Methods: In Part A of the study [NCT04629170] hyperoxaluria was induced in adult HV by a high oxalate (400-600mg), low calcium (400mg) diet over 4 days. Subjects were then randomized (6 active:3 placebo) to receive 5 days of SYNB8802 or placebo TID. 24hr UOx levels were measured daily. Primary outcome was safety and tolerability. Part B is a double-blind, placebo-controlled crossover study of SYNB8802 in subjects with enteric hyperoxaluria and a history of RYGB. Up to 20 subjects will be randomized in a crossover design with a 2-week washout period to receive SYNB8802 (at 3e11 live cells/dose) or placebo, dosed up to TID with meals. Urine samples for determination of 24hr UOx levels will be collected over 3 days at baseline and on the last 3 days of each dosing period. Subjects will maintain their normal diet throughout the study. The primary endpoint is change from baseline in 24hr UOx amount excreted with SYNB8802 treatment versus placebo. Secondary endpoints include change from baseline in UOx:creatinine ratio with SYNB8802 treatment versus placebo.

Results: In Part A, a well-tolerated dose of 3e11 live cells was identified in HV. At this dose, the percent change from baseline UOx levels was -28.6% (90% CI: -42.4 to -11.6) compared to placebo in diet-induced hyperoxaluria. This dose is being studied in Roux-en-Y patients with hyperoxaluria in Part B. The results from the RYGB population will be reported.

Conclusions: These results provide proof of mechanism for UOx lowering by SYNB8802 through GI consumption of oxalate in diet-induced hyperoxaluria. Part B seeks proof-of-concept in patients with enteric hyperoxaluria.

Tacrolimus Induces Ligand-Independent TGF-β Receptor Signaling to Promote Renal Fibrosis

Adaku C. Ume, Clintoria R. Williams. Kidney Pathophysiology Research Group *Wright State University Boonshoft School of Medicine, Dayton, OH.*

Background: Although calcineurin inhibitors (CNIs) such as tacrolimus and cyclosporin have dramatically improved the quality of patient care, long-term therapy causes **irreversible damage** to the kidneys in the form of renal fibrosis. These morphologic changes ultimately lead to a decline in renal function and can progress to end-stage renal failure. These detrimental outcomes present a critical need to identify the driving mechanisms by which CNIs cause renal damage. It is well established that TGFb is a major contributor to CNI-induced renal fibrosis. However, the underlying mechanisms remain unknown. The objectives of this study are to 1) investigate whether TGFb secretion is required to stimulate TGFb receptor signaling in a model of CNI-induced renal fibrosis and 2) investigate whether calcineurin plays a critical role in regulating TGFb receptor activity.

Methods: To examine the role of calcineurin inhibition in altered TGFb receptor signaling, wild type mice were treated with either vehicle (100% ethanol) or 10 mg/kg tacrolimus for 7 days. To confirm in vivo findings, wild-type mouse renal cortical fibroblasts were treated with either vehicle (100% ethanol) or 1nM tacrolimus for 24 hours in the presence and absence of anti-TGFb neutralizing antibodies. TGFb receptor expression and activation, TGFb receptor downstream signaling mediators, profibrotic markers and calcineurin activity were analyzed.

Results: Findings demonstrate that tacrolimus-induced loss of calcineurin activity is accompanied with enhanced TGFb receptor activation and signaling. Notably, increasing concentrations of anti-TGFb neutralizing antibodies failed to abolish aberrant TGFb signaling and increased expression of profibrotic markers.

Conclusions: Together, these results demonstrate that 1) CNIs promote ligand-independent TGFb signaling and 2) calcineurin plays a functional role in regulating TGFb receptor activity.

Immunoreactivity of CD3+CD4+ in Stable Young, Middle Aged, and Elderly Kidney Transplant Recipients Receiving Maintenance Tacrolimus and Mycophenolic Acid Immunosuppression

Kathleen M. Tornatore,[1,2] Aijaz A. Gundroo,[3,1] Shirley S. Chang,[1,2] Mahfuz Yonis,[1,2] Kris Attwood,[4,1] Brian M. Murray.[1,2] *[1]University at Buffalo, Buffalo, NY; [2]Erie County Medical Center, Buffalo, NY; [3]The Ohio State University, Columbus, OH; [4]Roswell Park Comprehensive Cancer Center, Buffalo, NY.*

Background: Tacrolimus and mycophenolic acid are the standard of care in most stable kidney transplant recipients (KTR) at U.S. transplant centers. However, there are limited data that determine within subject immunophenotypic responses over the adult age range. This study examined ex vivo immunoreactivity of CD3+CD4+ lymphocytes in stable young, middle age and elderly KTR receiving tacrolimus and mycophenolic acid.

Methods: Fifteen stable KTR greater than 1 yr post-transplant completed a 12-hour study with serial collections at pre-dose (trough-0 hr), 4, 8 and 12 hours. The immune response potential was evaluated by Interleukin-2 (IL-2) and Interferon gamma (IFN-γ) production by CD3+CD4+ T cells after ex-vivo treatment with PMA/Ionomycin with Brefeldin-A. Data was represented as within individual, timed collection and the mean for all time points of ex-vivo stimulation by cell sub-populations stratified by young, middle age and elderly. Comparisons were made using Kruskal-Wallis test.

Results: Table summarizes the major findings. There were no group differences between tacrolimus and mycophenolic acid troughs with all tacrolimus troughs within the therapeutic range. Increased IFN-γ from CD3+CD4+ T cells was quantitated by ex vivo immunoreactivity in middle age recipients at the 4 and 8 hours during the 12-hr study period. No significant differences were noted for interleukin-2 quantitated from CD3+CD4+.

Conclusions: These data indicate increased IFN-γ from CD3+CD4+ T cells for ex vivo immunoreactivity over a 12-hr dosing interval in middle age KTR receiving long-term maintenance immunosuppression. Variable immunodynamics and the implications of intra- and interpatient variability in immunoreactivity across the range of adult KTR require further investigation of clinical and allograft outcomes.

Urinary Proteomics and Effects of Dapagliflozin Treatment in Persons with Type 2 Diabetes and Kidney Disease

Tarunveer S. Ahluwalia,[1,2] Teemu K. Rönkkö,[1] Mie K. Eickhoff,[3] Harald Mischak,[3] Peter Rossing,[2] Frederik Persson.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Kobenhavns Universitet, Kobenhavn, Denmark; [3]Mosaiques Diagnostics Gmbh, Hanover, Germany.*

Background: About 40% of persons with type 1 (T1D) or type 2 diabetes (T2D) develop diabetic kidney disease (DKD) posing a major economic burden on health care systems. Sodium Glucose Co Transporter 2 inhibitors (SGLT2i) have emerged as a novel treatment option for T2D and DKD. Albeit the kidney-protective effects of SGTL2i are well documented, the mechanisms remain unclear. The current study aims to investigate SGTL2i function through urinary proteomics.

Methods: A double-blinded, randomized, placebo-controlled, crossover trial comprising 36 persons with T2D was treated with 10 mg of dapagliflozin for 12 weeks or matching portion of placebo on top of their standard diabetes treatment at the Steno Diabetes Center Copenhagen, Denmark. All participants had albuminuria (UACR ≥ 30 mg/g) and received RAAS medication. Clinical factors like BMI, blood pressure (BP), estimated glomerular filtration rate (eGFR), LDL and HDL cholesterol, were measured at baseline, and after trial. Changes in clinical factors were modelled using linear mixed effects model adjusting for relevant clinical covariates. Urinary proteomics data in pre and post treatment groups (n=32) were analyzed using paired Mann Whitney U test. Multiple testing correction was performed and $p < 0.05$ was considered significant. We further verified whether identified peptide levels differed significantly between T1D DKD vs. healthy controls (n=210) and performed pathway enrichment analysis with STRING database.

Results: Trial participants had a mean (SD) age of 63 (8) years, 88% males, diabetes duration 15.9 (4.7) years, BMI 33.7 (5.4) kg/m^2, HbA_{1c} 8.8 (1.2)%, median (IQR) UACR 154 (94–329), eGFR 85.5(19.1) ml/min/m^2, respectively. 19 proteins significantly changed after treatment. Type I and III collagen α (I), (II), and (III) chains, α-2-HS-glycoprotein, and polymeric immunoglobulin receptor peptides increased while albumin, α–1–antitrypsin, and α–1B–glycoprotein peptides decreased multifold. This was reflected in the DKD–control cohort.

Conclusions: We identified differential urinary peptide patterns in response to SGLT2i (Dapagliflozin) treatment on individuals with T2D and DKD. Extracellular matrix organization, inflammation, coagulation, renal fibrosis, and wound healing pathways were enriched. We suggest the involvement of expected and novel proteins.

PO2030

Antifibrotic Effects of Low-Dose SGLT-2 Inhibition in Comparison to Standard Angiotensin II Receptor Blockade in 5/6 Nephrectomised Rats on a High-Salt Diet

Shufei Zeng,[1,2] Denis Delic,[1,3] Yingquan Xiong,[1,4] Chang Chu,[1,2] Ting Luo,[2,8] Chen Xiao-Yi,[2,7] Mohamed M. Gaballa,[1,10] Yao Xue,[1] Xin Chen,[1,2] Yaochen Cao,[1,4] Ahmed A. Hasan,[1,5] Sandra Frankenreiter,[3] Lianghong Yin,[2] Bernhard K. Krämer,[1,6] Thomas Klein,[3] Berthold Hocher.[1,9] *[1]Universitatsklinikum Mannheim, Mannheim, Germany; [2]Jinan University First Affiliated Hospital, Guangzhou, China; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]Charite Universitatsmedizin Berlin, Berlin, Germany; [5]Universitat Potsdam, Potsdam, Germany; [6]Medical Faculty Mannheim of the University of Heidelberg, Mannheim, Germany; [7]Jiangmen Central Hospital, Jiangmen, China; [8]The Third Affiliated Hospital of Sun Yat-Sen University Lingnan Hospital, Guangzhou, China; [9]Hunan Normal University, Changsha, China; [10]Benha University, Benha, Egypt.*

Background: The lowest protective SGLT2 inhibitor dose is not well established.

Methods: We performed a dose-response pilot study. Based on the results of this study we compared the cardio-renal effects of the SGLT-2 inhibitor empagliflozin with placebo or telmisartan in rats with 5/6 nephrectomy (5/6 Nx) on a high salt diet (HSD), as follows: Sham operation (Sham) with normal diet and placebo; 5/6 Nx with 2% HSD and placebo; 5/6 Nx with HSD and empagliflozin (0.6 mg/kg/day, bid); 5/6 Nx with HSD and telmisartan (5 mg/kg/day, qd).

Results: Empagliflozin treatment increased urinary glucose excretion in parallel to empagliflozin plasma levels in a dose-dependent manner starting at doses of 1 mg/kg. 5/6Nx rats on HSD treated with this low empagliflozin dose showed significantly reduced cardiac (-34.85%; $p<0.05$) and renal (-33.68%; $p<0.05$) fibrosis in comparison to 5/6Nx rats on HSD treated with placebo. These effects were comparable to the effects of a standard dose (5mg/kg/day) of telmisartan (cardiac fibrosis: -36.37%; $p<0.01$; renal fibrosis; -43.96%; $p<0.01$). RNA-sequencing followed by confirmatory qRT-PCR revealed that both telmisartan and empagliflozin exert their cardiac effects on genes involved in vascular cell stability and cardiac iron homeostasis, whereas in the kidneys expression of genes involved in endothelial function and oxidative stress were differentially expressed. Urinary adenosine excretion, a surrogate marker of the tubuloglomerular feedback (TGF) mechanism, was not affected.

Conclusions: The antifibrotic properties of low dose empagliflozin were comparable to a standard dose of telmisartan. The underlying pathways seem to be TGF independent.

HIF Prolyl-4-Hydroxylase Inhibitor AKBX27922 Induces Cellular Metabolic Adaptation

Gyongyi Molnar, Zhihai Si, Sanjay Danthi, Vilmos Csizmadia, Jane Liu, Senkara Rao Allu, Michael Rabinowitz, Anna Zuk. *Akebia Therapeutics Inc, Cambridge, MA.*

Background: Inhibition of prolyl-4-hydroxylase (PHD) enzymes leads to the stabilization of hypoxia inducible factor (HIF) and the expression of HIF target genes. Because of effects on erythropoiesis, several PHD inhibitors are undergoing clinical evaluation for the treatment of anemia with chronic kidney disease. However, the impact on other biological functions is not well investigated. We demonstrate that AKBX27922, a novel small molecule PHD inhibitor, can shift cellular metabolism from mitochondrial oxidative phosphorylation to glycolysis, mimicking adaptation to hypoxia.

Methods: Inhibition of PHD enzymatic activity was determined using the time-resolved fluorescence resonance energy transfer assay. HIF1a stabilization in Hep3B cells was measured by meso scale discovery technology and protein expression of HIF target genes by enzyme linked immunosorbent assay. Oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) were measured in HepG2 cells with the Seahorse technology. Pharmacodynamics of HIF stabilization were confirmed in vivo.

Results: In vitro, AKBX27922 potently and in a concentration-dependent manner, and without chelating iron, inhibited PHD1 and PHD2 enzyme activity, leading to HIF1a stabilization and expression of HIF target genes implicated in erythropoiesis, angiogenesis, glycolysis, and cell survival. Pretreatment of HepG2 cells with AKBX27922 dose-dependently reduced both basal and maximal OCR without affecting cellular viability, while ECAR was significantly increased. Reactive oxygen species production in human primary renal epithelial cells was decreased. In vivo, AKBX27922 stabilized HIF in the liver and kidneys, as measured by luciferase activity in the oxygen-dependent degradation domain (ODD)-luciferase reporter mouse. In rats, AKBX27922 induced time-dependent stabilization of HIF1a in the kidney medulla and papilla, and increased expression of glycolysis related (ALDOC, CAR9, PDK1, PFKFB4, LDH) and other HIF-target genes (EPO, ADM, HMOX-1) in the kidneys and liver.

Conclusions: PHD inhibitor AKBX27922 mimics hypoxia, leading to HIF-driven metabolic adaptation. This novel small molecule will be useful as an in vitro and in vivo research tool for additional mechanistic studies that probe the pleotropic biology of HIF.

Comparative Kidney-on-Chip Toxicity Assessment in Human, Rat, and Dog Kidney Tissue Chips

Sepand Bafti, John R. Williford, Laura V. Balbiani. *Nortis, Inc., Seattle, WA.*

Background: The proposed project comprises of the development of a kidney proximal tubule (KPT) microphysiological system (MPS) from human cells as well as two experimental animal species that are typically used in kidney toxicity screening: rat and dog. These KPT-MPS can serve as an important new tool in chemical toxicity screening, allowing cross-referencing animal-based MPS data within vivoanimal data and with human-based MPS data and clinical outcomes. It also has the potential to result in a significant reduction of the use of live animals in studies.

Methods: The Nortis chip is made from silicone in a polycarbonate casing and is designed to use the "mandrel" method for generating channels within a 3D extracellular matrix using retractable small glass fibers. The channels serve as starting points for generating tubular tissue structures, such as vessels or kidney tubules. The chip is compatible with high-quality imaging, tissue sampling, and up- and down-stream fluid collection. Multiple publications have documented the suitability of the Nortis system to generate functional human KPTs and how well they resemble the function of *in vivo* tubules. All 3D MPS experiments are accompanied by 2D controls for comparison, using a traditional culture dish system. To assess viability of tissue, Live-Dead staining assays were run on canine tubules with Calcein-AM (live) and the nucleic acid stain ethidium homodimer I (dead), the results of which indicated sufficiently viable tubules. Confocal imaging and 3D rendering of these tubules demonstrates presence of key ion and drug transport proteins in their respective basolateral and lumenal domains.

Results: Preliminary studies have shown that rat and canine derived KPT-MPS in the Nortis platform produce structurally viable tissue structures that elicit injury markers in response to nephrotoxic insults using in vivo relevant toxic compounds in a differential manner.

Conclusions: Our preliminary data suggests that Nortis kidney chip allows for an ideal predicitive platfrom for comparative toxicity studies, allowing for fast and highly predictive preclinical simulations.

PO2033

Forced Saline Diuresis Successfully Treats Lithium Intoxication

Sabiha M. Khan, Spencer Hodgins, Daniel L. Landry, Jeffrey Mulhern, Gregory L. Braden. Kidney Care & Transplant Services of New England *UMASS/Baystate, Springfield, MA*.

Background: Forced 0.9% normal saline (NS) diuresis (FSD) is not advised by poison control centers for lithium intoxication (LI) but 2 papers in '71 & '78 showed 350 - 500 ml/hr of FSD treated LI at 4mEq/L successfully. We studied all pts with LI over 10 years with both acute (A) overdoses and chronic(C) LI to compare FSD in both groups to pts requiring hemodialysis (HD).

Methods: We found 20 LI pts seen over 10 years. Our team uses NS at 200-500 ml/hr as FSD in pts w/o CHF. 9 pts had Acute overdoses of L & 5 had C LI due to reduced gfr, ACE drugs or NSAIDS. These 14 got FSD, 200-500 ml/hr until L was < 1 mEq/L. 6 pts needed HD due to severe toxicity (seizures, coma, hypotension). We compared & show the mean +SEM values for peak L level mEq/L, GFR calculated by the Cockcroft-Gault equation, the rate of L decrease in mEq/hr, the normalized rate of L decrease in mEq/24 hr & time in hrs to reach a L level of 1.0 mEq/L amongst the 3 groups.

Results: The mean peak L levels were: FSD A LI, 2.8+0.2 (range, 2.3-4), FSD C LI, 2.8+0.4 (range, 2-4.2), HD LI 3.5+ 0.4 (range, 1.8-4.9). There were no differences in L levels. The mean GFR was: FSD ALI, 127+11, FSD C LI, 66+17, HD LI 142+7, p< .05 FSD C LI vs FSD ALI or HD LI. The GFR was significantly lower in the C LI pts. The hourly rate of L decrease in mEq/hr was: FSD A LI, 0.13+.03, FSD C LI, 0.05+.01, HD LI, 0.22+.04. There was no difference in the rate of L decrease in FSD A LI v HD LI but both were much faster than FSD C LI, p<.05. The mean 24 hour decrease (mEq/L) in L was: FSD A LI, 3.1+2.2, FSD C LI, 1.1+ 0.2, & HD LI, 5.3+ 1.6. p<.05 FSD C LI vs FSD A LI or HD LI. The time to L level of 1 mEq/L was: FSD A LI, 14.4+1.3 h, FSD C LI, 36+4.3 h, HD LI, 11.5+2.3 h due to rebound after HD. There was no difference in the time to normal L between FSD A LI & HD & both were much faster than FSD C LI. Linear regression of the rate of L decrease compared to the hourly rate of NS in FSD A LI pts showed greater decreases in L level with greater rates of FSD, r =.82, p=,.006. No pt had a serum Na > 145 mEq/L.

Conclusions: FSD with NS at rates of 200-500 ml successfully treats A LI and rates of L reduction approximate those of HD for LI. C LI can be treated with FSD but the rates of L decrease are slower possibly due to lower GFRs in these pts. This is the first study in 40 years showing efficacy of FSD in LI.

Snow White and the Apple: When Drugs Become Poisons

Irfan Agha,[1,2] Naseer Khan,[1,2] Gregory W. Proctor,[1,2] Paul L. Cespedes,[1,2] Rama Nadella.[1,2] *[1]Medical City Dallas Hospital, Dallas, TX; [2]Dallas Renal Group, Dallas, TX*.

Introduction: Commonly used drugs can cause significant toxicity in unfavorable clinical scenarios. We present a case of a pregnant female on a high dose of baclofen which led to significant neurotoxicity as her GFR dropped during an episode of acute pancreatitis

Case Description: A 29-year-old pregnant Caucasian Female presented to an OSH with abdominal pain of a day's duration. She was obese and had DM-II, hypertension as well as H/O a brain tumor treated when she was 10 years old. She was 29 weeks pregnant. Abdominal pain was sharp, epigastric and radiating to her back with nausea and vomiting. She was found to have severe acute pancreatitis. Her kidney function was normal (creatinine 0.5 mg/dl) on admission but on hospital day 2 it rose to 1.5 mg/dl and was at 2.3 mg/dl the next day. On hospital day #2 she became obtunded without response to naloxone and flumazenil. She was transferred to our hospital. She was comatose with minimal movement on sternal rub. Her neck was supple without obvious cranial nerve lesions. MRI of the brain revealed prior (L) frontal craniotomy, post-surgical gliosis and encephalomalacia, stigmata of her brain surgery. EEG suggested encephalopathy but no active seizures. A review of medicines at OSH revealed baclofen 20 mg TID scheduled for neck muscle spasms. Neurotoxicity due to baclofen was suspected and urgent CVVH was instituted. By 12 hours, she started improving and by 48 hours, recovered completely. Her AKI as well as pancreatitis resolved. She eventually delivered a healthy baby girl. Mother and baby were discharged in stable condition. Baclofen level drawn prior to initiation of therapy was reported at 862 ng/ml.

Discussion: This is a unique case of baclofen neurotoxicity in a pregnant female. She was prescribed a relatively high dose of baclofen which she was taking sporadically. On admission, she was placed on this standing dose and at the same time lost GFR due to acute pancreatitis. This precipitated neurotoxicity. She was urgently dialyzed, and the patient and baby were spared neurotoxic sequelae. Prolonged dialysis may be required to remove baclofen and treat neurotoxic manifestations. This was all the more important in the case due to risk of fetal neurotoxicity It was a careful review of records of medicines dispensed at the OSH that helped clinch the diagnosis clinically, subsequently confirmed with elevated baclofen levels demonstrated on a send out test.

PO2035

Efficacy of Pi-Binder Lanthanum Carbonate in Reversing Systemic Effects of a High-Phosphate Diet in Mice

Uma D. Alappan,[1] Manjula Viggeswarapu,[2] Jamie Arnst,[1] George R. Beck.[1,2] *[1]Emory University, Atlanta, GA; [2]VA Medical Center Atlanta, Decatur, GA*.

Background: Modulating dietary inorganic phosphorus (Pi) is particularly important for patients suffering from chronic kidney disease (CKD) as excess Pi consumption and subsequent elevated serum Pi levels can lead to significant health problems, including increased mortality. Recent data now suggests that high Pi consumption might also have negative health consequences even in those with clinically normal renal function. The predominant clinical therapy to reduce serum Pi and related health complications of CKD patients is orally administered Pi-binders with meals, including the commonly used Lanthanum Carbonate (LaC). Our study assessed the strategy of binding Pi in the gut to reduce health consequences of a high Pi diet including changes in bone volume, Pi-responsive circulating factors, and gene expression in the kidney.

Methods: Healthy 10-Week-old, female C57BL/6J mice were fed diets with varying Pi for 5 weeks: Low Pi (LPD, 0.2% Pi), Normal Pi (NPD, 0.6% Pi), High Pi (HPD, 1.8% Pi), and HPD supplemented with LaC (3%). All diets contained 0.6% Calcium, similar protein, Kcals, and fat%. Circulating Pi-responsive factors (FGF23, OPN) were measured by ELISA, bone volume by micro-computed tomography, and gene expression in the kidney by quantitative real-time (qRT) PCR.

Results: HPD resulted in increased serum FGF23 and OPN, decreased bone volume (trabecular, cortical), and significant changes in kidney gene expression of inflammatory protein Lcn2, Pi responsive Klotho, vitamin D synthesis Cyp27b1, and Pi-transporter Slc34a2. LaC completely reversed the HPD-induced increase in serum FGF23, partially reversed gene expression changes in the kidney but did not alter HPD-induced bone loss.

Conclusions: The clinically used Pi-binder LaC only reversed certain HPD-induced consequences, suggesting a multifactorial mechanism, and therefore may require a therapeutic strategy beyond reducing gut Pi-absorption. Decreasing Pi consumption was substantially more effective at minimizing physiological repercussions like bone loss. Changes in kidney gene expression after a sustained HPD also reveal potential long-term consequences on kidney health/function in otherwise healthy individuals. Given divergent claims concerning LaC binder efficacy, our study shows LaC corrects some—but not all—effects of a high Pi diet.

A Meta-Analysis Evaluating the Effect of Sacubitril-Valsartan on Renal Function in Heart Failure Patients

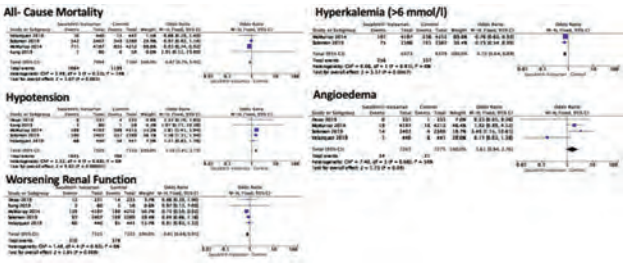
Karthik Seetharam, Jilan Shah, Vamsi Yenugadhati, Kelash Kumar, Maxine Orris, Prabhu Hejmadi, Tanveer Mir, Deepak Asti, Preety Chawla, Gopi Punukollu, Carlos M. Zapata, Luis Mercado, Pervez Mir, Priyank Patel, Utpal Bhatt, Bhavani D. Mahankali, Premila Bhat. *Wyckoff Heights Medical Center, Brooklyn, NY*.

Background: Cardiorenal syndrome (CRS) has been associated with increased morbidity and mortality in heart failure (HF). Sacubitril-Valsartan is the first- in-class angiotensin receptor- neprilysin inhibitor which has been found to reduce all-cause mortality in HF with reduced left ventricular ejection fraction. The effect of sacubitril-valsartan on renal outcomes is unknown. This meta-analysis analyzes recent studies comparing renal outcomes between sacubitril-valsartan and RAS inhibitors in heart failure patients.

Methods: We performed a comprehensive literature search for all eligible studies comparing Sacubitril-Valsartan and RAS inhibitors in Pubmed, EMBASE, SCOPUS, and google scholar. Only recent clinical trials were included. All retrospective studies were excluded. Clinical outcomes comprised of all-causes mortality and renal complications.

Results: 5 Randomized clinical trials (RCT) were deemed eligible, which consisted of 7325 sacubitril- valsartan patients and 7333 RAS inhibitor patients. Meta-analysis confirmed that Sacubitril-valsartan was associated with reduced all-cause mortality (OR= 0.87, p = .002). A lower risk of worsening renal function, defined as increase in ≥ 0.3 mg/dl in serum creatinine compared with the value on admission (OR = .81, p = 0.008), was seen in the sacubitril-valsartan group. Hyperkalemia, defined as potassium greater than 6 mil/L was lower in the sacubitril-valsartan group (OR= 0.75, p = 0.0007) in comparison to RAS inhibitors. However, sacubitril-valsartan had a higher risk of symptomatic hypotension (OR = 156, p < 0.00001). There was no observed statistically significant differences in angioedema.

Conclusions: Sacubitril-Valsartan reduces the risk of all- cause mortality, diminished renal function, and hyperkalemia compared with RAS inhibitors. Further evaluation is required.



PO2037

Combination Therapy of Neprilysin Inhibitor with AT2R Agonist C21 Provides Superior Renoprotection Compared to its Combination with AT1R Antagonist Valsartan in High-Sodium Diet-Fed Obese Zucker Rats

Elizabeth A. Gray, Sanket N. Patel, Tahir Hussain. *University of Houston, Houston, TX*.

Background: The neprilysin (NEP) inhibitor sacubitril (SAC) combined with the angiotensin II type 1 receptor (AT1R) blocker valsartan (VAL) (i.e. Entresto) is clinically approved for the treatment of heart failure (HF) associated with reduced ejection fraction, owing mainly to its ability to preserve atrial natriuretic peptide (ANP), a substrate of NEP. However, many HF patients treated with Entresto have presented with increased albuminuria. We have reported that the agonist of angiotensin II type 2 receptor (AT2R) Compound 21 (C21) prevents proteinuria and is reno-protective in obese Zucker rats (OZR) fed high sodium diet (HSD). Thus, we hypothesized that SAC/C21 combination provides superior reno-protection compared to the current SAC/VAL therapy.

Methods: Male OZR 10-11 wks. old were treated daily via oral gavage with vehicle, SAC (10mg/kg/day) + C21 (1mg/kg/day), or SAC (10mg/kg/day) + VAL (10mg/kg/day) while fed HSD (4%) for 16 days.

Results: Untreated HSD-fed OZR showed reduced plasma ANP and increases in renal cortical Ang II (all $p<0.05$ vs OZR-fed 0.4% normal sodium diet (NSD)). These changes were associated with a modest increase in kidney weight and kidney dysfunction, evident by increased proteinuria, and reduced urinary excretion of urea nitrogen and creatinine (all $p<0.05$ vs OZR-fed NSD). Other indices of renal injury include increased cortical expression of nephrin ($p<0.05$ vs OZR-fed NSD), podocin, megalin, albuminuria, and increased urinary osteopontin (OPN). Treatment with SAC/C21 significantly prevented increases in renal Ang II, proteinuria, albuminuria, nephrin expression and kidney weight (all $p<0.05$ vs OZR-fed HSD), while SAC/VAL did not affect these parameters. Furthermore, SAC/C21 prevented the decline in the excretion of urinary creatinine and decreased urinary OPN (all $p<0.05$ vs SAC/VAL). Moreover, SAC/VAL therapy increased plasma renin concentrations ~3-fold compared to OZR-fed HSD and SAC/C21.

Conclusions: Together, this study suggests that combination therapy with SAC/C21 afforded superior reno-protection compared to SAC/VAL therapy in HSD-fed OZR.

Is Basal Nitric Oxide Activity of the Renal Vasculature Altered? Analysis of a Randomized Controlled Trial Comparing Two Combination Therapies

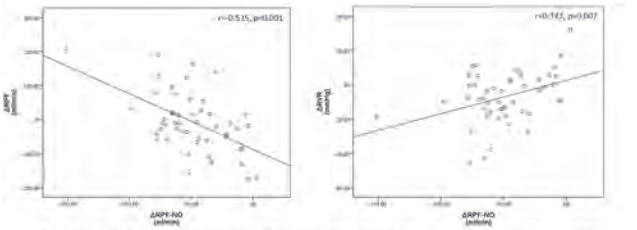
Dennis Kannenkeril, Christian Ott, Agnes Bosch, Kristina Striepe, Robert Pietschner, Mario Schiffer, Roland E. Schmieder. *Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany*.

Background: Recently we demonstrated that a combination therapy with empagliflozin and linagliptin in patients with type 2 diabetes mellitus(T2DM) induce changes in renal hemodynamics. The purpose of this study was to analyze the influence of basal nitric oxide(NO) activity of the renal vasculature on the described changes of the renal hemodynamic profile.

Methods: In this study patients with T2DM were randomized to receive either empagliflozin and linagliptin(E+L group, n=50) or metformin and insulin glargine(M+I group, n=46), for 3 months. Renal hemodynamics were assessed with constant-infusion input-clearance technique with p-aminohippuric acid and inulin at baseline and after treatment. Due to withdrawal of inulin from the market during the study, glomerular filtration rate and filtration fraction(FF) were measured only in a sub-group of patients(E+L: n=34; M+I: n=31). Intraglomerular hemodynamics were calculated according the model established by Gomez. The basal NO activity in the renal circulation has been assessed by analyzing change in renal plasma flow(RPF) in response to intravenously administrated NG-monomethyl-l-arginine(NO inhibitor).

Results: After 3 months of treatment, we did not observe any change in basal NO activity compared to baseline in either of the groups. In the E+L group, we found a correlation between basal NO activity of the renal vasculature after 3 months of treatment and change in RPF($r=-0.535$, $p<0.001$), renal blood flow($r=-0.468$, $p=0.001$) and renal vascular resistance($r=0.377$, $p=0.007$) induced by treatment. Similar correlations with change in FF($r=0.639$, $p<0.001$), preglomerular($r=0.350$, $p=0.046$) and postglomerular resistance($r=0.588$, $p<0.001$) have been found. No such relationships were found in the M+I group after 3 months and with basal NO activity at baseline in both treatment groups.

Conclusions: Basal NO emerged as a determinant of the renal hemodynamic response in the combination therapy of empagliflozin and linagliptin, but not in the combination therapy of insulin and metformin.



E+L group: ΔRPF- change in renal plasma flow with treatment, ΔRVR- change in renal vascular resistance with treatment, ΔRPF-NO- change in renal plasma flow in response to infusion of NG-monomethyl-l-arginine (nitric oxide inhibitor) with treatment

PO2039

Urinary Cell mRNA Profile Diagnosis of Borderline T Cell-Mediated Rejection in Kidney Allografts

Thalia Salinas, Carol Y. Li, Catherine Snopkowski, Kevin Chen, Shady Y. Albakry, Steven Salvatore, Surya V. Seshan, John R. Lee, Thangamani Muthukumar, Darshana M. Dadhania, Manikkam Suthanthiran. *Weill Cornell Medicine, New York, NY*.

Background: Borderline rejection (BR) is associated with inferior outcomes. In CTOT-04, we discovered and validated a urinary-cell signature of CD3ε mRNA, IP-10 mRNA and 18s rRNA diagnostic of TCMR (Suthanthiran et al. *N Engl J Med*,2013). We investigated whether this signature is diagnostic of BR.

Methods: Urinary cell mRNAs measured in 377 biopsy-matched urine samples from 300 kidney transplant recipients. Interstitial inflammation (i) and tubulitis (t) scored by Banff criteria. Diagnosis of BR=i1,t1, i2,t1, or i1,t2 and TCMR= i≥2,t≥2 (Loupy et al.*Am J Transplant*,2020). Exclusion criteria: inadequate biopsy;BKVN;+BKVN by urinary BKV-VP1 mRNA level(Dadhania et al.*Transplantation*,2010), i1 or t1 alone. RNA isolated from urinary cell pellet, absolute transcript levels measured by customized RT-qPCR and CTOT-04 signature computed.

Results: 293 biopsies included (Table 1). CTOT-04 signature distinguished i0,t0 biopsies from BR and TCMR($p<0.0001$,ANOVA)(Fig.1A).18S normalized CD3ε and IP-10 mRNAs elevated in BR and TCMR urine(Fig.1D-E). Accurate diagnosis of BR and TCMR shown(Table 2A-B).

Conclusions: Urinary-cell CTOT-04 signature discriminates i0,t0 from BR or TCMR biopsies. Our findings may help reduce biopsies performed to diagnose BR or TCMR and prognosticate graft outcome.

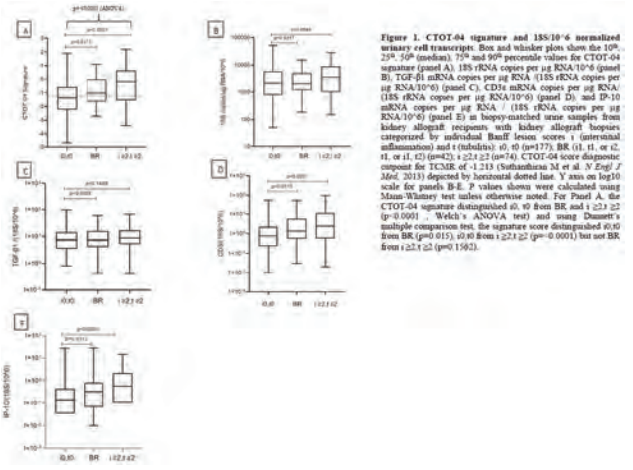

Figure 1. CTOT-04 signature and 18S/10^6 normalized urinary cell transcripts. Box and whisker plots show the 10th, 25th, 50th (median), 75th and 90th percentile values for CTOT-04 signature (panel A), 18S rRNA copies per µg RNA/10^6 (panel B), TGF-β1 mRNA copies per µg RNA (18S rRNA copies per µg RNA/10^6) (panel C), CD3ε mRNA copies per µg RNA/ (18S rRNA copies per µg RNA/10^6) (panel D), and IP-10 mRNA copies per µg RNA / (18S rRNA copies per µg RNA/10^6) (panel E) in biopsy-matched urine samples from kidney allograft recipients with kidney allograft biopsies categorized by individual Banff lesion scores i (interstitial inflammation) and t (tubulitis): i0, t0 (n=177); BR (i1, t1, or i2, t1, or i1, t2) (n=42); i ≥2,t ≥2 (n=74). CTOT-04 score diagnostic cutpoint for TCMR of -1.213 (Suthanthiran M et al. *N Engl J Med*, 2013) depicted by horizontal dotted line. Y axes on log10 scale for panels B-E. *P* values shown were calculated using Mann-Whitney test unless otherwise noted. For Panel A, the CTOT-04 signature distinguished i0, t0 from BR and i ≥2,t ≥2 (p<0.0001 , Welch's ANOVA test) and using Dunnett's multiple comparison test, the signature score distinguished i0,t0 from BR (p=0.015), i0,t0 from i ≥2,t ≥2 (p=<0.0001) but not BR from i ≥2,t ≥2 (p=0.1502).

PO2040

Preserved Kidney Allograft Function and Unique Urinary Biomarker Profiles in Living Donor Kidney Transplant (LDKT) Patients Tolerized with an Investigational Allo-Hematopoietic Stem Cell Transplantation Therapy

Joseph Leventhal,[1] John P. Galvin,[1] Michael G. Ison,[1] John R. Lee,[2] James M. Mathew,[1] Lorenzo G. Gallon,[1] Meg Gibson,[1] Dianne S. Belshe,[1] David Tollerud,[3] Manikkam Suthanthiran,[2] Suzanne Ildstad.[3] *[1]Northwestern University, Evanston, IL; [2]Weill Cornell Medicine, New York, NY; [3]Talaris Therapeutics, Louisville, KY.*

Background: We previously reported that 37 patients were transplanted in an open-label, single-arm phase 2 protocol to induce immune tolerance in LDKT recipients.

Methods: The protocol was based upon tolerogenic CD8+/TCR- facilitating cells (FCR001), nonmyeloablative conditioning and enrollment agnostic to the degree of HLA mismatch. Tacrolimus/MMF based immunosuppression (IS) was weaned and discontinued at one year if durable chimerism and normal kidney function and transplant biopsy were confirmed.

Results: Durable chimerism enabled complete withdrawal of IS in 26/37 patients. Comparison of clinical outcomes in FCR001 and a SOC cohort showed comparable patient survival and graft survival at two, three and five years. Cardiovascular medication usage was more frequent in SOC than in tolerant FCR001 subjects for hypertension (83% vs 18%) and hyperlipidemia (43% vs 9%). Graft function (eGFR) was better and more stable for the FCR001 cohort compared to SOC, with the difference due to patients with durable chimerism and off IS. Urinary cell mRNA profiling of a subgroup of FCR001 patients identified a potential signature of tolerance, characterized by increased levels of CTLA4 mRNA, and a higher ratio of CTLA4 mRNA to mRNA for granzyme B and perforin mRNA. If validated, such a signature of tolerance might help identify kidney transplant patients in whom reduction of IS drugs might be safely undertaken. To date, we have accumulated approximately 235 patient-years of exposure to FCR001 in LDKT, and the safety profile is consistent with that expected if a patient were to receive both a kidney transplant and an allo-HSCT with nonmyeloablative conditioning.

Conclusions: We continue to monitor the patients in the Phase 2 trial for long-term safety and durability of immune tolerance and graft function. We are currently enrolling patients in FREEDOM-1, a randomized, controlled, open-label Phase 3 trial in the US in adult LDKT recipients.

Urinary T Cell Subsets and Tubular Epithelial Cells as Biomarkers for Kidney Transplant Rejection

Emil Grothgar,[1,2] Nina Goerlich,[1,2] Bjoern Samans,[4] Jan Klocke,[1,2] Christopher Skopnik,[1,2] Michael Duerr,[1] Mareen Matz,[3] Sven S. Olek,[4] Alexander Paliege,[5] Philipp Enghard.[1,2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany; [3]Berlin Institute of Health, Berlin, Germany; [4]Precision for Medicine GmbH, Berlin, Germany; [5]Universitatsklinikum Carl Gustav Carus, Dresden, Germany.*

Background: Early detection of kidney transplant (KT) rejection remains a challenge in patient care. Previously we developed a biomarker combination to detect rejection by analyzing urine cells using Flow cytometry (FC). The aim of this study was to confirm our previous findings and develop further markers to detect KT rejection.

Methods: Urine samples of 275 KT patients were analyzed. Cell population were quantified in 150 and 125 cases by epigenetic analyses and FC, respectively. Professional diagnoses from renal biopsies served to uniquely group graft deterioration into borderline rejection (BR), T cell mediated rejection (TCMR), and antibody mediated rejection (ABMR), other specific pathohistological diagnosis (other) or no rejection (No RX). For FC analyses urine sediments were stained for T cells (anti-CD3, -CD4, -CD8, -CD45RO, -CD45, -CCR7, -HLA-DR, -CD28) and tubular epithelial cells (TECs) (anti-Cytokeratin, -Vimentin, -CD10, -CD13, -CD227, -CD326). Epigenetic qPCR approach was used to determine T cells und TECs based on specific DNA methylation patterns identified by bisulfite sequencing.

Results: Absolute numbers of urinary T cells and TECs discriminated patients with and without TCMR. Most strikingly in this regard were increased numbers of various T cell subsets observed by FC in patients with TCMR compared to patients without TCMR ($p<0.001$ for HLA-DR+ T cells and effector memory T cells) whereby CD8+ HLA-DR+ T cells were most distinctive ($p = 5.1e-07$, AUC = 0.866-0.967). Epigenetic analyses qualitatively confirmed T cell and TEC quantities as determined by FC. Furthermore, the ratio of absolute numbers of T cells and TECs determined by epigenetic analyses discriminated patients with TCMR from those with other specific biopsy proven diagnoses than rejection, but individual T cell populations showed a higher sensitivity and specificity in segregating both groups (TCMR vs other: CD8+ T cells p=5.1e-05, AUC 0.87 (CI 95% 0.77-0.98), CD3+ T cells/TEC p=0.004, AUC 0.78 (CI 95% 0.65-0.92); ABMR vs other: CD8+ T cells p=0.0041, CD3+ T cells/TEC p=0.04).

Conclusions: Urinary T cell subsets reflect intrarenal inflammation in TCMR. TECs mirror intrarenal damage accompanied by rejection. Jointly, they yield high potential to monitor KT patients and detect rejection.

PO2042

Elevation of Serum IL-8 in Patients with Hematopoietic Stem Cell Transplantation-Associated Thrombotic Microangiopathy

Vivek Kasinath, Fazilet Yilmaz, Hamza Aksu, David R. Walt, Reza Abdi. *Brigham and Women's Hospital, Boston, MA.*

Background: Hematopoietic stem cell transplantation (HSCT) is a potentially curative treatment for several different hematopoietic malignancies and disorders. However, HSCT-associated thrombotic microangiopathy (TA-TMA) represents a major obstacle to the success of this procedure in transplant recipients, and rapid progression to end-stage renal disease is a major complication of this disorder, affecting nearly 1 in 3 patients. Here, we sought to Identify a serum biomarker for the detection of TA-TMA and investigate its role in the pathogenesis of this severe disease.

Methods: We measured the concentrations of several different cytokines and vasoactive peptides in the sera of 14 adult human HSCT recipients at the time of transplantation and again at 5-6 weeks following HSCT. Levels of IL-1β, IL-6, IL-8, TNF-α, IFN-γ, VEGF-B, HIF1α, and GM-CSF were measured, using the highly sensitive ELISA single molecule array (Simoa) method.

Results: Statistical analysis of the change in each of the cytokines revealed that IL-8 was the sole marker that increased significantly over time in the TMA group. Next, we found that co-culture of irradiated peripheral blood mononuclear cells (PBMCs) with human umbilical vein endothelial cells (HUVECs) resulted in increased IL-8 expression by the PBMCs. Furthermore, *in vitro* treatment of HUVECs with IL-8 increased platelet adhesion and vWF expression. Treatment of platelets independently with IL-8 also increased their adhesion *in vitro* to HUVECs. Finally, treatment of HUVECs with IL-8 also induced senescence, and platelets were found to adhere more readily to senescent HUVECs *in vitro*. Moreover, exposure of these HUVECs to a senolytic agent abrogated the platelet adhesion.

Conclusions: These findings implicate IL-8 as a potentially important thrombogenic and pathogenic factor in TA-TMA. In addition, these data highlight senescence of endothelial cells for the first time as a possible mechanism for the microvascular thromboses observed in TA-TMA patients, suggesting that modulation of IL-8 could be an effective therapeutic pathway for this severe disease.

PO2043

Three Distinct Phases in the Amount of Total and Donor-Derived Cell-Free DNA Are Observed over Time in Plasma from Kidney Transplant Recipients

Paul Van Hummelen, Soong Lee, Ebad Ahmed, Philippe Gauthier, Hossein Tabriziani, Bernhard Zimmermann, Paul R. Billings, Ryan Swenerton. *Natera, Inc., San Carlos, CA.*

Background: Donor-derived cell-free DNA (dd-cfDNA) is a clinically validated biomarker for allograft rejection in kidney transplant (KT) recipients. Fluctuations in the total amount of cfDNA (including donor and recipient-derived cfDNA) can impact the reported dd-cfDNA fraction. Here we analyzed the changes in total and dd-cfDNA quantity, over time, in KT patients.

Methods: We selected 3,925 samples from 747 clinically stable patients with >3 longitudinal samples. The median time from KT to sample collection was 134 days (range: 1 day - 37 years). Total cfDNA and dd-cfDNA were measured using the Prospera™ test and expressed as relative units per ml plasma (RU/ml). Dynamic changes in dd-cfDNA and total cfDNA over time were compared to their respective medians for all samples at 3-year post-KT, defined as reference.

Results: One week following KT, median quantities of total cfDNA were elevated ~2-fold above the reference value (494 RU/ml), which normalized over the first month. At month 3, a 1.6-fold increase was observed, which normalized to the reference value over the first year post-KT. In contrast, the absolute quantity of dd-cfDNA was initially elevated ~100-fold above the reference (1.06 RU/ml) post-KT, which normalized over the first month to the reference level where it remained stable. The elevation in dd-cfDNA during the first week is likely due to trauma to the donor organ from surgery. Additionally, a significant elevation in both total and dd-cfDNA was observed in patients who received a kidney from a deceased donor as compared to a living donor.

Conclusions: Total and dd-cfDNA levels were highly dynamic in the first year post-KT but stabilized afterwards. Further investigation is needed to determine the causes of total-cfDNA increases at months 3 and 4. Potential factors include inflammatory responses and NETosis, viral infection or transient interstitial fibrosis and tubular atrophy (IF/TA) in the donor organ. The time dependent dynamics were statistically significant, but with a high coefficient of variance (CV>50%), which limits extrapolations to individual patients. Potential variability should be considered when interpreting dd-cfDNA tests performed within the first week post-KT.

PO2044

A Peripheral Blood Transcriptomic Signature Predicts the Progression of Chronic Kidney Damage Post Transplant

Weijia Zhang,[1] Zhengzi Yi,[1] Chengguo Wei,[1] Caixia Xi,[1] Weiqing Huang,[1] Zeguo Sun,[1] Samira S. Farouk,[1] Paolo Cravedi,[1] Madhav C. Menon,[2] Robert B. Colvin,[3] Philip J. O'Connell,[4] Barbara T. Murphy.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University, New Haven, CT; [3]Massachusetts General Hospital, Boston, MA; [4]Westmead Institute for Medical Research, Westmead, NSW, Australia*.

Background: Chronic kidney damage post-transplant is a major risk of allograft loss. The aim of this study was to identify a transcriptomic signature from peripheral blood collected at 3 months post-transplant to predict the progression of chronic kidney damage after transplant.

Methods: We inspected kidney functional and histologic changes from the baseline (pre-implantation) to 1 year post-transplant in 112 kidney transplant recipients from the prospective Genomics of Chronic Allograft Rejection (GoCAR) study and identified the patients who developed chronic kidney damage within 1 year (progressors). We then carried out RNA sequencing on the whole blood collected from these patients at 3 months post-transplant to identify a transcriptomic signature predictive of the progression of chronic kidney damage in the training set and validated by the testing set.

Results: Among 112 patients, we identified 30 progressors who developed kidney damage within 1 year post-transplant with a Chronic Allograft Damage Index (CADI) score increase by ≥ 2, and 55 non-progressors with a normal histology at both the baseline (CADI<2) and 12 months (CADI<=2) post transplant. The remaining 27 patients had a histological lesion at the baseline with a high CADI >=2 but no progression at 12 months. From the progressors and non-progressors (total n=85), we randomly selected 55 patients as a training set and the remaining 30 patients as a testing set. From the training set, we identified a 9-gene set that predicts kidney damage at 12 months with AUC=0.88 and validated the prediction model in the testing set with AUC=0.79, superior to the Kidney Donor Risk Index (KDRI) in the deceased-donor population. The 9-gene set performed moderately in the patients who received a kidney with an intermediate or severe pathological lesion (n=27, AUC=0.68).

Conclusions: We presented a useful blood transcriptomic signature to accurately risk-stratify the progression of chronic kidney damage post-transplant, especially for those patients who received a healthy kidney.

PO2045

Kidney Precooling Improves Renal Outcome After Transplantation due to Preserved Mitochondrial Function

Lei Wang. *University of South Florida, Tampa, FL*.

Background: Transplanted organs experience several episodes of ischemia and Ischemia-reperfusion. Ischemia-reperfusion injury (IRI) has remained one of the most serious hurdles for the survival of transplanted grafts. Temperature plays an important role in cellular metabolic rates since biochemical reactions are highly temperature dependent. Therefore, ischemia-triggered degradative reactions could be mitigated by lowering tissue temperature. Whether a local hypothermia on kidney before blockage of blood flow protects kidney grafts against IRI has not been investigated.

Methods: In the present study we performed kidney transplantation and applied local hypothermia on the donor kidney before blockage of renal blood flow, which procedure is called "kidney precooling". Kidney graft injury and function were evaluated at 7 days after transplantation.

Results: kidney precooling improved graft functions by >47% accompanied with about 50% less kidney graft injury. The protective mechanisms of kidney precooling are associated with preserved mitochondria function and significantly delayed ATP depletion. More impressively, the precooling enables us to double the storage time of the donor kidneys in preservation solution in rats. Retrospective analysis of patient data also showed close association between hypothermia and kidney graft function.

Conclusions: Taken together, reduction of the cellular metabolism and enzymatic activity to a minimum level before ischemia protects kidney graft against IRI during transplantation.

p53 Is Activated in Cold Storage/Transplantation to Mediate Tubular Injury and Renal Graft Dysfunction

Xiaohong Xiang,[1,2] Zheng Dong.[1,2] *[1]Second Xiangya Hospital, Changsha, China; [2]Augusta University, Augusta, GA.*

Background: Kidney injury associated with cold storage/transplantation is a leading cause of delayed graft function and poor outcome of renal transplants. p53 has been implicated in both ischemic and nephrotoxic kidney injury, but its involvement in kidney cold storage/transplantation is not clear. This study aimed to investigate the role of p53 in cold storage/transplantation kidney injury and test the therapeutic effects of p53 inhibition.

Methods: Donor kidneys from C57BL/6 mice were preserved in ice-cold University of Wisconsin (UW) solution for 0.5, 2, 6 or 8.5h and transplanted into syngeneic recipients for 24h. Tubular injury, cell death and p53 activation were observed and their correlations were assessed. The acute response of kidneys from pifithrin-α and DMSO (the vehicle solution) treated mice was examined and compared, as well as response of kidneys from p53 conditional knock out (KO) mice and their wild type (WT) littermates. To explore the therapeutic potential of p53 inhibition, pifithrin-α was also administered to test its effect on graft injury and function on day 6, when the graft became the sole life-supporting kidney after native kidney removal at day 5. Rat kidney proximal tubule cells (RPTCs) were incubated in UW solution at 4°C for cold storage, followed by full medium replacement at 37°C for rewarming. Pifithrin-α was added to UW solution or dominant negative p53 was transfected into RPTCs, for the purpose of evaluating their effect on RPTCs death in cold storage/rewarming.

Results: p53 was activated in kidney tubule cells during cold storage transplantation, which correlated with tubular injury and cell death. Pifithrin-α significantly reduced acute tubular injury, cell death and inflammation during cold storage/transplantation. Similar effects were shown by ablation of p53 specifically from kidney proximal tubule cells. Notably, pifithrin-α also ameliorated kidney injury and improved the function of transplanted kidneys as the life-supporting graft. In RPTCs, cold storage followed by rewarming induced cell death and p53 activation. Both pifithrin-α and dominant-negative p53 could attenuate RPTC cell death during cold storage/rewarming.

Conclusions: p53 plays a critical role in kidney injury and dysfunction during cold storage/transplantation. p53 inhibitors may provide therapeutic benefits for donor kidney preservation and transplantation.

Multi-Omics Analysis Reveals Regulatory Mechanisms in Chronic Cyclosporine A-Induced Nephrotoxicity Studied in a Rat Model

Hasan Demirci, Duygu E. Yilmaz, Suncica Popovic, Junda Hu, Kerim Mutig, Sebastian Bachmann. *Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: Chronic calcineurin inhibitor (CNI) nephrotoxicity is a major drawback in current immunosuppressive regimens. In the chronic setting, arteriolar hyalinosis, decreased glomerular filtration rate, interstitial fibrosis and tubular dedifferentiation are the major adverse side effects. Regimens with cyclosporine A (CsA) and tacrolimus (Tac) have been compared before the background of potentially more harmful effects of CsA. Conversely, CsA is still widely used in transplant recipients and has been considered for replacement of Tac in posttransplant diabetes. To identify regulatory mechanisms in CsA nephrotoxicity we used quantitative transcriptomic, proteomic and phosphoproteomic methods. We tested the hypothesis that tubulointerstitial pathomechanisms play a significant role in chronic CNI nepropathy.

Methods: Whole transciptome RNA-seq as well as global proteomic and phosphoproteomic methodologies were performed on kidney extracts from normal Wistar rats receiving CsA (25mg/kg b.w./day) or vehicle for 3 weeks. Differentially expressed genes and proteins as well as their phosphorylation status were obtained.

Results: CsA treatment stimulated genome-wide alterations in rat kidney according to the RNA-seq data. We identified 342 transcripts upregulated which included Ribosome and Oxidative phosphorylation pathways, whereas 331 transcripts were downregulated, with enrichment in genes critical for amino acid metabolism. Data were controlled by the established upregulation of renin and downregulation of calbindin in global proteomics. KEGG pathway and GO analysis from proteomics largely corresponded to the RNA-seq results. Upregulated proteins were further related to ECM-receptor interaction and focal adhesion pathways (padj<0,05). Phosphoproteomics demonstrated functional phosphorylation of components from unfolded protein response pathways, indicating an activation of the integrated stress response upon CsA.

Conclusions: In sum, using integrated -omics analysis in CsA nephrotoxicity proves to be a powerful approach. Chronic CsA treatment is associated with enhanced energy metabolism and activation of the unfolded protein-response pathways. A tubulointerstitial focus has been demonstrated. Potential biomarker candidates have further been obtained and are currently verified in the rat model.

PO2048

Calcineurin Inhibitor Nephrotoxicity as Viewed by Comparative Analysis of the Effects of Cyclosporine A vs. Tacrolimus on Epithelial Pathology in Rodent Models

Suncica Popovic,[1] Hasan Demirci,[1] Junda Hu,[1] Duygu E. Yilmaz,[1] Carsten Dittmayer,[1] David H. Ellison,[2] Kerim Mutig,[1] Sebastian Bachmann.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Oregon Health & Science University Oregon Clinical & Translational Research Institute, Portland, OR.*

Background: Calcineurin inhibitors (CNI) are widely in use for immunosuppression in transplant recipients. Although essentially beneficial, their nephrotoxicity may cause or aggravate renal disease. We have challenged the hypothesis that the safety of the commonly applied CNI, cyclosporine A (CsA), and tacrolimus (Tac), differs regarding tubulointerstitial pathology. Mechanisms of proteostasis, autophagy and lysosomal dysfunction are addressed.

Methods: We have compared the effects of CsA and Tac in rat and mouse models. A focus was set on epithelial alterations. Adult Wistar rats received CsA (25 mg/kg/d), Tac (2 to 6 mg/kg/d), or vehicle via subcutaneously implanted minipumps. A megalin-deficient mouse model was tested for the role of endocytosis. After 4 wk kidneys were prepared for histopathology or biochemical analysis.

Results: In rats, CsA and Tac produced similar alterations in the tubulointerstitium (Fig. 1). Preferentially the initial proximal tubule (S1, and S2 segments) was affected, displaying dysmorphic lysosomes with peripheral LAMP1 signal, autophagic and mitophagic vacuoles. Dedifferentiation was focally strong, with loss of brush border, basement membrane thickening, and interstitial collagen accumulation. Alterations in unfolded protein response (UPR) and autophagy parameters included significant increases in p-eIF2a, pPERK, CHOP, BiP, and LC3B, and ATG5 products and enhanced epithelial TUNEL signal. Endocytosis was substantially impaired. Cultured NRK cells indicated sensitivity to chemical chaperones ameliorating proteostasis and revealed similar apoptosis rates upon CsA and Tac.

Conclusions: These results suggest that alterations in tubular epithelial proteostasis upon long term CsA- or Tac-induced nephrotoxicity are similar. Addressing restitution of epithelial proteostasis may have renoprotective potential for both drugs.

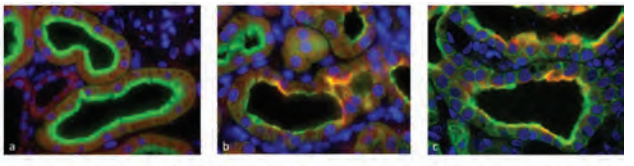

Figure 1. Proximal tubular damage with partial injury/loss of brush border after CsA (b; 25 mg/kg/day, 4 wk) and tacrolimus (c; 6 mg/kg/day, 4 wk) treatment in Wistar rats, compared to vehicle (a.). Green, aquaporin 1; red, kidney injury marker 1; blue, DAPI nuclear counterstaining.

Cyclosporine A but Not Tacrolimus Promotes Pro-Apoptotic Endoplasmic Reticulum Stress in Cultured Kidney Cells

Duygu E. Yilmaz, Karin M. Kirschner, Hasan Demirci, Sebastian Bachmann, Kerim Mutig. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Current immunosuppressive regimen in organ transplantation include calcineurin inhibitors (CNI), cyclosporine A (CsA) or tacrolimus (Tac), as the first-line therapy. Both CNI may produce renal side effects, which are typically stronger in patients receiving CsA. Sustained clinical demand for CsA requires improved understanding of mechanisms underlying its nephrotoxicity. CsA builds complexes with cyclophilins, whereas Tac recruits FKBP12 for calcineurin inhibition. We hypothesized that cytotoxic effects of CsA may be related with impaired chaperone function of cyclophilins resulting in endoplasmic reticulum (ER)-stress and pro-apoptotic unfolded protein response (UPR).

Methods: Effects of CsA vs. Tac (10 μM for 6 h) on the UPR signaling were compared in cultured native HEK293 cells, as well as in genetically modified cells lacking critical ER-stress sensors, PERK or ATF6. An established ER-stress inducer, thapsigargin (Tg) served as a positive control.

Results: CsA and Tg, but not Tac, induced ER-stress and UPR in native HEK293 cells, which was reflected by increased abundance of key UPR products (CHOP, spliced XBP1, and phosphorylated IRE1a). Furthermore, CsA but not Tac increased the abundance of caspase 3-(cCas3) suggesting stimulated apoptosis. Similar to CsA, knockdown of cyclophilin A or cyclophilin B using siRNA augmented CHOP and cCas3 levels. Deletion of PERK or ATF6 blunted the CsA-induced UPR. Furthermore, the CsA-dependent ER-stress was significantly reduced by concomitant application of chemical chaperones, TUDCA or 4-PBA.

Conclusions: In summary, these results suggest that renal side effects of CsA are partially mediated by suppression of cyclophilins, ER-stress, and pro-apoptotic UPR. Pharmacological modulation of UPR bears potential to alleviate the CsA nephrotoxicity.

Prolonged IL-6 Secretion Activates Inflammation Amplifier Loop (IL-6+IL-17) in Fibroblast Derived from Chronic Antibody-Mediated Rejection in Renal Allograft Recipient

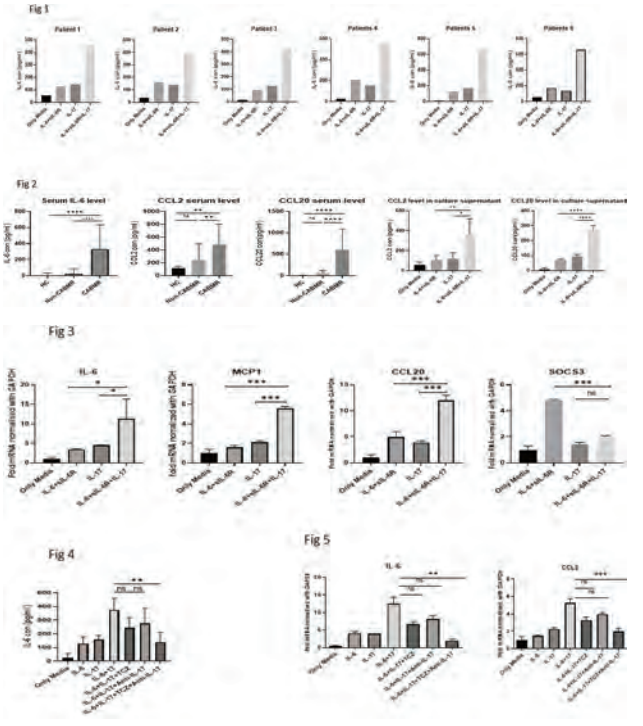
Mantabya K. Singh, Narayan Prasad, Vikas Agarwal. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Recently, non-immune cells like fibroblast have been postulated to mediate allograft rejection via activation of the IL-6 amplifier loop. We evaluated IL-6 amplifier loop activation by IL-6 and Il-17 in chronic antibody mediated rejection (CABMR).

Methods: Fibroblasts from grafted kidneys from CABMR patients (n=6) were cultured, stimulated with IL-6 (20ng/ μl), IL-17(50ng/ μl), IL-6 plus IL-17 for 24 hours. Levels of IL-6, MCP-1, and CCL20 were estimated in culture supernatants by ELISA as markers of IL-6 amplifier loop activation mRNA expression of IL-6, MCP1, CCL20, SOCS3 genes were measured in the stimulated fibroblasts. Additionally, IL-6, MCP1, and CCL20 levels were measured in Healthy control (n=10) CABMR (n=20) and non-CABMR (n=30) patients.

Results: IL-6 and IL-17 synergistically induced more IL-6, CCL-20 & MCP-1 production from fibroblasts. **Fig1** Gene expression analysis of IL-6, MCP1, and CCL20 was significantly higher with synergistic activation of IL-6 and IL-17 as compared to either IL-6 or IL-17 alone, while SOCS3 gene expression was downregulated. **Fig 3**. Additionally, concentrations of IL-6, CCL-20 & MCP-1 in sera were significantly higher in CABMR patients compared to non-rejection patients ($p<0.001$). **Fig 2**. There was a significant reduction in IL-6 concentration in culture supernatant with IL-6 and IL-17 inhibitor together **Fig 4** and mRNA expression of IL-6 and MCP-1 was significantly reduced. **Fig 5**.

Conclusions: CABMR is perpetuated by inflammation amplifier loop or synergistic induction of IL-6 and IL-17. Inhibition of IL-6 with Anti-IL-6 (Tocilizumab) and IL-17 with Anti-IL-17 together reduces the tissue injury marker IL-6, MCP1, CCL20 and allograft rejection.



PO2051

Circulating Donor-Specific Anti-HLA Antibodies Induce Immune Activation Independent of Kidney Transplant Histopathological Findings

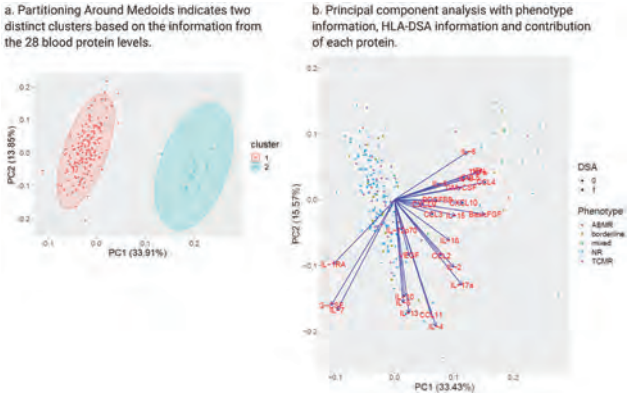
Elisabet Van Loon,[1] Baptiste Lamarthee,[1] Aleksandar Senev,[1] Marie-Paule Emonds,[1] Amaryllis H. Van Craenenbroeck,[1] Olivier Thaunat,[2] Maarten Naesens.[1] *[1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]Edouard Herriot Hospital Lyon, Lyon, France.*

Background: Despite the critical role of cytokines in allograft rejection, the relation of peripheral blood cytokine profiles to clinical kidney transplant rejection has not been fully elucidated.

Methods: Levels of 28 cytokines were assessed using multiplexed Luminex testing in 293 peripheral blood samples, collected at time of a kidney allograft biopsy for graft dysfunction within the first year after transplantation in a cohort of 192 consecutive transplants at a single kidney transplant center.

Results: Unsupervised hierarchical clustering identified a subset of patients with increased pro-inflammatory cytokine levels (Figure a, cluster 2). This patient subset (N=20) was hallmarked by high prevalence (75%) of donor-specific anti-human leukocyte antigen antibodies (HLA-DSA) (Figure b) and histological rejection (70%), and had worse graft survival compared to the group with low cytokine levels (N= 172, HLA-DSA in 1.7% and rejection in 33.7%). Serum C-reactive protein and polyomavirus and/or CMV viremia did not differ between the two clusters. Thirty percent of patients with high pro-inflammatory cytokine levels and HLA-DSA did not have histological rejection. Single-cell RNAseq analysis on public data from kidney transplant biopsies demonstrated expression of these cytokines in endothelial cells, non-classical monocytes and natural killer cells. We confirmed the inflammatory cytokine profiles in *in vitro* models of HLA-DSA-mediated crosstalk between endothelial cells, NK cells and monocytes.

Conclusions: The expression of pro-inflammatory cytokines is increased in peripheral blood of kidney transplant patients with circulating HLA-DSA, even in the absence of histopathology of rejection. These results challenge the vision that kidney transplant histology is the gold standard for identification of ongoing allo-immune processes.



PO2052

Increased Autoantibodies Against Ro/SS-A, CENP-B, and La/SS-B in Patients with Kidney Allograft Antibody-Mediated Rejection

Sergi Clotet Freixas,[1] Max Kotlyar,[1] Caitriona M. McEvoy,[1] Chiara Pastrello,[1] Sonia Rodriguez Ramirez,[1] Sofia Farkona,[1] Heloise Cardinal,[2] Mélanie Dieudé,[2] Marie-Josee Hebert,[2] Yanhong Li,[1] Rohan John,[1] Andrzej Chruscinski,[1] Ana Konvalinka.[1] *[1]University Health Network, Toronto, ON, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, QC, Canada.*

Background: Antibody-mediated rejection (AMR) causes >50% of late kidney graft losses. In addition to anti-HLA donor-specific antibodies (DSA), antibodies against non-HLA antigens are also linked to AMR. Identifying key non-HLA antibodies will improve our understanding of AMR.

Methods: We analyzed non-HLA antibodies in sera from 80 kidney transplant patients with AMR, mixed rejection, acute cellular rejection (ACR), or acute tubular necrosis (ATN). IgM and IgG antibodies against 134 non-HLA antigens were measured in serum samples collected pre-transplant or at the time of diagnosis.

Results: Fifteen non-HLA antibodies were significantly increased ($p<0.05$) in AMR and mixed rejection compared to ACR or ATN pre-transplant, and seven at diagnosis. AMR and mixed cases showed significantly increased pre-transplant levels of IgG anti-Ro/SS-A and anti-CENP-B, compared to ACR. Together with IgM anti-CENP-B and anti-La/SS-B, these antibodies were significantly increased in AMR/mixed rejection at diagnosis. Increased IgG anti-Ro/SS-A, IgG anti-CENP-B and IgM anti-La/SS-B were associated with the presence of microvascular lesions and class-II DSA ($p<0.05$). Significant increases in IgG anti-Ro/SS-A and IgM anti-CENP-B antibodies in AMR/mixed rejection compared to ACR were reproduced in an external cohort of 60 kidney transplant patients.

Conclusions: This is the first study implicating autoantibodies anti-Ro/SS-A and anti-CENP-B in AMR. These antibodies may participate in the crosstalk between autoimmunity and alloimmunity in kidney AMR.

PO2053

A Sliding Window Approach to Investigate the Role of Donor-Recipient Interindividual Genetic Distance on Kidney Transplant Outcome

Kane E. Collins,[1] Edmund H. Gilbert,[1] Peter J. Conlon,[2,1] Graham M. Lord,[3] Elhussein A. Elhassan,[2] Gianpiero Cavalleri.[1] Human Genetic Variation Research Group *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland; [3]The University of Manchester, Manchester, United Kingdom.*

Background: Although the role of HLA matching on kidney transplant outcome is well appreciated, the role of genetic matching between donors and recipients outside of the HLA region is less well understood. This is important as histological damage is a major issue in allografts and studies have suggested that non-HLA immune factors play a significant role in this process. However, the mechanism involved is presently unknown. Previous studies on relatively small datasets have looked at the role of genetic distance on kidney transplant outcome and found significant effects on graft survival. The regions of the genome which may contain these genes have not yet been searched for. Several methods can estimate genetic distance (mismatch) such as IBS, which measures allelic sharing or IBD which measures haplotype sharing.

Methods: Using 2,122 genotyped donor-recipient pairs from the United Kingdom and Ireland Renal Transplant Consortium (UKIRTC), we performed a survival analysis using a Cox Proportional Hazards model, investigating the role of various clinical and genetic factors. We focused investigation on the impact of IBS and total length of IBD between donor and recipient on kidney transplant outcome. We then used a sliding window approach to test the association between mismatch at any autosomal region of the genome and graft survival. This used a sliding window of 3 million base pairs on both IBS and IBD, resulting in 947 regions of the genome to be tested for association.

Results: Several clinical covariates were found to be significantly associated with graft survival; graft number (Bonferroni-Holm p-value: 1.5×10^{-7}), donor age (8×10^{-5}) and total HLA mismatch (0.03). These are well established risk factors, confirming the veracity of our methodology. Although a window at the start of chromosome 6 in the HLA region was the most significant, we did not detect a statistically significant association between IBS or total length of IBD and graft survival after correction for multiple testing.

Conclusions: We were unable to find an association between either IBS or total length of IBD and graft survival. In addition, there was no particular region of the genome that had a significant association with survival (though the effect of the HLA region was the most significant).

PO2054

Prevention of Triglyceridemia by (Non-)Anticoagulant Heparin(oids) Does Not Preclude Transplant Vasculopathy and Glomerulosclerosis

Pragyi Shrestha,[1] Kirankumar Katta,[2] Ditmer Talsma,[1] Annamaria Naggi,[3] Jan-luuk Hillebrands,[1] Bart Van de sluis,[1] Jacob van den Born.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Oslo University Hospital Ullevål, Oslo, Norway; [3]Ronzoni Institute, Milano, Italy.*

Background: Chronic Transplant Dysfunction (CTD) is associated with increased PCSK9 and dyslipidemia. We recently showed defective lipoprotein clearance by increased PCSK9–hepatic syndecan-1 interaction in renal condition. Targeting PCSK9 by heparin(oids) might be a therapeutic option to improve dyslipidemia and CTD. We investigated the effects of (non-)anticoagulant heparin(oids) on serum lipids, syndecan-1 and PCSK9 levels and CTD development.

Methods: Kidney allotransplantation was performed from female Dark Agouti to male Wistar Furth recipients. Transplanted rats received daily subcutaneous injections of saline, unfractionated heparin, RO-heparin or NAc-heparin (2mg heparin(oid)/kg BW) until sacrifice after 9 weeks of treatment.

Results: Saline-treated recipients developed hypertension, proteinuria, and loss of creatinine clearance, (all $p<0.05$ compared to baseline), along with glomerulosclerosis and arterial neointima formation. Saline-treated recipients showed significant increase in plasma TGs ($p<0.05$), borderline increase in non-HDLc to HDLc ratio ($p=0.051$), approximately 10-fold increase in serum syndecan-1 ($p<0.05$), without significant increase in serum PCSK9 level at 8 weeks compared to baseline. Heparin and non-anticoagulant RO-heparin administration in transplanted rats completely prevented increase in TGs compared to saline treated recipients at 8 weeks (both $p<0.05$). Heparin(oids) treatment did not influence serum TC, plasma syndecan-1 and PCSK9 levels, creatinine clearance, proteinuria, glomerulosclerosis and arterial neointima formation, 8 weeks after transplantation. Combining all groups, increased syndecan-1 shedding was associated with TC ($r=0.5$; $p=0.03$) and with glomerulosclerosis ($r=0.53$; $p=0.021$), whereas non-HDLc/HDLc ratio associated with neointima score in the transplanted kidneys ($r=0.65$; $p<0.001$).

Conclusions: Prevention of triglyceridemia by (non)anticoagulant heparin(oid) did neither influence PCSK9/syndecan-1, nor precluded CTD, which did however associated with shedding of lipoprotein clearance receptor syndecan-1 and unfavorable cholesterol profile.

PO2055

RBT-9 Antiviral Activity Against BK Virus

Stacey Ruiz,[1] Scott James,[2] Caroll Hartline,[2] Bhupinder Singh.[3] *[1]Renibus Therapeutics, Inc., Southlake, TX; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of California Irvine, Irvine, CA.*

Background: BK virus, a member of the polyomavirus family, is a significant risk factor for nephropathy and subsequent allograft loss in patients undergoing kidney transplantation. There are currently no approved treatments for BK virus-induced nephropathy. RBT-9, a novel formulation of stannous protoporphyrin (SnPP), exhibits broad antiviral activity against enveloped and nonenveloped viruses in vitro. It is also known to be protective against acute kidney injury (AKI) in animals when given prior to insult. Given the dual antiviral and kidney protective effects of RBT-9, the effect of RBT-9 against BK viral infection was investigated in vitro, as standard in vivo models that mimic BK virus complications are not currently available.

Methods: Two conditions were investigated: 1) standard qPCR-based antiviral assay – treatment with RBT-9 at the time of infection and 2) viral neutralization – pre-incubation of RBT-9 with BK virus for 1 hour prior to infection. RBT-9 was tested at concentrations up to 100 μM. Human foreskin fibroblast (HFF) cells were used as the host cell. Viral activity was assessed by real time qPCR and cellular viability was determined by CellTiter-Glo.

Results: RBT-9 exhibited moderate antiviral activity against BK virus under both treatment conditions. The 50% effective concentration (EC_{50}) averaged 5.5 μM in 2 independently run standard qPCR assays and 5.4 μM in the neutralization assay. The EC_{50} of RBT-9 in these assays is 11 times lower than the highest dose of RBT-9 tested in Phase 1 studies and considered to be well tolerated. The 50% cytotoxic concentration (CC_{50}) in the in vitro studies averaged 89.2 μM, indicating RBT-9 did not adversely affect host cell viability at concentrations 16.5 times higher than its effective concentration.

Conclusions: Given the antiviral activity of RBT-9 against BK virus in vitro and the safety profile of RBT-9 in Phase 1 human studies, a clinical study assessing the efficacy of RBT-9 is warranted in patients who are at risk of developing BK virus-induced nephropathy.

PO2056

The Survival Benefit of Re-Kidney Transplantation in Older and Younger Patients with Graft Failure

JiYoon B. Ahn,[1] Shaifali Sandal,[2,3] Dorry L. Segev,[1,4] Mara McAdams-DeMarco.[1,4] ERGOT [1]*Johns Hopkins University School of Medicine, Baltimore, MD;* [2]*McGill University Health Centre, Montreal, QC, Canada;* [3]*Research Institute of the McGill University Health Centre, Montreal, QC, Canada;* [4]*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: The survival benefit of re-kidney transplantation (re-KT) has been demonstrated two decades ago in younger patients. The proportion of patients with graft failure is increasing, particularly among those aged≥65. We compared the survival benefit of re-KT by patient age.

Methods: Using data from the Scientific Registry of Transplant Recipients, we identified 42,366 patients who experienced graft failure after their first KT and were listed for re-KT between 1990-2019. We treated re-KT as a time-dependent variable and used Cox regression to compare the risk of mortality between being listed for a re-KT and undergoing re-KT. We used the inverse probability weighting method to account for potential confounding. We also tested whether the risk of mortality differed by patient age at listing (18-64 versus ≥65 years) using a Wald test.

Results: Overall, 42,366 patients were listed for re-KT and 47.5% underwent re-KT by 10/31/2020. The number of patients being listed for re-KT tripled between 1990 and 2019. The mortality rate was 6.6 per 100 person-years among patients being listed and 3.0 per 100 person-years among those retransplanted. Overall, the risk of mortality was lower after re-KT than during listing (adjusted hazard ratio [aHR]=$_{0.42}0.43_{0.45}$). However, the association differed by age ($P_{interaction}$=0.03), but the survival benefit of retransplant was observed among both younger (aHR=$_{0.41}0.42_{0.44}$) and older patients (aHR=$_{0.43}0.49_{0.55}$).

Conclusions: Our finding suggests that re-KT is associated with a significant survival benefit in younger and older patients. In addition, long-term outcomes in older re-KT recipients were reported comparable to those in older first KT recipients. Transplant centers should consider expanding re-KT to appropriate older adults.

Funding: NIDDK Support, Other NIH Support - NIAID, NIA

Figure 1. Trends in being listed for retransplant and mortality rate per 100 person-years by calendar year of listing.

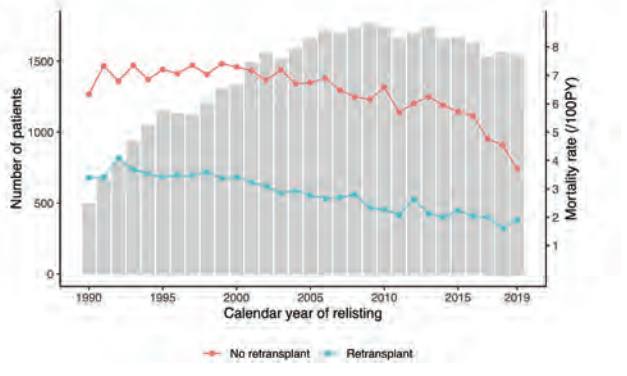

Table 1. Mortality rates per 100 person-years and adjusted hazard ratio for mortality comparing retransplant with being listed by age (18-64 versus ≥65 years)

	No retransplant (n=22,222)	Retransplant (n=20,144)	aHR (95% CI)[1]	P for interaction
Overall	6.6	3.0	$_{0.42}0.43_{0.45}$	-
Age, years				0.03
18-64 (n=40,016)	6.3	2.8	$_{0.41}0.42_{0.44}$	-
≥65 (n=2,350)	8.3	6.3	$_{0.43}0.49_{0.55}$	-

PO2057

Development and Determinants of Quality of Life After Kidney Transplantation in Elderly Recipients

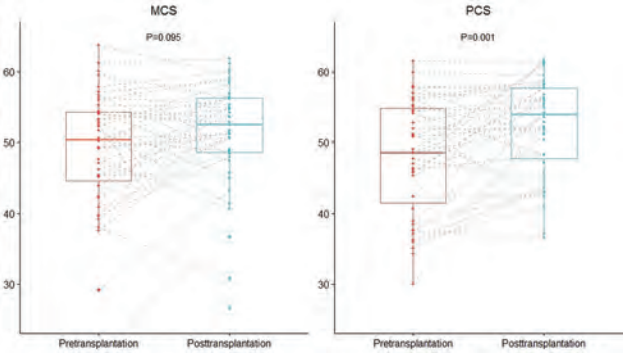
Silke de Boer, Daan Kremer, Stefan P. Berger, Stephan J. Bakker, Jan-Stephan Sanders. *Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Kidney transplantation is regarded as the best treatment for end-stage kidney disease, with survival benefits also in elderly patients. However, little is known regarding (determinants of) health-related quality of life (HRQoL), and changes in HRQoL in elderly kidney transplant recipients (KTR).

Methods: We used data from KTR ≥65 years old at the time of kidney transplantation, enrolled in the ongoing prospective TransplantLines Biobank and Cohort Study. Data on HRQoL were assessed using SF-36 mental and physical component scores (MCS and PCS). Side effects of immunosuppressive drugs were assessed using MTSOSD-59R questionnaires. In a subgroup with available data on HRQoL before transplantation, we investigated HRQoL trajectories.

Results: We included 111 KTR (age 70±4 years, 39% pre-emptive and 45% living procedures). At one year after transplantation, eGFR was 48±16 ml/min/1.73m, MCS was 51±8, and PCS was 52±7. MCS was lower in females ($P_{t\text{-}test}$=0.018), and in KTR that suffered from rejection in the first year ($P_{t\text{-}test}$=0.005). PCS was higher in KTR that were pre-emptively transplanted ($P_{t\text{-}test}$=0.010) and lower in those with post-transplantation diabetes mellitus (PTDM, $P_{t\text{-}test}$=0.008). Number of side-effects of immunosuppressive drugs was strongly associated with both MCS and PCS (both $P_{linear\ regression}$<0.001). Age, eGFR, hemoglobin, pre-transplant comorbidities, hospitalizations and infections in the first year were not associated with HRQoL. In 43 KTR with available data both before and after transplantation, PCS increased significantly after transplantation (48 to 52; $P_{paired\ t\text{-}test}$ = 0.001, **Figure 1**), while MCS did not significantly improve (49 to 51; $P_{paired\ t\text{-}test}$ = 0.095).

Conclusions: Medication-related side-effects, transplant rejection, transplantation after start of dialysis and PTDM were associated with worse HRQoL among elderly KTR, whereas eGFR and age were not. Moreover, HRQoL improves after kidney transplantation in KTR ≥65 years old.



PO2058

Elderly Kidney Transplantation Donors After Circulatory Death: Is It Worth It?

Aida Frías González, Esther Gonzalez monte, Amado Andres. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Kidney transplantation (KT) remains the treatment of choice for end-stage renal disease, since it offers better outcomes and quality of life and is less costly in the long run compared with stay on dialysis. In order to expand the donor pool, donation after circulatory death (DCD) has become an increasingly popular strategy, and eligibility criteria for this procedure have widened in the last few years.

Methods: Single-center retrospective study in which we described the clinical characteristics and outcomes of all the patients who underwent Maastricht category-III (controlled) DCD (cDCD) KT from January 2006 to October 2019. IBM SPSS (v25.0) was used for all the statistical analysis. Two-sided p values of <0.05 were considered statistically significant.

Results: We performed 54 cDCD KT, median follow-up was 36 (0.5-155) months. Donors' mean age was 50.2 years (range 19-81), 20.4% were ≥70 years, 64.8% male, 22.2% diabetics, 25,9% suffered hypertension. 24 (44.5%) recipients presented delayed graft function and 6 (11.1%) suffered primary nonfunction, with no differences depending on donor age (≥ or <70 years). Primary nonfunction was the main cause of graft loss, which occurred in 8 patients (14.8%), and it was significantly higher in donors ≥70 years old (p=0.021). In the multivariant analysis only donor age ≥70 years was related to graft loss. Other factors examined such as cold ischemia time >14 hours, warm ischemia time >17 minutes and the presence of cardiovascular disease, didn't show statistically significant differences. At one-year follow-up, renal function was significantly better in donors <70 years compared to donors ≥70 years, with mean serum creatinine 1.4 vs 2.1 mg/dl respectively (p=0.003), and estimated filtration rate 36.4 ± 19 vs 57.9 ± 18.9 ml/min per 1.73 m2 (p=0.008). The mortality rate was higher among recipients from older donors (3 [23.7%] vs 2 [4.6%], p=0.021).

Conclusions: cDCD KT donors ≥70 years have inferior outcomes than KT from donors <70 years concerning graft loss, overall survival and renal function 12 months after transplantation. Therefore, it is essential to evaluate cautiously whether or not to proceed with this transplants.

PO2059

Immunosuppression, Osteoporosis, and Fractures in Younger and Older Adults After Kidney Transplantation

Krista L. Lentine,[1] Sarat C. Kuppachi,[6] Ruixin Li,[1] Yasar Caliskan,[1] Wisit Cheungpasitporn,[2] Mark Schnitzler,[1] Mara McAdams-DeMarco,[3] Vikas R. Dharnidharka,[4] JiYoon B. Ahn,[3] Sunjae Bae,[3] Dorry L. Segev,[3] Gregory Hess,[5] Suphamai Bunnapradist,[7] Henry B. Randall,[1] David Axelrod.[6]
[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Johns Hopkins University, Baltimore, MD; [4]Washington University in St Louis, St Louis, MO; [5]Drexel University, Philadelphia, PA; [6]The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; [7]University of California Los Angeles, Los Angeles, CA.

Background: Osteoporosis and fractures are important complications among kidney transplant recipients (KTx) that may be exacerbated by immunosuppression (ISx) and aging. We examined relationships of osteoporosis and fractures with ISx among older and younger adults in a national sample of Medicare beneficiaries.

Methods: We examined USRDS data (2005-2017) to explore associations of ISx regimens (within 6 mo) with osteoporosis and fracture diagnoses >6 mo-to-3 yr post-KTx among Medicare-insured younger (age <55) and older (aged ≥ 55) adults. We used multivariate Cox regression with inverse propensity weighting to compare cancer risk vs. reference regimen of Thymoglobulin (TMG) or Alemtuzumab (ALEM) + Tacrolimus + antimetabolite + prednisone.

Results: Among 67,362 KTx Medicare-insured recipients, the 3-year composite risk of osteoporosis and fractures varied by age and ISx regimen. Among older adults, incidence ranged from 11% with TMG/ALEM no Pred, to 16% in those managed with CsA and mTORi-based regimens (**Fig. A**) In adjusted models, TMG/ALEM + no Pred was y associated with lower risk (aHR, $_{0.76}0.84_{0.792}$) than TMG/ALEM + triple therapy (**Fig. B**). Conversely, mTORi-based regimens (aHR,$_{1.08}1.23_{1.40}$) and CsA-based regimens (aHR, $_{1.07}1.21_{1.38}$) were associated with greater risk. Patterns were generally similar but relative impacts were amplified in younger patients, including greater benefits of steroid-avoidance (aHR, $_{0.55}0.55_{1.38}$).

Conclusions: Among Medicare insured KTx recipients, steroid avoidance after TMG/ALEM inductions is associated with reduced risk of fractures and osteoporosis. Fracture risk is a consideration in tailoring ISx in older KTx recipients.

Organ Procurement and Transplantation Network Effort to Increase Kidney Transplantation Through Kidney Accelerated Placement

Samantha Noreen,[1] David Klassen,[1] Matthew Cooper,[2] Andrew Placona.[1]
[1]United Network for Organ Sharing, Richmond, VA; [2]MedStar Health, Columbia, MD.

Background: In 2017 just over a quarter of kidneys deemed hard to place were transplanted while the rest were discarded. The Kidney Accelerated Placement (KAP) project aimed to increase the acceptance of these deceased donor kidneys, declined by a large proportion of programs, through the creation of a novel allocation system. Offering hard-to-place kidneys to transplant centers with a history of transplanting similar organs, utilization would increase by reducing time to find an acceptor and cold ischemia time (CIT) within the deceased organ allocation process. We hypothesized CIT mediated the effect of KAP on transplant center organ-level offer acceptance.

Methods: We used a pre/post design mediation analysis with OPTN database offers from kidney matches meeting criteria for KAP 7/18/18-7/15/19 (pre-KAP) and 7/18/19-7/15/20 (KAP). We employed logistic regression models of KAP and CIT on organ acceptance and a linear regression model of KAP on CIT, adjusting for additional risk factors (Fig 1).

Results: Transplant center organ-level offer acceptance rates were 0.37%(pre-KAP) and 0.23%(KAP). The total effect indicates that KAP increased odds of acceptance by 0.07. Decreases in CIT increased odds of acceptance by 0.02 (indirect effect) and the remaining portion of the total effect is attributable to other possible mechanisms (direct effect).

Conclusions: While KAP affected offer acceptance, the magnitude of the effect was small. Because the baseline level of offer acceptance was also small, our analysis indicates that KAP works conceptually to increase the use of these kidneys. At the same time, there is evidence that alternative approaches to KAP are needed to potentially decrease organ discard. Future iterations plan to consider complex risk adjustment including behaviors and the differential impact for donor types.

Figure 1. Directed acyclic graph (DAG) illustrating the relationships measured.

BMI = body mass index, CIT = cold ischemia time, DCD = donation after circulatory death, IV = intravenous, KAP = Kidney Accelerated Placement, KDPI = kidney donor profile index, PHS = Public Health Service, TXC = transplant center.

A Geospatial Method to Improve Sociodemographic Characterization of Transplant Referral Regions

Tyler Schappe, Sarah B. Peskoe, Jane F. Pendergast, Virginia Wang, L. Ebony Boulware, Lisa M. McElroy. *Duke University, Durham, NC.*

Background: Progress towards health equity in kidney transplant requires robust characterization of transplant center referral populations. Transplant referral regions (TRRs) define geographic catchment areas for transplant centers in the United States and have previously been linked to sociodemographic data using ZIP codes. We compared a spatial intersection method to a ZIP code crosswalk method of linking sociodemographic data to TRRs.

Methods: A spatial intersection method was used to assign census block groups to TRRs based on area of intersection. We compared the spatial congruence of the spatial intersection and ZIP code crosswalk methods by calculating the number of census block groups assigned to more than one TRR and calculating the total area assigned to the incorrect TRR.

Results: We defined 105 TRRs for 238 transplant centers (figure 1a). The ZIP code crosswalk method resulted in 4,627 census block groups being included in more than one TRR, while the spatial intersection method eliminated this problem. The spatial method resulted in a mean and median reduction in misassigned area of 65% and 83% across all TRRs, respectively, compared to the ZIP code crosswalk method (figure 1b).

Conclusions: Characterizing TRRs with census block groups increases spatial resolution, and provides more balanced population counts. Our spatial approach avoids errors due to duplicative assignments and allows more accurate characterization of referral population sociodemographics. This approach can enrich transplant center knowledge of local referral populations, assist researchers in understanding the influence of social determinants of health on access to transplant, and inform interventions to improve heath equity.

PO2062

Association of Medicaid Expansion with Medicaid Uptake and Uninsurance Among US Kidney Transplant Recipients

Elizabeth Kotzen, Randal K. Detwiler, Jennifer E. Flythe. *UNC Kidney Center, Chapel Hill, NC.*

Background: The differential uptake of Medicaid expansion among U.S. states following the Affordable Care Act created a natural experiment to investigate the association between Medicaid expansion and health insurance usage patterns among kidney transplant (KT) recipients. Adolescents and young adults (AYA) are at particular risk for insurance access disruption.

Methods: Using data from the Scientific Registry of Transplant Recipients, we constructed a multivariable difference-in-differences model to evaluate the association between living in a state with Medicaid expansion (vs. a state without) and two outcomes: primary insurance of Medicaid at the time of KT, and being uninsured 5 years following KT. We included U.S. recipients of kidney-alone transplantation between 1/1/2005 and 3/12/2020. We analyzed AYA (ages 15-26 years) and other nonelderly adults (ages 27-64 years) separately.

Results: The AYA group included 17,158 KT recipients, while the group of adults 27-64 years included 198,914 KT recipients. The effect of living in a Medicaid expansion state (vs. a nonexpansion state) on use of Medicaid as the primary insurance type at the time of KT was +1.9% (95% CI -0.4% to +4.3%) for the AYA group and +1.7% (95% CI +1.3% to +2.1%) for the non-elderly adult group. The effect of living in a Medicaid expansion state (vs. a nonexpansion state) on being uninsured 5 years after KT was -3.6% (95% CI -6.5% to -0.7%) for the AYA group and -0.9% (95% CI -1.3% to -0.4%) for the non-elderly adult group.

Conclusions: Living in a Medicaid expansion state was associated with greater use of Medicaid at the time of KT for adults ages 27-64, but not in the AYA group. In both age groups, living in a Medicaid expansion state was associated with a modest reduction in being uninsured 5 years following KT. Increased access to Medicaid may provide a protective effect against becoming uninsured after KT.

Funding: NIDDK Support

Results of difference-in-differences analysis examining the association of exposure to Medicaid expansion with insurance outcomes among U.S. KT recipients.*

Outcome	Age group (years)	Adjusted change after expansion in EXPANSION states, percentage points (95% CI)	Adjusted change after expansion in NON-EXPANSION states, percentage points (95% CI)	Adjusted difference-in-differences estimate, percentage points (95% CI)
Medicaid as primary insurance at the time of KT	15-26	+4.1 (+2.6, +5.6)	+2.6 (+0.9, +4.2)	+1.9 (-0.4, +4.3)
	27-64	+2.2 (+1.9, +2.5)	+0.8 (+0.5, +1.0)	+1.7 (+1.3, +2.1)
Uninsured 5 years following KT	15-26	-1.1 (-2.6, +0.3)	+2.8 (+0.2, +5.3)	-3.6 (-6.5, -0.7)
	27-64	-0.4 (-0.6, -0.1)	+0.2 (-0.1, +0.6)	-0.9 (-1.3, -0.4)

*Adjusted for gender, race/ethnicity, cause of kidney failure, year of KT, and state fixed effects.

Construct Validity of the Patient-Reported Outcomes Measurement Information System (PROMIS®) Profile Summary Scores in Patients with Kidney Failure

Istvan Mucsi,[1] Gaauree Chawla,[1] Anqi Chen,[1] Mark JP M. Sanchez,[1] Nathaniel Edwards,[1] John D. Peipert,[2] Madeline Li,[1] Doris Howell,[3] Susan J. Bartlett,[4] Ron D. Hays.[5] Kidney Health Education and Research Group *[1]University Health Network, Toronto, ON, Canada; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada; [4]McGill University, Montreal, QC, Canada; [5]University of California Los Angeles, Los Angeles, CA.*

Background: The PROMIS® profiles include a single pain intensity item and 7 multi-item scales (e.g., physical function, fatigue, depression, social participation, etc.). These domains can be summarized into physical (PHS) and mental health summary (MHS) scores. We examine correlations of the PHS and MHS with generic and kidney-disease targeted measures in patients treated with kidney replacement therapies and compare the summary scores between patients on dialysis vs kidney transplant.

Methods: Cross-sectional convenience sample of 606 adults. Higher PHS and MHS scores correspond to better health. We estimated correlations of the PHS and MHS with the SF-12 physical (PCS) and mental component score (MCS), the Patient Health Questionnaire (PHQ-9), EQ-5D-5L, KDQOL-36 symptom scores, and serum albumin. The PHS was hypothesized to be strongly associated with other measures of physical health, and the MHS with other measures of mental health.

Results: Correlations with the PROMIS PHS and MHS (Table) with legacy health-related quality of life measures were large. The patterns of correlations of the PHS and MHS were consistent with a-priori hypotheses. Patients on dialysis were older (mean[SD] age 64(14) vs 50(15) years), and less likely to be White (32% vs 68%); p<0.01 for all. Kidney transplant recipients reported better health than patients on dialysis: PHS (mean[SD] 47[10] vs 37[9], p<0.001) and MHS (50[9] vs 45[9], p<0.001) and this remained significant in multivariable adjusted (age, sex, ethnicity, marital status, comorbidity, serum albumin and hemoglobin) regression models (coefficient[95% CI] of difference between dialysis and transplant for PH:5.9 [3.8-7.9]; for MH: 3.2 [1.0-5.3]; both p<0.01).

Conclusions: These results support the construct validity of PROMIS PHS and MHS scores among patients treated with kidney replacement therapies. PHS and MHS was substantially better among kidney recipients compared to patients on dialysis.

Table

PROMIS Profile	PCS	MCS	PHQ-9	EQ5D5L	KDQOL-36 Symptoms	Serum albumin
PHS	0.81	0.39	-0.48*	0.66	0.58	0.44
MHS	0.65	0.66	-0.74*	0.67	0.69	0.24

Footnote: * : higher PHS and MHS indicates better health; higher PHQ-9 score indicates more severe depressive symptoms; the correlation is negative

PO2064

Association of Physical Performance with Death or Delisting in Patients Waitlisted for Kidney Transplantation

Anoop Sheshadri,[1,2] Elaine Ku,[2] Deborah B. Adey,[2] Jennifer C. Lai,[2] Kirsten L. Johansen.[3] *[1]San Francisco VA Health Care System, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]Hennepin Healthcare, Minneapolis, MN.*

Background: Patients awaiting kidney transplantation (KT) often report impairments in functional status, which are associated with higher risk of death or delisting. However, self-reported functional status is subjective and can differ from objective assessments of physical performance. We sought to determine whether objective metrics of physical performance were associated with death or delisting prior to KT and whether these metrics improve prediction of death or delisting compared with more routinely available clinical data.

Methods: We enrolled 443 patients from the UCSF KT clinic from 12/17–3/20 at an initial or re-evaluation for eligibility for a first KT. We administered the Short Physical Performance Battery (SPPB; including gait speed, balance, and sit-to-stand) and measured grip strength by dynamometer. We performed univariable and multivariable Cox models to examine the association between physical performance and death or delisting. We created models using combinations of metrics in addition to a "base" model for death or delisting (age, sex, diabetes, CAD, CVD, PVD, years on dialysis) and calculated Harrell's concordance index for each model.

Results: Median age was 55 years, and 63% were male. Median SPPB score was 10 (8, 11), with 25.1% having gait speed <0.8 m/s. In multivariable analysis, lower SPPB and slower gait were associated with higher risk of death or delisting, and higher grip strength with lower risk (Table 1). Compared with the base model (C-index 0.70, strongest predictor: age), addition of SPPB (0.74; p=0.03) and SPPB + grip strength (0.75, p=0.03) improved discrimination.

Conclusions: SPPB, grip strength, and slower gait were associated with death or delisting. SPPB and grip strength improved prediction of death or delisting. Transplant centers should consider routinely evaluating physical performance for waitlisted patients to help with clinical decision making.

Development of a Conceptual Model to Understand Disease Burden in Kidney Transplantation

Chris Marshall,[1] Garima Sharma,[2] Christel Naujoks,[2] Hakam Gharbi,[2] Hannah C. Pegram,[1] Natalie V. Aldhouse,[1] Fiona Brown,[1] Daniel Kuessner.[2] *[1]DRG Abacus (Part of Clarivate), London, United Kingdom; [2]Novartis AG, Basel, Switzerland.*

Background: While kidney transplantation offers patients with end stage kidney disease significant health benefits compared to dialysis, the immunosuppressive therapies designed to improve graft survival result in complex treatment regimens and side effects for patients. The development of new therapies to reduce this patient burden and improve long-term patient outcomes is needed. To guide selection of patient-reported outcome (PRO) measures for clinical trials, it is important to understand how patients feel or function related to a health condition or its treatment. This study sought to develop a preliminary conceptual model in kidney transplantation to provide a visual representation of the concepts of importance to patients (signs, symptoms, and impacts).

Methods: A targeted review of published literature was conducted in Embase, Medline, and PsycInfo databases to identify qualitative articles describing the patient experience following kidney transplantation and associated use of immunosuppressive treatment. Studies were selected based on number of concepts and direct patient quotations available for thematic analysis.

Results: From 61 eligible publications identified for full-text review, 20 were selected for data extraction. All studies involved qualitative interviews, focus groups, or analysis with kidney transplant recipients, and were conducted across various geographic locations (US, Europe and Australia). The most frequently reported concepts across studies included: 'feeling anxious/worried' (100%, n=20); 'feeling distressed, overwhelmed' (75%, n=15); 'fatigue' (60%, n=12); and 'weight gain/loss' (60%, n=12). The conceptual model identified nine domains to group the concepts as reported in the literature. These domains were delineated into the proximal effects of kidney transplantation (side effects and illnesses; physical/cosmetic changes; functional limitations; taxing medication regimen; and frequent medical appointments); and the more distal impacts (impacts on emotions, work, lifestyle, and relationships).

Conclusions: The conceptual model was based on a rich source of patient quotes and provides an important first step to understand the patient experience of kidney transplantation and inform the selection of PRO measures for use in clinical trials based on their conceptual coverage.

PO2066

Customizing PROMIS-Depression Computer Adaptive Testing Stopping Rules for Patients with Kidney Failure

Tibyan Ahmed, Nathaniel Edwards, Setareh Aghamohammadi, Kaiyi Liu, Nawang Yanga, Istvan Mucsi. Kidney Health Education and Research Group *University Health Network, Toronto, ON, Canada.*

Background: The Patient Reported Outcomes Measurement Information System Depression (PROMIS-D) computer adaptive testing (CAT) allows precise and tailored assessment of depressive symptoms. Due to the default stopping rules, many respondents without depression may need to answer 10-12 items. The maximum number of items required by the stopping rule can be reduced which could improve efficiency when the tool is used for screening. We assess the screening performance of customized CAT stopping rules in patients with kidney failure.

Methods: A cross-sectional convenience sample of adults with kidney failure treated with dialysis or kidney transplant completed PROMIS-D CAT as well as the Patient-Health Questionnaire-9 (PHQ-9). Moderate/severe depressive symptoms were defined as a PHQ-9 cut-off score ≥10. Sociodemographic and clinical characteristics were obtained from self-report and medical records. All patients completed CAT using the original stopping rule (CAT_0) that requires a reliability of >90% or maximum 12 items. We compare this to three simulated CAT customizations with maximum 8, 6 and 4 items (CAT_8, CAT_6 and CAT_4) respectively. Reliable T score range (reliability is >90%), sensitivity and specificity of each version were assessed.

Results: Of the 336 patients, the mean SD age was 55(16), 63% were male, 49% were Caucasian and 32% were on dialysis. Based on PHQ-9, 16% reported moderate/severe depressive symptoms. Using a PHQ-9≥10 as a reference for moderate/severe depressive symptoms, sensitivity and specificity of a T score of 55 with CAT_0 was 79% and 81% respectively. CAT_8 presented no change in the reliable range (T-score 41 to 84), while CAT_6 and CAT_4 presented a small reduction in the reliable range (41-76 and 45-73 respectively) compared to CAT_0. Sensitivity and specificity of the modified CAT versions remained essentially the same.

Conclusions: Customizing PROMIS-D CAT stopping rules have the potential to improve efficiency of screening for moderate/severe depressive symptoms. This reduces question burden without change in the discrimination of the T score. A PROMIS-D CAT with modified stopping rule (maximum 6 or even 4 items) could be used for screening for depressive symptoms among patients with kidney failure.

PO2067

Pre-Transplant Sarcopenia Does Not Predict Graft Function or Mortality in Kidney Transplantation

Taylor Norris, Neal Montgomery, Shelby Fishback, Diane M. Cibrik, Aditi Gupta. *University of Kansas Medical Center, Kansas City, KS.*

Background: Sarcopenia is common in end stage kidney disease (ESKD), and is associated with increased risk of cardiovascular events and mortality. The association between pre-transplant sarcopenia and post-transplant outcomes is unknown.

Methods: We conducted a single-center retrospective study to evaluate the association between pre-transplant psoas muscle cross-sectional area at level of L4 and post-transplant outcomes; change in graft function, length of hospitalization, rehospitalization at 30- and 90-days post-transplant, graft loss, and mortality.

Results: Of the 573 patients with pre-transplant CT images, 465 received kidney transplant (KT) alone, 71 received simultaneous liver-kidney transplantation (SLK), and 37 received simultaneous pancreas-kidney (SPK) transplantation. Pre-transplant psoas muscle cross sectional area was associated with longer hospitalization in KT alone and SPK transplants, but not with post-transplant graft function, rehospitalization rates or mortality (Table 1).

Conclusions: Unlike ESKD patients on dialysis, pre-transplant psoas muscle cross-sectional area is not associated with adverse post-transplant outcomes. Thus, sarcopenia should not be an exclusion criterion for transplant eligibility.

Cox proportional hazard models (adjusted for age, sex, race and diabetes) for normalized psoas cross sectional area and post-transplant outcomes.

PO2068

Utility of Genetic Testing in Kidney Transplant Evaluation

Lauren Beretich,[1] Neeraj Singh,[2,3] Arianna Palermini,[4] Aleeza Qamar,[2,3] Daniel Luksic,[1] Sarah McCormick,[1] Hossein Tabriziani,[1] Paul R. Billings.[1] *[1]Natera, Inc., San Carlos, CA; [2]John C. McDonald Regional Transplant Center, Shreveport, LA; [3]Willis-Knighton Physicians Network, Shreveport, LA; [4]Arkansas College of Osteopathic Medicine, Fort Smith, AR.*

Background: Genetic testing is an emerging tool in pre-kidney transplant (KT) evaluations for individuals with end-stage renal disease (ESRD). A known genetic etiology can inform the risk of disease recurrence, guide transplant management, and enable evaluation of living related donors. Despite these benefits, there is a paucity of literature describing the use of diagnostic genetic testing as part of the pre-KT evaluation. Here we describe the initial experience incorporating a broad renal genetic testing panel for KT candidates in one Louisiana center.

Methods: A retrospective review was conducted on 31 patients that underwent a KT evaluation in April 2021 with Renasight™, a NGS-based >380-gene kidney disease test. The patients were primarily female (20/31), African American (16/31), and <50 years of age (17/31). The primary clinical causes of CKD were hypertension (HTN) and/or diabetes (20/31).

Results: Positive findings were identified in 32.3% (10/31) of patients in the *APOL1*, *CFI*, *COL4A4*, and *PKD2* genes. Additionally, 29.0% (9/31) of the patients were identified as heterozygous carriers of autosomal recessive conditions. Of the positive cases, 60% (6/10) were either homozygous or compound heterozygous for the G1 and G2 risk alleles in the APOL1 gene. One individual, heterozygous for a likely pathogenic variant (c.57+1G>C) in the *CFI* gene, associated with atypical hemolytic uremic syndrome, along with biopsy-proven thrombotic microangiopathy was tested for complement proteins in plasma. Due to the potential increased risk of recurrence, simultaneous liver-kidney transplant and Eculizumab was considered.

Conclusions: In this initial experience, kidney genetic testing was an informative tool resulting in a change in patient management. The genetic testing yield in this cohort is likely enriched as many of these patients had a positive family history of kidney disease, significant proteinuria, or ESRD attributed to HTN. Genetic testing in pre-KT patients has potential clinical impact on post-KT management and selection of living-related donors. Further research is needed to describe the utility of genetic testing for kidney transplant candidates.

PO2069

Transplant Clinician Opinions on Use of Race in the Estimation of Glomerular Filtration Rate: A National US Survey Study

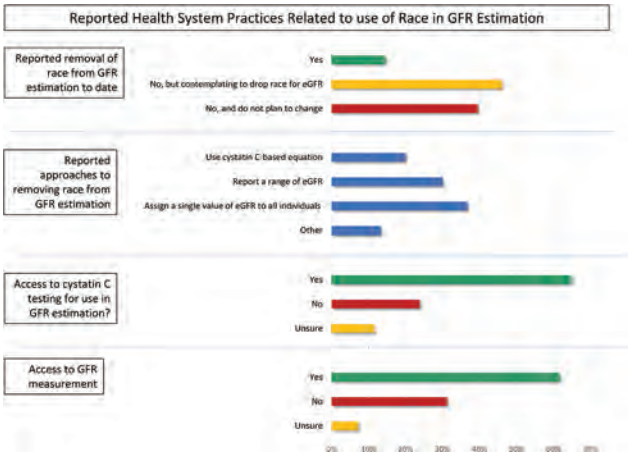
Krista L. Lentine,[1] Neeraj Singh,[2] Benjamin E. Hippen,[6] Kenneth J. Woodside,[5] Prince M. Anand,[3] Matthew Cooper,[7] Darshana M. Dadhania,[4] Sruthi Ainapurapu,[1] Mona D. Doshi.[5] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]LSU Health New Orleans, New Orleans, LA; [3]Geisinger Health, Danville, PA; [4]Weill Cornell Medicine, New York, NY; [5]University of Michigan Health System, Ann Arbor, MI; [6]Metrolina Nephrology, Charlotte, NC; [7]MedStar Health, Columbia, MD.*

Background: Inclusion of race in eGFR calculation has raised controversies based on concern that assigning a higher GFR to Black patients delays opportunity for pre-emptive kidney transplant listing.

Methods: We conducted a survey of adult kidney transplant center staff in U.S (12/17/2020–2/28/2021) to assess opinions on use of race-based estimated GFR (eGFR) equations for waitlisting and living donor candidate evaluation, availability of serum cystatin-C testing and measured GFR, and related practices.

Results: Respondents represented 57% (124/218) of adult kidney transplant centers and 70.3% of recent practice volume. Nearly 95% of respondents felt that current race-based eGFR calculators need revision, primarily due to concerns around healthcare disparities and inaccuracies around reporting of race, particularly among multi-racial individuals. A majority of respondents (70.5%) believed that elimination of race would allow preemptive kidney transplant wait listing for Black patients, but a similar number (69%) also raised concern that removing race from GFR estimation could incur harms. One-third of responding programs lacked or were unsure of availability of cystatin C or mGFR at their institution. Nearly 15% of responding centers have removed race from GFR estimation and were either reporting eGFR for non-Black or ranges; 46% were planning to do so and 39.5% did not plan to change for now (**Figure**). There was no difference in GFR acceptance threshold for Black versus non-Black living donors.

Conclusions: This national survey highlights a broad consensus that extant approaches to eGFR calculations are unsatisfactory, but a range of opinion on what should replace the status quo. National consensus, guidelines, and infrastructure for laboratory testing are necessary to facilitate best practices to prevent further disparities in transplant care.



PO2070

Defining the Living Donor Transplant Evaluation Process for Optimization of a One-Day Evaluation Program

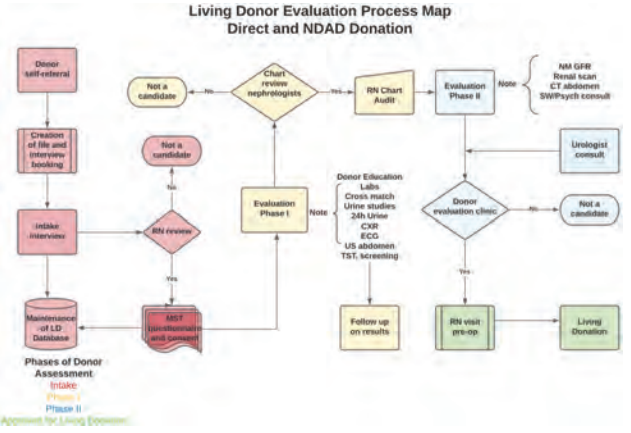
Ariana Noel,[1,2] Greg A. Knoll,[1,2] Ann Bugeja.[1,2] *[1]University of Ottawa, Ottawa, ON, Canada; [2]Ottawa Hospital, Ottawa, ON, Canada.*

Background: Living donor transplantation provides patients with end stage kidney disease increased longevity and quality of life compared with dialysis. The donor evaluation process can be inefficient and costly for patients and the healthcare system. There is a paucity of research on evaluation optimization in living kidney transplantation. We investigated our living donor evaluation process to develop a one-day program, improving program efficiency.

Methods: Living donor staff and patient partner from The Ottawa Hospital Living Kidney Donor program participated in individual, semi-structured interviews to develop a Lucidchart process map of the donor evaluation process and ascertain the time associated with each step. A one-day evaluation program model was developed based on our process map and interview participant feedback. Amount of time for each step of the process was collected for future cost assessment.

Results: Mean time to complete the evaluation process and reach donor approval is 9 months. The donor evaluation process can be divided into 3 phases: Initial Interview, Phase I, and Phase II. Phase I requires the most nursing and administrative time. The greatest barriers to process efficiency are 24-hour urine collections to estimate kidney function and coordinator time spent on correspondence with laboratories. A one-day evaluation will reduce the evaluation process and approval to approximately 4 weeks. Greatest barriers for patients included need for increased education and time off work. Next steps will include cost estimates of the current program with the goal of implementing a one-day evaluation program at The Ottawa Hospital.

Conclusions: A one-day evaluation program will increase the efficiency of the living donor process for donors, coordinators, and recipients. Phase I investigations are a barrier to program efficiency and can be streamlined with a one-day evaluation. The development of donor educational resources will improve the donation experience for patients.



PO2071

Comparison of CT Volumetry vs. Nuclear Renography to Predict Remaining Kidney Function After Living Kidney Donation

Sang Hun Eum, Hanbi Lee, Chul Woo Yang, Byung ha Chung. *Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Background: Computed tomography(CT) and nuclear renography are performed to decide kidney procurement. The aim of this study was to compare single kidney(sk) function and single kidney(sk) volume in predicting post-donation kidney function. Further, we aimed to investigate which modality is better to decide which kidney is more appropriate in terms of kidney function recovery, especially when the results were contradictory.

Methods: CT volumetry and nuclear renography from 835 kidney donors were retrospectively included. We investigated correlation between sk-volume and sk-mGFR and the agreement of two modalities. Mismatch was defined as sk-volume higher and sk-mGFR smaller than the other kidney, or vice versa. We compared the predictive value for post-donation kidney function between two modalities in total group and in mismatched group. Based upon decision preference, we compared kidney function recovery between two modalities at 6 months after donation.

Results: Mean baseline estimated GFR was 100.01ml/min/1.73m^2. The mean right and left sk-volume were 171.18 and 179.71cm^3 and mean right and left sk-mGFR were 53.72 and 53.44ml/min, respectively. 701(83.96%) donated left kidney. Sk-mGFR and sk-volume showed significant correlation(r=0.484, P<0.001) and the results showed significant agreement in Bland-Altman plot and Intraclass correlation coefficient was 0.647(P<0.001). In total group, CT volumetry was superior to nuclear renography in predicting kidney function after donation(1 month: β_{CT}=0.402, P<0.001, $\beta_{renography}$=0.242, P<0.001; 6 months: β_{CT}=0.448, P<0.001, $\beta_{renography}$ =0.214, P<0.001) by multivariable linear regression analysis. In mismatched group(326 donors), CT volumetry still outweighed nuclear renography(1 month: β_{CT}=0.453, P<0.001, $\beta_{renography}$=0.259, P<0.001; 6 months: β_{CT}=0.480, P<0.001, $\beta_{renography}$=0.285, P<0.001). When mismatch occured, 260(79.75%) procurements were decided by nuclear renography. Functional recovery was higher in CT volumetry preferred group, although it did not reach statistical significance(33.99% vs 30.09%, P=0.098).

Conclusions: CT volumetry was appropriate to assess single kidney function and it outperformed nuclear renography in predicting kidney function after donation. Therefore, when contradictory results between left and right kidney occur, CT volumetry can be preferred in procurement strategy.

PO2072

The Impact of New-Onset Diabetes After Transplantation on Survival and Major Cardiovascular Events in Korean Kidney Transplantation Recipients

Jangwook Lee,[1] Donghyun Kang,[5] Sehoon Park,[6] Ji Eun Kim,[7] Eunjeong Kang,[2] Yaerim Kim,[3] Yong Chul Kim,[4] Yon Su Kim,[4] Yaeji Lim,[5] Hajeong Lee.[4]
[1]Dongguk University Medical Center, Goyang, Gyeonggi, Republic of Korea; [2]Ewha womans University Seoul Hospital, Seoul, Republic of Korea; [3]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [4]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [5]Chung-Ang University, Seoul, Seoul, Republic of Korea; [6]Armed Forces Capital Hospital, Seongnam, Gyeonggi-do, Republic of Korea; [7]Korea University Guro Hospital, Seoul, Republic of Korea.

Background: New-onset diabetes after transplantation (NODAT) is a frequent complication in kidney transplant (KT) recipients with unfavorable outcomes, although a nationwide study on epidemiology and clinical outcome of NODAT in Korean KT recipients remain rare.

Methods: We identified KT recipients by using a Health Insurance Review and Assessment Service of South Korea from the year of 2008 to 2017. We excluded patients with preexisting diabetes, multi-organ transplantation, and being progressed to graft failure less than 1 year after KT. NODAT was defined as consecutive 30 days prescription history of antidiabetic medication after KT. We analyzed the impact of NODAT on death censored graft failure (DCGF), death without graft failure (DWGF), and major adverse cardiovascular events (MACE) by time-dependent Cox analysis.

Results: Among a total of 16,719 KT recipients, 10,311 were included after exclusion. 19.8 percent of KT recipients were diagnosed to NODAT. The proportion of patients developing NODAT tended to increase, and 64% of NODAT was diagnosed within the first 6-months after KT. NODAT patients were older, more men, having longer pre-KT dialysis vintages, and being exposed more basiliximab induction and more rejection episodes requiring high-dose steroids treatment after KT. During follow-up, 520 DCGF, 180 DWGF, and 213 MACE events were occurred. NODAT patients showed higher risks of DCGF (adjusted hazard ratio [aHR], 1.87; 95% confidence interval [CI], 1.52-2.3; p < 0.001), DWGF (aHR 1.77;95% CI, 1.28-2.43;p<0.001), and MACE (aHR 1.46;95% CI, 1.08-1.96;p=0.013) than patients without NODAT. Twenty-one percent of NODAT patients could be stopped their anti-diabetic medications after the diagnosis, although this did not affect the clinical outcomes.

Conclusions: About 20% of diabetes-naïve KT recipients were diagnosed with NODAT with a recently increasing pattern. NODAT in KT recipients affected worse graft and patients outcomes as well as MACE.

Funding: Government Support - Non-U.S.

Association Between Early Post-Transplant Hypertension or Related Antihypertensive Use and Prognosis of Kidney Transplant Recipients: A Nationwide Observational Study

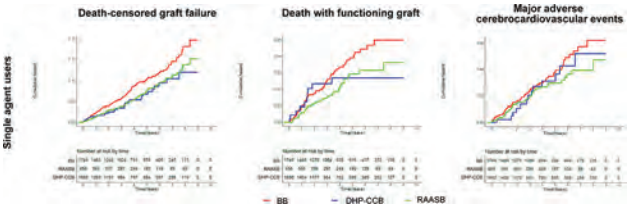
Sehoon Park,[1] Yaerim Kim,[2] Yong Chul Kim,[3] Yon Su Kim,[3,1] Hajeong Lee.[3,1]
[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.

Background: Additional research is warranted for the clinical significance of post-transplant hypertension and related antihypertensive medication usage in kidney transplant (KT) recipients.

Methods: This observational study included nationwide KT recipients who maintained functioning graft for at least 1 year after KT in South Korea during 2008 to 2017. The usage of antihypertensive medications between 6 months to 1 year was the main exposure, and those who had inconsistent/transient usage of antihypertensive drugs were excluded. The prognostic outcome included death-censored graft failure (DCGF), death-with functioning graft (DWGF), and major adverse cerebrocardiovascular events (MACCEs).

Results: We included 8014 patients without post-transplant hypertension and 6114 recipients who received treatments for hypertension in the post-transplant period. Those with post-transplant hypertension had significantly worse risk of DCGF than those without [adjusted hazard ratio (HR) 1.27 (1.09-1.48)]. Post-transplant hypertension patients who required multiple drugs showed significantly higher risk of DWGF [HR 1.57 (1.17-2.10)] and MACCE [HR 1.35 (1.01-1.81)] than the controls. Among the single-agent users, those who received beta-blockers showed a significantly higher risk of DCGF, although the risks of DWGF or MACCE were similar between the types of antihypertensive agents. Among the multiple agent users, the prognosis was similar regardless of the prescribed types of antihypertensive agents.

Conclusions: Post-transplant hypertension was associated with poor post-transplant prognosis, particularly when multiple types of medications were required for treatment. During initial prescription of antihypertensive medication, clinicians may consider that beta-blockers were associated with a higher risk of DCGF in the single-agent users.



PO2074

Mortality, Graft Survival, and Cardiovascular Outcomes in Adult Kidney Transplant Recipients with Post-Transplant Anemia: An Updated Meta-Analysis

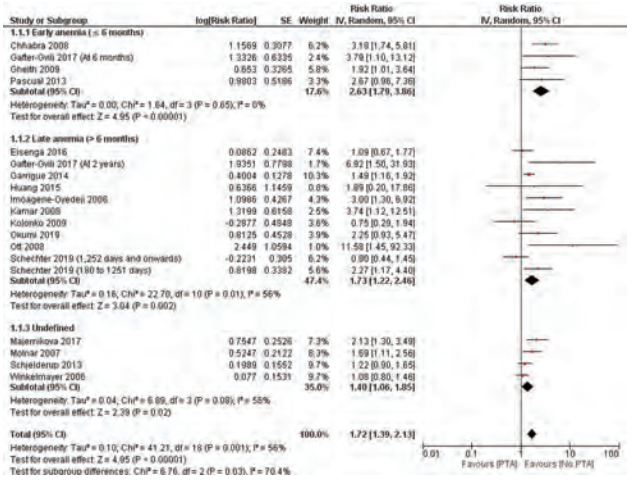
Poemlarp Mekraksakit,[1] Natnicha Leelaviwat,[1] Boonphiphop Boonpheng,[2] Wisit Cheungpasitporn,[3] Camilo Pena,[1] Gaspar Del Rio-Pertuz,[1] Ramesh Saxena.[4]
[1]Texas Tech University Health Sciences Center, Lubbock, TX; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Mayo Clinic Minnesota, Rochester, MN; [4]The University of Texas Southwestern Medical Center, Dallas, TX.

Background: Post-transplant anemia (PTA) is a common finding after kidney transplantation. A previous meta-analysis reported an association between PTA and graft loss. However, data on cardiovascular outcomes have not yet been reported. We conducted an updated meta-analysis to examine the association between PTA and prognosis in adult kidney transplant recipients.

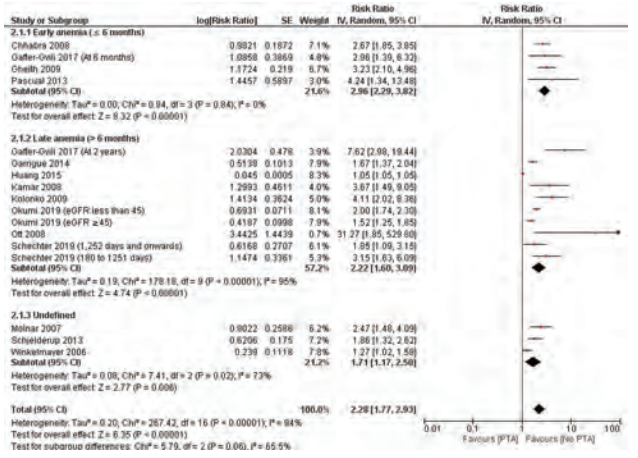
Methods: We comprehensively searched the databases of MEDLINE and EMBASE from inception to January 2021. Data from each study were combined using the random-effects model.

Results: Seventeen studies from August 2006 to April 2019 were included (16,463 KT recipients). The PTA was associated with overall mortality (pooled RR=1.72 [1.39, 2.13], I^2=56%), graft failure (pooled RR=2.28 [1.77, 2.93], I^2=94%), cardiovascular death (pooled RR=2.06 [1.35, 3.16], I^2=0%), and cardiovascular events (pooled RR=1.33 [1.10, 1.61], I^2=0%). Early PTA (≤ 6 months), compared with late PTA (> 6 months), has higher risk of overall mortality and graft loss with a pooled risk ratio of 2.63 (95% CI 1.79-3.86, I^2=0%) and 2.96 (95% CI 2.29-3.82, I^2=0%), respectively.

Conclusions: Our meta-analysis demonstrates that PTA was significantly associated with overall mortality, graft failure, cardiovascular death, and cardiovascular events.



The association between PTA and overall mortality



The association between PTA and graft loss

PO2075

Mortality Risk Factors of COVID-19 Infection in Kidney Transplantation Recipients: A Systematic Review and Meta-Analysis of Cohorts and Clinical Registries

Suwasin Udomkarnjananun,[1,2] Stephen J. Kerr.[1] [1]*Chulalongkorn University, Bangkok, Thailand;* [2]*Erasmus MC, Rotterdam, Netherlands.*

Background: Kidney transplantation recipients (KTR) with coronavirus disease 2019 (COVID-19) are at higher risk of death than general population. However, mortality risk factors in KTR are still not clearly identified. Our objective was to systematically analyze published evidence for risk factors associated with mortality in COVID-19 KTR.

Methods: Electronic databases were searched for eligible studies on 8 January 2021. All prospective and retrospective studies of COVID-19 in KTR were considered eligible without language restriction. Since data in case reports and series could potentially be subsets of larger studies, only studies with ≥50 patients were included. Random-effects model meta-analysis was used to calculate weighted mean difference (WMD) and pooled odds ratio (OR) of factors associated with mortality.

Results: From a total 566 articles retrieved, 10 were included in the meta-analysis comprising 1,778 KTR. Of these, 1,349 (76%) were survivors and 419 (24%) were non-survivors. Compared with survivors, non-survivors were significantly older (WMD 10.5 years, 95%-CI 9.0-12.0) and had shorter symptom onset before admission (WMD -1.3 days, 95%-CI -2.2, -0.3). KTR of deceased donor were at higher risk of death (OR 2.08, 95%-CI 1.03-4.20). Comorbidities including diabetes, cardiovascular disease, and cancer significantly increased mortality risk. KTR with dyspnea (OR 3.40, 95%-CI 2.51-4.60) and pneumonia (OR 3.01, 95%-CI 1.63-5.55) at presentation were at higher mortality risk, while diarrhea decreased the risk (OR 0.53, 95%-CI 0.39-0.72). Acute kidney injury was associated with mortality (OR 1.74, 95%-CI 1.01-2.98). Inflammatory markers were significantly higher in the non-survivors, including lactate dehydrogenase, C-reactive protein, D-dimer, pro-calcitonin, and interleukine-6.

Conclusions: A number of COVID-19 mortality risk factors were identified from KTR patient characteristics, presenting symptoms, and laboratory investigations. KTR with these risk factors should receive more intensive monitoring and early therapeutic interventions to optimize health outcomes.

PO2076

Impact of Native Kidney Disease on Post-Transplant Cancer Development

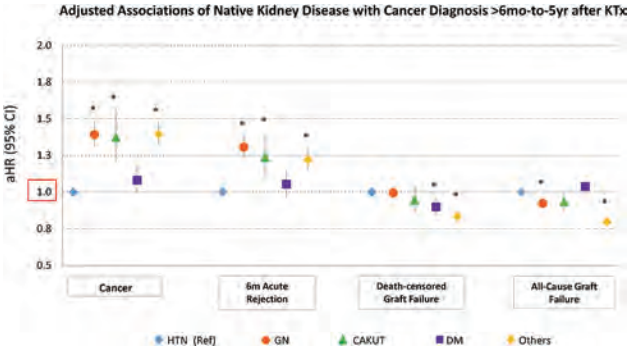
Yasar Caliskan,[1] David Axelrod,[2] Ruixin Li,[1] Wisit Cheungpasitporn,[3] Mark Schnitzler,[1] Tarek Alhamad,[4] Su-Hsin Chang,[4] Krista L. Lentine.[1] [1]*Saint Louis University School of Medicine, Saint Louis, MO;* [2]*The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA;* [3]*Mayo Clinic Minnesota, Rochester, MN;* [4]*Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Long-term risk of cancer development among patients with glomerulonephritis (GN) and congenital anomalies of the kidney and urinary tract (CAKUT) have been shown previously. However, the association between native kidney disease and *de novo* cancers after kidney transplantation (KTx) needed to be clarified.

Methods: We examined national Scientific Registry of Transplant Recipients (SRTR) data for patients underwent KTx (2000-2021) to investigate the association of native kidney disease with *de novo* cancer diagnoses after KTx. Patient with history of previous transplant and patients with history of cancer before KTx were excluded. We identified KTx recipients with hypertension (HTN) (n=68432), diabetes mellitus (DM) (n=79809), glomerulonephritis (GN) (n=54381), CAKUT (n=6508) and others (n=56048) as cause of native kidney disease.

Results: Compared with the reference HTN group, GN (aHR, $_{1.31}1.39_{1.48}$) and CAKUT (aHR, $_{1.20}1.37_{1.57}$) groups are significantly associated with higher risk of new onset cancers at 5 years post-KTx (Figure 1). GN (aHR, $_{1.23}1.31_{1.39}$) and CAKUT (aHR, $_{1.09}1.24_{1.40}$) groups are also associated with a higher risk of acute rejection within the 6 months post-KTx. Regarding graft failure, GN (aHR, $_{0.89}0.92_{0.95}$) and others (aHR, $_{0.77}0.80_{0.82}$) groups have significantly lower risk of 5 years all cause graft failure compared to reference group. However, the risk of death censored graft failure was significantly lower in DM (aHR, $_{0.84}0.90_{0.96}$) and others (aHR, $_{0.80}0.83_{0.87}$) groups.

Conclusions: Native kidney diseases, GN and CAKUT, have been associated with acute rejection and *de novo* cancers after KTx. Immunosuppressive treatment and cancer screening may need to be modified according to native kidney disease.



PO2077

Effect of Cold Ischemia Time on Death-Censored Graft Survival of Post-One-Year Survivor Deceased Donor Kidney Transplant Recipients in the United States

Bhamidipati V. Murthy, Ahmed A. Awan, Abbas Rana, John A. Goss. *Baylor College of Medicine, Houston, TX.*

Background: Prolonged cold ischemia has been associated with increased incidence of delayed graft function and poor short term graft survival among deceased donor allografts. However, the data on long term graft survival is less clear. Our aim was to evaluate long-term graft survival for deceased donor kidney recipients who survived one year after transplantation such that the immediate adverse outcomes do not cloud the long term outcomes

Methods: We retrospectively analyzed data from the United Network for Organ Sharing (UNOS) from 1995 to 2017. Living donor transplants, multi-organ transplants, recipients <18 years age at transplantation, and those who died within 1 year of transplantation were excluded. Using multivariable Cox regression analysis, a total of 145,680 recipients were analyzed with death censoring to estimate graft survival with varying cold ischemia times

Results: Compared with cold ischemic time of <5 hours, the graft failure probability steadily increased with increasing cold ischemia time such that the hazards of graft loss were 42% higher with ischemic time greater than 35 hours (Figure 1). Worse graft survival was also observed in males (HR 1.08), increasing donor age beyond 30 years, Blacks (HR 1.77), BMI >30 (HR 1.13), those who had dialysis prior to transplant (HR 1.41), diabetes (HR 1.12), and PRA >90% (HR 1.16). Recipients older than 40 years had a lower graft loss compared to those between 18 and 40 years age.

Conclusions: Prolonged cold ischemia time adversely affects long-term graft survival among deceased donor kidney transplant recipients in the US. The hazards of graft loss appear to be proportional to the duration of cold ischemia time.

Hazards of Graft Loss with Increasing Cold Ischemia Time In Deceased Donor Kidney Allografts

PO2078

Polygenic Burden for Intracranial Aneurysm and Hypertension in Deceased Kidney Donors Who Died of Intracranial Haemorrhage

Kane E. Collins,[1] Gianpiero Cavalleri,[1] Edmund H. Gilbert,[1] Elhussein A. Elhassan,[2] Peter J. Conlon.[2,1] Human Genetic Variation Research Group *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland.*

Background: A polygenic risk score (PRS) estimates the cumulative effect of common genetic variation on an individual's disease status. It is calculated by summing up all the effect alleles present in the individual, weighted by the effect size, as measured in a GWAS. Intracranial haemorrhage is a common cause of death among kidney donors, but limited research has been done to investigate polygenic burden for intracranial aneurysm (IA) and hypertension in deceased transplant donors.

Methods: Our data consisted of 2,122 genotyped donor-recipient pairs from the United Kingdom and Ireland Renal Transplant Consortium (UKIRTC) and 5,519 controls from the 1958 British Birth Cohort and UK Blood Service. We created polygenic risk scores for IA and hypertension using published GWAS summary statistics from 7,495 cases and 71,934 controls for IA and 76,566 cases and 206,305 controls for hypertension. We investigated the difference in PRS between the UKIRTC donors who died of intracranial haemorrhage (1,303 individuals) and the controls while adjusting for covariates of sex and the first 4 principal components.

Results: We found that the IA PRS explained 4.1% of the variance between case and control status (p-value: 9.6×10^{-39}). The odds ratio on the phenotype for those in the lowest demi-decile of the IA PRS was 0.52 (95% CI: 0.34-0.82) compared to 2.8 (1.9-4.0) for those in the highest demi-decile. Similarly, the PRS for hypertension explained 1% of the variance (p-value: 7.5×10^{-10}) and the corresponding odds ratios were 0.68 (CI: 0.46-1.0) and 1.5 (1.1-2.3) for those in the lowest and highest demi-deciles respectively.

Conclusions: PRSs for IA and hypertension based on these data appear to explain 4% and 1% respectively of the variance in case-control status between kidney donors who have died of intracerebral haemorrhage and controls. These observations could have utility in testing relatives of donors who died of intracranial haemorrhage to determine if they share the same risk for intracerebral haemorrhage and if so to may be useful in advising regarding screening or other precautions to minimise their risk of intracerebral haemorrhage. These observations need to be confirmed in other cohorts. Further studies using similar approaches could investigate other causes of death among kidney donors.

PO2079

Characteristics of Potential and Actual Living Kidney Donors: A Single-Center Experience

Liza Cholin, Jesse D. Schold, Emilio D. Poggio, John R. Sedor, Anne M. Huml. *Cleveland Clinic, Cleveland, OH.*

Background: Living kidney donors contribute only 28% of all transplanted kidneys. Our study aimed to examine characteristics of potential compared to actual living kidney donors, in order to better understand barriers to successful donation.

Methods: We performed a retrospective analysis of 1,815 intake forms completed by kidney donor candidates from 2016-2018 at a single transplant center. We analyzed data from all potential donors who completed the intake until they became ineligible or withdrew, or, until donation was reached. Baseline characteristics were compared between potential and actual donor groups.

Results: The donation process was deconstructed into 5 steps. The percentage of potential donor drop out at each step and the most common reason for drop out are shown in Table 1. Of the 125 actual donors, 115 (94.3%) were white and 81 (64.8%) were female. A family member was more likely than an unrelated individual to complete the process. At the intake step 35.5% of potential donors identified as family of the potential recipient; at donation 72.7% were family, $p < 0.001$. Many potential and actual donors were referred by the transplant candidate (56.0% and 43.5%, respectively). Social media networking was a larger contributor to the potential donor pool than a source for actual donors (16.5% in potential donors v 2.4% in actual donors, $p < 0.0001$). There were no significant differences between potential and actual donor group with respect to substance use, marital status, level of education, and employment status.

Conclusions: Kidney donor interest is high in the early steps, but few donor candidates become actual donors. A family relationship increases the likelihood a potential donor will become an actual donor. There is a significant drop out of potential donors for incompatible immunologic testing. Our ability to track all potential donors from initial touchpoint to transplant center will help us develop interventions to counteract identified barriers to successful donation, including better outreach to minority populations and education about kidney exchange programs.

Funding: NIDDK Support

Table 1: LKD Candidate Drop Out by Donation Step

	Intake Questionnaire	Donor Immunologic Compatibility Testing	Clinical Evaluation	Selection Committee Review	Successful Donation
Number of potential donors (% of total)	1266 (69.8)	305 (16.8)	53 (2.9)	66 (3.6)	125 (6.9)
Most common reason for drop out (% at each step)	No response to follow-up phone call (23.9)	Incompatible crossmatch (36.1)	Failure to complete required medical testing (41.5)	Medical disqualification (54.6)	N/A

PO2080

Remnant Kidney Hypertrophy Is Negatively Associated with Albuminuria After Donor Nephrectomy

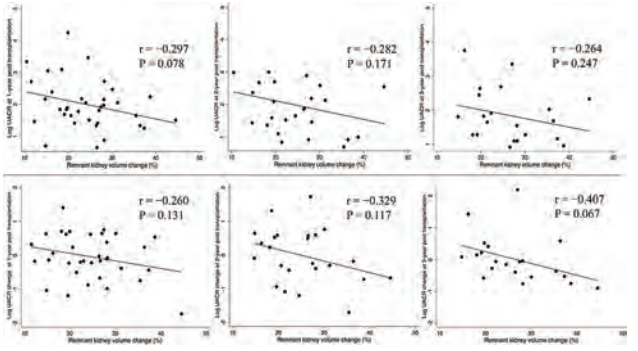
Masatomo Ogata, Takamasa Miyauchi, Kiyomi Osako, Maho Terashita, Naohiko Imai, Yugo Shibagaki, Masahiko Yazawa. *St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Glomerular ultrafiltration pressure in the remnant kidney remains after donor nephrectomy by the compensatory increase in the glomerular ultrafiltration coefficient, consisting of renal blood flow and cortex volume, namely compensatory hypertrophy. This compensation may be related to the protection for the newly or progressively incident albuminuria, a well-known predictor for kidney damage. To elucidate this theory, we analyzed the relationship between the percentage of change in the remnant kidney volume over 1-year post donation and albuminuria after donation.

Methods: This was a retrospective observational study, with 36 living donors who underwent nephrectomy at our hospital between 2011–2018. The mean age of the participants was 59±8 years and 72% of them were female. We reviewed the computed tomography before and 1 year after donation to calculate the change (%) in remnant kidney volume and investigated the associations with absolute values and relative changes in urinary albumin to creatinine ratio (UACR) 1, 2, and 3 years after donation. Pearson's correlation coefficients was used for the significance of association. This study is approved by Institutional Review Committee of St. Marianna University School of Medicine (No. 1574).

Results: Mean remnant kidney volume change percentage 1-year after donation was 24.2±8.0%. Although statistically non-significant, negative associations were suggested between the change in remnant kidney volume and both the absolute values of and % change in UACR (Figure).

Conclusions: Although relationships between change in remnant kidney volume and albuminuria were statistically insignificant due to the small sample size and analysis for not at-risk population, consistently negative associations would suggest the clinical significance. To assess the long-term safety of living donors, the focus might be on whether the remnant kidney can be hypertrophic by compensation.



PO2081

Short-Term Fast Does Not Alter Physiological Parameters in Living Kidney Donors

Keren Tzukert,[1,2] Roy Abel,[1,2] Iddo Z. Ben-Dov,[1,2] Michal Dranitzki Elhalel.[1,2] *[1]Hadassah Medical Center, Jerusalem, Israel; [2]Department of nephrology and hypertension, Hadassah Medical Center and Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel.*

Background: Living kidney donation is widely practiced and short and long-term outcomes are acceptable. Within the living Kidney donor population there are unique ethnic groups, such as Jewish or Muslim individuals, who practice customs that may affect kidney function. In Judaism, YOM KIPPUR (Day of Atonement) is a 25-26 hr fast practiced yearly. This fast, revered and practiced by secular and religious Jews, has enormous cultural significance. There are no studies that describe the effect of this fast on LKD's. We aim to compare kidney function and physiological parameters between healthy controls and LKD's

Methods: LKD's were approached via e-mail. Exclusion criteria were conditions considered prohibitive of fasting. Controls were potential LKD's that have been approved by the standard medical evaluation but have not yet donated. Blood and urine samples were obtained at three time points: Baseline –3 months before fast, Fasting: 1 hr after 24 hr fast, Follow up - 14 days after fast.

Results: 85 LKD's & 27 controls were included. Donors were older (42.8 vs. 38.8 years) and had a higher baseline creatinine (103 vs. 72 umol/L). All other parameters were the same. The change between fasting and non-fasting creatinine was smaller in LKD's than in controls (0.12 vs. 0.21% change P=0.04). Values of sodium, albumin & osmolarity were not different between groups. Time from donation did not influence these results

Conclusions: LKD's practicing a 24 hr fast show a different pattern from controls regarding the change in creatinine levels. This pattern cannot be considered hazardous for LKD's. The emotional wellbeing of LKD's is of utmost importance and this first report of the safety of a 24 hour fast is reassuring. These findings may be of interest to other religious groups, e.g. the Muslim community who practice RAMADAN. Further follow-up is needed to explore the long term effects of a 25-26 fast in the LKD population

PO2082

African American Kidney Donor Denial

Ivan E. Porter. *Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Background: Previous studies have demonstrated that the rate of living kidney donation is lower in African American (AA) compared to the Caucasian population but whether this low donation rate is related to higher denial rates in AA donors is unclear. Comorbidities play a major role in live donors exclusions, especially hypertension and DM, which could affect the pool of potential donors. The aim of our study is to report the rates and causes of living kidney donor denial in our facility and to further stratify the exclusion rate based on race.

Methods: A retrospective cohort study of 439 denied candidates (age ≥18) who underwent evaluation for living kidney donation at our facility in the period from 2006 to 2014 was performed. Donors underwent a 24 hour ambulatory blood pressure monitor, iothalamate GFR, 24 hour urinary protein excretion and CT angiography as part of their donor evaluations. Reasons for denying donors were identified and grouped into 4 groups: 1) Low GFR, 2) Anatomical variation 3) Hypertension and 4) Other causes.

Results: The cohort consisted of 84 AA, 304 Caucasian and 32 Hispanic donors. Hispanic donors were excluded from further analysis. AA donors were younger (P=0.01) compared to Caucasians. Day time and night time systolic and diastolic arterial blood pressure were comparable between AA and Caucasian (P>0.3 for all) Table 1 summarizes the different reasons for donor denial by donor race. There was no difference between AA and Caucasians or Hispanics in the reason for denial for donation

Conclusions: In this limited study the reasons for denial of kidney donation was not different between AA and Caucasians. Given that the disparity remains, other causes for the low donation in the AA population should be explored and mitigated.

Potential Donor Characteristics

	AA donors n=84	Caucasian Donors n=304	p
Caucasian Donors n=304	126 ± 15	127 ± 12	0.46
Day time average diastolic BP	76 ± 9	77 ± 9	0.43
Night time average systolic BP	114 ± 14	112 ± 16	0.39
Night time average diastolic BP	65 ± 8	65 ± 10	0.82
Reason for Denial			
Low GFR	6 (8)	31 (10)	0.70
Anatomical Variation	18 (21)	79 (26)	0.64
Hypertension	19 (23)	65 (21)	0.70
Other	48 (57)	164 (54)	0.61

PO2083

"I Just Don't Trust It": Exploring the Role of Mistrust in Shaping Living Donor Kidney Transplant Pathways for African, Caribbean, and Black communities in Toronto, Canada

Lydia-Joi L. Marshall. *University Health Network, Toronto, ON, Canada.*

Background: In Canada, African, Caribbean, and Black [ACB] patients with kidney failure are 40-70% less likely to receive a LDKT compared to Whites. To date, research has focused on individual factors, neglecting the impact of systemic racism in shaping ACB community attitudes toward LDKT. Further absent is Canadian research using qualitative methodologies.

Methods: We used an exploratory qualitative approach to understand perspectives and attitudes about LDKT in Canadian ACB communities. Using purposive and snowball sampling, we recruited 81 self-identified ACB community participants to take part in eight focus group discussions between January and November 2020. Participants were asked questions about their racial and ethnic identities, medical experiences and attitudes, and knowledge and perspectives on LDKT. We then applied a Critical Race analytical framework to analyze transcripts, focusing on the tenets of racial consciousness, social location, power dynamics, and counternarratives.

Results: Of the 81 participants 63% was female, 46% were <50 years of age, 53% were immigrants to Canada. 36% self-identified as North American Black/African; 48% as Caribbean; 6% as North African; and 4% as Central/West African. Three key themes emerged from the data. First, we found that like in the U.S., participants expressed medical mistrust. Second, this medical mistrust was rooted in a combination of processes of racialization (medical racism), historical legacies of medical mistreatment, and lived negative experiences within the health care system. Lastly, medical mistrust informed health and illness related decision-making risk assessment, perspectives on LDKT, (lack of) engagement with traditional health care settings, and medical needs.

Conclusions: ACB community attitudes and decision-making processes about LDKT are complex, historically-rooted, and informed by broader medical mistrust. This suggests that broader systemic racial barriers to adequate health care outside of the LDKT pathway, may have far-reaching effects. Further research is needed to better understand how the broader medical experiences of ACB communities may be an underappreciated factor that shapes racial disparities in transplantation, and the kinds of interventions needed to facilitate better access to LDKT.

PO2084

Employment Status and Work Functioning in Kidney Transplant Recipients

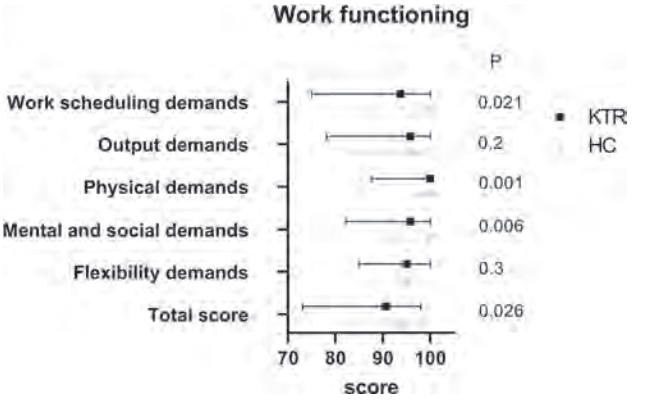
Tim J. Knobbe,[1,2] Daan Kremer,[1,2] Stefan P. Berger,[1,2] Coby Annema,[1,2] Annemieke Visser,[1,2] Stephan J. Bakker.[1,2] *[1]Rijksuniversiteit Groningen, Groningen, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Reliable employment figures of stable kidney transplant recipients (KTR) in Europe are lacking. Additionally, little is known about work functioning among employed KTR, and which clinical factors and (drug-related) side-effects are associated with work functioning.

Methods: We included 668 KTR of working age (59% male, age 51±11 years), at a median of 3 [IQR: 2 to 10] years after transplantation), enrolled in the ongoing TransplantLines Biobank and Cohort Study (NCT03272841, Groningen, The Netherlands). Work and work-related functioning were assessed using the work role functioning questionnaire (WRFQ). Self-reported work ability was assessed using an item of the Work Ability Index (WAI). Results were compared to 246 (43% male, age 53±9 years) potential kidney donors used as healthy controls (HC).

Results: Employment rates were significantly lower among KTR compared to HC (56% vs. 79%, respectively, p<0.001). Employed KTR reported lower work functioning compared to employed HC (median [IQR] WRFQ total score: 94 [75 to 100] vs. 100 [83 to 100], P=0.026, Figure 1). Similarly, self-reported work ability was lower in KTR compared to HC (mean 7.8±1.9 vs. 8.6±1.5, p<0.001). Among KTR, fatigue was most strongly associated with work functioning, independently of potential confounders. Other parameters including anemia, blood albumin, use of beta-blockers, and neurological and mental drug-related side-effects were also independently associated with work functioning.

Conclusions: In our large representative population, only 56% of KTR in their working age were employed. In addition, employed KTR frequently experience impaired work functioning and have limited self-reported work ability. These results underline the individual and societal need to improve employment rates and work-related functioning among KTR. Fatigue, anemia, nutritional status, beta-blocker use, and drug-related side-effects may be potential targets, and should be further investigated.



PO2085

A2 to B Deceased Donor Renal Transplantation Outcome Analysis: A Single-Center Experience

Sandiya Bindroo, Mona D. Doshi. *University of Michigan, Ann Arbor, MI.*

Background: A2 to B renal transplantation has been underused and significant knowledge gaps are noted in areas of rejections, infection rate, and anti-A titer thresholds post-transplant. The purpose of our study is to assess antibody mediated rejection (AMR) rates in A2 to B DDKT and determine association with anti-A IgG titers. We also assessed graft function, rejection and infection rates.

Methods: Retrospective chart review of 55 A2 to B DDKT performed at the University of Michigan from January 2015 to September 2020 was done. All patients received Thymoglobulin for induction and were maintained on triple immunosuppression. All patients underwent monitoring of anti-A2 titers and surveillance biopsy at 3-, 6- and 12- months after transplant. Other outcomes included graft function, rejection and infection rates at last follow-up.

Results: Our cohort consisted of 55 recipients with mean age of 54(±13) years, 67% males and 29% African Americans. The median follow-up time was 2.5 [0.5-5] years. Ten developed acute rejection at 3 [1-6] months after transplant. One patient developed hyper-acute rejection due to ABO incompatibility, five developed T cell mediated rejection, and four had AMR due to donor specific antibodies (DSA) against HLA. Anti-A titers remained undetectable or less (< 1:4) in 98% patients in post-transplant period with no increase in titers at 3-6 month follow up. Anti-A titer increased to 1:128 in one patient with hyper acute rejection. Overall, 20% mortality was noted, unrelated to graft dysfunction at median follow-up of 1.8 [0.08-4] years. Post-transplant infections (bacterial, viral and fungal) accounted for 41% cases. BK viremia noted in 20% with BK nephropathy in six. The mean (SD) glomerular filtration rate, creatinine and urine protein creatinine ratio at three months, one year and at last follow up post-transplant was 49 (14.69), 1.4(0.47), 0.32 (0.55); 54 (14.49), 1.3 (0.43), 0.17 (0.20) and 52.8 (14.69), 1.4(0.59), 0.22 (0.27) respectively.

Conclusions: Our study showed no overall increase in AMR due to ABOi in A2 to B DDKT and is the first study to assess AMR along with anti-A titers in A2 to B DDKT. More such studies are needed to assess anti-A trajectory with AMR. We also noted high infection and BK viremia rates, attributed to use of Thymoglobulin induction therapy. While A2B transplants have good graft outcomes, infectious complications are more frequent.

PO2086

A Successful Approach for A2 to B Cadaveric Renal Transplantation

Olusola Sogbein, Anand Kumar, Muhammad A. Mujtaba. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Background: Approximately 20% of blood group A individuals have reduced levels of A-antigen, termed A2, with less immunogenicity toward anti-A1 immunoglobulins. This allows the safe transplant of A2 kidneys into B or AB recipients. In 2014, the Kidney Allocation System was modified to encourage transplant centers to provide A2 kidneys for type B patients to reduce inequities in access. Studies have reported that rates of A2 to B transplants remain underutilized due to high rates of early acute rejection or thrombotic microangiopathy (TMA). We report on outcome metrics of A2 to B transplantation at the University of Texas Medical Branch (UTMB).

Methods: A retrospective, single center analysis of 29 patients who received A2 to B kidney transplants at UTMB between July 2015 and December 2020. We included stable (2 consecutive) anti-A IgG titers ≤ 1:8 for A2 identified individuals. Anti-A titers were monitored quarterly in B waitlisted patients. All A2/A2B to B eligible recipients underwent pre-transplant volume exchange plasmapheresis, followed by 2 additional sessions on post-op days 1 and 3. Thymoglobulin was used for induction and steroids for maintenance immunosuppression.

Results: A major concern in A2 to B transplant is the development of TMA or graft rejection. The incidence of rejection within the first year of all types of renal transplants ranges from 7.9% to 21.4%. We instituted an aggressive plasmapheresis protocol to reduce levels of potential pre-formed IgM anti-A antibodies that may induce graft failure. We report a rate of 3.4% for rejection or TMA within the first year of graft life which is less than previously published reports. This is due to pre- and post-transplant plasmapheresis in combination with intravenous immunoglobulin therapy. We elected not to follow anti-A titer levels post-transplant which did not result in higher rates of graft loss.

Conclusions: Our A2 to B transplant patients had a low rate of rejection and TMA demonstrating the efficacy of our triple maintenance immunosuppression protocol. Anti-A titers need not be followed post-operatively.

RESULTS

OUTCOME	
Cellular or Antibody mediated rejection at 1 year (%)	3.45
Thrombotic Microangiopathy at 1 year (%)	3.45
Kidney Allograft Survival at 1 year (%)	96.55
Patient Survival at 1 year (%)	100.00

PO2087

Pneumocystis Jiroveci pneumonia in Renal Transplant Recipients: Experience at a Tertiary Care Center

Arunkumar Subbiah, Sanjay K. Agarwal. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Pneumocystis jiroveci pneumonia (PJP) is an important cause of morbidity and mortality in post renal transplant recipients. Data on PJP in renal transplant recipients from India is lacking and we have attempted to address these lacunae.

Methods: This single center retrospective study included all cases of PJP in renal transplant recipients diagnosed at our institute. Demographic, clinical, laboratory and therapeutic outcomes of all these patients were analyzed.

Results: Of the 1870 renal transplant recipient records analyzed, 37 (1.9%) recipients were diagnosed with PJP. The median age of the patients was 38 years (17-74) with 31 males (83.8%). Three (8.1%) patients had deceased donors while 34 (91.9%) had living donors. Induction on the basis of immunological risk profile was ATG in 3 patients (8.1%), daclizumab in 2(5.4%), basiliximab in 11(29.8%) and 21 patients (56.7%) received no induction. All patients received steroid based triple drug immunosuppression along with Tacrolimus in 27(72.9%), Cyclosporine in 10(27.1%), MMF in 34(91.9%) and Azathioprine in 3(8.1%.). Septran prophylaxis was given for 6 months. The median time from transplantation to infection was 11 months(1-132). Eight recipients (22%) had PJP in the first six months post-transplant. Among them, five had co-infection with CMV, three had received prior anti-rejection treatment (ART) and three were non-compliant to PJP prophylaxis. The remaining 29 patients developed PJP after cessation of septran prophylaxis. Out of 29, 9 had received ART prior to PJP infection, 11 had CMV co-infection & 5 had prior history of CMV infection. Diagnosis was microbiologically confirmed in 17 patients by PJP PCR in BAL and in others, diagnosis was made by clinic-radiological features and response to treatment. The most common clinical presentation was dyspnea in 29(78.3%) and 9(31%) required mechanical ventilation. Patients were treated with septran + steroid (9,24%); Clindamycin + steroid (4,10.8%); septran + Clindamycin + steroid (24,64.8%). Three patients (8.3%) expired during PJP infection.

Conclusions: Prophylaxis and tailored immunosuppression explains the low incidence of PJP in our center. Majority of patients had prophylaxis noncompliance, prior anti-rejection therapy or CMV infection before PJP infection. Early diagnosis and timely therapy resulted in better patient outcome.

PO2088

COVID-19 Infection in Kidney Transplant Patients: An Italian One-Year Single-Center Experience

Mariarosaria Campise,[1] Carlo Alfieri,[1,2] Donata C. Cresseri,[1] Maria Teresa Gandolfo,[1] Valentina Binda,[1] Anna Regalia,[1] Piergiorgio Messa.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: COVID-19 is a life-threatening infection among elderly, comorbid patients, or transplanted patients. Lombardy (Region of Italy), accounts for 786.324 cases as of April 21st, 2021.

Methods: We retrospectively describe our single Centre experience in 82 adult kidney-transplant patients with COVID-19 infection during two pandemic outbreaks: 27 (first outbreak) and 65 (second).

Results: Thirty-seven patients were hospitalized (HP) and 65 were home managed (HM). Infection presented with fever (80 %), cough (51 %) and dyspnea (33 %). HP were older (60±11vs 50±14 years, p=0,001), had more severe respiratory symptoms (dyspnea 62.1%, p<0.0001 – cough 67% p=0.008), and a longer length of disease (30±28 vs 21±10, p=0.04). Incidence of acute kidney injury (AKI) was 29.7% (p<0.0001). Steroid dosage was increased in 66% of patients, p=0.0003 while Calcineurin Inhibitors were reduced up to one third in 45% of cases, p<0.0001. Eleven patients died (13%). HM patients recovered completely without sequelae. In the overall cohort, AKI development (p=0.006 OR 50.4 CI 95% 3.0-836) and age (p=0.04 OR 1.1 CI 95% 1.0-1.2) were the most important factors influencing the probability of death during the infection.

Conclusions: Although we report a relatively low incidence of infection (5.1 %) incidence of death is almost four times higher than in general population.

Variable	
Number of patients (n)	82
Gender (n) (M/F)	54/28

PO2089

The Impact of COVID-19 on Deceased Donor Renal Transplant Program in a Federal State of South India

Siddharth Herur, Swarnalatha Guditi, Srinivasa N. Kinjarapu, Megha Saigal. *Nizam's Institute of Medical Sciences, Hyderabad, India.*

Background: The Covid 19 pandemic has had an impact on all facets of health care system, including organ donation, procurement and transplantation in many countries. India is the country most affected with covid 19 and also the country with a huge waiting list for all solid organ transplants. ESKD is unique that different forms of RRT are available to sustain life. The risk - benefit ratio for delaying elective transplantation during the pandemic is not clear.

Methods: A decsriptive cross sectional study. All the deceased donor solid organ transplantations that took place in the state of Telangana from Jan 2020 to May 2021 were included. Live transplants were excluded. Comparison of the number of transplants of different organs, before and during the pandemic was done. Unpaired t test was used to compare the outcomes between the waitlisted and transplanted group.

Results: The total number of solid organ transplants from deceased donors in the pandemic year of 2020 dropped down to 54% compared to the previous year. Comparison between different organs revealed the maximum decline in number for kidney transplantation (51%), compared to liver (42%), heart (18%) as opposed to 110% increase in lung transplantation. Infectivity rate of covid 19 in the waitlisted group (top 50 in each blood group) registered for deceased renal transplantation is 0.16%. The infectivity rate in the transplanted group (deceased donor renal transplant) during the pandemic in the post transplant period of 6 months is 0.19%. The mortality rate of covid 19 between the two groups is also similar (0.04 in the waitlisted group and 0.06% in the transplanted group). The unpaired t test showed no statistical difference between the two groups.

Conclusions: There is a significant decline in the number of transplantations during the pandemic. Kidney is the most affected organ with 51% decline. Lung transplantation had a 110% rise in numbers during the pandemic. There is no statistical difference of the infectivity rate and mortality rate of covid 19 between waitlisted group and transplanted group of deceased donor renal transplant during the pandemic.

	waitlisted group (n = 200)	transplanted group (n=166)	p value (unpaired t test)
covid 19 infectivity rate	32/200 = 16 %	27/166 =16.2 %	< 0.05
covid 19 mortality rate	11/200 = 5 %	8/166 = 4.6 %	<0.05

PO2090

The Impact of COVID-19 on Kidney Transplant Listing and Referral on the Mexican-American Border

Arteen Pirverdian, Grace Mcnutt, Julio P. Zavala Georffino. *University of the Incarnate Word, Laredo, TX.*

Background: Laredo, Texas is a city on the Mexican-American border in South Texas that ranked as the most affected area in the United States relative to population in terms of COVID-19 in January 2021. The hospitalization rate, the area's total resources devoted to treating coronavirus patients, reached 45.8% and it averaged 229.9 cases daily per 100,000 citizens. We reviewed data early in the COVID-19 pandemic in May 2020 and later in May 2021 to evaluate whether the pandemic affected rates of referral and/or waitlisting.

Methods: Data was gathered from three dialysis clinics in Laredo, TX. The number of patients waitlisted or scheduled for living donor transplantation was determined early in the COVID-19 pandemic in May 2020 and later in May 2021. The number of patients referred for transplantation but not yet waitlisted was also obtained as well as the number of patients not referred both early in the COVID-19 pandemic in May 2020 and in May 2021.

Results: In May 2020, a total of 285 patients were available for analysis. 52 patients (18.2%) were waitlisted or scheduled for living donor transplantation. An additional 91 patients (31.9%) were referred but not yet waitlisted nor scheduled for living donor transplantation. A total of 140 (49.1%) were not referred. In May 2021, a total of 244 patients were available for analysis. 36 patients (14.8%) were waitlisted or scheduled for living donor transplantation. An additional 71 patients (29%) were referred but not yet waitlisted nor scheduled for living donor transplantation. A total of 135 (55%) were not referred.

Conclusions: There was a smaller percentage of ESRD patients waitlisted or scheduled for living donor transplantation in May 2021 than early in the COVID-19 pandemic in May 2020. There was also a smaller percentage referred but not waitlisted and a larger percentage not referred. The 3.4% decrease in patients waitlisted or scheduled for living donor transplantation may be a result of the high COVID-19 burden in Laredo, TX and the wariness to travel approximately 150 miles to the nearest transplant center. It is not known whether this decrease will have lasting implications on access to transplantation.

PO2091

Coronavirus Disease 2019 and Kidney Transplantation in Saudi Arabia

Meteb M. AlBugami,[1] Ali H. Alshaqaq,[1] Abdulrahman R. Altheaby,[2] Fayez F. Alhejaili,[2] Fahad E. Alotaibe.[1] *[1]King Fahad Specialist Hospital Dammam, Dammam, Saudi Arabia; [2]King Abdulaziz Medical City, Riyadh, Saudi Arabia.*

Background: Kidney transplant services all over the world were severely impacted by the coronavirus disease 2019 pandemic. The optimum management of kidney transplant recipients with coronavirus disease 2019 remains uncertain.

Methods: We conducted a multicenter cohort study of kidney transplant recipients with coronavirus disease 2019 infection in Saudi Arabia. Multivariable Cox regression analysis was used to study predictors of graft and patient outcomes at 28 days after coronavirus disease 2019 diagnosis.

Results: We included 130 kidney transplant recipients, with a mean age of 48.7(±14.4) years. Fifty-nine patients were managed at home with daily follow-up utilizing a dedicated clinic, while 71 (54.6%) required hospital admission. Acute kidney injury occurred in 35 (26.9%) patients. Secondary infections occurred in 38 (29.2%) patients. SARS-CoV-2 antibodies testing was carried out in 84 patients, of whom 70 tested positive for IgG and/or IgM. Fourteen patients died (10.8%). A multivariable Cox regression analysis showed that age, creatinine at presentation, acute kidney injury, and use of azithromycin were significantly associated with worse patient survival. Graft loss was associated with requiring renal replacement therapy and development of secondary infections.

Conclusions: Despite kidney transplant recipients with coronavirus disease 2019 infection having higher rate of hospital admission and mortality compared to the general population, a significant number of them can be managed using a telemedicine clinic. Most kidney transplant patients seem to mount an antibody response following coronavirus disease 2019 infection, and it remains to be seen if they will have a similar response to the incoming vaccines.

PO2092

Vitamin D Status and SARS-CoV-2 Infection in a Cohort of Renal Transplanted Patients

Anna Regalia,[1] Silvia Malvica,[1] Carlo Alfieri,[1,2] Mariarosaria Campise,[1] Donata C. Cresseri,[1] Maria Teresa Gandolfo,[1] Piergiorgio Messa.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: Immunomodulatory and anti-inflammatory properties have been hypothesized for native vitamin D (nVD). Very little is reported about nVD and risk of Sars-CoV-2 infection (COV) in renal transplant (RTx). In a cohort of renal transplanted patients (RTxp) we retrospectively evaluated: a) nVD status in patients with (COV+) and without (COV-) COV infection; b) the impact of nVD status on severity of COV.

Methods: The study includes 61 COV+ in whom nVD status was available in the year before the infection, and 122 COV- matched 1:2 for age (53[45-64]years), gender (M=60.7%), RTx vintage (7[2-15]years), presence of diabetes (18%), arterial hypertension (85%) and cardiac symptomatic disease (3%). Renal function, 24-h proteinuria, mineral metabolism (MM) parameters were evaluated at 1, 6 and 12 months before COV whereas nVD status was considered as the mean 25-OH-VD levels at the same timepoints. Severity of COV was based on the need for hospitalization (HOSP+: 27/61, 44.3%) and death (D+: 6/61, 9.8%).

Results: a) nVD levels were significantly lower in COV+ than in COV- (19 [12-26] ng/mL and 23[16-30] ng/mL, respectively, p=0.01). No differences in the other biochemical parameters were found. The COV discriminative power of nVD status was evaluated by ROC curve (AUC 0.61, 95% CI 0.54-0.68, p=0.01), with a value of 25-OHVD 23.9 ng/mL showing the best discriminative power (sensibility 72%, specificity 47%). b) nVD levels showed a trend towards lower values in HOSP+COV+ than HOSP-COV+ (17[8-25] ng/mL vs 20[14-26] ng/mL) and in D+COV+ than D-COV+ (13 [6-23] ng/mL vs 20[13-26] ng/mL), although these differences did not reach the statistical significance (p=0.1 and p=0.2, respectively).

Conclusions: With the limitations of the retrospective nature of the study and the small sample size, our data report that: a) COV+ showed lower nVD levels in the year preceding the infection compared to controls with similar main demographic features and comorbid conditions; b) No differences were found in renal function, proteinuria, and other MM parameters between the two groups; c) No association was found between nVD levels in the year preceding the infection and COV severity.

PO2093

Treatment with Monoclonal Antibodies Minimize Severity of COVID-19 Illness Among Kidney Transplant Recipients

Cindy T. Pynadath, Rachel Bartash, Yorg Al Azzi, Pablo Loarte Campos, Maria Ajaimy, Luz E. Liriano-Ward, Alesa Campbell, Enver Akalin. *Montefiore Health System, Bronx, NY.*

Background: The mortality rate of kidney transplant recipients with COVID-19 is significantly higher than the general population, indicating a need for effective treatment to minimize potential severe symptoms in this population. We sought to evaluate the efficacy of monoclonal antibody therapy in decreasing the severity of COVID-19 symptoms among our kidney transplant recipients.

Methods: We reviewed 17 kidney transplant recipients who were infected with SARS-CoV2 and received treatment with monoclonal antibody therapy. All patients were on standard immunosuppression with Tacrolimus and Prednisone, and 88% were on Mycophenolate prior to COVID diagnosis, which was subsequently reduced or held for at least 2 weeks.

Results: Of the 17 patients reviewed, median age was 61 years (range 42 to 77 years), 47% were male, 59% were Hispanic, and 29% were African American. Additionally 94% had history of hypertension, 47% diabetes mellitus, 18% coronary artery disease, and median BMI was 28.8 (range 23.4 to 41.9). Eighteen percent were transplanted <1 year, 29% between 1-5 years, 24% 6-10 years, and the remaining >10 years. All patients had mild symptoms without evidence of hypoxia, and 94% received monoclonal antibody therapy within 7 days of diagnosis. Bamlanivimab 700mg was the most commonly administered agent at 59%, while 18% received Bamlanivimab 700mg and Etesevimab 1400mg. Casirivimab 1200 mg and imdevimab 1200 mg was used in 24%. Only 2 out of the 17 patients (11.8%) required hospitalization, and both were non-COVID-19 related reasons. Five out of 17 patients (29.4%) were evaluated in the Emergency Department but not admitted. All 17 patients (100%) recovered from their COVID-19 illness. There were no episodes of graft failure.

Conclusions: Our experience suggests that monoclonal antibody therapies may be beneficial in preventing severe COVID-19 in renal transplant recipients and possibly reduce the need for COVID-19 related hospitalization in this high risk population. However, larger studies are needed to confirm these findings.

PO2094

Antibody Response to SARS-CoV-2 mRNA Vaccines in Pediatric Kidney Transplant Recipients

Clarkson Crane, Elizabeth G. Ingulli. *University of California San Diego, La Jolla, CA.*

Background: In the general population, mRNA SARS-CoV-2 vaccines are highly efficacious and patients form an antibody to S1 subunit of the SARS-CoV-2 spike protein. Early reports suggest a decreased antibody response in immunosuppressed adult solid organ transplant (SOT) patients. However, the serologic response in adolescent SOT patients has not yet been characterized.

Methods: Kidney transplant recipients (KTR) at our center who received both doses of an mRNA SARS-CoV-2 vaccine had SARS-CoV-2 spike protein antibody presence evaluated 4-8 weeks after their second dose of the vaccine as part of routine clinical care. We utilized the Abbott chemiluminescent microparticle immunoassay or Siemens Atellica IM SARS-CoV-2 IgG. Patients were characterized as vaccine responders or non-responders.

Results: Of 47 vaccine-eligible KTR in our program, 34 received both doses of a SARS-CoV-2 mRNA vaccine. Twenty-three patients had spike antibody titers obtained. The median age was 21.5 years and all except one were transplanted over 3 years ago. Twenty-two received Pfizer-Biontech vaccine and one received Moderna. Twelve patients (52%) had a positive spike antibody. Of those who responded, eight patients' immunosuppression regimens included mycophenolate (mean dose 719 mg/m2/day), three were treated with azathioprine and one was not taking an antimetabolite due to EBV viremia. All non-responders were treated with mycophenolate (average dose 755 mg/m2/day). Three patients had prior COVID-19 infection, and all had a positive antibody response.

Conclusions: Our results suggest vaccine response in adolescent KTR is suboptimal and lower than the general population. However, 52% response rate is similar to that previously described in adult SOT patients. While our study is limited by small sample size and lack of standardized timing for measuring antibodies, it provides further evidence of lower immunogenicity to SARS-CoV-2 vaccination in SOT. Those who did not respond tended to have a higher average dose of mycophenolate and this supports further study of alternative antimetabolite dosing strategies around the time of vaccination or the potential utility of a third vaccine dose in SOT patients. At our center, efforts to continue characterizing antibody response of pediatric KTR are ongoing and we anticipate additional data in the coming months as vaccine eligibility expands to younger patients.

PO2095

A Tale of Survival: COVID-19, Disseminated Cryptococcus, and Cytomegalovirus Disease in an ABO-Incompatible Kidney Transplant Recipient

Rishabh K. Jain, Sudhir R. Thaduri, Vineeta Kumar. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Introduction: We present a rare case of Collapsing Focal Segmental Glomerulosclerosis (FSGS) in Covid-*19* (COVAN), disseminated Cryptococcus and CMV infection in a kidney transplant recipient with dialysis dependent acute kidney injury and successful renal and critical illness recovery.

Case Description: 63yo black male with an ABO incompatible kidney transplant 8yrs ago, baseline creatinine (Cr) of 1.4 mg/dl with acute Covid-*19* infection with presenting Cr of 5.5 mg/dl and nephrotic range proteinuria (5.9gm/gm). Started hemodialysis on day 21 of the acute illness. Normal imaging, stable anti-ABO titers and transplant kidney biopsy with collapsing FSGS and ATN. Blood cultures ordered for persistent fevers were positive for Cryptococcus neoformis. Biopsy of painful indurated skin of the left flank revealed variably sized yeast forms within the dermis consistent with cutaneous Cryptococcus. Treated with amphotericin B/flucytosine followed by fluconazole with clearance of fungemia, resolution of fever and improvement of skin lesions. Immunosuppression was continued with reduced dose of tacrolimus and prednisone 10mg/day. Antimetabolite was discontinued. Persistent weakness and diarrhea lead to testing for CMV with PCR at 51,000copies/ml, treated with IV ganciclovir with complete resolution of symptoms. Discharged home on maintenance dialysis with valganciclovir and fluconazole prophylaxis. He returned on day 70 of illness with a Cr of 1.2 mg/dl, a 24hour urine collection with a creatinine clearance of 28 ml/min and 2gms of proteinuria. Dialysis was discontinued due to renal recovery. At last clinic follow up, day 100 from diagnoses, Cr remains stable at 1.7 mg/dl off dialysis.

Discussion: Immune dysregulation in the setting of acute Covid-*19* infection coupled with long term immunosuppression may have contributed to multiple opportunistic infections. Optimal approach for immunosuppression in KTRs with acute Covid-*19* infection is still evolving. Our patient was successfully treated without stopping all immunosuppression. Our case underscores importance of having low threshold to test for various opportunistic infections even in the setting of active Covid-*19* infection. While data on COVAN in KTRs is limited, our case shows potential for renal recovery even in a high immunologic risk kidney transplant recipient.

PO2096

Cytomegalovirus Infection in Renal Transplant Recipients: Incidence, Clinical Profile and Outcome

Phanisri Alaparthi, Swarnalatha Guditi, Srinivasa N. Kinjarapu. *Nizam's Institute of Medical Sciences, Hyderabad, India.*

Background: Cytomegalovirus (CMV) is one of the commonly encountered opportunistic infection following renal transplantation, usually seen in the first 6 months of transplant. CMV diseases, untreated has a mortality rate of about 90% however has good response with prompt detection and antiviral therapy. With the changing immunosuppressive regimen, variation in pattern and occurrence of CMV infection can be seen. We studied the incidence, clinical profile and outcomes of CMV infection in renal transplant recipients at our center.

Methods: 291 renal transplant recipients between 2014 and 2020 were reviewed, 27 patients who had CMV infection, diagnosed by CMV DNA detection with polymerase chain reaction were included in the study and their demographic details, clinical profile and outcome were noted and analyzed.

Results: Among the 291 renal allograft recipients, 27 patients had 34 episodes of CMV infection with an incidence of 9.27% with a mean follow up of 52.6 months. 37.1% received deceased donor renal transplant and 62.9% received live renal transplant. Mean age at transplant was 33.8yrs, 81.4% were males, 18.6% were females. rATG as induction was given in 11.1%, Basiliximab in 37.1% and 51.8% received no induction therapy, all of them received triple immunosuppression with steroid, tacrolimus and MMF as maintenance immunosuppression. PTDM was present in 33.4%. Valganciclovir prophylaxis post- transplant was given in 77.8% where as 22.2% did not receive prophylaxis. 20.5% infection episodes occurred in < 3months, 26.5% between 3-6 months, 11.8% between 6-12 months and 41.2% in >12months post-transplant. Symptomatic disease with fever, malaise and leucopenia was the most common presentation in 73.5% of patients and 26.4% had asymptomatic infection with leucopenia and transaminitis. All patients received iv Ganciclovir for 14-21days followed by oral valganciclovir for 90 days as treatment of infection episode. Patient survival and graft survival rate was 85.2% and 77.7% at our center.

Conclusions: Changing immunosuppressive regimen with early withdrawal of steroid and use of valganciclovir prophylaxis has been associated with lower incidence and milder form of CMV disease in our population. There seems to be a change in the traditional risk factors for CMV infection which needs to be further studied.

PO2097

Resistant Cytomegalovirus After Kidney Transplant: Reduced Immunosuppression, High-Dose Valganciclovir, and Letermovir Prophylaxis Guided by T Cell Immunity Assessment

William F. Hoffman,[1] Manpreet Singh,[1] Julie Mandel,[1] Fernanda P. Silveira.[2] *[1]UPMC Pinnacle, Harrisburg, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Introduction: CMV infections resistant to available antivirals are associated with increased morbidity and mortality after kidney transplant.

Case Description: A 58 yo male with ADPKD underwent pre-emptive LURTx. IS included Thymoglobulin, followed by tacrolimus, mycophenolate (MMF), and prednisone. Ten days after completing 6 mos. of valganciclovir(VGCV) prophylaxis (ppx) for CMV D+/R- serostatus he developed malaise and fever; CMV PCR was 197,033 IU/ml. VGCV 900 mg BID was started and MMF reduced. CMV PCR declined to 1399 IU/ml after 6 weeks, but then plateaued. CMV resistance testing (VGCV treatment day 62) found wild-type and mutated virus (UL54 T503I mutation and UL97 H520Q mutation) with predicted resistance to ganciclovir and cidofovir, but susceptibility to foscarnet. MMF was stopped and VGCV was increased to 1350 mg BID (150% dose for GFR). Foscarnet was avoided due to risk of nephrotoxicity, lack of disease, and time from transplant. There was no significant leukopenia on VGCV. Over the next 2 months, CMV PCR decreased to several hundred IU/ml to Below the Limit of Quantification. Letermovir ppx was started (VGCV t. day 85) and VGCV stopped 8 days later. CMV PCR remained negative to BLQ on letermovir. Low dose MMF was restarted. T cell immunity panel (Viracor) showed good CD8 (5.04%), but low CD4 (0.15%) response, suggesting CMV infection would recur without prophylaxis. The patient remains on letermovir ppx. Letermovir is a CYP3A inhibitor, and tacrolimus required 25% dose reduction. DSA is negative at 1 yr post-transplant; creatinine remains around 1.1 mg/dl. Letermovir is a new CMV selective antiviral with novel mechanism of action inhibiting the viral terminase complex in late stages of replication. It is approved for prophylaxis in HCT, active against resistant strains, and not associated with myelo or nephrotoxicity.

Discussion: Resistant CMV infection is a clinical challenge. While susceptibility to foscarnet was predicted in this case, it was avoided (nephrotoxicity). Instead, immunosuppression was cautiously reduced and higher-dose VGCV was tolerated well. Once CMV viral load was negligible, a newer agent with novel mechanism of action, letermovir, was used for prophylaxis. Letermovir has been continued based on a low level of anti-CMV CD4 response, predicting high-risk for CMV recurrence.

PO2098

Rare Oral Lesions from Cytomegalovirus in Kidney Transplant

Alka A. Tyagi,[1] Mohankumar Doraiswamy,[1] Priyamvada Singh,[1] Raja Damayanthi Murali.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]MetroHealth Medical Center, Cleveland, OH.*

Introduction: Cytomegalovirus (CMV) infection occurs frequently with kidney transplant recipients and it can affect any segment of gastrointestinal tract, but intra-oral localization is exceedingly rare. We present an interesting rare oral lesion from CMV infection in kidney transplant recipient

Case Description: A 49-year-old male with a history of kidney transplant admitted with odynophagia, pancytopenia, neutropenic fever and new tongue lesion for two weeks. Examination showed a 3X3 cm elevated, adherent plaque. He has a history of resistant CMV viremia with failed therapy to low-dose valganciclovir, ganciclovir, and letomovir. He attained an undetectable CMV viral load with Foscarnet but it was complicated with acute renal injury, and he was transitioned to a high dose valganciclovir. His CMV PCR was < 50 on admission and biopsy of the tongue-lesion revealed a positive immunohistochemical stain for CMV. We held his Valcyte on admission and his pancytopenia improved with filgrastim. Repeat CMV PCR increased to 17,000 IU/mL. He refused Foscarnet and was restarted on oral valganciclovir (1350 mg twice daily) and topical cidofovir. Even with undetectable CMV at presentation, he was noted to have disseminated infection. Myfortic and Gengraf were held and discharged on prednisone alone. At 2-week follow-up, the lesion and its associated symptoms had resolved

Discussion: The presentation of oral CMV infection is highly variable with mucosal erythema, painful deep ulcers, erosions, but elevated tongue lesion have rarely been reported in literature to our knowledge. Treatment options includes ganciclovir, valganciclovir, foscarnet, letomovir and cidofovir. Early diagnosis is important because CMV increases other opportunistic infection and allograft rejection. Saliva and periodontal packets serve as reservoirs for CMV infection and frequent monitoring of periodontal health is needed post-transplant

3X3 cm elevated, adherent tongue lesions

PO2099

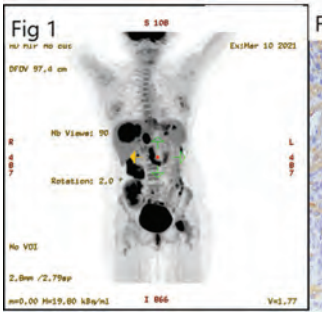
Use of Epstein-Barr Virus (EBV) Cytotoxic T Lymphocyte Therapy in a Kidney Transplant Recipient with EBV-Associated Smooth Muscle Tumors

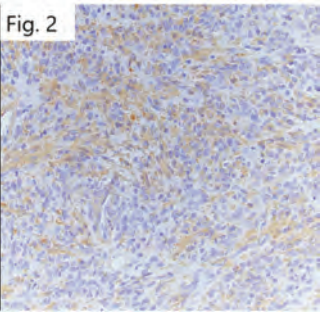
Rohan Saranu,[1] Richard S. Babicz,[1] Vickie Y. Jo,[1] Sarah Nikiforow,[2] Anil K. Chandraker.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Dana-Farber Cancer Institute, Boston, MA.*

Introduction: Epstein-Barr virus (EBV) is commonly associated with malignancies in transplant recipients, the most frequent being Post-transplant lymphoproliferative disorder. A rare, yet distinct, oncological entity are the EBV-associated smooth muscle tumors (EBV-SMTs). We present the case of multiple, malignant EBV-SMTs in a 34-year-old kidney transplant recipient, and the use of Tabelecleucel (EBV cytotoxic T lymphocyte therapy) as a targeted therapy for these tumors.

Case Description: A 34-year-old female kidney transplant recipient presented with fatigue, anorexia, and nighttime chills. Subsequent lab analysis revealed lymphopenia, elevated creatinine, hypercalcemia and high EBV viral load. PET scan revealed intensely avid FDG liver, splenic and lytic lesions of the left femoral head (Fig.1). Diagnosis of EBV-SMTs was confirmed by immunohistochemistry positive for smooth muscle actin, supporting smooth muscle differentiation (Fig.2), and confirmatory in situ hybridization for EBV-encoded RNA. Patient's immunosuppression was switched from tacrolimus to sirolimus, and treatment was initiated with Tabelecleucel. At the time of the writing of this report, the patient has completed the first cycle of treatment with Tabelecleucel and is preparing for a second cycle of treatment. The patient's symptoms have improved significantly and creatinine, calcium and white cell counts have returned to baseline, EBV viral load fell from 4120 to 133 and PET scan showed stabilization of disease. We will continue to report on the patient's progress.

Discussion: EBV-SMTs are rare tumors which can present in a variety of ways and are easily missed. They are typically aggressive, with a poor response to radiation and chemotherapy. Tabelecleucel is an EBV cytoxic T lymphocyte therapy, primarily used in immunosuppressed and stem cell transplant recipients. Use in kidney transplant recipients is promising but requires further investigation to better understand optimal HLA matching of cell lines with recipients and allografts.





PO2100

Economic and Insurance Outcomes for Living Kidney Donors and Matched Comparators in Korea

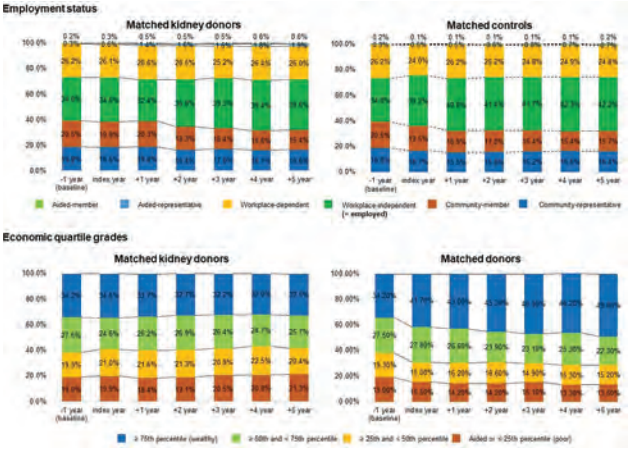
Sehoon Park,[1] Eunjeong Kang,[2] Yaerim Kim,[3] Yong Chul Kim,[4] Yon Su Kim,[1] Hajeong Lee.[4] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Ewha Womans University Seoul Hospital, Seoul, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [4]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Although studies have reported kidney donation's adverse health outcomes, its socioeconomic impact on living donors requires further study.

Methods: We performed a retrospective observational cohort study including a matched control group. We included 1,285 living kidney transplant donors from seven tertiary hospitals and a matched control group consisting of the same number of health screening examinees with similar baseline clinical and socioeconomic status from 2003 to 2016. Changes in employment status and household income were identified from the linked claims database, which includes employment and economic status information. The outcomes were compared between the donor and matched control groups on an annual basis using multivariable logistic regression analyses adjusted for various clinicodemographic characteristics.

