years). Mean eGFR at 3 months and 1 year were 48.1 ±18.5 and 48.1±14.5 ml/min. 30/36 patients had at least one biopsy following transplantation. Of those whose biopsies did not show recurrence, the mean time to the most recent biopsy was 2.9± 2.7 years (range 0.02-9.3) 8/36 patients (22%) had recurrent MN, 7 detected on indication biopsy and 1 on surveillance biopsy. The mean time to recurrence was 1.9±1. years (range 0.09-4.46 years). Granular C4d staining of the capillary wall was detected in 6/8 biopsies prompting immunofluorescence and electron microscopy, leading to the diagnosis of recurrent MN. Histological anti-PLA2R staining was positive in 3/8 biopsies. 2/8 patients had donor specific antibodies. In the 4 patients with clinically significant proteinuria rituximab was used to treat with a complete or partial response in all patients (mean time 22.5±16 months [range 4.4-43.8 months]). There are no significant differences in rejection, graft loss, death or death with functioning graft between those with recurrence and those without recurrence in our cohort.

Conclusions: Recurrent MN was frequent but not associated with increased allograft failure in our programme, with the use of rituximab in selected cases. Granular C4d staining of the glomerulus in transplant patients with MN could prompt further investigation with immunofluorescence and electron microscopy to look for recurrent disease.

PO1905

Secondary Polycythemia Associated with Membranous Nephropathy

Ramakrishna Thotakura,[1] Suman Siddamreddy,[2] Sruthi Kanuru,[4] Aditya Kadiyala.[3] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Baptist Health, Little Rock, AR; [3]University of Maryland Medical System Corporation, Baltimore, MD; [4]Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR.*

Introduction: Polycythemia has been recognized as a common occurrence in certain renal diseases such as cystic diseases of the kidney, renal cancer, tuberous sclerosis and hydronephrosis. However, polycythemia in association with membranous nephropathy has rarely been reported. Here we report a case of secondary polycythemia from membranous nephropathy. Although the mechanism of this phenomenon is unclear, decreased effective circulating volume leading to hypoxemia and thereby polycythemia seems to be the most likely explanation

Case Description: 37-year old white male with Hypertension, OSA using CPAP, tobacco use was admitted with 40-lb weight gain and anasarca. 24-hour urine collection revealed 17-gram protein excretion with serum albumin of 1.1 and marked hyperlipidemia. Kidney biopsy revealed membranous nephropathy. Staining for PLA2R and THSD7a were negative within the glomerular deposits. Evaluation for secondary causes of membranous nephropathy was negative for ANA, RPR/syphilis antibodies, Hepatitis, HIV, ANCA, Anti-GBM Ab and normal C3,C4 levels. CT of torso was negative for overt malignancy or hepatosplenomegaly. Patient's hemoglobin ranged between 16.5– 18.5 G/dl (hct 52-60%). Serum erythropoietin level was 12.3 IU/L (Normal 5-30IU/L) with corresponding hemoglobin of 18.2 G/dl. JAK2 exon12, V617F mutations were negative. Hematology evaluation concluded that primary polycythemia is unlikely. Patient received 2 doses of 1 Gm Rituximab given 2 weeks apart. Patient was placed on Apixaban for prophylactic anticoagulation. Follow up labs to evaluate response to therapy are currently pending. It is yet to be seen if polycythemia resolves with remission of membranous nephropathy.

Discussion: Polycythemia is seldom seen in patients with membranous nephropathy. We postulated that hypoxia induced by decreased renal perfusion is the main trigger for polycythemia. However, it is puzzling as to why more patients with membranous nephropathy are not polycythemic. This leads us to believe that there might be some unique processes leading to polycythemia in membranous nephropathy, as in this patient, which might need further investigation. Polycythemia would further enhance the risk of thromboembolism in such patients whose risk of hypercoagulability is already high in setting of severe hypoalbuminemia. Hence, prophylactic anticoagulation should strongly be considered in these patients.

PO1906

Membranous Nephropathy Preceding the Recurrence of Thymoma

Perola Lamba,[2] David L. Epstein.[1,2] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Introduction: Membranous nephropathy secondary to neoplastic processes is a recognized phenomenon, and it may be the first finding that leads to the diagnosis of the underlying malignancy. Here, we describe a case of secondary MN in a patient with a history of recurrent thymoma that led to a prompt evaluation for malignancy, which did not appear on PET imaging until a few months later.

Case Description: We describe the case of a 62 year old man with myasthenia gravis (on IVIG), history of thymoma with recurrence in 2017 and March 2019 requiring multiple surgeries and adjuvant chemoradiation. There was no evidence of disease in October 2019. Subsequently, he presented in December 2019 with anasarca, acute kidney injury and nephrotic syndrome (proteinuria greater than 9 g per day). He underwent diuresis and a kidney biopsy which was notable for secondary membranous nephropathy with negative PLA2R antibody. A PET-CT was performed in December 2019 which did not show any evidence of FDG avidity or active malignancy. In February 2020, he presented with worsening anasarca and a myasthenic flare, for which he was treated with steroids, five sessions of plasma exchange and rituximab. In order to search for possible recurrent thymoma, he had another PET-CT which found a new FGD avid focus in the left second rib, which was biopsied and consistent with recurrent thymoma. He was then treated with radiation therapy.

Discussion: When a patient is diagnosed with secondary membranous nephropathy without an identifiable cause, it is recommended to perform general screening for cancers. In order to compare conventional screening with PET imaging, Z Feng et al compared two groups of patients with different screening approaches. In this study the PET imaging group identified 5 cases of malignancy among 49 patients, while the conventional screening only identified 1 case of malignancy among 75 patients. While PET imaging may be the optimal imaging for undiagnosed malignancy or recurrent malignancy in patients with newly diagnosed membranous nephropathy, this case presentation suggests that thymoma recurrence with nephrotic syndrome may precede a positive result on PET imaging. Reference: Z Feng, S Wang, Y Huang et al. "A follow-up analysis of positron emission tomography/computed tomography in detecting hidden malignancies at the time of diagnosis of membranous nephropathy" Oncotarget 2016. 7(9): 9645-9651

PO1907

A New Approach to De Novo Minimal Change Disease in Pregnancy

Sarah Gleeson,[1] Filipa Cardoso,[1] Liz Lightstone,[1,2] Tom Cairns.[1] *[1]Imperial Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London Faculty of Medicine, London, United Kingdom.*

Introduction: Although proteinuria in pregnancy is common and usually due to preeclampsia, nephrotic range proteinuria especially early in pregnancy, warrants investigation and treatment. We present the first case of minimal change disease (MCD) presenting in pregnancy, treated only with tacrolimus.

Case Description: A previously well 20 year old G1P0, presented at 9 weeks gestation with 3 weeks of oedema and shortness of breath. Examination revealed marked oedema. Investigations: creatinine 44umol/L (55-110), albumin 7g/L (35-50), urine PCR 1456mg/mmol. A fetal scan confirmed a viable pregnancy. A renal biopsy was performed which demonstrated MCD. She was started on tacrolimus in addition to enoxaparin, frusemide and aspirin. At 12 weeks she had melena with a haemoglobin drop. There was no active bleeding on endoscopy and she had no further episodes in pregnancy. She was managed by the renal and joint renal-obstetric clinic throughout pregnancy. She was maintained on tacrolimus alone (levels 5-8ug/L). Her albumin rose and PCR fell throughout pregnancy. By 34 weeks her albumin was 28g/L and uPCR was 128 mg/mmol. Fetal growth was normal on serial growth scans. She did not develop preeclampsia. Labour was induced at 39 weeks and she had a normal vaginal delivery of a 3194g healthy baby

Discussion: There have only been 4 previous reports of de novo MCD in pregnancy all of whom were treated with steroids. In our patient who presented early in pregnancy with marked oedema and heavy proteinuria a kidney biopsy was performed. Kidney biopsy should be performed when the benefit of obtaining a diagnosis outweighs the risks of the procedure. In pregnancy the risks are increased (7% versus 1% outside pregnancy). Biopsy during the 1st trimester is safest. Corticosteroids are often used to treat MCD outside pregnancy. Prednisone is safe is pregnancy as the fetal dose is minimal. However, there is a risk of maternal complications including gestational diabetes and weight gain. The recent MinTac trial of prednisolone and tacrolimus in patients with MCD found no difference in remission rates at 8, 16 or 26 weeks and no difference in relapse rates. We achieved partial remission in this heavily nephrotic patient with use of tacrolimus alone allowing us to avoid steroid adverse effects, which was especially important after her GI bleed. We believe tacrolimus is a valuable option for treatment of MCD in pregnancy.

PO1908

Tiopronin-Induced Minimal Change Disease: The Third Reported Case

Sreedevi koppisetti Jenigiri, Jayesh B. Patel, Lisa M. Antes. *University of Iowa, Iowa City, IA.*

Introduction: Cystinuria, a rare inherited metabolic disorder characterized by defective proximal tubule cystine transport, manifests predominantly in childhood or young adulthood with renal colic and recurrent nephrolithiasis, often requiring urologic intervention. Insoluble cystine in the urine precipitates into hexagonal crystals that can coalesce into larger, recurrent calculi, with associated higher risk of chronic kidney disease. Prevention of stone formation is the primary goal, using conservative non-pharmacologic approaches and if unsuccessful then pharmacologic. Since its approval in 1986 tiopronin (TP), a thiol compound that forms a soluble mixed disulfide tiopronin-cysteine complex, has been used to increase urine cystine solubility. Adverse effects of TP most commonly are cutaneous and mucosal. Reports of TP-induced nephrotic syndrome (NS) are rare, especially due to minimal change disease (MCD).

Case Description: A 19-year-old male with cystinuria and bilateral nephrolithiasis requiring extensive urologic interventions was on TP 300 mg bid for 6 months, when he presented to the Emergency Department with foamy urine, decreased urine output and anasarca. Labs showed elevated urine protein:creatinine ratio 9.2 (UPCR), low serum albumin 1.6 mg/dL and elevated cholesterol. ANA, ANCA, anti-GBM, HBV, HCV, HIV, C3, C4, and cryoglobulins were negative. Renal biopsy demonstrated MCD. He was not treated with steroids. TP was discontinued and UPCR 2 months later was 0.21 and albumin 2.3, with complete resolution of symptoms. He was referred to Metabolic Stone Clinic to discuss alternative treatment options.

Discussion: Only 31 cases of TP-induced NS have been reported to date, the majority membranous glomerulonephritis (GN), with fewer cases of mesangioproliferative or membranoproliferative GN and only two cases of MCD. Although the exact mechanism is unclear, TP is speculated to play an antigenic role interfering with podocyte function. TP induced NS is not necessarily dose-dependent, with no relationship between mean daily dose and toxicity. The highest prevalence occurs in the first six months and is self-limited upon cessation of TP, without need for immunosuppressives. Clinicians should be aware of the rare but severe occurrence of NS due to TP. A weekly dipstick for protein may help in early detection.

PO1909

Recurrent Nephrotic Syndrome in Podocyte Infolding Glomerulopathy: Remission with Rituximab

Spencer Hodgins,[1,2] Barbara A. Greco.[1,2] Baystate Medical Center Renal Fellowship *[1]Baystate Medical Center, Springfield, MA; [2]University of Massachusetts Medical School, Worcester, MA.*

Introduction: Podocyte infolding glomerulopathy (PIG) is a recently recognized entity. The sentinel paper showed that it is associated with autoimmune disorders and is often responsive to corticosteroids (CS). We present a case of PIG with recurrent nephrotic syndrome (NS) who is maintaining remission on Rituximab off of CS.

Case Description: A 61-year old woman with type II diabetes mellitus, inflammatory bowel disease (IBD), and uveitis presented in 2009 with proteinuria. Kidney biopsy was read as focal segmental glomerulosclerosis (FSGS). She was treated with angiotensin converting enzyme inhibitor (ACE I) and prednisone, and proteinuria remitted. In 2012, an increase in proteinuria promped repeat biopsy resulting in a diagnosis of membranous glomerulonephritis. Anti-PLA2R was negative. ACE I and prednisone were continued and proteinuria remitted. In 2014, she developed nephrotic syndrome (NS). Repeat biopsy was read as showing FSGS. Prednisone 1 mg/kg/day induced remission. When prednisone was tapered, NS flared. She did not remit with high dose prednisone and at 8 weeks developed acute kidney injury (AKI). Tacrolimus was added and proteinuria and creatinine (cr) improved. Steroids were tapered over several months. On Humira for IBD and tacrolimus (level 11 mg/dl), NS and AKI flared 1 year later with urine protein:creatinine (UP/C) of 2 and cr 2.1 mg/dl. Prednisone was restarted. Intravenous cyclosphosphamide was started, steroids were tapered, and Humira was discontinued. Within 5 weeks, proteinuria worsened (UP/C 29) and cr rose to 4 mg/dl. Renal biopsy demonstrated foot process invagination yielding a diagnosis of PIG. At trial of cyclosporine was stopped at 1 week due to drug intolerance. Mycophenolate mofetil (MMF) in combination with prednisone and tacrolimus was started. MMF caused severe diarrhea. In September of 2019, 4 weekly doses of Rituximab 375 mg/m^2 followed by 1 gram doses at 4 month intervals were administered. Proteinuria remitted and creatinine improved to 1 mg/dl. She remains in remission off of steroids and on lower dose tacrolimus now for 11 months.

Discussion: This case is the first to describe the effectiveness of Rituxan as rescue and maintenance therapy following failure of other IS regimens in a patient with recurrent NS due to PIG. Rituxan should be considered in refractory cases of PIG to induce and maintain remission and allow for steroid sparing.

PO1910

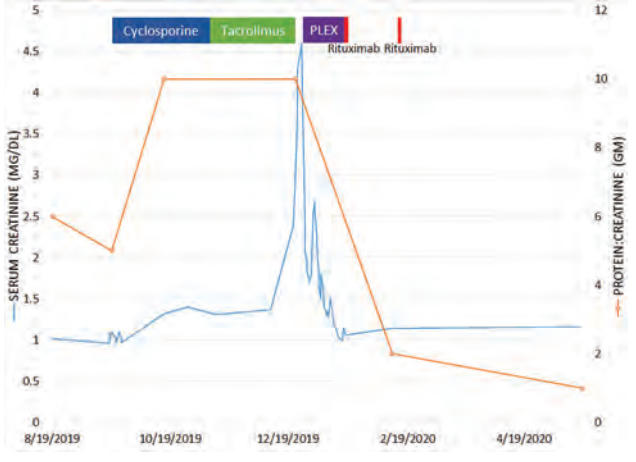
Glomerular Tip Lesion FSGS: A Rare Case of Nephrotic Syndrome in African Americans

Andrew A. Moses, Syed A. Husain, Wooin Ahn. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Nephrotic syndrome caused by focal segmental glomerular sclerosis (FSGS) in African Americans is known to have a poor prognosis and frequent treatment failure. Tip variant FSGS connotes good prognosis, usually responsive to calcineurin inhibitor (CNI) and steroid. We present a case of CNI resistant tip lesion FSGS requiring plasma exchange (PLEX) and rituximab

Case Description: A 25-year-old African-American male, initially presenting to outpatient clinic for edema associated with proteinuria. He had a past medical history of seizure disorder controlled with zonisamide. He trialed hydrochlorothiazide and furosemide without success. His urine showed nephrotic range proteinuria with 6g/g creatinine on spot urine. Outpatient workup was unrevealing, and was managed with enalapril and torsemide. He eventually had worsening edema and shortness of breath, prompting ED visit. Biopsy was performed which showed FSGS, tip variant. He was discharged on cyclosporine and increased diuretic. Cyclosporine caused gastrointestinal upset, and so patient switched to tacrolimus. He again had increasing swelling, and re-presented to hospital. He was found to have acute kidney injury, and 10g/g creatinine despite therapeutic tacrolimus levels. Patient trialed stress dose steroids but serum creatinine rose to 4.44. He started PLEX for 10 treatments, and then transitioned to rituximab. During treatment with PLEX patient creatinine quickly downtrended, and after second dose of rituximab as an outpatient he was back to baseline. He lost 30 kg with resolution of his edema. Patient then tapered off steroids, and will continue on rituximab alone.

Discussion: Glomerular tip lesion is more common in European Americans and associated with a favorable outcome compared to other subtypes of FSGS. Resistance to one immunosuppressive treatment is not always associated with resistance to other treatment modalities. PLEX and rituximab should be considered in glomerular tip lesion in African Americans



PO1911

Utility of Immunofluorescent Intensity of IgG3 and Phospholipase A2 Receptor-to-IgG4 Ratio to Presume the Prognosis of Patients with Membranous Nephropathy

Takatsugu Iwashita, Kaori Takayanagi, Maiko Yamasaki, Mai Aoyagi, Taisuke Shimizu, Hajime Hasegawa. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: Membranous nephropathy (MN) is likely to show the long-term course and is a frequent glomerulonephritis in the elderly. For this reason, effective use of immunosuppressive drugs in a short period of time is desirable. In this study, we aimed to investigate the factors that could predict treatment responsiveness, using the treatment outcome in a short period of time, and retrospectively analyzed patients with MN in our hospital.

Methods: We included 66 patients who underwent renal biopsy and were diagnosed with MN in our hospital between April 2009 and December 2017. The percentage reduction in proteinuria one month after initiation of steroids, immunosuppressants, and ARBs was set to the endpoint. Intensity of immunofluorescent siaining (IF) was scored according to the criteria of Japanese Scoiety of Nephrology. Hematuria was quantified by 7-grade scoring of RBC numbers in high powered microscopic field.

Results: The intensity of IF (IgG subclass, PLA2R, THSD7A) was numerically evaluated and used for the analysis. The mean age of the patients included in the analysis was 66.4±11.7 years and baseline eGFR 63.9±18.7 ml/min, baseline urine protein was 7.05±5.45 g/gCr. Multiple parameters in high responder (HR, n=39) that resulted in less than 50% of urine protein after one month and low responder (LR, n=27) that remained proteinuria more than 50% were compared. Baseline urine protein and scored baseline hematuria were both higher in HR group (urine protein: 6.95 in HR vs 3.86 g/gCr in LR, p=0.003; hematuria: 1.0 in HR vs 0.0 in LR, p=0.036), but there was no difference in baseline eGFR (70.5 in HR vs 60.4 mL/min in LR, p=0.087). The mean dose of prednisolone was also not different between the two groups (18.6 in HR vs 14.0 mg/day in LR, p=0.451). In IF, significant differences were observed between the two groups in the scored staining intensity of IgG3 and the staining intensity ratio of PLA2R to IgG4 (PLA2R-to-IgG4 intensity ratio:PGIR) were both lower in HR group (IgG3: 0.0 in HR vs 0.5 in LR, p=0.049; PGIR: 0.58 in HR vs 1.00 in LR, p=0.029).

Conclusions: From the result of the present examination, staining intensity of IgG3 and intensity ratio of PLA2R to IgG4 might be helpful to predict better therapeutic responsiveness in addition to the baseline proteinuria and hematuria.

PO1912

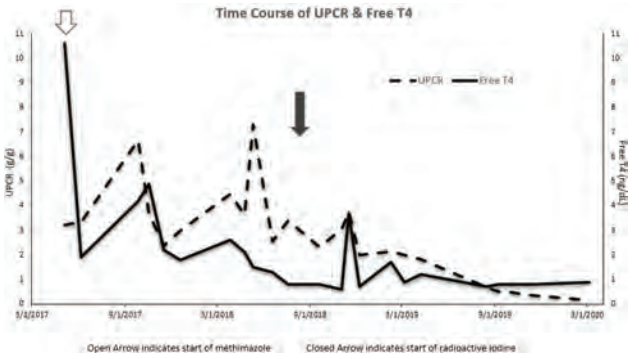
Graves Disease and Nephrotic Syndrome

Sajid Mahmood, Alaleh Mazhari, Nicholas Emanuele, David J. Leehey. *Loyola University Health System, Maywood, IL.*

Introduction: Disorders of the thyroid and kidney may co-exist. Isolated case reports of Graves' disease associated with various glomerular diseases, including membranous nephropathy, membranoproliferative GN, fibrillary GN, and minimal change disease have been published. A patient with membranous nephropathy and Graves' disease who had improvement but not resolution of proteinuria after treatment with radioactive iodine has been described (Sasaki et al. CEN Case Rep. 2014; 3(1): 90-93). We report a case of nephrotic syndrome associated with Graves' disease which completely resolved after treatment of the thyroid disease with radioiodine.

Case Description: A 33-year-old healthy female was seen for evaluation of proteinuria discovered during a routine life insurance evaluation. BP was normal, and she had trace-1+ lower extremity edema. Urinalysis showed 3+ protein, 1 red blood cell and 1 white blood cell per high power field. Urinary albumin/creatinine ratio was 4010 mg/g. Serum albumin was 2.7 g/dL. Renal function was normal. Tests for hepatitis B and C, HIV, RPR, ANA, C3, C4, cryoglobulins, immunofixation, and free light chains were normal. Renal biopsy was planned but the patient missed the biopsy date. Subsequently she returned to clinic complaining of neck swelling. Exam revealed tachycardia, palpable goiter, 1+ pedal edema, no tremor. She reported heat intolerance, occasional diarrhea, insomnia, diaphoresis, and weight loss for the past month. A thyroid panel showed TSH <0.01 UU/mL (0.40-4.60 UU/mL), free T3 >2000 pg/dL (230-420), and free T4 10.6 ng/dL (0.8-1.7). TSH receptor and thyroid peroxidase antibodies were present. The patient was treated with methimazole and tapering steroids. She refused thyroid surgery and ultimately underwent two sessions of radioactive iodine treatment. After this treatment, nephrotic syndrome went into complete remission (Figure).

Discussion: Although relatively uncommon, Graves' disease needs to be considered as a reversible cause of nephrotic syndrome.



PO1913

Treatment of Systemic Lupus Erythematosus with or Without Nephritis with the Immunoproteasome Inhibitor KZR-616: Initial Results of the MISSION Study

Mary K. Farmer,[1] Samir V. Parikh,[2] Richard Furie,[3] Christopher Kirk,[1] Ken Harvey,[1] Darrin Bomba.[1] *[1]Kezar Life Sciences, Inc, South San Francisco, CA; [2]The Ohio State University, Columbus, OH; [3]Northwell Health, Great Neck, NY.*

Background: Immunoproteasome inhibition demonstrated therapeutic potential in preclinical models of systemic lupus erythematosus (SLE) and lupus nephritis (LN). KZR-616 is a first-in-class selective immunoproteasome inhibitor, which has been safe and well tolerated in early clinical trials. One hundred subjects across 2 healthy volunteer studies, with dosing of KZR-616 up to 75mg SC, achieved target levels of immunoproteasome inhibition at doses ≥30mg. Here we report safety, tolerability and exploratory efficacy data from the Phase 1b portion of MISSION (KZR-616-002; NCT: NCT03393013), a clinical trial in which KZR-616 was administered to patients with active SLE with or without LN.

Methods: In this open-label dose-escalation study, SLE patients (per SLICC classification criteria) with SLEDAI ≥4 despite stable background therapy received KZR-616 at doses of 45mg (Cohort 1), 60mg (Cohort 2), or 60mg following a step-up dose (Cohorts 2a, 2b, 2c) SC weekly through Week 13 (W13) with 12 weeks of follow-up.

Results: To date, 39 patients with SLE, including 2 patients with active proliferative LN, have enrolled in MISSION. The majority of TEAEs have been mild or moderate with injection site reactions the most common TEAE. Tolerability has improved with an initial step-up dosing regime, subsequent doses and the introduction of a lyophilized formulation. To date, no patients have discontinued from cohorts after implementation of these protocol modifications. Multiple measures of disease activity improved from Baseline to W13 and persisted through W25; no patients worsened over 13 weeks. KZR-616 administration resulted in improvements in multiple serologic markers as well as reduced expression of inflammatory gene expression modules. Both patients with biopsy-proven active proliferative LN had reductions in proteinuria.

Conclusions: KZR-616 has been safe and tolerated at a target dose of 60 mg weekly. Step-up dosing, use of select pre-medications, and/or introduction of a lyophilized preparation have increased its tolerability. The administration of KZR-616 resulted in improvement across multiple disease activity measures as well as serologic markers, including improvement in proteinuria in patients with active proliferative LN. MISSION is an on-going study now focused on patients with LN.

PO1914

Rituximab as Maintenance Therapy in Lupus Nephritis

Anushya Jeyabalan, Jillian Rosenthal, Reza Zonozi, Noah Huizenga, Karen A. Laliberte, John Niles. *Massachusetts General Hospital, Boston, MA.*

Background: Rituximab (RTX) has been shown to be effective in refractory lupus nephritis (LN) in some studies. Minimal literature exists on using RTX as maintenance therapy for LN.

Methods: We performed a retrospective review of 21 patients (pts) with biopsy-proven LN who received RTX. We analyzed clinical data at baseline (pre-RTX) and up to 36 months (mo) of follow-up.

Results: Of 21 pts, 7 received RTX as part of first-line treatment, 7 for refractory LN and 7 for relapsing LN. All continued RTX (1gm q4-6 mo) as maintenance therapy. 15/21 (71%) pts were on RTX monotherapy (excluding prednisone and plaquenil) at 12 mo, 14/16 (88%) at 24 mo, and 11/13 (85%) at 36 mo. 17/19 (89%) had continuous B cell depletion at 12 mo, 13/14 (93%) at 24 mo, and 11/12 (92%) at 36 mo. At 12 mo, 16/21 (76%) achieved complete or partial remission. Median UPCR (g/g) decreased from 2.95 at baseline to 0.61 at 12 mo, 0.42 at 24 mo and 0.21 at 36 mo. 16/21 (76%) pts were on prednisone ≤5mg/day at 12 mo, 13/16 (81%) at 24 mo, and 10/13 (77%) at 36 mo. Over 36 mo, 2 pts had LN relapses while on RTX alone, and later progressed to ESRD. 2 pts developed hypogammaglobulinemia.

Conclusions: RTX monotherapy appears promising as maintenance therapy in LN. Given favorable renal outcomes and steroid-sparing effect, larger studies studying this effect may be warranted.

Definitions Table

Complete Remission	Normal creatinine (creat) (if abnormal at baseline (BL)), or creat <115% of BL (if normal at BL); inactive urinary sediment (<5 red blood cells (RBC)/hpf and 0 RBC casts); and UPCR <0.5 g/g
Partial Remission	Creat ≤115% of BL; RBCs/hpf ≤50% above BL and 0 RBC casts; and ≥50% decrease in the UPCR to <1.0 (if BL UPCR ≤3.0) or to ≤3.0 (if BL UPCR >3.0)
Relapse	Active urine sediment (RBC casts or >5 RBCs/hpf), rise in UPCR, or rise in creat, after achieving CR or PR.

Table 1. Baseline characteristics of 21 patients with lupus nephritis treated with Rituximab.

Therapeutic Effect of Belimumab in Lupus Nephritis with Impaired Renal Function

Miho Karube, Hiroko Uchida, Yoshinori Komagata, Shinya Kaname. *Division of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan.*

Background: To investigate the nephroprotective effect of belimumab (BEL) in SLE with mildly impaired renal function and proteinuria.

Methods: We studied 28 patients in the maintenance phase of SLE who was treated with BEL for more than 6 months. The median duration of treatment was 14 months. The patients were divided into those with reduced eGFR less than 60 ml/min/1.73 m2 (n=5; R group) and those with normal renal function (n=23; N group), and the effects of BEL were compared 6 months after treatment. In addition, the effect of BEL on lupus nephritis was investigated in patients with urinary protein of 0.2 g/gCr or more.

Results: The patients consisted of 26 females and 2 males, and the median age was 41 years. After BEL treatment, urinary protein decreased in both groups, 0.45 to 0.20 g/gCr in N group and 0.32 to 0.17 g/gCr in R group. The eGFR changed from 88.6 to 87.7 and from 50.8 to 61.2, while dsDNA antibodies (IU/mL) decreased from 54.9 to 30.5 and from

23.2 to 9.04, respectively. The doses of prednisolone (mg/day) decreased in both groups. The IgG level decreased from 1377 to 1204 (mg/dL) in N group and from 1009 to 865 in R group. In 18 patients with urinary protein of 0.2 g/gCr or more, proteinuria significantly decreased from 0.54 to 0.20 to 0.23 (g/gCr) and dsDNA antibody improved from 67 to 34 to 35.1 (IU/mL) at 3 and 6 months after BEL therapy.

Conclusions: BEL may improve SLE activities and also renal function in patients with renal insufficiency as effectively as in those with normal renal function, although hypogammaglobulinemia comparably develops in both groups.

PO1916

A Multicenter Double-Blinded Preclinical Randomized Controlled Trial (pRCT) on Jak1/2 Inhibition in Lupus Nephritis

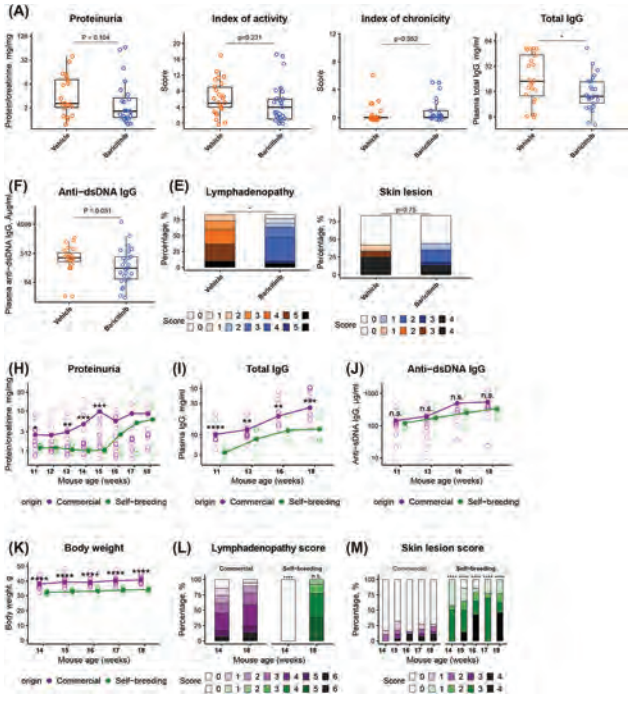
Yutian Lei,[5] Bettina Sehnert,[6] Reinhard E. Voll,[6] Conxita Jacobs Cachá,[4] Maria Jose Soler,[4] Maria Dolores Sanchez-Nino,[3] Alberto Ortiz,[3] Roman D. Bülow,[2] Peter Boor,[2] Hans J. Anders.[1] *[1]Division of Nephrology, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; [2]Institute of Pathology and Department of Nephrology, RWTH University of Aachen, Aachen, Germany; [3]IIS-Fundacion Jimenez Diaz, School of Medicine, Universidad Autonoma de Madrid, Fundacion Renal Iñigo Alvarez de Toledo-IRSIN and REDINREN, Madrid, Spain; [4]Nephrology Department, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Nephrology Research Group, Vall d'Hebron Research Institute (VHIR) and REDINREN, Barcelona, Spain; [5]Division of Nephrology, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; [6]Department of Rheumatology and Clinical Immunology, Medical Center-University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany.*

Background: We conducted the first multicenter double-blinded pRCT in the field of nephrology and tested the Jak1/2 inhibitor baricitinib in experimental lupus nephritis.

Methods: We conducted a pRCT at two Spanish and two German academic sites. One site included MRL/lpr mice from their own breeding colony and the other sites purchased MRL/lpr mice from the Jackson lab. Eligibility criteria included female and 13-14 weeks old. Mice were randomized at a 1:1 ratio and orally dosed with 20 mg/kg/d baricitinib or vehicle for 4 weeks. Samples were assembled for blinded analyses, including histology, which was assessed by an independent pathology institute. The primary endpoint was proteinuria.

Results: A total of 55 mice were randomly assigned to the vehicle (n=28) and baricitinib group (n=27). Baricitinib-treated mice showed a trend towards decreased proteinuria, but this did not reach statistical significance (p=0.104). In contrast, plasma total IgG and lymphadenopathy score were significantly improved in the baricitinib group. In the vehicle group, at the initiation of treatment, self-breed mice had less proteinuria, less plasma total IgG, and worse skin lesion compared to commercial-source mice.

Conclusions: In a pRCT, targeting Jak1/2 with baricitinib for 4 weeks had no significant effect on the primary end-point proteinuria in MRL/lpr mice, whereas total plasma IgG and lymphadonpathy score significantly improved. Mice of different origins had different lupus phenotypes and increased the variability. Placebo controlled multicenter trials are feasible in animal models of lupus, however, standard deviations may increase due to multiple factors, which requires higher numbers of animals.



PO1917

Management of Lupus Nephritis (LN) with Voclosporin: An Update from a Pooled Analysis of 534 Patients

Brad H. Rovin,[1] Samir V. Parikh,[1] Robert B. Huizinga,[2] Neil Solomons,[2] Simrat Randhawa.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: Voclosporin (VCS) is a novel calcineurin inhibitor (CNI) with a favorable metabolic profile and a consistent, predictable dose response potentially eliminating the need for therapeutic drug monitoring. VCS significantly improved renal response (RR) in patients with LN in two pivotal trials. Compared to MMF (target dose 2g/day) and prednisone (rapid taper), the addition of VCS 23.7 mg BID increased renal response by 25% in the Phase 2 AURA-LV (OR: 3.21; 95% CI: 1.68, 6.13; $p < 0.001$) and 18% in the Phase 3 AURORA (OR: 2.65; 95% CI: 1.64, 4.27; $p < 0.001$) studies at one year. To provide more information on VCS treatment effect we analyzed an integrated data set from AURA-LV and AURORA.

Methods: The two pivotal trials were of similar design, conducted in comparable patient populations and defined similar key outcome measures. The integrated data set included an intent to treat (ITT) population of 266 control and 268 VCS 23.7 mg/BID patients. Here we report key integrated data of interest including renal response, defined as: ● UPCR ≤ 0.5 mg/mg ● eGFR ≥ 60 mL/min or no decline > 20% from baseline ● ≤10 mg prednisone 8 weeks prior to endpoint measurement ● No rescue medications

Results: RR at one year was 43.7% for VCS vs 23.3% for control (OR 2.76, 95% CI: 1.88, 4.05; $p < 0.0001$), and at 6 months (VCS 31.7%; control 20.3%), [OR: 2.01; 95% CI: 1.34, 3.01; $p = 0.0008$]. In addition, 1-year RR for Hispanic patients was 37.9% in VCS arm vs 19.4% control. As expected, the largest estimated eGFR change from baseline for VCS vs control-treated patients occurred early, at week 4, (-5.6 mL/ min, $p < 0.0001$) which decreased to -3.7 mL/min by week 52 ($p = 0.0012$). Mean change from baseline of eGFR in the VCS arm at week 52 was -1.0 mL/min (p=ns). Finally, serious adverse events were similar between groups (22.8% VCS vs 18.8% control).

Conclusions: This integrated analysis provides further support to the efficacy of VCS seen in both AURA-LV and AURORA including in Hispanic patients, a high-risk LN patient population. Furthermore, VCS' expected impact on mean eGFR as a CNI was mild over the course of one year.

PO1918

Use of Therapeutic Drug Monitoring Does Not Add Clinical Value for Voclosporin in Patients with Lupus Nephritis

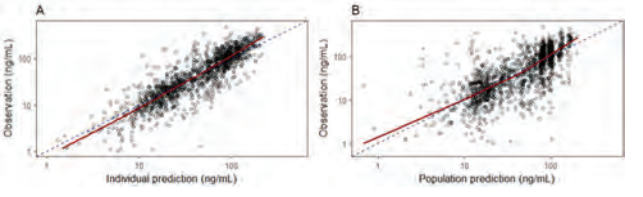
Teun van Gelder,[2] Robert B. Huizinga,[1] Jan Noukens,[3] Laura J. Lisk,[1] Neil Solomons.[1] *[1]Aurinia Pharmaceuticals Inc Victoria, Victoria, BC, Canada; [2]Universiteit Leiden, Leiden, Netherlands; [3]Curare Consulting, Leiden, Netherlands.*

Background: In a phase III clinical trial in patients with active lupus nephritis (LN), patients treated with 23.7 mg voclosporin bid in combination with MMF, achieved renal response rates of 40.8% vs. 22.5% for the control arm (OR 2.65; $p < 0.001$). The dose of voclosporin (VCS) was adjusted in response to decreases in eGFR. The objective of the present analysis was to evaluate the potential added value for therapeutic drug monitoring (TDM) in the LN patient population

Methods: Pharmacokinetic (PK) data was analyzed from patients with LN treated with VCS. Based on a population PK model, the influence of various covariates on the disposition of voclosporin was evaluated. Calcineurin inhibition (CNI) was estimated using concentration data in the LN population and previously measured inhibition. Obtained exposure were put into perspective of renal response and the established safety margin

Results: Sex, body weight, race, age, serum albumin, total bilirubin and eGFR demonstrated no significant or clinically relevant effect on the PK parameters. VCS has linear PK, and the goodness-of-fit plots (Figure 1 a/b) indicate that the model adequately describes observed and predicted concentrations of VCS. A strong correlation between VCS concentration and calcineurin inhibition is observed. VCS inhibits calcineurin in a dose-dependent manner up to maximum of 64 mg bid. In healthy subjects, a 96 mg bid dose was considered to be the upper limit of tolerability though did not present any safety concerns. At the 4-fold lower therapeutic dose of 23.7 mg bid, CNI was estimated to be 15.7% at C_{trough} and 58.1% at C_{max}. In a quartile exposure analysis, no relationship with the odds ratio for renal response was observed and favored VCS in all quartiles

Conclusions: At a therapeutic dose of 23.7 mg bid, sex, body weight, race, age, serum albumin, total bilirubin and eGFR demonstrated no clinically relevant effect on VCS PK parameters. The linear PK profile of VCS allows the use of a pharmacodynamic approach instead of a pharmacokinetic approach, in which the dose of VCS is adjusted in response to decreases in eGFR. These data suggest that TDM is unlikely to be of added benefit to patient management



PO1919

Clinical Outcomes in Lupus Nephritis by Renal Response Status: A Retrospective Analysis of the Hopkins Lupus Cohort

Michelle Petri,[1] Qinggong Fu,[2] Yulia Green,[3] Anuradha Madan,[4] Daniel W. Goldman,[1] Selin Cooper-Blenkinsopp.[5] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]GlaxoSmithKline, Upper Providence, PA; [3]GlaxoSmithKline, Uxbridge, United Kingdom; [4]GlaxoSmithKline, Collegeville, PA; [5]GlaxoSmithKline, Stevenage, United Kingdom.*

Background: A retrospective analysis of the Hopkins Lupus Cohort (a prospective, longitudinal study of patients [pts] with systemic lupus erythematosus) reported that renal response (complete/partial/none) at 24 months post-diagnosis of lupus nephritis (LN) predicts long-term renal survival.[1] Here, we compare long-term renal survival and chronic renal insufficiency-free survival in pts with and without a renal response (RR) to standard LN therapy, as defined by primary endpoint in the Phase 3 BLISS-LN study (GSK Study BEL114054; NCT01639339).

