Results: We analyzed 3684 patients with a mean age of 58±11 years, 45% were male, and 42% were Black. Baseline mean eGFR was 44.3 ± 14.9 ml/min/1.73 m2. Median FePi and FGF23 were 26.5% (IQR, 19.5-36.8) and 145 (IQR, 95.6-238.3) RU/ml, respectively. The median time of follow-up was 12 (IQR, 7-13) years. The total number of events was 796 for incident heart failure, 717 for composite ASCVD, 1233 for CKD progression and 1328 for all-cause mortality. The adjusted relative risk of incident heart failure was higher in the low-FePi/high-FGF23 group (HR, 1.31; 95%CI, 1.03 to 1.67) and higher in the high-FePi/high-FGF23 group (HR, 1.58; 95%CI, 1.23 to 2.02), comparing to the low-FePi/low-FGF23 group. Composite ASCVD was higher in the high-FePi/high-FGF23 group (HR, 1.42; 95%CI, 1.11 to 1.80), but not in the low-FePi/high-FGF23 group (HR, 1.25; 95%CI, 0.98 to 1.59). All-cause mortality was higher in the low-FePi/high-FGF23 group (HR, 1.56; 95%CI, 1.30 to 1.89) and higher in the high-FePi/high-FGF23 group (HR, 1.57; 95%CI, 1.29 to 1.90). The adjusted risk of CKD progression was not different between groups.

Conclusions: In contrast to previous reports in patients with mild renal disease, the combination of high FePi and high FGF23 was associated with the highest risk of heart failure and ASVCD events in moderate and advanced CKD.

PO0540

Pill Burden and Changes in Mineral Bone Disorder (MBD) Markers in Hemodialysis (HD) Patients Switched from Sevelamer to Sucroferric Oxyhydroxide (SO): A One-Year Follow-Up in a Contemporary Cohort

Meijiao Zhou,[1] Linda Ficociello,[1] Vidhya Parameswaran,[1] Claudy Mullon,[1] Michael S. Anger.[1,2] [1]*Fresenius Medical Care Global Medical Office, Waltham, MA;* [2]*University of Colorado, School of Medicine, Denver, CO.*

Background: About 80% of US dialysis patients are prescribed phosphate binders (PB) for serum phosphorus (sP) control; however, PB high pill burdens are associated with non-adherence and elevated sP levels. Clinical and observational studies have demonstrated that SO is effective in lowering sP with similar efficacy to sevelamer (Sev), but with a lower pill burden. The present study aims to assess the long-term changes in MBD markers and pill burden in a contemporary HD cohort switching from Sev to SO.

Methods: The study included adult, Fresenius Kidney Care maintenance HD pts receiving Sev during a 91-day baseline (BL) and first prescribed SO monotherapy during 5/2018- 5/2019. The one year follow up (FU) on SO therapy was divided into four consecutive 91-day intervals (Q1-Q4). Comparisons of PB pill burden and MBD markers between BL and FU were carried out using mixed-effects linear regression and Cochran's Q test.

Results: On average, patients (n=841) were 56.2 (13.3) years old with dialysis vintage of 50.5 (48.6) months. At BL, the % of pts was 21.2% for sP ≤ 5.5 mg/dL and 4.5% for sP≤ 4.5 mg/dL with 8.4 Sev pills/day; after switching to SO, the % of patients increased to 35.4%- 44.0% for sP ≤ 5.5 mg/dL and 11.4%-16.1% for sP≤ 4.5 mg/dL with 4.4- 4.9 pills/day. Mean iPTH and serum calcium (Ca) decreased progressively after SO conversion.

Conclusions: Maintenance HD patients switching PB prescription from Sev to SO during 2018 and 2019 as part of routine care showed significant reductions in sP and PB pill burden, and increases in the number of patients with sP ≤5.5mg/dL and sP ≤ 4.5 mg/dL. A trend toward decreased serum Ca and iPTH levels during SO therapy was also observed.

Serum Phosphorus (sP) and Pill Burden Among Hemodialysis (HD) Patients Prescribed Sucroferric Oxyhydroxide (SO): One-Year Follow-Up on a Contemporary Cohort

Jessica B. Kendrick,[1] Meijiao Zhou,[2] Linda Ficociello,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Michael S. Anger,[2,3] Daniel W. Coyne.[4] [1]*University of Colorado Anschutz Medical Campus, Aurora, CO;* [2]*Fresenius Medical Care Global Medical Office, Waltham, MA;* [3]*University of Colorado, School of Medicine, Denver, CO;* [4]*Washington University School of Medicine, St. Louis, MO.*

Background: A previous real-world analysis included HD patients (pts) prescribed SO during 2014-2015 followed for 1 year. Improvements in sP were observed along with fewer phosphate binder (PB) pills/day after pts switched from their previous PB to SO (2014 Cohort, Kendrick). To examine how PB prescription (Rx) patterns have changed over time, the present study compares the long-term effectiveness of SO in a contemporary cohort (prescribed SO in 2018-2019; 2018 Cohort) with 2014 Cohort results.

Methods: Adult Fresenius Kidney Care HD pts first prescribed SO monotherapy during 5/2018- 5/2019 as part of routine care and followed for one year were included. All pts were on a non-SO PB during a 91-day baseline (BL) before SO Rx. Mean PB pills/day and labs were compared for BL and SO follow-up (divided into 4 consecutive 91-day intervals; Q1-Q4) using mixed-effects linear regression and Cochran's Q test. These results were compared with findings from the 2014 Cohort.

Results: Compared to the 2014 Cohort (n=530), the 2018 Cohort (n=1793) was older (57 vs 55 yrs) with shorter HD vintage (34 vs 45 months), more likely prescribed calcium acetate (36 vs 28%) and ferric citrate (6% vs 0) and less likely prescribed sevelamer (47 vs 60%). The 2018 Cohort had better BL sP control; both cohorts showed reductions in sP and PB pills/day after SO conversion. During SO FU, iPTH decreased in the 2018 Cohort.

Conclusions: Despite different pt characteristics and treatment patterns in the 2014 and 2018 cohorts, HD pts from both cohorts had improvements in sP and % pts achieving sP ≤ 5.5 mg/dL or sP ≤ 4.5 mg/dL with fewer PB pills/day after SO conversion.

PO0542

One-Year Follow-Up of Maintenance Hemodialysis (HD) Patients Who Switched Phosphate Binder (PB) Prescription from Ferric Citrate (FC) to Sucroferric Oxyhydroxide (SO)

Linda Ficociello,[1] Meijiao Zhou,[1] Vidhya Parameswaran,[1] Claudy Mullon,[1] Michael S. Anger.[1,2] [1]*Fresenius Medical Care Global Medical Office, Waltham, MA;* [2]*University of Colorado, School of Medicine, Denver, CO.*

Background: A new class of iron based PBs have been prescribed to HD patients for hyperphosphatemia management. This one-year real-world data analysis in a contemporary cohort of HD patient who switched from FC to SO as part of routine care investigates changes in serum phosphorus (sP) and pill burden.

Methods: Adult Fresenius Kidney Care HD patients included in the analysis were first prescribed SO monotherapy between 5/2018-5/2019 and were on FC for 3 months (baseline; BL) prior to SO therapy. The one year SO therapy was divided into four consecutive 91-day intervals (Q1-Q4). Changes in lab measurements and PB pill burden were compared between BL and Q1-Q4, using mixed-effects linear regression and Cochran's Q test.

Results: Patients (n=115) were on average 55.5 (12.6) years old with 52.8 (46.4) months HD vintage, 38% female, 54% had diabetes and 20% had CHF. There were consistent improvements in pts achieving sP ≤ 5.5 mg/dL (from 20% at BL to 35.7%- 44.3% with SO; p<.0001) and in patients achieving sP≤ 4.5 mg/dL (from 6.1% at BL to 8.7%-16.5% with SO; p=0.02). Pts were prescribed 6.7 pills/day at BL and 4.7-5.2 pills/day with SO. SO conversion was associated with decreases in mean iPTH (620 pg/mL at BL, 496 pg/mL at Q4; p<.0001) and serum calcium (9.18 mg/dL at BL, 8.93 mg/dL at Q4; p<.0001).

Conclusions: Maintenance HD pts switched PB prescription from ferric citrate to sucroferric oxyhydroxide experienced significant increases in % patients achieving in-range sP (+111% for sP ≤5.5mg/dL and +144% for sP ≤4.5mg/dL) with a lower pill burden.

PO0543

Effects of Lanthanum Carbonate on Whole-Body Phosphorus Balance in Patients with Stage 3b-4 CKD and Normophosphatemia

Anna Jovanovich,[1,2] Taylor Struemph,[1] Tyson J. Marden,[1] Moshe Levi,[3] Gregory G. Schwartz,[2] Michel Chonchol,[1] Kathleen M. Hill Gallant.[4,5] [1]*University of Colorado - Anschutz Medical Campus, Aurora, CO;* [2]*VA Eastern Colorado Health Care System, Aurora, CO;* [3]*Georgetown University, Washington, DC;* [4]*University of Minnesota Twin Cities, St. Paul, MN;* [5]*Indiana University School of Medicine, Indianapolis, IN.*

Background: In CKD, elevated phosphorus, even within the normal range, is associated with cardiovascular disease (CVD) and mortality. However, in normophosphatemic CKD, phosphate binders do not improve vascular function, an independent predictor of CVD. Whether long-term treatment with phosphate binders affects phosphorus balance in CKD is unknown. Our objective was to determine phosphorus balance in normophosphatemic subjects with CKD 3b-4 after 12 weeks of treatment with lanthanum carbonate (LC) or placebo.

Methods: A subset of 15 subjects with CKD 3b-4 and serum phosphorus within normal limits randomized to receive 12 weeks of LC or placebo investigating effects of phosphate lowering on vascular function (NCT02209636) volunteered to participate in this ancillary aim. At the end of 12 weeks, participants consumed a controlled diet (1000 mg/day phosphorus and 800 mg/day calcium) for 9 days and continued their randomly-assigned study drug (N=7 LC, N=8 placebo). Fasting morning blood samples and all stool and urine were collected during a 48-hour inpatient clinical research center stay at the end of the 9-day balance period. Phosphorus balance (mg/d) was determined by values averaged over the 48-hour period: Dietary phosphorus intake minus urine phosphorus minus fecal phosphorus. T-tests were used to compare means.

Results: Mean age was 65±7y and mean eGFR was 33±6 mL/min/1.73m^2. One patient randomized to LC was excluded from fecal phosphorus and phosphorus balance results due to insufficient stool. 24-hour urine phosphorus was lower with LC compared with placebo, but this did not reach statistical significance (388±60 v. 513±51, p=0.15). Fecal phosphorus was higher with LC compared with placebo (775±163 v. 259±141, p=0.03), and whole-body phosphorus balance was lower with LC compared with placebo (-131±163 v. 320±141, p=0.06).

Conclusions: These results provide evidence that long-term treatment with the phosphate binder lanthanum carbonate may reduce whole-body phosphorus balance in patients with stage 3b-4 CKD and normophosphatemia. Whether this translates into beneficial clinical outcomes relevant to chronic-kidney disease-mineral and bone disorder warrants further investigation.

Impact of Tenapanor in Peritoneal Dialysis

David P. Rosenbaum,[1] Fredric O. Finkelstein,[2] Yang Yang,[1] Rebecca Galvin,[1] David M. Spiegel.[1] *[1]Ardelyx Inc, Fremont, CA; [2]Yale-New Haven Hospital, New Haven, CT.*

Background: Peritoneal dialysis (PD) utilization is being promoted worldwide as more emphasis is placed on the advantages and reduced cost of home dialysis. Serum phosphorus (sP) control for PD patients remains a challenge, particularly as residual kidney function is lost. Many PD patients receive stool softeners or laxatives to prevent constipation which may impede the treatment. Tenapanor (TEN) is a first-in-class phosphate absorption inhibitor (PAI) that targets the paracellular pathway of phosphate absorption by inhibiting the sodium-hydrogen exchanger 3 (NHE3) antiporter on the luminal surface of gastrointestinal epithelium. As a side effect of inhibiting NHE3, the sodium and water content of the stool is augmented, increasing stool frequency and volume. Here we compare the control of sP and the adverse event (AE) profile of TEN in the PD and hemodialysis (HD) subgroups in the phase 3 PHREEDOM trial.

Methods: PHREEDOM evaluated the safety and efficacy of TEN in patients on HD or PD with hyperphosphatemia. Following washout from phosphate binders, patients whose sP increased by 1.5 to ≥6.0 mg/dL were enrolled. Those randomized to the TEN arm received TEN 30 mg orally twice daily for 26 weeks. Counseling to discontinue stool softeners or laxatives was not provided to patients entering the trial. sP and AEs were recorded per protocol.

Results: Over the 26-week treatment period, the change in sP was similar for patients treated by PD (n=42) and HD (n=365) (figure). Diarrhea was the most common AE (56.1%) in the PD subgroup (with a similar incidence in the HD subgroup [51.6%]); no PD patients reported diarrhea as a serious AE.

Conclusions: These findings demonstrate that TEN may be a useful agent in reducing sP levels for patients treated with PD and have an added benefit of assisting with the management of constipation, which can be problematic for the PD patient. Prior counseling to discontinue stool softeners and laxatives when initiating TEN may decrease the AE of diarrhea and further reduce the number of medications when patients are switched from phosphate binders to TEN.

PO0545

Management of Serum Phosphorus (sP) Over One-Year Follow-Up in Peritoneal Dialysis (PD) Patients Prescribed Sucroferric Oxyhydroxide (SO) as Part of Routine Care

Kamyar Kalantar-Zadeh,[1] Linda Ficociello,[2] Meijiao Zhou,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Michael S. Anger.[2,3] *[1]University of California Irvine, School of Medicine, Orange, CA; [2]Fresenius Medical Care Global Medical Office, Waltham, MA; [3]University of Colorado, School of Medicine, Denver, CO.*

Background: Clinical and observational studies have shown the effectiveness of SO in controlling sP in PD patients (pts). A real-world retrospective analysis in a PD cohort prescribed SO for 6 months demonstrated an association between SO prescription and lower sP. The current analysis examines the changes in sP and PB pill burden over a one-year period in PD patients converting to SO.

Methods: We included adult Fresenius Kidney Care (FKC) PD pts (n=260) first prescribed SO monotherapy during 5/2018- 5/2019 who had sP measured 91 days before SO prescription (baseline; BL). Comparisons were made between BL and the four consecutive 91-day intervals of SO treatment (Q1-Q4). Means of PB pill burden and lab measures were calculated using mixed effects linear regression.

Results: At BL, mean age was 54 years old with PD vintage 18 months, 37% pts had no PB prescriptions recorded and the remaining pts were prescribed sevelamer (36%), calcium acetate (33%), lanthanum (1%), ferric citrate (13%), switched between PB (10%), or >1 PB recorded (6%). After switching to SO, % of pts achieving sP<= 5.5 mg/dL increased from 32.7% at BL to 46.9%- 53.8% during SO FU, % of pts achieving sP<= 4.5 mg/dL increased by 153% from BL to Q4, along with fewer PB pills per day (7.6 at BL vs 4.4-5.2 at FU).

Conclusions: During a one-year observation period, PD pts prescribed SO as part of routine care during 2018-2019 had significant reductions in sP and PB pills/day and increases in % of pts with sP≤ 5.5 mg/mL or sP≤ 4.5 mg/mL, suggesting improved sP management with concurrent reduction in pill burden.

PO0546

US Hemodialysis Facilities Switching from Cinacalcet to Etelcalcetide: Impact on Parathyroid Hormone (PTH) Levels

Angelo Karaboyas,[1] Daniel G. Muenz,[1] Yunji Hwang,[3] William Goodman,[3] Sunfa Cheng,[3] Pooja Desai,[3] Kathleen M. Fox,[3] Bruce M. Robinson,[1,2] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Amgen Inc, Thousand Oaks, CA.*

Background: Some US hemodialysis (HD) facilities switched from oral cinacalcet (Cina) to intravenous (IV) etelcalcetide (Etel) as the primary calcimimetic therapy to control parathyroid hormone (PTH) levels after the introduction of Etel in 2017. While clinical trial data have indicated superior efficacy of Etel vs. Cina, real-world evidence is lacking.

Methods: We evaluated facility calcimimetic use during 6-month intervals before (Period 1: May-October 2016) and after (Period 2: March-August 2019) introduction of Etel using US-DOPPS data. We compared the pre-post difference in outcomes – PTH, Ca, P – over the 6 months after each exposure period among calcimimetic users in HD facilities that "switched" from treating >75% of calcimimetic users with cinacalcet ("Cina-first") in Period 1 to treating >75% of calcimimetic users with etelcalcetide ("Etel-first") vs. facilities that remained Cina-first in Period 2.

Results: Among 32 US HD facilities that switched to Etel-first in Period 2, mean PTH decreased from 671 to 484 pg/mL and % PTH >600 pg/mL decreased from 39% to 21%. Among 34 facilities that remained Cina-first in Period 2, mean PTH increased from 632 to 698 pg/mL and % PTH >600 pg/mL increased from 37% to 43%. The adjusted difference-in-difference between switch to Etel-first and remain Cina-first was -169 (95%

CI: -249, -90) pg/mL for mean PTH and -14.5% (95% CI: -22.4%, -6.7%) for PTH >600 pg/mL. Serum Ca levels were slightly lower in facilities that switched to Etel-first, while serum P was not associated with facility calcimimetic type [*Table 1*].

Conclusions: In this natural experiment, we observed better PTH control in facilities that switched to etelcalcetide (vs. remained cinacalcet) as the primary calcimimetic therapy. Further research is needed to evaluate whether this clear difference in real-world effectiveness translates to a reduction in hospitalizations and mortality.

A Real-World Observational Study of Calcimimetic Use in Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) in Europe

Chidozie U. Nduka,[1] Andreja Marn Pernat,[8] Corrado Camerini,[5] Daniel Cejka,[13] Erzsebet Ladanyi,[7] Giorgina B. Piccoli,[9] Johannes M. Boots,[4] Jose-Vicente Torregrosa,[11] Laura Labriola,[3] Marianne Rix,[6] Matthew Hall,[14] Matthias Kohnle,[12] Kate Tsirtsonis,[1] Bruno L. Fouqueray,[10] Jürgen Floege.[2]
[1]Amgen, Uxbridge, United Kingdom; [2]Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany; [3]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium; [4]Maasstad Ziekenhuis, Rotterdam, Netherlands; [5]Spedali Civili Brescia, Brescia, Italy; [6]University Hospital Copenhagen Rigshospitalet, Copenhagen, Denmark; [7]Fresenius Medical Care Dialysis Centre, Miskolc, Hungary; [8]University Medical Center Ljubljana, Ljubljana, Slovenia; [9]Centre Hospitalier du Mans, Le Mans, France; [10]Amgen GmbH, Rotkreuz, Switzerland; [11]Hospital Clinic, University of Barcelona, Barcelona, Spain; [12]Nephrologisches Zentrum Mettmann, Mettmann, Germany; [13]Medizinische Universitat Wien, Wien, Austria; [14]Nottingham City Hospital, Nottingham, United Kingdom.

Background: Calcimimetics, Cinacalcet (CIN) and Etelcalcetide (ETEL), are approved for treating SHPT in adult patients on maintenance HD. Data on real-world use are needed to provide guidance in clinical practice.

Methods: In this observational study, chronic HD patients treated with calcimimetics for SHPT with ≥1 parathyroid hormone (PTH) measurement recorded within 90 days before calcimimetic initiation were included. Medical history, PTH, calcium (Ca) and phosphate (P) measurements, and calcimimetic use data were extracted from medical charts. Baseline period was defined as 6 months before calcimimetic initiation.

Results: Interim data for 974 HD (198 CIN and 776 ETEL) patients across 15 countries in Europe, recorded from June 2018 to March 2021, are reported. 43% (334/776) of ETEL patients had switched within 90 days after stopping CIN. ETEL patients were younger than CIN (median age: 62 vs. 65 yrs.). Dialysis vintage was longer for ETEL than CIN patients (median: 4.4 vs. 2 yrs.). Starting dose was 30 mg for 95% of CIN; and 5 mg and 2.5 mg for 58% and 40% of ETEL patients respectively. At 12 months, median PTH had decreased by 41% in ETEL and 31% in CIN patients (**Table 1**), however 54% of ETEL and 57% of CIN patients achieved target PTH range (150-600 pg/mL). The cumulative incidence of hypocalcemia (Ca <2.1 mmol/L) at 6 months (66% vs. 59%) was higher in CIN than ETEL patients, but no difference was recorded at 12 months (74% vs. 73%). As recorded in medical charts, nausea (2.2% vs. 2%) and vomiting (0 vs. 1.3%) were low for CIN and ETEL patients. ETEL persistence (88%) was greater than CIN (76%) at 12 months. 16% switched from CIN to ETEL and 2% from ETEL to CIN during follow-up.

Conclusions: ETEL and CIN patients achieved target PTH range to a similar degree at 12 months, however PTH decrease over time was better in ETEL patients. Treatment persistence was higher with ETEL than CIN. No new safety signals were observed.

Effects of Etelcalcetide on the Evolution of Cortical Porosity in Patients and Rats with CKD

Elizabeth A. Swallow,[1] Rachel K. Surowiec,[1] Corinne E. Metzger,[1] Joshua C. Sung,[2] Sanchita Agarwal,[2] Pascale Khairallah,[3] Max A. Hammond,[4] Sharon M. Moe,[1] Thomas Nickolas,[2] Matthew R. Allen.[1]
[1]Indiana University School of Medicine, Indianapolis, IN; [2]Columbia University Irving Medical Center, New York, NY; [3]Baylor College of Medicine, Houston, TX; [4]Indiana University Purdue University at Indianapolis, Indianapolis, IN.

Background: Suppression of chronically elevated parathyroid hormone (PTH) is a key treatment goal in patients with chronic kidney disease–mineral and bone disease (CKD-MBD). High PTH leads to increased cortical porosity which is associated to increased fracture risk. We tested the hypothesis that etelcalcetide, a calcimimetic agent, suppresses cortical pore development in CKD.

Methods: For our clinical cohort, etelcalcetide was dose-titrated to maintain serum PTH at 2-5 times the upper limit of normal of the local PTH assay, corresponding to the lower half of the KDIGO recommended target level. Patients were scanned at the distal tibia by high resolution peripheral QCT before and after 9-months of treatment. For our preclinical cohort, etelcalcetide was administered to an established model of progressive CKD (Male Cy/+ rat) for 3-5 weeks with *in vivo* microCT scans at the distal tibia taken at baseline and endpoint. Clinical and preclinical scans were registered across the two timepoints and individual cortical pores tracked for their dynamic action (filled, contracting, expanding, developed).

Results: Etelcalcetide significantly suppressed PTH in both the clinical (-64%) and pre-clinical (-77%) cohorts. Total cortical porosity did not increase over the course of treatment in either humans (baseline 5.8%; endpoint 5.8%) or rats (baseline 3.3%; endpoint 3.7%). However, changes were detected at the individual pore level by individual cortical pore analysis. In humans, of the baseline pores, 3% were unchanged, 25% had completely infilled, 40% had become smaller and 27% had increased in size. Twenty-one percent of the total pores at the end of treatment were formed de novo during treatment. The preclinical data followed similar trends, 43% of baseline pores had completely infilled, 20% had decreased in size, 22% had increased in size and 63% of the total pores end of treatment had formed de novo.

Conclusions: PTH suppression by etelcalcetide stabilizes overall cortical porosity yet permits dynamic activity of individual cortical pores during treatment. Further studies are needed to determine if de novo cortical porosity can be prevented by more aggressive PTH reduction.

Etelcalcetide Improves Central Skeleton Bone Quality and Density in Patients on Hemodialysis

Pascale Khairallah,[1] Joshua C. Sung,[2] Maria A. Aponte Farias,[2] Sanchita Agarwal,[2] Gail N. Frumkin,[4] Andrew Bohmart,[4] Karim El Hachem,[3] Jeffrey I. Silberzweig,[4] Donald J. Mcmahon,[2] Matthew R. Allen,[5] Thomas Nickolas.[2]
[1]Baylor College of Medicine, Houston, TX; [2]Columbia University Irving Medical Center, New York, NY; [3]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [4]Rogosin Institute, New York, NY; [5]Indiana University School of Medicine, Indianapolis, IN.

Background: Secondary hyperparathyroidism (SHPT) is an important complication of dialysis. It is associated with osteoporosis and fractures. Etelcalcetide is an intravenous calcimimetic superior to cinacalcet in control of parathyroid hormone (PTH) in hemodialysis (HD) patients. The effects of etelcalcetide on bone quality and density are unknown. We hypothesized that etelcalcetide improves spine trabecular bone score (TBS), a marker of central skeletal trabecular bone quality, and bone mineral density (BMD) by dual energy X-ray absorptiometry (DXA) in HD patients.

Methods: Eligible subjects were ≥18 yo, on HD ≥1 year, normocalcemic, without calcimimetic exposure within 3 months of enrollment. Treatment included a 3-month dose titration phase to target a PTH level 2-5 times the upper limit of normal, followed by a 6-month maintenance phase. TBS and DXA were obtained at both baseline (pre-treatment) and at 9-months (end of study). Intact PTH was obtained at pre-treatment, 3- and 9-months post-treatment. Mixed models assessed change in TBS and age, sex, race Z-Scores adjusted for change in PTH.

Results: 22 subjects were enrolled;13 completed follow-up. Among the 13 subjects: mean±SD age was 51±14 yrs; 53% male; 15% white. Median (min-max) PTH (pg/mL) levels at baseline, 3- and 9-months were 692(456-959), 266(18-1256) and 156(40-885) respectively. From baseline to 9-months of treatment, TBS improved by 7.4±2.6% (p=0.008). Z-Scores at the spine, femoral neck and total hip increased by 0.5, 0.4 and 0.3 SDs respectively (Table). There were no changes at the forearm.

Conclusions: Treatment of SHPT with etelcalcetide for 9 months was associated with improvements in trabecular quality and central skeleton BMD. Further studies are needed to determine the effects of etelcalcetide on tissue-level bone quality, bone strength and fracture resistance.

PO0550

Etelcalcetide Suppresses Trabecular and Cortical Bone Remodeling Without Altering Bone Quality in Patients with ESKD

Corinne E. Metzger,[1] Matthew R. Allen,[1] John G. Damrath,[3] Rachel K. Surowiec,[1] Joseph M. Wallace,[3] Joshua C. Sung,[2] Sanchita Agarwal,[2] Thomas Nickolas.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Columbia University Irving Medical Center, New York, NY; [3]Indiana University Purdue University at Indianapolis, Indianapolis, IN.*

Background: A key treatment goal in chronic kidney disease–mineral and bone disease (CKD-MBD) is suppression of chronically elevated parathyroid hormone (PTH). High PTH in CKD is associated with high bone turnover and fracture risk. Calcimimetics, such as etelcalcetide, are pharmacologic agents used clinically to reduce PTH to target levels. The goal of this study was to test whether 9-months of etelcalcetide treatment suppresses bone remodeling in patients with end stage kidney disease (ESKD) on hemodialysis with renal hyperparathyroidism (rHPT).

Methods: Five patients were enrolled. Mean age was 52±16 yrs and 80% were female. A quadruple label method was used to quantify pre- and post-treatment effects of etelcalcetide on bone turnover and quality. Prior to treatment, patients underwent tetracycline double labeling (3 days, 15 day interval, 3 days). Over 3 months, etelcalcetide was dose-titrated to maintain serum PTH at the lower half of the KDIGO recommended target (2-9x the upper limit of normal of the PTH assay). Patients were maintained on etelcalcetide at the specified PTH level for 6 months. At end of treatment, demeclocycline was administered (3 days, 15 day interval, 3 days) followed by transiliac crest bone biopsy.

Results: Mean PTH (pg/mL) levels at baseline and 9-months were 616±135 and 282±340, respectively. Following 9-months of treatment, trabecular bone formation rate was 80% lower (range of -54 to -96%) while intracortical rate was 83% lower (range of -61 to -94%). Suppressed remodeling of both trabecular and intracortical bone occurred through a reduction in both the amount of bone undergoing remodeling (~65%) and the mineral apposition rate (-35%). Static histomorphometry showed osteoclast surfaces (~1%) and eroded surfaces (5.3%) were within normal ranges. Raman and nano-indentation measures showed no differences in trabecular bone mineral/matrix properties between the two timepoints.

Conclusions: This work shows that etelcalcetide corrects high bone turnover in patients with rHPT on dialysis without affecting bone quality. More research is needed to determine whether the potent remodeling suppression by etelcalcetide can be used as a primary strategy to reduce risk of fracture in patients with ESKD.

Interim Analysis of Paricalcitol vs. Cinacalcet in Hemodialysis Patients with Secondary Hyperparathyroidism: A Multicenter, Randomized, Positive Controlled Study (PERMIT Study)

Yingjin Qiao,[1] Xiaoyan Sun,[2] Xinyu Liu,[3] Junxia Wang,[5] Jie Li,[4] Donghai Wang,[6] Huazhen Zhang,[7] Pei Wang,[1] Zhangsuo Liu.[1] PERMIT study collaboration group *[1]the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]Yantai Yeda Hospital, Yantai, China; [3]Nanyang Central Hospital, Nanyang, China; [4]Yongchuan Hospital of Chongqing Medical University, Chongqing, China; [5]The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China; [6]Zhumadian Central Hospital, Zhumadian, China; [7]Sanmenxia Central Hospital, Sanmenxia, China.*

Background: A randomized, controlled, open-lable, multi-center study was conducted in China to compare the safety, efficacy and cost effectiveness of paricalcitol-dominated therapy with cinacalcet-dominated therapy in maintainted hemodialysis (MHD) patients with secondary hyperparathyroidism.

Methods: Patients over 18 years old, accepted MHD over 3 months, serum intact parathyroid hormone (iPTH)>300pg/mL, serum calcium 2.1~2.5mmol/L and serum phosphorus≤1.78mmol/L were randomized into paricalcitol-dominated therapy group (GpP) or cinacalcet-dominated therapy group (GpC) for 24 weeks. Paricalcitol or cinacalcet monotherapy was prescribed at the beginning, and combination therapy would be carried out when monotherapy was unable to meet the expected target for 2 consecutive visits (Fig 1). The primary endpoint was iPTH maintained within 150~300pg/mL. The secondary endpoints were the combination therapy rate, more than 30% or 50% decline of iPTH from baseline.

Results: 271 patients in 23 centers were screened, 154 patients were enrolled and 93 patients completed the study up to May 2021. There was no statistical difference between groups in age, gender, iPTH, Ca and P at baseline. In GpP and GpC, 44.9% (22/49) *vs* 36.4% patients (16/44) achieved primary endpoint (*P*=0.406). 89.8% (44/49) *vs* 77.3% (34/44) and 73.5% (36/49) *vs* 63.6% (28/44) patients attained iPTH decline more than 30% (*P*=0.099) or 50% (*P*=0.306). 24.7% (19/77) patients in GpP have hypercalcemia, and 44.2% (34/77) patients in GpC have hypocalcemia. The incidences of hyperphosphatemia were similar (28.6% *vs* 26.0%, *P*=0.7174). Combination therapy rate had a rising tendency, 36.8% in GpP *vs* 59.1% in GpC.

Conclusions: Paricalcitol-dominated therapy was as effect as cinacalcet-dominated therapy with lower incidence of hypocalcemia and combination therapy rate. (chictr.org.cn registration number: ChiCTR2000031420)

PO0552

The Impact of Paricalcitol on Parathyroid Gland Size of Secondary Hyperparathyroidism Patients with Long-Term Maintenance Hemodialysis: An Observational Study

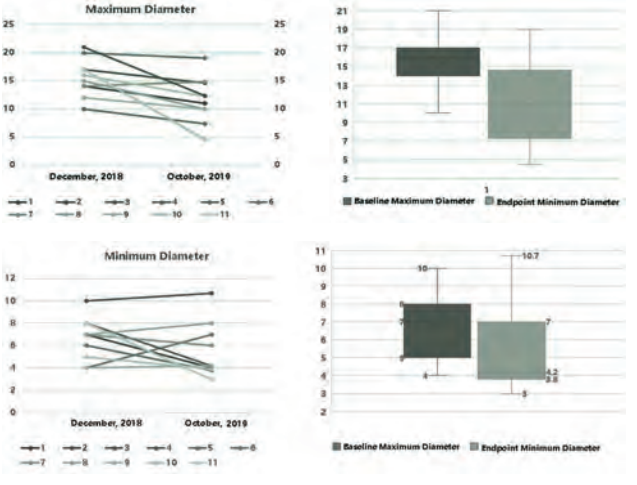
Chenghui Tao,[1] Xiaohui Liao.[2] *[1]Fengdu People's Hospital, Chongqing, China; [2]The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China.*

Background: This is an observational study to assess effectiveness of paricalcitol for treating secondary hyperparathyroidism (SHPT) patients with long-term maintenance hemodialysis, via changes in biochemical indexes, such as Calcium (Ca), Phosphate (P) and Parathyroid Hormone (PTH), and size of parathyroid gland (PG).

Methods: This single-centre and small sample study included 11 Long-term maintenance hemodialysis patients with SHPT, who were undergoing SHPT treatment with paricalcitol in the Blood Purification Centre of Fengdu people's hospital, Chongqing, China, from December 2018 to October 2019. We Administered Paricalcitol (Zemplar®) intravenously through a hemodialysis vascular access after dialysis as the following dosage: 5 ug tiw for iPTH<1000 pg/ml and 10 ug tiw for iPTH≥500 pg/ml. Titrations based on serum calcium and intact PTH levels. We collected biochemical indexes including Ca, P and iPTH, and imaging parameters of PG via ultrasonography (volume and number), evaluating variations between baseline and Month 11 of post-treatment.

Results: Compared to baseline, the maximum diameter lines of PG decreased significantly (mean 15.727 mm vs 10.936 mm, P=0.005) after 11 months' treatment, though the minimum diameter lines decreased without statistical difference (mean 6.727 mm vs 5.255 mm, P=0.089). The number of glands was less in Month 11 than that of baseline (mean 2.455 vs 2.182, P=0.277) and iPTH declined significantly (mean 1045.109 pg/ml vs 610.934 pg/ml, P=0.001). The overall effective rate of paricalcitol was 90.9% after 11 months' treatment. Moreover, there were no significant changes in serum calcium and phosphorus levels during the whole treatment.

Conclusions: Intravenous paricalcitol can decrease the size and number of parathyroid gland, and reduce iPTH concentrations in SHPT patients with Long-term maintenance hemodialysis, without significant influence for serum Ca and P levels.



PO0553

Burden of Secondary Hyperparathyroidism: A Matched Comparison Using Administrative Claims Data from Germany

Philipp Csomor,[1] Kim M. Schneider,[2] Timotheus Stremel,[2] Edelgard Kaiser,[1] Dominic Meise.[2] *[1]Vifor Pharma Ltd, Glattbrugg, Switzerland; [2]Xcenda GmbH, Hannover, Germany*.

Background: Secondary hyperparathyroidism (SHPT) is a frequent, early, and progressive complication in chronic kidney disease (CKD) characterized by excessive parathyroid hormone production. SHPT independently predicts serious complications like cardiovascular diseases (CVD), fractures, progression to dialysis, and death. Analysis of data on the burden of CKD patients with SHPT in the German health insurance system is lacking.

Methods: A German health insurance claims database comprising data from 2014-2018 served as a source to identify CKD stage 3 and 4 patients, who were stratified by the occurrence of incident SHPT using ICD-10-GM diagnosis and ATC prescription codes. SHPT patients were matched 1:1 to non-SHPT patients in the same CKD stage using propensity scores. Index date was the first SHPT diagnosis quarter in the SHPT cohorts, and a randomly chosen quarter of a CKD diagnosis within the CKD-only cohorts. Patients with evidence of dialysis or kidney transplant prior to the index quarter were excluded. Matched groups were compared with respect to the prevalence of CVD (acute and recurrent myocardial infarction (MI), chronic ischemic heart disease, congestive heart failure (HF), and atherosclerosis (ATH)), dialysis, and CKD progression in a two-year follow-up period.

Results: Overall, 1,156 incident SHPT patients in CKD3 and 517 in CKD4 and their respective matches were identified. Prevalence of combined CVD conditions was higher in SHPT patients (46.8% vs. 41.9% p<0.05 in CKD3, 56.5% vs. 51.8% p=0.13 in CKD4). HF was more frequent among SHPT patients (34.6% vs. 28.6% p<0.01 in CKD3 and 46.4% vs. 39.3% in CKD4 p<0.05) while acute MI was observed significantly more often among CKD4 patients in the SHPT cohort (9.1% vs. 5.8% p<0.05). ATH was more frequent in SHPT patients in CKD4 (18.6% vs. 14.3% p=0.06). SHPT patients progressed to CKD5 more often (6.1% vs. 1.2% from CKD3, 26.7% vs. 2.9% from CKD4, both p<0.01) which resulted in a higher proportion of dialysis (6.1% vs. 1.3% in CKD3, 22.1% vs. 3.7% in CKD4, both p<0.01).

Conclusions: Patients with CKD3&4 and incident SHPT presented with a significantly higher disease progression to CKD5 and dialysis and had a higher prevalence of CVD compared to patients without SHPT during a two-year follow-up period.

Calcium-Based Phosphate Binders and the Regulation of FGF-23

Cristian Rodelo-Haad,[1,2] Marta Ciudad-Montejo,[1] David Antonio Rodríguez Fuentes,[1] Isabel López-López,[1,2] Victoria Pendon-Ruiz de Mier,[1,2] Juan R. Munoz-Castaneda,[2,1] Mariano Rodriguez,[1,2] Alejandro Martin-Malo.[1,2] *[1]Hospital Universitario Reina Sofia, Cordoba, Spain; [2]Instituto Maimonides de Investigacion Biomedica de Cordoba, Cordoba, Spain*.

Background: Phosphate and calcium load are associated with FGF23 increase. Reduction of intestinal phosphate absorption by Calcium-based binders (Ca-bB) should decrease serum FGF23, but the opposed effect may result from calcium load derived from Ca-bB-administration. Since Ca-bB has been associated with vascular calcifications and FGF23 is an independent risk factor for cardiovascular disease (CVD), it is relevant to elucidate the effect of Ca-bB on FGF23. Thus, we aimed to determine the effect of Ca-bB on serum levels of FGF23 in hemodialysis (HD) patients.

Methods: We included 121 prevalent HD patients. Serum phosphate, Ca, iPTH and intactFGF23 were measured. 52 patients were on Calcium-free (NoCa-bB) binders, whereas 69 were on calcium-based (Ca-bB, n=69) binders. We also considered treatments with cinacalcet, paricalcitol and the calcium dialysate content. Multivariable regression identified the variables associated with FGF23 increase. Statistics were performed using R

Results: The mean age was 67.8±14.7. Serum levels of phosphate, Ca and iPTH were comparable between groups of binders (Fig 1A, B, and C). iFGF23 was higher in patients on Ca-bB than in NoCa-bB (2815.7vs1268.09 pg/ml, p<0.001). Multivariable regression, adjusted for iPTH, dialysate calcium, albumin, and the treatment with cinacalcet and paricalcitol, showed that the use of Ca-bB was associated with increased serum iFGF23 (beta=0.46, p=0.01).

Conclusions: At equivalent serum levels of serum phosphate, Ca, and iPTH, the use of Ca-bB is independently associated with higher serum iFGF23. This could partially explain the detrimental cardiovascular effects associated with Ca-bB use in HD patients.

Side Selective Renal Reduction of Intact and C-Terminal FGF-23

Shilpa Sharma,[1] Alfons J. Houben,[2] Abraham A. Kroon,[2] Peter W. de Leeuw,[2] Andrew N. Hoofnagle,[3] Ronit Katz,[3] Alexander Bullen,[4] Charles Ginsberg,[4] Joachim H. Ix.[4] *[1]University of California Los Angeles, Los Angeles, CA; [2]Universiteit Maastricht, Maastricht, Netherlands; [3]University of Washington, Seattle, WA; [4]University of California San Diego, La Jolla, CA.*

Background: Relative abundance of FGF23 measured by the C-terminal (cFGF23, which measures both intact FGF23 & c-terminal fragments) vs intact (iFGF23) assays is higher in persons with higher eGFR. Mechanisms are unclear. Individuals with vascular disease often have asymmetric renal function. We compared side selective (R vs L) renal reduction of iFGF23 and cFGF23 within the same individual.

Methods: 162 patients were referred for renal angiography at Maastricht University, the Netherlands, for clinically suspected RAS. Participants were maintained off anti-hypertensive meds for 21 days. Blood samples were obtained from the aorta and right (RV) and left renal vein (LV), and renal blood flow was measured using ^{133} Xenon washout. Creatinine (Cr), cFGF23 (Immutopics), and iFGF23 (Kainos) were measured. Difference of side selective % reductions of each metabolite ([Aorta – (RV or LV)/Aorta]*100) was calculated among each participant. Mean "RV-LV metabolite reduction difference" was calculated across all participants.

Results: Mean age was 54±12 years, 54% were women, and all were white. Mean eGFR was 75±25 ml/min/1.73m^2 and directly measured Cr clearance during angiography was 72±48 ml/min/100g. Median (IQR) aorta concentrations of cFGF23 was 82 (59, 105) RU/mL, and intact FGF23 was 47(37, 65) pg/mL. The mean difference in R vs. L Cr clearance was 6.0 ± 36.2 ml/min/100g. Side selective reduction differences of both cFGF23 & iFGF23 were significantly related to side selective Cr reduction. Side selective phosphate reduction also associated with iFGF23 reduction independent of Cr reduction, but not cFGF23 (**Table**). Results were similar in models adjusted for age, sex & BMI.

Conclusions: In hypertensive individuals, the kidney with greater Cr reduction also reduced plasma cFGF23 and iFGF23 more than the contralateral kidney. The kidney that removes more iFGF23 also removes more phosphate, independent of Cr removal; a finding not observed for cFGF23.

Funding: NIDDK Support

Table: Mutually Adjusted Associations* of Variables with Side Selective Kidney FGF23 Reduction

	ΔRV-LV C-terminal FGF23 Reduction		ΔRV-LV Intact FGF23 Reduction	
Variable	β (95% CI)	p-value	β (95% CI)	p-value
Age	-1.75 (-4.57, 1.07)	0.20	-0.81 (-2.04, 0.42)	0.19
Male	1.09 (-4.96, 7.14)	0.72	-1.27 (-3.92, 1.39)	0.35

PO0557

Potassium Supplementation Decreases Plasma Fibroblast Growth Factor 23 and Increases Plasma Phosphate in Stage 3b-4 CKD Patients: Single-Arm Intervention Study

Stanley M. Yeung,[1] Martin Gritter,[5] Rosa D. Wouda,[2] Stephan J. Bakker,[1] Jelmer J. Van Zanden,[3] Joris I. Rotmans,[4] Ewout J. Hoorn,[5] Liffert Vogt,[2] Martin H. De Borst.[1] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [3]Martini Ziekenhuis, Groningen, Netherlands; [4]Leids Universitair Medisch Centrum, Leiden, Netherlands; [5]Erasmus MC, Rotterdam, Netherlands.*

Background: Advanced chronic kidney disease (CKD) is characterized by mineral and bone disorders (MBD) including elevated fibroblast growth factor 23 (FGF23). Recent studies in healthy subjects showed that potassium supplementation decreases FGF23. Here, we investigated whether potassium supplementation reduces FGF23 and other MBD parameters in patients with CKD.

Methods: We performed a post-hoc analysis of a 2-week open-label run-in phase from a clinical trial in patients with CKD stage G3b-G4 (NCT03253172). Patients received potassium chloride (KCl, 40 mmol/day). Baseline and post-treatment blood and urine samples were collected. Mixed model analyses were used to assess effects of potassium supplementation on MBD parameters.

Results: We included 135 patients in whom KCl supplementation increased plasma phosphate (from 1.0±0.2 to 1.1±0.2 mmol/L, *P*=0.001) and tubular phosphate reabsorption (from 0.64±0.20 to 0.69±0.20 mmol/L, *P*<0.001). KCl supplementation, when adjusted for estimated glomerular filtration rate, decreased C-terminal FGF23 (cFGF23) (from 140.5 [Interquartile range [IQR] 105.9–217.4] to 131.5 [IQR 105.8–212.8] RU/mL, *P*=0.03), intact FGF23 (from 69.6 [IQR 46.6–107.1] to 62.9 [IQR 41.7–104.6] pg/mL, *P*=0.003) and vitamin D (72.5 [IQR 43.9–92.9] to 70.2 [IQR 44.2–90.1] nmol/L, *P*<0.001). Parathyroid hormone, plasma calcium, 24hrs urinary calcium excretion, α-Klotho, and IL-6 did not change. At baseline, 37 participants were vitamin D deficient (<50 nmol/L). The decrease in cFGF23 by KCl supplementation depended on baseline vitamin D status (*P*-interaction=0.02), and was present in vitamin D sufficient (147.2 [IQR 108.3–216.8] to 130.9 [IQR 105.5–218.0] RU/mL, *P*=0.03), while it was not in vitamin D deficient patients (131.5 [IQR 104.0–230.7] to 133.0 [IQR 106.8–211.0] RU/mL, *P*=0.32).

Conclusions: In this short-term interventional study, KCl supplementation reduced FGF23 and coincided with increased plasma phosphate levels and vitamin D. Reduction in cFGF23 by KCl was only present in vitamin D sufficient patients. Dietary potassium intake might decrease FGF23 levels and vitamin D status should be sufficient before FGF23 lowering strategies could be applied in patients with CKD.

The Dietary Supplement Chitosan Lowers Serum Phosphorus in a Hemodialysis Patient Not Tolerating Prescription Binders

Martin Sedlacek. Multidisciplinary patient care team, FMC Lebanon dialysis unit, Lebanon, NH *Dartmouth-Hitchcock Medical Center, Lebanon, NH.*

Introduction: Chitosan is a chitin derived, non-toxic, biodegradable biopolymer that binds negatively charged molecules. It's numerous industrial applications include phosphorus binding in agricultural wastewater. In humans it is used as a dietary supplement for weight loss, purportedly binding negatively charged lipids and bile acids and preventing their absorption. Here we report the case of a dialysis patient who did not tolerate prescription binders and who was able to control her serum phosphorus level for over a year by taking 3.5g of Chitosan with meals.

Case Description: A 66 y/o woman with no prior medical history and not taking any medications presented with emphysematous pyelonephritis with bilateral obstructing staghorn calculi requiring intensive care and hemodialysis. Her intial serum creatinine was 18 mg/dl. She recovered from sepsis but continued to require dialysis after discharge. Her residual creatinine clearance was 7.9ml/min six months after hospital discharge and 5.6ml/min two years later. The patient tried several prescription phosphorus binders but eventually decided to stop all prescription medications because of gastrointestinal side effects. Since over a year ago, at the recommendation of her dietitician, she purchased 500mg Chitosan tablets from the internet and used them like a phosphorus binder with meals, at a dose of 3.5 g per day. Her serum phosphorus levels have been stable and in a controlled range since (Figure 1). A quantitative analysis using urea kinetics to estimate phosphorus intake and removal reveals that Chitosan bind around 40 mg of phosphorus per gram, comparable to prescription binders.

Discussion: Chitosan acts as an over-the-counter non-calcium containing phosphorus binder that may provide an alternative option for patients who do not tolerate prescription phosphorus binders. Importantly, it may be psychologically more attractive for patients to take a dietary supplement for weight loss with their meals than a prescription medication.

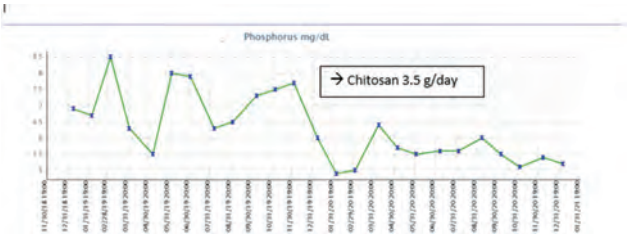

Figure 1: Effect of Chitosan on serum phosphorus levels

PO0559

Longitudinal Changes in FGF-23 in Children with CKD

Farzana Perwad,[1] Matthew Matheson,[2] Isidro B. Salusky,[3] Harald Jüppner,[7] Myles Wolf,[6] Bradley A. Warady,[4] Susan L. Furth,[5] Derek Ng,[2] Anthony A. Portale.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Johns Hopkins University, Baltimore, MD; [3]University of California Los Angeles, Los Angeles, CA; [4]Children's Mercy Hospitals and Clinics, Kansas City, MO; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]Duke University, Durham, NC; [7]Massachusetts General Hospital, Boston, MA.*

Background: Cross sectional studies show that plasma FGF23 is increased early in the course of chronic kidney disease (CKD) in children and adults and associates with disease progression and adverse cardiovascular outcomes. However, longitudinal changes in FGF23 have not been described in children with progressive CKD.

Methods: We measured C-terminal FGF23 and estimated GFR at baseline and every other year in 564 children with CKD stages 2-4 enrolled in the Chronic Kidney Disease in Children (CKiD) study. All subjects had 2 to 5 FGF23 measurements. We used linear mixed models to identify factors associated with baseline FGF23 level and longitudinal changes and latent group-based trajectory modeling to characterize distinct classes of FGF23 trajectories.

Results: Median age was 11 years and eGFR 55 ml/min/1.73m^2. In a univariate model with repeated measures, plasma FGF23 was 12% higher for every 10% lower eGFR (P<0.0001). In fully adjusted models, higher FGF23 at baseline was significantly associated with lower GFR, higher serum phosphorus, and glomerular diagnosis. Thereafter, FGF23 increased more rapidly in older subjects with lower GFR and higher proteinuria at baseline. We identified three distinct linear FGF23 trajectories: stable FGF23 in 62% of subjects (FGF23 slope 0% per yr); slowly rising in 32% (6% per yr) and rapidly rising in 6% (39% per yr). At baseline, median FGF23 in the trajectory groups were 90 [IQR:70,120], 166 [125, 242] and 461 [219, 924] RU/ml, respectively. Membership in the faster-rising trajectory groups was associated with lower eGFR, higher proteinuria and serum phosphorus, and glomerular diagnosis.

Conclusions: FGF23 was relatively stable in most children with CKD, but it increased more rapidly in those with traditional CKD risk factors. Further analyses of FGF23 trajectories will investigate whether FGF23 is a modifiable cause or a consequence of CKD progression and cardiovascular complications.

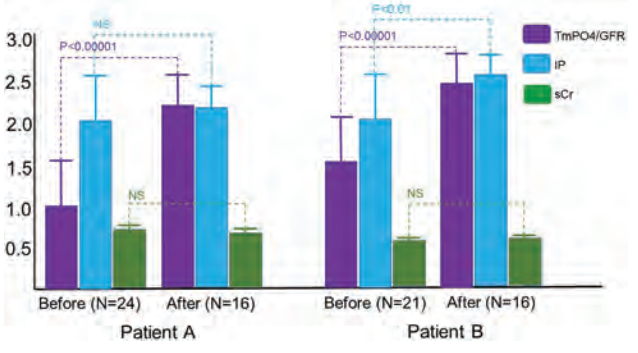
Two Siblings with X-Linked Hypophosphatemia (XLH) Treated with Burosumab: Is Therapeutic Regimen Recommended Now Supported by Real-World Data?

Hiroyuki Morita,[1] Kiyoko Inui,[2] Yoshihiko Inoue,[2] Fumihiko Koiwa,[2] Ashio Yoshimura,[3] Junko Takagi.[1] *[1]Aichi Ika Daigaku, Nagakute, Japan; [2]Showa Daigaku Fujigaoka Byoin, Yokohama, Japan; [3]Shinyokohama Daiichi Clinic, Yokohama, Japan.*

Introduction: Burosumab, a human monoclonal antibody to FGF 23, is used now to treat XLH. In phase III study, patients were selected and controlled. What is considered as "recommended" regimen of burosumab in that population within the controlled setting might be different from that in another population in real world. The present study was conducted in an attempt to address this issue.

Case Description: Patient A and patient B with XLH are siblings in their twenties. They were successfully managed in childhood, and have enthesopathy. They had had alpha calciferol and phosphate supplementation, and started to have 1 mg/kg BW burosumab 1.5 years ago. Changes in TmP/GFR, IP, and sCr after burosumab administration are shown (Figure). A significant increase in TmP/GFR ($p<0.00001$) was seen. IP and sCr levels almost did not change. Nephrocalcinosis, hyperparathyroidism, and vitamin D deficiency were mild and not worsened. Changes in bone mineral density (BMD) were assessed by DEXA scan. In 2018, young adult mean (YAM) of lumbar vertebra were 129% in Patient A, and 138% in Patient B. In 2021, these YAM values increased to 141% in Patient A and 140% in Patient B, respectively. ***Figure legend:*** Data for the past 6.5 years were retrospectively analyzed and shown as mean (colomn) plus standard deviation (bar). N numbers indicate the time they visited our hospital where they gave blood and spot urine samples. Dimensions of IP, and sCr are mg/dL. TmP/GFR; tubular threshold maximum for phosphorous per glomerular filtration rate.

Discussion: Using real-world data, we confirmed the efficacy and safety of recommended burosumab therapy regimen for 1.5 years, so far as laboratory indices used in phase III study were concerned. However, YAM values were above-the-average and increasing in the presence of hypophosphatemia and low TmP/GFR. The future consequence of this feature in relation to time-elapsed changes in renal physiological parameters including TmP/GFR, Ca, IP, and sCr should be seen.



PO0561

Burosumab in X-Linked Hypophosphatemic Rickets Adult Patients: An Italian Center Experience

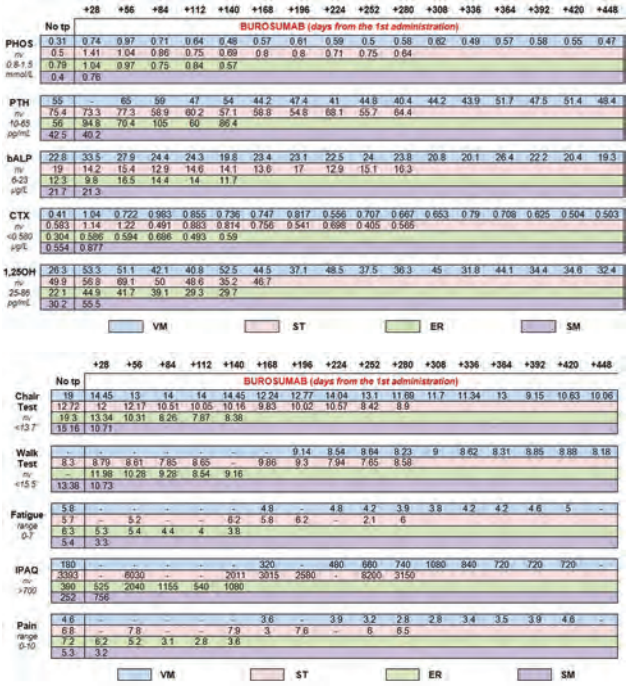
Nadia Edvige Foligno, Teresa Arcidiacono, Arianna Bologna, Elena Brioni, Monica Avino, Giuseppe Vezzoli. *Nephrology and Dialysis Unit, IRCCS San Raffaele Scientific Institute, Vita-Salute University, Milan, Italy.*

Background: X-linked Hypophosphatemic Rickets (XHR) is a rare disease caused by mutations in the PHEX gene leading to an increase in the serum levels of FGF23, which inhibits the tubular reabsorption of phosphates and the production of $1,25(OH)_2D$. This causes hypophosphataemia, rickets, bone deformities, growth retardation and muscle activity impairment.

Methods: Burosumab (B) is a monoclonal antibody against FGF23, used for the treatment of XHR patients. In Italy B can be employed in adults only as compassionate use. Starting in 2020 B (1 mg/kg sc every 4w) was administered to 4 adult subjects with XHR: VM (M, 32 yrs), ST (F, 47), ER (M, 46) and SM (F, 20) who showed legs deformities, musculoskeletal pain and severe movement limitations.

Results: In all patients, phosphorus levels were normalized by B, but tended to decrease during the 28 days following the administration. Plasma values of $1,25(OH)_2D$ and CTX (marker of bone resorption) also increased to a peak which then decreased over months. In contrast, PTH and bALP values did not change during B therapy. Scores provided by specific tests confirmed an improvement in the fatigue resistance and physical performance. Other tests showed the improvement of self-reported well-being and quality of life in all patients. These effects were not observed in adult patients on conventional therapy with phosphate salts and active vitamin D.

Conclusions: Despite the only temporary effect on phosphorus, Burosumab is right now the only therapy that improve the impact that XHR has on the quality of life of XHR patients.



PO0562

Regional Epidemiological Investigation of Calciphylaxis in Chinese Hemodialysis Patients

Yuqiu Liu, Canlin Yang, Bi-Cheng Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Calciphylaxis (calcific uremic arteriolopathy, CUA) is a grievous life-threatening vascular disease that commonly affects dialysis patients. This is the first epidemiological survey of CUA initiated in China.

Methods: In the cross-sectional survey during Oct. 2018 to Oct. 2019, a stratified sampling method was used to select 24 dialysis centers in Jiangsu Province in China. The participants were all adult patients in each center, who had been on hemodialysis for more than 6 months. This multicenter investigation was conducted in the form of questionnaires, which were filled in by doctors or nurses according to the actual situation of patients. CUA patients were uniformly diagnosed by the Calciphylaxis Study Group based on characteristic skin lesions and histopathological features.

Results: A total of 3867 hemodialysis patients (average age of 55.33±13.89 years; 61.81% of males) were included. 48 cases were diagnosed with CUA, and the prevalence was 1.24%. Among CUA patients, 68.75% of cases were male, and average age and median dialysis duration were 53.85±15.17 years and 84.00 (48.00, 138.75) months respectively. The average BMI of CUA patients was higher than that of controls, and patients with hyperparathyroidism, diabetes, atrial fibrillation, stroke, or tumors were more likely to suffer from the disease. Although only 4 CUA patients used warfarin therapy, there was still a significant statistical difference between two groups. Multivariate analysis indicated that increased BMI, prolonged dialysis duration, warfarin therapy, concomitant with hyperparathyroidism, diabetes mellitus or tumors, low ALB, and high serum ALP levels were high-risk factors for CUA. 394 (10.32%) of 3819 hemodialysis patients who didn't meet current diagnostic criteria for CUA had a variety of manifestations of skin lesions, mainly in lower limbs. 28.68% of these patients complained about a progressive deterioration of skin damage, and 44.67% suffered moderate to severe pain with potential CUA risks.

Conclusions: The prevalence of CUA in Chinese hemodialysis patients was 1.24% according to this regional epidemiological survey, but its actual prevalence would be presumably far beyond present data. Calciphylaxis, as a disease with such a high disability and fatality rate, should attract the attention of relevant specialists.

PO0563

Intraperitoneal Sodium Thiosulfate: Revisiting Route of Therapy for Calciphylaxis in Peritoneal Dialysis

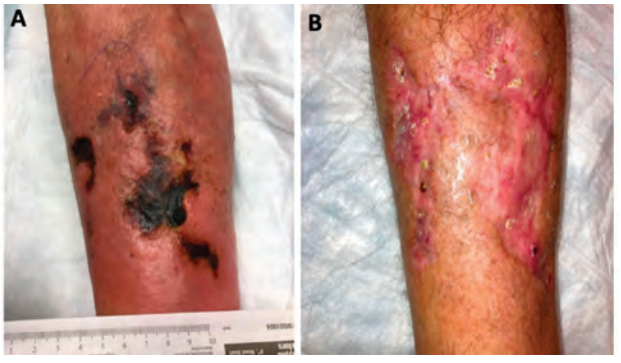
Khaled Janom, Salma Shaikhouni, Rachel Perlman, Richard D. Swartz. *University of Michigan, Ann Arbor, MI.*

Introduction: Intraperitoneal (IP) drug therapy provides a convenient route for medication administration in patients on peritoneal dialysis (PD). IP sodium thiosulfate (STS) has been used for treatment of calciphylaxis with demonstrated enhanced calcium extraction. However, the use of this therapy has been limited after a reported incident case of chemical peritonitis. This reported complication did coincide with an FDA recall for

STS, and the possibility remains that peritonitis may have been due to particulate matter contamination. We present a case of calciphylaxis which was successfully treated with IP STS without evidence of peritonitis.

Case Description: An 80 yo woman on PD presented with bilateral lower extremity pain and erythema. This progressed to a necrotic eschar (Figure 1A). Labs were notable for PTH 1267, and Ca x Phos product of 110. Biopsy confirmed calciphylaxis. She underwent subtotal parathyroidectomy and was treated with IV STS. Severe nausea with IV infusions necessitated discontinuation of therapy. She transitioned to IP therapy, 12.5 g of STS in 1L of normal saline as a long dwell day-time exchange to maximize absorption and subsequent mobilization of calcium from tissue. The patient's pain significantly improved within 1 week. Therapy was completed after 3 months. The lesions almost completely healed 6 months after starting treatment (Figure 1B). Interval PD effluent cell counts, on several occasions, did not change in the PD effluent, although a modest, unexplained decrease in kt/V was noted.

Discussion: The use of IP medications in patients on PD minimizes venous access complications and reduces clinic visits. In our case, we were able to effectively treat calciphylaxis in a patient who could not tolerate IV STS therapy. No inflammatory activity appeared in the PD fluid, and it is unclear if STS had any other adverse effects. Further studies are needed to understand the impact of this therapy on peritoneal membrane transport characteristics.



Calciphylaxis lesion at diagnosis (A) and 6 months later (B)

PO0564

Calciphylaxis in a Cohort with Normal Kidney Function: Improved Survival Compared to ESKD

Mohamed Hassanein, Emad Ababneh, Anas Saad, Eleanor E. Cook, Anthony P. Fernandez, Jennifer S. Ko, Steven D. Billings, Richard A. Fatica, Tushar J. Vachharajani. *Cleveland Clinic, Cleveland, OH.*

Background: Calciphylaxis is a rare, devastating disease, characterized by vascular calcification and is associated with increased mortality.

Methods: We studied the baseline characteristics and outcomes of 78 patients with biopsy-proven calciphylaxis that were stratified according to glomerular filtration rate (GFR) into normal kidney function (NKF): GFR ≥ 90 mL/min/1.73 m^2, chronic kidney disease (CKD): GFR 15 – 89 mL/min/1.73 m^2, and end-stage kidney disease (ESKD): GFR <15 mL/min/1.73 m^2.

Results: Forty-seven patients (60%) with calciphylaxis had ESKD, compared to 22 patients (28%) with CKD and 9 patients (12%) with NKF. Patients with NKF were younger (median age 55 years compared to 69 years in CKD and 65 years in ESKD, p=0.006). Across all 3 groups, there was a predominance of female gender, obesity, multiple and peripheral lesions involving the extremities. Among patients with ESKD, 39 patients (83%) were on hemodialysis (HD) and 7 patients (15%) were on peritoneal dialysis (PD). The probability of survival was significantly higher in patients with NKF compared to ESKD (p = 0.039)(figure 1). Sepsis was the most common cause of death.

Conclusions: Calciphylaxis can occur in patients with normal or abnormal kidney function. Female gender, obesity, multiple, and peripheral lesions were predominant in our cohort. Patients with NKF were younger, which may have contributed to their increased survival compared to ESKD. Sepsis due to secondary infection of necrotic wounds appears to remain the most common cause of death.

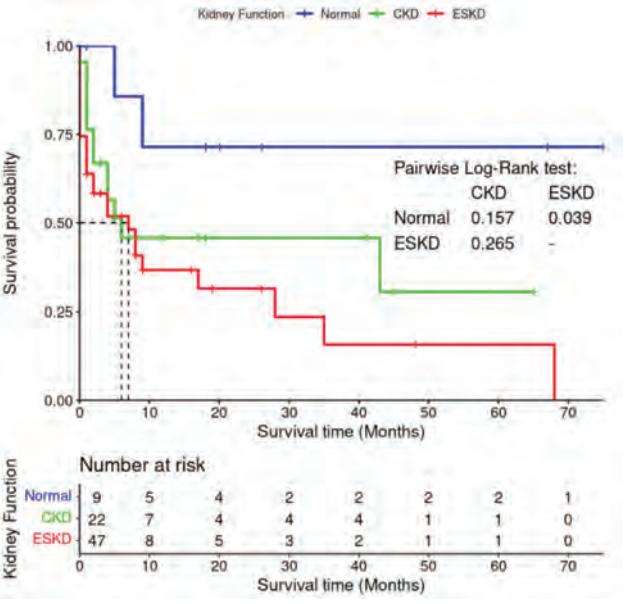


Figure 1: Kaplan-Meier curve showing survival in patients with calciphylaxis according to kidney function.

PO0565

Severe Tumoral Calcinosis of the Hip in a Hemodialysis Patient

Ian J. Da Silva Lugo, Juan C. Santiago-Gonzalez, Edilberto J. Ocasio Feliciano, Alexandra C. Pico-Ramirez, Yamiris Rodriguez, Krystahl Z. Andujar, Ileana E. Ocasio Melendez. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Tumoral calcinosis (TC) is a rare complication of patients with end-stage renal disease (ESRD) on hemodialysis (HD) in which precipitation of calcium salts occurs in periarticular soft tissue. This manifestation can lead to painful and function restricting lesions. We herein describe a case of a severe presentation of TC with associated ulceration.

Case Description: A 47-year-old female with medical history of arterial hypertension, heart failure, hypothyroidism, focal segmental glomerulosclerosis and ESRD on HD for 15 years presented to the emergency department after a right hip ulceration. The patient described a right hip hard mass with ten years of progressive growth that suffered a sudden rupture associated with sand-like secretions. Medication and dialysis compliance was reported. Vital signs were unremarkable. Physical examination showed a right hip swelling and ulcer. Laboratories revealed WBC of 19.98 103/µL, Hgb of 8.70 g/dL, calcium 9.9 mg/dL, phosphorus 6.6 mg/dL, 25-hydroxyvitamin D 12.72 ng/mL and PTH 288.90 pg/mL. Calcium Phosphate Product (CPP) resulted in 65.34 mg/dL. Pelvic CT scan showed a 11.4cm x 9.6cm mixed density calcified cystic mass with multiple fluid-calcium levels in the right hip, suggestive of TC. Treatment with intravenous Sodium Thiosulfate, Sevelamer and antibiotics were provided. Cleansing and debridement were performed by the plastic surgery team without complications. Patient was discharged and sodium thiosulfate treatment was continued at the hemodialysis center.

Discussion: TC is associated with the dysregulation of calcium phosphate metabolism. Altered renal phosphate excretion along with vitamin D activation leading to hyperparathyroidism with elevated CPP is the proposed mechanism. The precipitation of large periarticular deposits of calcium salts leads to inflammation and chronic pain. Consequently, limiting functionality and impairing quality of life. Surgical excision can relieve symptoms, but the deposits can recur. Sodium thiosulfate has been described as a potential treatment, but further studies are necessary to assess its role in dialysis patients. The recognition of this rare disease is important as optimization of medical therapy and dialysis regimen can improve the evolution and outcome of this disorder.

PO0566

Case Series of Penile Calciphylaxis in a Large Urban Hospital

Alfred T. Solomon, Sitarama Arvind Mudunuru, Jose E. Navarrete, Jason Cobb. *Emory University School of Medicine, Atlanta, GA.*

Background: Calciphylaxis or calcific uremic arteriolopathy (CUA) is a complex syndrome of deranged mineral metabolism and vascular calcification with subsequent tissue ischemia predominantly in end stage kidney disease(ESKD) patients on dialysis. The disease has been categorized as central or peripheral but in rare cases of peripheral calciphylaxis there may be penile involvement. Due to the paucity of data on penile calciphylaxis, this study was done to ascertain the characteristics, management and mortality of patients with this condition.

Methods: An observational study involving retrospective analysis of medical records of six(6) patients with biopsy proven penile calciphylaxis treated in a large urban hospital between January 2000 and March 2021 was performed.

Results: All patients with penile calciphylaxis had ESKD with mean duration on dialysis of 5.2±3.5 years. The mean age at diagnosis was 54±9.7 years. Sixty six percent of patients were African Americans with the remainder being Caucasians. Only one of six patients was obese with mean BMI of 23.2±5.5 kg/m^2. Similarly only one patient was on warfarin. None of the patients was on systemic steroids or vitamin D at the time of diagnosis. All patients had secondary hyperparathyroidism with median PTH of 264.5pg/mL (IQR 175.5). Surprisingly all patients had normal calcium phosphate products with mean of 36.1±11.6mg^2/dL^2(normal range for our lab is 21.5-51.5). Penectomy was performed in 4 patients and 2 patients had treatment with hyperbaric oxygen. The mean survival at diagnosis was 4.0±1.2 months. Mortality was 20% and 100% at 3 and 6 months post diagnosis respectively.

Conclusions: Penile calciphylaxis is a very rare entity. Although obesity has been associated with calciphylaxis, majority of our patients with penile calciphylaxis were not obese. Interestingly all our patients had normal calcium phosphate products suggestive of heterogeneous mechanisms in the pathophysiology of the disease. The PTH was lower than our previously reported level of 569pg/mL in our calciphylaxis database. Our mortality rate was very high with 100% mortality within six months of penile calciphylaxis diagnosis.

PO0567

A Case of Severe Penile Pain

Tatyana M. Joab, Valerie S. Barta. *Lenox Hill Hospital, New York, NY.*

Introduction: Calciphylaxis is a rare disease with skin necrosis, tissue ischemia and small to medium-sized vessel calcium (Ca) deposition and thrombosis. The prevalence of penile calciphylaxis is 0.24% in end stage kidney disease (ESKD). Given its rarity and location, it can be difficult to diagnose and has a poor prognosis. Identifying it is imperative.

Case Description: 56 year old male with ESKD on hemodialysis (HD) due to diabetes mellitus with secondary hyperparathyroidism and peripheral vascular disease was admitted with a painful, necrotic penile lesion for 1 month. Since starting HD 1 year prior, his serum phosphorous ranged 7.8-9.0mg/dL, Ca 8.0-9.0mg/dL and parathyroid hormone downtrended from 611 to 127pg/mL on hectorol, phoslo and Ca carbonate. CTA showed atherosclerotic stenosis of internal pudendal arteries with patent penile arteries. Interventional angiogram showed severe stenosis occluding distal pudendal arteries. After consensus with nephrology, interventional radiology, vascular surgery, urology, dermatology and infectious disease, the diagnosis of penile calciphylaxis was made. Treatment goals included phosphate normalization by 4 weekly HD sessions, low Ca dialysate, non Ca based phosphate binders; vasodilators sildenafil and pentoxifylline, and sodium thiosulphate (blocks calcification of smooth muscle cells). He is in a clinical trial for SNF472, a selective calcification inhibitor, for wound healing and pain management. His severe pain has resulted in disability and income loss.

Discussion: Penile calciphylaxis is associated with hyperparathyroidism, ESKD, and normal body mass index. Neither parathyroidectomy nor penectomy have shown mortality benefits and current treatments are not based on interventional trials. Kidney transplant may be curative. It is essential that we identify penile calciphylaxis, given its significant morbidity and mortality.

Penile calciphylaxis

PO0568

Painful Facial Swelling in a 33-Year-Old Male with ESRD: Sagliker Syndrome with 2-Year Follow-Up

Hannah Gaulden, Daniel Schumacher, Manasi Singh, Tibor Fulop, Blaithin A. McMahon. *Medical University of South Carolina, Charleston, SC.*

Introduction: Sagliker syndrome is a rare form of renal osteodystrophy seen in the setting of hyperparathyroidism. Disordered skeletal remodeling resulting in severe facial changes and possible psychological changes are seen

Case Description: We present a case of a 33 year-old African American male with end-stage renal disease on maintenance hemodialysis x3/week for 7 years and systemic lupus erythematosus on adalimumab, who presented with sudden onset severe facial swelling and pain. He has a history of tertiary hyperparathyroidism with intact parathyroid hormone level of 2,400 – 4,000 pg/mL (normal: 18.4 - 88.0 pg/mL). Cinacalcet (30 mg) dosing was inconsistent due to insurance difficulties. Laboratory studies showed a corrected serum calcium of 7.9 mg/dL, serum 25-hydroxy-vitamin D of 9.8 ng/mL (25.00 - 80.00 ng/ml), serum phosphorus of 5.9 mg/dL, intact parathyroid hormone of 1,206 pg/mL and alkaline phosphatase 427 U/L (35-150) with normal liver enzymes. The patient had severe facial pain, maxillary and mandibular enlargement with hypertrophic gums and widely-spaced teeth. Extensive brown tumor formation was detected with marked extension into the buccal spaces. Altogether, his presentation was consistent with an unsually severe Sagliker syndrome. Urgent subtotal parathyroidectomy was performed with immediate normalization of PTH (170, 75 pg/mL), but with subsequent severe postoperative hungry bone syndrome and a prolonged period of excessive calcitriol and calcium supplementation. At 2 year follow-up laboratory studies revealed corrected serum calcium of 7.5 mg/dL, serum phosphorus of 6.2 mg/dL, and intact parathyroid hormone of 36 pg/mL. While his facial abnormalities and pain improved, severe mandibular swelling persisted

Discussion: Genetic predisposition may be related to target exons of calcium-sensing receptors. Low vitamin D levels are thought to play a role in susceptible patients. Our case presents a rare documented long-term outcome for severe Sagliker syndrome. Furthermore, we are reviewing initial and follow-up pictures, with review of biochemical control and vitamin-D requirements over this period.

PO0569

Incident Diuretic Use and Subsequent Risk of Bone Fractures: A Large Nationwide Observational Study of US Veterans

Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Miklos Z. Molnar,[2] Elani Streja,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of Utah Health, Salt Lake City, UT; [3]University of California Irvine, Irvine, CA; [4]VA Memphis Medical Center, Memphis, TN.*

Background: Diuretics may affect bone metabolism by electrolyte imbalance (e.g., Ca and Na derangements). Inconsistent associations have been reported between diuretic use and risk of fracture, presumably due to the heterogeneity of study designs and populations.

Methods: In a nationwide cohort of 2,318,267 US veterans with an eGFR ≥60 mL/min/1.73m^2 from 2004-2006 and follow-up through 2018, we examined the association of incident diuretic use (thiazide, loop, and K-sparing diuretics, as time-dependent exposures) with incidence of any fractures (both vertebral and non-vertebral fractures), using time-dependent Cox models adjusted for sociodemographics, smoking and alcohol use, comorbidities, eGFR, vital signs, and medications (e.g., bone anabolic/antiresorptive agents, SERMs, steroids). Associations were also assessed by diuretic types.

Results: Patients were 59±15 years old; 91% were male; 14% were African American; and 18% were diabetic. Their baseline eGFR was 82±16 mL/min/1.73m^2. Among 2,318,267 patients, 835,054 (36.0%) started any diuretic therapy, and 146,017 (6.3%) experienced an incident fracture. After multivariable adjustment, incident diuretic use (vs. non-use) was significantly associated with higher risk of incident fracture (adjusted HR [95%CI], 1.13 [1.06-1.19]). The association was most pronounced for loop diuretics (1.37 [1.28-1.46]) but less evident for thiazide diuretics (1.07 [1.00-1.14]), and was not significant for K-sparing diuretics (1.16 [0.88-1.54]) (**Figure**).

Conclusions: Diuretic use, particularly loop diuretic use, was independently associated with higher risk of incident bone fractures. While our findings may be from confouding by medical indication, it might suggest a distinct pathogenic contribution of diuretics to bone metabolism and the need for careful attention to skeletal outcomes when initiating diuretics.

PO0570

Low Magnesium Is Associated with Weak Bone Strength in Pre-Dialysis CKD Patients: Results from the KNOW-CKD Study

Minjung Kang,[1] Eunjeong Kang,[2] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Ewha Womans University, Seoul, Republic of Korea.*

Background: In patients with chronic kidney disease (CKD), bone strength was weakened as CKD progressed. There are still controversy of the association between magnesium (Mg) deficiency and osteoporosis in pre-dialysis CKD patients.

Methods: We investigated the association between serum Mg and a decrease of bone mineral density (BMD) from the prospective, multicenter cohort of pre-dialysis CKD patients (n=928). Patients were divided into tertiles according to serum Mg. The primary endpoint is a decrease of BMD, defined as decline of BMD of lumbar spine <-0.05g/cm^2. We performed sensitivity analysis with decline of BMD of femur neck.

Results: After 4 years of follow-up, BMD decreased in 267 (28.7%) patients. In a multivariable binary logistic regression model, the lowest tertile of Mg was associated with risk of the decrease of BMD of lumbar spine (T1, serum Mg ≤2.2 mg/dL, Odd ratio (OR) 2.79 [1.58–4.92]; *P*=<0.001; T3, serum Mg ≥2.3 mg/dL, reference group). Similar results were obtained when sensitivity analysis was performed with BMD of femur neck. Subgroup analyses showed that low Mg was particularly associated with risk of the decreased BMD of lumbar spine in patients <50 years of age, in those without diabetes mellitus, and in those with low physical activity.

Conclusions: Low level of Mg is associated with a weak bone strength in pre-dialysis CKD patients.

PO0571

The Vitamin D Metabolite Ratio May Serve as an Important Biomarker of Vitamin D Status in Patients Undergoing Therapeutic Plasma Exchange

Anushree Dugar,[1] Andrew N. Hoofnagle,[2] Amber P. Sanchez,[3] David M. Ward,[3] Jonathan Cheng,[3] Joachim H. Ix,[3] Charles Ginsberg.[3] *[1]University of California San Diego School of Medicine, La Jolla, CA; [2]University of Washington, Seattle, WA; [3]University of California San Diego Department of Medicine, La Jolla, CA.*

Background: Recent studies suggest that 25-hydroxyvitamin D [25(OH)D] may be a poor marker of vitamin D status due to variability in levels of vitamin D binding protein (VDBP). The vitamin D metabolite ratio (VMR) is the ratio of 24,25$(OH)_2D_3$: 25$(OH)D_3$ and is thought to be independent of variability in VDBP. Therapeutic plasma exchange (TPE) is a procedure that removes VDBP and thus may lower vitamin D metabolites. The effects of TPE on free vitamin D concentrations and the VMR remains unknown.

Methods: We measured total 25(OH)D, 1,25$(OH)_2D$, 24,25$(OH)_2D_3$, and VDBP using Liquid chromatography–mass spectrometry, and free 25(OH)D using a DIAsource ELISA assay in 45 patients undergoing TPE. Levels were measured before and after a single TPE. We used the paired t-test to assess changes in 25(OH)D, 1,25$(OH)_2D$, 24,25$(OH)_2D_3$, free 25(OH)D, VDBP and VMR across TPE.

Results: Study participants had a mean age of 55 ± 16 years; 67% were female; 76% were white; one of 45 had CKD. TPE caused a significant decrease in total 25(OH)D, 1,25$(OH)_2D$, 24,25$(OH)_2D_3$, and free 25(OH)D. There was no change in the VMR from before to after TPE (Table 1).

Conclusions: Changes in VDBP concentration across TPE parallel changes in 25(OH)D, 1,25$(OH)_2D$, and 24,25$(OH)_2D_3$ suggesting that levels of these metabolites may be markers of VDBP levels. The lack of change in VMR across TPE despite a significant change in VDBP suggests that VMR is independent of VDBP levels. The VMR may therefore serve as an important biomarker of vitamin D status in populations with a large spectrum of VDBP concentrations.

Changes in Vitamin D Metabolites, VDBP, and VMR from Before to After a Single TPE Procedure (N=45)

	25(OH)D	Free 25(OH)D	24,25$(OH)_2D_3$	1,25$(OH)_2D$	VDBP	VMR
% change after TPE (95% CI)	-66% (-70%,-62%)	-31% (-38%,-24%)	-66% (-72%,-60%)	-68% (-72%,-64%)	-65% (-68%,-63%)	6% (-2%, 14%)

PO0572

Childhood Hypercalciuric Hypercalcemia with Elevated Vitamin D and Suppressed Parathyroid Hormone: Long-Term Follow-Up

Evgenia Gurevich,[1] Shelly S. Levi,[1] Yael Borovitz,[1] Hadas Alfandary,[1,3] Liat Ganon,[2,3] Dganit Dinour,[2,3] Miriam Davidovits.[1,3] *[1]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [2]Department of Nephrology and Hypertension, the Chaim Sheba Medical Center, Tel-Hashomer, Israel, Tel Aviv, Israel; [3]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Tel Aviv, Israel.*

Background: Hypercalcemia with low parathyroid hormone (PTH) level, hypercalciuria, nephrocalcinosis, or nephrolithiasis, was recently reported as caused by mutations in CYP24A1 and SLC34A genes. These encode for vitamin D-24A-hydroxylase and for the renal phosphate transporters NaPiIIa and NaPiIIc, respectively. We aimed to describe the course of these conditions during long-term follow-up

Methods: Ten patients with the above features were followed in our center during 1998-2019. Relevant laboratory and imaging data and results of genetic evaluation were retrieved from medical files

Results: The median age at presentation was 9.5 months (range 1 month-11 years), six were males, and the median follow-up time was 3.8 (1.1-14) years. Mutations in CYP24A1 and SLC34A3 were identified in three and one patients, respectively. Five patients presented with nephrocalcinosis, three with nephrolithiasis, and two had normal renal ultrasound. High blood calcium and 1,25-$(OH)_2D$ levels at presentation decreased during follow-up (11.1±1 vs 9.9±0.5 mg\dl (p=0.012), and 307±130 vs 209±65 pmol\l (p=0.03), respectively); this paralleled an increase in suppressed PTH levels (5.8±0.9 vs 11.8±7.3 pg\ml, p=0.2). Substantial improvements in hypercalciuria and renal sonography findings were not observed. Two patients had impaired renal function (eGFR 84-88 ml\min\ 1/73m^2) at the last follow up. Interventions included appropriate diet, citrate supplementation, and thiazides

Conclusions: In patients with the described clinical and laboratory profile, abnormal renal sonographic findings can persist despite appropriate treatment; and renal function may deteriorate. Long-term follow up and intervention to prevent nephrocalcinosis and nephrolithiasis are recommended in these children

PO0573

Performance Status (PS) as an Effect Modifier for Association Between Vitamin D Receptor Activator (VDRA) and Outcomes Among Hemodialysis Patients

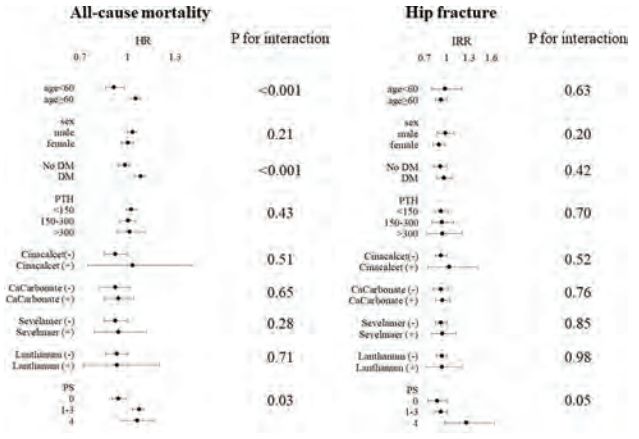
Miho Murashima,[1] Takayuki Hamano,[2] Kazuhiko Tsuruya,[3] Satoshi Ogata,[4] Eiichiro Kanda,[2] Masanori Abe,[2] Ikuto Masakane,[2] Kosaku Nitta.[2] *[1]Research Subcommittee of Japanese Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; [2]Renal Data Registry Committee, Japanese Society for Dialysis Therapy, Tokyo, Japan; [3]Nara Kenritsu Ika Daigaku, Kashihara, Japan; [4]Hiroshima Kokusai Daigaku, Higashiiroshima, Japan.*

Background: VDRA use has been reported to be associated with lower mortality and fracture among hemodialysis patients. However, PS has not been considered in previous studies.

Methods: This is a prospective cohort study based on JSDT Renal Data Registry. Subjects on hemodialysis with age 20-100 at the end of 2009 were included. Exposure of interest was VDRA use. Outcome variables were two-year all-cause mortality and hip fracture. Associations between VDRA use and mortality or fracture were analyzed using Cox or poisson regression, respectively and interaction between VDRA use and PS was tested.

Results: Among 210,001 subjects, 80,492 (61.7%) were on VDRA. VDRA use was not associated with all-cause mortality (HR 1.02 [0.99-1.05]) or hip fracture (IRR 0.93 [0.86-1.00]) after adjustment for confounders including PS. The use of VDRA was associated with lower mortality and incidence of fracture among those with good PS (PS0) but not with poor PS (P interaction 0.03 and 0.05, respectively). Poor PS was associated with higher corrected calcium (Ca), lower parathyroid hormone (PTH) levels, and proportion of intravenous VDRA use was lower among those with poor PS. Linear regression analysis showed that the association between higher corrected Ca levels and VDRA use were stronger among those with poor PS compared with those with good PS (P interaction 0.01).

Conclusions: VDRA use was associated with better outcomes only among those with good PS. The reasons may be higher prevalence of adynamic bone among those with poor PS suggested by lower PTH levels and greater increase in Ca levels by VDRA, or preclusion of higher dose VDRA prescription due to higher Ca levels.



PO0574

Prevalence of Vitamin D Deficiency in a Predominantly African-American Hemodialysis Patient Population

Anjana Easwar,[1] Omar Syed,[2] Spencer A. King,[3] Ibironke W. Apata,[1] Jose E. Navarrete,[1] Harold A. Franch,[1] Janice P. Lea,[1] Jason Cobb.[1] *[1]Emory University, Atlanta, GA; [2]New York Institute of Technology, Old Westbury, NY; [3]Morehouse School of Medicine, Atlanta, GA.*

Background: Vitamin D insufficiency and deficiency are common abnormalities and high risk groups include kidney disease patients and African-Americans. Recommendations on the evaluation of vitamin D levels in CKD and ESKD are ambiguous due to a lack of studies examining epidemiology and treatment. The COVID-19 pandemic has disproportionately affected minorities and has highlighted the need for evidence as studies have examined vitamin D deficiency as a risk factor for COVID-19 complications. We present a case series examining the prevalence of vitamin D deficiency in a predominantly African-American hemodialysis patient population.

Methods: Retrospective chart review of all in-center hemodialysis patients at Emory Dialysis in Atlanta, GA. Data extracted from Sep to Nov 2020. We excluded any patients on home therapies. Serum 25(OH)vitamin D concentration total was analyzed. We defined vitamin D insufficiency as 20-29.9 ng/mL and vitamin D deficiency as a level<20 ng/ml.

Results: Patients receiving in-center hemodialysis(n=615). Average length of time on dialysis was 5 years and average age was 59.4 years. Patients were 52.5% male(n=323). 91.5%(n=563) of patients were African-American. Mean calcium level for all patients was 8.73 mg/dL and PTH level of 554 pg/mL. Mean vitamin D in all patients was 26.32 ng/mL. 98%(n=603) of patients had a vitamin D level available. All patients with vitamin D level<30 ng/mL=412(68.3%) and all patients with vitamin D level<20 ng/mL=244(40.5%). African-American patients with a vitamin D level was 552. African-American patients with vitamin D level<30 ng/mL=382 (69.2%) and African-American patients with vitamin D level<20 ng/ml=229(41.5%). Mean vitamin D in African-American patients 25.7 ng/mL and non-African-American patients 32.7 ng/mL, p=0.01.

Conclusions: In comparison to others such as the DIVINE trial, we present a larger and more diverse cohort. In our study, African-Americans had a statistically significant lower vitamin D level. A case for replacing 25(OH) vitamin D even in ESKD patients is based on the action of vitamin D beyond mineral metabolism, especially with regard to autocrine regulation of immune function. Future directions include examining effects of treatment on PTH and study of vitamin D deficient patients' risks for adverse events like COVID-19 infection.

PO0575

Prescription Patterns of Osteoporosis Medications in Patients with CKD Stages 4-5: A Retrospective Cohort Study

Ignacio A. Portales Castillo, Cagri Aksu, Elaine W. Yu, Sagar U. Nigwekar. *Massachusetts General Hospital, Boston, MA.*

Background: Patients with CKD stages 4-5 are at greater than 2-fold risk of fractures than age-matched controls without CKD, but there is very limited data about the use of antiresorptive or bone anabolic medications in this population. Our goal was to compare the proportion of patients with CKD stages 4-5 vs CKD stages 2-3 who were prescribed these medications at our institution.

Methods: Using the Research Patient Data Registry (RPDR), a centralized clinical data registry at Mass General Brigham, we screened for all adults ≥55 years old with a diagnosis of CKD by ICD10 codes and a DXA scan available between years 2000-2019. We then identified CKD stages by eGFR and matched 100 patients with CKD stages 4-5 to 100 patients with CKD stages 2-3.

Results: Demographic characteristics were similar between the groups (Table 1). Despite having lower femoral bone density, patients with CKD stages 4-5 had lower rates of osteoporosis treatment than patients with CKD 2-3 (50% vs 72%, P=0.001). In all CKD groups, the most common class of medication used was bisphosphonates (Figure 1). Of note, 47% of patients using antiresorptive medications with stages 4-5 CKD had PTH levels lower than 100 pg/ml.

Conclusions: We found lower rates of osteoporosis treatment in patietns with CKD stages 4-5. Despite PTH levels consistent with normal or adynamic bone disease, most CKD patients are treated with antiresoprtive medicines. Our study calls attention to knowledge gaps in osteoporosis and CKD.

PO0576

Development of a Machine Learning Approach to Management of CKD-MBD Therapy

Adam E. Gaweda,[1] Michael E. Brier,[1,2] Eleanor D. Lederer.[3,4] *[1]University of Louisville School of Medicine, Louisville, KY; [2]VA Robley Rex Medical Center, Louisville, KY; [3]VA North Texas Health Care System, Dallas, TX; [4]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: We developed a Quantitative Systems Pharmacology (QSP) model of CKD-MBD that predicts changes in mineral metabolism. We incorporate the CKD-MBD model into an Machine Learning (ML)-based simulation to optimize the dosing of three drugs used in CKD-MBD to test the hypothesis that Reinforcement Learning (RL) approach would improve therapeutic goals.

Methods: We performed a simulated 24 month study in a virtual cohort of 80 Stage 5d CKD patients using the QSP model of CKD-MBD treated by a simulated physician (AI-Agent 0) or RL (AI-Agent 1). Agent 0 was a Deep Neural Network trained on a set of 128,061 instances. Agent 1 was developed using RL rewarding concentrations within the target range for Ca, P, PTH and avoiding Ca < 7.0 and > 10.2 mg/dL. Results of the simulation were compared using regression analysis of the dependent variable (Ca, P, PTH, calcitriol (CTL), lnFGF23, bCa(bone efflux), and vCa(vascular influx) over time with the factors RL (Agent1 vs Agent 0), P binder adherence, and equilibrium vs. steady-state. Doses of agents used to treat were compared at 24 months.

Results: Results of the statitical analysis are shown in the Table. Agent 1 using RL resulted in a greater rate of change in the dependent variables in all cases and resulted in lower model predicted concentrations of P, PTH, and FGF23 and higher concentrations

of Ca, and CTL. The time effect on FGF23 was not significant. Ca flux from the bone and into the tissue was also decreased in Agent 1. Drug utilization was also different between methods tested at 24 months. Agent 1: 734 mg/day less P binder (p=0.015), 0.71 ug/day more calcitriol (p<0.001) and 3.84 mg/day less cinecalcet (p<0.001).

Conclusions: Through simulation we have shown that a machine learning approach using reinforcement learning is superior to an expert system mimicking physician dosing practices. Concentrations of Ca, P, and PTH came into equlibrium faster and at more optimal levels while predicting decreased unwanted Ca movement.

PO0577

Role of Current Proposed Algorithm to Guide Osteoporosis Treatment in CKD: A Bone Biopsy Study

Marie-Eve Dupuis,[1] Nada Khelifi,[1] Myriam Labrecque,[1] Sylvain Picard,[2] Thomas Nickolas,[3] Pieter Evenepoel,[4] Marie-helene Lafage-proust,[5] Fabrice Mac-Way.[1] *[1]CHU de Quebec-Universite Laval, Quebec, QC, Canada; [2]Centre de recherche du CHU de Quebec-Universite Laval, Quebec, QC, Canada; [3]Columbia University, New York, NY; [4]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [5]Inserm U1059, université de Lyon, université J. Monnet, Saint-Étienne, France.*

Background: Recently, algorithms have been proposed to guide osteoporosis treatment in chronic kidney disease population. As suggested by Kharaillah et al, evaluation of bone turnover level by bone specific phosphatase alkaline (bALP) will determine the use of anabolic or antiresorptive therapy with or without prior bone biopsy. The aim of this study is to use a cohort of CKD patients who had a bone biopsy to evaluate accuracy of this algorithm in a real-world setting.

Methods: Single-center retrospective cross-sectional study at CHU de Québec, Canada from 2017 to 2021. CKD 4-5 patients with bone fragility and suspicion of low bone turnover or mineralization defects who had a bone biopsy were included. Results of bone biopsy were categorized based on the TMV classification. We compared the performance of the algorithm to identify potential contraindications to antiresorptive or anabolic therapy vs bone biopsy results. Receiver operating characteristic (ROC) curves were used to explore the predictive ability of bALP and tALP regarding low bone turnover and potential contraindication to antiresorptive therapy in our cohort.

Results: Twenty-six patients included (mean age 67,7 years, 11 men, 14 HD and 1 PD, 11 diabetic patients). Eleven patients had low, 8 normal and 7 high bone turnover on biopsy. According to the algorithm, no patient would have received anabolic treatment, bone biopsy would have been proposed to 10 patients and 16 would have received antiresorptive therapy. Based on the biopsy results, 8 out of these 16 patients had potential contraindications: 4 with low bone turnover and 4 with presence of mineralization defects. ROC curve for bPAL to predict low bone turnover was 0,749 (similar to tPAL). However, the AUC for bPAL to predict the presence of potential contraindication to antiresorptive was lower at 0,6667 (0,6095 for tPAL).

Conclusions: Algorithm using bone turnover markers can guide clinicians in approaching these patients. However, bone biopsy is still needed in many patients to better tailor anti fracture therapy until more accurate non-invasive markers are available.

Different PTH Responsiveness and Bone Turnover in Japanese as Compared to European Patients Treated with Hemodialysis

Pieter Evenepoel,[1,2] Hanne S. Joergensen,[1,3] Hirotaka Komaba,[8] Sandro Mazzaferro,[4,5] Marc G. Vervloet,[7] Etienne Cavalier,[6] Masafumi Fukagawa.[8] on behalf of the CKD-MBD working group of the JSN, and EUROD, an initiative of the CKD-MBD working group of the ERA-EDTA *[1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [3]Aarhus Universitetshospital, Aarhus, Denmark; [4]Universita degli Studi di Roma La Sapienza, Rome, Italy; [5]Umberto I Policlinico di Roma, Roma, Italy; [6]Universite de Liege, Liege, Belgium; [7]Amsterdam Universitair Medische Centra, Duivendrecht, Netherlands; [8]Tokai Daigaku, Isehara, Japan.*

Background: Parathyroid hormone (PTH) targets are lower in Japanese compared to European patients on dialysis. Whether this translates to lower bone turnover may depend on PTH responsiveness. This study tested the hypothesis that skeletal PTH responsiveness differs between Japanese and European hemodialysis patients.

Methods: Whole PTH (Roche), bone-specific alkaline phosphatase (BsAP, IDS-iSYS), and tartrate-resistant acid phosphatase type 5b (TRAP5b, IDS-iSYS) were centrally assessed in 378 prevalent hemodialysis patients from Japan and Belgium, matched 1:1 on age, gender, diabetes, and dialysis vintage. Patients with PTH levels at the extremes (<normal range or >15 xUNL) were excluded.

Results: Patients were well matched in age (59±12 yrs), gender (66% male), diabetes (34%), and dialysis vintage (39 [22-63] months). Japanese patients had lower PTH levels (109 vs 161 ρg/mL, $p<0.001$) and bone turnover markers (BsAP 15.3 vs 24.5 ug/L; TRAP5b 3.35 vs 5.79 U/L, $p<0.001$ both). Scatterplots and linear regression revealed higher bone turnover markers in European patients for any given level of PTH (Figure). In a multivariable model, Japanese nationality, male gender, higher BMI, and higher PTH were negative predictors of the TRAP5b/PTH ratio (Table).

Conclusions: Skeletal PTH responsiveness is lower in Japanese as compared to European patients on dialysis; thus, differences in PTH sensitivity cannot reconcile the current discrepancies in PTH target range.

Association of Metabolic Acidosis with Impaired Bone Quality

Rebecca Levy,[1] Donald J. Mcmahon,[2] Maria A. Aponte Farias,[2] Michal L. Melamed,[1,3] Thomas Nickolas.[2] *[1]Montefiore Medical Center, Bronx, NY; [2]Columbia University Irving Medical Center, New York, NY; [3]Albert Einstein College of Medicine, Bronx, NY.*

Background: Chronic kidney disease (CKD) is a state of impaired bone quality and strength, usually presenting as renal osteodystrophy. Metabolic acidosis (MA) is an important complication of CKD that alters bone quality and strength and is associated with increased fracture risk. Few studies have investigated bone tissue-level effects of MA in humans with CKD. We hypothesized that CKD patients with MA would have altered bone-tissue level mineral content.

Methods: This retrospective cross-sectional analysis included 22 patients with eGFR <90 mL/min/1.73m^2, including those receiving kidney replacement therapy, recruited from the general nephrology clinics of Columbia University Irvine Medical Center. Patients were considered to have MA for serum bicarbonate ≤22mEq/L. Transiliac crest bone biopsy was assessed for bone formation and mineralization measures from quantitative histomorphometry of tetracycline double labels, tissue mineral density (TMD) by microCT and bone mineral density distribution (BMDD) by quantitative backscatter electron imaging (qBEI). Spearman correlations (ρ) were adjusted for eGFR. Univariate Wilcoxon tests assessed between group differences.

Results: Twelve participants had MA. There were no differences in age, sex or race/ethnicity. After eGFR adjustment, there was a correlation between serum bicarbonate and TMD (ρ=0.60, p=0.004). Bone formation and mineralization measures did not differ. TMD by microCT showed a trend. Measures of calcium content by BMDD differed between groups.

Conclusions: MA is associated with lower TMD and altered calcium content in patients with CKD. Further investigation is needed to determine whether impairments in TMD and BMDD are associated with decreased bone strength and are corrected by bicarbonate supplementation.

PO0580

Impact of Urinary Calcium Excretion on Bone, Cardiovascular System, and Kidney Function in Caucasian Osteoporotic Patients: A Longitudinal Long-Term Follow-Up Study

Tapas Parikh,[1] Mohamed M. Abdalbary,[2,1] Emad A. Chishti,[1] Muna Shakhashiro,[1] Marie-Claude M. Faugere,[1] B. Peter E. Sawaya,[1] Amr E. Mohamed.[1] *[1]University of Kentucky Medical Center, Lexington, KY; [2]Mansoura University Faculty of Medicine, Mansoura, Egypt.*

Background: Urinary Calcium excretion (UCaE) is expected to reflect the bone activities, however this relationship in osteoporotic (OP) patients (pts) is not well understood. Moreover, the influence of UCaE on kidney function and cardiovascular (CV) system is controversial.

Methods: Longitudinal study for OP pts who had bone biopsies between January 2008 and December 2013. All pts were white, had 24 urine collection for UCaE, DEXA scan for BMD, bone histology, and at least two follow ups with a minimum of 1-y. Exclusion criteria included active malignancies and infections, liver failure, ESKD, organ transplant, or secondary OP.

Results: Study included 118 OP pts with median follow up of 5.3 (1-11) y. The mean age was 61 ± 12 y and 89% of pts were women. The mean eGFR at baseline was 83 ± 19 ml/min Trabecular bone volume was low in 95% of pts, 39% had high turnover bone turnover disease (HTBD) and 61% had low turnover bone disease (LTBD), while mineralization was defective in 9%. Serum calcium and 25 vitamin D were within normal range in vast majority of pts. At baseline, lumbar spine (LS) T-score was -1.9 (-5.5 to 3.9), and total hip (TH) T-score was -1.6 (-4 to 2). Pts with HTBD had lower LS T-scores (p=0.02). Hypercalciuria found in 23%. Mean UCaE was 195 ± 116 mg/d with no difference between LTBD and HTBD pts. CKD pts were older (p<0.001), had higher PTH (p<0.001), and lower UCaE (p=0.04). BMD significantly declined (>2%) in 46% of pts at TH, and 42% at LS. BMD losers at TH were older, had lower UCaE, and lower serum albumin. Lower UCaE was significant predictor of BMD loss after adjustment of age, eGFR, and serum albumin (p=0.039, β=1.01, 95% CI (1-1.01)). Fractures occurred in 18% of pts during follow up. Fractures were higher in pts with UCaE<100. GFR declined (>3.3%/y) in 19% pts with no difference in UCaE in pts with declined vs stable GFR. Pts with kidney stones (13%) tended to have higher UCaE. New CV events occurred in 14% of pts. Pts with CV events tended to be older (64 vs 61 y) and had lower UCaE (169 vs 199 mg/d).

Conclusions: LTBD is common in OP pts. UCaE is not different between LTBD, and HTBD pts. CKD pts had less UCaE. Lower UCaE predicted bone loss and fracture risk in white OP pts.

PO0581

The Incidence of Hypocalcemia After Denosumab Administration in Patients with CKD

Andrea Cowan,[1,2] Nivethika Jeyakumar,[2] Alexandra M. Ouédraogo,[2] Amit X. Garg,[2,1] Igor Karp,[4] Tayyab S. Khan,[1,3] Samuel A. Silver,[5] Jenny Thain,[1] Flory T. Muanda,[2] Matthew A. Weir,[1,2] Kristin Clemens.[3,2] *[1]London Health Sciences Centre, London, ON, Canada; [2]ICES, Toronto, ON, Canada; [3]St Joseph's Healthcare London, London, ON, Canada; [4]Western University, London, ON, Canada; [5]Kingston Health Sciences Centre, Kingston, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) are at increased risk of fragility fracture and its complications. Denosumab is an antiresorptive agent approved for use in CKD, but has been associated with hypocalcemia in those with advanced disease although the incidence is unclear. We examine the real-world incidence of hypocalcaemia in patients with CKD newly prescribed denosumab.

Methods: Using linked healthcare databases (ICES), we conducted a population-based cohort study of adults >65 years newly prescribed denosumab or bisphosphonates from 2012-2017 in Ontario, Canada. We captured the incidence of hypocalcaemia within 180 days of drug dispensing, stratified by eGFR.

Results: We identified 9,319 new users of denosumab and 9,052 new users of oral bisphosphonates. Compared with bisphosphonate users, denosumab users were older (78.8 vs 75.0 years), more often from long-term care, had a history of fragility fracture, and had more advanced CKD. Approximately one third of patients dispensed denosumab had a calcium level checked within 180 days of their prescription. The risk of hypocalcemia (<2.00mmol/L) with denosumab was low (0.74% 95% CI 0.58-0.93). One third of those had a calcium <1.8mmol/L (0.28% 95% CI (0.19-0.41). The risk of hypocalcemia increased substantially in those with eGFR <30 (8.4% [95% CI 5.5-12.0]). In new users of bisphosphonates, the risk of hypocalcemia was low across all eGFR groups.

Conclusions: In the largest population-based cohort of denosumab users with CKD to date, we found a modest increase in the risk of hypocalcemia with denosumab in those with stage 4 and 5 CKD. These rates are lower than reported in smaller cohort studies. This study was limited by the low numbers of patients with end stage renal disease. Our study emphasizes the importance of awareness of denosumab-induced hypocalcemia, routine monitoring post-denosumab, and benefit-risk assessment before prescribing this treatment to patients with kidney disease.

The cumulative incidence of mild hypocalcemia (Ca <2.00 mmol/L) at 180 days

eGFR Category (mean GFR ml/min/1.73m2 [SD])	Denosumab % (95% CI)	Bisphosphonate % (95% CI)
All	0.74 (0.58-0.93)	0.38 (0.27-0.52)
eGFR ≥60 (80 [10.4])	0.46 (0.32-0.65)	0.32 (0.21-0.47)
eGFR 30 - <60 (49 [8.1])	0.65 (0.39-1.03)	0.52 (0.27-0.93)
eGFR <30 or chronic dialysis (23 [6.0])	8.39 (5.49-12.06)	1.33 (0.26-4.35

PO0582

The Efficacy and Safety of Denosumab for Osteoporosis in Advanced CKD with or Without Dialysis

Illeon Cho, Jung Nam An, Young rim Song. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: Chronic kidney disease (CKD) is associated with an increased risk of osteoporosis and fragility fractures. However, studies assessing the optimal risk stratifications and treatments for osteoporosis in patients with advanced CKD are limited. This retrospective analysis evaluated the efficacy and safety of denosumab in patients with CKD and those on dialysis using data from a single-center

Methods: A total of 96 CKD patients with or without dialysis (CKD stages G3-G5D) in our hospital, who had osteoporosis diagnosed by dual-energy X-ray absorptiometry and received denosumab 60mg subcutaneously every 6 months at least twice, were enrolled. Annual changes in bone mineral density (BMD), annual incidence rate of new fractures (vertebral or non-vertebral) and adverse events focused on hypocalcemia were the major outcomes. The subjects were classified into non-dialysis dependent or dialysis-dependent CKD (NDD-CKD or DD-CKD) groups.

Results: The annual changes in BMD (T-score) at the lumbar spine from baseline were significantly increased in both groups. The annual changes in BMD at the total hip and femoral neck were increased in both groups, although only the DD-CKD group showed significantly improved changes (Figure 1). The annual incidence rate of new fractures was similar (4.7 % for DD-CKD vs. 7.5 % for NDD-CKD, p = 0.688). The incidence rate of severe hypocalcemia was comparable between both groups (2.3 % vs. 0.0 %, p = 0.448), whereas those of mild to moderate hypocalcemia were significantly higher in DD-CKD (25.6 % vs. 1.9 %, p = 0.000; 20.9 % vs. 1.9 %, p = 0.005). None required hospitalization due to severe symptoms such as tetany and seizure.

Conclusions: Denosumab significantly increased BMD and was safe in advanced CKD patients with osteoporosis. Although severe hypocalcemia or other severe adverse outcomes were rare, physicians should keep in mind that the patients essentially need adequate vitamin D and calcium replacement prior to administration of denosumab.

A Rare Cause of Reversible Granulomatous Lung Disease Leading to Hypercalcemia in a Peritoneal Dialysis Patient

Sanjeev Shrestha, Raza Zaidi, Conrad Schuerch, Gurmukteshwar Singh. *Geisinger Medical Center, Danville, PA.*

Introduction: Hypercalcemia is associated with poor outcomes in patients with end-stage kidney disease (ESKD). A meticulous work-up is essential to deduce the etiology and initiate appropriate management. We present a report where comprehensive work-up revealed a rare, environmental exposure as a cause of hypercalcemia: exposure to drywall dust.

Case Description: A 59-year-old man with ESKD had longstanding well-controlled mineral bone disorder. He developed worsening hyperphosphatemia of unclear etiology, and eventually presented with symptomatic hypercalcemia with corrected calcium level of 12.9 mg/dL. Biochemistry and imaging were consistent with hypercalcemia of granulomatous lung disease. CT chest showed numerous conglomerations of centrilobular nodules in multiple lobes of both lungs (Figure 1A). Transbronchial biopsy showed giant cell granulomas containing crystalline material and calcified inclusions (Figure 1C, 1D). Infectious and rheumatological work-up was unrevealing. Detailed patient interview revealed that he had been sanding drywall without respiratory protection due to N95 mask shortage in the global pandemic. No treatment was initiated because the environmental exposure had already terminated. Over a few months, the imaging (Figure 1B) and biochemical findings resolved. A year later, the patient has well controlled mineral bone disorder on calcium-containing phosphate binders again.

Discussion: Our report demonstrates how systematic work-up and careful history-taking are critical in diagnosing esoteric conditions associated with hypercalcemia. It also illustrates indirect health-related effects of the coronavirus-19 pandemic on non-infected ESKD patients.

PO0584

Holy Fanconi, My Bone Is Breaking!

Anum Hamiduzzaman, Wei Ling Lau. *University of California Irvine, Irvine, CA.*

Introduction: Tenofovir-induced Fanconi syndrome can be insidious with severe hypophosphatemia from renal losses leading to subclinical fractures.

Case Description: A 72 y/o woman with CKD stage 3a, chronic hepatitis B and osteoporosis was referred for hypophosphatemia. She had recently presented to the ER with dizziness/weakness, chronic bone pain and poor appetite. She was found to have a critically low phos of 1.0 mg/dL. X-rays revealed old C-spine and femur fractures. Labs were also notable for K 3.2 mmol/L, CL 111 mEq/L, bicarb 18 mEq/L, Cr 1.1 mg/dL, Ca 8.4 mg/dL, PTH 120 pg/mL and normal vit D. Medications included tenofovir disoproxil fumarate (TDF) started 5 years prior for hep B, and ibandronate for osteoporosis. The hypophosphatemia was initially attributed to poor nutrition vs bisphosphonate therapy. However, fractional excretion of phos (FEphos) resulted at 78% consistent with urinary phos wasting. Proteinuria and glucosuria in combination with hypokalemia and hyperchloremic metabolic acidosis led to a diagnosis of proximal renal tubulopathy (Fanconi syndrome) from TDF nephrotoxicity, with hypophosphatemic osteomalacia. The patient was started on Na bicarbonate, K, Ca, vitamin D and phos supplementation. Osteoporosis therapy was switched to denosumab. The patient's hepatologist switched TDF to tenofovir alafenamide (TAF) given the requirement for lifelong hepatitis B therapy. Phos improved to 3.2 mg/dL one month after TDF was discontinued, with decrease in FEphos. PTH normalized in tandem with Ca repletion (Figure).

Discussion: Tenofovir nephrotoxicity occurs via disruption of proximal tubular mitochondrial function. In our patient, prolonged 5-year exposure to TDF with renal phos wasting led to inadequate bone mineralization and subsequent osteomalacia, which may have been aggravated by concurrent bisphosphonate therapy. Subclinical bone fractures led to chronic pain, deconditioning and poor nutritional status. TAF is a prodrug of tenofovir thought to be less nephrotoxic than TDF because its pharmacokinetics requires lower doses for efficacy. Other forms of tenofovir nephrotoxicity include ATN, chronic interstitial nephritis and nephrogenic diabetes insipidus.

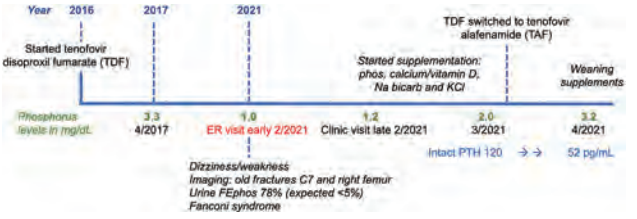

Figure: Case presentation of tenofovir-induced Fanconi syndrome.

PO0585

An Unusual Culprit of Severe Acute Refractory Symptomatic Hypocalcemia: Keyboard Cleaner

Si Yuan Khor, Nora H. Hernandez Garcilazo, Akhil Sharma, Enhua Wang, James Choi. *Michigan State University, East Lansing, MI.*

Introduction: 1,1-Difluoroethane is commonly found in gas dusters and aerosol products. It has emerged as a recreational drug due to its acute euphoric effect. Side effects from difluoroethane abuse include hypocalcemia, acute kidney injury, cardiac arrhythmias and seizures. We report a case of 1,1-difluoroethane abuse presented with severe acute symptomatic hypocalcemia post Zoledronic acid therapy for Paget's disease.

Case Description: A 35 year old male with a past medical history of Paget's disease presented with generalized muscle cramps, facial twitching and upper extremities spasms for a day. He received IV Zoledronic acid as outpatient a day prior to the onset of symptoms. He also reported a significant history of inhalant abuse with keyboard cleaners. Physical examination were unremarkable other than a positive Trousseau sign. EKG showed prolonged QTc interval of 523 ms. Initial labs revealed corrected serum calcium 4.50 mg/dL, phosphorus 1.8 mg/dL, alkaline phosphatase 455 U/L, parathyroid hormone (PTH) 201 pg/mL, 25-Hydroxyvitamin D 7.0 ng/mL and 1,25-Dihydroxyvitamin D 146 pg/mL. Over the course of 5 days, he received a total of 24 g of IV calcium gluconate and 30 g of oral calcium carbonate. His symptoms subsequently resolved and serum corrected calcium normalized to 8.04 mg/dL and PTH decreased to 169.7 pg/mL on day 5 of hospitalization. He was discharged on day 6 with plans to follow up with primary care physician for monitoring of serum calcium level.

Discussion: Incidence of severe symptomatic hypocalcemia related to Zoledronic acid therapy in Paget's disease is uncommon (1%). Our patient was treated with Zoledronic acid in the past without complication. Besides, he lacks the risk factors for bisphosphonate-induced hypocalcemia which include hypoparathyroidism, hypomagnesemia and renal failure. Low 25-Hydroxyvitamin D on presentation is likely due to the effect of secondary hyperparathyroidism in response to hypocalcemia. Thus, we conclude that 1,1-difluoroethane is most likely the major precipitating factor for hypocalcemia seen in this case. Healthcare provider should be aware of uncommon causes of hypocalcemia such as difluoroethane as a differential once common causes have been ruled out, especially in certain susceptible populations given the ease of access for abuse and potentially fatal associated adverse effects.

PO0586

Severe Hypercalcemia in a Patient with Acute Lobar Nephronia

Olesya Ilkun, Martin C. Gregory, Monique E. Cho, Josephine Abraham. *University of Utah Health Hospitals and Clinics, Salt Lake City, UT.*

Introduction: Acute lobar nephronia is a form of focal acute bacterial pyelonephritis without abscess formation or liquefaction.

Case Description: A 62-year-old Native American woman with a childhood history of left nephrectomy and treatment for tuberculosis was admitted for sepsis due to pyelonephritis and pan-sensitive E. coli bacteremia. Her creatinine was 5.2 mg/dL on admission, improved to 3.5 mg/dL with intravenous ceftriaxone, then increased to 4.2 mg/dL after transitioning to oral antibiotics six days later. At the same time, she developed hypercalcemia, which peaked at 13.7 mg/dL (ionized calcium 1.83 mmol/L). PTH was undetectable. Her 1,25-dihydroxy vitamin D (1,25-Vit D) was elevated at 120 pg/mL. The ultrasound showed right kidney hypertrophy to 16.3 x 9.9 x 10.5 cm, but no perinephric abscess or hydronephrosis. MRI abdomen showed wedge-shaped and cortical hyperintense striations through the kidney, the largest measuring 2.3 cm (Figure 1). Imaging showed no osteomyelitis, lytic lesions or suspicious masses. Kappa/lambda ratio was at 0.8 and IFE gel showed a faint band in lambda suggestive of a specific immune response or an early monoclonal protein. QuantiFERON Gold was indeterminate but imaging did not show pulmonary tuberculosis. Seven separate urine samples had negative acid fast stain and culture. Mycobacterium Tuberculosis PCR in urine was negative. She completed a prolonged course of antibiotics and over the six months of follow-up, her serum calcium and albumin normalized, and 1,25-Vit D fell to 16 pg/mL. Her serum creatinine decreased to 2.17 mg/dL. Right kidney size decreased to 9.8 x 5.7 x 5.4 cm and had normal contour and sonographic appearance.

Discussion: Acute hypercalcemia was likely due to a rare pathological activation of 1-alpha-hydroxylase (CYPb27b1) in renal proximal tubule cells due to inflammatory response. Common causes of severe hypercalcemia were ruled out. Supporting this etiology, resolution of hypercalcemia correlated with resolution of renal inflammation.

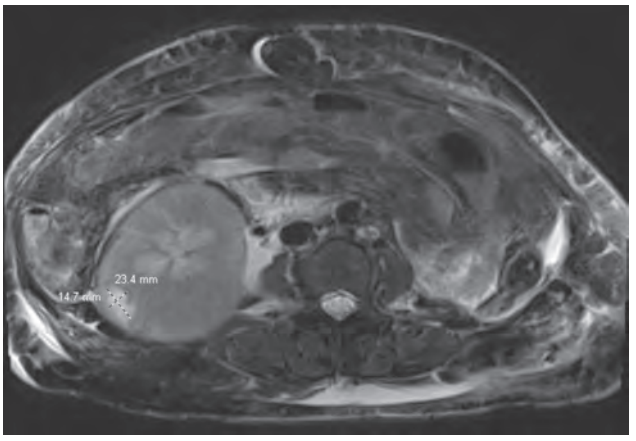

Figure 1.

Identification of Factors Affecting Changes in the Agatston Coronary Artery Calcification Score in Maintenance Hemodialysis Patients

Kenichi Morii,[1,2] Toshiki Doi,[1,2] Yoshiko Nishizawa,[1] Kenichiro Shigemoto,[1] Sonoo Mizuiri,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: Coronary artery calcification (CAC) has been implicated in cardiovascular disease, one of the leading causes of death in patients on maintenance hemodialysis (MHD). The Agaston CAC score is the most widely used scoring system for CAC evaluation. The factors affecting changes in the CAC score in MHD patients remain unknown. We characterized the associations between change in Agaston CAC score and clinical parameters in MHD patients.

Methods: A total of 288 patients on hemodialysis at Ichiyokai group facilities between January 2018 to February 2021 were retrospectively analyzed. Clinical parameters and Agaston CAC scores, determined by multi-detector computed tomography, were assessed at baseline and after 1 year. Patients with Agaston CAC score ≥ 30 were enrolled. A multiple regression analysis for change in Agaston CAC score was performed. The independent variables were sex, age, Agaston CAC score, glucose, albumin-corrected serum calcium, serum phosphate, β2-microglobulin, hemoglobin, blood urea nitrogen, albumin, angiotensin-converting enzyme (ACE) inhibitor/angiotensin II receptor blocker (ARB) use, calcimimetic use, and vitamin D use.

Results: The mean change in Agaston CAC score was 205.2 ± 545.1 and the mean percentage change in Agaston CAC score was 21.2% ± 43.5%. The multiple regression analysis for change in Agaston CAC score identified Agaston CAC score (regression coefficient [RC] = 0.3795, $p < 0.001$), serum phosphate (RC = 0.1230, $p = 0.0317$), albumin-corrected serum calcium (RC = –0.1165, $p = 0.0049$), and ACE inhibitor/ARB use (RC = –0.1262, $p = 0.0298$) as significantly related factors ($R^2 = 0.2011$, $p < 0.001$).

Conclusions: In patients on MHD, change in Agaston CAC score is positively associated with Agaston CAC score and serum phosphate, and negatively associated with albumin-corrected serum calcium and ACE inhibitor/ARB use.

PO0588

Qatar National Program for Screening and Management of Vascular Calcification in Hemodialysis

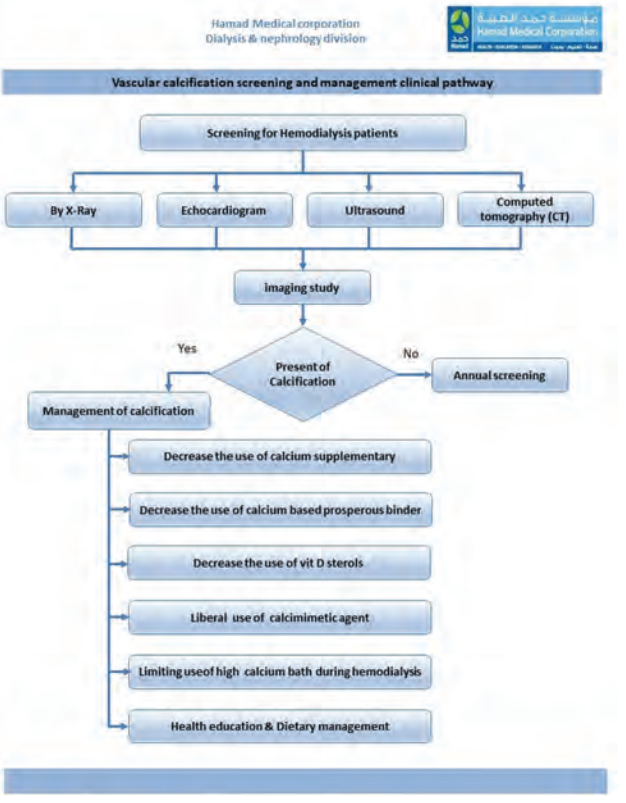
Tarek A. Fouda, Abdullah I. Hamad, Mohamed Yahya Abdelhai Mohamed, Anees J. Alomari, Alaa I. Alakhras, Abeer A. Amood, Thresiamma Abraham, Farrukh A. Farooqi, Sahar Aly, Fadwa M. Al-Ali. *Hamad Medical Corporation, Doha, Qatar.*

Background: Vascular calcification (VC) is an independent and important risk factor for cardiovascular events in (HD) patients. Trials aiming to reduce the progression of VC did not show a great success. We are presenting data from our national program for screening and management of VC in hemodialysis patients in State of Qatar.

Methods: All ambulatory HD patients in Qatar where included. Data were collected in 2020 from the Qatar national electronic medical record and it included all imaging studies (X-ray, echocardiogram, US, CT). VC then were classified into mild, moderate or severe. Patients with any VC were started on a newly created protocol to decrease calcium load (shift to non-calcium phosphate Binder, reduce active vitamin D, and liberalize calcimemitic dosing). Figure1 shows new pathway of screening and management of VC in HDpatients.

Results: Total patients were 650 During the study period. 559 were screened for VC (86%).423 (75%) had VC. We were able to classify 286 patients (67%) of them based on severity of VC on radiological findings to mild 201(70%), moderate 59(21%) or severe 26(9%). Following interventions, percentage of patients with calcium level of normal range (2.1-2.55mmol/l) increased by 5% from 83% in March 2020 to 88% in December 2020 (p value=0.004). Phosphorus level was maintained in the range 0.81-1.8mmol/l by 82% and PTH level in the range 150-500pg/ml by 72%. calcium based phosphate binder tables used weekly decreased by30%.

Conclusions: we created a screening and management protocol for VC in HD patients. Our protocol was successfully implemented and the initial outcomes was very promising. A follow up imaging to identify progression of VC should be considered in further studies.



PO0589

The Clinical Effect of Paricalcitol Treatment on Hemodialysis Patients with Secondary Hyperparathyroidism and the Influence of Abdominal Aortic Calcification

Yin Liu, Tao Yang. *Beijing Haidian Hospital, Beijing, China.*

Background: This is an observational study to investigate the clinical efficacy of paricalcitol in maintenance hemodialysis (MHD) patients with secondary hyperparathyroidism (SHPT) and its effect on the level of abdominal aortic calcification (AAC).

Methods: The study included 40 patients (24 males and 16 females) treated with regular MHD with SHPT in the hemodialysis clinic of Beijing Haidian Hospital from April 2019 to June 2020. After 12 weeks treated with Intravenous paricalcitol on the basis of regular hemodialysis, compared the blood calcium, blood phosphorus, and intact parathyroid hormone (iPTH) before and after the treatment and AAC score (Kauppila semi-quantitative method), and observed the clinical efficacy and the level of AAC after treatment with paricalcitol.

Results: Monitored blood calcium, blood phosphorus, and iPTH before starting treatment. Ande after 12 weeks of treatment, monitored blood calcium, blood phosphorus, iPTH, ALP changes and AAC score. The comparison found that the blood phosphorus, iPTH, and ALP levels after treatment were lower than the pre-treatment levels, and the blood calcium was higher than the pre-treatment levels, the difference was statistically significant ($P<0.05$)(Fig 1). At the same time, it is observed that patients with high levels of iPTH are often accompanied by severe AAC, while patients with mild to moderate AAC often maintain relatively low levels of iPTH. There were differences in the expression levels of iPTH among the three groups of patients with AAC with different conditions, and the differences between the groups were statistically significant ($P<0.05$)(Fig 2).

Conclusions: Intravenous paricalcitol has a significant effect on SHPT in hemodialysis patients, which can reduce the level of iPTH and reduce the risk of abdominal aortic calcification.

Progression of Renal Osteodystrophy and Vascular Calcifications in Patients with CKD Stage II-IV

Amr E. Mohamed,[1] Mohamed M. Abdalbary,[1] Mohamed Issa,[1] Michael Winkler,[1,2] Florence Lima,[1] Marie-Claude M. Faugere,[1] Habib Srour,[1] Hartmut H. Malluche.[1] *[1]University of Kentucky Medical Center, Lexington, KY; [2]Augusta University Medical College of Georgia, Augusta, GA.*

Background: Vascular calcifications (VC) are associated with renal osteodystrophy (ROD) but limited data are available on ROD and VC with progression of CKD.

Methods: 23 pts with CKD II-IV underwent iliac crest bone biopsies for bone histomorphometry, Dual-photon absorptiometry (DXA) of hip and spine for bone mineral density (BMD), and MSCT of the aorta (AOC) and coronaries (CAC) for assessment of VCs. Tests were done at baseline and after 2-3 years of observation with continuation of the same clinical management following KDIGO guidelines.

Results: Pts age was 60 ± 12 y with 56% female, 70% white, 26% black, 4% Asian, 57% DM II, 96% HTN, 9% CKD II, 74% CKD III, and 17% CKD IV. Results are shown in Table 1. There was an increase in VCs. GFR declined in 12 and was stable in 11 pts. Pts with declining GFR had greater increases in AOC and more loss in hip BMD. AOC correlated better than CAC with BMD. At baseline there was low bone turnover (LTO) in 87% of pts, and bone volume (BV) was low in 22%. LTO decreased to 78% and low BV was increased to 45% of pts at end of study. Defective mineralization was not observed at any time.

Conclusions: LTO and low BV are seen in early stages of CKD. With progression of CKD, turnover increases and low BV is more frequently seen. VCs are also seen early in CKD, AOCs progress faster than CACs and there is a relationship between VCs and bone loss.

Magnesium Supplements Reduce Arterial Stiffness in Patients with CKD Stage 3-4 but Do Not Affect Bone Mineral Density

Victoria Pendon-Ruiz de Mier,[1,2] Rafael Santamaria,[1,2] Cayetana M. Peregrin,[1,2] Isabel López-López,[1,2] Cristina Membrives González,[1,2] Maria Encarnacion Rodriguez Ortiz,[1,2] Jose E. Gordillo Arnaud,[1,2] Asuncion S. Chamizo,[1,2] Juan R. Munoz-Castaneda,[1,2] Cristian Rodelo-Haad,[1,2] Alejandro Martin-Malo,[1,2] Maria Sagrario Soriano Cabrera,[1,2] Mariano Rodriguez.[1,2] *[1]Hospital Universitario Reina Sofia, Cordoba, Spain; [2]Instituto Maimonides de Investigacion Biomedica de Cordoba, Cordoba, Spain.*

Background: Chronic Kidney Disease (CKD) entails to mineral metabolism disorders and vascular calcifications (VC). In vitro and in vivo, magnesium (Mg) supplements inhibits VC and show a beneficial effect on kidney function. However, some authors have suggested that Mg could affect bone turnover. We performed a study to evaluate the effect of dietary supplementation with Mg on arterial stiffness and bone mineral density in patients with CKD stage 3-4 and VC.

Methods: Randomized, open-label, parallel-group clinical trial (control/experimental) (n=8 per group). The experimental group received 360mg of Mg carbonate daily for 15±1.5 months. At the beginning and at the end of the study, blood and urinary biomarkers of bone mineral metabolism were measured; pulse wave velocity (PWV) was determined with Mobil-O-Graph device as an indicator of arterial stiffness, the Adragao index was calculated and bone mineral density was measured by densitometry.

Results: The included patients were in both groups mostly men and similar with respect to age and GFR. Serum Mg concentration were 1.9±0.1 vs 2±0.1mg/dl in control and experimental group respectively. At the baseline, no differences were found in demographic characteristics, comorbidities, treatments, PWV or biomarkers of bone mineral metabolism. The experimental group did not present hypermagnesemia or any other adverse event. The increase in urine Mg confirmed the therapeutic adherence. There was a decrease in GFR: 4ml/min in control and 1.71ml/min in experimental group, with no changes in serum Mg (both not statistically significant). An inverse correlation was found between urine Mg and the albumin/creatinine ratio (p=0.039). At the end of follow-up, serum Mg was inversely correlated with PWV (p=0.015). Urinary Mg was inversely correlated with iFGF23 (p=0.007). A non-significant trend of decrease in the Adragao index was observed in the experimental group. There were no changes in bone mineral density.

Conclusions: In CKD3-4 patients the Mg supplements reduce arterial stiffness without changes in bone mineral density.

PO0592

Phosphate, Blood Pressure, and Endothelial Cell Dysfunction in a Population Study

Peter N. Van Buren,[1,2] Meredith C. McAdams,[1] Pin Xu,[1] L Parker Gregg,[3] Susan Hedayati.[1] *[1]The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX; [3]Baylor College of Medicine, Houston, TX.*

Background: Hyperphosphatemia contributes to medial vascular calcification in chronic kidney disease (CKD) patients. There is emerging evidence that phosphate (Ph) is also associated with microvascular disease in individuals with normal kidney function, with in vitro data supporting a toxic effect of Ph on endothelial cells. We hypothesized there would be an association between serum Ph, blood pressure (BP), and endothelial cell dysfunction (ECD) markers in a large, diverse cohort.

Methods: Using data from the Dallas Heart Study, a multi-ethnic population-based cohort, we used serum Ph as the predictor variable and conducted linear regression analysis to determine its association with systolic BP and serum asymmetric dimethylarginie (ADMA) from a single visit. We controlled for numerous demographic and clinical variables including parathyroid hormone (PTH), calcium, vitamin D, estimated glomerular filtration rate (eGFR), and albuminuria.

Results: There were 3301 participants with a mean age of 43 years. The median systolic BP was 122 [112, 134] mmHg. The eGFR was 102 [88, 114] mL/min. Serum calcium, Ph, PTH, and vitamin D levels were 9.2 [9, 9.5] mg/dL, 3.2 [2.8, 3.5] mg/dL, 37.3 [27, 51] pg/mL, and 17 [12, 23] ng/mL. Serum Ph and PTH were independently associated with both systolic BP and ADMA (Table 1), although there was a negative relationship between Ph and BP.

Conclusions: Even in the physiologic range, serum Ph and PTH were independently associated with higher ADMA, an ECD marker, in a diverse population while accounting for known predictors of hypertension including age, diabetes, and kidney function. Higher systolic BP was predicted by higher PTH, but lower Ph. The presence of these associations in individuals with preserved renal function warrant further studies in CKD, where hypertension and hyperphosphatemia are both more prevalent.

Hyperphosphatemia Is Associated with Vasoconstriction and Endothelial Cell Dysfunction in Hemodialysis Patients

Jinwoo Jung,[1] Kamalanathan K. Sambandam,[1] Shani Shastri,[1] Peter N. Van Buren.[1,2] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX.*

Background: Hyperphosphatemia is associated with increased mortality in hemodialysis (HD) patients. High phoshate (Ph) causes vascular structural changes including medial calcification. While there is in vitro evidence that high Ph can induce endothelial cell dysfunction (ECD), little is known about the relationship between Ph and vasoconstriction or ECD in HD patients.

Methods: We studied hypertensive HD patients with the following outcome data: pre-HD systolic blood pressure (BP), total peripheral resistance index (TPRI) obtained with non-invasive cardiac output monitor, and serum levels of endothelin-1 (ET-1) and asymmetric dimethylarginine (ADMA). The most recent pre-HD serum Ph was the predictor variable. We conducted correlation and multivariate linear regression analyses while controlling for other clinical variables.

Results: Among the 60 participants, the mean age was 50 years. There were 62% male, 58% Black, and 60% with diabetes. Serum Ph had significant correlations with systolic BP, TPRI, ET-1, and ADMA (Figure 1). Multivariate regression analysis showed independent associations for Ph with all outcomes except ADMA (Figure 2), but PTH did have an independent association with ADMA.

Conclusions: Hyperphosphatemia is independently associated with vasoconstriction in HD patients. Serum Ph is also associated with ECD, but this is in part confounded by PTH. These data show the adverse cardiovascular consequences of hyperphosphatemia extend beyond vascular calcification. Further human studies are needed to determine 1) if lowering Ph improves endothelial function in HD patients and 2) if pharmacologic therapy aimed at improving ECD reduces the cardiovascular burden associated with hyperphosphatemia.

Funding: NIDDK Support, Veterans Affairs Support

Phosphate Indices and Atherosclerotic Cardiovascular Disease in CKD Patients: The CRIC Study

Jing Chen,[1] Myles Wolf,[3] Tamara Isakova,[4] Hua He,[2] Siyi Geng,[2] Sylvia E. Rosas,[5] Claudia M. Lora,[8] Bernard G. Jaar,[6] L. Lee Hamm,[1] Alan S. Go,[7] Jiang He.[2] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Tulane University, New Orleans, LA; [3]Duke University, Durham, NC; [4]Northwestern University, Evanston, IL; [5]Joslin Diabetes Center, Boston, MA; [6]Johns Hopkins University School of Medicine, Baltimore, MD; [7]Kaiser Permanente, Oakland, CA; [8]University of Illinois at Chicago, Chicago, IL.*

Background: Phosphate (Pi) overload may induce vascular calcification and inflammation. We studied prospective association of Pi indices with ASCVD events in the Chronic Renal Insufficiency Cohort (CRIC) Study.

Methods: 3939 CKD patients without cirrhosis were enrolled. 3096 were included in the analysis after excluding those with missing variables. ASCVD was defined as the first stroke, MI, or PAD. A new Pi burden index was calculated as [(urine Pi/Cr ratio) × serum Pi (sPi)× alkaline phosphatase (ALP)] to reflect the effect of high Pi diet on kidneys, cellular space, and bones. ALP was correlated with sPi and PTH. Cox proportional hazards models were used to study associations of Pi indices with ASCVD, adjusting for ACC/AHA ASCVD and other established risk factors.

Results: Over a mean of 9 years, 699 had ASCVD events. Pi burden index was correlated with 24-hr urine Pi. FGF23 and Pi burden index increased in early CKD. There were exposure-response associations of sPi, FGF23 and Pi burden index with ASCVD (**Table**). PTH, FEPi, and 24-hr urine Pi were not associated with ASCVD.

Conclusions: Pi burden is associated with ASCVD. FGF23 and Pi burden index increased in early CKD. They may be used for ASCVD risk classification and for monitoring phosphate overload. Future studies are warranted.

Bone-Vessel Relationships, the Association Between Calcifications of the Iliac Arteries with Vertebral Fractures in Hemodialysis Patients: Results from the VIKI Study

Maria Fusaro,[1,2] Cristina Politi,[3] Andrea Aghi,[4] Fulvia Taddei,[8] Enrico Schileo,[8] Thomas Nickolas,[5] Pascale Khairallah,[5] Maurizio Gallieni,[6] Maria cristina M. Mereu,[7] Giovanni Tripepi.[3] *[1]National Research Council (CNR), Institute of Clinical Physiology (IFC), Reggio Calabria, Italy; [2]Department of Medicine, University of Padova, Padova, Italy; [3]CNR-IFC, Reggio Calabria, Italy; [4]Department of Medicine, Clinica Medica 1, University of Padua, Padova, Italy; [5]Division of Nephrology, Department of Medicine, Columbia University Irving Medical Center, NewYork, NY; [6]Nephrology and Dialysis Unit, Azienda Socio-Sanitaria Territoriale (ASST) Fatebenefratelli Sacco, Department of Clinical and Biomedical Sciences 'Luigi Sacco', Università di Milano, Milano, Italy; [7]Independent Researcher, Cagliari, Italy; [8]Bioengineering and Computing Laboratory, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy, Bologna, Italy*.

Background: Vascular calcification and fragility fractures are common age-related disorders and associated with high morbidity and mortality especially in end-stage renal disease. Skeletal disorders occur in dialysis patients. Few studies have provided data on the prevalence of vertebral fractures (VFs) and their association with large artery calcifications. We evaluated the relationship of iliac arteries calcifications (IACs) and abdominal aorta calcifications (AACs) with the risk for VFs in hemodialysis (HD) patients

Methods: The VIKI Study is a cross-sectional study involving 387 HD patients from 18 Italian dialysis centers. Biochemical data included bone health markers such as vitamin K levels, vitamin 25(OH)D, alkaline phosphatase, parathormone, calcium, phosphate, osteocalcin and Matrix Gla Protein. The presence of VF, IACs and AACs were determined through standardized spine lateral radiographs. A >20% reduction of vertebral body height was considered a VF. We quantified vascular calcifications by measuring the length of calcium deposits along the arteries classifying the degree of severity for the IACs and AACs with a specific score (mild: 0.1–3 cm; moderate: 3.1–5 cm; and severe >5 cm) previously validated for AACs.

Results: The prevalence of IACs was 56.1%, and of AACs 80.6%. After adjusting for confounding variables, the presence of IACs was associated with 73% higher odds of VF (p=0.028), whereas we found no association (p=0.294) for AACs. The presence of IACs associated with VF irrespective of calcification severity. Patients with IACs had lower levels of the vitamin K2, menaquinone 7 (MK7) (0.99 vs 1.15 ng/ml; p=0.003), and deficiency of this marker became greater when adjusting for triglyceride levels (0.57 vs 0.87 ng/ml; p<0.001).

Conclusions: The presence of IACs, regardless of their extent, appears to be a clinically relevant risk factor for VFs. The association is further enhanced by including vitamin K, a main player in bone and vascular health, in the model. Prospective studies are needed to confirm these findings both in chronic kidney disease patients and in the general population.

Oral Calcitriol Use, Vertebral Fractures, and Vascular Calcifications in Hemodialysis Patients: Results from the Vitamin K Italian (VIKI) Study

Maria Fusaro,[1,2] Andrea Aghi,[2] Cristina Politi,[3] Thomas Nickolas,[5] Pascale Khairallah,[5] Maurizio Gallieni,[4] Maria cristina M. Mereu,[6] Giovanni Tripepi.[3] *[1]National Research Council (CNR) – Institute of Clinical Physiology (IFC), Pisa, Italy; [2]Department of Medicine, University of Padova, Padova, Italy; [3]CNR-IFC, Clinical Epidemiology of Renal Diseases and Hypertension, Ospedali Riuniti, Reggio Calabria, Italy; [4]Nephrology and Dialysis Unit, Azienda Socio-Sanitaria Territoriale (ASST) Fatebenefratelli Sacco, Department of Clinical and Biomedical Sciences 'Luigi Sacco', Università di Milano, Milano, Italy; [5]Division of Nephrology, Department of Medicine, Columbia University Irving Medical Center, New York, NY; [6]Independent Research, Cagliari, Italy.*

Background: Chronic Kidney Disease patients are characterized by alterations in bone and vascular metabolism associated to adverse clinical outcomes such as fractures, cardiovascular events and mortality. Dysregulation of vitamin D hormonal system, in levels of calcium, phosphate, PTH, FGF23/Klotho are the main responsible of these changes. We want to evaluate if oral calcitriol use can play a protective role on fractures in hemodialysis (HD) patients.

Methods: We included 387 HD patients of the VIKI database, a multicenter cross-sectional study. Biomarkers measured: vitamin K, VKDPs, vitamin 25(OH) D, ALP, PTH, Ca, P. Spine radiograph performed to define the presence of Vertebral Fractures (VF) and Vascular Calcification (VC). VF was indicated as >20% reduction of vertebral body height and VCs were quantified by measuring the length of calcium deposits along the arteries.

Results: 45.7% of patients were treated with oral calcitriol. No biochemical differences was observed between the treated and untreated patients. VFs were significantly lower in patients receiving oral calcitriol (48.6% vs 61%, **P=0.015**), the presence of VCs was similar (aortic: 81.9% vs 79.5% respectively, P=0.552; iliac: 52.0% and 59.5%, P=0.167). In a multivariable logistic regression analysis, after adjustment for all potential confounders, oral calcitriol was associated with a marked reduction (-40.2%) of the odds of fractures (OR: 0.598, 95% CI: 0.363-0.985, **P=0.043**).

Conclusions: In conclusion, we found a significant association between oral calcitriol use and lower VF rate in HD patients. Further prospective and interventional studies are needed to confirm these findings.

Significant Associations Between Vascular Calcification and Bone Mineral Density in CKD

Jana Uhlinova,[1,3] Anne Kuudeberg,[2,1] Margus Lember,[1,3] Mai Ots-Rosenberg.[1,3] *[1]Tartu Ulikool Arstiteaduskond, Tartu, Estonia; [2]Tartu Ulikool, Tartu, Estonia; [3]Tartu Ulikooli Kliinikum, Tartu, Estonia.*

Background: Vascular calcification (VC) demonstrated as a predictor of cardiovascular mortality in chronic kidney disease (CKD) patients (pts). There are uncertainties in term of factors that may explain the links between low bone mineral density (BMD) and mortality in CKD. We aimed to study associations between VC and BMD in CKD pts.

Methods: We studied 90 consecutive CKD pts. The following VC assessments used: 1) lateral lumbar X-rays and the scoring system to assess VC of the abdominal aorta using a semi-quantitative scoring (Kauppila,1997); 2) Ankle-brachial index (ABI) assessment (Winsor,1950). A simple, non-invasive, accurate tool to evaluate arterial stiffness and peripheral arterial disease providing diagnostic and prognostic information with values ≥1.3 or⟨0.9 (Gu,2019); 3) Echocardiography; 3) BMD assessed by total body dual-energy X-ray absorptiometry (DXA).

Results: Study group pts (N=90, 41% male) median age was 64 years. Diabetes mellitus and hypertension were the common causes of CKD (29% and 28%, respectively). Kauppila score ⟩1 detected in 41% of cases. The evidence of peripheral VC measured by ABI detected in 23% of causes. The heart valves calcinosis and fibrosis found in 41% of pts. Table demonstrates multivariate regression analysis with variables entering the equation as correlates of DXA measurements with Kauppila score and ABI as dependent variables. In pts with heart valves lesions total body BMD is significantly lower than in those who have normal heart valves. In factorial regression analysis BMD of femur, femur neck and total body BMD were significantly associated with heart valves calcinosis/fibrosis. BMD of femur and femur neck also inversely associated with age.

Conclusions: BMD associated with VC in pts with different CKD stages. Multi-interventional approach for diagnosis of CKD-BMD is necessary for early detection to prevent complications. Total body DXA is more informative in clinical practice for evaluation of BMD.

Increasing Bone Mineral Density Is Associated with Vascular Calcification in Children and Young Adults with CKD Stages 4-5 and on Dialysis

Alexander D. Lalayiannis,[1] Nicola J. Crabtree,[5] Charles Ferro,[8] David C. Wheeler,[2] Neill D. Duncan,[9] Colette J. Smith,[2] Varvara Askiti,[3] Andromachi Mitsioni,[3] Lorenzo Biassoni,[4] Simon Mcguirk,[5] Kristian H. Mortensen,[4] David Milford,[5] Jin Long,[6] Mary Fewtrell,[1] Mary B. Leonard,[7] Rukshana Shroff.[1] *[1]University College London Great Ormond Street Hospital Institute of Child Health, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Aglaia Kiriakou-Geniko Nosokomeio Paidon, Athens, Greece; [4]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [5]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [6]Stanford University, Stanford, CA; [7]Stanford University School of Medicine, Stanford, CA; [8]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [9]Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Bone mineral density(BMD) is inversely associated with coronary artery calcification(CAC) in older adults on dialysis. This association has not been shown in children and young adults where bone accrual may mitigate associations with vascular calcification

Methods: Multicenter longitudinal study in participants aged 5 to 30 years with CKD stages 4-5 and on dialysis. Measures included tibial cortical(Cort) and trabecular(Trab) BMD by peripheral quantitative CT, CAC, carotid intima-media thickness(cIMT), pulse wave velocity(PWV) and carotid distensibility, expressed as z-scores(BMDz, cIMTz, PWVz)

Results: 98 participants(age 13.8;IQR 10.7,16.5 yrs) were assessed at baseline and 55 again after 1.5(1.3 to 1.8) years. At baseline 10% had CAC, increasing to 18% at follow-up. Median cIMTz and PWVz were 2.17(1.14, 2.86) and 1.45(-0.16, 2.57) at baseline. At follow-up cIMTz and PWVz increased, and distensibility decreased in participants with static growth compared to children with linear growth (Fig 1A). TrabBMDz decreased from -0.26 to -0.38, p=0.01, particularly in growing children(Fig 1B); there was a non-significant decrease in CortBMDz (-0.47 to -1.13, p=0.09). On multivariable regression, baseline TrabBMDz was positively associated with cIMTz (β 0.35,p=0.001;Fig 1C). At follow-up, participants with increasing ΔTrabBMDz had 6-times greater odds of ΔcIMTz increase(95% CI 1.88 to 18.35). Growing people demonstrated greater declines in TrabBMDz but less progression of vascular calcification, compared to participants with static linear growth

Conclusions: In young people with CKD, an increase in vascular measures was seen despite an increase in BMD. Progression of vascular changes may be attenuated in the growing skeleton. Providing adequate calcium for optimal bone mineralization whilst avoiding vascular calcification remains challenging

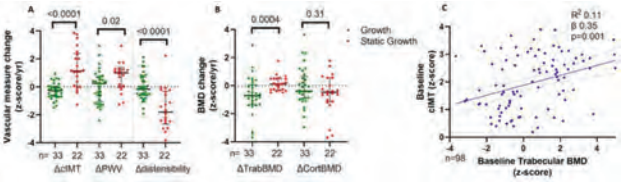

Fig1. Changes in (A) vascular measures and (B) BMD in growing children vs those with static linear growth; (C) Baseline trabecular BMDz and cIMTz

PO0599

A Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial Assessing Efficacy of Standard and Low-Dose Hydrochlorothiazide in Recurrent Calcareous Nephrolithiasis Prevention: The NOSTONE Trial

Nasser Dhayat,[1] Olivier Bonny,[2] Beat Roth,[2] Grazia M. Cereghetti,[3] Daniel G. Fuster.[1] NOSTONE investigators *[1]Inselspital Universitatsspital Bern, Bern, Switzerland; [2]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [3]Universitat Bern, Bern, Switzerland.*

Background: Nephrolithiasis is a global healthcare problem with a current lifetime risk of up to 18.8 % in men and 9.4 % in women. Without specific treatment, 5- and 20-year recurrence rates are 40 % and 75 %, respectively. Given the high cost of medical

treatments and surgical interventions as well as the morbidity related to symptomatic stone disease, medical prophylaxis for stone recurrence is an attractive approach. Efficacy of thiazides for kidney stone prevention was tested in 11 trials in the past. However, all these trials had major methodological deficiencies. Nowadays, thiazides are widely used in the treatment of recurrent nephrolithiasis and arterial hypertension, but at significantly lower doses. In the case of recurrent nephrolithiasis, however, this practice is not supported by randomized evidence. Thus, evidence for benefits and harms of thiazides in the prevention of kidney stones remains unclear.

Methods: NOSTONE is a multicenter, randomized, placebo-controlled, double-blind, parallel-group trial aiming to assess the dose-response relationship of three different dosages of hydrochlorothiazide (12.5mg, 25.0mg, 50.0mg) compared to placebo in the kidney stone prevention. The primary outcome incidence of stone recurrence at 3 years is a composite of symptomatic and radiologic recurrence (comparison of basal and end-of-study low-dose CT). The study included patients from 12 hospitals throughout Switzerland.

Results: The study was approved by all competent authorities by the end of February 2017. Recruitment started in Bern on March 9th 2017. All study sites are operative since June 30th 2017. The target number of 416 patients randomized in the trial was reached October 31st 2019 and recruitment stopped. In March 2020 the first patient randomized in the trial completed the treatment phase. All patients are expected to reach end of treatment by the end of August 2021 (www.nostone.ch).

Conclusions: The NOSTONE study will provide physicians with crucial information for the treatment of kidney stones. The impact of the results of this study will affect many patients currently under treatment with hydrochlorothiazide for the prevention of recurrent nephrolithiasis.

Funding: Government Support - Non-U.S.

Body Mass Index (BMI) and Kidney Stone Risk in Calcium Kidney Stone Formers

Jie Tang,[1,2] Uttam Bhetuwal.[2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Lifespan Health System, Providence, RI.*

Background: The role of obesity among calcium kidney stone formers remains poorly defined, and it is unknown whether there are effect modifications of stone risk by diabetes and insulin resistance (IR).

Methods: We examined the independent associations between BMI and 24-hour urine stone risk profile among 167 calcium kidney stone formers (CSF), and analyzed the effect modifications by diabetes and IR measured by Homeostatic Model Assessment of Insulin Resistance (HOMA-IR) in non-diabetics. Study participants were recruited from Lifespan Kidney Stone Clinic. We used linear regression and adjusted for demographics.

Results: The study population (n=167) had a mean age of 53 years, 77 (46%) were male, and 135 (81%) were Caucasian. 28 (17%) had diabetes. Mean BMI was 29 (Interquartile range (IQR) 25 to 33). Higher BMI associated strongly with diabetes ($p<0.0001$). Among 139 non-diabetic CSFs, mean BMI was 28 (IQR 25 to 31), and BMI had a strong positive association with HOMA-IR ($p=0.001$). 33% of nondiabetic CSFs had hypertension (vs. 100% in diabetics), 21% of nondiabetic CSFs had dyslipidemia (vs. 89% in diabetics). HOMA-IR ranged from 0.42 to 28.2 (mean 4.3). Overall, in the whole study population, BMI had significant positive associations with urine ammonium, urine uric acid (UUA), and UUA supersaturation ($p= 0.004$, <0.0001, <0.0001 respectively). The strong association between BMI and urine ammonium was only observed among diabetics ($p=0.006$), with a similar trend observed among non-diabetics with high IR ($p=0.09$ when HOMA-IR>10, $p= 0.9$ when HOMA-IR= 5-10, $p=0.2$ when HOMA-IR<5). On the contrary, the uricosuric effect of higher BMI was only observed in nondiabetics who had normal or near-normal IR ($p=0.3$ among diabetics, $p<0.0001$ when HOMA-IR<5, $p=0.003$ when HOMA-IR=5-10, $p=0.5$ when HOMA-IR>10). As a result, the UUA supersaturation tended to have weak associations with BMI among diabetics or non-diabetics who had high IR ($p=0.09$ in diabetics and those with HOMA-IR>10, $p= 0.2$ when HOMA-IR< 5, $p=0.9$ when HOMA-IR=5-10). Lastly, BMI did not have significant associations with serum levels of vitamin D and uric acid, plasma parathyroid hormone concentration and measurements of other urinary stone risk factors.

Conclusions: In our cohort of CSFs, higher BMI had strong associations with urinary uric acid and ammonium excretions, and these associations appeared to be modified by the presence of diabetes or IR.

Examining the Clinical Effectiveness of Calcium Oxalate Stone Treatments

Joseph T. Gutbrod, Charles C. Keys McKay, Elaine M. Worcester, Megan Prochaska. 1 and 2 are co-first authors *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Lowering urine calcium oxalate (CaOx) supersaturation (SS) is a primary clinical focus for CaOx kidney stone (KS) prevention and can be achieved by increasing urine volume, or decreasing urine calcium or oxalate excretions. Common clinical strategies to do this include advising patients to increase fluid intake, restrict dietary sodium, restrict dietary oxalate, or prescribing a thiazide-type diuretic. Several of these strategies have been validated in the controlled setting of randomized trials but efficacy in the real-world clinical setting is less clear. We investigated the efficacy of these treatment strategies in a clinical setting, observing whether trial-based findings on CaOx KS treatment hold true.

Methods: We reviewed medical charts for 204 CaOx KS formers with idiopathic hypercalciuria from University of Chicago Kidney Stone Clinic. Patients had three 24-hour urine collections before an initial clinic visit and one follow up 24-hour urine collection. Data collected included initial treatment advice and 24-hour urine composition. We analyzed patient groups based on treatment advice and used descriptive statistics and t-tests to analyze changes in urine variables from pre- to post-advice.

Results: Compared to those who did not receive the advice, advice to increase fluid intake resulted in a larger pre- to post-advice increase in urine volume (0.6 vs. 0.09L/day, $p<0.001$) and decrease in CaOx SS (-3 vs. -1, $p=0.001$). Compared with those who did not receive the advice, advice to restrict dietary sodium alone resulted in a larger pre- to post-advice decrease in urine sodium (-28 vs 13mg/day, $p=0.002$) but there was no change in urine calcium or CaOx SS without concurrent thiazide. Thiazide prescription resulted in a significant pre- to post-advice decrease in urine calcium for patients who also sodium restricted (-99mg/day, $p<0.001$) and those who did not sodium restrict (-58mg/day, $p<0.001$) with a trend towards a larger decrease in those who did both ($p=0.06$). Thiazide prescription resulted in a significant pre- to post-advice decrease in urine CaOx SS for patients who also sodium restricted (-3.3, $p<0.001$) and those who did not (-2, $p<0.001$).

Conclusions: In a real-world clinical setting, advice to increase fluid intake fluid or a thiazide diuretic prescription and reduction in sodium intake lowered CaOx SS and CaOx KS risk in follow up.

PO0602

Effect of Hydroxycitrate (HCA) on Urine Chemistry in Calcium Kidney Stone Formers

David S. Goldfarb,[1] Kumar Rohit,[5] Avinash G. Adiga,[7] Briony L. Norris,[6] Lee Yang,[2] Frank Modersitzki,[1] David A. Bushinsky,[3] Jeffrey D. Rimer,[4] John R. Asplin.[2] *[1]NYU Langone Health, New York, NY; [2]LithoLink Corp, Chicago, IL; [3]University of Rochester Medical Center, Rochester, NY; [4]University of Houston, Houston, TX; [5]Salem Health, Salem, OR; [6]The Royal Melbourne Hospital, Melbourne, VIC, Australia; [7]University of Alabama, Tuscaloosa, AL.*

Background: Potassium citrate is a mainstay of treatment to prevent recurrent calcium-containing kidney stones. However, it can increase urine pH and calcium phosphate (CaP) supersaturation (SS). HCA, extracted from *Garcinia cambogia,* is a potent inhibitor of calcium oxalate crystal growth in vitro and should not provide "potential base", as citrate does. Urine excretion of HCA has not been well-studied.

Methods: We enrolled 2 groups: calcium stone formers (SF; n = 9) and non-stone forming (NSF, n = 9) controls (after excluding 2 SF and 2 NSF whose urine creatinine excretion on the 2 collections differed by more than 20%). Mean age 49.3 years. Thiazides and citrate were held for 2 weeks prior to study. Participants recorded a self-selected diet for 2 days and performed 24-hour urine collection on day 2. HCA was purchased online from Amazon.com (Super CitriMax Garcinia Cambogia); 2 caps = 900 mg of HCA. Participants took 900 mg 3 times daily orally for 7 days. Diet from days 1 and 2 was replicated on day 6 and 7 of the HCA arm of the study. 24-hour urine was collected on day 7. Urine was sent to Litholink, Inc. (Chicago, IL) for analysis. Urinary excretion of hydroxycitrate and citrate were measured using LC/MS.

Results: According to label, 6 pills would provide 2700 mg (13.2 mmol) of HCA per day; we measured content as 3198 mg (15.6 mmol). Citrate content is supposed to be 0, but we found 126 mg (0.66 mmol) per day. Both NSF and SF had appearance of HCA in the urine: 1.86 ± 0.80 and 2.07 ± 0.67 mmol/day ($p = 0.56$). Urine chemistry seen in Table 1. In NSF, pH and citrate did not change. In SF, pH increased, citrate did not. K went up in both groups.

Conclusions: Administration of HCA, a potential inhibitor of Ca stone formation, leads to significant urinary HCA excretion. Citrate excretion was not affected. Urine pH increased, suggesting some alkalinizing effect. The difference in NSF and SF may be due to the lower starting pH in SF. The effect of HCA on stone formation remains to be determined.

Funding: Clinical Revenue Support

Urinary chemistry after HCA

	Baseline NSF	HCA NSF	p-value	Baseline SF	HCA SF	p-value
pH	6.67 +/- 0.62	6.63 +/- 0.50	0.87	5.81 +/- 0.57	6.32 +/- 0.57	0.007

PO0603

Factors Reducing Kidney Stone Risk in Patients with Enteric Hyperoxaluria (EH)

Megan Prochaska, Julianna Bianco, Francesca M. Chu, Elaine M. Worcester. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

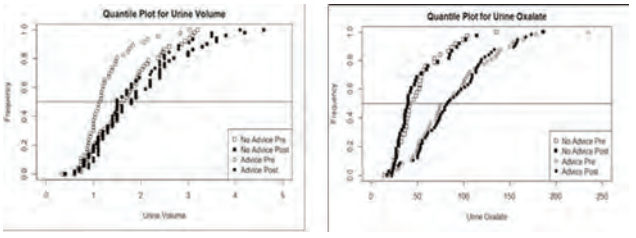
Background: There have been no trials examining efficacy of interventions aimed at decreasing stone risk in patients with EH. We drew upon data for patients in a kidney stone clinic who were treated with consistent methodologies over time. We asked how doctors made therapeutic choices and which therapies were effective at decreasing stone risk.

Methods: We selected 100 patients with EH from the Kidney Stone Evaluation and Treatment Program at the University of Chicago between 1970 and 2018. We analyzed 24-hour urine collections before and after patients' first clinic visit using multivariate linear regression and t-tests to compare effects of fluid intake and oxalate-focused interventions on outcomes.

Results: Patients told to increase fluid intake had low baseline urine volumes; volume increased from 1.3 to 2.0 L/day ($p < 0.001$). In those not told to increase fluid intake urine volume increased from 1.7 to 2.0 L/day ($p = 0.003$). Volume increased more in the advice group ($p = 0.03$). No interventions aimed at reducing oxalate absorption (low fat diet, calcium supplement, increased diet calcium, cholestyramine, and low oxalate diet) had a significant effect on urine oxalate. In those getting advice, urine oxalate was 88 mg/day at baseline and 91 mg/day on follow-up ($p = 0.90$) compared with 50 mg/day at baseline and 51 mg/day on follow-up ($p = 0.77$) in the non-intervention group. In a multivariate model, fluid intake advice was associated with a decrease in calcium oxalate supersaturation (95% CI -4.3 to -0.8), while oxalate-focused interventions were not (95% CI -1.2 to 2.3).

Conclusions: Physicians chose treatments based on baseline urine characteristics. Advice to increase fluid intake is associated with decreased risk of stone formation. Interventions aimed at reducing oxalate absorption are not associated with a decreased risk of stone formation on follow-up. This lack of effect may be the result of patient physiology or lack of compliance with treatments and advice.

Funding: NIDDK Support



Effect of advice to increase fluid intake (left panel) or lower oxalate absorption (right panel) in stone formers with EH.

High Oxalate Concentrations Increase Risk for Sudden Cardiac Death in Dialysis Patients

Anja C. Pfau,[1] Theresa Ermer,[2] Steven G. Coca,[3] Maria Clarissa Tio,[4] Bernd Genser,[5] Martin Reichel,[1] Fredric O. Finkelstein,[6] Winfried März,[7] Christoph Wanner,[8] Sushrut S. Waikar,[9] Kai-Uwe Eckardt,[1] Peter S. Aronson,[6] Christiane Drechsler,[8] Felix Knauf.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Universitatsklinikum Erlangen, Erlangen, Germany; [3]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [4]Brigham and Women's Hospital Department of Medicine, Boston, MA; [5]Ruprecht Karls Universitat Heidelberg Mannheimer Institut fur Public Health, Mannheim, Germany; [6]Yale University Department of Internal Medicine, New Haven, CT; [7]Ruprecht Karls Universitat Heidelberg, Heidelberg, Germany; [8]Julius-Maximilians-Universitat Wurzburg, Wurzburg, Germany; [9]Boston University School of Medicine, Boston, MA.*

Background: The clinical significance of accumulating toxic terminal metabolites such as oxalate in kidney failure patients is imperfectly defined. Our study evaluated whether oxalate concentrations are associated with risk of all-cause mortality and cardiovascular events in a cohort of patients with kidney failure requiring chronic dialysis.

Methods: To relate all-cause death and cardiovascular events to serum oxalate, we performed a post-hoc analysis of a randomized controlled trial conducted between March 1998 and October 2002 that comprised 1255 European hemodialysis patients with diabetes who were followed up for a median of 4 years (4D Study). The results obtained via Cox proportional hazards models were confirmed by competing risk regression and restricted cubic spline modeling in the 4D cohort, and validated in a separate cohort of 104 US dialysis patients after a median follow-up of 2.5 years.

Results: A total of 1108 patients with a mean (SD) age of 66.3 (8.3) years had baseline oxalate measurements with a median (IQR) oxalate concentration of 42.4 (30) micromolar. During follow-up, 548 patients died, including 139 (25.4%) patients who died from sudden cardiac death. A total of 413 patients reached the primary composite cardiovascular endpoint, which comprised cardiac death, nonfatal myocardial infarction, and fatal or nonfatal stroke. Participants in the highest oxalate quartile (above 59.7 micromolar) had a 40% increased risk for cardiovascular events (adjusted HR 1.40, 95% CI 1.08-1.81) and a 62% increased risk of sudden cardiac death (adjusted HR 1.62; 95% CI 1.03-2.56), compared to patients in the lowest quartile (below 29.6 micromolar). The associations remained when accounting for competing risks, and with oxalate as a continuous variable, and could be reproduced in a separate cohort of 104 US dialysis patients.

Conclusions: Elevated oxalate concentrations are a novel risk factor for cardiovascular events and sudden cardiac death in dialysis patients. Further studies are warranted to test whether oxalate lowering strategies improve cardiovascular mortality in dialysis patients.

Association of Serum Sclerostin Levels with Mortality in Maintenance Hemodialysis Patients: An 8-Year Prospective Cohort Study

Yosuke Nakagawa,[1] Hirotaka Komaba,[1] Takehiko Wada,[1] Takatoshi Kakuta,[2] Masafumi Fukagawa.[1] *[1]Tokai Daigaku, Isehara, Japan; [2]Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan.*

Background: Sclerostin is an osteocyte-derived inhibitor of bone formation and is increased in kidney failure. Sclerostin might be involved in the pathogenesis of vascular calcification, but few studies examined the association between sclerostin and mortality in hemodialysis patients.

Methods: We analyzed a cohort of 654 maintenance hemodialysis patients enrolled in the Tokai Dialysis Prospective Cohort Study. The primary exposure variable was the baseline serum sclerostin level, measured using a sandwich ELISA (Biomedica Medizinprodukte GmbH & Co KG). The primary outcome was 8-year all-cause mortality. Mortality risk was assessed using Cox regression models adjusted for potential confounders.

Results: aseline median (IQR) serum sclerostin level was 163 (120-215) pmol/L. Patients with higher sclerostin levels were likely to be male; have diabetes; have better nutritional status, higher hemoglobin, and lower intact PTH and bone turnover markers. No associations were observed between serum sclerostin and cardiovascular comorbidities. During a median follow-up of 7.6 years (IQR, 4.1-8.0 years), 229 of the 654 participants died. In univariate analysis, serum sclerostin levels were not associated with mortality (HR per doubling, 0.94; 95% CI, 0.76-1.17). This result was unchanged after adjustment for age, sex, dialysis vintage, diabetes, prior cardiovascular disease, body mass index, hemoglobin, albumin, and creatinine (HR per doubling, 1.07; 95% CI, 0.82-1.40).

Conclusions: Serum sclerostin levels were not associated with mortality in maintenance hemodialysis patients. Further research is required to determine the role of sclerostin in vascular calcification and cardiovascular disease in kidney failure.

Funding: Government Support - Non-U.S.

PO0606

Association Between 24-Hour Urine Sodium or Potassium Excretion and Cardiovascular Events in Veterans with Urinary Stone Disease

Ruth Y. Romero,[1] Calyani Ganesan,[1] I-Chun Thomas,[2] Glenn M. Chertow,[1] John Leppert,[1,2] Alan C. Pao.[1,2] *[1]Stanford Health Care, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: Urinary stone disease (USD) is associated with an increased risk of major adverse cardiovascular events. Recent studies that estimated 24-hour urine excretion from spot urine samples have demonstrated that high urine sodium excretion and low urine potassium excretion are independently associated with cardiovascular events. Since patients with USD undergo 24-hour urine testing for stone prevention, direct 24-hour urine testing for sodium and potassium excretion may provide insight into cardiovascular risk for patients with USD.

Methods: We identified 6,401 Veterans with USD and a 24-hour urine sodium measurement and 4,950 Veterans with USD and a 24-hour urine potassium measurement between 2007 and 2015 from national VHA data. We defined the primary outcome as an inpatient or emergency department diagnosis of acute myocardial infarction, unstable angina or stroke or a procedural code for percutaneous coronary intervention or coronary artery bypass graft surgery. We performed Cox proportional hazards regression to identify the risk of a cardiovascular event by level of 24-hour urine sodium and/or potassium excretion.

Results: Among the 6,401 Veterans with USD and a 24-hour urine sodium measurement, 715 (11.2%) had a major cardiovascular event. Veterans with a 24-hour urine sodium in the lowest 10th percentile (<113 mEq/day) had a higher risk of a cardiovascular event compared to those with a 24-hour urine sodium between the 10th and 90th percentile (HR 1.55, CI 1.25-1.92). We found no significant association between 24-hour urine potassium excretion and cardiovascular events.

Conclusions: Patients with lower 24-hour urine sodium excretion have a higher risk for cardiovascular events. Patients with higher 24-hour urine sodium excretion or lower 24-hour urine potassium excretion do not have a higher risk of cardiovascular events. These findings differ prior studies that used spot urine samples to identify patients who are at risk for cardiovascular disease, suggesting that direct measurement of 24-hour urine sodium or potassium excretion more accurately identifies patients who are at risk for cardiovascular disease.

PO0607

Indoxyl and Cresyl Sulfate Are Respectively Linked to Phosphocalcic Metabolism Abnormalities and to Cardiovascular Morbidity in Hemodialysed Patients

Arianna Bologna, Giuseppe Vezzoli, Nadia Edvige Foligno, Monica Avino, Teresa Del Mastro, Teresa Arcidiacono. *IRCCS Ospedale San Raffaele, Milano, Italy*.

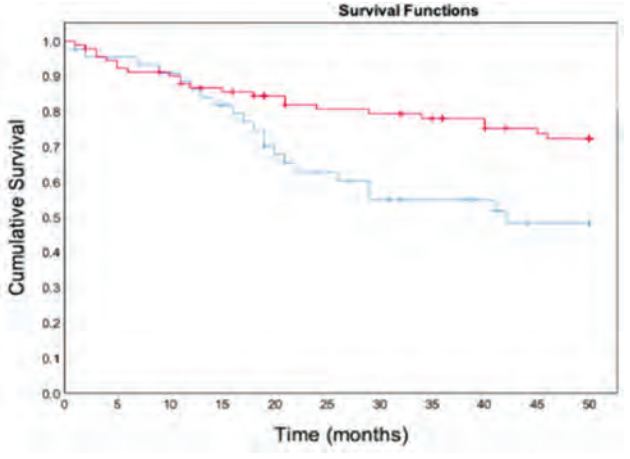
Background: Indoxyl sulfate (IS) and Cresyl sulfate (CS) are uremic toxins generated by the intestinal amino acid catabolism. Blood levels of these toxins increase in patients with CKD and are linked to cardiovascular events.

Methods: Therefore, we studied the relationship between serum levels of free IS and CS and divalent ion metabolism variables and cardiovascular morbidity (stroke, heart failure, angor and myocardial infarction) in 139 hemodialysis patients (age 68±13 yrs, weight 65±13 kg, dialysis vintage 69±71 months). We divided patients according to tertiles of free serum IS and CS.

Results: Patients in the highest tertile of serum free IS showed shorter dialysis vintage and higher body weight gain between dialysis sessions than patients in the other two tertiles. Patients in the highest tertile of IS showed lower body weight and serum concentrations of alkaline phosphatase, 1, 25$(OH)_2$D and PTH compared to the lowest tertile. No relationships of serum free CS concentrations with phosphate and calcium metabolism variables were observed. Kaplan-Meier survival analysis shows an increased cardiovascular morbidity in patients in the CS highest tertile (blue line in the figure) compared to those in the lowest and middle tertiles taken together (red line; p=0.01). This association was not found considering IS tertiles.

Conclusions: Our findings suggest that serum IS could predispose to adynamic bone disease, while CS may have higher cardiovascular toxicity.

	Serum IS lower tertile	Serum IS middle tertile	Serum IS highest tertile
N (M/F)	45 (12/33)	48 (13/35)	46 (19/27)
Free serum IS (µg/ml)	32±14	49±17	56±18
Free serum CS (µg/ml)	2.1±1.9	3.5±2.6	3.6±5.1
Dialysis vintage (months)	74±72	87±81	45±52
Interdialytic body weight gain (kg)	1,2±0,75	1.5±0.91	1.9±1.04
Body weight (kg)	69±12	64±15	62±12
1,25-vit D (ng/ml)	11,7±9,4	10,9±7,1	7,6±4,4
PTH (pg/ml)	106±68	83±89	65±57
Alkaline Phosphatase (U/l)	132±77	116±69	102±42



PO0608

Expression Pattern of the Runt-Related Transcription Factor (RUNX) Family and the Role of RUNX1 During Kidney Development

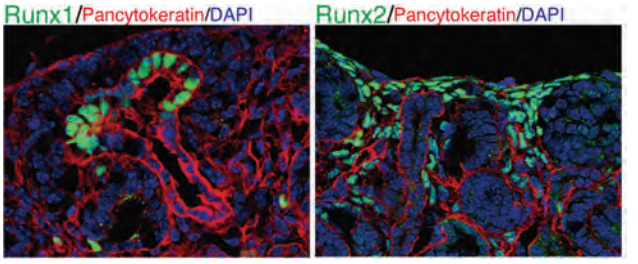
Keiko Sakamoto,[1] Yuichiro Kitai,[1] Motoko Yanagita.[1,2] *[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Institute for the Advanced Study of Human Biology, Kyoto University, Kyoto, Japan.*

Background: RUNX family plays critical roles during the developmental process in multiple organs. The mammalian RUNX family consist of RUNX1, RUNX2 and RUNX3, each of them has distinct tissue-specific expression and function but also has a redundancy. Here, we examined the distribution of RUNX family in the kidney. We also assessed the involvement of RUNX1 during renal development in the conditional knockout mice using Cre-LoxP strategy.

Methods: We examined the temporal and spatial expression pattern of RUNX family in the kidney by immunostaining and qPCR analysis. In order to analyze the role of RUNX1 in kidney development, we utilized HoxB7-Cre mice and R26CreER^{T2} mice. To induce activation of CreER^{T2}, we administered tamoxifen to pregnant mothers at E12.5 and analyzed the embryos at E16.5. Long-term observation was impossible due to the severe anemia caused by hematological toxicity of the systemic activation of CreER^{T2}.

Results: In the neonatal kidney, RUNX1 was strongly expressed in the uretic bud (UB) tip and also weakly expressed in the distal portion of renal vesicle, comma body, and S shaped body. RUNX1 was also expressed in the pelvic urothelium and immune cells. RUNX1 expression in the UB tips was detectable from E13.5 and disappeared by P7. In contrast, RUNX2 was restricted in the stroma firstly detected from E15.5 and was strongly expressed in both cortical and medullary fibroblasts at P2. RUNX3 was only expressed in the immune cells. There was no difference in the number of UB branching or Six2$^+$ nephron progenitor cells per UB tip in Runx1$^{fl/fl}$: HoxB7-Cre mice, which lack Runx1 expression in UB. Further analysis utilizing Runx1$^{fl/fl}$: R26CreER^{T2} mice showed no obvious abnormality. In addition, neither RUNX2 nor RUNX3 compensated the loss of RUNX1 in deficient embryos.

Conclusions: We precisely analyzed the unique expression pattern of RUNX family during kidney development and identified RUNX1 as the marker of UB tip and RUNX2 as the marker of fibroblasts in the embryonic kidneys, although RUNX1 was dispensable for nephrogenesis.



Expression of RUNX1 and RUNX2 in the developing kidney

PO0609

Rac1 Promotes Kidney Collecting Duct Integrity by Limiting Actomyosin Activity

Fabian Bock,[1] Bertha C. Elias,[1] Xinyu Dong,[1] Olga Viquez,[1] Agnes B. Fogo,[1] Ambra Pozzi,[1] Roy Zent.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Department of Veterans Affairs, Nashville, TN.*

Background: A polarized collecting duct (CD) is critical for an intact kidney. The branched kidney collecting system is formed from the ureteric bud (UB). This requires a dynamic actin cytoskeleton and balanced actomyosin activity allowing normal tissue polarization, morphology and function. The small Rho GTPase, Rac1, is a key molecular switch that controls actin polymerization and branching. We investigated the role of Rac1 in kidney collecting system morphogenesis by selectively deleting it in mice at the initiation of UB development.

Methods: We crossed Rac1$^{flox/flox\ (f/f)}$ with Hoxb7-cre deleting Rac1 in the ureteric bud starting at E10.5 and followed kidney development throughout adulthood. We also analyzed the role of Rac1 in regulating signaling, migration, spreading, tubulogenesis and polarity by utilizing primary inner medullary collecting duct Rac1 null cells.

Results: The kidneys of Hoxb7:Rac1$^{f/f}$ exhibited only a mild branching morphogenesis defect as Rac1 is expressed after most UB branching is complete. However, with aging the CD developed a disruption of epithelial integrity, resulting in fibrosis, and a urine concentration defect. Despite intact integrin signaling, Rac1-null CD cells had profound spreading, adhesion and polarity abnormalities that were independent of the major downstream Rac1 effector, Pak1. Instead, Rac1 null cells demonstrated defective WAVE2-Arp2/3 dependent actin cytoskeletal branching which resulted in excessive actomyosin activity and severe abnormalities in epithelial cell shape. The functional and morphological defects caused by Rac1 deficiency were reversed by direct myosin II inhibition using low dose blebbistatin.

Conclusions: Unexpectedly, Rac1 does not play a major role in early branching morphogenesis of the renal collecting system, however it is required for adult CD integrity. Mechanistically, Rac1 controls Arp2/3-dependent cytoskeletal branching which limits actomyosin hyperactivity allowing normal epithelial polarization, function and morphology.

Stromal Transcription Factor 21 Is Critical for Development of the Interstitium and Nephron Progenitor Cells via Interaction with Wnt/β-Catenin Signaling

Gal Finer,[1,2] Yoshiro Maezawa,[3] Shintaro Ide,[4] Tuncer Onay,[1] Tomokazu Souma,[4] Deborah R. Winter,[1] Susan E. Quaggin,[1] Tomoko Hayashida.[1,2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [3]Chiba Daigaku, Chiba, Japan; [4]Duke University, Durham, NC.*

Background: Reciprocal signaling between the collecting duct progenitors and the nephron progenitor cells (NPC) is the primary driver for kidney development. In addition, recent studies implicate input from the interstitial progenitor cells in multiple aspects of kidney development. However, the mode of insterstitial cell action on kidney development is poorly understood. We previously showed that the Transcription factor 21 (Tcf21) in interstitial progenitors is required for normal ureteric bud branching. Here, we examined roles for Tcf21 in renal interstitial progenitors in mediating stromal functions during kidney development.

Methods: Stromal Tcf21 was evaluated with the Foxd1Cre;Tcf21$^{f/f\ or\ +/+}$ mouse kidney by standard immunohistological analyses. MK3 and M15 metanephric mesenchymal cell lines were used for analyses of b-catenin signaling.

Results: In the Foxd1Cre;Tcf21$^{f/f}$ kidney, absence of Tcf21 from Foxd1+ stromal progenitors caused decrease in stromal cell proliferation, leading to marked reduction of the medullary stromal space. Lack of Tcf21 in FoxD1 stromal cells also led to defective differentiation to perivascular cells and mesangial cells. Non-autonomously, absence of stromal Tcf21 led to expansion of the Six2+ NPC, suggestive of delayed NPC differentiation, and to poor development of the Loop of Henle and the collecting ducts. We next examined whether Tcf21 modulates Wnt/ β-catenin signaling. Significantly less β-catenin was observed in stroma of the Foxd1Cre;Tcf21f/f mouse compared to their wild-type littermates. In MK3 and M15 cells, stabilization of β-catenin by Lithium Chloride upregulated Tcf21 expression, while over-expression of Tcf21 enhanced expression of Wnt-target genes upon β-catenin stabilization. Further, Tcf21 enhanced TCF/LEF reporter

activity upon β-catenin stabilization, while mutated-Tcf21 failed to increase TCF/LEF activity. Immunoprecipitation assay showed that Tcf21 is bound to β-catenin at basal and activated states in-vitro.

Conclusions: Together, our findings suggest that Stromal-Tcf21 is essential for medullary stroma development, by enhancing Wnt/β-catenin signaling to promote stromal cell proliferation and differentiation. Stromal Tcf21 is also required for the development of the adjacent nephron epithelia.

PO0611

ZEB2 Is Essential for FOXD1+ Kidney Stromal Progenitor Cell Differentiation During Kidney Development

Sudhir Kumar, Xueping Fan, Hila Milo Rasouly, Richa Sharma, David J. Salant, Weining Lu. *Boston University School of Medicine, Boston, MA.*

Background: FOXD1$^+$ derived stromal cells are essential for normal kidney development. They give rise to pericytes and resident fibroblasts that support the kidney vasculature and also cooperate with cells that give rise to the developing nephron. However, FOXD1$^+$ derived stromal progenitors may also serve as precursors of myofibroblasts in kidney fibrosis. The signals that regulate the differentiation of FOXD1$^+$ stromal progenitors are not well understood. Given that zinc finger E-box-binding homeobox2 (ZEB2), a SMAD-interacting transcription factor, is expressed in developing kidney stromal cells, we examined the role of ZEB2 in kidney stromal cell differentiation in the developing mouse kidney.

Methods: We generated *Zeb2* stromal-specific conditional knockout mice (cKO) by crossing *Zeb2* flox mice with *Foxd1Cre* mice and analyzed the phenotype of homozygous *Zeb2*$^{flox/flox}$;*Foxd1Cre*$^+$ mice (*Zeb2* cKO) and their wild-type littermate controls. Kidney histology, renal function, and lifespan were studied in *Zeb2* cKO mice. Cell fate mapping was performed using tdTomato mice. Protein expression analyses were performed by immunostaining and Western blotting of several markers for stromal progenitors, collagen, pericytes, fibroblasts, myofibroblasts, endothelial cells, renal tubules, and SMAD proteins in *Zeb2* cKO and wild-type controls. Nephrogenesis was analyzed by immunostaining using nephron morphogenesis markers SIX2, WT1, nephrin, and Jagged1.

Results: Deletion of mouse *Zeb2* in FOXD1$^+$ stromal progenitors produced dysplastic and hypovascular kidneys. The *Zeb2* deficient FOXD1$^+$ stromal progenitors in these kidneys took on a myofibroblast cell fate that led to kidney fibrosis and kidney failure. Cell marker studies confirmed that these myofibroblasts expressed pericyte and resident fibroblast markers including PDGFRβ, CSPG4, Desmin, GLI1, and NT5E. Notably, increased interstitial collagen deposition associated with loss of *Zeb2* in FOXD1$^+$ stromal progenitors was accompanied by increased expression of activated SMAD1/5/8, SMAD2/3, and SMAD4.

Conclusions: Our study identifies a key role of ZEB2 in maintaining the cell fate of FOXD1$^+$ stromal progenitors during kidney development and loss of ZEB2 leads to differentiation of FOXD1$^+$ stromal progenitors into myofibroblasts and kidney fibrosis.

PO0612

Uncovering the Podocyte Foot Process Proteome

Gary F. Gerlach, Lori L. O'Brien. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Podocyte foot process integrity is vital for kidney function and health. Disruptions to podocyte architecture, or effacement, is one of the most common observations in kidney disease. However, the full complement of players responsible for maintaining podocyte foot process integrity is still unknown. The membranous cellular environment and specialized junctional complexes have previously hindered their isolation and testing.

Methods: The discovery of a proximity-dependent biotin identification (BioID) moiety that utilizes a promiscuous biotin ligase has opened new avenues to generate spatially localized proteomes. Podocin (*Nphs2*) localizes to the slit diaphragm and is one of the most abundant foot process proteins. Therefore, we developed a novel genetic mouse model via knock in of the BioID moiety to the *Nphs2* locus (*podocin-BioID*) to identify the in vivo proteome of the podocyte foot process localized within the vicinity of podocin.

Results: We validated our transgenic *podocin-BioID* model by assessing correct expression and localization of the fusion protein via western blot, immunofluorescence (IF), and electron microscopy (EM). Injection of *podocin-BioID* mice with excess biotin leads to the significant biotinylation of proteins within podocytes. We isolated the biotinylated proteins and performed mass spectrometry analyses (MS) to uncover novel proteins localized to the foot process. In silico analysis of the top proteins uncovered from MS identified 'cell junctions', 'adherence', and 'adhesion' as the top gene ontogeny terms. One novel candidate we uncovered is the Immunoglobulin-like domain-containing receptor 2 (Ildr2) protein. We confirmed Ildr2 is expressed in mouse podocytes by immunofluorescence and utilized publicly available single cell RNA-seq data to confirm its restricted, conserved expression in both mouse and human podocytes.

Conclusions: Current efforts are aimed at knocking out Ildr2 specifically in the podocytes of mice and zebrafish to assess the functional significance of Ildr2 in podocyte foot process integrity. These biorthogonal assays have allowed us to identify and interrogate novel components of the foot process proteome leading to a new set of potential players and biomarkers for kidney disease.

PO0613

Autophagy Deficiency in Urothelial Cells Activates Progressive NF-κB Signaling

Michael Ortega,[1,2] Ross Villiger,[2] Malia H. Harrison-Chau,[2] Joshua Kepler,[2] Geetika Y. Patwardhan,[2] Kadee-Kalia Tamashiro,[2] Amanda J. Lee,[2,3] Ben Fogelgren.[2] *[1]The Queen's Medical Center, Honolulu, HI; [2]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [3]Kapiolani Community College, Honolulu, HI.*

Background: The urothelium is a specialized epithelium that functions as a urine permeability barrier along the upper urinary tract and bladder. We have shown that conditional knockout (CKO) of exocyst gene *Exoc5* in ureteric bud cells disrupts the urothelial stratification process during ureter development, which subsequently triggers cell death and ureter obstructions. This *Exoc5* CKO mouse is a novel model of congenital obstructive uropathy (COU) and may be useful for elucidating the underlying pathological mechanisms of COU. Here, we investigated the role of exocyst-mediated autophagy in the stress responses of urothelial cells.

Methods: Cre/loxP *Exoc5* urothelial ablation was accomplished with *Ksp-Cre* and *Upk3-Cre*^{ERT2} mouse driver strains for both embryonic and adult urothelial knockout. An immortalized human urothelial cell line (SV-HUC-1) was used for cellular assays. Autophagic flux and cell stress signaling were measured by immunofluorescence and western blotting.

Results: We report that urothelial *Exoc5* ablation disrupted autophagy and promoted non-canonical NF-κB signaling during ureter development in *Ksp-Cre* mice. Adult urothelial Exoc5-knockout mice also showed disrupted autophagy, with an accumulation of lysosomes in the bladder urothelium. In SV-HUC-1 cells, EXOC4 co-immunoprecipitated with ATG7, and silencing of *Exoc5* led to an accumulation of LC3II/I and p62, indicating poor autophagic flux. Direct inhibition of autophagy with BafA1 or VPS34i induced an early canonical RelA NF-κB response followed by a delayed p52 non-canonical NF-κB response and eventual cell death.

Conclusions: Here, we report that *Exoc5* contributes to autophagy in urothelial cells, and impaired autophagy triggers progressive NF-κB signaling. The initial stress response activates canonical RelA NF-κB signaling, which is associated with survival mechanisms and inflammation. However, when the injury is not resolved, a delayed p52 non-canonical NF-κB signaling follows. Under these conditions, non-canonical NF-κB mediators TWEAK and its receptor Fn14 were highly responsive. Further investigation of this progressive NF-κB signaling series in urothelial cells may be critical for understanding the etiology of COU and any lingering chronic response after COU is resolved.

PO0614

Mechanisms of VEGFR3 Signaling in Glomerular Development

Michael D. Donnan,[1] Tuncer Onay,[1] Rizaldy P. Scott,[1] Dilip K. Deb,[1] Jean-Leon Thomas,[2] Susan E. Quaggin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Yale University, New Haven, CT.*

Background: Dysregulation of Vascular Endothelial Growth Factor Receptor 3 (VEGFR3), known primarily for its role in lymphangiogenesis, is causally linked to the development of kidney diseases, including renal fibrosis and cystogenesis. However, the mechanisms of VEGFR3 signaling in kidney development, how it influences kidney disease, and the vascular beds involved remains uncertain.

Methods: We performed a detailed expression profile of VEGFR3 in the developing mouse kidney from embryonic age (E)13.5 through 3 months. We generated a new transgenic mouse model to investigate the role of *Vegfr3* in the kidney vasculature (*Vegfr3*^{Flx}). Conditional and cell-specific excision of the floxed allele was performed using the Rosa-rtTA-TetOCre, Cdh5-Cre/ERT2, and Prox1-Cre/ERT2 driver strains to evaluate global, pan-endothelial, and lymphatic endothelial cell deletion of Vegfr3 respectively. Additionally, breeding of mice carrying podocyte-specific deletion and overexpression of the VEGFR3 ligand, VEGF-C, are underway to define ligand-dependent and independent function of VEGFR3 in the glomerulus. Mice underwent a detailed phenotypic evaluation and kidney sections were processed for histology.

Results: VEGFR3 undergoes dynamic expression through development in glomerular endothelial cells (GECs), beginning with high expression in the angiogenic sprouts which invade the capillary cleft of the developing nephron. Constitutive deletion of *Vegfr3* during mid-embryonic development resulted in reduced viability, lymphatic vascular defects, a reduction in kidney size, and a reduction in average cross-sectional glomerular count on serial sectioning (mean difference -3.767 ± 1.238, $p < 0.005$). Additionally, deletion of *Vegfr3* at embryonic day 11.5 demonstrated marked disruption of glomerular development with cavernous capillary malformations. Immunofluorescence and electron microscopy revealed glomerular structures surrounded by simplified podocytes, abnormal attachment of endothelial cells with reduced fenestrations, and poor formation of the glomerular basement membrane. VEGF-C mutant mice will be characterized once available.

Conclusions: VEGFR3 is expressed in GECs and is integral to normal glomerular development. The mechanisms of VEGFR3 signaling in GEC crosstalk with podocytes will be essential to define prior to the development of therapeutics targeting this pathway.

The ATP-Binding Cassette Protein ABCG2 Marks Kidney Resident Endothelial Colony-Forming Cell Activity in Multiple Endothelial Clusters Identified by Single-Cell RNA Sequencing

Jered Myslinski, Ellen Go, Jason A. Collett, Mervin C. Yoder, Takashi Hato, David P. Basile. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Side-population cells (SP) were originally identified in hematopoietic stem cells based on their ability to efflux the DNA binding dye Hoechst 33342, an activity thought to be mediated by members of the ATP-binding cassette protein family such as ABCG2. We hypothesized that ABCG2-expressing endothelial cells (EC) are enriched in colony forming cell (ECFC) activity, and may contribute to vascular homeostasis in kidney.

Methods: The fate of ABCG2 expressing EC was investigated using adult Abcg2-CreERT X Td-tomato Rosa$^{fl/fl}$ reporter mice (ABCG2-TT). Transgene with tamoxifen (TMX; 50 μg/g, 1X) followed by FACS analysis for TdTomato in EC. For single-cell RNA sequencing, mouse kidney ECs were isolated following digestion with collagenase, and CD45 depleted/CD31+(positive) magnetic selection. Isolated single cells were sequenced using the 10X platform. Data were analyzed with Seurat.

Results: 24 hours following TMX, 2.9% of kidney EC (CD31+/CD45-) expressed TdTomato. The percentage of Td-Tomato+ EC progressively increased to 5.3% (p=0.4) by 1 week and 15.4% (p<0.0001) by 6 weeks post injection. To determine the EC subtypes expressing ABCG2-associated progenitor activity, scRNAseq was conducted on isolated kidney endothelial cells of ABCG2-TT mice 24 hours following TMX injection. A total of 10 endothelial clusters were identified. Analysis of top expressing genes suggested these clusters correspond to different kidney EC populations such as peritubular capillaries, venules, arteries, arterioles, AVR, DVR and lymphatics. The expression of the reporter was based on identification of WPRE response element expressed Rosa mice following Cre activation. Interestingly, no single discrete cluster of ECs expressing WPRE were identified. Rather, a variable percentage (4.3 to 38.7%) of WPRE expressing cells were identified in each cluster.

Conclusions: Taken together these data suggest that ABCG2+ expressing cells contribute to vascular maintenance in adult kidney and that such cells are found in most kidney EC populations. In addition, reporter expressing EC cells do not represent a transcriptionally distinct subset of EC but are transcriptionally similar to the surrounding tissue endothelial cell subsets.

Stromal-Derived Ntn1 Influences Renal Vascular Formation and Kidney Development

Samuel E. Honeycutt, Yubin Xiong, Deanna M. Hardesty, Lori L. O'Brien. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Renal vascular networks are critical to maintaining fluid homeostasis. Despite their important roles, formation and patterning of the renal endothelium and its effect on kidney development are poorly understood. Netrin-1 (*Ntn1*) is a secreted ligand critical for vascular guidance during embryogenesis and is highly expressed by renal stromal progenitors (SP). Therefore, netrin-1 is an ideal candidate for regulating endothelial network formation. In turn, the endothelium releases angiocrine factors that may influence the formation of surrounding tissues.

Methods: To investigate the role of netrin signaling during kidney development, we deleted *Ntn1* from SPs and interrogated the embryonic phenotype using immunofluorescence, high-resolution and 3D microscopy, and cellular analyses.

Results: Conditional knock-out (cKO) of *Ntn1* results in hypoplastic kidneys, extended nephrogenesis, and arterial mis-patterning. Using 3D light-sheet microscopy, we quantitated arterial tree defects. At p0 we found significant reductions in branch number (24%), vessel length (20%), end points (27%) and total area (18%) in our *Ntn1* cKOs. Vascular defects persist at 7 months of age but result in significantly increased arterial metrics across most parameters including branch number (17%), vessel length (23%), end points (33%), total area (25%) and branch level (26%). Bulk RNA-seq of E15.5 *Ntn1* cKO kidneys was performed to gain insights into the resulting phenotypes. We found changes in Notch and Bmp pathway components suggesting altered signaling may contribute to the observed defects. Additionally, analysis of scRNA-seq data has identified *Igf1* and *Tgfb1* as potential renal angiocrine factors and we are currently investigating their role in kidney development.

Conclusions: Taken together, our studies provide novel insights into the establishment of vascular networks in the developing kidney, which will help inform strategies to engineer kidneys *de novo*, where establishing proper vascular networks will be critical.

Three-Dimensional Visualization of Neonatal Glomerulogenesis in the PodoTRAP Model by Simplified Tissue-Clearing Approach

Mathieu Preußner, Andreas Hofmeister, Simon Bedenbender, Katrin K. Roth, Ulrich J. Steinhoff, Ivica Grgic. *Philipps-Universitat Marburg Fachbereich Medizin, Marburg, Germany.*

Background: The process of glomerulogenesis is complex and the dynamics and spatio-temporal coordination involved in the formation of the glomerular architecture are still poorly understood. Conventional histopathological methods and 2D-microscopy techniques allow only a limited visualization and reconstruction of processes in the developing kidney which can only be fully appreciated in a 3-dimensional context.

Methods: To specifically study the organisation, maturation and arrangement of podocytes during glomerulogenesis, we used neonatal kidneys from Podo^{TRAP} transgenic animals (P0, P3, P7) in combination with a modified ethyl cinnamate (ECi)-based clearing approach for immunostaining and subsequent 2-photon microscopy. We used IMARIS for comprehensive morphometric analysis and 3D-reconstruction of podocytes and glomeruli during postnatal kidney development.

Results: Tissue clearing is a technique to render biological samples transparent, thereby allowing for high resolution 3D-microscopic imaging of structures deep within the tissue without the need for conventional tissue-sectioning. We used this technique for 3D-imaging, reconstruction and analysis of different glomerular developmental stages (renal vesicles, S-phase, capillary loop, maturing glomerulus) in transparent kidneys of P0, P3, P7 as well as adult Podo^{TRAP} mice. Eci-clearing followed by 2-photon microscopy achieved significantly higher imaging depth compared to uncleared kidneys (~1600μm vs. ~150μm). GFP^{+} podocytes in ECi-treated Podo^{TRAP} kidneys were readily identified due to robust cellular epifluorescence, with GFP signal intensities increasing as podocyte maturation progressed. Amongst others, we conducted comprehensive quantification of glomerular volume increases during postnatal kidney development.

Conclusions: The combination of Eci-clearing and 2-photon microscopy in the Podo^{TRAP} model is well suited for high-resolution 3D-imaging of renal tissue including detailed morphometry of maturing glomeruli in whole neonatal mouse kidneys. Moreover, this approach could also be useful for holistic histopathological analyses and assessments in various glomerular disease models including FSGS.

PO0618

OSR1 Couples Intermediate Mesoderm Cell Fate with Temporal Dynamics of Vessel Progenitor Cell Differentiation

Elliot Perens,[1,2] Jessyka Diaz,[1] Deborah Yelon.[1] *[1]University of California San Diego, La Jolla, CA; [2]Rady Children's Hospital San Diego, San Diego, CA.*

Background: Transcriptional regulatory networks refine gene expression boundaries throughout embryonic development to define the precise dimensions of organ progenitor territories. Kidney progenitors originate within the intermediate mesoderm (IM), but the pathways that establish the boundary between the IM and its neighboring vessel progenitors are poorly understood.

Methods: We employ a combination of loss-of-function and gain-of-function genetics, RNA in situ hybridization, immunohistochemisty, and transgensis in the zebrafish model system.

Results: Here, we delineate new roles for the zinc finger transcription factor Osr1 in kidney and vessel progenitor development. Zebrafish *osr1* mutants display decreased IM formation and premature emergence of neighboring lateral vessel progenitors (LVPs). These phenotypes contrast with the increased IM and absent LVPs observed with loss of the bHLH transcription factor Hand2, and loss of *hand2* partially suppresses the *osr1* mutant phenotypes. *hand2* and *osr1* are both expressed in the posterior lateral mesoderm, but *osr1* expression decreases dramatically prior to LVP emergence. Induction of *osr1* expression after gastrulation is sufficient for inhibiting LVP development and rescuing IM and pronephron formation.

Conclusions: Together, our data demonstrate that *osr1* modulates both the extent of IM formation and the temporal dynamics of LVP development, suggesting that a balance between levels of *osr1* and *hand2* expression is essential to demarcate the dimensions of kidney and vessel progenitor territories.

Membrane Phosphoinositides and Renal Epithelial Cell Polarity Determination in the Xenopus Pronephros In Vivo

Giorgia Schena, Vanathy Rajendran, Mustafa Khokha, Michael J. Caplan. *Yale University School of Medicine, New Haven, CT.*

Background: Though only minor components of cell membranes, phosphoinositide lipids (PIs) participate in numerous signaling processes and in membrane identity determination. Many studies of cultured MDCK cells found that PIs are distributed with polarity among plasma membrane (PM) domains, and that their polarized distributions are required for the delivery of distinct populations of apical and basolateral membrane proteins. The extent to which PIs drive these processes in actual renal epithelial cells *in vivo* has never been examined. We investigate the distribution of PIs *in vivo* in the pronephros of Xenopus Tropicalis tadpoles using MCherry-tagged Pleckstrin Homology (PH) domains that selectively bind different PIs (PH-AKT, PH-PLCD1, which bind to (PI(3,4,5,)P3 and PI(4,5)P2 respectively) with the goal of assessing whether and how PI localizations affect cell polarity determination and the trafficking of proteins to their sites of ultimate functional residence in renal epithelial cells *in situ*.

Methods: mRNA encoding MCherry-PH-AKT or MCherry-PH-PLCD1 was injected into fertilized oocytes and their distributions were assessed in the developed pronephros at stage NF45 via fluorescence microscopy. Knockdown (KD) of PTEN, a lipid 3′ phosphatase that regulates membrane PI composition, was achieved via injection of targeted morpholinos and confirmed by western blotting. The effects of PTEN KD on MCherry-PH-AKT distribution were assessed by fluorescence microscopy.

Results: In MDCK cells PH-AKT and PH-PLCD1 localize to the basolateral and apical PMs, respectively. Their distributions are quite different in the pronephros, with both sensors showing a markedly apical signal in the proximal portion of the tubule and diffuse cytosolic staining in the distal part. PH-AKT staining dramatically re-distributes to the lateral domain of renal cells upon PTEN KD but this treatment does not alter the localization of protein markers of epithelial PM polarity.

Conclusions: These studies constitute the first effort to assess the role of PIs in establishing PM polarity in renal epithelial cells *in vivo*. Our data reveal discrepancies with previous reports from *in vitro* systems. These findings highlight the need to explore the processes that produce renal epithelial cell polarity *in vivo* and in the context of intact renal tubules.

Autonomous Calcium Signaling in Human and Zebrafish Podocytes Controls Kidney Filtration Barrier Morphogenesis

Lydia Djenoune,[1] Heiko J. Schenk,[2] Jan Hegermann,[3] Melissa H. Little,[4] Iain A. Drummond.[2] *[1]Massachusetts General Hospital, Boston, MA; [2]Mount Desert Island Biological Laboratory, Salsbury Cove, ME; [3]Medizinische Hochschule Hannover, Hannover, Germany; [4]Murdoch Childrens Research Institute, Parkville, VIC, Australia.*

Background: Mutations in nephrotic syndrome genes that lead to elevated cytoplasmic calcium in podocytes cause disruption of filtration barrier function and nephrotic syndrome. Whether calcium signaling plays a role in the initial formation of the filtration barrier is not known. Here we show that calcium signaling is active during podocyte differentiation, occurs independently of neighboring cell types, and is required for foot process and slit diaphragm formation.

Methods: The calcium biosensor GCaMP6s was expressed in zebrafish podocytes during larval development using a podocin:Gal4 x UAS:GCAMPs transgene cross to evaluate calcium signaling during development. Calcium signals in differentiating podocytes in human kidney organoids were detected using Fluo-4. Filtration barrier formation in zebrafish was evaluated by electron microscopy.

Results: Immature zebrafish podocytes generated calcium transients that correlated with interactions with forming glomerular capillaries. Calcium transients persisted until 4 dpf and were absent after glomerular barrier formation was complete. Similar calcium transients were detected in maturing human organoid glomeruli suggesting a conserved mechanism. In both models, inhibitors of SERCA or IP3 receptor calcium-release channels blocked calcium transients in podocytes, while lanthanum was ineffective, indicating the source of calcium is podocyte intracellular stores. Calcium transients were not affected by deficiencies in heartbeat, endothelium or endoderm, and persisted in isolated glomeruli, suggesting that they were generated cell autonomously. Inhibition of phospholipase C gamma 1 (PLCg1), but not Nephrin or phospholipase C epsilon1 (PLCe1), expression lead to a significant decrease in calcium activity. Finally, blocking calcium release impacted glomerular shape and podocyte foot process formation, supporting the critical role of calcium signaling in glomerular morphogenesis.

Conclusions: Our results establish cell autonomous calcium signaling as a prominent and conserved feature of podocyte differentiation and demonstrate the requirement for intracellular calcium elevations for podocyte foot process formation.

PO0621

Zebrafish Kidney Regeneration as a Model for Engraftment of Stem Cell-Derived Kidney Replacement Tissue

Caramai N. Kamei,[1] Samuel M. Hughes,[1] Amber M. Wolf,[1] Heiko J. Schenk,[2,1] Iain A. Drummond.[1] *[1]Mount Desert Island Biological Laboratory, Bar Harbor, ME; [2]Medizinische Hochschule Hannover, Hannover, Germany*.

Background: *In vivo* engraftment of iPS cell derived mammalian kidney organoids is a major goal for kidney regenerative medicine. A major challenge in engraftment is in establishing patent tubule conduits between organoid graft and host tubules to allow fluid filtration and excretion. Stem cell-derived nephrons are continuously made during zebrafish kidney growth and regeneration that “plumb into” the pre-existing collecting system, making the zebrafish a viable model of kidney tissue engraftment. Using the zebrafish adult kidney to model synchronous fusion, we investigated the role of growth factor signaling pathways in this process.

Methods: Tg(Lhx1a:eGFP) expression labels distal invading ends of new nephrons. Tg(TCFLef-miniP:dGFP) Wnt reporter expression was used to reveal high Wnt signaling domains in new nephrons. The Wnt inhibitors IWR1 and IWP2 were applied to injured adult zebrafish to test requirements for Wnt signaling. Homozygous adult Crispr/Cas9 indel mutants in *fzd9b* and *wnt9b* were generated.

Results: We find that new nephron aggregates are patterned by canonical Wnt signaling. Cells with high canonical Wnt signaling form a single cell thick dome within cell aggregates and polarize to form rosettes with an apical constriction predicting the site of future tubule lumen. *Tg(Lhx1a:eGFP)* marks cells at the distal end of the new nephron which extend invasive processes or invadopodia into the underlying tubular epithelium. Short term inhibition of Wnt signaling using IWR1 and IWP2 inhibits invadopodia formation and blocks tubule interconnection events. Adult homozygous *fzd9b* mutants exhibit ectopic distal cell proliferation and a failure of convergent extension in new nephrons after injury while *wnt9b* mutants produce fewer new nephrogenic aggregates. A quantitative RT-PCR screen of candidate genes highly upregulated in both zebrafish nephron progenitors after injury and human cancer metastasis implicates invadopodia markers *mmp14a/b, cortactin, tks5*, as well as *cdh11, c-jun*, and *id-1* in the invasion and interconnection process.

Conclusions: Wnt signaling is required for kidney tubule invasion and engraftment and correlates with expression of multiple genes associated with metastatic cell invasiveness. Manipulation of Wnt signaling is an opportunity to engineer kidney tubule interconnections.

Evidence for Convergence of NF-κB and Growth Hormone (GH) Signaling on Stem Cell Activation in the Adult Zebrafish Kidney

Heiko J. Schenk,[1,2] Caramai N. Kamei,[1] Amber M. Wolf,[1] Samuel M. Hughes,[1] Iain A. Drummond.[1] *[1]Mount Desert Island Biological Laboratory, Salsbury Cove, ME; [2]Medizinische Hochschule Hannover, Hannover, Germany*.

Background: Adult progenitor cells in the mesonephric kidneys are required both during neo-nephrogenesis replacing injured tubules but also during overall growth. Single-cell RNA transcriptomes of adult kidney progenitor cells point to at least two receptor systems that may initiate stem cell-based nephrogenesis: growth hormone (GH) and interleukin receptors. Here we present evidence for both injury (NF-κB activation) and growth-related pathways (GH) in stimulating stem cell-based nephrogenesis.

Methods: Adult zebrafish kidneys were injured by gentamicin *i.p.* injection. NF-κB signaling was determined four days post injury (dpi) by NF-κB:GFP detection of the NF-kB reporter line *Tg(NF-κB:EGFP)* and NF-kB-associated gene expression using qRTPCR. Requirement of NF-κB signaling during regeneration was evaluated by pharmacological NF-κB inhibition. GH signaling was evaluated after either GH or gentamicin injection by quantification of progenitor marker lhx1a:GFP in *Tg(lhx1a:GFP)* and stem cell marker expression by qRTPCR. Inhibitors of GH downstream signaling were used to determine GH signaling impact after kidney injury. Bulk RNAseq from positive selected GFP^+ and $mcherry^+$ single cells by FACS was performed from kidneys 7 dpi by gentamicin injection using *Tg(lhx1a:EGFP;cdh17:mCherry)* fish.

Results: Gentamicin-induced kidney injury leads to an increase in tubular NF-κB nuclear translocation at 4 dpi and is associated with an upregulation of NF-κB downstream target gene expression detected by qRTPCR. Gentamicin also causes GH receptors mRNA upregulation at 7 dpi along with the kidney progenitor markers *osr1* and *eya4*. GH injection induced the formation of new nephrons as marked by *Tg(lhx1a:GFP)* expression in new nephron aggregates.

Conclusions: Multiple pathways may converge on adult kidney stem cells to activate new nephron formation. Growth and growth hormone may induce new nephron formation in response to increased body mass and need for osmoregulation. Kidney injury and nephron replacement correlate with nuclear translocation of NF-κB in injured tubules, suggesting the possibility of cytokine-mediated nephrogenesis in response to injury.

PO0623

Dual Tubular Par1a/b cKO Is Protective Against Renal Fibrosis

Vellia Zhou, Zhongfang Du, Kaye E. Brathwaite, Kimberly J. Reidy. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Partitioning defective Par1a/b proteins are highly homologous serine threonine kinases and contribute to kidney development. Tubular Par1a/b expression increases following folic acid and unilateral ureteral obstruction (UUO). Loss of Par1a/b expression during development impairs Notch signaling pathway expression. Notch signaling activation contributes to renal fibrosis. We hypothesized that Par1a/b expression is maladaptive following injury and promotes renal fibrosis.

Methods: Using publically available single cell RNA sequencing data, we examined the cell types where Par1a (Mark3) and Par1b (Mark2) were expressed following UUO. Localization was confirmed using immuno-fluorescence with antibodies specific for Par1a and 1b. Conditional Par1a and 1b *flox* mice were generated using CRISPR/Cas9 gene editing. Dual tubular conditional Par1a/b knockout (cKO) mice (Pax8-rtTA:tet-O-Cre:Mark2flox:flox:Mark3flox/flox) mice were generated. Deletion of Par1a (*Mark3*) and Par1b (*Mark2*) was confirmed following doxycycline induction. UUO was performed in adult (10 week old) male tubular Par1a/b cKO mice and controls; phenotype was examined at 7 days. Tubular Par1a/b deletion was induced by feeding mice doxycycline in chow starting 7 days prior to UUO. Controls were uninduced (-dox) transgenic littermates and doxycycline treated *Mark2flox/flox:Mark3flox/flox* mice. 6-8 mice/group were studied. To detect renal fibrosis, Picro-Sirius Red staining of collagen was performed. Polarized light and Image J was utilized to quantify fibrosis on 200 x images.

Results: Single cell analysis demonstrated increased expression of Par1a/b in proliferating and injured proximal tubules following UUO. This was confirmed by co-expression of Par1a in ki67 and Sox9 positive tubules following UUO. Dual tubular Par1a/b deletion was protective against fibrosis, with % fibrosis decreasing from 1.6 to 0.65 percent 7 days following UUO (p=0.0048).

Conclusions: Dual Par1a/b knockout in tubules protected against fibrosis. Ongoing studies are examining optimal timing of deletion to promote repair vs. fibrosis. Par1 kinase inhibitors may be potential promising therapeutics for preventing fibrosis in chronic kidney disease.

TRIM72-Containing Exosome for Kidney-Targeted Expression and Protection

Pu Duann,[1,2] Haichang Li,[1] Brad H. Rovin,[1] Pei-hui Lin.[1] *[1]The Ohio State University, Columbus, OH; [2]VA Medical center, Roanoke, VA.*

Background: TRIM72 is a myokine and appears to confer protection to the kidney in ischemia-reperfusion (I/R) injury. There are low levels in the kidney. We did experiments to see if TRIM72 could be transferred to the kidney so it could be used therapeutically.

Methods: Exosomes were purified from C2C12 myotubes differentiated from C2C12 myoblasts by differential centrifugation. C2C12 exosomes were given to *TRIM72* null mice twice weekly for 4-weeks by tail-vein injection. Five-days post the last exosome injection, real time PCR and western blotting were used to examine tissue expression. For comparison, samples obtained from *wildtype* littermates served as positive controls.

Results: *TRIM*72 mRNA remained detectable five days post the final C2C12 exosome infusion. Moreover, *TRIM*72 mRNA delivered by exosomes reconstituted *TRIM72* to the same organ distribution as in *wildtype* littermates, with high levels in kidney, skeletal muscle and moderate levels in heart and skin. TRIM72 protein expression was detected in tissues accordingly to TRIM72 mRNA distribution. Compared to a TRIM72-deficient exosome derived from NIH3T3 condition media, treatment with C2C12 exosome mitigated high serum creatinine level of I/R injured *wildtype* mice. This suggested a sustained TRIM72 expression and protection in kidney when delivered in exosome format.

Conclusions: Adoptive transfer of C2C12 exosomes demonstrated TRIM72 could be reconstituted to its native organ distribution and expression in TRIM72-deficient mice. TRIM72-containing exosome mitigated elevated serum creatinine level of I/R injured mice. Pharmacologic administration of TRIM72-containing exosome might be a promising approach for the treatment of kidney disease.

Development of Noninvasive Clinically Applicable In Vivo Tracking of Extracellular Vesicles Using MRI

Johnny C. Akers,[1] Hasmik Soloyan,[2] Paola Aguiari,[2] Roger E. De Filippo,[2,3] Mya S. Thu,[1] Laura Perin,[2,3] Sargis Sedrakyan.[2,3] *[1]VisiCell Medical Inc, San Diego, CA; [2]Children's Hospital of Los Angeles, Los Angeles, CA; [3]University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Extracellular vesicles (EVs) derived from amniotic fluid stem cells (AFSC) hold great potential for the treatment of chronic kidney diseases (CKD). We showned that AFSC-EVs are renoprotective in a mouse model of CKD, Alport syndrome. However, there is an important unmet need for real-time *in vivo* monitoring of these therapeutic EVs to determine biodistribution to inform about safety, targeting, and effectiveness. While current optical imaging solutions like bioluminescence and fluorescence are useful for EV tracking studies in animal models, there is limited utility in clinical applications. Here we present a novel *in vivo* tracking solution for therapeutic EVs in Alport mice, utilizing clinically applicable MRI technology.

Methods: To generate trackable EVs, AFSC were labeled with a novel magnetic agent (VSCM). EVs secreted by the labeled AFSC were isolated by ultracentrifugation. The viability and morphology of labeled-cells were evaluated, and the *in vitro* MR properties of EVs were analyzed by magnetometer. Purity, potency and identity of labeled EV was compared to non-labeled EVs. *In vivo* biodistribution of labeled EVs was evaluated in WT and Alport mice by MRI at 10 min and 3 hr post injection, and retro-orbital and intra-cardiac routes of delivery were compared.

Results: The magnetic label did not affect the physiological characteristics of the cells and did not change identity, purity and potency (therapeutic effect in vivo) of EVs. MRI phantom studies confirmed the in *vitro/ex vivo* detectability of labeled-EVs. Importantly, as expected MRI studies showed that EV homing to the kidney injected intra-cardiacally into Alport mice was more efficient vs the retro-orbital route, and Prussian blue staining of sections confirmed EV homing to the kidney.

Conclusions: We have developed a clinically applicable novel magnetic nanoparticle agent that can be used to label and track the biodistribution of EVs in the kidney and other organs using non-invasive, safe, and effective MRI technology that's widely available. This technology is highly adaptable and can be deployed in both preclinical and clinical settings.

PO0626

Extracellular Vesicles Rescue Alport Glomerular Endothelial Lipid Dysfunction

Hasmik Soloyan,[1] Matthew E. Thornton,[2] Paolo Cravedi,[3] Andrea Angeletti,[3] Laura Perin,[1,2] Sargis Sedrakyan.[1,2] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]University of Southern California Keck School of Medicine, Los Angeles, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Glomerular endothelial dysfunction plays a key role in the development of chronic kidney disease (CKD). We have previously shown that glomerular endothelial cells (GEC) are damaged in Alport syndrome mice (AS, characterized by mutations in collagen IVα3α4α5), manifested by enlarged fenestrations and damaged glycocalix in the early stage of the disease. In the present study we report on the role of altered fatty acid utilization pathways leading to GEC dysfunction in AS, and the role of extracellular vesicles derived from amniotic fluid stem cells (AFSC-EVs) in re-establish lipid homeostasis.

Methods: GEC were isolated from tdTomato-reporter AS and WT mice at 4 months of age by FACS and transcriptome was analyzed and compared by bulk RNA-seq. Tissue samples from patients with AS were used to confirm our findings by immunohistochemistry. In vitro, silencing experiments using human primary GEC were performed to study the role of decreased fatty acid synthase (FASN) in GEC dysfunction, and AFSC-EVs (which contain FASN in their cargo) were applied as a rescue strategy to normalize FASN level and restore lipid homeostasis. Data were confirmed using AFSC-EV $^{FASN-/-}$.

Results: AS GEC were highly enriched for differentially expressed genes associated with cellular metabolism, and lipid metabolism in particular. Genes associated with fatty acid transport (CD36, FATP-1, FATP-2, Fabp3) and synthesis (FASN) among others were downregulated, which was further associated with glomerular accumulation of lipid droplets in mice. We observed similar findings in human biopsy samples from AS patients by histology. In vitro, AFSC-EVs were able to rescue FASN deficiency and improve GEC function, unlike AFSC-EV $^{FASN-/-}$.

Conclusions: We report for the first time a lipid metabolic dysfunction in Alport GEC, and the ability of AFSC-EVs to rescue this phenotype. Therefore, better understanding of the functional role of GEC in AS could lead to the development of targeted new therapies for the treatment of this and other forms of CKD.

PO0627

Administration of Mesenchymal Stromal Cell-Derived Exosomes Is an Effective Rescue Therapy for Progressive AKI in Rats

Anna Gooch,[1] Christof Westenfelder.[2,1] *[1]SymbioCellTech, Salt Lake City, UT; [2]University of Utah Hospital, Salt Lake City, UT.*

Background: Preclinical and clinical studies have shown Mesenchymal Stem Cells (MSCs) to be effective for prevention of AKI [NCT00733876]. Yet studies where MSCs are given 48 hrs. post-insult, a time at which most patients with severe AKI are diagnosed and when no rescue therapy is available, show them to be ineffective or even damaging due to compromised renal blood flow in capillary beds, where introduction of large cells has the potential to cause further deterioration of renal function [NCT01602328]. While MSCs' renoprotection is largely due to their release of beneficial cytokines and exosomes, their potential negative impact on renal blood flow is a concern. Administration of MSC-derived exosomes is known to exert beneficial effects that are similar to those of the parent cells. We hypothesized that since MSC-derived exosomes can prevent AKI, their small size and ability to move through the microvasculature might allow them to also be an effective rescue therapy for late stage AKI where MSCs are ineffective.

Methods: MSCs from Sprague Dawley (SD) rats were used. Their purified exosomes were characterized for size by nanoparticle tracking analysis, protein concentration, gene expression of relevant markers, FACS (CD44 and CD29), and rtPCR. I/R AKI (50-52 min bilateral renal pedicle clamp) was induced in 3 groups of SD rats (6-8/group). SCr was assessed at baseline, Days (D) 1 and 2. If the SCr value on D2 was greater than that on D1, then on D3, rats were given i.a. either 1 ml of Vehicle, 4x10e10, or 2x10e6 ASCs. Studied Endpoints: SCr at Days 0-9; survival and renal injury.

Results: In contrast to what is found when MSCs are administered to rats immediately upon reflow, when administered to rats 48 hrs post-I/R AKI, 2x10e6 MSCs prove ineffective at ameliorating injury, while MSC-derived exosomes significantly and sustainably improve renal function by D5 post-injury.

Conclusions: MSC-derived exosome therapy administered 2 days post-insult, when renal blood flow is compromised, but also when most clinical instances of AKI are diagnosed, is superior to MSC therapy for rescue of AKI, likely due to the mirrored paracrine content, but significantly smaller size of exosomes compared to MSCs. Our results support the hypothesis that MSC-derived exosomes could be used as a rescue therapy for non-spontaneously recovering AKI.

Human Induced Pluripotent Stem Cell-Derived Kidney Organoids to Model Idiopathic and Congenital Nephrotic Syndrome

Jitske Jansen,[1,2] Bartholomeus T. van den Berge,[1] Martijn van den Broek,[1] Brigith Willemsen,[1] Christoph Kuppe,[2] Gianluca V. Di Giovanni,[1] Fieke Mooren,[1] Naomi Parr,[1] Dirk den Braanker,[1] Rutger J. Maas,[1] Jack F. Wetzels,[1] Nicole Van De Kar,[1] Rafael Kramann,[2] Johan Van der vlag,[1] Michiel F. Schreuder,[1] Bart Smeets.[1] *[1]Radboudumc, Nijmegen, Netherlands; [2]Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany.*

Background: Recent advances in human stem cell-derived kidney organoid models have opened new avenues to accurately model podocytopathies in 3D *in vitro*. The aim of this study is to develop and characterize human induced pluripotent stem cells (iPSC)-derived 3D kidney organoids as a first step in modeling idiopathic and congenital nephrotic syndrome (NS) *in vitro*.

Methods: Human iPSC were successfully cultured into kidney organoids and characterized using scRNA sequencing, immunocytochemistry, TEM and RNAscope. The protamine sulphate (PS) model and FSGS plasma treatment were used to model idiopathic NS. Podocin mutant organoids were used to study congenital NS.

Results: Kidney organoids showed a clear podocyte population expressing, amongst others, podocin, nephrin, PLA2R, WT1, VEGFA and collagen IV alpha 3. The slit diaphragm was confirmed by TEM. To model podocyte injury, organoids were exposed to protamine sulphate (PS) or active FSGS plasma. PS-induced injury in organoids showed clear podocyte cytoskeleton rearrangements and the induction of pNPHS1-1176 protein expression. The induced podocyte injury was rescued by heparin sulphate, illustrating recovery of injury associated mechanisms in 3D podocytes. The PS effect was organoid-podocyte specific as their 2D iPS-derived podocyte counterparts did not express pNPHS1-1176. Organoids exposed to active FSGS plasma for 4h showed increased granule formation, a podocyte stress marker, in NPHS1+ podocytes which was less abundant when treated with remission plasma. To model congenital nephropathy, erythroblasts from a pediatric patient with compound heterozygous mutations p.Arg138Gln (exon 3) and p.Asp160Tyr (exon 4) in the podocin (*NPHS2*) gene, were successfully reprogrammed in iPSC. Aberrant localization and weak podocin expression was shown in organoids. Using CRISPR/Cas9 the exon 3 mutation was repaired and podocin expression was restored.

Conclusions: We successfully developed human iPSC-derived kidney organoids that will serve as a state-of-the-art tool to accurately study podocytopathies in a dish.

Five-Year Outcome in Patients with ESRD Who Received the Bioengineered Human Acellular Vessel for Dialysis Access

Jeffrey Lawson,[1,4] Laura E. Niklason,[1,2] Alison J. Pilgrim,[3] Robert D. Kirkton,[1] Heather L. Prichard.[1] *[1]Humacyte, Inc., Durham, NC; [2]Yale University Departments of Anesthesiology and Biomedical Engineering, New Haven, CT; [3]Competitive Drug Development SAS, Castillon-du-Gard, France; [4]Duke University, Department of Surgery, Durham, NC.*

Background: In a previous prospective, phase 2 trial, where 40 Human Acellular Vessels (HAV) were implanted into 40 hemodialysis patients at 3 sites in Poland from 2012 to 2014 (NCT01744418), initial results demonstrated the HAV provided safe and functional hemodialysis access in these subjects at 2 years. This long-term follow-up assessed subject and conduit status in patients who continued routine dialysis with the HAV at 60 months.

Methods: HAVs are bioengineered by culturing human vascular smooth muscle cells (SMC) on a biodegradable polymer matrix within bioreactors that provide pulsatile mechanical strain. After a quantitative decellularization process, the final complete vessel comprises human vascular extracellular matrix constituents and has the mechanical strength of the original vessel without cellular components that might stimulate host immunologic recognition. In this study, subjects with patent HAV implants were followed for subject and functional conduit status every 3 months, starting after the main portion of the study (at Month 27) through at least 5 years post-implantation. This current report contains 5-year follow-up functional and histological data on 29 patients who were previously enrolled in our initial Phase 2 trial.

Results: At Month 60, 1 subject maintained primary patency, two subjects maintained primary-assisted patency, and ten subjects maintained secondary patency. Secondary patency was estimated at 58.2% (95% confidence interval: 39.2 to 73.1%) at 5 years, after censoring for deaths (n=8) and withdrawals (n=1). No infections of HAV conduits reported during follow up period.

Conclusions: This long-term follow up shows that the HAV provides durable and functional hemodialysis access for patients with end-stage renal disease who dialyze three times per week.

PO0630

Mechanistic Elucidation of Nephron Progenitor Cell Expansion Using a Small Molecule, TCS21311, That Replaces BMP7 and Promotes Cell Proliferation

Hiraku Tsujimoto,[1] Toshikazu Araoka,[1] Hideyoshi Fuji,[2] Yukiko Yamagishi,[2] Kenji Osafune.[1] *[1]Kyoto Daigaku iPS Saibo Kenkyujo, Kyoto, Japan; [2]Astellas Seiyaku Kabushiki Kaisha, Chuo-ku, Japan.*

Background: Nephron progenitor cells (NPCs) give rise to all epithelial components of the nephron, which is the smallest functional unit of the kidney. The development of a stable supply of NPCs is expected to contribute to kidney regeneration research. Although most reports on the development of NPC expansion culture use BMP7, the detailed mechanisms of action of BMP7 are unknown. To elucidate the roles of BMP7 and improve the NPC expansion culture method, we sought small molecules that can replace BMP7 in the culture system.

Methods: We isolated NPCs from Six2-GFP reporter mice and screened 4,395 chemical compounds using a previously reported expansion culture system. The activity of analogous chemicals from the hits was examined. We predicted the molecular targets of the hit compounds by chemoinformatics analyses of molecular structures. Known downstream signaling pathways were examined by immunoblotting, and differentially expressed genes (DEGs) were analyzed by removing BMP7 from the NPC expansion culture. Furthermore, we improved the expansion culture method using mouse embryonic and human induced pluripotent stem cell (iPSC)-derived NPCs by adding the hit compounds to the expansion culture condition including BMP7.

Results: The chemical screening identified a JAK3 inhibitor, CP690550, in the mouse NPC expansion culture. Although several JAK3 inhibitors as well as some JAK2/3, JAK1/2 and JAK2 inhibitors showed similar activity, one JAK3 inhibitor, TCS21311, showed especially potent effects. A structural analysis of TCS21311 confirmed that JAK3 is its primary target. A pathway analysis of the DEGs by the BMP7 removal indicated STAT3 pathway activation. The phosphorylation of Smad1/5 was increased by TCS21311 even in the absence of BMP7, suggesting a mechanism by which TCS21311 replaces BMP7 via JAK3-STAT3. Furthermore, the addition of TCS21311 to the expansion culture containing BMP7 resulted in more efficient proliferation of mouse embryonic and human iPSC-derived NPCs.

Conclusions: These results will contribute to understanding the roles of BMP7 in NPC proliferation and to the stable supply of NPCs.

The Transcription Factor GATA3 Regulates Hyaluronan-Mediated Stromal-Cell Responses During Kidney Injury, Repair, and Fibrosis

Irina Grigorieva, Sarah Buckby, Charlotte V. Brown, Robert Steadman, Soma Meran. *Cardiff University, Cardiff, United Kingdom.*

Background: Stromal-mediated processes are critical in determining fibrosis progression. Stromal cells are essential for kidney development and homeostasis, but are also myofibroblast precursors and their maladaptive responses tip the balance from tissue repair to scarring. Our work shows that GATA3 is crucial for developing and mature renal stroma and its expression marks a distinct fibroblast subset associated with improved tissue outcomes following injury. Hyaluronan-(HA), a matrix glycosaminoglycan, is a key regulator fibroblast heterogeneity and predominance of distinct HA synthase (HAS) isoform expression separates fibroblasts into subsets which mediate fibrosis progression or resolution. Here, we investigated GATA3$^+$ fibroblasts in relation to factors that regulate HA-matrix synthesis and metabolism during fibrosis progression *versus* prevention.

Methods: Immunohistology was performed on rat kidneys with bilateral ischaemia-reperfusion-injury +/- ischemic pre-conditioning (IPC) or BMP7 administration (prevention models). Primary human fibroblasts were used to test the role of GATA3 in BMP7 antagonism of TGFβ1-driven myofibroblast differentiation. siRNA and plasmids were used for knockdown or over-expression. HA levels were correlated with fibrosis profiles using ELISA, RT-qPCR and immunofluorescence.

Results: GATA3$^+$ fibroblasts increased in abundance during regenerative phase following injury, co-stained for PDGFRβ and surrounded repairing tubules. More GATA3$^+$PDGFRβ$^+$ fibroblasts were observed in prevention models suggesting a protective, anti-fibrotic role. In prevention models, prominent co-localisation was observed between GATA3 and HAS1 in VSMCs, distal tubules and a distinct stromal population. In contrast, GATA3 expression was attenuated in α-SMA+ myofibroblasts in chronic fibrotic lesions where HAS2 was prominent. *In vitro*, BMP7 induced GATA3 expression and GATA3 knockdown attenuated BMP7-driven antagonism of TGFβ1-driven myofibroblast differentiation, in part by increasing HAS2 expression and pericellular HA. HAS2 promoter analysis confirmed enrichment of GATA binding motifs.

Conclusions: GATA3 is critical for maintaining a distinct stromal subset and mediating the reno-protective effects of IPC and BMP7 on IRI-induced renal damage by modulation of HA-matrix and HAS isoform expression.

The Regenerative Response to Renal Injury of the African Spiny Mouse Is Epigenetically Regulated Through H3K27 Methylation

Elizabeth D. Nguyen, Daryl M. Okamura, Scott R. Houghtaling, Sarah J. Collins, Andrew E. Timms, David R. Beier, Mark W. Majesky. *Seattle Children's Research Institute, Seattle, WA.*

Background: Lysine methylation of histones plays an important role in regulating gene expression. When tri-methylated, chromatin regions marked by H3K27me3 are inaccessible for transcription. EZH2 of the Polycomb group methylates H3K27, with opposing action carried out by histone demethylases JMJD3 & UTX. EZH2 activation and subsequent increase in H3K27me3 has been associated with renal fibrosis. We hypothesize that in the African spiny mouse, a mammalian model of kidney regeneration, demethylation of H3K27 is associated with regenerative wound healing after ischemia-reperfusion kidney injury.

Methods: Experiments were carried out on kidneys of spiny mouse and house mouse in normal kidneys and kidneys 1 & 3 days after unilateral ischemia-reperfusion injury. Mass spectrometry was used to profile histone modifications. Expression of key genes involved in methylation of H3K27 were quantified using RNA-sequencing, and protein concentration was quantified by western blot. H3K27me3 marks were visualized by immunofluorescent staining. Genes marked by H3K27me3 were identified using CUT&RUN ChIP-sequencing.