Results: The median ages of the donors and matched controls were 45 and 46 years, respectively; 44.6% of the sample was male. The living donors were at higher risk of being unemployed or struggling to maintain employment during the first two years after donation [e.g., first-year loss of employment, odds ratio (OR) 2.27 (1.55–3.33)]; however, this situation did not persist, compared with the matched control group. The donors also showed significantly lower odds for improvement in economic grades [OR 0.57 (0.47–0.71)] or higher odds for deterioration in financial status [OR 1.54 (1.23–1.93)] than the control group in the first year and succeeding time periods.

Conclusions: Live kidney donors may suffer from poor employment or low economic status even after their altruistic donation. Whether an advanced reimbursement program can reduce these disincentives should be further evaluated.



PO2101

When Is a Second Kidney Transplant Lifesaving? Effect of Waiting Time on Mortality in a Retrospective Cohort Study Using Target Trial Emulation

Alexander Kainz,[1] Michael Kammer,[1,2] Roman Reindl-Schwaighofer,[1] Susanne Strohmaier,[3] Vojtech Petr,[4] Ondrej Viklicky,[4] Daniel S. Abramowicz,[5] Marcel Naik,[6,9] Gert J. Mayer,[7,8] Rainer Oberbauer.[1] *[1]Medical University of Vienna, Department of Nephrology, Vienna, Austria; [2]Medical University of Vienna, Department of Biometrics, Vienna, Austria; [3]Medical University of Vienna, Department of Epidemiology, Vienna, Austria; [4]Institut klinicke a experimentalni mediciny, Praha, Czechia; [5]Antwerp University Hospital, Department of Nephrology, Antwerp, Belgium; [6]Charité Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany; [7]Medizinische Universitat Innsbruck Universitatsklinik fur Innere Medizin IV Nephrologie und Hypertensiologie, Innsbruck, Austria; [8]Austrian Dialysis and Transplant Registry, Innsbruck, Austria; [9]Berlin Institute of Health, Berlin, Germany.*

Background: The median kidney transplant half-life is 10 to 15 years, and because of the scarcity of donor organs and immunological sensitization of candidates for retransplantation, there is a need for quantitative information if, and when a second transplantation is no longer associated with a reduced risk of mortality compared to waitlisted patients treated by dialysis. Therefore we investigated the association of time on waitlist with patient survival in patients who received a second transplantation versus remaining on waitlist with continued dialysis treatment.

Methods: In this retrospective study we used data of 2346 patients from the Austrian dialysis and transplant registry merged with data from Eurotransplant who were waitlisted for second kidney transplantation during the years 1980 to 2019. The analysis was based on target trial emulation via a sequential Cox approach, in which each observed transplant allocation started a virtual trial mimicking a randomized trial via inverse probability weighting. The analysis was adjusted for recipient age and sex, year and duration of first transplantation, duration of dialysis, and time between first graft loss and initial joining date of the waiting list for the second transplantation.

Results: Second kidney transplantation showed an increased restricted mean survival time (RMST) at 10 years of follow-up compared to remaining on the waiting list (5.8 life-months gained, 95% CI 0.9 to 11.1). However, this survival benefit was diminished in patients with longer waiting time after first graft loss: RMST differences at 10 years of follow-up were 8.0 (95% CI 1.9 to 14.0) and 0.1 life-months gained (95% CI -14.3 to 15.2) for patients with a waiting time after first graft loss of less than one year, and eight years, respectively.

Conclusions: Based on these data we conclude that a second kidney transplant leads to prolonged patient survival compared to remaining waitlisted and treatment by dialysis, but that the survival benefit diminishes with longer waiting time. Nevertheless, the higher quality of life after transplantation could be an argument to favour retransplantation if a suitable donor organ is available.

Correlation Between CT Volumetric and Nuclear Renal Scans in Donors with Renal Asymmetry

Nisarg Gandhi, Hassan N. Ibrahim, Duc T. Nguyen, Edward A. Graviss, Hana Nguyen. *Houston Methodist Hospital, Houston, TX.*

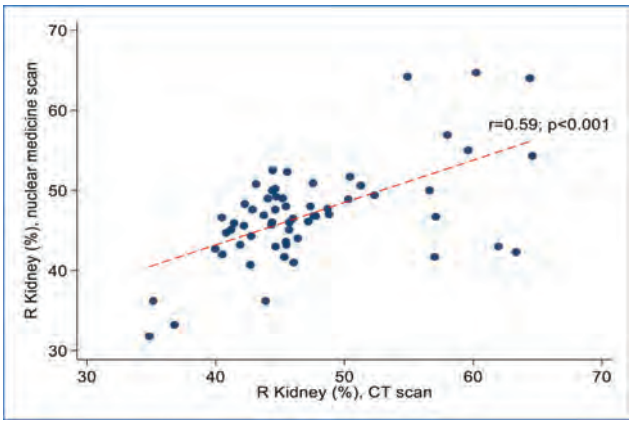
Background: The Organ Procurement and Transplant Network (OPTN) lists renal asymmetry as a relative contraindication to donation. Clinicians resort to nuclear medicine scans to address discrepancies in kidney size observed by commuted tomography (CT) volumetric. Our study looked at the correlation between CT volumetrics and nuclear medicine scan in addressing renal asymmetry.

Methods: At a large US transplant center, 62 potential donors with discrepancies in kidney size underwent both CT volumetric and nuclear medicine renal scans. The concordance correlation between the CT scan and nuclear medicine scan results was determined separately for the right and left kidney.

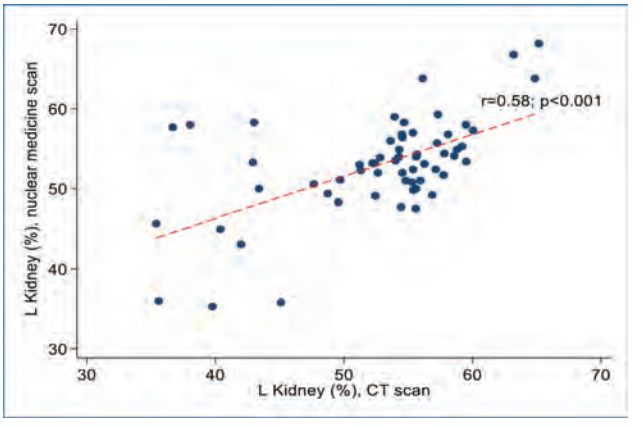
Results: The donors were 52.2 years of age (median IQR: 38.5, 61.7), 29.0% male, and 59.7% white. By CT, the right kidney was 45.5% and left kidney was 54.5% of the overall volume. On nuclear medicine scans, right kidney was 46.8% and left kidney was 53.3% (Table 1). The Pearson correlation coefficient was 0.59 for the right kidney and was 0.58 for the left kidney (Figure 1, 2).

Conclusions: Nuclear medicine seems to offer no advantage over CT volumetrics and it adds to the overall time (30-60 minutes) and cost (~$1,587) of the donor evaluation process.

	Right	Left
CT Volumetrics (%), median IQR	45.5 (43.0, 49.5)	54.5 (50.5, 57.0)
Nuclear Medicine Scan (%), median IQR	46.8 (43.6, 49.4)	53.3 (50.6, 56.4)



Correlation between CT scan and nuclear medicine scan for right kidney



Correlation between CT scan and nuclear medicine scan for left kidney

PO2103

The Effect of Race Coefficients on Preemptive Listing for Kidney Transplantation

Vinay Nair, Jamie S. Hirsch, Nicholas Jandovitz, Kenar D. Jhaveri, Ernesto P. Molmenti, Mersema Abate. *Northwell Health, New Hyde Park, NY.*

Background: Race coefficients of glomerular filtration rate estimation (eGFR) formulas may be partially responsible for racial inequality in preemptive listing for kidney transplantation. The objective was to determine whether differences in racial distribution of preemptively listed candidates are reduced by calculating eGFR irrespective of race.

Methods: The Scientific Registry of Transplant Recipients database was used to evaluate differences in racial distribution of preemptive listing before and after application of the MDRD and CKD-EPI race coefficients to all preemptively listed non-Black kidney transplant candidates (eGFR modulation). Non-Black patients who had a recalculated eGFR > 20 were removed from the preemptive group. Odds ratios of preemptive listing were calculated by race with Black as the reference before and after eGFR modulation. Variables known to influence preemptive listing were included in the multivariable model.

Results: Among 385,087 kidney-alone transplant candidates from January 1, 2010 to December 2, 2020, 118,329 (30.7%) were identified as preemptively listed (median [IQR] age 56 [45-64]; 57.7% male; 71.7% White, 19% Black, 7.8% Asian, 0.6% multi-racial, 0.6% Native American, 0.3% Pacific Islander). After eGFR modulation, non-Black patients with an eGFR ≥ 20ml/min were removed. Compared to Black candidates, the adjusted odds of preemptive listing for White candidates decreased from 2.01 (CI 1.78-2.26; p<0.001) before eGFR modulation to 1.18 (CI 1.0-1.39; p=0.046) with the MDRD and 1.37 (CI 1.18-1.58; p=0.001) with the CKD-EPI equations after adjusting for race coefficients.

Conclusions: The racial distribution of preemptively listed candidates closely mirrored the distribution on the wait list when all races were subject to the Black race coefficients. Removing race coefficients in GFR estimation formulas may result in more equitable racial distribution of preemptively listed candidates.

PO2104

Increasing Frequency of Kidneys Allocated Out of Sequence by Organ Procurement Organizations

Kristen L. King,[1] Syed A. Husain,[1] Sumit Mohan.[1,2] *[1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Mailman School of Public Health, New York, NY.*

Background: Allocation of deceased donor kidneys follows a ranked match-run list of potential recipients. Organ procurement organizations (OPOs) deviate from the mandated match-run in exceptional circumstances with unknown frequency.

Methods: Using SRTR data on all deceased donor kidney transplants (Ktx) in the US from 2015-2019, we identified cases where an OPO-initiated allocation exception occurred (Operational-OPO, Donor Medical Urgency, Expedited Placement). We examined the frequency of Ktx from these exceptions over time and characteristics of donors with kidneys placed out-of-sequence.

Results: From 2015-2019, 981 kidneys from 673 donors were transplanted via OPO-initiated allocation exception. These transplants (median KDPI 67, age 47 yrs) nearly doubled from 2015-2019: 153 kidneys in 2015 (1.5% of all Ktx) to 291 in 2019 (2.1%). 52 of 58 OPOs used this process at least once (median <1 per year), but 2 outlier OPOs accounted for 54% of the exceptions over 5 years [426 (43%) and 110 (11%), Figure 1]. Only 56% of transplant centers received any allocation-exception Ktx, with 2 centers receiving 26% [129 (13%) and 132 (13%)]. Donor kidneys placed via allocation exception had less favorable characteristics, but only 25% had KDPI≥85% (Table 1). Allocation exception Ktx went to recipients with 2 fewer priority points (median score: 4.3 vs. 6.3 in-sequence), equivalent to 2 less years of waiting time.

Conclusions: Two OPOs and a few Ktx centers are driving an Increase in OPO-initiated exceptions in kidney allocation. Although kidneys placed out-of-sequence were lower quality, the majority did not meet the traditional threshold for marginal kidneys. Without monitoring, increasing pressure to improve organ utilization risks increasing out-of-sequence allocation potentially exacerbating disparities in access to transplantation.

Figure 1. Temporal trends in kidneys transplanted with an OPO allocation exception

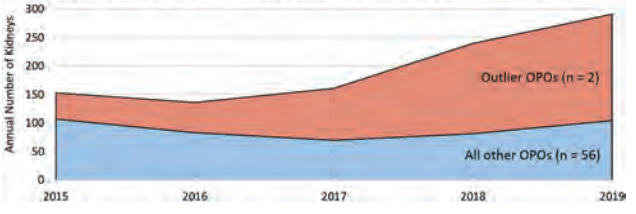


Table 1. Characteristics of donors with kidneys allocated through regular allocation policy or with an OPO-initiated allocation exception

Donor Characteristics, median (IQR) or n (col %)	Regular Allocation n = 35,359 (98%)	Allocation Exception n = 673 (2%)

Survival Time Gained by Kidney Transplantation Compared to Remaining Waitlisted on Dialysis: A National Registry Study Using Target Trial Emulation

Maria C. Haller,[1,2] Christine Wallisch,[1] Susanne Strohmaier,[1,4] Michael Kammer,[1,3] Georg Heinze,[1] Rainer Oberbauer.[3] *[1]Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems, Section for Clinical Biometrics, Vienna, Austria; [2]Ordensklinikum Linz, Elisabethinen Hospital, Department of Medicine III, Nephrology, Hypertension, Transplantation, Rheumatology, Geriatrics, Linz, Austria; [3]Medical University of Vienna, Department of Medicine III, Division of Nephrology and Dialysis, Vienna, Austria; [4]Medical University of Vienna, Department of Epidemiology, Center for Public Health, Vienna, Austria.*

Background: It is widely taken for granted that kidney transplantation improves survival compared to remaining on dialysis. However, the previous evidence based on cohort studies is at high risk of bias and randomized controlled trials are not feasible. We aimed to investigate survival differences of kidney transplantation compared to remaining waitlisted on dialysis across different transplant candidate ages as well as depending on waiting time applying causal inference methodology.

Methods: We included all dialysis patients recorded in the Austrian Dialysis and Transplant Registry who were waitlisted for their first kidney transplant between 2000 and 2018 and utilized repeated updates on waitlisting status and relevant covariates. To estimate causal effects of kidney transplantation across ages, we specified a target trial protocol mimicking a series of controlled clinical trials initiated at the ordered times of transplantation relative to waitlisting. At each trial in the series patients were classified as either treated (transplanted) or control (remained on waitlist). We estimated restricted mean time gained by transplantation using sequential Cox regression adjusted for confounding and adherence to the treatment strategy by inverse probability weights for treatment and censoring, and stratified our analysis by pre-transplant waiting time (up to 1 year, 1 to 2 years, more than 2 years).

Results: 4445 patients were included, 33% were women, mean age was 50 years. 3621 patients (81%) were transplanted, 1392 patients died. Transplanted patients had longer 5- and 10-year restricted mean survival times compared to patients remaining waitlisted across all ages. E.g. a patient aged 70 at transplantation gained 0.85 years within 5 years posttransplant. Stratified analyses showed a gain of 0.61 years conditional on having been waitlisted up to 1 year and 0.82 and 1.35 years conditional on having been waitlisted for 1 to 2 years or more than 2 years respectively.

Conclusions: Our study provides evidence based on state-of-the-art causal inference methodology for moderately increased survival after kidney transplantation in the elderly and irrespective of time on waiting list.

PO2106

Meta-Analysis of Association Between TCF7L2 rs7903146 and Risk of New-Onset Diabetes After Kidney Transplantation

Muhammad T. Khan. *Dow University Hospital, Karachi, Pakistan.*

Background: Single nucleotide polymorphisms may influence the risk of development of new-onset diabetes after transplantation (NODAT), a post-transplant clinical complication that is often implicated in allograft rejection and mortality. We performed a meta-analysis of association between TCF7L2 rs7903146 and risk of post-transplant diabetes mellitus.

Methods: A systematic search was conducted using PubMed and ScienceDirect electronic databases for studies published between January 2001 to January 2021. Case-control or cohort studies reporting association between NODAT (diagnosis based on American Diabetes Association [ADA] criteria) and TCF7L2 rs7903146 were included. MetaGenyo was used for meta-analysis (random effects model). Pooled odds ratios with 95% confidence intervals were reported to evaluate the strengths of association.

Results: Two reviewers independently screened for articles. A total of six case-control studies were included for full-text review and quantitative analysis after screening for eligibility. Genotypic distributions were in Hardy-Weinberg equilibrium for included studies. All papers reported statistically significant association of TCF7L2 rs7903146 for risk of NODAT, except for one study. There was moderate heterogeneity among studies ($I^2 = 60.6\%$). Pooled analysis revealed 51% odds of developing NODAT with TCF7L2 rs7903146 T allele (Allele Contrast Model: OR = 1.51, 95% CI 1.13 – 2.02, adjusted $p = 0.03$).

Conclusions: The present meta-analysis demonstrated association between TCF7L2 variant rs7903146 and risk of developing NODAT. This finding may have clinical implications for individuals undergoing kidney transplantation.

PO2107

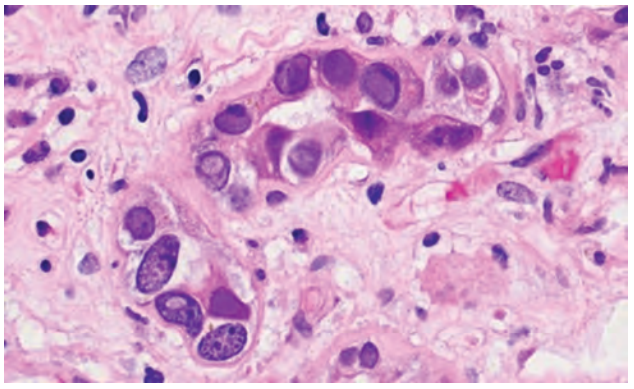
A Case of Native BK Virus Nephropathy in a Lung Transplant Patient

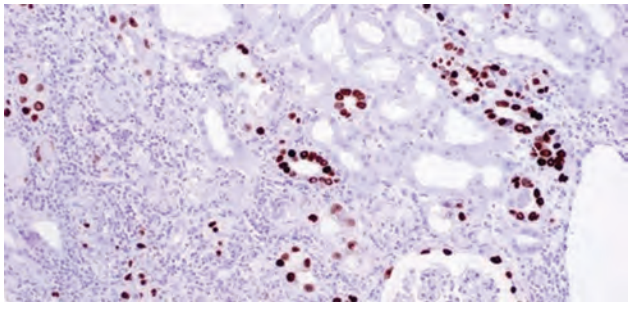
Waseem Albasha, Golnaz Vahdani, Ankita Ashoka, Erika R. Bracamonte, Amy Yau. *The University of Arizona College of Medicine Tucson, Tucson, AZ.*

Introduction: BK virus nephropathy (BKVN) is an opportunistic infection that can lead to progressive kidney dysfunction. Classically described in the allograft of kidney transplant patients, it is increasingly recognized in native kidneys of other non-renal solid organ transplants (NRSOTs). Here we describe a patient with a history of lung transplant with native BKVN.

Case Description: Our 68-year-old woman with a history of bilateral lung transplant for idiopathic pulmonary fibrosis was referred thirteen months post-transplant for worsening renal function. Her creatinine slowly increased from a baseline of 0.6 mg/dL to 1.9 mg/dL. Work up revealed a serum BK virus PCR level of 28,381,300 copies/ml. Kidney biopsy revealed numerous tubular epithelial cells with enlarged nuclei and intranuclear inclusions (Figure A) which stained positive for SV 40 (Figure B). Her tacrolimus and sirolimus were already reduced by the lung transplant team. Mycophenolic acid was discontinued. She was already on monthly intravenous immunoglobulin, and so she was admitted for intravenous cidofovir. Her creatinine preceding cidofovir treatment was 2.2 mg/dL with a serum BK virus PCR of 59,225,688 copies/ml. Unfortunately, after a total of 2.5 mg/kg of intravenous cidofovir, her creatinine worsened to 4.68 mg/dL with no significant change in BK viremia. Cidofovir was discontinued.

Discussion: Native BKVN is more common than previously recognized in NRSOTs. There is unclear guidance if lung transplant patients should be screened for BK viremia routinely, and there is a lack of safe and efficacious treatment options. This case adds to the growing literature of lung transplant recipients who develop native BKVN and the challenges of BKVN treatment beyond reduction of immunosuppression.





PO2108

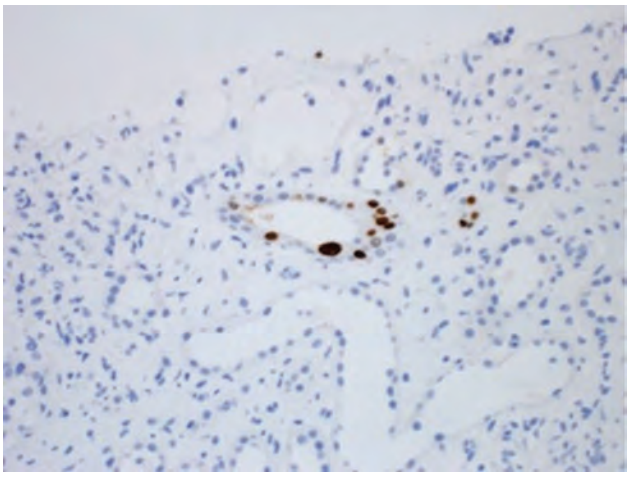
Late Presentation of JC Virus-Associated Nephropathy in a Renal Transplant Recipient

Mohamedanwar M. Ghandour, Samah S. Suleiman, Noreen F. Rossi, Mareena Zachariah. *Wayne State University, Detroit, MI.*

Introduction: JC virus (JCV) is a Polyomaviridae family member. JC virus-associated nephropathy (JCVAN) is more common in renal transplant recipients in comparison to other organ recipients. We report a case of JCVAN presenting after fourteen years post-renal transplantation.

Case Description: A 65-year-old female with primary kidney disease attributed to chronic hypertension, who received a preemptive renal transplant in 2006. Postoperatively, her hospital course was uneventful, with a baseline creatinine of 1.1 mg/dL at discharge. Induction immunotherapy consisted of anti-thymocyte globulin, maintenance immunosuppression (IS) regimen consisted of triple immunotherapy with mycophenolate mofetil, tacrolimus, and low dose prednisone. Approximately 14 years after renal transplant, the patient's renal function deteriorated with creatinine increasing from 1.55 mg/dL to 2.43 mg/dL. The patient underwent a renal biopsy, which revealed positive staining for SV40 in multiple tubular nuclei suggestive of a persistent polyomavirus in the renal tubules (Fig 1). Plasma levels of BK virus were negative. Plasma JC virus titers were 61,400 copies/mL. Mycophenolate was stopped, and tacrolimus was reduced to trough level 3-5ng/dl. JC Viremia responded to lowering IS and became negative. The allograft function declined and the patient returned to dialysis in less than a year.

Discussion: JCVAN is unusual in renal transplant recipients. Risk factors include previous acute rejection episodes and male gender. Notably, this female patient had no proven previous episodes of acute rejection. JCVAN usually occurs within the first year post-renal transplant. However, the reported case was an older female diagnosed with JCVAN fourteen years following the living donor kidney transplant. The diagnosis of JCVAN is confirmed histologically by obtaining a kidney biopsy and the mainstay of management is reducing the degree of immunosuppression.



PO2109

A Case of Unexplained Encephalopathy in a Kidney Transplant Recipient

Anjana Easwar, Laila S. Lakhani, Arpita Basu, Stephen O. Pastan. *Emory University, Atlanta, GA.*

Introduction: Progressive multifocal leukoencephalopathy is a fatal demyelinating disease caused by the JC virus. Kidney transplant patients who are immunosuppressed are at higher risk of this infection.

Case Description: A 42 year old woman with CKD5 from FSGS who underwent a living donor kidney transplant 5 months ago, on immunosuppression with tacrolimus, mycophenolate and prednisone, presented with acute confusion, expressive aphasia and gait disturbance. Differentials included structural, infectious, metabolic and nutritional causes. A lumbar puncture and MRI brain were unremarkable. She was treated for suspected thiamine deficiency with intravenous thiamine. She developed myoclonus and hyperreflexia. Benzodiazepines and cyproheptadine were started with concern for serotonin syndrome. Tacrolimus dose was reduced with concern for calcineurin neurotoxicity. On hospital day 10, she developed status epilepticus; but MRI brain was unremarkable and EEG showed generalized encephalopathy. A second lumbar puncture revealed high opening pressures, WBCs and protein concerning for meningoencephalitis with negative gram stain and culture. CNS virus panel including HSV was negative. Empiric treatment with broad spectrum antimicrobials was begun. Tacrolimus was switched to sirolimus without neurologic improvement. A third CSF sample showed pleocytosis and elevated protein. Extended viral panel testing was sent to an outside lab. On day 16, she developed hemodynamic instability with worsening neurological exam, rapidly progressing to fixed dilated pupils and absent cough and gag reflexes. Within hours she developed cardiac arrest and was successfully resuscitated. CT head post arrest demonstrated diffuse cerebral edema and tonsillar herniation indicating devastating neurological injury. She was declared brain dead on hospital day 17. The CSF metagenomic testing panel later returned positive for JC virus.

Discussion: This is a complex and unfortunate case of PML due to JC virus in a newly transplanted patient, highlighting the ability of opportunistic CNS infections to masquerade as a nutritional deficiency/drug toxicity and the challenges of pursuing advanced diagnostic work up beyond standard testing. Immunosuppression in kidney transplant recipients remains a double edged sword where tilting the fine balance in favor of over-immunosuppression can lead to catastrophic infectious complications.

PO2110

Boron Exposure and Decreased Risk of Mortality in Kidney Transplant Recipients

Daan Kremer,[1,2] Adrian Post,[1,2] Ulrike Seidel,[3] Yvonne van der Veen,[2] Dion Groothof,[1,2] Antonio W. Gomes Neto,[1,2] Tim J. Knobbe,[1,2] Gerald Rimbach,[3] Stephan J. Bakker.[1,2] TransplantLines Investigators *[1]Rijksuniversiteit Groningen, Groningen, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Christian-Albrechts-Universitat zu Kiel, Kiel, Germany.*

Background: In a search for potential modifiable factors to improve long-term outcome among kidney transplant recipients (KTR), we studied dietary patterns in the Blue Zones, and hypothesized that boron exposure is associated with improved long-term outcome in KTR.

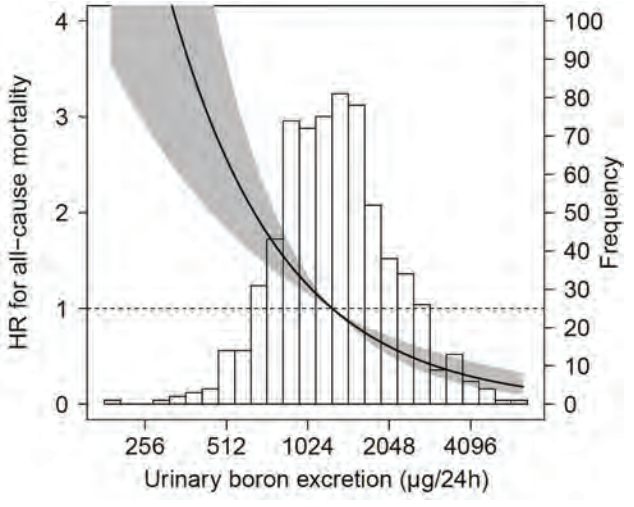
Methods: We determined 24h urinary boron excretion using inductively coupled plasma mass-spectrometry as a measure of boron intake in 693 stable KTR (57% male, mean age 53y), enrolled in the TransplantLines F&N Biobank and Cohort Study. Dietary intake was assessed using validated food-frequency questionnaires.

Results: Linear regression analyses showed that dietary intake of fruit, wine and nuts were key determinants of boron excretion. In contrast, boron excretion was negatively associated with homocysteine and inflammation parameters. In total, 73 (32%), 47 (20%) and 30 (13%) patients died among the lowest, middle and highest tertiles of boron,

respectively ($P_{log\text{-}rank}$ <0.001). Cox regression analyses showed that high boron excretion was strongly associated with lower risk of mortality, independent of age, sex, eGFR and history of cardiovascular disease (HR per doubling: 0.51, 95%CI:0.40 to 0.66, P<0.001, **Figure**), and other potential clinical and dietary confounders.

Conclusions: Boron may be an overlooked target to improve long-term outcome among KTR and potentially other patients, partly through suggested beneficial effects on inflammation, the methionine-homocysteine cycle, and ageing processes. Interventional trials are warranted to confirm the potential of dietary boron supplementation in KTR and other patient populations.

Funding: Clinical Revenue Support



Associations of urinary boron excretion with risk of all-cause mortality, based on a Cox proportional hazards regression model adjusted for age, sex, eGFR, and history of cardiovascular disease, presented in relation to the histogram of urinary boron excretion.

PO2111

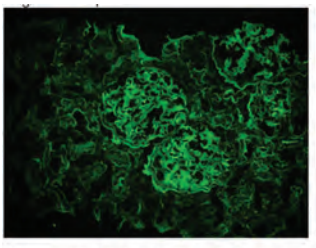
HIV-Associated Lupus-Like Nephropathy in a Transplanted Kidney: An Etiology for CKD

Kiran Shivaraj, Hay Me Me. *Westchester Medical Center, Valhalla, NY.*

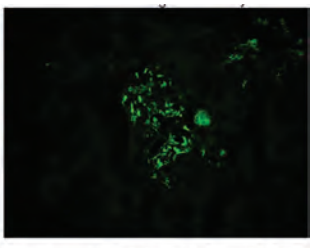
Introduction: The mortality of chronic Kidney disease in HIV is about 3 times higher in patients with HIV when compared to non HIV. With improved coverage of antiretroviral therapies with incidence of HIVAN a form of collapsing FSGS are decreasing but HIVICK a immune mediated form of nephropathy is increasing. One particular type called the HIV associated Lupus Like nephropathy has been described classically in a native kidney, we describe this lesion in a transplanted kidney and might be the cause of chronic kidney disease.

Case Description: 51 y o female patient with history of HIV on antiretroviral therapy who had a Living donor Kidney transplant from her HIV negative brother in about 4 years back and having a chronic kidney disease ckd stage 2 presented with intermittent watery diarrhea for 2 month and was found to have an acute kidney injury. The preliminary workup for Acute kidney injury including BK virus and DSA was negative. Renal transplant biopsy showed immune complex mediated glomerulonephritis with features of lupus like glomerulonephritis (full house stain with positive C1q), chronic transplant glomerulopathy with mild interstitial fibrosis and tubular atrophy, With a negative ANA and a negative ds DNA.

Discussion: The HIV lupus like nephropathy was picked up incidentally on biopsy while looking for acute rejection as the cause for the AKI which resolved with hydration. It was contributing to the underlying chronic elevated creatinine. The case is interesting as it has been described for the first time in a transplanted kidney and also that it's seen a kidney received from a non HIV donor as the pathogenesis requires the entry of viral particle into the renal cells in order to manifest the disease. The good immune system as indicated by the CD4 count and the viral titers supports the development of HIVICK. With the growing number of transplant in HIV positive patients HIV associated lupus like nephropathy a type of HIVICK should be considered as the cause of chronic elevated creatinine and might need adjustment of the immunosuppression accordingly.



IgG: granular stain in GBM and mesangial Areas.



C1q: granular staining in mesangial areas and GBM.

PO2112

Disseminated Adenovirus Infection in a Kidney Transplant Recipient

Boonyanuth N. Maturostrakul, Vinay Nair, Vanesa Bijol, Mersema Abate, Madhu C. Bhaskaran, Marcia Epstein, Gayatri D. Nair, Lewis Teperman, Hye Jeong Jang, Lawrence Lau. *Northwell Health, New Hyde Park, NY.*

Introduction: Adenovirus as an opportunistic pathogen can cause infections in immunocompromised hosts. Cases of disseminated adenovirus infection in renal transplant patients have been described to be detrimental.

Case Description: 28 year-old male with end stage renal disease from focal segmental glomerulosclerosis with 2 prior failed renal transplant on hemodialysis received a 3rd renal transplant from a deceased donor. Though initially planned for thymoglobulin induction, was switched to Basiliximab due to anaphylaxis during thymoglobulin infusion. Patient received plasmapharesis, IV immuglobulin and rituximab in view of his sensitized status and presence of donor specific antibodies with persistent elevated creatinine early post-transplant. Subsequent allograft biopsy showed Banff 1B rejection. He was treated with steroids and Alemtuzumab. Patient was discharged, but was readmitted with high fever. Blood and urine cultures were negative. Respiratory viral panel was positive for Adenovirus. Due to persistent high fever, immunosuppression was minimized. Hydronephrosis was drained with the nephrostomy. Repeat allograft biopsy was performed for rising creatinine. Light microscopy revealed severe necrotizing tubulitis with numerous basophilic nuclear viral inclusions and extensive polymorphonuclear inflammation consistent with adenoviral nephritis. Immunohistochemistry confirmed positive nuclear staining for adenoviral antigens. Patient was found to have moderate pericardial effusion and bilateral ground glass opacities. He was treated with Cidofovir, IV immunoglobulin and reduced immunosuppression. Due to persistent allograft dysfunction, he was maintained on dialysis. At the time of this report patient continues to be on dialysis.

Discussion: Adenoviral infection in healthy individual is often self-limited, rarely requiring more than symptomatic treatment. However, in immunosuppressed individuals it can lead to severe multisystem disease. In this patient, adenoviral infection following robust immunosuppression for early severe allograft rejection led to severe injury to allograft and near fatal illness. A high level of suspicion and prompt treatment can help improve the patient outcome.

PO2113

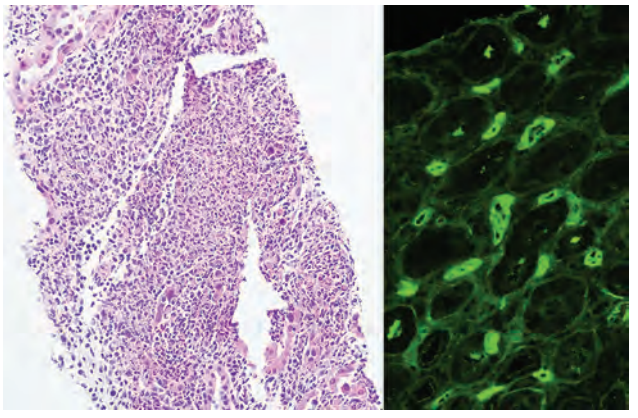
A Rare Case of Adenovirus Interstitial Nephritis and AMR Within Two Weeks of Kidney Transplant

Maliha Ahmed, Mohammed R. Karim, Hae Yoon Grace Choung. *University of Rochester, Rochester, NY.*

Introduction: Adenovirus nephropathy is a rare but devastating complication of kidney transplant. We report a case of adenovirus nephropathy associated with AMR within two weeks of renal transplant.

Case Description: 56 year old African American male with ESRD secondary to FSGS with history of LDKTXP in 2010 complicated by recurrent FSGS, BK viremia and chronic TCMR resulting in allograft failure and return to hemodialysis. He underwent DDKTXP in April, 2021 with rATG induction. He was noted to have slow graft function, serum creatinine trended down to 2.58 on post-op day 7 however again started to rise associated with fever and fatigue. PCR for BKV, EBV, CMV, COVID 19, influenza A and B remained negative. Adenovirus DNA was detected in sputum, urine and blood on post-op day 13. The patient underwent allograft biopsy on post-op day 16 which revealed severe necrotizing interstitial nephritis consistant with adenovirus nephropathy and early AMR (diffuse C4d positivity in peritubular capillaries with mild to moderate peritubular capillaritis, c4d3, ptc1-2). MMF was held, he received 5 plasmapharesis sessions and total of 1.1 g/Kg IVIGs. Cidofovir 1mg/Kg was staretd on alternate days. His course was complicated by anuric renal failure requiring return to hemodialysis. No evidence of donor associated ADV could be established.

Discussion: The case highlights the importance of distinguishing adenovirus interstitial nephritis from acute allograft rejection on biopsy . The case also highlights the dilemma of treating adenovirus interstitial nephritis and AMR concomitantly. Our patient has history of prior kidney transplant which is a risk factor for ADV infection. Viral infection of allograft predisposes it to rejection by stimulating various immune pathways



H&E stain shows Necrotizing interstitial nephritis with prominent tubular necrosis and destruction associated with poorly formed necrotizing granulomas and neutrophils.

IF shows diffuse C4d staining in peritubular capillaries

PO2114

Medial Arterial Calcification and Transplant Outcomes

Payaswini Vasanth, Tianen C. Yang, W. Charles O'Neill. *Emory University School of Medicine, Atlanta, GA.*

Background: Medial arterial calcification, a disorder distinct from atherosclerosis, is common in ESRD and associated with poor outcomes. Since this lesion does not regress after renal transplantation, it may be associated with poor outcomes in these patients as well. This was tested in a retrospective cohort of females undergoing renal transplantation using breast arterial calcification (BAC) as a specific marker of medial arterial calcification.

Methods: We identified all females with renal transplantation (Tx) through 2017 with digital mammograms performed at this institution. Mammograms were examined for arterial calcification, which was quantified by summing the lengths of calcified arterial segments. BAC was considered present at Tx if present any time prior to Tx or within 1.5 years after Tx. BAC was considered absent if absent within one year before Tx and any time after Tx. Medical records were reviewed for graft loss, cardiovascular disease (CVD: myocardial infarction, amputation, stroke, or any revascularization), and risk factors.

Results: 132 patients were identified with qualifying mammograms, which were performed a median of 0.50 years from Tx date. Clinical follow-up ranged from 3-13 years after Tx (mean: 6.4), time to graft loss 1.3-9.4 years (mean: 3.9), and time to CVD event 0.3-7.9 years (mean: 4.1). Patients with BAC (n=58) were older (55 vs. 50, p=0.004), had more diabetes (55 vs. 35%, p=0.02), parathyroidectomies (16 vs. 1.4%, p=0.005), and somewhat more pre-Tx CVD (12 vs. 4.1%, p=0.10). Graft loss (14 vs. 2.7%, p=0.022) and new CVD (21 vs. 5.4%, p=0.014) occurred more frequently in patients with BAC. BAC remained an independent predictor of graft loss in a logistic model including age, prior Tx, pre-Tx CVD, diabetes, and smoking (OR: 8.8; 95% CI: 1.2-62, p=0.029). The effect on CVD was no longer significant when pre-Tx CVD and diabetes were added to a logistic model. CVD was more common in those with BAC above vs. below the median quantity.

Conclusions: Medial arterial calcification was an independent predictor of renal allograft failure. It also predicted post-Tx CVD events but this was largely accounted for by the association with pre-Tx CVD and diabetes. Since all women undergo screening mammography prior to Tx, BAC could be a convenient marker of outcomes and targeting of risk factor modification and should be investigated in a larger cohort.

PO2115

Pre-Transplant Hypoalbuminemia Is Associated with Lower Risk for Rejection Among Kidney Transplant Recipients

Aahad N. Khan, Brad C. Astor, Aniruddha Srivastava, Fahad Aziz, Neetika Garg, Maha A. Mohamed, Didier A. Mandelbrot, Arjang Djamali, Sandesh Parajuli. *University of Wisconsin-Madison, Madison, WI.*

Background: Serum albumin is a marker of health status. Hypoalbuminemia is a common complication among patients with end-stage renal disease. Many patients would have hypoalbuminemia before getting a kidney transplant. The association of hypoalbuminemia and early post kidney transplant outcomes is not well studied.

Methods: All adult kidney transplant recipients at our center between 01/01/2001 and 12/31/2017 who had serum albumin levels ≤30 days prior to transplantation were included. Categorized recipients into four pretransplant albumin levels: normal albumin (≥4.0 gm/dL, reference group), mild (≥3.5-<4.0), moderate (≥3.0-<3.5), and severe (<3.0). We looked at pre-transplant hypoalbuminemia and outcomes incuding length of stay after transplant, readmission within 30 days, delayed graft failure, need for re-operation related to transplant. We also looked for the rate of rejection, graft failure, and death within the first six months of transplant.

Results: 2807 patients were included in the study. Of those, 1224 were identified as normal, 992 with mild, 466 with moderate, and 125 with severe. Albumin groups differed by age (p<0.001), BMI (p<0.001), pre-transplant dialysis (p=0.0011), cause of ESRD (p<0.001), and induction agent (p<0.001). The mild group was associated with -1.24 days less LOS (95% CI -1.73 to -0.75; p<0.001); and moderate by -0.82 day (95% CI -1.46 to -0.19, p=0.01) but not a significant difference in severe group, after adjustment of multiple confounding factors, compared to reference. There were no differences in the rate of DGF, re-hospitalization within 30 days across the groups. The moderate group was associated with a lower need for re-operation (HR: 0.39; 95% CI: 0.17 to 0.89; p=0.025). The moderate (HR: 0.54, 95% CI: 0.30-0.85; p=0.008) and severe (HR: 0.20, 95% CI: 0.06-0.65; p=0.007) groups were associated with a significantly lower rejection rate within six months compared to reference levels.

Conclusions: Our results suggest that the hypoalbuminemia is associated with a lower risk of acute rejections and some other complications, were also comparable compared to recipients with normal albumin levels. These findings may guide transplant providers in the selection of patients and anticipate and mitigate some of the post-transplant complications.

PO2116

Peripheral Arterial Disease and Risk of Infection-Related Complications After Kidney Transplantation

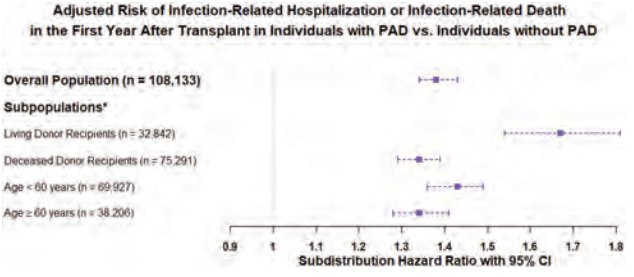
Alex Dinh, Timothy P. Copeland, Charles E. Mcculloch, Deborah B. Adey, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

Background: Infection-related hospitalizations after kidney transplantation are a common complication associated with significant morbidity and increased healthcare costs. Peripheral arterial disease (PAD) is a common comorbidity associated with poor wound healing and frailty, and may be an unrecognized risk factor for serious infections.

Methods: We included adults who received a kidney transplant in the US between 2006 and 2016. We used Fine-Gray models to assess the relationship between PAD and the composite outcome of infection-related hospitalization or infection-related death within the first year after transplant, while accounting for the competing risks of non-infection-related death or graft failure. We evaluated for presence of interactions between PAD and specific factors including age<60, diabetes, and donor type (living vs. deceased) for the outcome.

Results: Out of 108,133 kidney transplant recipients (KTRs), 22,442 experienced the composite outcome in the first year after transplantation. In adjusted models, PAD was associated with a 38% higher hazard of the primary outcome (95% CI 1.34-1.43) [Figure]. Statistically significant interactions were present between PAD and donor type and age category. In subgroup analyses, PAD was associated with a higher risk for the composite outcome in living donor KTRs and with slightly higher risk in younger vs. older KTRs.

Conclusions: PAD was associated with an increased risk of infection-related hospitalization or death in the first year after transplantation, especially in subgroups who traditionally may not be evaluated for PAD prior to transplant, such as living donor KTRs and younger populations. Better screening for PAD even in young populations may improve our ability to reduce the risk of complications post-transplant.



Models Adjusted for Sex, Race, BMI, Dialysis Vintage, Diabetes, Stroke, Primary Cause of Kidney Failure, Smoking History, and Transplant Year, and age or donor type depending on the subpopulation of interest; *P-interaction < 0.05.

PO2117

Pegloticase for Uncontrolled Gout in Kidney Transplant Recipients: Provisional Data Report of a Multicenter, Open-Label, Efficacy and Safety Study

Abdul A. Abdellatif,[1] Lin Zhao,[2] Paul M. Peloso,[2] Katya Cherny,[2] Brad Marder,[2] John D. Scandling,[3] Kenneth G. Saag.[4] *[1]Baylor College of Medicine, Houston, TX; [2]Horizon Therapeutics plc, Deerfield, IL; [3]Stanford University School of Medicine, Stanford, CA; [4]University of Alabama at Birmingham, Birmingham, AL.*

Background: Kidney transplant (KT) recipients have a high prevalence and severity of gout. Pegloticase (pegylated recombinant uricase) rapidly metabolizes urate and efficacy is not impacted by CKD stage. Immunomodulator co-therapy with pegloticase has improved treatment response rates over phase 3 monotherapy trials by attenuating anti-drug antibodies (ADAs). This ongoing Phase 4 trial (PROTECT NCT04087720) examines safety and efficacy of pegloticase in KT patients with uncontrolled gout (UCG).

Methods: KT recipients with UCG (serum urate [SU]≥7 mg/dL, intolerance/inefficacy to urate lowering therapy, and ≥1 of the following: tophi, chronic gouty arthritis, ≥2 flares in past yr) and functioning KT graft (eGFR≥15 ml/min/1.73m^2) on stable immunosuppressive (IMS) therapy are included (KT>1 y earlier). Pegloticase (8mg q2w for 24wks) safety and efficacy are examined. Primary endpoint was SU responders during Month 6 (SU <6 mg/dL for ≥80% of time). Health Assessment Questionnaire (HAQ) pain (most severe: 100) and Disability Index (HAQ-DI) scores (max: 3) were evaluated.

Results: 20 patients enrolled (mean±SD; age: 53.9±10.9 y, time since KT: 14.7±6.9 y, SU: 9.4±1.5 mg/dL, gout duration: 8.4±11.6 y; all on ≥2 IMS). At the time of analysis, 10 patients completed treatment, 3 discontinued study, 2 met SU monitoring rules (pre-dose SU>6 mg/dL at 2 consecutive visits) and discontinued pegloticase, and 5 were ongoing. All patients experienced initial substantial reductions in SU, which was maintained in the majority; 2 patients met monitoring rules. At week 24, no notable eGFR changes were observed. In patients that completed treatment, HAQ-pain and HAQ-DI scores improved by 26.7±30.3 (baseline: 35.9±30.2) and 0.2±0.5 (baseline: 1.0±1.0), respectively, at Week 24 (n=10). 7 SAEs (2 cellulitis, duodenal ulcer, sepsis, a-fib, diverticulitis, and localized infection) deemed unrelated to pegloticase, were reported in 5 patients. No anaphylaxis or IR events have occurred.

Conclusions: Preliminary results from the PROTECT trial, with Fall 2021 completion, demonstrate substantial and sustained SU decrease in the majority of KT recipients with uncontrolled gout. These findings are consistent with other reports on the effect of immunomodulation use with pegloticase.

PO2118

Discontinuation of Renin-Angiotensin System Blockade Among Kidney Transplant Recipients

Sophie Mcallister,[1] Salpi Siyahian,[2] Divya Seth,[2] Elaine Ku.[2] *[1]University of California San Francisco School of Medicine, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: Cardiovascular disease is common among recipients of kidney transplantation and is associated with high morbidity and mortality. While recent studies have shown evidence of cardiovascular benefit with the continuation of renin-angiotensin system (RAS) blockade for transplant-naïve patients with CKD there are little data on whether cessation of RAS blockade among kidney transplant recipients has kidney, cardiovascular, or survival benefits (or risks).

Methods: We performed a retrospective cohort study of kidney transplant recipients from the FAVORIT study. We included participants enrolled in the US who received an ARB or ACEi by self-report at one or more FAVORIT visits and performed a propensity score (PS) weighted Cox survival analysis to examine the risks or benefits of RAS discontinuation (vs. continuation). Outcomes were risk of death, return to dialysis, and major adverse cardiovascular events (MACE; stroke, myocardial infarction, coronary revascularization, or heart failure). Doubly robust estimation was also used on the PS weighted sample to provide conservative estimates.

Results: 2,009 US participants had at least one visit where they reported taking a RAS inhibitor. 30% (n=598) of participants discontinued RAS blockade. Compared to those who continued RAS blockade, participants who discontinued RAS blockade were significantly less likely to experience mortality, return to dialysis, and MACEs (Table).

Conclusions: Kidney transplantation recipients who stopped RAS blockade had lower rates of mortality, return to dialysis, and MACEs compared to those who continued RAS blockade. These data may be useful when deciding on the risks and benefits of continuing RAS blockade for patients receiving kidney transplantation.

Hazard of adverse outcomes for kidney transplantation recipients discontinuing vs. continuing ACEi/ARB

	Mortality HR (95% CI)	Dialysis HR (95% CI)	MACE HR (95% CI)
Unweighted adjusted model	0.72 (0.54-0.96)	0.71 (0.51-0.99)	0.63 (0.47-0.85)
Propensity-score weighted unadjusted model	0.75 (0.57-1.00*)	0.77 (0.56-1.07)	0.64 (0.48-0.85)
Propensity-score weighted adjusted model (doubly robust)	0.72 (0.55-0.96)	0.71 (0.51-0.99)	0.62 (0.46-0.83)

Blood Transfusion and Venous Thromboembolism in Kidney Transplant Patients

David Massicotte-Azarniouch. *University of Ottawa, Ottawa, ON, Canada.*

Background: Receipt of a red blood cell transfusion (RBCT) is common in kidney transplant patients and could have pro-thrombotic effects predisposing to venous thromboembolism (VTE). The aim of this study is to examine the risks for the development of VTE associated with the receipt of RBCT in kidney transplant patients.

Methods: We conducted a retrospective cohort study of all adult kidney transplant recipients at The Ottawa Hospital from 2002 to 2018, using administrative databases and medical chart review. The exposure of interest was receipt of a RBCT after transplant. Cox proportional hazards models were used to calculate hazard ratios (HR) for venous thromboembolism [VTE] (deep venous thrombosis [DVT] or pulmonary embolism [PE]) using RBCT as a time-varying, cumulative exposure.

Results: Out of 1,258 kidney transplants recipients, 468 (37%) received a total of 2,373 RBCT after transplant (incidence of 33 RBCT per 100 patient-years). During follow up, 79 study participants (6.3%) developed VTE, 72 had a DVT (5.7%) and 22 had a PE (1.8%). For the receipt of 1, 2, 3-5 and >5 RBCT, compared to individuals never transfused, the number of events and adjusted HR (95% CI) for VTE was 6 events (6.2%) HR 1.57 (0.69 to 3.58), 9 events (7.6%) HR 2.54 (1.30 to 4.96), 15 events (11.9%) HR 2.73 (1.38 to 5.41) and 23 events (18.1%) HR 5.77 (2.99 to 11.14) respectively; for DVT it was 6 events (6.2%) HR 1.94 (0.84 to 4.48), 9 events (7.6%) HR 2.92 (1.44 to 5.94), 14 events (11.1%) HR 3.29 (1.63 to 6.65) and 21 events (16.5%) HR 6.97 (3.53 to 13.76), respectively. For PE, among transfused individuals there were 14 events (3.0%) and the HR was 2.40 (1.02 to 5.61).

Conclusions: The risk for developing VTE, DVT and PE was significantly associated with the receipt of a RBCT in kidney transplant patients. Receipt of a RBCT should prompt considerations for judicious monitoring and assessment for possible thrombosis.

Cox model HRs for VTE events based on RBCT exposure

Outcome	# RBC units received	# events (%)	Unadjusted HR (95% CI)	Adjusted HR (95% CI)*	Any RBCT vs No RBCT: adjusted HR (95% CI)*
VTE (DVT or PE)	None 1 2 3-5 >5	26 (3.3) 6 (6.2) 9 (7.6) 15 (11.9) 23 (18.1)	Reference 1.85 (0.82 to 4.18) 2.67 (1.38 to 5.16) 3.59 (1.86 to 6.95) 7.45 (3.95 to 14.06)	Reference 1.57 (0.69 to 3.58) 2.54 (1.30 to 4.96) 2.73 (1.38 to 5.41) 5.77 (2.99 to 11.14)	2.75 (1.73 to 4.38)
DVT	None 1 2 3-5 >5	22 (2.8) 6 (6.2) 9 (7.6) 14 (11.1) 21 (16.5)	Reference 2.25 (0.98 to 5.15) 2.96 (1.47 to 5.95) 4.27 (2.17 to 8.43) 8.90 (4.62 to 17.13)	Reference 1.94 (0.84 to 4.48) 2.92 (1.44 to 5.94) 3.29 (1.63 to 6.65) 6.97 (3.53 to 13.76)	3.29 (2.01 to 5.40)

AV Fistula Leading to High-Output Cardiac Failure in a Kidney Transplant Population: Our Experience

Yahya R. Ahmad, Hasan Fattah. *University of Kentucky, Lexington, KY.*

Background: Among kidney allograft recipients, cardiovascular death continues to remain the major cause of mortality. Arteriovenous (AV) fistula is the optimal access for most end stage kidney disease (ESKD) patients. AV fistula can lead to hemodynamically significant left-to-right sided shunting resulting in permanent structural and functional cardiac changes. We herein reviewed our center cases of high cardiac-output cardiac failure secondary to AV fistula who were followed up after surgical intervention.

Methods: Retrospective chart review was performed on kidney transplant patients who had a diagnosis of high output cardiac failure confirmed on right heart catheterization and required AV fistula ligation for symptomatic high output cardiac failure at University of Kentucky.

Results: A total of 595 kidney transplants were performed at University of Kentucky during the study period (January 2015 until May 2021). 19 patients underwent fistula ligation, 7 of them (36.8%) required AV fistula ligation due to high output cardiac failure. Average peak blood flow across the AV fistula that required ligation was 2.8 L/min. Cardiac catheterization showed drop in cardiac output (CO) with AV fistula closure as seen in Figure 1. Improvement in renal functions was notable in most cases as seen in Figure 2. Symptoms of heart failure improved in all 7 patients with no re-admissions for heart failure exacerbation after AV fistula closure, up until writing this data.

Conclusions: High output heart failure from AV fistula is an under recognized entity. Early diagnosis and management is crucial as it can prevent irreversible changes in cardiac and renal physiology and improve quality of life.

Hypophosphatemia in the Context of Hematopoietic Stem Cell Transplantation: An Underappreciated Complication

Thangamani Muthukumar,[1] Carlos Flombaum.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Hypophosphatemia (and hypokalemia) occur frequently in the context of hematopoietic allogeneic stem cell transplantation (allo-SCT) and during autologous SCT (auto-SCT) and have been attributed to uptake of these electrolytes by the reconstituting bone marrow. Similar metabolic complications can also occur after chemotherapy and during stem cell mobilization prior to auto SCT. These metabolic abnormalities have not been well described in the nephrology literature and in current textbooks of onconephrology. Aim of the research was to describe the clinical course of patients with these electrolyte abnormalities in the context of SCT, chemotherapy and after bone marrow stimulation prior to SCT harvesting.

Methods: Chart review of patients undergoing SCT, after chemotherapy and SCT for harvesting.

Results: We identified 42 patients with 67 episodes of hypophosphatemia and hypokalemia. The clinical features and course are provided in the table.

Conclusions: Besides uptake of phosphorous and potassium by the reconstituting bone marrow under the stimulation of granulocyte colony a stimulation factor, other factors contributing to these metabolic abnormalities include poor oral intake, the use of phosphate binders, diuretics and losses during renal replacement therapy.

Characteristics	Chemotherapy-related	Auto-SCT-related	Allo-SCT-related	During Stem Cell Mobilization
Number of patients, N	15	17	9	9
Number of episodes, N	31	18	9	9
Kidney injury (acute or chronic), N	15 (48%)	12 (67%)	4 (44%)	8 (89%)
Renal replacement therapy, N	11 (36%)	6 (33%)	0 (0%)	6 (67%)
Use of G-CSF, N	29 (94%)	18 (100%)	9 (100%)	9 (100%)
Number of days with hypophosphatemia, median (IQR)	7 (4-12.5)	4 (2-9.5)	10 (7-13)	2 (2-3)
Nadir serum phosphate, median (IQR)	1.4 (1.15-1.80)	1.35 (1.05-1.88)	1.3 (1.1-1.5)	1.5 (1.2-2.2)
Use of phosphate replacement, N	22 (71%)	14 (78%)	9 (100%)	5 (56%)
Use of phosphate binders, N	8 (26%)	8 (44%)	1 (11%)	5 (56%)

Nadir serum potassium, median (IQR)	3 (2.9-3.1)	3.2 (3.1-3.3)	3.2 (3.1-3.2)	2.9 (2.6-3.1)
Use of diuretics, N	6 (19%)	7 (39%)	6 (67%)	1 (11%)
Use of potassium replacement, N	21 (68%)	15 (83%)	7 (78%)	3 (33%)

PO2122

Kidney Graft Ultrasound (US) After Elective JJ Stent Removal (EJJR)

Haridian Sosa Barrios,[1] Victor Burguera,[1] Elizabeth R. Viera,[1] Daniel Villa,[1] Cristina Galeano,[1] Sara Jimenez Alvaro,[1] Irene Martin Capon,[1] Milagros Fernandez-Lucas,[1] Maite Rivera Gorrin.[1,2] *[1]Hospital Universitario Ramon y Cajal, Madrid. IRYCIS, Spain; [2]Universidad de Alcala de Henares Facultad de Medicina y Ciencias de la Salud, Alcala de Henares, Spain.*

Background: Improving kidney transplant (KTx) outcomes remains a primary challenge and KTx ureter JJ stenting has been used to prevent urological complications. There is no consensus about EJJR timing, and literature regarding routine US imaging after EJJR to detect complications is lacking.

Methods: We retrospectively analysed all routine KTx US done in our Unit from 2016-2020 by an experienced interventional nephrologist. US post EJJR findings were compared with previous US. KTx characteristics, treatment and outcomes were recorded. We aimed to define incidence of urological complications diagnosed, US utility and best time interval to perform it.

Results: 345 KTx were done: 62.9% were male receptors, 81.7% had a first KTx and 91.5% of the organs were from a deceased donor. No routine US post EJJR was done in 20.9% due to COVID pandemic. Mean timing to elective JJ stent removal was 36.4 ± 25 days (SD). Mean time from EJJR to US was 16.3 ± 28.8 days (SD). Urinary tract ectasia was not considered pathological. Of those with an US, 45.1% (123) had a complication detected: 41.4% had a newly diagnosed collection and 21% had urinary tract dilatation (UTD): 10% grade I UTD. 6% grade II UTD. 5% grade III UTD. Of the 123 patients with a complication, 3 required a surgical approach, 2 had a drainage inserted, 2 nephrostomies, 11 required admission without surgical intervention and 51 had US follow up. Cumulative frequency analysis of complications post EJJR showed the highest diagnostic yield of US imaging was around day 10 post removal (figure 1).

Conclusions: Routine US after EJJR allowed timely diagnosis and early treatment of urological complications, a key factor for successful transplantation. KTx US is an effective, cheap and reproducible test that provides crucial information to guide clinical decisions, being most effective when performed 10 days post stent removal. Interventional nephrologists could do this examination promptly.

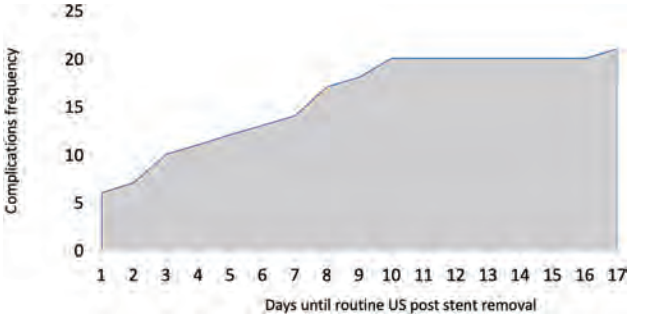

Figure 1. Cumulative frequency of complications

PO2123

A Cardiac Magnetic Resonance (CMR) Study with Native T1 Mapping in Patients Listed for a Kidney Transplant

Jordana Yahr,[1] Sadeer Al-Kindi,[2] Scott E. Janus,[2] Aparna Padiyar,[2] Mahboob Rahman,[2,3] Sanjay Rajagopalan,[2,3] Anne M. Huml,[1,3] Mirela A. Dobre.[2,3] *[1]Cleveland Clinic, Cleveland, OH; [2]University Hospitals, Cleveland, OH; [3]Case Western Reserve University, Cleveland, OH.*

Background: Uremia causes activation of cardiac fibroblasts, a decrease in capillary density and promotes fibrosis by impairing oxygen diffusion to cardiomyocytes and promoting apoptosis. Assessment of myocardial fibrosis can be done non-invasively by non-contrast CMR T1 mapping. Though reversal of myocardial fibrosis post kidney transplant has been postulated, no study has systematically assessed it in transplant recipients compared to patients who remain on the waiting list. We aimed to assess the change in T1 maps post transplant in comparison to that in waitlisted patients.

Methods: Patients from 2 clinical sites, scheduled to receive a living kidney transplant underwent a non-contrast CMR prior to and 9 months post-transplant. An age-, sex-, race- and dialysis vintage-matched control group was selected from the patients waitlisted for a deceased donor, and had non-contrast CMR performed at baseline and after 9 months. Cardiac fibrosis measured by T1 maps were compared between the 2 groups.

Results: A total of 34 participants underwent CMR at study baseline. Mean age±SD was 55±14 years, and 13(38%) were women, 7(21%) Black and 16(47%) were on dialysis. There was no difference in baseline T1 level in pre-dialysis (1063±50 ms) vs dialysis (1062±51 ms) participants, and in transplant (1063±60 ms) vs waitlisted (1063±48 ms) participants. In multivariable adjusted models, age, diabetes, and heart failure were significantly associated with T1 levels. In a subgroup of 7 participants with available follow-up CMR, compared to control group, those transplanted had a reduction in T1 levels (-64±59 ms vs 20±49 ms, p=0.09) Figure. Participants with high baseline T1 had the least decline in follow-up T1 levels.

Conclusions: Myocardial fibrosis as measured by native CMR T1 maps is reduced post kidney transplantation and continues to worsen for patients who remain actively listed for a transplant.

SGLT-2 Inhibitor Treatment in Renal Transplant Recipients: A Single-Center Experience

Luz E. Liriano-Ward, Simona Stefan, Alesa Campbell, Yorg Al Azzi, Maria Ajaimy, Cindy T. Pynadath, Pablo Loarte Campos, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

Background: Dapagliflozin, a sodium glucose transport protein 2 inhibitor (SGLT2-i), was recently approved for use in chronic kidney disease patients regardless of the presence of diabetes, after studies demonstrated improved renal and cardiovascular outcomes even in the absence of diabetes. The use of SGLT2-i in transplant recipients have been limited due to concerns for acute kidney injury (AKI) resulting from volume depletion or urinary tract infections (UTI) or other genital infections due to their glucosuric effect.

Methods: Retrospective review of all adult renal transplant recipients transplanted at our center between January 2013 and June 2020.

Results: 22 adult renal transplant patients at our center received treatment with an SGLT2-i during the study period. The patient's ethnicity was representative of our patient's population with 45% being Hispanic and 40% black. 68% of the patients were men and the median age was 64 years old. The vast majority of patients, 77%, had diabetes mellitus as the etiology of ESRD. 73% received a deceased donor kidney transplant and were started on SGLT2-i at a median time of 38 months post-transplant. 13 patients were treated with empagliflozin with a starting dose of 10mg daily, 7 with canagliflozin at 100mg daily, 1 dapagliflozin at 5mg daily, and 1 ertugliflozin at 2.5mg daily. The median creatinine at the start of treatment was 1.1mg/dl, urine protein creatinine ratio was 206 mg/g, and A1C 8.6 %. SGLT2-inhibitors were well tolerated without significant adverse events. 4 patients developed hypoglycemia. Two patients developed a UTI and only 1 patient developed AKI requiring discontinuation of the drug. The median creatinine one-year post treatment initiation was stable at 1.1mg/dl, UPCR was 448.4 mg/g, and A1C was 7.7. Finally, there was no significant interaction with the immunosuppression medications. The tacrolimus level remained stable and the patients did not require dose modifications post therapy initiation.

Conclusions: Treatment with SGLT2-i was well tolerated in our transplant population. Larger prospective studies are required to evaluate clinical outcomes in this patient population.

PO2125

Immunosuppression and Incident Cancer Risk in Older Kidney Transplant Recipients

Krista L. Lentine,[1] Yasar Caliskan,[1] Wisit Cheungpasitporn,[3] Ruixin Li,[1] Mark Schnitzler,[1] Mara McAdams-DeMarco,[4] Vikas R. Dharnidharka,[5] JiYoon B. Ahn,[4] Suphamai Bunnapradist,[6] Sunjae Bae,[4] Dorry L. Segev,[4] Gregory Hess,[7] David Axelrod.[2] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; [3]Mayo Clinic Minnesota, Rochester, MN; [4]Johns Hopkins University, Baltimore, MD; [5]Washington University in St Louis, St Louis, MO; [6]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [7]Drexel University, Philadelphia, PA.*

Background: Cancer is a serious complication after kidney transplant (KTx), especially among older adults. The relationship of immunosuppression (ISx) to cancer in older KTx recipients is not well described.

Methods: We examined USRDS data (2005-2017) to explore associations of ISx regimens (within 6 mo) with new-onset cancer diagnoses >6 mo-to-5 yr post-KTx among Medicare-insured older (aged ≥ 65) adults. We used multivariate Cox regression with inverse propensity weighting to compare cancer risk vs. reference regimen of Thymoglobulin (TMG) or Alemtuzumab (ALEM) + Tacrolimus + antimetabolite + prednisone. Cancer diagnoses were also examined as time-dependent mortality predictors.

Results: Among 12567 older recipients, skin cancer incidence was higher with Tac+antimetabolite avoidance (10.3%) and CsA-based ISx (8.9%) compared to TMG/ALEM+triple ISx (6.4%; P=0.03 and P=0.002), while non-viral driven/non-skin cancer was less common with CsA-based ISx (10.9% vs 14.7%; P=0.03) (**Fig. A**). In adjusted models, IL2rAb+triple ISx was associated with lower skin cancer risk (aHR, $_{0.60}0.76_{0.96}$). IL2rAb+steroid avoidance was associated with increased non-viral driven/non-skin cancer (aHR, $_{1.03}1.34_{1.75}$), while CsA-based ISx predicted lower risk (aHR $_{0.59}0.75_{0.95}$) (**Fig. B**). However, adjusted for time-varying impact of viral-driven (aHR $_{1.99}2.27_{2.58}$) and non-viral driven/non-skin cancers (aHR $_{2.11}2.27_{2.43}$), CsA use (aHR $_{1.12}1.24_{1.37}$) predicted increased mortality in older recipients.

Conclusions: Although CsA-based ISx appears beneficial for non-skin cancer risk in older KTx recipients, this regimen is associated with increased mortality. Cancer risk is a consideration in tailoring ISx in older KTx recipients.

PO2126

Belatacept Conversion in Proteinuric Kidney Transplant Recipients: Data from a Retrospective Cohort and a Prospective Trial

Orhan Efe,[1] Ayman Al Jurdi,[1] David Wojciechowski,[3] Kassem Safa,[1] Hannah M. Gilligan,[1] Anil K. Chandraker,[2] Jamil R. Azzi,[2] Astrid Weins,[2] Leonardo V. Riella.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Proteinuria is a strong predictor of graft loss in kidney transplant (KT) patients. Treatment options for proteinuria are limited to ACEis/ARBs. Belatacept targets B7-1 which is also expressed on podocytes and has been linked to proteinuria by inducing podocyte migration. We examined the utility of belatacept conversion in proteinuric KT recipients.

Methods: In the phase I multicenter trial, we recruited EBV IgG+ adult KT recipients > 6 months post-KT with an eGFR > 30ml/min/1.73m^2, proteinuria > 1g/day on CNI-based immunosuppression. Patients were converted from CNI to belatacept. The primary outcome was 25% reduction in proteinuria at 12 months. In the retrospective cohort, we included patients who were converted to belatacept in 2015-2019.

Results: In the retrospective cohort, 12 of 77 belatacept conversion patients had pre-conversion proteinuria > 0.4 g/g and follow up values. Baseline proteinuria decreased from 1±0.9 g/g to 0.69±0.9 g/g at >12 months (p=0.070). Mean eGFR increased from 37±12 to 49±15 ml/min/1.73m^2 at 12 months. In the prospective cohort, 15 KT recipients were recruited. At 12 months post-conversion, mean (+SD) eGFR remained stable at 43.7±12.9 ml/min/1.73m^2 and proteinuria improved from 2.5±1.9 to 1.7±1.8 g/g (p=0.068). Primary outcome was reached in 53% of the patients. None of the patients had graft rejection in the first year. One patient had worsening of proteinuria and discontinued belatacept. At 24 months, eGFR remained stable and proteinuria was 1.4±1.2 g/g. Figure 1 summarizes eGFR and proteinuria course from both cohorts.

Conclusions: Belatacept conversion in proteinuric KT recipients was associated with stable allograft function and reduction in proteinuria at 1 year and beyond.

Funding: Commercial Support - Bristol Myers Squibb

Outcomes of Thymoglobulin vs. Basiliximab Induction Therapies in 2DR Mismatch Living-Donor Renal Transplant Recipients

Mahmoud M. Mohamed,[1] Hafiz Muhammad Ali Raza,[1] Hatem Ali,[2] Shafi Malik.[2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University Hospital Coventry, Coventry, United Kingdom.*

Background: 2DR HLA mismatch indicates a high immunological risk of renal transplant. Induction therapy with Thymoglobulin and Basiliximab result in a marked reduction of acute allograft rejection rate and improve graft survival. However, the outcomes in 2DR HLA mismatched renal transplant recipients (RTRs) in the tacrolimus era remain understudied

Methods: Using data from UNOS, all 2 DR mismatched RTRs who were maintained on tacrolimus and mycophenolate mofetil immunotherapy between September 2017 and September 2019 were included. Follow-up data was until September 2020. Patients who received transplants from living donors were included in the study. Collected data included recipient (age, sex, ethnicity, diabetes, body mass index), transplant (delayed graft function, cold ischemia time, number of previous transplants, panel reactive antibodies, HLA-mismatches, induction therapies, maintenance immunotherapy, and donor factors (donor type, donor age). RTRs were divided based on induction therapy into r-ATG and IL-2RA. Instrumental variable regression models were used to assess the effect of induction therapy on acute rejection episodes at 12 months post-transplant, serum creatinine levels at 12 months post-transplant, and graft survival. Type of induction therapy was instrumented for the transplant center to reduce the center effect on the choice of the induction therapy. The regression models were adjusted for the collected recipient, donor, and transplant factors

Results: 788 patients received Basilximab while 1727 patients received Thymoglobulin induction. There were no significant differences between Basiliximab versus Thymoglobulin induction in acute rejection episodes at one-year post-transplant (coefficient=-0.229, P value=0.106, 95% Confidence interval:-0.508to 0.049), serum creatinine levels at one-year post-transplant (coefficient=-0.024, P value=0.128, 95% Confidence interval:-0.055to 0.006) or overall graft survival (coefficient=0.008, P value=0.801, 95% CI:-0.001 - 0.001)

Conclusions: The study showed no significant difference in acute rejection episodes or graft survival when using Thymoglobulin or Basiliximab in 2DR HLA mismatched living donor renal transplant recipients in the current tacrolimus-based maintenance immunosuppression era. Therefore, Basiliximab is a safe induction therapy in this group of patients

PO2128

Outcomes of Early and Late Calcium Oxalate Deposition Following Kidney Transplantation

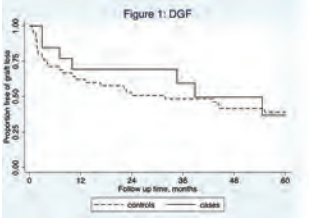
Thanh Thanh T. Nguyen, Brad C. Astor, Weixiong Zhong, Sandesh Parajuli, Fahad Aziz, Maha A. Mohamed, Arjang Djamali, Didier A. Mandelbrot, Neetika Garg. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

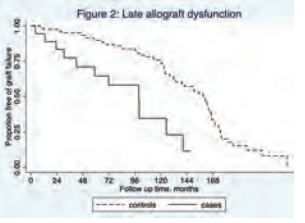
Background: Calcium oxalate deposition (CaOx) can result in progressive native kidney disease. The pathophysiology of hyperoxaluria in kidney transplant (KT) differs, especially early after surgery where the allograft encounters high levels. It is not clear whether CaOx in a kidney allograft portends worse outcomes. Determining its clinical relevance will influence the need for aggressive dietary or medication-based interventions.

Methods: All KT recipients at our center with CaOx on kidney allograft biopsy were categorized into two cohorts: delayed graft function (DGF; n=13) and late graft dysfunction (n=25). Up to 5 controls were selected per DGF case through event density sampling matched for organ type (kidney vs. simultaneous pancreas-kidney), prior transplants, and history of prolonged DGF prompting a biopsy (n=46). Controls for 'late' cases were matched for organ type, prior transplants, and living vs. deceased donor (n=125). Variables found to be statistically significantly associated with case status in bivariate analysis (p<0.10) were included in multivariate Cox regression analyses of allograft outcomes.

Results: DGF cases were more likely to have had gastric bypass surgery (7.7% vs. 0%, p=0.06) and less likely to have a history of rejection (7.7% vs. 37.0%, p=0.06) than controls. CaOx during DGF was not associated with increased risk of graft failure after adjustment (HR 1.1, p=0.87; Figure 1). 'Late' CaOx cases diagnosed median of 56.7 months (IQR: 9.8-108.9 months) after transplant were older at time of transplant (53.9 vs. 48.4 years, p=0.04) and less likely to be male (36% vs 61%, p=0.03) than controls. 'Late' CaOx was associated with a higher risk of allograft failure after adjustment (HR 3.2, p<0.001); Figure 2).

Conclusions: CaOx in kidney allograft during DGF may be a consequence of high circulating oxalate levels and was not associated with worse KToutcomes. 'Late' CaOx, likely related to increased intestinal oxalate absorption, a phenotype similar to secondary hyperoxaluria in native kidneys, was associated with increased risk of allograft failure.





PO2129

HLA Antibody Elevation Following Red Blood Cell Transfusions in CKD: Results from the START-CKD Trial

Matthew R. Weir,[1] Jeffrey Petersen,[2] Robert D. Toto,[3] Jeffrey S. Berns,[4] Qui Tran,[2] Carrie L. Butler,[5] Nicole M. Valenzuela.[5] *[1]University of Maryland Baltimore, Baltimore, MD; [2]AMGEN, Thousand Oaks, CA; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]University of Pennsylvania, Philadelphia, PA; [5]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Red blood cell (RBC) transfusion avoidance wherever possible is recommended in kidney transplant candidates in order to prevent the risk of allosensitization. We have previously reported allosensitization following RBC transfusions in dialysis patients with anemia and advanced CKD, but no study has addressed allosensitization in patients with CKD not on dialysis. The START-CKD trial evaluated an ESA treatment on the incidence of RBC transfusions in anemic CKD subjects. This study prospectively collected transfusion data along with antibody (Ab) samples. We hypothesized that RBC transfusions would be associated with: a) development of de novo Abs, b) increase in relative strength of existing HLA Abs, and c) increase in calculated panel reactive Ab (cPRA).

Methods: We used two different cohort designs: matched cohort containing subjects with RBC transfusion in between 2 HLA Ab samples, versus subjects with 2 HLA Ab samples without intervening RBC transfusion event. Each transfused subject was matched with up to 2 non-transfused subjects with 4 variables. The second identified cohort consisted of cross-over subjects with longitudinal pre- and post-transfusion Ab samples allowing the subject to serve as their own control. In total, 476 samples from 211 subjects were tested for Ab reactivity to HLA by LabScreen single antigen (OneLambda).

Results: We identified 72 transfused and 124 matched non-transfused patients, and 54 crossover transfused patients. A greater proportion of patients experienced changes in MFI ≥ 25% for class I and ≥ 30% for class II antigens in the transfused compared with non-transfused patients in both matched (any change, 25% vs 7%; significant change, 24% vs 3%) and cross-over cohorts (any change, 19% vs 9%; significant change, 17% vs 2%). In the matched and cross-over cohorts, positive cPRA change occurred in 19% and 11% of transfused subjects, respectively, vs 5% and 6% of non-transfused subjects respectively.

Conclusions: RBC transfusion in patients with anemia and advanced CKD not on dialysis was associated with new HLA antibody development, increased risk of relative strength of antibodies and higher cPRA. These findings establish an important causal relationship between RBC transfusions and clinically relevant HLA Ab development for the first time in this population.

PO2130

Chronic Active Antibody-Mediated Rejection: Response Rates to Treatment and Predictors of Graft Survival

Fahad Aziz, Sandesh Parajuli, Neetika Garg, Maha A. Mohamed, Didier A. Mandelbrot, Arjang Djamali. *University of Wisconsin System, Madison, WI.*

Background: There is limited information on response rates to Rx and predictors of graft survival following chronic active antibody mediated rejection (cABMR).

Methods: We reviewed changes in kidney function, DSA, and histology in 3-month surveillance biopsies after initial therapy with pulse steroids/IVIG ± rituximab in kidney transplant recipients with cABMR between 01/2017 and 08/2020. Rx response was defined as 3M eGFR within 10% of baseline, proteinuria (UPC) decline by > 15%, DSA decline by > 50%, and MVI (ptc + g) score = 0.

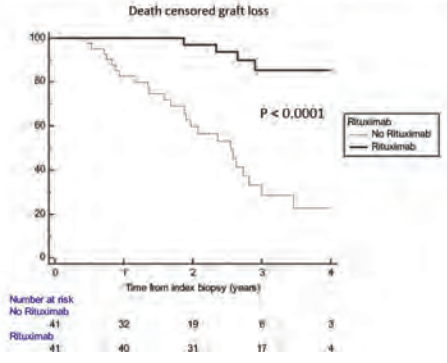
Results: The study included 82 patients. 50% received rituximab. Mean time from Tx to cABMR was 10 yrs. Mean ptc, g, C4d, and cg Banff scores at index biopsy were 1.1, 2.1, 0.2, and 2, respectively. 47 patients (57%) had measurable circulating DSA. Mean eGFR and UPC were 38 mL/min and 1.6 g/g. Thirty (37%) patients lost their allograft during the mean follow-up of 2.4 yrs. At 3M, Rx with pulse steroids/IVIG was associated with eGFR, UPC, DSA, and MVI response in 27%, 49%, 7%, and 19% of patients. The addition of rituximab improved response to 66%, 61%, 20%, and 69%, respectively. On univariate analysis, rituximab use (HR=0.13, p=0.0001, 95%CI 0.05 to 0.34) and a response in eGFR (HR=0.03, p=0.001, 95% CI 0.004 to 0.26), UPC (HR=0.38, p=0.01, 95%CI 0.18 to 0.82), and DSA (HR=0.11, p=0.004, 95%CI 0.02 to 0.49) were associated with improved death-censored graft survival. Multivariate analysis only retained eGFR response (HR=0.12, p=0.01, 95%CI 0.02 to 0.64).

Conclusions: Our study suggests that a return to baseline eGFR at 3M after initial biopsy is the best predictor of graft survival in patients with cABMR. Short-term histological and immunological response to treatment were not independently associated with graft survival.

Response Rate at Surveillance Biopsy

Response	Steroids/IVIG	Steroids/IVIG/Rituximab	p-value
eGFR	11/41 (27%)	27/41 (66%)	0.004
UPC	20/41 (49%)	25/41 (61%)	0.3
DSA	4/21 (19%)	18/26 (69%)	0.007

Figure. Rituximab was Associated with Improved Graft Survival



PO2131

Outcomes of Acute and Chronic Antibody-Mediated Allograft Rejection in Kidney Transplant Recipients

Ayman Al Jurdi,[1,2] Laura Goldfarb Cyrino,[1] Marie-Camille Lafargue,[3] Leonardo V. Riella.[1] Riella Lab *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Universite de Paris, Paris, France.*

Background: The optimal treatment regimen for antibody-mediated rejection (AMR) in kidney transplant recipients (KTRs) has yet to be established. The purpose of the study was to evaluate the outcomes of KTRs with acute and chronic AMR managed with different treatment regimens.

Methods: We conducted a retrospective cohort study of all KTRs with biopsy-proven acute or chronic AMR between January 2017 and September 2020 at a single center. The primary outcome was allograft loss at last follow up. Secondary outcomes included differences in allograft survival between treatment regimens, and changes in estimated glomerular filtration rate (eGFR) and urine protein-creatinine ratio (UPCR) at last follow up.

Results: 53 KTRs with AMR were included in the study. Mean age was 51 years, 50% were female and the most common cause of end-stage kidney disease was glomerular disease. 57% received living donor transplants, median number of human leukocyte antigen ABDR mismatches was 4, and 38% had pre-transplant donor-specific antibodies. For induction immunosuppression, 61% received anti-thymocyte globulin, 35% received basiliximab and 4% received alemtuzumab. 35% had acute AMR and 65% had chronic-active AMR. At the time of biopsy, median (IQR) eGFR was 32 (22-42) ml/min/1.73 m^2 and UPCR was 1.1 (0.4-2.5) g/g. For treatment, 72% received pulse steroids, 64% received intravenous immunoglobulin, 51% received plasma exchange (PLEX) and 43% received bortezomib. At a median follow up of 23 months, patient survival was 94% and death-censored allograft survival was 74%. Median (IQR) eGFR was 27 (11-43) ml/min/1.73m^2 and UPCR was 0.48 (0.17-0.97) g/g. There was no difference in the risk of allograft loss in patients who received PLEX compared to those who did not (RR=0.97, 95% CI: 0.4-2.4) and in those who received bortezomib compared to those who did not (RR=0.8, 95% CI: 0.3-2.0). The risk of allograft loss was higher in KTRs with UPCR>3g/g at AMR diagnosis compared to those with <3g/g (RR 4.3, 95% CI: 1.6-11.6).

Conclusions: Higher proteinuria at AMR diagnosis is associated with a higher risk of allograft loss. Use of PLEX or bortezomib was not associated with lower risk of allograft failure in KTRs with AMR. Novel treatment regimens are needed to improve the outcomes of KTRs with acute and chronic AMR.

PO2132

Cerebrovascular Response in Kidney Transplant Recipients During an Acute Bout of Exercise

Madhuri Ramakrishnan, Jaimie Ward, Andrew J. Jurgensen, Sandra Billinger, Aditi Gupta. *University of Kansas Medical Center, Kansas City, KS.*

Background: Kidney transplant (KT) recipients have a high risk of cerebrovascular disease. Cerebrovascular response (CVR) or change in cerebral blood flow (CBF) from rest to steady-state exercise is a measure of cerebrovascular reserve and is blunted with aging, and in stroke. In this study we explore CVR and middle cerebral artery (MCA) kinetics response in KT recipients.

Methods: We measured CVR and MCA kinetics response during moderate intensity exercise in KT recipients and compared findings with age- and sex- matched controls without kidney disease. Transcranial doppler ultrasound (TCD) was used to measure MCA velocity (MCAv). Our primary outcome was CVR and secondary outcome was MCAv kinetics response profile.

Results: Data from 50 KT recipients and 50 controls with adequate TCD signal were analyzed. There was no difference in the resting MCAv between KT recipients and controls, but CVR was lower in KT recipients (p< 0.001) (Table 1). Three KT recipients did not have a detectable rise in MCAv with exercise. The remaining 47 showed altered MCAv kinetics response profile compared to controls with a shorter time delay (time after exercise onset when MCAv rises exponentially) (p< 0.001), and lower peak amplitude (peak MCAv in response to the acute bout of exercise) (p= 0.01) (Table 1; Figure 1).

Conclusions: KT recipients had a blunted CVR and altered MCAv kinetics response during moderate intensity exercise compared to controls. These altered cerebral hemodynamics may explain the increased cerebrovascular risks in KT recipients.

Monoclonal Gammopathy in Kidney Transplanted Patients: Novel Insights into Long-Term Outcomes

Marie-Sophie Meuleman,[1] Juliette Gueguen,[1] Stephanie Vicca,[1] Olivier Aubert,[1] Bertrand Arnulf,[3] Dany Anglicheau,[1] Frank Bridoux,[2] Camille Cohen.[1] *[1]Hopital universitaire Necker-Enfants malades, Paris, France; [2]Centre Hospitalier Universitaire de Poitiers, Poitiers, France; [3]Hopital Saint-Louis, Paris, France.*

Background: Monoclonal gammopathy(MG) is a frequent condition affecting 0,05 to 6% of general population. Little is known about the prevalence of MG and its consequences on long-term outcomes in the setting of kidney transplantation(KT).

Methods: We conducted a monocentric retrospective cohort study based on 2272 patients who underwent a KT from January 2007 to June 2019 at Necker Hospital Paris, France. A systematic extraction of serum protein electrophoresis(SPE) results performed during this period was used to distinguish patients with MG at the time of KT(MGKT) and patients who developed de novo MG(DVMG) after KT. Serum free light chain(sFLC) were retrospectively measured on stored frozen sera from MGKT patients, taken at the day of KT.

Results: We identified 66 patients with MGKT and 79 with DVMG. Patient's characteristics are summarized in Table 1. Eleven (6%) patients developed a hematological disorder, i.e. post transplantation lymphoid disorder (n=6) and multiple myeloma (n=5), without difference between groups. Infectious complications were similarly frequent, regarding viral (n=68, 47%), bacterial (n= 96, 66%) and fungal infections (n=12, 14%). Strikingly, median overall survival was significantly lower in MGKT patients compared to DVMG patients (78 months vs not reached, respectively, p=0.005). The five MGKT patients with an abnormal sFLC ratio (<0,3 or >3,3) at the time of KT tended to have lower OS compared to those with normal sFLC ratio (p= 0.07), suggesting that abnormal FLC ratio might represent a risk factor for early death in KT recipients. Death censored graft survival was not different between groups.

Conclusions: By analyzing the most important cohort of KT patients with MG reported to date, we found that MGKT affects overall survival and that sFLC measurement at the time of KT may refine risk stratification. Measurement of sFLC and SPE should be incorporated to the pre-transplant evaluation workup.

Renal Outcome and Infectious Complications Associated with Induction Regimens for Kidney Transplantation Among Children: A NAPRTCS and PHIS Collaborative Study

Daniella Levy Erez,[1,2] Helen Pizzo,[4] Nancy M. Rodig,[3] Troy Richardson,[5] Michael J. Somers.[3] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [3]Boston Children's Hospital, Boston, MA; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]Children's Hospital Association, Overland Park, KS.*

Background: Few studies compare induction agents in pediatric kidney transplants (KTx), and induction is often guided by local practice more so than specific outcome data. We evaluated how different agents affected outcomes in children enrolled in both the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) registry and the Pediatric Health Information System (PHIS).

Methods: Retrospective study of merged data from NAPRTCS and PHIS between 1999-2019. Participants grouped by induction agent: no induction, IL2 RB only, rATG/ALG, alemtuzumab. Estimated GFR (eGFR) was calculated with adjustments for age, diagnosis, repeat KTx status, delayed graft function, and rejection. Subgroup analysis evaluated rejection rates and infectious complications between 2009-2019. Outcomes were compared using chi-square or Kruskal-Wallis tests.

Results: 2410 KTx recipients with data in both datasets were identified. 340 subjects (14.1%) received no induction, 960 (39.8%) IL2 RB only, 934 (39.1%) ATG/ALG, and 176 (7.3%) alemtuzumab. Table 1highlights eGFR decline, using ratios obtained by dividing any year's eGFR by the preceding year. Annual decline in eGFR was slower in the ATG/ALG group vs IL2RB or alemtuzumab and higher among children transplanted between ages 0-4 years. Table 2 summarizes rejection and infectious frequencies. Alemtuzumab had lower rates of rejection and BK viremia compared to IL2RB and ATG/ALG.

Conclusions: Longitudinal decline in eGFR was similar across all induction agents, though decline with ATG/ALG was lowest. Although rejection and BK viremia was lowest with alemtuzumab, there was no difference with EBV or CMV infection or post-KTx malignancy.

PO2135

Bacteremia in Kidney Transplant Recipients with Septic Arthritis Is Perilous

James D. Alstott, Margaret R. Jorgenson, Christopher Saddler, Sandesh Parajuli, Neetika Garg, Maha A. Mohamed, Didier A. Mandelbrot, Arjang Djamali, Fahad Aziz. *University of Wisconsin-Madison, Madison, WI.*

Background: Features and clinical sequelae of septic arthritis in the general population have been described; however, the epidemiology and outcomes of septic arthritis in kidney transplant recipients (KTRs) is limited, and the potential impact on graft function has not been reported.

Methods: A single-center, retrospective, observational cohort study including patients with a history of kidney transplant and subsequent septic arthritis between 1/1997-12/2017 was performed.

Results: During the 20-year study period 6,184 patients received kidney and kidney-pancreas transplants, of these 65 (1%) patients had documented diagnosis of septic arthritis. 51 patients had kidney alone transplants and 14 had simultaneous kidney and pancreas transplants. The mean age at the time of transplant was 50 ± 10.4 years. The mean time from the transplant to the septic arthritis diagnosis was 6.6 ± 6 years. The most commonly affected joint was the knee (38%), followed by the shoulder (11%) and hip (9%). Joints with hardware accounted for 14 (21.5%) cases. Staphylococcus species were the most commonly isolated bacteria (52%) followed by gram-negative rods (14%). Only two patients had fungus isolated from joint aspiration (one histoplasma and one aspergillus). Antimicrobials were used in all of the patients. The majority of patients were treated with either joint aspiration (39%) or I&D (39%). The need for curative amputation was uncommon (4%). When evaluating subsequent graft function, the mean eGFR declined 12 ± 8 ml/min/1.73 m2 at one year after diagnosis. The presence of bacteremia at time of diagnosis was associated with significant worse joint (HR 5.37, p 0.01, 95%Cl 1.57 to 18.41) and graft outcomes (HR 5.37, p 0.0004, 95%Cl 1.51 to 9.35). By last follow up, 21 patients lost their allografts and 28 patients died with functional kidney graft.

Conclusions: Septic arthritis is an uncommon complication in KTRs. When seen, it typically occurs >1 year after transplant with similar pathogens and management as in the general population. However, it appears to be associated with negative graft effects. A high index of suspicion, timely diagnosis, and appropriate management are needed to ensure optimal outcomes for septic arthritis in KTRs

PO2136

Clinical Significance of Vitamin D on Preexisting and Post-Transplant Diabetes Mellitus in Kidney Transplantation: Korean Cohort Study for Outcome in Patients with Kidney Transplantation (KNOW-KT)

Woo Yeong Park,[1,2] Yaerim Kim,[1,2] Jin hyuk Paek,[1,2] Kyubok Jin,[1,2] Seungyeup Han.[1,2] *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.*

Background: Kidney transplant recipients (KTRs) with preexisting DM or post-transplant diabetes mellitus (PTDM) have poor clinical outcomes. An association between vitamin D and diabetes mellitus (DM) has been reported, but there are few reports for impact of vitamin D on preexisting DM and PTDM.

Methods: A total of 995 KTRs were enrolled in KoreaN cohort study for Outcome in patients With Kidney Transplantation (KNOW-KT) between July 2012 and August 2016. KTRs were categorized into 3 groups: nondiabetic, preexisting DM and PTDM. Vitamin D status at KT was defined to deficiency (<10 ng/ml), insufficiency (10-30 ng/ml), and normal (≥30 ng/ml). This study aims to investigate clinical significance of vitamin D based on diabetic status in KTRs.

Results: Nondiabetic group was 643 (64.6%), preexisting DM group, 267 (26.8%), and PTDM group, 85 (8.5%). In all groups, vitamin D levels gradually increased after KT, then showed equilibrium at 2 years, and decreased after 4 years, but there was no significant difference of vitamin D levels. The proportion of vitamin D deficiency at KT was the highest in preexisting DM group compared with other groups, but there was no significant difference of that since 1 year after KT. There were no significant differences of immunologic findings among them. The rate of cardiovascular event was significantly higher in preexisting DM group compared with other groups (P<0.001). Death-censored graft survival rate was significantly lower in preexisting DM group compared with other groups (P=0.049), but there was no significant difference according to vitamin D status. Death-censored graft survival rate in KTRs with preexisting DM and vitamin D deficiency was the lowest, and it showed the significant synergistic effect on the allograft outcome (P=0.022). In the multivariate analysis, older age was an independent risk factors for allograft failure (HR 1.045, 95% C.I. 1.005-1.087, P=0.026). Patient survival rate was significantly lower in preexisting DM group compared with other groups (P=0.008).

Conclusions: The prognosis of KTRs with preexisting DM and vitamin D deficiency was the worst comparing nondiabetic and PTDM groups. Therefore, careful monitoring after KT of candidates with pre-transplant DM and vitamin D deficiency is required.

PO2137

Preeclampsia and Kidney Transplant: Offspring and Mother Outcomes in a Single-Center Cohort in the West of Mexico

Arantxa K. Aguilar, Marcos A. Elias Lopez, Luz Yareli Villegas Gutierrez, Jesús A. Rico sánchez, Alejandro Garcia Rivera, Ríos C. Katia yuritzi, Enrique Rojas-Campos, Renato Parra Michel. *Instituto Mexicano del Seguro Social, Guadalajara, Mexico*.

Background: Pregnancy in a kidney transplant recipient (KTR) is possible and safe after a 1-2 year post transplantation, stable serum creatinine (<1.5 mg/dl), controlled or no hypertension, proteinuria in 24 hours <500 mg and stable immunosuppressive levels. Preeclampsia is a common complication in KTR pregnant women associated to worse maternal and offspring outcomes, there is scarce available information this topic in a KTR in Latin America

Methods: Retrospective cohort study from October 2018 to April 2021 included 18 patients: >18 years who got pregnant after KT. Serum creatinine (SCr), proteinuria before, during pregnancy and after delivery, the presence of hypertension before pregnancy, episodes of kidney graft rejections, immunosuppressant therapy, and preeclampsia were recorded from medical chart, and compared it to the offspring's gestational age, weight, APGAR score, NICU requirement and NICU stay.

Results: The frequency of preeclampsia was 33%, none of them were diagnosed with hypertension before pregnancy. Three women died after delivering (no obstetric associated), 1 lost graft function (in PD). SCr was higher during pregnancy and after delivery, offspring's gestational age was lower, offspring's weight was considerably lower, as well as APGAR score in women with preeclampsia, all NICU requirement were in children whose mother had preeclampsia and they had a NICU media stay of 19 days. In a logistic regression analysis, preeclampsia is a risk factor to a lower APGAR SCORE (p<0.001), requirement of NICU (p=0.001) and NICU stay. Other results are shown in the table.

Conclusions: Age, time between KT and pregnancy, gestational age, hypertension, serum creatinine, cesarean delivery was not different among preeclampsia, compared to the control group. Children from preeclamptic women tend to have lower weight and had lower apgar score and higher NICU requirement.

Network Science and Hemodialysis Patients' Kidney Transplant Attitudes

Avrum Gillespie,[1] Rafaa Aljurbua,[2] Zoran Obradovic.[2] *[1]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]Temple University, Philadelphia, PA.*

Background: Hemodialysis patients' attitudes towards kidney transplantation may depend on their local (egocentric) and overall characteristics of their clinic social network. We determine whether these local and overall social network characteristics improve machine learning (ML) logistic regression and neural network models of the patient's transplant attitudes.

Methods: We surveyed hemodialysis patients' social networks and transplant attitifudes in two hemodialysis clinics. We evaluated which ML model (logistic regression vs. neural network) best classified a patient's transplant attitude using survey and egocentric network data. Then, we tested whether multidimensional overall network information represented as a vector (node2vec) improved the model. Models were evaluated for accuracy, precision, recall, and F1-score using Python (version 6.1.4) and Gephi (0.9.2).

Results: The mean age of the 116 surveyed participants was 60 ± 13 years old. Half (55%) identified as male, and 75% identified as Black. Figure 1 shows the 83 participants (circles) who were in a clinic social network. The 33 network isolates are not shown. Network members with postive attitudes (57%) are the red circles. Green circles are those with negative attitudes. Adding egocentric network data improved the accuracy of the ML logistic regression model of transplant attitudes from 58% to 68% and the F1 score from 65% to 74%. The ML logistic regression model outperformed the neural network model in F1 score (73% vs. 66%) when including isolated participants. Addition of the overall network data (node2vec) further improved the F1-score of the ML logistic regression model to 77%.

Conclusions: The participant's social network characteristics improved ML classification of the participant's attitude towards kidney transplantation. The ML logistic regression model outperformed the neural network model, testing the limits of ML models on smaller data. Future research will examine how patient social networks disseminate information and affect attitudes and behaviors towards kidney transplantation.

Assessing Social Difficulties in Patients Treated with Kidney Replacement Therapy (Dialysis or Kidney Transplant)

Aghna Wasim,[1] Yingji Sun,[1] Mengxi Yang,[1] Hiba Alhabbal,[1] Karma S. Gyatso,[1] Ghazaleh Ahmadzadeh,[1] Aysha Afzal,[1] Madeline Li,[2] Doris Howell,[3] Istvan Mucsi.[1] *[1]University Health Network, Toronto, ON, Canada; [2]Princess Margaret Hospital Cancer Centre Department of Supportive Care, Toronto, ON, Canada; [3]Princess Margaret Cancer Centre, Faculty of Nursing, University of Toronto, Toronto, ON, Canada*.

Background: The Social Difficulties Inventory (SDI) is used in the clinical management of patients with cancer in the UK. We examine the construct validity of the SDI in patients with kidney replacement therapy (KRT: dialysis or kidney transplant [KT]).

Methods: This is a secondary analysis of data collected in multicenter, cross-sectional studies. Adults receiving KRT completed the SDI and other patient reported outcome measures. Clinical and sociodemographic characteristics were also collected. For SDI, the degree of difficulty is rated: no difficulty, a little, quite a bit or very much. 16 items form the SD16 and three subscales: "Everyday Living", "Money Matters" and "Self and Others." We used Cronbach's alpha to assess reliability. We assessed the correlation of SD16 and its subscales with variables that measure similar constructs. Further, we compared scores between groups that are expected to have different degree of difficulties.

Results: 788 participants (mean[SD] age 57[15] years) completed the SDI. 61% of them were male and 58% were on dialysis. Internal consistency was good for all scales: α=0.87, 0.82, 0.75, 0.88, for "Everyday Living", "Money Matters", "Self and Others" subscales and the SD16, respectively. The "Everyday Living" subscale was moderately

correlated depression (Rho=0.61, p<0.001) and physical functioning (Rho=0.72, p<0.001). The Self and Other" subscale was moderately correlated with depression (Rho=0.56, p<0.001). SD16 scores were higher for patients on dialysis vs KT (median[interquartile range – IQR] 7[3,13] vs 3[1,8]p<0.001). "Everyday Living" scores were higher in patients with Charlson Comorbidity Index of ≥4 ([3[0,6.5] vs 1[0,3.5]p<0.001). "Money Matters" scores were higher in individuals facing high vs low material deprivation (1[0,4] vs 0[0,3] p<0.008). "Self and Other" scores were higher in participants that are uncomfortable or reluctant in relationships vs those that find it easy (3[1,7] vs 1[0,3]p<0.002).

Conclusions: These results suggests that the SD-16 and its subscales have good reliability and structural validity. Further research is required to explore the potential clinical benefits of using the SD16 in patients with kidney failure.

PO2140

Symptom Management Preferences of Kidney Transplant Recipients and Caregivers

Noor A. Kaabi, Istvan Mucsi, Sara Macanovic, Pearse O'Malley, Mahdiba Chowdhury, Rabail Siddiqui, Melika Dastgheib, Simran Chahal, Beth Edwards, Tibyan Ahmed. Kidney Health Education and Research Group *University Health Network, Toronto, ON, Canada.*

Background: Kidney transplant (KT) recipients frequently experience physical, emotional, and social challenges. These are often undermanaged and can lead to impaired quality of life. Better understanding of the perspectives of KT recipients and their caregivers about their symptom experiences and management needs will improve post-transplant care for KT recipients.

Methods: As part of a larger study aimed at developing a patient-centered electronic assessment toolkit, adult (≥18 years) KT recipients and caregivers of KT recipients were recruited for this study via flyers. Patients not fluent in English or cognitively impaired were excluded. Qualitative description was used to explore and understand participants' post-transplant experiences and preferences. A semi-structured interview guide with open-ended questions was used to facilitate in-depth, individual interviews. Interviews were recorded and transcribed verbatim. Transcripts were analyzed via content analysis using deductive and inductive coding strategies. Codes and categories were developed and refined by the research team.

Results: Seven KT recipients and one caregiver (age: 52-76 years, 8-20 years post-transplant, 5/8 male) participated. Participants identified significant challenges in physical (e.g. fatigue, sleep disturbances, weight or mobility issues); emotional (e.g. depression, anxiety); and social (e.g. financial challenges, self-care, social roles) domains. Participants considered fatigue as the most troublesome symptom. Furthermore, patients described the clustering of their post-transplant symptoms across domains. For example, fatigue overlapped with depression and the inability to perform self-care activities and maintain relationships. Participants also expressed that their post-transplant care centered on physical symptoms with little exploration and support of psychological and social issues. Finally, participants emphasized that a care plan integrating all aspects of health is needed to adequately support their needs.

Conclusions: This analysis identified a range of patient-valued physical, emotional, and social concerns, with fatigue being the most troublesome symptom. These findings will inform the development of future interventions to improve patient-centered post-transplant care.

PO2141

Airflow Limitation, Fatigue, and Health-Related Quality of Life in Kidney Transplant Recipients

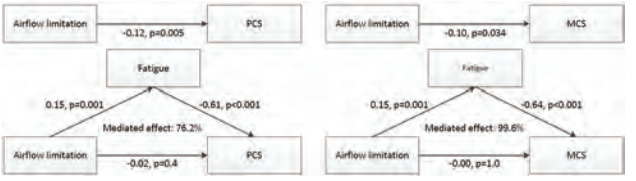
Tim J. Knobbe,[1,2] Daan Kremer,[1,2] Tji Gan,[1,2] Coby Annema,[1,2] Stefan P. Berger,[1,2] Stephan J. Bakker.[1,2] *[1]Rijksuniversiteit Groningen, Groningen, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Many kidney transplant recipients (KTR) suffer from fatigue and poor health-related quality of life (HRQoL). Airflow limitation may be an underappreciated comorbidity among KTR, which could contribute to fatigue and poor HRQoL in this population. In this study, we compared the prevalence of airflow limitation between KTR and healthy controls (HC), and investigated associations of airflow limitation with fatigue and HRQoL in KTR.

Methods: Data from the ongoing TransplantLines Biobank and Cohort Study (NCT03272841) were used. Airflow limitation was defined as forced exhaled volume in one second (FEV1) <5th percentile of the general population. Fatigue and HRQoL were assessed using CIS20R and SF-36 questionnaires.

Results: A total of 539 KTR (58% male, mean age 56±13 years) and 244 HC (45% male, mean age 57±10 years) were included. Prevalence of airflow limitation was higher in KTR than in HC (133 (25%) vs. 25 (10%), p<0.001). Airflow limitation was independently associated with higher risk of severe fatigue (OR 2.53, 95%CI 1.41 to 4.55, p=0.002) and poor HRQoL (physical component score (PCS): st. β -0.12, 95%CI -0.20 to -0.04, p=0.005 and mental component score (MCS): st. β -0.10, 95%CI -0.19 to -0.01, p=0.034) in KTR. Fatigue mediated the association of airflow limitation with PCS and MCS for 76.2% and 99.6%, respectively (Figure 1).

Conclusions: Airflow limitation is common among KTR. Its occurrence more than doubles the risk of severe fatigue, and is associated with poor HRQoL. Mediation analyses suggest that airflow limitation causes fatigue, which in turn decreases HRQoL. Since airflow limitation can be improved by treatment and training, it may be a promising therapeutic target to reduce fatigue, and consequently to improve HRQoL among KTR.



PO2142

Outcomes of Liver Transplant Recipients Who Developed AKI Before Liver Transplant

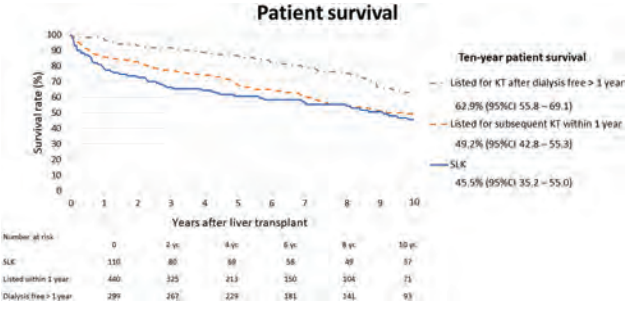
Piyavadee Homkrailas,[1,2] Suphamai Bunnapradist.[1] *[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

Background: Multiple factors including level of kidney function, patient comorbidities and functional status may influence the decision whether to simultaneous liver-kidney (SLK) transplant or waiting for kidney function recovery in end stage liver disease. Consequence of waiting for subsequent kidney transplant (KT) those without kidney recovery is unknown.

Methods: The Organ Procurement and Transplantation Network/United Network for Organ Sharing (OPTN/UNOS) data of patients who were initially listed for liver transplant (LT) alone who also developed acute kidney injury (AKI) requiring dialysis within 60 days before LT and subsequently listed for KT during year 2000 – 2018 were included. Kidney function recovery defined as discontinuing dialysis >1 year. Our cohort therefore included 1) SLK, 2) listed for subsequent KT within one-year after LT and 3) listed for subsequent KT after recovery.

Results: A total of 7,853 liver recipients received dialysis within 60 days before LT. There were 110 patients receiving SLK and 445 patients listing for subsequent KT within one-year. Seven thousand two hundred and ninety-eight patients had kidney function recovery and 301 (3.8%) patients were listed for subsequent KT after dialysis free >1 year. One-year patient survival rates were 78.1% (95%CI 69.2 – 84.8) and 86.0% (82.4 – 88.9) among receiving SLK and listing for subsequent KT within one-year group, respectively. Ten-year patient survival rates were 45.5% (35.2 – 55.0) and 49.2% (42.8 – 55.3), respectively. Patients who survive and had dialysis-free more than one year had the best ten-year survival which were 62.9% (55.8 – 69.1).

Conclusions: Only 7.1% of liver recipients who developed AKI requiring dialysis within 60 days before LT did not have kidney recovery and remain on dialysis. These patients who received SLK had lower one-year patient survival but comparable ten-year patient survival compared to patients who listed for subsequent KT within one-year after LT.



PO2143

Clinical Outcome After Combined Liver and Kidney Transplantation in Children in Europe: A CERTAIN Registry Analysis

Florian Brinkert,[1] Katja Gorontzi,[1] Justine Bacchetta,[4] Anja K. Büscher,[3] Luca Dello Strologo,[7] Deirdre Kelly,[2] Markus J. Kemper,[5] Lars Pape,[3] Marek Szymczak,[6] Burkhard Toenshoff,[8] Jun Oh.[1] *[1]Universitatsklinikum Hamburg Eppendorf Klinik fur Kinder- und Jugendmedizin, Hamburg, Germany; [2]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [3]Universitatsklinikum Essen Klinik fur Kinderheilkunde II, Essen, Germany; [4]Hospices Civils de Lyon, Lyon, France; [5]Asklepios Kliniken Hamburg GmbH Asklepios Klinik Nord Standort Heidberg, Hamburg, Germany; [6]Instytut Pomnik -Centrum Zdrowia Dziecka, Warszawa, Poland; [7]Ospedale Pediatrico Bambino Gesu, Roma, Italy; [8]Universitatsklinikum Heidelberg Zentrum fur Kinder und Jugendmedizin, Heidelberg, Germany.*

Background: Combined liver and kidney transplantation (CLKT) in children is still a challenging procedure and therefore performed only in specialized centers. Outcome of these patients is mostly published as single center reports. To gain more insights in outcome and specific challenges of this rare disease group we aimed for an European registry analysis.

Methods: We conducted a multi-center, retrospective, cohort study using data of the Cooperative European Pediatric Renal Transplant Initiative (CERTAIN) registry (www.certain-registry.eu). The CERTAIN registry provides transplantation-related data of kidney allograft recipients ≤ 21 years at transplantation of 75 pediatric renal transplant centers in Europe. For this specific study we established an additional dataset for liver allograft recipients which includes essential liver transplantation-related data. The survival curves were assessed with the Kaplan-Meier method and compared with the log-rank- test. The statistical analyses were performed with SPSS, Version 27.

Results: Included in the study were 159 patients from 13 transplantation centers. The diagnosis leading to transplantation was primary hyperoxaluria type 1 (PH1) in 64 patients, in 70 patients autosomal recessive polycystic kidney disease (ARPKD), and in 25 patients various other diagnoses. The median follow-up time was 3.9 years (range, 5 days-17 years). Patient survival was good with 9 deaths reported. This led to an overall patient survival of 94% with no difference between PH1 and ARPKD. The kidney and liver graft survival rates were 92.5% and 91.1%, respectively. Long-term eGFR calculations showed stable renal function until 9 years of follow-up. Thereafter, kidney function slowly deteriorates. Liver function tests were stable over the whole study period.

Conclusions: CERTAIN registry data showed that CLKT lead to an excellent patient and organ survival with no difference between PH1 and ARPKD patients. In addition, patient survival after CLKT is comparable to isolated liver or kidney transplantation. The retrospective study design may have led to a reporting bias.

PO2144

Renal Outcomes After Liver Transplantation in the MELD-Na Score Era in Patients with Pre-Transplant Renal Impairment

Roger Lin, Nevin Varghese, Sung Choi, Abdolreza Haririan, Wen Y. Xie, Daniel G. Maluf, Matthew R. Weir. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Post-liver transplant (LT) renal insufficiency is an established predictor of morbidity and mortality for liver transplant recipients. Current reports on renal outcomes after LT have exclusively focused on patients from the MELD era. There is little information on the progression of kidney disease since the implementation of the MELDNa scoring system. We sought to characterize the prevalence of kidney disease after LT and its risk factors during the MELDNa era.

Methods: This is a retrospective cohort study of 107 adult, single-organ, primary liver transplants performed at the University of Maryland Medical Center between January 2016 and January 2017, after implementation of the MELDNa scoring system. We determined the pre-transplant chronic kidney disease (CKD) status (defined as eGFR <60ml/min or dependence on renal replacement therapy) by using the CKD-EPI Creatinine equation, available lab values, and the renal replacement therapy (RRT) status within the 90 days prior to transplant. The primary outcome was persistent CKD or mortality at 12 months. Recipients of MELDNa exception scores as well as Status 1 liver transplants were excluded.

Results: The mean patient age was 54.2 ± 11 years, 74 male, 85 Caucasian, 30 had diabetes, 55 were hypertensive, and 27 had HCV. 32 patients had pre-LT renal insufficiency and 25 patients were on RRT at the time of LT. The overall 1-year mortality rate post-LT was 11.2%. 36 patients had CKD at 12 months. Among the patients with pre-LT renal insufficiency, 13 demonstrated improved renal function, 13 remained with CKD, 2 ended up on long-term RRT, and 4 died by 12 months. Renal insufficiency equivalent to CKD stage 4 prior to LT (OR 8.75, CI 0.97-78.7, p=0.053) and RRT at time of LT (OR 3.68, CI 1.42-9.55, P=0.007) were associated with increased risk of recipient death or CKD at 12 months. Other variables including age, sex, HCV, DM, HTN, CKD Stage 3, MELDNa score, BMI, and organ rejection were not predictive of the outcome.

Conclusions: Our study in the MELDNa era patients suggests that 40% of the patients with impaired renal function pre-LT recover renal function by 12 months post-LT. RRT at the time of LT, and moderate to severe renal impairment prior to LT are risk factors for recipient mortality or persistent CKD at 1 year post-LT.

PO2145

Gender Disparities in Access to Simultaneous Liver-Kidney Transplantation in the Pre- vs. Post-Allocation Policy Eras

Giselle Peschard,[1] Mei Wang,[1] Yazen Al-Hosni,[1] Krista L. Lentine,[2] Su-Hsin Chang,[1] Tarek Alhamad.[1] [1]*Washington University in St Louis, St Louis, MO;* [2]*Saint Louis University School of Medicine, Saint Louis, MO.*

Background: Gender differences in receiving simultaneous liver-kidney transplant (SLKT) is not well-understood. We recently found that women are disadvantaged in access to SLKT, especially women not initially listed for SLKT. No studies have examined these disparities in SLKT access after the implementation of the SLKT allocation policy in 2017, intended to facilitate equity and utility organ allocation.

Methods: Using retrospective data from the Organ Procurement and Transplantation Network (OPTN) database, we identified two cohorts of patients on the liver transplant (LT) waiting list with renal dysfunction (RD) from February 28, 2002 to August 9, 2017 (pre-SLK allocation policy) and from August 10, 2017 to March 31, 2020 (post-SLK allocation policy). Multilevel time-to-competing-events regression adjusting for center effect was used to examine the likelihood of receiving SLKT in both cohorts.

Results: A total of 23,389 candidates with RD listed for LT only were included and 5,823 candidates with RD listed for SLKT in the pre-SLKT allocation policy era. 9,668 candidates with RD listed for SLKT in the post-SLKT allocation policy era. Pre-SLKT allocation policy era, females with RD listed only for LT had a 55% lower likelihood of receiving SLKT (multivariable-adjusted hazard ratio, aHR 0.45, 95% confidence interval, CI, 0.28-0.72); and those listed for simultaneous organs had 12% lower likelihood of receiving SLKT (aHR 0.88, 95% CI 0.80-0.96), compared to males (Figure 1). Post-SLKT allocation policy era, females still had 22% lower likelihood of receiving SLKT (aHR 0.78, 95% CI 0.70-0.88), compared to males (Figure 1).

Conclusions: Prior to the implementation of the SLKT allocation policy, women had a lower likelihood of receiving SLKT compared to male candidates regardless whether they were listed for SLKT. After the policy implementation, these disparities are reduced but persist. This calls for further work on developing new policies that address gender disparities in access to organ transplantation.

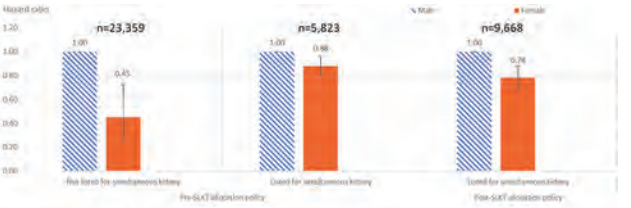


Figure 1. Multivariable-adjusted hazard ratios for receiving SLKT pre- and post-SLKT allocation policy by gender.

PO2146

Gender-Based Disparities in Access and Survival Outcomes of Simultaneous Liver-Kidney Transplant Among Liver Transplant Candidates with Renal Dysfunction in the United States

Giselle Peschard,[1] Mei Wang,[1] Yazen Al-Hosni,[1] Krista L. Lentine,[2] Su-Hsin Chang,[1] Tarek Alhamad.[1] [1]*Washington University in St Louis, St Louis, MO;* [2]*Saint Louis University School of Medicine, Saint Louis, MO.*

Background: The frequency of simultaneous liver-kidney transplantation (SLKT) has risen since the implementation of the Model for End-stage Liver Disease (MELD)-liver allocation system. Gender disparities in access to SLKT and outcomes post-transplantation are not well described. We examined these gender-based disparities in the MELD era.

Methods: We included a retrospective cohort of patients wait-listed for liver transplant (LT) between 2002-2017 with renal dysfunction (RD). Multilevel time-to-competing-events regression adjusting for center effect was used to examine the likelihood of receiving SLKT. Inverse probability of treatment weighted (IPTW) survival analyses were used to analyze posttransplant mortality outcomes. Sensitivity Analysis (SA) performed using 2 alternative definitions of RD for LT candidates: SA(1), either received dialysis or having creatinine ≥2.0 mg/dL at listing for LT, and SA(2), either received dialysis or having eGFR<35 mL/min/1.73 m2 at listing for LT.

Results: Among candidates not listed for SLKT at the time of listing for LT, females had ≥50% lower likelihood of receiving SLKT compared to males (Figure 1). Females continued to have reduced access despite being listed for SLKT. Once transplanted, we found no statistically significant difference in post-transplant survival by sex for SLKT or LT alone recipients (Figure 2).

Conclusions: Prior to the implementation of the SLKT allocation policy, gender disparities were found in access to SLKT but not in post-transplant survival. A tighter gender difference in access to SLKT was found amongst patients listed for SLKT compared to those not listed simultaneously.

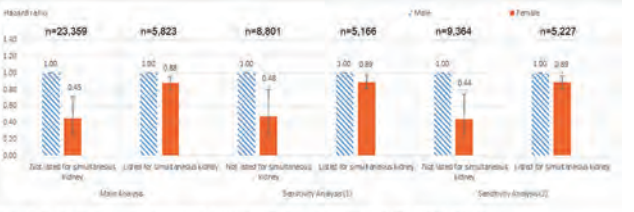

Figure 1: Multivariable-adjusted hazard ratios for receiving SLKT, 2002-2013*

**Covariates included age, race (non-Hispanic white, non-Hispanic black, Hispanic, or other), body mass index, year (2002-2013), ever had dialysis, estimated glomerular filtration rate, serum albumin, creatinine, bilirubin, MELD score, international normalized ratio, insurance, education, income, OPTN region, ascites, pathogenesis of liver disease, and diabetes status at the time of waitlisted.*

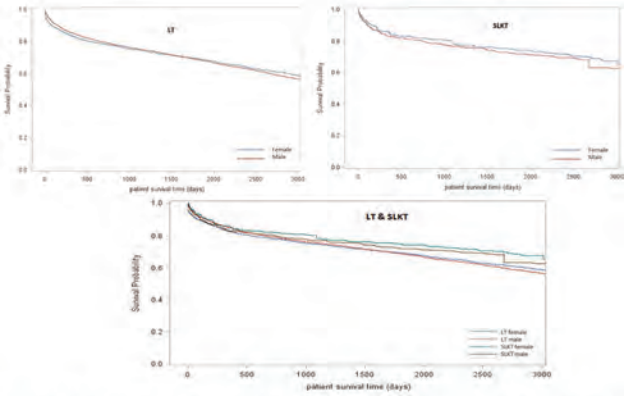

Figure 2: IPTW survival curves by gender comparing overall survival between patients receiving SLKT and LT alone.

PO2147

Development Following Paediatric Kidney Transplantation

Lars Pape, Jenny Pruefe. *Universitat Duisburg-Essen, Essen, Germany.*

Background: This study aims to assess quality of life, mental health, motor development, executive functioning and medication adherence in paediatric patients following kidney transplantation

Methods: In a cross-sectional study we used standardised tools (FABEL, KINDL, PedsQL, CBCL, M-ABC, WISC-V, BAASIS) to assess the relevant parameters and analyse them against the background of selected medical data.

Results: We included 53 kidney transplanted children age 0-18 (♂32 ♀21). Parents reported increased financial burden and fear of the future. Half of the patients showed some symptoms of mental distress. 13/40 (32.5%) patients fulfilled DSM-criteria for mental health problems. Most frequent symptoms linked to depression and anxiety. Participants who started renal replacement therapy in their first three years of life mainly expressed symptoms of the externalising spectrum. Motor-development could be assessed in 47 patients. Developmental deficits could manly be observed in the field of fine motor skills and dexterity as well as body-balance. In total 11/47 (23.4) patients had fine-motor-skills below the 2nd percentile, 14/47 (29.9%) had deficits in body-balance scoring below the 2nd percentile. Processing speed was assessed in a subgroup of 36 patients without cognitive developmental delay. Mean score was 84 (45-112; sd 16.0). 5/36 (13.9%) patients had results below the 2nd percentile.

Conclusions: Even after successful transplantation chronic kidney disease seams to impact on the overall health and development of the affected child. While nowadays allograft survival is considered to be acceptable, it is time to shift focus on quality of survival and non-renal consequences of a renal disease. Besides further research clinical programs are needed to offer tailored assessments and support.

PO2148

Long-Term Outcomes of Kidney Transplantation in a Disadvantaged Population in Mexico

Maria F. Garcia-Guevara, Jesus D. Lima-Lucero, L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Access to kidney transplantation in Mexico was limited to patients with social security. Since 2010 at the Dr. Eduardo Liceaga General Hospital of Mexico, a kidney transplant program was established for patients with terminal chronic kidney disease living in extreme poverty or without social security. We aim was to analyzed patient survival, graft survival, post-kidney transplant complications, and modification of work status before and after transplantation were analyzed.

Methods: Case-control study nested in a cohort. Kidney transplant recipients who were in disadvantaged conditions from 2010 to 2020 were analyzed.

Results: During the study period, 345 transplants were performed. The median age was 31.5 ± 11.58 years, 58.6% were men and 74% of the transplants were from living donors. Ninety patients (26%) with social security (With SS) and 255 patients (74%) without social security (Without SS) at the time of transplantation were analyzed. The With SS patients presented mainly peritoneal dialysis as renal replacement therapy, while the Without SS patients on intermittent hemodialysis (p≦0.05). There were significant differences in immunosuppressive induction and maintenance schedules between groups. Patients Without SS more frequently received only steroids as induction therapy and cyclosporine as maintenance therapy (p≦0.05). A higher frequency of acute rejection and chronic rejection was observed in patients Without SS (p≦0.05). No differences were observed in metabolic, cardiovascular or infectious complications after transplantation. With an average follow-up of 6.23 ± years, not difference was identified in graft survival (With SS: 84.7% vs Without SS: 85.9%, p=0.222); nor in patient survival (88.5% versus 84.3%, p=0.105). When comparing the work status of patients without social security, a significant increase was observed in the work status at baseline and after kidney transplantation (23.7% vs 45.8%, p=0.001).

Conclusions: Access to kidney transplantation in Mexico is uneven and this is due to the fragmented health system in Mexico. A national kidney transplant program without inequities is required where the entire population has access to health services and their post-transplant follow-up.

PO2149

De Novo Inflammatory Bowel Disease in Kidney Recipients: A Single-Center Experience

Masatomo Ogata, Takamasa Miyauchi, Marie Murata, Naohiko Imai, Kazunobu Shinoda, Yugo Shibagaki, Masahiko Yazawa. *St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Recipients of solid organ transplantation (SOT) receive immunosuppressants (IM) such as calcineurin inhibitors and steroids, both of which are also used for inflammatory bowel disease (IBD). However, the incidence of IBD following SOT (de novo IBD) is 5 to 10 times higher than that among the general population. Although reports of de novo IBD have been mostly reported in liver transplants, and that after kidney transplantation (KT) remains scarce.

Methods: Of the patients who underwent KT from 1998 to 2021 at St. Marianna University Hospital (N=241), we included those diagnosed by colonoscopy with de novo IBD including ulcerative colitis (UC) or Chron's Disease (CD). We retrospectively described the symptoms, time course, HLA typing, IM, and treatment of de novo IBD.

Results: Of 241 recipients, 6 developed de novo IBD posttransplant (incidence: 2.5%): 5 were diagnosed with UC and 1 with CD. The median time from KT to IBD diagnosis was 6 years (range, 2–12). Allograft function did not worsen after IBD in any recipients. The initial presentation was bloody stool in 5 recipients and mild diarrhea in 1. In the recipient with CD, severe and continuous abdominal pain, and bloody stool with moderately elevated C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were present (3.53 mg/dL and 71 mm/h, respectively). In recipients with UC, bloody stool or mild diarrhea without abdominal pain, and mild to moderate inflammation markers such as median CRP [0.28 mg/dL (range: 0.07–6.38 mg/dL)] and median ESR [26.5 mm/h [range: 9–81 mm/h] were present. Three recipients with UC had HLA B52, DR2, or DR15, which are known to associate with UC. All recipients received a triple maintenance IM for KT including tacrolimus and steroids. Regarding treatment for de novo IBD, infliximab for the recipient with CD and 5-aminosalicylate for recipients with UC were used as a primary treatment. One recipient with UC affected the whole colon was resistant to prednisolone, infliximab, and vedolizumab. He eventually underwent total colectomy at 1-year after diagnosis. The others achieved the remission of IBD after initial therapy.

Conclusions: De novo IBD should be a differential diagnosis of bloody stool after KT in spite of low or only mildly elevated inflammation markers. De novo IBD can present even without bloody stool.

PO2150

Renal Transplant Biopsy Outcomes: A Nephrology and Radiology Standpoint in an Academic Center

Rhea Patil,[1] Camilo Cortesi,[1] Mai Sedki,[1] Franco H. Cabeza Rivera,[2] Karla G. Carias Martinez,[1] Phillip Ruiz,[1] Jason T. Salsamendi,[1] Giselle Guerra,[1] Adela D. Mattiazzi.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]The University of Mississippi Medical Center, Jackson, MS.*

Background: Renal transplant biopsies are the gold standard for evaluating allograft dysfunction. Studies comparing biopsy safety outcomes between transplant nephrologist and interventional radiologist are lacking. We describe our academic center experience and identify their risk factors.

Methods: This is a retrospective study of patients who underwent percutaneous ultrasound-guided renal transplant biopsy (US-RTB) at a single center between January 2013 to August 2016. This cohort was stratified into two groups according to the team that performed the biopsy: interventional radiology(IR,n=447) and transplant nephrology(TN,n=231). The predictors of post-biopsy complications were assessed by multivariate logistic regression.

Results: A total of 678 US-RTB were performed in 573 patients. There was no significant difference in the rate of total complications, blood transfusion, or perinephric hematoma between the IR and TN groups. The regression analysis showed that the team that performed the biopsy was not a significant predictor for total complications, blood transfusion or perinephric hematoma. The significant predictors of total complications were uncontrolled blood pressure and anticoagulation therapy. The predictors of blood transfusion were female sex, antiplatelet therapy, anticoagulation therapy, and blood urea nitrogen. The predictors of perinephric hematoma were female sex, black race, uncontrolled blood pressure, and anticoagulation therapy(Figure).

Conclusions: Kidney transplant biopsies are safe when performed by transplant nephrologists and interventional radiologists in an academic center. Blood pressure control and management of anticoagulation are fundamental to decrease the risk of complications. Studies need to be done to understand why sex and race were predictors for blood transfusion and perinephric hematoma.

Figure. Post-Transplant Renal Biopsy Complications

	Interventional Radiology (n=447)	Transplant Nephrology (n=231)	p value
Total number of complicated biopsies	37 (8.27)	18 (7.79)	0.94
Blood transfusion	15 (3.35)	8 (3.46)	1.00
Perinephric hematoma	16 (3.57)	10 (4.32)	0.78

	Odds Ratio	95% Confidence Interval	p value
Predictors of Total Complications			
Uncontrolled blood pressure	2.50	1.24-5.04	0.009
Anticoagulation therapy	4.47	1.33-14.24	0.01
Predictors of Blood Transfusion			
Female sex	5.34	1.71-18.85	0.005
Antiplatelet therapy	3.29	1.12-10.81	0.03
Anticoagulation therapy	12.14	2.01-73.38	0.005
Blood urea nitrogen	1.03	1.001-1.06	0.03
Predictors of Perinephric Hematoma			
Female sex	5.48	1.94-17.26	0.002
Black race	3.29	1.18-9.80	0.02
Uncontrolled blood pressure	2.85	1.002-8.29	0.04
Anticoagulation therapy	6.34	1.10-34.55	0.03

Uncontrolled blood pressure defined as blood pressure ≥ 160/90 mmHg at the time of biopsy.

PO2151

Outcomes of Kidney Referrals from Donors with High Infection Risk in the Most Populous Donor-Specific Antibody

Mohammad Ahraz Hussain, Piyavadee Homkrailas, Gabriel M. Danovitch, Suphamai Bunnapradist. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Overdose-death donors (ODD) increased from 1.1% of donors in 2000 to 13.4% in 2017. Kidneys from ODDs were discarded at a higher rate than trauma-death donors. US Public Health Service defines organs from individuals with opioid abuse as being at increased risk of infection with HIV, HepB and HepC. CAOP is the most populous DSA in the country and improving utilization of organs within the DSA is of great importance. We aimed to study the utilization of kidneys from High-Infectious Risk Donors in this DSA.

Methods: We obtained data from UNOS and the Organ Procurement Organization (OPO), One Legacy between January 2015 and September 2020. We calculated the organ decline rate, organ refusal rate and rate of organs refused under the UNOS organ refusal code Donor age/quality and Donor Social History. We also compare these results to the trauma-death donors.

Results: Out of 2686 kidneys that were considered for recovery, 382 kidneys were from ODDs between 2015 and September 2020. 109 ODD kidneys (22.6%) were shared and successfully transplanted. 51 ODD kidneys were discarded locally in the DSA (22.2%). 47.5 % were refused by centers due to "Donor Age, Quality and Social History" before being either transplanted or being discarded. 103 kidneys of the ODDs were not recovered or offered for transplant. 82 kidneys were recovered from Hepatitis C positive donors, out of which 52 (66.7%) were shared and transplanted outside the DSA and 15 were discarded locally.

Conclusions: Higher infectious risk increased risk donors were being shared and discarded at a high rate. Given we have more evidence that these higher infectious risk kidneys are transplantable efforts to improve their utilization are needed.

PO2152

Lack of Insurance Predicts with Follow-up Deficiencies After Living Kidney Donation

Krista L. Lentine,[1] Ngan Lam,[2] Anthony N. Muiru,[3] Andrea Tietjen,[8] Huiling Xiao,[1] Christie P. Thomas,[5] Gwen E. Mcnatt,[5] Amit X. Garg,[4] Nagaraju Sarabu,[6] Bertram L. Kasiske.[7] *[1]Saint Louis University, Saint Louis, MO; [2]University of Calgary, Calgary, AB, Canada; [3]University of California San Francisco, San Francisco, CA; [4]Western University, London, ON, Canada; [5]The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; [6]University Hospitals Cleveland Medical Center Department of Orthopaedics, Cleveland, OH; [7]Hennepin Healthcare, Minneapolis, MN; [8]RWJBarnabas Health, West Orange, NJ.*

Background: Follow-up after living kidney donation in the United States has improved with recent policy mandates. We hypothesized that lack of insurance at donation may be a barrier to postdonation follow-up.

Methods: We examined Scientific Registry of Transplant Recipients (SRTR) data for 90.460 living kidney donors (LKD) in 2004-2018 to examine associations (adjusted odds ratio, aOR) of insurance status and other baseline factors with clinical and laboratory follow-up after donation.

Results: Follow-up increased over time, and was especially high in older LKD. Follow-up was lower in uninsured compared to insured LKD over time, including in the era of the Affordable Care Act (**Fig. A**). In 2018, for uninsured vs insured LKD, respectively, clinical follow-up was 87.5% vs 90.4% at 6-months, and 76% vs 86.7% at 12-months, while 12-month lab follow-up was 55.4% vs 68.4%. In multivariate regression including adjustment for donation year and other baseline factors, uninsured status was associated with 7% lower odds of 6-month clinical follow-up (aOR, 0.93) and 14% lower odd of lab follow-up (aOR, 0.86). Follow-up was also significantly (P<0.05) lower for LKD who were African American (aOR 0.85) or Hispanic (aOR 0.91), unrelated to their recipient (aOR 0.85), not working (aOR 0.81) and with less than college education (**Fig. B**).

Conclusions: While follow-up after living kidney donation is improving, uninsured LKD and those who are non-white, unemployed, and with lower education are less likely to receive follow-up. Novel initiatives are needed to provide access to follow-up care for at-risk LKD, including the uninsured and under-insured, to minimize the risk of socioeconomic disparities in long-term postdonation outcomes.

PO2153

Visualizing Waitlist Outcomes for Kidney Transplant Candidates Whose Centers Have Declined Deceased Donor Offers

Cory Schaffhausen,[1,5] Jon Miller,[3] Arthur J. Matas,[4] Ajay K. Israni,[1,5] Andrew Wey,[2] Allyson Hart.[5,1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]Scientific Registry of Transplant Recipients, Minneapolis, MN; [3]Chronic Disease Research Group, Minneapolis, MN; [4]University of Minnesota Department of Surgery, Minneapolis, MN; [5]University of Minnesota Department of Medicine, Minneapolis, MN.*

Background: While transplant centers closely monitor posttransplant outcomes for each transplant recipient, centers currently lack data to monitor waitlist outcomes of individual candidates. Waiting candidates may receive multiple deceased donor organ offers. Centers may decline offers on behalf of the candidate in order to wait for a better offer. These decisions may impact waitlist outcomes because a better offer may not arrive, and dialysis-related morbidity may worsen. We sought to develop waitlist outcome reports to facilitate monitoring of candidates receiving donor offers.

Methods: A report mockup used patient-level data from the Scientific Registry of Transplant Recipients (SRTR). Data included a deidentified random sample of 200 kidney waitlist candidates from across the United States who had received at least one offer between May 7, 2019 and May 6, 2020. For each candidate, offers were identified from match runs from January 1, 2014 to May 6, 2020. Match run data included any offer that was ultimately accepted somewhere and resulted in a transplant. Offers in the match run after the last accepted offer and multi-listed candidates were excluded.

Results: The report visually identifies several outcomes: candidates who died after receiving offers, additional time on dialysis, and changes to quality and frequency of donor offers over time. Figure 1A depicts multiple patients on a waitlist. Each horizontal row represents one candidate, and each colored cell represents the highest-quality donor offer for each month, indicated by Kidney Donor Profile Index (KDPI).

Conclusions: The waitlist reports are a potential method for centers to self-monitor candidates and may supplement posttransplant outcome monitoring and existing decision support tools such as statistical outcomes calculators. The reports illustrate how offer frequency and KDPI change while candidates wait, as well as candidates' dialysis burden. Additional research is warranted to evaluate additional relevant candidate and donor data for reports (eg, offer number) and understand the utility of visual representations of the impact of offer decisions made on behalf of waitlist candidates.

Funding: Other NIH Support - AHRQ R01 HS 24527, AHRQ and PCORI K12HS026379

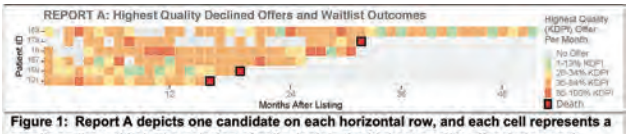

Figure 1: Report A depicts one candidate on each horizontal row, and each cell represents a month on the waitlist. The coloring of cells depicts the highest-quality offer during each month, in which low-KDPI donor organs (green and yellow cells) are highest quality.

PO2154

Guiding Kidney Transplant Candidates for Effective Weight Loss

Aleksandra Kukla, Tayyab S. Diwan, Maria L. Collazo-Clavell, Elizabeth C. Lorenz, Matthew M. Clark, Aleksandar Denic, Walter Park, Carrie A. Schinstock, Hatem Amer, Byron H. Smith, Naim S. Issa, Andrew J. Bentall, Patrick G. Dean, Yogish C. Kudva, Manpreet Mundi, Mark D. Stegall. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Acceptance criteria at most transplant centers for waitlisting include BMI. The best approach to weight loss to facilitate active listing is unknown.

Methods: We aimed to determine the weight loss, listing, and transplant rates in 28 candidates with a mean BMI of 44.4 (4.6) and diabetes treated conservatively for obesity for 1-year post weight loss consultations, where the surgical and non-surgical weight loss options were discussed. A comparator group (n= 15) included patients with the mean BMI of 43.1 (4.4) who had bariatric surgery by 1 year post consultation.

Results: The mean BMI at 1-year follow-up in the studied group (n=28) was 43.0 (4.8), and total body weight loss was 4.4 (8.2) kg (3.6% (6.5). BMI has not improved at 2 years (p=0.8; **Figure 2A**). Eighteen patients (64%) remained ineligible for a transplant due to excess weight and/or comorbidities over a mean follow-up of 4.0 (2.9) years. Most patients (75%) did not achieve an acceptable BMI for transplant. In contrast, total body weight decreased by 22.18 (10.1) kg (19% (7%)) at 6 months post-bariatric surgery with the BMI of 34.2 (4) and 32.5 (3.7) at 6 and 12 months, respectively (**Figure 2B**). Bariatric surgery was associated with subsequent kidney transplantation (HR = 5.75; CI [1.49, 22.14]; p = 0.01).

Conclusions: A conservative weight loss approach was ineffective in most kidney transplant candidates with diabetes to improve access to transplantation. These data suggest the need for larger controlled trials.

Baseline characteristics

Factor	No bariatric surgery	Bariatric surgery	p value	All
Age at evaluation	52.3 (11.9)	53.0 (9.2)	0.83	52.5 (11)
Male gender	15 (53.6%)	5 (33.3%)	0.20	20 (46.5%)
BMI at weight loss consultation	44.4 (4.6)	43.1 (4.4)	0.37	43.9 (4.5)
Dialysis	14 (51.9%)	9 (60.0%)	0.61	23 (54.8%)
Diabetes type 2 (vs. type 1)	23 (82.1%)	14 (93.3%)	0.31	37 (86%)
Follow up (years)	4.5 (3.1)	3.6 (2.2)	0.29	4.1 (2.8)

Risk Factors and Outcomes of Post-Transplant Erythrocytosis Among Adult Kidney Transplant Recipients: A Systematic Review and Meta-Analysis

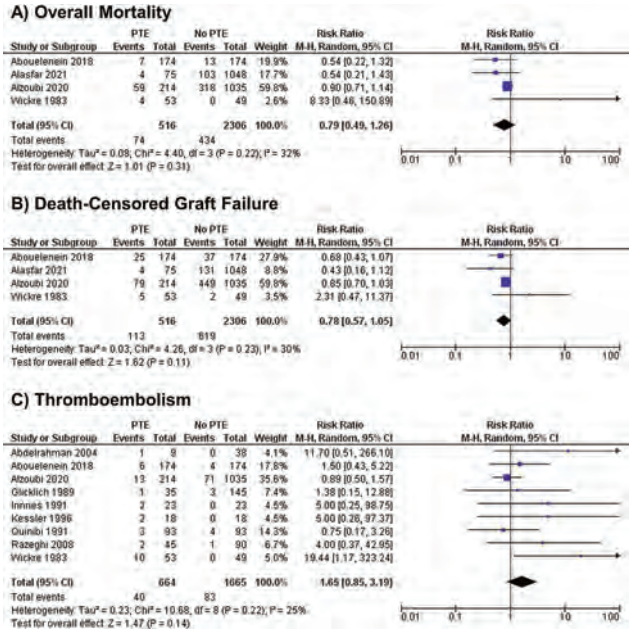
Poemlarp Mekraksakit,[1] Boonphiphop Boonpheng,[2] Natnicha Leelaviwat,[1] Samapon Duangkham,[1] Anasua Deb,[1] Kenneth Nugent,[1] Wisit Cheungpasitporn.[3] *[1]Texas Tech University Health Sciences Center, Lubbock, TX; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Post-transplant erythrocytosis (PTE) can occur in up to 10-16% after kidney transplant (KT). However, the post-transplant outcomes of recipients with PTE in the literature were conflicting. We performed systematic review and meta-analysis of published studies to evaluate risk factors of PTE as well as outcomes of recipients who developed PTE compared to controls.

Methods: A literature search was conducted evaluating all literature from existence through February 2, 2021, using MEDLINE and EMBASE. Data from each study were combined using the random-effects model. (PROSPERO: CRD42021230377)

Results: Thirty-nine studies from July 1982 to January 2021 were included (7,099 KT recipients). The following factors were associated with PTE development: male gender (pooled RR=1.62 [1.38, 1.91], I^2=39%), deceased-donor KT (pooled RR=1.18 [1.03, 1.35], I^2=32%), history of smoking (pooled RR=1.36 [1.11, 1.67], I^2=13%), underlying polycystic kidney disease (PKD) (pooled RR=1.56 [1.21, 2.01], I^2=44%), and pretransplant dialysis (pooled RR=1.6 [1.02, 2.51], I^2=46%). However, PTE was not associated with outcomes of interest including overall mortality, death-censored graft failure, and thromboembolism.

Conclusions: Our meta-analysis demonstrates that male gender, deceased donor, history of smoking, underlying PKD, and pretransplant dialysis were significantly associated with developing PTE. However, with proper management, PTE has no impact on the prognosis of KT patients.



Forest plots of the included studies assessing the association between PTE in KT patients and outcomes of (A) Overall mortality, (B) DCGF, (C) Thromboembolism

PO2156

Efficacy of Sodium Zirconium Cyclosilicate for Treatment of Acute Hyperkalemia in Solid Organ Transplant Recipients

Rachael B. Leek, Scott A. Rega, Irene D. Feurer, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Hyperkalemia is a common electrolyte abnormality following solid organ transplant (SOT). Limited data are available to support the use of sodium zirconium cyclosilicate (ZS-9), a novel gastrointestinal potassium (K^+) binder, in SOT recipients. The purpose of this study was to evaluate short-term efficacy and safety of ZS-9 in SOT recipients.

Methods: We conducted a retrospective single center study of adult hospitalized SOT recipients who received ZS-9 from 05/20-04/21. The primary endpoint was change in K^+ from baseline to within 50 hours of the first dose of ZS-9 among persons not receiving renal replacement therapy (RRT). Data were analyzed using descriptive statistics and multivariable linear models.

Results: The sample included 95 SOT recipients (Table), 68 of whom were not receiving RRT within 50 hours of ZS-9 administration. After adjusting for differences in follow-up time (34±11 hours), serum K^+ decreased by 0.88±0.81 mmol/L (p=0.002). The fully longitudinal downward trajectory of K^+ through up to 49 hours (p<0.001) is depicted (Figure). Adverse events were infrequent and mild as shown in the Table.

Conclusions: ZS-9 for treatment of acute hyperkalemia in hospitalized SOT recipients was efficacious and safe in this single center study. These findings are important in understanding the utility of ZS-9 broadly in SOT recipients.

Clinical Characteristics and Outcomes of FSGS in Kidney Transplant Recipients: A Single-Center Experience

Anne Marie Pop,[1] Jose L. Valdes,[2] Rohini Prashar.[2] *[1]Beaumont Hospital - Farmington Hills, Farmington Hills, MI; [2]Henry Ford Health System, Detroit, MI.*

Background: Focal segmental glomerular sclerosis (FSGS) is a common etiology of chronic kidney disease in adults. Many progress to end stage renal disease requiring dialysis initiation and/or renal transplantation. It is also known to recur in transplantation, however there is limited literature addressing treatment options and outcomes in these patients. The purpose of this study is to evaluate clinical characteristics and post-transplant outcomes in kidney transplant recipients (KTRs) with primary and secondary FSGS.

Methods: This is a single-center retrospective study where data was collected from November of 2014 to December of 2020 on all KTRs with the diagnosis of FSGS within the Henry Ford Health System in Detroit, MI.

Results: A total of 39 KTRs were studied. 28% had primary FSGS and 71% had secondary. Baseline characteristics of KTRs can be found in table 1. 5 had recurred and all had primary disease. Recurrence was suggested by worsening proteinuria (>3.5g/day), and/or albumin <3.5 g/dL, and confirmed by renal biopsy. Median time of recurrence was 24 months post-transplant. Median proteinuria at time of diagnosis was 5.6 g. 3 that recurred were African American, 1 was Caucasian and 1 was Indian. A total of 4 out of 5 were treated with plasmapheresis. 2 had complete remission which was defined by reduction in proteinuria to <300 mg/day. One who did not achieve remission continues to have stable allograft function with ongoing proteinuria and the other had allograft loss at 96 months. None experienced adverse effects from treatment.

Conclusions: Recurrence of FSGS is more prevalent in patients with primary disease. Response to treatment is associated with significantly better outcomes and complete remission was achieved in 50% of cases.

Table 1

Baseline Characteristics	Primary	Secondary
Number of patients (total)	11 (28.2%)	28 (71.7%)
Recurrence (# pt)	5	0
Age at diagnosis (yr)	33 (22-62)	34 (19-72)

PO2158

Glomerulonephritis After Kidney Transplantation: Prevalence, Clinical Characteristics, and Outcomes

Belen Martinez-Vazquez, Octavio R. Garcia-Flores, Cesar Flores Gama. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: The Glomerulonephritis after kidney transplantation (GNKT) is an unknown disease, being the third cause of kidney allograft loss. It is defined as the development of glomerulonephritis (GN) in the allograft and is classified in: recurrent, novo and with unknown primary disease. The prevalence varies to 2-12%, the majority report figures to 6-8%. Recurrent GN have a higher risk of kidney allograft failure (KAF), the most frequent reported are IgAN (9.7%), FSGS (12.7%), MPGN (14.4%) and MN (12.5%).

Methods: We conducted a single-center, retrospective cohort study during 10 years in a tertiary hospital in Mexico City. We included 50 patients with biopsy-proven GN in the kidney allograft. We examined the relationship between clinical, biochemical and histologic parameters to predict the KAF in GNKT. We used age and sex adjusted Cox proportional hazards models.

Results: 50 patients were included, median age 39 years, 50% were female, mean creatinine and proteinuria at biopsy were 2.6± 3.0 mg/dL and 2.8± 2.9 g/day respectively. The main biopsy indications was allograft dysfunction in 46%. The mean follow-up was 41.7±33.1 months. KAF occurred in 18 patients (36%). Of the total cases 7 corresponded to recurrent GN and 5 cases to de novo GN. The main etiologies were IgAN 12 (24%), MN 10(20%), DKD 9 (18%) and PGN 5 (10%). 12 patients had acute rejection and was not associated with kidney allograft loss (p= 0.06).

Conclusions: In the present study we found that the incidence of GNKT is similar to that reported in other series, with primary GN being the ones with the highest incidence, in our series IgAN was the most frequent. There were 7 cases of recurrent GN and only 5 cases of de novo GN, the rest GNKT with unknown primary disease. It is noteworthy that in our series we identified 5 cases of ANCA-associated vasculitis. The KAF was 36%, similar to that reported in the literature and MN was the main etiology.

Baseline Characteristics of Patients with glomerulonephritis in kidney allograft (n=50)

Outcomes of Renal Transplantation in Patients with AL Amyloidosis: An International Collaboration Through the International Kidney and Monoclonal Gammopathy (IKMG) Research Group

Andrea Havasi,[1] Cihan Heybeli,[2] Nelson Leung,[2] Avital Angel-Korman,[1] Vaishali Sanchorawala,[1] Oliver C. Cohen,[7] Ashutosh D. Wechalekar,[7] Frank Bridoux,[4] Insara Jaffer Sathick,[5] Victoria Gutgarts,[5] Paolo Milani,[6] Giovanni Palladini,[6] Giampaolo Merlini,[6] Ute Hegenbart,[3] Stefan O. Schönland,[3] Heather Landau.[5] The International Kidney and Monoclonal Gammopathy (IKMG) Research Group *[1]Boston University, Boston, MA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Amyloidosis Center, Heidelberg University Hospital, Heidelberg, Germany, Heidelberg, Germany; [4]Department of Nephrology, CIC INSERM 1402, CHU Poitiers, Poitiers, France; Centre national de référence Amylose AL & autres maladies par dépôts d'immunoglobulines monoclonales, CHU Poitiers, Poitiers, France; Centre National de la Recherche Scientifique UMR CNRS 7276/INSERM U1262, Université de Limoges, Limoges, France, Limoges, France; [5]Memorial Sloan Kettering Cancer Center, New York, NY; [6]Amyloidosis Research and Treatment Center, University ofFoundation "Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Policlinico San Matteo" and Department of Molecular Medicine, University of Pavia, Pavia, Italy, Pavia, Italy; [7]National Amyloidosis Centre, London, United Kingdom*.

Background: New systemic therapies that successfully suppress toxic light chain production have led to an increase in the number of patients with AL amyloidosis who survive longer albeit with end stage renal disease. There is a critical need to identify patients in this specific population who can have good outcomes with renal transplantation.

Methods: We evaluated renal transplant outcomes in 237 patients from 5 countries with AL amyloidosis who underwent renal transplantation between 1987 and 2020. Cox regression analysis and Kaplan–Meier method were used.

Results: The majority of the patients (62%) underwent high dose melphalan and autologous stem cell transplantation (HDM/SCT). Overall survival (OS) from renal transplantation was 8.6 years with a median follow-up of 8.5 years. One-, three- and five-year OS from renal transplantation was 95%, 83% and 73%, respectively. The median time of graft survival was 7.8 years. Death censored graft survival at one-, three- and five-years was 92%, 79% and 69%, respectively. Survival outcomes were analyzed based on degree of hematologic response to therapy at the time of renal transplantation. Overall and graft survival were better in patients with complete hematologic response and very good partial response (CR+VGPR) compared to partial response, no response or treatment naive (PR+NR+TN). Amyloid recurrence rate in the graft was lower (16% vs 37%, p=0.01) and the time to amyloid recurrence was significantly longer in the CR+VGPR group (median time not achieved vs 10 years, p=0.001). Comparing CR vs. VGPR there was no difference in OS and graft survival. A total of 69 patients (29%) experienced hematologic relapse requiring treatment post renal transplantation. Graft survival for those who had a hematologic relapse was not statistically different from that of patients without relapse. Successful hematologic treatment prevented graft loss in 87% of patients who had amyloid recurrence in the graft.

Conclusions: Our results show that selected patients with AL amyloidosis undergoing kidney transplantation have good outcomes.

PO2160

Primary Hyperoxaluria Type 2: Is Combined Liver Kidney Transplant the Answer?

Ayesha Mallick Imam,[1] Avantee V. Gokhale,[1,2] Ron Shapiro,[1] Graciela De Boccardo,[1] Fasika M. Tedla.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Recanati/Miller Transplantation Institute at Mount Sinai, New York, NY*.

Introduction: Primary Hyperoxaluria (PH) is a group of rare inborn errors of glyoxylate metabolism characterized by overproduction of oxalate. Oxalate is poorly soluble and is deposited as calcium oxalate in various organs, with the kidneys being the prime target leading to ESRD.

Case Description: 60-year-old female with a history of diabetes, hypertension and ESRD 2/2 obstructive uropathy from staghorn calculi in 2017. Patient underwent bilateral native nephrectomies in 2018 for staghorn calculi and was started on hemodialysis. Pathology showed extensive intratubular calcium oxalate crystals. Patient underwent a living donor kidney transplant in 2019 in India with allograft dysfunction by 2 months. Transplant biopsy showed oxalate deposition and severe ATN. 24-hr urine oxalate level was 182 mg. Genetic testing showed homozygosity for pathogenic variant in GRPHR gene, consistent with PH type-2. Repeat biopsy in 2020 confirmed oxalate nephropathy. Patient was started on daily dialysis for oxalate clearance. Pre-transplant plasma oxalate level on dialysis was 38mg. She underwent simultaneous liver-kidney transplant in 2021. Post-operatively, patient was maintained on CRRT for 4 days and transitioned to daily dialysis thereafter for delayed graft function and anuria. Renal allograft biopsy showed ATN and oxalate crystals. Patient was discharged on daily dialysis with serum oxalate level of 15. Patient finally recovered her kidney function almost 4 months later with current 24-hour creatinine clearance 25ml/min and 24-hour oxalate level of 55mg.

Discussion: PH type-2 was thought to have a more favorable prognosis than PH type-1 however, recent studies have found this disease has significant morbidity. While it was thought that a renal transplant may be the treatment for this 'milder' disease as oxalate deposition may take longer than the life of the allograft, reports have shown that recurrent PH type-2 has led to early post-transplant renal function loss. Dhondup and Del Bello each reported a case of successful treatment of PH type-2 with simultaneous liver-kidney transplantation. Similarly, while our patient remained dialysis dependent for almost 4 months post combined liver-kidney transplant, she is now successfully off dialysis. These 3 cases support the idea of a combined liver-kidney transplant as a better option for PH type-2.

PO2161

Early Post Renal Transplant Hypertension: Incidence of Masked Hypertension and Hemodynamic Correlates

Vijayakumar Paramasivam, Barbara A. Greco, Spencer Hodgins. *Baystate Medical Center, Springfield, MA*.

Background: Hypertension following renal transplantation is prevalent and impacts long term graft survival. Masked and white coat hypertension have been reported in patients with renal allografts. The onset and mechanism of masked hypertension in these patients is poorly understood. We report preliminary data from an ongoing prospective observational study of HTN in the early post-transplant period.

Methods: 40 patients with ESRD who undertook renal transplantation at Baystate Medical Center from June of 2019 to April of 2021 consented to participate in a prospective observational study assessing office BP and ambulatory blood pressure monitoring (ABPM). ABPM was performed at 1 month and at 3-4 months post-transplant. At the same time periods, bioimpedance measures including cardiac index (CI), total peripheral resistance (TPR) and total body water (TBW), were obtained using a whole body bioimpedance technology (NiCAS^{tm}). Patient demographics, office blood pressures (BP), ABPM and bioimpedance data were analyzed to determine rate of masked and white coat hypertension (HTN).

Results: 33 of 40 patients completed ABPM at 1 month and 16 completed the 3-4 month ABPM. Mean office BP at visit 1 and 2 were 133/79 and 132/78, respectively. There was an increase in percentage of patients with masked hypertension at the 3-4 month time period and a decrease in nondipping pattern. We did not identify significant differences in hemodynamic parameters between the 1 and 3 month time periods and between those with and without masked HTN.

Conclusions: In this preliminary analysis of a prospective observational study, we observed an increase in the rate of masked hypertension as patients get beyond 3 months post transplant. A significant percentage of these post transplant patients have non-dipping hypertension. Using whole body bioimpedance technology, we did not identify differences in CI, TPR and TBW between those with and without masked hypertension

	Visit 1	Visit 2
Office BP	N=40	N=21
Normal	6(15%)	4(19%)
HTN	34 (85%)	17 (81%)
Masked HTN	6/33 (18%)	7/17 (44%)
White Coat HTN	5/33 (15%)	2/35 (12%)
Non Dipping HTN	24/33 (85%)	10/17 (63%)

PO2162

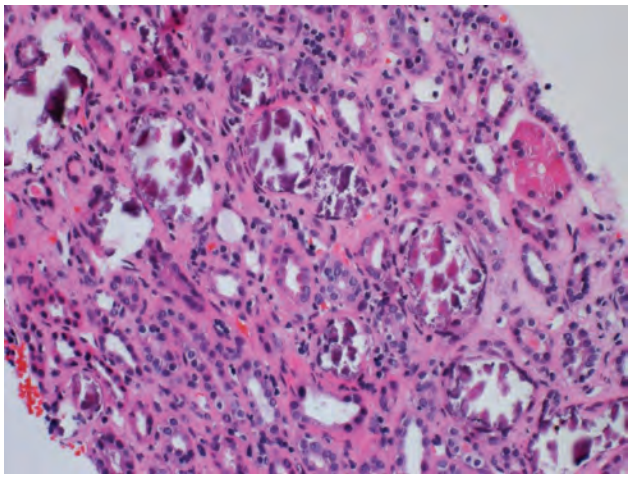
AKI Caused by Early Post-Kidney-Transplant Nephrocalcinosis Related to Severe Tertiary Hyperparathyroidism

Nghia Nguyen,[1,2] Daniel Varela,[1,2] Sergio A. Trevino Manllo,[1,2] Mourad Alsabbagh.[1,2] *[1]The University of Texas Rio Grande Valley, Edinburg, TX; [2]DHR Health, Edinburg, TX*.

Introduction: Persistent hyperparathyroidism is a common condition in post-kidney transplantation. We present a case of acute kidney injury (AKI) caused by nephrocalcinosis due to tertiary hyperparathyroidism in an early post-renal transplant patient, which was managed and improved with parathyroidectomy.

Case Description: A 42-year-old man with history of diabetes mellitus, hypertension and a deceased donor kidney transplant 3 months prior was evaluated for hypercalcemia. Medications included nifedipine, insulin, mycophenolic acid, tacrolimus and prednisone. Cinacalcet was started but calcium (Ca) level continued to rise. He was later hospitalized for AKI, cinacalcet was discontinued. Blood work showed creatinine (Cr) 2.6 mg/dL (baseline Cr 1.29 mg/dL), corrected Ca 9.9 mg/dL and tacrolimus 6.2 ng/mL. Images of the kidney graft were negative for obstruction. Kidney biopsy revealed no acute rejection or BK infection. However, there were findings of acute tubular injury with frequent calcium phosphate deposits, interstitial fibrosis and tubular atrophy involving 30-40% cortical surface. Interestingly, kidney biopsy obtained 2 months prior was unremarkable. Further workup showed parathyroid hormone 1220 pg/mL, 1,25 di-OH vitamin D 20.1 pg/mL. Given the rapid decline in kidney function and biopsy changes, subtotal parathyroidectomy was performed during the same admission. At 2-week follow-up visit, Cr improved to 1.5 mg/dL.

Discussion: Persistent hyperparathyroidism in post-kidney transplantation can lead to hypercalcemia with nephrocalcinosis, increased mortality and graft loss. These patients usually failed medical therapies. Our case demonstrates that early parathyroidectomy might be the treatment of choice for patients with severe hyperparathyroidism and symptomatic hypercalcemia.



Kidney biopsy in Nephrocalcinosis - Acute tubular injury with calcium phosphate deposits, interstitial fibrosis and tubular atrophy

PO2163

A Rare Case of Liver Failure in a Kidney Transplant Recipient with Polycystic Kidney Disease

Laila S. Lakhani, Payaswini Vasanth. *Emory University School of Medicine, Atlanta, GA.*

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) patients usually have great outcomes post kidney transplant. We describe a rare case (none reported in literature), where kidney transplantation led to progressive enlargement of liver cysts and liver failure physiology.

Case Description: A 51 year old female with end-stage kidney disease from ADPKD, underwent a deceased donor kidney transplant in July 2020. She was induced with basiliximab and maintained on Belatacept, Tacrolimus, mycophenolate and prednisone, with a baseline creatinine of 1 mg/dL. In October 2020, she presented with gross anasarca when CT imaging revealed large ascites, worsening of liver cyst burden, splenic enlargement and IVC compression. Ascitic fluid analysis indicated portal hypertension. Trans-jugular liver biopsy demonstrated nodular regenerative hyperplasia and vascular flow abnormality. MR Venogram showed severe narrowing of the IVC, hepatic and portal veins from mass effect of liver cysts. She underwent IVC stent placement; however, post procedure course was complicated by klebsiella bacteremia, that progressed to developing septic lung emboli and anuric acute kidney injury. She developed multi-organ failure requiring vasopressors, intubation, renal replacement therapy and worsening hepatic encephalopathy. This complex hospitalization culminated into her demise secondary to cardiac arrest.

Discussion: This is a very challenging yet fascinating case that highlights progressive liver failure from rapidly enlarging liver cysts within 3 months of kidney transplantation. Did immunosuppression contribute to accelerating the growth of liver cysts? Should a select group of patients with ADPKD be evaluated for combined liver and kidney transplant? Multi-disciplinary discussions between transplant nephrology and hepatology can guide decision making in these complex patients.

PO2164

Association Between Recipient-Donor HLA Genotypes and Recurrent Membranous Nephropathy After Kidney Transplantation

Edmund Y. Chung,[1] Katrina Blazek,[2] Ankit Sharma,[3] Siah Kim,[1] Armando Teixeira-Pinto,[2] Germaine Wong,[2,3] Stephen I. Alexander.[1] *[1]Children's Hospital at Westmead Centre for Kidney Research, Westmead, NSW, Australia; [2]The University of Sydney, Sydney, NSW, Australia; [3]Westmead Hospital, Westmead, NSW, Australia.*

Background: Recurrent membranous nephropathy (MN) occurs in up to 40% of kidney transplant recipients (KTRs) and is a major cause of graft loss. Recipient with alleles at the HLA-D loci were found to have an increased risk of disease recurrence in KTRs with primary MN. However, the association between recipient-donor HLA characteristics and disease recurrence has not been explored.

Methods: We integrated data from two registries: United Network for Organ Sharing, and Australian and New Zealand Dialysis and Transplant registries between 1963 and 2020. Least Absolute Shrinkage and Selection Operator (LASSO) regression was used for variable selection. The penalization parameter was chosen by cross-validation and the covariates with non-zero coefficients were included in a logistic regression, together with class, and fitted using maximum likelihood. The model performance was evaluated using C-statistics.

Results: 8058 KTRs with primary MN were included and 232 had recurrent MN. Of the 266 variables, group LASSO selected 59 variables considered as variables of importance and were included in the adjusted logistic regression model. Recipient HLA genotype at DR11 (odds ratio, 95% confidence interval) (1.81, 1.30-2.51, p<0.001), B38 (1.93, 1.00-3.43, p=0.04), and B46 (6.75, 1.55-26.30, p=0.007) and donor-recipient HLA-B65 match (3.38, 1.07-8.85, p=0.02) were associated with an increased risk of recurrent MN, adjusted for recipient sex, ethnicity, comorbidities (diabetes, hepatitis C and cancer), immunosuppression regime (T cell depletion induction therapy, B cell depletion induction therapy, tacrolimus, corticosteroid, or other maintenance therapy), donor type, biopsy-proven rejection, and country of origin. The overall performance of the model was good (C-statistic 82%).

Conclusions: Recipient HLA-DR11, B38, B46 and donor-recipient HLA-B65 match were associated with an increased risk of recurrent MN in KTRs.

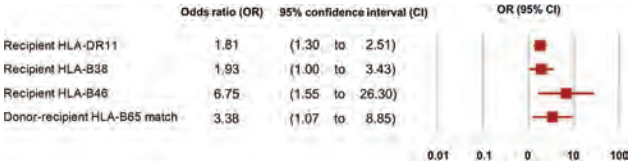


Figure 1. Recipient-donor HLA characteristics associated with recurrent membranous nephropathy in kidney transplant recipients

PO2165

The Cumulative Dose-Dependent Benefit of Metformin in Kidney Transplantation Recipients

Soie Kwon,[1] Yong Chul Kim,[1] Chan-Duck Kim,[5] Jang-Hee Cho,[5] Hyung Eun Son,[2] Jong Cheol Jeong,[2] Jeonghwan Lee,[3] Kyung Don Yoo,[6] Jong Soo Lee,[6] Hajeong Lee,[1] Yon Su Kim,[1,4] Jung Pyo Lee.[3,4] *[1]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital Department of Internal Medicine, Seongnam, Gyeonggi-do, Republic of Korea; [3]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Kyungpook National University, Daegu, Daegu, Republic of Korea; [6]Ulsan University Hospital, Ulsan, Republic of Korea.*

Background: The status of metformin as a primary choice is concrete, moreover it has recently been recommended for advanced chronic kidney disease. Although, the evidence of metformin usage in kidney transplant recipients (KTRs) is lacking. We investigated the effect of metformin in KTRs.

Methods: The primary outcomes were all-cause mortality and death censored graft survival (DCGS) and secondary outcome was biopsy proven acute rejection (BPAR). Cox analysis and propensity score matching were used. Time-varying and marginal structural cox was conducted for HbA1c. A defined daily dose (DDD) of WHO and a penalized spline curve were used to evaluate cumulative effect of metformin.

Results: In 2,048 diabetic KTRs, 1,199 patients were metformin user and 849 patients were non-metformin user. Pre-existing DM patients before transplantation were majority (78.7%) and tend to be less prescribed metformin than NODAT (DM 56.0%; NODAT 68.0%; *P*<0.001). The metformin user had a lower risk of all-cause mortality, DCGS and BPAR. Even after time varying adjustment of HbA1c, metformin usage was associated with significant reduction in all outcomes. (Table 1) Also, the more cumulative metformin exposure was correlated to the less risk of whole outcomes. (Figure 1)

Conclusions: In conclusion, metformin can be also considered as first-line anti-diabetic treatment in KTRs, not only from the benefit of lower mortality, graft survival and acute rejection, but also cumulative dose dependent protective effect.

PO2166

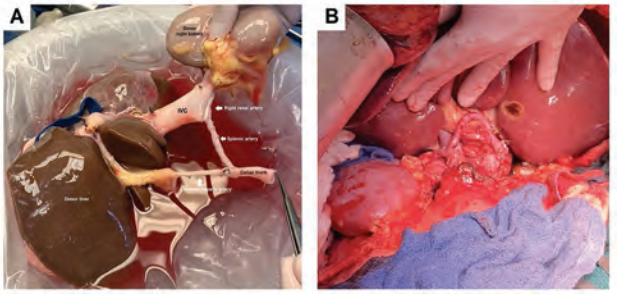
Successful En Bloc Liver Kidney Transplant in a Morbidly Obese Patient

Paola Vargas, Joseph T. Leeds, Shawn Pelletier, Nicolas Goldaracena, Angie G. Nishio Lucar. *University of Virginia, Charlottesville, VA.*

Introduction: *En bloc* liver and kidney transplant is a variant for the traditional simultaneous liver kidney transplant (SLKT) technique that, with simultaneous reperfusion of both grafts through a common vascular anastomosis, can decrease operative time, cold ischemia time and risk of surgical site infections.

Case Description: A 50-year-old morbidly obese (BMI >50) male with history of ESRD due to hypertension, on hemodialysis for 4 years, decompensated NASH cirrhosis, Factor V Leiden, previous episodes of venous thromboembolism and obstructive sleep apnea presented for SLKT. The donor was brain dead with a KDPI 22%, anatomy was normal. On backtable, the donor right renal artery and splenic artery were anastomosed end-to-end to leave these arterial systems in continuity and perfused from the celiac trunk. The infrahepatic IVC cuff was sutured using an endovascular stapler to close the left renal vein orifice and distal IVC (Fig. 1A). The liver transplant was done with a piggyback technique with a side-to-side cavocavostomy. Reperfusion occurred simultaneously in both allografts from the arterial inflow followed by the venous inflow (Fig. 1B). Direct flow assessments by doppler was excellent. The ureter was anastomosed to the recipient's right native ureter in an end-to-side fashion followed by a double J ureteral stent. Total operative time was 7 hrs, 10 min, CIT 7 hrs and WIT 46 min. The postoperative course complicated by DGF for 3 weeks. He was discharged home on POD 6 and the ureteral stent was removed on POD 48. At 3 months follow-up, the portal vein and renal artery remain patent and both allografts have excellent functioning without evidence of complications.

Discussion: This case illustrates that *en block* liver kidney is a feasible and effective option for well-selected patients. This technique should be considered in obese patients or those with extensive iliac arteries atherosclerosis who have increase morbidity with transplant and could benefit from single surgical incision. Close post transplant monitoring is key to surveil for potential complications.



PO2167

Little Goes a Long Way: Is Kidney Donor Profile Index (KDPI) a Good Predictor for Pediatric Kidneys from Donors Less Than 10 kg?

Liliia Harris, Uma Mahesh R. Avula, Bushra Syed, Pradeep Vaitla, Franco H. Cabeza Rivera. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Pediatric deceased donor kidneys (DDK) constitute 10-12% of the DDK supply and are allocated using the same criteria as adult kidneys. Kidney Donor Profile Index (KDPI) is designed to predict kidney graft performance in adult recipients based on 10 donor characteristics. A KDPI scale goes from 1 (best) to 100 (worst). Most child donor kidneys classified as KDPI-C (≥35% but ≤85%) and KDPI-D (>85%) which makes them less desirable. In addition, few programs use kidneys from donors less than 1 year.

Case Description: We report a case of pediatric en bloc kidney (EBK) transplantation procured from a 7-month-old female donor, with a bodyweight of 7.7 kg. KDPI is 87%. The recipient is a 39-year-old female with a bodyweight of 54 kg and a diagnosis of ESKD secondary to biopsy-proven FSGS. The recipient had been on PD for 37 months, baseline sCr of 12-15 mg/dL and was oliguric. Cold ischemic time of the kidneys was 8 h 33 mins, warm ischemic time - 24 mins, estimated blood loss - 200 mL. Intraoperative challenges included tedious organ preparation and extremely small vessels requiring complex reconstruction along with the creation of 2 ureteral anastomoses. A postoperative complication included delayed graft function required 2 hemodialysis sessions. Thereafter graft function improved and sCr trended from 15.48 mg/dL to 1.46 mg/dL at 4 weeks follow-up.

Discussion: KDPI is a valuable tool for adult donors but takes an oversimplified approach to the pediatric donor population. KDPI calculation includes donor age, weight, and height does not lead to a proportional scaling of the hazard in pediatric donors. It leads to misclassification and underestimation of a sizable number of kidneys from small pediatric donors. In addition, although it was found en bloc to be a significant factor and shown EBK versus SKT as an important predictor for graft performance, it was decided not to include this criterion in KDPI. Pediatric EBKs had the lowest acute rejection and delayed graft function rates in comparison with SKT. Furthermore, the eGFR for pediatric EBKs improves due to the continuous growth of pediatric kidneys after transplant. In summary, modified KDPI tailored to the pediatric donors is warranted to accurately represent pediatric donor kidney survival, attract recipients and surgeons to address the problem of organ shortage.

PO2168

Pickering Syndrome in a Kidney Transplant Recipient

Jad Tabbara, Mohamed Hassanein, Omar A. Aleter, Joshua J. Augustine. *Cleveland Clinic, Cleveland, OH.*

Introduction: Pickering syndrome (PS) refers to hypertensive urgency with recurrent flash pulmonary edema (FPE) due to bilateral renal artery stenosis (RAS) or unilateral RAS in patients with a solitary kidney or kidney allograft. We report a case of PS in a kidney transplant recipient.

Case Description: A 68-year-old gentleman with a history of end-stage kidney disease secondary to diabetic nephropathy treated with deceased donor kidney transplantation (on Belatacept, Mycophenolate Mofetil, and Prednisone) and a history of recurrent admissions for FPE presented 3-months post kidney transplantation with hypertensive urgency, acute kidney injury (AKI) and FPE. Blood pressure was 170/85 mmHg and serum creatinine was 2.5 mg/dL (baseline 1.8 mg/dL). Echocardiogram showed preserved left ventricular function. Kidney transplant ultrasonography (US) showed patent vasculature with no hydronephrosis. Kidney biopsy showed no evidence of acute rejection. Duplex ultrasound showed a high proximal peak systolic velocity (PSV) 622 cm/sec and a low renal arterial resistive index (RI = 0.55) with severe (60-99%) transplant RAS. An intravascular-ultrasound (IVUS) guided stent placement facilitated safe renal artery revascularization using only 2 mL of contrast agent subsequently leading to a complete resolution of AKI and no further episodes of FPE.

Discussion: Transplant RAS causes 1-5% of post-transplant hypertension, and usually occurs within the first 6 months post-transplantation. Activation of the renin-angiotensin-aldosterone system leads to worsening hypertension, allograft dysfunction and fluid retention with FPE. Although duplex US is used for screening, angiography with simultaneous percutaneous angioplasty is often needed for definitive diagnosis and treatment. IVUS guided stenting is beneficial in patients with AKI to minimize contrast exposure and further worsening of graft function. Early diagnosis and prompt treatment of PS are the key to minimize morbidity and mortality in these patients.

PO2169

Treatment of Transplant Renal Vein Thrombosis in a Pediatric Patient Using an EkoSonic Endovascular System (EKOS) Catheter

Siddharth A. Shah, Malavika Prasad. Pediatric Nephrology team *University of Louisville, Louisville, KY.*

Introduction: Transplant renal vein thrombosis (tRVT) is a critical complication after renal transplant with reported prevalence of 0.1% to 4.2% leading mostly to graft loss. Thrombolytic therapy and surgical thrombectomy has been described previously to treat tRVT. EKOS is a modern and innovative ultrasound-facilitated catheter directed thrombolysis technique that is approved primarily for treatment of pulmonary embolism, deep vein thrombosis and arterial occlusion. It requires ultrasound core wire and infusion catheter for delivery of fibrinolytic agent such as Tissue plasminogen activator (tPA).

The ultrasound core wire or transducer generates ultrasound waves that help accelerate fibrinolysis, decrease the treatment time and decrease the risk of bleeding. The use of EKOS for tRVT has not been reported in pediatric literature and we describe one such case.

Case Description: We describe a 17-year-old boy with history of congenital nephrotic syndrome who received living donor renal transplant in 2005. His post-transplant course was complicated by multiple episodes of deep venous thrombosis in right lower extremity, chronic right inguinal venous thrombosis with collaterals in lower extremities, maintained on anticoagulant therapy. He presented with serum creatinine elevation of 3.7 mg/dL (baseline of 1.4 mg/dL) and anuria. On renal US Doppler, the transplant renal vein was not seen and there was concern of lack of flow/RVT. CT venogram performed showed acute lumen occluding thrombus in left lower extremity venous system extending from left popliteal and femoral vein all the way to the left transplant renal vein in the left iliac fossa. He received tPA as per hematology without any improvement. Active discussions between hematology, nephrology and vascular surgery led to a trial of EKOS device to salvage the allograft. The patient then underwent thrombolysis using EKOS catheter with peripheral access to the left transplant renal vein, without any complications. The repeat renal US Doppler showed patent left renal transplant vein, with continued occlusion in the left external iliac vein. The serum creatinine returned to baseline 1.4-1.5 mg/dL one week after procedure.

Discussion: We describe a novel report of successful treatment of transplant renal vein thrombosis using EKOS catheter. Further studies are needed to provide more insight in this therapy.

Reversal of Prolonged Delayed Graft Function Following Kidney Transplantation with a Belatacept-Based Regimen

Sujit K. Routray, Bhavna Chopra, Khaled Nashar, Kalathil K. Sureshkumar. AHN Nephrology *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Delayed graft function (DGF) following kidney transplantation is associated with adverse graft and patient outcomes. Many factors contribute to the development of DGF including ischemia-reperfusion injury. There is concern that calcineurin inhibitors such as tacrolimus can perpetuate DGF through tubular injury and vasoconstriction. The non-nephrotoxic co-stimulation blocker belatacept could potentially be beneficial in improving allograft function in such scenario. We present a patient who experienced prolonged DGF following kidney transplantation that reversed following switching immunosuppression from a tacrolimus-based to belatacept-based regimen.

Case Description: A 73-year old non-sensitized female with a history of coronary artery disease, hypertension, and type 2 diabetes mellitus on maintenance hemodialysis underwent kidney transplantation from a 63-year old brain-dead donor with acceptable procurement kidney biopsy and kidney donor profile index (KDPI) of 88%. Cold ischemia time was 27.5 hours. She received induction with Thymoglobulin followed by tacrolimus/mycophenolic acid maintenance with early steroid withdrawal. In the peri-operative period, she experienced hemodynamic instability from cardiogenic shock requiring prolonged ICU stay. She developed DGF requiring dialysis support. Despite clinical improvement, she remained dialysis-dependent. Allograft biopsies at 2 weeks and 2.5 months post-transplant showed acute tubular injury and no rejection. Four months from transplant, immunosuppression was changed from tacrolimus-based to belatacept-based regimen. One week after this change, the urine output started improving and 10 days later the patient came off dialysis. Her serum creatinine continues to improve with a most recent value of 2.4 mg/dl and excellent urine output 3 weeks since stopping dialysis.

Discussion: The patient experienced very prolonged DGF after receiving a high KDPI kidney. We believe that replacing tacrolimus with belatacept facilitated the reversal of prolonged DGF and freedom from dialysis in this patient. Conversion of tacrolimus to belatacept in kidney transplant recipients experiencing prolonged DGF and utilization of de novo belatacept-based maintenance regimen in patients at high risk for developing DGF should be considered in order to improve graft and possibly patient outcomes.

PO2171

Disease-Specific Tissue RNAs as Diagnostic Tool for Kidney Transplant Pathology

Neva Bezeljak,[1] Emanuela Bostjancic,[2] Nika Kojc,[2] Miha Arnol,[1] Zeljka Veceric Haler.[1] [1]*University Medical Centre Ljubljana Department of Nephrology, Ljubljana, Slovenia;* [2]*Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.*

Background: MicroRNAs (miRNAs) play an important role in the development of renal diseases as epigenetic regulators of gene expression. However, there are limited data to date on tissue miRNA expression in transplantation-related kidney disease.

Methods: Study enrolled fifty-six transplant kidney patients with surveillance/indication kidney transplant biopsy including pretransplantation biopsies, which were divided into four (four + control) groups. The control group (CG, n = 12) consisted of patients without patohistological changes on surveillance biopsy. Patients with indication biopsy due to an increase in serum creatinine and nonspecific chronic changes in patohistological analysis were in the nonspecific group (NS, n = 6). The other three groups consisted of histologically proven antibody-mediated rejection (ABMR, n = 13), recurrent glomerulonephritis (rGN, n = 15), and acute tubular injury/necrosis (ATN, n = 10). We analyzed the expression of 6 selected miRNAs (miR-29c, miR-126, miR-146a, miR-150, miR-155, miR-223) and compared them with the respective disease process.

Results: When comparing mRNA expression before and after transplantation, there was no statistically significant difference in the expression of the analyzed miRNAs in CG, NS and rGN, but we observed a statistically significant change in the expression profile of miR-146a and miR-155 after transplantation in patients with ATN and ABMR. Post-transplant biopsies showed differential expression of miR-146a and miR-155 in ABMR and NS compared to CG, miR-155 in rGN compared to CG, miR-146a in ATN compared to CG and miR-223 in NS compared to CG. All but miR-146a showed differential expression in pretransplantation biopsies before transplantation of either NS, rGN, ABMR or ATN compared to CG, but the difference in expression after transplantation was more pronounced.

Conclusions: Our results suggest that miR-146a and miR-155 play an important role in pathological processes after kidney transplantation and also support the hypothesis that there are differences at the molecular level of the donor kidney that may predispose the kidney to certain types of patohistological damage.

PO2172

Trajectory of Gene Expression Profile and Donor-Derived Cell-Free DNA Before and After Subclinical Acute Rejection

Sookhyeon Park, Zachary Dietch, Kexin Guo, Lihui Zhao, John J. Friedewald. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Subclinical acute rejection (subAR) is associated with poor kidney allograft outcomes. Blood gene expression profile (GEP) and donor-derived cell-free DNA (dd-cfDNA) have been used to exclude or diagnose kidney allograft rejection non-invasively. However, the trajectory of GEP and dd-cfDNA are unknown after subAR. We investigated the changes in GEP and dd-cfDNA after subAR.

Methods: We analyzed 100 subjects with GEP and 87 with dd-cfDNA, with some subjects in both groups. GEP and dd-cfDNA were performed before, at, and after the time of subAR. The cohort was extracted from a previously reported prospective, multicenter observational study. GEP was performed using a microarray-based 120 gene expression profile. The study reported dd-cfDNA as a percentage of donor cell-free DNA over total cell-free DNA. Locally estimated scatterplot smoothing (LOESS) and linear mixed effect models were used to analyze longitudinal changes of GEP and dd-cfDNA scores.

Results: A total of 1,314 blood samples were assessed. The longitudinal changes of GEP scores at a sample level are shown in Figure 1. GEP scores peaked at the time of subAR and decreased after. The slope of GEP scores was significantly different after subAR (slope difference = -0.201 p-value <0.001) (Figure 2). On the other hand, dd-cfDNA continued to rise even after subAR (Figure 1). There were no significant changes to the slope of dd-cfDNA between pre-subAR and post subAR (0, p-value = 0.98) (Figure 2).

Conclusions: GEP scores significantly dropped, while dd-cfDNA persistently increased after subAR. How this may inform the biology of gene expression vs. dd-cfDNA after treatment of rejection requires additional study.

Early Experience with TruGraf in Kidney Transplant Recipients: The University of Maryland Medical Center Experience

Abdolreza Haririan,[1] Brian M. Masters,[2] Ian A. Booth,[2] Roberto S. Kalil.[1] [1]*University of Maryland School of Medicine, Baltimore, MD;* [2]*University of Maryland Medical Center, Baltimore, MD.*

Background: TruGraf, an assay based on PBMC gene expression profile, has been recently introduced as a non-invasive screening tool for subclinical rejection in kidney transplantation. Its utility as a screening tool is currently not well defined. In this preliminary study we examined the predictive value of TruGraf for subclinical acute rejection, and its concordance with dd-cfDNA and DSA results.

Methods: In this small, retrospective cohort study, we examined the results of TruGraf in 48 kidney transplant recipients with stable graft function (median 12.9 mo posttransplant, IQR 5.9-19.8). Patients were maintained on TAC/MMF+/-prednisone. We collected data on 11 biposies, 17 dd-cfDNA, and 16 DSA assays performed within 1 mo of TruGraf.

Results: There were 34 'TX" and 14 'Not-TX" results. 3 pts in former (1 with TCMR) and 8 in latter group (1 TCMR, 3 ABMR) had biopsies. Among those with DSA testing, out of 7 "Not-TX" cases 2 had DSA, compared with 4 out of 9 with "TX" (p=0.45). Combining biopsy results with DSA, "rejection or DSA" was present in 5/8 of "Not-TX" and 4/9 of "TX" groups (p=0.4). dd-cfDNA >1% was seen in 1/6 of "Not-TX" and 2/17 of "TX" cases, and 2/6 and 8/17, respectively, had values >0.5% (p=0.46). Comparing dd-cfDNA >0.5% and TruGraf, the former had 3/6 vs 4/6 negative results in absence of "rejection or DSA"; while positive results in presence of "rejection or DSA" was seen in 4/6 vs 2/6, respectively.

Conclusions: These preliminary observations in our cohort suggest that TruGraf could be a useful non-invasive tool for monitoring of allograft status in kidney transplant recipients. With implementing protocolized use of this test in our center along with dd-cfDNA and DSA screening at various time points, we will continue to prospectively collect data, and will be able to better define its utililty in our center toolbox.

Sparse Intragraft Molecular Classifiers for Antibody-Mediated and T Cell-Mediated Kidney Transplant Rejection: Development, Validation and Clinical Value

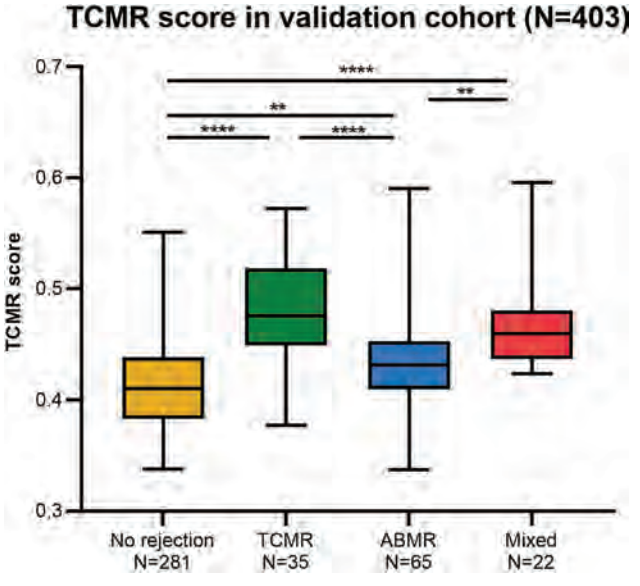
Jasper Callemeyn,[1] Josue M. Nava-Sedeño,[4] Wilfried Gwinner,[5] Dany Anglicheau,[3] Pierre Marquet,[2] Andreas Deutsch,[4] Haralampos Hatzikirou,[4] Maarten Naesens.[1] *[1]Department of Microbiology, Immunology and Transplantation, KU Leuven, Leuven, Belgium; [2]Universite de Limoges, Limoges, France; [3]Hopital Universitaire Necker-Enfants Malades Bibliotheque Jean Hamburger Pierre Royer, Paris, France; [4]Technische Universitat Dresden, Dresden, Germany; [5]Medizinische Hochschule Hannover, Hannover, Germany*.

Background: Although the transcriptional landscapes of antibody-mediated rejection (ABMR) and T-cell mediated rejection (TCMR) have been largely elucidated, applying these gene signatures in transplant clinics is hampered by the large number of features and difficult integration with histological findings. We aimed to develop and validate a sparse molecular classifier for ABMR and TCMR.

Methods: In a discovery cohort of 224 kidney transplant biopsies, microarray gene expression was applied to build two separate prediction models for presence of ABMR or TCMR. Variable selection for logistic regression was performed by lasso regularization. The diagnostic accuracy and prognostic value of the obtained ABMR and TCMR classifiers were assessed in two external validation cohorts.

Results: From the discovery cohort, a 2-gene ABMR classifier (*PLA1A, GNLY*) and 2-gene TCMR classifier (*IL12RB1, ARPC1B*) were derived. In the first validation cohort (N=403 biopsies), diagnostic accuracy was retained for both ABMR (ROC-AUC 0.80, 95% CI 0.75-0.85) and TCMR (ROC-AUC 0.83, 95% CI 0.77-0.89), also allowing discrimination between pure and mixed phenotypes. In the second validation cohort (N=282 biopsies), molecular ABMR and TCMR scores predicted graft failure (respective time-integrated AUC of 0.82 and 0.83) and identified kidneys at risk for graft failure which were not picked up by routine histology.