Methods: This retrospective analysis (GSK Study 213039) of the Hopkins Lupus Cohort included pts with biopsy-proven class III, IV, or V LN. Endpoints were: long-term renal survival (no end-stage renal disease [ESRD] and/or mortality) and long-term chronic renal insufficiency-free survival by RR status at 24 months post-biopsy, both assessed by Kaplan–Meier plots with log-rank test and Cox proportional hazards regression.

Results: 173 pts with LN were included; 91.3% were female and mean (SD) age at biopsy was 36.2 (11.8) years. At 24 months post-biopsy, 114 (65.9%) pts achieved RR. Pts with RR at 24 months were less likely to experience an ESRD/mortality event and chronic renal insufficiency (**Figure**), even after adjusting for covariates (HR [95% CI] 0.33 [0.13, 0.87], p=0.0255; and HR [95% CI] 0.26 [0.14, 0.47], p<0.0001, respectively).

Conclusions: Achieving BLISS-LN primary endpoint defined RR at 24 months post-biopsy is associated with long-term renal survival and chronic renal insufficiency-free survival in pts with LN. [1]Davidson JE, *et al. J Rheumatol* 2018;**45:**671–7.

Predictors of Doubling of Serum Creatinine at the Time of Biopsy in a Lupus Nephritis Cohort

Jaime (James) A. Vondenberg, Saeed K. Shaffi. *University of New Mexico, Albuquerque, NM.*

Background: Lupus nephritis is associated with significant morbidity and it is imperative to study the factors associated with renal survival. We study the determinants of doubling of serum creatinine in a predominantly Hispanic cohort.

Methods: We identified patients with biopsy-proven lupus nephritis from the biopsy registry that comprises of biopsies performed between 2002-2016. Demographic, clinical, and biochemical variables were obtained from the registry and electronic medical records. We studied the factors associated with the doubling of creatinine by performing univariate Cox proportional hazard analysis. All significant associations (p <0.05) were studied in a multivariate Cox regression model. Patients were censored upon death or the last follow-up.

Results: Out of 62 patients with biopsy-proven lupus nephritis, 53 (85.5%) were female. Whites, Hispanics, and Native Americans comprised 35.5, 30.6, and 16.1% of the cohort, respectively while 56% of the participants identified ethnically as Hispanic. Mean biopsy age, serum creatinine, and spot urine Protein/Creatinine were 34.5 (SD 15.3) years, 1.34 (SD 0.83) mg/dl, and 4.2 (SD 4.9) g/g, respectively. Class IV (48.4%) and III (16.1%) were the most prevalent lupus classes. Median (IQR) follow-up was 474.5 (1170) days. On multivariate analysis, higher age at biopsy was associated with decreased risk of doubling of serum creatinine (Figure 1). A higher spot urine Protein/Creatinine and C4 level at the time of biopsy were associated with increased risk of doubling of serum Cr.

Conclusions: Previous studies have shown that biochemical markers at the time of kidney biopsy are a poor prognostic marker of renal outcomes in lupus nephritis. In this study, demographic, biochemical, and histological markers failed to predict doubling of serum creatinine. The age and the level of proteinuria at the time of kidney biopsy were associated with doubling of serum creatinine.

Figure 1: Predictors of doubling of serum Creatinine

Univariate Analyses		
Variables at the time of biopsy	**Reference/ Interpretation**	**Hazard Ratio for doubling of serum Cr (95% CI)**
Hispanic	Not Hispanic	0.40 (0.28-0.57)
Age at Biopsy (years)	1-year increment	0.90 (0.88-0.92)
Male	Female	0.28 (0.10 – 0.77)
SSA/RO +	Negative	2.39 (1.95 -2.92)
SSB/LA +	Negative	2.39 (1.95-2.92)
Anti-Smith +	Negative	2.39 (1.95-2.92)
C4 (mg/dL)	1-unit increment	0.99 (0.98-0.99)
CRP (mg/dL)	1-unit increment	0.71 (0.62 – 0.82)
ESR	1-unit increment	0.98 (0.98-0.99)
Urine Protein/Creatinine (g/g)	1 gm increment	1.11 (1.09 -1.12)
Urine RBC (RBC/HPF) ≥3	Normal (<3 RBC/HPF)	0.00 (0.00-INF)
Multivariate Analyses		
Age at Biopsy	1-year increment	0.78 (0.74-0.82)
C4	1-unit increment	1.16 (1.14-1.19)
Urine Protein/Creatinine (g/g)	1 gm increment	1.13 (1.10- 1.16)

Lupus-Related Renal Disease Increases Inpatient Mortality: Analysis of the National Inpatient Sample

Ehizogie Edigin,[2] Precious Eseaton,[1] Augustine Manadan.[3,2] *[1]University of Benin Teaching Hospital, Benin City, Nigeria; [2]John H Stroger Hospital of Cook County, Chicago, IL; [3]Rush University Medical Center, Chicago, IL.*

Background: The aim of this study is to analyze the difference in outcomes of Systemic Lupus Erythematosus (SLE) with and without lupus-related renal disease. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the USA. The NIS was searched for adult SLE hospitalizations with and without lupus-related renal disease as principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There were over 71 million discharges included in the combined 2016 and 2017 NIS database. 355,740 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE. 51,875 (14.6%) and 303,865 (85.4%) of these hospitalizations were for SLE with and without lupus-related renal disease respectively. 7,060 adult SLE hospitalizations (2%) resulted in inpatient mortality. 1,110 (2.14%) of the deaths occurred in SLE with lupus-related renal disease vs 5950 (1.96%) without lupus-related renal disease (P=0.228). The adjusted odds ratio (AOR) for inpatient mortality for SLE with lupus-related renal disease compared to those without lupus-related renal disease was 1.38 (95% CI 1.17-1.63, P<0.0001). SLE with lupus-related renal disease hospitalizations had a mean increase in adjusted LOS of 1.14 days (95% CI 0.95-1.34, P<0.0001) compared to SLE without lupus-related renal disease. Hospitalizations for SLE with lupus-related renal disease had an increase in adjusted total hospital charges of $15,910 (95% CI 13,085-18,736, P<0.0001) compared to SLE without lupus-related renal disease.

Conclusions: Hospitalizations for SLE with lupus-related renal disease have increased inpatient mortality, LOS, and total hospital charges compared to those without lupus-related renal disease. SLE patients with lupus-related renal disease require a multidisciplinary approach involving the rheumatologist and nephrologist to optimize outcomes.

PO1922

Analysis of Characteristics and Risk Factors of Sepsis in Patients with Lupus Nephritis

Zhenjian Xu,[1] Meisheng Liang,[2] Anping Xu.[1] *[1]Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China; [2]The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, China.*

Background: Patients with lupus nephritis are at high risk of infection due to intrinsic immune dysregulation and treatment with glucocorticoids and immunosuppressants. Infection is a common complication in patients with lupus nephritis and is a major determinant of in-hospital mortality. Sepsis are the most frequent causes of infection-related mortality. In this research, we study the clinical characteristics and related risk factors of sepsis in patients with lupus nephritis according to a retrospective analysis.

Methods: A retrospective study was carried out for 322 hospitalized patients with lupus nephritis in Sun Yat-Sen Memorial Hospital from 2010 to 2019. The infected group consisted of 140 patients (The infected patients were subdivided into septic group and non-septic group according the sepsis criteria) while the non-infected group consisted of 182 patients without infection. Baseline data including sex, age, disease duration, hospitalization duration, associated organ involvement, use of glucocorticoid and immunosuppressants.

Results: Compared to the non-infected group, longer hospitalization duration(14 vs. 9d,P<0.05), pulsed methylprednisolone treatment within 1 month(10.7% vs. 1.6%,P<0.05), cyclophosphamide(22.9% vs. 14.3%,P<0.05), and calcineurin inhibitors(18.6% vs. 10.4%,P<0.05), and higher dose of oral corticosteroid(15 vs. 10mg,P<0.05)can be seen in the infected group (P<0.05). Compared to the non-septic group, higher proportion of male(21.2% vs. 8.0%,P<0.05), higher SELDAI score(9.0 vs. 6.0,P<0.05), higher proportion of pulsed methylprednisolone treatment within 1 month(13.5% vs. 10.7%,P<0.05)and higher dose of oral corticosteroid(20.0 vs. 15.0mg,P<0.05)can be seen in the septic group (P<0.05). About the laboratory results, lower level of platelet(129.0 vs. 194.5×10^9/L,P<0.05)and lymphocyte(0.6 vs. 0.9×10^9/L,P<0.05), while higher level of serum creatine(134.0 vs. 88.0μmol/L,P<0.05), C reactive protein(43.8 vs. 12.3mg/L,P<0.05)and erythrocyte sedimentation rate(60.0 vs. 45.5mm/h,P<0.05) can be seen in the septic group. Multivariate Logistic regression analysis revealed that male and pulse methylprednisolone treatment within 1 month were independent risk factors of sepsis in patients with lupus nephritis (P<0.05).

Conclusions: Male and pulse methylprednisolone treatment within 1 month were independently associated with sepsis in patients with lupus nephritis.

PO1923

An Evaluation of Costs Associated with Overall and Renal-Specific Organ Damage in Patients with Systemic Lupus Erythematosus in the United States

Christopher F. Bell,[1] Juliana Meyers,[2] Mayank Ajmera,[2] Benjamin Wu,[1] Joan Von Feldt.[3] *[1]GlaxoSmithKline, Research Triangle, NC; [2]RTI Health Solutions, Research Triangle Park, NC; [3]GlaxoSmithKline, Philadelphia, PA.*

Background: Systemic lupus erythematosus (SLE) is a chronic, multisystem, inflammatory, autoimmune disease affecting multiple organ systems, and characterized by fluctuating disease activity (flares). The combination of flares and SLE treatment toxicity increases the risk of organ damage (OD), including renal OD. Despite the high prevalence of OD and the associated poor disease prognosis, real-world studies on the economic impact of OD, especially renal OD, in SLE are limited.

Methods: This retrospective analysis (GSK Study 208380) used the IQVIA PharMetrics Plus Database to identify patients with SLE and OD during 01/01/09–06/30/18. Patients with OD were identified using International Classification of Diseases (ICD)-9/10 codes derived from the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index.[1] Inclusion criteria: ≥18 years of age; continuous enrollment 12 months both pre and post index (index: date of first observed OD medical claim); ≥1 inpatient (IP) or ≥3 outpatient (OP) claims within 6 months for an OD-related diagnosis code; ≥1 IP or ≥2 OP claims separated by ≥30 days for SLE (ICD-9: 710.0 or ICD-10: M32.X) prior to the OD index date. Patients with renal-specific OD at index were noted. Patient characteristics were identified in the 12-month pre-index period and all-cause healthcare costs (2018 US$) were reported in the 12-month pre- and post-index periods. Results were analyzed with descriptive statistics.

Results: A total of 8952 patients met OD criteria and 486 (5.4%) had renal-specific OD. Patients were 92% female, mean (standard deviation [SD]) age was 46.4 (12.2) years, and mean (SD) Charlson Comorbidity Index was 2.0 (1.1). Mean (SD) all-cause healthcare costs increased from $15,746 ($29,637) to $26,998 ($57,982) in pre- versus post-index periods, respectively. In patients with renal-specific OD, mean (SD) all-cause healthcare costs increased from $16,131 ($22,914) to $36,905 ($72,188) in pre- versus post-index periods, respectively.

Conclusions: In patients with SLE and OD, annual costs increased after OD diagnosis. A similar increase in annual costs was observed for patients with renal-specific OD at index. [1]Gladman DD and Urowitz MB. *Lupus.* 1999;8:632–7.

Characteristics of Lupus Nephritis in a Cross-Sectional Study of Hispanic and Native American Patients in New Mexico

Jaime (James) A. Vondenberg, Saeed K. Shaffi. *University of New Mexico, Albuquerque, NM.*

Background: In patients with lupus, nephritis develops in ~50% of patients, and is associated with significant morbidity. Therefore, it is important to characterize the demographic and biochemical variables associated with lupus nephritis. In this cross-sectional study comprised of many Hispanics and Native Americans, we investigate the demographic and biochemical variables at the time of lupus nephritis diagnosis.

Methods: We identified 62 patients with lupus nephritis from the University of New Mexico kidney biopsy registry that contains biopsies from 2002-2016. Demographics, comorbidities, outcomes, therapies, and laboratory data typically followed in lupus patients (complements, spot urine protein/creatinine (Pr/Cr) ratio, urine RBCs, serologies, etc) were collected from the registry and medical charts.

Results: 62 patients were included, 53 females and 9 males. White, Hispanic, and Native American races accounted for 35.5%, 30.6%, and 16.1% of the cohort, while 56.6% of patients identified ethnically as Hispanic. 3 patients had no labs. Overall mean age at the time of renal biopsy was 34.5 (SD 15.3) years old. Laboratory data among ethnicities is shown in Figure 1. Class IV was the most common classification in the whole cohort (48.5%), for Hispanics (56.7%), and Non-Hispanics (30%). Antibody status was similar among all ethnicities: ANA positive (95%; 80% titer ≥ 1:80), anti-dsDNA positive (73%), anti-Smith positive (56%), and SS-A positive (56%). The most common comorbidities were hypertension (n=46) and depression (n=16). For induction therapy, most Hispanics received low dose cyclophosphamide (CYC) (41%), and Non-Hispanics received mycophenolate mofetil (MMF) (35%). For maintenance therapy, both Hispanics (37%) and Non-Hispanics (35%) most often received MMF. 7 patients progressed to ESKD, by ethnicity: 5 Hispanic and 2 Unavailable (1 African American).

Conclusions: The lupus cohort predominantly consisted of females and class IV nephritis. Many patients of Hispanic ethnicity identified as White with respect to race. At the time of lupus nephritis diagnosis, antibody status, serum creatinine, and urine spot protein/creatinine ratio were similar among ethnicities. Hispanics were more likely to progress to ESKD. The most commonly used induction therapy was low dose CYC followed by MMF, and the most common maintenance therapy was MMF.

PO1925

The ISN/RPS 2016 Classification Predicts Renal Prognosis in Patients with First-Onset Class III/IV Lupus Nephritis

Asaka Hachiya,[1] Munetoshi Karasawa,[1] Takahiro Imaizumi,[2,1] Noritoshi Kato,[1] Takayuki Katsuno,[3] Takuji Ishimoto,[1] Tomoki Kosugi,[1] Naotake Tsuboi,[4] Shoichi Maruyama.[1] *[1]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Center for Advanced Medicine and Clinical Research, Nagoya University Hospital, Nagoya, Japan; [3]Department of Nephrology and Rheumatology, Aichi Medical University, Nagakute, Japan; [4]Department of Nephrology, Fujita Health University Graduate School of Medicine, Toyoake, Japan.*

Background: Lupus nephritis (LN) is a life-threatening complication of systemic lupus erythematosus. The 2003 pathological classification of LN by the International Society of Nephrology/Renal Pathology Society (ISN/RPS) was revised in 2016; it quantitatively evaluates the interstitium in addition to the glomeruli. To date, the clinical utility of the 2016 classification has not been fully investigated.

Methods: We performed a retrospective multicenter cohort study and investigated the utility of the 2016 classification—including the activity index (AI), chronicity index (CI), and each pathological component to predict CR or renal function decline defined as 1.5-fold increase in serum creatinine levels (sCr)—and compare with that of the 2003 classification. Adult patients with first-onset class III/IV LN who were newly prescribed any immunosuppressants were consecutively enrolled from January 2004 to December 2014 and observed until July 2016.

Results: We enrolled 91 patients (number of female, 65; median age [interquartile rage: IQR], 47 [30–62] years old; median estimated glomerular filtration rate (eGFR), 64 [IQR: 45–84] ml/min/1.73 m^2; median proteinuria, 1.9 [IQR: 0.9–4.6] g/gCr). During the observation period (median, 51 [IQR: 23–77] months), 35 patients achieved CR, and 16 developed 1.5-fold increase in sCr. The A or A/C subclasses based on the 2003 classification were not associated with clinical outcomes. After adjustments for eGFR and urinary protein levels, higher CI and interstitial inflammation scores were associated with failure to achieve CR (adjusted hazard ratios (HR) [95% confident interval (CI)]: 0.75 [0.64–0.88], 0.39 [0.25–0.61], respectively). Similarly, higher CI and higher interstitial fibrosis and lower hyaline deposit scores were associated with renal functional decline (adjusted HR [95%CI]: 1.24 [1.01–1.53], 2.66 [1.43–4.93], 0.45 [0.21–0.97], respectively).

Conclusions: We demonstrated the utility of CI and importance of assessing interstitial regions in predicting renal prognosis. The 2016 classification can predict the clinical outcomes more precisely than the 2003 classification.

Resolution of Immune Deposits in the Glomeruli of Patients with Lupus Nephritis (LN)

Ana Malvar,[2] Valeria G. Alberton,[2] Karina Fayolle,[2] Rocio A. Jones,[2] Pedro J. Davila Terreros,[2] Bruno J. Lococo,[2] Brad H. Rovin.[1] *[1]The Ohio State University, Columbus, OH; [2]Hospital Fernandez, Buenos Aires, Argentina.*

Background: Patients with proliferative LN have severe glomerular immune injury that resolves over time with treatment. The extent of resolution has been assessed by the NIH activity index (AI) in patients who have had a repeat kidney biopsy during maintenance immunosuppression, and many patients do achieve an AI=0, so-called histologic remission. The fate of glomerular immune complexes in treated LN patients has not yet been characterized. This study examined the immunofluorescence (IF) patterns in biopsies obtained during LN therapy.

Methods: A cohort of Hispanic LN patients (n=89) was studied. All patients had biopsy-proven (Bx1) proliferative (Class III, IV±V) LN, and were treated with corticosteroids plus cyclophosphamide or MMF for 6 months and then switched to MMF for maintenance therapy. After a median of 42 (range 30-52) months patients had a second protocol biopsy (Bx2) to determine if they had achieved histologic remission (AI=0) or had persistent histologic activity (AI≥1). Kidney biopsies were evaluated by standard IF microscopy (IgG, IgA, IgM, C3, C1q), and semi-quantitatively graded on a scale of 0-3 (not present-bright).

Results: cyclophosphamide (48%). These patients had a median serum creatinine of 0.7 mg/dl (0.5-2.2) and proteinuria of 0.2 g/d (0-0.8). The 26 patients who had persistent histologic activity at Bx2 had a median AI of 2 (1-6), serum creatinine of 0.75 mg/dl (0.6-1.1), and proteinuria of 0.2 g/d (0.1-0.9) and about half had been treated with MMF. No residual IF was present in 30% of patients with an AI of 0, but was present in all patients who had an AI≥1. IF for IgG became negative in 46% of patients with an AI=0 between Bx1 and Bx2, but in only 7.7% of patients with AI≥1 (P=0.0005). Similarly, IF for C3 became negative in 84% of patients with AI=0, compared to 31% of patients with AI≥1 (P<0.0001). After a median of 23 months (11-39) 7 patients who had been in histologic remission suffered an LN flare. None of these patients had had complete resolution of IF on Bx2. In contrast, no patient with an AI=0 and an absence of IF on Bx has had an LN flare during a follow-up of 44 months (19-105).

Conclusions: About one third of patients with LN can achieve histologic and immunologic kidney remission. These patients appear to have an outstanding long-term kidney prognosis.

PO1927

Vasculopathy Associated with Lupus Nephritis (Severity and Outcomes)

Marcial Torres, Muhannad Alqudsi, Juan Carlos Q. Velez, Muner Mohamed. *Ochsner Clinic Foundation, Ochsner Health System, New Orleans, LA.*

Background: Lupus nephritis (LN) is common in patients with systemic lupus erythematosus. Classification, prognosis, and treatment considerations of LN relays mainly on kidney biopsy features. Although few observational studies showed LN with vasculopathy has more severe course, literature reviews are scarce and mostly from Asian populations. The goal of the study was to shed more light on severity and response to Immunosuppression (IS) therapy in this subgroup of LN.

Methods: This was a single center retrospective chart review of LN patients from 2010-2019. Inclusion criteria were adult patients with native kidney biopsy proven LN documented in chart. Patients with systemic thrombotic microangiopathy (TMA) or possible secondary cause of renal TMA (other than SLE) were excluded. Two groups were identified for comparison, LN without vasculopathy (WOV) and LN with vasculopathy (WV). Vasculopathy was defined from kidney biopsy as vascular sclerosis (at least moderate), vascular immunoglobulins deposits, vasculitis, or TMA. Creatinine (Cr), albumin (Alb), urine protein-creatinine ration (UPCR), end-stage renal disease (ESRD) and treatment regimens were compared, p-values are calculated by Mann Whitney, chi square and ANOVA of repeated measures.

Results: There were 431 patients with LN, 65 patients qualified for the study. patients with LN-WOV (n=38), and LN-WV (n=27). Racial demographics: 49=black (75%),14=white (21%), 1=Hispanic, 1=Asian. Females 57 (88%). Median age 37 years. Average follow-up 3.5 years. Induction IS regimen for LN-WOV was mycophenolate mofetil (MMF) in 52%, Cyclophosphamide (CYC) in 11%, and Rituximab (RTX) in 15%. In LN-WV induction IS regimen was MMF in 52%, and CYC in 23%. At baseline, mean values of Cr 1.7 mg/dL, Alb 2.5 g/dL and UPCR 3.7 g/g for LN-WOV and LN-WV were similar (p = 0.38, 0.37, 0.53, respectively). At 6 and 12 months of follow-up, mean values of Cr, Alb, and UPCR remained similar (p = 0.59, 0.49, and 0.64 for 6 months, and 0.34, 0.41, 0.53 for 12 months). No difference was found in ESRD events: 7 (18%) in LN-WOV and 5 (18%) in LN-WV, p=0.86.

Conclusions: In our cohort, both groups of LN-WOV and LN-WV showed no statistical difference in the severity of presentation, nor in response to IS therapy assessed at 6 and 12 months follow-up of Cr, Alb, and UPCR, and ESRD. Hence, LN-WV was not associated with ominous outcomes or more resistance to IS.

PO1928

Urine Epidermal Growth Factor Levels Are Associated with Kidney Prognosis in Lupus Nephritis

Juan M. Mejia,[1] John P. Shapiro,[2] Xiaolan Zhang,[2] Cristinoc Cruz,[1] Grant R. Zimmerman,[2] Rossa A. Méndez,[1] Samir V. Parikh,[2] Haikady N. Nagaraja,[3] Luis E. Morales-Buenrostro,[1] Brad H. Rovin.[2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]The Ohio State University Wexner Medical Center Dorothy M Davis Heart and Lung Research Institute, Columbus, OH; [3]Department of Biostatistics, School of Public Health, The Ohio State University, Columbus, OH.*

Background: Epidermal growth factor is a protein specifically synthesized in the kidneys. EGF urine levels have been associated with progressive chronic kidney disease. This study evaluated the role of urine epidermal growth factor (uEGF) as a biomarker of chronic kidney damage in lupus nephritis (LN).

Methods: Through a proteomic approach we identified uEGF as a biomarker of interest in an LN discovery cohort. The expression of uEGF was characterized in two large multiethnic LN cohorts, and the association between uEGF at flare and long-term outcomes assessed in a subset of 120 patients. The expression of uEGF over time was observed in two longitudinal LN cohorts in which serial urine samples were collected.

Results: The proteomic analysis showed lower uEGF in patients with active LN than in normal controls. The peptide sequence was consistent with the proEGF isoform, and this was confirmed by immunoblotting. These findings were verified by ELISA. Patients with active LN had a significantly lower levels of uEGF than patients with active non-renal lupus, patients with inactive lupus, and kidney donors. Urine EGF was inversely correlated with the kidney biopsy chronicity index (r=-0.67, p<0.001). Multivariate survival analysis showed that uEGF at flare was associated with the time to doubling of serum creatinine (HR 0.88, 95% CI 0.77-0.99, p=0.045). In patients who progressed to doubling of serum creatinine (Figure 1A) and end-stage kidney disease (Figure 1B), uEGF was lower at flare and then decreased over the 12 months following flare. A uEGF cutoff <5.3ng/mg identified all patients who progressed to end-stage kidney disease.

Conclusions: Urine EGF levels correlate with histologic kidney damage. Low uEGF levels at flare and decreasing uEGF levels over time are associated with adverse long-term kidney outcomes.

Idiopathic Hypokalemia in Lupus Nephritis: A Previously Unrecognized Entity

Emmanuel A. Adomako,[1] Saira Bilal,[3] Yu-Lun Liu,[1] Ayesha M. Malik,[2] Kamalanathan K. Sambandam.[1] *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [2]Aga Khan University, Karachi, Pakistan; [3]George Washington University Medical Faculty Associates, Washington, DC.*

Background: The lupus nephritis (LN) population at Parkland Hospital is among the largest in the country. During the course of usual care in this population, we encountered a phenomenon of unexplained hypokalemia that has never been previously described. Here we begin to phenotype this cohort by comparing it to a group of LN controls as well as LN with distal renal tubular acidosis (RTA).

Methods: From our population of 403 LN patients followed in the Parkland Health and Hospital System, we identified a cohort of 20 patients with idiopathic hypokalemia (HK). This cohort is compared to 90 LN controls (control) and 10 LN patients with distal RTA (RTA). In contrasting the three groups, the Chi-squared test or Fisher's exact test were used for categorical data and the one-way ANOVA or Kruskal-Wallis test was used for continuous measures. For paired comparisons of continuous variables between the groups, the student's t-test was employed

Results: The HK cases had lower mean serum potassium compared to control and RTA (3.24 vs 4.06 vs 3.75 mmol/L, respectively; P< 0.001). The mean serum bicarbonate was normal in HK and control but lower in RTA (25.83 vs 25.20 vs 19.28 mmol/L, respectively; P< 0.001). The urine pH was abnormally high only in the RTA group (6.13 vs 6.22 vs 6.68; P= 0.012). The mean serum magnesium was modestly lower in HK compared to control-nml and control-RTA (1.75 vs 1.97 vs 1.97 mg/dL; P= 0.002) There were differences in serologic markers of autoimmunity. Compared with control, both HK and RTA were more likely to be seropositive for anti-SSA (P= 0.002 and 0.015, respectively). In contrast, compared to controls, only HK expressed a higher rate of anti-RNP seropositivity (P= 0.002) and only control-RTA had a higher rate of anti-SSB positivity (P= 0.044).

Conclusions: A syndrome of idiopathic hypokalemia was revealed in 20/403 (5%) of patients within our lupus nephritis population and is distinct from the RTA that is

known to rarely occur in lupus. This phenomenon has not been previously described. We speculate that idiopathic hypokalemia is the result of a novel target of autoimmunity in lupus affecting renal tubular potassium transport.

Outcomes of Lupus-Related Glomerular and Tubulointerstitial Disease: Analysis of the National Inpatient Sample

Ehizogie Edigin,[1] Precious Eseaton.[2] *[1]John H Stroger Hospital of Cook County, Chicago, IL; [2]University of Benin Teaching Hospital, Benin City, Nigeria.*

Background: The study aims to compare the differences in outcomes of hospitalizations for Systemic Lupus Erythematosus (SLE) with glomerular and tubulointerstitial related renal disease. The outcomes compared were inpatient mortality, hospital length of stay (LOS), and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient hospitalization database in the United States (U.S). The NIS was searched for adult SLE hospitalizations with lupus-related glomerular and tubulointerstitial disease as principal or secondary diagnosis using ICD-10 codes. The analysis was done using STATA. Multivariate logistic and linear regression analysis was used accordingly to adjust for confounders for the outcomes.

Results: There were combined 71 million discharges included in the 2016 and 2017 NIS database. 51,875 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE with lupus-related renal disease. 51,525 (99.3%) and 350 (0.7%) of these hospitalizations were for SLE with lupus-related glomerular and tubulointerstitial disease respectively. The mean age for SLE with lupus-related glomerular disease was 40.6 vs 44.2 years for lupus-related tubulointerstitial disease (P=0.084). 7,060 adult SLE hospitalizations resulted in inpatient mortality. 1,110 (2.14%) of the deaths occurred in SLE with lupus-related glomerular disease. The number of deaths for lupus-related tubulointerstitial disease was less than 10, hence it was omitted during the analysis by STATA. SLE with lupus-related glomerular disease had similar LOS (6.8 vs 6.7 days, p=0.865) and total hospital charges ($79,718 vs $83,006, p=0.961) compared to those with tubulointerstitial disease.

Conclusions: SLE with glomerular disease makes up the vast majority of SLE with lupus-related renal disease hospitalizations. Almost all the in-hospital deaths of SLE patients with lupus-related renal disease occurred in SLE with glomerular disease. LOS and total hospital charges were similar between hospitalizations for SLE with lupus-related glomerular and tubulointerstitial diseases.

PO1931

Lupus Podocytopathy Systematic Review

Ivan L. Claudio-Gonzalez, Ajai S. Rajabalan, Jose E. Navarrete, Jason Cobb. *Emory University Woodruff Health Sciences Center, Atlanta, GA.*

Background: Patients with lupus, can present with a renal lesion distinct from the ones described by the ISN/RPS classification of lupus nephritis called lupus podocytopathy. Lupus podocytopathy has been described as minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in patients with SLE with or without mesangial involvement but without proliferative or membranous lupus nephritis features. We have gathered the available data on lupus podocytopathy and analyzed it to provide a comprehensive report in this review.

Methods: We searched electronic databases including pubmed and google scholar, using keywords related to lupus podocytopathy and synonyms and treatment from inception to December 2019. Articles retrieved were screened for relevance, including reference list of retrieved. We included cohort studies, case series, and retrospective studies. Individual case reports were excluded.

Results: The search identified 8 studies, of which 6 were included with a total of 107 patients. The patients were predominantly female (88%). The average age was 35 years. Studies done outside of China had predominantly African-American patients 72.5%. The average serum creatinine was 2.06 mg/dL. The average proteinuria was 6.5 g/day. Four studies reported monotherapy corticosteroids, and three studies reported varied treatments. The average follow up was 3.7 years. Complete remission was reported to be 67% from 3 studies. Four studies reported relapse rate of patients, and it accounted to 72.5% of patients.

Conclusions: Our study is the first systematic review of lupus podocytopathy. The strength of this study is the merger of data from known studies in lupus podocytopathy which is a rare but important disease entity in lupus patients with renal disease. The treatment and possible prognosis of lupus podocytopathy patients are different from proliferative and membranous lupus nephritis, and physicians should be aware of this process. Patients can be spared from unwarranted immunosuppressive medications and their side effects. Greater collaborations and biopsies are needed to learn more about this interesting disease process.

Extended Follow-Up of Patients Recruited to a Randomized, Controlled Trial of Rituximab vs. Azathioprine, After Rituximab Remission Induction for Patients with Relapsing ANCA-Associated Vasculitis

Rona M. Smith,[1,2] David R. Jayne,[1,2] Peter A. Merkel.[3] *[1]University of Cambridge, Cambridge, United Kingdom; [2]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [3]University of Pennsylvania, Philadelphia, PA.*

Background: RTX is an effective remission induction therapy in AAV. However, the effect of RTX is not sustained, and relapse rates are high, especially in patients with a history of relapse. The RITAZAREM trial was an international, open-label, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy, after induction of remission with RTX, of repeat dose RTX or AZA as relapse prevention strategies.

Methods: Patients with relapsing AAV received induction therapy with RTX and glucocorticoids (GC). If remission was achieved by month 4, patients were randomized 1:1 to receive RTX (1000 mg every 4 months for 5 doses) or AZA (2 mg/kg/day) as maintenance therapy for 24 months. Patients continued to be followed until at least 36 months after enrolment, with a primary outcome of time to disease relapse. The final patient reached month 36 in the trial in November 2019.

Results: 190 patients were enrolled and 170 randomized at month 4 (85 to RTX; 85 to AZA): median age = 59 years (range 19-89); prior disease duration = 5.3 years (0.4-38.5); 123/170 (72%) with anti-PR3 ANCA, 47/170 (28%) with anti-MPO ANCA; 104 (61%) enrolled after a severe relapse, 66/170 (39%) after a non-severe relapse; GC induction regimen: 48/170 (28%) higher-dose, 122/170 (72%) lower-dose; 114 (67%) patients had prior renal involvement. We previously presented the results demonstrating the superiority of rituximab over azathioprine during the maintenance treatment period. Results of the follow up phase of the study after discontinuation of maintenance therapy will be presented at the 2020 meeting.

Conclusions: The results of the extended phase of RITAZAREM will examine the long-term impact of B cell depletion in patients with AAV on sustaining remission beyond the treatment period, clinical or biomarker factors associated with risk of relapse, and post-treatment safety of prolonged use of rituximab, including a focus on hypoimmunoglobulinemia.

PO1933

Renal Disease During Maintenance Treatment in ANCA-Associated Vasculitis (AAV) Remains a Problem and Glucocorticoid Use Is High

Peter A. Rutherford, Dieter K. Goette. *Vifor Pharma Ltd, Glattbrugg, Switzerland.*

Background: AAV is a relapsing remitting long term condition and patients are at risk of organ damage from active AAV and therapy in particular glucocorticoids (GC). The remission maintenance phase of AAV is critical for good long term renal outcomes. This retrospective study examined the pattern of renal disease during the maintenance phase in AAV patients managed in routine clinical practice

Methods: 1478 AAV patients managed by 493 EU physicians (61% Nephrologists) who completed induction therapy for organ/life threatening AAV and initiated therapy between 2014-16 were studied. Data were collected from when maintenance was determined to begin by the physician and then after 6, 12, 18 and 36 months

Results: 49% had GPA; mean age 54.2 years and 56% male. 49% had incident AAV and 51% were studied from relapse. 70% received cyclophosphamide/GC and 30% received rituximab/GC with 28% plasma exchange. Physicians defined time of start of maintenance as mean of 5.7 months from diagnosis. Over 36 months from maintenance start 38% patients had relapse (26% 1, 8% 2, 3% 3 and 1% 4). Only 22% had no comorbidity at diagnosis, hypertension and renal impairment were common. eGFR CKD stage changed over tme - stage 5 (8% to 11%), stage 4 (12 to 8%), stage 3 (43 to 37%) and stage2/1 (38 to 46%) – mean at 36 months of 53.3 ml/min. Hypertension and renal impairment were frequent comorbidities and renal related AEs were often reported. Many patients stayed on GCs and renal impairment and hypertension as well as active/chronic vasculitis activity were more frequent in patients remaining on GCs throughout maintenance. Renal function worsened in 24% patients and 46% were still receiving steroids vs 35% and 37% of those with improved or unchanged renal function ($p< 0.05$)

Conclusions: This study demonstrates relapse remains a problem iin AAV and many patients still receive long term GCs. Worsening renal disease is a challenge and associates with higher GC exposure suggesting ongoing renal inflammation and/or chronic damage. New therapeutic approaches are needed to improve renal outcomes

Funding: Commercial Support - Vifor Pharma

	Diagnosis - incidence or relapse	36 months
Receiving GCs %	71	39
Hypertension – comorbidity % All patients, No GC, Constant GC use	48	50, 39, 57
Renal impairment – comorbidity % All patients, No GC, Constant GC use	9	19, 13, 24
Adverse events		
Worsening eGFR %		10
Rising proteinuria %		4
Hypertension (new or worsening) %		18
Active or chronic renal vasculitis activity % All patients, No GC, Constant GC use		36, 28, 46

PO1934

Cost-Effectiveness of Maintenance Therapy with Azathioprine vs. Rituximab (Tailored or Fixed-Schedule) in Adults with Generalized ANCA Vasculitis in Colombia

Kateir Contreras, Viviana Orozco Ortiz, Eduardo J. Puche Carrascal, Paola Garcia, Camilo A. Gonzalez, Patricia Rodriguez, Diego Rosselli. *Hospital Universitario San Ignacio, Bogota, Colombia*.