Results: H3K27me3 is significantly increased in mouse kidney after ischemia reperfusion injury whereas no change in the repressive mark was noted in spiny mouse when quantified by mass spectrometry and western blot. H3K27me3 marks are abundant in fibrotic mouse kidneys and distributed throughout kidney tissue, while H3K27me3 is reduced in repaired kidneys of spiny mouse. RNA-sequencing demonstrated a 4-fold increase in *Ezh2* in mouse after injury vs 2-fold increase in spiny mouse. During the course of injury, *Jmjd3* expression increased in spiny mouse but decreased in expression in mouse. We previously identified nephrogenic progenitor genes potentially associated with regenerative wound healing in spiny mouse, including *Cdh1, Cdh6* and *H19*. CUT&RUN identified these genes as repressively marked by H3K27me3 in mouse but available for transcription in spiny mouse.

Conclusions: This work suggests that the regenerative response to renal injury in spiny mouse is orchestrated at least in part through the methylation of histone H3K27. Modification of the histone methylation landscape through small molecular modulators may redirect the outcome of kidney injury from fibrosis to regeneration.

Effect of Hypoxic Preconditioning on Angiogenesis and Senescence in Human Adipose Tissue-Derived Mesenchymal Stem Cells

Arjunmohan Mohan, Naba Farooqui, Busra Isik, Xiang yang Zhu, Kyra L. Jordan, Ishran M. Saadiq, Hui Tang, LaTonya J. Hickson, Stephen C. Textor, Alfonso Eirin, Lilach O. Lerman, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Hypertension(HTN) and chronic kidney disease(CKD) alter the angiogenic and immunomodulatory properties of human adipose-derived Mesenchymal Stem Cells(AMSC). Hypoxic conditions modify growth potential, paracrine functions and gene expression of AMSCs. We tested the hypothesis that AMSCs in CKD patients, preconditioned with hypoxia, will have reduced senescence, enhanced migratory, proliferative and angiogenic functions compared to healthy kidney donors.

Methods: We cultured AMSCs(P3-4) from healthy kidney donors(Controls), patients with HTN and CKD(n=6 each group) under normoxia(20%O_2) and hypoxia(1%O_2). We tested AMSC migration and proliferation, quantified angiogenic and inflammatory factors (VEGF,HGF,TNF-α,TGF-β) in cell culture supernatant, and analyzed gene expression(VEGF,HGF,P16,P21) using rt-PCR.

Results: The table shows characteristics of enrolled patients. Hypoxia suppresses AMSC migration in controls and HTN patients while enhancing it in CKD patients and increasing proliferation in all groups. Hypoxia increases VEGF secretion in controls and CKD while downregulating HGF gene expression in controls and HTN group. In CKD patients, TGF-β secretion was higher at baseline and under hypoxia, TNF-α was elevated. Senescence(gene expression of P16/P21) was not different among the groups at baseline but hypoxia attenuated it in all groups.

Conclusions: Hypoxic preconditioning of AMSCs increases migration, proliferation, upregulates VEGF secretion and gene expression, and downregulates pro-senescence genes. These results support hypoxic preconditioning to enhance the regenerative potential and overcome challenges in autologous stem cell therapy for nephropathies.

Effect of Hypoxia on the Regenerative Capacity of Adipose Tissue-Derived Mesenchymal Stem Cells in an Experimental Model of Atherosclerotic Renal Artery Stenosis

Naba Farooqui, Arjunmohan Mohan, Xiang yang Zhu, Ishran M. Saadiq, Christopher M. Ferguson, Kyra L. Jordan, Hui Tang, Stephen C. Textor, LaTonya J. Hickson, Alfonso Eirin, Lilach O. Lerman, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Atherosclerotic renal artery stenosis(ARAS) is a risk factor for parenchymal renal disease. Autologous mesenchymal stem cells(MSC) therapy reduces kidney fibrosis and inflammation in ARAS. Studies have shown that hypoxia preconditioning(Hx) improves MSC function by affecting DNA hydroxymethylation (5-hmC). But the effect of Hx MSCs *in vivo* ARAS model has not been evaluated. We hypothesize that Hx MSCs would improve renal histology better than normoxic (Nx) MSCs and also compare 5-hmC differences between MSC groups.

Methods: MSCs isolated from abdominal fat of ARAS pigs were cultured under normoxia(20%O_2) or hypoxia(1%O_2) till 70-80% confluence. Autologous Nx or Hx MSCs(10^7 cells each) were injected into the swine renal artery 6 wks after induction of ARAS(N=4 each) and compared to Normal and Untreated ARAS pigs(N=5 each). 4 wks later, *ex-vivo* renal trichrome and CD3(T-cell) staining was performed. MSC gene groups with significant 5-hmC fold change levels were grouped on Panther's database.

Results: ARAS pigs treated with either Nx or Hx MSC show reduced renal fibrosis and interstitial inflammation(CD3 cells) versus untreated ARAS pigs(Fig1A,1B). Interstitial fibrosis was less with Nx MSC therapy versus Hx MSC therapy(Fig1A). Interstitial inflammation shows a decreasing trend with Hx MSC therapy versus Nx MSC therapy(p=0.09). Epigenetic analysis showed higher DNA 5-hmC levels of profibrotic and inflammatory genes in ARAS MSC versus Normal Pig MSC(Fig1C). 5-hmC levels of some of these genes were lower in Hx MSC(Fig1D).

Conclusions: In swine model of ARAS, intra-arterial renal delivery of autologous MSCs with or without hypoxia preconditioning reduces kidney fibrosis and interstitial Tcell infiltration. Hx MSCs' effect was not different from Nx MSC. But, enhanced DNA hydroxymethylation of profibrotic and inflammatory genes in ARAS MSC could be mitigated by hypoxia preconditioning.

In Vivo Data to Support Induced Pluripotent Stem Cell-Derived Renal Progenitors as Potential Cell Therapy for Kidney Disease

Kevin Woollard, Ralph Gruber, Anna Jonebring, Anna K. Svensson, Elena Liarte Marin, Ulrika Dahlqvist, Ryan Hicks, Pernille B. Laerkegaard Hansen. Bioscience Renal, Early CVRM, BioPharmaceuticals R&D *AstraZeneca UK Ltd, Cambridge, United Kingdom.*

Background: Novel therapies are needed to deliver life changing medicines to renal patients and cell therapy is a relatively new strategy of kidney therapy. We have developed novel methodology to produce kidney organoids for target validation. Here we have used this learning, to derive human renal progenitor cells (RPC) and examine their differentiation in-vivo using 2 delivery models

Methods: We used iPSC modified to contain a GFP reporter of nephrin expression, to generate human RPC differentiated to day 6 and 10 using a previously described kidney organoid protocol. We then used kidney capsule implantation and intravenous delivery in naïve and Ischemia/Reperfusion Injury (IRI) NOD/SCID background mice respectively. For kidney capsule, we compared RPC implantation number (3 and $5x10^6$) and time (1 and 5 weeks). For IRI, we infused i.v RPC ($5x10^6$) directly after kidney clamping (24mins)/ reperfusion and measured systemic biodistribution of RPC at 2 and 25 days. Other readouts included kidney human RNAseq, renal function, plasma cytokines and histology

Results: We can currently show RPC implanted in kidney capsule continue differentiation towards mature renal cell types. Using histology and hRNA signatures, there is some enrichment towards tubular like cells particular at high dose, using day 10 matured progenitors at 5 weeks after implantation. These include differentiation of tubular transporters, such as nucleoside (ENT1) and water-transporting proteins (AQP1). In IRI experiments, i.v infusion was well tolerated with normal disease course based on increases in plasma creatinine, BUN and urinary KIM-1. Biodistribution and differentiation analysis is underway, focused on anti-human nuclear staining in multiple organs and qPCR. Plasma inflammatory, cardiac and renal biomarkers analysis will examine any RPC infiltrate response

Conclusions: These observations clearly demonstrate the use and differentiation potential of RPC in a pre-clinical setting. These studies may aid design and delivery modality, for any future effort in examining RPC therapy for renal disease

Synthetic Peptide Hydrogels as Support Matrices for the Generation of Distinct Cell Populations Within Induced Pluripotent Stem Cell-Derived Kidney Organoids

Niall Treacy,[1,2] Shane Clerkin,[1,2] Jessica L. Davis,[1,2] Ciarán Kennedy,[1,2] Jacek K. Wychowaniec,[3] Dermot F. Brougham,[3] John Crean.[1,2] *[1]University College Dublin School of Biomolecular and Biomedical Science, Dublin, Ireland; [2]UCD Diabetes Complications Research Centre, Dublin, Ireland; [3]University College Dublin School of Chemistry and Chemical Biology, Dublin, Ireland.*

Background: Kidney organoids that display improved maturity with reduced variability are needed to produce models that faithfully mirror the *in vivo* organ. We propose that organoid development will benefit from the biophysical support provided by a tunable, fully defined microenvironment. Synthetic self-assembling peptide hydrogels are ideal systems to support organoid development that more accurately mimics the *in vivo* environment due to the simplicity of the structure formed at the molecular level, their low immunogenicity, cell-retention, biodegradability, and tuneable mechanical properties.

Methods: Peptide hydrogel properties were investigated via transmission electron microscopy and rheology. Organoids were characterized by immunofluorescence and single cell RNA sequencing using the 10x Genomics platform.

Results: The self-assembling peptide hydrogels (SAPHs) were comprised of a fibrous structural architecture similar to that of natural polymer networks. The mechanical properties of the SAPHs were dynamic with Alpha4 increasing in G' stiffness over time while Alpha5 reached a peak G' on day 3 of media conditioning. Monolayer differentiation saw the loss of pluripotency markers, transient expression of primitive streak marker brachyury, and high levels of intermediate mesoderm markers PAX2 and HOXD11 by day 7. Suspension culture for 48 hours resulted in compacted pellets that allowed for encapsulation on day 9. By day 24 organoids displayed high levels of viability and were shown to have functionality through dextran uptake. Immunostaining confirmed the generation of key cell types of the maturing nephron. Organoids contained WT1+ve podocytes, LTL+ve proximal and ECAD+ve distal tubules, laminin+ve basement membrane and meis1/2/3+ve interstitial cells. scRNA-seq revealed distinct clusters comprising nephron and stromal compartments. Interestingly, growth within the SAPHs resulted in varying proportions between these two cell types particularly with increased stromal cells seen in Alpha4 organoids.

Conclusions: We propose that peptide hydrogels due to their defined and tunable nature provide an alternative to animal-derived support matrices. These results further support the use of designer matrices that will improve iPSC differentiation towards renal cell fate trajectories.

Gelatin Methacryloyl (GelMA) as a Tuneable Biophysical Environment for the Derivation of Human Induced Pluripotent Stem Cell-Derived Kidney Organoids

Shane Clerkin,[1] Jacek K. Wychowaniec,[2] Niall Treacy,[1] Jessica L. Davis,[1] Krutika Singh,[2] Dermot F. Brougham,[2] John Crean.[1] *[1]University College Dublin Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland; [2]University College Dublin School of Chemistry and Chemical Biology, Dublin, Ireland.*

Background: The translational utility of hiPSC-derived kidney organoids relies on our ability to comprehensively mimic both the biochemical and biophysical properties of the cellular milieu *in vitro*. An improved understanding of how the mechanical environment effects the renal progenitor niche during development and how perturbations to such biophysical environments effects cell fate are required. Within this context, Gelatin methacryate (GelMA), a derivative of collagen, represents a mechanically amendable scaffold to probe cell fate dynamics.

Methods: hiPSC-derived kidney organoids were differentiated within photo-crosslinked GelMA hydrogels of defined mechanical strengths. Hydrogels were characterised using rheological analysis and SEM. Enrichment of renal cell types in response to the various mechanical microenvironments was subsequently investigated.

Results: Rheological analysis revealed a diverse stiffness profile range from the formulated hydrogels. Hydrogels comparable to the stiffness of the gastrulation-stage embryo (G′ = 400 Pa), human kidney tissue (G′ = 2.5 kPa) and fibrotic tissue (G′ = 8-10 kPa) were generated. SEM revealed that hydrogel pore size was dependent on starting gelatin concentration in the hydrogel formulations. PCNA and cleaved caspase-3 staining of organoids embedded within scaffolds demonstrated high cell proliferation and viability in all hydrogel constructs by day 26 of differentiation. The formation of glomerular, proximal tubular and distal tubular structures, that were supported by basement membrane and interstitial cells was confirmed in all conditions using qRT-PCR and immunofluorescent analysis. Significant enrichment of MEIS1/2/3^{+ve} interstitial cells was noted in organoids differentiated within stiffer hydrogels. Interstitial expansion and increased extracellular matrix deposition was confirmed using H&E and Masson's trichrome staining within stiff GelMA scaffolds.

Conclusions: We propose the utility of GelMA hydrogels as faithful extracellular supports for the specification of hiPSC-derived kidney organoids. These scaffolds represent a mechanically tuneable microenvironment to investigate the effects of the biophysical milieu on renal development and disease perturbations.

Generation of Chimeric Nephrons in Newborn Mice for Testing Drug-Induced Nephrotoxicity

Kenji Matsui,[1] Shuichiro Yamanaka,[1] Naoto Matsumoto,[1] Yatsumu Saito,[1] Tsuyoshi Takamura,[1] Toshinari Fujimoto,[1] Susumu Tajiri,[1] Kei Matsumoto,[1] Eiji Kobayashi,[2] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Department of Kidney Regeneration, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Studies have reported certain limitations of experiments on animals for assessing nephrotoxicity. Due to species differences in tubular transporters, a model for evaluating nephrotoxicity in humans is desirable. Organoids are a novel research method, but the absence of their connection to the urinary tract makes them difficult for use in the evaluation of chronic nephrotoxicity. Therefore, our goal was to develop a new pre-clinical assessment model that is amenable to repeated dose toxicity studies. In particular, this model aimed to produce human nephrons chimerized in the kidneys of host animals. We previously reported "*exo utero*" cell transplantation in which exogenous renal progenitor cells (RPCs) were transplanted into the retroperitoneal cavity of mouse fetuses without lethality. Although transplanted cells differentiated into functional nephrons chimerized with host kidneys, this method requires proficiency. In this report, because continuous nephrogenesis takes place over several days after birth in mice, we used newborn mice as host animals and conducted a proof-of-concept study using mouse RPCs.

Methods: Metanephroi extracted from green fluorescent protein (GFP)-labeled mouse embryos were dissociated into single RPCs and injected into the subcapsular areas of newborn mice at postnatal days 0–1. After 2 weeks, kidneys of host mice containing

exogenous nephrons were extracted for the immunohistochemical evaluation. In addition, cisplatin was administered intraperitoneally to the host mice and the response of exogenous proximal tubular cells (PTCs) was evaluated.

Results: Immunohistochemistry revealed around 10% chimerism in glomeruli, proximal and distal tubules in the injected areas. Exogenous PTCs exhibited dose-dependent expression of Kim-1 in response to cisplatin administration. We aim to subsequently report data from single-cell RNA sequencing.

Conclusions: Mouse exogenous RPCs could form chimeric nephrons in newborn mice that reproduced drug-induced nephrotoxicity seen in native kidneys. The neo-tubules are expected to be a tool that can be applied to long-term repetitive drug administration because of its integration into the host functioning nephrons.

PO0639

Interrogating the Contribution of Innervation to Kidney Development and Disease

Pierre-Emmanuel N'Guetta, Lori L. O'Brien. O'Brien Lab *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Kidney functions range from blood filtration and regulation of body fluid homeostasis to promoting the production of red blood cells and active vitamin D. These functions are regulated by intrinsic cellular mechanisms including signaling through renal nerves. The kidney is innervated by axonal projections from exterior ganglia. These projections can be classified as either afferent sensory fibers which impact cardiovascular function by relaying information from the kidney to the central nervous system (CNS), or efferent sympathetic fibers which impact renal function by relaying information from the CNS to the kidney. While the role of innervation in adult renal pathophysiology is an area of active investigation, there is a significant deficit in our understanding of renal innervation during development. I hypothesize that renal nerves release spatially and temporally regulated signaling factors contributing to proper kidney development.

Methods: To first characterize the process of renal innervation, we generated 3D anatomical maps of renal innervation throughout development using light-sheet imaging of embryonic, neonatal, and adult kidneys. We also utilized confocal microscopy to interrogate the association of renal nerves (synapse formation) with distinct renal structures including tubules, glomeruli, and vasculature. To assess function, we genetically ablated renal innervation utilizing a knockout mouse for the TrkA receptor which is required for neuronal survival.

Results: Our analyses show that renal innervation begins at E13.5 as the renal arterial tree becomes smooth muscle actin (SMA) coated. Innervation continues via multiple branching events following SMA+ vasculature until the main renal nerve branches are established by E16.5. From there, renal nerves grow further via interstitial branching until projections reach renal target structures as early as E17.5. TrkA knockout kidneys assessed postnatally had a significant reduction in renal innervation and presented with abnormal glomerular and tubules phenotypes.

Conclusions: Future efforts will aim to conditionally delete sensory or sympathetic renal nerves independently and investigate the resulting functional phenotypes. Taken together our findings will significantly bridge the gap in knowledge concerning the establishment of renal innervation and the role of nerves in kidney development and disease.

PO0640

Constitutive Activation of Hedgehog Signaling in FOXD1+ Renal Stromal Cells Impairs Ureteric Epithelial Branching via CXCL12

Robert D'Cruz, Yun-Kyo Kim, Norman D. Rosenblum. *The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Renal dysplasia, characterized by disorganization of stromal tissue, malformation of collecting ducts, and decreased nephron number, is a major cause of renal failure in children. Nephrons and collecting ducts develop via reciprocal inductive interactions between two intermediate mesodermal tissue elements - the *Osr1*+ metanephric mesenchyme (MM), within which reside *Six2*+ nephrogenic and *Foxd1*+ stromal cell progenitors, and the *Hoxb7*+ ureteric bud, which gives rise to ureteric branches and their daughter collecting ducts. The key roles of expanded *Foxd1*+ stromal progenitors in the genesis of dysplastic tissue are largely undefined. Here, we identify a novel pathogenic stromal *Hh-Cxcl12* signaling axis driving impaired ureteric epithelial branching.

Methods: Mice with deficiency of *Ptch1* specific to FOXD1+ stromal cells (*Foxd1Cre;Ptch1*$^{loxP/-}$; referred to as stromal *Ptch1*-deficient) were analyzed by immunostaining, single-cell RNA sequencing, and bulk RNA sequencing. To investigate *Cxcl12* as a downstream target of increased stromal Hh signaling, *in vivo* analysis of ureteric branching was assessed in *Cxcl12* compound mutants (*Foxd1Cre; Ptch1*$^{loxP-}$*; Cxcl12*$^{loxP/+}$).

Results: Stromal *Ptch1*-deficient kidneys exhibited renal dysplasia characterized by a 41% reduction in nephron number ($P<0.01$, n=4) at E18.5 and a 26% reduction in ureteric epithelial branch tips at E12.5 ($P<0.01$, n=6). Whole kidney qRT-PCR analysis at E13.5 further demonstrated a reduction in ureteric branching effectors *Gdnf, Wnt11, Etv4,* and *Etv5* in stromal *Ptch1*-deficient mice ($P<0.05$, n=4). Bulk RNA sequencing of stromal *Ptch1*-deficient whole kidneys revealed a significant upregulation in numerous medullary stromal markers including the secreted stromal cell-derived factor *Cxcl12* ($P<0.01$, n=3). Complementary single-cell RNA sequencing analysis further demonstrated upregulation of *Cxcl12* in medullary stromal clusters of *Ptch1*-deficient kidneys relative to control samples. Analysis of branching morphogenesis in compound mutant mice heterozygous for *Cxcl12* in a stromal *Ptch1*-deficient background revealed a complete rescue of ureteric epithelial branching defects ($P<0.001$, n=6).

Conclusions: A pathogenic increase in stromal Hh signaling in mice causes nephron deficiency and impaired ureteric epithelial branching due to increased *Cxcl12* activation.

Maturation-Enhanced Proximal Tubules Enable Functionality, Toxicity Screening, and Infectious Disease Modeling in Kidney Organoids

Jessica M. Vanslambrouck,[1] Ker sin Tan,[1] Sean Wilson,[1,2] Ella Groenewegen,[1] Jessica A. Neil,[3] Rajeev Rudraraju,[3] Michelle Scurr,[1] Sara E. Howden,[1,2] Kanta Subbarao,[3,4] Melissa H. Little.[1,5] *[1]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [2]The University of Melbourne Department of Paediatrics, Parkville, VIC, Australia; [3]The University of Melbourne Department of Microbiology and Immunology, The University of Melbourne, Peter Doherty Institute for Infection and Immunity, Parkville, VIC, Australia; [4]WHO Collaborating Centre for Reference and Research on Influenza, Peter Doherty Institute for Infection and Immunity, Parkville, VIC, Australia; [5]The University of Melbourne Department of Paediatrics and Department of Anatomy and Neuroscience, The University of Melbourne, Parkville, VIC, Australia.*

Background: The highly specialised proximal tubule (PT) nephron segment is responsible for most kidney functions in mammals and is acutely vulnerable to disease, making it a key objective for toxicity screening and disease research. While induced pluripotent stem cell (iPSC)-derived kidney organoids represent a promising approach, the PT remains immature with limited evidence of functional transporters. Here we report the development of PT-enhanced organoids with nephron functionality, enabling improved modelling of PT-relevant conditions including drug-induced toxicity and infection such as SARS-CoV-2.

Methods: Standard and fluorescent reporter iPSC lines were subjected to prolonged monolayer differentiations (modified from: Howden *et al*. EMBO Rep 2019; Vanslambrouck *et al.* JASN 2019) and precisely-timed morphogens for targets such as WNT, BMP and NOTCH pathways prior to organoid generation (Takasato *et al*,. Nat Protoc 2016). Maturation was analysed via immunofluorescence, live confocal imaging of fluorescent reporters, transcriptional profiling, transporter function assays, and SARS-CoV-2 infectivity.

Results: Prolonged nephron progenitor differentiation with simultaneous prevention of spontaneous nephrogenesis resulted in PT-enhanced kidney organoids with elongated and aligned nephrons. Striking proximo-distal nephron orientation resulted from localised WNT antagonism. Improved upregulation of PT-specific markers compared to standard organoids was strengthened by evidence of transporter functionality, including uptake of albumin, organic cations, and cisplatin (eliciting appropriate KIM1 upregulation). This approach also improved expression of SARS-CoV-2 entry factors, confirmed by susceptibility to infection and viral replication.

Conclusions: We describe enhanced kidney organoids with improved PT maturity arising from alterations to early mesodermal patterning and delayed nephron initiation. The enhanced conditions also provided more stringent control over nephron spatial arrangement. PT-enhanced organoids provide an ideal model to better understand human PT maturation, inherited and acquired PT disease, and drug toxicity implications.

PO0642

Estrogen-Related Receptor Gamma Identified as a Novel Link Between Ciliogenesis and Nephron Development

Hannah M. Weselman, Rebecca A. Wingert. *University of Notre Dame Department of Biological Sciences, Notre Dame, IN.*

Background: Aberrant formation of cilia, hair-like projections that facilitate mechano- and chemo-sensing, has been linked to developmental disorders, kidney dysfunction, and renal cyst formation. Since prostaglandin signaling has been noted as a key regulator of ciliogenesis, we investigated potential upstream factors that could contribute to both kidney and cilia development. One nuclear receptor, *Esrrγ*, was of particular interest, as it interacts with known ciliogenic factors and causes renal cysts in mouse knockout models.

Methods: We confirmed that *Esrrγ* does indeed affect endogenous prostaglandin levels through an ELISA assay of *Esrrγ* deficiency models. We also assessed the effect of *Esrrγ* deficiency using whole mount in situ hybridization to characterize changes in distinct nephron cell populations. We used immunohistochemistry to quantify aberrant cilia formation, cell polarity, and cell turnover in the kidney, ear, and node. We utilized qRT-PCR to measure changes in transcription of potential downstream targets, and used overexpression or chemical treatments to rescue with these targets or their products to further support regulatory relationships.

Results: *Esrrγ* deficient embryos had decreased endogenous PGE2 levels and exhibited nephron composition defects including expanded expression of proximal markers and reduced distal segments. These were likely due to changes in cell fate choice, as no changes in cell death or proliferation were found. The formation of renal cilia was also disrupted, where both cilia length and number of ciliated basal bodies were significantly reduced in ciliated cell populations. Interestingly, *Esrrγ* was required for ciliogenesis in other tissues as well, as cilia length was also decreased in the node and the ear. These phenotypes were consistent with a disruption of prostaglandin signaling,

and we found that expression of the prostaglandin cyclooxygenase enzyme (Cox1) and prostaglandin regulator *Pgc1a* was reduced in *Esrrγ* deficient embryos. Treatment with dmPGE2 or *Cox1* overexpression was sufficient to rescue renal and cilia defects.

Conclusions: These data position *Esrrγ* as a novel link between ciliogenesis and nephrogenesis through regulation of prostaglandin signaling, and highlight *Esrrγ* as a potential new target for future ciliopathic treatments.

PO0643

Single-Cell Analysis of Senescent Epithelia Reveals Targetable Mechanisms Promoting Fibrosis

Eoin D. O Sullivan,[1] Katie J. Mylonas,[1] Cyril Carvalho,[1] Marie Docherty,[1] Carolynn Cairns,[4] Kevin M. Gallagher,[2] Alexander Laird,[2] Neil Henderson,[6] Tamir Chandra,[6] Kristina Kirschner,[3] Bryan Conway,[4] Laura Denby,[4] Gry H. Dihazi,[5] Michael Zeisberg,[5] Jeremy Hughes,[1] Hassan Dihazi,[5] David A. Background: Progressive fibrosis and maladaptive organ repair result in significant morbidity and millions of premature deaths annually. Senescent cells accumulate with ageing and after injury and are implicated in organ fibrosis, but the mechanisms by which senescence influences repair are poorly understood. Here, we address the role of senescence in maladaptive repair and identify new anti-fibrotic targets.

Methods: We analyse human kidney tissue samples post deobstruction and corresponding murine models to test involvment of senescent cells in maladpative repair via pharmacological depletion. We use single cell RNA-Seq to examine these cells in more detail. We validate our findings using in-vitro models of senescence and fibroblast activation. Finally we use murine models of injury to test inhibition of in silico targets as anti-fibrotic.

Results: We demonstrate for the first time in man that senescence and fibrosis persist in kidneys in the aftermath of a resolved obstructive injury. Using a relevant murine model of injury and repair we show senescent epithelia persist after relief of ureteric obstruction and that depletion of senescent epithelia reduces fibrosis and promotes repair. We next characterise senescent epithelia in murine renal repair using single cell RNA-Seq for the first time. We extend our classification to human kidney and liver disease, identifying conserved pro-fibrotic molecules which we validate in vitro and in human disease. Inhibition of one of these molecules is essential for TGFb mediated fibroblast activation in vitro and in vivo. Importantly for translation, inhibition of this molecule in vivo significantly reduces kidney fibrosis after injury.

Conclusions: Our data shed light on the role of senescent epithelia in renal disease and identify a new anti-fibrotic molecule. Analysis of signaling pathways of senescent epithelia connects the important pathways such as the cell stress response to organ fibrosis, permitting rational design of anti-fibrotic therapies.

Treatment of Diabetic NOD/SCID Mice with Human "Neo-Islets," 3D Organoids of Mesenchymal Stromal and Pancreatic Islet Cells, Normalizes Blood Glucose Levels: Significance for Clinical Trials

Christof Westenfelder,[1,2] Anna Gooch.[2] *[1]University of Utah Hospital, Salt Lake City, UT; [2]SymbioCellTech, Salt Lake City, UT.*

Background: We reported that allogeneic "Neo-Islets" (NI) are immune protected and permanently correct autoimmune diabetes in NOD mice by omental engraftment and endocrine cell redifferentiation. This new "endocrine pancreas" delivers islet hormones physiologically into the hepatic portal vein. Further, treatment of insulin-dependent dogs with allogeneic canine NIs (ongoing FDA-approved Pilot Study) consistently improved glycemic control without the need for antirejection drugs. The current preclinical study was undertaken in anticipation of a Phase 1 Clinical Trial with two objectives: to determine (a) whether human NIs (hNIs) can also restore euglycemia, and (b) whether redosing of suboptimally controlled diabetic animals could restore euglycemia in streptozotocin (STZ)-diabetic NOD/SCID mice, as has been previously shown for mouse and dog cell-derived NIs.

Methods: Passaged cells that were to be used to treat diabetic NOD/SCID mice were characterized for gene expression profiles by rtPCR. For *in vivo* testing, NOD/SCID mice were made diabetic with STZ, then randomized based on blood glucose levels into groups of 6 each, treated with insulin pellets, and once blood glucose levels were stabilized near normal animals were treated i.p. either with ~2x10e5 human cell-derived NIs/kg bw (n=6) or vehicle (n=6), then followed for 8 weeks. Once blood glucose levels were determined to be no longer significantly improved compared to controls without administration of exogenous insulin, mice in each group were again treated with either 2x10e5 NIs/kg bw or vehicle, and followed for an additional 6 weeks. Therapeutic efficacy was assessed by survival, 2x weekly blood glucose monitoring, and glucose tolerance tests administered 57 and 41 days post the 1st and 2nd doses, respectively.

Results: Human NI therapy significantly improved glycemic control and survival vs. vehicle. A 2nd dose given to the initial group normalized blood glucose levels long-term.

Conclusions: Despite the limitations of the diabetic NOD/SCID model, these data show that human NIs are curative, and in conjunction with data from the dog study, where allogeneic NI therapy reduces the need for insulin without need for antirejection drugs, have high translational relevance and support the planned conduct of human NI clinical trials.

IL-33 as a Novel Target for the Treatment of Diabetic Kidney Disease

Barbara Musial,[1] Asha Seth,[1] David J. Baker,[2] Stephanie C. Heasman,[4] James Conway,[5] Tim Slidel,[6] Xiaozhen J. Wang,[7] Tina Ryden-Bergsten,[8] Pernille B. Laerkegaard Hansen,[3] Kevin Woollard,[1] Elena Liarte Marin.[1] *[1]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [2]Bioscience Metabolism, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [3]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [4]Imaging and Data Analytics, Clinical Pharmacology & Safety Sciences, R&D, AstraZeneca, Cambridge, United Kingdom; [5]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD; [6]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [7]Translational Science & Experimental Medicine, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD; [8]Projects, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: Diabetic kidney disease (DKD) has classically been thought as a microvascular disorder, although inflammation has emerged as a key pathophysiological mechanism involved in the development of diabetic kidney injury. Consequently, inflammatory mediators have aroused as promising therapeutic targets.

Methods: IL-33 is a broad acting cytokine, expressed in endothelial and epithelial barriers, that mediates local tissue inflammation. It exerts its function by binding to a heterodimer formed by its specific receptor ST2 and co-receptor IL-1RAcP. Due to the evidence of the role of IL-33 in kidney injury, we generated MEDI3506, a potent IL-33 blocking mAb for the treatment of DKD.

Results: Transcriptomic analysis showed that expression of IL-33 RNA is upregulated in both the glomeruli and tubulointerstitium of DKD patients in two independent cohorts. Assessment of expression in both human and experimental DKD demonstrated that IL-33 is among the most regulated inflammatory genes. Preliminary data on IL-33 protein levels in human kidney biopsies indicates that IL-33 is increased in DKD versus controls. Preclinically, the db/db uninephrectomy model of DKD showed IL-33 protein levels in kidney lysates positively correlated with histological glomerular damage from week 7 to 21. More importantly, blockade of ST2 signalling by using a mAb, prevented the progression of albuminuria. In vitro mechanistic studies using primary human glomerular endothelial cells (GECs) and mesangial cells (MCs) showed that both cell types expressed ST2 and upregulated IL-33 in response to TNFα and IFNγ, commonly upregulated in diabetic kidney microenvironment. Moreover, GECs and to a lesser extent MCs, displayed a significant IL-33 induced proinflammatory cytokine release (e.g. IL-8, IL-6...) mediated by MAP kinase activation and NF-kB translocation. All these effects were inhibited by MEDI3506.

Conclusions: Upregulation of IL-33 in diabetic kidney, generates localised chronic kidney inflammation through autocrine signalling in GECs and MCs. This data suggest that targeting IL-33 with MEDI3506 arises as a promising therapeutic intervention for DKD, currently in Ph2b trial.

PO0646

Endogenous Interleukin 33 Contributes to the Progression of Diabetic Nephropathy

Zixuan Zhu. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Inflammation and fibrosis play a crucial role throughout the course of Diabetic Nephropathy (DN). Interleukin 33 (IL-33) is an early alarmin for inflammatory damage and also shows a relationship with fibrosis in multiple organs. However, it was little discussed in the field of chronic kidney disease. Here, we try to explore the role of IL-33 in DN.

Methods: 21 patients with DN diagnosed by renal biopsy were retrospectively included; 6 kidney tissue adjacent to carcinomawere were collected as normal kidney samples; 5 healthy controls were included. IL-33 levels in serum and urine were measured and IL-33 of renal tissue were evaluated. db/db mice were used as an animal model to evaluate the IL-33 expression in the early stage of DN. IL-33KO mice with STZ injection combined with unilateral nephrectomy were used as an animal model to explore the regulatory effect of endogenous IL-33.

Results: In human samples, DN group showed a significantly higher level of IL-33 than that in the normal kidney tissue ($P<0.0001$). And the level was positively related to the degree of kidney fibrosis(Spearman's $\rho=0.072$, $P=0.007$). The expression pattern of IL-33 in DN is different from that in normal condition. Further immunofluorescence staining suggested that IL-33 is expressed mainly by fibroblasts in the kidney of DN. And IL-33 level in DN group was also showed a higher level in urine ($P=0.017$). In animal models, IL-33 increased in the kidney of db/db group compared with db/m ($P=0.011$) during the early stage of DN, which was before the decrease of renal function and appearance of pathological lesions. In the IL-33 knockout mouse of STZ-induced diabetes combined with unilateral nephrectomy, the 32 weeks old IL-33KO group had lower blood glucose levels ($P<0.001$), reduced urinary albumin/creatinine level than ($P=0.021$) wild type group with diabetes. Staining of renal tissue also showed severe tubulointerstitial fibrosis, inflammatory cell infiltration, and glomerular mesangial expansion in wild type group, all of which were significantly attenuated in the IL-33KO group.

Conclusions: IL-33 is involved throughout the course of DN. The increase of IL-33 may play as an early warning factor in the disease and may participate in aggravating diabetic nephropathy by mediating the process of fibrosis. Based on our findings, IL-33 may have the potential to be a target for further mechanism research and treatment of DN.

PO0647

Beneficial Effects of Tumor Necrosis Factor α Blockade in a Mouse Model of Diabetic Nephropathy

Yamaji Takahiro,[1] Kengo Azushima,[2] Susan B. Gurley,[3] Thomas M. Coffman.[1,4] *[1]Duke-NUS Medical School, Singapore, Singapore; [2]Yokohama City University Graduate School of Medicine, Department of Medical Science and Cardiorenal Medicine, Yokohama, Japan; [3]Oregon Health & Science University School of Medicine, Portland, OR; [4]Duke University School of Medicine, Durham, NC.*

Background: Recent studies indicate that immune activation may play a role in pathogenesis of diabetic nephropathy (DN). We have previously described a mouse model exhibiting characteristics of human DN including high-grade albuminuria and glomerulosclerosis. In this model, glomerular immune and inflammatory pathways, including networks associated with tumor necrosis factor (TNF)-α signaling are upregulated. In this study, we examine the functional impact of the TNF-α pathway in DN.

Methods: We used a mouse model combining the *Akita Ins2* mutation, which causes profound type I diabetes, with a renin transgene (*ReninTg*) producing low level activation of the RAS. *Akita-ReninTg* mice on a susceptible 129 strain background exhibit cardinal features of human DN. To examine the role of TNF-α, 16-week old 129 *Akita-ReninTg* mice were injected with 1mg/kg/week etanercept (E) or saline vehicle (V) subcutaneously for 4 weeks while urinary albumin excretion and other parameters were monitored.

Results: At baseline, 16-week old *Akita-ReninTg* mice have substantial albuminuria (1850±207 μg/day), with no significant difference between E and V groups. Levels of albuminuria increased in the V group to 3626±1024 μg/day at 20 weeks. By contrast, etanercept treatment prevented this increase in albuminuria at 20 weeks (1448±236 μg/day; $p<0.01$ vs V). The extent of kidney hypertrophy was also attenuated with E. Blood glucose levels were similar in E and V groups throughout the treatment period. Renal levels of NF-κB, a key mediator activated by TNF-α was significantly reduced after etanercept consistent with effective pharmacological TNF-a blockade. In addition, renal expression of KIM-1 and TGF-β were both significantly suppressed by E, consistent with reduced kidney injury and pro-fibrotic state, respectively.

Conclusions: In a model of DN, TNF-α blockade administered to mice with established macro-albuminuria substantially suppressed the progression of proteinuria. Etanercept also protected against kidney injury and diminished pro-fibrotic signaling. Our findings support a causal role for TNF-a in the pathogenesis of DN and indicate potential utility of TNF-α blockade in the treatment of DN.

PO0648

A Novel Anti-Inflammatory Renoprotective Effect of GLP-1 Receptor Agonists in Type 1 Diabetes: Shifting Macrophage Polarization

Natalie Youssef,[1] Hilda E. Ghadieh,[1] Rachel Njeim,[1] Sami Azar,[2] Fuad N. Ziyadeh,[2] Nassim Fares,[3] Assaad Antoine Eid.[1] *[1]American University of Beirut Faculty of Medicine, Beirut, Lebanon; [2]American University of Beirut Medical Center, Beirut, Lebanon; [3]Universite Saint-Joseph, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) is a serious complication of diabetes. Increased evidence has shown a vital role of the immune system in the pathogenesis of DKD. Macrophages infiltrate the glomeruli and can polarize into an M1 pro-inflammatory phenotype versus an M2 anti-inflammatory one. Moreover, studies from our group and others highlighted the role of NADPH oxidases induced ROS production in the progression of DKD. Several hypoglycemic agents were investigated for their reno-protective effects. Among these agents, Liraglutide, a GLP-1 receptor agonist. However, its role in modulating DKD development still needs to be elucidated, especially in type 1 diabetes mellitus (T1DM). In this study, we aim to investigate the reno-protective effect of Liraglutide in regulating the NADPH oxidases family of enzymes which are well known for their role in ROS production. More importantly we will assess the involvement of Liraglutide with macrophage polarization, a major component of the immune system.

Methods: C57/BL6J adult male mice were allocated into 3 groups: control, STZ induced T1DM, STZ induced T1DM group treated with liraglutide (0.3mg/kg, SC twice daily) for a duration of 13 weeks. Functional, histopathological, biochemical and molecular studies were performed on kidney tissues for all groups.

Results: Liraglutide treatment improves kidney injury as assessed by blood urea nitrogen, serum creatinine levels, and more importantly proteinuria. The reno-protective effect of liraglutide was further validated via histopathological findings; increased M2 macrophage infiltration, reduced collagen deposition and extracellular matrix expansion. Of interest, these results were associated with decreased mRNA expression of M1 inflammatory markers and increased mRNA expression of the M2 anti-inflammatory ones. In addition, liraglutide treatment attenuated ROS overproduction by reducing NADPH oxidase enzymatic activity paralleled by a decrease in DUOX-1 and DUOX-2 isoforms protein expression and mRNA levels.

Conclusions: To the best of our knowledge, this is the first study to show a reno-protective effect of liraglutide in DKD through shifting macrophage polarization towards the M2 anti-inflammatory phenotype possibly via inhibiting NADPH oxidases induced ROS production.

Interferon-γ Signaling and the Progression of Early Diabetic Kidney Disease

Viji Nair,[1] Jennifer L. Harder,[1] Helen C. Looker,[2] Frank C. Brosius,[3] Markus Bitzer,[1] Robert G. Nelson,[2] Matthias Kretzler,[1] Wenjun Ju.[1] *[1]University of Michigan, Ann Arbor, MI; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ; [3]University of Arizona, Tucson, AZ.*

Background: Inflammation plays an important role in pathogenesis of diabetic kidney disease (DKD). However, the pathways by which circulating pro-inflammatory factors activate intrarenal signaling and mediate DKD progression remain poorly defined. Using multiscalar data integration we aimed to identify links between circulating factors in early DKD and activation of kidney signaling pathways and DKD progression

Methods: Transcriptomic data from kidney biopsies of Pima Indians with type 2 diabetes and early DKD (n=74) were used to identify differentially expressed genes (DEGs) and their upstream regulators (URs) associated with end-stage kidney disease (ESKD). Plasma proteomics (n=162) was used to identify ESKD-associated circulating proteins. URs were selected if their regulation in plasma was consistent with the prediction based on transcriptomic analysis. Activation scores were computed based on the downstream signaling cascade at the transcriptomic level and then associated with structural lesions and health outcomes in DKD patients. The findings were validated in podocyte-specific JAK2 transgenic $Ins2^{Akita/+}$ mice (Pod-Jak2TG-Akita) which develop progressive DKD and in human kidney organoid cultures.

Results: Five URs of ESKD-associated DEGs in both glomeruli (Glom) and tubulointerstitium (TI) were identified, with interferon gamma (IFNG) exhibiting the most significant association. IFNG receptor expression was detected in multiple kidney cell types by single cell RNAseq analysis. Higher IFNG pathway kidney activation scores in Glom and TI were associated with increased risk of ESKD and faster GFR decline over 10.5 years. Inhibition of the IFNG pathway reduced kidney IFNG score and ameliorated albuminuria and mesangial expansion in Pod-Jak2TG-Akita mice. IFNG significantly increased IFNG activation score in human organoids, which was reduced by baricitinib, an inhibitor of JAK1 and JAK2, which are major IFNG signaling mediators.

Conclusions: Increased circulating IFNG levels and IFNG pathway activation in kidney tissue in early DKD may lead to DKD progression. Therefore, the IFNG pathway may be a target for intervention in early DKD.

Nrf2 Activators Induce Inflammasome Attenuation: Possible Role in Diabetic Nephropathy

Ignacio J. Quevedo Romero, Andrea Carrasco Cremades, Laura H. Navarro, Pablo Pelegrin, Santiago Cuevas. Molecular Inflammation Group (IMIB-Arrixaca) *Instituto Murciano de Investigacion Biosanitaria Virgen de la Arrixaca, Murcia, Spain.*

Background: Kidney diseases remain a worldwide public health problem characterized by sustained inflammation. Inflammasome has recently emerged as crucial regulators of renal inflammation. In particular, the NLRP3 inflammasome, is involved in the activation of caspase-1 and the maturation of IL-1β and IL-18, which have been strongly associated with diabetic nephropathy. DJ-1 is a redox-sensitive chaperone with reported antioxidant and anti-inflammatory properties in the kidney, in part due to the regulation of transcription factor Nrf2, which regulates the expression of several antioxidant genes. The 20 amino acid (aa) peptide ND-13, is a new experimental treatment that consists of 13 highly conserved aa from the DJ-1 sequence.

Methods: In this study, we determined NLRP3 inflammasome activation in peripheral blood mononuclear cells (PBMCs) of diabetic nephropathy patients and the capacity of Nrf2 inducers to attenuate inflammasome activation. Mouse bone marrow macrophages were treated with Bardoxolone (1μM), an Nrf2 inducer, and ND-13 (1μM) for 24 hours.

Results: The IL-1β concentration in the medium increased by the stimulation of the NLRP3 inflammasome by LPS/ATP, and decreased in macrophages pre-treated with Bardoxolone (65.07±26%,n=4, P<0.05) but not in macrophages pre-treated with ND-13. Concentration-response curve demonstrates the capacity of Bardoxolone to inhibit NLRP3 inflammasome activation by LPS/ATP. Additionally, in presence of H2O2 (100nM), ND-13 (1μM) significantly decreased IL-1β release after NLRP3 activation (88.6±1.2%, n=4, P<0.05), suggesting the capacity of the ND-13 peptide to reduce NLRP3 inflammasome activity under pathological conditions. PBMCs isolated from the blood of controls patients, patients with diabetes, and patients with diabetes and renal disease were cultured in vitro and stimulated with LPS/ATP. Compared to controls and diabetic individuals, patients with diabetic nephropathy presented a trend to increase IL-1β release.

Conclusions: All these data point out that inflammasome pre-activation could have a role in the pathogenesis of diabetic nephropathy, that Nrf2 pathway stimulation is a promising approach to decrease immune cells inflammasome pre-activation, and ND-13 could be a new approach to protect the renal damage associated to inflammasome over-activation in renal diseases.

Activation of STING Causes Proteinuria in Mice and Contributes to Diabetic Kidney Disease

Antonio M. Fontanella, Matthew Tolerico, Shamroop Kumar Mallela, Judith T. Molina David, Jin Ju Kim, Sandra M. Merscher, George W. Burke, Alessia Fornoni, Alla Mitrofanova. Katz Family Division of Nephrology and Hypertension *University of Miami School of Medicine, Miami, FL.*

Background: Diabetic kidney diseases (DKD) is one of the major health problems worldwide with no current cure. Podocytes express elements of the innate immune system which may contribute to chronic inflammation and glomerular damage. Stimulator of interferon genes (STING) was identified as a crucial regulator of the DNA sensing pathway and the cGAS-STING signaling pathway has been shown to regulate inflammation and energy homeostasis under obesity conditions, kidney fibrosis and acute kidney injury. Whether STING activation contributes to development and progression of DKD remains unknown. We tested the hypothesis that activation of STING causes podocyte damage and proteinuria in DKD.

Methods: c-diAMP treatment to inhibit STING (10μM) in immortalized human podocytes was performed for 24h. 8-week-old C57BL6 mice were IP-injected with a single dose of c-diAMP (25mg/kg) and sacrificed 72h after injection. 16-week-old db/db mice were used ito evaluate activation of STING in experimental DKD. 10-week-old db/db mice were IP-injected with C-176 (750nM), STING-specific antagonist, for 4 weeks daily. STZ injected STING knockout (STING-/-) and C57BL6 mice were also utilized. Blood and kidneys were harvested and processed for in-depth phenotypical analysis, including urinary albumin-to-creatinine ratio, histological analysis, transmission electron microscopy, glomeruli isolation and serum analysis.

Results: Podocytes showed expression all of the cGAS-STING components at mRNA and protein levels under physiological conditions and treatment with c-diAMP lead to activation of the cGAS-STING pathway. Treatment of C57BL6 mice with c-diAMP resulted in an increased expression of STING in kidney cortex and this was associated with increased urine ACR. STING activation is also implicated in glomerular injury in db/db mice at the baseline, which could be ameliorated with pharmacological (C-176) inhibition. In STZ model of DKD, STING-/- mice did not develop albuminuria and had no changes in their BUN, serum creatinine levels or histological abnormalities compared to STZ controls.

Conclusions: Our findings demonstrate an important role of the cGAS-STING signaling pathway in mediating the glomerular injury in DKD and provide an evidence for STING as a potential treatment target in DKD.

PO0652

Blocking the ACE N-Domain Prevents Salt Sensitivity in Diabetes

Luciana C. Veiras, Ellen A. Bernstein, Kenneth E. Bernstein, Jorge F. Giani. *Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Angiotensin converting enzyme (ACE) can regulate inflammation independently of angiotensin II production. Specifically, blocking the ACE N-domain results in the accumulation of the anti-inflammatory peptide AcSDKP. We showed that interleukin-6 (IL-6) induces salt sensitivity through an upregulation of the epithelial sodium channel (ENaC) in diabetic mice. Here, we hypothesize that blocking the ACE N-domain reduces renal IL-6 levels and prevents salt sensitivity in diabetes.

Methods: 7-mo-old diabetic db/db mice lacking a functional ACE N-domain (db-nko) and db/db controls (db) were exposed to a high salt diet (HS, NaCl 4%w/w) for 4 weeks (n=6).

Results: Despite similar hyperglycemia and body weight, after HS, db-nko displayed lower mean arterial pressure (MAP) (107±5 vs. 123±4 mmHg, P<0.01), less expression of αENaC subunit (0.8±0.3 vs. 1.4±0.3 A.U., P<0.05), and lower renal IL-6 levels (112±16 vs. 270±17 pg/mg kidney, P<0.01) compared to db mice. Flow cytometry analysis of renal macrophages showed that db-nko mice have lower M1 ($CD45^+F4/80^+CD80^+$) to M2 ($CD45^+F4/80^+CD206^+$) ratio compared to db (2.4±0.6 vs. 4.8±0.7, P<0.05). Further, renal macrophages ($3x10^4$) were isolated by flow cytometry cell sorting, cultured for 16h, and IL-6 assessed in the culture media by ELISA. Macrophages from db-nko release significantly less IL-6 compared to db macrophages (2±1 vs. 7±2 pg/ml, P<0.01). To evaluate the role of AcSDKP, an additional group of db-nko were treated for 8 weeks with S17092, an inhibitor of prolyl-oligopeptidase that forms AcSDKP. After HS, MAP, renal αENaC expression, IL-6, and the macrophage M1/M2 ratio of db-nko+S17092 were similar to db mice. Finally, to evaluate whether the absence of the ACE N-domain affects immune or non-immune renal cells, db mice were transplanted with a bone marrow (BM) of db-nko while db-nko received a db BM. Strikingly, db-nko with db BM developed salt sensitivity but db with db-nko BM remained salt resistant (MAP after HS: 121±8 vs. 107±4 mmHg, P<0.05). The absence of salt sensitivity in db with db-nko BM was associated with less IL-6 levels and lower M1/M2 macrophage ratio in the kidney.

Conclusions: Thus, blocking the ACE N-domain and the consequent AcSDKP accumulation in immune cells, polarize macrophages towards an M2 phenotype resulting in less renal inflammation and no salt sensitivity in diabetes.

PO0653

Renal Type 1 Pericytes in the Development of Diabetic Kidney Disease

Tâmisa S. Honda,[1,2] Orestes Foresto-Neto,[1,2] Ana R. da Silva,[2] Fernanda P. Santana,[2] Hedden Ranfley,[2] Ingrid K. Watanabe,[1,2] Magaiver A. Silva,[1,2] Marcos A. Cenedeze,[2] Alvaro Pacheco-Silva,[2] Alexander Birbrair,[3] Niels O. Camara.[1,2] Transplantation Immunobiology Lab *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*

Background: Pericytes are described as regulators and keepers of the vascular system. They can recognize and respond to inflammatory stimulus, through secretory and phenotype alterations. So far, the involvement of pericytes during diabetic kidney disease (DKD) has not been demonstrated yet, as well as how they can change its inflammatory and metabolic profile in this condition. In addition, not much is known about how these cells trigger DKD-associated injury and inflammation.

Methods: DKD was induced in NG2-Dsred mice by the combination of unilateral nephrectomy (UNx) and multiple low doses of streptozotocin (50 mg/Kg). UNx controls received only vehicle. All the mice were followed for 12 weeks. Urine glucose, protein/creatinine and albuminuria were evaluated as markers of renal function. NPHS1, KIM-1, IL-6, PKM2, HK2, CPT1a and LDH (qPCR), pericyte frequency/phenotype/secretion profiles (FACS) were assessed in kidney samples.

Results: DKD mice had an increased in protein/creatine ratio, as well as in glucosuria when compared to non-DKD mice (p<0.01). The impaired renal function was accompanied by reduction in NPHS1 gene expression (p<0.05). Moreover, we observed increase in PKM2, HK2 and IL-6 expression (p<0.05). FACS analysis revealed increase in relative and absolute numbers of CD146+NG2+ cells (p<0.05), as well as an increase of type 1 pericytes (NG2+Nestin-), when compared to non-DKD mice (p<0.05). Furthermore, the analysis showed that pericytes from DKD context had increase LAP-1 and IL-6 MFI, and less Nestin MFI (p<0.05).

Conclusions: Type 1 pericytes seems to contribute to DKD progression, through IL-6 secretion and TGF-b conversion from LAP-1. However, it is still necessary to evaluate the metabolic profile of pericyte during the DKD progression and how this cells communicate with other renal cells. FAPESP (2019/ 19/21359-3 and 2017/05264-7), CAPES and CNPq.

PO0654

Follistatin, an Activin A Antagonist in an Accelerated Mouse Model of Diabetic Kidney Disease

Xiaohui Bian,[1,2] Sabena Conley,[1] Anastasia L. Smith,[1] Cody Gowan,[1] Zachary K. Snow,[1] LaTonya J. Hickson.[1] *[1]Mayo Clinic's Campus in Florida, Jacksonville, FL; [2]Shengjing Hospital of China Medical University, Shenyang, China*.

Background: We previously demonstrated that circulating activin A, an inflammatory mediator implicated in cellular senescence-induced adipose tissue dysfunction and profibrotic kidney injury, is increased in human diabetic kidney disease (DKD) and directly correlates with kidney dysfunction. We hypothesized that follistatin, an activin A antagonist, could negate the injurious effects of activin A in DKD.

Methods: An accelerated type 2 diabetes (db/db; 10-week-old) mouse model was generated by implantation of osmotic minipumps loaded with angiotensin (Ang)-II (1000 ng/kg/min, n=14). Mice were randomized to intraperitoneal follistatin (5μg/g) or vehicle at days 15 and 18 post-pump with euthanasia at day 28. Kidney injury markers included: proteinuria, kidney injury marker (KIM)-1, tumor necrosis factor soluble receptor 1 (TNFsR1), collagen I and histological changes were measured. Kidney gene expression of activin A and macrophage chemoattractant protein-1 (MCP-1) were measured by qPCR.

Results: Implantation of AngII (dbAngII) pumps induced proteinuria, mesangial matrix expansion, glomerular sclerosis, and increased fibrosis in db/db mice compared to saline-pump controls (dbSaline; Figure 1A-D). Collagen I, TNFsR1, MCP-1, KIM-1, and activin A gene expression was increased in dbAngII mice (Figure 1E). Follistatin therapy reduced activin A gene expression and other kidney markers in addition to morphology.

Conclusions: Follistatin attenuated diabetic kidney injury, reduced activin A expression and decreased macrophage chemoattractants. Activin A may be a novel therapeutic target for halting DKD progression.

The Functional Role of Neat1 in Diabetic Kidney Disease

Rui Xue, Wai Han Yiu, Joseph C K Leung, Loretta Y.Y. Chan, Sydney C. Tang. *University of Hong Kong, Hong Kong, Hong Kong*.

Background: Long non-coding RNA Nuclear Paraspeckle Assembly Transcript 1 (Neat1) serves as a key structural component of paraspeckle assembly, which has been implicated in a variety of biological processes. Increased Neat1 expression is associated with inflammatory responses and the pathogenesis of acute kidney injury. Yet, it remains unknown whether Neat1 also regulates inflammatory pathways in chronic kidney disease (CKD), especially in diabetic kidney disease (DKD).

Methods: Streptozotocin (STZ)-induced DKD was established in C57B6 mice with a low-dose injection protocol for 5 consecutive days. Neat1 gene was specifically knocked down in the kidney by shRNA gene silencing via ultrasound-mediated microbubble gene transfer. After 10 weeks, all mice were sacrificed for analysis of kidney function, morphology, and expression of inflammatory and fibrotic markers.

Results: Neat1 expression was induced in STZ-induced diabetic kidneys. Overexpression of IL-6 and CCL-2 in diabetic mice was attenuated by Neat1 knockdown in which kidney function was preserved with less kidney tubular injury compared to diabetic control mice. Expression of fibrotic markers, such as fibronectin and collagen-1 was decreased in diabetic mice with Neat1 knockdown.

Conclusions: Neat1 plays a pathogenetic role in DKD and its knock-down could alleviate diabetic kidney injury. *Funding: Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7018-16G), and Hong Kong Society of Nephrology/HK Kidney Foundation Research Grant 2019.*

Cell Surface GRP78 Regulates TGF-β1-Mediated Profibrotic Responses via TSP-1 in Diabetic Kidney Disease

Jackie Trink, Usman Ahmed, Kian S. O'Neil, Bo Gao, Joan C. Krepinsky. *McMaster University, Hamilton, ON, Canada*.

Background: Diabetic kidney disease (DKD) is the leading cause of kidney failure in North America, characterized by glomerular accumulation of extracellular matrix (ECM) proteins. High glucose (HG) induction of glomerular mesangial cell (MC) profibrotic responses plays a central role in its pathogenesis. We recently showed that the endoplasmic reticulum resident GRP78 translocates to the cell surface in response to HG, where it mediates Akt activation and downstream profibrotic responses in MC. Transforming growth factor β1 (TGFβ1) is recognized as a central mediator of HG-induced profibrotic responses, but whether it is regulated by cell surface GRP78 (csGRP78) is unknown. TGFβ1 is stored in the ECM in a latent form, requiring release for biological activity. The matrix glycoprotein thrombospondin-1 (TSP-1) is an important factor in TGFβ1 activation, known to be increased in DKD and by HG in MC. Here we determined whether csGRP78 regulates the expression of TSP-1 and thereby TGFβ1 activation in HG.

Methods: Primary rat and mouse MC were treated with 30mM HG. TSP-1 upregulation and deposition into the ECM and TGFβ1 activation were assessed using standard molecular biology techniques.

Results: TSP-1 transcript and promoter activity were increased by HG, as were cellular and ECM TSP-1, and these required PI3K/Akt activity. To determine whether csGRP78 was required, its activity was inhibited using vaspin or the C-terminal targeting antibody C38. Alternatively, GRP78 translocation to the cell surface was prevented with siRNA downregulation of its transport chaperone MTJ-1. All of these prevented HG-induced TSP-1 upregulation and deposition into the ECM. The HG-induced increase in active TGFβ1 in the medium was also inhibited, and this was associated with reduced intracellular Smad3 activation and signaling.

Conclusions: These data support an important role for csGRP78 in regulating HG-induced TSP-1 transcriptional induction via PI3K/Akt signaling. Functionally, this enables TGFβ1 activation in response to HG, with consequent increase in ECM proteins. Means of inhibiting csGRP78 signaling represent a novel target for preventing the DKD-associated fibrosis. TGFβ1 is a central mediator of DKD, but its inhibition is not feasible due to adverse effects. Thus, indirect methods of attenuation are of current interest.

Histone Acetyltransferase p300 Inhibition Attenuates Kidney Fibrosis Under Diabetic Conditions

Boyoung Nam,[1] Seung Hyeok Han,[2] Tae-Hyun Yoo,[2] Shin-Wook Kang,[2] Jung Tak Park.[2] *[1]Yonsei University College of Science, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea*.

Background: Diabetic nephropathy, the major cause of chronic kidney disease, is associated with progressive renal fibrosis. Transforming growth factor (TGF)-β1 plays important roles in extracellular matrix accumulation in diabetic nephropathy. Recently, acetyltransferase p300 has been shown to mediate intracellular TGF-β1 activity through facilitating Smad function. Therefore, in this study, the effect of p300 inhibition on kidney fibrosis under diabetic conditions was investigated to assess the therapeutic potential of p300 modulation.

Methods: Primary tubular epithelial cells (TECs) from C57BL/6 mice were treated with TGF-β1 with or without histone acetyltransferase p300 siRNA transfection of A485, a selective inhibitor for p300. For in vivo experiments, kidney samples were obtained from streptozotocin induced diabetic mice were administered with A485 (1mg/kg) oral gavage for 6 weeks.

Results: In vitro, TGF-β1 (5ng/ml) treatment significantly upregulated p300, PAI-1, connective tissue growth factor (CTGF), fibronectin, and type I collagen mRNA and protein expressions in TECs. These increases were attenuated significantly when TECs were transfected with p300 siRNA. Similar findings were found when the cells were treated with p300 specific inhibitor A485 (100nM). In vivo, the mRNA and protein expression of p300, PAI-1, connective tissue growth factor (CTGF), fibronectin, and type I collagen were significantly increased in kidney samples form DM mice compared to non-diabetic control mice. Oral A485 administration abrogated these increases significantly. In addition, the increased blood urea nitrogen and albuminuria levels were significantly attenuated with oral A485 treatment in the diabetic mice. Immunohistochemistry and Sirius Red staining also revealed that fibronectin expression was significantly higher and tubulointersititial fibrosis was significantly worse in diabetic mice kidneys compared with control mice. These changes were ameliorated by A485 treatment.

Conclusions: These findings suggest that inhibition of histone acetyltransferase p300 could improve diabetic-induced tubular fibrosis and may be a potential therapeutic strategy for diabetic nephropathy.

PO0658

Recombinant Slit2 Attenuates Renal Fibrosis in a Mouse Model of Diabetic Nephropathy

Xiaolin He,[1] Guang-Ying Liu,[2] Noah Vukosa,[1] Lisa Robinson,[2] Darren A. Yuen.[1] *[1]St. Michael's Hospital, Keenan Research Centre for Biomedical Science, Toronto, ON, Canada; [2]Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: We recently described Akita$^{+/-}$ Ren$^{+/-}$ mice as a model that replicates many features of human diabetic nephropathy (DN), including hyperglycemia, hypertension, albuminuria, reduced glomerular filtration rate, glomerulosclerosis and interstitial fibrosis. Previously, we showed that recombinant N terminal Slit2 (Slit2) inhibited renal fibrosis in mouse models of postischemic renal fibrosis and obstructive uropathy. To date, however, the anti-fibrotic effects of Slit2 have not been tested in a model of DN. Here we examine the effects of Slit2 therapy in the Akita+/– Ren+/– mouse.

Methods: At 6 weeks of age, Akita+/– Ren+/– and Akita-/– Ren-/– mice were randomized to receive thrice weekly intraperitoneal injections of Slit2 (2 ug) or saline, and followed for a further 20 weeks.

Results: When compared with saline-treated Akita+/– Ren+/–mice, Slit2-treated Akita+/– Ren+/– mice demonstrated improved survival (66.67% vs. 50%) and decreased systolic blood pressure (142±6.1mmHg vs.167±8.5 mmHg). Structurally, Slit2-treated Akita+/– Ren+/– mice displayed decreased glomerulosclerosis (glomerular picrosirius red score: 0.22±0.02 vs. 0.28±0.02) and interstitial fibrosis (picrosirius red staining: 0.08±0.01 vs. 0.10±0.01, a-smooth muscle actin (aSMA) staining: 0.02±0.00 vs. 0.05±0.01, and vimentin staining: 0.11±0.01 vs. 0.15±0.01). Slit2 treatment attenuated the nuclear translocation of the pro-fibrotic proteins YAP (26.44±7.87% vs 66.20±7.63%) and TAZ (28.55±2.99% vs. 71.42±7.90%, a marker of YAP/TAZ activation) in aSMA positive fibroblasts in mouse kidneys. In vitro, Slit2 decreased TGF-b-induced YAP and TAZ activation in cultured NRK49F fibroblasts, as evidenced by a reduction in YAP (55.55±4.67% vs 92.54±1.36%) and TAZ (30.85±7.877.319 % vs 80.2±3.44%) nuclear localization. All p values < 0.05.

Conclusions: Taken together, our results show that Slit2 attenuates diabetic kidney fibrosis, possibly through inhibition of fibroblast YAP and TAZ activity.

PO0659

Impact of Mineralocorticoid Receptor Antagonism in a New Model of Diabetic Kidney Disease

Roberto Palacios Ramirez,[1] Ixchel Q. Lima Posada,[1] Benjamin Bonnard,[1] Marie Genty,[1] Judith Hartleib-Geschwindner,[2] Fabienne Foufelle,[1] Krister Bamberg,[2] Frederic Jaisser.[1] *[1]INSERM, Paris, France; [2]AstraZeneca, Gothenburg, Sweden, Gothenburg, Sweden.*

Background: Diabetic kidney disease (DKD) is the most prevalent form of chronic kidney disease and is associated with cardiovascular diseases. Several studies reported beneficial effects of mineralocorticoid receptor (MR) antagonists in DKD, indicating the importance of aldosterone/MR axis in this pathology. To study the metabolic and renal alterations in a new model of DKD and explore the effect of the MR antagonist canrenoate.

Methods: Sham or 5/6 nephrectomy was performed in 6 weeks old C57Bl6J mice. After nephrectomy (Nx) mice were randomly assigned to chow diet (Sham), Nx, 60% fat diet (Nx-HFD) and 60% fat diet + 30 mg/kg/day canrenoate (Nx-HFD-CAN). Glycated hemoglobin (HbA1c) and glucose tolerance (ipGTT) were analyzed after 6 weeks. We evaluated plasma levels of leptin and albuminuria and IL-10 mRNA levels. RNA Nanostring analysis was performed in kidney samples. *In vitro* studies were performed in renal fibroblasts.

Results: HbAc1 was higher in the Nx-HFD group vs Sham or Nx, an effect prevented by canrenoate (see table). The glucose tolerance was impaired in NX-HFD vs Sham or Nx, an effect ameliorated by canrenoate. Kidney fibrosis was increased in Nx HFD group vs Sham or Nx and it was lower in the canrenoate treated group. Nanostring analysis highlighted the impact of canrenoate on inflammation, fibrosis and proliferation pathways. We found high plasma leptin and kidney IL-10 mRNA levels in the Nx-HFD mice which were lower after canrenoate treatment. The profibrotic effect of leptin observed in renal fibroblasts was mediated by IL-10 (Col1 mRNA levels: Ctl: 0.99±0.03, leptin + IgG: 1.19±0.07*#, leptin + anti-IL10 antibody: 0.90±0.05#, n= 6, p<0.05 * vs Ctrl; # vs Leptin+IgG).

Conclusions: MR antagonism improves metabolic and kidney derangements associated with DKD. The upregulation of leptin/IL-10 signalling observed in this DKD model may contribute to the renal fibrosis.

Role of GRP56 in Glomerular Endothelial Cell Injury in Diabetic Kidney Disease

Jia Fu, John C. He, Kyung Lee. He Lab *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: GEC injury is a key pathogenic event in early Diabetic kidney disease (DKD). However, the mechanisms of GEC injury in DKD remain unclear and the treatments by targeting specifically GEC injury are lacking.

Methods: By taking advantage of transgenic mice expressing enhanced yellow fluorescent protein (EYFP) under the endothelium-specific Flk1 promoter, we were able to sort GECs from both control and diabetic mice for RNA sequencing. We identified G-protein coupled receptor-56 (GPR56) as a highly upregulated gene in diabetic GECs. Then, we confirmed the role of GRP56 in GEC injury in DKD by both in vitro and in vivo studies.

Results: We searched the recent single-cell RNA-seq data and confirmed that GPR56 expresses predominantly in GECs in the glomeruli. We found that both mRNA and protein expression of GPR56 increased in human DKD and correlated negatively with eGFR, suggesting an important role of GPR56 in human DKD. In cultured GECs, GRP56 expression was upregulated by high glucose and advanced glycation endproducts (AGE). Collagen III, a major ligand of GPR56, was able to suppress eNOS phosphorylation and expression through activation of GPR56. We demonstrated that GPR56 reduced eNOS phosphorylation likely through G12/13-mediated RhoA pathway and inhibited eNOS expression via Gi-mediated inhibition of cAMP/PKA/KLF4 pathway in cultured GECs. *In vivo*, knockout of GPR56 attenuated albuminuria and glomerular injury and restored expression of eNOS and KLF4 in GECs in mice with DKD.

Conclusions: Taken together, these findings suggest a critical role of GPR56 and its underlined mechanism in regulation of GEC injury in early DKD.

Transcriptional Profiling of Renal Endothelial Compartments During Progression of Murine Diabetic Nephropathy

Alex X. Zhou,[1] Marie Jeansson,[2,3] Liqun He,[2,3] Pernilla Tonelius,[1] Lars Muhl,[2] Martin Uhrbom,[1,2] Jianping Liu,[2] Anna Granqvist,[1] Lilach O. Lerman,[4] Christer Betsholtz,[2,3] Pernille B. Laerkegaard Hansen.[1] Early CVRM Bioscience Renal *[1]AstraZeneca Gothenburg, Gothenburg, Sweden; [2]Karolinska Institutet, Stockholm, Sweden; [3]Uppsala Universitet, Uppsala, Sweden; [4]Mayo Clinic Minnesota, Rochester, MN.*

Background: Kidney endothelial cell (EC) injury and capillary rarefaction are key pathogenic events in diabetic nephropathy (DN). The molecular mechanisms and spatial and temporal patterns of EC responses in DN remain elusive. We hypothesized that single-cell RNA sequencing (scRNASeq) would reveal transcriptional changes in specific kidney EC populations during murine DN progression.

Methods: Kidney EC (n=5,464) collected from 6-, 11-, and 20-week-old BTBR *ob/ob* mice and lean littermates were analyzed by scRNASeq using SmartSeq2. By a combination of established markers, immunofluorescence, and *in situ* hybridization, we ascribed anatomical identity to EC clusters assigned by Pagoda2, assessed their individual transcriptional changes during disease progression, and performed Ingenuity Pathway Analysis.

Results: We identified EC clusters corresponding to afferent and efferent arterioles, glomerular and peritubular capillaries (PTC), ascending and descending vasa recta, veins and lymphatics. BTBR *ob/ob* mice developed progressive PTC rarefaction. Analysis of differentially expressed genes (DEGs) and pathway activity allocated most DN-associated changes to PTC and glomerular EC. Intriguingly, several consistent DEGs showed differential up- and downregulation depending on cell type and disease stage (Fig. 1). E.g., whereas glomerular EC showed DN stage-dependent activation of IGF1 signaling and inflammation, IGF1 signaling and cell cycle progression were inhibited in PTC-EC.

Conclusions: Using high-resolution scRNASeq, our study provides insight into the complexity and diversity of responses in different EC compartments during progression of DN, which may help pinpoint new therapeutic targets.

Transcriptomic Alterations of Angiogenesis Activity in Human Mesenchymal Stromal/Stem Cells in Diabetic Kidney Disease

Sabena Conley,[1] Xiaohui Bian,[1,2] Alfonso Eirin,[3] Eric A. Zimmerman Zuckerman,[3] Mrunal K. Dehankar,[3] Anastasia L. Smith,[1] Cody Gowan,[1] Zachary K. Snow,[1] Sandra Herrmann,[3] Tambi Jarmi,[1] Lilach O. Lerman,[3] LaTonya J. Hickson.[1] *[1]Mayo Clinic's Campus in Florida, Jacksonville, FL; [2]Shengjing Hospital of China Medical University, Shenyang, China; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Therapeutic interventions that optimize angiogenic activities may reduce rates of end-stage kidney failure and extremity amputations in individuals with diabetic kidney disease (DKD). Autologous mesenchymal stromal cells (MSCs) infusion is a promising novel treatment, but DKD-related factors, including hyperglycemia and uremia, might alter MSC angiogenic repair capacity.

Methods: To explore MSC angiogenic dysregulation in DKD, we characterized the transcriptome of adipose tissue-derived MSC obtained from DKD subjects (DKD-MSC) compared to age-matched controls without diabetes or kidney impairment. Next-generation RNA sequencing (RNA-seq) was performed to identify in MSCs differentially expressed (DE; adjusted $p<0.05$, $|\log_2$ fold change$| >1$) mRNA and miRNA involved in angiogenesis (GeneCards). DE miRNAs were further inspected to identify targets involving interactions with angiogenesis genes (miRWalk and Ingenuity pathway analysis).

Results: Mean age in DKD subjects was 65±8 years, 31% were females, and mean eGFR was 38.9±15.4 mL/min/1.73m^2 (n=29), while control subjects (n=9) had higher eGFR (80.5±13.3 mL/min/1.73m^2; $p<0.0001$). RNA-seq analyses revealed 133 DE mRNAs (77 up- and 56 down-regulated) in DKD-MSC compared to Control-MSC. Figure 1A shows the top 30 DE mRNAs. Of 208 DE miRNAs, 14 (Figure 1B) regulated 18 unique DE mRNA targets associated with angiogenesis. Among these miRNAs resulted in pro- and anti-angiogenic regulators including *miR-17-5p, let-7d-5p, miR-125a-5p* and *miR-30c-5p*.

Conclusions: MSC from individuals with DKD may have limited angiogenic potential and reparative capacity, warranting caution in autologous MSC transplantation in DKD.

Contribution of Endothelial ADAM17 in a Pre-Diabetic Mouse Model

Vanesa Palau, Javier J. Jarrín, Sofia V. Calle, Eva Márquez, Eva Rodriguez, Marta Crespo, Maria Jose Soler, Julio Pascual, Clara Barrios, Marta Riera. *Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain.*

Background: ADAM17 activates inflammatory and fibrotic processes through the shedding of various molecules such as TNF-α or TGF-α. In physiological situations, ADAM17 is expressed mainly in the distal tubular cell while, in renal damage, its expression increases throughout the kidney including the endothelium. Galectin 3 (Gal3) is a lectin that is postulated as a biomarker of kidney damage. Its overexpression in diabetic nephropathy could be a compensatory mechanism for damage induced by reactive oxygen species (ROS). To characterize, for the first time, an experimental mice model fed with high-fat diet (HFD) with deletion of ADAM17 in endothelial cells and to describe the expression of kidney Gal3.

Methods: After 25 weeks of HFD, glycaemia, glucose tolerance, body weight, albuminuria, glomerular microscopy (PAS staining) and Gal3 (immunohistochemistry) were analyzed in 15 wildtype (WT) mice and 15 endothelial ADAM17-KO mice.

Results: HFD mice had higher glucose levels, glucose intolerance, and higher body weight compared to standard diet (SD) mice. Moreover, HFD increased albumin/creatinine ratio in WT mice compared to ADAM17-KO mice. At the glomerular level, WT mice with HFD had bigger glomerular size and mesangial matrix expansion. In contrast, the deletion of ADAM17 prevented the increase in glomerular size and decreased the mesangial area and index. Gal3 increased its expression in ADAM17-KO mice on both SD and HFD mice (see table).

Conclusions: The deletion of ADAM17 in endothelium prevents the appearance of glomerular hypertrophy, expansion of the mesangial matrix, albuminuria and increases the expression of Galectin-3 in the renal cortex. The increase in the expression of Galectin-3 could be a compensatory mechanism for the lack of activation of the EGFR/TNFR pathway in the endothelium ADAM17-KO model.

Apolipoprotein C3-Rich Low-Density Lipoprotein Is Elevated in Diabetic Kidney Disease Patients and Enhances Endothelial Cell Injury

Jie S. Wang,[1,2] Ping H. Tsai,[1] Kuo F. Tseng,[3] Fang Y. Chen,[1] Ming-Yi Shen.[1,4] MYS Fat Research Lab *[1]Graduate Institute of Biomedical Sciences, China Medical University, Taichung, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan; [3]Department of Biological Science and Technology, China Medical University, Taichung, Taiwan; [4]Department of Medical Research, China Medical University Hospital, Taichung, Taiwan.*

Background: Diabetic dyslipidemia plays a pathogenetic role in the development and perpetuation of diabetic kidney disease (DKD). Apolipoprotein CIII (ApoC3), a component of some triglyceride-rich very-low-density and low-density lipoprotein, expression by glucose may contribute to diabetic dyslipidemia. Early endothelial damage is also associated with progression of DKD. Thus, we want to study the effect of ApoC3-rich low-density lipoprotein (AC3RL) on DKD and its underlying molecular mechanisms.

Methods: Plasma samples were obtained from clinically stable patients with DKD recruited at our outpatient clinic. AC3RL was isolated from plasma low-density lipoprotein with the affinity-purified method.

Results: Level of plasma AC3RL were significantly higher in DKD patients than in control subjects (Figure; $p<0.05$). AC3RL induced endothelial cells (ECs) apoptosis and reduction of the fenestrated endothelium. The level of phosphorylation of IKKa, p53 and Cleaved Caspase-3 (CC3) were markedly increased in AC3RL-induced ECs ($p < 0.05$ vs. control; $n = 4$). The contribution of P-IKKa, p53, and CC3 in AC3RL-mediated apoptosis were blocked in ECs transfected with si-IKKa.

Conclusions: AC3RL elevation may be a risk factor for DKD, and inhibiting IKKa may be novel protect endothelial damage and arrest DKD progression.

Funding: Clinical Revenue Support

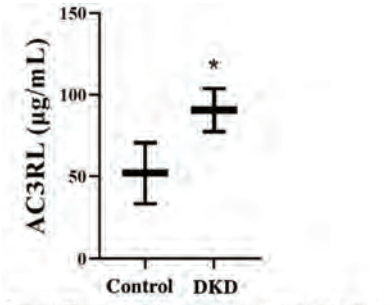

Figure: Plasma AC3RL are increased in patients with DKD. The AC3RL is plotted for the control subjects and the DKD patients (*: p< 0.05 vs. Control; n = 9).

PO0665

Identification of Cell-Specific Transcriptomic Changes and Cross-Talk in Diabetic Mice with Podocyte-Specific Induction of KLF6 Using Single Nuclei RNA Sequencing

Bismark Owusu Frimpong, Nehaben A. Gujarati, Sandeep K. Mallipattu. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Krüppel-Like Factor 6 (KLF6), a zinc finger transcription factor, is a key regulator of cytochrome c oxidase assembly in the podocytes. We previously reported that podocyte-specific loss of *KLF6* exacerbates diabetic kidney disease (DKD). However, the role of podocyte-specific induction of human *KLF6* in DKD remains unexplored.

Methods: A combination of unilateral nephrectomy and streptozotocin (UNx-STZ) was utilized to induce DKD in mice. Using the "Tet-on" system, mice with podocyte-specific induction of human *KLF6* (*hKLF6^{PODTA}*) were generated by crossing *NPHS2-rtTA* mice with *tre-hKLF6* mice and fed with doxycycline-containing diet. UNx-STZ-*NPHS2-rtTA* and SHAM UNx-Veh mice served as diabetic and non-diabetic controls, respectively. Single nucleus (sn)RNA-seq libraries were prepared from kidney cortex using the 10X Chromium System. Raw sequencing data was aligned to mouse pre-mRNA reference genome using Cell Ranger. Quality control, dimensionality reduction and clustering were performed using the R-package, Seurat.

Results: 23 clusters were generated using unsupervised clustering analysis. Enrichment and pathway analyses showed a downregulation of injury-related pathways such as inflammatory and interleukin signaling in the UNx-STZ-treated *hKLF6^{PODTA}* group across the podocyte, endothelial cell, mesangial cell, and proximal tubular clusters, compared to the UNx-STZ-treated *NPHS2-rtTA* group. Conversely, metabolic pathways such as oxidative phosphorylation and fatty acid metabolism were upregulated. A cross-reference of the differentially expressed genes (DEGs) in the podocyte cluster of the UNx-STZ-treated *hKLF6^{PODTA}* group with a KLF6 ChIP-seq data set revealed the presence of putative KLF6 binding sites in the regulatory regions of several DEGs. A unique proximal tubule (PT) cluster with distinctive gene expression signature was identified in the *hKLF6^{PODTA}* group, suggesting an intercellular communication between podocytes and the PT cells in the *hKLF6^{PODTA}* group that mediates the progression of DKD.

Conclusions: SnRNA-seq demonstrates potential mechanisms by which podocyte-specific induction of *KLF6* attenuates the progression of DKD.

Dynein-Driven Pathogenesis of Diabetic Podocytopathy

Hua Sun.[1,2] *[1]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [2]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.*

Background: Dynein-mediated trafficking of nephrin has been recently identified as a cause of INF2-mediated podocytopathy, where de-sequestrated dynein light chain (Dynll1) by mutant INF2 activated dynein transport complex, which subsequently facilitated nephrin degradation and impared its surface recycling to maintain the glomerular filtration barrier. Transcriptome study revealed upregulated expression of Dynll1 in human diabetic nephropathy (DN), suggesting a potential dynein driven pathogenesis. This work tested the hypothesis whether diabetic stresses cause podocytopathy via dynein-mediated mistrafficking of nephrin.

Methods: The transcription of dynein components in DN was analyzed in Nephroseq and compared to normal kidney, which was validated in cultured podocytes exposed to high glucose (HG, 30 mM), using cells exposed to normal glucose (NG, 5.5 Mm) as controls. The dynein-mediated post-endocytic sorting and recycling of nephrin was examined in an in vitro antibody-mediated trafficking model, with or without interference in the dynein trafficking pathway. The dynein-mediated nephrin trafficking in human DN was evaluated by the Dynll1-nephrin colocalization in kidney biopsy specimen, using normal kidney and other human podocytopathies as controls.

Results: 1. Data analysis in Nephroseq revealed a significant upregulation of Dynll1 in human DN, as compared to other dynein components, and it correlated with the decline of renal function. This upregulated expression was redemonstrated in cultured podocytes exposed to HG at mRNA and protein levels, suggesting Dynll1 is a diabetes-responsive component of dynein transport complex. 2. HG-induced podocytopathy was characterized by enhanced dynein-mediated trafficking reflected by increased recruitment of dynein components to endocytosed nephrin and impaired nephrin recycling, which could be reversed by knock-out of Dynll1 or by direct inhibition of dynein. 3. Immunohistochemistry staining revealed upregulated expression of Dynll1 with a significant colocalization with nephrin in kidney biopsy sections of human DN, as seen in dynein-driven FSGS mediated by INF2 mutations.

Conclusions: Dynein-mediated mistrafficking of slit diaphragm protein is a new mechanism by which high glucose stress causes podocytopathy, where Dynll1 plays a key role as a diabetes-reponsive component. Enhanced Dynll1-nephrin colocalization may be used as a biomarker for dynein-driven pathogenesis in human DN.

An Accelerated Method of Podocyte Differentiation from Human Induced Pluripotent Stem Cells for Modeling Diabetic Nephropathy

Julie Bejoy,[1] Lauren E. Woodard.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]US Department of Veterans Affairs, Nashville, TN.*

Background: Podocytes are highly specialized visceral epithelial cells that maintain glomerular barrier function and play important roles during both kidney development and progression of glomerular disease. Mature podocytes extracted from mammalian kidneys are difficult to culture long-term, hindering research on podocytopathies. Establishing an alternative, inexhaustible source of podocytes would be a valuable tool for understanding the molecular mechanisms underlying specific podocytopathies and developing targeted therapies. The discovery of induced pluripotent stem cells (hiPSCs) led to several protocols for deriving podocytes from hiPSCs, which could potentially serve as an unlimited source of podocytes.

Methods: All the existing effective methods for hiPSC- derived podocytes either require lengthy culture times (~ 30 days) or expensive media. Therefore, we sought to develop a faster and less expensive method. We found a simple and effective method to derive podocytes from hiPSCs in twelve days of culture and at lower cost. Our method followed a stepwise protocol in which the hiPSC were differentiated into primitive streak followed by intermediate mesoderm using activation of Activin A and Wnt signaling. Intermediate mesoderm cells were treated with FGF9 to generate nephron progenitors, followed by a cocktail of established growth factors to finally derive mature podocytes.

Results: The developed podocytes expressed podocyte markers including PODX, synaptopodin, MAFB, Nephrin at protein levels comparable to the existing methods. Flow cytometry analysis revealed that our method results in generation of ~80% mature glomerular podocytes. We confirmed the functionality of the hiPSC-derived podocytes via permeability assay for FITC-albumin uptake. Next, we treated the cells with media containing high glucose (100mM) to generate a hiPSC-derived podocyte model of diabetic nephropathy. The podocytes showed actin rearrangement upon treatment with high glucose, suggesting the ability of these cells to effectively model podocytopathies. In addition, treatment with high glucose resulted in increased cytotoxicity and reduced viability in the podocytes.

Conclusions: Altogether, we have discovered a faster and less expensive method of podocyte differentiation from hiPSCs, as well as a new tissue culture model of diabetic nephropathy for disease modeling.

Contribution of Proximal Tubular ADAM17 in a Pre-Diabetic Mouse Model

Vanesa Palau, Sofia V. Calle, Javier J. Jarrín, Eva Márquez, Eva Rodriguez, Marta Crespo, Maria Jose Soler, Julio Pascual, Clara Barrios, Marta Riera. *Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain.*

Background: Both acute and chronic kidney lesions induce an increase in ADAM17 that cleaves several transmembrane proteins, among them molecules related to inflammatory and fibrotic pathways. Our group demonstrated that in experimental type 1 diabetes, inhibition of ADAM17 decreases inflammation and renal fibrosis. Indeed, this protease is proposed as a possible therapeutic tool for the treatment of kidney disease. However, its role in pre-diabetic stages has not been fully analyzed.

Methods: In a knockout mouse model for tubular ADAM17 fed with high-fat diet (HFD), we determined glycemia, glucose tolerance, body weight, hypertrophy and mesangial expansion (PAS staining) and the number of podocytes (immunohistochemistry), after 25 weeks of a follow-up (n = 15 WT, n = 15 KO).

Results: Wild-type (WT) mice on HFD had higher body weight and higher glycaemia with dysregulation of glucose homeostasis compared to mice on standard diet (SD). At the glomerular level, WT mice with HFD had greater glomerular size and mesangial expansion. In contrast, the deletion of ADAM17 in the proximal tubular cell improved glucose

tolerance and protected against glomerular injury. The loss of podocytes observed in WT mice with HFD was not observed in HFD-mice with deletion of ADAM17 (see table).

Conclusions: The conditional knockout of ADAM17 at the proximal tubule level improves glucose tolerance and reduces kidney lesions typically observed in diabetes such as glomerular hypertrophy, mesangial expansion and podocytes loss, in a murine model with high-fat diet that mimics pre-diabetes. ADAM17 may therefore have an inducing role in pre-diabetic kidney injury.

	Body Weight (g)	3h-fasting blood glucose (mg/dL)	Glucose tolerance test (mg/dL)	WT-1 staining (podocyte number)	Mesangial Area (µm2)	Glomerular tuft Area (µm2)

The Role of Cytoskeleton-Associated Protein 4 in the Glomerulus and Diabetic Kidney Disease

Alva Johansson,[1] Emelie Lassen,[1] Janina Müller-Deile,[2] Roberto Boi,[1] Mario Schiffer,[2] Jenny C. Nystrom,[1] Kerstin Ebefors.[1] *[1]Goteborgs universitet Institutionen for neurovetenskap och fysiologi, Goteborg, Sweden; [2]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany*.

Background: Cytoskeleton-associated protein 4 (CKAP4) was first discovered in the endoplasmic reticulum (ER) where it links the ER to the cytoskeleton. It can also be located in the cell membrane and function as a receptor. CKAP4 has been shown to be involved in various physiological events besides its function in the ER, including cell proliferation and migration. In this study, we explored the function of CKAP4 in the glomerulus and its role in chronic kidney disease (CKD).

Methods: Glomerular CKAP4 gene expression was evaluated in different CKD cohorts. The expression of CKAP4 in human glomeruli was investigated via immunofluorescence and western blot. The CKAP4 homolog in zebra fish was knocked down (KD) *in vivo* and proteinuria and morphology were analyzed. shRNA was used to KD CKAP4 in human podocyte and mesangial cells *in vitro*. Changes in protein expression was analyzed via mass spectrometry and western blot, and the morphology of the actin cytoskeleton via immunofluorescence.

Results: Analysis of different human CKD cohort revealed that CKAP4 was down regulated in glomeruli from patients with diabetic kidney disease (DKD), but not in the other diseases investigated. CKAP4 was expressed by all glomerular cells, but to lesser extent in endothelial cells. KD of the zebra fish CKAP4 homolog rendered the fish proteinuric and led to podocyte effacement. KD of CKAP4 in human podocytes and mesangial cells led to loss of actin stress fibers in both cell types. In addition, the expression of several growth factor receptors was affected, with a prominent loss of PDGF receptors in the mesangial cells reducing their proliferative response to PDGF.

Conclusions: Our results from the *in vivo* and *in vitro* experiments show that reduced expression of CKAP4 leads to glomerular dysfunction and changes in the actin cytoskeleton. In podocytes, this is known to cause foot process effacement which we observed. Less is known about how dysregulation of the actin cytoskeleton affects the mesangial cells, but we found that mesangial cells with CKAP4 KD downregulated their PDGF receptors, and had a reduced proliferative capacity. As patients with DKD have a low expression of CKAP4, we suggest that CKAP4 regulation can be a part of the disease development and progression.

Store-Operated Ca2+ Entry Contributed to High Glucose-Induced Podocyte Injury

Yu Tao, Sarika Chaudhari, Parisa Yazdizadeh Shotorbani, Rong Ma. *University of North Texas Health Science Center, Fort Worth, TX*.

Background: Diabetic Nephropathy is one of the major microvascular complications of diabetes and the most common cause of end stage renal disease. Hyperglycemia is a known pathogenic stimulus for onset and progression of diabetic nephropathy. Podocyte injury is one of early features of the disease. However, the mechanism of the diabetes-induced podocyte injury is not fully understood. Store operated Ca^{2+} entry (SOCE) has multiple functions in both excitable and non-excitable cells. This ubiquitous Ca^{2+} signaling includes two key components, Orai1 (a plasma membrane protein mediating SOCE) and STIM1 (an ER membrane protein sensing Ca^{2+} level in the ER lumen). Previous studies have demonstrated that alterations in SOCE are involved in cell dysfunction in many cell types. However, whether and how SOCE contributes to podocyte injury in diabetes settings are not known. The present study was aimed to determine that enhanced SOCE mediated high glucose (HG)-induced podocyte injury by upregulating calpain activity.

Methods: All experiments were performed using cultured human podocytes. Western blot was conducted to estimate Orai1, STIM1 and nephrin protein abundance. Ca^{2+} imaging was used to analyze SOCE. Confocal microscopy was used to visualize podocyte actin arrangement. Calpain activity was determined by calpain activity assay kits.

Results: HG (25mM) treatment significantly increased Orai1, but not STIM1 protein abundance for time periods ranging from 2 to 12 hours. The HG-induced Orai1 response was dose dependent. Ca^{2+} imaging experiment showed that HG treatment for 12 hours significantly increased SOCE. In addition, HG treatment significantly decreased nephrin (a podocyte marker) protein abundance and resulted in cytoskeleton rearrangement by formation of cortical F-actin. Both HG responses were significantly blunted by BTP2 (4 μM), an SOCE inhibitor. Furthermore, we found that activation of SOCE by thapsigargin (1 μM) increased calpain activity which was abolished by BTP2. In addition, BTP2 blunted the increased calpain activity induced by HG treatment. Moreover, calpeptin (a calpain inhibitor) attenuated the HG-induced reduction of nephrin protein abundance.

Conclusions: The present study suggests that enhanced SOCE contributes to HG-induced podocyte injury by increasing calpain activity.

HDAC6 Inhibition with CAY10603 Alleviates Renal Fibrosis Against Pyroptosis in Tubular Injury

Qing Hou, Kan Shuyan, Song Jiang, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing, China, Nanjing, China*.

Background: The essential role of tubular damage has been highlighted during the progression of chronic kidney diseases (CKD), included diabetic nephropathy (DN), but the treatment options are still limited.

Methods: We interrogated the connectivity Map (CMap) with tubular transcriptomic profiles of biopsy-proven DN to identify a drug to reverse the regulated genes in tubulointerstitial component of DN. The effects of potential drug were validated in vivo STZ-induced early and late stage diabetic CD-1 male mice, as well as in non-diabetic mice including adenine-induced CKD and LPS-induced septic kidney injury.

Results: CAY10603, a specific inhibitor of histone deacetylase 6 (HDAC6), was identified as a drug to reverse the signature in both early- and late-stage DN. In patients with DN and mice with DKD, renal tubular expression of HDAC6 was significantly upregulated. In vivo, 5mg/kg dosage of CAY10603 significantly ameliorated tubular injury and tubulointerstitial fibrosis, reduced tubulointerstitial α-SMA and collagen I expression, and infiltration of $F4/80^+$ macrophages in both early and late stage of diabetic kidney disease. In addition, CAY10603 also conferred renoprotection in non-diabetic mice including adenine-induced CKD and LPS-induced septic kidney injury. Mechanically, in vitro HK-2 cells, HDAC6 inhibition with CAY10603 regulated NLRP3 activation and membrane repair upstream and downstream of GSDMD.

Conclusions: Collectively, CAY10603 exhibited therapeutic potential against pyroptosis in tubular injury of CKD

FRMD3/Protein 4.1O Increases Hippo Signaling in a Glucose-Dependent Manner

Eva Koenigshausen,[1] Larissa Matten,[1] Sonja Rieckmann,[1] Theresia Vienken,[1] Thorsten Wiech,[2] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany; [2]Institute of Pathology, University Hospital Hamburg-Eppendorf, Hamburg, Germany*.

Background: FRMD3 is as a candidate gene for diabetic nephropathy and encodes for protein 4.1O. Different splice variants 207, 204, 201 are expressed in the kidney cortex. Previous data show that protein 4.1O links nephrin to the actin cytoskeleton. In diabetic kidney disease Hippo signaling is increased. Phosphorylated Yes-associated kinase (YAP) and its paralogue TAZ are sequestered into the cytoplasm and degraded (Hippo signaling on). Unphosphorylated YAP/TAZ translocates into the nucleus and activates target genes via different transcription factors (Hippo signaling off).

Methods: Human kidney biopsy samples from healthy and diabetic patients were stained for protein 4.1O with immunohistochemistry. HEK293T cells were stimulated with low (5mmol/l) or high (25 mmol/l) glucose and an osmotic control (mannitol). RNA was isolated and PCR performed. HEK293T cells expressed protein 4.1O 207, 201, 204 or the control vector. Cells were stimulated with low, high glucose or mannitol. After cell lysis, westernblot was performed for phospho-YAP 397 and actin. Co-immunopreciptiation was performed under high, low and osmotic control conditions.

Results: Protein 4.1O expression is detected in healthy human glomeruli. In diabetic patients with CKD stage 3b to 5 and gross proteinuria protein 4.1O expression is increased in podocytes. High glucose leads to enhanced transcription of FRMD3. Under high glucose condition, protein 4.1O 207 and 201 significantly increase YAP phosphorylation. However, protein 4.1O 204 (lacking a c-terminal domain) does not increase YAP phosphorylation under high glucose condition. Functionally, protein 4.1O 207 and nephrin interaction is increased under high glucose conditions.

Conclusions: Expression of protein 4.1O is increased in human diabetic kidney disease and under high glucose conditions. Hippo Signaling is activated under high glucose conditions if protein 4.1O 207 and 201, but not 204, is expressed. The lacking cytoplasmic domain in protein 4.1O 201 may play the essential role in controlling Hippo signaling under high glucose conditions. Identifying the underlying pathomechanism for glucose-dependent regulation of the Hippo pathway by different splice variants of protein 4.1O will help to understand its molecular function in diabetic nephropathy.

PO0673

Human Proximal Tubular Cells in a 3D In Vitro Culture as a Model for Exploring Diabetic Lesions

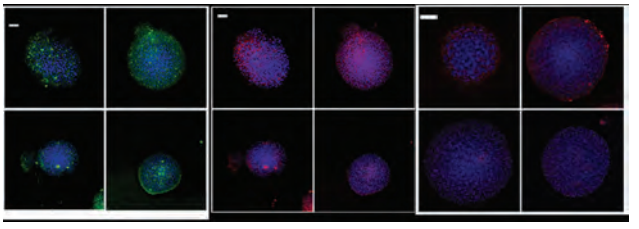
Vanesa Palau, Clara Barrios, Eva Márquez, Eva Rodriguez, Marta Crespo, Julio Pascual, Marta Riera. *Consorci Parc de Salut MAR de Barcelona, Barcelona, Spain.*

Background: We have previously demonstrated, the beneficial effect of ADAM17 deletion on human proximal tubular kidney cells (HKC-8) in 3D *in vitro* spheroids incubated with high glucose resembling the human kidney diabetic environment. Galectin-3 (Gal-3) is a potent pro-fibrotic protein and modulates the activity of fibroblasts and macrophages in chronically inflamed organs through activation of the TGF-β/Smad3 pathway and it is postulated as regulator of cardiac oxidative stress which can facilitate the development of fibrosis. Also, Dynamin related protein 1 (DRP-1) is a key regulator of the mitochondrial fission and ATP production under stress condition. As ADAM17 has been associated with TGF-β modulation during renal fibrosis, we wanted to evaluate the effect of ADAM17 deletion on Gal-3, Fibronectin and DRP-1 in HKC-8 spheroids incubated under high glucose conditions

Methods: ADAM17 deletion of renal tubular cells was performed using the CRISPR/Cas9 technology. HKC-8 cells grew inside an RGD-functionalized dextran hydrogel to obtain 3D spheroids. 13 days post-seeding, the spheroids were incubated with 35mM of D-glucose (HG), 5mM of D-glucose (LG) or 35mM of mannitol as osmotic control for 72h. Immunofluorescence for Gal-3, pDRP-1 and Fibronectin was performed

Results: HG increased the expression of fibronectin and pDRP-1 and tends to increase Gal-3 in wild-type (WT) spheroids. Interestingly, ADAM17 deletion decreased fibronectin expression in spheroids incubated with HG as compared to WT spheroids. Moreover, ADAM17 deletion abrogates the effect of HG on Gal-3 expression (see table and images, scale bar 50µm). The osmotic control, mannitol, did not affect the expression of the analysed proteins

Conclusions: ADAM17 blockade protects against fibrosis by decreasing fibronectin and Gal-3 and modulated the mitochondrial dynamic in human kidney tubular spheroids under high glucose conditions



PO0674

Animal Models Cannot Well Reflect the Transcriptomic Changes of Human Diabetic Nephropathy: A Comparative Study

Leting Zhou,[1] Li-Hua Ni,[2] Ling Hu,[1] Yu-Shan Zhu,[1] Yue Zhang,[1] Sisi Wang,[1] Liang Wang.[1] [1]*Wuxi People's Hospital affiliated to Nanjing Medical University, Wuxi, China;* [2]*Department of Nephrology, Zhongnan Hospital of Wuhan University, Wuhan, China.*

Background: Various mouse models have been developed and widely applied in investigating the pathogenesis of DN. Whether the models share the same underlying molecular changes with human DN is poorly understood. To this end, we performed a systematic analysis of the transcriptomes of the kidney tissues from patients with DN and various mouse models. To our knowledge, this is the largest analysis on this topic

Methods: This study included the bioinformatic analysis and in vivo validation. We comprehensively analyzed the genome-wide mRNA expression of kidney tissues collected from patients with biopsy-proven DN and widely used animal models(n=60). The bioiformatics workflow is shown in figure 1. Then, the expression levels of interested genes were further validated

Results: The transcriptomic profiles of all the animal models had poor correlation with those of patients with DN. However, we observed a much better correlation within species, regardless of the disease stages or modeling methods. In the GSVA analysis, we found the animal models shared similar pathological processes but could not well reflect the real circumstances in human DN. In enrichment analysis, we found the animal models shared the same pathways such as the accumulation of extracellular matrix and MAPK signaling with human DN. However, these models can not well mimic pathways such as cytokine signaling, vitamin D metabolism and SLC transporter disorders. Finally, the expression levels of the interested genes measured by the westernblot method showed good consistency with those generated by high throughput platforms

Conclusions: We found mouse models can not well reflect the transcriptomic changes of human DN in many aspects. We also provided a useful dataset to facilitate the translational research of DN

Funding: Government Support - Non-U.S.

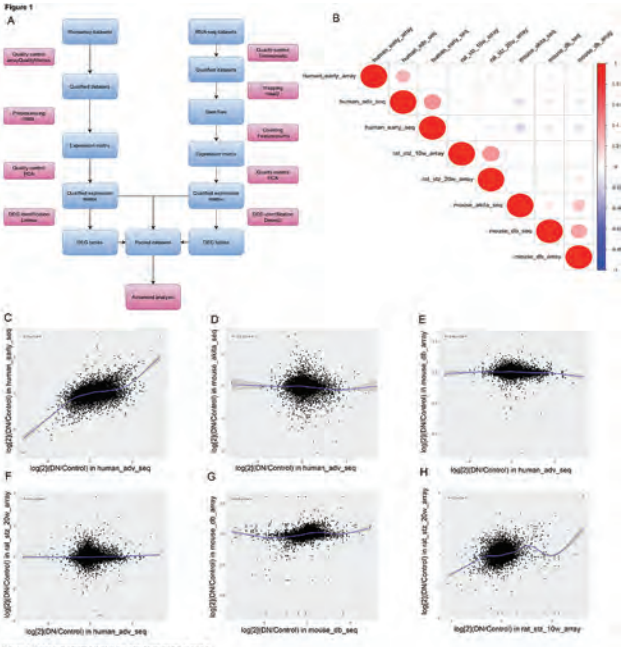


Figure 1 The bioinformatic workflow and correlation analysis
A. The bioinformatic workflow;
B. The correlation plot of the differential expressed genes(DEGs) of all studies. The degrees of correlation were measured using the Spearman' s r and indicated by the color intensities.(red: postive correlation; blue: negative correlation)
C-H. Scatter plots of the DEGs. The axis indicates the log2 fold changes of the DEGs in the DN group as compared to the control group. The generalized additive model was used for curve fitting.
C. the correlation of DEGs between early and advanced human DN. R = 0.4, P < 2.2e-16;
D. the correlation of DEGs between akita mice and advanced human DN. R=-0.11, P < 2.2e-16;
E. the correlation of DEGs between db/db mice and advanced human DN. R = -0.086, P < 2.2e-16
F. the correlation of DEGs between STZ-diabetic rats and advanced human DN. R = 0.027, P = 0.00035
G. the correlation of DEGs obtained by the microarray and RNA-seq in db/db mice. R = 0.29, P < 2.2e-16
H. the correlation of DEGs between STZ-diabetic rats at the age between 10 weeks and 20 weeks. R = 0.23, P < 2.2e-16

Figure 2. The gene set variation analysis(GSVA) and Functional enrichment analysis
A-E. Principal coordinates analysis (PCoA) plots of the GSVA. The PCoA was used to project the original high-dimension space calculated by the GSVA into a 2-dimension space for visualization. Points with smaller distances share more similar biological processes. The red color indicates the control group, while the blue color indicates the DN group. Different symbols represent different species or disease stages.
F-I. Pathway analysis of the dysregulated genes. The x-axis represents the gene-enrichment scores. The size of each dot represents the number of enriched genes, while the colors represent different databases used for enrichment analysis (KEGG or Reactome).
F. Pathway analysis of the down-regulated genes in mouse and down-regulated genes in advanced DN.
G. Pathway analysis of the up-regulated genes in mouse and down-regulated genes in advanced DN.
H. Pathway analysis of the down-regulated genes in mouse and up-regulated genes in advanced DN.
I. Pathway analysis of the up-regulated genes in mouse and up-regulated genes in advanced DN.

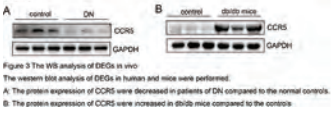

Figure 3 The WB analysis of DEGs in vivo
The western blot analysis of DEGs in human and mice were performed.
A: The protein expression of CCR5 were decreased in patients of DN compared to the normal controls.
B: The protein expression of CCR5 were increased in db/db mice compared to the controls

Integrative Transcriptome Analysis Reveals Involvement of Spermatogenesis-Related Genes in Diabetic Nephropathy

Xinxin Ma, Hongchun Lin, Yuanqing Li, Weiyan Lai, Shuangshuang Shu, Yuxiang Sun, Yongjie Li, Jun Song, Zengchun Ye, Hui Peng. *The Third Affiliated Hospital of Sun Yet-sun University Department of Nephrology, Guangzhou, China.*

Background: Cell heterogeneity has impeded the accurate interpretation of the bulk transcriptome data from patients with diabetic nephropathy (DN). We performed an analysis by integrating bulk and single-cell transcriptome datasets to uncover novel mechanism leading to DN, especially in the podocytes.

Methods: Microdissected glomeruli and tubules transcriptome datasets were selected from Gene Expression Omnibus (GEO). Then the consistency between datasets was evaluated. The analysis of bulk dataset and single-nucleus RNA dataset was integrated to reveal the cell type-specific responses to DN. The candidate genes were validated in kidney tissues from DN patients and diabetic mice.

Results: We compared 4 glomerular and 4 tubular datasets and found considerable discrepancies among datasets regarding the differentially expressed genes (DEGs), involved signaling pathways and the hallmark enrichment profiles. Deconvolution of the bulk data revealed that the variations in cell-type proportion contributed greatly to this discrepancy. Integrative analysis uncovered that the dysregulation of spermatogenesis-related genes, including *TEKT2* and *PIAS2* was involved in development of DN. Importantly, the mRNA level of *TEKT2* was negatively correlated with the mRNA levels of nephrin (r= -0.66, p<0.0001) and podocin (r= -0.85, p<0.0001) in human diabetic glomeruli. Immunostaining confirmed that the expression of TEKT2 and PIAS2 were up-regulated in podocytes of DN patients and diabetic mice.

Conclusions: The integrative strategy can help us to efficiently use the publicly available transcriptomics resources. Using this approach, we identified *TEKT2* and *PIAS2*, two spermatogenesis-related genes involved in the pathogenesis of DN.

PO0676

Understanding Genetic Mechanisms of Diabetic Nephropathy at the Single-Cell Level

Jing Guo,[1] Mien Nguyen,[2] Takahiro Yamaji,[2] Kengo Azushima,[3] Susan B. Gurley,[4] Enrico Petretto,[1] Thomas M. Coffman.[2,5] *[1]Duke-NUS Medical School Centre for Computational Biology, Singapore, Singapore; [2]Cardiovascular and Metabolic Disorders Program, Duke-NUS Medical School, Singapore, Singapore; [3]Yokohama City University Graduate School of Medicine, Department of Medical Science and Cardiorenal Medicine, Yokohama, Japan; [4]Division of Nephrology and Hypertension, Oregon Health and Science University, Portland, OR; [5]Division of Nephrology, Department of Medicine, Duke University, Durham, NC.*

Background: Diabetic nephropathy (DN) is a leading cause of end-stage kidney disease worldwide. Susceptibility to DN is inherited but genetic determinants have not been clearly defined. We have previously described a mouse model combining *Akita-Renin* transgene (AR) that exhibits human DN features including albuminuria, glomerulosclerosis, and genetic predisposition. Susceptible (S) 129 strain AR mice develop overt DN whereas resistant (R) C57BL/6 AR mice are largely free of kidney damage.

Methods: We performed single-cell sequencing of glomerular cell obtained from the wildtype (WT) and AR mice from both S and R strains at 10 weeks of age before overt pathological abnormalities are present in S mice.

Results: A total of 60,682 cells were sequenced from the four conditions. Within the main glomerular cell lineages: podocytes, mesangial and endothelial cells, there were distinct functional clusters corresponding to the S and R strains (see figure). Within the S but not R strain, well-defined cell clusters derived from AR and WT were identifiable within podocytes and mesangial cells, while in other cell types, the impact of strain was much greater than diabetes and renin-angiotensin activation in driving differential gene expression. Gene networks defining the strain differences have potential functional relevance in the development of glomerular diseases. For example, in podocytes, gene networks related to cytoskeleton are activated in the R strain, whereas the S strain shows upregulated oxidative stress responses. A number of candidate genes identified in human DN and other inherited nephropathies are also differentially expressed on the S and R backgrounds.

Conclusions: Single-cell sequencing analysis of glomerular cells from a DN mouse model has identified cell-specific transcriptomic profiles linked to genetic susceptibility and resistance to DN, suggesting causal mechanisms. Substantial overlap with pathways and candidate genes linked to human DN suggest that this model can be useful for understanding genetic pathophysiology of DN in humans.

Altered Cellular Signaling Pathways Identified by Proteomics and Phosphor-Proteomics in a Rat Model of Diabetic Kidney Disease

Aya Yoshimura,[1] Masanori Kugita,[1] Hisateru Yamaguchi,[2] Kazuki Nakajima,[1] Kanako Kumamoto,[1] Tamio Yamaguchi,[3] Kazuo Takahashi,[1] Yukio Yuzawa,[1] Shizuko Nagao.[1] *[1]Fujita Health University, Toyoake, Japan; [2]Yokkaichi Nursing and Medical Care University, Yokkaichi, Japan; [3]Suzuka University of Medical Science, Suzuka, Japan.*

Background: Alterations of cellular signaling are associated with onset and deterioration of various types of disorders, which could be the targets for new drug development and discovery. Currently, post-translational protein modification and glycosylation are identified by comprehensive proteomic analyses. Since diabetic kidney disease (DKD) is the leading cause of chronic end stage renal disease, exploring novel signaling pathways involved in the initiation and progression of DKD may have therapeutic potential. In the present study, we probed renal tissue in a DKD rat model for altered signaling cascades using proteomics and phosphor-proteomics analyses.

Methods: The animal model of type 2 diabetes mellitus, Spontaneously Diabetic Torii Fatty (SDT Fatty) rats were uninephrectomized at 9 weeks of age, and then from 10 weeks of age, 0.3% NaCl was added to drinking water to exacerbate DKD progression for additional 5 weeks (Group A) or 10 weeks (Group B). After the treatment period, blood was collected for biological measurements and kidney tissue was obtained for histology and proteomics and phosphor-proteomics analyses.

Results: In SDT Fatty rats, the stage of DKD was classified as 'early' (Group A) or 'advanced' (Group B) by SUN levels and expansion of mesangial matrix and glomerular sclerosis observed by PAS staining. 25 signaling cascades including the PPAR signaling pathway were activated at early stage DKD, and 41 cascades including the proximal tubule bicarbonate reclamation cascade were activated at advanced stage DKD, detected by proteomics analysis in the KEGG database (P<0.05). Further, 33 annotation clusters including the 'serpin family' as serine protease inhibitors and the 'S100 family' as RAGE ligands were newly detected by functional annotation clustering determination (P<0.05). In addition, five cascades including pathways of 'microRNA in cancer' indicated by Crk, Hnrnpk and Marcks at early stage and two cascades including 'RNA transport' indicated by Casc3, Eif3b and Eif3c at advanced stage were detected by phosphor-proteomics analysis in KEGG database (P<0.05).

Conclusions: These findings demonstrate that several groups of known and new signaling cascades may have important roles for the initiation and/or progression of DKD.

Funding: Government Support - Non-U.S.

PO0678

NETosis Contributes to the Pathogenesis of Diabetic Kidney Disease: A Proposed Mechanistic Pathway

Rachel Njeim, Hilda E. Ghadieh, Mohamad I. Nahlawi, Fuad N. Ziyadeh, Hala M. KFoury, Assaad Antoine Eid. *American University of Beirut Faculty of Medicine, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) is one of the most debilitating complications of diabetes. Considerable research has focused on the key role of NADPH oxidases (NOXs) in DKD. Of note, our group has demonstrated the role of mTOR signaling pathway in mediating NOX-derived reactive oxygen species (ROS) production in DKD. Inflammation and an overactive immune response are known to be major risk factors for the development and progression of DKD. Recently, NETosis, a novel neutrophil-specific cell death process, was described to be associated with inflammation and diabetes. However, the effect of NETosis on DKD remains uninvestigated. Interestingly, increasing evidence highlights a pivotal role for the mTORC1 pathway and NOXs in regulating NETosis. Herein, we hypothesize that hyperglycemia activates the mTOR/NOX signaling pathway, leading to excess neutrophil extracellular traps (NETs) formation and eventual kidney injury.

Methods: Control mice, mice treated with phorbol 12-myristate 13-acetate (PMA) to induce NETosis, and mice models of type 1 and type 2 diabetes treated either with Cl-amidine to inhibit NETosis or with Cl-amidine's vehicle were used. Functional, histological, and molecular parameters of the kidneys were determined. Human transcriptomics datasets from GEO were further used for validation.

Results: Our data show that increased NETs formation mediates renal dysfunction and histopathological alterations associated with DKD. Of note, treatment with PMA mimicked diabetes-associated renal injury, as assessed by UAE, UACR, BUN and serum

cystatin C, and induced glomerular hypertrophy, glomerulosclerosis, extracellular matrix expansion and podocyte depletion. Treatment with Cl-amidine attenuated diabetes-induced glomerular and podocyte injury. Increased NETs formation in diabetes was paralleled by an increase in NOX-dependent ROS production and mTOR signaling pathway activation. Our findings were further confirmed in transcriptomic analysis of human DKD, where a positive correlation between NETs and DKD was observed. Querying protein-protein interaction databases also revealed an association between NETs markers, mTOR signaling proteins, and NOXs.

Conclusions: To our knowledge, this study is the first to describe the role of NETosis in DKD, identifying NETosis as one of the final mechanistic drivers of DKD.

Alteration of Autophagy-Related Protein 5 (ATG5) Levels and Atg5 Gene Expression in Diabetes Mellitus with and Without Complications

Farid M. Nakhoul,[1,2] Nakhoul Nakhoul,[2,4] Evgeny Farber,[6,7] Aida Nakhoul-Armaly,[3,5] Hagar Tadmor.[2,3] *[1]Galilee Medical Center, Nahariya, Israel; [2]Faculty of Medicine Bar Ilan University, Ramat-Gan, Israel; [3]Diabetes and metabolism Lab Baruch Padeh Poriya Medical Center, Tiberias, Israel; [4]Ophtalmology Division baruch Padeh Poriya Medical center, Shefa-Amr, Israel; [5]Cardiology Division Baruch padeh Poriya Medical Center, Shefa-amr, Israel; [6]The Baruch Padeh Medical Center Poriya, Tiberias, Israel; [7]Nephrology Division, Tiberias, Israel.*

Background: Autophagy is a catabolic mechanism that involves lysosomal-dependent degradation of unnecessary or ineffective intracellular components. Autophagy is the process responsible for normal cellular homeostasis, by recycling organelles and proteins. Autophagy pathway and its key participant ATG5 are associated with several pathologies such as diabetes mellitus and its complications.

Methods: Levels and expression of autophagy key components ATG5 and LC3B were analyzed in both human model and murine tissues. One hundred and twenty human subjects were divided into four groups: Healthy (control), diabetic without complications, diabetic nephropathy and diabetic retinopathy. Additionally, we used kidneys from diabetic mice model (WT healthy mice and DN mice, Lysate derived from human peripheral blood mononuclear cells, and murine renal cortex lysates were subjected to western blot analyses of ATG5 and LC3B and immunohistochemical analysis was performed on mice renal tissues.

Results: Western blot and immunohistochemical analysis demonstrate that ATG5 protein levels were significantly decreased in DM, DN and DR patients (0.59±0.07; 0.67±0.06; 0.72±0.06 A.U. units respectively), vs. healthy controls (0.96±0.16 A.U. units), and in DN mice compared to healthy mice (0.65±0.04; 1.15±0.13 A.U. units respectively). Quantification of staining area (%) of ATG5 mice tissue expression also decreased in DN vs. healthy mice (4.42±1.08%; 10.87±1.01% respectively). LC3B levels and expression correlates with ATG5 results: significant reduction in peripheral blood mononuclear cells diabetic patients (with or without complications) vs. healthy controls (0.44±0.05; 0.42±0.035; 0.48±0.06 compared with 0.81±0.05 A.U. units). Renal LC3B levels were lower in DN vs. healthy mice (0.36±0.03; 0.68±0.07 A.U. units). Renal LC3B staining quantification revealed significant reduction in DN vs. healthy mice (1.7±0.23%; 8.56±1.7%).

Conclusions: We conclude that ATG5, as well as LC3B, are down regulated in diabetic patients with or without complications. This diminution contributes to deficiencies in the autophagy process. Our observations show a novel association between autophagy-related protein 5 (ATG5) and diabetic kidney and retinal diseases, with ATG5 as a candidate protein for diabetic nephropathy and retinopathy.

PO0680

The Emerging Role of the mTORC2/Rictor Signaling Complex in Autophagy Dysregulation-Associated Diabetic Kidney Disease

Sahar Alkhansa, Sami Azar, Assaad Antoine Eid, Fuad N. Ziyadeh. *American University of Beirut Faculty of Medicine, Beirut, Lebanon.*

Background: Podocyte injury has been implicated in the pathogenesis of many renal diseases including diabetic kidney disease (DKD). Dysregulation of podocyte autophagy has been positively correlated with podocyte loss and progression of proteinuria in patients with diabetes. Yet, the exact mechanisms behind diabetes-induced autophagy dysregulation remain to be elucidated. Various signaling pathways including the mTORC1 complex have been implicated in maintaining podocyte integrity in DKD. However, the role of mTORC2 in autophagy and its interaction with key mechanistic pathways involved in DKD, including the ROS-producing enzymes, are still unknown. Herein, we investigated the role of mTORC2, its crosstalk with the NADPH oxidases 4 (Nox4)-induced ROS, its effect on autophagy, and the possible link to podocyte integrity in animal models of type 1 and type 2 diabetes.

Methods: Type1 diabetes was induced in mice by streptozotocin (STZ) injections, and type 2 diabetes was initiated by a 'western' diet followed by low-dose STZ injections. Mice were divided into control, diabetic, and diabetic treated with a selective mTORC2 inhibitor (JR-AB2-011). Functional, pathological, and biochemical studies were performed.

Results: Diabetes-induced podocyte injury is reflected by alterations of the slit-diaphragm protein nephrin, paralleled by podocyte depletion as assessed by decreased WT1 staining and accompanied by autophagy dysregulation. The effect of autophagy was further highlighted in control mice treated with the autophagy inhibitor hydroxychloroquine, that mirrored the effect of diabetes on functional, phenotypic, histological, and molecular changes in the kidney. These observations were concomitant with an observed activation of the mTORC2/Rictor protein expression and increased levels of superoxide generation through Nox4. Of interest, these results were paralleled by activation of the mTORC1/p70S6K pathway. Moreover, specific inhibition of mTORC2 curbed the homeostatic function of the kidneys and restored the histological and phenotypical changes, concomitant with regulating the Nox4/mTORC1 signaling axis. More importantly, JR treatment regulated diabetes-induced autophagy protein dysregulation (Beclin, Atg3, and LC3).

Conclusions: Our data suggest that targeting mTORC2 signaling could be a potential therapeutic target for DKD.

Mitophagy-Related Renal and Proximal Tubular Protection During the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Ishii,[1] Pamela K. Carmines,[2] Yoshifumi Kurosaki,[1] Akemi Imoto,[1] Hiroyuki Takahashi,[1] Hideki Ikenaga,[3] Masanori Yokoba,[1] Takafumi Ichikawa,[1] Tsuneo Takenaka,[4] Masato Katagiri.[1] *[1]Kitasato University, Sagamihara, Japan; [2]University of Nebraska Medical Center, Omaha, NE; [3]Seiikai, Tochigi, Japan; [4]International University of Health & Welfare, Minato-ku, Japan.*

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria. Because accumulation of damaged mitochondria can contribute to renal dysfunction, we aimed to determine a) if oxidative stress in DM triggers mitophagy as a mitochondrial quality control mechanism, and b) the renal cortical structures in which these events occur.

Methods: Rats receiving i.p. injection of streptozotocin (STZ, 65 mg/kg) or vehicle (Sham) were either left untreated or treated with telmisartan (TLM, an angiotensin receptor blocker; 10 mg/kg/d). Two weeks later, blood glucose levels (BG), blood pressure (BP), glomerular filtration rate, and urinary excretion of albumin and *N*-acetyl-β-D-glucosaminidase (NAG) were measured. The oxidative stress marker, 3-nitrotyrosine (3-NT), was detected by HPLC. Mitophagy-related proteins (LC3-II, p62, PINK1, BNIP3) were quantified by Western blot and localized by immunoreactivity based on percent of cells staining with various intensities (HistoScore).

Results: STZ rats displayed hyperglycemia and hyperfiltration that were unaffected by TLM. BP, albumin excretion, and NAG excretion were similar in all groups. Renal cortical 3-NT levels were increased in STZ rats, a change that was prevented by TLM (STZ+TLM). Renal cortex from STZ rats displayed TLM-sensitive increases in LC3-II and PINK1 (all $P<0.05$), although BNIP3 and p62 levels did not differ among groups. HistoScore data failed to reveal mitophagy-related proteins in glomeruli. In contrast, immunoreactivity for all 4 proteins was readily evident in proximal tubules, with increased HistoScores in STZ rats; this effect was blunted in STZ+TLM rats. Mitophagy-related protein immunostaining was also apparent in distal tubules, but the Histoscores tended to be less than that of proximal tubules and were unaffected by STZ or TLM.

Conclusions: During the normoalbuminuric stage of DM, renal cortical mitophagy is most prominent in the proximal tubule. This effect is blunted by TLM in association with its antioxidant effect, suggesting a mitophagy-related proximal tubular protection mechanism triggered by oxidative damage.

PO0682

The Molecular Effect of the Sodium-Glucose Transporter 2 (SGLT-2) Inhibitor Empagliflozin on the Autophagy Pathway in Diabetes Mellitus and Its Vascular Complications

Ranin Saad,[1,2] Evgeny Farber,[2,1] Rola Nakhoul,[5] Offir Ertracht,[3,4] Farid M. Nakhoul,[3,4] Hagar Tadmor.[1,4] *[1]Diabetes Metabolism Lab Azrieli faculty of Medicine Bar Ilan University, Bar-Ilan, Israel; [2]Nephrology Division Baruch padeh Poriya Medical Center, Tiberias, Israel; [3]Galilee Medical Center, Nahariya, Israel; [4]Azrieli faculty of Medicine bar-Ilan University, Ramat-Gan, Israel; [5]Erlangen Univerity Hospital Anästhesiologische Klinik, Erlangen, Germany.*

Background: Diabetes mellitus (DM) is a severe metabolic disorder characterized by chronic hyperglycemia. DM is associated with increased oxidative stress that can lead to irreversible kidney damage and kidney failure. Empagliflozin (EMPA) is a novel anti-diabetic drug, known as SGLT2i in T2DM patients. Autophagy is a catabolic mechanism that involves lysosomal-dependent degradation of unnecessary or dysfunctional intracellular components, and is known to have an important role in DM complication (Diabetic Nephropathy-DN). We aim to investigate the protective role of EMPA treatment on DN via the autophagic proteins ATG5 & LC3B.

Methods: We used T2DM animal model-mouse strain BTBR with the ob/ob leptin-deficiency mutation that develops severe type II DM which is presented with hyperglycemia and DN. EMPA will be administrated to the diabetic mice via drinking water for a period of 12 weeks. Routine monitoring of blood and urine standard DM parameters will be carried through experiment duration. At the end of the experiment, mice kidneys will be removed and subjected to further biochemical and histological analysis: Western blot analyses, Immunohistochemistry staining will be performed to evaluate ATG5, LC3B, level and expression.

Results: Blood glucose concentration was normal in control mice (C57) throughout the experiment. In DM mice (BTBR) without EMPA, blood glucose concentration was higher than control, and lower in diabetic mice treated with EMPA compared to DM. Urine volume of BTBR mice treated with EMPA increased throughout the experiment and was higher in comparison to DM mice without EMPA treatment. Renal cortical

expression of ATG5 were 6.83±0.52%, 2.59±0.54% and 6.29±.74% for the C57, DM and DM+EMPA, respectively (P<0.001 vs. DM for both) and LC3B were 9.60±2.14%, 3.19±0.66% 7.39±1.74% in the C57, DM mice and DM+EMPA, respictevely (P<0.001 between all groups.

Conclusions: 1. EMPA Treatment induces glucosuria and body weight reduction in diabetic mice model 2. Chronic Hyperglycemia down regulates the expression of LC3 & ATG5, the two main proteins in the autophagy process. 3. Treatment EMPA for 12 weeks restore the the expression of these proteins in the kidney 4. EMPA can be first line treatment in type II DM patients to slow the progression of DN.

PO0683

Ferroptosis Is Involved in the Process of Diabetic Kidney Disease

Keping Wu,[1,2] Lingyan Fei,[1,2] Yang Liu,[1,2] Jiasi Chen,[1,2] Enyi Zhu,[1,2] Hui Guan,[1,2] Ming Zhong,[1,2] Zhihua Zheng,[1,2] Xiaohua Wang.[1,2] *[1]Sun Yat-Sen University, Guangzhou, China; [2]Department of Nephrology, Kidney and Urology Center, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China*.

Background: Diabetic kidney disease(DKD) is a major public health problem that threatens human health and causes substantial economic burden. DKD is accompanied by accumulation of ROS and iron in the kidney, a hallmark of ferroptosis. Ferroptosis is a condition that causes cell death by accumulation of lipid reactive oxygen species (ROS), in an iron-dependent mechanism that is different from apoptosis, necroptosis and autophagy. That ferroptosis is involved in DKD has been shown recently, but its role is still unknown.

Methods: We induced diabetic kidney disease in 8-week-old male rats with streptozotocin (STZ) and treated with ferroptosis inhibitor Fer-1 to analyze the degree of renal injury and the related indexes of ferroptosis.

Results: 1. Diabetic renal injury involves ferroptosis. Accumulation of iron was also confirmed by Prussian blue staining and presented morphological changes linked to ferroptosis in DKD group: reduced mitochondrial volume, ruptured mitochondrial membrane and missing mitochondrial cristae. 2. Blocking ferroptosis can alleviate proteinuria and renal tubular injury in STZ-induced DKD. Fer-1 treatment clearly decreased the urine protein-creatinine ratio, both α-1 microglobulin and N-acetyl-β-D-glucosaminosidase in DKD group and the levels of both MDA and Fe^{2+}. In addition, treating DKD rats with Fer-1 reduced iron in the kidney and alleviated kidney fibrosis.

Conclusions: Ferroptosis is involved in the process of diabetic kidney disease.

Markers of renal tubular injury α 1-microglobulin and N-acetyl-β-D-glucosaminosidase measured in urine

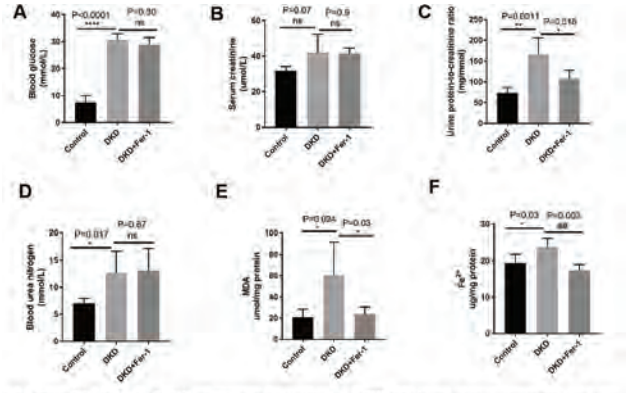

Fig 1. Ferrostatin-1 (Fer-1) alleviates proteinuria and renal injury in DKD rats. Levels of serum glucose (A), blood urea nitrogen (B), urine protein-to-creatinine ratio (C), serum creatinine (D), renal MDA (E) and renal non-heme iron (F) measured for 10 weeks after rats were injected with STZ (n=5).

Group (n=5)	α1-microglobulin (mg/L)	N-acetyl-β-D-glucosaminosidase (U/mmol creatinine)
Control	< 6.35	0.736±0.12
DN	7.54±1.19	2.24±0.96**
DN+Fer-1	< 6.35	0.94±0.67 *

Effect of Lisinopril and Pioglitazone in a Mouse Model of Diabetic Kidney Disease

Simon A. Hinke, Cassandre Cavanaugh, Gladys A. Nchaw, Tao Chen, Paul Stahle, Neetu Shukla, Hui Huang, Zhiyong Yang, Andrea R. Nawrocki. *Janssen Pharmaceutical Companies of Johnson and Johnson, Springhouse, PA.*

Background: Diabetic nephropathy affects up to one third of all diabetes mellitus patients, and is the major cause of end stage renal disease. The current study evaluated the uninephrectomized (UNx) obese and diabetic db/db mouse as a model of diabetic kidney disease (DKD), benchmarking a glycemic control agent (Pioglitazone) and an angiotensin-converting enzyme inhibitor (Lisinopril) to affect kidney structure and function.

Methods: Female lean control mice (Db/+, 2 kidneys), sham operated obese mice (db/db, 2 kidneys), and UNx db/db mice (1 kidney) were grouped based on body weight, blood glucose, %HbA1c, and urine albumin:creatinine ratio (UACR). Inclusion criteria were defined as blood glucose >350mg/dl and UACR >250ug/mg. Following grouping, animals were provided a diet admixture of Pioglitazone (169mg/Kg diet) or Lisinopril (0.1mg/mL) in drinking water. Compounds were administered for 8 weeks, during which body weight, food intake, water intake and blood glucose was measured.

Results: Control UNx-db/db animals showed progressive decline in renal function (UACR: 497±62mg/ug at baseline to 1054±159mg/ug at 8wks), whereas sham operated animals remained near baseline levels (284±40mg/ug). Pioglitazone treated mice had significantly lower UACR than control UNx-db/db after 2 weeks whereas lisinopril treated animals had significantly lower UACR after 4 weeks of treatment, primarily by limiting the progression of UACR increase. Increased mesangial matrix deposition in the glomeruli was the primary lesion observed (high incidence and high severity); tubular and interstitial structural findings were very limited; little to no fibrosis was observed. Pioglitazone and lisinopril both showed a comparable effect in decreasing the severity of mesangial matrix deposition.

Conclusions: Hence, the UNx-db/db animal model of diabetic kidney disease is a progressive model of renal function decline and limited histopathological damage which responds to both anti-diabetic and anti-hypertensive control agents, and is a valuable model for the assessment of new therapeutic targets for DKD.

PO0685

miR299a-5p Is a Novel Mediator of Fibrosis in Diabetic Kidney Disease

Ifeanyi K. Nmecha, Bo Gao, Joan C. Krepinsky. *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada*.

Background: Diabetic kidney disease (DKD) is the leading cause of kidney failure in North America, characterized by glomerular accumulation of extracellular matrix (ECM) proteins. High glucose (HG) induction of glomerular mesangial cell (MC) profibrotic responses, mediated by the cytokines TGFβ1 and activins, plays a central role in its pathogenesis. We recently showed that TGFβ1 upregulation of microRNA (miR) 299a-5p promoted its profibrotic responses in MC. Here we studied the role of this miR in DKD.

Methods: Primary mouse MC were treated with HG at 30 mM. miR299a-5p was detected by qPCR or ISH. miR overexpression and inhibition plasmids were transfected by electroporation. TGFβ1 and activin signaling was assessed by activity of their downstream mediator Smad3 using the $CAGA_{12}$ reporter. ECM production was assessed using immunoblotting and activity of the COL1α1 promoter luciferase reporter.

Results: HG increased the expression of miR299a-5p in MC. This was also increased in type 1 Akita diabetic kidneys in both glomeruli and tubules, as assessed by ISH. In MC, miR299a-5p overexpression increased Smad3 activation and COL1α1 promoter activity. Conversely, miR299a-5p inhibition attenuated HG-induced COL1α1 promoter and Smad3 activation, as well as upregulation of ECM proteins. miR299a-5p is predicted to target the TGFβ1 inhibitor Cripto-1 (CR-1), and we previously showed that it targeted the activin inhibitor follistatin (FST). Here we show that HG decreased expression of both CR-1 and FST. This was similarly seen with miR299a-5p overexpression. CR-1 or FST treatment individually attenuated the increased COL1α1 promoter and Smad3 activity seen with miR299a-5p overexpression, and together showed an additive inhibitory effect.

Conclusions: These data support an important role for miR299a-5p in regulation of the profibrotic response to HG. Through suppression of two important antifibrotic proteins, CR-1 and FST, miR299a-5p potentiates the action of TGFβ family profibrotic cytokines. Future studies will determine whether inhibition of this miR can attenuate DKD.

The Nonsteroidal Mineralocorticoid Receptor Antagonist Finerenone Improves Left Ventricular Function in Preclinical Diabetic CKD

Ixchel Q. Lima Posada,[1] Yohan Stephan,[2] Matthieu Soulié,[2] Benjamin Bonnard,[1] Roberto Palacios Ramirez,[1] Lionel Nicol,[2] Peter Kolkhof,[3] Paul Mulder,[2] Frederic Jaisser.[1] Diabetes, metabolic diseases and comorbidities *[1]Centre de Recherche des Cordeliers, INSERM 1138, París, France; [2]Normandy University, INSERM U1096, Rouen, France; [3]Bayer AG, R&D Pharmaceuticals, Cardiovascular Research, Wuppertal, Germany*.

Background: The steroidal MR antagonist (MRA) spironolactone and eplerenone reduce mortality in patients with heart failure with reduced ejection fraction (HFrEF) but their use in patients with CKD is not indicated due to the associated risk of hyperkalemia. Finerenone is a non-steroidal MRA which recently reduced the composite kidney and cardiovascular outcomes in the phase III study FIDELIO in CKD patients with T2D. Purpose: To test whether finerenone improves renal and cardiac function in preclinical CKD rat models with T2D.

Methods: 12 weeks old male Zucker Diabetic rats (ZSF1) were used as model of diabetic CKD. Finerenone was administered at the dose of 10 mg/kg/d po. GFR (transcutaneous FITC-sinistrin) and cardiac LV function/hemodynamics (LV catheterization) and LV tissue perfusion (MRI) were assessed *in vivo* at the age of 24 weeks.

Results: 24-week old ZSF1 rats showed classical signs of CKD, with reduced GFR (1.44±0.11 ml/min/100g body weight for non-diabetic rats vs 1.04±0.16 ml/min/100g body weight for ZSF1, $p<0.05$). This was associated with LV diastolic dysfunction, illustrated by the increases in LV end-diastolic pressure (LVEDP; 5.58±0.57 vs. 8.04±0.81 mmHg, $p<0.05$), and LV end-diastolic pressure volume-relation (LVEDPVR; 1.10±0.23 vs. 5.63±0.54 mmHg/relative volume unit, $p<0.05$) without significant changes in LV end-systolic pressure (LVESP; 173±10 vs 197±5 mmHg) or LV end-systolic pressure volume-relation (LVESPVR; 32.7±4.2 vs 28.2±1.09 mmHg/relative volume unit). LV perfusion was reduced (5.21±0.37 vs 4.11±0.21 ml/min/g LV tissue; $p<0.05$). Finerenone treatment did not impact GFR in ZSF1 rats (0.93±0.17 ml/min/100g body weight) but reduced significantly LVEDP (5.72±0.76 mmHg, $p<0.05$) and LV end-diastolic pressure volume-relation (LVEDPVR; 2.73±0.33 mmHg/relative LV volume unit; $p<0.05$). Finerenone increased LV tissue perfusion (6.90±0.34 ml/min/g LV tissue).

Conclusions: Finerenone treatment improves CKD related LV diastolic function in diabetic CKD rats, independently from changes in GFR.

Development and Benchmarking of a Non-Human Primate Model of Diabetic Kidney Disease

Raul Camacho,[1] Flordeliza P. De Villa,[2] Zhenghua Zhu,[2] Yong Yang,[2] Rosario M. Perez,[2] Jialin Xu,[1] David Polidori,[1] Andrea R. Nawrocki.[1] *[1]Janssen Pharmaceutical Companies of Johnson and Johnson, Spring House, PA; [2]Kunming Biomed International, Kunming, China.*

Background: Diabetic Kidney Disease (DKD) is the largest cause of end stage renal disease and is responsible for 40% of new patients that require dialysis. To test novel therapies for DKD, we sought to develop a non-human primate (NHP) model of DKD that would be more representative of the etiology of human disease than genetically modified mouse models and support human dose prediction and biomarker development.

Methods: Cynomologus monkeys were fed a high fat/cholesterol diet for 5.1±2.5 (mean±SD) years and became obese (9.1±1.6 kg), hyperglycemic (267±78 mg/dL), hypertensive (systolic blood pressure [SBP] 141±11 mmHg), and macroalbuminuric (urine albumin/creatinine ratio [UACR] 562±346 mg/g). The responsiveness of the monkeys to pharmacological intervention was benchmarked using irbesartan, an angiotensin II receptor blocker (ARB), which is clinically used to treat DKD. Animals were orally dosed daily for 8 weeks with either vehicle (n=8) or irbesartan (n=14, 3 mg/kg).

Results: Exposures 24-hours after dosing were 165±111 ng/mL, similar to exposure in humans with therapeutic doses. Treatment effects on SBP (-23±8 vs. +2±15 mmHg, irbesartan vs. vehicle), urinary albumin excretion (UAE; -23% vs. +55%, irbesartan vs. vehicle) and UACR (-42% vs. +43%, irbesartan vs. vehicle) were consistent with effects seen in humans with DKD treated with irbesartan for 12 weeks. Pharmacokinetic/pharmacodynamic modeling of the observed NHP UAE response at 8 weeks suggested a similar exposure-response relationship in the NHP model as in human DKD with the magnitude of reductions being somewhat larger in the monkeys than in humans.

Conclusions: Together, these data demonstrate that we have developed and benchmarked a novel NHP model for DKD that has characteristics similar to human pathology and responds to a treatment known to improve DKD in clinical trials. This model is expected to be a valuable translational model for testing novel interventions for DKD.

Insulin Receptor Signaling Is Necessary for NFκB-Activated Host Defense Responses in Murine Intercalated Cells

Laura Schwartz,[1] Tad Eichler,[1] Pearlly Yan,[2] John D. Spencer.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Urinary tract infection (UTI) disproportionately affects select groups, especially those with insulin resistance and diabetes mellitus. Kidney intercalated cells (IC) play a key role in preventing UTI by regulating urine pH and secreting cytokines and antimicrobial peptides (AMP). Our data show that insulin receptor (IR) deletion in murine IC causes insulin resistance and increases UTI risk *in vivo* while having no impact on glucose homeostasis or urine acidification. Here, we profile the transcriptomes of IC isolated from IR knockout (IRKO) mice and controls (WT) to identify IR-mediated host defenses.

Methods: *Insr* gene was deleted in murine IC by breeding *Atp6v1b1*-Cre transgenic mice with IR-floxed mice. A tdT reporter was added to aid fluorescence-assisted cell sorting (FACS) of IC. RNAseq was performed on IC and read count data were analyzed for differentially expressed genes (DEG) using edgeR. DEG were defined with FDR adjusted *p*-value < 0.05. Canonical pathway analysis of DEG was performed using Ingenuity Pathway Analysis. Sorted IC were cultured and challenged *in vitro* with uropathogenic *E.coli* (UPEC) to assess response and susceptibility to infection. To define the contributions of NFκB to UTI defense, *NFKB1* was silenced in human medullary cells using siRNA. UPEC attachment and invasion assays were performed.

Results: FACS-enriched IC express IC-specific genes like *Aqp6* and *Atp6v0d2*. Differential expression analysis reveals suppression of 138 genes and upregulation of 232 genes in IRKO vs WT IC. In IRKO IC, a decrease in *Insr* as well as downstream IR-regulated targets and host defense genes such as AMPs were observed. While diverse pathways implicated in innate immunity are suppressed in IRKO IC, many converge on one target: NFκB. When cultured IC from these mice are challenged with UPEC, IRKO IC exhibit suppressed NFκB activation and UPEC were more likely to invade them. Silencing *NFKB1* results in decreased AMP expression and increased UPEC attachment and invasion of human medullary cells.

Conclusions: These data suggest IR signaling impacts the IC host defense transcriptome and identifies IR-sensitive pathways that aid in UPEC defense by activating NFκB signaling and expressing AMPs. A greater understanding of the factors that predispose diabetics to UTI may reveal novel, targeted therapies to prevent/treat diabetes-associated UTI.

Differences in Kidney Integrin Alpha-2 Expression Between Humans and Preclinical Models

Pavlos Pissios,[1] Matthew M. Rankin,[2] Tao Chen,[3] Nikolay O. Bukanov,[1] Matthew D. Breyer,[1] Maria chiara Magnone.[1] *[1]CVM, Janssen Research and Development LLC, Boston, MA; [2]CVM, Janssen Research and Development LLC, Spring House, PA; [3]NCS, Janssen Research and Development LLC, Shanghai, China.*

Background: Integrin α2 (ITGA2) forms heterodimers with integrin β1 and is one of the four collagen binding integrins with preference for collagen I. Published results implicate α2 in the regulation of kidney injury. Whole body deletion of integrin α2 protects mice from kidney injury in the 5/6 nephrectomy and adriamycin models of nephropathy, and α2 expression in mesangial cells has been proposed to contribute to kidney pathology through regulation of matrix production. We assessed the distribution of α2 protein in human DKD kidney and in multiple preclinical species to get a better understanding of the cell types expressing α2.

Methods: Human kidneys from normal and DKD subjects, as well as kidneys from diabetic mice, rats and cynomolgus monkeys were evaluated by immunohistochemistry (IHC) for α2 expression. Staining antibody was validated with kidneys from α2-KO mice. Identification of α2-positive kidney cell types and scoring was performed by a trained pathologist. Protein expression was compared with RNA expression in snRNAseq datasets from human DKD kidneys and kidneys from db/db mice.

Results: All species showed strong staining in the medulla, but significant differences were noted in the cortical α2 expression between humans and other species. Mainly mesangial, endothelial and distal tubular staining was seen in human kidney cortex. Podocytes were negative while proximal tubules stained weakly. Consistent with IHC data, strong a2 expression in human distal tubules and weaker expression in proximal tubules and glomerular cell types is seen in snRNAseq data. In contrast, mice showed mainly podocyte and endothelial staining. Mesangial cells and mouse proximal tubules were negative for α2, and distal tubules in the cortex stained weakly. Rat kidneys were negative for glomerular α2 expression with medium to strong positivity in the distal tubules of the cortex. Finally, cynomolgus monkeys showed α2 expression in all glomerular cell types: podocytes, endothelial and mesangial, weak staining in proximal and medium to strong staining in distal tubules. Decreased α2 glomerular staining was observed in DKD kidneys compared to normal kidneys.

Conclusions: Differences in integrin α2 cellular expression pattern must be considered when extrapolating function from lower to higher species.

The HIV Protease Inhibitor Darunavir Protects Against Diabetic Kidney Injury in Mice and Alters Stress Granule-Associated Signaling

Xiaobo Gao, Fnu Sonia, Heidi Karttunen, Buadi Tandoh, Michael J. Ross. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Despite the success of antiretroviral therapy (ART) in improving mortality, persons living with HIV (PLWH) still have increased risk of death and kidney disease and diabetes mellitus are important contributors to this excess mortality. Previously published studies in our laboratory demonstrated that the HIV protease inhibitor darunavir (DRV) prevents kidney injury via mechanisms that are independent of HIV protease but the mechanisms by which DRV protects against renal injury remain unclear. Studies in our lab found that DRV binds to several stress granule (SG) associated proteins, including G3BP1. SG are membraneless organelles composed of translationally arrested mRNAs and ribonucleoproteins and have important roles in stress and injury responses.

Methods: Diabetes was induced in 9-week-old eNOS-/- C57BL/6 mice by administration of 5 daily 50 mg/kg doses of streptozotocin (STZ). 14 weeks later, mice were treated with either DRV (100mg/kg) or control by daily oral gavage for 4 weeks. Urinary albumin-to-creatinine ratio (UACR) assay, immunofluorescence (IF) microscopy, western blotting and real-time PCR were performed according to routine protocols in our laboratory. For in vitro studies, human proximal tubular cells (HPT1b) at 40-60% confluence were transfected with Accell siRNA for G3BP1 in Accell Delivery Media.

Results: STZ induced severe hyperglycemia and kidney injury in eNOS-/- mice, which resulted in marked increase in UACR. DRV treatment markedly reduced UACR, attenuated tubulointerstitial fibrosis as detected by type 1 collagen and fibronectin, and prevented loss of podocyte synaptopodin and endothelial CD31 expression in glomeruli as detected by IF. IF studies also demonstrated that G3BP1 and phosphorylation of Stat3,

Src, and Erk were increased in the kidneys of diabetic eNOS-/- mice and these changes were reduced by DRV treatment. To directly test the role of G3BP1 in promoting Stat3, Src, and Erk phosphorylation, we used siRNA to knock down G3BP1 expression in human tubular cells, which reduced phosphorylation of Stat3, Src and Erk.

Conclusions: These data suggest that DRV prevents diabetes-induced kidney injury in mice in part, via interactions with the SG protein G3BP1. Additional studies are needed to further delineate the effects of targeting SG function upon diabetic kidney injury.

The Role of Intestinal Flora in Cinnamaldehyde Alleviating Early Proteinuria in Diabetic Nephropathy

Huanhuan Yin, Xiaoxiao Shi, Yan Liu, Dan Yang, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Intestinal dysbiosis played a crucial role in chronic inflammation of diabetic nephropathy (DN). Cinnamaldehyde (CIN) is a traditional natural food addictive from a Chinese herb, recognized as antidiabetic and antibacterial medicine recently. This study was to observe the effects of CIN on renal injury and intestinal flora in DN.

Methods: A total of four groups of rats included DN group induced by streptozotocin (70mg/kg), treated with CIN (DNC), control (NC), and NC treated with CIN (NCC). CIN was given daily for 8 weeks. Blood glucose, bodyweight, 24h urinary volume (24hV), protein (24hUP), the pathology changes of kidney, and the protein expression of Megalin, Fibronectin, TGF-β were measured. We also sequenced 16S rDNA of the intestinal flora of the rats.

Results: Compared with DN, DNC showed significant improvement with lower 24hUP, decreased TBM thickness, Fibronectin, TGF-β, and increased Megalin. Simpson's diversity index of the intestinal flora significantly decreased in the DNC group. PCoA (Fig. A) showed different patterns of clustering between the 4 groups ($p<0.01$). At genera, compared with NC, *g__Lactobacillus* decreased significantly in DN, but recoverd in DNC, and it was also confirmed as significant biomarkers by LEfSe (Fig. B). Besides *g__Lactobacillus*, there were 12 other differentially enriched genera in DNC, such as *g__Alloprevotella*, and *g__Oscillospira*. At species, 3 species decreased in DN and recovered in DNC, including *s__Bacteroides_massiliensis*, *s__Oscillibacter_sp_ER4*, and *s__Lachnospiraceae_ bacterium_ A2*. They were anti-inflammatory probiotics that produce short-chain fatty acids. The abundance of 6 genera correlated well with 24hUP ($p<0.05$, Fig.C). Tax4fun (Fig.D) showed significant differentially enriched functional categories.

Conclusions: Cinnamaldehyde could alleviate renal injury in DN, which was associated with the recovery of the reduced intestinal *g__Lactobacillus.*

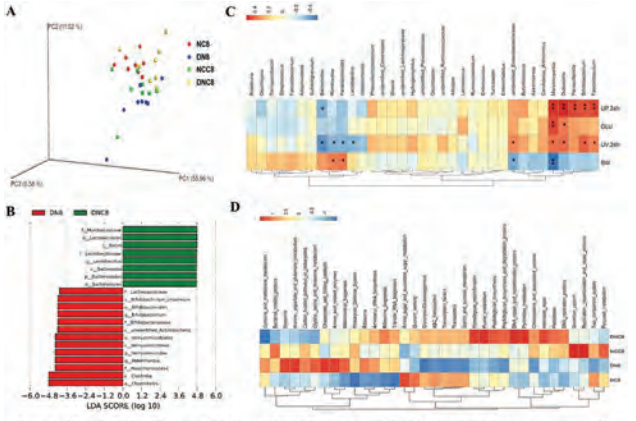

Figure 1. Altered intestinal flora. A: PCoA (weighted UniFrac distance). **B: LEfSe** (LDA>4). **C: Spearman** correlation analysis. **D. Tax4fun** function prediction (KEGG database). NC8: normal control 8W; DN8: diabetic nephropathy 8W; NCC8: normal control treated with CIN 8W; DNC8: diabetic nephropathy treated with CIN 8W. BW: bodyweight. GLU: blood glucose. 24hUP: 24-hour urinary protein. 24hUV: 24-hour urinary volume.

PO0693

Hyperglycemia-Induced Mitochondrial Dysfunction in Kidney and Brain Are Protected by β-Hydroxybutyrate Treatment

Viktor Drel, Deborah Holstein, Jiwan J. Kim, Annapurna Pamreddy, James D. Lechleiter, Kumar Sharma. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: The immediate effects of hyperglycemia on mitochondrial and organ dysfunction are poorly understood. Acute hyperglycemia could reveal key initiating events to determine how organ dysfunction ensues, particularly in response to repeated hyperglycemia exposures as occurs with poorly controlled diabetes. The potential protective benefit of ketone bodies on mitochondrial function across organs during hypergylcemia has also not been well characterized. Here, we evaluated effects of hyperglycemia and β-hydroxybutyrate (BHB) on ATP production in the mouse using a novel *in vivo* brain imaging approach in combination with MALDI-MSI.

Methods: GFAP-fLuc dual-glo transgenic mice were used to test the effect of BHB on brain luciferin-luciferase biolumenescence using a Xenogen IVIS spectrum live-imaging system. Transgenic dual-glo mice expressed the luciferase in astrocytes under the gfap promoter. MALDI-MSI analysis was used to detect the acute impact of BHB on small molecule metabolites in the kidneys and brains of C57BL/6J mice. For *in vivo* experiments, mice were administered either 2.5 g/kg of BHB, 2 g/kg of glucose, a combination of BHB and glucose, or 0.9% NaCl (vehicle control). We determined the timing effect of 20 mM BHB on mitochondria function and glycolysis in HK2 cells, in fresh mice kidney, and in brain tissue using pH and OCR measurements with the Agilent Seahorse instrument.

Results: We found reduced levels of ATP in both brain and kidney tissue slices of mice acutely treated with 25 mM glucose with MALDI-MSI. BHB treatments increased ATP levels in the brain and kidney tissues and cells. Acute glucose exposure in HK2 cells reduced OCR and increased ECAR, which was blocked by BHB treatment. *In vivo*, brain bioluminescence was significantly decreased when mice were injected with 25 mM glucose (4 minutes after luciferin injections), consistent with a loss in ATP production. In contrast BHB injections increased biolumenscence and blocked the loss of signal in the presence of high glucose.

Conclusions: These data indicate that acute glucose exposure reduces ATP production in the kidney and brain, and that BHB can reverse this effect. Together, these studies suggest the acute detrimental effects of hyperglycemia on metabolism and mitochondrial dysfunction can be reversed with ketone bodies treatment.

Dysfunction of the Renal Tubular Circadian Clock Leads to Enhanced Renal Gluconeogenesis and Exacerbated Hyperglycemia in Diabetes

Camille Ansermet,[1] Gabriel Centeno,[1] Yohan Bignon,[1] Andy Garcia,[1] Sylvain Pradervand,[2] Dmitri Firsov.[1] *[1]Department of Biomedical Sciences, University of Lausanne, Lausanne, Switzerland; [2]Genomic Technologies Facility, University of Lausanne, Lausanne, Switzerland.*

Background: The circadian rhythms define all biological process cycling with a periodicity of about 24 hours. They are believed to be an evolutionary adaptation that allows biological functions to anticipate variations of environmental conditions imposed by Earth rotation. These rhythms are driven by the circadian clock, a molecular system of interconnecting loops present in virtually each cell of the body. Disturbance of the circadian rhythms or its misalignment with external environment is a risk factor for development of numerous diseases, such as depression, obesity, diabetes or cancers. However, the pathophysiological role of intrinsic renal circadian clocks in the diabetic kidney remains unknown.

Methods: To address this question, we used mice with streptozotocin-induced type I diabetes, and carrying *Bmal1* deletion either in the podocytes (pcKO mice) or in whole renal tubular cells (tcKO mice).

Results: Although diabetic pcKO mice did not show any additional alterations compared to diabetic Control mice, diabetic tcKO mice showed exacerbated hyperglycemia, increased fractional excretion of glucose, enhanced polyuria and a more severe renal hypertrophy compared to diabetic Control mice. Interestingly, renal gluconeogenic pathway was enhanced in diabetic tcKO mice, as demonstrated by increased protein and mRNA expression levels of key enzymes. Moreover, deep sequencing transcriptome and functional analysis of diabetic cKOt mice showed alterations in several mechanisms affecting the gluconeogenic pathway.

Conclusions: Altogether, our data demonstrate that disturbance of renal tubular circadian clock enhances gluconeogenesis in proximal tubule, leading to the aggravation of the hyperglycemia of diabetic mice. These results highlight importance of circadian behaviour in diabetic patients.

Dysregulation of Thiosulfate Thiotransferase Pathway Contributes to Tubulointerstitial Injury of Diabetic Nephropathy

Jiaxiu Zhang, Kun ling Ma. *Institute of Nephrology, Southeast University, Nan Jing City, China.*

Background: Tubulointerstitial injury plays an important role in the progression of diabetic nephropathy (DN), and its severity is closely related to the prognosis of DN. Thiosulfate thiotransferase (TST) is a key enzyme that mediates protein S-sulfhydrylation and maintains mitochondrial metabolic homeostasis. This study aimed to investigate the role of TST in tubulointerstitial injury of DN and to explore its potential mechanisms.

Methods: Sodium thiosulfate (STS)-treated diabetic mice, adeno-associated virus with TST overexpression transfected diabetic mice, and cell culture model of HK-2 cells transfected by lentivirus with TST overexpression were used for experiments. The protein S-sulfhydration of very long-chain acyl-CoA dehydrogenase (VLCAD) was checked by Western blotting and mass spectrometry analysis. Tubular mitochondrial mitochondrial fatty acid β oxidation (FAO) was checked by ^{13}C labeling combined with mass spectrometry and Seahorse assay. Epithelial mesenchymal transition (EMT) related molecules of tubular epithelial cells were evaluated by immunofluorescent staining and Western blotting.

Results: Our results showed that the expression of TST was decreased in kidneys of diabetic mice and in high glucose-stimulated HK-2 cells, which was significantly correlated with decreased E-cadherin and increased protein expression of collagen I, fibronectin, and α-SMA. Furthermore, the down-regulation of TST expression led to the FAO dysfunction in kidneys of diabetic mice and in high glucose-stimulated HK-cells. On the contrary, STS treatment or overexpression of TST alleviated albuminuria and tubulointerstitial injury. The expression of collagen I, fibronectin, and α-SMA in TST transfected diabetic mice or HK-2cells were significantly decreased, while E-cadherin expression was increased. Further analysis showed that pharmacological inhibition of STS

or overexpression of TST improved mitochondrial FAO dysfunction and tubulointerstitial injury in diabetic mice and in high glucose-stimulated HK-2 cells, which was mainly through the increased S-sulfhydrylation modification of VLCAD.

Conclusions: These findings demonstrated that down-regulation of TST expression mediated the decrease of S-sulfhydrylation modification of VLCAD, which led to mitochondrial FAO dysfunction and then exacerbated the progression of tubulointerstitial injury in DN.

PO0696

CYP450: Protagonists in the Story of Diabetic Kidney Disease

Batoul Dia, Mohamad Noureldein, Sami Azar, Fuad N. Ziyadeh, Assaad Antoine Eid. *American University of Beirut, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) is a grave complication and a major contributor to all-cause mortality in patients with diabetes. Cytochrome P450 (CYPs) epoxygenases metabolize arachidonic acid into the vasoactive and renal-active HETEs and EETs. Our group, among others, advanced the discovery implicating CYPs and their metabolites in the pathogenesis of DKD by regulating reactive oxygen species. Of interest, CYPs-encoding genes possess different polymorphisms which alter the expression of these key enzymes, affecting the prognosis of patients with DKD. Noteworthy, the CYPs polymorphisms and their correlation with the production of 20-HETE and EETs in DKD remain poorly investigated. In the same spirit, extensive research has highlighted the role of different miRNAs in DKD. To our knowledge, the regulatory effect of miRNAs on the expression of different CYPs in DKD is not yet established. In this study, we aim to elucidate the role of CYPs polymorphism, their metabolites, and miRNAs regulating their expression in the disease onset and progression of DKD.

Methods: Blood and urine were collected from patients with type 2 diabetes (T2D) with or without clinical manifestation of DKD. Levels of 20-HETE and EETs were assessed in the urine samples of the patients alongside with the renal CYPs enzymatic activities in human kidney biopsies. Besides, miRNA analysis was performed on the plasma collected from these patients to study CYP enzymes regulation using the Target Scan online tool.

Results: Our data show that the circulating levels of 11,12-EETs were decreased in patients with DKD when compared to T2D patients with no clinical signs of DKD, concomitant with an increase in the 20-HETE levels. Our results show that in patients with DKD, the expression of miRNA was altered ultimately leading to the downregulation of CYP2B6, CYP4A11 and CYP4F8 enzymes. Furthermore, patients with DKD carry CYPs polymorph with the minor allele frequency resulting in an alteration in their enzymatic activity and subsequently increasing 20-HETE and decreasing EETs production concomitant with a positive correlation with the expression of the corresponding CYPs in human kidney biopsies.

Conclusions: This study yields crucial findings about novel genetic and epigenetic pathways involved in DKD and identifies biomarkers related to CYPs pathways that could be of diagnostic, prognostic, and therapeutic value.

Metabolic Images Using Fluorescence Lifetime Imaging Reveals Metabolic Alteration in Proximal Tubular Epithelial Cells in Type 2 Diabetes

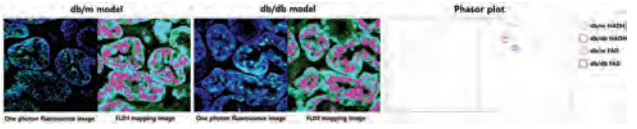
Woo Young Kwon,[1] Gun Tae Jung,[2] Su Woong Jung,[1] Yang gyun Kim,[1] Sangho Lee,[1] Kwang Pyo Kim,[3,2] Weon-Sik Chae,[4] Ju young Moon.[1] *[1]Division of Nephrology, Department of Internal Medicine, Kyung Hee University, College of Medicine, Seoul, Republic of Korea; [2]Department of Biomedical Science and Technology, Kyung Hee Medical Science Research Institute, Kyung Hee University, Seoul, Republic of Korea; [3]Department of Applied Chemistry, Institute of Natural Science, Global Center for Pharmaceutical Ingredient Materials, Kyung Hee University, Yongin, Republic of Korea; [4]Daegu Center, Korea Basic Science Institute, Daegu, Republic of Korea.*

Background: Although there is a massive metabolic alteration of the kidney in diabetes, it is difficult to detect and measure the single-cell nicotinamide adenine dinucleotide hydrogen (NADH), flavin adenine dinucleotide (FAD) production, and redox potential. In particular, proximal tubular epithelial cells (PTECs) are the most laborious and affected cells under high glucose environments. We investigated this study to evaluate quantitative PTECs-specific metabolic images in the diabetic kidney using fluorescence lifetime imaging (FLIM).

Methods: Kidney sections of 20 week-old db/db and db/m mice were used for FLIM. FLIM images are analyzed using the phasor approach. The FLIM image and phasor plot representing FLIM data in vector space were measured through Leica TCS SP8 SMD and LAS-X software. The NADH, FAD, and ATP levels in diabetic kidneys were measured using LC-MS analysis by Q-trap 5500.

Results: NADH and FAD located at the different subcellular levels in PTECs. The NADH phasor analysis of PTECs revealed a right-ward shift toward shorter lifetimes from the db/m to the db/db, while there was no significant alteration of FAD between the two groups. It could be indicative of an increase in the NADH-to-FAD ratio that alters metabolic flux. In addition, the levels of NADH in diabetic kidneys were significantly increased than db/m, while the levels of FAD were reduced in diabetic kidneys. Finally, ATP level decreased in the diabetic kidney compared to db/m.

Conclusions: NADH and FAD FLIM in PTECs is an optimal approach to characterize and monitor metabolism in diabetic kidneys. Quantitative metabolic imaging using FLIM enables to measure and analyze metabolic alteration with spatial information.



PO0698

Female Protection Against Diabetes-Induced Kidney Injury Is Eliminated in Kidney Tubule-Specific AMPK Gamma-2 Knockout Mice

Liang Min,[1] Jingli Gao,[1] Hak Joo Lee,[1] Guogang Xu,[1] Goutam Ghosh-Choudhury,[1,2] Balakuntalam S. Kasinath,[1,2] Kumar Sharma.[1,2] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX.*

Background: Reduction in renal AMPK activity is associated with obesity- and diabetes-induced kidney injury which is ameliorated by AMPK stimulation in male mice. Female mice resist obesity-induced kidney injury; this protection is abolished in kidney tubule specific α1 and α2 KO female mice. We tested if interruption of AMPK activity abolishes renal protection against diabetes in AMPK γ2 KO female mice. We also tested if diabetes worsens kidney injury in AMPK γ2 KO male mice.

Methods: 3-4 month-old tubule-specific AMPK γ2 KO male and female mice (n= 6-9 per group) were employed. To generate diabetic animal model, the mice were placed on high fat diet (HFD) for one month, then they received streptozotocin (STZ) 50mg/kg body weight by IP daily for 5 days. After 1 month STZ injection, urine was collected for analyzing urinary KIM-1 and ACR.

Results: Renal cortical expression of AMPK γ2 mRNA as well as protein was reduced in AMPK γ2 KO mice. There were no changes in body weight and random blood glucose level between control and AMPK γ2 KO male and female mice at the baseline. Body weight gain in control and AMPK γ2 KO mice in both genders was increased by HFD compared to normal fat diet fed groups. Random blood glucose level was increased in HFD and STZ-treated control and AMPK γ2 KO mice in both genders. As expected control female mice resisted HFD and STZ-induced kidney injury, whereas urinary KIM-1 excretion and albuminuria were increased in AMPK γ2 KO female mice. Urinary KIM-1 excretion and albuminuria were induced by diabetes in control and γ2 KO male mice with no statistical difference between two groups.

Conclusions: Renal protection against diabetes is abolished in kidney tubule specific AMPK γ2 KO female mice. Therefore, regulation of AMPK as well as its activity contributes to the protective mechanism against diabetes in female mice, and it could be used for a therapeutic target of diabetes.

PO0699

Mitochondrial Fission and Fusion Dynamics Are Regulated by Multiple Pathways in Renal Proximal Tubule Cells Treated with High Glucose

Kristan H. Cleveland, Rick G. Schnellmann. *The University of Arizona, Tucson, AZ.*

Background: In type 2 diabetes, hyperglycemia leads to proximal tubular dysfunction, which is accompanied by altered mitochondrial homeostasis. We previously demonstrated that in renal proximal tubule cells (RPTC) grown in high glucose, as well as in diabetic db/db mice, mitochondrial dynamics proteins were altered. Phosphorylation of the mitochondrial fission protein Drp1 increased and the mitochondrial fusion protein Mfn1 decreased. Studies have shown that Drp1 is activated by the RhoA/ROCK1 signaling cascade in the presence of high glucose, leading to increased mitochondrial fission. Conversely, Mfn1 can be activated by MEK/ERK signaling. However, these pathways have not been investigated in the proximal tubule. Therefore, we determined the signaling pathways responsible for altered Drp1 phosphorylation and Mfn1 expression in RPTC.

Methods: Primary cultures of RPTC were grown in the presence of high glucose (17mM), mannitol (17mM) or no glucose for 96hr and were co-treated with either RhoA (CCG-1423), ROCK1 (Y-27632) or MEK 1/2 (GSK 1120212) inhibitors 24 hr prior harvesting. Cells were subjected to GTPase assays to measure Drp1, RhoA and Mfn1 activity and maximal mitochondrial respiration was measured using Seahorse XF96e analyzer.

Results: RPTC treated with glucose for 96 hr exhibited an increase in RhoA and pDrp1 at 96 hr. This increase corresponded with an increase in GTP-bound RhoA and Drp1. Co-treatment with CCG-1423 or Y-27632 prevented the glucose-induced increase in RhoA and Drp1, respectively. Inhibition of RhoA and ROCK1 restored maximal mitochondrial respiration. Co-treatment with GSK 1120212 prevented the glucose-induced decrease in Mfn1.

Conclusions: Together, these results demonstrate that treatment of RPTC with glucose increases RhoA and Drp1 activity and maximal respiration. Pharmacological inhibition of RhoA and ROCK1 prevented increased activity of RhoA and Drp1 and restored respiration, indicating that the RhoA/ROCK1/Drp1 signaling pathway is responsible for increased mitochondrial fission and respiration in high glucose in RPTC. In contrast, we show that inhibition of the MEK/ERK signaling cascade prevents the decrease in Mfn1 observed in the presence of high glucose. These data indicate that the alteration of mitochondrial dynamics in high glucose in RPTC, are regulated by two independent signaling pathways.

Medications Targeting the Activation of Tubular Fatty Acid Oxidation Enhance the Renoprotective Effects of Roux-en-Y Gastric Bypass Surgery

William P. Martin,[1] Yeong Huei Desmond Chuah,[1] Mahmoud Abdelaal,[1] Anders Pedersen,[2] Daniel Malmodin,[2] Sanna Abrahamsson,[2] Michaela Hutter,[1] Catherine Godson,[1] Eoin Brennan,[1] Lars Fandriks,[2] Carel W. Le roux,[1] Neil G. Docherty.[1] *[1]Diabetes Complications Research Centre, University College Dublin, Dublin, Ireland; [2]Goteborgs Universitet, Goteborg, Sweden.*

Background: Roux-en-Y gastric bypass surgery (RYGB) improves biochemical and histological parameters of diabetic kidney disease (DKD). Targeted adjunct medical therapy may enhance renoprotection following RYGB.

Methods: The effects of RYGB (n=10) and RYGB plus fenofibrate 100mg/kg, metformin 300mg/kg, ramipril 1mg/kg, and rosuvastatin 10mg/kg (RYGB-FMRR; n=9) on metabolic control and histological and ultrastructural indices of renal injury were compared after 8 weeks of treatment in the Zucker Diabetic Sprague Dawley (ZDSD) rat model of DKD. Sham-operated ZDSD rats (n=9) and healthy Sprague Dawley rats (n=6) served as controls. Renal cortical transcriptomic (RNA-sequencing) and urinary metabolomic (^{1}H-NMR spectroscopy) responses were profiled and integrated. Omic correlates of improvements in structural and ultrastructural indices of renal injury were defined using a molecular morphometric approach.

Results: RYGB-FMRR was superior to RYGB alone with respect to metabolic control, albuminuria, and histological and ultrastructural indices of glomerular injury. RYGB-FMRR reversed DKD-associated changes in mitochondrial morphology in the proximal tubule to a greater extent than RYGB. Attenuation of transcriptomic pathway level activation of pro-fibrotic responses was greater after RYGB-FMRR than RYGB. Transcriptional induction of PPARα-regulated genes, expressed in the proximal tubule and governing fatty acid oxidation (FAO), was a unique feature of the RYGB-FMRR transcriptome associated with increased urinary PPARα-responsive nicotinamide metabolites and reduced urinary tricarboxylic acid (TCA) cycle intermediates. Multi-omic integration identified a strongly positively correlated network of FAO transcripts and nicotinamide metabolites as being distinctive to RYGB-FMRR. Changes in FAO transcripts, nicotinamide metabolites, and TCA cycle intermediates correlated strongly with improvements in glomerular and proximal tubular injury following RYGB-FMRR.

Conclusions: The renoprotective effects of RYGB can be enhanced through the deployment of medications targeting PPARα-mediated activation of tubular FAO responses.

Polyamine Catabolism Is Enhanced in Streptozotocin-Treated Mice and in Cultured Proximal Tubule Cells Exposed to High Glucose Levels: A Possible Role in Tubular Injury in Diabetic Nephropathy

Kamyar A. Zahedi,[1,2] Sharon L. Barone,[1,2] Marybeth Brooks,[1,2] Manoocher Soleimani.[1,2] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Raymond G. Murphy VA Medical Center, Albuquerque, NM.*

Background: Polyamines are indispensable to cell growth and survival. Their cellular levels are regulated via import, export and metabolism. Their catabolism is mediated via the activities of spermine oxidase (SMOX) and spermine spermidine-N1-acetyltransferase (SAT1)/Acetylpolyamine oxidase (PAOX) cascade. Enhanced polyamine catabolism mediates cellular injury by induction of DNA and mitochondrial damage, activation of the endoplasmic reticulum stress/unfolded protein response (ERS/UPR) pathway, and innate immunity. Studies indicate that mitochondrial dysfunction, innate immune response and ERS/UPR are important mediators of tubular injury in diabetic nephropathy. We posit that polyamine catabolism is activated in diabetes mellitus and plays an important role in tubular injury.

Methods: The expression of polyamine catabolic enzymes was examined in streptozotocin (STZ)-induced diabetes in mice and HK-2 proximal tubule cells exposed to high glucose (30mM) levels. The expression levels of SAT1 and SMOX were determined by northern and western blot analyses. Nephron segment expression and localization of SAT1 and SMOX in STZ-treated mice was determined by immunohistochemistry and immunofluorescence microscopy.

Results: Expression of SAT1 and SMOX were elevated in the kidneys of STZ-treated mice compared to their vehicle-treated counterparts. Immunohistochemical and immunofluorescence microscopic studies revealed that SAT1 and SMOX expression are increased the proximal tubule, distal convoluted tubule and collecting duct epithelial cells. *In vitro* studies using HK-2 cells demonstrated that the expression of both SAT1 and SMOX increases in response to exposure to 30mM glucose.

Conclusions: Expression of polyamine catabolic enzymes, SAT1 and SMOX, is increased in proximal tubules, distal convoluted tubules and collecting ducts of mice with diabetes mellitus. Similarly, exposure of HK-2 cells to 30mM glucose increased the expression of both SAT1 and SMOX transcripts. Based on these studies and their known injurious effects, we propose that SAT1 and SMOX play a significant role in the mediation of renal injury in diabetes mellitus likely through the induction of oxidative injury, mitochondrial damage, elevated ERS/UPR and activation of innate immune response.

An Interplay of Glucose, IL-1β, and PDGF-B Trigger cPLA2 Activation, Prostaglandin Secretion, and Proliferation in Human Mesangial Cells

Roberto Boi,[1] Kerstin Ebefors,[2] Jenny C. Nystrom.[2] *[1]Sahlgrenska universitetssjukhuset, Goteborg, Sweden; [2]Goteborgs universitet Sahlgrenska Akademin, Goteborg, Sweden.*

Background: Diabetic kidney disease (DKD) is commonly thought to be originated from diabetic hyperglycemia. DKD development is driven by early glomerular hemodynamic changes and characterized by progressive expansion of the mesangium. A connection between these findings is yet to be elucidated. We speculate that, after hyperglycemia priming, autocrine inflammatory and proliferative stimuli alter mesangial lipid metabolism activating the secretion of vasodilator hormones. Subsequently, this affects glomerular functions. Phospholipase cPLA2 was identified as the central enzyme of the metabolic cascade.

Methods: Human mesangial cells were stimulated with Glucose (30 mM), IL-1β (1 nM), PDGF-B (25 ng/ml). Their synergic counter activation was investigated by western blots and qPCR. Lipidomics was used to analyze lipid variations. Cox-2 induction and prostaglandin secretion were measured via western blot and ELISA. Activation of cPLA2, upstream of Cox-2, was studied using western blot, qPCR, activity assays. ELISA, migration, and proliferation assays were used to evaluate cPLA2 inhibition. Data were validated using the Nephroseq database.

Results: After stimulation with Glucose, NLRP3 and pro-IL-1β were upregulated. IL-1β stimulation increased PDGF-B mRNA levels. In turn, PDGF-B stimulation increased NLRP3 and pro-IL-1β protein levels. Lipidomics analysis after IL-1β and PDGF-B stimulations showed an increase of sphingosine 1 phosphate, a known activator of Cox-2. Cox-2 was induced and prostaglandins secreted accordingly. cPLA2 releases arachidonic acid, the substrate of Cox-2. cPLA2 was upregulated at gene and protein level and activated by phosphorylation. Upregulation of the pathway was confirmed in silico in DKD patients. Since cPLA2 reaction is the rate-limiting step in prostaglandin synthesis, its inhibition with AACOCF3 was studied. Inhibition of cPLA2 reduced migration, proliferation, secretion of prostaglandins in cells treated with IL-1β and PDGF-B.

Conclusions: External stimuli (hyperglycemia from the diabetic environment) and glomerular inflammatory and proliferative stimuli prime DKD early events. The upregulation of cPLA2 was found to be critical in these events. cPLA2 inhibition reduced mesangial secretion of prostaglandins, proliferation, and migration, making it a potential target for therapy.

CHOP-ASO Ameliorates Glomerular and Tubular Damage on Top of ACE Inhibition in Diabetic Nephropathy

Khurrum Shahzad,[1] Sameen Fatima,[1] Sven Michel,[2] Frank Jaschinski,[2] Richard Klar,[2] Berend H. Isermann.[1] *[1]Institute of Laboratory Medicine, Clinical Chemistry and Molecular Diagnostic, University Hospital, Leipzig, Leipzig, Germany; [2]Secarna Pharmaceuticals GmbH & Co. KG, Planegg, Germany.*

Background: Maladaptive ER stress signaling in diabetic nephropathy (dNP) is linked to increased glomerular and tubular expression of the cell death-promoting transcription factor C/EBP homologous protein (CHOP). We determined whether therapy with locked nucleic acid (LNA)-modified antisense oligonucleotides (ASOs) targeting CHOP ameliorates experimental dNP.

Methods: Following an *in vivo* dose-escalation study, we determined the efficacy of CHOP-ASO in the early and later stages of experimental dNP (8- or 16-week-old db/db mice, respectively) alone or in combination with an angiotensin-converting enzyme inhibitor (ACEi). Renal functional parameters and morphological analyses were used to determine the effects. Renal gene expression profiling was conducted to determine differentially regulated genes and pathways. Several human CHOP-ASOs were tested in hyperglycemia-exposed human kidney cells.

Results: CHOP-ASOs efficiently reduced renal CHOP expression in diabetic mice and reduced markers of dNP at early and late stages. Early combined intervention (CHOP-ASO and ACEi) efficiently prevented interstitial damage. At the later timepoint, the combined treatment reduced indices of both glomerular and tubular damage more efficiently than either intervention alone. A significantly larger number of genes and disease pathways were affected by CHOP-ASO, including reduced Slc5a2 (sodium-glucose transport protein 2). Human CHOP-ASOs efficiently reduced glucose-induced CHOP and SGLT2 expression and prevented cell death of human kidney cells *in vitro*.

Conclusions: The ASO-based approach efficiently reduced renal CHOP expression in a diabetic mouse model, providing an additional benefit to an ACEi in particular at later timepoints. These studies demonstrate that ASO-based therapies efficiently reduce maladaptive CHOP expression and ameliorate experimental dNP.

PO0704

Suppression of Endoplasmic Reticulum-Associated Degradation Process by Intraglomerular Cross-Talk Between Podocytes and Mesangial Cells Causes Podocyte Injury in Diabetic Kidney Disease

Daisuke Fujimoto, Takashige Kuwabara, Yusuke Hata, Ryosuke Date, Masashi Mukoyama. *Kumamoto University, Department of Nephrology, Kumamoto City, Japan*.

Background: Mesangial lesion and podocyte injury are essential for the progression of diabetic kidney disease (DKD). Although crosstalk between mesangial cells (MCs) and podocytes is recently suggested by single nucleus RNA-sequence analyses, its molecular mechanisms and role on disease progression still remain elusive.

Methods: We evaluated the ER stress responses of podocytes stimulated with mesangial cell-cultured medium (MC-sup) under high-glucose condition (HG) *in vitro*. Then, the effects of an ER-associated protein degradation (ERAD) inhibitor eeyarestatin I (EerI) in cultured podocytes and glomeruli of *db/db* (type 2 diabetic) mice were also examined by western blotting, immunofluorescence and TUNEL staining. Furthermore, we evaluated the effect of ERAD inhibitor on nephrin phosphorylation of podocytes by flowcytometric analysis and western blotting.

Results: *In vitro* experiments revealed the suppression of the ER-associated degradation (ERAD) pathway and induction of apoptosis in podocytes that were stimulated with the supernatant of mesangial cells cultured in high glucose conditions. In diabetic mice, ERAD inhibition resulted in exacerbated albuminuria, increased apoptosis in podocytes, and reduced nephrin expression associated with the downregulation of ERAD-related biomolecules. Flowcytometry analysis of podocytes isolated from MafB (a transcription factor known to be expressed in macrophages and podocytes)-GFP knock-in mice revealed that ERAD inhibition resulted in decreased nephrin phosphorylation. Decreased nephrin phosphorylation was also confirmed in *in vitro* experiments.

Conclusions: ERAD process has been reported to be important for avoiding ER stress and cellular damages. Our findings suggest that an intraglomerular crosstalk between MCs and podocytes can inhibit physiological ERAD processes and suppress the phosphorylation of nephrin in podocytes, which thereby lead to podocyte injury under diabetic conditions. Therapeutic intervention of the ERAD pathway through the crosstalk between these cells is potentially a novel strategy for DKD.

PO0705

DPP4 Inhibitors Ameliorates Endoplasmic Reticulum Stress in Diabetic Kidney Disease Through Upregulation of SIRT1

Qunzi Zhang, Ying Fan, Niansong Wang. *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China*.

Background: Endoplasmic Reticulum (ER) stress plays vital roles in the progression of diabetic kidney disease (DKD), and Dipeptidyl peptidase-4 (DPP4) inhibitors are widely used antihyperglycemic agents, further exerting renal beneficial effects in DKD, but the precise mechanism underlying the disruption of these processes remains unclear. We examined whether SIRT1/STAT3 pathway regulated ER stress in the progression of DKD.

Methods: *In vivo*, male DBA2/J mice were injected by streptozotoxin to form diabetic mice models, then sitagliptin(Sita) was gavaged to inhibit DPP4. We collected and analyzed kidney samples, urine and serum. *In vitro*, human HK-2 cells were exposed to human serum albumin (HSA), then regulated DPP4, SIRT1 with inhibitors, siRNAs and mutant plasmids. Outcome measures included ER stress, expression of GRP78, CHOP, phosphorylation of PERK (p-PERK), cleaved caspase3 (c-CASP3), SIRT1 and STAT3.

Results: ER stress were observed both in diabetic mice and in HSA-induced human HK-2 cells, as reflected by notably increased GRP78, CHOP, highly phosphorylation of PERK (p-PERK) and elevated cleaved caspase3 (c-CASP3), whereas Sita effectively attenuated these disorders. Meanwhile, Inhibited DPP4 increased the expression of SIRT1 both *in vivo* and *in vitro*, which has a protective effect on diabetic ER homeostasis, whereas decreased SIRT1 accentuated ER stress. Moreover, partly through elevated SIRT1, Sita regulated mitochondrial STAT3 and phosphorylation of STAT3 at ser727, which is required for STAT3 to import into mitochondria. Our work found that the inhibition of DPP4 ameliorated ER stress in DKD partly through SIRT1/STAT3 signaling pathway.

Conclusions: The results suggested a novel mechanism links the DPP4 enzyme to ER stress during tubular injury in DKD and highlight that SIRT1/STAT3 pathway may become a potential target for managing DKD.

PO0706

Wnt5a-Ca2+ Non-Canonical Pathway Mediates Mitochondrial Dysfunction in the Progression of Diabetic Nephropathy via Mitochondrial Calcium Uniporter

Yang Fei, Ying Fan, Qunzi Zhang, Niansong Wang. *Shanghai Sixth Peoples Hospital, Shanghai, China*.

Background: Mitochondrial abnormalities play crucial roles in diabetic tubular injury progression. Abnormal expression of Wnt5a has been detected in many metabolic diseases. However, the association of Wnt5a and mitochondrial dysfunction in diabetic nephropathy (DN) progression remains unknown.

Methods: Diabetic DBA2/J mice induced by streptozotocin were assigned to amlodipine (5mg/kg/d) and losartan (10mg/kg/d) for eight weeks. The expression of Wnt5a, mitochondrial dynamics associated proteins (Drp1 and Mfn2), mitochondrial calcium uniporter (MCU) were examined through Western blot and immunohistochemistry in kidney of STZ-induced diabetic and high glucose stimulated HK-2 cells. Calcium concentration in cells and mitochondria was detected through specific ELISA kit.

Results: In this study, upregulation of Wnt5a, increase of both cellular and mitochondrial Ca^{2+}, mitochondrial fragmentation and altered mitochondrial dynamics-associated protein expression were detected in the tubules of diabetic mice and in high glucose stimulated HK-2 cells. In vitro, Wnt5a overexpression induced the Ca^{2+} influx and aggravated mitochondrial fusion-fission disorder. After amlodipine treatment, this Wnt5a-Ca^{2+} pathway was restored, mitochondrial dynamics and morphological changes was improved. Additionally, increase of MCU was also observed in the mitochondrial of tubular cells in DN, suggesting a possible link between Wnt5a-Ca^{2+} pathway and mitochondrial dysfunction.

Conclusions: Our study presented that Wnt5a-Ca2+ signaling pathway might be involved in mitochondrial dysfunction in the progression of DN, and MCU was possibly recognized as the important link during the regulation.

PO0707

The Potential Roles of NAD(P)H:Quinone Oxidoreductase 1 in the Development of Diabetic Nephropathy and Actin Polymerization

Jin young Jeong,[1] Dae Eun Choi,[1] Yoon-Kyung Chang,[2] Kiryang Na,[1] Kang Wook Lee.[1] *[1]Chungnam National University School of Medicine, Daejeon, Daejeon, Republic of Korea; [2]Daejeon Saint Mary's Hospital, Daejeon, Daejeon, Republic of Korea*.

Background: Diabetic nephropathy (DN) is a major complication of diabetes mellitus. NAD(P)H:quinone oxidoreductase 1 (NQO1) is an antioxidant enzyme that has been involved in the progression of several kidney injuries. However, the roles of NQO1 in DN are still unclear. We investigated the effects of NQO1 deficiency in streptozotocin (STZ)-induced DN mice.

Methods: Wild-type (WT) and NQO1 KO male mice on C57BL/6N genetic background were used. For the diabetic nephropathy model, STZ was dissolved in citrate buffer (0.1 M; pH 4.5) and prepared immediately before use. Age-matched 8-week-old WT and NKO male mice were administered STZ (50 mg/kg body weight, intraperitoneal injection) after 4 h fasting, for five consecutive days. ACR were measued. Renal histology and molecular evaluation were done.

Results: NQO1 was upregulated in the glomerulus and podocytes under hyperglycemic conditions. NQO1 knockout (NKO) mice showed more severe changes in blood glucose and body weight than WT mice after STZ treatment. Furthermore, STZ-mediated pathological parameters including glomerular injury, blood urea nitrogen levels, and foot process width were more severe in NKO mice than WT mice. Importantly, urine albumin-to-creatinine ratio (ACR) was higher in healthy, non-treated NKO mice than WT mice. ACR response to STZ or LPS was dramatically increased in the urine of NKO mice compared to vehicle controls, while it maintained a normal range following treatment of WT mice. More importantly, we found that NQO1 can stimulate actin polymerization in an in vitro biochemical assay without directly the accumulation on F-actin.

Conclusions: NQO1 has an important role against the development of DN pathogenesis and is a novel contributor in actin reorganization via stimulating actin polymerization.

PO0708

The Renoprotective Effects of the Soluble Guanylate Cyclase (sGC) Activator Runcaciguat Are Associated with Distinct Changes in Renal Gene Expression Profiles

Jan R. Kraehling, Heidrun C. Ellinger-Ziegelbauer, Agnes M. Benardeau, Mira Pavkovic, Ilka Mathar, Julia Vienenkoetter, Frank Eitner, Peter Sandner. *Bayer AG, Leverkusen, Germany*.

Background: Chronic kidney disease (CKD) progression is associated with impaired NO-sGC-cGMP-signaling, low cGMP production and increased oxidative stress. Oxidative stress modifies the native sGC to oxidized, heme-free apo-sGC which cannot be activated by NO anymore. Runcaciguat is a novel potent and selective sGC activator that binds and activates heme-free sGC independently of NO and, thereby, restores cGMP signaling. In the ZSF-1 rat CKD-model, runcaciguat displays renoprotective effects (pronounced decrease in proteinuria and lowering of HbA1c and triglycerides). To understand the underlying mode of action of the renoprotective and metabolic effects of runcaciguat, we investigated the renal gene expression profile.

Methods: The renal expression profile of genes affected by 3mg/kg/bid runcaciguat in obese ZSF1 rats treated between 16 to 27 weeks of age was analyzed with a microarray (all known rat genes) and compared to gene expression changes of lean relative to obese ZSF1 rats aged 14 to 26 weeks to show deregulation over the course of the disease progression.

Results: With the selected deregulation thresholds, 45 and 82 genes were expressed at higher and lower levels after runcaciguat treatment, respectively. Thresholds were set as 1.6-fold differences between vehicle and treatment group with $p<0.05$. Most of the genes decreased by runcaciguat also show decreased expression in lean vs. obese ZSF1 rat kidney, suggesting that runcaciguat converts the kidney expression profile of obese ZSF1 rats partly to the lean pattern. Most of these genes encode proteins involved in fibrosis (e.g. collagens), inflammation (e.g. cytokines), and degeneration/regeneration (e.g. cell cycle progression genes, lipocalin 2) which is supported by the Ingenuity pathway analysis (IPA)

Conclusions: The runcaciguat-induced gene expression changes clearly indicate an at least partial reversal of the fibrotic phenotype and enhanced vascular-endothelial functions in the ZSF-1 CKD rat model. These changes could contribute to the renoprotective effect of runcaciguat. Runcaciguat is currently evaluated in a Ph2a clinical trial (CONCORD) for CKD.

Exogenous Hydrogen Sulfide Protects Kidneys of Diabetic Mice from Oxidative Injuries

Xueqi Chen,[1,2] Leijuan Xiao,[2] Zhiyun Ren,[1] Weiwan Wang,[1] Yutao Jia,[1,2] Yanting Yu,[1,2] Xiaoyan Wang.[1,2] The Core Laboratory for Clinical Research *[1]The Core Laboratory, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China, Nanjing, China; [2]Department of Nephrology, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China, Nanjing, China*.

Background: Exogenous hydrogen sulfide (H2S) protects kidneys from diabetic injuries in animal models. In order to explore its mechanisms, we determined the effects of H2S donor on renal reactive oxygen species (ROS) related enzymes in diabetic mice.

Methods: Male C57Bl/6J mice (8 weeks old) were intraperitoneally injected with STZ at 50mg/kg/day for 6 days. GYY4137 (20 mg/kg/day in 6 ml of drinking water, GYY+DM group, n=5) or vehicle (6 ml of drinking water, DM group, n=4) plus 60% fat diet were fed the mice 2 weeks after the initial STZ injection when blood glucose remained high relative to background mice. The 2 groups of diabetic mice were injected with long-acting insulin (10U/kg) weekly at week 3.

Results: GYY4137 ameliorated albuminuria and hyperglycemia at weeks 8 & 10. Serum insulin and creatinine were similar in the diabetic mice. Renal morphologic structures (HE, Massson, PAS) were improved by GYY4137 at week 10 when the mice were sacrificed. Renal nitrotyrosine (protein oxidative injury marker) was decreased along with the decrease of laminin (early fibrosis marker) in GYY+DM mice relative to DM mice (western blotting). NOX2, NOX4 were lower but NOS1, HO2, PON1, PON2 were higher in GYY+DM than those in DM group. NOS2, NOS3, NOX1, HO1, SOD1-3 and COX1 were similar between groups. The levels of mRNA were not in agreement with the changes in proteins with all enzymes but HO2.

Conclusions: Our findings suggest that exogenous H2S may decrease ROS production and increase ROS cleavage in kidney via the affected enzymes, thus improve the renal oxidative damage in diabetic nephropathy.

PO0710

Downregulation of Ehhadh and Tubular Dysfunction in Diabetic Nephropathy

Jianyong Zhong, Haichun Yang, Raymond C. Harris, Agnes B. Fogo. *Vanderbilt University Medical Center, Nashville, TN*.

Background: As a peroxisomal protein, enoyl-CoA hydratase and 3-hydroxyacyl CoA dehydrogenase (Ehhadh) catalyzes the second and third committed steps in the peroxisomal beta-oxidation pathway. Ehhadh also interacts with catalase and peroxisomal biogenesis factor 5 (PEX5), which decomposes hydrogen peroxide and regulates peroxisomal biogenesis, respectively. Previously we detected reduced tubular Ehhadh expression in human and mouse diabetic nephropathy. This study aims to investigate the potential impact of Ehhadh on peroxisomal/mitochondria functional change in response to high glucose in vitro.

Methods: Primary cultured proximal tubular epithelial cells (PTC) were exposed to high glucose, mannitol or control medium. Ehhadh subcellular localization and peroxisome quantitation (area per cell) were analyzed by confocal microscopy. Ehhadh, catalase, PEX5, ACOX1, Hsd17d4, scp2, ACAA1, cpt1a, Acadm, AHDHB, Acat1 and ACAA2 mRNA expression were assessed by qPCR. Peroxidase activity and oxidase stress were also analyzed.

Results: Ehhadh transcription and protein were significantly downregulated in PTC under high glucose conditions. Ehhadh was localized mostly to peroxisomes and rarely in mitochondria. Key enzymes for beta-oxidation in peroxisomes (ACOX1, Hsd17d4, scp2 and ACAA1) and mitochondria (cpt1a, Acadm, AHDHB, Acat1 and ACAA2) were not changed under high glucose conditions. Catalase transcription and peroxidase activity were reduced in high glucose vs control. PEX5 was also reduced, but peroxisome quantitation was increased 39.6% under high glucose conditions. Oxidative stress was also increased 7.6% in high glucose vs control.

Conclusions: Ehhadh downregulation is associated with reduced peroxidase activity, increased peroxisomal biogenesis and oxidative stress in PTC. Whether altering Ehhadh can impact such dysfunction awaits further study.

Oxidative Stress on the Kidney and Heart of Rats with Diabetic Nephropathy Treated with Esculin

Inri F. Rodrigues,[1] Giovana Punaro,[2] Deyse Y. Lima,[2] Tiphany C. De Bessa,[3] Margaret G. Mouro,[2] Angela Bertolini,[2] Robson S. Serralha,[2] Elisa M. Higa.[2] Laboratory of Nitric Oxide and Oxidative Stress *[1]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [3]Universidade de Sao Paulo, Sao Paulo, Brazil*.

Background: Diabetes mellitus is a chronic disease which progresses with complications such as diabetic nephropathy (DN) and diabetic cardiomyopathy. Esculin (ESC) and its metabolite, esculetin, are coumarin derivatives, belonging to the Oleaceae family, found also in some more known species in the southern hemisphere, such as the pink lemon (Citrus limonia). ESC has been related to antioxidant (AO), anti-inflammatory and anti-apoptotic actions. The aim of the present study was to verify the role of oxidative stress (OS) on the kidney and the heart of rats with DN, and the ESC effect on them.

Methods: We used adult male Wistar rats (N=20), Ethics Committee # 3511260318. Normal rats (CTL) or with blood glucose> 200mg/dL, diabetic (DM, treated with streptozotocin 60 mg/kg, IV, single dose), received ESC (50 mg/ kg, via gavage, for 8 weeks). After this period, we collected blood, 24-hr urine, the kidney and heart of these animals. The organs were homogenized for TBARS (OS marker) and Western blotting of OS and apoptosis markers.

Results: Renal function assessed by urea and creatinine was reduced in DM x CTL. Proteinuria and TBARS increased in plasma and urine in DM rats, with a reduction in DM+ESC group ($p< 0.05$). In DM heart, there were no alterations in TBARS; glutathione, a pro-oxidant, was elevated. In the heart, Nrf-2, responsible for the transcription of several AO, was elevated in the DM, both in its cytoplasmic form and in its active, phosphorylated form. Catalase, an enzymatic AO, and caspase-3 were elevated in DM ($p< 0.05$).

Conclusions: ESC protected the diabetic kidneys reducing proteinuria and OS. Unlike the kidney, the hearts of DM did not present OS, although glutathione and apoptosis were increased. It is important to note, however, that the increase in AO proteins such as Nrf2 and catalase, suggests that at this early stage of DN, they are still able to protect the cardiac tissue against OS. We believe that the monitoring of this disease evolution can better clarify the role of Redox balance/ imbalance in the heart of diabetic rats. This would be very useful in the approach of prevention and treatment of cardiomyopathy, including the possible use of esculin, with its important antioxidant, anti-inflammatory and anti-apoptotic effects, as an adjuvant therapy.

PO0712

Targeting Nox with Pan-Nox Inhibitor in Aging Diabetic Kidney

Sung Gi Yoon, Jin Joo Cha, Booyeun Park, Jungyeon Ghee, Ji ae Yoo, Young Sun Kang, Dae R. Cha. *Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea*.

Background: Aging process is a risk factor for altered glucose metabolism and insulin resistance. Moreover, diabetes with serious complications has been steadily increasing in older patients. Chronic inflammation and increased oxidative stress are commonly shared features of aging and diabetes mellitus. Therefore, we investigated the effect of pan-nox inhibitor on aging diabetic mice.

Methods: Diabetes was induced by intraperitoneal injection of streptozotocin at a 50mg/kg/day for 5 days in 52-week-old week C57BL/6J mice. An orally active pan-nox inhibitor from Aptabio was administered by oral gavage at a dose of 60mg/kg/day for 12 weeks in aging mice and diabetes induced aging mice.

Results: Nox inhibition significantly improved insulin resistance in both aging and diabetic aging mice. Additionally, fasting glucose and HbA1c level were significantly improved with Nox inhibition in diabetic aging group. Interestingly, oxidative stress measured by 8-isoprostane was significantly increased in both aging and diabetic mice. Pan-nox inhibitor significantly reduced plasma 8-isoprostane level in aging group, and urinary 8-isoprostane level in diabetic group. In diabetic aging condition, there was trend to decrease in urinary albumin and nephrin excretion with nox inhibition. Simply aging did not significantly altered PAI-1 and collagen IV expressions in the kidney compared to diabetic condition. However, nox 1 and 4 expressions was as well as increased in aging mice and diabetic mice. Pan-nox inhibitor significantly reduced renal PAI-1, collagen IV expressions in diabetic aging mice. Klotho level was significantly reduced in both aging and diabetic mice and nox inhibition restored klotho level in aging mice, but not in diabetic mice.

Conclusions: Our results provide evidence that pan-nox inhibition may improve systemic insulin resistance and oxidative stress in aging diabetic status, and therefore may have potential protective effects on aging diabetic kidney.

PO0713

NOX5 Promotes Diabetic Kidney Disease by Modulating Redox-Sensitive Pathways

Jay C. Jha,[1] Mark E. Cooper,[1] Chris R. Kennedy,[2] Karin Jandeleit-Dahm.[1] *[1]Monash University Department of Diabetes, Melbourne, VIC, Australia; [2]Kidney Research Centre, Ottawa University, Ottawa, ON, Canada.*

Background: Enhanced level of reactive oxygen species (ROS) in diabetes is considered a major contributor in aggravating renal injury. We aimed to examine the the role of pro-oxidant enzyme NOX5 and associated redox-sensitive pathways in diabetic kidney disease (DKD).

Methods: We examined the expression of NOX5 and associated redox-sensitive factors including NOX4, thioredoxin-interacting protein (TXNIP), a transcription factor, EGR1 (early growth response 1) and a protein kinase, PKC-α as well as ROS production in human kidney biopsies and in human renal cell lines as well as in human kidney organoids. We also assessed the effect of NOX5 expression independent of NOX4 in Nox5 transgenic mice in the presence or absence of diabetes.

Results: We identified increased expression of renal NOX5 in diabetic patients in association with upregulation of ROS-sensitive factors including EGR-1, PKC-α and TXNIP. We also observed upregulation of human NOX5 and TXNIP in renal organoids exposed to high glucose. Silencing of Nox5 attenuated high glucose induced gene expression of markers of fibrosis and inflammation as well as downregulation of EGR-1, PKC-α and TXNIP. Our data also suggest that Nox5 is upstream of Nox4 and that Nox5 inhibition also downregulates Nox4, but not vice versa. In vivo, overexpression of Nox5 independent of NOX4 pathways demonstrated an increase in albuminuria, renal fibrosis and inflammation in association with upregulation of EGR-1, PKC-α and TXNIP and enhanced ROS production in comparison to diabetic mice not expressing Nox5.

Conclusions: These findings suggest that NOX5 plays a key pathogenic role in renal inflammation and fibrosis, thereby providing impetus for the development of NOX5 specific inhibitor to combat DKD.

PO0714

Hyperpolarized MRI Detection of Dapagliflozin Effect on Gluconeogenesis in Live Animals: Proof of Principle

Waheed Shabbir, Enzo Takagi, Michael Ohliger, David Pearce. David Pearce group *University of California San Francisco, San Francisco, CA.*

Background: SGLT2 inhibitors including dapagliflozin (dapa) ameliorate hyperglycemia by inducing glucosuria but also induce gluconeogenesis (GNG), thus blunting efficacy. The lack of insight into the relative contributions of kidney and liver to GNG in different states is due at least in part to limitations in the technology to separately assess liver and kidney GNG in live animals. Our study exploits a powerful technology, Hyperpolarized Magnetic Resonance Imaging (HP-MRI), which can detect metabolic conversions non-invasively in specific organs in animals and humans, in real-time, in vivo. Notably, the chemicals based on stable isotopes of carbon (13-C) used here are approved for multiple diagnostic uses in humans, for example in monitoring metabolism in cancers.

Methods: Metabolic features of healthy WT (male, age ~12 weeks) rats were studied *in vivo* using hyperpolarized (HP) ^{13}C magnetic resonance imaging (MRI) is based on ~50,000-fold nuclear magnetic resonance (NMR) signal enhancements of ^{13}C-labeled substrates via dissolution dynamic nuclear polarization (DNP). To account for potential metabolic effects of infusion of pyruvate, we also performed [1- ^{13}C] pyruvate tolerance tests (PTT).

Results: We successfully detected the conversion of [1-^{13}C]pyruvate to [1-^{13}C]lactate and [1-^{13}C]alanine in the liver and kidneys of rats. We found that Intravenously injected HP [1- ^{13}C]pyruvate was rapidly metabolized to [1- ^{13}C]lactate and [1- ^{13}C]alanine in the liver and kidneys of rats. The PTT data show that there is a clear trend toward an increase in blood glucose following [1- ^{13}C]pyruvate injection. Dapa increased glycosuria, as expected. Furthermore, an effect of dapa was on the conversion of [1-^{13}C]pyruvate to [1-^{13}C]lactate and [1-^{13}C]alanine in the kidney but not the liver. This effect, however, was variable and appeared to be influenced by baseline GNG in the rats.

Conclusions: We establish here for the first time that HP-MRI technology can detect SGLT2i effects on metabolism in live rats, and can distinguish metabolic markers of GNG in kidney vs. liver in this context. Although the methodology requires further development to be useful as a consistent marker of SGLT2i effects on GNG, it could be useful in humans both for characterizing sub-categories of T2DM and detecting risk factors for SGLT2i resistance and/or side effects.

Investigation of the Renoprotective Effect of SGLT-2 Inhibitors Focused on Glomerular Hyperfiltration and Oxidative Stress in Mice with Diabetic Kidney Disease

Megumi Kondo, Kengo Kidokoro, Hiroyuki Kadoya, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Medical School, Kurashiki, Japan.*

Background: In recent clinical trials, sodium-glucose cotransporter 2 (SGLT2) inhibitors slowed the progression of DKD compared with placebo. One of the main mechanisms for the renoprotective effect of SGLT2 inhibitors in DKD is the improvement of glomerular hyperfiltration. We previously demonstrated that the adenosine/adenosine A1 receptor pathway played a pivotal role in the tubulo-glomerular feedback system in type 1 diabetic model mice (Circulation, 2019). We also reported that increased glomerular oxidative stress was involved in the progression of albuminuria in DKD (Diabetologia, 2010). Loss of tetrahydrobiopterin (BH4), which is a cofactor of eNOS, causes uncoupling of endothelial nitric oxide (NO) synthase (eNOS), resulting in increased superoxide production in DKD (AJPRP, 2005; JASN, 2013). In this study, we explored the renal protective effects of SGLT2 inhibition, with a focus on glomerular hemodynamics and glomerular oxidative stress.

Methods: We used db/db mice as a model for type 2 diabetes. Mice were treated with canagliflozin (CANA; 10mg/kg) for 8 weeks. We evaluated the change of single nephron glomerular filtration rate (SNGFR) and glomerular permeability of albumin using in vivo multiphoton microscopy imaging. Glomerular reactive oxygen species (ROS) and NO production were evaluated by ex vivo study. Low temperature sulfate-polyacrylamide gel electrophoresis was performed for detection of eNOS uncoupling. In addition, tomato lectin staining was carried out to estimate the vascular endothelial damage.

Results: Glomerular hyperfiltration and urinary albumin excretion in db/db mice was ameliorated by CANA treatment. Accelerated ROS production and diminished bioavailable NO caused by eNOS uncoupling in glomeruli were observed in db/db mice. CANA suppressed eNOS uncoupling and improved ROS/NO imbalance via maintenance of BH4. CANA inhibited degradation of endothelial surface layer due to increased glomerular oxidative stress.

Conclusions: SGLT2 inhibitor restore glomerular hyperfiltration in DKD. Simultaneously, intraglomerular ROS/NO imbalance via eNOS uncoupling was improved by SGLT2 inhibitor.

Empagliflozin (SGLT-2 Inhibitor) Ameliorates Early Features of Diabetic Retinopathy and Nephropathy in Type 2 Diabetic Mice Model via the Klotho Protein

Farid M. Nakhoul,[1,2] Offir Ertracht,[1,2] Nakhoul Nakhoul,[4,2] Evgeny Farber,[3,2] Hagar Tadmor,[3,2] Ranin Saad,[3,2] Shaul Atar,[1,2] Anas Igbariye.[1,2] *[1]Research Institute Galilee Medical Center, Nahariya, Israel; [2]Azrieli Faculty of Medicine Bar-Ilan University, Ramat-Gan, Israel; [3]Diabetes Research Lab. Baruch Padeh Poriya Medical Center, Tiberias, Israel; [4]Ophtalmology Division Baruch Padeh Poriya Medical Center, Tiberias, Israel.*

Background: The diabetic nephropathy (DN) and diabetic retinopathy (DR) are the most common serious vascular complications of diabetes Chronic hyperglycemia in DM triggers different processes that leads to Diabetic Retinopathy (DR) and Nephropathy (DN) development. α-Klotho (KL) is an anti-aging gene encoding a protein with multiple pleiotropic effects, involved in suppression oxidative stress and inflammation processes. We investigate the protective effect of Empagliflozin (EMPA) on the expression of KL on DN&DR in DM mice model.

Methods: BTBR mice with ob/ob leptin-deficiency develops severe type II DM with DN and DR. 8 weeks-old male mice were randomly divided into 3 groups: C57BL/6J Wild Type, BTBR ob/ob vehicle and BTBR ob/ob treated with EMPA. Mice were sacrificed after 13 weeks of treatment. Mice retinas were removed and fixed by immersion in 2% paraformaldehyde overnight at 4°C. After PBS rinses eyes were immersed in increased concentrations of sucrose-PBS solutions at 4°C and finally frozen in O.C.T. Cryostat sections (16 µm) were incubated overnight at 4°C with primary anti-KL antibody, then for 1 h with secondary antibody. We assessed immunohisto-fluorescence intensity of each experimental group, using an Olympus BX53 fluorescent microscope, and identical exposure for each image. Finally, the data is presented as percent area of the inner plexiform layer (IPL), especially the ganglionic cells, covered with positive signal to KL. Concomitantly, kidneys were removed and subjected to similar immunostaining for the KL protein.

Results: KL expression in the IPL (ganglionic cells) was 48.3±2.7 % in control mice, 11.9±2.% in DM mice ($P<0.001$ *vs.* control) and 20.4±2.% in DM mice treated with EMPA ($P<0.05$ *vs.* un treated DM mice). In control mice KL expression was 6.8% of the renal tissue area, expression was attenuated in the DM mice occupying 0.065 %, in DM mice treated with EMPA, the KL expression reached 4%.

Conclusions: The data suggested that KL protein can play a potential protective factor against retinopathy and nephropathy in DM mice. Early therapy with EMPA that targets the early pathogenesis of DR and DN, is wildly needed to prevent the onset & slow the progression of those pathologies to to vision loss and dialysis, respectively.

PO0717

SGLT-2 Inhibition Ameliorates Tubular Injury with Metabolic Suppression in Very Early Phase of Diet-Induced Diabetic Kidney Disease

Hiroshi Maekawa, Dorian Kaminski, Margaret E. Fain, Biliana Marcheva, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Therapies that target the sodium glucose cotransporter 2 (SGLT2) are known to benefit diabetic patients via both metabolic and hemodynamic effects, however, mechanisms promoting renal protection are incompletely known. Here, we investigated the mechanism of reno-protective effects by SGLT2 inhibition in diabetic kidney disease (DKD), focusing on kidney metabolism.

Methods: 10 week-old male SGLT2 mutant (Sweet Pee) and wildtype (WT) mice, fed with normal or high fat diet (HFD, 60% calories from fat) for eight weeks, were analyzed. Weekly changes in body weight, food intake, insulin and glucose tolerance were determined. Renal injury was evaluated by transdermal measurement of GFR, urinary

albumin creatinine ratio (uACR), KIM-1, NGAL and cleaved caspase 3 expression in the renal cortex and TUNEL staining of the kidney. Metabolic changes of the kidney were examined by qPCR of genes related to glycolysis, TCA cycle and fatty acid oxidation.

Results: Similar degree of HFD-induced obesity occurred in both SGLT2 mutant and WT mice while compensatory hyperphagia was observed only in mutant mice. HFD led to elevation of post-prandial blood glucose level, glucose intolerance and insulin resistance. Increases in postprandial blood glucose and glucose intolerance were blunted in SGLT2 mutant mice. Although changes of GFR and urinary albumin excretion were not observed, KIM1 and NGAL expression were upregulated by HFD feeding, indicating that this model represents an early phase of DKD. KIM1 and NGAL upregulation was abrogated in SGLT2 mutant mice. Furthermore, HFD feeding induced apoptosis in the cortex of WT mice, but not in SGLT2 mutants. Kidney/ body weight ratio was decreased by HFD in WT but increased in SGLT2 mutant mice, suggesting metabolic differences in the kidney. Genes related to glycolysis (PGK and PKM), TCA cycle (IDH2) and fatty acid oxidation (CPT1a, CPT2, PPARα and PGC1α) were suppressed in SGLT2 mutant vs WT HFD groups.

Conclusions: SGLT2 inhibition ameliorates tubular injury associated with renal hypertrophy and metabolic suppression in very early phase of diet-induced DKD.

mTORC2 Is Essential for Sodium-Glucose Cotransporter 2

Waheed Shabbir, John E. Demko, Enzo Takagi, Bidisha Saha, Deise C. Leite-Dellova, Bharathi Sambandam, David Pearce. David Pearce group *University of California San Francisco, San Francisco, CA.*

Background: The role of mammalian target of rapamycin (mTOR) complexes mTORC1 and mTORC2 in renal tubule ion transport has been well characterized. We and others have shown that mTORC2 is a key regulatory kinase for serum and glucocorticoid kinase 1 (SGK1) and that its activity is required for epithelial Na^+ channel (ENaC)-dependent sodium reabsorption in the aldosterone-sensitive distal nephron (ASDN). Also, it has been shown that mTORC1 activity is increased in renal proximal tubule cells (RPTCs) in diabetes, which was prevented by the inhibition of sodium-glucose co-transporter 2 (SGLT2), and that mTORC1 KO in mice causes a Fanconi's syndrome-like phenotype. However, the roles of mTORC2 in the regulation of RPTC transporters, particularly as it pertains to glucose reabsorption remain obscure. In this study we explored the relationship between mTORC2 and SGLT2 in CRISPR-modified HEK-293Tcells and in mice, using patch clamp and membrane expression studies

Methods: We used CRISPR-Cas9 to generate Sin1 (an essential component of mTORC2)-deficient HEK-293T cells, which were compared with wild-type cells. The cells were transiently transfected with SGLT2. We recorded in WT HEK-293T cells the Dapa-sensitive SGLT2 sodium current. We used an inducible Cre-Lox system (Pax8-LC1) to KO Rictor (another key component of mTORC2) in mice. Dapagliflozin-sensitive whole-cell SGLT2 sodium current was measured in the microdissected proximal tubules and HEK-293T cells

Results: Strikingly, in mTORC2-knockout HEK-293T cells the Dapa-sensitive SGLT2 sodium current was significantly reduced versus WT HEK-293T cells. In mice, mTORC2 KO caused glycosuria without hyperglycemia, and patch-clamp studies showed decreased glucose-induced, dapagliflozin-inhibited Na^+ current.

Conclusions: Knockout of mTORC2 in the HEK-293T cells or in mice inhibits SGLT2-sodium current. Our study delineates the essential role of mTORC2 in SGLT2 function. These observations may explain the broad role of SGLT2 inhibition therapy and variable resistance to their effects.

MAP17 and D-AKAP-2, Two Major Scaffolder Proteins, Are Upregulated in Experimental Diabetic Nephropathy in Response to Empagliflozin on Top of RAS Blockade

Ander Vergara,[1] Mireia Molina Van den Bosch,[1] Pamela Domínguez Báez,[1] Mandy Rettel,[2] Frank Stein,[2] Begoña Benito,[3] Sheila Bermejo,[1] Conxita Jacobs Cachá,[1] Maria Jose Soler.[1] *[1]Nephrology and transplantation group. Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Hospital Universitari, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; [2]Proteomics Core Facility. European Molecular Biology Laboratory., Heidelberg, Germany; [3]Cardiology group. Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Hospital Universitari, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain.*

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have proven to delay diabetic nephropathy (DN) progression on top of the standard of care renin-angiotensin system (RAS) blockade. This protection is mostly attributed to improvement in renal hemodynamics although direct effects on the kidney cannot be ruled out. Further, the molecular mechanisms underlying the synergic effect of SGLT2i and RAS blockers is unknown.

Methods: 12 weeks old diabetic db/db mice were given empagliflozin (10mg/Kg/day), ramipril (8 mg/Kg/day) or the combination of both drugs during 8 weeks. Vehicle treated db/db and db/m mice were used as controls. Serum glucose, blood pressure, GFR and albuminuria were measured at baseline and at the end of study. At the end of the experiment, mice were euthanized and the kidneys were saved to perform a differential high-throughput proteomic analysis by mass spectrometry using isobaric tandem mass tags (TMT labelling).

Results: Vehicle db/db mice showed increased glycaemia during the whole experiment and empagliflozin normalized blood glucose. Ramipril treatment decreased blood pressure. Diabetic vehicle mice showed incipient DN, mesangial expansion and albuminuria were significantly increased when compared to their non-diabetic littermates. All the treatments reduced mesangial expansion and albuminuria. The differential proteomic analysis revealed 207 proteins differentially expressed in one or more experimental groups (FDR < 0.05 and Log FC>1); among them MAP17 and D-AKAP-2 were upregulated in the kidney of the db/db treated with empagliflozin with ramipril. We validated these findings by western blot.

Conclusions: The combined therapy of empagliflozin with ramipril upregulated both MAP17 and D-AKAP-2 in the kidney of a diabetic mice model. MAP17 and D-AKAP-2 are two major scaffolding proteins found in the proximal tubular cells that place transporters together such as SGLT2 and NHE3 and also regulate the function of protein kinase A (PKA) which in turns inactivates NHE3 by phosphorylation. Our results suggest that SGLT2i on top of RAS blockade may protect the kidney by boosting the inactivation of NHE3 via the upregulation of key scaffolder proteins such as MAP17 and D-AKAP-2.

PO0720

Added Benefit of SGLT-2 Inhibitor with ACE Inhibition in a Mouse Model of Severe Diabetic Nephropathy

Savithri B. Kota, Vaja Chipashvili, Krista P. Farrington, Gang Zheng, Tao Chen, Maria Klass, Bin Gao, Romer A. Gonzalez-Villalobos, Maria chiara Magnone, Matthew D. Breyer. *Janssen Research and Development LLC, Boston, NJ.*

Background: The clinical success of sodium glucose cotransporter 2 inhibitor (SGLT2i) for the treatment of diabetic kidney disease (DKD) has ushered in a new phase in the discovery and development of novel drugs for DKD. As the development of SGLT2i did not follow the traditional drug discovery paradigm exemplified by testing efficacy in a relevant preclinical model, here we present the evaluation of combinatorial therapy of SGLT2i and standard of care in the hypertensive Renin AAV db/db uninephrectomy mouse model of severe DKD.

Methods: Severe DKD was established by AAV mediated hepatic overexpression of renin in uninephrectomized db/db mice. Mice were treated with Lisinopril (ACEi) in drinking water and SGLT2i (JNJ39933673) in diet, at a dose of 5 mpk for 8 weeks. Study groups included untreated DKD control (N=11), Lisinopril treated (N=11), Lisinopril + SGLT2i treated (N=11) and LacZ AAV control (N=10).

Results: SGLT2i significantly reduced blood glucose levels upon treatment inception (Day-3 vs. Day 4; 465.1±33.1 vs. 258.7±24.8; mean ± sem, mg/dl, p=0.001). ACEi reduced systolic blood pressure by 21 mm of Hg within 2 weeks of treatment (p=0.02), which was further reduced by 20 mm of Hg by SGLT2i co-treatment on week 7 (p=0.03). While ACEi treatment alone reduced UACR by 15% to 35% below baseline, dual treatment with SGLT2i led to a reduction of UACR by 49% to 67% during the 8 weeks treatment phase (p= n.s), leaving a residual albuminuria of 5561 ug/mg. Plasma creatinine doubled during the study period and was blunted only by ACEi+SGLT2i (No treatment vs. ACEi+SGLT2i; 0.38±0.06 vs. 0.24±0.02; mean ± sem; mg/dl, p=n.s). Histological assessments revealed additive benefits of ACEi+SGLT2i, in measures of glomerular, vascular and tubulointerstitial lesions. Reduced plasma levels of sTnfr1 reflected therapeutic benefits of SGLT2i on top of ACEi.

Conclusions: Our study demonstrates the possibility of testing combinatorial therapies in this translational preclinical model of severe DKD. Residual injury in ACEi+SGLT2i animals should enable testing of novel agents in this model on this new standard of care for CKD.

Assessment of Candidate Renal Protective Drug-Induced Biomarkers in Diabetic Kidney Disease Using Targeted Proteomic Profiling

Laura Goea,[1] Agnes M. Benardeau,[2] Shuya Liu,[3] Shun Lu,[3] Wenjun Ju,[4] Frank Eitner,[1] Tobias B. Huber,[3] Tibor Schomber.[1] Kidney Disease Research, Cardiovascular Department, Bayer AG *[1]Bayer AG, Wuppertal, Germany; [2]Novo Nordisk AS, Copenhagen, Denmark; [3]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [4]University of Michigan, Ann Arbor, MI.*

Background: The sodium-glucose cotransporter 2 inhibitor (SGLT2i) empagliflozin slows the progression of kidney function decline in type 2 diabetes in addition to lowering blood glucose levels. However, the underlying molecular mechanisms of SGLT2i for renoprotection are not yet completely understood. We assessed non-invasive biomarkers associated with empagliflozin or enalapril treatment in a rat model of diabetic kidney disease (DKD).

Methods: Obese diabetic and hypertensive ZSF1 rats were treated with vehicle, enalapril (10 mg/kg/d, p.o.), or empagliflozin (30 mg/kg/d, p.o.) for 8 weeks. Along with phenotypic parameters, Olink Mouse Exploratory panel was used to simultaneously detect the levels of 92 proteins in plasma and urine samples using the proximity extension assay.

Results: Compared to vehicle and enalapril**,** empagliflozin reduced blood glucose, HbA1c, total cholesterol, and triglyceride levels while increasing HDL levels in ZSF1 rats. Empagliflozin significantly affected the levels of 16 proteins in plasma samples. Lower plasma concentrations after empagliflozin-treatment were detected for Notch3, tenascin-R, glial cell line-derived neurotrophic factor, and erythropoietin. In urine, we found 23 proteins responding to empagliflozin, 6 of which overlapped with plasma markers. Of these, compared with enalapril, empagliflozin restored the levels of dihydropteridine reductase and dimethylarginine dimethylaminohydrolase 1, proteins known for their role in decreasing ROS activity and oxidative stress. Eight plasma proteins and one urinary protein were found to be differentially expressed after enalapril treatment. Plasma tenascin-R was the only protein associated with both enalapril and empagliflozin treatment.

Conclusions: We identified biomarkers that are associated with SGLT2i and ACEi treatment. Our results may additionally provide mechanistic insights into the beneficial effects of renoprotective drugs. Translation and validation of these preclinical findings in human patient samples is the proposed next step. *This project has received funding from the Innovative Medicines Initiative 2 Joint Undertaking under grant agreement No 115974. Elucidation of Glomerular Hemodynamic Changes by SGLT-2 Inhibitors and ARBs in a Type 2 Diabetic Animal Model Using In Vivo Imaging

Yoshihisa Wada, Kengo Kidokoro, Reina Umeno, Megumi Kondo, Hiroyuki Kadoya, Hajime Nagasu, Tamaki Sasaki, Naoki Kashihara. *Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan.*

Background: In recent clinical trials have shown that SGLT2 inhibitor (SGLT2i) inhibit the progression of diabetic kidney disease (DKD). We established the method for measuring single-nephron GFR (SNGFR) in mice by in vivo imaging and found that the adenosine / adenosine A1 receptor (A1aR) pathway in tubuloglomerular feedback (TGF) is involved in the pathogenesis of glomerular hyperfiltration (GH) in DKD using type1 diabetic animal model (Kidokoro K. et al. Circulation 2019). The mechanism of development of GH, and improvement of GH by SGLT2i is considered to be different in type 1 and type 2 DKD. However, the detailed regulatory mechanism of GFR has not been elucidated in type 2 DKD. We conducted experiments to elucidate the glomerular hemodynamic changes in type 2 diabetic animal model, using SGLT2i alone and in combination with RAAS inhibitor.

Methods: Zucker Lean (ZL) and Zucker Diabetic Fatty (ZDF) rats were used. Multi photon microscope was used to evaluate SNGFR, afferent arteriole (AA) and efferent arteriole (EA). The change in AA, EA, and SNGFR were observed every 30 minutes after SGLT2i administration. Furthermore, we investigated the involvement of the adenosine / A1aR pathway in type 2 diabetic animals using an A1aR antagonist (A1aRant). We made a SGLT2i + ARB combination group and measured AA, EA, and glomerular volume.

Results: ZDF showed a significant increase in blood glucose and urinary protein levels compared to ZL. SNGFR, AA and EA were significantly increased in ZDF compared to ZL, indicating GH. SGLT2i administration resulted in correction of AA hyperdilation and inhibition of GH. The inhibitory effect on hyperfiltration by SGLT2i was abolished by the concomitant use of A1aRant. There was no significant change about blood pressure, but urinary protein excretion was significantly suppressed by ARB treatment in ZDF. Glomerular volume was significantly increased, while there were no significant changes in AA and EA. SGLT2i ameliorated abnormal expansion of AA also in the presence of ARB, and no change in EA.

Conclusions: Our results showed that the regulation of AA vascular tonus by the adenosine/ A1aR pathway in TGF was involved in the GH in type 2 DKD.

GLP-1's Effect on Renal Perfusion and Oxygenation Measured with Quantitative MRI: A Potential Renoprotective Pathway in the Human GLP-1-Renal Axis

Bryan Haddock,[1] Kasper B. Kristensen,[1] Ulrich Lindberg,[1] Susan Francis,[2] Boye Jensen,[3] Ulrik B. Andersen,[1] Ali Asmar.[1] *[1]Department of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [2]Sir Peter Mansfield Magnetic Resonance Centre School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom; [3]Department of Cardiovascular and Renal Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark.*

Background: GLP-1 receptor agonism has shown significant beneficial cardiovascular effects that may be related to renoprotection. In the human kidney, a high GLP-1 extraction and its natriuretic effect are fully dependent on the GLP-1 receptor and associated with suppression of angiotensin II. Preclinical data showed that angiotensin II constricts vasa recta and lowers medullary blood flow. The current randomized and controlled study was designed to test the hypothesis that GLP-1 increases renal medullary perfusion.

Methods: Under fixed sodium intake (2 mmol NaCl/kg body weight/day) for 4 days before each study day, 10 lean healthy male participants were examined twice in random order during a 1-hour infusion of either GLP-1 (1.5 pmol/kg/min) or vehicle (0.9% NaCl) together with an intravenous infusion of 0.9% NaCl (750 mL/h). Interleaved measurements of renal artery flow, oxygenation (R2*), and perfusion (arterial spin labeling) were acquired in the renal cortex and medulla, using Magnetic Resonance Imaging (MRI) during infusions.

Results: During GLP-1 infusion, medullary perfusion increased 32 ± 7% ($p<0.001$) and cortical perfusion increased 13 ± 4% ($p<0.001$) compared to vehicle where medullary perfusion decreased -5 ± 2% ($p=0.007$) and cortical perfusion remained unchanged. R2* values increased 3 ± 2% ($p=0.025$) in the medulla and 4 ± 1% ($p=0.008$) in the cortex during vehicle infusion (indicative of decreased oxygenation) but remained unchanged during GLP-1 infusion. Renal arterial blood flow was not altered significantly by either intervention.

Conclusions: GLP-1 increases mainly medullary but also renal cortical perfusion and oxygenation during NaCl loading. In perspective, GLP-1 may promote Na excretion through this mechanism and exert long-term protective effects against hypoperfusion and ischemia.

Circulating SIRPα Is Upregulated in Type 2 Diabetes, Impairing Insulin Signaling in Skeletal Muscles and Adipose Tissues

Jiao Wu, William E. Mitch, Sandhya S. Thomas. *Baylor College of Medicine, Houston, TX.*

Background: A major etiology of chronic kidney disease (CKD) is diabetes mellitus. Even at early stages of CKD with near normal GFR, impaired insulin signaling is present, suggesting an early trigger of insulin resistance. We have discovered a potential driver of insulin resistance, signal regulatory protein alpha (SIRPα) which adversely influences skeletal muscles and adipose tissues in a model of type 2 diabetes.

Methods: Control mice vs. global SIRPα knockout (KO) mice were subjected to HFD >12 weeks. Glucose (GTT) and insulin tolerance tests (ITT), immunoblots, and treatment of myotubes with recombinant SIRPα were performed. n=4-6 mice/group, results are presented as mean ± SD.

Results: Control mice with HFD displayed impaired insulin signaling with reduced levels of tyrosine phosphorylation of the IGF1R, PI3 kinases and pAKT (ser473) in skeletal muscles. However, in SIRPα KO mice with HFD there was no downregulation of these insulin signaling proteins. Next, we examined adipose tissues of these mice and found impaired pAKT in control mice fed a HFD. In SIRPα KO mice pAKT signaling remained intact despite exposure to HFD. Next, control mice exposed to HFD displayed impaired GTT/ITT. However, KO mice had preserved GTT/ITT despite the presence of HFD. Finally, we identified a high level of serum SIRPα in control mice exposed to HFD. Therefore, we treated myotubes with exogenous recombinant SIRPα which led to downregulation of pAKT signaling.

Conclusions: Suppression of SIRPα in a HFD model of type 2 diabetes improves insulin resistance and is a potential therapeutic target for the treatment of type 2 diabetes.

Metabolic Acidosis Does Not Impair Insulin Sensitivity in Rats with CKD

Elinor Mannon, Paul O'Connor. *Augusta University, Augusta, GA.*

Background: Insulin resistance is common in patients with chronic kidney disease (CKD) without diabetes, however, the factors driving this remain unclear. Metabolic acidosis has been implicated in the development of insulin resistance. The current study was designed to quantify the effect of changes in blood pH on insulin sensitivity using a rodent model of CKD.

Methods: We hypothesized that alkali or acid loading would promote varying levels of acid-base disturbances and consequently decreased insulin sensitivity in rats with graded renal mass reduction. Male Sprague Dawley rats (12 wks, SD) underwent either

2/3 nephrectomy (n=7; Nx) or 5/6 Nx (n=4). Rats recovered for 4 weeks, then underwent insulin tolerance testing (ITT; 0.75 U/kg i.v.) before and after alkali (2 weeks 0.1M $NaHCO_3$) and acid loading (1 week 0.1M NH_4Cl) in the drinking water. Male Zucker obese rats (10 wks) underwent 5/6 Nx (n=4) and were also given 4 weeks of recovery before being placed on 0.1M NH_4Cl for 4 days.

Results: In Nx SD rats, 0.1M $NaHCO_3$ did not produce metabolic alkalosis (Table 1) or reduce insulin sensitivity (P_{Rx}=0.67). 0.1M NH_4Cl in Nx SD rats produced a mild metabolic acidosis (Table 1). However, this did not alter the response to insulin (P_{Rx}=0.56). 0.1M NH_4Cl produced a severe metabolic acidosis in Zucker rats with 5/6 Nx (Table 1). Again however, this was not associated with an impaired insulin response. Rather, following NH_4Cl loading, Zucker rats had a greater response to insulin (P_{Rx}=0.01). Unexpectedly, we observed a negative relationship between the magnitude of change in blood glucose (inverse area under the curve) and plasma pH (*r*=-0.27, P=0.03) and plasma HCO_3^- (*r*=-0.33, P=0.0098) in remnant kidney rats.

Conclusions: These data demonstrate that metabolic acidosis does not impair insulin sensitivity in rats. Our data suggest that the direct effects of metabolic acidosis are unlikely to underlie significant impairments in insulin sensitivity in CKD.

Understanding Mechanisms Underlying Diabetic Kidney Disease Using Integrative Transcriptome and Proteome Profiling of Insulin-Resistant Human Cell Lines

Abigail C. Lay,[1] Van Du T. Tran,[2] Florence Mehl,[2] Dmytro Kryvokhyzha,[3] Virginie M. Betin,[1] Marieangela C. Wilson,[1] Kate J. Heesom,[1] Richard Coward.[1] BEAT-DKD consortium *[1]University of Bristol, Bristol, United Kingdom; [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland; [3]Lunds Universitet, Lund, Sweden.*

Background: One of the strongest metabolic features of diabetic kidney disease (DKD), in both type 1 and type 2 diabetes, is insulin resistance and it is increasingly clear that disruptions to renal cellular insulin responses can drive DKD development. The present study aims to generate a comprehensive network of molecular changes occurring in the kidney in response to insulin resistance using cell models

Methods: Conditionally immortalised human podocytes (Pod), glomerular endothelial cells (GEC), mesangial cells (MC) and proximal tubular cells (PTC) were studied. A diabetic, insulin resistant, environment was established using a combination of TNFα, IL-6, high glucose and high insulin. The cellular proteome and transcriptome were studied simultaneously using Tandem-Mass-tagged mass spectrometry and RNA sequencing. To explore the changes occurring in insulin resistance, integrated transcriptome and proteome data were analysed using univariate and multivariate statistical models and gene set enrichment analysis (GSEA) was performed to identify significantly regulated cellular processes

Results: Initial results revealed that exposure to a diabetic environment induced differential insulin resistance between human kidney cell lines. Differential expression analysis of both transcriptome and proteome found that insulin resistance had the most pronounced effect on expression in Pod and PTC and highlighted 45 consistently regulated genes/proteins. GSEA identified consistent increases in the inflammatory response, ER stress and glycoprotein metabolism and a consistent decrease in hippo signalling across all insulin resistant cells. In contrast, mitochondrial-related signatures were significantly reduced at the protein level in Pod and PTC but increased in GEC. Investigation of these gene/protein signatures in human DKD cohorts is currently ongoing

Conclusions: By performing integrated omics profiling on renal cell models, we identified conserved and cell-specific changes occurring in insulin resistance. Integration with human cohort data will highlight conserved pathways and the utility of cell models in pre-clinical investigations, aiding the identification of molecular processes underlying the development and progression of DKD

PO0727

Insulin Resistance Is Associated with Decreased Renal Insulin Receptor Beta in Aged D4 Null Mice

Mingda Liu,[1] Weiwan Wang,[1] Quansheng Wang,[2] Zhiyun Ren,[1] Xiaoyan Wang.[1] *[1]The Core Laboratory, Nanjing BenQ Medical center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China; [2]Department of Endocrine, Nanjing BenQ Medical center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China.*

Background: Insulin resistance is a major concern in metabolic disorders related to diabetes.