Conclusions: We identified and validated an intragraft 2-gene ABMR classifier and 2-gene TCMR classifier that can be used as diagnostic and prognostic tools. Robust variable selection models can yield parsimonious molecular classifiers for kidney transplant rejection, facilitating their interpretation and clinical implementation.



PO2175

Evolving Experience with TruGraf® Gene Expression Profile and TRAC™ Donor-Derived Cell-Free DNA Testing in Kidney Transplantation: First Year Post Transplant and Beyond

Vijayakumar Paramasivam, Barbara A. Greco, Michael J. Germain. *Baystate Medical Center, Springfield, MA*.

Background: Non-invasive validated rejection biomarkers are available to monitor kidney transplant recipients (KTR). Our program has replaced 3 and 12 month protocol biopsies (BX) with biomarker surveillance using TruGraf (TG) gene expression profile (GEP) validated to rule out subclinical acute rejection (subAR) and TRAC donor derived cell free DNA (dd-cfDNA) as a marker of allograft injury. This is the evolving single center experience of TruGraf-TRAC surveillance for KTR within the 1st year post-transplant (post-txp) and beyond

Methods: Our immunosuppression (IS) protocol is alemtuzumab with tacrolimus maintenance, mycophenolate mofetil added in high risk KTR. TG and TRAC were done at 3, 12 months post-txp, and with IS changes (mTORi/belatacept conversion, IS decrease). Additionally, all KTR to be tested at least once to determine baseline status (immune quiescence). A positive (pos) TG, TRAC, or dynamic changes in post-op course prompts further evaluation and/or repeat TG/TRAC testing PRN. BX were done in cases with equipoise. Donor specific antibodies (DSA) tested in all patients.

Results: To date, 115 KTRs surveilled with TG and/or TRAC (149 TG and 90 TRAC tests). 30/41 KTR spared 3-month BX. Of 11 BX, 6 were for delayed/slow graft function (negative (neg) TG (Transplant eXcellence (TX)) and neg for acute rejection/DSA) and 5 were for pos TG (not-TX) with 3 neg for DSA/acute rejection. 12/16 KTRs avoided 1-year BX. 45 KTRs were > 1 year post-txp at testing (16 KTR > 10 years, 8 KTR >20 years). Table 1: TG/TRAC concordance (n=82). 45% concordant neg, confirming IS adequacy. 50% discordant (TG or TRAC pos) prompting eval and correlation with findings (DSA, proteinuria, renal function). 5% concordant pos prompting BX, diagnosis, and/or subAR treatment.

Conclusions: Non-invasive TruGraf GEP with TRAC dd-cfDNA spares protocol BX in KTR at 3 and 12 months, while providing enhanced monitoring >1 year post-txp by ruling out subAR and assuring IS adequacy. Combined TruGraf and TRAC testing is promising, warranting larger studies for optimal synergy/frequency of serial testing, especially as subAR persists beyond the 1st year post-txp.

TruGraf-TRAC Concordance

KTR (n=82)	TruGraf neg (TX)	TruGraf pos (not-TX)
TRAC neg (<0.7%)	37	16
TRAC pos (≥0.7%)	25	4

LIMS1 Risk Genotype and Clinicopathological Features of Kidney Transplant Recipients

Yasar Caliskan,[1] Yasemin Ozluk,[2] Safak Mirioglu,[2] Ahmet B. Dirim,[2] Cigdem Kekik,[2] Seda Safak,[2] Nurana Guller,[2] Halil Yazici,[2] Ozgur A. Oto,[2] John C. Edwards,[1] Fatma Savran Oguz,[2] Aydin Turkmen,[2] Krista L. Lentine.[1] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey*.

Background: LIM Zinc Finger Domain Containing 1 (*LIMS1*) homozygous risk genotype (rs893403 GG) is associated with increased risk of T-cell mediated rejection (TCMR) after kidney transplantation (KTx). However, prior studies lack detailed histopathological data. We examined the association of *LIMS1* genotype with histopathology of allograft rejection.

Methods: A total of 110 KTx recipients underwent allograft biopsy were genotyped for *LIMS1* rs893403 variant by Sanger sequencing followed by PCR confirmation of the deletion. The 2013 Banff scores from allograft biopsies were compared between recipients homozygous for *LIMS1* rs893403 genotype GG (n=24) versus AA/AG genotypes (n=86).

Results: There were no differences regarding demographic, clinical and laboratory features between the genotype groups (Table 1). Allograft biopsies were performed after a median 6.2 years after KTx. Serum creatinine, proteinuria and donor specific antibody levels at the time of biopsies were similar between groups. Banff median tubulitis score was significantly higher in GG group compared to AA/AG group (1.42±0.65 vs 1.12±0.66, p=0.03) (Figure 1). There were also no significant differences regarding histopathological diagnosis between the groups (Table 1).

Conclusions: Kidney transplant recipients with homozygous *LIMS1* deletion had higher tubulitis scores. Our data supports the role of *LIMS1* locus in the pathophysiology of allograft rejection and motivates ongoing work to elucidate mechanisms of association of *LIMS1* risk genotype and allograft injury.

Table 1. Demographic, clinical and histopathological characteristics of study groups based on *LIMS* gene rs893403 genotype.

	GG genotype (n=24)	AA/AG genotype (n=86)	p value
Age (years), mean±SD	30 ± 12	32 ± 12	0.41
Gender (M/F), n (%)	18 (75%) / 6 (25%)	49 (57%) / 37 (43%)	0.11
Donor gender (M/F), n (%)	16 (67%) / 8 (33%)	47 (55%) / 39 (45%)	0.29
Donor type (living/deceased), n (%)	17 (71%) / 7 (29%)	70 (81%) / 16 (19%)	0.26
HLA mismatches, mean±SD	3.4 ± 1.1	3.0 ± 1.2	0.07
Biopsy time after KTx (years), median (IQR)	7.6 (4.0-12.8)	5.4 (1.9-12.8)	0.35
Serum creatinine (mg/dL), median (IQR)	2.2 (1.5-2.5)	2.2 (1.68-2.8)	0.84
Proteinuria (g/day), median (IQR)	0.25 (0.03-1.43)	1 (0-2.5)	0.33

PO2177

Association of Vascular Endothelial Growth Factor Gene Polymorphism with Allograft Survival in Renal Transplant Recipients

Narayan Prasad, Manas R. Patel, Vinita Agrawal. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Endothelial cell dysfunction is a primary cause for late allograft loss in renal transplantation recipients. Vascular Endothelial Growth Factor (VEGF) is a pro-angiogenic factor that has an important role in the development and maintenance of physiological function of endothelium cell thus may determines the allograft function.

Methods: We did genotyping of VEGF SNPs among 320 renal allograft recipients(non-rejecters (160) and rejecters (160)) and 160 donors by PCR- RFLP technique. Intragraft VEGF mRNA and protein expression were analyzed by RT-PCR and immunohistochemistry. Serum VEGF level were analyzed by ELISA.

Results: On comparison between donors and recipients genotypes of VEGF +936 C>T [CT (OR=7.16; 95% CI=4.33- 11.84; P=0.00) and TT (OR=49.30; 95% CI=11.84-205.29; P=0.00)], -1154 G>A [AG (OR=2.22; 95% CI=1.40-3.50; P=0.00)], -1190G>A [GG (OR=2.21; 95% CI=1.22-4.01; P=0.00)], -634C>G [GG (OR=2.34; 95% CI=1.34-4.10; P=0.00)], -2549 18bp Insertion/Deletion [ID (OR=1.58; 95% CI=1.01- 2.46; P=0.04) were significantly associated with risk of rejection. On comparing mutant genotypes between non-rejecters and rejecters we found that genotypic frequencies of +936 C>T [TT (OR=2.43; 95% CI=1.33-4.44; P=0.004)], -1154 G>A [GG (OR=1.94; 95% CI=1.03-3.67; P=0.04)], -1190G>A [GA (OR=1.83; 95% CI=1.07-3.13; P=0.02)], -2549 18bp Insertion/Deletion [ID (OR=2.35; 95% CI=1.38- 3.99; P=0.002) and -1455T>C [TT (OR=3.13; 95% CI=1.07-9.10; P=0.03)] shown risk of allograft rejection whereas mutant genotypes of -2578 C>A [CA (OR=0.45; 95% CI=0.26-0.79; P=0.005) and CC (OR=0.23; 95% CI=0.11-0.46; P=0.000)] and +405 C>G [GG (OR=0.43; 95% CI=0.20-0.91; P=0.02)] have shown protective association with rejection. The VEGF mRNA expression was also significantly higher in rejecters compared to non-rejecters which both were higher compared to healthy donor. Mean serum VEGF levels was higher in rejecters compared to non-rejecters, which both were higher than those of donors. On IHC percentage of VEGF staining in glomerular capillaries and cortical peritubular capillaries was higher in rejecter as compared to non-rejecter.

Conclusions: The present study signifies genetic associations of all the mutant genotypes of VEGF +936 C>T, -1190G>A, -2549 18bp Insertion/Deletion, and -1455T>C SNPs to be at increased risk for renal allograft rejection.

Machine Learning and Bioinformatics Approaches to Discover Urine Gene Expression Biomarkers for Kidney Transplant Rejection

Manoj Kandpal,[1] Karen S. Keslar,[2] John J. Friedewald,[1] Robert L. Fairchild.[2] CTOT Consortium *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Cleveland Clinic Lerner Research Institute, Cleveland, OH.*

Background: While transplant biopsies are safe and accurate way for monitoring transplant progress, they are associated with defined risks and significant costs. Using the mRNA from urine, we proposed a non-invasive approach to diagnose acute rejection. The multi-step approach involved collection and mRNA analysis of urine samples, application of a machine learning algorithm to select an initial set of gene markers, adding known markers from prior work, and using the combined set for developing a final classifier. The classifier was developed on a training data consisting of 42 samples (17 rejection and 15 control) and a validation data set of 43 samples (13 rejection and 30 control).

Methods: RNA from urine samples was hybridized to customized NanoString panel, consisting of 796-gene Immune Profiling gene panel and 26 genes representing graft rejection or the development of fibrosis from published works. The RNA samples were processed on the nCounter GEN2 using the high sensitivity protocol and high-resolution data capture. Raw data were imported into nSolver4.0 (NanoString) followed by $\log_2$ gene counts and normalized data generation that was used in further analyses.

Results: Using Random Forest on NanoString data we first obtained a set of eight gene as our initial pool of markers. We combined them with the 20 gene markers from our previous work and developed a seventeen gene classifier (after removing duplicates and non-important genes). The combined signature of 17 genes had high AUC (0.875), accuracy (0.881), sensitivity (0.765), specificity (0.96), PPV (0.929) and NPV (0.857) on training data. Although the PPV dipped to 0.714 in the validation data, it still performed well resulting in high accuracy (0.84), sensitivity (0.77), specificity (0.87) and NPV (0.90).

Conclusions: This initial hybrid modeling approach has shown its significance and we plan to further strengthen its reliability and test robustness by incorporating more samples. The final classifier, a non-invasive approach to classify kidney graft heath, could help improve serial monitoring of graft recipients while reducing the cost and safety risks associated with biopsies.

PO2179

Discovery of Cellular and Genetic Signatures of Immune Tolerance in Kidney Transplant Recipients Through Single-Cell RNA Sequencing Analysis

Hanbi Lee, Chul Woo Yang, Byung ha Chung. *Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Background: Immune tolerance, defined by maintaining stable allograft function without immunosuppression after transplantation, is the ultimate goal of kidney transplant. Unlike bulk transcriptional analysis, single cell RNA sequencing (scRNA-seq) allows us to profile gene expression at the heterogeneous individual cell level. We aimed to investigate the difference of cellular and genetic signatures of immune tolerance in kidney transplant recipients (KTRs) through scRNA-seq analysis.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from 13 KTRs with immune tolerance (Tolerance, n=5), biopsy-proven allograft rejection (Rejection, n=4), and stable allograft function on maintenance immunosuppression (Stable, n=4) at 4 different transplantation centers. We used 20 cell surface marker antibody sequencing to cluster cell subsets, and 399 immune response panel to identify genetic expression difference at a single cell level. Single-cell distribution was visualized on UMAP plot.

Results: We generated 16,784, 10,180 and 7,280 single-cell transcriptomes of PBMCs from Tolerance, Rejection, and Stable groups, respectively. Ten known immune cell subsets were identified using cell surface marker antibody. Heatmap hierarchical clustering showed distinct differential cell surface marker expression in Tolerance group in comparison with other groups. The fractions of B cells and regulatory T cells in peripheral blood were increased in Tolerance group. B cell subsets showed that *Ybx3 (Y-BOX binding protein 3)* was downregulated in Tolerance group, compared with Rejection (fold change 0.12) and Stable group (fold change 0.30). *S100A9 (S100 calcium binding protein A9)* was highly expressed in Regulatory T cell subset of Tolerance group, compared with Rejection group (fold change 0.05).

Conclusions: It is the first study to identify difference in cellular distribution and genetic expression of immune tolerance in KTRs at single-cell resolution so far. Taken together with further scRNA-seq analysis of immune tolerance, it would provide us a better understanding of the mechanism and offer biomarkers to develop immune monitoring strategy, and allow cessation of immunosuppression.

PO2180

Can a Combination of Blood Gene Expression and Donor-Derived Cell-Free DNA Improve Detection of Acute Rejection in Stable and Unstable Kidney Allograft Recipients?

Sookhyeon Park, Kexin Guo, Lihui Zhao, John J. Friedewald. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Non-invasive biomarkers for the detection of acute clinical rejection or subclinical acute rejection (subAR) have shown modest diagnostic performance. Therefore, we hypothesized that a combination of gene expression profile (GEP) and donor-derived cell-free DNA (dd-cfDNA) would improve the diagnostic performance.

Methods: We analyzed 559 blood samples paired with kidney biopsies from CTOT-08 study. GEP probability scores were analyzed as both binary and continuous variables. GEP probability scores >50 were considered positive. dd-cfDNA results > 0.7 % were considered as positive for binary analysis. We calculated the area under the receiver operating characteristics (AUROC) for each test and the combination of both tests. We conducted a logistic regression to assess the performance of combined GEP and dd-cfDNA scores as continuous variables.

Results: 153 rejections consisted of 50 clinical and 103 subclinical rejection cases. Among 406 non-rejection cases, 81 cases had an acute elevation of creatinine, and 325 cases had stable kidney function. For binary analysis, dd-cfDNA showed better positive predictive value (PPV, 0.58, 95% CI 0.48-0.67) than GEP alone (0.49, 95% CI 0.41-0.58). When both tests were positive, PPV went up to 0.75 (95% CI, 0.61-0.88). GEP (0.82, 95% CI 0.78-0.86) and dd-cfDNA alone (0.81, 95% CI 0.77-0.85) had similar NPV. The NPV improved to 0.88 (95% CI, 0.84-0.92) when both assays were negative (Table 1). The logistic regression combining both continuous assay scores achieved an AUROC of 0.80 significantly higher than 0.75 (GEP alone, p-value <0.001) and 0.72 (dd-cfDNA alone, p-value <0.01).

Conclusions: Combining the GEP and dd-cfDNA can improve the ability to distinguish acute rejection in both stable and unstable patients.

Lymphocyte Subpopulations in Clinical Practice After Kidney Transplantation: B Cell Levels Predict Renal Function at 1 Year

Giorgia Comai, Valeria Corradetti, Gisella Vischini, Federica Maritati, Claudia Bini, Gaetano La Manna. *Nephrology, Dialysis and Kidney Transplantation Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*.

Background: Lymphocytes subpopulations play a key role in the immune response after kidney transplantation. Many different T-lymphocyte have been studied for their suitability to monitor allograft rejection. B cells have been associated with acute and chronic antibody mediated rejection and with poor outcome after transplant but are associated with tolerant kidney transplant recipients.

Methods: We retrospectively analyze the lymphocyte subpopulation (total lymphocyte, CD3+, CD4+, CD8+, NK, CD20+) pre transplant, after 1 week, at discharge and after 2 months post transplant in a cohort of kidney tranpslant recipients and we evaluate the impact of this subsets on kidney outcome.

Results: 187 kidney transplant recipients were included in the study and a total of 748 samples were analyze. We didn't find any association between lymphocyte subsets and delayed graft function, primary non function and graft rejection. We found an association between low level of B lymphocyte at 2 months and 1-year GFR less than 45 ml/min (Figure 1 and 2). Multivariate analysis including donor age, cold ischemia time, rejection, recipient age, induction theraphy and steroid withdrawal confirm these finding.

Conclusions: Low level of B lymphocyte at 2 months post transplant is associated with poor graft oucome suggesting that these finding may predict a worse renal function at 1 year. The changes in lymphocyte subset after transplant could represent an early outcome marker usefull to personalized immunosuppressive therapy.

Inflammatory Profile Associated with Non-HLA Antibodies to G-Protein Coupled Receptors in Pediatric Kidney Transplant Recipients

Meghan Pearl,[1] Lucia Chen,[1] Sitaram Vangala,[1] Patricia L. Weng,[1] Eileen T. Chambers,[2] David Elashoff,[1] Elaine F. Reed.[1] *[1]University of California Los Angeles, Los Angeles, CA; [2]Duke University School of Medicine, Durham, NC.*

Background: The inflammatory profiles associated with non-HLA antibodies to G-protein coupled receptors in kidney transplant recipients (KTRs) are unknown. We have recently shown that angiotensin II type 1 receptor antibody (AT1R-Ab) and Endothelin-1 Type A receptor antibody (ETAR-Ab) are prevalent and associated with poor clinical outcomes and elevations in TNF-α, IL-1β, IL-8, IFN-γ, IL-17, and IL-6 in pediatric KTRs. We aimed to expand this analysis by examining the association between these non-HLA antibodies and a broad panel of inflammatory markers in a different cohort of pediatric KTRs.

Methods: 157 blood samples from 35 pediatric KTRs followed for 2 years post-transplant were analyzed. ETAR-Ab (ELISA), AT1R-Ab (ELISA), and 38 cytokines (Luminex, Table 1) were measured in blood samples taken at 6 months (m), 12m, and 24m post-transplant and during episodes of rejection. Based on previous receiver operating curve analysis, > 10 and >17 units/ml was considered positive for ETAR-Ab and AT1R-Ab. Patients were serially monitored for viral infections (CMV, EBV, and BK Virus), HLA DSA (Luminex), and rejection (protocol and indication biopsies).

Results: Blood samples positive for AT1R-Ab and ETAR-Ab had elevations in 28 of 38 cytokines (Table 1). On principal component (PC) analysis, AT1R-Ab and ETAR-Ab positivity was highly associated with differences in PC1. This relationship remained significant even when controlled for potential confounders, including age, sex, rejection, viral infections, and HLA DSA status ($p<0.001$, Figure 1).

Conclusions: AT1R-Ab and ETAR-Ab positivity is associated with a distinct inflammatory profile in pediatric KTRs in the first 2 years post-transplant. This distinct profile may help inform mechanistic studies and potentially identify new therapeutic targets to treat non-HLA associated allograft injury.

Immunoglobulin G (IgG) Glycosylation, Renal Function, and Antibody-Mediated Rejection in Renal Transplant

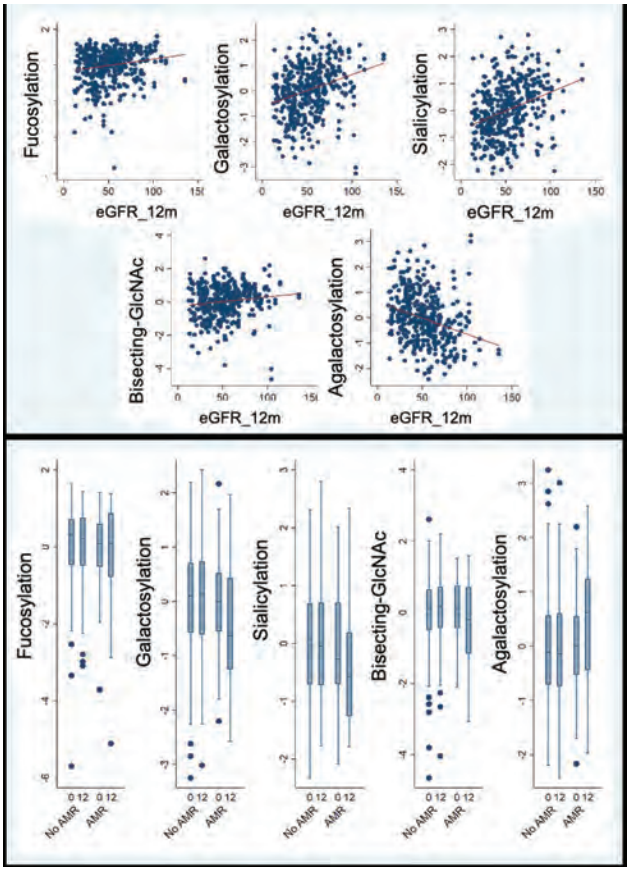
Clara Barrios, Dolores Redondo-Pachón, Maria jose Perez saez, Adriana Sierra Ochoa, Carlos E. Arias, Carla Burballa, Anna Buxeda, Julio Pascual, Marta Crespo. *Consorci Parc de Salut MAR de Barcelona, Barcelona, Spain.*

Background: IgG glycome composition is a key regulator of immune system modulating inflammation at multiple levels. It has been associated to aging, infections response, autoimmune diseases or early kidney failure. Its role in KT has not been studied. Our aim was to analyze the prognostic and diagnostic value of IgG_glycans in renal function after 1year of KT and in antibody-mediated rejection (AMR)

Methods: We analyzed 24 essential IgG glycans by Highperformance LiquidChromatography grouped them by biological function, according to the proportion of Galactosylated, Agalactosylated, Sialicylated, Fucosylated and Bisecting-GlcNAc structures. We measured baseline IgG_glycans and one year after KT in 248 recipients (62%M:38%M) of 55.9±13.6 years, 36 with AMR. Association models were adjusted by donor characteristics, baseline renal function, age/sex, BMI, ATN-postKT and comorbidities

Results: Differences between IgG_glycans at baseline and 1year values were associated with the achieved renal function: Higher Sialization (Coeff [95% CI] 2.07 [0.23-0.3.9]) and Galactosylation (1.84 [0.0-3.6]), the better renal function and higher proportion of agalactosylated glycans associated worse renal function -2.02 [-4.1- -0.34]. AMR occurred more frequently in patients with a higher proportion of Agalactosylated glycans (OR [95% CI]) 1.7 [1.15-2.51] and less in those with a greater proportion of Galactosylates 0.59 [0.4-0.87], Sialicylates 0.67 [0.45-0.9] and Bisecting-GlcNAc 0.66 [0-45-0.99] (*Figure*)

Conclusions: Glycans, that modulate the IgG function, are a potential prognostic tool for renal function in KT and as a diagnostic support in the identification of patients who develop AMR



PO2184

A Possible Effect of Glucagon-Like Peptide 1 Receptor Enhancement on Graft Kidney Function

Tetsuhiko Sato, Yoshinori Azuma, Yasuhiro Otsuka, Norihiko Goto, Shunji Narumi, Asami Takeda, Takahisa Hiramitsu, Manabu Okada, Kiyomi Osako, Yoshihiko Watarai. *Nagoya Daini Sekijuji Byoin, Nagoya, Japan.*

Background: Successful kidney transplantation (KTX) has revolutionary improved comorbidities related to diabetic kidney disease in type 2 diabetic patients. Enormous evidence has accumulated that incretin enhancer, glucagon-like peptide 1 receptor agonists (GLP-1RAs) have potential to boost native kidney function. However, little is known about a possible protective effect of its use on graft kidney function.

Methods: We conducted an observational cohort study to investigate the association between the use of GLP-1RA versus other antidiabetic medications (Non-GLP-1RA), and the 4-year risk of sustained eGFR decline (4 straight month-40% decrease from baseline) in consecutive kidney transplant recipients (KTRs) with type 2 diabetes who underwent KTX in our center from January 2012 through December 2018. Included were all KTRs with type 2 diabetes who were followed forward in time from month 1 post-transplant for 24 months or longer at the time of December 31, 2020. We calculated the propensity score of initiating GLP-1RA versus Non-GLP-1RA as a function of baseline covariates using logistic regression. Inverse probability of treatment weighting was generated from the propensity score and treatment-weighted odds ratio was estimated between the two treatment groups to better control for baseline confounding variables including presence or absence of protocol biopsy-proven interstitial fibrosis/tubular atrophy 1 month after KTX. Sodium-glucose cotransporter 2 inhibitors medication was treated as competing event.

Results: Seventy three were identified as GLP-1RA users, 73 were on Non-GLP-1RA medications, and no deaths with graft function were observed during the study period. There were 6 sustained eGFR decliners in Non-GLP-1RA group whereas 1 in GLP-1RA group. According to multivariate analysis, GLP-1RA use after KTX was associated with a lower risk of sustained eGFR reduction (weighted odds ratio, 0.105; 95% confidence interval, 0.012-0.961).

Conclusions: GLP-1RA initiation and continuous use had a lower eGFR decline compared with other antidiabetic medications and may contribute to better kidney graft survival after KTX.

PO2185

Impact of Low-Normal vs. High-Normal Baseline Donor-Derived Cell-Free DNA Levels on Two-Year Allograft Function Following Kidney Transplantation

Kalathil K. Sureshkumar, Angela Grazier, Bhavna Chopra. AHN Nephrology *Allegheny Health Network, Pittsburgh, PA.*

Background: Donor derived cell free DNA (dd-cfDNA) is a biomarker that helps to predict acute rejection in kidney allografts. Baseline dd-cfDNA levels are <1% in 96% of kidney transplant recipients (KTRs) and a value ≥ 1% suggests allograft injury usually from acute rejection. dd-cfDNA levels <1% are considered as normal. We tested whether low-normal vs. high-normal baseline dd-cfDNA values would have differing impact on longitudinal allograft function.

Methods: We identified patients who underwent kidney transplantation at our center between September 2017 and June 2020 and had dd-cfDNA (AlloSure, CareDx, Brisbane, CA) levels under the surveillance protocol at or around 8 weeks post-transplantation. Those KTRs with dd-cfDNA levels <1.0% were included in the analysis. Patients were divided into 2 groups based on the dd-cfDNA levels : group 1 with dd-cfDNA <0.5% (low-normal) and group 2 with dd-cfDNA 0.5-0.99% (high-normal). Estimated glomerular filtration rates (eGFR) between the groups at 3 month intervals were compared using box plots and longitudinal eGFR up to 2 years post-transplant were compared between the groups using lineal mixed model.

Results: There were 111 patients included in the analysis including 62 males and 49 females. Among the study group, 39 had living and 72 received deceased donor kidneys. There were 96 patients in group 1, and 15 patients in group 2. We observed no differences either in 3-month interval cross-sectional eGFRs (fig 1A) or 2 -year longitudinal eGFRs (fig 1B) between the groups.

Conclusions: Our analysis found no differences between early post-transplant low-normal and high-normal baseline dd-cfDNA levels in terms of the impact on eGFR up to 2 post-transplant years in KTRs. These findings support the use of 1% cut off as a threshold to separate normal from abnormal dd-cfDNA levels.

Funding: Commercial Support - CareDx

PO2186

Baseline Trends in Tacrolimus Intrapatient Variability in Pediatric Kidney Transplant Patients

Kim H. Piburn,[1] Vaka K. Sigurjonsdottir,[1,2] Lynn K. Maestretti,[3] Mary V. Patton,[3] Anne M. Mcgrath,[3] Olafur S. Indridason,[2] Abanti Chaudhuri,[1] Paul C. Grimm.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [3]Lucile Salter Packard Children's Hospital at Stanford, Palo Alto, CA.*

Background: High tacrolimus intrapatient variability (IPV) is a known risk factor for inferior graft outcomes in kidney transplant patients. Baseline trends in tacrolimus intrapatient variability have not been well-defined in pediatric kidney transplant patients.

Methods: Pediatric patients who received a kidney-only transplant from 2010-2018 at a single center were considered for inclusion. Patients with follow-up time of at least 1 year were included. Tacrolimus IPV was determined using the mean coefficient of variation over the immediate 6-month time period prior to each tacrolimus level at each year post-transplant. All available tacrolimus levels were included in the analysis. Patients were stratified by age at time of transplantation (ages 1-6, 7-12, 13-18 years). A paired t test was performed to evaluate the IPV change with increasing time post-transplant, with a specific post-transplant year tested against the prior year for each age group.

Results: 220 pediatric kidney transplant patients met inclusion criteria. Median age was 12.8 years. 117 patients (53.2%) were male, and 54 (24.5%) underwent living donor kidney transplant. IPV trends varied by age group, but IPV was high for all groups during the first year. After the first year, IPV decreased over time for patients in the 1-6 years group while it increased for those in the 7-12 and 13-18 years groups (Figure 1).

Conclusions: Tacrolimus IPV patterns differ in pediatric kidney transplant patients based on age at time of transplantation. It is likely that in the youngest group of patients, factors other than nonadherence explain their initial prolonged high IPV. More research is needed to quantitate and better understand the factors influencing variability in children given the association between IPV and adverse graft outcomes.

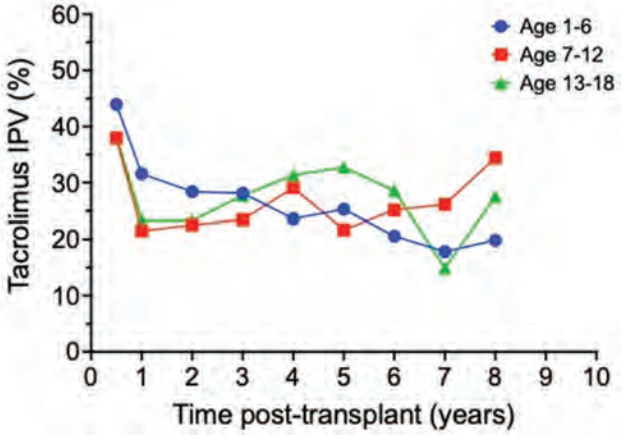

Figure 1. Tacrolimus intrapatient variability (IPV) trends over time post-transplant for different age groups

PO2187

The Impact of Intrapatient Tacrolimus Trough Level Variability over 2 Years Post Transplant on the Long-Term Allograft Outcomes in Kidney Transplant Recipients

Yohan Park,[1] Sang Hun Eum,[2] Hanbi Lee,[2] Hyung Duk Kim,[2] Chul Woo Yang,[2] Byung ha Chung.[2] *[1]Konyang University Hospital, Daejeon, Republic of Korea; [2]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Background: The current study aimed to determine the impact of tacrolimus (TAC) trough level (C0) intra-patient variability (IPV) over 2 years after kidney transplantation (KT) on allograft outcomes.

Methods: In total, 1,143 patients with low immunologic risk were enrolled. The time-weighted coefficient variability (TWCV) of TAC-C0 was calculated, and patients were divided into tertile groups (T1: <24.6%, T2: 24.6–33.7%, T3: ≥33.7%) according to TAC-C0-TWCV until post-transplant 1st year. Moreover, they were classified into the low/low, low/high, high/low, and high/high groups based on a TAC-C0-TWCV value of 33.7% during post-transplant 0–1st and 1st–2nd years. We compared the allograft outcomes among the three tertile and four TAC-C0-TWCV groups.

Results: The T3 group had the highest rate of death-censored allograft loss (DCGL), and T3 itself was an independent risk factor for DCGL (adjusted hazard ratio (HR) 1.853, P = 0.029). In addition, sustained TWCV ≥33.7% until 2 years after KT showed the highest risk for DCGL (HR 2.395, P = 0.013). Moreover, the changes in TWCV during the 1st–2nd post-transplant year significantly affect to DCGL occurrence (HR of low/high 2.086, P = 0.045, HR of high/low 1.813, P = 0.021). Patients with an average TAC-C0 of ≥5 ng/mL in the high/high group were at highest risk for DCGL as well.

Conclusions: In conclusion, TAC-IPV is an important factor that can significantly affect comprehensive allograft outcomes. TAC-IPV after 1st year of KT was also considered an important factor for allograft outcomes. Moreover, TAC-IPV can significantly affect allograft outcomes even with a high average TAC-C0.

Funding: Other NIH Support - This study was supported by a grant from the Korean Health Technology R&D Project, Ministry of Health & Welfare, Republic of Korea (HI20C0317).

PO2188

The Balance Between Memory and Regulatory Cell Populations in Kidney Transplant Recipients with Operational Tolerance

Claudius Speer, Matthias Schaier, Martin G. Zeier, Christian Morath, Caner Süsal. *University Heidelberg, Heidelberg, Germany.*

Background: Donor-reactive memory cells represent a barrier to long-term kidney graft survival. A better understanding of regulatory mechanisms that counterbalance alloreactive memory responses may help to identify patients with operational tolerance.

Methods: The prospective, bicentric BALANCE study investigated the equilibrium between memory T cell subsets and regulatory T or B cells (Tregs, Bregs) in peripheral blood of kidney transplant recipients with operational tolerance (N=8), chronic rejection (N=8), and different immunosuppressive treatment regimens (N=81). Patients on hemodialysis and healthy individuals served as controls (N=50). In addition, the expression of Treg- and Breg-associated molecule genes was analyzed.

Results: Patients with chronic rejection showed a disrupted memory T cell composition with a significantly increased frequency of circulating $CD8^+$ terminally differentiated effector memory (TEMRA) T cells than in patients with operational tolerance, patients on hemodialysis, or healthy controls ($P<0.001$). Compared to all other transplant recipients, the lowest ratios between $CD8^+$ TEMRA and naïve or effector T cells and the highest frequency of Tregs and transitional Bregs were found in operationally tolerant patients (for all $P=0.001$). Consequently, operationally tolerant patients showed, as compared to all other transplant recipients with different immunosuppressive regiments, the lowest ratios between $CD8^+$ TEMRA T cells and Tregs or Bregs (for both $P<0.001$). A specific peripheral blood transcription pattern was found in operationally tolerant patients with an increased expression of Breg- and Treg-associated genes *CD22* and *FoxP3* and a decreased *FcγRIIA/FcγRIIB* transcript ratio (for all $P<0.001$, as compared to all other transplant recipients).

Conclusions: Monitoring the balance between circulating $CD8^+$ TEMRA T cells and regulatory cell subsets and their transcripts may help to distinguish transplant recipients with operational tolerance from recipients at risk of graft loss.

PO2189

Steering of Immunosuppression by Virus-Specific T Cells After Pediatric Kidney Transplantation (KTx) in the Randomized Controlled IVIST Trial

Lars Pape, Thurid Ahlenstiel-Grunow. *Universitat Duisburg-Essen Medizinische Fakultat, Essen, Germany.*

Background: Pharmacokinetic monitoring alone is insufficient to estimate the intensity of immunosuppression after KTx. Levels of virus-specific CD4 T cells(CD4Tvis) have been shown to identify overimmunosuppression. The IVIST trial has demonstrated that additional steering of immunosuppressive therapy by CD4Tvis levels is safe and reduces exposure to immunosuppressants with significantly lower trough levels but without increasing the risk of acute rejections.

Methods: In the randomized controlled IVIST trial, 64 pediatric KTx recipients were randomized 1:1 to a control group with trough level monitoring of immunosuppressants or to an intervention group with additional steering by CD4Tvis levels against adenovirus(ADV), cytomegalovirus(CMV) and herpes simplex virus(HSV). The immunosuppression consisted of cyclosporine A, everolimus and glucocorticoids. CD4Tvis were quantified by cytokine flow cytometry in 20 visits during the two-year study period. In the intervention group we have analyzed the CD4Tvis levels and the number of Tvis-based dose adjustments of immmunosuppressants.

Results: At time of transplantation, ADV-CD4Tvis were detectable in 30/31 patients (intervention group), CMV-CD4Tvis and HSV-CD4Tvis only in 12/31. No significant ADV- or HSV-DNAemia was found; only two patients showed transient CMV-DNAemia based on CMV-reactivation. Five primary CMV-infections with seroconversion and boost of CMV-CD4Tvis were observed without significant CMV-DNAemia. The mean level of ADV-CD4Tvis was 1.63(SD1.25), 2.03(SD1.8), 2.18(SD2.51) and 1.97 cells/µl(SD1.34) 1,6,12 and 24 months after KTx. In case of CD4Tvis <2cells/µl 125 dose reductions of immunosuppressants (96% based on ADV-CD4Tvis) were performed in 28/31 children with a median of 4 Tvis-based dose reductions (range 0-10) per patient. 48% of these were carried out in the first six months.

Conclusions: Under the intensified immunosuppression during the initial post-KTx period low ADV-CD4Tvis levels were observed with subsequent increase after dose reduction of the immunosuppression. ADV-CD4Tvis are most suitable for immune monitoring because of their high prevalence (even in children) and stability combined with absence of ADV-DNAemia. Routine monitoring of ADV-CD4Tvis is recommendable especially in the first post-KTx year to prematurely identify overimmunosuppression.

Regulatory T Cells, BK Virus Infection, and Long-Term Outcomes in Kidney Transplant Recipients

Yasar Caliskan,[1] Bayram Kiran,[2] Cigdem Kekik,[3] Halil Yazici,[3] Hayriye Senturk Ciftci,[3] Ahmet B. Dirim,[3] Safak Mirioglu,[3] Ozgur A. Oto,[3] Henry B. Randall,[1] Fatma Savran Oguz,[3] Aydin Turkmen,[3] Krista L. Lentine.[1] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]Kastamonu Universitesi, Kastamonu, Turkey; [3]Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey.*

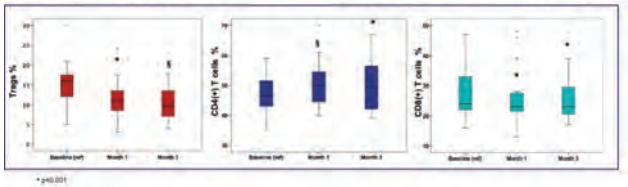
Background: Regulatory T cells (Tregs) may inhibit pathogen-specific immunity in infectious disorders. We monitored Treg levels during BK virus (BKV) viremia/viruria, examined pattern of Tregs that might contribute BKV infection, and assessed their prognostic value for the KTx outcomes.

Methods: We evaluated 20 KTx recipients (male:13, mean age:41±12 years, living donor 15) in whom BKV viremia/viruria was detected at a median 12.6 (IQR, 4.6-31.2) months after KTx. Serum and urine BKV DNA were measured by real-time PCR at baseline, 1 and 3 months after detection of BKV viremia/viruria. Lymphocyte profile and CD4(+)CD25(+)FoxP3(+) Tregs were measured by flow cytometry concurrently at these time points. Graft outcomes over 8 years were examined in relation to BK viremia, viruria levels, and lymphocyte profiles.

Results: At the time of diagnosis of BKV viremia/viruria, 17 (85%) patients were on calcineurin inhibitor (CNI)-based triple immunosuppression. CNI was discontinued in 9 patients, sirolimus was started in 3 of them. Mycophenolic acid was switched to azathioprine or the dose was decreased in all patients. Reduction in overall immunosuppression was associated with a decrease in serum and urine BKV DNA levels. Tregs and CD8(+) T lymphocytes were significantly decreased and CD4(+) T lymphocytes were increased during this period (Figure 1). After a median follow-up of 8.1 years (IQR, 3.3-8.5), 6 (30%) patients lost their allografts. There were no significant differences in mean Tregs levels between patients with and without graft failure (p=0.63). Serum and urine mean BKV DNA levels were similar between patients with and without graft failure (p=0.38 and p=0.20, respectively).

Conclusions: Tregs may play a role in BKV infection, reduction in the overall amount of immunosuppression is associated with improvement of BKV viremia/viruria accompanied by a decrease in Treg levels. Future work is needed to discriminate predictors of allograft failure in patients with BK nephropathy.

Figure 1. Tregs, CD8(+) lymphocytes were significantly decreased and CD4(+) T lymphocytes were increased during follow up.



PO2191

Expansion and Characterization of Regulatory T Cell Populations from Korean Kidney Transplant Recipients

Ho Sik Shin,[1,2] Youngchan Park,[1] Ye na Kim,[1,2] Yeonsoon Jung,[1,2] Hark Rim.[1,2] *[1]Kosin University Gospel Hospital, Busan, Busan, Republic of Korea; [2]Transplantation Research Institute, Kosin University College of Medicine, Busan, South Korea, Republic of Korea.*

Background: The development of immunosuppressants has enabled remarkable progress in kidney transplantation (KT). However, current immunosuppressants cannot achieve induction of immune tolerance and their nonspecific immunosuppressive effects result in many adverse effects. Regulatory T cells (Tregs) play crucial roles in controlling allospecific immune responses. This study evaluated the distribution of Tregs and their effects on kidney allograft function in Korean KT recipients.

Methods: We enrolled 144 KT recipients with stable graft function between 1989 and 2018. Differentiation and expansion of Tregs were studied by flow cytometry to compare the Tregs subpopulations. Tregs were defined as $CD4^{+}CD25^{high}CD127^{low/-}FoxP3^{+}$ cells.

Results: Among the 144 patients, 75 patients (65.8%) were males and mean follow-up period was 144.3 ± 111.5 months. All patients received calcineurin inhibitors as maintenance immunosuppressants. Patients with follow-up period more than 144.3 months tended to have more gating Tregs numbers than that in shorter follow-up period (92.3 ± 142.4 vs. 50.1 ± 76.4, p = 0.061, respectively). There were no significant differences in Tregs subpopulations between patients with serum creatinine more than 1.5 md/dL and patients with serum creatinine less than 1.5 mg/dL. In terms of the number of Tregs, when the trough level of tacrolimus was at an appropriate level, the number of Tregs tended to be higher than that of Tregs when the trough level of tacrolimus was low or high, and the organ function of the transplant was also stable.

Conclusions: Tregs counts may be associated with transplant outcomes considering that there is a relationship between these cells and kidney graft function.

Table 2-1. Regulatory T cell subpopulation according to the patient's characteristics.

	Gating cell number	P value	Gate
Male (n=73)	76.7 ± 129.5	0.295	29.1

Diagnosis of Early Delayed Graft Function (DGF) Using TIMP-2*IGFPB-7 Product in Transplant Recipients: Preliminary Results

Russell Leong,[2,1] Cassandra Rodd,[2,1] Kellyann M. Gomes,[2,1] Solomiia Savedchuk,[2,1] Paul S. Kellerman.[2,1] *[1]Oakland University William Beaumont School of Medicine, Rochester, MI; [2]Beaumont Health, Royal Oak, MI.*

Background: DGF is acute kidney injury (AKI) defined as need for dialysis within one week of renal transplant. AKI is defined by a change in serum creatinine (SCr), however early recognition is limited by delay in creatinine rise. Accurate early biomarkers may lead to prevention or treatment of established AKI. The product of two novel biomarkers of cell cycle arrest, tissue Inhibitor of metalloproteinase-2 (TIMP-2) and insulin-like growth factor binding protein (IGFBP-7) have shown promise in predicting AKI. In prior studies, TIMP-2*IGFPB-7 ≤0.3 had high negative predictive value, and ≥2 high positive predictive value for AKI. **Aims** - 1) Investigate the early diagnostic value of TIMP-2*IGFPB-7 for DGF; 2) Correlate TIMP-2*IGFPB-7 with long term graft function.

Methods: This is a prospective, double-blinded single center observational study with goal enrollment of 150 transplant recipients. Urine TIMP-2*IGFBP-7 was measured in $(ng/mL)^2/1000$ with a commercial kit, Nephrocheck (Astute Medical, San Diego, CA) at 4-12 hours, 48-72 hours and 72-96 hours post-transplant. SCr was measured just prior to transplant, 1 week post-transplant, and at 1, 3, 6, 9 and 12 months post-transplant.

Results: Thus far, 64 patient samples have been collected, 11 with DGF. Mean TIMP-2*IGFPB-7 were 3.08 ± 0.63 vs 0.54 ± 0.23 (p-value <0.001) at 4-12 hours, 3.39 ± 0.93 vs 0.38 ± 0.13 at 24-48 hours (p-value <0.001), and 1.73 ± 0.76 vs 0.62 ± 0.27 (p-value =0.09) at 72-96 hours in DGF vs non DGF patients respectively. Mean SCr at 1 week were 6.14 ± 0.71 mg/dL in DGF vs 2.13 ± 0.26 mg/dL (p-value <0.001) in non-DGF. Correlation between peak TIMP-2*IGFPB-7 at 24-48 hours and sCr at 1, 3, 6, 9, and 12 months, was nonsignificant.

Conclusions: These preliminary results confirm the use of TIMP-2*IGFBP product measured by Nephrocheck in the diagnosis and prediction of DGF in the post-kidney transplant period as early as 4-12 hours, and peaking at 24-48 hours. The non-DGF TIMP-2*IGFBP-7 means were higher than prior reports, suggesting mild renal injury in the peritransplant period in those patients without DGF. The current sample size is too small and underpowered as of yet to draw conclusions on prediction of long-term renal dysfunction.

Kidney Injury in Hematopoietic Stem Cell Transplant (HCT) Recipients: Transcriptome Profiling and Development of Urinary Biomarkers

Elly Varma, Thalia Salinas, Carol Y. Li, Catherine Snopkowski, Thangamani Muthukumar. *Weill Cornell Medicine, New York, NY.*

Background: In kidney biopsies of HCT recipients, thrombotic microangiopathy with/without tubulointerstitial/microvascular inflammation suggest the possibility of kidney being a target of graft versus host disease. We tested the hypothesis: (i) kidney inflammation/injury in HCT recipients is immune mediated, (ii) urinary mRNA profile may be used as a noninvasive biomarker.

Methods: (i) RNA-sequencing of native kidney from 6 HCT recipients with kidney injury was performed. We compared the transcriptome profile to that of allograft kidney. (ii) Urine samples from 9 HCT recipients were collected. We calculated the CTOT-04 signature score for each recipient. We compared the score to that of kidney allograft recipients.

Results: Of the 4188 genes (26% of 16375) that were different (FDR-P<0.05) between HCT and Normal, 2152 were shared among HCT, ACR, and AMR; 1442 were unique to HCT **(Figure 1)**. Shared genes revealed enrichment of innate and adaptive immune system pathways. Urinary cell CTOT-04 signature score was higher in AKI/tubulitis and interstitial inflammation in the native kidney and resembled ACR of kidney allograft recipients **(Figure 2)**.

Conclusions: In recipients of HCT: (i) kidney inflammation/injury is immune mediated, (ii) urinary cell mRNA profiling is useful for diagnosing kidney injury

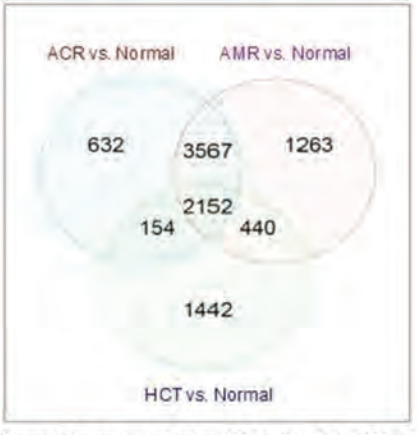

Figure 1. Differential expression of mRNAs. We did mRNA transcriptome profiling of kidney tissue by RNA sequencing (6HCT recipients with kidney injury and 51 allograft recipients [16 ACR, 17 AMR and 18 Normal]). Venn diagram depicts the number of mRNAs that were statistically significant (FDR-P <0.05) between HCT versus Normal, ACR versus Normal and, AMR versus Normal. Probability values were adjusted for false discovery rate using the Benjamini-Hochberg method and is the expected proportion of false positives among all the statistically significant P-values (<0.05)

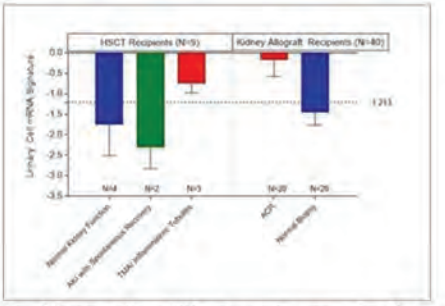

Figure 2. Urinary cell mRNA signature score in HCT recipients and kidney transplant recipients. CTOT-04 signature (Suthanthiran et al. N Eng J Med 2013) is a score derived from urinary cell mRNA profiling of kidney transplant recipients for the noninvasive diagnosis of acute rejection of kidney allograft. The score is a liner combination of urinary cell levels of CXCL10 mRNA, CD3e mRNA, and 18S rRNA, quantified by RT-PCR assay and expressed as copies/µg of total RNA. The dotted line in the figure is the cut point value (-1.213) for the diagnosis of ACR in kidney transplant recipients. We collected urine from HCT recipients and kidney allograft recipients, isolated total RNA from urinary cells, reverse transcribed to cDNA, measured the absolute quantity of urinary cell transcripts, and calculated the CTOT-4 signature score for each patient. Figure depicts the mean ± SE of the CTOT-04 signature score.

PO2194

The Role of Hyperleptinaemia and Low Values of Interleukin 10 in De Novo Donor-Specific Antibody Production After Kidney Transplantation

Ivana Dedinska.[1,2] Transplant center Martin [1]*Univerzita Komenskeho v Bratislave Jesseniova lekarska fakulta v Martine, Martin, Slovakia;* [2]*Univerzitna nemocnica Martin, Martin, Slovakia.*

Background: White adipose tissue secretes a number of peptide hormones, including leptin, adiponectin, and several cytokines. The aim of this paper was to determine the role of selected adipocytokines (leptin and adiponectin) and interleukins (IL-10 and IL-6) on the development of graft rejection in protocol biopsy after kidney transplantation.

Methods: In a prospective analysis (n=104), we monitored the values of leptin, adiponectin, IL-6, and IL-10 prior to the transplantation and in the 3rd month after the transplantation. The protocol biopsy of the graft was performed in the 3rd month after the transplantation. The group was divided into the following according to the biopsy result: negative result, IFTA 1, borderline, and DSA positive.

Results: After adjusting for the differences in the baseline recipient and donor characteristics, we identified the hyperleptinaemia baseline (HR=2.0444, P=0.0341) and month 3 (HR=49.8043, P<0.0001) as independent risk factors for borderline changes in the protocol biopsy. The hyperleptinaemia baseline (HR=7.4979, P=0.0071) and month 3 (HR=9.7432, P=0.0057) are independent risk factors for de novo DSA positivity. A low value of IL-10 month 3 is a risk factor for de novo DSA positivity (HR=3.0746, P=0.0388).

Conclusions: Higher leptin levels might play a role in rejection and de novo DSA production. We also confirmed the influence of low values of IL-10 on the development of de novo DSA. We assume that values of adipocytokines in context of other risk factors can predict the immunological risk of patients after kidney transplantation.

Diagnostic Performance of Donor-Derived Cell-Free DNA Assay (AlloSure®) in Kidney Transplant Recipients with Graft Dysfunction: A Single-Center Study

Muhammad S. Naseer, Ayush Singh, Neeraj Singh. *Willis Knighton Medical Center, Shreveport, LA.*

Background: Circulating donor-derived cell-free DNA (dd-cf-DNA) is a non-invasive biomarker of kidney allograft injury with a high negative predictive value for ruling out active rejection in patients with evidence of graft dysfunction. At our center, we

compared the AlloSure® test (CareDx®) for the dd-cfDNA assays using >1% as the cut-off value suggested by the DART study or an increase of >30% from the previous value against the gold standard biopsy results and calculated its performance metrics.

Methods: From Dec 2019 to Oct 2020, we found 16 patients who had their 21 AlloSure® assays drawn which were within 4 weeks of for-cause biopsy sampling. In assessing the cause of 21 biopsy samples, 20 had AKI, 5 had proteinuria, and 3 had clinical symptoms of volume overload.

Results: AlloSure® and biopsy results were concordant in 14/21 (66.7%) samples [*Table 1*]. Of the 21 for-cause biopsies, 8 biopsies were positive for rejection (2 borderline, 1 TCMR, 3 AMR, 1 mixed AMR/TCMR, 1 chronic). AlloSure® was positive in 2 of these rejections (1 TCMR, 1 mixed AMR/TCMR). However, it was false-negative in the other 6 rejections (2 borderline, 3 AMR, 1 chronic). Out of the 13 negative biopsy results, AlloSure® was negative in 12 samples and false-positive in one sample. The performance metrics in this patient population were: sensitivity 25%, specificity 92.3%, positive and negative predictive values of 66.7%, and accuracy of 66.7%.

Conclusions: Although we had a sample size, it can be concluded from this study that AlloSure® has a high specificity to diagnose active graft rejection in kidney transplant recipients.

Table 1: 2 x 2 Table

		Biopsy		
		Positive	Negative	Total
AlloSure®	Positive	2	1	3
	Negative	6	12	18
	Total	8	13	21

PO2196

Extremely Elevated Donor-Derived Cell-Free DNA Fractions in Kidney Transplant Recipients Are Strongly Indicative of Allograft Rejection

Rajesh Govindasamy,[1] Sandra L. Siegel,[1] Kerry Gaj,[2] Heather Wade,[2] Sarah McCormick,[2] Philippe Gauthier.[2] *[1]UPMC Hamot, Erie, PA; [2]Natera, Inc., San Carlos, CA.*

Background: Donor derived cell-free DNA (dd-cfDNA) is an established non-invasive biomarker for the identification of kidney allograft rejection. The Prospera™ test utilizes a single-nucleotide polymorphism (SNP)-based massively multiplexed-PCR (mmPCR) methodology to quantify dd-cfDNA as a fraction of total cfDNA in kidney transplant recipients. dd-cfDNA fractions ≥1.0% indicate high-risk for rejection and in a small fraction of patients, dd-cfDNA fractions can be elevated significantly over this threshold. Here we present a case series of 18 kidney transplant patients with extremely elevated dd-cfDNA fractions >10% along with clinical data, when available.

Methods: To better understand the relationship between highly elevated dd-cfDNA fractions with allograft health, we identified cases from quality assurance data with dd-cfDNA fractions >10% and corresponding clinical follow-up data.

Results: Among the 18 cases with dd-cfDNA levels >10%, the median dd-cfDNA fraction was 14.73% (range: 10.8-20.7%). Biopsy data was available for 83.3% (15/18) of the patients indicating mixed rejection in 40% (6/15), TCMR in 40% (6/15), ABMR in 7% (1/15) and chronic ABMR in 13% (2/15). In the remaining 3 patients, 1 patient had chronic complicated JC viremia with history of JC nephropathy, 1 had allograft loss associated with diffuse vasculopathy and 1 was admitted and treated for rejection without a biopsy. A 60-year-old female underwent surveillance testing with Prospera and dd-cfDNA results came back at 19.3%. SCr was 1.2 mg/dL compared to a baseline value of 1.1 mg/dL six weeks post-KT. Detailed patient follow up revealed constitutional symptoms of malaise and general discomfort and low grade fever. The patient underwent kidney allograft biopsy and was diagnosed with TCMR 1a rejection. Patient was subsequently treated with IV methylprednisolone 250 mg x 2 days with a rapid steroid taper. Follow-up Scr levels were 0.9 mg/dL accompanied by a decline in the dd-cfDNA fraction during a subsequent Prospera test.

Conclusions: These results suggest that highly elevated dd-cfDNA fraction in the absence of comorbidities can be a strong indicator of allograft rejection. Further investigation is needed to determine whether there is a relationship between elevated risk for rejection and dd-cfDNA levels elevated significantly above 1%.

PO2197

Can Donor-Derived Cell-Free DNA or Gene Expression Profile Be Used to Monitor Response to Treatment After Subclinical Acute Rejection?

Sookhyeon Park, Zachary Dietch, Kexin Guo, Lihui Zhao, John J. Friedewald. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Subclinical acute rejection (subAR) is defined as acute rejection with stable kidney allograft function. Creatinine is not sensitive enough to detect subAR. Donor-derived cell-free DNA (dd-cfDNA) and gene expression profile (GEP) have been used for acute rejection detection in kidney allograft. We hypothesized that dd-cfDNA and GEP could be used to monitor response to treatment of rejection after subAR.

Methods: We analyzed dd-cfDNA and GEP results from 14 unique subjects in the CTOT08 study with subAR who had 8 weeks follow-up biopsy after treatment. Blood samples were paired with kidney biopsies, and collected after subAR during the intensive monitoring periods. We calculated the mean and standard deviation (SD) for each group at the same time points. A paired T-test was used to generate p-values. We conducted locally estimated scatterplot smoothing (LOESS) and linear mixed effect models for the analysis of serial changes of dd-cfDNA scores.

Results: Of 14 patients, subAR resolved in 5 patients (36%) but 9 (64%) patients had persistent rejection after treatment. The slope of dd-cfDNA scores was not significantly different between the resolved and the unresolved group (p-value = 0.43) (Figure 1A). The slope of GEP scores in the resolved group tended to be steeper than unresolved group one after treatment but was not statistically significant between the two slopes (p-value = 0.06) (Figure 1B).

Conclusions: GEP scores showed a greater decrease after successful treatment compared to dd-cfDNA scores. Repeating GEP after subAR might be useful to monitor treatment of rejection.

PO2198

Immunosuppression Could Influence De Novo Angiotensin II Type Receptor Antibodies Development Early After Kidney Transplantation

Bogdan M. Sorohan,[1,2] Andreea Ioana Berechet,[2] Cristina Bucsa,[2] Corina Tincu,[2] Bogdan Obrisca,[1,2] Gener Ismail.[1,2] *[1]Universitatea de Medicina si Farmacie Carol Davila, Bucharest, Romania; [2]Institutul Clinic Fundeni, Bucharest, Romania.*

Background: Angiotensin II type I receptor antibodies (AT1R-Ab) are non-HLA autoAb associated with graft rejection and detrimental effects on graft function in kidney transplantation (KT). Nevertheless, the data regarding risk factors associated with AT1R-Ab development is scanty. To our knowledge, immunosuppression (IS) has not yet been reported as a potential risk factor. We sought to evaluate the incidence of de novo AT1R-Ab at 1 year after KT and risk factors associated with their formation.

Methods: We performed a prospective study on 58 KT recipients, transplanted between October 2018 and October 2019, who were followed for 1 year. Exclusion criteria: age <18 years and preformed AT1R-Ab. AT1R-Ab were evaluated at 1 year after KT using an ELISA technique and the cut-off value for detection was >10 U/ml. Logistic regression analysis was used to identify risk factors associated with AT1R-Ab formation.

Results: Twelve out of 58 patients (20.6%) had de novo AT1R-Ab at 1 year of follow-up. Mean age of the study cohort was 40.8±10.5 years, 60.3% were males and 17.2% had a preemptive KT. Glomerular diseases was the main cause for CKD (27.6%). Donors mean age was 48.6±15.6 years, 62.1% were cadaveric donors and 31% of patients had ≥4 mismatches. Monoclonal Ab directed against IL-2 receptor (84.5%) was the main induction IS used. Immediate-release tacrolimus (TAC) was used in 53.4% and mycophenolate sodium was preferred in 89.7% of cases. Patients with de novo AT1R-Ab had a significantly decreased BMI (21.4±1.8 vs 23.2±2.9 kg/m^2, p=0.04), received significantly more frequently IS with rabbit globulin anti-thymocyte (rATG) (41.7 vs 8.7%, p=0.01), immediate-release TAC (83.3 vs 45.7%, p=0.01) and had a significantly higher mean TAC level at 3 months after KT (13.8±5.6 vs 11.4± 3ng/ml, p=0.04). By multivariate logistic regression we found that rATG was an independent risk factor for de novo AT1R-Ab development (OR= 5.62; 95%CI: 1.11- 28.34, p=0.03) and immediate-release TAC had a trend of association with Ab (OR= 5.02; 95%CI: 0.93- 27.06, p=0.03) at 1 year after KT.

Conclusions: The incidence of de novo AT1R-Ab was 20.6% and rATG induction IS was an independent risk factor for Ab development at 1 year after KT. Our results suggest that IS could influence de novo AT1R-Ab formation.

PO2199

The Histological Fingerprint of Kidney from High Kidney Donor Profile Index Diabetic Donors Transplanted in Non-Diabetic Recipients

Giorgia Comai, Valeria Corradetti, Federica Maritati, Claudia Bini, Marco Busutti, Gaetano La Manna. *Nephrology, Dialysis and Kidney Transplantation Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: To face the persistent organ shortage and the increasing age and comorbidities of donors, criteria to donation have been expanded. Diabetic donors are recognized as a reliable source of organ, few data are available on the histological evolution of these organs for these reasons we compare the pre implantation biopsy of high-KDPI diabetic donor with a protocol biopsy of non diabetic recipients.

Methods: We performed a retrospective analysis of deceased donors from 2004 to 2015. We selected those with a diagnosis of diabetes and with available pre implantation kidney biopsy (T0) that was scored for diabetic and Karspinski score. Then we selected those recipients whose at time of analysis (T1) were still on follow up, had not a history of diabetes and executed at least one biopsy which has been compared with the previous one.

Results: A total of 10 cadaveric kidney donors (mean KDPI 95.7%) were selected. Diabetic lesions of all classes present already at pre-implantation biopsies associated with mild IF/TA and vascular damages. At follow-up the lesions showed variable modifications of DN class (fig.1) and moderate evolution of IF/TA and vascular damages. eGFRs were stable and proteinuria was mild.

Conclusions: In the ten patients and at the different follow-ups there was not a uniform trend of DN lesions, we demonstrated an amelioration in 3 cases, stability in 4 and worsening in 3, and did not find a relationship between these changes and the follow up time. Our data suggest that the diabetic kidneys keep after transplantation the histologic stigma that denote their origin and even in this very marginal extended criteria donation the diabetes status in the donor may not represent a limitation to transplantation in favorable conditions as euglycemia.

PO2200

Utility of Noninvasive Rejection Biomarkers to Assess the Risk of Rejection in Kidney Transplant Recipients with Post COVID-19 Infection

Samah Hoque, Young C. Hsu, Harsha Aramada, Aaron J. Ahearn, Thin Thin Maw. *University of Southern California, Los Angeles, CA.*

Introduction: COVID-19 infection is associated with 25% mortality in kidney transplant recipients (KTRs). Treatment of Coronavirus Disease 2019 (COVID-19) infection in KTRs has involved reduction of immunosuppressants (IS). This potentially increases the risk of allograft rejection in the setting of reduced immunosuppression. We reported 6 cases of kidney allograft rejection post COVID infection

Case Description: Total 123 kidney transplant recipients had COVID-19 infection between March 2020 and February 2021. Immunosuppression was reduced routinely in patients who had symptomatic COVID-19 infection. We implemented. We implemented the protocol of screening tests to assess for rejection which included dd-cfDNA, gene expression profile (TruGraf), donor specific antibody (DSA). Elevated serum creatinine greater than 25% over baseline, dd-cfDNA value greater than 1%, TruGraf value of Non-Tx (NT) or up-trending DSA prompted to allograft biopsy to rule out rejection.

Discussion: Twelve patients out of 123 KTRs received kidney biopsy for above mentioned indications Only 4.8% had kidney rejection (6 out of 123 patients) : 3 patients with acute cellular rejection (ACR) Banff 1B rejection, 2 patients with borderline ACR, and 1 patient with antibody mediated rejection (AMR). Of these 6 patients with rejection 5 patients have elevated dd-cf DNA peri COVID infection, 3 patients with elevated Cr and 1 patient had Non-Tx. Three patients with rejection were transplanted within 1 years. The patients with Banff 1B rejection were treated with anti- thymocyte globulin (ATG) and 1 patient with AMR due to AT1R antibody was treated with methylprednisolone, IV Ig and Losartan. Only 4.8% had kidney rejection post COVID infection. Despite reduction in IS, COVID infection did not increase the risk of allograft rejection and can monitor the risk of rejection by using non-invasive rejection biomarkers.

PO2201

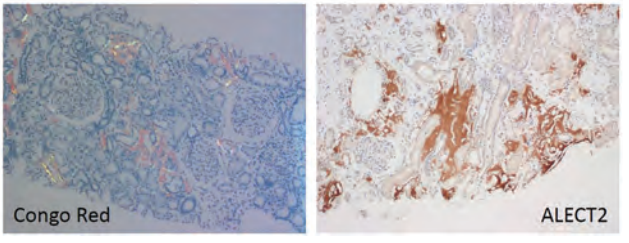
Donor-Derived Leukocyte Chemotactic Factor 2 Amyloidosis in Renal Allografts

Tiana Jespersen,[1] Vighnesh Walavalkar,[2] Muna Alnimri,[1] Mingyu Cheng,[1] Yihung Huang,[1] Kuang-Yu Jen.[1] *[1]University of California Davis, Sacramento, CA; [2]University of California San Francisco, San Francisco, CA.*

Introduction: Leukocyte chemotactic factor 2 amyloidosis (ALECT2) is a relatively common form of amyloidosis with strong ethnic predilection in the Hispanic population. Patients tend to be older and present with chronic kidney disease with variable proteinuria. Histologically, ALECT2 has a unique preference for interstitial accumulation. We report two cases of donor-derived ALECT2 in renal allografts.

Case Description: Case 1: 69-year-old (yo) Hispanic man with type II diabetes and end-stage renal disease (ESRD) received an 86% Kidney Donor Profile Index (KDPI) deceased donor renal transplant (DDRT) from a 52-yo Hispanic man who died of a stroke. The recipient had delayed graft function and suboptimal nadir serum creatinine (SCr) of 2.6 mg/dL. Proteinuria initially peaked at 2.3 g/g, which decreased to <1 g/g at 4-mo post-transplant (tx). Both time-0 and 3-mo protocol biopsies (bx) revealed widespread interstitial amyloid positive for ALECT2 on immunohistochemistry and mass spectroscopy. **Case 2:** 45-yo Hispanic female with ESRD of unknown etiology received a 78% KDPI DDRT from a 60-year-old female with no medical history who died from head trauma. The recipient experienced immediate graft function with new baseline SCr of 1.2-1.6 mg/dL. She had persistent proteinuria following tx and underwent bx at 2-, 3-, and 6-mo post-tx. The bx showed mostly interstitial amyloid, later confirmed to be ALECT2. Additionally, the patient developed focal segmental glomerulosclerosis (FSGS) as well as CMV infection of the allograft. She eventually lost her graft ~2 years post-tx, likely from FSGS rather than ALECT2.

Discussion: Rare cases of donor-derived ALECT2 have been reported in the literature and suggest that kidney allografts with limited and localized donor-derived ALECT2 involving <10% of the renal parenchyma have good outcomes. Our cases represent more severely affected donor kidneys. Although the clinical course for our patients were suboptimal, other factors aside from ALECT2 were likely the major contributing factors. Thus, donor-derived ALECT2 is likely of low consequence in the recipient allograft.



PO2202

Regardless of Donor-Specific Antibody, Do Not Forget Non-HLA

Matthew S. Wysocki, Heidi M. Schaefer, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Antibody-Mediated Rejection (AMR) remains an important cause of allograft rejection and loss of transplant. This is mainly attributed to donor-specific antibodies (DSA) directed against human leukocyte antigen (HLA). In patients with biopsy findings of AMR and undetectable DSA, non-HLA antibodies must be considered. Here we present two cases of AMR mediated by Angiotensin II type 1 receptor (AT1R) antibody, one of the most widely studied non-HLA antibodies.

Case Description: A 46 yo AA HIV-positive male underwent deceased donor kidney transplant, induced with Basiliximab and methylprednisolone, and maintained on tacrolimus, mycophenolate mofetil and prednisone. His post-op course was complicated by delayed graft function with biopsy performed on day 11 showing acute vascular rejection and severe microcirculation inflammation, highly suspicious for AMR. DSA was negative, but non-HLA panel resulted positive for anti-AT1R at 22 U/ml. He was treated with steroids, PLEX, IVIG, Rituximab, and started on ARB therapy with recovery and most recent creatinine 1.59 mg/dl. To our knowledge, this is the first reported case of an HIV-positive patient with anti-AT1R AMR. A 50 yo AA female underwent deceased donor kidney transplant induced with Alemtuzumab and methylprednisolone and maintained on tacrolimus, mycophenolate mofetil and prednisone. She had immediate graft function, but 5 days after discharge, presented with anuric AKI. Biopsy on day 10 showed thrombotic microangiopathy and diffuse C4d positivity, suggestive of AMR. DSA panel showed MFI values that correlated with high levels of anti-B18 and anti-B25. Non-HLA panel was positive for anti-AT1R at 29 U/ml. She was treated with steroids, PLEX, IVIG, Rituximab, and started on ARB therapy with recovery and most recent creatinine 1.23 mg/dl.

Discussion: Non-HLA antibodies including anti-AT1R have been recognized as possible mediators of allograft injury. They should be suspected in AMR with no identifiable DSA, or in early AMR regardless of DSA. Although no standardized treatment exists for non-HLA antibodies, early recognition may have implications for treatment, particularly with AT1R antibodies in which angiotensin receptor blockade effectively reduces anti-AT1R activity. Along with other AMR therapies, this may improve allograft function as seen in these two cases. To our knowledge, this is the first reported case of an HIV-positive patient with anti-AT1R AMR.

PO2203

Autoimmune Encephalitis with Concurrent Epstein-Barr Virus Infection in a Renal Transplant Patient

Danyi Zheng, Akshta Pai, Aleksandra De Golovine. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: Epstein-Barr virus (EBV) infection following renal transplant is typically associated with post-transplant lymphoproliferative disorder (PTLD). Autoimmune encephalitis (AE) is caused by antibodies against N-methyl-D-aspartate receptor (NMDAR), a ligand-gated ion channel with a crucial role in synaptic transmission. We describe a patient who developed encephalitis 1 year after renal transplant with cerebral spinal fluid (CSF) analysis positive for NMDAR antibodies and evidence of EBV infection on brain biopsy without PTLD or malignant processes. To our knowledge, this is the 1st case with tissue evidence of EBV infection on brain biopsy in renal transplant.

Case Description: A 70 year-old female with end stage renal disease from Type 2 Diabetes mellitus who received a deceased donor renal transplant one-year prior was admitted for 3 weeks of progressively worsening mentation. Immunosuppression included tacrolimus, mycophenolate mofetil, and prednisone. Brain MRI did not reveal any acute findings. EEG showed generalized slowing consistent with diffuse encephalopathy. CSF analysis showed lymphocytic pleocytosis and elevated protein level. The infectious workup was negative except for positive EBV PCR in CSF. Cytometry did not reveal any evidence of PTLD. CSF autoimmune panel demonstrated NMDAR1 antibody. Brain biopsy showed a chronic inflammatory process with features of EBV infection. EBV-infected cells were detected in tissue specimen via in-situ hybridization with EBV-encoded small RNA. Patient initially received ganciclovir, amBisome, and broad-spectrum antibiotics. Treatment then changed to steroids, IVIG and plasmapheresis for autoimmune encephalitis, all of which were stopped and ganciclovir was restarted when brain biopsy was positive for EBV. Unfortunately, patient did not show any clinical improvement possibly due to delayed diagnosis and went home with hospice care.

Discussion: EBV Encephalitis without PTLD following renal transplant is uncommon. Only a few cases have described renal transplant patients with encephalitis and concomitant findings of NMDAR antibodies and EBV DNA in CSF study. The relationship between EBV infection and AE remains unclear; however, EBV infection may play a role in the pathogenicity of NMDAR antibodies. AE can occur in the setting of chronic immunosuppression and should not be overlooked to avoid delay in diagnosis and treatment.

PO2204

2,8-Dihydroxyadenine Crystalline Nephropathy in Transplanted Kidney

Hafiz Muhammad Ali Raza,[1] Genesis Nieves,[1] Anshul Bhalla,[1] Barry M. Wall.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Introduction: 2,8-dihydroxyadeninuria (DHA) disease is a rare autosomal recessive disorder caused by adenine phosphoribosyltransferase (APRT) deficiency, that typically manifests with nephrolithiasis, but rarely can cause chronic kidney disease (CKD). Recurrence of DHA nephropathy after kidney transplant can cause persistent allograft dysfunction with increased risk of early graft failure if diagnosis and treatment are delayed. We describe a case of APRT deficiency which remained undiagnosed until evaluation of a poorly functioning kidney allograft due to DHA nephropathy, successfully managed with allopurinol and conversion to Belatacept.

Case Description: 72-year-old Caucasian male with ESRD secondary to diabetes mellitus type 2 and obstructive uropathy. The patient received a living donor kidney transplant from his daughter on 10/15/2020 with Thymoglobulin and steroid induction followed by maintenance immunosuppression with tacrolimus, mycophenylate, and prednisone. It was a one haplotype mismatch with no pre-formed donor specific antibodies. He had slow graft function with a creatinine of 4 mg/dL on discharge. At 6 weeks post-transplant, his creatinine remained elevated at 2.1 - 2.3 mg/dl with no clear cause for persistent allograft dysfunction. An allograft renal biopsy showed numerous polarizable pigmented brown intratubular crystals, in the absence of triamterene-based diuretics. A diagnosis of 2,8 DHA crystalline nephropathy was made and he was started on allopurinol and a low purine diet. To minimize tubular injury, Belatacept was added to maintenance immunosuppression and tacrolimus dose was reduced with a goal to wean over 9 months. To further confirm the diagnosis, a kidney gene panel was performed confirming homozygous ARPT deficiency with an autosomal recessive inheritance pattern. Kidney function continued to improve with creatinine of 1.5 mg/dl (eGFR 45 ml/min/1.73m2) at 7 months post-transplant.

Discussion: DHA nephropathy due to APRT deficiency is a rare but preventable cause of CKD and can remain undiagnosed until its recurrence after kidney transplant. To prevent allograft failure, high index of suspicion and early biopsy is important. In addition to allopurinol, low purine diet, and increased hydration, CNI minimization and utilization of Belatacept is an effective strategy to minimize vascular and tubular injury and prevent further precipitation of crystals.

PO2205

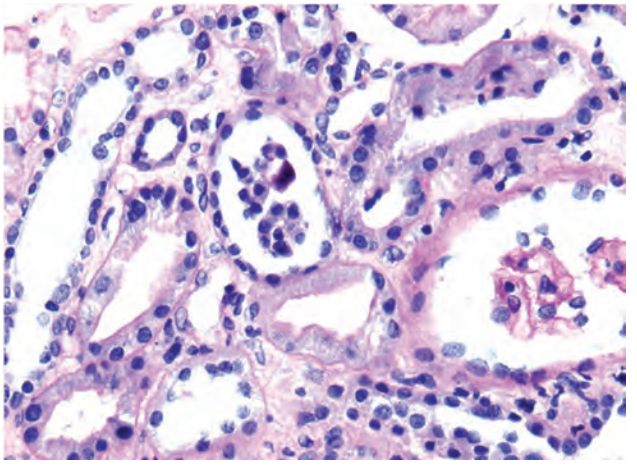
Anti-MDA5 Dermatomyositis as a Paraneoplastic Syndrome of Myelodysplastic Syndrome After Kidney Transplant in Autosomal Dominant Polycystic Kidney Disease

Belen Martinez-Vazquez, Victor H. Gomez Johnson, Francisco Rodríguez. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.*

Introduction: Malignancy after solid organ transplantation is increasing, there is 3 to 5-fold greater incidence than in general population. Major risk factors for non-cutaneous neoplasms are male sex, older age and Caucasians, there are no data on the prevalence of hematologic malignancies after kidney transplantation. We report a case of kidney allograft infarctions causing acute dysfunction secondary to myelodysplastic syndrome and amyopathic dermatomyositis as a paraneoplastic syndrome (PS).

Case Description: A 40-year-old man with chronic kidney disease (CKD) secondary to autosomal dominant polycystic kidney disease (ADPKD) was programmed for preemptive kidney transplant (KT); basiliximab induction and mycophenolate mofetil (1 year), tacrolimus and steroid was the maintenance therapy. Three years after KT he was admitted to the hospital with AKI (SCr 4.7mg/dL, baseline 1.7mg/dL), unexplained weight loss (17kg) and rash in face, hands and feet. Kidney biopsy showed cortical segmental infarction, focal hypoperfusion with negative C4d. MDA-5, Anti-Jo-1 and PL-7 were positive and Gottron papules were reported in skin biopsy, myopathy was excluded. PS was our conclusion, so PET-CT and BMA were done, with no metabolic activity and hypoplastic myelodysplastic syndrome with high risk for acute myeloid leukemia, respectively.

Discussion: Kidney infarctions were the etiology of AKI as a expression of a hypercoagulable state secondary to amyopathic dermatomyositis (paraneoplastic syndrome) presents and precedes hematologic malignancies in almost 50% cases, awarding poor prognosis at 1, 3 and 5 year with 96.9%, 78.1% and 51.4% overall survival, respectively. Dermatomyositis coexistence with kidney transplant has been described, nevertheless, ADPKD and dermatomyositis is anecdotal. In any case, the diagnosis of Anti-MDA5 dermatomyositis requires ruling out neoplasms.



PO2206

Bilateral Pyomyositis in a Kidney Transplant Patient

Olesya Ilkun, Divya Raghavan, Fuad S. Shihab, Josephine Abraham. *University of Utah Health Hospitals and Clinics, Salt Lake City, UT.*

Introduction: Immunocompromised hosts are susceptible to infectious complications including pyomyositis, a purulent bacterial infection of deep skeletal muscle that most commonly affects lower extremities (LE) and is acquired through hematogenous spread, trauma or injections.

Case Description: A 30-year-old man who received a kidney transplant in 2015 for ESRD due to congenital obstructive uropathy presented to an outside hospital with dysuria, bilateral LE pain, leukocytosis to 18.9 k/uL, and an elevated serum creatinine of 4.7 mg/dL. He was treated with intravenous (IV) antibiotics and his dysuria resolved but bilateral LE pain persisted and he was unable to ambulate. He denied recent vigorous exercise, trauma to his calves or history of IV drug use. Leukocytosis persisted at 20.2 k/uL and he had elevated CRP at 7.5 mg/dL. Ultrasound showed no venous thrombi but was notable for avascular fluid collections in the bilateral medial calves. MRI showed a 2.1 x 3.6 x 7.1 cm fluid collection centered in the gastrocnemius with marked muscle edema, and a similar fluid collection in the contralateral LE at the same location (Figure 1). On further questioning, the patient admitted that two months prior he injected B12, that he had purchased online, into his bilateral calves. Incisions and drainage yielded turbid-looking fluid. Bacterial and fungal cultures showed no growth. Acid-fast stain was negative. The patient's antimicrobial treatment was broadened and he rapidly improved leaving the hospital shortly thereafter.

Discussion: This is a rare case of bilateral pyomyositis in a kidney transplant patient. The inability to culture an organism is likely due to preceding IV antibiotic treatment. This case underscores the importance of keeping a broad differential diagnosis and obtaining a detailed history when treating immunosuppressed patients.

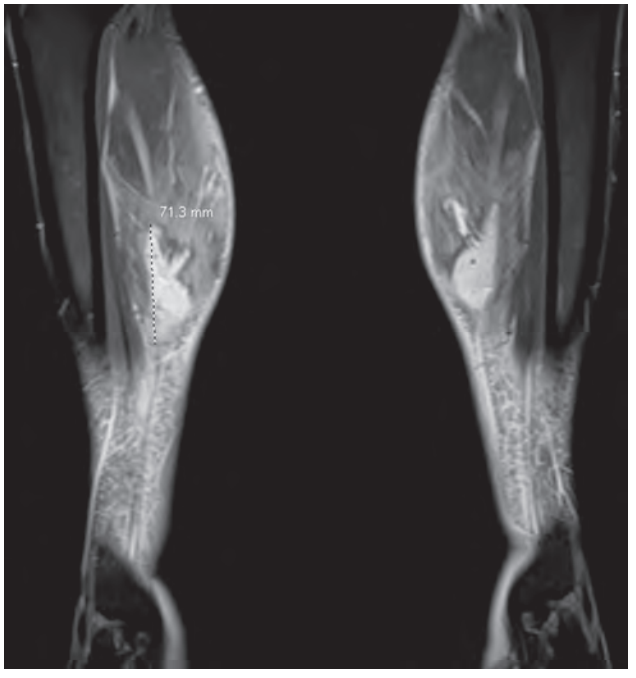


Figure 1

PO2207

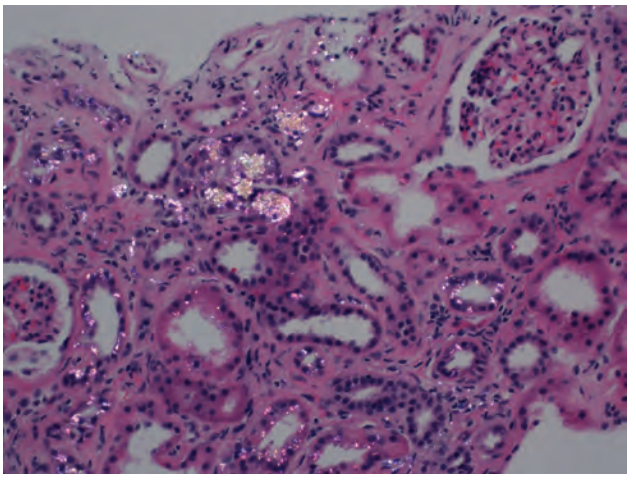
Dihydroxyadenine Crystals Leading to Renal Graft Loss

Niraj K. Yadav, Janame J. Kottey, Rama Kethineni, Zachary Drury, Marc Barry, Divya Raghavan, Josephine Abraham, Fuad S. Shihab. *University of Utah Health, Salt Lake City, UT.*

Introduction: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive disease which leads to excessive production and renal excretion of poorly soluble 2,8-dihydroxyadenine (DHA). This causes crystal-induced acute kidney injury and progressive chronic kidney disease (CKD). We describe a case of DHA nephropathy in a renal transplant recipient leading to graft failure.

Case Description: A 69 year old female with ESRD secondary to recurrent nephrolithiasis underwent a deceased donor kidney transplant. The stone composition was previously unknown but she underwent genetic testing and was found to be homozygous for APRT c.81-3C>G mutation which was reported as a variant of uncertain significance. Following transplantation, she was started on allopurinol for stone prevention and an APRT activity level was checked and was within normal range. As a result, allopurinol was stopped. Her serum creatinine which was 1.6 mg/dl started to gradually increase to 5.5 mg/dL. She underwent a kidney biopsy which showed extensive tubular cytoplasmic and luminal 2,8-DHA crystal deposits. Despite restarting allopurinol, renal function continued to worsen and she developed uremic symptoms. She was initiated on hemodialysis.

Discussion: APRT deficiency is a rare condition and novel mutations are being reported. It is likely that the mutation of unknown significance which our patient has might be another novel mutation associated with APRT deficiency. DHA stone formation can occur even when APRT levels are normal or detectable. It is of utmost importance to continue allopurinol in patients with known DHA stones as genetic testing and APRT level may be misleading and stopping allopurinol will result in irreversible kidney damage



Intratubular and cytoplasmic DHA crytals.

PO2208

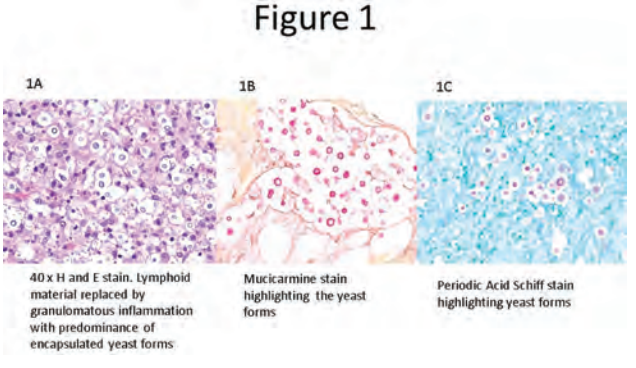
Hypercalcemia in Immunocompromised Host: Beware of Zebras

Ali W. Rizvi, Bhavna Chopra, Cody Marshall, Kalathil K. Sureshkumar. AHN Nephrology *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Hypercalcemia has varied etiology with treatment dictated by underlying cause. We present an immunocompromised host with weight loss, lymphadenopathy and hypercalcemia masquerading as malignancy.

Case Description: A 74 year old male construction worker with deceased donor liver transplant 4 months earlier on tacrolimus/mycophenolic acid (MPA) maintenance and stage 4 chronic kidney disease presented with constitutional symptoms and 20 pound weight loss. Serum creatinine was 2.5 mg/dl and corrected calcium 11.9 mg/dl. CT scan showed mediastinal and bilateral axillary lymphadenopathy. Serum EBV and CMV PCR were negative. Work up for hypercalcemia revealed: intact PTH 6.8 picogram/ml (11.0-68.0), 25 OH vitamin D 44.6 ng/ml (30-100), κ:λ ratio 1.45 (0.26-1.65) and absent M-spike on serum protein electrophoresis. Blood culture grew Cryptococcus neoformans and serum Cryptococcal antigen titer was positive at 1:4096. Lumbar puncture revealed CSF lymphocytic pleocytosis and positive cryptococcal antigen titer at 1:32. Axillary lymph node biopsy showed cryptococcal lymphadenitis with diffuse involvement by encapsulated yeast forms within non-necrotizing granulomatous inflammation (fig 1). Patient was started on induction treatment with intravenous liposomal amphotericin B and oral flucytosine till 2 weeks after negative blood cultures followed by 8 weeks of consolidative therapy with oral fluconazole. MPA was stopped and tacrolimus continued. Hypercalcemia resolved a week after initiating antifungal therapy. Patient doing well 4 months later on maintenance fluconazole.

Discussion: Hypercalcemia is a rare manifestation of disseminated fungal infection. The exact etiology is unclear but 1, 25 di (OH) vitamin D and PTHrp are implicated. Weight loss and lymphadenopathy in our immunosuppressed patient raised concern for malignancy. However, blood culture and lymph node histology clinched the diagnosis enabling prompt therapy with resolution of the symptoms and hypercalcemia.



PO2209

A Rare Case of Collapsing Focal Segmental Glomerulosclerosis Caused by Cytomegalovirus in a Renal Transplant Recipient

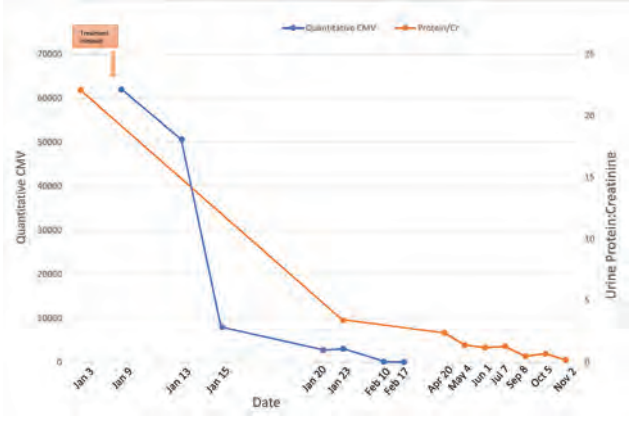
Abdelwahab Ahmed, Abdel-Rhman Mohamed, Abdullah Naji, Anita K. Patel, Rohini Prashar. *Henry Ford Hospital, Detroit, MI.*

Introduction: Cytomegalovirus (CMV) is a DNA virus that is associated with several clinical manifestations in renal transplant recipients (RTR), presenting often with asymptomatic viremia, CMV syndrome, and tissue invasive disease in the lungs, colon,

esophagus, and retina. CMV infection may occur in the renal allograft presenting as interstitial nephritis. We present a rare case of CMV nephritis in a RTR that presented as a collapsing focal and segmental glomerulosclerosis (FSGS).

Case Description: A 55 year old caucasian male with a history of end-stage renal disease due to hypertension on hemodialysis for 4 years received a living donor renal transplant with immediate graft function. Induction was with Thymoglobulin, maintenance immunosuppression was with MMF, Prednisone, and Tacrolimus. He completed valganciclovir prophylaxis for CMV, and soon after presented to an outside hospital with hypotension, lower extremity swelling, and diarrhea of 2 weeks duration. He had a proteinuria value of 22.1gm with hypoalbuminemia and an acute kidney injury. A presumptive diagnosis of FSGS was made and he received IV Solumedrol. Chart review revealed CMV viremia 4 weeks prior to presentation. He was transferred to a tertiary center for management, where a kidney biopsy was done that revealed interstitial inflammation, widespread collapse of glomerular tufts, podocyte hyperplasia and hypertrophy, extensive podocyte foot process effacement, microthrombi and CMV staining in tubular epithelial cells. He was treated with IV ganciclovir, and both viremia and proteinuria resolved (Figure 1).

Discussion: The patient's de novo collapsing-FSGS is a rare manifestation of CMV infection. While CMV is the most common opportunistic viral infection in RTR, renal involvement is unusual. This may be a cytokine related injury to podocytes in the setting of a viral infection. Our patient had complete recovery following treatment with renal function returning to baseline.



PO2210

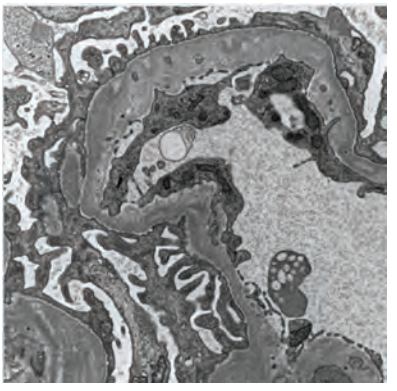
Use of Lipoprotein Apheresis in Recurrent Focal Segmental Glomerulosclerosis Following Transplant

Ruth E. Campbell, Monica Grafals. *University of Colorado, Denver, CO*.

Introduction: Primary focal segmental glomerulosclerosis (FSGS) recurs in 20-50% of transplanted kidneys and has a high rate of transplant failure. We report a case of recurrent FSGS treated with lipoprotein apharesis (LDL-A)

Case Description: A 27 year-old male with primary FSGS underwent a DBD kidney transplant. He was ESRD on PD and anuric. ATG and steroids were given for induction. On post-op day (POD) 2, his spot urine protein was > 2000 mg (unable to calculate urine protein/creatinine ratio (UPCR)). Serum creatinine was 1.47 mg/dL (pre-transplant: 9.65 mg/dL). With concern for recurrent FSGS, emergent therapeutic plasma exchange (TPE) and losartan were started. On POD 3 and 4, proteinuria was > 2,000 mg; TPE was done daily and adrenocorticotrophic hormone (ACTH) and rituximab started. Despite 5 days of TPE and medical therapy, proteinuria was > 2,000 mg. On POD 8, LDL-A was started. Prior to second LDL-A run, his proteinuria was 1990 mg but 294 mg afterwards. Proteinuria rebounded between treatments, but steadily decreased: by week 3, UPCR was 686 mg/g and by final LDL-A, was 200 mg/g. Renal function was stable and biopsy had no podocyte effacement. He completed LDL-A biweekly for 3 weeks, then weekly for 6 weeks. ACTH and rituximab were continued. Currently, his UPCR is 9 mg/g.

Discussion: Treatment of recurrent FSGS centers on plasma exchange and immunosuppression. By lowering LDL levels, LDL-A is thought to reduce proteinuria by reducing vascular permeability and improving response to immunosuppressive agents. Case reports indicate efficacy, but currently the use of LDL-A is designated as a humanitarian device exemption for drug resistant recurrent FSGS in transplanted kidneys by the FDA. Although this modality is uncommon, our case suggests that patients with recurrent FSGS may benefit from early initiation of LDL-A.



PO2211

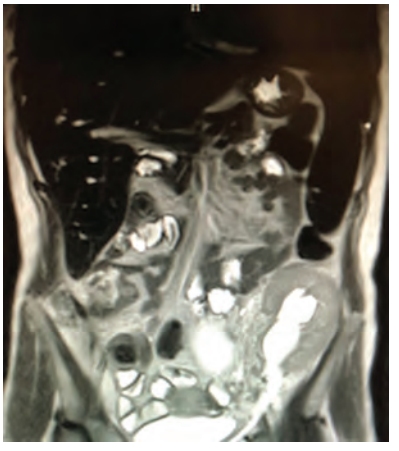
Iron Overload Syndrome and Primary Focal Segmental Glomerulosclerosis Recurrent with Monthly Plasma Exchange Therapy: Long-Term Second Kidney Allograft Survival

Belen Martinez-Vazquez, Pedro Gudiño Bravo, Octavio R. Garcia-Flores, Francisco Rodríguez. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico*.

Introduction: Patients who lose their allograft due to recurrent FSGS are usually not retransplanted since the risk of recurrence (80–100%). Proteinuria as a result of glomerular damage is linked to tubulointerstitial injury, which is associated with increased filtration of transferrin-bound iron and can lead to tubular accumulation.

Case Description: A 32-year old female with a history of collapsing FSGS, living related kidney transplant with loss of the allograft function due to recurrent disease underwent a 2nd kidney transplantation in October 2018. At 2 months post transplantation elevated levels of proteinuria (6 g/g), kidney biopsy (KB) demonstrated recurrent FSGS. She received treatment with high-dose steroids, CsA and an intensive course of plasma exchanges (PEs) due to persistent proteinuria. There is no history of blood transfusions, iron treatment and diseases with ineffective erythropoiesis. Ferritin levels (15000 ng/ml) and a MRI with liver and spleen iron deposition pointed to the diagnosis of Hereditary Hemochromatosis (HH), common mutations (C282Y, H63D and G320V genes) were negative. KB of 2020 demonstrated iron deposition (ID) in tubular epithelial cells.

Discussion: Histological evidence of ID in the tubulointerstitium can be related to persistent proteinuria. The negative genetic testing is common in the Hispanic race in which there is a lesser prevalence for the most frequent mutation, C282Y homozygosity (0.03% compared to 0.44% in Whites). We assume that this patient has a genetically unknown type of HH. To our knowledge this is the first reported case in which an Iron Overload Syndrome (IOS) is associated with FSGS. PEs is a therapeutic option in patients with recurrent FSGS, also used in IOS.



PO2212

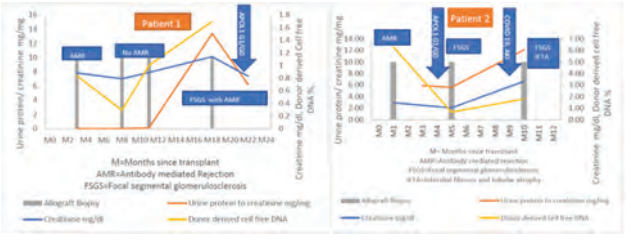
Is One Allele Enough to Cause APOL1-Associated Nephropathy?

Peace Johnson, Sindhura Bobba, Sravanthi Paluri, Gaurav Gupta. *Virginia Commonwealth University Health System, Richmond, VA.*

Introduction: The high risk APOL1 genotype are associated with an increased risk of developing non-diabetic kidney disease. In the post-kidney transplant setting, a high-risk donor APOL1 genotype (but not recipient genotype) is associated with an increased risk of graft failure and proteinuria, indicating that it is local glomerular APOL1 gene expression that confers disease rather than systemic gene expression. Here, we present 2 patients that developed post-transplant focal segmental glomerulosclerosis (FSGS) after an initial diagnosis and treatment of Antibody-mediated rejection (AMR).

Case Description: Two patients with end stage kidney disease, highly sensitized, received deceased donor kidney transplants from African American donors (one in 2019 and the other a regraft in 2020). Donors were without discernable proteinuria on urine dipstick. Initial post tranasplant courses were complicated by AMR treated as per center protocol. Tissue-based whole biopsy gene expression studies on kidney biopsy specimens (MMdx, using Molecular Microscope, Alberta, Canada) confirmed AMR along with grossly elevated interferon-γ gene expression. Subsequently each developed nephrotic range proteinuria with biopsy-confirmed FSGS and ongoing AMR . In both patients, in the absence of a prior history of FSGS and a delayed development of proteinuria in the first case (2019, patient1), an absence of recurrence in the first allograft in the second case (2020, patient2), a diagnosis of donor-derived APOL-1 nephropathy was considered and retrospective donor genotyping revealed the intermediate G1/G0 genotype. See Figure for more details.

Discussion: We hypothesize that extreme local interferon-γ activation due to AMR was the primary trigger that could have resulted in local APOL-1 gene activation and subsequent podocytopathy. Similar data was recently reported by Shetty et al, in a kidney transplant patient with COVID associated collapsing nephropathy and G1/G0 donor genotype. Based upon these data we hypothesize that the G1/G0 genotype may represent intermediate risk for podocytopathies. Further research is needed in this area to confirm these initial associations.



PO2213

Early Recurrence of Fibrillary Glomerulonephritis After Kidney Transplantation

Nicholas S. Niazi, Yanli Ding, Suverta Bhayana. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare glomerulonephritis characterized by glomerular congo red negative nonbranching fibrils on electron microscopy (EM). The optimal treatment for FGN is unclear and the renal prognosis is poor, with up to half of patients progressing to end-stage kidney disease (ESKD) by four years. Kidney transplantation has a variable recurrence rate after transplant ranging from 9 to 50%.

Case Description: A 57-year-old-male with a history of cirrhosis secondary to nonalcoholic fatty liver disease and ESKD secondary to FGN was hospitalized for acute kidney injury. The patient underwent simultaneous liver and kidney transplantation four weeks prior to presentation. The patient underwent induction with basiliximab and started on tacrolimus, mycophenolate mofetil, and prednisone for maintenance immunosuppression. The patient's serum creatinine had increased from the previous nadir of 2.0 mg/dL to 2.7 mg/dL. Given worsening allograft function, a transplant kidney biopsy was performed. The patient's biopsy showed evidence of recurrent fibrillary glomerulonephritis, including positive immunohistochemical staining for DNAJB9 and ultrastructural findings of mesangial nonbranching fibrils averaging 21.5 nm in diameter. The biopsy also showed acute tubular necrosis, secondary global and focal segmental glomerulosclerosis, and tubular atrophy and interstitial fibrosis in 20-30% of the cortex. There was no evidence of acute T-cell mediated rejection or antibody-mediated rejection. The patient's allograft function improved and ranged from 1.5 -1.7 mg/dL at the time of discharge. The patient is now six months from transplant and has stable allograft function and minimal proteinuria.

Discussion: FGN recurrence after kidney transplantation has been described in case reports and case studies. In the most recent and largest study, utilizing DNAJB9 and protocolized post-transplant biopsy, the authors showed a recurrence rate of 21% and a median time to recurrence of 10.2 years. Additionally, all biopsies before five years were negative in their cohort. Allograft failure was seen in 33% of patients with recurrent FGN. To our knowledge, this case is the earliest reported recurrence of FGN after transplantation. In patients with a history of FGN, recurrent disease should be considered in the differential of early allograft dysfunction.

PO2214

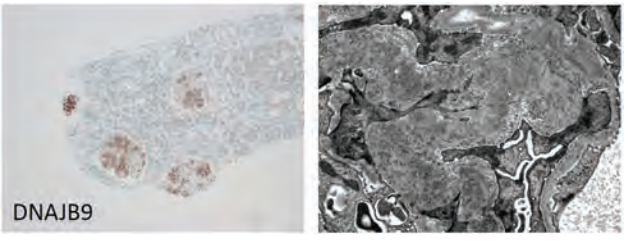
Donor-Derived Fibrillary Glomerulonephritis in a Renal Allograft

Tiana Jespersen, Yihung Huang, Muna Alnimri, Kuang-Yu Jen. *University of California Davis, Sacramento, CA.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare progressive renal disease that is defined by the presence of randomly oriented non-branching fibrils showing positive immunostaining for DnaJ homolog subfamily B member 9 (DNAJB9). Recurrent FGN in renal allografts have been described with an indolent course. We report a case of donor-derived FGN in a renal allograft.

Case Description: A 73-year-old female with history of end-stage renal disease (ESRD) due to anti-myeloperoxidase antibody-associated pauci-immune glomerulonephritis received a preemptive deceased donor renal transplant from a 62-year-old 79% Kidney Donor Profile Index female. The patient experienced slow graft function and nadir serum creatinine (Cr) of 1.7 mg/dL at 4 months post-transplant with subsequent Cr stabilizing in the 2.0-2.3 mg/dL range. Proteinuria mainly fluctuated between 1-2 g/g. Time-0 biopsy demonstrated mild mesangial widening/hypercellularity with rare glomerular capillary double contours. Ancillary studies revealed positive staining for DNAJB9 and kappa light chain-restriction, consistent with donor-derived FGN. 4-month surveillance biopsy showed similar findings. Background renal parenchyma showed moderate chronicity with prominent chronic vascular disease. At 10-months post-transplant, Cr remains at ~2 mg/dL and proteinuria remained in the 1-1.6 g/g range.

Discussion: FGN carries a poor prognosis with nearly half of patients progressing to ESRD within a few years. A case series of recurrent FGN after kidney transplantation suggests a relatively benign clinical course including a single report of donor-derived FGN (from a living related donor) without proteinuria in the recipient. Our case shows a more severely afflicted allograft that resulted in persistent low-grade but stable proteinuria in the recipient. Suboptimal Cr was also observed following transplant as well, although the allograft had other factors such as chronicity and chronic vascular disease.



PO2215

A De Novo Case of C1q Nephropathy in a Renal Allograft

Zachary Appelbaum, Muralidharan Jagadeesan, Joseph K. Melancon, Divya Shankaranarayanan. *George Washington University Medical Faculty Associates, Washington, DC.*

Introduction: C1q nephropathy (C1qN) is a rare idiopathic glomerulopathy that is characterized by mesangial C1q deposition in the absence of systemic lupus erythematosus or membranoproliferative glomerulonephritis. Clinical manifestations vary, but can include proteinuria, hematuria, and renal dysfunction. C1qN is not usually responsive to corticosteroids and outcomes are poor for most patients. We describe a de novo, but clinically silent case of C1qN in a renal allograft incidentally detected on surveillance biopsy.

Case Description: A 20 year old male, with history of end stage renal disease secondary to congenital renal hypoplasia, on maintenance tacrolimus, mycophenolate mofetil, and oral prednisone, underwent a surveillance biopsy 1 year after a deceased donor kidney transplantation. Laboratory studies revealed a baseline serum creatinine of 1.7 mg/dL and a spot urine protein to creatinine ratio of 258 mg/g. Urinalysis did not show hematuria and the rheumatologic workup was unremarkable. Light microscopy revealed minimal mesangial hypercellularity without endocapillary proliferation. Immunofluorescence microscopy demonstrated granular mesangial staining for C1q with positive staining for IgG, IgM, C3, C4, and kappa and lambda light chains. Electron microscopy revealed mesangial and paramesangial electron-dense immune deposits.

Discussion: Unlike other C1qN cases described in the literature, our patient did not have evidence of an underlying autoimmune disease or viral infection. Renal biopsy demonstrated positive immunofluorescence staining of IgG, IgM, C3, C4, and kappa and lambda light chains, in addition to C1q. Moreover, there was no evidence of proteinuria, hematuria, or renal dysfunction. One question that arises is whether this patient, with a history of congenital renal hypoplasia, was susceptible to developing an autoimmune process that was otherwise being masked by immunosuppression. This case emphasizes the following: (1) further research is needed to determine the frequency and length of monitoring of de novo C1qN in renal transplant recipients, and (2) further research is needed to determine the optimal therapeutic regimen.

PO2216

Repository Corticotropin (Acthar®) in Treating De Novo C3 Glomerulonephritis Post Transplantation

Muhammad S. Naseer, Ayush Singh, Neeraj Singh. *Willis Knighton Medical Center, Shreveport, LA.*

Introduction: De-novo C3 glomerulonephritis (C3GN) post-transplant is uncommon. Although eculizumab has been used successfully in several cases, the response is heterogeneous and treatment strategies remain undefined. The use of repository corticotropin in C3GN has not been described in the literature.

Case Description: A 48-year-old African American male with kidney transplantation secondary to diabetic nephropathy presented 6 years post-transplant with lower extremity edema and nephrotic range proteinuria of 8.2 g/g of creatinine. His renal allograft biopsy confirmed the diagnosis of C3GN (*Figure 1).* He was treated with eculizumab (Solaris®) 900 mg IV once weekly for 4 weeks and repository corticotropin (H.P. Acthar® gel) 80 units subcutaneous twice weekly for 6 months with complete resolution of proteinuria within 3 months of the treatment. However, the patient presented again after 6 months of completing therapy with a recurrence of proteinuria which peaked at 11.6 g/g of creatinine. The kidney allograft biopsy was consistent with C3GN. He was started on Acthar® 80 units subcutaneous twice weekly and the proteinuria was reduced to >50% within 2 months of therapy. When eculizumab 900 mg IV once weekly for 4 weeks was added with Acthar®, the proteinuria fully resolved within 10 weeks of treatment. Since then, the patient has been maintained on Acthar® monotherapy of 40 units subcutaneous twice weekly and has stayed in complete remission of proteinuria for more than a year till his last follow-up.

Discussion: In conclusion, this is the first case report describing the role of repository corticotropin as an effective therapy in reducing proteinuria and maintaining patients with C3GN in complete remission.

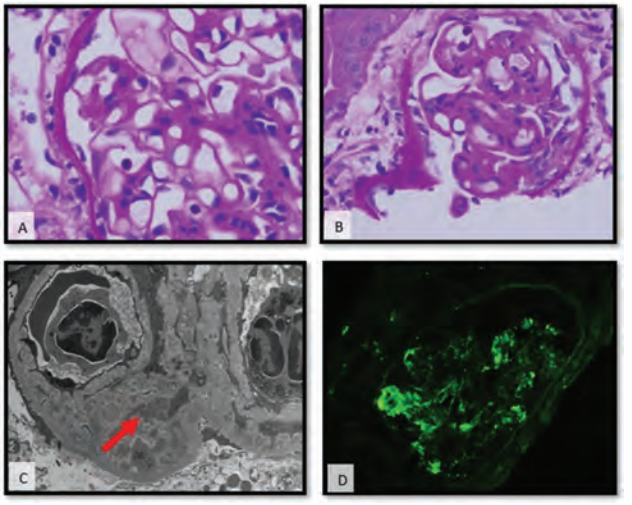


Figure 1. *Kidney Allograft Biopsy*

A & B: PAS shows a membranoproliferative pattern

C: EM shows large subendothelial deposits (red arrow)

D: IF shows a strong C3 reaction of mesangial and capillary walls

PO2217

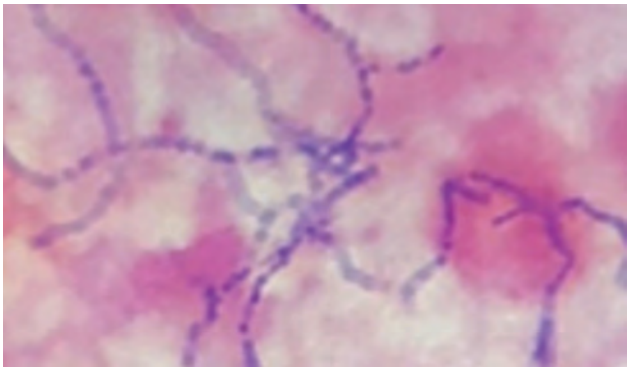
Rare Presentation of Disseminated Nocardia as Syndrome of Inappropriate Antidiuretic Hormone (SIADH) in Renal Transplant

Iskra Myers, Joseph C. Parker, Scott Richardson. *East Carolina University, Greenville, NC.*

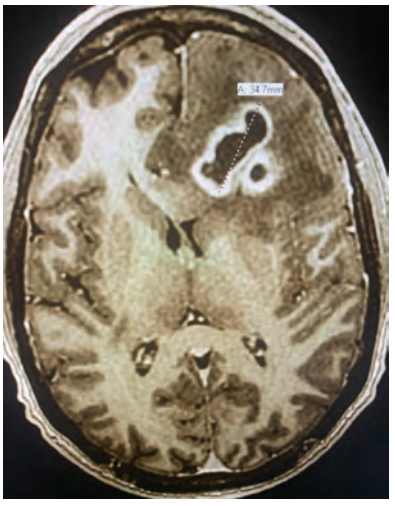
Introduction: Nocardia is a rare opportunistic pathogen that typically affects the immunocompromised host. Recently, Williams et. al. reported a third of patients have disseminated cerebral nocardiosis at presentation with most common isolate Farcinica species. SIADH has been reported in association with disease progression.

Case Description: A 31-year-old renal transplant recipient presented 4 years post-transplant with dyspnea and left upper extremity jerking. Immunosuppressives (IS) included Mycophenolate, Tacrolimus and Prednisone. He had non focal exam. Blood work showed Na 129, Uosm 500 mosm/kg, UNa 92. MRI brain showed multiple lesions, largest in left frontal area. CT chest revealed right pleural effusion. Biopsy of resected brain abscess and pleural fluid analysis both confirmed Nocardia Araoensis and Bejingensis. Imipenem and Bactrim were started, IS regimen was tapered down. Repeat scans month later showed resolution of vasogenic edema, pleural effusion and SIADH.

Discussion: Cerebral nocardiosis is life-threatening opportunistic infection that often presents with no specific clinical signs to guide diagnosis. High index of clinical suspicion is the key to early diagnosis. Presence of SIADH should prompt search for Nocardia which needs to be identified down to its species for targeted antibiotic treatment.



Branching g+ rod on gram stain, Nocardia.



Left frontal ring-enhancing lesion.

PO2218

Disseminated Mycobacterium Avium Complex in a Renal Transplant Patient with Subsequent Immune Reconstitution Inflammatory Syndrome Post Transplant Nephrectomy

William G. Middleton, Sridevi Govindarajulu. *Toowoomba Health Service, Toowoomba, QLD, Australia.*

Introduction: *Mycobacterium avium* Complex (MAC) are a group of pathogenic mycobacteria present in soil and water. Infection can present with respiratory symptoms, but in immunocompromised patients disseminated disease with fevers, weight-loss or diarrhoea is more common. Immune Reconstitution Inflammatory Syndrome (IRIS) is an excessive but protective inflammatory response against an existing pathogen when immune function is restored. It is usually seen in patients with Human Immunodeficiency Virus but has been described in renal transplant patients with MAC infection. It can lead to hypercalcaemia via increased macrophage 1α-hydroxylase activity, causing increased $1,25(OH)_2D_3$ production.

Case Description: A 54-year-old male presented 3 years post renal transplant with recurrent fevers, night sweats and pancytopenia with a haemoglobin of 76 g/L, leucocytes of $1x10^9$/L and platelets of $72x10^9$/L. He was on Tacrolimus, Mycophenolate and Prednisolone, and was previously treated with anti-thymocyte globulin for cellular rejection. Bone marrow and blood cultures were positive for MAC at 8 weeks. He was started on clarithromycin, ethambutol and rifampicin, with reduction in immunosuppression. Blood cultures were negative 1 month post anti-MAC therapy. He represented 7 months later with fevers and 22lb weight loss. Extensive bloodwork was negative. Computerised Tomography showed cervical lymphadenopathy and mesenteric stranding. Non-necrotising granulomas were demonstrated on fine needle aspirate of both a cervical lymph node and bone marrow, in keeping with disseminated MAC. Transplant nephrectomy was performed to allow cessation of immunosuppression. Renal histology showed granulomatous interstitial nephritis. He had ongoing fevers and hypercalcaemia for 1 month post nephrectomy with albumin corrected calcium of 3.32 μmol/L. Septic screen was negative. He was treated with oral prednisolone for suspected IRIS with resolution of symptoms.

Discussion: Disseminated MAC is a rare but life-threatening infection in renal transplant recipients that can require nephrectomy for cessation of immunosuppression. Non-tuberculous mycobacteria can take 6 weeks to culture and require specific culture media. Differentiation of IRIS vs drug resistance as a cause of persistent fevers is important.

PO2219

A Very Rare Presentation of Oral Invasive Aspergillosis Immediately Post Kidney Transplant

Walaa S. Dabbas, Zahraa F. Hajjiri, Prerna Kumar, Sajid Q. Ansari, Ruchi H. Naik. *University of Illinois at Chicago, Chicago, IL.*

Introduction: Although oral candida infection is very common opportunistic infection after kidney transplant, there are incidences of other fungal infections like aspergillosis, cryptococcosis, histoplasmosis, coccidioidomycosis, Blastomyces dermatiti etc. that are also important to be considered. Here we are reporting a very rare presentation of oral aspergillosis in very early phase post Kidney transplant.

Case Description: 38 years old Hispanic female with history of systemic lupus erythematosus and lupus nephritis since 2005, last lupus flare in June 2020 was treated with rituximab and high dose prednisone followed by maintenance with azathioprine and hydroxychloroquine. She received preemptive directed deceased donor kidney transplant in November 2020 with thymoglobulin induction followed by Tacrolimus and Mycophenolate mofetil maintenance therapy. 1 month post-transplant she received pulse dose intravenous Methylprednisone for acute T cell mediated rejection and prednisone was added to her maintenance immunosuppressive regimen. 2 months later she presented with a necrotic lesion with pain over the hard palate with a couple of more oral lesions with similar characteristics. she underwent debridement with excision and biopsy that confirmed oral aspergillosis. She was treated with isavuconazole for 3 months. The oral lesions eventually recovered after 12 weeks of treatment.

Discussion: Oral aspergillosis is very rare but associated with high morbidity and mortality if not treated timely. The diagnosis is based on tissue culture and histopathologic findings. The treatment is surgical combined with systemic fungal therapy for at least 3-6 months. Our patient developed the infection early post kidney transplant due to her recent extensive immunosuppression before and after kidney transplant.

PO2220

Simultaneous Occurrence of Actinomyces Gastritis and Severe Rejection in a Kidney Pancreas Transplant Recipient

Ravi K. Thimmisetty, Zohreh S. Soltani, Catherine G. Staffeld-Coit, Jorge C. Garces. *Ochsner Medical Center - New Orleans, New Orleans, LA.*

Introduction: We are presenting a 33 year old lady with history of Kidney Pancreas transplant admitted for rejection treatment and found to have co infection, actinomyces and CMV in gastric mucosa. Patient was managed well with modified net immunosuppression and discharged safely on long term antibiotics.

Case Description: 33 year old woman with h/o stage V CKD from type I diabetes mellitus had Simultaneous kidney pancreas transplant in 2018 admitted directly from clinic for rejection treatment. admission vitals were temperature 97 f, blood pressures of 151/99, heart rate 83, respiratory rate 18, on room air. exam unremarkable. home Immunosuppression is cyclosporine, sirolimus and prednisone. baseline creatinine

is 1.1-1.3 mg/dl. Admission creatinine is 5.0, BUN 33, lipase 290, amylase 124, cyclosporine level is 52, sirolimus level < 2, immuknow cylex 332, HbA1C is 5.3, c peptide is 3.13. renal biopsy showed acute cellular rejection, moderate microvascular inflammation, C4d positive, acute antibody mediated rejection. Class I and II DSA were positive. she got 3 doses of solumedrol, 3 doses of thymoglobulin, 2 sessions of plasmapheresis. She was found to have group B streptococcal bacteremia. Removed central line. CT scan of abdomen and pelvis was done for chronic abdominal pain showed diffuse gastritis or infiltrative disease such as gastric lymphoma. EGD showed gastric ulcer with Actiomyces colonization. Biopsy of gastric mucosa showed reactive gastropathy, purulent exudate, ample Actinomyces colonies, No lymphoma or cancer. CMV viral inclusions also seen. Serum CMV PCR negative. Further rejection treatment was placed on hold. Scheduled 2 doses of IV IG outpatient and resume mycophenolate mofetil as an outpatient after finishing antibiotics. Discharged with cyclosporine, prednisone, long term IV ampicillin, valcyte and follow up EGD in 4 weeks. Outpatient renal transplant biopsy was scheduled after completion of antibiotics to assess rejection. creatinine was plateud around 3.4. lipase and amylase were normalized.

Discussion: Actinomycosis is considered an endogenous, opportunistic infection of immunocompromised patients. Incidence is about one per 500 000 (0.0002%) in developed countries. Prevalence of actinomycosis was around 0.02% in transplant recipients. Infections alter the management and outcome of graft rejections.

PO2221

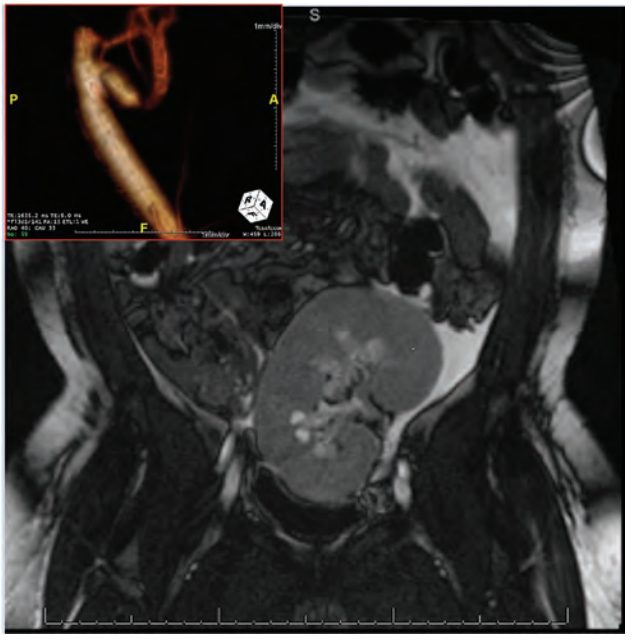
Recurrent Renal Allograft Torsion After Simultaneous Kidney and Pancreas Transplantation: Is Still Possible to Salvage the Graft?

Paolo Vincenzi, Shobana Sivan. Miami Transplant Institute, Kidney/Pancreas Transplant Surgery, Transplant Nephrology *Miami Transplant Institute, Miami, FL.*

Introduction: Kidney Allograft Torsion (KAT) is defined as a rotation of the renal allograft around its vascular pedicle. It is a rare complication with high rate of graft loss. The nonspecific presentation and inability to provide a definitive diagnosis by imaging, mainly in cases of partial torsion, often delay the diagnosis and treatment. We report a case of recurrent complete torsion of the renal allograft after simultaneous kidney and pancreas transplantation (SKPTx), requiring two emergency exploratory laparotomies.

Case Description: A 38-year-old woman with a history of intraperitoneal SKPTx underwent two separate emergency exploratory laparotomies secondary to complete renal allograft torsion, respectively seven and eleven months after the transplant. In both episodes, no adhesions were encountered. During the first operation, nephropexy was performed. During the second operation, an abdominal wall mesh was placed and fixed to the abdominal wall. Acute kidney injury (AKI) related to KAT recovered in both occasions with a creatinine of 1.3 mg/dl at four months follow-up.

Discussion: Renal torsion should be always suspected in intraperitoneally placed kidneys presenting with nonspecific symptoms, abdominal pain, oliguria and worsening kidney function. Surgical exploration should be considered to salvage the renal graft. This case illustrates the reversibility of a severe injury related to this vascular complication with an adequate return to baseline kidney function even when diagnosis and surgical treatment of KAT might be delayed secondary to its misleading clinical presentation.



PO2222

New-Onset Antibiotic Anaphylaxis Post Kidney Transplant: A Role of Calcineurin Inhibitors?

Jason T. Bau, Genevieve Mcmichael, Bevin B. Bart, Stefan Mustata. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada*.

Introduction: Calcineurin inhibitors (CNIs), such as tacrolimus and cyclosporin, are a mainstay of post-transplant immunosuppression. Immunosuppressive medications typically suppress type I allergic reactions, however, there have been reports of allergic sensitization post-transplantation, despite no known drug allergies.

Case Description: We report two cases of antibiotic-related anaphylaxis post kidney transplant. In case one, a 63-year-old male was admitted for an elective transurethral prostate resection having received an NDD renal allograft two-months prior and maintained on tacrolimus, mycophenolate and prednisone. Preoperatively, cefazolin was given for antibiotic prophylaxis, but he developed an anaphylactic reaction leading to hemodynamic collapse requiring ICU admission. Serum tryptase (37.6ug/L, normal <11.4ug/L) and histamine (20.4ng/mL, normal <1ng/mL) levels were markedly elevated confirming anaphylaxis. In case two, a 56-year-old male received a DCD renal allograft (on immunosuppression with prednisone, mycophenolate and tacrolimus), eleven months prior to admission for suspected sepsis. He was empirically treated with ceftazidime and vancomycin but developed an anaphylactic reaction, requiring intubation and ICU admission. Serum tryptase and histamine levels were not assessed. A comprehensive medication review revealed that both patients had received the offending antibiotics without issues prior to transplantation. In both cases, neither donor had a documented allergy to these medications.

Discussion: In these clinical vignettes, we describe two patients with anaphylaxis post transplantation, despite previously tolerating the offending medications without issue. Furthermore, these reactions were not donor derived. Type I allergic reactions are typically suppressed post-transplant, yet there is literature to suggest that allergic sensitization maybe mediated by CNIs. The rates of sensitization are cited to be as high as 10% in liver and kidney recipients. Risk factors for sensitization are not described, although we note both of our patients had anaphylactic events within one-year post transplant. Given the importance of CNIs in allograft immunosuppression balanced against the morbidity of anaphylaxis, these cases highlight the need to better identify high risk patients for such events.

PO2223

Immunosuppression Cessation During Chemotherapy for Post-Transplant Lymphoproliferative Disorders in Kidney Transplant Recipients

Mohammad Atari, Arnold B. Alper, Sixto G. Giusti. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Kidney transplant patients have a 20-fold higher risk to develop Post-Transplant Lymphoproliferative disorder (PTLD). PTLD requires reduction in immunosuppression (IS) medications to the lowest dose that prevents rejection. Here we report the safe withdrawal of IS in three kidney transplant recipients with PTLD receiving chemotherapy.

Case Description: Case 1: A 44-year-old male received a deceased donor renal transplant with alemtuzumab induction. He developed cellular rejection that was treated with steroids and thymoglobulin. He was maintained on cyclosporine, mycophenolate, and prednisone. Later on, he developed resistant EBV viremia and a retroperitoneal mass with diffuse lymphadenopathy. Biopsy revealed a high-grade, EBV-negative, monomorphic diffuse large B cell lymphoma (DLBL). IS medications were stopped except for low-dose prednisone. Creatinine remained stable post six cycles of chemotherapy, with complete response after three cycles. Case 2: A 59-year-old male with a history of membranous nephropathy (MN) treated with rituximab. Received a living-related donor renal transplant (LRDRT), with alemtuzumab induction. MN recured three years after transplantation and was treated with modified Ponticelli protocol. He was maintained on cyclosporine and mycophenolate. Ten years post-transplant, he had a large mesenteric soft tissue mass with lymphadenopathy. Biopsy showed EBV-negative, monomorphic high-grade DLBL. IS medications were stopped. The patient received six cycles of chemotherapy and achieved a complete response. Creatinine remained at baseline. Case 3: A 36-year-old male with a history of IgA nephropathy, received a LRDRT with alemtuzumab induction. He was maintained on tacrolimus and mycophenolate. Five months later, he was diagnosed with stage IIIB, EBV-positive, monomorphic DLBL via tonsillar mass biopsy. IS medications were stopped and he went into complete remission after eight cycles of chemotherapy. He was started on sirolimus monotherapy post-chemotherapy. Creatinine remained at baseline for five years.

Discussion: IS withdrawal seems to be a safe option during chemotherapy for PTLD. Chemotherapy causes prolonged immunosuppression or immune tolerance to the allograft. The safe cessation of IS while receiving chemotherapy for PTLD has been described, with reinstitution of low-dose IS post-remission.

PO2224

Sirolimus and Chyloperitoneum: A Rare Pair

Juanly N. Rodriguez, Ramon A. Seneriz, Adriana Dejman. *University of Miami School of Medicine, Miami, FL.*

Introduction: The mammalian target of rapamycin inhibitors (mTORi) are associated with complications like hyperlipidemia, lymphoceles, lymphedema and rarely chylous ascites (CA), characterized by a milky colored, triglyceride (TG) rich fluid leading to dehydration, electrolytes imbalances and immunosuppression. We present a case of sirolimus induced chyloperitoneum in an ESKD patient.

Case Description: 44 year old woman with heart failure reduced ejection fraction (HFrEF) secondary to transposition of great vessels and orthotropic heart transplant in 2007, NASH cirrhosis and ESKD from calcineurin inhibitor toxicity, switched to sirolimus in 2018. Renal function declined requiring initiation of peritoneal dialysis (PD) in December 2020. 3 months prior patient presented with right upper extremity (RUE)/ipsilateral breast swelling, erythema and dull pain. US doppler ruled out DVT. Lymphangitis/cellulitis was suspected, started antibiotics with some improvement. Lymphoscintigram showed diffuse skin/right breast soft tissue edema. PD catheter was placed, incidentally found mild clear ascites, liver cirrhosis and bilateral ovarian cysts, work up for malignancy was negative and discharged. She trained for PD and effluent for KT/V had milky appearance. Fluid anlaysis showed nucleated cell count 1151mcL, RBCs 1391mcL, total protein 2.4g/dl, albumin 1g/dL, amylase <30u/L, glucose 160mg/dL, LDH 248IU and TG level 141mg/dl consistent with CA. Sirolimus was held and 2 weeks after PD fluid cleared and RUE lymphedema slowly improved with right breast enlargement to date.

Discussion: CA results from disruptive lymphatic system and posterior leakage of lymph into the abdominal cavity. Diagnosis requires TG levels >110mg/dl and gold standard imaging test is lymphangiography. Multiple etiologies are proposed: malignancy, traumatic surgical injury, liver cirrhosis and cardiovascular disease. Less common, mycobacterium infections and medications (mTORi, calcium channel blockers). Sirolimus causes disruption in proliferative signals required to seal perivascular lymphatics leading to high rates of lymphedema/lymphoceles. This explains RUE/ipsilateral breast swelling in our case. As the PD fluid cleared after stopping the sirolimus, it was deemed the cause. Cornerstone of therapy is correcting underlying cause. Presence of CA warrants immediate attention and targeting underlying cause, crucial for rapid recovery and avoiding complications.

PO2225

Renal Transplant Recipient with Large Periorbital Basal Cell Carcinoma (BCC) Cured Nonsurgically with Vismodegib

Daniel Varela,[1,2] Desika Rocha,[2] Sergio A. Trevino Manllo,[2] Mourad Alsabbagh.[2] *[1]The University of Texas Rio Grande Valley, Edinburg, TX; [2]DHR Health, Edinburg, TX.*

Introduction: Renal transplant recipients (RTR) live a delicate balance between preserving allograft function with immunosuppression medications (IS) and the side effects (e.g malignancies), Skin cancers are prevalent with Squamous (SCC) & BCC (SCC), comprising 90% of skin cancers. These tumors are aggressive, exhibiting unique pathophysiologic characteristics. We present a case of a RTR who developed invasive periorbital BCC; successfully treated with novel chemotherapeutic Vismodegib

Case Description: A 66-year-old man with history of kidney transplant had a stable graft function with Cr 1.6 on IS for 35 years, on Prednisone and Tacrolimus. with a history of recurrent SCC and BCC treated with surgical and radiation therapy, During clinic, he was found to have a large tumor in the lateral canthus of the left eye. Patient was referred to dermatology, biopsy evealed BCC. Tumor grew rapidly, further invading the eye within a few weeks. Given the proximity to visual organs; ENT, Ophthalmology, Dermatology, and Transplant team decided to treat the BCC non-surgically with Vismodegib. Patient achieved complete remission in 6 months of treatment with successful preservation of eyesight.

Discussion: Surgical excision is considered first line therapy in BCC. Patients with periocular BCC can place visual organs at risk with surgical and/or radiotherapy. Vismedogib is indicated for metastatic BCC or locally advanced BCC that has recurred following surgery. Vismedogib binds and inhibits the smoothened receptor, leading to hedgehog signaling pathway inhibition and decreased tumor cell proliferation. Recent studies assessing Vismodegib benefit recruited patients with median tumor size of 22mm. Our case highlights that Vismedogib is efficacious in preserving essential visual structures and eyesight even in much larger tumor burden; 55mm. In conclusion, Vismodegib is now emerging in critical management of large and fast growing BCC affecting vital facial structures, especially in RTR on long term IS meds.

PO2226

Psychosis as a Neurotoxic Manifestation of Extended-Release Tacrolimus

Shannon Lyons,[1] Scott W. Harberts,[1] Alexander C. Wiseman,[2] Stanley C. Sicher.[1] *[1]Parkview Medical Center, Pueblo, CO; [2]University of Colorado, Denver, CO.*

Introduction: Tacrolimus is a calcineurin inhibitor used in renal transplant to reduce the risk of rejection. Common side effects include infection, nephrotoxicity, and neurotoxicity (7). The neurotoxic effects can manifest as psychosis, paranoia, and bipolar mania (4, 2). The unpredictable nature of tacrolimus pharmacokinetics has led to the development of extended-release tacrolimus such as Envarsus XR (8, 9, 12). While data is lacking, Envarsus XR is thought to have a lower incidence of neurotoxic side-effects (10, 1, 11). To our knowledge, there are no recorded cases in the literature of psychosis related to Envarsus XR (3,6). We present a case of acute paranoia secondary to Envarsus XR.

Case Description: Ms. H is a 62 year old woman who underwent allogenic renal transplant and was placed on immediate-release tacrolimus 0.5 mg twice daily. Due to high tacrolimus levels (average 9.6 ng/dl) she was switched to Envarsus XR 0.75 mg daily and subsequently reported new onset emotional disturbance. She was initially treated with fluoxetine then switched to citalopram without relief. She then developed paranoid ideation and refused to sleep. The patient and family felt this behavior correlated with starting Envarsus XR. This was discussed with her transplant team and Envarsus XR was continued as her tacrolimus levels were within goal (average 5.3 ng/dl). Her paranoia worsened and she was seen by psychiatry and placed on risperidone 2 mg daily. She continued to experience paranoid delusions and behavioral disturbance. She was then switched from Envarsus XR back to immediate-release tacrolimus and had complete resolution of symptoms. Her current average tacrolimus level is 5.05 ng/dl.

Discussion: This case presents a unique instance of extended-release tacrolimus induced psychosis. While immediate-release tacrolimus is well known to cause neurotoxicity (5, 13), extended release is generally felt to be safer (12, 9). This case illustrates that while extended-release Tacrolimus formulations may have a reduced incidence of neurological side effects, they are not devoid of them. The SIMPLE trial is currently ongoing and its data may shed more light on tacrolimus induced neurotoxicity (10). Regardless of the outcome of this research, the treatment for tacrolimus induced neurotoxicity should always be to decrease the dose or withdraw the medication (14).

PO2227

Deep Learning Identifies Pathological Abnormalities Predictive of Graft Loss in Kidney Transplant Biopsies

Zhengzi Yi,[1] Fadi E. Salem,[1] Madhav C. Menon,[1,2] Caixia Xi,[1] Sebastian O. Hultin,[3] Mohamed Rizwan Haroon Al Rasheed,[1] Li Li,[1] Zeguo Sun,[1] Chengguo Wei,[1] Weiqing Huang,[1] Samuel Fredericks,[1] Khadija Banu,[1,2] Germaine Wong,[3] Samira S. Farouk,[1] Paolo Cravedi,[1] Meena Shingde,[3] Philip J. O'Connell,[3] Robert B. Colvin,[4] Barbara T. Murphy,[1] Weijia Zhang.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University School of Medicine, New Haven, CT; [3]University of Sydney, Sydney, NSW, Australia; [4]Massachusetts General Hospital, Boston, MA.*

Background: Interstitial fibrosis, tubular atrophy, and inflammation are major contributors to renal allograft failure. Here we seek an objective, quantitative pathological assessment of these lesions to improve predictive utility.

Methods: We constructed a deep-learning-based pipeline recognizing normal vs. abnormal kidney tissue compartments and mononuclear leukocyte (MNL) infiltrates from Periodic acid-Schiff (PAS) stained slides of transplant biopsies (training: n=60, testing: n=33) that quantified pathological lesions specific for interstitium, tubules and MNL infiltration. The pipeline was applied to 789 whole slide images (WSI) from baseline (n=478, pre-implantation) and 12-month post-transplant (n=311) protocol biopsies in two independent cohorts (GoCAR: 404 patients, AUSCAD: 212 patients) of transplant recipients to correlate composite lesion features with graft loss.

Results: Our model accurately recognized kidney tissue compartments and MNLs. The digital features significantly correlated with Banff scores, but were more sensitive to subtle pathological changes below the thresholds in Banff scores. The Interstitial and Tubular Abnormality Score (ITAS) in baseline samples was highly predictive of 1-year graft loss (p=2.8e-05), while a Composite Damage Score (CDS) in 12-month post-transplant protocol biopsies predicted later graft loss (p=7.3e-05). ITAS and CDS outperformed Banff score or clinical predictors with superior graft loss prediction accuracy. High/intermediate risk groups stratified by ITAS or CDS also demonstrated significantly higher incidence of eGFR decline and subsequent graft damage.

Conclusions: This deep-learning approach accurately detected and quantified pathological lesions from baseline or post-transplant biopsies, and demonstrated superior ability for prediction of post-transplant graft loss with potential application as a prevention, risk stratification or monitoring tool.

PO2228

Dual Diagnosis of Thrombotic Thrombocytopenic Purpura and Atypical Hemolytic Uremic Syndrome in Pregnancy

Gabriela Dellapiana, Savannah Gonzales, Richard M. Burwick. *Cedars-Sinai Medical Center, Los Angeles, CA.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) and atypical hemolytic uremic syndrome (aHUS) are thrombotic microangiopathy (TMA) disorders which may initially occur in pregnancy. TTP, caused by severe ADAMTS13 deficiency, is treated with plasma exchange (PEX); whereas aHUS, caused by uncontrolled complement activation, is treated with complement inhibition (e.g., eculizumab). Because TTP and aHUS have different causes, the term TTP-HUS is no longer used. However, we describe a patient diagnosed and treated for both TTP and aHUS in pregnancy.

Case Description: A 38-year-old female at 9 weeks' gestation presented with hematuria. Labs revealed severe thrombocytopenia (platelets 5 k/μl), hemolytic anemia, and acute kidney injury. TTP was suspected, so PEX was initiated, but she did not fully respond (Fig 1). ADAMTS13 activity was low (11%) but with negative inhibitor, arguing against acquired TTP; genetic testing ruled out congenital TTP. Complement-mediated TMA (aHUS) was considered given low C3, C4, and proteinuria; Lupus and Anti-Phospholipid Syndrome were ruled out. Complement genetic testing revealed a rare C3 variant and polymorphisms in CFH and MCP, which are enriched in aHUS patients. After multidisciplinary review, the diagnosis of aHUS was made. PEX was stopped, and eculizumab was started with good response. At 35 weeks' gestation she presented with hypertension and petechiae, and labs showed recurrence of hemolytic anemia and thrombocytopenia (platelets 7 k/μl). She had cesarean delivery, after which PEX was initiated given renewed concern for TTP. ADAMTS13 activity was <5% with positive inhibitory antibody, now confirming acquired TTP. Eculizumab was stopped, and she received 14 cycles of PEX, prednisone, and rituximab for refractory TTP (Fig 1). Treatments were stopped after 6 weeks, and she remains in remission after 1 year.

Discussion: This case illustrates dual diagnosis of TTP and aHUS in pregnancy. Key points: a) Rarely, TTP and aHUS may coexist; b) ADAMTS13 activity and complement genetic testing may help identify TMA etiology; and c) Treatment of TMA in pregnancy with PEX or complement inhibition should be clinically-based.

Clinical course

PO2229

Pregnancy-Associated Atypical Hemolytic Uremic Syndrome in the Setting of a Rare THBD Mutation and Successful Treatment with Eculizumab

Nicole Wyatt, Katisha T. Vance, Erin Townsley, Phillip Madonia. *Brookwood Baptist Health, Birmingham, AL.*

Introduction: Pregnancy-associated atypical hemolytic uremic syndrome (PaHUS) is a rare but fatal thrombotic microangiopathy that results from uncontrolled complement activation during the peripartum and postpartum periods. Underlying complement gene mutations are found in a majority of cases. THBD, the gene responsible for encoding thrombomodulin, is a known risk variant associated with PaHUS. We present a case of PaHUS complicated by intrauterine fetal demise and acute renal failure in the setting of a rare THBD gene variance which was successfully treated with the terminal complement inhibitor eculizumab.

Case Description: 20-year G1P0 female presented at 30w4d with severe abdominal pain and diffuse vaginal bleeding. An emergent cesarian section revealed a placental abruption with intrauterine fetal demise. Hospital course was complicated by anuria with a maximum serum creatinine 8.43 mg/dL, hemoglobin 5.5 g/dL, platelets 15 x10^3/uL, lactate dehydrogenase 9051 U/L, and schistocytes seen on peripheral smear. She was initiated on renal replacement therapy, daily plasma exchange, and steroids. Despite this, she experienced persistent hemolysis, dialysis dependence, and worsening respiratory failure ultimately requiring intubation. ADAMTS13 activity was normal at 83%. Eculizumab was initiated, and after one week, hematologic parameters normalized with evidence of renal recovery. Outpatient genetic testing revealed a rare variant in THBD. Six months following discharge, the patient remains in remission on maintenance eculizumab.

Discussion: The diagnosis of PaHUS is very challenging; however, prompt recognition and subsequent genetic testing for complement variants are crucial given association with more severe outcomes, progression to ESRD, and increased risk of relapse. Pathologic variances in THBD account for 5% of aHUS cases and have been associated with earlier onset and higher mortality, however, risk of disease relapse with mutations in this gene is unknown. Although eculizumab has been shown effective in PaHUS, there is little data on treatment duration and recurrence rate with therapy in subsequent pregnancies. Further expansion of genetic testing is required to enhance our knowledge of all PaHUS susceptibility factors and improve management of patients similar to the presented case.

PO2230

Efficacy of Eculizumab Therapy in Delayed-Diagnosed, Hemodialysis-Dependent, Pregnancy-Triggered, Complement-Mediated Thrombotic Microangiopathy

Gaoyuan Huang, Nathan A. Arister, Ashrei Bayewitz, Adel S. El-Hennawy, Chibuzo C. Okoye, Elena Frolova. *New York City Health and Hospitals Coney Island, Brooklyn, NY.*

Introduction: Pregnancy associated atypical hemolitic uremic syndrome (p-aHUS) is provoked by pregnancy and affects 1/25,000 pregnancies in the general population. The delivery is vital for halting the disease process. The course of complement-mediated thrombotic microangiopathy(C-TMA) is not affected by delivery, but condition improves with anti-complement therapy. We are presenting a rare case of delayed diagnosed, pregnancy provoked C-TMA with significant improvement in blood pressure, stabilization of anemia, and resolution of thrombocytopenia after treatment with Eculizumab.

Case Description: A 25-year-old Hispanic woman with history of CKD stage IIIB presented with syncope. She developed renal failure, required hemodialysis(HD) and HTN during her first pregnancy. During postpartum, HD was stopped and HTN resolved. Two years later she was admitted with worsened renal function, severe anemia (Hb 4 g/dl), thrombocytopenia (36K/ul), and poor controlled HTN, needing 6 different classes of drugs to control her blood pressure. Blood smear showed schistocytes. Our extensive work up ruled out: TTP, HUS, DIC, lupus, scleroderma, and other disorders. Complement 3 was low. Renal ultrasound excluded post-renal obstruction and renal artery stenosis, but showed echogenic kidneys. Given echogenic kidneys and increased bleeding risk, renal biopsy was not performed. The diagnosis of C-TMA was established. Regular HD was resumed. She was started on Eculizumab and with maintenance treatment her HTN became well controlled with only two medications.

Discussion: Timely diagnosis and management are the key points to improve C-TMA prognosis. It may be a difficult diagnosis and mimic eclampsia, HELLP syndrome, or p-aHUS. Although it is related to inherited defects of complement alternative pathway or the proteins that regulate it, lack of linked gene mutations cannot exclude C-TMA. In this patient, the diagnosis of C-TMA was not made until two years after onset. Our case report showed that even though Eculizumab cannot completely reverse the renal injury at the late stage of C-TMA, it may still improve the blood pressure control, normalize platelets, help anemia, and prevent further injury.

parameters	before Eculizumab	Eculizumab induction dose (900mg/week)				Eculizumab maintenance dose (1200mg/ every 2 weeks)

Therapeutic Plasma Exchange Improved Pregnancy Outcomes in a Patient with Triple Positive Anti-Phospholipid Antibody Syndrome

Ahlim Al sanani, Noah J. Poznanski. Marshall University Joan C. Edwards School of Medicine- Department of Internal Medicine *Marshall University Joan C Edwards School of Medicine, Huntington, WV.*

Introduction: Antiphospholipid syndrome (APS) is an autoimmune disorder characterized by antibodies directed at platelet, monocyte, endothelial cell, and trophoblast moieties potentially causing venous and arterial thromboses. The placental vasculature is particularly vulnerable to these antibodies resulting in a marked increased risk of fetal growth restriction, placental infarction, abruption, stillbirth, and preterm severe preeclampsia. APS is diagnosed by clinical criteria in conjunction with laboratory findings, and the circulating anti-phospholipid antibodies commonly tested are lupus anticoagulant, anti-cardiolipin, and anti-beta-2-glycoprotein-1. The simultaneous presence of all three antibodies is associated with the highest risk of thrombotic complications in APS.

Case Description: A 29-year-old nulligravida with medical history was significant for APS on lifelong coumadin. Her APS labs at the time of preconception visit showed elevated lupus anticoagulant ratio, anticardiolipin and anti-beta2-glycoprotein-1antibodies (Triple- positive antibodies). Medications included twice daily LMWH 60 mg and hydroxychloroquine 200 mg. Fetal anatomic survey at 20 weeks demonstrated normal fetal growth, however, by 21 weeks 6 days ultrasound showed absent-end diastolic flow of the umbilical artery Doppler waveform. She was admitted to the hospital. A pre-eclampsia workup was completed due to hypertension and new onset proteinuria. LDA daily, pravastatin 20mg was added. Due to the diagnosis of preeclampsia with severe features, the decision was made to treat with therapeutic plasma exchange.

Discussion: High-risk obstetric APS profiles are linked to specific serological markers such as triple antibody positivity, clinical features such as a history of thrombosis, and the presence of pregnancies result in a liveborn infant, with that rate dropping to 30% in patients who are triple systemic autoimmune diseases. Therapeutic plasma exchange every 48 hours successfully prolonged the pregnancy for 11 weeks, resulting in an optimal pregnancy outcome for both mother and infant given the initial dire clinical situation at a pre-viable gestation. The rationale for TPE every 48 hours was based on the experience in plasmapheresis use in Catastrophic Antiphospholipid Syndrome (CAPS)

PO2232

Lupus Nephritis Kidney Biopsy Characteristics and Preterm Birth

Monica L. Reynolds, Caroline J. Poulton, Lauren N. Blazek, Keisha L. Gibson, Vimal K. Derebail. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Lupus nephritis (LN) in pregnancy is associated with high rates of preterm birth (PTB). Hypocomplementemia, elevated creatinine, proteinuria and hypertension serve as risk factors. Outside of pregnancy, class IV LN and interstitial fibrosis at initial biopsy associate with progressive disease. We performed a retrospective chart review to assess if timing of kidney biopsy and histologic features increased PTB.

Methods: We included women with LN enrolled in the Glomerular Disease Collaborative Network registry who delivered at University of North Carolina (UNC) Hospital from 2001-2019. Delivery data came from the UNC perinatal database. Fishers exact test assessed biopsy characteristics and PTB (< 37 weeks).

Results: There were 36 deliveries in 32 women. Figure 1 describes the cohort. Among preconception biopsies (n=25), pregnancy occurring ≤ 24m after biopsy was more likely to result in PTB than if biopsy was performed > 24m prior to conception (82% vs 29% p =0.02). A UPCR > 0.5 mg/g in the first trimester was also associated with PTB (81% vs 36% p=0.04). PTB occurred in 69% with proliferative LN vs 50% without (ie primary diagnosis class II or V), p=0.44. Class IV LN was not significantly associated with PTB; neither was the presence of crescents (n=21/36), activity ≥ 6 (n=16/25), chronicity ≥ 3 (n=12/27), or more than mild interstitial sclerosis (n=6/33).

Conclusions: Biopsy occurring within 2 years of conception and first trimester proteinuria were significantly associated with PTB. While this presumes greater LN activity, no specific biopsy characteristic impacted the outcome. This data may aid in preconception counseling for optimal timing of conception. Calcineurin inhibitors were not used in the first trimester in this cohort; their antiproteinuric qualities and effect on PTB requires evaluation.

Second Trimester eGFR and Adverse Pregnancy Outcomes in Women with Systemic Lupus Erythematosus

Anika Lucas, Amanda Eudy, Christina M. Wyatt, Megan Clowse. *Duke University, Durham, NC.*

Background: Adverse pregnancy outcomes are more common in women with SLE.2nd trimester eGFR was shown to predict adverse pregnancy outcomes in a general population cohort. We sought to evaluate 2nd trimester eGFR as a predictor of adverse pregnancy outcomes in women with SLE.

Methods: We evaluated 684 women with SLE(22% of Black race)who received care in North America and Europe from 1995-2017.2nd trimester eGFR was stratified based on studies demonstrating women with an eGFR 120-135 ml/min/1.73m^2 had the lowest odds of adverse outcomes. Outcomes of interest included preterm birth, preeclampsia, fetal loss and poor pregnancy outcome(composite outcome). 2nd trimester GFR was computed using the CKD Epi equation without adjustment for race. In sensitivity analysis, 2nd trimester GFR computed using the conventional race-based equation. Polynomial and logistic regression models used to evaluate 2nd trimester eGFR and adverse outcomes.

Results: Very low eGFR(eGFR<90ml/min/1.73m^2)and very high eGFR (>135ml/min/1.73m^2)were associated with higher adverse outcomes. In univariate and multivariable regression models adjusted for age, race, and SLE disease activity, very low eGFR was associated with preterm birth, preeclampsia, fetal loss and poor pregnancy outcome. Very high eGFR was associated with poor pregnancy outcome and preterm birth. In sensitivity analyses using race based GFR estimates, very low eGFR remained associated with adverse outcomes observed. No association was observed between very high eGFR and adverse outcomes.

Conclusions: We found a U-shaped relationship between 2nd trimester eGFR and adverse pregnancy outcomes. Women with eGFR <90ml/min/1.73m^2 and >135ml/1.73m^2 had higher odds of adverse outcomes. 2nd trimester eGFR may be a helpful tool to identify women with SLE at greater risk for adverse outcome. Our results further suggest that kidney hyperfiltration may become pathologic during pregnancy. There were notable differences using non-race based and race-based GFR estimating equations. These differences may have clinical implications when utilizing GFR estimating equations to predict health outcomes.

Funding: Private Foundation Support

Association of 2nd Trimester eGFR and Adverse Outcomes

eGFR strata	Preterm Birth Unadjusted OR (95%CI)	Preeclampsia Unadjusted OR (95%CI)	Fetal Loss Unadjusted OR (95%CI)	Poor Pregnancy Outcome Unadjusted OR (95%CI)
Very Low eGFR<90	3.16 (1.63, 6.12)	2.91 (1.32, 6.37)	5.82 (2.28, 14.86)	3.79 (2.00, 7.19)

Comparison of Clinical Features of Pregnant and Non-Pregnant Women with Primary Hyperoxaluria

Jing Miao,[1] Ramila A. Mehta,[2] Suzanne M. Norby,[1] Barbara M. Seide,[1] Genia Andrist,[1] Dawn S. Milliner,[3] John C. Lieske,[4,1] Andrea G. Kattah.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Division of Biostatistics, Rochester, MN; [3]Mayo Clinic Division of Pediatric Nephrology, Rochester, MN; [4]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN.*

Background: Primary hyperoxaluria (PH) is a rare monogenic disease characterized by oxalate overproduction in the liver, hyperoxaluria, and risk of kidney stones and chronic kidney disease. Data about the effects of pregnancy on women with PH are lacking. We aimed to compare clinical features and risk of incident kidney failure in women with PH with and without pregnancy.

Methods: Women with PH were identified from the Rare Kidney Stone Consortium registry, and pregnancy was identified by phone interview and medical record review. Kidney survival and risk of time-dependent kidney failure were estimated using the Kaplan-Meier method and adjusted proportional hazard Cox's model.

Results: We identified 47 women with PH and a history of pregnancy and 39 women without pregnancy. PH was diagnosed later in women with pregnancy vs. women without pregnancy (median age 32.4 vs. 13.4 years, p<0.001). Other clinical characteristics such as PH type, eGFR and 24-hour urine oxalate excretion ($U_{[ox]}$) at PH diagnosis did not differ between the 2 groups. **Fig 1A** shows the time course of the PH diagnosis, pregnancy and kidney failure in 29 women with known delivery date. In women with pregnancy versus non-pregnancy, the hazard ratio for incident kidney failure was 0.81 (95% CI 0.25-2.6, p=0.73) when adjusted for PH type, age, and eGFR and $U_{[ox]}$ at PH diagnosis. Among patients with PH1 who did not have kidney failure by the time of the 1st pregnancy (n=20), kidney survival estimates at 10, 20, and 30 years after delivery were 79%, 60%, and 45%, respectively (**Fig 1B**).

Conclusions: These results suggest that pregnancy did not greatly impact renal prognosis in women with PH.

PO2235

Narrowing Communication Gaps to Optimize Patient-Centered Pregnancy Counseling for Women with CKD

Andrea L. Oliverio, Maryn Lewallen, Kassandra Weber, Sarah Hawley, Julie A. Wright Nunes. *University of Michigan, Ann Arbor, MI.*

Background: Women with chronic kidney disease (CKD) face unique pregnancy decision-making challenges. Although there is an increased risk of adverse pregnancy outcomes in women with CKD, many women report strong pregnancy desires. There is little evidence on how to support pregnancy communication and decision-making needs in women with CKD.

Methods: We performed semi-structured interviews with women 18-45 years of age who have CKD stages I-V (n=30), and their practicing nephrologists (n=12) at one academic medical center. The average age of patients was mean(SD) 32.4(6.9) years; 50% already had children. 50% (n=15) identified as white, 26.7% (n=8) as Black, 13.3% (n=4) as Hispanic, 6.7% (n=2) as Asian, and one declined to answer. CKD etiologies included lupus nephritis (n=7, 23.3%), other nephrotic/nephritic syndromes (n=9, 30%), diabetes (n=4, 13%), hypertension (n=3, 10%), other (n=4, 13%), and unknown (n=3, 10%). Interview questions probed patients about counseling experiences and reproductive health in CKD, approaches to pregnancy decision-making, barriers and facilitators to effective counseling, and desires for future support. A codebook was iteratively developed, with double coding of transcripts and discrepancies resolved via consensus.

Results: Most women with CKD preferred their nephrologist introduce the concept of reproductive planning to elicit their values in care and reduce barriers to pregnancy counseling. Specific information about individual pregnancy risks and risks to potential offspring were desired. Women with strong reproductive intentions more often sought pregnancy information and indicated a higher risk tolerance especially when compared to physicians. Among women considering pregnancy, discussion of risks alone without discussion of strategies to manage or mitigate risks was perceived as alienating. Nephrology providers acknowledged importance of patient pregnancy desires, however, prioritized decision-making communication about absolute numerical risks to patients, and expressed high risk-aversion.

Conclusions: Patient-provider pregnancy communication and decision-making are critical for women who have CKD. Further research is needed to ensure nephrologists have tools to support pregnancy decision-making that incorporates patients' needs, values and goals in care.

PO2236

Maternal Hypertension and Hypertensive Disorders of Pregnancy Are Associated with Increased Risk of Hypertension in Offspring

Virginia Dines, Andrea G. Kattah, Amy L. Weaver, Alanna Chamberlain, Suzette J. Bielinski, Michelle M. Mielke, Vesna D. Garovic. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Hypertensive disorders of pregnancy (HDP) have significant effects on perinatal outcomes for offspring. Although there is increasing evidence of adverse effects of HDP exposure on long-term health outcomes in offspring, the impact of maternal hypertension beyond HDP is limited.

Methods: We performed a population-based cohort study of 7544 women with 8755 pregnancies from 1976 to 1982. HDP during each offspring's birth was identified using a previously validated algorithm. Diagnosis of hypertension in mothers (before or after the pregnancy) and in offspring was determined using diagnostic codes through 2019. Associations were evaluated using Cox proportional hazards models adjusted for maternal age at delivery, child's sex, fetal weight percentile and gestational age.

Results: Among offspring, the cumulative incidence of hypertension was 5.7% (95%CI 5.1-6.4%) by the offspring's age of 30, 9.5% (95% CI 8.7-10.3%) by age 35, and 16.2% (95% CI 15.0-17.5%) by age 40. HDP exposure at birth (HR 1.49, 95%CI 1.19-1.87) and maternal hypertension as a time-dependent covariate (HR 1.73, 95%CI 1.48-2.02) were associated with an increased risk of hypertension in offspring. Maternal hypertension was associated with a 1.6-fold (95%CI 1.37-1.92) increased risk of hypertension among offspring without HDP exposure compared to a 2.3-fold (95%CI 1.40-3.78) increased risk among offspring with HDP exposure; however this difference was not significant (p-interaction=0.18). We also performed a landmark analysis to evaluate maternal hypertension prior to age 55 as a static covariate. Compared to offspring without HDP exposure and without maternal hypertension prior to age 55, HDP exposure was not associated with risk of hypertension in offspring (HR 0.58, 95%CI 0.27-1.22) whereas maternal hypertension (HR 1.65, 95%CI 1.34-2.03) or the presence of both (HR 2.44, 95%CI 1.59-3.15) conferred an increased risk.

Conclusions: HDP exposure at birth and maternal hypertension are independently associated with an increased risk of hypertension in offspring. Our results suggest the possibility of an interaction effect for offspring exposed to HDP at birth and maternal hypertension, however this requires further research.

Complement Genetic Variants and Hypertensive Diseases of Pregnancy

Richard M. Burwick,[1] Shravya Govindappagari,[3] Gabriela Dellapiana,[1] Sarah Smithson,[1] Anuja Java.[2] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Washington University in St Louis, St Louis, MO; [3]Loma Linda University Medical Center, Loma Linda, CA.*

Background: Complement genetic variants are associated with thrombotic microangiopathy (TMA). Atypical hemolytic uremic syndrome (aHUS) is a classic complement-mediated TMA characterized by hemolytic anemia, thrombocytopenia and acute kidney injury. Clinical features of aHUS resemble those of preeclampsia and HELLP (Hemolysis, Elevated Liver Enzymes, Low Platelets) syndrome. Therefore, we sought to determine if complement genetic variants also predispose to these hypertensive diseases of pregnancy.

Methods: We conducted genetic testing for 20 complement genes in a cohort of 15 women with HELLP syndrome (Fig 1). Patients were evaluated between April 2018 and September 2019 at our institution; those with a diagnosis of aHUS were excluded. Variants were classified on the basis of clinical significance, according to published American College of Medical Genetics guidelines. Based on these standards, variants are classified as, Level 1: pathogenic; Level 2: likely pathogenic; Level 3: variant of uncertain significance (VUS); Level 4: likely benign; Level 5: benign.

Results: At the time of index pregnancy with HELLP syndrome, patients were 36 ± 5 years old; twelve of 15 (80%) were nulliparous, and delivery occurred at 34 ± 5 weeks gestation. Five of 15 patients (33%) had a pathogenic variant, 9 (60%) had a variant of uncertain significance (VUS), and one (7%) had a benign variant. Homozygous deletion of CFHR1-CFHR3 was detected in four patients. Fifteen unique missense variants were detected in various genes, including C3, CFD, CFH, CFHR2, CFHR5, CFI, MASP2, and PLG. One patient with a pathogenic variant developed recurrent severe preeclampsia and one patient with a VUS developed recurrent HELLP syndrome.

Conclusions: These results reveal that overactivity of the complement system, due to an underlying genetic variant, may define a subset of patients that develop preeclampsia and HELLP syndrome. Long term follow-up of these patients is needed to evaluate the risk for future cardiovascular and kidney disease.

Pregnancy Outcomes in C3 Glomerulopathy

Lauren O. Fergus,[1] Monica D. Hall,[1,2] Yuzhou Zhang,[1] Richard J. Smith,[1,2] Carla M. Nester.[1,2] *[1]University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: C3 Glomerulopathy (C3G) is a glomerular disease characterized by underlying dysregulation of the alternative complement pathway. Most patients approach ESKD within ten years of diagnosis. Recurrence in renal transplants is high. Little is known of the role of pregnancy in the natural history of C3G or whether a coincident diagnosis affects comorbidities or maternal-fetal outcomes.

Methods: Female subjects in the University of Iowa's C3G Natural History Study who met consensus biopsy criteria (n=76) and had at least one pregnancy (n=17) were included in the cohort. Clinical and lab data, including genetic and/or acquired drivers of disease studies were assessed. Standard peri-pregnancy outcomes were considered.

Results: 44 pregnancies and 34 deliveries were identified. Non-live birth pregnancy outcomes included eight miscarriages, one ectopic pregnancy and one elective abortion. The presumed driver of disease was known for eight patients; gene variants of unknown significance (n=3), nephritic factors (n=4), and a monoclonal protein (n=1). Six patients presented first C3G symptoms during pregnancy. Preeclampsia developed in 11. Six infants were premature. Five were born with low birthweight. One infant suffered a stroke. One infant presented with AKI. [Maternal nephritic factor was identified in neonatal sera.]

Conclusions: We provide a summary of maternal-fetal outcomes in C3G mothers. Our data supports an increased risk of preeclampsia in C3G mothers as compared to healthy mothers. There was no excess risk of miscarriage, cesarean section, ectopic pregnancy, prematurity, or low birth weight. This data indicates a relatively higher risk of preeclampsia and lower risk of cesarean section compared to women with IgA Nephropathy. A similar risk of miscarriage, prematurity, and low birth weight as other glomerular diseases was evident. Our data supports a reasonable maternal-fetal risk profile for C3G patients.

Maternal Health in Autosomal Dominant Tubulointerstitial Kidney Disease

Isai G. Bowline,[1] Anthony J. Bleyer,[1,2] Kendrah O. Kidd,[1,2] Adrienne H. Williams,[1] Dervla M. Connaughton,[3] Victoria C. Robins,[1] Abbigail Taylor,[1] Lauren Martin,[1] Alice Kim,[1] Carl D. Langefeld,[1] Martina Zivna,[2] Stanislav Kmoch.[2,1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; [3]London Health Sciences Centre, London, ON, Canada.*

Background: Autosomal dominant tubulointerstitial kidney disease due to *MUC1* mutations (ADTKD-*MUC1*) and *UMOD* mutations (ADTKD-*UMOD*) are becoming increasingly recognized as causes of chronic kidney disease (CKD). Genetic testing allows women to determine if they are affected with these conditions, and data on the outcomes in pregnancy in ADTKD would be of great interest to them as they prepare for future pregnancies.

Methods: We surveyed women with ADTKD and genetically unaffected family regarding past pregnancy outcomes. We also analyzed survival to end-stage kidney disease (ESKD) according to number of pregnancies.

Results: We received completed standardized questionnaires surveys from 52 women with ADTKD-*MUC1* (113 pregnancies), 74 women with ADTKD-*UMOD* (136 pregnancies), and 35 genetically unaffected women (64 pregnancies). At the time of pregnancy, only 16.5% of genetically affected women were aware that they had ADTKD. Results are summarized in Table 1. There was a nonstatistical increase in HTN and hospitalization for HTN. 10% of births to affected mothers were premature vs. 0% in unaffecteds (p<0.01); 12% of babies required a NICU stay vs. 6% in unaffecteds (p=0.06), but child outcomes were good. Survival analysis showed no statistical differences in age to ESRD based on number of pregnancies for affected women.

Conclusions: Patients with ADTKD had an increased prevalence of hypertension, anemia, and early delivery than controls, but overall pregnancy outcomes were good for mother and child. More information is needed on changes in glomerular filtration rate with pregnancy in ADTKD.

Funding: Private Foundation Support, Government Support - Non-U.S.

Effect of Reproductive History on Kidney Structure and Function in Women

Andrea G. Kattah,[1] Aidan F. Mullan,[1] Vesna D. Garovic,[1] Maxwell L. Smith,[2] Aleksandar Denic,[1] Mark D. Stegall,[1] Andrew D. Rule.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic, Scottsdale, AZ.*

Background: Varying estrogen levels from menarche to menopause and physiological changes of pregnancy may impact kidney health in women.

Methods: Female kidney donors from 2000 to 2017 were sent a survey on reproductive health, including menarche, pregnancy, and menopause. At the time of donation, donors had a medical evaluation, measured GFR, 24h urine albumin, CT angiography of kidneys, and a kidney biopsy. Kidney volumes were calculated from CT images. Non-sclerosed and globally sclerosed glomeruli counts and % interstitial fibrosis/tubular atrophy (IFTA) were assessed via kidney biopsy. Kidney function and structural findings at the time of donation were assessed by differences in reproductive factors prior to donation adjusting for age.

Results: There were 673 women studied with a mean (SD) age at donation of 47.4 (11.4) and 74% had at least one pre-donation birth. As compared to non-parous women, parous women had a higher total cortical volume (6.1%, p=0.009) and medullary volume (6.7%, p=0.038). However, among parous women, additional parity was not associated with further increases in kidney volumes. Among the 218 post-menopausal women, each year since menopause was associated with a higher likelihood of IFTA > 0% on biopsy independent of age (OR=1.052, p=0.027). With each 5-year increase in reproductive lifespan (years from menarche to menopause), there was a lower likelihood of having IFTA > 0% (OR=0.81, p=0.048). We did not find any significant association between past reproductive factors on GFR, urine albumin, glomerulosclerosis, or nephron number at the time of donation.

Conclusions: Past pregnancy is associated with larger kidneys among healthy women suggesting that the enlargement of kidneys with pregnancy does not fully resolve after delivery. Among healthy post-menopausal women, longer duration of menopause and shorter reproductive lifespan associated with detectable IFTA on kidney biopsy consistent with a protective effect of estrogen on preventing subclinical kidney injury.

Kidney Disease Prevalence in Transgender Individuals

Hannah Eckenrode, Orlando M. Gutierrez, Gunars Osis, Anupam Agarwal, Lisa M. Curtis. *The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.*

Background: Kidney disease in the transgender population is understudied which precludes the ability to derive appropriate care guidelines for promoting kidney health. The term transgender includes individuals for whom their assigned sex at birth doesn't align with their gender identity. Transgender individuals often choose gender-affirming hormone therapy (GAHT) to achieve greater alignment. The impact of this necessary treatment on their kidney health has not been studied.

Methods: We performed a cross-sectional study of 360 transgender individuals, using medical records from 2009-2019. Diagnosis codes were used to identify individuals with acute kidney injury (AKI) and chronic kidney disease (CKD), and comparisons were performed between the groups.

Results: The mean age of the population was 42 (SEM 0.91) and 40% were of black race. Black individuals made up a greater proportion of the transfeminine population who received GAHT but a lower proportion of transmasculine individuals who received GAHT. The transfeminine population receiving GAHT had a higher proportion of non-white/non-black populations than in the overall transfeminine population. There was a statistically significant difference in the prevalence of AKI in transfeminine individuals who received GAHT as compared to transfeminine individuals who did not receive exogenous GAHT; no such difference was found with CKD. In the transmasculine population, there was no statistically significant association of exposure to GAHT with prevalence of AKI or CKD. Transfeminine individuals who received GAHT showed a statistically lower prevalence of CKD than transmasculine individuals.

Conclusions: This single-center study of prevalence of kidney disease in the transgender patients demonstrates significant differences in kidney disease conditions in those who did vs. did not use GAHT. These studies highlight the need for further research to define the health and disease manifestations seen in the transgender population.

Dietary Inflammatory Potential and the Risk of Incident ESKD in the Women's Health Initiative

Tanya S. Johns,[1,2] Yasmin Mossavar-Rahmani,[1] James R. Hebert,[4] Nora Franceschini,[3] Michal L. Melamed.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY; [3]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [4]University of South Carolina, Columbia, SC.*

Background: Inflammation is implicated in the pathogenesis and progression of chronic kidney disease (CKD). Diet is an important modulator of chronic inflammation, and possibly kidney health. We evaluated the association of diet-associated inflammation with risk of incident end-stage kidney disease (ESKD) in the Women's Health Initiative (WHI) study.

Methods: Participants enrolled between 1993-1998 in the Observational Study and Dietary Modification Trial of the WHI with completed food frequency questionnaires (FFQs), Medicare enrollment data, and serum creatinine (sCr) measurements were included in our study. Dietary inflammatory potential was assessed from FFQs using the dietary inflammatory index (DII®). The index has been previously validated in the WHI. Medicare claims data were used to ascertain ESKD status. Analyses used DII® scores adjusted for energy-intake (E-DII®), which were categorized into quartiles (Q): scores in Q1 (reference group) having the lowest dietary inflammatory potential and Q4 being the most pro-inflammatory. We performed multivariable Cox proportional hazards models adjusted for important covariates of interest to compare dietary quartiles for risk of incident ESKD. Participants were censored at the time of study withdrawal, loss-to-follow-up, or death.

Results: Of the 15,722 women included in our study, the mean age was 64.2 years (standard deviation 7.01); 35% self-identified as African American, 12% as Hispanic/Latinx, and 50% as White; 40% had hypertension and 9% had diabetes mellitus at baseline. The mean baseline sCr and estimated glomerular filtration rate were 0.74 mg/dL and 89 ml/min/1.73m2, respectively. African American and Hispanic women compared to White women (30% vs 19%) were more likely to report consuming diets with scores in Q4. Over mean follow-up of 11.5 years, 515 women developed ESKD. Women with dietary patterns in Q4 compared to those in Q1 had a 20% higher risk of developing ESKD (hazard ratio 1.20 [95% confidence interval 1.05 – 1.38]; P=0.02) after adjusting for age, race/ ethnicity, comorbidities, body mass index, education, medications, trial vs cohort study status, and region.

Conclusions: A pro-inflammatory dietary pattern is associated with a higher risk of new-onset ESKD among Medicare-eligible post-menopausal women without baseline CKD.

Age-Stratified Sex Differences in the Risk of Cardiovascular Disease in Patients with CKD

Ester Oh, Zhiying You, Kristen L. Nowak, Anna Jovanovich. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: In the general population, females (vs. males) and younger individuals have a lower cardiovascular risk. However, little is known whether this age- and sex-specific risk pattern of cardiovascular disease (CVD) translates to individuals with chronic kidney disease (CKD). The purpose of this study was to examine if sex-specific risk of CVD differed across the age groups approximating premenopause (<45 y), perimenopause (45-54 y), and postmenopause (≥55 y) in patients with non-dialysis CKD who participated in the Chronic Renal Insufficiency Cohort (CRIC) observational study.

Methods: Cox proportional-hazards models were used to examine the age-stratified (<45 y, 45-54 y, and ≥55 y) association between sex and time to a composite of CVD events (heart failure, myocardial infarction, ischemic stroke, and peripheral artery disease). Secondary outcomes were individual components of the CVD composite.

Results: The median follow-up time was 7 years. In the entire cohort, males had a 32% higher risk of incident CVD (95% CI: 15-53%; Figure) than females after adjusting for age, race, clinic site, and traditional CVD risk factors, but not after further adjustment for markers of kidney disease (fully adjusted model). In the 45-54 y group, there was a 63% higher risk for CVD (95% CI: 4-157%) in males than females in the fully adjusted model. However, no sex-specific CVD risk was observed in the <45 y and ≥55 y groups in the fully adjusted model.

Conclusions: Our findings suggest that CKD may be a strong risk factor for CVD in females. Moreover, females may have a lower risk of CVD than males, particularly in the perimenopausal, but not premenopausal and postmenopausal ages.

Elevated Triglyceride-Glucose Index Predicts Renal Hyperfiltration in Young Adults

Donghwan Oh,[1,2] Kang Yoon Lee,[1,2] Eunji Yang,[1,2] Hyeong cheon Park,[1,2] Hoon Young Choi,[1,2] Jong Hyun Jhee.[1,2] *[1]Gangnam Severance Hospital, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Insulin resistance increases the risk for renal hyperfiltration (RHF), a proposed mechanism for kidney injury in diabetes. However, the association between triglyceride-glucose (TyG) index, a novel marker for insulin resistance, and RHF is not well established in young adults. This study aimed to investigate the association between TyG index and RHF in Korean young adults.

Methods: Data were retrieved from the Korean National Health and Nutrition Examination Surveys (2010-2019). A total of 15,764 participants aged 19~39 years with normal kidney function were enrolled. The participants were divided into tertile based on TyG index [ln(fasting triglyceride[mg/dL] x fasting glucose [mg/dL]/2)]. RHF was defined as eGFR with residuals >90th percentile after adjusting for sex, age, weight, and height.

Results: The mean age of the study participants was 30.4± 6.1 years, and 43.8% were male. The mean levels of TyG index were 7.70±0.25, 8.28±0.15 and 9.07±0.45 in tertile 1,2, and 3 respectively. The prevalence of RHF was significantly higher tertile (9.1%, 10.0%, and 10.9%, respectively, *P* for trend= 0.03). When the association between TyG index and the risk for RHF was evaluated by multivariable logistic regression analysis, the higher tertiles showed increased risks for RHF compared to lowest tertile. (odds ratio [OR],1.24; 95% confidence interval [CI],1.08-1.41, *P*=0.002 in tertile 2 and OR,1.64; 95%CI, 1.41-1.90, *P*<0.001 in tertile 3). This association was consistent when TyG index was treated as continuous variable (OR, 1.53; 95% CI, 1.39-1.38; *P*<0.001). When subgroup analysis stratified by hypertension or diabetes were performed, no significant interactions were found, suggesting TyG index is an independent predictor for RHF regardless of hypertension or diabetes.

Conclusions: This study showed that higher TyG index is associated with increased risk of RHF in Korean young adults with normal kidney function. Longitudinal studies are need to investigate whether elevated TyG index levels associated RHF is an early risk factor for kidney injury in young adults.

Screening for Early CKD in School Children in Kano, Nigeria

Abdullahi Mudi,[1] Aliyu Abdu,[1] Roy Zent.[2] VECD Fogarty Global Health Fellowship *[1]Bayero University College of Health Sciences, Kano, Nigeria; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: There has been an ongoing debate on the benefits of CKD screening in general especially as it relates to cost effectiveness and absolute relevance. However, screening for CKD in children will make a huge impact especially in low- and middle-income countries (LMIC) where treatment for End Stage CKD is not readily available due to high cost, shortage of skilled personnel and donor organs. This NIH/VECD Fogarty Funded research aimed to determine the burden of early CKD among school children in Kano, Nigeria.

Methods: The study screened 228 school children (5-15 years) within Kano metropolis for CKD from February 2020 to February 2021. Information of participants' socio-demographic profile and medical history was obtained through questioning. Participants' height, weight and blood pressure were measured. They also had their spot urine assessed for albumin creatinine ratio (ACR), and blood for serum creatinine and estimated glomerular filtration rate (eGFR). Participants with abnormal findings had a a repeat assessment after three months for BP, ACR and eGFR

Results: The median age of the children was 13.0 (11.1-14.0) years, with a male:female ratio of 1.1:1. Seventy-eight of the children (34%) had at least one abnormality in the form of hypertension, decreased eGFR (<90 ml/min/1.73m^2) or increased ACR (>30 mg/g) at recruitment. Following re-assessment, 43 of the 78 children had persistent abnormal findings suggestive of early CKD (19%). Factors such as age, sex, type of school, parent's education, history of family member with kidney disease, and nutritional status were not significantly associated with early CKD.

Conclusions: The outcome of this study indicates that a significant number of school children had persistent abnormal findings suggestive of early CKD. Thus, further emphasising the need for large scale CKD screening programmes in our setting. A long-term follow-up of these children will help determine the clinical significance of these findings and provide more information on the epidemiology of CKD. Abdullahi Mudi was supported by a VECD Global Health Fellowship, funded by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) and the Fogarty International Center (FIC) of the NIH (D43 TW009337). The views expressed are solely those of the authors and do not necessary represent the views of the NIH.

PO2246

Advanced Liver Fibrosis Predicts CKD Development in Patients with Nonalcoholic Fatty Liver Disease

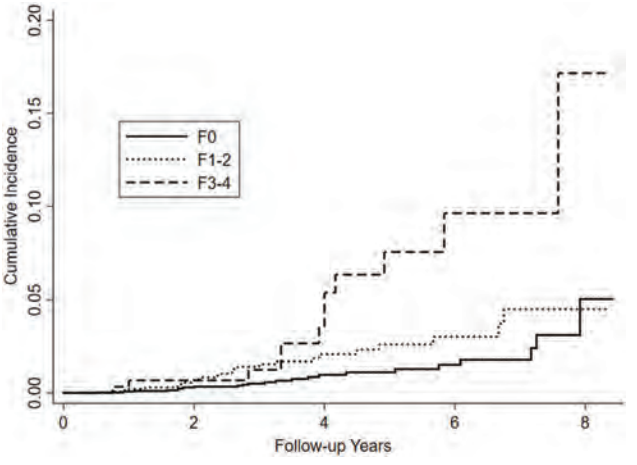
Chan-Young Jung, Hyung Woo Kim, Beom seok Kim. *Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea.*

Background: Nonalcoholic fatty liver disease (NAFLD) and chronic kidney disease (CKD) are progressive chronic conditions that share important cardiometabolic risk factors and pathogenic mechanisms. We investigated the association between liver fibrosis and the risk of incident CKD in patients with NAFLD.

Methods: A total of 5,983 participants with NAFLD (defined as controlled attenuation parameter >222 dB/m) but without CKD who underwent transient elastography (TE) between March 2012 and August 2018 were selected. The primary outcome was incident CKD, defined as the occurrence of estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 or proteinuria (≥1+ on dipstick test) on two consecutive measurements during follow-up. The secondary outcome was a 25% decline in eGFR measured on two consecutive visits.

Results: The mean age was 51.8 years and 3,756 (62.8%) participants were male. During 17,801 person-years of follow-up (mean follow-up of 3.0 years), 62 participants (1.0%) developed incident CKD. When stratified into TE-defined fibrosis stages, multivariable Cox models revealed that risk of incident CKD was 3.63-fold (95% CI, 1.64-8.06, *P*<0.001) higher in the F3-4 group (≥9.5 kPa), compared to the F0 group (<5.5 kPa). During 17,577 person-years of follow-up (mean follow-up of 3.0 years), 201 participants (3.4%) experienced the secondary outcome, for which the F3-4 group had a 2.69-fold increased risk (95% CI, 1.70-4.27, *P*<0.001), compared to the F0 group.

Conclusions: In this large cohort of NAFLD patients without baseline CKD, advanced liver fibrosis measured by transient elastography was significantly associated with a higher risk of incident CKD.



PO2247

Association Between Rates of In-Hospital Decongestion Among Patients with Heart Failure with Reduced Ejection Fraction with Longer-Term Kidney Outcomes

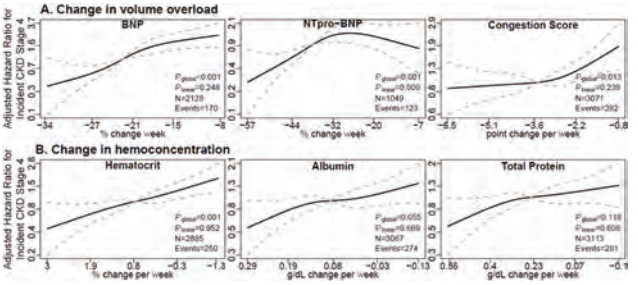
Wendy I. McCallum,[1] Hocine Tighiouart,[1] Jeffrey M. Testani,[2] Matthew Griffin,[2] Marvin Konstam,[1] James Udelson,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Yale University School of Medicine, New Haven, CT.*

Background: Achievement of decongestion in acute heart failure (AHF) is associated with improved cardiovascular outcomes, but can be associated with acute declines in estimated glomerular filtration rate (eGFR). We aimed to examine whether rate of in-hospital decongestion is associated with longer term kidney function decline among patients with heart failure with reduced ejection fraction (HFrEF).

Methods: Using data from the Efficacy of Vasopressin Antagonism in Heart Failure Outcome Study With Tolvaptan (EVEREST) trial, we used multivariable Cox regression models to evaluate the association between in-hospital change in assessments of volume overload, including b-type natriuretic peptide (BNP), N-terminal prob-type natriuretic peptide (NT-proBNP) and clinical congestion score (0-12), as well as change in hemoconcentration including hematocrit, albumin and total protein with risk of incident chronic kidney disease (CKD) Stage≥4 (as defined by a new eGFR <30 ml/min/1.73m^2) and eGFR decline of >40%.

Results: Among 3500 patients over 10-month follow-up, faster decreases in volume overload and more rapid increases in hemoconcentration were associated with decreased risk of incident CKD Stage≥4 and eGFR decline of >40%. In adjusted analyses, for every 6% faster decline in BNP per week, there was a 32% lower risk of both incident CKD Stage≥4 (HR=0.68, 95% CI 0.58, 0.79) and eGFR decline by >40% (HR=0.68 [0.57, 0.80]). For every 1% faster increase per week in hematocrit, there was a lower risk for both incident CKD Stage≥4 (HR=0.73 [0.64, 0.84]) and eGFR decline by >40% (HR=0.82 [0.71, 0.95]), with results consistent for other biomarkers.

Conclusions: These results provide reassurance that more rapid rates of decongestion in patients with AHF do not increase the risk of adverse kidney outcomes in patients with HFrEF, and may in fact be associated with better kidney function in the long term. The ability to rapidly decongest may also serve as a valuable proxy for better kidney outcomes.



PO2248

Hearing Impairment Among Patients with CKD

Api Chewcharat,[1,2] Weitao Liu,[1,2] Lipisha Agarwal,[1,2] Elizabeth A. Phipps,[1,2] Jill A. Melendez Young.[1,2] *[1]Mount Auburn Hospital, Cambridge, MA; [2]Harvard Medical School, Boston, MA.*

Background: Kidney and cochlear have similar physiologic mechanisms involving fluid and electrolytes. Impaired kidney function may affect cochlear function leading to hearing impairment (HI). Nevertheless, the association between chronic kidney disease (CKD) and hearing impairment is not clear. Moreover, the prevalence of HI among CKD patients has not been well-established.

Methods: We conducted a cross-sectional study among 8,105 US adults aged 20-69 years old in the National Health and Nutrition Examination Survey (NHANES) 2011-2012 and 2015-2016. CKD was defined as eGFR < 60 ml/min/1.73m^2. We calculated the prevalence of HI among CKD population by using analytic survey weights and design factors. We also examined the association between CKD and HI using weighted multivariable logistic regression.

Results: The prevalence of speech frequency HI among patients with CKD was 33.1% vs 14.0 % among control (p<0.001). The prevalence of high-frequency HI among patients with CKD was 74.9% vs 38.7% among control (p<0.001) **(Table 1).** The prevalence of speech frequency HI was 31.5% among CKD stage 3, 47.0% among CKD stage 4 and 53.6 among CKD stage 5 (p-trend = 0.26). The prevalence of high frequency HI was 74.8% among CKD stage 3, 75.9% among CKD stage 4 and 75.2% among CKD stage 5 (p-trend = 0.99). After adjusting for age, sex, race, income, diabetes, hypertension, history of smoking, alcohol drinking, history of cardiovascular diseases, and loud noise exposure, CKD was significantly associated with higher odds of overall speech frequency HI (OR = 1.94, 95% CI [1.03, 3.64]; p=0.04) and overall high-frequency HI (OR = 3.03, 95%CI [1.83, 5.02]; p<0.001).

Conclusions: Nearly one-third of CKD patients have speech frequency HI and about 75% have high frequency HI. Both speech frequency and high-frequency HI are common even in the early stage of CKD. CKD is independently associated with speech frequency and high frequency HI. Early screening and intervening on HI among CKD patients may enhance speech communication, prevent social isolation and improve quality of life.

Table 1 The prevalence of speech frequency and high frequency hearing impairment

	CKD (n = 256)	Controls (n = 7,382)	P-value
Speech frequency HI			
Overall	33.1 [25.4, 41.8]	14.0 [12.5, 15.7]	<0.001
Unilateral	13.6 [9.2, 19.8]	7.03 [6.2, 8.0]	0.001
Bilateral	19.4 [11.7, 30.5]	7.0 [5.9, 8.2]	0.001
High frequency HI			
Overall	74.9 [66.9, 81.5]	38.7 [36.0, 41.4]	<0.001
Unilateral	24.2 [18.3, 31.2]	14.3 [13.2, 15.4]	0.001
Bilateral	50.7 [41.1, 60.3]	24.4 [22.4, 26.5]	<0.001

PO2249

Genetic Determinants of Interleukin-6 Levels and Risk of ESRD

Lee Wheless,[1,2] Mindy Pike,[1,2] Hua-Chang Chen,[1,2] Ran Tao,[1,2] Shailja C. Shah,[3,4] Alexander Bick,[1,2] Cecilia P. Chung,[1,2] Cassianne Robinson-Cohen,[1,2] Adriana Hung.[1,2] Million Veteran Program *[1]Vanderbilt University, Nashville, TN; [2]Nashville VA, Nashville, TN; [3]University of California San Diego, La Jolla, CA; [4]San DIego VAMC, Nashville, TN.*

Background: Multiple observational studies indicate an association between circulating levels of interleukin-6 (IL-6) and end-stage renal disease (ESRD). However, these studies are prone to confounding and reverse causation, limiting their utility in identifying causal relationships. Mendelian Randomization (MR) studies can provide evidence for causality by examining the relationship between genetically-determined biomarker levels and outcomes. We used MR to evaluate whether genetically predicted higher IL-6 levels are associated with the risk of ESRD.

Methods: We performed two-sample MR of the relationship between IL-6 and ESRD. We selected 5 single nucleotide polymorphisms (SNPs) robustly associated with IL-6 levels at genome-wide significance among 30,931 individuals in the SCALLOP consortium as instrumental variables and examined their association with the odds of ESRD in the Million Veteran Program (MVP) among 5,503 ESRD cases and 6,354 controls.

Results: A genetically-driven increase in IL-6 levels was associated with a 30% higher odds of ESRD (95% confidence interval [CI] 1.01 to 1.67; p = 0.04). In race stratified models, among 3,112 Caucasians and 3,170 controls, there was a weaker association (OR 1.17, 95% CI 0.86 – 1.59) compared to 2,062 African Americans (OR 1.30, 95% CI 0.83 – 2.04).

Conclusions: IL-6 levels might be causally associated with the risk of ESRD. This association was stronger among African Americans, although was underpowered. Additional studies are needed to clarify the role of IL-6 in ESRD, and if inhibition of this cytokine could be a target for delaying kidney disease progression to ESRD. **Co-seniors: Robinson Cohen & Hung**

PO2250

Association Between Serum Metabolites and Adverse Renal Outcomes: The Atherosclerosis Risk in Communities (ARIC) Study

Lauren Bernard,[1] Linda Zhou,[1] Aditya L. Surapaneni,[1] Jingsha Chen,[1] Casey Rebholz,[1] Bing Yu,[2] Eric Boerwinkle,[2] Josef Coresh,[1] Pascal Schlosser,[1,4] Morgan Grams.[3] *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]The University of Texas Health Science Center at Houston, Houston, TX; [3]Johns Hopkins Medicine, Baltimore, MD; [4]Albert-Ludwigs-Universitat Freiburg, Freiburg im Breisgau, Germany.*

Background: Few metabolomic studies have characterized associations between metabolites and end-stage renal disease (ESRD) and kidney failure. Better characterization of the biological underpinnings may help identify at-risk individuals.