Background: Azathioprine has been the drug of choice for maintenance therapy in patients with generalized ANCA vasculitis. However, recent studies show that rituximab, a high-cost biological agent, which can be administrated in two different schedules, might be more effective, so it is necessary to know the cost- effectiveness. Our goal was to compare the cost-effectiveness of the 3 maintenance schemes: standard therapy with azathioprine; fixed-dose rituximab and rituximab tailored according to CD19 lymphocyte level and ANCA titres, from the perspective of the Colombian healthcare system.

Methods: We designed a 5-year annual cycle Markov model with the following stages: remission, minor relapse, mayor relapse and death. Transition probabilities were obtained from a systematic review of the literature (Scopus and Pubmed). Following national guidelines for economic studies, costs, in 2018, 1USD = 2.956 Colombian pesos (COP), were estimated based on national drug registries, and official tariff manuals for procedures and other resources. Main outcome was quality-adjusted life years (QALY), using lupus nephropathy as a proxy; values were obtained from Tufts CEA Registry and validated by local expert panel through a modified Delphi technique. Cost-effectiveness threshold was three-times per capita GDP (USD 17253). Discount rate was 5%. Univariate and probabilistic sensitivity analyses were performed.

Results: Overall discounted 5-years costs were USD 1356 for azathioprine; USD 4750 for tailored rituximab and USD 6162 for fixed rituximab. QALY gains were 2.94, 3.63 and 3.64, respectively. Both tailored and fixed rituximab were cost-effective (cost per QALY gained: USD 4.919 and USD 6.865 respectively), but tailored dosing was preferable due to its lower cost. Sensitivity analyses did not modify these results significantly.

Conclusions: To our knowledge this is the first economic evaluation that compare azathioprine with tailored and fixed rituximab regimens as a vasculitis maintenance treatment in adults with ANCA generalized. Due to its lower effectiveness azathioprine should not be the first line of treatment. Tailored rituximab should be a better option than fixed schedule due to its lower cost with similar effectiveness.

PO1935

Use of Subcutaneous IgG to Treat Hypogammaglobinemia in ANCA-Associated Vasculitis

Sam Kant, Antoine Azar, Eric J. Gapud, Duvuru Geetha. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Intravenous immunoglobulin (IVIG) has been used to treat ANCA vasculitis (AAV) patients with recurrent infections as a result of hypogammaglobinemia induced by treatment regimens such as rituximab. Subcutaneous immunoglobulin (SCIG) has a better safety and tolerability profile. We characterized the clinical features, treatment and outcomes of AAV patients treated with SCIG).

Methods: We conducted a retrospective chart analysis of 187 patients in our AAV database to identify patients with recurrent infections and hypogammaglobinemia subsequently treated with SCIG. Patient demographics, clinical characteristics, treatment and immunological parameters were assessed.

Results: Of the 187 patients identified with AAV, 6 were treated with SCIG. All were Caucasian, PR3 positive and majority (n=4) were females. All patients had pulmonary involvement, and regimens of cyclophosphamide (CYC) and/or rituximab (RTX) were employed for induction and remission. Ig levels (IgG, IgM, IgA) were reduced in all patients. CD19/CD20 B cells were depleted, and CD3/4/8 and NK cells were preserved in all patients. The majority of patients(n=4) experienced recurrent URIs, 3 had shingles, in addition to other infections(table 1). All patients had no discernible IgG antibody response to pneumococcal vaccine. Mean duration between first rituximab administration and initiation of SCIG was 6.4 years. Four patients continued to receive RTX every 6 to 12 months while 2 patients remained in remission off RTX for over 2 yrs. IgG levels normalized and none of the patients had recurrence of infections after initiation of SCIG

Conclusions: These data, albeit preliminary, is one of the first series that demonstrates SCIG can be a safe and reliable alternative to IVIG in AAV patients with recurrent infections secondary to hypogammaglobinemia. Our data also suggest that SCIG may have immunomodulatory effects to maintain disease remission in AAV

Table 1. Treatment regimens for ANCA Associated Vasculitis Prior to Commencement of SCIG

Patient ID	Induction	Maintenance	RTX details	IgG level prior to SCIG (mg/dL)	Duration of RTX cessation prior to SQIG (months)
1	S + CYC + PLEX + RTX	AZA	Induction 375mg/m^2 q week x 4	299	95
2	S + RTX	RTX	7 courses of induction 375mg/m^2 q week x 4 for initial disease and 6 relapses Maintenance q 6 months	484	RTX continued
3	S + CYC	RTX	Induction 375mg/m^2 q week x 4 1 dose 500mg for recurrence	318	10
4	S + CYC	RTX	Maintenance 1000mg q 6 months	393	RTX continued
5	S + RTX	RTX	Maintenance 1000mg q 6 months	213	RTX continued
6	S + CYC	RTX	Maintenance 1000mg q 1year	289	RTX continued

PO1936

Glucocorticoid Maintenance Therapy and Severe Infectious Complications in ANCA-Associated Vasculitis

Claudius Speer,[1] Christian Nusshag,[1] Florian Kälble,[1] Christian Morath,[1] Martin G. Zeier,[1] Raoul Bergner,[2] Matthias Schaier.[1] [1]*University of Heidelberg, Heidelberg, Germany;* [2]*Clinical Center Ludwigshafen, Ludwigshafen, Germany*.

Background: Although treatment and outcomes in anti-neutrophil cytoplasmic autoantibody associated vasculitis (AAV) have been improved over the last decades, intensified immunosuppressive burden is concurrently associated with life-threatening adverse effects which are the main cause of death during the first year after disease onset. Our study evaluates the impact of cyclophosphamide (CYC) induction dose and glucocorticoid maintenance dose and duration on patient outcomes with an emphasis on infectious complications.

Methods: A total of 130 AAV patients from two different German Vasculitis Centers diagnosed between 2004 and 2019 treated with CYC for induction therapy and glucocorticoids ± mycophenolate mofetil or azathioprine for maintenance therapy were included in this study. We evaluated the impact of CYC dose for induction therapy and glucocorticoid dose and treatment duration for maintenance therapy on time to relapse, kidney function, infectious complications, irreversible physical damage and mortality. Patients were separated into four groups: <3g versus ≥3g cumulative CYC dose and <7.5mg after 6 months versus ≥7.5mg glucocorticoids after 6 months.

Results: The baseline demographic and disease characteristics were comparable between groups. Cumulative CYC dose had no impact on relapse rate, kidney function, infectious complications or mortality. Patients receiving ≥7.5mg glucocorticoids after 6 months had an increased rate of infectious episodes per patient (0.6 vs. 1.7; p<0.001). Urinary tract infection (p=0.007), pneumonia (p=0.003) as well as opportunistic pneumonia (p=0.022) and sepsis (p=0.008) appeared more frequently. Especially pneumonia during the first 24 months after disease onset (hazard ratio, 3.0 [95% confidence interval (CI), 1.5–6.1]) led to more death by infections (p=0.034). Patients ≥65 years with ≥7.5mg glucocorticoids after 6 months were at particular risk for infectious complications. Glucocorticoid maintenance therapy had no impact on relapse rate or kidney function after the last follow-up.

Conclusions: An extended glucocorticoid maintenance therapy may induce severe infectious complications leading to an increased frequency of death by infection, has no effect on time to relapse and should therefore be critically revised throughout the aftercare of AAV patients.

PO1937

Country Differences Exist in the Treatment of ANCA-Associated Vasculitis (AAV), but High-Dose and Prolonged Glucocorticoid Use Is Observed Across Europe

Peter A. Rutherford, Dieter K. Goette. *Vifor Pharma Ltd, Glattbrugg, Switzerland*.

Background: European AAV guidelines recommend remission induction therapy with combination of high dose glucocorticoids (GC) and rituximab (RTX) or cyclophosphamide (CYC) and maintenance therapy with either RTX or azathioprine (AZA). This retrospective study examined the pattern of prescribing, including the use of GCs, across Europe in AAV patients managed in routine clinical practice

Methods: 1478 AAV patients managed by 493 physicians in France, Germany, Italy, Spain and UK who completed induction therapy for organ or life threatening AAV (49%

incident and 51% relapsing) and initiated maintenance therapy between 2014-16 were studied. Data were collected at the time maintenance was determined to begin by the physician and then after 6, 12, 18 and 36 months.

Results: AAV type varied with more GPA in Germany (52%) and UK (56%) compared to France (47%), Italy (47%) and Spain (40%). Proportion of patients with severe progressive disease varied - 41% Italy to 48% France. Induction therapy varied with lowest use of IV GC and rituximab (RTX) and highest cyclophosphamide (CYC) use in the UK. Maintenance was defined by clinicians as approximately 6 months following treatment start and GCs were used similarly across all countries with less RTX and less GC used in UK and more AZA in Germany and UK. At 36 months prescribing patterns were similar and a variable proportion of patients (13% Germany to 30% France) stopped therapy but with approximately 25% patients not in full remission

Conclusions: AAV treatment prescribing patterns vary across Europe particularly RTX, driven by economic as well as case mix differences. GC use is high across all countries with high GC use (including IV at induction) and prolonged use over 36 months being common. Sustained remission rates could be improved and there is need for more targeted therapies to reduce reliance on GCs

Funding: Commercial Support - Vifor Pharma

Validation of a Clinical-Pathologic Renal Risk Score in ANCA-Associated Glomerulonephritis: The US Experience

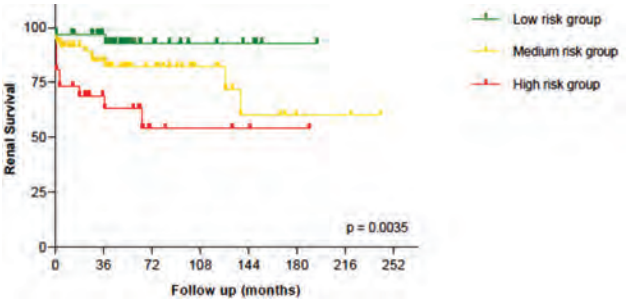
Sam Kant,[1] Silke R. Brix,[2] Francesca Costigliolo,[1] Paride Fenaroli,[1] Avi Z. Rosenberg,[1] Duvuru Geetha.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: The prognostication of renal disease in the setting of ANCA associated vasculitis (AAV) continues to pose a significant clinical challenge given lack of validated clinical and pathologic correlates. A risk score has been developed by a German consortium (Brix et al Kidney International 2018), to stratify risk of AAV-related renal disease progression to ESKD. We applied this risk score in our cohort of AAV patients to ascertain its reproducibility.

Methods: A single center retrospective cohort study was performed reviewing 148 renal biopsies of patients with AAV GN. Data for score calculation was available of 119 patients with a median follow up of 58 months (IQR 28 – 97 months). Three parameters were used in the risk prediction score: (1) # of normal glomeruli (N0 >25%, N1 10-25%, N2 <10%), (2) tubular atrophy and interstitial fibrosis (T0 <25%, T1 >25%) and (3) eGFR at the time of diagnosis (G0 >15, G1 <15). A weighted assignment of points to each parameter was as follows: N1 [4], N2 [6], T1 [2], G1[3], and the resulting aggregate risk score used to classify predicted ESRD risk was low (0), intermediate (2 to 7), or high (8 to 11 points).

Results: In the cohort of 148 patients, median age was 63 years and mean eGFR at diagnosis was 27.7. Seventy-six were MPO, 57 were PR3 positive and 15 were ANCA negative. With regards to risk stratification, 34 were in low risk category, 59 in the medium risk category and 26 patients in the high-risk category. Overall, 23 patients (19.3%) progressed to ESKD with 2 (5.9%), 11 (18.6%), 10 (38.5%) in low, medium and high risk groups, respectively. A Kaplan-Meier survival curve (Figure1) demonstrates worsening of renal survival across the risk groups (p=0.0035).

Conclusions: This AAV renal risk score was able to reliably predict risk for progression to ESKD. A further analysis revalidating cut-offs and risk score points would likely refine the score improving its prediction accuracy.



PO1939

Clinical Features and Outcomes of Anti-Neutrophil Cytoplasmic Autoantibody-Associated Vasculitis in Chinese Elderly and Very Elderly Patients

Ting Meng. *Departments of Nephrology, Xiangya Hospital Central South University, Xiangya Hospital Central South University, Changsha, China.*

Background: Anti-neutrophil cytoplasmic autoantibody-associated vasculitis (AAV) is predominantly a disease of the elderly, and the incidence increases with age. However, there are few data focusing on the clinical features in elderly-onset AAV, especially in very elderly-onset AAV in China. The aim of this study was to explore whether elderly-onset AAV shows any specific clinical features and outcomes in Chinese patients.

Methods: We performed a retrospective study in Xiangya Hospital, a mixed tertiary medical center in south China. A total of 177 patients presenting with AAV were included between January 1, 2010 and December 31, 2017. Patients were divided into younger group (age<65 years) and older group (age≥65 years) which was sub-divided into elderly group (age 65-74 years) and very elderly group (age≥75 years).

Results: We found patients in the very elderly group had more chest and cardiovascular involvement (P =0.033 and P =0.017). Older AAV patients had less renal involvement and lower serum C4 level (P =0.013 and P =0.003). Very elderly AAV patients had lower platelet counts. Patients in the younger group had a higher level of BVAS among three groups (P <0.05 younger group vs. very elderly group; P <0.05 younger group vs. elderly group). There were no significantly difference in the proportion of ESRD patients among the three groups (P =0.473). Patients in the very elderly group had the poorest patient survival (P = 0.002).

Conclusions: Older AAV patients had less renal involvement, lower serum C4 level and BVAS. The very elderly group got the most chest and cardiovascular involvement and had lower platelet counts. Older age is associated with higher mortality in AAV patients.

PO1940

Validation of the Renal Risk Score for ANCA-Associated Glomerulonephritis in a National Irish Cohort

Jennifer Scott,[1] Silke R. Brix,[2] Laura M. Slattery,[1] Michelle Clince,[1] Mark A. Little.[1] Trinity Health Kidney Centre, Trinity College Dublin, Ireland *[1]Trinity Health Kidney Centre, Dublin, Ireland; [2]The University of Manchester, Manchester, United Kingdom.*

Background: Histopathological examination is currently the gold standard for diagnosis of ANCA-associated glomerulonephritis (AAV GN). However, the commonly used Berden score is inconsistent at predicting renal outcomes across different cohorts. Furthermore, treatment related morbidity remains a major problem. Brix et al. recently published a clinico-pathologic score to predict End-Stage Kidney Disease (ESKD), using 3 parameters to stratify patients into 3 risk groups. Parameters include: percentage normal glomeruli (N0 >25% = 0 points, N1 10 to 25% = 4, N2 <10% = 6), percentage tubular atrophy and interstitial fibrosis (T0 ≤25% = 0, T1 >25% = 2), and estimated glomerular filtration rate at the time of diagnosis (G0 >15 ml/min/1.73 m2 = 0, G1 ≤15 ml/min/1.73 m2 = 3). The ultimate aim is to utilise this to personalise treatment, enabling the optimal balance of toxic immunosuppression for every patient.

Methods: The Rare Kidney Disease (RKD) registry is an Irish national longitudinal, multi-centre, cohort study which includes 567 AAV patients, to date, diagnosed using the European Medicines Agency Algorithm (1990-2019). Patients with Granulomatosis with polyangiitis (GPA) or Microscopic polyangiitis (MPA), with biopsy proven AAV GN and positive PR3 or MPO serology were included in our validation of the renal risk score.

Results: 248 patients, of whom 43 (17.3%) developed ESKD and 35 (14.1%) died, over a median follow up of 32 months (interquartile range, IQR 5 – 69.5 months), were identified. Outcome data and histopathologic details were available for 205 patients. Forty-five patients were in the lowest risk group (group 1) - two (4.4%) of which developed ESKD. Eight (8.6%) of the 93 patients in the middle risk group (group 2) reached ESKD. Sixty-seven patients were in the highest risk group (group 3) and 28 (41.8%) of them required permanent renal replacement therapy. Kaplan Meier survival analysis demonstrated a difference in renal outcome between the 3 risk groups ($p < 0.0001$).

Conclusions: The proposed renal risk score accurately predicts ESKD in patients with AAV GN, in our national Irish cohort. The next step is to further refine the predictive cut-off values for the 3 clinico-pathologic parameters using a regression tree analysis.

Hypocomplementemia Is Associated with More Severe Renal Disease and Worse Renal Outcomes in Patients with ANCA-Associated Vasculitis: A Retrospective Cohort Study

Aglaia Chalkia,[1] Konstantinos Thomas,[2] Panagiota E. Giannou,[1] Zoe Alexakou,[1] Athanasia Kapota,[1] Christina Tsalapaki,[2] Dimitrios Vassilopoulos,[2] Dimitrios I. Petras.[1] *[1]Nephrology Department Hippokration General Hospital, Athens, Greece; [2]Joint Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine - Clinical Immunology - Rheumatology Unit, 2nd Department of Medicine, Athens, Greece.*

Background: The complement system has been recently proposed to play an important role in the pathogenesis of ANCA associated vasculitis (AAV). Real life data assessing its predictive role in renal outcomes are limited. In this study, we evaluated the value of serum and kidney deposited C3 in predicting renal outcomes in patients with AAV.

Methods: In this retrospective study, patients with AAV were categorized according to their baseline serum C3 levels as hypo- or normo-complementemic and to those with positive or negative kidney biopsy immunofluorescence (IF) for C3. Clinical, serologic, treatment and histopathologic characteristics, as well as prognosis between the 2 groups were compared.

Results: Forty-seven patients (51% men) were enrolled with a mean age at diagnosis of 65 years and were followed up for a median period of 56 months. At baseline, 23% (11/47) of the patients were hypocomplementemic (C3 <75 mg/dL). These patients were older (74 vs. 65 years, p=0.013), had higher creatinine levels (4.9 vs. 2.2 mg/dL, p=0.006), were more often hemodialysis dependent (64% vs. 19%, p=0.009) and progressed more often to ESRD (55% vs .11%, p=0.01) compared to normo-complementemic patients (n=36). On multivariate analysis, serum Cr at diagnosis (HR=16.8, 95%CI: 1.354-208.62, p=0.028) and low serum C3 (HR=2.492; 95% CI: 0.537-11.567, p=0.044) were independent predictors for ESRD. Among 25 patients with kidney biopsy data, those with positive IF staining for C3 (56%, n=14) had more often a mixed histological pattern (72% vs. 27%, p=0.033), low serum C3 levels (42% vs. 18%, p<0.001) and serious infections during follow-up (57% vs. 18%, p=0.047) compared to those with negative (n=11) IF staining.

Conclusions: The subgroup of patients with AAV and low C3 levels at diagnosis (23%) have more severe renal disease and outcomes (ESRD) compared to patients with normal C3 levels. This should be taken into account in therapeutic and monitoring strategies.

PO1942

Clinical Features and Treatment Outcomes of Patients with Pauci-Immune Vasculitis with and Without a Medical History of Autoimmune Disease

Sophia Lionaki,[1] Smaragdi Marinaki,[1] Sofia Fragkioudaki,[1] Emmanuel Kalaitzakis,[1] Petros Kalogeropoulos,[1] Georgios Liapis,[2] Athanasios Tzioufas,[3] Ioannis Boletis.[1] *[1]Nephrology, Laiko Hospital, Athens, Greece; [2]Pathology, Laiko Hospital, Athens, Greece; [3]Pathophysiology department, Laiko Hospital, Athens, Greece.*

Background: A proportion of patients with **p**auci-immune vasculitis (PIV) report a past medical history (PMH) of other autoimmune disorder prior to the diagnosis of vasculitis. The purpose of this study was to identify the differences, if any, between patients with PIV with or without a PMH of other autoimmune disease prior to the onset of vasculitis.

Methods: Among 304 patients with biopsy proven PIV at any site, detailed information regarding their PMH was available in 235 patients (77.3%). Of these, 60 (25.5%) reported a PMH of other autoimmune disorder including Sjogren syndrome, Crohn's disease, autoimmune thyroiditis, psoriasis, rheumatoid arthritis, and scleroderma.

Results: The clinical characteristics and outcomes of the two groups are displayed in [table 1].

Conclusions: Patients with a PMH of other autoimmune disorder prior to the diagnosis of PIV were predominantly P/MPO-ANCA positive, had less impaired kidney function at presentation and a lower probability of relapse after achieving remission, compared to patients without a PMH of autoimmunity.

Characteristic Mean (sd) or N(%)	Patients with a PMH of autoimmune disease N=60	Patients without a PMH of autoimmune disease N=175	p-value
Age (years)	53.9 (±16.03)	51.2 (±15.08)	0.88

PO1943

Low Serum C3 at Diagnosis of Pauci-Immune Glomerulonephritis Is Associated with More Advanced Kidney Impairment and Worst Renal Prognosis

Sophia Lionaki,[1] Smaragdi Marinaki,[1] Emmanuel Kalaitzakis,[1] Sofia Fragkioudaki,[1] Petros Kalogeropoulos,[1] Georgios Liapis,[2] Athanasios Tzioufas,[3] Ioannis Boletis.[1] *[1]Nephrology, Laiko Hospital, Athens, Greece; [2]Pathology, Laiko Hospital, Athens, Greece; [3]Pathophysiology, Laiko Hospital, Athens, Greece.*

Background: Recent evidence supports the notion that complement activation plays a critical role in pauci-immune (PI) vasculitis pathogenesis. The aim of this study was to investigate if the clinical, serological and laboratory characteristics and treatment outcomes of patients with PI glomerulonephritis (GN) with low serum complement levels at diagnosis differ from those of patients with complement values within the normal range.

Methods: In a retrospective design we studied patients with biopsy proven PIGN with available serum complement measurements at diagnosis, or during a relapse, prior to initiation of immunosuppressive therapy. All patients were tested for antineutrophil cytoplasmic antibodies (ANCA) at presentation. Fisher's exact tests and Wilcoxon rank sum tests were used to compare the characteristics by serum C3.

Results: Of 96 patients included in the study, 22 (22.9%) had low serum C3 at diagnosis. Comparison of clinical, serological and laboratory characteristics and outcomes between the two groups is shown in [table 1].

Conclusions: Almost one quarter of patients with biopsy proven PIGN had low serum C3 at diagnosis in this cohort. These patients had more advanced renal impairment, required acute dialysis more frequently and were more likely to end up in end-stage kidney disease compared to patients with serum C3 within the normal range.

Characteristic Mean(sd) or N(%)	PIGN with low serum C3 N=22	PIGN with normal serum C3 N=74	p value
Age (years)	60.4(±13.1)	58.3 (±15.6)	0.42
Gender (male)	12 (57.1)	35 (47.3)	0.45
BVAS	16.6 (±5.35)	17.7 (±5.75)	0.89

PO1944

Serum and Urinary Metabolites Discriminate Disease Activity in ANCA-Associated Glomerulonephritis

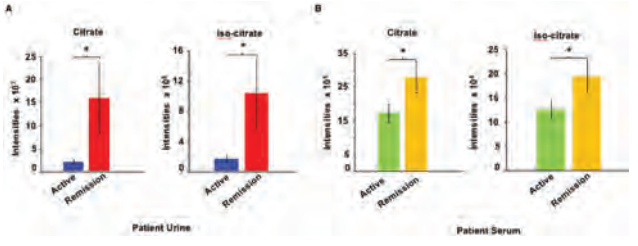
Sam Kant, Anne Le, Nabeel Attarwala, Duvuru Geetha. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Relapse of disease and treatment related morbidity due to lack of a reliable biomarker for disease activity continue to be a significant issue in patients with ANCA associated vasculitis (AAV). Renal biopsy is currently gold standard for reliable detection of active disease. Metabolomics have been used to successfully discern disease activity in a number of autoimmune diseases. We sought to investigate the use of serum and urinary metabolomics to discriminate disease activity in ANCA associated GN

Methods: Ten patients with AAV renal disease had paired serum and urine supernatant sample collections during active and remission phases of disease. Active renal disease was defined by presence of hematuria >5 RBC/hpf, urinary RBC casts or an increase in serum creatinine > 30% or < in eGFR by 25% or biopsy proven GN. The samples were then subjected to targeted metabolomics data acquisition using a Thermo scientific Q Exactive plus Orbitrap Mass Spectrometer Plus with a Vanquish UPLC at our metabolomics facility.

Results: The mean age in this cohort was 61 years, with 6 patients each being male and Caucasian. Nine patients had biopsy proven renal disease, with clinical diagnosis in one. Mean BVAS and mean GFR was 17 and 28 respectively. Intensities of urinary citrate and iso-citrate are significantly higher in the remission group compared to the active group (Fig 1A). Similar trend of higher citrate and iso-citrate intensities present in serum of patients in remission versus active disease (Fig 1B). There was a disproportionately high intensity difference in citrate and iso-citrate levels in serum and urine samples compared to other metabolites of the TCA cycle implying involvement of additional metabolic pathways.

Conclusions: This study indicates that serum and urinary citrate and iso-citrate may be utilized to monitor disease activity in AAV and emerge as an alternative to kidney biopsy.



PO1945

Renal Involvement in Granulomatosis with Polyangiitis Does Not Increase Inpatient Mortality Compared with No Renal Involvement

Ehizogie Edigin,[1] Precious Eseaton,[2] Augustine Manadan.[3,1] *[1]John H Stroger Hospital of Cook County, Chicago, IL; [2]University of Benin Teaching Hospital, Benin City, Nigeria; [3]Rush University Medical Center, Chicago, IL.*

Background: The aim of this study was to analyze the difference in outcomes of Granulomatosis with polyangiitis (GPA) with and without renal involvement. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the United States. The NIS was searched for adult GPA hospitalizations with and without renal involvement as the principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There over 71 million discharges included in the combined 2016 and 2017 NIS database. 23,670 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for GPA. 8,265 (34.92%) and 15,405 (65.08%) of these hospitalizations were for GPA with renal and without renal involvement respectively. Inpatient mortality occurred in 1,010 GPA patients (5.1%). 425 (5.1%) of the deaths occurred in GPA with renal involvement vs 585 (3.8%) without renal involvement (p=0.0287). The adjusted odds ratio (AOR) of inpatient mortality for GPA with renal compared to without renal involvement was 1.14 (95% CI 0.84-1.56, p=0.406). GPA with renal involvement hospitalizations had a mean increase in adjusted mean LOS of 1.36 days (95% CI 0.82-1.91, p<0.0001) compared to GPA without renal involvement. GPA with renal involvement hospitalizations had an increase in adjusted total hospital charges of $18,723 compared to GPA without renal involvement (95% CI 9,595-27,852, p<0.0001).

Conclusions: There is no statistically significant difference in inpatient mortality for hospitalizations of GPA with and without renal involvement. However, LOS and total hospital charges in GPA with renal involvement were greater than those without renal involvement. Hence GPA with renal involvement has a greater burden to the healthcare system compared to without renal involvement.

PO1946

Immunological Indexes Both in Renal and Serum Were Associated with Renal and Patient Outcome in Chinese Patients with Myeloperoxidase-ANCA-Associated Glomerulonephritis

Wei Lin, Zhong Yong. *Department of Nephrology, Xiangya Hospital, Central South University, China, Changsha, China.*

Background: Rapidly progressive glomerulonephritis (RPGN) caused by antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are typically characterized by few or no immune deposits in glomerulus which was defined as pauci-immune glomerulonephritis(GN). Immune complex (IC) deposits in glomerulus and abnormal serum immune indexes have also been reported in some studies. Most patients with AAV in China are positive for anti-myeloperoxidase (MPO), which more frequently had renal involvement and developed RPGN. Therefore, it is necessary to assess serum immunological indexes and the IC deposits in renal in MPO-ANCA-associated GN.

Methods: Clinical and histopathologic characteristics of 97 patients who had renal biopsy-proven as necrotizing and crescentic MPO-ANCA-GN from 2002 to 2019 were recruited in this study. Serum immunological indexes (sC3, sC4, sIgA, sIgG, sIgM), immune deposits in the kidney (C3, C4, IgA, IgG, IgM) in immunofluorescence (IF) at diagnosis were retrospectively analyzed.

Results: Patients with low sC3 (≤790 ml/L) and low sC4 (≤100 ml/L) at diagnosis showed poorer renal survival compared to patients with normal value (p=0.003, 0.011). Furthermore, among patients of low sC3 at diagnosis, the cases with persistent low sC3 showed an obviously worse renal survival than those whose sC3 recovered to normal after treatment (p<0.001). There are 41%(40/97) patients showed positive IF findings (≥2+ on a 0 to 4+ scale) for at least one Ig or complement component. in our study. The patients with IC deposits showed higher level of serum creatinine (p=0.01) and lower platelet counts (p=0.009), sC3 level (p=0.013) than patients with pauci-IC deposition at diagnosis. We also found IgG deposits related to worse renal outcome than the negtative cases (p=0.047). What's more, complement C1q deposits displayed significant poorer patient survival than the cases without C1q deposits (p=0.001).

Conclusions: Patients with a persistent low sC3 showed poorer renal prognosis than the patients whose sC3 level return to normal after a period of treatment, which was confirmed that both initial and continuously low sC3 can act as predictive indicators for renal outcome. IgG and complement C1q deposits associated with poorer renal and patient outcome, which can help to judge the prognosis of MPO-ANCA-associated GN to some extent.

PO1947

Rituximab vs. Cyclophosphamide in the Treatment of Anti-GBM Crescentic Glomerulonephritis: An Observational Study

Ajay Jaryal, Sanjay Vikrant. *Indira Gandhi Medical College, Shimla, India.*

Background: Anti glomerular basement membrane (GBM) crescentic glomerulonephritis (CsGN) is a rare disease affecting kidneys and/or lungs. At present most of the evidence for its treatment is with use of plasmapheresis (PP), high dose steroids (HDS) and cyclophosphamide (CYC). The use of Rituximab (Rtx) in addition to PP and HDS is only anecdotal. Herein, we are describing our experience with the use of both the regimens.

Methods: A retrospective analysis of all the patients with anti GBM CsGN admitted in our hospital from September 2018 to November 2019 was done. Anti GBM CsGN was diagnosed on the basis of ≥50% crescents on kidney biopsy and immunofluoroscence showing linear IgG deposition along GBM and/or by the presence of anti GBM antibodies.

Results: 11 patients were admitted with anti GBM CsGN, during this period (15 months). Kidney biopsy was done in 10 patients and in one anti GBM GN was diagnosed on the basis of raised anti GBM antibody titres. There were 8 females and three males (age range 37-72 years). The mean serum creatinine was 8.69mg/dl. Out of 11 patients 2 refused for treatment and 2 were lost to follow up. 3 out of 7 patients had diffuse alveolar hemorrhage (DAH) and in all it succeeded renal involvement (one had diagnosis of usual interstitial pneumonia for 1 year). 4 out of 11 patients had concomitant urinary tract infection, 5 out of 7 (71.42%) were ANCA positive, 2 out 11 had type 2 diabetes mellitus, 5 out of 11 were oligoanuric and 7/11 (63.6%) were dialysis requiring at presentation. PP was given on alternate days. Both the patients who refused for treatment died on follow up. Among remaining 7 patients 5 had received PP+HDS + CYC and 2 had received PP+HDS+Rtx. In CYC group 4 (all 4 were dialysis dependent and 3 were oligoanuric) out of 5 patients died whereas in Rtx group both the patients survived (one was dialysis dependent and oligoanuric).

Conclusions: In our study most of the patients presented late to the hospital due to vague symptoms at the onset (mean 30 days) and few had co-existing UTI (this delayed the treatment). 63.6 % were dialysis requiring at presentation and DAH was the most common cause of in-hospital death. Two out the three survivors achieved normal eGFR (one in CYC and one in Rtx arm) whereas third one had no progressive decline in eGFR (Rtx). The use of Rtx along with HDS and PP showed favourable outcomes in our study.

PO1948

Impact of Race on Hospitalization Outcomes for Goodpasture Syndrome in the United States

Juan A. Medaura,[1] Charat Thongprayoon,[2] Michael A. Mao,[4] Boonphiphop Boonpheng,[5] Wisit Kaewput,[3] Wisit Cheungpasitporn.[1] *[1]Division of Nephrology, Department of Internal Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [3]Phramongkutklao College of Medicine, Bangkok, Thailand; [4]Department of Medicine, Mayo Clinic, Jacksonville, FL; [5]Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA.*

Background: Goodpasture's syndrome is a rare and life-threatening autoimmune disease. While Goodpasture's syndrome is well described in Caucasian and Asian populations, its prevalence and outcomes among African American and Hispanic populations are unclear. We conducted this study to assess the impacts of race on hospital outcomes among patients with Goodpasture's syndrome.

Methods: The National Inpatient Sample database was used to identify hospitalized patients with a principal diagnosis of Goodpasture's syndrome from 2003-2014. Goodpasture's syndrome patients were grouped based on their race. The differences in-hospital treatments and outcomes between Caucasian, African American, and Hispanic Goodpasture's syndrome patients were assessed using logistic regression analysis.

Results: 964 patients were hospitalized with a primarily diagnosis of Goodpasture's syndrome. Of these, 786 were included in the analysis: 622 (65%) were Caucasian, 73 (8%) were African American, and 91 (9%) were Hispanic. The need for mechanical ventilation, non-invasive ventilation support, and renal replacement therapy in African Americans and Hispanics were comparable to Caucasians. There was no significant difference in organ failure, sepsis, and in-hospital mortality between African Americans and Caucasians. In contrast, Hispanics had higher in-hospital mortality than Caucasians but similar risk of organ failure and sepsis.

Conclusions: African American and Hispanic populations account for 8% and 9% of hospitalizations for Goodpasture's syndrome, respectively. While there is no significant difference in in-hospital mortality between African Americans and Caucasians, Hispanics with Goodpasture's syndrome carry a higher in-hospital mortality compared to Caucasians.

PO1949

Overlap Syndrome of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis and IgG4-Related Disease: Distinct Clinicopathologic Clues for Precise Diagnosis

Peifen Liang,[1] Qiongqiong Yang,[1] Wenfang Chen,[2] Shuling Yue,[3] Qianqian Han.[1] *[1]Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Pathology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [3]Guangzhou KingMed Center for Clinical Laboratory Co., Ltd, Guangzhou, China.*

Background: Both antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and IgG4-related disease (IgG4-RD) are multi-system inflammatory disorders. The coexistent of both diseases present the possibility of a new overlap syndrome which leads to different treatment and outcome. In this study, the symptomatic and pathological concurrence of AAV and IgG4-RD is investigated to explore the possibility and clinicopathologic clues to the diagnosis of this overlapped syndrome.

Methods: A case of a 67-year-old man in our hospital who exhibited the characteristics of both AAV and IgG4-RD was presented. The treatment response and outcome of the case were followed up for the next 15 months. Then, a systematic literature review of the overlap syndrome of AAV and IgG4-RD was performed on PUBMED database from 1976 until January 2020.

Results: Mild hematuria with rapid progressive renal failure of the patient was observed while renal biopsy revealed pauci-immune crescentic glomerulonephritis, especially with IgG4-related tubulointerstitial nephritis. Glucocorticoids combined with cyclophosphamide therapy led to partial remission. Literature review of 52 patients met both AAV and IgG4-RD criteria as overlap syndrome and four common clinicopathologic features were identified. First, atypical clinical and laboratory manifestations were characteristics of this entity. Second, positive MPO-ANCA are more common. Third, tissue samples showed overlapping histological patterns when kidneys were involved. Fourth, the combination of glucocorticoids and immunosuppressive therapy was often required and led to a remission within 3 months.

Conclusions: AAV may overlap with IgG4-RD while presenting atypical manifestations. Four common clinicopathologic characteristics could be used as specific clues to the diagnosis of overlap syndrome.

PO1950

Anti-IL-5 Therapy in Eosinophilic Granulomatosis with Polyangiitis (EGPA): An 18-Month Follow-Up Study of a Steroid-Sparing Therapeutic Approach

Allyson C. Egan,[1] Pasupathy Sivasothy,[1] Robin B. Gore,[1] Caroline M. Owen,[1] Rachel B. Jones,[1] Rona M. Smith,[1] Lisa C. Willcocks,[1] Stella M. Burns,[1] David R. Jayne.[2] *[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]University of Cambridge, Cambridge, United Kingdom.*

Background: EGPA is a small vessel vasculitis with protean renal manifestations including necrotizing glomerulonephritis, eosinophilic interstitial nephritis and obstructive uropathy. In the randomized, placebo-controlled MIRRA trial for relapsing and refractory EGPA, adjuvant therapy with 300mg anti-IL5 mAB Mepolizumab [MEPO], accrued longer times in remission, reduced steroid exposure and reduced relapse rates.

Methods: The aim of our study was to analyze the outcome for EGPA patients who received 100mg s/c of MEPO monthly for 18 months and beyond. This retrospective, descriptive study analyzed 13 patients with EGPA, who received 100mg s/c of MEPO therapy monthly. Time points of assessment included MEPO commencement [M0] and ≧ 18 months [>M18].

Results: This study demonstrates that anti-IL5 therapy serves as a favorable model for steroid minimization in EGPA, with an overall 50% reduction in steroid dosage. Additional reduction in conventional immunosuppressants was also observed in 3 patients. ANCA positive serology normalized in all four patients. Well tolerated, it demonstrated considerable clinical benefit, with 12 patients [92.3%] continuing anti-IL5 therapy beyond 18 months. Renal function was preserved. One patient had MEPO switched to Rituximab to treat both EGPA and new onset rheumatoid arthritis. Three patients were switched to alternative anti-IL5 therapies, benralizumab (x2) and Reslizumab (x1).

Conclusions: The relapsing nature of EGPA places a potential dependency of therapy on steroids, underscoring the importance of targeted pathway specific biologics to minimize steroid exposure, prevent tissue damage and ensure early response to therapy. There was a 50% reduction in steroid dosage in this study, with preserved renal function.