Methods: In order to explore the hypothesis that D4 dopamine receptor (D4R) increases insulin sensitivity through its activation of insulin receptor beta (IR-beta), we demonstrated the functional role of D4R in the prevention of insulin resistance by studying Drd4 null ($Drd4^{-/-}$) mice and wild-type ($Drd4^{+/+}$) littermates.

Results: We found that $Drd4^{-/-}$ mice (14 mos) had increased fasting blood glucose regardless of sex but their urines were negative for glucose and ketones, suggesting that the mice fed normal salt/normal fat diet were pre-diabetic. Serum insulin levels were increased in male $Drd4^{-/-}$ mice but not altered in female $Drd4^{-/-}$ mice after an 8 hr fast indicating that these mice have resistance or insensitivity to endogenous insulin. The aged male and female $Drd4^{-/-}$ mice had similar body weights, fasting serum total and free cholesterols, triglycerides, to their age and sex -matched $Drd4^{+/+}$ littermates, suggesting that the old $Drd4^{-/-}$ mice were not obese and had no dyslipidemia. Relative to $Drd4^{+/+}$ littermates (100±7 %, n=6), $Drd4^{-/-}$ mice had decreased IR-beta (19±4%, n=4) but normal protein expressions of IR-alpha, insulin degrading enzyme, insulin substrate 1, sodium glucose transporter 2 and glucose transporters in renal cortex homogenates, indicating that the decreased protein expression of IR-beta contributed to the insulin resistance in the aged $Drd4^{-/-}$ mice. $Drd4^{-/-}$ mice had decreased phosphorylated IR-beta at Tyr1631&1345, not Tyr972. Renal expression of insulin receptor beta was located in mouse renal glomeruli and tubules and co-localized n the apical membrane with NCC in the distal convoluted tubules in cortex and NKCC2 in the thick ascending limbs of loop of Henle in the outer medulla. D4R and IR-beta were co-immunoprecipitated in immortalized mouse renal distal convoluted tubule cells and the co-immunoprecipitation was increased by D4R agonist and not altered by D4R antagonist.

Conclusions: Our results suggest that disruption of D4R may play an important role in the insulin resistance via interactions with IR-beta in kidney.

PO0728

Renal Mass Reduction Enhances the Blood Glucose Response to Exogenous Insulin in Rats

Elinor Mannon, Paul O'Connor. *Augusta University, Augusta, GA.*

Background: The effect of chronic kidney disease (CKD) on responses to exogenous insulin are complex and may vary depending on the level of underlying insulin resistance. The kidneys play an important role in the catabolism of insulin, and progression of CKD in patients with diabetes mellitus is often associated with reducing insulin needs. Conversely, impairments in insulin sensitivity are observed in CKD patients absent diabetes, indicating that CKD itself may drive insulin resistance.

Methods: In order to clarify the roles of CKD and underlying insulin resistance on the response to exogenous insulin, in the current study we investigated the effect of graded renal mass reduction on the blood glucose response to insulin in healthy Sprague Dawley (SD) and insulin resistant Zucker obese rats. Male SD (12 wks) and Zucker obese (10 wks) rats underwent either sham (n=6 SD, 3 Zucker), 2/3 nephrectomy (n=7 SD; Nx), or 5/6 Nx (n=8 SD, 4 Zucker). Rats recovered for 4 weeks, then underwent insulin tolerance testing (ITT; 0.75 U/kg i.v.).

Results: There was a graded response in the blood glucose curves for SD rats ($P_{LevelofNx}$<0.0001; Fig 1A) with sham rats having the smallest blood glucose response to insulin, and 5/6 Nx rats having the greatest response to insulin. Similarly, the blood glucose response to insulin was about 5x greater for Zucker 5/6 Nx rats than for shams ($P_{LevelofNx}$=0.0019; Fig 1B). There were no significant differences in plasma insulin levels during the ITT between Nx and sham SD rats, while sham Zucker rats had greater plasma insulin levels than Nx rats ($P_{LevelofNx}$=0.0001).

Conclusions: These data indicate that renal mass reduction increases the response to exogenous insulin independent of the level of underlying insulin resistance, and that this is not mediated by an increased half-life of circulating insulin. Further investigation into the factors that contribute to greater insulin responses in CKD may identify novel targets for the treatment of insulin resistance.

PO0729

The Essential Role of Intact Mitochondrial Substrate Balance in Preventing Renal Injury

Allison N. Mccrimmon,[1] Kerin M. Cahill,[1] Daria Ilatovskaya,[2] Krisztian Stadler.[1] *[1]Pennington Biomedical Research Center, Baton Rouge, LA; [2]Medical University of South Carolina, Charleston, SC.*

Background: Alterations in mitochondrial function are linked to the development of chronic/diabetic kidney diseases. Proximal tubular cells (PTCs) are highly energy demanding, covering this need mostly from mitochondrial fatty acid oxidation. It is suggested, but not entirely clear whether derailments in mitochondrial metabolism and function are forerunners of tubular damage. In our previous studies we modeled mitochondrial substrate overload - an important aspect of metabolic disease - by creating mice lacking the enzyme carnitine acetyl-transferase (CrAT) in the PTC. These studies revealed that mitochondrial substrate overload in proximal tubules causes tubular injury and secondary glomerulosclerosis.

Methods: Here we demonstrate the importance of intact mitochondrial substrate efflux by titrating the amount of overload through the generation of a heterozygous CrAT knockout mouse model ("PT-CrAT^{HET}" mouse). We used an integrated approach of imaging, electron microscopy, functional studies (mitochondrial/cell respiration) and Next Generation RNA Sequencing combined with Ingenuity Pathway Analysis.

Results: PT-CrAT^{HET} mice developed tubular and glomerular injury similarly to their homozygous counterparts (N=5-7 mice examined, at least three separate cohorts). Mitochondria were structurally and functionally impaired in both sexes. Transcriptomic analyses, however, revealed striking differences in the pathways leading to renal injury in males vs females (evaluated using NextGenSeq and IPA with a threshold of $P<0.1$). In response to CrAT haploinsufficiency, males almost completely shut down fatty acid oxidation and related pathways. Females had a much weaker transcriptional response in metabolism-related pathways but activation of inflammation was more prominent when compared to males. Proximal tubular cells from these animals exhibited a shift in metabolism towards a more glycolytic phenotype (N=8 biological replicates, $P<0.05$ in at least three independent experiments), which was also more pronounced in males.

Conclusions: Our findings demonstrate that maintaining an intact mitochondrial substrate metabolism balance is crucial for the PTC. Potentially broad implications are: the metabolic shift and the sexual dimorphisms discovered herein offer new intervention points for the future and novel approaches to consider for treating kidney disease.

Spexin-Based Galanin Receptor 2 Agonist (NS200) Improves Diabetic Nephropathy in Type 2 Diabetes

Jin Joo Cha, Hye jin Park, Jungyeon Ghee, Ji ae Yoo, Dae R. Cha, Young Sun Kang. *Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea*.

Background: Spexin is a novel neuropeptide having an emerging role in metabolic diseases such as obesity and diabetes and involved in energy homeostasis and food intake. Spexin-based galanin receptor 2 agonist (NS200) has anti-depressive action and anxiolytic effect. The aim of this study is to investigate the effect of NS200 on insulin resistance and diabetic nephropathy in type 2 diabetic animal.

Methods: 8 to 10 week old *db/m* and *db/db* mice were treated with NS200 for 12weeks. NS 200 was administered by intraperitoneal injection at a dose of 1.0 mg/kg/day as reported in the previous study.

Results: There were no changes in body weight, food and water intake, urinary volume, fasting glucose level and HbA1c level by NS200 treatment in diabetic mice. Insulin tolerance test and glucose tolerance test were not also changed by treatment. NS200 lowered systolic blood pressure. Interestingly, NS200 improved urinary albumin excretion significantly in diabetic mice. Renal histology showed reduced glomerulosclerosis and tubulointerstitial fibrosis in treatment groups. Renal TGFβ and type IV collagen expressions were decreased in NS200 treated group, whereas PAI-1 and F4/80 expression were increased in treatment group. Insulin signaling pathway such as PI3K, p-AKT, and p-ERK protein expression were significantly suppressed by treatment in diabetic nephropathy. Despite there were no beneficial effects in basal metabolic parameters and insulin resistance, NS200 treatment in diabetic mice showed renoprotective effects in urinary albumin excretion and renal structural changes.

Conclusions: Our results provide the evidence that spexin-based galanin receptor 2 agonist by NS200 has renoprotective effect in diabetic nephropathy. These findings suggest the mechanism via its inhibition of renal insulin signaling pathway therefore provide a considerable promise as a new agent in diabetic nephropathy.

PO0731

Cell Sex and Sex Hormones Regulate Kidney Metabolism of Glucose and Glutamine: Implications for Diabetic Kidney Disease

Sergi Clotet Freixas,[1] Olga Zaslaver,[4] Chiara Pastrello,[1] Max Kotlyar,[1] Caitriona M. McEvoy,[1] Sofia Farkona,[1] Aninda D. Saha,[1] Alexander Boshart,[1] Allison Dart,[3] Brandy A. Wicklow,[3] Tom D. Blydt-Hansen,[2] James W. Scholey,[1] Hannes L. Rost,[4] Ana Konvalinka.[1] *[1]University Health Network, Toronto, ON, Canada; [2]The University of British Columbia Department of Pediatrics, Winnipeg, MB, Canada; [3]University of Manitoba Department of Pediatrics and Child Health, Winnipeg, MB, Canada; [4]The Donnelly Centre, University of Toronto, Toronto, ON, Canada*.

Background: Diabetic kidney disease (DKD) is the major cause of end-stage kidney disease. Male sex is a risk factor for DKD, but the reasons for this predilection are unclear. We demonstrated that androgens accentuate DKD *in vivo*, and increase enzymes involved in glucose and glutamine metabolism, in male proximal tubular epithelial cells (PTECs). We aimed to determine the effect of cell sex and sex hormones on kidney metabolism.

Methods: Male and female PTECs were stimulated with control, dihydrotestosterone (DHT), or estradiol. Sex differences in key metabolites were validated in diabetic mice, and in type 2 diabetic patients and their age- and weight-matched healthy controls (n=180, iCARE cohort).

Results: Male PTECs showed significantly higher glycolysis, oxygen consumption (OCR), glucose consumption, oxidative stress, and apoptosis, compared to female PTECs, especially in the presence of DHT. Higher OCR in male PTECs was further enhanced in the presence of glucose and glutamine, but not observed in the presence of pyruvate. Under high glucose, male PTECs showed a decline in OCR and ATP levels over time, and increased lactate production. Male PTECs had significantly higher intracellular levels of TCA cycle metabolites (glutamate, citrate, malate, aspartate) and glutathione metabolites. In turn, female cells had higher levels of pyruvate. *In vivo*, male sex was linked to increased circulating levels of glucose, lactate, and glutamate in healthy and diabetic mice. Male sex was also independently associated with increased serum levels of glutamate, succinate, fumarate, and 9 metabolites of the glutathione cycle, in healthy and diabetic individuals.

Conclusions: This is the first study to demonstrate that the kidney metabolism of glucose and glutamine is modulated by cell sex and sex hormones. Male sex was linked to increased oxidative stress, cell injury, glucose- and glutamine-related enzymes, lactate secretion, and levels of TCA cycle and glutathione metabolites. Our key findings were validated in the blood metabolome of healthy and diabetic humans. Our work has uncovered physiological sex differences that are important for DKD and may lead to new therapeutic paradigms based on patient sex.

PO0732

Circulating Fibroblast Growth Factor 20 (FGF-20) as a Novel Protein Protective Against Progression to ESKD in Diabetes

Zaipul I Md Dom,[1,2] Eiichiro Satake,[1,2] Hiroki Kobayashi,[1,2] Bozena Krolewski,[1,2] Jonathan M. Wilson,[3] Kevin L. Duffin,[3] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Eli Lilly and Company, Indianapolis, IN*.

Background: Growing evidence from animal, cellular and targeted biomarker studies supports an involvement of fibroblast growth factor (FGF) family members (FGF23, FGF21) in diabetic kidney disease (DKD) progression. However, the majority of the studies were cross-sectional and performed in a targeted manner focusing on individual proteins. Therefore, we aimed to comprehensively evaluate the profiles of circulating FGF proteins in progressive DKD leading to end-stage kidney disease (ESKD) in individuals with diabetes.

Methods: This was a prospective cohort study of individuals with type 1 (n=214) and type 2 (n=144) diabetes, persistent proteinuria and CKD Stage 3 followed for progression to ESKD within 10 years. Measurement of circulating FGF proteins (n=17) were performed in baseline plasma samples using aptamer-based (SOMAscan) proteomic profiling.

Results: One hundred eight (50%) and 35 (24%) individuals with T1D and T2D, respectively, developed ESKD within 10 years. Six out of 17 FGF proteins were protective against progression to ESKD in the univariable Cox regression model. The strongest protection was observed for FGF20 (HR (95% CI): 0.68 (0.59, 0.79), $p=7.0x10^{-7}$). The cumulative 10-year risk of ESKD was about 2 times lower in individuals with high versus low levels of FGF20. Three proteins remained significant after further adjustment by clinical covariates, however, only the protective effect of FGF20 was confirmed in a third cohort of T1D individuals (n=294) with early DKD (CKD Stage 1 and 2); (OR (95% CI): 0.48 (0.37, 0.61), $p=6.1x10^{-9}$). Interestingly, non-diabetic parents of T1D children with ESKD or Proteinuria had lower FGF20 concentrations than those parents with T1D children without kidney complications.

Conclusions: This study identified circulating FGF20 as protective against progression to ESKD in three independent cohorts of individuals with T1D and T2D and varying stages of DKD. The protective effect was independent from the clinical legacy measures of DKD. Identification of proteins that protect individuals from ESKD may be useful targets for the development of therapeutics for preventing or delaying the onset of ESKD.

Proteome Analysis of Glomerular Formalin-Fixed Paraffin Embedded Kidney Samples Distinguishes Diabetic Nephropathy from Controls

Sophie I. Nagelkerken,[1] George Janssen,[4] Kimberley Veraar,[1] Peter Van veelen,[4] Hans J. Baelde,[1] Roy Lardenoije,[2,3] Joris I. Rotmans,[5] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leids Universitair Medisch Centrum Afdeling Pathologie, Leiden, Netherlands; [2]University Medical Center Göttingen Department of Psychiatry and Psychotherapy, Göttingen, Germany; [3]Harvard Medical School Department of Psychiatry McLean Hospital, Belmont, MA; [4]Leids Universitair Medisch Centrum Center for Proteomics and Metabolomics, Leiden, Netherlands; [5]Leids Universitair Medisch Centrum Niercentrum, Leiden, Netherlands*.

Background: Liquid chromatography tandem-mass spectrometry (LC-MS/MS) is a sensitive technique for in depth proteome analysis but its usage as a diagnostic tool for kidney diseases is still in development. We investigated the potential use of LC-MS/MS in diagnosing diabetic nephropathy (DN) in renal biopsies.

Methods: Biopsies from 10 DN patients without renal comorbidity were compared to 10 pretransplantation biopsies. Glomerular cross-sections were collected using laser capture microdissection and tryptic peptides were analysed using LC-MS/MS. Resulting spectra were used for protein identification and further analysis.

Results: Based on all identified proteins, DN patients and controls clustered separately (Figure 1). Moreover, we identified 47 significant differentially expressed proteins after adjusting for multiple testing. In DN proteins with increased expression included collagens IV, VI and XVIII, fibronectin, vitronectin, fibulin, complement component C3, C4 and C9, complement factor H, clusterin, fibrinogen and apolipoprotein E. Proteins with decreased expression in DN included nephrin, chloride intracellular channel protein 5, Rab GDP dissociation inhibitor alpha and complement receptor 1.

Conclusions: Proteins identified by LC-MS/MS from glomerular cross-sections successfully distinguished kidney biopsies with DN from normal kidneys. Moreover, a set of differentially expressed proteins were identified, most of which were previously suggested to play a role in the development of DN, which further emphasizes the applicability of LC-MS/MS as a diagnostic tool.

Funding: Private Foundation Support, Government Support - Non-U.S.

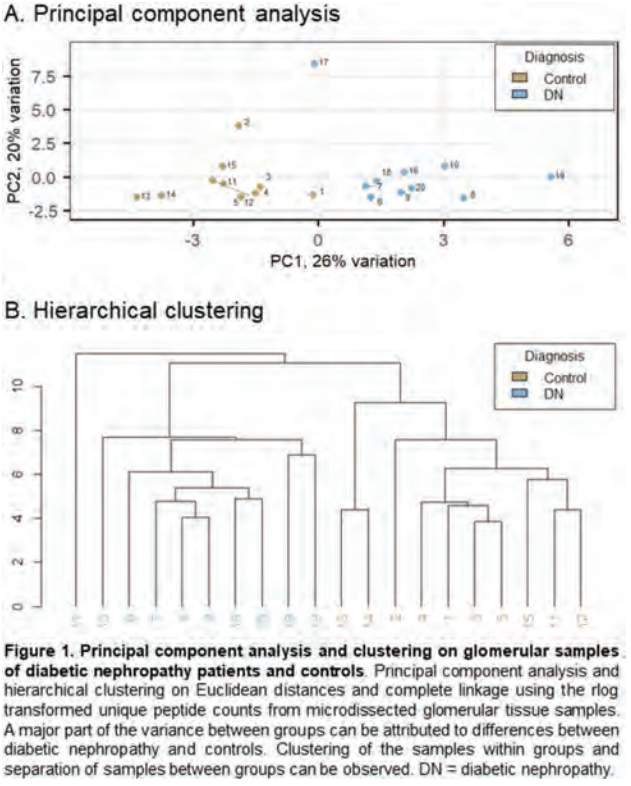

Figure 1. Principal component analysis and clustering on glomerular samples of diabetic nephropathy patients and controls. Principal component analysis and hierarchical clustering on Euclidean distances and complete linkage using the rlog transformed unique peptide counts from microdissected glomerular tissue samples. A major part of the variance between groups can be attributed to differences between diabetic nephropathy and controls. Clustering of the samples within groups and separation of samples between groups can be observed. DN = diabetic nephropathy.

PO0734

The Extracellular Matrix Signaling Molecule Endotrophin Is Associated with Diabetic Complications in Type 1 Diabetes

Alexandra L. Møller,[1,3] Daniel Guldager Kring Rasmussen,[1] Ninna H. Tougaard,[2] Pernille F. Rønn,[2] Federica Genovese,[1] Morten A. Karsdal,[1] Tine Hansen,[2] Peter Rossing.[2,3] *[1]Nordic Bioscience, Herlev, Denmark; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]University of Copenhagen, Copenhagen, Denmark.*

Background: Persons with diabetes have a high risk of late complications related to both the micro- and macrovascular circulation. Early intervention targeting several risk factors is implemented, but tools to predict complications before clinical manifestations are still lacking. The PRO-C6 assay reflects collagen (COL) type VI formation and levels of endotrophin (ETP), a bioactive molecule derived from COL VI. In this study, we investigated the cross-sectional association between ETP and microvascular complications. Follow-up data is currently being collected to investigate the potential of ETP to predict development of complications and mortality.

Methods: We measured ETP in 1444 serum (S-ETP) and 1249 urine (U-ETP) samples (collected from 2012 to 2016), using the PRO-C6 ELISA (Nordic Bioscience) in persons with type 1 diabetes recruited from Steno Diabetes Center Copenhagen. All urine samples were normalized to urinary creatinine levels.

Results: In crude analyses, S-ETP levels increased significantly with CKD stage and albuminuria stage, and presence of retinopathy and neuropathy (all P<0.0001). S-ETP could discriminate patients with eGFR < 60 ml/min/1.73 m² with an AUC of 0.83 (P<0.001). In multiple linear regression analyses including age, sex, SBP, smoking, BMI, LDL cholesterol, HbA1c, albumin excretion and eGFR, lower age (r=-0.16, P<0.0001), higher albumin excretion (r=0.35, P<0.0001) and lower eGFR (r=-0.30, P<0.0001) were associated with higher S-ETP levels. U-ETP levels were not associated with disease severity or any of the investigated parameters. Following multiple linear regression, none of the parameters were associated with U-ETP. There was no correlation between S-ETP and U-ETP.

Conclusions: In conclusion, we demonstrate that ETP released during COL VI formation was associated with kidney disease severity, retinopathy, and neuropathy in patients with type 1 diabetes. These findings may indicate that ETP identifies diabetic patients with active fibrogenesis, and tissue injury. The potential of ETP to predict complications and mortality will be investigated once follow-up data has been collected.

PO0735

Urinary Sphingolipids in Youth-Onset Diabetes

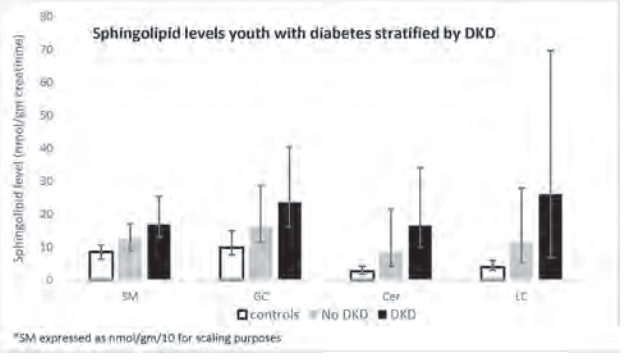
Edward Nehus,[1] Mark Mitsnefes.[2] *[1]Marshall University, Huntington, WV; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Sphingolipid metabolism is altered in diabetes has been implicated as a mediator of diabetic kidney disease (DKD). The purpose of this study was to evaluate urinary sphingolipids as an early marker of kidney injury in youth with type 1 (T1) and type 2 diabetes (T2DM).

Methods: A comprehensive panel of urinary sphingolipids, including sphingomyelin (SM), glucosylceramide (GC), ceramide (Cer), and lactoslyceramide (LC) species, was performed in patients with youth-onset diabetes from the Treatment Options for Diabetes in Youth (TODAY) cohort. Sphingolipid levels, normalized to urine creatinine, were compared in 57 youth with T1DM, 59 with T2DM, and 44 healthy control subjects. The association of sphingolipids with early markers of DKD (albumin-to-creatinine [ACR] ratio and estimated glomerular filtration rate [eGFR]) was evaluated.

Results: The median age (IQR) of youth with diabetes was 22.2 years (19.9, 23.6) and the median duration of diabetes was 9.3 (8.5, 10.2) years. Urinary sphingolipid concentrations in youth with and without DKD (ACR ≥ 30) were significantly elevated compared to healthy subjects (all p<0.001). There were no significant differences between youth with type 1 and type 2 diabetes. All sphingolipid species were positively correlated with eGFR (all p < 0.001) and negatively with albumin-to-creatinine ratio (p < 0.001 for SM, Cer, GC; p = 0.0015 for LC). In multivariable analysis that adjusted for BMI and HgbA1c, all urinary sphingolipid species remained significantly associated with eGFR (all p < 0.01). SM, GC, and Cer species remained independently associated with ACR (all p < 0.05).

Conclusions: Urinary sphingolipids are elevated in youth with diabetes and correlate with eGFR and albuminuria. Urinary sphingolipids may therefore represent an early marker of DKD.



PO0736

Long Non-Coding RNA Profiles and Declining Kidney Function in Patients with Diabetes and CKD

Eiichiro Satake,[1] Hiroki Kobayashi,[1] Zaipul I Md Dom,[1] Kristina V. O'Neil,[1] Bozena Krolewski,[1] Marcus G. Pezzolesi,[2] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]University of Utah, Salt Lake City, UT.*

Background: Long non-coding RNAs (lncRNAs) are endogenous molecules that are involved in gene regulation and play important roles in the pathogenesis of various renal diseases, including diabetic kidney disease (DKD). lncRNA signatures associated with DKD, however, have not been fully established. The objective of this study was to determine the whole blood lncRNA signature that is associated with increased risk of DKD progression.

Methods: Eighty-eight lncRNAs that were previously reported to be related to DKD were measured by quantitative PCR (qPCR) in RNA from whole blood (PAXgene RNA tubes) from 22 patients with type 1 diabetes and chronic kidney disease (12 of whom progressed to ESKD during 7-10 years of follow-up). GAPDH was used for sample normalization. We assessed declining kidney function as eGFR slope (ml/min/1.73m²/year).

Results: Seventy-two of the 88 lncRNAs were detectable in more than half of the samples included in this study (n>11). Using Pearson's test, eGFR slope was found to be significantly correlated with lncRNAs H19 (r=-0.56, P=0.0073) and CRNDE (r=-0.42, P<0.05). H19 and CRNDE were not correlated with HbA1c (r=0.22, P=0.32 and r=-0.15, P=0.52 respectively), suggesting that these lncRNAs are associated with progression of DKD mediated by distinct pathway(s) independent of hyperglycemic condition.

Conclusions: We investigated plasma lncRNA profiles associated with declining kidney function in patients with diabetes. Although we need to confirm the results in an independent validation panel, our findings suggest that H19 and CRNDE are associated with declining kidney function and have potential to serve as circulating biomarkers for progression of DKD.

A Comparison of PromarkerD to Standard-of-Care Tests for Predicting Renal Decline in Type 2 Diabetes

Kirsten E. Peters,[1,2] Scott D. Bringans,[1] Wendy A. Davis,[2] Richard Lipscombe,[1] Timothy Davis.[2] *[1]Proteomics International, Perth, WA, Australia; [2]The University of Western Australia Medical School, Perth, WA, Australia.*

Background: Diabetic kidney disease (DKD) can progress to end stage renal disease with associated increased morbidity and mortality. Current standard of care (SoC) for assessing DKD includes measurement of estimated glomerular filtration rate (eGFR) and urinary albumin:creatinine ratio (ACR), but both tests have limitations. This study compared the biomarker-based PromarkerD test with SoC for predicting renal decline in community-based patients with T2D.

Methods: Baseline plasma biomarkers (CD5L, ApoA4, IGFBP3) measured by mass spectrometry were combined with clinical data (age, serum HDL-cholesterol, eGFR) using a validated algorithm to provide PromarkerD scores categorized as low, moderate or high risk in 857 participants with T2D from the Fremantle Diabetes Study Phase II. The 1° endpoint was incident DKD (reduction in eGFR to <60 mL/min/1.73m^2 during follow-up) or eGFR decline ≥30% in participants with baseline eGFR <60 mL/min/1.73m^2. Logistic regression was used to compare the association of i) PromarkerD, ii) eGFR, iii) ACR, and iv) eGFR+ACR, with outcomes during 4 years of follow-up. Model performance was assessed by the ROC area under the curve (AUC).

Results: At baseline, participants (mean age 65 years, 54% males, median diabetes duration 7 years) had mean eGFR 82 mL/min/1.73m^2, geometric mean ACR 26 mg/g and were classified by PromarkerD as low (63%), moderate (13%) or high risk (24%) for renal decline. During 4.2±0.3 years of follow-up, 107 (13%) participants reached the 1° endpoint. PromarkerD had significantly higher predictive performance (AUC=0.88) compared to eGFR (0.82), ACR (0.63) and eGFR+ACR (0.82) (all P<0.001). Higher PromarkerD scores had a stronger association with the 1° outcome (odds ratio (OR) 3.26, 95% CI 2.67-3.99 per 1 standard deviation (SD) increase) compared to lower eGFR and higher ACR (OR=2.63 (2.13-3.23) and 1.21 (1.04-1.40) per 1 SD increase, respectively). PromarkerD remained significantly associated with the 1° outcome after adjusting for eGFR and ACR (OR=2.78 (2.19-3.53) per 1 SD increase). PromarkerD moderate and high-risk scores were increasingly prognostic for the 1° outcome (OR 8.11 and 21.34 versus low risk, respectively; both P<0.001).

Conclusions: PromarkerD outperformed the standard of care tests eGFR and ACR for predicting future renal decline in T2D.

PO0738

Urinary Interleukin 9 in Youth with Type 1 Diabetes Mellitus

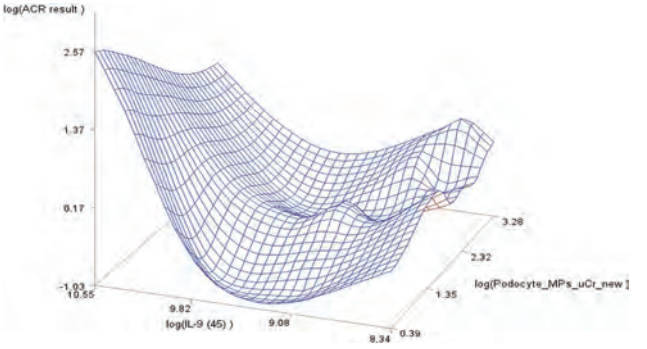
Julie A. Semenchuk,[1] Katie Sullivan,[3] Allison Dart,[4] Brandy A. Wicklow,[5] Dylan Burger,[6] James W. Scholey.[1,2] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]University of Toronto Department of Physiology, Toronto, ON, Canada; [3]University of Pennsylvania Department of Medicine, Philadelphia, PA; [4]University of Manitoba Department of Pediatrics and Child Health, Winnipeg, MB, Canada; [5]University of Manitoba Department of Pediatrics and Child Health, Winnipeg, MB, Canada; [6]University of Ottawa Faculty of Medicine, Ottawa, ON, Canada.*

Background: Interleukin-9 (IL9) is a cytokine that promotes podocyte health in mice with Adriamycin-induced nephrotoxicity but its role in human kidney disease is uncertain. Glomerular podocyte stress leads to the release of microparticles (MP) into the urine and we have reported that urinary Podocyte-derived MPs correlate with both eGFR and blood glucose (BG) in youth with type 1 diabetes (T1D). We first sought to relate urinary IL9 levels to Podocyte-derived MPs in youth with T1D. We then studied the impact of cytokines implicated in diabetic nephropathy, including VEGF, TNFα and IL6, on the relationship between IL9 and ACR, a functional measure of podocyte health.

Methods: We performed an analysis of urine samples and clinical data from youth with T1D (n = 53). We measured ACR and used flow cytometry to count urinary podocyte-derived MPs and a Luminex platform (Eve Technologies) to measure a panel of urinary cytokines.

Results: Mean age was 14.7±1.6 years and the duration of diabetes was 6.7±2.9 yrs. Mean HbA1c was 70.3± 13.9 mmol/mmol. The mean ACR was1.3±1.9 mg/mmol with a mean eGFR of 140.3±32.6 ml/min/1.73 m^2. MPs normalised to urinary creatinine (MP/UCr) were inversely related to IL9 (r= -0.56, p< 0.001) in males and females. BG and eGFR values were associated with IL9 (r=-0.44, p<0.001; r=-0.49, p<0.001; respectively) but the relationship between IL9 and ACR was modest (r=-0.26, p=0.06). There was a significant interaction between IL9, MPs, and ACR (p=0.0066). Urinary IL9 and VEGF levels were positively correlated (r= 0.72, p< 0.001) and the relationship of IL9 with ACR depended on VEGF levels (p=0.0032). The relationship between IL9 and ACR was strongly determined by TNFα levels (p=0.014) and IL6 (p=0.0096).

Conclusions: Our analyses show that IL9 is a determinant of podocyte health in early T1D, and that there are complex interactions between urinary IL9, inflammatory cytokines, and ACR.



A three-dimensional representation of the relationships between IL-9, MPs, and ACR.

PO0739

Human Kidney Proteomics Identifies Biomarkers Associated with Kidney Function in Patients with Diabetic Kidney Disease

Amin Abedini,[1] Salina Moon,[2] Monika A. Niewczas,[2] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Joslin Diabetes Center, Boston, MA.*

Background: Diabetic kidney disease (DKD) is the most common cause of chronic kidney disease (CKD) and end stage kidney disease, worldwide. However, the pathogenesis of DKD is poorly understood. While RNA sequencing emerged as an important tool to understand gene expression changes, protein level changes are poorly understood. SOMAscan is an emerging method that can robustly measure the level of thousands of proteins.

Methods: We have performed unbiased SOMAscan proteomics and quantified the amount of 1317 proteins in 24 snap frozen kidney tissues collected from nephrectomies. Our samples included 10 control healthy samples, 10 from subjects with overt DKD (CKD stage 3a), and 14 from subjects with late DKD (CKD stages 3b or 4). Demographic and clinical characteristics of the subjects were collected.

Results: The mean of age was 61 ± 16 and 65 % of the subjects were male. The median glomerular filtration rate (eGFR) was 108 (33) in control, 54 (5) in overt DKD, and 32 (28) in late DKD. We identified 279 proteins showing differences at overt DKD samples, and 381 proteins in late DKD samples compared to controls. Gene ontology analysis indicated enrichment for immune system and metabolic processes. The protein level of matrix metalloproteinase-7 (MMP-7) showed the strongest differences between control and DKD. Linear regression, adjusted for key co-variates identified 96 proteins those levels correlated with eGFR including cystatins C and MMP-7. We observed a moderate correlation between transcript and protein levels (r = 0.43, p < 2.2e-16).

Conclusions: SOMAscan proteomics identified important changes in protein expression in overt and late DKD, these could serve as important biomarkers or therapeutic targets.

PO0740

Diabetes Mellitus Associates with Differences in the Metabolome of Patients with CKD

Mingyao Sun,[1] Patrick Ten eyck,[3] Nicole G. Hines,[1] Jane Buchanan,[4] Eric Taylor,[4] Diana I. Jalal.[1,2] *[1]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA; [3]Institute for Clinical and Translational Science, Iowa City, IA; [4]University of Iowa, Department of Molecular Physiology and Biophysics, Iowa City, IA.*

Background: Diabetic Mellitus (DM), the most common cause of chronic kidney disease (CKD), is associated with increased risk of death, cardiovascular disease, and kidney failure even if the DM is well-controlled. We hypothesized that significant differences exist in the metabolome of CKD patients with well-controlled DM as compared to CKD patients without DM.

Methods: Gas chromatography mass spectrometry (GC-MS) was used to perform serum metabolomic analysis of 46 subjects (28 CKD with DM and 18 CKD without DM). Unpaired t-tests were performed to compare metabolites between the 2 groups and Spearman correlation was utilized to evaluate the potential correlation between the metabolites and measures of kidney function. MetaboAnalyst (V5.0) was utilized to identify metabolic pathways that differed between those with or without DM.

Results: In the subjects with CKD and DM, the mean(SD) hemoglobin A_{1C} was 7.11(1.8) vs 5.5(1.4) in those with CKD but without DM. Of the 90 metabolites detected by GC-MS, 17 differential metabolites were significantly altered in the CKD with DM vs CKD without DM groups (p≤0.10). MetaboAnalyst indicated galactose metabolism, glycerolipid metabolism, starch and sucrose metabolism, fructose and mannose degradation, and fatty acid biosynthesis are the top differential pathways between both groups. In those with CKD and DM, citrate correlated with estimated glomerular filtration rate (GFR) (r=0.42, p=0.031) and homoserine and glycerol correlated with ACR (r=0.42, p=0.048 and r=0.42, p=0.044, respectively).

Conclusions: We have identified significant differences in the metabolome of CKD patients with well-controlled DM compared to those without DM. Further research is needed to evaluate the potential role of these metabolic pathways and if they contribute to the high morbidity and mortality burden in CKD patients with DM.

Urine Biomarkers and ESKD Risk in Persons with Diabetes and CKD

Jonathan G. Amatruda,[1,2] Ronit Katz,[3,4] Mark J. Sarnak,[5] Orlando M. Gutierrez,[6] Jason H. Greenberg,[7] Mary Cushman,[8] Sushrut S. Waikar,[9] Chirag R. Parikh,[10] Jeffrey R. Schelling,[11] Joseph V. Bonventre,[12] Vasan S. Ramachandran,[13] Paul L. Kimmel,[14] Michael Shlipak,[15,2] Joachim H. Ix.[16,17] *[1]University of California San Francisco, San Francisco, CA; [2]Kidney Health Research Collaborative, San Francisco VA Medical Center & University of California, San Francisco, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]Kidney Research Institute, University of Washington, Seattle, WA; [5]Tufts Medical Center, Boston, MA; [6]Departments of Medicine and Epidemiology, University of Alabama at Birmingham, Birmingham, AL; [7]Section of Nephrology, Department of Pediatrics, Clinical and Translational Research Accelerator, Yale University School of Medicine, New Haven, CT; [8]University of Vermont College of Medicine, Burlington, VT; [9]Section of Nephrology, Department of Medicine, Boston Medical Center, Boston, MA; [10]Johns Hopkins Medicine, Baltimore, MD; [11]Case Western Reserve University Department of Medicine, Cleveland, OH; [12]Brigham and Women's Hospital Department of Medicine, Boston, MA; [13]Departments of Medicine and Epidemiology, Boston University School of Medicine and School of Public Health, Boston, MA; [14]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [15]Department of Medicine, San Francisco VA Health Care System, San Francisco, CA; [16]Division of Nephrology and Hypertension, Department of Medicine, University of California San Diego, San Diego, CA; [17]Nephrology Section, Veterans Affairs San Diego Healthcare System, La Jolla, CA.*

Background: Tubulointerstitial damage is a feature of diabetic CKD, but correlates poorly with eGFR and albuminuria. Urine biomarkers of kidney tubule health may be independently associated with risk of ESKD in diabetic CKD.

Methods: We identified 1,145 participants from the REGARDS study with baseline eGFR≤60 mL/min/1.73m^2 and diabetes. Per case-cohort design, we randomly selected a subcohort of 560. Within the subcohort there were 93 ESKD cases; we further sampled all remaining ESKD cases not included in the subcohort (N=68). These 161 ESKD cases were identified by USRDS linkage over mean follow-up of 4.3±2.7 years. In baseline urine samples, we measured biomarkers of kidney tubule injury (kidney injury molecule-1 [KIM-1]), inflammation and fibrosis (monocyte chemoattractant protein-1 [MCP-1]; chitinase-3-like protein [YKL-40]), function (alpha-1-microglobulin [α1m]; uromodulin [UMOD]), and cell repair (epidermal growth factor [EGF]). Using weighted Cox models, we calculated hazard ratios (HR) of ESKD by baseline biomarkers. LASSO regression identified a subset of biomarkers most strongly associated with ESKD.

Results: Subcohort participants had mean age 70±9 years, 47% male, 53% Black, mean eGFR=40±13 mL/min/1.73m^2 and median UACR 33 (IQR 10-213) mg/g. Adjusting for baseline eGFR and albuminuria, higher KIM-1, α1m, and MCP-1 were each associated with higher ESKD risk. Strengths of association were of comparable magnitude to urine albumin (**Table**). LASSO regression retained KIM-1 (HR per doubling=1.31 [1.06-1.62]) and α1m (HR per doubling=1.36 [1.08-1.70]) as most strongly associated with ESKD.

Conclusions: Among persons with eGFR≤60 mL/min/1.73m^2 and diabetes, urine KIM-1 and α1m captured the influence of kidney tubule health on longitudinal risk of ESKD. These biomarkers may facilitate identification of persons with kidney disease and diabetes at greatest risk of ESKD.

The Potential Value of Urinary Extracellular Vesicles VEGF-A165b in Diagnosis of Diabetic Kidney Disease

Jing Jing, Songtao Feng, Linli Lv. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China.*

Background: Novel biomarkers are needed for management of diabetic kidney disease (DKD). Urinary extracellular vesicles (uEVs) were served as an ideal resource of biomarkers in kidney disease. VEGF-A165b is a angiogenic factor secreted from podocytes correlated with DKD. The study was aimed to evaluate the diagnostic value of uEVs-VEGF-A165b in DKD.

Methods: Urine samples were collected from 36 patients with T2DM and 12 controls. Subjects with T2DM were stratified into three groups according to UACR, eGFR, and T2DM duration. To isolate exosomes, 25 ml urine was ultracentrifuged to obtain exosomes. Protein was extracted from uEVs and subjected to western blot (Wb) for detecting VEGF-A165b. Immunohistochemistry (IHC) staining of VEGF-A165b was performed in kidney paraffin sections from STZ-induced DM rats. ROC curve was used to evaluate the diagnostic value of uEVs-VEGF-A165b in DKD.

Results: Urinary MVs and exosomal VEGF-A165b were higher in T2DM with ACR>300mg/g than those with ACR<30mg/g. In addition, urinary MVs VEGF-A165b were higher in patients with ACR30-300mg/g than those with ACR<30mg/g, and exosomal VEGF-A165b levels were lower in patients with ACR30-300mg/g than whose ACR>300 mg/g. Furthermore, VEGF-A165b in uEVs increased with the DM duration. VEGF-A165b in patients with duration longer than 10 years were higher than whose duration less than 5 years. Correlation analysis revealed eGFR was negatively correlated with urinary MVs and exosomal VEGF-A165b. ROC curve showed that AUC of urinary MVs and exosomal VEGF-A165b for the diagnosis of DKD were 0.9091 and 0.8269. IHC revealed that VEGF-A165b was elevated in renal tubules in STZ-induced DM rats.

Conclusions: A increased level of uEVs-VEGF-A165b was observed in DKD patients and was correlated with decline of eGFR. uEVs-VEGF-A165b may be used as a promising biomarker reflecting the severity of DKD and may suggest a pathological role in the development of the disease.

Independent Predictive Factors of Estimated GFR Decline in Type 2 Diabetes Patients with Preserved Kidney Function

Daishi Hirano,[1] Hiroyuki Unoki-Kubota,[2] Toshiyuki Imasawa,[3] Hiroshi Kajio,[2] Shigeo Yamashita,[4] Yuka Fukazawa,[5] Yasushi Kaburagi.[2] *[1]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; [2]Kokuritsu Kokusai Iryo Kenkyu Center Tonyobyo Joho Center, Shinjuku-ku, Japan; [3]Department of Nephrology, National Hospital Organization Chibahigashi National Hospital, Chiba, Japan; [4]Tokyo Yamate Medical Center, Shinjuku-ku, Japan; [5]JR Tokyo Sogo Byoin, Shibuya-ku, Japan.*

Background: We examined predictors of annual decline in estimated glomerular filtration (eGFR) in patients with type 2 diabetes and preserved kidney function.

Methods: In a prospective, observational cohort study, 392 Japanese patients with type 2 diabetes and baseline eGFR ≥ 60 ml/min/1.73m^2 were followed over one year (mean period 5.5 years; IQR 3.9-7.3). Linear regression was used to estimate participants' annual decline rate in eGFR over time. We defined subjects with an annual eGFR decline ≥ 5% per year as rapid progression and the eGFR decline < 5% as slow progression. In addition, time-averaged values of each laboratory data were calculated and used for sensitivity analysis.

Results: The study population had a median age of 59.0 years (IQR, 53.0–64.0) and 75% were male. The median duration of diabetes was 15.9 years (IQR, 11.2–20.4). During the follow-up period, 46 (11.7%) patients had a rapid decline in eGFR (median decline -6.51%; IQR, -8.59 – -5.60). Compared to patients with a slow decline in eGFR (N = 346), those with a rapid decline in eGFR had significantly higher HbA1c levels and lower HDL-cholesterol (HDL-c) levels at baseline. Multivariable logistic regression models revealed

that lower baseline hemoglobin and HDL-c levels were independent predictors of annual decline in eGFR (OR, 0.69, 95% CI, 0.53–0.89, *P* = 0.005; OR, 0.97, 95% CI 0.94–0.99, *P* = 0.007, respectively). Furthermore, time-averaged hemoglobin and HDL-c levels were also independent predictors of annual decline in eGFR (OR, 0.62, 95% CI, 0.46–0.82, *P* = 001; OR, 0.97, 95% CI 0.94–0.99, *P* = 0.007, respectively).

Conclusions: Our findings highlight the important effect of lower hemoglobin and HDL-c levels as independent predictors of rapid decline in eGFR in patients with type 2 diabetes and preserved kidney function.

Post-Hospitalization Blood Pressure (BP) and Diabetes (DM) Control and Outcomes in Patients with Diabetic Kidney Disease (DKD)

Rimon Golovey, Mariela Navarro Torres, Sharon Rikin, Sunit Jariwala, Ladan Golestaneh. R Golovey, M Navarro-Torres share first author status *Montefiore Medical Center, Bronx, NY.*

Background: DKD is the most common cause of ESKD in the US but because the course of progression is prolonged, research to elucidate risks and effective interventions are difficult. In a high-risk cohort with DKD, do post-hospitalization BP and DM control act as good surrogate markers for outcomes?

Methods: Using Looking Glass, Montefiore Medical Center's clinical database, we created a cohort of patients with a first discharge in 2016 who met the following criteria: CKD stage 3b or 4 and Proteinuria >300 and <5000mg/gm. Follow up data regarding CKD outcomes up to 2 years, clinic visits, RAASi prescriptions, mean systolic BP (SBP) and HgbA1c levels within 1 year of discharge were collected. Cox proportional hazards was used in adjusted analyses, to estimate the HR of mean SBP and HgbA1c levels, both dichotomized at the 75th percentile, with ESKD incidence or death over 2 years of follow-up.

Results: A total of 572 individuals met DKD criteria and had a first discharge in 2016. The mean age for the cohort was 66.8 years (SD 11.5), 244 (42.7%) were male, 224 (39.3%) were Black, 210 (36.8%) were Hispanic and 33 (5.8%) were White. Sixty-eight percent had a readmission within 1 year of discharge with median time to readmission at 63 days (IQR 22-184). Ninety-three percent of individuals had an outpatient clinic visit and the median number of clinic visits was 30 (IQR 16-47) over 1 year, with median time from discharge to an outpatient visit of 8 days (IQR 4-18). Mean SBP was 138mmHg (SD 22.2) with 26.9% of individuals with a mean SBP >150mmHg during 1 year of follow up. Mean HgbA1c was 8.6 (SD 2.1) with 192 (33.6%) who had HgbA1c >9.7 over 1 year of follow up. Eighty-eight (15.4%) patients died and 99 (17.3%) progressed to ESKD over 2 years of follow up. In models adjusting for age, sex and race/ethnicity there was a positive association between SBP >150 (HR 1.53, 95% CI: 1.12-2.09) and HgbA1c>9.7 (HR 1.58 95% CI: 1.16-2.15) and time to ESKD or death.

Conclusions: High mean BP and HgbA1c levels during 1 year post-discharge are associated with adverse outcomes in a cohort of hospitalized patients with DKD. These measures serve as useful surrogate biomarkers to study DKD interventions in a high-risk population.

Finerenone Dose-Exposure-UACR Response Analyses of FIDELIO-DKD Phase 3 and the Effect of SGLT-2 Inhibitor Co-Medication

Hiddo J. L Heerspink,[1] Sebastiaan Goulooze,[2] Martijn van Noort,[2] Nelleke Snelder,[2] Meike D. Brinker,[3] Jörg Lippert,[4] Thomas Eissing.[5] TBC *[1]Department Clinical Pharmacy and Pharmacology, University of Groningen & University Medical Center Groningen, Groningen, Netherlands; [2]Leiden Experts on Advanced Pharmacokinetics and Pharmacodynamics (LAP&P), Leiden, Netherlands; [3]Bayer AG, Clinical Development, Wuppertal, Germany; [4]Bayer AG, Pharmacometrics, Wuppertal, Germany; [5]Bayer AG, Pharmacometrics, Leverkusen, Germany.*

Background: The mineralocorticoid receptor antagonist finerenone and sodium-glucose cotransporter 2 inhibitors (SGLT2i) have been shown to reduce albuminuria and the risk of kidney failure. The combination of these therapies holds promise to augment nephroprotection through activation of different pathways. Model-based approaches considering individual dosing and exposure and correcting for covariates can support stronger conclusions than stratification for baseline comedication. We developed a population pharmacokinetic/pharmacodynamics (popPKPD) model to assess the finerenone dose-exposure-response relationship for urine albumin-to-creatinine ratio (UACR) and the impact of combined SGLT2i-finerenone use on UACR.

Methods: We analysed 37296 UACR measurements in 5674 patients (549 patients with any recorded SGLT2i use) using nonlinear mixed-effects popPKPD modelling considering individual drug exposure. The model was used to characterize the trajectory of UACR progression over time, the exposure-response relationship of finerenone on UACR and the effect of SGLT2i.

Results: The popPKPD model described the observed UACR data well, with a proportional UACR progression over time, an indirect power model for the exposure-response relationship of finerenone and a constant effect of SGLT2i use. SGLT2i use did not modify finerenone efficacy (p=0.25) and indicated with 95% confidence that finerenone is at least 94.1% as efficacious in reducing UACR in patients using SGLT2i (Figure 1).

Conclusions: We successfully developed a popPKPD model that adequately described the dose-exposure-response of finerenone on UACR. The results demonstrate additive effects of SGLT2i on top of finerenone.

Funding: Commercial Support - Bayer AG

Effects of Ertugliflozin on Kidney End Points in Patients with Non-Albuminuric Diabetic Kidney Disease in VERTIS CV

David Cherney,[1] Samuel Dagogo-Jack,[2] Francesco Cosentino,[3] Darren K. Mcguire,[4,5] Richard E. Pratley,[6] Robert Frederich,[7] Mario Maldonado,[8] Chih-Chin Liu,[9] Christopher P. Cannon.[10] VERTIS CV investigators *[1]University of Toronto, Toronto, ON, Canada; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Unit of Cardiology, Karolinska Institute & Karolinska University Hospital, Stockholm, Sweden; [4]The University of Texas Southwestern Medical Center, Dallas, TX; [5]Parkland Health and Hospital System, Dallas, TX; [6]AdventHealth Translational Research Institute, Orlando, FL; [7]Pfizer Inc., Collegeville, PA; [8]MSD Limited, London, United Kingdom; [9]Merck & Co., Inc., Kenilworth, NJ; [10]Cardiovascular Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Non-albuminuric diabetic kidney disease (NA-DKD) is an increasingly recognised condition. Data from VERTIS CV (NCT01986881) were analyzed to study the impact of ertugliflozin on kidney outcomes in patients with NA-DKD.

Methods: Patients with type 2 diabetes mellitus and atherosclerotic cardiovascular disease were randomized (1:1:1) to ertugliflozin 5 mg, 15 mg (both doses were pooled for analyses) and placebo. Subgroups were defined by baseline eGFR (mL/min/1.73 m^2) and UACR (mg/g): No DKD (N-DKD), eGFR ≥60 + UACR <30 (n=3916); NA-DKD, eGFR <60 + UACR <30 (n=867); albuminuric-DKD (A-DKD), UACR ≥30 (n=3247). eGFR slopes (chronic from week [W]6 to W260 and total from W0 to W260) and Cox proportional hazards for the time to first event of a kidney composite were assessed.

Results: The NA-DKD subgroup had the slowest rate of total eGFR decline and the A-DKD subgroup the fastest rate of decline (Figure). The effect of ertugliflozin to slow the rate of eGFR decline vs placebo did not significantly differ across the subgroups. The hazard ratio for ertugliflozin showing reduction in the risk of the composite kidney outcome vs placebo was consistent across subgroups, $P_{interaction}$ = 0.26 (Table).

Conclusions: In VERTIS CV, participants with NA-DKD had the slowest rate of eGFR decline over time and lower kidney composite outcome event rates.

Funding: Commercial Support - The study and this analysis were funded by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA, in collaboration with Pfizer Inc. KidneyIntelX as an Enrichment Tool for Clinical Trials in Early Diabetic Kidney Disease

George Vasquez-Rios,[1] Girish N. Nadkarni,[1] Bruce Neal,[2] Kenneth W. Mahaffey,[3] Michael K. Hansen,[4] Fergus Fleming,[5] Hiddo J. L Heerspink,[6] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of New South Wales, Sydney, NSW, Australia; [3]Stanford University, Stanford, CA; [4]Janssen Research and Development LLC, Raritan, NJ; [5]Renalytix, New York, NY; [6]Rijksuniversiteit Groningen, Groningen, Netherlands.*

Background: Clinical trials in nephrology are often enriched for patients with high levels of albuminuria to increase event rates. KidneyIntelX is a composite risk score that incorporates plasma biomarkers and clinical data to predict progression of diabetic kidney disease. We sought to assess the value of KidneyIntelX for future clinical trials in patients with type 2 diabetes and normo- or microalbuminuria.

Methods: Plasma TNFR-1, TNFR-2, and KIM-1 were measured on the Renalytix KidneyIntelX platform in participants in the CANVAS trial with UACR <300 mg/g (n=3277). A logistic regression model incorporating the 3 biomarkers and clinical variables was applied to obtain the predicted probabilities for a composite kidney outcome of eGFR decline ≥5 ml/min/1.73 m², sustained 40% eGFR decline, or kidney failure. We assessed the potential utility of KidneyIntelX for enrichment in a hypothetical trial using BioPET (http://prognosticenrichment.com).

Results: 176 kidney outcomes occurred over a median of 6.1 years follow-up (5.6% incidence). The composite kidney endpoint occurred in 0.6% in the 1st decile and increased to 16.8% in the 10th decile of KidneyIntelX risk strata (**Figure 1a**). Application of an enrollment threshold at the top 20%-25% of KidneyIntelX score, assuming a 40% RRR of therapy, alpha 0.05, $1000 for screening and $50,000 for full trial run-through, would reduce the sample size needed by approximately 39-43%, and reduce trial costs by 53-57% (**Figure 1b**).

Conclusions: The KidneyIntelX platform facilitated a significant enrichment of kidney events in CANVAS participants that are typically excluded from kidney-specific randomized controlled trials due to low levels of albuminuria. KidneyIntelX has the potential to be an effective tool for trial enrichment.

Effects of Canagliflozin (CANA) on Kidney Outcomes: Pooled Analyses from the CANVAS Program and CREDENCE

Adeera Levin,[1] David Cherney,[2] David C. Wheeler,[3,4] Jagadish Gogate,[5] Marsha Haynes,[6] Vlado Perkovic.[3] *[1]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]The George Institute for Global Health, UNSW Sydney, NSW, Australia; [4]Centre for Nephrology, University College London, London, United Kingdom; [5]Janssen Scientific Affairs, LLC, Titusville, NJ; [6]Janssen Canada, Inc., Toronto, ON, Canada.*

Background: CANA reduced the risk of sustained loss of kidney function in patients with type 2 diabetes mellitus (T2DM) and high cardiovascular (CV) risk or nephropathy. We analyzed the effects of CANA on time to first occurrence of doubling of serum creatinine (SCr) and end-stage kidney disease (ESKD) events using pooled data from the CANVAS Program and CREDENCE.

Methods: This *post hoc* analysis included integrated data from the CANVAS Program and CREDENCE trials. The effects of CANA compared with placebo (PBO) on doubling of SCr and ESKD were examined in subgroups by baseline estimated glomerular filtration rate (eGFR; <45, 45-60, and >60 mL/min/1.73 m²). Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using a Cox proportional hazards model, stratified by trial.

Results: A total of 14,543 participants from the CANVAS Program (N = 10,142) and CREDENCE (N = 4,401) were included. Among participants with baseline eGFR measurements, 1919 (13.2%) had eGFR <45 mL/min/1.73 m², 2972 (20.4%) had eGFR 45-60 mL/min/1.73 m², and 9649 (66.3%) had eGFR >60 mL/min/1.73 m². CANA delayed the time to first doubling of SCr event and first ESKD event relative to PBO. Compared with PBO, CANA reduced the risk of doubling SCr (HR, 0.58; 95% CI, 0.47–0.71) consistently across eGFR subgroups (interaction P = 0.78; **Figure**). Reduced risk of ESKD was also seen with CANA versus PBO (HR, 0.69; 95% CI, 0.55–0.87), irrespective of baseline eGFR (interaction P = 0.86).

Conclusions: In patients with T2DM and high CV risk or nephropathy, CANA reduced the risk of doubling of SCr and ESKD, with consistent benefits observed across baseline chronic kidney disease stage, including those with preserved eGFR >60 mL/min/1.73 m².

Figure. Effects of CANA on Doubling of SCr and ESKD.

	Number of participants with an event (n/N)		HR (95% CI)	Interaction P value
	CANA	PBO		
First occurrence of doubling of SCr				
Overall	145/7995	221/6545	0.58 (0.47, 0.71)	0.78
eGFR <45 mL/min/1.73 m²	66/976	98/943	0.63 (0.46, 0.86)	
eGFR 45-60 mL/min/1.73 m²	35/1559	63/1413	0.53 (0.35, 0.81)	
eGFR >60 mL/min/1.73 m²	44/5460	60/4189	0.54 (0.36, 0.80)	
First occurrence of ESKD				
Overall	126/7995	173/6545	0.69 (0.55,0.87)	0.86
eGFR <45 mL/min/1.73 m²	84/976	113/943	0.70 (0.53, 0.93)	
eGFR 45-60 mL/min/1.73 m²	26/1559	42/1413	0.62 (0.38, 1.01)	
eGFR >60 mL/min/1.73 m²	16/5460	18/4189	0.74 (0.38, 1.46)

Phase Ib Study of the Soluble Guanylate Cyclase Activator BI 685509 in Patients with Diabetic Kidney Disease

David Cherney,[1] Dick de Zeeuw,[2] Hiddo J. L Heerspink,[2] Marc Desch,[3] Arne Wenz,[3] Friedrich Schulze,[3] Masaomi Nangaku.[4] *[1]University of Toronto, Toronto, ON, Canada; [2]University Medical Center Groningen, Groningen, Netherlands; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]The University of Tokyo Graduate School of Medicine, Tokyo, Japan.*

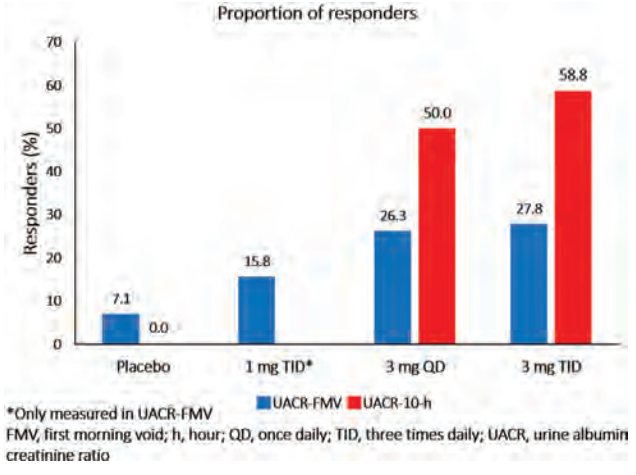
Background: Soluble guanylate cyclase (sGC) plays a key role in the kidney nitric oxide–cyclic guanosine monophosphate (NO-cGMP) pathway. Increased albuminuria is associated with kidney function loss. The NO-independent sGC activator BI 685509 lowers albuminuria in experimental models. This Phase Ib study (NCT03165227) assessed the safety and efficacy of BI 685509 in patients with diabetic kidney disease and albuminuria.

Methods: This placebo (PBO)-controlled, multiple dose study enrolled patients with type 1 or 2 diabetes, estimated glomerular filtration rate (eGFR) 20–75 mL/min/1.73m² and urinary albumin creatinine ratio (UACR) 200–3500 mg/g. Patients (N=74) were randomised to three active dose groups receiving oral BI 685509 (tested doses after titration: 1 mg three times daily [TID], n=20; 3 mg once daily [QD], n=19; 3 mg TID, n=20) or PBO (n=15) for 28 days. Efficacy was assessed by the proportion of responders, defined as patients with ≥20% decrease from baseline in UACR measured in first morning void ($UACR_{FMV}$) and 10-h ($UACR_{10h}$) (PBO, 3 mg QD and 3 mg TID only) urine.

Results: At baseline, median eGFR was 47.0 mL/min/1.73m² and median UACR was 641.5 mg/g, although this varied between groups. Drug-related adverse events (AEs) occurred in 12 patients (16.2%; BI 685509 15.3%, PBO 20.0%); the most frequent were hypotension (4.1%) and diarrhoea (2.7%). AEs leading to study discontinuation occurred in 4 patients (5.4%; BI 685509 5.1%, PBO 6.7%). Compared with PBO, the proportion of patients receiving BI 685509 classed as responders was higher (Figure).

Conclusions: BI 685509 treatment was generally well-tolerated with over 50% of patients in the 3 mg QD and 3 mg TID dose groups appearing to show a response in $UACR_{10h}$.

Funding: Commercial Support - Boehringer Ingelheim



Proportion of responders (≥20% decrease from baseline in UACR)

PO0750

Comparative Effectiveness of SGLT-2 Inhibitors, DPP-4 Inhibitors, and GLP-1 Agonists in US Veterans with and Without CKD

Yoko Narasaki,[1] Csaba P. Kovesdy,[2] Amy S. You,[1] Praveen Kumar Potukuchi,[2] Ankur A. Dashputre,[2] Keiichi Sumida,[2] Fridtjof Thomas,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: Recent clinical trials have shown that SGLT2 inhibitors (SGLT2i) vs. placebo substantially reduce the risk of eGFR decline, ESRD, and renal-/CV-related mortality in CKD patients. However, little is known about the comparative effectiveness of SGLT2i vs. other newer anti-diabetic medications (DPP-4 inhibitors [DPP4i], GLP1 agonists [GLP1a]) on CKD outcomes using real-world data in patients with and without CKD.

Methods: In US Veterans with diabetes receiving care from the VA healthcare system over 2004-18, we identified incident (new) users of SGLT2i vs. DPP4i vs. GLP1a therapy, excluding combined users of the examined classes. In analyses stratified by presence vs. absence of CKD defined by eGFR and albuminuria levels, we examined associations of SGLT2i vs. DPP4i vs. GLP1a use with the composite outcome of incident ESRD+all-cause death using multivariable Cox models.

Results: In 64,564 patients who met eligibility criteria, 51% patients had CKD, and 8%, 77%, vs. 15% were new users of SGLT2i, DPP4i, vs. GLP1a, respectively. Patients contributed a total of 182,177 person-years of follow up, during which 10,861 incident ESRD/death events were observed (crude rate 59.6 events/1000 person-years). Median (IQR) at-risk time was 2.1 (0.9, 4.0) years. Compared to DPP4i, use of SGLT2i was associated with lower risk of the composite outcome across all Cox models (adjusted HR [95%CI] 0.86 [0.75-1.00]). The beneficial association of SGLT2i use with the composite outcome was limited to patients with pre-existing CKD. Across all cohorts (overall, CKD, non-CKD), GLP1a had comparable risk of the composite outcome when compared to DPP4i in adjusted analyses.

Conclusions: In a national cohort of US Veterans with diabetes, SGLT2i use was associated with lower risk of the composite outcome of ESRD+mortality in CKD patients, yet had comparable risk to DPP4i in those without CKD. Further studies are needed to determine the long-term safety and effectiveness of novel anti-diabetic medications using real-world data.

PO0751

Phase 1c Study of the Aldosterone Synthase Inhibitor BI 690517 in Diabetic Patients with Kidney Disease

Stefan R. Bornstein,[1] Dick de Zeeuw,[2] Hiddo J. L Heerspink,[2] Friedrich Schulze,[3] Lisa Cronin,[3] Arne Wenz,[3] Katherine R. Tuttle,[4] Samy Hadjadj,[5] Peter Rossing.[6] *[1]University Hospital Carl Gustav Carus, Dresden, Germany; [2]University Medical Center Groningen, Groningen, Netherlands; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]University of Washington, Seattle, WA; [5]University Hospital Center Nantes, Nantes, France; [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark.*

Background: Preclinical studies showed aldosterone synthase inhibitors (ASis) to be beneficial in diabetic nephropathy. This placebo (PBO)-controlled, multiple dose, Phase Ic study (NCT03165240) assessed the safety and efficacy of the selective ASi BI 690517 in diabetic patients with kidney disease and albuminuria.

Methods: Patients with type 1 or type 2 diabetes, estimated glomerular filtration rate (eGFR) 20–75 mL/min/1.73m² and urine albumin creatinine ratio (UACR) 200–3500 mg/g, receiving stable angiotensin receptor blocker/angiotensin-converting enzyme inhibitor treatment were randomised to receive daily oral BI 690517 (3/10/40 mg), eplerenone (25–50 mg) or PBO for 28 days. Drug related adverse events (DRAEs) and seated systolic blood pressure (SBP) were recorded to assess safety. Efficacy was assessed by the proportion of responders, defined as patients with ≥20% decrease from baseline UACR (measured in first morning void [$UACR_{FMV}$] and 10-h urine [$UACR_{10h}$] [10/40 mg only]). Due to COVID-19, eplerenone and BI 690517 40 mg group enrolment were stopped early; BI 690517 doses were compared with matching PBO pooled from all dose groups.

Results: IIn total, 58 patients (3 mg n=18; 10 mg n=13; 40 mg n=14; eplerenone n=4; PBO n=9) with median baseline UACR of 873.5 mg/g and eGFR of 41.0 mL/min/1.73m² were treated. DRAEs occurred in 8 patients (14.8%), all receiving BI 690517; the most frequent were constipation and hyperkaliaemia (both 3.7%, n=2). Treatment was prematurely discontinued in 5 patients (9.3%: BI 690517 n=4; PBO n=1), 2 cases (3.7%)

due to DRAEs. Changes seen in SBP did not differ between PBO and BI 685509 dose groups. Compared with PBO, the proportion of patients receiving BI 690517 classed as responders was higher for $UACR_{FMV}$ (PBO 37.5% vs 3 mg 61.1%; 10 mg 53.8%; 40 mg 80.0%) but similar for $UACR_{10h}$ (PBO 50.0% vs 10 mg 50.0%; 40 mg 60.0%).

Conclusions: BI 690517 was generally well tolerated and appears to have an early effect on UACR, with over 50% of treated patients being classed as responders. These data need to be confirmed in larger studies.

PO0752

A Comparison of the Renal Composite Outcome Between Sodium-Glucose Cotransporter 2 Inhibitors and Glucagon-Like Peptide 1 Receptor Agonists in Japanese Diabetes Patients

Kazuo Kobayashi,[1,2] Nobuo Hatori,[1] Masao Toyoda,[3] Kouichi Tamura.[2] *[1]Kanagawa-ken, Yokohama, Japan; [2]Yokohama Shiritsu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Yokohama, Japan; [3]Tokai Daigaku, Isehara, Japan.*

Background: The renal outcome benefit in some large-scale clinical trials has been most pronounced for not only sodium-glucose co-transporter 2 inhibitors (SGLT2i), but also glucagon-like peptide 1 receptor agonists (GLP1Ra) in patients with type 2 diabetes mellitus (T2DM). However, there is not enough evidence of direct comparison between these drugs in clinical practice.

Methods: We retrospectively built two databases of T2DM patients who were visiting members of the Kanagawa Physicians Association. One database consisted of T2DM patients who were administered SGLT2i and the other of T2DM patients who were administered GLP1Ra for more than a year. We compared the renal composite outcome of 541 SGLT2i-treated patients without the concomitant use of GLP1Ra and 265 GLP1Ra-treated patients without the concomitant use of SGLT2i. We have set the renal composite endpoint as the progression of the stage of albuminuria or the decrease of estimated glomerular filtration rate (eGFR) by ≥15% per year. For comparative analyses, we built the cohort model of patients treated with SGLT2i or GLP1Ra, using a propensity score–matching method with the following algorithm: 1:1 nearest neighbor match with a ±0.063 caliper and no replacement.

Results: The comparison of 134 propensity-matched patients in each group was performed. The median values of the age, body mass index, eGFR, ACR, and duration of treatment when both groups were combined were 64.0 years, 26.9, 71.1 mL/min/1.73 m^2, 29.8 mg/gCr, and 36 months, respectively. The incidence of renal composite outcome was significantly lower in SGLT2i treated patients than in GLP1Ra treated patients (n = 15 [11%] and n = 27 [20%], respectively, $p = 0.001$ by McNemar's test). The estimate hazard ratios and robust 95% confidence intervals (CI) for the renal composite outcome by the analysis of cox proportional hazards models were 0.69(95% CI, 0.53, 0.90; $p = 0.006$) in SGLT2i treated patients. There was a significant difference in the annual change in eGFR between the two groups: -1.8 ± 5.1 % in SGLT2i treated patients and -3.4 ± 7.0 % in GLP1Ra treated patients ($p = 0.0049$).

Conclusions: By this retrospective study, SGLT2i treatment had shown more preferable influence on the change of eGFR than GLP1Ra treatment in Japanese T2DM patients.

PO0753

Role of β2-Adrenergic Receptor Agonists in the Treatment of Diabetic Nephropathy

Ehtesham Arif,[1] Ashish K. Solanki,[1] Bethany Wolf,[2] Kelly J. Hunt,[2,3] Joshua H. Lipschutz.[1,3] *[1]Medical University of South Carolina Division of Nephrology, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC; [3]VA Medical Center Ralph H Johnson, Charleston, SC.*

Background: Diabetes is the leading cause of end stage kidney disease (ESKD) and affects podocytes. We previously showed in cells and mice that pharmacological activation of mitochondrial biogenesis by the long-acting β_2-AR agonist formoterol contributes to podocyte recovery from injury.

Methods: We examined the association between COPD, in which the vast majority of patients receive β_2-AR agonists, and CKD progression in a national cohort created from patient records within the Veterans Health Administration (VHA). Cohort members were limited to age 65 to 85 years with stage 3 CKD defined based upon ICD-9 codes (ICD-9: 585.3, N18.3) or two eGFR values of 30-59 mL/min/1.73m^2 at least 90 days apart. COPD was defined based upon ICD-9 codes (ICD-9: 416.8, 416.9, 490.x-505.x, 506.4, 508.1, 508.8). Veterans entered the cohort in 2010 and were followed through 2016. We are also currently testing the efficacy of formoterol in restoring glomerular function in type I (streptozotocin) and type 2 (high fat diet) diabetic murine models.

Results: Of 194,119 Veterans with stage 3 CKD in 2010, 4,727 progressed to stage 5 CKD by 2016. The age- and sex-adjusted odds ratio for the association between baseline COPD and progression to stage 5 CKD was 0.89 (95% CI: 0.83, 0.96), indicating that Veterans with COPD at baseline had lower odds of progression to stage 5 CKD than Veterans without COPD at baseline.

Conclusions: Our large retrospective cohort study suggests that β_2-AR agonists slow the progression of CKD. Given that diabetes is the most common cause of ESKD, the effect of β_2-AR agonists on progression of CKD is likely driven by the effect on diabetic nephropathy. Animal studies to directly test this hypothesis are underway.

Comparative Effects of Sodium-Glucose Cotransporter 2 Inhibitors on Serum Electrolyte Levels in Patients with Type 2 Diabetes: A Network Meta-Analysis of Randomized Controlled Trials

JingJing Zhang,[1] Yonghong Huan,[2] Mark R. Leibensperger,[1] Bojung Seo,[3] Yiqing Song.[3] *[1]Thomas Jefferson University, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Indianapolis, Indianapolis, IN.*

Background: Previous studies have reported that sodium-glucose co-transporter 2 (SGLT2) inhibitors(SGLT2is) affect serum electrolytes levels, especially magnesium. This study aimed to integrate direct and indirect trial evidence to maximize statistical power to clarify their overall and comparative effects of all SGLT2is on electrolyte levels in patients with type 2 diabetes (T2D).

Methods: We systematically searched PubMed, EMBASE, CENTRAL, and ClinicalTrials.gov up to through January 2021 to identify eligible randomized controlled trials (RCTs) that reported the mean changes in serum electrolytes, including magnesium, sodium, potassium, phosphate, and calcium. We performed both random-effects pairwise and network meta-analyses to calculate the weighted mean difference (WMD) and 95% confidence intervals (CI).

Results: In total, we included 26 RCTs involving 28,943 T2D patients with 6 SGLT2is. Compared with the placebo, SGLT2is were significantly associated with elevations in serum magnesium by 0.7mmol/L (95% CI,0.06, to 0.08 mmol/L) and serum phosphate by 0.02 mmol/L (95% CI, 0.01 to 0.03 mmol/L). Our network meta-analysis showed no evidence of significantly superior efficacy of any specific SGLT2 inhibitor over the others, although dapagliflozin was associated with a larger magnitude in significant increment ases in serum magnesium associated with dapagliflozin (WMD = 0.16 mmol/L), compared to other SGLT2is. Similarly, no statistically detectable differences were evident between any two of SGLT2 inhibitors on serum levels of other electrolytes.

Conclusions: SGLT2is could significantly increased serum magnesium and phosphate levels, consistent with a class effect of SGLT2 inhibition. However, further investigation on more data for long-term efficacy and safety in T2D patients with different clinical phenotypes are needed for further investigation.

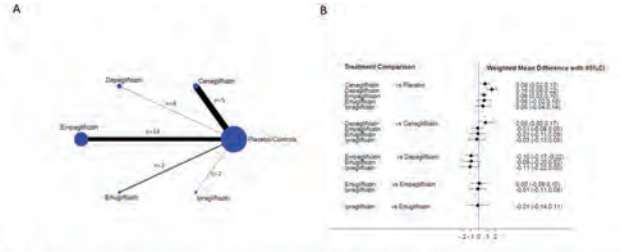

Figure A. Network of eligible comparisons for the multiple-SGLT2 inhibitors meta-analysis for effects on blood magnesium levels. Each node represents one treatment. The directly compared treatments are linked with a solid line, the width of the lines is proportional to the number of trials comparing every pair of treatments, and the size of every node is proportional to the number of randomized participants (sample size). B. Network meta-analysis combining direct and indirect evidence within a network of eligible trials for the effects of SGLT2 inhibitors on blood magnesium levels (μmol/L). The black solid lines represent the confidence intervals for weighted mean differences of blood magnesium levels for each comparison and the blue line is the line of no effect (WMD equal to 0).

PO0755

Association of Fibrate Use with Cardiovascular Disease Mortality Across CKD Stages

John G. Rizk,[1] Melissa Soohoo,[2] Leila Hashemi,[3] Jui-Ting Hsiung,[2] Elani Streja.[2] *[1]Arizona State University Edson College of Nursing and Health Innovation, Phoenix, AZ; [2]VA Long Beach Healthcare System, Long Beach, CA; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Elevated serum lipids are risk factors for cardiovascular disease (CVD) in the general population and common first-line treatment includes fenofibrates for those with high triglycerides (TG) or low high-density lipoproteins (HDL). Recent studies have suggested that fibrates may be beneficial for CVD death outcomes in those with chronic kidney disease (CKD). Yet how the relationship between fibrates and early CVD death differs across CKD stages remains uncertain.

Methods: In male Veterans with adverse lipid levels (TG≥150 mg/dL or HDL ≤40 mg/dL), initial fibrate users and non-users were matched on CKD stage, TG and HDL levels. The cohort of 233,082 patients were followed until 2014. We used inverse probability weighting in the fitting of marginal structural models to adjust for time-varying confounding and informative censoring in investigating the average direct effect of fibrate use (reference: non-use), with 24-month cardiovascular mortality. Models were stratified by CKD stage at baseline.

Results: Patients were a mean±SD age of 62±12 years, and 26% of patients had CKD or end-stage renal disease (ESRD). The median[IQR] of baseline TG and HDL were 310 [220,436], and 34 [30, 40] mg/dL, respectively. Across all baseline CKD stages, the use of fibrates were associated with lower risks of 24-month CVD mortality, compared with non-users. These associations gradually declined across advancing CKD stages, where patients with ESRD on renal replacement therapy had the lowest observed risks (Hazard Ratio[95%CI]: 0.54[0.34, 0.87]) [Figure 1].

Conclusions: Fibrate use was associated with lower CVD mortality. These risks varied across CKD stage, but those with ESRD tended to have better CVD death outcomes. Additional studies are imperative to better tailor lipid therapy and management against adverse outcomes among the late-stage CKD and ESRD patients.

PO0756

Effect of CKD Stage on Myocardial Infarction Risk with Niacin Use in Male Veterans

John G. Rizk,[1] Melissa Soohoo,[2] Jui-Ting Hsiung,[2] Leila Hashemi,[3] Elani Streja.[2] *[1]Arizona State University Edson College of Nursing and Health Innovation, Phoenix, AZ; [2]VA Long Beach Healthcare System, Long Beach, CA; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Niacin is a lipid therapy shown to have cardio-protective effects, particularly in those with high triglyceride (TG) and low high-density lipoprotein (HDL) levels. But, in chronic kidney disease (CKD) patients who have elevated risk of cardiovascular risk and altered lipid levels, it remains unclear if CKD stage impacts these associations.

Methods: In males with worse lipid levels (TG≥150 mg/dL or HDL ≤40 mg/dL), we matched patients with an incident niacin prescription to non-niacin users on CKD stage, TG and HDL levels. In this study of 336,178 niacin users and non-users, we evaluated the relationship of time-varying niacin use with 24-month myocardial infarction (MI) hospitalization. Cox models included adjustment for time-varying covariates and were stratified by baseline CKD stage.

Results: Patients were a mean 64 years old, with a median[IQR] of TG and HDL of 203[143, 297] and 34[29, 39] mg/dL, respectively. In unadjusted models, non-CKD, CKD 4/5 and end-stage renal disease (ESRD) niacin users had higher risks of a MI hospitalization, yet CKD 3A-3B patients had null risks, compared with non-users. With adjustment for case-mix variables, including comorbidities, we observed a linear relationship across baseline CKD stages, where risks progressively increased with worse stage. Non-CKD niacin users had lowest risks of 24-month MI hospitalization, while both CKD 4/5 and ESRD patients trended towards elevated risks of event. The relationships between niacin use and MI hospitalization remained the same with adjustment for laboratory and other lipids.

Conclusions: In time-varying analyses, niacin use was associated with lower risks of 24-month MI hospitalization in non-CKD and CKD 3A patients. The risks of MI hospitalization were progressively elevated with worse CKD stages. Additional studies are needed to further examine the relationship between lipid modulating therapies in the context of CKD patients.

PO0757

Advantages of Metformin for the Prevention and Mitigation of Diabetic Foot Ulcer in Diabetic Kidney Disease from a Large-Scale, Real-World Cohort

Soie Kwon,[1] Dong Ki Kim,[1,3] Chun Soo Lim,[2,3] Jung Pyo Lee.[2,3] *[1]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

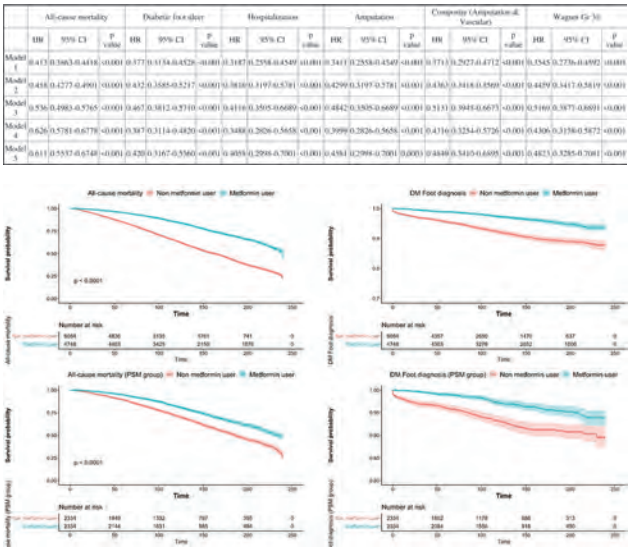
Background: Diabetic foot ulcer(DFU) and diabetic kidney disease (DKD) are diabetes-related microvascular complications strongly correlated with high morbidity and mortality. Metformin potentially confers a wound-healing advantage, although there are no well-established evidence. We first time investigated the effect of metformin on DFU among large retrospective cohort of DKD.

Methods: This retrospective cohort study enrolled DKD patients from two South Korean tertiary-referral centers. Primary outcomes were all-cause mortality and DFU events; secondary outcomes included hospitalization, amputation, composite of amputation or vascular intervention, and Wagner Grade >3. Multivariate cox analysis and Propensity score matching (PSM) was used to balance baseline intergroup differences between metformin users and metformin non-users.

Results: Among 10,832 patients (4,748 metformin users; 6,084 metformin non-users), the 117.5±66.9 months follow-up period, all-cause mortality rate and DFU incidence were, 37.1%, and 5.2%, respectively. Fully adjusted multivariate Cox analysis showed that metformin users had a lower all-cause mortality (adjusted hazard ratio 0.63; 95% confidence interval 0.58–0.68; p<0.001) and DFU events (0.39; 0.31–0.8; p<0.001, Table). After PSM, metformin users showed lower all-cause mortality (0.61; 0.55–0.67; p<0.001), DFU events (0.42; 0.32 –0.56; p<0.001), and secondary outcomes (hospitalization, amputation, composite of amputation or vascular intervention, and DFU with Wagner Grade >3. Table).

Conclusions: Metformin therapy in DKD patient can lower all-cause mortality, DFU incidence, and DFU progression.

Survival analysis of primary and secondary outcomes



PO0758

Gaps in CKD Awareness Among People with Type 2 Diabetes

Matthew Garza,[1] Julia Stevenson,[2] Sara Suhl,[2] Arvind S. Sommi,[1] Kelly L. Close,[1,3] Richard S. Wood.[2] *[1]The diaTribe Foundation, San Francisco, CA; [2]dQ&A Market Research Inc., San Francisco, CA; [3]Close Concerns, San Francisco, CA.*

Background: Diabetes is one of the most common causes of chronic kidney disease (CKD) in adults, with around 1 in 3 people with diabetes also living with CKD. Clinical guidelines recommend annual screenings of urinary albumin and glomerular filtration rate for people with type 2 diabetes (T2D). Previous studies have identified low awareness, testing and diagnosis of CKD among people with T2D and their healthcare providers (HCP). By drawing comparisons to cardiovascular disease (CVD), the present study aimed to assess awareness of CKD, renoprotective diabetes therapies, and kidney health metrics among people with T2D.

Methods: In February 2021, 1021 people with T2D from the dQ&A Patient Panel responded to an online survey assessing perceptions, knowledge, HCP engagement, and lifestyle behaviors related to CKD and CVD. Respondents received $10 USD for completing the survey. Data was collected with Qualtrics, prepared with IBM SPSS, and analyzed in MarketSight.

Results: Awareness of the link between T2D and CKD was lower than awareness of the link between T2D and CVD; 57% of respondents strongly agreed that having T2D increases the risk of CKD, compared to 63% who strongly agreed that T2D increases the risk of CVD. The percentage of respondents who often consider their personal risk of CKD (19%) was also lower than for CVD (26%). Awareness of renoprotective and cardioprotective therapies was low overall. While 37% were aware that some T2D drugs are cardioprotective, only 22% were aware of renoprotective benefits. Respondents on SGLT-2 inhibitors or GLP-1 agonists were more likely to be highly aware of their cardioprotective benefits than their renoprotective benefits (52% vs. 30% for SGLT-2 users, 45% vs. 31% for GLP-1 users). Knowledge of personal metrics for renal health indicators, eGFR (38%), and uACR (26%), lagged behind knowledge of diabetes and CVD metrics: weight (100%), A1C (98%), blood pressure (94%), and cholesterol (75%). Only 41% of respondents had discussed their CKD risk with a diabetes-related HCP, but those who had were more likely to be aware of CKD risks and therapies.

Conclusions: This data highlights a gap between T2D patients' awareness of CKD risks and protective therapies and those of CVD. To prevent CKD and improve outcomes, this study emphasizes the need for better patient education on CKD's connection to T2D.

Feature Selection and Machine Learning Model for Predicting Diabetic Kidney Disease Risk in Asians

Charumathi Sabanayagam,[1,2] Feng He,[1] Simon Nusinovici,[1] Cynthia C. Lim,[4] Jialiang Li,[3] Tien Yin Wong,[1,2] Ching-Yu Cheng.[1,2] *[1]Singapore Eye Research Institute, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]National University of Singapore, Singapore, Singapore; [4]Singapore General Hospital, Singapore, Singapore*.

Background: Machine learning (ML) techniques may improve disease prediction and interpretability of regression models by identifying the most relevant features in multi-dimensional data. We evaluated the ability of various ML classifiers for feature identification and improving the prediction accuracy of diabetic kidney disease (DKD).

Methods: We utilized longitudinal data from 1364 Chinese, Malay and Indian participants aged 40-80 years with diabetes but free of DKD who attended the baseline visit of the Singapore epidemiology of Eye Diseases Study in 2004-2011 and were followed up for 6 years (2011-2017). Incident DKD (n=162) was defined as an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2+25% decrease in eGFR at follow-up. We evaluated 339 features including demographic/clinical, retinal imaging, genetic and serum metabolomics profile and tested nine ML algorithms along with feature selection (gradient boosting decision tree, elastic net, random forest, support vector machine, neural network, LASSO etc.). The performance of the best ML model based on optimum features was compared to that of logistic regression (LR) with traditional risk factors using the area under the receiver operating characteristic curve (AUC), sensitivity and specificity.

Results: The best performing model was a combination of Recursive feature elimination (RFE) for variable selection and Elastic Net (EN) using 15 predictors from demographic/clinical +metabolite set with AUC, sensitivity and specificity of 0.852, 83.0% and 73.5% compared to 0.796, 83.0% and 61.8% by LR. The top-15 predictors of DKD risk included seven risk factors and eight metabolites: age, antidiabetic medication use, presence of hypertension, diabetic retinopathy, higher levels of systolic blood pressure, HbA1c, lower levels of eGFR; higher levels of triglycerides in IDL, phospholipids in chylomicrons and medium VLDL, total cholesterol in chylomicrons and very small VLDL, medium LDL, cholesterol esters in very large HDL and lower levels of DHA, lactate and acetate.

Conclusions: ML together with feature selection improved prediction accuracy of DKD risk in the general population with diabetes and identified novel risk factors including metabolites.

PO0760

Risk Score to Predict CKD Among Mexican Individuals with Diabetes Mellitus

Alejandro Raña,[1] Martín Lajous,[2] Edgar Denova,[2] Mildred Y. Chávez,[3] Ruy López,[4] Goodarz Danaei.[1] *[1]Harvard University T H Chan School of Public Health, Boston, MA; [2]Instituto Nacional de Salud Publica, Cuernavaca, Mexico; [3]Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico; [4]Centro Nacional de Programas Preventivos y Control de Enfermedades, Mexico City, Mexico*.

Background: The two major causes of CKD are type 2 diabetes (T2D) & hypertension, which are responsible for up to two-thirds of the cases. More than half of patients in Mexico with incident ESRD have an underlying diagnosis of T2D. Some prediction models have been developed for the purposes of screening CKD & its progression. However, their generalizability to the Mexican population is not known, & few have been validated in different populations & rarely in LMIC. We aimed to develop & validate a lab and office-based risk prediction scores for CKD among Mexican patients with T2D

Methods: The prospective cohort consisted of 105,310 patients enrolled in the Integral Management of Diabetes by Stages program. 18,148 patients were randomly assigned to the training & testing sets on an 80-20 ratio. Logistic regression models were used to assess risk factors for CKD. A stepwise selection process was performed to determine the best predictive equations

Results: A total of 1,617 patients developed CKD (mean follow up of 1.1 years). Age, BMI, duration of T2D, treatment with insulin & oral hypoglycemics, treatment with nephroprotective agents, retinopathy & alcohol use were predictors in both models. Triglyceride levels & eGFR proved to be important predictors in the lab model. The lab score had a C statistic of 0.77 & a calibration slope of 1, whereas the office score had 0.67 & 0.89, respectively

Conclusions: These models can be used to identify individual patients with T2D who are at risk of developing CKD. This can facilitate early detection to intensify T2D treatment in a timely manner

Table 1. Laboratory and office risk scores for the development of chronic kidney disease, defined as eGFR < 60 ml/min/1.73m².

	Laboratory Model	Office Model
	OR (95% CI)	OR (95% CI)
Age	1.03 (1.02, 1.04)	1.16 (1.08, 1.24)
Age²		1.00 (1.00, 1.00)
BMI [kg/m²]	1.01 (1.00, 1.02)	1.02 (1.01, 1.03)
Years of evolution of T2D	1.01 (1.00, 1.02)	1.02 (1.01, 1.02)
Treatment with oral hypoglycemics	1.10 (0.81, 1.53)	1.07 (0.79, 1.48)
Treatment with insulin	0.99 (0.57, 1.70)	1.01 (0.59, 1.69)
Treatment with OH & insulin	1.51 (1.09, 2.12)	1.46 (1.06, 2.04)
Treatment with ARB or ACEi	1.26 (1.11, 1.42)	1.37 (1.21, 1.54)
Retinopathy	1.29 (1.05, 1.57)	1.33 (1.09, 1.62)
Diabetic foot	1.43 (0.97, 2.05)	1.35 (0.92, 1.90)
Neuropathy		1.11 (0.97, 1.28)
Alcohol intake	1.41 (1.09, 1.84)	1.42 (1.11, 1.85)
GFR [mL/min/1.73m²]	0.94 (0.94, 0.95)	
Triglycerides [mg/dL]	1.00 (1.00, 1.00)	
Intercept	0.37 (0.13, 1.00)	0.00 (0.00, 0.00)

Selected from a Stepwise Selection based on AIC.
BMI: body mass index; T2D: type 2 diabetes mellitus; OH: oral hypoglycemic agents; ARB: Angiotensin II receptor blocker; ACEi: Angiotensin-convertor enzyme inhibitor; HTN: hypertension; FPG: fasting plasma glucose; GFR: glomerular filtration rate.

PO0761

Changes in Kidney Disease: Improving Global Outcomes (KDIGO) Risk Categories in Patients with Type 2 Diabetes and CKD

Kevin Pantalone,[1] C. Daniel Mullins,[2] Keith A. Betts,[3] Jinlin Song,[3] Aozhou Wu,[3] Sheldon X. Kong,[4] Rakesh Singh.[4] *[1]Cleveland Clinic, Cleveland, OH; [2]University of Maryland Baltimore, Baltimore, MD; [3]Analysis Group Inc, Los Angeles, CA; [4]Bayer U.S. LLC, Whippany, NJ*.

Background: UACR is an important measure of kidney damage, but it is under-utilized in clinical practice. To comprehensively characterize the course of CKD in patients with T2D and CKD, this study evaluated changes in KDIGO risk categories based on both eGFR and UACR.

Methods: A prevalent cohort of adult patients with T2D and both eGFR and UACR measures indicating CKD of moderate or high risk based on KDIGO risk categories were identified from the Optum electronic health records database (2007 - 2019). The index date was defined as the first record indicating CKD of moderate or high risk after T2D diagnosis. The proportion of patients moving to a higher risk category in 5 years was estimated using Kaplan-Meier analysis. Average eGFR and UACR were also calculated over time.

Results: The index risk categories among the 269,187 patients with T2D and CKD were 81% moderate risk and 19% high risk. The majority of high-risk patients with impaired eGFR moved to very high risk within 5 years (G2-A3: 72%; G3a-A2: 88%; G3b-A1: 87%). Patients with index moderate risk and impaired eGFR also had high risk of moving to a higher risk category (G2-A2: 54%; G3a-A1: 84%). (Table) Patients with comparable eGFR had faster eGFR decline if their UACR level was elevated. (Figure)

Conclusions: The majority of T2D patients with CKD of moderate or high risk moved to a higher risk category within 5 years, even with mildly decreased eGFR. Those with more impaired UACR had faster decline in eGFR, which confirms the value of UACR in CKD management.

Funding: Commercial Support - Bayer U.S. LLC

Table. Changes in KDIGO risk categories in 5 years

	Moderate Risk at Index Date			High Risk at Index Date			
	G1-A2 n=66,754	G2-A2 n=86,379	G3a-A1 n=65,558	G1-A3 n=6,085	G2-A3 n=8,989	G3a-A2 n=18,354	G3b-A1 n=17,068
Moved to high/very high risk (%)	18.8	53.9	83.7	12.8	71.6	88.0	87.1
Moved to high risk (%)	16.7	37.8	56.3	–	–	–	–

Using Machine Learning to Predict CKD upon Type 2 Diabetes Mellitus Diagnosis

Angier O. Allen, Zohora Iqbal, Abigail Green-Saxena, Ritankar Das. *Dascena Inc., Houston, TX.*

Background: Chronic kidney disease (CKD) accounts for the majority of increased risk of mortality for diabetic patients, manifesting in approximately half of patients diagnosed with type 2 diabetes mellitus (T2DM). Although increased screening frequency can avoid missed diagnoses, this is not implemented uniformly. We developed and retrospectively validated a machine learning algorithm (MLA) to predict CKD within 5 years upon T2DM diagnosis.

Methods: Electronic health records (EHR) data of 171,201 recently diagnosed T2DM patients (age ≥ 18) was extracted from a proprietary database of >700 healthcare sites across the US between 2007-2020. A random forest MLA was developed to assess risk of Stage 3+ CKD (CKD 3+) in T2DM patients using EHR data collected in the year prior to T2DM diagnosis. International Classification of Diseases codes (ICD-9 and ICD-10) were used to identify T2DM and CKD 3+ patients. The MLA was tested on a hold-out test set of 42,801 patients as well as a separate external validation dataset. The Centers for Disease Control and Prevention (CDC) CKD risk score was used as a comparator. Performance of the MLA and CDC CKD risk score was assessed on the hold-out test set and the external validation dataset via area under the receiver operating characteristic curve (AUROC).

Results: On a hold-out test set and an external validation dataset, the MLA outperformed the CDC CKD risk score when analyzed for prediction of CKD 3+ in recently diagnosed T2DM patients (Fig 1).

Conclusions: This retrospective study shows that a MLA can provide timely predictions of CKD among recently-diagnosed T2DM patients. Early detection of CKD in diabetic patients may enable therapeutic interventions, lifestyle changes, prevention of progression, and reduction of dialysis dependency, as well as healthcare costs.

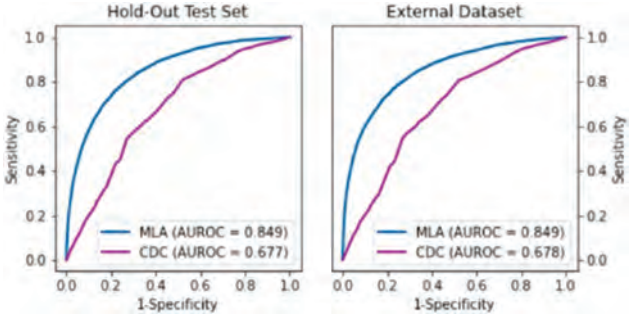

Figure 1. Area under receiving operating characteristic curves for the machine learning algorithm (MLA) and CDC CKD risk model (CDC) for Stage 3+ diabetic CKD predictions performed on the hold-out test set and external validation dataset.

PO0763

Contemporary CKD Incidence Rates in Diabetes by Race/Ethnicity, Sex, and Age

Katherine R. Tuttle,[1,2] Cami R. Jones,[1] Kenn B. Daratha,[1,2] Alain Koyama,[3] Susanne B. Nicholas,[4] Radica Z. Alicic,[1,2] Keith C. Norris,[4] Nilka Rios Burrows,[3] Meda E. Pavkov.[3] CURE-CKD *[1]Providence St Joseph Health, Renton, WA; [2]University of Washington, Seattle, WA; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of California Los Angeles, Los Angeles, CA.*

Background: Diabetes is the most common cause of chronic kidney disease (CKD), yet little is known about current CKD incidence rates and demographic predictors in these patients. The study aim was to estimate CKD incidence over time in adults with diabetes treated in two large healthcare systems.

Methods: The Center for Kidney Disease Research, Education, and Hope registry data is curated from electronic health records at Providence St. Joseph Health and University of California Los Angeles Health. Age, sex, and race/ethnicity adjusted CKD incidence rates were calculated over two-year time periods covering 2014–2019. CKD was identified by ≥2 laboratory measures (estimated glomerular filtration rate <60 mL/min/1.73m^2, urine albumin/creatinine ratio ≥30 mg/g, urine protein/creatinine ratio ≥150 mg/g) ≥90 days apart or administrative codes. Diabetes was identified by laboratory measures (HbA1c, blood glucose), use of glucose-lowering medication, or administrative codes.

Results: The overall CKD incidence (95% CI) rate in diabetes declined from 109.1 cases/1000 person-years (106.1–112.1) in 2014-15, to 104.2 cases/1000 person-years (101.7–106.8) in 2016–17, to 96.0 cases/1000 person-years (93.5–98.5) in 2018–19 (p<0.001 for trend, Figure). CKD incidence only declined in Whites over these time periods. CKD incidence rates were lowest in Whites and Asians and highest in American Indians/Alaska Natives (AI/AN) and Native Hawaiians/Pacific Islanders (NH/PI). CKD incidence rates were higher in men than women and increased with age.

Conclusions: CKD incidence has recently declined in patients with diabetes overall, and specifically among Whites. AI/AN and NH/PI patients with diabetes had the highest rates of CKD incidence. Studies of targeted strategies in high-risk populations will be important to prevent CKD.

Funding: Other U.S. Government Support

	New Cases/Person-years

Renal Oxygenation, Perfusion, and Blood Flow in Type 1 Diabetes with Albuminuria Compared with Healthy Controls

Jens christian Laursen,[1,2] Ida Rasmussen,[1] Joana Melo,[1] Bryan Haddock,[3] Farzaneh Safavimanesh,[1] Joachim Størling,[1] Christian S. Hansen,[1] Henrik Bo W. Larsson,[3] Per-Henrik Groop,[4] Marie Frimodt-Moller,[1] Ulrik B. Andersen,[3] Peter Rossing.[1,2] Complications Research *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Kobenhavns Universitet, Kobenhavn, Denmark; [3]Rigshospitalet, Kobenhavn, Denmark; [4]Folkhalsanin tutkimuskeskus, Helsinki, Finland.*

Background: The mechanisms behind the progression of diabetic kidney disease in type 1 diabetes (T1D) are poorly understood. We aimed to evaluate the renal oxygenation, perfusion and blood flow using magnetic resonance imaging (MRI) in persons with T1D and albuminuria and in healthy controls (CONs).

Methods: Cross-sectional study in 15 persons with T1D and albuminuria compared with 15 CONs. MRI (3 Tesla Philips Scanner) was used to assess renal R_2* (a low value corresponds to a high tissue oxygenation), renal perfusion (arterial spin labelling) and renal artery flow (phase contrast imaging). Differences in outcomes between groups and associations were adjusted for age and sex.

Results: There was no difference between groups in the mean (SD) age (T1D: 58 (14) years; CONs: 56 (15) years; p=0.82) or in the gender distribution (33% female in both groups, p=1). Participants with T1D had a mean duration of diabetes of 38 (18) years, a higher median urine albumin creatinine ratio (UACR) (T1D: 46 (IQR 21-58) mg/g; CONs: 4 (3-6) mg/g; p<0.0001) and a lower mean estimated glomerular filtration rate (eGFR) (T1D: 73 (32) ml/min/1.73m^2; CONs: 88 (15) ml/min/1.73m^2; p=0.12), although not significantly for the latter. There were no significant differences between groups in renal cortical R_2* (T1D: 22.2 (5.0) s^{-1}; CONs: 22.1 (2.6); p=0.92) or medullary R_2* (T1D: 33.9 (6.1) s^{-1}; CONs: 37.7 (4.6); p=0.14). Renal cortical perfusion was lower in T1D than in CONs (T1D: 163 (40) ml/100g/min; CONs: 224 (49) ml/100g/min; <0.01), but there was no difference in the medullary perfusion (T1D: 43 (11) ml/100g/min; CONs: 44 (15) ml/100g/min; p=0.92). Renal artery blood flow was lower in T1D than in CONs (T1D: 360 (130) ml/min; CONs: 430 (113) ml/min; p=0.01). A lower renal cortical perfusion was associated with a higher UACR (p<0.01) but not with eGFR (p=0.25). A lower renal artery blood flow was associated with a higher UACR (p<0.01) and with a lower eGFR (p=0.01).

Conclusions: Renal cortical perfusion and artery blood flow were lower in persons with T1D and albuminuria than in healthy controls, confirming findings from previous studies. Impaired renal cortical perfusion and blood flow were associated with impaired renal function.

CKD-Associated Frailty Risk Trajectory over Time Among Patients with Newly Diagnosed Diabetes Mellitus: A Population-Based Cohort Analysis

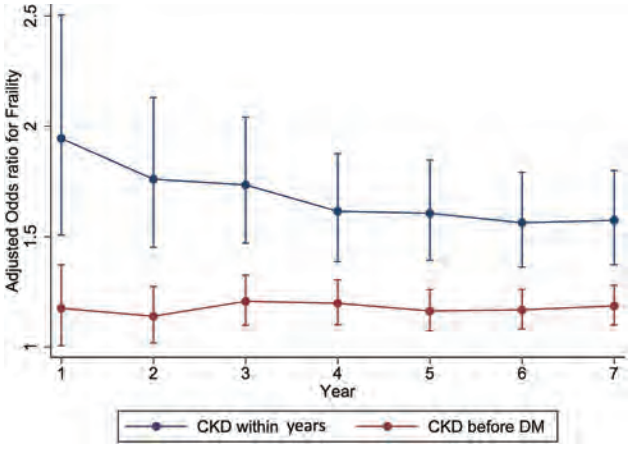
Chia-Ter Chao. *National Taiwan University Hospital Beihu Branch, Taipei, Taiwan.*

Background: Patients with chronic kidney disease (CKD) and diabetes mellitus (DM) are at high risk of frailty and adverse functional outcomes. CKD likely further aggravates the risk of frailty among patients with DM. However, whether the timing of CKD onset relative to incident DM affects the subsequent risk of frailty over time remains unclear.

Methods: We recruited patients with newly diagnosed DM but without frailty from a population-based cohort (n=488,458), dividing them into those without CKD throughout study period (7 years), with CKD prior to DM diagnosis, and with CKD years after incident DM. Their risk of frailty, based on a modified FRAIL scale, were examined. We used Cox proportional hazard regression to calculate CKD-associated risk of frailty, accounting for demographic, morbidities, medication, and prior hospitalization, followed by multiple regression analyses to calculate the annual probability of developing frailty starting immediately after DM occurrence.

Results: Among the enrolled patients with newly diagnosed DM, 80.8% (n=394,673) had no CKD throughout study period, while 3.3% (n=16,037) and 15.9% (n=77,748) had CKD prior to and after DM, respectively. Cox proportional hazard regression showed that newly diagnosed diabetic patients with CKD after DM had a significantly higher risk of developing frailty than those without CKD throughout study period (hazard ratio [HR] 1.649, 95% confidence interval [CI] 1.45 – 1.88), while those with CKD before DM had a higher but rather modest risk (HR 1.200, 95% CI 1.11 - 1.29). The annual probability of frailty occurrence was highest early during the course of DM and decreased slowly but gradually among CKD after DM group, while that of frailty remained stable throughout the study period among CKD prior to DM group (Figure).

Conclusions: The risk of CKD-related frailty exhibited temporal changes in patients with newly diagnosed DM. It would be prudent to carefully select the timing of providing frailty-oriented care in these patients.



PO0766

Understanding Patient Receptivity Towards Receipt of Prognostic Risk Score for Diabetic Kidney Disease

Tamara S. Muller, Nidhi Naik, Shivani Rathi, Sharlene Martin, Azadeh Zabetian. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Few studies examined the attitudes of patients with diabetic kidney disease (DKD) on risk stratification tools. An intrinsic barrier to undertake a risk stratification test is knowledge, awareness, and desire to know the risk of kidney disease. This study aimed at exploring the baseline knowledge about kidney disease and type 2 diabetes mellitus (T2DM) as a major contributing factor, alongside possible motivators, and the patient's receptivity towards risk score delivery of KidneyIntelX, a novel prognostic test that assesses the risk of kidney disease progression over the next 5 years in patients with DKD stages 1-3.

Methods: In May 2021, we contacted a subset of patients with stages 1-3 DKD and T2DM at one primary care site at the Mount Sinai Health System to communicate results obtained on their KidneyIntelX test and we administered a survey. We assessed patient knowledge about the test, their receptivity, and attitude on the usefulness of the test to improve their kidney health.

Results: A subset of patients (n=37) tested with KidneyIntelX in May 2021 were successfully contacted by the APRN on the DKD Care Navigation Team at Mount Sinai and completed the post-test survey. The majority of patients (70%) were aware diabetes is a contributing factor to kidney disease. 73% were unfamiliar with the prognostic test goals, while 27% were provided with an explanation by their physician. 89% were appreciative of the post-test call, and receiving risk scores through a post-test call were helpful for all patients (60% helpful, 40% very helpful) in improving their understanding of kidney health. Additionally, all patients were motivated to implement lifestyle changes to improve kidney health, and 63% desired educational content on diabetes, kidney disease and diet **(Table)**.

Conclusions: Dedicated phone calls from the Care Navigation Team after KidneyIntelX testing enhanced patient understanding about kidney disease and revealed substantial motivation to take appropriate actions and receive further education for their kidney health.

Funding: Commercial Support - Renalytix, Clinical Revenue Support

Table: Patient Responses on Post KidneyIntelX Test Survey Questions Categorized by Predefined Themes

Predefined themes	Questions	Patient response (%)
Prior Knowledge	Diabetes can affect the kidneys	Yes (70) No (30)
Prior Knowledge	Information received from physician about goal of the test	No information (57) Recognize just the name of test (16) Received information from physician (27)
Receptivity	Appreciative to receive calls from the DKD Care Navigation team	Yes (89) No (11)
Receptivity	Helpfulness of the KidneyIntelX test score in understanding patients' kidney health	Helpful (60) Very helpful (40) No (0)
Activation	Motivated to take appropriate actions to improve kidney health	Yes (100) No (0)
Activation	Desired educational materials on T2DM, CKD, diet/nutrition	Yes (63) No (37)

PO0767

Adequacy of Laboratory Monitoring of CKD for Diabetic Patients Empaneled with Primary Care

Bjoerg Thorsteinsdottir, LaTonya J. Hickson, Rachel Giblon, Joel A. Hickman, Suzanne M. Norby, Andrew D. Rule, Robert C. Albright. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Studies have shown poor adherence to chronic kidney disease (CKD) guideline adherence in primary care, contributing to late referral to nephrology and suboptimal clinical outcomes. We sought to assess the performance of our health system in adhering to laboratory monitoring guidelines for diabetic patients with laboratory confirmed CKD.

Methods: We identified all adult patients empaneled in a regional health system who had creatinine and urinary albumin measurements between 2014-2016 excluding pregnant patients, as well as those transplanted or already on dialysis or hospice and crossed this cohort with our existing diabetic patient registry. CKD defined based on calculated GFR and CKD risk defined per the Kidney Disease Improving Global Outcomes (KDIGO) guidelines. We defined laboratory monitoring compliance as meeting the number of creatinine measurements recommended by KDIGO per year with at least 3 months between measurement.

Results: 27943 diabetic patients had laboratory measurements allowing us to assess their CKD status. Of those 18466 (57%) had low risk/no CKD. Of those meeting CKD criteria, 13966 (50%) were missing a measure of albuminuria, 8030 (28.7%) had moderate, 3563 (12.8%) high and 2384 (8.5%) CKD risk. Compliance with laboratory monitoring was 82.7% for moderate risk, 59.9% for high risk and 44.8% of very high risk patients. Limitations include potential for access to disease monitoring outside of our health system.

Conclusions: Diabetic patients with CKD empaneled in our health system were often not adequately risk stratified for their CKD due to lack of attention to the need for albuminuria measures. For those who could be risk stratified, monitoring for low and moderate risk patients was adequate but the patients in the higher risk categories had worse guideline adherence. Better decision support systems are needed to improve kidney care for this high risk population.

Characteristics of Patients with CKD and Diabetes by Use of ACE Inhibitors or ARBs

Cami R. Jones,[1] Susanne B. Nicholas,[2] Kenn B. Daratha,[1] Radica Z. Alicic,[1] Samuel T. Fatoba,[4] Sheldon X. Kong,[3] Jay Elliott,[3] Katherine R. Tuttle.[1] CURE-CKD *[1]Providence Health Care, Spokane, WA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Bayer Corp, Whippany, NJ; [4]Bayer Pharma AG, Berlin, Germany*.

Background: The Center for Kidney Disease Research, Education and Hope (CURE-CKD) registry is curated from electronic health records (EHR) of >3.4 million patients with or at-risk of chronic kidney disease (CKD) at two, large healthcare systems. The study aim was to compare demographic and clinical characteristics of patients with CKD and diabetes (DM) by use of angiotensin converting enzyme inhibitors (ACEis) or angiotensin receptor II blockers (ARBs).

Methods: Demographic and clinical characteristics of adults (≥20 years) with CKD and DM (guideline-based laboratory criteria, use of glucose-lowering agents, administrative codes) were described for the time periods of 2015-17 and 2018-20. Pearson's chi-squared (categorical), Student's t-test (normal, continuous), or Mann-Whitney U (non-normal, continuous) analyses determined differences between users and non-users of ACEi or ARB defined by prescriptions in the EHR.

Results: ACEis/ARBs were used in 59% and 58% of patients with CKD and DM in 2015-17 and 2018-20, respectively. Adults >60 years old, men, and White/non-LatinX individuals more commonly used ACEis/ARBs (Table). In both time periods estimated glomerular filtration rate (eGFR) was significantly lower and systolic blood pressure was significantly higher in ACEi/ARB users versus non-users. The urine albumin-to-creatinine ratio did not differ by ACEi/ARB use. SGLT2 inhibitors and GLP-1 receptor agonists were more commonly given to ACEi/ARB users but prescribing of these agents was rare overall.

Conclusions: ACEi/ARB use remains sub-optimal in patients with CKD and DM and is more common in those who are older, men, and White/non-LatinX. Use of glucose-lowering agents recommended for kidney and heart protection remains very low. Further studies are needed to elucidate reasons for under-use of recommended therapies in patients with CKD and DM.

Funding: Commercial Support - Bayer

Impact of Non-Pharmacological Interventions in Indigenous Populations with Diabetes Mellitus on Cardiovascular and Kidney Disease: A Scoping Review Using the REAIM Framework

Ikechi G. Okpechi, Shezel Muneer, Mohammed M. Tinwala, Anukul Ghimire, Maryam Khan, Naima Sultana, Feng Ye, Deenaz Zaidi, Aminu K. Bello. *University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada*.

Background: Diabetes mellitus is a common cause of mortality from cardiovascular (CV) and kidney diseases. This scoping review utilized the RE-AIM (reach, efficacy, adoption, implementation, and maintenance) framework to assess the impact of non-pharmacological interventions on CV and kidney health outcomes (KHO) in Indigenous populations

Methods: We searched Medline, Embase, Cochrane Library, CINAHL, Web of Science, PsycINFO and other grey literature to identify studies that used non-pharmacological interventions (exercise, nutrition, telehealth, educational, health worker, and cultural) to achieve improved glycaemic control, and reduction of clinical or laboratory markers of CV or KHO in Indigenous communities

Results: Our search yielded 7,692 studies, from which 35 studies were selected. Culturally appropriate interventions were mostly utilized (77.1%); telehealth programs were least utilized (8.6%). Clinical and laboratory indices of CV and KHO were infrequently assessed (KHO assessed in 40%); improved kidney function was reported in 10.5% of health worker interventions. (Table 1). Reporting of items of the RE-AIM framework showed that internal validity items were more frequently reported than those of external validity: reach (60%), efficacy (52.1%), adoption (46.1%), implementation (41.9%), and maintenance (37.2%) (Table 2)

Conclusions: Due to the high prevalence of CV and kidney diseases in diabetic patients of Indigenous groups, studies using diabetes interventions need to report more items of external validity to allow the findings of such interventions to be translatable into practice

Table 1: Summary of outcomes by intervention type

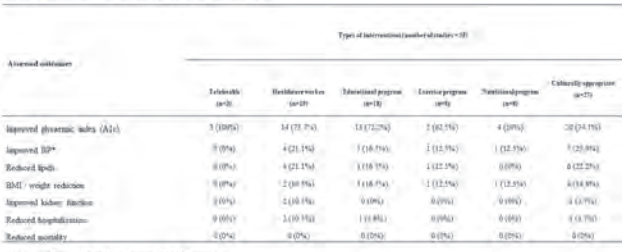

Table 1

Table 2: Proportion of diabetes interventions in Indigenous populations reporting the 21-item RE-AIM dimensions and components

RE-AIM dimensions and components	Total (n= 35; [%])
Reach	
• Method to identify target population	35 (100%)
• Inclusion criteria	26 (74.3%)
• Exclusion criteria	13 (37.1%)
• Participation rate	17 (48.6%)
• Representativeness	14 (40%)
Average across Reach components	60%
Efficacy / effectiveness	
• Results for at least one follow-up	35 (100%)
• Intent-to-treat analysis utilized	8 (22.9%)
• Quality-of-life or potential negative outcomes	9 (25.6%)
• Patient attrition	21 (60%)
Average across Efficacy/Effectiveness Components	52.1%
Adoption	
• Description of intervention location	24 (68.6%)
• Description of staff who delivered intervention	24 (68.6%)
• Method to identify staff who delivered intervention (target delivery agent)	13 (37.1%)
• Level of expertise of delivery agent	27 (77.1%)
• Inclusion/exclusion criteria of delivery agent or setting	9 (25.7)
• Adoption rate of delivery agent or setting	0 (0%)
Average across Adoption Components	46.1%
Implementation	
• Intervention duration and frequency	32 (91.4%)
• Extent protocol (program) delivered as intended	7 (20%)
• Measures of cost of implementation	5 (14.3%)
Average across Implementation Components	41.9%
Maintenance	
• Assessed outcomes ≥ 6 months post intervention	31 (88.6%)
• Qualitative measure of individual-level maintenance	7 (20%)
• Measures of cost of maintenance	1 (2.9%)
Average across Maintenance Components	37.2%

PO0770

Cause-Specific Death Differs Based on HbA1c Levels in Hemodialysis Patients with Diabetes

Soo-Young Yoon, Dae Kyu Kim, Jongho Kim, Shinyeong Kang, Jin sug Kim, Kyung hwan Jeong, Sangho Lee, Ju young Moon, Hyeon Seok Hwang. *Kyung Hee University Medical Center, Seoul, Republic of Korea*.

Background: Adequate glycemic control with achieving target HbA1c is critical in hemodialysis (HD) patients with diabetes and HbA1c level is closely associated with mortality risk. However, it is unclear whether different HbA1c levels affect mortality risk of cause-specific deaths or not.

Methods: A total 24,620 maintenance HD patients with diabetes were enrolled from the electronic health record-based registry data of Korean Society of Nephrology. Plasma HbA1c level was measured at the time of the study data entry, and patients were classified into six categories according to the HbA1c level (≤5.5%, 5.6-6.5%, 6.6-7.5%, 7.6-8.5%, 8.6%-9.5%, and >9.5%). In multivariable Cox regression analysis, we examined the relationship between HbA1c level and the risk of cause-specific death (cardiovascular, infection, non-cardiovascular/non-infection).

Results: Compared with the group with HbA1c 6.6-7.5%, the risk of all-cause mortality in each group tended to increase as HbA1c level rose; 0.99-fold (95% confidence interval [CI], 0.91-1.07) in HbA1c 5.6-6.5%, 1.08-fold (95% CI, 0.99-1.19) in HbA1c 7.6-8.5%, (95% CI, 0.99-1.19), 1.26-fold in HbA1c 8.6-9.5% (95% CI, 1.12-1.42), and 1.57-fold in HbA1c >9.5% (95% CI, 1.39-1.78). In cause-specific death analysis, cardiovascular-related mortality risk showed similar hazard ratio pattern like all-cause mortality risk and the adjusted risk for each group were 0.96 (95% CI, 0.84-1.09), 1.17 (95% CI, 1.01-1.35), 1.53 (95% CI, 1.29-1.82) and 1.57-fold (95% CI, 1.30-1.91) for HbA1c 5.6-6.5%, HbA1c 7.6-8.5%, HbA1c 8.6-9.5% and HbA1c >9.5%, respectively. However, infection-related mortality risk did not significantly increase across HbA1c strata except the risk in HbA1c >9.5% group (HR, 1.71; 95% CI, 1.29-2.26). Non-cardiovascular related/non-infection related mortality risk did not increase in all six HbA1c categories.

Conclusions: All-cause mortality and cause-specific mortality risk were different according to HbA1c levels in the patients who were undergoing HD with diabetes. Furthermore, this study showed that cardiovascular mortality risk needs to be assessed in priority than infection or non-cardiovascular related/non-infection mortality risk when HbA1c level is increased in HD patients with diabetes.

PO0771

In-Hospital Outcomes in Diabetic Ketoacidosis and Impaired Kidney Function

Karthik Gangu, Aniesh Bobba. *University of Missouri System, Columbia, MO.*

Background: Diabetes Mellitus is one of the most common causes of End-Stage Renal Disease (ESRD) in the United States. In this study, we used the National Inpatient Sample (NIS) database to compare the outcomes of Diabetic Ketoacidosis (DKA) admissions in Chronic Kidney Disease (CKD) and ESRD to DKA with normal creatinine.

Methods: We performed a retrospective study by utilizing the 2016 NIS, which comprises 20% of hospital discharges for that year. We included patients aged 18 or older admitted to the hospital with a principal diagnosis of DKA. Diagnosis data were obtained by utilizing ICD 10 CM codes. A multivariate logistic regression model was used to analyze the effect of ESRD on mortality and intubation rate. Linear regression was used to analyze the impact of ESRD on length of stay. All outcomes were adjusted to age, sex, race, insurance status, Elixhauser Comorbidity index, hospital location, and characteristics.

Results: A total of 184,050 patients were included in the study, of which 12,605 had CKD and 6025 had ESRD. The mean age was 44.1 years (SD 12.8), and 51.9 % of patients were female in ESRD. The mean length of stay was 5.2 days for the ESRD group and 3.1 for DKA with the normal creatinine group. The adjusted length of stay was 0.9 day longer (p<0.001), and the adjusted cost of hospitalization was 13,684 US dollars more expensive in the ESRD group. Adjusted Odds Ratio for mortality 1.2 (CI 0.58-2.4, p = 0.61), and intubation 0.95 (CI 0.64-1.4, p = 0.81) were not statistically significant. Outcomes for CKD patients were similar to patients with normal creatinine. (Table 1)

Conclusions: DKA in ESRD patients was associated with increased length of stay and cost of hospitalization. Further studies looking into factors contributing to the longer length of stay in the ESRD population will help in improving outcomes and significant cost reduction in taking care of these patients.

Table 1

Outcomes	DKA with normal creatinine(n=16960)	Stage 1 CKD(n=320)	Stage 2 CKD(n=1466)	Stage 3 CKD(n=7790)	Stage 4 CKD(n=2055)	Stage 5 CKD(n=440)	ESRD(n=6025)

PO0772

Hypoglycemia and Glycemic Status Ascertained by Continuous Glucose Monitoring vs. Blood Glucose in a Prospective Hemodialysis Cohort

Connie Rhee, Yoko Narasaki, Amy S. You, Rene Amel Peralta, Andrea C. Daza Aguilar, Yalitzi Guerrero, Tracy Nakata, Danh V. Nguyen, Kamyar Kalantar-Zadeh. *University of California Irvine, Irvine, CA.*

Background: In non-CKD patients, evidence shows continuous glucose monitoring (CGM) provides convenient, automated, and less invasive measurements vs. conventional self-monitored blood glucose, and leads to reduced hypo-/hyperglycemia and glycemic variability (hypoglycemia risk factor), as well as increased time in goal glucose range and quality of life. However, accuracy of CGM interstitial glucose vs. gold-standard blood glucose measures has not been well-studied in dialysis patients.

Methods: In 18 HD patients with diabetes hospitalized during 10/2020-5/2021, we conducted simultaneous protocolized glucose measurements using 1) Dexcom G6 CGM devices vs. 2) blood glucose levels using capillary fingerstick or venous blood glucose, with the latter measured ≥4 times per day (before each meal and at night), plus every 30 minutes during HD. We examined the correlation of averaged CGM and blood glucose levels, and compared the prevalence of hypoglycemia detected by these methods.

Results: During the overall assessment period, Pearson and Spearman correlations for averaged CGM vs. blood glucose were 0.65 and 0.66; similar correlations were observed when stratified by HD vs. non-HD periods. A similar proportion of patients were identified as having American Diabetes Association (ADA) Level 1 Hypoglycemia (<70mg/dl) using CGM and blood glucose (33%). In contrast, a higher proportion of patients were identified as having ADA Level 2 Hypoglycemia (<54mg/dl) by CGM (33%) vs. blood glucose (11%). A similar proportion of patients were identified as having high glucose variability (%CV >36%) using CGM vs. blood glucose (11%).

Conclusions: In a prospective cohort of hospitalized HD patients with diabetes, CGM interstitial glucose via the Dexcom G6 remote access system showed similar correlation with blood glucose levels. Whereas CGM vs. blood glucose had similar detection of Level 1 Hypoglycemia, CGM had greater detection of Level 2 Hypoglycemia vs. conventional approaches.

Effectiveness of Intradialytic Plantar Electrical Nerve Stimulation During Hemodialysis to Improve the Gait in Adults with Diabetes and Renal Failure: A Randomized Double-Blinded Controlled Trial

Abdullah I. Hamad,[1] Ram kinker Mishra,[2] Rania A. Ibrahim,[1] Mincy Mathew,[1] Mohamed Yahya Abdelhai Mohamed,[1] Heba M. Ateya,[1] Saifatullah Khan,[1] Talal Talal,[3] Bijan Najafi,[2] Fadwa M. Al-Ali.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Houston, TX; [3]Diabetic Foot and Wound Clinic, Hamad Medical Corporation, Doha, Qatar.*

Background: Impaired mobility is a persistent problem among patients undergoing hemodialysis (HD). Although exercise could be beneficial, factors such as post-dialysis fatigue, time limitation, and severe frailty to travel may result in poor adherence to conventional exercise programs. To address this gap, we are exploring an alternative therapy using intradialytic plantar electrical nerve stimulation (IPENS) provided during the routine hemodialysis process.

Methods: Participants were randomized into either an intervention group (IG: n=21, age=55±2.7 years, BMI=30.6±1.3 kg/m^2, female=31%) or a control group (CG: n=24, age=56±2.2 years, BMI=32.2±1.2 kg/m^2, female=41%). The IG received 1-hour IPENS during the routine HD process (3 sessions/week) for 12 weeks. The CG received an identical but non-functional device for the same period. Participants and therapy-providers were blinded to the group allocation. Gait performance was assessed under single-task (ST) and dual-task (DT) conditions at the baseline, 6 week, and 12-week under supervised condition. To determine the effect of intervention, we estimated Cohen's effect size d. In addition, time effect, group, and time×group effects were estimated using general linear model.

Results: All participants in the IG tolerated the IPENS and completed all therapy sessions, indicating the feasibility. While, under DT condition, cadence (steps/min) and stride time (sec) increased significantly in both groups over the time, we observed a trend towards higher improvement in IG group (Cohen's d=0.54, p=0.086 for cadence and d=0.52, p=0.09 for stride time) with a medium effect size compared to CG. We observed significant time effect on other gait parameters under ST and DT conditions with the similar trends towards group effect.

Conclusions: This pilot trial provides earlier results on IPENS therapy's feasibility and effectiveness as an alternative to exercise programs to improve gait in HD patients. Even though, the improvement didn't reach statistical significance in our current sample size. However, the effect size was medium, which is very promising.

Economic Burden Associated with CKD Progression Based on Kidney Disease: Improving Global Outcomes (KDIGO) Risk Categories in Type 2 Diabetes

C. Daniel Mullins,[1] Kevin Pantalone,[2] Keith A. Betts,[3] Jinlin Song,[3] Yan Chen,[3] Sheldon X. Kong,[4] Rakesh Singh.[4] *[1]University of Maryland Baltimore, Baltimore, MD; [2]Department of Endocrinology and Metabolism, Cleveland Clinic, Cleveland, OH; [3]Analysis Group Inc, Los Angeles, CA; [4]Bayer U.S. LLC, Whippany, NJ.*

Background: CKD progression adds substantial economic burden in T2D. This study evaluated the medical costs associated with CKD progression defined by KDIGO risk categories in patients with T2D and CKD.

Methods: A prevalent cohort of adult patients with T2D and CKD who had measures of eGFR and UACR indicating moderate or high KDIGO risk categories were identified from the Optum electronic health records database (Jan 2007- Dec 2019). CKD progression was defined as an increase in KDIGO risk category. Annualized costs for inpatient admissions, emergency room visits, and outpatient visits were evaluated for up to 2 years after the index date (i.e., the first record indicating CKD progression for progressors; the later of the first record indicating the patient's risk category or two years before the end of follow-up for non-progressors).

Results: Among 218,624 patients with baseline moderate risk, 41,986 (19%) progressed to high risk and 3,102 (1%) progressed to very high risk; among 50,461 patients with baseline high risk, 14,241 (28%) progressed to very high risk. Compared to non-progressors, the annual incremental costs were $5,193 for patients progressed from moderate risk to high risk, $18,168 for moderate risk to very high risk, and $15,280 for high risk to very high risk (Figure 1). Inpatient costs were the major driver of incremental costs. CKD-related medical costs contributed to 28%, 34%, 42%, and 44% of total medical costs in the 4 groups, highest in patients who progressed to very high risk.

Conclusions: Patients with T2D and CKD in KDIGO moderate or high risk categories had significantly higher medical costs when they progressed to a higher KDIGO risk category compared to those without progression. Preventing progression could bend the cost curve in patients with T2D and CKD.

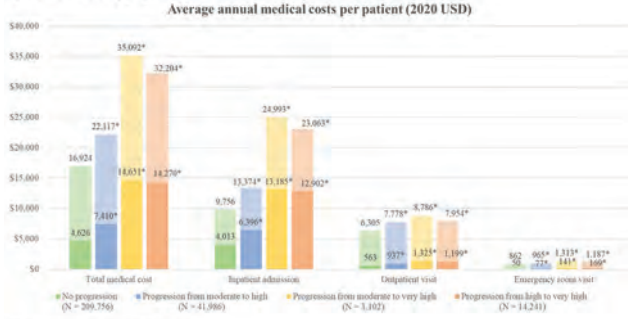
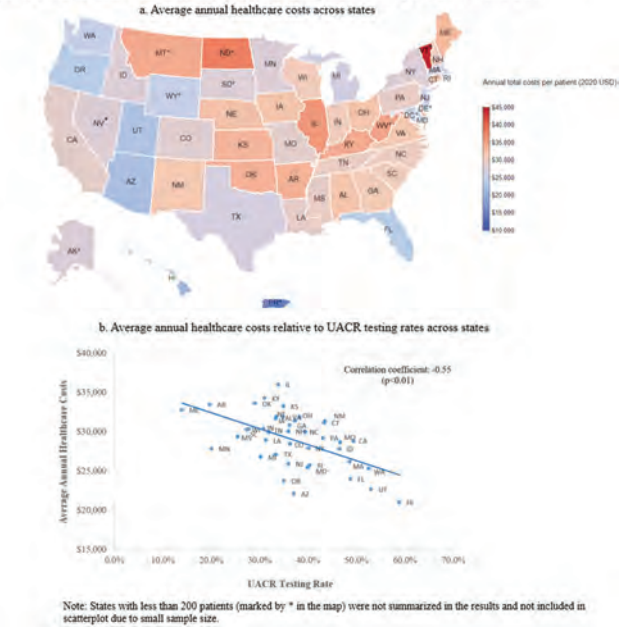
Figure 1. Medical costs by progression status[1,2]



[1] Solid areas represent CKD-related medical costs
[2] * denotes significance compared with patients with no progression

Figure 1. Average annual healthcare costs across states among patients with T2D and CKD (2020 USD)



Note: States with less than 200 patients (marked by * in the map) were not summarized in the results and not included in scatterplot due to small sample size.

PO0775

Geographic Variations in Healthcare Resource Utilization (HRU) and Costs and Their Associations with Albuminuria Testing in Patients with CKD and Type 2 Diabetes (T2D)

Rakesh Singh,[1] Keith A. Betts,[2] Jinlin Song,[2] Yao Wang,[2] Jay Elliott,[1] Neil Warnock,[1] Ryan Farej.[1] *[1]Bayer U.S. LLC, Whippany, NJ; [2]Analysis Group Inc, Los Angeles, CA.*

Background: Albuminuria monitoring is critical for CKD management. The study evaluated the geographical urine albumin-to-creatinine ratio (UACR) monitoring patterns in the US along with the associated economic outcomes in patients with CKD and T2D.

Methods: Adult patients with T2D and CKD were identified from the Optum Clinformatics® claims data (Jan 2015-Dec 2019). HRU, healthcare costs (in 2020 USD), and percentage of patients receiving at least one UACR test were summarized by state during the one-year after T2D and CKD diagnoses. Patients who had dialysis or kidney transplantation before or during the study period were excluded.

Results: Among the 101,057 patients with T2D and CKD, the average annual healthcare costs were $28,636 and increased with CKD severity, from $20,122 (stage I, n = 4,070) to $38,072 (stage V, n = 242). Large variation exists across states ranging from $21,003 [HI] to $35,995 [IL] (Figure 1a). The average number of inpatient visits (range: 0.3 [AZ] to 0.7 [AR]), outpatient visits (18.3 [CO] to 29.8 [CT]), and emergency room visits (0.4 [MI] to 1.0 [KS]) also varied substantially. The average UACR testing rate was 38.7%, consistently low across states (14.0% [ME] to 58.9% [HI]). States with lower UACR testing rates tended to have higher healthcare costs (Figure 1b).

Conclusions: Patients with CKD and T2D had high HRU and healthcare costs with large variations across states. Lower UACR testing rates were associated with higher economic burden.

PO0776

Cardiovascular and CKD-Related Healthcare Costs for Patients with Type 2 Diabetes and CKD

Rakesh Singh,[1] Jinlin Song,[2] Elizabeth Faust,[3] Yuxian Du,[1] Sheldon X. Kong,[1] Keith A. Betts.[2] *[1]Bayer Corp, Whippany, NJ; [2]Analysis Group Inc, Los Angeles, CA; [3]Analysis Group Inc, New York, NY.*

Background: Cardiovascular (CV) events and chronic kidney disease (CKD) management incur high medical costs in patients with type 2 diabetes (T2D) and CKD. This study aimed to provide reliable regression-based cost estimates of these events among patients with T2D and CKD.

Methods: This study used Optum Clinformatics® claims data from 52,599 adults with T2D and CKD identified during 2015-2019 and followed until disenrollment, death, or end of data availability. Medical costs (2020 USD) associated with CV events and CKD management were estimated using a generalized estimating equation model adjusting for age, sex, as well as CV complications and medical costs at baseline. Costs were assessed in 4-month cycles as commonly evaluated in clinical trials in this population, with acute event costs assessed in the first 4 months after the incident CV events and renal replacement therapies (RRT). Mortality costs were assessed in the last month prior to death.

Results: The estimated 4-month CKD management costs were $7,725 for stage 1 or 2, $8,928 for stage 3, $10,809 for stage 4, and $11,879 for stage 5 (without RRT). The estimated acute event costs for dialysis and kidney transplantation were $87,538 and $124,271, respectively. The costs decreased to $49,573 and $7,079 in subsequent 4-month cycles following dialysis initiation and kidney transplantation. The estimated costs for acute CV events were $31,063 for heart failure, $21,087 for stroke, $21,016 for myocardial infarction, and $19,954 for atrial fibrillation ($30,500 with hospitalization and $5,162 without). In subsequent 4-month cycles, costs were $4,931 for heart failure, $2,327 for stroke, and $1,941 for myocardial infarction. The acute cost of hyperkalemia was $15,149 ($31,212 with hospitalization and $1,782 without). In the month before death, the costs associated with CV-related death, renal-related death, and death from other causes were $17,031, $12,605, and $9,900, respectively.

Conclusions: CV events and CKD management incur significant healthcare costs for patients with T2D and CKD. The cost estimates from this study may support the parametrization of economic models and help clinicians determine the cost-effectiveness of interventions.

PO0777

Clinical and Histological Predictors of Renal Survival in Patients with Biopsy-Proven Diabetic Nephropathy

Ting Zhou, Yiyun Wang, Li Shen, Ze Li, Junjie Jia, Niansong Wang, Ying Fan. *The Sixth Hospital of Shanghai Affiliated to Shanghai Jiaotong University, Shanghai, China.*

Background: Diabetic nephropathy (DN) is one of the most important complications of diabetes and has become the leading cause of end stage renal disease (ESRD). However, clinical and pathological factors alone can't reliably predict renal survival in patients with biopsy-proven DN, potentially resulting in the delayed treatment of patients at a high risk of renal failure. Therefore, this study sought to develop and validate a predictive model incorporating both clinical and pathological markers to predict renal outcomes in patients with biopsy-proven DN.

Methods: A predictive nomogram was developed based upon data pertaining to 194 patients with biopsy-proven DN. The prognostic relevance of individual clinicopathological variables was assessed through univariate and multivariate Cox regression analyses. A prognostic nomogram was then developed and validated based upon concordance (C)-index values, area under curve (AUC) and calibration curves. Internal validation was conducted through bootstrap resampling, while the clinical utility of this model was assessed via a decision curve analysis (DCA) approach.

Results: Nephrotic-range 24-hour proteinuria, late-stage chronic kidney disease (CKD stage 3-4), glomerular classification III-IV, and an IFTA score 2-3 were all identified as independent predictors of poor renal outcomes in DN patients and were incorporated into our final nomogram. Calibration curves revealed good agreement between predicted and actual 3- and 5-year renal survival in DN patients, while the C-index value for this nomogram was 0.845 (95% CI 0.826–0.864) and the 3- and 5-Year AUC were 0.933 (95%CI 0.898-0.968), 0.923 (95%CI 0.886-0.960). DCA analysis revealed that our nomogram was superior to models based solely upon clinical indicators.

Conclusions: A predictive nomogram incorporating clinical and pathological indicators was developed and validated for the prediction of renal survival outcomes in patients with biopsy-proven DN. This tool will be of value to clinicians, as it can serve as an easy-to-use and reliable tool for physicians to guide patient management based on individualized risk in order to improve patient outcomes.

PO0778

Histological Diabetic Nephropathy in Autopsied Diabetic Cases with Normoalbuminuria from a Japanese Community-Based Study: The Hisayama Study

Takaya Sasaki,[1,2] Kaneyasu Nakagawa,[3] Jun Hata,[1,3] Yoichiro Hirakawa,[1,3] Mao Shibata,[1,4] Toshiaki Nakano,[3] Nobuo Tsuboi,[2] Yoshinao Oda,[5] Takanari Kitazono,[1,6] Takashi Yokoo,[2] Toshiharu Ninomiya.[1,6] *[1]Department of Epidemiology and Public Health, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [3]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [4]Department of Psychosomatic Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [5]Department of Anatomic Pathology, Pathological Sciences, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [6]Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Albuminuria is a clinical indicator of diabetic nephropathy (DN). However, it is controversial whether pathological DN lesions are present in diabetic individuals with normal albuminuria. We investigated the association between albuminuria levels and the frequency of DN lesions in autopsied diabetic cases from a Japanese community.

Methods: Autopsied specimens obtained from deceased people in the town of Hisayama from 2002 to 2017 were used in the present study. During this period, 131 deceased individuals with diabetes underwent autopsy examinations. A total of 106 autopsied cases with diabetes mellitus (mean age 76 years, 43.4% male) who died within 6 years since the last health examination were included in the study. Urinary albumin-creatinine ratio (UACR) levels were divided into three groups: <30.0, 30.0–299.9, and ≥300.0 mg/g. The kidney specimens were evaluated with light microscopy, and were categorized into class 0–I, IIa, IIb, and III glomerular DN lesions according to the Renal Pathology Society's criteria. A Cochrane-Armitage test was used to examine the association between the UACR levels and the presence of class IIa or higher glomerular DN lesions.

Results: In the overall cases, the frequency of class IIa or higher glomerular DN lesions was 63.2% (IIa, 36.8%; IIb, 3.8%; and III, 22.6%). Its frequencies increased significantly with higher UACR levels (P for trend = 0.02, **Figure**). Even in individuals with UACR of <30 mg/g, the frequency of class IIa or higher glomerular DN lesions was 51.2%.

Conclusions: The present study showed a positive association of the UACR levels with the presence of class IIa or higher glomerular DN lesions, which were also frequently found even in the normoalbuminuric range, among autopsied diabetic cases from a Japanese community.

Clinical and Pathological Significance of Orai1 Expression in Human Diabetic Nephropathy

Yoojin Kwak, Hanwul Shin, Jun Young Lee, Jae seok Kim, Jae Won Yang, Seung-Kuy Cha, Minseob Eom. *Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.*

Background: Diabetic nephropathy (DN) causes about half of ESRD. The attempts for targeted therapy for DN have been lacking to date. Store-operated Ca entry (SOCE) is a primary Ca influx mechanism in non-excitable cells that is mediated by pore-forming subunit Orai1. Currently, it has been argued whether Orai1 overexpression protects against renal pathologies. Here, we investigate the significance of Orai1 expression in human DN.

Methods: Ninety-three DN patients from 2009 to 2019 were enrolled. The paraffin blocks were used to perform immunohistochemical staining for Orai1 (figure). Renal Pathology Society DN classification (RPS) and clinical parameters were compared with Orai1 expression. The results were compared by dividing them into a glomerulus (G) and tubulo-interstitium (T-I).

Results: In T-I, Orai1 was overexpressed in DN, and Orai1 expression was significantly correlated with the higher RPS and interstitial fibrosis & tubular atrophy score ($p < 0.001$). While Orai1 expression was correlated with serum Cr and CKD stages, eGFR and HbA1c were inversely associated with Orai1 expression ($p < 0.001$). By logistic regression, Orai1 expression was significantly correlated with the higher RPS and the advanced CKD stage. Moreover, Orai1 expression was strongly associated with the advanced CKD stage by the multivariate logistic regression ($p = 0.002$) (table). The result of G was similar to that of T-I.

Conclusions: It is suggested that Orai1 is a valuable biomarker for predicting the progression and prognosis of DN, that provides new perspectives on therapeutic targets for DN.

Funding: Government Support - Non-U.S.

Prevalence and Risk Factors Associated with Diabetic Nephropathy in Patients with Diabetes Undergoing Nephrectomy

Laura Aponte Becerra,[1,2] Juan D. Salcedo Betancourt,[1,2] Alessia Fornoni,[5] Oleksii Iakymenko,[1] Gabriel Contreras,[5] Sara Marin,[1,2] Juanly N. Rodriguez,[5,2] Noreen Mohsin,[1] Oscar A. Garcia Valencia,[1,2] Abraham Santana Rodriguez,[5,2] Laura Barisoni,[3] David B. Thomas,[4] Jair Munoz Mendoza.[5] *[1]University of Miami School of Medicine, Miami, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]Duke University, Durham, NC; [4]IYM Health Financial services, PLLC, Charlotte, NC; [5]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.*

Background: Diabetic kidney disease (DKD) affects about 40% of patients with diabetes and is the most common cause of end-stage renal disease in the US. The prevalence of morphologic features of DKD, known as diabetic nephropathy (DN), is likely underestimated since kidney biopsies are performed when other diseases are clinically suspected. The availability of non-neoplastic kidney tissue from nephrectomies offers us the opportunity to evaluate the prevalence and risk factors associated with morphologic evidence of DKD.

Methods: A total of 198 nephrectomies of diabetic patients, where the status of the non-neoplastic kidney tissue was reported, were included. Clinical, demographic, and histological data were collected retrospectively. Logistic regression models were used to examine the association between clinical and demographic characteristics as primary exposure and morphologic evidence of DKD as the dependent variable.

Results: The mean age across all diabetic patients undergoing nephrectomy was 64±11 years, 59% were male, 9% African-American (AA), and 39% Hispanics. Clinical DKD was found in 47% of patients, 60% had hypertension, 66% had a GFR ≥ 60mL/min/1.73m^2 and 62% had no proteinuria. Morphologic features of DKD were observed in 56 (28%) patients. In multivariable-adjusted logistic regression analyses, the presence of morphologic features of DKD was significantly associated with older age (odds ratio [OR] per 10-year increase, 1.64 [95% confidence interval (CI), 1.08-2.48]), proteinuria (OR, 2.27 [95% CI, 0.99-5.17]), and neuropathy (OR, 4.92 [95% CI, 1.76-13.75]). The presence of morphologic features of DKD was associated with retinopathy only in univariate analysis (OR, 8.47 [95% CI, 1.65-43.47]). No association ((p>0.05) with AA race, hypertension, clinical DKD, and eGFR was noted.

Conclusions: Morphologic features of DKD are highly prevalent in patients undergoing nephrectomy. Older age, proteinuria, and neuropathy were independently associated with significantly greater odds of morphologic evidence of DKD. Future studies should evaluate the prevalence of non-diabetic renal disease in patients with diabetes undergoing nephrectomy.

PO0781

Biopsy Results in a Diverse Diabetic Cohort

Douglas R. Farrell, Aparna Saha, Joji E. Tokita, Shuchita Sharma, Lili Chan. *Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: Diabetes is the most common cause of kidney failure in the US. However, many of these patients never receive a biopsy, and therefore diabetic nephropathy (DN) is presumed based on clinical features. Therefore, we sought to determine the prevalence and outcomes of non-diabetic renal disease (NDRD) in a diverse cohort of diabetic patients referred for biopsy.

Methods: Patients were included if they had a biopsy performed at The Mount Sinai Hospital from 2018-2019, and if they had a hemoglobin A1c > 6.5% or diabetes was mentioned in their past medical history. Charts were excluded if no data existed after biopsy, dialysis-dependence occurred prior to biopsy, and if insufficient amounts of glomeruli were observed. Baseline characteristics including age, gender, race/ethnicity, blood pressure, creatinine, and urine protein/creatinine ratio (UPCR) were recorded. Outcomes measured were 1 year UPCR, 1 year creatinine, need for dialysis, and death.

Results: In total, 81 charts were included for analysis, of which 21 biopsies had DN alone, 26 had DN + NDRD, and 27 had NDRD alone (Figure 1A). In patients with NDRD, a broad range of pathology was seen (Figure 1B). There were no significant differences in characteristics of patients with DN alone and any NDRD (Figure 1C). There was a non-statistically significant difference in median one year creatinine and one year UPCR between patients with DN and NDRD (1.67 vs. 3.07 (p=0.1) and 2490 vs. 3540 (p=0.2)). Additionally, there was a non-statistically significant difference in death and dialysis treatment between DN and NDRD patients, 4 (14%) vs. 3 (6%) (p=0.2) and 5 patients (18%) vs. 19 (36%) (p=0.09), respectively. DN had lower odds of requiring dialysis at 1 year from biopsy OR 0.39 (95% CI 0.13-1.19).

Conclusions: In our selected diverse population of diabetic patients with kidney biopsies, the majority of patients had NDRD on pathology. While not statistically significant, DN patients had lower follow up creatinine and UPCR, and less patients on dialysis at 1 year.

Identification of Kidney Disease Diagnoses in Patients with Diabetes by Biopsies and Electronic Health Records

Eva Fast,[1] Cami R. Jones,[4] Kenn B. Daratha,[4] Susanne B. Nicholas,[2] Radica Z. Alicic,[4] Cynthia C. Nast,[3] Jonathan E. Zuckerman,[2] Sarthak Patel,[1] Adam Tebbe,[1] Michelle Penny,[1] Keith C. Norris,[2] Katherine R. Tuttle.[4] *[1]Goldfinch Bio Inc, Cambridge, MA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]Providence Washington, Spokane, WA.*

Background: Diabetic kidney disease (DKD) refers to chronic kidney disease in diabetes, but not a specific diagnosis. This report describes a patient cohort with electronic health record (EHR) data linked to manual data abstraction for kidney histopathology.

Methods: Patients were selected from the Center for Kidney Disease Research, Education, and Hope (CURE-CKD) registry which contains curated EHR clinical and administrative data from two large healthcare systems. Inclusion criteria consisted of a native kidney biopsy, diagnoses of diabetes and CKD but not on dialysis. Clinical investigators manually abstracted health history, laboratory data, and histological features from kidney biopsy reports. DKD was classified as: diabetic nephropathy (DN), DN mixed with nondiabetic lesions (Mixed), and nondiabetic lesions only (Other).

Results: In 523 patients with diabetes who underwent kidney biopsy in the years 2015-2017 (Table), diagnostic frequencies were DN 39.8% (n=208), Mixed 36.9% (n=193), Other 23.3% (n=122). Patients with DN were younger, displayed higher albuminuria, increased nodular glomerulosclerosis and arteriolar hyalinosis than the Mixed group. Those with DN more commonly had diabetes duration >10 years and higher albuminuria compared to the Other group, while lesions characteristic of DN (mesangial expansion, nodular glomerulosclerosis, GBM thickening, arteriolar hyalinosis, tubular basement membrane thickening) were uncommon in Other.

Conclusions: Higher levels of albuminuria, nodular glomerulosclerosis and arteriolar hyalinosis were distinctly more common in DN compared to Mixed and Other groups, and nodular glomerulosclerosis was rarely observed in the Other group. Future work will use machine learning models of the EHR data to predict DN and select precision therapies.

DKD – diabetic kidney disease, SD – standard deviation, IQR – interquartile range, eGFR CKD-EPI - estimated glomerular filtration rate (GFR) from serum creatinine using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation, UACR- urinary albumin-to-creatinine ratio, UPCR - urinary protein-to-creatinine ratio, GBM - glomerular basement membrane, TBM - tubular basement membrane

PO0783

Triglyceride-Glucose Index Is Associated with Renal Dysfunction in Stage 2 CKD Patients

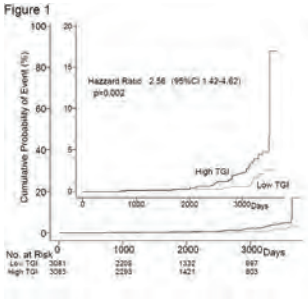
Makoto Araki. *Suwa Central Hospital, Chino, Japan.*

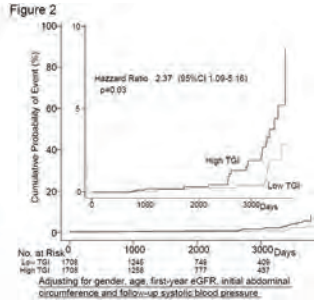
Background: SGLT2i, nephroprotective agent, are known to improve hyperinsulinemia and hyperlipidemia, especially triglyceride metabolism. However, their effects on renal function have not been clearly elucidated. Triglyceride-Glucose Index (TGI) has gathered attention as a new marker of metabolic syndrome. Since it reflects both lipotoxicity and glucotoxicity, we investigated the relationship between TGI and renal function.

Methods: In this single-institutional observational study, we screened subjects whose blood (triglyceride, creatinine, and blood glucose) and body profile (abdominal circumference, height, and weight) assessment on the same day at annual health examinations between 2008 to 2018. Among these individuals, those with an estimated glomerular filtration rate (eGFR) value of 60–90 ml/min/1.73 m^2, which indicates stage 2 chronic kidney disease (CKD) in the first year, were included in the study. The subjects were divided into two groups based on high and low mean TGI values during the course of the study. The changes in their renal function were compared. We evaluated both groups by time-to-event analysis in terms of a 30% eGFR decline.

Results: Of the 19,940 individuals (73,084 tests) who were assessed initially, only 8,203 individuals had health records beyond one year. Among these, we examined 6,164 patients with stage 2 CKD (mean age: 49.2 ± 11.1 years, observation period: 1,906.1 ± 1,084.3 days, mean eGFR 75.5 ± 7.8 ml/min/1.73 m2). Univariate analysis by the Lon-rank test showed that the renal function as significantly more deteriorated among individuals with a high TGI (P = 0.001). The difference remained significant after adjusting for gender, age, first-year eGFR, abdominal circumference, and follow-up systolic blood pressure using the propensity score matching method (p = 0.02).

Conclusions: In conclusion, among patients with mild renal dysfunction (stage 2 CKD), High TGI was associated with decreased renal function, and this did not change after adjusting for background factors.





PO0784

Effect of Dapagliflozin on Soluble Urokinase-Type Plasminogen Activator Receptor in Type 2 Diabetes with Albuminuria

Viktor Rotbain Curovic,[1] Mie K. Eickhoff,[1] Morten B. Houlind,[2] Marie Frimodt-Moller,[1] Tine Hansen,[1] Jesper Eugen-Olsen,[2] Peter Rossing,[1,3] Frederik Persson.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Clinical Research Centre, Amager Hvidovre University Hospital, Hvidovre, Denmark; [3]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Given the documented protective effect of the sodium-glucose co-transporter 2 inhibitor, dapagliflozin on chronic kidney disease and the potency of soluble urokinase-type plasminogen activator receptor (suPAR) as a risk marker of the same, we investigated the effect of treatment with dapagliflozin on plasma suPAR in individuals with type 2 diabetes and albuminuria. Secondarily, we examined the association between the level of suPAR and the established early urinary proteomic classifier CKD273.

Methods: Post-hoc analysis of a double-blind, cross-over trial where persons with type 2 diabetes and albuminuria received treatment with dapagliflozin (10 mg/d) or placebo for 12 weeks in random order. The original primary outcome was change in the urinary proteomic classifier CKD273. suPAR level was assessed in plasma samples collected at all 3 visits. Effect of dapagliflozin on suPAR level was determined using unpaired t-test for comparison between baseline and end-of-treatment for the dapagliflozin and the placebo treatment period, and paired t-test for comparison between the two treatment periods. A secondary analysis investigated the association between baseline suPAR and CKD273 using Pearson correlation.

Results: Of the 36 persons who completed study, 11% were female, mean±SD age was 64±8 years, HbA_{1c} 73±15 mmol/mol (8.9±1.4%), eGFR 84±19 ml/min/1.73m^2, and median (IQR) urinary albumin creatinine ratio was 154 mg/g (94-329). Median (IQR) suPAR at baseline was 3.44 ng/ml (2.49;4.35) and CKD273 score was 0.59 (0.18;0.77). suPAR change after 12 weeks dapagliflozin was -0.13 ng/ml (95% CI -0.72;0.36, p=0.50) and placebo -0.19 ng/ml (-0.71;0.33, p=0.46), mean difference 0.06 ng/ml (95% CI -0.15;0.27, p=0.57). Pearson correlation R between baseline suPAR level and CKD273 score was 0.17 (95% CI -0.17;0.48, p=0.32).

Conclusions: This post-hoc analysis could not demonstrate an effect of 12 weeks of treatment with dapagliflozin on plasma suPAR level in individuals with type 2 diabetes and albuminuria. In addition, plasma suPAR was not correlated to the urinary proteomic CKD273 classifier.

PO0785

Predictive Model of Non-Diabetic Nephropathy in Patients Affected by Diabetes

Sheila Bermejo, Irene Agraz, Ander Vergara, Maria Jose Soler. on behalf of GLOSEN group *Vall d'Hebron Hospital Universitari, Barcelona, Spain.*

Background: Between 50-60% of diabetics with renal involvement have non-diabetic nephropathy (NDN). Renal biopsy is crucial for renal diagnosis that includes diabetic nephropathy (DN), NND, or mixed form. The objective of the current study is to provide a tool in the daily clinical practice through a predictive model of NND that is clue for the indication of renal biopsy.

Methods: Observational, retrospective and multicenter study of the pathological results of kidney biopsies in patients with diabetes from 2002 to 2014. A logistic regression analysis and the probability of presenting NND was calculated using a punctuation score.

Results: The cohort of 832 patients includes 621 men (74.6%), median age 61.7±12.8 years, creatinine 2.8±2.2mg/dl and proteinuria 2.7 (1.2-5.4)gr/24h. Time of evolution of diabetes was 10.8±8.6 years. 26.6%(n=221) of patients presented diabetic retinopathy, 18.8% (n=156) peripheral vasculopathy and 17.7% (n=147) ischemic heart disease. 288 patients (34.6%) presented microhematuria. 39.5% (n=329) presented DN, 49.6% (n=413) NDN and 10.8% (n=90) mixed forms. In the multivariate analysis, age (OR:1.03;1.01-1.04; p=0.0002), absence of microhematuria (OR:0.6,;0.4-0.86;p=0.005), absence of diabetic retinopathy (OR:3.97;2.7-5.82;p<0.0001) and absence of peripheral vasculopathy (OR:1.61, 1.03-2.52, p=0.038) were identified as ndependent risk factors for NDN. A ROC curve with an area under the curve of 0.724 was obtained. A predictive model obtaining a score (see figure) for each variable and finally a NDN prediction score was performed. In our new score, the number increases as increased the probability of NDN.

Conclusions: In our study, around 66% of biopsied patients with diabetes presented NDN. Microhematuria, absence of diabetic retinopathy, absence of peripheral vascular disease, and older age were identified as independent risk factors for NDN. We obtained a Score that increases as increased the probability of NDN. This could be in a next future a useful tool for the clinical indication of renal biopsy in patients with diabetes and kidney disease.

PO0786

Metabolic Acidosis and the Risk of Progression to Diabetes in Patients with Prediabetes and CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Julie C. Lai,[1] Vandana S. Mathur,[2] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]MathurConsulting, Woodside, CA; [3]Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Background: Diabetes and metabolic acidosis are known risk factors for progression of CKD. Treatment of metabolic acidosis has been shown to reduce insulin resistance among patients with CKD and diabetes, but whether metabolic acidosis predicts progression from prediabetes to diabetes among patients with CKD is unknown.

Methods: Optum's de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried for patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate of 12 to <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) with ≥1 year prior data and ≥2 years of post-index data or death within 2 years. Patients with prediabetes (HbA1c 5.7 to <6.5%, fasting plasma glucose 100 to <126 mg/dL, or 75 g oral glucose challenge 140–199 mg/dL) were followed for up to 11.5 years for incident diabetes identified through lab values, diagnosis, or prescriptions. Cox proportional hazards models were used to evaluate metabolic acidosis as a predictor of incident diabetes, adjusting for age, sex, race, low-income status, geo-coded education level, and baseline BMI, eGFR, metabolic syndrome and polycystic ovary syndrome. Death was also evaluated as a competing risk.

Results: 7156/136,067 patients had evidence of prediabetes during the pre-index year. 47% (136/292) of patients with baseline metabolic acidosis and 46% (3143/6864) with normal serum bicarbonate developed diabetes during the outcome period (P=0.8).

Patients with metabolic acidosis developed diabetes sooner on average compared with normal serum bicarbonate (544 vs 643 days); however, baseline metabolic acidosis was not a significant predictor of time to incident diabetes in adjusted analyses (HR 1.20, 95% CI:0.96-1.49). Metabolic syndrome (HR 1.26, 95% CI:1.08 1.46), Black race (HR 1.28 [1.11-1.47]), male sex (HR 1.11[1.01-1.21]), and higher BMI (HR 1.03 [1.02-1.03]) were associated with a higher risk of progression to diabetes. Higher baseline eGFR was associated with lower risk of progression to diabetes (HR 0.993 [0.988 0.997]).

Conclusions: In this longitudinal analysis of non-dialysis CKD stages 3-5 patients with prediabetes, metabolic acidosis was not associated with progression to diabetes.

PO0787

The Gut Microbiome-Derived Phenyl Sulfate Is a Novel Predictive Marker and Cause of Albuminuria in Diabetic Kidney Disease

Koichi Kikuchi, Takaaki Abe. *Tohoku Daigaku, Sendai, Japan.*

Background: Diabetic kidney disease (DKD) is one of the major causes of end-stage renal diseases (ESRD), and it is important to prevent from onset or progression of DKD. However, it is difficult to identify type 2 diabetes patients who are at risk of developing progressive DKD based only on measurements of glomerular filtration rate and albuminuria. Therefore, specific biomarkers are needed for a breakthrough in the good management of DKD.

Methods: Among 777 patinets in a multi-center clinical study in diabetic nephropathy cohort (U-CARE), 362 patients with full data were selected. The plasma PS, PCS, IS and TMAO level were measured by LCMS/MS. The correlation between these level and various factors were calculated using the Spearman Rank-Order Correlation. Multiple regression analysis and a logistic regression analysis were used to identify the factors associated with PS, IS, PCS, TMAO, suPAR, urine acid or the development of 2-year ACR deterioration, respectively.

Results: As we previously reported (Kikuchi et al. Nat. Commun. 2019, ASN 2019), serum PS level significantly related with the basal albuminuria level in U-CARE study. In addition, logistic regression analysis showed among known ACR predictive factors, PS was the only factor which significantly related 2-year progression of albuminuria especially in patients with microalbuminuria. These data suggested that PS may have a potential as important predictive marker of DKD. Next, we examined the relationship between albuminuria or renal function and IS, PCS, TMAO which were well-known as gut derived uremic solutes as well as PS. In addition, we examined the relationship between albuminuria or renal function and suPAR, uric acid. As a result, IS, PCS, suPAR were inversely correlated with eGFR. PS, IS, suPAR and uric acid were correlated with albuminuria. Among them, PS and uric acid were the factor which significantly correlated with the 2-year albumin-creatinine ratio (ACR) deterioration. Furthermore, we clarified that serum PS concentration level was high even in same patients who are preserved renal function (eGFR>60 ml/min/1.73cm2), and high PS concentration patients were significantly increased 2-year ACR deterioration rate.

Conclusions: PS is predictive marker of albuminuria in the patients with microalbuminuria in DKD patients.

PO0788

Urinary Biomarkers for Prediction of Estimated GFR Decline in Patients with Type 2 Diabetes and Preserved Kidney Function

Hiroyuki Unoki-Kubota,[1] Emi Ito,[1] Daishi Hirano,[2] Toshiyuki Imasawa,[3] Hiroshi Kajio,[4] Shigeo Yamashita,[5] Yuka Fukazawa,[6] Yasushi Kaburagi.[1] *[1]Kokuritsu Kokusai Iryo Kenkyu Center Kenkyujo, Shinjuku-ku, Japan; [2]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; [3]National Hospital Organization Chiba-Higashi National Hospital, Chiba, Japan; [4]Kokuritsu Kokusai Iryo Kenkyu Center Byoin, Shinjuku-ku, Japan; [5]Tokyo Yamate Medical Center, Shinjuku-ku, Japan; [6]JR Tokyo Sogo Byoin, Shibuya-ku, Japan.*

Background: We have previously performed a urinary proteomic analysis of patients with diabetic kidney disease (DKD) and identified the differentially excreted proteins in the patients with DKD (Diabetes Res Clin Pract. 2019; 147:37-46). In this study, we evaluated the association of the differentially excreted proteins with an annual decline in estimated glomerular filtration (eGFR) in patients with type 2 diabetes (T2D) and preserved kidney function.

Methods: In a prospective, observational cohort study, 392 Japanese patients with T2D and baseline eGFR ≥ 60 ml/min/1.73m^2 were followed over one year (mean period 5.5 years; IQR 3.9 – 7.3). Linear regression was used to estimate participants' annual decline rate in eGFR over time. We defined subjects with an annual eGFR decline ≥ 5% per year as rapid decliner and the eGFR decline < 5% as slow decliner. Of the 392 participants, 218 patients were randomly selected and baseline levels of 75 urinary proteins were measured by multiple reaction monitoring (MRM) analysis.

Results: The study population had a median age of 59.0 years (IQR, 56.3 – 58.5) and 78.0% were male. The median duration of diabetes was 10.0 years (IQR, 9.8 – 12.0). During the follow-up period, 44 patients had a rapid decline in eGFR. Median eGFR decline was -6.51% (IQR, -8.54 – -6.47) and -1.29% (IQR, -1.43 – -0.65) per year in rapid decliner and slow decliner, respectively. Compared with slow decliner, rapid decliner had higher HbA1c level and lower levels of HDL-cholesterol (HDL-c), Hb, and Hct at baseline, however, their differences were not significant. In the MRM analysis, we found that 11 urinary proteins were differentially excreted in rapid decliner compared to the urinary proteins of slow decliner ($P < 0.05$). Multivariable logistic regression models revealed that 4 urinary proteins and Hb were independent predictors of annual decline in eGFR adjusted by age, HbA1c, HDL-c, eGFR, and urinary albumin-to-creatinine ratio ($P < 0.005$). When combining the 4 urinary protein levels, an area under the ROC curve for the detection of rapid decliner was 0.781 (95% CI 0.709 – 0.852).

Conclusions: Our findings highlight the important effect of 4 urinary proteins as independent predictors of a rapid decline in eGFR in patients with T2D and preserved kidney function.

PO0789

Comorbidity Burden Among Patients with CKD and Type 2 Diabetes in a US Commercially Insured/Medicare Advantage Population

Haechung Chung,[1] Nicole M. Thomas,[1] Vincent Willey,[1] Sheldon X. Kong,[2] Rakesh Singh,[2] Ryan Farej,[2] Jamie Partridge,[2] Jay Elliott.[2] *[1]HealthCore, Inc., Wilmington, DE; [2]Bayer US, Whippany, NJ.*

Background: While it is well-established that T2D is the leading cause of CKD, contemporary data describing the burden of CKD among patients with both T2D and CKD is scarce. We described 3 mutually exclusive patient cohorts: T2D only, CKD with T2D, CKD without T2D in the real-world setting.

Methods: This cross-sectional study utilized 3 calendar years (2017-2019) of administrative claims data from the HealthCore Integrated Research Database. Adults diagnosed with CKD with and without T2D (CKD in T2D and CKD, respectively) and T2D without CKD (T2D) in 2018 were identified. Index date was defined as the first claim with a diagnosis for either CKD or T2D in 2018. Eligible patients were required to have continuous health plan enrollment ≥1 year pre- and post-index. Clinical characteristics, comorbidity burden (as measured by the Quan- Charlson Comorbidity Index (QCI)) and hospitalizations were analyzed descriptively.

Results: Among 203,576 T2D, 22,689 CKD and 38,587 CKD in T2D patients, mean age was 59 (SD: 12), 66 (SD: 16) and 67 (SD: 13) years; 47%, 51%, and 47% were female, respectively. Both pre- and post-index, the CKD in T2D group had the highest proportion of comorbid conditions followed by the CKD and T2D group and overall comorbidity burden was elevated in a similar manner (QCI ≥3 in 6%, 19% and 31%, respectively). Hypertension (79-94%), dyslipidemia (68-87%) and obesity (28-44%) were the most prevalent comorbidities. Atherosclerotic cardiovascular disease (e.g. – myocardial infarction: 6.6%, 4.2%, 2.5%; ischemic stroke/TIA: 7.9%, 6.5%, 2.9%, respectively) and heart failure (19.1%, 13.4%, 4.5%, respectively) were most prevalent in the CKD in T2D group, followed by the CKD and T2D groups. During the year post-index, the proportion of all-cause hospitalization was 11% (T2D), 22% (CKD) and 28% (CKD in T2D).

Conclusions: CKD in T2D was associated with substantial overall and cardiovascular comorbidity burden in this contemporary real-world cohort, followed by CKD and then by T2D patients. Treatment strategies for CKD in T2D should consider the patient's individual comorbidity burden to reduce risk of cardiovascular and overall morbidity and mortality.

PO0790

The Usefulness of Calcium/Magnesium Ratio in the Risk Stratification of Early Onset of Renal Replacement Therapy

Rita S. Afonso, Ana Cabrita, Ana P. Silva. *Centro Hospitalar do Algarve EPE, Faro, Portugal.*

Background: Recently, a growing number of studies have reported a close relationship between high serum calcium (Ca) and low serum magnesium (Mg) with vascular calcification. Endothelial dysfunction and vascular inflammation seem plausible risk factors for enhanced progression of kidney disease. The aim of this study is to evaluate the role of calcium/magnesium ratio as risk factor in CKD progression.

Methods: Observational, prospective study involving 693 patients (female=371) with stage 4/5 CKD. Patients were divided into two groups, according to the development of ESRD: G1 (n=541), who did not start renal replacement therapy (RRT) and G2 (n=152), who had started RRT. Several laboratory parameters were measured. Baseline characteristics were recorded and compared. Multivariate Cox regression analysis was used to identify independent factors associated with RRT initiation. A modified Poisson regression with robust error variance was used to estimate the cumulative relative risk for RRT initiation.

Results: The mean age was 70.09±12.51 years and eGFR was 19.91±8.11 mL/min. G2 had significantly lower serum levels of Hb (11.75vs10.95 g/dl,p= 0.000), Ca (9.34vs8.95 mg/dl,p=0.000), Mg (1.92vs1.40 mg/dl,p= 0.0001), albumin (4.00vs3.88 g/dl, p= 0.03) and cholesterol (183.17vs172.39 mg/dl,p=0.01), and higher serum levels of phosphorus (3.88vs4.69 mg/dl,p=0.0001), Ca/Mg ratio (5.73vs7.56,p= 0.0001) and PTH (209.71vs338.84 pg/ml,p= 0.0001). In univariate Cox regression analysis, age, Hb, eGFR, Ca, Mg, phosphorus, Ca/Mg ratio and PTH correlated with onset of RRT, which were further tested using a multivariate COX regression. The results showed a relationship between high levels of phosphorus (HRa=1.638,p=0.001) and Ca/Mg ratio (HRa=1.292;p=0.002), and low levels of Mg (HRa=0.761,p=0.005) and eGFR (HRa=0.934;p=0.0001) were independent risk factors to start RRT. Poisson regression showed that high Ca/Mg ratios (aPR=1.986; 95% CI 1.026-3.051;p=0.002), high phosphorus levels (aPR=1.607;95% CI 1.324-1.950;p<0.0001) and low levels eGFR (aPR=0.927; 95% CI 0.891-0.964;p<0.0001) were associated with a cumulative risk for initiation of RRT.

Conclusions: Our results suggest that the calcium/magnesium ratio is an independent predictive factor for the initiation of RRT. Further studies are required to validate the use of this novel marker as predictor of CKD progression.

PO0791

Disparities in Quality of Care for Dialysis Patients

Marc Turenne,[1] Chad M. Cogan,[1] Jeffrey Pearson,[1] Edwin D. Huff.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: An understanding of disparities in quality of care for dialysis patients may inform priorities for quality improvement and approaches for achieving greater health equity. It is also not known whether disparities have been improving or worsening or whether they vary geographically.

Methods: We used Medicare claims and CROWNWeb data to evaluate disparities based on race, ethnicity, dual eligibility, and rural-urban location. Using criteria developed by AHRQ, we identified disparities in 2019 based on a statistically significant regression-adjusted difference in a quality indicator and at least a 10% relative difference between groups. We estimated generalized linear models with clustering for patients and adjustments for age, sex, cause of ESRD, duration of ESRD, and comorbid conditions at ESRD incidence. We examined national trends in disparities from 2015-20 and variation in disparities by ESRD Network in 2019.

Results: There is evidence of disparities in U.S. dialysis patients for a range of quality indicators in 2019 (Table), some of which relate to measures in the ESRD Quality Incentive Program. Disparities involving racial minorities and dual eligible beneficiaries accounted for 13 of 16 measured disparities nationally. These disparities largely persisted over time and were found in most ESRD Networks.

Conclusions: There are ongoing racial, socioeconomic, and rural-urban disparities among dialysis patients in a range of quality indicators. There may be valuable opportunities for quality initiatives in ESRD to improve health equity.

Funding: Other U.S. Government Support

Quality Indicator	Comparison	Disparity Group	Reference Group	Difference (disparity group vs. reference group)	Adjusted difference (all p<0.001)	Relative difference, as % of reference group

PO0792

Risk Factors and Outcomes of Gout in Dialysis Patients: A Cohort Study of the United States Renal Data System (USRDS)

Anthony J. Bleyer,[1] Yi Zhang,[3] Onkar S. Kshirsagar,[3] Brad Marder,[2] Brian LaMoreaux.[2] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Horizon Therapeutics plc, Deerfield, IL; [3]Medical Technology and Patterns Institute, Bethesda, MD.*

Background: Limited research exists regarding gout among dialysis-dependent end-stage renal disease patients. This study aimed to evaluate the epidemiology, risk factors, and outcomes of dialysis patients with gout.

Methods: Using 2017 USRDS data, this study identified dialysis patients ≥18 years of age with Medicare as the primary payer. Baseline characteristics and comorbid conditions for dialysis-dependent patients with gout were assessed at dialysis initiation as well as 3-months preceding their gout diagnosis and compared with non-gout dialysis patients. All-cause hospitalization and mortality risk were also estimated and compared between gout and non-gout patients.

Results: Of 275,651 dialysis patients in 2017, 41,312 (15%) had ≥1 gout claims following initiation of chronic outpatient dialysis. More than 1/3 of gout diagnoses were made by internal and family medicine physicians. Compared to non-gout patients, gout patients were more likely to be older (mean 64.5 vs 56.8 y), male (62% vs 54%), of Asian race (6.2% vs 3.7%), and obese (31.4 vs 30.2 kg/m^2). Gout patients were also found to be more likely to undergo hemodialysis via central venous catheter (15% vs 13%). Gout patients had a higher comorbidity prevalence of diabetes (67% vs 62%), hypertension (93% vs 74%), and cardiovascular conditions (heart failure [49% vs. 30%], ischemic heart disease [49% vs 30%], peripheral vascular disease [32% vs 22%], stroke [12% vs 8%], acute myocardial infarction [7% vs 3%] and angina [4% vs 2%]). Adjusted regression analysis showed that older age (OR=4.23 for ≥65 vs <65 y, 95% CI 4.03-4.43), previous transplant (OR=2.37, 95% CI 2.24-2.50), and comorbid hypertension (OR=2.71, 95% CI 2.59-2.83) are the 3 most significant factors associated with gout diagnosis. In multivariate analysis, risk of hospitalization and mortality was higher by 11% (95% CI 8-13%) and 9% (95% CI 5-12%), respectively in the year after diagnosis.

Conclusions: The prevalence of gout was 15% in the US Medicare dialysis-dependent population. Gout patients had a higher comorbidity burden especially for cardiovascular conditions and higher risk of hospitalization and mortality. Future studies are needed to elucidate whether improved recognition and management of gout may reduce the risk for worse cardiovascular outcomes.

PO0793

Real-World Clinical Performance Evaluation of the FX CorAL Dialyzer: A Retrospective Cohort Study

Melanie Wolf,[1] Hanjie Zhang,[2] Anke Winter,[1] Manuela Stauss-Grabo,[1] Pedro Ponce,[3] Erzsebet Ladanyi,[4] Otto Arkossy,[1] Peter Kotanko,[2,5] Stefano Stuard.[1] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Renal Research Institute, New York, NY; [3]Nephrocare Portugal SA, Lisboa, Portugal; [4]NephroCare Hungary, Miskolc, Hungary; [5]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: In-vitro dialyzer clearances as outlined in the Instructions for Use may not necessarily reflect clinical reality. Clinically, the in-vivo dialyzer performance is more relevant. Thus, we evaluated the clinical performance of two dialyzers (FX CorDiax, FX CorAL) with slightly different in-vitro clearances.

Methods: 18 Hungarian and 33 Portuguese NephroCare Dialysis centers were randomly allocated to an implementation scheme. European Clinical Database data from 1,924 adult patients who switched from the FX CorDiax to the FX CorAL dialyzer between July 2020 and January 2021 were analyzed. To evaluate the clinical performance, we compared intra-individual changes of various parameters between 3 months before and 3 months after the dialyzer switch using paired t-test or Wilcoxon signed-rank test.

Results: The patients median age was 70 years, 64.2% were male, 38.4% had diabetes and 63.3% hypertension. The median dialysis vintage was 55.1 months. 88.6% of treatments were performed with online hemodiafiltration (HDF); 75.3% of patients had a fistula. After the dialyzer switch, the online clearance monitor Kt/V increased by 0.05 (2.7%). Among HDF patients, the effective infusion and convective volume increased by about 0.5 l and the effective treatment time increased by 4.2 min (1.8%). All mean changes were statistical significant (Table 1).

Conclusions: In this analysis of real-world FX CorAL dialyzer utilization, we observed statistically significant changes in performance parameters. In contrast to in-vitro results, our data suggest that the clinical performance of the FX CorAL and FX CorDiax dialyzer is comparable.

Funding: Commercial Support - Fresenius Medical Care

Table 1: Overall mean change after switch versus before switch

Parameter	Mean before (SD)	Mean diff [95%-CI]	Paired t-test / Wilcoxon
Effective treatment time [min]	235.06 (18.73)	4.21 [3.80; 4.63]	<.0001
Mean blood flow [ml/min]	399.43 (48.49)	-0.58 [-1.45; 0.30]	<.0001
Dialysate flow [ml/min]	420.33 (56.18)	-2.41 [-3.37; -1.45]	<.0001
Effective infusion (HDF) [l]	23.18 (4.56)	0.48 [0.37; 0.59]	<.0001
Convective volume (HDF) [l]	25.33 (4.53)	0.54 [0.44; 0.65]	<.0001
Single-Pool Variable-Volume Kt/V	1.94 (0.33)	0.09 [0.07; 0.11]	<.0001
Urea reduction ratio [%]	79.93 (5.24)	1.29 [0.96; 1.63]	<.0001
Equilibrated Kt/V	1.66 (0.29)	0.09 [0.07; 0.11]	<.0001
Online Clearance Monitoring Kt/V	1.80 (0.39)	0.05 [0.04; 0.06]	<.0001

PO0794

Racial Disparities in Staff CPR Performance Within US Dialysis Clinics: The Role of Clinic Resources and Patient Factors

Patrick H. Pun,[1,2] Matthew Dupre.[1,2] *[1]Duke Clinical Research Institute, Durham, NC; [2]Duke University School of Medicine, Durham, NC.*

Background: Cardiac arrest occurs frequently in outpatient dialysis clinics, and immediate CPR provision improves patient outcomes. However, Black patients in dialysis clinics receive CPR from clinic staff less often compared to White patients. We examined the contribution of dialysis facility resources and patient factors to the observed racial disparity in CPR.

Methods: Retrospective cohort study linking the National Cardiac Arrest Registry to Enhance Survival (CARES) and Medicare Annual Dialysis Facility Report registries. We identified cardiac arrests occurring within US outpatient dialysis clinics via geolocation matching. Differences in facility size, quality, staffing and patient related factors were summarized and compared according to patient race. Multilevel multivariable logistic regression models including these factors were constructed to examine the influence of these factors on the observed disparity in CPR rates between Black and White patients.

Results: From 2013-2017, we identified 1,554 patients experiencing cardiac arrest in dialysis clinics. Compared to White patients, Black cardiac arrest patients dialyzed in larger facilities (26 vs 21 dialysis stations, p<0.001), facilities with less RNs per station (0.29 vs 0.33, p<0.001), and facilities with lower quality scores (# citations 6.8 vs 6.3, p=0.04). Facilities treating Black patients cared for a higher proportion of patients with a history of cardiac arrest (41 vs 35%, p<0.001), HIV/Hepatitis B (5.1% vs 2.9%, p<0.001) and Medicaid enrolled patients (15% vs 11%, p<0.001). After accounting for these differences and other covariates, there was no change in the racial disparity for CPR in Black vs. White patients (OR=0.45 (95% CI 0.27-0.75). The disparity was greater among older Black patients compared to younger patients (interaction p=0.04). Other patient related and facility quality-related factors did not moderate the racial disparity in receipt of CPR.

Conclusions: The racial disparity in CPR delivery within dialysis clinics cannot be explained by differences in facility resources and quality. Reducing this disparity will require a multi-faceted approach including developing dialysis clinic-specific protocols for CPR and addressing potential implicit bias.

PO0795

Weekly Risks of Death and Hospitalization Among Incident Patients Undergoing Dialysis

Eric D. Weinhandl,[1,2] Haifeng Guo,[1] Chuanyu Kou,[1] Jill Davis,[3] Henry D. Cremisi,[3] David T. Gilbertson.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]AstraZeneca PLC, Wilmington, DE.*

Background: During the first year of hemodialysis, risks of mortality and morbidity are elevated. However, it remains unclear when patients transition from relatively higher "incident" risk to relatively lower "prevalent" risk. We estimated trajectories of weekly risks of death and hospitalization among patients who recently initiated hemodialysis.

Methods: We analyzed data from the United States Renal Data System. The cohort included all patients who initiated outpatient hemodialysis in 2014-2017; for analysis of hospitalization, we limited the cohort to patients with Medicare Parts A and B coverage. We estimated the weekly incidence of each of death and hospitalization during the first 52 weeks of hemodialysis. We used joinpoint regression with a maximum of five knots to estimate best linear interpolations of incidence trajectories.

Results: The cohort included 395,233 incident patients. Risk of death peaked in dialysis week 4. As displayed with joinpoint regression, there were four phases of risk: high and sharply increasing risk from week 1 to 3; high but steadily decreasing risk from week 3 to 13; moderate and gradually decreasing risk from week 13 to 30; and consistent risk from week 30 to 52. Risk of hospitalization was highest in dialysis week 1. There were four phases of risk: high but sharply decreasing risk from week 1 to 5; moderate and steadily decreasing risk from week 5 to 11; moderate and gradually decreasing risk from week 11 to 24; and consistent risk from week 24 to 52.

Conclusions: Weekly risks of death and hospitalization are highest during the first 13 to 14 weeks after initiation of outpatient hemodialysis, and gradually decline thereafter. However, risk trajectory details—including the timing of the transition from "incident" to "prevalent" status—vary among outcomes.

PO0796

Shortened or Skipped Hemodialysis Sessions Attributed to Uremic Pruritus: A National Kidney Foundation Patient Survey

Johnson L. Gomez,[1] Joseph A. Vassalotti,[1,2] Gail Torres,[2] Linda Singleton-Driscoll.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]National Kidney Foundation, New York, NY; [3]Chleire Consulting, Inc, Richmond, VA.*

Background: Hemodialysis (HD) patients are at risk for uremic pruritus, a common and bothersome condition that may make it difficult for patients to complete the prescribed HD sessions. The purpose of this study is to investigate the extent to which pruritus contributes to patients shortening or skipping HD sessions. Studies have demonstrated that shortening and skipping HD treatments increases mortality risk.

Methods: An online survey of adults (18 years and older), across the U.S. from November 11-27, 2020, was conducted using two links posted on the National Kidney Foundation Facebook page. A $5 electronic Amazon gift card incentive was offered to the first 300 respondents with a valid email address.

Results: There were 692 participants among 2604 initial respondents, after excluding 1,252 for partial survey completion, 516 for not having kidney disease and 144 for kidney disease without HD treatment. Demographics and clinical characteristics include mean age 38.5 years ±11.8, 46.8% under 35 years, 45.5% females, 15% Black or African American, 9% Hispanic, 9% American Indian, 3% Asian, 74.7% employed or attending school, 45.3% with 1-5 years HD vintage, 81% treated with center HD and 19% treated with home HD. This population is younger and enriched for home HD and employment compared to 2018 results from the USRDS 2020 Annual Data Report, with only 11% HD age < 45 years, 2% treated with home HD and low employment prevalence. Pruritus was common with 64.0% (428/669) self-reporting itch that is at least somewhat intense on a Likert scale, including 25.7% (172/669) of patients reporting itch as very or extremely intense. Shortening or skipping an HD session because of pruritus was reported at least some of the time by 55.6% (334/601) and 50.4% (303/601) of participants, respectively. Patients reporting the itch as very or extremely intense were more likely to skip or miss HD treatments. Among the members of the HD care team, nephrologists 43.2% (299/692) were the most likely professional to be identified by patients to talk with about itchy skin.

Conclusions: This survey cohort of HD patients showed pruritus leading to skipped or shortened HD sessions occurred in about half of the patients. The results support uremic pruritus as a significant cause of skipped or shortened HD sessions for the dialysis care team to consider.

PO0797

Association of Length of Interdialytic Interval and Patient-Reported Symptoms

Huei Hsun Wen, Kinsuk Chauhan, Steven G. Coca, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Symptom burden of patients on in-center hemodialysis (HD) is high. Hospitalization and mortality is higher after the long interdialytic interval due to accumulation of fluid and electrolytes. It is unclear whether symptom burden is affected by the length of interdialytic interval.

Methods: We surveyed patients ≥18 years old, on HD for ≥30 days, and on HD three times a week at the Mount Sinai Kidney Center. Patients completed a survey about presence and severity (5 point scale) of 21 symptoms at the end of their HD treatments for 12 sessions. Symptom severity was calculated by multiplying the symptom with the severity and could range from 0 to 84, it was then summed per survey and the mean value per patient was calculated. We used negative binomial regression to determine the association of interval with symptom count.

Results: During the study period, 97 HD patients completed all surveys. The mean age was 56±14 years, 52% were female, and 52% were Black. The majority of patients reported symptoms, which ranged from a low of 8% for chest pain to 61% for fatigue **(Figure 1A).** More patients reported having ≥1 symptom after the long interdialytic interval than after the short interdialytic interval 67% vs 59%, P=0.01. Mean symptom severity was higher after the long interdialytic interval (5.8±0.5 vs. 4.7±0.5, P<0.001) **(Figure 1B)**. Symptoms that tended to be more common after the interdialytic interval were fatigue, itching, dry mouth, bone pain, and restless legs **(Figure 1C)**. After adjustment for age, gender, and race, the incidence rate of symptoms was 20% higher after the long interval (IRR 1.2, 95% CI 1.09-1.33).

Conclusions: Symptoms are common in patients on maintenance HD. Symptom burden is slightly higher after the long interdialytic interval than the short interdialytic interval.

Funding: NIDDK Support, Commercial Support - Renal Research Institute

PO0798

Modifiable Risk Factors Associated with Death over the Long Interval for In-Center Hemodialysis Patients

Antonia Harford,[1] Jonathan A. Wilson,[2] S. Paine,[1] Patti Ephraim,[4] Jane F. Pendergast,[2] Karen M. Majchrzak,[1] Dana Miskulin,[3] Daniel E. Weiner,[3] Eduardo K. Lacson,[1,3] Doug Johnson,[1] Keith Johnson.[1] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Duke University, Durham, NC; [3]Tufts Medical Center, Boston, MA; [4]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Routine thrice weekly in-center hemodialysis (HD) is associated with increased risk of death around the long interval without dialysis. We evaluated this risk and explored modifiable risk factors associated with increased risk of death.

Methods: Prevalent Medicare beneficiaries (21,331) receiving maintenance thrice weekly in-center HD in facilities operated by a large not-for-profit dialysis provider from 1/1 2009 -12/31 2016 were included. We calculated daily death rates for an observation week (consisting of days HD-2, HD-1, HD1, HD+1, HD2, HD+2, and HD3) occurring after a week of usual outpatient care, defined by at least 1 outpatient treatment, with no inpatient hospital days, excused absences, or SNF days. HD1 represents the Monday or Tuesday following the long interval. A logistic regression model with patient random effects estimated the effect of patient characteristics, including age and treatment vintage, and treatment parameters including inter-dialytic weight gain (IDWG) >4.6% of estimated dry weight (kg), pre-HD systolic blood pressure (SBP) <120 mm Hg, and intradialytic hypotension, on the probability of dying over the long interval (HD-2, HD-1 and HD1) as compared to either dying on any other day in the week or survival.

Results: Among 2,019 deaths included in analyses, the highest death rates were observed on HD1 and HD3. Factors associated with increased odds of death over the long interval included older age, IDWG >4.6% of estimated dry weight, pre HD SBP <120 mm Hg prior to last treatment in the observation week, and skipped treatment in the prior week (table).

Conclusions: High inter-dialytic weight gain, low pre-HD SBP, and skipped treatments during the preceding week are potentially modifiable factors associated with increased risk of death over the long interval. These factors can help identify patients who will benefit from HD prescription modification.

Variable	Comparison	Odds ratio for dying over long interval vs any other day or surviving (95% CI)
Inter-dialytic weight gain (kg)	≥4.6% vs <4.6%	1.767 (1.456, 2.145)
Age at start	One year change	1.032 (1.025, 1.039)
Vintage	One year change	1.055 (1.011, 1.100)
SBP absolute difference of 30 (mm Hg) pre to post treatment	Yes vs No	0.886 (0.739, 1.061)
Pre-HD SBP <120 (mm Hg)	<120 vs ≥20	2.898 (2.468, 3.404)
Prior week treatment sessions (n)	<3 vs 3	3.079 (2.533, 3.742)

PO0799

Real-World Use of Phosphate Binder Agents Among Dialysis-Dependent Patients with CKD in Medicare Fee-for-Service

Erika Szabo,[1] Christine Ferro,[2] Gabriela Dieguez,[2] Steve Metz,[2] Jennifer Moore,[1] Todd Berner,[1] Csaba P. Kovesdy.[3] *[1]Akebia Therapeutics Inc, Cambridge, MA; [2]Milliman USA, New York, NY; [3]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: Phosphate binders (PBs) are prescribed to control hyperphosphatemia among patients with chronic kidney disease. The need for phosphate intervention peaks among those with dialysis-dependent (DD) end-stage renal disease (ESRD). We used Centers for Medicare & Medicaid Services 100% Research Identifiable Files (RIF) data, representing 100% of Medicare fee-for-service beneficiaries, to characterize contemporary PB utilization among established and incident patients with DD ESRD across dialysis modalities.

Methods: We identified incident and prevalent patients with DD ESRD in the 2018-2019 RIF data, separating hemodialysis, continuous ambulatory peritoneal dialysis (CAPD), or continuous cycling peritoneal dialysis (CCPD) patients based on frequency of revenue codes. We assessed monthly PB use for calcium acetate, ferric citrate, lanthanum carbonate, sevelamer (hydrochloride and carbonate) and sucroferric oxyhydroxide. PB use was defined as a filled prescription covering 15+ days in a calendar month.

Results: We identified 233,564 patients with DD ESRD, of which 10% were incident. These patients reported 2,439,804 outpatient dialysis months in 2019. Among all patients, 28.4% did not report PB use in 2019 (26.4% among prevalent patients and 46.6% among incident patients). Among patients with any PB use, the average number of outpatient dialysis months was 10.9, of which 6.4 (60%) reported PB use. Average months with PB use were 3.8 for CAPD, 5.3 for CCPD, and 6.4 for hemodialysis.

Conclusions: We found gaps in PB use among patients receiving outpatient dialysis who were also prescribed a binder in 2019. Binder use was reported in 60% of all outpatient dialysis months for patients in our study, suggesting that PBs may have been underutilized or required only intermittently. Further studies are needed to determine the reasons for gaps in PB use and to identify opportunities for control of phosphate levels among patients with DD ESRD.

PO0800

Characterization of Gout in US Patients Treated with Hemodialysis (HD) and Peritoneal Dialysis (PD)

Angelo Karaboyas,[1] Junhui Zhao,[1] Brian LaMoreaux,[3] Brad Marder,[3] Barry R. Gorlitsky,[4] Vinicius Domingues,[5] Bruce M. Robinson,[1,2] Roberto Pecoits-Filho.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Horizon Therapeutics plc, Novato, CA; [4]Carolina Nephrology PA, Greenville, SC; [5]Florida State University College of Medicine, Tallahassee, FL.*

Background: Gout occurs frequently in patients with renal disease and can lead to a significant burden on quality of life and functional status. In the US hemodialysis (HD) and peritoneal dialysis (PD) population, there has been little reported on gout prevalence, patient characteristics, and associations with outcomes.

Methods: We used data from US cohorts of 70,297 HD (DOPPS, 2012-2020) patients and 5,117 PD (PDOPPS, 2014-2020) patients. We took a stepwise approach to define gout based on active prescription of (1) colchicine, (2) febuxostat, or (3) allopurinol; or (4) prior diagnosis of gout. Propensity score matching was used to compare outcomes – including erythropoietin resistance index (ERI = ESA dose/(hemoglobin*weight)), mortality and hospitalization, and baseline patient-reported outcomes (PROs) – among patients with vs. without a history of gout.

Results: Gout prevalence was 13% in HD and 21% in PD, and was highest among incident dialysis patients. Contributions of colchicine Rx (2-3%) and febuxostat Rx (1%) were lower than allopurinol Rx (9-12%), and additional contribution of gout diagnosis was minimal [Figure 1]. Both HD and PD patients with gout (vs. no gout) were older, more likely male, with higher BMI, and higher prevalence of cardiovascular comorbidities. After propensity score matching, mean ERI was 4% higher for gout vs. non-gout patients, while there was minimal evidence of association with clinical outcomes or PROs.

Conclusions: Gout was common in US HD and PD patients, with a large proportion of these patients treated with drugs indicated for hyperuricemia (allopurinol and febuxostat) and gout flares (colchicine). True prevalence was likely higher than observed when considering under-ascertainment of gout diagnosis history. This report provides a snapshot of gout in the US dialysis population and offers opportunities to expand on research to improve awareness and care for patients with gout and ESRD.

Fatigue Prevalence and Associations with Non-Diuretic Anti-Hypertensive Medications in the Maintenance Hemodialysis Population

Gwendolyn Derk,[1] Amy Barton,[2] Kenneth R. Wilund.[1] Renal and Cardiovascular Disease Research Laboratory *[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]Vifor Pharma Ltd, Glattbrugg, Switzerland.*

Background: It is well known that dialysis patients suffer from fatigue post dialysis. It is possible that fatigue is exacerbated by antihypertensive medications. We hypothesized that post-dialysis fatigue (PDF) duration was positively correlated with the number of antihypertensive medications.

Methods: We conducted cross sectional survey and 6 month retrospective medical record chart review at three privately owned dialysis clinics in Illinois. The survey consists of 50 questions related to fluid and blood pressure management, the validated Post-Dialysis Fatigue and Time to Recover from Dialysis Survey (PDF TIRD), and the validated National Institute of Health Patient Reported Outcomes Measurement System fatigue short form. A random mixed effect model was created through a reverse stepwise process in order to assess associations. Chi-squared analysis was performed with categorical symptom data.

Results: One hundred and two patients consented to the study, 96 had complete medical records with all research variables and survey values captured. The average number of dialysis sessions captured per patient was 50.0 +/- 19. The average time on maintenance hemodialysis was 5.06 +/- 4.93 years with a range of 0.2 to 28 years. Seventy six percent (73/96) of dialysis patients suffered from post-dialysis fatigue. Most patients 53/96 reported that their fatigue was the worst after dialysis. On average patients required 462.67 +/- 655.18 minutes (7.7 +/- 10.92 hours) to recover after dialysis. In our random mixed effect model, the time required to recover post-dialysis was positively associated with the number of non-diuretic antihypertensive medications: For every antihypertensive medication, patients experienced an additional 210 minutes (3.5 hrs) of fatigue post dialysis fatigue.

Conclusions: Post-dialysis fatigue is a pervasive problem in the dialysis population that has significant consequences on patients' quality of life. While fatigue has several important contributing factors, the number of non-diuretic blood pressure medications appear to exacerbate patients' fatigue. Further investigation on the survival and quality of life benefits, including fatigue, of patients maintained on antihypertensive medications versus volume control strategies is needed.

PO0802

Dialysis Adequacy and Risk of Dementia in Elderly Hemodialysis Patients

Hyung Woo Kim,[1] Jong Hyun Jhee,[1,3] Young Su Joo,[1,4] Ki Hwa Yang,[2] Jin Ju Jung,[2] Ji Hyeon Shin,[2] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Jung Tak Park.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Health Insurance Review and Assessment Service, Wonju, Republic of Korea; [3]Gangnam Severance Hospital, Seoul, Republic of Korea; [4]Yongin Severance Hospital, Yongin, Republic of Korea.*

Background: Dementia is prevalent among elderly patients undergoing hemodialysis. However, the association between dialysis adequacy and the risk of dementia is uncertain.

Methods: A total of 10,567 patients aged >65 years undergoing maintenance hemodialysis who participated in a national hemodialysis quality assessment program were analyzed. The patients were classified into quartile groups based on single-pool Kt/V levels. The associations between single-pool Kt/V and the development of dementia, Alzheimer's disease (AD), and vascular dementia (VD) were examined.

Results: The mean age of the patients was 72.9 years, and 43.4% were female. The mean baseline single-pool Kt/V level was 1.6 ± 0.3. During a median follow-up of 45.6 (45.6–69.9) months, there were 27.6, 23.9, and 2.8 events/1000 person-years of overall dementia, AD, and VD, respectively. The incidences of overall dementia, AD, and VD were lowest in the highest single-pool Kt/V quartile group. Compared with the lowest single-pool Kt/V quartile, the risks of incident overall dementia and AD were significantly lower in the highest quartile (sub-distribution hazard ratio [sHR]: 0.69, 95% confidence interval [CI]: 0.58–0.82 for overall dementia; sHR: 0.69, 95% CI: 0.57–0.84 for AD). Inverse relationships were found between the risks of developing overall dementia and AD, and single-pool Kt/V. However, no significant relationship was observed between single-pool Kt/V levels and VD development.

Conclusions: Increased dialysis clearance was associated with a lower risk of developing dementia in elderly hemodialysis patients.

PO0803

Risk of 30-Day Hospital Readmission in Patients with ESKD with and Without Autosomal Dominant Polycystic Kidney Disease

Aparna Saha,[1,2] Paulette Ericksen,[3] Cristina M. Liriano Cepin,[2] Steven G. Coca,[1] Girish N. Nadkarni,[1,2] Lili Chan.[1,2] *[1]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [2]Icahn School of Medicine at Mount Sinai Charles Bronfman Institute for Personalized Medicine, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Among end stage kidney disease (ESKD) patients with autosomal dominant polycystic kidney disease (ADPKD), relatively little is known about the epidemiology and risk factors for 30-day readmissions in the US. Therefore, we evaluated the 30-day unplanned readmission rates and predictors, and inpatient care costs among ESKD with and without ADPKD patients using a nationally representative, all-payer database.

Methods: We utilized the Nationwide Readmission Database from 2016-2018 to identify patients admitted for ESKD with and without ADPKD using ICD-10 codes. We used a propensity scoring method assigned to each hospitalization computed by multivariate logistic regression model to establish matched cohorts to reduce bias due to confounding covariates (age, gender, patients' insurance type, quartile classification of median household income extrapolated from zip code, Elixhauser comorbidity index (ECI), hospital location and teaching status) between the 2 groups. We used survey logistic regression to evaluate the association of ADPKD with 30-day hospital readmission.

Results: From 2016-2018, after propensity matching, there were 11,578 index admissions for ESKD patients with ADPKD and 11,422 index admissions for ESKD patients without ADPKD. Those who had ADPKD during index admissions had fewer 30 days readmissions(12.8% vs 15.3%, p<.0001). The cost of hospitalizations and readmissions in ESKD patients with ADPKD were higher than non-ADPKD patients (Figure 1A). Patients who were readmitted were more likely to have kidney transplant, non-routine discharges, and have non-elective index admissions. Longer length of stay, Medicaid insurance, discharge to short term hospital, specialized care, home health care and against medical advice were associated with increased odds of readmission, and higher ECI score and ADPKD was associated with decreased odds of readmission(aOR 0.85, 95% CI 0.8 – 0.9) (Figure 1B).

Conclusions: ESRD patients with ADPKD were less likely to have 30-day readmission than patients without ADPKD.

Figure 1A: Mean cost of index hospitalizations and readmissions in no ADPKD vs ADPKD, Figure 1B: Predictors of ESKD readmissions

PO0804

Pruritus in Hemodialysis (HD) Patients: Course of Symptoms After 12 Months

Angelo Karaboyas,[1] Daniel G. Muenz,[1] Sebastian Walpen,[3] Thilo Schaufler,[3] Elham Asgari,[4] Fitsum Guebre Egziabher,[5] Bruce M. Robinson,[1,2] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Vifor Pharma Ltd, Glattbrugg, Switzerland; [4]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [5]Hospices Civils de Lyon, Lyon, France.*

Background: The burden of chronic kidney disease-associated pruritus (CKD-aP) on HD patients has been well-established, including its association with adverse clinical events and patient-reported outcomes (PROs). However, prior studies have focused on a single baseline CKD-aP assessment, and have thus not investigated the course of CKD-aP severity over time.

Methods: We included 8178 HD patients across 21 countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS) who had 2 CKD-aP assessments 12 months (±6 months) apart. CKD-aP intensity was assessed by a single question on the KDQOL-36 asking about the extent patients were bothered by pruritus over the past 4 weeks (5 categories; Figure 1). We stratified responses at month 12 by baseline responses.

Results: The proportion of patients at least moderately bothered by pruritus was 37% at baseline, 37% 12 months later, and 51% at either assessment (including 28% at least very much bothered). Among patients 'not at all' or 'somewhat' bothered by pruritus at baseline, 22% became at least moderately bothered 1 year later. Among patients at least moderately bothered by pruritus at baseline, 60% remained at least moderately bothered 1 year later. Overall, 43% of patients provided the same response 1 year later, compared to 28% whose pruritus improved and 28% whose pruritus worsened.

Conclusions: Our findings suggest that at least half of chronic HD patients were affected by CKD-aP over the course of 1 year. CKD-aP symptoms remained unresolved 12 months later for the majority of HD patients bothered by itchy skin at baseline, reflecting an unmet medical need. Future research should investigate potential causes of CKD-aP symptoms more systematically as well as treatments used and their effectiveness. This will also highlight how changes in CKD-aP intensity may impact other key PROs.

Safety and Efficacy of Difelikefalin in Black or African American Patients on Hemodialysis with CKD-Associated Pruritus: Pooled Analysis of KALM-1 and KALM-2

Steven Fishbane,[1] Deborah J. Clegg,[2] Edgar V. Lerma,[3] Anjay Rastogi,[4] Jeffrey J. Budden,[5] Isabelle Morin,[6] Warren Wen,[7] Frederique Menzaghi,[7] Joel M. Topf.[8] *[1]Northwell Health, Great Neck, NY; [2]Texas Tech Medical Center, Rick Francis School of Medicine, El Paso, TX; [3]University of Illinois at Chicago, Chicago, IL; [4]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [5]Vifor Pharma Group, Redwood City, CA; [6]Vifor Pharma Ltd, Glattbrugg, Switzerland; [7]Cara Therapeutics Inc, Stamford, CT; [8]Oakland University William Beaumont School of Medicine, Rochester, MI.*

Background: Difelikefalin (DFK) is an investigational, peripherally restricted, selective kappa-opioid receptor agonist that significantly reduced itch intensity in hemodialysis (HD) pts with CKD–associated pruritus (CKD-aP) in the Phase 3 KALM-1 and KALM-2 trials. People of Black or African American (AA) race were well represented in these studies. This pooled analysis reports efficacy and safety of DFK in Black or AA pts.

Methods: HD pts with moderate-to-severe CKD-aP were randomized to intravenous DFK 0.5 mcg/kg or placebo (PBO) 3 times/wk for 12 wks. The primary endpoint was the proportion of pts achieving a clinically meaningful ≥3-point improvement from baseline (BL) in the weekly mean of 24-hr daily Worst Itching Intensity Numerical Rating Scale (WI-NRS) scores at wk 12. Secondary endpoints included proportion of pts achieving ≥4-point improvement in WI-NRS score and change in itch-related QoL score (5-D Itch and Skindex-10) from BL to wk 12. Adverse events (AE) through wk 12 were collected.

Results: Of 851 pts randomized in KALM-1 and KALM-2, 249 (29%) pts self-identified as Black or AA (DFK: 135; PBO: 114). Mean BL WI-NRS score was 7.2 and 7.3 in the DFK and PBO groups. A greater proportion of pts who received DFK vs PBO achieved clinically meaningful improvements in itch intensity and itch-related QoL (**Figure**). Most common treatment-emergent AEs (≥5%) with DFK occurring at ≥1% higher incidence vs PBO were diarrhea (10.4% vs 6.2%), dizziness (10.4% vs 2.7%), vomiting (7.4% vs 4.4%), headache (5.2% vs 0.9%), and hyperkalemia (5.2% vs 2.7%). Serious AE incidence was similar between groups.

Conclusions: DFK significantly reduced pruritus intensity and improved itch-related QoL in Black or AA HD pts with moderate-to-severe CKD-aP. DFK was well tolerated with an acceptable safety profile. The safety and efficacy of DFK in Black or AA pts was similar to the overall population.

PO0806

Prevalence of Latent Tuberculosis Infection and Its Risk Factors in Japanese Hemodialysis Patients

Yuji Kamijo, Yohei Ogawa, Makoto Harada, Koji Hashimoto. *Shinshu University School of Medicine, Matsumoto, Japan.*

Background: The majority of active tuberculosis (TB) cases develop from latent tuberculosis infection (LTBI). Since the risk of TB in hemodialysis (HD) patients is particularly high, interferon-gamma release assay (IGRA) forLTBI screening in HD patients is considered important. However, the prevalence and characteristics of LTBI in Japanese HD patients remain obscure.

Methods: We performed an observational cross-sectional study of LTBI using IGRA QFT-3G tests in 118 HD outpatients enrolled at 3 hospitals of varying location and function.

Results: Of the 118 patients, 96 were QFT negative, 7 were QFT indeterminate, 14 were QFT positive, and 1 was QFT judgment impossible. No patient had active TB. Confirmed (QFT positive) and possible (QFT positive+indeterminate) LTBI patients totaled 14 (11.9%) and 21 (17.8%), respectively. The LTBI possible group was significantly older and had a significantly higher rate of nephrosclerosis versus the QFT negative group. The indeterminate group had a significantly longer HD period. The QFT results were not remarkably affected by other clinical data, including hospital characteristics. The possible LTBI rate increased age dependently, with higher values from 60 years of age.

Conclusions: The prevalence of LTBI is high in Japanese HD patients, especially from the age of 60 years. Older age was a significant risk factor for LTBI, with prediction difficult using other clinical data. Extended HD may mask IGRA results. Therefore, aggressive screening for LTBI is advised in all HD patients regardless of hospital region or type, especially in patients over 60 years of age or newly commencing HD.

PO0807

Associations of Pre-Dialysis Care with Trajectories of Adverse Clinical Outcomes Among Patients Initiating Dialysis

Eric D. Weinhandl,[1,2] Chuanyu Kou,[1] Haifeng Guo,[1] Jill Davis,[3] Henry D. Cremisi,[3] David T. Gilbertson.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]AstraZeneca PLC, Wilmington, DE.*

Background: Health care during advanced chronic kidney disease likely influences outcomes during the first year of end stage kidney disease (ESKD). We assessed associations of nephrology care, erythropoiesis-stimulating agent (ESA) therapy, and red blood cell (RBC) transfusion before hemodialysis initiation with trajectories of adverse clinical outcomes during the first year after initiation.

Methods: We analyzed United States Renal Data System data. The cohort included patients who initiated outpatient dialysis in 2014-2017 and carried Medicare coverage during the year preceding dialysis initiation. We stratified the cohort by care in that one-year interval: nephrology care (per ESRD Medical Evidence Report), ESA therapy (per Medicare claims), and RBC transfusion (per Medicare claims). In each stratum, we estimated weekly incidence of all-cause death, hospitalization, and three-point major adverse cardiac events (MACE) during the first 52 weeks of dialysis. We used joinpoint regression to estimate incidence trajectories.

Results: The cohort included 132,879 patients. Before dialysis initiation, 65% received nephrology care, 14% used an ESA, and 32% received an RBC transfusion. As shown, nephrology care and ESA therapy were associated with lower risks of adverse clinical outcomes during the first year of dialysis, whereas RBC transfusion was associated with higher risks. However, trajectories of weekly incidence during the first year were similar in all subgroups.

Conclusions: Pre-ESKD nephrology care and pre-ESKD ESA therapy were associated with lower risks of adverse clinical outcomes during the first year of dialysis, whereas RBC transfusion was associated with higher risks. Regardless of pre-ESKD care, risks were higher during the early part of the first year.

Temporary Changes in Hemodialysis Parameters in Patients Affected by COVID-19 Infection: A Visual Guide

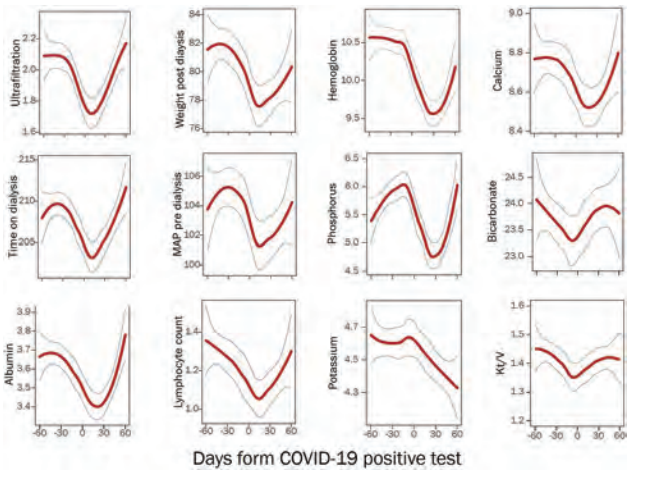
Jose E. Navarrete,[1] Harold A. Franch,[1] Janice P. Lea,[1] Jason Cobb,[1] Frederic F. Rahbari-Oskoui,[1] Ibironke W. Apata.[1,2] Emory Renal COVID-19 Project *[1]Emory University, Atlanta, GA; [2]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: ESKD patients on dialysis have been significantly affected by the COVID pandemic. By now, a substantial number of patients have survived the disease. We display graphically the temporary changes in dialysis parameters of patients that have survived COVID-19 infection.

Methods: All patients receiving hemodialysis at Emory dialysis centers diagnosed with COVID-19 infection between 3/1/20 to 1/31/21 who survived for at least 3 months were identified. The date of COVID-19 diagnosis was used to time-reference dialysis parameters including duration of hemodialysis, weight, ultrafiltration, mean arterial pressure pre-dialysis, hemoglobin, albumin, calcium, phosphorus, potassium, serum bicarbonate, absolute lymphocyte count and Kt/V. The temporary behavior of these parameters is presented graphically. Data manipulation, analysis and graphical display was performed using R-software and tidyverse package.

Results: 96 patients were identified. 82% were African-American with a median age of 64y/o. 52% were male and 60% were diabetics, The median time on dialysis was 2.5 years. All studied parameters showed a significant deviation from baseline measurements obtained in the 60 days prior to the diagnosis of COVID-19. The parameter with the least amount of change was Kt/V. In the subsequent 2 months after diagnosis, all of the parameters studied returned to baseline except for Potassium, that remained below pre-morbid levels 2 months after the COVID-19 diagnosis. These changes are presented in Figure 1.

Conclusions: COVID-19 infection has a significant impact on hemodialysis parameters as presented in figure 1. The temporary variation of the most common parameters associated with COVID-19 infection presented in this study can be used as reference for patients, dieticians, and nephrologists caring for ESKD affected by COVID-19.



PO0809

Reducing Haemodialysis Frequency in a Satellite Unit During the COVID-19 Pandemic

Owain Brooks,[1,2] Sadananda V. Aithal,[1] Aled W. Richards,[1] Bethany Davies,[1] James C. Birchall,[2] Hannah E. Parnell,[2] Eden Samuels.[2] *[1]Swansea Bay University Health Board, Swansea, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom.*

Background: People dependent on unit HD are vulnerable to COVID-19. We describe the safety and outcomes of reducing HD frequency to minimise patient exposure to the virus.

Methods: HD was reduced from thrice to twice-weekly in selected patients for 9 weeks from March 2020. Urine output, heart failure, fluid-overload, hyperkalaemia, medication and patient preference were considered. Patients were asked to restrict dietary potassium, salt and fluid. Selected patients reducing HD frequency received 10g once-weekly sodium zirconium cyclosilicate (SZC). Group 1: Continue thrice-weekly HD Group 2: Twice-weekly HD +SZC Group 3: Twice-weekly HD -SZC. Pre-HD serum potassium (sK^+) and bicarbonate ($sHCO_3^-$), systolic blood pressure (SBP) and weights were monitored. COVID-19 transmission, hospitalisation and death were recorded.

Results: Of 77 patients (mean age 70 years, 74% male), 17 continued thrice-weekly HD. 60 patients reduced to twice-weekly HD, of which 43 received SZC. There were 494 fewer HD treatments over 9 weeks. There was no significant difference in mean monthly sK^+ in any group between March (pre-intervention), April and May; but 6 patients returned to thrice-weekly HD early due to hyperkalaemia or fluid-overload. SZC was increased to 10g twice-weekly in 15 patients. There was a reduction in mean monthly $sHCO_3^-$ during twice-weekly HD. No changes were made to oral or HD bicarbonate prescriptions. There was no significant difference in pre-HD weight or SBP from baseline in patients dialysing twice-weekly. Only 2 of the 14 admissions over 9-weeks were related to hyperkalaemia or fluid-overload. 5 patients tested positive for COVID-19. 2 of the 3 deaths during this period were due to COVID-19. Both were elderly males with CVD and chronic respiratory disease. 1 patient died of a MI after returning home from HD. No deaths were attributed to a reduction in HD frequency. There was no evidence of COVID-19 transmission on the HD unit. No patients were transferred to the regional hub for HD due to COVID-19.

Conclusions: Reducing HD frequency in carefully selected patients is safe, and with strict infection control and timely COVID-19 testing, can reduce COVID-19 transmission and patient transfer to HD hubs. Dietetic review and SZC can reduce hyperkalaemia. Improved documentation of urinary output and cardiac function would optimise this approach.

PO0810

Paraoxonase 1 Gene Variants Concerning Spontaneous HCV Clearance in Hemodialysis Patients

Alicja E. Grzegorzewska, Adrianna Mostowska, Wojciech J. Warchol, Pawel P. Jagodzinski. *Uniwersytet Medyczny imienia Karola Marcinkowskiego w Poznaniu, Poznan, Poland.*

Background: We aim to explore associations between three *PON1* SNVs (rs705379, rs854560, and rs662) and spontaneous clearance of HCV infection in uremic patients treated with maintenance HD. Epistatic interactions between tested *PON1* SNVs and the *IFNL4* variant rs368234815 were also investigated.

Methods: The study included 83 HD patients who spontaneously resolved HCV infection (all had known *IFNL4* rs368234815 variant) and 104 subjects with persistently positive blood tests for HCV RNA (102 were successfully genotyped for *IFNL4* rs368234815 variant). We genotyped *PON1* by HRM method (rs662) or predesigned TaqMan SNV Genotyping Assay (rs854560, rs705379). We used a regression model including genetic and clinical data, which significantly differed patients with spontaneous HCV clearance and subjects with persistent HCV infection and could be

used as explanatory variables for HCV outcome. Epistatic interactions between *tested PON1* SNVs and *IFNL4* rs368234815 were analyzed by the multifactor dimensionality reduction method.

Results: *PON1* rs662 GG (OR 9.94, 95% CI 1.20 – 82.7, P = 0.022) and rs854560 TT (OR 4.31, 95% CI 1.62 – 11.5, P = 0.003) genotypes were associated with a higher probability for HCV resolution than the genotypes composed of at least one more frequent allele. The most common haplotype, rs662A_rs854560A, was inversely associated with spontaneous HCV clearance. Compared to this haplotype, the rs662G_rs854560T indicated a 5.09-fold (95% CI 0.99 – 26.2, P = 0.032) higher chance for HCV resolution. The closest to significance was the epistatic gene-gene interaction between *PON1* rs662, *PON1* rs854560, and *IFNL4* rs368234815 (P = 0.094). Regression model, including the *PON1* rs662 GG genotype, the *PON1* rs705379 TT genotype, the *IFNL4* rs368234815 TT/TT genotype, age at RRT onset, RRT duration, and chronic glomerulonephritis as possible explanatory variables for spontaneous HCV clearance, showed that significant predictors of spontaneous HCV elimination were the *IFNL4* rs368234815 TT/TT genotype (HR 2.841, 95% CI 1.434 - 5.625, P = 0.003) and RRT duration (HR 0.946, 95% CI 0.897 – 0.998, P = 0.042). The *PON1* rs662 GG genotype provided P-value of 0.053.

Conclusions: The *PON1* rs662 and rs854560 variant allele homozygotes are associated with a higher frequency of spontaneous HCV clearance in HD patients in univariate analyses.

PO0811

Cost-Effectiveness of Hepatitis C Virus Testing Strategies in US Hemodialysis Centers

Rachel L. Epstein,[1,2] Tannishtha Pramanick,[2] Peter P. Reese,[3] Benjamin P. Linas,[1,2] Deirdre L. Sawinski.[3] *[1]Boston University School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: The Centers for Disease Control and Prevention and the Kidney Disease: Improving Global Outcomes (KDIGO) guidelines recommend screening all patients for hepatitis C virus (HCV) infection prior to starting outpatient hemodialysis (HD), every 6 months thereafter, and every 1-3 months if a center outbreak is detected. Yet, the cost-effectiveness of such screening frequency is not clear. We therefore sought to compare the clinical and cost-effectiveness of HCV testing strategies in US hemodialysis centers.

Methods: We parameterized the Hepatitis C Cost-Effectiveness (HEP-CE) model to reflect the US HD population, using United States Renal Data System and literature data. We simulated HCV infection, progression, treatment, and outbreaks within dialysis centers at the literature-reported frequency (approximately 1%). We competed 5 strategies to compare clinical outcomes and cost-effectiveness of screening, ranging from no testing at all, to every 6-month HCV testing, each with every 3-month screening during a simulated outbreak in 1% of centers. We estimated life expectancy, quality-adjusted life years (QALYs), total HCV infections identified and cured, liver-related deaths, costs (US$ 2019) and incremental cost-effectiveness ratios (ICERs). We simulated cohorts of 100 million individuals over a 20-year time horizon and assumed a health sector perspective.

Results: With no HCV testing or treatment, average life expectancy was 5.22 years, with 2.5 million HCV infections, 678,350 cirrhotic individuals, and 182,646 deaths from liver disease (Table 1). Screening only at HD initiation increased HCV cure rates by 77% and decreased liver deaths by 79%, with an ICER of $71,533 per QALY saved compared to no screening. Increasing screening to every 2 years decreased liver-related deaths by an additional 51% with an ICER of $119,853 over screening at HD entry only. Screening annually or every 6 months was not cost-effective using a willingness to pay threshold of $150,000, even with halving baseline mortality rates or perfect linkage to care.

Conclusions: Testing for HCV in HD provides good economic value, but current CDC and KDIGO recommended intervals are not cost-effective.

Funding: NIDDK Support, Other NIH Support - NIDA, NIAID, Private Foundation Support

Table 1: Model outcomes and incremental cost-effectiveness ratios, simulated cohort of 100,000,000 individuals on hemodialysis

Strategy	HCV infections, Lifetime[a] (N)	HCV Infections Identified, Lifetime (%)	SVR Achieved (% of total infections)	Liver-related deaths (N)	Remaining Life Expectancy (Years)	Undiscounted Cost ($)	Discounted Cost ($)	Discounted QALYs	Incremental Cost-Effectiveness Ratio (ICER)
No Screening	2,513,110	0.0%	0.0%	182,646	5.2235	$500,893	$435,163	3.6508	Reference
Screen once at dialysis initiation	2,516,450	91.9%	76.9%	38,308	5.2307	$501,685	$435,826	3.6600	$71,533
Screen every 2 years	2,525,933	97.1%	87.4%	18,622	5.2313	$501,814	$435,932	3.6609	$119,853
Screen every year	2,527,643	98.1%	90.1%	14,769	5.2316	$501,924	$436,023	3.6613	$224,778
Screen every 6 months[b]	2,529,823	98.8%	92.3%	12,046	5.2318	$502,130	$436,199	3.6616	$665,164

Abbreviations: HCV, hepatitis C virus; SVR, sustained viral response (cure); QALYs, quality-adjusted life years; ICER, incremental cost- effectiveness ratio

[a]HCV infection numbers include re-infections after cure and are not dependent upon the number of prevalent infections in the population, only upon whether an outbreak is simulated in a center or whether a hypothetical individual is simulated to have ongoing injection drug use.
[b]Reflects current Centers for Disease Control and Prevention and Kidney Disease: Improving Global Outcomes (KDIGO) guidelines

PO0812

Disease Activity and Adverse Events in Patients with ANCA-Associated Vasculitides Undergoing Long-Term Dialysis: The DIAVAS Study

Maelis Kauffmann,[1,2] Cécile Couchoud,[3] Noemie Jourde-Chiche.[1,2] French Vasculitis Study Group and REIN registry *[1]Aix-Marseille Universite, Marseille, France; [2]Assistance Publique Hopitaux de Marseille, Marseille, France; [3]Agence de la biomedecine, La Plaine Saint-Denis, France.*

Background: Kidney impairment of ANCA-associated vasculitides can lead to kidney failure. Patients with kidney failure may suffer from vasculitis relapses, but are also at high risk of infections and cardiovascular events, which questions the maintenance of immunosuppressive therapy.

Methods: Patients with ANCA-associated vasculitides initiating long-term dialysis between 2008-2012 in France, registered in the national REIN registry, and paired with the National Health System database, were included. We analyzed the proportion of patients in remission off-immunosuppression over time, and overall and event-free survival on dialysis (censoring for kidney transplantation). We compared the incidence of vasculitis relapses, serious infections, cardiovascular events and cancers before and after dialysis initiation.

Results: 229 patients were included: 142 with granulomatous polyangiitis (GPA) and 87 with microscopic polyangiitis (MPA); 82 patients received a kidney transplant. Mean follow-up after dialysis initiation was 4.6 ± 2.7 years. The proportion of patients in remission off-immunosuppression increased from 23% at dialysis initiation to 62% after 5 years. Overall survival rates on dialysis were 86%, 66% and 54% at 1, 3 and 5 years, respectively. Main causes of death were infections (35%) and cardiovascular events (26%), not vasculitis flares (6%). The incidence of vasculitis flares decreased from 111 to 7 episodes/100 person-year before and after dialysis initiation (p<0.05). Overall, during follow-up, 53% of patients experienced a serious infection, 52% a cardiovascular event, while 17% experienced a vasculitis relapse.

Conclusions: The proportion of patients with ANCA-associated vasculitis in remission off-immunosuppression increases with time spent on dialysis. In this cohort, patients were far less likely to relapse from their vasculitis than to display serious infectious or cardiovascular events. Therefore, the benefit/risk balance of maintenance immunosuppressive therapies in patients on long-term dialysis should be carefully evaluated.

PO0813

Analysis of Costs, Quality of Life, and Nutritional Status Between Patients with Two Different Models of Hemodialysis in Mexico: Chronic vs. Intermittent Hemodialysis

Jesus D. Lima-Lucero, Angela M. Cordoba Hurtado, Rafael Valdez-Ortiz, L. M. Perez-Navarro. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: In Mexico, access to conventional chronic hemodialysis (cHD) programs (two or three hemodialysis sessions a week) is only possible in a few patients. In contrast, patients without social security usually are undergo intermittent hemodialysis (IHD) sessions, this is weekly, biweekly or even monthly sessions when the signs and symptoms of dialysis urgency are present. We aim was to compare the costs, quality of life and nutritional status among two different model hemodialysis: cHD versus IHD.

Methods: Pilot cost study. Costs generated by HD sessions and indirect costs reported by the patient are evaluated to obtain out-of-pocket expenses (medicines, transportation, food, medical supplies). Nutritional status was evaluated through the malnutrition and inflammation score (MIS) and quality of life through the SF-36 questionnaire.

Results: Twenty patients were analyzed 55% male, with a mean age of 40.5 ± 14.9 years, the main cause of CKD was unknown (60%), and the main comorbidity was HTA (95%). Eleven in cHD and nine in IHD. In Fig 1, shown biochemical characteristics, MIS, grip strength, and costs are presented by study group. The quality of life analysis showed worse scores in symptoms; effects of kidney disease, morbidity of kidney disease; physical component; and mental component (p ≦ 0.05).

Conclusions: Although not statistically significant differences were identified in out-of-pocket spending between models, patients with IHD presented worse score MIS and quality of life. A health policy is necessary that allows universal access to renal replacement therapies in Mexico.

PO0814

Potential Cost Savings Associated with the Reduction of Hospital Admissions by Using Online High-Volume Hemodiafiltration (Hv-HDF) vs. High-Flux hemodialysis (Hf-HD)

Farah Farahati,[1] Linda Ficociello,[1] Claudy Mullon,[1] Michael S. Anger.[1,2] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]University of Colorado, School of Medicine, Denver, CO.*

Background: On-line HDF for maintenance dialysis patients is available in Europe and Canada but is essentially absent in the US. The National Institute for Health and Care Excellence (NICE) conducted a systematic review and built economic models to compare hemodiafiltration (HDF) with Hf-HD. They found HDF to be cost-effective due to benefits such as increased survival and reduced medication requirements. In addition, NICE found HDF using high convection volumes ~20+ L (HvHDF) had greater mortality benefits compared to Hf-HD. Economic models built upon payment systems outside of

the US may be difficult to apply within the US due to differing payment structures. This analysis estimates the potential cost-savings associated with reducing hospital admissions with online HvHDF (vs Hf-HD) based on published studies and USRDS cost data.

Methods: We updated the NICE systematic literature review on HDF studies, especially for articles on hospitalization by searching EMBASE (Ovid), PubMed and NHS EED from 2010 to present. We used an input-output Microsoft Excel® database to calculate the potential cost-saving of online HvHDF compared to Hf-HD from reducing hospitalization and estimating the savings associated with those averted hospitalization and missed in-center HD. The average cost of hospitalization was derived from USRDS and adjusted to 2021 ($17,181), and the average hospital stay was 6.42 days and assuming thrice weekly would result in 2.75 missed HD treatments. It is assumed that reimbursement rate for in-center HD is $253.13 per treatment and costs of treating with HvHDF and Hf-HD are equivalent.

Results: Out of 107 studies found, 4 reported hospitalization rates for HDF and Hf-HD, and 1 compared HvHDF with Hf-HD. This study found 10.8 fewer hospital admissions with HDF per 100 patient-years (Maduell, et al, High efficiency postdilution online hemodiafiltration reduces all-cause mortality in hemodialysis patients. J Am Soc Nephrol, 2013: 487-97). We identified potential saving of $1,856 per patient per year (PPPY) due to averted hospitalizations and $75 PPPY due to avoiding missed HD treatment for a total of $1,931 PPPY.

Conclusions: The potential annual cost-savings of using HvHDF over Hf-HD in maintenance in-center HD was estimated as $1,931 PPPY or $193,071 per 100 patients.

PO0815

Predicting Decline in Residual Renal Urea Clearance via Random Forest Regression

Jacob S. Berkowitz,[1] Oguz Akbilgic,[2] Kamyar Kalantar-Zadeh,[3] Elani Streja.[3]
[1]University of Pittsburgh, Pittsburgh, PA; [2]Loyola University Chicago, Chicago, IL; [3]University of California Irvine, Irvine, CA.

Background: For incident hemodialysis patients, the decline of residual kidney function (KRU) over the first year of dialysis therapy is associated with adverse outcomes such as higher death risk. While several studies have identified biomarkers associated with higher risk of steeper KRU decline, we sought to employ more novel prediction utilizing a random forest regressor to identify important predictors of KRU after one year on hemodialysis.

Methods: We retrospectively reviewed a cohort of 5,141 patients who initiated in-center hemodialysis from 2007 to 2011 and had available KRU data at both baseline and during the 90 days after the one-year mark. 80% of the cohort was selected for the training dataset, with the remaining 20% used to test the model. Cross validation was utilized to optimize the number of trees and the mtry parameter. For feature selection, we used the 20 most important features from a random forest using all available predictors.

Results: In our cohort, mean age was 61 ± 14 years, with 66% men, 25% Black, 70% diabetes, and mean baseline albumin was 3.62 ± 0.42 g/dL. Median baseline KRU was 4.24 (6.39 – 2.69). Median KRU after one year was 1.74 (3.14-0.76). The random forest model yielded an overall mean squared error of 2.13 with noticeably stronger performance on the lower end of final KRU values. Using the median response as a classification threshold, the model achieved an AUC of 0.74. A variable importance analysis revealed that the model's five most important predictors consist of baseline KRU, albumin, weight post treatment session, blood urea nitrogen level, and body mass index.

Conclusions: We showed that a random forest regressor can predict KRU values for hemodialysis patients after one year of treatment with moderately high accuracy. Utilizing our predictive models could aid patients and clinicians in determining the best course of treatment, which should be validated in future studies.

Predicting Time to Dialysis and Unplanned Dialysis Start Using Machine Learning Models

Mahesh Shukla,[1,2] Brendan C. Garrett,[1,2] Ali Azari,[1,2] Emily Kipping,[1,2] Bruce F. Culleton.[1,2] *[1]CVS Health Corp, Woonsocket, RI; [2]CVS Kidney Care, Woonsocket, RI.*

Background: Despite advances in nephrology care, a majority of patients are not well prepared for starting dialysis. This puts patients at a heightened risk of adverse outcomes such as increased hospitalization, higher health care costs and poorer quality of life. Most studies report prevalence of unplanned dialysis start between 40% and 60%. We have implemented a solution that allows the care team to combine their clinical judgement with the outputs of state-of-the-art machine learning models. These models learn patterns in historical data which lead to outcomes of interest.

Methods: We have developed and deployed a set of supervised machine learning models using gradient boosted decision trees that estimate the likelihood a patient with chronic kidney disease (CKD) requiring dialysis and having an unplanned start in the coming 18 months. Unplanned Dialysis Start (UDS) Model sits downstream of Time to Dialysis or Temporal Risk (TR) Model and scores the CKD patients who are predicted to need dialysis. We trained these models in the medical and pharmacy claims and lab data of 751,242 CKD patients spanning multiple years. Input features included demographics, medical history, social determinants of health, and medication adherence. We are using the model output for selection of beneficiaries in a kidney care management program. In addition, the care team is using the risk scores at the point of care.

Results: TR Model has AUC of 93% and F1-score of 0.31 whereas UDS Model has AUC of 71% and F1-score of 0.30. The models are relying on clinically relevant features in making their predictions. Top predictors include serum creatinine, serum albumin, serum phosphate, hemoglobin, CKD Stage, age, comorbidities, nephrologist visits, social determinants of health, and uremic symptoms. We are able to discover patients who are not receiving nephrology care but are at risk for an unplanned start.

Conclusions: Machine learning models developed in large claims and lab datasets can predict time to dialysis and risk of unplanned dialysis starts. These models can be integrated into care management programs to target high risk patients with interventions calibrated to the individual patient's risk. An evaluation study is the next logical step.

PO0817

Kidney Function Recovery in Patients Undergoing Maintenance Hemodialysis After AKI Related to Immunological Disorders

Renata Carvalho, B. Faria. *Hospital de Braga, Braga, Portugal.*

Background: Acute kidney injury(AKI) associated with immunological disorders is an important cause of kidney disease leading to dialysis initiation. In most cases, immunosuppression(IS) is maintained after starting dialysis, hoping for dialysis discontinuation. We analyzed our population with AKI due to immune-mediated disease, who were still dialysis-dependent after hospital discharge and were followed at our outpatient hemodialysis(HD) unit.