Methods: A total of 3,799 participants with serum samples collected at ARIC visit 1 (1987-1989) were included in this analysis. Starting with 318 individual metabolites, we formed clusters of metabolites using Netboost. We then examined longitudinal associations with ESRD and kidney failure using Cox regression. For significant clusters, we also assessed associations of component metabolites with the outcomes. Because the metabolomic profiling was performed in two studies, analyses were performed within each study and then meta-analyzed.

Results: There were 160 ESRD events and 357 kidney failure events during a median follow-up of 23.5 and 23.3 years, respectively. Overall, mean age was 53.5 years, 59.9% were women, and 61.4% were African American. Mean GFR was 107.5 (SD 16.7). We classified metabolites into 43 clusters. Four clusters were significantly associated with ESRD, and all were associated with kidney failure in a directionally consistent manner. Cluster 26 was primarily sugars involved in glycolysis and anaerobic metabolism. Cluster 5 included amino acids involved in liver metabolism using glutathione and gamma glutamyl transferases. Cluster 34 was an assortment of lysolipids involved in creating phospholipid components of cell membranes. Significant component metabolites included: mannose and glucose from cluster 26; gamma-glutamyl tyrosine, gamma-glutamyl threonine, and 5-oxoproline from cluster 5; and 6 lipids in the phosphocholine family from cluster 34. With the exception of mannose and glucose, higher levels of these metabolites were significantly related to lower risk of ESRD and kidney failure.

Conclusions: We identified several related metabolites associated with ESRD and kidney failure. Additional work is needed to determine whether the relationship is causal.

Funding: NIDDK Support

Plasma Oxalate and Risk of Adverse Outcomes in CKD

Maria Clarissa Tio,[1] Anand Srivastava,[2] Gary C. Curhan,[1] Harold I. Feldman,[3] Eugene P. Rhee,[4] Vasan S. Ramachandran,[5] Paul L. Kimmel,[6] Sushrut S. Waikar.[7] CRIC Investigators, CKD Biomarkers Consortium *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Division of Nephrology and Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Department of Biostatistics, Epidemiology, and Informatics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [4]Division of Nephrology, Massachusetts General Hospital, Boston, MA; [5]Section of Preventive Medicine and Epidemiology and Cardiovascular Medicine, Departments of Medicine and Epidemiology, Boston University Schools of Medicine and Public Health, Boston, MA; [6]Kidney Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [7]Section of Nephrology, Department of Medicine, Boston University School of Medicine, Boston Medical Center, Boston, MA.*

Background: Oxalate is a novel risk factor for CKD but data on plasma oxalate (POx) and outcomes are limited to primary hyperoxaluria. We studied the associations of POx with CKD progression and death in common forms of CKD using the Chronic Renal Insufficiency Cohort (CRIC).

Methods: We measured POx in 1,800 randomly selected CRIC participants at the year 1 visit using the Broad's high-throughput liquid chromatography-mass spectrometry untargeted metabolomics panel. Multivariable Cox proportional hazards regression tested the associations of POx with CKD progression (50% eGFR decline/ESKD) and death. We also tested whether eGFR modified these associations.

Results: Mean eGFR decreased with higher POx quartiles. eGFR modified the associations of POx with CKD progression (P=0.01) and death (P=0.02). In participants with eGFR≥45, higher POx quartiles were associated with CKD progression after adjusting for demographic factors, comorbidities, medications, lab values (including hemoglobin, serum albumin, urine protein-to-creatinine ratio), and eGFR (Q3 vs Q1: HR 2.07, 95% CI 1.12-3.82; Q4 vs. Q1: HR 2.23, 95% CI 1.24-3.99). Higher POx was associated with death in participants with eGFR≥45 after multivariable adjustment (Q4 vs. Q1, HR 1.94, 95% CI 1.10-3.44). POx doubling was associated with a 34% increased risk of CKD progression and 28% increased risk of death (Table 1A). In those with eGFR<45, higher POx was associated with CKD progression after adjusting for demographic factors, comorbidities, medications, and lab values. Adjusting for eGFR attenuated these associations, with higher POx trending towards being protective of CKD progression. Associations of POx and death were not significant after adjusting for covariates and trended towards being protective after adjusting for eGFR (Table 1B). Sensitivity analyses adjusting for 24-hour urinary oxalate did not change these associations.

Conclusions: Higher plasma oxalate may be an independent risk factor for CKD progression/ESKD and death in persons with eGFR≥45.

Model 1: Stratified by site and adjusted for age, sex, race/ethnicity, systolic blood pressure, diabetes, and body mass index, medications (angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, diuretics, beta-blockers, statins, antiplatelet, and phosphorus binders), and laboratory values (hemoglobin, serum albumin, and natural-log-transformed urine-protein-creatinine ratio)
Model 2: Adjusted for model 1 plus estimated glomerular filtration rate
*HRs are per doubling of plasma oxalate

PO2252

Relationship Between 24-Hour Urinary Oxalate and Incident CKD Among Patients with and Without Underlying Gastrointestinal Disease

Marja Puurunen,[1] Gary C. Curhan,[2] Michael Behling,[2] Caroline B. Kurtz,[1] James Macdougall,[1] Aoife M. Brennan,[1] Richard Riese.[1] *[1]Synlogic, Cambridge, MA; [2]OM1, Cambridge, MA.*

Background: Hyperoxaluria may result from intake of high oxalate foods or enhanced intestinal absorption of dietary oxalate caused by gastrointestinal (GI) disorders with underlying malabsorption, including Crohn's disease, short bowel syndrome, gastric bypass surgery, and chronic pancreatitis. Hyperoxaluria has been associated with negative outcomes, including kidney stones and chronic kidney disease (CKD), but larger studies are needed.

Methods: This is a longitudinal retrospective observational cohort study of patients in the US who have completed at least one 24-hr urine collection analyzed by a central laboratory during the study period of January 2013 through December 2020. Outcome and covariate data were drawn from a multi-source data cloud containing deterministically linked, de-identified, individual-level healthcare claims and electronic medical records (EMR) data. Malabsorption was defined by the presence of a relevant ICD 9/10 or CPT code. The association between categories of urine oxalate (UOx) and incident CKD was modeled using logistic regression.

Results: 762,537 individuals age ≥ 18y with at least one 24-hr urine collection were identified. At least 6 months of baseline and 6 months of follow-up data (median follow-up time: 36.7 months; IQR: 20.4, 56.0) were available for 447,958. Of these, N=12,522 (2.8%) had an underlying malabsorptive condition preceding the index urine test. 426,896 patients had no evidence of CKD at baseline and were eligible for analysis of incident CKD. After adjusting for baseline urine calcium, urine citrate, age, sex, race, BMI, tobacco use, hypertension, diabetes, malabsorption, and CVD, a significant association between baseline UOx and the development of incident CKD was observed. Compared with patients with UOx <20 mg/d, the odds of developing incident CKD increased for 20-29 mg/d (OR: 1.22, 95% CI: 1.15, 1.30) through 80+ mg/d (OR: 1.67, 95% CI: 1.51, 1.86) and was statistically significant for each UOx category.

Conclusions: In this large population of patients with hyperoxaluria, the risk of incident CKD increased with increasing 24-hr urine oxalate excretion. Future studies should examine whether reducing urine oxalate diminishes the risk of developing CKD.

Associations of CKD Risk Factors and Longitudinal Changes in Urine Biomarkers of Kidney Tubules Among Women Living with HIV

Anthony N. Muiru,[1] Rebecca Scherzer,[1] Simon Ascher,[2] Vasantha Jotwani,[1] Derek Ng,[3] Deborah Gustafson,[7] Amanda B. Spence,[6] Chirag R. Parikh,[5] Anjali Sharma,[8] Joachim H. Ix,[4] Michelle M. Estrella,[1] Michael Shlipak.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of California Davis Department of Internal Medicine, Sacramento, CA; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [4]University of California San Diego School of Medicine, La Jolla, CA; [5]Johns Hopkins Medicine, Baltimore, MD; [6]Georgetown University, Washington, DC; [7]SUNY The State University of New York, Albany, NY; [8]Albert Einstein College of Medicine, Bronx, NY.*

Background: Among women with HIV (WWH), urine biomarkers of tubule dysfunction and injury allow detection of antiretroviral toxicity and prediction of CKD risk and mortality. However, risk factors for changes in urine biomarkers are unclear.

Methods: We assessed traditional and infection-related CKD risk factors and measured 14 urine biomarkers at baseline and at follow-up (median 2.5 years) among WWH in the Women's Interagency HIV Study. We used simultaneously adjusted multivariable linear regression models to evaluate the associations of CKD risk factors with changes in biomarker levels concurrently.

Results: Of the 647 women in this analysis, 67% were Black, median age at baseline was 45 years and eGFR was 104 ml/min/1.73m². Each CKD risk factor associated with distinct changes in urine biomarkers (**Figure**). For example**,** baseline hemoglobin a1c (HbA1c) associated with worse tubular injury (higher interleukin-18 [IL-18]), proximal tubular reabsorptive dysfunction (higher alpha-1 microglobulin), tubular reserve (lower umodulin) and heightened immune response to injury (higher chitinase-3-like protein [YKL-40]). Higher HbA1c at follow-up was associated with further worsening of tubular injury (higher kidney injury molecule-1 [KIM-1] and IL-18), and immune response to injury (higher YKL-40). Hepatitis C virus co-infection associated with worsening proximal tubular reabsorptive dysfunction (higher beta-2 microglublin [β2m]), and immune response to injury (higher YKL-40), whereas HIV viremia associated with worsening markers of tubular and glomerular injury (higher KIM-1 and albumin, respectively).

Conclusions: CKD risk factors associated with unique patterns of biomarker changes among WWH, suggesting that longitudinal biomarker measurements may help in detecting and monitoring kidney disease in WWH.

Correlation Between Urinary Sodium and Protein Excretion in CKD

Gulvahid G. Shaikh,[1,2] Elvira O. Gosmanova,[1,2] Paul J. Der Mesropian.[1,2] *[1]Albany Stratton VA Medical Center Albany, Albany, NY; [2]Albany Medical College, Albany, NY.*

Background: Urinary protein excretion often fluctuates in patients with chronic kidney disease (CKD). We aimed to establish a correlation between spot urine sodium (Na) measurement as a surrogate marker of 24hr urine excretion based on Kawasaki formula, and therefore, sodium intake, and urinary protein excretion. We hypothesize that urinary Na excretion may affect urinary protein excretion.

Methods: This was a retrospective study involving 213 US veterans with CKD followed in the Albany VAMC nephrology clinic for the period of 2 years. Patients with cirrhosis, end-stage renal disease, and renal transplant were excluded. Simultaneous measurements of serum Na, Creatinine (Cr) and urine Na, Cr and protein were performed on 2 separate visits. Kawasaki formula was used to estimate 24-hour urine Na excretion. Proteinuria was calculated using urine protein to creatinine ratio (UPCR). Correlations among percent change in estimated 24h urine Na and UPCR were determined with linear regression model.

Results: The mean age ± SD of the cohort was 74.4 ± 9.5 years. Mean estimated GFR was 47.4 ml/min/1.73 m² and UPCR was 1.0 g/g. About 97% of subjects were male and 51% had diabetes. Using multivariable linear regression, we found that weight, height,

BMI, and percent change in estimated 24h urine Na were significant predictors of percent change in UPCR (all $p < 0.05$). The percent change in UPCR correlated with estimated 24h urine sodium on univariate linear regression ($R^2 = 0.24$, $p < 0.01$). We found that 68% of cases of UPCR rise also had estimated 24h urine Na increase, while 70% of patients with UPCR fall also had estimated 24h urine Na decrease.

Conclusions: Urine sodium and urine protein excretion correlated in patients with chronic kidney disease. Therefore, the role of dietary sodium as a potential influencing factor of urine protein excretion requires further examination.

PO2255

Liver Disease Is a Predictor of Recurrent Hyperkalemia

Elani Streja,[1,2] Jui-Ting Hsiung,[1,2] Abiy Agiro,[3] Yasmin G. Brahmbhatt,[3] Kerry Cooper,[3] Kamyar Kalantar-Zadeh.[2,1] *[1]VA Long Beach Healthcare System, Long Beach, CA; [2]University of California Irvine, Irvine, CA; [3]AstraZeneca PLC, Cambridge, United Kingdom.*

Background: Liver disease is not a well-established predictor for recurrent hyperkalemia (HK) independent of mineralocorticoid receptor antagonist (MRA) therapy, which is a common treatment in this population. This study explores the relationship between liver disease and recurrent HK independent of MRA therapy and Renin Angiotensin System Inhibitors.

Methods: In a cohort of 9,894,683 US veterans that had at least one potassium measurement between 0.5-8 mEq/L during year 2004 and 2018, we identified 2,169,401 patients who had a HK event (sK >5.0 mEq/L) and complete data on covariates and examined the association of possible predictors of HK recurrence within 1 year after index HK event. Liver disease was defined according to the presence of mild, moderate, or severe liver disease ICD 9/10 codes using 1 inpatient or 2 outpatient records in one year prior to index HK event. HK recurrence is defined as the 3rd or later potassium measurement after index HK measurement subsequent to one or more normal (≤5 mEqL) potassium measurement. Fine and Gray competing risk regression model was used to evaluate the association between liver disease and HK recurrence, where HK recurrence was the outcome and the competing event was all-cause mortality within 1 year after index HK occurrence. The model was adjusted for demographics, comorbid conditions, eGFR, RASi and MRA treatment and potassium supplementation.

Results: Among the 2,169,401 patients, 376,358 (17%) patients had HK recurrence within 1 year after index HK event. Out of 2,169,401 patients, 93,141 (4%) patients had liver disease within 1 year prior to index HK event and 26,846 (29%) of patients had HK recurrence within 1 year after index HK event. Patients with liver disease had a 39% higher risk of HK recurrence within 1 year after index HK event (hazard ratio [HR] [95% CI]: 1.39 [1.37, 1.42]) in the fully adjusted model and was the 2nd strongest predictor after diabetes. Compared to patients without liver disease, patients with liver disease were younger, more likely to be African American, and had a higher Charlson Comorbidity Index.

Conclusions: In US veterans, liver disease is a predictor of 1 year HK recurrence independently of RAASi therapy. Further studies are needed to understand the possible cause underlying this association.

PO2256

Associations of Urinary and Dietary Sodium-to-Potassium Ratios with Albuminuria in Community-Dwelling Japanese Adults: A Cross-Sectional Study

Keiko Kabasawa,[1] Kunihiro Matsushita,[2] Ribeka Takachi,[3] Kazutoshi Nakamura,[1] Yumi Ito,[1] Junta Tanaka,[1] Ichiei Narita.[1] *[1]Niigata University, Niigata, Japan; [2]Johns Hopkins University, Baltimore, MD; [3]Nara Women's University, Nara, Japan.*

Background: Urinary sodium-to-potassium (Na/K) ratio is an indicator of dietary sodium intake and is associated with reduced kidney function. However, it is not known whether urinary Na/K ratio is also associated with albuminuria, the other key component of CKD, in community-dwelling adults.

Methods: We quantified the association of urinary Na/K ratio with albuminuria in 6,276 Japanese adults (age 40-97 years; 51.0% women) by using spot urine samples. Linear and logistic regression analyses were performed with adjustment for potential confounders. We also evaluated dietary Na/K ratio based on a food-frequency questionnaire.

Results: Median values of urinary and dietary Na/K ratios were 2.70 (interquartile interval: 1.87, 3.83) and 1.50 (1.20, 1.84), respectively, with median albumin-to-creatinine ratio (ACR) of 11.0 (6.0, 24.0) mg/g and mean eGFR of 74.7 (SD 15.7) mL/min/1.73 m^2. In multivariable linear regression analysis, urinary Na/K ratio (per one-unit increment) was significantly associated with log-ACR (e.g., β 0.023 [95% CI 0.008, 0.039] in Model 3) (Table). Similarly, dietary Na/K ratio was independently associated with ACR (Table). The results were consistent with those of multivariable logistic regression analysis with elevated ACR ≥30 mg/g as a dependent variable.

Conclusions: Both urinary and dietary Na/K ratios were associated with elevated albuminuria in community-dwelling Japanese adults. Our findings further support the potential usefulness of urinary Na/K ratio as an indicator of sodium intake and suggest a link between sodium intake and kidney damage.

Funding: Government Support - Non-U.S.

Table: Multivariable linear regression analysis between urinary or dietary sodium-to-potassium ratio and log albumin-to-creatinine ratio. Model 1 was adjusted for age and sex; Model 2 was additionally adjusted for current smoking and drinking habits; Model 3 was further adjusted for body mass index, diabetes, systolic blood pressure, use of any antihypertensive medication, and eGFR.

	Model 1	Model 2	Model 3
	β (95%CI)	β (95%CI)	β (95%CI)
Urinary sodium-to-potassium ratio, per one-unit increment	0.049 (0.033, 0.065)	0.048 (0.033, 0.064)	0.023 (0.008, 0.039)
Dietary sodium-to-potassium ratio, per one-unit increment	0.144 (0.090, 0.198)	0.140 (0.086, 0.194)	0.140 (0.089, 0.192)

PO2257

Urinary Sodium-to-Potassium Excretion Ratio Is Associated with Incident CKD in the General Population

Young Su Joo,[1,2] Jong Hyun Jhee,[1] Hyung Woo Kim,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Jung Tak Park.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Yongin Severance Hospital, College of Medicine, Yonsei University, Yongin, Gyeonggi-do, Republic of Korea.*

Background: Previous study suggests that urinary sodium to potassium (UNAK) ratio is associated with cardiovascular event and mortality, but the association of incident chronic kidney disease (CKD) and UNAK ratio in a preserved kidney function adult showed conflict results.

Methods: Data from the Korean Genome and Epidemiology, a prospective community-based cohort study were used to evaluate the between UNAK ratio and CKD development. 24 hour estimated sodium and potassium excretion amounts were calculated by a Kawasaki equation using spot urinary potassium and sodium measurements. A total 4088 participants were analyzed with a primary outcome of incident CKD that defined as estimated glomerular filtration ratio (eGFR) <60 mL/min/1.73m^2 in ≥2 consecutive measurements during the follow-up period.

Results: The mean age was 52.1 ± 88 years and 47.5% were male. The median estimated 24h urinary sodium excretion, potassium excretion, UNAK ratio were 4.9 (4.1-5.8) g/day, 2.1 (1.8-2.5) g/day, and 2.3 (1.9-2.7), respectively. During 37,950 person-year of follow-up (median 11.5 years), the primary outcome developed in 513 participants and corresponding incidence rate was 14.0 (95% Confidence interval [CI], 12.9 to 15.3) per 1000 person-year. When the participants were categorized into quartiles according to UNAK ratio, age, sex and baseline eGFR adjusted hazard ratios (HR) (95% CI) for the Cox proportional hazard model were 0.76 (0.59-0.96), 0.89 (0.70-1.14), and 1.15 (0.91-1.46) from UNAK ratio quartile 1, 2, and 3, respectively as compared with the highest quartile and this finding was consistent even after further adjustment. Similar results were observed when log-transformed UNAK ratio was treated as a continuous variable; for one increase in UNAK ratio, there was a 51% higher risk of adverse kidney outcome (HR 1.51, 1.12-2.04). Spline regression analysis show that HR increased more steeply up to 1 in log transformed UNAK ratio, but there was no significant increase of risk after that.

Conclusions: low UNAK ratio is significantly associated with a decreased risk of CKD development.

PO2258

Time on Patiromer Therapy and Impact on Serum Potassium Levels in Real-World German CKD Patients

Roberto Pecoits-Filho,[1] Daniel G. Muenz,[1] Keith McCullough,[1] Ziad Massy,[2] Brian Bieber,[1] Bruce M. Robinson,[1] Danilo Fliser,[3] John Golden,[5] Carol P. Moreno Quinn,[6] Viviane Calice-Silva,[7] Antonio Ramirez de Arellano,[6] Helmut Reichel.[4] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Centre Hospitalier Universitaire Ambroise Pare, Mons, Belgium; [3]Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany; [4]Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany; [5]Vifor Fresenius Medical Care Renal Pharma, Munich, Spain; [6]Vifor Pharma, Glattbrugg, Switzerland; [7]Pro-Kidney Foundation, Joinville, Brazil.*

Background: Hyperkalemia (HK) (serum K>5.0 mEq/L) is a frequent condition in patients with chronic kidney disease (CKD) associated with high morbidity and mortality and it is a common reason for RAASi discontinuation and dose limitation. Patiromer is a non-absorbed, sodium-free, potassium (K) binder that has been shown to chronically reduce serum K in patients with HK, enabling RAASi therapy, which is supported by randomized trial evidence in CKD patients. Data on patiromer use in patients with moderate-to-advanced CKD in the real-world setting in Europe is lacking. We describe time to discontinuation and changes in serum K levels among CKD stage 3-5 patients starting patiromer using 2018-21 data from German participants in CKD Outcomes and Practice Patterns Study (CKDopps).

Methods: Duration of patiromer use was estimated by Kaplan-Meier curve, starting at patiromer initiation and censoring for death, dialysis, transplant, or loss of follow-up. Serum K levels are described as mean/median at the baseline and in ranges of 1-30, 31-90 and 91-180 days during the follow up, restricted to patients remaining on patiromer.

Results: Patiromer use was limited to 34 of 90 clinics. We identified 155 Patiromer users, 131 with K measurements at baseline and 110 with at least one follow-up value. 79% of patiromer users were CKD stage 4/5, v. 28% of non-patiromer users in the sample. A large proportion (95%) of patiromer users stayed on treatment past 1 month, with 53%

of surviving users continuing for over a year (Fig 1A). Mean serum K levels decreased after patiromer initiation and remained stable under treatment during follow-up (up to 180 days) (Fig 1B).

Conclusions: Most patients were not observed to discontinue patiromer prior to one year after initiation. Mean levels of serum K were lower after patiromer initiation and remained stable during the follow-up period.

PO2259

Kidney Outcomes in Pediatric Non-Kidney Solid Organ Transplant Patients

Mital Patel,[1] Emily L. Joyce,[2] John A. Kellum,[4] Shawn C. West,[3] Priyanka Priyanka,[4] Dana Y. Fuhrman.[3] *[1]Duke University, Durham, NC; [2]UH Rainbow Babies and Children's Hospital Division of Pediatrics, Cleveland, OH; [3]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [4]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Acute Kidney Disease (AKD) is defined as impaired kidney function for < 90 days with or without an acute kidney injury (AKI) event. Adults with AKD have increased risk for progression to chronic kidney disease (CKD) and mortality. There are no data on the epidemiology of AKD in children after transplant. The aim of this study was to evaluate the incidence and risk factors for AKI, AKD and CKD at a large pediatric transplant center.

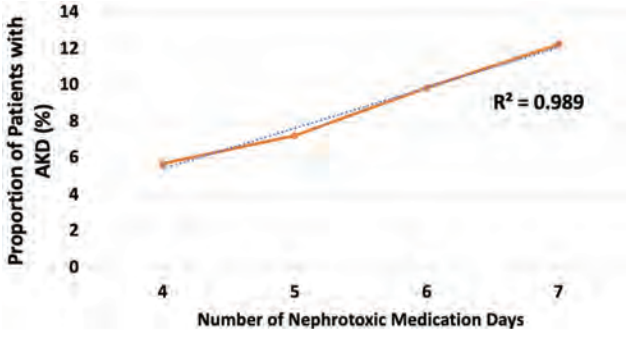
Methods: A retrospective chart review was done in children who underwent non-kidney solid organ transplant between 2011-2019 at UPMC Children's Hospital of Pittsburgh. AKI and AKD are defined using the Kidney Disease Improving Global Outcomes criteria. AKD is defined as serum creatinine >/= 50% times baseline or eGFR < 60 ml/min/1.73m^2 or a decrease in eGFR by >/= 35% times baseline for > 7 days and up to 3 months. Patients with a new eGFR of <60 ml/min/1.73m^2 persisting for > 3 months met criteria for CKD. Variables associated with AKI, AKD and CKD were analyzed.

Results: Among 338 patients 37.9% met criteria for severe AKI, 11.5% for AKD and 8% for a new diagnosis of CKD. Stage 3 AKI was independently associated with AKD (OR: 4.10; 95% CI: 1.64-10.25). AKD but not severe AKI was associated with new onset CKD (Table 1). There was a dose dependent relationship between nephrotoxic medication use and incidence of AKD (Figure 1).

Conclusions: In conclusion, children with AKD after transplant are particularly vulnerable to developing CKD and there are modifiable risk factors that could decrease the risk of progression of AKI to AKD and CKD in this population.

Multivariable logistic regression of risk factors for CKD

Characteristic	OR (95% CI)	P-value
Age (years)	1.00 (0.99-1.01)	0.51
Gender	2.67 (1.00-7.13)	0.05
Race	2.55 (0.88-7.38)	0.09
Severe AKI	0.94 (0.38-2.30)	0.89
All AKI	1.58 (0.62-4.00)	0.33
AKD	20.45 (7.48-55.87)	<0.01



Association between nephrotoxic medication use and AKD

PO2260

Cardiovascular Outcomes in Pediatric CKD: A CKiD Study

Rupesh Raina,[1,2] Ronith Chakraborty,[1,2] Siddhartha S. Singh,[1,2] Stephen D. Cha.[2] *[1]Cleveland Clinic, Akron, OH; [2]Akron Children's Hospital, Akron, OH.*

Background: Cardiovascular Disease (CVD) poses high risk to Chronic Kidney Disease (CKD) pediatric patients with existing literature noting decreased mortality and other comorbidities. Here, we use the Chronic Kidney Disease in Children Cohort Study (CKiD), a prospective cohort study of pediatric renal cystic patients, to assess CVD parameters in this vulnerable population.

Methods: We performed control-matched analysis of CKiD patents with renal cystic disease (PKD, MCDK, BOR) compared to a group of aplastic/dysplastic/hypoplastic kidney patients or those with obstructive uropathy. Variables were normalized using the Kolmogorov-Smirnov test; categorical variables were summarized as percentages while continuous variables as medians and inter-quartile ranges. Univariate associations were tested using chi-square statistic or Fischer exact test for categorical variables and Mann-Whitney I test for continuous variables.

Results: 41 patients in the renal cystic group were compared to 294 patients in the non-renal non-cystic group. Renal cystic patients demonstrated statistically significant increases in cystatin-C with no difference in iGFR or serum creatinine. Blood pressure was decreased [103 (97 - 112) vs. 107 (99 - 115) mm Hg; p=0.004] in the renal cystic group but cardiac parameters of ascending aortic stiffness [3.1 (2.11 - 5.21) vs. 2.53 (1.87 - 3.56); p=0.001] and incidence of left-ventricular hypertrophy (LVH) [12 (15.2%) vs. 44 (8.3%); p=0.049] was increased.

Conclusions: CVD mortality is the primary cause of death in patients with CKD, especially ADPKD. Previous literature conceptualized link between renal cystic disease and hypertension leading to poorer CVD outcomes however our analyses show this is an incomplete picture with almost 50% higher incidence of LVH but lower blood pressure in renal cystic group compared to other CKD pediatric patients. This suggests a need for further exploration of cardiac remodeling and structural changes to improve the understanding of CVD development in renal cystic pediatric patients.

PO2261

Biopsy-Proven CKD Etiology and Outcomes: The CKD Japan Cohort (CKD-JAC) Study

Takayuki Hamano,[1] Takahiro Imaizumi,[4] Takeshi Hasegawa,[2] Naohiko Fujii,[5] Hirotaka Komaba,[3] Masafumi Fukagawa.[3] *[1]Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; [2]Showa University Research Administration Center, Tokyo, Japan; [3]Tokai University, Isehara, Japan; [4]Nagoya University, Nagoya, Japan; [5]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan.*

Background: The KDIGO guidelines advocated cause-GFR-albuminuria (CGA) classification for predicting outcomes. However, a dearth of data exists supporting the use of the cause of chronic kidney disease (CKD). This study aimed to address how to incorporate prior biopsy-proven diagnosis in predicting outcomes.

Methods: We compared end-stage kidney disease (ESKD) and all-cause death before ESKD among various biopsy-proven diagnoses (n = 778) in Analysis A. In Analysis B, the same outcomes were compared among biopsy-proven diabetic nephropathy (DN), biopsy-proven other diseases, and no biopsy in those with a history of diabetes mellitus (n = 1117).

Results: In analysis A, adding biopsy-proven diagnoses to GFR-albuminuria (GA) classification significantly improved both net reclassification improvement and integrated discrimination improvement to predict the 8-year incidence of ESKD and all-cause death. Fine-Gray (FG) models with ESKD as a competing event showed significantly higher subdistribution hazard ratios (sHRs) for all-cause death in nephrosclerosis (4.12 [1.11–15.2]), focal segmental glomerulosclerosis (3.77 [1.09–13.1]), and membranous nephropathy (MN) (2.91 [1.02–8.30]) as compared to IgA nephropathy, while Cox model failed to show significant associations. Crescentic glomerulonephritis had the highest risk of all-cause death (sHR 5.90 [2.05–17.0]). MN had a significantly lower risk of ESKD than IgA nephropathy (sHR 0.45, [95% Confidence interval:0.24–0.84]). In analysis B, biopsy-proven other diseases had a lower risk of ESKD as compared to biopsy-proven DN in FG model with death as a competing event (sHR 0.62 [0.39–0.97]).

Conclusions: The Biopsy-proven cause of CKD is of great value in predicting outcomes in CKD adjusting for GA classification.

Ideal Cardiovascular Health and Risk for Incident CKD: Findings from the Hispanic Community Health Study/Study of Latinos (HCHS/SOL)

Christopher G. Viamontes,[1] Ana C. Ricardo,[2] Jinsong Chen,[2] Jianwen Cai,[5] Hector M. Gonzalez,[4] Milagros Yunes,[6] Wassim H. Tarraf,[3] James P. Lash.[2]
[1]University of Illinois at Chicago College of Medicine, Chicago, IL; [2]University of Illinois Hospital and Health Sciences System, Chicago, IL; [3]Wayne State University School of Medicine, Detroit, MI; [4]University of California San Diego, La Jolla, CA; [5]University of North Carolina System, Chapel Hill, NC; [6]Montefiore Medical Center, Bronx, NY.

Background: Prior studies have reported that measures of ideal cardiovascular health influence the risk of developing chronic kidney disease (CKD). However, U.S. Hispanic/Latino adults were not well represented in these studies.

Methods: We analyzed data from 8,770 U.S. Hispanic/Latino adults aged 18-64 years enrolled in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) who completed a baseline (2008-2011) and a follow-up (2014-2017) visit and did not have CKD at baseline (estimated glomerular filtration rate [eGFR] ≥ 60 ml/min/1.73m^2 and urine albumin-to-creatinine ratio [UACR] <30 mg/g). Cardiovascular health metrics were assessed using the American Heart Association's Life's Simple 7 (LS7, nonsmoker; body mass index <25 kg/m^2; ≥150 minutes/week of physical activity; healthy diet; total cholesterol <200 mg/dL; blood pressure <120/80 mm Hg; and fasting blood glucose <100 mg/dL). Outcomes included incident ACR (defined as UACR ≥30 mg/g) and incident low eGFR (defined as eGFR <60 ml/min/1.73m^2 and a decline in eGFR ≥1 ml/min per year). The association between LS7 and the outcomes was evaluated using Poisson regression with robust variance while accounting for the complex sampling design of HCHS/SOL.

Results: At baseline, the weighted mean age was 42.1 years, 56.3% were female, mean eGFR was 107 ml/min/1.73 m^2, median UACR was 7 mg/g, and 49% had ≥4 ideal health factors. After a median follow-up of 5.9 years, there were 598 incident albuminuria events, and 201 low eGFR events. Compared with the presence of <4 ideal factors, ≥4 ideal health factors was associated with lower risk for incident albuminuria but there was no association with incident low eGFR (**Table).**

Conclusions: Among U.S. Hispanic/Latino adults, the presence of a higher number of ideal health factors was associated with a lower risk of incident albuminuria. These findings may have implications for public health strategies for CKD prevention in this population.

Outcome	Number of Ideal Factors	Rate per 1000 Person Years	Incident Density Ratio (95% CI)
Incident Albuminuria	<4	14.5 (13.2, 16.0)	Referent
	≥4	7.6 (6.6, 8.8)	0.62 (0.46, 0.85)
Incident Low eGFR	<4	5.5 (4.7, 6.5)	Referent
	≥4	1.8 (1.3, 2.4)	1.11 (0.67, 1.84

*Adjusted for center, age, sex, background, education, eGFR, and log(UACR)

Inflammatory Biomarkers and Proteinuria Progression in CKD Patients: The CRIC Study

Jing Chen,[1] L. Lee Hamm,[1] Vecihi Batuman,[1] Siyi Geng,[1] James P. Lash,[2] Chi-yuan Hsu,[3] Panduranga S. Rao,[4] Amanda H. Anderson,[5] Sushrut S. Waikar,[6] Anand Srivastava,[7] Edward J. Horwitz,[9] Hernan Rincon-Choles,[10] Matthew R. Weir,[11] Hua He,[5] Lawrence J. Appel,[8] Jiang He.[5]
[1]Tulane University School of Medicine, New Orleans, LA; [2]University of Illinois at Chicago, Chicago, IL; [3]University of California San Francisco, San Francisco, CA; [4]Michigan Medicine and Veterans Affairs Ann Arbor Healthcare System, Ann Arbor, MI; [5]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [6]Boston University, Boston, MA; [7]Northwestern University, Evanston, IL; [8]Johns Hopkins University School of Medicine, Baltimore, MD; [9]MetroHealth Medical Center, Cleveland, OH; [10]Cleveland Clinic, Cleveland, OH; [11]University of Maryland Baltimore, Baltimore, MD.

Background: Proteinuria progression is considered a surrogate endpoint for CKD progression. We studied prospective association of inflammatory biomarkers with proteinuria progression in the Chronic Renal Insufficiency Cohort (CRIC) Study participants.

Methods: The CRIC Study recruited 3939 CKD patients in the US. After excluding those without urine protein measures at baseline or follow-up and those with missing covariables at baseline, 3177 patients were included in this analysis. Proteinuria progression was defined as a ≥ 30% increase in urine protein-to-creatinine ratio (UPCR) from baseline and UPCR ≥150 mg/g at follow-up visits. Incident proteinuria was defined as UPCR ≥150 mg/g among patients without proteinuria at baseline. Cox proportional hazards models were used to examine multivariate association of inflammatory biomarkers with proteinuria progression and incidence, adjusting for age, sex, race, current smoking, body mass index, systolic blood pressure, total cholesterol, hemoglobin A1C, eGFR, baseline UPCR, and use of ACE-Is/ARBs, statins, and aspirin.

Results: Over a mean follow-up of 6.6 years, 1478 participants developed proteinuria progression and 625 participants developed proteinuria. Multivariable-adjusted hazard ratios (95% confidence intervals [CI]) of proteinuria progression for the highest quartile vs. lowest quartile of inflammatory biomarker levels were 1.20 (1.01-1.42; P=0.03) for fibrinogen, 1.21 (1.03-1.43; P=0.02) for interleukin-6 (IL-6), 1.54 (1.30-1.81; P<0.0001) for tumor necrosis factor-α (TNF-α), and 1.22 (1.04-1.42; P=0.01) for CXCL12. Among 1635 patients without baseline proteinuria, similar relationships of fibrinogen, IL-6, TNF-α and CXCL12 with incident proteinuria were identified. C-reactive protein, white blood cells, IL-1β, IL-1 receptor antagonist, fetuin-A, transforming growth factor-β, and fractalkine were not significantly associated with proteinuria progression or incidence.

Conclusions: Our findings suggest that higher levels of fibrinogen, IL-6, TNF-α, and CXCL12 are independently associated with proteinuria progression and incidence. Future studies may test whether targeting specific inflammatory pathways will improve proteinuria and reduce CKD progression.

PO2264

Racial Disparities in Progression to ESRD and Mortality in Rural vs. Urban Veterans

Stephen R. Sammons,[1] Guo Wei,[1] Robert E. Boucher,[1] Judy Carle,[1] Victoria Gonce,[1] Sydney E. Hartsell,[1] Nikita Abraham,[1] Srinivasan Beddhu.[1,2]
[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: Little is known about how race and rurality interact to influence progression of CKD to ESRD and mortality in CKD patients.

Methods: We analyzed a national cohort (n=915,039) of veterans with CKD (eGFR < 60 on two or more outpatient serum creatinines >60 days apart) who received care from 1/1/2010-12/31/2015 and who had information on demographics, comorbidities, and residence coding available. ESRD data was obtained by linkage to USRDS. Cox linear regression models were used to relate rural and urban residence defined by RUCA codes with time to incidence of ESRD, as well as time to all-cause mortality. The models were adjusted for age, gender, and comorbidities. The full cohort was examined as well as two subgroups divided by race. Hazard ratios were calculated using the urban (RUCA 1.0 & 1.1) veterans within the full cohort or each subgroup as a reference.

Results: When compared to urban veterans, veterans who reside in rural regions had lower risk of ESRD (HR 0.89, 95% CI 0.87-0.91) but had a slightly higher risk of mortality (HR 1.03, 95% CI 1.02-1.03). Within race subgroups, White rural veterans had lower risk of ESRD compared to White urban veterans (HR 0.88, 95% CI 0.85-0.91) but not in Black rural versus Black urban veterans (HR 0.99, 95% CI 0.93-1.05). While rural White veterans had slightly higher risk of mortality compared to urban White veterans (HR 1.02, 95% 1.01-1.02), the difference in mortality between rural and urban veterans was much larger in the Black subgroup (HR 1.11, 95% CI 1.08-1.14).

Conclusions: Examination of CKD patients cared for by the VA reveals an intersection between race and rurality in which mortality is increased for Black rural veterans with CKD. Interventions to improve preESRD care in rural Black veterans are needed.

PO2265

Trends in Prevalence of Comorbid Conditions at Onset of CKD Among US Veterans with Incident CKD, 2004-2018

Meda E. Pavkov,[1] Devasmita Choudhury,[2,3] Wei Yu,[3] Nilka Rios Burrows,[1] Alain Koyama,[1] Robert Nee,[4] Alfred K. Cheung,[5,6] Keith C. Norris,[7] Guofen Yan.[3] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]VA Medical Center Salem, Salem, VA; [3]University of Virginia School of Medicine, Charlottesville, VA; [4]Walter Reed National Military Medical Center, Bethesda, MD; [5]VA Salt Lake City Health Care System, Salt Lake City, UT; [6]University of Utah Health, Salt Lake City, UT; [7]University of California Los Angeles, Los Angeles, CA.*

Background: Many comorbid conditions are strong risk factors for adverse outcomes in people with CKD. We examined trends in prevalence of major comorbidities at CKD onset in the US Veterans Health Administration (VHA).

Methods: Incident CKD was defined as the first time the estimated glomerular filtration rate (eGFR) decreased to <60 mL/min/1.73 m^2 for >3 months. We excluded veterans recorded in the VHA for <2 years prior to the first eGFR <60, or with CKD stage ≥4 when first identified. We identified 15 comorbidities at CKD onset using ICD-9/ICD-10 codes during the 2 years before and 6 months after CKD onset and calculated the Charlson comorbidity index (CCI), a composite score of total disease burden.

Results: The cohort included 892,005 veterans with new-onset CKD between 2004 and 2018. The mean age (72 years), eGFR (52 mL/min/1.73m^2), and body mass index (30 kg/m^2) at CKD onset were similar in 2004 and in 2018. Among the 8 comorbidities with >20% prevalence (left panel, Table), hypertension, cardiovascular disease, chronic obstructive pulmonary disease, and cancer declined from 2004 to 2018, with the largest decline (21%) for cancer. Diabetes, anemia, depression, and obesity increased in prevalence, with the largest increases for obesity (58%) and depression (30%). The percentage of patients with a CCI ≥6 increased from 9% in 2004 to 14% in 2018.

Conclusions: In US veterans, obesity, depression and the CCI score have significantly increased at CKD onset over the recent 15 years, underscoring the importance of a multifaceted approach to management of CKD and its risk factors.

Association Between Cardiac Autonomic Function and Coronary Artery Calcification in Persons with Type 2 Diabetes with and Without CKD

Suvanjaa Sivalingam,[1] Emilie Hein Zobel,[1] Christian S. Hansen,[1] Rasmus S. Ripa,[2,4] Bernt Johan Von Scholten,[3,1] Viktor Rotbain Curovic,[1] Tine Hansen,[1] Peter Rossing.[1,2] Complications reseach *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Kobenhavns Universitet, Kobenhavn, Denmark; [3]Novo Nordisk AS, Bagsvaerd, Denmark; [4]Rigshospitalet, Kobenhavn, Denmark.*

Background: Cardiac autonomic neuropathy and cardiovascular disease are concomitant complications to diabetes but the link between these complications are largely unknown, especially in relation to kidney function. We examined the association between measures of cardiac autonomic function and coronary artery calcification (CACS) in persons with type 2 diabetes stratified by presence of chronic kidney disease (CKD).

Methods: Post-hoc analysis of baseline data from a randomized clinical trial including 84 persons with type 2 diabetes. Cardiac autonomic function was evaluated using heart rate variability (HRV) indices and cardiovascular autonomic reflex tests (CARTs). Lower response in CARTs and HRV measures were taken as indicators of impaired cardiac autonomic function. CT based CACS was calculated using Agatston method.

Results: The participants had a mean age of 64.7 (SD 7.8) years, 15% were women, mean eGFR was 83.5 (SD 16.2) ml/min/1.73 m^2, median urinary albumin creatinine ratio 5.5 [IQR 3.5 – 11.8] mg/g and 10 (11.5%) had CKD (eGFR < 60 ml/min/1.73 m^2). In persons without CKD, a higher CACS was associated with a lower 30-to-15 ratio (-1.27, SE: 0.33), *p < 0.0001*), E-to-I ratio (-1.33, SE:0.32, *p < 0.0001*), standard deviation of normal-to-normal intervals (-0.73 ms, SE:0.34, *p=0.03*), high frequency power (-0.49 ms^2, SE:0.24, *p=0.045*) and total power (-0.86 ms^2, SE:0.33, *p=0.01*). All these associations remained significant after adjustment for age, heart rate (only for HRV measures), sex, LDL-cholesterol, HbA_1 c, systolic blood pressure, diabetes duration and weight (except for standard deviation of normal-to-normal intervals and high frequency power). In persons with CKD, no significant associations were demonstrated between measures of cardiac autonomic neuropathy and CACS.

Conclusions: In persons with type 2 diabetes but without CKD, we demonstrated an association between impaired cardiac autonomic function and higher coronary artery calcification. This association could not be demonstrated in persons with CKD.

PO2267

Characterization of Metabolome-Wide Biochemicals Associated with Kidney Function

Hongquan Peng. *Kiang Wu Hospital, Macau, Macao.*

Background: Chronic kidney disease (CKD) is a global public health problem. Identifying sensitive filtration biomarkers is a key diagnostic value contributing to an understanding of CKD at the molecular level. A metabolomics study indicated a snapshot of the biochemical activity of the human body at a particular time in the progression of CKD. This metabolome-wide study verified whether blood metabolite profiles are significantly different in CKD at various stages and characterized potential markers to assess kidney function in Chinese population.

Methods: An analysis of plasma and serum metabolites using ultrahigh-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) was performed on 198 participants (53 serum samples and 145 plasma samples) based on their measured GFR (by iohexol plasma clearance).

Results: A large number of metabolomics related to the mGFR were selected as the top 30 metabolites by the random forest method, and we found 15 amino acids, 8 nucleotides, and 2 carbohydrates strongly related to kidney function in the combined group (serum and plasma). Thirteen amino acids, 9 nucleotides, and 3 carbohydrates were identified in the plasma group, while 13 amino acids, 7 nucleotides, and 3 carbohydrates were found in the serum group. We observed that 10 of the top 15 ranked metabolites were concordant between the plasma and serum groups. Major differences in metabolite profiles with increasing stage of CKD were observed.

Conclusions: Our study identified 6 novel and potential metabolites that reproducibly strongly associate with mGFR, including pseudouridine, C-glycosyltryptophan, erythronate, N-acetylalanine, myo-inositol, and N-acetylcarnosine. However, pseudouridine may be an ideal biomarker that is nondependent on race. Specifically, a potential negative biomarker of kidney disease may be 1,5-anhydroglucitol (1,5-AG). Future studies will utilize the potential 3-5 novel biomarkers in estimating the glomerular filtration rate without race input.

PO2268

Lipid Accumulation Product Index and CKD

Keun Hyung Park, Chan-Young Jung, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang, Jung Tak Park. *Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea.*

Background: Obesity, a well-known risk factor for chronic kidney disease (CKD), is generally assessed using body mass index (BMI). However, because BMI does not take body composition into account, it may not reflect the metabolic abnormalities associated with obesity. Recently, lipid accumulation product index (LAP) has been proposed to effectively recognize metabolic syndrome. Therefore, the association between LAP and risk of incident CKD was investigated in a general population cohort.

Methods: A total of 180,268 subjects without CKD, who participated in the Korean Genome and Epidemiology Study from 2001 to 2018, were analyzed. LAP was calculated as [waist(cm)−65] × triglyceride(mmol/l) for males and [waist(cm)−58] × triglyceride(mmol/l) for females. The association between LAP and CKD, defined as eGFR<60mL/min/1.73m^2, was examined in the cross-sectional analysis. In the longitudinal analysis, the risk of incident CKD development was analyzed among 8,427 participants without CKD at baseline which was a subset of the main cohort.

Results: The mean age was 53.1±8.4 years, and 117,321 patients (65.1%) were female. Prevalent CKD was observed in 342 (0.6%), 707 (1.2%), and 1155 (1.9%) participants in the lowest, middle, and highest LAP tertile groups, respectively. In multivariate logistic regression analysis, a logarithmic increase in LAP was associated with a 47% increase

in CKD odds ratio (OR 1.47; 95% CI, 1.35-1.61; *P*<0.001). When stratified into tertiles, the risk of CKD prevalence was significantly higher in the highest tertile (OR 2.05; 95% CI, 1.72-2.45; *P*<0.001), when compared to the lowest tertile. During a mean follow-up of 182 months, CKD occurred in 720 (8.5%) participants. In the multivariable Cox analysis, LAP was significantly related with incident CKD risk (per 1-log LAP, HR 1.20; 95% CI, 1.13-1.27; *P*<0.001). The risk of incident CKD was significantly higher in the highest tertile (HR 1.48; 95% CI, 1.32-1.65) than the lowest tertile.

Conclusions: Increase in LAP was associated with higher prevalence of CKD and elevated risk of incident CKD.

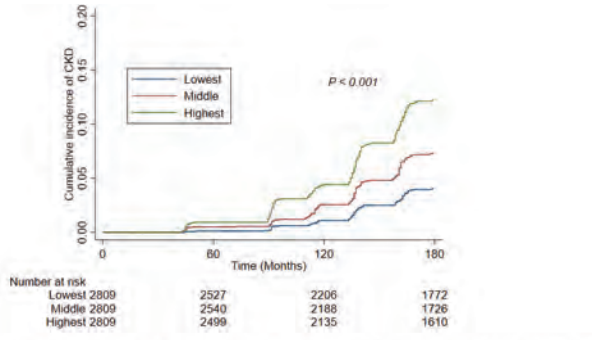

Figure. Cumulative incidence curve for incident chronic kidney disease according to lipid accumulation product index.

PO2269

Comparison of Two Immunoassay Technologies for Plasma Biomarker Measurement

Insa M. Schmidt,[1] Mia Colona,[1] Anand Srivastava,[2] Venkata Sabbisetti,[3] Joseph V. Bonventre,[3] Sushrut S. Waikar.[1] *[1]Boston Medical Center, Boston, MA; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Anti-double-stranded DNA (anti-dsDNA) antibodies in autoimmune diseases such as systemic lupus erythematosus (SLE) may interfere with immunoassay technologies that use oligonucleotide-based antibodies (Olink) or aptamers (SomaScan). In this study, we compare measurements of plasma kidney injury molecule-1 (KIM-1), a well-known marker of tubular injury, across two different immunoassay technologies in patients with and without SLE.

Methods: We measured plasma KIM-1 levels in 444 individuals enrolled into a prospective, observational cohort study of patients with chronic kidney disease using microbead-based sandwich ELISA and the proximity extension assay (PEA, Olink). The PEA uses oligonucleotide-labeled antibodies that bind to the target protein. We investigated differences in plasma KIM-1 measurements between the two assays in individuals with SLE (n=68) and individuals with other diseases than SLE (n=376) using Bland-Altman plots and Spearman correlation coefficients.

Results: Mean eGFR was 85.2±37 and 52.3±33 ml/min/1.73m^2 and the median proteinuria (IQR) was 1.5 (0.7, 3.2) and 1.7 (0.4, 4.2) g/g creatinine in individuals with and without SLE, respectively. The correlation between paired plasma KIM-1 measurements from both assays was 0.7 (p<0.001) in individuals with SLE and 0.9 (p<0.001) in individuals with other diseases than SLE (Figure 1A). The Bland-Altman plots show the bias between the mean differences in plasma KIM-1 in individuals with and without SLE, indicating that the bias in measurements was significantly greater in those with than without SLE (-2.8 vs. -3 units, p=0.008, Figure 1B).

Conclusions: Anti-dsDNA antibodies in SLE may interfere with measurements by oligonucleotide-labeled antibodies.

Funding: NIDDK Support

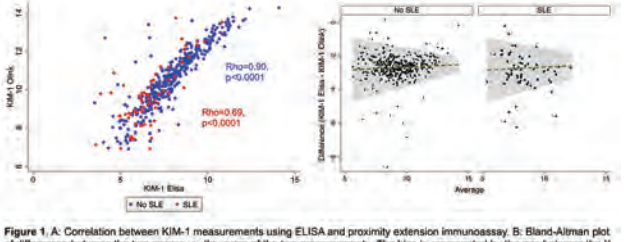

Figure 1. A: Correlation between KIM-1 measurements using ELISA and proximity extension immunoassay. B: Bland-Altman plot of differences between the two assays vs. the mean of the two measurements. The bias is represented by the gap between the X axis, corresponding to a zero difference, and the parallel line to the X axis.

Associations Between eGFR and Brain Atrophy

Michael Grasing,[1] Palash Sharma,[2] Rebecca J. Lepping,[2] Robyn Honea,[1] Aditi Gupta.[2] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: The associations between estimated glomerular filtration rate (eGFR) and both cognitive decline and brain atrophy have been less studied in elderly with kidney disease. The Alzheimer's Disease Neuroimaging Initiative (ADNI) is an NIH funded multicenter observational study characterizing progression of dementia in the elderly. Using the ADNI data, we analyzed the association between eGFR and brain volume.

Methods: We used multiple linear regression model to determine the association between eGFR and normalized (brain region divided by intracranial volume) whole brain and hippocampus volume (primary outcomes) and entorhinal cortex, and middle temporal gyrus volumes (secondary outcomes) as determined by brain MRI.

Results: Mean age of the 1596 ADNI participants was 74 ± 7 years; 53% had mild cognitive impairment (MCI), and 19% had dementia. 27% had eGFR <60 ml/min/1.73m^2. Participants with lower eGFR were older and had a higher prevalence of dementia. While increasing age, and female sex were associated with lower brain volumes, lower eGFR was not (table 1). The results persisted in sub analyses divided by tertiles of age in participants with normal cognition, MCI, or dementia.

Conclusions: Low eGFR was not associated with brain atrophy in the ADNI participants with mild-moderate reduction in eGFR.

Funding: Other NIH Support - NIA

PO2271

Correlation of Silent Brain Infarction with the Metabolic Abnormality of CKD Stage 3-5 (Nondialytic) Patients

Md Naheed Hasan. *Dhaka Medical College and Hospital, Dhaka, Bangladesh.*

Background: Silent brain infarction (SBI) is a hidden comorbidity, mostly unrecognized in CKD patients which increases the risk of symptomatic stroke, dementia and overt neurological mortality. The relationship between SBI and chronic kidney disease (CKD) is unknown. It is supposed that SBI will predict the progression of diseases processes in CKD patients.

Methods: This is a cross-sectional study. A total of 115 subjects were enrolled in this study. 85 patients of CKD stage3-5 (non dialytic) who have no neurological symptoms suggesting stroke were considered as group I and Group-II were 30 healthy controll. Glomerular filtration rate (GFR) was estimated using MDRD-equation. All study subjects underwent MRI.

Results: The proportion of Silent Brain Infarction is 52.9% in CKD patients. SBI was found in 45(52.9%) patients in group I and 4(13.3%) in group II which was significant (p<0.05). The proportion of SBI was also increased in higher CKD stages. (stage-3:8.9%; stage-4:35.6%; stage-5ND:55.6%). In a multivariate logistic regression analysis CKD had independent relationship with SBI along with serum phosphate and parathyroid hormone level (CKD had Odds ratio (OR)=1.847 (95.0% C.I 0.064 to 53.319), serum PO_4 had OR=0.958 (95.0% C.I. 0.885 to 1.038) and serum PTH had OR=0.996 (95.0% C.I. 0.993 to 1.000). Spearman rank correlation coefficient test showed positive correlation between SBI and serum PO4 level (r=0.416; p=0.001) and serum PTH level (r= 0.405; p=0.001) separately.

Conclusions: The proportion of SBI in CKD stage 3-5(non dialytic) patients is high which is 52.9% and serum PO4 and serum PTH level have positive correlation with the development of SBI in CKD stage 3-5(non dialytic) patients.

PO2272

Risk Factors for Incident Pruritus in Patients with CKD Not on Dialysis

Kendra E. Wulczyn,[1] Sahir Kalim,[1] Eugene P. Rhee,[1] Tariq Shafi.[2] *[1]Massachusetts General Hospital, Boston, MA; [2]The University of Mississippi Medical Center, Jackson, MS.*

Background: Pruritus is common in patients with CKD not on dialysis, but its incidence and risk factors have not been rigorously evaluated.

Methods: Using data from the Chronic Renal Insufficiency Cohort (CRIC) study, we identified 2,164 participants that were pruritus free at baseline. Pruritus was assessed annually by the Kidney Disease Quality of Life instrument. We used Cox models adjusted for age, sex, race, ethnicity, diabetes, smoking status, and opioid use to analyze the association of pruritus with baseline estimated GFR, categorized as <30, 30 to <45, 45 to <60, and ≥60 mL/min/1.73 m^2. In an exploratory analysis, markers of bone-mineral metabolism and inflammation, possible mediators of the association between eGFR and pruritus, were added to the models to evaluate their association with risk of pruritus.

Results: The mean age of participants was 58 years, 43% were women, and 43% Black. During a median follow-up of 6.0 years, 684 participants developed moderate-to-severe pruritus, with an overall unadjusted incidence rate of 4.6 per 100 person-years. The 5-year unadjusted cumulative incidence of pruritus was: overall 21%, eGFR ≥60 18%, eGFR 45 to <60 20%, eGFR 30 to <45 24%, and eGFR <30 20%. In the fully adjusted model, compared to eGFR ≥60, an eGFR of 30-45 was associated with a 39% (95% CI 1.08 – 1.80) higher risk of pruritus, and an eGFR <30 was associated with a 56% (95% CI 1.15 – 2.11) higher risk of pruritus (Figure 1). Female sex, diabetes, current smoking, and opioid use were associated with increased risk of pruritus, independent of eGFR. Notably, serum albumin and c-reactive protein were independently associated with pruritus, whereas calcium, phosphorous, and parathyroid hormone were not.

Conclusions: A significant proportion of patients with CKD develop pruritus, even at modestly reduced eGFR ≤ 45 mL/min/1.73 m^2. Careful assessment and management of pruritus should be considered as a part of routine CKD care.

Adjusted cumulative incidence of pruritus by eGFR in the CRIC study

PO2273

Subtle Changes in Uremic Symptoms with CKD Progression

Kendra E. Wulczyn,[1] Sahir Kalim,[1] Sophia Zhao,[1] Eugene P. Rhee,[1] Tariq Shafi.[2] *[1]Massachusetts General Hospital, Boston, MA; [2]University of Mississippi, University Park, MS.*

Background: Uremic symptoms are a major contributor to symptom burden in CKD and related to lower quality of life. However, factors associated with uremic symptom progression have not been rigorously examined.

Methods: We included 3,504 participants with CKD not on dialysis from the Chronic Renal Insufficiency Cohort (CRIC) study with at least two assessments of estimated GFR (eGFR) and uremic symptoms. The uremic symptoms fatigue, anorexia, and pruritus were assessed annually by the Kidney Disease Quality of Life instrument. Responses were transformed to a scale from 0-100, with lower scores indicating worse symptom severity. We used multivariate linear mixed effects models with random intercepts and random slopes to estimate the association between eGFR change and the change in uremic symptoms over time.

Results: The mean age of participants was 58 years, 45% were women, 41% Black, and the mean eGFR at baseline was 45 mL/min/1.73m^2. Over a median follow-up of 7 years (IQR 3-11), the average annual decline in eGFR was -1.3 mL/min/1.73m^2/year. The average annual change in the symptom scores for fatigue, anorexia, and pruritus were -0.27 (95% CI: -0.35, -0.19), -0.26 (95% CI: -0.33, -0.19), and -0.49 (95% CI: -0.59, -0.39), respectively. A 10-unit change in eGFR was significantly associated with worsening fatigue, anorexia, and pruritus (Table 1). The association was stronger for those with eGFR <30 than those with higher eGFR.

Conclusions: Decreasing kidney function is associated with worsening fatigue, anorexia, and pruritus; however, the absolute change in symptom severity scores is small and unlikely to be clinically meaningful. Regular symptom assessment should be incorporated into routine CKD care; however, caution should be used when attributing large changes in symptom severity solely to changes in the level of kidney function.

Funding: NIDDK Support

Change in symptom score per 10-unit decrease in eGFR

Conservative Kidney Management Practice Patterns in the United States: A CKDopps Analysis

Jennifer S. Scherer,[1] Daniel G. Muenz,[3] Brian Bieber,[3] Benedicte Stengel,[4] Tahsin Masud,[2] Bruce M. Robinson,[3] Roberto Pecoits-Filho,[3] Keith S. Goldfeld,[1] Joshua Chodosh,[1] David M. Charytan.[1] CKDopps Investigators *[1]NYU Langone Health, New York, NY; [2]Emory University, Atlanta, GA; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France.*

Background: Conservative kidney management (CKM) of kidney failure is an important treatment option for many patients. However, its availability in the United States (US) is not well described. We describe CKM resources and provider practice patterns in US Chronic Kidney Disease (CKD) clinics.

Methods: Cross sectional analysis of provider surveys (n=22) from unique clinics in the US from the CKD Outcomes and Practice Patterns Study (CKDopps) collected between 2014-2017.

Results: Only eight (36%) providers reported involving palliative care in planning for and educating patients about kidney failure. A majority (59%) were extremely comfortable discussing CKM and nearly 100% typically discussed CKM as a treatment option. Nearly all (95%) reported their clinics had the ability to routinely deliver CKM, but only one had a CKM protocol or guideline, and none offered a specific CKM clinic. Most providers said their clinics used the word "conservative" to describe CKM, with 24% choosing "palliative" or "supportive" terminology. Regardless of involvement of PC, most providers estimated that 5% of their patients with or approaching kidney failure were managed with CKM. Patient preference, functional status, frailty, and comorbidities were the most important factors influencing provider decisions in contemplating the suitability of CKM for patients. (Figure 1)

Conclusions: Most providers report feeling comfortable discussing CKM, yet almost no clinics report resources or dedicated infrastructure for CKM delivery. Despite reported high frequency of discussing CKM, few patients were described as choosing this treatment pathway. Factors that influence consideration of CKM are consistent with elements that generally influence well-informed geriatric and end-of-life care. Efforts to improve assessment of those elements may allow for more informed recommendations of CKM.

Factors influencing providers to consider conservative kidney management

PO2275

Association Between Monocyte Counts and All-Cause Mortality in Patients with CKD

Ester Oh, Zhiying You, Anna Jovanovich, Kristen L. Nowak. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: In the general population, monocyte counts are strongly associated with a higher risk of all-cause mortality. However, little is known whether this association translates to individuals with chronic kidney disease (CKD). The purpose of this study was to examine if monocyte counts are associated with the risk of all-cause mortality in patients with non-dialysis CKD who participated in the Chronic Renal Insufficiency Cohort (CRIC) observational study.

Methods: Patients were divided in tertiles according to their monocyte counts at baseline, and survival analysis was performed using Kaplan-Meier curve with statistical comparison by the log rank test. Cox models with time interaction effects were used to examine the association between monocyte counts and all-cause mortality.

Results: Among the 3,939 CRIC participants, a total of 3,391 participants (1,838 males and 1,553 females) were included in the final analytic cohort, with a mean ± SD eGFR of 45 ± 15 mL/min/1.73 m^2 and age of 58 ± 11 years. Participants in the highest tertile of monocyte count had a lower rate of survival than those in the lowest tertile (P<0.001, Figure). At follow-up time of 5 years, there was a 39% higher risk for all-cause mortality (95% CI: 22-59%) with every 2-fold increase of monocyte count after adjusting for age, sex, race, clinic site, traditional cardiovascular risk factors, markers of kidney disease, and c-reactive protein (fully adjusted model).

Conclusions: There may be an elevated risk for all-cause mortality in patients with CKD who have higher monocyte counts.

PO2276

Kidney Disease and Longitudinal Changes in Muscle Strength in Older Adults

Sarah J. Schrauben,[1] Brittney S. Lange-Maia,[2] Linda F. Fried,[3,4] Anne B. Newman,[5] Mark J. Sarnak.[6] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Rush University Medical Center, Chicago, IL; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; [6]Tufts Medical Center, Boston, MA.*

Background: Persons with chronic kidney disease (CKD) experience lower physical function and increased risk of disability, both of which have strong prognostic importance for poor clinical outcomes. To date, functional status studies in populations with CKD have focused on physical activity and/or individuals with end-stage kidney disease, and have largely neglected measures of muscle strength, especially among those with non-dialysis dependent CKD.

Methods: Participants were from the Health, Aging and Body Composition Study, a longitudinal cohort focused on functional decline in adults aged 70-79 years at baseline. Kidney function was defined by estimated glomerular filtration rate (eGFR) using the CKD-EPI Cystatin C Equation at each available visit (up to 5) during 10 years of follow up. Participants were grouped based upon their longitudinal eGFR: no CKD (eGFR ≥60 mL/min/1.73 m^2), prevalent CKD (baseline eGFR <60 mL/min/1.73 m^2), and incident CKD (baseline eGFR ≥60 but <60 mL/min/1.73 m^2 during follow up). Grip and quadriceps strength were also assessed longitudinally (8 and 6 visits, respectively). Linear mixed models stratified by sex tested associations between kidney function groups and grip and quadriceps strength over time.

Results: Of the 2,630 participants with median age 73 years, 64.9% had no CKD, 23.4% had prevalent CKD, and 11.7% developed incident CKD. At baseline, men and women without CKD had higher unadjusted grip and quadriceps strength compared to those with CKD. In adjusted linear mixed models for grip strength, men with CKD had faster decline over time, compared to men without CKD (Table). For women, changes in grip strength were not different across kidney function groups. In adjusted models of quadriceps strength over time, there were no differences among kidney function groups.

Conclusions: Men with CKD had faster decline in grip strength compared to those without CKD. Future studies can determine if recognizing decreased muscle strength and intervening can change this functional trajectory among those with CKD.

Health-Related Quality of Life in Patients with Inflammation and Non-Dialysis-Dependent CKD

Rachel Lai,[1] Lynda Szczech,[1] Sarah Clayton,[2] Lewis Harrison,[2] Mollie Lowe,[2] James Jackson.[2] *[1]FibroGen Inc, San Francisco, CA; [2]Adelphi Group Ltd, Bollington, United Kingdom.*

Background: Inflammation is common in chronic kidney disease (CKD) and can affect treatment of anemia, which is a common complication of CKD. Both inflammation and anemia in CKD have been linked with poor health-related quality of life (HRQoL), though evidence is limited. We aimed to assess the association between inflammation and HRQoL in patients with non-dialysis-dependent CKD (NDD-CKD).

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme™, a point-in-time survey of physicians and their patients with CKD (stage 3-5D) collected in the United States in 2018. Patients were also invited to complete a questionnaire which included subjective assessment of the impact of CKD, as well as the Kidney Disease Quality of Life-36 questionnaire (KDQoL-36). Patients with NDD-CKD who filled out the KDQoL-36 were included in this analysis. Inflammation was defined as C-reactive protein ≥4.9 mg/L, ferritin ≥700 ng/mL, or albumin ≤3.6 g/L. T-tests were conducted to assess differences in KDQoL-36 scores between patients with and without inflammation.

Results: Inflammation was present in 136/491 (28%) patients. Mean KDQoL-36 scores reported by patients with inflammation were lower than scores reported by patients without inflammation across all 5 domains (all p<0.05; Table 1). Most differences in KDQoL scores between patients with and without inflammation exceeded the distribution-based minimal clinically important difference (MCID).

Conclusions: We found that patients with inflammation in NDD-CKD reported poorer HRQoL compared with those without. Reducing inflammation in CKD may improve HRQoL.

Funding: Commercial Support - FibroGen Inc

Table 1: KDQoL-36 scores* by inflammation status

	Patients with inflammation N, Mean (SD)	Patients without inflammation N, Mean (SD)	p-value	Distribution-based MCID (½ SD)
KDQoL-36: SF-12 Mental Health Composite	76, 44.9 (10.6)	189, 50.1 (8.4)	<0.0001	4.7
KDQoL-36: SF-12 Physical Health Composite	76, 38.0 (10.1)	189, 41.8 (9.3)	0.0032	4.8
KDQoL-36: Effects of kidney disease	77, 70.9 (22.3)	195, 82.7 (19.4)	<0.0001	10.4
KDQoL-36: Symptoms/problems	77, 80.8 (17.5)	194, 87.9 (13.7)	0.0004	7.6
KDQoL-36: Burden of kidney disease	79, 56.1 (29.0)	196, 66.6 (26.2)	0.0039	13.7

*Lower KDQoL-36 scores represent lower HRQoL

Table includes only patients with a KDQoL score, therefore bases may vary from total.

PO2278

Higher Frequency of Physical Activity Reduces the Risk of Kidney Function Loss in a General Non-Diabetic Population

Renathe Rismo,[1,2] Bente Morseth,[2] Marit D. Solbu,[1,2] Bjorn O. Eriksen,[1,2] Toralf Melsom.[1,2] Metabolic and Renal Research Group. UiT The Arctic University of Norway *[1]Universitetssykehuset Nord-Norge, Tromso, Norway; [2]UiT Norges arktiske universitet, Tromso, Norway.*

Background: Physical activity (PA) reduces the risk of diabetes and hypertension, known risk factors for chronic kidney disease (CKD), but there is limited data on the independent association between PA and loss of kidney function. Previous population studies of PA have reported mixed results and relied on estimated glomerular filtration rate (eGFR). All eGFR equations are biased by non-GFR related factors such as muscle mass and inflammation, making confounding likely, particularly in studies of PA. We investigated the association between self-reported PA and the annual change of measured GFR in a general population cohort.

Methods: 1627 subjects aged 50-62 years, without diabetes, cardiovascular disease or CKD were recruited from the general population in Tromsoe, Norway, and included in the Renal Iohexol Clearance Survey (RENIS) in 2007. Participants completed a questionnaire regarding frequency, intensity and duration of leisure-time PA, medication and comorbidities. GFR was measured using iohexol clearance at baseline and follow-up in 2013-15 and 2018-20. Linear mixed regression was used to analyze the association of PA with annual change in GFR, and logistic regression was used to assess the risk of accelerated GFR decline, defined as being those with the 10% steepest GFR decline.

Results: Mean (SD) age was 58 (3.8) years and 51% were female, median follow-up time was 11 years. Relative to participants that never exercise, the annual GFR decline rate for participants with PA once a week, 2-3 times a week or almost every day was slower by 0.40 (95% CI 0.05-0.76, p=0.026), 0.49 (95% CI 0.15-0.84, p=0.005) and

0.52 (95% CI 0.16-0.89, p=0.005) ml/min/1.73m^2/year (linear trend p=0.002), in a fully adjusted model. Increasing frequency of PA was associated with a lower odds ratio (OR) of rapid kidney function decline, with an OR of 0.25 (95% CI 0.1-0.6, p=0.004) for the highest frequency of weekly PA compared to the group that never exercise, in a model adjusted for established risk factors for GFR decline (linear trend across groups p=0.011).

Conclusions: In this population-based study with repeated measurements of GFR during 11 years of follow-up, higher frequencies of leisure-time PA are associated with slower GFR decline.

Serum Uric Acid Levels and Nephrosclerosis in a Population-Based Autopsy Study: The Hisayama Study

Kenji Maki, Jun Hata, Satoko Sakata, Yoshihiko Furuta, Emi Oishi, Toshiaki Nakano, Yoshinao Oda, Takanari Kitazono, Toshiharu Ninomiya. *Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan.*

Background: The information regarding the influence of serum uric acid levels on the pathological changes in kidney is limited. We aimed to examine the association between serum uric acid levels and pathological findings of nephrosclerosis in population-based autopsy samples.

Methods: A total of 923 deceased subjects in a Japanese community underwent autopsy examinations between 1974 and 1994. Of these, 547 cases with available kidney tissues and health examinations data within a median of 3 years before death were eligible for the present study. Serum uric acid levels were categorized into quintiles (Q1, 1.8-3.9; Q2, 4.0-4.6; Q3, 4.7-5.4; Q4, 5.5-6.3; Q5, 6.4-12.7 mg/dL). The presence of the advanced degree of glomerular sclerosis, kidney arteriolar hyalinosis, and kidney arteriosclerosis were determined by the 90th percentile or more of a glomerular sclerosis index and an arteriolar hyalinosis index, and the 10th percentile or less of a wall-lumen ratio, respectively. A logistic regression model was used to evaluate odds ratios and their 95% confidence intervals of serum uric acid levels on each kidney lesions.

Results: Higher serum uric acid levels were associated significantly with greater age- and sex-adjusted glomerular sclerosis index and lesser wall-lumen ratio. Subjects in the Q5 groups had a significantly greater likelihood of advanced glomerular sclerosis and advanced kidney arteriosclerosis than in subjects in the Q1 group after adjusting for potential covariates. There was no evidence of significant associations of serum uric acid levels with arteriolar hyalinosis index and the presence of advanced arteriolar hyalinosis.

Conclusions: Elevated serum uric acid levels were associated significantly with advanced glomerular sclerosis and advanced kidney arteriosclerosis, but not with advanced arteriolar hyalinosis in community based autopsied samples of Japanese.

PO2280

Prescribed Medications for Nausea and Vomiting Symptoms and Incident CKD in US Veterans

Diana S. Kalantar,[1,2] Cachet Wenziger,[1,2] Praveen Kumar Potukuchi,[3,4] Ankur A. Dashputre,[3,4] Keiichi Sumida,[3] Csaba P. Kovesdy,[4,3] Kamyar Kalantar-Zadeh,[1,2] Elani Streja.[1,2] *[1]VA Long Beach Healthcare System, Long Beach, CA; [2]University of California Irvine, Irvine, CA; [3]The University of Tennessee Health Science Center, Memphis, TN; [4]VA Memphis Medical Center, Memphis, TN.*

Background: Unpleasant upper gastrointestinal symptoms including nausea and vomiting and prescribed medication for their management may have important clinical implications as prelude to incident of chronic kidney disease (CKD), a hypothesis we sought to examine in US Veterans without reduced kidney function.

Methods: In 2,524,842 US Veterans with normal baseline eGFR (≥60 ml/min/1.73m2) and available data on albuminuria in 2004-2006, we examined the association of de novo prescription of anti-emetic medications during the baseline period with incident CKD over 14 years. Associations were examined in hazard models adjusted for demographics, major comorbidities, baseline eGFR, and albuminuria category.

Results: We identified 14,813 Veterans who were incident new anti-emetic users. Patients were a mean 61±14 years old, 7% female, 16% Black, and 5% Hispanic. Anti-emetic medication users were more likely to be female, White, smokers, with higher frequencies of comorbidities such as chronic obstructive pulmonary disease, cancer, and diabetes. Anti-emetic medication users had an almost 2-fold higher incident rate of CKD compared to non-users [4.7 (95% CI 4.6-4.9) per 100 patient years vs. 2.4/100PY (2.4-2.4), a faster time to incident CKD (Figure 1), and a 73% higher multivariable adjusted hazard (HR: 1.73, 95%CI: 1.69, 1.78) of incident CKD.

Conclusions: De novo prescription of anti-emetic medications in Veterans without reduced kidney function is associated with 73% higher likelihood of incident CKD independent of comorbidities and other potential confounders. Higher incident CKD likelihood may be due to prescribed anti-emetic medications or this relationship may represent the association of the unpleasant upper gastrointestinal symptoms with CKD risk, which warrants additional studies.

PO2281

Polypharmacy and Potentially Inappropriate Medication Use in Patients with CKD Managed in Canadian Primary Care

Mohammed M. Tinwala,[1] Deenaz Zaidi,[1] Feng Ye,[1] Shezel Muneer,[1] Anukul Ghimire,[1] Maryam Khan,[1] Naima Sultana,[1] Ikechi G. Okpechi,[1] Paul E. Ronksley,[3] Neil Drummond,[1] Dee Mangin,[2] Aminu K. Bello.[1] *[1]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Polypharmacy and the use of potentially inappropriate medications (PIMs) are an increasingly serious public health challenge attributable to aging populations and multimorbidity. This study assessed the prevalence of polypharmacy and use of PIMs in chronic kidney disease (CKD).

Methods: A cross-sectional analysis using the Canadian Primary Care Sentinel Surveillance Network (CPCSSN) database (January 1, 2010 through December 31, 2018). Polypharmacy was defined as the use of ≥ 5 medications, excessive polypharmacy as ≥ 10 medications, and PIMs as medications recommended to be avoided in CKD.

Results: The cohort was comprised of 70,331 patients (mean [SD] age, 73.1 [11.4] years; 40,502 [57.6%] female) with CKD stages G3a to G5. The most common chronic conditions were hypertension (60.8%), diabetes (29.4%), and osteoarthritis (25.4%). Overall, the prevalence of polypharmacy and excessive polypharmacy was 91.5% and 74.9%, respectively. The median number of medications was 14 (IQR 9-23). The most commonly prescribed medications were atorvastatin (29.8%), amlodipine (28.9%), and rosuvastatin (27.2%). About 45% of patients with CKD had at least one PIM, 11.1% had two PIMs, and 3.6 % had three or more PIMs. The most commonly prescribed PIMs were metformin (21.7%), nitrofurantoin (16.2%), and rivaroxaban (4.5%).

Conclusions: Polypharmacy and use of PIMs are highly prevalent among patients with CKD managed in primary care. These findings highlight opportunities for interventions aimed at improving prescribing practices in the management of CKD.

PO2282

Association of SGLT2 Inhibitors and DPP-4 Inhibitors vs. GLP-1 Agonists with Incident CKD in US Veterans

Kamyar Kalantar-Zadeh,[1] Connie Rhee,[1] Yoko Narasaki,[1] Amy S. You,[1] Ankur A. Dashputre,[2] Keiichi Sumida,[2] Fridtjof Thomas,[2] Elani Streja,[1] Praveen Kumar Potukuchi,[2] Csaba P. Kovesdy.[2] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: Randomized controlled trials (RCTs) have demonstrated that SGLT2 inhibitors (SGLT2i) reduce the risk of eGFR decline and ESRD as compared with placebo in patients with pre-existing CKD. These RCTs showed an initial dip in eGFR with initiation of SGLT2i that stabilized over time. Little is known about the impact SGLT2i vs. other newer anti-diabetic medications (DPP-4 inhibitors [DPP4i], GLP1 agonists [GLP1a]) upon risk of developing de novo kidney dysfunction in patients without underlying CKD.

Methods: Among US Veterans with diabetes and absence of pre-existing CKD (normal eGFR and no proteinuria) followed over 2004-18, we identified incident (new) users of SGLT2i vs. DPP4i vs. GLP1a therapy, excluding combined users of the examined classes. We examined associations of SGLT2i vs. DPP4i vs. GLP1a use with the risk of incident CKD (primary outcome) and ESRD (secondary outcome) using multivariable Cox models.

Results: Among 39,065 diabetic patients without pre-existing CKD, 15%, 70%, vs. 15% were new users of SGLT2i, DPP4i, vs. GLP1a, respectively. Compared to DPP4i, use of SGLT2i and GLP1a were each associated with higher risk of incident CKD: adjusted HRs (aHRs) (95%CI) 1.32 (1.18-1.47) and 1.20 (1.11-1.31), respectively (**Figure 1A**). However, use of SGLT2i and GLP1a were not associated with higher risk of de novo ESRD: adjusted HRs (aHRs) (95%CI) 1.20 (0.15-9.32) and 0.62 (0.24-1.57), respectively (**Figure 1B**).

Conclusions: In a national cohort of diabetic US Veterans without pre-existing CKD, SGLT2i and GLP1a use were each associated with higher risk of incident CKD as compared with DPP4i use. However, neither medication was associated with incident ESRD, suggesting that early decline with SGLT2i and GLP1a use may be an acute/subacute effect that stabilizes over time.

PO2283

Insulin Use and CKD Are Risk Factors for Mild Cognitive Impairment (MCI) or Dementia in Persons with Type 2 Diabetes

Srinivasan Beddhu,[1,2] Robert E. Boucher,[1] Nikita Abraham,[1] Judy Carle,[1] Victoria Gonce,[1] Sydney E. Hartsell,[1] Guo Wei.[1] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Both insulin use and CKD are risk factors for hypoglycemic episodes in patients with diabetes. Recurrent hypoglycemia is associated with increased risk of dementia. Hence, we examined whether insulin use and CKD are associated with increased risk of MCI/dementia.

Methods: We analyzed a national VA cohort (N =855,133) with T2DM defined by ICD-9 codes and outpatient serum creat from 1/2008 to 12/2010. Index date was the date of first outpatient serum creatinne measurement. Baseline comorbidities were defined by ICD-9 codes from 10/1999 to the index date. MCI/ dementia were defined by ICD9/10 codes. Those with baseline MCI/dementia were excluded and new onset of MCI/dementia was tracked from index date to 12/31/2020. A multivariate logistic regression model of baseline variables was used to develop propensity scores of baseline insulin use (24% were on insulin at baseline). A propensity score matched cohort (N = 288,374) was used to relate baseline insulin use and CKD stages with subsequent MCI/dementia in Cox regression models.

Results: Baseline mean age was 65 ±11 yrs, 20% black and mean eGFR 72±24. There were 40,299 MCI/dementia events over 2,439,244 years of follow up. There was a graded increase in incidence rate of MCI/dementia by CKD stages and insulin use (Fig1). In a Cox regression model adjusted for propensity scores and covariates, both insulin use and advanced CKD were associated with higher risk of MCI/dementia (Fig2).

Conclusions: Both insulin use and advanced CKD are associated with higher risk of MCI/dementia in persons with T2DM.

Incidence of CKD Stages 3-5 Among Patients on Lithium Therapy

Gisli Gislason,[1] Olafur S. Indridason,[2] Engilbert Sigurdsson,[4] Runolfur Palsson.[1,3] *[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Division of Nephrology, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [3]Internal Medicine Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [4]Mental Health Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland.*

Background: The association between lithium use and chronic kidney disease (CKD) is not well understood, and the impact of comorbidities and other factors remains unknown. The aim of this study was to examine the risk of developing CKD stage 3 and above among individuals using lithium.

Methods: This was a retrospective cohort study of all patients in Iceland treated with lithium in the years 2008-2018. A control group was comprised of patients with affective disorders (ICD-10 codes F30-F39) who attended the outpatient clinics of the Landspitali–The National University Hospital Mental Health Services in 2014-2016 and had not been prescribed lithium. CKD stages 3-5 was defined according to the KDIGO 2012 guidelines and eGFR was calculated from serum creatinine (SCr) using the CKD-EPI equation. Individuals with CKD 3-5 prior to 2008 and those with fewer than 2 SCr measurements during the study period were excluded. Risk assessment was performed using logistic regression.

Results: A total of 2682 persons had received lithium treatment, of whom 2051 (76.5%) were included in the study. Of those 221 (10.8%) developed CKD 3-5. Of the 1426 persons in the control group, 1010 (70.8%) were included, of whom 29 (2.9%) developed CKD 3-5. Lithium use was significantly associated with CKD development (OR 1.94, 95% CI 1.25–3115) after adjusting for sex, age and comorbid diseases (Table).

Conclusions: Lithium treatment is a highly significant independent risk factor for the development of CKD in individuals with affective disorders.

Effect of Serum Testosterone on Kidney Function in Men and Women from the General Population

Anna C. van der Burgh, S.J.C.M.M. Neggers, Elif Aribas, M. Arfan Ikram, Maryam Kavousi, Ewout J. Hoorn, Layal Chaker. *Erasmus MC, Rotterdam, Netherlands.*

Background: Testosterone may prevent kidney function decline, but at population level evidence is sparse in males, and even lacking in females. Therefore, we investigated the association between serum testosterone and kidney function in males and females from a large population-based cohort study.

Methods: Linear regression and linear mixed models were used to assess the associations of serum free and total testosterone with kidney function, including baseline assessments of estimated glomerular filtration rate (eGFR) based on serum creatinine (eGFRcreat) or serum cystatin C (eGFRcys), and the urine albumin-to-creatinine ratio (ACR), and repeated assessments of eGFRcreat. Betas with their 95% confidence intervals (CI) were reported per 1 nmol/L increase in testosterone. Analyses were conducted for males and females separately.

Results: Our study population comprised 9,484 participants (mean age 65.2 years). In males (n=4,162), higher free testosterone was associated with lower eGFRcreat (beta -0.63, 95% CI -1.05;-0.21), but higher eGFRcys (beta 0.56, 95% CI 0.07;1.05), and lower ACR (beta -0.25, 95% CI -0.35;-0.16) at baseline. Higher total testosterone was associated with higher eGFRcreat at baseline and over time, but with lower eGFRcreat when additionally adjusted for sex hormone-binding globulin. In females (n=5,449), higher free testosterone was associated with lower eGFRcreat and eGFRcys at baseline (beta -1.03, 95% CI -1.36;-0.71, beta -1.07, 95%CI -1.44;-0.70) and lower eGFRcreat over time (beta -0.78, 95% CI -1.10;-0.46), but not with ACR. Similar results were obtained with total testosterone.

Conclusions: The association between serum testosterone and kidney function is sex-dependent, with a positive association in males and a negative association in females. The discrepant results with eGFRcreat in males may be explained by the effect of testosterone on muscle mass. Whether treatment with testosterone replacement therapy may be beneficial for kidney function in males with low serum testosterone still needs to be investigated. The association between testosterone and lower eGFR in females requires further study.

PO2286

Assessment of Circulating Inflammatory Cytokines Aids in the Prediction of Progression of CKD

Ross Doyle,[1,2] Susan L. Murray,[3] Eoin Brennan,[1] Peter J. Conlon,[3,4] Denise M. Sadlier,[2,1] Catherine Godson.[1] *[1]University College Dublin, Dublin, Ireland; [2]Mater Misericordiae University Hospital, Dublin, Ireland; [3]Royal College of Surgeons in Ireland, Dublin, Ireland; [4]Beaumont Hospital, Dublin, Ireland.*

Background: Though Chronic Kidney Disease (CKD) is common, only a small proportion of patients progress towards the need for dialysis or transplantation. Understanding the factors which drive progression of CKD may facilitate better prediction of outcomes for patients and streamline patient care.

Methods: Inflammatory cytokines, IL-6, IL-10 and TNF-α were measured in patients with CKD. Clinical data, including demographic, biochemical, histological, and longitudinal assessments of renal function were collected for these patients. Differences in levels of circulating inflammatory cytokines were examined using independent samples, two-sided T tests, with $\alpha < 0.05$. Linear regression models, using bootstrap resampling were explored to identify the ability of these cytokines to explain future eGFR. Cox proportional hazards models were explored to examine predictors of progression of CKD, defined as the need to commence dialysis or undergo transplantation.

Results: Levels of inflammatory cytokines were assessed in 226 patients with kidney disease. Higher levels were seen in those patients who experienced progression of CKD. 14% of the variance in eGFR at 12 month follow-up was explained by IL-6 levels at baseline (bias -0.0039, SE 0.036). TNF-α levels were predicted to explain 21% of 12 month eGFR (bias -0.005, SE 0.07). In a Cox proportional hazards model, patients with the highest quartile of IL-10 measurements were more likely to experience CKD progression towards the need for dialysis or transplantation (HR 4.99, 95% CI 1.62-15.32) (Likelihood ratio test = 45, on 13 df, $p = 2x10^{-5}$). Patients with lower levels of tubulointerstitial fibrosis (<50% on kidney biopsy) were less likely to experience progression of CKD (HR 0.38, 95% CI 0.19-0.73).

Conclusions: Higher levels of inflammatory cytokines in patients with CKD are predictive of eGFR decline and may be incorporated in models to help predict outcomes for CKD patients.

PO2287

Disturbance of Circadian Rhythm and CKD in Korean Adult Population

Yina Fang, Sewon Oh, Jihyun Yang, Ko Yoon Sook, Hee Young Lee, Sang-Kyung Jo, Won-Yong Cho, Myung-Gyu Kim. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Disturbances in circadian rhythm are known to cause a number of health problems (psychosis, metabolic syndrome, cancer, etc.), however their contribution to kidney disease is not well understood. Therefore, this study evaluated the association with chronic kidney disease (CKD), sleep disturbance, and shift work in a Korean adult population.

Methods: A total of 32,429 participants who completed the National Health and Nutrition Examination Survey from 2010 to 2018 were assessed for their sleep patterns, shift work, and renal function. CKD was defined by eGFR ≤60 mL/min/1.73 m^2 or urinary albumin-to-creatinine ratio ≥30 mg/g.

Results: First, sleep disturbances were assessed according to sleep onset time and total sleep duration. We observed that the early bedtime group (starting sleep before 9pm) had a significantly higher CKD prevalence (OR 2.757, $p < 0.001$) compared to the regular bedtime group (9pm-2am), but inadequate sleep duration (<6hr) had minimal effect on CKD (OR 1.052, p=0.745), which suggest that alterations in circadian rhythms due to sleep disturbance are associated with CKD development. In particular, there was a strong association between sleep disturbance and renal dysfunction in patients with comorbidities younger than 65 years of age. Next, work schedules were divided into two types; regular work (day or evening work) and shift work (fixed night shift, 24-hour shift, split-work). The shift-work group also had a higher prevalence of CKD compared to the regular work group (OR 1.32). However, in a multivariate analysis that adjusted for age, sex, BMI, smoking, drinking, diabetes, and hypertension, neither sleep disturbance nor shift work showed an independent association with the occurrence of CKD.

Conclusions: Our results suggest that impaired circadian rhythm may be associated with CKD development and that sleep disturbance can be an important therapeutic target for circadian rhythm.

PO2288

Mortality Risk and Life-Years Associated with CKD for Young and Older Adults

Alexander J. Kula,[1,2] David K. Prince,[3,2] Ronit Katz,[2] Nisha Bansal.[3,2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Kidney Research Institute, Seattle, WA.*

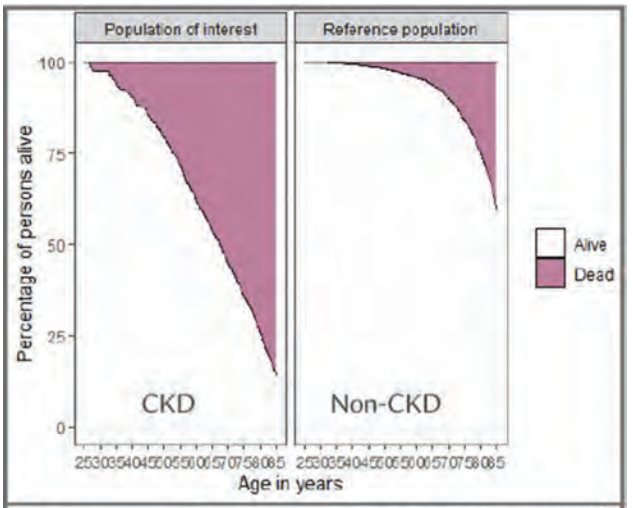
Background: Younger individuals living with CKD face a lifetime at risk for complications, including an increased risk of mortality. There is limited data to inform individual patients with CKD across the lifespan how their risk for mortality compares with equivalently aged individuals without CKD. The objective of this study is to provide age specific contexts to the risk of mortality associated with a diagnosis of CKD.

Methods: We created a pooled study cohort using participants with CKD enrolled in the Chronic Renal Insufficiency Cohort along with participants aged 21-75 years with an eGFR >70mL/min/1.73m^2 included in the 2002-2008 NHANES surveys. Age-stratified mortality rates, along with unadjusted and adjusted hazard ratios (HR) for mortality were generated to compare differences between those with and without CKD. Mean life-years-lost (LYL) relating to CKD were calculated using CDC life tables.

Results: A total of 17,550 participants (3,746 with CKD) were included. The adjusted HR for mortality relating to CKD was highest in the 21-35yr strata (HR [95% CI]: 5.6 [3.5, 9.0]) and lowest in the 65-75yr strata (HR [95% CI]: 1.9 [1.6, 2.1]). Mean LYL secondary to CKD was inversely related with increasing age (**Fig. 1**). An individual aged 21yrs old with CKD could expect a mean of 15.6 LYL compared to age-matched peers without CKD. A similar comparison in a 70-yr-old would translate to 2.9 LYL.

Conclusions: Compared to age-matched peers without CKD, the risk for mortality and LYL associated with a diagnosis of CKD is highest in younger individuals. Further research is needed to elucidate the societal and personal costs of premature mortality in young adults with CKD.

Funding: NIDDK Support



Age	Life years lost (95% CI) due to CKD
21-year-old	**15.6** (13.4, 18.7)
30-year-old	**14.7** (13.2, 16.3)
40-year-old	**12.6** (11.7, 13.8)
50-year-old	**9.8** (9.2, 10.5)
60-year-old	**6.1** (5.7, 6.5)
70-year-old	**2.9** (2.6, 3.1)
80-year-old	**0.7** (0.6, 0.9)

PO2289

Estimated Glomerular Filtration Rate (eGFR) and Myocardial Fibrosis Biomarkers in Hypertensives with and Without CKD

Shota Watanabe,[1] Zhengyi Chen,[2] Curtis Tatsuoka,[2] Mahboob Rahman,[1,2] Jackson T. Wright,[1,2] Mirela A. Dobre.[1,2] *[1]University Hospitals, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Background: CKD leads to accumulation of fibrotic tissue in the myocardium with subsequent loss of cardiac function. Two circulating biomarkers of collagen type I and III (PICP and P3NP) correlate with the amount of cardiac collagen deposition. Galectin 3 (Gal-3), a predictor of heart failure, is used to stratify patients at increased cardiovascular risk. We aimed to assess the association between eGFR and Gal-3, PICP, and PIIINP levels in individuals with and without CKD enrolled in the Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: A random sample of 1026 SPRINT participants 50 years or older were included in the study. Baseline demographic, anthropometric, co-morbid conditions and laboratory data were examined univariately for association with quartiles of Gal-3, CICP and PIIINP. The statistically significant variables were chosen for the multivariate quantile regressions at median (MQR) to assess the association between baseline eGFR and each biomarker.

Results: The mean age (SD) was 68.3±9.9 years, and 38.4% had CKD. In MQR models, baseline eGFR was negatively associated with Gal-3, PICP and PIIINP levels. (Figure) Similar results were found in participants with CKD, but not in participants without CKD, with significant correlation between eGFR with Gal 3 and PIIINP, but not with PICP. In combination, PIIINP was correlated with PICP (Coef 0.26, 95%CI (0.17, 0.35), p<0.001)), and Gal3 (Coef (0.35, 95%CI (0.26, 0.43), p<0.001) in the CKD subgroup, but not in the non-CKD subgroup (p=0.10, and p=0.07 respectively).

Conclusions: CKD status modifies the association between myocardial fibrosis biomarkers and eGFR, with high serum Gal-3, CICP, and PIIINP levels associated with low eGFR. Future research is needed to elucidate whether there is a causal link between kidney function decline and risk for myocardial fibrosis.

Quantile Regressions for eGFR and Myocardial Fibrosis Biomarkers

PO2290

Renal Biopsy Is Mandatory in Normal Urinary Findings with Unknown Origin Hypertension or CKD

Byoung-Soo Cho. *Dr.Cho's kidney Center, Deoul, Seoul, Republic of Korea.*

Background: One of th most common causes of end stage renal disease are diabetes mellitus, hypertension and chronc glomerulonephritis, however most centers do not try to find the origin of hypertension especially in chronic kideny disease patients. Most chronic glomerulonephritis patients usually associated with hematuria and or proteinuria. Most kidney centers do not recommend renal biopsy if proteinuria is absent even though associated with persistent hematuria. In order to clarify the causes of hypertension or chronic kidney diseases, our center performed renal biopsy who showed unkown origin chronic kidney disease or unknown origin hypertension even though urinalysis findings showed no abnormalities.

Methods: From 2014 to 2020, we performed 1,300 cases of renal biopsy, of which 272 cases showed no urinary abnormalities when performing renal biopsy. We perfomred renal biopsy not only in unknown origin hematuria and unknown origin proteinuria but also we perfomed renal biopsy in unkown origin CKD and unknown origin hypertension even though urinary findindings were normal at that time of renal biopsy.

Results: Of the 1,300 renal biopsy patients, 272(20.9%) showed normal urinalysis findings at that time of renal biopsy. Minor changes were detected in 2 cases among 272 cases. Most cases were serious chronic glomerulonephritis. Biopsy results were as follows: IgA nephrothy 98cases(36%), Mild focal nonspecific glomerulonephritis 43 cases(15.8%), Focal segmental glomerulosclerosis 39 cases(14.3%), Diffuse mesangial proliferative glomerulonephritis 39 cases(14.3%), Podocyte disease 8 cases (2.9%), Membranous nephropathy 6 cases ((2.2%), C1q nephropathy 5 cases(1.8%), Lupus nephritis 4 cases(1.5%), malignant hypertension 3 cases1.1%), obesity related glomerulopathy 2 cases(0.7%), Minor change 2 cases(0.7%), C3GN 1 case(0.3%)

Conclusions: Most patients with CKD /hypertension patients without urinary abnormalities showed serious chronic glomerulonephrits such as IgA nephroapthy, FSGS, diffuse mesangial proliferative glomerulonephritis etc. kidney biopsy is mandatory in unknown origin CKD /hypertension to clarify the original causes before considering antihypertensive medicine.

PO2291

Association Between Diabetes and Major Bleeding Complications of Renal Biopsy: Analysis of 76,304 Patients Using a National Inpatient Database in Japan

Sho Hasegawa, Akira Okada, Masaomi Nangaku. *Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: Nephrologists have recently recognized the heterogeneity of kidney diseases in patients with diabetes and actively performed percutaneous renal biopsies (PRBs). However, the association between diabetes and major bleeding complications of PRBs remains unclear.

Methods: In this retrospective observational study using the Japanese nationwide Diagnosis Procedure Combination inpatient database, we identified patients who underwent an elective PRB between July 2010 and March 2018. The primary outcome was the occurrence of major bleeding complications defined as (i) red blood cell transfusion within 7 days after the PRB or (ii) invasive hemostasis after the PRB. Multiple regression analysis was performed to analyze the association between diabetes and major bleeding complications with adjustment for patient and hospital characteristics.

Results: We identified 76,304 patients, including 8,245 patients with diabetes. The proportion of biopsies for patients with diabetes to total biopsies increased year by year (Figure 1). Major bleeding complications occurred in 678 (0.9%) patients, including 622 (0.8%) red blood cell transfusion and 109 (0.1%) invasive hemostasis. Diabetes was significantly associated with major bleeding complications (RR, 2.66; 95% CI, 2.12-3.34)

after adjusted for patient and hospital characteristics. Among patients with diabetes, multi-agent or insulin treatment showed a significant association with major bleeding complications (RR, 1.55; 95% CI, 1.16-2.08), compared with single-agent diabetes treatment.

Conclusions: Diabetes was an independent risk factor for major bleeding complications of PRBs. Moreover, severity of diabetes was associated with increase in major bleeding complications. Nephrologists should carefully judge whether the anticipated benefits counterbalance the relatively high risk of major bleeding complications when considering PRBs for patients with diabetes.

Funding: Government Support - Non-U.S.

Figure 1. Annual transition of renal biopsies for patients with diabetes

PO2292

Application of the Renal Chronicity Score on Native Kidney Biopsies: Results from the FCGG Biopsy Registry

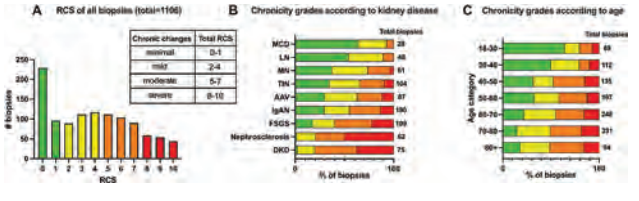
Dries Deleersnijder,[1] Wim Laurens,[2,3] Johan M. De Meester,[2] Amélie Dendooven,[4] Ben Sprangers.[1] *[1]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [2]AZ Nikolaas, Sint-Niklaas, Belgium; [3]Universiteit Gent, Gent, Belgium; [4]Universitair Ziekenhuis Gent, Gent, Belgium.*

Background: Chronic changes on kidney biopsy strongly predict renal outcome and have important treatment implications. Sethi *et al*. recently proposed the renal chronicity score (RCS), a standardized pathology scoring system which uniformly scores chronic changes on kidney biopsies. We report the RCS of the biopsies included in the FCGG registry in 2018 and 2019.

Methods: The RCS is derived from the sum of the degree of glomerulosclerosis, tubular atrophy, interstitial fibrosis and arteriosclerosis, and ranges from 0 (no/minimal chronic changes) to 10 (severe chronic changes). The FCGG registry is a population-based native kidney biopsy registry in Flanders (Northern part of Belgium) that covers a population of approximately 6.5 million inhabitants.

Results: In 2018 and 2019, the RCS was reported in 1106 of 1403 adult biopsies (78,83%), with a median value of 4 (mild chronic changes, Fig. 1A). Minimal change disease (MCD) and lupus nephritis (LN) showed mostly minimal to mild signs of disease chronicity (Fig. 1B). Membranous nephropathy (MN), tubulointerstitial nephritis (TIN), ANCA-associated vasculitis (AAV) and IgA-nephropathy (IgAN) showed an increasing proportion of moderate to severe chronic changes (26%, 35%, 37%, 45%, respectively, Fig. 1B). Finally, in focal segmental glomerulosclerosis (FSGS), nephrosclerosis and diabetic kidney disease (DKD) the proportion of biopsies with moderate to severe chronic changes exceeded 50% (60%, 79%, 80%, respectively, Fig. 1B). The RCS was also higher in biopsies from older patients (Fig. 1C), although this observation is likely confounded by the etiology of kidney disease in the older age categories (i.e., more nephrosclerosis in older patients).

Conclusions: We report on the first large population-based kidney biopsy registry that systematically scores chronic changes on kidney biopsy in a standardized manner, using the RCS. Future research should validate this score by assessing the correlation with prognosis and treatment outcome in individual kidney diseases and determine whether disease-specific modifications in the chronicity classification should be made.



PO2293

Cystatin C and Creatinine as Biomarkers of Pediatric Sarcopenia

Lokesh N. Shah, Jin Long, Jessica R. Whalen, Paul C. Grimm, Mary B. Leonard. *Stanford University School of Medicine, Stanford, CA.*

Background: Pediatric sarcopenia defines a state of reduced muscle mass and strength in chronically ill children. Since Creatinine is a byproduct of all skeletal muscle cells and Cystatin C is made by all nucleated cells, we hypothesized that a relationship between the two could estimate muscle mass and muscle strength.

Methods: In 217 recruited healthy children and adolescents, data collected included anthropometric measures, whole body DXA composition, handgrip strength, leg extension and leg flexion. Stored sera were sent for Creatinine and Cystatin C measurements. We developed 4 models to estimate muscle mass and strength. Low lean mass based on an NHANES Z-score of appendicular lean mass index < -1 defined sarcopenia.

Results: Univariate analyses demonstrated the following to be associated with muscle mass and strength: age, sex, weight, height, sexual maturity, serum creatinine, differences in eGFR, and ratio of serum Cystatin C to serum Creatinine ($p < 0.01$). When compared against a model of only physical exam biomarkers, adding creatinine and cystatin C did not lead to clinically significant improved estimates. Using a definition of sarcopenia defined by low lean mass, there was minimal added predictive ability in identifying sarcopenia in healthy children.

Conclusions: The addition of Cystatin C and Creatinine did not meaningfully improve the estimation of muscle mass or muscle strength in healthy children. Future work remains to evaluate these models in children with chronic kidney disease.

Funding: NIDDK Support, Private Foundation Support

Table 1A. Summary of R^2 values: Model Estimation in Healthy Children

	Appendicular Lean Mass	Whole Body Total Lean Mass	Handgrip Strength	Leg Strength in Knee Extension	Leg Strength in Knee Flexion

Behavioral Characteristics and Related Factors Among CKD Patients in South Korea During the COVID-19 Pandemic

Yaerim Kim,[1] Jeonghwan Lee,[2] Jae Yoon Park,[3] Jung Nam An,[4] Kyung Don Yoo,[5] Yong Chul Kim,[6] Woo Yeong Park,[1] Kyubok Jin,[1] Dong Ki Kim,[6] Jung Pyo Lee.[2] *[1]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [4]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [5]Ulsan University Hospital, Ulsan, Republic of Korea; [6]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: The recent novel coronavirus disease (COVID-19) pandemic has led to unprecedented changes in behavior. We evaluated the current status of precautionary behavior and physical activity in chronic kidney disease (CKD) patients during the COVID-19 pandemic.

Methods: A population of CKD patients (n=306) registered in a SKETCH (Study on Kidney disease and EnvironmenTal Chemicals, Clinical Trial No. NCT04679168) cohort recruited from June 2020 to October 2020 was included in the study. We conducted a questionnaire survey related to (1) risk perception of COVID-19, (2) hygienic behavior, (3) social distancing, and (4) physical activity during the past year (before the pandemic) and during the pandemic. To compare behaviors before and during the COVID-19 pandemic, the Wilcoxon-signed rank test was used. Logistic regression analysis was conducted to identify the relative factors related to risk recognition or behavior changes.

Results: There were 187 (61.1%) patients with eGFR <45 mL/min/1.73 m^2. This population showed a higher degree of risk perception for COVID-19 than the general population. During the pandemic, social distancing and hygiene-related behavior was significantly increased (P <0.001). The frequency of exercise was decreased only among those with regular exercise, without diabetes, or with a lower Charlson comorbidity index (CCI) (P <0.001), with no change among the other groups. Socioeconomic status and comorbidities significantly affected behavioral characteristics regardless of the category. Age was the most significant determinant of risk perception among CKD patients. Education and income were significantly associated with precautionary behaviors such as staying at home and hand sanitizer use. Also, patients with higher CCI status significantly increased their frequency of exercise (adjusted OR 2.10, 95% CI 1.01-4.38).

Conclusions: CKD patients showed higher risk-perception with active precautionary behavioral changes than the general population. Healthcare providers should be aware of the characteristics to comprise precautionary behavior without reducing the physical activity.

PO2295

AKI in Rural Workers: Is Mesoamerican Nephropathy in Fact an Agricultural Nephropathy?

Carlos G. Musso,[1,2] Gustavo Aroca Martinez,[2,3] Andres Cadena-Bonfanti,[2,3] Lil Geraldine Avendaño-Echavez,[2] Sergio Terrasa,[1] Maria D. Velez-Verbel,[3] William A. Peña-Vargas,[4] Rafael Perez,[2] Angelica Sierra.[2] *[1]Research Departament. Hospital Italiano de Buenos Aires, Argentina, Buenos Aires, Argentina; [2]Univiersidad Simon Bolivar, Barranquilla, Colombia; [3]Clinica de la Costa Ltda, Barranquilla, Colombia; [4]Hospital la divina misericordia, Cartagena, Colombia.*

Background: Mesoamerican nephropathy (MN) is a chronic tubule-interstitial nephropathy, originally described in Central America, and whose exact etiology is still unknown. Many inducing factors have been proposed such as severe dehydration, rhabdomyolysis, nephrotoxicity, chronic infections, genetic predisposition, etc. However, similar nephropathies to MN have been described in areas geographically far and ethnically diverse from Mesoamerica but which have a common factor: the intensity of hot weather and rural physical labor. For this reason, we suggest the term "agricultural nephropathy" as more appropriate name for this condition. Then, it was decided to study whether this entity could occur among rural workers of non Mesoamerican region but having similar climatic and working conditions, as is the case of the Colombian Caribbean countryside, and to consider how much repeated dehydration could weigh in its pathogenesis.

Methods: A descriptive, observational, cross-sectional study was carried out, based on field work in a farm in Sitio Nuevo (Magdalena, Colombia) in 28 rural worker volunteers (rice fields), who were measured for weight, blood pressure, blood and urine samples to measure electrolytes and osmolarity, at 2 times of the day (morning and evening).

Results: Of the 28 young men workers evaluated, 5 (18%) presented a significant increase in serum creatinine during the day (0.8±0.15 vs 1.2±0.17, p: 0.001). The volume of water ingested by the workers was highly variable (2,861 ± 1,591 cc). There was a significant increase in serum sodium (p: 0.001), and urinary osmolarity (p: 0.01) values between morning and afternoon values in these 5 patients

Conclusions: Some rural workers developed parameters compatible with AKI and dehydration during their work day in the Colombian Caribbean countryside

PO2296

A New Epidemiologic Methodological Approach Using Machine Learning in Prevalence Estimation of CKD

Maxime Dauvergne,[1] Raphaël R. Sigogne,[2] Milka Maravic,[3,2] Pablo A. Urena Torres.[1] *[1]Department of Dialysis AURA Nord Saint Ouen, Saint Ouen, France; [2]IQVIA, Data science and Advanced Analytics, La Défense, France; [3]Assistance Publique - Hopitaux de Paris, Paris, France.*

Background: Prevalence of chronic kidney disease (CKD), a pandemic condition, is generally estimated at 5-10% of the general population and increases with ageing. With the emergence of artificial intelligence, machine learning approaches could identify patients with such condition, improve our understanding of health, and provide opportunities for intervention. The aim was to automatically identify people with CKD and estimate more precisely its prevalence, which remains a real challenge.

Methods: Two sources of data were used, LPD (Longitudinal Patients Data) and LRx (Lifelink Treatments Dynamics), including data of near 2.5 and 40 million subjects, respectively. LPD, a medical database, included 191,905 patients receiving medications usually defined as specific for CKD from July 1st, 2019 to June 30, 2020. Of these subjects, 1.9% had a firm diagnosis of CKD, dialysis, or kidney transplant status. These patients were followed by 1,210 general practitioners who participated in a permanent longitudinal observatory of ambulatory medicine prescriptions (LPD). LRx contained all anonymized medication dispensing in outpatient care database from a representative panel of 45% of all French metropolitan retail pharmacies. A machine learning algorithm using a gradient boosting model was trained from CKD patients identified in LPD (metrics performance - sensitivity: 68%, specificity: 99%, positive predictive value: 52%, negative predictive value: 99%, F1 score: 59%). The model was implemented in LRx to obtain the overall number of CKD patients in the period of interest. As we will underestimate the true number of CKD patients, rules-based algorithm focused on erythropoietin delivery for renal condition and keto-analog was applied on LRx. We calculated the raw number of CKD patients and extrapolated it and described demographic characteristics from November 1st, 2019 to October 31th 2020.

Results: In LRx, we numbered 269,183 CKD patients corresponding to an extrapolated number of 678,102 patients with 40.8% of women and the mean age was of 77.0 years (±11.1) in the period of interest. This corresponded to a prevalence of 1%.

Conclusions: A combined approach using machine learning and rules-based algorithm may be useful in identifying CKD patients who require careful management of their renal condition.

CKD Among Patients with Dengue: A Comorbidity That Increases Hospitalization and Mortality

Geraldo B. Silva Junior,[1] Ana Amelia R. Jereissati,[1] Jose Reginaldo Pinto,[1] Janaina d. Ramalho,[1] Gdayllon C. Meneses.[2] *[1]Universidade de Fortaleza, Fortaleza, Brazil; [2]Universidade Federal do Ceara, Fortaleza, Brazil.*

Background: Dengue virus is one of the most important neglected tropical diseases in the world, with varying manifestations, including kidney involvement. The aim of this study was to investigate chronic kidney disease (CKD) and its association with outcomes among patients with dengue.

Methods: A cross-sectional study was conducted in Ceará State, northeast Brazil, in the period from January 2015 to December 2017, including all confirmed cases of dengue through clinical, epidemiology and laboratory tests (IgM specific antibodies or RT-PCR). We have made a comparison between patients with and without CKD, defined according to the KDIGO guidelines.

Results: A total of 161,880 patients were included. Patients with CKD were older (41±22 vs. 35±21 years, p<0.001), predominantly female (62 vs. 57%, p=0.004) and presented higher frequency of majority of symptoms and signs (fever: 89 vs. 86%, p=0.01; myalgia: 76 vs. 67%, p<0.001; rash: 35 vs. 22%, p<0.001; nausea: 42 vs. 23%, p<0.001). The most common comorbidities were hypertension and diabetes, which are also the most common causes of CKD (51 vs. 3.3% / 42 vs. 1.3%, p<0.001). Independent factors associated with CKD were: hematological disease (OR 8.08), auto-immune disease (OR 7.73), peptic ulcer disease (OR 7.19), hypertension (OR 5.06), diabetes (OR 2.57), leukopenia (OR 1.87), arthritis (OR 1.70), back pain (OR 1.43), petechia (OR 1.33) and nausea (OR 1.26). Need of hospitalization was significantly more frequent among the group with CKD (12.3% vs. 2.2%, p<0.001), and mortality was higher among CKD patients (2.2% vs. 0.1%, p<0.001), Figure 1.

Conclusions: CKD aggravates dengue severity, including the need of hospitalization and increased mortality. Patients with CKD and dengue should be carefully monitored, especially in epidemic periods.

Funding: Government Support - Non-U.S.

PO2298

Although Provider Awareness Is High, More Than Half of US Veterans with CKD Being Treated for Hypertension (HTN) Are Not Meeting Blood Pressure (BP) Targets

Jennifer L. Bragg-Gresham,[1] Diane Steffick,[1] Xiaosong Zhang,[1] Deidra C. Crews,[2] Neil R. Powe,[3] Alain Koyama,[4] Nilka Rios Burrows,[4] Kara Zivin,[5] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]Johns Hopkins University, Baltimore, MD; [3]University of California San Francisco, San Francisco, CA; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]Veterans Health Administration, Ann Arbor, MI.*

Background: HTN is a leading cause of kidney failure in the U.S. In people with CKD, BP control is critical to slow progression to kidney failure. We sought to assess HTN awareness among providers and BP control among Veterans with HTN and CKD.

Methods: We estimated both provider awareness (ICD code for HTN) and BP control (≤130/80 mmHg, ACC 2017) among ~12 million US Veterans between 2006 and 2018, aged 18+, with CKD and HTN, with 1+ outpatient visit each year. Veterans were determined to have CKD if they had either 1) an ICD diagnosis code, 2) eGFR < 60 ml/min/1.73m^2, and/or 3) urinary albumin-to-creatinine ratio 30+ mg/g; HTN if they had 1) a diagnosis, 2) were taking BP lowering medication, and/or 3) BP > 130/80. Treatment was defined as a prescription for BP lowering medication.

Results: From 2006 to 2018, ~94% of US veterans with CKD and HTN had a health provider-documented diagnosis code of HTN. The percentage of veterans with diagnosed HTN who were on BP-lowering medications, but did not have their BP under control (BP > 130/80 mmHg) declined from 57.6% to 51.3%. The percentage who had their BP under control increased from 30.2% in 2006 to 32.5% in 2010 but declined to 25.2% in 2018. The percentage with diagnosed HTN who were not receiving BP-lowering medications rose from 5.9% to 17.4%. The percentage of veterans with CKD and high BP who did not have a diagnosis of HTN remained between 5% and 6% throughout.

Conclusions: Provider awareness of HTN in the setting of an integrated health care system is high, as indicated by patients' recorded diagnosis of HTN. However, despite this high level of provider awareness, more than 50% of patients with diagnosed HTN in 2018 were not achieving the BP target of ≤130/80 mmHg, reflecting the difficulty in controlling BP in CKD patients. A better understanding of underlying factors, along with designing and implementing quality improvement programs may help improve this practice gap.

PO2299

Arterial Stiffness Is Associated with the Progression of Abdominal Aortic Calcification in CKD: From the KNOW-CKD Study

Sang-Eun Kim, Sunghoon Jung, Kyu-Beck Lee, Hyang Kim, Young Youl Hyun. *Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Jongno-gu, Republic of Korea.*

Background: Cardiovascular disease is an important cause of death in patients with chronic kidney disease. Vascular calcification is a hallmark of chronic kidney disease and an important risk factor for cardiovascular morbidity and mortality. Therefore, it is important to identify the factors that exacerbate vascular calcification for the prevention of cardiovascular complications in patients with chronic kidney disease. Although the relationship between arterial stiffness and vascular calcification is well-known, the association between the preexisting arterial stiffness and the progression of vascular calcification is not known. In this study, we analyzed the relationship between arterial stiffness measured by brachial-ankle pulse wave velocity (baPWV) and the progression of abdominal aortic calcification (AAC) evaluated by abdominal aortic calcium score (AACS).

Methods: We selected patients who underwent lumbar X-ray and AACS measurements at the start of the study and 4 years later from the KNOW-CKD cohort. After excluding 26 patients with previous peripheral vascular disease, we analyzed 906 patients. Participants were divided into 3 groups according to their baPWV. The progression of abdominal aortic calcification was defined as an increase in AACS after 4 years compared to the baseline.

Results: After 4 years, a total of 312 patients (34.4%) developed the progression of AAC. The progression of AAC was more frequent with higher baPWV. The incidence rates of AAC progression were 17.6%, 33.0% and 52.5% for T1 through T3 of baPWV (P<0.001). In multivariate logistic regression analysis adjusted for various cardiovascular risk factors, the odds ratio for the progression of AAC compared to T1 were 1.54 (95%CI 1.02-2.34) and 2.16 (95%CI 1.34-3.46) for T2 and T3 of baPWV.

Conclusions: Arterial stiffness is a risk factor for the progression of AAC in chronic kidney disease. This suggests that interventions that can improve arterial stiffness might be helpful in reducing cardiovascular complications in patients with chronic kidney disease.

Table. Multivariate-adjusted ORs (95% CI) for AAC progression according to baPWV

baPWV tertile	Model 1		Model 2		Model 3	
	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P
1	reference		reference		reference	
2	2.31 (1.57-3.37)	<0.001	1.54 (1.02-2.34)	0.041	1.54 (1.02-2.34)	0.042
3	5.17 (3.56-7.50)	<0.001	2.11 (1.32-3.37)	0.005	2.16 (1.34-3.46)	<0.001

Model 1: Unadjusted
Model 2: Adjusted for age, sex, systolic blood pressure, waist-hip ratio, diabetes, angiotensin-converting enzyme inhibitor or aldosterone receptor antagonist, statin, vitamin D analogue, calcium-base phosphate binder, eGFR, LDL cholesterol, HDL cholesterol, hsCRP, urine protein to creatinine ratio, calcium, phosphorus, vitamin D, and parathyroid hormone
Model 3: Adjusted for model 2 + current smoking status, alcohol intake, physical activity and baseline AAC-score

Provider Practice Evaluation Survey: Assessment of Primary Care Provider Perspectives on Care Delivery for CKD Patients in Alberta

Aminu K. Bello, Deenaz Zaidi, Feng Ye, Ikechi G. Okpechi. *University of Alberta, Edmonton, AB, Canada.*

Background: Chronic kidney disease (CKD) is highly prevalent in the adult population of Canada, with a steady rise in end-stage renal disease. The objective of this study was to assess current modes of practice regarding CKD patients, and assess barrier and facilitators in primary care for managing and referring CKD patients using electronic consultation (eReferral).

Methods: The Provider Practice Evaluation Survey was launched for primary care providers [PCPs (family physicians or general practitioners)] licensed to practice in Alberta. Associations between barriers and facilitators to electronic consultations and clinic practice parameters; and associations between screening for CKD in patients and clinic practice parameters were analyzed. Modified Poisson regression with robust error variance was used to estimate the relative risk (RR) and 95% confidence interval.

Results: A total of 48 PCPs responded to the survey. Awareness about the availability of the eReferral tool was more likely to be a barrier to use eReferral for PCPs of South Zone as compared to PCPs from Edmonton (RR: 2.00, 95% CI: 1.07-3.74). Compared to PCPs with >5% CKD patients in their clinical practice, PCPs with 16% to 26% CKD patients were more likely to perceive barriers to use eReferral; including the ease of use for the eReferral tool (RR: 1.62, 95% CI: 1.05-2.51), and limited staff and technical support as a barrier for eReferral (RR: 2.00, 95%CI: 1.18-3.40). There was a negative association between PCPs aged between 40 and 60 years and time constraints as a barrier compared with those younger than 40 years (RR: 0.66, 95% CI: 0.46-0.95). Regarding screening tools (criteria) to diagnose CKD, PCPs who had not used the eReferral tools were less likely to use hypertension (RR: 0.86, 95% CI: 0.75-0.98), diabetes (RR: 0.89, 95% CI: 0.79-0.999), and cardiovascular disease (RR: 0.72, 95% CI: 0.59-0.89) as CKD diagnostic tools compared to those using eReferral nephrology advice request tool.

Conclusions: The results will help implement innovative steps to rectify barriers to adoption of the eReferral system and standardized CKD diagnostic guidelines to improve patient care in Canada.

PO2301

Shrunken Pore Syndrome Is Associated with a Rise in Mortality in a Community-Based Population of Middle-Aged Individuals

Liana Xhakollari,[1,2] Anna Åkesson,[2] Jonas Björk,[2] Anders Christensson.[1,2] *[1]Dept of Nephrology, Skåne University Hospital, Malmö, Sweden; [2]Dept of Clinical Sciences, Lund University, Malmö, Sweden.*

Background: Chronic kidney disease (CKD) is a risk factor for increased mortality mainly due to cardiovascular disease (CVD). Glomerular filtration rate (GFR) is the best way to estimate kidney function, but it cannot be measured. Creatinine and cystatin C are two molecules that are used in clinical practice to estimate GFR (eGFR). The lower eGFR, the higher is the mortality. CKD staging is therefore a good marker of mortality and development of CVD. However, there are patients who have the same CKD stage and risk factors for development of CVD but different outcome in mortality. Shrunken pore syndrome (SPS) has shown to be a marker of increased mortality in different patients groups regardless of their measured GFR. The theory behind SPS is supposed to be a difference in the renal filtration of small molecules like creatinine compared to middle sized molecules like cystatin C. Little is known about the prevalence of SPS and the effect on mortality in the general population. The aim of our study is to investigate this.

Methods: The study population consisted of 5061 individuals from the Malmö Diet and Cancer Cardiovascular cohort community-based study that was gathered during 1991 and 1996 in Malmö, Sweden. The individuals were 44-64 years old. Blood samples, anthropometric measurement and a questionnaire about life style etc was available. $CAPA_{CYC}$ formula was used for eGFR based on cystatin C and LMR_{CR} formula was used for eGFR based on creatinine. SPS was defined as $eGFR_{CYS} \leq 70\%$ of $eGFR_{CR}$. Generalized propensity score was used to match individuals with SPS and those without. Kaplan–Meier estimates were used to present survival probabilities in four $eGFR_{CYS}/eGFR_{CR}$ ratio intervals. To account for within quartet correlation, or frailty, Cox proportional hazard models with shared frailty was employed. Results are presented as hazard ratios (HR) with 95 % confidence intervals (CI).

Results: 405 individuals (8%) fulfilled the criterion for SPS. Median (2.5-97.5 percentiles) $eGFR_{cys}$ was 63 (38-97) and median $eGFR_{cr}$ was 70 (49-92) mL/min/1.73m^2. HR for mortality in individuals with SPS in the matched data was 2.43 (1.15 - 5.14).

Conclusions: Healthy middle age individuals with SPS have a doubled risk of all-cause mortality. Further studies are needed to explore the mechanisms behind the association between SPS and mortality.

PO2302

Associations Between Serum Biomarkers of Iron Stores and the Progression to Kidney Failure in Patients with Moderate-to-Severe CKD

Viviane Calice-Silva,[1] Daniel G. Muenz,[2] Murilo H. Guedes,[1] Brian Bieber,[2] Benedicte Stengel,[3] Dominic S. Raj,[4] Helmut Reichel,[5] Sandra Waechter,[6] Tiziana Di Francesco,[6] Bruce M. Robinson,[2] Roberto Pecoits-Filho.[2] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [4]GWU Medical Faculty Associates, Washington, DC; [5]Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany; [6]Vifor Pharma Ltd, Glattbrugg, Switzerland.*

Background: We recently reported that lower levels of biomarkers of iron stores are associated with a higher risk of all-cause mortality and major adverse cardiovascular events in patients with moderate to severe chronic kidney disease (CKD). However, the impact of these parameters on the risk of kidney failure (KF), potentially a competing risk, has not been previously explored.

Methods: Patients from Brazil, France, Germany and the US in CKDopps (eGFR <60 mL/min at enrollment, under nephrology care) and with available TSAT and ferritin levels were included in the analyses. Cox models were used to estimate hazard ratios (HR) for the outcome of KF (defined as a composite endpoint including dialysis initiation, transplant, 40% decline of eGFR from baseline, or sustained eGFR <15 mL/min/1.73m^2).

Results: A total of 5,431 patients were evaluated (Brazil=337, France=2231, Germany=2112, US=751), mean eGFR 28±11mL/min/1.73m^2. Over median follow-up time of 2.0 [0.6-3.0] years, there were 1800 (33%) KF events (15.7/100 pt-years). TSAT had a U-shaped association with KF (with highest HR at TSAT<15%) in the crude analysis (Model 1 of Table 1). Neither TSAT nor ferritin had a directional association with KF after adjustment for confounders (Model 2).

Conclusions: Levels of biomarkers of iron stores, as captured by TSAT and/or ferritin, are not associated with development KF in patients with moderate to severe CKD under nephrology care. These findings further the understanding of our previous finding of a higher risk of mortality and cardiovascular events in this population with iron deficiency and high risk of CKD progression.

100-299	2352 (43%)	1 (ref)	–	1 (ref)	–
300+	991 (18%)	1.01 (0.90,1.14)	0.84	0.90 (0.77,1.04)	0.14

Model 1 is stratified by country but otherwise unadjusted; a separate Model 1 was fit with either (A) TSAT or (B) ferritin as the exposure. Model 2 is additionally adjusted for patient age, sex, Black race, body mass index, eGFR, albuminuria, 11 summary comorbidities, erythropoiesis stimulating agents use, serum albumin, white blood cell, hemoglobin, and either ferritin or TSAT (depending on the exposure variable).

PO2303

Association Between the Triglyceride-Glucose (TyG) Index and Coronary Artery Calcification Progression in Non-Diabetic CKD

Kang Yoon Lee,[1,2] Donghwan Oh,[1,2] Eunji Yang,[1,2] Hyeong cheon Park,[1,2] Jong Hyun Jhee,[1,2] Hoon Young Choi.[1,2] *[1]Gangnam Severance Hospital, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Patients with chronic kidney disease (CKD), the likelihood of complications of cardiovascular disease(CVD) may increase compared to general population. Quantity of coronary artery calcification (CAC) correlates with atherosclerotic plaque burden and increased quantity of CAC indicates a substantially increased cardiovascular events. In previous studies, the TyG index has been reported to associated with coronary artery calcification aggravation. We investigated whether the TyG index was related to coronary artery calcification aggravation in patients with mild renal insufficiency.

Methods: This retrospective longitudinal study included adult participants who voluntarily underwent at least two cardiac CT examination at the single center, between January 2006 and Octorbor 2018(n=1,516). The TyG index was determined using ln (fasting triglycerides [mg/dL] X fasting glucose [mg/dL]/2). Mean arterial pressure (MAP) was calculated as DBP + ((SBP – DBP)/3). Mild renal insufficiency CKD was defined as 60≤ eGFR ≤ 90ml/min/1.73m^2 by the Chronic Kidney Disease Epidemiology Collaboration equation (mild-CKD group). CAC aggravation was defined as an increased coronary artery calcification score (CACS) in the in the follow-up period. To calculate the odds ratio for incident CKD, logistic regression analyses were performed.

Results: 1,516 patients were enrolled, of which 746 were in the mild-CKD group without diabetes. The CACS aggravation was significantly higher in participants with a tyG index of 8.9 or higher [OR 1.705 (1.351-2.152), P-value <0.001]. After adjusting for age, sex, MAP, Hemoglobin, Ca X P, potassium associated with increased risk of CAC in participants with mild renal insufficiency [OR 1.534 (1.058-2.224), P=0.027].

Conclusions: Among mild CKD without diabetes, TyG index of 8.9 or higher had a positive correlation with CAC progression.

Table 1. Risk of CACS aggravation according to TyG index in mild CKD group without Diabetes

PO2304

Plasma Proenkephalin and Incident CKD in REGARDS

Alexander Bullen,[1,2] Ronit Katz,[5] Orlando M. Gutierrez,[4] Dena E. Rifkin,[1,2] Mary Cushman,[3] Joachim H. Ix.[1,2] *[1]VA San Diego Healthcare System, San Diego, CA; [2]University of California San Diego, La Jolla, CA; [3]University of Vermont, Burlington, VT; [4]The University of Alabama at Birmingham College of Arts and Sciences, Birmingham, AL; [5]University of Washington, Seattle, WA.*

Background: Plasma proenkephalin (PENK) is a precursor of active enkephalins. Higher blood concentrations have been previously associated with eGFR decline. Whether PENK concentrations vary by race and whether the association of PENK with incident CKD differs by race is uncertain.

Methods: In a nested cohort of 3,986 community-living participants within the REGARDS cohort, we measured PENK by ELISA. Primary outcomes were incident CKD (new eGFR < 60 mL/min/1.73m^2 plus 40% decline), significant eGFR decline (30% decline) and incident albuminuria (new UACR > 30mg/g) at a follow-up visit 9.4

years (mean) after baseline. We used logistic regression with inverse probability sampling weights for analysis, evaluating PENK per 2-fold higher level. We tested race interactions, and explored analyses stratified by race.

Results: Mean age was 63 years, 48% were black, and 51% were female. Baseline eGFR was 88 ml/min/1.73m^2. Higher PENK was associated with all 3 outcomes in unadjusted models. In the fully adjusted models, higher PENK remained associated with significant eGFR decline and incident albuminuria. Associations differed by race. P for interaction between PENK and race was <0.01. Higher PENK was more strongly associated with incident CKD and eGFR decline and incident albuminuria in Blacks.

Conclusions: In community-living individuals, higher PENK is associated with significant eGFR decline and incident albuminuria, independent of eGFR, albuminuria and CKD risk factors. These associations differed by race. Future studies should determine if PENK has utility to improve eGFR risk estimation without requiring race-specific adjustments in estimates.

Novel Approach to the Relation of Environmental Exposure and Kidney Dysfunction: Data Analysis from Korean National Environmental Health Survey (KoNEHS), 2015-2017

Kyung Don Yoo,[1,2] Junhyug Noh,[4] Inae Lee,[5] Jung Nam An,[6] Jae Yoon Park,[8] Jeonghwan Lee,[3] Kyungho Choi,[5] Jung Pyo Lee.[3,7] *[1]Ulsan University Hospital, Ulsan, Republic of Korea; [2]University of Ulsan College of Medicine, Songpa-gu, Seoul, Republic of Korea; [3]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [4]Lawrence Livermore National Laboratory, Livermore, CA; [5]Seoul National University, Gwanak-gu, Seoul, Republic of Korea; [6]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [7]Seoul National University College of Medicine, Seoul, Republic of Korea; [8]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Forecasting patient outcomes with kidney disease using standard statistical techniques is complex to estimate effects of the environmental chemicals. Herein, we aim to assess risk prediction for kidney disease in the general population using novel methods.

Methods: Serum POPs, serum creatinine or urinary albumin were measured in subpopulation (n=1,266) among the general adult participants from the 3rd Korean National Environmental Health Survey (KoNEHS) (n=3,787). Classification algorithms were used for the prediction of chronic kidney disease (CKD), defined by estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR). In addition, weighted quantile sum (WQS), which provides weights to the components of the mixture, was used to assess multi-pollutant effects.

Results: Of 1,266 adult subjects and 44 variables, including baseline characteristics and laboratory findings, were analyzed for the modeling process. The risk prediction of CKD was presented by machine-learning algorithms using bagging, ridge, lasso, random forest and was compared to conventional algorithms using logistic regression. A decision-tree algorithm was presented that outperformed a conventional method such as logistic regression (AUC 0.653 vs. 0.621). Among various decision-tree models, the lipid-corrected polychlorinated biphenyl congener 153 (PCB 153) was selected as the best predictor of CKD. Because persistent organic pollutants (POPs) accumulate with age, stratification analysis was conducted based on age. In the WQS model, PCB 153 showed the highest weight in its contribution to lower eGFR after adjusting covariates in the middle-aged group (under 50 yrs) (p=0.0135). If subjects with young age (under 50 yrs) were hemoglobin level > 13.25 g/dl, the CKD was predicted as 71.4% in the high serum PCB153 group.

Conclusions: We propose a machine learning-based prediction model. POPs and age were interrelated as notable risk factors for CKD in healthy Korean volunteers.

PO2306

Prevalence and Associated Factors for CKD in Rural and Peri-Urban Bangladesh

Mohammad H. Sarker,[1,2] Michiko Moriyama,[1] Md Moshiur Rahman,[1] Mohammod Jobayer Chisti,[2] Asg Faruque.[2] *[1]Hiroshima Daigaku Igakubu Hoken Gakka, Hiroshima, Japan; [2]International Centre for Diarrhoeal Disease Research Bangladesh, Dhaka, Bangladesh.*

Background: Chronic Kidney Disease (CKD) is an increasing public health threat worldwide. Studies have documented CKD among adult population in urban Bangladesh, however, in rural and peri-urban settings still lagging behind. We aimed to generate data in understanding the prevalence and CKD-related factors.

Methods: We recruited participants randomly from the Demographic Surveillance System of Mirzapur, Bangladesh in two phases. In phase 1, we screened participants using a laboratory-based creatinine and albumin to creatinine ratio (ACR) and collected information on socio-demographic, lifestyles, and health histories. We evaluated the participants' CKD status following the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation and their estimated glomerular filtration rate (eGFR). Those participants who had eGFR below 60 ml/min/1.73 m^2 and/or ACR ≥30 mg/g were considered for phage 2. After three months, in phase 2, we repeated the blood and urine test for GFR and ACR. A participant was diagnosed as a case of CKD if (s)he had eGFR below 60 ml/min/1.73 m^2 or had ACR ≥30 mg/g for more than three months as suggested by the Kidney Disease Outcomes Quality Initiative guidelines.

Results: We enrolled 928 participants; of them 872 completed the study procedure and included in the analysis. The mean ± standard deviation (SD) of age was 48.2 ± 16.4. In phase 1, probable CKD cases were 281 (32%), however, in phase 2, confirmed cases were 192 (22%) [stage-1, 4.0%; stage-2, 11.8%; stage-3, 5.5%; stage-4, 0.6%; stage-5, 0.11%]. In the multivariate logistic regression analysis, associated factors for prevalent CKD included aged ≥60 years (adjusted odds ratio [aOR], 5.02; 95% confidence interval [95% CI], 1.85 to 13.65), hypertension (aOR, 3.08; 95% CI, 2.07 to 4.59), diabetes (aOR, 2.52; 95% CI, 1.60 to 3.96), anemia (aOR, 2.50; 95% CI, 1.63 to 3.84) and presence of RBC in urine (aOR, 3.20; 95% CI, 1.71 to 5.98).

Conclusions: In rural and peri-urban Bangladesh, this is the first study of CKD prevalence, and repeated confirmatory testing revealed a prevalence of approximately 22%, which is higher than in urban setting. Findings suggested that CKD monitoring systems are required to assess the overall burden and effective steps should be taken to mitigate these major risk factors.

PO2307

Association of XOR Activity and NLRP3 Inflammasome Among CKD Patients

Zhang Yiyuan. *Xuzhou Medical University, Xuzhou, China.*

Background: Previous studies have shown few result on the relationship between XOR activity and NLRP3 inflammatory in non-hemodialysis patients.

Methods: CKD patients in nephrology department with normal uric acid were recruited. General clinical data, blood biochemistry and other data were collected. XOR activity was detected by fluorescence colorimetry, XO activity was detected by double antibody sandwich ELISA, and NLRP3 Inflammasome were detected by competitive binding method. After correlation analysis, multiple (stepwise) regression analysis was performed to explore the correlation between XOR and NLRP3 inflammasome and the relationship with clinical data of patients.

Results: The correlation analysis of XOR activity, XO activity, XO/XOR ratio and NLRP3 Inflammasome with biochemical indicators showed that XOR activity was positively correlated with eGFR, DBP, FBG, and alanine transferase, and was negatively correlated with age, serum total protein, serum creatinine, and serum chloride concentration; Log(XO) was positively correlated with eGFR and FBG, and negatively correlated with serum chloride concentration;The ratio of XO/XOR was positively correlated with total protein, age and UA, and negatively correlated with eGFR, XOR and alanine transferase;NLRP3 inflammasome were positively correlated with XOR, Log(XO) and serum sodium concentration, and negatively correlated with sex;Multiple linear (stepwise) regression results showed that eGFR, FBG and DBP were independent influencing factors of XOR;eGFR, FBG, UA and total cholesterol were independent influencing factors of Log(XO); Serum creatinine, serum sodium concentration and XOR activity were independent influencing factors of NLRP3 Inflammasome, and there was no collinearity in statistical analysis. According to the value of eGFR, the patients were divided into two groups. The XOR activity, Log (XO), XO/XOR ratio, serum creatinine, urea nitrogen, UA, K, serum chloride concentration were compared between the two groups, and the differences were statistically significant.

Conclusions: In CKD patients, elevated fasting blood glucose and diastolic blood pressure are independent risk factors for XOR activity, while elevated XOR activity is an independent risk factor for NLRP3 Inflammasome. Therefore, controlling FBG and DBP in CKD patients has certain clinical reference significance for reducing XOR activity and further reducing NLRP3 Inflammasome.

PO2308

Trends in Volume, Appropriateness, and Outcomes of Referrals to Nephrology over the Last Two Decades: A Retrospective Analysis Using the Alberta Kidney Disease Network Database

Anukul Ghimire,[1] Feng Ye,[1] Brenda Hemmelgarn,[1] Deenaz Zaidi,[1] Kailash K. Jindal,[1] Maryam Khan,[1] Mohammed M. Tinwala,[1] Naima Sultana,[1] Paul E. Ronksley,[2] Shezel Muneer,[1] Scott Klarenbach,[1] Ikechi G. Okpechi,[1] Aminu K. Bello.[1] *[1]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

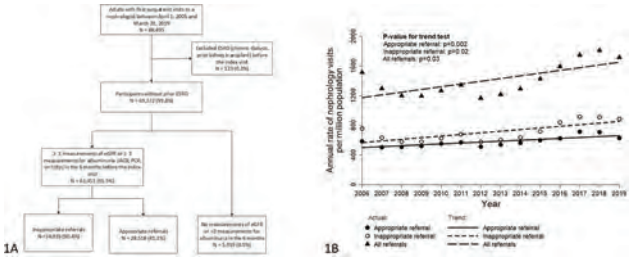
Background: It is well-established that guideline-concordant referrals to nephrology are associated with improved patient outcomes. However, some referrals are unnecessary (guideline-discordant) leading to high volumes and delays for referrals that are guideline concordant. We investigated the trends in the number of referrals to nephrology, and related outcomes in Alberta.

Methods: Retrospective cohort analysis of patients with at least one visit to a nephrologist from primary care between 2006 and 2019. A referral was considered appropriate based on the KDIGO defined criteria (estimated glomerular filtration rate

(eGFR) < 30 mL/min per 1.73m², albumin creatinine ratio (ACR) ≥ 30 mg/mmol or protein creatinine ratio ≥ 50 mg/mmol, or Urine dipstick ≥ 2+ protein on two consecutive measurements, and/or eGFR persistently declined ≥ 5 mL/min per 1.73m² from the first eGFR measurement).

Results: Of 69,372 patients (mean age 62.5; 50.7% female), only 28,518 (41.1%) referrals met criteria as guideline-concordant (Figure 1A). Patients referred in a guideline-concordant manner were significantly more likely to be older, men, and with comorbid conditions (diabetes, hypertension, and cardiovascular disease). There has been an increasing trend in the number of guideline concordant and discordant referrals from 2006 to 2019 (Figure 1B). Patients who met guideline-criteria for referrals were likely to be prescribed renoprotective medications but more likely to experience clinical outcomes of kidney failure, cardiovascular events, and all-cause mortality.

Conclusions: The number of referrals to nephrology from primary care continues to increase, and a large proportion of these referrals were guideline discordant. Interventions targeted to primary care at reducing the number of non-guideline concordant referrals are needed.



PO2309

Microscopic Hematuria and Leukocyturia Are Highly Prevalent in East Africa and Associated with CKD

Anthony N. Muiru,[1] Jane Kabami,[2] Moses Kamya,[2] Diane Havlir,[1] Edwin Charlebois,[1] Michelle M. Estrella,[1] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]The Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda.*

Background: Microscopic hematuria and leukocyturia may reflect parenchymal kidney disease; there have been few population-based studies of these urinary abnormalities in Africa.

Methods: We included a population-based sample of 3,686 East Africans. We defined hematuria and leukocyturia as heme and leukocyte esterase dipstick positive (≥1+), respectfully. We used sampling weights to estimate the community-based prevalence of hematuria and leukocyturia and used weighted multivariable log-link Poisson models to assess the association of potential risk factors with these abnormalities, and separately, the association of urine abnormalities with CKD (eGFR <60 mL/min/1.73m² or dipstick proteinuria ≥1+).

Results: Most participants with leukocyturia did not have hematuria or proteinuria; there was minimal overlap between hematuria and proteinuria **(Figure).** With sample weighting, the mean age was 38 years; 52% were female. The prevalence of hematuria was 3.7% in eastern Uganda, 2.8% in southwestern Uganda and 2.8% in Kenya. The prevalence of leukocyturia was 11.2% in eastern Uganda, 8.7% in southwestern Uganda and 1.6% in Kenya. Table 1 shows associations of potential risk factors with urine abnormalities. Both hematuria and leukocyturia were independently associated with prevalent CKD (aPR=2.7; 95% CI 1.4-4.9, and aPR=3.5; 95% CI 2.2-5.7, respectively).

Conclusions: Hematuria and leukocyturia are common in rural East Africa, with considerable regional difference. These urinary abnormalities may represent a unique pattern of kidney disease in this region.

Funding: NIDDK Support

Variables	Hematuria aPR (95% CI)	Leukocyturia aPR (95% CI)
Eastern Uganda (vs. Kenya)	0.96 (0.47-1.94)	9.79 (5.82-16.48)
Southwest Uganda (vs. Kenya)	0.90 (0.41-1.97)	8.44 (4.55-15.63)
Female	12.3 (4.57-33.22)	1.73 (1.09-2.76)
Age (Years)≥ 60 (vs. 18–29 years)	0.51 (0.19-1.36)	1.71 (1.06-2.78)
Primary school education (vs. Secondary school and beyond)	0.64 (0.31-1.33)	2.17 (1.03-4.60)
Any alcohol use	2.56 (1.23-5.33)	0.57 (0.30-1.11)
Any NSAIDs use	0.59 (0.36-0.98)	1.04 (0.72-1.52)

adjusted prevalence ratio (aPR); Adjusted for region, demographics (age, sex), wealth index, farming occupation, history of diabetes, hypertension, HIV, use of NSAIDs and traditional herbal medicines

The Effect of Cardiometabolic Comorbidities on Risk of CKD Incidence: A Longitudinal Cohort Study

Gregory A. Nichols,[1] Moe H. Kyaw,[2] Satabdi Chatterjee,[3] Dominik Steubl.[3] *[1]Kaiser Permanente Center for Health Research Northwest Region, Portland, OR; [2]Boehringer Ingelheim US, Ridgefield, CT; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany.*

Background: Chronic kidney disease (CKD) and cardiometabolic conditions are closely inter-related. We studied the risk of incident CKD among patients who had or developed type 2 diabetes (T2D), atherosclerotic cardiovascular disease (ASCVD), or heart failure (HF).

Methods: We conducted a longitudinal cohort study using the electronic medical records of Kaiser Permanente Northwest to identify 371,109 adult patients without CKD at baseline (first known eGFR ≥60ml/min/1.73m² between 2005-2017) and followed them through 2019 for incident CKD (two eGFR measurements <60 3-12 months apart). We assessed T2D, ASCVD and HF at baseline and prior to CKD incidence. We used generalized estimating equation (GEE) models to calculate age/sex-adjusted CKD incidence per 1,000 person-years independently for baseline T2D, HF, and ASCVD. Time-dependent Cox regression models were used to determine the effect of baseline or development of T2D, ASCVD and HF on CKD incidence adjusting for age, sex, race/ethnicity, renin angiotensin aldosterone system (RAAS) inhibitor and statin use, smoking, and blood pressure ≥140/90 mmHg.

Results: Study subjects were 49.7±14.9 years old and 56% were women. CKD incidence among patients with T2D or HF was more than double vs. patients without T2D or HF, and 55% higher among patients with vs. without ASCVD (Figure). In the time-dependent model, risk of CKD incidence was increased by more than 2-fold by HF (hazard ratio 2.12, 95% CI 2.05-2.19), 71% by T2D (1.71, 1.66-1.75), and 26% by ASCVD (1.26, 1.23-1.30).

Conclusions: Cardiometabolic conditions, particularly HF and T2D are independent risk factors of incident CKD. Treating the cardiometabolic-renal syndrome as a single clinical entity may benefit these patients.

PO2311

Determining the Association Between Continuity of Primary Care and Acute Care Use Among Adults with CKD in Alberta, Canada

Christy Chong, David Campbell, Meghan J. Elliott, Fariba Aghajafari, Paul E. Ronksley. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Acute care use is high among individuals with chronic kidney disease (CKD). It is unclear how relational continuity of primary care influences downstream acute care use. We aimed to determine if poor relational continuity of primary care is associated with higher rates of all-cause and potentially preventable acute care use among adults with CKD.

Methods: We conducted a population-based retrospective cohort study of adults with stages 3 and 4 CKD and at least three visits to a primary care provider between April 1, 2011 to March 31, 2014 in Alberta, Canada. Relational continuity was calculated using the Usual Provider Continuity index and descriptive statistics were used to summarize patient and acute care encounter characteristics. Adjusted rates (per 1,000 person-years) and incidence rate ratios for all-cause and CKD-related ambulatory care-sensitive condition (ACSC) hospitalizations and emergency department (ED) visits were estimated using negative binomial regression models.

Results: Among 86,475 individuals with CKD, 51.3%, 30.0%, and 18.7% of patients had high, moderate, and poor continuity of primary care, respectively. There were 77,988 all-cause hospitalizations, 204,615 all-cause ED visits, 6,489 (8.3% of all hospitalizations) CKD-related ACSC hospitalizations, and 8,461 (4.1% of all ED visits) CKD-related ACSC ED visits during a median follow-up of 2.3 years. Rates of all-cause hospitalization and ED use increased with poorer continuity of primary care in a stepwise fashion across CKD stages. Poor continuity of primary care was also associated with higher rates of CKD-related ACSC hospitalization and ED visits, particularly among individuals with stage 3 CKD.

Conclusions: Poor continuity of care is associated with increased acute care use and targeted strategies are needed to strengthen patient-provider relationships within primary care among those with CKD.

Submaximal Dose of Angiotensin Converting Enzyme Inhibitor and Angiotensin II Receptor Blockers Among Persons with Proteinuria

Chi D. Chu,[1,2] Neil R. Powe,[1,4] Michelle M. Estrella,[1,3] Michael Shlipak,[1,3] Ian Mccoy,[1] Delphine S. Tuot.[1,4] *[1]University of California San Francisco, San Francisco, CA; [2]OptumLabs Visiting Fellow, Eden Prairie, MN; [3]San Francisco VA Health Care System, San Francisco, CA; [4]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.*

Background: Underutilization of angiotensin converting enzyme inhibitors (ACEi) and angiotensin II receptor blockers (ARB) for treatment of albuminuria is a known quality of care gap. Among those treated with ACEi/ARB, submaximal doses represents another opportunity to improve CKD management.

Methods: Using the OptumLabs Data Warehouse®, a longitudinal, real-world dataset with deidentified claims and electronic health record data, we identified adults with proteinuria, defined as either urine albumin/creatinine ≥30 mg/g or protein/creatinine ≥150 mg/g, who were prescribed an ACEi/ARB between 1/1/2015 and 12/31/2016. Among patients without apparent contraindication to ACEi/ARB dose escalation (blood pressure <130/80 mmHg, eGFR <15 ml/min/1.73m^2, or prior diagnosis of acute kidney injury or hyperkalemia), we examined the proportion taking the maximal recommended dose of their ACEi/ARB, overall and by demographic and clinical factors. We used multivariable logistic regression to assess factors associated with submaximal dosing.

Results: Of 79,413 patients with proteinuria receiving ACEi/ARB therapy, 50% (n=39,733) had no apparent contraindication to dose escalation. 34% (n=13,566) of these patients were on maximal ACEi/ARB doses. In multivariable analyses, younger age, Asian race, Hispanic ethnicity, higher serum potassium, and non-diabetes status were associated with submaximal dosing (**Figure**).

Conclusions: Among persons with proteinuria and no apparent contraindication for ACEi/ARB dose escalation, over half were on submaximal doses. Concerns over hyperkalemia may drive underdosing. However, greater attention toward maximizing ACEi/ARB dose as tolerated, especially among patients without diabetes, could optimize cardiovascular and kidney health.

Genetic Variant rs671 of ALDH2 Gene Is Associated with Reduced Renal Function in Chinese Population

Jianfeng Lin,[1] Jing Li,[2] Jiaying Li,[1] Peili Ji,[1] Ling Qiu,[3] Tengda Xu,[2] Limeng Chen.[1] *[1]Peking Union Medical College Hospital Department of Nephrology, Dongcheng-qu, China; [2]Peking Union Medical College Hospital Department of Health Care, Dongcheng-qu, China; [3]Peking Union Medical College Hospital Department of Laboratory Medicine, Dongcheng-qu, China.*

Background: ALDH2 is a mitochondrial aldehyde dehydrogenase and ALDH2 rs671 genetic polymorphism was associated with hypertension and diabetes. Genome-wide association analysis of East Asians revealed ALDH2 rs671 variant associated with kidney function traits, but comprehensive epidemiological studies are lacking. We conducted this study to explore the associations between ALDH2 rs671 and kidney function traits in Chinese population.

Methods: A total of 15,856 individuals completed medical check-up in a single center were enrolled. ALDH2 gene mutation detection kit was used to genotype the rs671 polymorphism. Clinical laboratory data were collected from the records of medical check-up. Urine albumin creatinine ratio (UACR) was tested in 5,168 individuals and the data was log-transformed for further analysis. Linear and logistic regression analysis were used to estimate the association between rs671 SNP and renal function traits.

Results: The average age was 48.8±9.7 years and the individuals were mainly males (67.0%). 17.7%, 13.0% and 30.6% individuals were obese, diabetic, and hypertensive, respectively. Frequencies of GG, GA, and AA genotypes were 68.0%, 29.4% and 2.6%. Male individuals with A allele were associated with a significant increased level creatinine (β = 1.664, 95% CI: 1.141, 2.186) and blood urea nitrogen (β = 0.156, 95% CI: 0.107, 0.205), and reduced estimated glomerular filtration rate (eGFR, β = -1.057, 95% CI: -1.347, -0.767), uric acid (β = -8.893, 95% CI: -11.908, -5.877), logUACR (β = -0.066, 95% CI: -0.122, -0.011). Similar associations were not observed in female individuals. Besides, we did not observe association between ALDH2 genotype and chronic kidney disease (CKD), albuminuria, or proximal tubular injury.

Conclusions: ALDH2 rs671 polymorphisms were associated with decreased renal function in male individuals other than the females. Further analyses were needed for further explore the direct and indirect effects of ALDH2 SNP on CKD, albuminuria, and proximal tubular injury.

Impact of Dietary Fatty Acid on All-Cause Mortality According to Kidney Function Based on a Nationwide Population Study

Yaerim Kim,[1] Kyungho Ha,[6] Jeonghwan Lee,[2] Jae Yoon Park,[3] Kyung Don Yoo,[4] Yong Chul Kim,[5] Jin hyuk Paek,[1] Woo Yeong Park,[1] Kyubok Jin,[1] Seungyeup Han,[1] Dong Ki Kim,[5] Kwon Wook Joo,[5] Chun Soo Lim,[2] Jung Pyo Lee.[2] *[1]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [4]Ulsan University Hospital, Ulsan, Republic of Korea; [5]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [6]Jeju National University, Jeju, Jeju, Republic of Korea.*

Background: Although the relationship between fatty acids and the risk of mortality has been long-lasting discussed, there is little evidence to support that the effect of saturated fatty acids (SFA) and polyunsaturated fatty acids (PUFA). This study aims to investigate the association between dietary fatty acids and all-cause mortality among the general population.

Methods: We used data from the 92,062 participants of US National Health and Nutrition Examination Survey 1999-2015. The intake of fatty acids was adjusted with the total energy intake and divided by the quartile, the first quartile group was regarded as the reference. We used a multivariate Cox-proportional hazard model to identify the impact of fatty acids on all-cause mortality.

Results: A total of 36,747 subjects were finally included in the study. During 97.9 ± 53.9 months, there were 922 (4.4%) and 3,544 (22.4%) death cases in eGFR ≥90 and <90 mL/min/1.73m^2 groups, respectively. Among 8 different SFA, hexadecanoic acid (adjusted hazard ratio [aHR] 1.13, 95% confidence interval [CI] 1.15-1.26 in 4th quartile [Q4]) and octadecanoic acid (aHR 1.13, 95% CI 1.15-1.25 in Q4) showed that greater intake was associated with the increased risk for all-cause mortality. In addition, most PUFA except eicosatetraenoic acid showed a beneficial effect on all-cause mortality. Among subjects with eGFR ≥90, the harmful effect of SFA was attenuated and the beneficial effect of PUFA remained in only octadecatrienoic acid. On the contrary, for the subjects with eGFR <90, the harmful effect of hexadecanoic acid (aHR 1.17, 95% CI 1.05-1.32 in Q4) and octadecanoic acid (aHR 1.16, 95% CI 1.04-1.30 in Q4) was exacerbated. The beneficial effect of PUFA was also prominent in this group; octadecatrienoic acid (aHR 0.86, 95% CI 0.77-0.97 in Q4), eicosapentaenoic acid (aHR 0.86, 95% CI 0.79-0.98 in Q4), docosapentaenoic acid (aHR 0.88, 95% CI 0.79-0.99 in Q4), and docosahexaenoic acid (aHR 0.88, 95% CI 0.79-0.99 in Q4).

Conclusions: The impact of dietary fatty acid on all-cause mortality was different in according to the kidney function. More specified and targeted counseling for restricting SFA and encouraging PUFA needs to be considered especially for subjects with lower eGFR.

PO2315

Impact of Dietary Beta-Carotene on All-Cause Mortality According to Different Clinical Conditions, Including Decreased Kidney Function

Yaerim Kim,[1] Kyungho Ha,[6] Jeonghwan Lee,[2] Jae Yoon Park,[3] Kyung Don Yoo,[4] Yong Chul Kim,[5] Jin hyuk Paek,[1] Woo Yeong Park,[1] Kyubok Jin,[1] Seungyeup Han,[1] Dong Ki Kim,[5] Kwon Wook Joo,[5] Chun Soo Lim,[2] Jung Pyo Lee.[2] *[1]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [4]Ulsan University Hospital, Ulsan, Republic of Korea; [5]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [6]Jeju National University, Jeju, Jeju, Republic of Korea.*

Background: Beta-carotene has been announced that was inversely associated with the risk of all-cause mortality, but the association in the subgroup was not clear yet. Herein, we aimed to evaluate the impact of beta-carotene on all-cause mortality according to the different clinical settings among the general population.

Methods: We used employing data from the 92,062 subjects of US National Health and Nutrition Examination Survey 1999-2015. The intake of beta-carotene was divided into the quartile; the first quartile group was regarded as the reference. The subgroup was made by 1) the presence of hypertension, 2) diabetes, 3) the status of alcohol consumption, 4) smoking status, and 5) estimated glomerular filtration rate (eGFR) 90 mL/min/1.73m^2, respectively. We used a multivariate Cox-proportional hazard model to identify the impact of beta-carotene on all-cause mortality.

Results: A total of 36,747 subjects were finally included in the study. There were 14,469 (39.4%), 4,704 (12.8%), and 15,804 (43.0%) subjects with hypertension, diabetes, and eGFR <90 mL/min/1.73m^2, respectively. There were 8,774 (23.9%) of ex-smokers and 13,694 (37.3%) of non-alcoholics, respectively. During 97.9±53.9 months, there were 4,465 (12.2%) death were detected. After adjusted with multivariable, greater intake of beta-carotene significantly reduced the risk for all-cause mortality in subjects without hypertension (adjusted hazard ratio [aHR] 0.81, 95% confidence interval [CI] 0.66-0.99 in 4th quartile group [Q4]), without diabetes (aHR 0.85, 95% CI 0.75-0.96 in Q4), non-alcoholics (aHR 0.86, 95% CI 0.74-0.99 in Q4), and ex-smokers (aHR 0.79, 95% CI 0.66-0.93 in Q4), respectively. On the contrary, according to the eGFR, participants with eGFR <90 mL/min/1.73 m^2 had a beneficial effect of dietary beta-carotene (aHR 0.82, 95% CI, 0.73-0.93 in Q4) compared to the participants with eGFR ≥90 mL/1.73 m^2 (aHR 1.00, 95% CI, 0.78-1.27).

Conclusions: Among the various medical conditions, decreased kidney function status was the only condition to predict the beneficial effect of dietary beta-carotene. More specified and targeted counseling for encouraging intake of beta-carotene needs to be considered especially for subjects with lower eGFR.

PO2316

Reduced Differences in Clinical Outcomes Between Black and White Veterans with Incident CKD After Removal of Race from Estimated Glomerular Filtration Rate (eGFR)

Guofen Yan,[1] Keith C. Norris,[2] Robert Nee,[3] Julia J. Scialla,[1] Wei Yu,[1] Tom Greene,[4] Alfred K. Cheung.[4,5] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Walter Reed National Military Medical Center, Bethesda, MD; [4]University of Utah Health, Salt Lake City, UT; [5]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Assessing outcomes for racial subgroups can guide strategies to mitigate health and healthcare inequalities. We assessed differences in clinical outcomes by Black and White race following incidence of CKD defined when eGFR was computed with and without a race coefficient.

Methods: The study population was veterans, either non-Hispanic White or non-Hispanic Black, in the US Veterans Health Administration who had incident CKD stage G3 or higher (i.e., first eGFR<60 mL/min/1.73 m^2 for >3 months) between 2007 and 2016. eGFR values were calculated first using the Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) with its race term included and again using the same equation without the race coefficient (CKD-EPI-RACEout). We examined risks of initiating kidney replacement therapy (KRT) and death in Blacks and Whites, with follow-up from incident CKD until May 31, 2018 or up to 10 years.

Results: 115,374 Black veterans had incident CKD defined by CKD-EPI-RACEout vs. 84,090 by CKD-EPI; and 507,303 White veterans by CKD-EPI, with mean ages at CKD incidence of 64, 67 and 73 years, respectively. Blacks with CKD defined by CKD-EPI-RACEout had lower rates of both KRT and death (8.2 and 44.8 per 1000 patient-years, respectively) compared with Blacks by CKD-EPI (Table). After adjustment for age, sex, eGFR at CKD incidence, and CKD incidence year, Blacks by CKD-EPI-RACEout had a 41% greater risk of KRT than Whites, a markedly decrease from the 172% greater risk with CKD-EPI. Also, Blacks by CKD-EPI-RACEout had a 7% lower risk of death than Whites, in contrast to a 10% greater risk of death with CKD-EPI.

Conclusions: Compared to Whites, Blacks with incident CKD defined by CKD-EPI eGFR without the race coefficient remained more likely to develop KRT, though the relative risk was greatly attenuated; conversely, they had slightly longer survival after case-mix adjustment. Different methods of accounting for race in GFR estimation would affect measures of health outcome disparities in CKD.

Funding: NIDDK Support

Hazard ratios of outcomes for Black versus White veterans with incident CKD

	Kidney replacement therapy (KRT)			Death		
	Event rate (per 1000 patient-years)	Unadjusted hazard ratio (95% CI)	Adjusted hazard ratio (95% CI) (age, sex, eGFR and incident-year)	Event rate (per 1000 patient-years)	Unadjusted hazard ratio (95% CI)	Adjusted hazard ratio (95% CI) (age, sex, eGFR and incident-year)
Black, identified by CKD-EPI without race coefficient	8.2	2.42 (2.33-2.51)	1.41 (1.36-1.46)	44.8	0.60 (0.59-0.61)	0.93 (0.92-0.94)
Black, identified by CKD-EPI	15.2	4.56 (4.40-4.71)	2.72 (2.62-2.82)	62.9	0.85 (0.84-0.86)	1.10 (1.09-1.12)

Impact of Removing the Race Coefficient from Estimation of Glomerular Filtration Rate (eGFR) at the University of Washington

Sandra G. Carias Zuniga, Rajnish Mehrotra, Bessie A. Young, Nisha Bansal. *University of Washington School of Medicine, Seattle, WA.*

Background: The inclusion of the race coefficient in eGFR estimates for patients identified as Black has been widely debated. In response, our institution eliminated the race coefficient when reporting eGFR on June 1, 2020. We evaluated changes in prescription of metformin, dialysis initiation and referral to subspecialists among Black and non-Black patients before vs. after the change in eGFR reporting.

Methods: We manually reviewed data of self-identified Black patients with CKD within the UW system between June through November of 2019 (before change in eGFR reporting) and 2020 (after change in eGFR reporting). In addition, data from the electronic medical record (EMR) was extracted for subspecialty referral rates for Black and non-Black patients during this same time frame. We compared 6-month data pre/post change of eGFR and determined differences in: initiation and discontinuation of metformin, indication for and mean eGFR at dialysis initiation, and new referrals to nephrology, transplant and vascular surgery.

Results: After the change in eGFR reporting, rates of metformin initiation increased (4/223 in 2020 vs. 0/219 in 2019), while discontinuation rates were stable (18% in 2019 vs. 15% in 2020) among Black patients with CKD. Rates of dialysis initiation were comparable (2.7% in 2020 vs. 1.4% in 2019, mean eGFR 8 vs. 13 ml/min/1.73m^2) in Black patients with CKD, with the primary indication of uremic symptoms remaining unchanged. Comparing Black vs. non-Black patients, subspecialty referral rates for nephrology and transplant nephrology were higher for Blacks after the change in eGFR reporting (Figure 1).

Conclusions: After removing the race coefficient from eGFR reporting, patterns of medication prescription rates and dialysis initiation did not substantially change, however subspecialty referral rates increased for Black patients with CKD. We acknowledge that the COVID-19 pandemic may have impacted these trends, but the trends overall are encouraging for improving health outcomes and nephrology access to care for Black patients with CKD.

Figure 1. Differences in subspecialty referral rates at the University of Washington with the inclusion of the race coefficient in eGFR reporting (2019) and after exclusion of the race coefficient in eGFR reporting (2020)

	June 1-November 30, 2019 (with race coefficient in eGFR)		June 1-November 30, 2020 (without race coefficient in eGFR)		Change from 2019 to 2020*	
	Black patients	Non-Black patients	Black patients	Non-Black patients	% change for Black patients	% change for non-Black patients
New Nephrology referrals	133	783	157	874	+18%	+11.6%
Transplant Nephrology referrals	22	150	26	146	+18.2%	-2.7%

Elimination of the Race Coefficient from eGFR Calculation on Clinical Care and CKD Research Among a National US Veteran Cohort

L Parker Gregg,[1,2] Peter Richardson,[1,2] Julia Akeroyd,[1,2] Michael E. Matheny,[3,4] Salim S. Virani,[1,2] Sankar D. Navaneethan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]VA Tennessee Valley Healthcare System, Nashville, TN; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Elimination of the race coefficient from the CKD-EPI equation has been proposed as an important step to improve healthcare disparities faced by Black persons with chronic kidney disease (CKD).

Methods: We identified U.S. Veterans with incident non-dialysis CKD stages 3-4 based on laboratory data from 2005-2019 from the Veterans Affairs (VA) Corporate Data Warehouse. Demographic characteristics and laboratory values were used to calculate estimated glomerular filtration rate (eGFR) by the CKD-EPI equation with and without the race coefficient. We identified Black persons who were reclassified from non-CKD to CKD status or to a different CKD stage, as well as individuals whose race was not reported and eGFR could not be calculated using a race-based equation. The number of additional persons with CKD identified without the race coefficient was evaluated by VA station.

Results: There were 1,765,410 individuals with CKD stages 3-4 by race-based eGFR. Eliminating the race coefficient resulted in reclassification of 119,142 (35.2%) Black individuals as having CKD stages 3a, 3b, or 4, accounting for a 6.7% increase in incident CKD among all races and a 54.3% increase among Black persons. Of reclassified Black individuals, 77% had hypertension, 14% had cardiovascular disease, 51% were prescribed either an ACE inhibitor or an ARB, and 48% were prescribed statins. There were also 245,340 individuals with unreported race who were newly classifiable as having CKD when eliminating the race coefficient. Median (IQR) number of reclassified individuals per VA station was 470 (110.5-1,393) reclassified Black persons and 1,550 (584-2,665.75) individuals of unidentified race (Figure).

Conclusions: Eliminating the eGFR race coefficient will lead to substantial but variable impact on clinical care and CKD research across VA locations nationally. Ideally this shift will achieve more equitable clinical outcomes for Black persons and expand inclusion in CKD clinical trials and observational research to advance CKD care.

PO2319

Comparing Estimated Glomerular Filtration Rates (eGFR) for US Black Veterans with and Without the Black-Race Coefficient and Normalization to a Fixed Body Surface Area (BSA)

Jennifer L. Bragg-Gresham,[1] Hal Morgenstern,[4] Vahakn Shahinian,[1] Chi D. Chu,[2] Neil R. Powe,[2] Nilka Rios Burrows,[3] Meda E. Pavkov,[3] Kara Zivin,[5] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of California San Francisco, San Francisco, CA; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of Michigan School of Public Health, Ann Arbor, MI; [5]Veterans Health Administration, Ann Arbor, MI.*

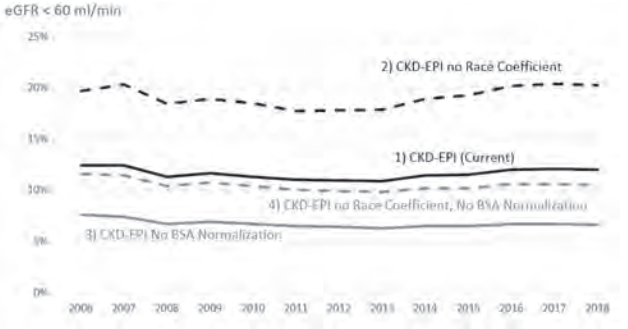
Background: The CKD-EPI estimation of GFR includes two corrections: 1) increasing eGFR for Blacks by 15.9% to more accurately reflect measured GFR; 2) normalizing eGFR in all races to a fixed value (1.73 m^2) of BSA to compare across populations. We aimed to assess the impact of removing both corrections—separately and together—on the prevalence of CKD in Black US Veterans.

Methods: Among 7 million Black US Veterans, aged 18+ with at least one serum creatinine lab measurement (2006-2018), we estimated the prevalence of eGFR < 60, using four GFR-correction methods: 1) eGFR using the CKD-EPI equation with the Black-race coefficient and normalized to a BSA of 1.73 m^2; 2) #1, without the Black-race coefficient; 3) #1, without normalization for BSA; and 4) #1, without the Black-race coefficient or normalization for BSA.

Results: Among Black Veterans, the average age was 57 years, 87% males, and average BSA was 2.11 m^2. The prevalence of CKD varied appreciably by the method of GFR estimation. CKD prevalence was highest (15-20%) throughout the 13-year study period without use of the Black-race coefficient (#2) and lowest (6-8%) without normalization for BSA (#3). The method with neither the Black-race multiplier nor BSA normalization (#4) yielded similar estimates of CKD prevalence as the CKD-EPI method of eGFR estimation (#1), differing by <2% throughout the study period. Patient-level agreement between the latter two methods was nearly 80%.

Conclusions: Our results show good agreement between Black Veterans classified as having CKD using the CKD-EPI equation with both corrections and those same veterans classified with CKD without either correction. Pending recommendations from the NKF-ASN Task Force, the latter method (#4) offers a simplified procedure to provide individualized GFR estimates on the original scale (mL/min) for all individuals.

Funding: Other U.S. Government Support



* eGFR without BSA normalization=eGFR (CKD-Epi)*(BSA/1.73), where BSA=(Wt$^{0.5}$*Ht$^{0.5}$)/60, according to Mosteller (1987)

Social Determinants of Health (SDOH), Environmental Inequities and ESRD Among US Veterans: An Integration of Ecological and Spatial Approaches

Yun Han,[1] Jennifer L. Bragg-Gresham,[1] Diane Steffick,[1] Xiaosong Zhang,[1] Brenda W. Gillespie,[1] Tiffany C. Veinot,[1] V. G. Vinod Vydiswaran,[1] April Wyncott,[1] William Weitzel,[3] Karandeep Singh,[1] Susan T. Crowley,[2] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]VA Connecticut Healthcare System - West Haven Campus, West Haven, CT; [3]VA Ann Arbor Healthcare System, Ann Arbor, MI.*

Background: Disparities in kidney health are often due to underlying environmental and social determinants of health (SDOH). We assessed geographic variation and the association between air pollution, SDOH, and ESRD in US veterans at county-level.

Methods: We used data from about 3 million Veterans with CKD between the years of 2006-2016 (prevalent and incident CKD cases). Environmental and SDOH were obtained from various data sets, including the American Community Survey (2009), the National Neighborhood Data Archive (2006) and others. County prevalence of ESRD was calculated as # ESRD cases/1000 person-years. County-level environmental factors and SDOH included average daily PM2.5, neighborhood disadvantage index, etc. A geographically weighted regression model (GWR) was applied to explore the relationship between SDOH, air pollution and prevalence of ESRD.

Results: Average of county-level prevalence of ESRD was 3.1/1000 person-years (SD=0.21, n=3,231). The prevalence of ESRD was higher in the rust-belt area of the Midwest and the Southeast region (Fig1a). Neighborhood disadvantage index was

associated with higher ESRD prevalence in the West and parts of the Midwest (Fig1b). PM2.5 was associated with higher prevalence in the East North Central and South West Central regions (Fig1c).

Conclusions: Variation exists in the association between environmental factors, SDOH and the presence of ESRD geographically. It highlights the importance of attention to the environment and community-based SDOH, toward preventing and managing ESRD based on residence and individualized patient care.

PO2321

Facility-Level Variation and Racial Disparities in Albuminuria and Serum Creatinine Dual Testing in the US Veterans Health Administration (VHA) Health Care System

Yun Han,[1] Nicole Bhave,[1] Diane Steffick,[1] Kara Zivin,[4,1] Alain Koyama,[2] Meda E. Pavkov,[2] Neil R. Powe,[3] Delphine S. Tuot,[3] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of California San Francisco, San Francisco, CA; [4]VA Ann Arbor Healthcare System, Ann Arbor, MI.*

Background: Simultaneous urine testing for albumin (UAlb) and serum creatinine (SCr), i.e., 'dual testing', is now an accepted quality measure in the management of diabetes. As kidney disease is defined by both UAlb and SCr testing, this approach could be more widely adopted in kidney care. We therefore sought to assess facility-level variation and racial differences in performance of dual testing in the integrated VHA health care system.

Methods: We included patients with any inpatient or outpatient visit to the VHA during the period 2009-2018. Dual testing was defined as UAlb and SCr testing in the outpatient setting within a fiscal year. A generalized linear mixed-effects model was applied to explore individual level (demographics and comorbidities) and facility level predictors of receiving dual testing.

Results: We analyzed data from approximately 6 million veterans per year (total n=69,102,389; 91.1% male). Dual testing increased on average from 17% to 21%, but varied substantially among VHA centers (0.3% to 43.7% in 2018) (Figure). Dual testing was strongly associated with diabetes (odds ratio [OR]: 10.4, 95% CI 10.3-10.5, p<0.0001) and not associated with VHA center complexity level. Despite a higher proportion of Black veterans receiving dual testing compared to White veterans (24.0% vs 21.7% in 2018), they were less likely to be tested after adjusting for other individual and facility characteristics (OR: 0.93, 95% CI 0.92-0.93, p<0.0001).

Conclusions: Performance of dual testing varied among VHA centers and is low in both White and Black veterans. Simultaneously incorporating UAlb and SCr for kidney care may help improve both risk stratification and management of individuals with or at risk of kidney disease.

Three New Race-Free, Community-Based Equations to Estimate GFR: The Machine Learning Estimation of Renal Function (MLERF) Equations

Xiaoqian Zhu,[1] Tariq Shafi,[1] Keith C. Norris,[2] Jeannette Simino,[1] Michael Griswold,[1] Seth Lirette.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]University of California Los Angeles, Los Angeles, CA.*

Background: As inclusion of race in glomerular filtration rate (GFR) estimation has become an increasingly controversial issue, it is of vital importance to propose race-free equations and evaluate their performance.

Methods: Using Multivariable Fractional Polynomials (MFP), Generalized Additive Models (GAM), and Random Forests (RF), we developed three new GFR estimating equations from the community-based Genetic Epidemiology Network of Arteriopathy Study (GENOA) study (N=1010). We then compared performance of the new equations to the CKD-EPI creatinine equation using the Epidemiology of Coronary Artery Calcification (ECAC) cohort study and the Assessing Long Term Outcomes in Living Kidney Donors (ALTOLD) (N=792). Due to lack of black participants in external data, we also evaluate performance of equations in Black participants internally using development data. A rigorous bootstrapping method, allowing equation coefficients to change for each bootstrap sample, was used to evaluate performance of our new equations to address the issue of overfitting.

Results: Our final equations were based on creatinine, age and sex. The addition of race yielded only minor nonsignificant improvements in RMSE and thus race was not included in the final equations. In external data (Figure), our new equations showed similar P30, RMSE, bias and precision compared to the CKD-EPI creatinine equation which included race as a predictor. Our equations also showed marked improvements in terms of bias and accuracy for Black participants over the CKD-EPI creatinine equation in the development data.

Conclusions: Performance of our new race-free equations using community-based cohorts were comparable to CKD-EPI creatine equation in external validation and superior in Black participants in internal validation. Our study indicated that race can be removed from equations to estimate GFR in Black and White participants without significantly sacrificing equation performance.

Non-GFR Determinants of Serum Creatinine and Race in GFR Estimating Equations: Findings from the CRIC Study

Chi-yuan Hsu,[1,7] Wei Yang,[3] Rishi V. Parikh,[9] Amanda H. Anderson,[5] Teresa K. Chen,[8] Debbie L. Cohen,[3] Jiang He,[5] Madhumita J. Mohanty,[4] James P. Lash,[10] Katherine T. Mills,[5] Anthony N. Muiru,[1] Afshin Parsa,[11] Milda R. Saunders,[12] Tariq Shafi,[2] Raymond R. Townsend,[3] Sushrut S. Waikar,[13] Jianqiao Wang,[3] Myles Wolf,[6] Thida C. Tan,[9] Harold I. Feldman,[3] Alan S. Go.[9,1] CRIC *[1]University of California San Francisco, San Francisco, CA; [2]The University of Mississippi Medical Center, Jackson, MS; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Wayne State University, Detroit, MI; [5]Tulane University, New Orleans, LA; [6]Duke University School of Medicine, Durham, NC; [7]Kaiser Permanente, Oakland, CA; [8]Johns Hopkins University, Baltimore, MD; [9]Kaiser Permanente Northern California, Oakland, CA; [10]University of Illinois at Chicago, Chicago, IL; [11]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [12]University of Chicago Department of Medicine, Chicago, IL; [13]Boston University School of Medicine, Boston, MA.*

Background: Understanding and controlling for the non-GFR determinants of serum creatinine (SCr) that correlate with race may facilitate development of GFR estimating equations without a race term.

Methods: This is a cross-sectional study of 1248 Chronic Renal Insufficiency Cohort (CRIC) participants who underwent urinary ^{125}I-iothalamate clearance GFR (iGFR) and 24-hour urine creatinine clearance measurement at study entry. We first evaluated if Black (vs. non-Black) race was independently associated with different components of creatinine production, secretion and excretion that may contribute to variations in SCr independent of measured GFR (i.e. non-GFR determinants of SCr). We then assessed whether any of these potential explanatory variables could independently or jointly replace the term for Black race in GFR estimating equations using SCr.

Results: Mean±SD age of the study population was 55.9±12.1 yrs; iGFR 48±20 ml/min/1.73m^2; median [IQR] SCr 1.5 [1.3-2.0] mg/dL; 43% were female and 37% self-identified as Black. Black race was associated with greater height, weight, BMI, BSA, bioelectrical impedance analysis (BIA)-phase angle and fat-free mass, and 24-hour urine creatinine excretion. Black race was not associated with higher dietary protein intake (assessed by either self-report or 24-hour urine urea nitrogen) or less tubular secretion of creatinine (quantified as difference between creatinine clearance and iGFR). In a model regressing iGFR on SCr, age, sex, and race (Black vs. non-Black), there were modest attenuations for the race terms when factors were considered individually (**Table**). A multivariable model maximized attenuation, but there remained a 8.7% higher iGFR in Black participants (vs. 12.8% in base model)(**Table**).

Conclusions: Modeling non-GFR determinants of SCr, which varied by race, did not eliminate the incremental value of including race in SCr-based GFR estimating equations.

PO2324

Effect of Removing Race Coefficient (RC) from Estimated Glomerular Filtration Rate (eGFR) Among Black Adults in the US Military Health System (MHS)

James D. Oliver,[1,2] Robert Nee,[1,2] Munziba T. Khan,[4] Amanda Banaag,[4] Alain Koyama,[3] Nilka Rios Burrows,[3] Meda E. Pavkov,[3] Tracey L. Koehlmoos.[2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services University of the Health Sciences, Bethesda, MD; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Henry M Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, MD.*

Background: The use of race in calculating eGFR is under scrutiny as a possible contributor to healthcare disparities in the US. Using the MHS electronic medical record, we evaluated the effect in Black adults of removing eGFR race adjustment on the overall prevalence of chronic kidney disease (CKD) and on the prevalence at specific levels of eGFR important in clinical decision-making.

Methods: Fiscal Year (FY) 2015 data were extracted from the MHS Data Repository for individuals of Black race aged ≥18 without end-stage kidney disease. eGFR was calculated from serum creatinine using the CKD-EPI equation both with and without adjustment for Black race. CKD was defined as having the most recent eGFRs in the FY persistently <60 mL/min/1.73m2 for more than 3 months (KDIGO criteria). Statistical significance was determined by chi-square.

Results: 136,934 Black individuals (age=43±14 years, 38% female, 40% active duty) had serum creatinine measured a total of 259,930 times. With RC, mean eGFR was 98.1±25.7, 4.5% had at least one eGFR <60, and 1.3% met CKD by KDIGO criteria (Table). Removal of RC decreased mean eGFR to 84.7±22.2 (Δ=−13.5±3.6) and increased CKD prevalence to 2.1% (Δ=+68%). Without RC, 0.9% of those with GFR≥60 were reclassified as having CKD stage 3 and 5.6% of those with CKD stage 3 reclassified into CKD stages 4-5. Without RC the prevalence of CKD stages 3b-5 increased by 75%, of CKD stages 4-5 by 65%, and of eGFR<20 (eligible for transplant listing) by 71%. Among active duty, removal of RC increased prevalence of CKD by 102% and of CKD stages 3b-5 by 68%.

Conclusions: Removal of the RC resulted in significant reclassification from non-CKD to CKD and from lower to higher stages of CKD. Consequences for patient education, treatment decisions, resource utilization, and clinical outcomes may benefit from further study. *The views expressed in this abstract are those of the authors and do not reflect official policy of the Departments of Army/Navy/Air Force, Department of Defense, Department of Health and Human Services, or the US Government.*

Social Determinants of Health and Estimated GFR in the MDRD Study

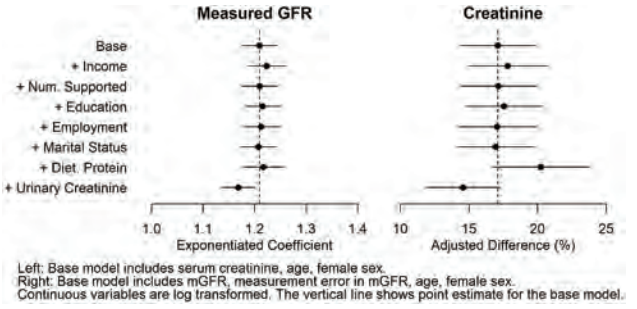
Lesley A. Inker,[1] Juhi Chaudhari,[1] Sophia Kostelanetz,[6] Tom Greene,[3] Robert E. Boucher,[4] Shiyuan Miao,[1] Keith C. Norris,[2] Nwamaka D. Eneanya,[5] Andrew S. Levey,[1] Julia Lewis.[6] *[1]Tufts Medical Center, Boston, MA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]The University of Utah Department of Internal Medicine, Salt Lake City, UT; [4]The University of Utah School of Medicine, Salt Lake City, UT; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]Vanderbilt University Medical Center, Nashville, TN.*

Background: Use of race in medical algorithms is facing increasing scrutiny. One concern is that race differences do not reflect biological differences, but rather differences in social determinants of health (SDH). The MDRD Study equation was the first eGFR equation to include race [self-identified and categorized as Black vs non-Black] in addition to age, sex and serum creatinine (Scr), due to observed differences between Black and non-Black individuals in mean measured GFR (mGFR) (1.21 times higher with the same age, sex and Scr) and mean Scr (17.1% higher for the same age, sex and mGFR, accounting for mGFR measurement error). Subsequent analysis suggested higher mean creatinine excretion and lower mean creatinine secretion in Black individuals. Here we explore the impact of SDH on the Black race coefficient in the MDRD Study equation and on the racial difference in observed Scr in the MDRD Study.

Methods: SDH and related variables included income, household size, education, employment, marital status, dietary protein and creatinine excretion. We examined the magnitude of the Black race coefficient and the observed race difference in Scr without and with adjustment for SDH variables.

Results: Among the 1628 participants at baseline visit 3, mean mGFR was 40 (range 5-168) and 12% were Black individuals. There were significant differences between Black and non-Black individuals for all SDH except dietary protein. Addition of SDH (Figure) did not substantially alter the Black race coefficient in eGFR (left) or the race difference in mean Scr (right).

Conclusions: We were not able to show that these SDH account for the observed race differences in the relationship between mGFR and Scr in the MDRD Study. Key limitations include availability of SDH variables, residual confounding between race and SDH, and a single study of patients with CKD from 30+ years ago which may not reflect a more contemporary diverse population. These results do not detract from concerns for use of race in GFR estimation.



Left: Base model includes serum creatinine, age, female sex.
Right: Base model includes mGFR, measurement error in mGFR, age, female sex.
Continuous variables are log transformed. The vertical line shows point estimate for the base model.

PO2326

Impact of Race/Ethnicity on the Current Screening Approach for CKD

Brechje Huisman, Bert-jan Van den born, Irene van Valkengoed, Liffert Vogt. *AmsterdamUMC, Amsterdam, Netherlands.*

Background: KDIGO recommends screening for chronic kidney disease (CKD) with both estimated glomerular filtration rate (eGFR) and urine albumin-to-creatinine ratio (ACR). Screening is advised for people with diabetes mellitus, hypertension and/or cardiovascular disease (CVD). People of African descent are at increased risk for CKD, while several reports indicate that the screening approach insufficiently capture CKD in this group. eGFR correction for African race/ethnicity may contribute to this discrepancy, but age and socioeconomic status (SES) may be involved. We assessed whether CKD detection is influenced by race/ethnicity correction and we defined how age >50 yr or lower SES influence CKD detection.

Methods: Baseline data of 21,617 participants (mean age 44 yr, 43% male) of Dutch (4,564), South-Asian Surinamese (3,043), African Surinamese (4,151), Ghanaian (2,339), Moroccan (3,614) and Turkish (3,096) ethnicity included in the multi-ethnic HELIUS cohort study (Amsterdam, The Netherlands) were analysed. We defined CKD as eGFR (CKD-EPI formula, <60mL/min/1.73m^2) and/or ACR (≥3mg/mmol). Detection rate was characterised by the c-statistic for three screening approaches in each ethnic group; I) the traditional approach (i.e. screening when having diabetes mellitus, hypertension or CVD); II) the traditional approach plus age >50yr; and III) the traditional approach plus low SES (i.e. none or elementary schooling). C-statistic with and without correction for race/ethnicity were compared.

Results: Of participants, 2335 (11%) had CKD. Estimated CKD was slightly more prevalent in participants of African Surinamese (11 vs 13%) and Ghanaian (12 vs 14%) descent, when the correction for race/ethnicity was discontinued. Compared to approach I, approach II and approach III did not have a higher c-statistic, overall and within African origin subgroups. Results with and without ethnicity/race were similar.

Conclusions: Our study shows that discontinuation of the race/ethnicity correction, or addition of age > 50 yr and low SES as criteria for CKD screening have little impact on the detection rate of the currently advised screening approach.

C-statistic (95%-CI)	Approach I		Approach II		Approach III	
	Corrected	Uncorrected	Corrected	Uncorrected	Corrected	Uncorrected

Impact of Race/Ethnicity and Age on Survival in Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Amy S. You,[1] Kamyar Kalantar-Zadeh,[1] Yoko Narasaki,[1] Csaba P. Kovesdy,[2] Dana B. Mukamel,[1] Susan T. Crowley,[3,4] Alejandra Novoa-Vargas,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Yale University School of Medicine, New Haven, CT; [4]Veterans Health Administration, Washington, DC.*

Background: Given evidence that dialysis may not offer survival benefit nor improved quality of life in certain groups (elderly, multi-morbid), there is growing interest in conservative management (CM) as an alternative treatment strategy for advanced CKD. Yet little is known about the impact of CM vs. dialysis on CKD outcomes, including mortality, across different racial/ethnic and age groups.