Table 1: EGPA patients receiving anti-IL5 therapy for greater than eighteen months [100mg s/c]

Demographics			**All [n=13]**	
Gender ratio M/F			4M:9F	
ANCA positive/ negative			ANCA: 3MPO, 1 PR3 positive/ 9 ANCA negative

Pauci-Immune Lupus Nephritis: A Case Report

Bharath Suryadevara, Anvita Anne, Varun kumar Bandi. *Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.*

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disease with multisystem involvement, and Lupus nephritis (LN) typically shows immune deposits on biopsy. Pauci-immune LN is a rare entity.

Case Description: A 35 year old female presented with pedal edema, reduced urine output & yellowish discoloration of eyes since 20 days. No vomiting, dyspnea, joint pains, rashes, or hematuria. She had similar episodes in 2011 and 2013 & was given blood transfusion and oral steroids. She is a hypertensive for 10 years and diabetic for 2 years. She had 2 normal vaginal deliveries with no obstetric complications. On examination she had pallor, icterus and generalized edema, blood pressure of 170/80mmHg. Rest of the examination was normal. She had severe anemia, renal failure, positive ANA, dsDNA and direct Coomb's test, with normal complements. There was no evidence of active hemolysis. SLE with Auto immune hemolytic anemia (AIHA) and probable lupus nephritis (LN) was diagnosed. Steroid pulse was started with stabilization of renal function and hemoglobin. Renal biopsy showed necrotising crescentic glomerulonephritis with no endocapillary proliferation. Immunofluorescence did not show any immune deposits. A diagnosis of pauci immune LN was made, and was started on cyclophosphamide. She had partial renal recovery with creatinine of 1.5 mg/dl, no hematuria, no hemolysis.

Discussion: Renal biopsy in SLE patients can reveal varied pathologies like ANCA or lupus vasculitis etc. In our case, renal biopsy was similar to ANCA vasculitis, however systemic features favored SLE. With a diagnosis of SLE, and absence of endocapillary proliferation, a diagnosis of pauci-immune LN was made.

Pulmonary Renal Connection: A Case of ANCA Vasculitis and Atypical Anti-GBM Antibody Associated with Vaping

Josephine Abraham, Laith Al-Rabadi, Monica P. Revelo Penafiel, Martin C. Gregory. University Of Utah *University of Utah Hospital, Salt Lake City, UT.*

Introduction: The use of e cigarettes and vaping is linked to the development of lung injury (EVALI). We present a case of ANCA (antinuclear cytoplasmic antibody) vasculitis with atypical Anti GBM (glomerular basement membrane) antibody in a patient with EVALI.

Case Description: A 17 year old male with a history of vaping presented with acute respiratory failure requiring mechanical ventilation. CT chest revealed diffuse bilateral consolidation. Evaluation for infection was negative. Nephrology was consulted for acute renal failure. Urine analysis was notable for hematuria and proteinuria. Urine microscopy identified dysmorphic erythrocytes. Renal biopsy showed pauci immune crescentic glomerulonephritis (panel A). ANCA with MPO (myeloperoxidase) specificity and Anti GBM antibody were positive. He was treated with methylprednisolone, therapeutic plasma exchange and oral cyclophosphamide initially and subsequently Rituximab. Four months later his creatinine was 1.2 mg/dL, improved from a peak level of 7.5mg/dL with negative ANCA and Anti GBM titers. Two other patients with vaping associated lung injury admitted to the intensive care unit were noted to have dysmorphic hematuria. Urine microscopy in one was notable for red cell casts (panel B) and numerous string casts (panel C).

Discussion: Anti GBM disease had been associated with alveolar injury from exposure to hydrocarbons or smoking. The presence of the erythrocyte casts and positive anti GBM antibody in patients with vaping associated lung injury raises the possibility of pulmonary and renal injury from a common mechanism. While the pathogenesis of vaping associated renal injury is unclear, examination of the urinary sediment should be performed in all patients presenting with vaping associated lung injury and hematuria.

Sabotaged: Hydralazine-Induced ANCA Glomerulonephritis

Larissa Kruger gomes, Esilida Sula Karreci, Krishna A. Agarwal, Ruth Schulman, Jeffrey H. William, Stewart H. Lecker, Isaac E. Stillman. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: While usually well known to cause SLE-like syndrome, hydralazine (HZ) can also be involved in a different clinical scenario with ANCA vasculitis.

Case Description: 77y/o woman with hypertension and COPD presents with 2 days of hemoptysis and hematuria, requiring urgent intubation. CT scan reveals multifocal infiltrates and bronchoscopy shows diffuse alveolar hemorrhage. Labs showed Hb of 6.8 and Cr of 1.9. Dysmorphic RBCs were seen in the urine sediment and proteinuria at 1.2g/g. Given concern for anti-GBM, she received 1g of methylprednisolone and plasma exchange. ANA 1:1280 with MPO-ANCA levels >8.0 U, along with positive anti-histone and SCL-70 antibodies, but with negative anti-GBM and ds-DNA. Kidney biopsy showed pauci-immune crescentic GN with trace staining for IgA, IgM, C3, kappa and lambda. As she had been on HZ, the diagnosis of HZ-induced ANCA-associated vasculitis was made. Offending agent was held and cyclophosphamide was started. After 2 months, kidney function returned to baseline, with resolution of proteinuria and hematuria.

Discussion: In patients with HAV, unusually high titers of MPO are present and can be used to differentiate drug-associated and spontaneous cases. A minority of patients can also present with other positive antibodies, such as ds-DNA, anti-histone, or Scl-70. As HZ can also cause SLE-like pattern of injury, it can be difficult to obtain a diagnosis based on serologies alone; biopsy is essential for diagnosis and prognosis. The treatment of HAV involves not only removing the inciting agent, but also further immunosuppression, as HZ is thought to lead to increased expression of MPO and PR3 breaking neutrophils tolerance and leading to auto-antibody formation. When choosing a treatment strategy, guidelines for spontaneous ANCA should be followed; in this particular case, as she had severe lung involvement, cyclophosphamide was chosen.

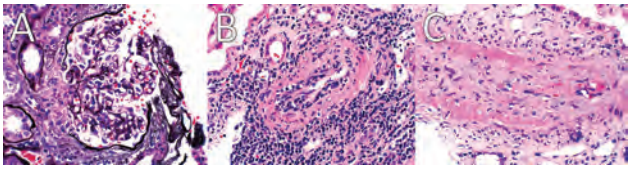
Isolated ANCA Renal Arteritis

Ishan Shah,[1] Nidia C. Messias,[2] Muhammad A. Siddiqui,[1] Sara Combs,[1] J Pedro Teixeira.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Vasculitis associated with antineutrophil cytoplasmic antibodies (ANCA) usually causes acute kidney injury (AKI) through crescentic glomerulonephritis (GN). Renal ANCA arteritis without GN is often accompanied by prominent interstitial nephritis (IN). We present a case of AKI due to ANCA renal arteritis without significant GN or IN.

Case Description: An 84-year-old woman with hypertension, chronic kidney disease [baseline creatinine (Cr) 1.6 mg/dL], and prior right nephrectomy for renal cell carcinoma presented with nausea and anorexia. She was admitted the prior month for pyelonephritis and AKI and discharged to a rehab facility. On return, her serum Cr was 4.9. She was readmitted and started on hemodialysis. Urine microscopy was consistent with acute tubular injury (ATI), but also showed non-glomerular hematuria which persisted on several UAs. Urine protein was 2.1 g/g Cr. Both p-ANCA (1:1280) and MPO (>8 AI) were strongly positive. She was given IV corticosteroids and renal biopsy was obtained [Figure]. She was evaluated by rheumatology and felt to have renal-limited disease. She was treated with plasma exchange followed by rituximab, but a week later she opted to stop dialysis and transition to comfort measures and she died 2 days later.

Discussion: Most patients with AKI from ANCA-associated vasculitis will have GN, often crescentic. Extraglomerular features on biopsy of ANCA disease are common and include IN and arteritis/arteriolitis, but often parallel the activity of glomerular disease. Prior case reports of ANCA renal disease without GN have featured prominent IN with or without arteritis/arteriolitis. This case of marked necrotizing arteritis, minimal IN, and absent GN represents a rare phenotype of ANCA renal disease.



Biopsy yielded 31 glomeruli; 7 were globally sclerotic and the rest were without crescents, necrosis, or endocapillary hypercellularity (panel A, silver stain, 400x). IF was negative. Diffuse ATI was seen, with moderate (35%) interstitial fibrosis and mild patchy mononuclear inflammation limited largely to areas of fibrosis. Multiple arteries and few arterioles exhibited fibrinoid necrosis, including focal areas of transmural necrosis and circumferential arteritis (panels B & C, H&E, 400x).

PO1955

Rare Case of Silicosis-Induced Pauci-Immune Glomerulonephritis

Sandheep Venkataraman, Matthew Ray, James F. Dylewski. *University of Colorado, Denver, CO.*

Introduction: Pauci-immune glomerulonephritis(GN) caused by ANCA was first described in 1982. Most cases are idiopathic, however, ANCA vasculitis may induced due to certain exposures. Here we report a case of ANCA vasculitis associated with pulmonary silicosis.

Case Description: A 37-year-old man with no prior history presented with anorexia, weight loss, fatigue, and arthralgias for 6 months. He was employed as a sandblaster, stonecutter, and as a mason. On initial exam he was found to have dactylitis and Raynaud's phenomenon. His presenting creatinine(Cr) was 2.9 mg/dL with urinalysis showing 3+ blood and 1.2 gm proteinuria. Renal ultrasound demonstrated enlarged kidneys bilaterally. Notable serologies were ANA positive 1:1280, p-ANCA positive 1:2560, C3 77 mg/dL, C4 6 mg/dL, and MPO at 78 AU/ml. CT Chest revealed innumerable pulmonary nodules, extensive fibrosis, and mediastinal lymph nodes with eggshell calcifications. Infectious workup was negative. Transbronchial biopsy demonstrated collection of histiocytes containing black pigment without granulomas. Kidney biopsy showed necrotizing crescentic GN, with marked interstitial inflammation and focal intralobular vessel infiltrates. IF and EM was negative, consistent with pauci-immune ANCA vasculitis. Given his history and presentation, he was diagnosed with silica-induced ANCA vasculitis. He was treated with 3 days of IV methylprednisolone, followed by a rapid prednisone taper. He also received IV Rituximab 1 gm on days 0 and 14, plus IV cyclophosphamide 500 mg every 2 weeks for 6 doses starting on day 0. The patient responded well with Cr improving to 1.0 and decreased proteinuria. Unfortunately he relapsed 3 months after last rituximab dose.

Discussion: Silica exposure is most often associated with pulmonary disease but there have been case reports of RPGN associated with it too. The majority of these patients were MPO positive. T-cell dysregulation and endothelial damage from PMNL free radical generation is a proposed mechanism for this disease. Duration and intensity of silica exposure are known risk factors. In addition to pulmonary-renal symptoms, these patients may have systemic manifestations of lupus, rheumatoid arthritis, scleroderma, or dermatomyositis. More research is needed to further understand the management of these patients. This patient represents a rare case of silica-induced ANCA pulmonary-renal vasculitis.

PO1956

ANCA-Negative Small-Vessel Vasculitis with IgG4-Positive Plasma Cell Infiltration: A Case Report and Literature Review

Huipeng Ge, Cuifang Li, Qiongjing Yuan. *Xiangya Hospital Central South University, Changsha, China.*

Introduction: Although the histopathology was critically important for differential diagnosis between AAV and IgG4-RD, overlapping morphologies and clinical manifestations put the clinicians in a dilemma of diagnosis sometimes. Here, we described a case of ANCA negative PICG with IgG4-positive plasma cell infiltration.

Case Description: A 60-year-old male patient presented with cough for 3 months and progressive renal impairment for 8 days. He had elevated serum IgG4 level with absence of anti-neutrophil cytoplasmic antibodies (ANCA). Lung CT as shown in Figure 1. Renal biopsy showed severe tubulointerstitial nephritis (TIN) with extensive infiltration of IgG4-positive plasma cells, suggesting a diagnosis of IgG4-related kidney disease(Figure 2). However, the identification of necrotizing glomeruloneohritis and crescents forming and the absence of storiform fibrosis and obliterative phlebitis led to a diagnosis of ANCA negative renal small-vessel vasculitis. The condition was improved by using corticosteroids and cyclophosphamide at beginning.

Discussion: ANCA negative cannot exclude the diagnosis of AAV. The elevated serum IgG4 and/or abundant IgG4-positive cell infiltration can act as one of the manifestations in AAV. ANCA-negative pauci-immune crescentic glomerulonephritis (PICG) might represent an independent disease entity from ANCA positive PICG. Besides, IgG4-related disease (IgG4-RD) is an exclusive diagnosis and needs to be differentiated from vasculitis and other diseases. It is suggested that ANCA-negative PICG with elevated serum IgG4 and/or abundant IgG4-positive cell need to be further studied.

PO1957

Adalimumab-Associated Pauci-Immune Glomerulonephritis: Coincidence or Causation Effect?

Nirav N. Patel, Emma Spangler, Pavan Annamaraju. *Johnston Memorial Hospital, Abingdon, VA.*

Introduction: Adalimumab is a TNF-blocker used in the treatment of hidradenitis suppurutiva (HS). Infections, lupus-like syndrome, and lymphoma are known safety concerns with TNF-blockers. We report a rare case of adalimumab associated pauci-immune crescentric GN (PICGN) in a patient with HS.

Case Description: A 19-yr-old male with a history of HS on adalimumab for 6 months was seen on 4/1/20 with a fever of 103°F, cough & epistaxis for 2 weeks. CT sinuses showed polyps and sinusitis. He was treated with antibiotics for sinusitis. CT chest, nasal PCR for COVID-19, blood, and urine cultures were negative. By hospital day 8, he remained febrile and developed AKI [Creatinine (Cr)1.9 mg/dl; baseline of 0.8 mg/dl]. Physical exam showed chronic scarred skin lesions on the chest and axilla with no signs of infection or rash. Hematuria and microalbuminuria were noted. Ultrasound showed renomegaly. Inflammatory markers were high (CRP 254 mg/L, Ferritin 1059 ng/mL). PR3-ANCA antibody was positive 530 IU/mL. A renal biopsy confirmed PICGN (Fig 1). Bone marrow biopsy showed no evidence of hemophagocytosis. The patient was treated with pulse doses of steroids and rituximab and plasma exchange (peak cr 6.4 mg/dl). On a 3-week follow up creatinine improved to 1.8 mg/dl suggesting a favorable outcome. The patient never required dialysis.

Discussion: AKI, microscopic hematuria, and proteinuria can be seen in a febrile illness. However, epistaxis and renomegaly prompted us to check for ANCA serology. To our knowledge, this is the first case of adalimumab associated PICGN in a patient with HS. Interestingly, our patient is much younger compared to previously reported cases (mean 51.4 years). It is possible that adalimumab may be unrelated to the vasculitis; however, due to a strong temporal association, it was felt to be the culprit agent. Nephrologists must be aware of the renal side effects of this class of drugs.

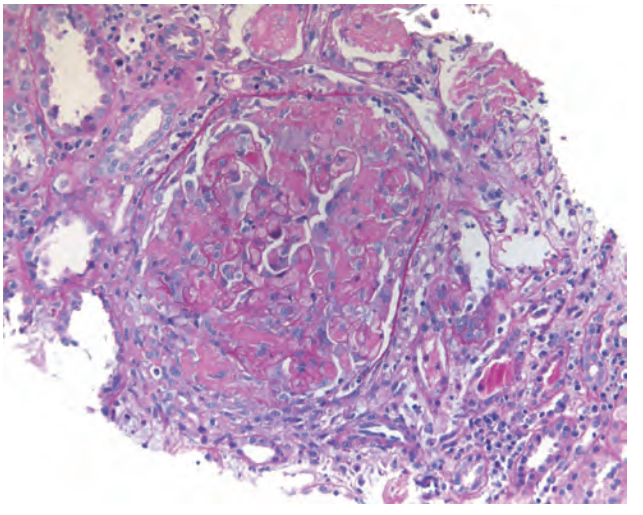

Fig 1. Necrotizing Crescent

PO1958

A Case of C-ANCA Associated Retroperitoneal Fibrosis and Periaortitis

Vinay Srinivasa. Darling Downs Health Service, QLD Australia *Darling Downs Hospital and Health Service, Toowoomba, QLD, Australia.*

Introduction: Granulomatosis with Polyangitis (GPA) is a type of small vessel vasculits that has prevalence rate of 25-160 cases per million population, and a incidental rate of 0.4 cases per 100,000 population per year. Clinical features of the disease invlove the respiratory and renal systems. However, large vessels such as the Aorta and retroperitoneal tissue are rarely involved.

Case Description: We present the case of a middle-aged male who presented with an obstructive nephropathy in which abdominal CT revealed a soft tissue mass encompassing the Aorta and Inferior Vena Cava causing obstruction of the Left ureter. Despite ureteric stenting, serum creatinine failed to improve. Furthermore urinanalysis demonstated an active urinary sediment; hemproteinuria. Serum c-ANCA and PR-3 antigen titres were positive. Renal biopsy was performed and confirmed pauci-immune vasculitis. Our patient was induced with pulsed intravenous methylprednisolone and cyclophosphamide and as part of his maintainence treatment received prednisolone and oral cyclophosphamide. On follow up, partial remission has been achieved with his serum creatinine returning to baseline level and proteinuria reduced, though erythrocytes are still evident. Repeat abdominal imaging has revealed a reduction in the size of the soft tissue mass with treatment.

Discussion: Biopsy proven vasculitis has been shown in patients with retroperitoneal fibrosis. Few case reports and series have described this association, inferring a pathogenic role of ANCA in the development of retroperitoneal fibrosis. Moreover it has been suggested that retro peritoneal fibrosis may be an early clinical manifestation of ANCA associated vasculitis. Consequently, ANCA associated vasculitis should be considered in the differential diagnosis of any patient who has Retroperitoneal fibrosis and an active urinary sediment

PO1959

A Rare Case of ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis in an Elderly Woman

Oscar A. Garcia Valencia, Eduardo Edelman Saul, Yanetsy Olivera Arencibia, Marie A. Sosa. *University of Miami /Jackson Memorial Hospital, Miami, FL.*

Introduction: Acute kidney injury is usually multifactorial with a broad differential diagnosis. Of those, rapidly progressive glomerulonephritis (RPGN) requires special attention as it represents a true diagnostic and therapeutic emergency that can lead to irreversible kidney failure.

Case Description: A 92-year-old female with a history of Chronic Kidney Disease Stage III, Diabetes Mellitus type II, hypertension, and recurrent deep vein thrombosis sent to the ER for evaluation of rapidly worsening kidney function found on outpatient laboratories for assessment of poor oral intake and fatigue for 2 weeks. On arrival, BP was 133/49mmHg, HR 70bpm, temperature 36.9°C, RR 17 rpm and SO2 of 99%. Mental status was at baseline and physical exam was unremarkable. Laboratory data were remarkable for serum creatinine of 10.55 mg/dl from baseline of 1.8 mg/dl, potassium level of 6 mEq/L and bicarbonate of 17 mEq/L. Urinalysis showed proteinuria (30+), hematuria (344 RBCs/hpf) and leukocyturia (68 WBC/hpf). Urine protein creatinine ratio of 2.4. No acute EKG changes. Renal ultrasound demonstrated increased bilateral echogenicity; otherwise unremarkable. Patient initially treated medically with no improvement requiring hemodialysis. Work up sent with ANCA panel, Anti-GBM, Serum protein electrophoresis, immunofixation, Free Light Chains, complement and Hepatitis panel all negative. Acutely worsening kidney function coupled with active sediment and proteinuria prompted a kidney biopsy which demonstrated pauci-immune crescentic GN. She was started on Methylprednisolone 500mg IV daily for 3 days, followed by prednisone 60mg qd and plasmapheresis every-other-day.

Discussion: PICG is a potentially life-threatening condition leading to renal failure within days or weeks and represents up to 80% of RPGN. The majority of cases (~90%) are ANCA positive and occur in younger patients. Here we present the clinical profile of a rare new diagnosis of ANCA negative PICG in an elderly lady. Renal damage is more severe and kidney survival poorer when compared to ANCA positive crescentic GN. Our patient received RRT throughout hospital stay showing signs of recovery on second week. She was discharged on oral Prednisone 30mg qd and Cyclophosphamide 50mg qd with close follow up.

PO1960

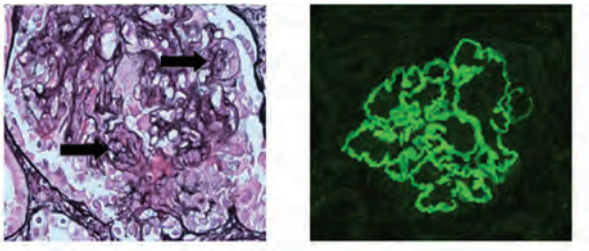
Anti-Glomerular Basement Membrane (GBM) Disease with Atypical Clinical and Histologic Features Precipitated by Parainfluenza

Fergal Fouhy, Louise M. Burke, Nick Mayer, Michelle M. O'Shaughnessy. *Cork University Hosptial, Cork, Ireland.*

Introduction: Anti-GBM disease typically presents with rapidly progressive glomerulonephritis (RPGN) and linear GBM staining for IgG1 or IgG3. We describe a case of anti-GBM disease with an initially indolent course that progressed to RPGN following parainfluenza infection. Serum anti-GBM antibodies were only mildly elevated and kidney biopsy showed linear GBM staining for IgG4.

Case Description: An otherwise healthy 23-year old male presented with a 2-week history of cough, dyspnea, and hemoptysis. He recently returned from China, where he smoked tobacco heavily. Hematuria and proteinuria were noted during a routine medical exam 2 months prior. Physical exam notable for BP 150/90mmHg, bibasilar chest crackles, and bipedal edema. Investigations: sCr 2.6mg/dL (1.5mg/dL 2 weeks prior); 3+blood and 3+protein by UA; negative/normal C3, C4, ANA, anti-dsDNA, ANCA; viral respiratory PCR positive for parainfluenza; serum anti-GBM 15u/ml (nl <10u/ml). CT Thorax showed bilateral pleural effusions and groundglass nodularity within the right middle and lower lobes. Kidney biopsy showed linear GBM staining for IgG4, wtih glomerular necrosis, crescents, and unusually prominent endocapillary proliferation (Figure). Treatment included diuretics, antibiotics, IV methylprednisolone, oral cyclophosphamide, and 8 plasma exchanges over 11 days. Serum anti-GBM was undetectable after 2 days. He progressed to dialysis-requiring ESRD over the next 6 weeks: a repeat kidney biopsy showed peristent crescentic GN with endocapillary proliferation and strong linear IgG4 staining, despite repeatedly negative serum anti-GBM.

Discussion: This case highlights complexities in the pathogenesis and diagnosis of anti-GBM disease. RPGN was likely triggered by parainfluenza infection, a rarely described association. Low anti-GBM antibody levels were likely explained by the poor sensitivity of ELISA to detect IgG4. Finally, prominent endocapillary proliferation is characteristic of "atypical anti-GBM disease", yet serum anti-GBM was positive in this case.



Left: Light microscopy (methenamine silver stain) showing areas of endocapillary proliferation (arrows). Right: IF microscopy showing linear IgG4 deposition along the GBM.

PO1961

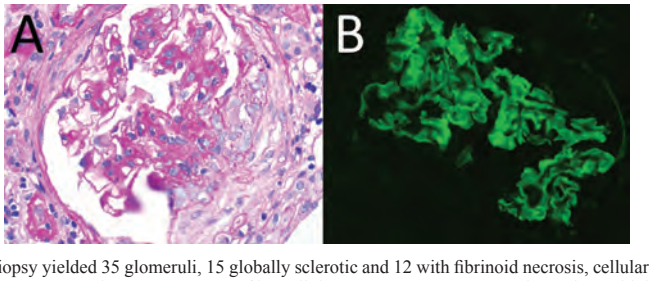
Seronegative Anti-GBM: A Spectrum of Disease

Alisa Illescas,[1] Michael B. Kuperman,[2] Sara Combs,[1] J Pedro Teixeira.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Glomerulonephritis (GN) due to anti-GBM disease is usually associated with detectable antibodies against the NC1 domain of the type IV collagen alpha-3 chain [NC1-α3(IV)], but a subset of seronegative atypical disease has been described with no lung involvement, non-crescentic GN on biopsy, and indolent course. We present a case of anti-GBM disease that is neither typical nor atypical.

Case Description: A 56-year-old woman with hypertension and obesity underwent renal biopsy after routine labs showed rise in creatinine (Cr) above baseline of 1.5 mg/dL 6 months prior and hemoproteinuria on UA. The results [Figure] prompted transfer to our center. On admit, she noted mild chronic dyspnea but denied cough or hemoptysis. She had mild hypertension (146/80) and trace edema. Cr had risen to 4.5, urine protein was 3.4 g/g Cr, and chest x-ray was clear. She was started on IV corticosteroids and plasma exchange (PLEX). Anti-GBM IgG [multiplex bead assay, ARUP], drawn prior to PLEX, was negative (4 AU/mL, upper limit normal 19). She was treated with IV cyclophosphamide and 7 PLEX sessions over 2 weeks and her Cr stabilized at 3.5. She avoided dialysis and was discharged on prednisone with plans to continue monthly cyclophosphamide.

Discussion: Our patient exhibited an intermediate phenotype of anti-GBM disease with crescentic GN, subacute Cr rise, no lung involvement, and negative serology. Modern assays for anti-GBM antibody have a sensitivity of 94-100%. However, negative serology is also seen in rare cases of anti-GBM GN due to antibodies against epitopes of the GBM other than NC1-α3(IV). Our case illustrates that a negative anti-GBM antibody does not exclude anti-GBM disease which is ultimately a pathologic diagnosis. It also suggests a spectrum exists between classic and atypical anti-GBM disease, but favorable outcome is possible regardless with biopsy-directed therapy.



Biopsy yielded 35 glomeruli, 15 globally sclerotic and 12 with fibrinoid necrosis, cellular crescents (panel A, PAS, 600x), or fibrocellular crescents. RBC casts and 50% interstitial fibrosis were seen. IF showed linear GBM staining with λ (3+), IgG1 (3+), and IgG4 (3+, panel B, 400x).

PO1962

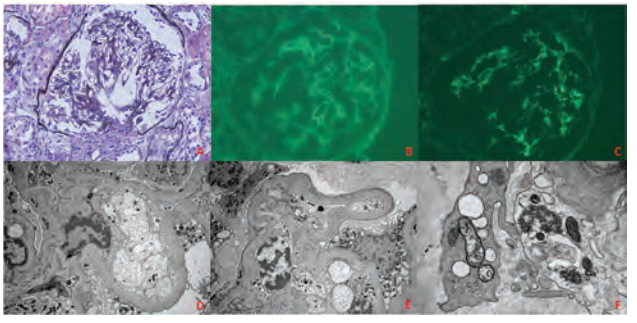
A Case of Lupus Podocytopathy (LP) with Focal Segmental Glomerulosclerosis (FSGS): Is It Time to Add LP to the Next Revision of the Classification of Lupus Nephritis?

Hasan Zahid, Jeremy Carlson, Muhammad usama shah Hamdani, Chintan V. Shah. *University of Florida Health, Gainesville, FL.*

Introduction: Lupus podocytopathy is not included in the commonly used International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification of Lupus Nephritis (LN). It has been reported in literature for the last 20 years. LP can have pathologic transition with variable outcomes. We describe a case of LP with FSGS in a young male patient with subsequent relapse.

Case Description: 25 year old male with past history of lupus without nephritis and chronic immune mediated thrombocytopenia presented with generalized fatigue. Physical exam revealed diffuse rash and vital signs were within normal limits. Relevant laboratory findings included platelet count of 21000/microliter, acute kidney injury with creatinine (Cr) of 1.6 mg/dl (baseline Cr of 0.8 to 1.1 mg/dl), spot urine protein creatinine ratio of 4.3 g, 24 hour urine protein of 4.1 g, low C3 and C4, hemoglobin of 9.6 g/dl and WBC count of 3.6/microliter. Serology was positive for ANA, dsDNA and SSA indicating active lupus flare. Left kidney biopsy showed mild mesangial expansion, no endocapillary proliferation and subtotal (>80%) podocyte foot process effacement. No subendothelial or subepithelial deposits were seen. He was treated with pulse dose steroids followed by oral steroids and serum Cr came back to baseline. Subsequently he was treated with mycophenolate mofetil 2 g/day. At 2 weeks, proteinuria came down to 1.8 g/day and by 12 weeks he achieved remission. However at 6 months, he had urine protein of 8.8 g in 24 hours with increase in Cr to 2.4 from 1.6, suggesting relapse.

Discussion: The presence of minimal or no capillary wall immune deposits with or without mesangial proliferation and effacement of podocyte foot processes in the setting of nephrotic range proteinuria is collectively termed as LP. LP must be considered in patients with lupus presenting with NS (Nephrotic Syndrome). It is cardinal that we consider adding this distinct entity in the classification of lupus nephritis.



PO1963

Minimal Change Disease in Systemic Lupus Erythematosus: An Infrequent Variant

Ehsun Naeem, Paul S. Kellerman, Saima Mansuri. *Beaumont Health, Royal Oak, MI.*

Introduction: Lupus Nephritis (LN) is thought to complicate the disease course of almost half of all patients diagnosed with Systemic Lupus Erythematosus (SLE). While nephrotic syndrome (NS) in these patients is usually due to type IV/V Lupus Nephritis (LN), it may in rare instances occur secondary to minimal change disease (MCD), a phenomenon known as Lupus Podocytopathy (LP). We report a case of a young female with LP with concomitant Acute Tubular Necrosis (ATN)

Case Description: 40 year old female, known case of SLE (not on maintenance immunosuppression) and Hypertension presented with bright red blood per rectum and dyspnea for 2 weeks. Review of systems was pertinent for generalized swelling and facial rash. On initial assessment, she was hypertensive and physical exam revealed facial swelling, discoid rashes and 2+ lower Extremity edema bilaterally. Workup revealed Normocytic Anemia, Acute Kidney injury, Hyperkalemia and Metabolic Acidosis. Urine studies showed nephrotic-range proteinuria and hematuria but were negative for casts. Free K/L ratio was high at 2.32 and C3 levels low at 42 mg/dL. Ultrasound guided kidney biopsy showed mild thickening of GBM and dilated tubules with diminished brush borders in the absence of crescentic changes. Electron Microscopy noted diffuse fusion of foot processes, along with rare intramembranous deposits. Immunofluorescence revealed a full house staining pattern within the Mesangium and the patient was diagnosed with Lupus Podocytopathy with concurrent LN Type I. Substantial reduction in proteinuria was noted with a brief course of Prednisone

Discussion: Our patient with SLE presented with NS and AKI, features typical of membranous/proliferative LN. Interestingly, her biopsy findings provided little evidence of endocapillary proliferation or sub-epithelial IC deposits and were more consistent with MCD, suggestive of Lupus podocytopathy. LP is rare to the extent that it does not form part of the official WHO classification for LN and has only been described a handful of times in prior literature, mostly in the form of case reports. However, given its prognostic implications, LP remains an important consideration in the evaluation of NS in SLE patients. While patients with Type IV/V LN require aggressive immunosuppressive therapy, patients with LP frequently respond well to steroids alone and have a much slower progression of disease

PO1964

Olinciguat Protects Renal Function and Podocytes in In Vivo and In Vitro Models of Podocytopathies

Emmanuel S. Buys,[1] Ehtesham Arif,[2] Suzana Marusic,[3] Deepak Nihalani.[2] *[1]Cyclerion, Cambridge, MA; [2]Medical University of South Carolina, Charleston, SC; [3]Hooke Laboratories, Lawrence, MA.*

Background: The nitric oxide (NO) receptor soluble guanylate cyclase (sGC) is a signal-transduction enzyme producing the secondary messenger cGMP. Impaired NO-sGC-cGMP signaling is associated with renal dysfunction. sGC stimulators, small molecules that enhance NO-mediated cGMP signaling, improve renal function in animal models of cardiorenal injury.

Methods: We studied the reno-protective effects of olinciguat, a clinical-stage sGC stimulator, by studying *in vitro* and *in vivo* models of glomerular injury.

Results: In an acute focal segmental glomerulosclerosis (FSGS) model of glomerular injury induced by nephrotoxic serum (NTS), treatment with olinciguat attenuated proteinuria and kidney pathology when compared to vehicle-treated mice. Additionally, olinciguat treatment prevented NTS-induced mislocalization of the slit diaphragm proteins synaptopodin and nephrin. Ultrastructural analysis by transmission electron microscopy revealed that podocyte foot process morphology was preserved in mice treated with olinciguat. To further assess the protective effect of sGC stimulation on podocytes, human podocytes injured by exposure to protamine-sulfate (PS) were treated with olinciguat. Olinciguat treatment restored PS-induced damage of podocyte actin cytoskeleton organization and the localization of podocyte cell membrane proteins. In the genetic MRL/MpJ-Fas^{lpr}/J mouse model of systemic lupus erythematosus (SLE), disease progression, assessed by increased proteinuria, was less pronounced in mice treated with the positive control cyclophosphamide or with olinciguat than in vehicle-treated mice. Fewer kidney lesions (interstitial infiltrates, tubular atrophy, tubular epithelium vacuolation, tubular and interstitial lesions, and glomerular lesions) were observed in mice treated with cyclophosphamide or olinciguat than in vehicle-treated mice. In contrast to cyclophosphamide, olinciguat treatment did not result in leukopenia, reduction in spleen weight, or lower anti-dsDNA antibody in serum, suggesting that olinciguat did not impact the auto-immune aspect of SLE.

Conclusions: In summary, olinciguat, an orally bioavailable sGC stimulator, exhibits significant reno-protective effects in nonclinical models and warrants further evaluation for the treatment of FSGS, other podocytopathies, or nephropathies associated with diseases such as sickle cell disease.

Urinary Rac1, a Novel Predictive Biomarker, Is Elevated in FSGS and Diabetic Nephropathy Patients and Reduced by TRPC5 Inhibition with GFB-887 in a Rat FSGS Model

Yossi Dagon, Hari Raghu, Tingting Ge, Liron Walsh, John F. Reilly. *Goldfinch Bio Inc, Cambridge, MA.*

Background: Activation of Ras-related C3 botulinum toxin substrate 1 (Rac1) plays a key role in podocyte injury and dysfunction in focal segmental glomerular sclerosis (FSGS) and diabetic nephropathy (DN). In diseased podocytes, Rac1 activation is mediated by calcium influx through the transient receptor potential canonical 5 (TRPC5) ion channel. GFB-887 is a sub-type selective, small molecule inhibitor of TRPC5 that reduces albuminuria in deoxycorticosterone acetate (DOCA)-salt and ZDSD rat models of FSGS and DN, respectively. Here, we aimed to develop a urinary biomarker to assess podocyte Rac1 activity in kidney disease and in response to GFB-887 treatment.

Methods: Using a sandwich ELISA, we measured Rac1 concentrations in supernatants from cultured human iPSC-derived podocytes, in urine from DOCA-salt rats following treatment with GFB-887, and in urine from healthy volunteers, FSGS, DN and Alport patients.

Results: Rac1 was detected in extracellular vesicles (EV) isolated from podocyte culture supernatant and rat and human urine. GFB-887 treatment lowered urinary Rac1 concentrations in normal and DOCA-salt rats, and the decreased Rac1 was associated with decreased albuminuria in the DOCA-salt rats. Urinary Rac1 concentrations were markedly elevated in FSGS and DN but not in Alport patients.

Conclusions: The TRPC5 inhibitor, GFB-887, targets the TRPC5-Rac1 pathway and suppresses urinary Rac1 associated with its therapeutic action in a rat model of FSGS. Urinary Rac1 concentrations are markedly higher in FSGS and DN compared to healthy subjects, but not elevated in Alport. GFB-887 is efficacious in rodent models of FSGS and DN, but not of Alport, suggesting that elevated urinary Rac1 is predictive of response. Together, these data support the potential for clinical utilization of urinary Rac1 as a pharmacodynamic and predictive biomarker for GFB-887 treatment in FSGS and DN. GFB-887 is currently being studied in TRACTION™, a Phase 2 clinical trial in FSGS and DN in which baseline and on-treatment urinary Rac1 measurements will support further development of the biomarker.

A Novel In Vivo Approach to Capture the Podocyte Foot Process Proteome

Lori L. O'Brien, Gary F. Gerlach. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Podocytes are an extraordinary cell of the kidney filtration system with their tentacle-like foot processes flowing out from each cell body and interdigitating with neighboring processes. Proper kidney function relies on these cells and the complex architecture created by the interdigitating processes. They are the most critical component of the glomerular filter. Podocytes are injured and their integrity is compromised in the majority of kidney diseases leading to progressive proteinuria. However, we know little about the full complement of proteins localized to the foot process and how they change with disease.

Methods: We have developed a novel genetic mouse model capable of generating a spatially restricted, real-time, in vivo proteome. Recently, proximity labeling techniques have been developed to provide snapshots of spatially localized proteomes. The BioID method utilizes a promiscuous bacterial biotin ligase flexibly linked to a target protein of interest to biotinylate proteins within the vicinity. We have adapted this approach to identify the podocyte foot process proteome. Using podocin as a handle, we have modified the *Nphs2* (podocin) locus to link the mutated, promiscuous BirA biotin ligase to podocin (*Nphs2*^{BioID}). A flexible, 13x linker allows for a generous proximity around podocin, thereby capturing the broad proteome of the podocyte foot process.