Methods: We retrieved the data from our HD unit files. Patients that started maintenance HD due to AKI related to immunologic disorders from 2014 to 2021 were included. We collected data on gender, age, AKI etiology, type and dose of IS, time until kidney function recovery, serum creatinine(sC) at admission and discharge, and the result of kidney biopsy if available. Primary outcome was kidney function recovery (with dialysis independence).

Results: 16 patients were included. The most common diagnosis was ANCA vasculitis(n=4), followed by ANCA-negative crescentic glomerulonephritis (GN)(n=3), IgA nephropathy(n=2), scleroderma renal crisis(n=2), acute interstitial nephritis(n=2), immune complex GN(n=1), granulomatous interstitial nephritis(n=1) and hemolytic uremic syndrome(n=1). Five patients(31,2%) recovered and are still dialysis-free. Concerning primary outcome, there were no differences in gender or age (58,6±15,1years) between the two groups, but sC at admission was greater in recovered patients (mean 10,7±2,3mg/dL vs 8,2±2,0mg/dL, p=0.047). No differences were found between the two groups when the following variables were analyzed: presence of previous chronic kidney disease (CKD), hypertension, diabetes, acute tubular necrosis or interstitial fibrosis/tubular atrophy in kidney biopsy. In patients who received cyclophosphamide(n=8), the outcome was observed only in one patient after eight cycles of IS(vs3,8±1,3 cycles,p=0.034). The time until recovery was 344±446days(range 66-1121days) and sC after discontinuation of HD was 4,0±0,9mg/dL.

Conclusions: Although rare, patients with immunologic kidney disease can recover kidney function more than 90 days after the start of maintenance HD. As nephrologists we should be aware of this situation. The small number of patients limits our analysis. Nevertheless, we concluded that higher pC at admission is not a risk factor for the outcome and that recovery can occur years after starting HD.

PO0818

Clinical Research Offers Potential Benefit to Patients and No Obvious Harm to Clinical Value

Vladimir Rigodon,[1] Yue Jiao,[4] John W. Larkin,[4] Len A. Usvyat,[4] Murilo H. Guedes,[3] Thyago P. Moraes,[3] Roberto Pecoits-Filho,[3] Jeffrey L. Hymes,[4] Robert J. Kossmann,[2] Michael S. Anger,[2] Franklin W. Maddux,[4] Kurt Mussina.[1] *[1]Frenova Renal Research, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [4]Fresenius Medical Care, Global Medical Office, Waltham, MA.*

Background: Randomized clinical trials (RCT) are underperformed in nephrology. This may be due to the uncertain impacts on quality measures. We assessed quality outcomes between research-conducting (RF) and research-naïve (NF) dialysis facilities, as well as respective patient outcomes.

Methods: We used data from adult HD patients treated at national provider in the United States from 2017-2018. RF were 1:1 propensity score matched (PSM) to NF on patients/year, patient/facility exposure, % Medicare, % accountable care, region and quality outcomes were compared cross-sectionally. Research participants (RP) from facility analysis were 1:1 PSM to research naïve participants (RNP) at baseline (research participation start or index date) on age, sex, race, Ethnicity, vintage, access, albumin, hemoglobin (hgb), congestive heart failure, ischemic heart disease, diabetes, missed treatments, and hospital day rates. Quality outcomes were compared longitudinally at 6 and 12 months.

Results: We found no differences in quality outcomes between RF and NF facilities. We observed RP had lower hospital day rates at 6 months after research participation start as compared to NRP, as well as higher % with albumin >=4g/dL at 6 and 12 months, higher % with iPTH 150-600 pg/mL within 12 months, and lower anemia target achievement (**Figure 1**).

Conclusions: We observed no significant differences in quality measures between facilities that conducted clinical trials vs those that did not. Participation in trials was associated with lower hospital day rates and better achievement of nutritional targets, but lower achievement of hemoglobin and transferrin saturation targets. Anemia results might be attributable to conservative hgb repletion in trials of new investigational drugs. Trial conduct appeared to do no harm to quality achievement and provide potential benefits to participants, which may be associated with additional evaluations/monitoring provided.

PO0819

Novel Insight About Pregnancy in Women on Chronic Dialysis: Systematic Review and Meta-Analysis Correlating Dialysis Regimen and Pregnancy Outcome

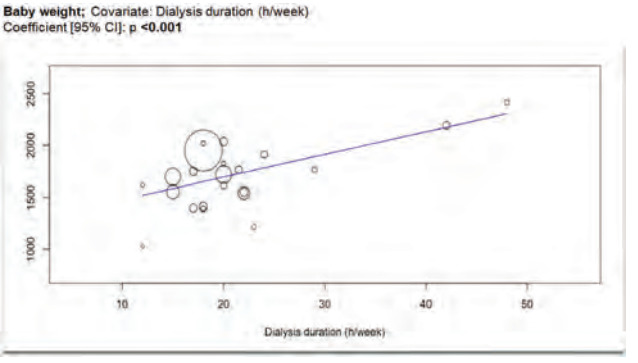
Emanuela Cataldo,[1,4] Elisa Longhitano,[2] Massimo Torreggiani,[3] Antoine Chatrenet,[3] Loreto Gesualdo,[4] Giorgina B. Piccoli.[3] *[1]Nephrology and Dialysis Unit, "Fabio Perinei Hospital", Bari, Italy; [2]Universita degli Studi di Messina Dipartimento di Medicina Clinica e Sperimentale, Messina, Italy; [3]Centre Hospitalier du Mans, Le Mans, France; [4]Azienda Ospedaliero-Universitaria Consorziale Policlinico di Bari, Bari, Italy.*

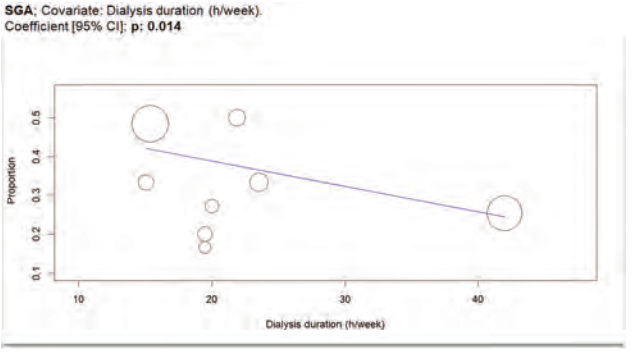
Background: Pregnancy in women on dialysis is an uncommon event, with a high rates of preterm delivery and neonatal death. Guidelines for management of dialysis in pregnancy are still lacking. Our aim is to identify dialysis regimens associated with best maternal-fetal outcomes

Methods: Rapid systematic review. MEDLINE, EMBASE and COCHRANE library were searched (1950–2019: free terms on pregnancy and dialysis). Meta-analysis and metaregression were performed in case series dealing with the larger subset of haemodialysis (HD) patients (>5 patients on chronic HD)

Results: The descriptive of 5204 pregnancies in 4746 HD patients, out of 52 case series and registry data highlighted the importance of intensifying HD in pregnancy (5-6 sessions, >20 hours/week) to achieve a reduction in mortality and an increase in neonatal weight. The meta-analysis showed an increased risk of preterm delivery in women on chronic HD, decreasesing with the increase in hours of HD and number of HD sessions. In addition, the meta regression demonstrated that increasing weekly hours of HD was associated to a lower risk of extreme preterm birth (<28 gestational weeks: p=0.016) and SGA (p=0.014) and with an increase in weight at birth (p<0.001). The same trend was observed for number of HD sessions. The high heterogeneity of data doesn't allow disentangling the effect of the center of care

Conclusions: Extendend hours HD regimens in pregnancy improve maternal fetal outcomes. This improvement is linked both to HD rhythm and duration. The results obtained during pregnancy lead to reconsidering the concept of adequate HD at least in the young population





PO0820

Thrombocytopenia Predicts Mortality in Chinese Hemodialysis Patients: An Analysis of the China DOPPS

Xinju Zhao,[1] Qingyu Niu,[1] Liangying Gan,[1] Fan Fan Hou,[2] Xinling Liang,[7] Zhaohui Ni,[3] Xiaonong Chen,[6] Yuqing Chen,[5] Keith McCullough,[4] Bruce M. Robinson,[4] Li Zuo.[1] *[1]Peking University People's Hospital, Beijing, China; [2]Southern Medical University Nanfang Hospital, Guangzhou, China; [3]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Peking University First Hospital, Beijing, China; [6]Ruijin Hospital AmMed Cancer Center Shanghai, Shanghai, China; [7]Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Mortality rate was high in Hemodialysis (HD) patients. Our previous study suggested platelet counts might be a potential risk factor. However, few studies have examined the association of platelet count with mortality in HD patients. The aim is to examine if there is an association of thrombocytopenia (TP) with mortality and cardiovascular (CV) death in Chinese HD patients.

Methods: China DOPPS5 data was used. Fifty-eight of 1427 patients were excluded for missing platelet records. Demographic data, comorbidities, lab data, and death records were extracted. Participants were divided into 2 groups according to their platelet counts as TP group (platelet<100*10^9), and Non-TP group (platelet >=100*10^9). The Non-TP could not be further divided into normal or above normal groups as limited by the sample size. Associations between platelet counts and all-cause and CV mortality were analyzed using Cox regression models. Stepwise multivariate logistic regression was used to identify related impact factors.

Results: Of 1369 patients, 201(14.7%) died and 102 (7.5%) died from CV disease. 11.2% (154) had TP at baseline. The mortality rates were 26.0% vs. 13.3% (p <0.01) in patients with and without TP. TP was associated with higher all-cause mortality after adjusted for covariates (HR:1.75, 95% CI: 1.12- 2.74), but was not associated with CV death after fully adjusted (HR: 1.75, 95% CI: 0. 89, 3.45, Figure 1). Multivariate logistic regression showed that Urine output <200 ml/day, cerebrovascular disease, hepatitis (B or C), and white blood cells were independent impact factors (P < 0.05).

Conclusions: Baseline TP is associated with higher risk of all-cause mortality in HD patients. Platelet counts may be used as early available outcome predictors among HD patients, though additional study is needed.

Funding: Government Support - Non-U.S.

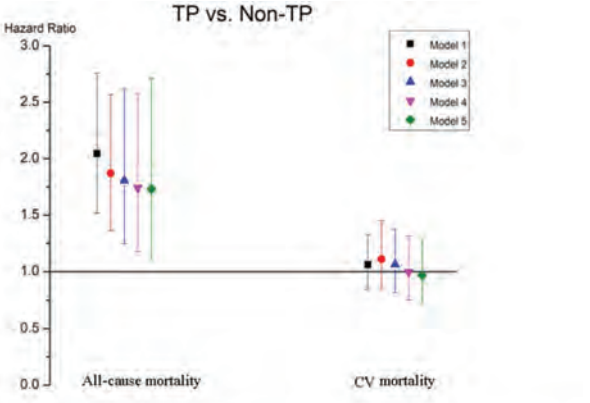


Figure 1. Associations between the platelet counts and all-cause mortality and CV mortality in different COX regression models (TP group: platelet<100*10^9; Nonp-TP group: platelet>100*10^9)

PO0821

Steady Exercise Improves Hand Grip and Leg Muscle Strength in Hemodialysis Patients

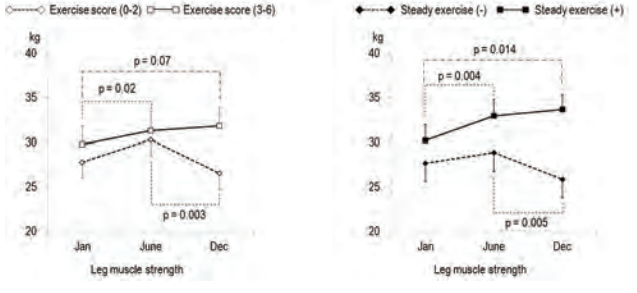
Ran-hui Cha. *National Medical Center, Seoul, Seoul, Republic of Korea*.

Background: Sarcopenia due to chronic inflammation and biochemical disturbances in chronic kidney disease is severer and more prevalent in patients on hemodialysis (HD). We longitudinally evaluated the hand grip (HGS) and leg muscle strength (LMS) in patients receiving HD and tried to find factors associated with muscle strength.

Methods: We screened (January 2020 (n=127)) and followed up (June 2020 (n=110) and December 2020 (n=104)) HGS (opposite the fistula side) and LMS (both sides) at single center by using digital hand and leg dynamometer (T.K.K.5401 and 5710e/5715, Takei scientific instruments Co. Ltd., Niigata, Japan).

Results: HGS and LMS showed good correlation ($r = 0.658$, $p < 0.001$). HGS (24.2 vs. 15.5 kg) and LMS (32.8 vs. 22.5 kg) were better in men ($p < 0.001$ and $p < 0.001$, respectively). Muscle strength was greater in men irrespective of age except for LMS in younger patients (< 60 years). Older patients (≥ 60 years) showed decreased LMS than others in women ($p = 0.01$). Patients who performed steady home- or hospital-based exercise showed marginally higher HGS (23.1 vs. 19.8 kg, $p = 0.07$) and significantly higher LMS (33.7 vs. 25.9 kg, $p = 0.004$). Steady exercise showed improvement of LMS throughout the study period (from January to June, $p = 0.004$, from January to December, $p = 0.014$). Multiple linear regression analysis proved male sex and steady exercise were factors associated with better HGS and LMS. Steady exercise showed greater impact on LMS in male patients with longer HD vintage (≥ 44 months) and on HGS in younger male patients with shorter HD vintage (< 44 months).

Conclusions: Sex, age, and steady exercise were important determinants of muscle strength in HD patients. And serum creatinine and dry weight, which reflects muscle mass, were also important in determining muscle strength. We need to encourage patients to do regular home- or group-exercise from the beginning of dialysis and introduce new feasible form of exercise for HD patients.



PO0822

The Association Between Prevalence of Peritoneal Dialysis vs. Hemodialysis and Patients' Home Distance to Dialysis-Providing Facilities

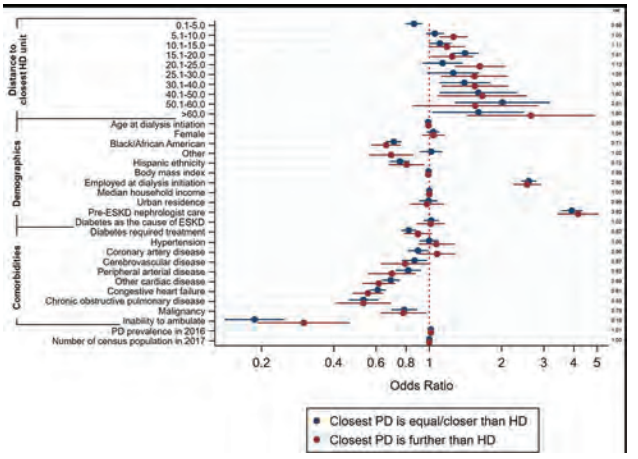
Pattharawin Pattharanitima, Osama El Shamy, Kinsuk Chauhan, Aparna Saha, Huei Hsun Wen, Shuchita Sharma, Jaime Uribarri, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Accessibility to dialysis facilities should play a role when deciding on a patient's long-term dialysis modality. Studies investigating the effect of distance to nearest dialysis-providing unit on modality choice, however, have yielded conflicting results. We investigated the association between patients' dialysis modality and the distances (driving and straight) to the closest HD and PD-providing units.

Methods: All ESKD patients (USRDS) who initiated in-center HD and PD in 2017, were 18-90 years old, and on dialysis for ≥30 days were included. Patients who resided in non-conterminous US or lived >90 miles from the nearest HD-providing unit were excluded.

Results: Among 102,247 included patients, median driving distance to the closest HD unit was greater for PD patients (3.9 vs 2.9 miles; $p < 0.001$). Compared to HD patients, PD patients had longer driving distances to their nearest PD unit (4.4 vs 3.4 miles; $p < 0.001$). PD utilization increased with increasing distance from patients' homes to the nearest HD unit (OR 1.11, 95% CI 1.08-1.14 per 10-mile increase). This association did not change whether the PD unit was farther/closer than the nearest HD unit (**Figure 1**). This association was not seen when analysis was performed using straight line distance.

Conclusions: PD utilization increases with increasing driving distances from the nearest dialysis providing units (HD or PD). Using driving distance, but not straight line distance affects data analysis and outcomes. Increasing the number of PD units may have a limited impact on increasing PD utilization.



Adjusted OR for PD utilization categorized by the driving distance (miles) from patient's residence to the closest HD-providing unit and distance to closest PD-providing unit (equal/closer or farther than the distance to HD-providing unit)

PO0823

Evaluation of Frailty Assessment Tools and Their Measurement Properties in CKD

Alisha Puri, Aminu K. Bello, Stephanie E. Thompson, Puneeta Tandon, Sandra M. Campbell, Anita Lloyd. *University of Alberta Department of Medicine, Edmonton, AB, Canada*.

Background: Frailty is three to seven times more common in people with chronic kidney disease (CKD) than in those with normal kidney function. Although frailty and its impact in CKD is well-recognized, the measurement properties of the tools used to assess this syndrome are not known. The aim of this systematic review was to evaluate frailty assessment tools and their measurement properties in CKD.

Methods: The study was conducted using the Consensus-based Standards for the selection of health Measurement Instruments (COSMIN) guidelines and Preferred Reporting Items for Systematic reviews and Meta-Analyses for Protocols (PRISMA-P 2015). We searched ten electronic databases (eg. OVID MEDLINE, OVID EMBASE, OVID Health and Psychosocial Instruments, Cochrane Central Register of Controlled Trials (CENTRAL)) and screened studies as per the following inclusion criteria: peer-reviewed original research, adults with CKD (non-dialysis, dialysis or kidney transplant (KT)), examines at least one established multidimensional tool used for the assessment of frailty, and presents information to evaluate the measurements properties of the tool. Methodological quality assessment and data synthesis will be performed as per COSMIN guidelines. This review was registered with PROSPERO (CRD42021234558).

Results: We retrieved 647 unique citations with 58 eligible studies (N=16,026) of which 60% were prospective cohort studies. The majority (59%) included patients on dialysis, 19% were KT, and the remaining non-dialysis CKD. The dialysis populations utilized hemodialysis (HD) (38%) and peritoneal dialysis (PD) (34%) modalities. Fried's phenotype was the most commonly tool used to assess frailty (57%). Predictive validity was the most frequently reported measurement property (86%) followed by responsiveness (12%). Thirty-one (53%) of the included studies using the Fried's Phenotype evaluated predictive validity.

Conclusions: In this review, a majority of the studies focused on the dialysis and non-dialysis populations. Fried's Phenotype, the most commonly administered tool, primarily evaluated predictive validity. Future research is required to identify the tool(s) that will be predictive of adverse health outcomes in the KT population and additional studies evaluating these tool's responsiveness to change are needed.

PO0824

Change in Physical Activity and Function in Patients with Baseline Advanced Non-Dialysis CKD

Christie Rampersad,[1] Oksana Harasemiw,[2,1] Ranveer S. Brar,[2,1] Paul Komenda,[2,1] Claudio Rigatto,[2,1] Bhanu Prasad,[3] Clara Bohm,[2,1] Navdeep Tangri.[2,1] *[1]University of Manitoba Faculty of Health Sciences, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [3]Saskatchewan Health Authority, Saskatoon, SK, Canada.*

Background: Progressive declines in physical activity and function are common in individuals with worsening chronic kidney disease (CKD). However, little is known about whether the transition to dialysis is associated with accelerated decline. We aimed to assess temporal rates of change in physical activity level and physical function in people with advanced CKD to determine whether the transition to dialysis was associated with accelerated decline.

Methods: Individuals with advanced CKD stages G4-G5 from the Canadian Frailty Observation and Interventions Trial (CanFIT) were included. Outcomes included change in physical activity level measured using the Physical Activity Scale for the Elderly (PASE) and physical function measured using the chair stand test, 4-meter gait speed, and grip strength. Unadjusted and adjusted generalized linear regression models were conducted to determine whether progression to dialysis was associated with greater decline in physical activity or physical function.

Results: Of 386 individuals, 162 individuals progressed to dialysis during the study period, whereas 224 did not. Both groups experienced statistically significant declines in self-reported physical activity, increased chair stand test times, and decreased gait speed. Compared to individuals with advanced nondialysis CKD, progression to dialysis was associated with greater increase in chair stand test time in unadjusted (beta estimate 6.05 seconds, 95% CI 2.36 – 9.74, p=0.001) and adjusted (beta estimate 5.23 seconds, 95% CI 0.75 – 9.71, p=0.02) models.

Conclusions: Although individuals with advanced CKD experience declines in physical activity and function over time, progression to dialysis is associated with accelerated decline in physical function as measured by the chair stand test. Future studies on interventions to delay or prevent declines associated with CKD progression and dialysis initiation are needed.

PO0825

Validation of the Surprise Question in an Ethnically Diverse Population to Identify Seriously Ill Dialysis Patients

Alvin H. Moss,[1] Glenda Harbert,[3] Annette Aldous,[2] Amanda C. Nicklas,[3] Dale Lupu.[3] *[1]West Virginia University Health Sciences Center, Morgantown, WV; [2]The George Washington University Milken Institute of Public Health, Washington, DC; [3]The George Washington University School of Nursing, Ashburn, VA.*

Background: Use of the surprise question (SQ)—Would I be surprised if this patient died in the next six months?—to estimate prognosis for dialysis patients has been largely studied in dialysis centers in central Massachusetts and West Virginia. Researchers have called for its value to be confirmed in more ethnically diverse dialysis settings. We tested the effectiveness of the SQ in three urban areas to identify seriously ill dialysis patients (SI) who could potentially benefit from being prioritized for goals of care discussions.

Methods: We recruited 10 dialysis centers (6 in NYC, 3 in Denver, CO, and 1 in Dallas, TX) with 1,507 patients. Dialysis staff screened patients monthly for 14 months (May 2019-June 2020) with the SQ to identify those who were SI and recorded outcomes including the number screened and number SI. In this rolling population of patients, we calculated the mortality risk per month of follow-up for SI and not SI and determined the relative risk of death for SI compared to not SI. In addition, after 14 months, the dialysis centers reported the vital status for an initial cohort of 266 SI identified in May 2019.

Results: Over the 14 months, dialysis centers screened a monthly average of 1,342/1,507 (89.1%) and identified 274 (18.2%) as SI. A total of 269 patients died, 134 (49.8%) SI and 135 (50.2%) not SI. The annualized mortality risk was 41.9% for SI and 9.4% for not SI (risk ratio 4.47, 95% CI, 3.49-5.72). For the 266 SI patients identified in May 2019, race included White 153 (57.5%), Black 68 (25.6%), Asian 20 (7.5%), and Other 25 (9.4%); 81 (30.5%) were identified as Hispanic. Vital status was known after 14 months for 231/266 (86.8%) SI: 96/231 (41.6%) had died, 86 (37.2%) were alive and SI, and 49 (21.2%) were alive and no longer considered SI. The annualized mortality rate for these 231 SI patients was 35.6%.

Conclusions: In this ethnically diverse, geographically dispersed dialysis population, we found that use of the SQ was pragmatically feasible and effective in identifying SI who were at considerably increased risk of one-year mortality. Future research is needed to determine if proactive identification of SI in this manner leads to improved palliative care with more goal-concordant care for this at-risk population.

Perspectives on Motivational Strategies to Improve Hemodialysis Treatment Adherence in African Americans: A Qualitative Study

Ebele M. Umeukeje,[1,2] Kemberlee R. Bonnet,[5] Devika Nair,[1,2] Rachel B. Fissell,[1,2] Joseph R. Merighi,[3] Ruth Q. Wolever,[1] Juliet Iwelunmor,[7] Collins Airhihenbuwa,[4] Kenneth A. Resnicow,[6] David G. Schlundt,[5] Kerri L. Cavanaugh.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt Center for Kidney Disease, Nashville, TN; [3]University of Minnesota Twin Cities, Minneapolis, MN; [4]Georgia State University, Atlanta, GA; [5]Vanderbilt University, Nashville, TN; [6]University of Michigan School of Public Health, Ann Arbor, MI; [7]Saint Louis University, Saint Louis, MO.*

Background: Compared to White patients, African American (AA) patients have a four-fold higher prevalence of kidney failure and higher hemodialysis non-adherence. Adherence behaviors are influenced by psychosocial factors, including personal meaning of a behavior and self-confidence to enact it. We assessed perspectives of patients and professionals on using motivational interviewing (MI), an evidence-based intervention to improve these psychosocial factors, hemodialysis adherence, and outcomes in AAs.

Methods: Self-identified AA hemodialysis patients (n=21), dialysis clinicians (MDs, NPs, RNs, LCSWs and RDs) and health equity researchers (n=30) watched a brief video describing MI and then completed a semi-structured interview. Planned questions targeted unique barriers to hemodialysis adherence faced by AAs, and the perceived utility of MI to address these obstacles. Verbatim transcripts and an iterative inductive/deductive approach were used to develop a hierarchical coding system. Two researchers independently identified and coded themes informed by social cognitive theory and the social ecological framework.

Results: See table below:

Conclusions: AA patients receiving hemodialysis, dialysis clinicians, and researchers view MI as a means to build trust, clarify patient priorities, and promote the patient-provider therapeutic alliance. Cultural tailoring of MI to address unique barriers of AAs with kidney failure will improve adherence and health outcomes in these vulnerable patients.

Funding: NIDDK Support

Key Themes And Illustrative Quotes

Barriers	
Mistrust	"'There's...a lot of mistrust among AAs.'" (MD)
Amotivation	"'...a lot of my patients are not motivated...'" (RN)
Inconsistent messages	[From] "you might not ... do dialysis that long" [to] "you're on dialysis the rest of your life" (patient)
Poor understanding	"'A man called me the 'N' word...I was sad...my MD said..sorry, I don't understand.." (patient)
Facilitators	
Engagement	"...don't talk in a condescending manner to an AA, talk to him at his level" (patient)
Empowerment	"help them understand, ...to see they're in charge" (RN)
Relationship	"anybody that has a relationship with a patient, can have a [talk] about not getting off [dialysis]" (LCSW)
Cultural awareness	"it would be good if [providers] become more culturally aware of AAs" (patient) "Not all African Americans are the same...get a sense of important nuances of your [AA] patients" (researcher)

PO0827

Feasibility and Acceptability of Electronic Patient-Reported Outcome Measures (e-PROMs) Collection and Feedback in Hemodialysis Patients

Andrea K. Viecelli,[1,2] Emily Duncanson,[5] Paul N. Bennett,[3] Matilda N. D'Antoine,[5] Kathryn Dansie,[5] Allison Tong,[4] Suetonia Palmer,[7] Shilpa Jesudason,[8] Stephen P. McDonald,[5] Rachael L. Morton.[6] SWIFT Investigator Team *[1]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [2]The University of Queensland Faculty of Medicine, Herston, QLD, Australia; [3]University of South Australia Division of Health Sciences, Adelaide, SA, Australia; [4]The University of Sydney, Sydney, NSW, Australia; [5]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [6]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [7]University of Otago, Christchurch, New Zealand; [8]Royal Adelaide Hospital, Adelaide, SA, Australia.*

Background: The "Symptom monitoring With Feedback Trial" (SWIFT) will assess whether 3-monthly symptom monitoring using the IPOS-Renal questionnaire with feedback to patients and clinicians with evidence-based symptom management recommendations, can improve health-related quality of life for adults on hemodialysis (HD). It is unclear whether regular collection of these data using tablet computers, and provision of symptom scores is acceptable and feasible.

Methods: The SWIFT pilot study collected e-PROMs across 4 Australian HD units for 6 months. We conducted semi-structured interviews and focus groups with 38 participants (13 nephrologists, 16 dialysis nurses, 12 patients on HD) about the uptake and implementation of e-PROMs. Transcripts were analyzed thematically.

Results: We identified four themes**:** enabling efficient, systematic and multidisciplinary patient-centered care (facilitating communication and holistic care, reliable assessment of change in PROMs, increased flexibility in data capture, and ease and convenience); limited data and options for symptom management (depersonalization of care, perceived inability to intervene, time lag for feedback, and uncertain validity and reliability of survey data); requiring familiarity with technology and processes (embedding e-PROMs collection into routine care, assistance to enhance uptake, clarity about e-PROMs purpose and use, comfort and willingness to use technology, and individualizing data collection);

and competing interests and barriers to PROMs data collection (physical limitations encumbering survey completion, low educational attainment and language limitations; fitting in with existing routines, and survey fatigue).

Conclusions: Clinicians and patients support the use of e-PROMs with feedback in HD. Clinician engagement and patient support, reliability of technology, timely symptom feedback, and interventions undertaken to address symptom burden are likely to improve acceptability and impact of symptom monitoring.

PO0828

Symptom Clusters in a Diverse Prospective Hemodialysis Cohort

Amy S. You,[1] Sara S. Kalantar,[2,1] Keith C. Norris,[3] Rene Amel Peralta,[1] Yoko Narasaki,[1] Ronald A. Fischman,[4] Michael A. Fischman,[4] Avedik Semerjian,[4] Zahra Azadbadi,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Berkeley, Berkeley, CA; [3]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [4]Southland Renal Medical Group, Long Beach, CA.*

Background: Hemodialysis (HD) patients experience a high symptom burden similar to that of patients with malignancy, which may adversely impact their quality of life and well-being. Given that emerging data in other fields (oncology) show that symptoms often occur in clusters, we examined the presence of symptom clusters in a diverse prospective HD cohort.

Methods: In 122 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Chronic Kidney Disease* study recruited across 16 outpatient dialysis clinics, the presence of CKD-associated symptoms was ascertained by the Dialysis Symptom Index (DSI), a 30-item validated survey that assesses symptom severity (score range 0-120, higher scores indicating greater severity), over 7/2020-8/2020. Using the DSI surveys, we examined the presence of symptom clusters (≥2 symptoms related to each other and occurring together) across domains categorized by organ system.

Results: The mean±SD age of the cohort was 60±13 yrs, among whom 51% were female, 22% were Black, and 62% were Hispanic. Across the 30-item DSI survey, the most common individual symptoms included feeling tired/lack of energy (71%), dry skin (61%), itching (42%), muscle cramps (42%), and numbness/tingling in feet (41%). Upon examining co-existing symptoms, there was a high prevalence of symptom clusters, with the most common pairings including: 1) having trouble falling asleep + feeling tired/lack of energy or trouble staying asleep, 2) having trouble staying asleep + feeling tired/lack of energy, 3) dry skin + itching, 4) dry skin + dry mouth, and 5) decreased interest in sex + difficulty becoming aroused.

Conclusions: We observed a high prevalence of symptom clusters in a well-defined, diverse prospective HD cohort. Further studies are needed to determine the physiologic underpinnings of concurrent symptoms in order to identify targeted therapies that can ameliorate the high symptom burden of HD patients.

PO0829

Implementing a Patient-Centric Educational Handout to Provide the Knowledge of Kidney Disease and Dialysis, Promote Self-Care, and Improve Quality of Life in Patients Starting Hemodialysis

Jennifer Griffiths, Kiran Shivaraj, Shruti Kore, Michael D. Klein, Savneek S. Chugh. *Westchester Medical Center, Valhalla, NY.*

Background: In the United States about 700,000 people need hemodialysis with most of them starting in the hospital. While patients on hemodialysis account for only 1% of Medicare beneficiaries, they account for 7% of total Medicare spending. While the cost of care is high amongst dialysis patient, the morbidity and mortality remain elevated with majority of deaths in the first 90 days of the start of dialysis. Studies has shown, lack of education in these patients about their treatments, dietary modification, fluid intake and vascular access. Early educational intervention of dialysis patient results in reduce re-hospitalizations and 90 days mortality in this vulnerable population

Methods: Extensive Pubmed search was performed to identify a validated clinical tool which will assess the pre-existing knowledge and post-interventional knowledge. Chronic Hemodialysis Knowledge Survey (CHeKS) was identified as a pre-test and post-test questionnaire to assess the efficacy of the project. CHeKS was distributed to 10 new-start hemodialysis patients admitted at Westchester Medical Center. An evidence based educational handoff was prepared and provided both verbally and in written on 10 new-start hemodialysis patients. Educational material were given to read independently as well. As post-test was performed couple of days later or at the time of discharge using the same CHeKS questionnaire. The mean and median pre-test and post-test scores were analyzed and efficacy of educational intervention was analyzed.

Results: The initial pre-test educational questionnaire on 10 patients showed a median score of 38.4% (5 out of 13 correct) and a mean score of 43.79%. The post-test score showed a median score of 92.3% (12 out of 13 correct) or a mean score of 90.9%. These results showed a 51.8% increase in educational score after the intervention was performed. Highest increase in patient's knowledge were related to renal diet and fluid restrictions.

Conclusions: This study showed that the institution of structured educational activity can result in higher knowledge in dialysis patients, leads to better adherence to dialysis prescription and dietary recommendations. This along with limiting excessive fluid intake can result in reduce re-hospitalization and better self-care.

PO0830

Implementation and Effectiveness of a Supportive Care Learning Collaborative for Hemodialysis

Manjula Kurella Tamura,[1,2] Margaret R. Stedman,[1] Jialin Han,[1] Steven M. Asch,[6] Alvin H. Moss,[3] Annette Aldous,[4] Glenda Harbert,[5] Amanda C. Nicklas,[5] Dale Lupu,[5] Laura Holdsworth.[1] *[1]Stanford Medicine, Palo Alto, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA; [3]West Virginia University Health Sciences Center, Morgantown, WV; [4]The George Washington University Milken Institute of Public Health, Washington, DC; [5]The George Washington University School of Nursing, Ashburn, VA; [6]Stanford University, Stanford, CA.*

Background: The objective of this study was to determine whether a learning collaborative for hemodialysis providers improved delivery of supportive care best practices.

Methods: Ten U.S. hemodialysis centers participated in a hybrid implementation-effectiveness pre-post study targeting seriously ill patients between April 2019 and September 2020. The collaborative educational bundle consisted of learning sessions, communication training and implementation support. The primary outcome was change in proportion of seriously ill patients with complete advance care planning (ACP) documentation. Healthcare utilization was a secondary outcome and implementation was assessed qualitatively.

Results: One center dropped out during the COVID-19 pandemic. Among the remaining nine centers, 22.9% (320/1395) of patients were identified as seriously ill in the pre-intervention period and 18.0% (226/1254) were identified in the post-intervention period. From the pre-intervention to post-intervention period, the proportion of patients with complete ACP documentation increased, and hospitalizations and emergency department visits decreased (Table). There was no difference in mortality, palliative dialysis, hospice referral or dialysis discontinuation. Screening for serious illness was widely and sustainably adopted. Goals of care discussions were adopted with variable integration and sustainment.

Conclusions: Supportive care best practices were feasible to implement in hemodialysis centers and largely sustained during the COVID-19 pandemic. We observed increased documentation of ACP and lower healthcare utilization after the intervention which could reflect a combination of collaborative and pandemic effects.

Funding: Private Foundation Support

Table. Advance care planning and health care utilization among seriously ill hemodialysis patients

ACP	Pre-implementation N=258	Post-implementation N=196	p-value
Complete ACP documentation, N (%)	94 (36.0)	77 (39.0)	<.001
Any ACP documentation, N (%)	156 (60.5)	151 (77.0)	<.001
Healthcare Utilization	Pre-implementation N=320	Post-implementation N=22	p-value
Died, N (%)	21 (6.6)	14 (6.2)	0.86
Emergency department visit, N (%)	92 (28.8)	43 (19)	0.005
Hospitalization, N (%)	153 (47.8)	73 (32.3)	<.001
Palliative dialysis, N (%)	4 (1.3)	5 (2.2)	0.29
Referred to hospice, N (%)	7 (2.2)	3 (1.3)	0.44
Discontinued dialysis, N (%)	6 (1.9)	1 (0.4)	0.10

PO0831

Anxiety, Comorbid Depression, and Dialysis Symptom Burden

Daniel Cukor,[1] Stephanie Donahue,[1] Sri Lekha Tummalapalli,[1,2] Andrew Bohmart,[1,2] Jeffrey I. Silberzweig.[1,2] *[1]Rogosin Institute, New York, NY; [2]Weill Cornell Medicine, New York, NY, New York, NY.*

Background: Anxiety is an understudied construct in patients with kidney failure. Its relationship to dialysis and patient reported outcomes, including symptom burden, is not well known. 'Anxiety' describes a category of diagnoses and it is unknown if its components of general worry, somatic anxiety, and anxiety sensitivity have differential relationships with outcomes. It is also not known if depressive affect moderates these relationships.

Methods: In this single center survey study, 100 participants completed an assessment of depressive affect (Patient Health Questionnaire-9, PHQ-9), worry (Generalized Anxiety Disorder-7, GAD-7), somatic anxiety (Beck Anxiety Inventory, BAI), anxiety sensitivity

(Anxiety Sensitivity Index, ASI), and dialysis symptom burden (Dialysis Symptom index – DSI). Medical charts were extracted for demographic information, number of missed dialysis sessions in the past 30 days (not rescheduled or due to hospitalization), and average interdialytic weight gain over the past 3 dialysis treatments.

Results: The characteristics of the sample are found in the table below. People with elevated somatic anxiety (BAI >15) had significantly higher rates of depression, worry, anxiety sensitivity, and dialysis symptom burden (p<.001, all cases). In a predictive model of symptom burden, age, race, and gender were not associated with symptom burden, and only somatic anxiety remained significant once adjusting for depression. In the final model, depression accounted for 40% of the variance and somatic anxiety accounted for an additional 37%.

Conclusions: It appears that the impact on symptom burden of depression and worry/anxiety sensitivity overlap significantly, but somatic anxiety, commonly found in panic disorder, may be a unique contributor to excess symptom burden.

Variable	Total Sample	Elevated somatic anxiety (>15 BAI) N=22	Non-Elevated somatic anxiety (>15 BAI) N=77
Age	60.3 (16.0)	57.5 (15.2)	61.1 (16.2)
Gender (% female)	61%	59%	62%
Race/Ethnicity	51% White 36% Black 13% Asian 26% Hispanic	48%White 36%Black 16%Asian 45% Hispanic	60% White 36%Black 2% Asian 20% Hispanic
Average IDWG (3 last visits)	2.06 (1.2)	2.3 (1.8)	2.0 (.9)
Missed dialysis (% who missed at least 1 session in 30 days)	16.5%	18%	15%
Dialysis Symptom Index (symptom number)	10.0 (6.5)	16.6 (5.4)	8.1 (5.4)
Depression (PHQ-9)	5.1 (5.2)	11.3 (4.6)	3.4 (4.0)
Worry (GAD-7)	3.9 (4.8)	9.7 (5.2)	2.2 (3.1)
Somatic Anxiety (BAI)	9.8 (9.0)		
Anxiety Sensitivity (ASI)	11.3 (12.1)	22.3 (15.4)	8.2 (8.9)

Values are expressed as mean (standard deviation) unless otherwise stated

PO0832

Palliative and Conservative Care Consultation in Hemodialysis: A Survey

Karen Cohen,[1] Geoffrey S. Teehan.[2] *[1]Philadelphia College of Osteopathic Medicine, Philadelphia, PA; [2]Lankenau Medical Center, Wynnewood, PA.*

Background: Prior to initiating dialysis for patients with End Stage Renal Disease (ESRD), options other than dialysis such as conservative or palliative care are under-utilized. There may be a subset of patients who may not be ideal candidates for dialysis. Conservative kidney management can address the symptoms of kidney failure and can articulate goals of care with or without dialysis. Given the costs of healthcare, high morbidity and mortality in the ESRD population, we believe greater attention to conservative care prior to dialysis would result in patients having more comprehensive information prior to initiating dialysis.

Methods: Patients were surveyed at a large for-profit dialysis center in the suburban Philadelphia area in late December 2020. They were administered a 5 question survey about recalled experiences regarding referral patterns prior to dialysis. Potential responses were "yes," "no," or "do not recall."

Results: 37 patients were surveyed. Mean age was 63 years +/- 14, 70% were male, 95% were black. 24% of subjects reported discussing hospice and palliative care prior to dialysis initiation. 25% of patients >65 years old and 22% of patients <65 years old had such discussions. Chi square analysis was not statistically significant.

Conclusions: Only a small percentage of patients with ESRD on hemodialysis recall discussions about alternatives such as hospice, palliative, or conservative care prior to initiating dialysis. There is likely some recall bias. The current paradigm for initiating dialysis fails to routinely include conservative options potentially exposing subjects to increasing morbidity. We believe conservative care should be part of the informed consent process prior to starting dialysis.

PO0833

Health-Related Quality of Life During Dialysis Modality Transitions: A Mixed-Methods Study

Chance S. Dumaine,[1] Danielle E. Fox,[2] Pietro Ravani,[2] Maria Jose Santana,[2] Jennifer M. MacRae.[2] *[1]University of Saskatchewan, Saskatoon, SK, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Dialysis transitions may have an impact on health related quality of life (HRQOL), a patient defined priority for research and clinical care. We measured HRQOL and explored perceptions of adults who were initiating dialysis for the first time or transitioning to a new dialysis modality in a large urban centre in Canada.

Methods: In this prospective convergent parallel mixed-methods study we recruited eligible patients who were transitioning to dialysis from pre-care (n=9, incident) or undertaking a dialysis modality change (n=10, prevalent) between July and September 2017. Patients completed the five domains of the Kidney Disease Quality of Life-36 (KDQOL-36) survey on their first day of dialysis treatment or first day of home dialysis training and underwent a semi-structured interview and follow up KDQOL-36 survey at 3 months.

Results: 19 patients completed KDQOL-36 at baseline and at 3 months; 15 also participated in an interview. Statistically significant increases in all measured domains of the KDQOL-36 were observed from baseline to three months: "Symptoms" [mean difference (MD)=14.9, p<0.01]; "Effects" (MD=14.3, p<0.01); "Burden" (MD=7.3, p=0.04); "PCS" (MD=7.5, p<0.01); "MCS" (MD=7.2, p=0.04). These patterns of change were similar for both incident and prevalent patients and across the different types of transitions. The qualitative interviews identified the following themes: 1) adapting to new circumstances (tackling change, accepting change), 2) adjusting together 3) trade offs, and 4) challenges of chronicity (the impact of dialysis, living with a complex disease, planning with uncertainty.

Conclusions: The transition to a new or different type of dialysis is associated with improvements in HRQOL. In addition, qualitative data provided an in depth understanding of the transition experience, and revealed significant emotional and psychosocial processes that need to be considered during both incident and prevalent dialysis transitions.

PO0834

Prevalence and Demographic Correlates of Pain, Depression, Fatigue, and Readiness to Seek Treatment for These Symptoms in Hemodialysis Patients

Susan M. Devaraj,[1] Jonathan Yabes,[1] Maria-Eleni Roumelioti,[2] Jennifer L. Steel,[1] Sarah J. Erickson,[2] Mark L. Unruh,[2] Manisha Jhamb.[1] *[1]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [2]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Patients with End Stage Renal Disease on hemodialysis (HD) experience a high burden of pain, fatigue and depressive symptoms. This study aims to better understand demographic differences in symptom burden and readiness to seek treatment among HD patients being recruited for an ongoing multi-center randomized controlled trial (TACcare).

Methods: Patients on in-center HD were screened for clinical levels of pain (Likert scale ≥4), fatigue (Likert scale ≥5), and depression (Patient Health Questionnaire-9 score ≥10) within the last 2 weeks. Patients with at least one clinical symptom were then screened to assess readiness for seeking treatment for symptoms, and eligible to enroll if they were at least in the contemplation stage of Readiness for Behavior Change. Demographic differences in symptom screening and readiness to change (yes/no) were assessed using t-tests (age) and Chi-Square or Fishers Exact tests (race, ethnicity, gender). Symptom burden by readiness to change status was assessed using Chi-Square tests.

Results: Of the 390 patients who met eligibility criteria (mean age 59 years, 45% females, 15% Black, and 32% American Indian/Alaska Native, 29% Hispanic), 303 (78%) displayed at least one clinically significant symptom - pain, fatigue, or depression. Of those experiencing symptoms, 39% reported experiencing 1 clinically significant symptom, 35% reported 2, and 26% reported 3. There were no statistically significant differences by age, race, ethnicity, or gender in those reporting symptoms versus those who were not, or those ready to seek treatment (80%) versus those not ready to seek treatment (20%). Of those who were experiencing symptoms, the percentage of patients willing to receive treatment increased as the number of symptoms increased (71%, 86% and 90% willing to receive treatment with 1, 2 or 3 symptoms respectively, p<.01).

Conclusions: The majority of HD patients report experiencing at least one clinically significant symptom and experiencing more of these symptoms increased readiness to seek treatment. Demographic difference in symptom burden and readiness for treatment were not evident in this sample and should continue to be the focus of additional research.

Funding: NIDDK Support

PO0835

Latinx Patients' Perspectives on Their Kidney Disease Education and Recommendations for Improvement: A Qualitative Study

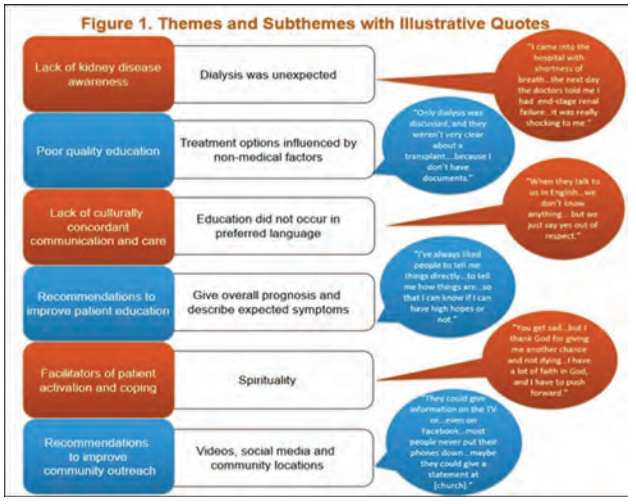
Tessa K. Novick,[1] Santiago Diaz,[1] Kavyaa D. Choudhary,[1] Doris A. Cubas,[1] Francisco A. Barrios,[1] Lilia Cervantes,[2] Elizabeth A. Jacobs.[3,1] *[1]The University of Texas at Austin Dell Medical School, Austin, TX; [2]University of Colorado, Denver, CO; [3]Maine Medical Center - Scarborough Campus, Scarborough, ME.*

Background: In most states, Latinx immigrants with kidney failure receive dialysis in acute care settings on an emergency-only basis. What and how much kidney disease education they receive, and how to improve kidney disease education and outreach among Latinx populations is unknown. The objective of this study was to understand the kidney disease educational gaps of Latinx individuals who need but lack access to scheduled outpatient dialysis.

Methods: We conducted a qualitative, semi-structured interview study in a Texas hospital system from March 2020 to January 2021 with 15 individuals who received emergency-only dialysis when they were first diagnosed with kidney failure. We collected demographic information, and performed thematic analysis using the constant comparative method on interviews after they were audio-recorded, translated and transcribed verbatim.

Results: All 15 persons interviewed (60% male; mean age 51 years) identified as Hispanic (73% Mexican), and none reported knowing about their kidney disease more than 6 months before starting dialysis. The themes were: 1) lack of kidney disease awareness; 2) education provided was incomplete and poor quality; 3) lack of culturally concordant communication and care; 4) elements Latinx patients receiving emergency-only dialysis want in their education; 5) facilitators of patient activation and coping; and 6) Latinx patient recommendations to improve community outreach.

Conclusions: Latinx adults receiving emergency-only dialysis are usually unaware of their kidney disease until shortly before or after they start dialysis, and the education they receive is poor quality, and often not culturally tailored. Participants made feasible recommendations on how to improve education and outreach among Latinx communities.



PO0836

Improving Education and Satisfaction of Hemodialysis Patients Through Anonymous Feedback

Arun Rajasekaran, Anand Prakash, Spencer Hatch, Yan Lu, Abolfazl Zarjou. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients on outpatient hemodialysis (OHD) are a particularly vulnerable population who may not feel comfortable sharing their experience given the complex and frequent nature of their care. This could lead to conceivable gaps in knowledge pertaining to improving their satisfaction and education. To account for this potential limiting factor and to build on previous surveys performed on OHD patients we conducted a study in nine of our university affiliated OHD units.

Methods: The study had 3 major objectives: 1) apprehend the level of satisfaction of patients with varying aspects of OHD related care, 2) evaluate level of understanding and education of patients regarding issues that pertain to their health and wellbeing, 3) identify potential avenues for improvement based on patients' input. The survey was in English, paper based, with individual answer choices graded using a 1-5 rating scale [1:very poor, 2:poor, 3:neutral, 4:good, 5:excellent]. To ensure anonymity, the completed surveys were folded and dropped into a box.

Results: Among 516 screened patients 228 did not participate. Additional 35 patients were excluded for ≥ 1 reasons: legally blind, unable to read/write/speak English, advanced dementia, too frail. 253 eligible patients completed the survey. While the overall results were reassuring with 18 out of 24 questions yielding an average of ≥ 4.2 per question, we found specific areas for improving care and education. These included providing additional resources and information regarding palliative care, mental health, cardiovascular diseases, transplant process, addressing discomfort during OHD, improving privacy, and improving the time that the nephrologist spends with patients.

Conclusions: The US centers for Medicare and Medicaid services ESRD prospective payment system and quality incentive program requires that dialysis centers meet predefined criteria for quality of patient care to ensure future funding. We took advantage of an anonymous survey to further reflect on the potential needs of this patient population to enhance their quality of life and education. Despite specific limitations, our survey demonstrated patients undergoing OHD were overall satisfied and had a good understanding about their overall health. However, we identified several aspects to improve upon as requested by our respondents.

PO0837

Provider Recognition of Patient-Reported Symptoms in Patients on Maintenance Hemodialysis

Huei Hsun Wen, Kinsuk Chauhan, Steven G. Coca, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Patients with ESKD on maintenance HD (HD) experience more symptoms than the general population. In order to enable better symptomatic management, it is critical that providers recognize and document these symptoms; however, recognition by nurses and physicians is unclear.

Methods: We surveyed patients that were receiving in-center HD for ≥30 days, and attended HD three times a week at the Mount Sinai Kidney Center. Patients were surveyed on if they experienced 21 symptoms over the past 24 hours at the end of their treatments for 12 sessions. The treating nurses were surveyed at the end of each iHD treatment to identify if the patient had any of the 21 symptoms. We considered a positive response on any of the 12 surveys as a positive during the study period. Physicians were asked during week three of the study period if the patient had experienced any of the 21 symptoms during the past 4 weeks.

Results: Of the 166 eligible patients, 101 consented to the study, and 97 completed all 12 surveys. The mean age was 56±14 years, 52% were female, and 52% were Black. The most common symptoms reported by the patients were fatigue (61%), cramping (59%), and dry skin (53%) **(Figure 1).** Nurses under-recognized 17/21 symptoms, mean relative difference of 54±33%. Physicians under recognized 16/21 symptoms, by a mean difference of 23±56%. Symptoms with the largest degree of under-recognition by nurses were dry skin (difference of 51 percentage points) and fatigue (difference of 42 percentage points). Physicians struggled most with recognition of cramping (difference of 39 percentage points) and fatigue (difference of 34 percentage points).

Conclusions: Patient symptoms were generally under-recognized by both dialysis nurses and physicians. While several symptoms such as shortness of breath, nausea, and vomiting were well recognized by nurses and physicians, nurses under-recognized dry skin and fatigue and physicians under-recognized cramping and fatigue.

PO0838

Improving Food Insecurity in Patients with ESKD on Hemodialysis: Partnership with Local Food Bank

Elaine T. Mccall, Emaad M. Abdel-Rahman. *University of Virginia, Charlottesville, VA.*

Background: Nutrition plays an important role in the management of ESKD on HD. Barriers to appropriate nutrition include medical, behavioral and socio-economic factors. Socio-economic factors may include poor purchase power and problems with transportation. Poverty rate at the area of University of Virginia (UVA) is 12.9%, which 1.3 times the state average.

Methods: UVA partnered with the local food bank to meet the basic nutritional needs of our patients by delivering renal appropriate diet to patients at the dialysis unit, with an aim of reducing individual food insecurity.

Results: The current UVA food bank collaboration program distributes more than 50 bags each month and roughly 80% of the entire dialysis program has received at least one bag since the inception of the program. Presently 34 patients consistently received bags each month (bi-monthly or greater distribution of bags). There was no significant changes in weight, serum albumin, calcium, phosphorus or potassium between baseline and 6 months of consistently receiving food bags. 28/34 (82.4%) patients responded to a survey. Patients were 64.3% African American with 57.1% females with average age of 61.3 years. Average household of these patients were 2.2, receiving 2.3 bags/week with an average of 3.3 meals /week. While 50% of patients reported satisfaction with the program, 14.3% were very satisfied, 32.1% neutral and 3.6% were unsatisfied. 57.1% viewed the food as healthy, with 21.4% perceived food to be very healthy, 17.8% were neutral and 3.6% viewed the food to be unhealthy. The majority of the patients reported improved nutrition with these food items (82.1%). While only 10.7% of the patients reported they had to skip a meal because of being short on food, 85.7% reported that these bags helped them eat more meals on a regular basis.

Conclusions: Partnership with local food banks helps decrease food insecurity and improved satisfaction in patients on hemodialysis. Nutritional parameters did not improve, which may be due to consumption of supplemental food outside of the program. Expanding such programs to other dialysis units and provision of more fresh fruits, vegetables, and meats could help decrease dependence on external sources of higher processed foods that contain high levels of potassium and phosphorus and may improve patients' outcomes.

PO0839

Medication Burden and Prescribing Patterns Among ESKD Patients on Hemodialysis in the United States, 2013-2017

Julie M. Paik, Min Zhuo, Seoyoung C. Kim, Rishi J. Desai. *Brigham and Women's Hospital, Boston, MA.*

Background: The medication burden of patients with ESKD on HD is amongst the highest of any of the chronic diseases. This study describes the medication burden and prescribing patterns in a contemporary cohort of patients with ESKD on HD in the U.S.

Methods: We used the United States Renal Data System database from January 1, 2013 and December 31, 2017 to quantify the medication burden of patients on HD aged ≥18 years. We included patients who had continuous Medicare parts A, B, and D coverage

for at least 3 months prior to January 1 of the respective year and excluded patients with a history of peritoneal dialysis or kidney transplant at any time prior to the year of interest. Patients could contribute data to multiple yearly cohorts. We calculated the average number of prescription medications per patient during each respective year, number of medications within classes, including potentially harmful medications, and trends in the number of medications and classes over the study period.

Results: We included 163,228 to 176,133 patients from 2013 to 2017. In 2013, the mean age was 63.5 years and increased to 65.1 years by 2017. The percentage in the age 18-64 years category decreased (51.3% in 2013 compared with 45.9% in 2017) and the percentage in the older age categories all increased. In 2013, 51.8% were male and 48.2% were female, compared with 53.6% male and 46.4% female in 2017. The overall burden of medications decreased slightly, from a mean of 7.4 (SD 3.8) in 2013 to 6.8 (SD 3.6) medications in 2017. Prescribing of potentially harmful medications decreased over time (74.0% with at least one harmful medication class in 2013 to 68.5% in 2017). In particular, the prescribing of non-benzodiazepine hypnotics, benzodiazepines, and opioids decreased from 2013 to 2017 (12.2% to 6.3%, 23.4% to 19.3%, and 60.0% to 53.4%, respectively). This trend was consistent across subgroups of age, sex, race, and low-income subsidy status.

Conclusions: Patients with ESKD on HD continued to have a high overall medication burden, with a slight reduction over time accompanied by a decrease in prescribing of several classes of harmful medications. Continued emphasis on assessment of appropriateness of high medication burden in patients with ESKD is needed to avoid exposure to potentially harmful or futile medications in this vulnerable patient population.

PO0840

The Impact of Late Initiation of Chronic Dialysis on Mortality: A National Retrospective Cohort Study

George L. Worthen,[1,2] David Clark,[1,2] Keigan More,[1,2] Amanda J. Vinson,[1,2] Karthik K. Tennankore.[1,2] *[1]Dalhousie University, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada*.

Background: Current Canadian guidelines recommend deferring dialysis initiation in asymptomatic patients until the glomerular filtration rate (GFR) reaches 6 mL/min/1.73m^2, (an "intent-to-defer" strategy). However, little is known about how dialysis initiation and post dialysis outcomes are impacted when patients start at or below this threshold.

Methods: We sought to characterize the impact of starting dialysis at or below 6 mL/min/1.73m^2 in a national retrospective cohort study of incident dialysis patients from 2004-2019. Dialysis data (excluding Manitoba and Quebec) was acquired from the Canadian Organ Replacement Register (CORR) and linked to hospitalization data using the well-established discharge abstract database (DAD). The cohort was restricted to only those who initiated dialysis as an outpatient and with previous nephrology follow-up of three months or more. Time to death was compared for those starting at or below 6 ml/min/1.73m^2 (using the CKD-EPI formula) to those initiating between an eGFR of 6-15 ml/min/1.73m^2 and analyzed using an adjusted cox proportional hazard model.

Results: A total of 63327 unique patients started dialysis from 2004-2019, of whom 39696 patients started dialysis as an outpatient after at least three months of nephrology follow-up. The mean age was 63+/-14, 68% were white, and 61% were male. 24% of the population started dialysis at an eGFR by CKD-EPI at or below 6 mL/min. Patients starting at 6 mL/min/1.73m^2 or below were more likely to start dialysis with a CVC (59% vs 50%, p<0.001). During the study period 18979 patients died (48%). Starting dialysis at or below 6 mL/min/1.73m^2 was associated with a longer time to death (HR 0.87; 95% CI 0.84,0.90) after adjusting for sex, race, age, dialysis access, diabetic kidney disease, and other comorbidities.

Conclusions: In this cohort of incident dialysis patients, those with an eGFR at or below 6 mL/min/1.73m^2 had a lower risk for mortality compared with those starting with a higher eGFR. These findings support deferral of dialysis initiation beyond the threshold of 6 mL/min/1.73m^2 in the absence of traditional indications.

PO0841

Hurricane Harvey Increased Need for Emergency Care in Patients with ESKD

Frederick I. Lemaistre,[1] Caroline M. Schaefer,[2] Donald A. Molony.[3] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]The University of Texas Health Science Center at Houston School of Public Health, Houston, TX; [3]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX*.

Background: During natural disasters, end-stage kidney disease (ESKD) patients may represent a particularly vulnerable population due to interruption in care. We hypothesize that mortality and medical complications significantly increased in ESKD patients as a result of the disruptions in care related to Hurricane Harvey (HH).

Methods: Ten outcome variables for patients receiving outpatient, inpatient and home dialysis in FEMA designate hurricane disaster areas during the months of Aug 2017 – Dec 2017 representing exposure to the effects of Hurricane Harvey, were compared with the same time periods in 2016 and 2018. In this retrospective cohort study, ESKD patients were stratified by dialysis modality. Inclusion criteria were patients identified with ESKD by Medicare, had received at least one dialysis treatment within the observed timeframe, and were continuously enrolled for the four months before and/or four months after HH landfall or enrollment was dropped due to death. Main outcomes of the study included mortality, inpatient admissions, emergency department (ED) visits, and diagnosis of complications.

Results: Using deidentified Medicare Claims data we identified 7,362 patients in the outpatient, 862 in the inpatient, and 810 in the home setting and compared outcomes in approximately stable populations in the years 2016 and 2018. Odds of ED visit was 31% greater (OR= 1.31, CI= [1.19, 1.44]) in 2017, compared to 2016 and 25% greater (OR= 1.25, CI= [1.14, 1.38]) compared to 2018. Odds of hyperkalemia was 37% greater (OR= 1.37, CI= [1.22, 1.55]) in 2017 than 2016. Nonwhite patients and men experienced lower odds of the outcomes of interest compared to white patients and women. Odds of gastrointestinal infection was 2.34 times more likely (OR= 2.33, CI= [1.32, 4.12]) in 2017 versus 2018. Black patients experienced increased odds of cerebrovascular accident (CVA) compared to white patients.

Conclusions: Using Medicare claims data we found significant differences in Emergency Department (ED) visits and incidence of hyperkalemia in HH exposed patients compared to patients receiving outpatient dialysis in 2016 and 2018. Catastrophic events represent dangers for ESKD populations with increased risk of complications and burden on the healthcare system. Better preparation for natural disasters may improve health outcomes associated with limited access to dialysis.

Tuscany Network Program for Evaluation of Functional Status in Hemodialysis: The Rehabilitation in Hemodialysis Area Centro Tuscany (REACT) Study

Alessandro Capitanini, Fiammetta Ravaglia, Giuseppe L. Spatoliatore, Matteo Paci, Alessandro M. Pacini, Alberto Rosati. *Nephrology and Dialysis Unit, USL Toscana Centro, Italy, Firenze, Italy*.

Background: Frailty is associated with adverse outcomes among hemodialysis patients. Hemodialysis sessions may represent an opportunity to reassess functional status, to plan and monitor long-term physical exercise, leading to considerable improvement of quality of life and physical performance. The objective of our study is to assess the prevalence and predictors of frailty among a cohort of prevalent dialysis patients in our area (REACT Study).

Methods: A regional program was designed to evaluate functional status in all patients performing hemodialysis in the 11 Dialysis Units of USL Toscana Centro. All patients are screened through the following tests: Short Form Health Survey (SF12); Elderly Falls Screening Test; Short Physical Performance Battery (SPPB); Handgrip test. Patients were assigned to three groups on the basis of the SPPB score: poor (SPPB <6), moderate (SPPB 7-9) and good performers (SPPB >9).

Results: Of the 920 hemodialysis patients assessed for eligibility, 446 were enrolled and divided in 3 groups on the basis of SPPB score. Characteristics of the participants and functional status evaluation are shown in Table 1. SPPB score shows a significant correlation with handgrip of right arm (r=.248, p<0.001), with handgrip of left arm (r=.211, p<0.001), with Elderly Falls Screening Test (r=.448, p<0.001), with SF12 physical component (r=.432, p<0.001), with SF12 mental component (r=.146, p<0.001). Principal predictors of SPPB score are Elderly Falls Screening Test (adjusted R^2=.235), and age (cumulative adjusted R^2=.361).

Conclusions: In our hemodialysis population, SPPB allowed identification of 3 frailty phenotypes. The information needed to determine patients' degree of frailty can be gathered relatively easily, making frailty assessment a routine activity in hemodialysis patients' evaluation.

Table 1

Variable	Poor performers (n=119)	Moderate performers (n=119)	Good performers (n=208)	p value
Female sex – no. (%)	57 (47.8)	44 (36.9)	76 (36.5)	
Age - yr	75.1±9.8	72.4±10	60.2±14.7	
Dialytic age – mo	74.7±9.89	72.4±9.99	60.0±14.7	
SPPB score	3.5±2.24	8.2±0.79	11.2±0.87	
Handgrip test - kg (right arm/left arm)	20.9±10.9/19.1±11.4	24.8±14.1/23.2±13.7	30.5±15.1/26.8±14.6	<0.001
Elderly Falls Screening Test - score	2.5±1.4	1.2±1.6	0.7±1.0	<0.001
SF12 physical score	32.8±9.8	38.9±9.9	44.0±9.5	<0.001
SF12 mental score	46.0±12.3	46.9±12.0	49.2±11.2	0.45

PO0843

Functional Prognosis Following Cerebral Hemorrhage in Patients on Hemodialysis

Yusuke Watanabe, Tsutomu Inoue, Hirokazu Okada. *Saitama Ika Daigaku Igakubu Daigakuin Igaku Kenkyuka, Iruma-gun, Japan*.

Background: It has been reported that patients on hemodialysis have a higher morbidity and mortality for hypertensive cerebral hemorrhage. However, little is known about the functional outcomes in the surviving patients.

Methods: We retrospectively analyzed 62 consecutive patients on hemodialysis who developed hypertensive cerebral hemorrhage between 2016 and 2020. Patient background data, data on the clinical presentation of cerebral hemorrhage, and details of the lifesaving brain surgery (craniotomy for removal of hematoma and ventricular drainage) were reviewed. The outcomes examined were in-hospital mortality and Glasgow Coma Scale (GCS), modified Rankin Scale (mRS), and Functional Independence Measure (FIM) scores at discharge.

Results: The median age of the patients was 66.5 years (interquartile range [IQR] 61.8–72.5). The median GCS score at admission was 13 (IQR, 6–14). Ventricular perforation was observed in 46.8% of patients. The median estimated hematoma volume

was 26.9 mL (IQR, 7.7–69.6). The in-hospital mortality rate was 29.0%. Palliative care policy was selected by 16.1% of patients at admission, and 27.4% of patients underwent a lifesaving brain surgery. Compared with survivors, the non-survivors had a lower level of consciousness at admission (GCS score, median [IQR]: 4.5 [3–8] vs. 14 [11–14], respectively, $p<0.001$), higher rate of ventricular perforation (88.9% vs. 29.5%, $p<0.001$), and larger estimated hematoma volume (55.5 [29.6–124.5] vs. 16.3 [5.5–43.6] mL, respectively, $p=0.003$). After excluding patients with palliative care policy at admission, the ventricular perforation rate and estimated hematoma volume were higher in patients who underwent surgery than those who did not undergo surgery. Patients who underwent brain surgery had a lower level of consciousness, mRS score (median [IQR], 4.0 [3.0–4.0] vs. 5.0 [5.0–6.0], respectively $p<0.001$), and FIM score (18 [18–53.8] vs. 59 [20–84.5], respectively, $p=0.009$) at discharge than patients who did not undergo surgery.

Conclusions: In our single-center experience, a lower level of consciousness at admission, larger estimated hematoma volume, and ventricular perforation were associated with high mortality in patients on hemodialysis with cerebral hemorrhage. Survivors who underwent the lifesaving brain surgery had very poor functional outcomes at discharge.

PO0844

Hyperammonemia in an ESRD Patient

Roy Rajan, Kimberly J. Manzella, Charles W. Hopley. *Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.*

Introduction: Carnitine is an important co-factor in long-chain fatty acid metabolism, and is involved in transport of long chain fatty acids into the mitochondria. Carnitine deficiency can present with hyperammonemia. We present a patient with ESRD with hyperammonemia and encephalopathy.

Case Description: This is a 48-year-old man with End Stage Renal disease due to neprocalcinosis secondary to treatment complications due to X- Linked Hypohposphatemic rickets, presented to emergency room with nausea vomiting and severe confusion. He had no known liver disease or seizure disorder and was not on valproate or any other psychotropic medications. His liver enzymes were normal AST, ALT, albumin levels but he had persistently elevated alkaline phosphatase of 313 unit / L (40-130). PCO2 levels were normal. L. His ammonia level of 578 micro mol/L. There was no intracranial abnormalities on imaging. Free carnitine (FC) levels came back as 26 nmol/ml (25-54), Acyl Carnitine (AC) 13 nmol/ml (5-30) AC/FC ratio of 0.5. Even though he had low normal FC levels, his AC/FC ratio was elevated and it has been proposed that car/acyl car ratio greater than 0.4 represents carnitine deficiency. Patient initiated on IV L carnitine 20 mg/Kg three times weekly without repeat episode of hyperammonia. It was also noted that patient no longer experienced intradialytic hypotension.

Discussion: Carnitine deficiency causes accumulation of non-oxidized fatty acyl-coenzyme A in the mitochondria, which inhibits degradation of ammonia. This typically responds to supplementation. An inverse correlation between plasma carnitine levels and ammonia has been observed in patients treated with valproic acid, and L Carnitine has been used as treatment reduce the ammonia levels in valproate induced hyperammonemia. Carnitine deficiency can present with hyperammonia, and clinicians should have high index of suspicion for this entity in malnourished dialysis patients without significant liver disease. Treatment is directed at replacement with intravenous Carnitine. Oral preparation containing mixture of D and L- carnitine is available but D- Carnitine is toxic. L- carnitine has limited oral absorption and has a limited bioavailability of 15%. The unabsorbed carnitine is degraded by intestinal bacteria to metabolites that are potentially toxic and have been shown to cause cognitive impairment. These limits use of oral supplementation of Carnitine.

PO0845

Neurocognitive Function with Conventional Hemodialysis vs. Post-Dilution Hemofiltration as Initial Treatment: A Randomized Controlled Trial (The DA-VINCI Study)

Enzo C. Vasquez jiménez,[1,2] María Guadalupe C. Núñez,[1] Salvador L. Gil,[1] Abel V. Lerma Talamantes,[3] Claudia V. Lerma Gonzalez,[1] Aloha V. Meave Gonzalez,[1] Magdalena Madero.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto de Seguridad Social del Estado de Mexico y Municipios, Toluca, Mexico; [3]Universidad Autonoma del Estado de Hidalgo Instituto de Ciencias de la Salud, Pachuca, Mexico.*

Background: The ideal modality choice and dialysis prescription during the first renal replacement therapy (RRT) session remains controversial. We conducted a pilot study to determine the safety risk for hemodialysis versus hemofiltration and its relationship with neurocognitive assessment on incident RRT patients.

Methods: Twenty-four incident RRT patients were included. Patients were randomized the conventional HD group or the post-dilution HF group. MMSE and MOCA tests were applied in all patients before and after RRT and brain MRI was performed in 7 patients from each group before and after the intervention.

Results: Baseline characteristics were similar between groups. Compared to conventional HD, post-dilution HF had longer treatment time and blood volume. There were no significant changes in blood pressure after RRT in both groups. The MMSE test showed no significant differences between groups or within groups. The MOCA test showed an increase in the total score for the post dilution HF group with no significant changes between groups. The magnetic resonance image (MRI) evaluation showed no differences between or within groups.

Conclusions: Post-dilution hemofiltration is a safe alternative for the first hemodialysis session in incidence RRT; it allows longer treatment time if ultrafiltration is required has a similar neurological risk than conventional HD.

Hemodialysis and hemodynamic variables.

	Conventional HD (n = 12)	Conventional HD (n = 12)	Post dilution HF (n = 12)	Post dilution HF (n = 12)

PO0846

Intradialytic Yoga-Based Breathing and Relaxation to Improve Anxiety, Depression, and Quality of Life: A Pilot Feasibility Study

Fran Conway,[1] Martha N. Desta,[2] Young sun Jung,[2] Daniel M. Levine,[2] Andrew Bohmart.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Background: In-center hemodialysis patients have high rates of depression and anxiety. Pharmacologic interventions to ameliorate psychological burdens have proven to be limited in efficacy. Alternative therapies are increasingly used for those with chronic disease. A small number of studies have looked at the impact of meditation and yoga to improve symptoms of anxiety and depression and to promote a better quality of life. The aim of this study was to test the feasibility of implementing a chairside intradialytic yoga-based breathing and relaxation technique. A secondary goal was assessing the efficacy of such an intervention.

Methods: Eligible subjects were patients with a below average score on the Mental Component Summary (MCS) of a previously completed Kidney Disease Quality of Life (KDQOL™-36) survey. Following consent, each subject was provided with an MP3 player, pre-loaded with a 12-minute recording of a specific yogic breathing and relaxation exercise, the Three-Part Breath. The intervention consisted of listening to the recording at each dialysis treatment over a 12-treatment period. Subjects completed a KDQOL™-36 survey both at the start and the end of the study. A Likert scale to measure anxiety was completed at each dialysis treatment both pre- and post-intervention.

Results: 11 subjects were enrolled over a 10-month period in 2020; 10 completed the study. As measured by the Likert scale, anxiety was significantly reduced after listening to the recording. Notably, there was a larger reduction in anxiety on a per treatment basis in the period after the start of the Covid-19 pandemic compared to the pre-pandemic period. Over the study period, there was a significant improvement in the scores of the Effects of Kidney Disease on Quality of Life component of the KDQOL™-36, and a trend toward significant improvement in the Mental Component Summary scores.

Conclusions: A chairside intradialytic breathing and relaxation program can be integrated into a dialysis treatment session. The study demonstrates an improvement in scores related to anxiety, depression, and measures of quality of life. Larger and randomized trials using this intervention are needed to better understand its benefits and adverse effects, as well as the obstacles to large scale implementation.

PO0847

Quality of Life and Symptom Burden Before and After Start of Dialysis in Older Patients

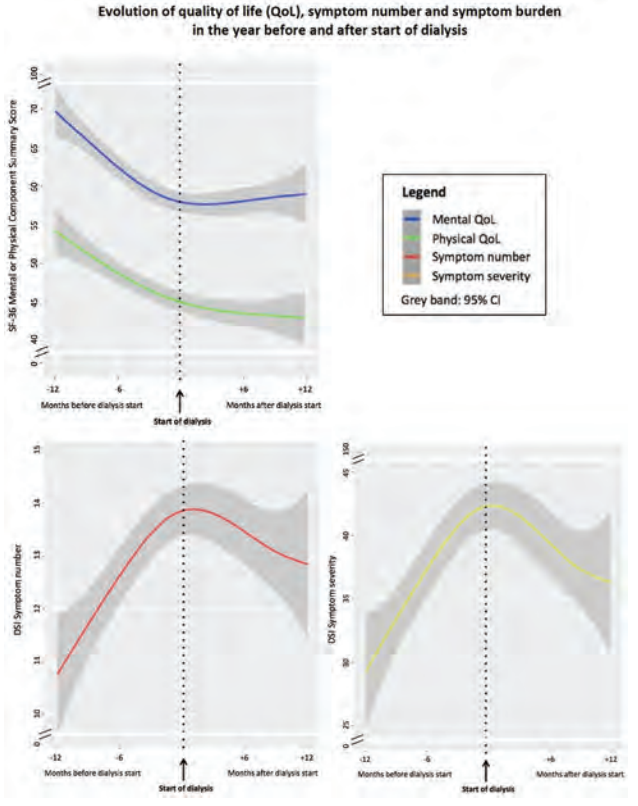
Esther N. de Rooij,[1] Yvette Meuleman,[1] Johan W. De Fijter,[1] Kitty J. Jager,[2] Nicholas C. Chesnaye,[2] Christoph Wanner,[4] Friedo W. Dekker,[1] Ellen K. Hoogeveen.[1,3] the EQUAL Study investigators *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [3]Jeroen Bosch Ziekenhuis, 's-Hertogenbosch, Netherlands; [4]Universitatsklinikum Wurzburg, Wurzburg, Germany.*

Background: The number of ESKD patients ≥65y starting chronic dialysis increases. Many of these patients have low quality of life (QoL) and high symptom burden. Little is known about the effect of dialysis initiation on QoL and symptoms. Therefore, we studied QoL and symptoms before and after start of dialysis in older patients.

Methods: The European Quality (EQUAL) study is an ongoing prospective multi-center cohort study in late stage 4/5 CKD patients ≥65 years. For this analysis, we included all patients who started dialysis. QoL was assessed every 3-6 months using the SF-36, resulting in a physical (PCS) and mental (MCS) component score, with higher scores meaning better QoL. Symptom number and severity were assessed every 3-6 months using the dialysis symptom index (DSI), with higher scores meaning higher burden. With linear mixed models we explored the evolution of mental and physical QoL, symptom number and severity in the year before and after dialysis start.

Results: We included 571 older patients at dialysis start. Mean (SD) age was 77 (6) years, 74% were men, 45% had diabetes or cardiovascular disease and mean eGFR was 8.2 (3.7) ml/min/1.73m^2. In the year before dialysis MCS decreased by -15.7 (95% CI: -19.5 to -11.8), PCS by -12.0 (-15.7 to -8.2), symptom number increased by +3.5 (+2.5 to +4.6) and severity by +14.8 (+10.9 to +18.8). In the year after, MCS increased by +1.9 (-2.7 to +6.4), PCS decreased by -2.1 (-6.9 to +2.7), symptom number by -0.9 (-2.1 to -0.3) and severity by -6.0 (-10.4 to -1.7).

Conclusions: Mental and physical QoL, symptom number and severity, worsened considerably in the year before dialysis, but stabilized after dialysis initiation. These results could inform older ESKD patients who consider starting dialysis.



PO0848

Objective Evaluation of Quality-of-Life Assessment as Predictors of Overall Health in Hemodialysis Patients in KSA

Afef Dridi, Laila Halawani, Ayman Sabri. *DaVita KSA, Riyadh, Saudi Arabia*.

Background: Dialysis effect on a patient's quality of life (QoL) is associated with death in regular hemodialysis (HD) patients and is a marker of wellbeing. In addition to clincal outcome measures QoL is influenced by socioeconomic status and education. Our aim was to explore the QoL in HD patients in population of prevalent HD patients in KSA.

Methods: The study consisted of 1032 patients undergoing HD in 17 centers. Data were collected by the completion of a specially designed questionnaire The Kidney Disease Quality of Life-Short Form (KDQOL-SF™) Arabic version 1.3 for assessing QoL.

Results: The study included 1032 patients (527 [51%] males and 505 [49%] females) with mean age 54.1 (±16.6) years and undergoing HD for 57.9 (±65.3) months. Multiple logistic regression analysis was done to identify parameters that independently associated with QoL. Lowest score was for the "burden of kidney disease" 33.1 (±23.4). Both "Physical Health Composite" (PHC) and "Mental health composite" (MHC) scores were poor as well, 36.5 (±8.7) and 42.0 (±8.7) respectively. "Patient satisfaction" and "Dialysis staff encouragement" scores were relatively higher 71.5 (±22.7) and 84.4 (±18.8) respectively. Age, duration of HD, cardiac comorbidity and abnormal phosphorus level were significant negative predictors for "overall health" scores while education and home medications' count were significant negative predictors for that domain. Abnormal phosphorus level and longer durations on HD treatment were significant negative predictors for "overall health", "MHC", "Burden of kidney disease" and perceived "Dialysis staff encouragement" scores. Age, female gender and hypoalbuminemia were significant negative predictors of "PHC" sores. Controlling serum phosphorus level and albumin might predict better QoL.

Conclusions: Misconceptions about QoL still represent a substantial barrier among HD patients. Most are educated about fundamental clinical outcomes after initiation of dialysis. In our study, Patients on hemodialysis have a poor QoL score. Different sociodemographic and clinical characteristics affect scores. Initiatives to promote and improve onboarding dialysis education and knowledge about QoL are needed to improve the low QoL in Saudi Arabia. Such patients may benefit from efforts on the part of the health care provider to support patient QoL as part of the monthly care plan.

PO0849

Fatal and Non-Fatal Gastrointestinal Events with Sodium Polystyrene Sulfonate Use in Hemodialysis: DOPPS

Ana C. Farfan Ruiz, Greg A. Knoll, Emily Rhodes, Manish M. Sood. *University of Ottawa Faculty of Medicine, Ottawa, ON, Canada*.

Background: There are increasing concerns regarding the gastrointestinal (GI) safety of sodium polystyrene sulfonate (SPS), a medication commonly used in the management of hyperkalemia. The objective is to compare the risk for fatal, non-fatal and their composite GI events following initiation of SPS in patients on hemodialysis compared to non-use

Methods: An international registry of adults (≥18) on chronic intermittent hemodialysis (Dialysis Outcomes and Practice Patterns Study, DOPPS, Phases 2-6 from 2002 to 2018, 17 countries, n=229,295) who were prescribed SPS (n=24,668, 10.76%) were compared with non-users of SPS. Individual patient and facility-level analysis of fatal and non-fatal GI events were examined using weighted models.

Results: Country-level variation in SPS use ranged from 0.74% (UK) to 47.42% (France). 934 fatal, and 837 non-fatal events occurred [3-year cumulative incidence for fatal GI events: SPS 9.0% vs. no SPS 7.6%; non-fatal: SPS 0.4% vs. non-use 0.5%]. The weighted risk of fatal and composite GI events was elevated with SPS use compared to non-use (fatal HR 1.18 95%CI 1.05-1.32, non-fatal HR 0.73 95%CI 0.64-0.84, composite HR 1.02 95%CI 0.82-1.26). Younger age (<=65), men, country (France, Belgium, Japan), dialysis vintage (>4 years), shorter HD treatment time (<3.5 hours) and a higher K gradient (serum potassium – dialysate potassium) were associated with a higher risk of a fatal GI event with SPS. The findings were consistent when limited to individuals with known vascular access (n=135, 628) and in an analysis examining the fraction of SPS use by facility.

Conclusions: SPS use in patients on hemodialysis is associated with a higher risk of fatal GI events.

Improved One-Year Survival and Decreased Hospitalization Rate in Incident Hemodialysis Patients with Incremental as Compared to Standard Hemodialysis Regimen: A Single-Centre Experience

Patrick Saudan, David A. Jaques, Cyrielle Alves, Pierre-Yves F. Martin. *Nephrology Unit, Geneva University Hospitals, Geneva, Switzerland*.

Background: Preservation of residual kidney function (RKF) in maintenance hemodialysis (HD) patients is associated with better survival and quality of life. RKF may be better preserved with an incremental HD regimen in patients starting HD. Since 2013, incremental HD (frequency < 3x/week) has been used in our center.

Methods: Incremental HD is implemented in incident HD patients who have a daily residual diuresis > 600 ml, a urea clearance ≥ 2 ml/mn and an interdialytic weight gain < 2.5 kgs. Patients are clinically assessed every week and a 24 hr-urine sample is collected every other month in order to measure RKF.

Results: From January 2013 to March 2020, 295 patients started chronic dialysis in our center, of whom 221 were on hemodialysis. Among them, 63 patients started maintenance HD with an incremental regimen. These patients did not differ significantly from those with a thrice-weekly HD regimen in terms of age, gender and comorbidity score. Residual diuresis, eGFR and urea clearance at incremental HD initiation were respectively 1842 ± 749 ml/day, 6.7± 3.1 ml/mn and 4.0 ± 1.8 ml/mn. Among those 63 patients, four could retrieve a sufficient RKF to become dialysis-independent after a mean 6-month duration of incremental HD and 2 were transplanted while on incremental dialysis. Among the remaining 57 patients, mean duration of incremental HD until transition to a thrice-weekly HD regimen or death was 12 ± 12 months (median, IQR: 10, 6-20). Within the first dialysis year, survival and hospital-free days (median, IQR) were higher in patients starting with incremental HD than in patients with a thrice-weekly HD regimen (91 vs 77%; p=0.02 and 344 (318-360) vs 338 (295-354) days; p=0.03).

Conclusions: These preliminary results show that incremental HD can be implemented in incident HD patients as long as regular clinical and RKF assessments are found adequate. However, randomised clinical trials assessing long-term survival and quality of life in incremental HD are necessary prior to its large-scale implementation.

PO0851

Association Between Systolic Blood Pressure Changes and Residual Kidney Function Decline Among Hemodialysis Patients After 1 Year

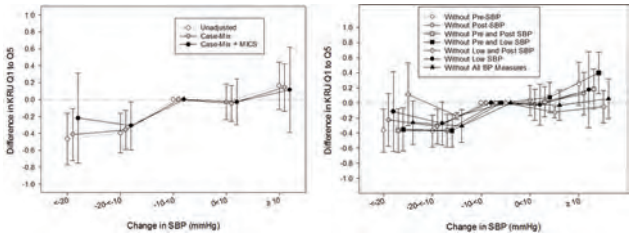
Miguel A. Morillo,[1] Jui-Ting Hsiung,[1] Csaba P. Kovesdy,[2,3] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]University of California Irvine, Irvine, CA; [2]VA Memphis Medical Center, Memphis, TN; [3]The University of Tennessee Health Science Center, Memphis, TN*.

Background: For patients undergoing hemodialysis, large changes in systolic blood pressure (SBP) from before to after the dialysis has been associated with worse survival. Declines in residual kidney function has also been associated with worse survival. However, the association between SBP changes and residual kidney function decline has not yet been examined.

Methods: We constructed a retrospective cohort of 6659 hemodialysis patients who started dialysis between 2007-2011 with data on average baseline changes in SBP and renal urea clearance (KRU) at the 1st and 5th patient quarter (91 day interval from dialysis start). KRU difference was measured as KRU difference between 5th minus 1st patient quarter. The association between baseline average changes in SBP and KRU difference was examined using linear regression analyses. Covariates included age, sex, race, BMI, dialysis modality type, and comorbidities.

Results: Linear regression analysis indicated a linear relationship between change in SBP and KRU decline even after adjusting for covariates. Trends across all models showed hemodialysis patients with increased systolic blood pressure showed increased residual kidney function compared to the reference (-10 to -0 mmHg). After adjusting for covariates, hemodialysis patients with SBP levels that increased by 10mmHg or more had the greatest increase of KRU (0.12, 95% CI (-0.39, -0.62)), while patients with a decrease of SBP by 10-20mmHg had the greatest decline (-0.31, 95% CI (-0.60, 0.02)). Models adjusting for SBP measures showed similar trends, while the model without low-SBP and post-SBP showed an increased in KRU when SBP decreased by 10-20mmHg (0.23, 95% CI (0.01, 0.05).

Conclusions: Increase in SBP was associated with a greater KRU decline in hemodialysis patients. Futher studies should examine the underlying causes of this association and determine if modifications to dialysis treatments can improve preserving KRU and patient survival.



PO0852

Respiratory Fluoroquinolones and the Risk of Sudden Cardiac Death Among Patients Receiving Hemodialysis

Magdalene M. Assimon,[1] Patrick H. Pun,[2] Lily Wang,[1] Sana Al-Khatib,[2] M. Alan Brookhart,[2] David Weber,[1] Wolfgang C. Winkelmayer,[3] Jennifer E. Flythe.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Duke University, Durham, NC; [3]Baylor College of Medicine, Houston, TX*.

Background: Respiratory fluoroquinolones are one of the most common classes of medications with QT prolonging potential prescribed to patients receiving hemodialysis. Some studies in the general population have linked their use to sudden cardiac death (SCD). However, evidence linking respiratory fluoroquinolones to adverse cardiac outcomes in dialysis patients, a population with an exceptionally high baseline risk of SCD, is limited to case reports of torsades de pointes.

Methods: Data were obtained from a cohort of Medicare-enrolled hemodialysis patients in the U.S. Renal Data System registry (2007–2016). Using a new-user design, we conducted a retrospective cohort study to assess the comparative 5-day risk of SCD between hemodialysis patients initiating a respiratory fluoroquinolone (levofloxacin or moxifloxacin) vs. an amoxicillin-based antibiotic (amoxicillin or amoxicillin/clavulanic acid). We used an intention-to-treat analytic approach and propensity score weighted survival models, adjusting for numerous demographic and clinical covariates, to estimate weighted hazard ratios (HRs) and their 95% confidence intervals (CIs). Non-SCD was treated as a competing event.

Results: The study cohort included 264,968 unique hemodialysis patients and 626,322 study antibiotic treatment episodes: 251,726 (40.2%) respiratory fluoroquinolone treatment episodes and 374,596 (59.8%) amoxicillin-based antibiotic treatment episodes. Respiratory fluoroquinolone vs. amoxicillin-based antibiotic treatment was associated with a higher 5-day risk of SCD, weighted HR (95% CI) = 1.95 (1.57, 2.41). The association was more pronounced among individuals concurrently taking other QT prolonging medications, weighted HR (95% CI) = 2.50 (1.61, 3.88). Sensitivity analyses 1) using longer follow-up durations and 2) evaluating a composite outcome of SCD or new-onset ventricular arrhythmia yielded similar results.

Conclusions: Respiratory fluoroquinolone (vs. amoxicillin-based antibiotic) treatment was associated with an increased risk of SCD. Future research is needed to determine optimal strategies for cardiac monitoring when these medications are prescribed to patients receiving hemodialysis.

PO0853

Variability of Plasma Refill Rate and Risk of Intradialytic Hypotension During Maintenance Hemodialysis

Hao Wang,[1] Dan Negoianu,[1] Hanjie Zhang,[2] Sabrina Rogg,[4] Jesse Y. Hsu,[1] Peter Kotanko,[2,3] Jochen G. Raimann,[2] Laura M. Dember.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany*.

Background: Continuous hematocrit data can be combined with time-updated ultrafiltration data to non-invasively estimate a semi-instantaneous plasma refill rate (PRR) throughout hemodialysis. The PRR is a dynamic metric that varies throughout hemodialysis, even during periods of constant rates of ultrafiltration, and is influenced by oncotic and hydrostatic forces. We aimed to determine whether variability in PRR is associated with intradialytic hypotension (IDH).

Methods: We used data from continuous hematocrit monitoring performed at 17 dialysis units from January 2017-October 2019 to calculate intradialytic plasma refill rates standardized to weight and height. PRR variability was defined as the coefficient of variance in PRR (PRR_{cov}) every 15 minutes and categorized into three groups: low (PRR_{cov} < 1.0), moderate (PRR_{cov} 1.0-2.0) and high (PRR_{cov} > 2.0). IDH was defined in three ways: (1) nadir systolic blood pressure (SBP) < 90 mmHg, (2) SBP < 90 mmHg or associated symptoms, and (3) either drop in SBP of 20 mmHg or mean arterial blood pressure of 10 mmHg with associated symptoms. Cox proportional hazard regression was used to assess the impact of starting PRR variability on time to first IDH. Marginal structural modeling was used to assess the impact of time-updated plasma refill rate variability on the risk of IDH.

Results: Among 2350 patients and 184,453 hemodialysis sessions, mean session time was 220 ± 26 min and ultrafiltration rate was 9.0 ± 3.3 ml/kg/hr. Median PRR_{cov} was 1.20 (IQR 0.68, 2.18) across all sessions. Compared to hemodialysis sessions with low PRR_{cov}, sessions with high PRR_{cov} in the first 15 minutes of treatment were associated with a 1.14 hazard of intradialytic hypotension (95% CI 1.05, 1.24). Accounting for repeated measures and changes in systolic blood pressure and ultrafiltration, sessions with high PRR_{cov} throughout the duration of hemodialysis were associated with an increased risk of IDH based across definitions: definition 1 (OR 1.29, 95% CI 1.16, 1.43), definition 2 (OR 1.85, 95% CI 1.77, 1.94), and definition 3 (OR 1.87, 95% CI 1.78, 1.98).

Conclusions: PRR variability was associated with higher risk of IDH, independent of time-varying confounding from SBP and UFR. PRR variability could be a promising bedside metric for hemodynamic instability during hemodialysis.

PO0854

Systemic Parameters of the Renin-Angiotensin-Aldosterone System Remain Unaffected by Changes in Fibroblast Growth Factor 23 Levels in Hemodialysis Patients

Katharina Dörr,[1] Michael Kammer,[1] Roman Reindl-Schwaighofer,[1] Matthias Lorenz,[1] Rodrig Marculescu,[1] Marko Poglitsch,[2] Rainer Oberbauer.[1] *[1]Medizinische Universitat Wien, Wien, Austria; [2]Attoquant, Vienna, Austria*.

Background: Fibroblast growth factor 23 (FGF23) is elevated in patients with chronic kidney disease and promotes the development of left ventricular hypertrophy (LVH). Decreasing the levels of FGF23 with the calcimimetic drug etelcalcetide can abate that effect in hemodialysis patients. It is unknown if the prohypertrophic effect of FGF23 is modified by the renin-angiotensin-aldosterone system (RAAS). The aim of the analysis was to determine whether changes in FGF23 levels are associated with differences in RAAS-parameters in hemodialysis patients, possibly explaining its influence on LVH.

Methods: Serum samples were obtained at baseline and one year from participants in the randomized EtECAR-HD trial. In this study 62 hemodialysis patients were treated with either calcimimetic or vitamin D treatment, which have opposite effects on FGF23. We analyzed PRA-S as the angiotensin-based marker for renin activity, angiotensin II (AngII), angiotensin-converting enzyme-2 (ACE2) and aldosterone using a high throughput mass spectrometry assay.

Results: The median levels of FGF23 were 2386 pg/ml (1st to 3rd quartile 819–5166) and 1386 pg/ml (288–4068) at baseline and end of study, respectively. The association of changes between baseline and end of study in FGF23 with the levels of the RAAS-components (i.e. PRA-S, AngII, ACE2, aldosterone) estimated by linear regression models was weak, with effect sizes for log2-fold-change in FGF23 close to zero. The amount of explained variation by FGF23 fold-change was generally small (drop-in-R^2 values all below 0.03). The median overall levels of PRA-S were 130 pg/ml (1st to 3rd quartile 46-269), of AngII 70 pg/ml (28-157), of aldosterone 130 pg/ml (54-278) and of ACE2 1.4 ng/ml (1.1-1.8), as compared with healthy controls (PRA-S 196 pg/ml [98-238], AngII 137 pg/ml [76-201], aldosterone 335 pg/ml [139-454], ACE2 1.38 ng/ml [1.17-1.65]).

Conclusions: In the present study we were able to show that systemic RAAS activity was grossly unaffected by the treatment induced changes in FGF23 levels in this cohort. Overall, the levels of PRA-S, AngII and aldosterone were well below the ranges measured in healthy controls suggesting that the RAAS is not systemically activated in hemodialysis patients.

PO0855

Prediction of Left Ventricular Function Using Electrocardiogram Data in Patients on Hemodialysis

Akhil Vaid,[1] David M. Charytan,[2] Lili Chan,[1] Girish N. Nadkarni.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]NYU Langone Health, New York, NY.*

Background: Left ventricular (LV) systolic dysfunction is common in patients on maintenance hemodialysis (HD). Early identification of patients with depressed left ventricular ejection fraction (LVEF) can facilitate disease modifying treatment. Electrocardiograms (ECGs) are routinely performed in patients on HD, however they have not been used for estimating LVEF in this population.

Methods: We analyzed data from five Mount Sinai facilities. Patients on HD with a transthoracic echocardiogram within 7 days of an ECG were identified using diagnostic and procedure codes. ECG data were preprocessed to remove recording artifacts, plotted to an image, and along with patient demographics were analyzed using a model comprised of a Multi-Layer Perceptron and a Convolutional Neural Network. We developed three models; 1) trained from scratch in only HD patients, 2) pre-trained on natural images (Imagenet), and 3) pre-trained on all LVEF:ECG pairs (n=696,890) excluding those for ESRD patients. Models 2 and 3 leverage transfer learning, which reuses knowledge gained from a task to perform a similar task. All models were trained/tested on LVEF:ECG pairs for ESRD patients within a Group Stratified K Fold (K=5) Cross Validation design, and performance was compared per Area Under Receiver Operating Characteristic curve (AUROC) for each category of LVEF, ≤40%, 41 to ≤50%, and >50%.

Results: We extracted 18,626 LVEF:ECG pairs for 2,168 ESRD patients. For detection of LVEF ≤ 40%, models trained from scratch and pre-trained on Imagenet had AUROCs of 0.74 (95% CI: 0.67-0.80) and 0.71 (95% CI: 0.65-0.77) respectively. These were outperformed by the model pre-trained on ECG data [AUROC of 0.91 (95% CI: 0.88-0.93)]. Similar results were seen at detection of LVEF 41 to ≤50% with the AUROC being 0.55 (95% CI: 0.49-0.6) for both the model trained from scratch and the Imagenet model, while the model pre-trained on ECG data achieved an AUROC of 0.82 (95% CI: 0.78-0.87).

Conclusions: A model pre-trained on non-HD LVEF:ECG pairs using transfer learning consistently outperformed models trained from scratch or pre-trained on Imagenet. This model can facilitate identification of LV systolic dysfunction in patients on HD.

Clinical Outcomes of Bioimpedance Analysis-Guided Hemodialysis: A Meta-Analysis of Randomized Controlled Trials

Panupong Hansrivijit,[1] Chenchen Qian,[1] Sumit Mohan.[2] *[1]UPMC Pinnacle, Harrisburg, PA; [2]Columbia University Irving Medical Center, New York, NY.*

Background: Determination of fluid status in hemodialysis patients could be a great challenge for providers. Body composition monitoring using bioimedance analysis (BIA) is an emerging tool in guiding fluid removal in hemodialysis population. However, although there are some randomized controlled trials (RCT), the reported outcomes remain heterogenous and inconclusive across studies.

Methods: Ovid MEDLINE, EMBASE and the Cochrane Library were searched for eligible articles through May 2021. Inclusion criteria were: 1) RCT comparing BIA against clinical assessment, 2) sample size > 50, 3) adults > 18 years on hemodialysis (HD), 4) clinical outcomes were reported. No publication bias detected by Egger's regression intercept analysis.

Results: A total of seven RCTs (n = 1029 total; 519 BIA, 510 control), dated from 2010 to 2019, with a mean follow-up duration of 15.0±10.6 months were identified. There was no difference in mortality between BIA and clinical group (odds ratio [OR] 0.797; 95% CI 0.431, 1.472; I2 13.2%). BIA group had significantly lower weight change during follow-up duration compared to clinical group (standard means difference [SMD] -0.270; 95% CI -0.532, -0.008; I2 9.6%). Clinical group had significantly higher systolic blood pressure compared to BIA group (SMD 0.157; 95% CI 0.034, 0.280; I2 2.3%) with a mean difference of 3.052 mmHg (95% CI 0.851, 5.253; I2 0%). Clinical group had significantly higher pulse wave velocity compared to BIA group (SMD 0.795; 95% CI 0.545, 1.045; I2 0%). Clinical group had significantly higher pre-HD body weight (SMD 0.280; 95% CI 0.130, 0.430; I2 48.1%) with a mean difference of 0.370 kg (95% CI 0.178, 0.563; I2 47.8%) compared to BIA group. There was no difference in post-HD body weight between the two groups (SMD 0.156; 95% CI -0.055, -0.366; I2 0%).

Conclusions: There was no mortality benefit to BIA-guided HD compared with clinical-guided HD. However, BIA-guided HD improved systolic blood pressure and weight gain compared to clinical-guided HD. Pulse wave velocity, which represents arterial stiffness, was also lower in BIA group. Although our findings suggest some non-mortality benefits to BIA-guided HD, however, the clinical impact of BIA-guided HD on cardiovascular events, intradialytic complications, and patients' quality of life remain to be elucidated in future RCTs.

PO0857

Point-of-Care Ultrasound Measurements to Predict Intradialytic Hypotension: A Cross-Sectional Pilot Study

Chrystel Pawly,[1] Wael Azzam,[1] Christy Costanian,[1] Gonzalo Matzumura Umemoto,[3] Enyo Ablordeppey,[3] Fadi Tohme.[1,2] *[1]Lebanese American University, Beirut, Lebanon; [2]University of Southern California, Los Angeles, CA; [3]Washington University in St Louis, St Louis, MO.*

Background: Intradialytic hypotension (IDH) results from excessive ultrafiltration in patients on chronic hemodialysis (HD) and has been linked to increased mortality. Prescribing the right amount of ultrafiltration can be challenging, partly due to the poor sensitivity of physical examination for detection of volume overload in HD patients. POCUS is emerging as a valuable tool in the assessment of volume status. The goal of this study is to determine whether pre-dialysis POCUS measurements are associated with development of IDH.

Methods: Patients >18 years old on HD for at least 6 months and ordered for 2 or more liters of ultrafiltration were included. Two blinded POCUS-trained physicians obtained the following measurements within the first 30 minutes of HD: left ventricular septal and lateral E/e', portal vein (PV) pulsatility and IVC size. The primary outcome was development of IDH events or post HD orthostasis. IDH was defined as a decrease in systolic blood pressure by ≥ 20 mmHg plus symptoms of IDH. Fischer's and Mann Whitney tests were used to examine the association between IDH events and various demographic, clinical, and POCUS related parameters.

Results: 54 measurements on 27 patients were obtained. Average time required by each examiner to obtain all images was 6 minutes (95% confidence interval [CI] 4.2,7.8). Average age was 57 (95% CI 52, 62), 85% were black and 44% were females. Average BMI was 32 (95% CI 28, 36), Charlson comorbidity index (CCI) score 7 (95 % CI 6,8), number of anti-hypertensive medications 2.1 (95% CI 1.5, 2.8) and average dialysis vintage 3.9 years (95% CI 2.1, 5.7). 8 out of 27 patients developed the primary outcome. There was no association between age, sex, ethnicity, BMI, dialysis vintage, Charlson comorbidity index, interdialytic weight gain, IVC size, PV pulsatility, septal E/e' and the primary outcome. There was a significant association between lateral E/e' and IDH events or post HD orthostasis (p=0.05).

Conclusions: In this pilot study, an elevated lateral E/E' was associated with lower rates of IDH events or post HD orthostasis. The role of POCUS in guiding fluid removal during HD warrants further exploration

PO0858

A Clinical Approach of Intradialytic Creatine Supplementation in Dialysis-Dependent CKD Patients: A Rationale and Study Design

Yvonne van der Veen,[1] Adrian Post,[1] Daan Kremer,[1] Ralf Westerhuis,[2] Casper F. Franssen,[1] Theo Wallimann,[3] Stephan J. Bakker.[1] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Dialyse Centrum Groningen, Groningen, Netherlands; [3]Eidgenossische Technische Hochschule Zurich, Zurich, Switzerland.*

Background: There is great need for identification of new, potentially modifiable risk factors for the poor HRQoL and excess risk of mortality in dialysis-dependent chronic kidney disease patients. Creatine is an essential contributor to cellular energy homeostasis, yet on a daily basis 1.6-1.7% of the total creatine pool is non-enzymatically degraded to creatinine and subsequently lost via urinary excretion, thus necessitating a continuous supply of new creatine to remain in steady-state. Due to an insufficient ability to synthesize creatine, unopposed losses to the dialysis fluid, and insufficient intake, hemodialysis patients are prone to creatine deficiency, and may benefit from creatine supplementation. To avoid problems with compliance, fluid balance and, furthermore, to prevent intradialytic losses of creatine to the dialysate, we aim to investigate the potential of intradialytic creatine supplementation in improving outcomes.

Methods: Here, we describe the rationale and design for a block-randomized, double-blind, placebo-controlled pilot study. A total of 16 hemodialysis patients will be included, divided into four groups receiving intradialytic creatine supplementation (0.5mM, 1.0mM, 1.5mM, 2.0mM), or a placebo for six weeks. The aim of the pilot study is to explore the creatine uptake in the circulation and tissues following different creatine supplementation dosages.

Results: The main parameters for the pilot study are the plasma creatine concentration and intra-erythrocytic creatine concentration of both pre- and post-hemodialysis samples. Secondary study parameters are handgrip strength as a measure of muscle strength, combined interdialytic urinary and intradialytic dialysate excretion of creatinine as a measure of muscle mass, and body composition measured with bioelectrical impedance analysis (BIA).

Conclusions: Intradialytic creatine supplementation may help to maintain creatine homeostasis among dialysis-dependent chronic kidney disease patients, and consequently improve important causes for impaired HRQoL, including protein energy wasting (PEW), fatigue, muscle weakness, depression, and cognitive impairment. The results from the pilot-study will serve as a basis for a larger double-blind, placebo-controlled supplementation trial.

PO0859

Relationship Between Fluid Overload and Hemoglobin Concentration in Hemodialysis Patients: A Longitudinal Analysis

Lemuel Rivera Fuentes,[1] Ariella E. Mermelstein,[1] George A. Kaysen,[2] Jochen G. Raimann,[1] Ulrich Moissl,[3] Stephan Thijssen,[1] Peter Kotanko.[1] Renal Research Institute *[1]Renal Research Institute, New York, NY; [2]University of California Davis, Davis, CA; [3]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany*.

Background: Quantification of fluid status by bioimpedance spectroscopy (BIS) has become routine outside United States (US). We performed the first assessment of fluid status in US hemodialysis (HD) clinics using a BIS device. We studied the longitudinal association between fluid overload (FO) and hemoglobin (Hgb) concentration adjusting for inflammation and erythropoiesis-stimulating agents (ESA).

Methods: Measurement of FO [Body Composition Monitor (BCM); Fresenius Medical Care] was conducted cross-sectionally in chronic HD patients in 4 HD clinics in New York. We built linear mixed effects models with Hgb as the dependent variable and calculated FO longitudinally to include as a fixed effect. We tested the robustness of the association to account for the influence of inflammation by including the neutrophil-lymphocyte ratio (NLR) as an additional fixed effect. As a subset analysis 2 separate models were built in subjects with or without ESAs. To corroborate the dilutional effect of FO we exchanged Hgb for albumin as a fixed effect.

Results: We studied 169 patients (Figure1). FO was inversely associated with Hgb [Estimate -0.16 (-0.20 to -0.12) g/dl per 1L of FO], a significant fixed effect that remained unchanged in magnitude even after inclusion of NLR [Estimate 0.04 (-0.05 to 0.06) g/dl per 1 unit of NLR]. The effect was larger in patients without ESA prescription [Estimate -0.22 (-0.32 to -0.12) g/dl per 1L of FO]. FO was a significant determinant of albumin [Estimate -0.02 (-0.03 to -0.01) g/dl per 1L of FO] with NLR being a significant fixed effect [Estimate -0.03 (-0.04 to -0.01) g/dl per 1 unit of NLR].

Conclusions: Hgb is inversely affected by FO, a significant effect independent of inflammation (NLR). The impact of FO on Hgb concentration is larger in those with no ESA treatment emphasizing that fluid status has to be considered in anemia management. The effect of FO on albumin supports hemodilution as the principal cause for the changes seen on Hgb.

Funding: Commercial Support - Fresenius Medical Care

Interpreting Home Blood Pressure Measurements in Haemodialysis: A Post Hoc Analysis of a Randomized Cross-Over Study

Vicki K. Sandys,[1] Lavleen Bhat,[1] Emer C. O'Hare,[1] Conall M. O'Seaghdha,[1] Donal J. Sexton.[2] *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]The University of Dublin Trinity College, Dublin, Ireland*.

Background: Home BP correlates better with ambulatory BP, target organ damage and mortality in dialysis patients. We aimed to determine the agreement of in-centre BP with home BP.

Methods: A post-hoc analysis of a pilot-scale, randomised two-period cross over study comparing self-monitoring of BP over 4 weeks with usual care in 41 haemodialysis patients. www.clinicaltrials.gov. NCT0340349. Dialysis clinic BP and home BP (using A&D model UA-651BLE device) were averaged over 2 weeks. Agreement was determined using kappa statistics and Bland Altman plots. BP variability was analysed using average real variability (ARV). Mixed effects models for repeated measures with a moving average window of 2 weeks were used to examine associations with BP and ARV.

Results: 33 out of 41 participants had sufficient home BP measurements for inclusion (mean age 52 +/- 13 years, 65% male). Post-dialysis SBP had moderate agreement with home SBP measurements (K = 0.6) compared with pre-dialysis SBP measurements (K = 0.4). The mean bias between home SBP and post SBP measurements was -4.15 mmHg (95% CI 23.5 to -31.8 mmHg) (Figure 1). Home SBP ARV (16 +/- 6) was as high as pre SBP ARV (14 +/-5) and post SBP ARV (13 +/-5). In univariate analysis only calcium channel blockers were consistently associated with pre-dialysis (P= 0.02), post-dialysis and home SBP (both P<0.001).

Conclusions: Post-dialysis SBP demonstrates moderate agreement with home BP when two week BP averages are used. Home BP measurements are as variable as clinic BP measurements and isolated measurements may lack interpretability. Averaging the home BP over two weeks may improve the utility of home BP monitoring.

Funding: Commercial Support - patientMpower

PO0861

Increased Tricuspid Regurgitation Jet Velocity as a Predictor of Acute Decompensated Heart Failure in ESRD Patients on Maintenance Hemodialysis

Youngchan Park,[1] Ye na Kim,[1,2] Ho Sik Shin,[1,2] Yeonsoon Jung,[1,2] Hark Rim.[1,2] *[1]Kosin University Gospel Hospital, Busan, Busan, Republic of Korea; [2]Transplantation Research Institute, Kosin University College of Medicine, Busan, South Korea, Republic of Korea*.

Background: Many patients with end-stage renal disease (ESRD) on hemodialysis (HD) experience left ventricular hypertrophy and reduced vascular compliance and are likely to develop heart failure (HF). We aimed to determine the hemodynamic factors associated with acute decompensated events among ESRD patients undergoing HD.

Methods: We retrospectively investigated ESRD patients on HD through a medical record review. We excluded patients with significant ischemic heart disease (IHD), percutaneous coronary intervention or coronary artery bypass graft, significant valvular heart disease (VHD), or malignancy. We divided patients into those experience who experienced any admission due to acute decompensated HF (ADHF) and those who did not.

Results: Of the 188 ESRD patients on HD, 87 were excluded, and 101 were enrolled (mean age: 63.7 years, 52.1% male). The ADHF group demonstrated significantly higher tricuspid regurgitation (TR) jet velocity (2.9 ± 0.6 vs. 2.5 ± 0.4 m/s, respectively; p=0.004) than the non-ADHF group. Multivariate logistic regression analysis demonstrated that TR jet velocity (odds ratio: 8.356, 95% confidence interval: 1.806–38.658; p=0.007) was an independent predictor of ADHF after adjusting for age and sex, while LVEF and E/E' were not. Per receiver operating characteristic curve analysis, TR jet velocity > 2.8 m/s was associated with ADHF with 47.7% sensitivity and 76.4% specificity (area under the curve: 0.656).

Conclusions: Our data showed that increased TR jet velocity was an independent predictor of ADHF events in ESRD patients on HD, but LVEF and E/E' were not.

Table 1. Baseline characteristics

Variable	Pt without admission for ADHF (n=71)	Pt with admission for ADHF (n=30)	p-value
Age, mean (year)	64.1±13.7	65.5±12.5	0.629
Male, n (%)	37 (52.1)	16 (53.3)	0.911

Benefit of More Frequent Dialysis on Dialysis Recovery Time in Nursing Home Patients with ESRD

Alice Hellebrand,[1] Eran Y. Bellin,[1,2] Steven M. Kaplan,[1] Jordan Ledvina,[1] William Markis,[1] Nathan W. Levin,[1] Allen Kaufman.[1] Dialyze Direct Brooklyn
[1]*Dialyze Direct Brooklyn, Brooklyn, NY;* [2]*Albert Einstein College of Medicine, Bronx, NY.*

Background: Dialysis patients admitted to a skilled nursing facility (SNF) are characterized by advanced age, frailty, and multiple comorbidities. Based on prior studies which demonstrated shortened dialysis recovery time (DRT) with more frequent dialysis (MFD) in populations aged ~50s living at home (FREEDOM Study 2010, FHN trial 2006), it was postulated that dialysis patients in a SNF would benefit from MFD.

Methods: Patients studied were admitted to SNFs in OH, TX, FL, NY, and PA from November-December 2019 (pre-COVID) and could reliably answer questions about DRT. 80% were undergoing subacute rehabilitation and 20% were permanent residents of the SNF. Patients received NxStage on-site staff assisted MFD 5x (80%) or 4x (20%) per week. StdKt/V was ≥ 2.1. At every dialysis, patients were asked by their RN caregiver "How long did it take you to recover from your last HD session?" Responses were deemed unreliable if a patient had cognitive impairment. Reliable responses were used for outcome analysis. In the present study, DRT data was collected by a caregiver nurse, differing from the methodology of the FREEDOM/FHN studies which collected DRT data via KDQOL form or phone interview. The implications of these differences in data collection methods are currently unknown.

Results: 485 unique patients were included in the study. Demographics included 53% males, mean age 67.5 +/- 13 years, African American 19%, Caucasian 25%, Hispanic 5%, Asian 0.4%, unknown or other 51%. Mean DRT was 1.5 +/- 2.6 hours. Mean DRT was calculated using the midpoint recovery time for intervals, or 18 hours when DRT was the next morning or beyond. In 69%, DRT was < 2 hours.

Conclusions: In the FREEDOM and FHN conventional HD 3x per week study arms, DRT averaged 6-8 hours. MFD reduced DRT to ~1.0 hour in those relatively young patients living at home. In our study, HD patients residing in a SNF and receiving MFD experienced DRT of 1.5 hours. Age, frailty and comorbid conditions therefore do not prevent DRT benefits of MFD. DRT benefits could stem from more effective, gentler fluid management by MFD. Further studies are needed to fully explore the impact of shortened DRT on rehabilitation scores, hospitalizations and deaths in elderly patients residing in SNFs.

The Combination of Arterial Stiffness and Peripheral Vascular Disease Aggravates Survival Among Hemodialysis Patient Using Competing Risk Analysis

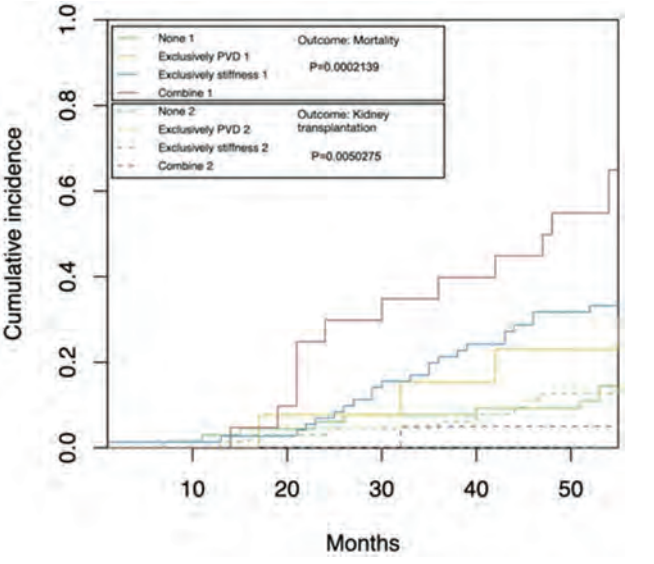
Adisorn Pathumarak, Kanin Thammavaranucupt, Chagriya Kitiyakara, Arkom Nongnuch. *Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: The survival in end state renal disease (ESRD) patient is unacceptable high. The Skin autofluorescence (SAF) for advance glycation end products (AGEs), peripheral vascular disease (PVD) (ankle-brachial index, ABI ≤0.9) and arterial stiffness (cardio ankle vascular index, CAVI>9) were reports as predictors of mortality. However, kidney transplantation (KT) competes the mortality outcome. We aim to explore these markers for precisely prediction of mortality using competing risk method.

Methods: Retrospective chart review in chronic hemodialysis patients was done in 3 hemodialysis centers in North Bangkok during November 2015 and March 2016. Arterial stiffness, SAF, IMAR and PVD were collected as a clinical predictor. Cumulative incidence of mortality was used as was a primary outcome. Logistic regression with competing risk model was used to analyze the factor affecting mortality.

Results: A Total of 176 patients were eligible and classified into 4 groups according to PVD and stiffness status. During follow up 44.5±14.8 months, the overall mortality rate was 27% which is 13.2, 28.6, 31.5 and 61.9% in no PVD and stiffness, exclusively PVD, exclusively stiffness, and combine group respectively. The PVD (HR 2.93, CI 1.2 to 7.14, P=0.018) and stiffness (HR 2.57, CI 1.16 to 5.73, P=0.021) were independent predictors of mortality. In competing risk method, the combination of PVD and stiffness associate with highest mortality (P=0.0002139), while the patients who no PVD and stiffness had the highest rate for KT (P=0.0050275).

Conclusions: The PVD and stiffness were an independent risk of mortality among hemodialysis patients. The combination of PVD and stiffness may stratify risk of mortality in hemodialysis patient using competing risk method.



Cumulative incidence of death and KT according to PVD and stiffness status in competing risk method

PO0864

Body Fat Mass Plays an Important Role in Over- or Underestimation of Bioimpedance Spectroscopy-Based Dry Weight for Patients with Hemodialysis

Dae Eun Choi,[1] Hae Ri Kim,[2] Jae wan Jeon,[2] Jin Ah Shin,[1] Soo hyun Han,[1] Haet Bit Hwang,[1] Eu Jin Lee,[1] Kiryang Na,[1] Kang Wook Lee.[1] [1]*Chungnam National University School of Medicine, Daejeon, Daejeon, Republic of Korea;* [2]*Chungnam National University Sejong Hospital, Sejong, Republic of Korea.*

Background: Accurate dry weight (DW) estimation is important for hemodialysis patients. Although bioimpedance spectroscopy (BIS) is commonly used to measure DW, the BIS-based DW frequently differs from the clinical DW.

Methods: We analyzed the characteristics of patients whose BIS-based DWs were over- and underestimated. In this retrospective cohort study, we evaluated 1,555 patients undergoing maintenance hemodialysis in Chungnam National University Hospital. The gap (DW_{CP-BIS}) was calculated by comparing the BIS and clinical DWs.

Results: We analyzed the clinical characteristics of patients with positive (n = 835) and negative (n = 720) gaps. Compared with other patients, the DW_{CP-BIS}-positive group was taller, had higher extracellular water (ECW) level and extracellular/intracellular water index (E/I); and had lower weight, body mass index (BMI), lean tissue index (LTI), fat tissue index (FTI), fat mass (FAT), and adipose tissue mass (ATM), as well as lower levels of hemoglobin, total protein, albumin, and phosphorous. The DW_{CP-BIS}-negative group exhibited higher levels of hemoglobin, total protein, albumin, and phosphorous, as well as elevated BMI, FTI, FAT, and ATM; however, it had lower height, ECW, and E/I. Linear regression analysis revealed that FAT significantly predicted DW_{CP} accuracy.

Conclusions: The clinical DW of patients with malnutrition and a low fat mass tended to be underestimated, while the clinical DW of patients with comparatively large fat reserves tended to be overestimated. These characteristics of dialysis patients will aid in the correction of BIS-associated DW errors

PO0865

Consistency of the Dry Weight of Hemodialysis Patients Predicted Using Bioelectrical Impedance Analysis Between Standing and Lying-Down Positions

Hyunsuk Kim. *Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-do, Republic of Korea.*

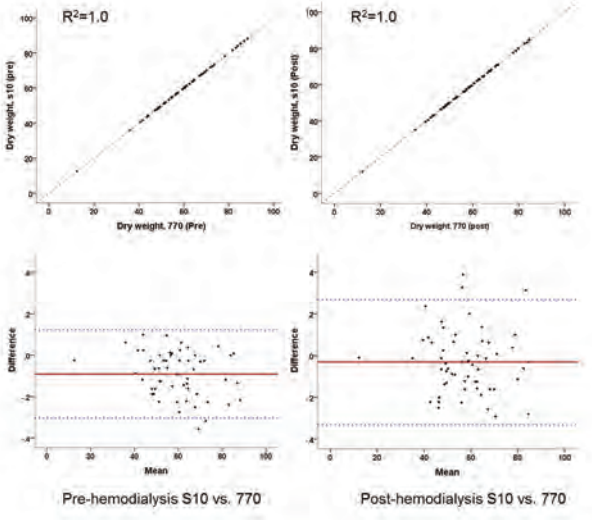
Background: Although the InBody S10 is widely used for hemodialysis patients in the lying position, clinicians must make the measurements in person. In contrast, patients can use the InBody 770 to obtain measurements by themselves in the standing position according to instructions provided by the machine, which may be more convenient. Therefore, this study compared the measurements of hemodialysis patients' dry weight obtained lying down using the S10 to those obtained in the standing position using the 770.

Methods: Measurements from 56 patients before and after hemodialysis were obtained. Dry weight was calculated using the ratio of extracellular water to total body water, taking into consideration diabetes status and albumin levels, and comparing the results according to body position (lying vs. standing).

Results: The patients' median age was 64 years old, and 51% were men. Their mean dry weight before hemodialysis was 60.0±12.5 kg using the S10 device and 60.1±12.5 kg using the 770 device (paired t-test; t=-6.472, *P*<0.001). The correlation between these

measurements was high (R^2=1.0000). Patients' mean dry weight after hemodialysis was 58.4±12.2 kg using the S10 device and 58.5±12.0 kg using the 770 device (paired t-test; t=-1.560, *P*=0.124). The correlation between these measurements was also very close (R^2=1.0000). The Bland-Altman test yielded similar results.

Conclusions: This study showed that patients' predicted dry weights in the lying position using the InBody S10 device and in the standing position using the InBody 770 device were consistent in both pre- and post-hemodialysis states. It can be concluded that the dry weight of a patient in the standing position can be measured with more convenience and autonomy using the InBody 770 device.



PO0866

Use of Crit-Line to Reduce Intradialytic Hypotension in Hospitalized Patients Receiving Dialysis

Marissa A. Martin, Luis M. Perez, Anip Bansal, Jessica B. Kendrick. *University of Colorado, University of Colorado, Denver, CO, US, academic/system, Denver, CO.*

Background: Intradialytic hypotension (IDH) is a frequent complication of hemodialysis (HD) in hospitalized patients with acute kidney injury (AKI) and end stage kidney disease (ESKD). Crit-Line is a device that monitors absolute hematocrit and oxygen saturation during dialysis and reads out the percent blood volume change. Whether the use of Crit-Line during HD in hospitalized patients results in less IDH is unknown.

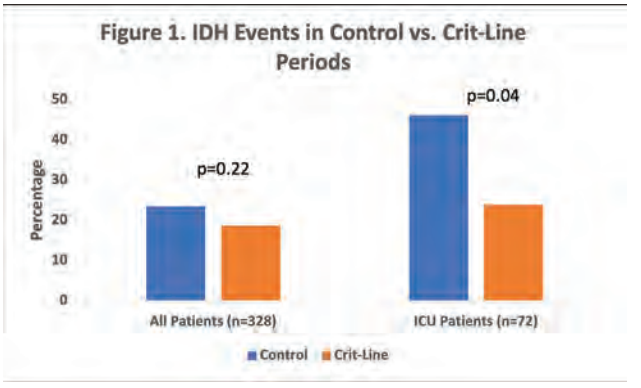
Methods: We performed a time series study in all hospitalized adult AKI/ESKD patients undergoing acute HD at the University of Colorado. During the control period baseline data was collected. During the intervention period, Crit-Line was used on all hospitalized patients undergoing HD including those receiving portable HD treatments in the ICU. During both time periods, nurses recorded number of hypotensive events, patient symptoms and modifications that were made to the dialysis prescription. The primary outcome was number of IDH events defined by the NKF KDOQI Guidelines.

Results: 328 patients were included, 161 from the control period and 167 from the intervention period. Patient characteristics were similar in both time periods and are shown in Table 1. IDH occurred in 23.5% of treatments during the control period and 18.7% during the intervention period, but the difference was not significant, p=0.22 (Figure 1). When examining portable dialysis treatments in the ICU, there was a significant reduction in IDH with Crit-Line compared to control (Odds Ratio 0.71 95% CI 0.51-0.99, p=0.04).

Conclusions: Use of Crit-Line in hospitalized patients undergoing dialysis in the ICU resulted in less IDH.

Funding: Commercial Support - Fresenius Renal Therapies

	Control Period (n=161)	Crit-Line Period (n=167)
Age (years)	56.9 ± 15.0	56.2 ± 15.0
Female N(%)	68 (40.7)	66 (41.3)
Race White N(%)	82 (50.9)	86 (51.5)
ESKD N(%)	114 (70.8)	120 (71.9)
Diabetes N(%)	84 (52.2)	81 (48.5)
ICU N(%)	33 (20.5)	39 (23.4)
Number of dialysis treatments N(%)	357 (52.7)	321 (47.4)



PO0867

Dry Weight Adjustments for Hemodialysis Patients Using Machine Learning

Hae Ri Kim,[1] Jae wan Jeon,[1] Youngrok Ham,[2] Kiryang Na,[2] Kang Wook Lee,[2] Yoon-Kyung Chang,[3] Dae Eun Choi.[2] *[1]Chungnam National University Sejong Hospital, Sejong, Republic of Korea; [2]Chungnam National University, Daejeon, Daejeon, Republic of Korea; [3]Daejeon Saint Mary's Hospital, Daejeon, Daejeon, Republic of Korea.*

Background: Knowledge of the proper dry weight plays a critical role in the efficiency of dialysis and the survival of hemodialysis patients. Recently, bioimpedance spectroscopy(BIS) has been widely used for set dry weight in hemodialysis patients. However, BIS is often misrepresented in clinical healthy weight. In this study, we tried to predict the clinically proper dry weight (DW_{CP}) using machine learning for patient's clinical information including BIS. We then analyze the factors that influence the prediction of the clinical dry weight.

Methods: As a retrospective, single center study, data of 1672 hemodialysis patients were reviewed. DW_{CP} data were collected when the dry weight was measured using the BIS (DW_{BIS}). The gap between the two (Gap_{DW}) was calculated and then grouped and analyzed based on gaps of 1 kg and 2 kg.

Results: Based on the gap between DW_{BIS} and DW_{CP}, 972, 303, and 384 patients were placed in groups with gaps of <1 kg, ≧1kg and <2 kg, and ≧2 kg, respectively. For less than 1 kg and 2 kg of GapDW, It can be seen that the average accuracies for the two groups are 83% and 72%, respectively, in usign XGBoost machine learning. As Gap_{DW} increases, it is more difficult to predict the target property. As Gap_{DW} increase, the mean values of hemoglobin, total protein, serum albumin, creatinine, phosphorus, potassium, and the fat tissue index tended to decrease. However, the height, total body water, extracellular water (ECW), and ECW to intracellular water ratio tended to increase.

Conclusions: Machine learning made it slightly easier to predict DW_{CP} based on DW_{BIS} under limited conditions and gave better insights into predicting DW_{CP}. Malnutrition-related factors and ECW were important in reflecting the differences between DW_{BIS} and DW_{CP}.

PO0868

Interdialytic Weight Gain in Long Intervals and Mortality Among Maintenance Hemodialysis Patients

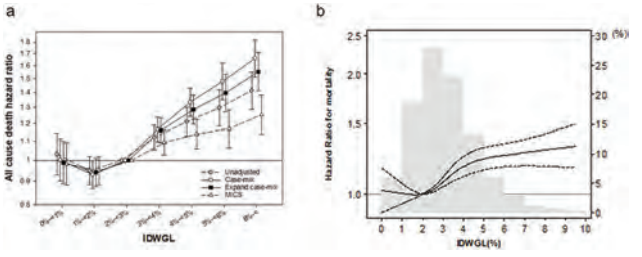
Yoshikazu Miyasato,[1,2] Tsuyoshi Miyagi,[1] Yoko Narasaki,[1] Hiroshi Kimura,[1] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]University of California Irvine, Irvine, CA; [2]Kumamoto Daigaku, Kumamoto, Japan.*

Background: Interdialytic weight gain (IDWG) is an important factor for sudden death on the first dialysis day right after long interdialytic intervals (i.e. 2-day breaks between dialysis treatments) in hemodialysis patients. We defined IDWG in long intervals (IDWGL) as the IDWG during 2-day breaks. In this study we examined the association between IDWGL and medium-term mortality.

Methods: This retrospective cohort study included patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWGL and all-cause mortality using Cox regression model. Seven categories of IDWGL were as follows: 0-<1%, 1-<2%, 2-<3%, 3-<4%, 4-<5%, 5-<6%, and ≥6%. We also examined continuous associations between IDWGL and mortality using restricted cubic spline analysis.

Results: We examined mortality in 35225 patients. The mean age (and standard deviation) was 62±15 years, and 8112 died during the median follow-up period of 1.4 years. Higher categories of IDWGL were associated with increased risk of mortality. The hazard ratios (95% confidence intervals) of all-cause mortality for 3-<4%, 4-<5%, 5-<6%, and ≥6% were 1.09 (1.03-1.16), 1.14 (1.06-1.23), 1.17 (1.06-1.29), and 1.25 (1.14-1.38) (Reference: 2-<3%) (Figure a). The restricted cubic spline analysis showed that risk of mortality increased when IDWGL exceeded 2% (Figure b).

Conclusions: IDWGL exceeded 2% was associated with higher risk of mortality. Our results suggest IDWGL can be a risk parameter for medium-term mortality.



PO0869

Coronary Artery Calcification Is a Risk Factor for Intradialytic Hypotension in Hemodialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[1,5] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Koji Usui,[2] Michiko Arita,[3] Takayuki Naito,[4] Shigehiro Doi,[5] Takao Masaki.[5] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Ichiyokai East Clinic, Hiroshima, Japan; [4]Ichiyokai Yokogawa Clinic, Hiroshima, Japan; [5]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: Vascular calcification and intradialytic hypotension (IDH) share common risk factors in hemodialysis (HD) patients, but there are few reports about the association. We investigated the association between IDH and coronary artery calcification (CAC) and their effects on mortality in HD patients.

Methods: Subjects were consecutive maintenance HD patients. IDH was defined as nadir systolic blood pressure <100 mmHg, or the requirement for bolus infusion of saline and vasopressor (etilefrine hydrochloride) during at least two of 10 HD sessions. Laboratory data and Agatston coronary artery calcium score (CACS) were obtained at baseline. Logistic regression analyses for CACS and Cox analyses for mortality were conducted.

Results: In all subjects (n=173), age and dialysis vintage were 66±12 years and 102±89 months, respectively. IDH occurred in 37 patients (21.4%), and CACS was higher in the IDH group than in the non-IDH group [1,845 (243–3,774) vs. 884 (161–2,465)]. IDH was significantly (P<0.05) associated with CACS [odds ratio (OR): 1.01], diabetes (OR: 2.90), mean predialysis systolic blood pressure (OR: 0.93), mean ultrafiltration (OR: 1.92), Kt/Vurea (OR: 11.27) and erythropoietin responsive index (ERI) (OR: 0.91), but not with serum albumin or use of calcium channel blockers. For 3-year all-cause mortality, the cut-off value of CACS, determined by receiver operating characteristics curve analysis, was 1,829 with sensitivity of 69% and specificity of 77%. Of the 173 patients, 45 all-cause deaths and 19 cardiovascular (CV) deaths occurred for 3 years. Patients with both IDH and CACS ≥1,829 had the highest 3-year cumulative CV death rate (33.3%, P<0.01) compared with 19.7%, 11.5%, and 4.5% in those with CACS ≥1,829 only, IDH only, and neither, respectively. In Cox models including age, sex, diabetes, albumin, phosphate, CRP, ERI and FGF23, hazard ratios (HRs) for 3-year all-cause mortality of IDH, CACS ≥1,829, or IDH with CACS ≥1,829 were similar, but HR for 3-year CV mortality was the highest in IDH with CACS ≥1,829 (9.68, P<0.001) compared with 7.29 (P<0.01) and 6.77 (P<0.01), in those with CACS ≥1,829 only, and IDH only.

Conclusions: CACS is an independent risk factor for IDH, and CACS provide additional risk-discrimination over IDH for CV mortality in HD patients.

PO0870

Cardiac Arrests During Hemodialysis Among Maintenance Hemodialysis Patients in a Large Dialysis Network in India

Suresh Sankarasubbaiyan, Venkatraman Ganapathi Subraman, Mallikarjuna Gowda B. Gowda, Sataynarayana R. Puvvada, Vikram A. Sonawane, Kaparaboina K. Kumar, Mohammad S. Husain, Kamal D. Shah. *Nephroplus, Hyderabad, India.*

Background: Cardiac arrest (CA) during a HD session carries a high mortality and is reported associations inclue age, comorbiity, dialysis characteristics. Since much is unknown in India, we aimed to study Incidence of CA, prediposing factors and outcome of CPR following intra HD cardiac arrests

Methods: Consecutive CA in a large dialysis network from July 2019 to March 2021 were reviewed for age, gender, HD frequency, adequacy, vascular access, HD facility location, size, nephrologist coverage, h/o DM and IHD, HD session timing, delivered HD frequency & hospitalization in recent past & ultrafitltration rate. Survivors vs non-survivors of CPR were compared with t-test, Chi-square test or Fisher's exact statistic and risk ratio (RR) for significance of associated factors were analyzed using STATA, v 14. 2. Two-sided tests with a P-value < 0.05 was considered significant

Results: 122 CA occured among 2,981,759 sessions; rate of 1/24441. 71 survived CPR and 51 died. μ age: 55.5 ± 1.2 yrs, M;F =77%:23%. Tier 1/2/3 cities: 11.4%,37.7% 50,8%, daily Nephrologist visits: 67.2%, Facilites monthly sessions: < 250 : 10.6%, 250-749: 42.6%, >750 :46.7%. μ Hb: 8.7 ± .2 g% Temp access: 43.4%, HD freq 1/2/3 per wk: 36.9/28.7/34.4%, DM: 48.4% IHD: 26.2%. Morn afternoon, eve session(%): 39.3/15.6/39.3%, hospitalized < 2mon: 40%, < 2HD/week in recent past: 27%, μ UFR: 10.4 ± .5 ml/kg/hr. RR for signifcant factors are shown in Table 1.

Conclusions: Incidence of CA in India mirrors developed countries experience; larger facilities & smaller cities form a high proportion of events. Age > 80 ↑ risk of death. Female, ↓ Hb & adequacy, UFR >10ml/kg/hour, low HD freq in 2 months prior to CA show tendency to higher risk for non survival. Limitation includes lack of analysis of CPR and post CPR hospitalization course

Relative risk of major factors associated with non-survival following CPR for CA

Factors	Relative risk (95% CI)
Age <39 ref ≥80	1.4 (1.1-2)
Gender (male: ref) Female	1.8 (.8 - 3.7)
Hb (10-12 g ref) <8	1.1 (0.7-1.5)

Clinical Significance of Plasma Matrix Metalloproteinase-2 and Matrix Metalloproteinase-9 Levels to Assess the Cardiovascular Risk in Hemodialysis Patients

Yu ho Lee,[1] So-young Lee,[1] Hyeyun Jeong,[1] Yang gyun Kim,[2] Ju young Moon,[2] Sangho Lee,[2] Jin sug Kim,[3] Kyung hwan Jeong,[3] Shin-Young Ahn,[4] Dong-Young Lee,[5] Hyeon Seok Hwang.[3] *[1]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea; [3]Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea; [4]Korea University, Seongbuk-gu, Seoul, Republic of Korea; [5]Seoul Veterans Hospital, Gangdong-gu, Seoul, Republic of Korea.*

Background: Matrix metalloproteinases (MMPs) are endopeptidases that control extracellular matrix synthesis and degradation. Two MMP subtypes, MMP-2 and MMP-9, are known to play important roles in the development and progression of cardiovascular (CV) disease, but its clinical relevance as predictors of cardiovascular events is unclear in hemodialysis patients.

Methods: We prospectively enrolled 435 patients undergoing maintenance hemodialysis from K-cohort between June 2016 and April 2019. Plasma MMP-2, MMP-9 levels, and several biomarkers were measured at the time of study data entry. Primary endpoint was defined as a composite of cardiovascular events.

Results: Plasma MMP-2 level were increased in patients with incident CV events than those without CV events, whereas plasma MMP-9 levels were not different between groups. MMP-2 levels were positively correlated with circulating cardiac markers including brain natriuretic peptides (BNP), N-terminal proBNP, and heart-type fatty acid binding protein. The cumulative event rate of the composite of CV events was significantly greater in patients with higher MMP-2 tertile 3 than in those with other MMP-2 tertile 1 ($p = 0.015$). MMP-2 tertile 3 was associated with a 2.77-fold higher risk of the composite of CV events (95% CI, 1.40–5.45) and 4.67-fold higher risk of cardiac events (95% CI, 2.06–10.56) after multivariable adjustments. However, plasma MMP-9 levels were not positively correlated with circulating cardiac markers, and not associated with risk of incident CV events.

Conclusions: Higher plasma MMP-2 levels, but not MMP-9 levels, had the positive relationship with circulating levels of cardiac pathology markers, and were associated with increased risks of incident CV events and cardiac events among hemodialysis patients.

PO0872

Utility of CHA2DS2-VASc Score to Predict Mid-Term Clinical Outcomes in Hemodialysis Patients

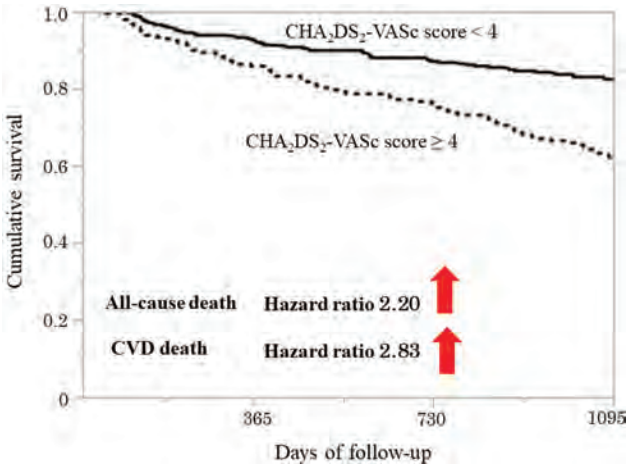
Aiko Okubo,[1] Toshiki Doi,[1,2] Yoshiko Nishizawa,[1] Kenichiro Shigemoto,[1] Sonoo Mizuiri,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: The CHA_2DS_2-VASc score has been widely used as a predictive score for stroke in patients with atrial fibrillation (AF). Recently, it was reported that the CHA_2DS_2-VASc score is useful for predicting cardiovascular disease (CVD) or all-cause mortality in patients with or without AF. However, few reports have examined the association between this score and mortality in hemodialysis patients.

Methods: We analyzed 525 consecutive patients who started hemodialysis at our facilities from March 2006 to October 2017. CHA_2DS_2-VASc score was calculated at time of initiation of hemodialysis. Multivariate Cox proportional hazards analysis was used to assess independent risk factors for 3-year all-cause mortality.

Results: During the 3-year follow-up period, 153 (29.1%) patients died (cardiovascular death, n=88). According to multivariate analysis, serum albumin [hazard ratio (HR) 0.62, 95% confidence interval (CI) 0.43–0.89, P=0.01], creatinine (HR 0.81, 95% CI 0.71–0.99, P=0.03), and CHA_2DS_2-VASc score (HR 1.33, 95% CI 1.21–1.46, P<0.001) were associated with 3-year all-cause mortality. Patients with CHA_2DS_2-VASc score ≥4 had higher risk of all-cause and CVD mortality than those with CHA_2DS_2-VASc score <4 (all-cause mortality: HR 2.20, 95% CI 1.42–3.71, P<0.001; CVD mortality: HR 2.83, 95% CI 1.37–5.44, P<0.001).

Conclusions: The CHA_2DS_2-VASc score is a useful predictor of 3-year all-cause and CVD mortality in incident hemodialysis patients.



PO0873

Fibrosis-4 Index May Predict Mortality and Non-Fatal Cardiovascular Events in ESKD Patients Starting Dialysis

Yeonhee Lee, Da won Kim, Seok Joon Shin, Hye Eun Yoon, Joo Eun Lee. *The Catholic University of Korea Incheon St. Mary's Hospital, Incheon, Republic of Korea.*

Background: CKD and ESKD are known risk factors of heart failure(HF). And liver dysfunction as congestive hepatopathy due to HF is also common. Recent studies report that Fibrosis-4(FIB4) index(age×AST(IU/L)/platelet count(10^3/uL)×square root of ALT(IU/L)), which was known to be useful tool for evaluating liver stiffness, can be prognostic factor of HF. Therefore, this study investigated whether FIB4 index may predict mortality and cardiovascular events(CVE) in patients with ESKD starting dialysis.

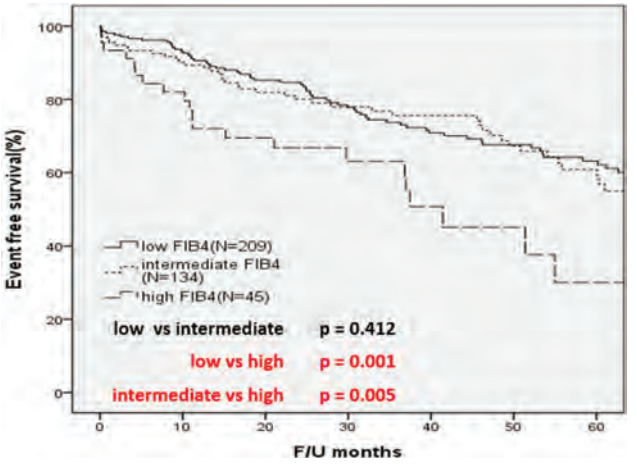
Methods: This was a retrospective cohort study including 388 patients who started dialysis at a single center. FIB4 index at dialysis initiation was calculated. Patients were stratified into three groups according to FIB4 index(<1.45:low, 1.45~3.25:intermediate, >3.25: high). The association between FIB4 index and event free survival rates for all-cause mortality and non-fatal CVE was analyzed. In addition, the association between FIB4 index and echocardiographic findings was analyzed.

Results: During a median follow-up duration of 40.0(0.03-142.3) months, 84 deaths(21.6%) and 83 non-fatal CVE(21.4%) occured. Event free survival rates were lower in high-FIB4 group, compared with those in low-FIB4 group(p=0.001) and intermediate-FIB4 group(p=0.005), respectively. In Cox proportional hazard model, the high FIB4 index was independently associated with event free survival rates (HR, 2.21; 95% CI, 1.17-4.18; p=0.015). When comparing echo findings, only left atrial diameter(LAD) showed difference among groups(p=0.033). However, there was no significant correlation between LAD and FIB4 index.

Conclusions: In conclusion, FIB4 index is associated with event free survival rates for all cause mortality and non-fatal CVE in ESKD patients starting dialysis.

Cox proportional hazard model of event free survival in ESKD patients who started maintenance

	Unadjusted model		Adjusted model	
	HR(95% CI)	P-value	HR(95% CI)	P-value
FIB4 trial		0.003		0.027
Low vs interdediate	1.166(0.81-1.68)	0.411	1.053(0.64-1.73)	0.838
Low vs high	2.351(1.43-3.86)	0.001	2.21(1.17-4.18)	0.015



PO0874

NT-ProBNP for Heart Function and Volume Status in Hemodialysis Patients

Kyung Ho Lee, Young seung Oh, Byung chul Yu, Moo Yong Park, Jin kuk Kim, Seung D. Hwang, Soo Jeong Choi. *Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.*

Background: N-terminal pro brain natriuretic peptide (NT-proBNP) is a biomarker that predicts heart failure and evaluates volume status in Hemodialysis (HD) patients. However, it is difficult to determine the cutoff value of NT-proBNP in HD patients. In this study, we analyzed whether NT-proBNP helps with predicting heart function and volume status in HD patients.

Methods: Retrospective study was conducted on 96 end-stage renal disease patients with HD. All patients underwent echocardiography and Bioelectrical Impedance Analysis (BIA) after a post HD session. Overhydration (OH) was measured by BIA. Laboratory data were obtained on preHD during the mid-week HD sessions. Serum NT-proBNP was measured after HD.

Results: There was an inverse correlation between NT-proBNP and ejection fraction (EF) (β= -0.34, P=0.001). Overhydration (OH) (β=0.33, p=0.001) and presence of diastolic dysfunction (β=0.226, P=0.027) had positive correlations with NT-proBNP. In the subgroup analysis with diastolic dysfunction grade, NT-proBNP increased as the dysfunction grade increased. (diastolic dysfunction grade 0; 4177(2637-10391), grade 1; 9736 (5471-21110), grade 2,3; 24627(16975-44988)) Elevation of NT-proBNP above 4058 pg/ml was associated with the presence of diastolic dysfunction (p<0.001) and Left ventricular hypertrophy (LVH) (p=0.004). Elevation of NT-proBNP above 11576 pg/ml was associated with the presence of diastolic dysfunction (P<0.001), LVH (p<0.001) as well as EF<55% (P=0.07). The group with lowered dry weight followed up NT-proBNP one month later, compared to the group with no change in dry weight, NT-proBNP showed a tendency to decrease, and the group with no change in dry weight showed a relatively low level of NT-proBNP variability. (-210 (-12899 - 3142) vs 330(-1090 - 3858); interquartile range, p=0.104)

Conclusions: We confirmed that NT-proBNP is associated with volume status as well as heart functions such as diastolic dysfunction, LVH and EF in HD patients.

Heart function according to NT-proBNP level

Variables		NT-proBNP		P value	NT-proBNP		P value
		<4058 (n=24)	≥4058 (n=72)		<11576 (n=48)	≥11576 (n=48)	
EF (%)	<55	1 (4.2)	12 (16.7)	0.174	3 (6.3)	10 (20.8)	0.070
	≥55	23 (95.8)	60 (83.3)		45 (93.7)	38 (79.2)	
Diastolic dysfunction	Yes	7 (29.2)	53 (74.7)	<0.001	20 (41.7)	40 (85.1)	<0.001
	No	17 (70.8)	18 (25.4)		28 (58.3)	7 (14.9)	
LVH	Yes	4 (16.7)	37 (51.4)	0.004	7 (14.6)	34 (70.8)	<0.001
	No	20 (83.3)	35 (48.6)		41 (85.4)	14 (29.2)	

PO0875

Dysregulation of Fatty Acid Binding Protein and Their Relationship with Inflammatory Biomarkers in ESRD

Emily Bontekoe, Vinod K. Bansal, Fakiha Siddiqui, Omer M. Iqbal, Jawed Fareed. *Loyola University Health System, Maywood, IL.*

Background: End stage renal disease (ESRD) patients are at high risk of cardiovascular disorders and hemostatic complications. Fatty acid binding proteins (FABPs) regulate the transport of fatty acids and other lipophilic mediators such as eicosanoids and retinoids by both intracellular and extracellular mechanisms. While upregulation of FABPs have been reported in ESRD, their relationship with inflammatory biomarkers is not fully understood. Liver fatty acid binding protein (L-FABP) also known as FABP-1 is a 14kDa protein expressed in the liver. This protein is also expressed in tubular kidney cells. Kidney damage and other pathologic conditions result in the marked upregulation of this protein.

Methods: Citrated blood samples from 95 ESRD patients undergoing maintenance hemodialysis were collected prior to hemodialysis. For comparison purposes normal human plasma collected from 50 normal healthy male and female individuals were used. Plasma prepared from these patients and normal individuals was analyzed for FABP-1 and such inflammatory biomarkers as IL-6, TNFa and inflammasomes as using commercially available ELISA methods. All results were compiled and correlation analysis between FABP-1 levels and biomarkers of inflammation was carried out using GraphPad prism software.

Results: The ESRD patients showed a marked increase in FABP levels (106 ng/ml ± 18ng/ml SEM) with a broad range (8 – 974 ng/ml) in comparison to normal (5.1 ± 0.2ng/ml SEM) with a range of (3.4 – 9.2 ng/ml). Marked increases in IL-6, TNFa and inflammation were also noted (2 – 4 fold). FABP-1 showed varying degrees of positive correlation with inflammatory biomarkers.

Conclusions: These studies suggest that plasma levels of FABP-1 is markedly increased (up to 10 fold) in ESRD patients undergoing maintenance hemodialysis. Other biomarkers of inflammation are also upregulated and demonstrate varying degrees of correlation suggesting inter-relationship between FABP-1 and inflammatory processes. These results also suggest that impaired renal function and tubular damage contribute to the marked increase of LFABP in ESRD patients. Simultaneous measurement of LFABP with biomarkers of inflammatory responses and kidney damage may be helpful in the risk stratification and prediction of the adverse outcome in ESRD patients.

PO0876

Transcapillary Refilling Rate Profile in Hemodiafiltration

Juan P. Rivas de Noriega, Gerardo Medina, Salvador L. Gil. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico*.

Background: Reaching dry weight in end-stage kidney disease (ESKD) patients is subject to high ultrafiltration rates (UFR) during their hemodiafiltration (HDF) sessions. We seek to profile the transcapillary refilling rate (TRR) during HDF, which we infer to be an important protective factor against intradialytic hypotension (IHD).

Methods: We studied 30 patients in HDF scheduled 3 times a week. Absolute blood volume was measured with the dilutional method and plasma volume was calculated based on the patient's hematocrit. Each session was divided in 18 intervals of 10 minutes each, we used a fixed UFR during each one in order to calculate the expected plasma volume. Real plasma volume at the end of each interval was calculated on the basis of the relative blood volume. The difference between the real and the expected plasma volume was the plasma refill volume, which divided by the time of each interval gave us the TRR. The HDF session prescription was determined by the nephrologist in charge of the HDF clinic.

Results: 84 HDF sessions were recorded. Mean age was 44 years (+/- 18.8), 66% were female. TRR:UFR ratio difference between patients with and without IDH was statistically significant (p <0.001, CI 95%), as well as the UFR-TRR delta (p <0.001, CI 95%). This ratio achieved stability after 30 minutes. Eight patients (27%) presented an IDH episode during HDF, during a total of 9 sessions (10.7%); 8 (89%) occurred in the final hour and 1 (11%) occurred in the first 10 minutes and corresponded to a patient who presented fever and bacteremia.

Conclusions: Both the TRR:UFR ratio and UFR-TRR delta were statistically significant for predicting IDH. Understanding each patient's TRR will help us plan interventions in order to try and optimize it and reduce the risk of IDH.

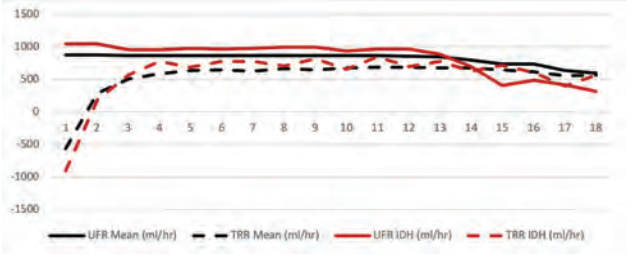

Figure 1. UFR (solid lines) and TRR (dashed lines) profiles.

PO0877

Impact of Hydration Status Measurement by Bioimpedance Analysis (BIA) on Haemodialysis Patients

Nasreen Samad,[1] Franel Ave,[1] Sara Z. Khan,[2,3] Jerilyn Lalu.[1] *[1]Barts Health NHS Trust, London, United Kingdom; [2]American University of Antigua College of Medicine, Saint Johns, Antigua and Barbuda; [3]Northwell Health, New Hyde Park, NY*.

Background: Volume status in haemodialysis patients is an important prognostic factor. Overhydration is associated with a higher frequency of mortality while dialysis-induced volume depletion is also an independent mortality risk factor. Clinical indices do not always accurately reflect volume status. Bioimpedance analysis (BIA) is used as a simple, noninvasive method which can measure normovolumic status in haemodialysis patients by measurement of height, weight, and body composition. Fluid overload is calculated by subtracting the normovolumic status from the overhydration status.

Methods: All patients at Queens satellite dialysis unit, Romford, United Kingdom, which has a prevalent population of 106 patients had BIA based assessment of fluid status every 3 months from July 2020 to May 2021 and dry weight adjusted accordingly. Outcomes were noted for blood pressure, overhydration, Interdialytic weight gains, intradialytic hypotension, hospitalisation and mortality.

Results: 121 haemodialysis patients were followed with male to female ratio of 55:66, mean age of 62 (25-87) of whom 46 were diabetics. By end of assessment period, 21 patients had died (13 due to COVID related illness). In July 2020, 31 patients had overhydration of 2 litres or more, which reduced to 20 patients, in May 2021. The number of patients who had underhydration of -1 litre or more remained similar with 12 patients in July 2020 compared to 11 in May 2021 in spite of more aggressive approach to reduction in dry weight. The dialysis population had high turnover due to deaths as well and 2 transplantations and 2 transfers out of the unit. During the time of study 15 patients were admitted to hospital with features of fluid overload.

Conclusions: Bioimpedence analysis (BIA) is a simple, non invasive tool helpful in assessing fluid status in haemodialysis patients. It is easier to convince a patient about their volume status by providing a machine assessed figure rather than clinical parameters. There was significant improvement in overhydration without increasing the number of dehydrated patients. The high mortality in prevalent patients during COVID pandemic highlights the need for continued body composition measurements in a larger population once COVID cases subside to come to a significant conclusion about the impact of BIA in improving patient outcomes including effect on residual renal function.

PO0878

Association of Different Definitions of Intradialytic Hypertension with Long-Term Mortality in Hemodialysis

Anika T. Singh,[1,2] Sushrut S. Waikar,[3,4] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Boston Medical Center, Boston, MA; [4]Boston University Renal Section, Boston, MA.*

Background: Hypertension is common in patients receiving maintenance hemodialysis (HD). A subset of patients experience increases in systolic blood pressure (SBP) from pre- to post-HD (intradialytic hypertension). This phenomenon is known to be associated with adverse short and long-term outcomes, but there is little consensus on an evidence-based definition.

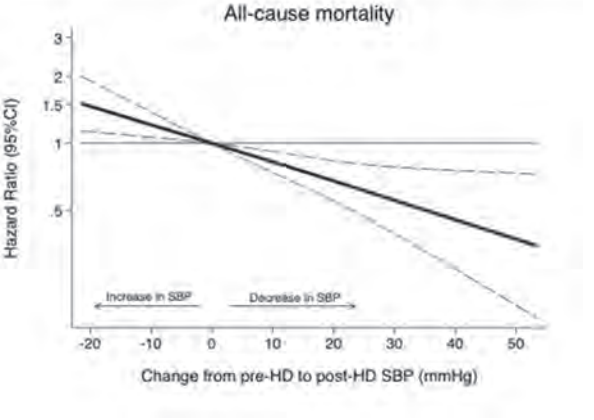
Methods: In a retrospective cohort of 3,198 HD participants, unadjusted and adjusted Cox proportional hazards models were fit to examine the association of various definitions of intradialytic hypertension (≥30% of baseline sessions with an increase in pre- to post-HD SBP of 1) ≥0 mmHg [Hyper0]; 2) ≥10 mmHg [Hyper10], or 3) ≥20 mmHg increase [Hyper20]) with all-cause mortality. Interaction terms were used to assess for effect modification according to pre-specified demographic (age, sex), HD-related (pre-HD SBP, ultrafiltration rate), and comorbid disease variables (diabetes, heart failure, and peripheral vascular disease [PVD]).

Results: At baseline, mean age was 62 ±15 years, 57% were male, and 14% were Black. Average change in BP from pre- to post-HD was 13 ±16 mmHg (median 12 [3 to 22] mmHg). During the baseline period, 47% of individuals met the Hyper0 definition and were at a 29% (HR 1.29; 95%CI 1.03 to 1.62) higher adjusted risk of death, compared with participants with no SBP increase. Hyper10 was present in 21.2% and associated with a 21% higher adjusted risk of death (HR 1.21; 95%CI 0.96 to 1.51). Hyper20 was present in 6.8% and associated with a 5% higher risk of death (HR 1.05; 95%CI 0.76 to 1.46). There was evidence for effect modification by age and PVD (P-interaction=0.02 for both), with a higher risk of death in those aged 45-70 years and those without PVD.

Conclusions: Individuals with any increase in SBP from pre- to post-HD experienced the highest adjusted risk of mortality, compared with other threshold-based definitions with effect modification by age and PVD.

Funding: NIDDK Support

Figure 1. Adjusted association of change in pre- to post-HD systolic BP with mortality.



PO0879

Outcomes of ESKD Patients on Hemodialysis vs. Peritoneal Dialysis Post Open Heart Surgery

Elias Bassil,[1] Milad Matta,[1] Aimen Liaqat,[3,1] Adam Fawaz,[1] Ali Mehdi,[3,1] Juan C. Calle,[3,1] Jonathan J. Taliercio,[3,1] Haytham Elgharably,[1] Serge C. Harb,[1] Remy Daou,[2] Susana Arrigain,[1] Jesse D. Schold,[1] Georges Nakhoul.[3,1] *[1]Cleveland Clinic, Cleveland, OH; [2]Universite Saint-Joseph, Beirut, Lebanon; [3]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH*.

Background: ESKD patients on dialysis suffer from poor outcomes following cardiac surgery compared to the non-dialysis populations. However, the impact of the dialysis modality and the type of cardiac surgery are not well studied.

Methods: We identified 590 patients with ESKD on HD or PD who underwent Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery using our Electronic Health Records-based Cardio-Thoracic Surgery (CTS) registry from 2009-2019. Baseline demographics and comorbidities of PD and HD were compared using Chi-square, and t-tests for categorical and continuous variables, respectively. In hospital death, hospital length of stay (LOS), intensive care unit LOS, red blood cell transfusions required, and the incidence of post-operative complications including (pericardial effusions requiring intervention, gastro-intestinal bleed (GIB), and sternal wound infections) were compared using Kruskal-Wallis test, Chi-square and Fisher's exact tests.

Results: Out of 590 patients, 62 (11%) were on PD, and 528 (89%) were on IHD. 277 (47%) underwent Valvular Surgery (VS) only, 158 (26.7%) CABG only, and 155 (26.3%) had combined CABG and VS. Baseline characteristics and comorbidities were similar between the PD and HD groups. In patients undergoing CABG only, PD patients

had more pericardial effusions (12.5% vs 2.3% p = 0.048) and more GIB (12.5% vs 2.2% p = 0.046) (Table 1). There were no differences in in-hospital mortality, hospital length of stay (LOS), ICU LOS, and sternal wound infections between groups across the different surgeries. 16 PD patients were converted to HD post-surgery, intent to treat analysis was applied for these patients.

Conclusions: In patients on maintenance dialysis, patients who underwent CABG, VS, and combined surgery had similar outcomes. PD patients appeared to experience more GIB and pericardial effusions requiring intervention in the CABG group.

PO0880

Progression of Coronary Artery Calcification in Unit vs. Nocturnal Haemodialysis Patients

Karen E. Brown,[1] Thomas Bucknall,[1] Giles Greene,[4] Helen Jefferies,[3] Ashraf I. Mikhail,[1] Sarah L. Prior,[2] Jeffrey W. Stephens,[2] Daniel R. Obaid.[1,2]
[1]Morriston Hospital, Swansea, United Kingdom; [2]Swansea University, Swansea, United Kingdom; [3]Cardiff and Vale University Health Board, Cardiff, United Kingdom; [4]Public Health Wales, Cardiff, United Kingdom.

Background: CT coronary artery calcium (CAC) predicts future cardiac events. Inflammation and deranged bone mineralisation may contribute to atherogenesis and arterial calcification. We compared progression of CAC in unit and nocturnal haemodialysis patients.

Methods: Patients commencing unit haemodialysis (UHD=7) and nocturnal haemodialysis (NHD=10) were prospectively enrolled. CAC scores (Agatson) were obtained at 0 and 12 months. Inflammatory (hsCRP, IL-18, hepcidin) and bone mineralisation (PO4-, Ca2+, PTH) biomarkers were obtained at 0, 3 and 12 months.

Results: Groups were well matched for age, gender, aetiology of ESRD and cardiovascular risk factors. Average baseline CAC scores were similar between UHD and NHD but significant progression occurred only in UHD (Figure). The relative increase in CAC score was significantly higher for UHD (71.2%) than NHD (6.7%), p=0.04. Over the study there were no significant changes in markers of bone mineralisation or inflammation for either group except patients undergoing NHD had a significant reduction in IL-18 (117pg/ml ± 59 to 75pg/ml ± 30, p=0.04). Significant CAC progression (increase in CAC >20AU and >15% occurred in 4/7 (57%) of UHD patients compared with 2/10 (20%) undergoing NHD. CAC scores regressed in 1/7 (14%) of UHD patients and 4/10 (40%) of NHD. Hepcidin was the only biomarker associated with CAC progression, it was higher in the progressors: 370pg/mL [321– 398] than regressors: 243pg/ml [138–349], p=0.045 with increase in CAC score correlated to the level hepcidin r=0.51.

Conclusions: Extended hours NHD significantly decreased progression of CAC compared with UHD. Progression appeared to be more dependent on levels of inflammation than deranged bone mineralisation with hepcidin the best predictor of CAC progression, but larger scale studies are required.

PO0881

Prevalence and Risk Factors for Development of Cardiac Arrhythmias and Electrocardiographic Abnormalities in Hemodialysis Patients: A Single-Center Experience in Mexico.

Andrea San-German Morales,[1] Pedro A. Escamilla Galindo,[2] Armando Castillo García,[1] Paulina Paniagua,[1] Juan M. Ardavin Ituarte,[2] Mario Jimenez Hernandez.[1,2]
[1]Universidad de las Americas Puebla, Cholula, Mexico; [2]Medica Santa Carmen, Puebla, Mexico.

Background: Mexico is among the countries with the highest number of patients on kidney replacement therapy (RRT). Despite this, the incidence and prevalence of CKD in Mexico is unknown, due to the lack of a national registry as a result we do not know risk factors associated to this population. Electrocardiographic abnormalities or arrhythmias are among the most frequent cardiovascular pathologies, being the first cause of death during the first month in RRT. That is why the present study aims to identify the prevalence of arrhythmias in a group of Mexican patients on hemodialysis as well as their associated risk factors.

Methods: A non-experimental, observational, descriptive, and cross-sectional study was carried out in the period from March to July 2020 with Mexican patients older than 18 years in maintained hemodialysis. The electrocardiograms and blood test analysis were taken on the day of hemodialysis therapy.

Results: The mean age of the population was 42.37 years, 57% were male. Arrhythmias were found in 50 patients (41.67%), the prevalence of arrhythmias found was bundle branch block (17.50%), sinus tachycardia (12.50%), sinus bradycardia (7.50%), atrial fibrillation (2.50%), extrasystoles (1.67%). A significant difference in mean ages was found between patients with (47.14) and without arrhythmia (38.97) (P = 0.041). A history of heart disease (OR 7.54 95% CI 1.05-184.7), and the diagnosis of chronic renal failure secondary to diabetic nephropathy (OR 2.5459 95% CI 1.1026-5.8785) were identified as risk factors. The diagnosis of chronic renal failure secondary to arterial hypertension was no related as risk factor (p=0.86). No laboratory study was identified as a risk or protective factor for the development of arrhythmia either the vascular access type.

Conclusions: The studied population presented similar characteristics to the described previously, a high prevalence of electrocardiographic abnormalities was identified, laboratory studies were not related to the presence of arrhythmias. History of heart disease and kidney disease secondary to diabetic nephropathy were associated as a risk factors, while the presence of arterial hypertension was not identified as risk factor.

PO0882

Evaluation of Venous Congestion in Chronic Hemodiafiltration Patients During Ultrafiltration: A Prospective Cohort Study

Pedro Gudiño Bravo, Mariana M. Cano Nieto, Nikein D. Ibarra Marquez, Gabriela Leal, Magdalena Madero, Edith L. Posada-Martinez, Salvador L. Gil.
Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.

Background: Fluid overload is deleterious in chronic hemodialysis patients. The combination of multiple POCUS markers can identify significant venous congestion. These markers have not been prospectively studied in this population.

Methods: We measured inferior vena cava (IVC) diameter, portal vein pulsatility fraction (PVPF), jugular vein at rest (YVR) and hepatic vein flow (HVF) at five points: pre-dialysis, three times during dialysis and post-dialysis. All measurements were done three times and averaged. All patients had at least 3% weight gain based on their estimated dry weight. We recorded ultrafiltration volume at each point.

Results: We performed measurements during 30 on-line post dilution hemodiafiltration sessions in 20 patients (13 were female, mean age 38.6 years old). The average total ultrafiltration (UF) volume was 2501.5 cc (1250-4250 cc). There was a significant reduction in PVPF, IVC diameter, YVR, HVF during sessions. See Figure 1. Likewise, UF volume correlated with IVC diameter: R -0.38 p<0.001; PVPF: R -0.31 p<0.001; and HVF: R -0.19 p=0.035.

Conclusions: In chronic hemodialysis patients, even in the absence of a dilated IVC, markers of venous congestion tracked ultrafiltration volume. This study warrants further research with regards to clinical decision to continue fluid removal in chronic hemodialysis patients.

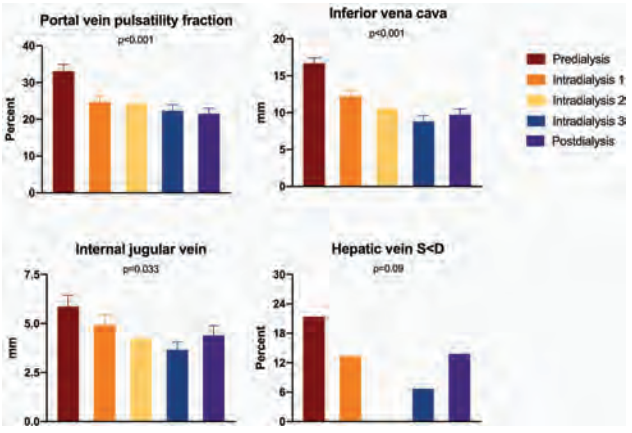

Figure 1. Different POCUS venous congestion markers measured pre-dialysis, intradialysis and post dialysis.

PO0883

Knowledge and Practice of Incremental Dialysis: A Survey of Canadian Nephrologists

Anita Dahiya, Aminu K. Bello, Stephanie E. Thompson, Kara Schick-Makaroff, Neesh I. Pannu. *University of Alberta, Edmonton, AB, Canada.*

Background: Incremental hemodialysis, a strategy to individualize dialysis prescription at initiation, is being linked to enhanced quality of life and acceptability by patients and decreased health care costs. We aimed to explore knowledge and practice pattern regarding facility-based incremental hemodialysis in Canada.

Methods: A web-based survey of nephrologists, elicited current incremental hemodialysis (HD) prescribing practices, clinical and patient factors used to determine suitability for treatment, and potential barriers to implementation. The survey was circulated over a period of six weeks (September 21, 2020 and October 30, 2020).

Results: The overall response rates 35% (243/691 nephrologists surveyed). Majority (66/111, 59%) of respondents prescribed incremental HD using an individualized approach at the discretion of the nephrologist. Most centers (200/203, 98%) did not report policy or guidance for implementation. Residual urine output was identified as the most important factor for eligibility (112/172, 65%), electrolyte stability (76/172,44%) and existing patient goals of care (69/117, 40%). The majority of nephrologists agreed that dialysis prescriptions are dynamic and should take residual kidney function into consideration; however, 74% of nephrologists did not think there was strong evidence supporting incremental dialysis. Potential barriers identified were patient safety, logistics of scheduling, limited evidence, and acceptance of dose escalation. Despite these barriers, 82% of participants felt that that facility-based incremental dialysis is feasible with their current resources and 78% agreed that with specific exclusion and inclusion criteria, incremental dialysis is a safe option.

Conclusions: Incremental hemodialysis is commonly practiced amongst Canadian nephrologists despite a lack of formal criteria for initiation and treatment escalation. This highlights a need for research to guide policy and practice for incremental hemodialysis in Canada.

PO0884

Thrice vs. Twice Weekly Hemodialysis in a Rural Community Center

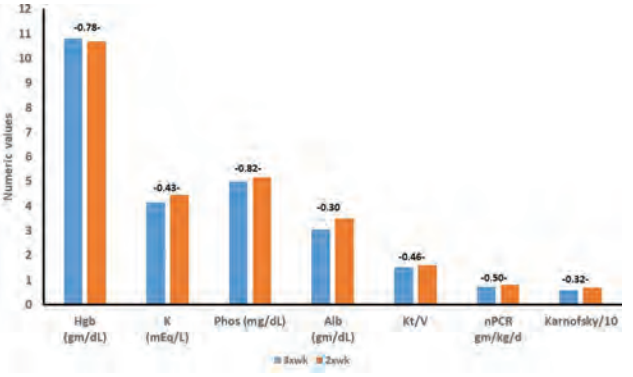
Paavan Bonagiri,[1] Namrata Singhania,[3] Girish Singhania,[2] Abutaleb A. Ejaz.[4] *[1]University of Virginia, Charlottesville, VA; [2]University of Utah Health, Salt Lake City, UT; [3]Mount Carmel East Hospital, Columbus, OH; [4]University of Florida, Gainesville, FL.*

Background: Converting stable ESRD patients from thrice to twice weekly HD sessions.

Methods: ESRD patients on 3xWkly HD sessions for at least 3 months duration were screened for eligibility for conversion to 2xWkly HD schedule in a university-affiliated community dialysis program. Eligibility criteria were: residual renal function > 3ml/min; urine output >500mL/day; intradialytic weight gain <2.5kg; hemoglobin >8gm/dL; manageable phosphorus and potasium levels. Clinical parameters on 3xwkly vs. 2xwkly HD sessions were then performed in the eligible patients. Patients were followed for 6 months post conversion.

Results: 9.8% of total HD pts were eligible. Baseline characteristics: age 65.1±4.5yrs, F 57.1%, HTN 71.4%, DM 14.2%, MM 14.2%. Major indication for HD initiation was symptomatic progression of disease. Less than 50% of patients had a functioning arteriovenous fistula at initiation of HD. In the current cohort, residual renal function > 3mL/min was maintained for > 200 days after initiation of HD. There were no significant changes in electrolytes, hemoglobin, nutrition staus or adequacy of dialysis. PTH levels were not significantly different: 3xwkly, 625.7±546.2pg/mL vs. 2xwkly, 399±344.2pg/mL; p=0.374). Karnofsky Performance Status Scale improved post conversion but did not achieve statistical significance (3xwkly, 57.1 vs. 2xwkly, 70; p=0.316). There were no hospital admissions since conversion to 2xwkly schedule during the study period.

Conclusions: 10% of total HD patients qualified for conversion from 3xWkly to 2xWkly maintenance HD without significant changes to laboratory or clinical performance measures. These observations stimulate discussion regarding increased application of incremental dialysis initiation strategies to preserve residual renal function, increase dialysis-free days and alleviate transportation and care provider-related burden to patients and families, especially in underserved areas.



Comparison of Clinical and laboratory parameters.

PO0885

Impact of the Ratio of Monocyte to High-Density Lipoprotein Cholesterol on Cardiovascular Outcome in Incident Dialysis Patients

Min Gyo Jeong, Hye Eun Yoon, Seok Joon Shin, Yeonhee Lee, Da won Kim. *Catholic University of Korea, Incheon, Republic of Korea.*

Background: Monocyte count to high-density lipoprotein ratio (MHR) is a well known risk factor of cardiovascular (CV) complications as an indicator of inflammation and atherosclerosis. We evaluated the impact of the MHR value on the CV outcomes in end-stage kidney disease (ESKD) patients. The primary outcome was comparison of cardiovascular event-free survival rate between the low MHR group and the high MHR group. The secondary outcome included all-cause mortality, overall CV mortality and possibility of MHR as an independent risk factor for CV complication.

Methods: The medical records of 719 ESKD patients who started maintenance dialysis between January 2006 and July 2017 were reviewed. Patients were divided into low MHR and high MHR groups based on the median MHR value.

Results: Overall CV event was 130 cases, 55 in the low MHR group and 75 in the high MHR group, respectively. The CV event-free survival rate was significantly lower in the high MHR group compared to the low MHR group (47.6% vs. 57.5%, $P = 0.017$). Of the 577 enrolled patients, there was no statistical difference in all-cause mortality between the two groups during a mean follow-up of 3.2 years ($P = 0.371$). Overall CV mortality rate was also comparable between the two groups ($P= 0.615$). In multivariate Cox regression analysis, high MHR was an independent predictor for CV events (HR 1.463, 95% CI, 1.019 – 2.102; $P = 0.039$) even after adjustment for age, smoking, diabetes, body mass index, C-reactive protein, and previous CV disease.

Conclusions: In conclusion, high MHR at the time of dialysis initiation in the incident ESKD patients may be a simple and useful method for predicting development of CV complication.

PO0886

Differences in Clinical Characteristics and Outcomes Between Hemodialysis-Dependent and Non-Hemodialysis-Dependent Patients with Gram-Negative Bacteremia

Matthew R. Sinclair,[1,2] Joshua T. Thaden,[1] Felicia Ruffin,[3] Lawrence Park,[1,4] Michael M. Dagher,[3] Christina M. Wyatt,[1,2] Vance G. Fowler.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]Duke University Hospital, Durham, NC; [4]Duke Global Health Institute, Durham, NC.*

Background: Gram-negative bacteremia (GNB) is a common and potentially lethal infection among hemodialysis (HD)-dependent patients. The determinants of clinical outcomes in HD-dependent patients with GNB are incompletely understood. We compared clinical characteristics and outcomes between HD- and non-HD-dependent patients with GNB in a large cohort of hospitalized patients and subsequently examined associations between specific characteristics and all-cause mortality among HD-dependent patients.

Methods: Hospitalized, non-neutropenic adults with GNB were prospectively enrolled from Jan 1, 2002 to July 1, 2015. Clinical characteristics and outcome data were collected. Differences between HD- and non-HD-dependent patients were estimated using means/standard deviations or counts/percentages with statistical significance evaluated with independent sample T-tests or Pearson's chi-squared test. Associations between clinical characteristics and outcomes were estimated using logistic regression.

Results: Among 1,827 unique participants, 180 were HD-dependent (9.9%). Compared to non-HD-dependent patients, HD-dependent patients were younger (58.6 vs 61.0 years, p=0.05) and more likely to be Black (55.6% vs 26.4%, p<0.001), to have diabetes (56.1% vs 32.1%, p<0.001), and to die prior to hospital discharge (28.9% vs

19.9%, p=0.01). Among HD-dependent patients, having a higher total APACHE II score (Odds Ratio [OR] 1.15, Confidence Interval [CI] 1.08-1.23), non-central venous access source of infection (OR 8.00, CI 2.71-23.60) or hospital-acquired infection (OR 4.46, CI 2.19-9.09) were associated with in-house mortality, while Black race (OR 0.31, CI 0.16-0.63) was inversely associated with mortality.

Conclusions: Clinical characteristics and outcomes differed significantly between HD- and non-HD dependent patients with GNB. Mortality among HD-dependent patients may be partially explained by source of infection, site of acquisition, and severity of illness at time of infection. The association between race and patient outcome requires further study.

PO0887

Predictors of Hyperkalemia Among Chronic Hemodialysis Patients Transported to the Emergency Department

Karthik K. Tennankore,[1,2] David Clark,[1,2] Patrick T. Fok,[1,2] Judah Goldstein,[1,2] Keigan More,[1,2] Megi Nallbani,[2] Amanda J. Vinson,[1,2] Hana Wiemer,[1,2] Wayel Zanjir.[1,2] *[1]Dalhousie University, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada*.

Background: Chronic hemodialysis (HD) patients often present to the emergency department (ED) with hyperkalemia, which in turn, is associated with morbidity and mortality. In this study we sought to identify pre-hospital predictors of hyperkalemia in patients transported to the ED via ambulance (ambulance-ED).

Methods: We analyzed all ambulance-ED transports in a cohort of chronic hemodialysis patients from 2014-2018 (using a province-wide emergency medical services database). The outcome was severe hyperkalemia using the first blood draw after ambulance-ED transport and defined as ≥6 mmol/L. Characteristics of interest included vital signs prior to transport, days from last dialysis and prehospital electrocardiograms (ECGs) interpreted by paramedics prior to transport. The association between prehospital factors and hyperkalemia was analyzed using adjusted logistic regression.

Results: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemic patients versus 24% of non-hyperkalemic patients required re-transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

Conclusions: A longer interval from last dialysis and prehospital ECG changes are strongly associated with hyperkalemia after transport to the ED. Having an awareness of these associations may allow healthcare providers to define novel care pathways to ensure timely diagnosis and management of hyperkalemia.

Adjusted predictors of severe hyperkalemia after transport to the emergency department (n=609)*

PO0888

Association of Potassium with Decline in Residual Kidney Function in Incident Hemodialysis Patients

Jessica A. Edward,[1] Cachet Wenziger,[1] Jui-Ting Hsiung,[1] Fridtjof Thomas,[2] Csaba P. Kovesdy,[2,3] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]VA Memphis Medical Center, Memphis, TN*.

Background: Hyperkalemia has been associated with higher risks for renal decline in non-dialysis kidney disease patients. However, it is unclear whether this relationship exists in hemodialysis (HD) patients.

Methods: A retrospective cohort study was conducted on 6,655 incident HD patients who received treatments from January 2007 to December 2011 and had renal urea clearance (KRU) data in the first and fifth patient quarter (91 day interval) post dialysis initiation. Renal decline was estimated by both KRU difference in the fifth minus first patient quarter as well as by a mixed-effect linear regression to estimate KRU slope over the first year. Baseline potassium levels were stratified into four groups: (≤4.0, > 4.0 to ≤4.5 (reference), > 4.5 to ≤5.0, >5.0 mEq/L) and linear regression models were used to analyze the relationship between potassium and KRU renal decline across models adjusted for demographics (case-mix), malnutrition-inflammation (MICS), and baseline KRU. Mediation analysis was also conducted to analyze if renal decline is a mediator in the association between potassium and mortality.

Results: The median (IQR) of one year difference in KRU was -1.24 (-2.91, 0.12) while the median KRU slope was -1.64 (-2.53, -0.95). Compared to the reference, potassium > 4.5 mEq/L was associated with the greatest difference in KRU in both the case-mix model (-0.28, 95% CI -0.44, -0.11) and in the case-mix + MICS model (-0.20, 95% CI -0.50, -0.06) [Figure 1A]. Similar results were seen for KRU slope [Figure 1B]. It was also observed that KRU slope mediated the relationship between potassium and mortality by 1.78%.

Conclusions: Hyperkalemia shows associations with renal decline over the first year on HD. Future studies should be conducted to investigate the pathways underlying these associations.

PO0889

Efficacy of Patiromer and Sodium Polystyrene Sulfonate on Potassium Levels in Chronic Hemodialysis Patients

David A. Jaques,[1] Fabien Stucker,[2] Thomas Ernandez,[3] Cyrielle Alves,[1] Pierre-Yves F. Martin,[1] Patrick Saudan.[1] *[1]Hopitaux Universitaires Geneve, Geneve, Switzerland; [2]Reseau hospitalier neuchatelois, Neuchatel, Switzerland; [3]Hopital de la Tour, Meyrin, Switzerland.*

Background: While hyperkalemia is frequent in haemodialysis (HD) patients and is associated with increased mortality, evidences regarding treatment options are limited. We compared the effect of sodium polystyrene sulfonate (SPS) and patiromer on potassium control in this population.

Methods: After screening 180 prevalent chronic HD patients, we included 52 patients with pre-HD potassium >5.1 mmol/l without potassium binder in a cross-over trial comparing on non-dialysis days SPS 15 g before each meal to patiromer 16.8 g once a day. Treatment duration was four weeks with a 2-week intermediate wash-out period. Treatment attribution order was randomized. Pre-HD potassium level was measured at each dialysis session and tolerability assessed on a semi-quantitative scale from 0 to 10.

Results: 45 patients terminated the study without missing values on considered variables. Mean age was 66.3 +/- 19.2 with 74 % male and 44% diabetic patients. Mean weekly pre-HD potassium were 4.5 +/- 0.7 mmol/L and 5.0 +/- 0.5 mmol/L under SPS and patiromer respectively. In mixed linear regression, treatment with SPS was associated with a decrease of 0.47 mmol/L in mean weekly pre-HD potassium compared to patiromer ($p<0.001$). Tolerability score was 6.0 +/- 2.4 and 7.0 +/- 1.8 under SPS and patiromer respectively ($p<0.001$).

Conclusions: In chronic HD patients, SPS 15 g before each meal on non-dialysis days resulted in lower pre-HD potassium values as compared to patiromer 16.8 g once a day, although tolerability was poorer. Those findings as well as dose titration need to be tested in larger randomized trials.

PO0890

Associations of Serum and Dialysate Potassium Concentrations with Incident Atrial Fibrillation in Older US Persons Initiating Hemodialysis for Kidney Failure

Austin Hu,[1] Sai Liu,[1] Maria E. Montez-Rath,[1] Pascale Khairallah,[2] Jingbo Niu,[2] Tara I. Chang,[1] Wolfgang C. Winkelmayer.[2] *[1]Stanford University School of Medicine, Stanford, CA; [2]Baylor College of Medicine, Houston, TX*.

Background: Atrial fibrillation (AF) is the most common arrhythmia and affects more than a third of U.S. patients with kidney failure on hemodialysis (HD). Hyperkalemia is a common concern in the HD population and been associated with higher mortality, especially sudden death. However, little is known about the associations of serum potassium ($S\text{-}K^+$) and prescribed dialysate potassium ($D\text{-}K^+$) concentrations with incident AF in persons on HD.

Methods: We used health records data of a large dialysis provider merged with the US Renal Data System (2006-11). We identified persons aged 67+ when initiating HD who had 2+ years of prior Medicare coverage and not been diagnosed with AF by day 120 after start of HD. Subsequent 30 day periods were created during which $S\text{-}K^+$ measurements were averaged; the most recent $D\text{-}K^+$ in the preceding 30 day window was also recorded. Demographic, comorbidity, and health utilization variables were defined as were other laboratory/biometric characteristics. The outcome, newly-diagnosed AF during the subsequent 30 days, was recorded from claims. This process was repeated after frameshifting all measurements by +30 day increments. Cox regression was used to estimate hazard ratios.

Results: We studied 15,190 persons on HD without prior AF diagnosis; average age was 76 yrs, 49% were male; 69% were white, 26% black, and 8% Hispanic. At baseline, 7183 persons had a S-K^+ ≥4.5 and 6988 <4.5 mEq/L. With the exception of race and ethnicity, all other characteristics, including D-K^+, which was 2 mEq/L in 52% and 3 mEq/L in 34%, were balanced between groups. During a mean follow-up of 527 days the overall incidence of AF was 13/100 person-years. Modeling S-K^+ as squared-term variable fit the data best. After multivariable adjustment, AF was associated with lower, but not with higher S-K^+ concentrations unless extreme values >6.5 mEq/L were reached. D-K^+ of 3 mEq/L, *vs.* 2 mEq/L, was associated with 14% (95%CI, 5-24%) lower adjusted rates of AF. No interaction between S-K^+ and D-K^+ was found (P=0.34).

Conclusions: Hypokalemia was strongly and independently associated with incident AF whereas hyperkalemia was not. However, choice of D-K^+ of 2 mEq/L *vs.* 3 mEqu/L did associate with higher AF rates, independent of S-K^+ and other measured characteristics.

PO0891

Serum Potassium Changes in US Veterans Receiving Patiromer with Dialysis-Dependent ESKD and Hyperkalemia

Csaba P. Kovesdy,[1] Elvira O. Gosmanova,[2] Steven D. Woods,[3] Christopher G. Rowan,[4] Jared Hansen,[5] Brian C. Sauer.[5] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]Albany Medical College, Albany, NY; [3]Vifor Pharma, Inc., Redwood City, CA; [4]COHRDATA, San Clemente, CA; [5]Salt Lake City VA Medical Center (IDEAS), Salt Lake City, UT.*

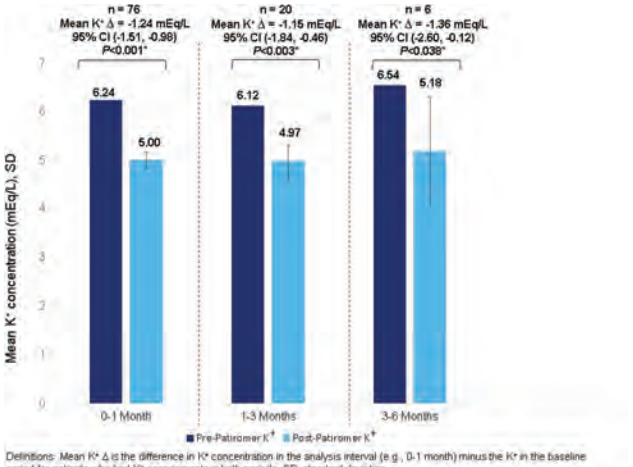
Background: Patiromer is a sodium-free, non-absorbed, potassium (K^+)-binding polymer approved for the treatment of hyperkalemia (HK). This retrospective cohort study aimed to describe serum K^+ changes in Veterans with HK and end-stage kidney disease (ESKD) receiving dialysis who initiated patiromer.

Methods: Serum K^+ concentrations were evaluated pre- and post-patiromer initiation using the National VA Corporate Data Warehouse (1/1/16–8/31/18). Changes in mean serum K^+ concentration were compared at 1, 3, and 6 months following first patiromer dispensing (index date) using the paired t-test (pre K^+ versus post K^+). All patients had a baseline K^+ ≥5.1 mEq/L and ESKD. Patients with continuous exposure to patiromer were analyzed. Follow-up began on the index date and ended at first censoring event (discontinuation or switch of index K^+ binder, death, end of follow-up, or 6 months post-index).

Results: 98 patients with ESKD requiring dialysis and HK initiated patiromer. Patient characteristics at baseline were median age 66 years, African-American race 39%, diabetes 71%, heart failure 40%, and mean K^+ value of 6.1 mEq/L (standard deviation = 0.7). The initial dose of patiromer was 8.4 g in 96% of patients with few observed increases in unit dose during the follow-up period. Following patiromer initiation, statistically significant reductions in serum K^+ concentration were observed at 1 month (–1.24 mEq/L), 3 months (–1.15 mEq/L), and 6 months (–1.36 mEq/L; Figure).

Conclusions: Among dialysis-dependent US Veterans with HK, patiromer was associated with clinically relevant reductions in serum K^+ concentrations at all study time points. These findings warrant additional investigation in a larger dialysis cohort with HK.

Funding: Commercial Support - Vifor Pharma, Inc.



Definitions: Mean K⁺ Δ is the difference in K⁺ concentration in the analysis interval (e.g., 0-1 month) minus the K⁺ in the baseline period for patients who had K⁺ assessments in both periods. SD, standard deviation
*P values and 95% confidence intervals were estimated using the paired t-test (H_0: Δ=0). The paired t-test compared the highest K⁺ value in the 3 months prior to initiating patiromer to the last K⁺ value in each monthly follow-up interval post-patiromer initiation

PO0892

Hyperkalemia: Medical Management vs. Hemodialysis

Joseph A. Gotesman, Maria V. DeVita. *Lenox Hill Hospital, New York, NY.*

Background: Hyperkalemia is a life-threatening electrolyte disorder for which there exists a paucity of data regarding benefit of urgent hemodialysis over medical management. We hypothesized there would be no difference in potassium levels among hyperkalemic patients who received *only* medical management compared to those who received hemodialysis, with out without hemodialysis.

Methods: This is a retrospective study of patients 18+ years old with hyperkalemia (K ≥ 5.5mmol/L). One group (medical management, or MM) had medication(s)—including insulin/dextrose, sodium zirconium cyclosilicate, sodium polystyrene sulfonate, calcium gluconate, albuterol, or furosemide—ordered within 3h of initial elevated potassium. The other group (hemodialysis, or HD), had hemodialysis ordered—with or without medical management—within 3h of elevated potassium. The initial potassium level was considered "time-zero" and subsequent timepoints were followed up to 100h. T1 readings were established between 0–3 hours; T6: 3–8h; T12: 8–16h; T24: 20–28h; T48: 40–56h; T72: 60–100h.

Results: Of 1365 patients screened between 2015 and 2020, we excluded 796 who were <18 years old or potassium level <5.5 mmol/L or without follow-up potassium levels. There were in-total 569 patients with 682 eligible patient visits; 64 (9%) of the 682 visits in HD group and 618 (91%) in MM group. The mean initial potassium was 6.45 ± 0.08 mmol/L in HD, versus 6.21 ± 0.03 mmol/L in MM. There was a progressive reduction in potassium levels over time in both groups. The reduction in potassium was similar in both groups across all timepoints (4.5-5.0 mmol/L in HD and 4.4-5.1 mmol/L in MM). The only timepoint that showed statistical difference was T12 where potassium level in HD was lower than in MM by 0.45 mmol/L (p-value = 0.0153). This may be secondary to the efficiency and permanence of potassium removal with dialysis or due to the relatively small sample size of the HD group; this difference is not clinically relevant.

Conclusions: Among patients presenting with hyperkalemia, we found no difference in potassium levels between those who received only medical management and those who received hemodialysis, with or without medical management. Further studies are necessary to confirm these findings. Nationally standardized treatment algorithms ought to be developed; a randomized trial would be conducive to that end.

PO0893

Metabolic Alkalosis in Hemodialysis Patients

Sitarama Arvind Mudunuru, Jose E. Navarrete, W. Charles O'Neill. *Emory University School of Medicine, Atlanta, GA.*

Background: Hemodialysis (HD) typically employs a high dialysate alkali concentration to counteract interdialytic acid production. Since acid production varies due to the amount and type of protein consumed, some patients may remain alkalotic throughout the interdialytic period and be more alkalotic during HD. This could have adverse effects including arrhythmias, hypotension, hypoventilation, and vascular calcification but dialysate alkali is rarely adjusted. Pre-HD alkalosis is usually ascribed to chronic illness and poor nutrition, but this has not been carefully examined.

Methods: We conducted a retrospective case-control study of all in-center HD patients from 2010 - 2020 at 4 outpatient HD units using citrate-containing dialysate (34.6 meq/L HCO3, 0.4 meq/L acetate, 2.4 meq/L citrate; citrasate, Fresenius). Interdialytic alkalosis was defined as pre-HD serum [HCO3] ≥26 in ≥ 7 months of any 12-month period. Persistent alkalosis was defined as interdialytic alkalosis in every subsequent 12-month period. Patients with serum [HCO3] 19-23 in ≥ 7 months of every 12-month period constituted the control cohort.

Results: Of 1271 patients with at least 12 months of HD, 444 met the alkalosis criteria for at least one 12-month period and 73 had persistent alkalosis. 189 patients met the control criteria for every 12-month period. Patients with persistent alkalosis were older (66 vs 55 years, p<0.001) and weighed less (69 vs 82 kg, p= 0.003), but the prevalence of comorbidities including cardiovascular disease, neoplasia, and diabetes was not increased. HD dose (kT/V) was greater (1.47 vs 1.37, p<0.001), protein catabolic rate was lower (0.85 vs 0.96 g/kg/day, p <0.001), and interdialytic weight gain was less (1.62 vs 2.28 kg, p<0.001). Despite significant weight loss over time (7 ± 13 vs. 0 ± 9 kg, p <0.001), mortality was not increased when adjusted for age, serum albumin was only slightly lower (3.71 vs 3.80 g/dl, p=0.03), and other markers of malnutrition/chronic illness such as serum cholesterol and hemoglobin did not differ from control patients.

Conclusions: Transient interdialytic alkalosis was common in this HD population and persistent alkalosis was not rare (>5%). Alkalosis appeared to result from a greater dialysis dose and lower protein intake but not chronic illness. Further studies are needed to determine whether this alkalosis is detrimental and adjustment of dialysate [HCO3] is indicated.

PO0894

Metabolic Alkalosis in Hemodialysis Patients: Worse Outcomes?

Gonçalo Ávila, Patrícia Matias, Ivo J. Laranjinha, Célia Gil, Manuel A. Ferreira. *Dialverca-dialysis clinic, Forte da Casa, Portugal.*

Background: The ideal serum bicarbonate levels in prevalent hemodialysis (HD) patients is still debatable. Metabolic alkalosis in these patients has been associated with increased morbimortality. The aim of this study was to evaluate the association between serum bicarbonate and nutritional and cardiovascular risk markers, hospitalizations and mortality.

Methods: This was a single-center, retrospective study, of a cohort of 158 in-center HD patients, with a duration of 24 months. Serum bicarbonate levels were evaluated predialysis every 3 months. Body Composition Monitor was used to assess nutritional and hydration status. Electrocardiogram and echocardiogram data were obtained to calculate the QTc interval and the left ventricular mass index, respectively. Vascular calcifications were assessed using the Adragão score (SVCS).

Results: Mean age of the population was 69.8±12.6, 73% were male and 45% had diabetes. Median HD vintage was 59 months (IQR: 65 months). Mean serum bicarbonate was 23,5±1,57 mEq/L. There was as inverse association between serum bicarbonate and body mass index (r=-0.22, p=0.006), lean tissue index (r=-0.35, p<0.001), hemoglobin (r=-0.19, p=0.016), albumin (r=-0.30, p<0.001), phosphorus (r=-0.33, p<0.001) and nPCR

(r=-0.41, p<0.001). Patients with greater SCVS (≥3) had higher mean serum bicarbonate (24.1±1.29 vs. 22.4±1.36 mEq/L, p<0.001). Higher serum bicarbonate was associated with an increased number of infection-related hospitalizations (p=0.009) and mortality (p=0.024), as well as all-cause mortality (p=0.012). Kaplan-Meier analysis revealed a significantly higher all-cause mortality in patients with serum bicarbonate ≥ 24.5 mEq/L at 24 months. The Cox regression analysis showed that serum bicarbonate was a predictor of all-cause mortality (p=0.004) in a model adjusted for age, dialysis vintage and the presence of diabetes.

Conclusions: In this population, higher serum bicarbonate was associated with a worse nutritional status and a higher cardiovascular risk, assessed by Adragão score. There was an association with an increased number of infection-related hospitalizations and mortality, as well as higher all-cause mortality. Serum bicarbonate levels ≥24.5 mEq/L were associated with lower survival at 24 months. Prospective studies are needed to determine the ideal serum bicarbonate levels in HD patients.

PO0895

The Use of Caffeine to Treat Intradialytic Hypotension

Indrani G. Das,[1] Shab E Gul Rahim,[2] Sri Lekha Tummalapalli.[1] *[1]Weill Cornell Medicine, New York, NY; [2]NewYork-Presbyterian Healthcare System Inc, New York, NY.*

Introduction: Intradialytic hypotension (IDH) affects over 10% of individuals on hemodialysis (HD) and can cause long-term multisystem ischemic damage. One proposed mechanism for IDH is the accumulation of local adenosine causing vasodilation. Agents such as midodrine and caffeine counter these vasodilatory effects. Herein we present a case of IDH where the ingestion of caffeine prior to HD sessions significantly reduced the severity of IDH.

Case Description: A 77-year-old female with CKD-5, longstanding hypertension, and type 2 diabetes mellitus was admitted for initiation of HD. During her 1st HD session, she experienced IDH with a sudden drop in her systolic blood pressure (SBP) from the 193 to 113, accompanied by loss of consciousness and convulsions of the bilateral upper extremities. She regained consciousness without a postictal state and no significant changes on ECG. Echocardiography ruled out pericardial effusion. On subsequent HD sessions, the patient continued to experience IDH with average decreases of over 100mmHg in her SBP. Initial management by lowering blood flow rate, lowering dialysate temperature, and holding the patient's pre-dialysis antihypertensive regimen had only a mild effect in preventing IDH. Given previous studies showing the efficacy of 250 mg caffeine capsules in preventing IDH, we tested the effect of caffeine on this patient's IDH. 30 minutes prior to her next inpatient HD session, we administered 10 oz of coffee (150 mg of caffeine). Her drop in SBP during that session was markedly reduced from 187 to 149.

Discussion: Non-pharmacological measures to prevent IDH have previously been implemented but lack well-powered clinical trial evidence. Using coffee as a vehicle for caffeine administration was an effective preventive measure for IDH in our patient. We hypothesize that this effect is adenosine inhibition mediated. Adenosine is released by cells undergoing localized ischemia during HD, causing vasodilation. Studies show an increase of serum adenosine during IDH. Caffeine is a non-selective adenosine receptor antagonist, and can prevent sudden vasodilation during dialysis. Thus, coffee may be an effective alternative to midodrine for the prevention of IDH. In conclusion, coffee provided a readily available, inexpensive, patient-centered, non-pharmacological measure to reduce IDH while also decreasing the risk of polypharmacy.

PO0896

A Case of Posterior Reversible Encephalopathy Syndrome (PRES) in an ESKD Patient with COVID-19

Victor J. Martinez, Daranee Chewaproug. *Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: Posterior reversible encephalopathy syndrome (PRES) is a clinico-radiological syndrome first reported in 1996 which describes the presence of a wide range of neurological symptoms, and posterior brain white matter edema on imaging studies which may be reversible. The clinical presentation is characterized by headache, altered consciousness, visual disturbances and seizures; hypertension is frequent, although not invariable.

Case Description: A 37-year-old male with past medical history of hypertension and end stage kidney disease on hemodialysis who presented with shortness of breath, occipital headache, and bilateral acute vision loss. On admission, he was afebrile with a blood pressure of 274/147 mmHg, RR of 16, HR 98 bpm and oxygen saturation of 89% on room air. Due to acute vision loss, a stroke alert was initiated. A head CT scan showed subcortical hypodensities in the bilateral occipital lobes consistent with PRES. He was started on Nicardipine drip in the ICU with subsequent decrease in blood pressure to 166/105 mmHg. His vision restored fully without further episodes of vision loss. Patient was found to be positive for COVID-19 and did not receive treatment for it as his shortness of breath and hypoxia resolved. The patient received maintenance hemodialysis, Nicardipine drip was weaned, and he was transitioned to oral blood pressure medications.

Discussion: The relationship between kidney disease and PRES is not fully understood. Reported cases of PRES have been linked with hypertension, autoimmune disease, and immunosuppressive states, common diseases in ESKD. The pathophysiology of PRES appears to be related to cerebral blood flow dysregulation and endothelial cell dysfunction. The proinflammatory response in COVID-19 produces dysfunction and death of endothelial cells which may increase vascular permeability, promoting the cerebral edema seen in PRES. The estimated prevalence of PRES in COVID-19 patients is between 1-4%. Reports of PRES in ESKD are rare. PRES may not be readily recognized given the heterogeneity of presentation. Therefore, high index of suspicion is needed in the ESKD population.

PO0897

Eye Pain During Hemodialysis: Ocular Dialysis Disequilibrium?

Sarah Abdel Massih,[1] Monika Aggarwal (Gupta).[2] *[1]Virginia Commonwealth University Health System, Richmond, VA; [2]VA Richmond Medical Center, Richmond, VA.*

Introduction: Changes in Intraocular pressure (IOP) during hemodialysis (HD) are underrecognized. We report a case of increased IOP during HD, successfully treated with adjustments to dialysis prescription.

Case Description: 39-year-old African American man with End Stage Renal Disease (ESRD) secondary to diabetic nephropathy on HD since 2017, presented with excruciating right eye pain during HD for 2 weeks. He described increasing right eye pain during HD, requiring early termination of dialysis after 3 hours. He has known right eye glaucoma with no vision. He was on atropine sulfate, prednisolone acetate, latanoprost, dorzolamide/timolol, and brimonidine tartrate eye drops. IOP in right eye were 63 and 80 mm of Hg, before and after hemodialysis, respectively. Left eye IOP were < 20 mm of HG and did not change significantly with dialysis. Due to concerns for ocular dialysis disequilibrium; blood flow rate, dialysate flow rate, dialysate temperature, and dialysate sodium were changed to 400 ml/minute from 450 ml/minute, 500 ml/minute from 800 ml/minute, 35.6 C from 37 C, and 145 mEq/L from 140 mEq/L, respectively. Subsequent to changes to dialysis prescription, patient was able to complete dialysis with no worsening of right eye pain and IOP (62 and 64 mm of HG before and after dialysis, respectively).

Discussion: Increase in IOP during HD is thought be due to rapid decline in plasma osmolality relative to aqueous humor, creating an osmotic gradient that causes movement of water into the eye. Patients with normal eye outflow have minimal rise in IOP as aqueous humor is drained simultaneously. However, patients with glaucoma are not able to drain excess water, causing increase in IOP and eye pain. Older age, diabetes mellitus, and African-American race are risk factors for ESRD and Glaucoma. Early recognition of ocular disequilibrium syndrome can allow for safe delivery of dialysis in patients with glaucoma. While acetazolamide is an effective treatment for raised IOP, it's efficacy and safety in ESRD remains unknown. Similarly role of Mannitol in mitigation of ocular dialysis disequilibrium is unclear. Our patient had resolution of ocular dialysis disequilibrium with decrease in blood and dialysate flow rates, increase in dialysate sodium, and decrease in dialysate temperature. Increase in ultrafiltration may also reduce risk of ocular dialysis disequilibrium by raising extracellular oncotic pressure.

PO0898

The Association of Interdialytic Weight Gain in Long Intervals with Residual Renal Function Decline

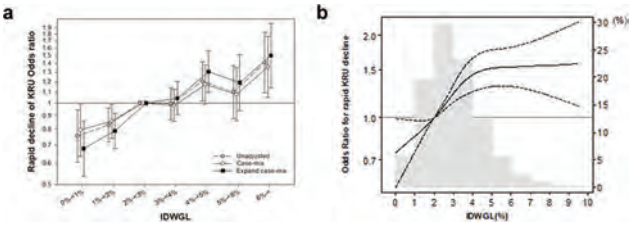
Yoshikazu Miyasato,[1,2] Tsuyoshi Miyagi,[1] Yoko Narasaki,[1] Hiroshi Kimura,[1] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]University of California Irvine, Irvine, CA; [2]Kumamoto Daigaku, Kumamoto, Japan.*

Background: Preservation of residual renal function (RRF) in dialysis patients is important for better prognosis. The effect of interdialytic weight gain (IDWG) on change of RRF has not been investigated well. We examined the association of IDWG in long intervals (i.e. 2-day breaks between dialysis treatments) with rapid decline of RRF.

Methods: This retrospective cohort study included 6425 patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWG in long intervals (IDWGL) and rapid decline of RRF using logistic regression model. Rapid decline of RRF was defined as the percent decline in renal urea clearance (KRU) greater than the median value of the cohort in the first year after dialysis initiation. Seven categories of IDWGL were as follows: 0-<1%, 1-<2%, 2-<3%, 3-<4%, 4-<5%, 5-<6%, and ≥6%. We also examined continuous associations between IDWGL and rapid decline of RRF using restricted cubic spline analysis.

Results: Higher categories of IDWGL were associated with increased risk of rapid decline of RRF. The odds ratios (95% confidence intervals) of rapid decline of RRF for 3-<4%, 4-<5%, 5-<6%, and ≥6% were 1.04 (0.90-1.20), 1.31 (1.09-1.56), 1.19 (0.94-1.51), and 1.50 (1.14-1.97) (Reference: 2-<3%) (Figure a). The restricted cubic spline analysis showed that risk of rapid decline of RRF increased when IDWGL exceeded 2% (Figure b).

Conclusions: Our results showed higher IDWGL was associated with higher risk of rapid decline of RRF. IDWGL exceeded 2%, especially ≥4%, seems to be thresholds for higher risk of RRF decline.



PO0899

Prevalence of Anti-Erythropoietin Antibodies in Patients with ESRD on Regular Hemodialysis: A Single-Centre Experience

Kevin T John Keeppallil, Manikantan Shekar, Ramprasad Elumalai. *Sri Ramachandra Institute of Higher Education and Research, Chennai, India*.

Background: Recombinant human erythropoietin (rHuEPO) is a glycoprotein that acts as a biological substitute for the endogenous substance used to treat anaemia in individuals with end-stage renal failure. Patients with rHuEPO resistance have been described, requiring higher and higher dosages of the drug to maintain an appropriate haemoglobin level. These antibodies probably cross react with the patient's endogenous EPO and lead to anemia that can be more severe than even before the onset of EPO therapy. The prevalence of anti-erythropoietin antibodies in renal patients who respond poorly to erythropoetin is unknown.

Methods: We screened 262 patients who were on maintenance haemodialysis and excluded patients who were malnourished and had chronic liver disease, hypothyroidism, ongoing active autoimmune disease, active infection, on steroid therapy, with bleeding or hemolysis and elderly. 96 ESRD patients who were on recombinant human erythropoietin > 6 months and hemoglobin < 10 g /dL were included. Serum anti-EPO antibodies were detected by enzyme-linked immunosorbant assay technique. All patients were subjected to full history taking and clinical examination. Complete blood count, reticulocytes count, serum creatinine, blood urea, serum albumin, serum ferritin, and hepatitis markers were performed for all patients.

Results: Results showed that 26 patients (27.08%) had the anti-EPO antibodies in their blood, while 70 patients (72.91%) did not have the circulating antibodies. The mean hemoglobin (Hb) level was significantly lower in the antibody positive group (8.4 g/dl ± 1.52) than in the antibody negative group (9.68 g/dl ± 1.14) (P = 0.000). The dose of EPO administrated in both studied groups were significantly different. Logistic regression analysis also revealed that gender or age were not associated with any significant variation of serum antibody level. High levels of serum antibodies to EPO are a risk factor for EPO resistance.

Conclusions: Many anaemic ESRD patients treated with recombinant human erythropoetin have a low-affinity immune response to the recombinant protein that is readily detected. Antibodies to rHuEPO were shown to be greater in patients who received high EPO weekly dose. More research into anaemia management protocols in HD patients with positive anti-EPO antibodies is needed.

PO0900

Posterior Ischemic Optic Neuropathy After Hemodialysis In a Patient with Uncontrolled Diabetes Mellitus

Abdelrhman Abo-Zed, Manuel A. Paez-Escamilla, Arjun L. Kalaria, Blaise W. Abramovitz, Evan L. Waxman. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Introduction: Posterior ischemic optic neuropathy (PION) results from ischemic damage to the retrobulbar optic nerve and presents as severe acute painless unilateral or bilateral loss of vision. Any procedure that results in sufficient optic nerve hypoperfusion can cause retrobulbar optic nerve damage. Hemodialysis (HD) as a cause of peri-procedural bilateral PION is a rare complication. While there are reports of successful cases of treatment with hyperbaric oxygen treatment and steroids, there is no established treatment protocol and the prognosis for recovery of vision in patients with peri-procedural PION is poor.

Case Description: A 34-year-old male with end-stage renal disease on HD presented with respiratory complaints and hypertensive emergency (BP 224/135 mmHg). His past ocular history was significant for proliferative diabetic retinopathy. Due to volume overload, he underwent emergent HDovernight with ultrafiltration of 3 L. He underwent a subsequent HD treatment with additional ultrafiltration of 3 L the following morning with lowest BP 117/73 mmHg. Shortly after the second HD treatment, he complained of bilateral painless complete loss of vision. He was found to have no light perception in either eye. Pupils were 3 mm and amaurotic. A dilated fundus exam showed perfused-appearing optic nerves. A presumptive diagnosis of bilateral PION was made due to relative hypotension during HD. The patient was treated with erythropoietin (EPO) 10,000 units twice daily and IV methylprednisolone for 3 days according to the protocol suggested by Nikkah et al for non-arteritic anterior ischemic optic neuropathy. Examination 14 hours after the first dose showed marked clinical improvement and he regained his vision. The patient underwent two more HD sessions with careful attention paid to avoiding hypotension. He had no subsequent vision loss. When he was seen in the eye clinic 4 days after discharge, his visual acuity remained stable.

Discussion: EPO has been proposed as a treatment agent for ischemic optic neuropathy. Bilateral loss of light perception is a rare complication related to hypotension on HD. The presumed etiology in this case was PION. Prompt treatment with EPO and intravenous steroids should be considered in similar situations that result in PION related to procedure-based hypotension.

PO0901

Ocular Dysequilibrium with Eye Pain During Hemodialysis

Zaiyara Adorno Rivera, Irtiza Hasan, Charles W. Heilig. *University of Florida Health, Jacksonville, FL.*

Introduction: Eye complications may occur ESRD patients with glucoma. Hemodialysis (HD) may lower plasma osmolality at a faster rate than changes in ocular osmolality can adapt. Here we are presenting two cases of ESRD patients who repeatedly developed eye pain only during HD.

Case Description: A 54 y/o Hispanic male with ESRD, right eye blindness & glaucoma who developed right eye pain only during dialysis treatments. The maintenance HD prescription was with duration of 4.5 hr, blood flow rate (BFR) 450mL/min, dialysate flow 800 ml/min, Sodium (Na) 138 meq/L, potassium 2meq/L, Calcium 2.5 mEq/L, CO2 30mEq/L & an average 2L fluid removal per HD. His BP was 130-140mmHg/ 80-90 mmHg. In response to the eye symptoms, the BFR was reduced to 350 ml/min & time was increased to 4.5 hr. This change gave the patient initial relief from intradialytic eye pain. Eventually, Ophthalmologist was able to perform a surgical procedure which would eliminate the intradialytic eye pain. The 2nd case was a 64 y/o AA female with ESRD and glaucoma developed recurrent left eye pain with headaches only during HD. She went to her Ophthalmologist who renewed her glaucoma medications. This relieved her eye symptoms, and normalized her intraocular pressure off of dialysis. By taking her eye medications, she no longer developed eye pain or headaches during HD.

Discussion: Glaucoma is an ocular disorder where there is an increased IOP most commonly >22mmHg, this elevated pressure can cause blinding optic neuropathy. The current hypothesis for the rise of IOP during HD is related to an osmotic disequilibrium between the plasma & IO fluid, where the IO fluid is slightly hypertonic compared to plasma. Several medical therapies have been reported to mitigate the IOP increase during HD, such as the use of daily acetazolamide, mannitol infusion or 20% hyperosmolar glucose solution, or modified dialysis parameters with colloid infusion to raise plasma tonicity and decrease fluid shift during HD. However, these maneuvers have not been proven to relive ocular symptoms. In general, use of higher dialysate Na conc. at hemodialysis are not considered a long term solution to intradialytic ocular hypertension, due to the tendency for increaser fluid intake between HDs. Lower BFR with longer duration of hemodialysis treatments has been beneficial in some cases.

PO0902

Transient, Severe, Unilateral Eye Pain and Vision Loss Associated with Hemodialysis

Anas Diab. *WVU Nephrology, Morgantown, WV.*

Introduction: Acute on chronic angle-closure glaucoma with elevated intraocular pressure is a well-established etiology of severe eye pain and profound vision loss, if not treated emergently. This case is a recurrent and episodic eye pain with transient visual loss during HD.

Case Description: 64 year-old Caucasian female with comorbidities including poorly-controlled insulin dependent type 2 diabetes, uncontrolled hypertension, obesity. She is on intermittent hemodialysis three times weekly the last 5 years. She was previously followed by a retina specialist for proliferative diabetic retinopathy with subsequent neovascular glaucoma. Initial onset approximately 1 year prior, with episodic pain and blurred vision with severe eye pain and complete unilateral vision loss start at initiating dialysis, symptoms resolved with cessation of treatment. Due to worsening pain symptoms, patient compliance becomes an issue, leading to frequent missing Dialyiss and Pulm edema required hospitalization. A glaucoma specialist, diagnosed neovascular glaucoma of the right eye. Maximal topical and oral tolerated medical therapy was started, but her disease was refractory to conservative management. Surgical intervention was pursued, Valved Drainage Device (New World Medical) was placed under topical anesthesia. Post-operatively, the patient was able to undergo dialysis sessions without ocular symptoms and compliance has improved.

Discussion: The effect of hemodialysis (HD) on intraocular pressure (IOP) is variable and the exact mechanisms are still not clear. Previous reports in the literature suggest both increased and decreased intraocular pressure during fluid shifts associated with hemodialysis. Argon Pan-retinal laser photocoagulation is known to reduce angle neovascularization induced by peripheral retinal ischemia in Neovascular glaucoma patients, IOP reduction is typically achieved with topical and systemic medications. Shunting and filtering procedures, including glaucoma valve implants and trabeculectomy surgery, may restore outflow and reduce IOP. After appropriate surgical intervention, the patient reported resolution of symptoms and improved tolerance to dialysis sessions.

PO0903

Caffeine Overdose Requiring Extracorporeal Mechanical Oxygenation (ECMO) and Hemodialysis

Luke Lundeen, Connie J. Wang. *Hennepin Healthcare, Minneapolis, MN.*

Introduction: Caffeine (1,3,7-trimethylxanthine) is the most widely consumed psychostimulant in the world. It is considered safe if consumed in moderation but can lead to cardiovascular collapse if the dose exceeds 150-200mg/kg. Extracorporeal removal of caffeine with intermittent hemodialysis (IHD) has been reported to improve outcomes. However, continuous veno-venous hemodiafiltration (CVVHDF), which is a routinely used extracorporeal therapy in patients with severe hypotension, is traditionally less favored for caffeine overdose because of inadequate rate of clearance. We present a case of combination therapy using both IHD and CVVHDF in the treatment of life-threatening caffeine overdose.

Case Description: A 33-year-old female weighing 63kg presented after ingestion of approximately 100g of guarana powder (22g of caffeine). She presented with refractory ventricular tachycardia (140-170 BPM) and severe hypotension (blood pressure 50/40 mmHg) resistant to 4 vasopressors at maximal dose. She required extracorporeal membrane oxygenation (ECMO). Baseline renal function was normal. IHD was initiated with blood flow rate (BFR) 200ml/min and dialysate flow rate (DFR) 500ml/min, which was gradually increased over 4 hours to a BFR of 400ml/min and DFR of 800ml/min; IHD continued for an additional 4 hours at this rate. During this 8-hour IHD treatment, her initial 4 pressor doses were halved, and she was transitioned to CVVHDF; the caffeine level remained unavailable. However, after 12 hours of CVVHDF, the patient did not experience continued hemodynamic improvement, so IHD was reinitiated for 12 hours. Following this second prolonged session of IHD, she was weaned down to moderate doses of just two pressors. She was then transitioned back to CVVHDF for an additional 36 hours, at which time she was able to come off ECMO and all pressors. She had a full neurologic recovery. We later received a serum caffeine level of 425mg/L (drawn soon after arrival at the hospital), which is the second-highest level ever reported; the established lethal concentration is 80mg/L.

Discussion: Despite continuous dialytic therapies being generally favored in patients with hemodynamic instability, a combination of IHD and CVVHDF may be used for hemodynamically unstable patients who ingest extremely high dose of caffeine. However, in such patients, continuous therapies are unlikely to supplant prolonged and repeated IHD treatment sessions.

PO0904

Anaphylaxis Secondary to Citric Acid Allergy in ESKD Patients

Hassaan Iftikhar, George Jarad. *Washington University in St Louis, St Louis, MO.*

Introduction: Dialysis reactions are common in ESKD patients undergoing hemodialysis (HD). We report first case of anaphylaxis related to citric acid solution used for dialysis disinfection & descaling.

Case Description: 61-year-old male with history of ESKD on HD for 7 years, presented after missing dialysis. Patient underwent urgent HD upon presentation and developed signs of angioedema within first 30 minutes, requiring nasal intubation & treatment with epinephrine, steroids & antihistamine. While intubated and hypotensive, patient had uneventful Slow Low Efficiency Dialysis. Angioedema was presumed secondary to antiemetics, which patient required due to severe nausea shortly after starting HD. Post extubation, patient developed similar reaction with milder symptoms with HD that responded to stopping HD and medical therapy. He had normal complement and mildly elevated tryptase. He was presumed to have a dialyzer reaction therefore, the dialyzer was changed from Revaclear to REXEED & it was tolerated well. He had similar severe reaction a week later while using the REXEED dialyzer. Investigations showed elevated anti-ethylene oxide antibodies (ETO) but clinical significance was questionable given the reaction only developed in inpatient setting. Later we discovered that dialysis machines are disinfected/descaled differently between inpatient & outpatient dialysis, even though both utilize citric acid, which might have led to more exposure to citric acid solution in inpatient setting. For next 2 weeks, patient was dialyzed using different combinations of dialysis machines, dialyzer & dialysis circuits including ones sterilized with ETO, however, all machines were disinfected/descaled using a combination of bleach & heat. After elimination of citric acid, patient had no further anaphylactic reaction.

Discussion: Dialyzer membrane reactions have been commonly described as Type A reactions mediated by dialyzer membrane (IgE mediated) and Type B membrane reactions mediated by complement activation. In our case clinical significance of ETO antibody was not clear, & angioedema was eliminated after removing citric acid from the machine disinfection process. Industrial citric acid mediated angioedema has not been reported before, & it might be an important mediator of allergy in ESRD, & careful review of the dialysis machine preparation should be reviewed in every case of severe allergic reaction.

PO0905

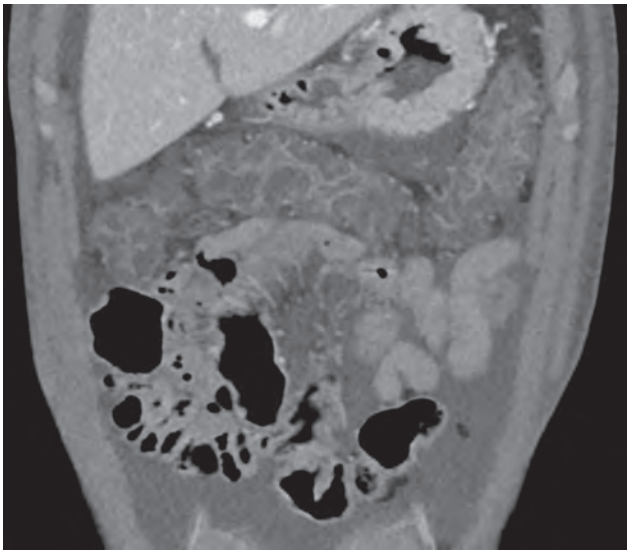
An Unexpected Cause of Colitis

Alon Bnaya, Ofer Benjaminov, Eyal Itzkowitz, Jawad Atrash, Omar Abu Lybdeh, Mohsen Abu Alfeilat, Linda Shavit. *Shaare Zedek Medical Center, Jerusalem, Israel.*

Introduction: Gastrointestinal manifestations are common among patients with advanced kidney disease. However, uremia associated colitis is rarely described in patients with ESKD. We present a unique case of uremic pancolitis in a patient with ESKD of unknown cause.

Case Description: An 18-year-old male with a history of asthma was admitted with nausea, vomiting and diffuse abdominal pain. He had no fever, arthralgias, rash, respiratory symptoms, or diarrhea. Mild peripheral edema and flapping tremors were noted on physical examination. Laboratory blood tests revealed severe kidney injury (creatinine 18.2 mg/dL, BUN 129 mg/dL). Urinalysis was positive for blood and protein. Immunologic and infectious serologies were unremarkable. An abdominal CT scan detected two small atrophic kidneys and diffuse severe bowel wall thickening of the colon with thumb printing noted (Figure 1), mimicking a pseudomembranous colitis pattern. Abdominal ultrasound revealed severe edema along with high vascularization of the colon wall. Uremia associated colitis was suspected due to the patient's extreme uremic state and hemodialysis was initiated. Following three weeks of hemodialysis, an abdominal ultrasound showed a significant improvement in edema and vascularization of the colon wall.

Discussion: Patients with advanced CKD often have a variety of gastrointestinal symptoms. However, severe uremic colitis mimicking pseudomembranous pattern is extremely rare in ESKD. Extensive literature review revealed only single case report of uremic pancolitis in a patient with severe kidney injury related to IgA nephropathy. With the improvement of care of patients with kidney disease, uremic colitis is rarely seen in the routine nephrology practice. However, it should be included in the differential diagnosis and evaluation of patient with ESKD, particularly if other more frequent etiologies of colitis have been excluded.



PO0906

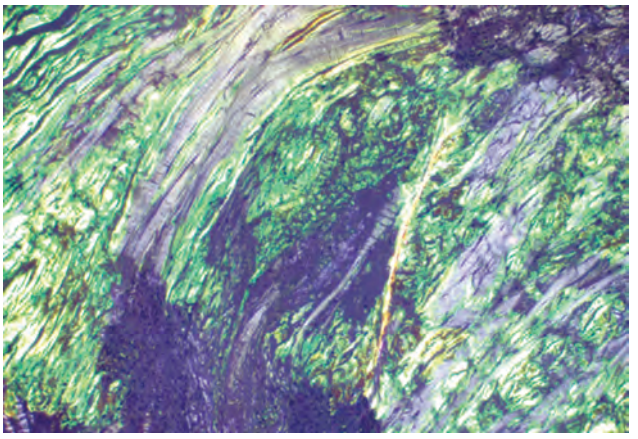
Reverse Shoulder Arthroplasty in Dialysis Amyloidosis

Jessica Schilling,[1] Srinath Kamineni,[2] Dana Richards,[2] Marie-Claude M. Faugere,[2] Florence Lima,[2] B. Peter E. Sawaya,[2] Madhumathi Rao.[2] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Introduction: The use of high-flux over cuprophane dialyzers, has led to Beta-2 microglobulin amyloidosis (B2M) becoming rare in long term hemodialysis (HD) patients. Amyloid fibers embed systemically, skeletal involvement producing bone cysts, tendinopathy and fractures.

Case Description: A 65-yo male on chronic HD for 30 years presented with progressive, right (R) shoulder intractable pain and limited range of movement (ROM). X-ray/MRI identified severe glenohumeral osteoarthritis (OA), tendinopathy and large irreparable rotator cuff tear. Past history included heart failure, pulmonary hypertension, hepatitis C, severe secondary hyperparathyroidism and chronic anemia. Surgical history included bilateral (b/l) total hip arthroplasties, b/l carpal tunnel release, R nephrectomy for renal cell carcinoma in renal cystic disease. Due to the intractable pain, disability and failure of physical therapy and corticosteroid injection therapy he underwent reverse shoulder arthroplasty. Operative findings showed large soft tissue deposits about the subscapularis, glenoid and labrum, attributed to amyloid. Histology of intra-articular soft tissue, labrum and synovium confirmed amyloid (apple-green birefringence by Congo Red Staining) with focal calcium pyrophosphate deposition. Undecalcified histology of humeral head showed moderate secondary hyper-parathyroid bone disease with peri-trabecular amyloid deposits. Following surgery patient noted marked improvement in pain and partial improvement in shoulder ROM.

Discussion: No treatment exists for HD patients with B2M, ineligible for kidney transplant. Physicians are tasked with treating clinical manifestations that severely impact quality of life (QOL). Concern for adverse outcomes and paucity of surgical precedent should not deter appropriate surgical intervention. This patient illustrates the clinical and surgical decision-making targeted to improving (QOL).



PO0907

Prediction of Severe Gastrointestinal Bleeding Events in Hemodialysis: Collaborative Development of Machine Learning Model Within INSPIRE

Suman K. Lama,[1] Sheetal Chaudhuri,[1] Joanna Willetts,[1] John W. Larkin,[1] Anke Winter,[2] Manuela Stauss-Grabo,[2] Len A. Usvyat,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux,[6] David C. Wheeler,[3] Peter Stenvinkel,[4] Jürgen Floege.[5] On behalf of the INSPIRE Core Group *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany; [3]University College London, London, United Kingdom; [4]Karolinska Institutet, Stockholm, Sweden; [5]RWTH Aachen University Hospital, Aachen, Germany; [6]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany*.

Background: **IN**itiative**S** on advancing **P**atients' outcomes In **RE**nal disease (INSPIRE) is an academia and industry collaboration set forth to identify critical investigations/models needed to advance the practice of nephrology. As an inaugural effort, INSPIRE group aims to develop a machine learning (ML) model that can identify a hemodialysis (HD) patient's 30-day risk for hospitalization due to gastrointestinal (GI) bleeding.

Methods: We used data from adult (age ≥18 years) HD patients (Jan 2017-Dec 2020) in the United States to build a XGBoost model considering 2,292 variables for classification of 30-day GI bleed hospitalization risk. Data were randomly split in 50%:20%:30% ratio for model training, validation, and testing. Unseen data by model (testing) was used for assessing performance via area under the curve (AUC) and feature importance of predictors via Shapley (SHAP) values.

Results: Among 58,187 HD patients included in the testing dataset, 1150 had a GI bleed hospitalization. ML model showed AUC=0.67 and top predictors of a GI bleed hospitalization in 30 days were the minimum hemoglobin level in prior 180 days, time since prior GI bleed hospitalization, and higher vitamin D levels (**Figure 1**).

Conclusions: ML model appears to have suitable performance for identifying a patient's 30-day risk for GI bleed hospitalization. Albeit further model iterations/tuning are needed, ML techniques that account for collinearity and missingness hold promise for early detection of potentially avoidable GI bleeding admissions. Model identified an important association between higher vitamin D levels and GI bleeding events, which is consistent with the increasing evidence suggesting antithrombotic and anticoagulant actions of vitamin D derivatives.

Funding: Commercial Support - Fresenius Medical Care

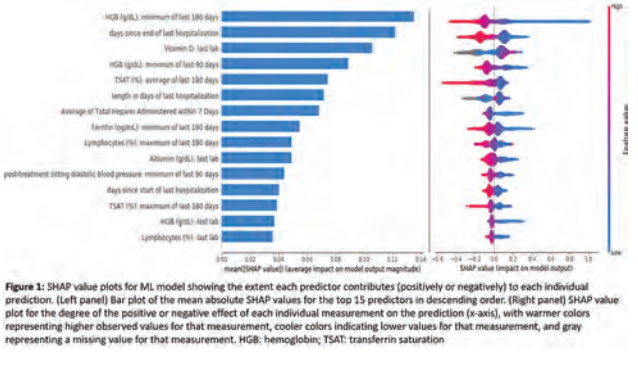


Figure 1: SHAP value plots for ML model showing the extent each predictor contributes (positively or negatively) to each individual prediction. (Left panel) Bar plot of the mean absolute SHAP values for the top 15 predictors in descending order. (Right panel) SHAP value plot for the degree of the positive or negative effect of each individual measurement on the prediction (x-axis), with warmer colors representing higher observed values for that measurement, cooler colors indicating lower values for that measurement, and gray representing a missing value for that measurement. HGB: hemoglobin; TSAT: transferrin saturation

PO0908

Artificial Intelligence-Driven System to Automatically Identify Arterial Oxygen Saturation Saw-Tooth Pattern in Hemodialysis

Hanjie Zhang,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

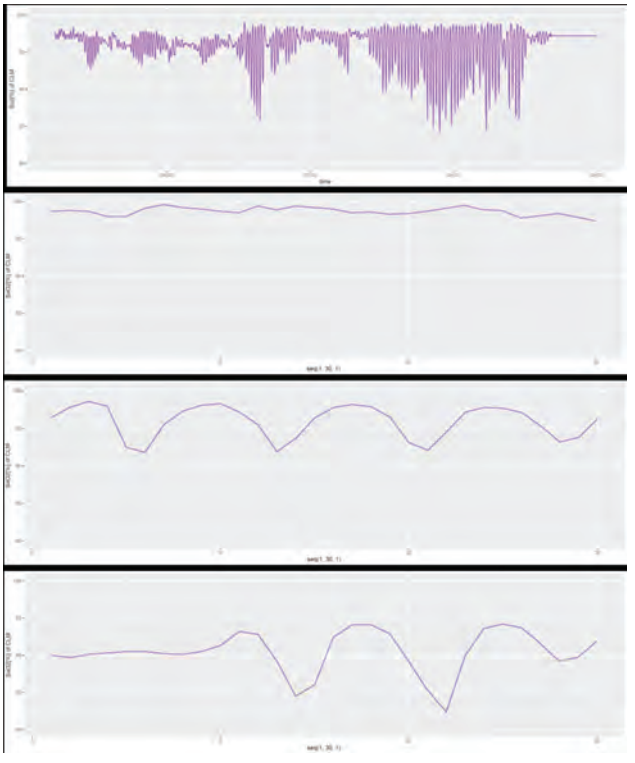
Background: Sleep apnea (SA) is a condition where normal respiration is disrupted by episodes of apnea because of disturbed respiratory control (central SA) or upper airway obstruction (obstructive SA). Arterial oxygen saturation (SaO2) saw-tooth pattern indicate respiratory instability. We aimed to automatically identify patients with repetitive episodes of intermittent SaO2 saw-tooth pattern.

Methods: The analysis was based on SaO2 recordings taken at a frequency of 0.1 by the Crit-Line® device (Fresenius Medical Care, Waltham, MA). Segments of 30 consecutive SaO2 recordings (i.e., 5 minutes of SaO2 time series) were adjudicated and categorized as (a) no saw-tooth pattern; (b) mild saw-tooth pattern; and (c) severe saw-tooth pattern (examples shown in Figure 1). We used one-dimensional convolutional neural networks (1D-CNN) for time series classification. We randomly assigned SaO2 time series segments to training (80%) and validation (20%) sets, respectively.

Results: We analyzed 89 hemodialysis (HD) treatments with 4,075 adjudicated SaO2 time series segments. Their distribution across the 3 categories was 78% (a), 11% (b), and 11% (c), respectively. In the validation data set of 815 SaO2 time series segments, we achieved an accuracy of 93.9%, 95.8% of category (a), 91.2% of category (b) and 82.8% of category (c) pattern were classified correctly by our 1D-CNN.