Methods: In a national cohort of 309,188 advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days), we compared mortality rates in patients treated with CM vs. dialysis from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were categorized according to receipt of dialysis vs. CM, defined as those who did vs. did not receive dialysis within 2-yrs of the index eGFR (1st eGFR <25), with the former group parsed according to timing of dialysis initiation, defined as late, intermediate, vs. early dialysis (eGFRs <5, 5-<10, vs. ≥10 at dialysis transition). We used Poisson regression to compare mortality rates in CM vs. dialysis patients across race/ethnicity and age.

Results: Whereas late, intermediate, and early dialysis had higher mortality rates than CM in Non-Hispanic Whites across all age groups, in Hispanic patients CM and dialysis had similar mortality rates across all ages. In Non-Hispanic Blacks, Asians, and Other races/ethnicities, CM vs. late dialysis had similar mortality rates among those ≥75 yrs old, whereas CM demonstrated survival benefit vs. all dialysis groups in younger ages.

Conclusions: In a diverse, nationally representative cohort of CKD patients, we observed differential relationships between CM vs. dialysis on mortality rates across race/ethnicity and age. Further research is needed to determine which patient characteristics and health services optimize candidacy and choice of CM vs. dialysis to enable a personalized approach.

PO2328

Evaluation of the Cambridge GFR Estimating Equation in a Diverse Population

Sara J. Couture,[1] Hocine Tighiouart,[1] Veronica T. Costa e Silva,[2] Lesley A. Inker,[1] Andrew S. Levey.[1] CKD-EPI *[1]Tufts Medical Center, Boston, MA; [2]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil.*

Background: Evaluation of GFR is not standardized in oncology; serum creatinine (Scr), estimated creatinine clearance (eClcr) using the Cockcroft Gault equation, and estimated GFR (eGFR) using Scr (eGFRcr) using the MDRD Study or CKD-EPI equation are often used interchangeably. KDIGO guidelines recommend eGFRcr, using standardized Scr and the CKD-EPI equation as the initial test in adults, and confirmatory tests using serum cystatin C (eGFRcys or eGFRcr-cys), measured creatinine clearance (mClcr) or measured GFR (mGFR) using exogenous filtration markers.

Methods: Janowitz and colleagues recently reported a new equation developed in patients with cancer that can be used with or without IDMS-traceable assays, CamGFRv2 (Williams et al. Clin Cancer Res 2021), which performed better than CKD-EPI eGFR in the development population, but which has not been evaluated in an external validation population. To determine if CamGFRv2 could be used in other settings, we evaluated CamGFRv2 and other commonly used equations in two large, diverse study populations.

Results: Study populations included the CKD-EPI 2009 external validation population [n=3771, mean (SD) age 49.2 (14.6), mGFR 69.2 (35.5) ml/min/1.73 m^2), men 54.1%, African American 10%, diabetes 28.2%, and CKD-EPI 2012 external validation population [n=1119, mean (SD) age, 49.9 (16.6) years, mGFR 69.8 (41.0) ml/min/1.73 m^2, men 59.3%, African American 3%, diabetes 53.1%]. (Note: study participants were not included in the development of the CKD-EPI equations.) No eGFRcr equation, including CamGFRv2, performed better than the CKD-EPI equation. As previously reported, CKD-EPI eGFRcr-cys performed better than CKD-EPI eGFRcr or eGFRcys (Inker et al. NEJM 2012).

Conclusions: In conclusion, eGFRcr using CamGFRv2 is not more accurate than using CKD-EPI in a diverse population. Studies comparing CamGFRv2 vs. CKD-EPI equations in patients with cancer are needed

eGFR marker	Equation	Demographic Variables	Bias	Precision IQR	Accuracy 1-P$_{30}$(%)	Accuracy RMSE

Bias is computed as the median of the difference between mGFR and eGFR. IQR, interquartile range; of the differences between mGFR and eGFR, is 25th and 75th percentiles of the differences. Units for bias and IQR are ml/min/1.73 m^2. 1- P$_{30}$ and RMSE are measures of accuracy. P$_{30}$ is computed as percent (%) of eGFR less than ±30% different from mGFR; 1-P$_{30}$ indicates large errors; RMSE, root mean square error, is a computed on the log scale.
*N=3750 (21 participants were missing height or weight)
Comparisons: CKD-EPI eGFRcr is the reference. Green shading indicates that the point estimate is closer to zero than the reference and CI does not overlap the reference, and as Orange shading indicates that the point estimate is further from zero than the reference and CI does not overlap the reference.

Racial and Ethnic Predictors of Hyperkalemia Recurrence

Elani Streja,[1,2] Jui-Ting Hsiung,[1,2] Abiy Agiro,[3] Yasmin G. Brahmbhatt,[3] Kerry Cooper,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]VA Long Beach Healthcare System, Long Beach, CA; [2]University of California Irvine, Irvine, CA; [3]AstraZeneca PLC, Cambridge, United Kingdom.*

Background: Understanding predictors of recurrent HK may help healthcare providers provide a more individualized approach to HK management. This study aims to explore if race and ethnicity are independently associated with recurrent HK.

Methods: The cohort consisted of 2,457,498 US veterans who had a HK event (sK >5.0 mEq/L) between 2004 and 2018. We evaluated possible demographic predictors of 1-year HK recurrence using Fine and Gray competing risk regression model, which the competing event was all-cause mortality within 1 year after index HK event. We defined HK recurrence as the third or later potassium measurement after the index HK measurement, and patients need to have at least one or more normal potassium measurements (≤5 mEq/L) between the HK events.

Results: Cohort mean age was 63±13yrs, mean index potassium level was 5.31±0.29 mEq/L, and median (IQR) index eGFR was 68 (49,86) mL/min/1.73m^2; 96% were male, 13% were Blacks, and 6% were Hispanic. Overall, 17% of patients had a HK recurrence within 1 year after index HK occurrence. Black patients had a 19% higher risk of 1-year HK recurrence (hazard ratio [HR] [95% CI]: 1.19 [1.18, 1.20]) compared to White patients. Hispanic patients had a 34% higher risk of 1-year HK recurrence (hazard ratio [HR] [95% CI]: 1.34 [1.32, 1.36]) compared to non-Hispanic patients. Other predictors for high risk of 1-year HK recurrence include older age (15% higher for each 15 year increment of age) and male (22% higher compared to female) (Table).

Conclusions: Being Hispanic, Black, male, or older age, was associated with a higher risk of HK recurrence within 1 year after index HK event. Further studies are needed to understand the reasons for these disparities and their potential associations with clinical management of HK.

Ethnic Differences for Incident CKD in Asians

Cynthia C. Lim,[1] Feng He,[2] Jialiang Li,[2] Yih-Chung Tham,[2] Chieh-suai Tan,[1] Ching-Yu Cheng,[2] Tien Yin Wong,[2,3] Charumathi Sabanayagam.[2,3] *[1]Singapore General Hospital, Singapore, Singapore; [2]Singapore Eye Research Institute, Singapore, Singapore; [3]Duke-NUS Medical School, Singapore, Singapore.*

Background: Chronic kidney disease (CKD) is a growing health burden in Asia but there is sparse data on incident CKD among different ethnic groups. We aimed to describe the incidence and risk factors associated with incident CKD in the major ethnic groups in Asia.

Methods: Prospective cohort study of 5580 general population participants age 40-80 years (2234 Chinese, 1474 Malays and 1872 Indians) in Singapore who completed both baseline and 6-year follow up visits. Incident CKD was defined as an estimated glomerular filtration rate <60 ml/min/1.73 m^2 in those free of CKD at baseline.

Results: The 6-year incidence of CKD was highest among Malays (10.0%), followed by Chinese (6.1%) and Indians (5.8%). Logistic regression showed that older age, diabetes, higher systolic blood pressure and lower eGFR were independently associated with incident CKD in all 3 ethnic groups, while hypertension and cardiovascular disease were independently associated with incident CKD only in Malays. The same factors were identified by machine learning approaches gradient boosted machine (GBM) and random forest (RF) to be the most important for incident CKD (Figure 1). Adjustment for clinical and socioeconomic factors reduced the excess risk in Malays by 60% compared to Chinese but only 13% compared to Indians.

Conclusions: Incidence of CKD is high among the main Asian ethnic groups in Singapore, ranging between 6-10% over 6 years. Differences between ethnic groups were partially explained by clinical and socioeconomic factors. These findings may inform policy development and resource allocation to target risks factors to reduce incident CKD.

Funding: Government Support - Non-U.S.

Muscle Mass and Estimates of Renal Function: A Longitudinal Cohort Study

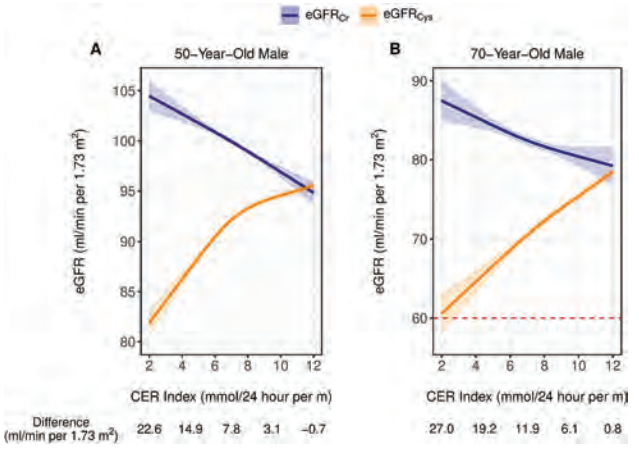
Dion Groothof,[1] Adrian Post,[1] Harmke A. Polinder-Bos,[3] Nicole Erler,[3] Jose L. Flores-Guerrero,[1] Jenny E. Kootstra-Ros,[1] Robert Pol,[1] Martin H. De Borst,[1] Ron T. Gansevoort,[1] Reinold O. Gans,[1] Daan Kremer,[1] Lyanne M. Kieneker,[1] Arjola Bano,[2] Taulant Muka,[2] Oscar Franco,[2] Stephan J. Bakker.[1] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Universitat Bern Institut fur Sozial- und Praventivmedizin, Bern, Switzerland; [3]Erasmus MC, Rotterdam, Netherlands.*

Background: Current guidelines suggest using creatinine-based estimated glomerular filtration rate ($eGFR_{Cr}$) as measurement of renal function, but muscle mass as key determinant of creatinine after renal function may lead to imprecise estimates. We explored effects of 24-hour height-indexed creatinine excretion rate (CER index) – as accurate marker of muscle mass – on $eGFR_{Cr}$ and muscle mass-independent cystatin C-based eGFR ($eGFR_{Cys}$) and predicted probabilities of misclassification given age, sex, and CER index.

Methods: We included 8,076 community-dwelling individuals enrolled in the PREVEND study. Misclassification was defined as $eGFR_{Cr}$ ≥60 ml/min/1.73 m^2 when $eGFR_{Cys}$ was <60 ml/min/1.73 m^2. Cross-sectional associations were quantified with quantile regression and logistic regression and longitudinal associations with linear mixed-effects models.

Results: In a simulated 70-year-old male with low muscle mass (CER index of 4 mmol/24 hour/m), predicted baseline $eGFR_{Cr}$ and $eGFR_{Cys}$ were 87.5 and 60.5 (difference: 27.0) ml/min/1.73 m^2, respectively (**Figure**). Percentages (95% CI) of misclassification in males and females older than 60 years with low muscle mass were 18.5% (14.8% to 22.1%) and 15.2% (11.6% to 18.8%), respectively. Over time, for that same 70-year-old male, $eGFR_{Cr}$ and $eGFR_{Cys}$ disagreed with 2.3, 4.9, 7.7, and 10.7 ml/min/1.73 m^2 at baseline, 5 years, 10 years, and 15 years of follow-up, respectively.

Conclusions: Low muscle mass may cause considerable overestimation of single measurements of $eGFR_{Cr}$. Muscle wasting may cause spurious overestimation of repeatedly measured $eGFR_{Cr}$. Implementing muscle mass-independent markers for estimating renal function, like cystatin C as superior alternative to creatinine, is crucial to accurately assess renal function in settings of low muscle mass or muscle wasting.



PO2332

Muscle Is a Non-GFR Determinant of Serum Filtration Marker Levels and Is Associated with Differential Accuracy of GFR Estimating Equations in Older Adults

Erin Flanagin,[1] Hocine Tighiouart,[2,3] Cynthia Delgado,[4,5] Vilmundur Gudnason,[6,7] Andrew S. Levey,[1] Lesley A. Inker.[1] *[1]Tufts Medical Center, Boston, MA; [2]Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Boston, MA, US, academic/medres, Boston, MA; [3]Tufts Clinical and Translational Science Institute, Boston, MA; [4]San Francisco VA Health Care System, San Francisco, CA; [5]University of California San Francisco Department of Medicine, San Francisco, CA; [6]Icelandic Heart Association, Haskoli Islands, Reykjavik, Iceland; [7]University of Iceland School of Medicine, Haskoli Islands, Reykjavik, Iceland.*

Background: Current GFR estimating equations using creatinine are limited by association with muscle. It is not known whether this is true for recently developed equations using novel filtration markers. These associations are relevant for older adults in whom reduced muscle mass is common.

Methods: In a cross-sectional analysis of 540 community dwelling older adults in Reykjavik, Iceland, serum levels of creatinine (Cr), cystatin-C (Cys), and novel filtration markers (beta-trace protein [BTP], beta-2-microglobulin [B2M], N-acetylthreonine, pseudouridine, phenylacetylglutamine, and tryptophan) were measured, and GFR was measured using clearance of iohexol (mGFR). GFR was estimated from Cr, Cys, or panels of novel filtration markers using CKD-EPI equations. Thigh muscle area (TMA) was assessed using computed tomography. The association of each filtration marker with TMA was determined using linear regression with adjustment for mGFR, GFR measurement error, age, and sex. The performance of the estimating equations was assessed using bias and percent of large (≥30%) errors (1-P_{30}) among those in the lowest sex-specific quintile of TMA compared to the upper four quintiles.

Results: Mean age was 80 (SD 3.8) years, with a mean mGFR of 63 (SD 16) ml/min/1.73m^2. After adjusting for mGFR, all filtration markers had a residual association with TMA, but Cr had a substantially greater association even after adjustment for age and sex. Both bias and 1-P_{30} were greater in the subgroup with low TMA for eGFR from Cr and/or Cys but not for panel eGFR equations (see figure).

Conclusions: Panel eGFR may be preferable in older adults with low muscle mass. Practical tests are needed to identify individuals with low muscle mass for whom eGFR from Cr and Cys may be less accurate.

Funding: Other NIH Support - The measurements and analyses were supported by grants from the National Institute of Diabetes and Digestive and Kidney Diseases grant R01DK097020 “Estimating GFR from a Panel of Endogenous Filtration Markers” to Tufts Medical Center. The AGES-Kidney study is supported by grants from the National Institute of Diabetes and Digestive and Kidney Diseases (R01-DK082447 and supplement 01A1S1 to A.S.L.). PO2333

Gender-Specific Glomerular Filtration Rate Reference Values for Healthy Individuals Aged 18 to 90 Years

Anne-Laure Faucon,[1,2] Marie Metzger,[1,2] Cedric Gauci,[3] Pascal Houillier,[3,4] Anne Blanchard,[3,4] Jean-Philippe Haymann,[3,4] Martin Flamant,[3,4] Benedicte Stengel,[1,2] Marc Froissart.[5] *[1]Centre de recherche en Epidémiologie et Santé des Populations Inserm U1018, Villejuif, France; [2]Universite Paris-Saclay, Paris, France; [3]Assistance Publique - Hopitaux de Paris, Paris, France; [4]INSERM, Paris, France; [5]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

Background: Normal glomerular filtration rate (GFR) values based on a reference method are lacking in the elderly. We measured GFR (mGFR) in healthy individuals 18 to 90 years of age to describe normal mGFR decline with age, by gender, and evaluated the performances of GFR-estimating equations in this population.

Methods: We measured GFR with renal clearance of ^{51}Cr-EDTA in 630 healthy men and women, aged 18-90 years. GAMLSS were used to provide reference values of GFR, and a piecewise linear regression model, to assess the relationship between GFR, age and gender. Bias, precision and accuracy of the CKD-EPI and FAS equations were evaluated.

Results: Participants (43% men) had a mean mGFR of 90.5±15.9 mL/min/1.73m^2. The 5th percentile stayed above 60 mL/min/1.73m^2 up to 80 years in men, but reached this threshold at age 63 in women, 25% of them getting below at age 76. In both genders, mGFR distribution physiologically declined as from 40 years (Figure), significantly faster in women than in men, 0.83±0.09 *vs* 0.67±0.07 mL/min/1.73 m^2 per year, p<0.001. Overall, median bias was significantly lower for the FAS than the CKD-EPI equation (-1.6 [95%CI: -2.9 ; -0.1] vs 3.4 [1.8 ; 4.9] mL/min/1.73 m^2, p < 0.001), whereas precision and P30 accuracy, 6.6 [4.9 ; 8.8] for FAS vs 8.5 [6.6 ; 10.9] for CKD-EPI, did not significantly differ between them. Performance metrics were similar in men and women, but differed across age classes. Above 65 years, CKD-EPI appeared to overestimate and FAS to substantially underestimate mGFR.

Conclusions: Ageing appears to be associated with faster GFR decline in women than in men, which may explain the paradoxical association of high CKD prevalence and low kidney failure incidence in women. Age- and gender-specific reference values should be considered for CKD diagnosis and drug dosing guidelines, particularly in the elderly.

PO2334

Epidemiology of CKD Based on Age-Adapted GFR Thresholds

Arnar J. Jonsson,[1,2] Sigrún H. Lund,[4] Runolfur Palsson,[2,1] Olafur S. Indridason.[3]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Internal Medicine Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [3]Division of Nephrology, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [4]deCODE Genetics Inc, Reykjavik, Iceland.

Background: Age-adapted GFR criteria for definition of chronic kidney disease (CKD) have been proposed to account for normal age-related decline in kidney function. The aim of this study was to determine the prevalence and incidence of CKD stages 1-5 based on age-adapted GFR thresholds compared with current KDIGO GFR criteria.

Methods: In this retrospective study, we obtained all serum creatinine (SCr) values and urine protein measurements from every clinical laboratory in Iceland in 2008-2016. Clinical data, including ICD-10 diagnosis codes, were retrieved from nationwide electronic medical records. Estimated GFR was calculated from SCr using the CKD-EPI equation. CKD was defined as presence of kidney damage, either proteinuria or ICD-10 diagnosis codes indicative of kidney disease, or reduced eGFR for ≥3 months. Reduced eGFR was defined as <60 mL/min/1.73 m^2 according to the standard KDIGO criteria or based on the following age-adapted thresholds: <75 mL/min/1.73 m^2 for age <40 years, <60 mL/min/1.73 m^2 for 40-65 years and <45 mL/min/1.73 m^2 for age ≥65 years. Incidence of CKD was calculated in individuals without evidence of CKD at study entry. Prevalence and incidence were standardized to the EU-27 population.

Results: We obtained 2,120,147 SCr values for 218,437 individuals. The median age was 46 (range, 18-107) years; 47% were men. A total of 25,996 individuals met the KDIGO criteria for CKD compared with 17,593 when the age-adapted criteria were applied. The mean annual age-standardized prevalence per 100,000 overall and for men and women was 5940, 5130 and 6750, respectively, using the KDIGO criteria, and 3640, 3270 and 4010, respectively, applying the age-adapted GFR thresholds. The mean annual age-standardized incidence of CKD per 100,000 overall and for men and women was 671, 649 and 694, respectively, using the KDIGO criteria and 501, 480 and 522, respectively, applying the age-adapted thresholds.

Conclusions: This nationwide Icelandic study comprising SCr values and other markers of kidney damage for the majority of the Icelandic population demonstrates a markedly lower CKD prevalence and incidence with use of age-adapted GFR thresholds as compared with the standard KDIGO criteria.

PO2335

Estimated Glomerular Filtration Rate Equations Based on Cystatin C Are Determined by Bioimpedance-Retrieved Fat Mass Index in Swedish Adults

Agne Laucyte-Cibulskiene,[1,2] Anders Christensson.[1,2] *[1]Lunds Universitet, Lund, Sweden; [2]Skane University Hospital Malmo Nephrology Clinic, Malmo, Sweden.*

Background: The growing burden of obesity and its associations with chronic kidney disease (CKD) is becoming a hot topic for nephrologist. CystatinC, a marker of kidney function, tends to be increased in obesity. We hypothesize that bioimpedance acquired fat mass index acquired is associated with estimated glomerular filtration rate (eGFR) based on cystatinC.

Methods: 5061 subjects, born 1926-45, were selected from the population based Malmö Diet and Cancer cohort (MDC CC). They underwent body composition analysis (BIA-103 RJL system) and biochemistry during the year 1991-95. Men and women were divided into 3 groups according calculated fat mass index z-score (FMIz): low(<-1), middle(>-1,<1), high(>1). eGFR calculated using 4 equations: Chronic Kidney Disease Epidemiology Collaboration 2012 (CKD-EPI creatinine, CKD-EPI cystatinC), cystatinC eGFR based on Caucasian, Asian, pediatric, and adult cohorts (CAPA), the Lund-Malmö revised creatinine equation (LMrev).

Results: CystatinC correlated with fat weight (kg), FMI and FMIz in both sexes, meanwhile creatinine was not associated with muscle mass. Significant sex difference observed in high FMIz group revealing lower CAPA and lower CKD-EPI cystatin C values in women and no differences in creatinine based eGFR both in men and women (Fig.1). Women with high FMIz tended to have higher body mass index compared to men (p<0.001) and no age difference. Muscle mass remained almost unchanged in FMIz groups in both sexes.

Conclusions: The correlation between cystatinC and fat weight may be due to several reasons. Obesity induced CKD is one. Further studies are warranted to exclude that cystatinC originates from adipose tissue. The use of cystatinC eGFR equations should be used with caution in obese individuals, especially in women.

Estimated GFR Slope and Risk of Subsequent ESKD in Japanese Patients with CKD: The CKD-JAC Study

Takahiro Imaizumi,[1] Hirotaka Komaba,[2] Takayuki Hamano,[4] Kenta Murotani,[5] Takeshi Hasegawa,[3] Naohiko Fujii,[6] Masaomi Nangaku,[7] Masafumi Fukagawa.[2]
[1]Nagoya University, Nagoya, Japan; [2]Tokai University, Isehara, Japan; [3]Showa University, Tokyo, Japan; [4]Nagoya city University, Nagoya, Japan; [5]Kurume University, Kurume, Japan; [6]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [7]The University of Tokyo, Tokyo, Japan.

Background: Slope of estimated glomerular filtration rate (eGFR), or rate of eGFR change, is a well-accepted measure of kidney disease progression. Previous studies have shown strong associations between eGFR slope and subsequent ESKD, but there is a dearth of evidence in Asian populations. We aimed to investigate the association between eGFR slope and subsequent ESKD in Japanese patients with CKD using data from the Chronic Kidney Disease Japan Cohort (CKD-JAC) Study.

Methods: We investigated the association of 2-year change in eGFR (slope) with ESKD over the long term. Slopes were estimated with the linear mixed models with an unstructured variance-covariance matrix, random intercept, and random slope for each individual to estimate slope (mixed model slope) or the least-squares linear regression (least-squares slope). We also conducted sensitivity analyses to investigate the association of 1- and 3-year changes in eGFR with ESKD.

Results: Of the total 2966 participants, we included 2381 individuals after excluding those who were censored within the 2-year baseline period (n = 509) and those with eGFR measured less than twice each year (n = 76). The mean slope was -1.70 ± 2.63 ml/min per 1.73 m^2 per year when estimated by the mixed-effects model and -1.69 ± 3.18 ml/min per 1.73 m^2 per year when estimated by least squares. The restricted cubic splines showed that the association between eGFR slope and ESKD was linear. The adjusted hazard ratio for ESKD associated with a lesser eGFR decline by 1 ml/min/1.73m^2 per year was 0.69 (95% CI: 0.66 to 0.73) for the mixed model slopes and 0.74 (95% CI: 0.71 to 0.77) for the least-squares slope. Sensitivity analysis showed that the association between eGFR slope and ESKD was pronounced when the slope was estimated over a longer baseline period.

Conclusions: Our study confirmed a robust and strong association between eGFR slope and subsequent ESKD in Japanese patients with CKD.

PO2337

REVEAL-CKD: Prevalence of Undiagnosed Early CKD in France and Japan

Jean Blaise J. Virgitti,[1] Toshiki Moriyama,[2] Eric T. Wittbrodt,[3] Salvatore Barone,[3] Matthew Arnold,[4] Supriya R. Kumar,[3] Hungta (tony) Chen,[3] Krister Järbrink,[5] Navdeep Tangri.[6] *[1]Cabinet Medical, Orry La Ville, France; [2]Osaka Daigaku, Suita, Japan; [3]AstraZeneca, Gaithersburg, MD; [4]AstraZeneca PLC, Cambridge, United Kingdom; [5]AstraZeneca, Gothenburg, Sweden; [6]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.*

Background: Screening and monitoring of at-risk populations, such as those with type 2 diabetes (T2D), is necessary for early detection and management of chronic kidney disease (CKD). Global prevalence of undiagnosed early CKD and associated factors have not been recently studied. The objective of the REVEAL-CKD study is to assess the prevalence of undiagnosed stage 3 (S3) CKD.

Methods: REVEAL-CKD is a multi-national, multi-region secondary data study. Data for the French study cohort was extracted from THIN Cegedim (Cegedim Health Data, Boulogne-Billancourt, France) an electronic medical record (EMR) database from outpatient primary care practices. RWD database (Real World Data Co., Ltd., Kyoto, Japan) linking hospital systems' EMR with reimbursement claims, was used for the

Japanese cohort. The study population included patients aged ≥18 years between 2015-2020 with two consecutive estimated glomerular filtration rate (eGFR) readings ≥30 and <60 mL/min/1.73 m² recorded >90 and ≤730 days apart. Undiagnosed CKD was defined as the absence of an associated CKD diagnosis code any time before 12 months prior to the first eGFR measurement and up to 6 months after the second eGFR. Presence of recorded urine albumin-to-creatinine ratio (UACR) was also assessed.

Results: After applying the eligibility criteria the study cohorts included 23,160 patients in France and 90,902 in Japan, and the proportions of patients with undiagnosed S3 CKD were 95.4% (95% confidence interval [CI] 95.1, 95.7) and 92.1% (91.9, 92.3), respectively. Prevalence in both cohorts was consistent across subgroups stratified by age (45-65, and >65 y), sex, and presence of comorbidities (T2D, HTN, and heart failure) with the exception of T2D in Japan, where undiagnosed prevalence was 82% (95% CI 81.9, 83.0). Only 2.4% of patients in the cohort in France and 5.5% in Japan had a record of a UACR value.

Conclusions: The results presented here indicate that a high proportion of early CKD patients in France and Japan are undiagnosed, with a very low frequency of UACR testing. With the advent of promising novel therapies to mitigate disease progression in patients at risk and the potential to improve patient outcomes, a clear imperative exists to highlight the importance of early CKD detection, diagnosis, and intervention.

Trends in CKD Awareness and Related Clinical and Demographic Characteristics in Korea from 1998 to 2018

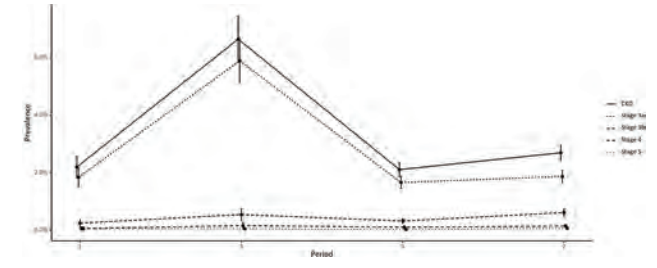
Dong-Young Lee. *Veterans Healthcare Service Medical Center, Seoul, Seoul, Republic of Korea.*

Background: Chronic kidney disease (CKD) is a common and growing problem in Korea. Although CKD awareness is the first step of CKD management, evidence indicates that the rate of CKD awareness is unsatisfactory worldwide. Thus, we investigated the trend of CKD awareness for CKD patients in Korea.

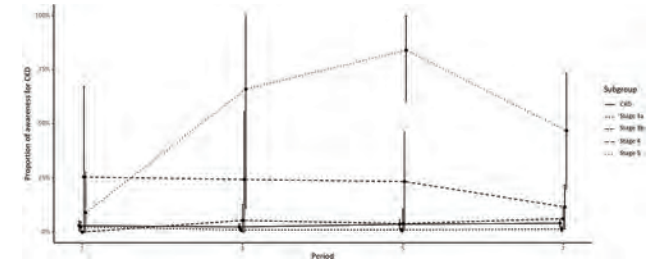
Methods: Through analyzing data of Korea National Health and Nutrition Examination Survey (KNHAES) in 1998 (phase I), 2005 (phase III), 2010-2012 (phase V), and 2016-2018 (phase VII), we evaluated the rate of CKD awareness according to CKD stage in each phase of KNHANES. CKD was defined when estimated glomerular filtration was below 59 ml/min/1.73m². Clinical and sociodemographic characteristics were compared between CKD awareness and unawareness groups. Multivariate regression analysis was used to calculate adjusted odds ratio (OR) and 95% confidence interval (CI) for CKD awareness (adjusted OR [95% CI]) in given socioeconomic and clinical factors.

Results: The overall rate of CKD awareness remained at low levels less than 4.1% across all phases of KNHANES. In particular, the rate of CKD awareness was remarkably low in stage 3 CKD. Compared to CKD unawareness group, CKD awareness group was of young age, higher income, higher education, more medical aid, higher prevalence of comorbidities, and more advanced CKD. In multivariate analysis, CKD awareness was significantly associated with younger age (0.95 [0.93-0.98]), medical aid (4.35 [1.95-9.73]) and renal function (0.90 [0.88-0.92]).

Conclusions: The rate of CKD awareness has been consistently low in Korea. This trend warrants the special endeavor to promote CKD awareness in Korea.



CKD prevalence in Korea from 1998 to 2018



CKD awareness in Korea from 1998 to 2018

Usefulness of Machine-Learning-Predicted Probability as a New Risk Index for Prediction of Renal and Life Prognoses of CKD

Eiichiro Kanda,[1] Bogdan I. Epureanu,[3] Taiji Adachi,[2] Tamaki Sasaki,[1] Naoki Kashihara.[1] *[1]Kawasaki Ika Daigaku, Kurashiki, Japan; [2]Kyoto Daigaku, Kyoto, Japan; [3]University of Michigan, Ann Arbor, MI.*

Background: Personalized and accurate prediction is useful for chronic kidney disease (CKD) therapy. Predialysis death is a competitive risk of dialysis in CKD patients and lowers the accuracies of the prediction of their renal and life prognoses. Thus, we determined whether machine-learning-predicted probability works as an index for the risks of predialysis death and dialysis in CKD patients and attempted its application.

Methods: We constructed a database of electronic-medical-record data of CKD patients in Japan, and developed risk prediction machine-learning models using random forest (RF), Gradient Boosting Decision Tree, and eXtreme Gradient Boosting for the prediction of dialysis and death over 1 year. The performances of the probabilities estimated using the models were compared by the bootstrap method with those of clinical indices in a prospective cohort study of CKD patients (n=67,957).

Results: Sixteen models were developed and showed statistically significantly higher C-statistics than clinical indices. Two RF models including 22 or 8 variables showed high C-statistics: 0.932 (95% CI 0.916, 0.948) and 0.93 (0.915, 0.945), respectively, which were higher than estimated glomerular filtration rate and urinary protein levels (p<0.0001). Cox proportional hazards models with the spline term showed the relationship between the high probabilities and the high outcome risks (p<0.0001). We also developed a Web-based risk prediction system using those two models.

Conclusions: This study showed that the machine-learning-based probability is useful as a new risk index for dialysis and death and applicable to clinical practice.

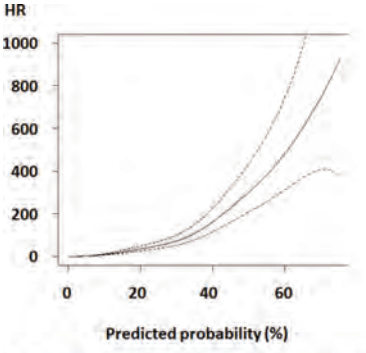

Fig. Relationships between the probabilities expected by the model of primary outcome and the outcome risks. p<0.0001.

PO2340

A Machine Learning Algorithm to Identify Patients with Possible Non-Dialysis-Dependent CKD

Thierry Lobbedez,[1] Karim Dardim,[2] Arnaud Panes,[3] Gwendoline Poinsot,[3] Jérôme Fernandes,[4] Laurence Dubel,[5] Josephine Wolfram.[6] *[1]University Hospital, Caen, France; [2]Association Limousine pour l'Utilisation du Rein Artificiel à Domicile (ALURAD), Limoges, France; [3]HEVA, Lyon, France; [4]Centre Hospitalier de la Côte Basque, Bayonne, France; [5]Astellas Pharma Europe, Levallois-Perret, France; [6]Astellas Pharma Europe B.V., Leiden, Netherlands.*

Background: The DAKOTAH study is a retrospective study of patients with non-dialysis-dependent chronic kidney disease (NDD CKD) in France based on data from the Echantillon Généraliste des Bénéficiaires database. A stepwise machine learning approach was used to identify patients with possible NDD CKD who could not be captured using the NDD CKD case definition (**Figure**).

Methods: First, the 'potential CKD' population was designated as patients with a diagnosis of diabetes, cardiovascular disease or hypertension, or with ≥3 prescriptions for antidiabetic and/or antihypertensive drugs, during 2012–2017. Second, an unsupervised algorithm was trained to identify patients very likely to have CKD ('possible CKD') in the potential CKD population. Similarity between patients was based on CKD-related variables: sex; number and duration of hospitalizations for renal failure; number of GP

visits; medications; and biological exams. A distance metric between patients was defined based on these variables, and patients having similar characteristics were positioned close to one another. The algorithm learned to construct a spherical boundary around the non-CKD population, to create a decision rule for possible CKD versus non-CKD, with outliers considered possible CKD.

Results: The algorithm was validated by application to both the potential CKD population and a confirmed CKD patient pool. From the potential and confirmed CKD populations, 21% and 65% of patients were classified as possible CKD, respectively. Similarities were observed between the two groups regarding hospitalizations and selected biological exams.

Conclusions: This machine learning-derived decision rule could be a tool to identify undiagnosed patients with NDD CKD.

PO2341

Developing an Electronic Health Record (EHR)-Based Model for Delineating Advanced CKD Cohort in Veterans Affairs (VA) System

Zachary P. Purvis,[1] Gajapathiraju Chamarthi,[2] Popy Shell,[1] Devin S. Fu,[1] Tatiana Orozco,[1] Ashutosh M. Shukla.[1,2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: Late diagnosis of chronic kidney disease(CKD) and non-referral to nephrology are important limiting concerns for pre-end stage kidney disease(ESKD) nephrology care, including dialysis modality education. Querying existing electronic database with longitudinal patient-level data can improve recognition of advanced, stage 4/5 CKD and facilitate evidence-based pre-ESKD care. Using a mixed approach of electronic query followed by manual chart review, we report the development of an Electronic Health Records (EHR)-based model that allows identification and quantification of advanced CKD burden in a regional Veterans Healthcare System(VHS).

Methods: We identified all Veteran enrollees at a large regional VHS using VA Informatics & Computing Infrastructure data set. Among these, we identified all Veterans with an eGFR below 30ml/min or an existing ICD-10 diagnostic code for stage 4/5 CKD within last 12 months. We applied diagnostic and procedure codes for dialysis, ESKD, and acute kidney injury(AKI) in an iterative approach to improve the accuracy of identifying non-dialysis advanced CKD cohort.

Results: Of 148,164 active enrollees within VHS, our initial model of using a single eGFR <30 ml/min identified 3,813(2.57%) Veteran enrollees with advanced CKD. Manual review of a select cohort(n=787) showed 63.3% error rate, with high rates of ESKD and AKI being major confounders. Successive iterations involved exclusions of ESKD and AKI codes and incorporation of a second latest eGFR >90 days before latest eGFR. The final EHR-based advanced CKD model included 1,329(0.89%) Veteran with the residual error of 14.4% on manual chart review without the possibility of further automated exclusions. Of these, 872 were found to have definite advanced CKD and 457 were classified as probable advanced CKD based on whether both or only one of the latest two eGFRs more than 90 days apart were below 30 ml/min with CKD.

Conclusions: An EHR-based model to identify advanced CKD can be successfully developed for a regional VHS with over 85% accuracy. Further testing is needed to determine its wider applicability across additional VHA sites, and if validated, this model can be applied across the VHA electronic data to identify the burden of advanced CKD for needs assessment and clinical care among Veterans.

PO2342

Developing a Prediction Model for Incidence of Newly Detected CKD Among US Veterans, 2009-2018

Jennifer L. Bragg-Gresham,[1] Brenda W. Gillespie,[2] Karandeep Singh,[1] Xiaosong Zhang,[1] Yun Han,[1] Diane Steffick,[1] Vahakn Shahinian,[1] William Weitzel,[3] V. G. Vinod Vydiswaran,[1] Tiffany C. Veinot,[2] Susan T. Crowley,[4] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan School of Public Health, Ann Arbor, MI; [3]Veterans Health Administration, Ann Arbor, MI; [4]Veterans Health Administration, New Haven, CT.*

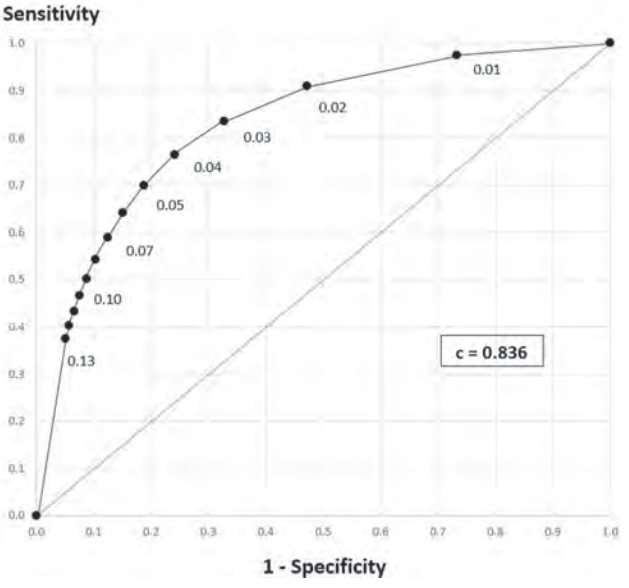
Background: Both screening and awareness of CKD remain low in the US. We sought to develop a tool to aid physicians and health systems in identifying patients most likely to develop CKD, using a large national sample of patients in the Veterans Health Administration (VHA).

Methods: Using 29,524,195 observations from Veterans, aged 18+ with outpatient s. creatinine data (2006-2018), we modeled the probability of newly detected CKD using discreet survival methods. Veterans were screened for 2-3 years to ensure no pre-existing CKD. Newly detected CKD was defined as a diagnosis or by laboratory measurement (eGFR <60 ml/min/1.73m^2 or UACR 30+ mg/g). Predictors included demographics, comorbidities, nephrotoxic medications, and laboratory values updated each year. Model fit assessed by the c-statistic.

Results: The cohort had a mean age of 59 years with 89% males and 15% Black race. The average eGFR was 87 ml/min/1.73m^2 and median UACR was 8 mg/g, with an average of 3.9 years follow-up. The largest predictors of incident CKD were diabetes, kidney stones, urinary tract infections, sickle cell anemia, and an eGFR between 60-69 ml/min/1.73m^2. Concordance was high (c-statistic=0.84, Fig: ROC curve). Using a threshold of 3% risk for screening would require testing ~1/3 of Veterans (~1 million per year), yielding an 83% true positive and a 17% false negative rate.

Conclusions: We are able to accurately predict the probability of incident CKD in the VHA. This predictive model has the potential for improving targeted screening efforts for CKD, facilitating its earlier detection, raising awareness, and reducing disparities. If externally validated, the impact of these findings would be generalizable to populations/ health systems beyond the VHA.

Funding: Veterans Affairs Support



PO2343

A Population Health Survey-Based Prediction Equation for Incident CKD: The CKD Population Risk Tool CKDPort/PREDICT-CKD LIFESTYLE

Ariana Noel,[1,2] Emily Rhodes,[3] Greg A. Knoll,[1,2] Manish M. Sood.[1,2] *[1]University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; [2]Ottawa Hospital, Ottawa, ON, Canada; [3]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Chronic kidney disease awareness among the general public is less than 10%. Patients' health behaviours are known to be associated with CKD development and disease progression. Prediction tools that engage the general public with their self-reported health information could increase awareness, identify modifiable lifestyle risk factors, empower patients, and prevent disease. The study objective was to develop and validate a population health survey-based prediction equation to determine the risk of incident CKD in the general public.

Methods: Participants who completed the Canadian Community Health Survey (CCHS) were linked to laboratory and hospital admission data between 2000 and 2015 in Ontario, Canada. The primary outcome was incident CKD (eGFR < 60 ml/min/1.73m^2) with up to 8 years of follow-up. Models accounted for the competing risk of all-cause mortality. The CCHS is a random, comprehensive, prospective, general population survey that captures information on demographics, co-morbid illnesses, lifestyle and behaviours, diet, body mass index and mood. External validation was performed using data from the UK Biobank.

Results: From 22,200 eligible adults, 1,981 (8.9%) developed incident CKD during a mean follow-up time of 8 years. Domains included in the final reduced model were baseline eGFR, smoking, alcohol, physical activity, education, mood, fruit and vegetable intake, diabetes, hypertension, heart and lung disease, urinary incontinence, cancer, and BMI. The model demonstrated excellent discrimination in individuals with and without a baseline eGFR measure (5-year c-statistic with baseline eGFR: 0.84 95%CI 0.82-0.85, without 0.81 95%CI 0.80-0.82), was well calibrated (Brier score at 5-years with baseline eGFR: 0.07 95%CI 0.007-0.08, without 0.08 95%CI 0.07-0.08), and was consistent in a sensitivity analysis using 2 measures of eGFR > 90 days apart to define the outcome. The model was consistent with external validation.

Conclusions: Lifestyle and health behaviour information from population-based health surveys can predict incident CKD in the population with excellent discrimination and can be used to improve public engagement in CKD awareness.

PO2344

Predicting ESKD Risk and Time to RRT Initiation Based on Past Slope and Current Value of eGFR: The CKD-JAC Study

Hirotaka Komaba,[1] Takahiro Imaizumi,[2] Takayuki Hamano,[3] Kenta Murotani,[4] Takeshi Hasegawa,[5] Naohiko Fujii,[6] Masafumi Fukagawa.[1] *[1]Tokai Daigaku, Isehara, Japan; [2]Nagoya Daigaku, Nagoya, Japan; [3]Nagoya Shiritsu Daigaku, Nagoya, Japan; [4]Kurume Daigaku, Kurume, Japan; [5]Showa Daigaku, Tokyo, Japan; [6]Hyogo Kenritsu Nishinomiya Byoin, Nishinomiya, Japan.*

Background: Past slope and current estimated glomerular filtration rate (eGFR) are used to predict future risk of end-stage kidney disease (ESKD) and time to renal replacement therapy (RRT) initiation in clinical practice, but there is limited quantitative evidence supporting this practice. To address this, we analyzed data from the Chronic Kidney Disease Japan Cohort (CKD-JAC) Study.

Methods: We investigated the association of 2-year eGFR slope, estimated using linear mixed models, with subsequent risk of ESKD using Cox regression models, adjusting for eGFR and other potential confounders collected 2 years after cohort entry. We calculated the net reclassification improvement (NRI) to assess whether adding past slope to age, sex, eGFR, and urine albumin-to-creatinine ratio (UACR) improves ESKD risk prediction. We predicted time to RRT initiation based on the past slope and current eGFR, assuming eGFR of 6 mL/min/1.73m^2 to be the timing of RRT initiation, and compared it with actual time to RRT initiation.

Results: We included 2381 participants who had survived free of ESKD for 2 years and with eGFR measurements at least twice each year. The mean 2-year eGFR slope was -1.70 ± 2.63 mL/min per 1.73 m^2 per year. During a median follow-up of 4.7 years after the 2-year slope evaluation period, 175 participants died and 810 reached ESKD requiring RRT. In adjusted analysis, lesser slope of eGFR decline was associated with lower risk of ESKD (hazard ratio per 1 mL/min per 1.73 m^2 per year, 0.89; 95% CI, 0.87 to 0.92). Adding past eGFR slope to age, sex, eGFR, and UACR substantially improved classification accuracy in 2-year risk prediction of ESKD, with an NRI of 0.343 (95% CI, 0.036 to 0.662). Among 560 individuals who were predicted to initiate RRT during the study period and actually reached ESKD, the median predicted time to RRT was 30.6 months (IQR, 13.0 to 55.7), the median actual time to RRT was 25.5 months (IQR, 12.3 to 47.0), and the median of these differences was -1.5 months (IQR, -14.3 to 7.3). The prediction became more accurate as RRT initiation was predicted to occur in the closer future.

Conclusions: Our results indicate that past eGFR slope adds information to ESKD risk assessment beyond current eGFR and that combination of these informs prediction of time to RRT initiation.

PO2345

Need and Preference Assessments for Renal Care and Comprehensive Pre-ESKD Education Services for Advanced CKD Veterans

Gajapathiraju Chamarthi,[2] Zachary P. Purvis,[1] Lina Ly,[1] Jennifer Hale-Gallardo,[1] Huanguang Jia,[1] Ashutosh M. Shukla.[1,2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: Current guidelines suggest Specialty Renal Care (SRC) and comprehensive pre-end-stage kidney disease (ESKD) education (CPE) Services for all patients with advanced, stage 4/5 chronic kidney disease (CKD). Despite this, half of incident ESKD patients receive none or <6months pre-ESKD renal care. Estimating outstanding needs and understanding Veterans preferences for receiving such care can improve resource allocations and quality of care for Veterans Health Administration(VHA). We conducted a community-based evaluation of advanced CKD Veterans to assess their current state of and outstanding needs and preferences for SRC and CPE at North Florida/South Georgia(NF/SG) VHA system(VHS).

Methods: Through an iterative approach of electronic health records(EHR) query followed by manual review of randomly selected EHRs, we created a model for isolating advanced CKD cohort at NF/SG VHS. We then sorted the cohort in a random order, and mail-invited Veterans with up to three attempted calls for those who do not call back to actively opt-out of participation. Surveys were conducted for those agreeable for participation.

Results: Of the 148,164 active enrollees, we identified 1329 (0.9%) Veterans with advanced CKD. Of the 226 Veterans randomly selected mail-invites, 166 made final contact; 94 completed, 50 asked for more time, and 22 refused to participate in the surveys. Awareness of CKD (91%) and prevalence of renal care (86%) were high among respondents albeit, 40(50%) received renal care from non-VA providers. Aggregate outstanding need for VA-preferred SRC and CPE were 14(15%) and 69(73%) respectively. Among these, the preferences for receiving SRC were 6(43%) & 8(57%) and receiving CPE were 21(30%) & 34(50%) through in-person and telemedicine-based care respectively. There were significant differences in needs and preferences across the socio-demographics and rural-urban spectrum.

Conclusions: Despite high awareness of CKD diagnosis and prevalence of SRC, there is significant outstanding need for targeted CPE services in advanced CKD Veterans. Further validation of this model at additional VHSs and its application across the system can allow projection of outstanding needs for SRC and CPE across the VHA and guide appropriate allocation of resources to improve Veteran outcomes.

PO2346

Artificial Intelligence-Based Prediction Model for Screening Veteran Patients at Risk of Developing CKD

Kamyar Kalantar-Zadeh,[1,4] Kelli A. Farr,[3] Robert Meints,[2] Darren A. Muliawan,[2] Peter Idanawang,[2] Devin Colvin,[2] Henky Wibowo.[2] Dialisa *[1]UCI Health, Orange, CA; [2]Dialisa, Inc, San Jose, CA; [3]VA Medical Center Salt Lake City, Salt Lake City, UT; [4]VA Long Beach Healthcare System, Long Beach, CA.*

Background: Developing effective screening tool for Chronic kidney disease (CKD) helps in reducing morbidity, mortality as well as cost and burden to the health system. Here we present preliminary result on feasibility and performance of employing Convolutional Neural Network (CNN) prediction model in detecting patients who are at-risk of CKD based on longitudinal data from Electronic Health Records (EHR).

Methods: A synthetic dataset containing a total of 100,000 synthetic patient records, derived from cross-sectional cohort of Veteran from the general population, was used to train and validate the prediction model. The dataset was generated by using Synthea™, a patient generator tool, and contains standard data elements that are commonly used in major Electronic Health Record systems. A total of 12,503 patients with CKD and 48,212 patients without CKD matched by propensity score along with 290 other features including anthropometrics, medication, comorbidities, and laboratory data were used to train and validate the prediction model.

Results: The CNN algorithm has been designed, implemented and tested using the synthetic dataset, achieving precision of 0.918, recall of 0.739, specificity of 0.983, accuracy of 0.932, and AUROC of 0.937 as depicted in Figure 1. Additionally, based on the dataset, age, diabetes, elevated BMI and medication taken, specifically 24 HR Metformin Hydrochloride, represent the topmost important features to predict the onset of CKD.

Conclusions: Using CNN and synthetic veteran patient dataset, we have demonstrated a viable prediction model for CKD detection in healthy patients at-risk of CKD using longitudinal data from EHR system. The prediction model can be easily deployed in a CKD screening program in healthcare institutions with existing EHR systems.

PO2347

Identifying Hotspots of CKD in the United States with Data from a Large National Clinical Laboratory Network

Jennifer L. Bragg-Gresham,[1] Linda Fraunhofer,[2] Jennifer L. Ennis,[2] Yun Han,[1] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]Laboratory Corporation of America, Burlington, NC.*

Background: CKD is typically detected through routine laboratory testing. We sought to assess the feasibility of analyzing data from one of the largest clinical laboratory networks in the US to map CKD hotspots across the nation.

Methods: Laboratory results for serum creatinine were analyzed from a nationally standardized laboratory platform with the Laboratory Corporation of America (Labcorp) across a 6-month period (July to December 2019, n=21,884,579). We assessed the percent of results with eGFR <60 ml/min/1.73m^2 (CKD stages 3-5) at US county-level (n=2,972 counties, <11 results supressed). Due to lack of race information, the CKD-Epi equation without the race coefficient was employed for the entire population. Hotspot analyses were conducted using the Getis-Ord Gi* statistic.

Results: The total population was 44% male with mean age of 56 years. eGFR results < 60 ml/min/1.73m^2 totalled 4,165,540 (19%) and county-level distribution ranged from 0% to 75% (Fig. A) with an overall mean age of 72 and 44% male. Results of the hotspot analysis (Fig. B) shows the percent of decreased kidney function varies markedly across

the US, with clear hot spots in the south and southeast, far northeast, Pacific Northwest, Missouri, Colorado, and Utah. The upper midwest and most of the northeast appeared as cold spots, with the southwest being neither a hot nor cold spot.

Conclusions: We demonstrate the feasibility of leveraging a large national laboratory network database for mapping the distribution of county prevalence of CKD and identification of CKD hotspots. Ongoing work is focusing on understanding factors underlying these hotspots and will help guide population health improvement, raise awareness, guide health policy and direct public health action and quality improvement efforts related to kidney disease.

Healthy People 2020 Final Review of National CKD Objectives

Asel Ryskulova,[1,4] Lawrence Agodoa,[3,5] Kevin C. Abbott,[3,5] Nilka Rios Burrows.[2,6] *[1]Centers for Disease Control and Prevention, Hyattsville, MD; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]National Institutes of Health, Bethesda, MD; [4]National Center for Health Statistics, Hyattsville, MD; [5]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [6]National Center for Chronic Disease Prevention and Health Promotion, Atlanta, GA.*

Background: Chronic Kidney Disease **(**CKD) is a significant public health problem in the United States (US) and a major source of disability and poor quality of life for those afflicted. An estimated 14.9% of adults ages 20 or older had physiological evidence of CKD determined from data collected through the 2015-18 National Health and Nutrition Examination Survey (NHANES). In 2018, more than 130,000 people in the US began treatment for end-stage kidney disease (ESKD), the final stage of CKD. Kidney diseases are one of the leading causes of death in the US, and CKD exacts a high economic burden. Overall Medicare costs for people with CKD were over $81.8 billion in 2018, or $23,700 per person. Total Medicare spending (excluding prescription drugs) for patients with ESKD reached $36.6 billion in 2018, or $80,000 per person, accounting for about 7% of the Medicare paid claims costs.

Methods: Reflecting the importance of CKD, 24 CKD objectives were included in Healthy People 2020 (HP2020) as national health goals. These objectives focused on improving cardiovascular care in patients with CKD; increasing the proportion of patients with CKD and diabetes who received recommended evaluation and treatment; improving follow-up care in people with acute kidney injury, reducing the death rate and percentage of the US population with CKD, and increasing CKD awareness in persons with impaired kidney function. All CKD objectives in HP2020 were measurable, having at least one data point from national data systems including the NHANES, National Death Index, and the US Renal Data System.

Results: As of the HP2020 Final Review, 15 objectives had met their target (n=11) or showed improvement (n=4). Four objectives, including CKD prevalence and awareness, showed little or no detectable change, and three objectives on receiving kidney transplant and on the number of deaths for persons with a functioning kidney transplant moved away from the target. The remaining two objectives were informational (i.e., no targets set) and were not evaluated. Disparities persisted by sex, race/ethnicity, and socioeconomic status.

Conclusions: Several of these measures will continue to be tracked over the next decade as CKD objectives in HP2030. The HP website includes HP2020 and HP2030 data.

PO2349

A Systematic Literature Review of Treatment Patterns, Safety Profiles, and Long-Term Disease Progression in Patients with CKD and Type 2 Diabetes Mellitus

Rakesh Singh,[1] Erika Wissinger,[2] Casey Dobie,[2] Yuxian Du.[1] *[1]Bayer US LLC, Whippany, NJ; [2]Xcenda LLC, Carrollton, TX.*

Background: CKD affects ~40% of patients with diabetes. Current guidelines recommend optimization of blood pressure and glycemic control in patients with T2D to reduce the risk of CKD progression. Despite this, patients with T2D are still advancing to ESRD. Real-world treatment patterns, safety profiles of current treatments, and residual risk for long-term disease progression in patients with CKD and T2D were explored.

Methods: A systematic literature review was conducted of real-world observational studies in the US in patients with CKD and T2D. Articles published in the past 10 years were identified from Embase and MEDLINE and were evaluated by 2 independent reviewers.

Results: A total of 17 studies were included in the review. In the 16 studies that examined treatment patterns among patients with CKD and T2D, all drug classes of interest (steroidal mineralocorticoid receptor antagonist [MRA], ACEI, ARB, GLP-1RA, and SGLT-2i) were reported. The proportions of patients treated with ACEIs (34%–70%) or ARBs (12%–66%) varied widely, with approximately 45% to 95% of patients prescribed either an ACEI or an ARB. Small proportions of patients (<10%) were treated with MRAs, GLP-1RAs, and SGLT-2is; though steroidal MRA does not have an indication in CKD in T2D. In the 4 studies that examined renal function decline while on a treatment of interest, 1-year progression rates ranged from 3.3% to 29.9%. Three studies reported rates of on-treatment ESRD progression, which ranged from 9.1% to 10%. In the 4 studies reporting AEs in patients treated with MRAs, ACEIs, and/or ARBs, notable clinical events included stroke (12.6% among MRA non-users to 31.3% among spironolactone users) and hyperkalemia (9.1% among MRA non-users to 29.9% among spironolactone users).

Conclusions: The identified studies suggest that patients with CKD and T2D may not be optimized on current treatment options to slow renal function decline and reduce the risk of CV events in these patients. Despite current treatment options, a residual risk of CKD progression and CV morbidity remains. New therapies are needed to slow long-term disease progression.

PO2350

International Variation in the Incidence of Kidney Failure in the CKD Outcomes and Practice Patterns Study (CKDopps)

Natalia Alencar de Pinho,[1] Roberto Pecoits-Filho,[2,3] Brian Bieber,[2] Daniel G. Muenz,[2] Antonio A. Lopes,[4] Helmut Reichel,[5] Christian Combe,[6] Bruce M. Robinson,[2] Benedicte Stengel.[1] *[1]Paris-Saclay University, UVSQ, Inserm, Center for Research in Epidemiology and Population Health, Villejuif, France; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [4]Universidade Federal da Bahia, Salvador, Brazil; [5]Nephrological center, Villingen-Schwenningen, Germany; [6]Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France.*

Background: Data from kidney replacement therapy (KRT) registries suggest large international variation in the incidence of kidney failure (KF). However, these data strongly depend on treatment availability and practices of KRT initiation. Measuring the incidence of sustained low eGFR, i.e. <15 mL/min/1.73 m^2, would enable to explore differences in progression to KF across countries after adjusting for individual characteristics.

Methods: We analyzed data from patients with CKD stages G3-G4, under nephrology care in representative samples of clinics in Brazil (n= 747), France (n= 2786), Germany (n= 2539), and the United States (n=1309), participating in the CKDopps. We used Weibull PH models to compare the risk of KRT initiation across countries, and Illness-death models for interval censored data, to compare the risk of sustained low eGFR and to estimate probabilities of KF (composite of KRT initiation and sustained low eGFR).

Results: Median age (years) ranged from 67 in Brazil to 75 in Germany, mean baseline eGFR (ml/min/1.73m^2) from 27 in Germany to 33 in France; male sex from 52% in the United States to 66% in France. After a median follow-up of 4.0 (2.6-5.0) years, 1648 patients met a sustained low eGFR, and 1343 initiated KRT. Compared with the United States, the adjusted hazard ratios indicated 44%- lower risk of KRT initiation in Brazil (95%CI 0.39 to 0.79), similar risk in France (1.05, 95%CI 0.83 to 1.33), and 41%- higher risk in Germany (95% CI 1.12 to 1.77). The same pattern was observed for sustained low eGFR, but differences were narrowed. Two-year cumulative probability of KF ranged from 13% in Brazil to 16% in Germany (Figure).

Conclusions: The incidence of KF varies across CKDopps countries, but to a much lesser extent than the incidence of KRT initiation. This finding highlights the relevance of such approach to disentangle the effects on CKD progression from those on access to care.

PO2351

Development and Validation of an Algorithm to Predict Risk of 90-Day Hospitalization for Patients with CKD

Steph Karpinski,[1] Scott Sibbel,[1] Kathryn S. Gray,[1] Adam G. Walker,[1] Jiacong Luo,[1] Carey Colson,[1] Justin M. Kindy,[2,3] Tiffany L. Bray,[2,3] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO; [3]DaVita Integrated Kidney Care, Denver, CA.*

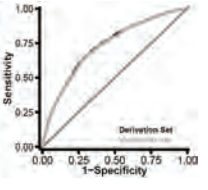
Background: Patients with chronic kidney disease (CKD) are at higher risk of being admitted to the hospital than the general population. Hospitalizations in CKD patients are often associated with higher medical costs, increased morbidity, and increased risk of transition to end-stage kidney disease (ESKD). Nationally, there seems to be an increasing focus on the management of CKD upstream of ESKD. Identification of CKD patients at greatest risk of hospitalization may hold promise to improve clinical outcomes and judicious allocation of health care resources.

Methods: This model was developed using Medicare Part A and Part B claims from calendar years 2017-2019. Data from 50,000 unique patients diagnosed with CKD stages 3-5, no evidence of ESKD, or claims for dialysis were split into derivation (n = 40,000) and validation (n = 10,000) sets. The predicted outcome was all-cause hospital admissions, which occurred in 10.4% of patients 90 days after scoring. Overall performance of candidate models was assessed using area under the curve (AUC) of the receiver operating curve in addition to positive predictive value (PPV) and sensitivity across a variety of thresholds.

Results: The best model that we tested was a gradient boosting machine algorithm based on 399 input terms, which represented 147 unique clinical constructs. The model demonstrated good ability to discriminate (AUC = 0.73), which was stable when tested in a validation set (AUC = 0.73). The PPV in the validation set was 30.6%, 24.0%, and 21.6% at the 10%, 20%, and 30% thresholds, respectively. The sensitivity in the validation set was 28.8%, 45.3%, and 60.9% at the 10%, 20%, and 30% thresholds, respectively.

Conclusions: We developed an algorithm that uses only information derived from medical claims to identify CKD 3-5 patients at highest risk of being hospitalized in the near-term. This algorithm could be used as a decision support tool for clinical programs focusing on the management of CKD patient populations.

	Derivation Set	Validation Set
Patients	40,000	10,000
Hospitalized	10.4%	10.6%
AUC	0.73	0.73
10% Threshold (PPV/Sensitivity)	29.6%/28.5%	30.6%/28.8%
20% Threshold (PPV/Sensitivity)	24.0%/46.6%	24.0%/45.3%
30% Threshold (PPV/Sensitivity)	21.2%/61.3%	21.6%/60.9%



PO2352

CKD and Risk of Incident Hospitalization with Clostridioides difficile Infection: Findings from the Atherosclerosis Risk in Communities Study

Junichi Ishigami,[1] Keiichi Sumida,[2] Morgan Grams,[3] Alex R. Chang,[4] Pamela L. Lutsey,[5] Andrew S. Levey,[6] Josef Coresh,[1] David W. Dowdy,[1] Kunihiro Matsushita.[1] *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Johns Hopkins Medicine, Baltimore, MD; [4]Geisinger Health, Danville, PA; [5]University of Minnesota Twin Cities, Minneapolis, MN; [6]Tufts Medical Center, Boston, MA.*

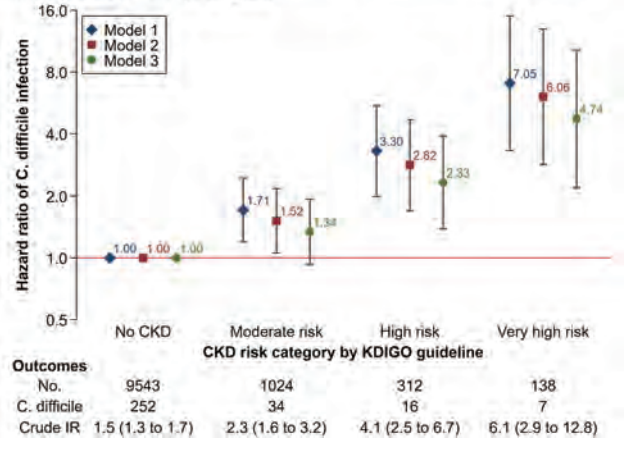
Background: *Clostridioides difficile* (*C. difficile*) infection is a major public health priority in the US. Individuals with CKD are at high risk of infection and hospitalization in general; however, the association of CKD with the risk of *C. difficile* disease has not been systematically evaluated.

Methods: We evaluated data from 11,017 participants of the ARIC Study (mean age, 63 years; 56% female; 22% Black) to explore the association of CKD with the risk of incident hospitalization with *C. difficile* infection. We categorized the study population into four risk categories defined by eGFR and ACR: CKD was defined as eGFR <60 ml/min/1.73m^2 or ACR ≥30 mg/g, and no CKD was defined as low risk. CKD was subdivided into moderate, high, and very high risk. Adjusted HRs were estimated using Cox regression models.

Results: During a median follow-up of 20.1 years, 309 participants had incident hospitalization with *C. difficile* infection. In multivariable Cox regression analysis, there was a graded association of CKD risk category with the risk of hospitalization with *C. difficile* infection, with adjusted HRs of 4.74 [2.29 to 10.23] for CKD with very high risk, 2.33 [1.39 to 3.90] for CKD with high risk, and 1.34 [0.93 to 1.93] for CKD with moderate risk compared to no CKD (P-for-linear-trend, <0.001) (Figure 1). These findings were consistent in subgroup analyses and sensitivity analyses, including analyses that accounted for frequency of prior hospitalization and for the risk of hospitalization itself.

Conclusions: In this community-based cohort, CKD was associated with the risk of hospitalization with *C. difficile* infection. Individuals with CKD should be a key target population for public health initiatives and clinical approaches to prevent *C. difficile* infection.

Figure 1: Hazard ratios of hospitalization with *C. difficile* infection according to the severity of CKD by KDIGO guideline. Model 1 was unadjusted. Model 2 was adjusted for age, sex, and race. Model 3 was further adjusted for body mass index, education level, ever smoking, lifetime alcohol use, hypertension, diabetes, total cholesterol, high-density lipoprotein cholesterol and prevalent cardiovascular disease. Crude incidence rates (IRs) and their 95% confidence intervals (CIs) are per 1,000 person-years.



Outcomes				
No.	9543	1024	312	138
C. difficile	252	34	16	7
Crude IR	1.5 (1.3 to 1.7)	2.3 (1.6 to 3.2)	4.1 (2.5 to 6.7)	6.1 (2.9 to 12.8)

PO2353

Lower Serum Bicarbonate Is a Risk Factor for Hospitalization for Infection Among Patients with CKD

Danielle L. Saly,[1] Ian A. Strohbehn,[2] Meghan E. Sise,[2] Gary C. Curhan.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Hospitalization due to infection is common in patients with CKD; both lower eGFR and albuminuria are risk factors. Metabolic acidosis impairs neutrophil function in ESRD patients via delayed apoptosis, enhanced phagocytosis, and increased oxidative burst reactions, however serum bicarbonate has not been investigated as a risk factor for infection in patients with non-dialysis CKD.

Methods: We utilized a central data warehouse from Mass General Brigham for patients with ≥1 diagnostic code for CKD between 2010-2020. CKD was defined as 2 outpatient eGFR values <60 mL/min/1.73m^2 at least 3 months apart. Patients were excluded if they had a kidney transplant, a humoral immunodeficiency, or ESRD on dialysis prior to index date. The primary outcome was hospitalization for infection (defined by primary diagnosis of urinary tract infection/ pyelonephritis, pneumonia, cellulitis, or bacteremia). We examined outpatient baseline serum bicarbonate and risk of initial hospitalization for infection using Cox proportional hazards models adjusting for potential confounders. Patients were censored at time of first infection, last lab value, or death.

Results: We included 36,647 patients with CKD, and 8,521 were hospitalized for infection. When adjusting for covariates, the risk for infection increased as serum bicarbonate decreased (Figure 1). A serum bicarbonate of <20 mEq/L compared to ≥28 mEq/L was independently associated with an 18% (95% CI 1.05-1.32) higher risk of hospitalization. In the adjusted model, CKD stage 5 was associated with a 69% (95% CI 1.47-1.94) increased risk of infection compared to CKD stage 3a. Albuminuria ≥300 mg/g was associated with a 28% (95% CI 1.14-1.44) increased risk of composite infection compared to <10 mg/g.

Conclusions: Our findings suggest that clinicians should consider lower serum bicarbonate a risk factor for infection in patients with CKD. Future studies should explore whether bicarbonate supplementation can reduce risk of infection.

PO2354

Albuminuria Testing in Hypertension and Diabetes

Jung-Im Shin, Alex R. Chang, Yingying Sang, Ron T. Gansevoort. Chronic Kidney Disease Prognosis Consortium *CKD Prognosis Consortium, Baltimore, MD.*

Background: Albuminuria is an under-recognized component of chronic kidney disease (CKD) definition, staging, and prognosis. Despite significant advances in therapies for patients with albuminuria, guidelines, particularly for hypertension, conflict on recommendations for urine albumin-to-creatinine ratio (ACR) measurement.

Methods: We separately analyzed 1,305,841 adults with diabetes in 25 cohorts and 2,111,587 non-diabetic adults with hypertension in 21 cohorts from the CKD Prognosis Consortium. We estimated ACR testing rates during a 2-year window, and developed and utilized risk prediction models for prevalent albuminuria (ACR ≥30 mg/g) to determine if high-risk patients for albuminuria are more likely to be tested and to estimate the burden of undetected albuminuria.

Results: Overall, the ACR testing rate was 35.3% in diabetes and 4.1% in hypertension. Among patients with diabetes, testing rates varied greatly across the different health systems and were largely unrelated to the predicted risk of prevalent albuminuria (**Figure A**). Among patients with hypertension, testing rates were low and also unrelated to the predicted risk of prevalent albuminuria (**Figure B**). The estimated ratio (cohort range) of undetected (due to lack of testing) to detected prevalent albuminuria was 1.8 (0.2-7.6) in diabetes and 19.5 (0.8-78.3) in hypertension.

Conclusions: Real-world ACR testing is low, particularly among non-diabetic patients with hypertension, and testing is unrelated to predicted risk. There are large swaths of the population with diabetes or hypertension with undiagnosed CKD, suggesting that regular albuminuria screening should be emphasized for early detection of CKD and appropriate initiation of treatment with cardiovascular and kidney benefits.

Funding: NIDDK Support, Private Foundation Support

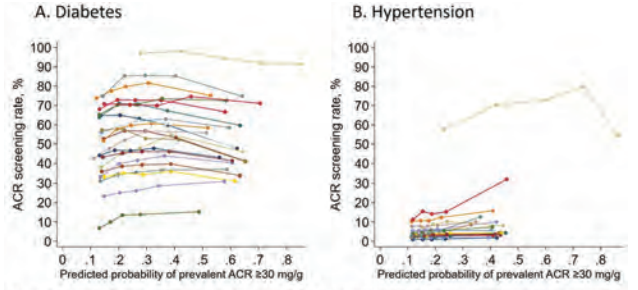

Figure. ACR screening rate (≥1 during 2-year period) in (A) diabetes (N=605,742 in 23 cohorts*) and (B) hypertension (N=1,057,825 in 19 cohorts*) by the quintiles of cohort-specific predicted probability of prevalent ACR ≥30 mg/g.
*Cohorts with in-house data only from three countries.

PO2355

Increasing Proteinuria Screening to Reduce CKD Progression in High-Risk Patients

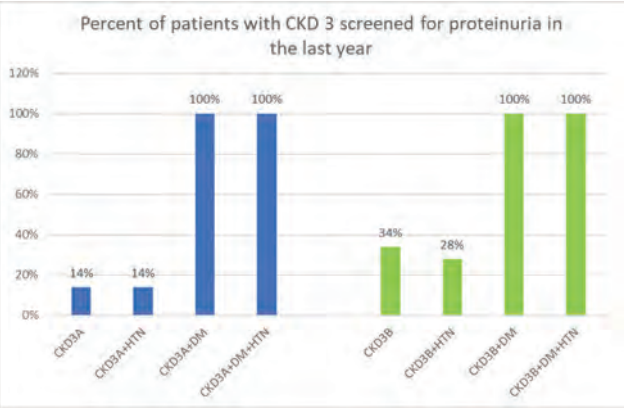
Jaclyn Khil, Nika Carrillo, Nirmala D. Ramalingam, H. Nicole Tran, Sijie Zheng. *Kaiser Permanente, Oakland, CA.*

Background: Chronic Kidney Disease (CKD) affects 15% of the US population and is underrecognized by patients and clinicians. Screening for proteinuria is essential in prompting primary care doctors (PCPs) to initiate treatments proven to decrease progression to end stage renal disease, cardiovascular events and mortality in these patients. However, screening rates remain low -- one study showed only 13% of adults with CKD had proteinuria/albuminuria testing. Our objective was to identify the high-risk patients with CKD who did not recieve annual proteinuria testing, with the long-term goal of addressing barriers to quality care.

Methods: We identified 4214 patients between October and December 2020 within our healthcare system who had a diagnosis of CKD 3 or 4 and categorized them as having diabetes/not having diabetes and having hypertension/not having hypertension. We then assessed how many patients had proteinuria testing in the last year, which included a urinalysis, urine protein to creatinine ratio or urine microalbumin.

Results: Results showed that 100% of patients with diabetes had screening in the last year regardless of CKD stage or hypertension (HTN). For those with CKD3A/HTN only 14% (171/1226) had screening in the last year and for those with CKD3B/HTN only 28% (98/347) had screening in the last year. For patients with CKD3A and CKD3B (without HTN/diabetes), 14% (125/892) and 34% (48/142) respectively had appropriate screening.

Conclusions: Within our large, integrated healthcare system, rates of proteinuria screening in diabetic patients were strikingly high. In contrast, most patients with CKD3 and HTN did not receive testing in the last year. One explanation for this is the workflow in place to help PCPs manage their patients with diabetes, which includes automated reminders and a dedicated multidisciplinary team. Applying a similar systematic, protocol-based workflow to all patients with CKD may help to increase screening rates and improve overall quality of care.



PO2356

The Association of CKD Severity with Stroke Subtype Using the TOAST Classification

Salmi T. Noor,[1] Sarah E. Bota,[2] Anna E. Clarke,[2] Dearbhla Kelly,[3,4] Greg A. Knoll,[1,5] Manish M. Sood.[1,5] *[1]University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Ottawa, ON, Canada; [3]University of Oxford Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom; [4]John Radcliffe Hospital, Oxford, United Kingdom; [5]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Ischemic stroke affects approximately 67.5 million people worldwide. The risk of acute ischemic stroke largely increases with advanced chronic kidney disease (CKD). However, whether the risk of specific ischemic stroke subtype varies with declining kidney function remains unclear. The purpose of this study was to assess the association between ischemic stroke subtypes (cardioembolic [CE], arterial, lacunar, other) classified using the Trial of Org 10172 in Acute Stroke Treatment (TOAST) and CKD stage.

Methods: This is a cross-sectional, retrospective cohort study of adults (≥18 years) with an ischemic stroke who presented to the emergency department in Ontario, Canada between April 1, 2002- March 31, 2013 and who had an inpatient serum creatinine measurement or were on chronic dialysis. All patients captured in the stroke registry with an estimated glomerular filtration rate (eGFR) were included and CKD severity was categorised as ≥60, 30-59, <30 mL/min/1.73m^2 or chronic dialysis.

Results: A total of 17,434 individuals with an ischemic stroke were included (58.9% eGFR ≥60, 34.7% eGFR 30-59, 6.0% eGFR<30, 0.5% on chronic dialysis; mean age of 73 years; 48% female). Among patients with an eGFR 30-59 (50.4%) and < 30 (50.6%), CE stroke was more common compared to those with an eGFR >60 (36.8%) or on chronic dialysis patients (37.3%). The odds of CE stroke vs. non-CE stroke were **eGFR 30-59** odds ratio (OR) 1.20 95% confidence interval (CI) 1.10-1.31, **eGFR<30** OR 1.21 95% CI 1.02-1.44, **dialysis** OR 0.86 95% CI 0.48-1.57, **eGFR>60** referent). We found lower adjusted odds of lacunar stroke in those with advanced CKD (lacunar vs. non-lacunar: **eGFR 30-59** OR 0.85 95% CI 0.77-0.93, **eGFR<30** OR 0.73 95% CI 0.61-0.88, **dialysis** OR 1.25 95% CI 0.68-2.28, **eGFR>60** referent). In subgroup analyses **(eGFR>=30 and <30)**, CE strokes were also more common in those >65 years, with atrial fibrillation, no anticoagulation or an INR <2.

Conclusions: Chronic kidney disease (eGFR<60, pre-dialysis CKD) is associated with a higher odds of CE stroke compared to patients with normal to high kidney function or those on chronic dialysis. Normal/mildly decreased eGFR were associated with the development of lacunar strokes. Detailed stroke subtyping in CKD may therefore provide mechanistic insights and refocus treatment strategies in this vulnerable group.

PO2357

Major Cardiovascular Events and Subsequent Risk of Kidney Failure: A CKD Prognosis Consortium Study

Patrick B. Mark, Juan J. Carrero, Frank L. Visseren, Benedicte Stengel. Chronic Kidney Disease Prognosis Consortium *CKD Prognosis Consortium, Baltimore, MD.*

Background: Chronic kidney disease (CKD) increases risk of cardiovascular disease (CVD). However, less is known about how CVD is associated with future risk of kidney failure. We quantified the association of incident major CVD events with subsequent risk of kidney failure requiring replacement therapy (KFRT).

Methods: We analyzed data on 18,671,338 individuals from 80 cohorts in the CKD Prognosis Consortium with baseline eGFR and CVD data. We assessed impact of incident coronary heart disease (CHD), heart failure (HF), atrial fibrillation (Afib) and stroke events as a time-varying exposure on the outcome of KFRT in Cox proportional hazard models.

Results: Mean age was 53 years and mean eGFR was 88 ml/min/1.73m^2, 57% were women, 9% were black, 12% had diabetes and 30% had ACR available (median 13 mg/g); 9% had prevalent CHD, 3% HF, 2% Afib, and 4% prior stroke. During follow up there were 175,886 CHD, 480,963 HF, 428,419 Afib and 211,423 stroke incident events and 85,513 (0.5%) patients required KFRT. Each CVD event increased the adjusted hazard ratio (HR) for subsequent KFRT (**Table**). The increased hazard was highest in the first year after CVD incidence and attenuated thereafter. HRs were modestly weaker at lower eGFR. HF showed the strongest association before and after adjustment for other CVD subtype incidence. Absolute risk of KFRT associated with incident CVD after accounting for competing risk of mortality was higher for lower baseline eGFR and higher ACR, with 2-year KFRT risk of 25%, 28%, 20% and 20% for CHD, HF, Afib and stroke in subjects with eGFR 15-29 ml/min/1.73m^2 and ACR >300 mg/g.

Conclusions: Incident CVD events are strongly and independently associated with risk for KFRT, with greatest risk in the first year following HF, then CHD and stroke. These data highlight need for greater awareness of KFRT risk following CVD events. Specific strategies to elucidate mechanisms and test interventions to reduce the KFRT risk post CVD events warrant investigation.

Funding: NIDDK Support, Private Foundation Support

Table. Adjusted hazard ratios for associations between incident cardiovascular diseases (CVD) with risk of kidney failure replacement therapy (KFRT)

	Myocardial Infarction	Stroke	Heart Failure	Atrial fibrillation
	KFRT Adjusted HR (95% CI)			
Incident overall	3.1 (2.9, 3.3)	2.0 (1.9, 2.1)	4.4 (4.1, 4.6)	2.8 (2.7, 3.0)
Incident < 1y	20.4 (17.8, 23.3)	10.2 (9.3, 11.2)	25.4 (22.1, 29.1)	15.2 (13.1, 17.8)
Incident 1-2y	3.6 (3.2, 4.1)	3.0 (2.6, 3.4)	5.2 (4.7, 5.9)	2.6 (2.3, 3.0)
Incident 2y+	1.0 (0.91, 1.1)	0.90 (0.83, 0.99)	1.3 (1.2, 1.5)	0.70 (0.62, 0.78)
	Model adjusting first incident CVD event subtypes for each other			
Incident overall	1.4 (1.4, 1.5)	1.3 (1.2, 1.4)	3.6 (3.3, 3.8)	1.5 (1.3, 1.6)
Incident < 1y	2.2 (1.9, 2.6)	2.5 (2.2, 2.8)	15.3 (13.7, 17.1)	2.7 (2.3, 3.2)
Incident 1-2y	1.5 (1.3, 1.7)	1.7 (1.5, 2.0)	4.6 (4.1, 5.2)	1.1 (0.93, 1.2)
Incident 2y+	0.88 (0.77, 1.0)	0.85 (0.76, 0.94)	1.4 (1.3, 1.6)	0.67 (0.58, 0.77)

*Adjusted for age, sex, race, smoking, diabetes, blood pressure, use of antihypertensive meds, total cholesterol, HDL cholesterol, lipid lowering meds, BMI, eGFR, ACR (or missing indicator & its interaction with diabetes and eGFR)

PO2358

Bidirectional Association Between Kidney Function and Atrial Fibrillation in the General Population

Anna C. van der Burgh, Sven Geurts, M.Arfan Ikram, Ewout J. Hoorn, Maryam Kavousi, Layal Chaker. *Erasmus MC, Rotterdam, Netherlands.*

Background: A potential bidirectional relationship between kidney dysfunction and atrial fibrillation (AF) has been suggested, but has not been studied in the general population. Therefore, we aimed to study the association of different assessments of kidney function with prevalent and incident AF in the general population.

Methods: Participants aged ≥ 45 years from the Rotterdam Study, a population-based cohort study, with information on kidney function and AF were included. Assessments of kidney function included single assessments of estimated glomerular filtration rate (eGFR) based on serum creatinine (eGFRcreat), serum cystatine C (eGFRcys), or both (eGFRcreat-cys), and the urine albumin-to-creatinine ratio (ACR), and repeated assessments of eGFRcreat. Incident chronic kidney disease (CKD) was defined as the first time eGFRcreat dropped <60 ml/min per 1.73 m^2. Cox-proportional hazards, logistic regression, linear mixed, and joint models were used to investigate the associations of eGFR with incident and prevalent AF. Absolute 10-year risk of AF was computed using a competing risk analysis. All models were adjusted for potential confounders including cardiovascular risk factors.

Results: During a median follow-up time of 8.0 years, 780 incident AF cases occurred in 9,288 participants (mean age 64.9 years, 57.2% female). Lower eGFRcys and eGFRcreat-cys were significantly associated with an increased risk of incident AF (hazard ratio (HR) 1.08, 95% confidence interval (CI) 1.03-1.14 and HR 1.07, 95% CI 1.01-1.14, respectively, per 10 ml/min per 1.73 m^2 decrease in eGFR), while eGFRcreat was not. No association between urine ACR and incident AF was found. Absolute 10-year risk of developing AF increased from 4.9% to 7.1%, when comparing eGFRcys levels of 90 to 60 ml/min per 1.73 m^2. Prevalent AF (409 cases) was associated with on average 2.85 ml/min per 1.73 m^2 lower eGFRcreat levels over time and furthermore, a faster decline of eGFRcreat with aging was revealed when compared to participants without prevalent AF. Prevalent AF was also associated with a 1.3 fold increased risk of incident CKD.

Conclusions: Kidney function and AF are bidirectionally associated. This insight may be used to improve prediction and prevention of both conditions, for example through targeted screening programs in the general population.

PO2359

Longitudinal Ankle Brachial Index and Risk of CKD Progression

Kirsten S. Dorans,[1] Jing Chen,[2,1] Xingyan Li,[1] Hua He,[1] Jordana B. Cohen,[3] Alan S. Go,[4] L. Lee Hamm,[2,1] Edward J. Horwitz,[9] Bernard G. Jaar,[5] James P. Lash,[6] Rupal Mehta,[7] Sylvia E. Rosas,[8] Anand Srivastava,[7] Jonathan J. Taliercio,[10] Jiang He.[1,2] CRIC Study Investigators *[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Kaiser Permanente Northern California, Oakland, CA; [5]Johns Hopkins Medicine, Baltimore, MD; [6]University of Illinois at Chicago, Chicago, IL; [7]Northwestern University Department of Medicine, Chicago, IL; [8]Joslin Diabetes Center, Boston, MA; [9]MetroHealth Medical Center, Cleveland, OH; [10]Cleveland Clinic, Cleveland, OH.*

Background: Individuals with chronic kidney disease (CKD) are more likely than the general population to have low or high ankle brachial index (ABI). Low ABI is a predictor of adverse outcomes in CKD, but the relationship of ABI with renal outcomes in CKD is not well studied. As ABI is a simple noninvasive measure, it is important to better understand how ABI relates to CKD progression.

Methods: We carried out a prospective study of 3216 participants with CKD in the Chronic Renal Insufficiency Cohort (CRIC) Study without clinical peripheral arterial disease. We used Cox proportional hazards regression to test the associations of baseline ABI and of cumulative average ABI with risk of CKD progression [50% reduction in estimated glomerular filtration rate (eGFR) or end-stage renal disease (ESRD)] and with risk of ESRD, adjusting for important confounding factors. ABI was measured at annual visits. The shapes of the relationships of exposures with outcomes were assessed with restricted cubic splines.

Results: At baseline, average age was 57.8 years and average eGFR was 44.8 ml/min/1.73m^2. During follow-up, 1297 individuals had CKD progression (median follow-up 6.9 years, 7 ABI measurements) and 1049 developed ESRD (median follow-up 10.8 years, 6 ABI measurements). In multivariable-adjusted models, there were U-shaped associations of baseline ABI with CKD progression and with ESRD (p for curves <0.001). In models adjusted for baseline ABI, similar U-shape relationships were observed for the associations of cumulative average ABI with CKD progression and with ESRD (p for curves <0.001; **Figure**).

Conclusions: This study indicates that both high and low ABI are associated with increased risk of CKD progression and ESRD and that even after adjustment for baseline ABI, repeated measures of ABI averaged over time are associated with CKD progression and ESRD. These findings suggest that ABI can be used to facilitate risk stratification for CKD progression.

Urinary Peptidome Analysis to Predict the Risk of CKD Progression to Kidney Failure

Ziad Massy,[1,2] Oriane Lambert,[2] Marie Metzger,[2] Mohammed Sedki,[6] Griet L. Glorieux,[5] Francis Verbeke,[5] Harald Mischak,[7] Justyna Siwy,[7] Benedicte Stengel,[2] Joost Schanstra,[3,4] Julie Klein.[3,4] CKD-REIN Investigators
[1]Service de Néphrologie, Hôpital Universitaire Ambroise Paré, Assistance publique des Hôpitaux de Paris, Boulogne-Billancourt, France; [2]CESP, INSERM U1018, Equipe Epidémiologie Clinique, Université Paris-Saclay, UVSQ, Université Paris-Sud, Villejuif, France; [3]INSERM, U1297, Institut of Cardiovascular and Metabolic Disease, Toulouse, France; [4]Université Toulouse III Paul-Sabatier, Toulouse, France; [5]Department of Internal Medicine and Pediatrics, Nephrology Section, Ghent University Hospital, Ghent, Belgium; [6]CESP, INSERM U1018, Pôle méthodologies et statistique, Université Paris-Saclay, UVSQ, Université Paris-Sud, Villejuif, France; [7]Mosaiques Diagnostics GmbH, Hannover, Germany.

Background: Urinary peptidomics (UP) has emerged as one of the most attractive areas in the identification of biomarkers for characterizing CKD but its potential to predict the risk of CKD progression has not been fully investigated. The aims of the present study were to explore if a UP signature can improve the prediction of kidney failure (KF), compared to the risk factors (RF) included in the KF risk equation.

Methods: Within the Chronic Kidney Disease-Renal Epidemiology and Information Network prospective cohort of patients with CKD stage G3-G5 (N=3033), we conducted a case-cohort study of 892 patients, including 262 who progressed to KF as defined by the initiation of dialysis or preemptive kidney transplantation over 3-year follow-up. UP analysis was performed on samples collected at baseline using capillary electrophoresis coupled to mass spectrometry. Three logistic regression models with elastic-net penalty were developed with different sets of predictors: (1) peptides alone, (2) RF including age, sex, eGFR and urinary albumin to creatinine ratio, and (3) peptides and RF. We performed 50-repeated 2-fold cross-validation to choose the 3 optimal models and measure their performances (AUC, sensitivity and specificity). External independent validation was performed in a Belgian cohort of 270 patients with CKD Stages G3-G5 including 28 progressing to KF over 3-year follow-up.

Results: A signature of 174 peptides predicted KF risk in the first model (Figure). The independent validation of the UP signature in the Belgian cohort confirmed the prognostic potential of the peptide signature displaying a AUC of 0.928 [0.887-0.969] (sensitivity, 86% [71%-96%] and specificity, 81% [65%-94%]). RF alone also predicted KF risk with high precision, and the addition of peptides did not significantly improve this prediction (Figure).

Conclusions: We have identified a UP signature that predicts KF risk with high precision, but did not significantly ameliorate the prediction obtained by a combination of age, sex, eGFR and albuminuria.

Plasma Biomarkers and Incident CKD in Individuals Without Diabetes

Mark J. Sarnak,[1] Ronit Katz,[2] Steven G. Coca,[3] Jason H. Greenberg,[4] Paul L. Kimmel,[12] Venkata Sabbisetti,[13] Chirag R. Parikh,[8] Casey Rebholz,[8] Sushrut S. Waikar,[9] Jeffrey R. Schelling,[11] Zihe Zheng,[7] Mary Cushman,[14] Vasan S. Ramachandran,[9] Joseph V. Bonventre,[13] Michael Shlipak,[6] Joachim H. Ix,[5] Orlando M. Gutierrez.[10] *[1]Tufts Medical Center, Boston, MA; [2]University of Washington, Seattle, WA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Yale University School of Medicine, New Haven, CT; [5]University of California San Diego, La Jolla, CA; [6]University of California San Francisco, San Francisco, CA; [7]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [8]Johns Hopkins Medicine, Baltimore, MD; [9]Boston University School of Medicine, Boston, MA; [10]The University of Alabama at Birmingham, Birmingham, AL; [11]Case Western Reserve University, Cleveland, OH; [12]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [13]Brigham and Women's Hospital, Boston, MA; [14]University of Vermont College of Medicine, Burlington, VT.*

Background: Earlier prediction of CKD may facilitate risk factor mitigation prior to advanced disease. Albuminuria and reduced GFR are relatively insensitive markers of early CKD. We examined the association of several novel plasma biomarkers with incident CKD.

Methods: We used a case cohort design in participants without diabetes in the Multiethnic Study of Atherosclerosis (MESA) and the Reasons for Geographic and Racial Differences in Stroke (REGARDS) cohorts with a baseline eGFR ≥60 ml/min/1.73 m^2. Incident CKD was defined as the development of an eGFR <60 ml/min/1.73 m^2 and ≥40% decline in eGFR from baseline. We measured plasma markers of inflammation/fibrosis—soluble tumor necrosis factor receptors 1 and 2 (TNF-R1 and TNF-R2), monocyte chemotactic protein-1 (MCP-1) and soluble urokinase-type plasminogen activator receptor (suPAR)—and tubular injury (kidney injury marker 1, KIM-1) and repair [chitinase 3-like protein 1 (YKL-40)]. Cox regression models weighted for the case cohort design were used to estimate hazard ratios.

Results: In MESA (median follow-up 9.2 years), there were 497 individuals in the subcohort and 163 cases of incident CKD. In REGARDS (median follow-up 9.4 years), there were 497 individuals in the subcohort and 497 cases of incident CKD. Plasma KIM 1, suPAR, TNF-R1, TNF-R2 and YKL-40 concentrations were all independently associated with incident CKD in MESA. In REGARDS, TNF-R1 and TNF-R2 were independently associated with incident CKD (Table).

Conclusions: Plasma concentrations of soluble TNF-R1 and TNF-R2 are consistently associated with incident CKD in non-diabetic community-living individuals, independent of eGFR, UACR, and other CKD risk factors.

Tubular Secretion Markers and Declining Kidney Function in the SPRINT Trial

Pranav S. Garimella,[1] Simon Ascher,[5] Ronit Katz,[3] Alexander Bullen,[1] Michelle M. Estrella,[2] Rakesh Malhotra,[1] Vasantha Jotwani,[2] Stein I. Hallan,[4] Rebecca Scherzer,[2] Michael Shlipak,[2] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of California San Francisco, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]UiT Norges arktiske universitet, Tromso, Norway; [5]University of California Davis, Davis, CA.*

Background: Tubular secretion is an important aspect of kidney function that is not routinely assessed. Emerging evidence suggests that impaired secretion may be associated with increased risk of kidney function decline.

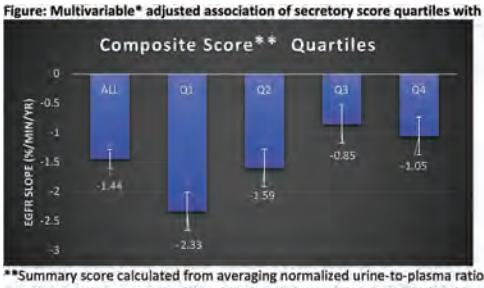
Methods: In a cohort of 2089 SPRINT trial participants with baseline eGFR < 60ml/min/1.73m^2, we measured a panel of 10 solutes in serum and urine, that were previously identified as markers of tubular secretion. We created a standardized composite secretory score using the urine to plasma ratios of all 10 biomarkers. We evaluated associations of this composite score with annual % eGFR decline and progression of CKD (>30% loss of eGFR) using multivariable linear regression and Cox regression models, respectively.

Results: Mean participant age at baseline was 73 years, 41% were female, and 24% identified as Black. The mean eGFR varied by secretion score quartile: from 39 ml/min/1.73m^2 in the lowest quartile to 51 ml/min/1.73m^2 in the highest quartile. In multivariable adjusted analyses, eGFR declined faster for participants in the lower two quartiles of secretory score compared with participants in the higher two quartiles (**Figure**). There was no significant interaction between secretion score and randomized treatment assignment for the outcome of eGFR decline. In unadjusted models, each 1-SD higher secretion score was associated with a lower risk of CKD progression (HR 0.49; 95% CI, 0.35, 0.70), but this association was attenuated by multivariable adjustment (HR 0.75, 95% CI 0.53, 1.07).

Conclusions: Impaired secretory function as measured by a panel of endogenous markers is associated with faster decline in eGFR among persons with CKD.

Funding: NIDDK Support

Figure: Multivariable* adjusted association of secretory score quartiles with annual % eGFR decline



**Summary score calculated from averaging normalized urine-to-plasma ratios of adipic acid, cinnamoylglycine, p-cresol sulfate, 1,7-dimethyluric acid, 2-furoylglycine, hippuric acid, m-hydroxy Hippurate, indoxyl sulfate, phenylacetylglutamine, tiglylglycine, and 1,3,7-trimethyluric acid.
*Adjusted for baseline age, sex, race, intervention arm, smoking, body mass index, systolic blood pressure, number of antihypertensive medications, prevalent cardiovascular disease, low-density lipoprotein cholesterol level, high-density lipoprotein cholesterol level, triglyceride level, statin use, baseline eGFR and urine albumin.

The Use of Plasma Biomarker-Derived Clusters for Clinicopathologic Phenotyping: Results from the Boston Kidney Biopsy Cohort

Insa M. Schmidt,[1] Prasad Patil,[5] Steele Myrick,[5] Ingrid F. Onul,[1] Anand Srivastava,[3] Ragnar Palsson,[6] Isaac E. Stillman,[4] Helmut G. Rennke,[2] Sushrut S. Waikar.[1] *[1]Boston Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Boston University School of Public Health, Boston, MA; [6]Landspitali, Reykjavik, Iceland.*

Background: Protein biomarkers may provide non-invasive insight into kidney disease pathology. Prior studies have not evaluated whether unsupervised clustering analyses of multiple plasma protein biomarkers may identify phenotypically distinct kidney diseases.

Methods: We performed unsupervised hierarchical clustering on 225 plasma biomarkers measured in 541 individuals enrolled into the Boston Kidney Biopsy Cohort, a prospective cohort study of individuals undergoing clinically indicated native kidney biopsy with adjudicated clinicopathologic diagnoses and semiquantitative scores of histopathology. Chi-square tests compared differences in proportions of clinicopathologic diagnoses by cluster membership. We examined contributions of biomarkers to each cluster and explored cluster-specific pathways using principal component analysis and pathway enrichment analysis, respectively.

Results: The biomarker-derived clusters partitioned subjects into 3 groups. The mean eGFR was 71.4±29.2, 72.5±34.3, and 39.3±31.3 ml/min/1.73m² in Cluster 1, 2, and 3, respectively. Compared to Cluster 1, individuals in Cluster 3 were more likely to have tubulointerstitial disease (p<0.001) and diabetic nephropathy (p<0.001), (Figure 1). The top-contributing biomarker in Cluster 1 was AXIN, a negative regulator of the Wnt signaling pathway. The top-contributing biomarker in Cluster 2 and 3 was Placental Growth Factor, a member of the VEGF family. The top ranked pathways were tumor-necrosis factor receptor-related signaling and interleukin and cytokine signaling in Cluster 1, 2, and 3, respectively.

Conclusions: Clusters of plasma biomarkers may identify individuals with distinct forms of CKD, which may uncover relevant pathways and biomarker candidates for clinicopathologic phenotyping of kidney diseases.

Background: The DAPA-CKD trial (NCT03036150) demonstrated that dapagliflozin reduced the risk of kidney and cardiovascular (CV) events in patients with chronic kidney disease (CKD) and albuminuria, with and without type 2 diabetes. We aimed to determine whether the effects of dapagliflozin varied by pre-specified geographic region.

Methods: We randomized 4304 adults with baseline estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73m² and urinary albumin-to-creatinine ratio 200–5000 mg/g to dapagliflozin 10mg or placebo once daily; median follow-up was 2.4 years. We compared baseline data, primary and secondary outcomes, and safety of the 4 regions (Asia, Northern America, Latin America, Europe).

Results: Compared to other regions, participants from Asia had lower body mass index, less frequent use of diuretics and better blood pressure control. The figure displays the primary and secondary outcomes by region and treatment assignment. Dapagliflozin consistently reduced the risk of the primary composite endpoint (eGFR decline ≥50%, end-stage kidney disease, or kidney or CV death) across the 4 regions by 30 to 49%, with no significant heterogeneity (p=0.77). Similarly, there was no evidence of differences in secondary outcomes between regions. Serious adverse events in the dapagliflozin and placebo groups were similar across the 4 regions.

Conclusions: Despite differences in patient characteristics, the beneficial effects of dapagliflozin on kidney and CV endpoints in patients with CKD and albuminuria were similar across pre-specified geographic regions.

Effects of Dapagliflozin in Patients with CKD and Albuminuria, with and Without Diabetes, by Use and Non-Use of Cardiovascular Medications: DAPA-CKD Trial

Ricardo Correa-Rotter,[1] Glenn M. Chertow,[2] Patrick B. Mark,[3] Michal P. Nowicki,[4] Priya Vart,[5] Niels Jongs,[5] Anna Maria Langkilde,[6] John McMurray,[3] Peter Rossing,[7,8] David Sjostrom,[6] Bergur V. Stefansson,[6] Robert D. Toto,[9] David C. Wheeler,[10] Hiddo J. L Heerspink.[5,11] *[1]The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; [2]Stanford University School of Medicine, Stanford, CA; [3]University of Glasgow, Glasgow, United Kingdom; [4]Medical University of Lódz, Lódz, Poland; [5]University Medical Center Groningen, Groningen, Netherlands; [6]AstraZeneca, Gothenburg, Sweden; [7]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [8]University of Copenhagen, Copenhagen, Denmark; [9]UT Southwestern Medical Center, Dallas, TX; [10]University College London, London, United Kingdom; [11]The George Institute for Global Health, Newtown, NSW, Australia*.

Background: The DAPA-CKD trial (NCT03036150) demonstrated that dapagliflozin reduced the risk of kidney and cardiovascular (CV) events in patients with chronic kidney disease (CKD) and albuminuria with and without type 2 diabetes. We aimed to determine whether baseline CV medications modified dapagliflozin treatment effect.

Methods: We randomized 4304 adults with baseline eGFR 25–75 mL/min/1.73m^2 and urinary albumin-to-creatinine ratio 200–5000 mg/g to either dapagliflozin 10 mg or placebo once daily. The primary endpoint was a composite of ≥50% estimated glomerular filtration rate (eGFR) decline, end-stage kidney disease, and kidney or CV death. Here we categorized patients according to baseline CV medication use.

Results: Patients were required by protocol to receive a stable dose of a renin-angiotensin system inhibitor. The figure shows the effect of dapagliflozin compared with placebo, according to use of angiotensin-converting enzyme inhibitors or angiotensin receptor blockers (97.0%), calcium channel blockers (50.7%), beta-blockers (39.0%), diuretics (43.7%), antithrombotic (47.4%) and lipid-lowering (69.4%) agents. The benefit of dapagliflozin was consistent across all background treatment subgroups, and findings were similar for pre-specified secondary outcomes (composite kidney endpoint, composite CV endpoint, and all-cause mortality).

Conclusions: The beneficial effects of dapagliflozin on kidney and CV endpoints in patients with CKD and albuminuria were evident among patients treated and not treated with a variety of CV medications.

Quételet (Body Mass) Index and Effects of Dapagliflozin in CKD

Glenn M. Chertow,[1] Priya Vart,[2] Anna Maria Langkilde,[3] John McMurray,[4] Ricardo Correa-Rotter,[5] Peter Rossing,[6,7] David Sjostrom,[3] Bergur V. Stefansson,[3] Robert D. Toto,[8] Tom Greene,[9] David C. Wheeler,[10] Hiddo J. L Heerspink.[2,11] *[1]Stanford University School of Medicine, Stanford, CA; [2]University Medical Center Groningen, Groningen, Netherlands; [3]AstraZeneca, Gothenburg, Sweden; [4]University of Glasgow, Glasgow, United Kingdom; [5]The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [7]University of Copenhagen, Copenhagen, Denmark; [8]UT Southwestern Medical Center, Dallas, TX; [9]University of Utah Health, Salt Lake City, UT; [10]University College London, London, United Kingdom; [11]The George Institute for Global Health, Newtown, NSW, Australia*.

Background: The DAPA-CKD trial (NCT03036150) demonstrated a reduction of the risk of kidney and cardiovascular (CV) events with dapagliflozin in patients with chronic kidney disease (CKD) and albuminuria with and without type 2 diabetes. We aimed to assess the effects of the SGLT2 inhibitor dapagliflozin in patients stratified by Quételet (body mass) index (BMI).

Methods: We randomized 4304 adult patients with estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73m^2 and urinary albumin-to-creatinine ratio 200–5000 mg/g to dapagliflozin 10 mg or placebo once daily. The primary outcome was a composite of sustained decline in eGFR of ≥50%, kidney failure, or death from kidney or CV causes. Secondary outcomes were a kidney composite endpoint, a CV composite endpoint, and all-cause mortality. We categorized patients according to World Health Organization criteria: lean or ideal (BMI <25 kg/m^2), overweight (BMI 25 to <30 kg/m^2), grade 1 obesity (BMI 30 to <35 kg/m^2), and grade 2/3 obesity (BMI ≥35 kg/m^2).

Results: Among 4296 (99.8%) randomized patients with available height and weight data, 888 (20.7%), 1491 (34.7%), 1136 (26.4%), and 781 (18.2%) were categorized as lean or ideal, overweight, grade 1 obesity, and grade 2/3 obesity, respectively. Hazard ratios (HRs) (dapagliflozin versus placebo) and 95% confidence intervals (CIs) for the primary composite endpoint were 0.60 (0.43–0.85), 0.55 (0.40–0.75), 0.71 (0.49–1.04), and 0.57 (0.37–0.87), among patients in the lean or ideal, overweight, grade 1 obesity, and grade 2/3 obesity groups (interaction p=0.72), respectively, indicating no significant heterogeneity in the dapagliflozin treatment effect. Corresponding HRs (95%CI) for the kidney composite endpoint: 0.55 (0.38–0.80), 0.54 (0.37–0.78), 0.51 (0.32–0.83), and 0.60 (0.36–0.98) (interaction p=0.98); CV composite endpoint: 0.88 (0.44–1.74), 0.72 (0.44–1.19), 0.94 (0.60–1.48), and 0.46 (0.27–0.77) (interaction p=0.21); and all-cause mortality: 0.78 (0.44–1.40), 0.51 (0.33–0.79), 0.98 (0.60–1.62), and 0.65 (0.36–1.18) (interaction p=0.27).

Conclusions: Among patients with CKD and albuminuria, with or without type 2 diabetes, kidney and CV benefits of dapagliflozin were evident across the spectrum of body size.

PO2367

Efficacy and Safety of Roxadustat for the Treatment of CKD Anemia in Patients Enrolled in the United States as Compared with the Global Cohort

Shweta Bansal,[1] George M. Nassar,[2,3] Robert I. Lynn,[4] Pablo E. Pergola,[5] Tyson T. Lee,[6] Khalil G. Saikali,[6] Lynda Szczech.[6] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Weill Cornell Medicine, New York, NY; [3]Houston Methodist Hospital, Houston, TX; [4]Albert Einstein College of Medicine, Bronx, NY; [5]Renal Associates PA, San Antonio, TX; [6]FibroGen Inc, San Francisco, CA.*

Background: Roxadustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor increases hemoglobin (Hb) in non-dialysis (NDD) and dialysis dependent (DD) chronic kidney disease (CKD). Because of different clinical practices and demographic factors, it is important to evaluate efficacy and safety by region.

Methods: In a secondary analysis of data from 3 phase 3 studies of Roxadustat vs. placebo in NDD-, and 3 phase 3 studies of Roxadustat vs. epoetin alfa in DD-CKD, US patients were compared to the global cohort. Mean change from baseline in Hb averaged over weeks 28–52 regardless of rescue therapy and treatment emergent adverse events with occurrence in ≥5% of patients were assessed.

Results: Of the patients enrolled in the NDD and DD trials, 23.2% and 45.4% were enrolled in the US, respectively. Compared with global patients, US patients were older, had a higher BMI, and more frequently had type I or II diabetes mellitus and cardiovascular/thromboembolic diseases (Table). US DD patients had a higher mean baseline Hb (SD) (10.16 g/dL [0.92]) compared with the global cohort (9.65[1.30]). Efficacy was similar between US and global patients; least square mean (LSM) differences in NDD patients were 1.61 g/dL (95% CI: 1.48, 1.74) vs. 1.72 (95% CI:1.65, 1.79) (both p<0.0001) comparing roxadustat to placebo; LSM differences in DD patients were 0.33 (95% CI: 0.24, 0.42) vs. 0.26 (95% CI: 0.20, 0.33) (both p<0.0001) comparing roxadustat to epoeitin alfa. Safety was comparable between treatment arms in US and global patients.

Conclusions: Patients enrolled in the US were older and were more likely to have comorbidities in both the NDD and DD trials, Roxadustat efficacy and safety in the US were similar to global patients.

Correlates and Consequences of an Acute Decline in Estimated Glomerular Filtration Rate in Response to the SGLT-2 Inhibitor Dapagliflozin

Hiddo J. L Heerspink,[1,2] Niels Jongs,[1] Glenn M. Chertow,[3] Anna Maria Langkilde,[4] John McMurray,[5] Ricardo Correa-Rotter,[6] Peter Rossing,[7,8] David Sjostrom,[4] Bergur V. Stefansson,[4] Robert D. Toto,[9] Tom Greene,[10] David C. Wheeler.[11] *[1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Stanford University School of Medicine, Stanford, CA; [4]AstraZeneca, Gothenburg, Sweden; [5]University of Glasgow, Glasgow, United Kingdom; [6]The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; [7]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [8]University of Copenhagen, Copenhagen, Denmark; [9]UT Southwestern Medical Center, Dallas, TX; [10]University of Utah Health, Salt Lake City, UT; [11]University College London, London, United Kingdom.*

Background: In the DAPA-CKD trial (NCT03036150), dapagliflozin slowed the rate of progression of chronic kidney disease (CKD) in CKD patients with and without type 2 diabetes. However, dapagliflozin can cause a reversible acute decline in estimated glomerular filtration rate (eGFR), which is considered to be a hemodynamic effect. Predictors of the initial eGFR decline and its association with safety outcomes are unknown.

Methods: In DAPA-CKD, 4304 participants with urinary albumin-to-creatinine ratio (UACR) 200–5000 mg/g and eGFR 25–75 mL/min/1.73m^2 were randomized to dapagliflozin 10 mg or placebo once daily, added to standard care, and followed for median 2.4 years. We categorized decline in eGFR from baseline to Week 2 in percentages (>10% decline; between 0 and 10% decline; and no decline) and absolute changes (>3 mL/min/1.73m^2; between 0 and 3 mL/min/1.73m^2; and no decline).

Results: A total of 4157 patients (96.6% of full cohort) had eGFR data available at baseline and Week 2. In the dapagliflozin and placebo groups, 1026 (49.4%) and 494 (23.7%) experienced an acute decline in eGFR of >10%, respectively. The odds ratio for a decline in eGFR of >10% with dapagliflozin compared with placebo was 3.2 (95%CI 2.8–3.6; p<0.001). The odds ratio for an acute eGFR decline of >10% was consistent across patient subgroups defined by baseline sex, eGFR, UACR, diabetes status, blood pressure, body mass index, or cardiovascular disease history. The only exception was that white participants and participants ≥65 years were more likely to experience an acute eGFR decline of >10% following dapagliflozin initiation relative to placebo (interaction p<0.025 for both). Rates of serious adverse events and adverse events of special interest in those treated with dapagliflozin were unrelated to the degree of acute eGFR decline.

Conclusions: Although acute declines in eGFR occurred more frequently with dapagliflozin, it is not associated with an increased risk of adverse events, supporting the safe use of dapagliflozin in patients with CKD stage 2 to 4.

PO2369

A Comparison of the Efficacy of Patiromer Plus RAAS Inhibitor Therapy in Patients with CKD and Diabetes to a Cohort of Patients Not Using Patiromer: A Real-World Analysis Using Propensity Score Matching

Murray Epstein,[1] Jeffrey J. Budden,[3] Rajkumar Chinnadurai,[2] Philip A. Kalra.[2] *[1]University of Miami School of Medicine, Miami, FL; [2]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [3]Vifor Pharma Group, Redwood City, CA.*

Background: The AMETHYST-DN trial evaluated the use of patiromer (PAT) to treat hyperkalemia in patients (pts) with diabetes and CKD treated with RAASi. This analysis compared the progression of proteinuria and eGFR in AMETHYST-DN pts with a matched, real-world group of CKD pts with diabetes not receiving PAT.

Methods: Pts from AMETHYST-DN were closely matched with Salford Kidney Study (SKS) pts (a large CKD cohort in the United Kingdom). Matching was performed for age, gender, baseline systolic and diastolic blood pressure (BP), heart failure (HF) status, serum K^+ and eGFR by propensity scores generated from a logistic regression analysis (1:1, nearest neighbour method). All pts were followed up for a median duration of 12 months. The median change in proteinuria and eGFR between baseline and 12-month follow-up were compared between groups.

Results: Out of 3564 pts recruited into the SKS from Oct 2002 to Dec 2019, 526 diabetic pts were eligible for matching with the 304 AMETHYST-DN pts. Propensity score matching yielded a well-matched cohort of 142:142 pts for the trend analysis. Median age was 68 yrs, 68% were male, median BP was 152/80 mmHg, and 27% had HF. Median eGFR was 32.5 mL/min/1.73m^2 and uACR was 283 mg/g. RAASi use was 100% at baseline and 99% at follow-up in AMETHYST-DN pts. In contrast, RAASi use was 60% at baseline declining to 43% at 12-month follow-up in the SKS cohort. Trend analysis showed a significant difference in the rate of change in proteinuria at 12 months in AMETHYST-DN vs SKS pts (−31 mg/g vs +9 mg/g, p=0.023). No significant difference was observed for eGFR change (Table).

Conclusions: PAT enabled sustained RAASi use in 99% of pts in AMETHYST-DN, compared to 43% pts in a matched SKS cohort over 12 months. AMETHYST-DN pts had significantly reduced proteinuria at follow-up compared to SKS CKD pts, possibly due to continuation of RAASi enabled by PAT. No significant changes in eGFR were observed in either group.

Funding: Commercial Support - Vifor Pharma

Table. Outcomes in the matched sample of patients from AMETHYST-DN and Salford Kidney Study

Variable	AMETHYST-DN (n=142)	SKS cohort (n=142)	*p*-value
Serum potassium, mEq/L			
Baseline	5.2 (5.2 to 5.5)	5.3 (5.2 to 5.5)	0.671
Last follow-up	4.7 (4.3 to 4.9)	5 (4.6 to 5.4)	<0.001
Median change from baseline	−0.46 (−0.89 to −0.005)	−0.30 (−0.70 to 0.10)	0.071
eGFR, mL/min/1.73m^2			
Baseline	32 (23 to 41)	33 (26 to 41)	0.536
Last follow-up	32.5 (23 to 46)	31 (21.5 to 45)	0.303
Median change from baseline	−2 (−9 to 6)	−1 (−5 to 2.5)	0.72
uACR, mg/g			
Baseline	422.3 (72.1 to 1516)	294 (82.3 to 902)	0.616
Last follow-up	321.7 (49.3 to 1384)	343 (103 to 923)	0.282
Median change from baseline	−31.3 (−420.5 to 64.5)	8.8 (−176.4 to 173.5)	0.023
RAASi use, n (%)			
Baseline	142 (100%)	85 (59.8%)	<0.001
Last follow-up	140 (98.6%)	61 (42.9%)	<0.001
Follow up (months)	12.13 (2.96 to 12.1)	12.2 (11.43 to 12.03)	<0.001

All laboratory variables are expressed as median (interquartile range) and *p*-value was generated by Mann-Whitney U Test. uACR, urine albumin-to-creatinine ratio; RAASi, renin-angiotensin-aldosterone system inhibitors; SKS, Salford Kidney Study.

PO2370

Patiromer Enables Sustained RAAS Inhibitor Therapy over 52 Weeks: A Post Hoc Analysis of 246 Patients Who Completed the AMETHYST-DN Study

Murray Epstein,[1] Susan Arthur,[2] Jeffrey J. Budden.[2] *[1]University of Miami School of Medicine, Miami, FL; [2]Vifor Pharma Group, Redwood City, CA.*

Background: Hyperkalemia (HK) is a common electrolyte abnormality in CKD patients (pts) with type 2 diabetes mellitus (T2DM) and leads to underutilization of RAAS inhibitors (RAASi). KDIGO guidelines recommend RAASi dose should be reduced or discontinued only as a last resort in HK pts after measures to control serum potassium (sK) have failed. Patiromer (PAT) is a non-absorbed, sodium-free, K binder documented to reduce sK in pts with HK, and consequently enables sustained RAASi therapy. This post-hoc analysis of AMETHYST-DN analyzed in-depth the ability of PAT to maintain RAASi in a large cohort of pts with diabetic kidney disease (DKD) and HK who completed 1 year of treatment with PAT.

Methods: AMETHYST-DN was a multicenter, open-label trial of PAT in adult pts on RAASi with eGFR 15–<60 mL/min/1.73m^2, T2DM, hypertension, and HK (sK >5.0 mEq/L). Pts were randomized to PAT 8.4–33.6 g/d to start. The 52-wk study included an 8-wk treatment phase, followed, in pts on a stable PAT dose for ≥3 consecutive wks, by a 44-wk long-term maintenance phase (LTMP). This analysis evaluated dose modifications of RAASi among pts who completed the LTMP.

Results: 304 pts were randomized and received ≥1 PAT dose. Of these, 246 pts were on a stable PAT dose and entered the LTMP, and 197 pts completed 52 wks of treatment. All pts were receiving RAASi at baseline. By protocol, RAASi could not be downtitrated or discontinued because of HK during the study. In total, 195/197 pts who completed the LTMP remained on RAASi for the entire 44-wk LTMP period. Most pts (n=176) had no RAASi dose change, 14 had RAASi dose changes but remained stable or uptitrated, and 5 had their dose downtitrated. Of the 49 pts who withdrew early from the LTMP, 27 did so

for clinical reasons (AEs, 12; low sK, 5; death, 4; deterioration of renal function, 4; high sK, 2), whereas 22 had reasons related to investigator/patient factors (consent withdrawal, 12; noncompliance, 7; investigator decision, 1; other, 2). During the LTMP, ≥1 AE was reported for 158/246 pts.

Conclusions: This analysis of AMETHYST-DN demonstrates that the vast majority of hyperkalemic pts with DKD who completed the LTMP of the study were able to sustain their RAASi dose over an extended 44 weeks without downtitration or discontinuation of RAASi therapy. Only 2 pts withdrew early from the LTMP due to recurrent HK.

Predict Hyperkalemia in Advanced CKD Patients Using Machine Learning Algorithms

Hsin-Hsiung Chang,[1] Chia-Lin Wu.[2] *[1]Paochien Hospital, Pingtung, Taiwan; [2]Changhua Christian Hospital, Changhua, Taiwan.*

Background: Hyperkalemia is a common and fatal problem in advanced chronic kidney disease patients. The incidence rate was about 40-50%. It may cause muscle weakness, paralysis, and even cardiac arrhythmia. Our goal is to develop machine learning models to predict hyperkalemia in advanced chronic kidney disease patients, which could help physicians make clinical decisions.

Methods: We collected clinical data for advanced CKD (CKD stage 4 and 5, eGFR < 30 ml/min/1.73m2) patients receiving Output Patient Care in one medical center in Taiwan from January 2010 to December 2019. 1,965 patients were included. Four machine learning models (multilayer perceptron [MLP], logistic regression with regularization, XGBoost, and random forest [RF]) were used to estimate serum potassium concentration 3 months later. 2 Nephrologists participated in human-machine competition. Area under the receiver operating characteristic curves (AUCs), sensitivity, specificity, positive (PPV) and negative (NPV) predicted values, and accuracy were used to evaluate the performance of machine learning models with that of these physicians.

Results: In a test set including 2,074 records, the AUC of machine learning models was highest for XGBoost (0.843; 95% confidence interval [CI], 0.822–0.864). Moreover, the NPV and specificity were 0.875 and 0.943, respectively. The AUC for detecting hyperkalemia by humans was 0.602, 95% CI, 0.580–0.623. XGBoost model performed significantly better than humans ($P < 0.001$, using the DeLong test).

Conclusions: Machine learning models may help physicians make clinical decisions in advanced CKD patients who suffer from hyperkalemia in outpatient department care and possibly reduce cardiac arrhythmia.

PO2372

Association Between Dietary Potassium Intake and Abdominal Aortic Calcification in US Adults

Yuping Xie,[1] Matthew K. Abramowitz,[2] Wei Chen.[2] *[1]Children's Hospital at Montefiore, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: In ApoE-deficient mice, low dietary potassium intake promoted vascular calcification and high dietary potassium intake attenuated vascular calcification. We hypothesized high dietary potassium intake was associated with lower abdominal aortic calcification (AAC) among adults in the US.

Methods: Cross-sectional analyses were performed on 2535 participants from the National Health and Nutrition Examination Survey 2013-2014. Dietary potassium intake was obtained from two 24-h recall interviews and were categorized into quartiles (Q1:0.3-1.9, Q2: 2.0-2.4, Q3: 2.5-3.1 and Q4: 3.2-6.8 g/day). AAC was measured using dual-energy X-ray absorptiometry in adults over 40 years old and quantified using the Kauppila score system. AAC scores were categorized into: no AAC (AAC=0, reference group), mild/moderate (AAC>0-≤6) and severe AAC (AAC>6). Multinomial logistic regression was used to study the association between AAC and dietary potassium intake. Model was adjusted for demographics, hypertension, diabetes, smoking, eGFR, albuminuria, BMI, energy intake and physical activity.

Results: In the entire cohort, mean dietary potassium intake was 2.4±0.9 g/day; 21% had mild/moderate AAC and 9.4% had severe AAC. Dietary potassium intake was not associated with mild-moderate AAC (table). For severe AAC, dietary potassium intake was only associated with AAC when comparing dietary potassium in Q2 with Q1: Q2 was associated with lower odds of having severe AAC (OR 0.65 (95% CI: 0.46-0.92), p=0.02). This association remained significant in the fully adjusted model (OR 0.50 (95% CI: 0.29-0.86), p=0.02).

Conclusions: We found that higher dietary potassium intake was associated with lower odds of having severe AAC, but the association is only significant when comparing dietary potassium intake in Q2 with Q1. This nonlinear relationship between dietary potassium intake and AAC requires further investigations.

Funding: NIDDK Support

Multinomial logistic regression models of AAC with dietary potassium intake(g/day) in quartiles, N=2535

PO2373

Association of Rosuvastatin Use with Risk of Hematuria and Proteinuria

Jung-Im Shin,[1] Derek M. Fine,[3] Yingying Sang,[1,6] Aditya L. Surapaneni,[1] Stephan C. Dunning,[6] Lesley A. Inker,[5] Thomas D. Nolin,[2] Alex R. Chang,[4] Morgan Grams.[3] *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]University of Pittsburgh, Pittsburgh, PA; [3]Johns Hopkins Medicine, Baltimore, MD; [4]Geisinger Health, Danville, PA; [5]Tufts Medical Center, Boston, MA; [6]OptumLabs, Minnetonka, MN.*

Background: Early safety signals suggested potential nephrotoxicity with rosuvastatin, and the US FDA recommends a maximum dose of 10 mg for patients with severe CKD. Whether these recommendations are followed and whether rosuvastatin use is associated with nephrotoxicity in real-world practice is uncertain.

Methods: Using data from OptumLabs® Data Warehouse, a database that contains de-identified claims and electronic health record data, we identified adult patients who initiated rosuvastatin (N=155416) or atorvastatin (N=793513) in 44 health systems ("cohorts") between 2011-2019, were free of ESKD, and did not have history of hematuria or proteinuria at the time of prescription. The outcomes were hematuria (dipstick hematuria≥+ or presence of ≥3 red blood cells in urine microscopy) and proteinuria (dipstick proteinuria≥++ or urine albumin-to-creatinine ratio≥300 mg/g). We fit Cox models with inverse-probability of treatment weights within cohorts and then meta-analyzed using random-effects models.

Results: Overall, 2.6% and 0.8% of patients developed hematuria and proteinuria during a median follow-up of 2.6 years. Compared with atorvastatin, rosuvastatin was associated with an increased risk of hematuria (HR, 1.07 [95% CI, 1.03-1.11]) and proteinuria (1.18 [1.11-1.26]). Among those with eGFR<30 ml/min/1.73 m^2, rosuvastatin use was associated with greater risk of hematuria (1.78 [1.25-2.54]) and proteinuria (1.80 [1.15-2.83]) (**Figure**). Patients with eGFR<30 ml/min/1.73 m^2 frequently were prescribed a higher rosuvastatin dose than the maximum recommended dose of 10 mg; 30.5% received 20 mg while 14.4% received 40 mg.

Conclusions: Among patients with eGFR<30 ml/min/1.73 m^2, the use of higher-than-recommended dose rosuvastatin was common, and rosuvastatin was associated with an almost 2-fold increased risk of hematuria and proteinuria.

Hydrophilic vs. Lipophilic Statin Treatments in Patients with CKD After Acute Myocardial Infarction: A Propensity Score-Matched Comparison

Jongho Kim, Soo-Young Yoon, Dae Kyu Kim, Shinyeong Kang, Jin sug Kim, Kyung hwan Jeong, Hyeon Seok Hwang. *Kyung Hee University Medical Center, Seoul, Republic of Korea.*

Background: Effect of statin treatment is critical to prevent major adverse cardiac and cerebrovascular events (MACEs) after acute myocardial infarction (AMI). Earlier studies demonstrated that the lipophilicity of statin did not affect prognosis in AMI patients without renal dysfunction. However, the effect of statin lipophilicity was not investigated in chronic kidney disease (CKD) patients.

Methods: We enrolled total 2,020 AMI patients with chronic kidney disease (CKD) from Korea Acute myocardial Infarction Registry between November 2011 and December 2015. CKD was defined as an eGFR < 60mL/min/1.73 m^2. Patients were divided into two groups based; hydrophilic (n = 663), lipophilic (n = 1399) statin treatment. The primary endpoint was a combination of 2-year major MACEs after AMI occurrence. Subsequently, a propensity score matched analysis was performed.

Results: The lowest cumulative event rate of MACE (HR 0.71 [95% CI 0.55-0.91], p=0.007), all-cause mortality (HR 0.68 [95% CI 0.50-0.94], p=0.018), recurrent MI (HR 0.42 [95% CI 0.23-0.76], p=0.005) was observed in patients treated with hydrophilic statin in propensity -matched population. In multivariable Cox-regression analysis, compared to patients treated with lipophilic statins, patients treated with hydrophilic statins were associated with lower risk for composite of MACEs (HR 0.70 [95%

CI 0.55-0.90], p=0.005), all-cause mortality (HR 0.67 [95% CI 0.49-0.93], p=0.016) and recurrent MI (HR 0.40 [95% CI 0.21-0.73], p=0.003), but not for composite of revascularization, and ischemic stroke.

Conclusions: Hydrophilic statin treatment was significantly better to reduce MACEs and all-cause mortality than lipophilic statins in CKD patients with AMI.

PO2375

The Effect of Fibrates on Kidney Function and CKD Progression: A Systematic Review and Meta-Analysis of Randomised Studies

Alexandros Hadjivasilis,[1] Andreas Kousios,[2,3] Panayiotis Kouis,[1] Andrie G. Panayiotou.[1] *[1]Technologiko Panepistemio Kyprou, Limassol, Cyprus; [2]Hammersmith Hospital, London, United Kingdom; [3]Imperial College London, London, United Kingdom.*

Background: Fibrates have proven efficacy in cardiovascular risk reduction and are commonly used, in addition to statins, to control hypertriglyceridemia. Their use is often limited due to reduction in glomerular filtration rate at treatment initiation. However, recent studies suggest benign change in kidney function and improvement of proteinuria; an established early marker of microvascular disease and kidney disease progression. We summarize the evidence from existing trials and provide summary effects of fibrates, alone or in combination, on kidney disease progression and proteinuria.

Methods: Systematic review and Meta-analysis of randomised controlled trials(PROSPERO CRD42020187764).

Results: Out of 12243 potentially eligible studies, 29 were included in qualitative and quantitative analysis, with a total of 20176 patients. Mean creatinine increased by 1.05 [95% CI(0.63 to 1.46)] units in patients receiving fibrates vs comparator, and this was similar in all other subgroups. eGFR showed a bigger decrease in the fibrates arm [SMD -1.99; 95% CI(-3.49 to -0.48)] when all studies were pooled together. Notably, short-term serum creatinine and eGFR changes remained constant in the long-term. Pool estimates show that fibrates improve albuminuria progression, RR 0.86; 95% CI(0.76 to 0.98); albuminuria regression, RR 1.19; 95% CI (1.08 to 1.310)]. Two studies showed reduction in progression to ESKD, albeit without statistical significance.

Conclusions: Fibrates improve albuminuria in patients with and without diabetes when used to treat hyperlipidaemia. The modest creatinine increase should not be a limiting factor for fibrate initiation in people with preserved renal function or mild CKD. The long-term effects on kidney disease progression warrant further study.

PO2376

The Effect of Atrasentan on Kidney and Heart Failure Outcomes by Baseline Albuminuria and Kidney Function: A Post Hoc Analysis of the SONAR Trial

Simke W. Waijer,[1] Ron T. Gansevoort,[1] George L. Bakris,[2] Ricardo Correa-Rotter,[3] Fan Fan Hou,[4] Donald E. Kohan,[5] Hirofumi Makino,[8] John McMurray,[6] Vlado Perkovic,[7] Sheldon W. Tobe,[9] Hans-Henrik Parving,[10,11] Dick de Zeeuw,[1] Hiddo J. L Heerspink.[1] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]The University of Chicago Medicine, Chicago, IL; [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [4]Southern Medical University Nanfang Hospital, Guangzhou, China; [5]University of Utah Health, Salt Lake City, UT; [6]University of Glasgow, Glasgow, United Kingdom; [7]The George Institute for Global Health, Newtown, NSW, Australia; [8]Okayama Daigaku, Okayama, Japan; [9]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [10]Rigshospitalet, Kobenhavn, Denmark; [11]Aarhus Universitet, Aarhus, Denmark.*

Background: Atrasentan reduces kidney failure risk, but increases risk of edema and possibly heart failure in patients with diabetic kidney disease. Patients with advanced chronic kidney disease (CKD) may obtain greater absolute renal benefit from atrasentan but may be at higher risk of fluid retention due to impaired renal excretory capacity. We assessed effects of atrasentan on kidney and heart failure events according to baseline eGFR and albumin:creatinine ratio (UACR) in a post-hoc analysis of the SONAR trial.

Methods: The effect of atrasentan versus placebo in 3668 patients with type 2 diabetes and CKD with elevated UACR was examined in SONAR. We used Cox regression to study effects on the primary kidney outcome (doubling of serum creatinine, end-stage kidney disease or renal death) and heart failure hospitalization across subgroups of eGFR (<30, ≥30-45, ≥45 ml/min/1.73m^2) and UACR (<1000, ≥1000-3000, ≥3000 mg/g).

Results: Atrasentan reduced the relative risk of the primary kidney outcome (HR 0.71, 95%CI 0.58-0.88) consistently across subgroups of baseline eGFR and UACR (table). Patients in the highest UACR and lowest eGFR subgroups showed the largest absolute benefit (all P-interaction <0.01). The relative (HR 1.39, 95%CI 0.97-1.99) and absolute risk of heart failure hospitalization was consistent across eGFR or UACR subgroups (all P-interaction >0.09).

Conclusions: Atrasentan reduced the relative risk of the primary kidney outcome consistently across baseline UACR and eGFR subgroups. The absolute risk reduction was greater among patients in the lowest eGFR and highest albuminuria subgroup who were at highest baseline risk. However, the relative and absolute risk of heart failure hospitalization were similar across baseline UACR and eGFR subgroups. These results support the initiation of atrasentan in high risk patients with CKD and significant albuminuria.

	Atrasentan n/N	Placebo n/N	HR (95% CI) for primary kidney outcome	P interaction
UACR <1000	36/1062	44/1065	0.82 (0.53-1.28)	0.208

PO2377

The Comparative Effectiveness and Safety of Rivaroxaban and Warfarin Initiation in Adults with Atrial Fibrillation (AF) by eGFR Category

Jeffrey Ha,[1,2] Martin P. Gallagher,[1,2] Min Jun.[1,2] KODIAC-AF Project Team *[1]The George Institute for Global Health, Newtown, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia.*

Background: The risk-benefit ratio of rivaroxaban, a commonly prescribed direct oral anticoagulant, relative to warfarin in patients with atrial fibrillation (AF) and CKD is uncertain.

Methods: We conducted an international multicenter cohort study(2011-2018) using healthcare data from 5 jurisdictions across Australia (530 participants of the 45 and Up Study [among 267153 recruited in 2006-09] with data, accessed via SURE, linked to hospital/laboratory data [by CHeReL] and the Medicare Benefits Schedule and Pharmaceutical Benefits Scheme data provided by Services Australia) and Canada (55038 patients in AB,BC,MB,ON; record linkage of provincial administrative/laboratory data). We propensity score matched adults with a new dispensation of rivaroxaban or warfarin, who had AF and a recorded eGFR grouped as≥60,45-59,30-44 and <30 ml/min/1.73m^2. Chronic dialysis or kidney transplant recipients were excluded. We assessed 2 composite outcomes within 1 year of initiating either therapy: ischemic (all-cause death, ischemic stroke or transient ischemic attack) and bleeding events (intracranial, gastrointestinal or other). We used Cox regression to estimate the hazard ratios of each outcome across eGFR categories and summarized centre data in random effects meta-analysis.

Results: Of the 55568 matched rivaroxaban and warfarin users, 4733(8.5%) experienced an ischemic event and 1144(2%) a bleeding event. As compared to warfarin initiation, rivaroxaban initiation was associated with lower or similar hazard for the ischemic outcome HR(95% CI) of 0.72(0.66-0.78), 0.82(0.58-1.16), 0.70(0.57-0.87) and 0.78(0.62-0.99), for eGFR ≥60, 45-59, 30-44 and <30ml/min/1.73m^2 respectively. Rivaroxaban initiation was also associated with lower or similar hazard for the bleeding outcome (0.70[0.49-1.00], 1.00[0.78-1.29], 0.85[0.64-1.12], 0.61[0.35-1.05]). We observed no evidence of heterogeneity across centers except for eGFR 45-59ml/min/1.73m^2 for the ischemic outcome(I^2=77%) and ≥60ml/min/1.73m^2 for the bleeding outcome(I^2=62%).

Conclusions: Compared to warfarin, rivaroxaban initiation was associated with lower or similar risk of both ischemic and bleeding outcomes independent of eGFR. Sufficiently powered randomized trials are needed to confirm findings from this large international cohort.

Risk of Bleeding Associated with Direct Oral Anticoagulants Is Higher Among Patients with Concomitant Use of Diltiazem in Patients with and without CKD

Yunwen Xu,[1] Alex R. Chang,[2] Lesley A. Inker,[3] Mara McAdams-DeMarco,[1,4] Morgan Grams,[1,4] Jung-Im Shin.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Geisinger Health, Danville, PA; [3]Tufts Medical Center, Boston, MA; [4]Johns Hopkins Medicine, Baltimore, MD.*

Background: Inhibitors of the cytochrome P450 3A4 (CYP3A4) and P-glycoprotein (P-gp) systems can increase blood levels of direct oral anticoagulants (DOACs). Diltiazem, a moderate CYP3A4/P-gp inhibitor, is commonly used for heart rate control in patients with atrial fibrillation (AF). We hypothesized that the co-administration of diltiazem with DOACs would be associated with bleeding events, particularly in patients with CKD.

Methods: We identified adult patients with AF and without end-stage kidney disease in the Geisinger Health System who initiated any DOAC between 2010-2018. We used Cox proportional hazard models with time-varying exposure to diltiazem, adjusting for characteristics at DOAC initiation as well as time-varying eGFR and use of antiplatelets and nonsteroidal anti-inflammatory drugs. We examined whether the risk of bleeding differed by CKD (eGFR <60 ml/min/1.73 m^2) status. As a negative control, we repeated the same analysis among warfarin users (n=13179), since there is no known interaction between warfarin and diltiazem.

Results: Among the 4544 patients who initiated apixaban (n=2373), rivaroxaban (n=1583), or dabigatran (n=588), the mean (SD) age was 72 (12) years, 45% were female, and the average eGFR was 69 (21) mL/min/1.73 m^2. At the time of DOAC initiation, 15% were on diltiazem and additional 4% initiated diltiazem during the follow-up. Among DOAC users, concomitant use of diltiazem was associated with a higher risk of bleeding (hazard ratio, 1.64; 95% confidence interval [CI]: 1.20-2.24), consistently across CKD status (**Figure A**). Among warfarin users (the negative control), concomitant use of diltiazem was not associated with bleeding (**Figure B**).

Conclusions: Concomitant use of diltiazem with DOACs was associated with a higher risk of bleeding in patients with AF, with similar risk with and without CKD.

Association of Long-Term Aspirin Use with Progression of Kidney Disease

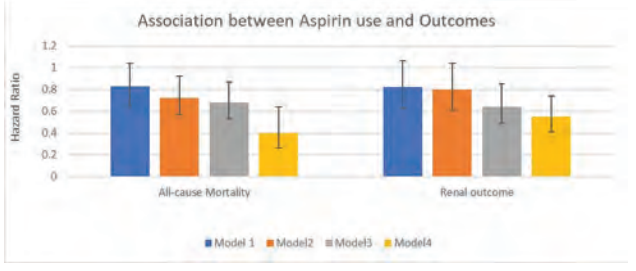
Jun Ling Lu,[1] Fridtjof Thomas,[1] Keiichi Sumida,[1] Waleed Hassan,[1] Csaba P. Kovesdy.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Background: Aspirin (ASA) has been used to control inflammation for over a century. Recently, chronic microinflammation was detected to be a major contributor to the progression of chronic diseases such as cancer and chronic kidney disease (CKD). However, it is unclear if long-term use of ASA could lower mortality and slow renal deterioration in patients with CKD.

Methods: We identified 860 US Veterans with non-dialysis dependent CKD followed at a single medical center between October 2014 to September 2015. Associations between long-term ASA use (at least 90 days) with mortality, and with a combined renal outcome (dialysis or eGFR dropping 40% from baseline) were examined in multivariable adjusted Cox proportional hazards models. Besides the crude model (model 1), we adjusted for demographics, BMI, smoking status, blood pressure (model 2), for comorbidities (Model3), and for antihypertensive medications, NSAIDs, steroids, baseline eGFR, medication adherence rate, and proteinuria (Model 4).

Results: The mean age (SD) of ASA users vs. non-users was 68.1 (9.9) vs. 64.2 (13.1) years, and the mean eGFR (SD) was 36.9 (0.7) ml/min/1.73m² vs. 43.7 (2.0). Over a 4.6-year median follow-up period, 37% of patients reached the combined renal endpoint (event rate: 102.8/1000 patient-years) and 372 (43%) patients died. ASA users demonstrated a lower risk of the renal outcome (Hazard Ratio [HR] 0.55[95%CI: 0.41, 0.74], p<0.001) and a lower mortality rate (HR 0.40[95%CI: 0.26, 0.64], p<0.001) in the fully adjusted model [Figure].

Conclusions: CKD patients receiving ASA for 90 days or longer had slower deterioration of kidney function and lower mortality. Further clinical trials are required to investigate the benefits of ASA in this population.



PO2380

Treatment of Hyperuricemia and Incident CKD in Patients with Normal Kidney Function

Waleed Hassan,[1] Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Keiichi Sumida,[1] Fridtjof Thomas,[2] Elani Streja,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Irvine, Irvine, CA; [4]VA Memphis Medical Center, Memphis, TN.*

Background: Hyperuricemia is associated with incident chronic kidney disease (CKD) independent of established metabolic risk factors. Treatment of hyperuricemia with uric-acid lowering therapy (ULT) was not beneficial in clinical trials of patients with CKD, but the effects of ULT on incident CKD in patients with no pre-existing CKD is unclear.

Methods: We identified a national cohort of US Veterans with normal kidney function (eGFR ≥60 ml/min/1.73m² and no proteinuria) and serum uric acid measurement. We examined the association of incident new ULT use (vs. no ULT), with the incidence of CKD (defined as 2 measurements of eGFR <60 ml/min/1.73m² or UACR >30 mg/gm at least 90 days apart), using time dependent Cox models adjusted for baseline demographic characteristics, comorbid conditions, and time dependent eGFR and serum uric acid concentration.

Results: We identified 1,152,040 patients with a serum uric acid measurement, of whom 111,508 (10%) patients received de novo ULT during 2006-2019. The overall mean (SD) age was 59 ±13 years, 94% were male, 76% were white, and the mean (SD) eGFR was 84 (17) ml/min/1.73m² at the cohort entry. There were 308,311 cases of incident CKD (event rate, 40.4/1000 PY; 95%CI, 40.3-41.6) over a median follow-up of 6.1 years. ULT was associated with higher risk of incident CKD in both crude models (hazard ratio, 2.57; 95%CI, 2.55-2.60) and after multivariable adjustments (HR, 1.45; 95%CI, 1.44-1.47) [table].

Conclusions: Although hyperuricemia is independently associated with risk of CKD, treatment of hyperuricemia with ULT was not associated with lower risk of incident CKD in patients with baseline normal kidney function and no proteinuria in a large national cohort.

Funding: Veterans Affairs Support

	N (%)	Incident CKD event rate	Crude hazard ratio (95% CI)	Multivariable adjusted hazard ratio (95% CI)
No ULT	1,040,532 (90)	36.5/1000 PY	Referent	Referent
ULT	111,508 (10)	91.8/1000 PY	2.57 (2.55-2.60)	1.45 (1.44-1.47)

PO2381

Trial Design of FRONTIER: Ferric Citrate for the Prevention of Renal Failure in Adults with Advanced CKD

Geoffrey A. Block,[1] Martha Block,[1] Stephanie Brillhart,[1] Mary O. Dittrich,[1] Glenn M. Chertow,[2] Navdeep Tangri.[3] *[1]US Renal Care, Inc, Plano, TX; [2]Stanford University School of Medicine, Stanford, CA; [3]University of Manitoba, Winnipeg, MB, Canada.*

Background: There are no approved therapies to delay progression to RRT or improve survival specifically in patients with advanced CKD regardless of etiology. A pilot, open-label randomized trial in 200 patients with estimated GFR < 20 ml/min/1.73m2 demonstrated statistically significant reduction in the risk of the composite endpoint of death, dialysis or transplantation in patients randomized to fixed dose ferric citrate coordination complex (FCCC) as compared to standard of care (SOC). The current trial is designed to overcome the limitations of this open-label RCT by using a pragmatic, placebo-controlled, randomized trial design.

Methods: FRONTIER will enroll 1000 patients with estimated GFR < 20 ml/min/1.73m2 who will be randomized 1:1 to either fixed dose FCCC (2 tablets/meal) or matching placebo. Enrollment will not be based on serum concentrations reflecting iron sufficiency or phosphate. Subjects will be followed for 18 months using a pragmatic schedule based solely on SOC visits. No additional trial specific visits or laboratory tests will be required. The primary objective is to determine the effect of FCCC on the time to a composite endpoint of initiation of maintenance dialysis or all-cause mortality compared to placebo. The secondary objective is to evaluate the impact of FCCC on all-cause hospitalization and the individual components of the primary endpoint.

Results: FRONTIER is a collaboration between Industry (Akebia Therapeutics is providing study medication and funding), community nephrologists (planned for 42 sites in the US) and academia. An executive steering committee has designed the clinical trial protocol and US Renal Care, Inc will be acting as the Sponsor-Investigator.

Conclusions: Based on supportive pilot data, FRONTIER will utilize a novel trial design incorporating a pragmatic approach while maintaining a randomized, placebo-control arm and generating real-world evidence to determine the effects of FCCC on clinically meaningful patient outcomes (time to dialysis or all-cause mortality).

Effect of Oral Sodium Bicarbonate on Biomarkers of Bone Turnover in CKD: A Secondary Analysis of the BASE Pilot Trial

Kalani L. Raphael,[1,2] Ronit Katz,[3] Tamara Isakova,[4] Stuart M. Sprague,[5] Myles Wolf,[6] Dominic S. Raj,[7] Andrew N. Hoofnagle,[3] Brett Larive,[10] Cynthia A. Kendrick,[10] Jennifer J. Gassman,[10] Linda F. Fried,[11] Alfred K. Cheung,[8] Joachim H. Ix.[9] *[1]Oregon Health & Science University School of Medicine, Portland, OR; [2]Portland VA Medical Center, Portland, OR; [3]University of Washington, Seattle, WA; [4]Northwestern University, Evanston, IL; [5]NorthShore University HealthSystem, Evanston, IL; [6]Duke University, Durham, NC; [7]George Washington University Medical Faculty Associates, Washington, DC; [8]University of Utah Health, Salt Lake City, UT; [9]University of California San Diego, La Jolla, CA; [10]Cleveland Clinic, Cleveland, OH; [11]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: CKD clinical practice guidelines recommend treatment with alkali to mitigate adverse effects of metabolic acidosis on several organ systems, including bone. The effect of alkali supplementation on bone turnover in CKD is unclear. We performed a secondary analysis of the Bicarbonate Administration to Stabilize eGFR (BASE) Pilot Trial to investigate the effect of $NaHCO_3$ on biomarkers of bone turnover.

Methods: BASE randomized 194 individuals with eGFR 20-59 ml/min/1.73m^2 to receive placebo (n=52) or one of two doses of $NaHCO_3$ (0.5 mEq/kg/d, n=52; 0.8 mEq/kg/d, n=90) for 28 weeks. We measured serum parathyroid hormone (PTH), bone-specific alkaline phosphatase (B-SAP), c-telopeptide (CTX, marker of bone resorption), and procollagen type I intact N-terminal propeptide (PINP, marker of bone formation) levels from stored samples collected at baseline, week 12, and week 28, and compared the mean change from baseline between placebo and those treated with $NaHCO_3$ using linear mixed models.

Results: 168 of 194 participants (86%) submitted samples for post-hoc measurements (placebo, n=46; lower-dose, n=47; higher-dose, n=75). Baseline characteristics were age 67±12 years, female 28%, Black, 32%, Hispanic 15%, eGFR 37±10 ml/min/1.73m^2, serum total CO_2 24±3 mEq/L, B-SAP 12.8±5.6 µg/L, CTX 0.36±0.38 ng/mL, PINP 57±31 ng/mL. $NaHCO_3$ treatment raised PTH and lowered B-SAP, however there was no significant difference when compared to placebo. $NaHCO_3$ treatment had no effect on CTX or PINP (Table).

Conclusions: $NaHCO_3$ treatment did not have consistent effects on biomarkers of bone turnover as assessed by PTH, B-SAP, CTX, or PINP, and no significant effects relative to placebo in patients with CKD.

Can Structured, Moderate Exercise Slow Kidney Function Decline in Sedentary Elders?

Michael Shlipak,[1,2] Fang-Chi Hsu,[6] Vasantha Jotwani,[1,2] Gregory J. Tranah,[7] Roger A. Fielding,[8] Christine Liu,[3] Joachim H. Ix,[4] Steven G. Coca.[5] *[1]University of California San Francisco, San Francisco, CA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]Stanford University, Stanford, CA; [4]University of California San Diego, La Jolla, CA; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Wake Forest University, Winston-Salem, NC; [7]California Pacific Medical Center, San Francisco, CA; [8]Tufts University, Medford, MA.*

Background: In numerous observational studies, higher physical activity is associated with slower declines in kidney function; however, no large trial has evaluated whether exercise can ameliorate kidney function decline in older adults. The Lifestyle Interventions and independence For Elders (LIFE) was a randomized clinical trial that demonstrated that a structured, moderate intensity physical activity (PA) intervention compared to a health education (HE) control intervention reduced the incidence of major disability among sedentary elders.

Methods: The LIFE-Kidney ancillary study evaluated whether this exercise intervention impacted the primary outcome of rate of eGFR change over two years. Participants were men and women aged 70-89 who reported being sedentary and were considered high risk for mobility impairment. Blood samples were collected pre-randomization (n=1,179), and at years 1 (n=1,155) and 2 (n=1,044) of follow-up; cystatin C was measured, and GFR was estimated by the CKD-EPI equation. Change in eGFR by cystatin C was the primary endpoint; rapid decline was defined by the high tertile threshold of 6.7%/year.

Results: At baseline, the two groups were well balanced by age, comorbidity and physical limitations, and had comparable eGFR. The PA group had eGFR values 0.5 and 1.5 ml/min/1.73m2 higher at years 1 and 2, respectively, and the average effect across the 2 follow-up visits was significantly different (p=0.04). Those in the PA arm were also less likely to experience a >6.7% annual eGFR decline compared to the HA arm (Table). In the PA arm, total steps completed was strongly associated with reduced eGFR decline (p=0.001), and mediated the effect of randomization to PA compared with HE (F statistic attenuated from 4.09 to 1.84).

Conclusions: Among sedentary elders, randomization to a program of moderate exercise slowed kidney function decline over 2 years compared with a control arm of health education.

Effect of Applying 6% Low-Protein Formula to Dietary Advice in Elderly CKD Patients: A Randomized Control Trial

Cheng-Hsu Chen, Wen-Ching Yang, Li-Chun Liu, Hui-Min Hsieh. *Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: The majority of researches have suggested the benefit of low-protein diet (LPD) could delay renal function progression in chronic kidney disease(CKD), but LPD increases the risk of malnutrition. The propose of this study to determine the effectiveness of dietary advices used by 6% low protein formula (6% LPF) for elderly CKD patients.

Methods: Patient were recruited aged over 65 years old who were diagnosed stages 3-5 CKD .There were randomized to general LPD advice (control group) or LPD advice combined with application 6% LPF (intervention group) for renal dietitian during 3 months treatment. 6% LPS were prescribed daily, providing 400 kcal energy, 6 g of protein. The data analyzed were measured body weight (BW), body mass index (BMI), hand grip strength (HGS)in nutrition status and blood urea nitrogen (BUN), creatinine and estimated glomerular filtration rate (eGFR) in kidney function parameter.

Results: 95 patients enrolled, and 47 completed of this study was distribution to intervention group (n=24) and control group (n=23). During the study period, HGS was maintain in intervention group but decreased significantly in control group (P<0.02) However, BW and BMI in both group were no significant differences. BUN was significantly reduced in intervention group (p = 0.003) but not control group (p = 0.059). There were no differences in creatinine and eGFR between groups at baseline to 3 months.

Conclusions: Compared with routine LPD prescription, which combined with supplement 6% LPF was associated with maintained nutrition status and prevention on of renal failure. Our findings suggested that 6% LPF was a complementary strategy routine LPD education protocol.

Incident Biologic Use and Risk of ESKD in Patients with Inflammatory Bowel Disease

Geeta G. Gyamlani,[1,2] Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Fridtjof Thomas,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN; [3]University of California Irvine, Irvine, CA.*

Background: Inflammatory bowel disease (IBD) is associated with reduced kidney function, possibly due to chronic inflammation or the use of nephrotoxic therapies. Little is known about the effects of IBD therapy using novel biologic agents on the risk of incident end-stage kidney disease (ESKD).

Methods: In a nationwide cohort of 66,602 US veterans with an eGFR ≥60 mL/min/1.73m^2 from 2004-2006 who were newly diagnosed with IBD (at least 2 IBD diagnoses that were 30-365 days apart) during follow-up through 2018, we examined the association of incident biologic use (as a time-dependent exposure) with incidence of ESKD, using time-dependent Cox models adjusted for sociodemographics, smoking and alcohol use, comorbidities, eGFR, vital signs, and relevant medications (e.g., antihypertensives, NSAIDs, steroids, nonbiologic DMARDs).

Results: Patients were 69±11 years old; 93% were male; 7.4% were African American; 30% were diabetic; and baseline eGFR was 77±16 mL/min/1.73m². Among 66,602 patients, 1,047 (1.6%) started biologic therapy, and 504 (0.8%) experienced an incident ESKD. In a sociodemographic-adjusted model, incident biologic use (vs. non-use) was associated with lower risk of incident ESKD (adjusted HRs [95%CI], 0.55 [0.20-1.49], in model 1) albeit not reaching statistical significance. This association was attenuated after further multivariable adjustment (0.98 [0.41-2.35], in model 4; **Figure**).

Conclusions: Biologic agent administration is not associated with higher risk of incident ESKD. Clinical trials are warranted to test whether active interventions with biologic agents are safe and effective in preventing adverse renal outcomes associated with IBD.

PO2386

Decreased Progression of CKD in Patients Undergoing Fecal Microbiota Transplantation (FMT)

Giovanna Y. Arteaga Muller, Adrian Camacho-Ortiz, Elvira Garza-Gonzalez, Samantha M. Flores-Treviño, Paola Bocanegra-Ibarias, Graciela C. Fabela-Valdez, Norma Y. Rodriguez-Arroyo. *Hospital Universitario Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico.*

Background: Prevalence of CKD is 8 to 16% in different stages, considered the main cause of emergency and hospital care in Mexico and catastrophic disease, its main causes: diabetes, arterial hypertension and glomerulonephritis. Treatment to prevent progression consists of inhibitors of the renin angiotensin aldosterone system, control of the underlying disease and blood pressure. The estimate of the loss of glomerular filtration rate is 2.3 to 4.5 ml/min per year in CKD patients. The intestinal microbiota has protective, structural and metabolic functions, there is a bidirectional interference of the microbiota and the host maintaining a symbiotic relationship, in CKD patients uremia affects the composition and metabolism of the microbiota, generating dysbiosis that is the absence of balance in the microbiological community generating an increase in the progression of CKD and an increase in the production of N-trimethylamine oxide, indoxyl sulfate and p-cresol sulfate associated with greater cardiovascular events in CKD patients, FMT has been used to correct dysbiosis in some pathologies.

Methods: A prospective, randomized, double-blind, comparative, placebo-controlled clinical trial, carried out at the University Hospital in Monterrey Mexico, in patients diagnosed with CKD due to diabetes and or hypertension, in stages 2, 3, 4 and 5 without renal replacement therapy, divided into 2 groups, MFT group: Microbiota fecal capsules, placebo group: placebo capsules, in both groups 15 capsules were administered every 12 hours for 2 days, on days 0, 10, 30, with a 6-month follow-up to demonstrate the difference in the progression of renal failure.

Results: 28 patients were randomized, the CKD of the placebo group progressed by 53.8% vs 13.3% of the TMF group Fisher's exact test *p* value = 0.0418 (Table 1).

Conclusions: The difference in the proportion of patients who did not decrease their GFR at 6 months was statistically significant, in the present study the patients who received FMT had less progression of CKD at 6 months. FMT was associated with a protective factor.

Association of Kidney Measures with Cardiovascular Events, Kidney Outcomes, and Mortality Among Older Adults

Valentina Turbay Caballero,[1] Ana C. Ricardo,[2] Jinsong Chen,[2] Kirolos Iskander,[2] Gustavo Aroca Martinez,[4] James P. Lash,[2] Carlos G. Musso.[3] *[1]Universidad del Norte, Barranquilla, Colombia; [2]University of Illinois at Chicago, Chicago, IL; [3]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [4]Universidad Simon Bolivar, Barranquilla, Colombia.*

Background: Based on current criteria (glomerular filtration rate [GFR] <60 ml/min/1.73m² or urine albumin-to-creatinine ratio [UACR] ≥30 mg/g), the prevalence of CKD in U.S. older adults is up to 42% among those aged 65-79 years. However, the risk implications of this CKD definition in this population are controversial. We evaluated the risk of adverse outcomes among older adults across CKD stages based on the Kidney Disease Improving Global Outcomes (KDIGO) definition.

Methods: This study included 2640 older adults (age ≥75 years) without diabetes enrolled in the Systolic Blood Pressure Intervention Trial (SPRINT). We compared the risk of the primary composite SPRINT outcome, and all-cause death, across GFR and albuminuria categories based on KDIGO guidelines. To estimate GFR, we used the CKD Epidemiology Collaboration (CKD-EPI) equation and the Berlin Initiative Study (BIS1), a novel estimator of GFR in elderly persons.

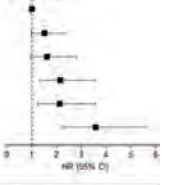
Results: Mean age was 79.8 years, 37.9% were female, 17.0% of participants self-identified as non-Hispanic Black, 6.6% as Hispanic, and 74.6% as non-Hispanic White. Mean estimated GFR was 63.3 ml/min/1.73 m², and median UACR 55 mg/g. In multivariable regression analysis, there was no statistically significant difference in the risk of the primary outcome among participants with UACR <30 mg/g, regardless of GFR level (**Table**). However, compared with participants with GFR ≥60 ml/min/1.73 m² and UACR <30 mg/g, those with UACR ≥30 mg/g had higher risk of the primary outcome at all levels of GFR, with the highest risk observed among those with GFR <45 ml/min/1.73 m². Similar results were observed with the BIS1 equation was used to estimate GFR.

Conclusions: Among older adults without diabetes, increased albuminuria was associated with adverse cardiovascular outcomes at all levels of GFR. However, low GFR was not associated with adverse outcomes in participants with normal albuminuria. These results support the proposal of an age-adapted definition of CKD.

Funding: NIDDK Support

Table. Primary composite SPRINT outcome by categories of GFR and albuminuria

GFR (ml/min/1.73 m²) and UACR (mg/g) categories	No. of events/ No. of participants (%)	Event Rate per 100 Person-Years	Hazard Ratio (95% CI)*
GFR ≥60 and UACR <30	44/1187 (3.7)	1.2	Referent
GFR 45-60 and UACR <30	34/538 (6.3)	1.99	1.53 (0.98, 2.41)
GFR <45 and UACR <30	19/242 (7.9)	2.49	1.62 (0.94, 2.81)
GFR ≥60 and UACR ≥30	24/282 (8.5)	2.91	2.16 (1.31, 3.56)
GFR 45-60 and UACR ≥30	21/210 (10.0)	3.31	2.12 (1.25, 3.59)
GFR <45 and UACR ≥30	35/181 (19.3)	6.47	3.57 (2.25, 5.65)



*Adjusted for age, sex, race/ethnicity, randomization arm, baseline systolic blood pressure, diastolic blood pressure, cardiovascular disease, total cholesterol and LDL-cholesterol.

Validation of Novel Cystatin C (CysC) Rapid Measurement Assay with Human Saliva

Manal Beshay,[1] Trong Nguyen,[1] Maria Ortega,[1] Danh V. Nguyen,[2] Connie Rhee,[2] Kamyar Kalantar-Zadeh.[2] *[1]Intelligent Optical Systems, Inc., Torrance, CA; [2]University of California Irvine, Irvine, CA.*

Background: Rapid, frequent point-of-care (POC) monitoring of kidney filtration markers such as cystatin C (CysC) that does not require laborious blood specimen draws/processing can improve chronic kidney disease (CKD) patient outcomes and care. Saliva as a non-invasive biofluid for monitoring kidney function addresses a clinical need for rapid diagnostics in POC and home-based testing. Emerging data suggests CysC as a more reliable kidney filtration marker than creatinine because it is not affected by age, race, ethnicity, or body mass.

Methods: Our Enhanced Lateral Flow (ELF) immunoassays were validated against a commercial ELISA kit for quantitative measurement of CysC in 76 human healthy and CKD patient saliva samples. We applied Pearson correlation and Bland-Altman analysis to compare the two data sets, and assessed inter-assay repeatability by validating the coefficient of variation (CV) across measurements for the samples. Each sample was measured in triplicate (n=3) to obtain the CV value. The ELF assay was tested with 116 samples, and ELISA with 51 samples, due to limited resources.

Results: The ELF assay CysC assessment showed high correlation to the ELISA measurements, with Pearson r=0.78 (Fig. A). Bland-Altman analysis showed a minor bias of -0.017 mg/L between the two assays (Fig. B). Both assays demonstrated a <10% CV for most of the tests, with the ELF assay presenting a lower overall mean CV (6.5%) than the ELISA kit (7.2%) (Fig. C). Data from stability studies verified that the ELF assay maintains functionality at Day 510 when stored at room temperature.

Conclusions: We have demonstrated rapid measurement of CysC in human saliva with our novel ELF assay, with acceptable POC characteristics, and repeatability and reproducibility equivalent to ELISA. The ELF assay provided more accurate and faster

results (<30 min. vs. 3 hr. for ELISA), and also demonstrated a longer shelf life (stable at 510 days at ambient vs. ELISA requirements for storage at -20°C with a 1 yr. expiration date). Future validation studies could lead to a saliva testing framework for kidney function markers, and a potential paradigm shift in the monitoring and care of CKD patients.

PO2389

Kidney Filtration Markers: Accuracy and Reproducibility of Novel Serum Cystatin C Measurements in a Point-of-Care Rapid Test Platform

Kamyar Kalantar-Zadeh,[1] Manal Beshay,[2] Connie Rhee,[1] Trong Nguyen,[2] Maria Ortega,[2] Amy S. You,[1] Rene Amel Peralta,[1] Danh V. Nguyen.[1] *[1]University of California Irvine, Irvine, CA; [2]Intelligent Optical Systems, Inc., Torrance, CA.*

Background: Emerging data suggests cystatin C (CysC) as a more reliable kidney filtration marker than creatinine because it is unaffected by age, race, ethnicity, or body mass. In the US, the standard approach to assess blood-based CysC measurements is invasive phlebotomy followed by laborious blood specimen processing. There is a major unmet need for non-invasive point-of-care (POC) measurement of this kidney filtration marker. To fill this gap, we have recently developed and validated novel Enhanced Lateral Flow (ELF) immunoassays to measure CysC in human blood.

Methods: Validation of our ELF assays was performed in two steps. First, Pearson correlation and Bland-Altman analysis were used to assess the correlation, agreement and bias of ELF measurements to UCI Medical Center lab standard measurements from a set of 70 serum samples obtained from chronic kidney disease (CKD) patients. Then, Receiver Operating Characteristic (ROC) curve analysis was used to assess the medical diagnostic value of the ELF assay, with ELF assay measurements of 70 CKD samples and 20 healthy reference samples to determine ROC curve and Area Under Curve (AUC) of the assay.

Results: The ELF assay measurements showed high correlation to standard lab measurements, with Pearson r=0.94 (Figure A). Bland-Altman analysis showed bias of -0.5 mg/L for the ELF assay, which could be adjusted if it is consistent when we continue monitoring the assay on a broader concentration set of samples (Figure B). The ROC analysis showed excellent diagnostic value, with AUC=0.83, which shows potential for discriminating healthy and CKD subjects (Figure C and D).

Conclusions: We have demonstrated feasibility and validation of a novel POC assay to measure CysC in human blood-based samples. The ELF assay possesses acceptable POC characteristics, correlates well to standard laboratory measurements, and shows good diagnostic value. Future development could lead to a fully available POC measurement framework for CysC as a kidney function marker, and a potential paradigm shift in patient monitoring and care.

PO2390

Serum Creatinine Concentration and Estimates of Muscle Mass Among Race/Ethnicity Groups with End-Stage Kidney Failure

Cynthia Delgado,[1,2] Neil R. Powe,[3,2] Glenn M. Chertow,[4] Barbara A. Grimes,[2] Kirsten L. Johansen.[5] *[1]San Francisco VA Health Care System, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; [4]Stanford University School of Medicine, Stanford, CA; [5]Hennepin Healthcare, Minneapolis, MN.*

Background: Racial differences in serum creatinine concentration have been attributed to differences in muscle mass. We examined this hypothesis among End Stage Kidney Disease patients receiving hemodialysis, whose serum creatinine concentration (SCr) should not be highly influenced by glomerular filtration.

Methods: 501 participants were enrolled from 2 centers who were at least 1 year post start of hemodialysis and for whom we measured SCr and body composition (including height-adjusted intracellular water [ICW] as a surrogate of muscle mass) using bioelectrical impedance spectroscopy. In multivariable linear regression we examined the independent association of race/ethnicity (Black, Asian, Non-Hispanic White (NHW), and Hispanic) with estimated muscle mass. We then examined whether race/ethnicity was associated with SCr with adjustment for demographics, clinical factors and body composition including ICW.

Results: Black (0.24 (-0.01,0.49)) and Hispanic (0.05 (-0.26, 0.37)) participants had similar ICW to that of NHW, but ICW was higher among Asians (0.42 (0.11, 0.72)). In contrast, SCr concentrations were significantly higher among Blacks, Hispanics and Asians compared with NHW. Adjustment for ICW did not change these associations or attenuate the difference in SCr between any racial/ethnic group and NHWs.

Conclusions: Among prevalent dialysis participants, ICW, a muscle mass surrogate, was higher among Asian, but not among Black, participants when compared to NHW. After adjusting for ICW, higher SCr was observed across all race ethnicity categories and muscle mass did not appear to explain differences in SCr by race/ethnicity.

PO2391

Patient-Reported Symptoms and Subsequent Risk of Myocardial Infarction in CKD

Benjamin Lidgard, Leila R. Zelnick, Kevin D. O'brien, Nisha Bansal. *University of Washington, Seattle, WA.*

Background: Patient-reported symptoms often precede clinical acute presentations of atherosclerotic cardiovascular disease (ASCVD), and include chest pain, shortness of breath, and inability to climb stairs. Patients on dialysis frequently have atypical or absent symptoms related to ASCVD; however, it is unknown whether these same findings are observed in patients with non-dialysis requiring chronic kidney disease. We examined time-updated symptoms of ASCVD and their associations with incident acute myocardial infarction (MI) in a large prospective CKD cohort.

Methods: We studied participants from the Chronic Renal Insufficiency Cohort (CRIC) study who had available symptom data. Chest pain, shortness of breath, and inability to climb stairs were evaluated using the Kidney Disease Quality of Life Instrument (KDQOL-36) at each annual study visit, and were categorized as "no symptoms", "mild symptoms", and "moderate or worse symptoms". Associations between categorical time-updated symptoms and interim MI were assessed using Cox regression models with adjustment for potential confounders. We tested for interaction by prior MI, eGFR, and diabetes.

Results: Among 3909 study participants, the mean age was 58 years, and the mean eGFR was 44.3 mL/min/1.73 m2; 22% had prior MI. There were 367 MIs over a median of 7.98 years; median time between symptom assessment and MI was 213 days (IQR 111 to 314 days). Moderate or worse shortness of breath was associated with 1.83-fold increased risk of MI (95% CI 1.25, 2.67) after adjustment. These associations were also seen for chest pain and inability to climb stairs (HR for moderate or worse chest pain 1.65, HR for severe limitation climbing stairs 1.85) (Table). P-values for interaction by prior MI, diabetes, and eGFR were all not statistically significant (p>0.05).

Conclusions: Chest pain, shortness of breath, and inability to climb stairs were significantly associated with increased risk of MI in a large cohort of participants with CKD. This highlights the importance of symptom assessment as early warning signs of ASCVD in patients with CKD.

SGLT2 Inhibitors: Will They Change the Face of Kidney Care?

Tucker B. Hurtado, Meghan Staudt, Jennifer Robinson. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: This research examines the evolving care and treatment of patients with chronic kidney disease (CKD) and type 2 diabetes (T2D), including the introduction and adoption of SGLT2 inhibitors. It includes trending on perceptions across specialists.

Methods: A total of 1,030 CKD non-dialysis patient records were collected from 183 nephrologists via an online, HIPAA-compliant form in October and November 2020

as part of an independent, retrospective chart audit. Data were also collected from an online survey of 74 endocrinologists, 75 cardiologists, and 76 primary care physicians in September and October 2020, and from 105 nephrologists in April 2021.

Results: CKD patients often experience a range of comorbidities and treatments throughout their disease. The optimal eGFR level nephrologists report they would initiate a CKD patient on an SGLT2 inhibitor is 57.1 ml/min/1.73m^2, or early in Stage 3, which is much earlier than the initiation of other treatments such as nutritional vitamin D and ESAs. Upon referral to a nephrologist, one-in-ten patients with CKD and T2D are already prescribed an SGLT2 inhibitor; this increases as the patient is under nephrology care, up to nearly one-in-five patients; however, there remains room for substantial growth - most notabably in CKD patients without T2D, with just 3% having ever been treated with an SGLT2 inhibitor. While nephrologists have been slow to adopt SGLT2 inhibitors firmly into their treatment paradigms, other physicians report a higher percentage of their DKD patients treated with an SGLT2 inhibitor, especially endocrinologists (34%). One-third of nephrologists report trepidation over prescribing SGLT2 inhibitors in their DKD patients, a percentage that has stayed remarkably consistent over the past year and is nearly mirrored by those who claim they have no trepidation in prescribing. This hinderance only increases (to 44%) when they consider prescribing the agents in non-diabetic CKD patients. However, anticipated use of SGLT2 inhibitors in DKD patients is high across specialists, highlighting the opportunity this class of drugs has to make an impact on the treatment of CKD non-dialysis patients.

Conclusions: As SGLT2 inhibitors offer benefits to diabetic and non-diabetic CKD patients, physicians are poised to begin treatment earlier in disease progression, especially with dapagliflozin now approved for CKD patients with and without diabetes.

PO2393

Prescribing Patterns of Sodium-Glucose Cotransporter 2 Inhibitors in Patients with CKD

Min Zhuo,[1,2] Jiahua Li,[2] David B. Mount,[2] David J. Steele,[3] David J. Lucier,[3] Mallika L. Mendu.[2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital Department of Medicine, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Since the publication of the EMPA-REG trial in 2015, sodium-glucose cotransporter-2 inhibitors (SGLT-2i) have been demonstrated to slow chronic kidney disease (CKD) progression in patients with diabetic kidney disease (DKD). More recently in October 2010, the DAPA-CKD trial demonstrated SGLT-2i slows CKD progression regardless of diabetes (DM) status. We evaluated the adoption of these novel therapeutics in CKD patients, without and with DM.

Methods: A cross-sectional study of the Mass General Brigham Health System CKD registry was conducted in March 2021. All adult patients with non-dialysis CKD stages 3-5 were included. Multivariable logistic regression models were used to assess factors associated with SGLT-2i use in patients without and with DM.

Results: Among 49,587 non-DM, CKD patients, only 145 (0.3%) were taking SGLT-2i. Of 22,653 DM, CKD patients, 1,442 (6.4%) were taking SGLT-2i. As shown in the **Figure**, younger age, Male sex, Black race, history of heart failure, and cardiologist visit in the past year were associated with higher rates of SGLT-2i use in both cohorts. In patients with DM, nephrologist visit in the past year was associated with a higher rate of SGLT-2i use, whereas advanced CKD stages were associated with lower rates of SGLT-2i use.

Conclusions: Despite a well-demonstrated benefit of SGLT-2i, the adaption of these novel agents remained extremely low in the CKD population, particularly among patients without DM. Given the approval of SGLT-2i for CKD in May 2021, interventions to increase SGLT-2i usage and improve outcomes in patients with CKD are urgently needed.

Table. Factors associated with sodium-glucose cotransporter-2 inhibitor use among chronic kidney disease patients without and with diabetes mellitus

	Non-diabetic CKD cohort		Diabetic CKD cohort[1]	
Characteristic	**Adjusted OR (95% CI)**	***P* value**	**Adjusted OR (95% CI)**	***P* value**
Age, years	0.95 (0.94-0.96)	<0.001	0.96 (0.96-0.97)	<0.001
Male	3.48 (2.36-5.13)	<0.001	1.80 (1.60-2.02)	<0.001

Nephrologist visit within one year	1.39 (0.82-2.34)	0.22	1.18 (1.00-1.39)	0.05
Cardiologist visit within one year	3.14 (2.16-4.56)	<0.001	1.48 (1.30-1.70)	<0.001
Endocrinologist visit within one year			2.36 (2.10-2.66)	<0.001
Renin-angiotensin-aldosterone system inhibitors	2.16 (1.53-3.06)	<0.001	1.87 (1.62-2.15)	<0.001
Diuretics	3.26 (2.14-4.99)	<0.001	0.99 (0.88-1.12)	0.88

[1] Other factors included in the multivariable analysis: coronary artery disease, hypertension, hemoglobin A1C at goal, primary care physician visit within one year, number of emergency room visits during last year, number of hospitalizations during last year, hospitalization during last 30 days, aspirin, beta-blockers, calcium channel blockers, and statins.

PO2394

Identification of Common Medication Therapy Problems in a High-Risk CKD Population

Melanie R. Weltman,[1] Manqi Cai,[2] Jonathan Yabes,[2,3] Khaled Abdel-Kader,[4] Manisha Jhamb,[5] Thomas D. Nolin.[1,5] *[1]University of Pittsburgh School of Pharmacy, Pittsburgh, PA; [2]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; [3]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [4]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN; [5]University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA.*

Background: Medication therapy problems (MTPs) are commonly experienced by patients with chronic kidney disease (CKD) and have the potential to increase morbidity, mortality, and healthcare costs. As part of the Kidney Coordinated Health Management Partnership (Kidney CHAMP), an NIH funded, pragmatic randomized controlled trial testing an electronic health record- (EHR) based population health management approach to improve CKD care, we characterize the types and prevalence of MTPs in a population of high-risk CKD patients.

Methods: Eligible patients are 18 to 85 years old with CKD who have a high risk of progression to ESKD and are not being followed by a nephrologist. MTPs are identified through pharmacist-led telephonic medication therapy management (MTM) and electronic consult by nephrology specialists. Recommendations for resolution of MTPs are provided in the EHR to the primary care provider for review at the upcoming office visit.

Results: To date, in 493 intervention patients, 724 MTPs have been identified. Most patients (76%) experienced at least one MTP. The most common MTP identified was 'needs additional medication therapy,' followed by 'suboptimal medication,' and 'dosage too high.' New indications for SGLT2 inhibitors contributed largely to the 'needs additional medication therapy' category. The most common suboptimal medications identified were NSAIDs, with 15% of patients reporting over the counter or prescription use.

Conclusions: Patients with high-risk CKD experience a sizeable burden of MTPs. Identification of existing MTPs in the community setting is an important first step in the optimization of a medication regimen, with the succeeding goal to resolve and prevent MTPs and improve CKD care and outcomes.

Funding: NIDDK Support

MTP category	n	% with regard to MTPs (N=724)
Needs additional med therapy	214	29.6%
Suboptimal medication	138	19.1%
Dosage too high	105	14.5%
Dosage too low	82	11.3%
Drug interaction	53	7.3%
Needs additional monitoring	47	6.5%
Unnecessary med therapy	44	6.1%
Adverse med event	25	3.5%
Failure to receive drug	16	2.2%

PO2395

Treatment with IL-17 Inhibitors Is Associated with Reduced eGFR in Patients with Psoriasis or Psoriatic Arthritis: A Retrospective Cohort Study

Peihsuan R. Tsai,[1] Daniel X. Gilroy,[2] Thu H. Le,[1] Erika Drury.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Rochester Institute of Technology, Rochester, NY.*

Background: The complex interplay of the cytokines within the IL family can both mediate and modulate inflammation. Specifically, the cytokine IL-17 has been implicated in several disease processes including hypertension, cardiovascular, autoimmune, and chronic inflammatory diseases. However, there is emerging evidence that IL-17 can also favorably modulate inflammation. It has been demonstrated that low-dose IL-17 therapy may prevent and reverse diabetic nephropathy in mouse models. We aimed to study the effect of IL-17 inhibitors on eGFR in human subjects.

Methods: We conducted a single-center retrospective cohort study of patients who had been treated with an IL-17 inhibitor (ixekuzumab or secukinumab), for the treatment of psoriasis (P) or psoriatic arthritis (PA). Demographics and serum creatinine values were extracted from the electronic medical record. Aggregated data in a 6 month window at 6-months prior to initiation of the IL-17 inhibitor and 12 months after initiation of the IL-17 inhibitor were analyzed using paired t-test. Estimated GFR was calculated using the CKD-Epi equation.

Results: We identified 307 patients who had been treated with IL-17 inhibitors. We included 65 patients who had serum creatinine values at pre-specified time periods before and after initiation of treatment. At baseline, the mean age was 50.3±12 years, 43% were men, 51(78%) had a diagnosis of hypertension, 11(17%) had a diagnosis of diabetes, and mean eGFR was 83.6 mL/minute/1.73 m^2. One year after initiation of IL-17 inhibitor therapy, mean eGFR was significantly lower at 78.7 mL/minute/1.73 m^2 ($p < 0.001$). After excluding patients taking medications known to affect eGFR (n=26), there was still a significant decrease in eGFR after 1 year (88.4 versus 83.2 ml/minute/1.73 m^2, $p < 0.01$).

Conclusions: In patients with P or PA, IL-17 inhibitor therapy is associated with a reduction in eGFR at 1 year after initiation of treatment. Prospective study with longer follow-up is needed to determine the long-term effect of IL-17 inhibitor therapy on kidney function.

PO2396

Network Meta-Analysis for Prevention of Kidney Function Decline Using Uric-Acid-Lowering Therapy in CKD Patients

Shunichiro Tsukamoto,[1] Hiromichi Wakui,[1] Kengo Azushima,[1] Takayuki Yamada,[2,1] Shingo Urate,[1] Toru Suzuki,[1] Eriko Abe,[1] Shinya Taguchi,[1] Shohei Tanaka,[1] Kouichi Tamura.[1] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [2]Mount Sinai Beth Israel Hospital, New York, NY.*

Background: Several previous studies have suggested that uric-acid-lowering therapy (ULT) can slow the progression of chronic kidney disease (CKD). However, few studies have evaluated the effects of each ULT treatment on kidney function, although this topic is crucial for CKD patients. This systematic review aimed to summarize evidence from randomized controlled trials (RCTs) concerning the effects of ULT on kidney function.

Methods: We performed a systematic search and selected RCTs in CKD patients comparing the effects of ULT on kidney function. We performed a network meta-analysis to compare each ULT indirectly. The primary outcome was change in estimated glomerular filtration rate (eGFR) from baseline. Treatment effects were summarized using random-effects model.

Results: Ten studies were selected with a total of 1480 patients. Topiroxostat significantly improved eGFR compared to placebo (MD [95% CI]; 1.49 [0.08; 2.90], $P = 0.038$) (Fig. 1). Although Febuxostat did not show a positive effect overall, it significantly improved renal function (eGFR) in a subgroup analysis of CKD patients with hyperuricemia (MD [95% CI]; 0.85 [0.02; 1.67], $P = 0.045$) (Fig. 2). Allopurinol and pegloticase did not show good effects.

Conclusions: Topiroxostat and febuxostat have better renoprotective effects in CKD patients. we believe that the results of this study allow us to recommend ULT with topiroxostat or febuxostat for patients with CKD.

Prevalence of Polypharmacy and Associated Adverse Health Outcomes in Patients with CKD: A Systematic Review and Meta-Analysis

Mohammed M. Tinwala,[1] Deenaz Zaidi,[1] Feng Ye,[1] Shezel Muneer,[1] Anukul Ghimire,[1] Maryam Khan,[1] Naima Sultana,[1] Ikechi G. Okpechi,[1] Paul E. Ronksley,[2] Neil Drummond,[1] Dee Mangin,[3] Aminu K. Bello.[1] *[1]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [3]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) are at increased risk of adverse health outcomes associated with excessive medication use (polypharmacy) due to impaired kidney function and multimorbidity. However, data on the associations of polypharmacy and adverse health outcomes in this population are limited. We conducted a systematic review and meta-analysis to determine the prevalence of polypharmacy and its associated health consequences in CKD.

Methods: The study was conducted using a pre-specified study protocol and adheres to PRISMA reporting guidelines. Six electronic databases were searched from inception to September 2020 for studies that included patients with CKD, use of polypharmacy, and associated adverse health outcomes. Random effects models were used to pool the prevalence of polypharmacy and associations with health outcomes.

Results: 53 eligible articles (n = 477,909 patients) met criteria for inclusion. The pooled prevalence of polypharmacy and excessive polypharmacy was 76.2% (95% CI 73.2%-79.1%; range 14.9% to 100%) and 37.4% (95% CI 30.0%-45.2%; range 11.4% to 63.0%), respectively (Figure 1). The prevalence of polypharmacy was 72.7% and 87.1% in non-dialysis CKD and dialysis populations, respectively. 17 studies reported significant associations between polypharmacy and adverse health outcomes. These studies found an increased risk for potentially inappropriate medication use, drug-drug interactions, drug-related problems, medication-related problems, adverse drug reactions, decreased quality of life, decreased kidney function, hospitalization, and mortality.

Conclusions: Polypharmacy is common in CKD and linked to adverse health outcomes. Our findings highlight the need for improved prescribing practices in CKD and the development of strategies to reduce polypharmacy.

Risk of Bias in Observational Studies Assessing the Relationship Between Proton Pump Inhibitors and Adverse Kidney Outcomes

Pradeep Rajan,[1] Kristy Iglay,[1] Thomas Rhodes,[1] Cynthia J. Girman,[1] Dimitri Bennett,[4,2] Kamyar Kalantar-Zadeh.[3] *[1]CERobs Consulting, Chapel Hill, NC; [2]University of Pennsylvania, Philadelphia, PA; [3]University of California Irvine, Irvine, CA; [4]Takeda Pharmaceuticals International AG, Cambridge, MA.*

Background: Proton pump inhibitors (PPIs) are widely prescribed as acid-suppression therapy. However, some observational studies suggest that long term use of PPIs is potentially associated with adverse kidney outcomes. We assessed potential bias in observational studies reporting on putative associations between PPIs and adverse kidney outcomes: AKI, acute interstitial nephritis, acute tubular necrosis, CKD, ESRD.

Methods: Searches in EMBASE and PubMed identified relevant English language articles published in the last 10 years. Risk of bias on an outcome-specific basis was evaluated using Risk of Bias in Non-randomized Studies of Interventions (ROBINS-I) by 2 independent reviewers (PROSPERO Registration: CRD42021227555).

Results: Of 620 identified records, 26 studies met *a priori* eligibility criteria and underwent risk of bias assessment. 19 studies were rated as having a moderate risk of bias for the reported adverse kidney outcomes, while 6 studies were rated as having a serious risk of bias (mainly due to inadequate control of confounders and selection bias) (Table 1). Effect estimates for the association between PPI and adverse kidney outcomes varied widely (0.24-7.34) but were mostly positive.

Conclusions: Observational studies suggesting kidney harm by PPIs were found to have a moderate to serious risk of bias using the ROBINS-I tool, making it challenging to establish causality. Additional high-quality, real-world evidence among generalizable populations is needed to better understand the relation between PPI treatment and acute/chronic kidney outcomes, taking into account the effects of varying time periods of PPI treatment, potential self-treatment with over-the-counter PPIs, and adequate control for potential critical confounders.

Treatment Adherence Support and Relationships with CKD Providers: A Qualitative Analysis

Eleanor Rivera,[1] Maya N. Clark-Cutaia,[2] Sarah J. Schrauben,[3] Raymond R. Townsend,[3] James P. Lash,[1] Derek J. Colaizzo,[3] Bernard G. Jaar,[4] Jeanne Charleston,[4] Hernan Rincon-Choles,[5] Jiang He,[6] Jing Chen,[6] Mary Hannan,[1] Karen B. Hirschman.[3] *[1]University of Illinois at Chicago, Chicago, IL; [2]New York University, New York, NY; [3]University of Pennsylvania, Philadelphia, PA; [4]Johns Hopkins University, Baltimore, MD; [5]Cleveland Clinic, Cleveland, OH; [6]Tulane University, New Orleans, LA.*

Background: Adherence is critical in chronic kidney disease (CKD) to delay progression to kidney failure. Treatment plans for CKD can include medications, diet, and exercise. Overall adherence to treatment is low in CKD, and also as few as 40% of new kidney failure patients have any documented CKD-related care. The purpose of this study was to explore CKD patients' experiences of adherence to treatment plans and what role their healthcare providers had in supporting adherence.

Methods: As part of a larger mixed-methods study of Chronic Renal Insufficiency Cohort (CRIC) study participants, a subset was randomly selected for 1:1 interviews. All CRIC participants are >45 years with CKD stages 1-4, and this sample consisted of University of Pennsylvania participants interviewed in 2019-2020. Participants described their experiences with adherence and what they have done when experiencing difficulty. Interviews were recorded, transcribed, and coded using conventional content analysis.

Results: The sample (n=32) had a mean age of 67 years, 53% women, 59% non-white. After analysis of factors relevant to treatment planning and adherence, four themes emerged: patient factors (multiple chronic conditions, motivation, outlook), provider factors (attentiveness, availability, communication), treatment planning factors (lack of plan, proactive patient research, provider-focused goals, and shared decision making), and patient responses to the treatment plan (disagreeing with treatment, frustration with their lack of adherence ["I know what to do"], lack of information, and positive feedback). Patients also described the impact of COVID on access to care and the positive impact of family, ancillary providers, and routines/habits.

Conclusions: These themes align with behavioral learning theory, which includes: internal antecedents (patient factors), external antecedents (provider factors), behavior (treatment planning and attempts at adherence), and consequences (adherence and responses to the treatment plan). Our results provide many potential points of intervention to support treatment adherence in CKD, and a tailored approach is needed to address patients' specific adherence factors.

PO2400

The Association Between the Adherence of Self-Management and Prognosis of Non-Dialysis CKD Stages 3-5 Patients

Min Zhang,[1] Nuo Lei,[1] Xianlong Zhang,[1] Lizhe Fu,[3] Fang Tang,[3] Xusheng Liu,[2] Yifan Wu.[2] *[1]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [2]Department of Nephrology, Guangdong Provincial Hospital of Chinese Medicine (The Second Affiliated Hospital of Guangzhou University of Chinese Medicine), Guangzhou, China; [3]Chronic Disease Management Outpatient, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.*

Background: Self-management plays a very important role in the prognosis of patients with CKD. However, there is a lack of evidence-based results to support this. This study aimed to evaluate the association between the adherence of self-management and prognosis of non-dialysis CKD stages 3-5 patients.

Methods: Data including basic information, laboratory test results, oral drugs, time of endpoint events were retrospectively collected. Patients were divided into good or poor adherence according to whether they participated in self-management education on time every month. Endpoints were the initiation of renal replacement therapy and death.