Results: We have obtained viable *Nphs2*$^{BioID/+}$ animals. Utilizing immunstaining, we have confirmed the proper expression and localization of the podocin-BioID. The HA-tagged BirA ligase appended to podocin colocalized with podocin and other foot process proteins. To test it's functionally, we injected biotin dialy for 7 days. This produced an increase of biotinylated proteins in *Nphs2*$^{BioID/+}$ podocytes versus wild type biotin injected controls or uninjected *Nphs2*$^{BioID/+}$ mice. We have affinity purified the biotinylated proteins from glomerular isolations and are currently performing proteomic analyses.

Conclusions: We have generated the first of it's kind in vivo mouse model to specifically identify the spatially localized proteome of the podocyte foot process. Our proteomics results will provide unprecedented insights into the make-up of this highly specialized and critical structure.

Soluble RARRES1 Induces Apoptosis of Podocytes to Promote Progression of Kidney Disease

Anqun Chen,[1,2] Ye Feng,[2] Yu Li,[1] Chengguo Wei,[2] Tianjun Guan,[1] Kyung Lee,[2] John C. He.[2] *[1]Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China; [2]Division of Nephrology, Department of Medicine, Icahn School of Medicine at Mount Sinai, NY, NY.*

Background: Podocyte loss is a major event leading to the progression of focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). Here, we found that retinoic acid receptor responder protein 1 (RARRES1) contributes to the podocyte loss in FSGS and DN.

Methods: We determined the role of RARRES1 in human and mouse with FSGS and DN. We investigated the mechanisms of RARRES1 in cultured human podocytes.

Results: The expression of RARRES1 increased in the glomeruli of patients with FSGS and DN and correlated with the eGFR. Single-cell RNA-sequencing of the kidney showed that RARRES1 expressed highly in podocytes. Immunostaining confirmed that podocyte expression of RARRES1 increased in patients with DN and FSGS as compared to MCD. RARRES1 expression was strongly induced by TNF-α in cultured human podocytes. RNA-sequencing of podocytes with RARRES1 overexpression revealed genes enriched in apoptosis. RARRES1 was cleaved into a soluble RARRES1 and the cleavage site was mapped at the aa70. Overexpression of wild RARRES1 or adding soluble RARRES1 in cultured human podocytes induced apoptosis, while overexpression of RARRES1 cleavage mutant lost the apoptotic effect. Further, we showed that soluble RARRES1 underwent endocytosis to interact with intracellular RIOK1, leading to the activation of p53 and apoptosis in podocytes. In vivo, podocyte-specific overexpression of RARRES1 resulted in marked glomerular injury and albuminuria in mice, while the overexpression of RARRES1 cleavage mutant had no renal phenotype. Finally, knockdown of RARRES1 in podocytes ameliorated kidney injury in mice with adriamycin-induced nephropathy.

Conclusions: we demonstrate a new role and mechanism of RARRES1 in regulation of podocyte apoptosis in glomerular disease, as summarized in the Figure: TNFα induces expression of RARRES1, which is cleaved, then undergoes endocytosis to interact with intracellular RIOK1, leading to the activation of p53 and apoptosis. High RARRES1 expression promotes the progression of FSGS and DKD.

The Glomerulus-on-a-Chip as a System to Unravel Novel Membrane Attack Complex (MAC)-Independent Role of Complement in Membranous Nephropathy

Stefano Da Sacco,[1] Astgik Petrosyan,[1] Susan Hartzell,[4] Valentina Villani,[1] Charmi Dedhia,[1] Andrea Angeletti,[3] Joaquin Manrique,[2] Roger E. De Filippo,[1] Laura Perin,[1] Paolo Cravedi.[4] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Complejo Hospitalario de Navarra, Pamplona, Spain; [3]Universita di Bologna, Bologna, Italy; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide due to the deposition of anti-podocyte-antibodies against in the glomerular subepithelial space. While complement deposition is thought to play a crucial pathogenic role, the exact effector mechanism of complement in MN is unclear due to the lack of in vitro and in vivo systems that recapitulate human disease. We have developed a novel glomerulus-on-a-chip system (GOAC) using human primary podocytes and human glomerular endothelial cells (GEC) in combination with OrganoPlates and assessed the functional response to human MN serum and the role of MAC deposition and C3a/C3aR1 signaling in MN pathogenesis.

Methods: Glomerular chips were cultured with serum from anti-PLA2R+ MN patients or healthy individuals. Functional response was assessed by albumin permeability assay to evaluate selective-permeability. Role of MAC and C3a/C3aR1 signaling pathway in glomerular filtration barrier damage was assessed by immunofluorescence and functional analysis while mechanisms of action were explored by PCR arrays, Western Blotting and immunostaining. Results were confirmed in vitro using podocytes on which C3aR1 was silenced and in vivo using a C3aR1 KO mice model.

Results: Following exposure to sera from MN patients, we have confirmed deposition of human IgG on podocytes and formation of MAC complex, accompanied by albumin leakage. GOAC supplemented with C3aR1 antagonists as well as GOAC using podocytes in which C3aR1 was silenced were able to prevent glomerular filtration damage on the GOAC as confirmed by rescue of permselectivity efficiency, while inhibition of MAC formation by protein S (an inhibitor of MAC formation) did not significantly reduce GOAC permeability.

Conclusions: We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying renal regenerative and disease mechanisms in proteinuric diseases. Using this model, w showed that C3a/C3aR signaling plays a dominant role in complement-mediated MN pathogenesis.

Dach1 Is Essential for Maintaining Normal Podocytes

Keiko Tanaka, Taiji Matsusaka. *Department of Basic Medicine, Tokai University School of Medicine, Isehara, Japan.*

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We, therefore, aimed to elucidate the function of Dach1 in normal podocytes *in vivo.*

Methods: Podocyte-specific *Dach1*-knockout (KO) mice were generated by mating *Dach1*-flox mice with *Nphs1*-Cre or *Nphs2*-CreERT2 mice. Podocyte injury was evaluated by urinalysis (SDS-PAGE) and histology. In addition, we analyzed primary cultured podocytes of Dach1 overexpressing knock-in transgenic (KI) mice (n=9), in which Dach1 is expressed under the control of Rosa26 promoter.

Results: Although the efficiency of Cre-mediated recombination was not high, all of the congenital *Dach1*-KO mice (n=20, more than 4 weeks old) presented abnormal albuminuria. Seven out of the 11 (63%) mice histologically analyzed showed focal segmental glomerulosclerosis. Injured podocytes lacked Dach1 staining, whereas intact podocytes retained Dach1. When Dach1 KO was induced in adult mice, the mice showed abnormal albuminuria within two weeks. Immunostaining revealed that podocytes lacking Dach1 causes leakage of albumin, while retaining WT1 protein. Since endogenous Dach1

expression in podocytes is very high compared with transgenic expression of Dach1 driven by the Rosa26 promoter, we analyzed primary cultured podocytes, in which endogenous Dach1 was downregulated. *Dach1* mRNA was 3.8-fold higher (p=0.0007) in *Dach1*-KI podocytes than in control podocytes. We previously found that *Dpp4* is one of the candidate target genes of Dach1 by knockdown experiments. *Dpp4* mRNA in *Dach1*-KI podocytes was found to be increased (1.5-fold, p=0.0022).

Conclusions: These results indicate that Dach1 is important in maintaining normal podocyte integrity, and *Dach1* gene deficiency induces podocyte injury.

PO1970

Dysregulated Dynein-Mediated Vesicle Trafficking Is a New Mechanism of FSGS

Hua Sun,[1,2] Martin R. Pollak.[1,3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Boston Children's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: Focal segmental glomerulosclerosis (FSGS) is a deteriorating kidney disease with poor prognosis. The lack of understanding of its mechanism has hindered the development of treatment. Mutations in INF2 cause FSGS characterized by a podocytopathy with mistrafficked slit diaphragm (SD) protein critical for the integrity of the glomerular filtration barrier (GFB). This feature has been found in FSGS of other etiologies, making INF2 related podocytopathy a good model to dissect the disturbed vesicle trafficking in podocytopathies prone to FSGS. By yeast two hybridization screening we identified the interaction of INF2 with Dynll1, a dynein component. We hypothesize that INF2 regulates dynein mediated vesicle trafficking, which shuttles endocytosed protein to proteolytic system. This interaction could be disrupted by pathogenic mutations in INF2, suggesting dysregulation of dynein mediated trafficking is an underlying mechanism of the disease.

Methods: The INF2-Dynll1 interaction was confirmed by yeast mating and CO-IP. The dysregulated dynein mediated trafficking of nephrin was investigated in cultured podocytes by fluorescent based and surface biotinylation based assays, and time-lapse imaging in vitro; and was also demonstrated in the puromycin aminoglycoside induced nephropathy (PAN) of INF2 transgenic mice with knockin (KI) of R218Q, a pathogenic mutant that disrupts INF2/Dynll1 interaction.

Results: 1. We demonstrated that INF2 limited dynein mediated retrograde trafficking of nephrin by binding to and sequestering Dynll1, a component essential for the integrity of dynein. 2. R218Q KI podocytes illustrated an impaired recycling of nephrin with enhanced recruitment of dynein components, which could be rescued by targeting dynein transport pathway using Ciliobrevin D (Dynein inhibitor), dominant negative Dynactin 1, siRNA for Dynll1 or overexpression of wildtype INF2 (to sequester Dynll1). 3. PAN of R218Q KI mice was characterized by increased recruitment of Dynll1 to nephrin, correlated to increased ubiquitination and decreased surface nephrin, suggesting an enhanced dynein trafficking pathway underlies the impaired functional trafficking of nephrin, disintegrity of SDs and malfunction of the GFB.

Conclusions: Recognition of the dysregulated dynein mediated trafficking of SD protein has enlightened a new understanding and therapeutic targets for INF2 related podocytopathy and FSGS.

Podocyte Cell Cycle Activation During CKD Progression

Laura Perin,[1,2] Camille H. Nicolas Frank,[1] Roger E. De Filippo,[1,2] Kevin V. Lemley.[1,2] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Podocytes, quiescent cells, seem not capable of regeneration to compensate for their loss during CKD progression. Their only adaptive response to loss is through hypertrophy, allowing the remaining podocytes to effectively cover the filtration surface. This adaptive response is associated with signs of cell cycle activation, but podocytes do not divide successfully: they detach from the basal membrane and are lost in urine. How the cell cycle phases modulate this "mitotic catastrophe" is not known. To study the cell cycle in CKD, we used an Alport Syndrome (AS) mouse model characterized by podocyte loss, combined with the FUCCI technology which allow the identification of the cell cycle phases using fluorescent reporters: red for G1/S, green for S/G2/M, no color for G0.

Methods: We established a mouse model where FUCCI proteins are under the control of *NPHS2* gene (podocytes specific) and crossed these mice with AS mice to generate AS-POD-FUCCI mice. Using flow cytometry, we isolated and evaluated podocyte number in different cell cycle phases in WT (male and female) and AS-POD-FUCCI mice (hemizygote males; heterozygote, Ht females) and perform proteomics in G1 and G0 podocytes. In vitro studies were performed in primary podocytes damaged with puromycin.

Results: In WT mice (males and females), as expected, 98.1% of podocytes were quiescent (G0). In AS mice, podocyte number in G0 decrease over time: at 2months (mild proteinuria) 89% are in G0, at 6months (end-stage kidney disease) 59% are in G0 while the percentage of podocytes in G1 increased from 7.6% at 2 months to 33% at 6 months. Podocytes also increased their cellular size (hypertrophy) along disease progression. In 6monts AS Ht females (mild proteinuria), only 15% of podocytes are in G1. PAN damage induced podocytes to switch from G0 to G1 phase, and rapamycin (a cell cycle regulator) rescue damage by maintaining cells in G0. Proteomics data showed important differences of cell cycle regulators (cyclins and CKDs, mTor, integrin signaling) between G0 and G1 of WT and AS mice.

Conclusions: We demonstrated that podocytes enter their cell cycle (in male and female) with an increase of cells in G1 (associated with proteinuria) as the disease worsens. Regulating cell cycle may be pivotal in developing novel therapies to prevent podocyte loss.

Sphingomyelin Phosphodiesterase Acid-like 3B (SMPDL3b) Affects Podocyte Lipid Metabolism and Lipid Droplets Formation

Shamroop Kumar Mallela,[1] Alla Mitrofanova,[1] Xiaochen Liu,[1] Lorenza Macrina,[1,2] Devang M. Patel,[1,3] Gloria Michelle Ducasa,[1] Hassan Al-Ali,[1] Brian Marples,[4] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Division of Nephrology and Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL; [2]Nephrology, University Vita Salute San Raffaele, Milan, Italy; [3]Monash University, Clayton, VIC, Australia; [4]University of Rochester, Rochester, NY.*

Background: Lipid droplets (LD) play an important role in many biological processes and LD size and number have been linked to several diseases such type 2 diabetes, heart disease, and non-alcoholic fatty liver disease. LD are mainly composed of triglycerides and cholesterol. We previously demonstrated that the accumulation of LDs occurs in glomeruli of experimental models of diabetic kidney disease (DKD), focal segmental glomerulosclerosis (FSGS) and Alport syndrome, and that lipid accumulation in podocytes is one of the factors contributing to disease progression and may be linked to glomerular TNF expression. We furthermore demonstrated that glomerular expression of sphingomyelinase phosphodiesterase like 3b (SMPDL3b), a glycosylphosphatidylinositol (GPI) anchored protein primarily localized at plasma membrane (PM), affects the function of podocytes in FSGS and diabetic kidney disease (DKD). With this study, we aimed at exploring the role of SMPDL3b in fatty acid uptake and in the formation of LDs ultimately contributing to podocyte damage

Methods: Fatty acid uptake Assay, Lipid droplets isolation, Western blotting, Mass spectrometry, Lipolysis, TNF IV injections.

Results: We demonstrate that decreased SMPDL3b expression (siSMPDL3b) in podocytes is associated with increased FATP5 protein expression, fatty acid uptake and an increased number of LDs. The number of LDs was decreased in podocytes with increased SMPDL3b expression (SMPDL3b OE). Similarly, TAGs and CE contents were increased in siSMPDL3b when compared to control podocytes. Finally, we demonstrate for the first time that SMPDL3b is present in isolated LDs suggesting a possible role for SMPDL3b in the formation of LDs and/or in lipolysis. *In vivo*, podocyte specific induction of SMPDL3b is sufficient to protect from TNF induced podocyte injury.

Conclusions: Our results identify a new role of SMPDL3b in the uptake of fatty acids, the accumulation of TAGs, CEs and the formation of LDs. Further experiments to understand the exact mechanism by which SMPDL3b expression contributes to the progression of podocyte damage in FSGS are underway.

RNA Sequencing and ATAC-Seq Reveal Gene Profiles in Injured Podocytes in Mice, and Podocyte-Specific Hypoxia Inducible Factor 2α Deletion Protects from Adriamycin-Induced Podocyte Injury

Xiaoyan Liang,[2] H. William Schnaper,[1,2] Tomoko Hayashida.[1,2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Roles for hypoxia-inducible factor (HIF) in kidney diseases have been controversial. Upregulating HIF expression is beneficial in protecting kidney from acute injury, while we and others showed that HIF aggravates chronic fibrosis. In podocytes, deletion of VEGFR caused progressive glomerular damage, prevented by overexpression of hypoxia inducible factor 2α. Here, using podocyte-specific HIF-2α deletion mice, we tested effects of HIF-2a deletion on gene profiles in injured podocytes.

Methods: HIF-1$\alpha^{f/f}$ or HIF-2$\alpha^{f/f}$ mice were crossed with either NPHS1 or 2-Cre mice. HIF-2$\alpha^{f/f\ or\ WT}$; NPHS1/2-Cre mice were further crossed with Z/EG mice that express GFP only in cells where Cre is active. At 8 weeks old, the mice were given Adriamycin (12 mg/kg BW, i.v.). Two weeks later, kidneys, urine and blood were harvested. Creatinine and albumin levels in urine and serum, and blood urine urea levels in serum were measured with ELISA kits. Podocytes were isolated from HIF-2$\alpha^{f/f\ or\ WT}$; NPHS2-Cre; Z/EG mice by flor sorting, and RNAseq and ATACseq were performed.

Results: HIF-2$\alpha^{f/f}$; NPHS2-Cre showed preservation of foot processes and kidney functions, and significantly less proteinuria compared to the WT littermates after being subjected to Adriamycin, while HIF-1$\alpha^{f/f}$; NPHS2-Cre mice developed a similar degree of proteinuria to that of WT. HIF-1 or 2$^{f/f}$; NPHS1-Cre mice did not show any protective effect. HIF-1 or 2$\alpha^{f/f}$; NPHS1-Cre; Z/EG mice showed little GFP expression in podocytes, suggesting that weak penetrance of NPHS1-Cre led to minimal functional effects. This group was therefore not further evaluated. Podocytes isolated from HIF-2$\alpha^{f/f\ or\ WT}$; NPHS2-Cre; Z/EG were subjected to RNAseq and ATACseq. In RNAseq, Ndufa12 [NADH:ubiquinone oxidoreductase subunit A12] was most significantly upregulated in podocytes subjected to ADR, while Slc22a30 [solute carrier family 22, member 30], Slc7a13 [solute carrier family 7, (cationic amino acid transporter, y+ system) member 13] and Pzp [PZP, alpha-2-macroglobulin like] were most significantly downregulated. Correlation with ATAC-seq results are being processed.

Conclusions: HIF-2α deletion in podocytes protects podocyte from acute adriamycin injury. Novel genes associated with podocyte injury were discovered by RNAseq and ATACseq of podocytes.

Shroom3-FYN Regulates Podometrics via LKB1-AMPK Signaling

Khadija Banu, John M. Basgen, Qisheng Lin, Arun Cumpelik, Lewis Kaufman, Marina Planoutene, Barbara T. Murphy, John C. He, Madhav C. Menon. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Previously, we showed Shroom3–FYN interaction regulated podocyte cytoskeleton via FYN activation. Intriguingly, global Shroom3 knockdown mice (CAGS-TG/Shr3 Kd) displayed reduction in glomerular volume-V_{glom}, podocyte & endothelial fraction of V_{glom} without podocytopenia [**1a**]

Methods: To examine mechanism of podometrics regulation by Shr3, we used Shr3 & FYN Kd human podocytes (hPodo) to study cell protein content & growth regulatory pathways; performed unilateral nephrectomy examining V_{glom} hypertrophy in remnant kidneys

Results: At day-7, CAGS-TG mice showed restricted V_{glom} hypertrophy with reduced expansion of PodoV_{glom} vs NTGs [**1b**]. We observed reduced hPodo volume (FSC), Protein:DNA ratios (n=5; P<0.01) & inhibited ribosomal biogenesis (18S RNA) *in vitro* & *in vivo* suggesting reduced protein synthesis and FYN to be downstream of Shr3 in regulating hPodo size. Notably, we observed increased AMPK activation, increased p-EF2 & autophagy (high p-ULK1 and LC3II levels) downstream of AMPK *in vitro*/*in vivo* by immunoblot (IB) & immunofluorescence (IF)[**1c**] suggesting negative regulation of protein synthesis. Next, we examined LKB1 localization (AMPK-kinase) by IB after subcellular fractionation & IF in Shr3/FYN Kd hPodo identifying increased LKB1 Cytosolic:Nuclear ratio, explaining AMPK activation due to increased cytosolic pool of active LKB1 [**1d**]. Finally, we used an AMPK inhibitor, Compound C in CAGS-TG mice and observed reversal of podometric changes-V_{glom} & V_{glom} fractions, induction of podocytopenia with AMPK-inhibition [**1e**]

Conclusions: Here, we show Shroom3-FYN interaction regulating podometrics via AMPK-signaling in podocytes. The protective morphometric effects have implications to disease models with podocyte/nephron loss requiring obligate V_{glom}/Podocyte hypertrophy

PO1975

The Role of Opioid Receptor Signaling in Podocytes and Renal Damage in Dahl Salt-Sensitive Rats

Daria Golosova,[1] Oleg Palygin,[1] Vladislav Levchenko,[1] Christine A. Klemens,[1] Ashraf El-Meanawy,[2] Alexander Staruschenko.[1] *[1]Medical College of Wisconsin Department of Physiology, Milwaukee, WI; [2]Medical College of Wisconsin Department of Medicine, Milwaukee, WI.*

Background: The rise in opioid use underscores the urgent need to better understand the direct and indirect effects of opioids on renal function, especially in patients with chronic kidney disease (CKD) or hypertension. The extensive use of opioids is strongly correlated with poor cardiovascular outcomes. We hypothesize that stimulation of opioid receptors (ORs) elevates intracellular calcium level in podocytes leading to kidney damage and progression of hypertension.

Methods: Freshly isolated glomeruli from Dahl salt-sensitive (SS) rats, human kidneys and immortalized human podocytes were used to elucidate the contribution of specific ORs to podocyte calcium flux. Calcium response in the podocytes was analyzed via ratiometric confocal fluorescent microscopy. For chronic studies Dahl SS rats were on a 0.4% (LS) or 8% (HS) NaCl diets for 14 days with or without a daily *intravenous* bolus infusion of BRL52537, a potent and selective kappa-OR agonist.

Results: Stimulation of kappa-ORs, but not mu-ORs or delta-ORs, mediated calcium influx in podocytes through activation of TRPC6 channels in rat and human kidney. The effect of BRL52537 was completely abolished when we used the 0 mM calcium media or when SAR7334 (a TRPC6 channel inhibitor) was applied. Triggering the kappa-OR/TRPC6 pathway induced podocyte cell shape changes via actin cytoskeleton remodeling. *In vivo* studies revealed that SS rats chronically treated with BRL52537 exhibited augmented blood pressure (MAP was 179 ± 15 mmHg vs. 151 ± 11 mmHg), nephrinuria, albuminuria, and elevation in podocyte calcium in BRL52537 treated Dahl SS rats.

Conclusions: Stimulation of kappa-OR modulates calcium influx in podocyte via TRPC6 channels. The opiate-induced increase in the calcium flux in podocytes is expected to contribute to podocytopathy, proteinuria, kidney injury and progression of salt-induced hypertension. These findings are important to advance our knowledge of the pathogenesis of the development of CKD and hypertension in the context of pain management.

Knockout of the Neonatal Fc Receptor (FcRn) Alters Lysosomal Function in Podocytes

Judith Blaine,[1] Madeline D. Ng,[1] Pantipa Tonsawan,[2] Linda Lewis,[1] James F. Dylewski.[1] *[1]University of Colorado Denver School of Medicine, Aurora, CO; [2]Khon Kaen University, Khon Kaen, Thailand.*

Background: FcRn is a trafficking protein that diverts monomeric IgG from the lysosome but sorts multimeric IgG and immune complexes (ICs) to the lysosome for processing. FcRn is required in dendritic cells to traffic ICs to the lysosome for proteolytic processing and presentation on MHC II. Podocytes express FcRn and previous work had proposed that podocytes can act as antigen presenting cells. Here we show that cultured podocytes are weak antigen presenting cells (APCs) and that knockout (KO) of FcRn in podocytes does not alter podocyte response to an immune stimulus but does result in significant downregulation of lysosomal function.

Methods: Cultured wild type (WT) and FcRn KO podocytes were treated with interferon gamma (IFNg) to simulate proinflammatory conditions. MHC II and costimulatory marker expression was assessed by flow cytometry. Antigen presentation was evaluated by examining T cell response when WT or FcRn KO podocytes were treated with ICs and used as APCs. Lysosomal size and cellular location in WT and FcRn KO podocytes were examined using confocal microscopy. WT or FcRn KO podocytes were treated with ICs and colocalization of lysosomes and ICs was quantitated. RNA-seq was used to examine lysosomal pathways.

Results: Both WT and FcRn KO podocytes upregulated MHC II after treatment with IFNg but there was no difference in expression levels between WT and KO. There was no change in CD80 expression between WT and KO after treatment with IFNg. CD86 and ICOSL expression levels in WT and FcRn KO were minimal at baseline and after treatment with IFNg. When used as APCs, WT podocytes induced a very modest amount of IL-2 production by T cells (a marker of T cell activation) whereas KO podocytes induced none. After treatment with ICs, lysosomes in WT podocytes were significantly larger and were also clustered around the nucleus, indicating lysosomal activation. In contrast, after IC treatment lysosomes in the KO were smaller and more peripherally located. Treatment with ICs also resulted in significantly greater colocalization between lysosomes and ICs in WT versus FcRn KO podocytes, demonstrating that ICs were not directed to the lysosome in the KO. RNA-seq showed significant downregulation of lysosomal pathways in KO podocytes compared to WT after treatment with ICs.

Conclusions: FcRn KO in podocytes alters lysosomal trafficking and function.

Apolipoprotein M as a Biomarker of Glomerular Lipotoxicity in Nephrotic Syndrome

Yelena R. Drexler, Judith T. Molina David, Sandra M. Merscher, Alessia Fornoni. *University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.*

Background: Dysregulation of intrarenal metabolic pathways involved in cholesterol efflux is implicated in lipid-induced podocyte injury in glomerular diseases. Among several genes that are involved in cholesterol efflux, we recently reported a significant downregulation of glomerular apolipoprotein M (APOM) expression in patients with FSGS. HDL-associated APOM facilitates reverse cholesterol transport and is the carrier for the bioactive sphingolipid sphingosine-1-phosphate (S1P). Mutations in S1P lyase, the enzyme responsible for S1P degradation, cause a familial form of FSGS. We hypothesize that glomerular APOM deficiency is a surrogate biomarker for lipid-induced kidney injury in NS.

Methods: Patients with FSGS, MN, and MCD enrolled in NEPTUNE, a multi-center observational cohort study of children and adults with NS, who had uPCR >1 g/g at baseline were selected for analysis. RNA expression data were obtained from the

glomerular compartment isolated from kidney biopsies and compared with living kidney donor controls. Plasma and urinary APOM levels were measured by ELISA using baseline samples. Linear regression analysis was used to correlate glomerular APOM expression with plasma and urinary levels of APOM and to correlate glomerular APOM expression and plasma and urinary APOM levels with eGFR at baseline.

Results: Among 84 patients, 68% were male, mean age was 40 years, mean baseline eGFR was 80.6 mL/min/1.73m^2, and mean uPCR was 4.9 g/g. Glomerular APOM expression was decreased in patients with NS compared to healthy controls ($p < 0.001$), irrespective of histologic diagnosis. APOM expression was positively correlated with plasma but not urinary APOM levels in the NS cohort ($R^2 = 0.089$, $p = 0.003$) and in the FSGS subgroup ($R^2 = 0.189$, $p = 0.0218$). Decreased APOM expression ($p = 0.005$) and decreased plasma APOM ($p = 0.031$) were associated with a lower eGFR at baseline in the NS cohort. After adjustment for age, sex, and race, each unit decrease in APOM expression was associated with a 9.83 mL/min/1.73m^2 (95% CI, 3.72 to 15.93, $p = 0.002$) lower eGFR at baseline.

Conclusions: Glomerular APOM deficiency and decreased plasma APOM levels were associated with decreased kidney function at baseline in the NS cohort. These findings identify APOM as a potential biomarker of lipid-induced kidney injury in NS.

The Sensitivity of Podocytes to ATP In Vivo Is Distinctly Lower than the Sensitivity of Glomerular Endothelial and Proximal Tubular Cells

Julia Binz,[1] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Matthias Hackl.[1] *[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; [2]CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.*

Background: ATP signaling is involved in a plethora of pathways, involving damage signaling. Cell culture models as well as experiments on isolated glomeruli indicate that podocytes respond to ATP with a calcium transient. To date a direct effect of ATP on podocyte calcium levels *in vivo* has not been demonstrated.

Methods: In this study mice expressing GCaMP3 in podocytes (Pod:cre), proximal tubular cells (Pax8:cre) or endothelial cells (Tie2:cre) underwent multiphoton *in vivo* imaging of the kidney. Mice were anaesthetized, an arterial catheter was placed into the right carotid artery or the aorta and the left kidney was exteriorized. The vasculature was labelled with a 70-kDa dextrane. Different doses of ATP were injected as a bolus via the catheter and dose-dependent calcium transients were monitored.

Results: Our data indicates that even doses of 5 mg/kg ATP did not induce calcium transients in podocytes when injected via a carotid artery catheter, while robust activation of calcium signaling was induced in endothelial and proximal tubular cells with 0.5 mg/kg ATP. Further increasing the ATP dose by injection via an abdominal aortic catheter resulted in a calcium transient in podocytes.

Conclusions: In contrast to endothelial cells and proximal tubular cells, podocytes show a low sensitivity to ATP-mediated calcium signaling. We therefore hypothesize, that the low sensitivity ATP of podocytes is a protection mechanism to avoid calcium signals from filtered ATP.

Cytomegalovirus Viremia-Associated Collapsing FSGS in an Immunosuppressed Systemic Lupus Erythematosus Patient

Emily Daniel, Dominick Santoriello, Andrew S. Bomback, Hilda E. Fernandez. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Maintaining a broad differential in evaluating AKI in SLE patients with a history of lupus nephritis (LN) is important. We describe a patient with SLE and AKI progressing to dialysis dependence due to collapsing FSGS in the setting of CMV infection.

Case Description: A 23 yo African American F with a history of LN class IV + V (maintained on MMF 1g BID) and APLS presented with one week history of nausea, vomiting and diarrhea. Admission labs were notable for a Cr of 10.5 mg/dl (baseline Cr 0.7), pancytopenia, with albumin of 1.7 mg/dl. Spot urine protein to creatinine ratio was >27 g/g. Serologies showed low C3 and C4, positive ANA, LDH 1437 and negative HIV test. Patient became anuric and required hemodialysis. Stress dose steroids were administered for presumed RPGN from LN. Renal biopsy on hospital day 8 demonstrated collapsing FSGS with 100% podocyte foot process effacement without significant IFTA and 4/9 globally sclerotic glomeruli. Testing revealed CMV viremia with viral load of >700,000 IU/mL. MMF was held. Ganciclovir was initiated with a subsequent decrease in viral load and sufficient renal recovery to stop hemodialysis. Patient was discharged off MMF on oral valganciclovir with a steroid taper. Three months after discharge, patient's viral load was undetectable and renal function had returned to baseline.

Discussion: Our patient with SLE had an atypical presentation. The appearance of significant proteinuria and severe AKI led to initial empiric treatment for LN. Rarely, collapsing FSGS has been described as the primary lesion in lupus podocytopathies. The high CMV viral load and robust response to antiviral therapy argue that the lesion was mediated by CMV infection rather than SLE. The development of collapsing FSGS is commonly due to a "second hit" on a high risk APOL1 genetic background, in our case from elevated interferon levels in the setting of CMV viremia. APOL1 has been implicated in collapsing FSGS due to CMV viremia in African American DDRT recipients, demonstrating the role of genetic testing in African American patients. Our case demonstrates an infectious trigger, rather than autoimmune cause of renal failure in an immunosuppressed patient with SLE.

PO1980

Transcriptional Reprogramming by WT1 Mediates a Repair Response During Podocyte Injury in Mice and Human Kidney Organoids

Sandrine S. Ettou,[1] Youngsook L. Jung,[2] Tomoya Miyoshi,[3] Ken Hiratsuka,[3] Ryuji Morizane,[3] Peter Park,[2] Jordan A. Kreidberg.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: We previously identified WT1 as one of the most upstream transcription factors regulating gene expression in podocytes, binding nearly all genes known to be crucial for maintenance of the glomerular filtration barrier. Here, we focus on understanding WT1 transcriptional mechanism in response to injury.

Methods: We used Adriamycin (ADR)-induced podocyte injury as a model for human Focal Segmental Glomerulosclerosis in mice and human kidney organoids, and a conditional *Wt1* inactivated mouse model to decipher the transcriptional mechanism through which WT1 regulates podocyte gene expression during injury, using transcriptomic approaches.

Results: After injury, we observed a transient increased expression of podocyte genes in mice and human kidney organoids. Transcriptomics analyses of podocytes isolated from *mTmG-Nphs2cre* mice during the course of injury revealed a transient increase in the expression of crucial podocyte genes, including *Nphs2, Synpo* and many others, reflecting a reparative response during the early stages of injury. ChIP-seq analyses demonstrated that WT1 binds nearly 50% of known genes in podocytes, and the vast majority of genes whose expression changes during the response to injury. We identified *de novo* binding of WT1 that were only bound during the course of injury, and the expression of novel WT1 target genes. It appears that WT1 increases gene expression during injury through both the acquisition of novel binding sites, and increasing its binding intensity at sites bound in uninjured podocytes. Additionally, motifs predicting binding of other podocyte-specific transcription factors were highly enriched at sites where WT1 binding increased after injury. Since the DNA binding of transcription factors is modulated by chromatin accessibility, we used FACS-isolated podocytes to study epigenetic reprogramming. Both ADR-mediated podocyte injury or inducible podocyte specific inactivation of *Wt1* resulted in the conversion of active to repressive histone marks at WT1-bound sites.

Conclusions: These results demonstrate that target gene binding of WT1 is highly dynamic in response to injury. WT1 directs the epigenetic regulation of gene expression, maintaining active chromatin marks at bound genes, that change to repressive marks in the absence of WT1.

PO1981

Atypical Caspase 3-Dependent Death Process in Podocytes

Kazuyoshi Yamamoto,[2,1] Masahiro Okabe,[1] Takashi Yokoo,[1] Taiji Matsusaka.[2] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Apoptosis of podocytes has been widely reported in many *in vitro* studies, but definitive apoptosis has been rarely documented *in vivo* podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes *in vitro* and *in vivo*.

Methods: Primary mouse podocytes were transiently transfected with hCD25 and EGFP expression plasmids and treated with a hCD25-targeting immunotoxin, LMB2 (1nM). 24 hours later, EGFP, cleaved-caspase 3 (cCasp3) and TUNEL staining were imaged. In *in vivo* experiments, podocyte injury was induced by injecting LMB2 into NEP25 mice, which express hCD25 in podocytes. In some experiments, NEP25 mice carrying another transgene expressing EGFP in podocytes were used.

Results: In *in vitro* studies, administration of LMB2 caused leakage of co-introduced EGFP in 56.8±13.6% of hCD25-transfected cells, incorporation of propidium iodide in 13.6±2.5%, activation of caspase 3 in 19.6±2.6% and TUNEL staining in 4.5±1.3%. However, LDH activity in the culture medium did not significantly increase. These phenomena were not observed in cells without hCD25 or without LMB2. Ac-DEVD-CHO (10μM), a caspase-3 inhibitor, attenuated the leakage of EGFP by 38.2%, while inhibitors for caspase-1, necroptosis or autophagy did not. These indicate that LMB2 induced typical caspase-3 dependent apoptosis in podocytes *in vitro*. In *in vivo* studies, injection of LMB2 (25ng/g BW) frequently induced leakage of EGFP from podocytes. In separate six NEP25 mice, 7 days after injection of LMB2 (1.25ng/gBW), 41.8±5.1% of glomeruli were found to contain cCasp3-positive cells, but no TUNEL-positive cell was observed. The urinary sediments contained podocalyxin-positive podocytes (2.5±0.3/μl). Among these, 39.1±3.7% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. To evaluate the effect of glomerular filtration, three NEP25 mice were similarly injected with LMB2 and subjected to UUO 1 day before sacrifice. Detaching podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: These collectively indicate that podocytes dying dependently on caspase 3 are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. Glomerular filtration facilitates detachment of dying podocytes.

PO1982

Systematic In Silico Exploration of the Kidney Rho-GTPase System Regulation in CKD

Anna Reznichenko, Lisa Buvall. *AstraZeneca R&D, Gothenburg, Sweden.*

Background: It has become evident that dysregulation of the RhoGTPase system would result in rearrangement of the actin cytoskeleton in the podocyte with resulting foot process effacement, a hallmark for glomerular diseases. To build further understanding how this disbalance in the RhoGTPase system occurs in CKD, we performed a systematic mining of kidney transcriptomics data to generate a full-picture view and insights on complex interplay between the members of the large family of RhoGTPases and their regulatory proteins, the Guanine Nucleotide Exchange Factors (GEFs) and the GTPase-activating proteins (GAPs).

Methods: A comprehensive list of 143 genes was compiled including the members of the three gene families according to HUGO Gene Nomenclature Committee (HGNC). Publicly available human transcriptomics data from healthy and CKD kidneys (microarray and RNA-seq, bulk-tissue and single-cell) were used for interrogation of gene expression patterns, including presence of detectable expression, its abundance, cell type specificity, modulation in disease, and co-expression structure. WGCNA and Cytoscape were used to correspondingly generate and visualize the gene co-expression network.

Results: All but one (142/143) genes were detectable in the human kidney, with 121 having robust levels >1TPM. The majority of genes were broadly expressed across the different tissues outside the kidney, however expression of several GEF and GAP members showed specific kidney enrichment. A number of GEFs and GAPs were modulated in CKD patient kidneys as compared to controls, predominantly with tendency for up-regulation and negative correlation with renal function, reflecting modulation in potentially pathophysiological or compensatory disease mechanisms. Hierarchical clustering of pairwise correlation values and WGCNA module analyses identified clusters of similarly expressed genes that may implicate functional similarities.

Conclusions: To our knowledge, this is the first systematic evaluation of the RhoGTPases, GEFs and GAPs kidney expression in the CKD context. Elucidation of the molecular interplay provides systems-level understanding and mechanistic insights that can lead to new biological hypotheses and therapeutic targets.