Conclusions: Our 1D-CNN algorithm accurately classifies saw-tooth pattern in SaO2 time series recorded in HD patients. The SaO2 pattern classification could be performed in real time during an ongoing HD treatment and provide timely alert in the event of respiratory instability.

Funding: Commercial Support - Fresenius Medical Care North America



Panel A: Intradialytic SaO2 saw-tooth pattern. Panel B to D: SaO2 time series with no saw-tooth pattern (B); mild saw-tooth pattern (C); severe saw-tooth pattern (D)

Leveraging Dynamic Data to Predict Mortality Risk in Patients Undergoing Chronic Hemodialysis

Benjamin A. Goldstein,[1] Anna Xu,[1] Jonathan A. Wilson,[1] Patti Ephraim,[2] Daniel E. Weiner,[3] Tariq Shafi,[4] Julia J. Scialla.[5] *[1]Duke University, Durham, NC; [2]Johns Hopkins University, Baltimore, MD; [3]Tufts University, Medford, MA; [4]University of Mississippi, University Park, MS; [5]University of Virginia, Charlottesville, VA.*

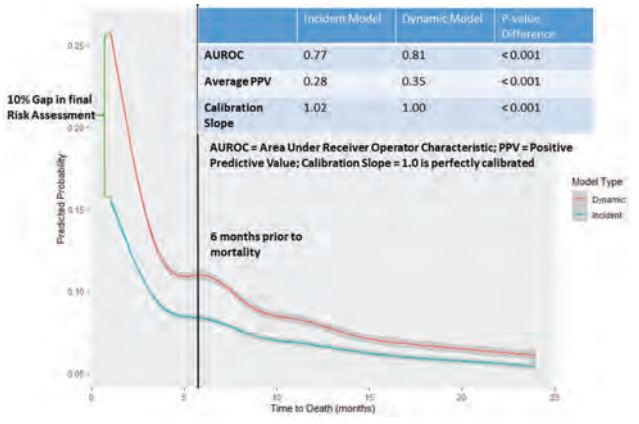
Background: Predictive models of mortality on HD typically use data collected at HD initiation. This is a missed opportunity that does not leverage the regularly collected data at HD treatments and is not reflective of how models would be used in practice. We compare performance of a risk model that uses static baseline data at incidence vs inclusion of time-varying data.

Methods: We used EHR data on pts new to HD between 2003-2016 from a national provider (n=54,148) linked with USRDS. We abstracted 86 predictor variables organized into person-mth and divided into training (n=32,488) and testing sets (n=21,660). The dynamic training set contributed > 800k person months. The static training set contained the first pt-month for those who initiated HD within 90-days (n=24,026). We fit LASSO logistic regression to predict mortality in the next 6-months and assessed both models on a time-varying test dataset. We report overall predictive performance metrics as well as visualization of time varying patient risk in the 24 mths before a pt dies.

Results: Pt median age at initiation was 64 yrs; 43% female, 63% Caucasian; 7% died w/in 6 mths of initiation and 53% w/in 5 yrs. Top predictor variables were similar between the two models: age, serum chloride and serum albumin. The table shows performance metrics for the two models on the test data with the dynamic model performing significantly better. The plot shows the predicted risk for pts in the 24 mths prior to mortality. The dynamic model more quickly responds to pts changing risk, producing a higher predicted probability leading up to mortality.

Conclusions: A risk model built using time-varying data performs better than one using baseline data. Incorporation of dynamic models in dialysis-EHR could be used as to direct appropriate population health interventions to the highest risk pts. Examination of dynamic risk models can elucidate pt-risk trajectories.

Funding: NIDDK Support



Predicted risk from each model as pts approach mortality. Dynamic data produces higher average risk more quickly.

PO0910

Machine Learning Classification of Tweets for Patient Dialysis Experience

Alexander S. Leidner, Hawkins Gay, Bing Ho. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

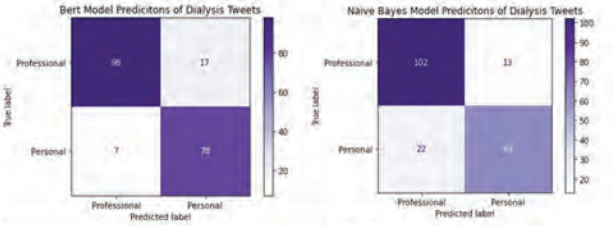
Background: Popular microblog (e.g. Twitter, Facebook) services provide a continuous stream of public health information. This data has been used to monitor viral spread, medication adherence, and false health information. There are thousands of posts on Twitter daily regarding personal dialysis experience, access, and side effects. While these posts include valuable public health information, evaluating these posts to meaningfully assist dialysis patients is difficult as there are even more tweets mentioning dialysis in a professional context. We aimed to modify a state of the art natural language model to classify posts about dialysis as personal or professional.

Methods: We filtered posts containing the word dialysis. Posts were manually labeled as personal or professional by a nephrologist depending on the context dialysis was mentioned. The data was randomized and split for 60% training, 20% validation, and 20% testing. The text was preprocessed to remove extraneous characters and input into a Bidirectional Encoder Representations from Transformers (BERT) model for fine tuning, and a term frequency inverse document frequency vectorized Multinomial Naive Bayes Classifier.

Results: We collected 6011 tweets from May 3, 2021 to May 14, 2021.1000 tweets were randomized and labeled. 57% were categorized as professional. BERT and Naive Bayes models attained 88% and 82% accuracy, respectively, on the testing data. The BERT model classified far less false negatives with a small increase in false positives (**Figure 1**).

Conclusions: BERT's semantically rich word embeddings can enhance social media mining algorithms on dialysis content. We show superiority of a BERT model over a traditional count-based language model. This method can be easily applied as a pre-processing step to remove noisy posts to better study dialysis and other health trends in social media. This novel processing task and pipeline have broad clinical and public health implications for reducing the amount of data and time required for accurate, real-time monitoring of patient level posts.

Figure 1: Model Test Set Classification Metrics



Model	Accuracy	Positive Precision	Positive Recall	Positive F1
BERT	0.88	0.82	0.92	0.87
Naïve Bayes	0.82	0.83	0.74	0.78

All metrics reported on 0 to 1 scale. Positive refers to 'personal experience'. All predictions performed on a held-out test set of data.

PO0911

Automating Dialysis Machine Alarms During Sustained Low-Efficiency Dialysis (SLED)

Gerard Zasuwa, Jerry Yee, Stanley Frinak. *Henry Ford Health System, Detroit, MI.*

Background: Sustained low-efficiency dialysis (SLED) with regional citrate anticoagulation (RCA) is frequently employed at our institution. RCA requires constant monitoring because a dialysis machines alarm that stops the blood pump (BP) or bypasses dialysate leads to an increased rate of citrate infusion into the patient, with consequence of ionized hypocalcemia. To enhance safety and surveillance efficiency, we developed an innovative computer/phone system that identifies SLED machine alarms and notifies clinical care staff directly via aproprietary phone network.

Methods: In 2017, we linked onboard SLED computer Wi-Fi systems to the hospital's internal phone network (ASCOM). An alarm recorded by the SLED machine's computer delivers an email to a dedicated email account that is subsequently transmitted to the ASCOM MailGate System. Mailgate produced and relayed text message alarms to dedicated ASCOM phones of dialysis technicians or nurses. Importantly, no additional training or changes in workflow are required for adoption of this method.

Results: This innovation has increased safety and efficiency. Response times for machine alarms improved and downtimes on dialysis were reduced, increasing dialysis dose of dialysis. To ascertain end-user satisfaction of the automated alarming system, we conducted a survey that demonstrates high-level satisfaction with the system (Table 1.)

Conclusions: Currently, no medical alert companies connect dialysis machine information to a medical alert phone system. ASCOM provides wireless messaging systems for dedicated hospital applications. Notably, ASCOM does not directly connect to dialysis machines. In addition, Email Alerts can be browsed by managers for archival retrieval, quality and safety report generation, and investigation of unanticipated events.

Funding: Clinical Revenue Support

Staff Satisfaction Survey

Survey Question	Response
Frequency of SLED alarm using ASCOM alert system per shift	65% respondents felt they receive between 1-3 per hour, 25% less than 1 per hour, 12.5% 4-6 per hour
Enhances Patient Safety	78% agreed, while 22% strongly agreed
Dialysis Technician Response Time	100% of respondents felt it improved response time
Need for ICU nurse to contact Dialysis Tech	75% strongly agreed that alert system reduced ICU nursing calls, 25% had no opinion

PO0912

Users of a Web-Based Communications Platform for Care Coordination of Hospitalized Dialysis Patients

Laura Plantinga,[1] Courtney E. Hoge,[1] Janice P. Lea,[1] Christopher M. O'Donnell,[1] Ann E. Vandenberg,[1] Kyle P. James,[1] Tahsin Masud,[1] Bernard G. Jaar,[2] Carol A. Gray,[1] Rich Mutell.[3] *[1]Emory University, Atlanta, GA; [2]Johns Hopkins University, Baltimore, MD; [3]Apex Health Innovations, Williamsburg, VA.*

Background: Better care coordination between dialysis clinics and hospitals may improve outcomes among hospitalized dialysis patients. To fill the gap created by separate electronic health record systems across the two settings, we rolled out a web-based communications platform ("DialysisConnect") in four dialysis clinics and one hospital in Atlanta. Here, we examine usage patterns of DialysisConnect.

Methods: DialysisConnect included automatically uploaded clinical information from dialysis clinics, forms for entering critical admission and discharge information, and a direct communications channel. Two nephrologists and two hospitalists served as project champions at the dialysis clinics and hospital, respectively. DialysisConnect was made available to 106 potential users [hospitalists, nephrologists, advanced practice providers (APPs) at the hospital and dialysis clinics, care coordinators (hospital), and nurses/nurse managers (dialysis clinic)] starting 10/29/20. Descriptive statistics were used to describe patterns overall and by user role through 4/15/21.

Results: While physicians comprised most of the potential users, APPs and dialysis nurses were the most active users (Table). Additionally, activity was unevenly distributed among users: *e.g.*, one hospital-based APP recorded most of the admissions (*n*=225, 89%) and discharges (*n*=226, 93%) among patients treated at the dialysis clinics included in the pilot.

Conclusions: We found that physicians were unlikely to use DiaylsisConnect. Our user statistics suggest that APPs and nurses may be the most likely to engage with a care coordination system, which informs future pragmatic research in this area.

Family-Friendly, Work-Friendly, Home-Hemodialysis and In-Center Hemodialysis Hybrid: The First of Its Kind

Adam Locke, Macaulay A. Onuigbo. *University of Vermont College of Medicine, Burlington, VT.*

Introduction: Hybrid dialysis is traditionally defined as the combination of peritoneal and hemodialysis (HD) in patients with end-stage renal disease. Its reported use is quite limited outside of Japan. We recently encountered major family-related and employment-related constraints that prevented a 39-yo man with ESRD on home HD from completing the four-times weekly HD treatments with HD inadequacy and worsening of patient's physiology. We successfully switched him to a new hybrid of twice-weekly Home HD + twice weekly In-Center HD. This is the first such report.

Case Description: A 41-yo male with ESRD secondary to SLE and hypertension on home HD, 4 x weekly, for some years experienced family-related constraints including non-availability of day-care for two young children due to COVID-19 pandemic, spousal illness and new work-related challenges with more travel and was missing his HD sessions. The result was inadequate HD delivery and worsening laboratory indices. He now receives 2 in-center HD treatments on Tuesdays and Thursdays, and 2 home HD treatments, one during the weekend and one during the week. This was started in February 2021. Each HD session lasts for 3.5 hours, 2000 units Heparin bolus, and his left brachiocephalic AVF is accessed by the button-hole method. The Home Dialysis Staff coordinates his dialysis care. Standardized Kt/V for May 2021 was 2.6.

Discussion: Hybrid dialysis is traditionally defined as the combination of peritoneal and HD in patients with ESRD. A 2020 Italian report described another type of hybrid dialysis that consisted of once-weekly in-hospital HD and home peritoneal dialysis to limit patient exposure to the hospital environment during the COVID-19 pandemic. We have described the successful application of a new Hybrid HD system that combined Home HD + In-center HD. To our knowledge, our report is the first of its kind and was designed and implemented primarily for the purpose of overcoming increasing family and employment demands on the patient. This new hybrid dialysis option was designed to facilitate a family-friendly work-friendly HD on a long-term continuous basis. The patient, the family with two young children and his employers are happy and very satisfied. Simultaneously, the patient has continued to do well with adequate dialysis and meeting all the required goals of management in the past 3 months.

PO0914

Triple I Study: Hubs of Care Survey

Melanie D. Talson,[1] Marcello Tonelli,[2] Clara Bohm.[1] Can-SOLVE CKD Triple I Study Team *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: The Can-SOLVE CKD Triple I Study identified continuity of care; access to a primary care provider (PCP) in the hemodialysis (HD) unit; and access to care for other medical conditions as key challenges to in-centre HD care (www.betterkidneycare.ca). The Hubs of Care project aims to address these challenges by incorporating health care providers (HCPs) from other settings in the HD unit; firstly, we identify current practice, potential interest and need and desire for different HCPs in HD units.

Methods: A cross-sectional self-reported survey administered Feb-May 2021 with HD patients and staff at four academic sites across Canada. Eligible participants included adults fluent in English or French who could complete the survey independently. The survey asked which HCPs are currently in HD units, which additional HCPs would be most useful to add and whether patients are in favor of other HCPs visiting them either virtually or in-person. Additional data were solicited by free text. Preliminary analyses using descriptive, median (IQR) and proportion and summative content analysis, are presented.

Results: Surveys were completed by 393 individuals (252 HD patients and 141 HCPs). Eighty-three percent of patients and 34% of HCPs were ≥50 years old. Forty-five percent of patients had been on HD >3 years. The majority of patients (81.5%) and HCPs (91%) agreed that having other HCPs in HD units would be beneficial; both prefer the addition of diabetic specialists/endocrinologists, mental health specialists and podiatrist/foot care specialists (Table 1). Patients indicated a need for cardiologists. Patients (85%) would like to see a PCP in the HD unit; of those, 87% prefer in-person and 13% prefer virtual. Qualitative analysis reveals privacy concerns due to the open concept of HD Units; however, the concept of bringing HCPs into the HD unit is regarded as beneficial and time-saving.

Conclusions: In this cross-sectional survey both HD patients and staff identified that, despite privacy concerns, bringing HCPs that provide foot, diabetic and mental health care into the HD unit was a priority with potential for benefit.

Funding: Government Support - Non-U.S.

PO0915

Utilization of the Tablo Hemodialysis System's Data Platform: An Analysis of 100,000 Acute Dialysis Treatments

Josh Schumacher, Brittany Lim, Michael A. Aragon. *Outset Medical, Inc., San Jose, CA.*

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on demand dialysate production and two-way wireless data transmission capable of providing therapy up to 24 hours in a hospital setting. Limited connectivity of traditional hemodialysis systems constrains the ability to drive improvement in quality and efficiency of dialysis care. Tablo's cloud-based data platform expedites care delivery in real time and informs on dialysis program metrics to facilitate quality improvement. The objective was to demonstrate Tablo's automated wireless data capabilities through analysis of 100,000 Tablo acute treatments.

Methods: Tablo data were collected through real-time transmission via a cloud-based, HIPAA compliant platform. Analysis was performed by combining prescribed and achieved data on consecutive treatments. Treatments were divided into groups based on treatment time of less than 6 hours (conventional therapy) or greater than 6 hours (extended therapy).

Results: A total of 100,000 treatments between April 2020 and May 2021 were analyzed. Treatments ranged from 2-24 hours. Treatment time success, defined as achieved within 10% of prescribed time, was 90.7% across the population. The most common reason for early termination was "User ended" (8.6%), with 0.7% due to "Device Directed". Mean total number of alarms per treatment was 2.5 across the population with no difference in alarm frequency (0.7 alarms per hour) between treatment groups. The most frequent clinically significant alarms were high and low venous pressures. Mean time to alarm resolution was 14 seconds with shorter alarm resolution time demonstrated in the IHD group (13 vs 22 secs).

Conclusions: With high utilization across a wide range of treatment times in the acute setting, Tablo successfully achieved treatment goals. The few observed alarms were quickly resolved by clinical users. Tablo's robust data reporting capability enables the identification of treatment trends that can be used to drive quality improvement.

Funding: Commercial Support - Outset Medical, Inc.

Summary of Tablo Treatment Parameters

Treatment Group	Treatment Parameters						Clinically Significant Alarms		
	Treatments Performed	Prescribed time (hours)	Actual Time (hours)	Actual Fluid Removal (L)	Alarms per treatment (mean)	Time to Alarm Resolution (seconds)	High Venous Pressure	Low Venous Pressure	Air Venous Bloodline
IHD (≤6 hrs)	94603	3.4 ± 0.6 (2.0 – 6.0)	3.3 ± 0.7	1.7 ± 1.1	2.3 ± 5.5	12.8 ± 32.1	1.7 ± 5.1	0.6 ± 1.6	0.1 ± 1.0
Extended (6< to ≤24 hrs)	5397	11.8 ± 3.4 (6.1 – 24.0)	9.7 ± 3.9	1.9 ± 1.7	6.7 ± 16.8	22.3 ± 55.9	5.0 ± 14.7	0.9 ± 2.6	0.1 ± 2.2
Overall:	100,000	3.8 ± 2.1 (2.0 – 24.0)	3.6 ± 1.8	1.7 ± 1.2	2.5 ± 6.7	14.2 ± 36.6	1.8 ± 5.9	0.6 ± 1.7	0.1 ± 1.1

PO0916

Impact of Medication Reconciliation by a Dialysis Pharmacist

Summer Dyer, Linda Awdishu, Sally Rafie, Victoria T. Nguyen. *University of California San Diego, La Jolla, CA.*

Background: Medication reconciliation (MR) improves patient outcomes, reduces cost, and is a reporting measure for the CMS End-Stage Renal Disease Quality Incentive Program. Most dialysis facilities do not have a clinical pharmacist to perform MR. The purpose of this study is to evaluate the impact of a pharmacist performing MR and medication management for patients receiving outpatient chronic hemodialysis at an academic institution.

Methods: We conducted a retrospective study from 10/1/18 to 11/2/20 to determine if MR by a pharmacist reduced medication discrepancies (MDs) and medication related problems (MRPs) over time. Secondary outcomes were to describe the type of MDs, type and severity of MRP, impact of a pharmacy delivery service, and number of emergency department (ED) visits and hospitalizations pre- and post-pharmacist integration. Discrepancies were categorized as: unintentional discrepancy, undocumented intentional discrepancy, and MRPs. MRP severity was categorized using the National Coordinating Council for Medication Error Reporting and Prevention index. Descriptive statistics were calculated for each variable and a repeated measures ANOVA test was conducted to determine if MDs or MRPs changed over time.

Results: A total of 135 patients with 479 unique pharmacist encounters were included. The mean (SD) age was 61.7 (14) years, 58% were male, 63% caucasian, mean (SD) time on dialysis 6.7 (6.4) years and most common comorbidities were diabetes and hypertension. The pharmacist conducted 3.5 MR/patient with a mean time spent of 39.7 (16) minutes and 16% required an interpreter. Unintentional discrepancies were noted in 53% encounters, undocumented intentional discrepancies in 71%, MRP in 59% but decreased significantly from the first to the second encounter (1.9 vs 0.9, 1.9 vs 1.2, and 1.1 vs 0.5 per patient, respectively, $p<0.05$). Most common MRP types included non-adherence, prescription renewals, and excessive drug doses. Over half (54%) were enrolled in a pharmacy delivery service and had significantly fewer undocumented intentional discrepancies compared to non-enrollees ($p<0.05$). ED visits and admissions pre- and post-pharmacist integration were not statistically different.

Conclusions: Integrating a pharmacist into a hemodialysis unit enabled effective medication reconciliation and management to significantly reduce medication discrepancies and problems, and improve safety.

PO0917

Interim Analysis of the Extension of Tablo Treatment Duration (XTEND) Study

Yaadveer Chahal, Josh Schumacher, Michael A. Aragon. *Outset Medical, Inc., San Jose, CA.*

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on demand dialysate production and two-way wireless data transmission and is approved for use in the acute, chronic and home settings. Prior reports have demonstrated Tablo's ability to achieve clinical goals, seamlessly integrate into hospitals and reduce cost across a wide range of treatment times. Extension of the Tablo cartridge to 24 hours (extended therapy; "XT") allows even greater flexibility for prescribers in the acute setting. The objective is to report on the experience with Tablo extended therapy between 12 and 24 hours utilizing an interim review of the XTEND study (NCT04912050).

Methods: Nursing staff were trained during a single training session on Tablo XT. After a run-in period of 5 treatments, Tablo data were collected via real-time transmission to a cloud-based, HIPAA compliant platform and reviewed by site staff. Clinical treatment success was defined as either ending within 10% of prescribed time or site investigator assessment that all patient treatment goals were met.

Results: Fifty (50) Tablo XT treatments had a median prescribed treatment time of 24 hours and a median achieved treatment time of 23.5 hours. Median cartridge use was 1.0 per treatment. Clinical treatment success was 84%. Treatments ended due to clotting/clogging were 4% (2 of 50). Median total ultrafiltration (UF) rate was 1.7 mL/kg/hr. Clinically significant alarms occurred at a median rate of 7 per treatment with a resolution time of 14 seconds. Most frequent alarms experienced were arterial and venous pressure (39% and 58%, respectively), of which none resulted in an end treatment.

Conclusions: Tablo's XT successfully achieves prescribed treatment time and favorable ultrafiltration rates with minimal therapy interruptions from alarms or cartridge changes. This data demonstrates the effectiveness of Tablo's newly expanded versatility in achieving personalization of treatments necessary for unstable patients and enabling successful delivery of extended therapy with minimal clotting. Tablo's 24-hour therapy meets the needs of critically ill patients that require renal replacement therapy for greater than 12 hours.

Feasibility Study of Wrist-Based Wearable Activity Tracker in Hemodialysis Patients

Maggie Han,[1] Ohnmar Thwin,[1] Xia Tao,[1] Lemuel Rivera Fuentes,[1] Amrish U. Patel,[1] Nadja Grobe,[1] Priscila Preciado,[1] Leticia M. Tapia Silva,[1] Mohamad I. Hakim,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Increased physical activity (PA) is associated with reduced risk of cardiovascular disease which is prevalent in hemodialysis (HD) patients. Wearable activity trackers (WAT) allow remote monitoring of PA. We aim to explore the feasibility of using a WAT for 1 year in HD patients.

Methods: HD patients from 4 NYC clinics were enrolled on a rolling basis starting June 2018 and followed for up to 1 year. Ambulatory patients ≥18 years, on maintenance HD, and owning a mobile device were included. Each patient was provided with and taught how to use the Fitbit Charge 2. A stepwise intervention plan was used to assess feasibility (Figure 1). We used Kaplan-Meier analysis to determine mean and median time to withdrawal for non-compliance (TW) and predictors of TW were assessed by univariate Cox Regression.

Results: 119 patients were enrolled into the study. Patients were 54±12 years old, 59% African American, 37% lived alone, and 54% had an education level of college and above. 16% of patients were withdrawn for non-compliance. Mean and standard deviation TW was 175 ± 103 days. Median and interquartile range of TW was 133 and 181 days (98 to 280 days), respectively. The probability of not being withdrawn for non-compliance is shown in Figure 2. Age, gender, race, living status, and education were not associated with non-compliance.

Conclusions: A small portion of patients were continuously non-compliant with wearing/syncing their Fitbit devices in our study. Based on a low risk (<20%) of being withdrawn for non-compliance, we determined that it is feasible to use a wrist-based wearable device in HD patients for up to a year. However, prolonged use of these devices may require additional counseling to patients.

Funding: Commercial Support - Fresenius Medical Care

Glycemic Status Ascertained by Continuous Glucose Monitoring in a Prospective Hemodialysis Cohort

Yoko Narasaki, Kamyar Kalantar-Zadeh, Amy S. You, Rene Amel Peralta, Andrea C. Daza Aguilar, Alejandra Novoa-Vargas, Tracy Nakata, Danh V. Nguyen, Connie Rhee. *University of California Irvine, Irvine, CA.*

Background: Hemodialysis (HD) patients with diabetes are at heightened risk of hypo- and hyperglycemia due to multiple pathways. While self-monitored blood glucose is the standard approach for glucose assessment in HD patients, it may not adequately capture glycemic status given its infrequent nature. We thus sought to measure glucose levels using continuous glucose monitoring (CGM) as a more frequent (every 5-minutes), convenient, and automated method of glycemic status in a prospective HD cohort with diabetes.

Methods: Among 18 HD patients with diabetes hospitalized during 10/2020-5/2021, we conducted simultaneous protocolized glucose measurements using 1) CGM measured by Dexcom G6 devices vs. 2) blood glucose levels using capillary fingerstick or venous blood glucose, with the latter measured ≥4 times per day (before each meal and at night), plus every 30 minutes during HD (total of 6-8 measures during HD). Using American Diabetes Association (ADA)-defined CGM targets, we examined the prevalence of patients achieving the recommended percentage (%) of CGM levels in the ranges of <54, <70, 70-180, >180, and >250mg/dl (ADA target % of glucose levels <1%, <4%, >70%, <25%, and >5%, respectively).

Results: Whereas 64% of CGM measurements (N=9444) were within target glucose range (time in range [TIR] 70-180mg/dl), 80% of blood glucose levels (N=100) were within TIR. The proportion of patients achieving the recommended % of CGM measurements within ADA-defined glycemic ranges of >250, >180, 70-180 (target range), <70, and <54mg/dl were 67%, 44%, 44%, 89%, and 78, respectively.

Conclusions: In a cohort of hospitalized diabetic HD patients who underwent concomitant CGM and blood glucose measurements using the Dexcom G6 remote access system, blood glucose testing overestimated the % of time patients were in target glycemic range as compared with CGM. CGM showed that less than half of patients achieved the recommended % of CGM measurements within target range. Further studies are needed to determine whether CGM can improve the glycemic management of HD patients compared to conventional approaches.

Validation of Automated Sodium Control in a Novel Dialysis System

Brandon D. Borrillo, Tzu Tung Chen, Osman Khawar, Clayton Poppe. *Diality Inc, Irvine, CA.*

Background: The Diality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: To test an automated feedback program designed to regulate the infusion of an alkali needed to maintain proper sodium concentration in a dialysate solution

Methods: A 125L volume of simulated dialysis was circulated at ~400 mL/min and ~37 C through a sorbent cartridge which removed the urea from the solution. The fluid exiting the cartridge had no Ca, Mg or K. These chemicals were reinfused through a pump in a solution containing Ca, K and Mg salts. A conductivity sensor (cond) was used in a feedback control of the alkali infusion pump. The feedback control adjusted the pump flow rate to maintain the conductivity of the infusate at 14.0 mS/cm. The sensor was programmed from a curve model of the alkali over time from previous experiments. Occasional spikes of Na^+ were added to test the feedback control. The experiment ran until a NH_4 reached 10ppm which defined filter breakthrough.

Results: The results are depicted in table 1. TP1, the mean sodium concentration [Na] in the dialysate at pump 1, after mixing in a 125L tank was in the range 139.8 – 141.7 mEq/L. TP2, the mean dialysate [Na] at pump 2 after leaving the sorbent filter was 124.2 (+/-2.4) mEq/L. This correlates with cond1 and was 12.8 (+/- 0.4) mS/cm. TP3, the mean dialysate [Na] after being replenished with the alkali solution immediately prior entering the tank for remixing was 139.5 (+/- 1.9) mEq/L and correlated with cond2 of 14.1 mS/cm).

Conclusions: The results validate the accuracy of the conductivity sensor in correctly regulating the alkali infusate.

Difference in Therapeutic Effects Between Roxadustat and Daprodustat, HIF-PH inhibitors, Depending on the Blood Type in Hemodialysis (HD) Patients

Satoshi Funakoshi,[1] Takashi Harada,[1] Jyunichiro Hashiguchi,[1] Kenji Sawase,[1] Akihiro Maekawa,[1] Tayo Kawazu,[1] Asami Nakamura,[1] Tomoya Nishino.[2] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki University Graduate School of Medicine, Nagasaki, Japan.*

Background: Human blood group antigens are glycoproteins and glycolipids expressed on the surface of red blood cells and a variety of human tissues. This study aimed to determine if there is an association between ABO blood type and the efficacy of HIF-PH inhibitors. Roxadustat and daprodustat are potent inhibitors of HIF-PH and capable of stimulating erythropoiesis in patients on patients with impaired renal function. These two compounds are reported to act mechanistically similar but display differences in their effects on cells, and the differences may affect their efficacy in the treatment of renal anemia in HD patients. In this study we compared the response rate by blood type between roxadustat and daprodustat, respectively.

Methods: Sixty-eight HD patients treated with roxadustat (20-100mg, 3/week) and ninety-five treated with daprodustat (1-12mg, daily) were recruited in our observational study. We defined >1.5g/dL increase in hemoglobin as effective, and <1.5g/dL decrease as ineffective.

Results: As shown in the figure, type A had the highest response rate at 47% in HD patients treated with roxadustat. On the other hand, type O had the highest response rate at 55% in those who were treated with daprodustat.

Conclusions: We found the association in the effectiveness of roxadustat on the treatment for anemia in HD patients in type A, while the effectiveness was higher in type O treated with daprodustat. The results suggest that the therapeutic effect of HIF-PH inhibitors may differ depending on the blood type.

Nanostructured Capillary Membranes for Size-Selective Hemofiltration

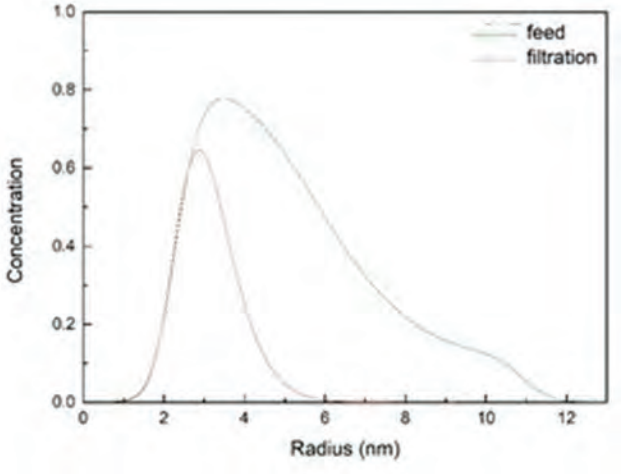
Peifu Cheng,[1] Francesco Fornasiero,[3] Nicholas J. Ferrell,[1] Shuvo Roy,[2] William H. Fissell,[1] Piran Kidambi.[1] *[1]Vanderbilt University, Nashville, TN; [2]University of California San Francisco, San Francisco, CA; [3]Lawrence Livermore National Laboratory, Livermore, CA.*

Background: Size-selective separations offer potentially transformative advances for hemofiltration. In the context of hemodialysis, the tradeoff between selectivity and permeability often results in large package sizes and high driving pressures that limit wearable and implantable options of therapy. Here, we report on composite membranes with vertically aligned precise nanoscale capillaries with improved permeability.

Methods: Arrays of carbon nanotubes (CNTs) were synthesized via chemical vapor deposition and the catalyst composition was carefully selected to achieve a uniform distribution of diameters. The area between the CNTs were filled with a polymer to form a membrane. The CNT membranes were backed with microporous silicon supports and mounted into a filtration cell. Hydraulic permeability was calculated from gravimetric flow rates at stepped transmembrane pressures. Size-selectivity was measured by filtering fluorescently-labeled polydisperse Ficoll in phosphate-buffered saline. Size-specific Ficoll concentrations in feed and filtrate were measured by size-exclusion chromatography.

Results: CNT membranes membrane exhibited a cut-off ~6nm and the measured hydraulic permeability was 102.3 ml h^{-1} m^{-2} $mmhg^{-1}$ compared to published data of 30 ml h^{-1} m^{-2} $mmhg^{-1}$ for conventional high flux dialyzers. CNT membranes retained large molecules while passing small and medium-sized molecules. Sieving coefficient at 2 nm, approximately the size of b2 microglobulin, was unity (Figure).

Conclusions: The CNT membranes provide excellent middle molecule clearance and hydraulic permeability multiples of conventional membranes. Further research is necessary to move to clinically implement this technology.



PO0923

Delivered Dialysate Potassium Is Higher Than What Is Prescribed When High Sodium and Low Bicarbonate Are Prescribed

Saiyed W. Ali, Andrew I. Chin. *University of California Davis Department of Internal Medicine, Sacramento, CA.*

Background: Most hemodialysis machines utilize the 3-stream method of making dialysate. In hospital settings, dialysate prescriptions are customized to the clinical setting. We determined the differences between delivered and prescribed dialysate K+ in unusual prescriptions.

Methods: Dialysate samples drawn 15 minutes into HD were analyzed via indirect ion-specific electrodes for Na^+, K^+, and HCO3-. 5200 HDs with extremes of ordered Na^+ and HCO3- were analyzed. Outcome was measured versus ordered K^+. Analysis used ANOVA using SPSS.

Results: Means of the difference between measured and ordered K+ and Na+ are shown in figure 1. For K+ there was significant difference amongst the groups ($p<0.001$). There were no differences amongst the groups for Na+.

Conclusions: When a very high Na+ is prescribed along with a low HC03- the the dialysate Na+ remains close to prescribed Na+. As the acid concentrate contains both Na+ and K+, a high Na+ and low HC03- prescription will use a relatively more of the acid concentrate and less of the bicarbonate concentrate. Dialysate prescriptions with a high Na+ and low HCO3- increased delivered dialysate K+ by an average of 0.5 mEq/L; we observed some HDs where dialysate K+ was 1 mEq/L higher than prescribed.

Ordered dialysate groups based on Na+ and HCO3-. The difference between measured and ordered potassium levels in the dialysate are shown

Groups based on ordered dialysate Na+ and HCO3-	Measured minus ordered K+	N
1. Na >145 and HCO3 ≤25	0.50 ± 0.38	43
2. Na 135-145 and HCO3 ≤25	0.37 ± 0.52	242
3. Na ≤130 and HCO3 ≤25	0.08 ± 0.60	19
4. Na ≤130 and HCO3 ≥35	-0.10 ± 0.35	11
5. Na 135-145 and HCO3 ≥38	-0.08 ± 0.39	61

PO0924

Urea Clearance Performance in a Modified Batch Dialysis System

Clayton Poppe, Nicholas Hyun, Sean C. Nash, Melany Yeung, Brandon D. Borrillo, Osman Khawar. *Diality Inc, Irvine, CA.*

Background: Urea clearance is the key measure of dialysis adequacy. The Diality Hemodialysis Machine will provide good clearance performance to ensure an adequate dose of dialysis. Specific Aims: To assess clearance performance during simulated dialysis utilizing a novel modified batch process. In this setup, dialysis was conducted by alternating dialysate delivery from subsequent two-liter reservoirs.

Methods: Simulated dialysis sessions were conducted utilizing blood flowrates of 300 ml/min, dialysate flowrates of 500 ml/min and no ultrafiltration. Dialysis occurs off of a two-liter batch of dialysate. Once two liters of dialysate has been circulated through the dialyzer, the spent dialysate is discarded and dialysis switches to a separate two-liter reservoir of dialysate while the first reservoir is drained and filled with fresh dialysate. A single compartment simulated patient was created by combining 50 L of DI water with a 20mM concentration of urea. Simulated blood samples were collected at the dialyzer inlet and outlet and dialysate samples collected at the dialyzer outlet to determine urea concentrations over the course of the simulated treatment.

Results: The results are provided in Figure 1. The urea concentrations in the blood decreased over the course of treatment as expected given the stated clearance values of the dialyzer used in the simulated treatment.

Conclusions: The initial experiments using a modified batch system show promising urea clearance. Future tests will better characterize performance compared with conventional devices that do not use a modified batch configuration.

Increasing the Clearance of Protein-Bound Uremic Solutes by Introducing an Activated Carbon Block into the Dialysate Stream

Seolhyun Lee,[1,2] Tammy L. Sirich,[1,2] Timothy W. Meyer.[1,2] *[1]Stanford University School of Medicine, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: The hemodialytic clearance of protein-bound solutes is limited because only the free solute concentration drives diffusion across the membrane. This study tested whether an activated carbon block could reduce accumulation of these solutes in the dialysate and thereby increase their clearance.

Methods: In vitro dialysis of artificial plasma containing urea and the protein-bound solutes p-cresol sulfate (PCS) and indoxyl sulfate (IS) was performed using two dialyzers in series with and without an activated carbon block at the midpoint of the dialysate stream (Figure). Six dialysis experiments were performed each with plasma flow 240 ml/min and dialysate flows of 200 ml/min and 600 ml/min. Nine additional experiments tested the capacity of the carbon block to take up solutes by measuring solute removal from spent dialysate collected at patient treatments. Spent dialysate was passed through the carbon block at 600 ml/min and fractional removal of solutes was assessed after more than 180 liters had passed through the block.

Results: Use of the carbon block increased the clearances of the tightly bound solutes PCS and IS by 70 ± 13 and 64 ± 19 %, respectively, when the dialysate flow was 200 ml/min. Lesser increases occurred when the dialysate flow was 600 ml/min (PCS 38 ± 5%, IS 33 ± 8%). Urea clearance was unchanged by the carbon block. The carbon blocks removed 97 ± 4 % of PCS and 96 ± 2 % of IS but only 2 ± 5 % of urea from spent dialysate flowing at 600 ml/min.

Conclusions: Use of a carbon block can increase the clearance of protein-bound solutes particularly at the low dialysate flows often used for home hemodialysis.

Funding: NIDDK Support, Private Foundation Support

Comparative Effectiveness Between Novel Medium Cut-Off Membrane Hemodialysis and Mixed-Dilution Online Hemodiafiltration on Middle Molecule Uremic Toxins Reduction: A Prospective Cross-Over Study

Jirarat Eiamcharoenying, Pajaree Chariyavilaskul, Kullaya Takkavatakarn, Paweena Susantitaphong, Yingyos Avihingsanon, Somchai Eiam-Ong, Khajohn Tiranathanagul. *King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Mixed-dilution online hemodiafiltration(mixed HDF), one of the best hemodialysis(HD) modes, provides superior removal of middle molecule uremic toxins to standard HD using high flux dialyzer. Due to the limited availabilities and high cost of HDF, we performed standard HD utilizing a novel medium cut-off membrane with a larger pore size and compared the effectiveness in removal of middle molecule uremic toxins with mixed HDF.

Methods: A prospective cross-over randomized controlled trial was conducted in 14 prevalent HDF patients who were randomly allocated into group1 (n=7): mixed-dilution online HDF with high flux dialyzer ELISIO21H and group2 (n=7): standard HD with MCO membrane, Theranova 500. In this 8-week study, the primary outcome was a reduction ratio(RR) of Beta$_2$-microglobulin (B_2M). Other small to middle molecules and protein-bound uremic toxins reduction ratio, dialysate albumin loss, and nutritional parameters were also compared.

Results: In this 8-week study, B_2M RR from both modalities was higher than the survival benefit cut-point of 80%. In comparison, B_2M RR was slightly lower but significant in MCO HD than mixed HDF (82.57±5.34% vs 85.12±3.87%, respectively) with the mean difference of 2.55 (95% confidence interval [CI], -4.07 to -1.03; P=0.001). The spKt/Vurea and URR, a small uremic toxin removal marker, were comparable. κFLC and Indoxyl sulfate RR also were similar in mixed HDF and MCO HD. Whereas RR of the larger middle molecule uremic toxin, Alpha$_1$M and λFLC was lower with mixed HDF compare to MCO HD (30.13±15.90 vs 41.49±11.46 and 40.85±13.92 vs 50.81±13.18, respectively; P <0.001). Dialysate albumin loss was 3.51 g/session with MCO HD and 0.58 g/session with mixed HDF (P=0.025). Regarding, nutritional parameter, serum albumin levels were not different.

Conclusions: Mixed HDF and MCO HD provided the RR values of B_2M and small uremic toxins above the recommended cut-point. Despite mixed HDF provided higher B_2M RR, MCO HD also provided more performance in the clearance of the larger middle molecules, particularly a_1M and λFLC. However, mixed HDF loss lower albumin than MCO HD. Therefore, both techniques can be used as alternative options.

PO0927

Clearance of Protein-Bound Uremic Toxins on the Tablo Hemodialysis System

Logan Rivas, Dean Hu, Michael A. Aragon. *Outset Medical, San Jose, CA.*

Background: The Tablo Hemodialysis system (Tablo) is an all in one, easy-to-learn device. While clearance of small and middle molecules has been documented in modern dialysis, the clearance of Protein Bound Uremic Toxins (PBUTs) merits further exploration. Clearance of albumin bound toxins such as indoxyl sulfate (IS) and p-cresol sulfate (PCS) can be limited in dialysis where removal is based on molecular size. Although a clear association has yet to be demonstrated, PBUTs have been considered to be a possible cause of adverse outcomes in patients requiring renal replacement therapy.

Methods: A simulated hemodialysis treatment using Tablo was performed with solution of bovine serum albumin and urea. PCS and IS were added to the solution to maintain a constant concentration. A screening design of experiment was performed utilizing the factors of dialysis flow rate (Qd), blood flow rate (Qb), and ultrafiltration (UF). After each factor was changed and allowed to equilibrate, samples were collected from the venous, arterial and spent dialysate lines. Samples of Urea, PCS and IS were analyzed and compared to predicted values from previously published models.

Results: The Tablo system cleared ICS and PCS as predicted or better at all conditions. See table and images for details.

Conclusions: The Tablo system aligned with the PBUT clearance model over the range of system flow settings. Continued investigation into the clinical benefits of PBUT removal is merited to better understand their impact on the overall quality of care for dialysis patients.

Dialysis Disequilibrium Syndrome (DDS) in Hemodialysis Patients: Systematic Review

Rupesh Raina,[1,2] Siddhartha S. Singh,[1,2] Ronith Chakraborty.[1,2] *[1]Cleveland Clinic, Akron, OH; [2]Akron Children's Hospital, Akron, OH.*

Background: Dialysis disequilibrium syndrome (DDS) affects patients who have missed multiple dialysis treatments, especially new initiates of hemodialysis (HD), and presents as a rare neurological complication. The conceptual pathogenesis of DDS is likely a result of multiple physiological abnormalities which we explore in this systematic review alongside preventive measures with focus on effective management strategies.

Methods: A literature search was conducted on PubMed/Medline and Embase and included studies if the patient developed DDS irrespective of age and gender. Two independent reviewers conducted the process of article selection with a thrid reviewer present to resolve any conflicts. The data was analyzed and a summary table was extracted with the following variables: study type, population group, age, patient characteristics, blood and dialysate flow rate, and study outcome. A descriptive analysis was performed analyzing the population size and frequency of symptoms and treatments utilizing the R software.

Results: A total of 49 studies (321 samples) were identified and analyzed. There were 72.4% of patients (based on 48 studies) who reported having DDS with most common symptoms of headache (39.4%), nausea (40.4%), vomiting (39.1%), confusion (66.7%) and seizure (78.6%). Within this sample, 12 studies switched from HD to alternative dialysis modalities including continuous venovenous hemofiltration/hemodiafiltration (CVVH/CVVHDF) or peritoneal dialysis (PD) with no further reported DDS symptoms.

Conclusions: We have provided a comprehensive clinical practice points for both the pediatric and adolescent and young adult population; interestingly, DDS was reported more often in the early dialysis era prior to recent advances and improvement of resource allocation. Existing literature shows it is crucial to recognize symptoms of DDS and implement timely prevention to improve outcomes.

PO0929

Protein Loss with Medium Cut-Off and High Flux Dialyzer: A Proteomic Analysis

Xiaoling Wang,[1] Xia Tao,[1] Leticia M. Tapia Silva,[1] Amrish U. Patel,[1] Mohamad I. Hakim,[1] Nadja Grobe,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Hemodialysis (HD) patients frequently suffer from low serum albumin levels, making dialytic albumin and protein loss a concern. Medium cut-off (MCO) dialysis membranes reportedly show a greater albumin loss compared to high-flux (HiFlux) membranes. To better understand the spectrum of proteins cleared with MCO membranes, we set up an *ex vivo* dialysis system and perform proteomic analysis of the dialysate.

Methods: Eight liters of human plasma (EDTA added) are split into two 4-liter batches and dialyzed for 4 hrs in single-pass, either with an MCO (Theranova 400) or HiFlux dialyzer (Optiflux F180NR) using a Fresenius 2008T machine. Blood flow was 400 ml/min. Dialysate flow was 600 ml/min for the first 3 hrs and zero for the 4th hr. Ultrafiltration rate was zero for the first 2 hrs and switched to 1 L/hr thereafter. This design allowed us to study three HD modes: diffusion only (2 hrs); diffusion with convection (1 hr); convection only (1 hr). Dialysates were sampled at multiple time points (**Fig 1B**).

Results: Three µg of initial plasma and 23 µl dialysate were loaded on an SDS-page gel and silver stained **(Fig 1A)**. Lanes 3 and 5 were from MCO, lanes 4 and 6 from HiFlux. Lanes 3 and 4 were collected 15 mins into dialysis, lanes 5 and 6 at 240 mins. Results show that dialysates contain less high molecular weight proteins compared to plasma, and MCO dialysates contain much more proteins compared to HiFlux dialysates. The strong band at ~62 kD is most likely albumin. Using mass spectroscopy, we can identify 56 different protein species in MCO dialysate. Dialysate protein levels (measured by Bradford assay) with the 3 dialytic modalities are shown in **Fig 1B,** the total protein losses are listed in **Fig 1C**. The ratio of protein loss between MCO and HiFlux dialyzers is 17-fold in the convection only mode.

Conclusions: Our results show a higher diffuse and convective protein loss with MCO compared to HiFlux membranes. Further characterization and quantitation of proteins cleared *in vivo* during HD are necessary to better understand the clinical impact of our *ex vivo* observations.

Intradialytic and Interdialytic Urea Dynamics in Blood and Cerebrospinal Fluid in Hemodialysis Patients

Xia Tao,[1] Lin-Chun Wang,[1] Xin Wang,[1] Ohnmar Thwin,[1] Nadja Grobe,[1] Amrish U. Patel,[1] Stephan Thijssen,[1] Joshua E. Chao,[1] Ludovic Debure,[2] Thomas Wisniewski,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]NYU School of Medicine, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

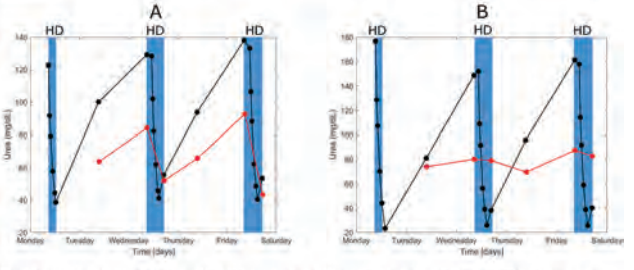
Background: Modern, highly efficient hemodialysis (HD) results in rapid decline of blood urea. Urea gradients across the blood-brain barrier (BBB) can drive water movements. A positive urea gradient, i.e. brain urea to plasma urea, can result in brain swelling and impair brain function. We explored the dialytic changes of urea in blood and cerebrospinal fluid (CSF) to better understand intradialytic osmotic gradients across the BBB and provide insights that support the development of brain-protective HD.

Methods: Two HD patients (39 and 26 years old) with ventriculo-peritoneal (VP) shunts were enrolled into this one-week IRB-approved study with a Monday/Wednesday/Friday dialysis schedule. CSF was collected via VP shunt tap 2 hrs before and 2 hrs after HD (Wednesday and Friday), and Tuesday and Thursday. Plasma samples were collected concurrently with CSF and during HD. In addition, the patients underwent test of executive function (Trail Making Test Part B; TMT B) and global cognitive function (Montreal Cognitive Assessment; MoCA) on Monday.

Results: Urea was removed efficiently from patients' blood by HD. While patient A showed a small post-HD plasma-to-CSF urea gradient, it was highly positive (~ 60 mg/dL) in patient B (Fig. 1). TMT B and MoCA score were normal for patient A but not patient B (TMT B 415 sec; TMT B error count: 2; MoCA score: 11).

Conclusions: Our patients showed very different post-HD plasma-to-CSF gradients. Theoretically, the positive gradient in patient B would favor intradialytic brain swelling. Patient B showed impaired neurological testing results which are not related to patient's pre-existing neurological conditions. We can only speculate if and to what extent trans-BBB water movements driven by dialytic urea dynamics may have impacted the patient's cognitive functions. We believe that patient-specific levels of osmotic stress need to be considered when developing neuro-protective HD technologies.

Figure 1. Urea concentrations in plasma (black line) and CSF (red line) (left panel: patient A; right panel: patient B).



The blue areas indicate duration of HD (1st session) and the period between 2 hrs pre-HD to 2 hrs post-HD (2nd and 3rd session).

PO0931

High-Throughput Analysis of Changes in Protein Biomarkers During Hemodialysis

Matthew B. Lanktree,[1] David T. Collister,[2] Guillaume Pare,[1] Michael Walsh.[1] *[1]McMaster University, Hamilton, ON, Canada; [2]University of Manitoba, Winnipeg, MB, Canada*.

Background: The impact of hemodialysis on the concentration of circulating protein biomarkers remains unclear. Biomarkers may decrease in concentration due to filter adsorption, diffusive clearance, or convective clearance, while others may increase in concentration due to production and secretion or intracellular release. Ultrafiltration of water is expected to also increase biomarker concentration. We sought to evaluate the impact of hemodialysis on 1,163 protein biomarkers in a high-throughput fashion.

Methods: A nested cohort of 44 patients (25 male, 19 female) including 29 with intradialytic hypotension and 15 without were selected from the prospective Hemodialysis Outcomes and Symptoms assessment (HOST) cohort. Intradialytic hypotension was stringently defined as a 60 mmHg drop in systolic blood pressure or a nadir systolic blood pressure of less than 70 mmHg during hemodialysis treatment. All hemodialysis treatments were done using the same hemodialysis filter type. 1,163 unique biomarkers were measured in each patient before and after a hemodialysis session using the Olink proximity extension assay (www.olink.com). Paired sample t-tests were used to compare pre- and post-dialysis concentrations with a Bonferroni-corrected significance threshold ($P < 5 \times 10^{-5}$).

Results: 54 biomarkers (5%) significantly increased during hemodialysis treatment, while 243 (24%) significantly decreased. Change in biomarker concentration was significantly associated with biomarker molecular weight ($r = 0.37$, $P = 2.8 \times 10^{-16}$), isoelectric point ($r = -0.26$, $P = 6.4 \times 10^{-14}$), and pre-dialysis concentration ($r = -0.21$, $P = 3.0 \times 10^{-9}$). There was a significant enrichment of cardiovascular biomarkers in the top 20 biomarkers associated with drop in systolic blood pressure ($P = 2.8 \times 10^{-10}$), including Kidney Injury Molecule 1 (KIM1, $P = 0.005$).

Conclusions: Hemodialysis is associated with significant changes in protein biomarker concentrations related to protein properties and clinical events during treatment. These changes are measurable on a high-throughput platform. Further high-throughput biomarker studies could assess dialysis adequacy, test biomarker-symptom associations, and improve risk prognostication.

Feasibility of Allo-Hemodialysis: First Experience from Porcine Studies

Xin Wang,[1] Amrish U. Patel,[1] Anil K. Gothi,[2] Dejan Nikolic,[6] Alexander Heide,[6] Jiaming Dong,[3] Hao Zhang,[3] Vaibhav Maheshwari,[1] Nadja Grobe,[1] K S Nayak,[5] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]Vivo Bio Tech Ltd, Hyderabad, India; [3]Fresenius Medical Care Shanghai Co Ltd, Shanghai, China; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Virinchi Hospitals, Hyderabad, India; [6]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany*.

Background: Annually, millions of kidney patients, predominantly in low and low-middle income countries, die prematurely because of unavailability of affordable kidney replacement therapy. We previously demonstrated through mathematical modeling and bench testing the feasibility of alloHD, an alternative low-cost hemodialysis treatment approach where the blood of a kidney failure patient flows counter-current to that of a healthy subject ("buddy") through a dialyzer. Herein we report first results from an alloHD feasibility study in a porcine model. We aimed to specifically address questions around hemolysis and coagulation of the dialysate compartment.

Methods: Ethics protocol was approved by Committee for the Purpose of Control and Supervision of Experiments on Animals, India. Under general anesthesia, healthy female white Yorkshire pigs of 30 to 80 kg with central venous catheter as vascular access were dialyzed 1-3x weekly for 2-4 hours. Ultrafiltration volume goals were set between 0 and 1000 mL. "Patient" and "buddy" pigs were connected to the dialysate and blood compartments, respectively, of a Nipro Cellentia 17H (Fig. 1). Pigs were anticoagulated with 5000 IU heparin per hour. Pre- and post-treatment blood samples were collected for biochemical measurements.

Results: We successfully completed 10 alloHD sessions. No coagulation was observed. Visual inspection of plasma samples indicated no signs of hemolysis. This was further corroborated by measurements of lactate dehydrogenase and haptoglobin, which were available in seven experiments (Fig. 2).

Conclusions: We found no indication of hemolysis and dialysate compartment coagulation in our experiments. Upcoming studies in a porcine renal failure model will address *in vivo* solute clearances by alloHD.

Funding: Commercial Support - Renal Research Institute

Figure 1. AlloHD setup.

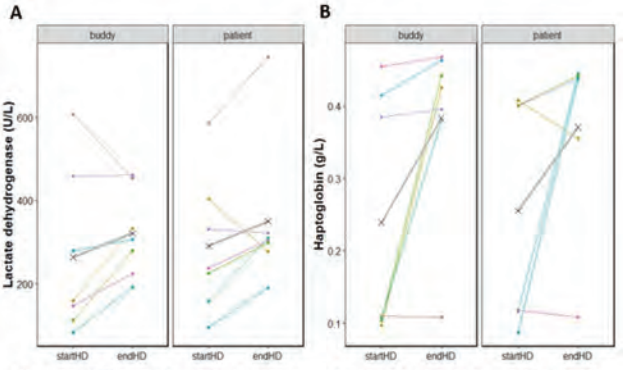

Figure 2. Plasma lactate dehydrogenase (A) and haptoglobin (B) levels in "patient" and "buddy" pigs dialyzed by alloHD (N=7). Individual experiments are color coded; the means are shown in grey.

Can Plasma Filters Be Reused for Plasmapheresis in Resource-Poor Settings? Experience from a Tertiary Care Hospital

Priti Meena, Sandip Panda, Rishita Mondal, Swati Das. *All India Institute of Medical Sciences - Bhubaneswar, Bhubaneswar, India*.

Background: Therapeutic plasma exchange (TPE) is used in the management of various life-threatening illnesses. It is widely performed by nephrologists, intensivists, pathologists, or experts of transfusion medicine worldwide. However, the costs of TPE sessions are exceedingly high and it has a huge impact on patients' financial burden. Most of the patients cannot afford such a high-cost treatment. Herein, we investigated the outcomes of reuse of plasma filters in TPE for several occasions

Methods: This was an ambidirectional study that included retrospective analysis of patients receiving TPE from January 1, 2020, to December 31, 2020, whereas the patients receiving TPE from January 1, 2021, to April 30, 2021, were prospectively analysed. The procedure was performed in our hospital's dialysis unit. Formulation of 4% peracetic acid and 24% hydrogen peroxide acid with RO water was used for reprocessing. Fresenius Plasma Flux P2 (0.6 m2) was used in the study. Clinical outcomes, risks, and cost-benefit were evaluated and compared between the plasma filter reuse group (GP-1) and no reuse group (GP-2).

Results: 46 patients were included in the study. 26 patients were in the Plasma filter reuse group. 122 and 119 TPE sessions were performed in GP-1 and GP-2 respectively. A total of 58 plasma filters were used in GP-1. In six patients single plasma filter was used on 3 occasions whereas, it was used for 2 occasions in other patients. The most common indication for TPE in both groups was Guillain barre syndrome. The rates of clinical improvement in disorders for which the TPE were performed were similar in both GP-1 and GP-2 (88 % vs 90%, p=0.4). None of the patients in either group had clotting of plasma filter, any allergic reaction, or increased bleeding risk. No higher chances of sepsis were noticed in GP-1 (P=0.08). No difference in patient survival was noticed between the two groups (97% vs 96 %, p=0.5). The cost of overall treatment was 2.5 times higher in GP-2, (P=0.003).

Conclusions: Reuse of plasma-filter is a safe and effective method for cost minimization in patients requiring TPE. This method can effectively be utilized in resource-poor settings without any increased risk of adverse effects

PO0934

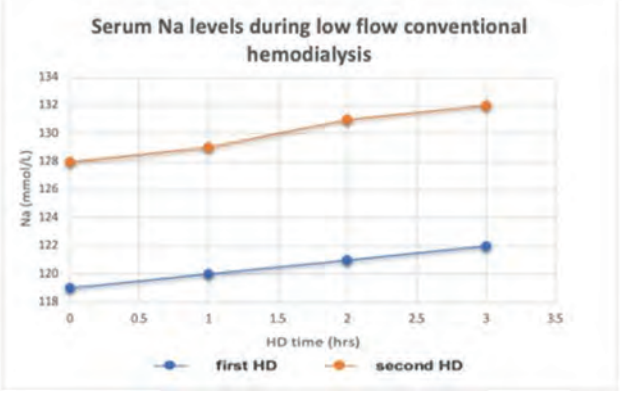
A Forgotten Technique of RRT for Correction of Severe Hyponatremia in CKD: Case Report

Rodolfo A. Moreno,[1,2] Alexandra M. Trochez,[1,2] Pedro Gonzales,[1,2] Antonio J. Palma,[1,2] Lidia B. Sánchez,[1,2] Rafael J. Hernández,[1,2] Jorge A. Hernández.[2] *[1]Centro Medico Militar, Guatemala, Guatemala; [2]Universidad Mariano Galvez de Guatemala Facultad de Ciencias Medicas y de la Salud, Guatemala, Guatemala.*

Introduction: Patients with chronic kidney disease (CKD) present electrolytes disorders. This represents a challenge when hyponatremia is below 125mmol/L associated with any criteria for urgent renal replacement therapy (RRT) with conventional hemodialysis because of higher risk of over correction above the security threshold of 10mmol/L/day and osmotic demyelination syndrome.

Case Description: A 49-year-old Guatemalan female with history of 15 days of edema and slurred speech. Only history of T2DM. Was brought to the ER with BP 100/80mmHg and anasarca. Initial laboratories: negative COVID-19Ag, Cr 5.12mg/dl, (previous 2mg/dl) BUN 105mg/dl, glucose 156mg/dl, Na 108mmol/L, K 5.2meq/L, Cl 70meq/L. SOsm 224mOsm/kg, UOsm 875mOsm/kg, UNa 28meq/L. Because of neurologic symptoms, received a 150ml bolus of 3% saline twice with a rise to 112mmol/L. After the bolus, we initiated a 24-hour infusion with 3% hypertonic solution reaching a rise of Na up to 119mmol/L in 48 hours, but because of persistence of neurologic symptoms plus fluid overload >10% of body weight and hyperkalemia, we initiated RRT. In the absence of CRRT or CVVH we planned a *conventional HD* with blood flow of 100ml/min, dialysate flow 600ml/min, dialysate Na 130meq/L (the lowest Na possible) and 3 hours duration. After the first session had neurological and edema improvement. After two sessions with interdialytic period of 48 hours, Na control of 122mmol/L and 132mmol/L respectively with resolution of uremic syndrome. Later was diagnosed with hospital-acquired pneumonia receiving antibiotic treatment for 14 days and was discharged home with ambulatory HD.

Discussion: In undeveloped countries where the access to CRRT or CVVH is unavailable, conventional modalities can be used with low blood flows and modification of the dialysate Na to a minimum (130mmol/L) offering a safe option to Na correction for patients with severe hyponatremia and any other HD criteria.



PO0935

Single-Bolus Tinzaparin Anticoagulation in Extended Hemodialysis Sessions: A Feasibility Study

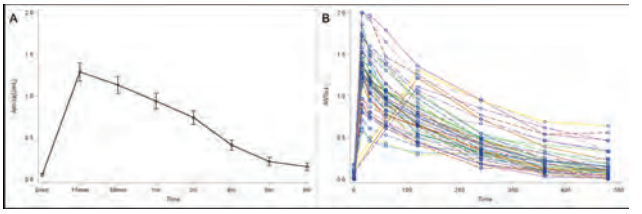
Benoît Harvey,[1] Simon Leclerc,[2] Naoual Elftouh,[2] Michel Vallee,[2] Louis-Philippe Laurin,[2] Annie-Claire Nadeau-Fredette.[2] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Few studies have assessed the use of low-molecular weight heparins for anticoagulation during extended hemodialysis (HD) sessions. This study aimed to evaluate the safety and efficacy of tinzaparin for anticoagulation of the extracorporeal circuit and dialyzer in extended, 8-hour, sessions.

Methods: This single-center study included all patients who underwent a single in-centre 8-hour session as part of their nocturnal home HD training between 2009 and 2020. Tinzaparin was delivered as a single bolus injection at time 0 with dosing based on the patient's weight and doubling of standard 4-hour session dose. Tinzaparin safety was assessed via anti-Xa measured at 15-, 30-min, 1-, 2-, 4-, 6-, 8-hour. Efficacy was examined via visual observations (score 1-4) of the dialyzer and venous bubble trap at the end of dialysis. Predictors of clotting levels were assessed in exploratory logistic regressions.

Results: Forty-seven patients were included: age 45 ±14 yrs, 28% women, 9% on warfarin, 42% on antiplatelets, BMI 29±7 kg/m^2, hemoglobin 114±15 g/L and platelet 203±61 10^9/L. Mean tinzaparin dose was 107 ± 20 IU/kg. Anti-Xa levels peaked at 15-min with 1.3 ± 04 IU/mL and progressively declined reaching 0.9 ± 0.3 IU/mL at 1-hour, 0.4 ± 0.21 IU/mL a 4-hour, and 0.15 ± 0.15 IU/mL after 8-hour. **Figure1** After the 8-hour session, none of the patients had severe clotting of their dialyzer or venous chamber. Moderate blood clotting was observed in the dialyzer of 6 (20%) patients and in the venous chamber of 22 (61%) patients. Tinzaparin dose was increased for 27 (81%) patients with a mean maintenance dose of 123 ± 28 IU/kg. None of the main baseline characteristics (including tinzaparin dose per kg) were associated with clotting scores.

Conclusions: This study shows that anti-Xa levels stabilize rapidly after administration on tinzaparin for 8-hour HD. Administration of a single bolus tinzaparin at the start of an eight-hour dialysis session appeared safe and effective, although dose adjustment may be required.



PO0936

Green Hemodialysis: Is It Really Possible to Save Water and Plastic Without Affecting the Quality of the Treatment?

Ismael A. Gómez Ruiz, Geovana Martin-Alemañy, Juan M. Ardavin Ituarte, Rossana Olmedo Ocampo. Santa Carmen *Médica Santa Carmen, Ciudad de México, Mexico.*

Background: Hemodialysis (HD) is essential for the preservation of life in many patients but represents a complex issue in ecology producing a large waste load that affects the environment. Sustainable waste management policies are scarce. The aim of the present study was to show the particular water and plastic savings in a mexican HD center that practices the reuse of dialyzers and reject water (RW) without affecting the quality of care provided for patients.

Methods: Prospective cohort study performed between January and May 2021 in a HD center with 90 patients (AK 98 Baxter®). HD center has 15 employees, 5 bathrooms and 12 sinks. Volumes of produced and reused RW were measured by flow meters. A detailed analysis of the residual biochemical content of RW was performed. The weight of plastic waste was compared between patients with reused membranes and patients with non-reused membranes. Finally, to evaluate the quality of the HD treatment in reused dialyzers (1-12 reuses), the difference between 5 monthly measurements of the spKt/V was determined using a repeated measure ANOVA considering a p>0.05 for no difference.

Results: During the study period 4158 HD sessions were provided, 394 m3 of RW were produced, 312 m3 (79%) were reused for all center sanitation purposes. Analysis of the residual biochemical content of RW is shown in Table 1. A total of 1902 HD sessions were performed with reused dialyzers. With each dialyzer reuse (Revaclear Baxter®) 0.88 lbs of plastic waste was spared. This translates into 1.53 tons less waste. No adverse effects were observed. No statistical significance difference was observed in single pool Kt /V between treatments with reused filters.

Conclusions: These results suggest that reuse of RW in the sanitation of the centers and dialyzer reuse resulted in significant savings in water and plastic without affecting the quality of treatment received by patients.

Table 1 | Assay results for RW compared with US Environmental Protection Agency (EPA) and the Association for the Advancement of Medical Instrumentation (AAMI standards)

Analyte	Our HD center-RW	US EPA standar	AAMI standar
Aluminum mg/dl	< 0.049	< 0.05	0.05

Targeted Alteplase Administration to Improve Hemodialysis Catheter Patency: A Quality Improvement Pilot Study

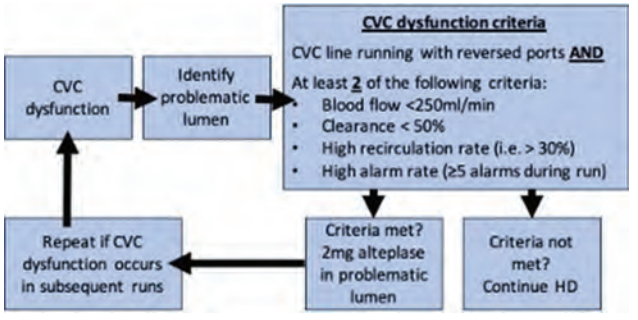
Jason T. Bau,[1] Tyrone Harrison,[1,3] Kokab Younis,[2] Nathen Gallagher,[2] Juliya Hemmett,[1] Elena Qirjazi.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]Alberta Health Services, Calgary, AB, Canada; [3]University of Calgary Department of Community Health Sciences, Calgary, AB, Canada.*

Background: Catheter dysfunction (CD) is a frequent complication during the provision of hemodialysis. Thrombolytic agents (i.e. alteplase) are the mainstay for resolving CD, however, alteplase usage has increased 16% (~$440,000CAD) annually in the Alberta Kidney Care South program without improved patient or dialysis outcomes. We assessed the implementation of a protocolized algorithm to reduce alteplase usage.

Methods: In this pilot quality improvement study, we designed an algorithm where CD was treated with high-dose (2mg) alteplase therapy to the problematic lumen only, after meeting pre-specified criteria (Fig 1). This protocol was implemented in a satellite hemodialysis unit (~110 patients) from Jan 2021 to Mar 2021. The baseline comparison period was Jan 2020 to Dec 2020 when CD was treated with low-dose 1mg/lumen alteplase. Outcome measures included total alteplase usage, changes in Kt/V, recirculation, clearance, line interventions and hospitalization rates. Statistical analysis was completed using Mann-Whitney and Z-score calculations.

Results: Sixty-nine alteplase administrations occurred over the two-month period, versus 438 in the baseline period. Patients in the 2mg group were more likely to achieve an increase in Kt/V of at least 10% in the next dialysis session (34.7% vs 28.9% p=0.04). Otherwise the 2mg alteplase with our protocol was not inferior to baseline with respect to blood volume processed (26.1% vs 20.1% p=0.13) and average clearance (37.7% vs 28.5% p=0.37). A 12% decrease (88 vs 100mg/mo p<0.05) in alteplase use was observed with no differences in frequency of hospitalizations (8% vs 5.9% p=0.39) or line interventions (12.3% vs 7.3% p=0.20).

Conclusions: Our protocol with 2mg alteplase therapy to the problematic lumen was not inferior with respect to patient outcomes compared to baseline practices and resulted in lower alteplase use. An expanded multi-center prospective study is underway to further assess the broader applicability of these findings.



Alteplase administration protocol.

PO0938

The Effect of Predilution Online Hemodiafiltration on Body Composition, Nutritional Status, and Mortality

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Aiko Okubo,[1,5] Toshiki Doi,[1,5] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Koji Usui,[2] Michiko Arita,[3] Takayuki Naito,[4] Shigehiro Doi,[5] Takao Masaki.[5] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Ichiyokai East Clinic, Hiroshima, Japan; [4]Ichiyokai Yokogawa Clinic, Hiroshima, Japan; [5]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: We evaluated the effect of predilution online hemodiafiltration (HDF) on body composition, nutritional status and all-cause and cardiovascular (CV) mortality in maintenance dialysis patients.

Methods: All subjects (n=215) had blood flow rate of ≥200 mL/min and underwent HDF with a convective volume of 40 L/session or hemodialysis (HD), 4h/session, 3 times/week. Predialysis clinical data and same day postdialysis body composition parameters based on BCM (Fresenius) were obtained at baseline in 46 patients on HDF and 169 patients on HD, and followed over 5 years. Logistic regression analysis for HDF, Kaplan–Meier analysis and Cox hazard analysis were conducted.

Results: In all subjects, age and dialysis vintage were 72±12 years and 73±6 months, respectively. Body mass index [22.4 (20.6–27.0) vs. 19.8 (16.4–22.7) kg/m^2], lean tissue index (LTI) [13.2 (10.8–15.7) vs. 11.0 (9.3–13.2) kg/m^2], geriatric nutritional risk index [94 (88–97) vs. 88 (81–93)], serum albumin [3.6 (3.3–3.8) vs. 3.3 (2.9–3.5) g/dl], creatinine, phosphate and magnesium were higher, but LDL-cholesterol (LDL-C) was lower in patients on HDF than those on HD (P<0.05). There were no significant differences in fat tissue index (FTI) [8.0 (5.5–11.2) vs. 7.8 (5.7–10.6) kg/ m^2], overhydration (OH) [0.8 (–0.5–2.2) vs. 0.9 (0.3–2.1) L], C-reactive protein (CRP), Kt/Urea or β2-microglobulin (β2m) between the groups. HDF was significantly (P<0.05) associated with serum albumin [odds ratio (OR):2.99], LDL-C (OR:0.98) and LTI (OR:1.22), but not with FTI, OH, CRP, Kt/Urea or β2m. Cumulative 5-year survival rate was significantly higher in patients on HDF than those on HD (67.9 vs. 43.7%, P<0.01). For 5-year all-cause mortality, HDF [hazard ratio (HR):0.31], age (HR:1.03), albumin (HR:0.48) and LTI (HR:0.91) were significant predictors (P<0.05), while FTI and OH were not. For 5-year CV mortality, HDF (HR:0.20), age (HR:1.05), diabetes (HR:2.61) and LTI (HR:0.80) [or either FTI (HR:1.08) or OH (HR:1.22)] were significant predictors, respectively (P<0.05).

Conclusions: Predilution online HDF with substitution volume 40 (20–40) L/session, 3 times/week is associated with better nutrition, increased muscle mass, and improved all-cause and CV mortality, but not with body fat and OH in dialysis patients.

PO0939

Monitoring of Intradialytic Sleep Apnea in Hemodialysis Patients

Paulo Paneque Galuzio,[1] Alhaji Cherif,[1] Xia Tao,[1] Ohnmar Thwin,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Breathing disorders are frequent in end-stage kidney diseases, with more than 50% of hemodialysis (HD) patients experiencing sleep apnea syndrome (SAS). SAS is associated with lower health-related quality of life and represents a significant cardiovascular risk factor. HD patients with SAS are at greater risk of mortality. The study aimed to monitor intradialytic SAS in HD patients using oxygen saturation (SaO_2) measurements.

Methods: Crit-Line® monitor was used to record SaO_2 at 1 Hz, for 2 HD sessions with a mean duration of 3.5±0.5 h. For each patient, we calculated: oxygen desaturation density (ODD_{10}), which counts 3% drops in SaO_2 from a baseline for at least 10 s long; a10th order permutation entropy to quantitate complexity; and optimal recurrence threshold ($\varepsilon_{optimal}$) to account for dynamic variations and degree of predictability in the SaO_2. These quantities were subjected to machine learning methods to predict intradialytic SAS, as quantified by the ODD_{10} value and the SAS classification by the American Sleep Disorders Association.

Results: We examine intradialytic SAS severity in 16 patients (age of 54±11 years, 63% males, 69% Black) with arteriovenous vascular access. Mean SaO_2 was 94.3±2.1%. Figure 1A shows a typical SaO_2 annotated with the SAS intensity assessed by ODD_{10} (Fig. 1B). The two calculated metrics are plotted in Figs. 1C-D. The results reveal dynamic characteristic patterns of SAS with differential severity scores during HD. Figures 1E-G show the ROC for the classifiers when considering episodes of at least mild, moderate, or severe SAS, respectively. The maximum AUC is 0.93 for severe SAS episodes.

Conclusions: Our analysis suggests that entropy and recurrent-based quantifiers could be used as predictive indicators of intradialytic SAS. However, further studies are needed to assess their relationships to clinical outcomes.

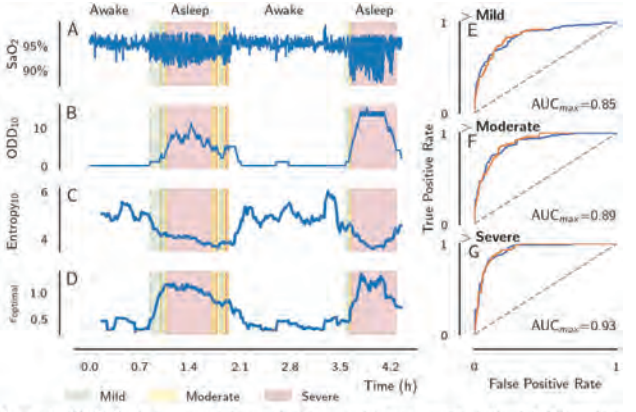

Figure 1: (A) SaO_2 for a representative patient, the shaded areas annotate different SAS intensities classified by (B) the oxygen desaturation density (ODD_{10}). (C) Entropy and (D) optimal recurrence threshold ($\varepsilon_{optimal}$) calculated from the SaO_2 time series (A). SAS intensity measured by ODD_{10} was classified based on ASDS categories as (E) mild, 5 – 15 events/hour of sleep, (F) moderate, 15 – 30 events/hour of sleep, and (G) severe, > 30 events/hour of sleep. Here, AdaBoost and Random Forest binary classifiers were used to predict SAS severity.

PO0940

DENALI, a Phase 3b Multicenter, Open-Label Single-Arm Study of Roxadustat: Operational Learnings Within US Dialysis Organizations

Arnold L. Silva,[1] Gopal Saha,[2] Jeffrey L. Hymes,[3] Lynda Szczech,[2] Yemisi Oluwatosin,[4] Zhiqun Gong,[2] Kerry Cooper,[4] John W. Larkin.[5] *[1]Boise Kidney & Hypertension Institute, Meridian, ID; [2]FibroGen Inc, San Francisco, CA; [3]Fresenius Medical Care North America Nashville, Nashville, TN; [4]AstraZeneca, Wilmington, DE; [5]Fresenius Medical Care North America, Waltham, MA.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase (HIF-PH) inhibitor that promotes erythropoiesis and improves iron availability in patients with anemia of chronic kidney disease (CKD). This trial aims to provide practical data on roxadustat use in dialysis patients with anemia via a semi-pragmatic evaluation of introduction into providers' practices (Fresenius Medical Care).

Methods: This open-label, single-arm study assesses the efficacy and safety of roxadustat in correcting/maintaining hemoglobin (Hb) in patients with CKD-related anemia receiving in-center/home dialysis at nine US sites (NCT04410198). Initial roxadustat dose is weight-based (erythropoiesis-stimulating agent [ESA]-naïve patients) or guided by an ESA dose-conversion algorithm (ESA patients), in this trial targeting Hb=11±1 g/dL. Roxadustat dose is titrated every 4 weeks based on Hb level or rate of change, with 24-week treatment duration and up to 1-year extension. Efficacy is assessed by change from baseline in Hb and proportion of patients achieving mean Hb ≥10 g/dL averaged over weeks 16-24. Exploratory endpoints include time to first red blood cell transfusion, proportion of patients achieving mean Hb ≥10 g/dL in first 8 weeks, intravenous iron use, and dosing adherence. Safety endpoints include treatment-emergent adverse events (AE), with COVID-19 positivity an AE of special interest.

Results: This ongoing trial was successfully initiated and enrolled (n=203) during the COVID-19 pandemic, with modifications for home dialysis. Baseline characteristics appear representative of the US dialysis population (Table).

Conclusions: This trial adds to phase 3 studies of roxadustat by evaluating its use in treating anemia of CKD in home/in-center dialysis patients during the COVID-19 pandemic, while providing a view into operationalization and ease of real-world use. Full study results will be presented.

Funding: Commercial Support - FibroGen and AstraZeneca

Modeling Low Muscle Mass Screening in Dialysis Patients

Daiki Senzaki,[1] Tatsuyoshi Ikenoue.[2] Sarcopenia Screening Tool Development Group *[1]Fujiidera Keijin-kai Clinic, Fujiidera, Japan; [2]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan.*

Background: Sarcopenia, regarded as low muscle mass, affects the prognosis of dialysis patients, and is a serious problem. Though bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DXA) are used in conventional sarcopenia screening, BIA and DXA may not accurately predict muscle mass because dialysis patients are easily affected by water content. On the other hand, computed tomography (CT) can measure muscle mass with accuracy even in dialysis patients. However, it is not easy to use CT at bedside screening. We aimed to create a prediction model of low muscle mass that can be used at bedside using the psoas muscle mass index (PMI) from CT measurement as the gold standard.

Methods: This is a multi-center, prospective cohort study. Between June 29, 2019 and December 31, 2020, outpatients who had been screened by dialysis and CT imaging for more than 6 months at each facility were included. They were divided into a development group and a verification group based on geographical factors. The PMI was manually measured from abdominal CT to diagnose low muscle mass. From the development group, a logistic regression model was created using 42 items of clinical information as predictor variables, and variables were selected by the stepwise method. External validity was examined using the verification group, and area under the curve (AUC), sensitivity, and specificity were calculated.

Results: Of the 619 subjects, 220 (35.6%) were diagnosed with low muscle mass. The subjects were divided into a development group of 441 and a verification group of 178 patients. A predictive model of low muscle mass was created with 6 variables (mean grip strength, height, dry weight, dialysis water removal, pre-dialysis albumin, and comorbidity of liver disease). The adjusted AUC of the development group was 0.78, sensitivity 82.7%, and specificity 63.3%. The adjusted AUC of the verification group was 0.71, sensitivity 64.3%, and specificity 72.2%.

Conclusions: It is expected that muscle mass screening of dialysis patients will be possible easily, and it is expected to support prevention and intervention decisions for sarcopenia. This study did not directly compare with BIA or DXA and did not show our model is superior to BIA or DXA. Therefore, further researches are needed to support its use.

PO0942

Validation of Urea Removal in Novel Sorbent Dialysis System

Brandon D. Borrillo, Tzu Tung Chen, Osman Khawar, Clayton Poppe. *Diality Inc, Irvine, CA.*

Background: The Diality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: To assess urea mass removal during a simulated dialysis utilizing a novel sorbent filter.

Methods: Nine simulated dialysis sessions were conducted utilizing between 50L and 125L volumes of dialysate circulated at approx. 400 mL / min & 37 C through a sorbent cartridge with a standard dialysate. (Table 1) It is expected that with each pass through the filter the dialysate urea mass will decline. The experiment is continued until breakthrough occurs or the infusate outlet reaches 10 ppm of NH_4. A solution containing K, Ca and Mg salts were constantly infused to replenish electrolytes lost in each pass. Another solution was infused at a variable rate as determined by conductivity to maintain Na Balance.

Results: The results are provided in table 1. The average URR was 63.8 % ranging from 53.3 to 87.0 %. The average starting BUN was 48.2 mg/dL and the average ending BUN was 16.8 mg/dL.

Conclusions: The initial experiments using a sorbent filter demonstrate a URR of near 65 is feasible. Future design changes will be scaled to handle larger amounts of urea and provide acceptable clearances.

Funding: Commercial Support - Diality Inc

Table 1:

Start BUN (mg/dl)	End BUN (mg/dL)	URR	Circulation Volume (L)	Breakthrough (mins)
42.0	19.6	53.3	125	225

PO0943

Effect of Hemodialysis on Amyloid-β in Cerebrospinal Fluid and Plasma

Lin-Chun Wang,[1] Ohnmar Thwin,[1] Joshua E. Chao,[1] Amrish U. Patel,[1] Ludovic Debure,[3] Nadja Grobe,[1] Xia Tao,[1] Hanjie Zhang,[1] Stephan Thijssen,[1] Thomas Wisniewski,[3] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]NYU Langone Health, New York, NY.*

Background: Hemodialysis (HD) can reduce amyloid-beta (Aβ) species in whole-body circulation by 30 to 50%. Due to the dynamic exchange of Aβ between the brain and the blood, we hypothesized that HD might lower Aβ levels in the cerebrospinal fluid (CSF).

Methods: In a dialysis network with over 160,000 patients, we identified three maintenance HD patients (age 36±9 years) with ventriculo-peritoneal (VP) shunts who were subsequently recruited for this IRB-approved research study. Study subjects were dialyzed on Monday, Wednesday, and Friday. Plasma samples were collected at 6 timepoints during the 3 HD sessions. One subject was withdrawn over safety concern related to the VP shunt tap procedure. Two subjects further underwent VP shunt taps for CSF sample collection before and after the Wednesday and Friday HD sessions, and once on interdialytic days (Tuesday, Thursday). $A\beta_{1-42}$ and $A\beta_{1-40}$ were quantified by Neuro 3-Plex SIMOA assays (Quanterix, MA, USA).

Results: HD effectively reduced plasma $A\beta_{1-40}$ by 41% and $A\beta_{1-42}$ by 34% (**Fig 1a and 1b,** $p < 0.01$). In CSF, levels of Aβ increased after Wednesday HD sessions in subject 1 ($A\beta_{1-40}$: 4.2-fold, $A\beta_{1-42}$: 5.5-fold) and subject 2 ($A\beta_{1-40}$ and $A\beta_{1-42}$: 1.06-fold), while Aβ decreased after Friday HD sessions in both subject 1 ($A\beta_{1-40}$: 0.1-fold, $A\beta_{1-42}$: 0.1-fold) and 2 ($A\beta_{1-40}$: 0.7-fold, $A\beta_{1-42}$: 0.7-fold) shown in **Figure 1c**–**f**.

Conclusions: This is the first report of Aβ dynamics in the CSF and plasma of HD patients. While plasma levels were in similar ranges, we found high inter-individual variations of CSF levels. Different plasma-to-CSF ratios after HD may reflect individual brain Aβ pools that are accessed by HD. We corroborate previous reports demonstrating the removal of Aβ from the blood compartment by HD.

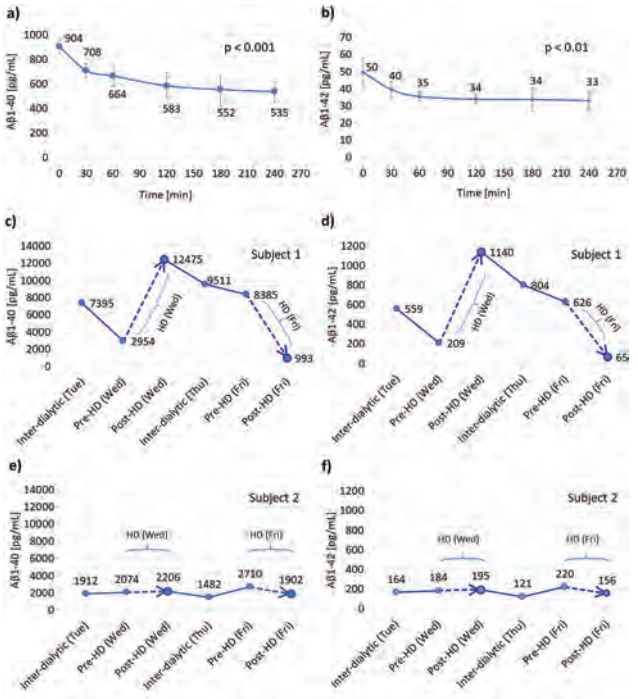

Figure 1. Values are means ± standard deviations in pg/mL. Plasma levels of $A\beta_{1-40}$ and $A\beta_{1-42}$ from three (n=3) study subjects and a total of seven treatments are shown in **a)** and **b)**. Analysis was done by linear mixed effect model, considering random effects over time throughout the hemodialysis treatments. Individual levels of $A\beta_{1-40}$ and $A\beta_{1-42}$ in cerebrospinal fluid (CSF) from the two study subjects who underwent ventriculo-peritoneal shunt tap are shown in **c)** CSF levels of $A\beta_{1-40}$ in subject 1, **d)** CSF levels of $A\beta_{1-42}$ in subject 1, **e)** CSF levels of $A\beta_{1-40}$ in subject 2, and **f)** CSF levels of $A\beta_{1-42}$ in subject 2.

PO0944

Circulating Microbiome and Cardiovascular Death in Patients with ESRD

Keiichi Sumida,[1] Joseph F. Pierre,[1] Zhongji Han,[1] Tahliyah S. Mims,[1] Praveen Kumar Potukuchi,[1] Susmita Datta,[2] Csaba P. Kovesdy.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of Florida, Gainesville, FL.*

Background: Patients with end-stage renal disease (ESRD) suffer from disproportionately high cardiovascular (CV) mortality. Accumulating evidence suggests a role for the circulating microbiome (CM) in the pathogenesis of CV disease; however, little is known about its association with premature CV mortality in ESRD.

Methods: In a pilot case-control study of 17 hemodialysis (HD) patients who died of a CV event and 17 matched HD controls who remained alive during a median follow-up period of 2.0 years, we compared the levels and composition of CM, including Bacteria, Archaea, and Fungi in serum samples by quantitative PCR and 16S or Internal Transcribed Spacer (ITS) ribosomal RNA (rRNA) sequencing, respectively. Association of the CM with CV death were examined using multivariable conditional logistic regression.

Results: 16S and ITS rRNA was detectable in all (except 3 for ITS) examined patients' serum samples. Despite no significant difference in 16S rRNA levels and α diversity between cases and controls, taxonomic analysis demonstrated differential community membership between groups, with significantly greater Actinobacteria and less Proteobacteria observed in cases than controls at the phylum level. At the genus level, *Staphylococcus* was numerically higher in cases than in controls, albeit not reaching statistical significance. Proportions of Actinobacteria and Proteobacteria phyla were marginally associated with risk of cardiovascular death (adjusted ORs [95% CI], 1.12 [0.98-1.29] and 0.88 [0.76-1.02] for 1% increase, respectively; **Table**). Although circulating fungal community α diversity was significantly elevated in cases than controls, no significant association was observed with CV death.

Conclusions: Alterations of the CM may be associated with a higher risk of premature CV mortality in ESRD patients.

Funding: NIDDK Support

Association of circulating microbiome with cardiovascular death in hemodialysis patients

Characteristics	Adjusted Odds Ratio	95% CI
16S rRNA (per log10 ng/uL)	0.38	0.002 to 85.7
Shannon Index (per unit)	0.92	0.17 to 4.92
Actinobacteria (per percent)	1.12	0.98 to 1.29
Proteobacteria (per percent)	0.88	0.76 to 1.02

Model was adjusted for age, sex, race, dialysis vintage, and vascular access type.

PO0945

Dysregulation of Fibrinolytic Process Contributes to the Thrombotic and Bleeding Complications in ESRD Patients

Fakiha Siddiqui, Vinod K. Bansal, Omer M. Iqbal, Emily Bontekoe, Jawed Fareed. *Loyola University Health System, Maywood, IL.*

Background: End stage renal disease (ESRD) is a complex syndrome involving both cellular and humoral mechanisms. Both thrombotic and bleeding complications are observed which may result in cardiovascular and cerebrovascular adverse outcomes. Fibrinolytic system placed an important role in the regulation of hemostatic process. A comprehenhesive profiling of the components of fibrinolytic process may provide additional understanding of the bleeding and thrombotic complications in ESRD.

Methods: Citrated whole blood samples were collected from a cohort of ESRD patients (n=95). Normal citrated plasmas were obtained from healthy male and female individuals. These samples were analyzed for prothrombin time (PT), activated partial thromboplastin time (aPTT), prothrombinase-induced clotting time (PiCT) and thrombin time (TT) using clot based technique. Fibrinolytic parameters such as urokinase type plasminogen acticator (uPA), plasminogen activator inhibitor-1 antigen (PAI-1A), and D-Dimer were measured by using ELISA method. Funtional PAI-1 was measured by using an amydolytic method. All results were compiled as group means ± SEM and respective ratios were calculated.

Results: All of the clotting results showed varying levels of elevated values in comparison to normal plasma. uPA levels showed wide variations and were increased (1.6 fold). D-Dimer was markedly increased in the ESRD patients (11.53 fold). Both functional (1.2 fold) and antigenic (3.07 fold) levels of PAI-1 were increased. Interestingly, the PAI-1 antigen levels was much higher in contrast to the functional levels suggesting a progressive consumption of this mediator.

Conclusions: These results suggest that the overall hemostatic system in ESRD patients is dysregulated due to the imbalance of the inhibitors such as PAI-1. The persistent activation of fibrinolysis is due to the increase production of uPA which facilitates endogenous fibrinolysis resulting in the elevation of D-Dimer. The generation of fibrinolytic enzymes results in increased fibrin/fibrinogen degradation products which may contribute to the observed intrinsic and extrinsic coagulation defects as measured by the elevation of PT and aPTT. Monitoring of fibrinolytic parameters along with clotting test may be helpful in the risk stratification and prediction of adverse outcomes in ESRD patients

PO0946

Successful Treatment of Systemic Calcinosis in a Teenager on Hemodialysis

Naile Tufan pekkucuksen,[1] Mohammed Al-Humiari,[1] Sai Sudha Mannemuddhu,[2] Lawrence R. Shoemaker.[1] *[1]University of Florida, Gainesville, FL; [2]East Tennessee Children's Hospital, Knoxville, TN.*

Introduction: Systemic calcinosis is rare in pediatric ESKD patients compared to adults. The subcutaneous tissues are most frequently involved. We present teenager in whom calcinosis was detected incidentally on chest radiograph, and review its successful treatment.

Case Description: A 15 yo anuric female who had received hemodialysis(HD) for 18 months after renal transplant failure, was treated for progressive respiratory distress in the ICU. Significant history included osteoporosis, hypertensive cardiomyopathy, and renal failure since age 1. Chest-XR revealed bilateral pulmonary infiltrates and calcified lesions. Thoracic CT scan demonstrated calcified tracheal and bronchial cartilage rings. Flexible bronchoscopy revealed diffuse white/gray nodules throughout the wall of tracheobronchial tree. All cultures were negative. When notified of the finding of calcifications on CT scan, patient's mother also asked about the firm nodules in the space between patient's fingers. Dialytic phosphate (P) clearance, and non-calcium(Ca), non-aluminum(Al) based binder use were maximized, using sevelamer and lanthanum carbonate. Sodium thiosulfate and etalcalcetide were given iv post each dialysis. Dialysate Ca varied between 2.5-3 meq/L, to avoid hypocalcemic stimulation of PTH and high CaXP. Lanthanum was discontinued after 3 months, once P levels declined. Other therapies were continued for 10 months; with monthly dose adjustment. PTH level decreased and P levels normalized. Etelcalcitide was reduced to maintain normal Ca level. After 10 months, iv pamidronate was initiated to prevent further demineralization. This led to transient marked elevation in PTH. Combined therapies led to resolution of calcinosis. However, tracheobronchial calcifications have not been reassessed, since neither chest imaging nor bronchoscopy have been clinically indicated.

Discussion: Calcinosis is an uncommon, yet treatable condition in pediatric dialysis patients. Combined use of old and new therapies was successful. Adverse side effects of therapies affect dosing. Etelcalcitide often causes hypocalcemia. Thiosulfate use is associated with nausea. Lanthanum is an effective metal Ca binder, but prolonged use may lead to accumulation and systemic deposition. The emergence of new P binders: ferric citrate, sucroferric oxyhydroxide, and bixalomer will offer exciting new treatment options.

PO0947

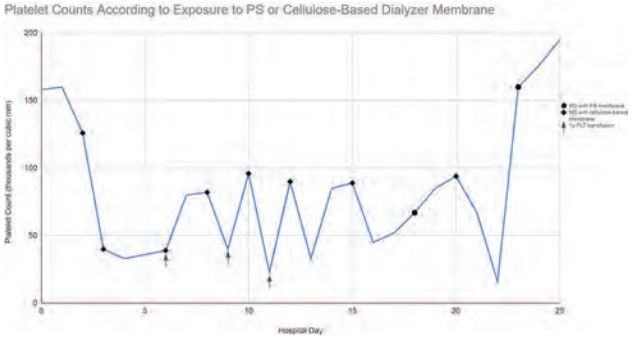
Severe Thrombocytopenia due to Electron-Beam Sterilized Polysulfone Dialyzer Membrane Reaction

Zachary Chandler, Irtiza Hasan, Vishal Jaikaransingh. *University of Florida Health Science Center Jacksonville, Jacksonville, FL.*

Introduction: We describe a case of severe thrombocytopenia due to reaction with an electron-beam sterilized polysulfone (PS) membrane. This phenomenon has been previously described but is rarely reported. E-beam sterilized PS membranes are classically more biocompatible than cellulose-based membranes but adverse reactions may occur as demonstrated in our case.

Case Description: A 74 y.o. woman with CKD Stage 4 and secondary hyperparathyroidism presented for evaluation of generalized weakness, anorexia, and weight loss. Her past medical history included gout, short bowel syndrome following prior bowel resection and osteoporosis. Home medications were allopurinol, calcitriol, gabapentin, fluoxetine, and mirtazapine. She was started on hemodialysis (HD) for suspected progression to ESRD. She developed progressive thrombocytopenia (Figure 1) that was worse following HD with improvement on non-HD days. Evaluation of usual culprits of thrombocytopenia was unrevealing. Reaction to the polysulfone filter was suspected and she was switched to a cellulose-based filter with resolution of her thrombocytopenia. She was dialyzed with a PS membrane on HD20 as proof of concept with recurrent thrombocytopenia following HD. She was dialyzed with cellulose-based filter thereafter with no further thrombocytopenia.

Discussion: We describe a case of PS-membrane induced thrombocytopenia. It is hypothesized that e-beam radiation may affect membrane integrity or structure, or produce intermediary products which may cause platelet activation, aggregation, and adsorption, and therefore thrombocytopenia. This entity should be considered in the differential diagnosis of patients undergoing HD who develop thrombocytopenia. Early recognition may reduce incidence of bleeding and need for blood products in these patients.



PLT counts during admission. HD days with PS membrane are denoted with a diamond label and HD days with cellulose-based membrane are denoted with a circle label. Single unit PLT transfusions are denoted with arrows.

PO0948

What Actually Happens at Home? A Data Linkage Study Between ANZDATA Registry and Sharesource

Stephen P. McDonald,[1,3] Gabriella Lincoln,[1,2] Maneesha Kandamby,[1,2] Christopher E. Davies,[1,4] Michelle Duddington,[5] Kylie L. Hurst.[1] *[1]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [2]South Australian Health and Medical Research Institute, Adelaide, SA, Australia; [3]The University of Adelaide Adelaide Medical School, Adelaide, SA, Australia; [4]The University of Adelaide, Adelaide, SA, Australia; [5]Baxter International Inc, Sydney, NSW, Australia.*

Background: In late 2018, the Claria automated peritoneal dialysis (APD) system was introduced into Australia and New Zealand. This device provides APD in a nocturnal setting, and automatically transmits data on the treatment session delivered utilising an inbuilt SIM card to a central database (Sharesource). We linked this with clinical and demographic information from the ANZDATA Registry to allow examination of actual events and delivered treatments and alerts.

Methods: Records from Claria APD treatments delivered in 2019 were linked with corresponding ANZDATA records using probabilistic linkage. The data structure (of repeated sessions per individual) was addressed using hierarchical (random effects) models for analyses.

Results: A total of 1641 people had 314,461 APD treatment sessions recorded over 2019. There were a median 189 treatments recorded per individual. Median age of participants was 62.0 years; median time from first kidney replacement therapy was 379 days. 33% of APD sessions had 4 drain cycles, 39% had 5 cycles and 16% 6 cycles. Mean drain time was 20.9 (SD 7.9) minutes; shorter with greater cycle number. Recorded treatment events included one cycle bypass in 8% of sessions, two bypassed sessions in 8 % and thee or more in 4% of sessions. At least one manual drain in 3.8% of sessions and 0.5% of sessions were user-terminated. One patient alert was recorded during therapy during 27% of sessions, and more than one in a further 10% of sessions. Of all recorded alerts the most common were "low drain volume", "Check patient line" and "low UF", all approximately 25% of alerts. The frequency of alerts did not vary across the day of week, but did vary with age, gender and diabetes (lower among older people, females). The frequency of treatments reported on a Saturday was only 92% of that on a Tuesday. The frequency of bypass (or alerts) was not related to day of week

Conclusions: The variation in frequency of treatment by the day of week suggests "social" causes --- i.e. a "night off" is more frequent on the weekend. Either some form of treatment event or alert is present in a substantial minority of APD sessions. The relationship of these events with technique survival is important, but not yet known. In time this linked data will allow examination of events recorded during treatment with patient outcomes.

Evaluation and Measurement Properties of a Patient-Reported Experience Measure for Home Dialysis

Matthew B. Rivara,[1] David K. Prince,[1] Kerstin Leuther,[2] Wael F. Hussein,[2] Brigitte Schiller,[2] Rajnish Mehrotra,[1] Todd C. Edwards,[1] Donald Patrick.[1] *[1]University of Washington, Seattle, WA; [2]Satellite Healthcare, San Jose, CA.*

Background: There are no validated patient-reported experience measures (PREMs) for use among patients undergoing home dialysis in the United States. We sought to test the home dialysis care experience (Home-DCE) survey, a newly developed 26-item PREM, in a sample of patients from 30 dialysis facilities operated by a single dialysis organization in the United States.

Methods: Using mail and phone survey modalities, we approached 1372 patients treated with peritoneal dialysis (PD) or home hemodialysis (HD) for participation. Using results from completed Home-DCE surveys, we hypothesized multi-item scales and used factor analysis to assess model fit. We assessed scale internal consistency reliability, and assessed floor and ceiling effects for scales and individual items. We evaluated test-retest reliability using intra-class correlation coefficients (ICCs) in a subset of patients who completed the Home-DCE twice. Finally, we evaluated patient demographic and home dialysis facility characteristics (nurse-to-patient ratio, hospitalization rate, star rating, and census) associated with Home-DCE scores.

Results: Overall, 495 eligible patients completed at least one survey (response rate 36%), including 399 treated with PD and 88 treated with home HD; 7 did not indicate their modality. Of these, 49 completed the Home-DCE in Spanish and 61 completed a second survey within 30 days. Analyses supported one 12-item composite scale with high internal consistency reliability: Quality of Home Dialysis Care and Operations (Cronbach alpha = 0.85). This scale was strongly correlated with overall staff rating (r = 0.73) and overall center rating (r = 0.70). ICCs in the test-retest population were 0.73 for the Quality scale, 0.88 for the overall staff rating, and 0.9 for the overall center rating. Patient demographic and dialysis facility characteristics were not consistently associated with Quality scale scores or overall staff or center ratings.

Conclusions: The Home-DCE includes one statistically robust multi-item scale and two global rating scores, and is an informative tool to evaluate patient-reported experience of care for home dialysis. Additional studies are needed to further evaluate the Home-DCE among different dialysis care providers, and to assess the feasibility of electronic administration.

Feasibility of a Staff-Assisted Peritoneal Dialysis Program in the United States: Results of a Pilot Study

Wael F. Hussein,[1,2] Graham E. Abra,[1,2] Paul N. Bennett,[1,3] Jugjeet Atwal,[1] Veronica Legg,[1] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]University of South Australia, Adelaide, SA, Australia.*

Background: Staff-assistance can support patients to utilize peritoneal dialysis (PD) and is available in many countries but not in the US. We report on the initial experience from a feasibility study for staff-assisted PD in the US.

Methods: An assisted PD program was initiated at one home dialysis center in Aug 2020, and expanded to a total of 6 centers by Feb 2021. Home assistance by non-registered nurse staff was offered to patients with barriers to self-care with the aim to support patients and families to become independent from staff assistance.

Results: Participating centers referred 33 patients (range: 0 – 16 referrals/center). 16 referrals were cancelled [admission from HD to the home program cancelled (3 referrals), transfer from PD to HD prior to starting staff assistance (5), resolution of the issue requiring assistance(7), and death (1)], 3 referrals are pending, and 14 patients received staff assistance at home. Of those who received assistance, median age was 72 (range 43-87) years, and 8 were new to PD. Indications included: physical weakness (10 patients), cognition (8), and psychosocial issues (7). One prevalent PD patient required assistance following a PD peritonitis episode. Anxiety and lack of confidence were common among referred patients. Staff member attending the patient's home assisted with removal and replacement of PD bags (5 patients), machine setup (9), dressing of exit site (7), checking the blood pressure (2), and other requests (8) such as documentation. Assisting staff worked with patients to build problem-solving skills, gain self-confidence, and arrange a safer home environment. Median length of time on the service was 17 (IQR: 6 – 23, range: 2 – 49) days, and median number of visits was 15 (range: 4 – 38, IQR: 5 – 26) visits/patient. Median visit duration was 64 (IQR: 55 – 90) minutes. Seven of the patients who finished are more than 90 days after starting assistance. Six of them remain on PD and one patient transferred to HD.

Conclusions: Staff-assistance can support patient transition to, and maintenance on, PD. Such programs are operationally feasible with non-RN staff in the US and should be supported by Medicare and regulatory agencies.

PO0951

Increasing the Prevalent Peritoneal Dialysis Patient Population Can Be Challenging

Hari Dukka, Emma Edwards, Anil Jain, Dhawal Arora. *University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom.*

Background: Peritoneal dialysis (PD) can provide better quality of life for patients requiring renal replacement therapy compared to in centre dialysis. It can be challenging to increase prevalent patient population on PD after a certain number is reached. We did a retrospective analysis to assess the turnover of patients on PD over a 8 year period and to understand the reasons for a stagnant prevalent PD population in the renal unit in Royal Derby Hospital.

Methods: Electronic database (Vital data, ICM) were used to document the number of patients starting and stopping PD each year from 2013 to 2020. The reasons for stopping PD and duration of technique survival were noted. If technique failure resulted in conversion to haemodialysis (HD) for more than 3 months, the cause of the failure was also noted. Patients who converted to HD for less than 3 months were excluded from the study.

Results: The number of patients starting (n=324) and dropping off PD (n=322) was similar for each year between 2013 to 2020 .Modality switch to haemodialysis accounted for 40-60% of patients stopping PD, followed by death (15-30%) and patients receiving renal transplantation (10-35%). Modality switch to haemodialysis was primarily due to infection (60- 80%), poor clearances and ultrafiltration failures (10-30%), social reasons (10-15%). Among patients who switched to HD due to an infection, peritonitis accounted for 75-85% of the cases followed by exit site and tunnel infections (15-25%). Introduction of Kidney quality improvement project in 2018 reduced numbers switching from PD to HD, with no affect on prevalent patient population due to decrease in incident patient population.

Conclusions: Increasing the prevalent population on PD can be challenging even with a high incident PD population. Having mechanisms which prevent infections, early identification and treatment of infections may help improve prevalent PD population.

PO0952

Disparities in Kidney Care: Where Care Needs to Be Equal

Tucker B. Hurtado, Meghan Staudt, Skylar Malone. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: Disparities in kidney care are widespread and gaining more attention. This research focuses on care differences that existed between home hemodialysis (HHD) and in-center hemodialysis (ICHD) patient from 2017 to 2020.

Methods: Using a HIPAA-compliant, online chart review tool, nephrologists submitted de-identified clinical and non-clinical demographic information beginning at the time of patient referral and concluding with details from the most recent visit. These data, from 2017 through 2020, were then merged with the physician demographic profile and attitudinal responses. The full data set of 4,062 patient charts submitted from 1,021 nephrologists was analyzed in SPSS.

Results: Given the new efforts to promote home modalities, nephrologists are following status quo and continue to initiate new dialysis patients on in-center hemodialysis. Nephrologists' current patient loads consist of, on average, 5 HHD patients and 96 ICHD patients. On average, they initiate one new patient on HHD compared to 17 new ICHD patients per year. When comparing HHD and ICHD patient charts there are substantial differences between the two patient types. HHD patients tend to be Caucasian and from higher education and socioeconomic levels: 52% are Caucasian and 25% are African American, 37% have some college (14% have an advanced degree), and 67% are middle or upper class. Conversely, ICHD patients tend to be more diverse (40% are Caucasian, 40% are African American), less educated (24% have some college and 5% have an advanced degree) and from lower socioeconomic classes (44% are lower or lower-middle class). Further, 40% of patients on home modalities are employed part- or full-time, versus 18% of patients on ICHD. Insurance coverage – both at dialysis initiation and current – influence modality choice as well. Notably, 70% of patients on home modalities were followed prior to dialysis, whereas only 48% of patients on ICHD were followed pre-dialysis, and patients on home modalities are substantially more likely to be on the transplant list versus ICHD patients (62% versus 37%).

Conclusions: Disparities in care exist between patients receiving home hemodialysis versus in-center home hemodialysis. As kidney care continues to evolve, physicians will need to account for these differences in their treatment paradigms to ensure they provide comparable care across patients.

PO0953

Characteristics and Treatment Patterns of Dialysis Providers Randomly Assigned to the Medicare ESRD Treatment Choices Model

Adam S. Wilk,[1] Kelsey M. Drewry,[1] Zhensheng Wang,[1] Rebecca Thorsness,[2] Amal Trivedi,[2] Rachel E. Patzer.[1] *[1]Emory University, Atlanta, GA; [2]Brown University, Providence, RI.*

Background: In January 2021, Medicare's End-stage Renal Disease Treatment Choices (ETC) model randomly assigned 30% of US dialysis facilities to receive financial bonuses and penalties on the basis of home dialysis use, waitlisting, and living-donor transplantation among their patients, compared with benchmarks from non-ETC-assigned facilities. We assessed whether sampling variance may influence ETC performance assessments by comparing pre-ETC treatment use among ETC-assigned and non-assigned facilities.

Methods: We compared rates of transplantation (living and deceased donor transplant, waitlisting) and home dialysis use (peritoneal dialysis, home hemodialysis) at 12 months among patients with incident kidney failure during July 2014-June 2018 in future ETC and non-ETC dialysis facilities (n=7527 facilities, n=192755 patients). In logistic regression models with region random effects and Bonferroni-adjusted robust standard errors, we assessed the adjusted relationships between ETC-assignment and facility characteristics (ownership, home dialysis offerings, staffing), patient case-mix (demographic, clinical, and insurance characteristics; mortality), and area-level socioeconomic status (e.g., median household income).

Results: Prior to ETC implementation, patients in ETC-assigned facilities had 22% (0.71 pp) higher rates of living-donor transplant receipt (p=0.005), 24% (0.89 pp) higher rates of deceased-donor transplant receipt (p<0.001), and 9% (3.3 pp) lower mortality rates (p<0.001) at one year versus in non-assigned facilities. Rates of home dialysis use were similar. Relative to non-assigned dialysis facilities, ETC-assigned facilities were 21% (2.0 pp) more likely to be owned by a small for-profit chain and 16% (5.8 pp) more likely to be owned by the second largest dialysis organization (p<0.001). Adjusting for other factors, dialysis facilities were more likely to be ETC-assigned if their patients were younger and if they had a lower percentage of patients who were Hispanic (both p<0.001).

Conclusions: Due to sampling variance, ETC-assigned facilities may be disproportionately likely to receive bonuses (vs penalties) under the model, even if they do not increase home dialysis treatment and transplant receipt among their patients.

PO0954

Novel Transitional Care Unit Design Achieves >50% Home Dialysis Choice in Incident ESRD Patients

Arley Diaz, Gregory L. Braden, Daniel L. Landry, Jeffrey Mulhern. Kidney Care & Transplant Services of New England *UMASS/Baystate, Springfield, MA.*

Background: In 1983 Eschbach reported that a 6 station Home Dialysis (HD) Oriented Unit at Northwest Kidney Center had a 62% success rate in incident ESRD pts choosing HD.The RVCARE study of intensive in center HD education during routine thrice weekly dialysis had 38% of pts chose HD. Satellite Dialysis found that with their Transitional Care Unit (TCU) 30 % of pts chose HD.

Methods: We designed a 6 station dedicated TCU staffed with the added benefit of its main teaching nurse having 4 years each of being a home hemodiaysis (HHD) & peritoneal dialysis (PD) nurse coordinator. The unit contains 3 NxStage & 2 Liberty Select Peritoneal cyclers. Pts are dialyzed 4 times weekly on the Nxtage or eventually the cycler. Added support is given by dialysis nurses trained in HHD & PD as are the social worker and dietitian educators. Intensive education with a defined curricula in all forms of HD are given including shared decision making with families. A medical director highly skilled in HD therapies also re-enforces the education delivered by the entire team every week. All 67 of our pts starting dialysis since July 2020 received standard dialysis education with several phone or virtual education sessions from our outpatient CKD coordinator, description of the TCU, plus a home visit by one of our HD coordinators.

Results: Since July, 2020 67 pts have started ESRD therapy, with 35 choosing not to enter the TCU and 32 choosing the TCU. Only 7 of 35 pts educated the standard way chose HD, 4 PD & 3 HHD but 17 TCU pts out of 32 chose HD, 10 HHD & 7 PD, 53%, p=.004 compared to standard education. There were no signiicant differences in duration of nephrology followup, age, sex or causes of ESRD between the 2 groups.

Conclusions: We conclude: The success of our TCU is due to it design using: 1) Pre-ESRD educaton about the benefits of starting dialysis in a TCU & 2) Most importantly having a skilled and experienced home HD and PD nurse coordinator to be the main educactor and pt champion for both HHD adn PD. 3) Utilizing a HD skilled medical director & social worker using shared decision making adds confirmational education on the benefits of HD.

PO0955

Home Hemodialysis with the Tablo System: The First 1000 Real-World Treatments

Michael A. Aragon, Yaadveer Chahal, Brittany Lim, Josh Schumacher. *Outset Medical, Inc., San Jose, CA.*

Background: The Tablo® Hemodialysis System is an all in one, easy-to-learn device capable of achieving clearance goals in as little as three treatments per week. It features integrated water purification, on demand dialysate production and two-way wireless data transmission. Tablo obtained FDA clearance for home hemodialysis (HHD) in March 2020. Approval was based on a prospective, crossover trial (in-center and at home dialysis) where Tablo successfully met all safety and effectiveness endpoints, reported high rates of treatment adherence and patient retention, with greatly reduced training time (NCT02460263). The objective is to report on the first 1,000 treatments performed on Tablo by patients at home in the real-world.

Methods: Incident and prevalent patients currently performing in-center dialysis, PD, or HHD were initiated on Tablo at participating Home Dialysis programs. Patients underwent training by facility nurses on the Tablo device prior to beginning treatments at home. Data on the first 1000 treatments was obtained wirelessly via Tablo's data platform along with corresponding patient training data.

Results: The first 1000 treatments occurred in 20 patients, with a mean follow-up duration of 3.4 months. Patient training on Tablo was completed over an average of 7.4 training days. Patient retention was 100% with no patients opting out of HHD with Tablo. Mean prescribed treatment time was 3.2 hours with a mean frequency of 3.7 treatments

per week. Mean total UF per treatment was 1.9 L. Mean UF rate per treatment was 7.3 mL/kg/hr. Treatment adherence was 93%, with 95% of treatments completing within 10% of prescribed time. The mean number of clinically significant alarms per treatment was 1.0 (± 3.0), with an average time to resolution of 10.7 (± 18.5) seconds.

Conclusions: Results from the Tablo IDE demonstrating reduced training time, increased treatment adherence, high treatment success rate and a low occurrence of treatment alarms are reproducible in the real world at a frequency of 3-4 treatments/week. This data supports that Tablo is capable of successfully achieving clinical goals while reducing the overall patient burden often associated with HHD.

Recent Trends in Utilization of Home Dialysis Modalities, Overall and by Duration of ESKD

Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1] Kirsten L. Johansen.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: The Executive Order on Advancing American Kidney Health and the End Stage Renal Disease Treatment Choices payment model have focused attention on increasing utilization of home dialysis. We assessed trends in home dialysis utilization between 2016 and 2021, including variability in trends among strata defined by duration of end stage kidney disease (ESKD).

Methods: We analyzed dialysis facility admission and discharge data extracted from the End Stage Renal Disease Quality Reporting System in May 2021. During the first epidemiologic week of each year from 2016 to 2021, we identified patients undergoing maintenance dialysis at the beginning of the week. For each patient, we identified the current dialytic modality. We estimated trends in utilization of each modality, overall and by duration of ESKD at the beginning of the week (<2, 2-4, 5-9, and ≥10 years).

Results: Between 2016 and 2021, home dialysis utilization increased from 11.5% to 14.3%, with the majority of growth occurring since the beginning of 2019 (figure). Concurrently, HHD utilization increased from 1.57% to 2.23%, whereas PD utilization increased from 10.0% to 12.0%. Among patients with ESKD duration <2 years, home dialysis utilization increased from 14.8% in 2016 to 20.0% in 2021, with >90% of utilization in this stratum due to PD. Among patients with ESKD duration of 2-4 years, home dialysis utilization increased from 11.7% in 2016 to 13.7% in 2021. Among patients with ESKD duration ≥10 years, home dialysis utilization hovered around 9%, although HHD utilization reached a high of 3.65% in 2021, representing nearly 40% of home dialysis utilization in this stratum.

Conclusions: Growth of home dialysis utilization has accelerated since 2019, with greater absolute growth of PD and greater relative growth of HHD. Longer duration of ESKD is associated with lower utilization of PD, but higher utilization of HHD.

The Impact of Seasonality on Crash Starts and Home Dialysis Use

Eugene Lin,[1,2] Khristina I. Lung,[2] Darius Lakdawalla.[2] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]University of Southern California Leonard D Schaeffer Center for Health Policy and Economics, Los Angeles, CA.*

Background: The US has made a concerted effort to increase home dialysis use. Dialysis "crash starts," when patients emergently initiate dialysis in the hospital, are a barrier to home dialysis because they often preclude successful planning. We studied whether the season of the year was associated with crash starts and with home dialysis use among incident patients with end-stage kidney disease (ESKD).

Methods: From the United States Renal Data System, we identified all adults with at least 30 days of continuous Medicare Parts A and B coverage initiating dialysis from 2007-2017. We identified home dialysis use and whether patients were hospitalized within 14 days prior to the first outpatient dialysis treatment (i.e., "crash start"). Using multivariable logistic regression, we studied the association between season, likelihood of crash start, and starting dialysis at home. We used a Cox model to study whether crash starts were associated with **ever** using home dialysis in the first year. We adjusted for demographics, comorbidities, facility and geographic characteristics, and year of dialysis start.

Results: After adjusting for confounders and year of dialysis start, patients were less likely to start dialysis in the winter versus the summer (OR: 0.86, 95% CI: 0.82, 0.90). Conversely, patients were more likely to "crash start" into dialysis in the winter versus the summer (OR: 1.14, 95% CI: 1.11, 1.17). Patients with a crash start were substantially less likely to initiate with home hemodialysis (OR: 0.16, 95% CI: 0.15, 0.16) and were less likely to ever use home dialysis in the first year (HR: 0.41, 95% CI: 0.40, 0.42). We observed seasonal heterogeneity in the admission diagnoses. Hospitalizations due to pneumonia, myocardial infarction, and congestive heart failure were 1.6, 1.4, and 1.3 times more likely to occur in the winter versus the summer, respectively. Hospitalizations due to diabetes, complications of devices, and chronic kidney disease were 1.05, 1.08, and 1.08 times more likely to occur in the winter, respectively.

Conclusions: We observed more dialysis crash starts in the winter and a subsequent decrease in home dialysis use in the first year. Winter hospitalizations were more often acute and due to cardiac and pulmonary etiologies. Clinicians should remain vigilant that patients may be prone to crash starts in the winter and should accelerate dialysis planning accordingly.

Comorbidity Is Not Associated with Home Dialysis Choice

Sanne Vonk,[2] Anna A. Bonenkamp,[1] Yolande Vermeeren,[3] Anita van Eck van der Sluijs,[2] Tiny Hoekstra,[1] Alferso C. Abrahams,[2] Frans J. van Ittersum,[1] Brigit C. van Jaarsveld.[1] DOMESTICO *[1]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands; [3]Department of Internal Medicine, Apeldoorn, Netherlands.*

Background: Over the past 15 years the proportion of Dutch home dialysis patients has decreased markedly. In addition, the rate of home dialysis varies significantly among centers. It is unclear whether this is the result of increased comorbidity, other patient characteristics or because dialysis centers perceive barriers for home dialysis differently. Our aim was to investigate the association between comorbidity and home dialysis.

Methods: The DOMESTICO study is a multicenter retrospective cohort study on home dialysis and randomly selected in-center hemodialysis patients. Comorbidity data was collected of patients who started dialysis between 2012 and 2017, including those who had previously received dialysis or obtained a kidney transplant. Patients who stopped dialysis or died within 30 days were excluded. Comorbidity was assessed with the Charlson comorbidity index (CCI). Home dialysis was defined as any peritoneal dialysis or home hemodialysis treatment during follow-up. Patients were followed until kidney transplantation, wish to stop dialysis, death or study end on 1 January 2017. Multivariable logistic regression analysis was used to assess the association between comorbidity and home dialysis, with a mixed model approach to adjust for dependency of patients within dialysis centers and for other patient characteristics including age, sex, and body mass index (BMI).

Results: Of 1358 included patients, 46% were treated with home dialysis. A high comorbidity score (CCI ≥5) was associated with a lower probability to receive home dialysis compared to patients without comorbidities (unadjusted OR 0.74, 95% CI 0.54–1.00). After adjustments for patient characteristics including age and BMI, there was no association between comorbidity and home dialysis. Only obese patients (BMI ≥30 kg/m^2) with comorbidities had a significant lower likelihood to receive home dialysis compared to obese patients without comorbidities (medium comorbidity score (CCI 3-4) adjusted OR 0.40, 95%CI 0.18–0.86 and high comorbidity score (CCI ≥5) adjusted OR 0.43, 95%CI 0.20–0.93).

Conclusions: Comorbidity is not associated with home dialysis, after adjustment for several confounding factors including age and BMI. Future studies should aim at unraveling the center-specific characteristics that play a role in dialysis treatment.

Reducing Routine Bloodwork in Home Dialysis Patients: A Quality Improvement Initiative

Epsita Shome-Vasanthan, Sophia Chou, David Ward, Juliya Hemmett, Jennifer M. MacRae, Elena Qirjazi. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: There is a paucity of evidence for routine bloodwork frequency in maintenance dialysis patients to assess and manage complications such as anemia and mineral bone disease (MBD). Recent studies showed that decreasing the frequency in conventional in-center hemodialysis (ICHD) patients had no negative impacts. Given the strain on lab services from the COVID-19 pandemic, Alberta Kidney Care-South (AKC-S) decreased the frequency of routine labs from monthly to every 2 months in home hemodialysis (HHD) and peritoneal dialysis (PD) patients. We studied the effect of this change on patient outcomes.

Methods: We retrospectively compared prevalent home dialysis patients (>3 months) in AKC-S over two 6-month periods: a) Pre-pandemic May-Oct 2019 and b) Pandemic May-Oct 2020. Primary outcomes were number of routine bloodwork days and percentage of patients within target for anemia (hemoglobin, iron saturation) and MBD (calcium, phosphorus, parathyroid hormone). We also compared hospitalizations, mortality, technique failure (defined as transition to ICHD for >60days), and cost.

Results: There were 366 home dialysis patients in 2019 (270 PD, 96 HHD) and 400 in 2020 (296 PD, 104 HHD). The number of routine bloodwork days decreased in 2020 compared to 2019 ($p<0.01$) (Fig 1). The proportion of patients who achieved anemia (33% vs 35%, p=0.44) and MBD (34% vs 28%, p=0.1) targets was similar. There was no difference in the number of hospitalizations (155 vs 141, p=0.34), deaths (13 vs 17, p=0.71) or technique failure (8% vs 5%, p=0.06). Projected cost savings were $102 per patient year from reduced labs.

Conclusions: AKC-S reduced the frequency of routine labs during the pandemic in home dialysis without negative consequences on patient biomarkers or outcomes. Our study suggests that bloodwork frequency in home dialysis patients may be safely reduced.

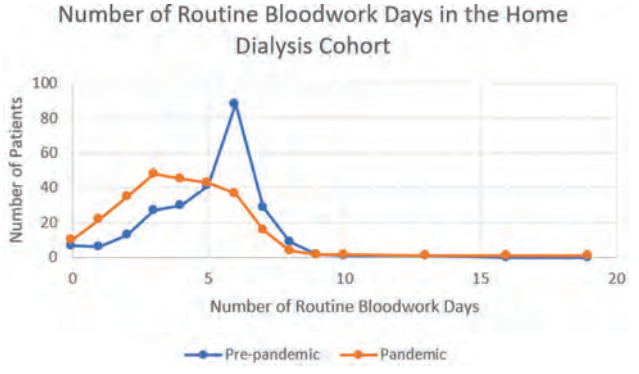

Figure 1. Distribution of the number of routine bloodwork days Home Dialysis patients had during the pre-pandemic (blue) and pandemic (orange) periods.

On-Demand Automated Peritoneal Dialysis Solution Generation

Jaime Uribarri,[1] Nabeel Aslam,[2] Clinton Edwards,[3] Lara M. Yamagata,[4] Anders J. Wellings,[5] Alyssa Wilmington,[5] Ha Tran.[5] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mayo Clinic's Campus in Florida, Jacksonville, FL; [3]Saint Bernards Healthcare, Jonesboro, AR; [4]Baxter Healthcare Corporation, San Gwann, Malta; [5]Baxter Healthcare Corporation, Deerfield, IL.*

Background: While automated peritoneal dialysis (APD) is an effective treatment for kidney failure, ordering, delivery and storage of supplies can be challenging. The APD Solution Generation System (SGS) allows for dialysate solution generation using tap water in a patient's home with fewer supplies (Figure 1).

Methods: A 12-week single-arm, prospective, descriptive study was conducted with in-home APD patients. Patients were screened, trained and treated with the SGS. Endpoints included testing the final product against specifications for Dianeal and water purification ISO Standard 13959 and measuring PD adequacy. Adverse events and device deficiencies were collected.

Results: 22 patients were enrolled; 14 patients completed the study. Demographics are shown in Table 1. See Figure 1 for primary efficacy and safety endpoint results. All tested post-sterilization filter and final dialysis solution samples passed. Missing data for water purity attributed to only 56.9% of samples passing. Mean (SD) change from baseline for Kt/V was -0.15 (0.370). There were 2 peritonitis events (0.43 episodes per patient-year), 1 occurring in a patient with HIV. There were no safety signals.

Conclusions: The SGS has the technical capability to accurately and safely generate dialysate at home using tap water. Logistical challenges with lab sampling require further exploration to understand the impact in future trials and real-world settings. Lessons learned from the study allow for transition of the device to future development.

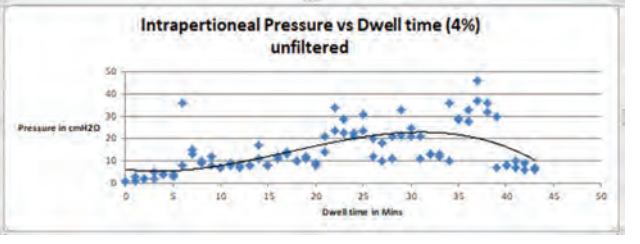
SmartPD™ Automated Peritoneal Dialysis System as a New Sophisticated Choice for Urgent Integration in Replacement Therapy for a Patient with ESRD

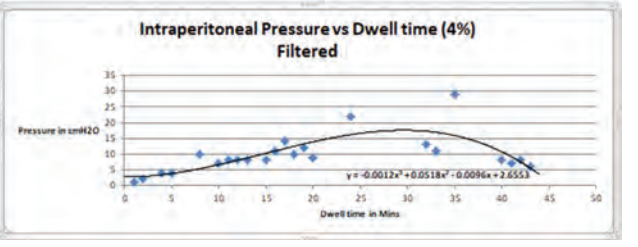
Ioannis Griveas. *Army Share Fund Hospital of Athens, 417 NIMTS, Athens, Greece.*

Introduction: Peritoneal dialysis (PD) is used to treat approximately 11% of dialysis patients globally despite wishes for 30%, due to Covid-19 pandemic. Expanded use of PD is impacted by clinician experience and confidence with "efficient", and "in home friendly" automated peritoneal dialysis (APD) system.

Case Description: A 60 years old lady presented from a remote island -under Covid-19 pandemic- with uremic features and started APD with *SmartPD*™ (Newsol technologies). *SmartPD*™ continuously monitors the intra-peritoneal pressure (IPP) during the Dwell. It can use this information to (a) determine optimal fill volume (b) automatically determining the optimal time to infuse or remove the dialysate from the peritoneum cavity (Fig 1a,b) and (c) records and provides UF transport characteristics (Fig 1a,b). From this composite data stream additional information can be evaluated or derive to determine the clinical health of the Peritoneal cavity. We noticed rapidly improvement in the metabolic profile and volume status (Bioimpedance measurement). Using the ability of SPD to independently adjust the dialysate concentration, number of exchanges and the dwell duration of each exchange we establish a best fit treatment time of typically 9-10 hours, with tidal volume 900 mils, 2% concentration over 9 cycles (40 mins a cycle). Our patient was under evaluation every month and today six months since starting APD with *SmartPD*™ she is in excellent condition, with no peritonitis episodes, zero incidence of overfill and minimal drain pain.

Discussion: *SmartPD*™ enables the formulation of prescribed dialysate at the point-of-care, maximizes dialysis performance, and optimizes treatment protocol. Remote monitoring capability by *SmartPD*™ allows remote supervision and management, an efficient choice especially in Covid-19 times.





PO0962

Animal Trial of Sorbent Cartridge for Portable Artificial Kidney (PAK)

Christian G. Bluechel,[1] Yen N. Koh,[1] Chieh-suai Tan,[2] Kenneth Chen,[2] Kun D. Zhuang.[2] *[1]Dialyss Pte Ltd, Singapore, Singapore; [2]Singapore General Hospital, Singapore, Singapore.*

Background: The NextKidney/Dialyss HD Sorbent Cartridge (SC) uses a novel type of sodium-neutral sorbent to regenerate spent dialysate for standard hemodialysis (HD) therapies. The SC is intended to be used with the NextKidney sorbent HD device, where it produces fully physiological dialysate meeting today's industry standards. We tested the safety and efficacy of the sorbent system in a total kidney failure pig model. The animals were maintained exclusively on sorbent HD for up to 2 weeks.

Methods: Three highly uremic pigs (60–75Kg) underwent a total of 14 alternate-day, 4h sorbent HD therapy sessions. Total renal failure was induced via bilateral renal artery embolization (pig #1), or bilateral laparoscopic ligation of renal arteries (pigs #2 and 3). A palindrome catheter provided blood flow rates of 200 – 300mL/min. A hemoperfusion machine was used for the blood circuit, coupled with a prototype device controlling the dialysate circuit. Dialysate was continuously purified in the SC at a flow rate of 300 mL/min. Therapy efficacy and mass balances were calculated from blood and dialysate samples collected before and after the dialyzer at specific time points.

Results: The animals tolerated the therapies well. The incision site at the femoral artery of pig #1 re-opened on day 5 after surgery, resulting in internal bleeding and loss of the animal. Fourteen 4hr dialyses were averaged to calculate toxin removal efficacy and mass balances. The average clearances for urea, creatinine and phosphate were 139, 146 and 141mL/min, respectively. Dialysate sodium and bicarbonate concentrations remained within the permissible deviations of +/-5% and +/-25%, respectively.

Conclusions: The biocompatibility of the sorbent system has been confirmed in fourteen 4h HD therapies conducted on three highly uremic pigs. The sorbent system was able to maintain the highly uremic animals. There were no severe adverse events related to the sorbent HD therapy. We currently plan to proceed to a first-in-human trial to evaluate the safety and efficacy of the sorbent cartridge for human use.

Funding: Commercial Support - Dialyss Pte Ltd and Neokidney B.V.

Thirty Days of Maintenance Peritoneal Dialysis Using a Sorbent-Based Automated Wearable Artificial Kidney (AWAK) PD Device in a Porcine Model

Marjorie W. Foo,[1] Htay Htay,[1] Edwina A. Brown,[2] Sridhar Chirumarry,[3] Marcin Pawlak,[3] Siti N. Huda,[3] Jason T. Lim,[3] Sanjay Singh,[3] Mandar Gori,[3] Suresha B. Venkataraya,[3] Arsh Jain.[4] *[1]Singapore General Hospital, Singapore, Singapore; [2]Hammersmith Hospital, London, United Kingdom; [3]AWAK Technologies Pte Ltd, Singapore, Singapore; [4]Western University, London, ON, Canada.*

Background: In sorbent-based PD, spent dialysate is processed and clean dialysate is re-introduced into the abdomen. Our aim was to determine if AWAK dialysis can maintain euvolemia and biochemistry for 30 days in a porcine model.

Methods: The study was conducted in a 5/6 nephrectomised pig (Sus Scrofa, male). Post nephrectomy, the animal was treated with CAPD (14 weeks) before commencing sorbent-based PD for 7 hour per day with initial fill of 2L 1.5% Dianeal for 30 consecutive days. Thereafter, the animal was maintained on standard of care (SOC) for 3 days (5x2L exchanges over 10 hour APD, with 1L last fill, 2.5% Dianeal).

Results: Stable serum concentration of toxins, electrolytes and inflammatory markers were noted during AWAK therapy (Table); with no significant change after switch to SOC. pH of regenerated dialysate was consistent with biocompatible solutions (figure 1) and appropriate change in ultrafiltration was observed in response to glucose infusion (figure 2).

Conclusions: AWAK PD therapy successfully treated a CKD animal model for 30 days, without adverse impact on volume status or clinical parameters. Future long-term human studies are needed for device enhancement.

Funding: Commercial Support - AWAK Technologies Pte Ltd

Smartphone Application to Assist Peritoneal Dialysis Patients for Timely Detection of Peritonitis

Mia Garbaccio,[1] Xia Tao,[1] Xiaoling Wang,[1] Xin Wang,[1] Zahin S. Haq,[1] Amrish U. Patel,[1] Lela Tisdale,[1] Ohnmar Thwin,[1] Lin-Chun Wang,[1] Nadja Grobe,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Timely detection of peritonitis in patients undergoing peritoneal dialysis (PD) is critical to lower the risk of catheter loss, morbidity and mortality (Muthucumarana, 2016). Current practice of screening potential peritonitis events at home relies on patients' visual detection of turbid spent dialysate and symptoms recognition. To assist patients with the timely capture of a potential peritonitis episode, we developed a smartphone app, which uses light detection to quantitate cloudiness and estimate white blood cell (WBC) count in PD effluent (PDE).

Methods: The app uses the built-in light sensor and compares measurements taken from the ambient light ($L_{ambient}$) and light through PD bags (L_{bag}) to estimate dialysate cloudiness. PDE samples were obtained as part of two IRB-approved clinical studies over a period of 6 months. Cloudiness of each sample was measured 3x with the app. Cloudiness (in %) was calculated as $(1 - L_{bag} / L_{ambient}) * 100$. WBC were counted using a hematology analyzer (Horiba 80XL).

Results: Patients maintained a stable baseline cloudiness of 2-5% (Fig 1). A peritonitis episode (subject PDMET0002) increased the cloudiness to 40%, which is 32 percentage points over the patient's peritonitis-free baseline. One suspected peritonitis sample (albeit WBCs <100 cells/mL) showed slightly higher cloudiness than non-peritonitis samples (Fig 2).

Conclusions: Our smartphone app can distinguish peritonitis from normal PDE samples. Smartphone-enabled detection of cloudiness in PDE samples using light transmission is possible and has the potential to easily monitor and diagnose patients at risk for peritonitis. Studies to define diagnostic performance in a large patient cohort are underway.

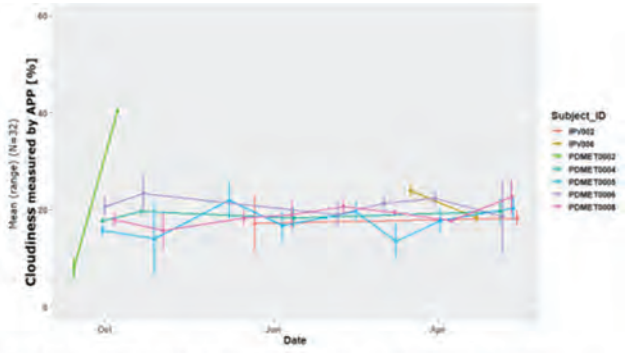

Figure 1: Mean (range) cloudiness for spent peritoneal dialysate collected repeatedly in 7 subjects over 6 months (N=32). Note the increased cloudiness during a peritonitis episode (subject PDMET0002).

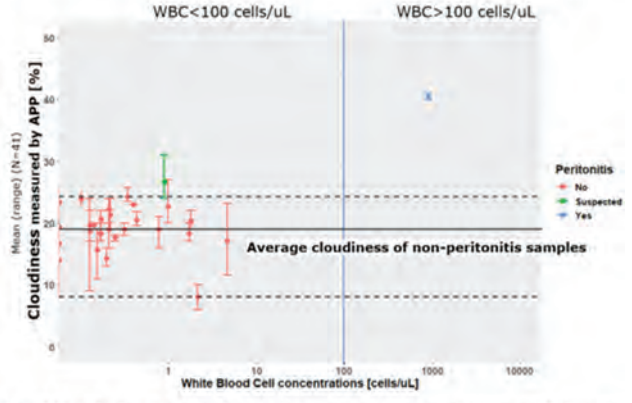

Figure 2: Mean cloudiness % measured by the smartphone app in spent peritoneal dialysate stratified according to white blood cell (WBC) concentration (N=41).

Remote Monitoring of Patients with Automated Peritoneal Dialysis May Improve Clinical Outcomes: Analysis by Competing-Risk Regression Models

Ramón Paniagua,[1] Marcela Avila,[1] Alfonso Ramos,[3] Abdul Rashid T. Qureshi,[2] Bengt Lindholm.[2] Mexican Nephrology Collaborative Study Group *[1]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; [2]Baxter Novum CLINTEC | Karolinska Institutet, Stokolm, Sweden; [3]Baxter México, Mexico City, Mexico.*

Background: Current information technologies allow remote monitoring (RM) of patients on automatic peritoneal dialysis (APD) and the adoption of proactive behaviors to prevent complications and improve treatment quality. We analyzed the effect of RM-APD on survival and preventable complications through a controlled clinical trial.

Methods: In a two-branched cluster RCT, hospitals with >100 prevalent, >50 new patients per year, and >5 years APD experience were randomly assigned to perform RM-APD or conventional APD with equivalent APD-equipment in adults beginning APD. The primary outcome was a composite index (CI) of death, first adverse event (AE) or first hospitalization. Secondary outcomes were the same variables considered individually and for their specific causes. All-cause and cardiovascular disease (CVD) mortality risk and AEs were analyzed with competing-risk regression with transplantation as competing risk.

Results: Eleven hospitals per arm were included and 815 patients were followed-up by at least one year, 417 using RM-APD and 398 on APD. Patients in hospitals using APD reached earlier the CI as well as its individual components. Patients with APD as compared to RM-APD were older, more inflamed, and had higher all-cause and CVD mortality. In competing risk analysis, after adjusting for age, sex, presence of smoking, hypertension, CVD and diabetes, APD as compared with RM-APD associated with higher subdistribution hazard ratio (sHR) for *all-cause mortality* (sHR 1.79, 95%CI (1.15-2.81); p=0.01), *CVD-related mortality* (sHR 2.21, 95%CI (1.07-4.58); p=0.03), and *AE* (sHR 1.74, 95% (1.34-2.25); p=0.001).

Conclusions: Use of RM-APD may improve survival and prolong the time to first AE and hospitalization in comparison with APD, suggesting that RM-APD may improve clinical outcomes in APD patients.

Peritoneal Dialysis Discontinuation: Trends and Risk Factors

Andrew Breck,[1] Jeffrey Marr,[1] Dominick Esposito,[1] Edwin D. Huff.[2] *[1]Insight Policy Research Inc, Arlington, VA; [2]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: Increasing use of dialysis home modalities among ESRD patients is a Centers for Medicare and Medicaid Services priority. This can be accomplished by increasing use of home dialysis among incident patients or by reducing PD discontinuation. We explore trends in PD persistence and risk factors associated with PD discontinuation.

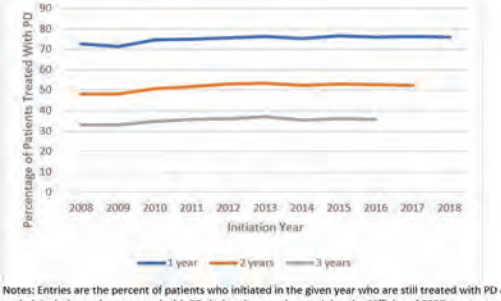
Methods: We identified incident ESRD patients from 2008 to 2018 who received peritoneal dialysis in their third month of ESRD treatment. We used data from CROWNWeb and Medicare claims to determine the patient's modality 1, 2, and 3 years after initiation of ESRD treatment. We summarize trends in share of incident PD patients who were treated with PD at each follow up and describe differences by patient and facility characteristics.

Results: From 2008 to 2017, approximately 70 percent of incident PD patients remained on PD after 1 year of dialysis, 50 percent after 2 years, and 30 percent after 3 years of dialysis (figure 1). Over these years the percentage of incident PD patients treated with PD after two years rose from 47.9 to 52.3 percent. The rate of two-year PD persistence has declined modestly since a peak of 53.1 percent in 2013. PD patients treated at DaVita facilities were more likely than those treated at FMC or independent facilities to remain on PD after two years. PD patients treated at facilities with a higher share of PD patients were more likely to remain on PD after two years. Among incident PD patients, the rate of peritonitis during the first year of dialysis declined from 33.5 to 21.7 between 2010 and 2018. Peritonitis was more common among dual eligible patients, Black and American Indian/Alaska Native patients, and overweight or obese patients.

Conclusions: Differences in PD discontinuation and peritonitis incidence across patient and facility subgroups represent opportunities for future quality improvement efforts.

Funding: Other U.S. Government Support

Figure 1. Percentage of Incident PD Patients Treated With PD at Follow-Up, 2008-2018



Notes: Entries are the percent of patients who initiated in the given year who are still treated with PD at the relevant follow-up period. Includes patients treated with PD during the month containing the 90th day of ESRD treatment.

PO0967

Peritoneal Dialysis Supplemental Telephone Support Program to Reduce 90-Day Drop-Out

Lucy B. Todd,[1] Mary Gellens,[1] Ann Mooney,[2] Ann Mancini.[1] *[1]Baxter International Inc, Deerfield, IL; [2]American Renal Associates, Beverly, MA.*

Background: Improving PD technique success is critical to meet Advancing American Kidney Health Initiative's (AAKHI) aggressive growth goal by 2025. Per results in the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) 2017, the United States First 90-day (F90) dropout rate was 11.4% vs. 8.4% for all PDOPPS countries. Focused clinical intervention may lessen F90 dropout. The objective of this study is to evaluate the impact of a Peritoneal Dialysis Supplemental Support (PDSS) service to reduce F90 loss in Automated Peritoneal Dialysis (APD) patients utilizing remote monitoring. The PDSS service consists of telephone calls to patients and clinic nurses. PDSS provides pre-emptive technical support to patients and actionable clinical insights to clinicians.

Methods: A dialysis provider enrolled non-randomized, incident PD patients, who were being treated with a 2-way APD cycler enabled with a remote management system, into a PDSS program. The PDSS nurse reviews remote monitoring data and looks for trends in alerts and alarms that may lead to F90 dropout. For technical alerts and alarms, a member of the PDSS team proactively calls the patient to discuss technique and training reinforcement. For clinical alerts and alarms, the PDSS nurse contacts the clinic PD nurse (PDRN), who remains the only party in control of clinical care.

Results: The dialysis provider enrolled 202 incident patients from 23 clinics into the PDSS program. The dialysis provider's historical F90 loss within these clinics was 15.9%, N=69 for 2018-2020. PDSS began in November 2019 and continued through December 2020. Data revealed a decrease in F90 loss to 8.4%, N=17, for patients enrolled in PDSS, a 46.9% reduction in F90 loss (p=0.0032).

Conclusions: A supplemental PD telephone support service enhances the benefits of two-way remote patient monitoring. The patient benefits from timely support. The nurse benefits from additional analysis of clinical trends in the data. This enables the nurse to implement appropriate clinical interventions as needed. The result is a statistically significant reduction in F90 loss rate.

PO0968

Contemporary Incidence of Peritoneal Dialysis Attrition and Variability Therein Among Age Strata

Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1] Kirsten L. Johansen.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: With an increasing percentage of patients performing dialysis in the home setting, quality measurement systems should increase focus on home dialysis outcomes. Considering the central role of peritoneal dialysis (PD) in home dialysis, an important and readily estimable measure is the duration of PD before initiation of hemodialysis. We estimated the cumulative incidence of attrition due to initiation of hemodialysis among patients who recently initiated PD in the United States and assessed variability of incidence among age strata.

Methods: We analyzed United States Renal Data System Standard Analysis Files. We identified all patients who initiated PD in the home setting between January 1, 2011, and September 30, 2018, and within one year after diagnosis of end stage kidney disease (ESKD). We classified patients into cohorts of age 18-44, 45-64, 65-74, and ≥75 years. Overall and within age strata, we estimated the 5-year cumulative incidence of conversion to hemodialysis, with accounting for the competing risks of death and kidney transplantation.

Results: The cohort included 111,464 patients who initiated PD. The cumulative incidence of conversion to hemodialysis was 22.4% at 1 year, 33.9% at 2 years, 41.4% at 3 years, 46.3% at 4 years, and 49.4% at 5 years (figure). During those 5 years, 25.4% of patients died while receiving PD and 12.8% received a kidney transplant, thereby resulting in only 12.4% of patients still performing PD after 5 years. Among patients aged 18-44 years, 1-year (5-year) cumulative incidence of conversion to hemodialysis was 23.3% (51.1%); corresponding estimates were 22.3% (52.0%) among patients aged 45-64 years (48.3%), 21.9% among patients aged 65-74 years, and 22.5% (41.6%) among patients aged ≥75 years.

Conclusions: Regardless of age, between 22% and 23% of patients who initiated PD during the first year of ESKD transferred to hemodialysis within one year.

PO0969

Length of Peritoneal Dialysis Training and Risk of Early Treatment Attrition

Harold E. Giles,[1] Vidhya Parameswaran,[2] Linda Ficociello,[2] Claudy Mullon,[2] Dinesh K. Chatoth,[2] Michael A. Kraus,[2] Michael S. Anger,[2,3] Robert J. Kossmann.[2] *[1]Nephrology Associates PC, Nashville, TN; [2]Fresenius Medical Care, Global Medical Office, Waltham, MA; [3]University of Colorado, School of Medicine, Denver, CO.*

Background: Patient training is a critical component of the peritoneal dialysis (PD) program to ensure safe dialysis outcomes. However, there is a lack of clarity on how long patients should be trained before initiating PD at home. In this analysis, we evaluate the associations between the length of PD training and patient outcomes (early treatment attrition, peritonitis, and hospitalizations) among patients prescribed automated PD (APD).

Methods: Adult patients who initiated APD between 2017-2019 and received PD training at Fresenius Kidney Care facilities within 30 days of home treatments were included. Crude and case-mix adjusted risk of early PD attrition (discontinuation from PD within 3 months of enrollment due to switch to HD, death, or loss to follow-up) were compared between patients with a shorter (≤ 5 days), medium (6 to 10 days), and longer (>10 days) lengths of training. Early rates of peritonitis and hospitalizations were compared between patients with ≤ 10 days vs >10 days of training.

Results: 11,039 patients who received training ≤ 30 days prior to APD initiation were included. Compared to patients with a shorter PD training (n=3,333), patients with a medium length of training (n=6,310) had no significant difference in the risk of early attrition (Figure 1). Patients with longer PD training (n=1,396) had a lower risk of early attrition when compared to shorter PD training patients in the crude analysis, and no significant difference when controlled for case-mix variables (significant confounders: vintage, residual kidney function, and body surface area). There were no differences in the early rates of peritonitis and all-cause and peritonitis-related hospitalizations between patients receiving training for >10 days vs ≤10 days.

Conclusions: There were no significant associations between length of PD training and risk of early treatment attrition, hospitalizations, or peritonitis among automated PD patients.

PO0970

Identifying Patients on Peritoneal Dialysis at High Risk of Transfer to Hemodialysis Using a Modified Surprise Question

Ayesha Anwaar,[1,2] Graham E. Abra,[2,1] Hatsumi Nielsen,[2] Sumi J. Sun,[2] Sai Liu,[1] Maria E. Montez-Rath,[1] Brigitte Schiller,[2,1] Wael F. Hussein.[2,1] *[1]Stanford University School of Medicine, Stanford, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Transfer from peritoneal dialysis (PD) to hemodialysis (HD) is associated with poor outcomes. Available prediction models of modality transfer are limited to the incident PD population. Simple predictive tools are needed to help guide risk stratification and subsequent clinical interventions to avoid unwanted modality transfer. We report on the correlates of nurse prediction of high risk using the question "Would you be surprised if this patient transfers to HD in the next 6 months?" (PD Surprise Question [PDSQ]).

Methods: This observational study included 1362 adults on PD receiving care at 35 centers in 3 states in the US, managed by a non-profit dialysis organization. A 'no' response to the PDSQ indicated high risk. Using multivariable logistic regression with backward elimination, we evaluated characteristics associated with being identified as high risk, including socio-demographic variables, BMI, primary kidney disease, vintage, comorbid conditions, renal and dialysate clearances, serum albumin, sodium, phosphorus, potassium, nPNA, last 3 months peritonitis and hospitalization, and insurance type. We used multiple imputations to handle missing data.

Results: Responses were obtained from 95/112 (85%) nurses for 1193/1362 (88%) patients. Mean age was 59 (SD: 16) years, 41% were female, median ESRD vintage 37 (IQR: 11 – 44) months and 46% had diabetes. 198 (17%) patients were identified as high risk. In the final model, patients were more likely to be identified as high risk if they were hospitalized in the last 3 months (odds ratio [OR]: 1.52, 95% confidence interval [CI] 1.30-1.74, p=0.0002). Having a higher serum sodium (for 1 meq/L: OR: 0.95, 95% CI 0.90-1.00, p=0.032), being married (OR: 0.76 95%CI 0.52-1.00, p=0.029), and longer PD vintage (for 1 month: OR: 0.99, 95%CI 0.0.98-1.00, p=0.013) were associated with lower odds of being identified as high risk.

Conclusions: The PD surprise question is a simple tool to assess the risk of transfer from PD to HD. Identified correlates of risk are consistent with high risk factors from the literature for transfer to HD. We are currently observing outcomes of included patients to examine the performance of the PDSQ to predict transfer to HD.

PO0971

Machine Learning-Driven Prediction of Peritoneal Dialysis Technique Failure

Caitlin Monaghan,[1] Joanna Willetts,[1] Hao Han,[1] Michael A. Kraus,[3,4] Dinesh K. Chatoth,[3,4] Len A. Usvyat,[1] Franklin W. Maddux.[2] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany; [3]Fresenius Kidney Care, Waltham, MA; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: Despite increased focus on starting and keeping dialysis patients on home therapy, Peritoneal Dialysis (PD) and Home Hemodialysis (HHD) rates are lower than desired. Two areas of opportunity are 1) keeping PD patients healthy so they can remain on PD longer and 2) transitioning PD patients to HHD when appropriate. To identify patients at risk of leaving PD in the short- (1-3 month) and long-term (3-6 month) timeframes, two machine learning (ML) models were developed. Along with risk scores, these models identify the factors driving increased risk to aid in prolonging time on PD while also allowing adequate notice to prepare for permanent access placement and HHD education.

Methods: Data were extracted for PD patients (n=53022) from 2016-2019; patients contributed one set of observations for each month they were on PD (n=823892 patient months). PD failure was defined as the first discharge from PD lasting over 30 days, and was coded as '1' if the patient changed modality in the next 1-3 or 3-6 months for the short- and long-term models, respectively. All other observations were coded as '0,' including censored events such as transplantation, loss to follow-up, or death. Two XGBoost ML models were trained using 80% of the dataset, with 20% used for evaluating model performance using 237 variables, derived from laboratory measurements, infection and hospitalization history, and other relevant clinical parameters.

Results: Evaluation of model performance on withheld data showed an area under the curve of 0.75 and 0.67 for the short- and long-term models, respectively. Patients were classified as High, Medium, or Low risk for each of their short- and long-term predictions. In the test dataset, 24% of high short-term risk patients dropped in the next 1-3 months, a rate almost 5 times higher than average and 12 times higher than low risk patients. For long-term predictions, 14% of high risk patients dropped in the next 3-6 months, 6% of medium risk, and 2% of low risk.

Conclusions: The two ML models showed good discrimination between patient risk categories for both short- and long-term timeframes. While further work is underway to gauge the clinical utility of these tools, these tools offer the potential to improve care of "failing" PD patients, reduce morbidity of transitions, and increase optimal starts with dialysis transitions.

PO0972

Technique Failure in the Dominican Republic National Peritoneal Dialysis Program

Erwin I. Campos,[1,2] Miguel A. Cuevas Budhart,[5] Elianny S. Polanco,[1] Jhanna H. Collado,[1] Mercedes Aquey,[1] Janny Guzman Chavez,[4] Alfonso Ramos.[3] Macrotech *[1]Macrotech, Santo Domingo, Dominican Republic; [2]Hospital Salvador B. Gautier, Santo Domingo, Dominican Republic; [3]Baxter Mexico, Ciudad de México, Mexico; [4]Baxter Colombia, Bogota, Colombia; [5]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: Technique failure is a critical concern in peritoneal dialysis (PD), and it's associated with significant risk of patient lost. Technique failure is defined as transfer to HD 30 days after initiation of therapy or death within 30 days of transfer to HD.

Methods: This is a retrospective multicenter observational cohort study of incident Peritoneal Dialysis patients conducted between January 1st 2016 to December 31st 2020. Competing risk events were death and kidney transplantation, and patients were censored for recovery of kidney function, withdrawal or suspension of the therapy, and loss of a caregiver. Disease characteristics and baseline demographics were included. Data are expressed as mean ± standard deviation for continuous variables and as frequency counts and percentages for categorical variables. Incidence rates were performed for transfer to HD and finally, logistic regression analysis between the inferential type variables to determine the risk between having a history of diabetes mellitus and the variables of death and transfer to HD were calculated using an Odds Ratio analysis with 95% confidence intervals for parameters B.

Results: A total of 2326 patients were included, 59% men; the mean age was 57 ± 16 years, 53% had a diagnosis of Diabetes Mellitus (DM) and 65% had a basic educational level. 151 patients were censored (11%). Risk events were 1096 of which death accounts for 1084 (74%) and transplantation (0.8%). At the end of the first year, the cumulative incidence risk to HD transfer was 1%, the second year 4%, the third year 6%, the fourth 11%, and the fifth 16%. Based on the regression analysis between the variables of interest and the patients with a history of DM, there is a higher risk of death (p<0.001; OR. 2.123; CI 95% 1.781-2.532), however, for transfer to HD, no statistical significance was found (p=0.39; OR 1.14; CI 95% 0.838-1.564). The most frequent reason for technique failure was psychosocial and medical conditions 44%, followed by catheter malfunction 30%, peritonitis 13% and ultrafiltration failure 13%.

Conclusions: The technique failure rate is similar to the reported in RTS Colombian PD Program, but better than the mean of Latin American countries reports. Still, Improvement needs to be done in the catheter implant technique and mortality rates.

PO0973

Nurse-Based Educational Interventions in Patients with Peritoneal Dialysis: A Systematic Review and Meta-Analysis

Tanawin Nopsopon,[1,3] Piyawat Kantagowit,[1] Chitsanucha Chumsri,[1] Krit Pongpirul.[1,2] Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]Harvard University T H Chan School of Public Health, Boston, MA.*

Background: Peritoneal dialysis (PD) is a major renal replacement therapy modality for patients with end-stage renal disease (ESRD) worldwide. As poor patient self-care could lead to serious complications, including peritonitis, exit-site infection, technique failure, and death; several nurse-based educational interventions have been introduced. However, these interventions varied and have been supported by small-scale studies so the effectiveness of nurse-based educational interventions on clinical outcomes of PD patients have been inconclusive.

Methods: We performed a systematic search using PubMed, Embase, and CENTRAL. Selection criteria included Randomized Controlled Trials (RCTs) relevant to nurse-based education interventions in ESRD patients with PD in the English language up to February 20, 2020. The meta-analyses were conducted using a random-effects model to evaluate the summary outcomes of peritonitis, PD-related infection, mortality, transfer to hemodialysis, and quality of life (QOL).

Results: Of 7,240 potential studies, 61 theme-related abstracts were selected for further full-text articles screening against eligibility criteria. Ten studies (1,404 PD patients in seven countries) were included in the systematic review. Eight studies (1,363 PD patients in five countries) were included in the meta-analysis. Sleep QOL in the intervention group was significantly higher than control (mean difference 12.76, 95% CI 5.26–20.27). There was no difference between intervention and control groups on peritonitis, PD-related infection, transfer to hemodialysis, and overall QOL.

Conclusions: Nurse-based educational interventions could help reduce some PD complications, of which only the sleep QOL showed statistically significant improvement. High-quality evidence on the nurse-based educational interventions was limited and more RCTs are needed to provide more robust outcomes.

Quality of Life (Sleep)

PO0974

Immediate Start PD: A Single-Center Experience

Harold E. Giles,[1] Thomas H. Watson,[1] Michael A. Kraus,[2] Dinesh K. Chatoth,[2] Melissa Herman.[2] *[1]Nephrology Associates, Birmingham, AL; [2]Fresenius Kidney Care, Waltham, MA.*

Background: Peritoneal Dialysis catheters are felt to require a healing time prior to initial use. Concern for increased risk of leak, has led many to use supine intermittent low volume exchanges (<1000 mL) initially for earlier start peritoneal dialysis. We undertook a study to prospectively monitor and track peritoneal dialysis complications when catheter use was early (prior to 14 days post placement) and the nephrologist chose to start with higher volume dialysate (>= 1000mL) without regard to maintaining a supine position. Higher volume dialysis with earlier initiation should allow for better PD clearances when clinically warranted and more salt and water removal compared to supine intermittent low volume exchanges.

Methods: In this single center prospective observational study, peritoneal dialysis catheters were placed laparoscopically ensuring tunneling through the abdominal rectus muscle with the deep cuff placed just within or below the rectus abdominal muscle. Purse strings sutures were only used at the surgeons' discretion. Surgeons did undergo consistent education from two experienced surgeons prior to the study. Patients were included in the study if the nephrologist felt early start dialysis was indicated. Prescriptions were at the discretion of the nephrologist.

Results: Since January 2021, 23 PD catheters have been placed using this technique with only one adverse event. 8 patients (35%) initiated PD 24 – 72 hours post placement and 15 patients (65%) started dialysis between 73 hours and 2 weeks post catheter placement. All patients first exchanges were 1000 ml, and volumes were increased rapidly at the discretion of the nephrologist as patient condition warranted. In these 23 patients, 1 patient experienced a peritoneal leak which resolved with rest. That patient was in the > 72 hour group. No other catheter complications were noted.

Conclusions: In this single center observational study, peritoneal catheters placed laparoscopically with careful abdominal rectus tunnelling allowed for larger volume dialysis exchanges without concern for supine positioning or intermittent use. One leak was noted and no other complications for an acceptable leak rate of 4% in this small study. This study demonstrates that PD can be initiated sooner post dialysis and larger volumes are well tolerated.

PO0975

Converting ESKD Patients on Peritoneal Dialysis to Hemodialysis Post Cardiac Surgery: A Necessity or Comfort

Elias Bassil,[1] Milad Matta,[1] Aimen Liaqat,[2,1] Adam Fawaz,[1] Georges Nakhoul,[2,1] Jonathan J. Taliercio,[2,1] Juan C. Calle,[2,1] Serge C. Harb,[1] Haytham Elgharably,[1] Susana Arrigain,[1] Jesse D. Schold,[1] Remy Daou,[3] Ali Mehdi.[2,1] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH; [3]Universite Saint-Joseph, Beirut, Lebanon.*

Background: End-stage kidney disease (EKSD) patients on peritoneal dialysis (PD) undergoing cardiac surgery are sometimes converted to hemodialysis (HD) post-surgery. The reasons for this conversion are not well defined in the literature. We sought to examine the reasons cited for converting PD patients to HD post operatively after undergoing major cardiac surgery.

Methods: We examined ESKD patients on PD undergoing cardiac surgery from 2009-2019 using an electronic health records (EHR)-based Cardio-Thoracic Surgery (CTS) registry at the Cleveland Clinic. We identified PD patients who were converted to HD perioperatively. We reviewed the EHR to identify the main causes for conversion.

Results: 62 ESKD patients on PD undergoing major cardiac surgery were identified. 16 patients, representing more than a quarter, were converted to HD post operatively. Out of those converted, 31.25% were converted for absolute indications (18.75% for PD catheter malfunction, 6.25% for gadolinium exposure and 6.25% for concern of pericardio-peritoneal communication). 68.75% were converted for less clear and relative indications (25% based on clinician preference, 43.75% for hemodynamic instability or requiring vasopressors). Results are displayed in (Table 1).

Conclusions: A small percentage of PD patients are converted to HD for absolute indications. Most patients are converted based on relative indications including lack of familiarity with PD and hemodynamic instability. As the number of ESKD patients on PD is expected to increase, a better understanding of the outcomes of PD patients post cardiac surgery is needed. In addition, more education is urgently needed to increase the comfort of practitioners managing PD patients in special situations that might be amenable to prescription alterations without premature transition to hemodialysis.

Reasons for PD to HD conversion post cardiac surgery

Absolute Indications (N=5)			Relative Indications (N=11)		
Reason Cited	N	Percentage	Reason Cited	N	Percentage
Catheter Malfunction	3	18.75%	Clinician Preference	4	25%
Gadolinium Exposure	1	6.25%	Hemodynamic Instability / Vasopressor requirement	7	43.75%
Pericardio-peritoneal shunt	1	6.25%			

Table 1

PO0976

Effect of Low-Dose PD in Elder Population on Protein Energy Wasting, Functionality, and Quality of Life

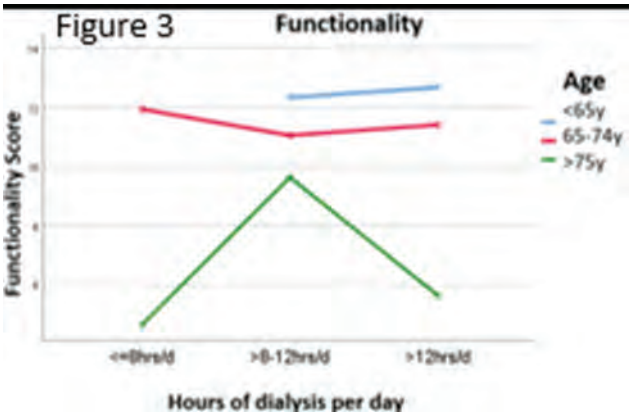
Gloria G. García Villalobos, L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Elder population currently involves 55% of those who initiate dialysis. Age, comorbidities, functional status (FS), protein energy wasting (PEW) and quality of life (QoL) need to be considered. CAPD can cause PEW, loss of functionality and QoL decline, adjusting treatment to Intermittent Ambulatory PD (IAPD) (low-dose) has the intention to decrease disadvantages while maintaining the benefits. The aim of this study was to to evaluate the effect of low-dose PD on PEW, functionality and QoL.

Methods: A retrospective cohort of patients 60 years and older was analyzed. IAPD was defined as less than 16hrs of treatment per day. Clinical, biochemical data were collected. Katz, Lawton-Brody scales and EQ-5D-5L questionnaire were applied.

Results: 91 patients were on IAPD: Prescription of hrs/day of dialysis did not correlate with residual uresis (r -0.052, p 0.612). Questionnaires: **QoL.** EQ-5D-5L found the majority of patients were in the highest/positive scores for every category assessed. In the same way, 44% of the patients had 80 points or more in their perception of QoL (figure 1), and it was found to be associated with albumin and phosphorus (r.296, p 0.015; r .312, p 0.027). **Functionality.** 67% of patients were classified as independent (figure 2) and FS was associated with albumin, uresis and VAS QoL (r 0.462, p0.000; r 0.416, p0.000; r 0.407, p0.000 respectively). A model to identify the predictors of functionality was made. It was found that female, age >75y, uresis<500ml/d, albumin <3.5g/dl and hours of dialysis predict negatively scores. The interaction between hours of dialysis and age have the biggest effect size.

Conclusions: IAPD in this elder population does not mean suboptimal dialysis: there were found favorable results in regard to biochemical parameters; FS and QoL scores maintained despite the dialysis vintage. Of notice the group of 75years and older are more likely to be affected in a negative way by prescription of dialysis.



PO0977

A Uremic Pig Model for Peritoneal Dialysis Research

Joost C. de Vries,[1] Maaike K. van Gelder,[1] Anneke S. Monninkhof,[1] Sabbir Ahmed,[2] Diënty Hazenbrink,[1] Tri Q. Nguyen,[1] Koen Vaessen,[2] Jaap A. Joles,[1] Marianne C. Verhaar,[1] Karin G. Gerritsen.[1] *[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]Utrecht University, Utrecht, Netherlands.*

Background: The renewed interest in home dialysis requires a translational uremic large animal model to evaluate innovations in peritoneal dialysis. Ideally, toxin plasma levels should be comparable to those in dialysis patients, without requiring maintenance dialysis for survival. To this end, we developed a pig model with stable moderate chronic kidney disease.

Methods: CKD was induced in five female pigs by bilateral subtotal renal artery embolization aiming for embolization of ~85-90% of total kidney tissue. Temporary aggravation of uremia was induced with gentamicin (10 mg/kg twice daily for 7 days). We hypothesized this approach would lead to stable CKD without the need for maintenance dialysis. Peritoneal transport was assessed with a standard peritoneal permeability assessment.

Results: After embolization, urea and creatinine levels increased from 1.6±0.2 to 7.5±1.0 mM and 103±12 to 338±60 μM, respectively, followed by stabilization within 2 weeks to 2.5±1.0 mM and 174±25 μM, respectively. GFR (iohexol clearance) decreased from 49 mL/min to 28 mL/min. Gentamicin induced temporary acute-on-chronic kidney injury with peak urea and creatinine concentrations of 17.0±6.1 mM and 932±504 μM, respectively (Figure 1), while potassium (range 4.1-4.7 mM) and phosphate (range 2.33-2.67 mM) remained stable. Peak indoxyl sulfate and hippuric acid levels were 10.5 ± 0.85 mg/L and 75.3 ± 81.5 mg/L respectively. Peritoneal dialysis, although complicated by peritonitis, could be successfully applied. Peritoneal transport assessment showed a low transport status (D/P creatinine (4h): 0.45±0.12) with an MTAC of 9.6±3.0, 4.6±2.5, 3.4±2.2 mL/min for urea, creatinine, and phosphate respectively.

Conclusions: We have established a pig model with stable moderate CKD without the need for maintenance dialysis. Temporary on-demand acute-on-chronic kidney injury, resulting in uremic solute levels representative for ESKD, allows evaluation of novel dialysis methods.

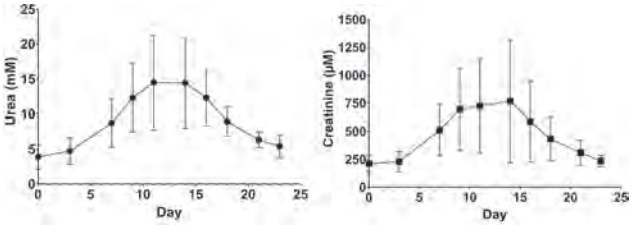


Figure 1. Urea (left) and creatinine (right) plasma levels after administration of gentamicin (day 0). Mean ± SD, n=10 administrations in n=5 pigs.

PO0978

Recurrent Abdominal Pain in a Patient on Peritoneal Dialysis

Sandipan Shringi, Sri Vibhavari Guntupalli, Kristin M. Corapi. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Abdominal pain can have many differentials in patients on peritoneal dialysis (PD). Some of them, including fungal peritonitis, requires PD catheter removal and a change in dialysis modalities. Here we present a case of recurrent abdominal pain in a patient on peritoneal dialysis which highlights the importance of prompt diagnosis.

Case Description: 40-year-old female with end stage renal disease secondary to systemic lupus erythematosus on PD for 3 years presented for urgent clinic appointment after her system was disconnected with leakage of PD fluid. PD effluent revealed white count of 300 with 2% neutrophils. She was treated empirically for peritonitis. 11 days later her fungal culture grew Candida famata and she was admitted with intermittent abdominal pain associated with vomiting and weakness. She was hemodynamically stable, and her exam was significant for epigastric tenderness with normal looking PD catheter site. Her white count was elevated to 13,000 with unremarkable metabolic panel. CT abdomen was unremarkable. A repeat PD effluent had white count of 40. Her PD catheter was removed the next day and she was switched to hemodialysis. She was treated with 10 days of oral fluconazole. On review, she had been having intermittent abdominal pain with PD effluent sometimes showing high white count for which she got multiple antibiotic courses for either presumed or culture positive bacterial peritonitis. She had also grown positive fungal culture about 18 months ago with Candida albicans and Stereum complicatum which went unnoticed.

Discussion: Fungal peritonitis can be catastrophic for patients on PD. Treatment involves prompt catheter removal and systemic antifungal treatment. Given its dire consequences, prevention is paramount. The ISPD recommends using anti-fungal prophylaxis when PD patients receive antibiotic courses. Risk factors include previous bacterial peritonitis and antibiotic use. This case demonstrates the need to follow cultures as fungal growth is slow and can take weeks. It is important to have a high index of suspicion for a fungal organism when cultures are negative. This patient received antibiotics on several occasions but only developed fungal peritonitis on 2 occasions which raises concern on antifungal prophylaxis. Further studies are indicated to determine number needed to treat to decide on need for antifungal prophylaxis.

PO0979

Micrococcus Peritonitis Complicating Peritoneal Dialysis

Martin L. Li,[1] Ankur Shah.[2,1] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Introduction: Peritonitis is one of the most common and consequential complications of peritoneal dialysis. *Micrococcus sp* are catalase-positive, coagulase-negative, gram-positive cocci that are increasingly recognized as opportunistic pathogens in patients with immunocompromise or indwelling catheters. These bacteria have been rarely implicated as causative in peritonitis. We present a case of peritonitis due to *Micrococcus sp* and review the pertinent literature.

Case Description: A 55-year-old female with history of ESKD due to diabetic kidney disease, CAD s/p CABG, and hypertension presented with a 1 day history of cloudy effluent. She had no prior peritonitis episodes. Vital signs were stable and exam was notable for a soft non-tender abdomen and clean and dry exit site without discharge or granulation tissue. Effluent was hazy in appearance. Administration of empiric vancomycin and gentamicin was initiated, resulting in clearing of effluent within 48 hours. Effluent leukocyte count was 204 cells/uL with 58% neutrophils. Intraperitoneal vancomycin was continued for 3 weeks due to intermittent low troughs. Further history revealed intermittent mask use while performing exchanges. After completion of treatment, there was a complete resolution of symptoms and peritoneal cell count. Cell count and culture were repeated 1 month later during evaluation of abdominal pain eventually found to be due to constipation. Leukocyte count was 6 cells/uL but culture again grew *Micrococcus sp*. After culture was repeated once more and remained persistently positive, repeat treatment to eradicate was attempted with 2 more weeks IP vancomycin but culture remained positive. Eventually the catheter was removed due to a change in living situation. After 5 months of hemodialysis, peritoneal catheter was replaced and the patient was restarted on peritoneal dialysis, after which time she has not had any peritonitis episodes.

Discussion: We present the 10th case of *Micrococcus sp.* Peritonitis in a peritoneal dialysis patient. Prior cases have been associated with breaks in technique and have shown a pattern of recurrence with resultant technique failure being very common. Attempted treatments have included vancomycin, cefazolin, ceftazidime, and teicoplanin. In the prior 9 published cases, 4 resulted in technique failure. This case and review of the literature can serve to inform future occurrences.

PO0980

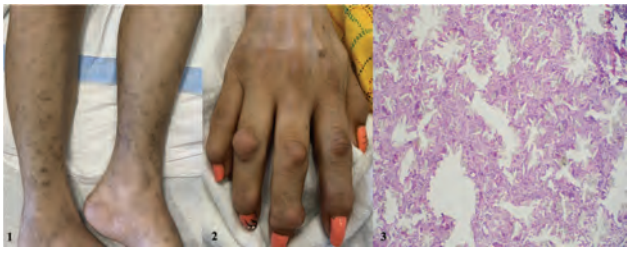
Cutaneous Oxalosis in a Patient on Peritoneal Dialysis

Stephanie Torres Rodriguez, Hunter Pyle, Audrey Rutherford, Arturo R. Dominguez, Shani Shastri. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Introduction: Oxalosis is the systemic deposition of calcium oxalate in multiple tissues and can be of primary or secondary etiology. Skin manifestations due to secondary hyperoxaluria (SH) attributable to renal insufficiency are rare. We present a case of cutaneous oxalosis in a patient with end stage renal disease (ESRD) receiving peritoneal dialysis (PD).

Case Description: A 45-year-old female with ESRD due to lupus nephritis (LN) on PD for 11 years presented with hypertensive encephalopathy. Dermatological evaluation revealed pseudoreticular hyperpigmented patches overlying firm, non-tender, subcutaneous nodules and plaques on bilateral lower extremities (Figure 1) and upper arms and firm nodules overlying the joints of her hands (Figure 2). With history of lupus, cutaneous findings were concerning for dystrophic calcinosis cutis. Skin biopsy showed radially arranged yellow-brown rhomboid crystals in the subcutis and deep dermis surrounded by histiocytes consistent with cutaneous oxalosis (Figure 3). Additional history revealed daily intake of Vitamin C 1g for past year and no prior gastrointestinal surgeries or chronic diarrhea. Non-obstructive bilateral nephrolithiasis were seen on imaging in 2020 but absent previously.

Discussion: Absence of early-age nephrolithiasis, negative family history & renal biopsy findings are inconsistent with primary hyperoxaluria (PH). SH is a result of excessive oxalate accumulation from increased intake, increased reabsorption due to small bowel disease, or decreased excretion in renal failure (retention oxalosis). Although dialysis patients may have high serum oxalate, clinical calcifications are rare. We speculate vitamin C supplementation and ESRD status contributed to the production of these deposits in our patient. Ascorbic acid is metabolized to oxalate; in long term dialysis patients doses of 500 mg daily may raise plasma oxalate by 50% to 100%. Management includes lowering serum calcium and oxalate levels by eliminating Vitamin C supplements or reducing dose < 100 mg daily, limiting dietary oxalate, increasing dialysis clearance and lowering dialysate calcium concentration if needed.



PO0981

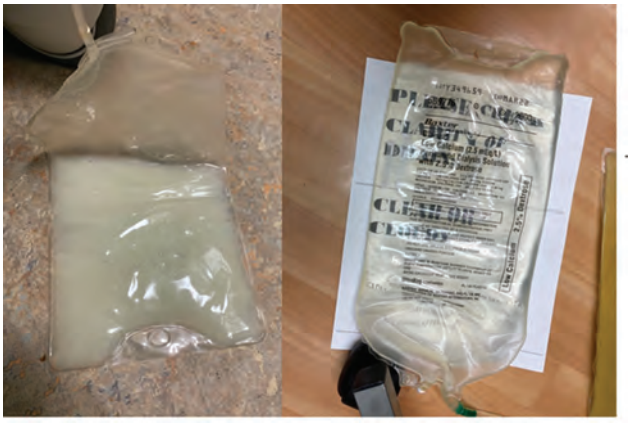
Chylous Peritoneal Fluid in a Patient on Peritoneal Dialysis Taking Nifedipine

Lauren E. Macaraeg, Dena E. Rifkin, Tyler Woodell, O. Alison Potok. *University of California San Diego, La Jolla, CA.*

Introduction: Chylous fluid in peritoneal dialysis (PD) patients may appear with lymphatic system disruption. This can be due to lymphatic obstruction, exudation through vessels, or via a lymphoperitoneal fistula.

Case Description: A 78 year-old man with ESKD due to diabetic nephropathy, transitioned five weeks prior from HD to PD, presented with newly cloudy PD fluid. His past medical history included hypertension, coronary artery disease, and monoclonal gammopathy of undetermined significance. He reported a newly cloudy white initial drain with lower abdominal pain, but denied fever, vomiting or diarrhea. He denied a breach in sterile technique. Medications included hydralazine, cinacalcet, furosemide, nifedipine, omeprazole, calcium acetate and darbepoietin. He was hemodynamically stable and had no abdominal tenderness. Laboratory results revealed a leukocytosis of 11.7 /cm3. Peritoneal fluid was milky (figure 1a) with 101 white blood cells (4% neutrophils); gram stain and culture were negative. Triglycerides were 96 and 62 mg/dL in the PD fluid and serum, respectively. Etiologic work-up was negative for malignancy, pancreatitis, cirrhosis, trauma and tuberculosis. Chylous nature of the PD fluid resolved within a day of nifedipine discontinuation (figure 1b). The patient self-resumed nifedipine weeks later and the milky fluid recurred the following day before again subsiding after its repeat cessation.

Discussion: This patient had the onset of chylous PD fluid 5 weeks after initiating PD, which resolved with cessation and recurred with reinitation of his long-term nifedipine. The mechanism of calcium channel blockers (CCB) – related chylous ascites is not well established. Some have suggested it may be related to the lipophilic nature of CCB. Patients on PD with higher peritoneal membrane transport may be at higher risk. Genetic factors may predispose to this phenomenon. Nephrologists should be aware of this rare complication of CCB use in PD patients. More research is needed to better understand the underlying pathophysiology of this rare condition.



PO0982

Severe Bleeding and Deep Inferior Epigastric Pseudoaneurysm After PD Catheter Removal

Nicola Matthews,[1] Tamara Glavinovic,[2] Bourne L. Auguste.[2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Introduction: In this case, the removal of a PD catheter with deep cuff calcification results in pseudoaneurysm formation with hemorrhage and hospitalization.

Case Description: A 24-year-old woman with end-stage kidney disease was switched from PD to HD due to worsening uremia and PD catheter removal was organized. At the time of catheter removal heavy calcification around the deep Dacron cuff embedded into the rectus muscle was seen. Upon catheter removal, the deep inferior epigastric perforating (DIEP) vessel was sheared, creating a pseudoaneurysm where urgent angiographic embolization to stop the bleeding was needed (Fig. 1). Intimate relationship between DIEP vessel and Dacron cuff was felt to be secondary to heavy calcification of these structures that developed during her time on PD (Table 1). The patient required an urgent transfusion and was admitted to hospital for monitoring. She was discharged the following day in stable condition.

Discussion: This is an important learning case in PD catheter removal and highiglights the following: -Poorly controlled bone mineral disease may lead to excessive calcification of the deep Dacron cuff and DIEP vessels. -When heavy calcification of the PD cuff is seen, catheter removal should be done in settings equipped with interventional radiology support in the event of complication.

Calcium-phosphate balance while on PD

	Month 1	Month 2	Month 3	Month 5	Month 7
Creatinine (mg/dL)	17.2	13.8	11.3	12.0	14.5
Urea (mg/dL)	75.1	78.1	67.2	66.7	85.7
Phosphate (mmol/L)	3.28	2.18	1.92	1.95	2.43
Calcium (mmol/L)	2.55	2.55	2.59	2.51	2.45
Albumin (g/L)	35	37	38	38	35

PO0983

A Case of Abdominal Wall Abscess Caused by Aeromonas hydrophila in Prior Peritoneal Catheter Site in an Immunocompromised Patient Post Kidney Transplant

Angelica P. Trilleras Gomez,[1] Maya Antony,[2,1] Ahmed A. Waheed.[3,2] *[1]Holy Cross Hospital, Ft Lauderdale, FL; [2]University of Miami School of Medicine, Miami, FL; [3]Holy Cross Hospital Department of Nephrology, Ft Lauderdale, FL.*

Introduction: *Aeromonas hydrophila* is a gram-negative rod-shaped bacterium found in aquatic ecosystems; it has been identified as the causative organism of different opportunistic infections in the immunocompromised and there is growing evidence of infection in the immunocompetent. This pathogen has been implicated in acute gastroenteritis, soft tissue infections, meningitis, peritonitis and sepsis among others.

Case Description: We report a case of a 56 year old woman with end stage kidney disease previously on peritoneal dialysis (PD) with subsequent live donor kidney transplant on immunosuppression, who presented with right lower quadrant abdominal cellulitis and deep abscess around the catheter site. Post transplant, her PD catheter was removed, however, the catheter site never healed completely. Although she did have multiple superficial skin infections in the past, those resolved with antibiotics. But this specific cellulitis, did not improve despite multiple antibiotic regimens, and further imaging studies revealed she had developed an abscess. The abscess was managed by surgical incision and drainage with debridement of the skin, subcutaneous tissue, fascia, and muscles around the whole catheter tract. *Aeromonas hydrophila* was found as the causative organism.

Discussion: To our knowledge, this is the first case of an *A. hydrophila* abscess associated with a peritoneal dialysis catheter. Firm association between aeromonads and the use of intravenous indwelling devices has already been demonstrated. We hypothesize that her deep seeded infection could be associated with the intrinsic ability of *A. hydrophila* to form biofilms upon detecting a suitable surface, making them more virulent. The formation of biofilm has been associated with exponential growth as the source of pathogenicity of this bacteria in pisciculture studies. This characteristic could be one of the factors contributing to reported cases of peritonitis and intravenous hemodialysis catheters by *A. hydrophila*. Further elucidation of *A. hydrophila* virulence factors in humans can provide insight on prevention of PD catheter associated infections by *A. hydrophila*.

PO0984

Mesenchymal Stem Cell Exosomes Protect Mouse Peritoneal Injury Induced by Human Peritonitis Dialysis Effluent

Fang Yu, Kehong Chen, Jia Chen, Yani He. *Army Military Medical University, Daping Hospital, Department of Nephrology, Chongqing, China.*

Background: Peritoneal fibrosis is a severe complication of peritoneal dialysis, but there are few effective therapies for it. The purpose of this study was to investigate the protective effect of exosomes secreted by mouse bone marrow mesenchymal stem cells(MSC) on peritoneal injury and to reveal the mechanism.

Methods: Forty-two male C57BL/6 mice were randomly divided into a normal group, a control group (2.5% glucose dialysate), a peritonitis-effluent group (The overnight 2.5% glucose dialysate of patients with peritonitis), a high glucose (4.25%) dialysate group, a peritonitis-dialysate+exosome group, and a high glucose dialysate+exosome group. The mouse model of peritoneal injury was constructed by intraperitoneal injection of human peritonitis dialysis effluent continuously for 42 days. The mice in the exosome treatment group received intraperitoneal injection of MSC-exosomes twice. The level of peritoneal structural and functional damage was detected. The effect of MSC-exosomes was validated in vitro.

Results: Peritoneal transport and structure was significantly impaired in the peritonitis-effluent group and the high glucose dialysate group after 42 days, and was significantly higher than control group. The results suggested that human peritonitis dialysis effluent could be used to construct a mouse model of peritoneal injury. Masson staining showed that fibrosis degree of exosome treatment group was significantly less than peritonitis-effluent group. Immunohistochemical analysis showed that expressions of mesothelial markers E-cadherin and ZO-1, neutrophil granulocytes (MPO) and macrophages (F4/80), and fibrosis markers (collagen I,a-SMA) in exosome treatment group were significantly lower than peritonitis-effluent group. Peritoneal ultrafiltration function of exosome treatment group was significantly improved than peritonitis-effluent group. In vitro experiments showed that exosomes could down-regulate the secretion of IL-1β, IL-6 and TGF-β1 by peritoneal mesothelial cells stimulated by high glucose dialysate, maintain expression of mesothelial cell marker (E-cadherin), and inhibit mesenchymal marker (a-SMA), suggesting that exosomes could inhibit the transdifferentiation of peritoneal mesenchymal cell-mesenchymal cells (MMT).

Conclusions: MSC-exosomes can alleviate peritoneal fibrosis by inhibiting peritoneal mesothelial cell-mesenchymal cell transdifferentiation.

PO0985

Dual Therapy with JAK1/2 Inhibitor and Losartan Attenuates Dialysate-Induced Angiogenesis in Polycystic Rats

Pei Zhang,[1,2] Kana N. Miyata,[2] Madisyn Mahoney,[2] Janine A. La page,[2] Cynthia C. Nast,[3] Sharon G. Adler,[2] Tiane Dai.[2] *[1]Department of Nephrology, the First Affiliated Hospital of Anhui Medical University, Hefei, China; [2]The Lundquist Institute at Harbor-UCLA Medical Center, Torrance, CA; [3]Cedars Sinai Medical Center, Los Angeles, CA.*

Background: Long term peritoneal dialysis (PD) is limited by reduced efficacy over time. Early peritoneal membrane (PM) injury is characterized by inflammation which progresses to hypervascularity and fibrosis. JAK/STAT signaling mediates inflammatory pathways, including angiotensin signaling. Our previous study showed dual therapy with JAK1/2 inhibitor (JAK1/2i) and an ARB maintains PM structure and function in rats with polycystic kidneys (PCK) chronically infused with 4.25% Dianeal x 16 wks. By using VEGFR2 as an endothelial marker, we further investigated if this dual therapy can attenuate chronic dialysate infusion induced hypervascularity in this rat model.

Methods: PCK rats were used. Dialysate infusions were performed BID via an implanted subcutaneous port in the neck tunneled to the intraperitoneal cavity. The following treatments were administered: **(1)** No surgery/infusions; **(2)** 4.25% Dianeal; **(3)** 4.25% Dianeal + JAK1/2i (5mg/kg BID); **(4)** 4.25% Dianeal + Losartan (5mg/kg BID); and **(5)** 4.25% Dianeal + Losartan +JAK1/2i (5mg/kg BID each). Parietal peritoneum was used for immunohistochemical staining of VGEFR2, which was digitally quantified by using Qu Path program. Data were analyzed by one-way-ANOVA followed by Tukey test. Results are mean ± SEM.

Results: VEGFR2 staining was significantly elevated after 16 weeks IP infusion of 4.25% Dianeal alone. JAK1/2i significantly reduced VEGFR2 expression; losartan tended to reduce VEGFR2, but this did not reach significance. Dual therapy with JAK1/2i and losartan resulted in the greatest reduction of VEGFR2

Conclusions: Long-term JAK1/2i, or JAK1/2i plus losartan intraperitoneal treatment reduces angiogenesis. Angiotensin inhibition is advocated to maintain residual renal function, by adding JAK1/2i, the combination also protects peritoneal structure/function by reducing angiogenesis.

PO0986

The Effect of Far-Infrared Therapy on the Peritoneal Expression of Glucose Degradation Products in Diabetic Patients on Peritoneal Dialysis

Chih-Ching Lin, Chih-Yuan Niu. *Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Peritoneal dialysis (PD) is a treatment modality for end-stage renal disease (ESRD) patients. Dextrose is a common osmotic agent used in PD solutions and its absorption may exacerbate diabetes mellitus. PD solutions also contain glucose degradation products (GDPs) that may lead to encapsulating peritoneal sclerosis (EPS). A previous study showed that far-infrared (FIR) therapy improved a patient's gastrointestinal symptoms due to EPS. Due to limited literature, this study aims to investigate dialysate GDPs and peritoneal function in diabetic patients on PD.

Methods: A prospective analysis conducted in a single center. The participants were recruited from the peritoneal dialysis outpatient department from November 25, 2016 to September 5, 2018. We included the patients who met the following criteria: (1) ESRD patients aged 20–90 years without receiving FIR therapy within 12 months; (2) receiving continuous ambulatory peritoneal dialysis or automated peritoneal dialysis; (3) no history of peritonitis, cerebrovascular accident, myocardial infarction, or receiving any cardiovascular intervention in the past 3 months. Patients were allocated to two groups based on their underlying DM history. Both groups of PD patients received FIR therapy for 6 months. We collected the last daily bag of peritoneal dialysate and compared the dialysate concentration of GDPs and clinical data in PD patients pre- and post-FIR therapy.

Results: Thirty-one PD patients were enrolled and underwent 40 min of FIR therapy twice daily for six months. We demonstrated the effect of FIR therapy on the following: (1) decrease of methylglyoxal ($p = 0.02$), furfural ($p = 0.005$), and 5-hydroxymethylfurfural ($p = 0.03$), (2) increase of D/D0 glucose ratio ($p = 0.03$), and (3) decrease of potassium levels ($p = 0.008$) in both DM and non-DM patients, as well as (4) maintenance and increase of peritoneal Kt/V in DM and non-DM patients, respectively ($p = 0.03$). FIR therapy is a non-invasive intervention that can decrease dialysate GDPs in PD patients by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

Conclusions: In conclusion, our study demonstrated that FIR therapy can decrease PD patients'dialysate GDPs by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

PO0987

Cumulative Dialysate Glucose Exposure Is a Risk Factor for Peritoneal Sclerosis in Pediatric Peritoneal Dialysis Patients Using Neutral-pH Fluids

Yoko Shirai,[1] Kenichiro Miura,[1] Taro Ando,[1] Atsutoshi Shiratori,[1] Naoto Kaneko,[1] Kiyonobu Ishizuka,[1] Sekiko Taneda,[2] Daishi Hirano,[3] Yutaka Yamaguchi,[4] Kazuho Honda,[5] Motoshi Hattori.[1] *[1]Department of Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Pathology, Tokyo Women's Medical University, Tokyo, Japan; [3]Department of Pediatrics, The Jikei University School of Medicine, Tokyo, Japan; [4]Yamaguchi Pathology Laboratory, Chiba, Japan; [5]Department of Anatomy, Showa University School of Medicine, Tokyo, Japan.*

Background: The benefits of neutral-pH fluids for preventing peritoneal dialysis (PD)-related peritoneal sclerosis have been established, however, advanced peritoneal sclerosis still has been described in pediatric PD patients using neutral-pH fluids (Kidney Int 2018). The factors associated with peritoneal pathological changes after long-term use of neutral-pH fluids have not been elucidated.

Methods: Pediatric PD patients using only conventional acidic fluids (conventional group, n=31) and those using only neutral-pH fluids (neutral-pH group, n=33) for more than one year were analyzed. Propensity score matching was performed to compare the peritoneal pathological changes between groups. Clinical risk factors including PD duration and cumulative dialysate glucose exposure for peritoneal pathological changes in the neutral-pH group were analyzed using generalized linear model. Furthermore, immunofluorescence studies were performed on vascular endothelial growth factor-α (VEGF-α), cytokeratin; an epithelial marker, and α-smooth muscle actin (α-SMA); a myofibroblastic marker of epithelial-mesenchymal transition (EMT).

Results: Age at biopsy was 11.5 [8-17] years (median [IQR]) and duration of dialysis was 3.2 [1.7-5.3] years. The neutral-pH group showed less peritoneal deterioration except for higher submesothelial microvessel density (P <0.01) than conventional group. In the neutral-pH group, the cumulative dialysate glucose exposure was an independent risk factor for increased thickness of the submesothelial compact zone [OR, 1.004; 95%CI, 1.001, 1.007] and submesothelial microvessel density [OR, 1.003; 95%CI, 1.000-1.005]. Cumulative dialysate glucose exposure correlated with the proportion of VEGF-α positive areas (P<0.01, r=0.55). In immunofluorescence study, VEGF-α (+) cells comprised cytokeratin (+) cells and α-SMA (+) cells.

Conclusions: The neutral-pH fluids showed less deteriorations of the peritoneal membrane than acidic fluids except for increased angiogenesis. Cumulative dialysate glucose exposure was an independent risk factor for peritoneal fibrosis and angiogenesis in pediatric patients using neutral-pH fluids, which might be associated with increased VEGF-α production by mesothelial cells presenting EMT.

PO0988

Predicting Patient and Technique Survival in a Cohort of Incident Peritoneal Dialysis (PD) Patients According to Peritoneal Small Solutes Transport Rate (PSTR)

Rafael A. Gomez,[1] Abdul Rashid T. Qureshi,[2] Joanna Stachowska-Pietka,[3] Malgorzata Debowska,[3] Jacek Waniewski,[3] Bengt Lindholm.[2] *[1]Baxter Renal Care Services, Cali, Colombia; [2]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [3]Nalecz Institute of Biocybernetics and Biomedical Engineering Polish Academy of Sciences, Warsaw, Poland.*

Background: The association between PSTR and clinical outcomes in patients undergoing chronic peritoneal dialysis (PD) is uncertain. We explored the association of PSTR with mortality and technique survival in a large cohort of incident patients undergoing PD in Colombia.

Methods: In a cross-sectional study, 8170 PD patients, treated with APD (2705, 33.1%) and with CAPD (5465, 66.9%), who underwent peritoneal equilibration test to determine dialysate/plasma creatinine ratio at 4 hours were classified into slow (16.0%), slow average (35.4%), fast average (32.9%) and fast (15.7%) PSTR categories. Demographic, clinical and laboratory variables were evaluated. During median follow-up of two years, 2633 (32.2%) patients died, 1079 (13.2%) patients transferred to hemodialysis, and 661 (8.1%) patients underwent renal transplantation. All-cause and cardiovascular disease (CVD) mortality risk and technique survival were analyzed with competing-risk regression with transplantation as competing risk.

Results: Patients with fast as compared to slow PSTR were older, more often male or diabetic (DM), and had lower Hb and serum albumin levels. In competing risk analysis, after adjusting for age, sex, body mass index, residual kidney function, presence of diabetes and hypertension and circulating albumin, Hb, and phosphate levels, higher PSTR associated with greater risk (subdistribution hazard ratio, sHR) for *all-cause mortality* (fast average: sHR 1.13, 95%CI 1.00-1.26; p=0.04) and fast: sHR 1.19, 95% CI 1.04-1.36; p=0.01), and *CVD-related mortality* (fast average: sHR 1.18, 95%CI 0.99-1.41; p=0.05) and fast: sHR 1.19, 95%CI 0.97-1.46; p=0.08), and reduced *technique survival* (fast average: sHR 1.15, 95%CI 0.95-1.38; p=0.13) and fast: sHR 1.24, 95% CI 0.99-1.54; p=0.05).

Conclusions: These results suggest that fast and fast average PSTR associates with increased mortality risk and tendency towards reduced technique survival when analyzed using adjusted competing-risk regression models.

PO0989

Multifrequency Bioimpedance Is a Useful Adjunct to Control Fluid Overload in PD Patients

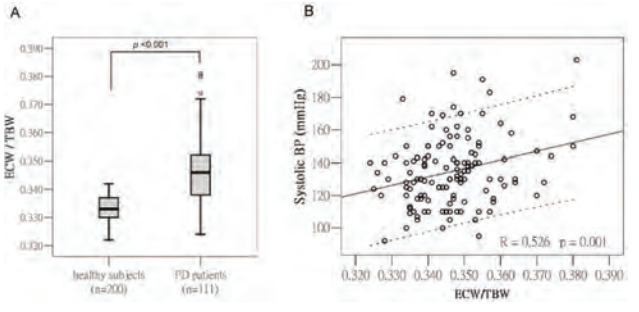
Szu-Yuan Li, Chiao-Lin Chuang, Jinn-Yang Chen. Taipei Veterans General Hospital PD team *Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Fluid overload is a well recognized phenomenon in many peritoneal dialysis (PD) patients, but a balance between reduction of dry weight and preservation of residual renal function (RRF) is mandatory. We hypothesize that, to achieve an ideal dry weight, adjustment by multi-frequency bioimpedance (MF-BIA) guide offers less adverse effect on residual renal function than that by clinical judgment alone.

Methods: The hydration status of various body compartments were measured using a MF-BIA device (Inbody 720, Biospace). The normalized hydration score was defined as extracellular water (ECW)/total body water (TBW). All patients were evaluated monthly for 6 months. The dry weight of study group was adjusted according to MF-BIA to avoid dehydration, and the dry weight of control group was determined clinically. Ambulatory blood pressure, anti-hypertension medication dosage, serum biochemical parameters, and RRF were recorded monthly. IL-6 and hs-CRP will be checked before and after the study.

Results: 93 stable PD patients (48 in study and 45 in control group) completed the study. ECW/TBW ratio was higher in PD patients than sex- and age- matched healthy subjects. (Figure 1). In PD patient, the ratio of ECW/TBW was positive correlated to age ($r = 0.534$), peritoneal D/P ratio ($r = 0.518$), systolic BP ($r = 0.526$) and negative correlated to urine volume ($r = -0.526$), serum albumin ($r = -0.658$). After 6 months intervention, study group decreased 1.2 kg and control group gained 0.2 kg. The study group had a better systolic and diastolic BP control and a higher serum albumin (3.75 ± 0.61 vs 3.48 ± 0.68 g/dl, $p = 0.047$). The RRF has no difference between two groups.

Conclusions: Our results showed that correction of fluid overload would improve blood pressure control. Being an objective tool to assess hydration status of various body compartments, MF-BIA is a useful adjunct to correct fluid overload without the loss of RRF in our short-term study.



PO0990

Associations Between Loop Diuretic Use and Outcomes Among Patients Treated with Peritoneal Dialysis

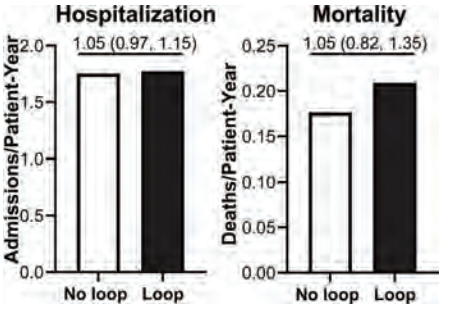
Jiacong Luo,[1] Dena E. Cohen,[1] Carey Colson,[1] Steven M. Brunelli,[1] Francesca Tentori,[1] Martin J. Schreiber.[2] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Among hemodialysis patients, an active loop diuretic prescription at the time of dialysis initiation is associated with a lower hospitalization rate and other favorable outcomes, compared to no prescription. Whether this finding extends to patients initiating peritoneal dialysis (PD) is not known.

Methods: Data used for this retrospective study comprised electronic health records and US Renal Data System claims data merged through direct linkage. Included patients initiated PD at a large dialysis organization between 01 Jan 2006 and 30 June 2014, were nonoliguric at dialysis start (24-hour urine collection >200 cc), and had Medicare insurance. Exposure was determined on the basis of an active, filled supply for a loop diuretic spanning day 90 of PD. Outcomes were considered from day 91 of PD through the first of death, loss to follow-up, or study end (31 Dec 2014) and were compared across exposure groups using appropriate statistical models adjusted for imbalanced patient characteristics.

Results: Among patients initiating PD with a loop diuretic prescription (N=792), the hospitalization rate during follow-up was 1.77 admissions/patient-year (pt-yr), compared to 1.75/pt-year for those without (N=1363), corresponding to an adjusted incidence rate ratio (aIRR) of 1.05 (95% confidence interval [CI] 0.97-1.15). Mortality was likewise comparable between groups, with crude rates of 0.21 and 0.18 deaths/pt-yr, respectively (aIRR 1.05, 95% CI 0.82-1.35). No substantial differences were observed between exposure groups with respect to serum potassium, renal Kt/V, or time to transition to hemodialysis.

Conclusions: Among patients initiating PD, no beneficial associations were observed between loop diuretic use and any of the outcomes examined.



PO0991

Nationwide Standardized Peritonitis Reporting: Preliminary Results from the Optimizing the Prevention of Peritoneal Dialysis-Associated Peritonitis in the United States (OPPUS) Study

Jeffrey Perl,[1] Geoffrey A. Block,[4] Martin J. Schreiber,[8] Beth M. Piraino,[9] Suzanne Watnick,[3] Shweta Bansal,[7] Vesh Srivatana,[5] Tahsin Masud,[6] Leslie Garcia,[2] Lauren Kane,[2] Keith McCullough,[2] Isaac Teitelbaum,[10] Ronald L. Pisoni.[2] OPPUS Peritonitis Tracker Study consortium *[1]St. Michaels, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Northwest Kidney Centers, Seattle, WA; [4]US renal care, Plano, TX; [5]Rogosin Institute, New York, NY; [6]Emory University, Atlanta, GA; [7]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [8]DaVita Inc, Denver, CO; [9]University of Pittsburgh Medical Center, Pittsburgh, PA; [10]University of Colorado School of Medicine, Aurora, CO.*

Background: Peritoneal Dialysis (PD) associated peritonitis is the leading cause of transfer to hemodialysis (HD) in the US. No formal mechanism or surveillance system exists for nationwide peritonitis reporting. Our primary aim was to develop a uniform widescale peritonitis reporting mechanism and evaluate its implementation via a one-year pilot study.

Methods: Following literature review, stakeholder consultation, and ISPD guidelines review, a web-based peritonitis tracker tool (OPPUS-Link) was developed. Pilot sites for one-year data collection were selected based on geography and reported peritonitis rates, including 3 medium-large dialysis organizations. We provided formal training, central data review, and adjudication of all peritonitis episodes and outcomes.

Results: Initial data for 31/64 participating facilities includes 86 peritonitis episodes (rate of 0.26 episodes/year [326 patient years of follow-up]). PD catheter removal and hospitalization occurred in 14% and 41% of episodes respectively (see table). Ongoing challenges include high rates of culture-negative peritonitis (24% overall) and data retrieval for peritonitis episodes occurring during hospitalization.

Conclusions: Standardized, uniform peritonitis reporting is feasible, a first step in national PD-peritonitis surveillance, allowing for benchmarking, outbreak identification, and quality improvement initiative implementation. Further data validation is necessary and integrating routine peritonitis reporting in electronic health records with an overall goal of peritonitis reduction and improved outcomes for PD patients.

Preliminary results for 31/64 clinics

Measure/variable	Total
Total patient follow-up (patient-years)	325.8
Total peritonitis episodes reported*, no.	86
Peritonitis episode count (rate/patient-year) by organism type:	
Gram-positive	46 (0.14)
Gram-negative	9 (0.03)
Culture-negative	21 (0.06)
Polymicrobial	6 (0.02)
Yeast	3 (0.01)
Unknown to clinic	1 (0.00)
Peritonitis episodes after catheter insertion, but prior to or during PD training, no.	0
Patients with 1 peritonitis episode, no.	72
Patients with 2 peritonitis episodes, no.	7
Peritonitis rate, overall, event per patient-year	0.26
Peritonitis episodes associated with a hospitalization, no. (%)	35 (40.7%)
Hospitalizations with pre-existing peritonitis, (%)	85.1%
Peritonitis acquired in hospital [>24 hrs post-admission], (%)	14.9%
Peritonitis episodes associated with death (within 60 days), no. (%)	2 (2.3%)
Peritonitis episodes in which PD catheter was removed, no. (%)	12 (14.0%)
Peritonitis episodes associated with HD transfers, no. (%)	10 (11.6%)
Permanent HD transfer (%)	9.3%
Temporary HD transfer (%)	2.3%

*Total peritonitis episodes reported, excluding relapse episodes.

PO0992

Identifying Peritoneal Dialysis (PD)-Associated Peritonitis Using Medicare Claims

Eric W. Young,[1,8] Junhui Zhao,[1] Ronald L. Pisoni,[1] Keith McCullough,[1] Beth M. Piraino,[3] Jenny I. Shen,[7] Neil Boudville,[4] Douglas E. Schaubel,[2] Isaac Teitelbaum,[5] Jeffrey Perl.[6] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]University of Western Australia, Perth, WA, Australia; [5]University of Colorado School of Medicine, Aurora, CO; [6]St. Michaels, Toronto, ON, Canada; [7]The Lundquist Institute, Torrance, CA; [8]University of Michigan Health System, Ann Arbor, MI.*

Background: Medicare fee-for-service (FFS) claims offer a population-based approach to PD-associated peritonitis that may offer valuable insights into predictors, trends and preferred practices.

Methods: We used United States Renal Data System (USRDS) standard analysis files for claims (inpatient, outpatient and physician-supplier), eligibility, modality and demographic information. The sample consisted of PD patient-months from 2013 through 2017 characterized by Medicare FFS coverage and paid claims for dialysis or hospital services. We identified ICD-9 and ICD-10 diagnosis codes for peritonitis, including those that do not clearly distinguish peritonitis from catheter infections/inflammation ("catheter codes"). A new peritonitis episode was defined as a peritonitis claim 30+ days from any prior peritonitis claim or 50+ days from the initial peritonitis claim for a prior episode.

Results: The sample included 88,396 adult patients (128,000 observed patient-years), yielding 510,000 peritonitis claims and 75,000 peritonitis episodes. Coding was heterogeneous with no single diagnosis code present on the majority of claims. Peritonitis episodes were inferred from aggregated claims (mean 6.3, median 2). Half of episodes were exclusively outpatient, 7% exclusively inpatient, and 16% exclusively comprised of catheter code claims. The overall peritonitis rate was 0.59 and 0.49 episodes per patient-year with and without inclusion of catheter codes respectively. Peritonitis rates declined by 4%/year from 2013-2017, and varied by age, race (Black > White >Asian), and ESKD vintage.

Conclusions: Coding heterogeneity indicates a lack of standardization and need for clearer coding guidance. We found differences between races, ages, and patient vintages, and declining rates from 2013-2017. These rates are 2-fold higher than reported in US-PDOPPS by Perl et al (AJKD 2020) which is not restricted to Medicare. Claims are an important data source for peritonitis, but more work is needed to validate these rates.

PO0993

Improving Peritoneal Dialysis Effluent Sample Collecting Techniques to Lower Culture-Negative Peritonitis Rate: A Single-Center Experience

Jie Ouyang, Shraddha Raghavan, Angelika C. Gruessner, Subodh J. Saggi. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: The most common and severe complication of peritoneal dialysis (PD) is peritonitis. Patients usually present with abdominal pain and cloudy peritoneal effluent. An accurate diagnosis is critical to treatment and avoiding technique failure. Culture negative peritonitis (CNP) rate can be up to 20% with standard bedside collection. The rate among PD centers in the US was reported to be 13.4%-40%. The causes of CNP include recent antibiotic use, Gram-positive infections which fail to reach the threshold of detection, or technical imperfection. The culture techniques were highly variable across centers. Due to a high rate of CNP at our facility, we instituted a new policy of PD effluent culture techniques on 7/30/2013 that was recommended by ISPD guideline. We conducted a quality improvement analysis to examine the outcome of this intervention.

Methods: Data were collected for patients who received PD from 2009 to 2018. The new policy required that a 50 ml of PD effluent be collected and centrifuged prior to the sediment being cultured. Diagnosis of peritonitis was analyzed with culture results before and after the policy change.

Results: This study enrolled 38 patients and total 122 visits for potential peritonitis were observed. As shown in table1, our CNP rate prior to the policy change was 41.7%. After the implementation of the new culture strategy, the rate significantly decreased to 25%. However, the false positive rate increased from 4.9% to 23.1% with a drop of the true positive rate (sensitivity) from 95.1% to 76.9%, when the peritonitis rate in our facility declined from 0.43 to 0.09 /patient year.

Conclusions: This analysis showed that the new PD effluent culture policy effectively lowered the culture negative peritonitis rate in our PD center. However, constant reinforcement of this policy and proper sterilization is required for the purpose of due diligence.

Table 1

	1/1/2009-7/29/2013	7/30/2013-12/31/2018
- Peritonitis with no culture growth	58.3% (21/36)	75% (24/32)
+ Peritonitis with no culture growth	41.7% (15/36)	25% (8/32)
- Peritonitis with culture growth	4.9% (2/41)	23.1% (3/13)
+ Peritonitis with culture growth	95.1% (39/41)	76.9% (10/13)

PO0994

Protective Association Found Between Peritoneal Dialysis Patients Prescribed Home Antibiotics Kits and In-Center Hemodialysis Transition

Derek M. Blankenship,[1] Michelle Carver,[2] Dinesh K. Chatoth,[1] Chance Mysayphonh,[1] Debu Ray,[1] Patricia Mccarley,[1] Len A. Usvyat,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Peritonitis is a complication of peritoneal dialysis (PD) and is likely associated with technique failure. To decrease time to peritonitis treatment, Fresenius Kidney Care (FKC) clinicians can prescribe broad-spectrum intraperitoneal and oral antibiotic kits. Kits are self-administered by home PD patients for suspected wet contamination or peritonitis per algorithm. The study purpose is to assess hemodialysis (HD) transition as well as peritonitis among PD patients receiving a home antibiotic kit.

Methods: This retrospective cohort study identified FKC PD patients prescribed home antibiotic kits between June 1st, 2019 and June 30th, 2020. Home FKC PD patients not receiving kit during same period composed the control pool. Patients are matched in a 1:4 ratio on clinical and demographic data using propensity scores. Patients were followed up to 6 months for transition to HD and first peritonitis event. Outcomes were analyzed with weighted competing risk Cox Proportional Hazards Models.

Results: 2,888 treatment and 10,613 controls were studied. Of the 2,888 treatment patients and weighted 1,921.2 matched controls, 11.9% and 13.5% transitioned to HD, respectively. A 0.88 hazard ratio (p=0.0448) determined treatment group is 12% less likely to transition to HD at any point during follow-up period. 10.4% treatment patients and 8.5% controls have at least one peritonitis event. The treatment group is 23% more likely to have a Peritonitis event (p=0.0019).

Conclusions: The study identified a protective association in HD attrition for home PD patients receiving peritonitis kits despite a positive association between patients receiving the kits and peritonitis. These findings may reflect residual confounding factors such as clinicians prescribing kits for patients at higher risk of peritonitis for uncontrolled or unmeasurable factors since kits do not prevent peritonitis but increase uniformity of treatment. The findings justify need for further research including prospective randomized studies.

PO0995

Assessing Physician Clinic Practices and Competencies in Performing Peritoneal Dialysis Catheter Flushes During the 10-Day Global Period

John H. Crabtree,[1,2] Marcus Pecora,[2] Mark H. Shapiro,[3,2] Eduardo Zanatta,[2] Martin J. Schreiber.[2] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]DaVita Inc, Denver, CO; [3]Balboa Nephrology Medical Group, San Diego, CA.*

Background: Early flushing of peritoneal dialysis (PD) catheters theoretically reduces the incidence of catheter obstruction by decreasing formation of fibrin strands or blood clots. Early flushing also enables timely identification of catheter dysfunction, creating an opportunity to revise the catheter prior to scheduled training and initiation of therapy. It is unknown how frequently PD access providers perform flushes in their clinics, but Centers for Medicare & Medicaid Services (CMS) has indicated that services performed within 10 days following catheter placement (global period) are the responsibility of PD access providers. Therefore, under existing regulations, dialysis organizations generally defer to access providers to perform catheter flushes during this global period. The purpose of this study is to assess current practices of PD access provider clinics (surgeon, interventional nephrologist or radiologist) in performing catheter flushes.

Methods: PD access providers placing catheters for a large dialysis organization in the southwestern United States during 2020 were surveyed. The 3-question survey asked 1) PD access provider specialty, 2) if the clinic performed catheter flushes, and 3) the background of the staff person assisting the physician with clinic procedures. Responses were acquired by direct or telephone contact with the physician or clinic staff.

Results: Survey responses were obtained for all 201 providers who placed PD catheters during 2020 (Table).

Conclusions: Significantly, none of the PD access provider clinics elected to perform catheter flushes. This lack of service may indicate a lack of expertise or readily accessible supplies. While PD nurses are trained and equipped by dialysis organizations to competently perform catheter flushes, current regulations generally prevent them from providing these services during the global period. The survey supports a re-examination of the CMS policy, suggesting a need for more flexibility for dialysis organizations to provide these services during the global period for patient safety and optimal patient outcomes.

Peritoneal Dialysis Catheter Flushing Leading to Syncope from Vagal Nerve Stimulation

Sylvester Barnes.[1,2] *[1]Loyola University Health System, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL.*

Introduction: Peritoneal dialysis is the most common form of home dialysis. Complications can arise however any time the peritoneum is invaded such as during surgery. The patient is a 37-year-old male on PD secondary to developing progressive IgA nephropathy. The patient suffered from an inguinal hernia which required open repair with mesh placement. This required the patient to be subsequently bridged with HD.

Case Description: After 6 weeks the patient was in the process of beginning to transition back to PD dialysis. The patient underwent flushing of his peritoneal catheter and subsequently developed hypotension, diaphoresis and near syncope. This process continued every time the patient's peritoneal catheter was flushed. 500 mL's of 2.5% warm dialysate was also attempted to fill the patient resulting in the same near syncopal episode. There was no problem with aspiration of the catheter. There was no resistance involved in aspiration or flushing. KUB was obtained showing the catheter placed in the left lower pelvis as well as a significant amount of stool burden. Despite aggressive regimen of laxatives the patient continued to suffer from hypotension and near syncope with catheter flushing. The patient was referred to surgery for catheter repositioning. Operative report identified that the tip of the catheter was caught in anterior abdominal adhesions. The catheter was repositioned to the right lower pelvis. After 2 weeks the patient was able to tolerate flushing of his dialysis catheter with progressively increasing fill volumes to the point that he was able to be completely converted back to peritoneal dialysis.

Discussion: It was theroized that catheter tip was uniquely postioned leading to vagal nerve stimulation when liquid was infused though the catheter. This case illustrates a unique complication of catheter malposition and adhesions resulting in near syncope secondary to vagal nerve stimulation. With repositioning of the patient's catheter the symptoms completely resolved.

PO0997

Pharmacokinetics of Intraperitoneal Vancomycin in Patients on Automated Peritoneal Dialysis

Edwin Lam,[1,2] Walter K. Kraft,[1] Douglas F. Stickle,[1] Beth M. Piraino,[3] JingJing Zhang.[1] *[1]Thomas Jefferson University, Philadelphia, PA; [2]National Institutes of Health, Bethesda, MD; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: It is unclear if the pharmacokinetics of vancomycin is the same during automated peritoneal dialysis (APD) where cycler exchanges may affect the systemic, peritoneal, and urinary disposition of drug.

Methods: This was a prospective pharmacokinetic study in peritonitis-negative patients on APD. A single dose of vancomycin (20 mg/kg) was administered through the peritoneum and allowed to dwell for at least 15 hours. Patients underwent four drug-free exchanges following the initial dwell period. Plasma, dialysate and urine were collected over the course of 7 days for pharmacokinetic analysis. A non-compartmental analysis was used to estimate vancomycin pharmacokinetic parameters.

Results: Four patients enrolled and completed the study with no adverse events. Three patients had residual renal function. Following a median (range) dwell of 14.6 (14.2 – 17.6 hours), the mean (± SD) observed maximum plasma concentration was 28.7 ± 4.9 mg/L with a mean (± SD) bioavailability of 98.5 ± 1.4% prior to starting the cycler. The overall mean plasma clearance estimated from study start to completion was was 7.3 ± 1.2 mL/min. In patients with residual renal function, the mean (± SD) vancomycin renal clearance was 3.1 ± 1.5 mL/min.

Conclusions: Despite the small sample size, this pilot study suggest that the dwell time has important implications for systemic vancomycin exposure, time to therapeutic plasma concentration, and dosing. Dose is driven by dwell time while the cycler determines the dosing interval. Rapid exchanges from APD will determine the frequency of dosing rather than the adequacy of absorption when vancomycin is given in the peritoneum.

Funding: Other NIH Support - Edwin Lam was supported by an NIH T32 training grant (GM008562) at the time of study conduct.

Effect of Velphoro on Serum Phosphate and Albumin in Peritoneal Dialysis Patients

Luis M. Perez, Zhiying You, Jessica B. Kendrick, Isaac Teitelbaum. *University of Colorado, Denver, CO.*

Background: Hyperphosphatemia is common in patients on peritoneal dialysis (PD). Restricting phosphorus in the diet often leads to a decrease in protein intake, which may result in hypoalbuminemia. Hypoalbuminemia is associated with an increased risk of morbidity and mortality in PD patients. In observational studies, sucroferric oxyhydroxide (SO), an iron-based phosphate binder, was associated with improved phosphate control and higher serum albumin in hemodialysis patients. Whether SO improves phosphate control and nutritional status in PD patients is unknown.

Methods: We performed a prospective, open-label, 6-month, pilot study of 17 adult PD patients from the Denver Metro Area. Patients had to use automated peritoneal dialysis for at least 3 months, have a serum albumin ≤ 3.8 g/dL, and have serum phosphate ≥ 5.5 mg/dL or ≤5.5 mg/dL on a binder other than SO. Patients currently on phosphate binders underwent a 2-week washout period. Participants were started on SO at a dose of 1 tablet daily with meals. Serum phosphate was checked monthly and the dose of SO was titrated to a goal serum phosphate of < 5.5 mg/dL. The primary outcome was change in serum phosphate and serum albumin over 6 months.

Results: The mean (SD) age and dialysis vintage was 55 ± 13 years and 3.8 ± 2.7 years, respectively. The majority of patients were male (65%), white (82.4%) and non-Hispanic (64.7%). 88% of patients were on a phosphate binder at baseline and the majority were on sevelamer (73%). Twelve patients completed the study. Two patients withdrew due to side effects (diarrhea), 1 patient changed to hemodialysis and 2 patients died (unrelated to the study). Mild diarrhea and change in stool color were the most frequently reported side effects. Results are shown in Table 1. Serum phosphate decreased significantly from baseline but there was no significant change in serum albumin. Phosphate binder pill burden significantly decreased

Conclusions: Serum phosphate decreased significantly with fewer phosphate binder pills/day after switching to SO. There was no change in serum albumin.

PO0999

Prognostic Significance of Plasma Vaspin and Adiponectin Levels in Peritoneal Dialysis Patients

Win H. Than,[1,2] Cheuk-Chun Szeto.[1,2] *[1]Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Shatin, Hong Kong; [2]Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.*

Background: Adiponectin and vaspin are key adipokines that play important roles in the physiology of adipose tissue and contribute to the pathogenesis of metabolic disturbance in chronic kidney disease (CKD). We explored the prognostic role of plasma adiponectin and vaspin levels in peritoneal dialysis (PD) patients – a population that metabolic syndrome, obesity, and cachexia are all common.

Methods: We measured plasma adiponectin and vaspin levels in a cohort of new PD patients and analyzed their relation with patient survival.

Results: We studied 152 patients. Their mean age was 58.38 ± 11.67 years; 102 (67.1%) were men, 92 (60.5%) were diabetic. The median plasma adiponectin level was 31.98 (Interquartile range [IQR]: 16.81-49.49) mg/ml; median vaspin level 0.18 (IQR: 0.11-0.32) ng/ml. There was no significant correlation between plasma adiponectin and vaspin levels. Plasma adiponectin level had modest correlations with Charlson's comorbidity score (r = -174, p = 0.039), triceps skin fold (r = -269, p = 0.001), and mass transfer area coefficient of peritoneum (r = 0.211; p = 0.015). In contrast, plasma vaspin level correlated with carotid-to-femoral pulse wave velocity (r = -240, p = 0.005), triceps skin fold (r = 0.198, p = 0.018), and extracellular to Intracellular fluid volume ratio (r = 170, p = 0.047). After adjusting for clinical confounders, plasma adiponectin and vaspin levels significantly predicted patient survival (adjusted hazard ratio [AHR] of adiponectin 1.018, 95% confidence interval [Cl] 1.004-1.031, p=0.010; AHR of vaspin 1.018, 95%Cl 1.008-1.029, p=0.001).

Conclusions: Plasma adiponectin level also correlated with peritoneal transport status, while plasma vaspin level correlated with the severity of fluid overload and atherosclerosis. Plasma levels of both adiponectin and vaspin are independent predictors of patient survival. Our results suggest that adiponectin and vaspin are involved in different pathways of metabolic disturbance in uremia.

PO1000

The Impact of Peritoneal and Urine Protein Losses on Nutritional Status in Peritoneal Dialysis Patients

Cátia R. Figueiredo, Marisa Roldão, Hernâni M. Gonçalves, Francisco Ferrer, Flora Sofia. *Centro Hospitalar do Medio Tejo EPE Unidade de Torres Novas, Torres Novas, Portugal.*

Background: The etiology of malnutrition in peritoneal dialysis (PD) patients is multifactorial, but the peritoneal protein losses (PPL) and proteinuria may be important contributing factors. We aimed to evaluate if the total protein losses (into urine and dialysate) in PD patients have an impact on their nutritional status.

Methods: A retrospective observational study of PD patients over the first year in PD. Demographic, clinical, and analytical data were collected at baseline (time of PD initiation), 6 and 12 months later. Nutritional status was assessed using normalized protein catabolic rate (nPCR), body mass index (BMI), lean body mass (LBM), and body fat mass (BFM). The total amount of 24h urine and dialysate protein losses (ProtUrDial) and delta (Δ) values (difference between the end of follow-up period and baseline) of continuous variables were also calculated.

Results: Twenty patients were enrolled (55.8±10.8 years; 65% male). Except for serum albumin (sAlb), which changed significantly from the baseline to the end of the follow-up period (p=0.001), there were no differences in protein loss into dialysate (ProtDial), proteinuria (ProtUrine), nPCR, BMI, LBM, and BFM over time. In the 3 time points there was a significative positive correlation between ProtUrine and nPCR (r=0.563, p=0.01; r=0.584, p=0.031; r=0.611, p=0.004, respectively). At the end of the follow-up period, we verified a negative correlation between sAlb and ProtUrDial (r=-0.477; p=0.033). There was no correlation between ΔProtDial and nutritional parameters status, however, there was a positive correlation between ΔProtUrine and ΔBMI (r=0.492; p=0.028). Regarding ΔProtUrDial, we verified a negative correlation with Δ%LBM (r=-0.664; p=0.026) and, although not significant, a positive correlation with Δ%BFM (r=0.573; p=0.066).

Conclusions: The PPL has already been linked to malnutrition in PD patients. However, we found that the total amount of protein losses daily (into urine and dialysate), and not each one individually, seems to influence the nutritional status of PD patients. Besides, proteinuria appeared to have a greater impact on nutritional changes than peritoneal losses. However, more studies with larger samples are needed to clarify this association.

PO1001

MMP-7 Affects Peritoneal Ultrafiltration Associated with Elevated Aquaporin-1 Expression via MAPK/ERK Pathway in Peritoneal Mesothelial Cells

Yue Yin,[1] Fen Zhang,[1] Zhiwen Xiao,[1] Daming Zuo,[2] Jun Ai.[1] *[1]Southern Medical University Nanfang Hospital, Guangzhou, China; [2]Southern Medical University, Guangzhou, China.*

Background: Peritoneal membrane dysfunction and the resulting ultrafiltration failure are the major disadvantages of long-term peritoneal dialysis (PD). It becomes increasingly clear that mesothelial cells play a vital role in the pathophysiological changes of the peritoneal membrane. Matrix metalloproteinases (MMPs) function in the extracellular environment of cells and mediate extracellular matrix turnover during peritoneal membrane homeostasis. Aquaporin-1 (AQP-1), one of the water-specific channel proteins distributed in the endothelium lining the peritoneal capillaries, facilitates the osmotic transport of water across the capillary endothelium, thereby playing an essential role in ultrafiltration during PD.

Methods: Human peritoneal mesothelial cell (HPMCs)line (HMrSV5) strain was continuously cultured in vitro and stimulated with MMP-7. The concentration gradient and time gradient stimulated were set up respectively. HMrSV5 cells were incubated with the suggested volume of lenti-virus negative and lenti-virus MMP-7. Western Blot, RNA isolation, real time PCR and immunofluorescence assay were used to detect the expression of MMP-7, AQP-1 and mitogen-activated protein kinases (MAPKs) phosphorylation in HMrSV5 cells, to verify that MMP-7 affects peritoneal ultrafiltration associated with elevated aquaporin-1 expression via MAPK/ERK pathway in peritoneal mesothelial cells.

Results: We showed that dialysate MMP-7 levels markedly increased in the patients with PD, and the elevated MMP-7 level was negatively associated with peritoneal ultrafiltration volume. Interestingly, MMP-7 could regulate the cell osmotic pressure and volume of human peritoneal mesothelial cells. Moreover, we provided the evidence that MMP-7 activated mitogen-activated protein kinases (MAPKs) extracellular signal-regulated kinase 1/2 (ERK) pathway and subsequently promoted the expression of aquaporin-1 (AQP-1) resulting in the change of cell osmotic pressure. Using a specific inhibitor of ERK pathway abrogated the MMP-7-mediating AQP-1 upregulation and cellular homeostasis.

Conclusions: In summary, all the findings indicate that MMP-7 could modulate the activity of peritoneal cavity during PD, and dialysate MMP-7 might be a noninvasive biomarker and an alternative therapeutic target for PD patients with ultrafiltration failure.

PO1002

Psychosocial Impact of COVID-19 Pandemic on Patients with ESKD on Peritoneal Dialysis

Jin Joo Cha, Booyeun Park, Sung Gi Yoon, Dae R. Cha, Young Sun Kang. *Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.*

Background: The mortality rate from COVID-19 is remarkably high in elderly patients and those with chronic conditions. Increases in physical and mental stress among patients with chronic conditions, especially end-stage kidney disease, were expected to have occurred in response to the COVID-19 pandemic. This study reports that the psychosocial impact of the COVID-19 pandemic on patients receiving peritoneal dialysis.

Methods: During the pandemic, we surveyed the mental health of patients with end-stage kidney disease on peritoneal dialysis at a single center. Depression using with BDI scoring was evaluated and then compared in peritoneal dialysis patients between before and the pandemic declaration. We also surveyed patient satisfaction with the self-care services associated with peritoneal dialysis under the pandemic period.

Results: One-third of the survey respondents (n=176) were moderately to extremely worried about their physical health being impacted by the pandemic, while 20% moderately to extremely worried about their mental and emotional health being impacted. About half of participant reported feeling that they were unable to handle their personal problems and that things were out of their control. However, most felt that they could retain control over the important things and overcome their difficulties. Despite COVID-19 pandemic, no significant changes in depression scores were apparent between before and during the pandemic. Most participants were satisfied with the in-home self-care services delivered by either telephone or remote monitoring.

Conclusions: Many participants reported that they were afraid of COVID-19, but most patients with PD felt that they could overcome the crisis. The COVID-19 pandemic did not affect the depression of patients receiving peritoneal dialysis.

PO1003

Peritoneal-Mediastinal Communication Complication in Peritoneal Dialysis

Janina Paula T. Sy-Go, Lagu A. Androga, Fawad Qureshi, Andrea G. Kattah. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Increased intra-abdominal pressure is a well-recognized non-infectious complication of peritoneal dialysis (PD) resulting from instillation of dialysate fluid into the peritoneal cavity. Peritoneal-pleural communication causing hydrothorax is well-described in the literature, but cases of peritoneal-mediastinal communication are scarce.

Case Description: A 36-year old Caucasian man with end-stage kidney disease secondary to calcineurin inhibitor nephrotoxicity and BK virus nephropathy transitioned to continuous cycler peritoneal dialysis (CCPD) after one year of intermittent hemodialysis (iHD). He presented to our institution nine months after starting CCPD primarily because of complications related to prior heart transplantation. He underwent cardiac surgery and did not have any problem with his CCPD in the immediate post-operative period and was discharged. One month later, however, he presented with increased serous drainage from his sternal incision site and reduced ultrafiltration. A chest CT scan revealed a partially loculated anterior chest wall subcutaneous fluid collection. He was taken to the operating room and was found to have a peritoneal-mediastinal communication. He was successfully managed with "low-pressure" PD by using reduced fill volumes for all his exchanges, which also allowed optimal healing of the muscle flap closing the communication. Transition to iHD was considered, but he had no vascular access options because of multiple prior thromboses. He was able to subsequently return to his outpatient CCPD prescription about two months after his surgery by doing very gentle uptitration of his fill volumes. Unfortunately, one and a half months after his last hospitalization, he succumbed to septic shock secondary to trans-lumbar PICC-associated Candida glabrata fungemia.

Discussion: A peritoneal-mediastinal communication should be suspected in an otherwise asymptomatic patient on PD with reduced ultrafiltration who underwent any form of chest surgery. Clinical suspicion can be confirmed either through CT peritoneography or intraoperatively. Management with a trial of "low-pressure" PD is feasible and can be successful, particularly if iHD is not an option. A multi-disciplinary approach involving our surgical colleagues is also crucial to ensure appropriate patient care.

PO1004

Sweet Pleural Effusion in a Peritoneal Dialysis Patient

Karla G. Carias Martinez,[1] Nityasree Srialluri,[1] Jose M. Monroy-Trujillo.[2] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD.*

Introduction: Pleural Effusions are frequently seen in dialysis patients with an incidence as high as 80%, with a variety of possible differential etiologies

Case Description: A 62-year-old female with HFpEF, DM and ESRD due to biopsy proven diabetic nephropathy recently started on nightly continuous cyclic PD with a prescription of 4 exchanges of 2.5% Dextrose solution with 2 liters fill volumes with a dwell time of 1h40 min for a total time of 8.5 hrs with no day dwells presented with dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining ultrafiltration volumes. On exam tachypneic on 4L of oxygen and saturating 100%, had decreased breath sounds on the right pulmonary base, no JVD or lower extremity edema. Laboratory showed creatinine 4.19 mg/dl, BUN 41 mg/dl, proBNP 30,186 pg/ml, Hemoglobin 11 gm/dl and WBC 5.91 mg/dl. Chest X- Ray revealed small to moderate right pleural effusion and opacities in the right mid and lower lung. CT Chest showed a large right sided pleural effusion. With her unilateral pleural effusion and recent start of PD the presence of a peritoneal pleural fistula was suspected. A therapeutic thoracentesis was done draining 1 liter of fluid consistent with a transudate, no microorganism or malignant cells were isolated. Pleural fluid glucose was 274 mg/dL compared to a serum glucose of 155 mg/dL. A peritoneal perfusion scan was done detecting radiotracer uptake in right hemithorax Image 1 confirming a peritoneal pleural communication. She was transitioned to HD and maintained on it per the patient's preference

Discussion: A pleuroperitoneal leak is a rare but important cause of pleural effusion in patients on PD and should be considered in any patient presenting with a unilateral effusion. Incidence is less than 2%. The diagnosis is made by measuring the ratio between the pleural to serum glucose which usually is > 1. Other tests include technetium-99m labeled peritoneal scintigraphy. Treatment usually requires cessation of PD for 4-6 weeks and transition to HD. For patients willing to return to PD, a diaphragmatic repair is usually required

PO1005

Progression of Left Ventricular Mass Index After Peritoneal Dialysis Initiation: A Potential Killer

Yun Chen, Shuqi Dai, Chuan-Ming Hao, Tongying Zhu. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Left ventricular hypertrophy (LVH), defined by the left ventricular mass index (LVMI), is highly prevalent in dialysis patients. LVMI has been widely accepted as a strong predictor of cardiovascular events. However, the dynamic changes of LVMI are rarely discussed, especially among peritoneal dialysis (PD) patients. The study aimed to investigate the prognostic significance of LVMI-progression in PD patients, and explore risks factors for LVMI-progression.