Results: 785 patients were included in this study. 111 and 674 patients were considered to have good and poor adherence, respectively. 12 and 162 endpoint events occurred in the good and poor adherence groups. Propensity score matching was performed. After 1:2 matching, the outcomes of 315 patients were analyzed(109 : 206). Univariate Cox regression was performed to screen variables with $P < 0.05$, then we further performed Cox proportional hazards regression with three adjusted models. The results of the 3 models all showed that the good adherence of self-management was an independent factor associated with reduced risk of incident endpoints(HR95%CI: Model 1: 0.47(0.25, 0.89); Model 2: 0.31(0.15, 0.64); Model 3: 0.26(0.12, 0.60)). The Kaplan-Meier analysis demonstrated that the cumulative incidence of endpoint events in the good adherence group was significantly lower than that in the poor adherence group (log-rank test, $P < 0.05$).

Conclusions: This study suggests that good adherence with self-management could effectively reduce the incidence of endpoint events in CKD stages 3-5 patients

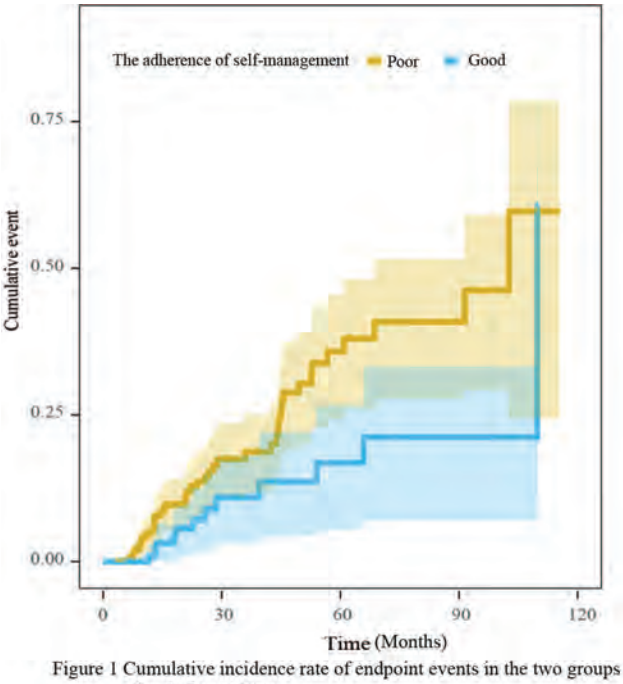

Figure 1 Cumulative incidence rate of endpoint events in the two groups after 1: 2 matching.

PO2401

Impact and Outcomes of Advance Care Planning in CKD

Shanti Tan, Timothy J. Koh, Eileen Pang, Wan Limm Looi, See Cheng Yeo. *Tan Tock Seng Hospital, Singapore, Singapore.*

Background: The incidence of chronic kidney disease (CKD) is rising, with patients being older and having more chronic disease at time of dialysis initiation. Advance care planning (ACP) has been advocated to better align treatment with patient preferences, facilitate shared decision making and improve patient-centred care. We aim to evaluate the impact of ACP on patient-centred outcomes and describe patient preferences expressed during ACP.

Methods: We conducted a retrospective cohort study of patients who underwent ACP from January 2013 to March 2021, comparing outcomes with age-, gender-, aetiology- & renal replacement therapy (RRT) decision-matched patients without ACP. Outcome

measures include intensive care unit (ICU) admissions, number of hospitalisations per year, change in decision for renal palliative care (RPC) and referral to palliative physician.

Results: 198 patients underwent ACP during the study period, with a median age of 77 years old. 52.5% of patients in the ACP cohort were referred as they chose RPC. Other reasons for ACP included patients with difficulty tolerating dialysis, vascular access issues, long-term catheter-based dialysis and significant comorbidities. Majority of patients who underwent ACP elected not for cardio-pulmonary resuscitation (80.8%) or admission to ICU (77.8%), 9.6% of the cohort changed their mind about subsequent treatment plan. Compared to 197 patients in the matched-control group, patients with ACP were less likely to be admitted to ICU (5.0% vs 14.7%, p=0.001). In patients who chose RPC, those with ACP were less likely to have a change in decision for conservative management of CKD (8.6% vs 20.2%, p=0.018), had fewer hospital admissions a year (1.21 vs 1.92, p=0.001) and were less likely to require palliative referral (44.2% vs 61.5%, p=0.013).

Conclusions: ACP should be considered in CKD patients to help align goals of care and treatment preferences. When considering patients who chose RPC, patients who undergo ACP are more likely to be consistent with their plan for conservative management of CKD, including a reduced utilization of resources like ICU care, palliative care involvement and hospital admissions. This ensures appropriate diversion of resources and allows alignment to patient's treatment preferences.

PO2402

Well-Managed CKD and Its Association with Healthcare Resource Utilization and Costs

Yong Li,[1] Kanchan Barve,[2] Meghan M. Cockrell,[2] Amal Agarwal,[2] Adrianne W. Casebeer,[2] Insiya B. Poonawalla.[1] *[1]Humana Healthcare Research, Louisville, KY; [2]Humana Inc, Louisville, KY.*

Background: Diabetes and hypertension are prevalent in CKD. The association of coordinated care with outcomes in the setting of these coexisting comorbidities is not well understood. This study evaluated the association between well-managed care and healthcare resource utilization (HCRU) and costs.

Methods: Using the Humana Research Database, this retrospective cohort study identified 241,628 patients with CKD Stage ≥ 3a (3% diabetes, 40% hypertension, 50% diabetes and hypertension, 7% neither diabetes nor hypertension) in 2017. Eligible patients were indexed on first evidence of CKD and required to be enrolled in a Medicare Advantage Prescription Drug plan for ≥ 12 months pre- and post-index date. Patients who had kidney transplant or hospice election pre-index were excluded. Well-managed care measures included hemoglobin A1c (HbA1c) monitoring, adherence to glucose medications, cardiovascular (CV) therapy, angiotensin-converting enzyme inhibitors/ angiotensin receptor blockers (ACEi/ARBs), and routine primary care provider (PCP)/ nephrologist visits. HCRU and costs were evaluated within 12-months post-index.

Results: The cohort was 55% female, 77% White, average age of 75 years, and comprised of 67%, 23%, 10%, and 1% patients with Stages 3a, 3b, 4 and 5 CKD, respectively. Patients with diabetes and hypertension who were adherent to well-managed care were significantly less likely to experience an inpatient (IP) admission or emergency department (ED) visit (Table 1) and incurred lower mean monthly costs compared with patients who were not adherent to well-managed care. Similar results were observed for patients with diabetes only, hypertension only, or neither condition.

Conclusions: Well-managed diabetes and/or hypertension in patients with CKD was associated with lower HCRU and costs. Findings may inform innovative models of CKD care coordination.

Measures of well-managed care*

	Odds ratio [95% Confidence Interval]

Opt-In vs. Opt-Out Approach for Kidney Disease Education and Associated Research

Ashutosh M. Shukla,[1,2] Popy Shell,[1] Devin S. Fu,[1] Zachary P. Purvis,[1] Tatiana Orozco,[1] Gajapathiraju Chamarthi.[2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: Clinical research mail-invites require patients to call back for their ability to participate (opt-in). This patient-initiative need reduces efficiency, requires more effort, and limits external validity. Opt-out approach, where research team actively contacts those not choosing to call back, can improve efficiency, especially when evaluating recommended but uncommonly used interventions. Current guidelines recommend comprehensive pre-end stage kidney disease (ESKD) education (CPE) for all advanced, stage 4/5 CKD patients but, CPE is uncommonly used prompting patient preference research. Evaluating enrollment statistics for the initial year of randomized controlled Trial to Evaluate and Assess the effects of CPE on Home dialysis among VETerans(TEACH-VET), we report the effectiveness and efficiency of the 'opt-out' approach in CKD education research.

Methods: TEACH-VET (NCT04064086) aims to evaluate universal CPE strategy on Veteran outcomes, including home dialysis. It uses an EHR-based source cohort to mail-invite advanced CKD Veterans; those who do not call-back within 15 days to opt-out, are telephoned for upto 3 times for their interest. Staff surveys(n=6) are used to determine effort (time) associated with each study activity and aggregated for opt-in/opt-out processes. We examined approach success rates, and study enrollments and efficiency(time per enrollments) as outcomes.

Results: Of the total of 226 randomly selected Veterans mail-invited for study participation over the initial 15 months, approach success rate was 3.9%(n=9) for opt-in method, resulting in 2(22%) enrollments, while 4(44.3%) requested additional time for decision. Of the remaining 217, study staff were able to approach 157 invitees(success rate of 72.4%), resulting in 86(54.8%) enrollments, while 18(10.8%) requested additional time. Significant differences in personnel efforts were seen with an estimated 147±69.2 and 183±70 min, minutes per enrollments($p<0.05$) in the opt-in vs. opt-out respectively though, efficiency for enrollment was signficantly better for opt-out vs. opt-in (60.2 vs. 30.7min) approach.

Conclusions: Patient driven opt-in approaches are less effective and efficient for enrollments in clinical and research activities involving the universally recommended services like kidney disease education.

Funding: Veterans Affairs Support

PO2404

CKD Healthcare Utilization Preceding Unplanned Dialysis in a Large Accountable Care Organization

Leslie P. Wong, Anindita Ghosh. *Cleveland Clinic, Cleveland, OH.*

Background: Unplanned dialysis initiation or "crash starts" is associated with worse outcomes and higher costs in chronic kidney disease (CKD). Avoiding these events should be a quality improvement priority for accountable care organizations (ACOs). We examined care utilization associated with unplanned dialysis initiation in a large ACO.

Methods: Cleveland Clinic is an academic health system with a 100,000+ member ACO and value-based care (VBC) program. A claims analysis of CKD patients who transitioned to dialysis attributed to the ACO or a VBC contract in 2020 with a lookback 2017-2020 was done. Crash start patients initiated hemodialysis (HD) with a central venous catheter in the hospital. Optimal start patients initiated dialysis with outpatient HD or peritoneal dialysis (PD). Those with acute kidney injury, hospital death, urgent start PD, or preemptive transplant were excluded.

Results: A total of 261 patients met criteria for crash starts and 133 for optimal starts. Outpatient utilization and average visits per specialty by patient category are shown in Table 1. Forty percent of crash start patients had no preceding nephrology care in the 12 months prior to dialysis. Optimal start HD patients had more visits with nephrologists and vascular surgery than crash start patients. PD patients had the highest percentage and number of nephrologist visits. Crash start patients with outpatient pre-dialysis care saw a mix of employed nephrologists (45%), independent nephrologists (35%), and non-ACO nephrologists (20%). Average total cost of care was $95,036 for crash starts versus $25,671 for optimal starts in the 12 months prior to dialysis start date including the index admission.

Conclusions: In a large ACO, unplanned dialysis initiation was associated with lower pre-dialysis nephrology and vascular surgery utilization and substantially higher costs. ACOs managing CKD population risk should address the systemic factors leading to crash dialysis starts.

CKD care utilization in 12 months prior to dialysis initiation

	Crash start n=261	Optimal HD start n=96	Optimal PD start n=37
Any PCP visit	88%	74%	80%
Average PCP visits	7.3	7.7	6.2
Any nephrologist visit	60%	61%	73%
Average nephrologist visits	2.2	3.1	3.8
Any vascular surgeon visit	23%	62%	10%
Average vascular surgeon visits	0.4	1.1	0.2

PCP = primary care provider

PO2405

Comparing Telenephrology (TN) vs. Face-to-Face (F2F) Visits: A Comprehensive Outpatient Nephrology Patient Perspective-Based Cohort Study

Lagu A. Androga, Rachel H. Amundson, Sandhya Manohar, Bjoerg Thorsteinsdottir, Ziad Zoghby, Suzanne M. Norby, Vesna D. Garovic, Robert C. Albright. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Little is known about patient perspectives on the quality of care provided via TN compared to F2F visits. We aimed to use objective survey data to study patients' perspectives on outpatient nephrology care received via TN (phone and video) versus F2F visits

Methods: We retrospectively studied adults who received outpatient nephrology care at Mayo Clinic, Rochester, MN, from March 1st - July 31st 2020. We used a standardized structured survey methodology to evaluate patient satisfaction across TN versus F2F visits. The primary outcome was the percent of patients who responded with a composite of a score of *good (4)* or *very good (5)* on a 5-point Likert scale on survey questions that asked their perspectives with regard to *access* to their nephrologist, their relationship with *care provider*, and when relevant – their opinions on the *telenephrology technology*, and

their *overall assessment* of the care they received during the nephrology visit. Wilcoxon rank sum tests and chi-square tests were used as appropriate to compare telenephrology versus face-to-face visits

Results: 3,486 of the patient encounters were face-to-face, 808 via phone and 317 via video. 443 patients responded to satisfaction surveys, and 21% of these had TN encounters. Established patients made up 79.6% of TN and 60.9% of F2F visits. There was no statistically significant difference in patient perceived *access* to health care, satisfaction with their *care provider*, or *overall quality* of care between patients who received care via TN versus F2F

Conclusions: Patient satisfaction was equally high amongst those patients seen face-to-face or via telenephrology

PO2406

Depressive Symptom Trajectory and CKD Progression: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

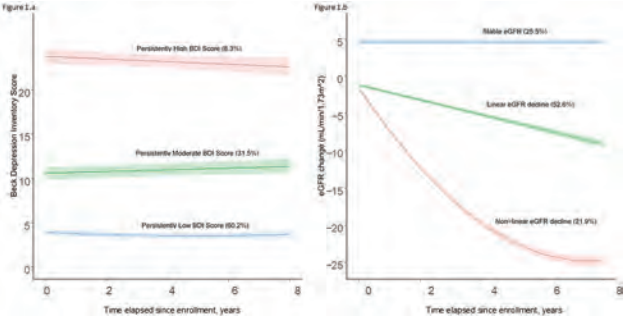
Celestin Missikpode,[1] Ana C. Ricardo,[1] Ramon Durazo-Arvizu,[2] Julia Brown,[1] Michael J. Fischer,[1] Rosalba Hernandez,[3] Anna C. Porter,[1] James P. Lash.[1] *[1]University of Illinois at Chicago College of Medicine, Chicago, IL; [2]University of Southern California, Los Angeles, CA; [3]University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: While depressive symptoms (DS) are highly prevalent in adults with early-stage chronic kidney disease (CKD), little is known about its course over time. We identified trajectories of DS and evaluated their association with CKD progression in adults with CKD enrolled in the CRIC study.

Methods: DS were assessed using the Beck Depression Inventory (BDI), at baseline and biennially. Higher BDI scores are consistent with more severe DS. Glomerular filtration rate (GFR) was estimated at baseline and annually. Group-based trajectory models were used to determine trajectories of BDI and eGFR over time. The association between these trajectories was assessed using multinomial logistic regression, adjusting for socio-demographics, lifestyle factors, and comorbidities.

Results: Among 3113 participants at baseline: μ_{age}=58 years, 45.5% female, μ_{eGFR}=47 mL/min/1.73 m^2 and μ_{BDI}=7.6. We identified three BDI trajectory patterns (persistently low, persistently moderate, and persistently high [Figure 1a]), and three trajectory patterns for eGFR (non-linear decline, linear decline, and stable [Figure 1b]). Odds of non-linear eGFR decline were higher for adults with persistently moderate BDI (OR, 1.51; 95% CI, 1.11-2.06) and those with persistently high BDI (OR, 1.75; 95% CI, 0.99-3.07), compared to counterparts with persistently low BDI scores. No association was evident between BDI scores and linear eGFR decline.

Conclusions: In this CKD cohort, moderate and high DS that persisted over time were associated with non-linear eGFR decline. Intervention studies are warranted to test the effect of depression prevention and treatment on CKD progression.



PO2407

Health-Related Quality of Life and Depression Score Differences in Brazilian and US CKD Patients

Danwen Yang,[1] Lisa Henn,[2] Daniel G. Muenz,[2] Brian Bieber,[2] Antonio A. Lopes,[3] Elodie Speyer,[4] Bruce M. Robinson,[2] Roberto Pecoits-Filho,[2] Ronald L. Pisoni,[2] Fredric O. Finkelstein.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Universidade Federal da Bahia, Salvador, Brazil; [4]INSERM, Paris, France.*

Background: CKD patients suffer from many issues, increasing in prevalence and severity as disease progresses, that may affect their perceptions of health-related quality of life (HRQOL) and increase depression symptoms (DS). A patient-centered care approach including systematic assessment of self-reported HRQOL and DS as CKD progresses facilitates tailoring the treatment to individual patient concerns. This study examines the relationship at baseline between CKD stage and patient responses to the KDQOL-36 and CESD-10.

Methods: We studied 1901 CKDOPPS participants (629 Stage 3, 1009 Stage 4, and 263 Stage 5) from Brazil (n=598) and the U.S. (n=1310). Patients at different CKD stages at study selection were compared for differences at baseline in scores of DS (CESD-10 [Kohout], higher score worse, max 40) and HRQOL (KDQOL-36, higher score better, each scale max 100). The KDQOL-36 yields the Physical Component Summary (PCS) and Mental Component Summary (MCS) from the SF-12v1; Burden of Kidney Disease (BKD); Symptoms of Kidney Disease (SKD); and Effects of Kidney Disease (EKD). The Kruskal-Wallis Test assessed differences among groups.

Results: Patients' mean age, albumin, and BP did not differ in the 3 CKD groups. Mean Hb was lower for CKD 5 (10.8) and 4 (11.9) than for CKD 3 (12.7) patients, but only slight mean difference occurred in DS and MCS by CKD stage. Mean PCS score was 39.8 and 37.9 in CKD 3 and 5 respectively. The largest mean difference in HRQOL scores by CKD stage was for BKD: 77.7 in CKD 3, 69.4 in CKD 4, and 58.0 in CKD 5 ($p < 0.0001$). Lower HRQOL scores for more advanced CKD stage occurred for EKD: (85.13, 79.7, and 76.0 in CKD 3, 4, and 5, $p<.0001$) and SKD (79.95, 77.8, 77.1, $p=0.0007$). Compared to U.S. patients, those in Brazil had higher PCS scores (40.1 vs 37.5) but lower BKD scores (62.3 vs 74.4); other scores did not differ by country.

Conclusions: HRQOL baseline scores for CKD patients show a greater difference in the BKD scores; differences by CKD stage were not seen in MCS and CESD-10 scores; and minimal difference occurred for PCS scores. These results potentially can help address patients' problems and concerns at different CKD stages.

PO2408

The Spectrum of Kidney Disease and Outcomes in US Veterans with Inflammatory Bowel Disease

Prasanth Ravipati,[1] Scott Reule,[2] Alyssa Bren,[1] Lihong Bu,[1] Patrick H. Nachman.[1] *[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]VISN 23 VA Midwest Health Care Network, Eagan, MN.*

Background: Glomerular and tubulointerstitial diseases have been associated with inflammatory bowel disease (ulcerative colitis, UC and Crohn's disease, CD). However, the clinical outcomes of UC and CD patients who underwent kidney biopsy are not well described. We present a case series of the kidney biopsy findings and clinical outcomes of veterans with UC and CD from the US department of Veteran's Affairs (VA) health system.

Methods: We performed a retrospective review of the VA electronic health record. Patients were included if they had UC or CD diagnosed by gastroenterology evaluation and biopsy. Kidney biopsy data including primary and secondary diagnoses, degree of interstitial fibrosis and tubular atrophy (IFTA), and degree of arteriosclerosis were extracted from biopsy reports. Incident end-stage kidney disease (ESKD) was defined as requirement of renal replacement therapy. All analyses were performed using SAS.

Results: Of 59,007 patients with an ICD code of inflammatory bowel disease, 66 patients had kidney tumor biopsies and 140 patients (91 with UC and 49 with CD) underwent biopsy to evaluate intrinsic kidney disease. At the time of kidney biopsy, the mean serum creatinine was 2.9 mg/dL for UC and 3.4 mg/dL for CD and the mean

urine protein to creatinine ratio was 3.8 g/g for UC and 3.0 g/g for CD. The 5 most common primary diagnoses were IgA nephropathy (16%), diabetic nephropathy (14%), acute interstitial nephritis (12%), FSGS (8%), and membranous glomerulopathy (6%). Additionally, 13% of patients had interstitial nephritis (acute or chronic) as a secondary diagnosis. Moderate or severe IFTA was seen in 45% of biopsies. 24 UC patients (26%) and 10 CD patients (20%) progressed to ESKD, with a mean time from kidney biopsy of 3.1 and 1.9 years, respectively. 41 UC patients (45%) and 17 CD patients (34%) died, with a mean time from kidney biopsy of 4.3 and 4.6 years, respectively.

Conclusions: Among US Veterans with UC or CD who underwent kidney biopsy, the most common findings were: IgA nephropathy, interstitial nephritis, and diabetic nephropathy. Patients had advanced kidney disease at biopsy, and subsequent ESKD or death were common within a relatively short time period. These findings suggest a delay in diagnosis and possibly a low rate of diagnosis. Greater provider awareness may lead to earlier detection and improve outcomes.

PO2409

Healthcare Costs Associated with Systemic Lupus Erythematosus (SLE) in the Year Prior to Diagnosis of ESKD: Real-World Evidence from Two Databases in the United States

Christopher F. Bell, Shirley Huang, Amy Guisinger. *GlaxoSmithKline, Research Triangle Park, NC.*

Background: Approximately 40% of patients with SLE develop lupus nephritis (LN), many of whom may progress to ESKD[1]; however, data on of the economic burden of ESKD in patients with SLE are scarce. This study described healthcare resource utilization (HCRU) and costs for patients with SLE in the 12 months before ESKD diagnosis in the US.

Methods: This was a retrospective study (GSK Study 215295) of 2 US administrative claims databases (IBM MarketScan [DB#1], Optum Research [DB#2]), conducted from March 1, 2011, to December 31, 2019. Patients were adults with SLE and newly diagnosed ESKD. Study results focus on patients with 12-month continuous enrollment pre ESKD diagnosis reporting on HCRU and costs (2019 US$) during this period.

Results: In total, 1356 (DB#1) and 425 (DB#2) patients with SLE and ESKD were identified (DB#1/DB#2): female 81.8%/79.3%; mean (standard deviation [SD]) age: 46.7 (12.3)/46.3 (14.0) years. Mean (SD) Quan-Charlson Comorbidity Index score in the 12 months pre ESKD was 2.95 (1.9) and 3.05 (2.0) in DB#1 and DB#2, respectively. The mean (SD) healthcare cost in the 12 months pre ESKD was $64,887 (106,822) (DB#1) and $68,219 (137,704) (DB#2) (**Table**). In the 12-month pre-ESKD period, HCRU was similar across databases and oral corticosteroids were the most commonly prescribed SLE-related medications (**Table**).

Conclusions: Patients with SLE incur substantial HCRU and costs 1 year before ESKD diagnosis, reflecting the clinical and economic burden of SLE and ESKD.

PO2410

Patterns of Progression of Stage 2 CKD and Associated Costs in Medicare Advantage Enrollees

Clarissa J. Diamantidis,[1,2] Amy Storfer-Isser,[4,5] Virginia Wang,[2,3] Lindsay Zepel,[2,5] Sarah H. Scholle,[4] Matthew L. Maciejewski.[2,3] *[1]Duke University Department of Medicine, Durham, NC; [2]Duke University Department of Population Health Sciences, Durham, NC; [3]Durham VA Health Services Research and Development, Durham, NC; [4]National Committee for Quality Assurance, Washington, DC; [5]Optum Labs Visiting Fellow, Minnetonka, MN.*

Background: The prevalence of chronic kidney disease (CKD) in Medicare beneficiaries has quadrupled in the past two decades. Little is known about patterns of progression in older adults with early CKD. We identify CKD progression trajectories, risk factors and health care costs for these trajectories in a large cohort of Medicare Advantage (MA) enrollees with stage 2 CKD.

Methods: In a cohort of 418,930 MA enrollees, we identified trajectories of stage 2 CKD progression (measured by estimated glomerular filtration rate (eGFR)) from 2014-2018 via group-based trajectory modeling. Multinomial logistic regression was used to identify patient factors associated with each trajectory. Mean total costs one year before and two years after baseline are described.

Results: The cohort had a mean age of 72.6 years, was predominantly female (57.2%) and White (67.8%), with mean baseline eGFR of 75.3 ml/min/1.73m^2. Median follow-up was 2.6 years. We identified 5 trajectories of kidney function: stable kidney function (22.1%); slow decline with mean baseline eGFR 78.3 (30.1%), slow decline with mean baseline eGFR 71.0 (28.5%); steep decline (16.4%); accelerated decline (2.9%). In adjusted analyses, higher odds of accelerated decline (vs. stable kidney function) were found in those age 75 and older, (odds ratio (OR)=2.84, 95% confidence interval (CI): 2.38-3.38), living in a non-metropolitan area (OR=1.26, 95% CI: 1.18-1.35), with lower eGFR at baseline (OR=0.64, 95% CI: 0.63-0.64), greater comorbidity (OR=1.28, 95% CI: 1.27-1.29), having a nephrologist visit (OR=2.06, 95% CI: 1.81-2.34) or clinical diagnosis of CKD (OR=4.41, 95% CI: 4.11-4.74) during the year prior to baseline. Mean total MA costs of enrollees with accelerated kidney function decline were nearly twice as high as costs of MA enrollees in the other 4 trajectories in every year ($27,856 versus $13,507) for stable kidney function during the first year.

Conclusions: The small fraction of MA enrollees with accelerated loss of kidney function have disproportionately higher costs than other enrollees with stage 2 CKD and may benefit from closer clinical management to minimize progression and contain costs.

PO2411

The Kidney Failure Risk Equation as a Predictor of Healthcare Costs

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Julie C. Lai,[1] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]Mathur Consulting, Woodside, CA; [3]Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Background: The Kidney Failure Risk Equations (KFRE) are accurate and validated to predict the risk of kidney failure in individuals with CKD, but little is known about their potential to predict healthcare costs. We assessed the 4- and 8-variable 2-year KFRE models as independent predictors of monthly healthcare costs in patients with CKD stages 3-4.

Methods: Optum's de-identified Integrated Claims-Clinical dataset of US patients (2007-2017) was queried to identify patients with non-dialysis CKD stages 3-4 (90-day average eGFR ≥15 to <60 mL/min/1.73 m^2) followed by 2 consecutive serum bicarbonate 12 to <30 mEq/L, 28–365 days apart, with 6 months pre-index data and ≥2 years of post-index or death within 2 years, plus concurrent medical claims. The first qualifying serum bicarbonate test established the index date. KFRE elements were evaluated during the pre-index period and predicted risk scores of 2-year kidney failure were computed for each patient. Monthly medical costs were calculated for each patient from individual healthcare insurance claims and log-transformed due to skew. Patients were also stratified by index CKD stage. Generalized linear regression models were used to examine the association of KFRE score and costs. The individual components of the KFRE were similarly analyzed.

Results: 1721 patients qualified for this observational study (1475 and 246 with CKD stage 3 and 4 at index, respectively). Both the 4- and 8-variable KFRE assessments were associated with log monthly medical costs. Per 1% increased risk for 2-year kidney failure risk predicted by KFRE, costs were increased significantly: for CKD stage 3 (parameter estimates: 0.065 [P=0.016] and 0.126 [P<0.0001]) and for CKD stage 4 (parameter estimates: 0.029 [P=0.001] and 0.040 [P<0.0001]). Of the individual components, lower serum albumin and lower serum bicarbonate were consistently associated with higher monthly medical costs.

Conclusions: Both the 4- and 8-variable KFRE were associated with higher medical costs for patients with CKD stages 3 or 4, with monthly medical cost increases of 6.7% - 13.5% for CKD stage 3 and 2.9% - 4.1% for CKD stage 4, respectively, for each 1% increase in 2-year kidney failure risk. The KFRE may be a useful tool to anticipate medical costs for patients at risk of kidney failure.

PO2412

Applying Predictive and Causal Analytics to Design Intelligently Targeted Outreach to Address Underrecognition of CKD

Anthony T. O'Brien,[1] Ali Azari,[2] Emily Kipping,[2] Bruce F. Culleton.[2] CVS Kidney Care *[1]Aetna Inc, Hartford, CT; [2]CVS Health Corp, Woonsocket, RI.*

Background: 43% of adults with advanced Chronic Kidney Disease (CKD) are unaware of their diagnosis. 2 priorities for The National Institute of Diabetes and Digestive and Kidney Research are to create diagnostic models of kidney function, and to promote studies with responsive outcomes. We propose a novel approach to identify undiagnosed members and increase CKD testing.

Methods: To target Commercial and Medicare members for CKD testing, we combined 3 techniques: i) machine learning, ii) causal inference, and iii) clinical practice. Our machine learning model predicted members' risk of stage 3b+ CKD. With causal inference, we calculated the average per member per year costs-difference over 6 years between an early or late CKD test. Using the members' risk score, their associated costs, and their expected behavior change we created a targeting threshold. When the cost-difference of testing a member was larger than the threshold, we enrolled those members into the study. Our intervention consisted of low-cost member outreach like emails and

direct mailers (Dir. M). Members were randomized into a i) control group for Dir. M, ii) a control group for email and Dir. M, iii) Dir. M with interactive voice response (IVR), iv) Dir. M only, v) Dir. M and email, and vi) Dir. M and email with IVR. Logistic regression was used for the primary outcome of testing for CKD.

Results: We enrolled 76,388 members of which 35,933 were allocated to the control group. Baseline features were comparable across test and control (age: 80.4±8.3 vs 80.4±8.3, male: 36% [36.3-36.4%] vs 35.9% [35-36%], diabetes: 40.8% [40.3-41.2%] vs 41.1% [40.5-41.6%], hypertension: 88.8% [88.5-89.1%] vs 88.6% [88.3-88.9%]). Members that received only Dir. M were not ever statistically different from control. In the other test arms, testing increased by 1.6-2.1 percentage points at 90 days ($p < 0.05$). Post-hoc analysis found an increase in laboratory services, PCP and Nephrologist usage, nephroprotective drug claims, and new or updated CKD diagnosis at 90 and 180 days (all $p<0.05$). Direct medical costs were unchanged.

Conclusions: Low-cost outreach with individualized targeting led to significant increases in CKD stage diagnosis and care-gap closure. The study was under powered to observe direct medical cost savings.

PO2413

Association of Kidney Function with Major Postoperative Events After Noncardiac Ambulatory Surgeries: A Population-Based Cohort Study

Tyrone Harrison,[1] Brenda Hemmelgarn,[2,1] Matthew T. James,[1] Braden J. Manns,[1] Marcello Tonelli,[1] Mary E. Brindle,[1] Shannon M. Ruzycki,[1] Kelly B. Zarnke,[1] James Wick,[1] Paul E. Ronksley.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: Though people with chronic kidney disease (CKD) frequently receive outpatient surgical procedures, the associated risks of major perioperative outcomes is unknown. In this study, we estimated the association between estimated glomerular filtration rate (eGFR) and a composite of acute myocardial infarction (AMI) or death after ambulatory non-cardiac surgery.

Methods: This retrospective population-based cohort study used administrative health and laboratory data from Alberta, Canada, and included adults with measured preoperative kidney function undergoing ambulatory non-cardiac surgery between April 2005 and February 2017. We categorized participants into six eGFR categories (in mL/min/1.73m^2) of ≥ 60 (G1-2), 45-59 (G3a), 30-44 (G3b), 15-29 (G4), < 15 not receiving dialysis (G5ND), and those receiving chronic dialysis (G5D). The odds of AMI or death within 30 days of surgery were estimated using multivariable generalized estimating equations. Secondary outcomes included the odds of hospitalization, emergency department (ED) and urgent care center (UCC) visits.

Results: We identified 543,160 procedures in 323,521 people with a median age of 66 years (IQR 56-76); 52% were female. Overall, 2,338 people (0.7%) died or had an AMI within 30 days of surgery. Compared with the G1-2 category, the adjusted odds ratio (OR) of death or AMI increased from 1.1 (95% Confidence interval [CI]: 1.0, 1.3) for G3a to 3.1 (CI: 2.6, 3.6) for G5D. The associations between eGFR and the independent components of this outcome were consistent for both death and AMI, and similar for 30-day hospitalization. ED and UCC visits within 30 days were frequent (17%), though similar across eGFR categories.

Conclusions: We found that ambulatory surgery was associated with a low overall risk of major postoperative events, though was significantly higher for people with CKD. This study may inform their perioperative shared decision-making and management, and suggests that more refined risk stratification approaches based on eGFR may be warranted.

Funding: Government Support - Non-U.S.

PO2414

Association of Multimorbidity and Mortality Risk in US Veterans with New-Onset CKD

Nilka Rios Burrows,[1] Devasmita Choudhury,[2,3] Wei Yu,[3] Alain Koyama,[1] Robert Nee,[4] Alfred K. Cheung,[5,6] Keith C. Norris,[7] Guofen Yan.[3] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]VA Medical Center Salem, Salem, VA; [3]University of Virginia School of Medicine, Charlottesville, VA; [4]Walter Reed National Military Medical Center, Bethesda, MD; [5]VA Salt Lake City Health Care System, Salt Lake City, UT; [6]University of Utah Health, Salt Lake City, UT; [7]University of California Los Angeles, Los Angeles, CA.*

Background: Many patients with CKD live with multiple chronic conditions. We examined the association of multimorbidity at CKD onset and the 10-year risk of death in US veterans with incident CKD.

Methods: The cohort included 892,005 veterans with new-onset CKD (estimated GFR<60 mL/min/1.73 m^2 for >3 months) between 2004 and 2018 in the US Veterans Health Administration, followed for up to 10 years or December 31, 2018. Multimorbidity was measured by the total number of comorbidities among 16 conditions based on ICD-9/ICD-10 codes during the 2 years before and up to 6 months after CKD onset, and categorized as 0–1, 2, 3, 4, 5, 6, 7, and ≥8 conditions. We estimated mortality risk by age groups at CKD onset.

Results: The median number of comorbidities at CKD onset was 4 (interquartile range: 3-6). After multivariable adjustment, the association between increasing multimorbidity and mortality risk was seen in all age groups, but was stronger in younger than older groups (Table). Death risk when having ≥5 comorbidities was >8-fold higher in ages 18-44, but only >2-fold higher in ages 85-100, compared to their age counterparts with 0-1 comorbidity. Multimorbidity patterns also differed by age. For example, among those with only 2 concurrent comorbidities, hypertension and depression co-occurred most frequently in ages 18-44, as compared to hypertension and cardiovascular disease in older age groups.

Conclusions: At CKD onset, 95% of patients had multiple comorbidities. The association of multimorbidity and mortality was greater for younger patients. Effective plans for early CKD diagnosis and timely treatment of comorbidities may improve survival in CKD, especially for younger patients.

Funding: NIDDK Support, Other U.S. Government Support

Hazard ratios (95% CI) of death across multimorbidity categories at CKD onset

Number of comorbidities at CKD onset	Percent of patients in each category	Ages 18-44	Ages 45-64	Ages 65-84	Ages ≥85-100
0-1	5.2	1	1	1	1
2	11.8	2.7 (1.4-5.5)	1.8 (1.6-1.9)	1.4 (1.4-1.5)	1.2 (1.1-1.2)
3	18.0	3.8 (2.0-7.5)	2.6 (2.4-2.8)	1.9 (1.8-1.9)	1.4 (1.4-1.5)
4	19.3	5.9 (3.1-11.4)	3.5 (3.3-3.8)	2.4 (2.3-2.4)	1.7 (1.6-1.8)
5	16.7	8.5 (4.4-16.2)	4.6 (4.3-5.0)	3.0 (3.0-3.1)	2.1 (2.0-2.2)
6	12.4	10.5 (5.4-20.2)	5.8 (5.4-6.3)	3.7 (3.6-3.8)	2.5 (2.3-2.6)
7	8.1	13.1 (6.7-25.5)	7.4 (6.9-8.0)	4.6 (4.5-4.8)	3.0 (2.8-3.2)
≥8	8.5	15.6 (8.1-30.1)	10.8 (10.0-11.7)	6.5 (6.3-6.7)	3.9 (3.7-4.1)

PO2415

Self-Reported Walk Pace and Cardiovascular Events in Adults with CKD

Jacob Bruinius,[1] Mary Hannan,[1] Jiang He,[2] Julia Brown,[1] Mayank Kansal,[1] Milda R. Saunders,[3] Jinsong Chen,[1] Ana C. Ricardo,[1] James P. Lash.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]Tulane University School of Medicine, New Orleans, LA; [3]University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Physical function, as measured by self-reported walk pace, is lower in patients with CKD compared to the general population. While slower walk pace has been found to be associated with cardiovascular outcomes in non-CKD populations, its relationship to cardiovascular outcomes in CKD patients has not been fully explored.

Methods: We used data from 3925 adults with mild-to-moderate CKD enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study. Walk pace (scored 0-4) was self-reported using the Multi-Ethnic Study of Atherosclerosis Typical Week Physical Activity Survey. Outcomes included atherosclerotic events (a composite of myocardial infarction, stroke or peripheral arterial disease), incident heart failure, all-cause death, and cardiovascular death. Multivariable Cox proportional hazard models with time-updated covariates were used to evaluate the association of walk pace with outcomes.

Results: At baseline, mean age was 58 years, 45% were women, 33% had self-reported cardiovascular disease, mean eGFR was 45 ml/min/m^2, 12% reported brisk or striding walk pace (>3 mph), 39% reported average walk pace (2-3 mph), and 48% reported walk pace of none or casual (<2 mph). During a median follow-up of 11.5 years, there were 725 atherosclerotic events, 790 incident heart failure events, 1333 deaths from any cause, and 434 cardiovascular deaths. In fully adjusted models, there was a graded association between walk pace and risk for each outcome (**Figure**).

Conclusions: In this cohort of adults with CKD, faster self-reported walk pace was associated with lower risk of cardiovascular events and mortality. These findings may have implications for risk stratification, as well as for future interventions targeting physical function in patients with CKD.

PO2416

Low Magnesium Predicts Cardiovascular Outcomes in Pre-Dialysis CKD Patients: Results from the KNOW-CKD Study

Minjung Kang,[1] Eunjeong Kang,[2] Seung Seok Han,[1] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Ewha Womans University, Seoul, Republic of Korea.*

Background: There are few large-scale studies of the association between magnesium (Mg) and cardiovascular (CV) outcomes in pre-dialysis chronic kidney disease (CKD) patients. Therefore, we analyzed the effects of Mg on CV outcomes in a large-scale cohort of pre-dialysis CKD patients.

Methods: We investigated the association between serum Mg and CV outcomes in a prospective, multi-center cohort of pre-dialysis CKD patients (n=1,646). Patients were divided into four groups according to serum Mg concentration. The primary endpoint was composite outcome, defined as either a CV event and/or all-cause death. Secondary outcomes were coronary artery calcification (CAC) progression and arterial stiffness progression as assessed by mean brachial-ankle pulse wave velocity (baPWV).

Results: During a median follow-up of 6.0 years, 196 (11.9%) patients had the composite outcome of a CV event and/or all-cause death. In a multivariable cause-specific model, patients in the lowest Mg group (serum Mg ≤2.0 mg/dL) had an elevated risk of a composite outcome (hazard ratio (HR) 1.71 [1.02–2.84]; *P*=0.038; serum Mg =2.2 mg/dL as the reference group). Subgroup analyses showed that low Mg was particularly associated with risk of a composite outcome in patients with early CKD and those who were male. Patients in the lowest Mg group also had increased risks of progression to CAC and arterial stiffness relative to the reference group (Mg =2.2 mg/dL).

Conclusions: Low Mg level is a predictor of cardiovascular outcomes in pre-dialysis CKD patients.

PO2417

Baseline Renal Function and Left Ventricular Assist Device Outcomes Among Patients with CKD

Muhammad Abdulbasit, Omar K. Salameh, Mujahed M. Dauleh, Ronald P. Miller, Umar Farooq, Naman Trivedi, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Chronic kidney disease (CKD) is associated with increased risk of cardiovascular disease. Coronary artery disease is one of the most important causes of heart failure with reduced ejection fraction, a condition for which advanced therapies such as left ventricular assist device (LVAD) and orthotopic heart transplant (OHT) are increasingly utilized. Information about outcomes of CKD patients with LVAD is limited. We studied the outcomes of patients with CKD who had received LVAD in a large cohort.

Methods: We performed a retrospective multi-center cohort study using TriNetX Research Network database, a federated electronic medical records network, to identify 4939 patients≥ 18 years from 31 healthcare organizations, from the United States, who had undergone LVAD implantation between 1/1/2010 and 12/31/2019. We excluded 1552 patients with estimated glomerular filtration rate (eGFR) ≥ 90 mL/min/1.73 m^2. We grouped the eligible patients into stages of CKD, based on eGFR: [stages: 2 (n=1140), 3a (n=821), 3b (n=563), 4 (n=182), and 5 (n=681)]. The primary and secondary outcomes were survival and receiving an OHT within one year of LVAD implantation, respectively. We used CKD stage 2 as the reference and calculated the odds ratio (OR) [with 95% confidence interval (CI)] of each of the two outcomes.

Results: A total of 172 patients died within one year of LVAD implantation. When compared with Stage 2 CKD, and after propensity score matching, there was a decrease in the OR of survival at one year with higher stages of CKD: —Stage 3b: OR: 0.64 (CI: 0.41, 0.99); —Stage 4: OR: 0.42 (CI: 0.24, 0.73); —Stage 5: OR: 0.57 (0.38, 0.86). There was no significant difference in the odds of survival between stage 3a and the reference group. A total of 274 heart transplants were performed within the first year after LVAD implantation. Patients in the reference group were more likely to receive an OHT within the first year in comparison with CKD stage 5 patients (OR: 1.61; CI: 1.06, 2.45).

Conclusions: Presence of a more advanced stage of CKD is associated with decreased survival in LVAD patients. Patients with CKD stage 2 are more likely to undergo OHT compared to those with CKD stage 5.

PO2418

Associations of eGFR and Albuminuria with Physical Performance

Ryan Mello,[1] Allyson Hart,[1] Anne M. Murray,[1,2] Cynthia S. Davey,[3] Kirsten L. Johansen.[1] *[1]Hennepin Healthcare, Minneapolis, MN; [2]Berman Center for Outcomes and Clinical Research, Hennepin Healthcare Research Institute, Minneapolis, MN; [3]University of Minnesota Medical School Twin Cities, Minneapolis, MN.*

Background: Reduced physical performance is associated with increased all-cause mortality, and individuals with chronic kidney disease (CKD) are at an increased risk of suffering from impaired physical function. However, most studies have not included assessment of albuminuria. We hypothesized that eGFR and albuminuria would be independently associated with physical performance.

Methods: The Brain in Kidney Disease (BRINK) cohort was designed to examine cognitive and physical function among adults with CKD. Intentional recruitment ensured participants with an eGFR (ml/min/1.73m^2) range from <30 to 59 were included, in addition to a control group with eGFR ≥60. We estimated GFR using creatinine ($eGFR_{Cr}$) and, in separate analyses, cystatin C ($eGFR_{CysC}$), and measured urine albumin to creatinine ration (UACR). We assessed physical performance using the Short Physical Performance Battery (SPPB; range 0-12). 571 community-dwelling adults with baseline SPPB scores were included. Univariate and multivariable logistic regression models, adjusted for demographics and comorbidity, examined associations of eGFR and UACR with SPPB <10.

Results: Mean age was 69.3 years. 157 (27.5%) participants had $eGFR_{Cr}$ <30, 276 (48.3%) 30 to <60, and 138 (24.2%) ≥60. In separate univariate analyses, both lower $eGFR_{Cr}$ and higher UACR were associated with higher odds of low SPPB (Table). In the adjusted model with $eGFR_{Cr}$, UACR and covariates, UACR retained a significant association with low SPPB, but $eGFR_{Cr}$ did not. Similar results were found in models with $eGFR_{CysC}$ and UACR.

Conclusions: Both low $eGFR_{Cr}$ and high UACR were associated with poor physical performance in univariate analyses, but only UACR remained associated in the fully adjusted model. Similar results with $eGFR_{CysC}$ suggest that confounding based on muscle mass does not explain the lack of association between $eGFR_{Cr}$ and physical performance and raises the possibility that vascular or endothelial function may be important factors.

PO2419

Association Between Estimated Glomerular Filtration Rate Decline and Clinical Outcomes in Nondiabetic CKD

Christoph Wanner,[1] Johannes Schuchhardt,[2] Chris Bauer,[2] Meike D. Brinker,[3] Frank Kleinjung,[3] Tatsiana Vaitsiakhovich.[3] *[1]Universitatsklinikum Wurzburg Medizinische Klinik und Poliklinik I, Wurzburg, Germany; [2]MicroDiscovery GmbH, Berlin, Germany; [3]Bayer AG, Berlin, Germany.*

Background: There is limited evidence on association between surrogate laboratory endpoints and hard clinical outcomes in chronic kidney disease (CKD). This real-world data analysis investigated dependence between relative estimated glomerular filtration rate (eGFR) decline of ≥30%, 40%, 57% and cardio-renal outcomes in non-diabetic CKD patients treated in routine clinical practice.

Methods: Individual-level data from the US claims database, Optum Clinformatics Data Mart (CDM), for years 2008 – 2018 were analysed. Adult individuals were required to have CKD stage 3 or 4 (index date), 365 days of continuous insurance prior to index (baseline period). Individuals with diabetes mellitus, CKD stage 5 or end-stage kidney disease (ESKD) prior index or kidney failure, transplant or dialysis in the baseline period were excluded. Patients were followed until insurance/data end, or death. Two selected hard clinical outcomes were hospitalisation for heart failure (HHF) and a composite of ESKD/kidney failure/need for dialysis. To investigate the association between eGFR decrease and clinical outcomes, an intercurrent event analysis was performed using eGFR decline of ≥30%, ≥40% or ≥57% as an intercurrent event.

Results: Of 64 million individuals in Optum CDM, 504,924 satisfied the selection criteria, median age 75 years, 60% female, 10% black. At baseline, eGFR values were available for 62% of individuals; median eGFR was 53; 94% of those patients had at least one eGFR value in the follow-up period of a median 744 days. Proportion of the patients with eGFR decline of ≥30%, 40%, 57% was 5%, 3% and 1%. More rapid eGFR decline was associated with increased risk of the outcome. The hazard ratio for HHF was 3.03, 3.41, 3.86 and for ESKD/kidney failure/need for dialysis it was 5.61, 8.29 and 18.63 in patients with eGFR decline of ≥30%, 40%, 57% as compared to those with no such decline, respectively.

Conclusions: In this analysis of the US non-diabetic CKD patients treated in routine clinical practice, a relative eGFR decline of ≥30%, ≥40%, ≥57% was associated with a subsequent HHF and ESKD/kidney failure/need for dialysis, supporting that carefully selected lab-based surrogate measures may be used as early indicators of hard clinical outcomes.

PO2420

Effect of Obesity and Metabolic Dysfunction on Cardiovascular Events and Progression to ESRD in CKD

Jin sug Kim,[1] Shinyeong Kang,[1] Kyung hwan Jeong,[1] Dae Kyu Kim,[1] Jongho Kim,[1] Soo-Young Yoon,[1] Yang gyun Kim,[2] Sangho Lee,[2] Hyeon Seok Hwang.[1] *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.*

Background: Obesity and metabolic dysfunction increased the risk of cardiovascular event and chronic kidney disease (CKD) progression. However, there are conflicting results on clinical outcomes in obese patients without metabolic dysfunction and it is unclear whether metabolically healthy obesity increases the risk of cardiovascular events and progression to end-stage renal disease in CKD patients.

Methods: We enrolled 166,397 CKD patients from Korea National Health Insurance Service Health Examinee Cohort between January 2009 and December 2011. Obesity is defined as body mass index greater than 23kg/m^2. Metabolic dysfunction was assessed using following components: waist circumference, blood pressure, fasting blood sugar, triglyceride level, high-density lipoprotein cholesterol level. The primary endpoint was the ischemic heart disease, ischemic stroke and progression to end-stage renal disease (ESRD).

Results: Of total CKD patients, the proportion of patients with metabolic dysfunction was significantly higher in obese patients than in non-obese patients (25.1% vs. 5.4%; $p < 0.001$). In multivariable Cox-regression analysis, compared to metabolically healthy non-obese patients, metabolic dysfunction significantly increased the risk of ischemic heart disease and progression to ESRD in patients with and without obesity. Patients with metabolically healthy obesity were significantly associated with increased risk of ischemic heart disease (HR 1.22; 95% CI 1.00-1.50) and ischemic stroke (HR 1.48; 95% CI 1.10-1.19). However, the risk of progression to ESRD was not significantly increased (HR 0.98; 95% CI 0.87-1.10).

Conclusions: The metabolic dysfunction was significantly associated with worse clinical outcomes in CKD patients, irrespective of obesity. The metabolically healthy obesity increased risk for ischemic heart disease and ischemic stroke, but not for progression to ESRD.

PO2421

Diet Quality and Kidney Outcomes in Adolescent and Adult American Indians: The Strong Heart Family Study

Reya H. Mokiao,[1,2] Amanda M. Fretts,[2] Jason F. Deen,[1,2] Jason G. Umans.[3,4] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA; [3]MedStar Health Research Institute, Hyattsville, MD; [4]Georgetown University, Washington, DC.*

Background: The burden of chronic and end stage kidney disease (CKD and ESKD), is exceedingly high amongst American Indians (AIs). We sought to examine the relationship of diet quality, a modifiable risk factor, and kidney outcomes in AI adolescents and adults, hypothesizing that poorer quality diets would be associated with incident albuminuria and accelerated eGFR decline in this population.

Methods: This is a secondary analysis of data from the Strong Heart Family Study, a longitudinal study of cardiovascular disease and its risk factors among AIs from Arizona, North and South Dakota, and Oklahoma (n=1721, mean age 39 +/- 16 years, 16% adolescents aged 14-21 years, 61% female, 28% with hypertension, 13% with diabetes, 52% with obesity, 4% with CKD at baseline). Participants completed two exams (baseline: 2001-2003; follow-up: 2007-2009). The primary exposure (at baseline) was the Alternative Healthy Eating Index (AHEI), a measure of diet quality on a 110-point scale (assessed using a 119-item Block food frequency questionnaire). The primary outcomes (at follow-up) were: 1) incident albuminuria (albumin to creatinine ratio 30mg/g); 2) eGFR decline of 30%. Generalized estimating equations were used to examine the association of AHEI (in quartiles) with incident albuminuria and eGFR decline.

Results: In total, 9.9% (5.6% of adolescents) had incident albuminuria and 5.6% of participants (9.2% of adolescents) had eGFR decline of 30%. Median AHEI for the poorest diet quartile was 34 compared to 55 for the healthiest diet quartile, each 10-20 points lower than AHEI scores from studies of the general population. The unadjusted odds ratio (OR) for incident albuminuria comparing extreme quartiles of diet quality (poorest versus healthiest [reference] quartiles) was 1.32 (95%CI 0.92, 1.89). After adjustment for baseline diabetes, eGFR and age, the OR for incident albuminuria was 1.79 (95% CI 1.24, 2.58). There were no significant unadjusted or adjusted associations of diet quality with eGFR decline.

Conclusions: These preliminary results suggest an association of diet quality and incident albuminuria in AI. Given the high burden of CKD in this population, further research is required to determine whether interventions to improve diet quality may improve kidney outcomes.

PO2422

Renal Function and Effect of Body Mass Index on Mortality Risk After Acute Myocardial Infarction

Shinyeong Kang, Hyeon Seok Hwang, Kyung hwan Jeong, Jin sug Kim. *Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea.*

Background: Obesity is paradoxically linked to greater survival benefit after acute myocardial infarction (AMI). In patients with renal impairment, higher body mass index (BMI) is also associated with protective effects against cardiovascular and all-cause mortality. However, there are no studies investigating the interactive effects of BMI and renal function on mortality risk after AMI.

Methods: We enrolled 12,647 AMI patients from Korea Acute myocardial Infarction Registry between November 2011 and December 2015. Patients were categorized based on renal function; normal (≥90 mL/min/1.73m^2), mild (90-45 mL/min/1.73m^2), and moderate impairment (<45 mL/min/1.73m^2). BMI was divided into four groups; underweight (<18.5 kg/m^2), ideal (18.5-23 kg/m^2), overweight (23-25 kg/m^2) and obesity (≥25 kg/m^2). The primary endpoint was 2-year mortality after AMI treatment.

Results: In multivariable Cox-regression analysis, compared to Ideal weight patients, overweight and obese patients were associated lower risk of mortality and underweight patients had the increased risk of mortality in all renal function categories. However, the survival effect of each BMI stratum was decreased as renal function worsened. The adjusted mortality risk of obesity was 0.63 (95% CI 0.0.41-0.99), 0.76 (95% CI 0.59-0.97) and 0.84 (95% CI 0.65-1.08) for patients with normal, mild and moderate renal function impairment, respectively. There was a significant interaction between BMI and renal function ($P = 0.010$). We found that the survival benefit of obesity for noncardiac death was decreased with decreasing renal function (P for interaction = 0.03), but obesity-related advantage was not changed between different renal function (P for interaction = 0.03).

Conclusions: The effect of BMI on mortality risk after AMI was dependent on renal function. The association between greater BMI and survival benefit was weakened as renal function was worsened. We suggest that the association between renal function and effect of BMI on mortality originated in non-cardiac death, not cardiac death.

PO2423

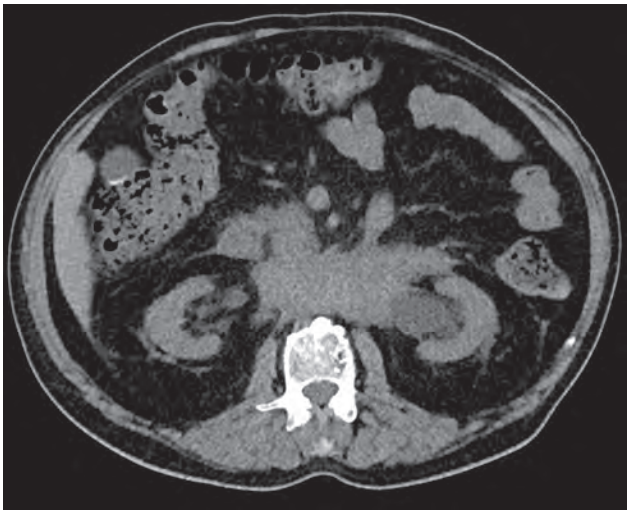
Steroid-Resistant Retroperitoneal Fibrosis in the Elderly

Ahmed Abdallah, Awais Nauman, Essa Abuhelaiqa. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Retroperitoneal fibrosis (RPF) is a rare disease characterized by chronic inflammation and fibrosis that involve multiple organs, including the ureters leading to obstructive uropathy. IgG4-related RPF accounts for the majority of cases. We present a case of obstructive uropathy secondary to RPF that is steroids resistant

Case Description: A 71-year-old male known case of atrial fibrillation on warfarin presents with urinary hesitancy and decrease output. No history of fever, weight loss or night sweats. His creatinine was 1.8mg/dL from baseline of 0.9mg/dL. A CT scan of the abdomen revealed a 15x14cm retroperitoneal lesion extending from aortic bifurcation and obstructing both ureters with moderate left-sided hydronephrosis. The patient required double J-stent (DJS) placement with no improvement in creatinine. Workup revealed elevated IgG4 levels (1215mg/L), normal CBC, negative quantiferon test. Chest X-ray, malignancy screening and PET scan were unremarkable. The patient refused the biopsy given the risk of bleeding. He was started on prednisolone 80 mg for one month with no improvement of hydronephrosis. The patient developed hypertension, hyperglycemia, and edema, hence switching to mycophenolate mofetil (MMF) with low-dose prednisone. Repeated CT scan showed a partial reduction in retroperitoneal fibrosis (12x13cm) with mild hydronephrosis

Discussion: Although rare, secondary causes of RPF such as tuberculosis, Castleman disease, Erdheim-Chester disease, lymphoma and bladder carcinoma should be identified. In idiopathic RPF, high-dose glucocorticoids are the first line of treatment. Several studies have shown the effectiveness of low-dose steroids in combination with immunosuppressive drugs like MMF or rituximab. The use of a combination treatment as a first-line treatment is still debatable, however, patients who cannot tolerate high doses of prednisolone and have poor treatment response should be considered for alternative therapy



PO2424

Peripheral Blood Mononuclear Cell Mitochondrial Bioenergetics Is Associated with Physical Performance in Patients with CKD

Armin Ahmadi,[1] Jennifer E. Norman,[1] Gwenaelle Begue,[3] Chenoa R. Vargas,[1] Usman Rehman,[1] Tae Youn Kim,[1] Henning Langer,[1] Thomas Jue,[1] Jorge Gamboa,[2] Baback Roshanravan.[1] *[1]University of California Davis, Davis, CA; [2]Vanderbilt University, Nashville, TN; [3]California State University Sacramento, Sacramento, CA.*

Background: Patients with CKD suffer from skeletal muscle dysfunction and impaired physical performance. Impaired muscle and systemic mitochondrial metabolism are central candidate mechanisms of skeletal muscle impairment in CKD. Live peripheral blood mononuclear cells (PBMC) mitochondrial bioenergetics may link altered metabolism in CKD with exercise intolerance. The association of PBMC bioenergetics with physical performance in CKD is unknown.

Methods: We recruited 13 participants with eGFR<60 ml/min/1.73m2. Cardiopulmonary fitness (absolute VO2 peak), total work performed, and work efficiency were measured using COSMED K5 wearable metabolic system during cycle ergometry testing. PBMC bioenergetics analysis were performed using the high resolution respirometry (Oroboros O2k). PBMC oxygen consumption rate was measured with sequential additions of pyruvate, oligomycin, FCCP, and antimycin A. We estimated basal, maximal uncoupled respiration (MUR) and spare respiratory capacity (SRC). SRC was defined as the difference between basal respiration and MUR. Pearson correlation coefficient was used to assess correlation of PBMC bioenergetics with muscle performance.

Results: The mean age of participants was 60.6 +/-9.5 years, eGFR was 35 +/-12.5 ml/min/1.73m^2 and 53% were females. PBMC MUR correlated with total work (r= 0.57, *P*-value=0.041) and efficiency (absolute) (r=0.58, *P*-value=0.034). PBMC SRC correlated with total work (r=0.58, *P*-value=0.036) and efficiency (r=0.60, *P*-value=0.029). VO2 peak correlated with PBMC basal respiration (r=0.56, *P*-value=0.044), MUR (r=0.69, *P*-value=0.007), and SRC (r= 0.71, *P*-value=0.006).

Conclusions: These results suggest that PBMC respiration is strongly associated with exercise capacity and efficiency. Further studies are needed to investigate biologic determinants of PBMC bioenergetic health and its validity as a surrogate marker of skeletal muscle metabolic health in CKD.

PO2425

Association of Proximal Tubular Secretory Clearance with Decline in Cognitive Function

Benjamin Lidgard,[1] Nisha Bansal,[1] Leila R. Zelnick,[1] Andrew N. Hoofnagle,[1] Jing Chen,[2] Derek J. Colaizzo,[3] Mirela A. Dobre,[4] Katherine T. Mills,[2] Anna C. Porter,[5] Sylvia E. Rosas,[6] Mark J. Sarnak,[7] Stephen L. Seliger,[8] James H. Sondheimer,[9] Manjula Kurella Tamura,[10] Kristine Yaffe,[11] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Tulane University, New Orleans, LA; [3]University of Pennsylvania, Philadelphia, PA; [4]University Hospital Chicago, Chicago, IL; [5]University of Illinois at Chicago, Chicago, IL; [6]Harvard University, Cambridge, MA; [7]Tufts University, Medford, MA; [8]University of Maryland Medical System, Baltimore, MD; [9]Wayne State University, Detroit, MI; [10]Stanford University, Stanford, CA; [11]University of California San Francisco, San Francisco, CA.*

Background: Persons with chronic kidney disease (CKD) are at risk for cognitive decline. The retention of protein bound organic solutes, normally cleared by renal tubular secretion, is hypothesized to contribute to cognitive dysfunction in CKD. We tested whether lower kidney clearance of secretory solutes is associated with cognitive decline in a multi-center CKD cohort.

Methods: We studied participants from the Chronic Renal Insufficiency Cohort (CRIC) study, excluding persons with prior stroke or baseline cognitive impairment. We estimated tubular secretory clearance by 24-hour kidney clearance of eight solutes primarily eliminated by tubular secretion. Cognitive function was measured by annual Modified Mini Mental Status (3MS) exams. We defined cognitive decline as a sustained >5 point decrease in the 3MS score from baseline. Associations were assessed with Cox survival models; we controlled for multiple comparisons by calculating q-values compared to the false discovery rate.

Results: Among 2366 study participants, the mean age was 58 years, mean eGFR was 46 mL/min/1.73 m2, and median baseline 3MS score was 96; 235 developed cognitive decline over a median of 7.22 years of follow-up (1.48 events per 100 person-years). Lower kidney clearance of five of the eight solutes was associated with cognitive decline after adjustment for baseline eGFR, urinary albumin excretion, and other potential confounders (Table).

Conclusions: Lower kidney clearance of secreted solutes was associated with cognitive decline over long-term follow-up in a prospective CKD cohort. The retention of secretory solutes may be a novel cause of impaired cognition in persons with CKD.

Funding: NIDDK Support

Clinical Features and Outcomes of Immunoglobulin G4-Related Disease Including Kidney Involvement

Sua Lee. *Eulji University College of Medicine, Daejeon, Republic of Korea.*

Background: Immunoglobulin G4-related disease (IgG4-RD) is a newly recognized disease, and a few epidemiologic studies about this disorder have been published. This research aimed to describe the clinical, laboratory, and histopathological features and outcomes of IgG4-RD.

Methods: Ninety-four patients who satisfied the comprehensive diagnostic criteria on IgG4-RD were included in this study. Fifty-eight (61.7%) were men. The mean age was 54.8 years, and the median follow-up duration was 32.9 months. The clinical feature between single and multiple organ involvement and with or without kidney involvement groups were evaluated based on symptoms and laboratory findings. The clinical outcome was assessed according to treatment strategies and response.

Results: Of 94 patients, 56 (59.6%) had multiple organs involvement. It showed a variety of symptoms and organs involved. Patients with multiple organ involvement had higher serum IgG and IgG4 levels than those with single organ involvement. Those with IgG4-related kidney disease (IgG4-RKD) had worse renal function. The incidence of peripheral blood eosinophilia and hypocomplementemia was higher in patients with renal involvement than in those without. Glucocorticoids-based therapy was most commonly used. (79.8%). Thirty-nine (41.5%) achieved complete remission. Eighteen (19.1%) relapsed after response to treatment. Eight (61.5%) of 13 patients with IgG4-RKD experienced improvement in renal function after treatment. None of the patients died during the follow-up period.

Conclusions: Kidney or other organ involvement is not significantly associated with clinical outcomes. Since IgG4-RD has different clinical features, it should be accurately diagnosed. Therefore, all physicians must actively diagnose and treat the condition.

Evaluation of Changes in Renal Microperfusion in Hyperuricemic-Induced Kidney Injury by Contrast-Enhanced Ultrasound Imaging

Ying Fan, Li He, Ze Li, Ting Zhou, Junjie Jia, Niansong Wang. *Department of Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: The diagnostic tools for early detection of renal injury caused by hyperuricemia are particularly lacking. Our study investigated the application of contrast-enhanced ultrasound (CEUS) in both hyperuricemic nephropathy (HN) rats and patients with hyperuricemia induced kidney injury.

Methods: Animal study was performed in hyperuricemic rat induced by feeding with a mixture of adenine and potassium oxonate for 4 weeks. In addition, 10 healthy volunteers and 40 patients with hyperuricemia induced kidney injury from CKD 1 to 4 stage were enrolled. CEUS was performed and low acoustic power contrast-specific imaging was used for quantitative analysis. Time-intensity curves (TICs) and quantitative indexes were created by Qlab software.

Results: In HN rat model monitored by CEUS technique, a significant decline in renal cortical perfusion as reflected by lower Peak Intensity (PI) value (25.43±1.31 vs. 37.9±1.75db) and longer time to reach peak (TTP) intensity (34.5±5.9 vs. 8.58±1.6s) was found when compared to control rats one week after administration of adenine and potassium oxonate, with more pronounced decline in HN rats at 4 weeks. Quantitative assessment of PI was well corelated with the serum Kim-1 level as well as the fibrosis scores in hyperuricemic rats from mild to advanced disease stage. Clinically, an early decline of PI in renal cortical perfusion was found in CKD stage 1 patients with hyperuricemia induced kidney injury as compared to the control group (61.1±4.52 vs. 65.80±7.10 db), which became progressively less visible in patients with more severe kidney injury in these patients of CKD 4 stage (40.93±13.36 db). An early increase of TTP could also be detected in HN patients with CKD 1 stage as compared to normal control (15.14±1.75 vs. 14.52±4.75s), which became the most pronounced in these patients of CKD 4 stage (67.32±3.29s). In addition, Peak value measured by CEUS was correlated with renal function in patients with hyperuricemia induced kidney injury.

Conclusions: CEUS is able to detect the renal perfusion in a dynamic way. Renal perfusion measured by CEUS correlates with the renal functional impairment and tubulointerstitial fibrosis, suggesting a sensitive, reliable and non-invasive method that could be applied in the diagnosis of hyperuricemia induced kidney injury in clinical practice.

PO2428

The Effect of Kidney Function on Reference Intervals of Serum-Free Light Chains and Free Light Chain Kappa/Lambda Ratio

Thorir E. Long,[1,2] Olafur S. Indridason,[2] Runolfur Palsson,[1,2] Stephen Harding,[3] Ola Landgren,[4] Sigurdur Y Kristinsson.[1,2] *[1]Haskoli Islands, Reykjavik, Iceland; [2]Landspitali, Reykjavik, Iceland; [3]The Binding Site, Birmingham, United Kingdom; [4]Sylvester Comprehensive Cancer Center, Miami, FL.*

Background: A kidney reference interval has previously been published for serum free light chain (FLC) ratio (0.37–3.10) but does not take into account the degree of kidney failure. The aim of this study was to establish a kidney reference interval for FLC and validate the current and propose new kidney reference interval for FLC ratio.

Methods: A total of 80,759 participants of the Iceland Screens, Treats or Prevents Multiple Myeloma (iStopMM) study were included. Participants were screened with serum FLC (FREELITE) measurements and serum protein electrophoresis (SPEP) and immunofixation (IFE). Serum creatinine (SCr) value closest to the screening was used to calculate eGFR. Participants with M-protein, eGFR > 59 mL/min/1.73 m^2, missing SCr measurement or > 1 year from the iStopMM screening were excluded. A nonparametric method was used to calculate the 95% CI. Partitioning was determined based on the proportion in each subgroup outside reference interval.

Results: Serum FLC were measured in 4885 (12%) participants with eGFR <60 mL/min/1.73 m^2, without evidence of monoclonality on SPEP or IFE. Median (IQR) kappa level was 20.6 mg/L (16.0–27.7), lambda level 18.6 mg/L (14.7–24.2) and FLC ratio 1.13 (0.95–1.35). Using current reference intervals, 58% and 20% of persons had values outside the normal range for kappa and lambda, respectively. The FLC ratio was outside the standard reference interval (0.26–1.65) in 8% and the kidney reference interval (0.37–3.10) in 0.6% of persons. Based on these findings, new reference intervals for FLC and FLC ratio have been established (Table).

Conclusions: Current reference intervals for FLC and FLC ratio are inaccurate for patients with decreased kidney function. We propose new reference intervals for FLC and FLC ratio for use in patients with chronic kidney disease.

Funding: Government Support - Non-U.S.

Reference intervals for kappa, lambda, and FLC ratio depending on kidney function

	New reference interval (2.5 - 97.5th percentile)		
Kidney function (ml/min/1.73 m2)	Kappa (2.5–97.5 percentile)	Lambda (2.5–97.5 percentile)	FLC ratio (2.5–97.5 percentile)
eGFR 45 – 59	10.0 – 45.3	9.2 – 37.7	0.63 – 1.88
eGFR 30 – 44	11.8 – 67.6	10.2 – 50.7	0.67 – 2.05
eGFR < 30	17.9 – 109.6	14.4 – 87.9	0.67 – 2.14

Background: Current classification of chronic kidney disease (CKD) into stages based on the indirect measures of kidney functional state, estimated glomerular filtration rate and albuminuria, is agnostic to the heterogeneity of underlying etiologies, histopathology, and molecular processes. We used genome-wide transcriptomics from patients' kidney biopsies, directly reflecting kidney biological processes, to stratify patients from three independent CKD cohorts.

Methods: Self-Organizing Maps (SOM), an artificial neural network machine-learning algorithm, assembled CKD patients into four novel subgroups, molecular categories, based on the similarity of their kidney transcriptomics profiles.

Results: The unbiased, molecular categories were present across CKD stages and histopathological diagnoses, highlighting heterogeneity of conventional clinical subgroups at the molecular level. CKD molecular categories were distinct in terms of biological pathways, transcriptional regulation and associated kidney cell types, indicating that the molecular categorization is founded on biologically meaningful mechanisms. Importantly, our results revealed that not all biological pathways are equally activated in all patients; instead, different pathways could be more dominant in different subgroups and thereby differentially influencing disease progression and outcomes.

Conclusions: This first kidney-centric unbiased categorization of CKD paves the way to an integrated clinical, morphological and molecular diagnosis. This is a key step towards enabling precision medicine for this heterogeneous condition with the potential to advance biological understanding, clinical management, and drug development, as well as establish a roadmap for molecular reclassification of CKD and other complex diseases.

Determinants of Serum β2 Microglobulin and β-Trace Protein in South Asians

Yeli Wang,[1,2] Andrew S. Levey,[3] Lesley A. Inker,[3] Saleem Jessani,[4] Rasool Bux,[4] Zainab Z. Samad,[4] Sonia Yaqub,[4] Amy B. Karger,[5] John C. Allen,[1] Tazeen H. Jafar.[1,6] *[1]Duke-NUS Medical School, Singapore, Singapore; [2]Harvard University T H Chan School of Public Health, Boston, MA; [3]Tufts Medical Center, Boston, MA; [4]The Aga Khan University, Karachi, Pakistan; [5]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [6]Duke University, Durham, NC.*

Background: β2-Microglobulin (B2M) and β-trace protein (BTP) are being considered for use with creatinine and cystatin C to improve the GFR estimation (Inker, AJKD 2020). In a Pakistani population, we showed that B2M and BTP did not improve the performance of eGFRcys and eGFRcr-cys (Wang, Kidney Week 2021). We aimed to evaluate non-GFR determinants of B2M and BTP in a general population in Pakistan.

Methods: We used linear regression models to assess associations between possible determinants and log-transformed levels of B2M and BTP adjusting for measured GFR among 557 participants (≥40 years) from Pakistan. The strength of significant associations was defined as strong, intermediate, or weak if the absolute percent difference in B2M or BTP levels was >10%, 5%-10% and <5%, respectively. R^2 was calculated in a model including all determinants.

Results: Non-GFR determinants with intermediate and strong associations with higher BTP included male sex, history of heart disease, and lower waist circumference. Non-GFR determinants of higher B2M included male sex, higher total body fat, and lower serum albumin. As shown in Table below, the non-GFR determinants assessed in our study along with measured GFR could explain 64.2% and 78.2% variance of BTP and B2M, respectively.

Conclusions: Factors associated with non-GFR determinants of BTP and B2M differ from those of cystatin C and creatinine. These and unidentified factors limit their usefulness in improving eGFR among South Asians.

Performance of Serum β2 Microglobulin and β-Trace Protein-Based Glomerular Filtration Rate Estimating Equations in South Asians

Yeli Wang,[1,2] Andrew S. Levey,[3] Lesley A. Inker,[3] Saleem Jessani,[4] Rasool Bux,[4] Zainab Z. Samad,[4] Sonia Yaqub,[4] Amy B. Karger,[5] John C. Allen,[1] Tazeen H. Jafar.[1,6] *[1]Duke-NUS Medical School, Singapore, Singapore; [2]Harvard University T H Chan School of Public Health, Boston, MA; [3]Tufts Medical Center, Boston, MA; [4]The Aga Khan University, Karachi, Pakistan; [5]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [6]Duke University, Durham, NC.*

Background: Previously we showed that glomerular filtration rate (GFR) estimation based on cystatin C alone (eGFRcys) had a large bias in a general population in Pakistan, and the GFR estimation based on cystatin C and creatinine (eGFRcr-cys) was not substantially better than eGFRcr-PK (Wang, KI Reports 2021). β2-Microglobulin (B2M) and β-trace protein (BTP) are being considered for use in a panel including creatinine and/or cystatin C to improve GFR estimation (Inker, AJKD 2020). We aimed to evaluate whether adding B2M and BTP would improve the performance of eGFRcys and eGFRcr-cys in a general population in Pakistan.

Methods: We assessed panel eGFR equations using B2M and BTP in addition to cystatin C (3-marker panel) or creatinine and cystatin C (4-marker panel) in a cross-sectional study of 557 participants (≥40 years) from Pakistan. We compared bias (median difference in measured GFR [mGFR] and eGFR), precision (interquartile range of differences), and accuracy (percentage of eGFR within 30% of mGFR [P_{30}] and root mean square error [RMSE]).

Results: As shown in the Table, the 4-panel equation (addition of BTP and B2M to creatinine and cystatin C) had lesser bias, better precision, and better accuracy (all *P*s<0.001) compared to the 3-panel equation (addition of BTP and B2M to cystatin C). The 3-panel equation worsened bias (*P*<0.001) and did not improve precision or accuracy (*P*>0.05 for both) relative to eGFRcys. Similarly, the 4-panel equation worsened bias (*P*<0.001) and did not improve precision or accuracy (*P*>0.05 for both) compared to eGFRcr-cys.

Conclusions: B2M and BTP did not improve the performance of eGFRcys and eGFRcr-cys in South Asians. Evaluation of non-GFR determinants of BTP and B2M would be of interest.

Equation	Filtration marker	Demographics	Bias[a], median difference (ml/min/1.73 m²)	Precision[b], IQR (ml/min/1.73 m²)	Accuracy[c], P_{30} (%)	Accuracy[d], RMSE
CKD-EPI eGFRcr	Creatinine	Age, sex, race	-6.76 (-9.10 to -5.90)	22.6 (20.3 to 25.4)	76.1 (72.4 to 79.6)	0.269 (0.263 to 0.323)
CKD-EPI eGFRcr-PK	Creatinine	Age, sex, race	NA	22.7 (20.6 to 25.8)	82.4 (79.0 to 85.5)	0.265 (0.243 to 0.297)
CKD-EPI eGFRcys[e]	Cystatin C	Age, sex, race	12.7 (10.7 to 15.2)	25.6 (23.2 to 28.3)	75.3 (69.4 to 76.9)	0.322 (0.303 to 0.349)
CKD-EPI eGFRcr-cys[f]	Creatinine, Cystatin C	Age, sex, race	2.73 (1.16 to 4.58)	21.2 (18.6 to 24.3)	83.1 (79.8 to 86.1)	0.253 (0.231 to 0.255)
2020 Cystatin C-B2M-BTP equation[g]	Cystatin C, B2M, BTP	Age, sex	15.3 (13.6 to 18.1)	26.7 (25.0 to 29.0)	70.7 (66.8 to 74.5)	0.331 (0.312 to 0.355)
2020 Creatinine-Cystatin C-B2M-BTP equation[h]	Creatinine, Cystatin C, B2M, BTP	Age, sex	5.12 (3.49 to 7.20)	22.1 (19.5 to 25.7)	81.3 (77.8 to 84.5)	0.256 (0.235 to 0.288)

[a]Bias was expressed as the median difference in measured GFR minus estimated GFR (95% confidence interval). A negative bias indicates overestimation of the measured GFR, and a positive bias indicates underestimation of the measured GFR. NA, not applicable because bias was expected to be zero (the equation was developed in the study population).
[b]Precision was expressed as the interquartile range (IQR) of differences between measured GFR and estimated GFR (95% confidence interval).
[c]P_{30} was defined as the percentage of individuals with estimated GFRs within 30% of measured GFR (95% confidence interval). The 95% CI of P_{30} was calculated using the Clopper-Pearson (Exact) method.
[d]RMSE was defined as the square root of the average squared different of measured GFR and estimated GFR on the logarithmic scale.
[e]The significance of differences among equations was determined with the use of the Wilcoxon sign rank test for bias, the McNemar test for P_{30}, and the bootstrap method for IQR and RMSE with 10,000 replications. *P* values for the 4-panel equation compared to the 3-panel equation were *P*<0.001 for bias, *P*<0.001 for precision, *P*<0.001 for accuracy, and *P*=0.24 for RMSE. *P* values for the 3-panel compared to eGFRcys were *P*<0.001 for bias, *P*=0.32 for precision, *P*=0.08 for accuracy, and *P*=0.55 for RMSE. *P* values for the 4-panel equation compared to eGFRcr-cys were *P*<0.001 for bias, *P*=0.71 for precision, *P*=0.12 for accuracy, and *P*=0.84 for RMSE.

Table. The performances of GFR estimating equations in comparison with measured GFR (N=557).

PO2432

Rare Variant Analyses in 171,172 UK Biobank Participants Reveals Novel Genetic Associations with Renal Function and Kidney Diseases

Shuwei Li, Brian Mautz, Jonghanne Park, Hideo Makimura, Matthew D. Breyer, Dermot F. Reilly, Mary Helen Black. *Janssen Research and Development LLC, Spring House, PA.*

Background: GWASs have identified hundreds of common genetic variants associated with chronic kidney disease (CKD), but the burden of rare loss-of-function (LoF) or pathogenic/likely pathogenic (P/LP) variants has not been systematically examined.

Methods: We tested gene-based and variant-level association for 5 renal biomarkers (Glomerular Filtration Rate estimated from serum creatinine and/or cystatin-C, Blood Urea Nitrogen, Urine Albumin-to-Creatinine Ratio) measured at enrollment and kidney-related diseases (e.g. End-Stage Renal Disease and stage4/5 CKD, CKD defined by biomarker and/or diagnosis from NHS data, Cystic kidney disease and Renal calculi) in 171,172 UK Biobank participants of genetically assessed European ancestry and with whole exome sequencing (WES). For each trait, we fit a genome-wide regression model and tested for association using REGENIE V2.0, adjusting for age, sex, 10 ancestry PCs, assessment center, and BMI where appropriate. For gene-based analyses, we generated 15 models to collapse ClinVar-classified P/LP, putative LoF and deleterious variants predicted by 16 *in silico* scores (SIFT, Polyphen, BayesDel, etc.) from dbNSFP 4.1c.

Results: We identified 33 and 18 genes associated with ≥2 biomarkers and ≥1 kidney diseases across collapsing models (FDR<0.05), respectively. *PKD1/2, COL4A3/4, CUBN, IFT140* were associated with both biomarkers and kidney diseases. Association analyses also highlighted genes including: *COL4A1, CST3, LAMC1, LRP2, SLC22A2, SLC34A3* and *SH2B3*. Variant-level analyses further informed impact on protein, e.g. the *SLC22A2* association signal was mainly driven by a frameshift (rs8177505) with lowering effects on eGFR (p=1e-27, beta=-6.2, MAF=0.12%). The exome-wide variant analyses revealed 29 genes (eg. *UMOD*) with variant associations (p<5e-8) with >3 biomarkers or ≥1 endpoint, including 2 that were also implicated from gene-based analyses (*COL4A4* and *CUBN*).

Conclusions: This large-scale study elucidates the genetic landscape of kidney diseases. Our findings validate established genes and reveal novel genetic associations with renal function and kidney diseases.

High Dietary Phosphate Intake Causes Inflammatory Tubular Injury and Fibrosis in Mice

Isabel Vogt,[1] Beatrice Richter,[1] Stefanie Walter,[1] Jessica Schmitz,[2] Jan H. Braesen,[2] Roland Schmitt,[3] Dieter Haffner,[1] Maren Leifheit-Nestler.[1] *[1]Hannover Medical School Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover, Germany; [2]Hannover Medical School Institute of Pathology, Nephropathology Unit, Hannover, Germany; [3]Hannover Medical School Department of Nephrology and Hypertension, Hannover, Germany.*

Background: Due to the increasing consumption of processed food, the dietary inorganic phosphate intake clearly exceeds the recommended daily allowance. Elevated phosphate levels are associated with a higher cardiovascular and all-cause mortality in the general population and accelerated progression of chronic kidney disease (CKD). It is under investigation whether chronic phosphate load represents a renal health risk in the absence of CKD.

Methods: Male C57BL/6 mice were fed with a 2% high phosphate diet (HPD) or respective 0.8 % normal phosphate diet (NPD) for six months. We collected blood, urine and kidneys to investigate phosphate metabolism, kidney function, tissue alterations and inflammation.

Results: Six months HPD significantly increased plasma levels of the phosphaturic hormone fibroblast growth factor (FGF) 23 resulting in enhanced phosphaturia and elevated serum phosphate level. HPD in mice caused albuminuria and increased plasma creatinine level. Histological analyses revealed that mice on HPD develop proximal tubular injury characterized by loss of cell polarity and brush border membranes, flattened

epithelia, increased proliferation, mononuclear interstitial infiltration and fibrosis. The kidney damage in HPD was accompanied by increased renal expression of the kidney injury marker *Kim-1* und *Ngal* mice. Kim-1 accumulated in regions of tubular lesions. Flow cytometry analysis demonstrated that the HPD reduced storage of $Ly6C^{hi}$ monocytes in the spleen and concurrently, enhanced accumulation of $F4/80^{+}$ macrophages and dendritic cells in the kidney. Histological analyses proofed accumulation of $F4/80^{+}$ macrophages and $CD3^{+}$ T-cells in areas of tubular injury that associated with increased renal expression of chemotaxis and growth factors for monocytes and macrophages *Ccl2, Csf1* and *Il34* in HPD mice. Finally, HPD caused renal fibrosis associated with increased *collagen 1, Ctgf*, and *Tgfb1* expression.

Conclusions: Chronic high phosphate load impairs kidney function by causing a strong inflammatory response and proximal tubular injury in healthy mice. Our results indicate that chronic high phosphate intake might be a renal health risk not only for CKD patients but also for the general population.

PO2434

Apabetalone Downregulates Fibrotic, Inflammatory and Calcific Processes in Renal Mesangial Cells: Mechanism for Reduced Cardiac Events in CKD Patients

Dean Gilham,[1] Li Fu,[1] Brooke D. Rakai,[1] Sylwia Wasiak,[1] Laura Tsujikawa,[1] Chris Sarsons,[1] Stephanie Stotz,[1] Jan O. Johansson,[3] Michael Sweeney,[3] Norman C. Wong,[1] Kamyar Kalantar-Zadeh,[2] Ewelina Kulikowski.[1] *[1]Resverlogix Corp, Calgary, AB, Canada; [2]University of California Irvine, Irvine, CA; [3]Resverlogix Inc., San Francisco, CA.*

Background: Major adverse cardiac events (MACE) are prevalent in patients with chronic kidney disease (CKD). Apabetalone inhibits BET proteins, which regulate expression of genes involved in fibrosis, inflammation & calcification. In the phase 3 BETonMACE trial, apabetalone reduced MACE in patients with CKD (eGFR<60) implying favorable effects on the kidney-heart axis. Here we examine apabetalone's impact on pathways of nephropathy in human renal mesangial cells (HRMCs).

Methods: HRMCs were stimulated with TGF-β1 or LPS ± 1-25μM apabetalone. Gene expression was measured by real-time PCR & RNA-seq. Smooth muscle actin (a-SMA) was examined by immunofluorescence & alkaline phosphatase (TNALP) activity in biochemical assays. RNA-seq from TGF-β1 stimulated HRMC was evaluated by GO and Ingenuity Pathway Analysis (IPA).

Results: In HRMCs, apabetalone suppressed TGF-b1 induced pro-fibrotic gene expression including (a) a-SMA, a fibrotic marker, by 90% $p<0.001$ & de novo a-SMA protein production (b) fibronectin, an extracellular matrix (ECM) component, by 44% $p<0.001$ (c) NOX4, promoting reactive oxygen species (ROS) production, by 82% $p<0.001$ (d) TNALP, promoting calcification, by 96% & TNALP activity by 96% $p<0.001$. Apabetalone opposed LPS induced inflammatory gene expression: IL6 by 94%, IL1B by 95% & PTGS2 (COX2) by 94% $p<0.001$. In GO, ECM gene sets were in the top 20 affected by apabetalone, indicating reduced fibrosis. IPA predicted inhibition of NfkB-RelA and NFkB complex to suppress inflammation, and activation of glucose utilization & tolerance of ROS production pathways, such as Oxidative Phosphorylation (z-score 5.7 $p<0.01$ at 25μM; z-score 3.5 $p>0.05$ at 5μM) and NRF2-Mediated Oxidative Stress Response (z score 2.3 $p<0.001$ at 25μM; z-score 1.6 $p<0.001$ at 5μM).

Conclusions: Apabetalone downregulates responses to TGF-β1 or LPS that promote fibrosis, inflammation & calcification in HRMCs. Changes in energy metabolism pathways predict apabetalone enables HRMC to cope with elevated glucose. Our results provide mechanistic insight into reduced MACE in CKD patients receiving apabetalone in the BETonMACE trial, & predict efficacy in the upcoming phase 3 BETonMACE2 trial.

Characterization of Nano-Sized Silica in Sugarcane Ash and Its Potential Role in the Pathogenesis of CKD of an Unknown Etiology

Keegan L. Rogers,[1] Carlos A. Roncal-jimenez,[2] Richard J. Johnson,[2] Jared M. Brown.[1] *[1]University of Colorado Anschutz Medical Campus, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Division of Renal Diseases and Hypertension, Aurora, CO.*

Background: Sugarcane burning by farmers in developing countries is hypothesized to contribute to an endemic kidney pathology called chronic kidney disease of an unknown etiology (CKDu). Further, elemental analysis of the sugarcane stalks was shown to have a high percentage of amorphous silica (SiO_2). We hypothesized that burning of sugarcane generates nano-sized particles that are easily inhaled and translocated to the kidney thereby contributing to CKDu in sugarcane workers.

Methods: To determine if nano-sized particles are present in sugarcane ash, we utilized single particle inductively coupled plasma mass spectrometry (ICP-MS) and dynamic light scattering (DLS). To determine the effects of SiNPs on the kidney, we used a human proximal convoluted tubule cell line (HK-2) to recapitulate the nephron's exposure to sugarcane ash, desilicated ash, sugarcane ash derived SiNPs, and pristine 200 nm SiNPs at 0.25, 2.5, and 25 μg/mL.

Results: Using single particle ICP-MS, we identified silica nanoparticles (SiNPs) within digested sugarcane ash which ranged in size from 190-212 nm. DLS analysis of digested ash confirmed the presence of nanoparticles with a hydrodynamic diameter of ~180 nm and Despite not being directly cytotoxic to HK-2 cells at 6 hours at any dose, SiNPs are taken up leading to significant production of reactive oxygen species and mitochondrial superoxide within the first hour of exposure at all doses.

Conclusions: This indicates that the presence of silica nanoparticles from sugarcane ash in the kidney may lead to NLRP3 inflammasome activation and epithelial mesenchymal transition occurring which will lead to a CKDu phenotype and disease pathogenesis.

Release of ATP from Renal Tubular Epithelial Cells via Connexin 43 Deteriorates Renal Fibrosis After Unilateral Ureteral Obstruction

Rui Zeng. *Huazhong University of Science and Technology Tongji Medical College, Wuhan, China.*

Background: As a kind of DAMPs (Danger associated molecular patterns), ATP is released after stress or injury through ATP-permeable channels, most likely to be connexin hemichannel proteins. Among which, connexin 43 (Cx43) is the most common member. However, its role on renal injury and the following fibrosis has not been examined.

Methods: We analyzed renal samples from patients with obstructive nephropathy and applied unilateral ureteral obstruction (UUO) to induce renal fibrosis in mice. Cx43-KSP mice were generated to deplete the Cx43 gene of renal tubular epithelial cells (TECs). Through transcriptomics, metabolomics, and single-cell sequencing multi-omics analysis, the relationship among Cx43, ATP, and macrophage in renal fibrosis was explored.

Results: The expression of Cx43 upregulated in TECs after UUO in mice or in patients with obstructive nephropathy. Knockdown of Cx43 in TECs or using Cx43 specific inhibitors reduced UUO induced-inflammation and fibrosis. Single cell RNA sequencing and immunoflurence showed that the distribution of ATP specific receptors is mainly on macrophages, including P2rx4 and P2rx7. These receptor positive macrophages were undergoing pyroptosis after UUO. In vitro, ATP directly induced macrophage pyroptosis. The administration of P2 receptor and P2rx7 receptor inhibitors to UUO mice inhibited macrophage pyroptosis and demonstrated a similar renoprotection as the Cx43 knocking out. Further, we found the GAP19/26 (Cx43 hemichannel inhibitor peptide) and A-839977 (the inhibitor of pyroptosis receptor) alleviated UUO induced fibrosis, while BzATP (the agonist of pyroptosis receptor) exacerbated fibrosis. Single cell sequencing demonstrated that the pyroptotic macrophages upregulated the expression of CXCL 10, which in turn activated fibroblasts.

Conclusions: Cx43 hemichannel mediates the outflow of ATP in TECs inducing macrophage pyroptosis, which subsequently secretes CXCL 10 promoting fibroblast activation and renal fibrosis.

Single-Nucleus RNA-Sequencing Analysis Elucidates Intercellular Interactions Between Inflammatory Parenchymal Cells and Immune Cells in the Kidneys with Tertiary Lymphoid Tissues

Takahisa Yoshikawa,[1] Akiko Oguchi,[1,2] Yuki Sato,[1] Takuya Yamamoto,[3,4] Yasuhiro Murakawa,[2,4] Motoko Yanagita.[1,4] *[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; [3]Department of Life Science Frontiers, Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan; [4]Kyoto University Institute for the Advanced Study of Human Biology, Kyoto, Japan.*

Background: After acute kidney injury (AKI), elderly patients sometimes fail to recover and develop chronic kidney disease (CKD). We previously demonstrated that tertiary lymphoid tissues (TLTs) are formed in aged kidneys after AKI, resulting in prolonged inflammation and impaired regeneration, leading to CKD. However, the mechanism of TLT formation in aged kidneys remains unknown.

Methods: Single nucleus RNA-sequencing (snRNA-seq) for three aged murine kidneys 30 days after ischemic reperfusion injury (IRI) as well as an aged kidney after sham operation was performed using the 10X platform. Computational analysis including subset analysis, ligand-receptor analysis, and pseudotime trajectory analysis were performed. Gene expression was validated by immunostaining and high sensitivity in situ hybridization.

Results: SnRNA-seq generated 15968 and 7485 nuclei transcriptomics from IRI kidneys and a sham kidney, respectively, and demonstrated heterogeneous cell populations including parenchymal cells and immune cells in IRI kidneys with TLTs. We identified a subset of proinflammatory proximal tubules with sustained injury in IRI kidneys with TLTs, and confirmed that some of them surrounded TLTs. Ligand-receptor analysis suggested that this proinflammatory proximal tubules intensively interact with immune cells and fibroblasts. We also identified subsets of profibrotic fibroblasts and proinflammatory fibroblasts, and validated that the latter population being TLT-associated fibroblasts. Pseudotime trajectory analysis of fibroblasts showed that these two types of fibroblasts acquired distinct transcription factors and gene expression patterns along differentiation into distinct populations. Ligand-receptor analysis suggested that proinflammatory fibroblasts possibly contribute to survival and proliferation of B cells through BAFF production in TLT formation.

Conclusions: SnRNA-seq elucidated proinflammatory populations both in proximal tubules and fibroblasts in aged injured kidneys. Various intercellular interactions between the proinflammatory parenchymal cells and immune cells might contribute to TLT formation and these interactions have the potential to be promising therapeutic targets for AKI to CKD transition in the elderly.

NGAL Is Necessary for Antigen-Presenting Cells Recruitment and Proteinuria in the Mouse Kidney with Ureteral Obstruction

Patricio A. Araos, Stefanny M. Figueroa, Orlando M. Rubio, Javier I. Reyes Osorio, Cristián A. Amador. Laboratorio de Fisiopatología Renal, Instituto de Ciencias Biomédicas *Universidad Autonoma de Chile - Campus El Llano Subercaseaux, San Miguel, Chile.*

Background: Elevated levels of proteinuria are present in patients with chronic kidney disease (CKD) even with preserved kidney function. In this line, immune cells play a major role in the development and progression of renal inflammation in CKD. In particular, antigen presenting cells (APCs), such as macrophages (MØ) and dendritic cells (DCs) may play a pivotal role. Previous studies have demonstrated that neutrophil gelatinase-associated lipocalin, NGAL, is overexpressed during renal lesion. However, it is unknown whether there is a relationship between proteinuria and the APCs recruitment, and if it is dependent on NGAL. Our objective was to determine whether NGAL promotes proteinuria and APCs recruitment during the unilateral ureteral obstruction (UUO).

Methods: Male C57BL/6 Wild type (WT) and NGAL-KO mice (8-12 w.o.) were undergoing to UUO and to Sham surgery (Control) during 14 days (n=8). Creatinine and proteinuria were measured from pelvis urine of obstructed kidney. DCs ($MHC\text{-}II^+/CD11c^+/F4/80^-/CD11b^+$ for DCs type-2 phenotype) and MØ ($MHC\text{-}II^+/CD11c^+/F4/80^+/CD11b^+/CD80^+$ for M1 phenotype) recruitment were measured by flow cytometry. Additionally, WT-MØ were stimulated with albumin (10mg/mL, 24 h) and M1 genes evaluated by real-time PCR.

Results: We observed that the increased protein/creatinine ratio in the obstructed kidney of UUO WT mice was reduced in NGAL-KO mice (24.4±9.0 vs. 12.2±5.6 $p<0.01$). *In vitro* stimulation with albumin on macrophages from WT mice increased the mRNA levels of pro-inflammatory M1 markers (IL-12b, IL-23a, TNFα and iNOS; $p<0.001$). We did not observe changes in the M2 profile. Finally, we observed an early increase in the recruitment of DCs and M1 macrophages in WT UUO ($MØ_{Sham}$=6.9±1.2 vs $MØ_{UUO}$=60.0±24.4 cell/mg renal tissue; DCs_{Sham}=54.7±20.0 vs DCs_{UUO}=242±99.9 cell/mg renal tissue; $p<0.01$), which was prevented in UUO NGAL-KO mice ($MØ_{WT}$=60.0±24.4 vs $MØ_{NGAL\text{-}KO}$=30.2±7.8 cell/mg renal tissue; DCs_{WT}=242±99.9 vs $DCs_{NGAL\text{-}KO}$=83.1±9.6 cell/mg renal tissue; $p<0.05$).

Conclusions: Our results show that NGAL is necessary for DCs and MØ recruitment, in addition for the proteinuria increment in the obstructed kidney, suggesting a new pro-inflammatory mechanism of NGAL in CKD. Supported by Fondecyt #1201251 and #3201016

PO2439

Role of Mast Cells in the Progression of Peritoneal Fibrosis in Rats with Chronic Renal Failure

Itsuro Kazama. *Miyagi University, School of Nursing, Kurokawa-gun, Japan.*

Background: Mast cells, that are originally derived from hematopoietic stem cells, secrete inflammatory cytokines besides their exocytotic release of chemical mediators. Recent studies also demonstrated that mast cells synthesize fibroblast-activating factors in chronic inflammatory diseases, thereby facilitating the progression of organ fibrosis.

Methods: Using rat models with chronic renal failure (CRF) induced by 5/6 nephrectomy, the histopathological features of CRF rat peritoneum were examined. We also treated the CRF rats with tranilast, a mast cell stabilizer, to reveal the involvement of mast cells in the progression of peritoneal fibrosis.

Results: In fibrotic areas of CRF rat peritoneum, mast cells proliferated *in situ* and increased their activity by producing fibroblast growth factors. Therapeutic intervention with tranilast, a potent mast cell stabilizer, actually slowed the progression of peritoneal fibrosis. Therefore, the activation of mast cells were considered to be responsible for the progression of peritoneal fibrosis in uremic condition. Additionally, we employed the standard patch-clamp whole-cell recording technique in mast cells to examine the effects of other mast cell stabilizers, since the process of exocytosis in mast cells can continuously be monitored electrophysiologically by the changes in the membrane capacitance (Cm). Second generation anti-histamine drugs, such as olopatadine and loratadine, markedly suppressed the increase in the Cm and directly inhibited the exocytotic process, suggesting their potency as mast cell stabilizers. In additional morphological studies, these drugs actually caused inward bending of mast cell membranes and counteracted the exocytosis-induced cellular surface deformation.

Conclusions: Taken together these *in vivo* and *in vitro* evidence, our results strongly indicated the therapeutic efficacy of targeting mast cells to ameliorate organ fibrosis in chronic diseases, besides the treatment of allergic diseases.

PO2440

Pro-Inflammatory HLA-DRhi Intermediate Monocytes Are Increased in CKD

Sarah Cormican,[1,2] Serika D. Naicker,[1] Rachael Power,[1] Neema Negi,[1] Barbara Fazekas,[1] Md Nahidul Islam,[1] Michael C. Dennedy,[1,2] Matthew D. Griffin.[1,2] *[1]National University of Ireland Galway, Galway, Ireland; [2]Galway University Hospitals, Galway, Ireland.*

Background: People with Chronic Kidney Disease (CKD) suffer high rates of cardiovascular disease and have high numbers of circulating intermediate monocytes (IMs). IM numbers are associated with cardiovascular risk. We previously defined novel IM subpopulations termed $HLA\text{-}DR^{mid}$ and $HLA\text{-}DR^{hi}$ IMs, of which $HLA\text{-}DR^{hi}$ IMs are increased in CKD. To understand how these cell populations contribute to endothelial damage in CKD we determined the functional properties of $HLA\text{-}DR^{hi}$ IMs.

Methods: People with CKD, age-matched patient controls (PC) and healthy volunteers (HV) were recruited. Blood samples were used for profiling of IM subpopulation number and phenotype, functional assays and serum isolation. Intracellular cytokine production, migration and endothelial adhesion assays were performed using *ex vivo* cells.

Results: Numbers and proportions of circulating $HLA\text{-}DR^{hi}$ IMs were higher in CKD compared to PC ($3.0x10^4$ vs. $1.9x10^4$ cells/ml, $p=0.007$). Following LPS stimulation in vitro, $HLA\text{-}DR^{hi}$ IMs from both HV and CKD patients produced markedly higher amounts of TNF-α ($p<0.0001$) and IL-1β ($p<0.0001$) than other monocyte subpopulations. LPS-stimulated cytokine levels of $HLA\text{-}DR^{hi}$ IMs did not differ for HV vs. CKD. Surface profiling revealed that $HLA\text{-}DR^{hi}$ IMs expressed relatively high levels of specific chemokine receptors (CCR5, CX3CR1) and adhesion proteins (CD11a, CD11b, CD11c). Total monocyte migration toward CCL5 and CX3CL1 was increased in CKD vs. HV. Total monocyte adhesion to both resting and TNF-α-activated endothelial cells was increased in CKD vs. HV. Monocyte adhesion to TNF-α activated endothelial cells was partially dependent on CX3CR1-CX3CL1 binding. Finally, serum CX3CL1 was increased in CKD compared to PC ($p=0.004$) and correlated with CKD-EPI eGFR ($R=0.33$, $p=0.002$).

Conclusions: CKD-associated monocytosis is characterised by increased circulating $HLA\text{-}DR^{hi}$ IMs with high capacity for inflammatory cytokine production and high surface levels of specific adhesion proteins and chemokine receptors. CCL5 and CX3CL1-dependent chemo-attraction and CX3CL1-dependent endothelial adhesion of monocytes are increased in CKD. The results highlight targetable mechanistic links between intermediate monocytosis, accelerated atherosclerosis and progressive renal injury in CKD.

Parenteral Iron Therapy Alters Polarization of Kidney Macrophages and Mitigates Kidney Fibrosis in Mice

Edwin Patino,[1] Divya Bhatia,[1] Steven Z. Vance,[3] Francesca Vinchi,[3] Stefano Rivella,[4,5] Mary E. Choi,[1,2] Oleh M. Akchurin.[1,2] *[1]Weill Cornell Medicine, New York, NY; [2]NewYork-Presbyterian Healthcare System Inc, New York, NY; [3]New York Blood Center, New York, NY; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]University of Pennsylvania, Philadelphia, PA.*

Background: Iron therapy is common in patients with chronic kidney disease (CKD). Macrophages are a major cell type capable of handling and storing iron. At the same time, macrophages play a critical role in the pathogenesis of kidney fibrosis. Iron has been shown to modulate macrophage polarization in other pathologic conditions. However, the effect of iron therapy on polarization of kidney macrophages during kidney fibrosis is unclear.

Methods: To elucidate this, we took advantage of two mouse models of kidney fibrosis: adenine and the unilateral ureteral obstruction (UUO) models. A subset of mice received weekly intraperitoneal injections of iron dextran (0.5 g/kg body weight) in addition to adenine. Same iron administration regimen was used to treat a sub-group of mice for 4 weeks prior to UUO. Mice were euthanized after 8 weeks of adenine diet or 7 days after UUO. Blood for serum creatinine and CBC measurements and kidneys were collected at euthanasia.

Results: Iron therapy improved anemia and mitigated kidney function decline in CKD mice, as indicated by serum creatinine improvement. Kidney fibrosis was less severe in mice treated with iron compared to untreated mice in both the adenine and UUO models, as indicated by Masson trichrome staining and reduced kidney expression of fibronectin. Prussian blue staining identified iron accumulation in the kidney interstitium of CKD mice treated with iron, specifically within kidney macrophages, as confirmed by electron microscopy. Flow cytometry demonstrated reduced infiltration of kidney tissue by $Ly6C^{high}$ monocytes and neutrophils and lower percentage of kidney $CCR2^+$ and $CX3CR1^+$ myeloid cells in CKD mice treated with iron compared to untreated CKD mice. While macrophage surface markers MHCII, CD86, and CD206 were altered by iron therapy, they did not follow the classical M1/M2 dichotomy. However, expression of pro-inflammatory cytokines TNF-α, IL-6, and IL-1β by kidney macrophages was reduced in CKD mice treated with iron compared to untreated CKD mice.

Conclusions: Chronic parenteral administration of iron mitigated kidney fibrosis in two different mouse models, which, at least in part, was likely mediated by iron-induced kidney macrophage skewing towards an anti-inflammatory phenotype and reduced recruitment of pro-inflammatory cells into the kidney.

Loss of Macrophage Mitofusin 2 but Not Mitofusin 1 Suppresses Mitochondrial Biogenesis and Promotes Kidney Fibrosis

Divya Bhatia,[1] Allyson M. Capili,[1] Kiichi Nakahira,[1,2] Thangamani Muthukumar,[1] Augustine M. Choi,[1] Mary E. Choi.[1] *[1]Weill Cornell Medicine, New York, NY; [2]Nara Kenritsu Ika Daigaku Yakurigaku Kyoshitsu, Kashihara, Japan.*

Background: Mitochondrial biogenesis, dynamics (fusion/fission) and mitophagy exert critical roles in maintaining mitochondrial function and protect against oxidative stress. Macrophages are well-known to aggravate kidney injury-induced inflammation and fibrosis in the pathogenesis of chronic kidney disease (CKD). We studied the effects of macrophage mitofusins: *Mfn1* and/or *Mfn2* deficiency on mitochondrial biogenesis during CKD.

Methods: Myeloid-specific *Mfn1* (*Mfn1$^{fl/fl}$, LysM-Cre$^{+/-}$*), *Mfn2* (*Mfn2$^{fl/fl}$, LysM-Cre$^{+/-}$*), & double knockout (DKO) mice and corresponding controls were fed with control (Ctl) or adenine diet (AD) for 28-days. Kidneys, kidney macrophages, bone marrow-derived macrophages (BMDM) were analyzed by western blot, flow cytometry, immunohistochemistry. Blood urea nitrogen (BUN), creatinine were measured.

Results: Expression of mitochondrial biogenesis regulator: PGC-1α, antioxidant enzyme: superoxide dismutase-2, mitochondrial fusion proteins: *Mfn1*, *Mfn2*, and *OPA-1* decreased while fission proteins: DRP-1 and phospo-DRP-1-Serine-616 increased in the kidneys after AD and BMDM after TGF-β1 treatment. Kidney macrophage superoxide levels increased after AD. However, kidney macrophages from AD-fed *Mfn2$^{fl/fl}$, LysM-Cre$^{+/-}$* and DKO mice but not *Mfn1$^{fl/fl}$, LysM-Cre$^{+/-}$* mice displayed higher superoxide & increased expression of galectin-3, TGF-β1, & CD206 than corresponding controls. In addition, *Mfn2$^{fl/fl}$, LysM-Cre$^{+/-}$* and DKO mice displayed greater collagen accumulation, and increased BUN and creatinine after AD than wild-type and *Mfn1$^{fl/fl}$, LysM-Cre$^{+/-}$* mice. Wild-type and *Mfn1$^{fl/fl}$, LysM-Cre$^{+/-}$* mice showed similar increases in collagen deposition in the kidney and worsening of kidney function after AD. BMDM from *Mfn1$^{fl/fl}$, LysM-Cre$^{+/-}$* and wild-type mice also showed similar expression of profibrotic macrophage marker, arginase-I after TGF-β1-treatment. However, TGF-β1-treated *Mfn2$^{fl/fl}$, LysM-Cre$^{+/-}$* and DKO BMDM and kidney macrophages displayed greater polarization towards profibrotic phenotype while lower expression of PGC-1α and defective mitophagy than *Mfn1$^{fl/fl}$, LysM-Cre$^{+/-}$* and wild-type macrophages.

Conclusions: Macrophage-specific deficiency of *Mfn2* but not *Mfn1* causes impairments in mitochondrial biogenesis and mitophagy, thereby promoting polarization towards profibrotic macrophage phenotype and kidney fibrosis.

F4/80hi Resident Macrophages Contribute to Cisplatin-Induced Kidney Fibrosis and M2 Polarization in C57BL/6 Mice

Sophia M. Sears, Alexis Vega, Mark A. Doll, Parag P. Shah, Levi J. Beverly, Leah J. Siskind. *University of Louisville School of Medicine, Louisville, KY.*

Background: Cisplatin is a mainstay in the treatment of many solid-organ cancers. Its therapeutic benefits, however, are hindered by dose-limiting nephrotoxicity. Cisplatin causes acute kidney injury (AKI) in 30% of patients. Development of AKI puts patients at risk for development of fibrosis and chronic kidney disease (CKD). Cisplatin-induced kidney fibrosis can be modeled in rodents using repeated, low doses of cisplatin once a week for four weeks. Understanding the mechanisms that promote fibrosis in this model could improve long-term care of cancer patients who receive cisplatin. Macrophages are known to respond to kidney injury and correlate with progression of fibrosis in CKD patients, indicating they may be key regulators of fibrosis development following kidney insults. We hypothesize that chronic macrophage activity promotes cisplatin-induced kidney fibrosis.

Methods: In this study, we depleted populations of F4/80^{hi} resident macrophages and F4/80^{lo} infiltrating macrophages in C57BL/6 mice using either clodronate encapsulated liposomes or CCR2 genetic knockout, respectively. In parallel with this macrophage depletion, mice were given 4 weekly doses of 9 mg/kg cisplatin. After euthanization, we evaluated kidney function, injury, and fibrosis development.

Results: Our data suggests that F4/80^{hi} resident macrophage depletion ameliorates development of cisplatin-induced fibrosis, as measured by statistically significant decreased collagen deposition and myofibroblast accumulation. In contrast, CCR2 knockout and subsequent F4/80^{lo} infiltrating macrophage depletion did not alter pathological outcomes after cisplatin treatment. Additionally, depletion of resident macrophages, but not infiltrating macrophages, decreased accumulation of CD206+ M2 macrophages in cisplatin treated kidneys.

Conclusions: Taken together, these data suggest that F4/80^{hi} resident macrophages may be key drivers in the development of cisplatin-induced kidney fibrosis and the primary source of M2 macrophages in the kidney. Therefore, kidney resident macrophages represent a possible target for preventing long-term kidney damage associated with cisplatin treatment.

Lactate Dehydrogenase A Influences Pro-Inflammatory Polarization of Murine Bone Marrow-Derived Macrophages

Gunars Osis, Yan Lu, Amie Traylor, Anna A. Zmijewska, Stephen Barnes, Anupam Agarwal. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Background: Excessive inflammation is a major underlying pathogenic process in the progression of chronic kidney disease (CKD). Infiltration of pro-inflammatory macrophages can provoke such inflammatory responses. Macrophages undergo transcriptomic and metabolic reprogramming and rely heavily on glycolysis. Lactate Dehydrogenase A (LDHA) is a key enzyme involved in the glycolytic switch which catalyzes the conversion of pyruvate to lactate and regenerates NAD+ from NADH. Utilizing LDHA deletion, we investigated the effect of suppression of the glycolytic switch in macrophages and its effect on CKD.

Methods: Mature bone marrow-derived macrophages (BMDMs) from wild-type and LDHA knockout mice (KO) mice were cultured and then polarized for 24 hours using IFN-γ. Bulk RNA-seq (transcriptomic) and LC-MS/MS (metabolomic) experiments were performed. For in vivo studies, wild-type littermate and myeloid deficient LDHA KO were treated with aristolochic acid (AA) for 6 weeks as a model of CKD.

Results: BMDMs lacking LDHA showed a significant decrease in transcript counts of key metabolic genes involved in the glycolytic switch (HIF1a and GLUT1). LDHA deletion resulted in significantly decreased levels of aspartate indicating the arginine-succinate shunt is affected. Carnitine levels and fatty acid metabolism were significantly downregulated in the LDHA deficient macrophages. In contrast, mannose-6-phosphate levels were significantly upregulated. Combined, these changes suggest an anti-inflammatory shift. The Multi-omics approach of combining metabolomics and transcriptomic data revealed significant changes in multiple pathways including purine, nicotinate and nicotinamide metabolism. Lastly, mice lacking LDHA in myeloid cells showed a significant decrease in renal fibrosis 6 weeks post-exposure to AA in the model of CKD.

Conclusions: LDHA deficient BMDMs exhibited diminished pro-inflammatory profile in vitro and decreased renal fibrosis in vivo. These results highlight LDHA's role as a potential target for manipulation in immunometabolism and may have a significant impact on approach to CKD.

PO2445

Major Vault Protein Promotes Macrophage-to-Myofibroblast Transition and Tubulointerstitial Fibrosis in a Murine Model of CKD

Cheuk Yin Wong, Susan Yung, Caleb C. Chan, Tak Mao D. Chan. *Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong.*

Background: Chronic kidney disease (CKD) is characterized by progressive interstitial fibrosis and tubular atrophy, and inflammatory cell infiltration. We found that major vault protein (MVP), a key component of the vault complex, contributed to increased matrix protein deposition in an adenine-induced murine CKD model. We continued to investigate whether MVP contributes to interstitial fibrosis.

Methods: CKD was induced in MVP wild-type (WT) and knockout (KO) mice by feeding with casein-based chow containing 0.2% adenine for 8 weeks, and mice were sacrificed and renal cortical tissue harvested for qPCR, immunohistochemistry and flow cytometry analysis. Mice fed casein-based chow served as controls.

Results: MVP WT mice with CKD showed increased MVP mRNA compared to control WT mice. In MVP WT mice with CKD there was increased macrophage infiltration in the tubulo-interstitium that co-localized with collagen I, fibronectin and a-smooth muscle actin, suggesting macrophage-to-myofibroblast transition. Flow cytometric data showed increased CD45^{+} cells and F4/80^{+} / CD11b^{+} macrophages in MVP WT mice with CKD. MVP KO mice with CKD showed reduced infiltration of macrophages in the tubulo-interstitium, with lower transition to myofibroblasts (P<0.01); and there was decreased MCP-1, MCP-1 receptor and TNF-a mRNA expression, with better preservation of normal renal histology.

Conclusions: The findings suggest that MVP may contribute to the pathogenesis of CKD by promoting macrophage infiltration and their transition to myofibroblasts.

Classical Dendritic Cells Mediate Nephrotoxic Serum Nephritis by Activating T Cells

Xiaohan Lu,[1,2] Jiafa Ren,[1,2] Yi Wen,[1,2] Jamie Privratsky,[1,2] Steven D. Crowley.[1,2] *[1]Duke University Hospital, Durham, NC; [2]Durham VA Medical Center, Durham, NC.*

Background: Glomerulonephritis is a prominent cause of chronic kidney disease (CKD) and features robust chronic inflammation. Following an inflammatory insult, myeloid cells infiltrate the kidney and drive CKD progression. Flt3L-expressing classical dendritic cells (DCs) are the most potent antigen-presenting cells, and heterozygous deletion of the ubiquitin editor A20 spontaneously activates DCs. However, the role of Flt3L-expressing classical DCs in the regulation of inflammatory CKD requires elucidation. We hypothesized that classical dendritic cells exacerbate inflammatory kidney injury by promoting the activation of renal T cells.

Methods: We induced nephrotoxic serum nephritis (NTS) in flt3L-deficient mice lacking DCs (DC KO), mice with spontaneous DC activation (CD11c Cre^{+} A20$^{flox/wt}$ = DC ACT), and wild-type (WT) controls. After 14 days of NTS, kidney injury was assessed by pathology scoring and ACRs. In addition, mRNA levels of renal injury biomarkers were determined by RT-PCR and western blot. NTS kidneys were harvested for flow cytometric analysis to determine intra-renal immune cell lineage distributions and test their mRNA levels of inflammatory cytokines.

Results: On day 14 of NTS, DC KO mice had attenuated kidney injury scores compared to WTs (1.6±0.3 vs 3.0±0.3 au, p=0.01), while kidney injury was more severe in DC ACTs than in WTs (2.3±0.3 vs 1.4±0.2 au, p=0.02). Compared to WTs, DC KOs had lower ACRs (432±36 vs 267±11, p=0.001) and reduced renal mRNA levels for NGAL (1.0±0.1 vs 0.2±0.1 au, p=0.001), collagen-I (1.0±0.1 vs 0.4±0.1, p=0.003), and fibronectin (1.0±0.1 vs 0.5±0.1, p=0.01). In contrast, DC ACTs had higher ACRs (623±84 vs 1171±243, p=0.001) and upregulated mRNA for NGAL (29.2±7.4 vs 1.0±0.3 au, p=0.004), collagen-I (6.5±0.9 vs 1.0±0.2, p=0.001), and fibronectin (3.9±0.4 vs. 1.0±0.1, p=0.001). Renal protein levels for collagen-I and fibronectin recapitulated the mRNA patterns. In DC ACT kidneys, absolute numbers of CD8^{+} effector memory T cells, marked by a CD62L^{lo}CD44^{hi} surface expression were higher (2864±648 vs 836±107 cells, p=0.006) and had higher cytokine mRNA levels for TNFα (4.2±0.5 vs 1.0±0.1, p=0.001) and IL1β (2.0±0.3 vs 1.0±0.1, p=0.02) than in WTs at day 14 of NTS.

Conclusions: The pathogenesis of CKD requires classical DC-mediated T cell activation. Inhibition of classical DCs may ameliorate autoimmune nephritis.

Targeting Innate Immune-Polyamine Axis Prevents CKD-Associated Cardiac Hypertrophy

Ke Yang, Wenhao Han, Yingguo Zhu, Jinghong Zhao. Department of Nephrology, the Key Laboratory for the Prevention and Treatment of Chronic Kidney Disease of Chongqing, Chongqing Clinical Research Center of Kidney and Urology Diseases, Xinqiao Hospital, Army Medical University (Third Military Medical University) *Xinqiao Hospital, Army Medical University (Third Military Medical University), Chongqing, China*.

Background: It is well recognized in clinic that patients with chronic kidney disease (CKD) have a higher risk for developing cardiovascular diseases including cardiac hypertrophy. However, the pathogenetic mechanisms remain poorly understood.

Methods: The hypertrophic phenotype changes and metabolic characteristics of neonatal rat cardiomyocytes were studied after incubated with serum from 5 stage CKD patients, as well as myocardium from mice with or without CKD, accompanied by bulk RNA-seq analysis. The role and mechanism of CKD in inducing cardiac hypertrophy were evaluated in vivo and ex vivo, and confirming in targeted gene knockout and cardiomyocyte-specific knockout mice.

Results: Here, we show that adult cardiomyocytes are characterized by restrained polyamine metabolism, while CKD activates polyamine metabolism especially ornithine decarboxylase (ODC1)-putrescine metabolic axis in cardiomyocytes. Then, we reveal that nuclear factor kappa B (NFκB) in cardiomyocytes not only drives hypertrophic program under CKD milieu, but also conservatively dominates the transcriptional activation of ODC1-putrescine metabolic axis. Meanwhile, activation of ODC1-putrescine metabolic axis in cardiomyocytes acts as a prerequisite for the efficient initiation of NFκB-driven hypertrophic program, rather than a pathogenic factor for cardiac hypertrophy. Furthermore, mitochondrial oxidative damage is a prominent feature of cardiomyocytes under CKD milieu. The damaged mitochondria release mitochondrial DNA into the cytosol and stimulates the innate immune cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) pathway in cardiomyocytes, which subsequently activates NFκB. Therefore, myocardial cGAS-STING-NFκB pathway plays a critical role in CKD-associated cardiac hypertrophy through immune surveillance of mitochondrial fitness as well as integrating hypertrophic program and polyamine metabolism.

Conclusions: Our study uncovers a previously unrecognized role of innate immune-polyamine axis in CKD-associated cardiac hypertrophy. Targeting innate immune-polyamine axis may represent a promising strategy to prevent and treat CKD-associated cardiac hypertrophy.

The Active Ingredient in the Nuphar lutea Plant, 6,6′-Dihydroxythiobinupharidine (DTBN), Ameliorates Kidney Fibrosis, Inflammation, and Anemia in a Mouse Model of CKD

Jannat Khalilia,[1] Daniel Landau,[2,3] Jacob Gopas,[1] Yael Segev.[1] *[1]Faculty of Health Sciences, Ben Gurion University, Beer Sheva, Israel; [2]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [3]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel*.

Background: EPO resistance and iron deficiency in CKD-related anemia are associated with an increase in inflammatory cytokines associated with the innate immune response, such as IL-6, IL-1, and TNF-α. Recently (Bandach et al, Sci Reports 2021) we reported that kidney fibrosis and anemia of CKD can be worsened or relieved when IL1 effects are enhanced or inhibited respectively. The Water lily (*Nuphar lutea)* plant has been widely used as a traditional remedy for the treatment of rheumatism, scars, pain, and more. Gopas, Golan-Goldhirsh et al (Cancer Biology Therapy 2009) extracted an active ingredient from the family of nupharidines: 6,6′-Dihydroxythiobinupharidine (DTBN) which showed anti-inflammatory properties, mainly through the inhibition of NF-κB. The purpose of this study was to test the effects of DTBN in a mouse model of CKD-associated anemia.

Methods: 8 weeks old male C57BL/6 mice were divided into 3 groups: Control, CKD (induced by adenine diet) and CKD- DTBN. CKD groups were injected with saline-DMSO or 30 μg DTBN, every two days and sacrificed after 3 weeks from dietary intervention.

Results: Serum urea and kidney TGFβ mRNA were significantly decreased in CKD- DTBN Vs CKD. Kidney histology in CKD mice showed macrophage infiltration and renal fibrosis, which was ameliorated in CKD-DTBN. A significant improvement in inflammation indices (blood lymphocytes, kidney and liver IL-6 and p-STAT3, liver CRP), as well as kidney immunoreactive NF-κB and F4\80, which were increased in CKD, were decreased in CKD-DTBN. CKD anemia indices (hemoglobin, hematocrit, and RBC count) significantly improved in CKD-DTBN. Kidney HIF-2α and EPO mRNA were significantly decreased in both uremic groups, but was unchanged in CKD- DTBN Vs CKD. However, serum iron and transferrin saturation significantly increased in CKD-DTBN Vs CKD.

Conclusions: Uremic mice treated with DTBN show improvement in kidney fibrosis, inflammation and anemia indices. Thus, DTBN may be a novel therapeutic alternative for CKD and its complications.

PO2449

Exploring the Presence of Endogenous Retroviruses in CKD

Kelly A. Mulholland, Poonam Dhillon, Hailong Hu, Hongbo Liu, Xin Sheng, Katalin Susztak. Susztak Lab *University of Pennsylvania Department of Medicine, Philadelphia, PA*.

Background: Chronic kidney disease (CKD) affects more than 1 in 7 US adults and is the fourth leading cause of death worldwide. However, the mechanism of CKD is poorly understood. Endogenous retroviruses (ERVs) are transposable elements (TEs) that have integrated into mammalian genomes millions of years ago, accounting for about 8% of the human genome. ERVs remain inactive in the genome due to mutations and deletions during evolution, however recent studies have found that reactivation of ERVs is possible and their increased expression has been identified in a variety of human diseases. Here, we examine ERVs in human and mouse kidneys and their potential role in CKD.

Methods: We performed RNA sequencing and collected clinical and histopathological data from 300 human kidney samples, both healthy and with varying degrees of CKD. We mapped the genomic landscape of TEs, including LINE, SINE and ERVs, using RepeatMasker and quantified their expression in healthy and diseased kidney tissues. Associations between ERV expression, gene expression and methylation level were analyzed. Similar analyses were performed on three kidney disease mouse models.

Results: We found increased expression of several ERV elements in diseased human kidney tissues. Using a linear regression model adjusted for 7 covariates, we identified 2,486 TEs whose expression showed a significant linear correlation with interstitial fibrosis. We also found that ERVs trigger a strong interferon response through the activation of cytosolic nucleic acid sensors such as RIG-I and STING. Furthermore, ERV expression was correlated with methylation level of overlapping methylation sites and we found that loss of cytosine methylation and epigenetic repression may have contributed to the increase in ERV level. We also identified several differentially expressed TEs between healthy and diseased kidney tissues in three kidney disease mouse models, many overlapping between models. An increase in expression of cytosolic nucleic acid sensors was also observed in mice. Furthermore, genetic deletion of RIG-I and STING ameliorated kidney inflammation and fibrosis in mouse disease models.

Conclusions: Our study provides the first comprehensive analysis of ERVs in the kidneys of both humans and mice and suggests the potential role of ERVs in kidney disease by aggravating immune response during disease progression.

Funding: NIDDK Support

PO2450

Interleukin 1α (IL-1α) Is a Central Regulator of Leukocyte-Endothelial Adhesion in Myocardial Infarction and in CKD

Thimoteus Speer, Emmanuel Ampofo, Danilo Fliser, Stefan J. Schunk. *Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany*.

Background: Cardiovascular diseases (CVD) and chronic kidney disease (CKD) are highly prevalent, aggravate each other, and account for substantial mortality. Both conditions are characterized by activation of the innate immune system. The alarmin IL-1α is expressed in a variety of cell types promoting (sterile) systemic inflammation. The aim of the present study is to examine the role of IL-1α in mediating inflammation in the setting of cardiorenal diseases.

Methods: We assessed the expression of IL-1α on the surface of monocytes from patients with acute myocardial infarction (AMI) and patients with CKD and determined its association with atherosclerotic CVD events during follow-up in an explorative clinical study. Furthermore, we assessed the inflammatory effects of IL-1α in several organ injury models in *Il1a*$^{-/-}$ and *Il1b*$^{-/-}$ mice and investigated the underlying mechanisms *in vitro* in monocytes and endothelial cells.

Results: IL-1a is strongly expressed on the surface of monocytes from patients with AMI and CKD compared to healthy controls. Higher IL-1α surface expression on monocytes from patients with AMI was associated with a higher risk for atherosclerotic CVD events, which underlines the clinical relevance of IL-1α. In mice, IL-1α, but not IL-1β, mediates leukocyte-endothelial adhesion as determined by intravital microscopy. IL-1α promotes accumulation of macrophages and neutrophils in inflamed tissue *in-vivo*. Furthermore, IL-1α on monocytes stimulates their homing at sites of vascular injury. A variety of stimuli such as free fatty acids or oxalate crystals induce IL-1α surface expression and release by monocytes, which then mediates their adhesion to the endothelium via IL-1 receptor-1. Besides, IL-1α promotes expression of the vascular cell adhesion molecule-1 (VCAM-1) on endothelial cells thereby fostering the adhesion of circulating leukocytes. IL-1α induces inflammatory injury after experimental AMI and abrogation of IL-1α prevents the development of CKD in oxalate or adenine-fed mice.

Conclusions: IL-1α represents a key mediator of leukocyte-endothelial adhesion and inflammation in cardiorenal diseases. Inhibition of IL-1α may serve as a novel anti-inflammatory treatment strategy.

PO2451

Complement C5a Receptor in Macrophage-Mediated Renal Inflammation and Fibrosis in Lupus Nephritis

Chris Li, Bin N. Zhao, Carolyn Dunlap, Linda Ertl, Zhenhua Miao, Israel Charo, Kathleen M. Sullivan, Thomas J. Schall. *ChemoCentryx Inc, San Carlos, CA.*

Background: Lupus nephritis (LN) is caused by autoimmune responses and is a significant driver of end-stage renal disease in systemic lupus erythematosus patients. Complement activation, pro-inflammatory cytokine production, and the influx of macrophages have all been implicated in LN pathogenesis. The anaphylatoxin complement 5a (C5a) receptor 1 (C5aR) is a major driver of the pro-inflammatory functions of complement activation. We examined C5aR's expression in kidney in lupus nephritis and investigated its role in controlling pro-fibrotic functions of macrophages.

Methods: C5aR expression, infiltrating immune cells, and fibrosis were examined by immunohistochemistry in LN patient kidney biopsies. M1 and M2 macrophages derived from human peripheral blood monocytes were used in in vitro assays to examine the effect of C5a stimulation and avacopan, a specific C5aR inhibitor, on the secretion of cytokines and other factors.

Results: In LN kidney biopsies, large numbers of macrophages, identified by CD68 staining, were observed in areas with severe fibrosis, and expressed C5aR. In addition, C5aR was detected on distal tubules in biopsies of both normal and lupus nephritis kidneys. C5a increased the production of inflammatory cytokines TNFa and IL-6 from both M1 and M2 macrophages in vitro. Chemokines (MCP-3, MIP-1a, MIP-1b and MIP-3a), matrix metalloproteinases (MMP3 and MMP8), and pro-fibrotic growth factors (fibroblast activation protein, platelet-derived growth factor-AA) were strongly increased in M2 macrophages with C5a stimulation, and these increases were blocked by the C5aR inhibitor avacopan.

Conclusions: C5aR activation induced macrophage secretion of factors that are known to drive inflammation, fibroblast activation and tissue fibrosis, and thus may contribute to LN disease progression. Inhibiting C5aR activity with avacopan blocks these pathological changes, and may provide therapeutic benefit to LN patients.

PO2452

Remdesivir Inhibits Tubulointerstitial Fibrosis in Obstructed Kidneys

Lin Xu, Ming Wu, Chaoyang Ye. *Shuguang Hospital, Shanghai, China.*

Background: Kidney impairment is observed in patients with COVID-19. The effect of anti-COVID-19 agent remdesivir on kidneys is currently unknown. We aimed to determine the effect of remdesivir on renal fibrosis and its downstream mechanisms.

Methods: Remdesivir and its active nucleoside metabolite GS-441524 were used to treat TGF-β stimulated renal fibroblasts (NRK-49F) and human renal epithelial (HK2) cells. Vehicle or remdesivir were given by intraperitoneal injection or renal injection through the left ureter in unilateral ureteral obstruction (UUO) mice. Serum and kidneys were harvested. The concentrations of remdesivir and GS-441524 were measured using LC-MS/MS. Renal and liver function were assessed. Renal fibrosis was evaluated by Masson's trichrome staining and Western blotting.

Results: Remdesivir and GS-441524 inhibited the expression of fibrotic markers (fibronectin and aSMA) in NRK-49F and HK2 cells. Intraperitoneal injection or renal injection of remdesivir attenuated renal fibrosis in UUO kidneys. Renal and liver function were unchanged in remdesivir treated UUO mice. Two remdesivir metabolites were detected after injection. Phosphorylation of Smad3 that was enhanced in cell and animal models for renal fibrosis was attenuated by remdesivir. In addition, the expression of Smad7, an anti-fibrotic factor, was increased after remdesivir treatment *in vitro* and *in vivo*.

Conclusions: Remdesivir inhibits renal fibrosis in obstructed kidneys.

Heightened Innate Immune Response to COVID-19 Infection in CKD: Implications to Poorer Outcome During CKD

Xiaojia Guo,[1] Leyuan Xu,[1] Tian-Min Chen,[1] Fred Gorelick,[1,2] Gary V. Desir,[1,2] Robert L. Safirstein.[1,2] *[1]Yale University School of Medicine, New Haven, CT; [2]VA Medical Center West Haven, CT, West Haven, CT.*

Background: Meta-analyses reveal show a significant association of chronic kidney disease (CKD) with severe COVID-19. The double stranded RNA virus SARS-CoV-2 can evoke a damaging inflammatory response. To understand the mechanism for the greater severity of the disease in patients with CKD, we studied an animal model of CKD exposed to polyinosinic-polycytidylic acid [poly(I:C), a synthetic analog of double-stranded RNA that recapitulates the innate immune response provoked by SARS-CoV-2].

Methods: C57Bl6j mice were injected with 2 doses of cisplatin at 15 mg / kg or vehicle control subcutaneously, 2 weeks apart. After CKD established, control and CKD mice were subsequently injected with poly(I:C) at 30 mg/kg intravenously and monitored for body weight loss and mortality. Bone marrow cells were isolated 2 weeks post poly(I:C) treatment and grown in serum-free medium supplemented with macrophage colony stimulation factor for 7 days to obtain bone marrow derived macrophages (BMDM). These cells were stimulated with 10 ug / ml poly (I:C), followed by measurement of proinflammatory cytokines. Single cell RNA sequencing was used to compare transcriptome between normal and CKD kidneys.

Results: CKD animals had elevated plasma creatinine (0.14 ± 0.02 mg / dL, n=8, control mice 0.09 ± 0.01 mg / dL, n=5, $p<0.05$) and elevated plasma levels kidney injury marker 1 (KIM-1; 133.6 ± 29.9 pg /ml, vs undetectable, n=5, $p<0.05$). Poly (I:C) treatment induced a greater body weight loss in CKD animals (9.9± 2.9 %, n=8 vs control mice 6.8 ± 2.0 %, n=5, $p<0.0005$) and greater mortality of CKD mice (46% mortality within 24h in CDK mice vs no mortality in control mice). BMDMs from CKD mice produced greater levels of IL-6 than control BMDM upon poly (I:C) stimulation at both the mRNA and protein levels. In addition, Single cell RNA sequencing revealed that there is 3-fold higher relative number of macrophages in CKD kidneys.

Conclusions: Our results show that CKD mice are more sensitive to foreign double strand RNA insult. BMDM isolated from cisplatin-induced CKD demonstrated a greater innate immune response during CKD. We propose that the inherent hyperinflammatory nature of CKD drives a greater innate immune response in this model of viral injury and may be responsible, at least partially, for the poor outcomes in CKD patients with Covid-19 infection.

Combined Soluble Epoxide Hydrolase Inhibition and Epoxyeicosatrienoic Acid Administration Attenuates the Renal Fibrogenesis Without Additivity or Synergy

Mira Noh, Hee-Seong Jang, Babu J. Padanilam. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Epoxyeicosatrienoic acids (EETs) are arachidonic acid metabolites with biological effects, including anti-apoptotic, anti-inflammatory, and anti-fibrotic functions. Soluble epoxide hydrolase (sEH)-mediated hydrolysis of EETs to dihydroxyeicosatrienoic acids (DHET) attenuates these effects. Recent studies have demonstrated inhibition of sEH prevents renal tubulointerstitial fibrosis and inflammation in chronic kidney disease (CKD) model. Here, we demonstrated the role and underlying mechanism of EETs in unilateral ureteral obstruction (UUO)-induced renal fibrogenesis.

Methods: Eight-week-old male wild type (*Ephx2*$^{+/+}$) and *Ephx2*$^{-/-}$ mice underwent sham or UUO surgical procedures and were treated with the combination of 11,12- and 14,15-EETs (15 μg/kg/day, respectively) using osmotic pump for 7 days following UUO surgery.

Results: EETs administration abolished tubulointerstitial fibrogenesis, as demonstrated by reduced fibroblast activation and collagen deposition after UUO. Furthermore, inflammatory response was prevented as demonstrated by decreased macrophage infiltration and expression of inflammatory cytokines (TGF-β, IL-1β and IL-6) in EETs-administered UUO kidneys. The genetic inhibition of sEH also mitigated UUO-induced renal inflammation and interstitial fibrogenesis. The combination of EET administration and genetic sEH inhibition also attenuated inflammation and renal interstitial fibrogenesis after UUO, but no additive or synergic effect of combined sEH inhibition and EETs administration.

Conclusions: Taken together, our findings provide that the underlying mechanism of EETs in kidney fibrogenesis during obstructive nephropathy, suggesting EETs as a potential therapeutic target of kidney fibrosis progression.

EP1 Receptor Antagonism Mitigates Early and Late-Stage Renal Fibrosis

Jean-Claude Kresse,[1] Henricus A. Mutsaers,[1] Michael S. Jensen,[1] Stine Julie H. Tingskov,[1] Mia G. Madsen,[2] Rikke Norregaard.[1] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Aarhus Universitetshospital, Aarhus, Denmark.*

Background: Renal fibrosis is a hallmark of Chronic Kidney Disease (CKD), which affects 10-16% of the world's adult population. Yet current treatment strategies are ineffective in attenuating renal fibrogenesis. Therefore, we are in urgent need for new therapeutic strategies against renal fibrosis. The cyclooxygenase/prostaglandin (COX/PG) system plays a key role in renal fibrosis and holds great promise as a suitable therapeutic target. Here, we used a translational approach to evaluate the role of the PGE_2-EP_1 receptor in the pathogenesis of renal fibrosis in several models of kidney injury, including human (fibrotic) kidney slices.

Methods: The anti-fibrotic effect of SC-19220 - an EP_1 receptor antagonist - was studied in Madin-Darby Canine Kidney (MDCK) cells, mice subjected to seven days of unilateral ureteral obstruction (UUO), and healthy and fibrotic human precision-cut kidney slices (PCKS). Progression of fibrosis was evaluated on gene and protein level using qPCR, Western blot and immunohistochemistry.

Results: Pharmacological inhibition of the EP_1 receptor using SC-19220 reduced TGF-β-induced fibronectin (FN) expression, ERK1/2 phosphorylation and epithelial-to-mesenchymal transition in MDCK cells. Moreover, SC-19220 diminished fibrosis in UUO mice, measured by decreased protein expression of FN and α-smooth muscle actin (αSMA), and a reduction in collagen deposition. In addition, treatment of healthy human PCKS with SC-19220 reduced TGF-β-induced fibrosis as shown by decreased gene levels of collagen 1A1, FN and αSMA as well as reduced collagen deposition. Moreover, similar observations were made using fibrotic human PCKS.

Conclusions: This study highlights that the EP_1 receptor is a promising target for preventing both the onset and late stage of renal fibrosis. Moreover, we provide strong evidence that the effect of SC-19220 may translate to clinical care since its effects were observed in UUO mice and human kidney slices.

PO2456

Selective Activation of the Prostaglandin E2-EP4 Receptor Can Slow or Reverse the Fibrotic Process in Human Kidney Slices

Michael S. Jensen,[1] Henricus A. Mutsaers,[1] Mia G. Madsen,[2] Rikke Norregaard.[1] Nørregaard group [1]*Aarhus Universitet, Aarhus, Denmark;* [2]*Aarhus Universitetshospital, Aarhus, Denmark.*

Background: Chronic kidney disease (CKD) affects approximately 10% of the population, and renal fibrosis, *i.e.* excessive scar formation in the kidney, is one of the major pathological processes leading to end-stage renal disease (ESRD). Despite overwhelming efforts to find therapies to reduce renal fibrosis, current management strategies are ineffective at preventing disease progression in CKD patients. Activation of the prostaglandin E2-EP4 receptor has been shown to have renoprotective effects in cell and animal studies. However, translational studies using human kidney tissue are lacking.

Methods: In this project, we studied the anti-fibrotic effect of the selective EP4 receptor agonist Rivenprost using a translational model of renal fibrosis, namely human precision-cut kidney slices (PCKS). This model is ideal to study multicellular pathological processes, *e.g.* fibrosis, directly in human tissue, since cellular diversity and organ architecture is maintained in the slices. Macroscopically healthy renal tissue (n = 13) was obtained from tumor nephrectomies, whereas fibrotic renal tissue (n = 6) was obtained from ESRD nephrectomies. Subsequently, PCKS were incubated with Rivenprost (75μM) to evaluate its anti-fibrotic effect directly in human tissue. Fibrogenesis was evaluated on a gene level using qPCR. Viability was assessed by ATP measurements using ELISA. Protein and histological analyses are ongoing.

Results: The expression of the EP4 receptor in PCKS was increased twofold after 48h of incubation with the pro-fibrotic cytokine TGFβ, suggesting that the EP4 receptor might play a role in the fibrotic process. Treatment with Rivenprost mitigated TGFβ-induced fibrogenesis in healthy tissue. Moreover, Rivenprost halted disease progression in fibrotic PCKS and appeared to partly reverse fibrosis, as illustrated by a reduction in the gene expression of α-smooth muscle actin, fibronectin and collagen 1A1 by at least 50%, without affecting the viability of the human PCKS.

Conclusions: Selective stimulation of the PGE2-EP4 receptor can slow and reverse the process of fibrosis directly in human renal tissue. These findings warrant further research into the clinical application of Rivenprost, or other EP4 receptor agonists, as a treatment for (established) renal fibrosis.

PO2457

Mice with a Deficient Myeloid COX-2/EP4 Axis Developed More Severe Kidney Dysfunction in Response to a High-Fat Diet

Shirong Cao, Yu Pan, Jiaqi Tang, Yinqiu Wang, Aolei Niu, Xiaofeng Fan, Suwan Wang, Ming-Zhi Zhang, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Obesity leads to a state of chronic, low-grade inflammation that contributes to insulin resistance and type 2 diabetes as well as chronic kidney injury. Macrophages are major contributors to obesity-associated adipose inflammation and dysregulated metabolism. When fed a high fat diet (HFD), cyclooxygenase-2 (COX-2) expression increased in adipose tissue macrophages (ATMs). Mice with myeloid deletion of COX-2 or its EP4 receptors resulted in increased obesity after the HFD. The current studies investigated whether kidney dysfunction was exacerbated in mice with myeloid COX-2 or EP4 deletion fed a HFD.

Methods: αααWe developed myeloid COX-2-/- mice (CD11b-Cre; COX-2$^{f/f}$) and myeloid EP4-/- mice (CD11b-Cre; EP4$^{f/f}$). COX-2$^{f/f}$ mice and EP4$^{f/f}$ mice were used as corresponding WT controls. The mice were fed a HFD (36% fat accounting for 60% of calories) for 12 weeks.

Results: The HFD induced greater increases in body weight, fasting blood glucose, and plasma concentrations of insulin, free fatty acids, TNF-a, and leptin. The HFD-treated myeloid COX-2-/- mice and myeloid EP4-/- mice had albuminuria, kidney weight, and kidney weight vs. body weight ratio, compared to WT mice. Histologically, HFD-treated myeloid COX-2-/- mice and myeloid EP4-/- mice had more mesangial expansion, increased glomerular volume and lipid deposition in epithelial cells as well as increased immune cell infiltration. Flow cytometry and qPCR analysis showed increased renal macrophages and cytotoxic CD8 T cells and increased mRNA levels of renal proinflammatory cytokines such as *Ccl2* and *Il6* and profibrotic and fibrotic components including *Col1α1, Col3α1, Col4α1, Fn,* and *Tgfb1*.

Conclusions: These studies found that mice with myeloid cell deletion of COX-2 and EP4 are more sensitive to high fat diet-induced obesity and develop more severe kidney dysfunction and immune cell infiltration. The potential role of increased adipokines, insulin, free fatty acids, and leptin in the observed exacerbated kidney dysfunction are under investigation.

PO2458

Functional Role of Tumor Necrosis Factor α Pathway in Aristolochic Acid-Induced Kidney Injury Model

Shinya Taguchi,[1] Kengo Azushima,[1] Hiromichi Wakui,[1] Takahiro Yamaji,[2] Shingo Urate,[1] Toru Suzuki,[1] Eriko Abe,[1] Shohei Tanaka,[1] Shunichiro Tsukamoto,[1] Kouichi Tamura.[1] [1]*Yokohama City University Graduate School of Medicine Department of Medical Science and Cardiorenal Medicine, Yokohama, Japan;* [2]*Duke-NUS Medical School, Singapore, Singapore.*

Background: Tumor necrosis factor (TNF)-α is a potent mediator of inflammatory responses and is suggested to be involved in the pathogenesis of kidney injuries. However, little is known about modulating effects of TNF-α inhibition on the development of kidney fibrosis. The aim of this study is to examine the effects of TNF-α inhibition on kidney inflammation and fibrosis in a mouse model of chronic kidney disease (CKD) with fibrosis.

Methods: Aristolochic acid nephropathy (AAN) was employed as the mouse model of CKD with fibrosis. To induce AAN, C57BL/6J mice were intraperitoneally administered 3 mg/kg AA twice a week followed by 4-week remodeling period. Meanwhile, 5 mg/kg etanercept (ETN) or saline were subcutaneously administered twice a week for a total of 8 weeks. At the end of experimental period, 24-hour urine samples were collected in metabolic cages, and then kidneys and blood samples were collected.

Results: TNF-α inhibition by ETN partially but significantly attenuated kidney fibrosis estimated by the picrosirius red staining, and ameliorated albuminuria without affecting kidney function in the AAN model. Treatment with ETN significantly suppressed an AA-induced increase in kidney expression of pro-inflammatory cytokines and fibrosis-related genes, including IL-1b, IL-6, type I and III collagen. Moreover, the TNF-α inhibition tended to reduce an AA-induced increase in renal interstitial TUNEL positive cells along with the suppression of kidney Bax mRNA expression. Although the kidney phosphorylated-p38 MAPK, a key mediator activated by TNF-α, was significantly up-regulated by the AA administration, this pathological up-regulation was ameliorated upon the TNF-α inhibition by ETN.

Conclusions: TNF-α inhibition by ETN significantly attenuated the development of albuminuria and kidney fibrosis, concomitant with suppression of kidney inflammation and interstitial cell apoptosis in the mouse model of CKD with fibrosis. These findings indicate that the TNF-α pathway plays a role in the pathogenesis of kidney fibrosis, and further suggest that TNF-α inhibition could become an adjunct therapeutic strategy to treat CKD.

PO2459

Endoglin Is Upregulated in CKD and Is Associated with Increased Extracellular Matrix Production

Tessa Gerrits, Kyra L. Dijkstra, Jan A. Bruijn, Hans J. Baelde, Marion Scharpfenecker. Department of Pathology - Immunopathology group *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Chronic kidney disease (CKD) may result from any cause of renal dysfunction of sufficient magnitude, including diabetic nephropathy (DN) and different glomerulopathies like IgA nephropathy or focal segmental glomerulosclerosis (FSGS). Irrespective of the etiology, the common pathway in the pathophysiology of CKD involves glomerular sclerosis and tubulointerstitial fibrosis. TGF-β is an important cytokine in the development of renal fibrosis. Transmembrane glycoprotein endoglin, a TGF-β co-receptor could be a possible new therapeutic strategy to counteract the development of renal fibrosis in CKD.

Methods: Biopsies of patients with chronic kidney diseases including chronic allograft dysfunction (n=43), DN (n=11), FSGS (n=48), IgA nephropathy (n=85) and were selected; kidneys excluded for transplantation for technical reasons were used as controls (n=8). Sequential sections were stained for endoglin and Sirius Red. Human kidney fibroblasts were lentivirally transduced with either an empty vector or an endoglin knock-in construct and mRNA levels of genes involved in extra cellular matrix (ECM) production were measured with qPCR after TGF-β1 stimulation.

Results: The endoglin-positive area was significantly increased in the interstitium of patients with chronic allograft dysfunction, DN, FSGS and IgA-nephropathy compared to the controls ($p<0.05$). Endoglin-positive areas also co-localized with the Sirius Red-positive areas. The knock-in cell line showed an 7 times upregulation of the endoglin protein level compared to control cells. SERPINE-1 ($p<0.05$) and fibronectin ($p<0.05$) mRNA levels were significantly upregulated (respectively 2.5 and 2.8 times) after stimulation with TGF-β1 in endoglin overexpressing cells compared to controls.

Conclusions: Endoglin was upregulated in different chronic kidney diseases, which were characterized by interstitial fibrosis. We also showed that upregulation of endoglin increases TGF-β-dependent ECM production. This indicates that endoglin could be a potential target in reducing the development of fibrosis and offers an interesting opportunity to slow formation of fibrosis in CKD.

PO2460

Guanidinylated Apolipoprotein C3 (ApoC3) Causes Kidney and Vascular Injury

Stefan J. Schunk,[1] Juliane Hermann,[2] Joachim Jankowski,[2] Danilo Fliser,[1] Vera Jankowski,[2] Thimoteus Speer.[1] *[1]Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany; [2]Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany.*

Background: Cardiovascular diseases (CVD) and chronic kidney diseases (CKD) are highly prevalent in Western populations and account for a substantial proportion of mortality. We found that apolipoprotein C-3 (ApoC3), a constituent of triglyceride-rich lipoproteins, induces alternative NLRP3 inflammasome activation in human monocytes and thus causes sterile inflammation. The aim of the present study was to screen ApoC3 for the presence of posttranslational protein modifications and to assess its relevance in vitro, in vivo, as well as in a prospective cohort of CKD patients.

Methods: ApoC3 was subjected to proteomic analysis. The proinflammatory properties of ApoC3 were assessed in human monocytes and in humanized mice. Moreover, posttranslationally modified ApoC3 was quantified in prospective cohort of 543 patients with various etiologies of CKD and linked to kidney and cardiovascular outcomes.

Results: We identified posttranslational guanidinylation of lysine residues of ApoC3 (gApoC3) in patients after acute myocardial infarction and in patients with CKD. gApoC3 accumulates in kidneys and hearts after injury as determined by 2D-proteomic analyses. In human monocytes, guanidinylation enhanced the binding of ApoC3 to the cell surface and exerted substantially stronger pro-inflammatory effects as compared native ApoC3. In humanized mice, gApoC3 strongly induced kidney fibrosis and abolished the regeneration after vascular injury. In a prospective clinical trial of 543 patients, higher gApoC3 blood levels as determined by mass spectrometry were associated with increased mortality as well as cardiovascular and renal events during a long-term follow-up.

Conclusions: The present study provides evidence from preclinical models and a prospective clinical trial that gApoC3 plays an important role in the development of organ injury in patients with CKD, myocardial infarction and other clinical conditions. The clinical study represents one of the largest trials, in which the association of a specific PTM and clinically relevant outcomes was assessed. These findings highlight gApoC3 as a pathophysiologically relevant factor in development of organ dysfunction.

PO2461

Endothelial Function, Oxidative Stress, and Cognitive Performance in CKD

Nicholas Kruse,[1] Katharine M. Geasland,[1] Chaorong Wu,[3] Carinda Linkenmeyer,[1] Patrick Ten eyck,[3] Karin Hoth,[1] Diana I. Jalal.[1,2] *[1]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA; [3]Institute for Clinical and Translational Science, University of Iowa, Iowa City, IA.*

Background: Cognitive impairment, common in patients with chronic kidney disease (CKD), can be explained at least partially by the high prevalence of cerebrovascular disease in the population. Here, we hypothesized that endothelial dysfunction associates with reduced cognition in patients with CKD.

Methods: We conducted a cross-sectional study of 63 middle-aged/older adults with CKD stage 3b and 4. Cognitive function domains including executive function, memory, language, and processing speed were assessed via the NIH-Toolbox. Endothelial function of the brachial artery was assessed via flow-mediated dilation (FMD) using Doppler ultrasound. The influence of oxidative stress on FMD was determined by infusing a supraphysiological dose of ascorbic acid vs. isovolumetric saline (control). Regression models evaluated if measures of vascular function associated with each domain of cognition, and were adjusted for education (< college degree vs. ≥ college degree).

Results: The mean(SD) age, estimated glomerular filtration rate (eGFR), and FMD of the participants were 64(9), 34(11), and 2.6(1.4). Ascorbic acid increased FMD by 4.5±1.7 as compared to saline which increased FMD by 2.5±1.3 ($p<0.001$). Table 1 illustrates the age-adjusted standard scores for each cognitive domain. We found no association between FMD and any of the cognitive domains. However, a greater response to ascorbic acid correlated with better age-adjusted memory performance independently of education (95% CI: 2.08: 0.51,3.65; $p<0.05$).

Conclusions: Oxidative stress contributes to endothelial dysfunction in CKD and a greater response to ascorbic acid is associated with better memory performance. More studies are needed to understand the role of oxidative stress in cognitive impairment in patients with stage 3b/4 CKD.

Funding: Other NIH Support - NHLBI, Veterans Affairs Support

Table 1: NIH Toolbox Cognitive Domain Standard Scores

Executive function	95.9±9.5
Memory	99.5±10.4
Language	100.6±11.1
Processing speed	98.8±11.0

Normatively age-adjusted standard sores are presented. Standard scores have a mean of 100 and SD of 15.

PO2462

Key Role for EphB2 Receptor in Kidney Fibrosis

Zhimin Huang, Simeng Liu, Anna Tang, Yufeng Huang. *University of Utah Health, Salt Lake City, UT.*

Background: Eph-Ephrin receptor-ligand signaling has been implicated in the development of tissue fibrosis, though it has not been well defined in the kidney.

Methods: We then firstly made use of male EphB2-knockout and littermate control mice (n=5/per group) to receive unilateral renal ischemia-reperfusion (IR) surgery for 35min. In addition, EphB2 signaling was further determined in varied kidney disease models, particullary in diabetes- or hypertension-induced kidney disease models and in the kidney biopsy tissue from IgA nephropathy with glomerulosclerosis and tubular fibrosis.

Results: We detected substantial upregulation of expression and phosphorylation of the EphB2 receptor tyrosine kinase in fibrotic kidney tissue obtained both from mice subjected to either the unilateral renal IR model at 14 days or type 2 diabates or DOCA & Ang II-infused hypertension and in patients suffering from chronic kidney disease (CKD). Knockout mice lacking EphB2 expression exhibited a normal renal structure and function, indicating no major role for this receptor in kidney development or action. Although IR injury is well known to cause tissue damage, fibrosis, and renal dysfunction, we found that kidneys from *EphB2* knockout mice showed much less renal tubular injury and retained a more preserved renal function. IR-injured kidneys from *EphB2* knockouts exhibited greatly reduced fibrosis and inflammation compared to injured wild-type (WT) littermates, and this correlated with a significant reduction in renal expression of pro-fibrotic molecules, inflammatory cytokines, NADPH oxidases, and markers for cell proliferation, tubular epithelial-to-mesenchymal transition, myofibroblast activation, and apoptosis. A panel of 760 fibrosis-associated genes were further assessed, revealing that 506 genes in WT mouse kidney following IR injury changed their expression. However, 70.9% of those genes were back to or close to normal in expression when *EphB2* was deleted.

Conclusions: These data indicate endogenous EphB2 expression and signaling are abnormally activated after kidney injury and subsequently contributes to the development of renal fibrosis via regulation of multiple pro-fibrotic pathways.

PO2463

Apelin, a Novel Apelin Receptor Analog, Improves Endothelial Dysfunction in Uremic Rats with 5/6 Nephrectomy

Mehmet Koc,[1,2] Zarife Ozdemir,[2] Seckin Akcay,[3] Berrak Yegen,[2] Hizir Kurtel.[2] *[1]Marmara University Medical Faculty, Division of Nephrology, Istanbul, Turkey; [2]Marmara University Medical Faculty, Department of Physiology, Istanbul, Turkey; [3]Marmara University Medical Faculty, Division of Endocrinology, Istanbul, Turkey.*

Background: Endothelial dysfunction (ED), characterized by a reduction in vasodilation as a response to endothelial stimuli, has been reported in patients at almost all stages of chronic kidney disease (CKD). Considering that apelin is a vasoactive molecule causing nitric oxide release from endothelial cells, we aimed to investigate the regulatory role of apelin receptor on CKD-induced ED.

Methods: Adult Sprague Dawley male rats were randomized into sham-operation or 5/6-nephrectomy (CKD) groups. CKD groups were treated subcutaneously with saline (S-CKD) or 100 μg/day (each) of apelin (A-CKD), ala-apelin (Ala-CKD) or apelin+ala-apelin (A+Ala-CKD) for eight weeks. Isolated aortas were mounted in organ baths and their vasorelaxatory responses to carbachol (CCh) and apelin were evaluated following pre-contraction with phenylephrine.

Results: Aortas of S-CKD group demonstrated an impaired CCh-induced relaxation as compared to sham group ($P<0.05$), while pre-incubation with L-NAME further inhibited CCh-induced vasorelaxation in both sham and S-CKD groups ($P<0.05$) (Fig A). In A-CKD group, CCh-relaxation response was significantly improved compared to S-CKD group, but L-NAME attenuated the improvement in relaxation (Fig B-C). When apelin was added to organ bath, despite that S-CKD group showed no relaxation, a dose-dependent relaxation was observed in sham group, which was abolished in the presence of L-NAME (Fig D). In A-CKD, Ala-CKD and A+Ala-CKD groups, the relaxation response to apelin was enhanced as compared to S-CKD, while L-NAME pre-incubation abolished the relaxation (Fig E-F).

Conclusions: Apelin, which directly relaxes aortic rings of intact rats in an endothelium-dependent manner, ameliorates CKD-induced endothelial dysfunction when given as a treatment. Moreover, this beneficial effect of apelin treatment on endothelial vasomotor function appears to act by the preserving the activity of nitric oxide-signaling pathway.

Funding: Government Support - Non-U.S.

Apelin and FGF-23 as Biomarkers for Vascular Calcification in Type 2 Diabetic Patients with CKD

Rita S. Afonso, Ana Cabrita, Ana P. Silva. *Centro Hospitalar do Algarve EPE, Faro, Portugal.*

Background: Cardiovascular disease is the leading cause of death in chronic kidney disease (CKD) patients. CKD-Mineral and Bone Disorder occur from the earliest stages of estimated glomerular filtration rate (eGFR) loss and is associated with an increased risk of vascular calcification (VC), which is one of the strongest predictors of cardiovascular risk and mortality in patients with CKD. Apelin and FGF-23 have emerged as potential markers of VC. The main objective of this study is to evaluate the role of apelin and fibroblast growth factor 23 (FGF-23) in the development of VC in type 2 diabetic CKD patients

Methods: Observational prospective study enrolling 150 type 2 diabetes mellitus patients with CKD. Sample characteristics were analyzed using descriptive statistics. Independent-samples t-test, Pearson's correlation test and partial correlations were used to evaluate the association and correlation of several demographic and clinical parameters with vascular calcification score (VCS). Univariate logistic regression and multivariate logistic regression were used to find out predictors of VC.

Results: Lower levels of apelin, 1,25-dihydroxycholecalciferol and eGFR were negatively associated with higher VCS and higher levels of phosphate, calcium × phosphate, parathyroid hormone, interleukin-6 and FGF-23 were positively associated with higher VCS. A negative correlation was found between VCS and apelin ($r = -0.429$, $p<0.0001$), and between apelin and FGF-23 ($r = -0.483$, $p<0.0001$), while a positive correlation was found between VCS and FGF-23 ($r = 0.232$, $p=0.005$). Variables significantly associated with VCS in univariate logistic regression analysis were used in multivariable logistic regression analysis. Multivariable logistic regression analysis demonstrated that lower apelin levels and diminished eGFR were associated with a higher VCS. Contrarily, higher levels of inorganic phosphorus and FGF-23 were linked with a higher VCSA.

Conclusions: The results suggest that apelin and FGF-23 are predictors of VC on type 2 diabetic patients with CKD. Therefore, these osteo-mineral markers might be used as diagnostic/therapeutic targets in order to improve management of CKD complications.

PO2465

Endothelial Dysfunction in Dermal Biopsies of Patients with CKD Associates with Markers of Inflammation and Volume Overload

Josephine Koch, Ryanne S. Hijmans, Manuela Ossa Builes, Wendy Dam, Robert Pol, Stephan J. Bakker, Hendri H. Pas, Casper F. Franssen, Jacob van den Born. *Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Cardiovascular (CV) morbidity is a major health problem in patients with chronic kidney disease (CKD). Besides traditional risk factors, CKD-induced endothelial dysfunction (ED) is involved in CV pathology. Of note, the luminal side of the vascular endothelium is covered by a protective endothelial glycocalyx (eGC) and indirect evidence indicates eGC loss and/or ED in CKD patients. So far, no direct endothelial profiling in non-renal tissue from renal patients has been performed. We aimed to investigate possible eGC loss and ED in CKD patients and its association with inflammation and volume overload.

Methods: During kidney transplantation, abdominal skin biopsies were taken from 11 kidney transplant recipients, of which 4 received hemodialysis. Abdominal skin biopsies from 9 healthy kidney donors served as control. Biopsies were stained for the eGC marker *Ulex Eur I* and the endothelial markers VEGFR2 and vWF. Subsequently, they were quantified and normalized in an immunofluorescence double staining for the pan-endothelial marker CD31. We also studied associations between the quantified endothelial markers and plasma markers of inflammation (CRP) and volume overload (NT-proBNP).

Results: Compared to healthy subjects, there was severe loss of eGC marker *Ulex Eur I* in renal patients (P=0.0008). Conversely, VEGFR2 was increased in renal patients, especially in those on dialysis (P=0.01). The same trend was seen for vWF, although this did not reach statistical significance. Skin water content was identical in all groups, which excluded dermal edema in patients with CKD. Compared with controls, plasma levels of CRP were increased in dialysis patients (P=0.02), whereas NT-proBNP was highly upregulated in all renal patients (P=0.03) which associated with VEGFR2 (R=0.29; P=0.03) and vWF (R=0.63; P<0.0001). Also, VEGFR2 and vWF were correlated (R=0.97; P<0.0001).

Conclusions: This study is the first to show direct evidence of dermal ED in patients with CKD. eGC damage has been shown by loss of *Ulex Eur I* and endothelial activation by increased VEGFR2 and vWF levels. In line with previous research, our results show ED to associate with inflammation and volume overload. More research is needed to further explore this pathophysiology.

CCN2/CTGF Causes Renal Fibrosis Progression Through the Integrin/FAK Signal Pathway

Daichi Fukaya, Tsutomu Inoue, Hiroaki Amano, Yusuke Watanabe, Hirokazu Okada. *Saitama Ika Daigaku, Iruma-gun, Japan.*

Background: Focal adhesion kinase (FAK) is a non-receptor tyrosine kinase that accumulates with integrins at focal adhesions and is involved in intracellular signal transduction. We have focused on CCN2, and demonstrated that FAK phosphorylation is also reduced when the progression of fibrosis is suppressed in a tubular cell-specific CCN2 knockdown mouse. In this study, we examined in greater detail the relationship between CCN2 and FAK.

Methods: A mouse ischemia-reperfusion (IRI) model, cultured human renal tubular epithelial cells (HK-2), 3 types of anti-phosphorylated FAK antibody (Y397, Y576 / 577, Y925), and anti-total FAK antibody were used to perform Western blotting. Furthermore, we examined what subunits of the integrin were expressed in HK-2 by using RT-PCR. A specific neutralizing antibody against integrin was also used to suppress the binding of CCN2 to integrins.

Results: A significant increase in total FAK was observed in the chronic phase (day 12) as fibrosis progressed (total FAK/GAPDH; control 0.81 ± 0.10 vs. day 12 1.96 ± 0.20). Among the phosphorylated FAK (pFAK), Y397 was particularly significant (pFAK/FAK: control 0.39 ± 0.01 vs. day 12 0.75 ± 0.17). Positive staining for pFAK was observed in tubular epithelial cells. In serum-stimulated HK-2, FAK was phosphorylated, but the addition of the decoy peptide of the CCN2 VI-module decreased the amount of Y397. Results of RT-PCR confirmed the expression of several integrin subunits. The results of studies using neutralizing antibodies revealed that the decrease in pFAK was most remarkable when the anti-integrin αv antibody was added (pFAK/FAK: control 0.99 ± 0.13 vs. 0.48 ± 0.06 after addition of the antibody).

Conclusions: By using the IRI model, we found that not only the expression of FAK was increased but also its phosphorylation was promoted in the injured kidney. CCN2 produced in tubular epithelial cells acts via cellular integrin αv in autocrine/paracrine manner, and promotes renal fibrosis through phosphorylation of the tyrosine 397 residue of FAK. CCN2 has been previously shown to activate Wnt/β-catenin and TGF-β/Smad pathways. However, here we identified another pathway for CCN2 in relation to kidney fibrosis. Several FAK inhibitors have already been investigated as anticancer agents. Further clarification of the pathways may prove the therapeutic effects of these inhibitors on CKD.

Multitarget Soluble Epoxide Hydrolase/Farnesoid X Receptor Agonist Combats CKD

John D. Imig. *Medical College of Wisconsin, Milwaukee, WI.*

Background: Chronic kidney disease (CKD) is characterized by progressive fibrosis leading to end-stage renal disease. There has been little success in developing agents that can slow the progression of CKD to ESRD. The current study investigated the efficacy of an innovative multi-target ligand drug, DM509, in mitigating renal fibrosis using the unilateral ureteral obstruction (UUO) mouse CKD model.

Methods: DM509 acts concurrently as a soluble epoxide hydrolase inhibitor and farnesoid X receptor agonist. UUO or sham surgery was conducted in C57BL/6J male mice (n=8/group). Interventional DM509 treatment (10 mg/kg/d p.o.) or vehicle was started three days after UUO induction and continued for 7 days. Plasma and kidney tissue were collected at the end of the experimental protocol. Several biochemical, histopathological, immunohistopathological, and gene expression studies were carried out to determine the antifibrotic actions for DM509

Results: UUO mice demonstrated fibrosis with higher kidney hydroxyproline content (267±46 vs. 53±14 μg/mg protein), collagen area (4.3±0.1% vs. 0.7±0.3%). DM509 reduced hydroxyproline by 41% and collagen area by 65%. Renal inflammation was evident in UUO mice with elevated MCP-1, increased CD45 immune cells, and increased TNF-a, IL-6, IL-1b expression. Interventional DM509 treatment markedly reduced renal inflammation in UUO mice. Vascular inflammation was evident in UUO mice with increased higher ICAM and VCAM expression. DM509 reduced vascular inflammation by 40-50% in UUO mice. In addition, peritubular vascular density assessed by CD31 was reduced by 35% in UUO mice and DM509 attenuated vascular loss. Kidney fibrosis in UUO mice was associated with epithelial-to-mesenchymal transition (EMT) with higher expression of mesenchymal markers a-SMA, FSP-1, and FN, as well as a marked decrease in the epithelial marker, E-cadherin. UUO mice treated with DM509 had markedly reduced EMT. UUO mice also had tubular epithelial barrier injury with increased renal KIM-1, NGAL expression and lower claudin-1, -2 and -4 expression. DM509 treatment reduced tubular injury markers by 25-50% and maintained tubular epithelial integrity by restoring claudin expression in UUO mice.

Conclusions: These data reveal that DM509 is a promising multi-target antifibrotic drug that combats epithelial and vascular kidney fibrotic disease and CKD progression.

Single-Nucleus Transcriptional Profiling of CKD After Repeated Low-Dose Cisplatin Treatment

Zhengwei Ma,[1,2] Xiaoru Hu,[1,2] Zheng Dong.[1,2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]VA Medical Center Augusta Downtown, Augusta, GA.*

Background: Cisplatin induces both acute and chronic kidney problems during chemotherapy. Recent studies have established the models of chronic kidney problems after repeated low dose cisplatin treatment (RLDC). RLDC-induced global transcriptional changes in specific renal cells associated with the development of chronic kidney problems is unclear.

Methods: Male C57BL/6 mice were given 4 consecutive weekly injections of 8 mg/kg cisplatin. Renal function was measured at 5 and 9 weeks after the first cisplatin injection. Kidney tissues were collected for histology and single-nucleus RNA sequencing (Sn-RNA-seq). Cell-type-specific changes in gene expression were compared between the samples from control and cisplatin treated mice. Transcriptional regulators in proximal tubular cells were identified and qPCR was used to validate the critical genes involved in renal fibrotic and inflammation.

Results: RLDC induced decreases in eGFR and kidney weight in mice at 5 and 9 weeks. The kidneys of these mice showed tubular degeneration and dilation. There was also increases in KIM-1 positive tubules and atubular glomeruli. Sn-RNA-seq identified transcripts corresponding to 23021 genes. The markers for 11 cell types and 12 cell clusters were detected. Cluster-by-cluster comparison demonstrated cell-type-specific changes in gene expression that are important for transport, fibrosis and inflammation in RLDC mouse kidneys. In particular, compared with the untreated control, RLDC resulted in 425 differentially expressed genes ($log2FC>1$, $p<0.05$) in proximal tubular cells. >400 and >300 genes displaying altered expression were enriched in profibrotic and proinflammatory pathways, respectively. Consistently, RLDC induced NF-κB activation and proinflammatory cytokines (TNFa, IL6 and IL7), and the expression of fibrosis markers (fibronectin, collagen I, vimentin and α-SMA). Furthermore, Runx1 and Spp1 were identified as critical transcriptional factors that drive inflammation and fibrosis progression after repeated cisplatin treatment.

Conclusions: Single-nucleus RNA sequencing revealed altered gene expression and identified critical transcriptional regulators that promote renal inflammation and fibrosis during the development of chronic kidney problems after repeated low dose cisplatin treatment.

PO2469

Activation of EGFR in Myofibroblasts Promotes Renal Fibrosis in Unilateral Ureteral Obstruction

Yu Pan, Shirong Cao, Andrew S. Terker, Aolei Niu, Yinqiu Wang, Xiaofeng Fan, Suwan Wang, Ming-Zhi Zhang, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: In response to injury, renal fibroblasts and pericytes differentiate into highly specialized myofibroblasts, which are essential for maintaining kidney structural integrity. It is imperative to identify the molecular mechanism initiating and sustaining myofibroblast activation in order to identify novel therapeutics to stop or reverse kidney fibrosis. The activation of epidermal growth factor receptor (EGFR) plays an important role in mediation of recovery of epithelial integrity following ischemic acute kidney injury (AKI). However, sustained activation of EGFR triggers renal fibrogenesis after AKI. The role of EGFR in fibroblasts/myofibroblasts in development of renal fibrosis after severe AKI has not been previously investigated.

Methods: Both PDGFRβ-Cre/ERT2; mCherry mice (WT) and PDGFRβ-Cre/ERT2; mCherry; $EGFR^{f/f}$ mice (PDGFRβ EGFR-/-) were treated with tamoxifen 2 weeks before unilateral ureteral obstruction (UUO) was performed for 3 or 7 days. Quantification of proliferation of PDGFRβ-positive cells was determined at day 3 after UUO. PDGFRβ-positive cells were isolated using PDGFRβ antibody/IgG microbeads.

Results: EGFR mRNA in isolated renal PDGFRβ+ cells was increased >5-fold after 7d UUO. In PDGFRβ EGFR-/- mice, selective EGFR deletion was confirmed by >80% EGFR mRNA reduction in isolated renal PDGFRβ+ cells as well as absence of immunofluorescent EGFR expression in α-SMA+ myofibroblasts. Flow cytometry determined that renal $CD45^{-}CD31^{-}$PDGFRβ+EdU+ cells were markedly lower in PDGFRβ EGFR-/- mice than WT mice 3d after UUO. PDGFRβ EGFR-/- mice had markedly decreased renal fibrosis, indicated by Sirius red and Masson's Trichrome staining, and increased mRNA and protein levels of profibrotic and fibrotic components including α-SMA, collagen I, collagen IV, IL-11, fibronectin, and PDGFRβ. Isolated PDGFRβ+ cells from PDGFRβ EGFR-/- mice also expressed less *col1α1* and *col4α1*. Unexpectedly, the mRNA levels of proinflammatory cytokines, including *Tnf, Il6, Il1α,Il1b, Ccl2, Ccl3, Il23α, Infγ,* and *Il12* in whole kidney tissue as well as in isolated renal myeloid cells were comparable between WT mice and PDGFRβ EGFR-/- mice.

Conclusions: In response to UUO, increased EGFR expression in PDGFRβ+ cells induces myofibroblast proliferation and differentiation to promote subsequent fibrosis.

Activins Facilitate TGF-β1 Profibrotic Signaling in Kidneys

Asfia Soomro,[1] Dan Zhang,[1] Renzhong Li,[1] Neel Mehta,[3] Kian S. O'Neil,[1] Bo Gao,[2] Melissa Macdonald,[2] Joan C. Krepinsky.[1,2] *[1]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [2]St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [3]The University of British Columbia, Vancouver, BC, Canada.*

Background: Chronic kidney disease (CKD) is a rising health issue in North America. It is characterized by progressive renal fibrosis leading to end-stage kidney disease requiring dialysis or transplantation. TGFβ1 is a central mediator of kidney fibrosis in CKD of diverse etiology. Directly blocking it is unfeasible due to adverse effects. Alternate approaches to inhibit TGFβ1 signaling are needed to develop tolerable antifibrotic therapies. Recent studies suggest that TGFβ1 requires activins for its profibrotic effects. Interesingly, both signal through the same canonical Smad pathway. Here we study the mechanisms by which activins enable TGFβ1-induced fibrosis and assess efficacy of specific activin inhibition *in vivo*.

Methods: Primary mouse kidney mesangial cells (MC) were used. Activin A and B (AA, AB), the predominant activins, were inhibited with a neutralizing antibody or follistatin. ELISA, IF and IB were used to assess cytokine levels, signaling pathways and profibrotic responses. Smad3 transcriptional activity was assessed by CAGA12 luciferase reporter and the alpha smooth muscle actin (αSMA) promoter luciferase. Unilateral ureteral obstruction (UUO) was created in mice overexpressing (OE) TGFβ1 or wild-type controls, and effects of neutralizing anti-AA antibody on kidney fibrosis was assessed.

Results: TGFβ1 stimulated the production of AA more than AB, and AA neutralization inhibited the profibrotic effects of TGFβ1. TGFβ1 provoked strong early Smad3 activation (30-60min), while AA did so later (24-48h). Inhibition of AA decreased TGFβ1 (24h)-induced Smad3 activation, assessed by its phosphorylation, nuclear accumulation, and transcriptional activity. Cells retained responsiveness to AA signaling even after becoming refractory to TGFβ1 restimulation, enabling ongoing Smad3 activation. AA additionally regulated noncanonical TGFβ1 signaling. Its inhibition reduced nuclear accumulation of MRTFA, a Smad3 co-mediator of αSMA induction by TGFβ1. Fibrosis was augmented in TGFβ1 OE mice. Neutralizing AA attenuated Smad3 activation and fibrosis in both wild-type and TGFβ1 OE mice.

Conclusions: AA facilitates TGFβ1 profibrotic effects through regulation of both canonical (Smad3) and non-canonical (MRTFA) signaling. Importantly, AA inhibition reduced fibrosis in vivo, suggesting a novel potential therapeutic for fibrosis in CKD.

CircHIPK3 Aggravates Folic Acid-Induced Renal Interstitial Fibrosis by Sponging miR-30a

Hua Zhou, Junjun Luan, Congcong Jiao. *Department of Nephrology, Shengjing Hospital of China Medical University, Shenyang, China.*

Background: Renal interstitial fibrosis is a major pathological feature of end stage kidney disease and currently lacks effective treatment. CircHIPK3 is reported to participate in various diseases. However, the role of circHIPK3 in renal fibrosis is unreported. We aimed to verify whether circHIPK3 participates in the pathogenesis of renal fibrosis and its corresponding.

Methods: C57BL/6 mice were intraperitoneally injected with folic acid (FA) (250 mg/kg) for 30 days. Renal tissue samples were used for paraffin section PAS and Masson staining to confirm the occurrence of renal fibrosis. The expressions of circHIPK3, miR-30a, Transforming growth factor β (TGF-β1),Fibronectin (FN) and Collagen 1 (COL1) in kidney were detected. Those three parameters were further confirmed by immunoblotting. Then the expressions of miR-30a, TGF-β1, FN and COL-1 were detected in immortalized human tubular epithelial cells HK-2 cells overexpressed of circHIPK3 and stimulated with TGF-β1. Finally, fluorescence in situ hybridization (FISH) to measure the localization of circHIPK3 and miR-30a, and immunofluorescence was to detect the expressions of TGF-β1, FN and COL1.

Results: In mice, renal fibrosis features and expression of profibrotic FN and COL1 were increased at day 30 after peritoneal injection of FA. Renal circHIPK3 was up-regulated while miR-30a was down-downregulated in FA-induced kidney injury, as shown by qPCR and FISH. TGF-β1 expression was increased. In addition, renal circHIPK3 negatively correlated with miR-30a and kidney miR-30a also negatively correlated with TGF-β1 mRNA expression. In HK-2 cells, circHIPK3, miR-30a, and TGF-β1 co-localized in the cytoplasm on FISH and immunofluorescence staining. Importantly, transient transfection of circHIPK3 down-regulated miR-30a and up-regulated TGF-β1, FN, and COL1 assessed by qPCR and immunoblotting. Furthermore, exposure of HK-2 cells to human TGF-β1 resulted in increased circHIPK3, decreased miR-30a, and increased expression of profibrotic fibronectin and collagen 1 protein. Kidney biopsies from patients with chronic tubulointerstitial nephritis manifested the same directional changes of circHIPK3, miR-30a, and profibrotic proteins including TGF-β1, FN and COL 1.

Conclusions: A pro-fibrotic feedback involving in circHIPK3, miR-30a, and TGF-β1 and further indicated that circHIPK3 might contribute to renal fibrosis by sponging miR-30a.

ROCK-Binding ASD2-Domain of Shroom3 Has a Profibrotic Role

Qisheng Lin,[1] Khadija Banu,[2] Anand Reghuvaran,[2] Chengguo Wei,[3] John C. He,[3] Barbara T. Murphy,[3] Madhav C. Menon.[2] *[1]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [2]Yale University School of Medicine, New Haven, CT; [3]Mount Sinai Health System, New York, NY.*

Background: We previously showed that a CKD-associated Shroom3 allele was a quantitative trait locus for *SHROOM3* expression and promoted CKD and allograft nephropathy.

Methods: Here we investigated the mechanism of increased fibrosis downstream of Shroom3. We systematically deleted consensus domains in Shroom3 and evaluated profibrotic signaling in tubular cells (Fig-1).

Results: Overexpression of ASD2-domain deleted SHROOM3 mutant (ASD2-SH3 with deficient ROCK binding) consistently reduced TGF-B signaling responses in TGF-B reporter 293-Tcells and in Smad-reporter luciferase assays (vs ASD1-, PDZ-, Fyn-binding domain deletion mutants and intact SHROOM3; n=3 sets each). Based on these data we generated doxycycline inducible transgenic mice for SHROOM3 and ASD2-SH3 mutants. Two founder lines of each transgene crossed with CAGS-rTTA mice were selected based on transgene expression in kidney tissues upon DOX-feeding. Adult CAGS-rTTA:SHROOM3-Tg, ASD2-S3-Tg and control mice were dox fed, and UUO surgery performed (n=5 each). At 7 days, UUO kidneys from ASD2-SH3-Tg mice showed reduced Phospho-Smad3, and reduced profibrotic transcripts (Col1a1, Fn1) vs other groups. ASD2-SH3 UUO kidneys had significantly reduced interstitial fibrosis (masson trichrome and sirius red), and reduced COL1A1 immunofluorescence (fig 2).

Conclusions: Our sequential findings show that the profibrotic role of Shroom3 excess is mediated via its ASD2-domain.

PO2473

EPAC1-Mediated cAMP Signaling in Podocytes Protects Kidneys from the Progression of Glomerulonephritis

Lilia Abbad,[1] Panagiotis Kavvadas,[1] Maximin Detrait,[2] Niki Prakoura,[1] Christos E. Chadjichristos,[1] Frank Lezoualch,[2] Christos Chatziantoniou.[1] *[1]Inserm UMR 1155, Paris, France; [2]Inserm UMR S 1297, Toulouse, France.*

Background: Many efforts are made to identify new therapeutic targets to slow down, prevent or even reverse Chronic Kidney Disease (CKD) progression. One of the therapeutic approaches is the targeting of the renoprotective cAMP pathway, especially by stimulation of its downstream effector, the protein kinase A (PKA). PKA was considered as the unique cAMP effector, however, the exchange factor directly activated by cAMP 1 (EPAC1) has been recently identified as a novel, PKA-independent, mediator of cAMP signaling. Epac1 is a guanidine exchange factor that promotes the exchange of GDP for GTP regulating important cellular functions. Of the two isoforms described, Epac1 is the most expressed in the kidney. Epac1 activation exerts a renoprotective effect during acute kidney injury, via maintenance of epithelial adhesion and protection from oxidative stress. However, the role of EPAC1 in CKD remains poorly understood.

Methods: Here we aim to determine the role of EPAC1 in CKD progression, by inducing nephrotoxic serum glomerulonephritis (NTS-GN) in genetically modified mice with total and conditional EPAC1 deletion.

Results: Following the induction of NTS-GN, genetic deletion of EPAC1 aggravates renal disease, characterized by increased proteinuria, glomerular damage, tissue inflammation and fibrosis compared to wild-type mice. Conversely, pharmacological activation of Epac1, with the agonist 8-pCPT-2-OMe-cAMP, delays NTS-GN progression. Since in normal mouse kidney tissues we have observed EPAC1 expression in podocytes, mice with conditional deletion of EPAC1 in podocytes (Nphs2Cre:epac$^{fl/fl}$) are generated. Similar to the whole-body knockout, mice with EPAC1 deletion in podocytes show increased renal damage and worsened disease progression compared to control mice.

Conclusions: Our results suggest a protective role of podocytes-derived EPAC1 against the development of GN. Targeting the cAMP-EPAC1 signaling axis could represent a new therapeutic option to delay the development of CKD. Further investigations are needed to better define the molecular mechanisms involved, and to define its relevance in human CKD.

A Novel Allosteric HIPK2 Inhibitor Attenuates Renal Fibrosis with Superior Pharmacokinetic, Selectivity, and Safety Profiles

Kyung Lee,[1] Ye Feng,[1] Ya Chen,[1] Richard T. Beresis,[2] Robert Drakas,[3] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]ChemPartner, South San Francisco Innovation Center, San Francisco, CA; [3]ShangPharma Innovations Inc., San Francisco, CA.*

Background: Renal fibrosis is considered the final convergent pathway for progressive CKD, regardless of the original etiologies of the disease. Although much has been learned of the molecular mechanisms underlying renal fibrogenesis, there is still a paucity of success in translating this knowledge to clinical application. We previously demonstrated HIPK2 as a multifunctional activator of TGF-β/Smad3, NF-κB, and p53 pathways and that the global knockout of HIPK2 in mice attenuated kidney fibrosis in vivo. We recently developed a small molecule inhibitor of HIPK2, BT173, that specifically blocked TGF-β/Smad3 pathway to attenuate renal fibrosis without causing adverse systemic effects. Importantly, BT173 did not alter the activity of p53 to produce unwanted oncogenic side effects. However, the in vivo use of BT173 was limited by its poor solubility and potency.

Methods: Based on BT173, we used iterative cycles of chemical synthesis and biological assays to optimize the solubility, bioavailability and potency of TGF-β/Smad3 pathway inhibition. ADME, selectivity, and safety profiling were performed on the optimized HIPK2 inhibitor compounds. The lead inhibitor was then tested in CKD models to test its efficacy in reducing renal fibrosis.

Results: 1) Repeated iteration and in vitro screening assay led to a lead compound, HIPK2i-174. 2) HIPK2i-174 showed greater potency (IC50<200nM) to disrupt the HIPK2-Smad3 interaction in vitro with enhanced solubility. 3) It showed pharmacokinetics suitable for oral *qd* dosing. 4) No appreciable kinase inhibition was observed when tested against a panel of 30 diverse kinases. Acceptable selectivity profiles were observed with Eurofins Safety 44 and CEREP selectivity panels. 5) Safety profiling did not show any relevant CYP inhibition, hERG, or other cardiac ion channel liabilities. 6) Daily *qd* dosing of HIPK2i-174 in mouse models of proteinuric CKD significantly reduced proteinuria and renal fibrosis development.

Conclusions: The optimized HIPK2i-174 effectively improved renal function, reduced renal fibrosis development and CKD progression in vivo. Moreover, its enhanced selectivity, bioavailability, and biological activity demonstrate a favorable safety profile in preclinical species for IND-enabling studies.

PO2475

Inhibition of RNA-Binding Protein HuR Protects Kidney from Ischemia-Reperfusion-Induced Injury and Fibrosis

Zhimin Huang, Simeng Liu, Yufeng Huang. *University of Utah Health, Salt Lake City, UT.*

Background: Upregulation of an RNA-binding protein HuR has been implicated in glomerular diseases both in patients and in animal models. Herein, we further evaluated whether upregulation of HuR occurs in and promotes renal tubular injury and subsequent fibrosis by using a renal ischemia/reperfusion (IR) mouse model and a selective HuR inhibitor, KH3.

Methods: All mice were received unilateral renal IR surgery for 35 min. The contralateral kidneys without surgery served as controls. Mice were then randomly assigned into either vehicle or KH3-treated groups (n=5/group). KH3 was given via daily intraperitoneal injection from day 3 after IR at the dose of 50 mg/kgWB/day to day 14. In additon the effect of HuR inhibition on TGFß-induced tubular cell injury was further investigated in vitro.

Results: IR-injured kidneys showed a significant upregulation of HuR in tubular and tubulointerstitial cells determined by postive cytoplasmic staining of HuR and western blot assay, which was accompanied by extensive tubular damage and fibrosis. However, KH3-treated and IR-injured kidneys exhibited greatly reduced damage and fibrosis, and this correlated with a reduction in renal expression of profibrotic molecules, inflammatory cytokines, NADPH oxidases, and markers for cell proliferation, tubular epithelial-to-mesenchymal transition (EMT), and apoptosis. A panel of 760 fibrosis-associated genes were further assessed, revealing that 519 genes in mouse kidney following IR injury changed their expression and 71.3% of those genes that are involved in 50 annotated

pathways were ameliorated when treated with KH3. Among those, TGFß1 as a HuR target was elevated in the IR-injured kidney. KH3 abrogated TGFβ1-induced tubular HuR cytoplasmic translocation and subsequent tubular EMT in cultured HK-2 cells.

Conclusions: These results suggest that upregulation of HuR contributes to renal tubular injury and fibrosis by dysregulating multiple pro-fibrotic pathways. HuR-targeted inhibitory therapeutics offer a promising novel treatment in the future for preventing or reversing the progression of CKD.