Hepatocyte Growth Factor-Induced Activation of NEPHRIN and NEPH1 Serves as a Novel Mechanism for Recovery of Podocytes from Injury

Ashish K. Solanki,[1] Pankaj Srivastava,[1] Ehtesham Arif,[1] Pei Wen,[4] Bushra Rahman,[1] Wayne R. Fitzgibbon,[1] Joshua H. Lipschutz,[1] Lawrence B. Holzman,[1] Sang-Ho Kwon,[2] Glenn P. Lobo,[1] Zhe Han,[4] Matthew J. Lazzara,[3] Deepak Nihalani.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Augusta University, Augusta, GA; [3]University of Virginia, Charlottesville, VA; [4]University of Baltimore, Baltimore, MD.*

Background: Podocytes (podo.) and their slit diaphragm(SD) are critical components of glomerular filtration barrier, whose dysfunction leads to ESRD (end stage renal disease). Treating ESRD remains a global challenge due to our poor understanding of the mechanisms that participate in recovery of podo. from injury. Glomerular injuries commonly induce podo. cell death and loss of SD, which is a modified tight junction and is constructed through a trans-interaction between the extracellular domains of NEPHRIN and NEPH1 that maintain its structural integrity. Here, we present a novel concept showing that apart from structural organization, NEPHRIN and NEPH1 constitute a receptor-based function, and can be activated in a ligand-induced fashion.

Methods: Proteomics, SPR, Immunofloroscence

Results: The ability of NEPHRIN and NEPH1 to interact with tyrosine phosphatase SHP-2 in a phosphorylation (phos.) dependent manner prompted us to investigate whether ligands that induce PTPN11 stimulation also induced activation of NEPHRIN and NEPH1. Ligands screening identified HGF as a prominent inducer of both NEPHRIN and NEPH1 phos. To further establish HGF as a ligand, we used baculovirus system to generate purified NEPHRIN and NEPH1 proteins and confirmed not only a direct interaction between HGF and the extracellular domains of NEPHRIN and NEPH1, but also, the ligand-induced phos. of these proteins. In addition to their ligand-induced activation, we demonstrate that SHP-2 can directly dephos. these proteins, thus presenting for the first time activation and deactivation mechanism for these proteins. Since HGF has a protective role in podo. and NEPHRIN and NEPH1 phos. participates in actin cytoskeletal reorganization, we hypothesize that HGF-induced activation of these proteins is critical for recovery of podo. from injury. We demonstrate that while HGF treatment repaired cultured podo. or nephrocytes in Drosophila that were injured by protamine sulphate, addition of inhibitory NEPHRIN or NEPH1 peptides that bind HGF, significantly attenuated this recovery.

Conclusions: We provide compelling evidence for the first time that HGF is a novel ligand and can stimulate signaling of slit diaphragm proteins NEPHRIN and NEPH1 in podocytes

Bag3 as a Potential Mechanoprotector in Podocytes

Ingo Plagmann,[1,2] Markus M. Rinschen,[3,1] Karim Heinlein,[1,2] Jan C. Degenhardt,[1,2] David Unnersjö-Jess,[1,2] Sybille Kohler,[4] Bernhard Schermer,[1,2] Thomas Benzing.[1,2] *[1]Department II of Internal Medicine and Center for Molecular Medicine, University of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging- Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [3]The Scripps Research Institute, La Jolla, CA; [4]The University of Edinburgh Centre for Discovery Brain Sciences, Edinburgh, United Kingdom.*

Background: Podocyte loss is a hallmark of glomerular diseases leading to glomerulosclerosis and progresssion of kidney disease. Sitting on the outside of the glomerular tuft podocytes have to withstand extensive mechanical stress due to perfusion and filtration. Hyperfiltration und hyperperfusion e.g. in disease states cause podocyte detachment when overwhelming their mechonoprotective capacity, which start a vicious cycle of mounting strain on the remaining podocytes. Bag3 is an important mechanoprotector in many mechanical strained tissues and by inducing chaperone-assisted autophagy (CASA) maintains the proteostasis of e.g. Filamin and Synaptopodin – indispensable for podocyte biology. Additionally Bag3 insufficiency renders susceptibility to diabetic nephropathy in a mouse model. These findings point toward Bag3 as a candidate for mechanical stress protection in podocytes.

Methods: Using immunofluorescence, super-resolution-microscopy and mass-spectrometry we examined glomeruli and podocytes for Bag3/CASA expression and characterized the CASA-complex composition in podocytes by immunoprecipitation. The influence of mechanical clues was examined by stiff matrices and cyclic stretch. The role of Bag3 in vivo is being evaluated in different mouse lines (Bag3.P209L mutation, a conditional knockout, fusion-protein).

Results: In the glomerulus the Bag3 and the entire CASA-complex is enriched in podocytes in mass-spectrometry. Bag3 staining localizes to the slit diaphragm protein nephrin in superresolution microscopy. Importantly the co-chaperone Bag3 shows interaction with essential actin-cytoskeleton regulators like RhoA, Arpc2 and Dynamin2 in co-immunoprecipitation. The expression of Bag3 and the CASA-complex in podocytes is regulated by mechanical clues. Knockdown of the Bag3 homologue starvin in drosophila nephrocytes displays a mild filtration disturbance. The dominant-negative Bag3.P209L mutation causes a mild proteinuria in a whole-body overexpression mouse line.

Conclusions: The data further emphasize the role of Bag3 and chaperone-assisted-selective-autophagy in podocyte mechanoprotection and maintenance of podocyte cytoskeleton architecture. Currently undergoing characterization of podocyte specific Bag3 mouse lines and the use of disease models will further help to understand the role of Bag3 at the kidney filtration barrier.

Knockout of the Neonatal Fc Receptor in Podocytes Ameliorates Nephritis by Reducing Glomerular Apoptosis

Judith Blaine,[1] James F. Dylewski,[1] Linda Lewis,[1] Pantipa Tonsawan.[2] *[1]University of Colorado, Aurora, CO; [2]Khon Kaen University, Khon Kaen, Thailand.*

Background: There are few targeted treatments for immune mediated kidney diseases which can result in progressive renal failure. Podocytes express the neonatal Fc receptor (FcRn), a trafficking protein that sorts immune complexes (ICs) to the lysosome. In dendritic cells FcRn mediated trafficking of ICs to the lysosome is required for antigen processing and presentation on MHC II. We have found that podocyte specific knockout (KO) of FcRn ameliorates nephrotoxic serum (NTS) nephritis but that this protection occurs via a non-immune mediated mechanism. Here we show that KO of FcRn in podocytes results in a significant reduction in apoptosis both in vitro and in vivo after an immune challenge

Methods: Wild type (WT) and FcRn KO podocytes were cultured in the presence or absence of ICs. The intrinsic and extrinsic apoptotic pathways were assayed by Western blot and ELISA. RNA-seq was performed to evaluate changes in apoptotic pathways. NTS nephritis was induced in control and podocyte specific FcRn KO (podFcRn KO) mice. Glomerulosclerosis and crescent formation were quantitated on PAS sections. Flow cytometry was used to measure renal CD4+, CD8+ or FoxP3+ T cells. Glomerular apoptosis was assayed using the TUNEL assay.

Results: In vitro, after treatment with ICs, FcRn KO podocytes expressed significantly less caspase-3 and caspase-9 (intrinsic pathway caspases) and caspase-3 activity was significantly decreased in KO podocytes compared to WT. There was no difference in caspase-8 expression (a marker of extrinsic apoptosis) between WT and KO podocytes. RNA-seq analysis demonstrated significant downregulation of intrinsic apoptotic pathways in FcRn KO podocytes compared to WT. In vivo, after induction of nephrotoxic serum nephritis, there was no change in renal CD4+, CD8+ or FoxP3+ T cells in podFcRn KO mice compared to controls but podFcRn KO mice had significantly less glomerulosclerosis and crescent formation. Podocyte-specific KO of FcRn also resulted in a significant reduction in the number of apoptotic cells within the glomerulus.

Conclusions: KO of FcRn reduces apoptosis via the intrinsic pathway in cultured podocytes after an immune challenge and ameliorates immune-mediated nephritis in vivo by reducing glomerular apoptosis.

PO1986

The African APOL1 E150 SNP and Cell Surface Expression Are Required for Kidney Risk-Variant (G1/G2)-Mediated Cytotoxicity in Podocytes

Nidhi Gupta, Suzie J. Scales. *Genentech Inc, South San Francisco, CA.*

Background: Apolipoprotein L1 (APOL1) variants G1 and G2 protect against trypanosome infection, but homozygosity greatly increases the risk of chronic kidney diseases, purportedly by acting as surface cation channels in kidney podocytes. "Wild type" APOL1-G0 exhibits various single nucleotide polymorphisms (SNPs), most commonly haplotype E150K, M228I and R255K ("KIK", where the Reference Sequence is "EMR"), whereas G1 and G2 are only found in a single African haplotype background ("EIK"), also seen in some G0 Africans. Lannon *et al* (*Kidney Int.* **96**: 1303) recently documented that differential cytotoxicity of APOL1 G1 and G2 variants versus G0 in HEK-293 cells depended on the haplotype. However, HEK-293 cells are unusually sensitive to APOL1, and podocytes are a more relevant cell type. Furthermore, only the small fraction of APOL1 that is transported to the cell surface (from its major expression site in the ER) is responsible for cytotoxicity and cell surface levels were not shown in that study. Since APOL1 residue 150 can differ in G0 Africans, we focused on comparing the cytotoxicities of E150 vs K150 SNPs in podocytes expressing equal surface levels of APOL1.

Methods: We generated podocytes stably expressing APOL1 G0, G1 or G2 under a doxycycline-inducible promoter and compared the effect of the African E150 (EIK) vs K150 (KIK) SNPs on cytotoxicity (by the Cyto-Tox Glo™ assay). Surface and total APOL1 were measured by FACS and Western blotting at increasing doxycycline levels. Brefeldin A was used to prevent APOL1 transport to the cell surface.

Results: Cell surface APOL1 levels increased in a doxycycline dose-dependent manner, but only the E150 G1 and G2 variants caused toxicity to podocytes as compared to E150 G0 at equal surface expression levels; K150 G0, G1 and G2 were not toxic. E150 G1 and G2 cytotoxicity was dose-dependent and required exit of APOL1 from the ER.

Conclusions: Using a physiologically relevant podocyte cell line, we confirmed that the African haplotype (EIK) is required for APOL1 G1 and G2 to exert cytotoxicity. Non-natural KIK versions were not toxic. Additionally, APOL1 G0 was not toxic in either the KIK or EIK background. Furthermore, African (E150) G1 and G2 cytotoxicity required ER exit, supporting the surface cation channel hypothesis. Our data thus suggest two potential therapeutic avenues for APOL1 nephropathies.

PO1987

Glomerular Heterogeneity and Modulation of miR-93: The Role of Extracellular Vesicles

Laura Perin,[1,2] Charmi Dedhia,[1] Paola Aguiari,[1] Roger E. De Filippo,[1,2] Sargis Sedrakyan.[1,2] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Modulation of miRNA in podocytes and glomerular endothelial cells (GEC) has been associated with development of renal diseases. miR-93 is a potent regulator of pathways responsible for glomerular damage, like VEGF, TGFb and Msk2. We have evidence that miR-93 is altered in the glomeruli of mice with X-linked Alport syndrome (AS), carrying the Col4a5 mutation, and in glomeruli of AS patients. Here, we investigated the role of miR-93 in mesangial cells, podocytes and GEC from WT and AS mice. We also used extracellular vesicles (hEVs) derived from human amniotic fluid stem cells (hAFSC) to assess their disease modifying activity in vitro and in vivo by regulation of miR-93.

Methods: miR-93 expression was evaluated by qRT-PCR in mesangial cells, podocytes and GEC sorted from glomeruli of male and female WT (C57BL6/J), and homozygous and heterozygous AS (Col4a5-/-) mice at different stages of disease (2m, 3.5m and 5.5m) and in biopsies of AS patients. Modulation of miR-93 by hEVs was evaluated in vitro and EV therapeutic effect was evaluated in vivo by RNA-seq and survival.

Results: miR-93 expression is different between male and female mice along disease progression. In AS males miR-93 level was significantly lower in GEC, but not in podocytes or mesangial cells vs WT cells. miR-93 expression was downregulated also in AS patients. Expression of WT1 in puromycin aminonucleoside damaged podocytes, and expression of fibronectin and VEGF in damaged GEC was restored by miR-93 hEV cargo transfer. In vivo, hEVs showed therapeutic effect by ameliorating the level of proteinuria and increasing life span. Transcriptomic analysis showed that WT male and female present differences in respiratory and metabolic pathways, extracellular matrix and cell adhesion molecules. AS males injected with hEVs showed improved gene modulations in metabolic function and in the development of vasculature, angiogenesis and fibrosis pathways, important miR-93 targets.

Conclusions: Gender specific variation in miR-93 expression in glomerular cells might indicate important differences in response to injury in progressive disease. hEVs demonstrate great potential to restore lost miR-93 expression and its targets, thus presenting a targeted approach for treatment of CKD.

GDC-0879 Rescues Lipid Peroxidation and Podocyte Dysfunction in Coenzyme Q-Deficient Kidney Disease

Eriene-Heidi Sidhom,[1,2] Choah Kim,[1,2] Maria Alimova,[2] May Theng Ting,[4] Julian R. Avila-Pacheco,[2] Andrew J. Watts,[1,2] Katherine A. Vernon,[1,2] Jamie L. Marshall,[2] Astrid Weins,[3] Jillian Shaw,[2] Anna Greka.[1,2] *[1]Harvard Medical School, Boston, MA; [2]Broad Institute, Cambridge, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Columbia University Irving Medical Center, New York, NY.*

Background: Mutations affecting mitochondrial coenzyme Q (CoQ) biosynthesis lead to kidney failure due to selective loss of essential cells of the kidney filter called podocytes. Curiously, neighboring tubular epithelial cells are spared early in disease, despite their higher mitochondrial content. We therefore sought to illuminate new, cell-specific roles for CoQ, independent of its role in the electron transport chain (ETC).

Methods: Here we use CoQ deficiency caused by a monogenic disorder due to *PDSS2* mutations as a model system with which to investigate the cell-specific mechanisms of disease. The resolution afforded by single nucleus RNA sequencing revealed podocyte-specific disease pathways in homozygous *kd/kd* (kidney disease) mice, the result of a spontaneous missense mutation in *Pdss2* (V117M, *Pdss2*$^{kd/kd}$). We combine single nucleus transcriptomics with *in vitro* metabolomics and transcriptomics analyses to better understand the metabolic perturbations within this disease.

Results: Single nucleus RNA sequencing from kidneys of *Pdss2*$^{kd/kd}$ mice, characterized by nephrotic syndrome and CoQ deficiency in all cells, identified a podocyte-specific perturbation of the Braf/Mapk pathway. Treatment with GDC-0879, a Braf/Mapk-targeting compound ameliorated kidney disease in *Pdss2*$^{kd/kd}$ mice. *In vitro,* mechanistic studies in Pdss2-depleted podocytes revealed a previously unknown perturbation in PUFA metabolism leading to lipid peroxidation. Aberrant PUFA metabolism was confirmed *in vivo,* where the abundance of Gpx4, an enzyme that protects cells from lipid peroxidation, was elevated in disease and restored after treatment with GDC-0879. We demonstrate broader human disease relevance of these findings by uncovering patterns of Gpx4 and Braf/Mapk pathway gene expression in tissue from patients with several kidney diseases.

Conclusions: Our studies reveal ETC-independent roles for CoQ in podocyte injury and point to Braf/Mapk as a conserved, podocyte-specific pathway for the treatment of kidney diseases.

PO1989

Noncanonical PAR-1 Signalling Leads to Profibrotic Effects in Podocytes in Response to Steroid-Resistant Nephrotic Syndrome Disease Plasma

Musleeha Chesor, Jack P. Tuffin, Carl J. May, Gavin I. Welsh, Moin Saleem. Bristol Renal *University of Bristol, Bristol, United Kingdom.*

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to the presence of an unknown "circulating factor", the identity of which has so far remained elusive. Our previous works suggest a role for protease-activated receptor-1 (PAR-1) involving an unknown circulating protease leading to increased podocyte motility. We have now further elaborated the signalling pathways downstream of PAR-1, which suggests pro-fibrotic activation in podocytes.

Methods: Conditionally immortalised human podocytes (ciPods) were treated with PAR-1 agonist peptide or post-transplant SRNS relapse and paired-remission plasma with or without PAR-1 antagonists, RWJ 56110, SCH 79797, Vorapaxar, and FR171113. ciPods were also treated with TGF-β1 or SRNS plasma along with SB-43152, an effective TGF- β1 receptor inhibitor. A new 3D co-culture glomerular spheroid model was used to study both signalling pathways and podocyte loss.

Results: We found that PAR-1 agonist and patient relapse disease plasma, but not paired remission plasma significantly induced the phosphorylation of VASP, JNK, and proteins involved in pro-fibrotic pathways. These changes were inhibited by co-incubation of ciPods with certain PAR-1 inhibitors, but not by TGFb1 inhibitor. These four PAR-1 inhibitors demonstrate distinct antagonistic properties and among 4 inhibitors, only FR17113 was effective in inhibiting effects of relapse plasma, suggesting a non-canonical agonism of PAR-1 by disease plasma. The phosphorylation of VASP and JNK on a 3D spheroid model corroborates the finding from a 2D ciPods model. Functionally, the circulating factor enhanced podocyte motility and podocyte loss.

Conclusions: We propose that the SRNS circulating factor acts as a pro-fibrotic effector that can activate PAR-1 leading to increased podocyte injury. A greater understanding of these signalling pathways will lead to the identification of novel therapeutic targets for this disease.

Funding: Government Support - Non-U.S.

TRPC6 Is a Key Mediator of a PAR-1 Activation Pathway in Podocytes That Is Responsible for FSGS

Carl J. May, Musleeha Chesor, Gavin I. Welsh, Moin Saleem. *University of Bristol, Bristol, United Kingdom.*

Background: There is good evidence for the role of a circulating factor in the pathogenesis of idiopathic nephrotic syndrome (iNS). We have previously presented our work hypothesising the role of circulating plasma proteases. An active form of the protease activated receptor, PAR-1 expressed in the podocytes of SV129 mice (PAR-1_{Active}) led to proteinuria, sclerosis and death at 42 days. It was found that the signalling

response to PAR-1 agonist treatment of podocytes *in vitro* was also present in the kidney IHC sections from the PAR-1_{Active} mouse, and in human podocytes treated with post-transplant recurrence plasma. This response includes the phosphorylation of VASP, JNK and Paxillin. We hypothesised that the downstream response to PAR-1 signalling involves activation of TRPC6.

Methods: Conditionally immortalised human WT podocytes and TRPC6 KO mouse podocytes were treated with a PAR-1 agonist (15 μM PAR-3931-PI Peptides International). The PAR-1_{Active} mouse was crossed with a TRPC6 KO on a C57 Bl6 background to develop the *NPHS2* Cre PAR-1_{Active} TRPC6 KO mouse. Biopsy tissue was obtained via the UK Nephrotic Syndrome Study, NephroS, housed within the UK Renal Rare Disease Registry, RaDaR.

Results: We present data confirming activation of the same signalling pathways *in vitro* in podocytes treated with a PAR-1 agonist, and *in vivo* in our *NPHS2* Cre PAR-1_{Active} mouse. Then *in vivo* in human nephropathy biopsies pVASP and pJNK signalling was significantly higher in FSGS and Minimal Change Disease biopsies when compared to IgA nephropathy biopsies. TRPC6 is a calcium channel that can be found at the slit diaphragm and can signal to the actin cytoskeleton. TRPC6 Knock Out (T6KO) podocytes showed an altered response to PAR-1 agonist treatment. There was no phosphorylation of VASP and only brief phosphorylation of JNK and no phosphorylation of Paxillin. When we crossed a T6KO mouse with our *NPHS2* Cre PAR-1 Active mouse we saw significantly increased survival from a median of 40 days in the *NPHS2* Cre PAR-1 Active mouse to 60 days when TRPC6 is knocked out.

Conclusions: We have identified a common signalling response to PAR-1 activation in podocytes *in vitro* and *in vivo*, including in human disease. We identified TRPC6 as being a key player in the response, suggesting a unique role of this ion channel in mediating circulating factor disease, and a direct therapeutic target.

A Novel Insulin Sensitizer Targeting Nuclear Receptor PPARγ Provides Beneficial Effects in a Glomerular Disease Model

Galen Rask,[1] Amanda P. Waller,[1] Bryce A. Kerlin,[1,2] Francisco R. Neves,[3] Shipra Agrawal.[1,2] *[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]Universidade de Brasília, Brasilia, Brazil.*

Background: Thiazolidinediones (TZDs) are nuclear receptor peroxisome proliferator-activated receptor γ (PPARγ) agonists traditionally used to treat type II diabetes due to their insulin-sensitizing effects. These have recently been demonstrated to be beneficial in protecting podocytes and reducing proteinuria in glomerular disease. Since these FDA-approved drugs are associated with adverse effects such as weight gain, edema, bone loss and increased risk for heart failure and bladder cancer, we hypothesized that disparate beneficial vs. adverse molecular activities of PPARγ can be modulated. We determined if GQ-16, a novel insulin sensitizer and a partial PPARγ agonist, which de-phosphorylates PPARγ at Ser273 like other TZDs, provides therapeutic advantage in glomerular disease.

Methods: The studies were approved by the Institutional Animal Care and Use Committee at Nationwide Children's Hospital. Proteinuria was induced in male Wistar rats by single intravenous puromycin amino-nucleoside (PAN) injection, while the control group received saline. PAN-injected rats received sham vehicle, pioglitazone (Pio) or GQ-16 by oral gavage daily (n = 7/group). The rats were weighed daily, and urine samples were collected and analyzed for proteinuria. Plasma with sodium citrate and corn trypsin inhibitor was collected from the inferior vena cava. Endogenous thrombin potential was determined by thrombin generation assay.

Results: PAN induced robust proteinuria (P=0.009) on Day 11 and Pio reduced PAN-induced proteinuria significantly with 63.3% mean reduction (P=0.038). Interestingly, GQ-16 reduced proteinuria even further by 81.2% (P=0.008), and these were comparable to healthy control levels (ns, P=0.66). Furthermore, proteinuria reduction correlated with correction of disease associated hyper-coagulopathy. GQ-16 improved PAN-induced hyper-coagulopathy as measured by improved endogenous thrombin potential and peak thrombin. No significant differences in body weights were observed in treatment vs. PAN groups.

Conclusions: GQ-16, a novel insulin sensitizer and partial PPARγ agonist, shows better efficacy profile in an experimental glomerular disease model than Pio, a traditional TZD with full PPARγ agonistic activity.

Tropomyosin Isoforms Play a Role in Healthy and Injured Kidney Podocytes

Dina Hammad, Jeffrey H. Miner, Hani Suleiman. *Washington University in Saint Louis School of Medicine, Saint Louis, MO.*

Background: The podocytopathies are a group of glomerular diseases that affect the kidney's ability to filter the blood, and often lead to kidney failure. Healthy podocytes cover the glomerular capillaries with thousands of extensions called foot processes that interdigitate with one another and maintain their elaborate cell shape by tightly regulating their actin cytoskeleton. Podocytes respond to insults in a typical fashion by undergoing foot process effacement (FPE), a dramatic shift in podocyte morphology and the disappearance of the intricate foot processes. Tropomyosins (Tpms) are coiled-coil dimers that form co-polymers along actin filaments and change the filaments' biophysical properties. Over 40 different Tpm isoforms have been identified as the gene products of 4 *Tpm* genes: *Tpm1, 2, 3* & *4*. Various Tpm isoforms target to different locations inside cells and change the type of actin cables assembled in those locations. We hypothesize that podocyte shape is controlled by a specific set of Tpm isoforms that regulate actin cytoskeletal dynamics. Changing the tropomyosin isoforms after injury might be linked to changing podocyte shape and the FPE phenomenon.

Methods: To test our hypothesis, we used RT-PCR and RNAseq (Illumina and PacBio) to identify the whole array of Tpm isoforms that are enriched in podocyte and in isolated healthy glomeruli. Using different mouse models for podocyte injury (i.e., *Cd2ap* KO, *Lamb2* KO, *Col4a3* KO & Adriamycin-nephropathy (AdrN)), we identified a change in Tpm isoforms in the glomeruli isolated from these mice.

Results: RNAseq results from WT glomeruli show a different pattern of Tpm expression than the injured glomeruli counterparts, with the most significant changes occurring in Tpm 1.7 & Tpm 3.4. PacBio data also showed an interesting novel Tpm-related gene product only in injured glomeruli. We isolated RNA from WT and AdrN glomeruli and compared them to primary podocytes taken from podocyte-specific translating-ribosome-affinity-purification ("TRAP") mice. This system allowed us to purify podocyte mRNA for RNAseq, away from that in other glomerular cell types. Comparing the isolated RNA from WT-TRAP & AdrN-TRAP mice, we are able to identify the podocyte-specific Tpm isoforms that are associated with injury.

Conclusions: This study suggests roles for tropomyosin isoform changes in regulating podocyte shape in health and injury conditions.

IRE1α Is Essential for Podocyte Proteostasis and Mitochondrial Health

José R. Navarro-Betancourt,[1] Joan Papillon,[1] Julie Guillemette,[1] Takao Iwawaki,[2] Andrey V. Cybulsky.[1] *[1]McGill University, Montreal, QC, Canada; [2]Kanazawa Medical University, Kahoku-gun, Japan.*

Background: Glomerular epithelial cell (GEC)/podocyte proteostasis is disrupted in glomerular diseases. To maintain proteostasis, the endoplasmic reticulum (ER) orchestrates the unfolded protein response (UPR), which includes upregulation of chaperones and clearance of misfolded proteins via autophagy. Inositol requiring enzyme-1α (IRE1α) resides in the ER membrane and is a transducer of the UPR. This study characterizes the mechanisms by which IRE1α regulates proteostasis in GECs.

Methods: Mice with podocyte-specific deletion of IRE1α (IRE1α KO) were produced by breeding IRE1α flox/flox mice with mice expressing podocin-Cre recombinase. Nephrosis was induced with a single injection of adriamycin (ADR). GECs were cultured from glomeruli of IRE1α flox/flox mice and IRE1α was deleted by transduction of Cre recombinase. Cellular oxygen consumption rate (OCR) was quantified using the Seahorse mitochondrial stress test. Mitochondria were visualized using MitoTracker Red CMXRos or MitoTracker Green FM.

Results: Podocyte-specific IRE1α KO mice had greater ADR-induced albuminuria compared to control littermates. ADR increased expression of ER chaperones in glomeruli of control mice, but this upregulation was impaired in IRE1α KO mice. Autophagy induction was blunted in ADR-treated IRE1α KO animals, evidenced by reduced LC3-II and increased p62 levels, compared to treated controls. Electron microscopy showed prominent swelling of the ER and mitochondrial injury in podocytes of ADR-treated IRE1α KO mice. In cultured GECs incubated with tunicamycin (TM), deletion of IRE1α or chemical inhibition of the IRE1α RNase with 4μ8C attenuated upregulation of ER chaperones and LC3 lipidation compared to control. LC3 transcription and total LC3 protein levels were also reduced in TM-treated IRE1α KO GECs. Compared to control, IRE1α KO GECs showed decreased maximal and ATP-linked OCR. Mitochondrial membrane potential was lower in IRE1α KO GECs than in control, while total mitochondrial mass was similar in both groups. Inhibition of IRE1α signaling increased ER stress-induced apoptosis.

Conclusions: Stress-induced chaperone production, autophagy and mitochondrial health are compromised by deletion of IRE1α. The IRE1α pathway is cytoprotective in glomerular disease associated with podocyte injury and ER stress.

Studying the Pathogenesis of Congenital Nephrotic Syndrome Using NPHS2 Mutant Kidney Organoids

Aude Dorison,[1] Sara E. Howden,[1,2] Thomas A. Forbes,[1,3] Irene Ghobrial,[1] Melissa H. Little.[1,4] Kidney Development, Disease and Regeneration *[1]Murdoch Children's Research Institute, Melbourne, VIC, Australia; [2]Department of Anatomy and Neuroscience, The University of Melbourne, Melbourne, VIC, Australia; [3]Department of Nephrology, Royal Children's Hospital, Melbourne, VIC, Australia; [4]Department of Paediatrics, The University of Melbourne, Melbourne, VIC, Australia.*

Background: Nephrotic syndrome (NS) is one of the most common forms of renal disease in children. NPHS2 mutations are the most common cause of congenital NS with missense NPHS2 mutations reported to result in misfolding and mistrafficking of the encoded slit-diaphragm protein, Podocin. Such studies overexpressed mutant protein in immortalised podocyte and non-podocyte cell lines, which may not reflect the *in vivo* consequences of the mutant protein. Here we generated NPHS2 mutant iPSC-derived kidney organoids as a model to dissect the pathogenic process.

Methods: We have simultaneously reprogrammed and CRISPR/Cas9 gene edited a control human fibroblast line, generating 3 iPSC lines containing mutations of the endogenous NPHS2 locus as well as a control wild type (WT) line. These include the sequence variants c274G>T, c353C>T and c503G>A leading to the protein changes G92C, P118L and R168H respectively. Control and mutant lines were used to generate

kidney organoids containing all nephron segments. Podocin localisation was assessed using immunofluorescence together with known markers of subcellular compartments.

Results: Podocin protein was evident in the glomeruli of all organoids, however all mutant lines revealed a marked reduction of the Podocin protein. While the G92C mutant protein co-localised with Nephrin at the plasma membrane, the R168H mutant protein displayed a punctate perinuclear staining suggesting of Golgi retention, together with peripheral co-localisation with the early endosome marker EEA1. Interestingly, the R168H mutant was previously predicted to mislocalise in the endoplasmic reticulum (ER). The P118L mutant was previously predicted to accumulate in the ER and present a transmembrane localisation in cell lines. This mutant protein was observed both in ER and cytosol in kidney organoids. Finally, all 3 mutants displayed significantly more apoptotic podocytes as evidenced by an increased cleaved-Caspase3 staining in glomeruli compared to the control WT line.

Conclusions: Discrepancies between mutant protein localisations in previous reports and our kidney organoids highlight the need for a more appropriate model to study the pathobiology of NPHS2 mutations. These organoids will allow us to explore approaches to rescue individual Podocin defects, ultimately guiding the development of therapeutic strategies for such patients.

PO1995

OASIS in Podocytes Promoted Tubular Injury by Suppressing PRKCI Expression

Yoshiaki Miyake,[1] Masanori Obana,[1] Ayaha Yamamoto,[1] Takeo Harada,[1] Takafumi Nakae,[1] Shunsuke Noda,[1] Sayuri Mitsuoka,[1] Koki Tanaka,[1] Shota Tanaka,[1] Makiko Maeda,[1] Kazunori Imaizumi,[2] Katsuhiko Asanuma,[3] Yasushi Fujio.[1] *[1]Osaka University, Suita, Japan; [2]Hiroshima Daigaku, Higashihiroshima, Japan; [3]Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan.*

Background: Old astrocyte specifically induced substance (OASIS), a transcription factor, plays important roles in physiological and pathophysiological processes, such as bone formation. Previously, we found that OASIS is expressed in podocytes in murine kidney. However, the pathophysiological roles of OASIS in podocytes remains unknown. The aim of this study is to investigate the functional roles of OASIS in podocytes in the development of kidney diseases.

Methods: The expression of OASIS protein was investigated in glomeruli of murine kidney and cultured mouse podocytes cell line after lipopolysaccharide (LPS) treatment. To examine the roles of OASIS in podocytes on kidney injury, podocyte-specific OASIS knockout (OASIS CKO) mice were established and subjected to LPS. Twenty-four hours after LPS treatment, serum creatinine and urinary albumin ratio were measured. Podocytes injury was assessed by electron microscope analysis and tubular injury was analyzed by PAS staining and by measuring LCN2 mRNA expression. To explore the secretory molecules downstream of OASIS, DNA microarray analysis was performed using podocytes with lentiviral overexpression of OASIS. In order to examine the effects of the downstream molecule of OASIS on proximal tubule cells, HK-2 cells were cultured.

Results: LPS treatment increased OASIS expression in glomeruli of murine kidney and in cultured podocytes. Podocyte-specific *OASIS* deletion suppressed LPS-increased serum creatinine (sCr) level (sCr (mg/dL): control-LPS; 1.01±0.27, OASIS CKO-LPS; 0.76±0.16, n=8-10, $p<0.05$), but did not influence albuminuria and podocyte injury. Surprisingly, on the other hand, OASIS CKO mice were protected from LPS-mediated tubular injury. DNA microarray analysis using OASIS-overexpressed podocytes revealed that PRKCI was negatively regulated by OASIS in podocytes. Finally, we found that recombinant PRKCI suppressed LPS-induced LCN2 mRNA expression in HK-2 cells in a dose-dependent manner.

Conclusions: Suppression of OASIS in podocytes attenuated LPS-induced tubular injury in part by increased PRKCI secretion. Targeting OASIS-PRKCI signaling in podocytes could be of therapeutic value in kidney diseases.

PO1996

The Renal Risk Variants of Apolipoprotein L-1 Lead to an Influx of Sodium and Calcium That Drive Cytotoxicity

Joseph A. Giovinazzo,[1] Russell P. Thomson,[1] Nailya Khalizova,[1] Patrick J. Zager,[2] Ryan Schreiner,[2] Jayne Raper.[1] *[1]Hunter College, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Background: Apolipoprotein L-1 (APOL1) is an innate immunity gene that protects against protozoan parasites. Recently evolved variants, G1 and G2, provide increased immunity against African trypanosomes while increasing the risk of chronic kidney disease. There is little consensus on how these renal risk variants (RRVs) lead to cell death or kidney disease, or which pathways to target for drug development. As APOL1 kills trypanosomes by forming cation channels, and because many of the pathways associated with the RRVs are linked to pore-forming toxins, we hypothesize that a similar mechanism is involved in kidney disease. In this study, we performed a series of experiments to delineate the events leading up to RRV-mediated cell death.

Methods: Stable cell lines were generated to express the RRVs and non-toxic G0 variant of APOL1. We also generated constructs using the retention using selective hooks system (RUSH) to control the trafficking of APOL1. Live-cell fluorescent microscopy was performed to measure the influx of cations Ca^{2+} and Na^{+} with GCaMP6f and FliCR sensors (membrane voltage), respectively. Confocal imaging was performed to test APOL1 localization. Ion reduction experiments were performed to test the effect of each ion on cell death. Finally, planar lipid bilayers were used to test for APOL1 channel selectivity.

Results: We discovered that in addition to K^{+} and Na^{+}, the APOL1 channel is permeable to Ca^{2+}. The RRVs led to an influx of Ca^{2+} and Na^{+} that preceded cell swelling and lysis by several hours. These events required RRV trafficking out of the ER and to the plasma membrane, where they localized prior to cation flux. Reduction of Ca^{2+} and Na^{+} in the media inhibited RRV-mediated cell death. We also found that the previously reported high K^{+} media protects against the RRVs due to a lack of Na^{+}.

Conclusions: We report that the earliest event in RRV-mediated cytotoxicity is localization to the plasma membrane, followed by cation flux driven by Ca^{2+} and Na^{+}. Because many of the proposed models of RRV cytotoxicity and kidney disease can be activated by pore-forming toxins, we propose that the cytotoxic cation channels at the cell surface are the upstream even that links them together. Our data suggests that targeting RRV channel activity represents a promising avenue for drug development.

PO1997

Cloning of an IgG Autoantibody Specific for Phospholipase A2 Receptor (PLA2R) Using IgG-Producing Cells from a Patient with Membranous Nephropathy

Zhi qiang Huang,[1] Rodney G. King,[1] Barbora Knoppova,[1] Colin Reily,[1] Qi Bian,[1] Stacy D. Hall,[1] David J. Salant,[2] Laurence H. Beck,[2] Bruce A. Julian,[1] Jan Novak.[1] *[1]university of alabama at birmingham, Birmingham, AL; [2]Boston University Medical Center, Boston, MA.*

Background: Primary membranous nephropathy (MN) is a common autoimmune kidney disease, in which 70% of patients exhibit circulating autoantibodies to one or more conformational epitopes in PLA2R. Anti-B cell therapies have proved effective to decrease autoantibody production and limit further development of the glomerular subepithelial immune deposits of PLA2R and IgG. However, better characterization of anti-PLA2R autoantibodies is needed.

Methods: We used Epstein-Barr virus (EBV)-immortalized B cells isolated from peripheral blood from an anti-PLA2R seropositive MN patient to develop a protocol for the cloning and expression of recombinant IgG (rIgG) specific for PLA2R. A C-terminally His-tagged fragment consisting of the first 5 domains of human PLA2R was expressed in Expi293 system and affinity purified. B cells were enriched by incubation with biotin labeled reagents (recombinant PLA2R or IgG-specific antibody) and streptavidin-conjugated magnetic beads. A FITC-conjugated N-terminal PLA2R peptide was used to isolate B cells with antigen-specific B-cell receptor (membrane IgG) by FACS. Variable segments of IgG heavy (VH) and light (VL) chains were cloned through a single-cell workflow that allowed expression of rIgG for follow-up screening using an in-house ELISA to assess IgG binding to human PLA2R. Sera from anti-PLA2R seropositive MN patients and healthy controls served as positive and negative controls, respectively.