Methods: It was designed as a prospective, observational study. Incident PD patients between February 2008 and July 2018 were recruited. Echocardiography was performed yearly to collect LVMI and evaluate its progression. Participants were divided into two subgroups: group with LVMI-progression and group without LVMI-progression. The end points include all-cause mortality, cardiovascular mortality and cardiovascular events. Cox regression models were performed to identify the associations between LVMI-progression and these endpoints. Multivariate logistic regression was conducted to identify factors associated with LVMI-progression.

Results: A total of 216 PD patients (130 men,60.2%) with a mean age of 54.3±16.7 years were recruited. LVMI-progression was identified in 65 patients (30%) after PD initiation. The cohort was followed for a median duration of 65.9 months. Multivariable Cox regression analysis revealed that LVMI-progression was an independent predictor of all-cause mortality (HR, 2.111; 95%CI, 1.148–3.881; p = 0.016), cardiovascular mortality (HR, 2.785; 95%CI, 1.151–6.741; p = 0.023), and cardiovascular events (HR, 1.869; 95% CI, 1.016–3.439; p = 0.044). Multivariable logistic regression showed that hemoglobin (OR, 0.967; 95% CI, 0.939–0.996; p = 0.027), ferritin (OR, 0.995; 95% CI, 0.992–0.999; p = 0.007) and mean arterial pressure (MAP) (OR, 1.048; 95% CI, 1.001–1.097; p = 0.043) were significantly associated with LVMI-progression.

Conclusions: LVMI-progression after PD initiation was independently associated with all-cause mortality and cardiovascular outcomes in PD patients. The dynamic monitoring of LVMI might therefore help identify high-risk patients early. Further studies are needed to clarify whether treatment interventions for factors such as anemia could improve patient outcomes.

PO1006

Estimation of Residual Kidney Function with Serum Levels of β2-Microglobulin in Peritoneal Dialysis

Fernando L. Strufaldi, Luciana G. Lutf, Rosilene M. Elias, Hugo Abensur. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

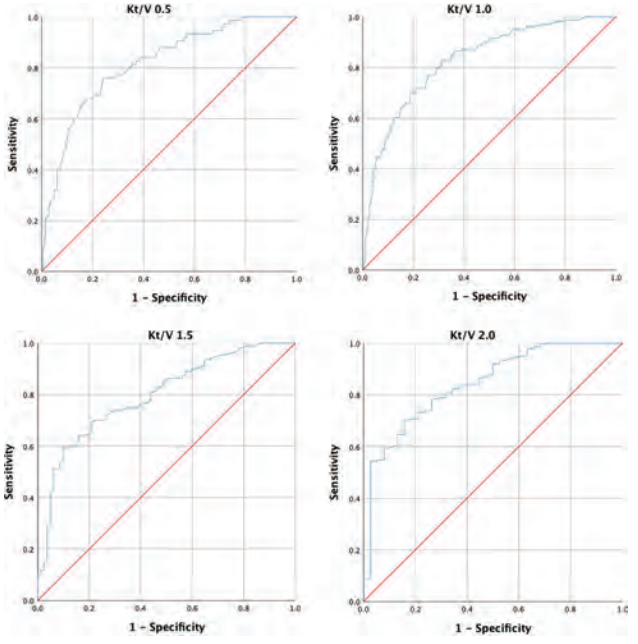
Background: Residual kidney function (RKF) is defined as the kidney function in patients with end-stage renal disease (ESRD) who are receiving dialysis. The ideal method to evaluate and measure RKF is still uncertain and the estimated glomerular filtration rate (eGFR) and urea clearance may over- and underestimate RFK, respectively. ß2-microglobulin (ß2M) is a 11818 Da protein freely filtered and metabolized in kidney

tubules, thus its accumulation reflects an impaired RKF. Our study aimed to evaluate if serum levels of ß2MG could be used as a complementary tool for evaluating RKF in peritoneal dialysis (PD) patients.

Methods: For this retrospective cohort study, we evaluated 423 urine samples of 166 patients who were in the PD program of Hospital das Clínicas, HCFMUSP, Universidade de Sao Paulo, Brazil from January first of 2014 up to August 10th of 2020. We correlated serum ß2M levels with the urea renal Kt/V (urea clearance adjusted by the total body water (TBW), measured with bioimpedance), serum creatinine and urinary volume.

Results: We found a correlation between renal Kt/V and ß2 microglobulin (r= -0.656, p<0.0001), serum creatinine (r= -0.603, p<0.0001), and urinary volume (r= -0.682, p<0.0001). ROC curve revealed that ß2 microglobulin had a high performance to predict renal Kt/V, with a sensitivity of 70 to 81.7% according to the best cutoff. The specificity varied from 71.5% to 84.2%for Kt/V cutoff 0.5, 1.0, 1.5 and 2.0.

Conclusions: Based on the good correlation between serum ß2M and urea renal Kt/V, we suggest that ß2M can be a useful tool to estimate the RFK. This findings can be particularly useful in patients who have difficulties in storing or collecting a 24-hour urine sample.



PO1007

A Rare Case of Roseomonas gilardii Peritonitis in a Peritoneal Dialysis Patient

Temi-Ete I. Ediale, Saeid Karandish, Ayesha Mallick Imam, Aaron S. Stern, Ellena A. Linden. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: We report a case of *Roseomonas gilardii* peritonitis in a continuous ambulatory peritoneal dialysis patient.

Case Description: A 71-year-old woman with end stage renal disease (ESRD) on continuous ambulatory peritoneal dialysis (CAPD) for 5 years presented with cloudy effluent without abdominal pain or fever. Laboratory studies revealed a fluid cell count of 800 wbcs/mm^3 with 87% neutrophils. She was started on empiric antibiotic therapy with intraperitoneal vancomycin and ceftazadime. Effluent remained cloudy with elevated WBC despite a 2-week course of antibiotics. Eventually culture grew *Roseomonas gilardii*, a slow growing gram-negative bacillus sensitive to aminoglycosides. Her antibiotic was changed to IP gentamycin and her effluent cleared by day three. Gentamycin was continued for three weeks to ensure she didn't have a relapse as per prior described experience in a similar case.

Discussion: Peritoneal dialysis peritonitis is known to be caused mainly by gram positive and occasionally gram-negative organisms, the usual culprits being pseudomonas, Klebsiella etc. Roseomonas has recently been implicated as a rare cause of bacterial peritonitis with only six reports between 1997 till date. It was first described in 1993 as a cause of bacteremia in humans. *Roseomonas gilardii* is a pink-pigmented, oxidized, gram-negative coccobacillus genus of Roseomonas associated with contaminated water source and soil. Our patient was unaware of being in contact with contaminated water or soil however this could not be ruled out as she did endorse having plants. Of the six cases reported, ours is the third case of R. *gilardii* reported till date. Although the incidence of peritoneal dialysis peritonitis caused by *Roseomonas gilardii* is rare, it is causative agent to be considered by physicians and laboratory staff in the differential diagnosis of refractory bacterial peritonitis in peritoneal dialysis patients. It also serves as a point to emphasize when educating PD patients on the hand-washing techniques and ensuring sterility of water source used for this.

PO1008

Unusual Cause of Recurrent Shortness of Breath in a Peritoneal Dialysis Patient

Sonali Gupta, Meenakshi Sambharia, Lama A. Noureddine. *The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Pleuroperitoneal leak (PPL) is an unusual cause of recurrent pleural effusion in patients on peritoneal dialysis (PD). It is a rare complication and occur in less than 2% of cases. Diagnosis is challenging and requires high clinical suspicion and awareness of this life threatening complication. Pleural fluid to serum glucose ratio of >50 mg/dl is highly specific for detecting leak of high glucose dialysate into pleural cavity, however this needs to be interpreted in relation with the last dialysis session.

Case Description: A 72 year-old-female with history of end stage renal disease due to biopsy proven focal segmental glomerular sclerosis thought to be secondary to obesity started on CCPD one-month prior presented with worsening shortness of breath of 1 week duration. Workup was unremarkable except for chest X-ray that showed right side pleural effusion. A non-contrast CT chest did not show a diaphragmatic defect. She continued to have worsening SOB prompting an emergent thoracentesis that drained 1.6 L transudate pleural fluid. Pleural fluid to serum glucose gradient was normal at 5 mg/dl but pleural fluid to serum glucose ratio was >1. However, last PD session was 2 days prior to thoracentesis, which could explain this lower ratio. Due to inconclusive[NL1] results, it was decided to instill 300 ml gastrografin in 6L of 2.5% dialysate bags and repeat CT chest. It showed interval re-accumulation of high-density pleural effusion, suggesting trans-diaphragmatic communication. Cardiothoracic surgery was consulted for repair of diaphragmatic defect; however, patient opted for hemodialysis instead.

Discussion: It is important to maintain high clinical index of suspicion in PD patients presenting with hydrothorax. Although high pleural fluid to serum glucose gradient is specific for PPL, pleural to serum glucose ratio >1 is another index that should be considered in addition to post- gastrografin imaging or technetium 99 peritoneal scintigraphy, especially if the last dialysis session was not recent and could potentially alter the biochemical assay results as happened in our case Most cases of PPL occur soon after PD initiation, common on right side. For those who wish to continue PD, surgical repair is often required while transitioning to HD temporarily or doing low volume recumbent PD. Some case series have noted the defect to close spontaneously after holding PD.

PO1009

The Association Between Lower Serum Potassium Level and Increased Cardiovascular Death Among Patients Undergoing Peritoneal Dialysis

Hiroaki Tsujikawa,[1] Toshiaki Nakano,[1] Shotaro Ohnaka,[5] Shunsuke Yamada,[1] Kazuhiko Tsuruya,[2] Kumiko Torisu,[1,3] Hidetoshi Kanai,[4] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, Fukuoka, Japan; [2]Nara Kenritsu Ika Daigaku Yakurigaku Kyoshitsu, Kashihara, Japan; [3]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [4]Kokura Kinen Byoin, Kitakyushu, Japan; [5]Tagawa Shiritsu Byoin, Tagawa, Japan.*

Background: In patients undergoing peritoneal dialysis (PD), lower serum potassium concentration has been related to low nutrition status and suggested as a risk factor for all-cause and cardiovascular mortality. However, the risk of lower serum potassium concentration for cardiovascular death in patients using renin-angiotensin system (RAS) inhibitors or β-blockers is not clear. This study investigated the relationship between lower serum potassium concentration and cardiovascular death among Japanese patients undergoing PD.

Methods: We retrospectively included the 549 patients from our previous multicenter cohort study (Fukuoka Peritoneal Dialysis Database Study). The participants who had undergone PD for at least 90 days were registered from 1 January 2006 to 31 December 2016 and followed until they were transferred to hemodialysis, received a kidney transplantation, died during PD, or were lost to follow-up, or until 31 December 2017. The patients were divided into three groups according to the baseline serum potassium concentration (T1 ≤ 4.0, 4.0 <T2 ≤ 4.5, T3> 4.5 mEq/L). We estimated the relationship between serum potassium concentration and cardiovascular mortality using a Cox proportional hazards model.

Results: During the median observation period of 2.3 years, 111 patients died of any cause, and 38 died of cardiovascular. After multivariable adjustment in the Cox proportional hazard model, lower serum potassium concentration was shown to be an independent risk factor for cardiovascular death; (hazard ratio 95% confidence intervals) T2 and T1 vs. T3 were 2.21 (0.77–6.27) and 2.67 (1.01–7.07), respectively. Stratified-analysis according to the use of RAS inhibitors, β-blockers, or a combination of both drugs showed that this relation was not modified by the use of these drugs.

Conclusions: This study showed that lower serum potassium concentration was associated with increased cardiovascular mortality in PD patients. There was no difference in the risk of lower serum potassium concentration for cardiovascular death according to the use of the RAS inhibitors and/or β-blockers in PD patients.

PO1010

Higher Serum Total Cholesterol to High-Density Lipoprotein Cholesterol Ratio Was Associated with Increased Mortality Among Incident Peritoneal Dialysis Patients

Hee Won Noh, Soojee Jeon, Jeong-Hoon Lim, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. Department of Internal Medicine, Kyungpook National University Hospital, Korea *Kyungpook National University Hospital, Daegu, Republic of Korea*.

Background: A few studies have shown that serum total cholesterol to high-density lipoprotein cholesterol ratio (TC/HDL-C) was a risk factor for cardiovascular mortality in the general populations. This study aimed to evaluate the association of TC/HDL-C with mortality in incident peritoneal dialysis patients.

Methods: We enrolled Total of 630 incident peritoneal dialysis patients from 2008 to 2015 in a multi-center, prospective cohort study of Korea. Participants were stratified into quintiles according to the baseline TC, HDL-C, or TC/HDL-C. The association between all-cause mortality and each lipid profile was evaluated using multivariate Cox regression analysis.

Results: During a median follow-up period of 70.3 ± 25.2 months, 185 deaths were recorded. The median TC/HDL-C was 4.54 ± 2.51. Highest TC/HDL-C group showed highest body mass index, percentage of diabetes, and serum albumin level. Multivariate analysis revealed that the highest quintile of the TC/HDL-C (>5.60) was associated with increased risk of all-cause mortality (hazard ratio 1.69, 95% confidence interval 1.04 to 2.76; P = 0.036), whereas neither of TC and HDL were associated with mortality. Increased serum TC/HDL-C was also independent risk factor for mortality in the patients with old age over 50 years, non-diabetes, and any cardiovascular disease.

Conclusions: The single lipid marker of TC or HDL-C could not predict mortality in PD patients. However, non-traditional lipid profile such as increased serum TC/HDL-C ratio was independently associated with an increased risk of all-cause mortality in PD patients.

Peritoneal Dialysis Caregiver Scope and Functions: A Systematic Scoping Review

Tanawin Nopsopon,[1,2] Chitsanucha Chumsri,[1] Piyawat Kantagowit,[1] Krit Pongpirul.[1,3] Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Harvard University T H Chan School of Public Health, Boston, MA; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Caregivers play important roles in peritoneal dialysis (PD) care. Classifying PD self-care tasks is important for determining the PD caregiver roles. As the scope and functions of PD caregiver in published literature have been inconsistent, we aimed to systematically explore the variations of the term caregiver in high-quality PD studies.

Methods: We performed a systematic search using PubMed, Embase, and CENTRAL for randomized controlled trials and observational studies relevant to a caregiver in ESRD (end-stage renal disease) patients with PD in the English language up to February 20th, 2020. Outcomes were choice of words used in articles for "caregiver," the definition of "caregiver," persons defined as caregiver, and detailed functions of caregivers.

Results: Of 2,514 potential studies relevant to a caregiver in ESRD patients with PD, 299 theme-related abstracts were selected for further full-text articles screening against eligibility criteria, and 111 were included in the systematic review (72,101 patients in 34 countries). In terms of word choice, "caregiver(s)" was used in 86.4%, "carer(s)" in 20.7% and other words were used in 13.5% of included studies. Only 8.1% of studies gave the explicit definitions of those words. The most referred person is the parents (40.5%), followed by a spouse (37.8%), other family members (37.8%), children (34.2%), non-relative non-healthcare workers (25.2%), friends (20.7%), and healthcare workers (19.8%). The explanation of functions for each word comprises 41.4%, with the PD-specific functions by 32.4%, instrumental activities of daily living by 9.9%, and basic activities of daily living by 5.4%.

Conclusions: PD caregiver has been broadly defined and vary across studies. PD-specific functions should be used for making the definition of PD caregiver clearer.

PO1012

Autophagy Response and Arteriovenous Fistula Maturation

Tatyana Isayeva Waldrop, Maheshika S. Somarathna, Kevin A. Ingle, Timmy C. Lee. *The University of Alabama at Birmingham, Birmingham, AL*.

Background: Arteriovenous fistula (AVF) are the preferred vascular access for hemodialysis. AVF creation results in disturbed blood flow within the AVF anastomosis. The objectives of this study were to: 1. Characterize autophagy flux after AVF creation, and during the remodeling process, 2. Use an in vitro model to evaluate autophagy status during the laminar and turbulent flow.

Methods: Femoral AVFs were created in male rats. Yorkshire pigs were used to create carotid artery-jugular vein AVF. Autophagy flux was evaluated after 1 hour and 7 days. AVF and contralateral vessels were harvested for histology and Western blot (WB). Autophagy-related proteins were analyzed in the AVF human vein samples. Effects of hemodynamic changes were investigated by utilizing an in vitro model. Human umbilical vein smooth muscle cells and endothelial cells were co-cultured in the vessel-like system under laminar or disturbed flow conditions. After 24 hours, cells were harvested for histology and WB.

Results: In the rat model impaired autophagy flux was observed in the vein 1 hour after AVF creation. At day 7 expression of ATG3 and ATG7 protein was significantly higher ($p<0.003$) in the AVF vein compare to contralateral control. Significant increases in p62 expression was detected in 7 days AVF vein ($p<0.001$) in both in vivo models. Disturbed autophagy flux also observed in human vein samples collected during new AVF creation. In vitro model showed dysregulation of autophagy flux in disturbed flow, as compared to laminar flow.

Conclusions: Our in vitro and in vivo studies both demonstrated that autophagy response may play an important role in vessel remodeling in the setting of disturbed flow as seen in AVFs. Autophagy may be a potential target to improve AVF maturation.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

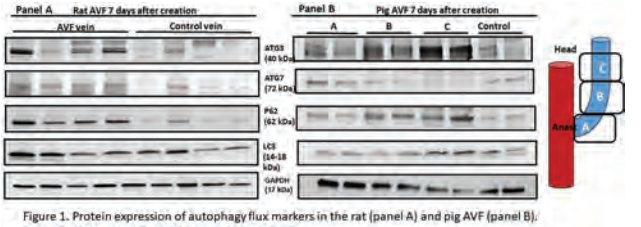

Figure 1. Protein expression of autophagy flux markers in the rat (panel A) and pig AVF (panel B). Control veins were collected from contralateral side.

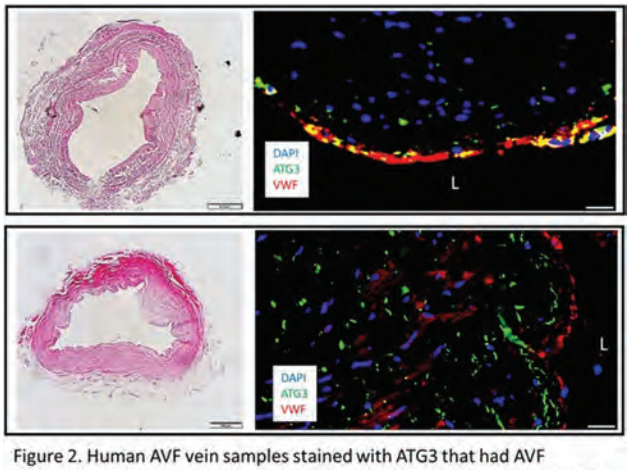

Figure 2. Human AVF vein samples stained with ATG3 that had AVF maturation failure (lower panel) and successful AVF use (upper panel). Co-localization (yellow stain) of ATG3 (red) with VWF (an EC marker) was observed in endothelium in AVF with successful use. L=vein lumen.

PO1013

The Rat Arteriovenous Fistula in the Setting of CKD Displays a Senescence Phenotype

Anthony J. Croatt,[1] Joseph P. Grande,[2] Allan W. Ackerman,[1] Karl A. Nath.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN*.

Background: We previously demonstrated that the murine arteriovenous fistula model in the setting of CKD (AVF-CKD) exhibits a senescence phenotype including increased expression of hallmark cell cycle inhibitors, senescence-associated β-galactosidase (SA-β-Gal) and senescence-associated secretory phenotype (SASP) factors, along with evidence of telomere erosion [Am J Physiol Renal Physiol. 315(5):F1493-F1499, 2018]. In the present study, we questioned whether this senescence phenotype exists in an AVF created in another species, namely the femoral AVF in the rat.

Methods: An end-vein to side-artery AVF was surgically created in the femoral vessels of rats which had previously been subjected to uremia via subtotal nephrectomy. At 1 and 2 weeks after AVF formation the arterial and venous limbs of the AVF were harvested for the assessment of gene and protein expression and the assay of SA-β-Gal activity. Femoral veins and arteries from rats subjected to sham surgery were used as controls.

Results: At 1 week after AVF creation mRNA levels of senescence drivers p16 and p21 were markedly elevated in AVF veins compared to sham veins, as were p21 protein levels; the AVF artery also displayed elevated p21 protein levels at this time point. At 2 weeks, p21 protein was again upregulated in both the vein and artery of the AVF, and protein levels of an upstream mediator in the p21 senescence pathway, p53, were significantly increased in the AVF artery; p53 levels did not achieve significance ($p=0.083$) in the AVF vein at this time point. Upregulation of SASP factors was also observed in the AVF vein at 1 week: mRNA expression of PAI-1, IL-6, TNF-α and MCP-1 was robustly increased as compared to sham veins at 1 week after AVF creation. Additionally, miR21, which has been associated with vascular senescence, was markedly elevated in the AVF vein at 1 week post AVF placement. Finally, SA-β-Gal activity, an established marker of senescence was significantly increased in both the artery and vein compared to their sham counterparts at both 1 and 2 weeks post AVF surgery.

Conclusions: Using established criteria, this study demonstrates that the rat femoral AVF in the setting of CKD has a senescence phenotype similar to the murine AVF-CKD model. These findings thus demonstrate the development of senescence in another species subjected to an AVF in the presence of uremia.

PO1014

The Adaptive Response of the Vein to CKD: A Transcriptomics Perspective

Laisel Martinez,[1] Akshara Sree Challa,[1] Marwan Tabbara,[1] Miguel G. Rojas,[1] Juan C. Duque,[1] Loay H. Salman,[2] Roberto I. Vazquez-Padron.[1,3] *[1]University of Miami School of Medicine, Miami, FL; [2]Albany Medical College, Albany, NY; [3]VA Miami Healthcare System, Miami, FL.*

Background: The impact of CKD on gene expression in the vascular wall remains unknown, particularly in veins, despite their fundamental role as conduits for hemodialysis.

Methods: In this study, we investigated the CKD fingerprint on the transcriptome of basilic veins by analyzing 48 pre-access veins from end-stage renal disease patients and 20 veins from non-CKD trauma donors by bulk RNA sequencing.

Results: We uncovered 16,893 differentially expressed genes (DEG) between CKD and control individuals ($\log_2$FoldChange>1, FDR<0.05). The presence of kidney disease caused a noticeable decrease in transcriptional activity in veins, with the downregulation of >97% of DEG transcripts. These included 6,081 non-coding RNAs, 3,826 protein-coding genes, and other miscellaneous transcripts. In contrast, a unique set of 462 genes was upregulated in CKD veins vs. controls, 161 of which corresponded to non-coding RNAs, 201 to protein-coding genes, and the rest to minor RNA biotypes. Gene set enrichment analysis (GSEA) identified a suppression of pathways related to vascular maintenance, cell morphogenesis, cell metabolism, and microtubule-based cytoskeletal functions. Interestingly, the protein-coding genes upregulated in CKD veins belonged to processes related to gas transport and detoxification of oxidative stress byproducts.

Conclusions: In conclusion, we have uncovered a profound suppressive effect of CKD on the venous transcriptome, likely affecting basic cell functions such as metabolism, cell division, and migration. We also identified a transcriptomic signature of upregulated genes in response to oxidative stress which may play a fundamental role in cell survival in the CKD environment.

PO1015

Gender-Specific Risk Genes in Arteriovenous Fistula Failure

Roberto I. Vazquez-Padron,[1,2] Marwan Tabbara,[1] Miguel G. Rojas,[1] Akshara Sree Challa,[1] Juan C. Duque,[1] Loay H. Salman,[1] Laisel Martinez.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]VA Miami Healthcare System, Miami, FL.*

Background: Gender is known to play a role in arteriovenous fistula remodeling and risk of failure. However, the clinical and molecular mechanisms behind this phenomenon have not been elucidated.

Methods: To address this question, 48 pre-access veins obtained at the time of two-stage AVF creation (24 matured and 24 failed postoperatively) and 40 postoperative transposition samples (20 matured and 20 failed) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Females and males were equally represented in both outcome groups and were similar in demographics and baseline characteristics. We searched for common and sex-specific differentially expressed genes (DEG) in pre-access veins and postoperative samples in association with failure.

Results: In the pre-access vein, we found 28 DEG between veins that matured or failed postoperatively ($\log_2$FoldChange>1, FDR<0.05) and in common between both sexes. In male veins, 1180 transcripts were differentially expressed between both outcomes, whereas no female-specific DEG were detected in the same number of individuals. Principal component analyses demonstrated more transcriptional variability in both outcome groups in females, decreasing our power to identify female-specific genes in the vein. In postoperative samples, we found 156 DEG between fistulas that matured or failed and in common between both sexes. In addition, 143 female-specific and 153 male-specific genes were differentially expressed between outcomes, indicating gender relevant processes of postoperative remodeling. Both sexes showed a downregulation of genes related to responses to external stimuli and stress. However, gene set enrichment analysis (GSEA) revealed a suppression of cell-surface receptor signaling and cell adhesion mechanisms in males but not in females, suggesting a sex-specific effect in cell migration.

Conclusions: In conclusions, these analyses uncover potential differences in postoperative remodeling between females and males in relation to AVF failure. They also indicate a more complex transcriptional landscape in female tissues which may affect our ability to predict remodeling in this group of patients. These data may open the door to personalized medicine in preventing or treating vascular access complications.

PO1016

Inhibition of Phosphodiesterase Type 5A Prevents Pathological Cardiac Remodeling Following Arteriovenous Fistula Creation

Maheshika S. Somarathna,[1] Taylor G. Lewis,[2] Kevin A. Ingle,[1] Tatyana Isayeva Waldrop,[1] Timmy C. Lee.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.*

Background: Cardiac events are the most common etiology of mortality in hemodialysis patients. The gold standard of vascular access, the arteriovenous fistula (AVF), may adversely affect cardiac structural and functional remodeling leading to heart failure. We hypothesize that inhibition of cGMP catabolism with a selective phosphodiesterase type 5A (PDE5A) inhibitor, sildenafil, may induce more favorable cardiac remodeling following AVF creation

Methods: Sildenafil was administered to 12-16 weeks old Sprague-Dawley rats two weeks prior to AVF creation and continued until sacrifice at 28 days. Cardiac structural and functional changes were evaluated by 1) 2D-echocardiography 2) measurement of collagen volume and oxidative stress and 3) evaluation of cardiomyocyte cytoskeletal-mitochondrial architecture

Results: Sildenafil treatment significantly improve pathological collagen degradation, reduces HNE4 expression, reverse desmin degradation and focal mitochondrial clustering following AVF creation, as compared to the control. We also observed a significant increase in cardiac output and stroke volume without reversing LV dilation which may suggest improvement in cardiac contractility.

Conclusions: PDE5A inhibition may provide a new treatment strategy for pathological cardiac remodeling following AVF creation

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

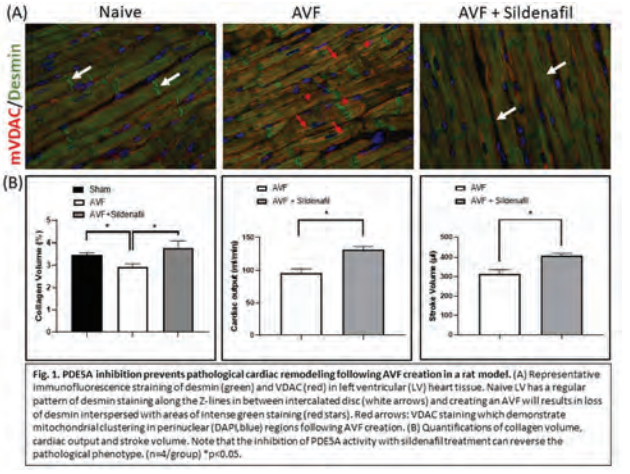

Fig. 1. PDE5A inhibition prevents pathological cardiac remodeling following AVF creation in a rat model. (A) Representative immunofluorescence straining of desmin (green) and VDAC (red) in left ventricular (LV) heart tissue. Naive LV has a regular pattern of desmin staining along the Z-lines in between intercalated disc (white arrows) and creating an AVF will results in loss of desmin interspersed with areas of intense green staining (red stars). Red arrows: VDAC staining which demonstrate mitochondrial clustering in perinuclear (DAPI,blue) regions following AVF creation. (B) Quantifications of collagen volume, cardiac output and stroke volume. Note that the inhibition of PDE5A activity with sildenafil treatment can reverse the pathological phenotype. (n=4/group) *p<0.05.

Pre-Access Vein Transcriptomics as a Predictor of Arteriovenous Fistula Failure: A Machine Learning Approach

Miguel G. Rojas,[1] Laisel Martinez,[1] Akshara Sree Challa,[1] Marwan Tabbara,[1] Juan C. Duque,[1] Loay H. Salman,[2] Roberto I. Vazquez-Padron.[1,3] *[1]University of Miami School of Medicine, Miami, FL; [2]Albany Medical College, Albany, NY; [3]VA Miami Healthcare System, Miami, FL.*

Background: As the number of patients with end-stage renal disease continues to rise, the creation of a robust and efficient hemodialysis access is more important than ever. A mature arteriovenous fistula (AVF) is the preferred method for long-term hemodialysis. However, the nationwide maturation rate continues to be as low as 50-60%, and we currently lack an effective risk stratifying method to identify patients at higher risk of AVF failure.

Methods: To address this clinical need we developed a predictive model based on supervised machine learning from transcriptomics of the pre-access vein. Forty-eight pre-access veins obtained at the time of AVF creation (24 matured and 24 failed postoperatively) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Both outcome groups were matched by age, sex, demographics, and baseline clinical characteristics. The highest expressing genes (normalized gene expression counts >200) were used as input in KNN, SVM, XGBoost, and other machine learning algorithms. Area under the curve (AUC) and receiver-operating characteristic (ROC) plots were used to compare the performance of the models relative to each other. The best performing algorithm, XGBoost, was optimized with the following hyperparameters {gamma=0.25, learning_rate=0.001, max_depth=4, reg_lambda=10, scale_pos_weight=3}. The SHapley Additive exPlanations (SHAP) analysis was then used to evaluate the highest contributing features to the XGBoost model.

Results: Ten highly predictive and abundantly expressed genes were identified using this methodology (RIC1, CLIC5, DNAL1, FOXO4, TIMMDC1, GALNT11, CDH13, KLHDC10, ZNF8, and DBT). Using these transcripts, the AUC in the logistic regression model is 97.6%.

Conclusions: In conclusion, this study has identified 10 potential pre-access gene predictors of postoperative AVF failure, which could be used clinically as a stratifying or risk management tool in vascular access patients.

Arteriovenous Fistula Non-Maturation: Does the Immune System Play a Role?

Crystal A. Farrington,[1] Gary R. Cutter,[2] Michael Allon.[1] *[1]The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; [2]The University of Alabama at Birmingham School of Public Health, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) non-maturation is a persistent problem, particularly among female and Black patients. The immune system promotes several vascular disease processes, but its contribution to AVF non-maturation has not been well-studied. We evaluated the association of serum panel reactive antibodies (PRA), a measure of immune system reactivity assessed in patients undergoing kidney transplant evaluation, with AVF non-maturation.

Methods: We identified 132 patients at our institution who underwent surgical AVF creation between 2010-2019 and had PRA testing within one year of AVF creation. Multivariable logistic regression was used to determine the association of patient demographic, clinical, and vascular factors with AVF maturation. Receiver operator characteristic (ROC) curves were generated to determine the predictive value of key variables on AVF non-maturation.

Results: AVF non-maturation was more common in females than males (44% vs 20%, p=0.003) and in Black than white patients (40% vs 13%, p=0.001). Class II PRA was higher in females than males (12% +/- 23% vs 4% +/- 13%, p=0.02), but did not differ by race. In the multivariable model, AVF non-maturation was associated with class II PRA (adjusted odds ratio [aOR] 1.34 per absolute 10% increase; 95% confidence interval [CI], 1.04 to 1.82, p=0.02) and Black race (aOR 3.34; 95% CI, 1.02 to 10.89, p=0.03). An ROC curve using seven key variables (Table 1 and Figure 1) showed an area under the curve of 0.73 (95% CI, 0.63 to 0.82, p<0.0001)

Conclusions: The novel association of elevated class II PRA with AVF non-maturation suggests a role for the immune system in AVF maturation outcomes, especially for female patients.

Variable	Adjusted Odds Ratio	95% Confidence Interval	P-value
Age, per 10 yr increase	1.09	0.76 to 1.56	0.64
Sex, female	1.96	0.80 to 4.81	0.14
Race, Black or African American	3.34	1.02 to 10.89	0.03
Preoperative arterial diameter, per 1 mm increase	0.72	0.44 to 1.15	0.17
Preoperative venous diameter, per 1 mm increase	0.82	0.45 to 1.47	0.51
Class I PRA, per 10% increase	0.91	0.72 to 1.14	0.42
Class II PRA, per 10% increase	1.34	1.04 to 1.82	0.02

Functioning Tailor-Made 3D-Printed Vascular Graft for Hemodialysis: A Proof-of-Concept In Vivo Study

David Chih-Yu Yang,[1,2] Der-Cherng Tarng.[1,2] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

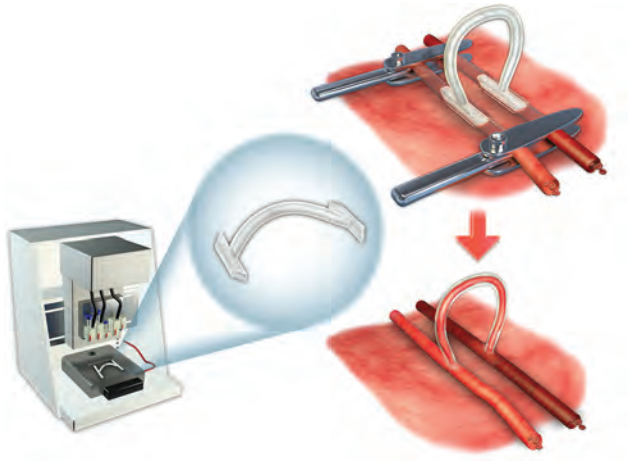
Background: The two ends of arteriovenous graft (AVG) are anastomosed to the upper limb vessels by surgery for hemodialysis therapy. However, the size of upper limb vessels varies to a large extent among different individuals. With advances in three-dimensional (3D) printing technology, it is now possible to realize tailor-made AVG for personalized surgery. In this study, we aim to investigate the function of 3D-printed AVGs *in vivo*.

Methods: The computed tomography angiographic scan of the rabbit neck was performed before the surgery. According to the shape and size of neck vessels, an H-shape AVG was produced by the 3D printer and then sterilized. The 3D-printed AVG was trimmed and inserted in the rabbit's common carotid artery and common jugular vein.

Results: The tailor-made 3D-printed AVGs can be implanted in the rabbit's neck vessels with ease and function *in vivo*. The surgical procedure was quick, and no suture was required. The blood loss was minimal, and no hematoma was noted at least one week after the surgery. The blood flow velocity within the implanted AVG was 14.9 ± 3.7 cm/sec.

Conclusions: Through the 3D printing technology, the AVG can be tailored to fit the specific vessel size. This kind of 3D-printed AVG is functioning *in vivo*, and our results realize personalized vascular implants. Further studies conducted in large animal models are warranted to validate our promising results.

Funding: Government Support - Non-U.S.



Graphical Abstract. The schematic diagram of the three-dimensional (3D)-printed vascular graft implantation. After surgically free of the rabbit's common carotid artery and common jugular vein, the 3D-printed vascular graft was trimmed and inserted into the blood vessels. The blood recirculates at once after releasing the vascular clamps.

Far Infrared Radiation on the Arteriovenous Fistula Induces Changes in VCAM and ICAM in Patients on Hemodialysis

Kristine Lindhard,[1] Boye Jensen,[5] Brian L. Pedersen,[3] Christine L. Meyer-Olesen,[1] Marianne Rix,[3] Henrik P. Hansen,[1] Casper Schalkwijk,[4] Marjo van de Waarenburg,[4] James G. Heaf,[2] Ditte Hansen.[1] *[1]Herlev Hospital, Herlev, Denmark; [2]Sjaellands Universitetshospital Roskilde, Roskilde, Denmark; [3]Rigshospitalet, Kobenhavn, Denmark; [4]Universiteit Maastricht, Maastricht, Netherlands; [5]Odense Universitetshospital, Odense, Denmark.*

Background: The risk of stenosis in the arteriovenous fistula (AVF) in hemodialysis patients is substantial. Development of an AVF stenosis is due to neointimal hyperplasia. Far infrared radiation (FIR) is a non-invasive intervention with a potentially beneficial effect on AVF patency and survival, although the mechanism is not fully understood. The aim of this study was to investigate the effect of a single FIR treatment on inflammatory and vasodilating factors

Methods: Forty hemodialysis patients with an AVF from the Faith-in-Fistula-Trial were included in the study. Each patient was randomized to receive either FIR (FIR group) or no FIR (control group). Blood samples were drawn from the AVF arm and the non-AVF arm before (T0) and after (T40) treatment in both groups during a hemodialysis session. The changes (median [interquatile range]) in several inflammatory and vasodilating factors during FIR were explored in both groups.

Results: In the FIR group 19 patients were included, 21 patients in the control group. No differences in baseline characteristics between the groups were seen. After one FIR treatment, both Vascular Cell adhesion molecule (VCAM) and Intercellular adhesion molecule (ICAM) changed, although the change was significantly lower in the AVF arm compared to the control group. VCAM: -31.55 (-54.33;22.1) vs. -89.87 (-121.55;-29.31), p:0.005 and ICAM: -24.19 (-43.53;25.26) vs. -49 (-79.91;-11.58), p:0.02. Other factors, such as interleukines, nitric oxide and tumor-necrosis-factor 1 also declined, but with no significant differences related to FIR

Conclusions: A single FIR treatment attenuated the decrease in VCAM and ICAM in the AVF arm compared to a control group. These findings do not support the hypothesis of FIRs beneficial effects on the endothelium, although the long term effects of FIR on these factors and their beneficial effects are unknown.

The Association of Transition-to-Dialysis Planning and Healthcare Resource Use and Mortality in Patients with ESRD

Insiya B. Poonawalla,[1] Kanchan Barve,[2] Meghan M. Cockrell,[2] Amal Agarwal,[2] Adrianne W. Casebeer,[2] Yong Li.[1] *[1]Humana Healthcare Research, Inc., Louisville, KY; [2]Humana Inc, Louisville, KY.*

Background: The onset of ESRD is associated with poor outcomes and high mortality, and the role of transition-to-dialysis planning is not well understood. We evaluated the association between dialysis transition planning factors such as nephrologist care, vascular access placement, and place of index dialysis, with inpatient (IP) stays, emergency department (ED) visits, and mortality.

Methods: This retrospective study used the Humana Research Database to identify 7,026 patients, 19-89 years of age, diagnosed with ESRD between 1/1/17 and 12/31/17, enrolled in a Medicare Advantage Prescription Drug plan, with ≥12 months of continuous enrollment pre- and post-index date (i.e., first evidence of ESRD). Patients with a kidney transplant indication, hospice election, or dialysis pre-index were excluded. Transition-to-dialysis planning was defined as optimal, partial, or unplanned (Table 1). IP stays, ED visits, and mortality were evaluated within 12 months post-index.

Results: The cohort was 41% female, 66% White, with an average age of 70 years. An optimally planned, partially planned, and unplanned transition to dialysis occurred for 15%, 34%, and 44% of the ESRD cohort, respectively. Among patients with pre-index CKD stages 3a and 3b, 64%, and 55%, respectively, had an unplanned dialysis transition. For patients with pre-index CKD stages 4 and 5, 68% and 84%, respectively, experienced planning prior to dialysis initiation. In adjusted models, patients with partially or optimally planned transition to dialysis were 57% to 72% less likely to die, 20% to 37% less likely to experience an IP stay, and 80% to 100% more likely to experience an ED visit than patients with an unplanned transition. Higher ED utilization with planned transition was attributed to longer time to mortality, allowing more time for healthcare utilization.

Conclusions: A planned transition to dialysis was associated with improved outcomes and lower mortality. Targeting care coordination for patients with CKD stages 3a/3b may help slow disease progression and ensure a planned, safer transition to dialysis.

Table 1. Transition-to-Dialysis Planning Definitions

Optimal: Vascular access placed
Partial: Nephrologist care but no vascular access
Unplanned: Dialysis in IP stay or ED visit

PO1022

Prediction of Stenosis in Arteriovenous Fistula Using Video Image Analysis

Fansan Zhu,[1] Lin-Chun Wang,[1] Alhaji Cherif,[1] Ohnmar Thwin,[1] Lela Tisdale,[1] Xia Tao,[1] Paulo Paneque Galuzio,[1] Norbert Shtaynberg,[2] Dean C. Preddie,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Azura Vascular Care, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We developed a video image processing (VIP) technique with frequency domain analysis to predict stenosis in AVF. The study aimed to evaluate whether the degree of stenosis can be assessed using parameters from frequency domain signal analysis.

Methods: We employed VIP in 100 hemodialysis patients (age 63.3 ±14.1 years, 47 females) prior to endovascular arterio-venous fistula (AVF) interventions. A 1-minute video of the AVF area was recorded using a smartphone (Fig 1). We constructed time series based on pixel changes between two consecutive video frames (Fig 2-A) and used Fast Fourier Transform (FFT) to transform the time domain signals into the frequency domain (Fig 2-B). Parameters in the frequency domain included maximal (Max) and minimum (Min) amplitude, and frequency (F_{Max} and F_{Min}). ΔF was defined as F_{Min} - F_{Max}. M2 was calculated by the squared ratio of the Max-to-median magnitude. The degree of AVF stenosis (%ST) was determined by angiography, the access flow (AF) by thermodilution (HVT100; Transonic Systems Inc., Ithaca, NY, USA).

Results: Data from 98 patients were analyzed. %ST was categorized into three groups: 60% stenosis (n=8), 70-80% (n=76), and 90% (n=14). AF correlated with %ST. Max, F_{Max}, F_{Min} and ΔF were associated with %ST (Table 1). An algorithm was developed to predict degree of %ST based on patient characteristics and parameters of frequency domain analysis. In the respective three %ST groups the sensitivities to detect AVF stenoses were 88%, 86% and 100%, and the specificities 99%, 82% and 98% (Table 1).

Conclusions: VIP applied to videos taken with a smartphone may provide a contact-free method to estimate the degree of AVF stenosis. Validation studies in independent cohorts are needed to further assess the diagnostic capability of the proposed method.

Catheter-Related Bloodstream Infection Incidence and Associated Mortality Risk: Analysis of Merged USRDS-Medicare Claims

Kenneth Massey,[1] Krithika Rajagopalan,[2] Srinivasan Rajagopalan,[2] Aaron Grossman,[2] Paul Chew.[1] *[1]Cormedix, Berkeley Heights, NJ; [2]Anlitiks Inc, Dover, MA.*

Background: Despite policy and provider initiatives, nearly 80% of end-stage-renal-disease (ESRD) patients initiate hemodialysis (HD) with a central venous catheter (CVC). However, CVCs may elevate risk of catheter hub contamination resulting in catheter-related blood stream infections (CRBSIs) and potentially serious consequences. This analysis aims to estimate the incidence, risk, and associated mortality of CRBSIs among CVC-dependent HD patients in the US.

Methods: A propensity score matched case-control analysis of 2013-2017 linked data from the United States Renal Data System (USRDS), dialysis organizations (i.e., CROWNWeb), and Medicare claims was conducted. Occurrence of CRBSI and associated mortality among incident CVC-dependent HD patients between 2014-2016 with a 1-year pre- and ≥1-year post-index were assessed. CRBSI case group index date was the first date of occurrence of any of the following post CVC insertion: ICD-9/10-CM 999.32, T80211x; 999.31, T80219x, T80218x and sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median days to CRBSI reported in CRBSI-case group). Frequency, mean, median, and chi-square and *t*-tests assessed group differences. Adjusted cox proportional hazards models examined time to CRBSI and time to mortality post CRBSI.

Results: Of the 55,727 CVC-dependent HD patients (mean age 67.8, 45% female), nearly 29% (n=15,882) developed a CRBSI (median time, 69 days); 54% (n=8,393), 67% (n= 10,327), and 80% (n=12,705) occurred within 90, 180 and 365 days of CVC insertion, respectively. After CRBSI occurrence, 40% and 50% died within 60 days and 180 days, respectively. CRBSI patients also had a significantly lower median survival (25.1 vs. 37.3 months) compared to non-CRBSI patients [hazard ratio: 0.74, 95% CI: 0.71-0.76].

Conclusions: CRBSIs occur in a third of CVC-dependent HD patients, with over half of the initial infections occurring within 90 days of CVC insertion. Patients with CRBSI had a higher risk of death compared to patients without CRBSI; with a 40% mortality within 60 days post-CRBSI.

PO1024

The Association of Incremental Hemodialysis with Complications of Arteriovenous Access

Mengjing Wang, Jing Chen. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Protection of arteriovenous vascular access by incremental hemodialysis was not examined. We conducted a historical cohort study to investigate the association of incremental hemodialysis with complications of arteriovenous access among incident hemodialysis patients.

Methods: Incident hemodialysis patients from Huashan hospital in Shanghai, China, over the period of 2012 to 2019 were enrolled and followed every three months. Complications of arteriovenous access included surgical interventions for failure, stenosis, or thrombosis. The risks of time to first complication of arteriovenous access for incremental versus conventional hemodialysis were examined by cox proportional hazards models. The risk of time to recurrent complications of arteriovenous access was examined by Andersen-Gill model (AG model) and Prentice, Williams and Peterson model (PWP-TT model).

Results: Of the 113 patients enrolled in the study, 45 patients underwent incremental and 68 conventional hemodialysis. The incidence rates of arteriovenous access complications between groups were 8.5 and 29.8 per 100 person-years, respectively. A decrease in risk for having an arteriovenous access complication was also observed for incremental hemodialysis by Cox models with an adjusted HR of 0.26 (95% CI, 0.08-0.82). Moreover, the adjusted risk of recurrent complications of arteriovenous access for incremental hemodialysis decreased in AG model (HR, 0.27; 95% CI, 0.10 – 0.74; $P = 0.01$) and in PWP-TT model (HR, 0.31; 95% CI, 0.12 – 0.80; $P = 0.02$) after multiple adjustments.

Conclusions: Incremental hemodialysis was significantly associated with reduced complications of arteriovenous access.

Vascular Access in Kidney Transplant Patients with Allograft Failure Returning to Hemodialysis

Molly Fisher,[1,2] Anirudh R. Gone,[1] Linda Mathew,[1] Crystal K. Jobson,[1] Enver Akalin,[1,2] Michele H. Mokrzycki,[1,2] Tanya S. Johns.[1,2] *[1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Central vein catheters (CVC) are the predominant vascular access (VA) in incident hemodialysis (HD) patients and are associated with worse outcomes compared to arteriovenous (AV) access. Limited data exist on VA type and association with outcomes in kidney transplant recipients (KTR) with allograft failure. We aimed to determine factors associated with VA type among KTR with allograft failure who return to HD.

Methods: We performed a retrospective study of 147 KTR >18 years with allograft failure between 2010-2021 at an academic hospital in the Bronx, NY. KTR with immediate allograft failure or <1 month of HD following allograft failure were excluded. Data was collected on pre-transplant dialysis modality, vintage, and VA type. Data at allograft failure included sociodemographics, comorbidities, clinic visits, VA type. Descriptive analyses and logistic regression were performed to evaluate factors associated with VA among KTR who return to HD.

Results: At allograft failure, mean age was 53 years (SD 15), 62% were men and 46% were of Black race. Pre-transplant, 91.8% patients were on HD, 2.7% were on peritoneal dialysis (PD), and 5.5% were not on dialysis. Mean vintage was 4.6 years (SD 4.4). Pre-transplant VA included AV access in 87.7% and CVC in 4.1% of patients. At allograft failure, 82.3% and 17.7% KTR initiated HD with an AV access and CVC, respectively. Compared to pre-transplant HD patients, those on PD or who received a preemptive transplant were less likely to initiate HD with an AV access at time of allograft failure (80.6% vs 50% vs 12.5%, p<0.001). KTR were 19% less likely to initiate HD with an AV access for each year increase between the time of transplant and allograft failure (OR 0.81, 95% CI 0.69-0.94). Sociodemographics, comorbidities and number of clinic visits 1 year prior to allograft failure were not associated with VA. One year mortality was 10.7% in KTR initiating HD with a CVC vs 3.4% in those with an AV access (p=0.12).

Conclusions: The majority of KTR with allograft failure returned to HD with an AV access. CVC use was higher in those with longer allograft survival, previously on PD or who received a preemptive transplant, highlighting a need for transition of care optimization. Larger studies are needed to determine if VA type is associated with mortality in this population.

PO1027

Reusing Occluded Veins: Inside-Out Central Venous Access for Hemodialysis, Our Institutional Experience

Emad A. Chishti, Sayee Sundar Alagusundaramoorthy. *University of Kentucky Medical Center, Lexington, KY.*

Background: Central venous occlusion is a challenge in end-stage renal disease (ESRD) patients dependent on hemodialysis. The inside-out central venous access (IOCVA) procedure is an established method of re-using occluded veins.

Methods: Retrospective single-center study examining characteristics of patients with ESRD who underwent IOCVA between 01/01/2017 – 05/01/2021. All procedures were performed with moderate conscious sedation by an interventional cardiologist or nephrologist.

Results: 46 IOCVA procedures were performed in 39 ESRD patients. All procedures were performed to re-use the occluded right internal jugular vein (RIJ) for tunneled dialysis catheter placement. Mean patient age was 58 ± 14.6 years. 20 (51.3%) patients were male. Hypertension and diabetes were comorbid conditions in 29 (74.4%) and 20 (51.3%) patients, respectively. A total of 7 (17.9%) patients had prior kidney transplant.

The average number of prior vascular accesses (defined as venous access or arteriovenous fistula/graft) in patients prior to IOCVA was 2.6 ± 1.7 (range 1-9). 9 (23.1%) had two prior accesses, and 30 (76.9%) had >3 prior accesses. 5 (12.8%) patients had >1 prior IOCVA procedure. 5 (12.8%) patients had complete superior vena cava occlusion. 17 (43.6%) patients had failed AVF/AVG and 2 (5.1%) had failed translumbar venous access. Technical success rate was 100% with no complications.

Conclusions: The RIJ vein is the most effective and durable site for long-term hemodialysis access. Occlusion, stenosis of this vein can lead to a downward spiral of access crisis with venous exhaustion resulting in trans-lumbar or trans-hepatic catheter placement for dialysis. These approaches are associated with high rates of dysfunction as well as infection, catheter migration and thrombosis. The transhepatic approach can also cause life-threatening intraperitoneal hemorrhage. The use of IOCVA alleviates the need to sacrifice subsequent veins and allows for the occluded RIJ to be re-accessed as many times as needed via the femoral vein. Our data provides further evidence in support of the safety and efficacy of IOCVA for long-term hemodialysis access in ESRD patients.

PO1028

Real-World Efficacy of Paclitaxel-Coated Balloons (P-DCB) in the Treatment of Initial and Recurrent Arteriovenous Fistula (AVF) Stenosis

Richard S. Fernandes Almeida, Min S. Cho, Pye Oo, Muhammad Sohaib Karim, Conrad D. Pun, Micah R. Chan, Brad C. Astor, Ali I. Gardezi. *University of Wisconsin-Madison, Madison, WI.*

Background: A 2-year randomized trial has shown variable efficacy of P-DCB in AVF angioplasty when compared to non coated balloons (NCB). A subsequent study at our center showed the average time to lesion recurrence after P-DCB AVF angioplasty to be significantly shorter than NCB. Selection bias of using P-DCB more often in frequently recurring lesions was attributed to this observation. Our study was conducted to evaluate if use of P-DCB has better outcomes in initial lesions.

Methods: We retrospectively reviewed charts of 277 AVF balloon angioplasties performed over a 19 month period (July 2018 through January 2020). Patients were stratified into 4 groups: P-DCB initial lesions (n=26), NCB initial lesions (n=95), P-DCB recurrent lesions (n=46), NCB recurrent lesions (n=110). Patients were followed until recurrence or until January 2021 for lesions that did not recur.

Results: Groups were similar in terms of baseline characteristics. In the initial lesion group, 15 of 26 patients (57.69 %) treated with P-DCB and 64 of 95 patients (67.3 %) treated with NCB had recurrence during the follow up period of 1 year. There was a trend toward less recurrence in the P-DCB group but it did not reach statistical significance. (p=0.358). In the recurrent lesion group, 34 of 46 patients (73.9 %) treated with P-DCB and 71 of 110 patients (64.5 %) treated with NCB had recurrence during follow up. The difference was not statistically significant. (p=0.255).

Conclusions: There is no significant difference in recurrence rates for initial or recurrent lesions between the 2 balloons. However, there is a trend towards lower recurrence rates with P-DCB in initial lesions. There may be more benefit in treating initial lesions with P-DCB compared to recurrent lesions but further studies with larger number of patients are needed to substantiate these findings.

Hymes,[1] John W. Larkin,[1] Len A. Usvyat,[1] Franklin W. Maddux.[4] *[1]Fresenius Medical Care, Waltham, MA; [2]Azura Vascular Care, Malvern, PA; [3]Renal Research Institute, New York, NY; [4]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany.*

Background: Over 23% of primary arteriovenous fistula (AVF) placements fail for patients on chronic hemodialysis (HD); interventional procedures can be performed to prevent fistulas from failing completely or to correct the malfunction of fistulas (Al-Jaishi AJKD 2014). We developed a Machine Learning (ML) model to predict the likelihood of an AVF failure within 30 days.

Methods: We used data from a cohort of HD patients with a functioning AVF treated at an integrated kidney disease company from Jan-Dec 2018 to develop an ML model (XGBoost) that predicts AVF failure within 30 days from the last use. AVF failure was defined as a status change (active to permanently/temporarily unusable), or if an interventional procedure (IP) was performed for the first time. Model used approximately 2400 variables, which included baseline and derived lab values, treatment data, clinical notes entered by physicians and dialysis staff, and care providers. The cohort was randomly split into 60% training, 20% validation, and 20% test datasets.

Results: We identified a cohort of 15,449 HD patients actively using an AVF to develop the ML model. We achieved area under the receiver operating characteristic curve as 0.76 in the test dataset. When using a 0.5 probability threshold for classifying predictions as positive or negative for AVF failure in the next 30 days, the model showed suitable performance with precision as 0.57, and recall as 0.29. Variables such as prediction score from clinical notes, days since last treatment, and days since fistula was placed had a positive relationship with the fistula failure prediction whereas comorbidity counts had a negative relationship with the failure of fistula (**Figure 1**).

Conclusions: Our AVF failure prediction model appears to have the potential to provide an early identification of an access that is likely to malfunction. Further evaluation and clinical testing is warranted to validate the ML model.

Artificial Intelligence to Evaluate Vascular Access Aneurysms in Hemodialysis Patients

Hanjie Zhang,[1] Dean C. Preddie,[2] Warren S. Krackov,[2] Murat Sor,[2] Peter Waguespack,[4] Zuwen Kuang,[4] Xiaoling Ye,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Azura Vascular Care, Malvern, PA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: Vascular access aneurysms are a frequent finding in hemodialysis patients with arterio-venous (AV) fistulas and grafts. Of great concern is aneurysm rupture that may result in fatal hemorrhage. To that end we used artificial intelligence (AI) to automatically evaluate vascular access aneurysms.

Methods: We collected images of a diverse range of AV vascular accesses using mobile devices. Vascular access experts adjudicated the images and diagnosed the severity of AV fistula and graft aneurysms. We then randomized the images for training (70%) and validation (30%). We trained a convolutional neural network (CNN) utilizing Amazon SageMaker platform. CNN performance was measured by the area under the receiver operating characteristics (ROC) curve in the validation images.

Results: We collected 1,341 AV access images in patients dialyzed in 20 Renal Research Institute clinics in six U.S. states. The adjudication of images identified 1,093 not advanced and 248 advanced aneurysms; examples are shown in Figure 1. With the validation images, we achieved an area under the ROC curve of 0.96. Considering different probability threshold for advanced aneurysm, if threshold is 0.37, we achieved sensitivity of 80%, specificity of 95%, false positive rate of 5%, precision of 79%, if threshold is 0.7, sensitivity of 66%, specificity of 99%, false positive rate of 1%, precision of 92%.

Conclusions: Our solution of applying advanced AI technologies achieved very high sensitivity, specificity, precision, and a low false positive rate. The CNN could assist the clinical staff with actionable information and improve clinical outcomes.

Evaluation of a Wearable Device for Continuous, Noninvasive Monitoring of Hematocrit Levels in Hemodialysis Patients

David J. Kuraguntla, Forrest Miller. *Alio, San Francisco, CA.*

Background: Maintenance of euvolemia is a major challenge for hemodialysis patients, who account for a combined 6.5M annual hospital days. Clinical outcomes could be improved, and healthcare costs lowered, by enabling better management of fluid status and anemia, which is common among ESRD patients. This study presents a novel wearable device, SmartPatch, that uses multi-wavelength photoplethysmography (PPG) and other sensors to measure blood hematocrit (Hct), a key metric for monitoring fluid status and anemia. The SmartPatch is a component of a novel Remote Monitoring System (RMS) that facilitates secure data transmission and analysis and generates actionable alerts. Data demonstrating the feasibility of the RMS were previously presented at Kidney Week 2019 (Kuraguntla et al.). The aim of this study was to evaluate the system's ability to accurately and precisely measure Hct in a real-world dialysis setting.

Methods: 14 ESRD patients with arteriovenous fistulae currently undergoing dialysis were recruited to participate in this study. Each of these patients had a SmartPatch device placed on the skin over their fistula at each of three dialysis sessions two weeks apart. Reference Hct measurements were taken immediately before and after the session, timed to coincide with SmartPatch data recordings. A total of 83 sets of multi-channel PPG data were recorded and analyzed to determine the accuracy and precision of Hct measurement.

Results: The RMS measured Hct with root-mean-square error (RMSE) of 2.13 Hct compared to reference values obtained from a Sysmex XN-1000 blood analyzer. The standard deviations for each read on the same patient–with the same device–were computed and averaged, weighted by group size, as a measure of precision. The RMS measured Hct with a mean standard deviation of 1.15 Hct. These error and standard deviation values compare favorably to available point-of-care devices like the HemoCue Hb 201+, which has been reported to measure Hct with a mean of 4.32-4.81 Hct and standard deviation of 1.56-3.88 Hct.

Conclusions: The results of this study illustrate the ability of the wearable SmartPatch to non-invasively measure blood Hct in ESRD patients with AV fistulae, to a degree of accuracy and precision that may outperform available point-of-care methods. This study also demonstrated the efficacy of the end-to-end Remote Monitoring System.

PO1032

Impact of a Change in Vascular Access Flow Volume After Percutaneous Transluminal Angioplasty on Cardiac Function

Koji Hashimoto, Makoto Harada, Yosuke Yamada, Yuji Kamijo. *Shinshu Daigaku Igakubu Fuzoku Byoin, Matsumoto, Japan.*

Background: Vascular access (VA) is necessary for patients on hemodialysis, and percutaneous transluminal angioplasty (PTA) is a useful treatment for maintaining VA function. PTA immediately increases the VA flow volume, which can affect cardiac function. We investigated the relationship between changes in VA flow volume and cardiac function in patients who underwent PTA.

Methods: This was a single-center retrospective observational study, including patients who underwent PTA between June 2016 and August 2016. VA flow volume and cardiac function were measured by sonography before and 1 hour after PTA.

Results: This study included 50 PTA procedures in 50 cases. PTA significantly increased the median VA flow volume from 445 (range, 150–1229) to 725 (350–1268) mL/min. Although the ejection fraction and diameter of the inferior vena cava were unchanged, the cardiac output (CO) and cardiac index increased significantly in most cases. Surprisingly, the CO was obviously decreased in 18% of cases despite the increased VA flow volume. In this atypical group, a high CO before PTA was found to be a significant factor for the decrease in CO by PTA.

Conclusions: In most cases, both VA flow volume and CO were increased by PTA, whereas in some cases, the CO was decreased despite increase in VA flow volume. This atypical phenomenon may be due to the insufficient adaptive response in the peripheral artery and heart and could predict risks for future cardiac events. Therefore, it is important that such patients are carefully followed up.

PO1033

Predicting Arteriovenous Graft Failure with Sound Signatures in Patients on Hemodialysis

Tiffany W. Shien,[1,2] Juan-Wei Xu,[3] Yi-Ren Yeh,[3] Hugo Y. Lin.[1,2] *[1]Kaohsiung Municipal United Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University, Kaohsiung, Taiwan; [3]National Kaohsiung Normal University - Yanchao Campus, Kaohsiung, Taiwan.*

Background: The fast-growing prevalence of end stage renal disease leads to an increasing burden of population requiring dialysis worldwide. Specifically, patients on hemodialysis face the problem of maintaining their vascular accesses. Unfortunately, occurrence of stenosis and clots is not uncommon, especially in arteriovenous grafts (AVG). Graft longevity can be improved by effectively detecting and preventing these circumstances. The aim of this study is to develop a portable recording device that detects stenosis by extracting information from blood flow sounds.

Methods: Blood flow sounds were collected at four different locations on the arm, including venous and arterial ends of arteriovenous access. Measurements were conducted weekly, with four one-minute recordings per patient. A logistic regression model is used to analyze sound data. Recordings obtained prior to percutaneous transluminal angioplasty (PTA) procedures were labeled abnormal and those after PTA were labeled normal. Extracted features from each labeled recording include energy, spectrum, mel-frequency cepstrum, and chroma, as shown in Figure 1.

Results: In total, we have 109 labels, 25 of which are abnormal cases. Note that each case contains 4 separate recordings. For evaluation purposes, we randomly chose 75% of the labels as training cases and used the rest as testing cases. Each random trial compares single-location detection models to one integrated model, which combines data from all four locations. The trial was repeated 100 times. Our results in Table 1 indicate that arterial sounds are more informative than venous sounds in detecting stenosis. Note that the integrated model also significantly outperforms the other single-location models.

Conclusions: Our proposed model shows excellent performance in screening for AVG failure. This algorithm has potential to provide reliable and reproducible detection of vascular access abnormalities, optimizing AVG outcome and management for clinicians and patients.

Funding: Clinical Revenue Support

Type I and Type II error rate of detection models

Model	Venous end	Arterial end	Graft (v)	Graft (a)	Integrated model
Type I error rate	0.516	0.279	0.513	0.298	0.124
Type II error rate	0.278	0.118	0.267	0.161	0.060

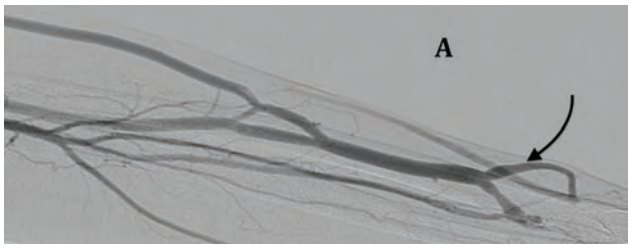
A Novel Method for Ligation of Accessory Veins: A Case Series of Eight Patients

Khaled Boubes,[1] Nabil J. Haddad,[1] Anil K. Agarwal.[2] *[1]The Ohio State University, Columbus, OH; [2]VA Central California Health Care System, Fresno, CA.*

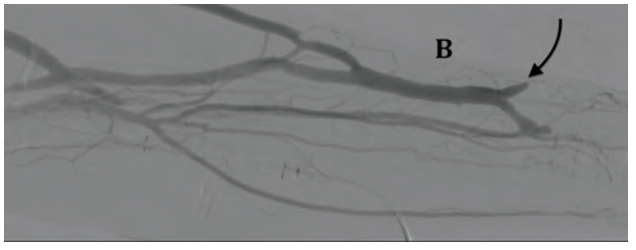
Introduction: Accessory veins are a common cause for decreased blood flow through the body of arteriovenous fistulae (AVF). A common practice is to have these ligated surgically through a cut-down procedure. Alternatively, these can be blocked by coiling, embolization, or by percutaneous ligation. We present a case series where accessory veins were ligated percutaneously under direct ultrasound (US) visualization.

Case Description: A total of 8 patients underwent percutaneous accessory vein ligation from Dec 2020 through May 2021. None had any immediate complications. Cessation of blood flow through the accessory vein was confirmed by color doppler ultrasonography and by angiography. Technique description: After identifying the accessory vein on angiography and its impact on the flow through the AVF, the vein is then identified using the US. The location to ligate the vein is then chosen as close as possible to the vein "take-off". Using a 4-0 absorbable suture and under direct US visualization, the needle is inserted from one side of the vein and passed underneath to come out from the other side. Then, the needle is flipped and inserted back subcutaneously, passing above the vein to come out eventually next to the initial insertion site. The suture is then tied firmly. Depending on the size and location of the vein, another suture can be done in a similar fashion a few millimeters away. Color doppler is then used to detect any flow through the vein. Confirmation of the cessation of flow can also be achieved by repeat angiography.

Discussion: Percutaneous ligation of the accessory veins is a technique that saves the patients from undergoing an open surgical intervention. Utilizing the US for direct visualization of the needle during the procedure enhances its safety and efficiency.



Flow through the accessory vein before the ligation.



Cessation of the blood flow through the accessory vein after the ligation.

Feasibility of Treating Stenotic Fistula Lesions with a Drug-Coated Balloon Prior to Using a Standard High Pressure Balloon

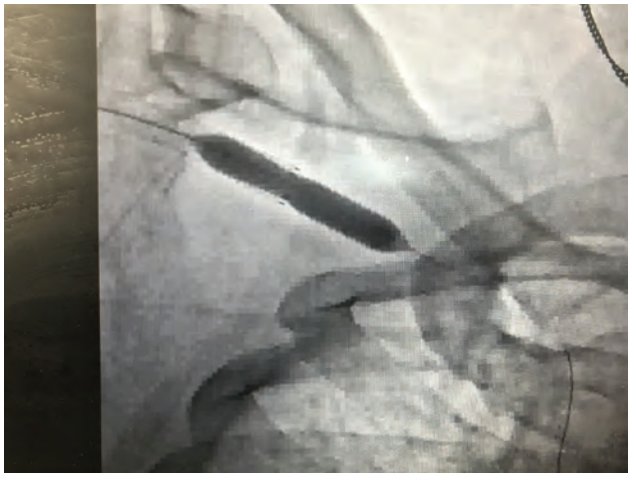
Sylvester Barnes.[1,2] *[1]Edward Hines Junior VA Hospital, Hines, IL; [2]Loyola University Chicago, Chicago, IL.*

Background: Hemodialysis access maintenance is a major cost expenditure for dialysis care. Patients often require multiple procedures per year, often treating the same access lesion in a AVF / AVG. A large proportion of stenotic lesions develop secondary to neointimal hyperplasia. Standard treatment has been angioplasty using high pressure non-compliant balloons. Recently drug coated balloons (DCB), coated with the medication paclitaxel; to help decrease neointimal hyperplasia, have been used in dialysis access treatment. The safety profile and efficacy have been proven to decrease lesion reoccurrence at 6 months when compared to regular angioplasty. Traditionally the recommendation for use of DCB is to follow after the lesion has been primarily dilated with a high-pressure balloon (HPB).

Methods: For DCB use the manufacture recommends pretreatment of the lesion with a HPB followed by secondary DCB treatment. This Arthur decided to modify the technique and treat lesions needing angioplasty with DCB first (example in figure 1) and only secondary treatment with HPB if there was not sufficient resolution of the lesion / ballon inflation to acheive less than 30% residual stenosis. Observational data is being tracked for patients undergoing fistulograms to provide a single center observational prospective cohort to look into this issue.

Results: Currently 11 patients with 15 total lesions have undergone this modification of treatment in the past 9 months, with 3 of the 11 patients having repeat fistulograms post treatment. Nine of the 11 patients required no HPB follow up. One of the 11 patients suffered a cephalic arch rupture and required stent graft placement.

Conclusions: Early data from this observational study shows that treatment of a stenotic lesion using a DCB as the only treatment is effective in the majority of cases to achive full lesion angioplasty. Preliminary results indicate no change in long term efficacy in the DCB lesion treatment.



PO1036

Predictors of Vascular Access Thrombosis in Maintenance Hemodialysis Patients: An Historic Cohort Study

Rita Veríssimo,[1,2] Luís Leite de sousa,[1,3] Tiago J. Carvalho,[1,4] Artur P. Mendes.[1,2] *[1]DaVita Vascular Access Center - Lisbon, Lisbon, Portugal; [2]DaVita Sacavém Hemodialysis Unit, Lisbon, Portugal; [3]DaVita Sintra Hemodialysis Unit, Lisbon, Portugal; [4]DaVita Cascais Hemodialysis Unit, Lisbon, Portugal.*

Background: Vascular access (VA) thrombosis is a known complication in patients with end-stage kidney disease on hemodialysis (HD), but its risk factors are not completely established. We performed a study with the aim of ascertaining risk factors for VA thrombosis.

Methods: A multicenter retrospective cohort study was performed in three HD units to determine VA thrombosis rate and associated risk factors in maintenance HD patients, from July 2019 to April 2021. Descriptive statistics were calculated and expressed as median (IQR) or count (%). Univariate and multivariate logistic regression was used to calculate the adjusted odds ratio (aOR) with 95% CI for the variables associated with VA thrombosis.

Results: From a total of 178 maintenance HD patients, there were 30 (16.9%) VA thrombosis during follow-up. Our cohort had a median of 71 years (61-80), 59,6% (n=106) were male, were on HD for a median of 63.52 months (37.58-98.87), 37.6% (n=67) had diabetes, 60.1% (n=107) cardiovascular disease and 55.6% were on anticoagulant or antiplatelet agents. As to the VA, 87.1% (n=155) had arteriovenous fistulas (AVFs) and 28.1% (n=50) had history of previous percutaneous or surgical interventions. When comparing cases that led to thrombosis to VAs that maintained patency, thrombosis was more likely in arteriovenous grafts (AVGs) versus AVFs (60.9% vs 19.3%, p< 0.001), in VAs that had previous percutaneous or surgical interventions (34% vs 10.2%, p<0.001), had a VA flow (Qa) slope ≥ 25% or Qa value < 500ml/min, excluding radiocephalic AVFs (30.4% vs 11.7%, <0.001) and those with spKt/V < 1.4 (40% vs 11.2%, p<0.001). Multivariate analysis risk factors independently associated with VA thrombosis were AVGs [aOR 13.35 (4.38-40.74), p<0.001], Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs [aOR 5.00 (1.76-14.18), p=0.003], and spKt/V <1.4 [aOR 8.23 (2.90- 23.35), p<0.001]. The model had a Nagelkerke R2 of 42.1%, Hosmer-Lemeshow goodness-of-fit test performed well ($\chi 2$= 0.215, df=3, p=0.975) and showed very good discriminative ability [AUROC (95% CI) 0.85 (0.77-0.94)].

Conclusions: Our study showed AVGs, Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs, and spKt/V < 1.4 were independent predictors of VA thrombosis. Interestingly, patients' demographic characteristics and comorbidities were not associated with VA thrombosis.

PO1037

Efficacy and Safety of Plastic Cannulae Compared with Metal Needles in the Initial Use of an Arteriovenous Fistulae in Incident Hemodialysis Patients: A Randomized Controlled Study

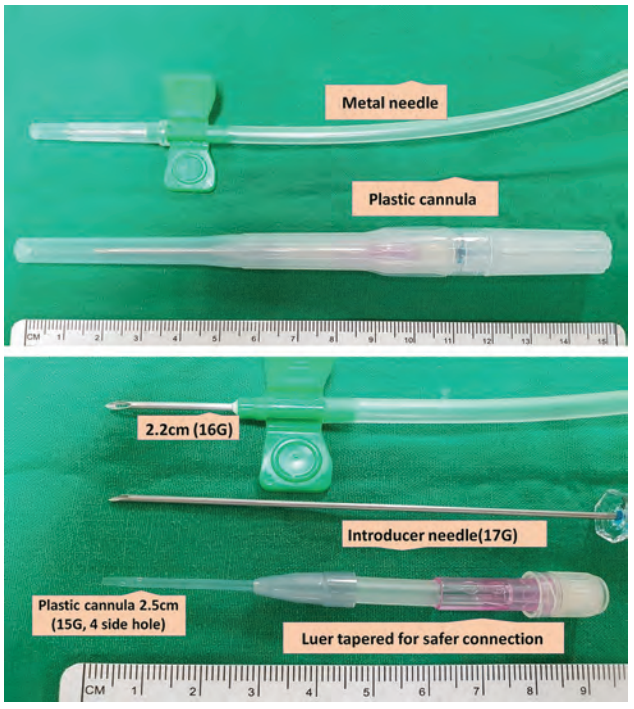
Sung gyun Kim, Hoi Woul Lee, Jwa-kyung Kim. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: Successful cannulation of an arteriovenous fistula (AVF) is important in patients starting hemodialysis (HD). Metal needles have been used for decades, but the usefulness of plastic cannulae has recently been demonstrated as a new technique.

Methods: As a prospective, randomized study, eligible patients were randomized into two groups in a 1:1 ratio (n=45/group). Maturation of the AVF was confirmed using Doppler ultrasound. The primary endpoint was the initial cannulation failure rate, defined as the failure of successful completion of three consecutive dialysis sessions. The secondary endpoints were time for hemostasis at the end of HD, degree of patients' pain, degree of cannulation difficulty felt by the nursing staffs, and achieving optimal HD adequacy.

Results: The mean time from AVF creation to the first cannulation was 48.1±16.7 days. A total of 17 cases of cannulation failure occurred, and the failure risk tended to be higher in the metal needle group than the plastic cannula group (HR 2.6, 95% CI 0.95-7.41) after adjusting for age, gender, comorbidities, and location. The overall incidence of vessel injury was higher and time for hemostasis was significantly longer in the metal group than the plastic group. The use of plastic cannula was associated with better HD adequacy compared to metal needle. However, the patients' pain score (*P*=0.004) and nursing staff's cannulation difficulty score (*P*=0.084) were higher in the plastic group, emphasizing the great importance of practice using plastic cannulae.

Conclusions: The vascular outcomes of plastic cannulae were much favorable compared to metal needles in incident HD patients. The use of plastic cannulae could be a new and innovative way to improve the quality of dialysis.



PO1038

Alignment Between Patient and Provider Perspectives on Hemodialysis Vascular Access Decision-Making: A Qualitative Study

Angela R. Schneider,[1] Pietro Ravani,[1] Kathryn M. King--Shier,[1] Robert R. Quinn,[1] Jennifer M. MacRae,[1] Matthew J. Oliver,[3] Swapnil Hiremath,[2] Matthew T. James,[1] Meghan J. Elliott.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: Recent updates to the KDOQI Clinical Practice Guideline for Vascular Access emphasize attaining the "right access, in the right patient, at the right time, for the right reasons". Yet, how patients, their caregivers, and healthcare providers integrate medical factors with care preferences in patient-centered vascular access decision making is unknown. We sought to explore the extent to which these diverse perspectives align in hemodialysis vascular access selection.

Methods: In this qualitative descriptive study, we purposively sampled patients receiving maintenance hemodialysis via an arteriovenous fistula or catheter, their informal caregivers, and healthcare providers. We conducted semi-structured interviews in person or by telephone with 19 patients, 2 caregivers, and 21 healthcare providers (7 hemodialysis nurses, 6 vascular access nurses, 8 nephrologists). We coded transcripts in duplicate and generated themes through an inductive, content analysis approach.

Results: While participants across roles shared perspectives related to vascular access decision making, we identified several areas where views diverged. Participants acknowledged the importance of decisional timing and readiness, the iterative nature of decision making, and a desire for vascular access selection to be a shared decision. Perspectives differed in the following key aspects: 1) priorities for vascular access type – providers' preferences for fistulas and physiological optimization contrasted with patients' focus on quality of life; 2) provider involvement in the decision – patients desired guidance from their trusted providers, whereas care providers tried to avoid unduly influencing the decision; 3) informational needs – tools and resources offered by the care team may not meet patients' need for pragmatic, experiential knowledge about vascular access options.

Conclusions: While patients and providers identified common perspectives related to the nature and timing of the vascular access decision, conflicting priorities and preferences may impact the decisional outcome. This study highlights opportunities to address decisional conflicts and enable shared decision making in vascular access selection.

PO1039

Vascular Access Selection Among People Receiving Hemodialysis: A Qualitative Study of Shared Decision-Making

Meghan J. Elliott,[1] Pietro Ravani,[1] Robert R. Quinn,[1] Jennifer M. MacRae,[1] Shannan Love,[1] Matthew J. Oliver,[3] Swapnil Hiremath,[2] Matthew T. James,[1] Kathryn M. King--Shier.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: The vascular access decision process for people receiving maintenance hemodialysis involves weighing the likelihood of having a functional access with its associated risks. How patient and clinician preferences are integrated alongside best evidence to make joint vascular access decisions is unclear. We aimed to explore how such decisions are made from the perspectives of patients, their caregivers, and their kidney care providers.

Methods: In this qualitative descriptive study, we purposively sampled patients receiving in-centre hemodialysis for >3 months via either an arteriovenous fistula or a central venous catheter, their informal caregivers, and their hemodialysis care providers. We conducted semi-structured interviews by telephone or in person with 19 patients, 2 caregivers, and 21 healthcare providers (8 nephrologists, 7 hemodialysis nurses, 6 vascular access nurses). We coded transcripts in duplicate and generated themes through an inductive, thematic analysis approach.

Results: Participants described a decisional hierarchy, whereby decisions regarding vascular access were predicated on upstream decisions (i.e., dialysis initiation, transplantation, home dialysis) that were preference sensitive and prioritized over vascular access type. Upon reaching a decision for hemodialysis, vascular access decision making was influenced by the following: 1) preferences for kidney replacement therapy, including anticipated timeline to transplantation or transition to home dialysis modalities; 2) urgency and timing of dialysis need, where urgent starts undermined expressed preferences; 3) limitations of individualized decisions, as when preferences and practicalities diverged; 4) occasions to re-visit the vascular access selection; and 5) availability of support for vascular access decision making and the decisional outcome.

Conclusions: Although patients and care providers prioritized upstream decisions, several influences on vascular access decision making were identified once the decision for hemodialysis was made. These findings can inform approaches to integrating shared decision making in dialysis and vascular access selection.

PO1040

Racial Disparities in Arteriovenous Fistula Use Among Hemodialysis Patients: The Role of Vascular Surgeon Availability

Yi Zhang,[1] Mae Thamer,[1] Timmy C. Lee,[2] Deidra C. Crews,[3] Michael Allon.[2] *[1]Medical Technology and Practice Patterns Institute, Bethesda, MD; [2]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [3]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Factors contributing to persistent racial disparities in the use of arteriovenous fistulas (AVF) among HD patients are unclear. A recent study reported significant geographic variation in the availability or supply of vascular access (VA) surgeons. We examined whether racial disparity in AVF use is affected by VA surgeon availability.

Methods: Using CROWNWeb and Medicare claims data from the US Renal Data System (USRDS), longitudinal competing risk analyses of all adult outpatients initiating HD with a central venous catheter (CVC) in 2016 and 2017 (n=103,286) were performed. Likelihood of successful AVF use was compared between Black and White patients after adjusting for VA surgeons supply, calculated as the number of surgeons normalized by the number of HD patients in each hospital referral region (HRR).

Results: Patient, facility, and area characteristics varied significantly among different levels of surgeon supply. At month 12 of hemodialysis, 40% of patients who initiated with a CVC had successful AVF use. Compared to the 1st quartile of surgeon supply, higher supply levels were associated with modestly increased likelihood of AVF use: 3% (95% CI 0.4-6.1%), 4% (95% CI 0.7-6.9%, and 3% (0.0-6.1%) for 2nd, 3rd, and 4th quartiles, respectively. However, residing in areas with a greater surgeon availability was not associated with less racial disparity in likelihood of AVF use (Figure 1). Specifically, compared to White patients, Black patients were 10% (95% CI 7 to 13%) and 8% (95% CI 5 to 11%) less likely to have successful AVF use in low and high surgeon supply areas, respectively.

Conclusions: VA surgeon supply was not associated with racial disparities in AVF use among patients initiating with a CVC. Additional studies of patient, provider, practice, and regional factors are needed to identify relevant factors to mitigate lower rates of AVF use among Black HD patients.

PO1041

Feasibility of Creation of an Endovascular Arteriovenous Fistula in Patients Undergoing Preoperative Vascular Mapping

Alian Albalas, Salam Madi, Ammar Almehmi, Michelle L. Robbin, Michael Allon. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: The endovascular arteriovenous fistula (endoAVF), a novel percutaneous technique of AVF creation, was approved by the Food and Drug Administration in 2018, and has been placed in a small number of U.S. hemodialysis patients. It is unknown how often patients with advanced chronic kidney disease have vascular anatomy suitable for endoAVF creation. The goal of the present study was to determine the proportion of patients with a vascular anatomy suitable for endoAVF creation, and to assess patient characteristics associated with such suitability.

Methods: All patients referred for vascular access placement at a large academic medical center underwent standardized preoperative sonographic vascular mapping to assess suitability for an AVF. During a two-year period (March 2019 to March 2021), we assessed the suitability of the vessels for creation of an endoAVF. We then compared the demographic characteristics, comorbidities, and vascular mapping measurements between patients who were or were not suitable for an endoAVF.

Results: During the study period, 223 patients had preoperative vascular mapping results suitable for creation of a surgical AVF. Of these, 140 patients (63%) were also suitable for an endoAVF. Patients with a vascular anatomy suitable for an endoAVF were younger (age 55±15 vs 60±14 years, p=0.01), but similar in sex, race, diabetes, hypertension, coronary artery disease, and peripheral artery disease.

Conclusions: Among patients with chronic kidney disease with vascular anatomy suitable for a surgical AVF, 63% are also suitable for an endoAVF. Older patients are less frequently suitable for an endoAVF.

PO1042

Endovascular Arteriovenous Fistula Closure with Covered Stent Placement

Ravi V. Patel, Conrad D. Pun, Micah R. Chan, Muhammad Sohaib Karim, Ali I. Gardezi. *University of Wisconsin System, Madison, WI.*

Introduction: WaveLinQ™ endovascular arteriovenous fistula (EndoAVF) system is a new technique that uses radiofrequency energy to create AVF. It has been gaining popularity as it avoids major surgery, has less recovery time and better success rates than surgical AVF creation. Pseudoaneurysm, dissection of brachial artery, intra-procedure brachial artery thrombosis, device embolization, and steal syndrome are described complications of the procedure. We present a case of EndoAVF creation complicated with forearm swelling and its successful management.

Case Description: Patient is a 45 y/o male with End-Stage Renal Disease due to Hypertensive Nephrosclerosis and obstructive uropathy, now s/p failed kidney transplant, currently on Peritoneal Dialysis (PD). PD was failing and decision was made to transition patient to hemodialysis (HD). In preparation of HD, AVF using WavelinQ EndoAVF system was placed in right forearm between intraosseous artery and vein with coiling of the medial brachial vein. A week after fistula creation, patient developed right forearm swelling with numbness and tingling. Fistulogram demonstrated stenosis in the perforator vein with poorly developed cephalic vein and diversion of blood flow to multiple superficial collateral veins in the forearm causing swelling. Multiple attempts at balloon assisted maturation of the cephalic outflow were unsuccessful. Due to persistent forearm swelling with discomfort a decision was made to close the fistula. A 5 x 15 mm self-expanding ViaBahn™ stent was deployed in interosseus vein across the anastomosis to close the fistula. Post fistula closure, arm swelling resolved completely.

Discussion: Covered stents have been used in the maintenance of hemodialysis AVF for various purposes including dialysis access stenosis, central vein stenosis, pseudoaneurysm exclusion and angioplasty associated vascular rupture that cannot be repaired using balloon catheter. This is the first reported case of successful use of covered stent graft to occlude anastomosis to close EndoAVF. As these fistulae are created more often, more novel complications will be encountered. It will be imperative for interventionalists to find creative solutions as well as actively report the successful management of complications.

PO1043

Long-Term Prognosis of Vascular Access in Hemodialysis Patients with Systemic Lupus Erythematosus

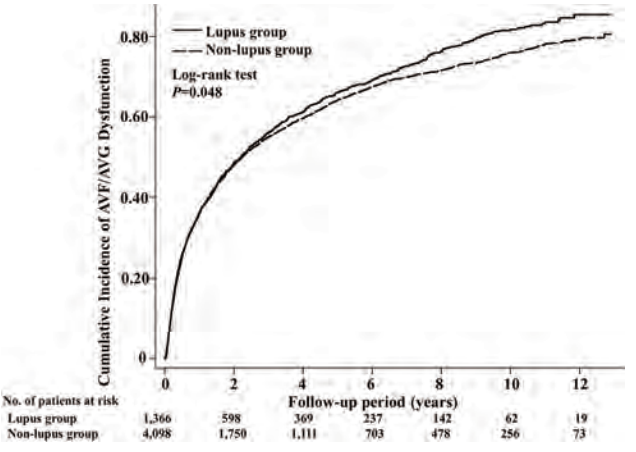
Chih-Ching Lin.[1,2] [1]*Taipei Veterans General Hospital, Taipei, Taiwan;* [2]*National Yang Ming Chiao Tung University - Yangming Campus, Taipei, Taiwan.*

Background: Patients with systemic lupus erythematosus (SLE) have a higher risk of vascular complications.

Methods: This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation. This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation.

Results: Totally, 1366 HD patients with SLE had higher incidence rates of AVF/AVG dysfunction than 4098 non-SLE HD patients in the following 4 periods, (1) after 1 year (incidence rates were 15.21% and 13.01% respectively; subdistribution hazard ratio (SHR) = 1.16; P = 0.007), (2) 1st-to-10th-year period (15.36% and 13.25%; SHR = 1.16; P = 0.007), (3) 5th-to-10th-year period (11.91% and 8.1%; SHR = 1.42; P = 0.003), and (4) overall period (23.53% and 21.66%; SHR = 1.09; P = 0.027). There were significantly higher incidence rates of AVF/AVG dysfunction in SLE patients during the long-term follow-up period.

Conclusions: In conclusion, regular surveillance of vascular access function by clinical examination after 1 year, especially during 5 to 10 years, is needed to improve vascular access patency and dialysis adequacy in SLE patients undergoing maintenance hemodialysis.



PO1044

Arteriovenous Access Creation and Re-Intervention Before Starting Hemodialysis

Epiphane E. Kolla,[1] Raphael Coscas,[3,1] Cécile Couchoud,[4] Ziad Massy,[2,1] Benedicte Stengel,[1] Marie Metzger,[1] Natalia Alencar de Pinho.[1] [1]*Paris-Saclay University, UVSQ, Inserm, Center for Research in Epidemiology and Population Health, Villejuif, France;* [2]*Div. Nephrology, Ambroise Paré University Hospital, APHP, Boulogne Billancourt, France;* [3]*Div. Vascular Surgery, Ambroise Paré University Hospital, APHP, Boulogne Billancourt, France;* [4]*Biomedicine Agency, La Plaine Saint Denis, France.*

Background: Arteriovenous fistulae and grafts are preferred to catheters for patients undergoing maintenance hemodialysis. They require early creation to be functional at time of hemodialysis initiation, but may need re-interventions to mature and remain functional.

Methods: Using data from the French REIN Registry linked to the national healthcare system database (Système National des Données de Santé - SNDS), we assessed: A) the timing of first arteriovenous access creation before hemodialysis initiation; B) vascular access re-intervention rates before hemodialysis initiation; and C) the frequency of catheter use at hemodialysis initiation in 43,495 matched incident patients from 2010 through 2015.

Results: Median age was 71 years, 64% were men, 43% had diabetes, and 33% started hemodialysis urgently. Half (51%) underwent a first arteriovenous access creation: a fistula in 21,240 patients, created a median of 5 months (IQR, 2-12), and a graft, in 741 patients, 3 (1-8) months before hemodialysis initiation. Among patients with a first fistula attempt, 30% underwent at least one vascular access re-intervention before hemodialysis initiation, versus 21% among those with a first graft attempt (p<0.001). The types of intervention substantially differed according to vascular access (Figure). When dialysis start was urgent, catheter was used in 43% of patients in both access groups (p=0.86); when it was not, catheter was used in 12 and 14% of patients with a first fistula or graft attempt, respectively (p=0.15).

Conclusions: In incident hemodialysis patients in France, fistula is typically the first attempted arteriovenous access. Early arteriovenous access creation prevents from using catheter at dialysis initiation in a majority of patients, but requires close monitoring of potential complications.

Incidence of De Novo Central Vein Stenosis in Hemodialysis Patients Following Their First Tunneled Central Vein Catheter (CVC) Placement

Alian Albalas, Salam Madi, Ammar Almehmi, Michael Allon. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Central vein stenosis is a common complication in hemodialysis patients following tunneled CVC insertion. Little is known about its incidence, association with patient characteristics, or relationship with duration of CVC placement. We systematically evaluated central vein stenosis in hemodialysis patients receiving their first CVC at a large medical center.

Methods: All new hemodialysis patients underwent an ultrasound prior to their internal jugular tunneled CVC placement, to exclude venous stenosis or thrombosis. If they were subsequently referred for CVC exchange, a catheterogram/venogram was performed to assess for hemodynamically significant (≥50%) central vein stenosis. During a five-year period (January 2016 to January 2021), we quantified the incidence of central vein stenosis in patients undergoing CVC exchange. We also evaluated the association of central vein stenosis with patient demographics, comorbidities, and duration of CVC dependence prior to exchange.

Results: During the study period, 273 patients underwent exchange of a tunneled internal jugular vein CVC preceded by a catheterogram/venogram. Of these, hemodynamically significant central vein stenosis was observed in 36 patients (13%). Central vein stenosis was not associated with patient age, sex, race, diabetes, hypertension, coronary artery disease, peripheral artery disease or CVC laterality (**Table 1**). The frequency of central vein stenosis was progressively higher with greater duration of CVC dependence, being 10%, 12%, 24%, and 28% in patients with <3 months, 3 to 6 months, 6 to 9 months and >9 months of catheter dependence, respectively (p=0.025).

Conclusions: Among incident hemodialysis patients receiving their first tunneled internal jugular CVC, the overall incidence of hemodynamically significant central vein stenosis was 13%. The likelihood of central vein stenosis was directly associated with the duration of CVC dependence.

PO1046

Hospitalization Risk and Long-Term Complications Associated with Catheter-Related Bloodstream Infection Among Hemodialysis Patients

Krithika Rajagopalan,[1] Kenneth Massey,[2] Srinivasan Rajagopalan,[1] Stephen Imperiale-Hagerman,[1] Paul Chew.[2] *[1]Anlitiks Inc, Dover, MA; [2]Cormedix, Berkeley Heights, MA.*

Background: Central venous catheters (CVC) are frequently required for vascular access in hemodialysis (HD) and are commonly associated with catheter-related bloodstream infections (CRBSIs). CRBSIs may have devastating consequences leading to increased hospitalizations, and long-term complications such as stroke, myocardial infarction (MI), heart failure (HF), and endocarditis, among others. This analysis explores the risk of CRBSI-associated hospitalizations and long-term complications among HD patients.

Methods: A 1:1 propensity score matched case-control analysis was conducted using merged data from United States Renal Data System (USRDS), CROWNWeb (dialysis organizations), and Medicare claims database (2013-2017). All CVC-dependent HD patients from 2014-2016 with a 1-year pre- and ≥ 1-year post-index period were included. CRBSI was defined as a composite measure of its ICD codes or sepsis/bacteremia diagnosis with hospitalization or without occurring pneumonia, gangrene, or urinary tract infections and hospitalization. An assigned index date (i.e., CVC insertion date + median days to CRBSI reported in CRBSI-case group) was used to identify non-CRBSI patients. CRBSI/non-CRBSI group differences were described using frequency, mean, median, chi-square, and t-tests. At 1-year post CRBSI, adjusted differences in hospitalizations and hospital days and time to long-term complications were modeled using generalized linear models cox proportional hazard models, respectively.

Results: CRBSIs result in higher 1-year incremental rates of: stroke (6.6%), MI (9.2%), HF (13.4%), PVD (13.6%), and endocarditis (9.4%). Mean number of hospitalizations and hospital days were 3.79 and 25.0 days for CRBSI, and 1.96 and 5.86 days for non-CRBSI patients, respectively. Mean hospitalizations and hospital days were significantly higher for CRBSI vs. non-CRBSI patients (p<0.05) at 1-year post-CRBSI. Hazard ratios for CRBSI patients were: stroke (1.64, 95% CI 1.53-1.75), MI (2.56, 95% CI 2.37-2.78), HF (2.01, 95% CI 1.88-2.14), and endocarditis (13.42, 95% CI 10.97-16.42).

Conclusions: Results show HD patients with CRBSIs incur a significant morbidity burden due to increased hospitalizations, hospital days, and long-term complications such as stroke, MI, HF, PVD, and endocarditis.

PO1047

Hemorrhagic Shock due to Cutting of the Tunneled Dialysis Catheter

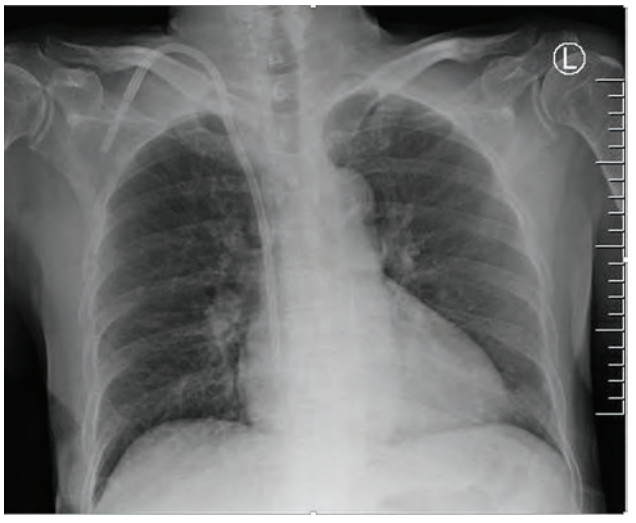
Lucia Bogdan,[1] Tushar S. Malavade.[2,1] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

Introduction: Bleeding is a relatively rare complication of dialysis CVC overall.

Case Description: We describe the case of a 68-year-old non English speaking dementia patient with ESRD on HD. While in hospital, he had tried to cut the tape that was causing itching, but accidentally cut CVC. He was found in shock, bleeding from the exit site, which required aggressive resuscitation and compression to stop bleeding. After stabilisation examination revealed a palpable, well retracted catheter that was not visible (Fig 1). X ray showed the catheter in situ, but the Y along with the arterial and venous ports were absent (Fig 2). In retrospect, bleeding was particularly difficult to control because the cuff at this location is rigid and not compressible. This places the patient at increased risk for exsanguination leading to hemorrhagic shock, air embolism and mortality.

Discussion: To our knowledge, this is the first report of a cut tunnelled CVC proximal to the Y. This case demonstrates the risk of significant hemorrhage when a tunnelled CVC is damaged at this location and need for early recognition and control of bleeding. It also highlights important patient safety considerations given the risk of self-inflicted trauma in patients with dementia and language barrier for communication.

Catheter palpable, but not seen.



X Ray showing the retained tunnelled catheter proximal to Y

PO1048

Facial Swelling: Angioedema or Superior Vena Cava (SVC) Syndrome

Moarij A. Qazi,[1] Huma Qazi,[2] Anne M. Huml,[1] Tushar J. Vachharajani.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Army Medical College, Rawalpindi, Pakistan.*

Introduction: Central venous stenosis is a common complication of recurrent central venous catheters (CVCs). Diagnosis can be challenging given its versatile presentation. Facial, unilateral breast or upper extremity swelling and signs of congestion mimicking pulmonary edema can be subtle clues. We describe a case of SVC syndrome that eluded clinicians as angioedema.

Case Description: 55-year-old female with history of morbid obesity, CKD 4, recurrent bacteremia, endocarditis and anemia presented with 1-day history of facial and oropharyngeal swelling, requiring intubation for airway protection. She was unsuccessfully treated for presumed angioedema with steroids, H2 blocker and C1 esterase inhibitor. She deteriorated, requiring tracheostomy tube, dialysis and then transferred to our hospital. She had episodes of worsening facial swelling, drooling and dyspnea with dialysis. Her medical records revealed multiple infections of her more than 10 CVCs placed in the past 12 years for frequent IV draws, iron infusions and antibiotics. Six portacaths were on the right side including 3 in subclavian, 1 in internal jugular vein and 2 peripherally inserted central catheters. A CO2 angiogram revealed stenosis of the right internal jugular, subclavian and brachiocephalic veins. The left internal jugular had the dialysis catheter with some narrowing around it. Endovascular interventions were unsuccessful at recanalization. Surgical bypass was not an option given her comorbidities. She was being evaluated for sharp or radiofrequency recanalization and/or inside-out device intervention. Unfortunately, devastated with failures, she opted for hospice.

Discussion: A high index of suspicion is crucial in patients with prior CV accesses and frequent access clotting, poor flows and facial or upper extremity swelling. The number, duration and infections of CVCs increase the risk of CV stenosis. Dialysis related dyspnea, drooling or treatment resistant angioedema should be evaluated with a venogram urgently. Prompt use of advanced treatments like endovascular recanalization can be lifesaving.

SVC syndrome

PO1049

Rare Cause of Pleural Effusion in a Dialysis Patient

Mingyue He, Waqas Ahmad Khan, Iris J. Lee, Ilay Rakhman, Serban Constantinescu. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: The most common causes of pleural effusion in dialysis patients are congestive heart failure, infections, and tumors. However, in some dialysis patients, identifying the rare cause of pleural effusion requires careful consideration.

Case Description: A 29-year-old African American female with ESRD secondary to Lupus Nephritis (LN) s/p deceased donor kidney transplant, developed allograft failure and restarted dialysis. Upon initiating dialysis and weaning of immunosuppression she had episodes of fever, myalgias, synovitis and pleural effusions thought to be manifestations of lupus flare. Despite restarting immunosuppression, she presented frequently with dyspnea and recurrent bilateral transudative pleural effusions requiring repeat thoracenteses. Her physical exam was notable for swelling of bilateral upper extremities and face with minimal lower extremity edema. Lupus serologies were normal. Echo was unrevealing. CT angiogram (CTA) revealed complete occlusion of the distal superior vena cava (SVC) with extensive collateralization in the chest and abdominal wall.

Discussion: Her initial symptoms were attributed to volume overload and lupus serositis. However, inactive serologies, ongoing immunosuppression, and the transudative nature of the effusion were not consistent with lupus flare. Aggressive UF also failed to prevent recurrent pleural effusion. Given CTA and clinical findings, we concluded that the persistent pleural effusion is a manifestation of the SVC syndrome in our patient. The occlusion of the SVC was below the junction of the arch of the azygos vein. Venous blood flow from the upper body and extremities was shunted into the azygos system and flowed counter-current, returning to the right heart through the inferior vena cava. This results in increased hydrostatic pressure in the intercostal veins, contributing to the development of edema of the head, upper chest, bilateral upper extremities, and pleural effusions. Our patient had multiple central venous catheters increasing her risk for SVC syndrome. Clinicians should consider SVC stenosis as a potential cause of recurrent pleural effusions in a dialysis patient.

PO1050

Innovative Care Model for Vascular Access Strategy in AKI in Critically Ill Patients

Korey Bartolomeo, Tarik Hanane, James E. Lane, Tushar J. Vachharajani. *Cleveland Clinic, Cleveland, OH.*

Background: Central venous catheter (CVC) is the preferred vascular access in critically-ill patients needing kidney replacement therapy (KRT). Non-tunneled CVC (NT-CVC) is frequently selected for bedside placement and provider familiarity. With hemodynamic instability, tunneled CVC (T-CVC), despite its known advantages of lower infection risk, lower mechanical complications, better blood flow rates and patient comfort, is infrequently considered due to competing demands for central vein access, and provider inexperience. We report our early experience of building a collaborative training program to improve vascular access approach in the critically-ill patients.

Methods: A single center retrospective study of T-CVC placed in an adult medical ICU between March 1, 2020 and December 31, 2020 by a nephrologist or an intensivist. The T-CVCs were placed in hemodynamically unstable patients for KRT and other medical therapies. Statistical analysis was limited to assess feasibility and safety of implementing a collaborative procedural service in an academic medical ICU.

Results: A total of 120 CVC related procedures were completed during the study period. 106 were T-CVC placements (68 for KRT, 38 small bore non-KRT), seven T-CVC removals, one difficult NT-CVC for KRT, one T-CVC exchange, one fluoroscopy guided repositioning of NT-CVC, four aborted for suspected central vein occlusion. Twenty-seven T-CVC (23 in COVID-19 positive and 4 for other compelling reasons) were placed at bedside with ultrasound guidance and anatomical landmarks without fluoroscopy. A safety pre-procedure checklist was developed for eligibility based on this experience. A minimum of 48-hr sterile blood culture report was essential to proceed. Complex comorbidities included coagulopathic patients. A minimum training competency was established and 2 critical care staff physicians were credentialed during this period. No major complications were encountered.

Conclusions: A collaborative care model between nephrology and medical ICU for T-CVC focused strategy is feasible. T-CVC can be placed safely in a carefully selected critically-ill patient population. Training intensivists with basic procedural skills for T-CVC procedure is achievable over a short period.

PO1051

Acute Atypical Chest Pain from Hemodialysis Access as a Culprit

Alfonso Ortiz, Marwan Tabbara, Laisel Martinez, Roberto I. Vazquez-Padron, Juan C. Duque. *University of Miami School of Medicine, Miami, FL.*

Introduction: Cardiovascular mortality is a well-known fact in CKD and ESKD patients specially in patients who are experiencing a cardiovascular event. There is an increased rate of cardiovascular complications and death. Frequent causes of acute chest pain in patients with ESKD include myocardial infarction, pericarditis, air embolism, acid reflux and complications from catheters but is rare to have complications from functional AVF.

Case Description: 40-year-old male with history of ESKD and was on hemodialysis via left brachial- brachial arteriovenous fistula with graft extension, DDKT in 02/2020, HTN and HIV who presented to the ED 1 year after transplant with a week history of

worsening sharp, non-radiating chest pain localized at the left hemithorax. Patient referred nausea and vomiting for 2 days. Emesis was as thick mucus possibly blood-streaked; however, no coffee-grounds. Stated he had never experienced this chest pain before. He reported not taking any medication at home for pain. On examination there was no cardiac murmurs, no lung abnormalities on auscultation and he had a patent arteriovenous fistula with good thrill and bruit and no signs of stenosis. Had 2 negative troponin levels with serial EKGs without ischemic changes. An echocardiogram that was negative for wall motion abnormalities or any changes in ejection fraction, ruling out an acute coronary syndrome. He had CXR showing curvilinear density projecting over the left lung base with a CT chest that reported a small curvilinear metallic density at the right ventricular apex. He was not on hemodialysis but before his transplant, he had multiple endovascular procedures including a stent placement to keep a patent AV access. A left upper extremity xray showed a left AV access stent fracture; findings were consistent with an embolized fragment from AVG stent. He underwent explant of the stent from AVG, but embolized fragment was not removed by CT surgery. Currently patient is chest pain free and asymptomatic.

Discussion: Stent fractures are commonly seen when they are in arteries, however this is an uncommon event in venous system specially in hemodialysis vascular access. Some of the complication associated with stent fracture are related to in-stent stenosis and central vein stenosis, but this is the first report of chest pain from stent fracture migrated to the left ventricle.

PO1052

Agitated Saline Bubble-Enhanced Ultrasound to Visualize Appropriated Position of Hemodialysis Catheter: Does Catheter Venous Site Matter?

Gessica Sabrine Braga Barbosa, Rayra G. Ribeiro, Jorge L. Espinosa Armijos, Lucia Andrade, Igor Smolentzov, Camila E. Rodrigues. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: The hemodialysis non tunneled catheter (HDC) is the most common access of starting renal replacement therapy. Malposition of catheter is associated with delays in treatment. Agitated saline bubble-enhanced ultrasound (SBUS) has become a new method to visualize the HDC position. Delayed appearance of microbubbles (≥ 2-second) in the right atrium indicates malposition. Our objective is to analyze the accuracy of SBUS between right and left internal jugular vein (IJV) HDC insertion, comparing to chest radiography (standard method).

Methods: From December 2019 to May 2021, we evaluated 145 hospitalized patients submitted to HDC insertion in IJV. We compared SBUS with chest radiography (CR); the time spent to perform the CR; complications; patient characteristics; catheter blood flow and quality of dialysis.

Results: Total of 145 patients were analyzed, the median age was 62 years old [50.5-70], and there was no statistical difference between the site of insertion. In RIJV, 91% catheters were placed. AKI was more frequent than CKD (75% vs 25%), except when the site was LIJV (46% vs 54%, p<0.05). AKI-related COVID-19 was the most common etiology (54%). The confirmation of catheter placement by SBUS was correlated with position by CR (All: r=0.6603, p<0.0001; RIJV: r=0.7044, p<0.0001; LIJV: r=0.6396, p=0.0769). SBUS was highly accurate in identifying adequate location of HDC, especially in RIJV (All: 97.9%; RIJV: 99.2%; LIJV: 84.6%, p< 0.05). The time of the catheter insertion to perform radiography was 191 minutes [83.5-287]. Adequate syringe blood flow and an effective hemodialysis session was more frequent in RIJV catheter (99.2% vs 53.8%, p<0.05; 96.8% vs 72.7%, p <0.05, respectively). Complications occurred only in 4.2%, without statistical difference between catheter sites.

Conclusions: Comparing with chest radiography, agitated saline bubble-enhanced ultrasound was more accurate in identifying adequate placement of RIJV than LIJV hemodialysis catheters.

PO1053

Using the Seraph® 100 Microbind® Affinity Blood Filter Under Slow Flow Conditions Through a Normal Central Line

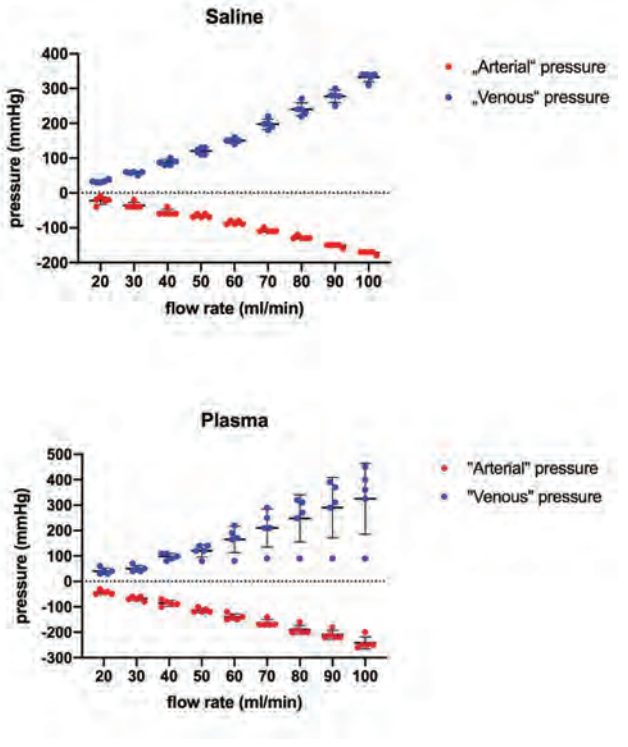
Malin-Theres Seffer,[1] Julius Schmidt,[2] Jan T. Kielstein.[1,2] Kielstein Lab *[1]Academic Teaching Hospital Braunschweig, Braunschweig, Germany; [2]Medizinische Hochschule Hannover, Hannover, Germany*.

Background: The Seraph® 100 Microbind® Affinity blood filter has been in use since 2019 for the treatment of difficult to treat blood stream infections.and since 2020 for the treatment of critically ill COVID-19 patients. It is operated under blood flow rates of 100 – 350 mL/min, which requires a large bore central line a dialysis catheter. The aim of our study was to evaluate to evaluate the usability of the Seraph® 100 under slow flow conditions through a normal central line (in clinical practice).

Methods: A standard hemoperfusion blood tubing system as well as the Seraph® 100 (Exthera Medical, CA, USA) was used. Vascular access was a 20 cm trillumen central venous line (2 x 18 G and 1 x 16 G) that was inserted into a reservoir. The Multifiltrate (Fresenius Medical Care) was used to pump normal saline (n=5) or human plasma (n=5) through the Seraph® 100. Pressures were recored at any given flows (Qb). In two patients connected to a five lumen 20 cm catheter (Certofix Safety Quinto S1220, B. Braun, Melsungen, Germany - 1 x 12 G, 1 x 16 G, 3 x 18 G) blood flow as well as arterial and venous pressure were recorded through the 24 h treatment.

Results: Using saline or human plasma the Seraph® 100 Microbind®Affinity Blood Filter can be operatied at blood flow rates of up to 100 mL/min even through a 16 & 18 G lumen at tolerable arterial and venous pressures. In men using either the 12 G or the 16 G lumen as "arterial line" blood a blood flow rate of 50 mL/mon could be onbtained for 24 hours without problems.

Conclusions: The Seraph® 100 Microbind®Affinity Blood Filter can be operated at blood flow rates of 50 mL/min even through 16 & 18 G catheters.



"Arterial" and "venous" pressures depending on the flow (Qb) during hemoperfusion with the Seraph® 100 Microbind® Affinity Blood Filter.

PO1054

Keeping the Vascular Access Alive During the COVID-19 Pandemic

Min S. Cho, Cesar F. Hernandez-Arroyo, Muhammad Sohaib Karim, Micah R. Chan, Brad C. Astor, Ali I. Gardezi. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: Delay in care of suspected stenosis or thrombosis can increase the chance of losing hemodialysis access. Many procedures were canceled or postponed at the start of the COVID-19 pandemic. We have done a study to determine if the COVID-19 pandemic affected dialysis access care.

Methods: We performed a retrospective chart review to evaluate the incidence of both fistula and graft thrombectomies between April 1, 2020, and March 31, 2021, designated as the COVID-19 group and compared it with an incidence between April 1, 2019, and March 31, 2020, designated as the pre-COVID-19 group. Unsuccessful thrombectomy was defined as subsequent tunneled hemodialysis catheter placement within 48 hours after thrombectomy due to clotted access.

Results: There was no significant difference in the total fistula and graft thrombectomies between the two time periods: 44 cases in the pre-COVID-19 era, the incidence rate of 0.12 per patient-year; 54 cases in the COVID-19 era, the incidence rate of 0.14 per patient-year (HR=1.23, 95% CI= 0.81-1.89, p=0.31). However, there was a significant increase in the fistula thrombectomy in the COVID-19 era: 9 cases in the pre-COVID-19 era, the incidence rate of 0.024 per patient-year; 21 cases in the COVID-19 era, the incidence rate of 0.057 per patient-year (HR=2.38, 95% CI= 1.03-5.88, p=0.02). In addition, the incidence of unsuccessful fistula thrombectomy also increased significantly: 2 cases in the pre-COVID-19 era, the incidence rate of 0.005 per patient-year; 9 cases in the COVID-19 era, the incidence rate of 0.024 per patient-year (HR=4.54, 95% CI= 1.01-50, p=0.03). There was no significant difference in total as well as unsuccessful graft thrombectomy between the two eras.

Conclusions: We noticed a significant increase in fistula thrombosis and unsuccessful fistula thrombectomy in 1-year of the COVID-19 pandemic. This could be due to a delay in referring the patients for treatment of fistula stenosis. Even though the dialysis access procedures were considered essential, there might have been hesitancy on part of patients and referring dialysis center which led to this result. However, we did not notice this trend in AV graft. Timely referral for intervention is important to prevent vascular access thrombosis and loss.

PO1055

Virtual Interviewing in the COVID-19 Era: What Have We Learned?

Koyal Jain, Gerald A. Hladik, Prabir Roy-Chaudhury, Pankaj Jawa. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: The COVID-19 pandemic forced institutions across the US to switch to virtual interviewing. While some institutions were already offering virtual interviews on a limited basis, this was the first time all interviews were conducted using a virtual platform. Herein, we describe the experience of the nephrology fellowship interviewees at the University of North Carolina (UNC).

Methods: We distributed an anonymous Qualtrics survey to all the nephrology fellowship interviewees (N=80) at UNC. The survey included questions on quality of virtual interviews and was completed after the match to avoid bias related to the matching process.

Results: Thirty-one candidates completed the survey (39%), although not all questions were answered by everyone. The total number of interviewees increased from 41 in 2019-20 to 80 in 2020-21. 95% were satisfied with their virtual experience. 82% indicated that the virtual interview process enabled an informed decision about the fellowship program. Everyone was satisfied with the organization of the interview day (N=22). 28% responders (5/18) identified as underrepresented minority (URM). In 2019-20, 6/41 interviewees identified as URM as compared to 14/80 in 2020-21. The most common reasons for not ranking our program amongst the top three included limited job opportunities for partners, inability to visit the area, and lack of family in the area. Candidates valued the people they met and were able to get a good feel for the program despite virtual interviews. They were particularly satisfied with the opportunity to meet fellows one on one. Interviewees specified lower cost and time efficiency as advantages of virtual interviews.

Conclusions: This is the first report of the virtual interview experience for nephrology fellowship applicants. The virtual interview process increased the applications to our program although the number of URM applications were similar compared to previous years. There was uniform satisfaction with the virtual format and interviewees were able to appreciate the culture of the division. Most applicants found the virtual interview format favorable because of reduced cost and time expenditure, enabling them to interview at more programs. Our data suggest that serious consideration should be given to a virtual format in future years to provide opportunity and flexibility to the applicant pool and improve geographical diversity.

PO1056

"Breaking Bad News" During the COVID-19 Epidemic: A Virtual Objective Structured Clinical Examination (OSCE) for Nephrology Fellows

Maura A. Watson,[1] Anna M. Howle,[1] Oliver Lenz,[3] Ross J. Scalese,[3] Joshua D. King,[2] Jonathan A. Bolanos,[2] Christina M. Yuan.[1] Nephrology Education Research & Development Consortium *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]University of Maryland School of Medicine, Baltimore, MD; [3]University of Miami School of Medicine, Miami, FL.*

Background: The "Breaking Bad News" OSCE assesses fellow counselling/communication skills in 20-minute simulation scenarios: kidney replacement therapy (KRT) in ESKD, urgent KRT in AKI, and kidney biopsy. In-person simulation was impractical during the COVID epidemic, so we adapted the OSCE to a virtual platform.

Methods: The AKI scenario was audio only. Fellows called a simulated patient (SP) surrogate for urgent KRT consent. The ESKD and kidney biopsy scenarios were video encounters between fellows and SPs. Faculty observed while muted/video off. After each scenario, fellows received feedback from SPs and faculty (unmuted/video on). Fellows from 3 programs at 2 centers completed the OSCE in May 2021. Post-OSCE, fellows were anonymously surveyed about each scenario, the OSCE overall, and their estimate of the percent of outpatient encounters and inpatient KRT counseling they had done virtually in the past year.

Results: 15 fellows did the OSCE; 14 completed the survey (93% response rate). 93% rated the OSCE overall as a good/very good approximation of a telemedicine experience. 100% were satisfied/very satisfied with the AKI scenario, 79% with the ESKD, and 77% with the kidney biopsy scenarios. Several commented that the AKI scenario was most realistic—they often counseled surrogates by telephone for urgent KRT. Fellows estimated that about 25% (median 27.5%; IQR 16-50%) of counseling for acute inpatient KRT was done virtually in the past year. They estimated about 50% (median 52.5%; IQR 36-70%) of outpatient encounters were done virtually in the past year, but several (dissatisfied with the ESKD and kidney biopsy scenarios) indicated they would not have counseled similar outpatients using telemedicine.

Conclusions: Overall, fellows felt the OSCE well-approximated virtual encounters. All were satisfied with the AKI scenario. The majority were satisfied with the ESKD and Kidney Biopsy scenarios, but some did not feel they were consistent with normal practice. The OSCE allows fellows to practice telemedicine communication skills that will remain relevant post-pandemic. *The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Defense or U.S. Government.*

PO1057

Well-Being of Nephrology Fellows: Evolution over the Course of a Pandemic Year

Hitesh H. Shah,[1] Kurtis Pivert,[2] Susan M. Halbach,[3] Anna M. Burgner,[4] Benjamin S. Ko,[5] Lili Chan,[6] Suzanne Boyle,[7] Joshua S. Waitzman,[8] Stephen M. Sozio.[9] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]American Society of Nephrology, Washington, DC; [3]Seattle Children's Hospital, Seattle, WA; [4]Vanderbilt University Medical Center, Nashville, TN; [5]University of Chicago, Chicago, IL; [6]Icahn School of Medicine at Mount Sinai, New York, NY; [7]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [8]Beth Israel Deaconess Medical Center, Boston, MA; [9]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: We sought to assess changes in well-being of nephrology fellows over the first year of the COVID-19 pandemic in the U.S.

Methods: The Resident Well-Being Index (RWBI), a validated tool assessing physician distress, was distributed as part of ASN's annual nephrology fellow survey to 920 current adult, pediatric, and adult/pediatric fellows. An RWBI ≥ 5 (range 0–7) indicated distress. Demographic and fellowship factors associated with meeting the distress threshold were evaluated in univariable and multivariable logistic regression.

Results: A total of 511 fellows participated (56% response), of whom 463 completed the RWBI instrument. After 1 year of the COVID-19 pandemic, there were a higher proportion of nephrology fellows meeting the RWBI distress threshold—22% in 2021 versus 15% in 2020. Female nephrology fellows had higher RWBI scores (median 3 [IQR 5]) than their male colleagues (median 1 [IQR 3]). Higher proportions of 1st-year fellows (50% vs 42% for 2nd years, OR 0.61 for 2nd years [95% CI 037–0.99], p=0.046) and women (27% vs 18% of men, OR 1.71 [95%CI 1.06–2.76], p=0.028) met the distress threshold (Figure 1). There were no significant differences by race, ethnicity, medical school location, or adult vs pediatric fellowship. Despite the higher proportion of distress overall, 88% of respondents would recommend nephrology to medical students and residents.

Conclusions: Our follow-up assessment of nephrology fellows' well-being after the first year of the COVID-19 pandemic indicate the continued need for supportive measures to ensure the health of the future nephrology workforce, especially among 1st year and women trainees.

The Battle Between Home Call and Fellows Well-Being

Min S. Cho, James D. Alstott, Richard S. Fernandes Almeida, Laura J. Maursetter, Tripti Singh. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: Night call is traditionally taken by nephrology fellows to provide exposure to after-hour care. Lack of physician wellness and development of burnout are being seen more frequently and may have been enhanced during the COVID-19 pandemic. In an attempt to quantify the burden of call, nephrology fellows at the University of Wisconsin tracked home call activities and aimed to identify areas for improvement.

Methods: Each of the 6 nephrology fellows filled out a daily survey between November 9, 2020 and January 31, 2021, which was the peak of the COVID-19 pandemic in Wisconsin to address: 1) the total amount of sleep hours 2) quality of sleep (restful or fragmented) and 3) whether on-call fellow reported to hospital from home. Responses were collected the following morning to decrease recall bias.

Results: Over the 3-month study period, 100% of the call night data was recorded. The average amount of sleep per night was 5.3 hours. When necessary to report, the average hours of sleep dropped to 4.3 hours. However, if not called in, sleep increased to 5.8 hours per night. The percentage of nights requiring patient evaluation by coming to the hospital overnight was 50% during the study period, with a range of 48% of nights in December and 61% in January. Sleep during night call was described as 55% restful vs. 45% fragmented.

Conclusions: This survey has generated discussion amongst fellowship leadership and current fellows regarding novel ways to improve the night call experience to maximize education and clinical experience during training as well as improve fellow wellness. It was determined that the burden of call did not detract from the fellow education enough to warrant a change to a night float system. However, it did identify changes in management processes such as the timing of labs, implementation of dot phrases, and a sleep expert discussion to improve duration and quality of sleep.

Fellows Home Call Data

	November (11/9/20 - 11/30/20)	December (12/1/20 - 12/31/20)	January (1/1/21 - 1/31/21)	Total Average
Average Hours of Sleep (n)	5.3	5.1	5.5	5.3
Average Hours of Sleep if Called in (n)	4.4	3.9	4.6	4.3
Average Hours of Sleep if Not Called in (n)	5.9	5.8	5.8	5.8

Percent of Nights Called in (%)	45	61	42	49
Percent of Nights with Restful Sleep (%)	55	48	61	55
Percent of Nights with Fragmented Sleep (%)	45	52	39	45

PO1059

Integrating Healthcare Education for Nephrology Best Practice – Topic Tagging and What Is "Deemed" Clinically Relevant Context: A Quantitative Perspective

Shahid N. Muhammad.[1,2] *[1]The University of the West of England (UWE), Bristol, United Kingdom; [2]The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.*

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations. 1) To understand, retrospectively, whether there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education.

Methods: Fourteen (14) topic tags were applied over 1-month (March and April 2020) between groups the Renal Patient Support Group (RPSG) (est.2009) and the Kidney Disease and Renal Support (KDARs) (est.2014) for Kids platforms. Group disclaimers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice surrounding confidentiality and data protection.

Results: 2,560 threads were topic tagged between two groups. For adults, educational gaps surround Renal Replacement Therapy (166 tags, 12.66%); Lab Tests and Biomarkers (137 tags, 10.50%) and Medication and Pharmacy (135 tags, 10.29%). For paediatrics and young people, educational gaps include Medication and Pharmacy (148 tags, 11.85%); Renal Replacement Therapy (133 tags, 10.65%); Peer Support (125 tags, 10.01%) and Nursing (115 tags, 9.20%).

Conclusions: Online educational modules should complement CKD pathways, and be delivered by wider Allied Health Professionals. This is the first UK retrospective study that examines clinically relevant educational gaps between online paediatric and adult renal cohorts close to two decades. Education is where healthcare requires investment.

PO1060

Nephrology Education Needs Assessment: Five Years and a Pandemic Later

Benjamin S. Ko,[1] Rob Rope,[3] Kurtis Pivert,[2] Anna M. Burgner,[5] Joshua S. Waitzman,[4] Susan M. Halbach,[6] Suzanne Boyle,[7] Lili Chan,[8] Hitesh H. Shah,[9] Stephen M. Sozio.[10] *[1]University of Chicago, Chicago, IL; [2]American Society of Nephrology, Washington, DC; [3]Oregon Health & Science University, Portland, OR; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Vanderbilt University Medical Center, Nashville, TN; [6]Seattle Children's Hospital, Seattle, WA; [7]Temple University, Philadelphia, PA; [8]Icahn School of Medicine at Mount Sinai, New York, NY; [9]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [10]Johns Hopkins Medicine, Baltimore, MD.*

Background: We sought to identify how educational tools utilized in nephrology training had evolved in the past 5 years and through the COVID-19 pandemic.

Methods: Questions about educational tools were distributed as part of ASN's annual nephrology fellow survey to 920 current adult/pediatric fellows.

Results: 511 fellows participated in 2021 (56% response rate), compared with 377 fellows in 2016 (31% response rate). Fellows indicated that UpToDate was still the most used (82%) and most effective educational tool (66% rated it "Very Effective"); however, ASN KSAP increased in popularity (27% in 2016, 58% 2021) and was also highly rated (65% Very Effective). Use of online resource and social media increased, including both new opportunities and prior available ones such as NephJC (7% to 32%, with 46% rated Very Effective) (Figure 1). A majority of fellows (84%) rated their education as good or excellent in 2021, a percentage similar to 2016 (81%).

Conclusions: Our follow-up assessment of nephrology fellows' educational tools found an increase in the adoption of online resources with similar effectiveness ratings as traditional resources.

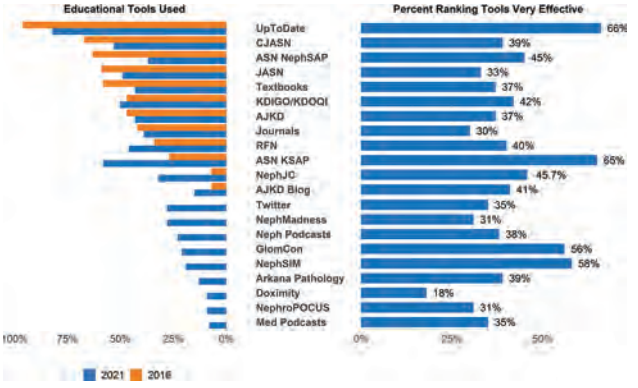

Figure 1: Educational Tools Used by Nephrology Fellows in 2016 and 2021 *(left)* and Percentage 2021 Nephrology Fellows Ranking Tools as Very Effective *(right).*

PO1061

Curriculum-Based Online Education Improves Nephrologists' Ability to Manage Hyperkalemia in Practice

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape Education, New York, NY.*

Background: The goal of continuing medical education (CME) is professional growth and improved patient care. We sought to determine if series of online continuing medical education (CME) activities will improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The online CME curriculum consisted of 5 online activities housed on a dedicated collection page. All used repeated pairs pre-/post-assessment study design was used and McNemar's test ($P < .05$ is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions using a McNemar's test to determine *P* values. The activities launched between March and October, 2020 and data were collected for up to 12 weeks.

Results: The education reached over 15,000 physicians, including over 1,706 nephrologists. Overall, knowledge improved by 24% (P<.001) and competence by 4% (P=NS) (all relative improvements) by nephrologists. Specific improvements: 40% relative increase in knowledge related to impact of hyperkalemia (P<.001) 31% relative increase in knowledge related to clinical use of potassium binders (P<.001) 24% relative increase in knowledge related to optimizing RAAS inhibitors in patients with hyperkalemia (P<.05) 7% relative increase in competence related to clinical use of potassium binders (P=NS) Of the nephrologists who were included, 30% (P<.001) had a measurable increase in confidence in hyperkalemia management.

Conclusions: This curriculum demonstrates that a curriculum is effective at moving learners on the continuum for knowledge improvements to competence improvements. Some gaps remain after education. Among these learners, 49% need knowledge improvements related to optimizing RAAS inhibitors in patients with hyperkalemia and 41% related to clinical use of potassium binders. As such, further education needed in these areas.

PO1062

Level of Confidence, Knowledge, and Literacy in Genetics Among US Nephrologists

Hila Milo Rasouly, Olivia Balderes, Maddalena Marasa, Hilda E. Fernandez, Marissa Lipton, Fangming Lin, Ali G. Gharavi, Maya Sabatello. *Columbia University Irving Medical Center, New York, NY.*

Background: Increased availability of genetic tests in nephrology and at reduced costs are promising for improved patient diagnostic and clinical care. Nephrologists' confidence, knowledge and genetic literacy are likely to impact the utilization of genetic testing (GT). Identifying gaps in nephrologists' knowledge and confidence and preferred methods of learning are needed to develop tailored approaches to improving it.

Methods: An online survey assessing genetic confidence, knowledge, and genetic literacy measured using GeneLiFT, a rapid word recognition screening test, was administered between January-May 2021 to nephrologists working in the US (self-identification).

Results: 201 nephrologists completed the survey, 67% working in an academic setting. All clinicians reported treating patients with genetic forms of kidney disease, but only 32% have to date referred >20 patients to GT. We observed limited genetic knowledge in 32% of respondents (Table), and 68% did not recognize the word "actionability" as real. Only 20% reported high confidence in all aspects of GT (ordering, discussing risks and benefits, results' interpretation, and using results to guide clinical care), and high level of confidence was significantly associated with working in an academic setting ($p= 2.6x10^{-5}$). Preferred methods for continued genetic education were "conferences" (70%), "self-directed methods" (45%) and "workshops" (40%). Methods used were mostly "reading specialty texts" (65%) and "internal specialty seminars and conferences" (55%).

Conclusions: There is a need to improve nephrologists' genetic literacy, knowledge, and confidence in genetics to ensure to ensure broad adoption of genetic testing in nephrology. Employing diverse educational methods will prevent widening the gap between the adoption of genetic testing in different clinical settings.

Funding: NIDDK Support

Table 1: Genetic knowledge amongst surveyed nephrologists (n=201)

Do you think the following statements are correct or incorrect? (5-point Likert scale from 'Definitely incorrect' to 'Definitely correct')		
Concept	Sentence	Incorrect answer
Genetic risk	Genetic testing may find genetic mutations that increase a person	42 (21%)
Panels/ exome	Genetic testing may give a person information about their chance of developing several different genetic conditions.	31 (16%)
Pharmaco-genomics	Genetic testing may find genetic variants that determine how a person responds to certain medicines.	21 (11%)
Heritability	Genetic testing may find genetic variants that a person can pass on to his/her children.	9 (5%)
Inheritance	Healthy parents can have a child with a genetic condition.	9 (5%)
Penetrance	Some people with a genetic mutation may not develop the genetic condition.	9 (5%)

PO1063

Mind Map, an Educational Tool for Teaching Clinical Reasoning in Nephrology: A Mixed-Method Study

Aghiles Hamroun,[1] Eléonore Lepers,[2] Aurélie Dupré,[2] Patrick Truffert,[1] François Glowacki.[1] *[1]Centre Hospitalier Universitaire de Lille, Lille, France; [2]Universite de Lille Faculte de Medecine, Lille, France.*

Background: Nephrology is commonly considered as one of the most complex disciplines for medical students, justifying the implementation of new educational tools. Although its relevance has been well-established, the mind map is still marginally used in medical education. The objective of this study is to assess the contribution of mind map for teaching clinical reasoning in nephrology.

Methods: Between November 2020 and April 2021, three groups of med students (4th to 6th year) were provided with a teaching program of 5 weekly sessions of 30-45 minutes focused on three topics (serum creatinine elevation/AKI, glomerular syndromes, dysnatremia), each developed through a specific mind map. The contribution of this program was evaluated by a mixed method: 1. quantitative assessment: comparison of three quiz scores respectively the day before, day after and two weeks after each learning session (paired Wilcoxon tests); 2. qualitative assessment: focus group interviews with each group at the end of the teaching program.

Results: In total, 12 med students took part in this educational experience (respectively four in 4th, 5th and 6th years). Quiz scores were significantly higher after each teaching session and overall (28.0 [26.0; 31.4], 33.0 [31.2; 36.1], 34.4 [32.4; 37.0] respectively at baseline, immediately after and after two weeks, $p < 0.001$) (Fig1). Moreover, focus group interviews highlighted several themes about the specific contribution of mind map (in addition to previous standard lessons): logical and intuitive tool, effective for quick knowledge transmission, promoting long-term memorization and providing a global/ integrated vision of clinical reasoning in nephrology.

Conclusions: Mind map appears to be an interesting educational tool in teaching clinical nephrology reasoning to medical students.

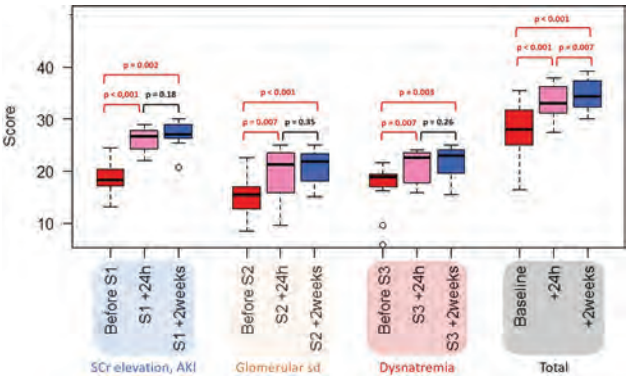

Figure 1. Quiz scores at three assessment times (day before, day after and two weeks after each session) and by topic. On the right, global results pooling the scores of all topical sessions.

PO1064

Improving the Management of Gout in Patients with CKD or Kidney Transplant: Effect of Online Education

Nimish Mehta, John Maeglin, Karen Badal. *Medscape LLC, New York, NY.*

Background: Gout is a chronic condition with a considerable effect on patient health and quality of life. Hyperuricemia and gout are associated with declining renal function, and recent studies have shown that renal dysfunction and kidney transplant are risk factors for gout. A study was conducted to determine if online, segmented education could improve knowledge, competence, and confidence of nephrologists regarding the management of gout in patients with chronic kidney disease (CKD) or kidney transplant (KT).

Methods: Educational design included a 45-minute video activity with slides, segmented into a series of 5 mini-lectures by different faculty covering various aspects of gout in patients with or without CKD and KT. Educational effectiveness was assessed with a repeated-pairs pre-/post-assessment study design with 3 knowledge questions and 1 confidence question, in which each individual served as his/her own control. A chi-squared test assessed statistical significance at the P <.05 level. The activity launched 9/25/2020, with data collected through 12/4/2020.

Results: The analysis set consisted of responses from nephrologists (n=89) who answered all assessment questions during the study period. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge; average correct responses increased from 52% pre to 76% post education. Specific areas of improvement include: Treat-to-target strategy with a target of serum UA level < 6 mg/dL in patients taking urate lowering therapy (20% relative improvement, P<.05) Starting low-dose allopurinol in a patient previously diagnosed with gout and stage 3 CKD, presenting with painful subcutaneous tophi (25% relative improvement, P<.01) Recommending pegloticase without dose adjustment for the management of refractory gout in patients with stage 4 or 5 CKD (222% relative improvement, P<.001) Post-education, 48% of nephrologists had a measurable increase in confidence in their ability to manage patients with CKD who may develop gout.

Conclusions: This study demonstrated the success of online, segmented, mini-lectures on improving the evidence-based knowledge, competence, and confidence of nephrologists in appropriately managing gout in patients with CKD or kidney transplant.

PO1065

Development and Implementation of an Immune Suppression Toolkit to Guide Nephrology Fellow Medication Prescribing and Monitoring

Lauren Lamie, Panduranga S. Rao, Laura H. Mariani, Andrea L. Oliverio, Julie A. Wright Nunes, Markus Bitzer. *University of Michigan, Ann Arbor, MI.*

Background: There are many important considerations when prescribing high risk medications like immune suppression (IS). Informed by surveys administered to nephrology faculty and fellows, we developed a training curriculum and a concise, clinically applicable guide for IS prescription and monitoring.

Methods: A cross sectional survey was administered to nephrology faculty and fellows in November 2017 to assess perceptions, self-efficacy, and knowledge about prescribing, monitoring, and adjusting IS (12 questions with item-responses from 1=strongly agree to 4=strongly disagree). Informed by this survey we developed and implemented a toolkit (one-time training curriculum and IS reference guide) for fellows and assessed their perceptions of the toolkit using pre-and post-surveys. Results are reported using mean (SD) or N (%), with associations examined using linear regression.

Results: Twenty-eight nephrology faculty and fellows completed the baseline survey; 19 (68%) were attending physicians and 9 (32%) fellows. Twenty (71%) were men, 16 (59%) Caucasian, 11 (41%) Asian. Collectively, 19 (77%) reported prescribing IS ranging from 1 to 40 times yearly. Attending physicians exhibited higher self-efficacy in prescribing IS (1.7 (0.6) compared to 3.3 (0.8) p=0.02) and both attendings and fellows strongly agreed there was a need for IS guides 1.4 (0.8) and would use them if available 1.4 (0.6). In particular, fellows strongly disagreed they understood all steps needed to use

IS (3.3 (0.8) compared to 2.3 (.07) for attending physicians). In May 2021, 5 nephrology fellows received the IS toolkit and completed the surveys. Self-efficacy improved post intervention from mean (SD) 3.0 (1.2) to 2.2 (1.6). All 5 fellows (100%) strongly agreed that the toolkit added value to training, provided a guide they would use and recommended the toolkit for future fellows.

Conclusions: Nephrology faculty and fellows strongly agreed that there is a need for guides and protocols for prescribing and monitoring IS medications. Our pilot IS toolkit incorporated into nephrology fellow training was well received and improved fellow self-efficacy.

PO1066

Quality Improvement Study on Dialysis Education for Residents in an Outpatient Nephrology Clinic

Young C. Hsu, Jonas Kwok, Annika K. Khine, Thanh Cao. *University of Southern California, Los Angeles, CA.*

Background: In a large safety net hospital outpatient nephrology clinic in Southern California, resident physicians provide a significant portion of care to patients who have chronic kidney disease (CKD) stages III to V. Many of these patients eventually require initiation of long-term renal replacement therapy (RRT). However, there are many barriers to a timely and safe initiation of RRT in this patient population. One such barrier is a deficiency in education regarding dialysis between residents and patients in nephrology clinic. We attempted to identify barriers of resident education with patients regarding the topic of RRT and assess the effects of our educational intervention. Objectives: 1. Increase resident's knowledge regarding RRT based on pre and post intervention questionnaire 2. Increase resident's subjective preparedness/comfort level regarding discussions of RRT 3. Increase the frequency with which residents discuss RRT with patients

Methods: We created and distributed a pre-assessment survey to all Internal Medicine and Internal Medicine+Pediatrics residents at a large teaching hospital and received an approximately 50% response rate. Residents overwhelmingly responded that they do not feel patients have an adequate understanding of dialysis by the time they are deemed to require renal replacement therapy, nor did residents feel that they were adequately prepared or knowledgeable about the nuances of dialysis in order to counsel patients with CKD. We created a short teaching presentation with video reviewing dialysis topics and strategies to approach discussions with patients for residents who rotate through nephrology clinic, after which a post-survey was administered. Results are currently being collected.

Results: Results are currently being collected. We expect resident physicians will demonstrate increased knowledge regarding RRT based on pre- and post-intervention questionnaire, feel more comfortable discussing RRT with patients, and will discuss RRT more often with patients in clinic.

Conclusions: We expect to be able to conclude that resident education is a vital aspect in increasing patient understanding and comfort in regards to their disease process and dialysis at similar teaching centers where residents represent the majority of patient-physician interface in renal subspecialty clinic.

PO1067

The Impact of Electronic Sign-Out Dot-Phrase and Simulation Exercises on Inpatient Nephrology Transitions of Care

James D. Alstott,[1] Anand K. Ramadorai,[1] Sayee Sundar Alagusundaramoorthy,[2] Samantha J. Strennen,[1] Laura J. Maursetter,[1] Gauri Bhutani.[1] *[1]University of Wisconsin-Madison, Madison, WI; [2]University of Kentucky, Lexington, KY.*

Background: A fellow-led QI project was initiated in 2018 after division surveys indicated a need for change in the ongoing division transitions of care (TOC) practice.

Methods: We developed a standardized "sign-out score" to objectively assess TOC on the EMR sign-out. We next developed and implemented a standardized electronic medical record (EMR) dot-phrase as our first QI intervention. Case-based simulation sessions highlighting TOC pearls were conducted as the second QI intervention. Pre- and Post-intervention data for sign-out score was evaluated.

Results: A total of 647 patient EMR sign outs were assessed between 2018-2021. Overall sign-out accuracy score (0-2) significantly improved with QI interventions (pre-intervention mean 0.9 [95% CI: 0.9-1; N=298] to 1.6 post-dot phrase [1.5-1.6; N=220] to 1.7 post-simulation [1.6-1.8; N=129]; p<0.001). Table 1 provides details on the results of sign-out score. After adjustment for level of training, improvement in overall accuracy was independently associated with both dot-phrase (adjusted odds ratio (aOR) 7.6 [95% CI: 4.9-11.9]; p<0.001) and simulation (aOR 1.88 [1.1-3.16]; p=0.01). Although 2 sign-out score measures which were high performing pre-intervention worsened with dot-phrase implementation: anticipated changes and non-RRT management (aOR 0.15 [0.1-0.23]; p<0.001 and 0.07 [0.02-0.23]; p<0.001, respectively), improvement was seen following simulation (aOR 1.36 [0.84-2.2]; p=0.21 and 4.6 [1.74-14.5]; p=0.002).

Conclusions: A standardized EMR sign out dot-phrase and simulation exercises both improved the overall accuracy of TOC practiced for inpatient Nephrology consult service. The impact of dot-phrase alone on previously high performing TOC measures suggests the need for further optimization of dot-phrase and continuing simulation to enhance provider self-realization of important components of TOC.

Table1: Frequency of best possible "sign-out score" before and after QI interventions

Sign-out score measures:	Pre- intervention (N=298)	Post-dot phrase (N=220)	Post- simulation (N=129)	Overall p-value
Renal Diagnosis (% [N])	14 (41)	72 (159)	90 (116)	<0.001
Baseline serum creatinine (% [N])	41 (123)	81 (178)	82 (106)	<0.001
Renal replacement treatment (RRT) details (% [N])	66 (112/170)	80 (90/112	89 (67/75)	<0.001
Non-RRT treatment details (% [N])	97 (83/86)	67 (70/104)	91 (51/56)	<0.001
Overall accuracy (% [N])	18 (55)	67 (147)	76 (98)	<0.001
Anticipated Changes (% [N])	67 (199)	30 (66)	35 (45)	<0.001

PO1068

Point-of-Care Ultrasound Training for Nephrologists: A National Survey of Nephrology Fellows

Catherine A. Moore,[1] Daniel W. Ross,[2] W. Charles O'Neill.[3] *[1]University of Rochester Medical Center, Rochester, NY; [2]Northwell Health, New Hyde Park, NY; [3]Emory University, Atlanta, GA.*

Background: Despite many potential applications of PoCUS in nephrology, nephrologists have been slow to adopt this technology. The past five years have seen an increase in ultrasound training within nephrology fellowship programs, although the scope of training is unknown. We conducted a national survey of nephrology fellows in United States-based training programs. The main objective of this survey was to identify the current landscape and clinical use of POCUS in US nephrology training programs.

Methods: We surveyed post-graduate year (PGY) 4-8 trainees in US nephrology fellowship programs. Survey items were included in a broader trainee survey disseminated to all programs by the American Society of Nephrology in April, 2021. The six-item survey instrument probed attitudes toward POCUS, current use, preferred instruction format, and perceived competence.

Results: Out of 822 US nephrology fellows surveyed, 631 (76.8 %) responded. A majority of respondents were 30-34 years of age with the majority of participants graduating from international medical schools. The majority of fellows (64.6%) indicated interest in PoCUS education, with highest interest in procedural ultrasound and diagnostic kidney imaging. Only 240 (38%) of fellows reported receiving PoCUS education during training. Of the fellows who received PoCUS training, 112 of 227 (49%) reported incorporation of PoCUS at a frequency of less than monthly, with only 62 of 227 (27%) incorporating PoCUS once per week or more. 83 of 226 (36%) fellows reported receiving adequate instruction to independently perform P0CUS, and 74 of 224 (33%) reported that they expect to be competent to independently perform PoCUS by the end of training. Hands-on training, particularly with an instructor, was highly valued as a teaching technique.

Conclusions: Despite high trainee interest in POCUS, the majority of current nephrology fellows are not receiving training in this domain and do not feel competent to independently perform PoCUS procedures. Hands-on training guided by a skilled instructor is a highly valued PoCUS teaching technique. This survey identifies a need for the development of PoCUS programs within nephrology fellowships that incorporate hands-on teaching techniques.

PO1069

Point-of-Care Ultrasound Education in Nephrology During the COVID-19 Pandemic

Andrew A. Moses, Hilda E. Fernandez. *Columbia University Irving Medical Center, New York, NY.*

Background: The COVID-19 pandemic led to changes in the way people taught and learned, with higher reliance on online learning. Unfortunately, point of care ultrasound is a difficult topic to teach without hands-on practice. Here we discuss the implementation of a novel ultrasound curriculum during the COVID-19 pandemic.

Methods: The curriculum was based on published curriculum on point of care ultrasound for the nephrologist, with focus on four fundamental exams: kidney, lung, cardiac, and volume status. We employed a flip the classroom approach with pre-reading and videos, a pre-session quiz, followed by hands on application of skills. Standardized patients or volunteers would have been used for the hands-on session, but this was eschewed for safety concerns. The fellows and instructors themselves modeled, with proper sanitation and PPE. The hands-on sessions were well received and attended by all fellows. The skills were then applied on the wards.

Results: As the restrictions lifted and vaccines were available, standardized patients were available in small groups. The learners were scheduled for two hour-long sessions with standardized patients, for practice of the skills acquired as well as the Objective structured clinical examination (OSCE). After the first session with all learners, we added a third session focused on OSCEs, as well as line placement as requested by the learners. By the end of the third session, all learners felt more confident in their skills and had passed their OSCEs.

Conclusions: Given the positive reception, this course is planned to continue as currently structured as well as expanded upon by rising fellows. The use of flipped classroom helped maximize the time of supervised scanning by learners. The use of ultrasound by fellows has risen and will continue to climb with further development of this important curriculum.

Osce Station 1: Focused Renal Ultrasound

Instruction to the Candidate:

1. Introduce yourself to the patient, your role, and explain, in brief, what you will be doing today
2. Access the correct probe and materials within the room
3. Access the correct views in a timely manner
4. Give the patient a brief overview of your findings
5. Clean and sterilize equipment
6. Document your findings

Instructions to the Assessor

1. Indicate that this is a practical skill session. Instruct them to speak out loud all of their actions so they can be credited appropriately
2. Help locate any materials that may not be obviously accessible when asked
3. Instruct them to perform a focused renal ultrasound
4. Instruct them to perform a quick bladder scan

Equipment:

1. Hand sanitizer
2. Butterfly iQ and iPhone
3. Ultrasound gel
4. Drapes
5. Tissues
6. PDI purple wipes

Checklist

Action/Response	Maximum	Actual
Proper Hand hygiene, introduces self to patient and explains role and procedure coherently	1	
Drapes patient appropriately	1	
Chooses correct probe setting (abdominal) and adjusts depth and gain if needed	1	
Obtains Coronal image of L Kidney, fans to view whole kidney, Saves image	1	
Obtains Sagittal image of L Kidney, fans to view whole kidney, Saves image	1	
Obtains Coronal image of R Kidney, fans to view whole kidney, Saves image	1	
Obtains Sagittal image of R Kidney, fans to view whole kidney, Saves image	1	
Obtains image of bladder, attempts to visualize ureteral jets on both side	1	
Wipes patient off, ensures comfort	1	
Explains findings	1	
Sterilizes Probe and phone prior to returning to document	1	
Documents procedure and finding	1	
Total Marks	12	

PO1070

Teaching Application of Ultrasound in Nephrology Practice in Medical Schools Using Student Peer Teaching: A Prospective, Randomized Pediatric Trial

Rainer Büscher, Philip Geiling, Fiona Schmitt. *Universitatsklinikum Essen, Essen, Germany.*

Background: Ultrasound has become the leading diagnostic technology in pediatrics due to its high sensitivity, easy applicability and lack of invasiveness and plays critical roles in many aspects of nephrology practice. However, it is associated with a higher examiner dependent variance. Teaching ultrasound in medical schools has grown in importance over the past years, while pediatric aspects are mainly reserved for postgraduate education. Student peer teachers take on the task of lecturers at many faculties with promising results in ultrasound education.

Methods: We designed a prospective, randomized trial in a pre-/post-test design for 257 4th year medical students in our pediatric classes to investigate the effectiveness of peer teaching in pediatric ultrasound. Besides a mandatory theoretical training by a student peer teacher prior to the course for all students (group A and B), half of the participants received a supporting manual (group B). All students had to measure the right kidney volume of their partners in advance to test pre-existing practical skills and a multiple choice progress test was performed prior and after the course. Afterwards, students were spitted in smaller groups and received a standardized practical training by a student peer teacher in our skills lab using similar ultrasound machines. The success was examined using an objective structured clinical examination (OSCE) at the end of semester using a pediatric-nephrologic case vignette.

Results: All students (groups A and B) showed an impressive increase of knowledge and the course and clinical trial was well received. Over 95% of students presented the renal topography sonographically well with no significant differences between both groups. However, we also observed a high interindividual variance in the volumetric results. The use of a supporting pediatric ultrasound manual did not show any significant benefit.

Conclusions: The concept of student peer teaching seems to work very well also in specific disciplines such as pediatric ultrasound and pediatric nephrology education. Therefore peer teaching seems to be of value in medical schools also in teaching complex learning contents.

Patient Navigators and Study Coordinators: A Team Approach Towards Patient Support in Decentralized Clinical Trials

Cynthia J. D'Alessandri-Silva,[1] Kimberley D. Cranstoun,[2] Anna Klochak.[3] *[1]Connecticut Children's Medical Center, Hartford, CT; [2]Advicenne Inc., Ardmore, PA; [3]Children's Hospital Colorado, Aurora, CO.*

Background: COVID-19 related restrictions have accelerated adoption of decentralized clinical trials(DCT). DCTs offer increased patient flexibility via online study platforms, telemedicine and home-based nursing. DCTs reduce travel, hospitalization and in-person interactions, all problematic under COVID. Potential drawbacks exist for both patients and study coordinators, however. In DCTs, removal of study-site visits may leave patients feeling confused, unsafe, disempowered and disengaged, potentially increasing drop-out risk. While DCTs may mean increased enrollment for sites, management of novel patient pathways may prove more time-consuming for study coordinators. Crucial protocol driven events or patient concerns/questions may be missed due to complex patient tracking.

Methods: The role of the patient navigator(PN) was developed to support both patients and study coordinators in DCTs. PNs will provide culturally-appropriate psychosocial education to ensure patients feel safe, informed, and supported. PNs serve as conduits between the patient and the study site, ensuring bi-directional communication of patient progress. This unique approach is being trialed in ARENA2, a pediatric Phase III study in primary distal renal tubular acidosis, a rare renal disease.

Results: A multi-lingual team with unique educational and counseling experience was recruited and trained on the protocol and disease. The team will provide weekly check-ins with patients to foster engagement as well as identify any concerns the patient may be having in home healthcare. This role will offer around the clock patient support which will increase accessibility and decrease burden experienced by study coordinators with heavy caseloads. PNs have also developed educational videos in target languages using lay-friendly terminology to ensure patient understanding. Topics include clinical trials, ARENA2 and research in rare diseases. The study website contains additional resources including written articles that help set expectations and provide subjects with strategies for success as they go through ARENA2.

Conclusions: The concept of sponsor-driven PN team services in DCTs will offer both patients and study sites the added benefits of support.

Funding: Commercial Support - Advicenne Inc.

PO1072

Do Undergraduates Know "Nephrology?"– A Single-Site Survey of College Students

Julia M. Hopkins,[1] Juan Carlos Q. Velez,[2] John M. Arthur,[3] Michael G. Janech.[1] *[1]College of Charleston, Charleston, SC; [2]Ochsner Medical Center - New Orleans, New Orleans, LA; [3]University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Over the past decade, Nephrology has experienced a 43% decline in fellowship applicants. A factor to choosing Nephrology could be a lack of early exposure. While studies have been conducted to explain why residents choose a specific fellowship program, none have surveyed the undergraduate student population to inquire whether the name "Nephrology" was even a recognizable medical specialty compared to other medical specialties. To this end, we conducted a survey of undergraduate students at the College of Charleston (CofC) to test the hypothesis that Nephrology will rank amongst the least recognizable specialties.

Methods: 274 undergraduates at CofC responded to a survey where they were asked to select every medical specialty they recognized by name (15 real specialties/1fictious). Demographic questions regarding sex, race, collegiate level, high school location, pre-med track, and household income were included. Differences were considered by comparing 95% confidence intervals or Chi-Square test. Spearman-Rank test was used to examine whether the number of applicants per specialty fellowship position was correlated with the proportion of responses.

Results: Out of 15 medical specialties, Nephrology ranked lowest (29%); whereas, Pediatrics (97%) and Surgery (97%) ranked highest. The fictious specialty, "diasymptomology" was recognized least (4%). Sex, race, collegiate level, and household income were not different between those students that recognized the word Nephrology versus those that did not. Pre-med students were about twice as likely ($p<0.001$) to have recognized Nephrology versus non pre-med students (49% vs. 22%, respectively). There was no correlation between the proportion of undergraduate students who recognized a specific medical specialty and the number of applicants per fellowship position in 2019 ($r=0.2$, $p=0.7$).

Conclusions: Nephrology was the least recognized, non-fictional, specialty amongst undergraduates. Lack of correlation between student responses and fellowship applications, suggest that name recognition alone will not predict fellowship applicant number. The discrepancy between Nephrology and other specialties highlights a gap in name recognition at an early career stage, even amongst premedical students.

PO1073

The Information Dilemma

Tejas Desai. *NOD Analytics, Harrisburg, NC.*

Background: The Internet has changed search. The amount of searchable information is growing as more bytes are added/modified than deleted and the criteria by which search results are obtained has also changed. Results are not exclusively obtained by their relevance to the query. Social media search uses predictive algorithms to display results with which the learner is most likely to engage (retweets, likes, replies, clicks). Results that promote engagement are valued more than those pertinent to the query. Known as customized search, this strategy is obvious when 2 individuals make an identical query and receive different search results and in a different order. Customized search protocols increase engagement but at the cost of creating an information dilemma. In this dilemma, each learner is exposed to a different set of facts upon which scientific discussions are started. In order to establish a common set of facts, I created a search engine based on a standard search protocol.

Methods: NephTwitterArchive.com is a non-commercial search engine that identifies scientific tweets from various NephTwitter communities. I coded 51 algorithms to identify scientific tweets at 15-minute intervals. Scientific tweets have informative text and a slide, URL to a scientific resource, or both. The engine uses a standard search protocol in which search results are based only on the query. All searches are anonymous. I measured learner-affinity for the engine by number of completed searches. Four elements are required for a single completed search to be recorded: query is made & executed, results are displayed, and a link to the primary scientific tweet is clicked.

Results: From 11/2011 to 4/2021, the engine identified 341742 tweets from 517 NephTwitter communities. A third of these were scientific tweets. From 10/2019-4/2021 learners completed 28313 searches (monthly median 1368, IQR 1264-1580). From 2019 to 2020, median monthly completed searches changed +12%; from 2020 to 4/2021, a +38% change. Nearly half of all learners used the engine immediately after visiting Twitter or Facebook; 37% visited the engine directly.

Conclusions: Scientific discourse is valuable if all participants start the conversation with a common set of facts. Social media search tools do not support this goal. A search engine that uses standard search protocol can mitigate the information dilemma and restore search to its primary function of providing results based on query alone.

PO1074

Understanding Healthcare Education for Nephrology Best Practice – A Question of Which Health Professionals: A Quantitative Investigation

Shahid N. Muhammad.[1,2] *[1]The University of the West of England (UWE), England UK, Bristol, United Kingdom; [2]The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.*

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations. 1) To understand, whether, retrospectively, there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education.

Methods: Group disclaimers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice surrounding confidentiality and data protection. Fourteen (14) topic tags were applied over 1-month (March and April 2020) between the Renal Patient Support Group (RPSG) (est.2009) and the Kidney Disease and Renal Support Group (KDARs) for Kids (est.2014) platforms. Two surveys were developed with several themes and implemented via online Qualtrics Software., one for health professionals, and one for CKD patients. Participants only had to complete once.

Results: 19 surveys completed from Health Professionals and 45 completed from CKD patient cohort. Descriptive statistics was used to analyse quantitative data and inform results. Relating Health Professionals, highest responses included Female (57.14%) vs. Males (42.86%). Relating CKD Patients, highest responses included Females (55.00%) vs. Males (38.89%). 2,560 threads were topic tagged between two groups. Health professionals who contributed highest included Healthcare Scientists (47 %), second were Nephrologists, other Allied Health Professionals (AHPs) and other (all 17.65 %), and GPs (5.88 %). CKD patients who contributed highest included Transplant patients (60.53%), second were ESRD (Haemodialysis) (13.16%), and CKD patients (stages 3-5) (10.53%). AHPs will increasingly work with GPs to provide laboratory screening, and POCT advice and/ or education (16.67%). CKD patients who contributed relating Appropriate Support Surrounding Healthcare, highest response included I have ability to communicate with a health professional about blood tests and investigations (25.49%).

Conclusions: Online educational modules should complement CKD care, and be delivered by broader Allied Health Professionals. This is the first UK retrospective study that examines clinically relevant educational gaps between online paediatric and adult renal cohorts close to two decades. Education is where healthcare requires investment.

PO1075

A Survey of Current Trends in Urinary Extracellular Vesicle Research

Uta Erdbruegger,[1] Elena S. Martens-Uzunova,[3] Alicia Llorente,[4] Luca Musante,[1] Charles J. Blijdorp,[3] Dylan Burger.[2] *[1]University of Virginia, Charlottesville, VA; [2]Ottawa Hospital, Ottawa, ON, Canada; [3]Erasmus MC, Rotterdam, Netherlands; [4]Oslo Universitetssykehus, Oslo, Norway.*

Background: The Urine Task Force of the International Society of Extracellular Vesicles (ISEV) was created to advocate for best practices in this emerging area of research. Here we present the results of a survey, conducted using SurveyMonkey by the Urine Task Force, to better understand current research practices in the study of urinary extracellular vesicles (uEVs).

Methods: Two separate, identical surveys were administered: one directed to Urine Task Force members (28 respondents at the time of reporting) and one directed to the ISEV community (42 respondents).

Results: The mean time studying uEVs was 7.8 years for task force members and 5.4 years for community respondents. For task force members: 48.3% of respondents primarily focus on kidney, 44.8% prostate and 6.9% bladder. For the community focus was 29.4% kidney, 21.5% prostate, 19.6% bladder and 29.4% "other". Both communities largely collect spot urines compared with timed collection (Task force: 78.6% spot vs 21.4% timed, Community: 75.8% spot vs 24.2% timed). Urine storage was a significant focus of the survey. For the Task Force: 92.9% of respondents studied samples stored >3 months, 57.1% samples stored <3 months, and 50% studied fresh samples. The community studied less often fresh samples. Both groups predominantly stored samples as "cell-free urine": 85.7% for task force and 65.6% for community. All task force respondents study samples frozen at -80 °C with 10.7% of respondents also studying samples stored at 4 °C. By contrast, 93.8% -of community respondents stored samples at 80 °C, 9.4% at -20 °C and 6.3% at 4 °C. The task force ranked the following isolation methods in order of priority 1) centrifugation, 2) size exclusion chromatography, and 3) filtration. For the community survey this was similar. Both surveys prioritized the same downstream applications: 1) protein analysis, 2) RNA analysis, 3) functional assays. The urine task force identified "understanding of approaches to normalization" while the community identified "Impact of renal disease and comorbidities on EV analysis" as key knowledge gaps.

Conclusions: In summary, the present survey identified key similarities and differences between current practices for the Urine Task Force and the urinary EV research community. Such information will be used to help guide future efforts to address key knowledge gaps.

PO1076

A Potential Novel Variant of Slc4a4 Can Regulate the Functional Activity of the Electrogenic Na/HCO3 Cotransporter NBCe1-B

Seong-Ki Lee,[1] Marie Michenkova,[1] Michael F. Romero,[2] Rossana Occhipinti,[1] Walter F. Boron.[1] *[1]Case Western Reserve University School of Medicine Department of Physiology and Biophysics, Cleveland, OH; [2]Mayo Clinic Department of Physiology and Biomedical Engineering, Rochester, MN.*

Background: The electrogenic Na/HCO_3 cotransporter (NBCe1) regulates intracellular pH in many tissues and elicits vectorial HCO_3^- flow across many epithelia. Five variants of NBCe1 have been identified: -A, mainly in kidneys; -B, ubiquitous; -C, in brain; -D/E, in mouse reproductive organs. Because the A/D and B/C/E variants are transcribed from two distinct promoters, they have different NH_2-termini (Nt). The Romero Lab developed an isoform-specific knockout (KO) mouse of NBCe1-A/D by causing a frameshift mutation in the A/D variants' unique Nt region (Chen et al, *JASN* 25:71A, 2014). Fang et al found that NBCe1-B (e1B) is expressed in kidneys of both WT and KO mice, and that e1B expression increases with metabolic acidosis in KOs (*AJP Renal*, 2018). They reached this conclusion by RT-PCR-amplification of B-variant–specific bands from KO kidneys. However, these amplifications generated several unidentified bands. Intrigued by these additional bands, we repeated the RT-PCR in an attempt to identify them.

Methods: Using TA cloning, we determined the sequences of two of the unidentified bands: (1) partial *Slc4a4* product missing exon 4, which would lead to a frameshift, and (2) partial *Slc4a4* product missing exons 4 & 5, but remaining in-frame. Because Fang et al confirmed lack of C/D/E variants, we introduced mutations (1) and (2) in e1B and studied functional activity by two-electrode voltage-clamping in *Xenopus* oocytes. We also determined protein abundance/interaction by surface protein biotinylation. Inasmuch as e1B has low activity, we co-expressed WT e1B and/or mutant e1B with super-IRBIT (which lacks PP1 binding site).

Results: We found that neither mutant, alone, has activity even though Δexon 4/5-e1B interacts with super-IRBIT. However, Δexon 4/5-e1B has a dominant-negative (DN) effect on WT e1B. To test if these mutants are specific for KO mice, we inspected other WT tissues.

Conclusions: Contrary to our hypothesis, we found that e1B mutants (1) and (2) exist at least in kidneys, brain, and pancreas, leading us to conclude that cells could in principle regulate NBCe1-B activity by adjusting the amount of the novel DN variant Δexon 4/5-e1B.

Funding: NIDDK Support, Other U.S. Government Support

PO1077

A Novel I551F Variant of Na+/HCO3- Cotransporter NBCe1 Shows Reduced Cell Surface Expression and May Exert a Dominant Negative Activity

Osamu Yamazaki,[1,2] Tadashi Yoshida,[2] Junichi Hirahashi,[2] Matsuhiko Hayashi,[3,2] Shigeru Shibata.[1] *[1]Teikyo Daigaku, Itabashi-ku, Japan; [2]Keio Gijuku Daigaku Byoin, Shinjuku-ku, Japan; [3]Kawakita Sogo Byoin, Suginami-ku, Japan.*

Background: Homozygous mutations in *SLC4A4*, encoding the electrogenic Na^+/HCO_3^- cotransporter NBCe1, cause proximal renal tubular acidosis (pRTA) associated with extrarenal symptoms. Although 17 mutated sites in *SLC4A4* have thus far been identified among pRTA patients, physiological significance of other nonsynonymous single nucleotide variants (SNVs) in this gene remains largely undetermined.

Methods: We investigated the functional properties of SNVs in NBCe1 using immunocytochemical, western blotting, and electrophysiological assays. From NCBI data base, we identified 13 SNVs that have not previously been characterized in highly conserved, transmembrane domains of NBCe1-A.

Results: Immunocytochemical analysis revealed that I551F variant was present predominantly in the cytoplasm in HEK293 cells, whereas all other SNVs did not show obvious changes in subcellular distribution. Western blot analysis in HEK293 cells demonstrated that the I551F variant showed impaired glycosylation and a 69% reduction in cell surface levels. To determine the role of Ile551 in more detail, we examined the significance of various artificial mutants both in non-polarized HEK293 cells and polarized MDCK cells, which indicated that only I551F substitution resulted in cytoplasmic retention. Moreover, functional analysis using *Xenopus* oocytes demonstrated that the I551F variant had a significantly reduced activity corresponding to 39% of that of wild-type, whereas any other SNVs and artificial I551 mutants did not show significant changes in activity. Finally, immunofluorescence study in HEK293 cells indicated that the I551F variant retains wild-type NBCe1-A in the cytoplasm.

Conclusions: These data demonstrate that I551F-NBCe1-A shows impaired transport activity predominantly through cytoplasmic retention, and suggest that the variant can have a dominant-negative effect by forming complexes with wild-type NBCe1-A.

PO1078

Diacidic Motif Is Required for Efficient Transport of NKCC2 to the Plasma Membrane

Dalal Bakhos Al Douaihy,[1,3] Elie Seaayfan,[2] Sylvie Demaretz,[1,3] Kamel Laghmani,[1,3] Martin Kömhoff.[2] Inserm, CNRS-ERL8228 *[1]Sorbonne Universite, Paris, France; [2]Philipps-Universitat Marburg Fachbereich Medizin, Marburg, Germany; [3]Centre de Recherche des Cordeliers, Paris, France.*

Background: Mutations in the apical Na-K-2Cl cotransporter, NKCC2, cause type I Bartter syndrome (BS1), a life-threatening kidney disease. We have previously demonstrated that BS1 nonsense mutation Y998X, which interferes with the highly conserved dileucine like motifs of NKCC2 C-terminus, compromises NKCC2 surface delivery through ER retention mechanisms. However, whether these dileucine like motifs are sufficient for anterograde trafficking of NKCC2 remained to be determined. Consequently, the aim of the present study was to investigate whether additional motifs are required for NKCC2 efficient transport to the plasma membrane.

Methods: NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 surface expression was assessed by cell surface biotinylation assay. NKCC2 stability and maturation was monitored by cycloheximide chase assay.

Results: Among the motifs identified as ER export signals in ion channels are the diacidic D/E-X-D/E motifs, which have been shown to promote interaction of cargo with the coat complex II (COPII) budding machinery. Interestingly, sequence analysis of NKCC2 C-terminus revealed the presence of two di-acidic motifs, ^{949}EEE^{951} and ^{1019}DAE^{1021}, located upstream and downstream of BS1 mutation Y998X, respectively. Importantly, mutation of ^{1019}DAE^{1021} to ^{1019}AAA^{1021} disrupted glycosylation and cell surface expression of NKCC2, whereas mutation of ^{949}EEE^{951} had no effect. Cycloheximide chase analysis demonstrated that the absence of the terminally glycosylated form of ^{1019}AAA^{1021} was not due to increased rates of degradation of mutant co-transporters, but was instead caused by defect in maturation. Accordinglty, co-immunolocalization experiments showed that ^{1019}AAA^{1021} was trapped in the ER. Finally, overexpression of dominant negative mutant of Sar1 GTPase completely abolished NKCC2 maturation, clearly indicating that NKCC2 exit from the ER is COPII dependent.

Conclusions: Our data indicate that in addition to highly conserved dileucine like motifs of NKCC2 C-terminus, the cotransporter uses also a di-acidic exit code for export from the ER and targeting to the cell surface. Elucidating the molecular mechanisms of the motif-facilitated ER export may help to develop therapeutic strategies targeting NKCC2 transport from the ER to the cell surface.

PO1079

Furosemide Alleviates Hypercalciuria and Hypomagnesemia in Claudin 16-Deficient Mice

Natalia Kriuchkova, Tilman Breiderhoff, Dominik Müller, Duygu E. Yilmaz, Sebastian Bachmann, Kerim Mutig. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Loss-of-function mutations in the CLDN16 gene encoding for claudin-16 lead to Familial Hypomagnesaemia with Hypercalciuria and Nephrocalcinosis (*FHHNC*) in human. Claudin-16 resides in tight junctions of the thick ascending limb (TAL) and mediates paracellular reabsorption of divalent cations. The ensuing distal convoluted tubule (DCT), connecting tubule (CNT) and cortical collecting duct (CCD) perform transcellular Ca^{2+} and Mg^{2+} reabsorption via the transient receptor potential (TRP) channels, TRPV5 and TRPM6. DCT, CNT, and CCD exhibit unique functional and structural plasticity enabling them to compensate for defects of proximal salt reabsorption. Using claudin-16-deficient (*Cldn16*-/-) mice as a FHHNC model, we tested the hypothesis that enforcement of distal nephron function using a loop diuretic furosemide may enhance the transcellular reabsorption of Ca^{2+} and Mg^{2+} thus compensating for the paracellular TAL defect.

Methods: Wild-type (WT) vs. Cldn16-/- mice were treated with furosemide (50 mg/kg body weight) for 7 days followed by physiological, morphological and biochemical evaluation of kidneys.

Results: Compared to WT, *Cldn16*-/- mice showed significantly increased urinary excretion of Ca^{2+} and Mg^{2+} and hypomagnesemia at baseline. Furosemide enhanced urinary Ca^{2+} excretion without concomitant increase of urinary Mg^{2+} levels in WT. In contrast, *Cldn16*-deficient mice responded to the diuretic with a marked reduction of urinary Ca^{2+} levels and normalization of plasma Mg^{2+} levels. Evaluation of distal Ca^{2+} and Mg^{2+} transport proteins by immunoblotting and immunofluorescence showed furosemide-dependent increases of TRPV5 and calbindin levels in *Cldn16*-/- kidneys along with signs of hyperthrophy of the distal nephron.

Conclusions: The present results suggest that loop diuretics bear potential to alleviate symptoms of Cldn16-deficiency due to compensatory stimulation of electrolyte reabsorption in DCT, CNT, and CCD.

Funding: Government Support - Non-U.S.

PO1080

Cholesterol Efflux on Sodium-Sensitive Blood Pressure

Karin C. Oliveira,[1,2] Robert L. Repetti,[1,2] Rajeev Rohatgi.[2,1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Northport VA Medical Center, Northport, NY.*

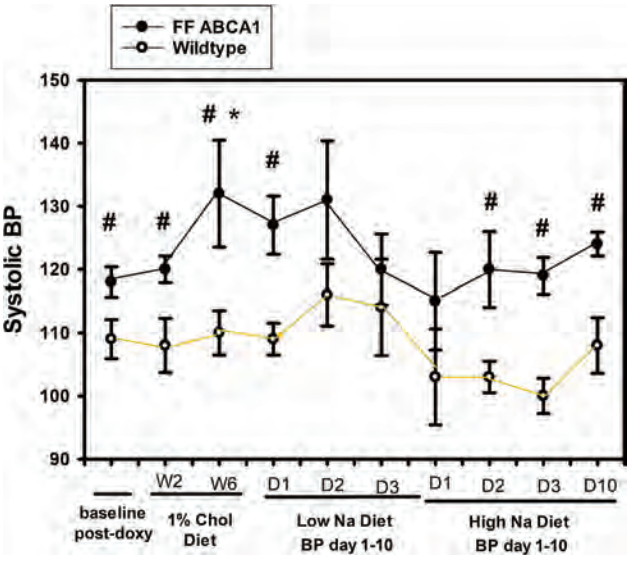
Background: Na sensitive BP is linked to greater mortality than Na resistant hypertension. Dyslipidemia and changes in plasma membrane (PM) lipid composition contribute to Na sensitivity. In addition, diets enriched in cholesterol (chol) (1) raise cortical collecting duct (CCD) chol, (2) stimulate ENaC, and (3) repress natriuretic factors. Renal ABCA1, a chol efflux protein, increases in chol fed mice to mitigate cellular chol integration. Therefore, we hypothesize renal tubular ABCA1 ablation will lead to Na dependent changes in BP.

Methods: Transgenic mice ($Tg^{PAX8rtTA;tetO\text{-}Cre/+}$), which express CRE recombinase in tubular epithelia when fed doxycycline (dox), were bred with mice expressing floxed ABCA1 to generate a model deficient in tubular ABCA1 (FF). Tail cuff systolic BP (SBP; Visitech) and urine volume after diuretic administration was measured in mice. Immunoblotting was performed on kidney protein lysate.

Results: Immunoblotting of renal PM showed reduced ABCA1 (50±11%; n=6, $p<0.05$) in FF compared to littermate wildtypes (WTs; 100±7% (n=5)) mice. The SBP of FF (n=11) mice was greater immediately post-dox and during chol or high Na feeding (Fig.1; #, $p<0.05$ vs WT) compared to WTs (n=15). Low Na diet abolished SBP differences between mice, while 6 weeks (W) of 1% chol diet raised the SBP in ABCA1 FF vs FF mice post-dox feeding (Fig. 1; *, $p<0.05$ vs. FF post-dox). No difference NKCC2, NCC or α-ENaC protein abundance was noted in whole kidney lysate; however, γ-ENaC 83 kD and cleaved 70 kD subunits were increased in FF compared to WT kidney. Furosemide injection induced a greater diuretic effect in FF (n=4; 1.35±0.08 mL) vs WT (n=4; 0.88±0.08 mL; $p<0.05$).

Conclusions: Tubular ABCA1 deficiency stimulates Na dependent SBP which we speculate is related to enhanced Na dependent ENaC and NKCC2 activity.

Funding: Veterans Affairs Support, Private Foundation Support



SBP of FF and WT mice in days (D) and weeks (W) of diet

PO1081

WNK4 Is a Transductor of V2 Receptor Signaling in the Thick Ascending Limbs and Distal Convoluted Tubules

Hector Carbajal-Contreras,[1,2] Adrian R. Murillo-de-Ozores,[1,2] German R. Magaña,[1,2] Norma H. Vázquez,[1] Gerardo Gamba,[1,2] Maria Castañeda-Bueno.[2] Molecular Physiology Unit *[1]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico*.

Background: Vasopressin (AVP) is essential for water and Na^+ homeostasis. In the kidney, its actions are mediated by the V2 receptor (V2R), which signals through protein kinase A (PKA). The phosphorylation of the Na^+-Cl^- cotransporter (NCC) and the Na^+-K^+-Cl^- cotransporter 2 (NKCC2) by the WNK-SPAK signaling pathway upregulates their activity and increases in response to AVP. WNK4 can be regulated by PKA through the phosphorylation of its RRxS motifs in *in vitro* models. Thus, we hypothesized that WNK4 mediates the activation of NCC and NKCC2 in response to AVP.

Methods: We transfected HEK293 cells with NKCC2 or the V2R with SPAK and either WNK1, WNK3, WT WNK4 or WNK4 with Ala instead of Ser in its 5 RRxS motifs. Cells were stimulated with 30 nM forskolin or 1 nM desmopressin (dDAVP). We cross-bred our WNK4$^{-/-}$ strain (in a C57BL/6 background) with 129Sv mice while selecting for the full-length allele of NKCC2 to evaluate the phosphorylation status of NKCC2. dDAVP (5 ng/h) was administered in miniosmotic pumps for 3 days. Protein extracts were subjected to immunoblot. qRT-PCR of *Wnk4*, *Slc12a3*, and 18S was carried out with Taqman probes. 12 h urine collections were conducted and water intake between the groups was equalized using gelled diets.

Results: In HEK293 cells, we found that an increase in phosphorylation of SPAK and of NKCC2 at T100 and T105 (SPAK regulated sites) with forskolin requires of WT WNK4. In contrast, phosphorylation of S130 of NKCC2 was WNK-independent. Only cells with WT WNK4 and the V2R showed an increase in SPAK phosphorylation when stimulated by dDAVP. dDAVP also increased WNK4's phosphorylation at S1196. dDAVP-infused WT mice increased their total and phosphorylated WNK4, NCC, and NKCC2, as well as phosphorylated SPAK and *Slc12a3* mRNA levels. These effects were absent in WNK4$^{-/-}$ animals. In contrast, WNK4$^{-/-}$ mice did respond to dDAVP by increasing AQP2 protein levels. In addition, WNK4$^{-/-}$ mice had increased water consumption at baseline and an increased urine output when water-restricted, with a tendency towards lower total kidney osmolality.

Conclusions: Our data suggest that WNK4 is a transductor of AVP signaling in the TAL and DCT, modulating NKCC2 and NCC. This might contribute to the anti-natriuretic effects of this hormone and the increase in medullary osmolality that occurs with antidiuresis.

Upregulation of NCC by Hypokalemia Involves Additional Mechanisms to Direct Cl- Sensing by WNK4

Adrian R. Murillo-de-Ozores,[1] Hector Carbajal-Contreras,[1] German R. Magaña,[1] Norma H. Vázquez,[1] Eric J. Delpire,[2] Gerardo Gamba,[3] Maria Castañeda-Bueno.[3] *[1]Universidad Nacional Autonoma de Mexico, CDMX, Mexico; [2]Vanderbilt University, Nashville, TN; [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, CDMX, Mexico*.

Background: Cl^--sensitive WNK4 kinase plays an important role in the modulation NaCl reabsorption in the distal convoluted tubule (DCT). WNK4 activates the NaCl cotransporter (NCC) in response to hypokalemia, promoting its phosphorylation. Low plasma $[K^+]$ decreases intracellular $[Cl^-]$ ($[Cl^-]_i$) and thus Cl^- binding to WNK4's active site, leading to its activation. We have previously shown that hypokalemia and low $[Cl^-]_i$ increase WNK4 phosphorylation at S64 and S1196. Hypokalemia also promotes phosphorylation of KLHL3, the substrate adaptor of the Cullin-Ring ligase that regulates WNK degradation, at a site that is similar to S64 and S1196 of WNK4. Thus, we wondered if KLHL3-mediated modulation of WNK abundance in the DCT is also regulated by $[Cl^-]_i$.

Methods: Transient transfection of HEK293 cells and incubation with media with varying electrolyte concentrations. Hydrochlorothiazide (HCTZ) administration in the diet to WT mice for 12 hrs. Generation of WNK4-L319F mice with CRISPR/Cas9, which were fed with normal or low K+ diets for 7 days. Immunoblot assays of cell and kidney lysates. Immunofluorescence (IF) of kidney slices.

Results: Co-expression of WNK4 and KLHL3 in HEK293 cells promoted a decrease in WNK4 abundance, which was partially prevented by incubation with a low K^+ medium or a hypotonic low Cl^- medium. Next, HCTZ-treated mice showed no changes in plasma $[K^+]$, but increased pNCC and KS-WNK1 protein levels were observed by immunoblot, possibly due to decreased $[Cl^-]_i$. In addition, WNK1- and WNK4- positive cytoplasmatic puncta were observed in the DCTs by immunostaining. In WNK4-KO mice, which might also have decreased $[Cl^-]_i$ in their DCT, we also observed increased KS-WNK1 levels as well as WNK1-positive cytoplasmic puncta. Finally, WNK4-L319F mice were capable of upregulating pNCC, despite having a Cl^--insensitive WNK4. We also observed an increase in WNK4 protein levels and its phosphorylation at Ser64 and Ser1196 in WNK4-L319F mice on low K^+ diet.

Conclusions: Our work shows that low K^+ mediated upregulation of NCC does not solely depend on the Cl^--sensing capability of WNK4. A yet unidentified Cl^--regulated mechanism can regulate WNK4 phosphorylation and KS-WNK1 and WNK4 abundance, which converges in the increase of the WNK4-NCC pathway in the DCT.

Calcium-Sensing Receptor-Mediated Activation of the WNK4-SPAK-NCC Pathway by Glucose/Fructose In Vivo and Ex Vivo

Jessica P. Bahena-López,[1,3] Lorena L. Rojas,[1] Maria Chavez-Canales,[2] Ju Hye Lee,[1] Silvana Bazua-Valenti,[1] Rocio Bautista,[4] Norma H. Vázquez,[2] Maria Castañeda-Bueno,[1] Gerardo Gamba.[1,2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico; [2]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico; [3]PECEM, UNAM, Mexico City, Mexico; [4]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico*.

Background: NCC is activated via the CaSR-WNK4-SPAK pathway. Glucose and other sugars act as positive allosteric modulators of the CaSR. In vitro data from our lab (ASN 2019-2020) showed that extracellular glucose or fructose increases activity of the WNK4-SPAK-NCC pathway via the CaSR. Since glucose reabsorption occurs proximally in the nephron, delivery to the distal convoluted tubule (DCT) is negligible. Fructose delivery depends largely on intake. Thus, sugars delivery to DCT could result in NCC activation via CaSR-WNK4-SPAK pathway.

Methods: We used wild-type mice treated with vehicle, oral fructose +/- calcilytic NPS2143, or a single dose of dapagliflozin 1mg/kg ip to induce transient glycosuria +/- NPS2143. Kidneys were extracted after 3 hours to assess activation of the WNK4-SPAK-NCC pathway by immunoblotting. To rule out an effect of dapagliflozin in the WNK4-SPAK-NCC by angiotensin II, we pre-treated mice with losartan. The response to a thiazide challenge in vehicle, fructose or dapagliflozin treated mice was assessed. Finally, we used an ex vivo Langerhans rat kidney preparation to evaluate the effect of different concentrations of glucose infusion in the renal artery.

Results: In WT mice, we observed increased activity of the WNK4-SPAK-NCC pathway in the kidney after exposure to 20% fructose or administration of dapagliflozin ($p<0.01$). These effects were abrogated by NPS2143 ($p<0.01$) and was not observed in WNK4-KO mice ($p<0.001$). Additionally, the effect of dapagliflozin was present in mice pre-treated with losartan ($p<0.01$). Natriuresis induced by a thiazide challenge was significantly higher in fructose or dapagliflozin, than in vehicle treated mice, suggesting activation of NCC. Finally, we observed increased NCC and SPAK phosphorylation by infusing glucose above proximal tubule reabsorption threshold levels to ex vivo rat kidney preparations ($p<0.001$); notably, this effect was prevented by NPS2143.

Conclusions: Glycosuria or fructosuria increases NCC, SPAK and WNK4 phosphorylation in a CaSR-dependent fashion. Our data thus suggest a calcimimetic-like behavior for sugars in the DCT. This effect may have implications for salt-retention mechanisms induced by disorders of glucose metabolism and increased dietary fructose intake.

Kidney-Specific WNK1 Amplifies NCC Responsiveness to Potassium Imbalance

Cary R. Boyd-Shiwarski,[1] Rebecca T. Beacham,[1] Shawn E. Griffiths,[1] Daniel J. Shiwarski,[2] Sophia Knoell,[1] Katherine E. Querry,[1] Sean D. Stocker,[1] Arohan R. Subramanya.[1,3] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Carnegie Mellon University, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA*.

Background: The distal convoluted tubule (DCT) NaCl cotransporter NCC is activated by phosphorylation, a process that is potassium (K+)-regulated and dependent on With-No-Lysine (WNK) kinases. KS-WNK1, a kidney-specific WNK1 isoform lacking the kinase domain, controls WNK signaling pathway localization in the DCT. Its role in NCC regulation, however, is unresolved: while early studies proposed that KS-WNK1 functions as an NCC inhibitor, recent work suggests that it activates NCC.

Methods: To evaluate the role of KS-WNK1 on K+-dependent NCC regulation, we studied KS-WNK1$^{-/-}$ mice across a wide range of plasma K+ (2.0-9.0 mmol/L), induced by dietary maneuvers and diuretic challenges.

Results: K+-restricted KS-WNK1$^{-/-}$ mice exhibited blunted NCC phosphorylation compared to littermates, indicating that KS-WNK1 activates NCC during K+ deficiency. In contrast, NCC phosphorylation was augmented in K+-loaded KS-WNK1$^{-/-}$ mice relative to controls, consistent with KS-WNK1-mediating NCC inhibition during hyperkalemia. Focusing on K+-restricted mice: 1) KS-WNK1$^{-/-}$ mice had mislocalized WNK-SPAK proteins, 2) KS-WNK1$^{-/-}$ mice had blunted activation of the WNK-SPAK/OSR1 kinase cascade, 3) KS-WNK1$^{-/-}$ mice had sex-specific alterations to K+ and Ca2+ plasma levels, 4) KS-WNK1$^{-/-}$ mice had no change to blood pressure, but were less sensitive to thiazide diuretics compared to littermates.

Conclusions: KS-WNK1 has a bimodal effect on NCC, activating NCC during K+ restriction and inhibiting NCC during high K+, thus expanding the inverse relationship between NCC phosphorylation and plasma [K+]. During K+ deprivation, KS-WNK1 facilities the localization and activation of the WNK-SPAK/OSR1 pathway. Mice that lack KS-WNK1 have sex-specific differences in electrolytes, as well as thiazide resistance. These observations clarify the role of KS-WNK1 on NCC, and identify a novel mechanism that contributes to sexual dimorphism in the mammalian nephron.

High Dietary Potassium Increases Blood Pressure in a Rat Model of CKD

Martin Gritter,[1] Kuangyu Wei,[1] Alexander H. Danser,[1] Liffert Vogt,[2] Martin H. De Borst,[3] Ewout J. Hoorn,[1] Joris I. Rotmans.[4] *[1]Erasmus MC, Rotterdam, Netherlands; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [3]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [4]Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Potassium dephosphorylates the sodium chloride cotransporter (pNCC) thereby increasing natriuresis and reducing blood pressure. However, it is unclear if this response is intact in chronic kidney disease (CKD).

Methods: To address this, CKD was induced by 5/6th nephrectomy in rats which were fed a low KCl diet (0.03%), normal KCl diet (0.1%), modestly high KCl diet (0.8%), high KCl diet (2.5%) or high KCitrate diet (2.5%). The latter group was included to analyze the effect of the accompanying anion. All diets contained 0.16% Na^+. The effects of these diets on telemetric blood pressure, plasma potassium (K^+), plasma aldosterone, plasma bicarbonate, and pNCC were analyzed.

Results: Both the low and the high KCl diets increased blood pressure compared to the normal KCl diet, although the effect of the high KCl diets was more pronounced (**Table**). Higher dietary K^+ intake caused higher plasma aldosterone levels, and high KCitrate further increased plasma aldosterone. pNCC was significantly increased by the low KCl diet and decreased by the moderately high KCl diet. The effect of dietary KCl on pNCC, however, was lost with the high KCl diet. The high KCitrate diet attenuated the rise in blood pressure despite the highest plasma aldosterone and pNCC levels.

Conclusions: Although the inverse relationship between potassium and pNCC is intact in experimental CKD, high potassium diets cause hypertension possibly mediated by aldosterone. This rise in blood pressure is attenuated when potassium is given with citrate, despite high aldosterone and pNCC levels.

	Low KCl diet	Normal KCl diet	Moderately high KCl diet	High KCl diet	High KCitrate diet
Δ Systolic BP, mmHg	3*	Ref.	9*	21*	8*

Rescuing Low Blood Pressure in Amiloride-Treated Mice by Low-Potassium Diet Relies on NCC Activation

German R. Magaña,[1,2] Hector Carbajal-Contreras,[1,2] Adrian R. Murillo-de-Ozores,[1,2] Norma H. Vázquez,[1] Norma Bobadilla,[2,1] Gerardo Gamba,[2,1] Maria Castañeda-Bueno.[2] *[1]Universidad Nacional Autonoma de Mexico, CDMX, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, CDMX, Mexico.*

Background: NCC activity has been widely recognized to impact on blood pressure levels, as Gitelman syndrome, caused by inactivating mutations in the Slc12a3 gene, features arterial hypotension. In contrast, Familial Hyperkalemic Hypertension (FHHt) is a mendelian disease mainly driven by NCC overactivation. NCC activity is exquisitely regulated by changes in extracellular [K^+], and it has been shown that this regulation might be at least in part responsible for the inverse relationship observed between dietary K^+ consumption and blood pressure levels in animal models and in human populations. It has been shown that amiloride-induced hyperkalemia results in NCC inhibition, which can be prevented with administration of a low K^+ diet. Thus, we decided to evaluate the role of NCC inhibition in the volume depletion and hypotension induced by amiloride treatment.

Methods: We treated 12-week-old C57Bl/6 male mice with amiloride at 25mg/L in the drinking water. During treatment, mice were kept on normal chow (0.4% NaCl, 0.8% K^+) for 4 days, then switched to low K^+ diet (0.1% K^+), and at the 4th day of low K^+ diet hydrochlorothiazide (HCTZ, 60 mg/kg/d, in the diet) treatment was started in a subset of mice.

Results: Amiloride-treated mice developed a PHA1-like syndrome (a severe hyperkalemic, salt losing nephropathy, with marked hypotension). Hyperkalemia and hypotension were prevented by low K^+ diet. Basal blood pressure levels were re-established by day 4 on low K^+ diet, while further treatment with HCTZ produced a steep drop in the blood pressure of these animals. Immunoblot analysis of whole kidney lysates from amiloride-treated mice showed decreased levels of NCC and pNCC that were reversed by low K^+ diet.

Conclusions: We show that the salt losing hyperkalemic phenotype induced by amiloride can be fully recovered by low K^+ diet and that this recovery is mediated by the increased activity of NCC.

SALL3 Is a Salt-Responsive Distal Convoluted Tubule-Specific Transcription Factor Induced in Distal Nephron Remodeling

Hyun Jun Jung,[1] Eric J. Delpire,[2] Paul A. Welling.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Adaptive remodeling of the distal nephron provides a physiological mechanism to control electrolyte transport and body fluid homeostasis. Activation of the sodium chloride cotransporter (NCC, Slc12a3) in the DCT is paralleled by an increase in DCT mass as an adaptive response to intravascular volume depletion or hypokalemia. The downstream regulatory factors that induce structural expansion of DCT are unknown.

Methods: Mice were genetically engineered to constitutively activate the SPAK kinase (CA-SPAK) in the DCT, causing constitutive NCC activation, and DCT hypertrophy and hyperplasia. Genome-wide RNA-Seq transcriptomic analysis was performed in renal cortical tissue. Differential gene expression analysis was performed to compare 1) CA-SPAK vs wild type (WT-CT) on control diet and 2) CA-SPAK on high salt diet (CS-HS) and WT on high salt diet (WT-HS). Bioinformatic approaches were applied to identify the DCT-specific transcription factors (TFs) that are dependent on the NCC activation. TF protein localization and expression was evaluated by immunofluorescence and confocal microscopy, and image analysis tools.

Results: Differential expression analysis and cell deconvolution of the bulk RNA-Seq, using kidney single-cell transcriptome datasets, revealed 10 TFs (Camta1, Emx1, Hoxd8, Hoxd9, Hoxd10, Tfap2b, Tfcp2l1, Tsc22d2, Sall3 and Zfp467) that were significantly induced in DCT of the CA-SPAK mice with high salt diet. Among 10 TF candidates, Spalt like transcription factor 3 (Sall3) was the only DCT-specific TF that was induced by CA-SPAK, and further increased by high salt diet. Network analysis revealed that Sall3 interacts with eight of the other induced TFs (Emx1, Hoxd10, Tfcp2l1, Hoxd9, Hoxd8, Camta1, Tfap2b and Zfp467). Microscopy confirmed Sall3 is specifically expressed in DCT cells, where it localizes predominately to the nucleus and is significantly increased in the CA-SPAK mice, and increased further upon dietary salt loading.

Conclusions: In summary, Sall3 is the predominate DCT-specific TF that is activated during DCT expansion, suggesting that it is a key component of the core transcriptional regulatory circuit maintaining DCT cell identity as the DCT expands.

PO1089

Chemogenetic Activation of the Distal Convoluted Tubule Enhances Sodium Excretion Through Rapid Dephosphorylation of the Sodium-Chloride Cotransporter

Kevin J. Martz,[1] Xiao-Tong Su,[1] Yujiro Maeoka,[1] Avika Sharma,[1] James A. McCormick,[1] David H. Ellison,[1,2] Jonathan W. Nelson.[1] *[1]Oregon Health & Science University, Portland, OR; [2]Veterans Affairs Portland Health Care System, Portland, OR.*

Background: The distal convoluted tubule (DCT) plays a crucial role in the regulation of sodium and potassium balance, predominantly through its apical sodium chloride entry pathway, NCC, which is activated by N-terminal phosphorylation. This nephron segment is rich in G protein-coupled receptors (GPCR), including *ptgfr* (prostacyclin F), *avpr2* (arginine vasopressin), and others. The role that these GPCRs play regulating DCT function has been a challenge to investigate as they are expressed within multiple cell types that alter kidney physiology. Designer Receptors Exclusively Activated by Designer Drugs (DREADD) technology can be used to explore the physiological role of GPCR activation.

Methods: To explore the role of Gq-coupled GPCRs along the DCT, we bred DCT-specific inducible Cre Recombinase mice (NCC-cre^{ERT2}) to Gq-coupled DREADD mice to create DCT-DREADD mice. We verified the localization of the Gq DREADD protein using immunohistochemistry. We then activated Gq signaling in DCT cells with i.p. injection of DREADD-specific agonist deschloroclozapine (DCZ) and determined the abundance of phosphorylated NCC by Western blot. Lastly, we measured sodium excretion in metabolic cages for 4 hours following DCZ administration in WT compared to DCT-DREADD mice.

Results: We found that the Gq-DREADD protein was specifically expressed within the basolateral membrane of the DCT (**Figure A**). DCZ injection caused rapid dephosphorylation of NCC within 30 minutes to 15% of the abundance observed in DCT-

DREADD mice not treated with DCZ (**Figure B**, 100 ± 15 vs. 15 ± 3, t-test: p<.001). Injection of DCZ increased sodium excretion (UNaV) by 215% in DCT-DREADD mice compared to wildtype controls (**Figure C**, 100 ± 13 vs. 215 ± 24, t-test: p<.001).

Conclusions: We conclude that chemogenetic activation of the DCT enhances sodium excretion through rapid dephosphorylation of NCC. These findings support a role for Gq GPCR-mediated regulation of NCC. The DCT-DREADD mouse is a novel model for exploring the molecular mechanisms that underlie the regulation of NCC activity by GPCRs absent the confounding effects of other epithelial cells along the nephron.

PO1090

Mechanistic Importance of Reduced KLHL3 and CUL3 Expression in CUL3-Δ9-Mediated Familial Hyperkalemic Hypertension

Yujiro Maeoka, Mohammed Z. Ferdaus, Avika Sharma, Ryan J. Cornelius, Xiao-Tong Su, Joshua A. Robertson, Susan B. Gurley, David H. Ellison, James A. McCormick. *Oregon Health & Science University, Portland, OR.*

Background: Mutations in the ubiquitin ligase scaffold protein Cullin 3 (CUL3) cause the disease familial hyperkalemic hypertension (FHHt). In the kidney, mutant CUL3 (CUL3-Δ9) cannot interact with COP9 signalosome subunit JAB1 that negatively regulates CUL3 activity. This leads to CUL3-Δ9 autodegradation, and increased abundance of With-No-Lysine [K] Kinase 4 (WNK4), which inappropriately activates the downstream kinase SPAK, which then phosphorylates and hyperactivates the Na^+-Cl^- cotransporter (NCC). We showed lower that CUL3 alone does not increase WNK4, so the precise mechanism by which CUL3-Δ9 causes FHHt is unclear. We hypothesized CUL3-Δ9 degrades Kelch-like 3 (KLHL3), the CUL3 substrate adaptor for WNK4; thus reduced abundance of KLHL3 combined with reduced CUL3 are mechanistically important in CUL3-Δ9-mediated FHHt.

Methods: We studied *Cul3* KO (*Cul3*$^{-/-}$) mice, *Cul3* KO mice expressing CUL3-Δ9 (*Cul3*$^{-/-/\Delta 9}$), *Cul3* heterozygotes expressing CUL3-Δ9 (*Cul3*$^{+/-/\Delta 9}$), compound *Cul3* and *Klhl3* heterozygotes (*Cul3*$^{+/-}$*Klhl3*$^{+/-}$), and *Jab1* KO (*Jab1*$^{-/-}$) mice. All mouse lines were inducible and renal tubule-specific.

Results: CUL3-Δ9 did not promote degradation of CUL3 targets that accumulate in *Cul3*$^{-/-}$ kidney: WNK4, cyclin E, or NQO1 (a surrogate for the CUL3 substrate Nrf2). In *Cul3*$^{-/-/\Delta 9}$ mice, CUL3-Δ9 prevented KLHL3 accumulation seen in *Cul3*$^{-/-}$ kidney and promoted KLHL3 degradation in *Cul3*$^{+/-/\Delta 9}$ mice. Higher NQO1 and lower cyclin E abundances were observed in *Cul3*$^{+/-/\Delta 9}$ mice compared to control mice. *Cul3*$^{+/-}$*Klhl3*$^{+/-}$ mice displayed increased WNK4-SPAK activation and phospho-NCC abundance, and FHHt-like phenotype with increased plasma [K^+] and salt-sensitive blood pressure. Similarly, reduced CUL3 and KLHL3 abundances and increased abundances of WNK4 and phsopho-NCC were observed in *Jab1*$^{-/-}$ mice.

Conclusions: Together, these data provide evidence for a mechanism of reduced KLHL3 and reduced CUL3 in CUL3-Δ9-mediated FHHt. CUL3-Δ9 potently degrades KLHL3, but also exerts modest effects on other CUL3 targets, raising the possibility of unidentified renal phenotypes in the human disease.

PO1091

Non-Reabsorbable Anions Enhance Potassium Excretion by Multiple Mechanisms

Lama Al-Qusairi,[1] Paul R. Grimm,[1] Truyen D Pham,[2] Ava Zapf,[1,3] Delaney C. Abood,[2] Susan M. Wall,[2] Paul A. Welling.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Emory University School of Medicine, Atlanta, GA; [3]University of Maryland Baltimore, Baltimore, MD.*

Background: Potassium (K^+) secretion in the distal nephron (DN) is governed, in part, by the lumen-negative transepithelial potential (Vte), created by ENaC-mediated sodium reabsorption, and partially attenuated by paracellular chloride (Cl^-) reabsorption. K^+ secretion increases when nonreabsorbable anions (NRA), such as $HCO3^-$ or beta-hydroxybutyrate, replace luminal Cl^-. Although this allows an appropriate response to alkaline-ash rich diets, it can drive exaggerated K^+ secretion in alkalosis. According to textbook views, NRA facilitates K^+ secretion solely by increasing the lumen-negative Vte. However, the effects of NRA on the potassium secretory machinery have not been determined.

Methods: Wild-type C57BL6J mice were randomized to control (1%K^+), potassium chloride (KCl:5%K^+) or potassium bicarbonate (KHCO3:5%K^+) diets for 10 days. Physiological, molecular and imaging analysis were performed. Pendrin-KO mice were examined to assess the specific role of pendrin in NRA-mediated potassium excretion.

Results: Consumption of the high KHCO3 diet increased urinary potassium K^+ excretion and the trans-tubular K^+ gradient (TTKG) significantly more than with the high KCl diet, consistent with an NRA response. Both diets increased aldosterone to the same extent, correlating with similar increases in ENaC expression and proteolytic activation. Surprisingly, the high KHCO3 diet significantly enhanced ROMK protein expression and apical localization in the late distal convoluted tubule and CNT more than the high KCl diet. The diets also induced opposite changes in Pendrin protein and apical membrane localization; Pendrin decreased with the high KCl diet but increased in the high HKCO3 diet. The high KHCO3 diet also uniquely induced a remodeling of the intercalated cells in the late DCT and CNT, whereby the number of pendrin-positive cells increased without change in principal cells. Pendrin-KO mice excrete the high dietary KHCO3 load to the same extent as WT mice but develop metabolic alkalosis.

Conclusions: In summary, NRA stimulates potassium excretion beyond a Vte effect. By increasing apical membrane ROMK and Pendrin expression, and remodeling the DN, mice increase the capacity to adapt to alkaline-ash rich diets, preventing hyperkalemia and alkalosis.

The Effect of Epidermal Growth Factor Inhibition on Distal Nephron Sodium Reabsorption in Mice

Keyona N. King,[1,2] Robert S. Hoover.[3,1] *[1]Emory University School of Medicine, Atlanta, GA; [2]VA Medical Center Atlanta, Decatur, GA; [3]Tulane University School of Medicine, New Orleans, LA.*

Background: Studies have shown that the epidermal growth factor (EGF) decreases the activity of ENaC while the influence of EGF on renal Na^+ transport via NCC is unknown. Previous investigations in mDCT-15 cells showed that EGF increases endocytosis of NCC. Using radio-telemetry, we found that EGF inhibition increases systolic blood pressure in response to increasing the dietary Na^+ intake. Our results in consolidation with other researchers, suggest that EGF affects BP by influencing the activity of ENaC and NCC. Our goal is to determine whether EGF inhibition increases BP via alterations in Na^+ reabsorption.

Methods: Using metabolic cages, we collected urine samples at three time points over 24 hours in 7 week old male mice. Normal salt (LS) diet (0.4% Na chow) was given for baseline collections and high salt (HS) diet (4% Na chow) for experimental collections. Only the experimental (E) group, n=4 received gefitinib (an EGF receptor tyrosine kinase inhibitor) orally at 100 mg/kg/d and the control (C) group, n=4 received placebo. Hydrochlorothiazide (HCTZ) 2.4mg per 10g BW orally and amiloride 1.45 μg/g via IP injection were administered. Following a washout period, HCTZ and amiloride were given simultaneously to assess the total effect on NCC and ENaC.

Results: There was no difference in the average urinary Na^+ excretion over 24 hours for baseline measurements between the groups when receiving the LS diet (experimental (E) group: 105 ± 13 mmol vs. control (C) group: 82 ± 23 mmol, N.S.). However, when giving the HS diet and HCTZ, the E group had a higher average urinary Na^+ excretion over 24 hours in response to a higher dietary Na^+ intake (E group: 966 ± 108 vs. C group: 517 ± 139 mmHg, p<0.05). For amiloride with HS diet there was no difference in average urinary Na^+ excretion between the groups (E group: 1130 ± 127 vs. C group: 920 ± 48 mmol, N.S.). When giving both HCTZ and amiloride to the mice while receiving the HS diet, the E group had a higher urinary Na^+ excretion compared to the C group (E group: 997 ± 66 vs. C group: 777 ± 48 mmol, p<0.05).

Conclusions: Therefore, our data suggests that inhibition of EGF increases Na^+ reabsorption via NCC. As previously suggested, this may indicate that EGFR ligands act as tonic inhibitors of NCC tubular sodium reabsorption. Future experiments will explore the in vivo effects of EGFR inhibition on sodium excretion along other components of the nephron.

PO1093

Role of mTORC2/SGK1 Signaling in Rapid Response to Acute K Load to Maintain K+ Homeostasis

Bidisha Saha,[1] Waheed Shabbir,[1] Enzo Takagi,[1] John E. Demko,[1] Mads V. Sorensen,[3] Deise C. Leite-Dellova,[1,2] David Pearce.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Universidade de Sao Paulo Faculdade de Medicina Veterinaria e Zootecnia, Sao Paulo, Brazil; [3]Aarhus Universitet, Aarhus, Denmark.*

Background: The kinase mTORC2 phosphorylates SGK1 and is required for normal K^+ secretion in the aldosterone-sensitive distal nephron. Aldosterone is known to play a role in mediating a sustained response through effects on SGK1 gene transcription, however, it is unknown how rapid responses are mediated. Here we have explored the role of mTORC2 and ENaC activity in the early response to an acute K^+ load to regulate K secretion.

Methods: Inducible tubule-specific Rictor (a core component of mTORC2) knockout mice (TRKO) were generated (Pax8-rtTA/LC-1/Rictorflox/flox). Both WT and TRKO mice received control or 2% KCl via gavage following intraperitoneal vehicle or Benzamil (ENaC inhibitor) injection. Spot urine was collected. ENaC and ROMK activity were measured in split open tubules by apical membrane patch clamp 3h post gavage. Membrane and cytoplasmic proteins were extracted from kidneys for immunoblot analysis.

Results: Adult TRKO mice on normal diet displayed no abnormality except significantly elevated aldosterone. K^+ administration by gavage triggered markedly greater Na^+ excretion and lower K^+ excretion in TRKO than WT mice, with differences detectable within 1 h of gavage. Benzamil induced a greater natriuresis in WT than in TRKO mice, and more strongly suppressed kaliuresis, consistent with greater ENaC activation in WT than in TRKO. The response of WT occurred rapidly, before significant change in aldosterone. In benzamil-treated mice, the natriuresis and kaliuresis of WT and TRKO mice were comparable, strongly supporting the idea that KCl induced

ENaC-dependent K^+ secretion in WT, and that this response is defective in TRKO. Patch clamp measurement demonstrated increased ENaC activity in WT but not in TRKO mice and no change in ROMK activity in WT or TRKO by KCl gavage. Membrane expression of cleaved α- and gENaC were significantly increased in WT but not in TRKO mice receiving KCl gavage. No significant increase in membrane expression of ROMK was observed in WT or TRKO post gavage. Finally, both SGK1 and Nedd4-2 phosphorylation were increased in WT but not TRKO mice receiving KCl gavage.

Conclusions: Overall, the data strongly suggest that an acute K^+ load acts through mTORC2/SGK1 to rapidly stimulate ENaC but not ROMK to promote K^+ secretion. These effects are primarily due to local renal tubular K^+ sensing.

Structural Determinants of mTORC2 Substrate Specificity and SGK1 Phosphorylation Revealed by Cryogenic Electron Microscopy

Junliang Chen,[1] Zanlin Yu,[2] Feng Wang,[2] Xi Liu,[2] Enzo Takagi,[2] Lydia-Marie Joubert,[3] Mingliang Jin,[2] Carlos Nowotny,[2] David Agard,[2] Yifan Cheng,[2] David Pearce.[2] *[1]SinoUnited Health, Shanghai, China; [2]University of California San Francisco, San Francisco, CA; [3]Stanford University, Stanford, CA.*

Background: mTORC2 is a multi-subunit kinase complex central to multiple essential signaling pathways. Notably, it responds to hormonal signals and local electrolyte concentrations to phosphorylate SGK1 and regulate K+ secretion in the renal tubules. Two core subunits, Rictor and mSin1 distinguish mTORC2 from its much better characterized relative, mTORC1. Two other subunits, mTOR itself and a small scaffold, mLST8, complete the core complex. Previous mTORC2 reconstructions have lacked key regions of the > 1 MDa complex, particularly determinants of specificity.

Methods: Core mTORC2 subunits were expressed in Expi293F cells and purified using new methods for on grid purification. cryo-EM was peformed using Krios at SLAC for high energy electrons for density maps of human mTORC2. Structures were solved for apo-complex at overall 3.23 Å resolution, and for co-complexes with substrates, SGK1 and Akt, at 3.38 and 3.44 Å, respectively.

Results: The apo-complex reveals architectural features of functionally important domains, including specific side chain positions and interactions, which are visualized for the first time. In particular Rictor/Ser-1624 and Ser-1625 were observed to engage in hydrogen bond interactions with mTOR/Thr-2098, in a manner that provides steric hindrance to binding of Rapamycin, and explains mTORC2 resistance to the effects of this clinically important mTORC1 inhibitor. In addition, mSin1, the other defining subunit of mTORC2, is seen to form extensive contacts with Rictor, including an extended strand, which makes multiple weak contacts with a Rictor helical cluster. Most notably for the role mTORC2 plays in renal electrolyte handling, in the co-complex structure with SGK1—but not the Akt co-complex, we see a marked change in the conformation of the mSin1 N-terminal extended strand in a manner consistent with previous functional data identifying this region as required for phosphorylation of SGK1, but not Akt, thus providing a structural basis for differential regulation.

Conclusions: These findings provide new structural insight into mTORC2 specificity and context-dependent activities, and foundation for further mechanistic studies. Further, these findings provide a potential avenue toward highly selective mTOR modulators with potential clinical utility.

In Vivo Influence of a Protease-Resistant Epithelial Sodium Channel Gamma Subunit on Fluid Homeostasis

Evan C. Ray, Tracey R. Lam, Alexa S. Jordahl, Allison L. Marciszyn, Lei Zhang, Shaohu Sheng, Shujie Shi, Thomas R. Kleyman. University of Pittsburgh P30 O'Brien Center for Kidney Research *University of Pittsburgh, Pittsburgh, PA.*

Background: Extracellular fluid depletion promotes proteolytic processing of ENaC's γ subunit. Removal of the subunit's inhibitory tract enhances channel open probability. Although several cleavage sites exist distal to the γ subunit's inhibitory tract, only one known site resides proximal to the inhibitory tract: a furin cleavage site ($RKRK^{143}$). We hypothesized that a mouse expressing a protease-resistant ENaC γ subunit would exhibit signs consistent with reduced renal tubular ENaC activity, such as attenuated ability to adapt to dietary Na restriction.

Methods: We used TEV in Xenopus oocytes to confirm the ability of disruption of the γ subunit's furin cleavage site ($RKRK^{143}$ to $QQQQ^{143}$, or "Q4") to reduce ENaC activity. In 129sv mice, we used CRISPR-Cas9 to introduce this amino acid substitution into ENaC's γ subunit. Altered cleavage of ENaC's γ subunit was confirmed by Western blot of tissues from mice on a low (0.04%) Na diet (LSD). Lysates of kidneys from these animals were digested in PNGase to deglycosylate proteins, facilitating interpretation of molecular weights. Blood electrolytes were evaluated by iSTAT at sacrifice. Animal body fluid was assessed in live animals using quantitative magnetic resonance (Echo-MRI).

Results: Expression of the protease prostasin in oocytes, along with ENaC (N = 15), increased amiloride-sensitive currents, compared to oocytes with ENaC but no prostasin (N = 15; $p < 0.0001$). In oocytes expressing a Q4 gamma subunit (N = 15), prostasin no longer increased currents (N =15). Western blot of PNGase-digested tissue lysates revealed a full-length (~60 kDa) γ subunit and two shorter proteins, consistent with subunits either cleaved at the furin site (~53 kDa) or at a more distal site. Tissues from Q4 mice lacked the 53 kDa band, suggesting impaired Furin site cleavage. Blood K+ was normal in Q4 mice (N ≥ 7 for each sex and genotype). On a LSD, Q4 male mice exhibited greater loss of body water than control males ($p = 0.04$; N = 6-7), but females exhibited no difference in body water (N = 7-8).

Conclusions: These findings support a role for proteolytic activation of ENaC in male mice maintaining total body fluid in response to dietary Na depletion. Females did not show a impaired body fluid retention, suggesting additional compensatory mechanisms.

A Rare Case of Acquired 11-Beta-Hydroxysteroid Dehydrogenase Deficiency

Khalid Elharrif,[1,2] Nidal Alhosainat,[2] Mica Alex,[2] Petersen Greti,[1] Hania Kassem.[2] *[1]Kern Medical Center, Bakersfield, CA; [2]The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: 11-Beta Hydroxysteroid Dehydrogenase (HSD11B) is an enzyme that is involved in steroid hormone physiology. HSD11B enzyme exists in two isoforms, HSD11B-type 1 and type 2. Type 2 isozyme is responsible for converting cortisol to inactive cortisone. Plasma concentration of cortisol is approximately 100-fold higher than aldosterone and activation of mineralocorticoid receptors by cortisol is normally limited due to its conversion to inactive cortisone at the sites of aldosterone action by the enzyme HSD11B-type 2. We are presenting a rare case of HSD11B deficiency in a patient taking herbal supplementation.

Case Description: A 73-year-old female with PMH of hypertension, hyperlipidemia and chronic pain was admitted to the hospital with fatigue and shortness of breath. She denied any history of diarrhea or recent use of diuretics or laxatives. She has a history of using some herbal supplements in large quantities for pain control. Initial blood pressure was 140/80 mmHg. EKG showed sinus bradycardia with PVCs and bigeminy. The lab results are summarized in **table A**. She received aggressive potassium supplementation and spironolactone with subsequent improvement of her condition.

Discussion: HSD11B deficiency is either congenital or acquired by ingestion of licorice or its derivatives (glycyrrhizic and glycyrrhetinic acids). The deficiency results in a decreased conversion to cortisone and accumulation of cortisol. The effect of cortisol on the mineralocorticoid receptor results in hypokalemia, metabolic alkalosis, and low aldosterone and renin activity. The diagnosis requires careful history and identification of specific clinical features and biochemical abnormalities.

Blood work	
Sodium	142 mmol/L
Potassium	1.5 mmol/L
Bicarbonate	43 mmol/L
Creatinine	0.68 mg/dl
Serum cortisone	< 0.1 ug/dL
Renin	0.1 ng/mL/hr
Aldosterone	<3.0 ng/dL
Aldosterone Renin Ratio	30

PO1097

New Method to Discriminate Function of A and B Type of Intercalated Cells in Split-Opened Collecting Ducts

Naghmeh Hassanzadeh Khayyat, Victor N. Tomilin, Kyrylo Pyrshev, Oleg L. Zaika, Oleh Pochynyuk. *The University of Texas Health Science Center at Houston, Houston, TX.*

Background: The collecting duct (CD) is a highly adaptive terminal part of the nephron, which is essential for maintaining systemic homeostasis. Electrically uncoupled principal and intercalated cells (PCs and ICs) perform different physiological tasks and exhibit rather distinctive morphology. However, acid-secreting A- and base secreting B-type of ICs cannot be easily separated in functional studies despite virtually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether and how systemic pH stimuli affect function and A/B cell type ratio in the CD. The technique of split-opening isolated CD allows unambiguous monitoring of alterations in function in many individual cells within the split-opened area. However, it is not possible to specifically change the driving force for Cl- at luminal or basolateral sides, which is used in perfused tubule studies to identify IC types of certain cells on periphery.

Methods: We used BCECF-sensitive intracellular pH (pH_i) measurements in split-opened CDs followed by immunofluorescent (IF) detection of AQP2 and pendrin from WT and ClC-K2-/- mice to demonstrate that inhibition of this Cl- channel enables sorting out signals from A- and B- types of ICs.

Results: We show that ClC-K2 Cl- channel is exclusively expressed on the basolateral side of AQP2-negative ICs, where it likely participates in Cl-dependent H+/HCO3- transport. Indeed, ClC-K2 blocker, NPPB, had no effect on pHi in PCs, whereas it caused acidification or alkalization in different subpopulations of ICs in WT but not ClC-K2-/- mice. IF assay of the same CDs revealed that NPPB decreased pHi in pendrin-positive B-type and increased pHi in A-type of ICs. Induction of metabolic acidosis markedly increased A/B cell ratio from 74% to 145%. Furthermore, dietary acidification also resulted in significantly augmented H+ secretion (assessed as recovery after acidification) in A-type and decreased pH transport in B-type of ICs.

Conclusions: We show that inhibition of ClC-K2 can be employed to discriminate between A- and B-type of ICs in split-opened CD preparations. Using this method, we found that metabolic acidosis leads to augmented transport rate and increased total population of A-type in the CD.

Piezo1 in Intercalated Cells (ICs) Mediates Flow-Induced [Ca2+]i Transients in Mouse Cortical Collecting Duct (CCD)

Rolando Carrisoza-Gaytan,[1] Stephanie Mutchler,[2] Joanne Soong,[1] Marianela G. Dalghi,[2] Gerard Apodaca,[2,3] Thomas R. Kleyman,[2,3] Lisa M. Satlin.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Pediatrics, New York, NY; [2]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [3]University of Pittsburgh Department of Cell Biology and Physiology, Pittsburgh, PA.*

Background: Within the CCD, an acute increase in tubular fluid flow rate (TFFR) exposes principal cells (PCs) and ICs therein to hydrodynamic forces. In response, a biphasic increase in $[Ca^{2+}]_i$ is observed, with an immediate high amplitude increase due to release of IP3-sensitive internal Ca^{2+} stores coupled to extracellular Ca^{2+} entry at the basolateral membrane. This is followed by a decay to a plateau level that is higher than baseline and sustained by luminal Ca^{2+} entry (Liu et al., 2003; 2005; 2007). This increase in $[Ca^{2+}]_i$ is necessary for BK channel-mediated flow induced K^+ secretion (FIKS) in the microperfused mammalian CCD. We have recently reported that PIEZO1, a mechanosensitive, Ca^{2+} permeable channel, is expressed on the basolateral membranes of PCs and ICs in the mouse CCD (Dalghi et al., 2019).

Methods: To examine whether IC *Piezo1* expression contributes to the increase in $[Ca^{2+}]_i$ triggered by TFFR, we generated a mouse with targeted deletion of *Piezo1* in ICs (IC-Piezo1-KO).

Results: Immunofluorescence analyses of kidneys harvested from mice (C57BL/6) expressing PIEZO1-tdTomato revealed a significant increase of PIEZO1 expression in ICs from mice fed a high K (HK, 5% K^+, n=4) vs. standard K (SK, 1% K^+, n=4) diet for 10 days. Fluorescence intensity ratios (FIRs; ratio of the Ca^{2+} indicator Fura-2 emission signals measured at excitation wavelengths of 340 nm and 380 nm), corresponding to $[Ca^{2+}]_i$, were measured in individually identified PCs and ICs in CCDs isolated from (i) HK-fed IC-*Piezo1*-KO (n=3), (ii) SK-fed littermate control (n=3), and (iii) HK-fed control (n=3) mice and then exposed to the PIEZO1-activator Yoda1 (1 μM). PCs and ICs from HK-fed control mice exhibited a greater increase in $[Ca^{2+}]$i in response to Yoda1 than SK-fed control mice ($p \leq 0.001$). However, ICs from HK-fed IC-Piezo1-KO mice exhibited a reduced or absent increase in $[Ca^{2+}]_i$ in response to Yoda1 vs. SK-fed control mice ($p \leq 0.001$). In microperfused CCDs isolated from IC-*Piezo1*-KO mice, an increase in TFFR did not elicit a typical increase in $[Ca^{2+}]_i$ in ICs ($p \leq 0.001$, n=3 controls and n=4 KOs).

Conclusions: We conclude that *Piezo1* is upregulated in the CCD by a HK diet and contributes to the TFFR-induced increase in $[Ca^{2+}]_i$ in ICs necessary for FIKS.

An Extremely Rare Interaction Between Two Commonly Used Drugs

Maria Teresa Furtado, Catarina A. Gonçalves, Patrícia Valerio. *Hospital de Sao Bernardo, Setubal, Portugal.*

Introduction: The use of Paracetamol and Flucloxacillin can result in an elevated anion gap metabolic acidosis. Interaction between these drugs is a rare disorder that results from accumulation of pyroglutamic acid. Affected patients are usually women with chronic illness, sepsis, and malnutrition.

Case Description: We present the case of a 79 year-old hypertensive and diabetic woman with a past medical history of chronic kidney disease (baseline creatine of 1.6 mg/dl). She was admitted to the hospital due to a Methicillin-Sensitive Staphylococcus Aureus spondylodiscitis and she underwent surgical decompression with postoperative severe pain complaints. In that context, she was started on opioids, NSAIs and high-dose paracetamol (4 g daily), and Flucloxacillin (12 g daily). After 10 days she presented with dyspnea and generalized weakness. Blood gas analysis revealed metabolic acidosis (pH 7.35; pCO2 16 mmHg; pO2 102 mmHg; HCO3 8 mmol/L; anion gap 22 mmol/L; lactate 0.4 mmol/L). Laboratory tests showed hypoalbuminemia of 1g/dl in the context of severe malnutrition, and no worsening of kidney function. The patient was screened for lactic acidosis, ketoacidosis, toxic alcohol ingestion and salicylate poisoning with no positive findings. Finally, we concluded accumulation of pyroglutamic acid secondary to concomitant use of flucloxacillin and paracetamol in high doses as the leading cause of elevated anion gap metabolic acidosis. Despite these drugs were immediately stopped and sodium bicarbonate was started, the patient showed no clinical improvement and presented with respiratory exhaustion. Hemodialysis was started to correct the acid-base disorder.

Discussion: Despite being extremely rare, metabolic acidosis induced by drug interaction between Paracetamol and Flucloxacillin is a severe and potentially life-threatening disorder. We recognize the relevance of this case since these drugs are commonly prescribed together.

Dietary Ammonium Exacerbates Pyelonephritis in Mice Prone to Vesicoureteral Reflux

Jeffrey M. Purkerson, George J. Schwartz. *University of Rochester Medical Center, Rochester, NY.*

Background: In a mouse model of urinary tract infection with Uropathogenic E. Coli (UPEC-UTI) dietary NH_4Cl (AC) induces metabolic acidosis and increases UPEC burden in reflux prone C3H-HeN, but not Tlr4 deficient, C3H-HeJ mice[2]. We have confirmed and extended these studies by comparing the inflammatory response in C3H-HeN mice fed AC-diet vs. standard chow (SC), and by examining the effect of HCl-acidosis.

Methods: Female C3H-HeN mice were fed: standard chow (SC), NH_4Cl (2% w/w; AC), or 1g/ml 0.4 N HCl supplemented chow (HCl-A). Acid-base state was assessed by blood /gas analysis using an iSTAT® G3+ and urine pH. UPEC-UTI: Urinary Tract Infection of mice (6-8 wks) with Uropathogenic E. Coli (UPEC strain CFT073; 10^7-10^8 cfu/50 μl) was induced via transurethral inoculation. UPEC burden (cfu/g) was determined by culture of tissue homogenates. NOS2 mRNA in bladder and kidney cells was quantitated by qRT-PCR. Ly6G+ kidney neutrophil infiltrates, phagocytosis of UPEC-GFP (GFP mean fluorescent intensity, MFI, in Ly6G+ neutrophils) and oxidative burst (DHR123 fluorescence, MFI) were quantitated by flow cytometry. Statistics: Two-tailed T-test or Mann-Whitney U-Test $p<0.05$.

Results: Consistent with higher UPEC burden in bladder and kidney and increased chemokine/cytokine production[2], Ly6G+ neutrophil infiltrates were 4.5±0.6 fold higher in kidneys from AC vs. SC-infected mice (N=3; $p<0.01$)[2], and NOS2 (iNOS) mRNA was increased 8.7±1.8 vs. SC-infected bladder and 10.5±2.5 fold vs uninfected kidney (N=10; $p<0.002$). The % double (GFP^+Ly6G^+) neutrophils (Mean±SE: SC= 66.6±3.6%, N=5; AC= 69.1±7.5%, N=4), UPEC-GFP MFI in Ly6G+ neutrophils (SC=4.6E3±756, N=5; AC = 6.3E3±2.8E3, N=4), and DHR123 fluorescence of Ly6G+ cells (DHR123 MFI: SC =5E3±712; AC=8.1E3±107) were not significantly different between groups ($p>0.5$) indicating that neutrophil phagocytosis and oxidative burst were unaffected by dietary ammonium. HCl-acidosis (s[HCO3-]: HCl-A=16.3±0.1 vs. SC=23.2±0.6, N=4; $p<0.01$) did not increase UPEC burden (Kidney cfu/g: SC: 4E3±2E3 vs. HCL-A: 2E3±8E2, $p>0.05$) indicating that acidosis per se does not impair UPEC-UTI clearance. [2]Purkerson et al. (2020) Physiolog.Rep. 8(19)e14525.

Conclusions: Dietary ammonium chloride impairs clearance of UPEC-UTI and exacerbates pyelonephritis. The effect of dietary ammonium is unrelated to acidosis and neutrophil function.

Molecular Insights into the Structural and Dynamical Changes of Calcium Channel TRPV6 Induced by Its Interaction with Phosphatidylinositol 4,5-Bisphosphate

Lingyun Wang,[1] Ruiqi Cai,[2] Xing-Zhen Chen,[2] Ji-Bin Peng.[1] *[1]Divison of Nephrology, Department of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL; [2]Membrane Protein Disease Research Group, Department of Physiology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada.*

Background: Transient receptor potential vanilloid subfamily member 6 (TRPV6) is a Ca^{2+}-selective channel that mediates Ca^{2+} entry into epithelial cells as the first step of the transcellular Ca^{2+} transport pathway. TRPV6 is expressed in the kidney, intestine, and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol 4,5-bisphosphate (PIP_2); however, it is less clear how PIP_2 activates TRPV6 at the molecular level.

Methods: Recently, a structure of rabbit TRPV5 in complex with dioctanoyl (diC8) PIP_2, a soluble form of PIP_2, was determined by cryo-electron microscopy. Based on this structure, a structural model of human TRPV6 with PIP_2 was set up. This model was then embedded in a 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) lipid bilayer with water molecules added on both sides of the bilayer using CHARMM-GUI. Using the AMBER18 software, three 500-ns molecular dynamics simulations were performed for the two systems of TRPV6 with and without PIP_2.

Results: Interaction energy analyses show that the positively charged residues K300, R302, R305, K484, and R584 of TRPV6 play important roles in the binding of PIP_2, which is consistent with the structural data that residues R302 and K484 in TRPV5 are responsible for the binding of diC8 PIP_2. The binding of PIP_2 to TRPV6 increases the distance between the diagonally opposed residues D542 in the selectivity filter as well as the distance between the diagonally opposed residues M578 in the lower gate. Secondary structure and density analyses show that residue M578 in TRPV6 in the presence of PIP_2 undergoes structural and position changes, suggesting the opening of the lower gate. Principal component analysis also indicates that the binding of PIP_2 increases the dynamic motion of both the selectivity filter and the lower gate of TRPV6.

Conclusions: Simulation results indicate that PIP_2 increases the fluctuation of the key residues in both the selectivity filter and the lower gate of TRPV6. In addition, PIP_2 reduces the helix occupancy of a key residue in the lower gate. Furthermore, the diameters of both the selectivity filter and the lower gate are increased by PIP_2. These changes likely contribute to the opening of the TRPV6 channel.

Lithium Treatment Induces Changes in E-Cadherin, β-Catenin, and Na+/K+-ATPase β1 in Rat Inner Medullary Collecting Duct in a Time-Dependent Manner

Xabier Sørtvedt, Jeppe Praetorius, Birgitte M. Christensen. *Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark.*

Background: Lithium (Li)-induced Nephrogenic Diabetes Insipidus (NDI) develops in around 40% of psychiatric patients receiving Li treatment. NDI is characterized by the inability of the kidney to concentrate urine due to insufficient water reabsorption in the kidney collecting duct (CD). Studies in rats have shown that Li induces a cellular compositional change of the CD with a fractional decrease in the ratio of principal-to-intercalated cells after 4 weeks of Li. This cellular remodeling is reversible in rats undergoing recovery for 19 days following 4 weeks of Li treatment. We aimed to investigate if regulation of the cell-contacts E-cadherin and β-catenin have a role in the cellular remodeling. The Na^+/K^+-ATPase was also investigated due to previously shown influences on cell polarity and cell-contact formation in kidney cells (Rajasekaran et al, Mol Biol Cell, 2001).

Methods: Immunohistochemistry (IHC) was performed on rat kidney sections used in previously published studies (Christensen et al, AJP, 2006; Trepiccione et al, AJP, 2013). Sections from rats treated with Li for 4, 10 and 15 days and 4 weeks were stained using antibodies against the cytoplasmic domain of E-cadherin, β-catenin and Na^+/K^+-ATPase β1-subunit. Sections from rats that had undergone recovery for 6 and 12 days following 4 weeks of Li treatment were stained for β-catenin.

Results: E-cadherin and β-catenin labeled basal and lateral plasma membrane domains in the inner medullary CD (IMCD). In the proximal part of IMCD, the labeling was absent from the basal plasma membrane domains of multiple cells after 4 and 10 days of Li treatment and was present again after 4 weeks of Li. In addition, the basal labeling of β-catenin was absent from some cells after 12 days of recovery. IHC of the Na^+/K^+-ATPase β1-subunit revealed a similar subcellular localization, and the protein was not present in the basal plasma membrane domains of multiple cells in the proximal part of the IMCD already after 4 days of Li.