Spiny Mice (Acomys cahirinus) Activate Unique Transcriptional Programs After Severe Kidney Injuries and Regenerate Organ Function Without Fibrosis

Daryl M. Okamura,[1,2] Chris M. Brewer,[1,2] Sarah J. Collins,[1] Elizabeth D. Nguyen,[1,2] Adrian Piliponsky,[1,2] Branden R. Nelson,[1,2] David R. Beier,[1,2] Kathleen J. Millen,[1,2] Mark W. Majesky.[1,2] *[1]Seattle Children's Research Institute, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: Fibrosis-driven solid organ failure is a pervasive burden on global health. Muroid rodents of the genus *Acomys* (spiny mice) are terrestrial mammals that evolved remarkable abilities to regenerate severe skin wounds without scar formation to avoid predation. Whether regenerative wound healing extends beyond skin to vital internal organs in spiny mice is not known.

Methods: Models of acute and chronic kidney injury (UUO, unilateral IRI, unilateral IRI+nephrectomy) were utilized in *Acomys* and compared to C57Bl6/J and CD-1 mice. Fibrosis, myofibroblasts, macrophages were measured. Total kidney RNA Seq, western blotting and confocal image analysis was performed.

Results: Using two aggressive kidney injury models, we show that despite equivalent kidney injury there was rapid regeneration of nephron structure and function without fibrosis in *Acomys* compared to extensive fibrosis and renal failure in *Mus*. Comparative genome-wide analysis of gene expression after injury suggested that the *Acomys* genome is poised to initiate and sustain regenerative wound healing. Among the 843 differentially regulated genes between *Acomys* and *Mus* were metabolic enzymes, transcription factors, and nephrogenic genes such as *Osr1*, *Ror1/2* and *Cdh6*. Interaction analyses revealed 6 clusters of genes that were differentially regulated with injury between *Mus* and *Acomys*. Clusters 1 and 4 represented *Mus*-specific genomic responses to UUO injury whereas the response to injury in *Acomys* is to maintain expression at homeostatic levels. In contrast, clusters 2 and 3 represent *Acomys*-specific kidney response gene sets which are unchanged or downregulated in *Mus*. Early after injury, a cluster 3 gene, *Cdh6* appeared in rapidly expanding renal tubular mosaic patches throughout the injured *Acomys*, but not *Mus*. Regeneration of nephron function was accompanied by cell cycle entry and DNA replication in tubular and glomerular cells, including podocytes and endothelial cells.

Conclusions: Our findings have important implications for an evolutionary solution to mammalian regenerative repair of the kidney, and by extension, to the heart and coronary vessels, lungs, liver, and other internal organs similarly prone to organ failure as a result of progressive tissue fibrosis.

PO2477

Graphene Quantum Dots Protects Against Renal Fibrosis After Restoring Mitochondria Function in Rat 5/6 Nephrectomy

Kyu hong Kim,[1] Soie Kwon,[1] Semin Cho,[1] Kyung Don Yoo,[2] Yong Chul Kim,[1] Jae Wook Lee,[3] Dong Ki Kim,[1] Yon Su Kim,[1] Seung Hee Yang.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Ulsan University Hospital, Ulsan, Republic of Korea; [3]National Cancer Center, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Graphene Quantum Dots (GQDs) are carbon-based nanoparticles and spotlighted in biological application due to their biocompatibility, quantum confinement and low toxicity. Rat with subtotal 5/6 nephrectomy exhibit mitochondrial dysfunction mediated by TRPC5 channel, a core calcium channel in podocytes and tubular cells. With current limited understanding of the interaction on between nanomaterials and renal cells, we show GQDs as a potential therapeutic nano-sized material in 5/6 nephrectomy rat model.

Methods: To evaluate GQDs therapeutic effect on 5/6 nephrectomy Sprague Dawley (8-week; male) rat model, GQDs (4mg/kg) was administered by intraperitoneal for 3 times per week up to 8 weeks. *In vitro* stimulation, recombinant TGF-beta (2mg/mL) was treated in both human primary podocytes and tubular cells with GQDs in dose-dependent manner (0.1ug/mL, 0.5ug/mL, 1ug/mL). Renoprotection in 5/6 nephrectomy were assessed through combination of flow cytometry, Annexin V – FTIC Apoptosis staining, histomorphometry, functional manipulations, protein and mRNA expressions. Intracellular Calcium permeability was measured from Fura 2-AM.

Results: GQDs pivotal role in 5/6 nephrectomy led to identification of the partial proteinuria recovery and antihypertensive effects. *In Vivo* study discloses GQDs anti-fibrosis role as impeding MMT process that co-express macrophage (CD68) and myofibroblast (a-SMA). Thus, *in vitro* study after TGF-beta induction show similar results. GQDs-treated group in rats have increased potential cell viability by downregulating the cyclin kinase inhibitors after decreasing Bax-2, P53, P21 but increasing BCL2 expression. Next, Annexin staining result shows GQDs-treated group have a higher viable cells population (-/-) than 5/6 nephrectomy. Computing differential gene expression (DGE), RNA sequencing (RNA-seq) highlights the significant folding changes in *TRPC5* gene from GQDs-treated group. Acute stimulation of calcium movement measured by Fura 2-AM was lowered in GQDs group and TRPC5 protein function expression. Interestingly, after TRPC5 modulation by GQDs, mitochondrial dysfunction is repaired.

Conclusions: GQDs restores mitochondrial function associated with TRPC5 activation pathways. This gratitude of GQDs for renal preservation will promote next generation of CKD treatments.

Critical Role of Histone Demethylase JMJD3 in the Regulation of Macrophage Polarization and Renal Fibrosis

Changlong An,[1] Baihai Jiao,[1] Yanlin Wang.[1,2] *[1]University of Connecticut School of Medicine, Farmington, CT; [2]VA Connecticut Healthcare System - West Haven Campus, West Haven, CT.*

Background: Chronic kidney disease is characterized by macrophage infiltration and fibrosis. Macrophage infiltration and polarization play an important role in the development of renal fibrosis. However, the mechanisms underlying macrophage polarization and development of renal fibrosis are not fully understood. In this study, we examined the role of histone demethylase JMJD3 in the regulation of macrophage polarization and renal fibrosis.

Methods: To examine the role of JMJD3 in vivo, we generated mice with global or myeloid cell-specific deletion of JMJD3, and we treated wild-type mice with vehicle or GSK-J4, a selective JMJD3 inhibitor. Unilateral ureteral obstruction (UUO) model were used to induce renal fibrosis.

Results: JMJD3 expression was increased in the kidneys during the development of renal fibrosis. Mice with tamoxifen-inducible deletion of JMJD3 (CAG-Cre, floxed JMJD3) or myeloid cell specific deletion of JMJD3 (LysM-Cre, floxed JMJD3) were born normal and had no obvious morphological abnormality in the kidney. Compared with Cre negative, floxed JMJD3 mice, mice with global or myeloid cell-specific deletion of JMJD3 displayed fewer F4/80-positive macrophages, CD206-positive M2 macrophages, and myofibroblasts, and expressed less α-SMA protein in the kidneys following UUO. Furthermore, global or myeloid cell-specific deletion of JMJD3 significantly reduced total collagen deposition and ECM protein production in the kidneys after UUO injury. Real-time RT-PCR showed that global or myeloid cell-specific deletion of JMJD3 attenuated M2 macrophage polarization, fibroblast activation, and extracellular matrix protein production. Moreover, genetic deletion of JMJD3 increased histone Lys 27 dimethylation. Wild-type mice treated with GSK-J4 exhibited fewer M2 macrophages and myofibroblasts and produced less amounts of extracellular matrix proteins in the kidney following UUO.

Conclusions: Our study identifies JMJD3 as a critical regulator of macrophage polarization and development of renal fibrosis. Therefore, JMJD3 may represent a novel therapeutic target for chronic kidney disease.

PO2479

DNA Methylation in Repeated Low-Dose Repeated Cisplatin-Induced CKD

Xiaoru Hu,[1,2] Zhengwei Ma,[1,2] Zheng Dong.[1,2] *[1]Augusta University, Augusta, GA; [2]VA Medical Center Augusta Downtown, Augusta, GA.*

Background: DNA methylation is an epigenetic mechanism that regulates gene expression by adding methyl groups to DNA molecules via DNA methyltransferases (DNMTs). Aberrant DNA methylation changes have been implicated in the pathogenesis of kidney diseases. Recent work indicates that DNA methylation protects against cisplatin-induced acute kidney injury partially through hypomethylation of interferon regulatory factor 8 (Irf8). However, little is known about DNA methylation in chronic kidney problems following cisplatin exposure.

Methods: Mice and HK2 cells were subjected to repeated low-dose cisplatin treatment (RLDC). We analyzed the expression of DNMTs and the methylation marker 5-methyl-cytosine following RLDC. We further conducted representation bisulfite sequencing (RRBS) to analyze the genome-wide DNA methylation changes. To explore the pathogenic role of DNA methylation, we initially tested the effects of 5-aza, a pharmacological DNMT inhibitor. We further established and tested a conditional knockout mouse model in which DNMT3a is specifically ablated from kidney proximal tubules (PT-DNMT3a-KO).

Results: RLDC induced notable increases in DNMT1 and DNMT3a (but not DNMT3b) expression, which were accompanied by an overall increase in DNA methylation as shown by 5-methyl-cytosine staining. Genome-wide DNA methylation assay identified differentially methylated regions (DMRs) in 171 genes after RLDC. Five of these genes (*Oxgr1, Smim22, Sec61a2, lhx1, Nsd1)* had hypermethylation in their promoter regions, which was associated with decreased mRNA expression, suggesting the regulation of these genes by DNA methylation. Functionally, 5-aza reduced the expression of fibrosis-related proteins in cisplatin-treated HK2 cells including collagen I and CTGF. In vivo, 5-aza and ablation of proximal tubule DNMT3a both alleviated the decline of renal function, kidney atrophy, and renal fibrosis after repeated cisplatin treatment.

Conclusions: DNMTs are induced in renal tubular cells after cisplatin exposure, accompanied by an overall increase of DNA methylation. Under this condition, DNA methylation contributes to the development of chronic kidney problems. Inhibition of DNMTs may afford therapeutic effects against cisplatin-induced chronic kidney disease.

Targeting Histone Demethylase LDS1 Inhibits Renal Epithelial-Mesenchymal Transition and Attenuates Renal Fibrosis

Xiaoqin Zhang,[1,2] Xiaoyan Li,[1] Xiaogang Li,[1] Ewud Agborbesong.[1] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Shanghai Tongji Hospital, Shanghai, China.*

Background: Lysine-specific histone demethylase 1 (LSD1) as the first identified protein demethylase plays a special role in the regulation of gene expression by removing methyl groups from mono- and di-methylated lysine 4 and 9 on histone H3 and functions as an oncogenic factor in cancers. However, its role in renal fibrosis is unknown.

Methods: To evaluate the role and mechanisms of LSD1 in the development of renal epithelial–mesenchymal transition (EMT) and renal fibrosis, we inhibited LSD1 with its inhibitor, ORY1001, in mouse unilateral ureter obstruction (UUO) model and rat kidney fibroblasts (NRK-49F) and rat kidney proximal tubular (NRK-52E) cells stimulated by TGF-β1.

Results: We found that the expression of LSD1 was increased and the methylation of its histone targets were decreased in mouse kidneys with unilateral ureteral obstruction and NRK-52E cells undergoing EMT. Inhibition of LSD1 with ORY1001 decreased the deposition of extracellular matrix proteins and the expression of fibrotic markers, including α-smooth muscle actin (α-SMA) and fibronectin, which was associated with preserving E-cadherin expression and inhibiting N-cadherin upregulation in the obstructed kidney. Injury to the kidney enhanced the phosphorylation and activation of Smad2/3, AKT and Stat3, and that could be prevented by ORY1001 administration. Targeting LSD1 with ORY1001 and siRNAs inhibited TGFβ1 induced the activation of renal fibroblasts, NRK-49F, and EMT of NRK-52E cells. The expression of Snail family transcriptional repressor 1 (Snail-1) was upregulated in UUO kidneys and cultured NRK-52E cells treated with TGFβ1. Snail-1 repressed the expression of E-cadherin via the interaction of its N-terminal SNAG domain with LSD1. LSD1 inhibition with ORY1001 or siRNA silencing prevented the upregulation of Snail-1 and disrupted Snail/LSD1 interaction, resulting in the expression of E-cadherin. ORY1001 was also effective in suppressing TGF-β1-induced renal epithelial cells arrest at the G2/M phase.

Conclusions: This study indicates that LSD1 participates in the expression of profibrotic genes and contributes to renal EMT and fibrosis through activation of diverse signaling pathways, and places an emphasis that LSD1 has potential as a therapeutic target for the treatment of renal fibrosis.

PO2481

Does Senescence Induce Muscle Wasting in CKD?

Bin Wang,[2,1] Ying Huang,[1,3] Janet D. Klein,[1] Hui Cai,[1] Xiaonan H. Wang.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]Southeast University, Nanjing, China; [3]Central South University, Changsha, China.*

Background: Muscle wasting is a common complication of CKD and associated with higher mortality and morbidity. The mechanism of muscle wasting in uremia has been widely studied; however, uremic stress-induced senescence might be a missing connection between chronic kidney disease and muscle wasting. Senescent cells are capable of producing and secreting various growth and proinflammatory factors, cytokines, and chemokines, which is known as the S-ASP. We hypothesized that senescence and senescence associated secretary phenotype (S-ASP) play important roles in the CKD-induced muscle loss.

Methods: CKD mice were induced by 5/6 nephrectomy. Senescence was confirmed by using senescence associated beta gal (SA-βgal). The levels of S-ASP (interleukin 6 (IL-6), TNFα, TGFβ and IL-8) were measured by immunohistochemistry and ELISA. Senescence pathway markers p16, p21 and p53 were measured by Western blots. To limit senescence, dasatinib (5 mg/kg BW) + quercetin (50 mg/kg BW) (D&Q) were given by oral gavage 2 days per week for 8 weeks. Muscle function was measured with a grip force detector.

Results: CKD stress-induced premature senescence phenomena have been evidenced in the skeletal muscle of uremic mice by 1) the increases in senescence pathway indicators p21 and p16, but not p53 protein; 2) phosphorylated histone H2AX (γH2AX, DNA damage marker); 3) the level of the senescence biomarker SA-β gal; and 4) S-ASP components present in the uremic muscle, which include high levels of interleukin 6 (IL-6), TNFα, TGFβ and IL-8. The D&Q treatment eliminated CKD-induced elevation of p21, p16 and γH2AX, abolished positive SA-β gal, and depressed the high levels of S-ASP cytokines. The muscle cross-sectional area was increased by D&Q treatment compared with the vehicle treatment in 5/6 nephrectomy mice. Skeletal muscle function was also improved with D&Q treatment in uremic mice.

Conclusions: Senescence and S-ASP are important factors in development of muscle wasting during CKD progression. Limiting senescence with D&Q ameliorates muscle wasting and improves muscle function. These results provide new approaches for developing therapeutic strategies to improve muscle health in chronic kidney diseases.

Chronic Aristolochic Acid Administrations Induce Renal Senescence in Mice

Shingo Urate, Hiromichi Wakui, Shohei Tanaka, Eriko Abe, Shunichiro Tsukamoto, Shinya Taguchi, Toru Suzuki, Kengo Azushima, Kouichi Tamura. *Yokohama City University Graduate School of Medicine Department of Medical Science and Cardiorenal Medicine, Yokohama, Japan.*

Background: The kidneys are one of the most susceptible organs to age-associated impairments. Recently, although renal aging research has been extensively performed, appropriate models of renal aging are still limited. Generally, renal aging is strongly associated with renal fibrosis, which is the final common pathway of chronic kidney disease. Aristolochic acid (AA), a renal toxic agent, causes aristolochic acid nephropathy (AAN) characterized by progressive renal fibrosis and functional decline. Here, we examined the potential of AAN as a model of renal senescence using chronic AA administrations into C57BL/6 mice.

Methods: 8-week-old male C57BL/6 mice were assigned to AA or vehicle control group after 1-week acclimatization. Mice were intraperitoneally administered with AA (3mg/kg) or vehicle (75% dimethyl sulfoxide) twice a week for 4 weeks, followed by a 4-week recovery period.

Results: Compared to controls, the AA group showed aged kidney-like phenotypes such as renal atrophy, renal functional decline, and tubulointerstitial fibrosis. In addition, AA provoked cellular senescence specifically in the kidneys, concomitant with an increase in renal p16 mRNA expression and senescence-associated β-galactosidase activity. Additionally, AA-induced mice exhibited proximal tubular mitochondrial abnormalities, followed by accumulation of reactive oxygen species.

Conclusions: Collectively, the results of the present study indicates that AAN partially mimics aged kidney and could become a useful mouse model for kidney aging research.

Hypervitaminosis A Contributes to Kidney Injury Through Excessive Endoplasmic Reticulum Stress in CKD

Yuichiro Adachi,[1] Masashi Masuda,[1] Kohei Sasaki,[1] Hirokazu Ohminami,[1] Hisami Yamanaka-Okumura,[1] Hironori Yamamoto,[1,2] Yutaka Taketani.[1] *[1]Department of Clinical Nutrition and Food Management, Institute of Biomedical Sciences, Tokushima University Graduate School., Tokushima, Japan; [2]Department of Health and Nutrition, Faculty of Human Life, Jin-ai University, Fukui, Japan., Echizen, Japan.*

Background: Endoplasmic reticulum (ER) stress is activated upon the accumulation of misfolded proteins in the ER. PERK signal, one of the downstream pathways of ER stress response, mediates some transcription factors such as activating transcription

factor 4 (ATF4) and C/EBP-homologous protein (CHOP). It has been known CHOP induces renal dysfunction and leads to chronic kidney disease (CKD) via apoptosis. ATF4 promotes transcriptional activation of DNA damage-inducible protein 34 (GADD34/Ppp1r15a), which is the negative-feedback protein of PERK signaling and essential for cell survival. It is reported that the levels of plasma vitamin A and its metabolites, all-trans retinoic acid (ATRA), increase in CKD patients from the early CKD stage. One recent report shows excessive vitamin A in CKD patients induces renal dysfunction, however, the effects of ATRA on ER stress have been unclear. In this study, we investigated the role of ATRA on ER stress in the kidney of CKD.

Methods: NIH3T3 cells were treated with 100 nM ATRA and 100 nM thapsigargin (Tg), a major ER stress inducer, for 12 to 48 hours. Eight-week-old male C57BL/6J mice were fed a control diet (control) or adenine-contained diet (0.2%) and treated with either vehicle (CKD) or ATRA (10 mg/kg/3 days) for 8 weeks (CKD + ATRA). Gene and protein expressions were evaluated by real-time qPCR and western blotting.

Results: Although ATRA did not change the mRNA and protein expressions of ATF4 and CHOP in NIH3T3 cells, ATRA additively increased ATF4 and CHOP induced by Tg. Interestingly, ATRA decreased GADD34 protein expression induced by Tg, even though ATRA increased Tg-induced expression of ATF4, the positive upstream regulator of GADD34. The evaluation of protein levels of cleaved-Caspase 3, a major apoptosis marker, and flow cytometry indicated ATRA increases Tg-induced apoptosis. ATRA did not change CKD-induced high plasma levels of phosphate and BUN. However, ATRA increased the protein expression of BiP, CHOP, and cleaved-Caspase 3, but decreased GADD34 expression in CKD mice. Furthermore, the evaluations of Masson's Trichrome staining in the kidney suggested ATRA increase CKD-induced fibrosis.

Conclusions: These results indicate hypervitaminosis A on CKD exacerbates ER stress via decreasing GADD34, which induces kidney injury.

PO2484

Time-Restricted Feeding Ameliorates Fibrosis by Restoring Disrupted Peripheral Clock in Adenine-Induced CKD Model

Yina Fang, Sewon Oh, Jihyun Yang, Ko Yoon Sook, Hee Young Lee, Sang-Kyung Jo, Won-Yong Cho, Myung-Gyu Kim. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Circadian disruption has recently been demonstrated to be closely associated with various metabolic diseases. Time restricted feeding (TRF) is a dietary strategy that limit the time of eating to a window of 4-12hr per day and has been shown to resynchronize peripheral clock. In this study, we aimed to investigate the relationship between circadian disruption and chronic kidney disease (CKD). We also tested whether TRF confer renoprotective effect via restoration of peripheral clock.

Methods: First, to determine the effect of CKD on circadian rhythm in the kidney, oscillation of several peripheral clock genes (*Bmal1, Per1, CLOCK* and *Rev-erbα*) as well as physiologic parameters (GFR, transporter protein expression and urine output) were compared between control and adenine induced CKD mice. To determine the role of circadian disruption on CKD progression, renal function and fibrosis were compared between WT and Bmal-1 knockout mice. In addition, adenine-induced CKD mice were given either a 24-hour ad libitum diet or a TRF for 8 weeks and the effect of TRF on CKD progression as well as oscillation of peripheral clock genes were measured.

Results: Adenine induced CKD mice showed disrupted oscillation of peripheral clock genes (*Bmal1, Per1, CLOCK* and *Rev-erbα*) and this was associated with loss of rhythmic oscillations of glomerular filtration rate, tubular functions and urine output. Meanwhile, more severe fibrosis and lower GFR were observed in Bmal1 (principal driver of molecular clock) knockout mice compared to WT mice, showing a bidirectional relationship between disturbed circadian rhythm and CKD progression. TRF in adenine induced CKD mice significantly suppressed interstitial inflammation as well as cell cycle arrest and ultimately ameliorated worsening of renal function and fibrosis. These changes were accompanied by partial restoration of disturbed oscillation of peripheral clock genes, suggesting that renoprotective effect of TRF is partially mediated by restoration of peripheral clock.

Conclusions: Our data demonstrated a unique bidirectional relationship between the circadian disruption and CKD and suggest that disruption of peripheral clock might contribute to CKD progression. The renoprotective effect of TRF might be mediated via resynchronizing disrupted peripheral clock in the kidney.

PO2485

The Role of Abnormal Expression of Clock Gene DBP Mediated by Gut Microbiota Dysbiosis in Cognitive Dysfunction in ESRD and the Underlying Mechanism

Lei Chen, Yulong Luo. *Dialysis Department of Nephrology Hospital, the First Affiliated Hospital of Xi'an Jiaotong University., Xi'an, China.*

Background: The objective of this study is to explore whether gut microbiota dysbiosis is one of the main cause of cognitive dysfunction (CD) in CKD and to reveal its specific mechanism, bringing a new insight for its pathogenesis.

Methods: The fecal microbiota of normal rats was transplanted into CKD rats by intragastric gavage for 4 weeks. The gut microbiota was analyzed by 16S rRNA sequencing. The cognitive function (CF) was evaluated by Morris Water Maze. The level of microinflammatory biomarkers were detected by ELISA, and their correlation with CF was analyzed. The expression of DBP in rat macrophages was detected by qPCR. Further, the level of DBP in macrophages was verified in CKD patients, and the serum of CKD patients was used to stimulate the differentiation of THP-1 cells into macrophages. The proportion of M1 and M2 macrophages was detected by flow cytometry. The expression of DBP and cytokines in THP-1 was detected by qPCR. Finally, DBP in THP-1 cells was knocked down and overexpressed before treating with PMA, respectively, to measure the expression of cytokines.

Results: The ability to search the target quadrant decreased significantly in CKD rats, which were partially reversed by FMT. FMT improved the β-diversity of CKD microbiota, and increased the abundance of Prevotella_9, Prevotella_1 and Roseburia. Compared with sham rats, serum levels of IL-6, TNF-α and hsCRP were significantly increased in CKD rats, while they were decreased after FMT. The levels of above markers were negatively correlated with CF. DBP expression was higher in CKD rats macrophages, which was reversed by FMT. The percentage of M1 macrophages was increased in CKD patients, and DBP expression in macrophages was increased. Moreover, the serum of CKD patients induced the differentiation of THP-1 cells into M1 macrophages, during which the expression of DBP and cytokines was increased. Furthermore, DBP knockdown decrease the expression of proinflammatory cytokines, while DBP overexpression induced the expression of these cytokines significantly.

Conclusions: The microinflammation mediated by gut microbiota dysbiosis is an important cause of CD in CKD. DBP, induced by dysbiosis, positively regulates the expression of inflammatory factors in macrophages differentiation, leading to microinflammation, which may be involved in the pathogenesis of CD in CKD.

PO2486

Circadian Cycle Exaggerates Sympathoexcitatory Responses to Activation of Chemosensitive Renal Sensory Nerves

Leon J. DeLalio, Sean D. Stocker. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Renal sensory nerves contribute to renovascular hypertension and renal dysfunction in chronic kidney disease. These sensory nerves are activated by chemokines (e.g., bradykinin and capsaicin) and produce reflexive changes in efferent sympathetic nerve activity (SNA) and arterial blood pressure (ABP). SNA, renal function, and ABP exhibit clear circadian patterns. Yet, it is unknown whether the circadian cycle alters renal-reflex responses to chemosensitive stimuli. We hypothesized renal sensory nerve activation would elicit larger SNA and hemodynamic responses during the dark versus the light periods.

Methods: To test this hypothesis, male and female Sprague-Dawley rats (250-400g) were anesthetized with Inactin and prepared for simultaneous nerve recordings of renal and splanchnic SNA and ABP at dark (D; 20:00-04:00; n= 12M, 10F) and light (L; 09:00-16:00; n= 8M, 8F) periods.

Results: Intrarenal capsaicin infusion (0.1μM – 30.0μM; 50μl over 15s) produced concentration-dependent increases in renal and splanchnic SNA in both the dark and light periods. Interestingly, a greater increase in renal SNA in dark versus light groups occured with 10 μM (D: 723±136 vs L: 409±79 %; p=0.03) and 30 μM (D: 826±181 vs L: 509±80 %; p=0.03) capsaicin. Intrarenal capsaicin produced greater increases in splanchnic SNA between dark versus light periods at 10 μM (D: 501±117 vs L: 204±53 %, p=0.03) and 30 μM (D: 537±101 vs L: 295±68 %; p=0.03). ABP was similarly increased during the dark (7±1 mmHg; 30 μM) and light (6±1 mmHg; 30 μM) periods. Intrarenal bradykinin infusion (0.1μM – 30.0μM; 50μl over 15s) produced concentration-dependent increases in renal and splanchnic SNA in both the dark and light periods. A greater increase in renal SNA during the dark versus light periods occured at 10 μM (D: 1773±216 vs L: 1249±112 %; p=0.01) and 30uM (D: 2605±263 vs L: 1783±163 %; p=0.001). Splanchnic SNA responses were also greater during the dark versus light periods at 0.1 μM (D: 163±65 vs L: 0±0 %; p=0.02), 1.0 μM (D: 566±114 vs L: 184±52 %; p=0.005), 10 μM (D: 1110±193 vs L: 583±87 %; p=0.006) and 30 μM (D: 2008±193 vs L: 1044±162 %; p<0.001). ABP was similarly increased between the dark (10±2 mmHg; 30 μM) and light (6±1 mmHg; 30 μM) periods.

Conclusions: Thus, the circadian cycle exaggerates sympathoexcitatory responses produced by activation of chemosensitive renal sensory nerves.

D-Serine Promotes Kidney Remodeling via an mTOR-Related Pathway

Atsushi Hesaka,[1,2] Yoshitaka Isaka,[2] Tomonori Kimura.[1,2] NIBIOHN [1]*Kokuritsu Kenkyu Kaihatsu Hojin Iyaku Kiban Kenko Eiyo Kenkyujo, Ibaragi, Japan;* [2]*Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan.*

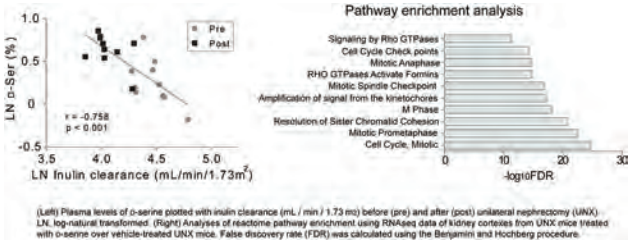
Background: D-Serine, a long-term undetected enantiomer of serine, is a biomarker that reflects kidney function and disease activity, whereas the physiological functions of D-serine have been unclear. Here, we investigated the physiological functions of D-serine in human living kidney donors and in unilateral nephrectomy (UNX) mice model.

Methods: Dynamics of D-serine was assessed by measuring D-serine in human samples of living kidney donors using two-dimensional high-performance liquid chromatography before and after UNX. Effects of D-serine on kidney from UNX mice and genetically modified cells were examined by gene expression profiling and histological studies.

Results: Human living kidney donors after UNX decreased urinary excretion and thus increased the blood level of D-serine. The plasma ratio of D-serine correlated well with glomerular filtration rate (GFR). Treatment of D-serine at physiological dose promoted the enlargement of remnant kidney in UNX mouse model. Profiling of pathway enrichment analysis using RNAseq in the kidney of UNX mice revealed dominant activation of the cell cycle-related pathways by D-serine treatment. Mechanistically, D-serine activated the cell cycle for tissue remodeling through an mTOR-related pathway, and inhibition of mTOR suppressed D-serine-induced cellular proliferation.

Conclusions: D-Serine is a physiological molecule that promotes kidney remodeling. Besides its function as a biomarker, D-serine has a physiological activity that influences kidney function.

Funding: Commercial Support - Shiseido Company, Limited, Government Support - Non-U.S.



(Left) Plasma levels of D-serine plotted with inulin clearance (mL / min / 1.73 m2) before (pre) and after (post) unilateral nephrectomy (UNX). LN, log-natural transformed. (Right) Analyses of reactome pathway enrichment using RNAseq data of kidney cortexes from UNX mice treated with D-serine over vehicle-treated UNX mice. False discovery rate (FDR) was calculated using the Benjamini and Hochberg procedure.

PO2488

First-in-Class PRS Inhibitor DWN12088 Ameliorates Folic Acid-Induced Kidney Fibrosis

Seung Seob Son,[1] Seong Woo Lee,[1] Mi Ju Park,[1] Min Sun Choi,[1] Eun Soo Lee,[2] Jeong suk Kang,[1] Choon Hee Chung,[2] Joon Seok Park,[3] Eun Young Lee.[1] *[1]Department of Internal Medicine, Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea; [2]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; [3]Daewoong Pharmaceutical Co., Ltd., Drug Discovery Center, Yongin, Republic of Korea.*

Background: Fibrosis is characterized by the upregulated extracelluar matrix (ECM), which drives organ damage and abnormal cell proliferation. According to recent studies, PRS (prolyl- tRNA synthetase) is known to play a role in synthesizing collagen during ECM components. It has been reported that PRS is greatly increased in the lung and liver fibrosis animal model, but the role of PRS in the renal fibrosis model has not been elucidated.

Methods: In this study, we investigated the protective effect of novel PRS inhibitor (Daewoong Pharmaceutical Co., Ltd, Korea), in folic acid (FA)-induced kidney fibrosis and aimed to determine whether this role depends on the inhibition of mitochondria dysfunction and the STAT3 signaling pathway. Renal fibrosis was induced by FA (250 mg/kg) intraperitoneal injection in C57BL/6 mice. DWN12088 (10, 30 mg/kg) was administered by intraperitoneal daily injection for 4 weeks. Histological changes were examined by Masson's trichrome staining. The expression of ECM markers was evaluated by immunohistochemistry, western blot analysis and real time-PCR. Mitochondria was also examined by electron microscopy.

Results: FA induced renal fibrosis and mitochondria dysfunction and upregulated PRS expression. When the FA induced decreased weight in mice, there was an effect on body weight by administering the DWN12088. We also examined the blood urea nitrogen (BUN), serum creatinine (Cr), creatinine clearance (CCr) and urine protein creatinine ratio (UPCR) levels. DWN12088 attenuated the levels of clinical data of renal injury (it decreased the BUN levels, Cr levels and UPCR levels, and increased the CCr levels). The administration of DWN12088 decreased the PRS levels and improved FA-induced renal fibrosis and mitochondria. Moreover, DWN12088 effectively inhibited the ECM markers (FN and Collagen 1A1) and the levels of SIRT1/STAT3 induced by TGF- β1 induced fibrotic condition in HK-2 cells. DWN12088 also improved mitochondria function in HK-2 cells.

Conclusions: This study provides evidence for the detrimental role of upregulated PRS in the pathogenesis of renal fibrosis. The findings highlight a DWN12088 that improves renal fibrosis and mitochondria dysfunction. As a result, blockade of PRS is a potential therapeutic intervention to prevent renal fibrosis (NRF-2020R1A2C2003438).

PO2489

AIM2 Modulates Renal Metabolic Profile and Inflammation in Acute and Chronic Kidney Injury

Magaiver A. Silva,[1,2] Ingrid K. Watanabe,[1] Orestes Foresto-Neto,[1] Tâmisa S. Honda,[1] Ana R. da Silva,[2] Marcos A. Cenedeze,[2] Alvaro Pacheco-Silva,[2] Niels O. Camara.[1,2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: The absent in melanoma 2 (AIM2) is cytosolic double-stranded DNA receptor expressed in the kidney. AIM2 activation initiates the assembly of the inflammasome, culminating in inflammatory response. Inflammasomes cause metabolic dysregulation and drive pathology in a wide variety of human diseases. So far, the function and how AIM2 affects inflammatory and renal metabolic profile in acute and chronic injury is poorly described.

Methods: The wild-type (WT) and AIM2 KO mice were submitted to cisplatin-induced acute kidney injury or unilateral ureter obstruction (UUO), a chronic kidney disease model. We evaluated renal structure and function, fibrotic molecules, fibronectin (FN) and type I collagen (COL1) and inflammation (IL-1β, IL-6). The expression of carnitine palmitoyltransferase 1 (CPT1a), involved in fatty acid oxidation (the main energy source of kidneys), and glycolytic enzyme expression, pyruvate kinase M2 (PKM2) were used as an indicative of metabolic alteration. The AIM2 activation was also investigated in proximal tubular cells (PTCs).

Results: The severe tissue injury induced in WT mice by cisplatin was markedly attenuated in AIM2 KO mice, evidenced by reduction in tubular dilatation and amelioration of renal function. Moreover, AIM2 deletion impaired the reduction of CPT1a expression. In mice model of UUO, we observed an increase of AIM2 expression, concomitantly with increase of IL-1β, IL-6, FN and COL1. Moreover, the animals presented reduction of CPT1a and increase of PKM2, suggesting a metabolic reprogramming in the kidneys. The AIM2 deficiency attenuated the renal injury, fibrosis, inflammation, and CPT1a levels did not change after kidney injury. In vitro study, the AIM2 activation caused metabolic reprogramming in PTCs, accompanied by increase of proinflammatory and profibrotic markers.

Conclusions: AIM2 activation drives acute e chronic kidney injuries. However, a better understand on how AIM2 affects PTCs metabolism and its connection with inflammation and kidney injury is needed.

Identification of Post-Translational Guanidinylated Proteins in the Context of Systemic Lupus Erythematosus by Using Mass-Spectrometric Methods

Vera Jankowski, Ute Raffetseder, Michaela Lellig, Juliane Hermann, Joachim Jankowski. *Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany.*

Background: With continuous identification of post-translational modified isoforms of proteins, it is becoming increasingly clear that post-translational modifications limit or modify the biological functions of native proteins are majorly involved in development of various chronic disease. This is mostly due to technically advanced molecular identification and quantification methods, mainly based on mass spectrometry. Mass spectrometry has become one of the most powerful tools for the identification of proteins and lipids.

Methods: In this study, we used sophisticated high-resolution mass-spectrometric methods to analyze the soluble ligand of receptor Notch-3, namely the Y-*box* protein (YB)-1, in serum from systemic lupus erythematosus (SLE) patients. In addition, kidneys of lupus-prone (MRL.*lpr*) mice were analyzed by mass-spectrometric imaging techniques to identify the underlying pathomechanisms. Serum YB-1 was isolated by chromatographic methods, afterwards digested by trypsin and analyzed by matrix assisted laser desorption/ionization mass spectrometry (MALDI-MS). The kidneys were fixed in paraffin, then kidney sections were deparaffinized, tryptic digested and analyzed by mass-spectrometric imaging techniques

Results: Mass-spectrometry of extracellular YB-1 in SLE patient serum revealed post-translational guanidinylation of two lysine's within the highly conserved cold shock domain (CSD) of the YB-1 protein (YB-1-2G). Patients with increased disease activity and those with active renal involvement (lupus nephritis, LN) had a higher degree of dual-guanidinylation within the CSD. Of note, at least one of these modifications was present in all analyzed LN patients, whereas single-guanidinylated YB-1 was present in only one and double modification in none of the control individuals. Mass-spectrometric imaging analyses specifically localized YB-1-2G and increases Notch-3 expression in kidney sections from MRL.*lpr* mice.

Conclusions: The data from this study clearly demonstrate the high potential of high-resolution mass spectrometric methods as well as mass spectrometric imaging techniques to identify pathomechanisms of diseases like SLE/LN.

PO2491

Deletion of Tubular Cpt1a Does Not Worsen Kidney Aging or Response to Injury

Leslie S. Gewin,[1] Alla V. Ivanova,[1] Yosuke Osaki,[1] Rachel Delgado,[1] Mark P. de Caestecker,[1] Roy Zent,[1] Louise Lantier.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Proximal tubules (PT) preferentially use fatty acid oxidation to generate the energy necessary to support their high reasborptive capacity. Carnitine palmitoyltransferase 1 (CPT1) is required for long chain fatty acids to enter mitochondria, and CPT1a is considered the rate-limiting enzyme for PT fatty acid oxidation. CPT1a expression is decreased in kidney injury and its overexpression reduces fibrosis, so we hypothesized that Cpt1a deletion would exacerbate kidney aging and injury.

Methods: We inducibly deleted Cpt1a in adult mouse tubules using Pax8-rTTA;tetO-Cre mice and confirmed robust recombination. Mice were aged for 2 years or injured by either aristolochic acid nephropathy (AAN) or unilateral ureteral obstruction (UUO). Primary PT-enriched cell populations were generated from aged mice, and fatty acid-dependent respiration and glycolysis were measured using Seahorse bioflux analyzer.

Results: Old mice lacking tubular Cpt1a ($Cpt1a^{CKO}$) had increased intracellular fatty acid accumulation (Oil Red O staining) and inflammation (F4/80 staining), but there were no significant differences in oxidative stress, fibrosis or renal function (GFR, proteinuria) compared with aged floxed controls. Similarly, $Cpt1a^{CKO}$ mice had no differences in tubular injury or fibrosis after either AAN or UUO-induced injury. Palmitate-dependent respiration was reduced but not blocked in primary cells from $Cpt1a^{CKO}$ aged mice, and glycolytic capacity was significantly increased. RNAseq from aged $Cpt1a^{CKO}$ revealed significantly upregulated genes in several pathways including PPARα that may compensate for Cpt1a loss.

Conclusions: Surprisingly, tubular deletion of Cpt1a did not worsen aging or response to kidney injury in mice, suggesting that compensatory responses can partially correct the metabolic impairment. A better understanding of these compensatory responses may inform future treatments for kidney injury.

Multi-Omic Analysis of Mouse Renal Tubule Cell Responses Following Unilateral Nephrectomy

Hiroaki Kikuchi, Mark A. Knepper. *National Institutes of Health, Bethesda, MD.*

Background: The kidney increases in size following resection of the contralateral kidney. Modern '-omics' methods provide an opportunity to understand this response at a cellular level.

Methods: Experiments were done in mice after unilateral nephrectomy (UNx) or sham nephrectomy. MRI was used to measure kidney volume. The earliest portion of the kidney proximal tubule (PCT) and the cortical collecting duct (CCD) were microdissected at different time points (24 hours and 72 hours). Microdissected tubules were analyzed by quantitative immunofluorescence microscopy to determine cell size and number, and by RNA-seq to identify gene expression changes. Quantitative protein mass spectrometry was used to identify proteomic changes.

Results: Increased kidney volume was already detectable at the 24 hour-time point after UNx (versus sham), and was increased further at 72 hours. Morphometry of microdissected PCT and CCD, labeled with apical and basolateral markers and DAPI, revealed a marked increase in total cell volume per unit length, but no significant change in mean cell volume in both PCT and CCD, revealing that the increase in total cell volume was due to cellular proliferation rather than hypertrophy of individual cells. Consistent with this observation, RNA-Seq at 72 hours after surgery showed significant increases in the abundance of transcripts associated with cell cycle regulation in both segments (Gene Ontology enrichment analysis) such as Cdk1 and Cdc20 among many others. To identify the earliest signaling events, RNA-seq was employed at 24 hours after UNx revealing that in PCT, UNx produced upregulation of numerous transcripts associated with free fatty acid generation and sterol metabolism including many genes that are known targets of the transcription factor PPARa such as Angptl4, Acot1 and Cyp4a14. Protein mass spectrometry of whole kidneys at 24 hours, composed chiefly of proximal tubule cells, confirmed upregulation of many PPARa-regulated proteins such as HMGCS2, CYP4A14 and ANGPTL4.

Conclusions: Increased kidney size in response to UNx was due to cellular proliferation not hypertrophy of individual cells. Many lipid-metabolism related mRNAs were highly upregulated that predict increased free fatty acid levels in proximal tubule cells. Lipid mediators, including those derived from the fatty acid arachidonic acid, may be involved the cellular proliferation.

PO2493

Calponin 2 Determines AKI to CKD Transition Through Alternating Fatty Acid Oxidation

Yuan Gui, Dong Zhou. *University of Connecticut School of Medicine, Farmington, CT.*

Background: Calponin 2 (CNN2) is an actin filament-associated regulatory protein that plays a central role in numerous fundamental biological processes, including cell proliferation, motility, and adhesion to substrates and others cells. Emerging evidence suggests that cell mechanics can have direct, non-transcriptional influences on cell metabolism. The kidney is a highly metabolically active organ. Fatty acid oxidation is one of the major metabolic processes that occurred in the kidney under pathophysiological conditions. It remains unknown whether CNN2 plays a role in mediating kidney disease progression from the perspective of cell metabolism.

Methods: We constructed ischemic reperfusion injury (IRI) and unilateral ureter obstruction (UUO) animal models in this study. *In vitro* and *in vivo* translational experiments and proteomics were performed.

Results: Our quantitative proteomics revealed that CNN2 was induced at 1d and peaked at 10d after ischemic injury. In AKI or CKD patients' kidney biopsy specimens, CNN2 expression was markedly induced and predominantly localized in the interstitial compartment. *In vivo*, knockdown CNN2 significantly preserved kidney function after ischemic AKI at 1 day. In two classic CKD models induced by 10-d IRI or 7-d UUO, the mice with CNN2 knockdown exhibited reduced expression of fibronectin, α-SMA, and collagen type I, compared to controls. In the meantime, Oil-Red staining showed reduced lipid accumulation in CNN2 knockdown mice kidneys than in controls. Mechanistically, we revealed that knockdown CNN2 could promote fatty acid oxidation to repair injured kidneys and subsequently halt disease progression, as assessed by the increased expression of PPARα, CPT1α, and ACOX1.

Conclusions: Our findings suggested that CNN2 is a crucial determinant in mediating the transition from AKI to CKD through alternating fatty acid oxidation.

Decreased Renal Gluconeogenesis Is a Hallmark of CKD

Thomas Verissimo,[1] Anna Faivre,[1,3] Anna Rinaldi,[2] Maja Lindenmeyer,[4] Carolyn Heckenmeyer,[1] Marylise Fernandez,[1] Pietro E. Cippa,[2] David Legouis,[1,3] Sophie M. De Seigneux.[3,1] *[1]Universite de Geneve Departement de Physiologie Cellulaire et Metabolisme, Geneve, Switzerland; [2]Repubblica e Cantone Ticino Ente Ospedaliero Cantonale, Bellinzona, Switzerland; [3]Hopitaux Universitaires Geneve, Geneve, Switzerland; [4]University Medical Center Hamburg-Eppendorf - III. Medical Department - Germany, Hamburg, Germany.*

Background: Chronic kidney disease (CKD) is associated with alterations of tubular function. Renal gluconeogenesis is responsible for 40% of systemic gluconeogenesis during fasting, but how and why this process is affected by CKD and the repercussions of such regulations are unknown.

Methods: We used data from more than 200 renal biopsies performed in CKD patients and from 43 kidney allograft patients. We studied three complementary mice models of chronic kidney disease *in vivo* and *ex vivo*. We analyzed a cohort of patients having benefitted from renal catheterization and a retrospective cohort of patients hospitalized in the intensive care unit (ICU).

Results: Renal biopsies of CKD and kidney allograft patients revealed a stage-dependent decrease in the renal gluconeogenic pathway. Three different animal models of CKD confirm a proximal tubular cell-specific gluconeogenic down-regulation. This resulted in an alteration of renal glucose production and lactate clearance during an exogenous lactate load. Decreased renal glucose production and lactate clearance were confirmed by the isolated perfused kidney technique in animal models, and by renal venous catheterization in CKD patients. In CKD patients hospitalized in the ICU, systemic alterations of glucose and lactate levels were more prevalent and associated with increased mortality and worse renal prognosis at follow-up. Decreased expression of the gluconeogenesis pathway and its regulators predicted faster histological progression of renal disease in kidney allograft biopsies.

Conclusions: Renal gluconeogenic function is impaired during CKD. Altered renal gluconeogenesis leads to systemic metabolic changes with a decrease in glucose and increase in lactate level, and associates with a worse renal prognosis.

Localization of Metabolites in Tubulointerstitial Disease

Annapurna Pamreddy,[1] Guanshi Zhang,[1,2] Dusan Velickovic,[3] Manjeri A. Venkatachalam,[1] Theodore Alexandrov,[4] Christopher R. Anderton,[3] Kumar Sharma.[1,2] CRPM and KPMP *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX; [3]William R Wiley Environmental Molecular Sciences Laboratory, Richland, WA; [4]European Molecular Biology Laboratory, Heidelberg, Germany.*

Background: Tubulointerstitial (TI) disease plays a critical role in the outcome of patients with chronic kidney disease, however the basic biochemical pathways that generate the TI damage remain unclear. The application of metabolomics in chronic kidney disease (CKD) studies provide researchers the opportunity to gain new insights into metabolic profiling and pathophysiological mechanisms. Mass spectrometry imaging (MSI) is a promising approach that has the potential in reveal spatially-resolved metabolic information within kidney tissue across different disease states.

Methods: In the current study, we employed a high-resolution matrix-assisted laser desorption/ionization (MALDI)-MSI approach to characterize small molecules in human kidney biopsy core samples (n=6) were received from KPMP recruitment sites (CCF, JOS, UTSW, CLU, JHMI, YLE, UPMC, BMC, CIN-HRT and UMI-CBR). The data output was uploaded to METASPACE for molecular annotation, and SCiLS Lab, Metaboanalyst, and Cytoscape were utilized for data processing and statistical analyses.

Results: In total, 600 small metabolites (*m/z* 80-1000) were annotated by METASPACE using the human metabolome database (20% FDR) in human kidney biopsy core sections. MALDI-MSI of human kidney biopsy core sections exhibited different spatial distributions of intermediates in the tricarboxylic acid cycle, glutamate-glutamine cycle, malate-aspartate shuttle, and phospholipid metabolism, simultaneously. Specifically, D-4′-phosphopantothenate (*m/z* 298.0697) was identified as a new glomerular-enriched marker in normal glomeruli but was also present in atrophic tubule. The glycolytic metabolite glucose-6-phosphate (*m/z* 259.0224) was enriched in normal tubules and not over expressed in atrophic tubule.

Conclusions: MALDI MSI is potentially an effective tool for small molecule *in situ* analysis of human kidney tissue. MALDI-MSI technology, coupled with METASPACE, shed new light on omics data integration studies. In summary, from an individual patient with CKD, we found spatial restrictions of metabolites to normal tubule and potentially with atrophic tubule.

Blockade of Transglutaminase 2 Ameliorates CKD Progression

Jong joo Moon,[1] Soie Kwon,[2] Yong Chul Kim,[2] Jae Wook Lee,[4] Dong Ki Kim,[2] Yon Su Kim,[2] Seung Hee Yang.[3] *[1]Seoul National University Biomedical Research Institute, Seoul, Republic of Korea; [2]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [3]Kidney Research Institute, Seoul National University Medical Research Center, Seoul, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, National Cancer Center, Goyang, Gyeonggi-do, Republic of Korea*.

Background: Transglutaminase 2 (TG2) is a calcium dependent enzyme of the protein- glutamine γ-glutamyltransferases family that associated with fibrosis in CKD. The purpose of this study is to identify the relationship between expression of TG2 and the CKD progression in human kidney tissues, and to determine the biological activity of TG2 and TGFβ associated pathways in vitro and in vivo models.

Methods: We conducted immunohistochemistry staining of TG2 on kidney biopsy core derived from who were diagnosed chronic kidney disease. Plasma TG2 concentrations were measured by ELISA. Analyses were performed to reveal the relationship between TG2 and pathologic, functional markers of kidney disease. TG2 mRNA were evaluated at 3, 7, 14 days after from unilateral ureteral obstruction (UUO) mice model establishment with the fibrosis aggravation. To investigate the effect of TG2 inhibition on CKD progression, we used cystamine, well known TG2 inhibitor that induces the oxidation of vicinal cysteine residues of TG2 in primary cultured human tubular epithelial cells (hTECs) that injured with rTGFβ.

Results: Plasma TG2 concentrations showed positive relationships with CKD progression. Samples from progressed CKD patients showed higher plasma TG2 level. The tissue expression of TG2 were increased with CKD progression in human samples. After the establishment of the UUO model, elevation of TG2 mRNA levels were observed over time. TG2 inhibition by cystamine reduced 5.4% of apoptosis in hTECs that injured with rTGFβ (rTGFβ vs. rTGFβ+cystamine; 12.47% vs. 7.033%). Inhibiting TG2 using cystamine were associated with decreased fibronectin and increased E cadherin in rTGFβ inducted hTECs in a dose dependent manners.

Conclusions: The increased expression of TG2 were associated CKD progression in kidney. Suppressing TG2 activity could protect kidney cells from CKD deterioration through its anti-apoptotic and anti-fibrotic effect.

PO2497

Glutathione-Specific Gamma-Glutamylcyclotransferase 1 (Chac-1) Is a CKD Risk Gene

Katie Sullivan,[1] Yuting Guan,[1] Xiangchen Gu,[1] Tomohito Doke,[1] Xin Sheng,[1] Steven S. Pullen,[2] Jay Kuo,[3] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [3]Chinook Therapeutics Inc, Vancouver, BC, Canada*.

Background: Genome-wide association studies (GWAS) have identified more than 300 loci where genetic variants associated with CKD development, however the causal variant, gene, cell type and the disease mechanism remain mostly unknown

Methods: We used expression of quantitative trait loci (eQTL) and computational integration coloc and transcriptome wide association analysis, to identify target genes for GWAS variants. We integrated human kidney single cell RNA and ATAC-seq to fine map likely causal variants. Using CRISPR technology we generated mice with genetic deletion of Chac1. Kidney injury was induced by folic acid injection, and uninephrectomy followed by streptozotocin injection. We have also analyzed primary tubule cells isolated from control (Chac1 +/+) and heterozygous (Chac1 +/-) mice.

Results: Integration of GWAS and human kidney eQTL dataset prioritized Chac1 as potential kidney disease risk gene. Lower CHAC1 level was protective. Single cell and immunofluorescence studies highlighted strong Chac1 expression in kidney tubules. Mice with a heterozygous deletion in C showed no phenotypic differences at baseline, however exhibited less fibrosis both in the folic acid and diabetic injury models compared to wild type animals. In vitro, Chac1 heterozygous cells showed improved survival following cisplatin treatment compared to wild type cells, but no difference in apoptosis or necroptosis. Chac1 +/- cells showed protection from cisplatin induced ferroptosis, including preserved cell viability, less lipid peroxidation and higher expression of ferroptosis inhibitors such as Aifm2 and Gpx4. Gluthathione levels were also higher in kidneys of Chac1 heterozygous mice when compared to controls potentially explaining their ferroptosis resistance.

Conclusions: Via the integration of kidney function GWAS and eQTL, mouse model and cell culture studies we identified Chac1 as a new kidney disease risk gene.

PO2498

Association of Metabolic Syndrome with Hyperfiltration in a General Non-Diabetic Population: The Renal Iohexol Clearance Survey

Erikka W. Bystad, Toralf Melsom. *UiT Norges arktiske universitet, Tromso, Norway*.

Background: Metabolic syndrome (MS) affects approximately one quarter of the world, making it a global epidemic. Although MS has been associated with increased risk of rapid decline in the glomerular filtration rate (GFR), only a few studies have investigated the association of MS with abnormally elevated GFR, known as hyperfiltration. Previous studies of MS and hyperfiltration were limited by the use of estimated GFR and the results were divergent. As there are promising treatment options for hyperfiltration, establishing the relationship between MS and hyperfiltration is of clinical importance.

Methods: In the Renal Iohexol Clearence Survey (RENIS) we included 1551 subjects from the population based Tromsø survey (2007-2009). The participants were 50-62 years old without known diabetes, cardiovascular disease or kidney disease. The GFR was measured using iohexol clearance. The aim was to investigate the relationship between MS and RHF. The dichotomous variable for RHF was defined as an absolute mGFR (ml/min) above the 90th percentile after adjusting for gender, age and height.

Results: Metabolic syndrome was associated with increased absolute GFR (ml/min) and renal hyperfiltration (yes/no) independent of age, sex and height (OR 2.44 95% CI; 1.71 – 3.46, p<0.001). All risk factors except for hypertension were independently associated with RHF and increased absolute GFR. The risk of renal hyperfiltration was highest in subjects fulfilling 5 out of 5 criteria (OR 4.06, 95% CI; 1.54-10.67, p=0.005) compared to those fulfilling 0 or 1 criteria. Conversely, MS was not associated with higher estimated GFR based on creatinine or cystatin C.

Conclusions: Subjects with MS have a higher absolute GFR and increased risk of renal hyperfiltration compared to subjects without MS. RCTs are needed to explore whether treatment of hyperfiltration can prevent accelerated GFR decline and CKD in persons with MS.

PO2499

Hydrogen Sulfide Ameliorates High Fat Diet-Induced Hypertension and Kidney Injury in Mice

Hak Joo Lee,[1] Goutam Ghosh-Choudhury,[1,2] Kumar Sharma,[1,2] Balakuntalam S. Kasinath.[1,2] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX*.

Background: The role of hyperinsulinemia caused by high fat diet (HFD) in kidney injury is not known. Employing kidney proximal tubule specific insulin receptor (IR) KO mice, we have shown recently that HFD-induced kidney injury requires hyperinsulinemia-induced IR activation (Lee et al., JCI insight, 2021, 6(3): e143619). Furthermore, HFD reduced kidney hydrogen sulfide (H_2S) generation in an IR-dependent manner. We tested if H_2S administration ameliorates HFD-induced kidney injury in mice and cell models.

Methods: 5 month-old C57BL6 male mice were placed on normal fat diet (NFD) or HFD for 2 months followed by randomization to receive for 2 months, H_2S as sodium hydrosulfide (NaHS) 30 μmoles/L in drinking water or. water alone (n=5-6 in each group).

Results: HFD or NaHS did not affect blood glucose level. HFD increased body weight, and induced systolic hypertension (NFD: 118 ± 8 vs. HFD: 144 ± 10 mmHg), albuminuria (25.5 ±16 vs. 139.7 ±48 μg/mg), and kidney accumulation of matrix proteins. NaHS reversed these HFD-induced changes (systolic hypertension: 112 ± 7 mmHg, urinary ACR: 76.1 ± 29 μg/mg) without affecting body weight. In the renal cortex, HFD reduced level of H_2S, which was restored by NaHS administration. HFD stimulated IR phosphorylation and inhibited AMPK activity, which promotes synthesis of proteins including matrix proteins. NaHS did not affect IR phosphorylation but increased AMPK activity. We employed proximal tubule cells to test the effect of H_2S on insulin-induced matrix synthesis. Insulin increased fibronectin synthesis likely through stimulation of its mRNA translation by inhibiting AMPK and activating mTORC1. This effect of insulin was abolished by NaHS.

Conclusions: Taking in vivo and in vitro data together, we conclude: (1) HFD induces kidney IR activation and reduces H_2S generation in association with kidney injury. (2) H_2S acts as a signling molecule to activate AMPK, downstream of IR, and inhibits mTORC1 to ameliorate HFD-induced kidney injury. (3) H_2S could be a therapeutic agent for obesity-related kidney injury.

PO2500

Proximal Tubule Cyclophilin D Mediates Kidney Fibrogenesis in Obstructive Nephropathy

Hee-Seong Jang, Mira Noh, Babu J. Padanilam. *Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Proximal tubule (PT) is highly vulnerable to acute injury, including ischemic insult and nephrotoxins, and chronic kidney injury. It is established that PT injury is a primary cause of development of chronic kidney disease, but the underlying molecular mechanism remains to be defined.

Methods: Here, we tested whether PT cyclophilin D (CypD), a mitochondrial matrix protein, is a critical factor to cause kidney fibrosis progression. To define the role of CypD in kidney fibrosis, we used an established mouse model for kidney fibrosis, unilateral ureteral obstruction (UUO) model in global and PT-specific CypD knockout (KO).

Results: Global CypD KO blunted kidney fibrosis progression with inhibition of myofibroblast activation and fibrosis. UUO-induced tubular atrophy was suppressed in kidneys of global CypD KO, but not tubular dilation or apoptotic cell death. PT cell cycle arrest was highly increased in WT-UUO kidneys, but markedly attenuated in global CypD KO-UUO kidneys. The number of macrophages and neutrophils was less in UUO kidneys of global CypD KO than those of WT. The pro-inflammatory and -fibrotic factors were all inhibited in global CypD KO. In line with those of global CypD KO, PT-specific CypD KO also blunted kidney fibrosis progression, along with less tubular atrophy, renal parenchymal loss, cell cycle arrest in PT and inflammation, indicating a critical role for PT CypD in fibrogenesis.

Conclusions: Collectively, our data demonstrate that CypD in PT is a critical factor contributing to kidney fibrosis in UUO, providing a new paradigm for mitochondria-targeted therapeutics of fibrotic diseases.

PO2501

Reduction of Hnf4α Expression in CKD Accelerates Disease Progression

Marta Martinez-Calle, Guillaume Courbon, Xueyan Wang, Bridget Hunt-Tobey, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Renal mitochondrial dysfunction is a common feature of Chronic Kidney Disease (CKD) and is associated with cardiovascular disease. HNF4α is highly expressed in proximal tubules and controls the expression of genes involved in various metabolic pathways. Mutations in *Hnf4α* are associated with mitochondrial defects. We tested the hypotheses that renal *Hnf4α* decline in CKD contributes to mitochondrial dysfunction, CKD progression and onset of cardiovascular outcomes and that *Hnf4α* reduction in CKD is result of hyperphosphatemia.

Methods: We confirmed *Hnf4α* expression was reduced in the kidneys Col4a3^{KO} mice, model of progressive CKD. Next, we performed RNA sequencing (RNAseq) on kidneys collected from WT and Col4a3^{KO} mice to identify genes and molecular pathways altered by HNF4α reduction in CKD. We treated mice with a continuous administration of HNF4α antagonist (BI-6015, 3µg/g/day) for 8 weeks to study the effects of HNF4α suppression on renal and cardiac functions. To further evaluate the role of HNF4α reduction in CKD progression, we injected 30µg/g BI-6015 to Col4a3^{KO} mice for 5 days. We also generated WT and Col4a3^{KO} mice with a *Hnf4α* deletion in kidney proximal tubules (Hnf4α^{Pax8cKO} and Col4a3^{KO}/Hnf4α^{Pax8cKO}). Finally, to demonstrate that hyperphosphatemia reduces *Hnf4a* expression in the kidney, we fed WT mice a control and a high phosphate diet (HPi) for 6 weeks.

Results: RNAseq of Col4a3^{KO} mice kidneys showed impaired molecular pathways regulated by HNF4α, including increased mitochondrial dysfunction and reduced oxidative phosphorylation. Inhibition of HNF4α in WT mice led to kidney interstitial fibrosis and left ventricular hypertrophy, while in Col4a3^{KO} mice a shorter administration of HNF4α antagonist accelerated the decline in kidney function (+450% serum creatinine vs. Col4a3^{KO}-Ctr mice), demonstrating the crucial role of HNF4α in CKD progression. Similarly, *Hnf4α* deletion in proximal tubules impaired kidney function in WT mice and further worsened it in CKD animals. WT mice fed a HPi diet showed a 70% reduction in renal *Hnf4α* expression, suggesting that hyperphosphatemia contributes to renal HNF4α suppression.

Conclusions: Our results suggest that HNF4α is a master regulator of kidney mitochondrial function and might represent a novel therapeutic target to improve renal and cardiovascular outcomes in CKD.

PO2502

Wasp Homologue Associated with Membranes and Microtubules Is a Kidney Disease Risk Gene

Dhanunjay Mukhi, Tomohito Doke, Shizheng Huang, Katalin Susztak. Institutes of Diabetes Obesity & Metabolism *University of Pennsylvania, Philadelphia, PA.*

Background: Genome-wide association studies identified hundreds of risk variants that are associated with kidney function traits. More than 90% of these variants are located in non-coding region of the genome and therefore their target genes, target cell type and encoded molecular pathways remain not known.

Methods: Here we used human kidney expression and methylation of quantitative trait (eQTL and mQTL) information and complex computational integration to identify target cell types for genetic variants. We obtained mice with genetic loss of *WHAMM*. We induced acute kidney injury by cisplatin injection and chronic disease by folic acid injection. Kidney function was analyzed by serum creatinine and blood urea nitrogen, real time PCR, western blotting, and histology analyses. We cultured primary kidney tubule epithelial cells, in addition, autophagy was assessed by *ptf-LC3B GFP-RFP* plasmid and mitophagy was assessed by using *mitoCox- VIII GFP-RFP* plasmid.

Results: Using Bayesian colocalization, summary mendelian randomization, and transcriptome-wide association studies we prioritized *WHAMM* as a kidney disease risk gene. Risk variant rs12903411 was associated with higher WHAMM expression. WHAMM is an Arp2/3 complex activator protein that is associated with membrane dynamics by utilizing microtubules. WHAMM heterozygous and knock-out mice subjected to cisplatin and folic acid injury presented with improved kidney function (BUN, creatinine) and lower expression of injury markers (Kim1, N-gal) and fibrosis markers. Primary tubular cells with *WHAMM* loss showed increased autophagy flux compared to wild type. Furthermore, WHAMM heterozygous and knock-out mice and cells showed improved mitophagy and reduced expression of inflammatory markers such as *IL-1β, IL-18* and *Nlrp3*. Mice with genetic deletion of *WHAMM* showed lower pyroptosis indicated by cleaved caspase1 and gasdermin D levels compared to WT mice in the folic acid model.

Conclusions: In summary, this study identified *WHAMM* as a new kidney disease risk gene.

Autophagy Gene ATG7 Regulates Albumin Transcytosis in Renal Tubule Epithelial Cells

Yushi Uchida,[1] Kumiko Torisu,[1] Kenji Ueki,[1] Kazuhiko Tsuruya,[2] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Nephrology, Nara Medical University, Kashihara, Japan.*

Background: Receptor-mediated albumin transport in renal proximal tubule epithelial cells (PTECs) is important to control proteinuria. Autophagy is an evolutionarily conserved degradation pathway and its role in intracellular trafficking through interaction with the endocytic pathway has recently been highlighted. In this study, we determined whether autophagy regulates albumin transcytosis in PTECs and suppresses albumin-induced cytotoxicity.

Methods: Human tubular epithelial cell line (HK-2) was used for all experiments. The cells were exposed to 10 mg/mL BSA for 6 h or 24 h as required. For autophagy related 7 (*ATG7*) knockdown (KD), cells were transfected with *ATG7* siRNA. The intracellular trafficking of FcRn was examined by biotin-labeled recycling assay. Immunofluorescence of FcRn and Rab7 or Rab11 was observed by confocal microscopy. The transcytosis of albumin in HK-2 was evaluated using FITC-BSA-based transcytosis assay. The release of IL-8 and KIM-1 caused by excess albumin were measured by ELISA, and mitochondrial damage was measured by MitotrackerCMXRos.

Results: FcRn partially co-localized with autophagosomes. FcRn was accumulated and recycling of FcRn was attenuated in *ATG7* KD cells. Colocalizations of FcRn with RAB7-positive late endosome or RAB11-positive recycling endosomes were reduced in *ATG7* KD cells. In *ATG7* KD cells, albumin transcytosis was significantly reduced, and albumin accumulated in the cells. Exposure to excess albumin reduced autophagic flux in HK-2. Consequently, excess albumin-induced mitochondrial damage is enhanced in *Atg7* KD cells. The release of IL-8 and KIM-1 from *ATG7* KD cells was increased in response to excess albumin.

Conclusions: In PTECs exposed to excess albumin, autophagy is decreased and intracellular transport of FcRn is impaired, resulting in decreased albumin transcytosis. The resulting accumulation of albumin induces cytotoxicity in tubules. Preventing dysfunctional autophagy in PTECs might be beneficial in the clinical management of nephropathies with proteinuria.

Leveraging High-Content Imaging Platforms for Drug Discovery

Xiang Pan, Timothy A. Norman, Alyssa Fanelli, Justin A. Gallagher, Sergii Kyrychenko, Rachel Gallagher, Thomas A. Gustafson, Maria Lalioti. *Goldfinch Bio Inc, Cambridge, MA.*

Background: Disruption of the structure and function of the glomerular filtration barrier leading to proteinuria is a hallmark of several podocytopathies. Efficacy in translatable *in vitro* models is a critical first step to develop new therapies. For example, free fatty acids such as palmitic acid and protamine sulfate are well characterized in-vitro models to model DN and FSGS. However, these models are low throughput, making them unsuitable for target and compound screening.

Methods: We used immortalized murine podocytes and adapted the readouts of *in vitro* assays to a high content imaging /screening (HCS) platform. Readouts in response to Palmitic Acid (PA) included: apoptosis and cell viability by annexinV and propidium iodide staining or MTT; mitochondrial membrane potential by JC-1 and Mitotracker Deep Red; and mitochondrial and cytosolic reactive oxygen species by MitoSOX and DCF. Actin cytoskeleton dynamics were assessed by quantification of actin aggregation (Phalloidin) and synaptopodin reduction in response to Protamine Sulfate (PS). Fluorescent staining followed by high content imaging and custom image analysis were performed on the BioTek-Cytation 5 cell imaging reader.

Results: Podocyte apoptosis and cell death was comparable to the readout by FACS, but capacity was increased by at least 4x. We observed a dose-dependent, incremental change in mitochondrial ROS and membrane depolarization. Mitotracker Deep Red was less sensitive than other assays for PA injury. PS treatment resulted in loss of Synaptopodin and increase of Phalloidin aggregation, and is usually assessed by confocal microscopy, which is difficult to quantify. We developed an automated imaging pipeline to quantify 9 fields per well of a 96-well plate. We showed that there was a dose- and time-dependent actin aggregation that was partially rescued by cyclosporin A, a known positive control.

Conclusions: We established a reliable and semi-automated high-content imaging platform, which will facilitate a better mechanistic understanding of podocyte injury, as well as drug discovery, including target validation and compound screening in podocytes.

The eNOS–NO Pathway Attenuates the Progression of Age-Related Kidney Diseases via Suppression of C/EBPβ-Associated Inflammaging

Reina Umeno, Hajime Nagasu, Yoshihisa Wada, Hiroyuki Kadoya, Kengo Kidokoro, Naoki Kashihara. *Kawasaki Medical School Department of Nephrology and Hypertension, Kurashiki, Japan.*

Background: Chronic kidney disease (CKD) is a very common clinical problem in elderly patients and is associated with increased mortality. As life expectancy continues to improve worldwide, the prevalence of comorbidities and risk factors, such as hypertension and diabetes, that predispose this population to a high burden of CKD is rising. Chronic inflammation (inflammaging) is also an important cause of age-related organ damage, such as kidney disease, and we hypothesized that endothelial dysfunction accelerates the progression of age-related kidney injury.

Methods: We evaluated the anti-inflammatory effects of nitric oxide (NO) as an endothelial function in bone marrow–derived macrophages (BMDM) using in vitro experiments. BMDM derived from Wild Type (C57BL/6J; WT) were stimulated through NLRP3 inflammasome activation using LPS-ATP, and the IL-1β secretion was examined. To determine the importance of inflammasome activation in age-related kidney diseases, we used mice deficient in apoptosis-associated speck-like protein containing CARD (ASC) —which is an essential molecule for inflammasome activation—in vivo. We evaluated those mice (ASCKO), eNOS knockout (eNOSKO) mice, and eNOS-ASC double-knockout mice (eNOS-ASC-DKO).

Results: S-nitrosoglutathione (GSNO) attenuated the NLRP3 inflammasome activation that followed treatment with LPS-ATP. This indicates that NO directly inhibits NLRP3 inflammasome activation. GSNO also decreased the expression of inflammasome-related genes. To investigate the detailed mechanisms (epigenetic regulation), we performed ATAC-seq using BMDM. The binding region of the transcription factor CCAAT/enhancer-binding protein (C/EBP) β was significantly closed in the LPS+GSNO, compared with the LPS; it has recently been reported that C/EBP is associated with the NLRP3 inflammasome and is activated in aging kidneys. These mice were sacrificed at 15 months of age; the glomerular injury was found to be exacerbated, and serum Crn was elevated in the eNOSKO-15M, but not in the WT-15M. These changes were improved in the eNOS-ASC-DKO-15M.

Conclusions: The eNOS–NO pathway ameliorated the progression of renal injury by regulating the inflammaging of the aging kidney. NO directly inhibits NLRP3 inflammasome activation via the suppression of C/EBP β activation.

PO2506

Symmetric Dimethylarginine Inhibits Renal Fibrosis in Obstructive Kidneys

Yanzhe Wang, Ming Wu, Chaoyang Ye. *Shuguang Hospital, Shanghai, China.*

Background: Symmetric dimethylarginine (SDMA) is regarded as an independent cardiovascular risk factor in patients with chronic kidney diseases. Renal interstitial fibrosis is a common pathway of all kinds of chronic kidney diseases progressing to the end stage of renal diseases. In this study we investigated the role of SDMA in renal fibrosis and its underlining mechanisms.

Methods: Normal saline (NS) and SDMA (2.50 μmol/kg) were administered into the kidney through the left ureter in a mouse model of unilateral ureteral obstruction (UUO). UUO kidneys were harvested at day 7. Western blotting and Masson's trichrome staining were performed to evaluate renal fibrosis. Moreover, human kidney 2 (HK2) cells were treated with various concentrations of SDMA (0.01 μM to 10 μM) in the presence of 2.5 ng/ml TGF-β. Protein samples were collected from cells to measure the expression of fibrotic markers.

Results: We observed that intrarenal administration of SDMA attenuated renal fibrosis as shown by Masson staining and Western blotting analysis of the expression of fibronectin, collagen-I and α smooth muscle actin (αSMA). In parallel, SDMA dose-dependently reduced the expression of pro-fibrotic proteins in TGF-β stimulated HK2 cells. Phosphorylation of Smad3 protein was analyzed in vivo and in vitro, which showed that SDMA inhibited phosphorylation of Smad3 in UUO kidneys and TGF-β stimulated HK2 cells.

Conclusions: Thus, our data suggest that renal SDMA exerts direct anti-fibrotic effects in fibrotic kidneys probably through inhibition of Smad3 signaling pathway.

PO2507

Targeting ARG1+ Macrophages Slows the Progression of AKI to CKD

Rui Zeng. *Huazhong University of Science and Technology Tongji Medical College, Wuhan, China.*

Background: Recently, $ARG1^+$ myeloid cells were defined as a new subgroup that express a large number of pro-inflammatory and pro-fibrotic genes. However, its function and clinical application in kidney disease has not yet been identified.

Methods: We clarified the source of $ARG1^+$ macrophages via the bone marrow transplantation and the parabiosis, and constructed macrophage-specific ARG1 knockout mice ($ARG1^{fl/fl}$; $CX3CR1^{creERT2}$) and $CX3CR1^{CreERT2}$-DTR mice. Kidney samples were analyzed through 10X single-cell sequencing technology. The arginase inhibitor nor-NOHA and RNAi lentiviral vector of ARG1 were applied to ischemia-induced kidney injury.

Results: Most of the intra-renal $ARG1^+$ macrophages were from bone marrow. Knocking down ARG1 in macrophages alleviated ischemia-induced AKI and the subsequent chronic fibrosis, and reduced the infiltration of macrophages in the kidney, while depletion of $CX3CR1^+$ cells aggravated ischemia-induced renal injury. GSEA analysis found that the function of $ARG1^+$ macrophages significantly enriched in the regulation of the release of inflammatory factors, activation of immune inflammatory response, and secretion of extracellular matrix. More biological macrophage ligand–mesenchymal receptor pairs expressed in $ARG1^+$ macrophages between mesenchymal cells, compared to $ARG1^-$ macrophages. Inhibiting ARG1 activity alleviated the proliferation of $ARG1^+$ macrophages and reduced ischemia-induced renal fibrosis. The application of RNAi lentiviral vector of ARG1 via the tail vein injection alleviated the renal fibrosis, reduced ARG1 expression and macrophage infiltration.

Conclusions: $ARG1^+$ macrophages accelerated the development of AKI to CKD by promoting inflammation response, activating fibroblasts and secreting extracellular matrix proteins. Inhibiting the activity or expression of ARG1 in macrophages alleviate IR-induced renal fibrosis.

PO2508

UBE-1099, a Novel Non-Covalent Keap1-Nrf2 Inhibitor, Protects Against Renal Ischemia-Reperfusion Injury via Nrf2 Activation

Sayaka Ogi, Hidetoshi Sunamoto, Hirohiko Fukiya, Futoshi Nara, Kazuhiro Onuma. *Pharmaceuticals Research Laboratory, UBE industries, LTD., Ube, Japan.*

Background: Patients with chronic kidney disease (CKD) showed a decline in renal function, as represented by glomerular filtration rate (GFR), as the disease progresses. A covalent Kelch-like ECH-associated protein 1 (Keap1) - Nuclear factor erythroid 2-related factor (Nrf2) inhibitor, bardoxolone methyl, has been reported to increase the estimated GFR in patients with advanced CKD. However, it is unclear how the Nrf2 activator improved GFR. Previous studies have shown that bardoxolone imidazole suppresses tubular damage in a mouse model of unilateral ischemic reperfusion without contralateral nephrectomy (U-IR). In this study, we evaluated in detail the effect of a novel non-covalent Keap1-Nrf2 inhibitor UBE-1099 on U-IR model.

Methods: A fluorescence polarization-based (FP) assay and NAD(P)H:quinone oxidoreductase 1 (NQO1) enzyme activity-inducting assay on murine Hepa1c1c7 hepatoma cell were used to investigate a non-covalent Keap1-Nrf2 inhibitor. U-IR model was established using 10 week old male C57BL/6 mice. These mice were orally administered either the inhibitor (30 mg/kg, 10 mL/kg, once a day) or vehicle for 14 days. Renal damage was then evaluated by histopathological analysis and measurement of GFR using a percutaneous GFR measurement system (MediBeacon, St. Louis, Missouri). Protein and mRNA expression in the whole kidney were assessed by Western blot analysis and real-time PCR, respectively.

Results: UBE-1099 directly inhibited Keap1-Nrf2 interaction as assessed by the FP assay, and induced NQO1 enzyme activity at Hepa1c1c7. UBE-1099 showed *Nqo1* mRNA induction activity as well as bardoxolone imidazole in the kidney of a normal mice by single oral administration. Oral administration of UBE-1099 to U-IR model mice increased NQO1 protein and mRNA expression in the kidney and improved the atrophic pathology, including renal tubular damage. More surprisingly, UBE-1099 also showed an increasing trend in GFR in that model.

Conclusions: A novel non-covalent Keap1-Nrf2 inhibitor UBE-1099 improved the atrophic pathology and reduced tubular damage resulting from Nrf2 activation in U-IR model mice. UBE-1099 has been suggested to be a promising drug for renal diseases associated with oxidative stress.

PO2509

Peroxiredoxin 5 Regulates Cyst Growth and Ciliogenesis via Modulating Aurora A and Plk1 Stability and Wnt Signaling Activation

Ewud Agborbesong,[1,2] Xia Zhou,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: Peroxiredoxin 5 (Prdx5) is an antioxidant enzyme that catalyzes the reduction of H_2O_2 and alkyl hydroperoxide and plays a protective role in neurological and cardiovascular disorders. However, the role and mechanism of Prdx5 in autosomal dominant polycystic kidney disease (ADPKD) is unknown.

Methods: To investigate the role and mechanism of Prdx5 on cyst growth and cilia biogenesis in ADPKD, we knocked down Prdx5 in mIMCD3 and RPE cells with siRNA and shRNA, and performed Western blot, qRT-PCR and immunostaining analysis in renal epithelial cells and tissues. A 3-dimensional cell culture system was used to evaluate the effect of Prdx5 knockdown on cyst growth.

Results: We found that Prdx5 was downregulated in cystic renal epithelial cells and tissues. Knockdown of Prdx5 resulted in: 1) abnormal centrosome amplification and multipolar spindle formation in mIMCD3 cells; 2) the upregulation of Polo-like kinase 1 (Plk1) and Aurora kinase A (AurA), essential in cell division and checkpoint regulation of mitosis; 3) the formation of cysts in a three-dimensional matrigel culture system using IMCD3 cells, which correlated with the phosphorylation and activation of PKD associated proliferation signaling, including ERK and mTOR; and 4) impaired primary cilia formation in mIMCD3 and RPE cells, which could be rescued by inhibition of Plk1 activity. In addition, we show that Prdx5 plays a crucial role in the regulation of Wnt signaling pathway activity in renal epithelial cells. Stimulation of Wnt3a ligand had no effect on ciliogenesis in Prdx5 knockdown cells. In contrast, stimulation of Wnt5a exacerbated ciliogenesis defect in Prdx5 knockdown cells. Consistent with Wnt5a activity on regulating primary cilia biogenesis, knockdown of Prdx5 decreased the recruitment of centriolar satellites PCM1 and CEP290, to the centrosome/basal body.

Conclusions: This is the first study to show that Prdx5 regulates cyst formation and cilia biogenesis via affecting the stability of Plk1 and AurA, and the activation of PKD associated signaling pathways. Prdx5 could also control noncanonical Wnt5a-dependent regulation of ciliogenesis, a cascade of events that regulate the recruitment of centriolar satellites necessary for, primary cilia biogenesis.

Comparison of the Renal Effects of Heme-Dependent and Independent Soluble Guanylate Cyclase Targeting Drugs in 5/6 Nephrectomized Rats on High-Salt Diet

Yingquan Xiong,[1,2] Shufei Zeng,[2,1] Ahmed A. Hasan,[3,1] Denis Delic,[4,1] Mohamed M. Gaballa,[1] Mira Pavkovic,[5] Peter Sandner,[5] Bernhard K. Krämer,[1] Berthold Hocher.[1,6] *[1]Fifth Department of Medicine (Nephrology/ Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Heidelberg, Germany; [2]Department of Nephrology, Charité - Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany; [3]Institute of Nutritional Science, University of Potsdam, Potsdam, Germany; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [5]Bayer AG, Pharmaceuticals R&D, Pharma Research Center, Wuppertal, Germany; [6]Reproductive and Genetic Hospital of CITIC-Xiangya, Changsha, China.*

Background: Soluble guanylate cyclase (sGC) targeting drugs were reported to have beneficial renal effects in chronic kidney disease (CKD). The sGC stimulators bind to reduced, heme-containing sGC, while sGC activators bind to oxidized, heme-free sGC and their actions are heme-independent. Regarding renal outcomes, the potential differences between these two classes of drugs are unknown so far. This study aimed to provide a head-to-head comparison of the renal effects of BAY 41-8543 (sGC stimulator) and BAY 60-2770 (sGC activator) in 5/6 nephrectomized rats on high salt diet as a model of CKD.

Methods: Rats were allocated to the following groups: Sham + normal diet + placebo (PBO); 5/6Nx + 2 % high salt diet (HSD) + PBO; 5/6Nx + HSD + Telmisartan (5mg/kg/day); 5/6Nx + HSD + BAY 60-2770 (1mg/kg/day); 5/6Nx + HSD + BAY 41-8543 (1mg/kg/day). The treatment period was 8 weeks.

Results: Blood pressure was significantly decreased by BAY 60-2770 and BAY 41-8543 versus placebo (-32.52/-27.20 mmHg, $p<0.001$; -23.83/-29.90 mmHg, $p<0.001$, respectively), which was also comparable to the effects of telmisartan (-24.24/-31.90 mmHg, $p<0.001$). Plasma creatinine was not altered by any of the 3 drugs, however, renal fibrosis was significantly decreased by Bay 60-2770 (44.76%, $p<0.05$) and telmisartan (43.96%, $p<0.05$) versus placebo. On the other hand, BAY 41-8543 did not ameliorate renal fibrosis. RNA-sequencing in renal tissues revealed that 144 genes were differentially regulated among the groups. Interestingly, 23 genes including collagen type VI alpha 5 (*Col6a5*), phospholipase C Eta 1 (*Plch1*) and claudin 19 (*Cldn19*) were exclusively differentially regulated by BAY 60-2770 and these genes might explain anti-fibrotic renal effects.

Conclusions: Only the sGC activator BAY60-2770 ameliorated renal fibrosis comparable to the gold-standard treatment of CKD with an ARB (telmisartan). These effects were blood pressure independent since blood pressure was similar in all treatment groups. Inactivation of the sGC by oxidative stress in our CKD model may explain the failure of the sGC stimulator in reducing kidney fibrosis. The mechanisms underlying the renal anti-fibrotic effects of BAY60-2770 might involve the differential regulation of *Col6a5*, *Plch1* and *Cldn19*.

PO2511

In-Depth Proteomic Analysis to Identify the Cellular Proteins and Secretome of Human Tubular Epithelial Cells with Fibrotic Injury

Ji Eun Kim,[1] Yong Chul Kim,[2] Kyung Don Yoo,[3] Jae Wook Lee,[4] Dong Ki Kim,[2] Yon Su Kim,[2] Seung Hee Yang.[2] *[1]Korea University Guro Hospital, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Ulsan University Hospital, Ulsan, Republic of Korea; [4]National Cancer Center, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Fibrosis is the major pathophysiology in the development of chronic kidney disease. While there are several proteomic studies to reveal the mechanism of renal fibrosis, the in-depth analysis which elucidate the repertoire of proteins expressed on cell or released into extracellular space are lacking.

Methods: To induce the fibrosis on kidney cells in stages, two different dose (1ng/ml and 2ng/ml) of TGFbeta were treated on primary cultured human renal proximal tubular epithelial cells (TECs). For global proteome and secretome profiling, liquid chromatography-tandem mass spectrometry based quantitative proteomic analysis were performed on isolated TECs and their media, respectively.

Results: When comparing the cellular proteins expressed in control and in cells with fibrotic damage, we identified 691 and 1344 differentially expressed proteins (DEP) in low and high dose treated cells, respectively. And the DEPs in secretomes from low and high dose treated cells were 168 and 283, respectively. Then we identified overlapping 74 DEPs which showed significant difference in both cell and secretome analysis. Eleven proteins including NAMPT and KRT18 were decreased in same manner in both cell and secretome analysis, suggesting overall decrease in expression of these proteins with fibrosis. Seventeen proteins including STRAP and EIF3B were significantly decreased in cells while increased in secretome, representing the possible extracellular release of proteins with the response to fibrosis injury. There were 25 proteins including SERPINE1 and CTGF significantly elevated in both cell and secretome identified. And the other proteins which increased in cells and decreased in secretome were identified as 15 including PIEZO1 and ABCD4, which are presumably translocated into the cells with damage.

Conclusions: We identified different protein expression changes in cells and secretomes following fibrotic injury. Further studies are needed to validate the pathophysiological role of these proteins on kidney tubulointerstitial fibrosis.

PO2512

Hyaluronan Synthase-2 Antisense (HAS2-AS1) Is a Novel Long Non-Coding RNA That Regulates Pro-Fibrotic Cell Responses in the Kidney

Irina Grigorieva, Emma L. Woods, Usman Khalid, Timothy Bowen, Robert Steadman, Soma Meran. *Cardiff University, Cardiff, United Kingdom.*

Background: Renal interstitial fibrosis drives CKD and increased synthesis of hyaluronan (HA) in the tubulointerstitium correlates with fibrosis and renal outcomes. Our work shows that of the three HA synthase enzymes, HAS2 expression is causally linked with fibrosis *in vivo*, a pro-fibrotic cell phenotype *in vitro*, and is regulated by a long non-coding RNA, *HAS2-AS1*. Here we investigated the mechanisms that regulate *HAS2-AS1* expression and function and influence HA-dependent regulation of pro-fibrotic cell phenotype.

Methods: Primary human fibroblasts were used to test effects of siRNA-mediated *HAS2-AS1* knockdown on TGFβ1-driven myofibroblast differentiation and HA levels by ELISA, RT-qPCR and immunofluorescence. ChIP-Seq determined binding of HYAL2 to *HAS2-AS1* and *HAS2* promoters. Alterations in *HAS2-AS1* expression were assessed from acute to chronic kidney injury and in fibrosis prevention using kidneys from a rat-model of bilateral ischaemia-reperfusion-injury (IRI) or from rats that underwent ischaemic-preconditioning prior to IRI (prevention model).

Results: In fibroblasts, TGFβ1 increased *HAS2-AS1* expression concomitantly with *HAS2*. *HAS2-AS1* knockdown resulted in significant attenuation of *HAS2* expression demonstrating that *HAS2-AS1* is a positive regulator of HAS2. *HAS2-AS1* knockdown led to a decrease in soluble and cell-surface HA, attenuated TGFβ1-driven expression of pro-fibrotic markers, and modified expression of the principal HA receptor, CD44 and its variant isoforms suggesting a link between *HAS2-AS1* and CD44 alternative splicing relevant to progression of renal disease. In turn, we showed that HYAL2 (a novel regulator of DNA/RNA processing) regulates *HAS2-AS1* expression. Anti-HYAL2 ChIP-Seq analysis identified enrichment of *HAS2-AS1*, but not *HAS2* promoter sequence, and HYAL2 knockdown resulted in attenuation of TGFβ1-driven *HAS2-AS1* and decrease in myofibroblast marker expression. Kidneys with progressive fibrosis had significantly increased *HAS2-AS1* expression versus kidneys that were protected from fibrosis through IPC, suggesting an *in vivo* role for *HAS2-AS1* in modulation of pro-fibrotic renal responses.

Conclusions: *HAS2-AS1* is a novel lncRNA causally-linked with pro-fibrotic responses both *in vitro* and *in vivo* and a new potential therapeutic target for intervention in fibrosis.

PO2513

Renoprotective Effects of Soluble Guanylate Cyclase (sGC) Activation vs. ACE Inhibition in a CKD Model with Volume/Salt-Dependent Hypertension

Karen A. Griffin,[1,2] Perianna Sethupathi,[2] Shehla Sheikh,[1,2] Geoffrey A. Williamson,[4] Jan R. Kraehling,[3] Agnes M. Benardeau,[3] Frank Eitner,[3] Anil K. Bidani.[1,2] *[1]Edward Hines Junior VA Hospital, Hines, IL; [2]Loyola University Health System, Maywood, IL; [3]Bayer AG, Leverkusen, Germany; [4]Illinois Institute of Technology, Chicago, IL.*

Background: BP control using renin-angiotensin system (RAS) blockade is the current standard of care for CKD. However, outcomes remain suboptimal in part because adequate BP reductions are difficult to achieve in the volume expanded CKD states with RAS blockade even with additional antihypertensives. Given that endothelial dysfunction and/or NO loss accelerate the progression of both diabetic and non-diabetic CKD, sGC activators represent potential novel therapeutic interventions in CKD.

Methods: Two weeks after 3/4 nephrectomy and instrumentation for chronic BP radiotelemetry, male Sprague-Dawley rats were switched to a 4% NaCl diet after proteinuria measurements. After 2 weeks on the 4% NaCl diet and repeat proteinuria measurements, the rats started receiving vehicle only (5 ml/kg), the ACE inhibitor, enalapril (50 mg/kg), the sGC activator (BR-11257) (10 mg/kg), or the combination of BR11257 + enalapril by daily gavage. After 6 weeks of therapy and final proteinuria measurements, the rats were sacrificed for a blinded histologic assessment of % glomerulosclerosis (GS).

Results: In this CKD model with volume (salt) dependent hypertension (HTN), BR-11257 alone or in combination with enalapril but not enalapril alone, significantly lowered BP, ameliorated proteinuria and reduced the development of GS (Table). Linear regression analysis showed a strong correlation between individual systolic BP (SBP) and % GS ($r=0.69$, $n=63$, $p < 0.0001$), without a significant difference in the slope of the relationship (0.3 ± 0.04) between treatment groups.

Conclusions: These data strongly support the therapeutic potential of sGC activators alone or in combination with RAS blockade in hypertensive and proteinuric CKD states.

Oxysterol-Binding Protein Like 7 in CKD

Jeffrey D. Pressly, Javier T. Varona Santos, Mengyuan Ge, Sandra M. Merscher, Alessia Fornoni. *University of Miami School of Medicine, Miami, FL.*

Background: ATP-binding cassette transporter A1 (ABCA1)-mediated, cholesterol ester-induced podocyte injury plays a major role in the progression of glomerular disease and pharmacological inducers of ABCA1 (ABCA1i) are sufficient to partially rescue glomerular injury in proteinuric mice. Interestingly, these ABCA1i's compete specifically with oxysterol binding to oxysterol-binding protein (OSBP) like 7 (OSBPL7), a member of a group of lipid-binding proteins involved in lipid transport between intracellular membranes. OSBPs are implicated in cholesterol transfer from the endoplasmic reticulum (ER) to the Golgi, in cholesterol efflux and in the regulation of ABCA1 expression. However, if OSBPL7 is expressed in the kidney and if it is involved in the preservation of ER function has not been explored.

Methods: In this study, we utilized podocytes and tissues obtained from wildtype and Col4a3$^{-/-}$ mice, an experimental model of CKD. siOSBPL7 Podocytes and HEK293 cell lines were established using siRNA yielding these cells deficient in OSBPL7. HEK cells do not express ABCA1 making them a valuable tool to study the ABCA1 independent effects of OSBPL7. OSBPL7 levels were determined from kidney cortex and isolated podocytes from WT and Col4a3$^{-/-}$ mice by western blot, immunohistochemistry, and RT-PCR. siOSBPL7 podocytes and HEK cells were analyzed for changes in ER stress markers, reactive oxygen species (ROS), cytotoxicity, and apoptosis.

Results: OSBPL7 is expressed in podocytes isolated from wildtype and Col4a3$^{-/-}$ mice, an experimental mouse model of chronic kidney disease. Western blot analysis revealed that OSBPL7 protein levels are reduced in kidney cortex of Col4a3$^{-/-}$ mice. siOSBPL7 podocytes and HEK293 cells show increased levels of ER stress, ROS, cytotoxicity, and apoptosis. Overexpression of OSBPL7 in Col4a3$^{-/-}$ podocytes lead to a reduction in apoptosis levels further indicating a beneficial role of OSBPL7 in podocytes.

Conclusions: This study represents the first time that OSBPL7 has been implicated in CKD. OSBPL7 deficiency in podocytes leads to ER stress and ultimately apoptosis suggesting that OSBPL7 levels are beneficial to podocyte function. Future studies will address the role of OSBPL7 in podocyte lipid trafficking in chronic kidney disease that may lead to the identification of novel therapeutic targets for the treatment of this prevalent and costly disease.

PO2515

Determinants of Serum Phosphate Concentration in CKD

Sunny Dharia,[1] Kenneth R. Phelps,[2,1] Paul J. Der Mesropian,[2,1] Gulvahid G. Shaikh,[2,1] Csaba P. Kovesdy,[3,4] Elvira O. Gosmanova.[2,1] *[1]Albany Medical College, Albany, NY; [2]Albany Stratton VA Medical Center Albany, Albany, NY; [3]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [4]VA Memphis Medical Center, Memphis, TN.*

Background: The serum phosphorus concentration (SP) is the sum of rates of P excretion and reabsorption per volume of filtrate (EP/Ccr and TRP/Ccr). EP/Ccr is calculated as UPxScr/Ucr (U-urine, S-serum, P-phosphorus, cr-creatinine). In a steady state, EP/Ccr rises as P intake rises or Ccr falls. TRP/Ccr, calculated as SP – EP/Ccr, is hormonally regulated. We aimed to analyze the evolution of SP and its determinants over CKD stages G1-G5 (dialysis excluded).

Methods: This was a retrospective study involving 200 US veterans followed in the nephrology clinic of the Albany VAMC from 1/2020 to 4/2021. CKD stages were based on 4-variable MDRD eGFR. There were 293 simultaneous random measurements of SP, UP, Scr, Ucr, PTH, and eGFR. Means of these parameters were plotted against CKD stage. Correlations among variables were determined with linear regression models.

Results: The mean age (SD) of the cohort was 73 (10) years. 96% were male, and 48% had diabetes. In comparison to stages G1-2, EP/Ccr rose and TRP/Ccr fell significantly starting at stage G3b (Figure). EP/Ccr correlated with eGFR (R^2 = 0.28, p < 0.001), but TRP/Ccr and SP did not. SP correlated with EP/Ccr (R^2=0.24, p<0.001) and TRP/Ccr (R^2=0.38, p<0.001). PTH correlated with EP/Ccr (R^2= 0.32, p<0.001), and TRP/Ccr correlated with [PTH] (R^2= 0.10, p< 0.001).

Conclusions: EP/Ccr rises consistently as eGFR falls. At stage G3b, the decrement in TRP/Ccr equals the increment in EP/Ccr, and SP remains stable. In stages G4 and G5, the rise in EP/Ccr is greater than the fall in TRP/Ccr, and SP ascends accordingly. As eGFR declines, PTH rises, but its apparent effect on TRP/Ccr is blunted. As CKD progresses, maintenance of stable SP depends primarily on reduction of intestinal P absorption.

PO2516

Tubular Urate Controls Intracellular Lactate in the Proximal Tubule with Implications for CKD

Owen M. Woodward,[1] Victoria L. Halperin Kuhns,[1] Allison C. Lane-Harris,[1] Krister Bamberg.[2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]AstraZeneca Early CVRM Biopharmaceuticals R&D, Molndal, Sweden.*

Background: Alterations in cell metabolism in the proximal tubule are a recognized component in the initiation and progression of chronic kidney disease (CKD). Previously, a mouse model of hyperuricemia revealed elevated serum urate was associated with hyperglycemia and altered expression of key mitochondrial complex I and complex IV genes in the kidney, changes implicated in human CKD. Further, a recent human trial showed that blockade of proximal tubule urate transporter, URAT1, in conjunction with urate lowering therapy, slowed the progression of CKD as defined by change in albuminuria. Here, we focused on the role of renal urate handling in controlling the intracellular levels of lactate, a key metabolite and substrate of cellular respiration. Lactate is a substrate of URAT1 (*SLC22A12*) moving in *trans* with the apical entry of urate from the renal tubule lumen. We hypothesized that increased extracellular urate would promote the secretion of lactate and lower intracellular levels.

Methods: We used cultured primary normal human cortical renal epithelial cells (NHCRE) and a new hyperuricemia mouse model, produced by the inducible inactivation of the uricase gene, *Uox*, to explore the relationship between urate and CKD.

Results: In NHCRE cells we found that increasing the extracellular urate to 500μM significantly lowered intracellular lactate with high (4.5g/l) or reduced levels of glucose (1g/l) in the culture media, and that additional extracellular lactate could rescue intracellular levels. Further, the application of probenecid, a general anion transporter blocker with affinity for URAT1 abolishes the effects of extracellular urate on lactate levels, though probenecid alone has no effect. Finally, we sought to confirm the mechanistic connection between urate and lactate handling in the mammalian nephron. In the inducible *Uox* knockout hyperuricemia mouse model we found the increased plasma urate and resulting increased urinary urate excretion was associated with an increased urinary lactate excretion as well as a significant increase in the fractional excretion of lactate.

Conclusions: We conclude that increased tubular urate alters intracellular lactate levels, which potentially alters cellular respiration in the proximal tubule and affects kidney disease progression.

A Severe Case of Secondary Hyperoxaluria Successfully Treated

Veronica Zamora-Olivencia, Cybele Ghossein. *McGaw Medical Center of Northwestern University, Chicago, IL.*

Introduction: Bariatric Surgery for the treatment of obesity is categorized as either restrictive or malabsorptive. Malabsorption procedures are often used for long lasting weight loss in morbidly obese patients. The Biliopancreatic Diversion and Duodenal Switch (BPD/DS) is preferred for patients with more severe comorbidities as it provides best durability, minimal dumping syndrome and less dietary restriction. Malabsorption weight loss surgeries have been associated with AKI, CKD, nephrolithiasis and metabolic and nutritional derangements. Here we report a patient with history of BPD/DS with CKD due to hyperoxaluria.

Case Description: A 70-year-old female with history of morbid obesity since childhood, status post BPD/DS surgery in 2004 with persistent hypocalcemia, severe osteoporosis and newly recognized chronic kidney disease (CKD) was referred for nephrology consultation. Serum creatinine pre-surgery was 0.9. Her eGFR at the time of referral was 42cc/min and her urinalysis was without proteinuria. Renal Ultrasound was without nephrolithiasis. As part of her work up, a 24-hour urine collection for oxalate was obtained and revealed severe oxaluria at 168mg/day. Patient's medications included 4 grams a day of Calcium Citrate along with multiple other supplements. Patient admitted to non-compliance with her calcium supplements. After two months of strict compliance

with low oxalate diet and calcium supplements a 24-hour urine collection showed improvement of oxaluria to 62 mg/day. Her renal function remains stable.

Discussion: Patients who undergo malabsorptive weight loss surgery are at risk for AKI, CKD and nephrolithiasis from hyperoxaluria. Kidney damage can continue years after the surgical procedure. Treatment involves low oxalate diet and aggressive oxalate binding with use of calcium supplements. Bariatric surgery reversal is the definitive treatment if conservative management fails. Bariatric patients should be referred promptly to a nephrologist if change in renal function is noted.

Increasing Acid Retention with Progressive GFR Decline Is Associated with Decreasing Urine Ammonium Excretion

Nimrit Goraya,[1] Jan Simoni,[2] Abdullah A. Mamun,[3] Donald E. Wesson.[4] *[1]Baylor Scott and White Central Texas, Temple, TX; [2]Texas Tech University Health Sciences Center, Lubbock, TX; [3]Baylor Scott & White Health, Dallas, TX; [4]Texas A and M College of Medicine, Dallas, TX.*

Background: Our laboratory showed that acid (H^+) retention without metabolic acidosis increased as eGFR declined while plasma total CO_2 ($PTCO_2$) remained within normal ranges (AJP 314: F985, 2018) but the mechanisms for this potential accelerator of GFR decline were not explored. We now examine if changes in urine net acid excretion (UNAE) or its components associated with changes in H^+ retention in longitudinally followed patients with CKD 2 (eGFR 60-89 ml/min/1.73 m²) without metabolic acidosis.

Methods: One hundred twenty macroalbuminuric, non-diabetic participants with CKD 2 (eGFR=73.4±6.1 ml/min/1.73 m²), 40 treated with 0.5 mEq/kg bw $NaHCO_3$, 40 with 0.5 mEq/kg bw NaCl, and 40 with usual care (UC) were evaluated annually for 5 years. We assessed H^+ retention by comparing observed to expected increase in plasma [HCO_3] in response to retained HCO_3 (dose-urine excretion) 2 hours after an oral $NaHCO_3$ bolus (0.5 mEq/Kg bw), assuming 50% body weight HCO_3 space of distribution. Specifically, H^+ retention = [(retained HCO_3/0.5 x body weight) – observed increase in plasma [HCO_3]] x (0.5 x body weight). We measured 8-hour urine NAE as the sum of ammonium (8h UNH_4^+V), titratable acidity (8h UTAV) and bicarbonate ($UHCO_3V$).

Results: Although 5-year vs. baseline H^+ retention was higher in UC (19.2±10.2 vs. 17.4±9.7 mmol, $p<0.05$) and NaCl (23.2±13.8 vs. 19.2±16.4 mmol, $p<0.05$) but was lower in $NaHCO_3$ (16.0±12.8 vs. 18.1±14.6 mmol, $p<0.05$), 5-year vs. baseline 8h UNAE was not different for any group and was not different among groups at baseline or at 5 years. Nevertheless, longitudinal change in 8h UNH_4^+V was inversely associated with change in H^+ retention for UC ($p<0.01$, $R^2=0.82$), NaCl ($p<0.01$, $R^2=0.71$), and $NaHCO_3$ ($p<0.01$, $R^2=0.20$). Combining all three groups, the change in 8h UNH_4^+V was also inversely associated with the change in H^+ retention ($p<0.01$, $R^2=0.48$) but the longitudinal change in 8h UTAV was directly associated with change in H^+ retention ($p<0.01$, $R^2=0.19$).

Conclusions: These longitudinal data support that less ability to maintain UNH_4^+V as eGFR declines contributes to worsening H^+ retention, despite maintenance of overall UNAE. Further studies will help determine reasons for individual variability in UNH_4^+V with progressive eGFR decline and the apparent greater importance of UNH_4^+V than greater UTAV in avoiding increasing H^+ retention.

Kidney Function and Renin-Angiotensin-Aldosterone System in Hypouricemia

Lashodya V. Dissanayake, Adrian P. Zietara, Vladislav Levchenko, Oleg Palygin, Alexander Staruschenko. *Medical College of Wisconsin, Milwaukee, WI.*

Background: Uric acid (UA), the end-product of human purine catabolism, is produced using xanthine dehydrogenase (XDH) and xanthine oxidase enzymes. Both enzymes are encoded by the *XDH* gene. Disruption of UA homeostasis has been implicated in chronic kidney disease for many years. However, the mechanisms behind the correlation remain unclear. Increased level of UA (hyperuricemia) has been shown to activate the intrarenal Renin-Angiotensin-Aldosterone system (RAAS) in many studies. RAAS in the decreased levels of UA (hypouricemia) has not been studied adequately.

Methods: We have created a new rat model with genetic ablation of the *Xdh* gene in the Dahl salt-sensitive rat background ($SS^{Xdh-/-}$) to study hypouricemia. RAAS components were quantified using liquid chromatography-tandem mass spectrometry. Rats were kept on a standard diet, and their plasma, urine, and kidneys were collected when they were 6 weeks old. Mean arterial blood pressure (MAP) was measured by using radio telemetry.

Results: The rat model is hypouricemic (UA in plasma 0.25± 0.03 mg/dl & not detectable for $SS^{Xdh+/+}$ & $SS^{Xdh-/-}$ respectively). Histology of $SS^{Xdh-/-}$ kidneys shows severe damage. The $SS^{Xdh-/-}$ rats show renal function decline with different parameters. They demonstrate significantly higher diuresis (2.7± 0.9 & 14.4± 5.1 ml; N=9 & 8 for $SS^{Xdh+/+}$ & $SS^{Xdh-/-}$) , lower creatinine clearance (0.51± 0.19 & 0.12± 0.04 ml/min; N=7 & for both $SS^{Xdh+/+}$ & $SS^{Xdh-/-}$) and Na^+ retention (136± 1.8 & 150± 3.7 mmol/l; N=10 & 9 for $SS^{Xdh+/+}$ & $SS^{Xdh-/-}$). The $SS^{Xdh-/-}$ rats have significantly lower levels of Angiotensin I/II and Renin and an increased level of Aldosterone compared to $SS^{Xdh+/+}$ rats (**Table 1**). The 10-week-old $SS^{Xdh-/-}$ compared to $SS^{Xdh+/+}$ rats did not have a difference in MAP on the standard diet. When they were challenged with a 4% NaCl diet, they failed to survive.

Conclusions: These results show that the Xdh enzyme is crucial for kidney function, and lack of the enzyme can lead to electrolyte imbalance and changes in RAAS.

Funding: Other NIH Support - NHLBI R35 HL135749

Table 1: RAAS in plasma

RAAS component	$SSXdh+/+$ (pmol/l) (N=5)	$SSXdh-/-$ (pmol/l) (N=4)
Angiotensin I (1-10)	650 ± 291	178 ± 80*
Angiotensin II (1-8)	583 ± 261	171 ± 77**
Renin (indirect measurement using Ang I + Ang II)	1233 ± 551	349 ± 156*
Aldosterone	870 ± 389	4106 ± 1836*

Angiotensin II Type 2 Receptor Agonist C21 Acutely Prevents the Loss of Megalin in the Kidney Cortex and the Onset of Proteinuria in Obese Zucker Rats Fed with High-Sodium Diet

Kalyani Kulkarni, Tahir Hussain, Sanket N. Patel. *University of Houston System, Houston, TX.*

Background: The appearance of protein in the urine (i.e. proteinuria) is a function of the glomerular filtration rate of protein and the reabsorption of protein from the post-glomerular filtrate by the endocytic receptors, megalin and cubilin, localized in the renal proximal tubules. We have shown that treatment with the angiotensin-II type 2 receptor (AT_2R) agonist C21 for 2 weeks reduces proteinuria in obese Zucker rats (OZR) fed HSD. The consumption of sodium-rich diet (HSD) can acutely precipitate proteinuria which is a risk factor and indicator of kidney injury. Therefore, the objective of this study was to identify the acute and chronic mechanism that may have been involved in proteinuria upon consumption of HSD and to identify the anti-proteinuric mechanism upon AT_2R activation in obesity.

Methods: Male OZR were treated acutely (2 days) or chronically (14 days) without or with AT_2R agonist C21 (1mg/kg/day) while fed with normal salt diet NSD (0.4%) or HSD (4%).

Results: The effects of HSD feeding on the expression of endocytic receptor megalin was biphasic. The HSD feeding for 2 days decreased, but for 14 days, increased megalin expression ($p<0.05$ vs. OZR). However, at 2- and 14-days, HSD feeding caused significant proteinuria ($p<0.05$ vs. OZR). The expression of cubilin remain unaffected. The AT_2R agonist treatment significantly prevented the HSD-associated changes in the expression of megalin at 2-days and 14-days, and prevented the onset of proteinuria. The expression of glomerular proteins, nephrin and podocin, which are part of the renal filtration apparatus, in the kidney cortex remains unaffected at 2-days, which suggest that glomerular filtration of protein due to the loss of these glomerular proteins, per se, is not affected by HSD intake and that altered tubular reabsorption is involved in the initiation of proteinuric injury.

Conclusions: Collectively, these data suggest that AT_2R activation protects against HSD induced proteinuria in obese rats by preventing the early loss of endocytic receptor megalin.

Revealing the Antifibrotic Mechanism of Finerenone in the DOCA-Salt Nephropathy Rat Model Using Single Nuclei and Bulk Transcriptomics

Amin Abedini,[1] Junnan Wu,[1] Ziyuan Ma,[1] Julia Frederick,[1] Hana Cernecka,[2] Peter Kolkhof,[2] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Bayer AG, Leverkusen, Germany.*

Background: Finerenone is a nonsteroidal mineralocorticoid receptor antagonist (MRA) which has been proposed to possess pronounced antifibrotic efficacy with a reduced risk to develop hyperkalemia in comparison to steroidal MRAs. However, the exact mechanism of this investigational medication has not been revealed. Single nuclei RNA-sequencing by determining the transcriptional signature at single cell level is an emerging method for elucidating the molecular mechanism of drug action.

Methods: Uninephrectomized, Sprague-Dawley rats were treated with DOCA and salt with an equivalent antihypertensive dose of finerenone (10mg/kg/d), spironolactone (50mg/kg/d), or vehicle. Kidney interstitial fibrosis was considered as outcome. Single nuclei RNA-seq using 10X Genomics Chromium platform in 11 and bulk RNA-seq in 14 specimens were generated.

Results: Interstitial fibrosis was significantly lower in the finerenone group than rats who received DOCA or spironolactone. Unbiased clustering was performed on 85′661 nuclei. All kidney cell types were represented in the final dataset. Comparison of cell type fractions in each group demonstrated that injured and proliferative proximal tubule (PT) cells as well as principal cells of the collecting duct and immune cells were significantly different. Side by side comparison of differential gene expression in PT cells demonstrates that finerenone normalizes genes involved in metabolic processes. Trajectory analysis on the PT cells indicates that PT cells in DOCA and spironolactone treated rats are more susceptible to the injury and transforming to injured PT cells. The results of bulk RNA-seq analysis is consistent with single nuclei transcriptomics indicating the normalization of the genes enriched in metabolic processes and immune responses by finerenone.

Conclusions: Overall, our results demonstrate that treatment with finerenone protects the kidney from interstitial fibrosis. Using single nuclei and bulk transcriptomics revealed that the protection of the PT cells via normalizing the expression of genes which are enriched in metabolic processes and immune response could be a putative further protective mechanism of finerenone in renal diseases.

PUB001

Regional Citrate and Systemic Heparin Are Adequate to Maintain Filter Half-Life for COVID-19 Patients on CRRT

Cassandra Chiao, Hilary Faust, Tripti Singh. *University of Wisconsin-Madison, Madison, WI.*

Background: The aim of our study is to compare clotting of CRRT filters in patients with COVID-19-associated AKI vs. septic shock-associated AKI.

Methods: Retrospective single center study of adult patients with COVID-19 infection compared to those with septic shock admitted to the ICU at a tertiary university hospital April-October 2020. We used independent t-test and chi square test to determine statistical significance of CRRT filter clotting and related factors in COVID-19 patients compared with septic shock patients in the ICU. Time to event data was analyzed with Kaplan-Meier curves. Analyses were performed on Microsoft Excel and MedCalc.

Results: A total of 27 ICU patients with AKI requiring CRRT were included in the study, 13 with COVID-19 infection and 14 with septic shock. The mean half-life of CRRT hemofilter was similar in COVID-19 patients compared to non-COVID-19 patients (27.4 hours vs 27.5 hours, p=0.79). The number of CRRT hemofilter changes per day were also similar in both groups (0.6 filter changes per day, p=0.84) (fig. 1). However, However, significantly more patients with COVID-19 were on systemic heparin compared to the non-COVID-19 patients (69% vs 13%, p= 0.02) (fig. 2).

Conclusions: We found that COVID-19 patients with AKI requiring CRRT had similar CRRT hemofilter half-life compared with sepsis-associated AKI patients with use of regional citrate anticoagulation and systemic heparin use. Further studies are needed to find which methods of anticoagulation is optimal in patients with COVID-19 infection with AKI requiring CRRT.

Figure 1. Details about CRRT in COVID-19 and non COVID-19 patients with AKI

Filter Changes Per Day (Median, 25-75 P)		
COVID-19 (N=13)	**Non-COVID-19 (N=14)**	**p-value**
0.6 (0.5 to .7)	0.6 (0.5 to 0.8)	**0.84**

Elevation in Donor-Derived Cell-Free DNA Triggered by COVID-19 Vaccination

Kalathil K. Sureshkumar, Anwar Khokhar, Krista Gregory, Khaled Nashar, Bhavna Chopra. AHN Nephrology *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Donor derived cell free DNA (dd-cfDNA) is a biomarker that helps to predict acute rejection in kidney allografts. Baseline dd-cfDNA levels are <1% in 96% of kidney transplant recipients (KTRs) and a value ≥ 1% suggests allograft injury usually from acute rejection. Adjuvants used to amplify vaccine immunogenicity could elicit non-specific inflammatory responses and thus could potentially incite immune mediated allograft injury. Here we present a KTR who developed elevated dd-cfDNA within one week of SARS-Cov-2 vaccination.

Case Description: A 70-year old man who underwent pediatric en bloc deceased donor kidney transplantation 30 months earlier with peri-operative Thymoglobulin induction and tacrolimus/mycophenolic acid maintenance and excellent allograft function was found to have an elevation in surveillance dd-cfDNA (AlloSure, CareDx, Brisbane, CA) level at 3.0%. Patient had multiple negative dd-cfDNA values on all prior testing with a last level of 0.17% 3 months earlier. Serum creatinine was 0.8 mg/dl with no DSA and negative urinalysis. Serum BK virus and CMV PCR were negative. Patient did receive first dose of Pfizer/BioNTech Covid-19 vaccination (BNTb162b2) one week prior to the current dd-cfDNA measurement. Subsequent kidney allograft biopsy done due to elevated dd-cfDNA level did not show any evidence for rejection. Repeat dd-cfDNA 10 weeks later normalized to 0.15%.

Discussion: We believe that elevation in dd-cfDNA in our patient with stable renal allograft function was triggered by SARS-Cov-2 vaccination. Pfizer/BioNTech utilizes an mRNA platform in which mRNA is encapsulated in lipid nanoparticles which act as delivery devices and possess natural adjuvant activity. Even though the allograft biopsy did not show clear evidence for rejection, we feel that the adjuvant lipid nanoparticles caused immune stimulation in the host thus triggering dd-cfDNA elevation. Since more and more KTRs will be receiving SARS-Cov-2 vaccination, temporal relationship between vaccination and dd-cfDNA elevations should be entertained. Post-marketing surveillance will be essential to delineate any potential association between SARS-CoV-2 vaccine components and allograft rejection.

PUB003

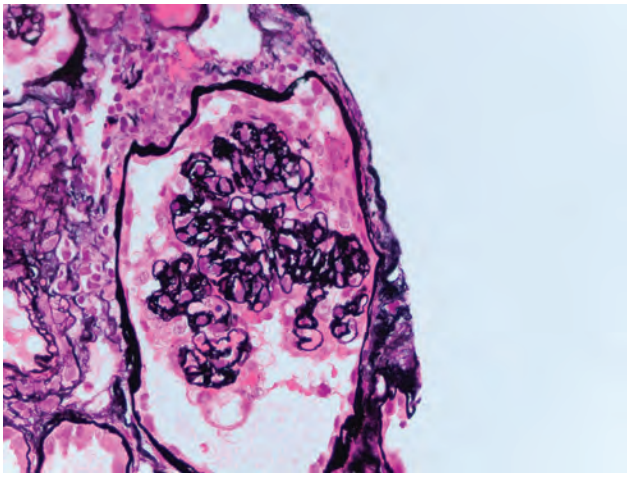
Kidney Disease in the Aftermath of COVID-19 Infection

Megan K. Gallagher, Demetrio Sharp Dimitri, Diping Wang, Sharmeela Saha. *University of Cincinnati College of Medicine, Cincinnati, OH.*

Introduction: COVID-19-associated nephropathy (COVAN) is a known, but potentially missed cause of AKI. We present a case of COVAN presenting with a severe AKI in a previously healthy patient.

Case Description: A 48-year-old African American male with no known past medical history and a recent COVID-19 infection presented with hypertension and lower extremity edema. Initial work-up showed BUN 60, Cr 4.8. Urinalysis was significant for proteinuria. Urine protein to Cr ratio was 1.4. Renal ultrasound did not show any hydronephrosis. Initial management included blood pressure control and intravenous hydration, and his Cr downtrended to 3.1. Of note, his Cr was 1.2 two weeks prior to admission. Given his acute renal failure and significant proteinuria, a renal biopsy was obtained which showed collapsing FSGS consistent with COVAN.

Discussion: Glomerular disease is a known complication of COVID-19. The most distinct presentation is the collapsing FSGS seen in this case (Image 1). This has primarily been reported in patients of African descent, specifically those with high-risk APOL1 genotypes. Patients may recover kidney function, but some may also develop CKD. One month after the hospitalization, this patient's Cr was 4.3 and we suspect he will likely have significant CKD. COVAN can be a difficult diagnosis to make. Proteinuria can often be attributed to common co-morbidities, therefore confounding its diagnosis. The timing also complicates the diagnosis, as in our patient who presented a week after his COVID-19 symptoms resolved. With COVID-19 vaccines, perhaps COVAN may become rarer, but the prevalence and incidence in the era of vaccines must be studied. The long-term repercussions of COVAN are unknown; COVAN should be considered in patients with recent COVID-19 infection presenting with proteinuria. We should make people aware of the possible renal consequences of COVID-19 and sharing this knowledge may help with vaccine hesitancy.



PUB004

Treatment Outcome of New-Onset Collapsing Focal Segmental Glomerulosclerosis in a Patient with COVID-19

Kaitlyn E. Spinella, R Geoffrey Motz. *Christ Hospital, Cincinnati, OH.*

Introduction: COVID-19 has been shown to cause acute kidney injury (AKI) in as high as 46% of hospitalized patients. This case describes a patient who developed an AKI during her admission for COVID-19 pneumonia and was found to have collapsing focal segmental glomerulosclerosis (FSGS). Several cases of FSGS associated with COVID-19 have been described in the literature with varying outcomes. Unfortunately, the patient described in this case has not had significant recovery despite months of high-dose prednisone.

Case Description: A 57-year-old African-American female with a history of diabetes mellitus type 2, hypertension, and small cell lung cancer was admitted for intractable vomiting and found to be positive for COVID-19. Despite no history of kidney disease, patient developed an AKI over the first few days of hospitalization with creatinine 1.96mg/dL (which continued to rise) from baseline 0.7-0.8mg/dL. Urinalysis demonstrated new onset high urine protein/creatinine ratio greater than 12 g/g. Renal biopsy demonstrated collapse of the glomerular tufts and associated hypertrophic podocytes, consistent with collapsing FSGS. No significant immunofluorescence staining was seen. Other serologies were negative, including HIV. Following discharge, she was started on prednisone 60mg daily. Despite several months of prednisone, patient's creatinine remained elevated, mostly in the range of 2.5-3.5mg/dL, never returning to baseline. She continued to have nephrotic range proteinuria and no response to prednisone therapy was noted.

Discussion: As COVID-19 is a new and rapidly evolving disease, extrapulmonary disease is being newly identified, necessitating development of effective treatment strategies. Many of the cases that described collapsing FSGS in COVID-19 patients required initiation of dialysis. The patient in this case recovered from the respiratory symptoms of COVID-19, but continued to have impaired renal function despite several months of treatment. This case demonstrates prednisone failure for our patient, and further study is needed to determine more effective treatment regimens.

Incidence and Prognosis of COVID-19 in People with CKD

Edmund Y. Chung,[1] Suetonia Palmer,[6] Patrizia Natale,[4,3] Anoushka Krishnan,[5,3] Tess E. Cooper,[1,3] Valeria M. Saglimbene,[4] Marinella Ruospo,[4,3] Eric H. Au,[2,1] Sumedh Jayanti,[2] Amy Liang,[3] Danny Deng,[3] Juanita N. Chui,[1] Gail Y. Higgins,[1] Allison Tong,[3,1] Germaine Wong,[3,2] Armando Teixeira-Pinto,[3] Elisabeth M. Hodson,[1] Jonathan C. Craig,[7] Giovanni Strippoli.[4,3] *[1]Children's Hospital at Westmead Centre for Kidney Research, Westmead, NSW, Australia; [2]Westmead Hospital, Westmead, NSW, Australia; [3]The University of Sydney, Sydney, NSW, Australia; [4]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [5]Sir Charles Gairdner Hospital, Nedlands, WA, Australia; [6]University of Otago, Dunedin, New Zealand; [7]Flinders University, Adelaide, SA, Australia.*

Background: Coronavirus-disease-2019 (COVID19) disproportionately affects people with chronic diseases such as chronic kidney disease (CKD). We assessed the incidence and outcomes of COVID19 in people with CKD.

Methods: We searched MEDLINE, EMBASE and PubMed through February 2021 for cohort and case-control studies measuring the incidence or outcomes of COVID19 in people with CKD. We extracted data on COVID19 incidence, death, respiratory failure, dyspnoea, COVID19 recovery, intensive care admission, acute dialysis, and acute kidney injury. Certainty evidence was adjudicated using GRADE.

Results: We included 348 studies (382407 participants with COVID19, 1139979 with CKD). In low-certainty evidence, the incidence of COVID19 was higher in people with dialysis-dependent CKD (105/10000-person-weeks [pw]; 95% confidence interval [CI] 91-120; 95% prediction interval [PrI] 25-235; 59 studies; 468233 participants) than pre-dialysis CKD (16/10000-pw; CI 4-33; PrI 0-92; 5 studies; 70683 participants) and kidney transplant recipients (KTRs) (23/10000-pw; CI 18-30; PrI 2-67; 29 studies; 120281 participants). In low-certainty evidence, the incidence of death in people with CKD and COVID19 may be higher than those without COVID19 (incidence rate ratio 10.26; CI 6.78-15.53; PrI 2.62-40.15; 4 studies; 18347 participants). In low/very low-certainty evidence, people with CKD may experience a high incidence of other outcomes (Table 1).

Conclusions: The incidence of COVID19 may be higher in people with dialysis-dependent CKD compared to pre-dialysis CKD or KTRs. People with CKD and COVID19 may have a higher incidence of death than those without COVID19.

Table 1. Summary of findings: the incidence of COVID19 and outcomes in people with CKD

Outcomes	Number of events	Number of individuals	Incidence (95% confidence interval) [95% prediction interval]	Number of studies	Evidence certainty
Incidence of COVID19 for people with CKD (pre-dialysis, dialysis-dependent or kidney transplant recipient)	14,972	740,452	66 per 10,000 person weeks (58-75) [10-169]	88 studies	Low
Death	19,938	70,922	32 per 1000 person weeks (30-35) [4-81]	229 studies	Low
Respiratory failure	14,635	68,840	31 per 1000 person weeks (27-35) [3-81]	101 studies	Low
Dyspnoea	2587	5767	80 per 1000 person weeks (66-95) [2-234]	75 studies	Low

Safety and Efficacy of Bedside Insertion of Tunneled Hemodialysis Catheters in Critically Ill Patients with COVID-19

Mohammad A. Sohail,[1] Tarik Hanane,[1] James E. Lane,[1] Tushar J. Vachharajani.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Background: Critically ill patients with coronavirus disease-2019 (COVID-19) and kidney dysfunction often require tunneled hemodialysis catheter (TDC) placement for kidney replacement therapy (KRT), typically under fluoroscopic guidance to minimize catheter-related complications. This entails transportation of patients outside the intensive care unit (ICU) to a fluoroscopy suite, which may potentially expose many health care providers to COVID-19. One potential strategy to mitigate the risk of viral transmission is to insert TDCs at the bedside, using ultrasound (US) and anatomic landmarks only, without fluoroscopic guidance.

Methods: We reviewed all COVID-19 patients in the ICU who underwent right internal jugular (RIJ) TDC insertion at the bedside utilizing anatomic landmarks under US guidance between April-December 2020. Outcomes included procedural complications such as bleeding, arterial puncture, venous air embolism, arrhythmias, pneumothorax, hemothorax and catheter tip malposition. TDC insertion was considered successful if the catheter was able to achieve blood flow sufficient to perform a single hemodialysis treatment.

Results: We collected data on 25 patients with COVID-19 who had RIJ TDCs placed at the bedside, 10 of whom underwent simultaneous insertion of small-bore (5 Fr) RIJ tunneled central venous catheters (T-CVC). The median age and body mass index of the cohort were 62 years (interquartile range [IQR]:55-70) and 28.8 kg/m^2 (IQR:25.2-33.2) respectively; comorbid conditions included chronic kidney disease (n=14), diabetes mellitus (n=12) and hypertension (n=18). Continuous veno-venous hemodialysis was the KRT modality employed in all patients. A median catheter blood flow rate of 200 ml/min (IQR:200-200) was achieved in all patients without any deviation from the dialysis prescription. No catheter related complications were observed and none of the catheter tips were mal-positioned on post-insertion chest radiographs.

Conclusions: Bedside RIJ TDC placement in COVID-19 patients, using US and anatomic landmarks without fluoroscopic guidance, may potentially reduce the risk of COVID-19 transmission amongst health care workers without compromising patient safety or catheter function. Concomitant insertion of small-bore RIJ T-CVCs may also be safely accomplished and further help limit personnel exposure to COVID-19.

PUB007

Irreversible Damage from a Pandemic Outbreak: A Rarely Described Case Report

Maria Teresa Furtado, Patrícia A. Domingues, Ana D. Piedade, Catarina A. Gonçalves, Patrícia Valerio. *Hospital de Sao Bernardo, Setubal, Portugal.*

Introduction: Renal cortical necrosis (RCN) is a rare cause of acute kidney injury (AKI) in developed countries with frequency of 1.9%-2% of all patients with AKI. Drugs especially non-steroidal anti-inflammatory drugs (NSAID's) are very rarely described to cause cortical necrosis. It happens due to a permanent occlusion of afferent arterioles and interlobular arteries in the cortical vasculature, either by prolonged vasospasm or primary vascular damage with thrombosis.

Case Description: We present the case of a 20 year-old black man who was admitted to the hospital due to abdominal pain and decreased urine output. He had been symptomatic with severe toothache due to a dental abscess. Since it happened during the pandemic outbreak of COVID-19 he was unable to contact any dentist and he was given regular oral paracetamol and ibuprofen in doses he could not quantify (ibuprofen exceeded 600 mg every 8 hours daily in a week). Initial laboratory tests revealed anemia (Hb 11 g/dL), slight increase in inflammatory parameters and acute renal failure (sCreatinine 12.7 mg/dL, sUrea 109 mg/dL) and a urine protein-to-creatinine ratio of 1.8 g/g. Renal ultrasound excluded obstruction. Viral serologies were negative, clonal gammopathies were excluded, autoimmune study and serum complement levels were normal. Blood and urinary cultures were also negative. He underwent tooth extraction and completed 10 days of amoxicillin-clavulanate and metronidazole with resolution of

infection. Despite proper fluid replacement the patient showed no clinical improvement and presented with anuria, so hemodialysis was started. Abdominal and pelvic CT scan showed no positive findings. A renal biopsy was obtained showing extensive cortical necrosis. At that moment we concluded renal cortical necrosis probably secondary to NSAIDs intoxication. Unfortunately, the patient did not recover and became dependent on renal replacement therapy.

Discussion: This case illustrates the need to be aware of the effect of NSAIDs. Despite being readily available, a subset of individual is susceptible to serious renal toxicity and caution should be exercised when these drugs are used. Our patient presented with bilateral renal cortical necrosis with irreversible renal failure secondary to prolonged use of over-the-counter NSAIDs in the setting of pandemic outbreak of COVID-19.

Challenges in Conducting a Clinical Trial During the COVID-19 Pandemic

Meredith C. McAdams,[1] L Parker Gregg,[2] Joseph M. Trombello,[1] Rajnish Mehrotra,[3] Susan Hedayati.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Baylor College of Medicine, Houston, TX; [3]University of Washington System, Seattle, WA.*

Background: The COVID-19 pandemic has caused a global upheaval in daily life, economics, clinical care, and research. We report challenges faced and addressed based on our experiences conducting an NIH-funded randomized controlled clinical trial during the pandemic.

Methods: Combination of Novel Therapies for CKD Comorbid Depression (CONCORD) is an ongoing multi-center randomized trial comparing two novel 16-week treatment strategies for depression, *vs.* a placebo and attention control group, in 200 patients with stages 3b-5 non-dialysis CKD. One strategy is to deliver bupropion antidepressant drug for 8 weeks, with augmentation to combination bupropion and behavioral activation teletherapy (BAT) for an additional 8 weeks if depression did not remit. The second strategy is to deliver BAT for the first 8 weeks, with addition of bupropion for 8 more weeks for non-remitters.

Results: Since October 2020 to-date, 690 patients were screened at the University of Texas Southwestern, Dallas, and at the University of Washington, Seattle, of whom 151 (21%) met the screening cutoff for depression. Despite the ongoing pandemic, this percentage was similar to previously reported rates for CKD patients. Thirty-one (80%) of the 39 target to-date were randomized, and 22 (71%) have completed the trial. Only 2 exited before 16 weeks. The national shift away from in-person visits to telehealth slowed screening from outpatient clinics. A lower number of screening surveys were conducted due to unavailability of patients via telephone. Because CKD patients have a high burden of healthcare contact and barriers to accessing in-person care, CONCORD was designed prior to COVID-19 to use teletherapy instead of in-person visits to minimize burden. Telehealth intervention delivery has been especially beneficial in minimizing in-person contact during the pandemic. Blinded assessments of primary outcome were also conducted by computer-assisted telephone interview. Thus, the protocol allowed minimization of in-person visits, which were further decreased from every 4 to every 8 weeks only for phlebotomy and drug dispensation.

Conclusions: Despite challenges posed by COVID-19, CONCORD successfully upheld near-target recruitment, due to perseverance of staff, use of teletherapy to minimize in-person visits, and patients' willingness to participate.

PUB009

Mortality and Evolution Between Community and Hospital-Acquired COVID-AKI (CA-AKI and HA-AKI)

Jonathan Chavez,[1,2] Fidel Ramos Avellaneda,[1,2] Andrea Luna,[1,2] Marcela Plascencia Cruz,[2,1] Alejandro Martínez Gallardo González,[2,1] José D. González Barajas,[1,2] Frida Margarita d. Méndez,[1,2] Guillermo Garcia-Garcia.[1,2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: Differences between HA-AKI and CA-AKI are not well stablished

Methods: Retrospective cohort. We included 877 patients hospitalized with COVID at two hospitals in Mexico. Primary outcome was all-cause mortality at 28 days compared between COVID with CA-AKI and HA-AKI. Secondary outcomes included the need for KRT, and risk factors associated with the development of CA-AKI and HA-AKI.

Results: A total 33.7% developed AKI. CA-AKI occurred in 59.9% and HA-AKI occurred in 40.1%. Patients with CA-AKI had more comorbidities than those with HA-AKI. Patients' survival with CA-AKI it was 75.4%, and with HA-AKI 69.6%. Age > 60 years (OR 1.12), COVID severity (OR 1.09), mechanical ventilator (OR 1.67), and HA-AKI 3 (OR 1.16) increase mortality. The presence of CKD (OR 1.48), serum lymphocytes < 1000 μL (OR 1.03), the need for mechanical ventilator (OR 1.06), and CA-AKI stage 3 (OR 1.37) were the only variables associated with a KRT start.

Conclusions: We found that COVID complicated by CA-AKI have more comorbidities and worse biochemical parameters than HA-AKI patients, but despite these differences, their probability of dying is similar

Predictors of Short- and Longer-Term Mortality After COVID-19 Presentation Among Dialysis Patients in the Americas

Adrian M. Guinsburg,[1] Yue Jiao,[2] Maria Ines Diaz Bessone,[1] Caitlin Monaghan,[2] Michael A. Kraus,[4] Peter Kotanko,[3,5] Jeffrey L. Hymes,[2] John W. Larkin,[2] Len A. Usvyat,[2] Robert J. Kossmann,[4] Juan Carlos Berbessi,[1] Franklin W. Maddux.[6] *[1]Fresenius Medical Care Latin America, Rio de Janeiro, Brazil; [2]Fresenius Medical Care, Global Medical Office, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Fresenius Medical Care North America, Waltham, MA; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany.*

Background: We aimed to build machine learning (ML) models to understand the predictors of short- and longer-term mortality among hemodialysis (HD) patients affected by COVID-19 in four countries in the Americas.

Methods: We used data from adult HD patients treated at regional institutions of a global provider in Latin (LATAM) & North America (NA) who had COVID-19. We used data on 96 variables from Jul-2019 through Dec-2020 to develop XGBoost models (60%:20%:20% random split for training, validation, & testing) to predict the likelihood of death in 0-14, 15-30, >30 days after COVID-19 presentation, and identify importance of predictors. Models were developed in a side-by-side manner and used same programing for datasets in LATAM (Argentina, Columbia, Ecuador) & NA (United States) countries.

Results: Among HD patients with COVID-19 in LATAM (n=12,121) and NA (n=21,624), 15.8% and 7.3% died within 0-14 days, 8.2% and 4.6% died within 15-30 days, and 4.8% and 8.6% died >30 days after presentation, respectively. Models in LATAM & NA had area under cure (AUC) in testing datasets of 0.64 & 0.70 for death within 0-14 days; top predictors at presentation were diabetes, lower interdialytic weight gain (IDWG) in LATAM, and higher age and longer vintage in NA. AUCs were similar across models. Top predictors of death 15-30 days were higher pre-HD weight and post-HD systolic blood pressure (SBP) in LATAM, and same as 0-14 days in NA. Top predictors after >30 days were diabetes and higher pre-HD SBP in LATAM, and higher age and lower dry weight in NA.

Conclusions: Profiles of mortality in HD patients after COVID-19 were distinct in LATAM & NA. Mortality more often occurred within 0-14 or 15-30 days after COVID-19 in LATAM versus NA. About 5% to 9% of COVID-19 patients died >30 days after presentation. Top two predictors of mortality differed in LATAM & NA during earlier and later periods after COVID-19, albeit when considering top 15 predictors similarities exist. Comorbidities, demographics, weight, and BP appear risk factors for death after presentation. Use of underexplored follow-up timeframes along with ML modeling techniques that account for collinearity and missingness provide novel insights related to mortality in COVID-19.

SARS-CoV-2 Breakthrough Infection in a Fully Vaccinated Hemodialysis Patient

Robert B. Robey,[1,2] Luiz M. Kolankiewicz,[1,2] Marcus E. Lane,[1] Fariha Chaudhry,[1,2] Clay A. Block.[1,2] *[1]White River Junction VA Medical Center, White River Junction, VT; [2]Geisel School of Medicine at Dartmouth, Hanover, NH.*

Introduction: End-stage kidney disease (ESKD) is associated with immunosuppression manifesting as both increased infection rates & impaired vaccine immunoresponsiveness. Nonetheless, COVID-19 vaccines have proven highly effective in dialysis-dependent ESKD patients, with reported seroconversion rates as high as ~96%. Herein, we describe a case of breakthrough SARS-CoV-2 infection in a fully-vaccinated hemodialysis patient.

Case Description: A 69 year-old white male with dialysis-dependent ESKD presented for routine rural in-center hemodialysis with a new intermittent nonproductive cough following known COVID-19 exposure. He tested positive for COVID-19 via both rapid antigen testing & RT-PCR despite full mRNA-1273/Moderna SARS-CoV-2 vaccination ~2 mo prior, & was admitted for inpatient management pending availability of isolated outpatient dialysis. He was afebrile, normoxemic, & clinically stable at presentation & throughout his subsequent hospital course. Following 10 d of uneventful isolation, during which he received thrice-weekly hemodialysis but no COVID-19-specific therapies, he resumed maintenance outpatient dialysis. Of note, he was current on all recommended vaccinations for dialysis patients, but had required multiple courses of hepatitis B vaccination for a documented history of impaired serocoversion. The patient ultimately developed both anti-nucleocapsid IgM & anti-spike IgG antibodies directed against SARS-CoV-2, & viral genome sequencing revealed a novel SARS-CoV-2 variant of interest (B.1.526).

Discussion: While breakthrough COVID-19 is rare – reported in <0.001% of the fully vacciniated U.S. population as of 20 Apr 2021 – incidence rates may be higher in specific immunosuppressed subgroups such as ESKD patients. This case illustrates the potential for fully-vaccinated ESKD patients to contract COVID-19, particularly following known exposure(s) or in the setting of viral variants. It is also consistent with accumulating anecdotal clinical experience suggesting that breakthrough infections are generally milder phenotypically than primary infections in vaccine-naïve individuals. As such, high levels of suspicion may be required for identification & proper isolation. Constrained local resources in rural settings may also require different risk mitigation & management strategies for in-center hemodialysis patients with breakthrough COVID-19.

PUB012

Membranous Nephropathy in a Patient with Recent COVID-19 Infection

Weiwen Guo, Shashidhar Baikunje. *Sengkang General Hospital, Singapore, Singapore.*

Introduction: Membranous nephropathy (MN) associated with COVID-19 infection is rare and most reported cases are anti-phospholipase A2 receptor(PLA2R) negative. We report a case of PLA2R seropositive MN with COVID-19 infection.

Case Description: A 29-year-old Asian male presented with fever, myalgia and lower limb swelling for 3 days. 4 weeks prior, he was treated symptomatically for COVID-19 infection. He was diagnosed with acute kidney injury and nephrotic syndrome. Immune markers, virology and imaging of kidneys were normal.(Table1) MN was diagnosed on renal biopsy (Figure1&2). PLA2R was negative in the glomeruli by immunofluorescence but serum PLA2R antibodies was positive at 139RU/ml. Workup for other causes of secondary MN was unrevealing. Due to increasing COVID-19 infections at that time, immunosuppression was deferred. ACE inhibitor was titrated to the highest tolerated dose. After 8 months, he remained nephrotic and Modified Ponticelli regimen was commenced with oral cyclophosphamide 2mg/kg and prednisolone 0.5mg/kg. 2 months after initiation of immunosuppression, patient has shown partial response.

Discussion: Seropositive but biopsy-negative PLA2R associated MN is uncommon, and occurs rarely in patients with possible secondary MN. PLA2R positivity on renal biopsy has been reported in viral hepatitis and some cases had circulating serum PLA2R antibodies. To our knowledge, there are no reported cases of circulating PLA2R antibodies with COVID-19 infection. Our case illustrates the diagnostic and management challenges of MN in the era of widespread COVID-19 infection. Clinical course and PLA2R antibody titres remain useful guides for consideration of immunosuppressive treatment.

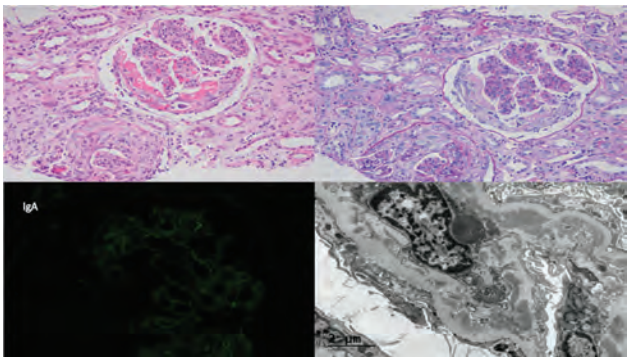
IgA Nephropathy Post COVID-19 Infection

Zachary Drury, Laith Al-Rabadi, Martin C. Gregory, Sarah Gilligan, Ritika Ohri, Monica P. Revelo Penafiel, Josephine Abraham. *University of Utah Hospital, Salt Lake City, UT.*

Introduction: Acute kidney injury (AKI) occurs in > 20% of hospitalized patients with SARS-CoV2 infection. Etiology of renal injury includes acute tubular injury, collapsing focal segmental glomerulosclerosis, and thrombotic microangiopathy. Rarely COVID-19 has been associated with antineutrophil cytoplasmic antibody associated vasculitis, anti-glomerular basement membrane antibody disease, and IgA nephropathy. We report a case of crescentic IgA nephropathy in a patient with recent COVID-19 infection.

Case Description: A 55-year-old man with prolonged hospitalization for COVID-19 complicated by pulmonary embolism presented with hemorrhage secondary to a spontaneous retroperitoneal bleed. On admission, he was hemodynamically stable but received large-volume blood product transfusion. Significant admission labs included serum creatinine 3.54 mg/dl (baseline 1.34mg/dl), urinalysis with large blood and protein, spot urine protein to creatinine ratio 6,697 mg/g. Renal function and hemoglobin continued to decline despite stabilization of his bleed. Hemolysis workup revealed haptoglobin <10, lactate dehydrogenase 714, occasional schistocytes on the peripheral blood smear, concerning for TMA secondary to COVID-19 infection. Renal biopsy revealed crescentic IgA nephropathy with moderate acute tubular injury. He was started on prednisone 80mg daily for crescentic IgA nephropathy. Unfortunately his kidney function continued to worsen, and renal replacement therapy was initiated. He continued to require dialysis while inpatient with no meaningful renal recovery.

Discussion: AKI is a common complication in COVID-19, however, this is not typically due to glomerular disease. Although viral infections such as COVID-19 can trigger IgA nephropathy, to the best of our knowledge, there is only one other case report of IgA nephropathy in a patient with a COVID-19 infection. COVID-19 associated glomerular disease, including IgA nephropathy, should be considered in patients with nephrotic range proteinuria, and hematuria in the setting of recent COVID-19 infection.



PUB014

Impact of COVID-19 on Kidney Transplantation

Subodh J. Saggi, Jie Ouyang, Yasmin N. Mahmoud, Felicia Mckoy, Moro O. Salifu, Okwudili Nnaji, Angelika C. Gruessner. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: Detrimental impact of COVID-19 on renal function unraveled over time. Nephrology community was in a dilemma whether transplantation should continue under such circumstances. We investigated which States within the US continued to perform kidney transplantation despite such odds.

Methods: Retrospective data from Organ Procurement and Transplantation Network (OPTN) regions for kidney transplant alone (KTA) performed across the US from 2019 to 2020, reflecting the peak of the first wave of COVID -19 pandemic were analyzed. To address whether the COVID-19 had an impact on transplanted kidneys, we analyzed graft survival at 3- and 6-months post-transplant during that era. We further investigated the statewide variation of KTA in both deceased donor (DD) transplants and living donor (LD) transplants.

Results: There was a 3.1% decrease in KTA from 2019 to 2020 (22,429 to 21,731). There was an overall trend of a decrease in number of transplants across all states with a peak decline in March-April 2019 era and rebound in May 2019 onwards. Statewide regional decline or variation of DD KTA was most significant in region 9 (NY, Vermont) while regions 4 (Oklahoma and Texas) continued to perform transplants unabated. In 2019, 30.6% of KTA were from LD while in 2020 the rate decreased to 24.1%. The transplantations of DD increased from 15,562 to 16,497 in 2020. Overall, 3-month graft survival was significantly negatively impacted for DD KTA performed between February and May. The decrease in KTA in the southern regions was less compared to the north-eastern regions.

Conclusions: The COVID-19 pandemic had a major impact on kidney transplantation with a significant reduction within all OPTN regions. While LD transplantation could presumably be rescheduled, DD organs must be procured immediately, or they are lost. Therefore, the number of DD transplants decreased initially between March and May but recovered afterwards. Transplanted kidneys during COVID-19 first wave pandemic era performed reasonably well but with an increase rate of injury and rejection.

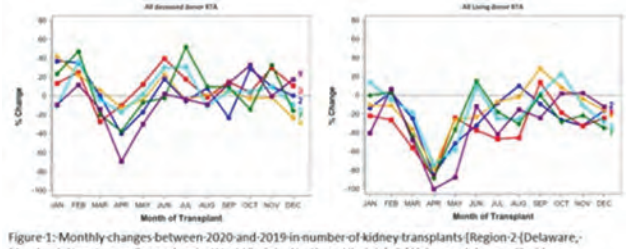


Figure-1: Monthly changes between 2020 and 2019 in number of kidney transplants [Region-2 (Delaware, Maryland, New Jersey, Pennsylvania, West Virginia, Northern Virginia), 3 (Alabama, Arkansas Florida, Mississippi, Puerto Rico), 4 (Oklahoma, Texas), 5 (Arizona, California, Nevada, New Mexico, Utah), 7 (Illinois, Minnesota, North Dakota, South Dakota, Wisconsin), 9 (New York, Western Vermont)]

SARS-CoV-2 Antibody Dynamics in Chronic Hemodialysis Patients

Ohnmar Thwin,[1] Nadja Grobe,[1] Xiaoling Ye,[1] Priscila Preciado,[1] Leticia M. Tapia Silva,[1] Alhaji Cherif,[1] Yuedong Wang,[2] Abhijit V. Kshirsagar,[4] Alan S. Kliger,[3] Fredric O. Finkelstein,[3] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]University of California, Santa Barbara, Santa Barbara, CA; [3]Yale University School of Medicine, New Haven, CT; [4]UNC Kidney Center and Division of Nephrology & Hypertension. University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Data on the persistence of COVID-19 antibodies against SARS-CoV-2 in maintenance hemodialysis (MHD) patients from the U.S. is still scarce and an association with race and ethnicity is unknown. We explore antibody dynamics in MHD patients from three U.S. states with a diverse racial and ethnic background.

Methods: We obtained consent from MHD patients with COVID-19, confirmed by RT-PCR, from 12 clinics. Phase 1 antibody testing was done between June and August 2020. Re-testing was done 6-8 months later. Antibodies were tested with an emergency use authorized assay (Diazyme DZ-LITE SARS-CoV-2 IgG CLIA kit). Linear mixed-effects models were employed to estimate the IgG half-life in patients with repeated IgG measurements. Patients were stratified by sex, race, ethnicity, obesity, and medians of age, dialysis vintage and body mass index.

Results: 104 patients (age 63.8±13 years, 67 (64.4%) males; 48 (46.2%) Africa-American, and 34 (32.7%) Hispanics) were studied. IgG was obtained 82 days (range 13 to 151) and 253 days (range 170 to 309) post-COVID-19. At initial testing, 101 (97.1%) patients were positive for IgG. 89 of them were available for repeated testing, where 74 (83.1%) showed persistent IgG. The luminescence signal was declined by 35.5 AU/mL (95% CI 28.7 to 42.4) from 47.8 ± 44.9 to 12.3 ± 21.1 AU/mL (P<0.0001; paired t-test; **Figure.1).** The estimated half-life of IgG was 62.8 days (95% CI 56.8 to 68.8). We observed no significant differences in the stratified analysis (**Table 1;** all p > 0.05).

Conclusions: The half-life of IgG against SARS-CoV-2 was approximately 63 days, corroborating reports from both the general and other MHD populations. Importantly, we found no association between IgG half-life, race and ethnicity.

Figure 1: Dynamics of IgG antibodies over time.

The x-axis indicates days since COVID-19 diagnosis. The y-axis indicates the natural log of IgG levels. The light lines indicate the patient-specific changes (N=89), the heavy line indicates the average change.

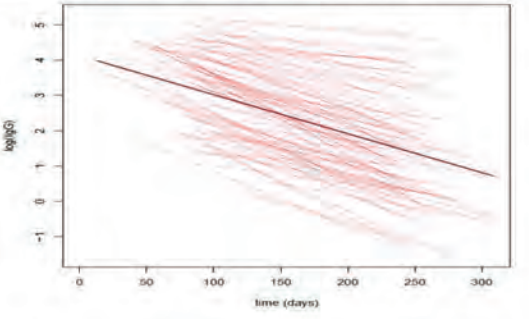

Table 1: IgG half-life ($t_{1/2}$) for the entire population and stratified by patient characteristics.

Incidence and Risk Factors for SARS-CoV-2 Infection in Patients with Lupus Nephritis

Bogdan Obrisca, Alexandra Vornicu, George Dimofte, Valentin Mocanu, Bogdan M. Sorohan, Roxana A. Jurubita, Andreea G. Andronesi, Achim Camelia Adriana, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania.*

Background: Patients with lupus nephritis (LN) are known to be at higher risk for severe infections due to both an underlying immune dysfunction and as a consequence of immunosuppressive therapy (IS). We sought to investigate the impact of COVID-19 pandemic in patients with LN.

Methods: A total of 95 patients with LN actively monitored in our department between 26th February 2020, when the first case of COVID-19 was diagnosed in Romania, and 1st May 2021 were included in the study. Demographics, comorbidities, clinical and laboratory characteristics, current IS therapy, COVID-19 symptoms and outcome were collected. A COVID-19 diagnosis was made if clinical symptoms were accompanied by a positive SARS-CoV-2 PCR.

Results: Fifteen patients (15.8%) were diagnosed with COVID-19 at a median 279 days (IQR:218-341) since the first case was diagnosed in Romania. The majority of infections were mild (73.3%), moderate infections being encountered in the remaining patients (26.7%), while none has developed a severe infection. The most common

symptoms were fatigue (73.3% of patients), followed by loss of taste and/or smell (53.3%) and fever (46.7%). Overall, 40% of patients were hospitalized for a median of 11.5 days (IQR:3.75-14). Of these, 2 patients needed supplemental oxygen and 1 patient non-invasive ventilation. There were no COVID-19-related deaths during the study period. Of the clinical variables associated with infection development, fewer patients with COVID-19 were on hydroxychloroquine (66.7% vs. 89%, p=0.04) or were on clinical remission during the study period (40% vs. 67.5%, p=0.04), while the median maintenance oral corticosteroid dose was significantly higher in those with SARS-CoV-2 infection compared to those without [16 mg (IQR:7-21) vs. 6 mg (IQR:4-10), p=0.007]. In multivariate Cox regression analysis, use of hydroxychloroquine (HR, 0.23; 95%CI, 0.04-1.26) and oral corticosteroid dose (HR, 1.11; 95%CI, 1.01-1.22) remained the most important predictors of COVID-19.

Conclusions: The burden of SARS-CoV-2 infection in patients with LN seems to be low. Use of hydroxychloroquine seems to be associated with a lower risk for COVID-19, while from different immunosuppressive agents corticosteroid dose was identified as an independent risk factor for infection development.

PUB017

Long-Term Mortality Risk of Hemodialysis Patients Surviving Initial COVID-19: A Report from the Quebec Renal Network COVID-19 Study

Annie-Claire Nadeau-Fredette,[1] William Beaubien-Souligny,[2] Remi Goupil,[4] Fabrice Mac-Way,[3] Daniel Blum,[5] Rita Suri.[5] For the Québec Renal Network Study Group *[1]Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada; [2]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]CHU de Quebec-Universite Laval, Quebec, QC, Canada; [4]Hopital du Sacre-Coeur de Montreal Centre de Recherche, Montreal, QC, Canada; [5]McGill University Health Centre, Montreal, QC, Canada.*

Background: Dialysis patients are at high-risk of morbidity and mortality early after SARS-CoV-2 infection. Long-term consequences of SARV-CoV-2 infection are however still not well described in this population. We aimed to compare long-term mortality between dialysis patients who survived 30-day after a SARS-CoV-2 infection and dialysis patients negative to SARS-CoV-2.

Methods: We included patients with SARS-CoV-2 PCR tests performed between March 1st 2020 and February 30th 2021 from 7 dialysis centers in Quebec. Patients alive at 30 days after SARS-CoV-2 diagnosis were matched by age, sex, center and PCR test date to patients negative for SARS-CoV-2 and followed for up to one year, starting at 30 days after initial infection (or negative test). We assessed mortality risk in unadjusted and adjusted multivariable Cox regressions.

Results: Ninety-eight patients with SARS-CoV-2 infection alive 30-day after diagnosis were matched to 166 SARS-CoV-2-negative patients. Baseline characteristics were similar between the two groups. Patients were followed for a median of 331 (301-347) days. Overall, 32 patients died during the study period (15 [15%] in the SARS-CoV-2-positive group and 17 [10%] in the SARS-CoV-2-negative group, p=0.22). There was no statistically significant association between mortality risk and previous SARS-CoV-2 infection (HR 1.5, 95% CI 0.8-3.1), even after adjustment for residual imbalance (aHR 1.4, 95% CI 0.7-3.1). Results remained similar after exclusion of 4 patients who died of SARS-CoV-2 infection > 30-day after diagnosis (**Table 1**).

Conclusions: One-year survival of dialysis patients surviving SARS-CoV-2 infection was similar to those never infected.

Impact of COVID-19 on Hemodialysis Patients: The Quebec Renal Network (QRN) COVID-19 Study

Marie-Chantal Fortin,[1,2] Marie-Françoise A. Malo,[1] Aliya O. Affdal,[1] Fabián A. Ballesteros Gallego,[2] Annie-Claire Nadeau-Fredette,[1,3] William Beaubien-Souligny,[2,1] Rita Suri.[4] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Centre Hospitalier de l'Universite de Montreal Centre de Recherche, Montreal, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: Hemodialysis patients had to face numerous challenges during the COVID-19 pandemic. They are at increased risk of severe complications of COVID-19 and continued to visit hospitals thrice weekly, increasing their risk of being infected. The objective of this study was to document the impact of the COVID-19 on patient's experience in hemodialysis in Quebec.

Methods: Between November 2020 and May 2021, we conducted semi-structured interviews with 20 patients who were undergoing dialysis treatments in six hemodialysis units in Montreal. Interviews were transcribed and analyzed using thematic content analysis.

Results: Patients were satisfied by the measures implemented within their units in order to prevent COVID-19 outbreaks, such as making masks mandatory, restricting access to the dialysis ward, and even limiting the number of accompanying persons allowed. Participants reported that following the public health guidelines (social distancing, wearing a mask and washing hands) was easy and important in order to ensure their own and their family members' safety. Because of this, participants were more likely to refuse to see their family resulting in feeling of isolation. This was particularly relevant for Indigenous patients who were having their hemodialysis treatment away from their home and family. This sub-group experienced particular issues due to the prolonged remoteness from their loved ones, change in their hemodialysis center and with the measures put in place by the hotel they were residing at. Even though their usual routine outside of dialysis might have changed due to the pandemic, hemodialysis treatments allowed patients to keep a certain normality in their lives. Positive consequences were mentioned such as frequent contact through telemedicine and the existing solidarity between patients during the pandemics.

Conclusions: Patients undergoing hemodialysis faced particular challenges due to the COVID-19 pandemic. Nonetheless, they showed great resilience in their capacity to adapt to the new reality of their hemodialysis treatments.

PUB019

Financial Hardships in a Population of Inner-City Dialysis Patients During the COVID-19 Pandemic and Relationship to Attitudes About Dialysis

Sae Morita, Lauren B. Gruffi, Basim Ahmad, Lawrence M. Langan, Tatyana Yatsenko, Alexander S. Imas, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: We studied inner-City hemodialysis pts who reported financial difficulties and how this affected their attitudes towards dialysis and other aspects of life during the height of the COVID-19 pandemic.

Methods: 21 randomly selected hemodialysis pts were interviewed by telephone during the summer of 2020 using the Stress and Social Support Survey, the Attitude Towards Dialysis survey and questions regarding food scarcity, financial stressors, and feelings about COVID-19.

Results: There were 12 (57%) female, 9 (42%) male, 20 (95%) Black, 1 Other, mean age 53.7±3.4 yrs, mean yrs on dialysis 5.0±1.1, 3(15%) employed, 7 (35%) on disability, 14% Medicaid only, 38% Medicaid/Medicare, 40% living alone. 55% (11) reported that finances affected how well they could control their medical condition (FIN+). FIN+ were more likely to agree that it was difficult to buy their medications because of expense (r=0.58, p+0.007), but that they made dialysis a priority (r=0.5, p=0.03), could discuss their financial concerns with their MD (r=0.75, p<0.001), and that their healthcare team was a source of support (r=0.65, p=0.002). There was no difference in age, insurance type, education or gender but FIN+ pts had much lower mean BMI (22.1±1.1 vs 32.0±1.1, p=0.001) due to lower weight (67.6±3.7 vs 88.8±4.9 kg, p<0.001). No pt was receiving SNAP benfits and there was no difference in albumin or creatinine. FIN+ were more likely to believe they knew how to protect themselves from COVID (r=0.98, P<0.001), and did not fear COVID-19 itself, but were more likely to report feeling things were out of control over the preceding several weeks (r=0.9, p<0.05).

Conclusions: In our population of Inner-City Dialysis pts: 1. Over half of pts surveyed reported financial stress and were more likely to report difficult affording medication, but were more reliant on the dialysis team for social support and made dialysis a priority. 2. Pts reporting financial stress weighed signficiantly less, although mean creatinine and albumin values did not differ. 4. These patients were not afriaid of COVID-19 and felt knowledgeable, but reported feeling out of control, possibly due to financial stressors affecting other aspects of their lives, including ability to pay for food.

AKI-D in Ventilated Critical Patients with COVID-19

Carlos A. Arias, Belén Farías, Ernesto Caliva, Fernando Perez de Pedro, Sebastian Nuñez. *Sanatorio Guemes, Buenos Aires, Argentina*.

Background: Acute Kidney Injury (AKI) is a frequent complication in critical patients with Coronavirus Disease 2019 (COVID-19) and has been associated with a poor prognosis, especially when it is necessary to implement renal replacement therapy (KTR). The mortality reported in COVID-19 patients with AKI and KTR (AKI-D) is variable according to studies published today.

Methods: In this retrospective cohort study, we analyzed the clinical characteristics, comorbidity and prognosis of 87 COVID-19 patients, older than 18 years, ventilated and AKI-D between March 2020 and February 2021. We divided our patients into two groups: Group 1: Patients who start KTR in the period of time between the onset of COVID-19 symptoms and day 21. Group 2: Patients who initiate KTR after day 21 of the onset of COVID-19 symptoms. The Charlson Comorbidity Index and SOFA Score were calculated on the day of admission to hemodialysis.

Results: Our cohort of 87 patients had a mortality 95%, Group 1: 98%, Group 2: 82%. We found no significant differences in age, SOFA before KTR, Charlson score, AKI at admission and survival after the start of KTR between the two groups. Of the total patients, 10 recovered kidney function; four patients were discharged from hospital without KTR (1 from group 1 and 3 from group 2), the other six died during hospitalization. 29 patients (33,3%) died within 48 hours of starting dialysis, with a median pre-KTR SOFA: 15 (IQR =13-16)

Conclusions: In this study, a high mortality is reported, particularly in ventilated patients with the need for KTR in the first 21 days from the onset of COVID-19 symptoms (Group 1). We observed an excess of mortality compared to Group 2. We assume that it may be due to the severity of the underlying viral condition during the initial days of infection, a matter that would become less relevant as time goes by.

Cardiac Troponin and AKI in COVID-19 Sepsis-Related Patients

Beatriz V. Weffort, Marcelo R. Bacci. *Faculdade de Medicina do ABC, Santo Andre, Brazil*.

Background: The COVID-19 pandemic become the major reason of hospitalization of patients in ICU worldwide. AKI is a major disease and continue closely related with sepsis and COVID-19 infection. Cardiac injury is frequent in patients with septic schock and higher levels of cardiac troponin are expected in AKI patients however whether this is related with a poor outcome in the pandemic scenario still remain unknown. The objective of the study was evaluate the impact of the occurrence of AKI and cardiac troponin levels in patients with severe SARS-CoV-2 infection and their major outcomes

Methods: We conducted an observational study during COVID-19 pandemic in 2020 first wave outbreak in Brazil. The research was approved by IRB and patients of a Sao Paulo major public hospital. The main inclusion criteria were the occurrence of COVID-19 infection confirmed by oropharyngeal swab in the last 3 days of admission and the need of permanence of at least 3 days. Patients with a poorer expectancy of survival in the next 24 hours of inclusion were not considered elegible. Blood sample at admission was used to confirm sepsis and AKI and the patients were followed daily untill discharge of the unit or dead. AKI occurrence was seen as the rise of serum creatinine happened according KDIGO AKI guideline. Patients were divided in groups regarding the development of AKI and major outcome (mechanical ventilation or dead)

Results: A total of 86 patients with sepsis were included. Female patients represented 58.3% of the sample. About 96,51% of the patients had at admission a level of d-dimer above 500 ng and 77,91% of patients had a cardiac troponin I above 20 ng in AKI patients group with a p level 0f 0,003. About 44 patients had AKI due to COVID-19 sepsis related by admission in the ICU Median serum creatinine at admission was 2.44 mg/dL (1.64-4.02). There was a higher proportion of patients in mechanical ventilation with development of AKI after admission (14) than those without AKI during the whole hospitalization (11) with a p of 0,299 The mortality of patients with higher cardiac troponin were significantly higher in AKI patients than the non AKI patients.

Conclusions: IIn patients with COVID-19 sepsis related disease, there is a positive correlation between AKI and higher levels of cardiac troponin and higher days with mechanical ventilation.

PUB022

Predicting Factors of Humoral Response to Pfizer BNT 162b2 in Hemodialysis Patients

Rui A. Duarte, Cátia R. Figueiredo, Marisa Roldão, Ivan A. Luz, Francisco Ferrer, Hernâni M. Gonçalves, Flora Sofia. *Centro Hospitalar do Medio Tejo EPE Unidade de Torres Novas, Torres Novas, Portugal*.

Background: Immunization against COVID19 has become the cornerstone in prevention of Sars-CoV-2. Maintenance Hemodialysis (HD) patients are at higher risk of both exposure and mortality. This study aims to describe humoral immunogenicity and suggest risk factors for low or absent response to Pfizer BNT162b2 in an HD cohort.

Methods: Observational prospective study including a group of HD patients followed in a Portuguese Nephrology Center who received BNT162b2. Anti-Spike IgG measured as arbitrary units per milliliter (AU/mL) was obtained on two separate occasions, corresponding to the first and second doses' humoral response. Absolute IgG value, rate of Non-Responders (NR), IgG<1AU/mL after each dose, and Weak-Responders (WR), under Percentile 25 after each dose, were evaluated for risk factors that included demographic and analytical variables.

Results: IgG anti-Spike levels showed a strong correlation with CCI and PTH after each inoculation (ρ=–0.64;–0.66/ ρ=0.56/0.65, respectively; p<0.01). Higher CCI and lower PTH was observed in NR subgroup after the 1st (p<0.01), whereas with the 2nd there was a lower albumin and PTH (p=0.01) and an association with female sex (p<0.01). Similarly, WR also showed higher CCI and lower PTH after the 1st (p=0.02) and 2nd doses (p<0.01), adding older age (p=0.03) and lower albumin (p=0.05) to the 2nd. After both inoculations, WR subgroup was associated with age over 75 yo (p=0.03); female sex (p=0.01), CCI over 8 (p=0.01), CVC over AVF/AVG (p<0.01), dialysis vintage under 24 mo (p=0.01) and PTH under 150 μg/L (p<0.01). A model combining CCI, sex (male) and vascular access (CVC) as a regression model associated those factors to WR after the 2nd dose with OR (95% CI): 1.81 (1.06-3.08); 0.05 (0.01-0.65); 13.55 (1.06-174.18), respectively (p=0.01).

Conclusions: Older age, high CCI, low PTH and albumin, CVC over AVF/AVG and recently started dialysis (less than 2 years) relate to lower response. High comorbidity burden is suggested as a more significant risk factor than age alone. THe role of PTH as a marker of low immunogenicity in the HD population should be target of further investigation. Signalization of HD patients at risk of low response may play a key role in policy making, namely the necessity for booster doses, follow-up measurements and isolation methods.

PUB023

COVID-19 and Kidney Disease: A Follow-Up Study

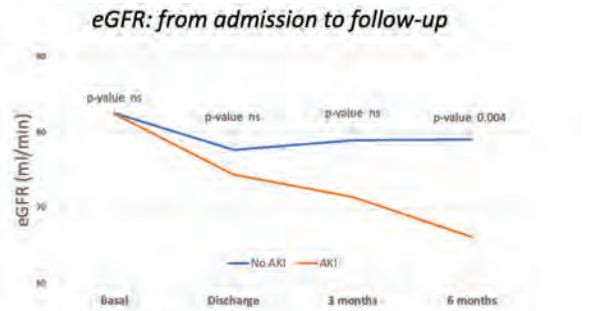
Marta De Filippo, Marco Simonini, Lorena Citterio, Simone Fontana, Teresa Arcidiacono, Paolo Betti, Elena Cinel, Rebecca De Lorenzo, Paolo Manunta, Patrizia Rovere Querini, Chiara Lanzani. *IRCCS Ospedale San Raffaele, Milano, Italy*.

Background: It is well known that SARS-CoV-2 infection is associated with the development of acute kidney disease; however, not much is known about the long-term kidney effects of this pathology.

Methods: We analyzed kidney function data during hospitalization and subsequent follow-up (6 months) of 150 (of which 51 with CKD) patients hospitalized for COVID-19.

Results: 28% of subjects developed AKI during hospitalization; proteinuria and microhematuria were present in 53% and 40% of subjects respectively. At discharge, 61% of patients had already fully recovered their basal kidney function; the presence of proteinuria and microhematuria was reduced to 4% and 6% at subsequent follow-up. However, looking at the trend of the eGFR during the follow-up, an accelerated reduction in the glomerular filtration rate at 3 and 6 months was observed in subjects with AKI being admitted (73.30±17.08 ml/min vs 62.43±17.13 ml/min at six months; p=0.004). This result was confirmed even after exclusion from the analysis of those patients already known for CKD (eGFR < 60 ml/min) at the time of admission for COVID (eGFR 79.05±14.28 vs 66.17±16.99; p=0.004; figure 1).

Conclusions: Starting from these data, we can assume that COVID-19 patients, with intra-hospital AKI development, have an accelerated loss of renal function during follow-up. Further studies are needed to identify pathogenic mechanisms and the long-term evolution of kidney damage after Sars-Cov-2 infection.



eGFR (ml/min) at different times		All patients (150)		No CKD (99)

COVID-19 and Kidney Transplantation in a Colombian population

Carlos E. Duran, Mayra A. Estacio, Daniela Espinosa, Fredy S. Lozano, Juan Posada, Liliana Mesa, Johanna Schweinberg. *Fundacion Valle del Lili, Cali, Colombia.*

Background: Patients with kidney transplants seem to be at particularly high risk for severe COVID19 disease due to their impaired immune responses and comorbidities

Methods: We performed an observational study of kidney transplant recipients with SARS-CoV2 infection admitted at Fundación Valle del Lili from June to December 2020. To be eligible for this study, patients have symptoms compatible, a positive RT-PCR and inpatient management. Asymptomatic patients were excluded

Results: We enrolled a total of 50 patients. 64% were male, and the median age was 53.5 years (range 46-60). The comorbidities were: 36(70%) hypertension, 16(32%) diabetes mellitus, 5(10%) obesity. The most common immunosuppressive regimen was tacrolimus 76% and prednisone 88%.The median time from symptoms onset to the positive RT-PCR was 7 days. The most common initial symptom was fever (64%), and fatigue (58%), cough (44%) and dyspnea (36%). Baseline levels of CRP was 6.43 mg/dL (3.25-11.22). The median lymphocyte count was 785 mm3/uL (550-1230). Baseline D-Dimer was 0.767 ug/ml (0.484-1153.5), ferritin median level was 1011ng/ml (670-2145). Clinical outcomes are shown in **Table**. Six of the patients died (12%), 4/6 were by sepsis-related multi-organ failure and 2/6 were by ARDS

Conclusions: Major complications such as acute kidney injury, acute respiratory distress syndrome and mortality related to COVID-19 infection observed in our study are lower than those reported in other countries

Clinical outcomes of the hospitalized patients

Predictors of In-Hospital Mortality Among Hospitalized Patients with COVID-19 and AKI: A Single-Center Study

Bennett W. Wisner,[1] Sahitya Allam,[2] Abhijit Ravindran,[1] Kambiz Kalantari.[3] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]University of Maryland Medical System, Baltimore, MD; [3]University of Virginia, Charlottesville, VA.*

Background: AKI and COVID-19 infection are both independently associated with high mortality rates and those with COVID-19 who develop AKI have higher mortality rates. We investigated the predictors of mortality in patients admitted to our hospital with COVID-19 who developed AKI during their hospital stay.

Methods: We conducted a retrospective analysis of all patients hospitalized at University of Virginia Medical Center for COVID-19 infection who developed AKI from March 2020 through April 2021. In-hospital mortality was defined as death during admission or within 7 days of discharge to hospice. Data on patients' demographics, comorbidities, AKI stage, dialysis requirement, admission to ICU, serum albumin, ferritin, d-dimer, fibrinogen, hemoglobin, as well as mortality at hospital discharge and 90 days were collected through chart review. Univariate analysis and a multivariate logistic regression model were used to identify factors associated with in-hospital mortality.

Results: 219 patients qualified for study inclusion criteria. The average age was 66.2 years and 56.6% of patients were men. The in-hospital mortality rate was 27.9%. An additional 1.37% died in the 90-day follow-up period. Age ($p = 0.001$), male sex ($p = 0.049$), AKI-D ($p < 0.001$), AKI stage ($p < 0.001$), serum albumin ($p < 0.001$), and ICU admission ($p < 0.001$) were associated with mortality in the univariate analysis (Table 1). After adjustments for covariates, age ($p < 0.001$), AKI-D ($p = 0.001$), and ICU admission ($p < 0.001$) were predictors of mortality in our multivariate analysis [AUC: 0.863, 95% CI (0.815-0.911)].

Conclusions: Age, dialysis requirement, severity of AKI, and ICU admission are predictors of mortality among patients with COVID-19 and AKI at our institution.

Impact of COVID-19 in Quebec Hemodialysis Units: Health Care Providers' Experiences

Marie-Chantal Fortin,[1,2] Aliya O. Affdal,[2] Marie-Françoise A. Malo,[2] Fabián A. Ballesteros Gallego,[1] Annie-Claire Nadeau-Fredette,[3,2] William Beaubien-Souligny,[1,2] Rita Suri.[4] *[1]Centre Hospitalier de l'Universite de Montreal Centre de Recherche, Montreal, QC, Canada; [2]Universite de Montreal, Montreal, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: Chronic kidney disease is a risk factor for the severe form of COVID-19 and the hemodialysis unit represents a high-risk setting for virus transmission. Healthcare providers (HCPs) have the duty to keep patients safe and healthy, and also to protect themselves from the virus. The objective of this study was to gather health care providers' experiences working in dialysis units.

Methods: We conducted semi-directed interviews by phone or video with 21 HCPs working in 6 hemodialysis units - nurses, nephrologists, pharmacists, social workers, security agent and housekeeping attendant - between November 2020 and May 2021. The content of the interviews was analyzed using thematic content analysis.

Results: Participants identified positive and negative impact of Covid-19 pandemic. In their professional life, HCPs declared developing more collaboration, creativity and mutual support. However, due to the pandemic restrictive measures and lack of resources, HCPs felt a lot of distress not being able to provide adequate care for patients' needs. Participants also reported disruption in communication between HCPs and patients because of physical distancing and wearing a mask. They also described problems associated with patient transportation leading to delays or even absence of patients to their treatment. In their personal life, some HCPs declared being concerned by these new challenges at work and reported difficulties balancing work and family life. Also, most of them feared to contaminate their family and adopted certain routine cleaning to alleviate this fear.

Conclusions: HCPs working in hemodialysis unit faced multiple challenges during the Covid-19 pandemic that impacted their wellbeing. However, they have shown high level of resilience and dedication to ensure health care delivery and to support hemodialysis patients.

In-Hospital Mortality in Patients with ESRD Undergoing Hemodialysis Admitted with COVID-19 Compared to Those Without COVID-19

Laura Aponte Becerra,[1,2] Jhoan B. Rozas,[3,2] Carlos A. Torres,[3,2] Patrick Francois,[3,2] Juanly N. Rodriguez,[3,2] Juan D. Salcedo Betancourt,[1,2] Abraham Santana Rodriguez,[3,2] Maria Ortiz,[1] Alessia Fornoni,[3] Gabriel Contreras,[3] Jair Munoz Mendoza.[3] *[1]University of Miami School of Medicine, Miami, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.*

Background: Patients with end-stage renal disease (ESRD) undergoing chronic hemodialysis (HD) have higher cardiovascular and infection-related death compared to the general population. ESRD patients have many of the comorbidities associated with COVID-19-related death, are at increased risk for severe COVID-19, and have higher COVID-19-related mortality. Whether patients with ESRD and COVID-19 have higher in-patient mortality than patients with ESRD without COVID-19 is unknown.

Methods: Retrospective chart review of hospital admissions due to COVID-19 infection or those with ESRD admitted for any other reason between March to June 2020. We collected data on demographics, comorbidities, hospital length of stay, ICU utilization, and mortality. We categorized patients in three groups: ESRD with COVID-19, ESRD without COVID-19, and COVID-19 without ESRD. Mortality analysis was performed using Pearson's Chi-Square and logistic regression analysis.

Results: A total of 494 patients with a mean age of 64 years were included, of which 55% were males, 33% were African American, 55% were Hispanic, 49% had hypertension, and 49% had diabetes. 20 patients had ESRD with COVID-19, 195 had ESRD without COVID-19, and 279 had COVID-19 without ESRD. The crude in-hospital mortality rate was 25% in patients with ESRD and COVID-19, 18% in patients with ESRD without COVID19, and 15% in those with COVID-19 without ESRD (p=0.465 for all comparisons). In multivariable logistic regression analyses, the adjusted odds ratio [OR] for in-hospital mortality in patients with ESRD with COVID-19 was 1.46 [95% confidence interval (CI), 0.77-2.80], the OR in patients with ESRD without COVID19 was 1.02 [95% CI, 0.73-1.42], as compared to patients with COVID-19 without ESRD.

Conclusions: In-hospital mortality in patients with ESRD with COVID-19 is higher but not significantly different than in patients with ESRD without COVID-19 or than in those with COVID19 without ESRD. Further studies should evaluate the long-term COVID-19-related mortality in patients with ESRD.

PUB028

Gross Hematuria Following Moderna SARS-CoV-2 Vaccination

Maryam Sattari, Jourdan A. Mckinnis, Amir Kazory. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: While knowledge about coronavirus disease of 2019 (COVID-19) has been rapidly growing, healthcare systems are still challenged by uncertainties surrounding currently available preventive measures. The mRNA-1273 vaccine (Moderna Inc., Cambridge, Massachusetts, USA) encodes the spike glycoprotein of the coronavirus. Whereas pain at the site of injection and headache are among the most recognized adverse events, little is known about the vaccine's less frequent side effects in the setting of rapid deployment.

Case Description: 1) A 71-year-old man noted frank blood in his urine the day after he received his second dose of Moderna COVID-19 vaccination. He also experienced two episodes of epistaxis. The patient's past medical history was significant for a non-ST elevation myocardial infarction about 2 months prior to presentation, after which he had been on aspirin 81 mg daily and clopidogrel 75 mg daily. Lab results were significant for blood in the urine. Both hematuria and epistaxis resolved without intervention, and he has not had any further bleeding episodes to-date. 2) A 72-year-old man noted "wine-colored" urine the day after he received his second dose of Moderna COVID-19 vaccination. His past medical history was significant for a remote history of nephrolithiasis (22 years ago) and atrial flutter. His medications included aspirin 75 mg daily and rivaroxaban 20 mg daily. Urine dipstick confirmed large blood. Hematuria resolved completely after cystoscopy with bladder irrigation and has not recurred to-date.

Discussion: COVID-19 Moderna post-vaccination bleeding events (e.g. epistaxis and vaginal bleeding) have been recorded as infrequent adverse events. While actual COVID-19 infection has been associated with hematuria, development of gross hematuria following the second dose of the Moderna vaccine has also been reported in patients with IgA nephropathy. However, to our knowledge, these are the first two reported cases of gross hematuria associated with COVID-19 Moderna vaccine in men without a history of kidney disease. Raising the awareness of clinicians is important in that entering these events into the vaccine adverse events reporting system can clarify their true incidence. Whether these patients need to be followed to determine if they will develop signs of a previously undiagnosed nephrologic disease in the future remains to be elucidated.

PUB029

Renal Manifestations and Their Association with Mortality in COVID-19 Patients at a Safety-Net Hospital

Sandra Gomez Paz,[1] Eric Lam,[1] Luis Gonzalez Mosquera,[1] Diana Cardenas-Maldonado,[1] Joshua Fogel,[1,2] Sofia Rubinstein.[1] *[1]Nassau University Medical Center, East Meadow, NY; [2]Brooklyn College, Brooklyn, NY.*

Background: Renal involvement in COVID-19 leads to severe disease and higher mortality. We study additional previously not studied renal parameters in COVID-19 patients and their association with mortality.

Methods: A retrospective study (n=340) of confirmed COVID-19 patients with renal involvement determined by the presence of acute kidney injury. Multivariate analyses of logistic regression for mortality and linear regression for length of stay (LOS) adjusted for relevant demographic, comorbidity, disease severity, and treatment covariates.

Results: Mortality was 54.4% and mean LOS was 12.9 days. For mortality, creatinine peak (OR:35.27, 95% CI:2.81, 442.06, p<0.01) and persistent renal involvement at discharge (OR:4.47, 95% CI:1.99,10.06, p<0.001) were each significantly associated with increased odds for mortality. Increased blood urea nitrogen peak (OR:0.98, 95%CI:0.97,0.996, p<0.05) was significantly associated with decreased odds for mortality. For LOS, increased blood urea nitrogen peak (B:0.001, SE:<0.001, p<0.01), renal replacement therapy (B:0.19, SE:0.06, p<0.01), and increased days to acute kidney injury (B:0.19, SE:0.05, p<0.001) were each significantly associated with increased length of stay.

Conclusions: As persistent renal involvement at discharge is associated with increased odds for mortality, this suggests that early identification of renal involvement characteristics in COVID-19 patients is useful for treatment management. Clinicians should focus on renal parameters of blood urea nitrogen peak, renal replacement therapy, and days to acute kidney injury for predicting patient length of stay.

PUB030

COVID-19 and Vitamin D in an Urban US Hemodialysis Population

Derrick E. Ridley,[1] Anjana Easwar,[1] Omar Syed,[3] Marcellus Edwards,[1] Spencer A. King,[2] Rosie Jardina,[4] Jose E. Navarrete,[1] Harold A. Franch,[1] Janice P. Lea,[1] Jason Cobb.[1] *[1]Emory University, Atlanta, GA; [2]Morehouse School of Medicine, Atlanta, GA; [3]New York Institute of Technology, Old Westbury, NY; [4]Emory Healthcare, Atlanta, GA.*

Background: Due to logistical constraints of in-center hemodialysis (HD) ESKD patients have endured increased risk during the COVID-19 pandemic. Minorities are overrepresented in EKSD, making this group more susceptible to poor outcomes given existing racial disparities. Studies have emerged spotlighting vitamin D's effects on autocrine regulation of immune function and the relevance of extra-renal one alpha hydroxylase. Many studies describe links between vitamin D deficiency and severity of SARS-CoV-2 infection in high-risk patients, but there is a paucity of data specific to ESKD patients. This study explored the association between vitamin D status and COVID-19 infection in a primarily black HD population.

Methods: Emory Dialysis patients' vitamin D levels [25(OH) D] were collected November 2020 as part of a quality improvement project. All SARS-CoV-2 positive HD patients were identified (October 2020 to April 2021). Retrospective chart review including baseline data and labs were collected. An unpaired t-test was used to compare vitamin D levels between COVID-19 positive and negative patients.

Results: 620 patients were included. All patients enrolled in-center HD three times per week. Patient identified race makeup included black (n=570) and non-black n= 50. Average age was 59 years. Gender: males (n=324) and females (n=296). 73 patients developed COVID-19 and 68 patients identified as black race. Average vitamin D levels for COVID-19 positive patients 27.33 and COVID-19 negative patients 26.2 (p=0.55).

Average PTH in COVID-19 positive patients 507.3±371 and COVID-19 negative patients 557.57±458 (p=0.25). Average calcium level in COVID-19 positive patients 8.74±0.66 and COVID-19 negative patients 8.73±0.72 (p=0.48). Relative risk of developing COVID-19 in black HD patients was 1.14 compared to others (p=0.75).

Conclusions: Our study showed no statistically significant correlation between Vitamin D level and COVID-19 acquisition. The role of vitamin D deficiency as a risk factor and the role of Vitamin D supplementation for prevention or treatment COVID-19 in this population is unclear. Further studies investigating the relation between Vitamin D levels and severity of COVID-19 infection in this population should be explored.

PUB031

Antibody Response Following Vaccination to SARS-CoV-2 in Dialysis-Dependent Patients

Lauren Floyd, Chad L. Pardoe, Ajay P. Dhaygude. *Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.*

Background: SARS-CoV-2 is a novel virus resulting in the loss of lives globally. Recently it is recognised that dialysis dependence and end stage renal disease are risk factors for severe COVID-19 infection. In addition, those receiving renal replacement therapy are thought to be immunosuppressed as a result of persistent uraemia and chronic inflammation. The effects of immune dysfunction including T and B cell suppression have caused concerns that haemodialysis (HD) patients may have a reduced immunological response to the vaccine. Recent studies looking at SARS-CoV-2 antibodies demonstrated different outcomes, with some showing diminished antibody responses following vaccination in HD patients whilst others suggest good efficacy and persistence of antibodies.

Methods: In January 2021 Royal Preston Hospital, UK commenced a COVID-19 vaccination programme for all HD patients in accordance with the UK government advice and guidelines. In May 2021 a prospective study including 546 patients receiving incentre and home HD started. SARS-CoV-2 antibodies are being collected during routine dialysis visits and serum samples for spike and nucleocapsid proteins are being measured as markers of immune response. Antibodies are measured monthly alongside secondary outcomes including hospital admissions, mortality and subsequent COVID-19 infection. This study has been approved by the Health Research Authority and the Research and Development team at Lancashire Teaching Hospitals NHS Foundation Trust.

Results: Data collection is ongoing. Sixteen patients (2.9%) declined the vaccine and the majority (85.1%) received the Oxford-AstraZeneca vaccine. The median age is 63.34 years (IQR 54-75 years) and there is a 59.9% male predominance (n=327). 48 patients (10.5%) are receiving home haemodialysis and the remaining 498 patients receive in centre haemodialysis on a twice or thrice weekly basis. Initial results are due in June 2021 and 6 month data will be available in November 2021.

Conclusions: We aim to quantify antibody response to the COVID-19 vaccine in HD patients. This will potentially allow us to identify those patients who may still be vulnerable to COVID-19 despite vaccination and guide further management options in the future. Ongoing research and data analysis is required to investigate both the initial and chronic immune mediated response.

PUB032

Mortality Among ESKD Patients with COVID-19: Comparison Between Kidney Transplant and Hemodialysis

Muhammad Abdulbasit, Omar K. Salameh, Mujahed M. Dauleh, Ali M. Zebi, Navin Verma, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: The COVID-19 pandemic has had an impact on almost every aspect of human life. With more than 170 million cases and more than 3.5 million deaths worldwide (as of May 30, 2021), new facets of the fallout are being uncovered day after day. We analyzed the effects of COVID-19 on end stage kidney disease (ESKD) patients and compared the demographic profile and mortality in patients on hemodialysis (HD) to those who received kidney transplant (KT) in a large multicenter cohort.

Methods: We performed a retrospective multi-center cohort study using TriNetX Research Network database, a federated electronic medical records network, to identify 3601 ESKD patients ≥ 18 years who had either received a kidney transplant (KT) (n=1849 from 34 healthcare organizations [HCOs]) or had been started on hemodialysis (HD) before 12/31/2019 (n=1752 from 31 HCOs) and who had been diagnosed with COVID-19 infection between 1/1/2020-12/31/2020. We used the KT group as the reference and calculated the comparative risk of 6-month mortality after COVID-19 infection for the HD group, reported as the odds ratio (OR) and 95% confidence interval (CI).

Results: Compared with KT patients, HD patients were more likely to be older at the time of COVID-19 infection (57.4±14.5 vs. 53.3±13.8 years; p<0.0001), more likely to be African-American (<0.0001), diabetic (p<0.0001), hypertensive (p=0.0002), and with a history of coronary artery bypass graft (CABG) (0.0021). A total of 366 patients died within 6 months of diagnosis of COVID infection. After propensity matching, COVID-19 positive patients on HD had a higher odds of mortality (OR: 1.48; CI: 1.14, 1.90) compared with COVID-positive patients with a KT.

Conclusions: Among ESKD patients who contracted COVID-19 infection during 2020, the patients on HD were more likely than patients who had received a KT to be African-American, to have a history of diabetes, hypertension and CABG. HD patients were more likely to die within 6 months of COVID diagnosis compared to patients who received a KT.

PUB033

Outcomes in Critically Ill COVID-19 Patients with AKI Requiring Renal Replacement Therapy

Aaron Douen,[1,2] Gregory M. McGraw,[1] Bei Xiong,[1] Rohan Banan,[1] Joshua Samuel,[2] Elena Frolova,[1] Adel S. El-Hennawy,[1] Winston Lee.[1] *[1]New York City Health and Hospitals Coney Island, Brooklyn, NY; [2]St.George's University, School of Medicine, True Blue, Grenada.*

Background: In the past year acute kidney injury(AKI) has been shown to be a common complication of COVID19[1]. with 61-78% of all patients who had COVID developing AKI and needing renal replacement therapy (RRT) [2]. There are still many facets of the novel coronavirus' effect on the kidneys and our approach has changed over time. We report on our experience with AKI requiring RRT early on in the pandemic.