Results: Starting with $1x10^{8}$ EBV-immortalized cells, we first isolated $3.6x10^{5}$ cells with membrane IgG specifically reactive with non-reduced PLA2R. This subpopulation was next stained with FITC-conjugated PLA2R peptide and the corresponding VH and VL of IgG were cloned using our single-cell workflow. We expressed the cloned VH and VL as rIgG in Expi293 system. ELISA confirmed that the rIgG bound PLA2R.

Conclusions: This is the first report of cloning a PLA2R-specific IgG autoantibody from a patient with MN. These approaches can be used for further characterization of the molecular mechanisms of autoimmunity and epitope spreading in MN.

PO1998

Pharmacologic Blockade of the Natriuretic Peptide Clearance Receptor Ameliorates Glomerular Disease in an Animal Model of FSGS

Liming Wang,[1] Yuping Tang,[1] Anne Buckley,[1] Robert F. Spurney.[1,2] *[1]Duke University, Durham, NC; [2]Durham VA Medical Center, Durham, NC.*

Background: Glomerular podocytes play a key role in glomerular disease processes. Accumulating evidence suggests that cGMP signaling has podocyte protective effects in kidney diseases (J Am Soc Nephrol 28: 260, 2017). cGMP is produced by nitric oxide and by natriuretic peptides (NPs). NPs are the predominant source of cGMP generation in podocytes. NPs stimulate cGMP production by binding to NP receptors (NPRs). NPRA and NPRB stimulate cGMP generation. In contrast, NPRC binds and degrades NPs. Podocytes express all three NPRs (NPRA, NPRB, and NPRC). We hypothesized that blockade of NPRC would enhance local NP levels, promote cGMP signaling in podocytes and attenuate glomerular injury.

Methods: We blocked clearance of NPs by NPRC using the pharmacologic agent ANP (4-23), which specifically binds NPRC without binding NPRA or NPRB. For the experiments, we used a mouse transgenic (TG) model of focal segmental glomerulosclerosis (FSGS) created in our laboratory (J Clin Invest 125:1913, 2015). These TG mice express a constitutively active Gq α-subunit specifically in podocytes. In these animals, treatment with a single dose of the podocyte toxin puromycin aminonucleoside (PAN) causes robust albuminuria in TG mice, but only mild disease in non-TG animals.

Results: PAN induced heavy proteinuria in vehicle-treated TG mice at day 14 (1426 ± 425 [day 14] vs. 49 ± 19 [baseline] ug/mg creatinine; $P = 0.0002$). The increase in albuminuria at day 14 was significantly reduced by treatment with ANP(4-23) (1426 ± 425 [vehicle] vs. 383 ± 157 [ANP(4-23)] ug/mg creatinine; $P = 0.003$). Treatment with ANP(4-23) also tended to reduce the number of mice with glomerular injury (83% [vehicle] vs 54% [ANP(4-23)]; P = NS). Systolic BP was similar in mice receiving ANP(4-23) and in the vehicle treated group (129 ± 3 [vehicle] vs. 127 ± 3 [ANP(4-23)] mm Hg; P = NS). Urinary cGMP excretion tended to be higher in ANP(4-23) treated mice (6.7 ± 1.0 ng/mg creatinine) compared to mice treated with vehicle (4.9 ± 1.0 ng/mg creatinine), but this difference was not statistically significant.

Conclusions: These data suggest that: 1. Pharmacologic blockade NPRC may be a useful strategy for treating proteinuric kidney diseases, and 2. Treatment outcomes might be improved by optimizing blockade of the NPRC to more effectively inhibit clearance of NPs from the circulation.

PO1999

Mitochondrial Damage in FSGS due to ANLN Mutation

Brandon M. Lane,[1,2] Guanghong Wu,[2] Megan Chryst-Stangl,[2] Gentzon Hall,[3,2] Rasheed A. Gbadegesin.[1,2] *[1]Department of Pediatrics, Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Department of Medicine, Duke University School of Medicine, Durham, NC.*

Background: We previously identified *ANLN R431C* as a cause of focal segmental glomerulosclerosis (FSGS). In addition to defects in actin bundling, targeted evaluation of this variant in cultured human podocytes identified disruption of AKT/mTOR signaling as a cause of ER stress and reduced podocyte viability. Creation of the orthologous *R431C* point mutation in mice confirmed the increased podocyte ER stress and identified mitochondrial damage as another possible feature of disease. To gain an unbiased view of the molecular mechanisms driving *ANLN R431C* induced disease, we used transcriptomic analysis and automated live cell imaging to interrogate cultured human podocytes.

Methods: Conditionally immortalized human podocytes overexpressing wildtype *ANLN* or the *R431C* variant were evaluated by mRNA-Seq and smRNA-Seq analysis to identify differentially expressed genes and microRNAs, as well as the molecular pathways involved. Potential therapeutic strategies were examined by evaluating cultured podocyte cellular and organelle-specific viability using automated live cell imaging.

Results: The top differentially expressed genes encode molecules that interact with previously identified pathological mechanisms including F-actin bundling (*SYNPO2L*) and AKT/ mTOR signaling (*CAVIN3, KIT*), with mTOR signaling identified as a pathway likely to be affected by *ANLN R431C*. A common feature of the top differentially expressed gene and microRNA candidates is the potential to regulate mitochondrial viability. When evaluated for changes in mitochondrial membrane potential, *ANLN R431C* podocytes displayed increased susceptibility to mitochondrial damage that could be rescued by treatment with AKT/mTOR pathway inhibitors. Additionally, compounds targeting improved mitochondrial viability through increased bioenergetic function (AP39), reduced oxidative stress (MitoQ, MitoTEMPO) and prevention of pore opening (Olesoxime) could all rescue the increased susceptibility to apoptosis *in ANLN R431C* podocytes.

Conclusions: Unbiased transcriptomic analysis confirmed that *ANLN R431C* disrupts AKT/mTOR signaling and actin cytoskeletal dynamics, resulting in increased ER stress and mitochondrial damage that reduce podocyte viability. Targeting various aspects of mitochondrial regulation may present viable alternative treatment strategies for FSGS due to defects in *ANLN* gene.

PO2000

Prothrombin Modulates Podocyte Health and Function During Glomerular Proteinuria

Amanda P. Waller,[1] Katelyn Wolfgang,[1] Tasha K. Wilkie,[1] Sagar Bhayana,[1] Kyle Davis,[1,2] William E. Smoyer,[1,2] Bryce A. Kerlin.[1,2] *[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH.*

Background: Ongoing podocyte injury is a known critical determinant of glomerular disease progression. Recent research suggests thrombin exacerbates *in vitro* podocyte injury, however, pharmacologic manipulation may cause both on- and off-target effects. Thus, the purpose of this study was to directly examine the effects of thrombin on glomerular proteinuria by manipulating its zymogen precursor, prothrombin (**PT**). We hypothesized that circulating PT would directly modulate both podocyte function and *in situ* survival in a rat model of nephrotic syndrome.

Methods: Puromycin aminonucleoside (PAN)-induced proteinuria was treated with: 1) PT antisense oligonucleotide to induce hypoprothrombinemia (LoPT), 2) Serial i.v. PT infusions to sustain hyperprothrombinemia (HiPT), or 3) sham (PAN only) controls (Con; n=12/group). Morning spot urine and citrated plasma were collected at day 10 post-PAN. Plasma PT activity was measured by chromogenic kit. Glomeruli were isolated from the kidney, dissociated into single-cell suspension and analyzed by flow cytometry following immunofluorescent antibody and TUNEL staining.

Results: Circulating plasma PT levels (**Figure A**) modulated proteinuria (**B**) such that it was significantly decreased in LoPT and increased in HiPT, compared to Con. LoPT also decreased *in situ* podocyte death (**C**), while HiPT increased *in situ* podocyte death, and resulted in fewer podocytes per glomerulus (**D**).

Conclusions: In conclusion, prothrombin modulates podocyte function (proteinuria) and survival (death and numbers) in the PAN model of glomerular proteinuria. Future studies should work to determine the prothrombinase mechanism that enables thrombin formation and signaling in the glomerulus and evaluate its potential as a novel therapeutic target to slow glomerular disease progression toward chronic kidney disease.

Funding: NIDDK Support

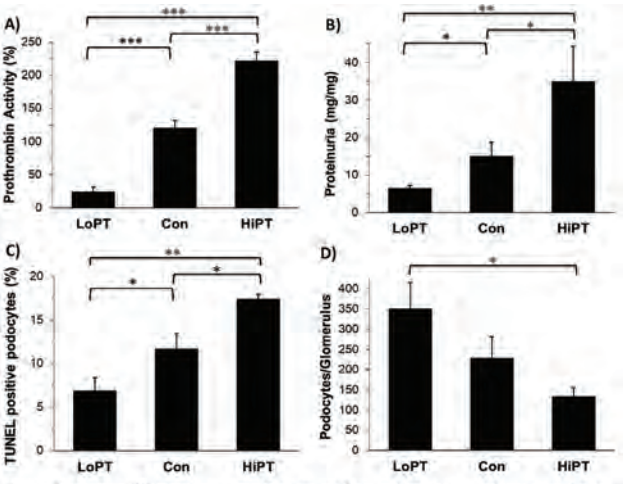

Figure: Prothrombin (PT) modulates podocyte health and function during glomerular proteinuria. Graphs depicting mean ± SE of **A)** plasma PT activity, **B)** proteinuria, **C)** TUNEL positive podocytes, and **D)** count of podocytes per glomerulus, in rats with glomerular proteinuria treated with i) an antisense oligonucleotide to knockdown circulating PT (**LoPT**), ii) serial PT i.v. infusions to induce hyperprothrombinemia (**HiPT**), or iii) sham (**Con**) (n=12/group). *; P<0.05, **; P<0.01, ***;P<0.001.

PO2001

Exosomal Long Non-Coding RNA-G21551 as a Potential Predictive Biomarker for Segmental Sclerosis Change in IgA Nephropathy

Qianqian Han, Jiajia Li, Xiaona Wei, Peifen Liang, Qiongqiong Yang. *Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Guangzhou, China.*

Background: Segmental sclerosis (S) is an independent pathological predictor for renal progression in IgAN patients, and is closely related to proteinuria. However, there is less invasive biomarker for pathological S change. We investigate the difference in expression profiles of exosomal long non-coding-RNAs (lncRNAs) in plasma from IgAN patients compared with their healthy first-degree relatives, then explore the possible lncRNA associated with S.

Methods: To isolate exosomes from the plasma of both IgAN patients and their healthy first-degree relatives. High-throughput RNA sequencing and real-time quantitative polymerase chain reaction (qRT-PCR) was used to validate lncRNA expression profiles. Target lncRNAs were selected by bioinformatics analysis. The relationship between target lncRNA and S was analyzed by Spearman correlation. ROC curve evaluated the area under curve (AUC) of the target lncRNA for diagnosis S and its predictive sensitivity and specificity.

Results: 18 pairs of IgAN patients and their healthy first-degree relatives were enrolled in this study. The mean age was 29.71±6.06 years and urinary protein was 1.00±0.63 (g/24h) in these IgAN patients. LncRNA-G21551 was significantly down-regulated in IgAN patients. The predicted target genes of lncRNA-G21551 are FCGRs, which encode family of Fc gamma receptors (FcγRs). S was observed in 12 IgAN patients (66.7%) and was positively correlated with lncRNA-G21551 relative expression (r=0.545, *P*=0.019), but had no correlation with proteinuria, blood pressure, mesangial hypercellularity(M), endocapillary proliferation(E), tubulointerstitial fibrosis (T) and crescent(C). The relative expression (fold change) of lncRNA-G21551 was significantly higher in S1 group than in S0 group (11.26(9.79,20.38) *vs* 7.04(1.39,11.00), P=0.025). The AUC of lncRNA-G21551 to predict S change was 0.81(95% confidence interval, 0.62~1.00) with a sensitivity of 83.3% and a specificity of 83.3% when a cutoff value of 9.58 was used for lncRNA-G21551 relative expression (Fold change). In addition, patients with higher lncRNA-G21551 relative expression had more severe podocyte injury.

Conclusions: Exosomal lncRNA-G21551 was down-regulated in IgAN patients, but positively correlated with S change. Exosomal lncRNA-G21551 may be a potential independent predictor for S lesion in IgAN patients.

PO2002

Analysis of the Relationship Between Proteasome and Autophagy in Podocytes Using Podocyte-Specific Proteasome Impairment Mice

Shinichi Makino,[1] Hiroyuki Yamada,[1] Ika N. Kadariswantiningsih,[1] Maulana A. Empitu,[1] Motoko Yanagita,[2] Katsuhiko Asanuma.[1] *[1]Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan; [2]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan.*

Background: Ubiquitin-proteasome system and autophagy-lysosome system are major intracellular protein degradation mechanism. The relationship of these systems in podocyte has not well been understood.

Methods: In this study, we generated podocyte-specific proteasome impaired mice (Rpt3pdKO) by deletion of Rpt3, which is essential for construction of 26S proteasome, using Cre-loxP system. Albuminuria and number of sclerotic glomeruli increased in the Rpt3pdKO mice compared with Rpt3control mice. Oxidative stress and podocytes apoptosis were related to podocyte injury. To evaluated autophagic activity, LC3 dots

in podocytes were evaluated after administration of chloroquine, inhibitor of autophagic flux. In vitro experiment, cultured podocytes were treated with bortezomib (BTZ), proteasome inhibitor, which lead to podocyte apoptosis. The expression of LC3 was evaluated in podocytes after administration of bortezomib in the presence of E64d/pepstatinA, inhibitor of autophagic flux.

Results: In vivo, after administration of chloroquine, LC3 dots decreased in podocytes of Rpt3pdKO mice compared with Rpt3control mice. In vitro, the expression of LC3 decreased and the accumulation of p62 increased in cultured podocytes after treatment of BTZ in the presence of E64d/pepstatinA. These results indicated autophagic activity was suppressed in podocytes with proteasome impairment. pULK1, which is a down stream of mTOR signal, was phosphorylated in podocytes with proteasome impairment, suggested that suppression of autophagic activity was associated with mTOR activation. Pre-treatment of rapamycin, inhibitor of mTOR, ameliorated podocyte apoptosis induced by BTZ in vitro. In vivo, the number of sclerotic glomeruli decreased in Rpt3pdKO mice with rapamycin administration compared with in Rpt3pdKO mice without rapamycin administration.

Conclusions: Impairment of proteasome suppressed autophagic activity associated with mTOR activation in podocytes. Activation of autophagy have the protective effect on podocyte injury due to proteasome impairment.

PO2003

Functionally Resolving *WT1* Variants of Uncertain Significance in Nephrotic Syndrome

Jennifer Lai Yee,[1] Xiaoyan Jia,[1] V. Vega-Warner,[1] Matt G. Sampson,[2] Jacob O. Kitzman.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Boston Children's Hospital, Boston, MA.*

Background: Patients with Mendelian forms of nephrotic syndrome (NS) are likely to progress to end stage kidney disease. Because of the increased availability and promise to guide clinical decision, genetic screening among affected patients is proliferating. However, accurate attribution of pathogenicity to rare variants found during genetic screening remains challenging. *WT1* is the second most common gene causing Mendelian NS. Therefore, this project aims to develop a model system to test the transcriptional activity of *WT1* variants, as a first step towards high-throughput functional analysis to comprehensively classify variants in this key NS gene.

Methods: Wild-type and several bona fide pathogenic *WT1* variants were tested for transcriptional activity in a standard dual-luciferase assay. Several cell lines including HeLa, HEK293, and HK2, were co-transfected with variant or wild-type *WT1* and an *NPHS1* promoter luciferase vector. Furthermore, potential *WT1* target genes specific to HEK293 cells were identified by analyzing differential gene expression in RNA-Seq data of *WT1* over-expressing HEK293 cells, in order to identify additional *WT1*-responsive promoters for use as *WT1* activity reporters.

Results: Overexpression of wild-type *WT1* in HeLa cells and HEK cells increased expression of luciferase under the *NPHS1* promoter by ~2-fold relative to truncated *WT1*. The luciferase activity of bona fide pathogenic WT1 variants was also significantly lower than the wild-type *WT1* and bona fide benign *WT1* variants ($P<0.05$). Overexpression of wild-type *WT1* in HEK293 resulted in upregulation (log2 fold change>0.4, adjusted $p<0.05$) of *IGF1R*, *EGFR*, *TGFB2*. These candidates are being developed as *WT1*-responsive reporters.

Conclusions: Previous reports suggested *NPHS1* promoter reporters as a model system to investigate mutant *WT1* function. However, the transcriptional effect of *WT1* was subtle and may be cell specific. Future work to establish a robust *WT1* reporter is ongoing using cloned *IGF1R*, *EGFR*, *TGFB2* promoters.

Sources of Variability in Podocyte Foot Process Width Measurements and Approaches to Mitigation

Molly Geraghty,[1] Morgan P. Thompson,[1] Donal Gorman,[2] Hui Chen,[1] Kondala R. Atkuri,[2] Stephen Berasi,[2] J. B. Copley,[2] Joel M. Henderson.[1] *[1]Boston Medical Center, Boston, MA; [2]Pfizer Inc, New York, NY.*

Background: Podocyte foot process (FP) morphometry is used in the research setting to quantify podocyte injury and has the potential to be leveraged for diagnostic use. However, the impact of pre-analytic and analytic variables on these measurements are not well understood. We sought to identify these sources of variability and develop a robust method for podocyte foot process width (FPW) measurement within various kidney diseases.

Methods: We examined the impact of operator bias and sample size on FPW measurement in electron micrographs from nephrectomies (Nx) and podocytopathy (Px) cases, including primary focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD), and other glomerular lesions effecting the podocyte. FPW was measured for each individual FP between the midpoints of flanking filtration slits and the geometric mean of these measurements was reported by image. We found that identification of filtration slits was subjective, but interoperator variability was mitigated through use of standardized morphologic criteria, operator training, adjudication of ambiguous features, and a mapping process that eliminated duplicate measurements in adjacent images. These methods reduced interoperator variability in FPW, averaged by image, from 12% to 7%.

Results: Preliminary analysis suggests that, in addition to the expected larger FPW mean in MCD cases vs. Nx cases, there is also larger FPW *variability* in MCD cases. Related analysis shows ~125 FPW measurements within each of 2 glomeruli (~250 total) in a Nx case has the same precision as ~100 FPW measurements in each of 10 glomeruli (~1,000 total) in a MCD case. We also found that intraglomerular variability among 3 glomeruli in each of 2 cases (1 Nx, 1 MCD) ranged from 29% to 46% (Geometric CV), whereas interglomerular variability within these cases ranged from 0.5% to 6.3%, signifying that number and selection of FP within glomeruli is more impactful than number and selection of glomeruli within a specimen.

Conclusions: Our results suggest that careful measurement standardization and sampling improves validity of FPW measurements as a supplement to other diagnostic approaches or for assessment of podocyte injury in the course of treatment.

Glomerular Transcriptomic Analysis of Glucocorticoid- and Pioglitazone-Treated Nephrotic Syndrome

Sagar Bhayana, Shipra Agrawal, Melinda A. Chanley, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Bryce A. Kerlin, William E. Smoyer. *Nationwide Children's Hospital, Columbus, OH.*

Background: Nephrotic Syndrome (NS) is among the most common glomerular diseases in children. Glucocorticoids (GC) are the primary treatment for NS, but 15-20% of children have or develop steroid resistant NS, creating an unmet need for novel treatments. Thiazolidinediones (TZDs) such as pioglitazone (Pio) have been reported to slow diabetic nephropathy progression, and to reduce proteinuria in animal models of NS. Since both GC and Pio act via binding to nuclear receptors we hypothesized that the reported similar degrees of proteinuria reduction by GC and Pio are driven via common molecular pathways.

Methods: We performed transcriptome analyses on glomeruli isolated from GC- and Pio-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Principal component analyses revealed distinct transcriptional profiles between control vs. PAN-treated rats, with 319 and 126 differentially up- and down-regulated genes in PAN respectively, which were largely reversed by both GC and Pio. Ingenuity pathway analyses (IPA) combined with drug-target interaction network analyses and gene set enrichment analyses identified 29 glomerular genes that were commonly regulated by GC, Pio, and their respective nuclear receptors (NR3C1 and PPARγ). Gene ontology annotation revealed these 29 genes to be involved in: ECM modification, plasma membrane dynamics, DNA damage/repair, transcription factor binding, lipid metabolism, and cytoskeletal organization. Gene segregation into their cells of origin using reported glomerular single cell transcriptomes revealed most dysregulation and restoration of gene expression within podocytes, with moderate changes within mesangial cells and minimal changes within endothelial cells. IPA-based disease and toxicity algorithms developed from these cell-specific data also revealed enhanced cytoskeletal organization and improved cell viability after both GC and Pio vs. PAN.

Conclusions: GC and Pio treatment reduced proteinuria similarly in NS, but by inducing alterations in both distinct and overlapping glomerular gene-sets. Notably, informatics analyses of overlapping genes identified ECM proteins, as potential novel targets for future therapies for NS, distinct from current immunosuppressive approaches.

Novel Podocyte Protective Compounds Identified Using Ultra-Miniaturized High-Content Screening (HCS) Assays

Manuel Noben,[1] Danish Qavi,[1] Shreyaa Khanna,[1] Ha Won Lee,[1] Mehmet M. Altintas,[1] Jochen Reiser,[1] Susanne Heynen-Genel,[2] Vineet Gupta.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.*

Background: Podocytes are specialized epithelial cells which are part of the filtration barrier in the kidney. Podocyte dysfunction is part of kidney pathology hallmarked by proteinuria. Using a high-content imaging based assay, we have shown that podocytes can be used to identify novel therapeutic compounds.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates. After 10-14 days of differentiation, cells were exposed to puromycin aminonucleoside (PAN, podocyte injury inducing agent), with compounds from the screening library or newly identified targets, or DMSO as control, for 48 hours. After, cells were fixed with 4% paraformaldehyde and permeabilized with 0.1% Triton X-100. Cells were labeled with cytoplasmic stain HCS CellMask Green, and actin fibers were detected by using labelled phalloidin. Cell images were taken with using Opera High-Content Screening (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. We utilized commercial libraries containing >50k unique compounds to identify podocyte protective hits.

Results: Using PAN as a podocyte damaging agent, we noticed marked reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes. Screening of a library of chemical compounds identified >25 hits which had favorable profiles.

Conclusions: Using our optimized podocytes high-throughput screening assay in 1536-well plates, we have identified a number of highly novel compounds. Further validation on smaller well formats reproduced these findings. In vitro and in vivo mechanistic studies provide new insights about podocyte pathways that can be therapeutically targeted.

The Role for FNBP1L in Podocytes

Qiaoli Tang, Lu Ren, Hui Song, Zhang Sipan, Zheng Tang, Shaolin Shi. *Jinling Hospital National Clinical Research Center of Kidney Diseases, Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China.*

Background: Podocytes exhibit a complex cellular morphology characterized by the formation of foot processes. The normal structure of podocytes depends on their unique cytoskeleton, of which actin microfilaments are one component. Nucleation of actin monomers is the rate limiting step in actin polymerization. There are two distinct nucleators for actin nucleation in podocytes, Arp2/3 complex and formins, which mediate branch and linear actin filament formations, respectively. Our previous study identified hundreds of genes expressed in every single podocyte, which were potential podocyte essential genes. Of them, FNBP1L is known to be involved in Arp2/3 complex and formins activity in nucleation, supporting FNBP1L's essentiality for podocytes. Here, we test this hypothesis.

Methods: Cultured podocytes were used for this study. FNBP1L was knocked down by siRNA, and immumostaining, immunoblotting, qPCR, wound healing assay, co-immunoprecipitation were performed to test FNBP1L essentiality and mechanism.

Results: FNBP1L was specifically expressed in podocytes in glomeruli, and its expression was decreased in purimycin aminonucleasides-treated in podocytes. When FNBP1L was knocked down, we found that the expression of WT1, SYNPO and CD2AP was decreased; that the migratory capability was impaired; that F-actin stress fibers were reduced and disorganized; and that focal adhesion number was decreased while their size increased as shown by p-FAK staining. Mechanistically, FNBP1L regulated Arp2/3 complex and INF2 (a formin) actin nucleation activities. Co-IP and IF showed that FNBP1L colocalized and interacted with CDC42 and N-WASP to facilitate interaction of N-WASP with Arp2/3 complex, thereby increasing the activity of Arp2/3 complex in actin nucleation. FNBP1L also interacted with INF2 and affected its localization in cytoplasm and its actin nucleation. Consistently, the reduction of FNBP1L impaired the interaction between N-WASP and Arp2/3 complex and mis-localized INF2 in the cytoplasm.

Conclusions: FNBP1L may regulate branched and linear actin filament polymerization by regulating Arp2/3 complex and INF2 actin nucleation activities in podocytes, thereby maintaining podocyte normal structure and function. Reduction of FNBP1L expression is involved in podocyte injury and targeting FNBP1L may represent a novel therapeutic approach for podocytopathies.

Role of ATE1 in Radiation-Induced Nephrotoxicity

Anis Ahmad,[1] Cameron Bader,[5] Saba Ansari,[1] Jumana Afaghani,[1] Sandra M. Merscher,[3] Alessia Fornoni,[3] Youssef Zeidan,[1,2] Robert B. Levy,[5] Brian Marples.[1,4] Radiation Oncology *[1]Department of Radiation Oncology, University of Miami, Miller School of Medicine, Miami, FL; [2]Department of Radiation Oncology, Anatomy, Cell Biology, and Physiology, American University of Beirut School of Medicine, Beirut, Lebanon; [3]Peggy and Harold Katz Family Drug Discovery Center and Division of Nephrology, Department of Medicine, University of Miami, Miami, FL; [4]Department of Radiation Oncology, University of Rochester Medical Center School of Medicine and Dentistry, Rochester, NY; [5]Department of Microbiology and Immunology, Miller School of Medicine, University of Miami, Miami, FL.*

Background: Arginylation increases actin polymerization and supports cellular morphology. However, the effect of radiation therapy (RT) on arginylation is not known. This study investigated the impact of RT on arginyltransferase 1 (ATE1) and its role in podocyte morphology and kidney function

Methods: Human podocytes were irradiated with 4 Gy, and preceded by rituximab mAb (100 μg/ml) or IgG (100 μg/ml) treatment, 30 min before RT. Additionally, 6-8-week-old C57BL/6 male and female mice were submitted to either (i) 1x14Gy bilateral kidney-only RT (ii) lethal-dose total body irradiation (TBI 10.5Gy) and rescued by strain-donor hematopoietic stem cell transplantation (HSCT) or (iii) left untreated (sham-RT control). Functional, histopathological, and biochemical changes were studied at baseline and 10 weeks post RT

Results: In podocytes, RT (4Gy) produced time-dependent downregulation of ezrin (30%) and ATE1 (50%) and a significant increase in apoptosis at 4h ($p=0.001$). Rituximab pretreatment protected from ezrin relocalization and ATE1 downregulation, and podocyte apoptosis. In C57BL/6 mice, RT significantly decreased glomerular surface area and increased mesangial expansion scores in 14Gy and TBI animals compared to controls ($p<0.01$). Similarly, both RT schedules resulted in significant increases in renal fibrosis ($p<0.01$), serum BUN ($p<0.01$), and serum creatinine levels ($p<0.01$). Western blot analysis showed downregulation of ATE1 in the kidney cortex: 67.7±9.6% (14Gy); 69.3±13.3% (TBI) compared to control. Similarly, IHC data showed a decrease in ATE1 expression in glomeruli after 14Gy (50%) and TBI (70%) compared to control. Podocyte number (WT1) in kidney cortex, also decreased significantly after both RT treatments. TEM showed that both RT schedules resulted in significant increases in GBM thickness when compared to control ($p<0.001$). Foot process width also increased significantly in 14Gy and TBI animals compared to controls ($p<0.001$)

Conclusions: Our study demonstrates that rituximab pretreatment protects from ATE1 downregulation and confers radioprotective effects in cultured podocytes. ATE1 may be an important therapeutic target for radiation-induced kidney injuries in HSCT patients

Podocyte Infolding Glomerulopathy: New Disease or Pattern of Injury?

Sri Vibhavari Guntupalli, Suzanne G. Martin. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Occasional podocyte infolding is reported in membranous nephropathy, but global and diffuse infolding is rare. Whether this is a new disease entity or a pattern of podocyte injury may influence therapy.

Case Description: 52 year-old-male with hypertension developed lower extremity edema, pleuritic chest pain and dyspnea. CT chest showed bilateral pulmonary emboli. Creatinine was 0.92 mg/dL, cholesterol 239 mg/dL, albumin 3.2 g/dL, urine protein:Cr ratio 32,647 mg/gCr. Renal biopsy showed immune complex deposition in a membranous pattern, and subepithelial deposits with targetoid microvesicular substructures, suggesting a podocyte infolding glomerulopathy (PIG) [Fig.1 Electron microscopy showing PIG]. Immune deposits were dominantly reactive for IgG4, and also for other IgG subclasses, C3, IgM, and kappa and lambda light chains. Deposits were reactive for PLA2R. Serum PLA2R antibody and other serologies were negative. He was anticoagulated and treated for 6 months with the modified Ponticelli protocol. Creatinine remains normal, but hypoalbuminemia and proteinuria (190mg – 1.2g) persist 8 months after starting treatment.

Discussion: In 1985, Dales and Wallace [1] described massive deposits of spherular organelles in the subepithelial space of glomerular capillary walls in a patient with membranous nephropathy. In 2008, Joh et al [2] studied 25 Japanese patients with microspheres and microtubular structures associated with podocyte infolding, coining the term "podocyte infolding glomerulopathy." Rare cases are reported in India, Latin America, and Europe. It is unclear whether PIG is a subtype of membranous nephropathy or a distinct glomerular lesion. Identification of PIG associated with vesicoureteral reflux, myeloma, and autoimmune diseases, and the absence of immune complexes in many biopsies, suggest a distinct type of podocyte injury. Ultimately, the pathophysiology of PIG is not understood. Response to therapy and prognosis are not well-described. This patient was treated with the modified Ponticelli protocol, given findings of membranous nephropathy, with a reduction in proteinuria but not full remission. This may represent a partial response to therapy or may imply that podocyte infolding glomerulopathy is a separate disease entity not responsive to immunosuppression.

PO2010

CKD Remodels Skeletal Muscle Metabolism Toward Carbohydrate Oxidation

Keith G. Avin,[1,2] Neal X. Chen,[2] Shruthi Srinivasan,[2] Meghan C. Hughes,[3] Thomas Oconnell,[2] Robert L. Bacallao,[2] Christopher G. Perry,[3] Sharon M. Moe.[2] *[1]Indiana University Purdue University at Indianapolis, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]York University, Toronto, ON, Canada.*

Background: Skeletal muscle health progressively declines from chronic kidney disease (CKD). To test the hypothesis that exercise mitigates abnormal muscle metabolism in CKD, we utilized high-resolution mitochondrial respiration and metabolomics techniques for indices of skeletal muscle carbohydrate and fat metabolism in a progressive CKD rat model.

Methods: *Animals-* 1) Cy/+ (CKD) rats, 2) CKD + wheel running, and 3) normal littermates (NL) (N=12/gr). Running wheel was accessible 24 hr/day 25-35 weeks of age; moderate to severe CKD, respectively. Extensor digitorum longus (EDL) and soleus were harvested at sacrifice. Mitochondrial respiratory subunit complexes were quantified by Western blot. *Mitochondrial respiration:* Measured in the presence of multiple substrates (Oxygraph-2k, Oroboros). *Metabolomics:* Targeted mass spectrometry (MS) and nuclear magnetic resonance (NMR) were performed.

Results: In the EDL, protein content of Complex 1 was reduced, but pyruvate-stimulated respiration increased with CKD wheel running. Metabolomic analysis (MS) of the EDL supported this, as wheel running lowered long-chain fatty acids (C14-18; $p<0.05$). In the soleus, Complex 1 content decreased and pyruvate-stimulated respiration increased in both CKD and CKD running compared to NL ($p<0.05$). Soleus MS demonstrated lower long-chain fatty acids (C14-18; $p<0.05$). Serum NMR demonstrated increased pyruvate and reduced lactate concentrations suggesting greater re-direction of pyruvate to mitochondrial oxidative phosphorylation. Carnitine levels were low in serum and muscle, suggesting impaired transport of fatty acids to the mitochondria.

Conclusions: These intriguing results indicate CKD impairs skeletal muscle mitochondrial oxidative capacity despite increased pyruvate oxidation. In addition, metabolomics data suggests impaired fatty acid oxidation that worsened with wheel running due to low carnitine levels. These results suggest dual alterations in response to mild exercise in CKD: 1- impaired fatty acid oxidation from deficient carnitine; 2- enhanced pyruvate oxidation consistent with lower lactate production. These cellular metabolic reprogramming events suggests that skeletal muscle may shift away from fatty acid metabolism towards carbohydrates which may explain why patients with CKD do not experience the usual benefit of exercise.

Podocyte-Derived Testican 2 Promotes In Vitro Glomerular Angiogenesis

Donghai Wen,[1] Debby Ngo,[3] Benjamin D. Humphreys,[2] Martin R. Pollak,[3] Robert Gerszten,[3] James G. Wilson,[3] Eugene P. Rhee.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Washington University in Saint Louis, Saint Louis, MO; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: In addition to their fundamental role in clearance, the kidneys release select molecules into the circulation, but whether any of these anabolic functions provides insight on kidney function is unknown.

Methods: Using aptamer-based proteomics, we characterized arterial (A) to renal venous (V) gradients for >1,300 proteins in 22 human individuals who underwent invasive sampling. To localize testican-2, immunohistochemistry, immunofluorescence, immunogold electron microscopy and single cell RNA sequencing in human kidney tissue were used. Functional effects of testican-2 were tested on cultured primary human glomerular endothelial cells (HGEC).

Results: Although most of the proteins that changed significantly decreased from A to V, consistent with renal clearance, several were found to increase, the most significant of which was testican-2 (V/A = 1.40, $P = 1.5 \times 10^{-9}$). Imaging and single cell RNA sequencing demonstrated testican-2 expression in human podocytes. Testican-2 promoted angiogenesis and migration in cultured HGEC, but not proliferation. Further, testican-2 upregulated MMP-2/MMP-9 activity in the culture media of HGEC.

Conclusions: Testican-2 is a circulating protein that is synthesized in the human podocyte. Testican-2 promotes angiogenesis in cultured HGEC, which may be mediated by upregulating MMP-2/MMP-9 activity and increased endothelial cell migration.

Funding: NIDDK Support

(**B**) Violin plot demonstrating podocyte-specific *SPOCK2* expression (encodes testican-2), with *NPHS2* as positive control. (**C**) Tube formation of primary HGECs treated with vehicle, testican-2, or VEGF.

PO2012

Mitochondrial Quality Control Mechanisms in Renal Cortex During the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Ishii,[1] Pamela K. Carmines,[2] Yoshifumi Kurosaki,[1] Akemi Imoto,[1] Hideki Ikenaga,[4] Masanori Yokoba,[1] Takafumi Ichikawa,[1] Tsuneo Takenaka,[3] Masato Katagiri.[1] *[1]Kitasato University, Sagamihara, Japan; [2]University of Nebraska Medical Center, Omaha, NE; [3]International University of Health & Welfare, Minatoku, Japan; [4]Seiikai, Tochigi, Japan.*

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria. Because accumulation of damaged mitochondria can contribute to renal dysfunction, we aimed to determine if oxidative stress in DM triggers 1) mitochondrial fission or fusion, 2) increased fatty acid metabolism, and/or 3) mitophagy as quality control mechanisms.

Methods: Rats receiving i.p. injection of streptozotocin (STZ, 65 mg/kg) or vehicle (Sham) were either left untreated or treated with telmisartan (TLM, an angiotensin receptor blocker; 10 mg/kg/d). Two weeks later, blood glucose levels (BG), blood pressure (BP), glomerular filtration rate, and urinary excretion of albumin and *N*-acetyl-β-D-glucosaminidase (NAG) were measured. The oxidative stress marker, 3-nitrotyrosine (3-NT), was detected by HPLC. Fission-, fusion-, and mitophagy-related proteins were quantified by Western blot. Levels of acylcarnitine, which transports fatty acids into mitochondria for β-oxidation, were calculated as the difference between total and free carnitine levels measured by the enzymatic cycling method using commercial kits.

Results: TZ rats displayed hyperglycemia and hyperfiltration that were unaffected by TLM. BP, albumin excretion, and NAG excretion were similar in all groups. Renal cortical 3-NT levels were increased in STZ rats, a change that was prevented by TLM (STZ+TLM). Renal cortical acylcarnitine levels in STZ rats were more than double those of Sham rats ($P<0.05$) and were further elevated in STZ+TLM rats ($P<0.05$ vs STZ alone). Renal cortex from STZ rats displayed TLM-sensitive increases in the mitophagy-related proteins LC3-II and PINK1 (all $P<0.05$). Renal cortical Drp1 levels were 3-fold higher in STZ than in Sham, with STZ+TLM rats exhibiting intermediate levels of this fission marker. Levels of the fusion marker Mfn2, and mitophagy-related proteins BNIP3 (dimer) and p62 did not differ among groups.

Conclusions: During the normoalbuminuric stage of DM, renal cortical mitochondria undergo increased fatty metabolism, as well as enhanced fission and mitophagy that are blunted by TLM in association with its antioxidant effect and, thus, are likely quality control mechanisms triggered by oxidative damage.