Conclusions: The subcellular localization of the adherens junction proteins E-cadherin, β-catenin and Na^+, K^+-ATPase b1 is affected by Li treatment in the proximal part of the IMCD. In addition, the absence of labeling from the basal plasma membrane domains appears to occur prior to the cellular remodeling.

Deletion of the EP3 Receptor in the Kidney Tubule of Adult Mice Has No Impact on the Major Channels and Transporters Involved in Kidney Water Handling

Cristina Esteva-Font,[1] Frank Geurts,[2] Ewout J. Hoorn,[2] Robert A. Fenton.[1] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Erasmus MC, Rotterdam, Netherlands.*

Background: Prostaglandin E2 (PGE2) is an important lipid mediator modulating various aspects of kidney function. PGE2 exerts its effects via four PGE2 receptors, EP1-EP4, but it is unclear which PGE2 effects are mediated through which receptor. The EP3 receptor is expressed in the thick ascending limb (TAL) and the collecting duct, where it is proposed to inhibit cAMP generation and NaCl and water reabsorption. However, EP3 is also expressed in endothelial cells of arteries and arterioles, that also play a role in kidney function.

Methods: To assess the tubular role of EP3 in adult mice we generated a mouse model based on the Pax8Cre system with doxycycline-dependent deletion of EP3 along the renal tubule and assessed their renal phenotype in respect to water handling. qPCR and RNAscope confirmed that EP3 was highly expressed in cortical and medullary TAL and collecting ducts, but it was not detected in proximal tubule and thin limbs.

Results: Two weeks after treatment with doxycycline, EP3 mRNA expression was reduced by >80% in whole kidney (RT-q-PCR) and non-detectable (RNAscope) in tubules of knockout mice compared to control mice. The other EP receptors expression remained unchanged in the kidney except for a slightly increase in EP4 expression. Under basal conditions, there were no significant differences in food and water intake, bodyweight, urinary output or plasma and urine biochemistries in both male and female control and knockout mice. There were no differences between genotypes in their kidney handling of water during an acute water load, or in their response to the vasopressin V2 receptor agonist dDAVP. Moreover, the expression levels of the main channels and transporters involved in kidney water handling, including AQP2, AQP3, AQP4, NKCC2, αENaC, UT-A1, ROMK and NaK-ATPase remained similar to the control mice.

Conclusions: This new model provides a novel tool for examination of the role of EP3 in other aspects of kidney function or kidney disease independently of potential developmental abnormalities or systemic effects.

PO1104

Bayesian Identification of Transcription Factors That Regulate Aqp2 Transcription

Hiroaki Kikuchi,[1] Hyun Jun Jung,[2] Mark A. Knepper.[1] *[1]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Renal collecting duct and connecting tubule cells selectively express the water channel aquaporin-2 (AQP2) and *Aqp2* gene transcription is strongly regulated by vasopressin. However, the transcription factors (TFs) responsible for regulation of expression of AQP2 remain largely unknown. Here, we used Bayesian data integration techniques to identify these TFs.

Methods: The general strategy is to use Bayes' Rule to integrate several -omic datasets to stratify a curated list of 1344 TFs present in the mouse genome with regard to probability of regulating *Aqp2* gene transcription. To prioritize TFs, existing proteomic and transcriptomic data, ATAC-Seq, histone H3K27-acetylation ChIP-Seq, and RNA-polymerase II ChIP-Seq data are used. Beyond this, we use additional -omic datasets to prioritize TFs that are regulated by vasopressin. Finally, we carried out new RNA-Seq experiments mapping the time course of vasopressin induced changes in the transcriptome of mouse mpkCCD cells to further prioritize TFs that change in tandem with AQP2.

Results: The analysis identified 17 TFs out of 1344 in the mouse genome that are most likely to be involved in regulation of *Aqp2* gene transcription. These TFs included eight that have been proposed in prior studies to play a role in Aqp2 regulation, viz. Cebpb, Elf1, Elf3, Ets1, Jun, Junb, Nfkb1, and Sp1. The remaining nine represent new candidates for future studies (Atf1, Irf3, Klf5, Klf6, Mef2d, Nfyb, Nr2f6, Stat3, Nr4a1). The RNA-Seq time course experiments in mpkCCD cells showed a rapid increase in Aqp2 mRNA, within 3 hour of vasopressin exposure. This response was matched by an equally rapid increase in the abundance of the mRNA coding for Cebpb, which we have shown by ChIP-seq studies to bind downstream from the *Aqp2* gene.

Conclusions: The Bayesian analysis has identified the TFs most likely to bind to Aqp2 cis-regulatory elements and likely to be regulated by vasopressin stimulation, providing a roadmap for future studies to understand regulation of *Aqp2* gene expression.

The Enhanced Expression of AQP4 in Cerebral Ischemia Is Attenuated in AQP11 Heterologous Knockout Mice

Yasuko Tanaka, Kenichi Ishibashi. *Meiji Yakka Daigaku, Kiyose, Japan.*

Background: The role of aquaporins (AQPs) in the brain edema needs to be clarified to advance its treatment. Since the importance of AQP4 for the formation of brain edema has been shown, AQP11, expressed in the brain capillary, may also be important for the regulation of brain edema. In fact, we recently reported the associated expression of AQP4 and AQP11 in osmotically challenged AQP11 heterologous knockout mice (HKM) (Koike S et al. Biochimie. 2021).

Methods: Both common cervical arteries were ligated for 15 min or 60 min to produce an ischemic-reperfusion model of brain infarction. On one or two days after the reperfusion, total RNA in the brain between Bregma and Lambda was isolated from wild mice and HKM. A real-time RT-qPCR was employed to examine the expression levels of several genes including AQP1, AQP4, AQP11, Iba1 (microglial marker), GFAP (astrocyte marker), Lamp2 (pro-autophagic factor), Bax (pro-apoptotic factor).

Results: Gene expression profiles were similar between wild mice and HKM in Iba1 (increase), Lamp2 (increase) with more severity in 60 min ligation and in the second day. A similar profile was also observed with slightly decreased AQP1 by 5-22%. In contrast, the expression profiles of AQP4 and GFAP were outstanding in that both were more highly induced in wild mice than HKM, by 56% vs. 21% and by 570% vs. 335%, respectively, with further increases in 60 min ligation and in the second day. The results suggested the activation of astrocytes expressing AQP4 by the reperfusion, which might be attenuated in HKM. In agreement with this, the expression of Bax was increased in wild mice by 18% with 60-min ligation while it was decreased by 12% in HKM, suggesting a smaller brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased more in HKM by 25-30%. The results suggest that this further AQP11 decrease in HKM may have attenuated the increasing AQP4 expression after reperfusion.

Conclusions: The decreased AQP11 expression in HKM attenuated the enhanced expression of AQP4 and Bax in a mouse ischemia-reperfusion brain model. Thus, the inhibition of AQP11 may alleviate the brain edema by attenuating the expression of detrimental AQP4 in brain infarction.

PO1106

Acute Hemoglobin Level Drop Based on Body Volume Gained

Phuong-Chi T. Pham, Phuong-Thu T. Pham. *UCLA Medical Center Olive View, Sylmar, CA.*

Background: Hemoglobin (Hb) changes with blood transfusions have been widely studied, but to our knowledge, Hb drop associated with volume gained have not been studied. High fluid volume infusion in critically ill patients always result in Hb drop, but the acceptable extent of Hb drop is generally a clinical guess. We herein started a pilot study to assess Hb changes based on daily volume gained among anuric hemodialysis patients.

Methods: Chronic anuric hemodialysis (HD) patients without active bleed admitted to our institution for reasons other than dialysis were included. Strict input/output measurements and Hb levels peri-HD were obtained. Post-HD levels were measured at least 12h post treatment to allow for equilibrated fluid comparmentalization. Changes in Hb per L of body volume gained were calculated.

Results: 10 consecutive HD individuals were included. Average age 60.7±7.2 years, 6 males, 4 females, estimated fat free mass (FFM) 49.3±5 Kg, pre-HD Hb 9.74±1.28, post-HD Hb 9.36±1.28 g/dL, positive fluid balance per patient 1182±775 mL. Average Hb drop was -0.19±0.58 g/dL per L of fluid gained, or 0.004±0.12 g/dL/L of fluid gained/Kg of FFM.

Conclusions: Hemoglobin drop with large fluid infusion may be studied in the anuric HD population. Our pilot study indicates thus far that Hb drop may be ~0.2 g/dL/L on average or a maximum of ~0.8 g/dL per liter of positive fluid balance. Additional data are being collected. Our study may help clinicians gauge for possible blood loss during large fluid infusion required for hemodynamically unstable patients.

PO1107

A Salty Goodbye to Diuretic Resistance: Hypertonic Saline

Sean Barnett. *Brooke Army Medical Center, Fort Sam Houston, TX.*

Introduction: Understanding the complex interplay of Cardiorenal physiology and pathophysiology in diuretic resistance requires a deep understanding of RAAS, ADH, and virtually all segments of the nephron. To treat, requires not only understanding but also the ability to investigate and differentiate. However, a treatment that can inhibit RAAS (directly and indirectly), stimulate Cardiac Output, improve GFR, and increase natriuesis could be the universal answer. 3% Saline has the ability to improve Cardiac Output and decrease SVR, increase GFR, increase natriuresis, inhibit RAAS and ADH (directly and indirectly), *and stimulate ANP.* **Therefore, the answer to Diuretic Resistance is 3% Saline.**

Case Description: A 55 y.o. AAF presented to the hospital for severe edema and shortness of breath. PMHx of HFpEF, DM, HTN, CKDg3a3 (non-nephrotic). She presented with AKI III, severe hyponatremia, and anasarca. Echo revealed EF 40%, biatrial enlargement, RV overload and reduced RV function. She was initially treated with high dose furosemide but did not improve. She was given Metolazone which caused worsening hyponatremia which was treated with 100mL of 3% Saline. This caused an immediate increase in urine output and sodium. She was then changed to a bumex drip and high dose spironolactone (200mg) with some improvement (via objective urine electrolyte assessment) she was still inadequately diuresed. She was then treated with 3% + Loop pulse dosing and sustained a robust diuresis of >3L of urine and maintained urinary sodium >50.

Discussion: The potential causes of diuretic resistance arise from the RAAS system *and* the individual nephron segments. The RAAS system however is the most universal target (when inhibited). While DCT, ASDN, CD and CCT. are involved, regardless of which segment is primary, targetting the RAAS system would likely have significant benefits in all diuretic resistance. 3% Saline works as a potent IVF to improve Cardiac Output, decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. Using 100mL of 3% saline to augment diuresis (or alone) causes improvement in virtually all Cardiorenal parameters. The NaCl load directly inhibiting RAAS through distal NaCl delivery (salt load also increases salt wasting), this causes decreased afferent arteriolar constriction and thus further improving GFR. It also stimulates ANP in the RA to inhibit RAAS and ADH indirectly.

PO1108

Enhanced Diuresis with Sequential Nephron Blockade

Shawn Alonso,[1,2] Raymond T. La,[1,2] Chavely Valdes Sanchez,[1,2] Gabriel A. Valle.[1,2] *[1]University of Miami School of Medicine, Miami, FL; [2]Holy Cross Hospital, Ft. Lauderdale, FL.*

Introduction: Achieving volume control in patients with severe edema can be challenging, as diuretic resistance may occur. In such cases, sequential nephron blockade (SNB), a targeted multi-diuretic use strategy should be considered.

Case Description: A 60-year-old woman with HIV and Dilated Cardiomyopathy s/p CRT-D presented with dyspnea and anasarca despite torsemide and losartan. In the ED she weighed 370 Lbs., had stable hemodynamic parameters, hypoxemia, diffuse lung infiltrates and low CD4 count. Oxygen, IV loop diuretics and Bactrim were initiated for concerns of PCP and HF. Despite an average UO of 3 L/day she had no meaningful weight loss, protracted lung congestion, hyponatremia and developed radiocontrast nephropathy after CTA. Fluid restriction and SNB with IV thiazide and loop agents were instituted. Tolvaptan was added intermittently and led to an impressive diuresis of 8-11 L/day, restored normonatremia and was hemodynamically and metabolically well tolerated. Within 12 days, weight loss of 154 Lbs. was achieved with major clinical improvement.

Discussion: Loop agents are a mainstay for diuresis in patients with volume overload. However, diuretic resistance can occur through various mechanisms, including hypertrophy of the distal nephron and loss of function due to AKI. SNB provides a unique approach by strategically targeting ultrafiltrate dynamics in a stepwise manner and interfering with fluid reabsorption within various tubular segments. Central to this premise is the ability to maximize drug bioavailability and parenteral administration is initially necessary. Close hemodynamic and metabolic surveillance are mandatory as the mobilization of vast amounts of extracellular fluid may result in significant complications. Remarkably, in this case, while her eGFR was 25% she achieved 11 L diuresis (30% of UF) safely. This underscores the enormous capacity for fluid sequestration in the extracellular space and the crucial role of trans-compartmental fluid shifts in HF. SNB has been available for years and various diuretics combinations are plausible. This case exemplifies the effectiveness of a novel regimen with vaptans in promoting voluminous diuresis and aquaresis, improving outcomes and decreasing length of stay.

PO1109

Functional Sodium Magnetic Resonance Imaging of Human Kidney

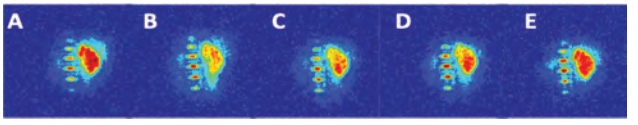
Sandrine Lemoine, Alireza Akbari, Fabio R. Salerno, Timothy J. Scholl, Guido Filler, Andrew A. House, Christopher W. McIntyre. Kidney Clinical reserach unit, Western of Ontario, Pr McIntyre *Western of ontario, London, ON, Canada.*

Background: Maintenance of a cortico-medullary concentration gradient (CMG) is required for urine concentration. We explored the ability of ^{23}NaMRI in measuring 1) the dynamics of CMG for the first time compared to urinary osmolarity after a water load and 2) the CMG in kidney disease.

Methods: We conducted an exploratory pilot study for 10 healthy controls following water load then 5 cardiorenal patients with kidney disease. 1) Fasting healthy controls provided urine samples to measure osmolarity and baseline ^{23}NaMRI scans were performed. They were instructed to ingest water (15 mL/kg) within 15 minutes. Four subsequent sodium images and urine samples were acquired at 15 min intervals starting one hour after water ingestion. 2) Cardiorenal patients underwent an MRI scan, provided a blood and urine sample, but no water loading.

Results: Mean age of the 10 healthy controls was 41.8 ± 15.3 years. In the morning fasting, medulla/cortex ratio was 1.55 ± 0.11 with concurrent urinary osmolarity measured at 814 ± 121 mOsm/L. Mean ± SD fasting urinary osmolarity dropped significantly to 73 ± 14 mOsm/L, p=0.001. Mean medulla/cortex ratio dropped significantly to 1.31 ± 0.09 mOsm/L for maximal dilution, p=0.002. Figure 1 displays changes of ^{23}NaMRI pictures before (A) then 1h (B), 1H15 (C), 1h30 (D) and 1h45 (E) after a water load. Urinary osmolarity and medulla/cortex ratio are significantly correlated, r=0.54, p=0.0001. Mean age of the 5 cardiorenal patients was 76.6 ± 12.2 years, eGFR was 54 ± 37 mL/min/1.73m^2. Urinary osmolarity was 498 ± 145 mOsm/L and medulla/cortex ratio was 1.35 ± 0.11. We measured corticomedullary gradient in cardiorenal patient with different level of eGFR to show the ability and feasibility to measure this gradient in pathological settings.

Conclusions: We explored CMG dynamically every 15 min in healthy controls and demonstrated significant changes after a water load. We were also able to acquire ^{23}NaMRI pictures in cardiorenal patients with kidney disease with plans for future analyses.



PO1110

Validity of a Simple Equation to Estimate Urine Output in Outpatients with Suspected Nephrolithiasis

Luke Webster,[1] Alexander Bullen,[1] John R. Asplin,[2] Michael Shlipak,[3] Seth Bechis,[1] Manoj Monga,[1] Joachim H. Ix.[4,1] *[1]University of California San Diego, La Jolla, CA; [2]LithoLink Corp, Chicago, IL; [3]University of California San Francisco, San Francisco, CA; [4]VA San Diego Healthcare System, San Diego, CA.*

Background: We previously developed and validated an equation to estimate urine volume from spot urine creatinine, demographic variables, and body weight in patients with kidney disease. We hypothesized this equation could accurately estimate daily urine output in outpatients with nephrolithiasis.

Methods: Among persons submitting specimens to Litholink Laboratories between May 2013 and January 2016, we identified 19,884 individuals who had two 24 hour urine collections on consecutive days, with creatinine excretion rates ±10%. We used Pearson correlations and Bland-Altman analysis to evaluate equation estimated with measured urine volume on the first of the two 24 hour urine collections. We also tested the equation's test characteristics to accurately identify producers >2L/day; a guideline directed urine output goal among stone formers.

Results: Estimated and measured urine volumes were strongly correlated (r=0.76, p < 0.001). The estimated urine flow rate was 195 ml/day (8.7%) higher than measured. Overall, 78% of individuals had an estimated urine volume within 30% of measured. Performance was similar in men and women, across strata of body weight, in those with and without CKD, and when evaluating the second day measured urine volume. An estimated urine volume ≥ 2L/day had 86% sensitivity, 83% specificity, 76% PPV and 91% NPV for identifying individuals with measured urine volumes > 2L/day **(Figure 1).**

Conclusions: A simple equation using urine creatinine, demographics and body weight can predict urine flow rate among patients with nephrolithiasis. The equation may provide a tool to enhance diagnostic accuracy in the urinary risk factors for stones, and to identify patients among whom efforts to increase hydration could be targeted to diminish risk of stone recurrence.

Funding: NIDDK Support

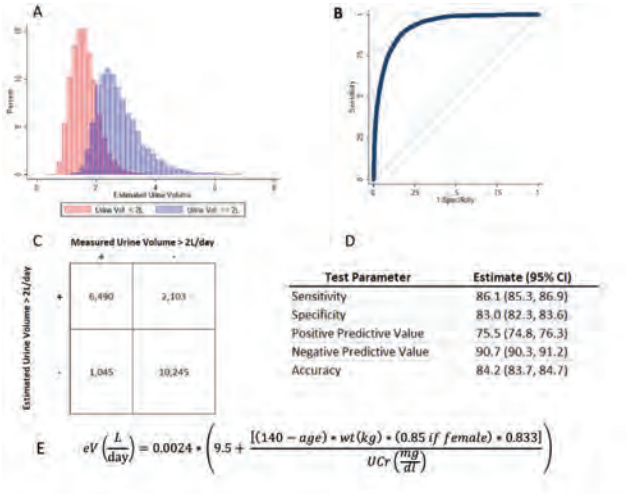


Figure 1. Test Characteristics of Estimated Urine Volume Equation to Predict Measured Urine Volume > 2L/Day.

Panel A depicts overlaying histograms showing estimated urine volume among those who had measured urine volume ≤ vs. ≥ 2L/day. **Panel B** shows the area under the receiver operator curve (AUC) when estimated urine flow rate is used to predict whether a patient has a measured urine volume ≥ 2L/day (AUC 0.845). **Panel C** depicts the 2 X 2 table comparing estimated vs. measured urine volume ≥ 2L/day, and **Panel D** provides the corresponding sensitivity, specificity, positive and negative predictive values, and overall accuracy, along with 95% confidence intervals of these estimate. **Panel E** depicts the estimated flow equation (eV) used for this analysis.

PO1111

Attenuated Urinary Sodium and Volume in Response to Saline Load in Heart Failure with Preserved Ejection Fraction

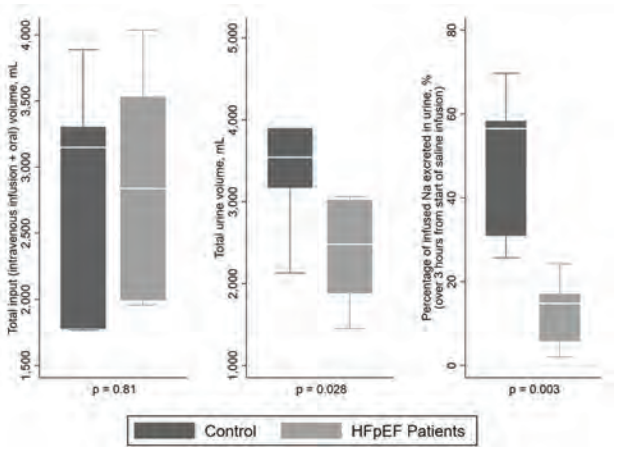
Adhish Agarwal, Srinivasan Beddhu, Robert E. Boucher, Aylin R. Rodan, Habeeb Mohammad, Guo Wei, Kevin S. Shah, James C. Fang, Alfred K. Cheung. *University of Utah Health, Salt Lake City, UT.*

Background: Heart failure (HF) is characterized by fluid overload due to impaired sodium (Na) excretion. Impaired urinary Na excretion in response to intravenous Na load has been demonstrated in HF with *reduced* ejection fraction (HFrEF). We hypothesized that patients with HF with *preserved* ejection fraction (HFpEF) also have impaired urinary sodium excretion and volume in response to intravenous Na load.

Methods: All participants were instructed to follow a low (2-3 g/d) sodium diet for one week prior to the study and held their diuretic (if prescribed) the morning of the study. After obtaining approval from our center's institutional review board, saline was infused intravenously at 0.25 ml/kg/min for 60 minutes in 9 patients with HFpEF and 5 controls (no known renal or cardiac disease). Urine output was measured throughout, and blood and urine samples were collected at baseline and 2 hours after ending the infusion. Urine volume and urinary sodium excretion between the groups were compared using Wilcoxon rank-sum tests.

Results: Mean age (yrs) and body mass index (kg/sqm) were 62+/-12 and 36.3+/-8.5 respectively in the HFpEF participants, and 47+/-18 and 24.6+/-3.7 in controls. The fraction of intravenous sodium that was excreted in the urine over 3 hours was significantly lower in cases (12% versus 46%, p=0.003). Mean urine output was significantly lower in cases (2480 versus 3541 ml; p=0.028), even though the total fluid intake (intravenous + oral) during the same time period was similar (2839 versus 3149 ml; p=0.81).

Conclusions: In this rigorous, controlled human pilot study, patients with HFpEF had lower urinary volume and attenuated urinary sodium excretion compared to controls after intravenous sodium and volume load. Data and biospecimens collected in this study should inform the pathogenesis of sodium retention in HFpEF.



PO1112

Attenuated Renal Response to Endogenous Natriuretic Peptides in Heart Failure with Preserved Ejection Fraction

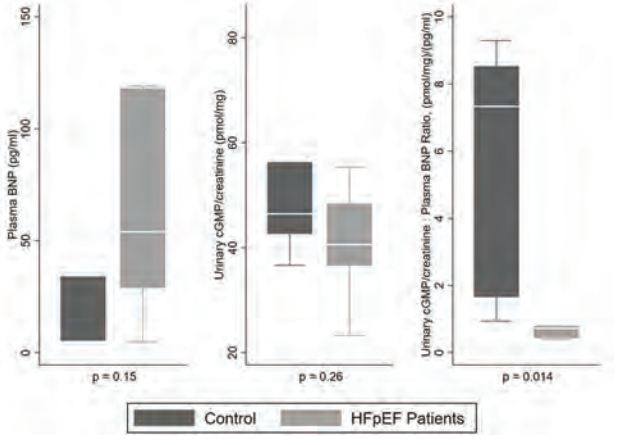
Adhish Agarwal,[1] Srinivasan Beddhu,[1] Robert E. Boucher,[1] Nirupama Ramkumar,[1] Aylin R. Rodan,[1] Veena Rao,[2] Habeeb Mohammad,[1] Elizabeth Dranow,[1] Guo Wei,[1] Kevin S. Shah,[1] James C. Fang,[1] Alfred K. Cheung.[1] *[1]University of Utah Health, Salt Lake City, UT; [2]Yale University, New Haven, CT.*

Background: The pathophysiology of sodium retention in heart failure with preserved ejection fraction (HFpEF) remains largely unknown. A potential mechanism is attenuated renal response to natriuretic peptides (NPs). Urinary cyclic guanosine monophosphate (ucGMP) is an intracellular messenger of NPs, and an attenuated ucGMP/B-type NP (BNP) ratio suggests decreased renal response to BNP. We hypothesized that patients with HFpEF have attenuated response to NPs.

Methods: We studied ucGMP/plasma BNP ratios in 9 HFpEF patients and 5 controls (no history of renal or heart disease). All participants were placed on a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

Results: Mean age and body mass index for the HFpEF participants were 62+/-12 years and 36.3+/-8.5 Kg/m^2, and for control participants were 47+/-18 years and 24.6+/-3.7 Kg/m^2 respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) (pmol/mg)/(pg/ml); p = 0.014) in cases as compared to controls.

Conclusions: Our pilot study shows that ucGMP/plasma BNP ratio, which reflects renal response to BNP, was attenuated in patients with HFpEF. These data suggest that impaired renal response to NPs may be implicated in the pathogenesis of fluid retention in HFpEF.



PO1113

Association of Urinary Potassium Excretion with Progression of CKD

Daisuke Mori, Yuta Namiki, Ayaka Sugimachi, Manabu Kado, Shinjiro Tamai, Hiroki Nomi, Ryota Haga, Katsuyuki Nagatoya, Atsushi Yamauchi. *Osaka Rosai Hospital, Osaka, Japan.*

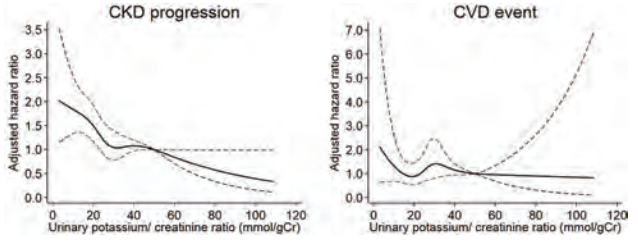
Background: Out of range serum potassium levels are associated with worsening renal function and increased occurrence of cardiovascular disease (CVD) events in

chronic kidney disease (CKD). However, conflicting results have been reported regarding the predictive value for adverse health outcomes of urinary potassium excretion. Therefore, we conducted a cohort study to determine whether urinary potassium excretion is an independent risk factor for renal function deterioration or increased CVD events.

Methods: We identified 650 patients with pre-dialysis CKD who were hospitalized for CKD educational program between 2010 and 2018. Study outcomes analyzed were CKD progression and incidence of CVD events. Baseline urinary potassium to creatinine ratio (UK/Cr, expressed as mmol/gCr) was ranked into quartiles as follows: Q1, <19.8; Q2, 19.9–27.7; Q3, 27.8–37.9; and Q4, >38.0.

Results: During follow-up (median 35 months), 509 CKD progression and 129 CVD events were identified. Further, 62 patients died during follow-up. Multivariate Cox models showed that an increased risk of CKD progression was observed in patients with low UK/Cr compared to those with high UK/Cr, after adjustment for demographic factors and laboratory data. In a fully adjusted model, adjusted hazard ratios (HRs) with the fourth (highest) quartile as reference category were 2.02 (95% CI, 1.50–2.71), 1.34 (95% CI, 1.02–1.77), and 1.14 (95% CI, 0.87–1.50), for Q1–3 respectively (trend: $P < 0.001$). Similarly, an inverse probability weighting analysis showed an increased risk of CKD progression in Q1 and Q2 comparing with Q4. We did not observe any significant modification in subgroup analyses. Furthermore, consistent association was confirmed between low fractional excretion of potassium and worsening renal function. However, UK/Cr had no association with the incidence of CVD events.

Conclusions: A low UK/Cr is independently associated with worsening renal function but not with an increased risk of a CVD event in patients with pre-dialysis CKD.



PO1114

Licorice-Induced Syndrome of Mineralocorticoid Excess

Nisarg Gandhi, Hassan N. Ibrahim. *Houston Methodist Hospital, Houston, TX.*

Introduction: Edema and volume overload are common complaints. Here, we present a case of a chronic licorice consumption resulting in edema and generalized weakness.

Case Description: A 34 y/o Caucasian women with history significant for hypothyroidism and recurrent episodes of bronchitis presented for evaluation of recurrent facial, arm, and lower extremity swelling over the past year. She has been evaluated extensively with no etiologies found in the past. She takes Bumex 0.5 mg at least once weekly when she has swelling. She does not have any evidence of kidney dysfunction, heart failure, liver failure, or evidence of proteinuria on laboratory findings. She has been evaluated by rheumatology and was only found to have a weakly positive ANA with no other associated findings (hematuria, arthralgias, or muscle pain). She denies any shortness of breath or orthopnea. Her vitals were within normal limits (BP: 115/70, Pulse: 55). She is very active and exercises daily. Despite limiting her sodium intake, she continues to have recurrent swelling. On further questioning, she mentioned drinking a tea high in licorice. Her basic metabolic panel shows Na^+ at 140, K^+ at 4.3, Cl^- at 100, and CO_2 at 26. Her urinalysis was bland with her urine $Na^+ < 20$. Measured plasma renin and aldosterone activity, shown in the table, were found to be low at baseline. Afternoon free cortisol level was measured to be 0.199. After discontinuation of licorice, they increased back to normal limits with complete resolution of symptoms.

Discussion: Chronic ingestion of licorice is a rare but a known cause of syndrome of mineralocorticoid excess (AME). Licorice contains a steroid, glycyrrhetinic acid, which inhibits the function of the enzyme 11-beta-HSD2. This same enzyme is deficient in AME. This can occur at even low amounts of licorice (50g per day). Typically, these cases present with hypertension, hypokalemia, metabolic alkalosis, low plasma renin activity, and low plasma aldosterone levels. The only treatment necessary is cessation of licorice and symptoms typically resolve in about 1 week. This case illustrates the importance of obtaining a complete medication history including supplement use.

	At Presentation	3 Months after Discontinuation
Aldosterone (ng/dL)	2.3	32.4
Renin (ng/mL/hr)	1.111	2.235

PO1115

Not Just Licorice: Abiraterone and Apparent Mineralocorticoid Excess

Natalie M. Beck,[1] Katherine Rizzolo,[1] Sophia L. Ambruso.[1,2] *[1]University of Colorado, Denver, CO; [2]VA Eastern Colorado Health Care System, Aurora, CO.*

Introduction: Abiraterone is a CYP17A1 inhibitor which blocks androgen synthesis and is used to treat castration-resistant prostate cancer. This drug also decreases cortisol synthesis, causing a compensatory increase in adrenocorticotropic hormone (ACTH) and accumulation of mineralocorticoids. The result is the syndrome of apparent mineralocorticoid excess (AME) which manifests clinically as hypokalemia, metabolic alkalosis and hypertension. Abiraterone is approved for use only with concurrent glucocorticoid replacement to prevent these effects. We present a case of refractory hypokalemia resulting from abiraterone use.

Case Description: A 74-year-old man with metastatic prostate cancer and head and neck cancer presented with urinary retention and acute kidney injury (AKI) as well as hypokalemia and metabolic alkalosis which were present a week prior. Home medications included abiraterone, cisplatin (given two weeks prior), prednisone 5 mg daily (recently decreased from 5 mg twice daily) and spironolactone. A urinary catheter was placed, the AKI improved rapidly and the patient remained with refractory hypokalemia. A urine potassium-to-creatinine ratio was high. Post-obstructive polyuria was considered as a reason for kaliuresis; however, hypokalemia and metabolic acidosis preceding this event made it unlikely to be the sole cause. Given abiraterone use, serum cortisol was checked and was low with no increase after giving cosyntropin. Serum aldosterone, renin and their ratio were normal. The patient was diagnosed with abiraterone-induced AME. Prednisone was increased to 5 mg twice daily and eplerenone was started in place of spironolactone. Two months later, the serum potassium was normal without supplementation.

Discussion: Abiraterone-induced AME is characterized by low serum cortisol but unlike adrenal insufficiency, presents with hypokalemia, metabolic alkalosis and hypertension. In this case, AME results from inhibition of the 17α-hydroxylase activity of the CYP17A1 enzyme, leading to decreased cortisol, increased ACTH, and accumulation of the potent mineralocorticoid dexoycorticosterone. Glucocorticoid supplementation (prednisone 5 mg twice daily recommended) is needed to suppress ACTH and prevent these effects. Eplerenone is an adjunct and is preferred over spironolactone in patients with castrate-resistant prostate cancer as spironolactone interacts with the androgen receptor.

PO1116

Jägermeister-Induced Pseudohyperaldosteronism

Joseph A. Gotesman, Jordan L. Rosenstock. *Lenox Hill Hospital, New York, NY.*

Introduction: Hypertension and hypokalemia is known to be caused by hyperaldosteronism. We report a case of hypertension, hypokalemia, and supressed renin and aldosteronen levels. Dietary work-up revealed copius ingestion of Jagermeister liquor which contains licorice, a known cause of pseudohyperaldosteronism.

Case Description: A 54-year-old man with a history of HIV on Genvoya and CAD, HTN on metoprolol and isosorbide monoitrate was referred to nephrology for evaluation of hypokalemia and accelerated hypertension. Prior to nephrology referral, he was started on oral potassium for 6 weeks and the repeat potassium was 3.5 mmol/L. On review of systems, he had no specific complaints except occasional diarrhea. On exam, his BP was 190/110, 1+ lower extremity edema; his exam was otherwise unremarkable. Initial workup revealed serum sodium 143 mmol/L, bicarb 24 mmol/L, potassium 3.5 mmol/L, creatinine 1.1 mg/dL, magnesium 1.5 mg/dL, urine K 78 mmol/L, FeK 13.6%, TSH 2.95 uIU/mL, plasma renin activity 1.191 ng/mL/hr, and aldosterone <3.0 ng/dL, and plasma metanephrines <10 pg/mL. Repeat K was 3.1, bicarb 30, plasma renin activity 0.195 ng/mL/hr, and aldosterone <3.0 ng/dL; urine K 34, FeK 11%; renal dopplers without evidence of RAS. Given hypokalemia, metabolic alkalosis with evidence of potassium wasting, and suppressed renin and aldosterone levels, a thorough dietary review was conducted which revealed chronic Jagermeister ingestion of up to 500mL per day. He stopped drinking Jagermeister and on subsequent follow-up, his BP was controlled on amlodipine, carvedilol, and isosorbide mononitrate, and he no longer required potassium supplementation.

Discussion: Licorice contains glycyrrhizic acid which inhibits 11 beta-hydroxysteroid dehydrogenase, preventing inactivation of cortisol to cortisone, and resulting in excess mineralocorticoid activity manifested by suppressed renin and aldosterone levels, sodium retention, hypervolemia, hypokalemia, hypertension, and edema. According to the manufacturer, Jagermiester liquor contains under 10 mg/L of licorice, however, the amount that can cause toxicity is not certain and literature suggests that the glycyrrhizic acid content of licorice is widely variable. Physicians ought to consider dietary, non-medication causes for electrolyte abnormalities in patients with initial negative workups.

PO1117

Posaconazole-Related Mineralocorticoid Excess in a Patient with Acute Myeloid Leukemia

Venkata Kishore R. Mukku,[1,2] Adnann S. Polani,[3,2] Vishnupriyadevi Parvathareddy,[3,2] Sreedhar A. Mandayam.[2] *[1]The University of Texas Medical Branch at Galveston, Galveston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]Baylor College of Medicine, Houston, TX.*

Introduction: Posaconazole is an antifungal used for treatment and prophylaxis of invasive fungal infections in cancer patients. We report a case of posaconazole related mineralocorticoid excess in a patient with acute myeloid leukemia (AML).

Case Description: Patient is a 40-year-old male with past medical history of relapsed AML status post stem cell transplant, was admitted on 08/16/2020 to UTMDACC for pain, nausea, vomiting, diarrhea, and fatigue. He developed multiple complications streptococcus viridans bacteremia, candidemia, Graft Versus Host Disease, disseminated adenovirus, fungal pneumonia on posaconazole, tracheostomy due to severe mucositis with HSV-1 on Foscarnet. Nephrology was consulted for hypernatremia, hypokalemia and alkalosis. No nausea, vomiting, diarrhea was reported. Due to a combination of hypertension, metabolic alkalosis, hypokalemia and being on Posaconazole, we suspected

Pseudo-hyperaldosteronism. Renin, aldosterone levels were checked which are low. CT scan of abdomen/pelvis did not show any adrenal tumors. Fractional excretion of potassium was high suggestive of renal loss. High 24-hour urine cortisol/cortisone ratio suggestive of mineralocorticoid excess. Posaconazole was changed to Voriconazole on 10/28/20. Due to persistent hypertension, spironolactone was increased and due to hypokalemia, amiloride was added. Twelve days after stopping Posaconazole all electrolyte and acid base abnormalities are resolved.

Discussion: Combination of hypokalemia, hypertension and metabolic alkalosis need to suspect mineralocorticoid excess. Posaconazole inhibits 11 beta-hydroxysteroid dehydrogenase2 which prevents conversion of cortisol to cortisone. High cortisol than aldosterone leads to amplification of mineralocorticoid receptor action causing increase in activity, number of epithelial sodium channels (ENaC), Na-K-ATPase channels. Excess uptake of sodium leads to hypertension and creates increased negativity causing K^+ and H^+ losses leading to hypokalemia and alkalosis. Patients with mineralocorticoid excess can be treated with aldosterone receptor antagonist or ENaC blockers or by stopping or decreasing the dose of Posaconazole. Patients on posaconazole need to be monitored for hypokalemia, hypertension and alkalosis. However, not every patient will develop these which may be likely due to genetic predisposition.

PO1118

Prednisolone-Related Mineralocorticoid Excess: Case of Hypokalemia and Metabolic Alkalosis

Lauren E. Macaraeg, Anna Astashchanka, Rakesh Malhotra, Cynthia Miracle. *University of California San Diego, La Jolla, CA.*

Introduction: We report a case of the mineralocorticoid effect of prednisolone resulting in hypokalemia, metabolic alkalosis and hypertension in a patient treated with checkpoint inhibitor in the setting of oropharyngeal cancer.

Case Description: A 78 year-old male with past medical history of oropharyngeal squamous cell carcinoma presented with fatigue. One week prior, he was treated with pembrolizumab. Admission vital signs were significant for fever to 39.1°C and normotensive blood pressure 130/58. Laboratory results revealed serum potassium (K) 4.1 mmol/L, bicarbonate (HCO_3) 26 mmol/L and newly elevated liver enzymes. He was diagnosed with immune checkpoint inhibitor hepatitis and treated with prednisolone 70 mg via nasogastric tube (NGT). Two days later, blood pressure increased to 170/80 and laboratory studies revealed hypokalemia and metabolic alkalosis with serum K 3.0 mmol/L and HCO_3 30 mmol/L. Potassium was repleted with a total of potassium chloride (KCl) 80 mEq via NGT. The next morning, blood pressure 164/78, serum K 2.7 mmol/L and HCO_3 33 mmol/L. Nephrology was consulted for persistent hypokalemia and metabolic alkalosis. The triad of hypokalemia, metabolic alkalosis and hypertension lead us to suspect a hyper mineralocorticoid state. Workup revealed spot urine K of >100 mmol/L, serum aldosterone <3.0 ng/dL and serum renin <0.1 ng/dL. Findings were consistent with an exogenous source of mineralocorticoid activation. Prednisolone was thought to be the cause. He required a total of KCl 180 meq (40 mEq intravenous, 140 mEq NGT) to raise serum K to 3.4 mmol/L in 24 hours. As such, we recommended discontinuing prednisolone in favor of dexamethasone which has no mineralocorticoid effect. Two days after discontinuation of prednisolone, serum K was 5.1 mmol/L on KCl 40 mEq via NGT twice a day and serum HCO_3 was 28 mmol/L. Supplemental KCl was discontinued. One week later, serum K remained in normal range at 4.1 mmol/L.

Discussion: We demonstrated clinically significant mineralocorticoid effect of prednisolone resulting in hypokalemia and metabolic alkalosis. Physicians should be aware of electrolyte disorders associated with steroid use. With increased used of checkpoint inhibitors, this scenario may be encountered more often. Treatment may require stopping prednisolone and using alternative steroids with no mineralocorticoid activity.

PO1119

From Hypokalemia to Sjögren Syndrome: What a Twist!

Elizabeth Pabon-Vazquez, Jose Rivera Sepulveda. *Mayaguez Medical Center, Mayaguez, Puerto Rico.*

Introduction: Potassium disorders are one of the many serious conditions that could attempt against a patient's life. Understanding the clinical presentation, diagnosis, management, and treatment of hypokalemia is fundamental for the development of successful clinical physician. In addition, being aware of the associations between electrolyte disturbances and rheumatologic conditions increases the benefits of correctly treating and educating patients.

Case Description: This is the case of a 24 y/o female patient, G1P2A0, with a past medical history of hypoglycemia and hypokalemia since pregnancy with twins. Patient presented to emergency department with shortness of breath, general malaise, muscle weakness, and unable to ambulate. Physical examination was remarkable for proximal muscle weakness, diminished reflexes with intact sensation. Laboratory bloodwork reported positive mycoplasma pneumonia infection, normal anion gap metabolic acidosis with severe bicarbonate and potassium deficiency with EKG changes as ST depression with flattening of T wave and U-wave. Urinalysis had a basic pH with positive urine anion gap. Findings were suggestive of renal tubular acidosis (RTA). In addition, patient reported several episodes of nephrolithiasis during childhood, supporting distal RTA. Hypokalemia history and renal findings trigger were unknown. However, due to association of RTA type 1 and autoimmune disease, workup was performed. Rheumatoid factor, ANA screen, aldolase and SS-A/Ro antibody were positive consistent with Sjogren syndrome diagnosis. There are only a few documented cases. After discussing results with patient, she reported the daily use of artificial tears due to xerophthalmia. She did not report it sooner because, she considered the fact irrelevant to her clinical presentation.

Discussion: Sjogren syndrome is a chronic autoimmune inflammatory disease that could negatively affect the patient's quality of life. Triggers have not been completely identified due to multifactorial involvement and diversity of clinical manifestation. In Puerto Rico, there is a small population currently diagnosed with the syndrome. However, research studies of epidemiological characteristics or clinical profile in Puerto Rico are still ongoing.

PO1120

Idiopathic Bartter Syndrome-Like Phenotype Diagnosed in a Diabetic Patient with COVID-19 Infection

Abhinaya Sridhar,[1,2] Aromma Kapoor.[1,2] *[1]Westchester Medical Center, Valhalla, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Bartter's syndrome (BS) is a rare genetic tubulopathy affecting the loop of Henle leading to salt wasting. Acquired BS is very rare and is associated with underlying medical conditions or certain drugs. We report a unique case of idiopathic BS-like phenotype that was diagnosed in the setting of COVID infection.

Case Description: 71-year-old man with coronary artery disease, hypertension and diabetes presented after a mechanical fall. On admission, he was found to be hypotensive to 107/88 mmHg. Physical exam was within normal limits. Initial blood work was significant for Potassium 2.6 mEq/L, Bicarbonate 34 mEq/L, Calcium 8.0 mg/dL and Magnesium 1.7 mg/dL. Patient also tested positive for COVID-19. Upon further questioning, patient reported a remote history of hypokalemia but never needed any oral supplementation. He denied diuretic use or surreptitious vomiting. Hypokalemia work up revealed increased urinary potassium of 85.4 mEq/L, Renin 15.72 ng/mL/hour and Aldosterone 8 ng/dL. Patient was then started on aggressive intravenous and oral potassium repletion. He continued to require multiple doses of intravenous potassium to maintain potassium levels of 3 mEq/L. He was subsequently started on Eplerenone on Day 3 of admission with excellent response. He remained otherwise asymptomatic from COVID and as his infection improved, hypokalemia stabilized and he was ultimately discharged with a Potassium level of 3.6 mEq/L.

Discussion: The primary defect in BS is in sodium chloride reabsorption in the medullary thick ascending limb of the loop of Henle resulting in hypokalemia, metabolic alkalosis and secondary hyperaldosteronism. Rare cases of acquired BS are reported in association with tuberculosis, sarcoidosis, sjogrens, and certain drugs. All of these were ruled out in our patient and hence a diagnosis of idiopathic BS like phenotype was made. In our patient, we attribute the BS like phenotype to underlying COVID infection. As his infection improved, his hypokalemia also resolved. Hyperkalemia is a more common finding in COVID infection. However, in our patient, hypokalemia secondary to BS like phenotype was a unique presentation which was challenging to treat. In the absence of usual causes of acquired BS, unexplained hypokalemia in a patient with COVID infection should prompt suspicion for BS-like phenotype. Early and aggressive correction of electrolyte abnormalities is crucial.

PO1121

Late-Onset Bartter Syndrome

Mica Alex,[1] Khalid Elharrif,[2,1] Omar S. Al-Taweel,[1] Petersen Greti,[2] Hania Kassem.[1] *[1]The University of Texas Medical Branch at Galveston, Galveston, TX; [2]Kern Medical Center, Bakersfield, CA.*

Introduction: Bartter syndrome (BS) is an autosomal recessive disorder that results from mutations in sodium chloride reabsorption in the thick ascending loop of Henle. The age of onset is usually late childhood or early adulthood and it is rare to have the disease onset in adulthood. We are presenting a rare case of late-onset Bartter syndrome.

Case Description: A 55-year-old female with PMH of supraventricular tachycardia was admitted to the hospital with chest pain and palpitations. She had a history of multiple hospital admissions in the past with hypotension and electrolyte abnormalities. She denied any history of diarrhea or recent use of diuretics or laxatives. Initial Blood pressure was 100/60 mmHg and HR was 100 bpm. **The lab results are summarized in Table A**. CT scan of the pelvis showed bilateral nephrocalcinosis. She received IV fluid resuscitation, magnesium and potassium supplementation and spironolactone with subsequent improvement of her symptoms.

Discussion: BS is classified into five types based on the genetic characters of the disease. Type 3 is associated with classic BS. The chromosomal mutations are associated with a variable degree of disease severity. The mutation types have been identified as large deletions, missense and nonsense mutations. This patient likely has type 3 BS but her mutation type could be a missense mutation so that only one or few amino acids are altered leading to late-onset of her syndrome. The standard treatment is electrolyte repletion. Specific treatment therapy continues to be an ongoing source of research. ACE inhibitors and spironolactone can play a role in blocking the RAAS system. NSAIDs can be used to suppress the high level of PGE2 associated with the disease.

Urine study		Blood Work	
POTASSIUM	30 meq	SODIUM	135 med
CACLIUM	15 mg/dl	POTASSIUM	2.9 meq
Calcium creatinine ratio	0.2	PHOSPHORUS	1 meq

PO1122

Colonic Pseudo-Obstruction and Hypokalemia

Akbar H. Hamid,[1,2] Isha Puri,[1,2] Mary C. Mallappallil,[1,2] Man S. Oh,[1,2] Moro O. Salifu.[1,2] *[1]SUNY Downstate Health Sciences University Department of Medicine, New York, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: Ogilvie's syndrome, or colonic pseudo-obstruction, is the pathologic dilation of the colon without underlying mechanical obstruction. It is caused by increased sympathetic activity or reduced parasympathetic activity. The common manifestation is constipation, but sometimes it may be associated with diarrhea when potassium secretion is greatly increased by stretch-activated maxi-K channel, also known as BK channel, resulting from dilatation of the colon. While exact mechanism is unclear, diagnosis is based on clinical and radiologic grounds.

Case Description: A 69 year old African American female with history of diabetes mellitus, hypertension, hyperlipidemia, and HIV infection presented with worsening lower back pain. Initial labs showed leukocytosis, anemia, mild renal impairment, and paraprotein gap. MRI of the spine showed extensive compression deformities and epidural extension, with lytic lesions on skeletal survey. Bone biopsy showed >80% blast cells with marked increase in circulating plasma cells, confirming plasma cell leukemia. Abdominal CT showed dilated ascending colon suggestive of obstruction, but she was having normal bowel movements. She successfully underwent induction therapy and was discharged. When she was readmitted for second cycle of chemotherapy, serum potassium of 1.8 mmol/L with U wave on ECG noted. She also complained of abdominal distension, diarrhea, and bilateral lower extremity edema. Despite aggressive potassium supplementation, her potassium level persistently remained below 3.5 mmol/L. Initial urine potassium was 23 mmol/L, which peaked at 45.8 mmol/L before becoming anuric. First stool potassium was >100 mmol/L with stool volume of 900 mL. Repeat stool study after a week showed stool potassium 95.9 mmol/L with stool sodium 42 mmol/L. Abdominal x-ray on admission showed colon distension measuring up to 11.4 cm at the cecum. Serial imaging of the bowel showed worsening diffused colonic dilation. Remarkably, our patient required large doses of potassium supplement while she remained anuric.

Discussion: Colonic pseudo-obstruction may result, in some patients, in dramatic upregulation of the maxi-K channel. When potassium secretion is greatly increased, diarrhea rather than constipation becomes predominant manifestation. Diarrhea is the result of high potassium content of the stool, unlike most other secretory diarrhea which contains sodium as the main cation.

PO1123

Prevalence and Recurrence of Hyperkalemia (HK) in Medicare Patients Admitted to Long-Term Care or Post-Acute Care (LTC/PAC) Settings

James F. Neuenschwander,[1] Alison R. Silverstein,[2] Christie Teigland,[2] Dakota C. Powell,[2] Shambhavi Kumar,[2] Jill Dreyfus,[2] Edric Y. Zeng,[2] Abiy Agiro,[3] William Pottorf,[3] William Peacock.[4] *[1]Genesis HealthCare System, Zanesville, OH; [2]Avalere Health, Washington, DC; [3]AstraZeneca Pharmaceuticals LP, Gaithersburg, MD; [4]Baylor College of Medicine, Houston, TX.*

Background: HK is a common electrolyte imbalance among elderly populations with comorbidities such as chronic kidney disease (CKD) and congestive heart failure (CHF). This study describes the prevalence and recurrence of HK in patients in the LTC/PAC setting.

Methods: This retrospective study used 100% Medicare Fee-For-Service data for patients age ≥65 with ≥1 LTC/PAC stay from 01/01/2017 to 11/30/2019; index date was admission date of first LTC/PAC stay. HK-related stay was defined as ≥1 HK diagnosis (ICD-10: E87.5) or evidence of potassium binder use during LTC/PAC stay or within 14 days pre-index. Baseline characteristics and prevalence of HK during 1 year of follow up among HK index stays were compared to non-HK index stays. HK index stays were stratified into 3 cohorts: CHF, CKD or end-stage renal disease (ESRD), and CHF+CKD/ESRD.

Results: Of 4,562,231 patients with ≥1 LTC/PAC stay, prevalence of HK during pre-index, index, or follow up periods was 14.7%. The final sample (4,081,103) excluded patients with an HK event only during follow up. Of the final cohort, 290,567 (7.1%) of index stays were HK-related. All-cause (HK-related) index stays consisted of 54.0% (46.8%) home health agencies, 27.8% (41.4%) skilled nursing facilities, 6.7% (8.8%) inpatient rehabilitation facilities, and 0.9% (3.1%) long term acute hospital settings. HK vs non-HK patients were more often male (43.0% vs 35.4%), Black (13.5% vs 8.0%), and dual eligible for Medicaid (34.2% vs 25%), with higher mean Charlson Comorbidity Index scores (6.19 vs 3.93) (all p<0.0001). Mean annual HK events during follow up were highest in patients with CHF+CKD/ESRD (all patients=1.47; HK=6.98), followed by CKD (0.66; 5.53), and CHF (0.18; 3.00), with similar patterns across settings. In the HK cohort, 34.5% had HK recurrence during follow up; 2.7% filled a potassium binder prescription during index LTC/PAC stay, and 4.3% did so within 1 year.

Conclusions: HK patients were more often non-White and low income, indicating possible disparities in care. Prevalence and recurrence of HK was high among patients with LTC/PAC stays, but few patients filled a potassium binder prescription, suggesting potential gaps in treatment during or after an LTC/PAC stay.

PO1124

Impact of Hyperkalemia and the Disruption of Emergency and Surgical Care

Douglas P. Slakey,[1] Marybeth Ingle,[1] Abiy Agiro,[2] Craig G. Schilling,[2] William Pottorf,[2] Rasha Khatib.[1] *[1]Advocate Health Care Inc, Downers Grove, IL; [2]AstraZeneca UK Ltd, Cambridge, United Kingdom.*

Background: Due to the increasing prevalence of kidney disease, hyperkalemia (HK) may be diagnosed with greater frequency in Surgical and Emergency Departments (ED). Despite this, specific guidelines do not exist and patients with elevated potassium (K+) are typically managed on a case by case basis.

Methods: An anonymous structured survey was emailed to (n=11,287) clinicians in the Advocate Aurora Health system regarding HK knowledge and treatment paradigms (n=237 responded). Survey was conducted from Feb to March 2021.

Results: Nearly half (47%) of respondents treat > 10 HK patients annually, with most primary diagnosis of HK occurring in the ED (34%) and surgical (33%) setting. HK was considered a significant concern by 47% of respondents at a serum K+ level of 5.6-5.9 mEq/L and by 39% at K+ >6 mEq/L. Only 50% of respondents recognized RAASi medications as a potential risk factor for HK. IV fluids and kayexalate were the two most common treatments for HK. Limitations to pharmacological management included the need to monitor potassium, patient compliance, and time of onset. In the surgery survey, 66% felt that K+ more than 5.5. mEq/L on day of surgery will lead to cancelations and 52% believed pharmacologic agents having a shorter onset of action may reduce surgery cancellations and delays. Vascular (34%) and general (30%) surgeries were reported to be most impacted by HK. 82% stated urgent dialysis is difficult to arrange and admission is inevitable for dialysis.

Conclusions: The presences of HK creates challenges to ED or surgical clinical teams to manage and avoid cancellations. Standard treatment options for lowering serum K+ are limited due to time of onset and compliance considerations. Dialysis is difficult to arrange on short notice and almost always requires patient admission. In cases of emergent HK, newer K+ binding agents having a more rapid onset of action to lower serum K+, may reduce avoidable admission, surgical cancellation, and delay of surgery. More evidence-based care is needed in surgical settings to characterize patients at high risk for HK to prevent unnecessary surgical cancellation and limit health care costs.

PO1125

Transient Hyperkalemia Following Treatment of Chronic Hypokalemia: A Case Report and Review of Distal Tubule Physiology

Matthew C. Breeggemann, Stephen L. Gluck. *University of California San Francisco, San Francisco, CA.*

Introduction: Hypokalemia is a frequently encountered electrolyte disorder usually resulting from decreased dietary intake, gastrointestinal, and/or renal wasting. In distal tubule cells, with no lysine (WNK) kinases bind with Ste20-related proline-alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) to form WNK bodies. WNK bodies are thought to increase the activity of the sodium-chloride cotransporter (NCC) leading to decreased sodium delivery to the epithelial sodium channel (ENaC) found in principal cells. This process is critical in hypokalemic states as it results in decreased urinary potassium wasting through the renal outer medullary potassium channel (ROMK). Here we report a case of a young man with alcohol use disorder and chronic hypokalemia who was hospitalized for muscle weakness, abdominal pain, and intractable emesis. During treatment of his hypokalemia, he unexpectedly developed transient hyperkalemia.

Case Description: The clinical intrigue of this case was the unexpected finding of acute transient hyperkalemia during treatment for hypokalemia. His potassium was 2.5 mEq/L on the day of admission. Four days later, with a creatinine at baseline (0.9 mg/dL), potassium abruptly increased to 6.7 mEq/L. Repeat measurement one hour later was 6.4 mEq/L. Over the course of his hospitalization prior to the critical hyperkalemia lab result, he had received approximately 340 mEq of potassium supplementation. 24 hour urine potassium was 35 mEq/L. Aldosterone was 5.8 ng/dL and renin was 0.3 ng/mL/hr (ratio 19). Potassium levels returned to normal following administration of furosemide and sodium polystyrene sulfonate.

Discussion: We propose that the adaptive mechanisms of the distal tubule during hypokalemia require time to revert back to a nonactive state. Transient hyperkalemia may be observed during these "refractory" periods. The time required for disassembly of WNK bodies following resolution of hypokalemia is unknown. Our postulation could explain a

similar observation of transient hyperkalemia seen in a case published in 1953 of a young woman treated for chronic hypokalemia (Schwartz, 1953). Critical hyperkalemia is an important consideration when treating patients with chronic hypokalemia.

PO1126

Pseudohyperkalemia with Concurrent Hyperkalemia

Momen M. Ismail,[1,2] Akbar H. Hamid,[1,2] Yasmin N. Mahmoud,[1,2] Mary C. Mallappallil,[1,2] Man S. Oh,[1,2] Sabu John,[1,2] Moro O. Salifu.[1,2] *[1]SUNY Downstate Health Sciences University Department of Medicine, New York, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: In sickle cell patients, acute hemolytic crisis and sickle cell nephropathy are relatively common. Risk of hyperkalemia increases with hemolysis and tubular dysfunction. Sepsis can also worsen the complication of hemolytic crisis with significant thrombocytopenia, a well-known cause of pseudohyperkalema. We report a case of concurrent true hyperkalemia and pseudohyperkalemia in the setting of thrombocytosis due to acute sickle cell crisis.

Case Description: A 36 year old African American male with history of sickle cell disease, asthma and DVT presented with bilateral shoulder, knee, and back pain. In ED, he was hypotensive, and tachycardic. Labs were notable for leukocytosis, anemia, reticulocytosis, renal failure, and elevated lactate dehydrogenase. Chest x-ray showed left base atelectasis. He was admitted for acute sickle cell crisis and fluctuant right thigh abscess, which was surgically drained and managed with antibiotics. Platelet level was 585 K/uL; serum potassium was 4.7 mmol/L; and creatinine was 1.78 mg/dL with normal urine output. Potassium level steadily rose and peaked at 6.5 mmol/L with sinus bradycardia but no other ECG changes. At the same time, platelet level peaked to 1105 K/uL.

Discussion: In our patient with significant thrombocytosis, pseudohyperkalemia was suspected. Degranulation of platelets during clotting releases about 50% of potassium inside platelets. For platelet count of 1000 K/uL with normal MPV, serum potassium level is expected to be higher than plasma potassium level by about 0.7 mmol/L. Serum-plasma potassium differences in our patient were within the expected range. In our patient, as shown below, mild concurrent true hyperkalemia is also noted likely due to sickle cell nephropathy, a known cause of hyperkalemia due to hyporeninemic hypoaldosteronism. Due to potassium release from platelets during clotting, serum potassium is always higher than plasma potassium in all normal persons by 0.2 to 0.3 mmol/L. With thrombocytosis, the difference becomes larger, and serum potassium is likely to reach hyperkalemic level if the baseline potassium is already higher than usual due to concomitant impairment of renal potassium excretion.

Platelet (K/uL)	Plasma Potassium (mmol/L)	Serum Potassium (mmol/L)
1105	5.3	6.1
942	4.9	5.8
464	4.3	4.9

PO1127

Missing the Obvious? A Story of Salt, Water, and Unexplained Hyperkalemia

Aaron M. Spring,[1] Mathieu Lemaire.[1,2] *[1]The Hospital for Sick Children Department of Paediatrics, Toronto, ON, Canada; [2]SickKids Research Institute, Toronto, ON, Canada.*

Introduction: Most clinicians are familiar with the differential diagnosis of hyperkalemia, from pseudohyperkalemia to rare tubulopathies. Herein, we describe three patients with years-long histories of unexplained hyperkalemia despite extensive investigations (details in Table 1). While all achieved normokalemia with various prescription regimens, the underlying etiology remained elusive. We suggest that all cases were likely due to chronic, mild hypovolemia in the context of self-imposed dietary salt restriction.

Case Description: Patient A: A 6-week-old girl with persistent hyperkalemia and very low urine Na^+. Normokalemia was achieved with hydrochlorothiazide and dietary K^+ restriction but maintained with optimized fluid and Na^+ intake alone. **Patient B**: An 11-year-old boy with spastic cerebral palsy with persistent hyperkalemia after a mild AKI attributed to rhabdomyolysis. Serum K^+ improved with sodium polystyrene (SPS) and dietary K^+ restriction; it normalized after IV saline infusion, while NPO. **Patient C**: A 5-month-old boy with Stüve-Wiedemann Syndrome and feeding difficulties with persistent hyperkalemia that normalized on SPS. After G-tube insertion at 2 years, K^+ remained normal despite stopping the SPS due to improved fluid and Na^+ intake.

Discussion: It has long been established that adequate Na^+ and fluid delivery to distal nephrons is necessary for optimal K^+ handling. It is therefore surprising to find almost no mention of Na^+-responsive hyperkalemia in the literature for children beyond the neonatal period. Our patients all had hyperkalemia in the context of normonatremia, but very low fractional excretion of Na^+ (FeNa) and low trans-tubular K^+ gradient (TTKG). They all remained normokalemic when salt and water intake was optimized, despite stopping their hyperkalemic prescriptions. Careful, early consideration of low distal Na^+ and water delivery as a cause for unexplained hyperkalemia could prevent extensive workups and unnecessary prescriptions.

Relevant investigations

Patients	Time points	Serum values (mmol/L)				Serum creat (μmol/L)	Urine values (mmol/L)			TTKG	FeNa (%)

Machine Learning Models to Predict Cardiovascular and Renal Outcomes and Mortality in Hyperkalemic Patients

Eiichiro Kanda,[1] Suguru Okami,[2] Shun Kohsaka,[5] Xiaojun Ma,[3] Masafumi Okada,[3] Takeshi Kimura,[4] Toshitaka Yajima.[2] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]AstraZeneca K.K., Osaka, Japan; [3]IQVIA Solutions K.K., Tokyo, Japan; [4]Real World Data, Co.Ltd., Kyoto, Japan; [5]Keio University, Tokyo, Japan.*

Background: Hyperkalemia is associated with increased risks of mortality and adverse clinical outcomes. To date, limited evidence is available for personalized risk evaluation in this heterogeneous and multifactorial pathophysiological conditions.

Methods: We developed prediction models using extreme gradient boosting (XGB), logistic regression (LR), and neural network. Models were derived and cross-validated in a retrospective cohort of hyperkalemic patients with either heart failure or stage ≥3a chronic kidney disease and aged ≥18 years from a Japanese administrative hospital database (April 1, 2008–September 30, 2018). The outcomes of interest included all-cause death, introduction of renal replacement therapy (RRT), hospitalization for heart failure (HHF), and cardiovascular events within 3 years after first hyperkalemic episode. The best performing model was further validated using a separate hospital-based database.

Results: 24,949 adult patients with hyperkalemia were selected for the model derivation and internal validation. The mean age was 75 years and 54% were male. Among machine learning algorithms tested, XGB outperformed other models, showing AUROC of XGB vs. LR for all-cause death, RRT, HHF, and cardiovascular events as 0.823 vs. 0.809, 0.957 vs. 0.947, 0.863 vs. 0.838, and 0.809 vs. 0.798, respectively. In the external validation set including 86,279 patients, AUROC of XGB for all-cause death, RRT, HHF, and cardiovascular events were 0.747, 0.888, 0.673, and 0.585, respectively. The Kaplan-Meier curves of high-risk predicted group showed a significant differentiation from that of low-risk predicted group for all outcomes (Figure).

Conclusions: These findings suggest the possible use of machine learning models for real-world risk assessment as a guide for treatment decision making that may lead to the improvement of cardiovascular and renal outcomes, and mortality in hyperkalemic patients.

PO1129

Severe Hyperkalemia Secondary to Hypermagnesemia in a Patient with Preeclampsia

Atif Ibrahim, Alice Chedid. *The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Introduction: Mg infusion remains the first-line treatment of preventing and controlling eclamptic seizures. While hypocalcemia is a well-known side effect, hyperkalemia is not. We present a case of severe hyperkalemia secondary to magnesium infusion requiring hemodialysis.

Case Description: 36-year-old healthy female with no HTN or liver disease, pregnant at 25 weeks with twins, admitted for close monitoring given concern for intra-uterine growth restriction. Initial vitals on admission: BP 149/88 mm Hg, HR 89,

RR 20, and T 36.4. Physical exam: Grossly unremarkable except for gravid uterus. Lab workup showed elevated liver function tests (>2x UNL) and LDH, low haptoglobin, and normal renal function. BP remained >140s with medical treatment. Patient also started complaining of new-onset severe headache. Given concern for pre-eclampsia with severe features, Mg infusion was started (6 grams followed by 2 g/hr as a continuous infusion) and was scheduled for emergent c-section. Post-delivery course was complicated by severe hyperkalemia at 6.6 meq/l in a setting of supratherapeutic Mg levels at 9.1 mg/dl (figure 1). Creatinine was normal at 0.7. Mg infusion was stopped. Other etiologies for hyperkalemia were ruled out including rhabdomyolysis or worsening hemolysis. Patient required one session of emergent hemodialysis which led to improvement in all electrolyte abnormalities.

Discussion: While the relationship between hypomagnesemia and hypokalemia is well understood, the relationship between hyperkalemia in the presence of hypermagnesemia remains not clear. Some of the mechanisms suggested (1) direct effect of magnesium on suppressing renin and aldosterone leading to impaired renal handling of K homeostasis (hyporeninemic hypoaldosteronism). (2) direct inhibition of the ROMK channel by Mg. Our case highlights a rare cause of hyperkalemia in a pre-eclampsia patient. Monitoring electrolytes closely while on Mg infusion is advised.

	Before starting Mg infusion	Day 1	Day 2	After HD	Day 4	Day 5	Day 6
Mg 2+		9.1	4.5	1.9	2.3	1.7	1.8
K+	4.2	6.6	6.5	3.4	4.5	4.4	4.4
Ca 2+	9.5	6.9	7.1	7.3	7.4	8.1	8.6

Changes in potassium and calcium concentrations in relation to hypermagnesemia (figure 1)

PO1130

Severe Hypermagnesemia: A Potential Cause of Acute Hyperkalemia

Lusine Nahapetyan, Sindhuri Prakash-Polet, Raphael J. Rosen, Heedeok Han. *Columbia University Vagelos College of Physicians and Surgeons, New York, NY.*

Introduction: Hypermagnesemia is not a well-established cause of hyperkalemia. In this case report we explore the association of acute hypermagnesemia and hyperkalemia.

Case Description: 30 year old female G1P0 with chronic HTN since age 26, CACUT was admitted for preeclampsia with severe features (new proteinuria 5.5 g/24h, AKI (cr peaked at 1.33 from baseline 0.65), HTN, LE edema). Patient delivered via C-section at 27 weeks 6 days. Extensive AKI work-up was negative. At admission had normal K 4.4, Na 143, Ca 8.6 (albumin 3.4), bicarb 21, cr 0.96, LDH 213, glucose 111, Hb 10, Plt 177, renin 1.39, aldosterone 13.6. At admission, she was started on Mg sulfate infusion for seizure prophylaxis. After patient's serum Mg acutely increased (peak 8), she simultaneously developed acute hyperkalemia (peak K 6.1, bicarb 19, cr 1.1, normal EKG). Hyperkalemia improved to 5.3 with IV Lasix, bicarbonate, and NS but persisted until Mg infusion was discontinued and Mg levels normalized to 2.5 leading to normalization of K (4.3). Only two previous case studies have described a potential association between hypermagnesemia and hyperkalemia. We described a case when acute hypermagnesemia led to acute hyperkalemia, which persisted until Mg levels normalized. There were no other etiologies of hyperkalemia in this case (AKI was not severe to lead to hyperkalemia; patient was on beta-blocker but this was a chronic medication; no other medications known to cause hyperkalemia; normal aldosterone, no significant change in bicarb).

Discussion: Magnesium plays an important role in potassium homeostasis in kidney and intestines. One possible mechanism is that cytoplasmic magnesium concentration has a profound effect on ROMK potassium channels (expressed in the thick ascending and cortical collecting tubules); a high intracellular Mg concentration blocks channel activity. Additionally, ROMK is an important pathway for potassium secretion in the distal nephron. Therefore, potassium levels should be closely monitored in patients who receive high dose magnesium infusions and are at high risk of hypermagnesemia and subsequent hyperkalemia.

PO1131

When Sipping K Is Not OK

Arun Rajasekaran, Ammar Hasnie, Ashita J. Tolwani. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Hyperkalemia is one of the most common and potentially lethal electrolyte abnormalities that occurs in approximately 1% to 10% of hospitalized patients. It is associated with an increased risk of arrhythmias, poor cardiovascular outcomes, and increased morbidity and mortality. We highlight an unusual etiology of severe hyperkalemia in a patient with underlying CKD.

Case Description: A 74-year-old Black male with known arterial hypertension, coronary artery disease, CKD 3 [baseline serum creatinine (Cr) 1.7 mg/dl] presented with syncope secondary to severe bradycardia (heart rate 30/min) consequent to severe hyperkalemia, which necessitated a pacemaker placement, and non-oliguric AKI on CKD. Pertinent serum labs on presentation include Cr 2.8 mg/dl, potassium (K) 7.6 mmol/L, and bicarbonate 19 mmol/L. Serum osmolarity, glucose, and creatinine kinase levels were within normal limits. Urine pH was 5. Renal imaging was unremarkable. He was not on any medication(s) commonly attributed with a propensity to elevate serum K, including renin angiotensin inhibitors, non-selective β blockers, or non-steroidal anti-inflammatory agents. Given that the hyperkalemia was out of proportion to his kidney injury, upon further questioning he attributed consuming a diet rich in K along with drinking multiple cups of Essiac tea daily for the last 2 months. Hyperkalemia was managed medically, including initial temporizing measures, bicarbonate supplementation, K binders, and intravenous crystalloids to enhance distal nephron K excretion. Emphasis was placed on consuming a K restricted diet along with discontinuing Essiac tea use. Serum K normalized in 3 days; however Cr was 3 mg/dl on discharge.

Discussion: Essiac tea contains red clover, sheep sorrel, burdock root, and rhubarb which has extremely high potassium content. It is hepatotoxic and nephrotoxic when consumed in large amounts. We highlight the importance of obtaining a thorough dietary history, especially when the degree of hyperkalemia cannot be solely attributed to the extent of kidney injury. Dietary counselling is paramount in such cases.

PO1132

Metabolic Acidosis That Exists with Hyperkalemia (HK) Among Patients That Initialize Binder Therapy: The MAXIMIZE Study

Seth P. Kuranz,[1] Abiy Agiro,[2] Kaylen Brzozowski,[1] William Pottorf,[2] Pamela B. Landsman-Blumberg,[1] Joachim H. Ix.[3] *[1]TriNetX, LLC, Cambridge, MA; [2]AstraZeneca, Global Medical Affairs, Wilmington, DE; [3]University California San Diego, San Diego, CA.*

Background: Approximately 25% of chronic kidney disease (CKD) patients with serum potassium (sK^+)>5.0 mEq/L may also have metabolic acidosis (MA). However, successful management of comorbid HK and MA in CKD patients is unclear. This real-world evidence study examines the association between patient characteristics and binder treatment among CKD patients with HK and MA.

Methods: This was a retrospective study of stage 3-5 CKD patients with HK (sK^+>5.0 mmol/L) and MA (serum bicarbonate ($sHCO3^-$) between 16-20 mmol/L) in a US EMR network of 64 million patients. The index event was the first qualifying sK^+ result between 07/01/19 and 12/31/20. Baseline demographic and clinical characteristics were assessed among SZC, SPS, and NKB treated cohorts including age, sex, race, HK severity, $sHCO3^-$ level, visit type, and comorbidities. Logistic regression produced adjusted odds ratios (ORs) and 95% confidence intervals describing the association between baseline characteristics and treatment: sodium zirconium cyclosilicate (SZC) vs sodium polystyrene sulfonate (SPS) and SZC vs no potassium binder (NKB).

Results: Of the 32,113 patients who met study criteria 11.6% were treated with SZC (n=939) or SPS (n=2,774), 88.4% with NKB (n=28,400), and 11.1% with sodium $HCO3^-$ (n=3,572). Age and sex were similar among SZC, SPS, and NKB cohorts and 81%, 77%, and 70% had moderate-to-severe acidosis ($sHCO3^-$ <20mmol/L), respectively. Baseline characteristics associated with increased odds of SZC vs SPS and SZC vs NKB treatment included $sHCO3^-$<20mmol/L [OR=1.29 (1.03-1.61); OR=1.24(1.04-1.47)] and liver disease [OR=1.61(1.16-2.23); OR=1.47(1.14-1.89)], respectively. Treatment with SZC vs NKB treatment was more likely in inpatient settings [OR=3.73(3.06-4.55)] and in patients with comorbid congestive heart failure [OR=1.43 (1.12-1.84)].

Conclusions: Clinicians were more likely to treat HK with SZC than SPS or NKB in CKD patients with moderate-to-severe acidosis in a recent large, US, real-world sample. Secondary findings from prior clinical trials suggest that SZC may improve MA as well normalize sK^+. Future clinical trials are needed to assess the impact of SZC on $sHCO3^-$ concentrations.

PO1133

Real-World RAAS Inhibitor Use and Its Predictors Among Patients Initiating Sodium Zirconium Cyclosilicate

Abiy Agiro,[1] Alpesh Amin,[2] Fan Mu,[3] Joshua A. Young,[3] Erin Cook,[3] Esteban J. Lemus Wirtz,[3] Yasmin G. Brahmbhatt,[1] Keith A. Betts,[3] Charles V. Pollack.[4] *[1]AstraZeneca, Wilmington, DE; [2]University of California Irvine, Irvine, CA; [3]Analysis Group Inc., Boston, MA; [4]University of Mississippi School of Medicine, Jackson, MS.*

Background: Renin-angiotensin-aldosterone system inhibitors (RAASi) are associated with reduced risk of death and slower disease progression in patients with heart failure (HF) and chronic kidney disease (CKD). However, RAASi use increases the risk of hyperkalemia (HK), which may disrupt RAASi use and mitigate its benefits. There is limited real-world evidence characterizing RAASi use after sodium zirconium cyclosilicate (SZC) treatment.

Methods: Adult patients initiating SZC (index date) while on a RAASi in outpatient care were included from a large US claims database (January 2018-June 2020). Analyses were conducted among all patients, patients with CKD and patients with CKD + diabetes (DM). The percent of patients with a RAASi prescription after index was summarized. Characteristics among patients with and without a new RAASi fill were compared using descriptive statistics. A multivariable logistic regression model assessed predictors of a new RAASi fill.

Results: A total of 589 patients initiating SZC while on a RAASi were included (mean age 61 years, 65.2% male). Overall, 82.7% of patients had a new RAASi fill after index. The median time to discontinuation was not reached among patients with a new RAASi fill, of whom 88.1% at day 180 and 74.0% at 1 year remained on RAASi therapy. Median time on RAASi was 29 days (95% CI [27-43 days]) for those with no new RAASi fill. Compared to patients without a new RAASi fill, patients with a new fill had a higher burden of CKD (69.4% vs 58.8%) but a similar prevalence of DM (70.6% vs 67.6%) and HF (24.6% vs 28.4%). Results were similar in the CKD cohort (N=398; 84.9% had a new RAASi fill) and CKD and DM cohort (N=311; 85.2% had a new fill). Predictors of having a new RAASi fill included fewer prior hospitalizations (0.77 [0.60-0.98]; p<0.05) and emergency department (ED) visits (0.78 [0.63-0.97]; p<0.05).

Conclusions: In a real-world setting, 83% of patients had a new RAASi fill within 90 days after ending their index RAASi. Results are consistent with clinical trial finding and similar among patients with CKD and patients with CKD + DM. Patients with hospital and ED visits will require follow up care to encourage RAASi continuation.

PO1134

Compatibility Study of Patiromer with Juices/Liquids and Soft Foods

Martin Khoeiklang,[1] Maria Wilhelm,[1] Lingyun Li,[2] Carol P. Moreno Quinn,[1] Tamara Popov.[1] *[1]Vifor International AG, Saint Gallen, Switzerland; [2]Vifor Pharma Group, Redwood City, CA.*

Background: Patiromer is a novel, once-daily, sodium-free K+-binder approved for treatment of hyperkalemia. The drug–a tasteless, odorless powder–is administered orally suspended in water. Recently, the FDA approved apple or cranberry juice as suspension vehicles. As patients may prefer to take patiromer with alternative liquids/foods, the ability to mix patiromer with small amounts (per allowed dietary intake recommendations) of various liquids and foods may improve palatability and medication adherence. This *in vitro* study assessed the compatibility of patiromer with six different juices/nectars and six soft foods or other liquids (**Table**).

Methods: For all mixtures, compatibility was assessed at two ratio levels: low (8.4 g patiromer in 40 mL of vehicle, ~1/6 cup); high (12.7 g patiromer in 20 mL of vehicle, ~1/12 cup), equivalent to patiromer doses of 8.4 g and 25.2 g per 80 mL (1/3 cup), respectively. Mixtures with soft foods were spoon stirred for 30 s; juices were stirred for 5 min on a magnetic stirrer. After a 45-min rest period, suspensions were diluted with 50 mL (juices) or 100 mL of water (soft foods) and centrifuged at 1000 rpm for 30 s. Residues were washed, vacuum filtered, and dried. Total potassium binding capacity (TKEC) was tested (acceptance criterion: 8.4–10 mmol/g).

Results: Mean TKEC for patiromer mixed with juices/nectars were 8.7–8.9 mmol/g for the low ratio and 8.5–8.6 mmol/g for the high ratio (**Table**). For soft foods or other liquids, the mean TKEC at low and high ratios was 8.5–8.7 mmol/g (reference: 9.2 mmol/g); exchange capacity for tested vehicles was within the prespecified range.

Conclusions: Mixing of patiromer with small amounts of juices/nectars, soft foods, and other liquids does not adversely affect the drug's potassium-binding capacity. Use of different vehicles for mixing patiromer may improve palatability and reduce the risk of nonadherence.

Funding: Commercial Support - Vifor Pharma

Mean total potassium binding capacity (TKEC) after mixing of patiromer with juices and soft foods. RSD, relative standard deviation

Risk of Heart Failure in Patients Who Initiated Sodium Zirconium Cyclosilicate vs. Patiromer

Min Zhuo,[1,2] Seoyoung C. Kim,[2] Elisabetta Patorno,[2] Rishi J. Desai,[2] Julie M. Paik.[2,3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital Department of Medicine, Boston, MA; [3]VA New England Geriatric Research Education and Clinical Center, Boston, MA.*

Background: Hyperkalemia is common in patients with chronic kidney disease (CKD), heart failure, and diabetes. Sodium zirconium cyclosilicate (SZC) and patiromer were recently approved for the treatment of hyperkalemia. Since SZC contains significant amounts of sodium, we assessed the risk of heart failure hospitalization (HHF) associated with the initiation of SZC versus patiromer in non-dialysis patients.

Methods: We used a U.S. commercial insurance claims database (Optum Clinformatics® Data Mart) between May 2018 (after SZC approval) and September 2020. Participants were non-dialysis adults who had ≥ 180 days of insurance enrollment and were newly prescribed SZC or patiromer. The primary outcome was a hospitalization with a discharge diagnosis of heart failure. The secondary outcome was a hospitalization or an emergency room visit with a diagnosis of any edema. Propensity score (PS) matching in a variable ratio up to 1:3 was used to adjust for more than 80 variables, including demographic characteristics, comorbidities, medication use, and health care utilization. Cox proportional hazards regression models were used to generate hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Our cohort included 1,126 SZC initiators and 2,839 PS-matched patiromer initiators (total N=3,965). The mean age was 72 (±10) years, 30% had a history of heart failure and 85% had CKD stages 3-5. The risk of HHF was higher in the SZC initiators compared to patiromer initiators (HR 1.22, 95%CI 0.95-1.56), but the confidence interval included the null value (**Table**). Edema was more common in the SZC initiators (HR 1.89, 95%CI 1.05-3.39). In subgroup analyses, initiation of SZC was associated with an increased risk of HHF (HR 1.58, 95%CI 1.01-2.46) amongst patients without a history of heart failure.

Conclusions: Patients initiating SZC may need to monitor volume status and consider dietary salt restrictions and initiation or adjustment of diuretics. Larger studies are needed to more precisely evaluate the safety of SZC in routine practice.

Number of events, incidence rate (IR)*, rate difference (RD)*, and HRs before and after PS-matching

Outcome	Before PS-matching				After PS-matching			
	SZC N=1,265	Patiromer N=3,388	RD (95% CI)	HR (95% CI)	SZC N=1,126	Patiromer N=2,839	RD (95% CI)	HR (95% CI)
HHF, N (IR)	97 (35.0)	309 (26.5)	8.6 (1.0, 16.1)	1.32 (1.05, 1.66)	88 (35.8)	245 (25.1)	10.7 (2.6, 18.9)	1.22 (0.95, 1.56)
Edema, N (IR)	21 (7.3)	43 (3.5)	3.8 (5.0, 7.1)	2.08 (1.24, 3.51)	18 (7.1)	35 (3.4)	3.6 (1.7, 7.1)	1.89 (1.05, 3.39)

RDX013, a Novel, Oral, Small Molecule Being Developed for Treatment of Hyperkalemia, Increases Colonic Secretion and Fecal Excretion of Potassium

Kenji Kozuka,[1] Matthew Siegel,[2] Andrew J. King,[3] Jill N. Kohler,[1] Zhengfeng Jiang,[1] Allison Quach,[1] Cyra Fung,[1] Ying He,[1] Padmapriya Kumaraswamy,[1] Limin He,[1] Cathy M. Le,[1] Catarina Tran,[1] Jeremy Caldwell,[4] David P. Rosenbaum,[1] Jeffrey Jacobs.[1] *[1]Ardelyx Inc, Fremont, CA; [2]Anwita Biosciences, San Carlos, CA; [3]Chinook Therapeutics Inc, Vancouver, BC, Canada; [4]Inception Therapeutics, San Diego, CA.*

Background: Potassium (K^+) homeostasis is maintained by the balance of dietary K^+ intake, extra- and intracellular K^+ distribution, and renal and intestinal excretion. Hyperkalemia (serum K^+>5.0 mM) occurs frequently in CKD patients and can lead to cardiac arrhythmias and sudden death; controlling serum K^+ may reduce mortality in this population. Current therapeutic options for the chronic treatment of hyperkalemia are limited to K^+-binding agents. Here, we describe the discovery of RDX013, a novel, oral, small molecule K^+ secretagogue in development for treatment of hyperkalemia.

Methods: Male Sprague Dawley rats (n=6/group) were orally administered vehicle or 6 mg/kg RDX013 twice daily for 6 days. 24-hour fecal samples collected from rats housed individually in metabolic cages on the final study day were homogenized, and K^+ and sodium were analyzed by cation exchange chromatography.

Results: RDX013 significantly increased fecal K^+ excretion compared to vehicle control animals (figure). Fecal sodium was also increased by RDX013 (figure), which was expected as luminal sodium retention in the intestine is key to the pharmacodynamic response.

Conclusions: Based on its unique mechanism of action which involves pharmacologically enhancing K^+ secretion through apical K^+ channels in the colon, RDX013 is a potential first-in-class therapy which may provide a new approach to managing serum K^+ in patients versus commonly prescribed K^+ binders. A phase 2 clinical study with RDX013 (NCT04780841) is ongoing in non-dialysis CKD patients with hyperkalemia.

PO1137

Artificial Intelligence-Assisted Electrocardiography for Early Diagnosis of Thyrotoxic Periodic Paralysis

Shih-Hua P. Lin,[1] Chih-Chien Sung,[1] Min-hua Tseng.[2] *[1]Tri-Service General Hospital, Taipei, Taiwan; [2]Chang Gung Memorial Hospital, Tao-yang, Taiwan.*

Background: Thyrotoxic periodic paralysis (TPP) characterized by acute weakness, hypokalemia and hyperthyroidism is a medical emergency with a great challenge in early diagnosis since most TPP patients do not have overt symptoms. Since both hypokalemia and hyperthyroidism in TPP significantly affect the cardiovascular system, electrocardiography (ECG) as a prompt and non-invasive bedside tool universally used in the ED may detect these electrical changes. To assess artificial intelligence (AI)-assisted electrocardiography (ECG) combined with routine laboratory data in the early diagnosis of TPP.

Methods: A deep learning model (DLM) based on ECG12Net, an 82-layer convolutional neural network, was constructed to detect hypokalemia and hyperthyroidism. The development cohort consisted of 39 ECGs from patients with TPP and 502 ECGs of hypokalemic control; the validation cohort consisted of 11 ECGs of TPP and 36 ECGs of non-TPP with weakness. The AI-ECG based TPP diagnostic process was then consecutively evaluated in 22 male patients with TTP-like features.

Results: In the validation cohort, the DLM-based ECG system detected all cases of hypokalemia in TPP patients with a mean absolute error of 0.26 mEq/L and diagnosed TPP with an area under curve (AUC) of ~80%, surpassing the best standard ECG parameter (AUC=0.7285 for the QR interval). Combining the AI predictions with the estimated glomerular filtration rate (eGFR) and serum chloride (Cl^-) boosted the diagnostic accuracy of the algorithm to AUC 0.986. In the prospective study, our AI ECG system achieved perfect performance (F-measure 100%) on the task of hypokalemia detection in them and the integrated AI with routine laboratory had a PPV of 100% and F-measure 87.5% for TPP diagnosis.

Conclusions: An AI-ECG system reliably identifies hypokalemia in patients with paralysis and its integration with routine blood chemistries provides valuable decision support for the early diagnosis of TPP to avoid life-treatening complication.

PO1138

Will the Real Sodium Stand Up!

Nia Flemming, Michael Basir, Ro-Kaye A. Simmonds, Latoya N. Gayle, Zachary Banbury, Deborah A. Fein. *Englewood Health, Englewood, NJ.*

Introduction: Hyponatremia is a common finding as it could be precipitated by multiple factors ranging from medications to simply dehydration. Accurate approach to management depends on assessing serum osmolality in an effort to distinguish cases of true, factitious or pseudohyponatremia. We present a case of hyponatremia secondary to hyperlipidemia.

Case Description: 36 year old Asian woman with HTN, Type 2 DM, HLD presented with 1 day of epigastric pain. On exam S1, S2 were heard with vesicular breath sounds throughout, epigastric tenderness and no focal neurological deficits. Initial labs: sodium 114 potassium 3.5 chloride 85 glucose 254, BHB 3.7. Sodium corrected for glucose 116 CO2, BUN, Cr and AG were incalculable. Urinalysis: ph 6.0, ketones > 160, glucose > 1000, protein > 1000. Total cholesterol 1020, HDL 25, Triglycerides >5680, LDL incalculable, serum osmolality 314, lipase 57. Venous blood gas: 7.37/30.1/94.8/17.8, sodium on VBG 132. Abdominal ultrasound revealed a normal pancreas with hepatic steatosis. She was treated in ICU with normal saline, insulin infusion, icosapent ethyl and gemfibrozil. Abdominal pain resolved and insulin was changed to Glargine. Over three days triglycerides trended down to 1744 and sodium to 132. She was discharged on icosapent ethyl, gemfibrozil, atorvastatin, glargine, metformin and lisinopril, with a sodium of 132.

Discussion: Sodium is most commonly measured by indirect potentiometric (ISE) measurement. By this method serum specimens are diluted based on estimated typical balance of serum to solid blood components. By this method factitious low sodium results are known to occur in patients with significantly elevated lipids and protein. As in this case, direct sodium measured by VBG/ABG are most accurate. Typically markedly elevated serum triglyceride with concentrations> 1500 mg/dl are thought to be responsible for factitious hyponatremia. In our patient the value of serum sodium on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+ (Plasma triglycerides (g/L) x 0.002); measured serum sodium would have been expected to be 125 meq. Thus in cases of extremely high lipids, one must consider lab techniques for measuring serum sodium, as well as full lipid panel in the evaluation and treatment of factitious hyponatremia.

PO1139

Admission Sodium and Related Features to Predict Falls in Machine Learning Models

Alexander S. Leidner,[1] Biruh Workeneh,[2] Bing Ho.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.*

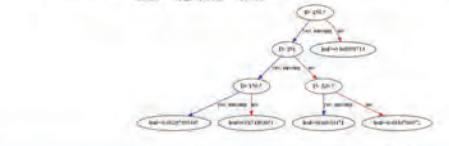
Background: Hyponatremia has been associated with an increased risk for falls, but evidence is primarily limited to outpatient events. Hyponatremia is a potential surrogate of conditions that may lead to falling including volume depletion, malignancy, pain, polypharmacy, and weakness. We hypothesized that a model could be developed to predict falls based upon accessible variables present on all hospital admissions. An accurate model could allow for measures to lower in-hospital falls.

Methods: Medical records from a single institution were collected over a period of 2011 to 2019. Subjects included admitted patients who suffered a recorded in-hospital fall and were admitted, and controls matched for admission on the same date. Variables collected include sodium, glucose, age and gender. There were 17,013 patients total of which 1,203 had unique falls. Data was split into an 60% training, 20% validation and 20% testing split. We computed an unadjusted odds ratio of falls for those with very low sodium (<126). We trained logistic regression, random forest, XGBoosted forest, and neural net classifiers. Classifier cutoff was calculated using Youden values.

Results: We did not see an increased incidence of falls in the population with a low sodium (N=377) with an unadjusted odds ratio of 0.62 (CI 0.38-1.01). Similarly, the model performances did not result in clinically useful predictions with a unanimously high false positive and false negative rates (**Figure 1**).

Conclusions: Despite reports of hyponatremia as an indicator of fall risk we did not observe this. The fall-prediction models did have the capacity for high performance on the training data, but this does not translate to validated performance. This discrepency is termed 'overfitting' and is important to evaluate as machine learning models have a much larger capacity than traditional statistical models to incorporate previously seen examples. If a model cannot make predictions on new data it cannot be clinically useful. These models may be enhanced using other basic admission features and is the subject of future work.

Figure 1: Decision Tree Example and Model Characteristics



Model	Accuracy	Positive Precision	Positive Recall	Positive F1	Negative Precision	Negative Recall	Negative F1
Logistic Regression	0.46	0.08	0.59	0.13	0.94	0.45	0.61
Random Forest	0.55	0.08	0.48	0.13	0.93	0.56	0.7
XGBoost Forest Small	0.65	0.09	0.42	0.14	0.94	0.67	0.78
XGBoost Forest Large	0.9	0.13	0.07	0.09	0.93	0.97	0.95
Neural Net Small	0.57	0.45	0.08	0.13	0.58	0.93	0.72
XGBoost Forest Train	0.95	0.59	1	0.74	1	0.95	0.97

Example of decision tree. Metrics on scale 0 to 1. All data predicted on held out data set except for final "XGBoost Forest Train" which is included to show How a model can fit to training data but not to unseen data.

PO1140

Association of Serum Sodium Levels with Bone Mineral Density, Fracture, and Mortality in Patients Undergoing Maintenance Hemodialysis

Keisuke Soeda,[1] Hirotaka Komaba,[1] Yosuke Nakagawa,[1] Takehiko Wada,[1] Takatoshi Kakuta,[2] Masafumi Fukagawa.[1] *[1]Tokai Daigaku, Hiratsuka, Japan; [2]Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan.*

Background: Hyponatremia is implicated in pathological bone resorption and has been identified as a risk factor for bone fracture in the general population, but limited data exist in patients undergoing dialysis.

Methods: We analyzed a historical cohort of 2,292 patients undergoing maintenance hemodialysis in Japan. We first examined the association of baseline serum sodium levels with metacarpal bone mineral density (BMD) in a subcohort of 456 patients with available data. Next, we examined the association of baseline serum sodium levels with incident fracture and mortality in the overall cohort, using Cox regression models adjusted for potential confounders (age, sex, dialysis vintage, diabetes, prior cardiovascular disease, history of fracture, body mass index, hemoglobin, albumin, and creatinine) and competing risks regression models accounting for death as a competing endpoint.

Results: Baseline mean ± SD serum sodium level in the overall cohort was 139.7 ± 2.9 mEq/L, and among patients with available data, median metacarpal BMD T-score was -2.05 (IQR, -3.35 to -0.99). Serum sodium levels were not associated with metacarpal BMD T-score in unadjusted or adjusted models. During a median follow-up of 5.4 years (IQR, 2.5-7.0 years), 712 patients died; 113 experienced clinical fractures; and 64 experienced asymptomatic vertebral fractures as estimated by height loss. In adjusted Cox regression models, serum sodium levels were associated with mortality (HR, 0.95 per 1 mEq/L higher; 95% CI, 0.92-0.98) but not incident clinical fracture (HR, 0.97 per 1 mEq/L higher; 95% CI, 0.90-1.04) or any fracture (a composite of clinical fracture and vertebral fracture). Similar results were obtained in competing risks regression models.

Conclusions: Serum sodium levels were associated with mortality but not BMD or incident fracture in maintenance hemodialysis patients.

PO1141

Hyponatremia, Inflammation, and Hospital Mortality in Hospitalized COVID-19 Patients

Juan Carlos Ayus,[1] Michael L. Moritz,[2,3] Kyung Min Lee,[4,6] Daniel Caputo,[4] Maria E. Borda,[4] Alan S. Go,[5] Carlos Eghi.[4] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]UPMC Children's Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]Hospital Posados, Buenos Aires, Argentina; [5]Kaiser Permanente, Oakland, CA; [6]University of California San Francisco, San Francisco, CA.*

Background: Systemic inflammation has been associated with severe COVID-19 disease. Hyponatremia can result from inflammation due to non-osmotic stimuli for vasopressin production. Hyponatremia is an independent risk factor for hospital mortality.

Methods: Hospitalized patients with COVID-19 were prospectively evaluated between March and November 2020 at Hospital Posadas in Buenos Aires, Argentina, in order to evaluate the association between hyponatremia and inflammation and its impact on clinical outcomes. Admission biochemistries, high-sensitivity C-reactive protein (hsCRP), ferretin, patient demographics, and outcome data were recorded. Outcomes (within 30 days after symptom) that were evaluated included admission tothe ICU during hospitalization, mechanical ventilation, dialysis-requiring AKI, and in-hospital deaths. In-hospital mortality, length of hospital stay (in days), and hospital readmission for any cause within 30 days after discharge were evaluated using comprehensive data from the EHR.

Results: Among 799 hospitalized COVID-19 patients, hyponatremia was present on admission in 366 (45.8%). Hyponatremic patients had higher hsCRP levels than normonatremic patients (median 10.3 [IR 4.8-18.4] mg/dl vs 6.6 [IR 1.6 – 14.0] mg/dl, respectively, p< 0.01), and hsCRP level was inversely correlated with plasma sodium level (Spearman's correlation coefficient = – 0.23; p = < 0.01). Hyponatremic patients had higher serum ferritin levels than normonatremic patients (median 649 [IQR 492-1168] ng/dl vs 393 [IQR 156-1440] ng/dl, respectively, p = 0.02), and serum ferritin level was inversely correlated with plasma sodium level (Spearman's correlation coefficient= – 0.26; p = < 0.01). Hyponatremic patients had increased mortality on unadjusted (odds ratio 1.87, 95%CI:1.28-2.73) and adjusted (odds ratio 1.61, 95%CI:1.05-2,49) Cox proportional hazard models. Crude 30-day survival was lower for patients with hyponatremia at admission (mean [SD] survival 22.1 [0.70] days) compared with patients who were normonatremic (mean [SD] survival 27.1 [0.40] days, p < 0.01).

Conclusions: This study demonstrates that hyponatremia on admission is common in patients with COVID-19 and is associated with inflammation and in-hospital mortality. Thus, hyponatremia could be a novel marker for identifying patients with COVID-19 at risk for hospital mortality.

PO1142

Trends of Overall Mortality by Severity of Hyponatremia: Five-Year Mortality Rates

Peter E. Umukoro,[1] Fahad A. Lodhi,[2] Javad Najjar Mojarrab.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Marshfield Clinic Health System, Marshfield, WI.*

Background: We have previously reported increasing strengths of association between degree of hyponatremia on hospital admission and proportions of overall mortality at 1 year post-hospitalization. It is unclear if this association persists in the long term and if this association with overall mortality occurs in a linear manner. Here, we further explore this association over a longer mean follow up period. We hypothesized that a dose response relationship occurs between varying degrees of hyponatremia and overall mortality.

Methods: We obtained data from 46,783 patients, average age 62.2 years, 51.3% males, admitted from January 1, 2012 to December 31, 2016 at a tertiary referral hospital in Central Wisconsin. Of these, 7468 patients had admitting serum sodium <135 and 39315 controls with normal serum sodium (135-145). We parsed hyponatremia based on their admitting serum sodium as mild (130-134), moderate (125-129) and profound (<125) degrees of hyponatremia and compared them with controls. We obtained their vital status (alive or deceased) up to December 31, 2018 over a mean follow up period of 4.7 years. We used Cox proportional hazards model to estimate hazard ratios between varying degrees of hyponatremia compared with normonatremia group after adjusting for covariates.

Results: Hyponatremia occurred in 17.9% of total hospitalizations during the study period. Of 7468 patients with hyponatremia, there were 6,135 (82.2%), 995 (13.3%) and 338 (4.5%) with mild, moderate, and profound degrees of hyponatremia respectively. Hazard ratios for mild, moderate and severe hyponatremia when compared to controls was 1.35 (95% CI: 1.28 – 1.43), 1.81 (95% CI: 1.24 – 2.56) and 2.01 (95% CI: 1.24 – 3.27) respectively (all p<0.001) after adjusting for covariates.

Conclusions: All-cause mortality from CVD, stroke, cancer, liver cirrhosis deaths were occurring to a significant proportion even in patients with milder degrees of hyponatremia with a dose response relationship. Clinicians should incorporate hyponatremia in their assessment of critical patients as this is associated with mortality. These findings need to be explored further with research geared towards elucidating mechanisms that contribute to death in hyponatremia, and if correcting sodium levels early in hospitalizations may prevent mortality in the future.

PO1143

The Prognostic Importance of Serum Sodium for Mortality Among Critically Ill Patients Requiring Continuous Renal Replacement Therapy

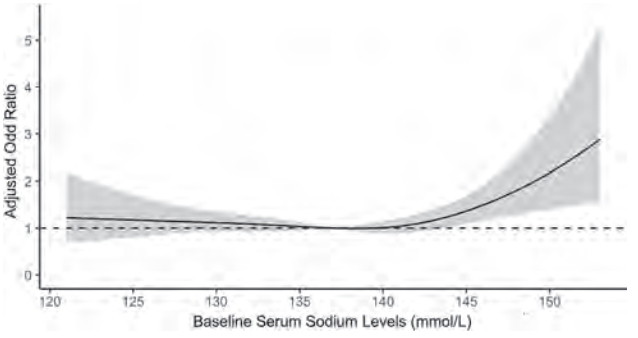
Charat Thongprayoon,[1] Wisit Cheungpasitporn,[1] Khaled Shawwa,[1,2] Kianoush Kashani.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]West Virginia University, Morgantown, WV.*

Background: Serum sodium derangement is common in critically ill patients requiring continuous renal replacement therapy (CRRT). We aimed to assess the association between serum sodium (normal range 138-142 mmol/L) before and during CRRT with mortality.

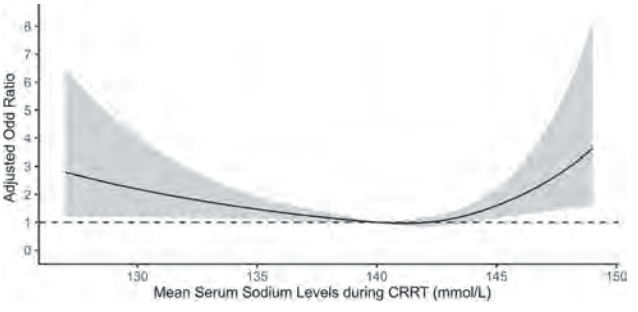
Methods: This is a historical cohort study of 1,520 critically ill patients who received CRRT for at least 24 hours from December 2006 through November 2015 in a tertiary hospital in the United States. Using logistic regression analysis, we used serum sodium before CRRT, mean serum sodium, and serum sodium changes during CRRT to predict 90-day mortality after CRRT initiation.

Results: Compared with the normal serum sodium levels, the odds ratio (OR) of 90-day mortality in patients with serum sodium before CRRT of 143-147 and ≥148 mmol/L were 1.45 (95% CI 1.03-2.05), 2.24 (95% CI 1.33-3.87), respectively. There was no significant increase in 90-day mortality in serum sodium of ≤137 mmol/L. During CRRT, the mean serum sodium levels of ≤137 (OR 1.41; 95% CI 1.01-1.98) and ≥143 mmol/L (OR 1.52; 95% CI 1.14-2.03) were associated with higher 90-day mortality. The greater serum sodium changes during CRRT were associated with higher 90-mortality (OR 1.35; 95% CI 1.21-1.51 per 5-mmol/L increase).

Conclusions: Before CRRT initiation, hypernatremia and during CRRT, hypo-, and hypernatremia were associated with increased mortality.



Restricted cubic spline of the association between serum sodium before CRRT and 90-day mortality



Restricted cubic spline of the association between mean serum sodium during CRRT and 90-day mortality

PO1144

Use of Tolvaptan to Maintain Eunatremia in Acute Brain Injury-Induced SIADH

Maria Christina Victoria M. Capistrano,[1] Ankur Shah.[2] *[1]Kent Hospital, Warwick, RI; [2]Brown University Warren Alpert Medical School, Providence, RI.*

Introduction: Eunatremia is a predictor of in-hospital mortality in intracerebral hemorrhage. In hyponatremia from SIADH, usual therapies may not be ideal in patients with stroke. We present a case of hyponatremia from acute brain injury induced SIADH being managed with Tolvaptan.

Case Description: Our patient is a 68 year old man with a history of hypertension who was admitted for an acute hemorrhagic stroke. He had a blood pressure of 204/127 mmHg and an NIHSS of 10. His initial work up shows: glucose 199 mg/dL, creatinine 0.75 mg/dL, Na 137 mmol/L, potassium 3.8 mmol/L, HCO3 of 25 mmol/L, chloride 95 mmol/L. A head CT scan demonstrated a 10 cc right thalamic hemorrhage. He was then started on a nicardipine drip. On the next day, he was noted to have a Na of 129 mmol/L. His serum osmolality, urine osmolality, urine Na were 289 mOSM/kg, 6,783 mOSM/kg and 146 mmol/L respectively. He was given salt tablets with

improvement of Na to 131. However, he developed headaches and became hypertensive at 188/94 mmHg. Instead, he was started on a high protein diet, 1 liter fluid restriction and lasix. The next Na level was 129. He was given Tolvaptan 15 mg, which improved the Na to 132, urine osm 645, and urine Na to 12. The dose was increased to 30 mg to achieve eunatremia with these values: Na 135-138, urine Na 12, urine osm 487. His BP improved, tolvaptan was discontinued and salt tablets were resumed. The patient maintained eunatremia throughout the hospital stay.

Discussion: Hyponatremia is a predictor of mortality due to cellular edema. Eunatremia with Na levels between 135-145 mmol/L is targeted in acute brain injury. SIADH induced by brain injury may be due to an increase in ADH from the overstimulation of the neurohumoral axis. ADH promotes water reabsorption at the cortical and medullary collecting tubules, and inappropriate levels lead to hyponatremia. Tolvaptan is a V2 receptor antagonist which combats this mechanism, thus increasing free water excretion. Additional therapies for hyponatremia from SIADH include fluid restriction, a high protein diet and salt tablets. However, salt tablets increases fluid retention; which increases blood pressurre, and leads to recurrent hemorrhage and poor outcomes. The use of Tolvaptan increases free water excretion to achieve eunatremia, thereby decreasing the risk of brain edema and controls blood pressure, especially in this patient population.

PO1145

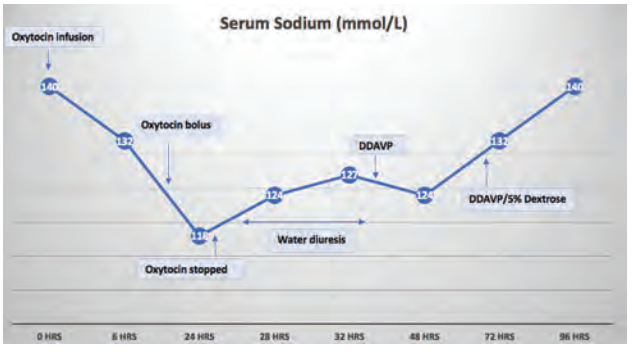
Acute Severe Symptomatic Hyponatremia in the Post-Partum Period: The Syndrome of Oxytocin-Induced Anti-Diuresis (SOIAD)

Muhammad A. Shahzad, William L. Whittier, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Oxytocin (OXT) is a neuropeptide used in pregnancy to induce uterine contraction. It is structurally related to vasopressin (AVP) by a difference of only 2 amino acids. While it does not have antidiuretic activity at physiologic levels, it can when administered at pharmacologic doses (>20 mU/min). We present a case of severe symptomatic hyponatremia after receiving oxytocin in the post-partum period.

Case Description: A 31 y/o G1PO woman was admitted with premature membrane rupture at week 38. An IV oxytocin infusion (2mU/min) was started to augment labor. Her serum sNa 6 hrs later was 132 mmol/l (baseline sNa 140). Her delivery was c/b uterine atony and postpartum hemorrhage requiring a bolus of IV oxytocin (10 U over 30 min) followed by infusion at 8 mU/min. The sNa 18 hr later was 118 mmol/l. She reported nausea. Her sOsm was 252 mOsm/kg with UNa of 95 mmol/l and Uosm 880 mOsm/kg consistent with the syndrome of anti-diuresis (SIAD). OXT was suspected and was stopped. 2 hr later, a rapid water diuresis ensued (u vol 150-200 cc/hr, with uOsm 92 mOsm/kg). The sNa 4 and 8 hrs later increased to 124 and 127 respectively. Because of concern for over-correction, she was given DDAVP and D5W. This resulted in a gradual (6-8 mmol/l/24 hr) sNa increase to 140 mmol/l over the next 48 hr (Fig 1).

Discussion: Therapeutic OXT can result in anti-diuresis with water retention. OXT half-life is only 1-6 min and is further reduced during pregnancy. Women are more likely to have severe neurologic sequelae of hyponatremia so it is fortuitous that the half-life of OXT is so short, and discontinuation alone should result in a rapid water diuresis. Still, although acute hyponatremia can usually be safely corrected rapidly, concern over what could have been an increase in sNa of 28 mmol/l over several hrs necessitated a DDAVP clamp to slow correction. She had a complete recovery. SOIAD can be a severe complication of OXT. Since it can occur rapidly and severely, sNa should be followed closely when patients are on OXT infusion.



PO1146

A Rare Cause of Hyponatremia: Renal Salt Wasting Syndrome of Unclear Etiology Post Autologous Hematopoietic Stem Cell Transplant

Adnann S. Polani,[1] Vikas D. Reddy,[2] Venkata Kishore R. Mukku,[3] Vishnupriyadevi Parvathareddy,[1] Sheldon Chen.[4] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [3]The University of Texas Medical Branch at Galveston School of Medicine, Galveston, TX; [4]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Hyponatremia is common in cancer patients. We report a rare case of acute hyponatremia in a patient with multiple myeloma (MM) who developed renal salt wasting syndrome (RSWS) as a complication of autologus hematopoietic stem cell transplant (SCT)

Case Description: A 57-year-old female with history of Plasmacytoma treated with radiation therapy that subsequently relapsed as MM with POEMS syndrome and was treated with VRd regimen presented for autologous SCT. MM was in remission and patient underwent Melphalan pre-conditioning with last melphalan dose 48 hours prior to transplant. 36 hours post-transplant patient had a seizure. Labs revealed acute drop in serum sodium from 137 to 117 over 17 hours. CT head revealed mild generalized cerebral edema. Patient also had acute polyuria (> 4 L/day). Patient was treated emergently with hypertonic saline bolus and had resolution of neurological symptoms however, serum sodium continued to drop and she required around 2 L of hypertonic saline infusion over the next 24 hours to correct sodium at desired rate. Urine studies at the time of hyponatremia revealed urine osmolality of 477, sodium 161 and potassium 34. Initial working diagnosis was SIADH that was quickly revised to RSWS based on high urine sodium, hypovolemia and polyuria. The patient was able to be transitioned to salt tablets once polyuria resolved over the next 36 hours. Urine sodium remained elevated. A repeat CT head showed resolution of cerebral edema.

Discussion: RSWS post SCT is rarely reported. Among the few reported cases an underlying CNS complication or a post-transplant hyponatremia inducing medication exposure that predated acute hyponatremia was present. Moreover the reported cases appeared to be non autologous transplants. SIADH and RSWS (including CSWS) are similar in the sense that both present with similar urine studies. Volume status and urine output are the key factors to help differentiate between the two entities. Clinically differentiating between these two entities is important as fluid restriction is the key management in the one and solute plus volume replacement in the other. Based on our case we recommend that hyponatremia post SCT should be carefully evaluated and RSWS be considered in the differential even if there is no obvious underlying cause.

PO1147

An Unexpected Case of Osmotic Demyelination Syndrome (ODS)

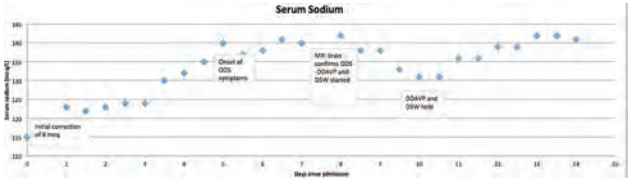
Raphael J. Rosen,[1] Shelief Robbins-Juarez,[2] Pallavi S. Utukuri,[1] Eric Siddall.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Vagelos College of Physicians and Surgeons, New York, NY.*

Introduction: ODS is a neurological condition characterized by altered mentation, extrapyramidal symptoms, and pseudobulbar palsy in response to a rapid increase in serum osmolality. Classically ODS was been described after rapid correction of severe, chronic hyponatremia but can occur with slower rates of correction in high-risk patients, as described herein.

Case Description: A 44-year-old man with alcoholism presented with a sodium of 115meq/L. Normal saline was administered and his sodium corrected to 123meq/L over the initial 24 hours. His sodium corrected slowly over the next 5 days to normal range, never exceeding 8 meq/L per day. On day 5, he developed nystagmus, cogwheeling rigidity, hallucinations and aspirations. Brain MRI revealed abnormalities in the central pons (fig. 1), and a diagnosis of ODS was made. D5W and desmopressin were administered, lowering the sodium from 142meq/L to 131meq/L over 2 days, where it was maintained for 24 hours. No clinical improvement resulted and neurological sx progressed. The sodium was then allowed to rise slowly to normal over 2 days, shown in fig. 2. By discharge the patient had moderate improvement in speech and swallowing.

Discussion: This case of ODS was unusual in that it occurred despite modest hyponatremia, which corrected at only 8meq / day. ODS can occur despite slow sodium correction in the context of risk factors such as alcoholism. Therapeutic relowering of sodium resulted in no improvement, possibly because relowering was not pursued until MRI confirmation, leading to a delay of 72 hours from symptom onset.

MRI brain (DWI sequence) demontrating restricted diffusion in the central pons (arrow).



PO1148

Cerebral Salt Wasting in a Renal Transplant Patient

Prashanth Reddy, Sahityan Viswanathan. *The University of Texas Southwestern Medical Center, Dallas, TX*.

Introduction: Hyponatremia is a common occurrence in patients with cerebral injury and is usually thought to be secondary to SIADH. Though cerebral salt wasting is documented in literature it has been debated on if it is truly a phenomenon. Among patients with CNS disease, CSW is a much less diagnosed cause of hyponatremia and remains underdiagnosed owing to the challenge of proving its existence. Here we present a patient with a CNS injury who showed clear benefit from treatment not centered around SIADH, thus pushing us to diagnose him with CSW.

Case Description: A 63yo Male with a PMHx of DDKT presented with nausea/vomiting. A cerebellar abscess from a previous biopsy site was found and he underwent a debridement and washout. On POD#4 the patient had a drop in sodium to 131. Urine studies [urine osmolarity: 789, urine Na: 72]. With continued drop in sodium and orthostatic hypotension he was started on NS 75cc/hr. The sodium continued to drop to a low of 123. At that time the NS was increased to 125cc/hr. This resulted in an upswing in serum sodium to 130. A drop in NS rate was trialed with sodium dropping back to 127. The NS was eventually ramped up to 200cc/hr with good response. During the uptitration of fluids there was no significant drop in urine osmolality noted. The patient was eventually transitioned to a dose of salt tabs close to the equivalent to the amount of fluids he was receiving [5g Q4H]. He was also started on Fludrocortisone 0.1mg daily. This resulted in our ability to drop the Salt tabs to 4g Q6H with stability in serum sodium noted. He was discharged on this regimen and was noted to have stable serum sodium on follow up a few weeks later.

Discussion: CSW is difficult to diagnose due to the similarities in laboratory diagnostic markers with SIADH. One major difference is that in CSW patients are usually hypovolemic. Another aspect that differs from SIADH is the approach to treatment. In SIADH a combination of fluid restriction, lasix, and salt tabs are used. What makes our case unique is the successful use of NS to correct the patient's sodium. If this was SIADH, continuous administration of NS would have dropped the sodium level. We believe we met the burden of proof to diagnose this patient with CSW. Though there may still be debate about the existence of CSW, we believe that with the difference in treatment approach it should always be considered in the differential in patients with CNS injury.

PO1149

Explainable Prediction of Overcorrection in Severe Hyponatremia: A Post Hoc Analysis of the SALSA Trial

Huijin Yang,[1] Seon Ha Baek,[1] Sejoong Kim.[2] *[1]Hallym University Dongtan Sacred Heart Hospital, Gyeonggi-do, Republic of Korea; [2]Seoul University Bundang Hospital, Gyeonggi-do, Republic of Korea*.

Background: Overcorrection of hyponatremia can result in irreversible neurologic disability like osmotic demyelination syndrome. Few prospective studies have identified the individuals at high risk of overcorrection under controlled hypertonic saline treatment.

Methods: We performed a post hoc analysis of a multicenter, prospective randomized controlled study – the SALSA (Efficacy and Safety of Rapid Intermittent Correction Compared With Slow Continuous Correction With Hypertonic Saline In Patients With Moderately Severe or Severe Symptomatic Severe Hyponatremia) trial in 178 patients older than 18 years with symptomatic hyponatremia (mean age 73.1 years, mean serum sodium (sNa) concentrations 118.2 mmol/L). Overcorrection was defined as an increase in sNa by >12/18 mmol/L within 24/48 hours at any time.

Results: Thirty-seven of 178 patients experienced overcorrection (20.7%). Overcorrection was independently associated with initial sNa level (≤ 110 mmol/L: 7 points; 110-115 mmol/L: 4 points; 115-120 mmol/L: 2 points; 120-125 mmol/L: 0 point). chronic alcoholism (7 points), severe symptoms of hyponatremia (3 points), and initial potassium level (< 3.0 mmol/L: 3 points). The NASK score was derived from these four risk factors for overcorrection (hypoNatremia, Alcoholism, Severe symptoms, and hypoKalemia) and was significantly associated with overcorrection (odds ratio 1.41, 95% CI 1.24 to 1.61; P <.001) with good discrimination (area under the receiver operating characteristic curve 0.76, 95% CI 0.66 to 0.85; P <.001). The AUROC value of the NASK score was statistically better comparing to those of each risk factor.

Conclusions: In treating patients with symptomatic hyponatremia, individuals at high risk of overcorrection were predictable using a novel risk score summarizing baseline information.

Figure 1A. Marginal plot of the NASK score against overcorrection

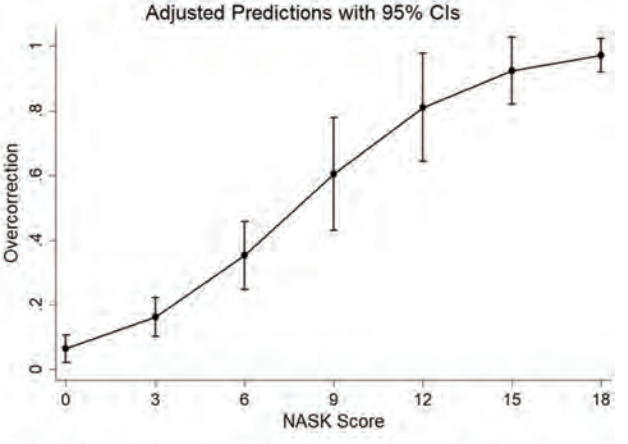


Figure 1B. The area under the receiver operating characteristics curve for the NASK score and each risk factor for overcorrection

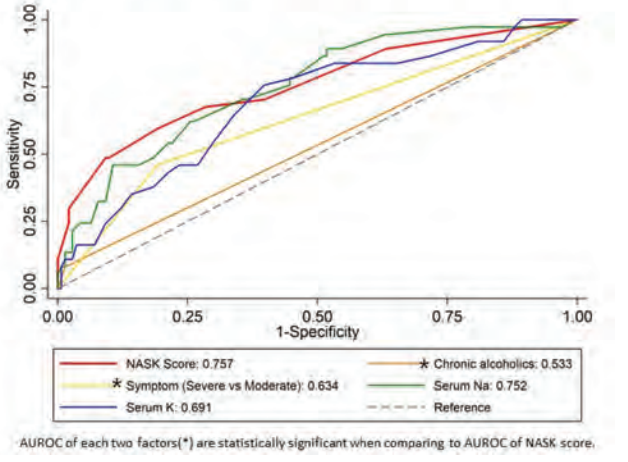

AUROC of each two factors(*) are statistically significant when comparing to AUROC of NASK score.

PO1150

On the Correction of Plasma [Na] in Hyperglycemia

Alan Segal. *Steady State Nephrology, South Burlington, VT.*

Background: The effect of hypertonic states on metabolism was first considered by Seldin *et al* in 1949. An empirical equation to correct the plasma [Na] for hyperglycemia was put forth by Katz (*NEJM, 1973*). About 25 years later, Hillier *et al* (*AJM, 1999*) presented another equation based on normal volunteers with experimentally induced hyperglycemia. Both equations are linear with correction factors (in mM [Na]/100 mg/dL [glucose]) of -1.6 (Katz) and -2.4 (Hillier). Non-linearity, however, is apparent in the original data of Hillier, which are better fit by a second-order equation (corrected plasma [Na] = $\{-3.49 * 10^{-5} * (plasma\ [glucose])^2 - (3.91 * 10^{-5} * plasma\ [glucose]) + 140\}$). Previous equations also presume normonatremia prior to hyperglycemia and a constant volume of distribution for glucose.

Methods: Here, a new model is proposed that also provides a reasonable fit to the patient data of Seldin *et al* from 70 years ago (*JCI, 1951*) and Hillier *et al*. Unlike previous equations that are based solely on current plasma [glucose], this program takes weight, sex, the presence of edema, and the apparent volume of distribution (aVd) of glucose into consideration. The latter is especially important because the aVd of glucose may change in hyperglycemia.

Results: For example, consider a patient from the 1951 *JCI* study by Seldin *et al*: a 59.1-kg edematous patient with cirrhosis who initially had a plasma [Na] of 130 mM when the plasma [glucose] was 126 mg/dL. The program starts by calculating the number of effective osmoles in the ICF and ECF based on the initial labs, and then incorporates the change in ECF volume measured by the investigators, which in this case was +1.9 L. Following infusion of hypertonic glucose, the plasma [Na] fell to 110 mM at the peak plasma [glucose] of 666 mg/dL. The corrected plasma [Na] predicted are (in mM): 130.9 (Katz), 126.4 (Hillier), and 124.5 (quadratic fit of Hillier's data); all of which do not compare well with 110 mM. Although the program predicts 121.3 mM, after correction for the change in the aVd of glucose, it predicts 112 mM, in good agreement with the measured value of 110 mM.

Conclusions: Now that making numerous calculations can be done easily and efficiently with apps most physicians have on their phones, it is proposed that equations with linear correction factors be replaced by this new program when clinicians would like to predict or correct the measured serum [Na] in the presence of hyperglycemia.

PO1151

Extreme Hyponatremia with Serum Sodium Less Than 100 mEq/L: A Case Report and Review of the Literature

Kirti Basil, Kenneth M. Ralto. *UMass Memorial Medical Center, Worcester, MA.*

Introduction: Hyponatremia is the most common electrolyte abnormality in hospitalized patients and is associated with increased mortality, hospital length of stay and cost. Rapid overcorrection of hyponatremia can increase the risk of osmotic demyelination syndrome (ODS) which can have debilitating and often fatal consequences. Extreme hyponatremia with serum sodium concentration less than 100 mEq/L is rare, but is associated with high a rate of morbidity and mortality.

Case Description: A 52-year-old woman presented with a one-week history of weakness and fatigue. She was cachectic and had signs of severe hypovolemia and malnutrition. Her serum sodium concentration was less than 100 mEq/L on three separate samples. She did not have any focal neurological deficits or any witnessed seizures. Additionally, she was found to have oliguric acute kidney injury and critical hyperkalemia. She was treated with aggressive volume expansion with subsequent increase in serum sodium concentration and resolution of AKI and hyperkalemia. Desmopressin and 5% dextrose infusion were used to prevent rapid overcorrection of hyponatremia and minimize the risk for ODS. Her sodium level was corrected at the recommended rate of 6 mEq/L per day. She was discharged with serum sodium concentration of 136 mEq/L on hospital day 16 and did not have any long-term neurological sequelae.

Discussion: Extreme hyponatremia with serum sodium concentration less than 100 mEq/L is a rare but critical situation. Review of the previously published cases found that the main risk factors are female gender, age greater than 40 years, malnutrition, alcohol use, thiazide use or SIADH due to antidepressant use. Serum osmolality should be used to estimate serum sodium concentration and guide the rate of correction if the precise sodium value below 100 mEq/L cannot be determined. Careful management is required due to the high risk of ODS in these patients and proactive administration of desmopressin is recommended to avoid overcorrection. Continuous venovenous hemofiltration with hypotonic replacement fluid is an effective strategy for patients with extreme hyponatremia who also require renal replacement therapy for AKI and/or critical hyperkalemia.

PO1152

SIADH and Postoperative Urinary Retention

Khawaja M. Bakhtawar, Abdullah Jalal. *Overlook Medical Center, Summit, NJ.*

Introduction: Hyponatremia is a common electrolyte abnormality in hospitalized patients with increased prevalence noted in geriatric populations. The increased susceptibility is multifactorial from age-related GFR reduction in addition to medication effects (diuretics, antidepressants), decreased solute intake and endocrinopathies (SiADH). Herein we present a case of severe hyponatremia induced by urinary retention, an infrequently described and often overlooked etiology of hyponatremia in elderly patients.

Case Description: A 58-year-old male with past medical history of hypertension on amlodipine and losartan presented with nausea, emesis and abdominal pain. The patient was recently discharged 2 weeks earlier s/p uncomplicated distal pancreatectomy with splenectomy for pancreatic adenocarcinoma. Post-operative course was stable with no complications and patient was discharged home on oxycodone/acetaminophen for pain. At home, the patient noticed constipation with worsening abdominal distension with bilateral lower extremity swelling. He had been oliguric for the past week, performing manual suprapubic compression to void. On readmission patient was noted to be severely dehydrated with a large, distended abdomen. Vital signs were BP 102/53, HR 87, SpO2 97%. Notable labs include (mEq/L): Na 111, BUN 132, Cr 4.4, HCO3 18. Urine studies noted (mEq/L): Na 8, Cl <10, K 25, serum osmolality 366 mOsm/kg. Abdominal CT noted a large LUQ fluid collection, distal colonic distension with fecal retention and mild bilateral hydronephrosis. Subsequent foley insertion immediately drained 2.5L. Repeat labs 12 hours later were (mEq/L): Na 118, BUN 118, Cr 2.89. Hypotonic fluids were started to prevent Na overcorrection. Over the next several days the patient's Serum Na (135) and renal function improved (BUN 21, Cr 0.9) back to baseline.

Discussion: During the post-operative period urinary retention is commonly noted due to anesthesia, analgesics, pain and constipation. This can be exacerbated in elderly male patients due to the ubiquity of BPH. Therefore physicians must be aware of common post-operative complications of urinary retention like hyponatremia, especially given the higher prevalence and predisposition of geriatric populations to develop hyponatremia. The proposed mechanism of urinary retention induced hyponatremia involves bladder distension and/or pain-mediated ADH release.

PO1153

La Belle Indifférence: Unusual Adaptation to an Antidiuretic Hormone Deficit

Jesse E. Diaz Correa,[1] Samina Fazal,[2,1] Harold M. Szerlip.[2,1] *[1]Baylor University Medical Center at Dallas, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Langerhans cell histiocytosis (LCH) also known as Histiocytosis X is a rare granulomatous disease characterized by abnormal proliferation of Langerhans cells. LCH may be systemic or localized and its clinical manifestations are variable. Diabetes Insipidus (DI) is the most commonly found endocrine anomaly, with a prevalence varying between 5 and 50%.

Case Description: 48-year-old Hispanic male previous smoker with a history LHC was admitted c/o rectal pain. Three years prior to admission he had developed recurrent bilateral pneumothoraxes requiring multiple video assisted thoracoscopic surgeries with lysis of adhesions. A lung biopsy at that time demonstrated LHC. He had not had follow-up care since that time due to economic issues. He said he was drinking 4 liters of water a day to be proactive with his health. He denied thirst. On admission he was noted to have a large anterior anal ulcer, which was positive for Langerhan cell. While waiting in the emergency department without access to water his sodium increased from 137 mEq/L to 147 mEq/L in 6 hours. On evaluation his urine osmolality (osm) was 93 mosm/kg with a serum osm of 305 mosm/kg, and a serum sodium of 146. A repeat sample demonstrated a serum osm of 311 mosm/kg and Copeptin level of 4.0 pmol/L confirming central diabetes insipidus. Brain MRI shown in Figure 1 demonstrated abnormal thickening and nodularity of the distal pituitary stalk. Patient was started on nasal desmopressin.

Discussion: Although this patient denied thirst or polyuria, with incidental water restriction while in the ED, DI became apparent. The pathological diagnosis of an infiltrative disease such as LHC should provoke a high degree of suspicion for the evaluation of DI.

PO1154

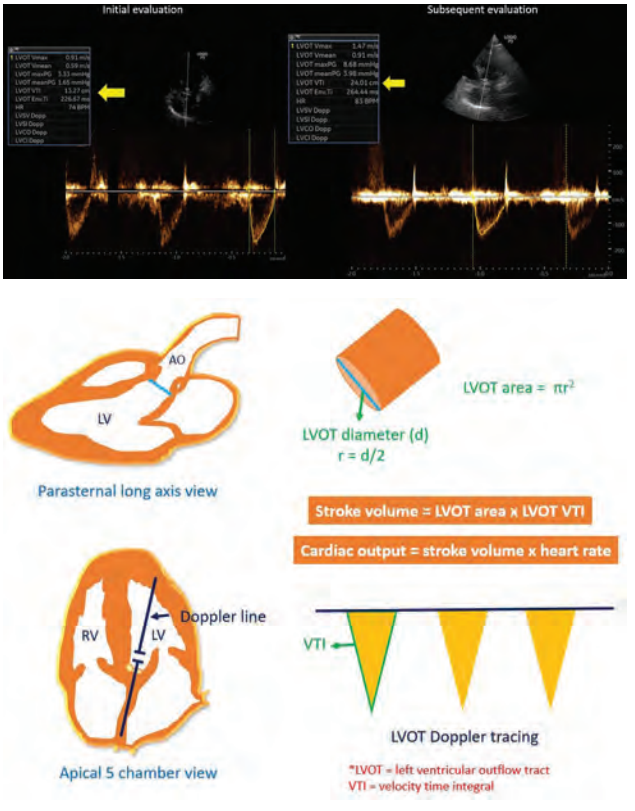
Point-of-Care Ultrasound-Assisted Management of Hyponatremia

Totini S. Chatterjee, Abhilash Koratala. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Point of care ultrasound (POCUS) is emerging as a valuable adjunct to conventional physical examination in patients with complex fluid and electrolyte disorders. Herein, we present a case of hyponatremia where nephrologist-performed focused cardiac ultrasound (FoCUS) aided in accurate diagnosis.

Case Description: A 73-year-old woman was admitted for the treatment of fractures after sustaining a fall. Nephrology was consulted for decrease in serum sodium level (to 123 mmol/L; baseline 130s). Laboratory data was significant for a urine sodium level of 46 mmol/L, urine osmolality 257 mOsm/kg, serum creatinine 0.5 mg/dL and BUN 9 mg/dL. As the patient had exertional dyspnea and crackles at lung bases, IV diuretic was administered by the rounding physician prior to urine studies. No active pain or thiazide use. X-ray showed a huge hiatal hernia with bowel contents in the chest, which was possibly mimicking crackles on auscultation and causing dyspnea. Systolic BP was in 140s. Urine sodium, though suggestive of euvolemic state, was confounded by diuretic. We performed a FoCUS exam. Left ventricular outflow tract velocity time integral (LVOT-VTI), which is a surrogate for stroke volume was lower than expected (~13 cm [normal 18-22]) suggestive of hypovolemia. Flow changes precede drop in BP. We recommended to administer normal saline and the serum sodium improved to 130 mmol/L in 2 days; VTI normalized to ~22 cm [Fig. 1]. Fig.2 illustrates stroke volume estimation using LVOT diameter and VTI. As the diameter is constant for a given person, VTI alone can be used to monitor response to therapy.

Discussion: POCUS is a valuable bedside diagnostic tool in day-to-day nephrology practice.



PO1155

Polyethylene Glycol-Induced Pseudohyponatremia

Swetha Reddy, Sundararaman Swaminathan. *Mayo Clinic Arizona, Scottsdale, AZ.*

Introduction: Pseudohyponatremia due to Polyethylene glycol (PEG) is poorly described and goes unrecognized. We describe a case of hyperosmolar hyponatremia due to PEG absorption into the systemic circulation.

Case Description: An 84-year-old lady with hypertension and CKD stage 4 was admitted with an asymptomatic serum sodium of 121. Initially thought be due to SIADH. She was started on 1-liter fluid restriction, sodium chloride tablet and torsemide. Nephrology was consulted on day 3 as her serum creatinine was 2.9 (baseline 2.3 mg/dl) and sodium improved to only 124. Patient complained of increased thirst and had dry mucus membrane on examination. Labs on admission revealed a serum sodium of 121 mEq/L, a serum osmolality of 286 mOsm/kg, urine osmolality of 230 mOsm/kg and urine sodium of 40. Serum creatinine was 2.3 mg/dL, BUN 50 mg/dL, glucose of 100mg/dl, uric acid 8.1 mg/dL. Thyroid function tests and cortisol were within normal range. An osmolar gap of 22 was noted. In the absence of hyperglycemia and other potential causes of an osmotic gap, such as mannitol or alcohols, a careful review of medication showed that she was on 3 weeks of PEG for constipation. PEG was held, fluid restriction and torsemide discontinued. Resolution of osmolar gap was confirmed in two weeks with return in sodium to 134 and creatinine to 2.3.

Discussion: The prevalence of hyponatremia is reported at 7% in bowel prep patients. Etiology in these cases was due to increased free water intake. Hyperosmolar hyponatremia is caused by the addition of an 'effective solute' (e.g. glucose, mannitol or sucrose) to the serum. Commonly used as an osmotic laxative, PEG is described as 'a nonabsorbable, nonmetabolized polymers' that when administered orally acts as a 'pure osmotic agent' in the gastrointestinal tract. Systemic absorption can occur in rare cases. When PEG absorption occurs, most of its clearance occurs via renal filtration, this process is likely impaired in a patient with CKD such as seen in our patient. When a patient presents with hyponatremia, the expectation of a low-serum osmolality needs to be confirmed with the actual measurement of serum osmolality. This case highlights the importance of detecting the etiology of hyponatremia without which treatment of the same can be impossible and expands the understanding of normal to high serum osmolality can go beyond the commonly known mannitol, paraproteinemia and lipidemia.

PO1156

Identifying Hypernatremia Subgroups with Differing Survival by Machine Learning Among Hospitalized Patients

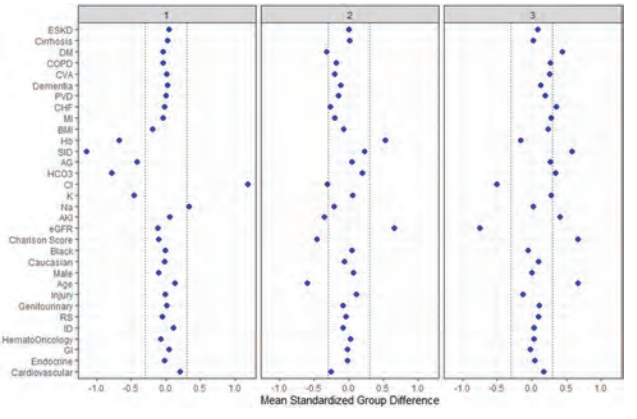
Grace Y. Chong,[1] Charat Thongprayoon,[1] Michael A. Mao,[2] Andrea G. Kattah,[1] Mira T. Keddis,[3] Stephen B. Erickson,[1] John J. Dillon,[1] Vesna D. Garovic,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Division of Nephrology and Hypertension, Jacksonville, FL; [3]Mayo Clinic Division of Nephrology and Hypertension, Phoenix, AZ.*

Background: The objective of this study was to characterize patients with hypernatremia on hospital admission into clusters using an unsupervised machine learning approach and to evaluate the mortality risk among these distinct clusters.

Methods: We performed consensus cluster analysis based on demographic information, principal diagnoses, comorbidities, and laboratory data among 6,297 hospitalized adult patients with hypernatremia present at admission. We calculated the standardized difference of each variable to identify each cluster's key features. We assessed the association with each hypernatremia cluster with in-hospital and one-year mortality.

Results: There were three distinct clusters of hypernatremia: 1,570 patients (25%) in cluster 1; 2,648 (42%) in cluster 2; and 2,079 (33%) in cluster 3. Figure 1 is a plot of standardized mean differences to visualize key features for each cluster. Compared to cluster 2, the odds ratios for in-hospital mortality were 6.99 (95% CI 4.03-12.13) for cluster 1 and 5.73 (95% CI 3.31-9.90) for cluster 3, whereas hazard ratios for one-year mortality were 3.38 (95% CI 2.69-4.25) for cluster 1 and 4.71 (95% CI 3.82-5.80) for cluster 3.

Conclusions: The characteristics and outcomes of hospitalized patients admitted with hypernatremia were heterogenous. Our cluster analysis identified three clinically distinct phenotypes with differing mortality risks. Identification of heterogeneity in hypernatremic patients using this approach may provide guidance for the management of hospitalized patients with hypernatremia at the time of hospital admission.



The standardized differences across three clusters for each of the baseline parameters. The x axis is the standardized differences value, and the y axis shows baseline parameters. The dashed vertical lines represent the standardized differences cutoffs of <-0.3 or > 0.3.

PO1157

A Rare Case of Acute Myeloid Leukemia Presenting as Central Diabetes Insipidus

Dharika P. Shah, Alka A. Tyagi, Mohankumar Doraiswamy, Sethu M. Madhavan. *The Ohio State University Wexner Medical Center, Columbus, OH*.

Introduction: Central Diabetes Insipidus (CDI) is an uncommon condition, with an overall incidence of approximately 1:25,000 and is usually associated with neurosurgery, trauma, autoimmune and vascular disease, infiltrative disorders, hypoxic brain injury, and brain metastasis. Patients with acute myeloid leukemia (AML) mostly present with symptoms of pancytopenia, noted to have hematologic abnormalities and are subsequently diagnosed with AML after bone marrow biopsy. Here we describe a unique case of a patient who presented with symptoms of CDI and incidentally diagnosed with AML.

Case Description: A 64-year-old male with a history of coronary artery disease presented to his primary physician complaining of polyuria and polydipsia which affected his work as a truck driver. Labs were notable for mild anemia (Hgb 11 g/dL) with macrocytosis, thrombocytosis (platelet 667 K/uL), serum sodium was 146 mmol/L, Hgb A1c 5%, prostate-specific-antigen 1.4 ng/dL, normal lipid panel, and normal thyroid function. No definitive diagnosis was made and he underwent evaluation by hematology. Peripheral smear showed increased (44%) blasts/promyelocytes, consistent with acute leukemia. Cytogenetic analysis showed an abnormal clone of cells with an inverted chromosome 3 and monosomy for chromosome 7. He was admitted for induction therapy and presenting symptoms worsened (~10 L urine output per day) along with hypernatremia which peaked at 160 mmol/L, serum osmolality 319 mOsmo/kg and urine osmolality of 174 mOsmo/kg despite large oral and peripheral free water supplementation. MRI brain was negative for intracranial findings or abnormal enhancement. Given the degree of hypernatremia, and history concerning for CDI, empiric treatment with intra-nasal vasopressin (DDAVP) was given with significant improvement of symptoms, serum sodium, serum osmolality and urine osmolality.

Discussion: The presentation of AML with concurrent CDI is associated with chromosome 3 or 7 abnormities, not brain lesions, as in this case; the management of CDI involves continued DDAVP administration. Unfortunately this translocation has been associated with poor clinical outcome. With this case, we suggest screening patients for CDI who have an unclear reason of developing of polydipsia and polyuria and if hematologic abnormalities are noted, should undergo prompt evaluation for AML.

PO1158

A Case of Ketamine-Induced Diabetes Insipidus

Karim T. Attia, Kara Kaplan, Alka A. Tyagi, Joshua Leisring. *The Ohio State University Wexner Medical Center, Columbus, OH*.

Introduction: To our knowledge there have been six previously published case reports describing central diabetes insipidus (DI) related to ketamine. We present a unique case of central DI associated with ketamine infusion in a critically ill patient with acute respiratory failure.

Case Description: A 52-year-old African American man with medical history of bipolar disorder, polysubstance abuse, chronic obstructive pulmonary disease, hypertension, and deep vein thrombosis was admitted to the medical intensive care unit with hemoptysis and acute respiratory failure. Due to agitation and refractory hypoxemia he required multiple sedating agents. Within hours of starting a ketamine infusion his urine output increased from a mean of 71 mL/hr to 305 mL/hr. Over 48 hours serum sodium (SNa) rose from 142 to 159 mmol/L. Urine osmolality (Uosm) was 132 mOsm/kg. 4 mcg intravenous (IV) desmopressin was administered. 90 minutes later Uosm had increased to 646 mOsm/kg. Urine output fell to 49 mL/hr. About 28 hours after the initial dose of desmopressin polyuria recurred and Uosm fell to 272 mOsm/kg. IV desmopressin was re-administered at 2 mcg with a similar response to the first dose. SNa normalized with free water replacement. Ketamine was stopped. Urine output, Uosm, and SNa remained stable without further intervention. Alternative etiologies for central DI such as hypoxic brain injury were considered but felt to be less likely due to the strong temporal relationship with ketamine. The Naranjo adverse drug reaction (ADR) likelihood score was 5 indicating a probable ADR.

Discussion: This case reinforces the association between ketamine and central DI which has been described in prior case reports. A hypothesized mechanism is ketamine's antagonism of N-methyl-D-aspartate receptors in the posterior pituitary thus inhibiting arginine vasopressin production. Ketamine is being used with greater frequency in critical care. It's important to recognize this rare but potentially serious complication. Monitoring of SNa, Uosm, and urine output should be considered. When central DI related to ketamine is identified, withdrawal of the drug appears to be corrective.

PO1159

Multi-Electrolyte Storm Associated with Non-Exocrine Manifestations of Sjögren Syndrome

Sahityan Viswanathan, Kamalanathan K. Sambandam. *The University of Texas Southwestern Medical Center, Dallas, TX*.

Introduction: Kidneys are one of the more commonly affected non-exocrine glands by Sjögren's syndrome. Renal involvement includes glomerulonephritis, interstitial nephritis, or both. Chronic TIN is the most common renal manifestation in Sjögren's syndrome. Clinical manifestations of TIN present as abnormalities of tubular function such as Fanconi syndrome, Distal RTA and Nephrogenic DI.

Case Description: 26 y/o Hispanic female with no known past medical history present with nausea and vomiting at 21 weeks gestation of her second pregnancy. Workup was significant for elevated creatinine with proteinuria and pyuria, normal anion gap metabolic acidosis, hypokalemia, and hyphosphatemia. Urine studies revealed an inappropriately alkaline urine with impaired renal reclamation of potassium and phosphorous. Serological workup was significant for positive ANA, SSA, and SSB antibodies. Kidney biopsy revealed acute tubulointerstitial nephritis. The patient was started on an IV steroid course with oral taper and hydroxychloroquine with improvement in Cr from 2.2 to 1.2 mg/dL. with a potassium, phosphate and sodium bicarbonate supplementation regimen.

Discussion: Sjögren's syndrome is typically associated with lymphocytic infiltration of exocrine glands. However, this can also affect the kidneys causing tubulointerstitial nephritis and defects in tubular function initiating a cascade of electrolyte abnormalities. Understanding the renal physiology behind the observed electrolyte abnormalities is important to optimize our treatment regimen. While the management of a distal RTA that has been well described in Sjögrens syndrome typically involves judicious potassium and alkali supplementation, this case highlights the worsening potassium wasting and phosphorous wasting which also needs to be addressed with a concomitant proximal tubulopathy. We propose that this set of features can best be explained by dysfunctional carbonic anhydrase, a cause of the extremely rare type III RTA. We use this case presentation to highlight the spectrum of renal manifestations of Sjogren's syndrome and their treatment principles.

PO1160

Estimating 24-Hour Urinary Excretion Using Spot Urine Measurements in Kidney Stone Formers

Pietro Manuel Ferraro,[1] Fernando Lopez Osma,[3] Silvia Barbarini,[1] Gary C. Curhan,[4] Eric N. Taylor.[2] *[1]Università Cattolica del Sacro Cuore, Rome, Italy; [2]VA Maine Healthcare System, Augusta, ME; [3]Maine Medical Center, Portland, Portland, OR; [4]Brigham and Women's Hospital Channing Division of Network Medicine, Boston, MA.*

Background: One limitation of the use of the 24-h collection, a key element in the management of kidney stone (KS) disease, is impracticality. To overcome this limitation, we analyzed the performance of spot urine measurements to estimate 24-h excretion in patients with KS.

Methods: 74 adult KS patients from two centres were instructed to perform a 24-h urine collection. A sample of the last micturition (fasting, upon awakening) was sent for spot urine analysis. Twenty patients were asked to collect two additional spot urine samples, one before dinner (pre-prandial) and the other after dinner (post-prandial). Urinary concentrations of creatinine, calcium, oxalate, uric acid, citrate and magnesium were measured in the 24-h and each of the spot urine samples. Three approaches were used to estimate 24-h urinary excretion, multiplying the ratio of the spot urinary analyte to creatinine concentration by 1) measured 24-h urinary creatinine excretion ["Prediction #1"], 2) estimated 24-h urinary creatinine excretion ["Prediction #2"], or 3) assumed 1 gram 24-h urinary creatinine excretion ["Prediction #3"]. For each parameter we computed Lin's concordance correlation coefficients (CCCs), Bland-Altman plots, and 95% limits of agreement.

Results: The performance of estimates obtained with Prediction #1 and Prediction #2 was similar for all parameters, except for citrate and uric acid for which Prediction #2 performed significantly worse. Both estimation approaches performed moderately well: citrate CCC 0.82 (95% CI 0.75, 0.90), oxalate 0.66 (0.55, 0.78), magnesium 0.66 (0.54, 0.77), calcium 0.63 (0.50, 0.75), uric acid 0.52 (0.36, 0.68). The performance of Prediction #3 was consistently worse. Post-prandial samples tended to perform numerically worse compared with fasting morning and pre-prandial samples except for uric acid.

Conclusions: Utilizing measured or estimated 24-h creatinine substantially increases the utility of spot urine samples in estimating 24-h excretion of urinary analytes in KS formers.

PO1161

Evidence for Abnormal Linkage Between Urine Oxalate and Citrate Excretion in Human Kidney Stone Formers

Megan Prochaska,[1] Orson W. Moe,[2] John R. Asplin,[3] Fredric L. Coe,[1] Elaine M. Worcester.[1] *[1]University of Chicago Division of the Biological Sciences, Chicago, IL; [2]The University of Texas Southwestern Medical Center, Dallas, TX; [3]LithoLink Corp, Chicago, IL.*

Background: Animal models have demonstrated an interactive relationship between the epithelial anion exchanger SLC26A6 and transporter NaDC-1 that regulates citrate and oxalate homeostasis. This relationship is a potential mechanism to protect against kidney stones as higher urine oxalate is accompanied by higher urine citrate but it has not been explored in humans.

Methods: We examined 24-hour urine data on 13,155 kidney stone forming patients (SF) from separate datasets at the University of Chicago and Litholink, a national laboratory, and 143 non-kidney stone forming participants (NSF) to examine this relationship in humans. We used multivariate linear regression models to examine the association between oxalate and citrate in all study participants and separately in SF and NSF.

Results: Higher urinary oxalate was associated with higher urinary citrate in both SF and NSF. In NSF, the multivariate adjusted urine citrate excretion was 3.0 (1.5 to 4.6) (mmol)/creatinine (mmol) per oxalate (mmol)/creatinine (mmol). In SF, the multivariate adjusted urine citrate excretion was 0.3 (0.2 to 0.4) (mmol)/creatinine (mmol) per oxalate (mmol)/creatinine (mmol).

Conclusions: Higher urinary oxalate excretion was associated with higher urinary citrate excretion and this effect was larger in non-kidney stone forming participants compared with those who form kidney stones.

PO1162

Higher Risk of Incident Kidney Stones in Patients with Metabolic Acidosis and CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Julie C. Lai,[1] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]MathurConsulting, Woodside, CA; [3]Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Background: Epidemiological studies have shown an association between kidney stones and risk for CKD and its progression. Some types of stones are less likely to form at higher urine pH. Metabolic acidosis is a risk factor for CKD progression, but the association of serum bicarbonate with risk of incident kidney stones is not well understood.

Methods: Optum's de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values of 12 to <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) with data ≥3 years pre-index. The first qualifying serum bicarbonate test established the index date. Primary exposure variables were baseline serum bicarbonate and change in serum bicarbonate over time. Adjusted time-dependent Cox Proportional Hazards models were performed to evaluate time to first occurrence of kidney stones (by ICD-9 or ICD-10 diagnosis codes) during an average 3.6 year follow-up period. Other covariates included age, sex, race-ethnicity, education and income status, history of kidney stones, pre-index comorbidities associated with kidney stones, bariatric surgery, obesity, smoking history, baseline eGFR.

Results: 142,904 patients qualified for the study cohort. Patients with metabolic acidosis at index experienced kidney stones at greater frequency than those with normal serum bicarbonate at index (12% vs 9%, p<0.0001). Other significant factors associated with incident kidney stones included male sex, history of kidney stones, hyperoxaluria, gout and osteoporosis. Both higher serum bicarbonate at baseline (HR 0.956, 95% CI: 0.948-0.964) and higher serum bicarbonate over time (HR 0.968, 95% CI: 0.961-0.974) were associated with reduced risk of kidney stone development. The observed associations were unchanged in analyses examining death as a competing risk.

Conclusions: In patients with CKD, metabolic acidosis (vs. normal serum bicarbonate) was associated with a higher incidence of kidney stones and shorter time to incident stone formation. Future investigations should evaluate these associations by stone type.

PO1163

The Association of Body Mass Index with the Development of Metabolic Acidosis in Patients with CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Thomas W. Ferguson,[3] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]MathurConsulting, Woodside, CA; [3]Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Background: Bone is the largest body buffer and body mass index (BMI) is directly related to bone mass. We explored the relationship between BMI and incident metabolic acidosis in patients with CKD.

Methods: Optum's de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values in the normal range (22 to <30 mEq/L), 28–365 days apart, with data ≥12 months pre-index during which covariates were assessed. The first qualifying serum bicarbonate test established the index date. The primary exposure variable was BMI category (World Health Organization classification). Other exposures included hypertension diagnosis, triglycerides ≥1.7 mmol/L, HDL cholesterol ≤1 mmol/L in women or ≤0.9 mmol/L in men. Adjusted Cox Proportional Hazards models were performed to evaluate the time to development of new-onset metabolic acidosis (serum bicarbonate 12 to <22 mEq/L) over a follow-up period of ≤11.5 years. Other covariates included age, sex, race, education and income status, diabetes or heart failure, eGFR, log albumin-to-creatinine ratio, angiotensin converting enzyme inhibitors or angiotensin receptor blockers prescription, and diuretic prescription.

Results: 97,294 patients qualified for this study. There was an inverse association between BMI category and the risk of developing metabolic acidosis. Compared to BMI category of 18.5-25, each incremental category of higher BMI was associated with a decreasing risk of developing metabolic acidosis: BMI 25 to <30, HR 0.866, 95% CI: 0.824-0.911; BMI 30 to <35, HR 0.770, 95% CI: 0.729-0.813; BMI 35 to <40, HR 0.664, 95% CI: 0.622-0.709; BMI 40+, HR 0.612, 95% CI: 0.571-0.655. Additionally, hypertension decreased and low HDL cholesterol and elevated triglycerides increased the risk of new-onset metabolic acidosis.

Conclusions: In this large cohort of patients with CKD, an incremental increase in BMI was inversely associated with the development metabolic acidosis. The mechanism of this association merits further study.

PO1164

Effects of Pseudohyponatremia on the Diagnosis of Severe Metabolic Acidosis

Hafiz Muhammad Ali Raza,[1] Barry M. Wall.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Introduction: Pseudohyponatremia is defined as falsely low sodium levels in plasma caused by severe hyperlipidemia or hyperproteinemia. We discuss a case of pseudohyponatremia due to hypertriglyceridemia in a patient admitted with severe metabolic acidosis and acetaminophen induced liver toxicity.

Case Description: 43-year-old male with hyperlipidemia, diabetes mellitus, and obesity presented with 4 day-history of abdominal pain, nausea, vomiting, and polydipsia. He had decreased intake and was not taking his insulin for 4 days. Medications include glargine insulin, dulaglutide, empagliflozin, glimepiride, rosuvastatin, fenofibrate and losartan. BP:141/59 mmHg, HR:125 bpm, respirations 28/min, Temperature: 98.7, SpO2. 95% on room air. He appeared clinically volume depleted. Laboratory testing revealed severely lipemic serum, elevated acetaminophen level 44.1 ug/ml, severely elevated transaminases, arterial pH: 7.03, pCO2 11 mmHg, HCO3 <5 mEq/l. Plasma sodium:109 mEq/L and chloride 81 mEq/l using indirect potentiometry and 131 and 111 mEq/l using direct potentiometry. Serum triglycerides 2951 mg/dl, blood glucose 204 mg/dl, plasma lactate 7.5 mmol/l, and creatinine 0.6 mg/dl. Plasma anion gap was 11 mEq/l using direct potentiometry and could not be calculated using indirect potentiometry, as bicarbonate concentration could not be determined due to lipemia. Based on severe metabolic acidosis, elevated lactate, and positive urinary ketones, a diagnosis of lactic acidosis and suspected euglycemic DKA was made. Patient was treated with DKA-protocol with insulin and fluid resuscitation, and N- acetylcysteine for acetaminophen induced liver toxicity. Metabolic acidosis markedly improved over the next 72 hours. Hypertriglyceridemia, transaminase elevations, and metabolic acidosis fully resolved during 6 week follow up visit.

Discussion: Severe hyperlipidemia reduces water content of plasma such that autoanalyzers utilizing indirect potentiometry requiring sample dilution, result in pseudohyponatremia. Direct potentiometry does not require sample dilution and measures true sodium concentration, however, plasma anion gap is reduced due to higher measured chloride concentrations with direct potentiometry. Therefore, physicians must be familiar with the laboratory methods to correctly interpret the plasma anion gap in mangagement of metabolic acidosis when using direct potentiomery measurements.

PO1165

Anion Gap Metabolic Acidosis on Continuous Renal Replacement Therapy: Are You Missing Something?

Mustafa Dawood, Vandana D. Niyyar. *Emory University School of Medicine, Atlanta, GA.*

Introduction: Anion gap metabolic acidosis is a common metabolic abnormality seen in the clinical practice. Causes includes Lactic acidosis, Ketoacidosis, Renal failure, volatile acid toxicity and salicylate poisoing. Ketoacidosis is due to decreased glucose and insulin availability leading to starvation ketosis and diabetic ketoacidosis respectively. Ketoacidosis is uncommonly seen in patients on prolonged continuous renal replacement therapy. We present 2 cases at Grady Hospital admitted with Acute hypoxic Respiratory Failure due to COVID 19 pneumonia, developed euglycemic ketoacidosis on Continuous Renal Replacement Therapy

Case Description: case 1: 73 male with the history of HTN, DM, CKD III admitted for acute hypoxic respiratory failure due to COVID 19 pneumonia. He was intubated on admission day 9. Course got complicated by hypotension during intubation leading to Acute Renal Failure on day 11. Patient was started on Renal Replacement Therapy on day 12 due to volume overload and acidosis. Day 19, Anion gap worsened and betahydroxybutyrate was elevated. Patient was started on insulin drip with resolution of acidosis on day 20. Case 2: 48 yo male with the history of HTN, DM II, CKD stage III admitted for Altered mental status, hypertensive emergency and cough. He was diagnosed with COVID 19 Pneumonia. Patient had non oliguric acute kidney injury on admission. Hospital day 11, patient was oliguric, volume overloaded and hyperkalemia prompted Renal replacement therapy initiation. Day 14, Anion gap worsened and betahydroxybutyrate was elevated. Tube feed were initiated and Dialysate prescription was reduced leading to resolution of anion gap on day 12.

Discussion: Diabetic ketoacidosis is a medical emergency commonly in patients with Type I DM but also in Type II DM patients as well. It occurs due to decrease insulin concentration or increase insulin resistance with or without decreased glucose availability leading to release of counterregulatory hormone and fatty acid metabolism producing ketoacids. Diagnostic criteria include pH <7.3, Serum HCO3 <18, Serum glucose >250 mg/dl and positive serum +/- Urine ketones. Euglycemic DKA is a subtype of DKA with serum glucose of <200 mg/dl. Incidence of Euglycemic DKA varies from 2.6-3.2%. Continuous renal replacement therapy is an under-recognized cause of Euglycemic DKA in patients with Diabetes Mellitus.

PO1166

A Wide-Awake Patient with Severe Hypoglycemia and Lactic Acidosis

Sarah Abdelsamad, Madhumita J. Mohanty, Mili J. Shah. *Wayne State University, Detroit, MI.*

Introduction: Severe hypoglycemia is associated with altered mental status or loss of consciousness. We report an intriguing patient who had advanced liver disease and presented with severe hypoglycemia and lactic acidosis without any alteration in mental status.

Case Description: 57-year-old female with severe decompensated alcoholic liver cirrhosis, ascites and recurrent hepatic hydrothorax presented to the Emergency Room with worsening shortness of breath. She had poor oral intake except for actively consuming ethanol. Chest X ray revealed worsening right hydrothorax. Routine blood tests revealed severe hypoglycemia (serum glucose 28mg/dL, severe anion gap metabolic acidosis (arterial pH 7.11, serum bicarbonate 6mmol/L, anion gap 40 mmol/L) and acute kidney injury with elevation of serum creatinine to 2.2 mg/dl. Subsequent laboratory investigation revealed serum lactic acid level of 23mmol/L. Serum ethylene glycol, methanol, salicylate and acetaminophen levels were undetectable. She had no seizures, malignancy or hypoxia. The patient was alert and oriented. She was hemodynamically stable. There was no evidence of sepsis, tissue hypoperfusion or bowel ischemia. She was not taking any medications which may have led to hypoglycemia or lactic acidosis. The patient was administered intravenous glucose with rapid improvement of her serum glucose and lactate level.

Discussion: This patient had no alteration in mental status despite severe hypoglycemia. Under normal circumstances, the brain primarily depends on glucose as the primary fuel. Studies have shown that under conditions of hypoglycemia and elevated serum lactic acid levels, lactate may serve as an alternative source of energy for the brain. We hypothesize that hyperlactatemia, by providing an alternate energy source, prevented mental status changes in this patient with severe hypoglycemia. Correction of hypoglycemia led to rapid correction of hyperlactatemia suggesting that perhaps lack of glucose may have contributed to hyperlactatemia. We did not identify any obvious cause of hypoglycemia or hyperlactatemia except for her end stage liver disease, continued ethanol use and perhaps also her oliguric acute kidney injury. This patient illustrates that hyperlactatemia may be neuroprotective in severely hypoglycemic patients.

PO1167

Sleeping Beauty: Hypersomnolence and Hyperammonemia in a Patient with Multiple Myeloma

Stephen P. Regina,[1] Roberto L. Collazo-Maldonado,[2] Muhammad R. Qureshi.[2] *[1]Methodist Health System, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Metabolic encephalopathy in a patient with multiple myeloma is commonly reported in association with prevalent biochemical syndromes such as uremia, hypercalcemia, and or hyperviscosity due to immunoglobulin, but very rarely hyperammonemia has been described as another cause of encephalopathy.

Case Description: The patient is a 45 year old woman with a prior diagnosis of multiple myeloma in July 2020. A bone marrow biopsy confirmed plasma cell neoplasm with 90% plasma cells, and SPEP was positive for monoclonal IgA kappa. The patient was brought to the hospital again in August 2020, with the chief complaint of worsening confusion and hypersomnolence over two weeks. Labs included hemoglobin 7.3 g/dL, serum calcium 13.8 mg/dL, chloride 108 mEq/L, bicarbonate 16 mEq/L with anion gap of 19, lactate 1.4 mmol/L, albumin 3.2 g/dL, and a CT of the head showed numerous lytic skull lesions, including a 3.8 cm posterior skull lesion with extraosseous intracranial extension. ABG showed pH 7.56, pCO2 24.5 mmHg, pO2 63.3. Hypercalcemia was treated with medical therapies and improved. The nephrology service was called due to metabolic acidosis. Given the respiratory alkalosis, a plasma ammonia level was checked and noted to be elevated at 89 umol/L. Imaging of the liver was not compatible with cirrhosis. The patient was given oral lactulose for several days without improvement. To address the hyperammonemia, the patient was transferred to the ICU to begin CRRT and she also required intubation due to unsustainable respirations. The plasma ammonia level improved while on CRRT but the patient had a grim prognosis, was not a candidate for chemotherapy, and the family elected to pursue palliative care.

Discussion: Hyperammonemia is a rare complication of multiple myeloma and is associated with high inpatient mortality. CRRT can treat hyperammonemia that is refractory to medical therapy (Gupta et al, CJASN 2016). However, hyperammonemia is a poor prognosticator in patients with multiple myeloma. Hyperammonemia should be included in the differential diagnosis of metabolic encephalopathy in patients with multiple myeloma.

PO1168

Renal Outcomes and Safety Profile of Direct Peritoneal Resuscitation (DPR)

Kiran Shivaraj, Michael D. Klein, George N. Coritsidis. *Westchester Medical Center, Valhalla, NY.*

Background: DPR is a novel technique used after damage control surgery where peritoneal dialysis fluid is continuously irrigated and drained from the peritoneal cavity in a open abdomen. This has been shown to improve intestinal perfusion, leading to faster abdominal closure. We analyzed the safety profile in terms of changes in the electrolyte profile.

Methods: This is a retrospective study of 17 patients who underwent DPR. All were treated using Dianeal 2.5% Ca 2.5 PD fluid for 2-16 days. The renal outcomes were analyzed. Patients who did not develop AKI were studied further. We evaluated changes in the serum sodium, potassium, phosphorus, calcium, and magnesium levels. The trend of creatinine was also evaluated.

Results: Our study showed that the AKI occurred in 11/17 patients (64.7%) of which 5 (45%) required renal replacement. Of the 6 patients without AKI, 3 had a rising trend of sodium which needed correction. Potassium trended downward slightly. All patients had low calcium even prior to initiation of DPR possible releated to the underlying clinical diagnoses, and the creatinine trended downward with levels remaining in the normal range.

Conclusions: Frequent AKI in these critically ill patients was not unexpected. It is plausible, though not demonstrated, that DPR by its mechanism of visceral vasodilation may have reduced this incidence somewhat. The trend toward higher sodium could be due to increased ultrafiltration effects. The downward trend of creatinine could have resulted from increased clearance by DPR. All the patients had decreased ionized calcium. Though present at the outset, the lower calcium bath may have contributed to its persistence. Magnesium, phosphorus and potassium remained stable. Due the convective and diffusive effects of the PD fluid used, safe use requires close monitoring of electrolytes and ultrafiltration to prevent volume shift and dysnatremia. Hypocalcemia can be mitigated by using a high calcium PD solution such as Dianeal 3.5% Ca.

Pyroglutamic Acidosis: Gaps in the Gaps

Roy Rajan, Martin Sedlacek. *Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.*

Introduction: Prolonged use of acetaminophen can lead to an acquired form of pyroglutamic acidosis, a form of anion gap metabolic acidosis (AGMA) from increased production of 5- Oxoproline (pyroglutamic acid). 5- Oxyproline accumulates in the body due to the failure its breakdown by 5- Oxoprolinase and is excreted in urine causing positive urine anion gap (AG).

Case Description: Case 1: First patient is a 59 y/o man with normal prior renal function with baseline creatinine (Cr) of 0.7mg/dl, admitted with severe pancreatitis. At the time of presentation his serum calcium level 15mg/dL (8.5-10.5) and his serum Cr level was 2.21 mg/dl. His hospital course was complicated by sepsis due to multiple intra-abdominal infections and required iv pressor and ventilator support. He was later started on continuous veno-venous hemofiltration (CVVH) temporarily with recovery of renal function. Acetaminophen 1 gram three times daily was administered for pain control. On the 65th day of hospitalization, his bicarb was 15 with an AG of 14, but when corrected for low albumin of 1.8, it increased to 20. HE had a positive urine AG and his urine 5-Oxyroline was 1583 mmol/mol Cr (range < 62). Case 2: Second patient is a 74-year-old man with a history of stage 4 CKD admitted with sepsis due to perforated viscus. He had long hospital course due to ischemic gut with continued bleeding and sepsis due to perforation. He was on Acetaminophen 1 gram four times daily for pain control. His serum bicarbonate started trending down to a nadir of 11 mmol/L on the 43rd day of admission. He had an anion gap of 12, but corrected anion gap was 18 and had a positive urine AG. His urine 5- oxyproline was 6361 mmol/mol creatinine (range <62).

Discussion: Both patients in our case series had critical illness, were malnourished, and was recovering from prolonged infection and sepsis which are risk factors for pyroglutamic acidosis and low serum albumin levels. Their AG might appear to be within normal range if not corrected for albumin. Urine anion gap is an indirect method of measuring urine ammonia excretion and is elevated in renal tubular acidosis and from excretion of organic anions like 5-Oxyproline and ketone bodies. Correction for AG is proposed as measured AG + 2.5× (“normal” albumin ~4.2 – measured albumin [g/dl]). This uncorrected “normal AGMA” with a positive urine AG due to pyroglutamic acidosis can mimic renal tubular acidosis and can be easily missed.

PO1170

Diffuse Large B Cell Lymphoma and Synchronous Colon Adenocarcinoma Presenting with Type B Lactic Acidosis Secondary to the Warburg Effect in a Hispanic Man

Daniel Varela,[1,2] Leonardo Pozo Garcia,[1,2] Daniela Hernandez,[1,2] Mourad Alsabbagh,[2] John Manllo,[3] Sergio A. Trevino Manllo.[3] *[1]The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; [2]DHR Health, Edinburg, TX; [3]South Texas Kidney Specialists, McAllen, TX.*

Introduction: Lactic acidosis is a major metabolic dysregulation characterized by hyperlactatemia and acidemia that is commonly associated with tissue hypoperfusion. In very rare circumstances, hematological malignancies have been associated with a paraneoplastic syndrome characterized by the modification of the metabolism of cancerous cells from aerobic to anaerobic glycolysis.

Case Description: A 61-year-old male presented to the hospital due to generalized body weakness. He was recently admitted to the hospital due to left knee pain; at that time incision, drainage, and tissue sample were done. The patient was discharged to home with wound care and antibiotics. On presentation, patient was found to be tachypneic, hypotensive with Kussmaul breathing. A warm erythematous lesion was seen on left lower extremity. Laboratory results showed WBC 20200/mm3, Hemoglobin 10 g/dL, Platelets 340 /mm3, creatinine 7.9 mg/dL, Bicarbonate 5 mmol/L, Lactate 6.21 mg/dL, and Ferritin 326 ng/dL, blood cultures positive for Enterobacter. Broad-spectrum antibiotics were administered. Nephrology consulted and dialysis started emergently. The pathology report showed Diffuse Large B-Cell Lymphoma. During the hospital stay, patient acidosis was persistent despite adequate renal replacement therapy and resolution of the septic process. ABG was done showing serum pH of 7.2, Bicarbonate 9 mmol/L, Lactic acid 17.5 mg/dL. Bowel ischemia was ruled out with CT angiogram however imaging showed neoplastic infiltration of peritoneal abdominal structures associated with multiple small nodules. Colonoscopy demonstrated synchronous colon adenocarcinoma. The decision was made to treat the patient with chemotherapy. One week after chemotherapy lactic acid trended down to 1.1 mg/dL. The metabolic acidosis and renal function improved and RRT was stopped.

Discussion: Usually, lactic acidosis is a sign of hypoperfusion and septic shock. In this case, the source of lactic acidosis was not hypoperfusion but rather a rare paraneoplastic syndrome that leads to anaerobic metabolism of malignant cells, known as the Warburg effect. This condition can be fatal. Prompt initiation of chemotherapy is recommended

PO1171

Distal Renal Tubular Acidosis in Patients with Autoimmune Diseases

Oana Ion,[1] Ioana Ailincai,[1] Georgiana Fratila,[1,2] Gener Ismail.[1,2] *[1]Institutul Clinic Fundeni, Bucuresti, Romania; [2]Universitatea de Medicina si Farmacie Carol Davila, Bucuresti, Romania.*

Background: Distal renal tubular acidosis (DRTA) is reported in association with autoimmune diseases. DRTA can evolve without symptoms and systemic acidosis, this form being defined as incomplete DRTA. The incomplete form necessitates the use of a urinary acidification test like the Furosemide and Fludrocortisone test for establishing the diagnosis.

Methods: We conducted a prospective observational study in a selected cohort of 48 patients diagnosed with autoimmune diseases (SLE, Sjögren syndrome, ANCA vasculitis, cryoglobulinemic vasculitis), who presented in our clinic from December, 2020 until May, 2021. The patients were submitted to Furosemide and Fludrocortisone test.

Results: The study included 48 patients (36 females, mean age 41.92 ± 15.7 years), diagnosed with SLE (33 patients), pANCA vasculitis (7 patients), cANCA vasculitis (1 patient), Sjögren syndrome (3 patients) and cryoglobulinemic vasculitis (4 patients). There was a significant difference regarding age ($p<0.001$) and eGFR ($p<0.001$) between the groups with vasculitis (mean age 60.7523roups with vasculitis ± 7.47 years, eGFR 41.66 ± 16.71 ml/min/1.73 m^2), SLE (mean age 35.18 ± 11.74 years, eGFR 73.24 ± 25.18 ml/min/1.73 m^2) and Sjögren syndrome (mean age 40.65 ± 20.03 years, eGFR 35.56 ± 17.24 ml/min/1.73 m^2). The test was positive for 11 patients out of 48. There was not a significant change in kalemia during the test ($p=0.860$). There was a significant increase in the level of serum bicarbonate (26.23 ± 3.5 mmol/l before the test vs 28.21 ± .13 mmol/l after the test, $p<0.001$) and also in the level of serum pH (7.36 ± 0.44 before the test vs 7.38 ± 0.43 after the test, $p=0.001$). None of the patients reported digestive or allergic side effects. There was not a significant difference regarding eGFR ($p=0.665$), proteinuria ($p=0.372$) and CRP ($p=0.246$) between the patients with or without a positive test. Regarding immunological activity, patients with a positive test had a higher ANA value at the moment of the test (4.71 ± 3.04 U/ml vs 2.50 ± 2.55 U/ml, $p=0.05$) and a lower C4 value (12.66 ± 9.39 mg/dl vs 23.4 ± 11.54 mg/dl, $p=0.016$).

Conclusions: Incomplete DRTA was found in 11 out of 48 patients with autoimmune diseases. None of the patients developed severe hypokalemia or metabolic alkalosis or any other side effect after Furosemide and Fludrocortisone test.

PO1172

Effect of Continuous Dialysis on Blood pH in Acidaemic Hypercapnic Animals with Severe AKI: A Randomized Experimental Study Comparing High vs. Low Bicarbonate Affluent

Thiago Gomes Romano G. Romano.[1,2] *[1]Sirio Libanes, research and teach institute, Sao Paulo, Brazil; [2]Faculdade de Medicina do ABC, Santo Andre, Brazil.*

Background: Controlling blood pH during acute ventilatory failure and hypercapnia in individuals suffering from severe acute kidney injury (AKI) and undergoing continuous renal replacement therapy (CRRT) is of paramount importance in critical care settings. In this situation, the concentration of sodium bicarbonate in dialysate is still an unsolved question in critical care since high concentrations may worsen carbon dioxide levels and low concentrations may not be as effective in controlling pH.

Methods: We performed a randomized, non-blinded, experimental study. AKI was induced in twelve female pigs via renal hilum ligation and hypoventilation by reducing the tidal volume during mechanical ventilation with the goal of achieving a pH between 7.10 - 7.15. After achieving the target pH, animals were randomized to undergo isovolemic haemodialysis with one of two concentrations of bicarbonate dialysate (40 mEq/L [*group 40*] vs. 20 mEq/L [*group 20*]).

Results: The haemodynamic, respiratory, and laboratory data were collected. The median pH value at CRRT initiation was 7.14 [7.12, 7.15] in *group 20* and 7.13 [7.09, 7.14] in *group 40* (P=ns). The median baseline $PaCO_2$ was 74 [72, 81] mmHg in *group 20* vs. 79 [63, 85] mmHg in *group 40* (P=ns). During the last hour of CRRT, the pH value was 7.05 [6.95, 7.09] in *group 20* and 7.12 [7.1, 7.14] in *group 40* ($P<0.05$), with corresponding values of $PaCO_2$ of 85 [79, 88] mmHg vs. 81 [63, 100] mmHg (P=ns). The difference in pH after three hours was due to a metabolic component [standard base excess: -10.4 [-12.5, -9.5] mEq/L in *group 20* vs. -7.6 [-9.2, -5.1] mEq/L in *group 40*) ($P<0.05$)]. Despite the increased infusion of bicarbonate in *group 40*, the blood CO_2 content did not change during the experiment. The 12-hour survival rate was higher in *group 40* (67% vs. 0, p=0.032).

Conclusions: A higher bicarbonate concentration in the dialysate of animals undergoing hypercapnic respiratory failure was associated with improved blood pH control increasing the $PaCO_2$ levels.

PO1173

CRRT-Associated Ketoacidosis: A Series of 5 Cases

Rushang Parikh,[1] Yuriy Khanin,[2] Rimda Wanchoo,[2] Purva D. Sharma.[2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Continuous renal replacement therapy (CRRT) is a dialysis modality used in critically ill patients with acute kidney injury (AKI). Although most dialysate and replacement fluids are dextrose-containing, CRRT-associated hypophosphatemia sometimes warrants the use of phosphorus containing solutions which are dextrose-free. As glucose is a small molecule which is readily cleared with dialysis, use of these solutions can result in increased dialysate caloric loss, net glucose deficit, and shifting of the metabolic pathway towards gluconeogenesis and ketogenesis. Starvation ketoacidosis can result, which at times can be severe.

Case Description: We describe five patients who developed worsening metabolic acidosis despite adequate clearance from CRRT, and were diagnosed with CRRT associated ketoacidosis (Figure 1 describes the clinical details, lab values and follow up of these patients) Administration of dextrose containing fluids or tube feeds promptly resulted in resolution of ketonemia and acidosis.

Discussion: These cases present an interplay of three processes ultimately culminating in a state of net glucose deficit: (1) decreased glucose supplementation in the critically ill patient, (2) increased clearance of glucose via CRRT with dextrose-free solutions and (3) AKI leading to deranged kidney gluconeogenesis. New HAGMA in patients on CRRT in the ICU can frequently be attributed to inadequate CRRT dose. The reflex increase in dialysate or replacement fluid flow rate is associated with a slew of problems including electrolyte abnormalities, decreased effectiveness of antibiotics due to increased clearance all of which can be detrimental to the patient. A new consideration that must be made when utilizing dextrose free CRRT fluids is CRRT associated ketoacidosis. Early identification of this diagnosis is important and easily reversible.

PO1174

A Patient with Combined Metformin-Induced Lactic Acidosis and Euglycemic Diabetic Ketoacidosis

Kamil Sardarli, Russell Leong, Inayat Gill, Sami S. Zarouk. *Beaumont Health, Royal Oak, MI.*

Introduction: Metformin is a small, non-protein-bound molecule that can cause lactic acidosis in 6 out of 100,000 patients with a mortality rate of 30-50%. Concurrent euglycemic diabetic ketoacidosis (DKA) from sodium-glucose co-transporter-2 (SGLT2) inhibitor has been reported in one case. We report a unique case of a patient with acute kidney injury (AKI) in the setting of metformin-induced lactic acidosis and osmotic diuresis due to euglycemic DKA complicated by celecoxib use.

Case Description: A 66-year-old female with a past medical history of type 2 diabetes mellitus for 21 years on metformin 1000 mg twice daily and empagliflozin 25 mg daily with baseline eGFR 51 mL/min/1.73m^2 5 months prior, who was also on celecoxib 200 mg daily for 40 days presented for elective cervical discectomy which was canceled due to AKI. On exam, blood pressure was 119/59 mmHg, pulse was 92 beats/min, and the temperature was 36.1°C. She was tachypneic at 24 breath/min. Labs showed sodium 136 mg/dL, potassium 8.4 mg/dL, bicarbonate 9 mg/dL, BUN 83 mg/dl, creatinine 8.78 mg/dL, and glucose 117 g/dL. Lactic acid was 13.5 mmol/L, beta-hydroxybutyrate 5.9 mmol/L, serum osmolality 336 mOsmol/kg with no osmolar gap. She underwent conventional hemodialysis (HD) for 3 hours followed by 18 hours of continuous kidney replacement therapy (CKRT). She required an insulin drip with 5% dextrose in normal saline for 24 hours. Lactic acid was 3.8 mmol/L after 24 hours. Creatinine improved to 2.46 mg/dL on day 4 without further intervention. She was discharged home off metformin, empagliflozin, and celecoxib.

Discussion: Metformin is readily dialyzable but has a large volume of distribution. There is no specific antidote available to reverse the toxic effects of metformin or consensus on the modality of renal replacement therapy. Previously demonstrated biphasic elimination pattern of metformin intoxication suggests that a brief HD session is not sufficient to eliminate metformin due to a rebound phenomenon, but it is essential to correct severe acidosis and electrolyte derangements. Hyperkalemia required the use of HD which needed to be followed by CKRT as a more physiological way to maximize metformin removal and prevent ongoing lactic acid production. We suggest prudence in the combination of metformin with SGLT2 inhibitor use, specifically in patients exposed to nephrotoxic drugs or procedures.

PO1175

Mind the Gap: An Anion Gap of 52 Fully Explained

Uma Mahesh R. Avula, Liliia Harris, Tariq Shafi, Neville R. Dossabhoy. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: The Anion Gap (AG) remains the main clinical tool to elucidate acid-base disturbances in patients with metabolic acidosis. We present a case with an extremely elevated AG of 52 mmol/L, and describe our search for its biochemical explanation.

Case Description: A 66-year-old female was admitted with loss of consciousness, shock, and severe acute kidney injury. She had type 2 diabetes mellitus, treated with metformin. At presentation, she had an AG of 52 mmol/L and osmolal gap of 34 mOsm/kg. Her arterial blood gas showed: pH <7, HCO3 7.5 mmol/L, pCO2 16 mm/Hg. Phosphorus level was unusually high, 21.3 mg/dL, with unknown etiology. There was no history of enema or laxative use. A significant contributor of AG was lactate at 14.5, given her history of metformin use. Urine drug screen was positive for amphetamines. The volatile alcohol panel was positive for acetone; methanol, ethanol, ethylene glycol and isopropyl alcohol were not detected. Continuous venovenous hemofiltration (CVVH) was initiated. After 3 days, renal function started recovering, lactate and phosphorus levels normalized and AG closed. The patient did not need CVVH thereafter. Two months later, the patient was discharged to a nursing facility in a stable condition.

Discussion: Extremely elevated AG of 52 in this patient can be explained by a rise in concentrations of organic acid anions, lactate, ketoacids, hyperphosphatemia, and retention anions.

AG 52 **Albumin cAG 55**	Lab values **Sodium 135 mmol/L, Chloride 76 mmol/L, Bicarb 7 mmol/L, Phosphorus 21.3 mg/dL, Albumin 3.2 g/dL, Lactate 14.5 mmol/L, β-hydroxybutyrate 8.17 mM**
Contributions to Anion Gap, mmol/L	Explanation
P/ 12.36	([Lab phosphorus, mg/dL*10] / 31 (molecular weight of phosphorus)) * 1.8 (average valency depending on pH) [(21.3 *10)/31] * 1.8 = 12.36 mM/L
Lactate 14.5	Lactate is univalent and not influenced by pH Measured lactate = contribution to AG=14.5 mM/L
βHB 8.17	β-hydroxybutyrate is univalent and not influenced by pH Measured βHB = contribution to AG = 8.17 mM/L
Normal AG 12	Unmeasured anions Various inorganic and organic anions
Remaining AG 7.97	Accumulated anions due to severe Acute Kidney Injury (creatinine 12.4 at presentation) (sulphate and hippurate)

Explanation of the high AG: The Figure describes the calculation of AG. In this patient, phosphate was a major contributor to the AG.

PO1176

Is an Increase in Anion Gap a Predictor of Hemodialysis Initiation in Patients with Advanced CKD?

Hikaru Kukimoto, Kazuhito Fukuoka, Soko Kawashima, Noriko Ikegaya, Takahisa Kawakami, Mitsumasa Kishimoto, Yoshinori Komagata, Shinya Kaname. *Kyorin Daigaku, Mitaka, Japan.*

Background: Because uremic symptoms and manifestations vary among patients with advanced chronic kidney disease, it is sometimes difficult to decide on the timing of dialysis initiation only from them. Thus, we attempted to investigate whether anion gap (AG) that may reflect the accumulation of total organic acids in uremia can be a marker of uremia and may predict the timing of dialysis initiation.

Methods: This study included pre-dialysis patients who attended to our hospital for more than six months prior to the beginning of hemodialysis (HD), and retrospectively analyzed the relationship between their serological data, AG, and various uremic symptoms. The AG was calculated as the corrected AG (cAG) = Na-Cl-HCO_3 [nmol/L]+2.5 x (4-serum albumin concentration [g/L]). The statistical analysis was performed by logistic regression analysis, correlation analysis, and factor analysis using SPSS®.

Results: A total of 283 patients [diabetes mellitus: 136 (48.1%), nephrosclerosis: 66 (23.3%), glomerulonephritis: 36 (12.7%)] were included in this study. The most common clinical symptom before dialysis initiation was fluid overload, which was seen in 134 patients (47.3%), followed by anorexia 104 patients (36.7%) and general malaise 96 patients (33.9%). The cAG began to increase 3 months before the initiation of HD (14.2 mmo/L), which showed a rapid increase just before the initiation, and was correlated with anorexia and fatigue, better than fluid retention. Of note is that cAG was most significantly associated with dialysis initiation among various factors. The ROC of cAG for dialysis initiation showed the highest value of AUC 0.797 (95% CI=0.72 to 0.85, p=0.05), with a cutoff value of adjusted cAG 15.975 (sensitivity 0.689, specificity 0.786).

Conclusions: Uremic symptoms and some serological markers including azotemia, metabolic acidosis, and hyperphosphatemia have been usually used to predict the magnitude of uremia and the timing of dialysis initiation. In our study, it is suggested that a rapid increase in cAG over 16 mEq/L may also be a good predictor of dialysis initiation within the subsequent 3 months.

PO1177

Mysterious Case of Recurrent Life-Threatening Lactic Acidosis

Zakir Shaik, Waqas Ahmad Khan, Ajay D. Rao, Jean Lee. Temple University Hospital *Temple University Health System Inc, Philadelphia, PA.*

Introduction: Patients living with diabetes are prone to type-B lactic acidosis, often presenting with profound acid-base derangements. The reason for lactate production is not obvious hence management can be challenging. We present a case of life-threatening recurrent lactic acidosis in a diabetic patient.

Case Description: A 67-year-old man with type 2 diabetes, hypertension, presented to the hospital with malaise for 2 days. He had been on metformin in the past but had recently switched to insulin. There was no history of alcohol ingestion nor use of herbal supplements. The lactic acid level was 24.2 mmol/L with Ph of 6.82, PCO2 of 27 mmHg, serum bicarb of 7 mEq/L, anion gap of 28, and serum Cr of 1.4 mg/dL with baseline of 1 mg/dL. No evidence of infection or ischemia found. Toxicology screen was negative and serum metformin level was undetectable. Lactic acidosis resolved with continuous renal replacement (CRRT) for 24 hours. A month later he returned with similar complaints

and his lactate level was 14.8 mmol/L. This was treated with supportive care alone. Six months later he returned again with lactate of 13.5 mmol/L, worsening to 18.6 mmol/L. He improved after treatment with CRRT and supportive care. Alcohol levels, liver function tests, pyruvate, glutamate, metformin levels were all negative or normal. The thiamine level was not checked during his first admission. During the second visit, the value was normal but this was drawn after thiamine had been given. During the third visit, the thiamine level was noted to be less than 6 nmol/L. The patient was started on thiamine and has not had further episodes of lactic acidosis.

Discussion: Patients with diabetes are prone to excess lactic acid generation due to the derangement in mitochondrial oxidative phosphorylation with relative hypoxia at the microvascular level. In addition, it has been noted that many diabetics are thiamine deficient. In the absence of thiamine, pyruvate cannot enter the Krebs cycle and is converted to lactic acid predisposing diabetics to type-B lactic acidosis. Thiamine is filtered in the glomerulus and is reabsorbed in the proximal tubule through the thiamine/H+ antiporter. Long term use of diuretics has been associated with thiamine deficiency. However our patient was not taking any nor did he have chronic kidney disease or any evidence of malnutrition.

PO1178

Serum Bicarbonate and Gait Abnormalities in Older Adults

Jim Q. Ho, Joe Verghese, Matthew K. Abramowitz. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Low serum bicarbonate levels are associated with slow gait speed in older adults. However, the association between serum bicarbonate and other quantitative gait markers is unknown.

Methods: Quantitative gait assessments were performed on 330 community-dwelling, nondisabled adults ≥65 years old. Serum bicarbonate was categorized into tertiles (≤24, 25-27, ≥28 mEq/L). The relationship between bicarbonate and gait markers was investigated with multivariable linear regression adjusting for demographics, comorbidities including COPD, medication use, smoking status, BUN, and eGFR (CKD-EPI). Factor analysis on eight gait markers was performed to synthesize individual gait characteristics into unifying domains. CKD was defined as eGFR<60 mL/min/1.73 m^2.

Results: There were 116 (35%), 146 (44%), and 68 (21%) participants in the low (mean bicarbonate 22 mEq/L), middle (26 mEq/L), and high (29 mEq/L) bicarbonate tertiles, respectively. After multivariable adjustment, compared with participants in the middle tertile, those in the low tertile had significantly slower speed (8.4 cm/s [95% CI 3.1-13.8]), shorter stride length (7.7 cm [95% CI 3.4-12.1]), and longer time in the double support phase of the gait cycle (0.03 s [95% CI 0.002-0.05]). Within the lowest tertile, there was a graded association of lower bicarbonate with greater severity of gait deficits (Figure 1). Associations were similar when limited to participants with CKD. Associations remained significant after additional adjustment for muscle strength, cognitive function, sensory nerve function, and balance. No significant associations were found for the high tertile or for other gait markers (e.g., cadence). Factor analysis produced 3 independent gait domains: pace, rhythm, and variability. Compared with the middle tertile, the low tertile had significantly poorer performance in the pace domain (0.3 standard deviation [95% CI 0.1-0.6]).

Conclusions: Low serum bicarbonate is associated with gait abnormalities in older adults.

Funding: Other NIH Support - NIA

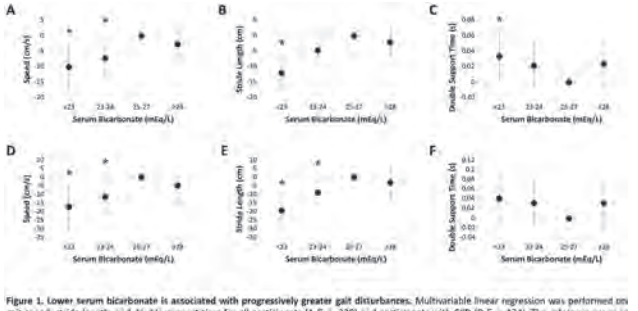

Figure 1. Lower serum bicarbonate is associated with progressively greater gait disturbances. Multivariable linear regression was performed on gait speed, stride length, and double support time for all participants (A-C, n=330) and participants with CKD (D-F, n=134). The reference group is serum bicarbonate 25-27 mEq/L (middle tertile). Models were adjusted for age, sex, race, education, smoking status, BMI, number of comorbidities, number of medications, diuretic use, diagnosis of neuropathy, cardiovascular disease, hypertension, diabetes, COPD, BUN, and eGFR (CKD-EPI). Error bars denote 95% confidence intervals. Asterisks denote $P < 0.05$.

PO1179

Bicarbonate Target in Treating Renal Acidosis: Is Higher Better?

Ashraf Dwal. *Ochsner Medical Center - New Orleans, New Orleans, LA.*

Background: Metabolic acidosis is commonly seen in patients with CKD from a decrease in ammonium excretion which gets buffered by the extracellular bicarbonate, hence, low plasma carbon dioxide is a surrogate of acidosis. treatment of acidosis (usually sodium bicarbonate to decrease the progression of, maintain bone health, nutrition status, In clinical practice, we aim for plasma bicarbonate of ≥ 22 mmol/L, the upper limit target is unclear.

Methods: This was a single-center retrospective chart review of CKD patients with acidosis from 2010-2017. Inclusion criteria were adult patients receiving NaHco3 for CKD-associated acidosis with baseline estimated glomerular filtration rate (eGFR) ≥25 and < 60 ml/min/1.73 m^2 when starting NaHco3. Patients with glomerulonephritis, kidney transplant, acute kidney injury (not back to at least 75% of (eGFR) baseline) were excluded. Four groups were identified for comparison based on mean serum Co2 (in mmol/L), from outpatient measures during 3 years follow-up, group A (< 22), group B (22 - < 24), group C (24 - <25), and Group D (≥ 25). Albumin, urine protein-creatinine ratio (UPCR), PTH, and eGFR were compared, p-values are calculated by a one-way ANOVA model.

Results: There were 383 patients with CKD-associated acidosis receiving NaHco3, 93 patients qualified for the study. Group A (n=21), group B (n=41), group C (n=13), and Group D (n=18). Racial demographics: 35=black (38%), 57=white (61%), 1=Other. Females 49 (53%). Median age 69 years. Follow-up 3 years. At baseline mean eGFR, UPCR, and albumin, and diuretics use and osteoporosis diagnosis in the four groups were similar (p = 0.46, 0.32, 0.15, 0.09, 0.36 respectively). Mean hemoglobin A1C in each group did not exceed 8.2. At 3 years of follow-up, changes in eGFR, UPCR, and osteoporosis status between the four groups were similar (p ≥ 0.14, ≥ 0.27, ≥ 0.19 respectively). Change of albumin was significantly worse in group A comparing to groups B, and C (p = 0.007, 0.049 respectively), and average PTH was significantly worse in group A comparing to group C (p = 0.045).

Conclusions: In our cohort, all groups of treated CKD-associated acidosis (B, C, and D) showed no statistical difference in CKD progression, the severity of parathyroidism, developing osteoporosis, or nutrition status assessed after 3years follow-up. Hence, higher Co2 targets don't carry worse outcomes.

PO1180

Acute Metabolic Alkalosis due to Citrate-Containing Oral Rehydration Solution

Megan Chalupsky,[1] Sydnie Espiritu,[1] Shubha Ananthakrishnan,[2] Baback Roshanravan,[2] Brian Y. Young.[2] *[1]University of California Davis Department of Internal Medicine, Sacramento, CA; [2]UC Davis Department of Nephrology, Sacramento, CA.*

Introduction: Patients with ileostomies have high obligatory gastrointestinal (GI) losses, predisposing to volume depletion and electrolyte derangements. Over-the-counter oral rehydration solutions (ORS) are advertised for dehydration. We present a case of acute metabolic alkalosis associated with an ORS containing citrate.

Case Description: 66 year old man with Crohn's disease, status post small bowel excision, sigmoid colectomy with Hartman's pouch, and ileostomy presented with weight loss and hypotension. He had high output ileostomy loss of > 3 L per day. Initial lab work showed acute kidney injury (AKI), hyponatremia, hypokalemia, and metabolic alkalosis. Nephrology obtained history that for several months he consumed about 8-10 ORS packets daily (Figure). The patient was treated with IV 0.9% sodium chloride, potassium repletion, and cessation of ORS, which resulted in complete resolution of his metabolic disturbances.

Discussion: We present a novel case of acquired acute metabolic alkalosis due to consumption of citrate containing ORS. In the body, 1 citrate is converted by liver, kidney, and muscles to 3 bicarbonate equivalents. Our patient's volume contraction and pre-renal AKI due to high GI output resulted in elevation of aldosterone leading to increased urine potassium excretion, and alkalosis secondary to augmented ammonia excretion. This was compounded by the high citrate load and low GFR. The ORS distributor would not disclose the full amount of citrate per packet despite several contact attempts. Each standard size ORS contains 330 mg of sodium. Presuming similarity to prescription sodium citrate-citric acid solutions, which are 1:1 equimolar sodium and bicarbonate equivalent, we estimate a minimum bicarbonate equivalent of 14.3 mmol per ORS packet, or 143 mmol daily for our patient. This is before accounting for contributions of potassium and magnesium citrate components, thus potentially higher. We recommend cautious use of citrate-containing ORS, particularly in patients with risk for severe volume depletion and AKI.

	Admission Value
Blood	
Sodium (mmol/L)	130
Potassium (mmol/L)	2.3
Chloride (mmol/L)	66
Total CO2 (mmol/L)	43
BUN (mg/dl)	47
Creatinine (mg/dl)	2.27 (baseline 1.03)
Urine	
pH	7
Sodium (mmol/L)	< 10
Potassium (mmol/L)	57
Chloride (mmol/L)	< 15

PO1181

Pseudo-Hypobicarbonatemia with Severe Hypertriglyceridemia Corrected by Insulin Infusion

Noah J. Poznanski, Howide Eldib, Ahlim Al sanani. *Marshall University Joan C Edwards School of Medicine, Huntington, WV.*

Introduction: Anion gap metabolic acidosis (AGMA) is a condition characterized by low serum bicarbonate and unaccounted anions in the blood. Lactate or ketones are the most common anions causing AGMA. Severe hypertriglyceridemia and paraproteinemia can result in Pseudo-hypobicarbonatemia due to interference by these components when the commonly used enzymatic assay is utilized for serum bicarbonate measurement. The calculated bicarbonate derived from blood gas machines show accurate bicarbonate level. It is very important to recognize Pseudo- hypobicarbonatermia to avoid expensive work-up.

Case Description: A 42-year-old-male patient with a past medical history significant for diabetes mellitus type 2, obesity, and hyperlipidemia. The patient presented with nausea, vomiting and epigastric pain. Physical examination was significant for tenderness in the epigastrium and xanthelasma. The basic metabolic profile (BMP) was significant for Na^+ 127meq/L, Cl^- 94mEq/L, $HCO3^-$ 9mEq/L, glucose 408mg/dL, BUN 10mg/dL, creatinine 0.87mg/dL and AGAP 24. A lipid panel showed a cholesterol 461mg/dL and triglycerides 4061mg/dL. Lipase and amylase were 1183U/L and 202U/L respectively. Urinalysis revealed trace ketones. CT abdomen revealed peripancreatic stranding. The patient was diagnosed with AGMA due to diabetic ketoacidosis and pancreatitis secondary to hypertriglyceridemia. An arterial blood gas analysis (ABG) subsequently revealed a pH 7.39, paCO2 40, PaO2 73 and a HCO3- 24. A significant dissociation between the calculated and measured bicarbonate was noted. Following aggressive lowering of the triglycerides, with Insulin infusion there was an immediate resolution of the pseudo-hypobicarbonatemia and anion gap metabolic acidosis.

Discussion: This measurement error is due to the mechanism by which the analyzer interprets the bicarbonate level in the serum. Most analyzers utilize either anion-selective electrode (ISE) or function via an enzymatic/photometric method. High amounts of lipid particles may cause light scattering altering the photometric analysis. This likely caused the discrepancy between the enzymatic/photometric measured serum bicarbonate and the calculated bicarbonate of the aqueous phase ISE analyzer used by the ABG. Clinicians should be able to recognize that its essential to obtain a blood gas sample for determination of the acid-base status to avoid expensive work up.

PO1182

Pseudohypobicarbonatemia in a Patient with Paraproteinemia

Marvi M. Bukhari,[1] Cary R. Boyd-Shiwarski,[2] Blaise W. Abramovitz.[2] *[1]UPMC Mercy, Pittsburgh, PA; [2]University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA.*

Introduction: The first step in acid-base disorders' diagnosis is obtaining measurement of blood bicarbonate (HCO3-), pH and partial pressure of carbon dioxide (pCO2) levels. Blood HCO3- levels are estimated via two methods: direct measurement of serum total carbon dioxide (TCO2), or via Henderson-Hasselbalch equation using arterial blood and directly measuring pH and pCO2 levels. With the enzymatic method, there have been reported cases of falsely low serum HCO3- due to interference by elevated triglyceride levels, but only two cases have been reported of spuriously low serum HCO3- due to interference by paraproteins.

Case Description: A 74-year-old male with a history of bladder carcinoma in situ and hypertension presented with complaints of malaise after a recent bladder irrigation. Basic metabolic panel (BMP) was unremarkable except for a HCO3- of 8 mmol/L measured using a Siemens Vista (SV) enzymatic chemistry analyzer. He was hospitalized for high anion gap metabolic acidosis with anion gap of 22. He was started on intravenous NaHCO3 (150 mEq/L) after nephrology was consulted. Repeat serum HCO3- was 11 mmol/L the next day with transition to oral NaHCO3 650 mg therapy thrice daily. On outpatient follow-up, he had low serum HCO3- ranging from 8-11 mmol/L (using SV analyzer) despite his reported compliance with NaHCO3. He was evaluated by another nephrologist with repeat BMP and an arterial blood gas (ABG). The results revealed a serum HCO3- of 8 mmol/L in contrast with ABG pH of 7.41 and HCO3- of 25 mmol/L. Due to the discrepancy, his serum HCO3- was analyzed at a different facility using a Beckman Coulter analyzer which revealed a normal serum HCO3- level of 21 mmol/L. Further work up was pursued with SPEP and SIFE revealing an M-spike and presence of IgM and IgA kappa monoclonal proteins respectively, which led to a diagnosis of monoclonal gammopathy.

Discussion: Paraproteins have been reported to cause interference with multiple laboratory test results. Paraproteins in our case may have resulted in artifactual error of serum HCO3- by direct interaction with assay reagents, binding of paraproteins to an assay reagent, or turbidity caused by precipitation of the monoclonal proteins. Our case highlights the importance of being aware of this phenomenon of pseudohypobicarbonatemia that can occur with certain chemical analyzers.

PO1183

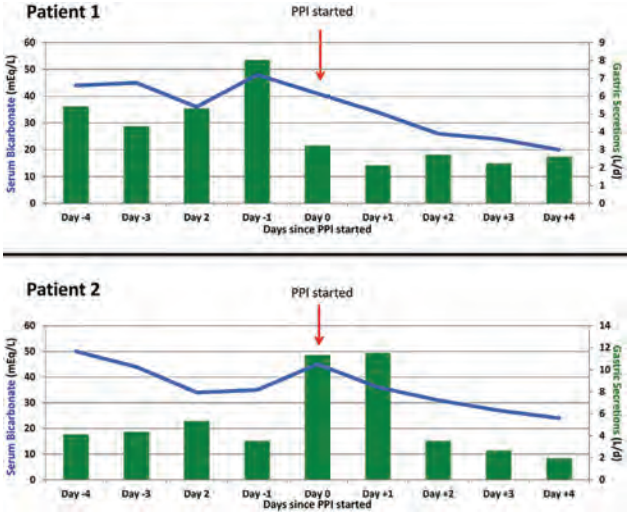
Proton Pump Inhibitor (PPI) for the Treatment of Metabolic Alkalosis due to Gastric Losses

Raphael J. Rosen, Heedeok Han, Sindhuri Prakash-Polet, Yonatan A. Peleg. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Gastric losses of hydrochloric acid can result in severe metabolic alkalosis (met alk). We describe two cases where patients with significant losses of gastric secretions presented with severe met alk and AKI. In both cases, PPI therapy was used to reduce the volume of the gastric secretions with excellent effect.

Case Description: Patient 1: A 44 year-old woman with Gardner Syndrome with near-total enterectomy and colectomy on total parenteral nutrition with a venting gastric tube (G-tube), presented with met alk (HCO_3 50 meq/L) and AKI (Scr 4 mg/dL from baseline 1.3 mg/dL). Met alk persisted despite normal saline (NS) administration and gastric tube losses ranged from 4-8 liters per day. Twice daily intravenous PPI was started with immediate decrease of gastric losses and normalization in HCO_3. This patient was admitted one year later (off PPI therapy) with a similar derangements and resuming PPI therapy caused similar improvement. Patient 2: A 59 year-old man with gastric outlet obstruction and venting G-tube presented with met alk (HCO_3 47 meq/L) and acute kidney injury (SCr 4.5 mg/dL from 1.3 mg/dL). Met alk persisted despite NS administration and his gastric tube losses ranged from 4-11 liters per day. Daily intravenous PPI was started with decrease of gastric losses and normalization of HCO_3. This patient presented again to the hospital one month later with normal HCO_3, on PPI therapy. Both patients' bicarbonate and gastric fluid output trend relative to PPI therapy is detailed in figure 1.

Discussion: There are few reported cases of PPI therapy for metabolic alkalosis due to gastric losses. Generally, met alk that occurs due to gastric losses is readily rectified by increased renal bicarbonate excretion, but this compensatory mechanism is limited in the setting of AKI. We report two cases in which PPI therapy successfully decreased the quantity of gastric fluid losses and rapidly improved metabolic alkalosis.



PO1184

A Case of Extreme Metabolic Alkalosis

Muhammad S. Ajmal. *Baylor College of Medicine, Houston, TX.*

Introduction: Metabolic alkalosis results from an increase in serum bicarbonate concentration due to loss of hydrogen ions and/or gain in bicarbonate ions. We present a case of extreme metabolic alkalosis due to multiple etiologies rarely co-existing.

Case Description: A 30-year-old male with Duchenne muscular dystrophy, chronic respiratory failure on mechanical ventilation via tracheostomy, gastrojejunostomy (G-J) tube dependent and genetic cardiomyopathy presented with drowsiness and lethargy for last 2 days per mother. His tube feed regimen was Nutren 1 can with 120 cc free water 4 times/day. He was recently started on Lasix 20 mg daily. Initial labs showed blood PH of 7.81, bicarb 66 and PCo2 53. He had AKI with Creatinine (Cr) of 2.66, BUN 266 and Cystatin C 11. His baseline Cr was 0.9-1.1. UA showed 3+ protein and no sediment. Urine (Ur) sodium 87, Ur chloride <15, Ur Cr <10 and Ur PH was 9. Chest Xray showed cardiomegaly with mild venous congestion and kidney ultrasound showed bilateral small echogenic kidneys. He was treated with normal saline (NS) IV @100 cc/hr, acetazolamide IV, potassium IV, proton pump inhibitor to decrease gastric acid and minute ventilation was decreased to allow for compensatory hypercapnia. AKI improved with adequate diuresis and PH normalized (Image 1) by day 5. He had hypernatremia after 24 hours of IV NS and fluid were changed to hypotonic + free water via G-J tube. High daily output of ~700cc was recorded from the G-J tube. He was discharged home without diuretics and tube feeds were changed to Suplena + increase free water but was re admitted in 1 week with hyponatremia and severe metabolic alkalosis. He underwent G-J tube exchange during 2nd admission followed by persistent normalization of blood PH.

Discussion: This is a unique case of extreme metabolic alkalosis primarily due to the loss of gastric acid in the G-J tube, but volume depletion, hypokalemia, AKI, high protein tube feeds, lack of respiratory compensation due to ventilator dependence and loop diuretics contributed to the development and maintenance of metabolic alkalosis.

We corrected his metabolic alkalosis and AKI with cautious use of IV fluids and Acetazolamide without needing dialysis, although metabolic alkalosis relapsed until the G-J tube was changed.

	PH	Bicarbonate	Creatinine	BUN	Sodium	Potassium
Day 1	7.81	64	2.47	266	147	2.7
Day 2	7.65	56	2.47	191	162	3.3
Day 3	7.50	36	1.25	97	149	4.1
Day 5	7.37	28	0.75	51	145	3.1

Daily PH and Cr

PO1185

Hypercalcemia and Metabolic Alkalosis Induced by the Novel Potassium Binder Patiromer: Report of Rare Event

Kathryn J. Suchow, Swetha Rani Kanduri, Juan Carlos Q. Velez. *Ochsner Medical Center - New Orleans, New Orleans, LA.*

Introduction: Patiromer is a calcium (Ca)-potassium (K) exchange resin approved for the treatment of hyperkalemia. Disorders of Ca or acid base balance were not reported in pre-approval clinical trials. Post-marketing, only 2 case reports of hypercalcemia associated with the use of patiromer have been recently published. We present a case of a patient with chronic kidney disease (CKD) with an unusual picture of hypercalcemia, metabolic alkalosis and hypokalemia upon intensification of patiromer dosing.

Case Description: A 56-year-old white man with CKD stage 4 (baseline creatinine 2.8 mg/dL) due to type 1 diabetes mellitus, proteinuria (1.5 g/g) and persistently high serum potassium (sK, 5.5 – 5.9 mEq/L) attributed to type 4 renal tubular acidosis was evaluated in clinic. Due to high risk of CKD progression, patiromer 8.4 g qd was prescribed to enable RAS blockade. Five months later, sK remained elevated at 5.0 mEq/L. Patiromer dosage was thus increased to 16.8 g qd. Three months later, sK fell to 4.1 mEq/L. Hence, patiromer was maintained at 16.8 g qd and irbesartan initiated. At that time, corrected serum calcium (sCa) was 9.3 mg/dL and serum bicarbonate ($sHCO_3$) 26 mEq/L. Five months later, routine laboratory tests revealed a sK 2.5 mEq/L, sCa 12.6 mg/dL and $sHCO_3$ 34 mEq/L. The patient denied recreational or over-the-counter drugs, diuretics or calcium supplements. Patiromer was discontinued. Thorough investigation (PTH, PTH-related peptide, 1,25-OH-vitamin D, 25-OH-vitamin D, TSH, serum protein electrophoresis, free light chains, cortisol and ACTH) was negative for other causes of hypercalcemia. Five days later, sK was 4.1 mEq/L, sCa 7.7 mg/dL and $sHCO_3$ 32 mmol/L.

Discussion: Patiromer promotes gastrointestinal elimination of potassium by binding of the molecule to potassium in exchange for calcium. Increased in intestinal absorption of calcium results in hypercalciuria but not sustained hypercalcemia. The clinical course of our patient suggests that the increased dose of patiromer led to a profound exchange of calcium and potassium ions leading to hypercalcemia, iatrogenic hypokalemia and resulting metabolic alkalosis. The role of secondary hyperparathyroidism in this case remains unclear. We recommend cautious vigilance of patients receiving patiromer and undergoing dose escalation

PO1186

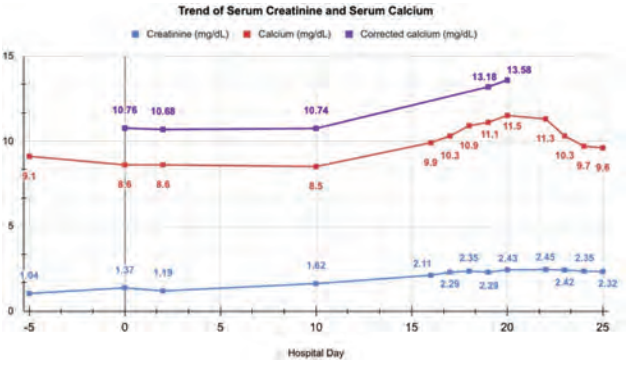
Beads of Calcium

Nityasree Srialluri, Karla G. Carias Martinez, Elizabeth Kiernan, Jose M. Monroy-Trujillo. Hopkins Nephrology *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Hypercalcemia is a common disorder that can cause acute kidney injury (AKI) and result in significant morbidity and mortality.

Case Description: A 50-year-old male with diabetes and hypertension presented with left knee septic arthritis. He had an AKI from volume depletion and vancomycin toxicity (trough level 35.1). Incision and drainage (I&D) was done on day 13 for refractory knee infection. Postoperatively, serum creatinine (Cr) and Calcium (Ca) rose to peak Cr of 2.45mg/dL (baseline 1.04mg/dL) and a corrected Ca of 13.58mg/dL. Workup showed PTH-rP 14pg/mL, PTH 8pg/mL, 1,25-Dihydroxy Vitamin D 13pg/mL, 25-Hydroxy Vitamin D 29pg/mL and normal SPEP. Kappa/Lambda ratio was 1.55. SIFE showed IgG Kappa Monoclonal gammopathy and lambda free light chain proteinemia. Given normal SFLC and an unquantifiable M-Spike, it was ascribed to monoclonal gammopathy of undetermined significance. Recent studies including, MRI cervical, thoracic, lumbar spine, CT chest, abdomen, pelvis, and left lower extremity, did not show lytic lesions. Urine sediment showed calcium oxalate crystals. These results ruled out primary hyperparathyroidism, hypervitaminosis D, paraneoplastic syndrome, and granulomatous disease. Serum Ca improved with intravenous fluids and furosemide. It was found that in I&D, 20cc of stimulan spacer was placed, which can cause hypercalcemia. Hypercalcemia coincided with spacer placement.

Discussion: Hypercalcemia has been reported with antibiotic-eluting calcium sulfate beads (CSBs) such as stimulan in several case reports and a large cohort assessing antibiotic spacers. CSBs are used for periprosthetic joint infections for new bone formation or local antibiotic delivery. Agitation of the beads during washout is hypothesized to cause postoperative hypercalcemia. Thus, it is necessary to monitor serum Ca and Cr levels with CSBs placement. Patients with intrinsic calcium or parathyroid disorders, prolonged immobility, existing renal impairment, or critical illness are at elevated risk of developing hypercalcemia and should be observed closely.



PO1187

Prediction of Ionized Hypocalcemia and Hypercalcemia: External Validation of a Novel Model

Jie Ouyang,[1] Yohannes Melaku,[1] Isha Puri,[1] Ernie Yap,[1] Philip Goldwasser.[2] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]VA New York Harbor, Brooklyn, NY.*

Background: The popular adjustment of serum total calcium (tCa) for albumin (Alb) yields a corrected value (cCa) that doesn't detect abnormal ionized calcium (iCa) well in critical care patients (pts), possibly because it ignores the fraction of tCa complexed by small anions. To account for such anions, we derived a model that estimates iCa (iCa_{EST}) by adjusting tCa for Alb and the anion gap's 3 components, Na, Cl, and tCO_2. It was far better than cCa in detecting low iCa (↓iCa) on internal validation (Yap, JALM 2020). In this study, we externally validated iCa_{EST} in a large, publicly available critical care database.

Methods: From the MIMIC III v1.4 database, we paired chemistry panel tCa (mg/dL), Alb (g/dL), Na, Cl, and tCO_2 values with gas panel iCa values (ref range: 1.12-1.32 mM) measured up to 20 min. apart. Limiting each pt. to the most closely-timed pair left 4105 pairs (median:10 min apart). We calculated cCa (tCa +0.8×[4-Alb]) and iCa_{EST} (0.219 +0.091×tCa -0.034×Alb -0.0042×Na +0.0073×Cl +0.0047×tCO_2) and compared their ROC curves (area±SE) for detecting ↓iCa (iCa<1.10; rate=33.1%), and high iCa (↑iCa) (iCa>1.32; rate=3.8%).

Results: ICa_{EST} was better than cCa by ROC analysis for both ↓iCa (0.834±0.007 vs 0.752±0.008, $p<10^{-300}$) and ↑iCa (0.975±0.004 vs 0.963±0.006, p<.0006). The table compares the sensitivity and specificity (SENS/SPEC) and positive and negative predictive values (PPV/NPV) of iCa_{EST} and cCa at similar cutoffs. ICa_{EST} overestimated iCa by 0.04 mM (1.17±0.002 vs 1.13±0.002, $p<10^{-166}$), a bias that was fairly consistent across the full prediction range.

Conclusions: The iCa_{EST} model is superior to cCa in ranking critically ill pts for both ↓iCa and ↑iCa. It can help clinicians decide when to directly measure iCa. ICa_{EST} overestimated iCa but applying a local correction of -0.04 would make its absolute predictions accurate, on average, in the MIMIC setting.

Diagnosis	Cutoff	N	SENS / SPEC	PPV / NPV
↓iCa	iCaEST <1.15	1572	74.1% / 79.4%	63.9% / 86.1%
	cCa < 9.0	1561	64.0% / 74.8%	55.6% / 80.8%
↑iCa	iCaEST > 1.30	247	80.5% / 96.9%	50.2% / 99.2%
	cCa > 10.76	247	72.7% / 96.6%	45.3% / 98.9%

PO1188

A Case Report of Hypercalcemia Secondary to Calcium Sulfate Antibiotic Beads

Golnaz Vahdani, Michael Bernaba, Ankita Ashoka, Sangeetha Murugapandian, Waseem Albasha, Alvaro J. Altamirano, Roshanak Habibi. *The University of Arizona College of Medicine Tucson, Tucson, AZ.*

Introduction: Periprosthetic joint infections are rare complications in arthroplasties of the hip or knee, happening in ~0.7% of these procedures. Placement of antibiotic eluting beads, sometimes referred to as calcium sulfate beads (CSB), which are bio-compatible hydrophilic crystals used to deliver antibiotics locally, are one solution to prevent such complications. Hypercalcemia post-CSB placement is a rare complication that has only been presented in the literature a handful of times. We report on a such a patient, illustrating the importance of surgical history in investigating the cause of hypercalcemia.

Case Description: 63 yo F with PMH of HTN, HLD, Crohn's, T2DM, CKD3 who had a recent hospital admission 2 weeks prior for new arthritis secondary to pseudogout crystals, s/p bilateral synovectomy and CSB placement by orthopedics. She re-presented to hospital for AMS and worsening knee pain. Labs showed evidence of AKI with creatinine 1.9, severe hypercalcemia at 17.5 mg/dl with concomitant hypophosphatemia at 1.1 mg/dl. PTHrP WNL & PTH low at 7pg/ml and histo antigen neg, suggesting this was not related to PTH. Malignancy ruled out based on past imaging that was done in 2 months prior. MM ruled out since normal SPEP, UPEP, and kappa:lambda. Unlikely that this was milk alkali as patient did not have alkalosis. Vitamin 1,25 low at 10pg/ml ruling out sarcoidosis. Vitamin 25 WNL. Urine Ca 24hr WNL suggesting no FHH. Hypercalcemia improved after pamidronate, IV fluids and calcitonin. Chart review suggested that CSB implanted in her knees as the likely cause of her hypercalcemia.

Discussion: One of the rare and underappreciated causes of severe hypercalcemia is CSB placement. Vigilant monitoring of calcium levels pre and post CSB placement is indicated, particularly in patients with a history of CKD. It has been hypothesized that there is a dose-dependent relationship between CSB volume and hypercalcemia, and limiting CSB to less than 40ml per operation may be beneficial. A 10ml pack of CSB contains 5.73 grams of elemental calcium which is released over a 30–60-day interval. There is limited information on the mechanism of hypercalcemia in CSB use, so further studies need to be implemented. It is crucial for physicians to have a high suspicion for CSB induced hypercalcemia post-arthroplasty as CSB use expands.

PO1189

Hypercalcemia in a Patient with Visceral Leishmaniasis (VL) and Immune Reconstitution Inflammatory Syndrome (IRIS)

Lubin Juarez,[1] Jacob M. Winograd,[1] Jie Tang.[2,1] *[1]Lifespan Health System, Providence, RI; [2]Brown University Warren Alpert Medical School, Providence, RI.*

Introduction: Hypercalcemia is a relatively common clinical problem with a wide range of etiologies. We report an unusual case of hypercalcemia due to visceral leishmaniasis triggering immune reconstitution inflammatory syndrome in a patient with AIDS.

Case Description: A 45-year-old male with history of previously treated VL complicated by a relapse now on suppressive amphotericin presented with 2 weeks of poor appetite, weight loss, and malaise. Recent history was notable for AIDS restarted on Triumeq in the preceding 2 months with slow recovery of CD4 count to 18 but robust reduction in HIV viral load. He denied other infectious symptoms. Labs were notable for AKI, calcium of 13.1, and pancytopenia. Work up revealed low PTH, low calcidiol, elevated ACE levels and high-normal calcitriol levels with bone marrow biopsy revealing non-necrotizing granulomas. Remainder of infectious work up including mycobacterium, histoplasma, and fungal cultures all remained negative. Of note, CD4 count rebounded to 354 during his month-long stay. He was ultimately diagnosed with IRIS secondary to VL leading to granulomatous hypercalcemia. Initial therapy consisted of fluids which resolved AKI and improved calcium. However, he proved to be fluid dependent as attempts at weaning would result in rise in calcium and creatinine. Definitive therapy consisted of steroids which resolved his hypercalcemia allowing him to come off fluids. Appetite improved and fatigue resolved over course of his stay with stabilization of calcium levels and creatinine returning to baseline. He was continued on suppressive Amphotericin B for VL.

Discussion: Granuloma formation is a known effect of leishmania infection to combat the invading parasites. Presumably, such inflammation could lead to hypercalcemia via increased conversion of calcidiol to calcitriol. To our knowledge, this is the first case of hypercalcemia caused by VL in humans. It was likely triggered by the reconstitution of his immune system given recent re-initiation of anti-retroviral therapy and rebound of CD4 cell count. Initial management consists of fluids and bisphosphonates with definitive management consisting of steroids and amphotericin. We report this novel case of hypercalcemia in hopes of expanding the literature on the various potential manifestations of VL, particularly in the setting of IRIS and AIDS.

PO1190

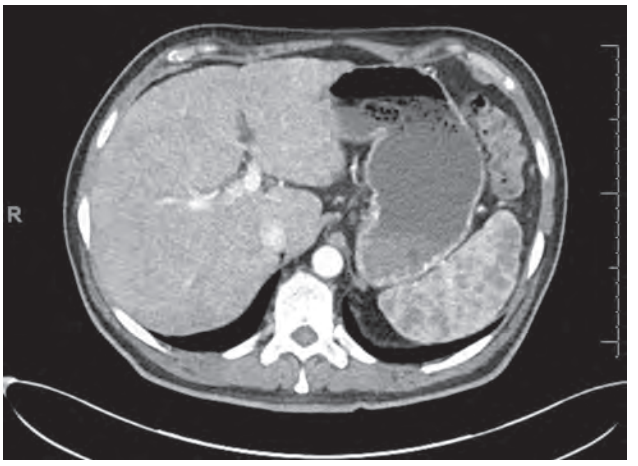
Systemic Sarcoidosis Presenting with Hypercalcemia

Salman B. Mahmood, Milind Y. Junghare, Tetyana Mettler. *University of Minnesota Twin Cities, Minneapolis, MN.*

Introduction: Sarcoidosis is an idiopathic autoimmune illness that typically presents with pulmonary involvement but can affect virtually any organ. This often makes it challenging to diagnose as its manifestations can be quite varied. We report an interesting case of systemic sarcoidosis presenting with hypercalcemia of unclear mechanism.

Case Description: A 53-year-old Caucasian male presented to the clinic with polyuria, forgetfulness and weight loss. Medical history included hypercalciuria with recurrent nephrolithiasis, diabetes and positive ANA (titer 1:160) without any prior history of constitutional, respiratory or joint symptoms. Serum calcium returned 13 mg/dl. The patient also had an AKI and an elevated ALP. Further workup revealed a suppressed PTH, normal 25-OH and 1,25-OH vitamin D, but a borderline elevated PTHrP (2.5 pmol/L [0-2.3 pmol/L]). This prompted a CT CAP with contrast to rule out malignancy that instead showed mediastinal lymphadenopathy, heterogeneous liver enhancement suggestive of cirrhosis and an enlarged, nodular spleen. Transbronchial lymph node biopsies were normal and an extensive infectious and malignancy workup remained negative. The patient was given fluids followed by zoledronate with resolution of hypercalcemia and AKI. A liver biopsy was ultimately pursued which showed non-caseating granulomas. The patient was prescribed steroids with improvement in symptoms and normalization of ALP.

Discussion: In patients with sarcoidosis, the development of hypercalcemia is thought to be mediated via aberrant activation of vitamin D leading to calcitriol excess. Our patient's calcitriol level was normal and hypercalcemia may also occur in the absence of elevated levels. Possible described mechanisms include "inadequate normal" calcitriol concentration without elevation in systemic levels, elevated PTHrP and direct action of pro-inflammatory cytokines causing osteolysis.



CT with contrast showing heterogenous liver enhacement and a nodular spleen.

PO1191

Disseminated Histoplasmosis Presenting as Severe Hypercalcemia

Sushma Medikayala, Carla S. Mcwilliams, Shane A. Bobart, Silvia T. Bunting, Dianne T. Sandy, Mauro Braun, Surafel K. Gebreselassie. *Cleveland Clinic Florida, Weston, FL.*

Introduction: Hypercalcemia (HC) is a significant complication of Disseminated Histoplasmosis (DH). While there are case reports on DH causing HC in immunosuppressed patients including HIV and chemotherapy, there are very rare case reports on DH causing HC in Non-immunosuppressed hosts. The diagnosis of DH in HC may be delayed due to other differential diagnoses such a Sarcoidosis leading to prolonged and worsening hypercalcemia and subsequent renal failure. We report a case of HC in a patient who presented with generalized skin ulcers and bilateral adrenal masses. The initial manifestation of DH with HC, painful skin ulcers, bilateral large lobulated adrenal masses, prompted an initial concern for sarcoidosis. After presenting to our institution 5 months later, a diagnosis of DH was made as the cause of his Hypercalcemia.

Case Description: A 58-year-old male with new onset generalized skin rash was diagnosed with HC, empirically treated with prednisone for sarcoidosis due to elevated 1,25 di hydroxy Vitamin D, 5 months ago at an outside hospital. After starting prednisone, his skin lesions progressed to disseminated painful ulcers and was referred to our institution after developing AKI with a serum creatinine of 4.6mg/dl (Cr 1.6mg/dl, 5 months ago) calcium 14mg/dl, PTH 2pg/ml. CT abdomen revealed large lobulated bilateral adrenal masses. Bone marrow biopsy revealed non-necrotizing granulomas with yeast form fungal organisms on GMS stain. A Shave skin biopsy of an abdominal ulcer revealed Fungal yeast forms consistent with histoplasmosis, associated with ulcers on GMS stain. Urine Histoplasma antigen positive. Adrenal mass biopsy revealed necrotic material and fibroconnective tissue. DH was initially treated with IV liposomal amphotericin and transitioned to oral Itraconazole. At the time of discharge, calcium was 9.8 mg/dl and serum creatinine was 2.9mg/dl.

Discussion: Hypercalcemia, in the setting of elevated 1,25 di hydroxy Vitamin D levels, prompts concern for granulomatous disease. Sarcoidosis is a common etiology, however, other causes must be entertained. The cluster of findings of adrenal non caseating granulomas coupled with diffuse skin ulcers with hypercalcemia should prompt the provider to consider infectious etiologies such as disseminated histoplasmosis as early diagnosis and prompt treatment can result in improved outcomes

PO1192

Electrolyte Disturbances Among Those with Malignancy on Anti-Neoplastic Agents

Miho Murashima, Atsuki Ide, Minamo Ono, Masashi Mizuno, Taisei Suzuki, Takayuki Hamano. *Nagoya Shiritsu Daigaku, Nagoya, Japan.*

Background: The clinical characteristics of electrolyte disturbances among patients with malignancy in contemporary cohorts are lacking.

Methods: This is a retrospective cohort study on 2644 patients with malignancy on anti-neoplastic agents from 2019 to 2020. Antineoplastic agents associated with electrolyte disturbances were examined by multi-level mixed-effects logistic regression analyses. The data were adjusted for age, sex, serum albumin, eGFR, kinds of malignancy, and other medications which potentially affect electrolytes.

Results: Mean age was 64.8 (15.8) years, 55.5% were male, and median eGFR was 72.9 (58.1-88.1) mL/min/1.73m^2. The prevalences of hyponatremia (Na ≤130 mEq/L), hypomagnesemia (Mg ≤1.5 mg/dL), hypophosphatemia (P ≤2.0 mg/dL), and hypokalemia (K≤3.0 mEq/L) were 2.1 (1.8-2.2), 2.0 (1.7-2.3), 1.7 (1.6-1.9), and 1.2 (1.1-1.4) events/100 patient-measurements, respectively. The use of bortezomib was associated with hyponatremia (OR: 3.04 [1.96-4.71]) and three immnue checkpoint inhibitors were significantly associated with hyponatremia. The use of cetuximab and gemccitabine were strongly associated with hypomagnesemia (OR 11.79 [7.56-18.38] and 5.95 [3.36-10.55],

respectively). Other agents associated with electrolyte disturbances were shown in Table. Other than anti-neoplastic agents, lower albumin levels were consistently associated with development of electrolyte disturbances.

Conclusions: Electrolyte disturbances were common and associated with the use of novel anti-neoplastic agents among those with malignancy. Identifying the agents and patient population at high risk of developing electrolyte disturbances is important in taking appropriate preventive measures and monitoring for those undergoing treatments with anti-neoplastic agents.

Anti-neoplastic agents associated with hyponatremia

	OR (95% CI)
Bortezomib	3.04 (1.96-4.71)
Ipilimumab	2.30 (1.00-5.29)
Docetaxel	1.69 (1.27-2.27)

PO1193

Resistant Hypophosphatemia with Vitamin D Deficiency

Yasmin N. Mahmoud,[1,2] Akbar H. Hamid,[1,2] Ammar N. Mohamed,[1,2] Mary C. Mallappallil,[1,2] Man S. Oh,[1,2] Moro O. Salifu.[1,2] *[1]SUNY Downstate Health Sciences University Department of Medicine, New York, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: The renal regulation of phosphate homeostasis is mediated mainly by reabsorption of P by NaPi-IIc in the proximal tubule, whereas intestinal absorption is mediated by NaPi-IIb. Normally, about 2/3 of dietary intake (1500 mg/day) is absorbed, but when given by mouth as Na or K phosphate, absorption is nearly 100% in a normal person. We report here a patient with severe hypophosphatemia due to phosphate malabsorption caused by prior gastric bypass surgery along with vitamin D deficiency.

Case Description: A 34 year old African American female with past medical history of benign carcinoid syndrome, pernicious anemia, Hashimoto thyroiditis, and gastric sleeve surgery for morbid obesity 3.5 years ago, was admitted for acute dizziness and lightheadedness at rest without vertigo. Initial labs were: BUN 4 mg/dL; creatinine 0.6 mg/dL; Ca 9.2 mg/dL; Mg 2.17 mg/dL; P 1.3 mg/dL; 25-OH vitamin D 10.88 ng/mL; 1,25(OH)2 vitamin D 15.3 pg/mL; PTH 77.7 pg/mL; urine P 77 mg/dL; urine creatinine 342.51 mg/dL. She has been getting vitamin B12 injections for her pernicious anemia. She was treated with oral Na and K phosphate solution containing 560 mg of P, 320 mg of Na, and 500 mg of K in each dose for every 4 hours, and once daily dose of IV K phosphate containing 465 mg of phosphate for 14 days. She was also treated with 800 units of vitamin D2 daily. Serum phosphate remained persistently low around 1.8 mg/dL despite the above treatment.

Discussion: Hypophosphatemia in our patient was caused by impaired intestinal absorption of phosphate, and inappropriately increased urinary excretion due to secondary hyperparathyroidism due to vitamin D deficiency. The total daily amount of phosphate the patient received while in the hospital was 3825 mg per day. A 24 hour urine excretion of P estimated from urine creatinine concentration (342 mg/dL), assuming normal GFR (180 L/day), is very low (245 mg/day). Although P administered as Na or K salt is well absorbed in a normal person, she was unable to absorb P likely due to the gastric sleeve surgery causing rapid emptying of the gastric content, simulating the dumping syndrome, resulting in diarrhea by unabsorbed Na and K phosphate. Further impairment in intestinal P absorption may have been caused by vitamin D deficiency due to the inadequate dosing (800 units daily) and the inappropriate vitamin D type (Vitamin D2 instead of D3).

PO1194

Severe Hypophosphatemia Induced by Oncogenic Osteomalacia

Abdullah Jalal, Ryan P. Brown. *Overlook Medical Center, Summit, NJ.*

Introduction: Oncogenic Osteomalacia (OncOM) is an uncommon paraneoplastic syndrome characterized by FGF-23 overexpression from benign mesenchymal tumors causing severe hypophosphatemia. Very few cases of OncOM with concomitant paraneoplastic syndromes have been described. Herein we present a rare case of carboplatin-associated hyponatremia in the setting of SiADH-induced chronic hyponatremia unmasking an even rarer secondary paraneoplastic syndrome; oncogenic osteomalacia.

Case Description: A 52 year old male with past medical history of chronic hyponatremia on salt tablets secondary to recently diagnosed metastatic small cell lung cancer was admitted for initiation of chemotherapy with carboplatin/etopside. Two days after competing cycle 1 the patient developed acute hyponatremia; serum Na decreased from 141 to 129 mEq/L. Serum electrolytes were (mEq/L): K 3.9, Cl 94, HCO3 28, BUN 20, Cr 0.47. Cortisol (17.8 ug/dl) and TSH (2.28 uIU/ml) were within normal limits. Urine studies noted (mEq/L): Na 75, Cl 69, K 43.5, elevated osmolality 860 mOsm/kg. Etiology of acute hyponatremia was attributed to platinum chemotherapy in the setting of SCC-associated SiADH and patient was treated with tolvaptan after several days of non-response to fluid restriction and urea. Patient's hyponatremia subsequently corrected but was incidentally noted to have severe hypophosphatemia (<1 mEq/L) refractory to aggressive IV and PO phosphate repletion. ALP was elevated 279 U/L, corrected Ca 10 mEq/L, low 25(OH)-vitamin D 23.8 ng/mL, normal PTH 45.6 pg/mL and PTHrP <0.4 pmol/L. Urinary fractional excretion of phosphorus was increased at 24%. An FGF-23 level obtained 12 days after completing cycle 1 of carboplatin-etopside was considerably elevated at 219 pg/mL. Thus, the patient was diagnosed with oncogenic osteomalacia.

Discussion: This case highlights a unique and diagnostically challenging patient presentation of severe hypophosphatemia in the setting of dual paraneoplastic syndromes. OncOM should be considered in the differential for severe refractory hypophosphatemia. This occurs via FGF-23 mediated downregulation of PCT Na-Pi transporters and 1a-hydroxylase causing renal phosphate wasting and reduced 1,25-hydroxyvitamin D levels. Over time chronic hypophosphatemia impairs bone mineralization causing osteomalacia. Measurement of the fractional excretion of phosphorus is critical and FGF-23 levels should be obtained to confirm diagnosis.

PO1195

Phenotypes of Patients with Abnormal Phosphate on Admission by Consensus Clustering and Associated Mortality Risks

Carissa Y. Dumancas,[1] Charat Thongprayoon,[1] Andrea G. Kattah,[1] Michael A. Mao,[2] Stephen B. Erickson,[1] John J. Dillon,[1] Vesna D. Garovic,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Background: Hospitalized patients with abnormal phosphate are heterogeneous and cluster approaches may identify specific homogenous groups. This study aimed to cluster patients with abnormal phosphate on admission using unsupervised machine learning approach and to evaluate the mortality risk among these distinct clusters.

Methods: Consensus cluster analysis was performed on hospitalized adult patients with abnormal phosphate on admission, based on clinical and laboratory data. We determined each cluster's key features using the standardized mean difference. We assessed the association of the clusters with hospital and one-year mortality.

Results: Cluster 2 patients with hypophosphatemia had older age, higher comorbidity burden, hypertension, diabetes, coronary artery disease, lower eGFR, and more acute kidney injury (AKI) (Fig 1a). Cluster 2 patients with hyperphosphatemia had older age, more admission for kidney disease, hypertension, end-stage kidney disease, AKI, and higher admission K^+, Mg^{2+}, or PO_4 levels (Fig 1b). Both cohorts in cluster 2 had higher one-year mortality while hyperphosphatemic cluster 2 patients had higher hospital mortality (Fig 2).

Conclusions: The cluster analysis identified clinically distinct phenotypes with differing mortality risk in hospitalized patients with abnormal phosphate on admission. The age, comorbidities, and kidney function were key features.

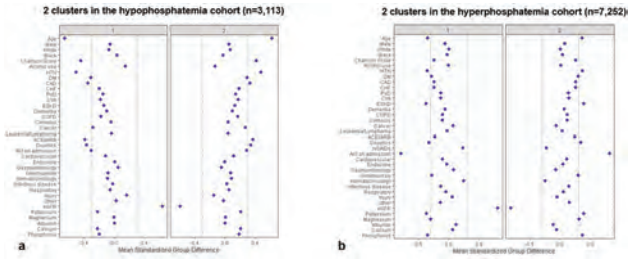

Fig 1. The Manhattan plot of standardized differences in the hypophosphatemia (a) and hyperphosphatemia cohort (b).

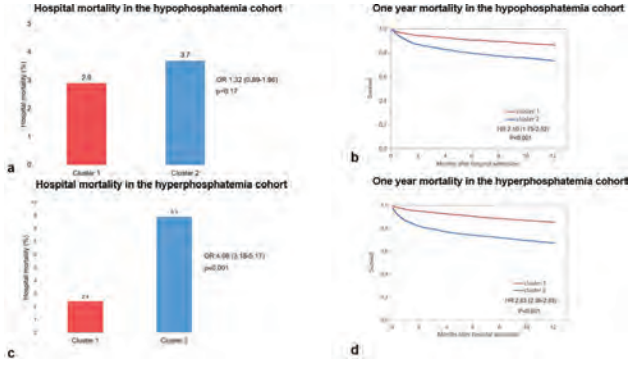

Fig 2. The hospital mortality (a) and one-year mortality (b) in the hypophosphatemia cohort, and the hospital mortality (c) and one-year mortality (d) in the hyperphosphatemia cohort.

PO1196

Annatto Leaf Tea Intoxication: An Unusual Cause of Green Urine

Eduardo d. Valle, Rayra G. Ribeiro, João Lucas M. Gorzoni, Guilherme P. Santa Catharina, Bernardo V. Reichert, Marcia Fernanda Arantes de Oliveira, Victor F. Seabra, Paulo R. Lins, Igor Smolentzov, Camila E. Rodrigues, Lucia Andrade. *Hospital das Clinicas, University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Introduction: The roots and leaves of the annatto ("urucu") tree (*Bixa Orellana*) are used by the lay population in the treatment of many diseases. We describe a case of AKI with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use.

Case Description: A 59-year-old male without known comorbidities presented with a 2-week history of severe diarrhea. Three days prior to admission, he was diagnosed with renal dysfunction, received 500 mL of saline and was discharged. Subsequently, he presented with muscle weakness, uremic encephalopathy, severe AKI, F+E imbalance and greenish urine (Figure). He received fluid resuscitation and underwent two sessions of hemodialysis. He reported having ingested annatto leaf tea to treat his diarrhea. Blood and urine cultures were negative and there was no history of drug use. He was discharged on day 14 with no remaining F+E imbalance or renal dysfunction.

Discussion: The diuretic effect of annatto leaf extracts has been shown in experimental models. To our knowledge, this is the first report of severe AKI and F+E imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and the diuretic effect of the tea.

Table 1.

	Admission	Discharge	Reference range
Hemoglobin (mg/dL)	17.3	11.6	13.5 - 17.5 g/dL
Serum creatinine (mg/dL)	8.09	0.79	0.7 - 1.2 mg/dL
Urea (mg/dL)	502	23	10 - 50 mg/dL
Sodium (mEq/L)	111	136	135 - 145 mEq/L
Potassium (mEq/L)	4.8	4.6	3.5 - 5 mEq/L
Chloride (mEq/L)	55	99	98 - 107 mEq/L
Magnesium (mg/dL)	2.99	1.7	1.58 - 2.55 mg/dL
Phosporus (mg/dL)	20.5	2.5	2.7 - 4.5 mg/dL
Ionizide calcium (mg/dL)	3.15	4.92	4.49 - 5.29 mg/dl
Uric acid (mg/dL)	25.5	2.9	3.4 - 7 mg/dl

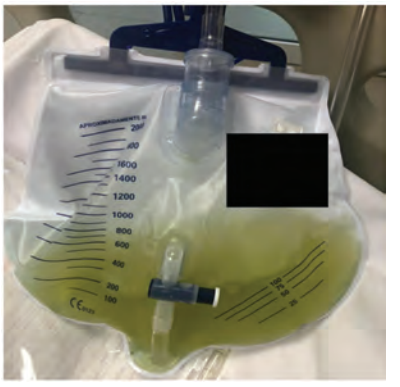
Bicarbonate (mmol/L)	12	22.5	23 - 27 mmol/L



PO1197

Foam Sclerotherapy for Directed Treatment of Symptomatic Cysts in Autosomal Dominant Polycystic Kidney and Liver Disease

Marie C. Hogan,[1] William P. Martin,[2] Emily Bendel,[1] Kristin C. Mara,[1] Adriana Gregory,[1] Grace Y. Chong,[1] Vicente E. Torres,[1] Newton Neidert.[1] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]University College Dublin, Dublin, Ireland.*

Background: Patients frequently describe mass symptoms & reduced quality of life (QoL) that correlate with large (≥5cm diameter) organ cysts in ADPKD/ADPLD. Since 1/18/2017, we have studied the safety & impact of cyst drainage followed by sotradecol foam sclerotherapy (SFS) to treat symptomatic, large cysts.

Methods: In this single-center, single-arm, prospective observational study, ADPKD and ADPLD patients with compressive symptoms due to liver or kidney cysts are referred for SFS. Small volumes (20cc max) of 3% sotradecol sclerosant admixed with air are injected (fluoroscopy-guided under local anesthesia) to ablate the epithelial cyst lining. QoL measures using polycystic liver disease QoL tool (PLD-Q) & organ volumes (planimetry using CT/MR) are recorded at baseline & 12+ months post-SFS. Changes over time were tested using Wilcoxon tests and confirmed using repeated measures mixed models. Improvements >0.5 SD were considered clinically meaningful.

Results: We performed 148 SFS procedures among 68 cases (mean age 55yr 77% Female, mean 2.2 procedures per pt): 53 (77.9%) with ADPKD/ADPLD, 5 (7.4%) with ADPLD, & 10 (14.7%) with cystic disease NOS. PLD-Q scores improved by 7.7 (IQR 0.1, 24.8) (p=0.012) at mo 12. A subgroup (13 patients) (mean age 54.7yr, 69% F) have undergone multiple sequential SFS procedures: 10 (77%) with ADPKD/ADPLD, 2 (15%) ADPLD, & 1 (8%) cystic disease NOS. Among 5 with multiple kidney procedures, median kidney volume decreased by 135mL/yr. Among 5 with multiple liver procedures, median liver volume decreased by 114mL/yr. SFS was well tolerated with low complication rates.

Conclusions: SFS directed at large, symptomatic liver and kidney cysts was well tolerated, improved QoL at 12 months, & decreased early satiety, SOB, pain & fullness. Furthermore, multiple sequential SFS procedures are feasible, efficacious, and have an acceptable safety profile.

ADPKD Case Who Underwent 5 sequential SFS Procedures

PO1198

Development of AL01211, a Novel Glucosylceramide Synthase Inhibitor, to Treat Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Michael C. Babcock,[1] Jianhong Zheng,[1] Li Li,[1] Changlin Mei,[2] Marvin R. Garovoy,[1] Yuqiao Shen.[1] *[1]AceLink Therapeutics, Newark, CA; [2]Shanghai Changzheng Hospital, Shanghai, China*.

Background: ADPKD is a common genetic disease affecting ~1:1000 individuals and is characterized by progressive renal cysts growth, kidney enlargement and renal dysfunction. Glycosphingolipids (GSL) are elevated in the kidneys of ADPKD animal models and ADPKD patients where they promote renal epithelial cell growth and kidney inflammation. Glucosylceramide synthase inhibitors (GCSi) reduce GSL production, slow cyst growth, and preserve kidney function in multiple animal models. Clinical development of other GCSi have shown that this enzyme can be safely targeted therapeutically. We are developing AL01211, a potent and selective GCSi with excellent drug-like properties, for the treatment of ADPKD.

Methods: The IC50 of AL01211 against GCS was determined in cells and cell-free activity assays. PK, PD, tissue distribution and clearance studies were conducted in mice, rats and dogs. AL01211's pharmacological profile was characterized *in vitro* including off-target selectivity panels, plasma protein binding, transporter assays, cyp inhibition and induction, and other assays. Disease model efficacy studies were conducted in several murine models including *pkd1* cKO and *jck* models.

Results: AL01211 binds the active site of GCS and has an IC_{50} toward GCS of ~7 nM with limited off-target activity. PK studies support once daily, oral administration. AL01211 has low renal clearance in rats. AL01211 readily distributes to peripheral tissues (such as kidney) but does not cross blood-brain-barrier. Thus, it efficiently reduces GSL production in mouse, rat and dog kidney (reduced by >85% of control levels) with minimal effects in brain GSL. Importantly, AL01211 reduces cyst growth and kidney weight and preserves kidney functions in murine models.

Conclusions: Relative to other GCSi in development, AL01211 is more potent with single digit nanomolar potency, has greater reduction of GSL (>85%), is not subject to kidney clearance, and does not enter the brain. Phase I clinical trials, consisting of Phase IA (single ascending dose study in healthy volunteers), Phase 1B (14-day multiple ascending dose study in healthy volunteers, and Phase IC (28-day biomarker study in ADPKD patients), are underway.

PO1199

The Tyrosine Kinase Inhibitor Nintedanib Ameliorates Autosomal Dominant Polycystic Kidney Disease

Abeda Jamadar, Reena Rao. *University of Kansas Medical Center, Kansas City, KS*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease and is characterized by progressive growth of fluid-filled cysts in the kidneys. Growth factor binding to receptor tyrosine kinases (RTKs) are known to stimulate cell proliferation and cyst growth in PKD. In the current study we tested the effect of Nintedanib, an RTK inhibitor and FDA approved drug for non-small cell lung carcinoma and idiopathic lung fibrosis, in mouse models of ADPKD. Nintedanib is a triple RTK inhibitor which targets vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR) and fibroblast growth factor receptor (FGFR).

Methods: The effect of Nintedanib on renal cyst growth and fibrosis was tested in two orthologous models of ADPKD, the *Pkd1$^{f/f}$Pkhd1^{Cre}* mouse, and *Pkd1$^{RC/RC}$* mouse. Nintedanib treatment (20 mg/Kg on alternate days by intraperitoneal injections) was from postnatal day P10 to P18 in *Pkd1$^{f/f}$Pkhd1^{Cre}* mice and in for 8 weeks starting at the age of 3 months in *Pkd1$^{RC/RC}$* mice. *In vitro* studies were performed using primary culture human ADPKD renal cystic epithelial cells and renal myofibroblasts.

Results: Nintedanib treatment significantly reduced kidney-to-body weight ratio, renal cystic index, cystic epithelial cell proliferation and blood urea nitrogen levels compared to vehicle treated *Pkd1$^{f/f}$Pkhd1^{Cre}* and *Pkd1$^{RC/RC}$* mice. Western blot data indicates reduction in the phosphorylation of ERK1/2, AKT, STAT3 and mTOR activation and pro-proliferative factors, including Yes associated protein (YAP), c-Myc and Cyclin D1 protein levels. Moreover, nintedanib treatment significantly reduced renal fibrosis in *Pkd1$^{RC/RC}$* mice, however, fibrosis in *Pkd1$^{f/f}$Pkhd1^{Cre}* mice remained unaffected. *In vitro* data suggests that nintedanib significantly reduced proliferation and cyst size of human ADPKD cystic epithelial cells as well as cell viability and migration of human ADPKD renal myofibroblasts.

Conclusions: The results suggest that Nintedanib is effective in reducing cyst growth and may be repurposed to treat ADPKD.

KidneyNetwork Uses Kidney-Derived Gene Expression Data to Predict and Prioritize Novel Genes Involved in Kidney Disease

Laura R. Claus,[1] Floranne Boulogne,[2] Henry Wiersma,[2] Roy Oelen,[2] Floor Schukking,[2] Niek de Klein,[2] Shuang Li,[2,3] Harm-Jan Westra,[2] Bert Van der zwaag,[1] Dana Sierks,[4] Ria Schönauer,[4] Jan Halbritter,[4] Nine V. Knoers,[2] Patrick Deelen,[1,2] Lude Franke,[2] Albertien M. van Eerde.[1] *[1]Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands; [2]Department of Genetics, University Medical Center Groningen, Groningen, Netherlands; [3]Genomics Coordination Center, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [4]Medical Department III - Endocrinology, Nephrology, Rheumatology Department of Internal Medicine, Division of Nephrology, University of Hospital Leipzig Medical Center, Leipzig, Germany*.

Background: Genetic testing in patients with suspected hereditary kidney disease does not always reveal the genetic cause for the patient's disorder. Pathogenic variants can reside in genes that are not yet known to be involved in kidney disease. To help identify candidate genes for kidney disease we have developed KidneyNetwork, in which tissue-specific expression is utilized to predict kidney-specific gene functions.

Methods: KidneyNetwork is a co-expression network built upon 878 kidney RNA-sequencing samples and a multi-tissue dataset of 31,499 samples. It uses expression patterns to predict which genes have kidney-related functions and which phenotypes might result from variants in these genes. As proof of principle, we applied KidneyNetwork to prioritize rare variants in exome-sequencing data from 13 kidney disease patients.

Results: We assessed the prediction performance of KidneyNetwork by comparing it to GeneNetwork, our previously developed multi-tissue co-expression network. In KidneyNetwork, we observe significantly improved prediction accuracy of kidney-related HPO-terms and an increase in the total number of significantly predicted kidney-related HPO-terms (figure 1). Applying KidneyNetwork to exome-sequencing data allowed us to identify *ALG6* as candidate gene for kidney and liver cysts.

Conclusions: KidneyNetwork is a kidney-specific co-expression network that predicts which genes have kidney-specific functions that can result in kidney disease. Gene-phenotype associations of genes unknown for kidney-related phenotypes can be predicted. We show its added value by applying it to kidney disease patients without a molecular diagnosis. KidneyNetwork can be applied to clinically unsolved cases, but it can also be used by researchers to better understand kidney physiology and pathophysiology.

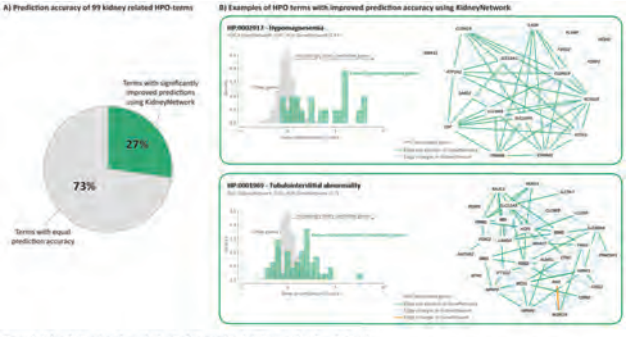

Figure 1. KidneyNetwork performs better for kidney-related HPO terms than GeneNetwork
A) 27% of kidney-related phenotypes are predicted significantly better using KidneyNetwork, as compared to GeneNetwork (a multi-tissue co-expression network we previously developed). B) Density plots of gene prediction scores within two of the most improved phenotypes, hypomagnesemia and tubulointerstitial fibrosis, show higher prediction values for genes annotated for the phenotype, while also predicting potential unknown candidate genes. The networks predicted using KidneyNetwork shows more and stronger correlations between the annotated genes than the networks predicted using GeneNetwork.

PO1201

Modeling Gene-Targeted Strategies for Therapeutic Correction of PKD1 Loss-of-Function Mice

Marie Trudel, Almira Kurbegovic, Kevin Loayza-Vega, Rey Christian Pacis, Camila Parrot. *Institut de recherches cliniques de Montreal, Montreal, QC, Canada*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) causes cyst progression leading to renal failure, mainly by PKD1 mutations. Since microscopic cysts in ADPKD kidneys are likely formed *in utero*, we targeted at fetal stage wild type *Pkd1/Pc1* protein in *Pkd1$^{-/-}$* mouse from 3 series of transgenic (Tg) lines, to assess for long-term cure of severe cystogenesis and neonatal death.

Methods: Pc1 re-expression in *Pkd1$^{-/-}$* mouse was targeted by 3 genetic matings: a) a systemic *Pkd1$_{TAG}$* mouse b) 2 renal-specific *SBPkd1$_{TAG}$* mice mild and high expressor (1&10 Tg copies) c) a novel Tg line targeting Pkd1 cDNA with renal-specific elements, *SBP* (16 Tg copies). Longitudinal renal molecular (Q-PCR, IB), histologic (tubular origin IF, RNAScope) and survival analyses were performed.

Results: Mice *Pkd1$_{TAG}$;Pkd1$^{-/-}$* expressing 7-fold over endogenous Pkd1 gene and intense signal over all tubular segments are totally rescued. Mice *SBPkd1$_{TAG}$;Pkd1$^{-/-}$* with mild (~0.64) Pc1 expression are not only rescued from neonatal death but renal cysts are delayed to P5 affecting mainly collecting tubules, causing death at P15, generating a 4-fold increased life expectancy. Mice *SBPkd1$_{TAG}$;Pkd1$^{-/-}$* with high (7-fold) Pc1 expression, initiate distal renal cysts at P15 and survive till ~4 mo with 25-fold increased life expectancy. Mice *SBP;Pkd1$^{-/-}$*, with ~16 SBP copies expressed 0.87-fold the Pkd1 endogenous level, exhibit few renal cysts at P0 whereas at P5 are mainly of distal and

collecting tubular origin and survived until P12-15. While *SBP* reached Pkd1 therapeutic levels similar to the mild *SBPkd1*$_{TAG}$, the additional Tg copies suggest the presence of regulatory region within Pkd1 gene-body. Renal cysts in *SBPkd1*$_{TAG}$*;Pkd1*$^{-/-}$ and *SBP;Pkd1*$^{-/-}$ co-detected by RNAScope and IF, arise likely from insufficient and chimeric Pkd1 re-expression. These analyses also shed light on Pkd1 spatio-temporal expression pattern with highest expression in collecting tubules during renal maturation that shifts to distal tubules following maturation.

Conclusions: Pkd1 is regulated by elements both upstream for spatio-temporal pattern and intragenic sequences for expression levels. The renal-specific SB minimal regulatory region is sufficient for therapeutic correction in one copy Tg. Our study demonstrates that Pc1 re-expression can substantially delay cystogenesis and markedly extend lifespan.

Wheat-Gluten Diet Attenuates Ccl2-Mediated Immune Response and Slows Polycystic Kidney Disease

Jifeng Huang, Shinobu Yamaguchi, Jung-Shan Hsu, Takamitsu Saigusa. Department of Medicine, Division of Nephrology *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Disease severity of autosomal-dominant polycystic kidney disease (ADPKD) is highly variable, even among families with the same gene mutation. A high protein diet is a well-recognized ADPKD progression-accelerating factor. Dietary protein composition is important, as pre-clinical studies have shown a soy protein-based diet slows kidney cyst formation in rodent PKD models. Recruitment of macrophages in the kidney are known to promote cystogenesis in PKD. We hypothesize that type of protein in the diet may serve as a potential environmental stimulant to immune response and cyst growth.

Methods: Using tamoxifen-inducible *Pkd1*-global knockout mice, we fed the mice with either a high casein-protein (animal-based protein: 60%), a low casein-protein (6%) or a high wheat-gluten (plant-based protein: 60%) for a total of 1 week or 6 weeks. Some mice fed a high casein protein diet were treated with liposomal clodronate or saline for a total of 5 weeks. Mice were euthanized and kidney cyst area, number of macrophages and chemokine/cytokine levels were measured.

Results: *Pkd1*-knockout mice fed a high casein diet increased the number of kidney macrophages, expression of macrophage-recruiting chemokine *Ccl2* (but not chemokines *Csf1 or Ccl5*), pro-inflammatory cytokine (*Il6*, *Tnf-a*) and accelerated cyst growth compared to counterparts fed an iso-caloric high wheat-gluten (WG) diet or a low casein protein diet. We found that in very early stages during dietary casein load (1 week after diet modification), cyst expansion precedes macrophage recruitment in the kidney, indicating that diet *per se* triggers early cyst growth rather than as a consequence of macrophage recruitment and inflammation. High casein protein diet fed *Pkd1*-knockout mice treated with liposomal clodronate, resulted in decreased number of macrophages, cytokine and fewer cysts.

Conclusions: Wheat-gluten diet fed *Pkd1*-knockout mice resulted in decreased the number of macrophages, suppressed levels of kidney *Ccl2*, but not *Csf1* or *Ccl5*, and slowed cyst growth compared to counterparts fed an isocaloric casein based diet. Dietary protein modification may suppress immune response and cyst growth in PKD.

High Prevalence of Kidney Cysts in Hereditary Hypophosphatemic Rickets with Hypercalciuria

Christian Hanna,[1] Jennifer Arroyo,[1] Peter Tebben,[1] Vicente E. Torres,[1] Peter C. Harris,[1] David S. Goldfarb,[2] David J. Sas,[1] Dawn S. Milliner,[1] John C. Lieske,[1] Fouad T. Chebib,[1] Theodora A. Potretzke.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]NYU Langone Health, New York, NY.*

Background: Hereditary Hypophosphatemic Rickets with Hypercalciuria (HHRH) is a rare monogenic disorder caused by *SLC34A3* pathogenic variants, characterized by renal phosphate wasting, hypophosphatemia, hypercalciuria (HC), elevated 1,25-dihydroxyvitamin D, nephrocalcinosis (NC), and urinary stone disease (USD). Previously we reported a high prevalence of kidney cysts in CYP24A1 deficiency. Thus, in the current study, we characterized cyst presence in HHRH, another monogenic cause of HC, NC, and USD.

Methods: Medical records from Mayo Clinic and Rare Kidney Stone Consortium research results were queried for all patients with genetically confirmed HHRH diagnosis. Clinical characteristics and imaging data are summarized in **table 1**.

Results: Among 12 patients with *SLC34A3* pathogenic variants (7 monoallelic, 5 biallelic), 42% (5/12) were males. Median age at clinical presentation was 17 yrs (range 8-46) and at genetic confirmation 42 yrs (range 9-66). None had a family history of cystic kidney disease. Kidney cysts (**Figure 1**) were present in 75% (9/12), among whom median age at first kidney imaging and first cyst detection was 41 yrs (range 9-64). Median number of cysts per patient was 3 (range 1-23). The number of cysts ≥ 5 mm in size was above the 97.5th percentile of an age- and sex-matched control population in 6/9 (67%). At least 2 cysts ≥ 5 mm in size were found in 100% of children.

Conclusions: We found a strong association between HHRH and kidney cysts. Similarities in the biochemical profiles of HHRH and CYP24A1 deficiency suggest elevated active vitamin D, and/or HC may be potential factors in cyst formation. Further studies are needed to evaluate the role of the *SLC34A3* gene in cyst formation.

Funding: Other NIH Support - This work was funded by the Rare Kidney Stone Consortium (RKSC; U54DK83908), which is part of Rare Diseases Clinical Research Network (RDCRN), an initiative of the Office of Rare Diseases Research (ORDR), National Center for Advancing Translational Sciences (NCATS) and R21TR003174. The RKSC was funded through collaboration between NCATS, and the National Institute of Diabetes and Digestive and Kidney Diseases.

Table 1 | Kidney cyst characteristics in the HHRH cohort

Case number	Age at first kidney cyst detection (yr)	Age at imaging for study data collection (yr)*	Imaging modality	Total number of cysts, location	Smallest cyst size, mm	Largest cyst size, mm	No. of cysts ≥5 mm
1	9	10	US	3, M	5	9	3

PO1204

Dysregulated Tryptophan Metabolism Promotes Polycystic Kidney Disease Progression

Dustin Nguyen, Emily K. Kleczko, Nidhi Dwivedi, Berenice Y. Gitomer, Michel Chonchol, Raphael A. Nemenoff, Jelena Klawitter, Katharina Hopp. *University of Colorado - Anschutz Medical Campus, Aurora, CO.*

Background: Metabolic reprogramming is a feature and modifier of autosomal dominant polycystic kidney disease (ADPKD) progression. Moreover, immune cells regulate cyst growth. In cancer, a disease with parallels to PKD, the metabolic landscape created by tumors significantly impacts immune cell function and tumor growth. Yet, this link is unexplored in PKD. Here, we study tryptophan metabolism, a known immunosuppressive pathway, in cyst growth.

Methods: Metabolites were profiled in ADPKD patient plasma and kidneys of an orthologous ADPKD model (C57Bl/6J *Pkd1*$^{RC/RC}$). We also crossed the ADPKD model to *Ido1*$^{-/-}$ mice, the enzyme metabolizing tryptophan to kynurenines, and inhibited IDO1 using the tryptophan analog 1-MT (400mg/kg, twice daily, orally). From these mice, kidney immune cells were profiled via flow cytometry.

Results: Tryptophan metabolites were significantly increased in *Pkd1*$^{RC/RC}$ mice at 3-, 6-, and 9-months compared to wildtype and correlated with disease progression. Plasma levels of kynurenines significantly associated with HtTKV at baseline, and positively correlated with annual percent change of HtTKV in adult ADPKD patients. IDO1 levels were significantly increased in kidneys of PKD mice and patient cell lines. At 6-months of age, *Pkd1*$^{RC/RC}$; *Ido1*$^{-/-}$ mice had significantly milder PKD compared to *Pkd1*$^{RC/RC}$ mice as measured by % KW/BW and cystic/fibrotic index. Similarly, treatment of 1-month-old *Pkd1*$^{RC/RC}$ mice with 1-MT for 3 weeks slowed cyst growth; overall providing functional evidence of the pathway's relevance to PKD. Kidney immune profiling of *Pkd1*$^{RC/RC}$; *Ido1*$^{-/-}$ and 1-MT-treated mice revealed a significant reduction of resident macrophages, regulatory T cells, and immune checkpoint protein expression (PD-1/PD-L1), while the percentage of CD8^{+} T cells/total T cells increased.

Conclusions: Our data highlight tryptophan metabolism as a novel dysregulated pathway in murine and human ADPKD and suggest that tryptophan metabolites are biomarkers of disease progression. Further, inhibition of the pathway presents a new treatment approach. IDO1 inhibitors are FDA approved for various cancers. Our data suggest a link between metabolic reprogramming, immune cell function, and disease progression, as IDO1 loss/inhibition impacted immune cell populations/pathways shown to regulate cyst growth.

Creatine Kinase Elevation in Patients with Autosomal Dominant Polycystic Kidney Disease on Tolvaptan Treatment

Diana Rodriguez-Espinosa, Elena C. Payán, Elena Guillen, Josep miquel Blasco pelicano. *Hospital Clinic de Barcelona, Barcelona, Spain*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease worldwide. Studies such as the TEMPO 3:4 and 4:4 have demonstrated tolvaptan's (vasopressin V2 receptor antagonist) effectiveness in slowing the progression of this disease. The best described adverse effect seen with this treatment is drug-induced liver injury, however, creatine kinase (CK) elevation has also been described anecdotally in a couple of case reports.

Methods: This is a prospective observational study of adult patients with rapidly progressive ADPKD on tolvaptan treatment under follow-up at Hospital Clínic de Barcelona from October 2018 to March 2021. Quantitative variables are described as mean and standard deviation, while qualitative ones are reported as absolute and relative frequencies.

Results: A total of 37 patients started treatment with tolvaptan during this period. In 34 of them, serum CK levels were measured as part of the monthly biochemical follow-up. A total of 29.11% (10 of 34) of the patients elevated this parameter with a mean of 1368.2 ± 2807.28 U/L. Seven patients had a transient elevation with a mean of 446.43 ± 359.22 U/L, which reversed upon dose decrease or treatment pause. However, treatment had to be interrupted in the remaining three patients (mean 3519 ± 5016.36). In one of them due to concomitant drug-induced liver injury and in the other two due to persistent CK elevation despite dose reduction or temporary treatment interruption. CK elevation was not related to exercise (although one patient did report a weekly intense cycling exercise with increased myalgia afterward) and was not significantly correlated with LDH levels, liver enzymes, calcium, potassium, urinary or plasma osmolarity.

Conclusions: By performing a general screening, we found that CK elevation is more frequent than previously described in the literature, reaching significantly increased levels or producing symptomatology requiring definitive treatment interruption. Based on these results, although the studied sample is small, we suggest adding this parameter as a part of tolvaptan treatment's follow-up, at the beginning of treatment and when increasing its dose, to promptly detect undesirable adverse effects and gain a better understanding of this phenomenon.

PO1206

Protein Kinase A Downregulation Delays the Development and Progression of Polycystic Kidney Disease

Xiaofang Wang,[1] Li Jiang,[1] Ka Thao,[1] Caroline R. Sussman,[1] Timothy P. Labranche,[2] Michael R. Palmer,[2] Peter C. Harris,[1] Stanley Mcknight,[3] Klaus P. Hoeflich,[2] Stefanie S. Schalm,[2] Vicente E. Torres.[1] *[1]Mayo Clinic, Rochester, MN; [2]Blueprint Medicines, Waban, MA; [3]University of Washington, Seattle, WA.*

Background: Upregulation of cAMP-dependent as well as -independent PKA signaling is thought to promote cystogenesis in polycystic kidney disease (PKD). We have shown that the PKA-I regulatory subunit RIα is increased in kidneys of orthologous mouse models and that kidney specific knockout of RIα upregulates PKA activity, induces cystic disease in wild-type mice, and aggravates it in *Pkd1*$^{RC/RC}$ mice.

Methods: This study was designed to ascertain (1) the effect of PKA-I activation or inhibition compared to EPAC or PKA-II inhibition on *ex vivo* cystogenesis using *Pkd1*$^{RC/RC}$ metanephric organ cultures, (2) whether PKA (preferentially PKA-I) downregulation by kidney specific expression of a dominant negative RIαB allele (obtained by crossing *Prkar1α*$^{R1αB/WT}$, *Pkd1*$^{RC/RC}$, and *Pkhd1*-Cre mice) is protective *in vivo* in *Pkd1*$^{RC/RC}$ mice on the C57BL/6 background, (3) whether a novel, small molecule, selective PRKACA inhibitor (BLU0588) blocks *in vitro* mIMCD3 and *ex vivo* cystogenesis (40-200 nM) and is protective *in vivo* in *Pkd1*$^{RC/RC}$ mice on the C57BL/6 x 129S6/Sv F1 background (30 mg/kg b.w. by oral gavage starting at 4 weeks of age). Mice were sacrificed at 16 weeks of age.

Results: PKA-I activation promoted, and inhibition prevented, *ex vivo* cystogenesis, whereas EPAC activation or PKA-II activation or inhibition had no or only minor effects. BLU0588 inhibited *in vitro* mIMCD3 cystogenesis and *ex vivo* cystogenesis. Genetic and pharmacological downregulation of PKA activity were both protective *in vivo* (Table). BLU0588 had no detectable on- or off-target adverse effects.

Conclusions: PKA-I is the main effector of cAMP in cystogenesis. Direct downregulation of PKA activity is demonstrated as a novel strategy to treat PKD. By acting directly on PKA, PKA inhibitors may be more effective alone or substantially augment the efficacy of treatments that only affect the cAMP-dependent PKA activity by lowering cAMP.

Protein 4.1O Links Polycystin 1 to the Actin Cytoskeleton and Modulates Hippo Signaling

Theresia Vienken, Eva Koenigshausen, Lars C. Rump, Lorenz Sellin. *Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany*.

Background: The majority of ADPKD patients have a PKD1 gene mutation. PKD1 codes for Polycystin-1 (PC-1). Cyst formation is caused by altered renal tubular cell proliferation. Protein 4.1 family members are actin adaptors, which link plasma membrane receptors to the actin cytoskeleton. Protein 4.1O (FRMD3) is a candidate gene for diabetic nephropathy. Furthermore, protein 4.1O has properties of a tumor suppressor. This study investigates the molecular and cellular properties of protein 4.1O as a potential ADPKD modifier and therapeutic target.

Methods: PC-1 full-length and truncation mutants were transiently expressed. PC-1 interaction with protein 4.1O and its truncation mutants were investigated. Truncation mutants cover the N- and C-terminal domains of protein 4.1O (Band 4.1, FERM, actin-binding domain and coiled coil domain). Coimmunoprecipitations of protein 4.1O with PC-1 in IMCD cell lysates were done. Pulldown experiments with bacterial recombinant protein 4.1O and F-actin were performed. The modulation of the PC-1 signaling properties by protein 4.1O were investigated in luciferase assays for c-myc and TEAD. FRMD3 core promotor regions were cloned into luciferase reporter.

Results: Coimmunoprecipitations show an interaction of protein 4.1O to PC-1 full-length. The C-terminus of PC-1 interacts with four isoforms of protein 4.1O (201, 202, 204, 207). The truncation mapping and isoform alignment identfies a potential leucine zipper domain in protein 4.1O as the C-terminal binding domain to PC-1. The N-terminal protein 4.1O FERM domain is also sufficient to mediate PC-1 interaction. Protein 4.1O C-terminus binds to F-actin and links the PC-1 C-terminus to the cytoskeleton. Protein 4.1O silences the PC-1 mediated transactivation of c-myc and hippo signaling (TEAD). Furthermore, F-actin destabilization influences the PC-1 induced hippo signaling. PC-1 activates the protein 4.1O promotor.

Conclusions: Both, the FERM domain and leucine zipper containing coiled coil domain of protein 4.1O interact with the PC-1 C-terminus. The interaction of protein 4.1O links PC-1 to the actin cytoskeleton. The protein 4.1O interaction inhibits the PC-1 mediated activation of c-myc and hippo signaling. Furthermore, protein 4.1O provides a F-actin based sensitivity to the PC-1 mediated hippo signaling. In summary, protein 4.1O shows features of an anti-cystogenic protein.

PO1208

Polycystin 2 Mediates Endoplasmic Reticulum K+-Ca2+ Exchange to Protect Against Polycystic Kidney Disease

Biswajit Padhy, Jian Xie, Chou-Long Huang. Huang Lab *University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: Prevailing view is that PKD is a ciliopathy. Yet, PC2 is most abundantly expressed in ER. Early studies showed that PC2 is involved in agonist-induced ER Ca2+ release. Decrease in ER Ca2+ release in PC2-deficient cells is believed to contribute to cAMP overproduction and cystogenesis. Recent patch-clamp recordings reveal that PC2 channel is ~40X more selective to K+ than Ca2+, raising the question regarding how PC2 mediates ER Ca2+ release and role of ER-localized PC2 in PKD pathogenesis. To avoid potential polarization impeding ion fluxes, Ca2+ release from ER lumen to cytosol requires coupled counter cation exchange and/or parallel anion movement.

Methods: ER Ca2+ release is assayed by fura2 fluorimetry stimulated by ATP. PC2-deficient morphant zebrafish and doxycycline-inducible adult-onset PC2-deficient mice are used for in vivo PKD model.

Results: ATP-stimulated ER Ca2+ release is blunted in PC2-null epithelial cells in which re-expression of WT, but not LOF, PC2 restores ER Ca2+ release. TricB (trimeric intracellular cation-B) is an ER resident K+ channel mediates K+-Ca2+ exchange for IP3R-mediated Ca2+ release. Expressing WT, but not LOF mutant, TricB rescues ER Ca2+ release in PC2-null cells. Vice versa, TricB-null cells have defective ER Ca2+ release, which is rescued by expression of recombinant WT PC2. Zebrafish injected with PC2 antisense morpholino develops dorsal curvature. Co-injecting WT, but not LOF mutant, PC2 RNA rescues phenotypes in PC2-deficient morphant fish. Co-injecting WT, but not LOF, TricB RNA rescues defects in PC2-morphant fish. ER targeting of ROMK K+ channel normally expresses on the cell surface rescues Ca2+ release defect and PC2-morphant phenotypes. PC2L1, a PC2 related channel normally expresses on cell membrane and cilia, does not rescue PC2-deficient morphant fish. Transgenic expression of TricB in adult-onset kidney-specific Pkd2-inactivated mice ameliorates cystogenesis. Double deletion of TricB and Pkd2 in mice reveal synergistic genetic interactions.

Conclusions: Our results provide compelling support for the notion that ER resident PC2 plays an important role in anti-cystogenesis of PKD. The mechanism of action is likely through mediating cytosol-to-ER lumen K+ flux to facilitate Ca2+ release via IP3R.

Interactions Between TULP3 and ARL13B in Lipidated Protein Transport to Cilia and Regulation of Renal Cystogenesis

Saikat Mukhopadhyay, Vivek R. Palicharla, Sun-hee Hwang. *The University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Signaling outputs from cilia maintain renal tubular homeostasis preventing cystogenesis; however, the ciliary proteins in this process are not well understood. The tubby family protein–TULP3 coordinates with the intraflagellar transport

complex-A (IFT-A) in trafficking transmembrane proteins to cilia. Lack of Tulp3 in mouse promotes renal cystogenesis during embryogenesis but suppresses adult-onset polycystic kidney disease. Discovering cargoes of TULP3 and deciphering mechanisms underlying ciliary compartmentalization will help understand how signaling at and by cilia contributes to cystogenesis.

Methods: We used direct *in vitro* binding, proximity biotinylation and mass spectrometry to map TULP3-cargo interactions. We generated knockouts of *Tulp3* and cargoes in kidney epithelial cells stably co-expressing different variants of *TULP3* or cargoes, respectively. We generated conditional knockout of *Tulp3* in mouse kidney nephrons using *Cre*-drivers and performed immunofluorescence for lipidated proteins with respect to kidney cystogenesis.

Results: The transmembrane cargoes have short motifs that are necessary and sufficient for TULP3-mediated trafficking. We now show that TULP3 is required for transport of the atypical GTPase ARL13B into cilia, and for ciliary enrichment of ARL13B-dependent farnesylated and myristoylated proteins. ARL13B transport requires TULP3 binding to IFT-A core but not to phosphoinositides, unlike transmembrane cargo transport that requires binding to both by TULP3. A conserved lysine in TULP3′s tubby domain mediates direct ARL13B binding and trafficking of lipidated and transmembrane cargoes. An N-terminal amphipathic helix in ARL13B flanking the palmitoylation site mediates binding to TULP3 and directs trafficking to cilia. Tulp3 trafficked lipidated proteins are depleted with distinctive temporal kinetics from kidney epithelial cilia during *Tulp3* deletion-induced cystogenesis.

Conclusions: We conclude that TULP3 transports transmembrane proteins and ARL13B into cilia by capture of short sequences through a shared tubby domain site. Drugging this interaction domain could provide therapeutics in polycystic kidney disease. The depletion of lipidated cargoes with distinct kinetics from kidney epithelial cilia following *Tulp3* deletion suggests their differential roles in cilia in regulating renal cystogenesis.

PO1210

Augmented Renal TRPV4 Activity Attenuates Cystogenesis in ARPKD Rats

Kyrylo Pyrshev, Victor N. Tomilin, Naghmeh Hassanzadeh Khayyat, Oleg L. Zaika, Oleh Pochynyuk. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: PKD is characterized by development of cysts in the kidney. Abundant evidence suggested that the impaired mechanosensitivity and disturbed $[Ca^{2+}]_i$ homeostasis are the major determinants of the rate of cystogenesis. The rapidly progressing ARPKD is caused by missense mutations in fibrocystin. ARPKD is characterized by the development of cysts almost exclusively in the collecting duct. We have previously demonstrated that mechanosensitive Ca^{2+}-permeable TRPV4 channel is preferentially expressed in the collecting duct where its activity is imperative for setting resting $[Ca^{2+}]_i$ levels and mediating flow-dependent $[Ca^{2+}]_i$ elevations. TRPV4 activity and expression is markedly augmented by high K^+ intake, known to increase flow in the collecting duct. Thus, we hypothesized that dietary K^+ supplementation would be beneficial in counteracting cystogenesis during ARPKD by stimulating TRPV4-dependent Ca^{2+} influx.

Methods: We used dietary and pharmacological inputs to establish a correlation between the rate of cystogenesis and TRPV4 function in freshly isolated cyst monolayers in a homologous ARPKD rodent model, PCK453 rats.

Results: We report that treatment of PCK453 rats with high KCl (10%) diet for 1 and 2 months significantly reduced kidney-to-body weight ratio, cystic index, and interstitial fibrosis. We also found a greatly increased total renal TRPV4 expression, channel activity and higher basal $[Ca^{2+}]_i$ levels in native cyst cells compared with respective controls. Importantly, the beneficial effects of high KCl diet were abrogated when PCK453 rats were also treated with the selective TRPV4 inhibitor, GSK2193874. GSK2193874 treatment also exacerbated cystogenesis in control PCK453 rats by modestly increasing kidney-to-body weight ratio. Surprisingly, high K^+ alkali diet (10% $KHCO_3$/Citrate) also aggravated the disease progression despite augmented renal TRPV4 expression. However, TRPV4-dependent Ca^{2+} fluxes were dramatically suppressed in freshly isolated cyst cell monolayers from high K^+ alkali fed rats, which is consistent with impaired TRPV4 activity.

Conclusions: Our experiments establish the direct link between TRPV4 function and diminished cystogenesis during ARPKD. We propose that stimulation of TRPV4 by pharmacological or dietary cues could be of clinical relevance to counteract PKD progression.

PO1211

The Transcription Factor Tfap2a Maintains the Epithelial Integrity of Renal Collecting Ducts

Janna Leiz,[1,2] Christian Hinze,[1,2] Kai M. Schmidt-Ott.[1,2] [1]*Charite Universitatsmedizin Berlin, Berlin, Germany;* [2]*Max-Delbruck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.*

Background: The transcriptional regulator Tfap2a is a member of the AP-2 family of transcription factors. In humans, heterozygous mutations of Tfap2a result in branchio-oculo-facial syndrome (BOFS), which is associated with renal anomalies, including dysplastic, absent and multicystic kidneys. In this project, we aimed to elucidate the molecular functions of Tfap2a in the renal collecting duct.

Methods: We generated mice carrying a collecting duct-specific knockout of Tfap2a ($Tfap2a^{CD-/-}$) by crossing Hoxb7;Cre and $Tfap2a^{flox/flox}$ mice. Newborn and adult mice were analyzed using histology, in situ hybridization, bulk RNA sequencing and single nucleus RNA sequencing.

Results: Tfap2a was expressed in the ureteric bud and distal region of the S-shaped body in kidneys of newborn wildtype mice and expression was maintained in mature distal tubules and collecting ducts. $Tfap2a^{CD-/-}$ mice displayed moderately reduced kidney weights (20 % reduction compared to controls) and a progressive dilation of outer medullary collecting ducts throughout six months of life. Bulk and single nuclei RNA sequencing of kidneys of three months old $Tfap2a^{CD-/-}$ mice and littermate controls indicated deregulated expression of genes associated with cellular adhesion and epithelial integrity, such as Cldn8 and Npnt. In addition, Wnt9b, a factor previously described as a regulator of planar cell polarity and tubule diameter, was downregulated in collecting ducts of $Tfap2a^{CD-/-}$ mice.

Conclusions: Our data indicate that the transcription factor Tfap2a regulates kidney size and contributes to the continued integrity of the collecting duct epithelium. Our data provide insights into potential molecular mechanisms underlying renal defects observed in BOFS.

PO1212

Comparative Multiple-Species Analysis of Renal Disease Mutations in HNF1B

Kelli Grand,[1] Thomas Naert,[1] Ludovica Rizzo,[1] Maike Getwan,[1] Roman Pichler,[2] Soeren S. Lienkamp.[1] [1]*Universitat Zurich, Zurich, Switzerland;* [2]*Albert-Ludwigs-Universitat Freiburg Medizinische Fakultat, Freiburg, Germany.*

Background: Hepatocyte nuclear factor 1-beta (HNF1B) is a transcription factor involved in various stages of nephrogenesis and maintenance of renal tubular functions. Mutations in *HNF1B* are the most common monogenic causes for developmental renal disease, yet the underlying pathways affected are not fully understood. By comparative analysis in *Xenopus* and directly reprogrammed mammalian cells (iRECs) we investigated a patient-specific mutation (R295C) associated with cystic-dysplastic kidneys.

Methods: We used HNF1B to form renal-like organoids from *Xenopus* explants. In parallel, we analyzed how HNF1B R295C affects nephrogenesis in iRECs. Transcriptional changes were comparatively analyzed in two different species. We confirmed HNF1B target candidates *in vivo* using CRISPR/Cas9 editing of *Xenopus* embryos.

Results: We show that HNF1B is not only an essential component in direct reprogramming but can also induce ectopic pronephric tissue in *Xenopus* ectodermal explants. Changes in the transcriptomic profile demonstrated alterations in specific transcriptional modules and identified novel direct and indirect targets of the transcription factor HNF1B, which are linked to signaling pathways associated with renal morphogenesis, cilia and organic anion transport.

Conclusions: In conclusion, the combined use of directly reprogrammed mammalian cells and *Xenopus* renal organoid experiments allow us to gain a unique perspective into evolutionary conserved mechanisms of renal development and HNF1B associated kidney disease.

PO1213

Mosaic Inactivation of Pkd1 in Resistance Arteries Leads to Endothelial Dysfunction in Mice

Vivian C. Dourado, Patrizia Dardi, Luciana V. Rossoni, Luiz F. Onuchic. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Cardiovascular problems are the leading cause of mortality in autosomal dominant polycystic kidney disease (ADPKD) and hypertension is observed in 50-70% of patients before significant reduction in renal function. The pathogenesis of ADPKD-associated vasculopathy, however, remains largely unclear.

Methods: Mesenteric resistance arteries (MRA) of male normotensive non-cystic $Pkd1^{+/-}$ mice (HT) and their $Pkd1^{+/+}$ controls (WT) as well as in hypertensive cystic $Pkd1^{flox/flox}$:$Nestin^{cre}$ mice (CY) and their non-cystic $Pkd1^{flox/flox}$ controls (NC) were studied. HT and WT animals were analyzed at the ages of 8-12 and 55-60 weeks and had systolic blood pressure (SBP) recorded by tail plethysmography from 15 to 55 weeks of life, while CY and NC mice were analyzed at 8-12 weeks of life. The endothelium-dependent [acetylcholine (ACh) 10^{-9}-10^{-5} M] and -independent relaxation [sodium nitroprusside (SNP) 10^{-11}-10^{-5} M]; norepinephrine (NE, 10^{-9}-10^{-4} M)- and KCl (120 mM)-mediated contraction were assessed in MRA rings by wire myograph. Structural and mechanical parameters (SMP) were evaluated at 55-60 weeks in HT and WT rings using pressure myograph.

Results: At 8-12 weeks, no significant difference in ACh-induced relaxation was observed in MRA between HT and WT mice. CY mice, on the other hand, displayed lower ACh-induced relaxation compared to NC animals (Maximal response: 44.5±7.7 *vs* 19.9±6.7%; $P<0.05$), although this parameter was impaired in NC compared to WT ($P<0.0001$). SNP-induced relaxation was similar among groups. The contraction induced by NE or KCl did not differ between HT and WT or between CY and NC mice. At 55-60 weeks, vascular reactivity and SMP did not differ in MRA between HT and WT mice. Interestingly, no difference in SBP was identified between these groups.

Conclusions: Mosaic inactivation of both copies of *Pkd1* led to endothelial dysfunction in MRA, a phenotype not induced by *Pkd1* haploinsufficiency. Aging did not lead to development of hypertension or vascular dysfunction and remodeling in *Pkd1*-haploinsufficient mice. While our data suggest that the endothelial abnormality observed in these cystic mice may be a primary dysfunction, current investigation is assessing a potential contribution of chronic hypertension.

Autophagy Inhibition Ameliorates Polycystic Kidney Disease

Daniel Atwood, Deepak Pokhrel, Nidhi Dwivedi, Katharina Hopp, Charles L. Edelstein. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: We published that there is a decrease in autophagy proteins in Pkd1$^{RC/RC}$ mouse kidneys. Our study aimed to determine the mechanistic role of suppressed autophagy in causing cyst growth using pharmacological and genetic autophagy inhibition.

Methods: Male *Pkd1*$^{RC/RC}$ (RC) mice were treated with 2-Deoxyglucose (2DG) or Chloroquine (CHLQ) from 50-120d of age. Kidney specific *Pkd1, Atg7* double knockout mice were generated by Ksp1.3 Cre-lox recombination. Relative densitometry units (RDU) were determined on immunoblot. Autophagic flux was measured by the change in LC3-II (autophagosomes) -/+ Bafilomycin (Baf).

Results: Autophagic flux was present in wild type (WT) and 120 d old RC but suppressed in 150 d old RC kidneys. LC3-II (RDU) -/+ Baf was 0.1 vs 0.7 in WT ($p<0.01$), 0.6 vs 1.0 in 120 d old ($p<0.05$) and 2.4 vs 2.1 (NS) in 150 d old RC. 2DG resulted in a decrease in ATG12-5 complex and suppressed autophagic flux in RC kidneys. LC3-II (RDU) -/+ Baf was 0.5 vs 0.8 in VEH ($p<0.05$), 0.7 vs 0.7 in 2DG (NS). 2DG significantly reduced cyst growth and improved kidney function. Cystic index (%), count -/+ 2DG: 7.7 vs 3.7 ($p<0.01$), 211 vs 161 ($p<0.05$). BUN (mg/dL) -/+ 2DG: 35 vs 27 ($p<0.01$). Next, RC mice were treated with CHLQ, a specific autophagy inhibitor. CHLQ resulted in suppressed autophagic flux, less PKD and improved kidney function in RC mice. LC3-II (RDU) -/+ Baf was 1.2 vs 1.2 (NS) in CHLQ treated kidneys. Cyst index (%), Cyst no -/+ CHLQ in RC mice was 15.5 vs 7 ($p<0.07$), 231 vs 105 ($p<0.05$). BUN and creatinine (by HPLC) (mg/dL) -/+ CHLQ: 41 vs 26 ($p<0.05$), 2.9 vs 2.3 mg/dL ($p<0.05$). Next, autophagy was inhibited in PKD kidneys by generating double Pkd1 Atg7 KO mice. The 2 kidney/BW (%) was improved in Pkd1 Atg7 KO vs. single Pkd1 KO mice (32 vs 39 $p<0.05$). Atg7 KO kidneys had a massive increase in p62 indicating a build-up of autophagic cargo. p62 in WT vs Atg7 KO (RDU) 0.1 vs 1.8 $p<0.001$. Interestingly Atg7 KO kidneys were filled with tertiary lymphoid organs (TLO): large condensed infiltrates of T and B cells. pAMPK^{T172} was increased in Atg7 KO kidneys. AMPK activation is known to reduce PKD.

Conclusions: Both 2DG and CHLQ suppressed autophagic flux in RC kidneys and resulted in less PKD and improved kidney function. Double Pkd1 Atg7 KO mice had significantly lower kidney weight than single Pkd1 KO mice. Both pharmacological and genetic autophagy inhibition resulted in less PKD.

PO1215

ARL13B Negatively Regulates Kidney Cysts from Within Cilia

Robert E. Van Sciver,[1] Eduardo Gigante,[1,2] Tamara Caspary.[1] *[1]Emory University, Atlanta, GA; [2]Georgia Institute of Technology, Atlanta, GA.*

Background: Polycystic kidney disease (PKD) is intricately linked to the primary cilium. Polycystin proteins localize to cilia and loss of cilia leads to renal cysts. PKD mouse models often disrupt ciliary genes, removing both ciliary and cellular pools of these gene products; however, the molecular pathway(s) that drive cyst formation is unknown. ARL13B is a regulatory GTPase highly enriched in cilia due to a VxPx motif near its C terminus. ARL13B is also localized to extraciliary sites within the cell. In most tissues, complete deletion of *Arl13b* leads to short cilia but in kidney *Arl13b* deletion leads to a loss of cilia and kidney cysts. As cilia loss leads to renal cysts, it was impossible to determine whether these cysts were due to the loss of cilia or the loss of ARL13B-dependent signaling in cilia. In order to determine the specific function of ARL13B within cilia, we needed a genetic tool that would allow us to isolate the ciliary function of ARL13B.

Methods: We engineered mice in which we mutated the valine to alanine within ARL13B's VxPx cilia-localization motif so the mice express cilia-excluded ARL13B^{V358A} from the endogenous locus. ARL13B^{V358A} protein retains all known ARL13B biochemical functions, is stably expressed and is undetectable in cilia. We measured renal cysts and cilia phenotypes to functionally characterize the cystic phenotype of cilia-excluded *Arl13b*$^{V358A/V358A}$ mice.

Results: *Arl13b*$^{V358A/V358A}$ mice are viable and fertile with slowly progressing renal cysts. *Arl13b*$^{V358A/+}$ mice exhibit no cystic phenotypes and *Arl13b*$^{V358A/null}$ mice develop cysts at a more rapid rate than *Arl13b*$^{V358A/V358A}$ mice. We detect cysts in all nephron segments of *Arl13b*$^{V358A/V358A}$ mice. Renal epithelia of *Arl13b*$^{V358A/V358A}$ mice retain cilia in normal nephrons as well as cystic regions.

Conclusions: Our findings indicate that ARL13B plays a critical role within the cilium in regulating kidney cystogenesis. These results suggest that ARL13B functions as a negative regulator of renal cysts, specifically from within the cilium. Further studies are ongoing to dissect the mechanism(s) by which ciliary ARL13B regulates kidney cystogenesis.

Tsc Gene Locus Disruption and Differences in Renal Epithelial Extracellular Vesicles

Prashant Kumar,[1] Fahad Al-Zadjali,[3,1] Ying Yao,[1] John J. Bissler.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]St. Jude Children's Research Hospital, Memphis, TN; [3]Sultan Qaboos University, Muscat, Oman.*

Background: In tuberous sclerosis complex (TSC), *Tsc2* mutations are associated with more severe disease manifestations than *Tsc1* mutations and the role of extracellular vesicles (EVs) in this context is not yet studied. We report a comparative analysis of EVs derived from isogenic renal cells except for *Tsc1* or *Tsc2* gene status and hypothesized that in spite of having similar physical characteristics, EVs modulate signaling pathways differently, thus leading to TSC heterogenicity.

Methods: We used mouse inner medullary collecting duct (mIMCD3) cells with the *Tsc1* (T1G cells) or *Tsc2* (T2J cells) gene disrupted by CRISPR/CAS9 methodology. EVs were isolated from the cell culture media by size-exclusion column chromatography followed by detailed physical and chemical characterization. Physical characterization of EVs was accessed by tunable resistive pulse sensing and dynamic light scattering, electron microscopy, and western blot analyses.

Results: Physical characterization of EVs revealing similar average sizes and zeta potentials (at pH 7.4) for EVs from mIMCD3 (123.5 ± 5.7 nm and –16.3 ± 2.1 mV), T1G cells (131.5 ± 8.3 nm and –19.8 ± 2.7 mV), and T2J cells (127.3 ± 4.9 nm and –20.2 ± 2.1 mV). EVs derived from parental mIMCD3 cells and both mutated cell lines were heterogeneous (>90% of EVs < 150 nm) in nature. Immunoblotting detected cilial Hedgehog signaling protein Arl13b; intercellular proteins TSG101 and Alix; and transmembrane proteins CD63, CD9, and CD81. Compared to *Tsc2* deletion, *Tsc1* deletion cells had reduced EV production and release rates. EVs from *Tsc1* mutant cells altered mTORC1, autophagy, and β-catenin pathways differently than EVs from *Tsc2*-mutated cells. Quantitative PCR analysis revealed the down regulation of miR-212a-3p and miR-99a-5p in EVs from *Tsc2*-mutated cells compared to EVs from *Tsc1*-mutant cells.

Conclusions: EV-derived miR-212-3p and mIR-99a-5p axes may represent therapeutic targets or biomarkers for TSC disease.

ADPKD Mutations in the Stalk/Tethered Agonist of Polycystin-1 CTF Affect Signaling and GPS Cleavage

Robin L. Maser, Brenda S. Magenheimer, Ericka Nevarez Munoz. *University of Kansas Medical Center, Kansas City, KS.*

Background: Like Adhesion G protein-coupled receptors (aGPCRs), the N-terminal ectodomain of polycystin-1 (PC1) contains a membrane-proximal GAIN domain that catalyzes self-cleavage at its embedded GPCR proteolysis site (GPS), dividing these proteins into extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. PC1 GPS cleavage is required for JAK/STAT signaling, PC1 maturation/trafficking and for prevention of renal cystogenesis in mice. ADPKD mutations that map within the GAIN domain inhibit GPS cleavage. We previously reported that the PC1 CTF utilizes an aGPCR-like tethered agonist mechanism to activate G-protein signaling to an NFAT reporter, which involves the short, N-terminal, extracellular stalk of the CTF serving as the tethered agonist. Deletion of the stalk dramatically inhibited signaling, while synthetic stalk-derived peptides could rescue signaling by the stalkless CTF and inhibit cystogenesis in metanephric organ cultures of hypomorphic *Pkd1*$^{RC/RC}$ kidneys. Here we assess the effect of stalk-localized ADPKD missense mutations on signaling by the dissociated CTF subunit and on GPS cleavage of full-length (FL) PC1 to gain additional insight for this regulatory mechanism.

Methods: Wild type (WT) or mutant, FL or CTF forms of PC1 were expressed in HEK293T cells and compared for activation of an NFAT promoter-luciferase reporter, levels of total and cell surface expression and GPS cleavage. Homology modeling of the PC1 GAIN domain was also performed.

Results: Of 11 substitutions throughout the stalk, 6 significantly reduced, 2 increased, and 3 had no effect on signaling by PC1 CTF. Total and surface expression levels of the CTF mutants ranged from 62-125% of WT CTF. Most mutations had no effect on GPS cleavage of FL-PC1. Mutations that inhibited signaling or GPS cleavage mapped to the N-terminal portion of the stalk, while the 2 mutations that increased signaling were in the latter half.

Conclusions: PC1 stalk has more than one region important in regulation of CTF signaling- perhaps as part of the agonistic sequence or for its proper orientation. This study underscores the importance of PC1 GPS cleavage and suggests disruption of a tethered agonist mechanism may also contribute to renal cystogenesis. Better understanding of the tethered agonist mechanism is necessary for development of *PKD1* mutation-specific therapies.

Metabolomic Analysis of Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Associations with Disease Progression and Treatment

Shirin Sundar,[1] Sharin Roth,[1] Sachin S. Hajarnis,[1] Lucas Westcott-Baker,[1] Linda Mccormick,[1] Bharath Ramaswamy,[1] Arlene B. Chapman.[2] *[1]Otsuka Pharmaceutical Development & Commercialization, Rockville, MD; [2]University of Chicago, Chicago, IL.*

Background: ADPKD is characterized by epithelial proliferation and cyst growth. Metabolic abnormalities have been identified in murine models, but little is known about alterations in metabolic pathways in human ADPKD. We evaluated plasma metabolomic profiles in ADPKD subjects prior to and after exposure to tolvaptan (T) as compared to healthy controls to better understand metabolic alterations in ADPKD and potential associations with disease progression and treatment response.

Methods: Plasma samples were collected and analyzed at baseline and month 12 in 100 ADPKD subjects (50 in T and 50 in placebo [P] arms) enrolled in TEMPO 3:4 (NCT00428948). The protein fraction was removed, and the remaining extract split into equal parts for analysis on liquid chromatography tandem mass spectrometry and gas chromatography mass spectrometry platforms. Proprietary software (Metabolon, Inc., Durham, NC) matched ions to an in-house library of standards for metabolite identification and quantitation. Forty age- and sex-matched healthy subjects were analyzed as a control group. Linear mixed effect modeling identified associations of metabolites with ADPKD vs control, height-adjusted total kidney volume (htTKV), Mayo Imaging Classification (MIC), and T vs P.

Results: Baseline metabolic profiles differed between ADPKD and controls, with significant differences in lipid metabolism, TCA cycle, and amino acid metabolism. Baseline MIC 1C, 1D, 1E (vs 1B) were associated with accumulation of the uremic toxin pseudouridine, elevated fatty acid synthesis, and altered tryptophan metabolism, with similar findings when baseline htTKV was analyzed. Thyroxine, urea, and dimethylsulfone were decreased in T vs P at month 12, as well as other metabolites involved in lipid and amino acid metabolism.

Conclusions: We identified novel associations of amino acid and lipid metabolic pathways with ADPKD vs control and with measures of disease severity (MIC and htTKV). Metabolite intensity was differentially affected in T vs P at 12 months of treatment, supporting a role for discovery metabolomics in evaluating response to therapy.

Short-Term Ketogenic Interventions Are Feasible and Effective in Triggering Ketosis in Autosomal Dominant Polycystic Kidney Disease (ADPKD): Results from the RESET-PKD Study

Simon Oehm,[1] Konstantin Steinke,[1] Sita Arjune,[1] Polina Todorova,[1] Christoph Lindemann,[1] Fabian Wöstmann,[1] Franziska I. Meyer,[1] Florian Siedek,[1] Thomas Weimbs,[2] Franziska Grundmann,[1] Roman-Ulrich Mueller.[1] *[1]Universitat zu Koln, Koln, Germany; [2]University of California Santa Barbara, Santa Barbara, CA.*

Background: Short-term ketogenic dietary interventions slow disease progression in animal models of ADPKD. The RESET-PKD study translates these promising results to a pilot study in humans.

Methods: 10 ADPKD patients with rapid disease progression were enrolled (baseline V1) and initially followed their usual carbohydrate-rich diet for up to 4 weeks. At visit 2 (V2) patients chose to either perform a 3-day water fast (WF) or a 14-day ketogenic diet (KD) until V3 and returned to their normal nutrition until V4. MRI kidney volumetry was performed at all visits. Ketone bodies were evaluated at all visits and in between. Feasibility was examined using questionnaires.

Results: All participants (KD: n=5, WF: n=5; age 39.8±11.6 years; eGFR 82±23.5 ml/min; TKV 2224±1156 ml) were classified as Mayo Class 1C to 1E. The dietary interventions did not alter serum creatinine (V2: 1.17±0.33 mg/dl vs. V3: 1.20±0.35 mg/dl, p = 0.826) but serum glucose levels decreased significantly (V2: 84±3 mg/dl, V3: 70±13 mg/dl, p = 0.004). Acetone levels in breath as well as BHB blood levels increased in both study arms (average acetone before dietary intervention (V1 to V2): 2.6±1.18 ppm, on diet (V3): 22.8±11.9 ppm, p< 0.0001; BHB before dietary intervention: 0.22±0.08 mmol/l, on diet: 1.89±0.92 mmol/l, p<0.0001). 9 out of 10 patients reached a ketogenic state during the intervention and 90 % evaluated ketogenic interventions as feasible. No significant TKV changes were observed (ΔTKV V1 to V2: +0.75±0.54%, ΔTKV V2 to V3: -1.06±1.16%).

Conclusions: RESET-PKD shows that ADPKD patients adhere to short-term ketogenic interventions, reliably reach ketosis without ADPKD-specific adverse effects, and judge this diet as feasible in every-day life. Short-term ketogenic interventions did not lead to a significant reduction in TKV or serum creatinine. Larger clinical trials examining longer-term dietary interventions will be crucial to further evaluate long-term feasibility and the therapeutic potential of ketogenic diets in ADPKD.

PO1220

Analysis of MicroRNAs as Regulators of Expression of Transcripts Associated with Stem Cell Pluripotency in Pkd1-Deficient Mouse Models

Juan J. Moyano muñoz,[1] Mirian A. Boim,[1] Luiz F. Onuchic,[2] Ita P. Heilberg.[1] *[1]Universidade Federal de São Paulo, São Paulo, Brazil, São Paulo, Brazil; [2]University of São Paulo School of Medicine, São Paulo, Brazil.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by cysts formation deriving from collecting ducts. Pluripotent stem cells associated with the formation of renal structures have been used in *in vitro* studies of nephrogenesis or cystogenesis related to ADPKD. However, the association between transcripts integrating pathways involved in stem cells pluripotency and cystogenesis deserves further investigation. The microRNAs (miRNAs) that participate in the regulation of these transcripts in kidney tissues of mouse models orthologous to ADPKD have not yet been validated. To identify regulatory miRNAs and differently expressed transcripts associated with stem cell pluripotency in kidney tissues of *Pkd1*-deficient mouse models.

Methods: A transcriptomic computational identification and validation of the expression level of regulatory miRNAs and genes by RT-qPCR, normalized by their respective housekeepings, *miR-26a* and *Ppia* was performed. The analyses were performed on kidneys from 10- to 12-week-old cystic mice ($Pkd1^{flox/flox}$:$Nestin^{cre}$ or $Pkd1^{flox/-}$:$Nestin^{cre}$, CY, n = 10) and their non-cystic controls ($Pkd1^{flox/flox}$ or $Pkd1^{flox/-}$, NC, n = 10); mice haploinsufficient for *Pkd1* ($Pkd1^{+/-}$, HT, n = 6) and their wild controls ($Pkd1^{+/+}$, WT, n = 6); and 15-day-old severely cystic mice ($Pkd1^{V/V}$, SC, n = 7) and their controls (CO, n = 5).

Results: The validation of the computational analyses performed in our three animal models with reports from the literature in other *Pkd1*-deficient models, identified 10 differently expressed genes associated with the regulation of stem cells pluripotency. Increased expression of *Stat3* and *Map3k1* genes and decreased regulatory miRNA *Let-7a* were observed in SC versus CO kidneys. On the other hand, *Mapk14* gene showed decreased expression while its potential regulator, *miR-21*, revealed increased expression in SC versus CO kidneys. *Fgf10* expression was decreased in SC versus CO kidneys whereas a trend of increased expression in the CY versus NC group has been observed.

Conclusions: Present results suggest a potential regulatory effect of *miR-21* on *Mapk14* expression and of *miR-Let-7a* on the expression of *Stat3*, *Map3k1* and *Fgf10*, namely transcripts involved in stem cells pluripotency and cystogenesis in kidney tissues of *Pkd1*-deficient mouse models.

Funding: Government Support - Non-U.S.

PO1221

Investigation of Lad1 as a Candidate Modifier of Polycystic Kidney Disease in Pkd1 Mouse Models

Elisabeth Pearson, Luis F. Menezes, Gregory G. Germino. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Polycystic Kidney Disease (PKD) is a monogenic disease caused by mutations in either *PKD1* or *PKD2*, which encode polycystin-1 (PC1) and polycystin-2 (PC2), respectively. One proposed function for PC1 is to regulate cell migration and cell-cell interaction, possibly through modulation of the cytoskeleton. In prior transcriptomic studies of *Pkd1* mutant kidneys, we had identified *Lad1* as one of the few genes whose expression was dysregulated early in the course of the disease. The limited available literature suggests *Lad1* may encode a cytoskeleton protein that acts as an anchoring filament to the basement membrane of epithelial cells. The goal of this study is to investigate the role of Lad1 in mediating/modifying PKD phenotypes.

Methods: We quantified *Lad1* gene and protein expression in the tissues of *Pkd1* conditional mutant mice, kidney epithelial cell lines derived from *Pkd1* conditional mice and human keratinocyte HaCat cells by quantitative polymerase chain reaction (qPCR) and western blot analyses. We used CRISPR technology to generate two *Lad1* mutant mouse lines that have large deletions spanning most of the coding region of *Lad1* and characterized the phenotype of homozygous mutants. *Lad1* mutants were crossed with $Pkd1^{cond/cond}$ mice with Ksp-Cre and tamoxifen-Cre to test for genetic interaction in early and late onset PKD models.

Results: We confirmed that *Pkd1* mutant kidneys and epithelial cells have lower *Lad1* expression levels compared to wild type samples. Mice with homozygous deletion of *Lad1* exons 3 to 8 were born at normal mendelian ratios and lacked obvious abnormalities up to 1 year of age. Histopathologic analyses of the kidney and organs with the highest expression of *Lad1* also were normal. *Pkd1/Lad1* double mutants were born at expected rates and lacked distinctive phenotypic features. However, early data suggest that $Pkd1^{cond/cond}$; Ksp-Cre+/ *Lad1* homozygous mutants have increased kidney-body weight ratios with worse cystic disease. Further analysis, including *Lad1* CRISPR knock-out animals crossed with late-stage conditional *Pkd1* knock-out animals, is ongoing.

Conclusions: *Lad1* expression is reduced in *Pkd1* mutant kidneys. CRISPR knock-out of *Lad1* alone shows no obvious phenotype. Loss of *Lad1* may worsen disease in the early onset *Pkd1*-cystic model.

PO1222

Sildenafil Inhibits ADPKD-Derived Cyst Growth in 3D Culture and Induces Apoptosis in the Han/SPRD Cy+/Cy+ Rat Model of Renal Cystic Disease

Robert L. Bacallao,[1,2] Weimin Xu,[1] George Rhodes.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Richard L Roudebush VA Medical Center, Indianapolis, IN.*

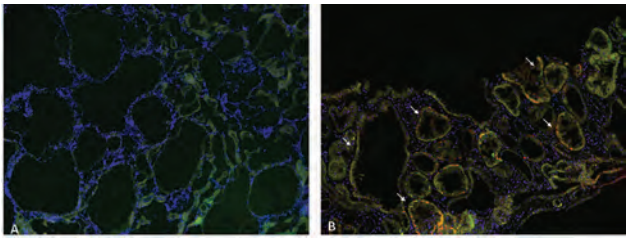
Background: In prior studies we found that human renal cyst cells express high levels of cGMP phosphodiesterase 5, 6 and 9 as compared to normal human kidney cells. In breast cancer, inhibition of cGMP phosphodiesterases induces apoptosis. We tested the hypothesis that sildenifil blocks cell proliferation and/or induces apoptosis in cyst epithelia.

Methods: PKD Q4004X cells were grown in Matrigel and treated with vehicle or sildenifil for 7 days. Cyst size was assayed by light microscopy. Differences in cyst area were analyzed by two-way ANOVA. In separate experiments, male cy+/cy+ rats were given either vehicle or sildenifil in their water supply for 7 or 28 days. Kidneys were harvested and apoptosis was assayed by staining with anti-M30, a monoclonal antibody that binds to apoptosis mediated cleavage of cytokeratin 18 in epithelial cells.

Results: In 3D cultures of PKD Q4004X cells, cultures treated with sildenafil (1, 2 and 4 ug/ml) are significantly smaller than vehicle-treated cultures ($p<0.05$ for all doses). Further analysis showed that cysts larger than 150 um^2 were not observed in any sildenafil treated cultures. Figure 1 shows M30 staining in sildenafil (20 ug/kg/day x 7 to treated rats (panel B, red channel merged with the green autofluorescence channel) versus vehicle treated animals. M30 positive cells are found predominantly around cyst lumens. Apoptotic changes in cyst epithelia were also observed in rats treated with sildenafil for 40 days.

Conclusions: Sildenafil inhibits human kidney cyst cyst growth in 3D culture. In male $cy^{+/+}$ rats, sildenafil at a dose of 20 mg/kg/day for 7 or 40 days results in apoptosis of cyst epithelia.

Funding: Private Foundation Support



Seven days of sildenafil treatment induces apoptosis in cystic kidneys. Sections stained with anti-cytokeratin 8/18 (red channel). Nuclei are labeled with Hoechst 33342. Green channel is autofluorescence. A: Vehicle treated male rats. Note the absence of cytokeratin 8/18. B: Vehicle + 20 mg/kg sildenafil treated for 7 days. Arrows point to cytokeratin 8/18 positive (red cytosolic stain) in cyst epithelia.

PO1223

Polycystin 1 Ciliary Localization Is Regulated by Its aGPCR Activity

Nikolay P. Gresko, Michael J. Caplan. Caplan Lab *Yale University School of Medicine, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by loss of function mutations in the PKD1 and PKD2 genes, which encode PC1 and PC2, respectively. PC1 is a 460kD multi-spanning membrane protein that undergoes multiple proteolytic cleavages, one of which occurs at a G Protein Coupled Receptor (GPCR) Proteolytic site near the junction between the large extracellular N terminus (NTF) and the first transmembrane domain. PC1 and 2 both localize to the primary cilium where they may participate in mechano-sensation and other sensory processes. Recent studies demonstrate that PC1 can function as an atypical GPCR and that it binds to Wnt ligands. We have shown that removal of the PC1 NTF exposes a tethered agonist (TA) peptide that activates the PC1 GPCR function. Activation of GPCRs in the cilia induces their trafficking out of the cilium in association with their ligand-induced desensitization.

Methods: Confocal IF, Mechanical stimulation, PC1 mutagenesis.

Results: We find that the localization of PC1 to cilia is similarly regulated by its GPCR activity. A constitutively active PC1 construct that lacks the NTF ($PC1^{\Delta NTF}$) is absent from the primary cilia when expressed in LLC-PK_1 cells, whereas a constitutively inactive PC1 construct that lacks the NTF and the TA ($PC1^{\Delta NTF\Delta TA}$) resides in the primary cilia. Addition of a soluble form of the TA peptide to cells expressing $PC1^{\Delta NTF\Delta TA}$ results in redistribution of the $PC1^{\Delta NTF\Delta TA}$ protein out of the cilium. Blocking β-arrestin-mediated receptor desensitization with barbadin prevents the removal of $PC1^{\Delta NTF}$ and of TA peptide-treated $PC1^{\Delta NTF\Delta TA}$ from the cilium. When full length PC1 is co-expressed with PC1 in LLC-PK_1 cells both proteins localize to the cilium. Extended exposure to the Wnt9b ligand or to mechanical stimuli both lead to reduced quantities of PC1 in the cilium and at the apical cell surface, and this redistribution is blocked by β-arrestin inhibitor barbadin.

Conclusions: Our data demonstrate that PC1 ciliary localization is regulated by physiological stimuli including ligand binding and mechanical stress and, like GPCR regulation, is subject to receptor desensitization processes. Our findings indicate that the GPCR activation state of PC1 can be observed by examining the distribution of PC1, suggesting new approaches through which PC1 activity can be assessed in vivo and in the context of drug discovery.

Mutation Position and Genetic Background Modulate Disease Expression in Pkhd1 Mouse Models

Maryanne Odinakachukwu,[1] Chaozhe Yang,[1] Zsuzsanna M. Bebok,[2] Lisa M. Guay-Woodford.[1] *[1]Children's National Research Institute, Washington, DC; [2]The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: Multiple *Pkhd1* mutant mouse models have been generated by gene-targeting methods (*del3-4*, *del67*) or resulted from spontaneous mutations (*cyli*). When these mutations are homozygous on inbred backgrounds (DBA/2J (D2); C57BL/6 (B6)), there is either no renal cystic disease or very mild dilatation of the PCTs rather than CCDs. A recent ARegPKD report showed that the position of human *PKHD1* mutations correlates with ARPKD kidney and liver disease severity (*Burgmaier, KI 2021*). In the current study, we examined the impact of age, mutation position, and mixed genetic background on kidney, liver, and pancreatic disease in *Pkhd1* mutants.

Methods: D2-$Pkhd1^{cyli/+}$; B6-$Pkhd1^{del3\text{-}4/+}$ and B6-$Pkhd1^{del67/+}$ mouse lines. Intercross strategy to generate a suite of F2 mutants on mixed genetic backgrounds (D2.B6). Histopathological analysis of the kidney, liver, and pancreas from 18-month-old, nulliparous mutant females.

Results: D2.B6-$Pkhd1^{cyli/cyli}$ mutants expressed both marked dilatation of the CCDs and liver ductal plate malformation (DPM); no pancreatic cysts were observed. Similarly, D2.B6-$Pkhd1^{del3\text{-}4/del3\text{-}4}$ mutants expressed corticomedullary cysts, involving DCTs and CCDs and DPM lesion but no pancreatic cysts. In contrast, D2.B6-$Pkhd1^{cyli/del3\text{-}4}$ compound heterozygotes had occasional dilated DCTs, a marked DPM lesion, and diffuse cyst formation in the pancreatic ducts. The D2.B6-$Pkhd1^{cyli/del67}$ and D2.B6-$Pkhd1^{del67/del67}$ mutants had occasional dilated DCTs, no DPM or pancreatic cysts.

Conclusions: Age, genetic background, and mutation position modulate organ-specific disease expression in *Pkhd1* mutants. On the mixed D2.B6 background both *cyli* and *del3-4* aged F2 mutants develop CCD cysts, similar to human *PKHD1 renal* disease. Surprisingly, D2.B6-$Pkhd1^{cyli/del3\text{-}4}$ mice had minimal kidney pathology but marked pancreatic duct cysts, suggesting that genetic background differentially modulates kidney and pancreatic cystic phenotypes. Mice heterozygous or homozygous for the *del67* mutation expressed minimal kidney, liver, or pancreatic cystic changes. Thus, defects at the 3′ end of *Pkhd1* appear to have minimal pathobiological impact, that is not influenced by age or the mixed D2.B6 genetic background. These findings will inform our experimental strategies to identify organ-specific *Pkhd1* genetic modifiers.

Rab GTPase Regulation in Ciliogenesis and Polycystic Kidney Disease

Dominique J. Mcconnachie,[1] Andrew J. Mallett,[2,1] Jennifer L. Stow.[1] Professor Jennifer Stow, Protein trafficking and inflammation group *[1]The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia; [2]Townsville Hospital and Health Service, Townsville, QLD, Australia.*

Background: Primary cilia are sensory organelles with widespread roles in development and epithelial function. Mutations resulting in dysmorphic cilia and ciliary dysfunction are associated with renal ciliopathies such as polycystic kidney disease (PKD), yet primary cilia remain enigmatic in terms of their molecular and functional characterisation. Rab GTPases are master regulators of vesicular trafficking that have been shown to regulate ciliogenesis and cilium composition, with downstream effects on ciliary function and signalling. Rabs are therefore poised to vary or modify primary ciliary function, by working in conjunction with key cilia proteins, including those mutated in PKD and other ciliopathies. Hence, we are examining novel roles for Rab GTPases in cilia formation and function and Rab13 has been the focus of recent studies.

Methods: Expression of fluorescently tagged, recombinant Rab13 and knockout of endogenous Rab13 were used to assess the roles of Rab13 GTPase in ciliogenesis and cilia function in mouse renal epithelial cell lines grown as monolayers and spheroids. Ciliary morphogenesis, cell polarity and growth were assessed by confocal imaging in live and fixed cells, while biochemical approaches were used to test cilia-dependent signalling and associated molecular pathways, along-with Rab13 expression, activation and effector functions.

Results: Our data show that Rab13 localises to the primary cilia of mouse kidney cells and Rab13 loss of function affects ciliogenesis in a variety of *in vitro* and *in vivo* models including zebrafish embryos. Characterisation of Rab13 knockout epithelial cells reveal altered cilia, the perturbation of ciliopathy-associated protein localisation, and the formation of dysmorphic renal spheroids. Rab13 knockout zebrafish embryos display a range of cilia-associated developmental defects and Rab13 expression is diminished in mouse PKD cells.

Conclusions: Here we reveal a novel cilia-associated role for Rab13 GTPase. Investigating the genes and molecules that contribute to the cilial landscape is important to improve knowledge, for potential translation and discovery of new therapeutic approaches for renal ciliopathies including PKD.

Efficacy and Adverse Effects of a Novel Mesoscale Nanoparticle-Guided Sirolimus Delivery Strategy in a Pkhd1PCK Rat Model

Michal Mrug,[1] Daniel A. Heller,[2] Chintan H. Kapadia,[3] Ryan Williams,[4] Phillip H. Chumley,[1] Sean Mullen,[1] Ronald E. Roye,[1] Gabriel Rezonzew,[1] Juling Zhou,[1] Edgar A. Jaimes.[2] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Goldilocks Therapeutics, New York, NY; [4]The City College of New York, New York, NY.*

Background: Pre-clinical studies have shown that mTOR inhibition attenuated renal cystic disease progression but it did not improve outcomes in patients with autosomal dominant polycystic kidney disease (ADPKD). This was attributed to the dose limitations in humans due to mTOR inhibitor toxicity. To increase the mTOR inhibition efficacy and reduce its toxicity in renal cystic diseases, we studied mesoscale nanoparticle (MNP)-guided delivery of an mTOR inhibitor, sirolimus (MNP-sirolimus), in *Pkhd1*$^{PCK/PCK}$ rats. We used our recently developed MNPs that selectively and with high affinity target the renal tubular epithelium.

Methods: We synthesized Empty-MNPs or MNP-sirolimus and used them in an experiment that resembles seminal pre-clinical studies of tolvaptan, the only FDA-approved ADPKD therapeutic. Newly outbred *Pkhd1*$^{PCK/PCK}$ rat males were divided into 3 groups (each N= 8-9) and treated for 8 weeks (p22 to p77) with: Empty-MNP (50 mg/kg IV q96 hours), Free-sirolimus (0.15 mg/kg IV q48 hours) and MNP-sirolimus (50 mg/kg IV equivalent to 0.3 mg/kg sirolimus q96 hours). Pre- and post-treatment cyst volumes were assessed by MRI at p21 and p78.

Results: The MNP-sirolimus or Free-sirolimus both inhibited renal mTOR activity in *Pkhd1*$^{PCK/PCK}$ rats. The mean pS6/total S6 ratios were: 7.9 for MNP-Sirolimus vs 19.1 for Free-Rapa and 105.1 for Empty-MNP ($p<0.001$) while total S6 levels did not differ ($p=0.806$). Similarly, an 8-week mTOR inhibition reduced mean renal cyst volumes: 39.9 mm^3 for MNP-sirolimus vs 59.3 mm^3 for Free-sirolimus vs 148.4 mm^3 for Empty-MNP (overall $p=0.011$). However, in pairwise comparison with Empty-MNP treatment, this difference was significant only for MNP-sirolimus ($p=0.017$) while for Free-sirolimus, the significance was marginal ($p=0.052$). The pre-treatment renal cyst volumes at 3 weeks were not significantly different ($p=0.772$). Among side effects, mTOR inhibition reduced body and heart weights ($p<0.001$ and $p=0.004$); in both cases, their averages were less severely reduced in MNP-Sirolimus as compared to Free-sirolimus treated rats.

Conclusions: Together, our studies support the concept that a novel MNP-guided sirolimus delivery increases renal mTOR inhibition and therapeutic efficacy in renal cystic diseases, while reducing systemic toxicity.

PO1228

Biomarkers Reflecting Extracellular Matrix Turnover Are Prognostic for Kidney Function Decline in Patients with ADPKD

Federica Genovese,[1] Judith E. Heida,[3] Nadja Sparding,[1,2] Morten A. Karsdal,[1] Ron T. Gansevoort,[3] Daniel Guldager Kring Rasmussen.[1] *[1]Nordic Bioscience, Herlev, Denmark; [2]Biomedical Sciences, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; [3]Dept. Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common inherited disorders in humans and is caused by mutations in the PKD1 and PKD2 genes. The disease is characterized by development and growth of cysts leading to loss of kidney function. Fibrosis is a driving force in progression to end-stage kidney disease in ADPKD and is characterized by an imbalanced turnover of extracellular matrix (ECM). Here, we investigated the association of ECM biomarkers with rate of kidney function decline in patients with ADPKD.

Methods: We measured four markers of ECM turnover in serum and urine from 305 patients with ADPKD from the DIPAK-1 study (NCT01616927): three markers of interstitial collagen turnover (C3M, PRO-C3 and PRO-C6) and one laminin degradation marker reflecting basement membrane turnover (LG1M). The association of the biomarkers with kidney function decline was investigated with a linear mixed model (change in eGFR/year) and logistic regression (decline in eGFR of >30%). Data was log-transformed if appropriate.

Results: All four markers of kidney fibrosis in serum were associated with eGFR at baseline when adjusting for sex, age, height adjusted total kidney volume (htTKV) and PKD mutation in serum (C3M, $P<0.05$; PRO-C3, $P<0.001$; PRO-C6, $P<0.001$; LG1M, $P<0.001$). In urine, only C3M and PRO-C6 (C3M, $P<0.001$; PRO-C6, $P<0.01$) and not PRO-C3 and LG1M (PRO-C3, $P=0.07$; LG1M, $P=0.31$) were independently associated with eGFR. Serum C3M ($P=0.005$) as well as urinary PRO-C3 ($P=0.001$) and PRO-C6 ($P<0.001$) were associated with the rate of eGFR decline per year when adjusting for age, sex, baseline eGFR, htTKV and PKD mutation. A total of 60 patients had a decline in eGFR of >30% and when adjusting for sex, age, baseline eGFR htTKV and PKD mutation, only serum C3M (OR=1.48, $P=0.02$) was independently associated with a decline in eGFR of more than 30%.

Conclusions: Serum C3M as well as urinary PRO-C3 and PRO-C6 were associated with the rate of kidney function decline when adjusting for known determinants of disease severity. Also, serum C3M could identify fast progressors (decline in eGFR of >30%). These markers hold promise that components from the ECM may be used as prognostic markers in ADPKD, but should be validated first in an independent ADPKD cohort.

PO1229

Magnetic Resonance Fingerprinting (MRF) Identifies Potential Imaging Biomarkers for Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Elise Keshock,[1] Jacob R. Perino,[1] Christina J. Macaskill,[1] Ashlee Parsons,[2] Jenna M. Hach,[2] Susan Farr,[1] Chris Flask,[1] Katherine M. Dell.[1,2] *[1]Case Western Reserve University, Cleveland, OH; [2]Cleveland Clinic Children's Hospital, Cleveland, OH.*

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) is an important cause of morbidity and mortality in children with chronic kidney disease (CKD). Novel therapies have shown efficacy in ARPKD animal models, but clinical trials in ARPKD patients have not been possible due to the lack of sensitive measures of kidney disease progression. Non-invasive Magnetic Resonance Imaging (MRI) techniques, including novel MR Fingerprinting (MRF), show promise in addressing this unmet need. We previously identified MRF-based T1 and T2 mapping as potential biomarkers of ARPKD kidney disease in animal models and initial human studies. In the current study, we evaluated the relationship between these imaging parameters and renal function in ARPKD subjects with mild CKD.

Methods: ARPKD subjects (age 6-25 yrs) with estimated glomerular filtration rate (eGFR) >60ml/min/1.73m^2 (bedside Schwartz <18 yo; CKD-EPI ≥18 yo) were scanned on a Siemens 3T MRI scanner utilizing novel MRF technology to simultaneously generate mean kidney T1 and T2 maps in 15 secs/imaging slice with no sedation or injectable contrast agent. The relationship between eGFR (U25 eGFR formula) and imaging parameters was assessed by Pearson correlations with significance set at <0.05.

Results: 7 subjects (2M/5F, age=12±5 years) were imaged. eGFR was 87±21, range=52-109 ml/min/1.73m^2; 5 had hypertension. Mean kidney T2 (94±10 msec) showed a significant negative correlation with eGFR ($R=-0.86$, $p=0.013$). Mean kidney T1 (2162±376 msec) also showed a strong negative correlation ($R=-0.69$) but did not yet reach significance ($p=0.086$). Mean T1 and T2 values for the right and left kidneys also demonstrated a significant correlation (T1: $R=0.99$, T2: $R=0.79$).

Conclusions: This is the first study to establish a relationship between MRI-derived imaging biomarkers (T1 and T2) and kidney function (eGFR) in ARPKD subjects. Despite the small cohort, data clearly demonstrate that mean T1 and T2 both increase with declining eGFR. These important findings suggest that MRF-based T1 and T2 mapping may provide a safe, non-invasive, quantitative, and reproducible measure of kidney disease severity to support future clinical trials to identify subjects at high risk for disease progression and monitor response to treatment.

Interaction/Modulation of PKD2 by TACAN

Xiong Liu,[1] Mohammad Fatehi,[2] Rui Zhang,[3] Jingfeng Tang,[3] Peter E. Light,[2] Xing-Zhen Chen.[1] *[1]Membrane Protein Disease Research Group, Department of Physiology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; [2]Department of Pharmacology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; [3]National "111" Center for Cellular Regulation and Molecular Pharmaceutics, Hubei University of Technology, Wuhan, China.*

Background: TACAN (also named TMEM120A), recently reported as a mechano- and pain-sensing ion channel, is distributed in diverse non-neuronal tissues such as heart, intestine and kidney, which indicates its potential role besides pain sensation. Previous proteomic screenings suggested the presence of an interaction between PKD2 and TACAN. In this study, we investigated the physical and functional interaction between the two proteins.

Methods: We employed mutagenesis, molecular cloning, co-immunoprecipitation, immunofluorescence, biotinylation, two-electrode voltage clamp in *Xenopus* oocytes to measure whole-cell currents and patch-clamp in Chinese hamster ovary (CHO) cells to measure single-channel currents.

Results: We found that TACAN is co-localized and in complex with PKD2 in primary cilia of different kidney cell lines and oocytes. Using oocyte expression, we found that TACAN inhibits the channel activity of PKD2 gain-of-function mutant F604P. Using CHO cell expression, we found that TACAN inhibits both wild-type PKD2 and mutant F604P through reducing their single-channel conductance and open probability. Co-expression of TACAN significantly enhanced the sensitivity of PKD2 to stretch. Further, our data showed that while the first and last transmembrane domains (TM1 and TM6) of TACAN are involved in interaction with transmembrane domains of PKD2 only the TACAN TM6 is functionally relevant.

Conclusions: Our study revealed inhibition of PKD2 channel activity through physical TACAN-PKD2 complexing and that TACAN, but not PKD2, mediates mechanosensitivity of the channel complex. Whether and how TACAN participates in the pore formation remains to be determined.

Suppressed Autophagy Drives Increased Cellular Metabolic Activity in Human ADPKD Cells

Daniel Atwood, Deepak Pokhrel, Charles L. Edelstein. *University of Colorado, Aurora, CO.*

Background: We published that the autophagy phenotype in *Pkd1*$^{RC/RC}$ mouse kidneys is characterized by decreases in crucial autophagy proteins (Cell Signal 2020). We attempt to determine the mechanistic role of suppressed autophagy as it relates to cell metabolic activity (viability and proliferation) in ADPKD cells.

Methods: Human primary immortalized cultured cells were used: normal renal cortical tubular epithelium (RCTE, PKD1+/+) and ADPKD cyst-lining epithelium (9-12, PKD1-/-). To measure autophagic flux, cells were treated with lysosomal inhibitor chloroquin (C) and LC3-II (immunoblot), a marker of autophagosomes or mCherry LC3 (fluorescence) was analyzed. MTT assay was used to measure cellular metabolic activity (cell viability and proliferation). Relative densitometry units (RDU) were measured on immunoblots.

Results: There was an increase in MTT and a decrease in AnnV in 9-12 vs RCTE cells. MTT OD was 0.36 in RCTE vs 0.44 in 9-12 ($p<0.01$). AnnexinV (AnnV) (% gated), marker of apoptosis, was 67 in RCTE vs 18 in 9-12 ($p<0.0001$). The increase in LC3-II with C in RCTE was not seen in 9-12 indicating suppressed autophagic flux. LC3-II (RDU) -/+ C was 0.6 vs 1.4 in RCTE ($P<0.01$) and 0.9 vs 1.1 (NS) in 9-12. mCherry (% gated) -/+ C was 6 vs 16 ($p<0.05$) in RCTE and 6 vs 13 (NS) in 9-12 cells. p62, marker of autophagic cargo, was increased in 9-12 vs RCTE. p62 (RDU) was 0.7 in RCTE and 1.2 in 9-12 ($p<0.05$). Cells were treated with an ATG7 shRNA (SH) to inhibit a crucial autophagy protein. There was a 50% decrease in LC3-II and ATG7 protein in SH-treated 9-12 cells. SH resulted in an increase in MTT and a decrease in AnnV indicating that suppressed autophagy drives MTT and inhibits apoptosis. MTT OD was 0.7 with scrambled shRNA (SCR) and 0.9 with SH ($p<0.05$). AnnV was 26 with SCR vs 16 with SH ($p<0.05$). Tat-Beclin peptide (TAT), a specific autophagy inducer, resulted in a decrease in MTT in 9-12 suggesting that autophagy decreases MTT. MTT OD was 0.5 with Veh vs. 0.2 with TAT ($p<0.001$). TAT did not affect AnnV.

Conclusions: In ADPKD cyst lining epithelial cells there is increased MTT, suppressed autophagic flux, and decreased apoptosis. Autophagy inhibition increased MTT and autophagy induction decreased MTT. Suppressed autophagy drives increased cellular metabolic activity in ADPKD cells. The effect of autophagy inhibition/induction on cyst growth in vivo merits further study.

Tsc2 Mutation Induces Renal Tubular Cell Nonautonomous Disease

Prashant Kumar,[1] Fahad Al-Zadjali,[3] Ying Yao,[1] John J. Bissler.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]St. Jude Children's Research Hospital, Memphis, TN; [3]Sultan Qaboos University, Muscat, Oman.*

Background: TSC renal cystic disease is poorly understood and has no approved treatment. In a new principal cell-targeted murine model of Tsc cystic disease, the renal cystic epithelium is mostly composed of type A intercalated cells with an intact *Tsc2* gene confirmed by sequencing, although these cells exhibit a Tsc mutant disease phenotype.

Methods: We used a newly derived targeted murine model in lineage tracing and extracellular vesicle (EV) characterization experiments and a cell culture model in EV characterization and cellular induction experiments to understand TSC cystogenesis. For the lineager tracing experiments we used Aquaporin-2 Cre, Floxed Tsc2, and Confetti mice in breeding experiments. To characterize the EVs, we used tunable resistive pulse sensing, dynamic light scattering, electron microscopy, and western blot analyses.

Results: Using lineage tracing experiments, we found principal cells undergo clonal expansion but can contribute very few cells to the cyst. We determined that cystic kidneys contain more interstitial EVs than noncystic kidneys, excrete fewer EVs in urine, and contain EVs in cyst fluid. Moreover, the loss of the *Tsc2* gene in EV-producing cells greatly changes the effect of EVs on renal tubular epithelium, such that the epithelium develops increased secretory and proliferative pathway activity. We demonstate that the mTORC1 pathway activity is independent form the EV production, and that the EV effects for a single cell line can vary significantly. mTORC1 inhibition reduces EV production.

Conclusions: TSC cystogenesis involves significant contribution from genetically intact cells conscripted to the mutant phenotype by mutant cell derived EVs.

Funding: Other U.S. Government Support

PO1233

Exploring the Heterogeneity of Kidney Resident Macrophages Using Single-Cell RNA Sequencing

Alex Yashchenko,[1] Sarah J. Bland,[1] Zhang Li,[2] Cheng Song,[3] Kurt Zimmerman.[1] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL; [3]University of Southern California, Los Angeles, CA.*

Background: Tissue resident macrophages are highly diverse, even when located within the same tissue. This diversity is thought to be driven by localization, ontological origin, time in tissue, and niche specific cues. Importantly, these underlying factors likely influence resident macrophage phenotype and function during disease initiation and progression.

Methods: To understand the diversity of kidney resident macrophages (KRM), we performed single cell RNA sequencing, parabiosis, and fate mapping on kidneys isolated from wild type and transgenic knock-in reporter mice.

Results: Using single cell RNA sequencing, we identified three subpopulations of KRM including one with enriched expression of *Ccr2*. Using *Ccr2*-RFP knock-in mice and Ms4a3^{cre} Rosa Stop$^{f/f}$ TdT mice, we confirm that these resident macrophages were derived from monocyte precursors and preferentially localize to the renal cortex. Based on our single cell RNA sequencing data, we propose that monocytes undergo a series of differentiation steps upon entering the kidney in order to become *Ccr2*+ KRM. Analysis of single cell data using RNA Velocity and Monocle suggest that monocytes require *Cx3cr1* in order to differentiate into *Ccr2*+ KRM. Loss of *Cx3cr1* prevented the accumulation of *Ccr2*+ KRM and resulted in a skewed macrophage profile that prevented cilia mutant mice from developing severe cystic disease.

Conclusions: Collectively, our data indicate that monocytes undergo a series of differentiation steps upon entering the kidney and require *Cx3cr1* for differentiation into pathogenic *Ccr2*+ KRM.

Species-Specific Differences in FPC-CTD Trafficking: Implications for Differential Activation of Intracellular Signaling Pathways

Chaozhe Yang,[1] Naoe Harafuji,[1] Maryanne Odinakachukwu,[1] Ljubica Caldovic,[1] Zsuzsanna M. Bebok,[2] Lisa M. Guay-Woodford.[1] *[1]Children's National Research Institute, Washington, DC; [2]The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: ARPKD (MIM 263200) is caused by mutations in *PKHD1,* which encodes FPC. But, orthologous mouse *Pkhd1* models either have no renal cystic disease or very mild PCT dilatation. We previously showed that *MYC/Myc* is overexpressed in human ARPKD and mouse *Cys1*$^{cpk/cpk}$ (*cpk*) kidneys, but not in several *Pkhd1* mutants. We also showed that expression of the intracellular carboxy-terminus of mouse FPC (mFPC-CTD), but not human (hFPC-CTD), activates the *Myc/MYC* P1 promoter (ASN 2020). The current study focused on: 1) the intracellular trafficking of mFPC-CTD and hFPC-CTD, and 2) activation of the Src/STAT3 signaling pathway, linked to hFPC-CTD (*Strubl 2020*), in a mouse *Pkhd1* mutant lacking FPC-CTD and in the *cpk* mouse model of ARPKD, with and without *Cys1* rescue.

Methods: Comparative informatic analysis. Immortalized mouse CCD (mCCD) and human (hCCD) cell lines stably expressing mFPC-CTD and hFPC-CTD, respectively. Kidneys from *cpk, Cys1*-rescued *cpk,* and *Pkhd1*$^{del6/del67}$ (*del67*) mutant mice; western blot and immunofluorescence.

Results: FPC-CTD is the least conserved domain, with 55% identity between human-mouse CTDs, compared with 73% identity across the full-length FPC. The CTD is unique, with an AA-sequence not found in other terrestrial vertebrate proteins. In stable cell lines, mFPC-CTD localized to both nuclei and cilia, whereas hFPC-CTD primarily localized to the apical membrane. In non-cystic *del67* kidneys (lacking FPC-CTD), pSTAT3^{Y705} and c-Myc levels were similar to wild-type controls. In *cpk* kidneys, pSTAT3^{Y705} and c-Myc were upregulated, but their levels in *Cys1*-rescued *cpk* kidneys (*Yang 2021*) were comparable to wild-type.

Conclusions: Differences in intracellular trafficking of mFPC-CTD and hFPC-CTD may explain the species-specific differences in *Myc/MYC* P1 promoter activation. Distinct subcellular localizations may reflect divergence in the functional evolution of human and mouse FPC-CTD, with mFPC-CTD evolving to function as a nuclear regulatory factor, whereas hFPC-CTD functions as a membrane-associated signaling regulator of Src-STAT3. Activation of Src-STAT3 signaling and *Myc* upregulation are signatures of cystic epithelia, suggesting that renoprotective mechanisms in FPC-deficient mouse kidneys may modulate these pathways.

PO1235

Reduction of Klotho Promotes Cyst Growth and Epigenetic Age Acceleration in ADPKD

Xiaoyan Li,[1] Xiaoqin Zhang,[1] Xia Zhou,[1] James P. Calvet,[2] Chou-Long Huang,[3] Xiaogang Li.[1] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]University of Kansas Medical Center, Kansas City, KS; [3]The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA.*

Background: Symptoms of ADPKD vary in severity and age of onset and tend to accelerate quickly in older patients, eventually resulting in kidney failure. αKlotho has been identified as an anti-aging protein, and the kidney is the organ expressing the highest levels of αKlotho protein and the main origin for systemic αKlotho. The soluble serum form of αKlotho (extracellular domain of αKlotho) was found to be decreased in ADPKD patients, however, the role of αKlotho in ADPKD remains unknown.

Methods: To investigate the role and mechanism of αKlotho in ADPKD, we introduced an αKlotho transgene into *Pkd1* conditional knockout mice and performed single cell RNA sequencing (scRNA-seq) in kidneys collected at postnatal days 7, 14 and 21 to determine the differentially expressed genes (DEGs) and signaling pathways mediated by αKlotho in different renal cell types. The expression of key DEGs identified with scRNA-seq was confirmed with qRT-PCR analysis.

Results: We found that full length αKlotho was decreased in collecting duct cells, macrophages, fibroblasts and T/NK immune cells in *Pkd1* homozygous kidneys. Transgenic αKlotho delayed cyst growth in *Pkd1* conditional knockout mice by normalizing the expression of genes associated with a number of diverse functions, including the genes associated with the transitions between collecting duct cell subtypes and genes involved in epigenetic mechanisms. In addition, we found that the genes associated with the epigenetic clock (DNA methylation age) were dysregulated in those cells in cystic kidneys, and that they could be normalized by transgenic αKlotho, suggesting that transgenic αKlotho might slow down the process of epigenetic age acceleration in cystic kidneys. The dysregulation of the epigenetic age-acceleration genes, *Apoe, Cldn4, Mgp* and *Slc38a2,* might contribute to PKD pathogenesis and might serve as potential biomarkers for ADPKD. Finally, transgenic αKlotho affected a large number of genes associated with metabolic and oxidative signaling, suggesting that αKlotho might act by slowing down metabolic processes to extend the life span of mice.

Conclusions: Reduction of aKlotho regulates cyst growth through diverse signaling pathways. *Pkd1* mutation accelerates epigenetic age in ADPKD. Transgenic aKlotho not only delayed cyst growth but also slowed down epigenetic age acceleration.

Funding: NIDDK Support

PO1236

Mechanistic Interaction Between Cystin and Fibrocystin/Polyductin in Model Cell Lines and cpk/cpk Kidneys

Yiming J. Zhang,[1,2] Chaozhe Yang,[3] Naoe Harafuji,[3] Wei Wang,[1] Phillip D. Bell,[1] Lisa M. Guay-Woodford,[3] Zsuzsanna M. Bebok.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Massachusetts Institute of Technology, Cambridge, MA; [3]Children's National Research Institute, Washington, DC.*

Background: *Cys1$^{cpk/cpk}$ (cpk)* mice exhibit ARPKD-like renal phenotype due to a mutation in the *Cys1* gene and loss of cystin. ARPKD (MIM 263200) is caused by mutations in *PKHD1,* encoding FPC. Both cystin and FPC are present in the primary cilium, but no physical interaction has been reported. Using mouse CCD cell lines, we have shown that FPC levels were reduced in *cpk* cells by 75% relative to wt. Cystin deficiency is specifically linked to FPC reduction and did not affect cilia development, but altered ciliary architecture (ASN 2020). The current study focuses on cellular mechanisms driving FPC reduction in cystin-deficient cells, and the consequences of FPC loss. We note that FPC is necessary for proper E3 ubiquitin ligase function and consequently cellular proteome management (Kaimori 2017).

Methods: Immortalized wt and *cpk* mouse CCD cells. Wt and cpk mouse kidneys. siRNA silencing of *Cys1;* qRT-PCR, western blot, confocal microscopy, morphometry, patch clamp.

Results: Silencing *Cys1* in wt cells results in a siRNA dose-dependent reduction of both cystin and FPC. Correlative studies showed marked reduction of FPC in *cpk* kidneys. Similar *Pkhd1* mRNA levels in wt and *cpk* cells, and kidneys implicate FPC regulation at the protein level. Proteasome or lysosome inhibition did not recover FPC, but activation of autophagy further reduced FPC levels, suggesting a role for selective autophagy in FPC removal. Diminished FPC levels lead to E3 ubiquitin ligase defects and reduced polyubiquitination of proteins, necessary for proteome management. In *cpk* cells, we observed membrane retention of the epithelial sodium channel and increased sodium transport.

Conclusions: Our studies provide the first functional link between cystin and FPC in renal epithelial cells. We propose cystin as a gatekeeper for FPC at the base of the cilium and in the E3 ligase complex. In cystin-deficient cells, FPC is continuously degraded leading to dysregulated ubiquitination and altered proteome homeostasis. These data show a mechanistic connection between the renal phenotypes observed in human ARPKD and *cpk* mice. The recent identification of human *CYS1*-related ARPKD (*Sci Report, in press*) highlights the potential significance of the cystin-FPC mechanistic interaction in the complex pathobiology of ARPKD.

PO1237

Tubular Flow Disruption During Cyst Development in Polycystic Kidney Disease

Isis Thomas, Hanan Chweih, Courtney J. Haycraft, Mandy J. Croyle, Zhang Li, Bradley K. Yoder. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Polycystic kidney disease is an inherited disorder in which clusters of cysts develop within the kidneys, causing the kidneys to enlarge and lose function. Cyst development can be due to functional changes caused by mutations in ciliary localized proteins Pkd1 and Pkd2 or changes in cilia formation/structure (e.g. ift88 mutants). It is currently unknown how cysts impact tubule flow and cilia, or whether flow alterations occur prior to or after cyst formation is initiated.

Methods: We used inducible Cre conditional mutant mouse models with an optical imaging chamber along with injection of fluorescent dextran to analyze tubule flow at multiple timepoints during cystogenesis in live kidneys. Additionally, we evaluated dextran absorption into proximal tubules as an indicator of tubule flow in mutant and control mice during cyst development. We determined the number of dextran+ proximal tubule cells by FACS to quantify changes in the percentage of tubules with flow in cystic versus non cystic kidneys. We performed H&E staining to quantify cyst severity and analyzed sections by immunofluorescent microscopy to assess changes in flow.

Results: Our results suggest that during the cyst formation, there is a marked decrease in flow through the tubules and that this reduction in flow occurs early during cyst formation. This corresponds to a 56.8% of cells that are both dextran+ and LTA+ (proximal tubule) by flow cytometry and similar results were obtained by IF analysis. We also find an increase in resident and infiltrating macrophages around the forming cysts.

Conclusions: The use of intravital imaging approaches allows us to evaluate changes in tubule flow as cysts progress. With the addition of cilia markers, we will examine the responses of the cilium to the changes in flow. Preliminary data suggests that that alterations in tubule flow occur at early time points during cyst initiation with larger cysts seldom containing epithelium that are dextran+. These data indicate that loss of tubule flow may be an early event associated with cystogenesis. Our data also suggests that disruption of tubule flow is progressive with fewer tubules with flow at later time points (4-6 months post induction). We are currently assessing whether there is an association between the disruption of flow in a tubule and localized immune responses.

FoxM1 Promotes Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Wenyan Yu, Guojuan Wang, Xiaoyan Li, Xia Zhou, Xiaogang Li. *Mayo Clinic Department of Internal Medicine, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is driven by mutations in *PKD1* and *PKD2* genes and is characterized by renal cyst formation, inflammation and fibrosis. Forkhead box protein M1 (FoxM1) is a transcription factor of the Forkhead box (Fox) protein super family which is defined by a conserved winged helix DNA-binding domain 1. FoxM1 has been reported to promote tumor formation, inflammation and fibrosis in many organs. However, the role and mechanism of FoxM1 in regulation of ADPKD progression is still poorly understood.

Methods: To evaluate the role and mechanisms of FoxM1 in cyst growth *in vivo,* we treated early stage and long lasting *Pkd1* mutant mice with the FoxM1 specific inhibitor, FDI-6. To identify novel FoxM1 target genes involved in cystogenesis, we performed ChIP-sequencing analysis.

Results: We found that FoxM1 was upregulated in cyst-lining epithelial cells in polycystin-1-deficient murine kidneys and human ADPKD kidneys. Inhibition of FoxM1 with FDI-6 delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in *Pkd1* mutant mice (all $p < 0.01$). Targeting FoxM1 also decreased renal fibrosis in long last Pkd1 mutant kidneys. Upregulation of FoxM1 promotes cyst growth through: 1) upregulation of the expression of Akt and Stat3 and activation of ERK and Rb signaling to increase cystic renal epithelial cell proliferation, 2) inhibition of p65-dependent cystic renal epithelial cell death, 3) facilitation of the recruitment and retention of renal macrophages, and 4) upregulation and activation of fibrotic markers to promote renal fibrosis. In addition, FoxM1-dependent macrophage recruitment was associated with upregulation of monocyte chemotactic protein 1 (MCP-1) and inflammatory cytokine TNF-α. Further, we identified novel FoxM1 target genes by ChIP-seq analysis, which may connect FoxM1 signaling to the ciliopathy hypothesis in PKD.

Conclusions: FoxM1 promotes renal cyst growth and fibrosis in ADPKD through Akt, ERK, Rb and STAT3 signaling as well as NF-kB and ciliopathy associated signaling. Targeting FoxM1 in cystic renal epithelial cells may be a viable new therapy for ADPKD.

Allosteric Mechanism of PC1 Tethered Agonist-Mediated Signaling

Shristi Pawnikar,[1] Brenda S. Magenheimer,[2] Ericka Nevarez Munoz,[2] Robin L. Maser,[2] Yinglong Miao.[1] *[1]University of Kansas College of Liberal Arts and Sciences, Lawrence, KS; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Polycystin-1 (PC1) is the 11-transmembrane protein product of the human autosomal dominant polycystic kidney disease (ADPKD) gene PKD1. PC1 functions as an atypical GPCR and shares multiple features with the Adhesion GPCRs, including a GPCR autoproteolysis-inducing (GAIN) domain that catalyzes cis-cleavage of the receptors into extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. We previously reported that CTF-mediated signaling to an NFAT promoter-luciferase reporter is dependent on the presence of the stalk, is reduced by ADPKD-associated missense mutations within the stalk, and can be rescued by synthetic, stalk-derived peptides, supporting a tethered ligand mechanism of PC1-G protein signaling (JASN 2018;29:671, JASN 2019;30:882).

Methods: We have combined highly complementary experiments and computer simulations to investigate mechanism of the tethered agonist-mediated signaling of PC1 CTF. A computer model of the human PC1 CTF was generated using the cryo-EM structure of the PC1-PC2 complex with important missing regions added through I-TASSER homology modeling. All-atom enhanced simulations (1000 ns) using a robust Gaussian accelerated molecular dynamics (GaMD) technique were performed, followed by calculations of residue correlation matrices and free energy profiles. GaMD simulation-predicted residue interactions important for WT stalk-mediated activation of PC1 CTF were further investigated by mutagenesis and cellular assay experiments.

Results: GaMD simulations were consistent with experimental signaling data obtained with PC1 CTF expression constructs encoding wild type and stalk variants of the PC1 CTF. Correlation matrices revealed regions of highly correlated residue motions involving the stalk, TOP and putative pore loop domains. Key residue interactions predicted from the GaMD simulations were validated with newly designed mutation experiments.

Conclusions: Complementary experiments and simulations studies support the function of the PC1 CTF stalk region as a tethered agonist and suggest a mechanism whereby it can induce TOP-pore loop interactions which can be further translated to the C-tail for G protein activation. This in-depth knowledge is expected to facilitate future drug design efforts targeting this function of PC1 for more effective treatments of ADPKD.

Analysis of Calcium Signaling in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Dorien Van Giel,[1] Jean-Paul Decuypere,[1] Djalila Mekahli,[1,2] Rudi Vennekens.[1] *[1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]KU Leuven University Hospitals Leuven, Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Flanders, BE, academic/hospital, Leuven, Belgium.*

Background: ADPKD is an inheritable kidney disease characterized by the development of fluid-filled renal cysts, mainly caused by mutations in the *PKD1* and *PKD2* genes, leading to loss of renal function. Molecular mechanisms underlying cystogenesis are poorly characterized but it is postulated that disturbed calcium homeostasis is a primary event in cystogenesis. The precise molecular players that cause this disturbance are still a poorly explored area, especially in relevant human cell types. We therefore aim to characterize the profile of calcium-coupled G-protein coupled receptors (GPCRs) in a human renal epithelial cell models, to identify which receptors are present, whether their function is affected in ADPKD and whether they can be used to modulate cyst formation and growth.

Methods: Urine-derived conditionally immortalized proximal tubule epithelial cells (ciPTECs) of ADPKD patients and healthy controls were screened for calcium-coupled GPCRs, using an agonist library on Fura-2 loaded cell populations seeded in 96-well format. Validation of specific hits was done using single-cell measurements with a fluorescence microscope and built-in perfusion system in the ciPTECs as well as in tissue-derived conditionally immortalized cystic cells (ciCCs). Matrigel-based 3D cell culture was used to grow ciCCs to assess their ability to form cystic structures. Structures were stained with nuclear and cytosolic stains and imaged via confocal microscopy.

Results: From a library of 418 GPCR agonists a selective amount of calcium-coupled GPCRs was found functionally active in ciPTECs. ciPTECs from both healthy controls and ADPKD patients were found to functionally express purinergic -, histamine -, serotonin and dopamine receptors. In single-cell experiments, we did not find any significant differences in functionality between healthy controls and ADPKD patients, but observed that response characteristics are mainly donor-specific, suggesting patient-specific disease mechanisms. ciCCs grown in in 3D cell culture were found to form hollow, cell-lined cyst-like structures.

Conclusions: We describe the first thorough characterization of calcium-coupled GPCRs in a human proximal tubule epithelial cell model. We established a 3D cyst growth assay using tissue-derived cystic cells to explore the possibility to use the identified GPCRs to modulate cyst formation and growth.

Loss of Polycystin Function in Lymphatic Cells Impair CTP1a Expression and Fatty Acid Uptake

Denis Basquin, Jinqing Liang, Terry J. Watnick, Patricia Outeda. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Homozygous *Pkd1* or *Pkd2* null mutant mice die at mid-gestation due to vascular abnormalities including edema and hemorrhage. We have previously shown that edema in *Pkd1* and *Pkd2* knock out mice is due to abnormal lymphatic morphogenesis, with grossly dilated, blood filled dermal lymphatic vessels. Because proper lymphatic development is supported by fatty acid β-oxidation (FAO), we probed fatty acid transport in PC1/PC2 lymphatic endothelial cells (LECs).

Methods: *Pkd1* and *Pkd2* mutant LECs were isolated from mouse E14.5 embryos or generated using lentiviral shRNAs against *PKD1* or *PKD2* in human dermal LECs (HDLECs). Protein levels of PC1, PC2 and CPT1a were determined by western blotting and CPT1a/CPT2 mRNA levels were analyzed by qRT-PCR. Fatty acid uptake was assessed by BODIPY® 558/568 C_{12} staining of control and *Pkd* mutant LECs pre-incubated with or without 50 μM palmitate, and counterstained with mitotracker. Cells were imaged by confocal microscopy and the relative abundance of lipid droplets were quantified using ImageJ software. Each experiment was repeated 3 times and pairs of means (mutant versus control) were compared using Student's T-test.

Results: Embryonic *Pkd1*$^{-/-}$ and *Pkd2*$^{-/-}$ murine LECs exhibit a robust decrease of CPT1a protein levels. In addition, CPT1a protein levels were significantly reduced in *PKD1* and *PKD2* depleted HDLEC, suggesting a conserved role of Pkd1/2 in CPT1a regulation. PC1 and PC2 depletion in HDLECs results in an accumulation of cytoplasmic lipid droplets which often colocalized with mitochondria, indicative of impaired fatty acid utilization. The ability of *PKD* mutant cells to metabolize fatty acids is further challenged by pre-treatement with 50μM palmitate, which exacerbates the accumulation of lipid droplets.

Conclusions: Our results highly suggest that polycystin function is required to maintain normal levels of CPT1a expression and fatty acid transport to mitochondria in LECs. We thus speculate that a defect in FAO with consequent dysregulation of gene expression is the basis of impaired lymphangiogenesis in Pkd1/2 mutant embryos.

Pharmacological Activation of Long-Form PDE4 Enzymes Suppresses Disease Progression in Pkd1RC/RC and Pkd1 Knockout (iKspCrePkd-1lox,lox) Mouse Models of ADPKD

David J. Henderson,[1] Xiaofang Wang,[2] Li Jiang,[2] Miles D. Houslay,[1] Peter C. Harris,[2] Julia M. Adam,[1] David R. Adams,[1] Adele Rowley,[1] Vicente E. Torres.[2] *[1]Mironid Limited, Glasgow, United Kingdom; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Upregulation of cAMP signaling is thought to promote cystogenesis in ADPKD. Phosphodiesterase 4 (PDE4) enzymes degrade cAMP and contribute to its compartmentalized signaling. We have previously described novel small molecules that allosterically activate long isoforms of PDE4 and lower intracellular cAMP. Here we demonstrate significant efficacy with MR-L22, an advanced PDE4 activator compound, on suppressing cystic burden and preserving kidney health in orthologous models of ADPKD.

Methods: The effects of the long isoform PDE4 activator MR-L22 (administered by oral gavage) were assessed in rapidly (iKspCre*Pkd1*^{lox,lox} induced at P10, treated from P14 to P27) and slowly progressive (*Pkd1*$^{RC/RC}$, treated from 4 to 16 weeks of age) mouse models of ADPKD. Test groups were compared to control groups receiving vehicle alone or V_2 receptor antagonist.

Results: Compared to vehicle treated controls, MR-L22 treated *Pkd1*$^{RC/RC}$ mice exhibited reduced kidney cAMP levels, cystic indices, kidney weight/body weight ratios (Kw/Bw) and MRI measured total kidney volumes (TKV) (Table and Figure). Long isoform PDE4 activation significantly protected kidney function and, when compared to tolvaptan, animals receiving MR-L22 produced significantly less urine volume. MR-L22 also suppressed the aggressive cystic disease exhibited by tamoxifen induced (P10) iKspCre*Pkd1*^{lox,lox} mice, where Kw/Bw and cystic indices were reduced in comparison to vehicle control (results not shown).

Conclusions: Small-molecule activators of long isoforms of PDE4 suppress cystic disease progression in key translational models of ADPKD and may be better tolerated and more effective than vasopressin V_2 receptor antagonists.

RGLS4326 Increases Urinary PC1 and PC2 Levels in Individuals with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Edmund Lee,[1] Tania M. Valencia,[1] Tate Owen,[1] Steven Neben,[1] Karl F. Cremer,[1] Rekha Garg,[4] Denis Drygin,[1] Christopher J. Ward,[2] Alan S. Yu,[2] Vishal Patel.[3]
[1]Regulus Therapeutics Inc, San Diego, CA; [2]University of Kansas Medical Center, Kansas City, KS; [3]The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; [4]PharmaDRS Consulting LLC, San Diego, CA.

Background: ADPKD is caused by mutations of either *PKD1* or *PKD2* genes, leading to reduced function of their respective protein products PC1 and PC2. Both proteins are secreted in exosomes, and their urinary levels inversely correlate with ADPKD severity. RGLS4326, a novel oligonucleotide inhibitor of miR-17, preferentially delivers to kidney tubules and cysts, derepresses miR-17 targets *Pkd1* and *Pkd2*, increases PC1 and PC2, and attenuates cyst growth in multiple PKD mouse models. Whether RGLS4326 treatment would increase PC1 and PC2 in individuals with ADPKD was unknown.

Methods: An open-label, adaptive design, dose-ranging, Phase 1b clinical study is ongoing to evaluate RGLS4326 safety, pharmacodynamics and pharmacokinetics in individuals with ADPKD. The study will enroll ~27 patients (9 per cohort) treated subcutaneously with one of three RGLS4326 doses (1, 0.3, and 0.1 or 0.5 mg/kg Q2W x 4 doses) and will be followed for 28 days after the last dose (Day 71). The major inclusion criteria are Mayo Imaging Classification of 1C, 1D, or 1E, and GFR between 30-90 mL/min/1.73 m^2. The urinary biomarkers include PC1 and PC2 on exosomes, kidney injury marker 1 (KIM1), and neutrophil gelatinase-associated lipocalin (NGAL).

Results: Nine patients (mean GFR 49 mL/min/1.73m^2, mean age 50 yr) were enrolled in the first cohort; each patient received four doses of 1mg/kg of RGLS4326 Q2W. RGLS4326 was well tolerated with no serious adverse events. PK profiles were similar to healthy volunteers, with a plasma half-life of 9 hours and plasma AUC levels after the first and fourth dose ~2x higher in patients. Changes in both PC1 and PC2 at the end of study from baseline were statistically significant (p=0.0004 and p=0.026, respectively), with mean % increase in PC1 and PC2 of 58% and 38%, respectively.

Conclusions: These data provide clinical proof that RGLS4326 delivers to cystic kidneys of individuals with ADPKD, where it inhibits miR-17 and thereby derepresses PC1 and PC2. The results also imply ongoing miR-17-mediated repression of *Pkd1* and *Pkd2* in humans, further validating miR-17 as a therapeutic target for ADPKD treatment.

PO1245

Mutations to ALG5 Cause Autosomal Dominant Fibrocystic Kidney Disease

Hugo Lemoine,[1] Loann Raud,[1] Eric G. Olinger,[3] John A. Sayer,[3] Peter C. Harris,[4] Yannick Le Meur,[2] Marie-Pierre Audrezet,[2] Emilie Cornec-Le Gall.[1,2] Genkyst Study Group
[1]INSERM UMR1078, Brest, France; [2]CHU Brest, Brest, France; [3]Newcastle University, Newcastle upon Tyne, United Kingdom; [4]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by variants in *PKD1* or *PKD2* encoding polycystin (PC)1 and PC2, or in genes involved in PC1 biogenesis. Seven to 10% of the pedigrees remain genetically unresolved (GUR). We hypothesized that other genes involved may cause ADPKD.

Methods: Whole exome sequencing (WES) was performed in a large GUR ADPKD-like pedigree from the Genkyst cohort, and targeted next-generation sequencing (TNGS) was performed in ~250 additional ADPKD/ADTKD GUR pedigrees.

Results: WES identified a heterozygous *ALG5* frameshift variant (c.703_704delCA) in 3 sisters who developed end-stage renal disease (ESRD) at ages 62, 69, and 68 respectively and presented atrophic kidneys with small renal cysts and few to no liver cysts. Four affected relatives from three generations were subsequently identified. *ALG5* encodes an endoplasmic reticulum (ER) resident enzyme, the dolichyl-phosphate beta-glucosyltransferase that catalyzes the transfer of glucose residues to the growing N-glycan precursor in the ER lumen. TNGS led to the identification of *ALG5* likely pathogenic variants (p.Trp258*, p.Arg212His) in 2 additional families. Two other unrelated individuals harboring likely pathogenic variants of *ALG5* were identified in the Genomics England 100,000 genomes project. The clinical phenotype was consistent in the 16 affected members, with non-enlarged cystic kidneys that often evolved to kidney atrophy and few or no liver cysts; 7 subjects reached ESRD from 62 to 91y. Characterization of *ALG5*$^{-/-}$ RCTE cells showed that *ALG5* is required for maturation and surface localization of PC1. PC1 surface localization in *ALG5*$^{-/-}$ cells was rescued by wild-type (WT), but not mutant, *ALG5*. Unfolded protein response (UPR) effector analysis revealed marked upregulation in *ALG5*$^{-/-}$ and *ALG5*$^{+/-}$ as compared to WT RCTE cells.

Conclusions: *ALG5* is a novel disease gene in the genetically heterogeneous ADPKD spectrum. Mutations to *ALG5* impair PC1 maturation and localization, and are likely associated with a dysregulation of the UPR, causing renal cystogenesis and fibrosis.

Background: *NEK8* encodes a protein that localizes to the primary cilium. Biallelic *NEK8* variants are known to cause multiorgan developmental defects including renal cystic dysplasia, with heterozygous carrier parents being asymptomatic. This autosomal recessive inheritance is most common for ciliopathies. Complementary to this, we now propose a dominant-negative effect for certain heterozygous *NEK8* missense variants in the kinase domain.

Methods: We performed genetic testing in patients from several medical centers. To explore the consequences of the identified *NEK8* variants we are performing cilia staining assays in patients' skin fibroblast and kidney cells, as well as in mIMCD3 cells overexpressing the identified variants.

Results: We identified three distinct heterozygous *NEK8* variants in eight families (table 1), all leading to missense alterations in the kinase domain. The large symptomatic family and the de novo occurrences are also in favor of a dominant mode of inheritance. All patients have a kidney phenotype, varying in severity, age of onset and presence of kidney failure. Interestingly the p.Arg45Trp variant is a recurrent variant found in six unrelated families. Our preliminary results from functional studies show normal localization of the NEK8 protein to the Golgi region, but abnormal primary cilia formation, in serum starved patient derived cells – a finding consistent with pathogenicity.

Conclusions: We present the first evidence for a pathogenic effect of heterozygous *NEK8* variants. Remarkably our patients present with a renal limited phenotype as compared to the multiorgan defects found in patients with biallelic variants. This reveals a new mode of inheritance for *NEK8* variants and expands genotype-phenotype correlations for this gene.

Table 1. Clinical features of individuals with heterozygous *NEK8* variants

Beneficial Effects of Bempedoic Acid Treatment in ADPKD Mice

Kenneth R. Hallows,[1] Hui Li,[1] Biagio Saitta,[1] Saman Sepehr,[1] Jessica Pham,[1] Valeria Mancino,[1] Stephen L. Pinkosky,[2] Nuria M. Pastor-Soler.[1] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]Esperion Therapeutics Inc, Ann Arbor, MI.*

Background: ADPKD has limited therapeutic options. Bempedoic acid (BA), an inhibitor of ATP citrate-lyase (ACLY) FDA-approved for hyperlipidemia, catalyzes a key step in cholesterol synthesis that is important for cell growth and proliferation. BA also activates AMPK in mice. We hypothesized that BA could be a novel ADPKD therapy by inhibiting cyst growth and proliferation and promoting oxidative metabolism via ACLY inhibition and AMPK activation.

Methods: Murine *Pkd1*-null kidney cell lines derived from either proximal tubule (PT) or collecting duct (IMCD) were grown in Matrigel cultures and treated ± BA before cyst analysis by microscopy. In vivo, male and female *Pkd1$^{fl/fl}$; Pax8-rtTA; Tet-O-Cre* transgenic C57BL/6 mice were induced with IP doxycycline injection on P10&11. Mice were then treated ± BA (30 mg/kg/d) ± tolvaptan (30-100 mg/kg/d) by oral gavage from P12-21. As measures of disease severity, total kidney weight to body weight (TKW/BW) and blood BUN levels at euthanasia (P22) were measured. Kidney homogenates were immunoblotted for expression of key disease biomarkers and other relevant cell signaling markers.

Results: BA dramatically inhibited cystic growth in 3D cultures in PT and IMCD *Pkd1*-null kidney cells. In ADPKD mice, BA reduced TKW/BW vs. vehicle at euthanasia (6.9 vs. 11.9%; $P<0.01$). Similarly, tolvaptan (100 mg/kg/d) reduced TKW/BW to 7.8% vs. vehicle ($P<0.05$). Addition of BA to tolvaptan caused a further reduction in TKW/BW (4.9%; $P<0.05$) vs. tolvaptan alone. BA reduced BUN vs. vehicle (59 vs. 107 mg/dL; $P<0.05$). Tolvaptan also decreased BUN vs. vehicle at 30 mg/kg/d (68; $P<0.05$). Again, addition of BA to tolvaptan at 30 mg/kg/d caused a further significant reduction in BUN (38; $P<0.05$). BA reduced ACLY and stimulated AMPK activity in kidneys vs. controls. BA also inhibited mTOR and ERK signaling, which are upregulated in ADPKD. BA also sharply reduced kidney injury markers KIM-1 and, to a lesser extent, NGAL. These BA effects occurred alone and in concert with tolvaptan.

Conclusions: BA inhibited cyst growth in vitro and ADPKD severity in vivo. Combined BA and tolvaptan treatment further improved ADPKD outcomes in vivo. BA significantly reduced kidney injury markers and mTOR and ERK signaling. BA may be a promising new ADPKD therapy, having beneficial effects on disease severity when used alone and with tolvaptan in mice.

Unraveling Fundamental Mechanisms of UMOD Quality Control and Their Role in UMOD-Associated CKD

Silvana Bazua-Valenti,[1,2] Eriene-Heidi Sidhom,[1,2] Moran Dvela levitt,[1,2] Valeria Padovano,[1] Julie Roignot,[1] Keith H. Keller,[1,2] Nina Himmerkus,[3] Markus Bleich,[3] Kerim Mutig,[4] Sebastian Bachmann,[4] Astrid Weins,[2] Jillian Shaw,[1] Jamie L. Marshall,[1] Maria Alimova,[1] Anna Greka.[1,2] *[1]Broad Institute of MIT and Harvard, Cambridge, MA; [2]Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Department of Physiology, Physiology of Membrane Transport, Christian-Albrechts-Universität, Kiel, Germany; [4]Department of Functional Anatomy, Charité-Universitätsmedizin, Berlin, Germany.*

Background: UMOD is a GPI-anchored protein expressed in the Thick Ascending Limb of the Loop of Henle. When properly folded, it transits from the ER to the membrane via the Golgi. Little is known about UMOD's specific trafficking partners and its quality control mechanisms in the early secretory pathway. Mutations in UMOD disrupt protein folding and promote ER retention, triggering ER-stress pathways and cell death that causes UMOD-related autosomal-dominant tubulointerstitial kidney disease. It was recently shown that mutant misfolded MUC1-fs is trapped in TMED9-containing vesicles and that treatment with compound BRD4780, releases it to the lysosome. We hypothesize that a similar pathogenic quality control mechanism is active in ADTKD-UMOD.

Methods: Co-immunoprecipitation (co-IP) of UMOD and TMED cargo-receptors was assessed in HEK293 cells transfected with wild type (wt) or mutant (C126R) human UMOD. Next, we performed untargeted Affinity Purification Mass Spectrometry followed by tandem MS to generate a list of UMOD interactors. We also conducted *in vivo* studies in UMOD$^{+/C125R}$ mice.

Results: We identified distinct wt and mutant UMOD interactomes using an unbiased AP-MS proteomics approach. Several interactors, including members of the TMED family, were significantly enriched in the mutant UMOD interactome. Targeted co-IP in lysates of HEK293 cells transfected with UMOD and interacting protein candidates confirmed the results from proteomics studies. Interestingly, when pulling down TMEDs, we found abundant immature non-glycosylated UMOD, suggesting entrapment in early secretory compartments. *In vivo*, treatment with BRD4780 was suggestive of disrupted interactions between mutant UMOD and interacting partners responsible for toxic entrapment in the ER, as assessed by immunoblots of kidney lysates and immunofluorescence microscopy of tissue from UMOD$^{+/C125R}$ mice.

Conclusions: Our results suggest that UMOD interacts with TMED cargo-receptors and other proteins that may mediate the pathogenic quality control mechanisms responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTKD-UMOD.

Restricted Feeding Diet Overrides the Cyst Promoting Effect of Cisplatin-Induced Renal Injury in Both Ift88 and Pkd2 Mutant Mouse Models

Zhang Li, Sreelakshmi Cherakara, Courtney J. Haycraft, Bradley K. Yoder. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Multiple renal cystic diseases, including PKD, are caused by dysfunction of the primary cilium. Links between cilia dysfunction, cyst formation, and renal injuries have been reported with evidence showing that injury exacerbated the rate of cyst formation in kidney. In addition, dietary restriction has been reported to ameliorate cyst growth in several PKD animal models. Here we evaluate the effects of both renal injury and dietary restriction on cyst formation in two different cilia-mutant mouse models.

Methods: To test the effect of renal injury on cyst formation, we established an alternative approach to induce chronic renal injury by utilizing a low-dose repeated cisplatin treatment (5.0mg/kg; IP; once a week for 4 wks). To evaluate the impact of dietary restriction and renal injury on cyst formation, adult induced conditional Ift88 and Pkd2 mutant mice were utilized. The study design including cisplatin treatment along with 85 % dietary intakes are shown in Figure 1. Mice were euthanized at 5 wks post last cisplatin injection for analysis. Multiple features including renal injury, proliferation, fibrosis, macrophage accumulation, and cystic index were analyzed.

Results: Low-dose repeated cisplatin treatment resulted in increased Kim1 expression in both Ift88 and Pkd2 mutant mice compared to controls. Analysis of the cystic phenotype showed that there was a significant increase in cyst formation in mutant mice after cisplatin comparing to saline-treated group and the location of cysts corresponded to the injured regions. Interestingly, the rapid cyst formation in cisplatin-treated kidneys was ameliorated when the mice were on the restricted diet (Figure 1). More importantly, kidneys from mice with restricted feeding displayed decreased levels of proliferation, fibrosis and macrophage accumulation around the cystic area.

Conclusions: These data show that low-dose repeated cisplatin treatment could be used as an alternative approach to IRI to accelerate cyst formation in in both ift88 and pkd2 mutant models. More importantly, it suggests that cyst progression associated with injury in cystic kidney disorders could be ameliorated through dietary interventions.

Peroxisomes Are Dispensable for Normal Renal Function

Yohan Bignon,[1] Camille Ansermet,[1] Gabriel Centeno,[1] Andy Garcia,[1] Sylvain Pradervand,[2] Dmitri Firsov.[1] *[1]Universite de Lausanne Faculte de biologie et medecine, Lausanne, Switzerland; [2]Genomic Technologies Facility, University of Lausanne, Lausanne, Switzerland.*

Background: Peroxisomes are single membrane-bound cellular organelles identified in the kidney in 1954. Peroxisomes are ubiquitously present in eucaryotic cells with highest abundance in renal proximal tubule cells and hepatocytes. The variety of metabolic and antioxidant functions in which peroxisomes are involved is highlighted by human mutations in *PEX* genes encoding peroxins proteins required for proper peroxisome biogenesis. Hence, the complete loss of peroxisomes causes Zellweger's spectrum disorders (ZSD), devastating multiorgan failure which include renal impairment. However, the (patho)physiological role of peroxisomes in the kidney remains unknown.

Methods: Here we addressed the role of peroxisomes in renal function in male and female adult or infant mice with conditional ablation of Pex5-driven peroxisomal biogenesis in the renal tubule (cKO mice).

Results: Functional and histological analyses of both infant and adult cKO mice did not reveal any overt kidney phenotype. However, male cKO mice exhibited substantial reduction in kidney weight to body weight ratio. Stereological analysis of electronic microscopy results showed a complete absence of peroxisomes accompanied by increase in the number and in the volume of mitochondria in proximal tubule cells of cKO mice. Integrated deep transcriptome-sequencing and metabolome analyses revealed profound reprogramming of a great number of metabolic pathways, including biosynthesis of different classes of lipids such as plasmalogens and sphingomyelins (two major classes of membrane lipids) and the metabolism of glutathione. Although this analysis suggested compensated oxidative stress, four weeks of high fat feeding challenging the ability of proximal tubule cells to metabolize lipids did not induce significant renal impairments in cKO mice.

Conclusions: We demonstrate that renal tubular peroxisomes are dispensable for normal renal function. This indicates a large flexibility of proximal tubule cells both in terms of lipid membrane composition and metabolic/antioxidant functions. Our data also suggest that renal impairments in ZSD patients are of extrarenal origin.

Weight Loss to Slow Cyst Growth in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Kristen L. Nowak,[1] Victoria Catenacci,[1] Timothy L. Kline,[2] Wei Wang,[1] Zhiying You,[1] Kristen Bing,[1] Bhavya Poudyal,[2] Cortney Steele,[1] Michel Chonchol,[1] Berenice Y. Gitomer.[1] *[1]University of Colorado - Anschutz Medical Campus, Aurora, CO; [2]Mayo Clinic College of Medicine and Science, Rochester, MN.*

Background: Recent studies in animal models of ADPKD support that food restriction can profoundly slow cyst growth and maintain renal function. We have also reported that overweight and obesity are strong independent predictors of ADPKD progression. Thus, it is plausible that weight loss, caloric restriction, and/or periods of fasting may slow ADPKD progression in humans; however, the feasibility of these dietary interventions, and whether the driver of therapeutic efficacy is periods of fasting or reduction in body weight, is unknown.

Methods: We conducted a one-year study evaluating feasibility of delivery of a behavioral weight loss intervention based on either daily caloric restriction (DCR) or intermittent fasting (IMF) in adults with overweight/obesity, ADPKD, and eGFR ≥30 m/min/1.73m^2 (targeted weekly energy deficit of ~34% in both groups). We also evaluated the safety, acceptability, and tolerability of each intervention, and obtained exploratory insight into changes height-corrected total kidney volume (htTKV).

Results: 28 participants (16F/12M; 46±9 yrs, body mass index 34.7±5.0 kg/m^2, eGFR of 69±22 m/min/1.73m^2) were randomized to either DCR (n=15) or IMF (n=13). Clinically significant (>5%) weight loss was achieved in both groups at month 3 (DCR: -7.1±4.2%; IMF: -5.5±3.3%). At 12 months DCR lost additional weight while weight loss in IMF plateaued (DCR: -9.1±6.0%; IMF: 4.9±5.6%; p<0.05 DCR vs. IMF). Overall, DCR had a more favorable safety, tolerability, and adherence profile than IMF. Annual htTKV %Δ was qualitatively low in both groups in comparison to historical data, despite comparable clinical characteristics (DCR: 1.5±3.4%, IMF: 1.7±6.1%). Annual htTKV %Δ was highly correlated with %Δ in weight (r = 0.68, p=0.001). Abdominal saturated adipose tissue (SAT), visceral adipose tissue (VAT) and total adipose tissue (TAT) quantified by MRI were all reduced at one year (p<0.05). Change in VAT (r = 0.49, p<0.05) and TAT (r = 0.46, p<0.05) also correlated with annual htTKV %Δ.

Conclusions: IMF, and particularly DCR, were feasible interventions over a one-year period in adults with ADPKD and overweight/obesity and showed favorable effects on kidney growth as compared to historical controls, supporting conduction of a phase II randomized controlled trial.

PO1252

Social Determinants of Health (SDOH) and Healthcare Resource Utilization (HRU) in Autosomal Dominant Polycystic Kidney Disease (ADPKD) by CKD Stage

Karl M. Kilgore,[1] Iman Mohammadi,[1] Hina Japes,[2] Laura L. Frank,[2] Tazin R. Aijaz,[2] Christie Teigland,[1] Kristin Pareja.[2] *[1]Avalere Health, Washington, DC; [2]Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ.*

Background: SDOH contribute to health disparities in CKD. This study describes SDOH and HRU in ADPKD patients with commercial (COM) insurance compared to a lower income managed Medicaid (MM) population.

Methods: The study included 8,766 COM and 5,416 MM patients from a national claims database. Patients had ≥2 ADPKD diagnoses between 7/1/2016- 12/31/2018 and were continuously enrolled for minimum 12 months. Patients were linked to SDOH by 9-digit ZIP address providing a precise assignment compared to Census data. HRU included inpatient days and emergency room (ER) visits per 1000 patients per month (PPPM) over 1-year follow-up.

Results: MM patients were more likely to be female (60% vs 54% COM) and on average 8 years younger. MM patients had 1.3x higher Charlson Comorbidity Index (CCI) scores, 40% lower income, were 2x more likely to live below federal poverty level, 1.3x less likely to complete high school, 2.7x more likely to speak English not well or at all, 2.6x less likely to own a vehicle, 53% more likely to be unemployed, and lived in a primary/mental health care shortage area 6.8%/6.4% more often. The differences between payers were consistent across CKD stages, except CCI scores increased with higher CKD stage for both groups. Disparities in income, unemployment rates and provider shortages tended to increase with CKD stage. Mean bed days ranged from 34.6 (Stage 1) to 402 (ESRD) PPPM for COM patients and were 3-4x higher overall in MM, ranging from 112 to 874 across CKD stages. Similarly, ER visits PPPM ranged from 38 to 114 for COM and 154 to 376 for MM. Hospital readmissions and use of post-acute care were high in both groups, with 15% of COM and 20% of MM readmitted within 30-days of inpatient stay and 2.8%-15.2% COM and 3.5%-25.8% MM having at least one PAC stay during follow-up. HRU increased with CKD stage.

Conclusions: ADPKD patients have large variation in SDOH by type of insurance. Lower social status of MM patients may be associated with higher HRU, and these disparities appear to increase as CKD stage progresses. In the clinical care of this vulnerable population, consideration of SDOH such as language barriers, transportation insecurity, and poverty is recommended.

Eliosin, a Protein Encoded by a Transcript from the HmPKD1 Locus, Is a Component of Mitochondria-Endoplasmic Reticulum Contact Sites (MAMs) and Repairs Mitochondria Fragmentation in Polycystic Kidney Disease 12-7 Cells

Robert L. Bacallao,[1,2] Weimin Xu,[1] Virginie Lazar.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Richard L Roudebush VA Medical Center, Indianapolis, IN.*

Background: The HmPKD1 gene locus is predicted to produce multiple transcripts whose functions are largely unknown. We studied one such alternative transcript that starts at intron 40 but has a protein start site in exon 41. This transcript has a splice from the 3′ end of exon 41 to the 5’ end of exon 43. Subsequent splices follow the same splicing pattern found in the full-length polycystin-1 mRNA. The subcellular localization and function of this alternative transcript is not known.

Methods: We made PCR primers designed to detect the unique splice features of the transcript which are not a feature of full-length HmpKD1 transcripts. RT-PCR studies were conducted to identify the alternative transcript. cDNA encoding the alternative transcript and its product (Eliosin) were expressed in COS-1, 293 and NIH 3T3 cells for immunoblot and light microscopy analysis. Co-localization studies were performed between mCherry-Eliosin fusion protein and dynamin related protein-1 (DRP-1) or mitofusion-1 (MFN-1). Anallysis of mitochondria morphology in co-transfection studies was performed in 293 and PKD 12-7 cells.

Results: RT-PCR reactions performed using RNA from human kidney, confirmed that a shortened PCR fragment from the PKD1 gene’s exons 41-43 is expressed. Immuneblot analysis revealed that the protein we named Eliosin is a 48 kDa protein and it is expressed by cDNA isolated from human testes. Flourescence microscopy studies show co-localization between Eliosin and inositol-3-phosphate receptor or MFN-1, known components of MAMs. However when Eliosin and DRP-1 are co-expressed, DRP-1 is found in the cytosol. Since DRP-1 mediates mitochondria scission we reasoned that it is the mutation in Eliosin that leads to unopposed mitochondria scission in PKD12-7 cells. We found that untransfected PKD 12-7 cells have fragmented mitochondria while Eliosin transfected PKD 12-7 have normal appearing mitochondria.

Conclusions: Eliosin is a 48 kDa protein that is expressed in human kidney. It is a component of mitochondria-ER membrane contact sites and it acts to displace dynamic related protein-1 from MAMs. Based on these findings we conclude that Eliosin plays a role in altering the balance between mitochondria fusion and scission. This finding extends the HmPKD1 locus role in mitochondria metabolic physiology.

Overweight and Obesity Predict Kidney Growth in Children and Young Adults with ADPKD

Cortney Steele, Zhiying You, Heather Farmer-Bailey, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. *University of Colorado - Anschutz Medical Campus, Aurora, CO.*

Background: We have previously reported that overweight and obesity are independently associated with more rapid progression in adults with early-stage autosomal dominant polycystic kidney disease (ADPKD). We now evaluated whether overweight and obesity are also associated with faster kidney growth in children and young adults with ADPKD.

Methods: 54 non-diabetic children and young adults (6-25 years of age) with ADPKD and estimated glomerular filtration rate (eGFR) >80 ml/min/1.73m^2 who participated in a randomized controlled trial on curcumin supplementation were categorized based on BMI (if ≥18 years; n=27) or BMI percentile for age, sex, and height (if <18 years of age; n=27) as normal weight (n=40 [74%]) or overweight/obese (n=14 [26%]). The longitudinal (1-yr) association of overweight/obesity with change in height-corrected total kidney volume (htTKV) by magnetic resonance imaging was evaluated using multinomial logistic regression models.

Results: Mean±s.d. age was 18±5 years, annual % change in htTKV was 6.1±9.0%, and eGFR (full-age-spectrum equation) was 112±18 ml/min/1.73m^2. The annual % change htTKV was 5.5±9.1% in the normal weight participants and 7.9±8.6% in overweight/

obese participants. After adjustment for demographics, randomization group, SBP, and glucose, overweight/obesity was associated with a nearly significant increased odds of annual % change htTKV ≥7% compared to <5% (Odds ratio: 5.23 [95% confidence interval: 0.99, 27.75]). This association was attenuated slightly after further adjustment for baseline htTKV and eGFR (5.58 [0.89, 34.96]).

Conclusions: Consistent with data in adults, our results suggest that overweight and obesity are associated with faster htTKV growth in children and young adults with ADPKD, although power is limited in this small sample size. These results highlight the importance of children with ADPKD maintaining a normal body mass index.

PO1255

Metabolomic Changes over 1 Year Following Drug or Lifestyle Interventions in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Cortney Steele, Jelena Klawitter, Wei Wang, Zhiying You, Victoria Catenacci, Taylor Struemph, Diana George, Berenice Y. Gitomer, Godela M. Brosnahan, Michel Chonchol, Kristen L. Nowak. *University of Colorado - Anschutz Medical Campus, Aurora, CO.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited progressive kidney disease. Studies have shown differences in metabolomic profiles in those with ADPKD; however few studies assess change over time.

Methods: We performed metabolomics to assess patterns of change across four groups of participants with APDKD pooled from 2 randomized clinical trials: placebo control (CON), metformin (1,000/mg/day) (MET), intermittent fasting (IMF; 3 day/wk of 80% energy restriction from baseline weight maintenance requirements), and daily caloric restriction (DCR, daily restriction of 34% per day from baseline weight maintenance requirements). Analyzed plasma samples were collected during the trials at baseline and 1-year for each group. A total of 163 metabolites were measured using liquid chromatography-mass spectrometry (LC-MS). Differences in metabolomic profiles over time and within study groups were evaluated by a one-way ANOVA and Bonferroni correction for multiple comparisons.

Results: Baseline characteristics for each trial included CON (n=22, 14 female (F), 49±7 yrs of age (mean±s.d.), estimated glomerular filtration rate [eGFR] 73±13 ml/min/1.73m^2, body mass index (BMI) 28.3±4 kg/m^2), MET (n=22, 14 F, 48±7 yrs of age, eGFR 69±14 ml/min/1.73m^2, BMI 29.7±7 kg/m^2), IMF (n=10, 5 F, 47±6 yrs of age, eGFR 77±16 ml/min/1.73m^2, BMI 34.6±5 kg/m^2), and DCR (n=9, 5 F, 46±13 yrs of age, eGFR 68±21 ml/min/1.73m^2, BMI 34.1±5 kg/m^2). Age and eGFR did not differ between groups. BMI was higher in the IMF compared to CON (p=0.031). Metabolite changes are depicted in Figure 1.

Conclusions: There are changes at one year in metabolites in adults with ADPKD between control, metformin, intermittent fasting, and daily caloric interventions. Further research is needed to identify metabolomic profile shifts involving drug and dietary interventions.

Identification of CLC-5, the Electrogenic 2Cl-/H+ Exchanger, as the Dominant Apical Chloride Secreting Transporter in Kidney Cyst Epithelium in Tuberous Sclerosis

Sharon L. Barone,[1,2] Marybeth Brooks,[1,2] John J. Bissler,[3] Jane J. Yu,[4] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Raymond G. Murphy VA Medical Center, Albuquerque, NM; [3]Le Bonheur Children's Hospital and St. Jude Children's Research Hospital, Memphis, TN; [4]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Cyst expansion in Tuberous Sclerosis Complex (TSC) or PKD requires secretion of chloride into the cyst lumen as the driving mechanism for salt accumulation. In PKD, Cl^- secretion into the cyst lumen is mediated via the cAMP/PKA-stimulation of CFTR in principal cells consequent to the V2 receptor activation by AVP. Kidney cystogenesis in TSC differs from PKD in that cyst epithelia in TSC is comprised of genotypically normal A-intercalated cells, which do not exhibit noticeable expression of either CFTR or the V2 receptor. The identity of the Cl^- secreting molecule(s) in TSC cyst epithelia remains unknown. Based on RNA Seq analysis in kidneys of *Tsc1* KO mice, we hypothesized that the chloride transporter ClC-5 is expressed on the apical membrane of A-intercalated cells in cyst epithelia of humans and animal models of TSC. CLC-5 is a $2Cl^-/H^+$ exchanger that is located in collecting duct A-intercalated cells where it is predominantly localized to endosomes and plays a critical role in dissipating H^+ secretion and membrane depolarization by H^+-ATPase. This allows parallel movement of Cl^- and H^+ into the endosomes.

Methods: Double immunofluorescent studies utilizing CLC-5 and H^+-ATPase antibodies were performed on kidney tissue from mice with principal cell inactivation of Tsc1 (*Tsc1/Aqp2* Cre), pericyte inactivation of Tsc1 (*Tsc1/Renin* Cre), principal cell inactivation of Tsc-2 (*Tsc2/Aqp2* Cre), global heterozygous Tsc2 (*Tsc2*+/-) and cysts from TSC patients.

Results: Double immunofluorescence labeling demonstrated remarkable co-localization of CLC-5 and H^+-ATPase on apical membranes of an overwhelming numbers of cyst epithelial cells in all models of TSC, including the human kidney cysts. In contrast, kidney cysts in Pkd1 mutant mice showed no apical ClC-5 expression and very few H^+-ATPase expressing cells.

Conclusions: These are the first reports on apical membrane localization of CLC-5 in A-intercalated cells in any disease state, and suggest that similar to late endosomes/lysosomes, CLC-5 and H^+-ATPase may function synergistically on cyst epithelia by secreting Cl^- and H^+ into the cyst lumen. These results strongly point to enhanced translocation of CLC-5 and H^+-ATPase from late endosomes/lysosomes to the apical membrane of cyst epithelia in TSC.

Two Years In: The Development and Basic Characteristics of a National Patient-Powered Registry in ADPKD

Elise Hoover,[1] Beverly A. Benson,[1] Neera K. Dahl,[2] Berenice Y. Gitomer,[3] Amy Manelli,[1] Michal Mrug,[4] Meyeon Park,[5] Chris Rusconi,[1] Stephen L. Seliger,[6] Ronald D. Perrone,[7] Terry J. Watnick.[6] *[1]PKD Foundation, Kansas City, MO; [2]Yale University, New Haven, CT; [3]University of Colorado - Anschutz Medical Campus, Aurora, CO; [4]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [5]UCSF Medical Center, San Francisco, CA; [6]University of Maryland Baltimore, Baltimore, MD; [7]Tufts Medical Center, Boston, MA.*

Background: The therapeutic pipeline in autosomal dominant polycystic kidney disease (ADPKD) has grown, generating a need for more patient participation in clinical trials. To facilitate US ADPKD patient enrollment and to encourage the utilization of patient-reported outcomes in trial design, the PKD Foundation (PKDF) designed a national ADPKD Registry.

Methods: The ADPKD Registry is hosted on a secure, online platform (IQVIA, oc-meridian.com/pkdcure). Participants are consented through the online system and complete a series of modules. The Core Questionnaire includes diagnosis, latest kidney function tests, and comorbidities. Family history, diet and lifestyle, quality of life, and complications of liver cysts, and vascular outcomes are queried.

Results: Between 9/4/19 and 5/1/21, 1,580 ADPKD patients have registered and completed the Core Questionnaire. Participants have a median age of 49 years, 73% have not reached ESKD, and 79% reported a family history of the disease. Currently, the cohort is 71% female, 93% Caucasian, 4.8% Hispanic/Latino and 2.5% African American. Strategic efforts are in development to increase diversity in the cohort. Nearly three quarters of participants had not previously participated in research, with only 27% indicating that they had been in another PKD study or clinical trial. All participants have consented to be contacted about future studies. Many will likely qualify for ongoing trials based on completed module data. Thus far, the Registry platform has made over 2,200 participants contacts regarding six clinical studies, with some individual overlap due to similar eligibility criteria.

Conclusions: The ADPKD Registry is a longitudinal research tool intended to capture ADPKD patient-reported data and is designed to impact research in multiple ways. It will allow for a range of research questions related to the clinical management of ADPKD from early disease through dialysis and post-transplant outcomes. Additionally, modules on health care access & utilization and COVID-19 impact will help the PKDF better understand the challenges of this community.

PO1258

Polycystic Kidney Disease and Race

Alexandra Hayward, Rita L. McGill, Milda R. Saunders, Arlene B. Chapman. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Racial/ethnic differences in the development of kidney failure (ESKD) and transplant (TX) access are well-documented. ESKD is anticipated in familial autosomal dominant polycystic kidney disease (ADPKD), providing the opportunity for greater ESKD preparation. We sought to define the impact of race on ESKD/TX outcomes in ADPKD.

Methods: White (W), African-American (A), or Hispanic (H) ADPKD patients were identified in USRDS 1/2000-6/2018; demographic and laboratory data were obtained. Median income was derived from US Census. Models included: age at ESKD (linear), pre-emptive TX (logistic), and TX after dialysis initiation (Cox), adjusted for age, sex, albumin, hemoglobin, eGFR, insurance, income, ESKD Network, and employment, with W as referent.

Results: Among 41,485 patients, (77.3% W, 13.3% A, 9.4% H), characteristics/ outcomes are shown in Table 1. AA and H had lower median income and less private insurance, pre-ESKD nephrology care, and employment. For AA and H, peritoneal dialysis and TX were less common than in W. Albumin, hemoglobin, and GFR were lowest in A. ESKD occurred 2.2 ± 0.2 and 4.8 ± 0.3 years earlier in A and H, compared to W. Adjusted odds of pre-emptive TX were 0.38(0.33, 0.42) and 0.47(0.40, 0.55) for A and H. Adjusted hazards for TX after dialysis initiation were 0.60(0.55, 0.65) for A and 0.78(0.72, 0.85, for H, *P*<0.001 for all. TX rates for A vs W by network are shown in Figure 1.

Conclusions: Despite the hereditary nature of ADPKD, renal outcomes differ by race, attributed to in part, economic and geographic factors. Health inequity is a contributing factor to patient outcomes in ADPKD that needs to be addressed.

PO1259

A New Ally in Evaluation of Progression of Autosomal Dominant Polycystic Kidney Disease

Sara Fernandes, Adriana Fernandes, Beatriz C. Donato, Luis F. Goncalves, Mario R. Raimundo, Catarina Teixeira, Edgar A. de Almeida. Neprhology Department *Hospital Beatriz Ângelo, Loures, Portugal*.

Background: The available tools for evaluation of progression of Autosomal Dominant Polycystic Kidney Disease (ADPKD) are suboptimal. The study aim is to evaluate the use of urinary glutathione S-transferase (alpha-GST) in predict progression of this disease.

Methods: Prospective, cohort study of ADPKD patients followed on Nephrology clinic. Urinary alpha-GST was normalized to urinary creatinine (U alpha-GST/U Cr), KTV adjusted to height was determined by CT and sequential measures of Scre were done on the following 3 years. The discriminatory ability of U alpha-GST to predict a decline > 30% of eGFR was determined through Sensitivity (S), Specific (SP), Positive Predictive Value (PPV) and Negative Predictive Value (NPP) using as optimal cut-off point the U alfa-GST mean and the ROC curves.

Results: 21 patients (61.9% women) were included, mean age of 45,0 (IQR 19) years. Initial Scre was 0,98 (IQR 0,64) mg/dL, KTV was 1079 (IQR 1543) mL and U alpha-GST/ U Cr was 6,88 (IQR 6,88) ug/g. U alpha-GST/ U Cr positive correlated with initial Scr (rs 0,614; p=0,002) and latest Scr (rs 0,622, p=0,003). There wasn't a significant statistical correlation between U alpha- GST/ U Cr and the percent decline of eGFR (rs 0,043, p=0,07). U alpha-GST/ U Cr demonstrated S of 71%, SP of 64%, PPV of 50% and NPV of 82% to identify patients with a decline >30% of eGFR over a 3 year period. On ROC curves, U alpha- GST/ U Cr and KVT showed a fair ability to predict a decline >30% of eGFR (AuROC 0,704 e 0,735, respectively), but when used together, the discriminatory ability significatively improve (AuROC 0,833 for the U alpha- GST/ U Cr x KVT variable).

Conclusions: Although, the small size population is limitation of the study, the ability to predict disease progression was improved through the use of KVT and urinary biomarker variable. Larger studies are need to validate its use.

PO1260

Curcumin Therapy to Treat Vascular Dysfunction in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Kristen L. Nowak,[1] Heather Farmer-Bailey,[1] Wei Wang,[1] Zhiying You,[1] Cortney Steele,[1] Melissa A. Cadnapaphornchai,[1] Jelena Klawitter,[1] Nayana Patel,[1] Diana George,[1] Anna Jovanovich,[1,2] Danielle Soranno,[1,3] Berenice Y. Gitomer,[1] Michel Chonchol.[1] *[1]Rocky Mountain Hospital for Children, Denver, CO; [2]VA Eastern Colorado Health Care System, Aurora, CO; [3]Children's Hospital Colorado, Aurora, CO*.

Background: Clinical manifestations of autosomal dominant polycystic kidney disease (ADPKD) can begin in childhood, including evidence of vascular dysfunction, an important predictor of cardiovascular events and mortality. Curcumin is a polyphenol found in turmeric that reduces vascular dysfunction in rodent models and humans free from ADPKD. It also slows kidney cystic progression in a murine model of ADPKD.

Methods: We hypothesized that curcumin supplementation would reduce vascular dysfunction (brachial artery flow-mediated dilation [FMD_{BA}] and aortic pulse-wave velocity [aPWV]) in children and young adults with ADPKD. In a prospective, randomized, controlled, double-blind trial, n=68 participants 6-25 years of age with ADPKD and an estimated glomerular filtration rate >80 mL/min/1.73 m^2 were randomized to receive either curcumin supplementation (25 mg/kg body weight/day) or placebo administered in powder form for 12 months. We also assessed change in circulating and urine biomarkers of oxidative stress/inflammation and kidney growth (height-adjusted total kidney volume [htTKV]; exploratory endpoint) by magnetic resonance imaging. In a sub-group of participants ≥18 years, we also assessed vascular oxidative stress as the change in FMD_{BA} following an acute infusion of ascorbic acid.

Results: Fifty-seven participants completed the trial. Participants were 18±5 (mean±s.d.) years, 55% female, and 85% non-Hispanic White. The co-primary endpoint, FMD_{BA} (%Δ), did not change in the curcumin group (baseline: 9.4±4.1; 12-months: 10.6±3.9), as compared to the placebo group (baseline: 8.9±4.0; 12-months: 9.3±4.5; p=0.22), nor did the other co-primary endpoint, aPWV (cm/sec) (curcumin: 517±106; 12-months: 517±81; placebo: baseline: 518±82 cm/sec 12-months: 525±95 cm/sec; p=0.53). There was no curcumin specific reduction in vascular oxidative stress, nor any changes in mechanistic biomarkers. htTKV also did not change over the 12-month study with curcumin administration as compared to placebo.

Conclusions: Curcumin supplementation does not reduce vascular dysfunction or slow kidney growth in children/young adults with ADPKD.

PO1261

Polycystic Kidney Disease Associates with Increased Myopia and Retinal Breaks

Brady M. Dangelser, Uyi J. Imasuen, Jonathan Chang, Heather A. Potter, Arjang Djamali, Gauri Bhutani. *University of Wisconsin-Madison, Madison, WI.*

Background: Ophthalmologic manifestations in Polycystic Kidney Disease (PKD) are not known.

Methods: We conducted a retrospective cohort study using EMR data extraction. All adult patients with polycystic kidney disease ("PKD") and CKD from another cause ("non-PKD/CKD"), seen at our center between 1/1/2000-4/30/2020, and Eye disorders of interest in these 2 cohorts were identified using ICD-9/10 diagnostic codes. The date of the first visit to Nephrology clinic was regarded as "Index date". The prevalence of Eye disorders at the index date was compared between "PKD" and "non-PKD CKD" cohorts.

Results: A total of 859 patients with "PKD" and 8309 patients with "non-PKD/CKD" were seen at our center over the study duration. Majority of patients in both groups were male (58% [498] and 54% [4457]) and identified as White (88% [758] and 86% [7185]). At the index date, PKD patients were younger (mean age 55 vs 60 years in non-PKD/CKD; p<0.01) and had shorter follow up time (median 901 vs 1311 days; p<0.01). PKD patients had higher eGFR (52 [31-81; N=795) vs 43 ml/min/1.73m2 [29-59; N=7342]; p<0.01) and lower prevalence of diabetes mellitus at the index date (23% [198] vs 39% [3270]; p<0.01). Hypertension prevalence was similar between the two groups (91% [778] and 90% [7444]). Myopia and all Retinal breaks (with or without detachment) were found to be higher in PKD as compared to non-PKD/CKD after multivariable adjustment for age, gender, race, diabetes and follow up time (adjusted odds ratio 1.4 [95% CI: 1.1-1.7] and 1.7 [1-2.8], respectively; p<0.01). Retinal breaks with detachments by themselves were also more frequent in PKD but did not reach statistical significance (Table). Peripheral retinal degeneration was similar between the two groups.

Conclusions: There is increased prevalence of Myopia and Retinal breaks in PKD compared to non-PKD/CKD. These ophthalmologic findings could be potential extra-renal manifestation of PKD. Comparison with general population prevalence and investigations into the mechanism are needed for confirmation.

Prevalence of Eye Disorders in PKD vs non-PKD/CKD

Disorder group	Prevalance at Index Date (% [N])			Adjusted Odds Ratio (95% CI)	P-value
	PKD (N=859)	Non-PKD/CKD (N=8309)	P-value		
Myopia	12 (103)	11.2 (928)	0.47	**1.4 (1.1-1.7)**	**<0.01**
Peripheral Retinal Degeneration	1.4 (12)	1.6 (134)	0.63	1 (0.6-1.9)	0.91
Retinal break without detachment	**1.6 (14)**	**0.8 (69)**	**0.02**	**2.4 (1.3-4.3)**	**<0.01**
Retinal break with detachment	1.3 (11)	0.95 (79)	0.35	1.6 (0.8-3)	0.17

PO1262

TSC2 Loss-of-Heterozygosity Mutations Drive Cystogenesis in Kidney Organoids Generated from Tuberous Sclerosis Complex Patient-Derived Induced Pluripotent Stem Cells

Dario R. Lemos. *Brigham and Women's Hospital, Boston, MA.*

Background: Kidney cysts are the second most common renal manifestation of TSC, accounting for 50% of kidney lesions. The genetic mechanisms driving TSC-associated cystic kidney disease remain poorly understood.

Methods: We induced nephric differentiation of a series of TSC patient-derived iPSC lines that included a line carrying a heterozygous microdeletion in the *TSC2* locus (*TSC2*$^{+/-}$), and a TALEN-engineered isogenic cell line carrying microdeletions in both *TSC2* alleles (*TSC2*$^{-/-}$).

Results: Analysis of Day-21 two-dimentsional cell cultures showed that nephrons derived from *TSC2*$^{+/-}$ and *TSC2*$^{+/+}$ hiPSCs presented normal morphology, and were sequentially segmented into distal tubules expressing cadherin 1 (CDH1), proximal tubules containing brush borders labeled by lotus tetranoglobus lectin (LTL) and glomeruli containing podocytes expressing podocalyxin 1 (PODXL). By Day-21 of differentiation *TSC2*$^{-/-}$ hiPSC-derived kidney tissues showed cavitated structures resembling cysts. Analysis of nephron segments showed positive signal for both CDH1 and LTL, indicating the cyst lining could comprise distal tubule and/or proximal tubule cells. The observed frequency of cyst formation was ~4.7 cysts/well for *TSC2*$^{-/-}$ cultures, compared with 0 and ~0.5 cysts/well for *TSC2*$^{+/+}$ and *TSC2*$^{+/+}$ cultures, respectively. Of note, 2-D cyst-like structures developed in a spontaneous manner, that is without addition of cAMP modulators. Analysis of the three-dimensional anatomy of *TSC2*$^{-/-}$ organoids also showed that while individual tubule segments were involved in cyst lining, in certain cases a combination of both proximal and distal tubule cells were detected, suggesting improper segmentation mechanisms in the absence of TSC2. While single-cell lining layers were associated with well-defined tubule segments, mixed-cell lining regions were multi-layered, resembling the columnar epithelium observed in the renal cysts of TSC patients. The distribution of LTL staining, in proximal tubules of *TSC2*$^{-/-}$ organoids indicated loss of cell polarity in contrast to the polarized cells observed in *TSC2*$^{+/-}$ tubules. Cyst formation in *TSC2*$^{-/-}$ organoids did not involve loss of polycystin 1 (PKD-1) expression.

Conclusions: Our kidney organoid models provide evidence supporting LOH events resulting in complete TSC2 inactivation in nephron tubule cells as a mechanism driving kidney cyst formation in TSC.

PO1263

Six2Cre-Mediated Deletion of Anks6 leads to Proximal Tubule Developmental Defects

Rannar Airik, Amy B. Huynh, Merlin Airik. *University of Pittsburgh, Pittsburgh, PA.*

Background: Nephronophthisis-related ciliopathies (NPHP-RC) are a group of autosomal recessive kidney diseases that are characterized by renal cysts, tubulointerstitial fibrosis and basement membrane disruptions. Mutations in *ankryrin repeat and sterile alpha motif domain containing 6 (ANKS6)* gene were recently identified as causing nephronophthisis type 16 (NPHP16) in humans. Although, several mouse models with *Anks6* mutations have been reported, its function in the kidney remains incompletely understood. In order to investigate the disease mechanisms of nephronophthisis and the function of *Anks6* in kidneys we deleted *Anks6* expression in the nephron progenitor population using the Six2Cre transgenic mouse line.

Methods: *Six2Cre* transgenic mice were crossed with *Anks6fl/fl* mice to generate *Six2Cre;Anks6fl/fl* mice. Gross morphological characterization and tissue histological analysis of mutant mice was performed on E15.5, E18.5 and P1 kidneys. Kidneys were embedded in paraffin and sectioned at 5µm thickness for histological staining with hematoxylin and eosin. Immunofluorescence (IF) staining was performed to label nephron segments and glomerular components. *Anks6* expression in the kidney was examined using X-gal staining. ANKS6 role in epithelial cell polarity was investigated using a spheroid assay after *ANKS6* siRNA knockdown in IMCD3 cells.

Results: *Six2Cre;Anks6fl/fl* mice die at birth due to kidney failure. *Anks6* expression was ubiquitous in the developing kidney. Histological analysis revealed that deletion of *Anks6* in nephron progenitors leads to proximal tubule morphogenesis defects and glomerular cysts. Immunostaining of the glomeruli showed reduced recruitment of mesangial cells and decreased poodcyte numbers in mutant kidneys. Proximal tubule development was similarly arrested at an early tubular morphogenesis stage resulting in short straight tubules. Knock down of ANKS6 in cell culture resulted in polarization and lumen formation defects.

Conclusions: Our data demonstrate that Anks6 is required for proximal tubule morphogenesis and glomerular development. Deletion of Anks6 in nephron progenitors leads to severe kidney morphogenesis defects that are incompatible with life. Spheroid assay revealed that ANKS6 has an important role in epithelial polarity and lumen formation. Future work will address which morphogenic pathway(s) are regulated by Anks6 during nephrogenesis.

PO1264

The Impact of Salt Deficiency on Acid-Base Homeostasis in Autosomal Recessive Polycystic Kidney Disease

Jonathan Mallory,[1] Morgan J. Spicer,[1,2] Mark Domondon,[1] Ryan Schibalski,[1,2] Denisha R. Spires,[1,2] Mikhail Fomin,[1,2] Thelma Amoah,[1] Daria Ilatovskaya.[1,2] *[1]Medical University of South Carolina, Charleston, SC; [2]Augusta University, Augusta, GA.*

Background: In healthy subjects, dietary salt restriction exacerbates imbalances of acid-base homeostasis. The disease progression of autosomal dominant PKD is associated with decreasing serum bicarbonate levels and metabolic acidosis, however very little is known about acid-base imbalance in autosomal recessive (AR) PKD, particularly, in response to dietary restrictions. Here we hypothesized that a salt-deficient (SD) diet leads to electrolyte and acid-base imbalance in ARPKD.

Methods: Male and female PCK/CrljCrlPkhd1pck/CRL (PCK) rats were fed a SD (0.01% NaCl, Dyets Inc) diet for 1, 3, 5, 7 and 9 weeks beginning at 4 weeks of age. Before each endpoint, urine was collected, and plasma and tissue samples were harvested. Urine and plasma creatinine, pH and electrolytes, BUN, and plasma aldosterone levels were measured. Cystic index was analyzed with ImageJ. Statistical analysis was performed with 2-way ANOVA.

Results: Two-kidney-to-body-weight, water consumption, plasma K+ and urine output decreased over the course of the SD diet in both sexes. Plasma Na+ and Cl- as well as creatinine increased; and BUN did not change. Plasma aldosterone increased from week 1 to week 5 (week 1: 2.6±1 (M) and 3.7±0.9 (F), week 5: 10.5±1.5 ng/ml (M) and 7.7±1.1 (F), $p<0.001$ (over time)), followed by a return to baseline by week 9 of the SD diet. There was a significant increase in cystogenesis in female rats from week 1 to week 9 of the SD diet (week 1: 14.2±1.9%, week 9: 36.3±2.4%). Further, we observed an increase in plasma pH (week 1: 6.98±0.08 (M) and 6.83±0.03 (F), week 9: 7.16±0.08 (M) and 7.13±0.02 (F), $p<0.001$ (over time)) and a decline in urine pH (week 1: 7.69±0.42 (M) and 8.75±0.08 (F), week 9: 5.80±0.07 (M) and 5.72±0.08 (F), $p<0.001$ (over time)) in both sexes throughout the dietary challenge.

Conclusions: PCK rats on a SD diet exhibit acidification of urine pH and an increase in plasma pH. We can speculate that acid base transporters such as NHE1, NBCe2, and pendrin are upregulated to conserve plasma sodium leading to a shift in acid-base homeostasis. Further studies aimed at elucidating the role of these transporters may add to the current knowledge regarding the pathogenesis and dietary management of ARPKD.

PO1265

A Combination Therapy with Two Dietary Supplements Acting on Different Mechanisms Ameliorates Disease Progression in a Rat Model of Polycystic Kidney Disease

Jacob A. Torres, David A. Asplund, Bradley C. Kroes, Nickolas J. Holznecht, Tselmeg Amarlkhagva, Juliette R. Rebello, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

Background: Recently, our lab reported that dietary interventions to induce ketosis ameliorate disease progression PKD animal models, and that this effect involves the natural ketone beta-hydroxybutyrate (BHB). Additionally, we have recently shown that renal microcrystals exacerbate disease progression in PKD models. We now show that a combination of citrate and BHB effectively inhibits PKD progression. These compounds act on separate mechanisms, synergistically preventing cyst formation and cyst growth in young rats. In adult rats, the combination treatment leads to a partial reversal of existing renal cystic disease.

Methods: Juvenile and adult Han:Sprague-Dawley rats were treated with BHB, citrate or in combination via drinking water for 5 or 4 weeks respectively, then sacrificed and analyzed for changes in cystic burden and markers of disease progression. Additonally, rats were placed in metabolic cages to assess changes in urine parameters.

Results: Administration of either BHB or citrate alone in the drinking water effectively ameliorates PKD progression in a rat model. Combining BHB and citrate produced a synergistic effect. Cystogenesis and cyst growth were inhibited in juvenile animals. In adult animals with pre-existing renal cystic disease, the treatment leads to partial disease regression. We also find that administration of excess sodium and potassium alone, at doses that would be provided from the salts of citrate and BHB, lead to a worsening of PKD in our rat model.

Conclusions: The beneficial effects of ketosis are mimicked by administration of BHB in the drinking water and are consistent with a number of groups findings suggesting an underlying metabolic defect in PKD. Our other recent findings suggest excessive renal crystal burden leads to accelerated disease progression in PKD models. Renal crystal formation can be prevented by administration of citrate to both chelate calcium and raise urinary pH. These results are of high clinical significance because BHB and citrate

are widely available and classified as safe dietary supplements. These results suggest that a combination of widely available and generally safe dietary supplements, when appropriately formulated, demonstrate high promise for supporting kidney health in PKD.

PO1266

A Single-Center Experience of ARPKD in Adults

Meenakshi Sambharia, Sonali Gupta, Christie P. Thomas. *The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is an inherited ciliopathy with 50% presenting with enlarged kidneys *in utero* or early infancy. ARPKD has an incidence of ~1:20,000 live births and arises from biallelic variants in *PKHD1* encoding for fibrocystin, with variants in *DZIP1L* accounting for <1% cases. Imaging findings include large echogenic kidneys, poor cortico-medullary differentiation, renal cysts or "salt and pepper appearance". ARPKD-congenital hepatic fibrosis (ARPKD-CHF) complex consists of renal disease with biliary dilatation portal hypertension and splenomegaly. 50% develop ESRD in childhood with limited data on renal prognosis for those that present later.

Methods: A retrospective chart review of patients > 16 yr of age with cystic kidney disease and/or congenital hepatic fibrosis to identify possible cases of ARPKD. Clinical phenotype (compatible hepato-biliary and renal involvement) and/or genetic testing were used to verify the diagnosis.

Results: We identified 29 patients with ARPKD-CHF, out of which 13 were > 16 yr (mean 32.4 yr). 38% were males, 15% identified as Hispanic and the rest as non-Hispanic whites. All had radiographic evidence of renal and/or hepato-biliary involvement and 5 of 13 patients had biallelic variants in *PKHD1*. On the most recent imaging study, 92% had renal cysts, 23% large echogenic kidneys, 23% poor renal corticomedullary differentiation, 15% medullary sponge kidney, 23% with salt and pepper pattern. Only 3 of 15 (20%) had reached ESRD or received a kidney transplant, while the remaining had a mean eGFR of 46ml/min/1.73m^2. Of these, 50% had eGFR ≥ 60ml/min/1.73m^2. Amongst those with hepato-biliary involvement, 40% had CHF, 53% portal hypertension, 40% splenomegaly, 26% liver cysts.

Conclusions: We describe a cohort of patients with ARPKD, the majority presenting as adults, with an eGFR ≥ 60ml/min/1.73m^2. A significant number of these patients had multiple large renal cysts. Absence of obvious renal phenotype in patients with congenital hepatic fibrosis can make the diagnosis challenging, requiring a high degree of clinical suspicion. We believe that we may have missed a significant number of patients without obvious combined hepatic and renal abnormalities who may have had delayed onset ARPKD. Our small series suggest that some patients with ARPKD present as adults with a more limited phenotype that can easily be mistaken for ADPKD.

PO1267

Analysis of Somatic Mosaic Mutations in Nephropathy-Associated Genes Reveal Candidate Disease-Causing Mutations in Previously Germline-Negative Cases

Enrico Cocchi, Ali G. Gharavi. Gharavi Lab. *Columbia University, New York, NY.*

Background: Somatic mosaicism variant (SMV) arises due to postzygotic mutations that results in two genetically distinct populations of cells in the same person. SMVs may be missed by standard search for germline (or inherited) mutations, and the use of dedicated analytic pipelines for SMVs can potentially explain "exome negative" cases.

Methods: We searched for SMVs in 248 patients who underwent exome sequencing for congenital kidney anomalies. Somatic mutations were identified through GATK Mutect2 software, and clinically annotated following the American College of Medical Genetics and Genomics (ACMG) guidelines We focused the analysis on 625 nephropathy-associated genes previously used for the germline analysis.

Results: Previous analyses germline variants had identified 52 diagnostic variants in this cohort (20.9% diagnostic rate). In addition, the SMV pipeline identified candidate disease-related SMVs 4 "exome-negative" patients (1.6% of cases). The SMVs were detected in *RET, ENG* and *COL4A5*, and are reported in Table 1. This improved the diagnostic rate of the cohort to 22.5%

Conclusions: Analysis of somatic mosaic variants can increase diagnostic yield in patients with congenital kidney anomalies. Application of the SMV pipeline may increase diagnostic in other forms of kidney disease

SVM identified in congenital anomalies kidney patients

Comparison of Imaging Approaches for Quantifying Total Kidney Volume (TKV) and Fibrosis in a Mouse Model of Polycystic Kidney Disease (PKD)

Caroline R. Sussman, Heather L. Holmes, Ka Thao, Adriana Gregory, Ryan J. Meloche, Yaman G. Mkhaimer, Harrison H. Wells, Slobodan Macura, Peter C. Harris, Timothy L. Kline, Michael F. Romero. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: 3D imaging and histology are critical tools for assessing PKD in patients and animal models. Magnetic resonance (MR) imaging provides μm resolution, but is time consuming, expensive, and access to equipment and expertise is limiting. Robotic ultrasound (US) imaging is lower resolution but fast. Similarly, picrosirius red (PR) staining and standard light microscopy is used to assess fibrosis; however, alternative methods for quantifying PR staining have been shown in other tissues to allow greater sensitivity and more detailed characterization.

Methods: *Pkd1*$^{RC/RC}$ mice were compared to *Pkd1*$^{+/+}$ (WT). TKV was quantified from US and MRI (7T and 16T) at 1, 3, and 4 months old. US measurements of kidney and heart were made using the robotic Vega system from SonoVol. Inter-observer variation was assessed using Bland-Altman analysis. PR-stained kidneys were imaged using standard light microscopy, circularly (*c*) polarized light with binning into four categories of collagen thickness, and fluorescent imaging with analysis using ctFire. Renal cAMP and BUN were measured using standard approaches, and GFR was measured using a transdermal fluorescent sensor (MediBeacon).

Results: US detected increased TKV at 1 month and was similar to MR (7T or 16T). Inter-observer variability (2 observers) was greater for US than MR, but still able to detect differences between genotypes and time points. US allowed scanning in 2-5 minutes/mouse while MR required 20-30 minutes. *C*polarized light showed a greater percentage of the thickest collagen fibers in RC/RC mice, and a corresponding lower percentage of each of 3 categories of thinner collagen fibers. Preliminary data using fluorescence and ctFire showed a higher density of collagen fibers in RC/RC mice vs. WT. Analysis of collagen fiber angle, length, straightness, and width is ongoing. RC/RC had a lower GFR, higher BUN, and elevated cAMP vs WT. No differences were observed in cardiac function (ejection fraction, heart rate, or cardiac output).

Conclusions: These studies demonstrate the utility of US and alternative approaches of quantifying fibrosis using PR.

PO1269

Phenotypic Heterogeneity in Type IV Collagen-Associated Nephropathy: The Cystic Phenotype

Letizia Zeni,[1,2] Cinzia Mazza,[1] Diego Toso,[3] Laura Econimo,[1] Roberta Cortinovis,[1] Chiara Dordoni,[1] Gianfranco Savoldi,[1] Francesco Scolari,[3,1] Claudia Izzi.[1] *[1]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy; [2]Universita degli Studi della Campania Luigi Vanvitelli, Caserta, Italy; [3]Universita degli Studi di Brescia, Brescia, Italy.*

Background: Exome sequencing (ES) revealed mutations (mut) in type IV collagen (COL4) genes in patients (pt) diagnosed with other forms of chronic kidney disease (CKD), supporting the concept of *spectrum* of phenotypes for COL4-Nephropathy. Unexpectedly, some pt with CKD presenting with cystic phenotype were identified with COL4-Nephropathy by ES.

Methods: The retrospective study included 130 pt referred to outpatient clinic of genetic kidney diseases of ASST Spedali Civili of Brescia from 2002 to 2021 and diagnosed with COL4-Nephropathy. Based on the presence of multiple and bilateral renal cysts on imaging (fig1), a group of pt with cystic phenotype was selected (27/130;21%).

Results: Among cystic group (CG), diagnosis was based on genetic test (gt) and kidney biopsy in 10/27 pt, whereas it was 'biopsy-proven only' in 7 pt, gt-based in 3 pt and clinically in 7 pt. Fifteen pt underwent gt (fig2): heterozygous mut in COL4A3 and COL4A4 were detected in 9 and 3 cases, respectively; 1 patient showed mut in COL4A5 and 2 pt had a digenic pattern. At baseline, comparison between CG to non-CG showed lower eGFR (70[IQR 35;91] vs 91[IQR 74;114] mL/min/1.73m^2 p<0,001) and higher proteinuria (1.1vs0.38g/24 hrs), although the statistical significance was not reached for proteinuria (p=0.058). At last censoring, data confirmed a lower eGFR (26[IQR 7;55] vs 86[IQR 44;104]) and a tendency (p=0.0545) of greater proteinuria in CG. Prevalence of arterial hypertension, CKD (defined as eGFR < 60) and ESKD was higher in CG.

Conclusions: The study contributes to expand the emerging phenotypic heterogeneity of COL4-Nephropathy and suggests that cystic phenotype could predict progression of kidney disease.

Rare Variants in Syndromic Ciliopathy Genes as Novel Causes of Isolated Renal Disease in Adults

Zachary T. Sentell,[1,2] Lina Mougharbel,[1] Sima Babayeva,[1] Natascia Anastasio,[2] Lee lee Chu,[1] Murielle M. Akpa,[1] Paul R. Goodyer,[1,2] Elena Torban,[1,2] Thomas M. Kitzler.[1,2] *[1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada; [2]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: Renal ciliopathies are among the commonest genetic causes of end-stage renal disease (ESRD). Ciliopathies are caused by defects of the primary cilium, an antenna-like organelle with mechanosensory roles, crucial for organ development and maintenance. Disorders of the cilium present early with multi-organ involvement, but some individuals present as adults with organ-specific phenotypes, potentially due to milder mutations and organ-specific effects.

Methods: We identified rare variants in two ciliopathy genes in two unrelated adults presenting with ESRD. ACMG guidelines did not classify these variants as pathogenic, requiring functional validation to establish a causal genotype-phenotype relationship.

Results: Bi-allelic *C2CD3* missense variants were identified in a proband with ESRD, suggestive of an isolated renal ciliopathy. *C2CD3* is essential for ciliogenesis, with complete loss of cilia in knockout mice (*Development* 135:4049 2008). Severe mutations were reported in patients with a syndromic ciliopathy (OFD XIV; OMIM# 615948), but no cases of isolated renal disease have been reported. We detected a moderate but consistent shortened cilia length in skin fibroblasts and renal epithelial cells from our proband, suggestive of a milder ciliary defect. Remarkably, the proportion of ciliated cells was significantly reduced in renal epithelial cells but not in fibroblasts, indicating an organ-specific ciliogenesis defect. Pathogenic variants in *CC2D2A* cause Joubert and Meckel syndrome, with no isolated renal presentations observed to date (*Mol. Genet. Genom.* e1603 2021). We identified a novel homozygous nonsense variant (Arg34*) in *CC2D2A*, classified as not pathogenic due to an alternate start-codon, in a previously healthy 37-year-old male with isolated ESRD of unknown etiology. Using public data (GTEx), we show that protein-coding transcripts harbouring this variant are the predominant trancripts in the kidney when compared to tissues relevant to *CC2D2A*-related phenotypes (e.g., cerebellum, liver).

Conclusions: Rare variants in known syndromic ciliopathy genes cause isolated renal disease in adults due to potential organ-specifc effects. Using variant classification schemes without functional analysis may not accurately capture the genetic contribution to adult ESRD.

Targeted Exome Sequencing Application for Genetic Diagnosis of Pediatric Patients with Cystic Kidney Disease

Jeesu Min,[1] Hyeonju Lee,[1] Peong Gang Park,[5] Yo Han Ahn,[1,2] Hee Gyung Kang,[1,2] Ji hyun Kim,[3,2] Eujin Park.[4] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [4]Hallym University Medical Center, Yeongdeongpo-gu, Seoul, Republic of Korea; [5]Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea.*

Background: Detection of a monogenic cause of chronic kidney disease accounts for almost 30% of cases in the pediatric cohort. Of these, the highest yield in the genetic diagnosis is currently seen in cystic kidney disease. Nearly 100 monogenic causes of renal cystic ciliopathies have been identified and the genetic diagnostic yield is reported to be approximately 50%. Here, we report the results of genetic testing in a cohort of Korean pediatric patients with cystic kidney disease.

Methods: From July 2019 to February 2021, children under the age of 18 with three or more cysts in both kidneys on imaging studies were recruited from three pediatric nephrology centers in Korea. Genetic identification was performed by targeted exome sequencing (TES) including 89 genes known as cystogenesis-related or causative-ciliopathy.

Results: A total of 46 pediatric patients with cystic kidney disease were recruited. The median age was 9.2 years (IQR, 5.49-14.53) and 60.9% were boys. Twelve patients (27.9%) had a family history of cystic kidney disease. The clinical diagnoses of the patients were 10 patients with autosomal dominant polycystic kidney disease, 5 patients with autosomal recessive polycystic kidney disease, 2 patients with multicystic dysplastic kidney, 1 patient with nephronophthisis, and the others were undiagnosed. The mutation detection rate was 52.2% (24 of 46). *PKD1* was the most common causative gene (16 patients, 34.8 %), followed by *HNF1B* (3 patients), *PAX2* (2 patients), *PKD2* (1 patient), *PKHD1 (*1 patients) and *NPHP3* (1 patient). Genetic mutations were identified in all patients (12 of 12) with a family history of cystic kidney disease. In patients without a family history, genetic mutations were found in 35.3 % (12 of 34).

Conclusions: The mutation detection rate in this cohort of Korean pediatric patients with cystic kidney disease was 52.2% by TES. Mutations in *PKD1* were found most commonly, and the mutation detection rate was higher in patients with a family history of cystic kidney disease. For children with cystic kidney disease, molecular genetic testing is essential for an accurate diagnosis, personalized treatment, and prognosis prediction.

PO1272

The Prognostic Factors of Cyst Infection due to ADPKD

Hiroki Mizuno,[1] Junichi Hoshino,[2] Yoshifumi Ubara.[1] *[1]Toranomon Byoin Bunin, Kawasaki, Japan; [2]Toranomon Byoin, Minato-ku, Japan.*

Background: Renal or hepatic cyst infection is a complication of autosomal dominant polycystic kidney disease (ADPKD), which requires hospitalization and causes death. Cyst aspiration was the gold standard to diagnose this disease. Because of its invasiveness, several diagnostic criteria without using cyst aspiration have been proposed, but prognostic factors of cyst infection have not been analyzed in this setting.

Methods: Inclusion criteria of this retrospective cohort are ADPKD patients who were admitted in Toranomon hospital and Toranomon hospital Kajigaya between 2016 April and 2021 March, and who were diagnosed as cyst infection based on MRI findings, which we previously published. Primary composite endpoint was defined combination of death, septic shock, or hospitalization for more than four weeks, and secondary outcomes were defined by each outcome mentioned above. Logistic analysis was planned to assess the predictors of the outcomes.

Results: One hundred ninety patients were eligible to this study. The average age was 65.0±9.2 years old, 116 (61.1%) were female, and the average height-adjusted total liver volume (htTLV) was 3322±2286 mL per meter, and 164 (86.3%) had hemodialysis therapy. Composite outcome occurred in 109 (57.4%): 25 death, 36 shock, and 98 longer-hospital-stay. Multivariable logistic regression model after adjusted related variables showed that older age (odds ratio(OR) 1.10 (95% confidence interval: 1.10-2.54), p-value=0.02), male (OR 2.49(1.16-5.33), p-value=0.02), higher htTLV (OR 2.29 (1.39-3.77), p<0.01), lower mean blood pressure at admission (OR 0.735(0.5798-0.9319), p=0.01), larger size of infectious cyst (OR:1.42(1.06-1.91), p=0.02) were significantly associated with the composite outcome. Although the culture-positive case or higher white blood cell count were not significantly associated with the primary outcome, they were associated with septic shock due to cyst infection.

Conclusions: Baseline characteristics at admission were associated with the prognosis of cyst infection diagnosed by MRI-based criteria, which was similar to cyst infection diagnosed by cyst aspiration. Culture-positive case or higher white cell count were reported as risk factors requiring more invasive therapies that could lead to septic shock and need longer hospitalization in our study's cohort.

PO1273

ExoGAG, a New Method for Extracellular Vesicle and Glycoprotein Isolation in Urine That Unmasks the Pathophysiology of the Kidney and Identifies New Biomarkers of Kidney Disease

Marta Vizoso,[1] Nerea Lago,[5] Tamara Camino,[5] Olaya Lamas-Gonzalez,[1] Susana Bravo,[2] Carmen Vazquez,[3] Manuel Fidalgo diaz,[3] Cándido D. Rodríguez,[3] Maria Pardo,[5] Miguel A. Garcia-Gonzalez.[1,4] *[1]Nephrology Laboratory, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; [2]Proteomic Group, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; [3]Nephrology Service, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain; [4]Galician Public Foundation of Xenomic Medicine, Santiago de Compostela, Spain; [5]Obesidomic Laboratory, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain.*

Background: Glycosaminoglycans (GAGs) are large polysaccharides that interact through glycosidic bonds with proteins and lipids, forming the extracellular matrix; or with secreted proteins, as uromodulin. Glycosylation is altered in pathologies, as cancer or kidney diseases. GAGs are present in extracellular vesicles (VEs), nanometric structures delimited by lipid bilayer that cells release and whose charge (RNA/miRNA, DNA and proteins) is essential in intercellular communication. Our group developed a method for GAG, glycoproteins and VEs isolation in any biological sample, called ExoGAG (commercialized by Nasas Biotech), which led us to identify and characterize new signalling mechanisms, and identify new prognostic/diagnosis biomarkers, for example, in polycystic kidney disease (PKD).

Methods: Urine samples have been collected from patients genetically diagnosed with type I and II PKD at different stages of disease. Using ExoGAG, GAG-glycoprotein-VEs complex has been isolated and characterized by different proteomic techniques (Western Blot, mass spectrometry), gene expression (RT-PCR), and image characterization (electron microscopy, immunofluorescence).

Results: ExoGAG has allowed us to identify a new biomarkers in urine (in protection) in PKD patients, which are altered in disease progression, even anticipating currently used kidney damage markers. The characterization of these complexes has led us to discover signalling mechanisms between the different segments of the nephron, and whose function is altered in different pathologies. These findings have served other researchers deepen knowledge in different specialties such as Oncology and Endocrinology.

Conclusions: This new method for isolating the fraction associated with GAG in urine samples has allowed us to identify prognostic/diagnostic biomarkers of kidney diseases, based on glycoprotein and vesicular profile. Likewise, it has led us to identify new signalling mechanisms of the nephron, which opens a new field for a better understanding of renal pathophysiology. These results uncovered the potential as a method of EVs isolation for its use in the research of new cellular communication pathways or cellular mechanisms.

PO1274

Deposition of an Abnormal Extracellular Matrix as an Initiating Event in Cyst Formation

Valerie A. Schumacher,[1,2] Mary E. Taglienti,[1] Jordan A. Kreidberg.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Extracellular matrix (ECM) refers to the proteins and other macromolecules outside of cells that provide a scaffolding to maintain tissue architecture. The distinct ECMs to which these cells are attached, epithelial cells to a laminin-rich basement membrane vs. interstitial cells to a collagen/fibronectin (FN) ECM, has profound implications for cell behavior and tissue architecture. These differences in cell behavior are mediated through a family of receptors known as integrins, used by cells to attach to the ECM. Here we provide evidence that cyst formation in ADPKD is a manifestation of abnormal cell behavior in response to an atypical extracellular matrix and changes in integrins.

Methods: To understand the pathological contribution of integrins and FN to ADPKD, we measured their expression and localization *in vivo* using a postnatal murine model of ADPKD and kidney samples from human ADPKD.

Results: We observed increased expression of FN in murine cystic kidneys and also in kidneys from humans with ADPKD. In mice, increased fibronectin expression preceded cyst formation. Moreover, laminin basement membrane underlying cyst lining cells was discontinuous and replaced in some sections by a FN-rich ECM. Some sections were conspicuous for expressing the FN receptor $\alpha5\beta1$ integrin, and for cell morphology being cuboidal instead of flattened. In other areas of the FN rich ECM, αv-integrins, were present on flattened cyst lining cells. $\alpha3\beta1$ integrin was more abundant on cyst lining cells than on non-cystic tubules. Interestingly, *in situ* hybridization revealed that *Fn1* was not expressed in all cyst lining cells but in the specific subset of cells that had a cuboidal appearance.

Conclusions: Our studies presented here identify a distinct subset of cuboidal cyst lining cells that express *Fn1*. They also demonstrate distinct integrin repertoires among subsets of cyst lining cells. As FN deposition precedes cyst formation, these FN-expressing cuboidal cells may have a role in the initiation or early progression of cysts in ADPKD.

PO1275

Uncovering the Role of the Extracellular Matrix in ADPKD Progression

Elisa Pellegrino,[1,2] Maria Elena Steidl,[1,2] Marco Chiaravalli,[2] Alessandra Boletta,[2] Elisa Agnese Nigro.[2] *[1]Universita Vita Salute San Raffaele, Milano, Italy; [2]IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Polycystic Kidney Disease (PKD) is a genetic disorder due to mutation in either *Pkd1* or *Pkd2* genes and characterized by bilateral cysts formation. We recently uncovered a direct role of PC-1, the protein product of *Pkd1* gene as a mechanosensor of extracellular stiffness. We found that PC-1 interactors mediate inhibition of actomyosin contraction that mediates the cellular response to the rigidity of the Extracellular Matrix (ECM). Based on these findings we speculated that *Pkd1*$^{-/-}$ cells fail to properly respond to the extracellular mechanical force of ECM leading to excessive matrix deposition and proliferation. In line with this, kidneys of end-stage PKD patients show enhanced fibrosis typical of cystic kidney disease and tumors. We then wondered whether PKD ECM is a part of an active Cyst Microenvironment (CME), exerting a key role in the evolution of the disease.

Methods: We characterized CME in the renal tissue of an aggressive *Pkd1*$^{\Delta C/flox}$: Ksp-Cre and a low progressive *Pkd1*$^{\Delta C/flox}$:Tam-Cre inducible mouse models. To study the composition and the mechanical properties of the cystic ECM we decellularized cystic kidneys obtaining ECM-derived kidney scaffolds. Furthermore, we isolated matrix from *Pkd1*$^{-/-}$ fibroblasts *in vitro*.

Results: We have characterized the renal tissue microenvironment of two *Pkd1* inducible mouse models at a late stage of the disease confirming the presence of fibrosis, immune infiltrates and progressive accumulation of collagen I. In line with an active role played by fibroblasts in the deposition and remodeling of the ECM, our data showed the presence of activated fibroblasts in cystic kidneys. We performed a proteomic analysis of cystic kidney scaffolds by Mass Spectrometry (MS). Cluster analysis of MS data showed a clear separation between cystic and control scaffolds. Finally we found that matrix isolated from *Pkd1*$^{-/-}$ cells was able to influence differently key cellular properties such as adhesion, polarization, proliferation and migration.

Conclusions: ECM plays an active role in the progression of ADPKD disease.

PO1277

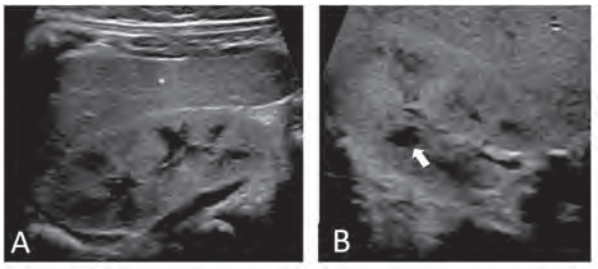
17q12 Deletion Syndrome Presenting as Congenital Diaphragmatic Hernia in a 2-Month-Old Infant

Leah S. Heidenreich, Paul G. Thacker, Fouad T. Chebib, David J. Sas, Christian Hanna. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: 17q12 deletion syndrome results from the loss of as many as 15 genes on the long arm of chromosome 17 including the hepatocyte nuclear factor-1-beta gene (*HNF1B*). Heterozygous pathogenic variants, whole gene deletion, or duplication in *HNF1B* are frequently linked to inherited kidney malformations including hyperechoic kidneys, kidney cysts, solitary kidney, and hydronephrosis as well as extrarenal phenotypic features. 17q12 deletion syndrome has also been linked to congenital diaphragmatic hernia (CDH). We present a case of an infant with hyperechoic and cystic kidneys, diagnosed postnatally with CDH.

Case Description: A 2-month-old female with a history of hyperechoic kidneys on prenatal ultrasound presented to the emergency department with increased work of breathing. A chest x-ray revealed left hemidiaphragm elevation, normal cardiac silhouette, and no focal pulmonary consolidation. Computed tomography of the chest confirmed the diagnosis of CDH. A repeat kidney ultrasound revealed diffuse hyperechoic kidneys and a focal kidney cyst within the right upper pole (**Image 1**). Genetic workup revealed a 1.9 megabase deletion on the long arm of chromosome 17 consistent with the diagnosis of 17q12 deletion syndrome.

Discussion: Pathogenic variants in *HNF1B* or whole gene deletion as part of 17q12 deletion syndrome should be considered in infants with hyperechoic kidneys with cysts, particularly in the context of extrarenal manifestations. Studies have examined the link between *HNF1B* and the development of a CDH. It is proposed that *HNF1B* is involved in the WNT signaling pathway that is critical to mesodermal differentiation and proper diaphragm formation. Only 4 other cases of *HNF1B* mutations associated with CDH are reported in the literature. Two cases describe *HNF1B* deletions, and 2 cases describe *HNF1B* duplications. It is possible that the high prenatal mortality of CDH could explain the paucity of this association.



(A) Grayscale, longitudinal ultrasonographic image of the right kidney demonstrates diffusely increased renal parenchymal echogenicity when compared to the adjacent liver **(asterisk)**. The corticomedullary differentiation is diminished. **(B)** A magnified, transverse ultrasonographic image of the right kidney demonstrates a right upper pole cyst **(arrow)**.

PO1278

Recurrent Pneumothorax in a Marfanoid Adolescent with Autosomal Dominant Polycystic Kidney Disease

Allison Miller. *Legacy Health System, Portland, OR.*

Introduction: Pneumothorax may be a rare extra-renal manifestation of autosomal dominant polycystic kidney disease (ADPKD), and may indicate co-inheritance of other genetic diseases.

Case Description: A 21 year-old man with ADPKD and pneumothoraces presented to nephrology clinic. A screening ultrasound in late childhood was completed due to his family history and confirmed ADPKD. The patient was normotensive and had a tall, thin habitus. His musculoskeletal examination was pertinent for several marfanoid findings, including increased arm span ratios, pes planus, and positive thumb and wrist signs. His eGFR was normal and he did not have proteinuria. He was hospitalized several times between ages 13-20 for recurrent pneumothoraces requiring left apical wedge and lower bleb resections with pleurectomy, and right upper lobectomy and pleurectomy.

Discussion: The patient's lung collapse was attributed to primary spontaneous pneumothorax due to his tall stature and intermittent tobacco use. However, this cannot account for his high rate of recurrence. The extent of pneumothorax burden in this patient should be considered in context of his underlying polycystic renal disease. Pulmonary manifestations of ADPKD are not well understood and have only been described in a handful of case reports. Bronchiectasis and cystic lung disease are thought to occur as a downstream consequence of impaired parenchymal healing. Mutated polycystin-1 in ADPKD prevents normal ciliary function, which is imperative for coordination of cellular repair in bronchial smooth muscle cells. Evolving cystic lung disease in the setting of underlying ADPKD could explain this patient's recurrent pneumothoraces. The possibility of a co-inherited connective tissue disease should also be considered in patients with ADPKD and pneumothoraces. "Overlap" disorders between ADPKD, Marfan syndrome and Tuberous Sclerosis (TSC) have been examined in linkage studies, and have chromosomal proximity. Marfan syndrome and TSC are associated with pneumothorax. Though our patient did not manifest criteria for TSC, his examination is consistent with a Marfan's variant phenotype. This patient may be an example of co-inherited disease, and raises the question of whether it is under this circumstance that rare pulmonary complications become apparent. Clinicians should be aware of these overlap disorders in relation to ADPKD.

PO1279

Ruptured Intracranial Aneurysm as the Initial Presentation of ADPKD in a Pediatric Patient

Maroun Chedid, Fouad T. Chebib, Christian Hanna. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is associated with multiple extra-renal manifestations, most notably intracranial aneurysms (ICA). Approximately 10% of ADPKD patients develop ICA during their lifetime. Subarachnoid hemorrhage (SAH) is a major complication of ICA and usually occurs during the end of the 3rd decade. Aneurysm rupture in children <18 years of age is extremely rare. We report a case of a 9-year-old boy presenting with symptomatic ICA rupture as the initial presentation of ADPKD, despite a negative family history of ICA.

Case Description: A 9-year-old boy presented to the emergency department with an abrupt onset of severe headache and lethargy after a fall. His family history was remarkable for ADPKD in his father and grandfather. None of his affected family members developed ICA or intracranial hemorrhage. Initial non-contrast computed tomography scan of the head showed frontal lobe hemorrhage. Additional imaging studies revealed a ruptured anterior communicating artery with SAH. Urgent aneurysm coiling was performed, his bleeding was controlled, and the patient survived. Due to his strong family history for ADPKD, a kidney ultrasound was performed and showed enlarged kidneys with multiple renal cysts bilaterally confirming the diagnosis of ADPKD. The patient's father underwent a screening MRI of the brain at the age of 48 years and was negative for ICA.

Discussion: Our case of SAH due to ICA rupture as the initial presentation of ADPKD, in the absence of a positive family history of ICA or hemorrhage, has not been reported in children. Rare cases of subarachnoid hemorrhage in pediatric patients with ADPKD and a positive family history of ICA or hemorrhage have been described. Based upon available data, it is unclear if either widespread or targeted screening for intracranial aneurysms is beneficial for pediatric patients with ADPKD. Screening is reserved for patients with a family history of hemorrhage, migraine, stroke, patients undergoing major surgery, or patients with high-risk jobs. However, we do not screen children <18 years of age because of the extreme rarity of aneurysmal rupture at that age. Though extremely rare, primary care physicians and pediatricians should stay aware that ICA rupture occurs in children with ADPKD and can lead to devastating complications, even in the absence of positive family history.

PO1280

Congenital Solitary Kidney in ADPKD: A Genotype-Phenotype Correlation

Romina Bucci, Marta Vespa, Maria Teresa Sciarrone Alibrandi, Giancarlo Joli, Giulia Mancassola, Giuseppe Vezzoli, Paolo Manunta. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Introduction: There are a very few cases of ADPKD associated with Unilateral Renal Agenesis (URA). The total amount is currently 9 cases known in the world and their renal function outcome is somewhat undefined.

Case Description: ZG is a pleasant 41-year-old man with a congenital solitary left kidney with multiple cysts and a genetic diagnosis of ADPKD. Familiarity is negative for ADPKD, but positive for URA (present in his sister and her son). Except for hypertension, there are no extrarenal ADPKD manifestations. Poster et al. analyzed 3 patients with a similar phenotype in a cohort of 182 ADPKD subjects, comparing how the volume of the single kidney increased (SKV) over time and how the GFR dropped, stratifying them for sex and age. A greater SKV in time has been recorded in these 3 patients, caused by both compensatory hypertrophy and cyst growth. Surprisingly though, their kidney function was better compared to controls. Late onset kidney failure is probably caused by hyperfiltration, and it is linked with a long-term worse outcome. In our case, ZG's SKV increased less compared to another subject with same age and sex and with controls found in literature. Same goes for kidney function, which was better and more stable in a 10-year time-lapse compared to controls.

Discussion: The reason for this could be found in the PKD1 mutation: ZG has a missense mutation, while the aforementioned 3 cases had truncating ones. ZG's increased SKV is probably more related to hypertrophy than cyst growth itself. Therefore, even in an unorthodox situation like this one, long-term outcome seems to depend on the genotype of the subject.

	Patient ZG (male, 41 y/o)	Matched 2-kidney ADPKD groups (males, y/o 34.3 to 41.4)	Patient with polycystic solitary kidney (male, 38 y/o)
SKV (cm3) baseline	490	546(431-691)	780
Annual SKV progression (%)	2	6.7 (3,9-9,5)	10,2
CCr (ml/min/1.73 m2)	114	91 (85-98)	77

Note: Table shows values of SKV for patient ZG and patient with polycystic solitary kidney. For the matched 2-kidney ADPKD group is reported the SKV mean values with 95% CI. For this last group the volume given is that of the left kidney present in the other 2 cases. SKV is calculated from RMN scans. Creatinine clearance is estimated according to the Cockcroft-Gault formula. In the 2-kidney ADPKD group CCr is estimated by calculating both kidneys.

PO1281

Management of a Patient with ADPKD Who Needs Lithium

Katharine I. Senter, Omar H. Maarouf, JingJing Zhang. *Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.*

Introduction: N/A

Case Description: A 35-year-old female with borderline personality disorder and schizoaffective disorder presented to nephrology for autosomal dominant polycystic kidney disease (ADPKD). Her biological father had ADPKD and was on dialysis at the time of death. The patient has taken lithium for 10 years, and only lithium allows her to work and live independently. She presented with polydipsia and polyuria, indicating possible nephrogenic diabetes insipidus (DI) from lithium, essential hypertension since age 30, and constant headache; brain MRI was negative for aneurysm. Labs showed a lithium level between 0.3-0.9 mmol/L, creatinine between 0.6-0.75 mg/dL, eGFR of 85-90 ml/min, urine protein:creatinine ratio of 0.27-0.32 g/g, and urine osmolality <100 mOsmol/kg. She has been treated with 2.5 mg lisinopril, 10 mg amiloride, and 1350 mg lithium daily. Abdominal MRI without contrast showed scattered liver cysts and innumerable bilateral kidney cysts. Kidney volume indicated Mayo Class 1C PKD. Her father developed ESRD in his late 50s, suggesting rapidly progressive ADPKD class. Lithium nephropathy is usually characterized by 1-2 mm renal microcysts (Khan et al, *Int J* Psychiatr Med 50(3):290-298). The patient's larger cysts, total kidney volume, and liver cysts suggest ADPKD. Genetic testing showed that the patient has a heterozygous mutation in c.12445-1G>T, expected to cause altered splicing and function of the PKD1 gene.

Discussion: Finding an appropriate agent to slow CKD progression is the current strategy to manage PKD. Her condition is complicated by likely lithium nephropathy. The TEMPO trial (Torres et al, N Engl J Med 367:2407–2418, 2012) showed that tolvaptan helps slow rapidly progressive ADPKD by inhibiting vasopressin's effect, reducing cAMP production, further inhibiting cyst formation and growth (Wang X et al, J Am Soc Nephrol 19: 102–108, 2008; Aihara M et al, J Pharmacol Exp Ther 349: 258–267, 2014). Lithium can also inhibit vasopressin in the kidney, leading to nephrogenic DI (Bokenhauer et al, Nat Rev Nephrol11(10):576-88, 2015). In ADPKD, tolvaptan helps achieve a urine osmolality of less than 300 mOsmol/kg (Torres, Clin J Am Soc Nephrol. 13(11):1765-1776, 2018). Our patient already has polyuria and urine osmolality below 100 mOsmol/kg. Her condition requires agents targeting other pathways. For now, she is on lisinopril, with BP <110/75, and amiloride to limit polyuria.

PO1282

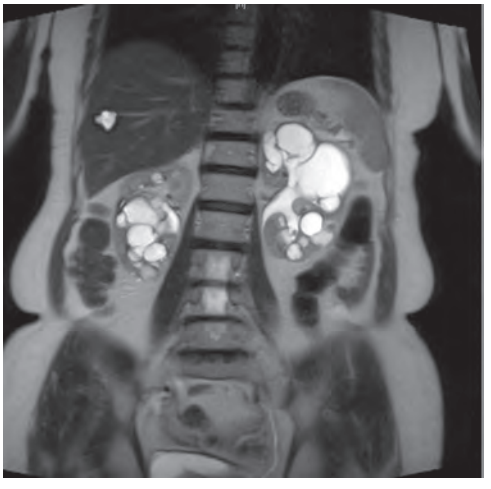
A Case of Mistaken Identity: Alport Syndrome Masquerading as Polycystic Kidney Disease

Kana R. Amari, Jennifer A. Tuazon. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

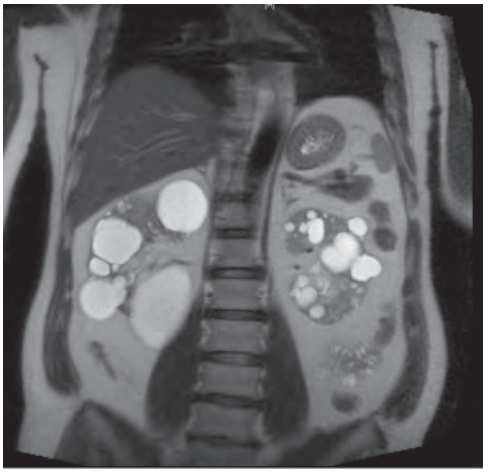
Introduction: Alport Syndrome (AS) is an inherited nephritis caused by a collagen-IV-related mutation leading to abnormalities in the glomerular basement membrane. Patients may present with unexplained hematuria, proteinuria, with or without renal insufficiency. Here, we describe two cases of patients presenting with multiple bilateral renal cysts, initially diagnosed with autosomal dominant polycystic kidney disease(ADPKD), and who were later found to have Alport syndrome via genetic testing.

Case Description: We report two cases of patients followed in our nephrology clinic who were initially thought to have ADPKD. The first patient is a 75-year-old woman who was followed for long-standing hematuria, CKD3bA3, innumerable bilateral renal cysts, few livers cysts, cerebral aneurysms, and a family history of cystic kidney disease. Due to normal kidney sizes, genetic testing was done which revealed a pathogenic COL4A3 mutation, c.1372G>C (p.Gly458ARg). Our second patient is a 64-year-old man with a history of hematuria, CKD3aA2, sensorineural hearing loss, retinal detachment, and family history of hematuria. His genetic testing revealed an X-linked COL4A5 mutation c.367G>C (p.Gly123Arg).

Discussion: Very few cases have described an association with AS and cystic kidney disease. The causal mechanism for renal cyst formation and Alport syndrome is unknown. These cases illustrate the importance of considering alternate diagnosis when suspected ADPKD has atypical features such as normal kidney sizes or kidney dysfunction more than expected for the cyst burden.



Case #1 Bilateral renal cysts in COL4A3-related Alport syndrome



Case #2 Bilateral renal cysts in X-linked Alport syndrome

PO1283

Heterozygous HSD11B2 Gene Mutations and Apparent Mineralocorticoid Excess (AME) in a Patient with Heterozygous ADPKD1

Celeste S. Chang,[1,2] Hsiang C. Liu.[3] [1]*Chinatown Kidney Care, New York, NY;* [2]*Mount Sinai Beth Israel Hospital, New York, NY;* [3]*Wei Gong Memorial Hospital, Toufen, Taiwan.*

Introduction: HSD11B2 gene which locates at Chromosome 16q22.1 and encodes the Type 2 isoform of 11-beta-Hydroxysteroid Dehydrogenase that interconverts biologically active cortisol and inactive cortisone. Polycystin-1, encoded by the PKD1 gene, which locates at Chromosome 16p13.3. PKD1 gene forms a complex with polycystin-2 (PKD2) that regulates multiple signaling pathways to maintain normal renal tubular structure and function. We present a new finding of HSD11B2 gene in a patient with polycystic kidney disease.

Case Description: 58-year-old Chinese male presented with bilateral renal cysts and CKD Stage 3 A. PMHx is significant for early onset HTN at the age of 45, Left ICH without residual weakness at the age of 46 years and episode of hypokalemia. Denied Licorice ingestion. Family history is positive for HTN and polycystic kidney disease in his mother and all three siblings. His BP was 145/91 mmHg, not controlled well with daily dose of oral Lisinopril 40 mg and Amlodipine 10 mg. His Na 141, K 4.7, CO2 27, BUN 20, Cr: 1.6, GFR: 46, Hb: 12.5 and Urine protein/ Cr ratio was 0.324. He was started with low dose of Spironolactone 12.5 mg daily for BP control and proteinuria. Renal ultrasound showed Right kidney was 19.5 cm, left kidney was 18.6 cm and presence of multiple bilateral renal cysts. Abdominal CT without contrast disclosed HtTKV: 1724 ml/m. Mayo clinic class was 1 C, estimated frequency of ESRD at 10 years was 37.8%. Kidney gene panels detected the gene of PKD1 (Autosomal Dominant) and HSD11B2 (Autosomal Recessive). BP stable at 125/78 mmHg, 24-hour urine protein was 125 mg per day, Serum cortisol 11 mcg/dl (normal: 8-19 mcg/dl), Serum cortisone: 0.74 mcg/dl (normal: 1.34- 2.65 mcg/dl), Serum cortisol/cortisone ratio: 17.6 (normal: 3.9-11), 24 hours Urine free cortisol: 7 mcg/day (normal 5-64 mcg/day), 24 hours Urine free cortisone: 31 mcg/day (normal 16-128 mcg/day), 24 hours Urine free cortisol/cortisone ratio: 0.22 after spironolactone. However, it was discontinued upon repeated serum K was at the higher side of normal. He is currently treated with oral Tolvaptan.

Discussion: This is an unique case which could be the first case report of HSD11B2 mutations with apparent mineralocorticoid excess associated with heterozygous ADPKD1.

PO1284

A Rare Presentation of Autosomal Recessive Polycystic Kidney Disease in Adulthood

Katerina Hysi, Saira Sajid, James Drakakis. *NYU Winthrop Hospital, Mineola, NY.*

Introduction: Autosomal recessive polycystic kidney disease (ARPKD) belongs to a group of congenital hepatorenal fibrocystic syndromes and causes significant renal and liver related morbidity and mortality in children. Renal cysts, congenital hepatic fibrosis, and recessive inheritance characterize ARPKD. The disorder usually manifests infancy, with a high mortality rate in the first year of life. For the patient who survives the neonatal period, the probability of being alive at age 15 ranges from 50-80%, with the majority requiring renal replacement therapy at that age. This diagnosis is rarely made in the adult years with the clinical course and prognosis much less well defined.

Case Description: 57 year-old male with PMHx of gout and long standing CKD with baseline creatnine 1.8 - 2.0 mg/dL, dating back to 2010 with little progression presented for evaluation. Urinalysis was without microscopic hematuria or proteinuria. Historic imaging showed small kidneys and medical renal disease. An updated MRI noted bilateral kidneys cysts with areas of atrophy and scarring, which along with an increase in GGT and family history of a sister with congential hepatic fibrosis, raised possibility of ARPKD. The patient subsequently underwent whole exome sequencing, which confirmed two pathogenic variants (specifically S3018F and R1624W) in the PKHD1 gene, consistent with ARPKD. His brother was eventually tested as well and found to have the same two variants.

Discussion: The classic presentation for ARPKD is systemic hypertension with progression to ESRD by the age of 15. In a typical presentation, a small number of those with ARPKD live to adulthood with some compromise of kidney function; but with significant liver disease. Due to its wide phenotypic variability, the diagnosis of ARPKD may be made during any stage of childhood; in rare cases, it does not present until adolescence or adulthood. A minority of affected individuals present as older children or young adults with evidence of hepatic dysfunction or otherwise unexplained renal cysts as the prominent presenting feature. This case exhibits reveals the silent menace of ARPKD with a delay in recognition of clinical manifestations and thus an unusually older age at the time of diagnosis.

HDR: A Novel Mutation in GATA-3 with Variable Expressivity in an Affected Family

Meenakshi Sambharia, Jason Misurac, Christie P. Thomas. *The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.*

Introduction: Hypoparathyroidism, deafness, and renal disease (HDR) syndrome, also known as Barakat syndrome, is a rare autosomal dominant disorder caused by heterozygous variants in *GATA-3*. *GATA-3* belongs to a family of dual zinc finger transcription factors that is involved in embryonic development of the inner ear, kidneys, and parathyroids. The exact prevalence of HDR syndrome is unknown, but less than 200 cases have been described. The disease has variable expressivity even within the same family. Making a diagnosis can be challenging, more so in individuals with no laboratory abnormalities. Herein we describe a father-daughter dyad with HDR syndrome with variable disease expression.

Case Description: A 7-year-old female with history of congenital deafness, multicystic dysplastic kidney, reflux nephropathy, and multiple urinary tract infections underwent genetic testing. Exome sequencing revealed a heterozygous missense variant in *GATA-3*, a threonine to arginine substitution (c.1058G>C, p.Arg353Thr). The missense variant was ultrarare, predicted pathogenic, and classified as likely pathogenic. Laboratory evaluation demonstrated hypoparathyroidism with hypocalcemia and hyperphosphatemia, fulfilling all criteria for HDR syndrome. Calcium levels normalized on calcium and calcitriol supplementation. Cascade screening revealed that her father carried the same genetic variant. Father's history was pertinent for sensorineural hearing loss diagnosed at 2 years of age with normal renal function, serum calcium, and PTH.

Discussion: Hypoparathyroidism is the most specific symptom of HDR syndrome, absent in 5-7% of affected patients, whereas sensorineural hearing loss is present in 96% of affected patients. Kidney manifestations are variable and may include aplasia, hypoplasia, dysplasia, cysts, vesicoureteral reflux, hematuria, and/or proteinuria. The missense variant described in our patient has not been previously reported, although an alternate amino acid change at the same residue has been reported with HDR syndrome. As the father had isolated deafness, he remained undiagnosed for almost 25 years, until the identification of HDR syndrome in his daughter. Screening family members is important for recognition and treatment of hypoparathyroidism and of renal disease as patients are at risk of symptomatic hypocalcemia and progressive kidney disease.

Assessing Genomic Needs

Jordan G. Nestor,[1] Sumit Mohan,[1,2] Ali G. Gharavi,[1] Chunhua Weng.[1] *[1]Columbia University, New York, NY; [2]Columbia University Mailman School of Public Health, New York, NY.*

Background: Interventions must address nephrologists' knowledge gaps, perceived needs and willingness to utilize genomic data to guide more personalized patient care.

Methods: U.S. Boarded nephrologists were invited to complete an anonymous electronic needs assessment survey on genomic implementation that incorporated multiple themes e.g., objective knowledge, attitudes perceived barriers. Its design was informed by a comprehensive literature review and adapted published tools. Descriptive statistics were used to summarize demographics and baseline characteristics.

Results: Between January-May 2021, 319 complete surveys were eligible for analysis by nephrologists across 47 U.S. States, (86% adult vs. 14% pediatric), with 34% community-based (vs. 66% academic) including 36% who perform transplant evaluations and 75% with prior experience ordering genetic testing; 77% responded that genetic test results have meaningful implications for a patient's care ≤ 50% of cases. Community nephrologists were more likely to cite limited experience, educational resources and access to experts as perceived barriers to implementation of genomics compared to those in academic practice.

Conclusions: Our findings highlight variable levels of experience and comfort using genomics and can inform the design of tailored interventions that address nephrologists' specific needs, including education, workflow and clinical-decision support tools. Together, such tools can promote wider utilization of genomic resources and empower nephrologists to use genomic data.

n (col %)		Overall (*n*=319)
Cohort characteristics		
Age group	25-44 years old	149 (37%)
	45-74 years old	161 (50%)
	75 years or older	9 (3%)
Sex	Female	107 (34%)
Race	White	176 (55%)
	Asian	112 (35%)
	Other/Prefer not to answer	41 (13%)
Ethnicity	Hispanic/Latino	29 (9%)
Clinical Role	Adult nephrologist	276 (86%)
	Pediatric nephrologist	43 (14%)
Years in nephrology practice, excluding training	≤ 15 years	199 (62%)
	≥ 16 years	120 (38%)
Practice location	South	110 (35%)
	North-East	102 (32%)
	Mid-West	56 (18%)
	West	38 (12%)
	Hawaii/Alaska	13 (4%)
	Missing	7 (2%)
Practice setting	Academic or Academic-affiliated (including Veterans Affairs)	210 (66%)
	Community-Based	109 (34%)
How are most patients insured?	Government-sponsored insurance	219 (69%)
	Private insurance	49 (15%)
	Other/Uninsured/self-pay/Unsure	51 (16%)
Participate in kidney transplant evaluations		115 (36%)
Prior experience ordering genetic testing		241 (75%)
How often do you think genetic test results have meaningful implications for a patient's care?		
	Never	0
	Rarely (in less than 10% of cases)	58 (18%)
	Occasionally (in about 30% of cases)	99 (31%)
	Sometimes (in about 50% of cases)	90 (28%)
	Frequently (in about 70% of cases)	54 (17%)
	Usually (in about 90% of cases)	13 (4%)
	Every time	5 (2%)
How often are you involved in returning genetic test results to patients?		
	Never/Almost never	140 (44%)
	Occasionally/Sometimes	71 (22%)
	Almost every time/Every time	108 (34%)
Participated in genomic education within last 2 years		119 (37%)
Objective knowledge	Total score: mean (± SD) on a scale of 0 to 8	5.65 (± 1.17)
Perceived barriers to implementation	Total barrier score: mean (± SD) on a scale of 0 to 22	7.60 (± 4.30)
Which workflow do you prefer? (*n*=317)	Nephrologist refers patient to a genomic professional who orders the test and returns the results	146 (46%)
	Nephrologist orders the genetic testing and returns the results	102 (32%)
	Other	69 (22%)

Pediatric Nephrologists' Perspectives on Genetic Testing and Return of Results to Children

Hilda E. Fernandez, Marissa Lipton, Olivia Balderes, Hila Milo Rasouly, Fangming Lin, Maddalena Marasa, Ali G. Gharavi, Maya Sabatello. *Columbia University, New York, NY.*

Background: Pediatric (ped) nephrologists care for children with genetic causes of chronic kidney disease (CKD). While genetic testing (GT) is now more accessible in nephrology, little is known about the utility, clinical application, and relevance of GT in determining underlying CKD or other actionable secondary genetic findings for ped nephrology patients. We explored ped nephrologists' views regarding GT in clinical and research settings.

Methods: An online 30-item survey was developed and distributed via professional listservs. Inclusion criteria required self-identification as a U.S. licensed nephrologist. Data collection was from 1//22/21-5/4/202 and analyzed by STATA 15.1. Descriptive statistics are reported.

Results: 85 ped nephrologists completed the survey. Respondents range in yrs in practice (35% 6-15 yrs, 21% 16-25 yrs, 28% > 25 yrs), and 75% practiced in a university hospital. Most had referred > 20 patients for GT (61%). GT was considered clinically important for disease diagnosis (92%), understanding (85%), prognosis (86%), treatment (84%), family counseling (88%), and kidney transplant planning (93%). 68% report they have reliable information for care of patient with genetic results. Top 3 challenges to GT were interpretation of results, selection of test, and ordering test. 86% identified fitting GT into practice as a challenge, and 61% report offering counseling with a genetic expert after return of genetic results. 53% felt patients could not afford GT. Most indicated the importance of having clear guidelines for GT (84%). Majority (70%) would recommend GT for family members, especially in the presence of a tailored lab report (91%). Most

are involved in the return of results in their own practice (60%). Regarding the return of research-based results, most thought diagnostic (92%) and actionable secondary findings (75%) should be returned.

Conclusions: Ped nephrologists report on the importance of GT in CKD. They also report on their personal challenges with GT and structural barriers to the utilization of GT.

Attitudes and Perceptions of APOL1 Genetic Testing in Black Patients with Hypertension: A Pilot Study

Krista L. Lentine,[1] Anthony N. Muiru,[2] Kathryn K. Lindsay,[1] Amy Mosman,[1] Yasar Caliskan,[1] Barry I. Freedman,[3] Amber Carriker,[4] Chi-yuan Hsu,[2] Kana N. Miyata,[1] Thanh-Mai N. Vo,[1] John C. Edwards,[1] Marie D. Philipneri.[1] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]University of California San Francisco, San Francisco, CA; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]Mid-America Transplant Services, Saint Louis, MO.*

Background: A portion of the chronic kidney disease risk in Black persons appears due to polymorphisms in the gene encoding apolipoprotein L1 (*APOL1*). While applications of *APOL1* genotyping for prognostication (e.g. in evaluation of organ donors) are emerging, the interest of Black patients in *APOL1* genotyping and implications for individual kidney risk management are not well defined.

Methods: In this pilot study, we offered *APOL1* genetic testing and assessed attitudes and concerns related to *APOL1* testing and kidney risk management among Black persons seen in the Hypertension & Nephrology clinics at one urban, Midwestern center.

Results: Among 110 participants with genotyping results to date, 56% were women, mean age was 58 years, 72% were obese, and a mean of 3 antihypertensive agents were used (**Table**). 13% had 2 *APOL1* renal risk variants (high-risk genotypes), and 42% had 1 risk variant. At baseline, most participants (86%) reported that they were concerned about kidney disease, 90% thought it was a good idea to be tested for genes that may impact kidney disease, 82% would want *APOL1* testing for their children, and only 26% expected to feel upset if they were *APOL1* high risk. Most participants reported that knowledge of a high-risk *APOL1* genotype would lead to changes in health-related behaviors (**Figure**).