PO2013

Indoxyl Sulfate Modulates Expression of Myosin Heavy Chain Isoforms and induces Sarcopenic Phenotype in Mouse

Takaaki Higashihara, Hiroshi Nishi, Koji Takemura, Masaomi Nangaku. *Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan.*

Background: In patients with chronic kidney disease, sarcopenia is frequently associated with decreased renal function and correlates with increased morbidity and mortality. However, the molecular mechanism to underlie uremic sarcopenia is not fully elucidated yet. We hypothesized that the accumulation of uremic toxin might have a direct negative effect on skeletal muscle, and investigated the mechanism of indoxyl sulfate (IS) induced toxicity on mouse skeletal muscle.

Methods: We conducted the vivo experiments using C57BL/6j mice. After unilateral nephrectomy, vehicle (PBS) or high dose IS was intraperitoneally administered daily for 1 week, and evaluated exercise tolerance (treadmill fatigue test and four limbs grip test), skeletal muscle wet weight, cross-sectional area, and protein levels of myosin heavy chain isoforms characterizing fast/slow twitch muscle fibers (fluorescent immunostaining and western blot, respectively), and the expression of muscle atrophy related genes (quantitative-PCR).

Results: In mice treated with IS, exercise tolerance was deteriorated and gastrocnemius muscle wet weight were decreased compared to the control group. Intriguingly, IS administration also reduced a cross-sectional area of fast twitch myofiber and protein levels of fast twitch myosin heavy chain. Also, IS treatment tended to up-regulated mRNA expression of muscle atrophy related genes (*Atrogin-1* and *Myostatin*) of the gastrocnemius muscle tissue.

Conclusions: IS induces direct sarcopenic effect on mouse skeletal muscle and predominantly decreases on fast-twitch muscle fibers. In the future, we will further investigate the molecular mechanism of uremic toxin induced sarcopenia.

PO2014

Lnc-Gm43360 Regulates TCMK-1 Senescence by the miR-141/Sirt1 Pathway

Jie Li, Hongli Jiang, Lei Chen. *the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Aging is a complex process, which will lead to the gradual decline of physiological functions of all organ systems. The kidney, which is a metabolically active organ, is extremely susceptible to aging, but the mechanism of kidney aging is not clear. Long-chain non-coding RNA (lncRNA) is an non-coding RNA consisting of 200 nucleotides, which play an important role in kidney fibrosis and diabetic nephropathy, but there is no study on kidney senescence.

Methods: Dectection of lnc-Gm43360 expression by qRT-PCR. Transfection with lnc-Gm43360 siRNA and overexpressed plasmid to measure the miR-141 and Sirt1 expression by qRT-PCR, and the p53, p21 and p16 expression by western blot, and SA-β-gal expression. Transfection with miR-141 mimic and inhibitor to measure Sirt1 expression by qRT-PCR, and p53, p21 and p16 expression by western blot, and and SA-β-gal expression.

Results: Lnc-Gm43360 expression in 24-month-mouse lower than 3-month-mouse kidney tissue. The reduction of lnc-Gm43360 expression significantly increases miR-141 expression, decrease Sirt1 expression on both the mRNA and protein level, and induces the SA-β-gal expression. miR-141 mimic and inhibitor decrease and increase Sirt1 expression. lnc-Gm43360 negatively regulates miR-141 expression and positive negatively regulate Sirt1 expression at both the mRNA and protein level. The function of lnc-Gm43360 in regulating Sirt1 expression depends on modulating miR-141 expression.

Conclusions: Lnc-Gm43360 can induce TCMK-1 senescence by miR-141/Sirt1 pathway.

PO2015

Modified Lipoproteins Modulate Renal Lymphatic Vessel Vasodynamics via NKCC1 on Lymphatic Endothelial Cells

Jianyong Zhong, Jing Liu, Elaine L. Shelton, Eric J. Delpire, Haichun Yang, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: In addition to its pivotal role in chloride transporting epithelia, the sodium–potassium–chloride cotransporter 1 (NKCC1) is increasingly recognized as a key modulator of vascular tone. We previously documented NKCC1 expression in renal lymphatic endothelial cells (LECs) of rats and cultured human LECs. *Ex vivo* we showed that blocking NKCC1 by furosemide caused a dose-dependent dilation in renal lymphatic vessels, decreased amplitude, and decreased frequency of spontaneous contractions. Since lymphatic vessels clear interstitial lipids and kidney injury increases lipid peroxidation products including isolevuglandins (IsoLG) which modify lipoproteins (apoAI), we examined if IsoLG-modified apoAI can affect renal lymphatic vessel contractility through NKCC1.

Methods: Puromycin nephrotoxicity (PAN) was induced in Sprague Dawley rats, while non-injected rats served as controls (Cont). Renal lymphatic vessels were isolated and mounted in a perfusion chamber to assess vasoactivity. The effects of apoAI or IsoLG-apoAI on the NKCC1 signaling pathway were assessed in LECs.

Results: PAN rats had significantly higher renal lymph flow which contained significantly more IsoLG vs Cont. *Ex vivo* studies showed renal collecting lymphatic vessels from PAN were more dilated vs Cont. Immunostaining revealed NKCC1 expression on LECs that was more prominent in PAN renal lymphatic vessels vs Cont.

LECs (prox-1 positive cells) isolated from PAN kidneys also had more NKCC1 gene expression than cells from Cont. In LECs, IsoLG-apoAI increased NKCC1 expression vs apoAI. Similarly, WNK1, OxSR1 and SPAK, upstream activators of NKCC1, were significantly increased in LECs exposed to IsoLG-apoAI vs unmodified apoAI, which was accompanied by increased eNOS expression. *Ex vivo* renal collecting lymphatic vessels significantly increased diameter, amplitude, and frequency of spontaneous contractions when exposed to IsoLG-apoAI vs with apoAI.

Conclusions: IsoLG-apoAI change renal lymphatic vessel vasodynamics through the WNK1-OxSR1/SPAK-NKCC1 pathway on LECs which we propose is a novel target to improve lymphatic vessel function in kidney disease.

Progranulin Deficiency Exacerbates High-Fat Diet-Induced Inflammation in Kidney

Maki Murakoshi, Tomohito Gohda, Yusuke Suzuki. *Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Progranulin (PGRN) has been reported to bind to tumor necrosis factor (TNF) receptor (TNFR) and inhibit TNFα signals. Conversely, PGRN is a 'bad' adipokine that can contribute to insulin resistance in some metabolic diseases. We evaluated the effect of augmentation of TNFα signals by PGRN deficiency on the progression of kidney injury in high-fat diet-induced obesity model mice.

Methods: Eight-week-old PGRN knockout (KO) mice and their wild-type (WT) mice were fed a standard diet or high-fat diet (HFD) for 12 weeks. Mouse proximal tubule (mProx24) cells knocked down with PGRN siRNA were treated with TNFα stimulation.

Results: The body weight and albuminuria were significantly increased in WT-HFD group compared with WT-standard diet (SD) group. The body weight of KO-HFD group was significantly decreased compared with WT-HFD group. However, albuminuria and the expression of renal inflammatory markers including TNFα in KO-HFD group were increased than those in WT-HFD group. On the other hand, the WT-HFD mice showed vacuolization in the proximal tubule, but KO-HFD mice did not. Immunohistochemical analysis showed that vacuolar membranes were clearly positive for a lysosomal marker, LAMP-1, suggesting impairment in lysosomal function. The expression of megalin which plays a critical role in the reabsorption of protein in proximal tubules was found to be decreased in KO mice compared with WT mice, and also reduced in mProx stimulated with TNFα.

Conclusions: PGRN deficient exacerbated renal inflammation caused by high-fat diet, while the results also showed improvement in tubular vacuolation. Anti-inflammatory treatment with PGRN for kidney diseases should be considered based on the opposing function of PGRN.

Diet Has a Stronger Impact on the Gut Microbiota Than Kidney Function in Rats with Moderate CKD

Annabel Biruete,[1] Tzu-Wen L. Cross,[2] Stephen R. Lindemann,[2] Kelly Swanson,[3] Neal X. Chen,[1] Sharon M. Moe.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Purdue University, West Lafayette, IN; [3]University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Diet and CKD have been shown to alter the gut microbiota. However, whether diet or kidney function plays a stronger role in the gut microbiota in moderate CKD is not well established. We assessed the effects of two diets on the gut microbiota in rats with moderate CKD.

Methods: Cy/+ rats (CKD) and normal littermates (NL) consumed an autoclaved grain-based diet containing 0.7% phosphorus (0.3% phytate-bound) and 3.5% crude fiber from birth. At 17-wk-old, half of the animals were maintained on the same diet (Grain) and the other half switched to a semi-purified casein-based diet containing 0.7% phosphorus (0% phytate-bound, 0.6% phosphate additives) and 5% non-fermentable cellulose (Casein) until 28-wk-old (n=8-10 rats/group). DNA was extracted from cecal and fecal samples collected at euthanasia, the V4 region of the 16S rRNA gene was sequenced via Illumina MiSeq, and data were analyzed using QIIME2 and LEfSe.

Results: Intestinal microbial a-diversity, or diversity within a sample, was significantly greater in rats fed the grain diet compared to casein diet regardless of kidney function. Diet and kidney function both had significant impacts on microbial β-diversity (diversity between samples), but diet explained a larger portion of the observed variability (27%) than kidney function (11.5%). Consumption of the grain-based diet increased many genera with short-chain fatty acid (SCFA) producing capacity, including *Bifidobacterium, Ruminococcus, Roseburia,* and *Prevotella* than the casein diet. Whereas the casein diet drove greater *Bacteroides* abundance that can metabolize tryptophan to indoles, which may exacerbate the formation of uremic toxins. Notably, the casein diet led to a greater abundance of *Bilophila* in NL rats and greater *Allistipes* in CKD. Both of these taxa have been suggested to drive the pathogenesis of inflammatory bowel disease. Additionally, CKD rats fed the casein diet had a higher relative abundance of *Akkermansia,* which has been shown to be greater in fiber-free or low fiber interventions, as it may degrade the mucus layer.

Conclusions: In rats with moderate CKD, diet had a stronger effect on diversity and gut microbial taxonomic differences than kidney function. Particularly, those fed the grain-based diet had higher bacterial genera known to produce SCFA.

PO2018

Effect of High Fiber or Probiotics-Enriched Diets on Kidney Injury in Mice Model of Bilateral Ischemia Reperfusion

Shirin Pourafshar, Nabin Poudel, Nataliya Skrypnyk, Junlan Yao, Mark D. Okusa. *University of Virginia Health System, Charlottesville, VA.*

Background: Changes in dietary intake have a significant effect on the incidence and development of chronic kidney disease (CKD). The progressive decline in kidney function during CKD can lead to increased systemic chronic inflammation and worsening of kidney injury. Fibers and probiotics are used by gastrointestinal bacteria to produce metabolites with anti-inflammatory activities. The objective of our study was to investigate the role of fiber and probiotics in ameliorating kidney injury using bilateral ischemia reperfusion (IR) surgery as a CKD model in mice.

Methods: Thirty-six C57BL/6J wild type, male mice were purchased from the Jackson Laboratory (Bar Harbor, ME, USA). After co-housing for a week, they were then isolated and randomly assigned to a diet: normal chow (C; control), high fiber (HF; modified AIN-93G with increased Hi-Maize Corn), and probiotics (P; AIN-93G with added *Bifidobacteria* spp.). After 14 days, mice underwent sham surgery (5 per group) or IR surgery (7 per group) and then resumed assigned diet for 28 days. Blood and fecal samples were collected both before surgery and after surgery. Mice were euthanized after 42 days to collect kidneys, small intestine, colon, fecal, and blood samples. Measurements of plasma creatinine, markers of kidney injury, and tissue staining were performed. Fecal samples were further processed to assess diversity of gut microbiota. Two-way ANOVA with Tukey's multiple comparisons was used for statistical analysis.

Results: On each diet, the IR increased serum creatinine compared to sham ($p<0.005$), confirming kidney injury. Transcripts of kidney injury markers, neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM1), were also higher with IR in all groups ($p<0.05$). However, NGAL and KIM1 were lower in HF and P compared to C, respectively ($p<0.005$). The histology sections in control group appeared to be more fibrotic compared to the other two groups. The sequencing of 16s rRNA gene was completed and is currently being used to assess the composition and diversity of gut microbiota in each group.

Conclusions: Supplementation with fiber or probiotics may reduce kidney injury after ischemia. Additional studies to identify specific changes in metabolites driving this protection are needed.

Nutritional Status and Oral Nutritional Supplement (ONS) Use Among Patients with Non-Dialysis CKD in British Columbia (BC)

Michelle M. Wong,[1] Dani Renouf,[2] Yuyan Zheng,[3] Zainab Sheriff,[1] Adeera Levin.[1,2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]St. Paul's Hospital, Vancouver, BC, Canada; [3]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Malnutrition and protein-energy wasting are complications of advanced CKD that are associated with increased risk of mortality and morbidity. In BC, a government-funded Nutritional Supplement Policy stewarded by renal dietitians guides ONS prescription for CKD patients who meet weight or nutrient intake criteria.

Methods: We conducted a retrospective study of CKD-ND patients who entered multidisciplinary CKD clinics in BC during 2013-2018 (N=15859). We used Wilcoxon signed-rank test to compare baseline nutrition/inflammation parameters among patients with any ONS prescription within 1 year of clinic entry and those not prescribed ONS. Longitudinal ONS prescription patterns over 3 years were described in the 2013-2015 entry cohort (N=7611).

Results: 1389 patients (9%) were eligible for and prescribed ONS, with variation between health regions. Patients taking ONS had lower eGFR, BMI, bicarbonate, hemoglobin, and greater age, ferritin, phosphate, PTH, neutrophil-to-lymphocyte ratio compared to those who did not receive ONS ($p<0.0001$ for all comparisons). Overall ONS use during the first 3 years of follow-up remained stable, with 40% new ONS users and 60% previous ONS users during year 2 and 3 of follow-up. For patients prescribed ONS within the 1st year of clinic entry, 65% had 1-2 ONS prescriptions/year, and among those continuing follow-up in year 2, 38% discontinued ONS, 35% had 1-2 ONS prescriptions/year, and 27% had 3+ ONS prescriptions/year (Figure).

Conclusions: This is the first Canadian study to describe ONS use among CKD-ND, which provides an estmate of incidence of undernutrition, as defined by dietitian assessment and corroborated by nutritional lab parameters. Among patients prescribed ONS, the majority have infrequent ONS use, while another subset has regular ONS use longitudinally.

Dietary Fat Intake and Mortality Across Kidney Function in a Nationally Representative Cohort

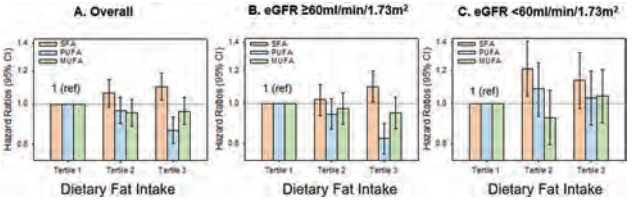
Yoko Narasaki,[1] Amy S. You,[1] Tsuyoshi Miyagi,[1] Yoshikazu Miyasato,[1] Hiroshi Kimura,[1] John Sy,[1] Anna Jin,[1] Csaba P. Kovesdy,[2] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: In the general population, lower dietary intake of saturated fatty acids (SFA) and higher intake of polyunsaturated fatty acids (PUFA) are associated with greater survival. However, the optimal amount and type of dietary fat intake in patients with kidney disease is unknown. We assessed the relationship between dietary fat intake and mortality in a cohort of US adults with and without kidney disease.

Methods: We examined the association between dietary intake of fat subtypes (SFA, PUFA, monounsaturated fatty acids [MUFA]) ascertained by 24-hour dietary recall with mortality in continuous NHANES adult participants (1999-2014) stratified by absence vs. presence of kidney dysfunction (eGFRs ≥60 vs. <60ml/min/1.72m^2, respectively). Dietary fat intake was estimated as a proportion (%) of total energy intake, and associations with all-cause mortality were estimated using adjusted Cox models.

Results: Among 37,155 participants who met eligibility criteria, 7% (N=2,677) had kidney dysfunction. In participants with normal kidney function, those with the highest tertile of SFA intake had higher death risk (ref: lowest tertile) (HRs [95%CI] 1.10 [1.01,1.19]), whereas those with the highest tertile of PUFA intake had better survival (HR [95%CI] 0.82 [0.76, 0.90]). In participants with kidney dysfunction, those in the second and third highest tertiles of SFA intake had significantly higher mortality risk and trended towards higher mortality, respectively: HRs (95%CIs) 1.21 (1.04, 1.41) and 1.13 (0.97, 1.32), respectively; however, PUFA was not associated with survival. In participants with and without kidney dysfunction, MUFA intake was not associated with mortality.

Conclusions: Higher dietary SFA intake was associated with a higher mortality in US adults with and without kidney dysfunction, whereas higher PUFA intake was associated with greater survival in those with preserved kidney function only. Further studies are needed to elucidate mechanisms behind the association of dietary fat intake with mortality.



PO2021

Predictors of Healthy Behavior Engagement in CKD

Sarah J. Schrauben,[1] Jesse Y. Hsu,[1] Julie A. Wright Nunes,[7] Ana C. Ricardo,[2] Michael J. Fischer,[2] Raquel C. Greer,[3] Cheryl A. Anderson,[8] Madhumita J. Mohanty,[9] Sankar D. Navaneethan,[4] Jing Chen,[5] Amanda H. Anderson,[6] Laura M. Dember,[1] Harold I. Feldman.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Illinois at Chicago College of Medicine, Chicago, IL; [3]Johns Hopkins University, Baltimore, MD; [4]Baylor College of Medicine, Houston, TX; [5]Tulane University School of Medicine, New Orleans, LA; [6]Tulane University, New Orleans, LA; [7]University of Michigan, Ann Arbor, MI; [8]University of California San Diego School of Medicine, San Diego, CA; [9]Wayne State University School of Medicine, Detroit, MI.*

Background: Guidelines for chronic kidney disease (CKD) management recommend healthy behaviors to mitigate disease progression, but behavior engagement is low. Identifying predictors of behavior engagement could inform strategies to increase healthy behaviors.

Methods: Using data from the Chronic Renal Insufficiency Cohort Study, potential predictors of behavior engagement included demographics, clinical and psychosocial factors, and behaviors at baseline. We dichotomized behaviors (recommended vs. not): smoking (no vs. current), body mass index (BMI <18.5 or ≥30 kg/m^2), physical activity (≥150 vs <150 minutes/week), diet (score of ≥2 vs 0-1), and hemoglobin A1c (<7 vs ≥7) if diabetes. Relationships between predictors and behaviors at 2 years were estimated by multivariable adjusted logistic regression models.

Results: Among 5,209 participants at baseline, mean age was 60 years, mean eGFR was 48 ml/min/ml^2, and 51% had diabetes. In multivariable analyses, baseline behaviors were most strongly associated with behaviors at 2 years (**Table**). Higher SF-12 physical component scores, which relate to better physical function and pain control, associated with recommended behaviors at 2 years. In models that did not adjust for baseline behaviors, no smoking was associated with older age, female sex, and non-White race, but the other behavior associations were not notably changed.

Conclusions: Interventions to increase healthy behavior engagement should be implemented and tested to evaluate whether they improve physical function and pain control, and possibly mitigate CKD progression.

Funding: NIDDK Support

Associations with Recommended Behaviors at 2 years. ORs and 95% CI reported.

Predictors^	Diet score 2-4 (vs 0-1)	BMI 18.5 to <30 kg/m^2 (vs <18.5 or ≥30 kg/m^2)	Physical Activity ≥150 minutes/week (vs <150)	Non-smoking (vs. current smoking)	Hemoglobin A1c <7 (vs. ≥7)

Impact of Participation in Food Assistance Programs Among NHANES Dialysis Patients from 2001-2016

Hannah Chen, Lea Borgi. *Brigham and Women's Hospital, Boston, MA.*

Background: Food insecurity and malnutrition are recognized risk factors for poor outcomes and mortality among end-stage renal disease (ESRD) patients on dialysis. However, little is known about the effect(s) of participation in food assistance programs such as Supplemental Nutrition Assistance Program (SNAP) on outcomes among dialysis patients.

Methods: This study is a cross-sectional analysis of dialysis patients in the National Health and Nutrition Examination Survey (NHANES) cohorts from 2001-2016. Food assistance program participation was self-reported as part of the NHANES interview. Differences in baseline characteristics were determined through null hypothesis testing. Logistic and linear regressions were used to examine the association between food assistance program participation and outcomes including hospitalizations and albumin as

a marker of nutrition status. The analyses were adjusted for demographics, BMI, diabetes, hypertension, and hyperlipidemia.

Results: A total of 156 dialysis patients were analyzed across all NHANES cohorts. Dialysis patients receiving food assistance were more likely to be younger, female, and obese ($p<0.05$). Food assistance participants had significantly larger household size, but lower income and lower levels of post-secondary education ($p<0.05$). These patients also reported significantly higher daily sugar intake. Dialysis patients receiving food assistance were significantly more likely to report very low food security and less likely to report full food security. Specifically, they reported more concerns regarding food running out, food not lasting, and not being able to afford balanced meals. Approximately 30% of dialysis patients report food insecurity but do not participate in food assistance programs. When adjusted to be representative of the non-institutionalized U.S. population, there was a non-significant trend towards increased hospitalization among dialysis patients on food assistance programs (OR 1.73 [95% CI: 0.42-7.12]). There was a non-significant negative correlation between food assistance program participation and serum.

Conclusions: Food assistance programs are not widely used among dialysis patients, even when patients report food insecurity. Food assistance program participation among dialysis patients did not significantly impact hospitalizations and serum albumin.

PO2023

Trends in the Prevalence of Food Insecurity Across Racial-Ethnic Groups with CKD: An Analysis of NHANES 2003-2016

Tanushree Banerjee,[1] Deidra C. Crews,[2] Charles E. McCulloch,[1] Nilka Rios Burrows,[3] Karen R. Siegel,[3] Rajiv Saran,[4] Yun Han,[4] Neil R. Powe.[1]
[1]University of California San Francisco, San Francisco, CA; [2]Johns Hopkins University, Baltimore, MD; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of Michigan, Ann Arbor, MI.

Background: Food insecurity has been associated with CKD and its progression. Trends in food insecurity among adults with CKD have not been well characterized in the US population, particularly across racial/ethnic groups.

Methods: Data from NHANES from 2003-2016 were used to estimate the prevalence of food insecurity among individuals with CKD (defined by albuminuria or eGFR 15-59 ml/min/1.73 m^2), overall and by racial/ethnic group. We included individuals aged≥20 years and with a household income≤400% of the federal poverty level (n=3180). Food insecurity was defined as ≥3 yes responses on the 18-item questionnaire. Racial/ethnic groups were defined as non-Hispanic white (NHW) and non-NHW. Survey years were collapsed into time periods 2003-2006, 2007-2010, and 2011-2016. Prevalence rates were estimated after standardization to the 2010 age population distribution from the US Census. Log binomial regression model was used to estimate adjusted risk ratios (RR) for the association of food insecurity and racial/ethnic groups.

Results: Overall prevalence of food insecurity in adults with CKD was 19.9%. During the period, the age-standardized prevalence rate of food insecurity increased from 5.7% to 32.8% among NHW and from 23.2% to 35.8% among non-NHW (p-trend=0.001). After adjusting for age, sex, education level, and annual household income, non-NHW had a significantly higher prevalence of food insecurity compared to NHW in 2007-2010 but not in 2003-2006 or 2011-2016 (Figure).

Conclusions: From 2003 to 2016, food insecurity among both NHW and non-NHW increased, with the highest RR among non-NHW compared to NHW during 2007-2010. One potential explanation may be the US economic recession during that period. Targeted interventions such as medically tailored meals for individuals with CKD and poverty may be evaluated for their impact on reducing healthcare utilization and costs and in reversing the increasing trend in food insecurity.

Approach to Nutritional Protein Intake in Hemodialysis Patients with Hyperphosphatemia: Associations with Mortality in the DOPPS

Suguru Yamamoto,[2] Brian Bieber,[1] Hirotaka Komaba,[4] Hiroki Kitabayashi,[3] Takanobu Nomura,[3] Aleix Cases,[5] Christian Combe,[6] Ronald L. Pisoni,[1] Bruce M. Robinson,[1] Masafumi Fukagawa.[4]
[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [3]Kyowa Kirin Co., Ltd., Tokyo, Japan; [4]Tokai University School of Medicine, Isehara, Japan; [5]Universitat de Barcelona, Barcelona, Spain; [6]Université de Bordeaux, Bordeaux, France.

Background: Pts undergoing hemodialysis (HD) have poorer nutritional status than the general population, and worse nutritional status is associated with poor outcomes. Hyperphosphatemia is common in HD pts due to abnormal mineral and bone metabolism. Nephrologists manage hyperphosphatemia by prescribing phosphate binders and/or promoting dietary protein restriction; the latter may, however, adversely affect nutritional status. We address the hypothesis that, even in the presence of hyperphosphatemia, liberalizing dietary protein leads to better outcomes.

Methods: The analysis includes 11,628 HD pts in 12 countries in DOPPS phase 4 (2009-11), from 254 facilities where the medical director reported facility practices. The primary exposure variable was response to the following question: "For pts with s. albumin 3.0 g/dL and phosphate 6.0 mg/dL, do you typically recommend to (A) increase or (B) not change/decrease dietary protein intake?" The primary outcome was all-cause mortality, analyzed by Cox regression. Linear regression was used to model associations between the exposure and intermediate nutrition markers. Models were adjusted for country, case-mix, and lab values.

Results: In the case scenario, 91% of medical directors in N. America recommended to increase protein intake compared to 58% in Europe (range=36-83% in 7 countries) and 56% in Japan. Advice to increase dietary protein intake was associated with 0.33 mg/dL higher s. creatinine levels (95% CI: 0.08-0.57) while clinically meaningful associations were not observed for s. albumin and phosphorus. Advice to increase dietary protein intake was weakly associated with lower mortality-HR (95% CI)=0.89 (0.77-1.03). The association with survival was stronger in pts with age 70+ yrs and for those without diabetes (p=0.08 and 0.20 for interaction).

Conclusions: In this large international cohort study, the medical director's preference to recommend increase in dietary protein intake for HD pts with low albumin and high phosphorus levels was most common in N. America and associated with higher s. creatinine levels and potentially lower all-cause mortality. Further research into the possible benefits of protein intake liberalization for HD pts, even in the presence of hyperphosphatemia, is warranted.

Dietary Acid Load Is Associated with the Risk of Mortality and Kidney Replacement Therapy in Diabetic CKD Patients but Not in Non-Diabetics

Alisson D. Machado,[1] Dirce Marchioni,[2] Paulo Lotufo,[3] Isabela M. Bensenor,[3] Silvia M. Titan.[1,4]
[1]Department of Nephrology, Hospital das Clínicas, Faculty of Medicine, University of São Paulo, São Paulo, Brazil; [2]Department of Nutrition, School of Public Health, University of São Paulo, São Paulo, Brazil; [3]Clinical Research Center, Universitary Hospital, University of São Paulo, São Paulo, Brazil; [4]Tufts Medical Center, Boston, MA.

Background: Dietary acid load (DAL) may be related to CKD progression but results are still conflicting. In addition, no studies have evaluated the association of DAL with mortality in CKD. The aim of this study was to evaluate two estimates of DAL, PRAL (potential renal acid load) and NEAP (net-endogenous acid production), in relation to events of mortality and kidney replacement therapy (KRT) in CKD.

Methods: Baseline clinical and dietary data (food frequency questionnaire) from the PROGREDIR Cohort (n=454), a CKD cohort based on Sao Paulo, Brazil, composed predominantly of older people with CKD G3 and G4 was used in this analysis. PRAL and NEAP were computed using previously validated formulas, and those with missing values were excluded (n=11). Events of death (n=190) and KRT (n=62) were ascertained after a median follow-up time of 6 years. Uni and multivariable Cox proportional hazards and Competitive Risk models were computed.

Results: Mean age was 68 ± 12 y, mean eGFR was 38 ± 15 mL/min/1.73m^2, 63% were male and 56% were diabetic. Mean intake of PRAL and NEAP were 4.1 ± 18.5 and 51.9 ± 17.4 mEq/d, respectively. Initially, neither PRAL nor NEAP were associated with mortality or KRT. However, after stratification for diabetes, both estimates were positively related to the risk of KRT and death in diabetics only, even after adjustments (Table). Competing risk analysis were consistent with the Cox findings. By entering interaction terms between diabetes and DAL estimates, which were significant, both PRAL and NEAP showed an inverse association with the risk of clinical events.

Conclusions: Our results suggest the existence of a relevant interaction between PRAL/NEAP and diabetes: whereas DAL estimates were associated with mortality and KRT in diabetics, this association was not observed in non-diabetics.

Mediterranean Diet and the Risk of CKD: A Systematic Review and Meta-Analysis

Panupong Hansrivijit,[1] Sharad Oli,[5] Resha Khanal,[1] Nasrollah Ghahramani,[2] Charat Thongprayoon,[3] Wisit Cheungpasitporn.[4] *[1]UPMC Pinnacle, Harrisburg, PA; [2]Penn State College of Medicine, Hershey, PA; [3]Mayo Clinic Minnesota, Rochester, MN; [4]University of Mississippi Medical Center, Jackson, MS; [5]Maimonides Medical Center, Brooklyn, NY.*

Background: Mediterranean diet has been shown to be associated with lower risk for cardiovascular disease. However, its association with chronic kidney disease (CKD) remains inconclusive as the results were not consistent among population-based studies. Thus, this study aims to assess the association between Mediterranean diet adherence and CKD prevention.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched from database inception to March 2020 without language restrictions. We included studies describing the risk for CKD in community-dwelling subjects > 18 years of age. CKD was defined by eGFR < 60 mL/min/1.73m^2. Mediterranean diet adherence was assessed by standardized food frequency questionnaires. Meta-analysis and meta-regression analysis were used to evaluate the risk of CKD and the association between clinical factors and incidence of CKD, respectively.

Results: Of 168 citations, a total of ten (n = 19,151) and five studies (n = 9,099) were included in the systematic review and meta-analysis, respectively. Only studies adopting Mediterranean Diet Scale (MDS) were included in the meta-analysis. The mean score was 4.0 ± 0.1 points. The mean age was 53.1 ± 8.2 years. The mean eGFR was 77.3 ± 29.6 mL/min/1.73m^2. The average total daily energy intake was 1,989.4 ± 258.0 kilocalories per day. Up to 50.4% were male, 7.1% were black, and 14.9% had a history of diabetes mellitus. With the mean follow-up duration of 11.5 ± 9.5 years, the pooled adjusted odds ratio (OR) for CKD was 0.897 (95% CI, 0.865-0.930; I^2 26.5%). By excluding kidney transplant patients, the pooled adjusted OR for CKD was 0.901 (95% CI, 0.868-0.935; I^2 9.4%). Both findings remained significant on sensitivity analysis. No publication bias was detected. The incidence of CKD was 0.028 events per person-year (95% CI, 0.012-0.044). From meta-regression analysis, male sex was associated with higher incidence of CKD in an adjusted model. There was no significant association between age, black race, eGFR, and total daily energy intake vs. CKD incidence.

Conclusions: Adherence to Mediterranean diet by a 1-point increment of MDS was associated with 10% lower risk of CKD. However, this only applies to healthy individual without a history of pre-existing CKD, whether Mediterranean diet slows CKD progression is to be discovered.

Attitudes Toward Plant-Based Eating (PBE), Self-Reported Habits, and Relationship to BMI and Blood Pressure in a Population of Inner-City CKD/ESKD Patients

Ahmad Saleh, Kingsley Cruickshank, Takisha Morancy, Iqra Nadeem, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: The benefits of a PBE dietary pattern are well described, yet there is scarcity in the literature on the attitudes of CKD/ESKD patients regarding PBE as well as their self-reported habits.

Methods: A face-to-face survey was conducted in a random convenience sample patients from CKD clinic (15), Transplant clinic (12), and the Dialysis Unit (4). Pts were asked to answer questions assessing their attitudes and understanding of PBE using a 5-point Likert scale, and to rate their daily vegetable intake. There was no difference noted in answers among the clinics so all data were analyzed together. All comparisons are by t-test unless noted.

Results: Mean age was 54.7±1.7 yrs. There were 16 (53%) men and 14 (47%) women with 25 Black (81%). 12 people (40%) had an income < $20K, with 10 (33%) between $20K and 40K. 10 (33%) were employed. 64.5% (20) were interested in learning more about PBE; 35% had never heard of it. 22(71%) reported consuming animal protein 1-3x/d or more. 20 (57%) reported consuming plant-based foods less <1/d or never. Pts who did not eat plant-based foods had a higher BMI than those who consumed plants (30.9±1.86, p<0.05), and higher systolic and diastolic BP (144.3±5.9 vs 126±5.2, p<0.05 and 77.9±3.5 vs 66.3±4.1, p=0.019). 46.4% thought it would be difficult to find things to eat at restaurants, 51.7% thought it would be difficult to buy food or groceries on a budget; 46.4% thought they could not get all the protein they need from plant-based foods without eating animal meat or products; 40.7% thought it would be hard to get all the vitamins and nutrients but 63.1% thought it would be easy to find recipes that taste good if they followed PBE.

Conclusions: In our population: 1. The majority of pts were interested in learning about PBE but ate few to no vegetables on a daily basis. 2. Possible obstacles to introducing PBE in this populations are misconceptions including the difficulty of affording food, getting enough protein and finding something to eat when eating out, believed by almost half of those surveyed. 3. Intensive educational programs targeted towards our population should be developed as pts who ate more vegetables had lower BMI and both systolic and diastolic BP and in general PBE has been shown beneficial for pts with CKD/ESKD.

Higher Estimation of Dietary Phosphorus Content with More Plant-Based Protein in Hemodialysis Patients Across Race/Ethnicity Using 3-Day Food Records with Interviews

Amanda R. Tortorici,[1] Connie Rhee,[1] Amy S. You,[1] Elani Streja,[1] Keith C. Norris,[2] Kamyar Kalantar-Zadeh.[1] *[1]University of California Irvine, Orange, CA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Dietary phosphorus (P) restrictions are commonly recommended based on the estimated phosphorus (P) content of foods, not accounting for P type or its absorbability. Whereas plant-based diets have important benefits, they are traditionally not recommended to dialysis patients given perceived higher P content in plant vs. animal-based proteins, although P is less absorbable in plant foods. We examined dietary differences across race/ethnicity in a group of hemodialysis (HD) patients from several dialysis centers in Southern California.

Methods: The self-administered 3-day diet diary with face-to-face *interview* was conducted by a trained dietitian among 80 in-center HD patients, and the data were entered into a diet software (Nutrition Data System for Research), and dietary components of the individuals and subgroups were obtained.

Results: Patients were 57±15 years and included 25% Blacks, 36% Hispanics and 18% non-Hispanic Whites. Table shows dietary data across race/ethnicity. [table] Figure shows the association of the phosphorus-to-protein ratio with the percentage of plant protein, correlation coefficient r was 0.58 (p<0.001) for all including 0.28, 0.61 and 0.38 for Blacks, Hispanics and Whites, respectively.[figure]

Conclusions: Whereas estimated dietary potassium was not substantially different across race/ethnicity or different plant- vs. animal based protein proportions, dietary phosphorus content analyses may not account for varying phosphorus bioavailability across sources, which may lead to incorrect assumptions that higher plant-based protein for dialysis patients is associated with more phosphorus burden.

Funding: NIDDK Support

Analyses of 3-day diet diary across race/ethnicity

	P to protein ratio, mg/g	Plant to total protein, %	P, mg/1000Cal	Potassium, mg/1000Cal
Blacks	11.6±2.0	23%	595±107	1,034±249
Hispanics	13.4±2.6	27%	614±137	1,059±235
Whites	12.9±2.1	31%	600±127	1,025±220

Benefits of Home-Delivered, Low-Sodium Meals in Hemodialysis Patients

Luis M. Perez, Hsin-Yu Fang, Brett Burrows, Alexis King, Sadia anjum Ashrafi, Kenneth R. Wilund. Renal and Cardiovascular Research Laboratory *University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Patients undergoing maintenance hemodialysis (HD) therapy are routinely counseled to reduce dietary sodium intake to reduce sodium retention, volume overload (VO), and hypertension. Unfortunately, low-sodium trials in HD are sparse and mostly indicate that dietary education and behavioral counseling alone are ineffective in reducing sodium intake. The purpose of this study is to determine if 4-weeks of a low-sodium home delivered meals intervention will reduce interdialytic weight gain (IDWG) and subsequent VO and hypertension in patients undergoing HD when compared to 4-weeks of a usual diet.

Methods: We recruited 20 subjects (55±12 years, BMI 40.7±16.6 kg/m^2, 45% male, 65% AA, 70% DM, 50% CVD) from a HD clinic in central IL. Participants followed a usual-control diet for the first 4-weeks. PurFoods, LLC prepared and shipped 3 low-sodium kidney meals (<700 mg sodium, potassium, and phosphorus each) per day to patients in the following 4-weeks. We collected monthly IDWG, bioelectrical impedance, standardized blood pressure, 3 days (HD, non-HD, and weekend day) of dietary recalls, and blood at baseline (0M), after a usual diet (1M), and post-intervention meals (2M).

Results: Home-meal delivery significantly reduced both dietary sodium intake, IDWG, systolic blood pressure (SBP), and diastolic blood pressure (DBP) (Table). These changes were accompanied by reductions in total body water (TBW) and calculated VO (Table). These changes were mostly driven by reductions at 2M, except for a significant increase in IDWG from 0M to 1M ($p < 0.05$).