Methods: We performed a retrospective chart review between the months of April to July 2020 at Coney Island Hospital, a public hospital in New York City. Upon identifying those with COVID-19 and AKI requiring RRT, we collected data regarding medications administered, inflammatory markers, demographic data and outcomes.

Results: 62 patients had AKI requiring RRT. 22.6% were female, 77.4 % were males with the mean eGFR on admission being 57.34 with SD OF 29.4. Average age of our cohort was 63 years old. In our cohort the average max values of the following were: ferritin 3495, IL-6 284 and D-dimer 12,460. Average BMI of our cohort was 31 with SD OF 7 (table 1). On average there was 16.5 days between initiation of dialysis and death. After initiation of RRT 30 day mortality and 90 day mortality was found to be 80.6% (50/62) and 87.1% (54/62) respectively. Overall 98.4 % of the cohort died. Using Cox regression analysis no treatments were associated with survival, including thrombolytic administration, full dose anticoagulation, IL-6 administration, plasma, steroids and hydroxychloroquine. Of all the variables collected, only age was associated with mortality.

Conclusions: Acute Kidney injury requiring renal replacement therapy carried significant mortality in the early stages of the pandemic. Our numbers are similar to, but worse than other reports from other New York area hospital systems which had a mortality rate of 79%[3]. Our initial numbers may be partially explained by the population served by the New York City public hospital system. As our experience with this disease expands, hopefully our management of AKI in these patients will improve.

Table 1

	N	maximum	Mean	SD

PUB034

Impact of Different COVID-19 Vaccines on Platelet Count Changes in a Dialysis Cohort

Gracie Fisk, Cassim Schott, Barian Mohidin, Kieran Mccafferty, Suzanne H. Forbes, Andrea Cove-smith. *Barts Health NHS Trust, London, United Kingdom.*

Background: Mortality rates from COVID-19 are significantly higher in patients requiring renal replacement therapy (20-30%) than the overall estimated mortality of 1-4% worldwide. COVID-19 vaccines offer a strategy to protect this vulnerable cohort. Patients on hemodialysis are at higher risk of exposure to COVID-19 due to an inability to self-isolate, and were prioritised for vaccination in the UK. The Oxford Astra-Zeneca (Ox/AZ) vaccine allows administration on the dialysis unit, due to ease of storage and transportation. During the time period between the 1st and 2nd dose in the vaccination schedule, a rare clinical syndrome of thrombocytopenia and thrombosis was observed in patients after receiving the Ox/AZ vaccine.

Methods: We undertook a retrospective analysis of routine dialysis bloods, examining any significant changes in platelet count pre and post vaccine in our dialysis cohort, prior to offering 2nd doses.

Results: Data for 780 hemodialysis patients with platelet count pre and post first dose Covid-19 vaccine were analysed. Of these, 471 patients received the Ox/AZ vaccine, 145 received Pfizer, and the remainder were vaccinated elsewhere, therefore data on vaccine type not available. Mean platelet count for the whole cohort pre-vaccine was $215x10^9$/L, and post was $218x10^9$/L. 126 patients had a platelet count below $150x10^9$/L pre-vaccine, and this number was the same post vaccination. No difference was observed based on vaccine type (see table).

Conclusions: No signal of vaccine-induced thrombocytopaenia was detected in this cohort, though the numbers were small to detect such a rare event. The benefits of completing the vaccine schedule outweigh any small risk of vaccine-associated thrombocytopaenia and thrombosis in this clinically extremely vulnerable cohort.

Results of platelet count changes pre post COVID-19 vaccination by Vaccine type

	Oxford AZ	Pfizer	p
Baseline Platelet count	211 (173-257)	204 (263-248)	0.13
Post vaccine platelets	212 (170-264)	202 (164-247)	0.1
Change in platelet count pre/post vaccine	-2 (-26-16)	-4 (-29-18)	0.99

Platelet count values given as 10^9/L

PUB035

The Tale of Two Collapsing Glomerulopathies Associated with COVID-19 in Stamford Hospital

Mariana A. Chang, Revekka Babayev. *Stamford Hospital, Stamford, CT.*

Introduction: One pattern of kidney injury seen in COVID 19 is collapsing glomerulopathy (CG), a type of Focal Segmental Glomerulosclerosis (FSGS). It has been hypothesized that direct viral effect or increased circulating cytokines from the inflammatory response of the virus, or both, can lead to CG especially in patients with high-risk alleles of APOL1 gene.

Case Description: Patient 1: 63-year-old man, COVID-19 positive, who received only supportive care while hospitalized (Results in table 1). **Patient 2:** 62-year-old man, COVID-19 positive, who required brief treatment with dialysis and received high-dose steroids (Results in table 1).

Discussion: We present 2 cases who achieved partial renal recovery despite different treatments, raising the question of the role of steroids in patients with COVID associated CG.

Table 1

Impact of First vs. Second COVID-19 Surge in Dialysis Patients in San Antonio

Mohammad Sadeddin, Thuylinh M. Nguyen, Nicholas S. Niazi, Shweta Bansal. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: San Antonio, Texas witnessed a COVID-19 surge during July and December 2020. COVID-19 had disproportionately severe impact on dialysis population during first surge; however, experiences from second surge is not known. The aim of our study is to compare the effect of two surges on prevalence and outcomes of COVID-19 infections in dialysis patients within University Health System

Methods: First surge was from April 20 to Sept 20; second was from Oct 20 to Mar 21. Over12-month period, we recorded COVID-19 infections and outcomes for adult patients receiving dialysis at three centers (1st surge n=359 including 25 home and 2nd surge n=362 including 37 home). Demographic, clinical, laboratory, treatment and outcomes data were analyzed

Results: COVID-19 infection were similar during surges (36 [10%] vs.43 [12%]). There was no difference in age, sex, ethnicity, smoking, co-morbidities, cause of ESKD, access and medications. However, patients during second surge were more obese (28 ±4.5 vs 30.4±7.5 kg/m^2 p=0.015), less dialysis vintage (6.2±4.5 vs. 5.7±3.1 yr, p=0.006), higher WBC (6.5±2.2 vs. 7.3±3.6 x 10^3/ml, p=0.016), ferritin (939±719 vs. 12273±1621 µg/L, p=0.048), and D-dimer (2285±2120 vs. 5670±12410 IU ng/ml, p=0.02). No infection occurred in home dialysis patients during first surge compared to 6 (14%) during second surge (p=0.02). Table shows outcomes

Conclusions: Incidence of COVID-19 infections in our dialysis population were similar in the two surges. Hospitalization rates were similar, but more patients required ICU admission, ventilation and longer stay during second surge, although non-significantly. Death was significantly higher during second surge. Home dialysis patients more frequently affected than first surge suggesting change in health behaviors

Table 1

Outcome	1st Surge (N=36)	2nd Surge (N=43)	P Value

A Single-Center Experience: SARS-Cov-2 in ESKD and Kidney Transplant Patients

Angela Pauline P. Calimag,[1,2] Dana Mueller,[1,2] Anthony Guglielmi,[1,2] Spencer Deleveaux,[1,2] Caroline Youssef,[1,2] Vinay Raju,[1,2] Edgar V. Lerma.[1,2] *[1]Advocate Christ Medical Center, Oak Lawn, IL; [2]University of Illinois at Chicago, Chicago, IL.*

Background: A new strain of coronavirus was first recognized in late 2019 resulting in a worldwide pandemic by early 2020. This pandemic challenged health care systems worldwide. The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), resulted in a spectrum of illnesses ranging from asymptomatic, mild, and self-limiting to severe disease. To this date, there are no clear treatment guidelines or protocols for the management of patients in general and for hemodialysis and transplant patients in particular. The Centers for Disease Control and Prevention (CDC) lists patients with chronic kidney disease and immunocompromised patients as high risk for severe disease from SARS-CoV-2.

Methods: Our study is a single-center retrospective study. We conducted an observational, retrospective study in ESKD and Kidney transplant recipients hospitalized and diagnosed with COVID-19 disease at Advocate Christ Medical Center admitted between March 1 to May 31, 2020, a 3-month period. We describe our experience in patients with ESKD and kidney transplants during the COVID 19 pandemic. With particular attention to the treatments used, prognosis, and kidney outcomes in these patients.

Results: From the aggregate total of patients diagnosed with SARS-COV 2 between March 1 to May 31, 2020, there were 34 patients with ESKD on KRT and 3 kidney transplants. The median age of our ESKD cohort was 63.5 years while the KT cohort was 69 years. For both patient populations were predominantly male with 52.9% for ESKD and 66.7% for KT. With 64.7% of ESKD being composed of African Americans, while our KT patients were predominantly Caucasian at 66.7%. The average length of hospital stay was longer for KT patients at an average of 22 days. The incidence of in-hospital death was significantly higher in ESKD patients at 27.8% while we had no mortality for KT pts. For in-patient mortality serum Na, K and BUN were not statistically significant from those who survived. D-dimer peak was significantly higher in mortality.

Conclusions: COVID-19 infection is associated with a high rate of mortality amongst patient's with pre-existing End Stage Kidney Disease. This study redemonstrates this high mortality rate at a single center institution. More research is needed in understanding and managing these patients.

PUB038

D-Dimer Levels as a Prognostic Marker for Developing AKI in Those Hospitalized with COVID-19

Anjali Acharya, Tianying Li. *Jacobi Medical Center, Bronx, NY.*

Background: Severe COVID-19 is associated with higher levels of inflammatory markers than mild disease. D-dimer levels correlate with disease severity and are a prognostic marker for in-hospital mortality. Tracking these markers may allow prediction of disease progression. Data on role of D -Dimer levels in AKI are scant.

Methods: We retrospectively analyzed the clinical and laboratory characteristics of 3,212 consecutive cases of COVID-19 in the Bronx, between March 01, 2020 and July 16th and again between October 15th 2020 and February 28th 2021. D dimer levels were separated by increments of 1000/2000 when over the normal value. Bivariate and generalized estimating equation (GEE) methods were used to explore risk factors associated with in-hospital AKI. Correlations of D-dimer and developing AKI during admission was analyzed.

Results: Results: The first surge data showed that, after adjusting for and controlling for age, race/ethnicity, peak CRP, Diabetes, Chronic Kidney Disease and Hypertension, patients with a peak D-Dimer greater than normal had significantly higher odds of having AKI during admission with highest risk for levels over 3000. The second surge data showed that a peak D-Dimer greater than 2000 was associated with highest odds of AKI. Both surges indicated an increase in D-Dimer was correlated with increased odds of AKI.

Conclusions: Monitoring D- Dimer levels may serve as warning for development of AKI. This may facilitate categorization of patients into risk groups, and help in the identification of those who might potentially benefit from continuous vigilance and prompt intervention. Evidence is still lacking as to the causal mechanisms and whether the associations are specific effects of SARS-CoV-2 infection or are consequences of an intense systemic inflammatory response. Dysregulation of coagulation/anti-coagulation cascades is also a known phenomenon in COVID-19. This finding may help us better understand the pathogenesis of AKI in Covid 19. Significantly elevated D Dimer levels in COVID-19 may serve as an early warning for AKI and help ensure optimal resource allocation.

PUB039

ICU Admission During the COVID-19 Pandemic in Overwhelmed Institutions: Is CKD a Significant Risk Factor for Consideration in ICU Admission?

María F. Zavala Miranda, Luis E. Morales-Buenrostro, Juan M. Mejia-Vilet, Ricardo Correa-Rotter, Megan Ashley N. Gerrard. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico.*

Background: The SARS-CoV-2 pandemic has strained healthcare systems worldwide. Increasing age and comorbidities, as CKD are associated with worse outcomes. Information is needed to assist the decision-making process for ICU admission. The aim of this study was to evaluate mortality rates of COVID-19 CKD patients, percentage of patients admitted to ICU and the role of CKD as a risk factor (RF) for mortality.

Methods: Prospective cohort study from a referral center for COVID-19 in Mexico City. All patients hospitalized between March 2020 and March 2021 with complete follow up were included. Subjects were segregated into 4 groups: 1) CKD stages 3-4 (CKD3-4, n=109), 2) renal replacement therapy (RRT, n=103), 3) kidney transplant (KT, n=31), and 4) patients without CKD (no CKD, n=2520). We registered if ICU admission was requested and if patients were admitted or rejected. RF associated with mortality were evaluated by Cox-regression analysis.

Results: Mean age of the population was 56 years (IQR 46-67), 1697 (61%) were male, 837 (30%) had diabetes, and 1105 (40%) were obese. The group of CKD3-4 patients was older (median 62 years, IQR 38-86), diabetic (58%), and had higher incidence of acute kidney injury (76%). ICU admission was requested for 52 (48%), 32 (31%), 10 (32%), and 1043 (41%) patients in the CKD3-4, RRT, KT, and no CKD groups, respectively ($p<0.001$). Of these, 17/52 (33%), 12/32 (38%), 4/10 (40%), and 576/1043 (55%) were admitted ($p<0.001$). Mortality in each group and in patients admitted in ICU is shown in Figure 1. The adjusted multivariate analysis for mortality showed that CKD was not associated with increased mortality.

Conclusions: CKD patients during the COVID-19 pandemic, conditioning high mortality rates. However, adjusted analysis suggests that CKD should not be considered as a single criterion for the decision of admission to ICU.

Funding: NIDDK Support

PUB040

Rate of Developing Hyponatremia and Outcomes in Kidney Transplant Recipients During COVID-19 Hospitalization

Ekamol Tantisattamo,[1,2] Natsuki Eguchi.[1] *[1]University of California Irvine School of Medicine, Orange, CA; [2]Oakland University William Beaumont School of Medicine, Royal Oak, MI.*

Background: Hyponatremia is one of the surrogate markers of poor clinical outcomes especially in hospitalized patients. Outcomes related to hyponatremia particularly rate of developing hyponatremia in kidney transplant recipients (KTR) with COVID-19 is unknown. We aim to examine association between the degree of hyponatremia and outcomes in hospitalized KTR with COVID-19.

Methods: This is a single-center retrospective cohort study including consecutive KTR admitted for COVID-19. Association of delta serum sodium (ΔSNa) defined by percent drop of admission serum Na (SNa) from a 3-month pre-admission SNa with outcomes including acute kidney injury (AKI) defined by rising serum creatinine (SCr) 0.3 mg/dL from the baseline SCr 3-month prior, death, and length of stay (LOS) is examined by multiple logistic and linear regression as appropriate.

Results: Of 125 KTR, mean age±SD was 47.03±15.19 years old and 53% were male. The majority were White 87 patients (70%) followed by others 27 (22%), Asian 9 (7%), and Black 2 (1%) patients. Mean SNa was 133±6 mmol/L and ΔSNa were -4±5 mmol/L. Mean ΔSNa were -3.02±4.09%. Seven patients (6%) died, and 24 (19%) patients developed AKI. Every one percent increase in ΔSNa was associated 2% decrease the odds of death and developing AKI (OR_{death} 0.98, p 0.81, 95%CI 0.81, 1.18 and OR_{AKI} 0.98, p 0.74, 95%CI 0.86, 1.11). Mean LOS was 12.6±15.4 days (range 1 to 70). Every one percent increase in ΔSNa was associated 0.33 day increase in the LOS (β_{LOS} 0.33, p 0.547, 95% CI -.76, 1.41). After adjusted by age, gender, race, presence or absence of diabetes or hypertension, the magnitude and direction of the association were similar in those all three outcomes.

Conclusions: Hyponatremia appears to be protective for mortality and AKI in KTR hospitalized for COVID-19 but associated with increased LOS; although the statistical significance was limited by small sample size. Future studies are required to elucidate the association of hyponatremia particularly degree of worsening SNa in immunocompromized patients such KTRs who are generally at risk for poor clinical outcomes.

PUB041

The Relevance of Urinalysis in the Hospitalization of Patients with COVID-19 and Nephrology Early Intervention

Lilia M. Rizo Topete,[1,2] Giovanna Y. Arteaga Muller,[1] Elisa M. Guerrero Gonzalez,[1] Adrian Camacho-Ortiz,[1] Luis C. Mata,[1] Luis F. Rangel,[1] Gabriela E. Aguilar Díaz.[1] Hospital Universitario de Monterrey "José Eleuterio González", UANL *[1]Hospital Universitario "José Eleuterio Gonzalez", UANL, Monterrey, Mexico; [2]Hospital Christus Muguerza Alta Especialidad, Monterrey, Mexico*.

Background: Multidisciplinary management of the COVID's patients is essential for their evolution, and the early detection ok AKI is a important role to avoid morbi-mortality. In March 2020, the pandemic by COVID-19 appeared in Mexico, and it led all the health system to change the intrahospital management.

Methods: In a retrospective, observational analysis of all the patients >18 Y that were hospitalized at the Hospital Universitario de Monterrey, in the COVID area, from March to August 2020, we notice how the urinary sedimentation evaluation from the beginning could detect patients who could develop AKI or the need of RRT. All data were analyzed using SPSS statistical software (version 25; IBM Corporation, Armonk, New York).

Results: A total of 344 patients hospitalized from March to August 2020. 220 patients with EGO since the beginning (obtained when our nephrology team take place on the presential participation on AEMA) 102 did not have proteinuria, and, on the other hand, the rest (61 or 37%) reported it. 95 patients (41.7%) had hematuria. Hematuria were more likely to be treated with KRT. Patients with hematuria demonstrated an increased tendency to require RRT: 38.2% of patients with hematuria versus 11.6% without hematuria, the greater chance that needs RRT (P<.001).

Conclusions: The presence of active sedimentary urinary on COVID patients is frequent. The patients who present the combination of hematuria and proteinuria develop severe AKI (KDIGO 3 without RRT) or the need for RRT. Factors in patients such as to be on their upper edge of 40 years old, the presence of hyperkalemia, metabolic acidosis, also the hematuria and proteinuria, suggest the AKI risk that required RRT.

Thrombotic Microangiopathy Following COVID-19 Infection

Mahdis Ghahramanpouri, Amir Abdi Pour, Mita Zahra E. Co, Sayna Norouzi. *Loma Linda University, Loma Linda, CA.*

Introduction: The relationship between COVID-19 infection and the activation of a wide spectrum of pro-inflammatory and pro-thrombotic mechanisms such as antiphospholipid syndrome (APS) and Thrombotic Microangiopathy (TMA) is not yet well understood. However, there is emerging evidence on the link between COVID-19 and TMA. Here, we report a case of a biopsy-proven chronic TMA following COVID-19 infection.

Case Description: A 48-year-old Hispanic female with a past medical history of diabetes, and hypothyroidism, who was recently discharged from the hospital following a COVID-19 infection (complicated by ICU admission requiring intubation about a month ago), presented with severe abdominal pain. No prior history of miscarriage in the past; the patient has two kids with uneventful pregnancies. Denies any family history of autoimmune disease. Initial workups indicated that splenic and renal infarcts concerning primary antiphospholipid syndrome were further supported by positive serological testing confirming the presence of positive Antineutrophil antibody, Cardiolipin antibody, B2glycoprotein, and Lupus anticoagulant. In addition, the urinalysis showed active urinary sediment with dysmorphic RBCs and nephrotic range proteinuria. The patient had a kidney biopsy which was consistent with chronic TMA and was initiated on anticoagulation therapy with warfarin for antiphospholipid antibody syndrome.

Discussion: The possibility of occurrence of TMA following COVID-19 infection and the possible association between markers of endothelial activation, intravascular hemolysis, coagulation and organ damage in infection should be considered. This understanding is clinically relevant as it may necessitate the need for early APS antibody and TMA panel testing and initiation of anticoagulation in the amplified hypercoagulable state in COVID-19, especially in preventing life-threatening thrombosis.

PUB043

Algorithm for Predicting AKI

Shivangi Patel. *Morristown Medical Center, Morristown, NJ.*

Background: Current detection of AKI relies on acute rise in serum creatinine (sCr) and/or a decline in urine output over given time interval. However, biomarkers for AKI have been shown to be elevated prior to change in sCr, suggesting that the time to intervene and prevent AKI is before the change in sCr occurs, when irreversible damage has already occurred. The purpose of the present study was to identify variables that would predict patients at risk for developing AKI without relying on sCr or urine output.

Methods: Retrospective chart review was conducted on all patients admitted from Jan. 2019 to Jul. of 2019. Comparison was made between those that developed AKI defined as change in sCr >1.5mg/dL and those that did not develop AKI, a change of sCr <0.3mg/dL. After exclusion criteria, the final data set consisted of a total of 547 patients and was basis to detect variables that are readily available.

Results: Data showed the higher the rise in sCr the worse the renal injury requiring renal replacement therapy and worse the patient outcome. sCr ≥ 1.5 x baseline correlated with prerenal or mild AKI, while contrast induced nephropathy correlated with ≥ 2x baseline sCr and acute tubular injury and need for renal replacement therapy correlated with ≥ 3x baseline sCr. 20 specific variables were identified in differentiating those that will develop AKI and those that did not develop AKI. Individually some variables weighed more than others in differentiating between AKI and no AKI, however same variables were present across any severity of AKI. Using the 20 variables a specific algorithm was developed to identify any patient admitted and their risk to develop AKI in any inpatient clinical setting. To confirm the accuracy of the data, the same variables were extracted via computer (instead of manually) on a new pool of 769 patients with retrospective admissions yielding same result as the clinician with 81% sensitivity, 80% specificity and 80% accuracy in detecting AKI.

Conclusions: The variables are readily available without need to change patient management or increasing cost. Further study is being conducted to answer the following: How early and accurately will this algorithm predict AKI? Will this prevent AKI by altering management of clinicians when alerted? This could potentially be integrated into hospitals' electronic health records for real time patient monitoring and detection of early AKI and modify patient care and outcomes.

PUB044

Not Everything Is About COVID-19: An Unusual Case of Rhabdomyolysis and AKI After Physical Activity

Marclebio M. Dourado, Luiz H. Miranda. Multirim *Universidade Federal de Pernambuco, Recife, Brazil*.

Introduction: Rhabdomyolysis is the breakdown of striated muscle, leading to systemic manifestations that typically include myoglobinuria, being responsible for 5 to 7% of non-traumatic acute kidney injury(AKI). It can be caused by trauma, status epilepticus, metabolic myopathies, drugs, infections, thryroid disease and hemoglobinopathies

Case Description: We report a case of 31 year old woman who was admitted with muscle pain and choluria 12 hours after physical exercise for a public contest, having mild SARSCoV2 infection 3 weeks before. She was previously healthy, without regular use of any medication, in training for a physical test, with no family history of blood or muscle diseases. At admission she was dehydrated. Exams are shown in table 1. During hospitalization she was conducted with vigorous hydration, diuretics when necessary and urine alkalinization, without hemodialysis. After 12 days, she was discharged. In outpatient follow-up, although the history fits as rhabdomyolysis after extenuating physical activity in a post-covid patient, additional tests were performed:TSH 2,41 mU/L, negative serology for HIV, normal CRP and ESR. Despite negative family history of hemoglobinopathy, hemoglobin electrophoresis was compatible with sickle cell trait (HbA1 57.8%, HbA2 3.1%,HbF 0.3%, HbS 38.8%)

Discussion: Sickle cell disorder(SCD) is a genetic disease where hemoglobin (Hb) S mutation is present on at least one beta chain. When both β chains of HbA carry HbS mutation, the patient exhibits phenotypic features of SCD. If a mutation affects only one β globin chain and the other is normal, the patient is said to have sickle cell trait(SCT), which is a relatively benign carrier state and does not have the classic phenotypic features of SCD. It is estimated that affects 1 million to 3 million americans, and 8 to 10 percent of African Americans, configuring a serious public health problem. SCT does not appear to be associated with increased overall mortality, but studies demonstrate that it is associated with a significantly higher risk of severe exertional rhabdomyolysis, and this case is a reminder to perform this assessment

Laboratory

Exams	23/12	25/12	29/12	04/01 (discharged)	14/01	17/03

Kidney Involvement in Hantavirus Infection: The Importance of Kidney Biopsy

Gabriela Lupusoru,[1,2] Ioana Ailincai,[1] Georgiana Fratila,[1] Mircea Lupusoru,[2] Andreea G. Andronesi,[1,2] Achim Camelia Adriana,[1,2] Mihaela A. Banu,[2] Gener Ismail.[1,2] *[1]Institutul Clinic Fundeni, Bucuresti, Romania; [2]Universitatea de Medicina si Farmacie Carol Davila, Bucuresti, Romania.*

Introduction: Hantavirus infection, a rare zoonosis, associates two major syndromes: hemorrhagic fever with renal syndrome (HFRS) and cardiopulmonary syndrome (CPS). We present two cases of HFRS in which kidney biopsy (KB) was the key in guiding diagnosis

Case Description: Case 1: 26-year-old female (no medical history) presented with acute kidney injury (AKI), nephrotic syndrome (NS), hematuria, high blood pressure (HBP), hepatic cytolysis, severe thrombocytopenia, anemia, leukocytosis, elevated LDH, normal haptoglobin, positive Coombs test, negative immunological and viral tests (C3/C4, ANA, ANCA, antiGBM, hepatitis B/C, HIV, Epstein-Barr, Cytomegalovirus), normal ADAMTS13 activity KB showed macroscopic features of hemorrhage in the renal medulla, light microscopy with normal glomeruli, proximal tubules with intratubular erythrocytes and important interstitial hemorrhage in the medulla, electron microscopy with endotheliosis and interstitial inflammation, features suggesting Hantavirus infection. Serological testing of IgM/IgG antibodies (Ab) for Hantaan serotype (HTNV) established the final diagnosis of HTNV hemorrhagic interstitial nephritis Therapy included steroids and Ramipril. Serum creatinine and liver enzymes returned to normal **Case 2:** 30 year-old male (no medical history) presented with AKI, macroscopic hematuria, NS, HBP, the same laboratory modifications as the previous case and low complement level KB showed the same macroscopic and histological features of massive interstitial hemorrhage in the medulla and arterial endothelial swelling. Serological testing revealed IgM/IgG Ab for Dobrava Hantavirus. The final diagnosis was Dobrava Hantavirus Hemorrhagic Interstitial Nephritis Therapy included steroids and 3 hemodialysis sessions with good evolution and correction of laboratory abnormalities

Discussion: HFRS is most often caused by Dobrava and Puumala serotypes in Balkan Peninsula. Both presented cases live in the same rural area. Case 1 had positive serology for HTNV, usually found in China and Russia, but our patient didn't travel abroad before she got ill. This emphasizes that HTNV nephritis remains an underdiagnosed disease and the need to re-evaluate geographic distribution of different strains. Both cases presented as thrombotic microangiopathies and KB had a decisive role in guiding diagnosis

PUB046

Electronic AKI Alert at the Brandenburg Medical School: Implementation and Follow-Up

Daniel Patschan. *Medical School of Brandenburg, Brandenburg, Germany.*

Background: Acute kidey injury (AKI) substantially worsens the prognosis of hospitalized patients worldwide. In order to optimize early AKI recognition and therapeutic intervention, so-called AKI alert systems have been implemented and evaluated in the past. Herein, we aimed to analyze outcome variables of AKI subjects under the conditions of a de-novo established AKI alert system at the Brandenburg Hospital of the Brandenburg Medical School.

Methods: Based on an electronic algorithm, an automated e-mail message was generated and sent to the nephrologist in responsibility. The message was exclusively generated if one of the two first KDIGO criteria was fulfilled. During period 1, all alerts were ignored. During the second period, every alert was followed-up, coupled with therapeutic management of respective individuals according to an AKI care bundle. Endpoints were in-hospital death, need for dialysis, and renal recovery.

Results: In period 1 and 2 n=200 and n=112 patients were included. In period 1, n=150 out of 200 AKI alerts were identified as correct (75%), in the second period, n=93 out of 112 AKI alerts were accepted as correct (83%) (p=0.16). Renal replacement therapy (RRT) was initiated in n=21 (14%) of all period 1 subjects and in n=32 (34.4%) of the period 2 patients (p=0.001). In-hospital mortality of affected subjects was n=24 (16%) in period 1 and n=21 (22,6%) (p=0.19). Restoration of kidney function was exclusively evaluated in surviving patients. It was n=62 (49.2%) in period 1 and n=40 (55.5%) in period 2. In both periods, higher age was not associated with differences in the endpoints death and renal recovery.

Conclusions: We finally conclude that an AKI alert system as implemented and followed-up in our study did not significantly improve clinical relevant endpoints in AKI subjects. Potential weaknesses were: (I) the lack of documentation of the time between receiving the alert and patient contact, (II) physicians in responsibility were not particularly informed about the alert system, (III) it is questionable whether serum creatinine is suitable for AKI alert systems in general.

PUB047

Precipitous AKI due to Acute Renal Artery Thrombosis in a Patient with Protein S Deficiency

Tyler Reed, Mujahed Abualfoul, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Renal arterial thrombosis and infarction is an under-recognized condition due to its rarity and ability to mimic other disease processes. It can lead to secondary hypertension, acute kidney injury, and chronic kidney disease. Clinical manifestations include nausea, vomiting, flank pain, and sudden elevations in blood pressure. Here, we present a case of a patient with previous normal kidney function presenting with a severe AKI due to an acute renal arterial thrombus.

Case Description: A 58-year-old woman with previously normal kidney function (baseline Cr of 0.8 mg/dL) presented with complaints of nausea and vomiting and was found to have a stage 3 AKI with a creatinine of 4.65 mg/dL. Her creatinine level continued to rise, peaking at 8.5 mg/dL, despite volume expansion. Her urinalysis showed moderate blood and moderate protein. Her FeNa was calculated to be 6.5% and the P/creatinine was found to be 4.56 grams. Renal ultrasound revealed right renal atrophy and a normal appearing left kidney. She remained non-oliguric with good urine output and initially did not meet requirements for renal replacement therapy. Due to the unknown etiology of her AKI, a left kidney biopsy was performed which revealed fulminant acute cortical necrosis. Subsequently, an MRA revealed complete occlusion of the left renal artery. No angioplasty or stent placement was performed, and she eventually required renal replacement therapy. Hypercoagulable testing revealed protein S deficiency. Other serologic work up was negative. She was tested multiple times for COVID19 infection during her hospital stay and each test was negative.

Discussion: The majority of renal thromboembolisms originate as emboli from the heart. Much less commonly, thrombi may form in the renal arteries themselves, especially in those with a hypercoagulable state such as this patient. In light of the recent global COVID19 pandemic, renal artery thromboembolism has gained increased recognition and prevalence. As such, our patient tested negative multiple times for COVID19 as a potential explanation for her hypercoagulable state. Acute renal artery thrombosis should be considered as an explanation for AKI of unknown etiology, especially in those who have underlying risk factors. In the appropriate context, imaging studies should be obtained promptly to prevent permanent kidney injury.

PUB048

Serum Cystatin C as an Early Marker for AKI for Coronary Angiography Patients in a Mexican Population

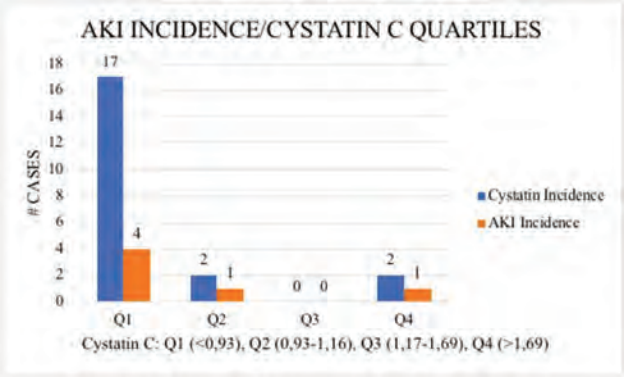
Lilia M. Rizo Topete,[1,2] Francisco J. Alvarado Villarreal,[1] José Ramon Azpiri López,[1] Bernardo Urrutia,[1] Melissa Villegas Mejía.[1] Christus Muguerza Alta Especialidad, UDEM *[1]Hospital Christus Muguerza Alta Especialidad, Monterrey, Mexico; [2]Hospital Universitario "José Eleuterio González" de Monterrey, Monterrey, Mexico.*

Background: Cystatin C is only filtered and metabolized in the kidney, which makes it the ideal marker of kidney function. High sensitivity and specificity for early detection of acute kidney injury (AKI) and contrast induced kidney injury (C-AKI). Early identification of C-AKI after percutaneous coronary intervention may help to change the prognosis of this patients.

Methods: Prospective, observational study, 21 patients, Feb-2020 to Jan-2021. Capillary serum samples prior to contrast administration. Cystatin C was quantified by quantitative immunofluorescence analysis (GETEIN1100). AKI was defined by the KDIGO-AKI criteria. Follow up with creatinine every 24 H for up to 72 H. Primary outcome was to determine the incidence of AKI, secondary outcome was to determine comorbidities and epidemiological risk factors.

Results: From the 21 patients, 14 men (67%), the average age was 63 years. 28.5% had DM, 74.5% HTA, 38.1% ischemic heart disease, and 4.6% had a history of cancer. GFR rate by MDRD was 76.27 ml/min in the group without AKI and 68.7 ml / min in the group with AKI, without statistically significant differences (p= 0.56). There was statistically significant difference between both groups in the serum tests: Cystatin C 1.11 vs 1.20 (p= 0.047), Creatinine at 48h 0.91 vs 1.64 (p= <0.001), Phosphorus 3.81 vs 4.8 (p= 0.024), Glucose 105.86 vs 134.6 (p= 0.021), Cholesterol 178.7 vs 117.7 (p= 0.046), Iron 77.8 vs 45.7 (p= 0.027). It was divided into interquartile groups of cystatin C; Q1 (<0.93 mg / dl), Q2 (0.93-1.16 mg / dl), Q3 (1.17-1.69 mg / dl), Q4 (> 1.69 mg / dl) where the incidence is 23.5%, 50%, in Q3 no data, and 50% respectively.

Conclusions: We founded higher incidence of C-AKI than previously reported. Major risk factors were hyperglycemia, iron deficiency and low cholesterol levels. Cystatin C use must continue to grow, it can be efficiently used as a screening tool in the Cath lab.



PUB049

AKI in Newborns with Infection, Including Sepsis, Detected by Novel Biomarkers

Joycilene d. Barbosa,[1] Luan R. Castelo,[1] Geraldo B. Silva Junior,[2] Gdayllon C. Meneses,[1] Alice Maria C. Martins,[1] Elizabeth D. Daher,[1] Tiago L. Sampaio,[1] Amanda d. Gomes,[1] Paula Roberta de Lima,[1] Nicole C. Lopes,[1] Rosangela P. Machado,[2] Romelia P. Lemes.[1] *[1]Universidade Federal do Ceara, Fortaleza, Brazil; [2]Universidade de Fortaleza, Fortaleza, Brazil.*

Background: Acute kidney injury (AKI) is still poor understood in newborns and hard to detect by traditional means. The aim of this study was to evaluate novel biomarkers in the early diagnosis of AKI in premature newborns (NBs) with infection, including sepsis.

Methods: This is a prospective observational study with 62 NBs admitted to a tertiary hospital in Fortaleza, northeast Brazil, between August 2019 and September 2020. Using serum samples and urine, the biomarkers were measured by ELISA and compared to the determination of AKI by neonatal *Kidney Disease: Improving Global Outcomes* (KDIGO), by urinary output.

Results: No AKI was found by using the traditional biomarkers. CysC levels were 4.78 (1.9 – 25.63) ng/mg-Cr, uCysC 0.64 (0.2 – 2.29) ng/ml; NGAL 27.81 (14.29 – 58.98) ng/mg-Cr; sNGAL 0.85 (0.4 – 1.39) ng/ml; and uNGAL 3.14 (1.74 – 5.51) ng/ml. In the group of sick NBs, the levels of uCysC and uNGAL were associated with a longer period of hospitalization. As a consequence, after combining the two biomarkers, it was possible to observe a poor prognosis in NBs with neonatal infection or sepsis (AUC: 0.783; p = 0.016), Figure 1.

Conclusions: Our study evidenced that uCysC, uNGAL and sNGAL were associated with kidney injury in premature NBs with neonatal infection or early sepsis. Also, there was an association of uCysC and uNGAL with hospital stay time longer than 30 days and the prognosis of NBs.

Funding: Government Support - Non-U.S.

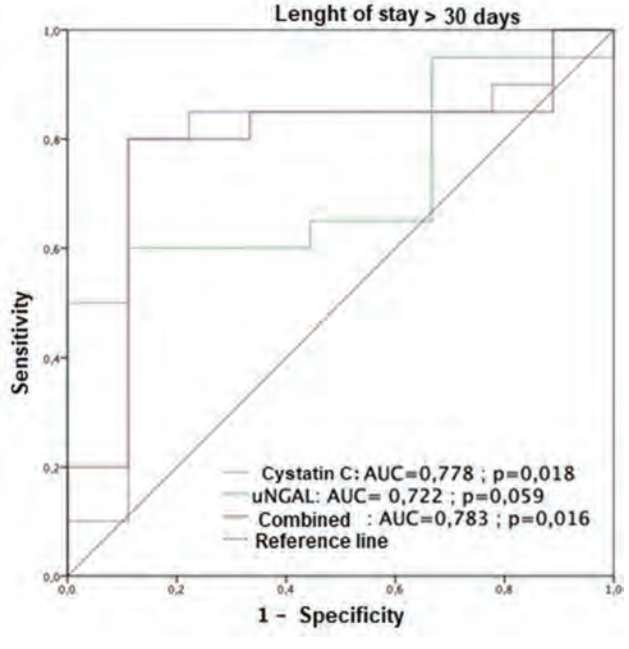


Figure 1. Urinary cystatin C and NGAL sensitivity and specificity for better prognosis for hospital stay time longer than 30 days. uCysC: urinary; uNGAL: urinary lipocalin associated with neutrophilic gelatinase; AUC: area under the curve.

Risk of Clinical Outcomes Following AKI After Major Surgery

Christoph Ohlmeier,[1] Charlie Scott,[2] Sheldon X. Kong,[3] Johannes Schuchhardt,[4] Chris Bauer,[4] Meike D. Brinker,[1] Tatsiana Vaitsiakhovich.[1] *[1]Bayer AG, Berlin, Germany; [2]Bayer Public Limited Company, Reading, United Kingdom; [3]Bayer US LLC, Pittsburgh, PA; [4]MicroDiscovery GmbH, Berlin, Germany.*

Background: Risk of acute kidney injury (AKI) is high among patients undergoing major surgery. Limited evidence suggests that AKI episodes increase the risk of subsequent chronic kidney disease, regardless of the AKI cause. Aim of this study was to investigate clinical outcomes in patients with AKI following major surgery as seen in routine clinical care.

Methods: A retrospective cohort study was conducted in a US claims database (Optum Clinformatics Data Mart) using data from Jan 1st, 2009 to Jul 31st, 2020. Adults with an inpatient AKI diagnosis (index date) and a major surgery during the 30 days prior to the AKI were included and followed-up for a maximum of three years until end of enrolment, death or end of study period. Individuals with CKD stage ≥ 3, end-stage kidney disease (ESKD), dialysis or kidney transplant prior to the index AKI were excluded. The primary outcome was CKD stage ≥ 3. Further kidney and cardiovascular outcomes were investigated. The period of 90 days after index AKI was not used for outcomes identification to allow for kidney function recovery. Outcomes were assessed by time-to-first-event analysis.

Results: In total, 41,134 patients were included in the cohort, mean age was 71.3 years (standard deviation: 11.4); 60.9% were male. Coronary artery bypass graft, open heart surgery with extracorporeal blood circulation and hip replacement were most frequent major surgeries prior to AKI. End of follow-up during the 90-day post-AKI period happened in 9,882 (23.0%) patients with death being the main reason (7,518; 76.1%). 31,252 patients were available for time to event analysis. The 3-year cumulative risk of CKD stage ≥ 3 was 41.2% with the majority of events seen in the first 3 months of outcomes assessment period. The 3-year cumulative risk of all-cause hospitalization, myocardial infarction, stroke, ESKD, dialysis and kidney transplant was 64.2%, 14.4%, 17.7%, 6.6%, 6.2% and 0.2%, respectively.

Conclusions: This study demonstrates that patients experienced AKI are at high risk of subsequent serious clinical outcomes, including CKD stage ≥ 3. The study underlines the high unmet medical need in patients with AKI to prevent CKD, its progression and consequences.

A Case of Neurotoxicity in a Patient with Cefepime-Induced Nephrotoxicity

Danielle Zezoff,[1] Andreea I. Dinicu,[1] Christopher D. Nguyen,[1,2] Emin Zargarian,[1] Ramy M. Hanna,[1] Hoang Anh Nguyen.[1] *[1]University of California Irvine, Irvine, CA; [2]University of Southern California, Los Angeles, CA.*

Introduction: Cefepime-induced neurotoxicity is a phenomenon which may occur due to its ability to cross the blood brain barrier and act as a GABA antagonist. There is an increased risk of neurotoxicity in patients with renal dysfunction. Additionally, there are well documented instances of cefepime-induced nephrotoxicity. We describe an unusual case of a patient with acute toxic encephalopathy with cefepime in the setting of cefepime-induced acute interstitial nephritis.

Case Description: A 79-year-old man was brought in by family with new onset expressive aphasia and confusion which had progressively worsened over the past two days prior to admission. His past medical history was significant for chronic left skull base osteomyelitis currently on the sixth week of an eight-week course treatment of cefepime. His laboratory results were significant for oliguric acute kidney injury (AKI) without significant uremia. On early admission, he was observed to develop truncal and upper extremity choreiform movements with mutism. Then, he progressed to a catatonic like state with upper and lower extremity rigidity and immobility. A lumbar puncture was performed. The analysis of the cerebrospinal fluid was unrevealing and no infectious etiology was identified. Continuous electroencephalogram (EEG) showed nonspecific slowing without epileptiform activity. Microscopic urinalysis showed muddy brown casts suggestive of possible acute tubular necrosis (ATN). A follow-up Gallium-67 radionuclide imaging study confirmed increased bilateral renal uptake suggesting intermediate probability for AIN. Cefepime was discontinued and patient was started on hemodialysis. There was rapid improvement of neurologic symptoms with return to baseline mental status after three rounds of hemodialysis, as well as eventual recovery of renal function.

Discussion: This case illustrates the linked multi-organ adverse effects that may result from cefepime including reversible neurologic and nephrotoxic effects. Early hemodialysis can be considered for rapid symptomatic improvement in instances where neurotoxicity is directly secondary to nephrotoxicity.

PUB052

Interaction of Acute Respiratory Failure and AKI on In-Hospital Mortality of Patients with Acute Exacerbation COPD

Dawei Chen. *Nanjing First Hospital, Nangjing, China.*

Background: Both acute respiratory failure (ARF) and acute kidney injury (AKI) are two common complications in patients with acute exacerbation of chronic obstructive pulmonary disease (AECOPD). Moreover, both ARF and AKI are reported as increasing the risk of mortality of patients with AECOPD. However, the interaction of ARF and AKI

on the mortality of patients with AECOPD remains unknown. Therefore, the aim of this study is to investigate the joint effect of ARF and AKI on mortality in AECOPD patients.

Methods: We performed a retrospective, observational cohort study of data from Nanjing First Hospital. The effect of AKI and ARF on in-hospital mortality was assessed using a multivariate logistic regression model. Additive interaction was assessed with the relative excess risk due to interaction.

Results: 1647 participants were enrolled for analysis. Most (77%) patients were male, and the median age of the overall cohort was 78 years (IQR: 71 - 84). ARF and AKI occurred in 515 (31.3%) and 357 (21.7%) patients, respectively. Overall, in-hospital mortality was 5.7% (94/1647). The in-hospital mortality of the neither ARF nor AKI group, the ARF only group, the AKI only group, and the both ARF and AKI group were 0.8%, 7.0%, 7.5%, and 29.9%, respectively. After multivariate logistic regression analysis, the independent risk factors for in-hospital death included: albumin (OR 0.88, 95% CI 0.83-0.93, $P < 0.001$), ARF only (OR 8.53, 95% CI 3.64-19.99, $P < 0.001$), AKI only (OR 8.99, 95% CI 3.58-22.55, $P < 0.001$), and both ARF and AKI (OR 39.13, 95% CI 17.02-89.97, $P < 0.001$). The relative excess risk due to interaction was 22.62 (95% CI, 0.31 to 44.93), the attributable proportion due to interaction was 0.59 (95% CI, 0.36 to 0.79), and the synergy index was 2.46 (95% CI, 1.44 to 4.20), indicating ARF and AKI had a significant synergic effect on in-hospital mortality.

Conclusions: ARF and AKI were independent risk factors for in-hospital mortality in AECOPD patients. Moreover, those two complications had a synergistic effect on in-hospital mortality.

PUB053

Vanquishing Vancomycin-Associated Acute Interstitial Nephritis

Nolan M. Giehl, Niloofar Nobakht, Jonathan E. Zuckerman. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Introduction: Intravenous (IV) vancomycin is a ubiquitously used antibiotic for a variety of infections that can cause nephrotoxicity. We present a remarkable biopsy-proven case of acute interstitial nephritis (AIN) attributed to supratherapeutic vancomycin levels successfully treated with corticosteroids.

Case Description: A 44-year-old woman monitored by an outpatient parenteral antibiotic therapy (OPAT) program presented with a morbilliform rash 2 weeks after starting postoperative IV vancomycin (goal trough 15-20 mcg/mL) for mastoiditis. Baseline serum creatinine (SCr) was 0.92 mg/dL, which had increased to 3.8 mg/dL on labs through the OPAT program 3 days prior. Her vancomycin trough was notably >80 mcg/mL. Repeated values on admission were 5.27 mg/dL and 74.3 mcg/mL, respectively. Last vancomycin dose was 1 day prior. Urine microscopy showed 1+ protein, 104 white cells and 36 non-dysmorphic red cells. Urine culture and eosinophils were negative, but peripheral eosinophilia was present. SCr nadired to 3.93 mg/dL after IV hydration. A subsequent kidney biopsy showed severe acute interstitial nephritis with eosinophils, concerning for drug-induced AIN. She was started on prednisone 1 mg/kg with eventual taper leading to improved SCr (0.85 mg/dl) after 6 weeks.

Discussion: Acute kidney injury (AKI) in this case was attributed to vancomycin. Interestingly, only 12 biopsy-proven cases of vancomycin-induced AIN have been reported prior to this case. To help mitigate AKI from vancomycin, a vital strategy is monitoring plasma drug levels during therapy because there is a linear relationship between risk of AKI and higher plasma trough concentrations. In this case, OPAT monitoring was imperative in helping to promptly identify kidney injury. The role for steroid therapy remains controversial in AIN, especially drug-induced AIN, with no prospective trials and conflicting evidence from retrospective series. Nevertheless, our case demonstrates how prompt steroid use can improve AKI from vancomycin-associated AIN and may mitigate development of chronic kidney disease and need for kidney replacement therapy.

N-acetylcysteine and Contrast-Induced AKI: An Umbrella Review of Systematic Reviews

William He, Emma Ruzicka, Edward G. Clark, Jennifer Kong, Swapnil Hiremath. *University of Ottawa, Ottawa, ON, Canada.*

Background: There have been numerous trials and metaanalyses of n-acetylcysteine (NAC) in contrast-induced acute kidney injury (CI-AKI). The large trials do demonstrate the futility of NAC. In this umbrella review, we synthesize the evidence as collated from the systematic reviews and metanalyses.

Methods: A literature search was done to identify all systematic reviews on NAC and CI-AKI using databases from inception to end 2020. Two independent reviewers screened the studies and extracted data on including assessment of heterogeneity, publication bias and we used the A MeaSurement Tool to Assess systematic Reviews (AMSTAR 2) to appraise the included studies.

Results: The literature search retrieved 273 citations, of which 42 systematic reviews were eligible. The quality assessment using the AMSTAR-2 was variable (see table) with high quality noted for certain domains (eg explicit question, explanation of study designs), low for others (funding, reasons and list of excluded studies). All studies reported high heterogeneity; 39/42 (93%) performed a meta-analysis, all with an overall benefit with NAC (pooled relative risks range 0.38 - 0.84). 26/42 (62%) reported on the presence of publication bias, and 31/42 (74%) reported the risk of bias. Only 2/42 studies (5%) reported on efforts to resolve heterogeneity did not report a summary effect size as a result.

Conclusions: Systematic reviews can provide misleading results if heterogeneity and publication bias are not taken into account.

AMSTAR Checklist

Critical domain question	N (%) of studies judged as yes
Did the research questions and inclusion criteria for the review include the components of PICO?	42 (100%)
Did the report of the review contain an explicit statement that the review methods were established prior to the conduct of the review and did the report justify any significant deviations from the protocol?	5 (12%)
Did the review authors explain their selection of the study designs for inclusion in the review?	42 (100%)
Did the review authors use a comprehensive literature search strategy?	37 (88%)
Did the review authors perform study selection in duplicate?	27 (64%)
Did the review authors perform data extraction in duplicate?	29 (69%)
Did the review authors provide a list of excluded studies and justify the exclusions?	3 (7%)
Did the review authors describe the included studies in adequate detail?	42 (100%)
Did the review authors use a satisfactory technique for assessing the risk of bias (RoB) in individual studies that were included in the review?	31 (74%)
Did the review authors report on the sources of funding for the studies included in the review?	3 (7%)
If meta-analysis was performed did the review authors use appropriate methods for statistical combination of results?	37 (100%)
Did the review authors assess the potential impact of RoB in individual studies on the results of the meta-analysis or other evidence synthesis?	26 (70%)
Did the review authors account for RoB in individual studies when interpreting/ discussing the results of the review?	25 (69%)
Did the review authors provide a satisfactory explanation for, and discussion of, any heterogeneity observed in the results of the review?	39 (93%)
Did the review authors carry out an adequate investigation of publication bias (small study bias) and discuss its likely impact on the results of the review?	26 (62%)

Nephrologist Interventions to Avoid Kidney Replacement Therapy in AKI

Jonathan Chavez,[1,2] Jorge I. Michel González,[1,2] Andres E. De la torre quiroga,[1,2] Andres Aranda,[1,2] Alexia C. Romero,[1,2] Bladimir Diaz Villavicencio,[1,2] Guillermo Garcia-Garcia.[1,2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: We investigated the impact of 5 early nephrology interventions on starting kidney replacement therapy (KRT), AKI progression and death in AKI patients

Methods: In a prospective cohort, we followed-up for 10 days AKI patients. We analyzed 5 interventions of the nephrology team (fluid adjustment, nephrotoxic withdrawal, antibiotic dose adjustment, nutritional adjustment and removal of hyperchloremic solutions) and multivariate analysis for the risk of starting KRT (primary objective), AKI progression to stage 3 and death (secondary objectives).

Results: We analyzed 288 AKI patients. The mean age was 55.3 years, 60.7% were male, AKI KDIGO stage 3 was present in 50.5% of them, sepsis was the main etiology 50.3%, and 72 (25%) patients started KRT. The overall survival was 84.4%. Fluid adjustment was the only intervention associated with a decreased risk for starting KRT (OR 0.58, 95% CI 0.48-0.70, p = <0.001) and AKI progression to stage 3 (OR 0.59, 95% CI 0.49-0.71, p = <0.001). Receiving vasopressors and KRT were associated with mortality. None of the interventions studied was associated with reducing the risk of death.

Conclusions: In this prospective cohort study of AKI patients, early nephrologist intervention and fluid prescription adjustment was associated with lower the risk of starting KRT and progression to AKI stage 3.

Acute Interstitial Nephritis (AIN): Current Presentation and Therapy Beyond Corticosteroids (CS)

Yonatan A. Peleg, Syeda B. Ahmad, Satoru Kudose, Wooin Ahn, Jai Radhakrishnan, Pietro A. Canetta, Andrew S. Bomback, Gerald B. Appel. *Columbia University Irving Medical Center, New York, NY.*

Background: AIN is most often caused by drugs (DI-AIN) and autoimmune disease (AI-AIN). Many patients (PTS) are treated with CS. There are sparse data on management of relapsing disease.

Methods: 53 PTS with AIN followed at our center between 2010-2020. Median (IQR) are reported. T-Test, Fisher's exact were used as appropriate.

Results: Median age was 55 years (31-64) at diagnosis and 28 (53%) were female. The cohort included 26 (49%) DI-AIN, 20 (38%) AI-AIN, 1 (2%) infection, and 6 (11%) unknown etiology. Antibiotics were the most common drug; Sjogren's predominated AI-AIN. **Table 1** summarizes the clinical course. Serum Creatinine (SCR) at biopsy was higher in DI-AIN. 4 (15%) DI-AIN were dialysis dependent at diagnosis vs. 0 AI-AIN PTS (p=0.12). 44 (83%) PTS received CS as initial therapy, and DI-AIN PTS received shorter courses. 2 (8%) DI-AIN and 6 (30%) AI-AIN reached ESKD (p=0.06) after 66.5 months (mo) (33-97). Among the CUIMC-AIN cohort not reaching ESKD, the follow up SCR was 1.7 mg/dl (0.9-2.1) after 51 mo (20-83). More AI-AIN PTS than DI-AIN PTS received steroid sparing therapy (SST) for relapsing disease. 19 (95%) SST PTS received MMF, and 8 (41%) received more than one SST. 30% of SST PTS reached ESKD after 111.5 mo (44.8-151.25). Among SST patients not reaching ESKD, the follow up SCR 1.8 mg/dl (1.2-2.2) after 60 mo (38-114).

Conclusions: DI-AIN and AI-AIN continue to be the most common forms of AIN. DI-AIN PTS presented with worse renal function but were CS responsive. AI-AIN PTS were more likely to receive SST due to relapsing disease. 70% of SST PTS were with stable CKD after 60 mo. Further study in the role of SST in relapsing AIN is warranted.

CUIMC AIN Cohort: Treatment Response and Outcomes

The Impact of Elective Withdrawal of Long-Term Concurrent RAAS Blockade in CKD Patients Presenting with Progressive AKI: A Prospective 40-Months' Single-Unit Analysis

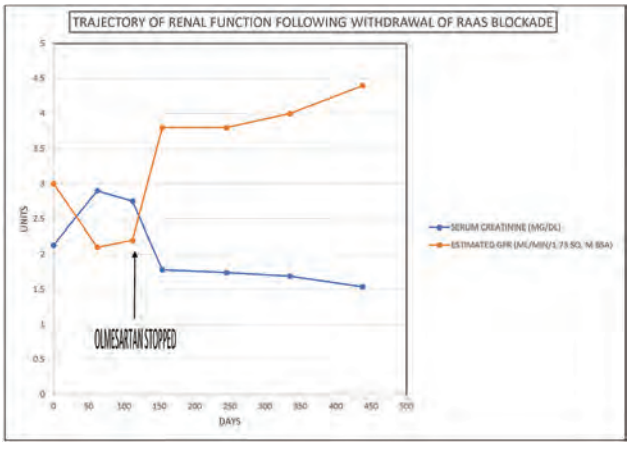
Macaulay A. Onuigbo. *University of Vermont College of Medicine, Burlington, VT.*

Background: There is consensus that RAAS blockade is renoprotective for both diabetic and non-diabetic proteinuric CKD. Nevertheless, there remains considerable debate and controversy regarding renal and cardiovascular (CV) outcomes with discontinuation of concurrent RAAS blockade in advanced CKD. Recent studies demonstrated discordant renal and CV outcomes.

Methods: In a Nephrology Office at the University of Vermont Medical Center, in Burlington, VT, USA, over 40 months, February 2018 – May 2021, concurrent RAAS blockade was electively discontinued in all patients who presented with progressive and >25% increase in baseline serum creatinine. Kidney function of this cohort was followed prospectively.

Results: 71 patients, 69 Caucasians, 1 African American and 1 Hispanic, 42:29 (M:F), mean age 69.4 (37-95) years were treated. Medical co-morbidities included diabetes mellitus (37) and hypertension (66). They were mostly asymptomatic. Lisinopril was commonest agent in 40 (56%) patients. Mean duration of RAAS blockade before discontinuation was 2057 (112-4043) days. Baseline creatinine was 1.38 ± 0.49 (0.66 - 2.7) mg/dL, n=70. Peak creatinine was 2.31 ± 1.09 (1.1 – 8.3) mg/dL, n=67, P<0.0001, t=6.4872, df=135. Nadir creatinine after drug discontinuation was 1.49 ± 0.45 (0.84 – 3.3) mg/dL, n=54, p<0.0001, t=5.1805, df=119. There were 5 (7%) deaths from nonrenal causes. Hyperkalemia in 34 (48%) and hyperphosphatemia in 13 (18%) resolved with improved kidney function.

Conclusions: The elective withdrawal of concurrent RAAS blockade in CKD patients who present with progressive worsening AKI generally demonstrate clearly improved renal outcomes. We posit that in selected CKD patients with progressive AKI such as in our study, RAAS blockade discontinuation indeed is the correct next step in their management for both improved renal and CV outcomes.



Kidney function trajectory after stopping Olmesartan

PUB058

A Case of Acyclovir Neurotoxicity Masquerading as Progression of Zoster Encephalitis

Jonathan Vincent M. Reyes, Arpita Joshi, Dawn Maldonado, Aaron S. Stern, Maritza Brown. *Mount Sinai Health System, New York, NY.*

Introduction: We present a case of varicella zoster virus (VZV) central nervous system infection complicated by acyclovir neurotoxicity.

Case Description: A 53-year-old male with ESRD on hemodialysis presented with acute encephalopathy. He had been diagnosed with VZV labyrinthitis 10 days prior to presentation, and was discharged on oral valacyclovir. He now presents with altered mental status. As the CSF was positive for VZV IgM and his symptoms persisted, this raised concern that his VZV infection was progressing to encephalitis. He was therefore transitioned to intravenous acyclovir for better coverage. However, the patient's encephalopathy did not improve. Acyclovir level was found to be elevated at 4.9 mcg/mL (normal <2 mcg/mL). Acyclovir was then held and he improved – demonstrating that his encephalopathy was most likely due to acyclovir.

Discussion: Valacyclovir is a renally-cleared prodrug of acyclovir. Acyclovir neurotoxicity has been rarely described in literature, and was only first recognized in the 1980s. Symptoms include lethargy, confusion, visual hallucinations, dysarthria, myoclonus and death delusions. The diagnosis is clinical. Studies suggest a temporal association between symptoms and acyclovir administration as patients typically present within 24 to 72 hours; while VZV encephalitis patients present 1 week after the onset of skin eruptions. MRI findings for VZV encephalitis include clustered subcortical plaque-like lesions with rapid demyelination. CSF demonstrates pleocytosis with mononuclear predominance and high protein. The pathophysiology for acyclovir neurotoxicity remains

under investigation. Currently the presumed mechanism is via high concentrations of 9-carboxymethoxymethylguanine (CMMG), a metabolite of acyclovir. Large doses of CMMG may inhibit mitochondrial DNA polymerase and alter mitochondrial function. Hemodialysis serves as the only treatment as the half-life of acyclovir in patients with ESRD can reach up to 20 hours, as compared to 3 hours in patients with normal kidney function. Acyclovir neurotoxicity poses a diagnostic dilemma since VZV encephalitis carries a mortality rate of up to 20%. Recognizing the risk factors and the temporal relationship between acyclovir administration and symptoms will lead clinicians to a timely diagnosis.

PUB059

Severe AKI Leads to Worse Patient-Centered Outcomes in Survivors of Critical Illness

Victor M. Ortiz-Soriano,[1] Kirby Mayer,[1] Joshua Lambert,[2] Javier A. Neyra.[1]
[1]University of Kentucky, Lexington, KY; [2]University of Cincinnati, Cincinnati, OH.

Background: Acute kidney injury (AKI) is a detrimental condition that occurs in about half of critically ill patients. Survivors of critical illness are at high risk of persistent impairments in physical, cognitive, and emotional health, which may be worse in patients who suffered from AKI. The main objective of this study was to evaluate patient-centered outcomes of critical illness survivors who did and did not have severe AKI.

Methods: Retrospective observational study of adult patients surviving an ICU admission due to critical illness who attended outpatient follow-up in the ICU Recovery Clinic at the University of Kentucky. Patients with end-stage kidney disease were excluded. Patients were also excluded if they had an acute neurologic, traumatic, or orthopedic injury that prevented participation in outcomes testing at their follow-up visit. The primary outcomes were distance patient ambulated on the six-minute walk test (6-MWD) and self-reported health-related quality of life (HrQoL) in a visual analog scale ranging from 0 to100 with higher scores indicating better quality of life at 3-month follow-up.

Results: A total of 105 patients were studied. Mean age (SD) was 54.6 (13) years, 53% were male, and 73% white. Sixty-eight (65%) patients had AKI, 46 of them severe AKI (KDIGO stage ≥2). ICU survivors that suffered from AKI stage ≥2 had lower HrQoL scores than those with AKI stage 1 or no AKI (69.1 ± 20.6 vs. 77.8 ± 14, p=0.015) and ambulated shorter distances on 6WMD (195.0 [153.8-285.0] vs. 300.0 [180.0-408.0]293 ± 153 meters, p=0.059). In multivariable regression analyses, older age, longer ICU length of stay, and AKI severity were associated with lower HrQoL scores; while older age and need for tracheostomy were associated with shorter distances achieved on 6-MWD.

Conclusions: Survivors of critical illness who suffered from severe AKI during their ICU stay had increased physical disability and worse quality of life compared to ICU survivors without severe AKI. Critical illness/AKI survivors may benefit from specialized post-ICU care and rehabilitation treatments. Future studies should focus on testing interventions that could ameliorate patient-centered outcomes in this special patient population.

PUB060

High Symptom Burden in Medical ICU Patients with Any Degree of AKI

Sarah Ramer,[1,4] Yulin Yang,[2] Holly G. Prigerson,[2] Khaled Abdel-Kader.[3]
[1]James J Peters VA Medical Center, Bronx, NY; [2]Weill Cornell Medicine, New York, NY; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Icahn School of Medicine at Mount Sinai, New York, NY.

Background: We know little about patients' physical symptoms during acute kidney injury (AKI). Here we provide one of the first descriptions of symptoms in medical intensive care unit (MICU) patients with varying degrees of AKI.

Methods: This is a cross-sectional study from the MICU of an urban teaching hospital conducted 07/2016-01/2019. Study staff obtained informed consent from patients able to provide it or from a proxy (family member / friend) present at the bedside. Study staff then asked the patient or proxy if 12 specific symptoms had bothered the patient in the past 2 days. A nephrologist ascertained the presence and KDIGO stage of AKI at the time of study participation. This analysis excluded patients with end-stage kidney disease or a kidney transplant.

Results: Patient characteristics and symptom prevalence are shown in the table. In a linear regression model adjusting for AKI category, age, sex, race, ethnicity, reporter type, MICU length of stay, mechanical ventilation, and receipt of pressors / inotropes, only patient (rather than proxy) as symptom reporter was significantly associated with total number of symptoms (β=1.6, P<0.01).

Conclusions: MICU patients with any degree of AKI have a high symptom burden. The inability of most MICU patients to report their own symptoms might lead to underestimation of this burden.

Expanded Hemodialysis (HDx) May Improve Inflammation in AKI due to COVID-19 Disease Requiring Renal Replacement Therapy

Giuseppe Gernone. *ASL Bari, Bari, Italy.*

Background: A baseline hyperinflammatory state afflict COVID-19 positive patients (pts). AKI as a final common pathway of systemic inflammation and increased immunologic response leading to uncontrolled circulating levels of pro-inflammatory mediators and direct cytokine-induced organ damage. HemoDialysis expanded (HDx) represents an innovative strategy to remove uremic toxins up to 50 Kda, thanks to the medium cut-off membrane (MCO) and internal convection. Transcription of pro-inflammatory cytokines in peripheral leukocytes is markedly reduced and removal of soluble mediators of inflammation is enhanced by HDx. In vitro studies confirm that HDx limit neutrophil activation by decrease of ROS, TNF-alpha and IL6 and increase of apoptosis. Aim of this study is to evaluate the response to treatment with HDx and HF-HD in AKI due to COVID-19 disease.

Methods: Six pts were enrolled in a retrospective observational study: 3 pts were treated with HF-HD (FX80-Fresenius) and 3 with HDx (Theranova 400-Baxter) during COVID-19 infection. 2 pts treated with HDx and 1 with HF-HD showed hemodynamic instability and need for vasopressors. They were daily assessed using the following: urea, creatinine, C-reactive protein (CRP), procalcitonin (PCT), D-Dimer and Albumin. The values have been reported as mean±SD.

Results: HDx (Qb=218±48 ml/m) discovered in every patient a significant reduction for CRP (-59.7% average) and PCT (-11,2% average), whereas HF-HD (Qb=205±27 ml/m) showed an opposite trend (+69,1% and +39,1% average). Moreover HDx induce a greater reduction of D-Dimer (51.4% vs 19.8% average), Urea and serum Creatinine in comparison to HF-HD (average), (Tab.1) and better hemodynamic stability (Pam 75 vs 67 mm/Hg).

Conclusions: HDx effectively impact on inflammation and renal markers, compared to HF-HD, in COVID-19 positive. HDx, due to the increased clearance of cytokines, has recently been confirmed as a support for COVID-19 positive treatment in some Italian dialysis centers. Our preliminary results has to be confirmed by enlarged studies but in the meantime could help to build a new scientific evidence.

Enhanced Recovery After Surgery (ERAS) Protocol and the Risk of AKI

Adriana Fernandes, Daniel P. Ribeiro, Lidia S. Baptista, Mario R. Raimundo. *Hospital Beatriz Angelo, Loures, Portugal.*

Background: Two of the components of ERAS protocol are the maintenance of euvolemia and the use of multimodal analgesia, which includes NSAIDs. Given the restrictive fluid therapy strategy and the potential use of nephrotoxic analgesics, it's pertinent to assess the risk and potential consequences of acute kidney injury (AKI). The objectives of this study are to assess the incidence of AKI and its outcomes.

Methods: Descriptive and single-center retrospective study. It included the first two hundred adult patients consecutively enrolled for colorectal surgery according to the ERAS protocol. AKI was defined according to KDIGO criteria.

Results: The median age was 71 years (IQ 62-78) and 64.5% of patients were male. The clinical follow-up time was 39 months (IQ 33.8-44.2). Compliance with the ERAS protocol was 81.5% (IQ 71.4-66.5). The median length of stay was 7 days (IQ 5-11). AKI occurred in 23% (46), mostly KDIGO 1 (71.7%). There was a need for renal replacement technique (RTFR) in 8.7%. Patients who developed AKI had a higher median age (76 vs. 70, p<0.001), incidence of diabetes (32.6% vs. 15.6%, p=0.011), hypertension (84.8% vs. 57.8%, p<0.001) and chronic kidney disease (65% vs. 48%, p=0.041). Weight loss in the first 24h was higher in patients who developed AKI (-1.9kg vs. -0.5kg, p=0.010). There was no statistical difference in the administration of NSAIDs. Patients who developed AKI had a greater need for postoperative aminergic support (13% vs. 1.9%, p=0.001) and mechanical ventilation (13% vs. 0.65%, p<0.001). They were more often submitted to laparotomy (41% vs. 25.3%, p=0.036) and exposed to intravenous iodinated contrast (34.8% vs. 17.5%, p=0.012). Patients with AKI had greater need for admission to intensive care (23.9% vs. 9.7%, p=0.019) and lower survival at follow-up (log rank 19.030, p<0.001). None of the patients were dependent of dialysis at discharge. In the first 2 years of follow-up, patients who developed AKI had a more pronounced decline in eGFR (6.3mL/min/1.73m2/year vs. 3.48mL/min/1.73m2/year, p=0.030).

Conclusions: AKI was associated with a worse clinical prognosis with reduced survival. Additionally, the development of AKI negatively influenced the reduction of glomerular filtrate in the first 2 years. Some clinical factors were identified, as age and comorbidities, that may help us to identify patients at higher risk.

PUB063

Renal Surgery and Postoperative AKI Risk in Normal Renal Function Patients: A Hidden Threat

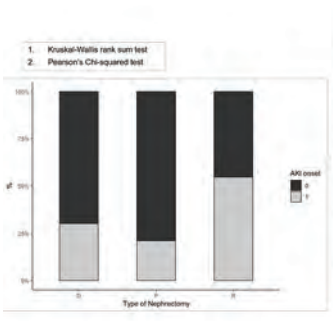
Francesco Trevisani,[1] Federico Di marco,[1] Matteo Floris,[4] Francesco Trepiccione,[2,3] Giuseppe Rosiello,[1] Antonello Pani,[4] Giovambattista Capasso,[2,3] Caterina Vitagliano,[2,3] Giacomo Mascia,[4] Francesco Fiorio,[1] Alessandra Cinque,[1] Arianna Bettiga,[1] Alessandro Larcher,[1] Umberto Capitanio,[1] Andrea Salonia,[1] Francesco Montorsi.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita degli Studi della Campania Luigi Vanvitelli Dipartimento di Scienze Mediche Traslazionali, Napoli, Italy; [3]Biogem, Institute for molecular biology and genetics, Avellino, Italy; [4]Ospedale Giuseppe Brotzu, Cagliari, Italy.*

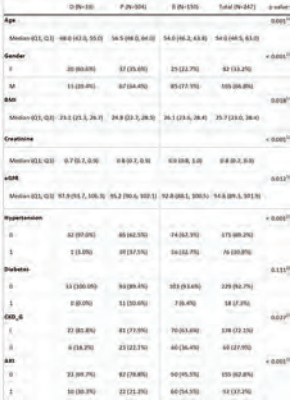
Background: Acute kidney injury(AKI) is a major postoperative complication in renal surgery, both in radical(RN) than in partial nephrectomy(PN). One of the most intriguing arguments is to understand if normal renal function patients(pts) can develop post-operative AKI after renal surgery, both in the oncological and in the living donors' assets. Aim of our study was to compare the AKI incidence in the two major renal surgeries approaches in a selected cohort of pts with normal renal function

Methods: We enrolled a cohort-study of 214 pts who underwent RN or PN due to the presence of a kidney mass suspected of malignancy in a tertiary Institution. A control group of 33 kidney living donors was also enrolled to measure the impact of RN in non-oncological pts. Serum creatinine (s-Cr) values were collected before surgery (t_0), at 48 hours after surgery and at dismissal to detect renal function fluctuations and the subsequent risk of AKI. GFR was estimated at each time point using CKD-EPI 2012 formula. Comparisons between groups were performed using Kruskal-Wallis ranks sum test for numerical variables and Pearson's Chi square test for categorical variables

Results: Descriptive analysis is reported in table1. AKI onset showed a significantly different distribution(p<0.001) between the three groups. In the oncological RN asset the AKI developed in the 55% of pts, whereas in the PN group occurred in 21% of pts. In RN for living donation AKI happened in 30% of pts(Figure1). AKI onset was not significantly correlated with any other variables(Age, Gender, BMI, basal eGFR, Hypertension, Diabetes)

Conclusions: Our study highlights that both radical(55%- 30%) than partial(21%) nephrectomies harbor a non negligible risk of post-operative AKI even in normal renal function patients without renal abnormalities





PUB064

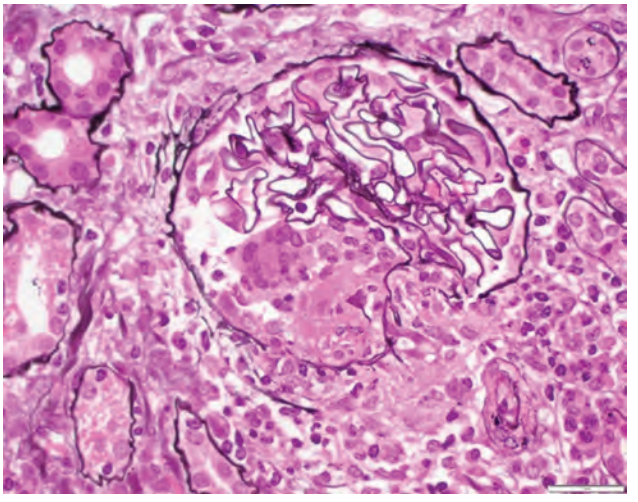
Mind the Gut: Gastric Complications of Immunosuppressive Therapy in a Patient with ANCA Vasculitis

Mariana A. Chang, Revekka Babayev. *Stamford Hospital, Stamford, CT.*

Introduction: Granulomatosis with polyangiitis (GPA) is one of three ANCA-associated vasculitidies which frequently affects the small vasculature of the pulmonary and renal systems. Management has evolved due to several pivotal trials, and recent data from PEXIVAS trial suggests lower prednisone doses maybe just as effective as the higher doses, with fewer complications.

Case Description: A 76-year-old - previously healthy woman presented with shortness of breath and cough. She was treated as an outpatient for presumed atypical bacterial pneumonia without improvement. On admission, she had a RR of 24 and oxygen saturation of 87% on room air and examination revealed crackles in bilateral lung bases. Labs were remarkable for Hgb 7.1 mg/dL and Cr 4.2 mg/dL from a baseline of 1mg/dl. UA showed moderate blood and 100mg/dl protein. On day 2, she developed new-onset hemoptysis. Kidney function deteriorated over the next several days requiring temporary dialysis. She was started on empiric pulse dose steroids and kidney biopsy confirmed severe diffuse crescentic, necrotizing pauci-immune glomerulonephritis with anti-MPO antibody/P-ANCA sero-positivity. She was treated with steroids and rituximab. She continued to have hemoptysis, prompting initiation of plasmapheresis as well as discharge on a 6-month course of prednisone. She was also discharged with GI prophylaxis, which unfortunately she was not taking and she was readmitted 1-month later for gastric ulcer perforation likely as a complication of steroid use, and unfortunately expired.

Discussion: This case outlines the severity and high risk for mortality in patients with GPA. Not only can the associated inflammation itself be fatal but immunosuppression is not without risk; such as the risk for peptic ulcer disease with steroid use as highlighted in this case. Data from trials such as PEXIVAS should be considered.



Renal Biopsy (Jones stain) showing cresecentic glomerulonephritis.

Magnetic Resonance Imaging Contrast Leads to Acute Tubular Damage and Accumulation of Gadolinium-Rich Nanoparticles in Renal Cortex

Joshua Deaguero,[1,2] Tamara A. Howard,[1] Donna F. Kusewitt,[1] Adrian Brearley,[3] John D. Watt,[4,5] G. P. Escobar,[1,2] Brent Wagner.[1,2] Kidney Institute of New Mexico *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Raymond G Murphy Department of Veterans Affairs Medical Center, Albuquerque, NM; [3]The University of New Mexico, Albuquerque, NM; [4]Center for Integrated Nanotechnologies, Albuquerque, NM; [5]Los Alamos National Laboratory, Los Alamos, NM.*

Background: Intravenous administration of gadolinium-based contrast agents leads to long-term gadolinium retention in every vital organ, including the kidney and the brain, regardless of brand. The *safety profile of gadolinium-chelate agents remains the subject of debate.*

Methods: Male and female C57/BL6 mice were randomized by age and weight to GBCA-treatment (Omniscan, 2.5 mmol/kg, intraperitoneally, 20 doses over 4 weeks) or control (n = 20 each). Kidneys were isolated, fixed, sectioned at 200 nm, and supported with carbon holey grids. Scanning electron microscopy and multiple elemental analyses by energy-dispersive x-ray spectroscopy (EDS) were performed using JEOL 2010F FEGSTEM (200kV) microscope and the FEI Tecnai G(2) F30 S-Twin (300kV) transmission electron microscope.

Results: Renal proximal tubule cells of GBCA-treated animals exhibited lipid-laden vacuoles and extensive mitochondrial damage. Spiculated, electron-dense nanoparticles self-assembled in the tubular epithelia of gadolinium-treated animals. The electron densities were rich in gadolinium, phosphorous, and calcium. Gadolinium and phosphorous co-localized within the electron densities.

Conclusions: Systemic magnetic resonance imaging contrast treatment leads to the self-assembly of gadolinium-rich nanostructures in kidney tubular cells. These *in vivo* findings demonstrate that transmetallation is occurring (and this may be a mechanism for the resultant fibrosis) (**Figure**). Speciating the gadolinium-rich precipitates may aid in prophylactic strategies and therapies for gadolinium-induced diseases (including acute kidney injury, gadolinium deposition disease, gadolinium-associated plaques, 'nephrogenic' systemic fibrosis, and gadolinium-induced encephalopathy).

PUB066

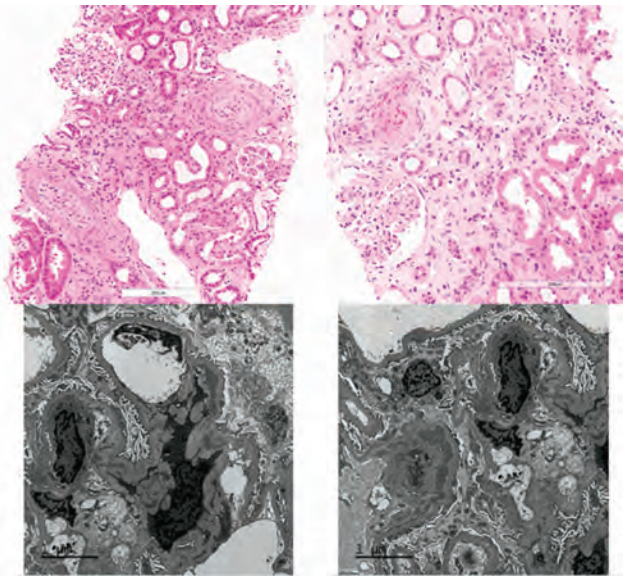
Scleroderma Renal Crisis Sans Scleroderma

Zachary Drury,[1] Adhish Agarwal,[1] Martin C. Gregory,[1] Niraj K. Yadav,[1] Monica P. Revelo Penafiel,[1] Isaac Lloyd,[2] Josephine Abraham.[1] *[1]University of Utah Hospital, Salt Lake City, UT; [2]Intermountain Healthcare, Salt Lake City, UT.*

Introduction: Scleroderma renal crisis (SRC) is an uncommon autoimmune disease that can present with hypertension, acute kidney injury (AKI), proteinuria, hematuria. Rarely is SRC the initial manifestation of scleroderma (scleroderma renal crisis sans scleroderma). We report a case of a patient presenting with SRC complicated by malignant hypertension, thrombotic microangiopathy, and acute kidney injury (AKI).

Case Description: A 47 year old female with four months of headache, blurry vision, and chest palpitations who presented to an outside hospital in hypertensive crisis. Serum Creatinine (Scr) was 1.1 mg/dl initially, however steadily increased to a peak level of 4.46 mg/dl. Urinalysis showed small blood and protein, and spot urine protein to creatinine ratio was 1,412 mg/g. SSA antibody was positive, while SLC 70 antibody and centromere antibody were negative. Serum aldosterone was 60.3 ng/dl and plasma renin activity 43.4ng/ml/hr with aldosterone/renin ratio 1.4. Evaluation for renal artery stenosis was negative. A kidney biopsy showed thrombotic microangiopathy with scattered subendothelial immune complex deposits. The patient was transferred to our facility where her SCr continued to worsen. She was started on lisinopril 2.5mg when her creatinine level was 3.89 mg/dl. SCr stabilized after three days of ACE inhibition.

Discussion: SRC is a medical emergency requiring prompt diagnosis and treatment. Diagnosis can be challenging when this is the initial presentation of scleroderma. SRC should be considered in the differential diagnosis for patients presenting with AKI, new-onset microscopic hematuria, proteinuria, malignant hypertension and thrombotic microangiopathy. ACE inhibition is crucial for patient survival and can lead to renal recovery, which could take as long as 24 months after a renal crisis.



PUB067

Fenofibrate-Induced AKI: An Underrecognized Adverse Effect

Soo H. Kae,[1] Sankar N. Niranjan.[2,1] *[1]UConn Health, Farmington, CT; [2]Greater Hartford Nephrology, Bloomfield, CT.*

Introduction: Fenofibrate is widely used as a second-line agent for hyperlipidemia refractory to statin therapy, especially in the setting of nephrotic syndrome and severe hypertriglyceridemia. There is growing evidence that fenofibrate can cause acute kidney injury (AKI) and that this might be occurring more often than previously thought.

Case Description: 42-year-old male patient with a history of hypertension and hyperlipidemia (predominantly hypertriglyceridemia in the 500-600 mg/dL range) had been on fenofibrate and angiotensin-II receptor blocker (ARB) for 18 months (no recent dose changes) and had a serum creatinine (S Cr) 1.0 mg/dL at baseline. He developed sub-acute kidney injury with S Cr peaking at 2.2 mg/dL over 6 months. He underwent kidney biopsy that showed tubular injury. Possibility of fenofibrate-induced AKI was entertained, as he was not on any other potential nephrotoxic medications. The drug was stopped and renal function returned to his prior baseline within a month. It remains normal and unchanged 9 months after stopping the drug.

Discussion: It is known that fenofibrate can cause fully reversible isolated elevations in serum creatinine by inducing increased metabolic secretion of creatinine. It causes a true AKI by means of rhabdomyolysis, often when used with a statin, and in patients who have other risk factors like chronic kidney disease (CKD). However, there are recent studies showing fenofibrate causing true AKIs evidenced by rise in cystatin C, an independent marker for kidney function, with subsequent decline in glomerular filtration rate (GFR). The exact mechanism of fenofibrate-induced AKI is still not fully understood but one hypothesis is that it impairs the production of renal vasodilatory prostaglandins, leading to renal vasoconstriction, and subsequently causing reduced renal plasma flow and glomerular pressure. Fenofibrate-induced AKI remains an under-recognized adverse effect of the drug. Although there is growing evidence and reports of these incidences, the exact mechanism remains unclear. Further studies showing the effects of fenofibrate on renal tissues at the molecular level are needed to better understand the pathophysiology of renal injury.

Serum creatinine (SCr) trend

Date	5/2019	11/2019	5/2020	7/2020	5/2021

PUB068

Granulomatous Interstitial Nephritis Unrelated to Drug Exposure in a Patient with Ulcerative Colitis

Josean O. Flores Santiago, Juan Carlos Q. Velez, Muner Mohamed. *Ochsner Medical Center - New Orleans, New Orleans, LA.*

Introduction: Granulomatous interstitial nephritis (GIN) has been reported in patients with inflammatory bowel disease (IBD) treated with mesalamine but rarely as inherent manifestation of IBD. Herein, we report a rare case of a young adult with a non-bloody diarrhea and acute kidney injury (AKI) caused by GIN and subsequently newly diagnosed with ulcerative colitis (UC).

Case Description: A 24-year-old man presented to an outside hospital with non-bloody watery diarrhea for 4 months, abdominal pain and unintentional weight loss. No report of voiding disturbance. He was taking no medications. Upon arrival, his vital signs and physical exam were normal. Laboratory data were pertinent for a serum creatinine of 8.0 mg/dL (baseline 0.6 mg/dL), and severe anemia. Urine studies were only relevant for sterile pyuria, no proteinuria. A kidney ultrasound showed no abnormalities. A kidney

biopsy was performed on the 9th day of hospitalization. He was discharged the next day. He presented to clinic 6 days post-discharge with persistent diarrhea. His vital signs and physical examination remained normal. Serum creatinine was still elevated at 7.2 mg/dL. Microscopic examination of the urinary sediment only revealed coarse granular casts. The kidney biopsy specimen revealed a diffuse cellular infiltrate involving 80% of the interstitium**,** 70% interstitial fibrosis with atrophy, acute tubular injury and tubulitis. No glomeruli was present for immunofluorescence. Electron microscopy showed no deposits. Treatment of GIN with prednisone 60 mg qd was begun. After 3 weeks, his serum creatinine improved to 4.8 mg/dL. A colonoscopy showed severe pancolitis consistent with UC and adalimumab and azathioprine were added. Six months later, his serum creatinine value remains at 4.8 mg/dL (eGFR 16 ml/min).

Discussion: GIN is a rare histologic diagnosis that may be the first manifestation of a systemic disease or caused by drugs. GIN causing AKI has been rarely described in therapy-naïve patients with IBD, primarily in Crohn disease. Given the profound inflammation and young age and despite the severe chronicity in the biopsy specimen, the patient was treated with immunosuppressive therapy (IST). IST was later escalated to treat the UC lesion. Drug-naïve IBD should be listed as potential cause of GIN.

PUB069

Post Coronary Angiography Cholesterol Embolization Syndrome Resulting in Atheroembolic Renal Disease

Ravi Thakker, Anand Kumar, Abdul-Rehman Syed, Anjali Muraleedharan, Shancy Jacob. *The University of Texas Medical Branch at Galveston, Galveston, TX*.

Introduction: Cholesterol embolization syndrome (CES) has been characterized as being a multi-system disease resulting from embolization of cholesterol crystal from atherosclerotic plaque of large arteries to small class arteries resulting in organ insult. A poorly recognized subgroup of CES is atheroembolic renal disease (AERD) or renal CES which accounts for a considerable subgroup. We present a case of a 69-year-old female who developed renal CES after undergoing coronary angiography.

Case Description: Our patient was a 69-year-old female with past medical history of chronic kidney disease stage 3, diabetes mellitus, hypertension, and heart failure with ejection fraction 40-45%, coronary artery disease, and chronic obstructive pulmonary disease who presented with progressive dyspnea and lower extremity edema for several months. Two months prior to this admission she had undergone coronary angiography. Her initial creatinine was 1.28 mg/dL. Over the next two months her creatinine up trended to 2.93 mg/dL. The inciting factor was initially attributed to acute kidney injury secondary to over diuresis. On examination the patient looked euvolemic but continued to have dyspnea despite diuresis. Right heart catheterization was performed to better assess volume status which demonstrated normal filling pressures. Laboratory results were notable for persistent eosinophilia. In the context of recent contrast, rising eosinophilia, and normal filling pressures a renal biopsy was performed which demonstrated acute tubular injury, arterionephrosclerosis, and cholesterol emboli. Despite medical management, the patient's renal function did not recover.

Discussion: Our patient's initial presentation was concerning for decompensated heart failure with a possible cardiorenal insult. Post-diuresis instead of having improvement in her dyspnea and acute kidney injury, she continued to decompensate. Further complicating her presentation was recent contrast exposure for coronary angiography and rising eosinophilia. Biopsy ultimately showed cholesterol emboli that most likely dislodged post catheterization and caused acute tubular injury. The teaching point of our case is to consider atheroembolic renal injury irrespective of coronary angiography timing in patients with preexisting cardiac and kidney disease non-responsive to medical therapy.

PUB070

Checkmate? A Rare Case of Immune Checkpoint Inhibitor-Related AKI

Steffi Sathiyaraj, Daniel Varela, Leonardo Pozo Garcia, Sergio A. Trevino Manllo. *The University of Texas Rio Grande Valley, Edinburg, TX*.

Introduction: With the advent of Immune checkpoint inhibitors (ICPIs) used in cancer therapy, there has been improved prognosis in various malignancies; however, with the use of these novel class of drugs, there has been a rise in associated immune-related adverse events reported, including acute kidney injury (AKI). ICPI-associated AKI is an emerging entity and in this case we highlight one such ICPI, Nivolumab, an antibody directed against programmed death-1, causing renal dysfunction.

Case Description: An 80-year-old man with renal cell carcinoma with baseline creatine of .58 mg/dl (RCC) was referred to Nephrology services to evaluate AKI, with serum creatinine 2.3mg/dl, found in routine labs. The patient received immunotherapy with Nivolumab every four weeks. Urinalysis revealed no active sediment and renal ultrasound remarkable for solid mass in the left kidney, consistent with previous imaging of his RCC. The patient was diagnosed with Nivolumab-induced immune tubulointerstitial nephritis. At the time of presentation, the immunosuppression was placed on hold, and he was started on steroids. His kidney function gradually improved to serum creatinine of 1.3 mg/dl, with the withdrawal of Nivolumab and initiation of steroid therapy.

Discussion: In this case, we highlight an instance of Nivolumab-induced AKI, which poses a unique diagnostic and management challenge to clinicians due to lack of clinical awareness in the account of the rarity of such immune-related side effects. With the rise in the use of new novel biologic agents, a multidisciplinary approach is essential so that clinicians can make a timely diagnosis when there is a high suspicion. Prompt discontinuation and early steroid therapy institution is crucial in management and can prevent further kidney injury or potential chronic kidney disease.

PUB071

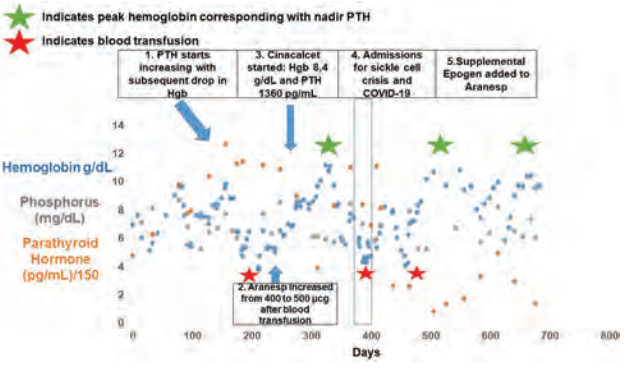
Severe ESA Resistance Reversed by Cinacalcet in a Hemodialysis Patient with Sickle Cell Anemia

Peter N. Van Buren, Shani Shastri. *The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX*.

Introduction: Hematologic diseases such as sickle cell disease (SCD) complicate anemia of end-stage renal disease (ESRD). Hyperparathyroidism is another etiology of ESA resistance that can cause irreversible bone marrow fibrosis. We present a case of severe anema in a SCD patient on hemodialysis (HD) that dramatically improved with cinacalcet.

Case Description: The patient is a 28 year old Black man with SCD and ESRD from FSGS on thrice weekly HD. His anemia had been treated with hydroxyurea and high dose subcutaneous Aranesp (400 µg every 2 weeks) with a mean hemoglobin (Hgb) of 6.4 (1.4) mg/dL over several years. He developed worsening hyperparathyroidism on phosphate binders and vitamin D. Despite stable Aranesp doses, Hgb decreased until a blood transfusion was needed. Aranesp was increased to 500 µg every 2 weeks with some increase in Hgb. After starting cinacalcet, parathyroid hormone (PTH) decreased (1390 to 593 pg/mL), and Hgb further increased (8.2 to 11.2 mg/dL). Intermittent nonadherence to cinacalcet led to PTH variability until hospital admissions for sickle cell crisis and then COVID-19. Afterwards, PTH was more consistently suppressed. Following day 500, supplemental Epogen was given in addition to Aranesp, but Hgb increased only when PTH was most suppressed. During the first year on cinacalcet, there was a strong inverse correlaton between Hgb and PTH (r=-0.6, p=.001). Figure 1 shows the Hgb, phosphorus, and PTH (divided by 150 to simplify y-axis) where Hgb peaks correspond to PTH nadirs.

Discussion: We demonstrate a case of severe anemia from both ESRD and SCD where Hgb dramatically improved with cinacalcet. We acknowledge that Aranesp increases preceded the initial Hgb rise, but Hgb peaks following PTH suppression exceeded any prior levels. These Hgb peaks were reproducible and sustained whenever PTH suppression was achieved. This case demonstrates that some hyperparathyroidism-related ESA resistance may be reversible and supports how important control of bone mineral disease is in specific populations of HD patients that are susceptible to severe anemia.



PUB072

Addition of Roxadustat to Erythropoiesis-Stimulating Agent (ESA) Effectively Corrects ESA-Hyporesponsive Anemia in Peritoneal Dialysis Patients

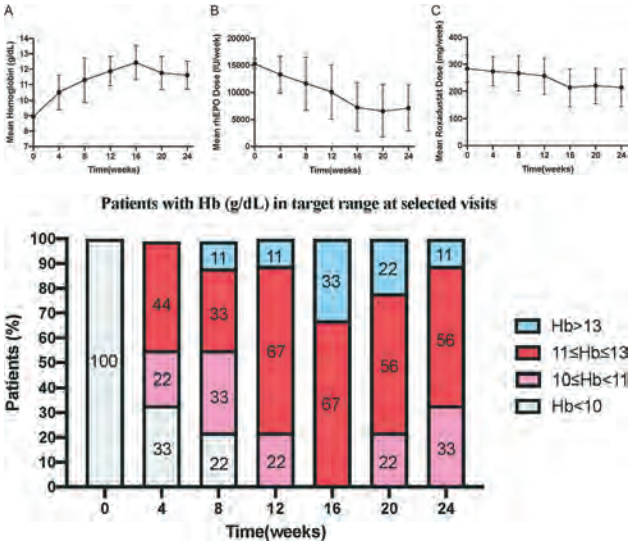
Shuqi Dai, Chuan-Ming Hao. *Huashan Hospital Fudan University, Shanghai, China*.

Background: Erythropoiesis-stimulating agent (ESA) hyporesponsiveness is an important cause for the undertreatment of anemia. This study aimed to investigate the effectiveness and safety of adding HIF-PHI (roxadustat) to ESA for the treatment of ESA-hyporesponsive anemia in Peritoneal Dialysis (PD) patients.

Methods: This was a single-center prospective-designed study in PD patients of Huashan Hospital, Fudan University. Patients with ESA-hyporesponsive anemia were enrolled from January 2020 to April 2020 with a 24-week follow-up period. Patients were added with roxadustat at a starting dose of 50 or 100 mg thrice weekly without changing the ESA dose. Roxadustat and ESA dose adjustments were made as needed to maintain Hb levels within 11.0–13.0 g/dL. Efficacy outcomes and safety were assessed.

Results: A total of nine patients were recruited in the study. Both the cumulative responsive rate and the maintenance rate of patients with Hb>11g/dL were 100%. Six out of nine patients had ESA dose reduced from 15,000 UI/week or more to 7000 IU/week or less at week 24. No drug-related severe adverse event was reported in this study.

Conclusions: The present study showed that the addition of roxadustat not only effectively corrected anemia in patients who were resistant to ESA, but also reduced the dose of ESA.



PUB073

Hypercalcemia Secondary to Silicon Injections (Granulomatous Disease): Case Report

Syed Aown,[1] Benjamin J. Wilcox.[1,2] *[1]Lehigh Valley Health Network, Allentown, PA; [2]Valley Kidney Specialists PC, Allentown, PA.*

Introduction: Hypercalcemia is a relatively common clinical problem. Among all the causes of hypercalcemia, primary hyperparathyroidism and malignancy are most common. Other less common causes include granulomatous diseases (tuberculosis and sarcoidosis), milk alkali syndrome, immobility, medications and familial hypocalciuric hypercalcemia. We Have seen a case of hypercalcemia secondary to silicone injections leading to granulomatous inflammation.

Case Description: 39 y/o F with a history of Sjogren's disease (+ ANA 1:80 cytoplasmic, 1: 2,560 speckled, +SSA/SSB + sicca symptoms), recurrent hypercalcemia, malnutrition, history of silicone injections (gluteal), at age 19, who presented to the hospital with facial swelling and found to have hypercalcemia (calcium 17, ionized calcium 1.89, serum albumin 2.3). On examination she had severe soft tissue changes in her bilateral legs, ankles, buttocks and hips. Initial differential was malignancy, primary hyperparathyroidism and soft tissue tumor. Work up consistent with elevated 1,25-Vit D(280), ACE (77; nml 9-67), PTHrP (11.3; nml 0.0-3.4) and PTH was found to be appropriately suppressed (<6.3; nml 18.5-88). CT Scan reveal marked edema gluteal region bilaterally, pelvic wall, perineum and proximal thighs due to foreign body granulomatous/silicone injections. There was no evidence of malignancy on CT scans. She had no clinical signs of sarcoidosis. She has been treated with IVF, pamidronate, and calcitonin, with minimal improvement of her calcium levels. She continues to have recurrent hypercalcemia requiring steroids and repeat treatment with pamidronate, despite extensive excisional debridement of silicone implants.

Discussion: Our patient diagnosed with the granulomatous disorder secondary to silicon injections as the etiology of hypercalcemia. This is supported by her low parathyroid hormone (PTH) level and high (1,25) dihydroxy vitamin D level. Her Skin and soft tissue fragments from debridement/excision showed foreign body (silicone) granulomas, associated scarring and dystrophic calcification. Cosmetic filler injections are known to cause several acute and chronic effects, including local inflammation, nodule formation, and granulomatous reaction. Treatment includes steroids, bisphosphonates, and the removal of implants. Hypercalcemia may persist, and long-standing low dose steroid recommended to maintain calcium and kidney function.

PUB074

Lack of Testing, Urgency to Treat, Consensus, and Concrete Guidelines All Contribute to Subpar Management of Secondary Hyperparathyroidism and Vitamin D Insufficiency for Non-Dialysis Patients with CKD

Jennifer Robinson, Skylar Malone, Tucker B. Hurtado. Spherix Advanced Analytics Group *Spherix Advanced Analytics Group, Exton, PA.*

Background: During October and November 2020, we conducted an independent, retrospective patient chart audit of 1,030 non-dialysis patients with CKD (eGFR<60) who were most recently seen by their nephrologist (n=183). The purpose of this study was to understand the real world patient presentation and treatment priorities for non-dialysis CKD patients as it pertains to the management of CKD MBD.

Methods: Using a HIPAA-compliant, online chart review tool, nephrologists submitted de-identified clinical and non-clinical demographic information beginning at the time of patient referral and concluding with details from the most recent visit. These data were then merged with the physician demographic profile and attitudinal responses. The full data set was analyzed in SPSS.

Results: When asked about their top interest in nephrology, only 6% selected bone and mineral metabolism/SHPT; respondents were most interested in glomerular diseases, AKI, and diabetic kidney disease. At the time of first referral, 38% of patients had a 25,D level in their chart and 36% had an iPTH level. At the most recent visit, only slightly more than half of the patients had at least one measure for 25,D and iPTH. Among patients treated with active vitamin D (AVD), more than half (57%) had increases in the serum calcium level and 7% had a level of at least 10.0mg/dL at last measure. Importantly, among patients currently prescribed AVD, 31% did not have a iPTH test in the past 12 months. Among treated patients with a iPTH test, 19% had a level >300pg/dL. Unlike the use of AVD, which increases as renal function declines, treatment with nutritional vitamin D (NVD) is more consistent across stages, with 46% of patients being treated; at referral, more than one-in-five are already on NVD (vs. just 2% for AVD). Similar to AVD testing patterns, there are gaps in follow-up testing. Furthermore, treatment patterns reveal that AVD is often added to the NVD regimen instead of a switch, resulting in about half of the AVD-treated patients also on NVD. Less than 10% of NVD-treated patients achieve a 25,D level of 50ng/mL, despite that, 28% have iPTH levels >100.

Conclusions: Improved monitoring of 25,D and iPTH among CKD-ND patients could lead to better outcomes.

PUB075

Use of Alkaline Phosphatase as a Bone Marker in Patients on Hemodialysis

Jessica Kachmar,[1] Caroline Albert,[2] Marie-Eve Dupuis,[3] Michel Vallee.[3] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Some patients on hemodialysis may suffer from high turnover bone disease despite having levels of parathormone (PTH) within the targets set by KDIGO. Recent international guidelines suggest the use of other bone markers, such as serum total and bone-specific alkaline phosphatase (TALP and BALP respectively). The caveat of using TALP to assess bone turnover status is that other conditions, such as hepatic cholestasis, also cause increases in TALP. We can, however, use it as an alternative to BALP as long as gamma-glutamyl-transferase (GGT) is normal. Though it would generally be expected that PTH and TALP move in the same direction with changes in bone turnover, these two markers can sometimes evolve in opposite directions. Our study aimed to evaluate the correlation between PTH, TALP and BALP.

Methods: Cross sectional study including all patients on hemodialysis at the Hôpital Maisonneuve-Rosemont from May 9, 2019 to June 7, 2019 (N=264 patients). We measured PTH, TALP and BALP in these patients and correlation coefficients were calculated. Regression analyses were performed for multiple potential confounding factors.

Results: The correlation between PTH and TALP was found to be positive and moderate (Rho 0.36; p-value < 0.0001). It was not statistically significant in patients having high GGT levels (above 60 IU/L) and was stronger in patients with normal GGT (Rho 0.40; p-value < 0.0001). The correlation between PTH and BALP was also positive and moderate, but stronger than with TALP (Rho 0.43; p-value <0.0001) and statistically significant even in patients having high GGT levels. The correlation between TALP and BALP was positive, strong and statistically significant (Rho 0.86 ; p-value <0.0001) ; it was stronger when GGT levels were normal compared to patients with high GGT levels (Rho 0.94 and Rho 0.71 respectively).

Conclusions: There is a positive correlation between PTH and TALP but it is only moderate. It is thus important to take into consideration TALP in patients with normal GGT levels when evaluating the bone status of patients on hemodialysis.

Correlation coefficients for all patients and stratified by GGT level

		All patients (N=264)		Patients with normal GGT levels (≤60 IU/L) (N=237)		Patients with high GGT levels (>60 IU/L) (N=27)	
		Rho	p-value	Rho	p-value	Rho	p-value
PTH	TALP	0.36	<.0001	0.40	<.0001	0.31	0.1156
PTH	BALP	0.43	<.0001	0.42	<.0001	0.48	0.0116
TALP	BALP	0.86	<.0001	0.94	<.0001	0.71	0.0003

PUB076

Intravenous Paricalcitol Treatment in Chinese Hemodialysis Patients: A Real-World Database Analysis

Niansong Wang. *Shanghai Sixth Peoples Hospital, Jiaotong, China.*

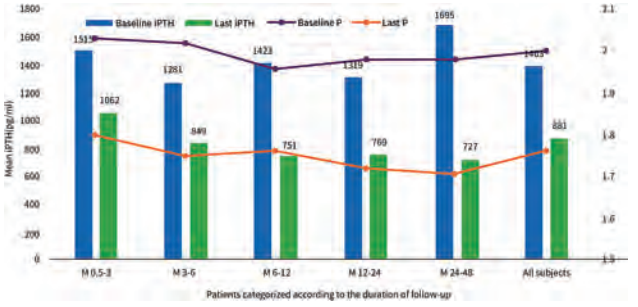
Background: The aim of this analysis based on the real-world database was to observe the effect of paricalcitol on blood calcium and phosphorus and the safety profile in Chinese hemodialysis patients with secondary hyperparathyroidism under routine clinical practice.

Methods: A total of 668 Chinese hemodialysis patients from 104 dialysis centers between 2015 and 2019 were included. Intact parathyroid hormone (iPTH), total serum calcium (Ca), phosphate (P), dosage of paricalcitol (Zemplar®) were analyzed via retrospective analysis of the database during the treatment.

Results: Patients were divided into five groups according to the duration of follow-up. Median iPTH levels decreased from 1183 pg/ml at baseline to 676 pg/ml at the final visit, or 30.88% (p < 0.0001). Serum Ca levels shown significantly increased just in the group of Month 12–24 (P=0.0479). The incidence of hypercalcemia for three consecutive laboratory draws was significantly lower than the incidence of hypercalcemia for two consecutive laboratory draws in all groups (0.5-3 months 0.49% vs 2.96%, respectively,

3-6 months 0.49% vs 4.88%, 6-12 months 4.00% vs 8.00%, 12-24 months 4.00% vs 20.00% and 24-48 months 2.10% vs 5.99%, respectively). Subgroup analyses of patients with hyperphosphatemia showed a rapid phosphate reduction, within the first few weeks, along with the reduction in the iPTH level.

Conclusions: This is the first national retrospective real-world observational study since intravenous paricalcitol is available in China since 2014. This study adds valuable information to real-world data investigating the use of paricalcitol in Chinese hemodialysis patients and demonstrated the use of paricalcitol as an effective and well-tolerated treatment for the control of PTH during its use in routine practice. The occurrence of hypercalcemia is mostly transient, followed by continuous treatment, the blood calcium level tends to be stabilized, and the blood phosphorus level will be improved with the control of PTH.



PUB077

Paricalcitol in Hemodialysis Patients with Secondary Hyperparathyroidism: A Long-Term Case Report

Haoxiong Chen. *Guangzhou First People's Hospital, Guangzhou, China.*

Introduction: A case analysis of a HD patient with SHPT was performed, who was in paricalcitol treatment for 72 months, to provide a reference for SHPT management.

Case Description: A 67-year-old female HD patient had calcitriol 0.25 ug qd since 2014. On April 2015, biochemical indexes were Ca 2.02 mmol/L, P 2.1 mmol/L, iPTH 810.1 pg/ml, ALP 88 U/L, without significant abnormality in Parathyroid ultrasonograpy. While Coronary CT showed high-density calcified plaque in the left anterior descending branch, with a calcium score of 39. Then, she discontinued calcitriol and initiated Paricalcitol (Zemplar®) treatment (Detailed treatment regimen and indexes variations in Figure 1). On Month 24, iPTH level decreased to 176 pg/ml (78%), and the left anterior descending artery calcium Agatston score was 51. During Month 24-48, iPTH were 150-500 pg/mL, with stable Ca and P levels in normal range. On Month 72, the left anterior descending calcium Agatston score was 115 and a total calcium score of 147 (CT Images in Figure 2).

Discussion: Paricalcitol can selectively activate VDR especially in parathyroid, to correct the CKD-MBD and prevent cardiovascular events. In this long-term case, we have seen its efficacy and safety in SHPT treatment, especially in controlling the risk of vascular calcification. There is still a lack of data on the clinical application of paricalcitol for long-term use in China, Further studies are needed to confirm its benefit, and to explore best dosage for preventing vascular calcification in dialysis patients.

PUB078

A Missing Key or Faulty Lock: Use of an Alternative Vitamin D Analog Opens the Door to Success

Linda-Marie U. Lavenburg, Ryan Spiardi, Sandeep Aggarwal, Yonghong Huan. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Secondary hyperparathyroidism is a complication of chronic kidney disease and characterized by high FGF-23 with low levels of 1,25-$(OH)_2$-vitamin D due to low renal 1α-hydroxylase activity. Doxercalciferol requires 25-hydroxylation by the liver, a step preserved in end-stage kidney disease (ESKD), but may be subject to genetic polymorphisms that determine responsiveness. We present a case of secondary hyperparathyroidism resistant to high dose doxercalciferol but responsive to calcitriol.

Case Description: A 76-year-old man with ESKD due to diabetes on thrice-weekly hemodialysis with uncontrolled secondary hyperparathyroidism (intact parathyroid hormone (iPTH) 1348 pg/mL) was started on a calcium-based phosphate binder and doxercalciferol 1 mcg IV three times a week. Doxercalciferol was titrated to 20 mcg three times a week, an equivalent calcitriol dose of 19 mcg/week, but his secondary hyperparathyroidism remained poorly controlled (iPTH 732 pg/mL, corrected calcium (cCa) 8.0 mg/dL, phosphorus (P) 5.1 mg/dl). He had normal liver function and did not take CYP3A4 inhibitors. He was changed to calcitriol 0.5 mcg daily with dramatic improvement over three months (iPTH 247 pg/mL, cCa 9.2 mg/dL, P 3.3 mg/dL).

Discussion: We highlight the use of an unusually high dose of doxercalciferol (60 mcg per week) resulting in suboptimal iPTH and calcium response. This dose is significantly higher than the annual mean IV doxercalciferol dose of 112 mcg per patient (~2 mcg per week). Our patient had a rapid reduction in iPTH and normalization of cCa using a relatively low dose of calcitriol. Unlike calcitriol, doxercalciferol lacks a 25-OH group requiring activation by hepatic 25-hydroxylase. A deficiency, or loss of function in this key enzyme, is a rare polymorphism seen in vitamin D dependent rickets type 1B, usually treated with 25-OH-vitamin D, but needs 1α,25-$(OH)_2$-vitamin D in ESKD. Alternatively, genetic variation of the vitamin D receptor-ligand binding domain may reduce its affinity for some vitamin D analogs. Clinicians should suspect potential polymorphisms at fault when high doses of vitamin D analog are used with inappropriate response. We recommend switching vitamin D analogs and consider genetic testing. Characterizing vitamin D receptor protein polymorphisms may influence prescribing practices of vitamin D analogs in the future.

PUB079

Persistent Severe Hyperparathyroidism After Parathyroidectomy

Tammy Yu, Jie Tang. *Brown University Warren Alpert Medical School, Providence, RI.*

Introduction: Parathyroidectomy is the definitive treatment for secondary hyperparathyroidism (SHPT) refractory to medical management. We report a case of persistent severe hyperparathyroidism after subtotal parathyroidectomy in a hemodialysis patient.

Case Description: A 35-year-old male with ESRD on HD due to idiopathic membranous nephropathy presented with progressive fatigue and bone pain. PTH was 3709 pg/ml, Phos 9.7 mg/dl, Ca 10 mg/dl, and ALKP 919 IU/L in the setting of noncompliance with his medications, including cinacalcet, calcitriol, and sevelamer. He was transitioned to IV etelcalcetide given at HD, but had poor response, with PTH levels between 2000-4000. After discussion, he opted for parathyroidectomy. Preoperative

sestamibi scan demonstrated a focus of increased uptake in the lower right thyroid lobe without evidence of ectopic uptake. Intraoperatively, the bilateral inferior parathyroids appeared nodular and were removed. Surgical pathology confirmed nodular hyperplasia. The normal-appearing left superior gland was autotransplanted to a subcutaneous pocket. Despite extensive exploration of the retroesophageal space and carotid sheath, the right superior gland could not be located, so a right thyroid lobectomy was performed. Intraoperative PTH (ioPTH) levels were 2612 pg/ml before resection, 519 pg/ml 10 minutes post-resection, and 560 pg/ml at 20 minutes. The patient had severe postoperative hypocalcemia which responded well to calcium supplementation. However, by post-operative day 8, his PTH had rebounded to 2524 pg/ml.

Discussion: Persistent hyperparathyroidism has been defined as PTH elevation developing within 6 months of surgery despite adequate ioPTH drop. Prior case series have attributed this to the presence of missed ectopic or supernumerary glands, although the unmasking of ectopic PTH secretion is a process that typically takes weeks to months. Despite an initial >75% reduction in ioPTH after 10 minutes, our patient's rapid return to preoperative PTH levels is atypical, and is concerning for the concurrent development of tertiary HPT in his residual parathyroid tissue. These observations suggest that a history of longstanding secondary HPT may lead to poorer outcomes after parathyroidectomy.

PUB080

Hospitalization Is Related to Osteoporosis in CKD Patients: Data from the Brazilian Registry of Bone Biopsy (REBRABO)

Cinthia E. Carbonara, Célia R. Pavan, Kelcia Rosana da Silva Quadros, Rodrigo B. de Oliveira. LEMON - Laboratory for Evaluation of Mineral and Bone Disorder in Nephrology *Universidade Estadual de Campinas Departamento de Clinica Medica, Campinas, Brazil*.

Background: Mineral and bone disorder (MBD) is related with chronic kidney disease (CKD) and associated with significant morbidity and mortality. REBRABO database contains clinical, laboratorial and histological information about Brazilian CKD patients with MBD. The relationship between the type of renal osteodystrophy (RO) and clinical outcomes is unclear.

Methods: This is a national, observational and prospective clinical study. Clinical, demographics, laboratorial and bone histology data were collected from CKD patients between Aug/15-Dec/18. Patients were followed by five years and clinical outcomes such as bone fractures, hospitalization and death were registered.

Results: Data from 179 patients who were submitted to bone biopsy were analyzed. Patients aged 52±12 years, 93 (52%) men and 80 (45%) white; 133 (85%) patients were under hemodialysis treatment. Serum intact parathormone, alkaline phosphatase, calcium, and phosphate levels were 456 (63-514) pg/mL, 174 (73-205) IU/L, 9.2±1 mg/dL and 5.0±1.7 mg/dL, respectively. Osteitis fibrosa, mixed uremic osteodystrophy, adynamic bone disease, osteomalácia and osteoporosis occurred in 69 (39%), 39 (22%), 59 (33%), 7 (4%) and 82 (47%), respectively. The average follow-up time was 1,318 days; during follow-up 19 bone fractures, 61 hospitalizations and 47 deaths were detected. However, diagnosis of osteoporosis was related with hospitalization (p=0.03).

Conclusions: Osteitis fibrosa was the most prevalent type of RO in our sample. A high prevalence of osteoporosis was detected and related with increased hospitalization. Type of RO apparently is not related with outcomes.

PUB081

A Case of Tumor-Induced Osteomalacia (TIO) with Paradoxical Fibroblast Growth Factor 23 (FGF-23) Response After Surgical Excision

Shab E Gul Rahim,[1] David L. Epstein.[1,2] [1]*Weill Cornell Medicine, New York, NY;* [2]*Rogosin Institute, New York, NY.*

Introduction: FGF-23's role in TIO and renal phosphate wasting in mesenchymal & certain other tumors is increasingly being identified. We present a case of TIO in a patient with End Stage Renal Disease (ESRD) & on hemodialysis (HD) whose FGF-23 remained elevated despite normalization of phosphorus (Phos) levels after surgical excision of tumor, raising a question if there are other yet unidentified tumor associated factors affecting phosphorous levels in these patients.

Case Description: A 59 year old male with ESRD status post renal transplant followed by allograft failure after 3 years, gradually progressing to Chronic Kidney Disease stage V, presented with oliguria & was restarted on hemodialysis. Hospital course was complicated by episodes of severe hypophosphatemia (Phos < 1.5) despite aggressive repletion. Pertinent lab work included: corrected calcium 9.5-10.5 mg/dl, ionized calcium 1.1-1.2 mmol/L & PTH 268 pg/ml. He developed blurry vision & was found to have a fourth ventricle mass in brain. FGF-23 came back elevated at 2303 (measured via manual enzyme-linked immunosorbent assay by Quidel Corporation) & TIO was suspected. After surgical excision of the tumor, serum Phos normalized. Over the course of next 2 to 3 days, patient developed hyperphosphatemia, as expected in patients with ESRD. However, interestingly FGF-23 level, in contrast to returning to normal as would be expected with the tumor excision, increased 5 times. 10 days later, FGF-23 was found to have increased to 11,120. At this time, serum Phos ranged between 3.6-4.5 as patient was receiving HD 3 times a week. Repeat CT head showed some residual calcification within the resection cavity raising the possibility of residual tumor however minimal only. MRI brain could not be done as patient clinically deteriorated in the setting of septic shock & died. Pathology of the tumor mass was consistent with both ependymoma & subependymoma.

Discussion: TIO is thought to be caused by FGF-23 released by tumor cells that cause phosphate wasting. Our case is unique as serum Phos normalized post tumor excision but FGF-23 continued to rise raising the possibility of yet unidentified tumor associated factors that might be involved in Phos homeostasis. Based on the FGF-23 response in our patient, we also hypothesize that FGF-23 might not be a useful tumor marker in ESRD patients.

PUB082

Normocalcemic Hyperparathyroidism in Calcium Kidney Stone Formers

Eric W. Tang,[1,2] Jie Tang.[3,2] [1]*Harvard College, Cambridge, MA;* [2]*Lifespan Health System, Providence, RI;* [3]*Brown University Warren Alpert Medical School, Providence, RI.*

Introduction: Primary hyperparathyroidism is a strong risk factor for calcium kidney stone (CKS) formation. However, the kidney stone effect from normocalcemic hyperparathyroidism have not been described. Here we present a case series of six recurrent CKS formers who had elevated plasma parathyroid hormone levels with normal serum calcium.concentration. All of them underwent nuclear imaging of the parathyroid gland showing features consistent with parathyroid adenoma and underwent subsequent resections of the adenoma. We compared pre- and post-operative 24-hour urine calcium (UC) and phosphorus (UP) standardized by urine creatinine, as well as changes in kidney stone burden assessed 2-12 months after the surgery. All patients included in this report were instructed to maintain their diet before and after the surgery.

Case Description: Of these six stone formers, three were men, and the mean age was 60 years. All had vitamin D deficiency with normal serum 1,25-$(OH)_2$-vitamin D. Two had hypertension. Two others had dyslipidemia. Of the three who had DEXA scan performed, all had osteopenia. Mean serum calcium was 9.8 mg/dl, mean serum phosphorus was 3.0 mg/dl. Five had baseline 24-hour UC >240 mg (median 309 mg), one had normal 24-hour UC (186 mg). 24-hour UP ranged from 663 mg to 1672 mg. None of them were prescribed with thiazide diuretics, calcium containing supplements or medications that could affect phosphorus absorption during the study period. After partial parathyroidectomy, mean serum calcium reduced by 0.75 mg/dl, mean serum phosphorus increased by 0.1 mg/dl, and neither serum 25-(OH)-vitamin D nor 1,25-(OH)2-vitamin D changed significantly (mean, -0.8 ng/ml, +0.7 pg/ml, respectively). For the urine studies, two had increases in UC (mean 61 mg, 18%), four had reductions in UC (mean -23mg, -9%). One had an increase in UP (349 mg, 53%), five had reductions in UP (mean -244 mg, -19%). Of the five patients who had kidney ultrasound performed before and 2-12 months after the surgery, four had increases in the post-operative stone burden (mean +43%), one had a 100% reduction.

Discussion: In this small case series, normocalcemic hyperparathyroidism did not appear to have a consistent effect on the risk of calcium kidney stone formation.

PUB083

Misregulation of Interstitial Matrix Fiber Patterning in a Model of Stromal Cell Abnormalities

Sarah N. Lipp,[1,2] Kathryn R. Jacobson,[1] David S. Hains,[2] Andrew L. Schwaderer,[2] Sarah Calve.[3,1] [1]*Purdue University, West Lafayette, IN;* [2]*Indiana University School of Medicine, Indianapolis, IN;* [3]*University of Colorado Boulder, Boulder, CO.*

Background: Murine kidney interstitial extracellular matrix (ECM) is a network of proteins and glycosaminoglycans outside cells. The ECM forms intricately patterned fibers in the developing kidney capsule, vertically aligned in the cortex, and surrounding the medullary rays. Forkhead box D1, $(Foxd1)^+$ cells synthesize interstitial matrix and are required for kidney stromal cell patterning of the nephron; however, the role of *Foxd1* in interstitial ECM fiber patterning has not been investigated.

Methods: Murine embryonic day (E)18.5 *Foxd1* knockout ($Foxd1^{-/-}$) and phenotypically normal littermate controls ($Foxd1^{+/-}$) kidneys were decellularized with sodium dodecyl sulfate, fixed and stained for ECM proteins, and rendered in 3D.

Results: Vertical fibers were abnormally, perpendicularly aligned relative to the branching nephron in $Foxd1^{-/-}$ kidneys (open arrow), suggesting *Foxd1* is important for stromal cell orientation of interstitial ECM (Figure 1). However, the organization of capsule and fibers around the medullary ray sheath was maintained when compared to $Foxd1^{+/-}$ controls.

Conclusions: Kidney interstitial ECM dramatically changes with development. Abnormalities in the vertical fibers in the $Foxd1^{-/-}$ mouse correlate with the loss of the nephrogenic zone, suggesting the fibers are involved in nephron morphology development.

Funding: Other NIH Support - 1DP2AT009833-01 to SC

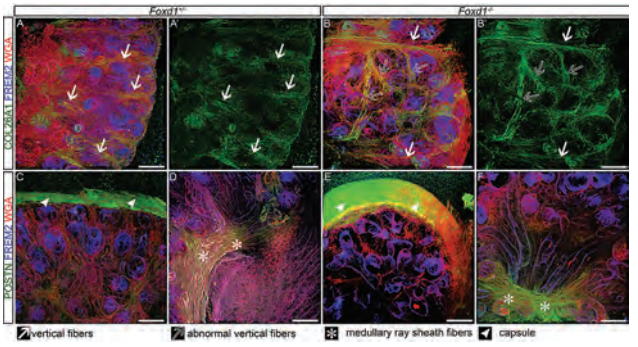

Figure 1: *Foxd1* knockout alters vertical fiber orientation, but capsular and medullary ray sheath fibers were maintained. (A-A′) Control kidneys showed vertical fibers (closed arrow) (green = COL26A1) aligned parallel to the developing nephron (FREM2 = blue, WGA = red). **(B-B′)** In the *Foxd1*$^{-/-}$ kidney, the vertical fibers (closed arrow) were present, but some vertical fibers were abnormally perpendicular to the nephron (open arrow). **(C-F)** POSTN^{+} (green) capsular fibers (arrowhead, C-D) and medullary ray sheath fibers (*, E-F) appear retained in the *Foxd1*$^{-/-}$ kidney. Scale bar = 100 μm. 25× confocal z-stacks 590 × 590 × 171 μm (A-B′), 57 μm (C-F).

PUB084

Adipose-Derived Regenerative Cells Treatment of Injured Kidney Organoids

Rachanchai Chawangwongsanukun,[1,2] Rashida Lathan,[1] Patrick B. Mark.[1] *[1]University of Glasgow Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; [2]Mahidol University, Salaya, Thailand.*

Background: Adipose derived regenerative cells are a heterogeneous cell population that include mesenchymal stem cells (ADRCs) and are derived from adipose tissue. Previous studies showed that ADRCs have beneficial effects of an anti-oxidative activity, an anti-inflammatory activity, and an anti-apoptotic activity. Reactive oxygen species (ROS), inflammation, and apoptosis play a deleterious role in injured kidney repair. Therefore, we hypothesis that ADRCs will aid in the repair of the injured kidney.

Methods: Kidney organoids were assigned into four groups including non-injury (control), injury, ADRCs-treated in non-injury and ADRCs-treated in injury groups. Injured kidney organoids were induced by exposure to 10 μM hydrogen peroxide for 60 minutes.

Results: Kidney organoids in this study, ADRCs-treated injured kidney organoids had significantly larger diameter than injured kidney organoids (p=0.014).

Conclusions: ADRCs showed a positive effect by increasing or maintaining the diameter size of organoids. ADRCs show promise as a therapy of injured kidney organoids.

Funding: Government Support - Non-U.S.

Urine-Derived Stem Cells Attenuate Renal Inflammation and Fibrosis After Renal Ischemia Reperfusion

Dae Eun Choi,[1] Jin young Jeong,[1] Jin Ah Shin,[1] Yoon-Kyung Chang,[2] Kiryang Na,[1] Kang Wook Lee.[1] *[1]Chungnam National University School of Medicine, Daejeon, Daejeon, Republic of Korea; [2]Daejeon Saint Mary's Hospital, Daejeon, Daejeon, Republic of Korea.*

Background: After renal IRI, regeneration and recovery of the renal tubular cell occurs. However, if the renal repair process is maladaptive, it progresses to renal fibrosis. The role of stem cells in kidney regeneration or fibrosis has not been fully elucidated. we evaluated the urine drived stem cells(UDSC) for renal inflammation and fibrosis after renal ischemia reperfusion(IR).

Methods: 10 week old balb/c nude male mice were used. sham, sham with UDSC, sham with adipose drived stem cell(ADSC), IR, IR with UDSC, IR with ADSC. UDSC and ADSC were infused 1 times via tail vain 7 day After renal IR. Urine NGAL/creatinine(Cr) were checked. The kidneys were harvested at day 14 day. for. *in vitro* fibrosis model, HK2 cell were treated with TGF beta. Co-culture of UDSC and ADSC were performed. Molecular and histologic study were performed.

Results: Urinary NGAL/Cr were significantly increased in IR mice after 14 day IR, compared to sham mice. Urinary NGAL/Cr significantly decreased in UDSC treated IR mice, compared to IR and ADSC treated IR mice. we confirmed UDSC migrate into renal tubular area after 2 weeks renal IRI. In H&E and PAS stain, renal tubulo interstitial injury were significantly decreased in UDSC treated IR mice, compared to IR and ADSC treated IR mice. In masson trichrom stain, renal fibrosis area were were significantly decreased in UDSC treated IR mice, compared to IR and ADSC treated IR mice. The renal expression of MCP-1, ostemopontine, TGF beta, alpha SMA, collagne IV, and F4/80 positive cellswere significantly decreased in UDSC treated IR mice, compared to IR and ADSC treated IR mice. in vitro, alpha SMA, collagen IV, smad 2/3 were significantly increased in TGF beta treated HK2 cells. co-culture of UDSC decreased the alpha SMA, collagen IV, smad 2/3 in TGF beta treated HK2 cells. however, co-culture of ADSC did not decreased the alpha SMA, collagen IV, smad 2/3 in TGF beta treated HK2 cells.

Conclusions: UDSC ameliorate renal inflammation and fibrosis after renal IR.

PUB086

Effects of Açai on the Inflammatory Response of NLRP3 in Experimental Diabetes Mellitus

Deyse Y. Lima, Robson S. Serralha, Angela Bertolini, Lucas Ferres, Margaret G. Mouro, Manoel V. Silva, Giovana Punaro, Elisa M. Higa. Laboratory of Nitric Oxide and Oxidative Stress *Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.*

Background: Inflammatory factors associated with innate immunity, such as Nod-like receptors, constituents of the NLRP3 inflammasome complex has been linked to the development and progression of diabetic nephropathy. Recent research in our Laboratory showed that açai extract (EA, *Euterpe oleracea*), a tropical fruit from Amazon with high antioxidant capacity, rich in polyphenols, exhibited also an anti-inflammatory activity, through the modulation of NF-kB/Nrf-2 system in a diabetes mellitus (DM) model, in cultured cells. The aim of the present study was to analyze the effects of EA on the inflammatory response of NLRP3 in experimental DM.

Methods: Human immortalized mesangial cells (HiMC) were grown in DMEM 10% FBS according to the groups: normal glucose (NG, 6.7 mmol/L), high glucose (HG, 30 mmol/L) or mannitol (osmotic control). HiMC in HG medium were treated with EA (500, 100 or 50 μg/mL). Cell viability and proliferation were determined by MTT after 72 hours and protein content of NLRP3 by Western Blot. In male adult Wistar rats DM was induced by streptozotocin (60mg/ kg, i.v.); control rats (CTL) received the drug vehicle. Both groups were treated with EA 200mg/kg BW, diluted in water, via gavage

for 8 weeks. The rats were euthanized and the kidneys stored at -80°C. We analyzed the metabolic profile, nitric oxide (NO, for nitrosative stress), TBARS (an indirect measure of oxidative stress, OS) and renal function in plasma and urine. The results were described as mean ± SE, $p < 0.05$.

Results: Viability was 100% in all HiMC groups; there was a significant increase in cell proliferation and in NLRP3 expression in HG group, which were reduced with EA. In DM rats EA reduced glycemia and normalized other metabolic parameters, in addition to improving renal function and OS analyzed after 3 days, 4 and 8 weeks of treatment, being the more prolonged treatment, more effective. The histology analysis showed that EA reduced structural lesions of the renal cortex such as diffuse sclerosis and glycosidic degeneration, in DM animals.

Conclusions: The consumption of EA could contribute to a better control of OS associated with the reduction of inflammatory factors, suggesting the importance of these bioactive compounds as non-pharmacological adjuvants, to delay the complications in diabetic patients.

PUB087

Pentoxifylline in Diabetic Kidney Disease (VA PTXRx): Protocol for a Pragmatic Randomized Controlled Trial

David J. Leehey,[1] Rajiv Agarwal,[2] James S. Kaufman,[3] Kimberly Carlson.[4] *[1]Edward Hines Junior VA Hospital, Hines, IL; [2]Richard L Roudebush VA Medical Center, Indianapolis, IN; [3]VA New York Harbor Healthcare System, New York, NY; [4]Edward Hines Junior VA Hospital Cooperative Studies Program, Hines, IL.*

Background: Diabetic kidney disease (DKD) is the most frequent cause of end-stage renal disease (ESRD) in the U.S. and worldwide. Recent experimental and clinical data suggest that the non-specific phosphodiesterase inhibitor pentoxifylline (PTX) may decrease progression of kidney disease. However, a large-scale randomized clinical trial is needed to determine whether this agent can reduce ESRD and death in patients with DKD.

Methods: VA PTXRx is a pragmatic, randomized, placebo-controlled multicenter Veterans Affairs (VA) Cooperative Study to test the hypothesis that PTX, when added to usual care, leads to a reduction in the time to ESRD or death in type 2 diabetic patients with DKD when compared to usual care plus placebo. The study aims to enroll 2510 patients over a 4-year period with an additional up to 5-year follow-up to generate a total of 646 primary events. The primary objective of this study is to compare the time until ESRD or death (all-cause mortality) between participants randomized to PTX or placebo. Secondary endpoints will be: (1) Health-related quality of life, (2) Time to doubling of serum creatinine, (3) Incidence of hospitalizations for congestive heart failure (CHF), (4) Incidence of a three-point major adverse cardiovascular events (MACE) composite (cardiovascular death, non-fatal myocardial infarction, non-fatal stroke), (5) Incidence of peripheral vascular disease (PVD), (6) Change in urinary albumin-to-creatinine ratio (UACR) from baseline to 6 months, (7) Rate of annual change in estimated glomerular filtration rate (eGFR) during the study period. **Ethics and Dissemination:** This study was approved by the VA Central Institutional Review Board (cIRB) (ID: 1382143) and will be conducted in compliance with the Declaration of Helsinki and the Guidelines for Good Clinical Practice. The Hines Cooperative Studies Program (CSP) will finalize the study results, which will be published in accordance with the CONSORT statement in a peer-reviewed scientific journal. **Trial Registration:** This study is registered with clinicaltrials.gov (Identifier: NCT03625648)

Results: Study enrollment began in November 2019. Through April 2021, 146 patients have been randomized during the ramp-up phase of the study.

Conclusions: PTX is a readily available, safe, and inexpensive medication which might be effectively repurposed to treat DKD.

Perceptions of Care Coordination During and After Hospitalization Among Patients Receiving In-Center Hemodialysis

Christian Park,[1] Courtney E. Hoge,[1] Ann E. Vandenberg,[1] Bernard G. Jaar,[2] Janice P. Lea,[1] Laura Plantinga.[1] *[1]Emory University, Atlanta, GA; [2]Johns Hopkins University, Baltimore, MD.*

Background: In the United States, 34% of hospital discharges among patients receiving dialysis are followed by a 30-day unplanned readmission. As part of an ongoing pilot study (DialysisConnect), we examined the perceptions of patients receiving hemodialysis (HD) regarding care coordination between providers at the hospital and dialysis clinic.

Methods: Our study targeted all 113 patients receiving in-center HD who were being treated at one of four dialysis clinics and had been hospitalized at a single hospital in Atlanta, Georgia, in the prior 6 months. We administered a one-time survey about their care coordination during their hospitalization episode and used descriptive statistics to summarize the results.

Results: Respondents (n=24, 21% response rate) had an average age of 62 years, 100% were Black, 46% were male, and on average patients had been receiving HD for 4 years; non-respondents were similar in terms of demographics. The percentages of patients who reported that their hospital and dialysis providers knew key information or performed care coordination tasks during and after hospitalization were generally high (Figure). Most patients reported that hospital providers asked about their reason for hospital stay (79%), dialysis schedule (75%), symptoms (75%), current medications (71%), vascular access (67%), nephrologist name (67%), dialysis facility name (54%), and/or dry weight (50%). Only half (48%) brought discharge instructions to the next outpatient HD session.

Conclusions: Most patients (62-91%) perceived that both hospital and dialysis providers were aware of the patient's clinical situation and had exchanged necessary clinical information, which might discourage patients from actively engaging in their own care coordination. Future efforts to improve coordination of care between dialysis clinics and hospitals should target not only providers in both settings but also patients and their healthcare surrogates.

Leptin Levels and Appetite Score in Patients on Hemodialysis Using High Flux or Medium Cut-Off Membranes

Rachel G. Armani, Lidia D. Silva, Aluizio B. Carvalho, Silvia R. Manfredi, Renato Watanabe, Maria Eugenia F. Canziani. *Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.*

Background: Chronic kidney disease (CKD) patients on hemodialysis may have a modified appetite due to several factors including a lack of uremic toxins elimination. The use of new dialysis membranes, such as medium cut off (MCO) has been suggested as an alternative to improve the removal of toxins, especially those of medium and high molecular weight. This study aimed to evaluate if the use of the MCO membrane would decrease toxin levels, particularly leptin and improve the appetite of CKD patients on hemodialysis program.

Methods: This is a pre-defined exploratory analysis of a randomized, open study, with a crossover design of 28 weeks of follow-up, which compared the effects of MCO and high flux membranes in 32 CKD patients on hemodialysis. Appetite assessments were performed using the Appetite and Food Satisfaction Questionnaire (AFSQ).

Results: The high-flux group had an appetite score of 3.25 ± 3.62 and 2.80 ± 3.14 at the beginning and at the end of treatment period, respectively, and the MCO group 3.62 ± 3.21 and 3.26 ± 3.28. There were no effects of treatment ($p = 0.573$), time ($p = 0.376$) and interaction ($p = 0.770$) between the high-flux and MCO groups. Leptin levels, at the beginning and at the end of the treatment period, were 2.47 ± 1.57 and 2712,72 ± 1.54 ug/L in the high-flux group and 2.45± 1.65 and 2.78 ± 1.62 ug/L in the MCO group, respectively. There was a time effect ($p = 0.014$), showing an increase in leptin levels in both Groups, while treatment ($p = 0.771$) or interaction ($p = 0.218$) effects were not observed.

Conclusions: There is no difference between the effects of MCO or high flux membranes on leptin levels or appetite of CKD patients in hemodialysis during the study.

Can Restoration of Heart Rate in ESRD Lower Brain Natriuretic Peptide?

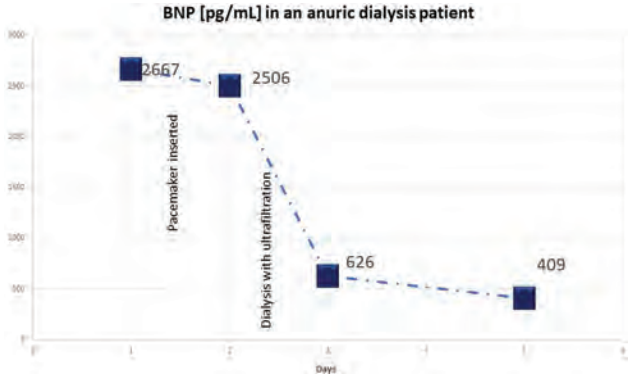
Mahmoud M. Mohamed,[1] Joel Raja,[1] Atif Ibrahim,[1] Hafiz Muhammad Ali Raza,[1] Barry M. Wall,[1,2] Mihaly B. Tapolyai.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Introduction: Brain Natriuretic Peptide (BNP), is predominantly produced by the left ventricular (LV) myocytes. BNP's production is triggered in response to stretch of the left ventricular myocytes by either increased volume or pressure within the LV cavity. Elevation of BNP is induced by bradyarrhythmia and high degree atrioventricular blocks. We describe a case of a dialysis-dependent patient presenting with complete heart block with an elevated BNP from his baseline and review whether correcting the rhythm problem resulted in correction of his BNP.

Case Description: 98 yr old male with ESRD receiving maintenance hemodialysis presented with shortness of breath and decreased heart rate. He reported shortness of breath on ambulation but denied chest pain, increased swelling, or any other symptoms. Heart rate (HR) was 40 bpm and blood pressure 138/52 mm Hg. Electrocardiogram (ECG) revealed a complete heart block. the chest x-ray did not reveal any acute cardiopulmonary abnormalities. BNP was 2667 pg/ml. Cardiac pacing pads were placed in the Intensive Care Unit while planning for permanent pacemaker placement. He remained hemodynamically stable with HR in the 30s-40s bpm and a dual-chamber pacemaker was placed 24 hr later. Symptoms of dyspnea improved after the procedure with a paced rhythm of 60 bpm. BNP repeated 90 min after the procedure remained

elevated, 2506 pg/ml. The patient underwent a hemodialysis session with ultrafiltration to his usual estimated dry weight and BNP decreased to 626 pg/ml. Repeat BNP after two more dialysis sessions was 409 pg/ml.

Discussion: Our patient provided a unique opportunity to differentiate between the effects on BNP of an improved cardiac output with restored cardiac rhythm versus changes in intravascular volume. This case demonstrates that this anuric patient's rhythm restoration was not sufficient to lower BNP values, while ultrafiltration did. Thus, we seem to be able to confirm that, it is solely the volume status that affects BNP value, not the cardiac rhythm or cardiac output.



PUB091

Temporal Changes in Physiology During Inpatient Hemodialysis Sessions

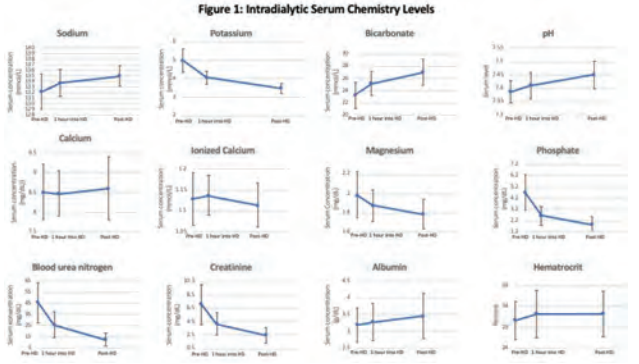
Katherine M. Scovner,[1,2] Caroline Espersen,[1,2] Katherine Curtis,[1,2] Elke Platz,[1,2] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Patients receiving maintenance hemodialysis (HD) in the United States have an average of 1.6 admissions per year (>700,000 inpatient HD sessions). Little is known about the temporal changes in laboratory values, ECGs, and volume status during HD sessions in these vulnerable patients.

Methods: We performed a prospective cohort study (n=30) of hospitalized HD patients to measure serum laboratory concentrations (electrolytes, blood gases, and ionized calcium levels), ECGs, and ultrasonographic measures of volume status (8-zone lung images for the number of B-lines and internal jugular vein diameter) pre-, one hour into, and post-HD during one inpatient HD session. Ultrasound images were analyzed offline by a core imaging laboratory blinded to clinical information and imaging time point.

Results: The mean age of participants was 62 years. 53% were male and 43% were Black. Serum chemistry levels were dynamic, with the most rapid changes occurring within the first hour for all biomarkers (Figure 1). The median increase in QTc duration on ECG (post-HD QTc minus pre-HD QTc) was 7.5 [-5-19] msec. Though the sum of pulmonary B-lines decreased from pre- to post-HD (median decrease: 5 [1-6.5], p=0.02), internal jugular vein diameter did not change (p=0.73).

Conclusions: Among hospitalized patients undergoing HD, there are dynamic changes in serum chemistry parameters, QTc durations, and volume status during their HD sessions. Further research is required to assess how variations in these changes during HD are associated with clinical outcomes and whether HD prescriptions can be tailored to optimize patient care.



PUB092

Predictors of Mortality in Hemodialysis Patients in a Large Dialysis Network in India

Suresh Sankarasubbaiyan, Venkatraman Ganapathi Subraman, Mallikarjuna Gowda B. Gowda, Vikram A. Sonawane, Kamal D. Shah, Kaparaboina K. Kumar, Satyanarayana R. Puvvada, Mohammad S. Husain. *Nephroplus, Hyderabad, India.*

Background: Mortality of HD pts is influenced by age, cormorbidity, dialysis, facility and socioeconomic factors. With much unknown regarding MHD mortality in India, we aimed to study the incidence and factors predicting mortality in a large dialysis network in India

Methods: Consecutive deaths, Jan 1 to March 31, 2021 in a HD network were reviewed for age, gender, HD freq, vascular access, Hb, comorbidity, MHD duration, payer type, eductional status, and BMI. An age stratified matched control was used to comparefactors using t test and Chi sqaured test. Bianry logistic (uni & multi) was used to identfy risk factors associated with death. Significance: 5%. SPSS ver 26 was used

Results: 797(4.8%) deaths occured among 16516 patients. Table 1 shows pt characteristics. Simple logistic regression: Tier III city, ↓ education, <6 mon HD, public Insurance, ↓ Hb, temporary access, Kt/v <1.2, Alb <3.5, DM, h/o MI and hospiltalization <3 mon had significant OR (not shown). Multiple logistic regression showed OR for illiteracy: 2.7 (1.7-4.4), secondary school: 1.7 (1.1-2.5), public insurance 2 .3 (1.3-3.8), <1 mon on HD: 2.3 (1.3-4.4), temporary catheter:1.7 (1.3-2.7), Alb <3.5 g%: 2 (1.3-3.8), ↓ Hb 2.9 (1.5 -5.9), DKD: 1.5 (1.1-2), HD in PPP centre: 2.1 (1.3-3.2) and hospitalizations <3 mon: 4.7(3.3-6.6) were significant.

Conclusions: Mortaltiy is high in MHD pts in India and is associated with temp access, ↓ alb, ↓ Hb, recent hospitlization, DM, ↓ education & public Insurance status.

A Multicenter, Retrospective, Observational Study of Dialysis Facility-Level Hyperkalemia Burden in China: Rationale and Design of the Visualize-HD Study

Xinju Zhao, Li Zuo. *Peking University People's Hospital, Beijing, China.*

Background: Hyperkalemia (HK) is a deadly complication in patients (pts) undergoing hemodialysis (HD), accounting for about 1/4th of emergent dialysis treatment. Excess mortality and hospitalization have been associated with HK, especially after the long (2-day) interdialytic interval (LIDI) in thrice-weekly HD pts compared with the short (1-day) intervals. Research on disease burden, risk factors and association of HK and mortality in Chinese pts is scanty.

Methods: This multicenter (300 HD centers), observational study will involve Chinese patients with chronic HD from eastern, central and western parts of China (except Hong Kong, Macao and Taiwan) (**Figure 1**). HD centers having >100 chronic pts (≥3 months on HD) within 3 years before study initiation, participation willingness, having routine blood collection post LIDI and death records will be included. Pooled data (at HD facility-level) about pts characteristics, sK levels, dialysis prescriptions on facility practice patterns, and death records will be collected retrospectively.

Results: The primary and secondary endpoints will be to examine the association between suspected risk factors and HK-proportions and to describe HK burden respectively. Suspected risk factors include dialysis and sK testing frequency; patient characteristics and medication usage. The constitution ratio of different sK levels after LIDI will be collected [(0-3.5), (3.5-5), (5-5.5), (5.5-6), (6-6.5), (6.5-7), (>7.0) mmol/L] to calculate the HK (≥5 or 5.5 mmol/L) burden. Meanwhile, we propose to explore crude mortality rates association with HK-proportions. Final results are planned to be released in 2022.

Conclusions: The results of Visualize-HD will generate contemporary evidence to fill epidemiological research gaps of HK in Chinese HD pts and explore risk factors associated with HK disease burden.

PUB094

Predicted Rebalancing of Sodium in a Sorbent Dialysis System

Tzu Tung Chen, Brandon D. Borrillo, Osman Khawar, Clayton Poppe. *Diality Inc, Irvine, CA.*

Background: The Diality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: To test sodium ion rebalancing in a 125L circulating volume over 270 minutes using a predicted alkali infusion to maintain a Na concentration of approx. 140 mEq/L.

Methods: A 125 L volume of dialysate was circulated at approx. 400 mL / min & 37 C through a sorbent filter. It is expected that with each pass through the filter the dialysate will be depleted of electrolytes and sodium [Na] and pH will lower. Dialysate is refurbished with an additional infusion of Ca, Mg and K salts. Based upon the predicted [Na] profile another pump will infuse an alkali solution at a varying rate to maintain the final [Na] at approx. 140 mEq/L. The experiment is continued until breakthrough occurs or the infusate outlet reaches 10 ppm of NH_4.

Results: The [Na] over 270 mins are depicted in table 1. TP1, the [Na] of the dialysate taken prior to passing through the sorbent filter after leaving a stirring tank containing 150L of dialysate was 137.9 – 143.4 mEq/L. TP2, the [Na] in the fluid upon leaving the filter was an average of 129.5 mEq/L ranging from 119.1 – 136.0 mEq/L. TP3, the [Na] in the dialysate after refurbishing with an alkali solution prior to reentering the stirring tank was an average of 139.3 mEq/L ranging from 138.1 – 143.4 mEq/L.

Conclusions: The results validate the ability to maintain dialysate sodium balance over the dialysis period using a sorbent filter while refurbishing dialysate with a predicted alkali infusion.

Funding: Commercial Support - Diality Inc

Bicarbonate and pH Maintenance in a Sorbent Dialysis System

Brandon D. Borrillo, Tzu Tung Chen, Osman Khawar, Clayton Poppe. *Diality Inc, Irvine, CA.*

Background: The Diality Hemodialysis Machine is designed for a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One of the modalities uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: Demonstrate bicarbonate and pH can be balanced with an alkali infusion.

Methods: Dialysate volumes of 125 L were circulated at approx. 414 mL/min & 37 C through a sorbent filter. The starting dialysate concentrations for electrolytes, pH and Urea are provided in table 1. The dialysate will be regenerated by an infusate solution containing Ca, Mg and K salts. In the first experiment a predicted [Na] profile pump will infuse an alkali solution at a varying rate to control the final [Na] at approx. 135mM. A second experiment a constant infusion of the same alkali was used as a reference. The total bicarbonate buffer was measured by titration. The pH was measured by a laboratory grade probe.

Results: The total bicarbonate buffer as alkalinity for an experiment with a constant infusion of alkali is compared to an experiment with varied infusion of alkali (controlling outlet sodium) in Figure 1. The same two experiments also show pH data in Figure 2.

Conclusions: The results show that the alkali infusion can simultaneously balance alkalinity and pH in a sorbent system using this infusion to maintain sodium at a set point.

Effect of Hemodialysis Rounding Report Availability on Hospitalized ESRD Patient Parameters

Khalid Elharrif,[1,2] Nidal Alhosainat,[2] Petersen Greti,[1] Ratha V. Kulasingam,[1] Omar S. Al-Taweel,[2] Hania Kassem.[2] *[1]Kern Medical Center, Bakersfield, CA; [2]The University of Texas Medical Branch at Galveston, Galveston, TX.*

Background: Each ESRD patient has a rounding outpatient HD report which is established by the outpatient dialysis unit and contains pertinent information including dry weight (EDW), dialysis prescription, and current medications. In this study, we compared inpatient dialysis-related parameters between 2 groups of patients, those for whom rounding reports were made available and those whose reports were not able to obtain.

Methods: The outpatient hemodialysis facility list was available for all healthcare providers. The facilities were contacted to obtain the hemodialysis report for the hospitalized patients with ESRD. The relevant parameters were obtained from these reports, which included hemoglobin, phosphorus, and EDW. The aforementioned identical parameters were monitored during the course of the hospitalization on all ESRD patients. Patients with available outpatient dialysis reports were restarted on the same outpatient doses of Epogen, phosphate binders, and EDW was adjuted to the same outpatient HD EDW. For those who do not have HD report available, their regimen was adjusted based on their clinical parameters. The dry weight was adjusted based on their volume status during the hospitalization.

Results: Sixteen ESRD patients admitted to the hospital were included. Upon discharge, those who had outpatient dialysis reports (10 out of 16) had significant improvement of phosphorus levels, better control of the volume status, and no significant changes in hemoglobin. Three out of ten patients developed intradialytic hypotension. The average length of hospitalization was 9 days. Those who didn't have the outpatient dialysis reports available during their hospitalization (6 out of 16) had no significant changes in phosphorus levels, post-dialysis weights, or hemoglobin. Five out of six patients developed intradialytic hypotension. The average length of stay was 10 days. **Table 1.**

Conclusions: Patients who have dialysis rounding reports available to guide their treatment while hospitalized have better dialysis-related parameters than those who don't.

	Dialysis report available			Dialysis report not available		
	On admission	On discharge	P Value	On admission	On discharge	P Value

Caustic Injury After Ingestion of Naturalyte®

Gaoyuan Huang, Carly Bowser, Chibuzo C. Okoye, Elena Frolova, Winston Lee. *New York City Health and Hospitals Coney Island, Brooklyn, NY.*

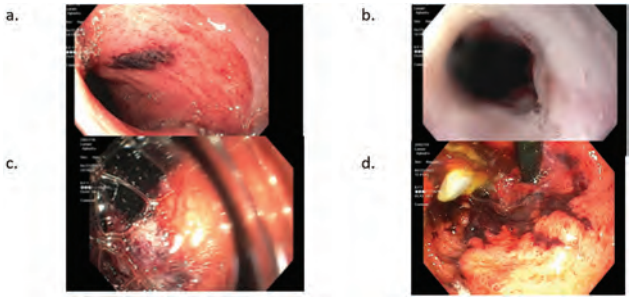
Introduction: Naturalyte® is a liquid acetic acid solution--a common dialysate concentrate in the United States.

Case Description: A 43-year-old man with ESRD on hemodialysis (HD) and depression presented with suicidal ideation. Vital signs: BP 235/142, P 99. He was agitated, but otherwise, his exam was unremarkable. Labs showed potassium (K) of 3.7 mmol/L and bicarbonate (CO2) of 25 mmol/L. He was admitted to intensive care and scheduled for dialysis. While HD was being set up, he ingested 100ml of the Naturalyte® dialysate concentrate in attempted self-harm. He vomited immediately. After ingestion labs showed K 4.1 mmol/L, CO2 20 mmol/L and venous pH 7.4. The patient received HD and underwent endoscopy (EGD) which revealed grade 2 esophagitis and stomach ulceration. He was treated with intravenous pantoprazole. Follow-up EGD showed healing lesions (fig 1) and the patient did well.

Discussion: To our knowledge, suicide attempt by ingesting dialysate concentrate has not been reported. Naturalyte® has a composition with a pH of 2.4-2.7 and various electrolytes (1) (table 1). Acetic acid ingestion can cause life-threatening toxicity and multiorgan failure (2). In our case ingestion of Naturalyte® did not have any systemic effects; this was due to several factors. Acidic solutions often cause an immediate reaction with emesis, which limits absorption (3). Our patient was also treated with early hemodialysis. In summary, ingestion of Naturalyte® can cause severe mucous membrane injury and potentially life-threatening complications.

Composition of Naturalyte®

Component	Weight %
Acetic Acid	0.8
NaCl	20.4
KCl	0.5
CaCl	0.4
MgCl	0.2
Dextrose	3.8



PUB098

Use of Electronic Consent and Navigating the Ethical and Governance Issues: Experience from the NightLife study

Niamh A. Quann,[1] Victoria Cluley,[1] Katherine L. Hull,[1,2] James Burton.[1,3] NightLife Study *[1]University of Leicester, Leicester, United Kingdom; [2]Leicester General Hospital, Leicester, United Kingdom; [3]Loughborough University, Loughborough, United Kingdom.*

Background: UK Government COVID-19 restrictions have necessitated rethinking the conduct of healthcare research. Obtaining informed, written consent remains a necessity that requires adaptation to accommodate the virtual environment. Here we report the experience of implementing electronic consent as part of the NightLife study. NightLife is a randomised controlled trial assessing the effectiveness of thrice weekly, extended, in-centre nocturnal haemodialysis. Continuation of the qualitative workstream during the COVID-19 pandemic resulted in the implementation of electronic consent where face-to-face consent was unfeasible.

Methods: As electronic consent was not part of the original study design, the proposal to use DocuSign to obtain electronic consent was discussed with the Trial Management Group (TMG), patient representatives and study Sponsor; a substantial protocol amendment was submitted. The study team liaised with the University's Information Governance (IG) and IT Risk and Continuity departments to mitigate potential data protection issues. A data protection impact assessment was completed to outline the data handling, management and storage arrangements. The functionality and practicality of the DocuSign portal was trialled and the Database Development team confirmed it integrated well with the clinical study database.

Results: The substantial protocol amendment was reviewed by the Research Ethics Committee, Health Research Authority and Confidentiality Advisory Group and received regulatory approvals less than three weeks after submission. As part of capacity and capability assessments at participating centres, approval was sought from local Privacy and Data Protection Officers with no issues identified.

Conclusions: Implementation of DocuSign as an electronic consent platform highlighted the importance of early and effective dialogue with the TMG, patient representatives, Sponsor, IG and Data Protection departments. While advantageous in the COVID-19 climate, face-to-face consent is still favoured and will recommence once restrictions are lifted. Integrating electronic consent is feasible from an ethical and governance perspective and represents an alternative for other studies that now require virtual engagement.

PUB099

Delivering Patient and Public Involvement During the COVID-19 Pandemic: Experience from the NightLife Study

Victoria Cluley, Katherine L. Hull, Niamh A. Quann, James Burton. NightLife Study *University of Leicester, Leicester, United Kingdom.*

Background: Patient and Public Involvement is essential for research as it provides a supportive environment for patients to share their opinions. Traditionally, involvement events are held in person. National lockdowns due to the COVID-19 pandemic limit such meetings. Alternative approaches to enable continuation have been undertaken by the NightLife study team.

Methods: Patient and Public Involvement opportunities were advertised through: leaflets, social media and the Kidney Patient Involvement Network (KPIN). Patients expressed their interest by completing and returning leaflets using a pre-paid envelope, direct message on social media, or emailing the dedicated email address. A virtual introductory event was held.

Results: Over the course of a two month period, 16 expressions of interest were received via social media (n = 3), KPIN (n = 2) and leaflets (n = 11) from 10 men and 6 women. The patients were of a variety of ethnic backgrounds and renal replacement therapy modalities. An introductory, virtual meeting was completed. The main reasons for patients' inability to attend were conflict with healthcare appointments or work. One patient expressed nervousness about attending the meeting due to unfamiliarity with virtual platforms. Communication and engagement methods were discussed with patients at the meeting: Flexible meeting times due to commitments (dialysis schedules, work and personal responsibilities) Virtual calls during dialysis treatment may be preferable All forms of communication (e.g. letters, email, social media, phone) and meeting options (e.g. virtual, face-to-face, phone) Offer follow-up interviews after group discussions so patients feel they can effectively express personal experiences Advertise in all formats possible including patient organisations Use different languages and interpreters

Conclusions: Patients are enthusiastic to engage in Patient and Public Involvement events for research making it is achievable despite social restrictions. Flexibility of approach and delivery is essential, especially for individuals on haemodialysis where there are already significant healthcare commitments. Using multiple formats for engagement will enhance inclusivity and ensure the panel is representative.

PUB100

Prevalence and Severity of Pruritus in Patients on Maintenance Hemodialysis

Huei Hsun Wen, Kinsuk Chauhan, Wonsuk Oh, Steven G. Coca, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Chronic kidney disease associated pruritus (CKD-aP) is a common symptom in patients on in center-hemodialysis (HD), reported in approximately 40% of patients. Recent clinical trials have identified novel agents for treatment of CKD-aP. Understanding the prevalence of uremic pruritus and its association with other symptoms can aid in identifying patients who would most benefit from this treatment.

Methods: We surveyed patient's ≥18 years old who had been on iHD for ≥30 days, and were receiving HD three times a week at the Mount Sinai Kidney Center. Patients completed surveys asking about the presence of absence of 21 different symptoms during the final 15 minutes of their HD treatments for 4 weeks. We performed multiple correspondence analysis (MCA) to identify associations between symptoms and group individuals with similar symptom profiles.

Results: Of the 97 HD patients who completed the study, 40 (41%) of them reported itching at least once during the study period. There were no significant differences in patient characteristics between patients who did and did not report itching **(Figure 1A)**. Of the patients who reported itching, on average they reported itching on 30±24% of their treatments **(Figure 1B)**. On MCA analyses, symptoms most correlated with itching was dry skin and fatigue (**Figure 1C**), Spearman correlation coefficient 0.63, P<0.001 for dry skin and 0.37, P<0.001 for fatigue **(Figure 1D)**. Using symptom data only, there was no obvious patient groupings.

Conclusions: CKD-aP affects a large proportion of patients on HD, occurs repeatedly, and clusters with dry skin and fatigue.

Funding: NIDDK Support, Commercial Support - Renal Research Institute

Hyperkalaemia Prevalence, Recurrence, and Treatment in Haemodialysis: A Prospective Multicentre Cohort Study (PRECEDE-K Trial)

Zhaohui Ni,[1] Haijiao Jin,[1] Renhua Lu,[1] Li Zuo,[2] Weimin Yu,[3] Junsheng Wang,[4] Rong Wang,[5] Yuqing Ren,[6] Qiongqiong Yang,[7] Jie Xiao,[8] Qinghong Zhang,[9] Lihong Zhang,[10] Xinzhou Zhang,[11] Qinkai Chen,[12] Chaosheng Chen,[13] Guojian Shao,[14] Qun Luo,[15] Li Yao,[16] Shuguang Qin,[17] Hui Peng,[18] Qing Zhao,[19] Hongyan Shang.[19] The PRECEDE-K study group *[1]Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China; [2]Peking University People's Hospital, Beijing, China; [3]Shanxi Bethune Hospital, Taiyuan, China; [4]Suqian People's Hospital of Nanjing Drum-Tower Hospital Group, Suqian, China; [5]Shandong Provincial Hospital, Jinan, China; [6]Yangquan Coal Industry (Group) General Hospital, Yangquan, China; [7]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [8]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [9]Taihe Hospital of Shiyan City, Shiyan, China; [10]The First Hospital of Hebei Medical University, Shijiazhuang, China; [11]Shenzhen People's Hospital, Shenzhen, China; [12]The First Affiliated Hospital of Nanchang University, Nanchang, China; [13]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [14]Wenzhou Central Hospital, Wenzhou, China; [15]Ningbo No.2 Hospital, Ningbo, China; [16]The First Hospital of China Medical University, Shenyang, China; [17]Guangzhou First People's Hospital, Guangzhou, China; [18]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [19]AstraZeneca Investment China Co Ltd, Shanghai, China.*

Background: Hyperkalaemia (HK) is a potentially life-threatening electrolyte imbalance associated with several adverse clinical outcomes and is common in patients with kidney failure. However, there is no evidence on the occurrence, recurrence, and treatment of HK in patients on haemodialysis (HD) in China.

Methods: The HK Prevalence, Recurrence, and Treatment in Haemodialysis Trial (PRECEDE-K; NCT04799067) is a prospective, multicentre, observational cohort study being conducted across 18 sites in China. Approximately 600 patients with end-stage kidney disease on HD are anticipated to be enrolled and will be followed up with for 24 weeks. Patients will be in the long interdialytic interval (LIDI) at enrolment and will receive follow-up care every four weeks in LIDI for pre-dialysis and post-dialysis (at enrolment only) serum potassium measurements. To obtain pre-dialysis serum potassium levels in the short interdialytic interval (SIDI), a follow-up visit in SIDI in Week 1 will be performed. Concomitant medications, blood gas analysis, and biochemistry measurements will be obtained at enrolment and at each follow-up visit.

Results: The primary endpoint is the proportion of patients experiencing any HK (defined as serum potassium > 5.0 mmol/L) at the study enrolment or during a 24-week follow-up. The key secondary endpoint is the proportion of patients experiencing HK recurrence (defined as any HK event after the first HK event) within 1–6 months (if applicable) during a 24-week follow-up, including enrolment assessment.

Conclusions: PRECEDE-K will generate high-quality evidence on the occurrence, recurrence, and treatment pattern of HK in patients on HD in China, and is expected to help inform practice guidance for HK management.

Dialysis in New Old Patients. Ten Years of Experience

Tatiana Tanasiychuk, Daniel Kushnir, Alon Antebi, Oleg Sura, Amnon Gil, Jerom Marcuson, Yasir Sanalla, Yosef Shihada, Victoria Svistunov, Muhammad Abd Elhalim, Victor Frajewicki. *Department of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel.*

Background: The most fast growing dialysis population during the last decades is old- age people. Mortality on dialysis patients is still high, especially among old patients. The two-year mortality rate for patients who initiate chronic dialysis over the age of 75 may exceed 50%. The risk of Acute Kidney Injury (AKI) also rises with age, while mortality risk increases dramatically in old patients with AKI. The prognosis and benefit of dialysis treatment are still unclear in very old patients. We performed a retrospective analysis of outcomes in all cases of first dialysis performed to very old patients (75 and more years old) during a 10 years period in our center.

Methods: The analysis included all ≥75 years aged patients started hemodialysis in our hospital for every indication (AKI, Acute on Chronic Renal Failure (CRF), End Stage Renal Disease (ESRD)) during the period January 1, 2009 - November 31, 2019. Patients were followed for one year from the first dialysis. The study main end point was one year all-cause mortality.

Results: In this period, 951 patients had their first hemodialysis treatment. Mean age was 82.4±5 years, 58.5% were male, 55.3% diabetics. Mean Charlson Comorbidity index was 8.3±2.2, Dementia was diagnosed in 11.4% of patients and 34.6% were nursing care dependent. Indications for dialysis were AKI in 16%, Acute on CRF in 64 % and ESRD in 20% of cases. One year mortality was 72.4%, 60% and 26.6% in AKI, Acute on CRF and ESRD respectively. Age, Nursing State, Dementia, AKI, Acute on CRF, and dialysis in a Intensive Care Unit (ICU) were associated with worse prognosis. Multivariate Cox regression models stratified by age, nursing state, AKI, Acute on CRF and ICU showed an OR of 1.3, 1.4, 3.2, 2.5, 2.0 respectively. Neither Charlson Score nor Diabetes mellitus (DM) were not associated with worse prognosis. DM, in opposite, was associated with a trend of better survival although the difference was not statistically significant.

Conclusions: The outcome of very old patients started with elective maintenance dialysis was much better than in acute unscheduled hemodialysis. The baseline general condition and severity of acute illness seems to be the main prognostic factors for one year mortality. Charlson Score and Diabetes Mellitus did not influence the outcomes in this age group.

PUB103

Vaccination Rates Among Hemodialysis Patients in Nueva Ecija and Aurora Provinces

Rommel P. Bataclan. *University of the East Ramon Magsaysay Memorial Medical Center Inc, Quezon City, Philippines.*

Background: Infections is one of the most common causes of morbidity and mortality in dialysis patients. Vaccinations have been proven to give seroprotection & reduce incidences of infection. This study investigates vaccination rates among out-patient hemodialysis patients in two provinces in the Philippines.

Methods: A cross-sectional study based on hemodialysis records among patients in 12 hemodialysis centers. Vaccination records from 2018 were checked & verified in all individuals. Descriptive statistics & chi-square analysis among selective clinical characteristics were performed.

Results: A total of 550 hemodialysis patients were included in this study. 67.5% have completed their Hepatitis B vaccination. 59.1% of patients had Tetanus Toxoid 59.1% but only 46.2% had pneumococcal vaccine. Influenza vaccinations were low (2018, 11.1%; 2019, 8.4% and 2020, 8.9%). On further analysis, there are significantly more females who received Tetanus Toxoid (66.0% vs. 50.2%, p<0.01).

Conclusions: There is still a significant percentage of patients who did not receive the recommended vaccinations. Lack of access even prior to last year, financial constraints and misconceptions on vaccines may have played important roles. These have to be addressed in order to increase vaccine confidence among hemodialysis patients.

Impact of Menaquinone 7 Intake on Mortality in Hemodialysis Patients

Mabel Aoun,[1,2] Dania Chelala,[1,3] Serge S. Finianos,[1,3] Hiba Azar.[1,3] *[1]Universite Saint-Joseph, Beirut, Lebanon; [2]Saint-George Hospital, Ajaltoun, Lebanon; [3]Hotel Dieu de France Hospital, Beirut, Lebanon.*

Background: Vitamin K deficiency was shown to be associated with vascular calcifications in hemodialysis patients. Studies evaluating the impact of vitamin K2 therapy on long-term outcomes are still scarce. This study aims to assess whether treatment with Menaquinone 7 (MK7) reduces mortality in hemodialysis patients.

Methods: This is a two-center longitudinal retrospective study that included all patients on hemodialysis during August 2016 and followed until August 2020. Some patients were treated with MK7. Data collection included vascular calcification score and dp-ucMGP at baseline, mean serum calcium, phosphate, PTH and albumin of the last year of follow-up and mortality at 1, 2, 3, 4 years. Kaplan Meier analysis was used to compare survival between the MK7 group and the control.

Results: A total of 143 patients were included. Table 1 summarizes the main differences between the two groups. Mortality was not significantly different between the two groups (Figure 1), even after adjustment to risk factors such as age, phosphate and coronary artery disease.

Conclusions: This study showed no significant difference in mortality at 4 years in hemodialysis patients treated or not by Menaquinone 7.

Outcome of Migrant Patients Starting Maintenance Hemodialysis in Switzerland

Thomas Ernandez,[1,2] Amalie Frandsen,[1,3] Pierre-Yves F. Martin,[1] Patrick Saudan.[1] *[1]Hopitaux Universitaires Geneve, Geneve, Switzerland; [2]Hopital de la Tour, Meyrin, Switzerland; [3]Inselspital Universitatsspital Bern, Bern, Switzerland.*

Background: ESRD migrants without permanent resident status is a particularly vulnerable population in regards of chronic renal replacement therapy or kidney transplantation access. Healthcare policies greatly vary between different countries which influence their clinical outcomes. Switzerland grants medical healthcare including renal care to anyone living in the country for more than 3 months.

Methods: In this report, we retrospectively analyzed the characteristics and the outcome of migrants starting dialysis at the University Hospital of Geneva (Switzerland) between January 2000 and December 2019.

Results: 775 patients started hemodialysis during this period. 38 patients (4.9%) were non-permanent residents being either asylum-seekers or undocumented. Compared to resident patients, they were significantly younger (42 and 63 years old, respectively) with less male gender (50% and 66%, respectively). The cause of ESRD was more frequently unknown with no difference for diabetes prevalence. Their modified Charlson

comorbidity index was overall lower. Emergency hemodialysis initiation was more frequent and mean eGFR at dialysis start was significantly lower (5 vs 7 ml/min/1.73m2). Most of the migrant patients eventually obtained a stable resident status (24/38, 63 %). Seven were sent back to their home country (7/38, 18 %) and 3 were lost of follow-up (3/38, 8%). Among the 28 migrant patients who stayed in Switzerland, 6 patients died during the follow-up period and 17 (61%) obtained a kidney transplantation. To account for their characteristic differences, propensity score matching was performed. Time to transplantation after dialysis initiation was significantly delayed for migrants with a median time to transplantation of 60 (43-99) and 25 (12-49) months for eligible migrants and propensity-score matched residents, respectively. Survival censored for kidney transplantation was overall significantly much higher in migrants compared to resident patients with a 5-year survival rate of 85% and 55%, respectively. When censored for kidney transplantation, survival remained better among migrants compared to matched resident patients (85% and 65% at 5 years, respectively).

Conclusions: In conclusion, ESRD clinical outcomes are excellent when standard care is provided. Aside the ethical issue, previous data from the US suggested that it is economically sustainable.

PUB106

The Cost of the Quanta SC+ Hemodialysis System for Sustained Low-Efficiency Dialysis in the Intensive Care Unit

Thomas W. Ferguson,[1] Paul Komenda,[2,1] Christos Argyropoulos.[3] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]Quanta Dialysis Technologies Ltd, Alcester, United Kingdom; [3]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Over 20% of patients in the intensive care unit (ICU) experience acute kidney injury requiring treatment with dialysis. There are several modalities available to provide dialysis in the ICU, including conventional hemodialysis, continuous renal replacement therapy (CRRT) and sustained low-efficiency dialysis (SLED). Recent meta-analyses have found that there is no definitive advantage of either of these modalities with respect to patient outcomes; however, they are associated with different cost and resource requirements. The SC+ Hemodialysis System is a commercially available, portable hemodialysis system that can be operated with minimal training by ICU nurses.

Methods: We described the incremental costs of CRRT, regular 4-hour conventional dialysis provided by specialized hemodialysis nurses, and SLED with the SC+ Hemodialysis System in the ICU. The analysis was performed from the perspective of the US health payer with results presented in 2020 US dollars. We considered costs with respect to the dialysis console, dialysis-related supplies (cartridges, tubing, dialyzers, dialysate, bags, and saline), and nursing-related human resources modeled from a large US based hemodialysis program.

Results: The cost of CRRT assumed that ICU nursing staff would provide the therapy, with consumables costs ranging between $320 and $380 per ICU-day. Dialysis provided with conventional 4-hour therapy in the HD unit ranged between $205 and $245 per day including both incremental nursing and renal technician expenses and consumables. Dialysis provided with the SC+ as 8-hour SLED treatments was estimated to cost between $59 and $85 for consumables and operated by the ICU nursing staff.

Conclusions: SLED treatment with the Quanta SC+ operated by ICU nurses offers significant cost advantages over CRRT and conventional HD treatments with no demonstrable disadvantage to patient outcomes.

Incident Dialysis Patients in Latin America (LA): An Unpaid Debt

Adrian M. Guinsburg,[1] Maria Ines Diaz Bessone,[1] Juan Carlos Berbessi,[1] Alejandro Kohn Tuli,[6] Ana Beatriz L. Barra,[2] Eduardo A. Machuca,[3] Jesus E. Munoz,[7] Leonor E. Briones,[4] Maria L. Quintanilla,[5] Maria M. Resk,[8] Gabriela R. Cannatelli,[6] Beatriz P. Schritzmeyer,[1] Jorge M. Caseiro.[1] Fresenius Medical Care LatAm *[1]Fresenius Medical Care LatinAmerica, Rio de Janeiro, Brazil; [2]Fresenius Medical Care Brazil, Rio de Janeiro, Brazil; [3]Fresenius Medical Care Chile SA, Santiago, Chile; [4]Fresenius Medical Care Ecuador, Quito, Ecuador; [5]Fresenius Medical Care Peru, Lima, Peru; [6]Fresenius Medical Care Argentina SA, Buenos Aires, Argentina; [7]Fresenius Medical Care Colombia, Bogota, Colombia; [8]Fresenius Medical Care Caricam, Panama, Panama.*

Background: Predialysis care in LA is conditioned by uneven accesibility to adequate treatment and odds healthcare systems. Timely initiation, vascular access (VA) creation and anemia and bone disease management are still barriers to overcome. The aim of this study was to compare incident (INC) and prevalent (PRV) dialysis patients outcomes from Fresenius Medical Care LA (FME LA) and possible correlations with survival

Methods: Patients from FME LA (Argentina, Brazil, Chile, Colombia, Ecuador, Perú) on hemodialysis between Jan 1 and Dec 31, 2020 were included. INC were defined with <90 days since first treatment in life and PRV >90 days. INC accounted during first 90 days, then they became PRV. Thus, results and time collected during first 90 days accounted to INC and after that to PRV. Values are expressed as mean ± SD. Means were compared using Student t-test. Kaplan-Meier (KM) and Cox regression models (CM) were created to evaluate survival

Results: 43,390 patients were included (7,969 INC / 35,421 PRV). Main differences between INC and PRV are shown in table 1. KM showed mean survival time INC 322.4 vs PRV 338.7 days (LogRank p<0.0001). Cox Model showed RR for Diabetes 1.30 / Age 1.03 / Male 1.08 / Hb 0.96 / Ca 1.06 / Alb 0.44 / Creat 0.98 / Graft 1.31 / Cuffed cath 1.31 / Uncuffed cath 1.48 (vs fistula), all p<0.0001, but INC vs PRV showed no statistical difference after covariables were included

Conclusions: Alb, Hb, Ca and P were lower in INC than PRV while catheter prevalence was considerable higher suggesting late referral, poor clinical management and dificulties in VA creation before dialysis initiation. Survival in INC was markedly inferior than PRV, but this effect vanished when the model was adjusted, suggesting non modifiable (diabetes, age, gender) and modifiable factors (Hb, Ca, P, Alb, Creat and VA) may be driving survival. Efforts to improve the latest should be done in order to ameliorate INC survival in our region

	Age (yrs)	Gender (male, %)	Diabetes (%)	Hemoglobin (Hb, g/dl)	Albumin (Alb, g/dl)	Serum Calcium (Ca, mg/dl)	Serum Phosphorus (P, mg/dl)	AV fistula (%)	AV graft (%)	Cuffed cath (%)	Uncuffed cath (%)

PUB108

Ultrafiltration Accuracy in a Modified Batch Dialysis System

Clayton Poppe, Nicholas Hyun, Sean C. Nash, Melany Yeung, Osman Khawar. *Diality Inc, Irvine, CA.*

Background: Ultrafiltration accuracy is an important way of improving mortality and morbidity on dialysis. The Diality Hemodialysis Machine will provide tight control of ultrafiltration during treatment. Specific Aims: To assess ultrafiltration accuracy during simulated dialysis utilizing a novel modified batch process. In this setup, ultrafiltration was conducted by alternating collection into two-liter reservoirs that contain both dialysate and ultrafiltrate.

Methods: Two simulated dialysis sessions were conducted utilizing blood flowrates of 300 ml/min, dialysate flowrates of 300 ml/min and ultrafiltration flowrates of 2500 ml/hr. (Table 1) Dialysis and ultrafiltration occur off of a two-liter batch of dialysate. Once two liters of dialysate has been circulated through the dialyzer, the collected ultrafiltrate and spent dialysate are discarded and dialysis switches to a separate two-liter reservoir of dialysate while the first reservoir is drained and filled with fresh dialysate.

Results: The results are provided in Table 1. The average ultrafiltration accuracy was measured by comparing the machine-calculated ultrafiltration volume with the weight of the simulated patient. The mean error represents the average difference between machine and patient during the simulated treatments, while the total error represents the total error after the simulated run was completed.

Conclusions: The initial experiments using a modified batch system show promising ultrafiltration accuracy. Future tests will demonstrate accuracy over a larger range of flowrates, volumes and times.

Recruitment Experience for a Year-Long Prospective Observational Study Using a Commercially Available Wearable Device

Maggie Han,[1] Xia Tao,[1] Ohnmar Thwin,[1] Lemuel Rivera Fuentes,[1] Priscila Preciado,[1] Leticia M. Tapia Silva,[1] Mohamad I. Hakim,[1] Jochen G. Raimann,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Wearable activity trackers can allow healthcare providers to access patients' health parameters remotely. These commercially available devices may provide valuable insights at low cost. Research of the use and acceptance of this technology is necessary to scale the use of trackers and integrate them into clinical care. We aim to share our experience of recruiting hemodialysis (HD) patients to a research study using a wearable activity tracker.

Methods: Patients were recruited in 4 dialysis clinics in Manhattan, NYC. Patients who received their attending nephrologist's approval to participate in the study were approached for recruitment. Patients ≥18 years on maintenance HD, able to walk, owning smartphone, tablet or PC were included in the study. Patients were observed for up to 1 year and were asked to wear a Fitbit Charge 2™. Questionnaires were administered to capture subjective physical and emotional wellness. Subjects who inconsistently synced their Fitbits were withdrawn. We enrolled continuously from May 2018 to November 2019.

Results: Only a third of patients who were approached consented to participate in our study. 79% of patients who were eligible choose not to participate in the clinical study. Details of the recruitment and enrollment process are shown in the flowchart in **Figure 1**.

Conclusions: With most eligible patients choosing to not participate, the value of patients' contributions to research needs to be emphasized. We encourage healthcare providers take the time to educate patients on the importance of clinical research.

PUB110

Anemia Status and Root Cause Analysis of Maintenance Hemodialysis (MHD) Patients in Shaanxi Province

Hua Liu. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: According to the national nephrology professional medical quality control index (2020 version) and the related quality control index of renal anemia in hemodialysis patients, combined with the Chinese National Renal Data System (CNRDS) system feedback data in 2019, the anemia control rate of MHD patients in Shaanxi Province was analyzed and the root cause analysis was carried out to promote the continuous improvement of the anemia.

Methods: Based on CNRDS feedback data, the data of the routine timing test rate, anemia control rate, serum ferritin and transferrin saturation timing test completion rate of MHD patients in Shaanxi Province were analyzed and compared with the national situation. Meanwhile, the anemia compliance rate of different regional in Shaanxi Province was compared.

Results: According to the CNRDS statistics in 2019, 54.4% of the patients registered for hemoglobin at least once in 2019, while 79.7% in Shaanxi Provincial website. However, the monitoring of iron indicators was lower than the national average (9.5% vs 16.2%). We can also find that the compliance rate of renal anemia in MHD patients in Shaanxi Province is only 35%, which is lower than the national compliance rate of 39.3%. There are differences in the compliance rate and average value among different regions of Shaanxi Province, but 75.2% of the total patients have hemoglobin>90g/L. There are many reasons for the low control rate of MHD renal anemia in Shaanxi Province, including lack of process and homogeneous training and implementation of anemia management in various cities, lack of grass-roots training by local quality control centers, some test items, such as iron index test, can not be generally achieved in district and county hospitals, there are regional differences in economic level and reimbursement ratio of medical insurance.

Conclusions: We need to continue to focus on the standard operating procedure (SOP) of blood purification, strengthen the grass-roots training, strengthen the promotion of the integrated mode of medical care Strengthen the task implementation of quality control centers in various cities, strengthen the supervision and rectification of CNRDS network report.

Serratia liquefaciens Bacteremia in Two Dialysis Patients

Jeffrey I. Silberzweig,[1,2] Diane Morris,[1] Rachael DiRienzo-Lawless,[1] Catherine Reydel,[1] Clarence L. Waltrous.[1] *[1]The Rogosin Institute, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Introduction: *Serratia* are an unusual cause of bacteremia but can present a risk for patients receiving maintenance hemodialysis.

Case Description: Two patients who were sitting proximately receiving maintenance dialysis via central catheters developed chills and fever. Cultures grew *E. cloacae;* vancomycin and gentamicin were administered. They were hospitalized; cultures grew *S liquefaciens*. Both recovered with antibiotics and returned without sequelae. An experienced RN with excellent catheter technique cared for both patients. The only common medication was a multi-dose heparin vial with clear solution. The patients had no relationship outside the facility and neither had evidence of catheter or exit site infection. No other patients had signs of infection.

Discussion: *Serratia* are water dwelling bacteria which infect humans via environmental sources. Five cases of transfusion-related septic shock were reported between 1992 and 1999; no source was identified[1]. Ten cases of *S. liquefaciens* blood stream infection and six pyrogenic reactions at a hemodialysis center in 2001 were found to be related to multiple punctures of single-use vials with pooling of preservative-free Epogen®[2]. In 2017, two cases of bacteremia were reported among nine patients who underwent myocardial perfusion scanning. Bacteria were found in the saline used to reconstitute the radiopharmaceutical[3]. The treatment area including handwashing sinks and water boxes were in good order; no bacteria were identified. Dialysate water cultures were without significant growth. In addition to reviewing catheter care and hand hygiene, we are reviewing proper storage and handling of multidose heparin vials. Water-borne bacteria are a threat to patients receiving maintenance dialysis. Vigilance must be paid to reduce the risk of infection. The differential diagnosis for bacteremia must be broad and treatment must cover relatively unusual etiologies.

PUB112

Adjusting Dialysate Bicarbonate for Chronic Respiratory Failure

Yasmin N. Mahmoud,[1,2] Akbar H. Hamid,[1,2] Ammar N. Mohamed,[1,2] Momen M. Ismail,[1,2] Mary C. Mallappallil,[1,2] Man S. Oh,[1,2] Moro O. Salifu.[1,2] *[1]SUNY Downstate Health Sciences University Department of Medicine, New York, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: Lung disease has been noted to be an independent predictor of mortality in patients with chronic kidney disease. With increased prevalence of obesity, coexistence of chronic lung and kidney disease in the same patient is expected to rise. We report a case of a patient with restrictive lung disease on maintenance hemodialysis who presented with acute hypoxic and hypercapnic respiratory failure, and her CO_2 retention during and after assisted ventilation was managed by adjusting dialysate bicarbonate.

Case Description: A 48 year old African American female with history of restrictive lung disease secondary to severe kyphoscoliosis on home oxygen therapy and end stage kidney disease on hemodialysis secondary to horseshoe kidney disease was brought to ED for decreased responsiveness. In ED, she was unresponsive with O_2 saturation of 60%. On initial ABG, pH was 7.02 and pCO_2 was 101 mmHg. Her baseline pCO_2 was 50-60 mmHg. She was intubated for acute hypoxic and hypercapnic respiratory failure and admitted to ICU. While she was intubated, she was dialyzed with the dialysate bicarbonate of 35 mEq/L. Her pCO_2 level was maintained within the range of 45-50 mmHg. Following extubation, dialysate bicarbonate was reduced to 30 mEq/L, and she was able to remain stable without worsening hypercapnia.

Discussion: In a person with normal renal function, the response to hypercapnic respiratory failure is to increase extracellular concentration of bicarbonate by renal compensation. In a person on maintenance hemodialysis, extracellular bicarbonate concentrations are dictated by nephrologist who can set plasma bicarbonate concentration by adjusting dialysate alkali concentration. In principle, the lower the bicarbonate concentration, the greater the respiratory drive. As uremia per se depresses respiratory drive, the higher extracellular bicarbonate concentration is expected to further suppress the respiratory drive, resulting in respiratory failure. In our patient, maintenance of a lower than usual extracellular bicarbonate concentration by reducing dialysate bicarbonate concentration was successful in achieving stable ventilation. One additional maneuver to prevent precipitation of respiratory failure would be avoiding aggressive home oxygen therapy by maintaining PaO_2 between 50 and 60 mmHg, since a higher PaO_2 is likely to suppress respiratory drive.

PUB113

Vitamin D Independently Related to Right Ventricular Dysfunction in ESRD Patients on Maintenance Hemodialysis

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

Background: Right ventricular (RV) dysfunction is a major cause of death in patients undergoing maintenance hemodialysis (HD) and a major determinant of mortality in pulmonary hypertension that is common in HD patients. There is tremendous amount of data on the changes in left ventricular function in HD patients, but data on RV dysfunction and its mechanisms in HD patients are scarce. It has been suggested that vitamin D could be involved in the development or progression of heart failure by modulating oxidative stress. We investigated changes in RV function in HD patient and its correlation with vitamin D level.

Methods: In a university affiliated dialysis center, a retrospective cohort of ESRD patients treated with HD for at least 1 month followed in a dialysis unit. Patients without vitamin D assessment, prior myocardial infarctions, heart failure, or prevalent valvular disease were excluded. Subject characteristics were recorded, including age, gender and race. Echocardiography including tissue Doppler imaging (TDI) of the RV was evaluated. PH was defined as an estimated systolic pulmonary artery pressure (PAP) higher than 25 mm Hg using echocardiograms performed by cardiologist.

Results: A total of 77 HD patients were included in the study. The mean age of the patients was 53±7.4 years. The mean dilaysis vintage was 27± 14 months. The mean ejection fraction was 45±7%. The prevalence of PHT was 53%. 59% of patients with PH were female that was statisticaly ($p<0.05$). 30% of patients had RV dysfunction on echo. 72% of patients with RV dysfunction had a 25(OH)D level <30ng/ml ($p<0.05$).

Conclusions: Our findings demonstrate high incidence of RV dysfunction among ESRD patients under maintenance HD and it is strong association with suboptimal vitamin D. Further investigations are required to evaluate the beneficial effects of cholecalciferol in ESRD patients with RV dysfunction.

PUB114

Mortality and Associated Factors in Patients Under Hemodialysis in a Latin American Tertiary Center

Annette G. Garcia Delgado,[1] Jennifer P. Khouri,[1] Nicole De Los Santos,[1] Anthony J. Gutierrez,[1,2] Eliana Dina-Batlle.[2,1] *[1]Pontificia Universidad Catolica Madre y Maestra Facultad de Ciencias de la Salud, Santiago De Los Caballeros, Dominican Republic; [2]Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic.*

Background: Risk factors are associated with the prognostic and early diagnosis of chronic renal disease. We evaluated modifiable and non-modifiable factors related to mortality in patients who receive hemodialysis therapy.

Methods: Retrospective cohort study.

Results: A total of 347 patients were included. The mean age was 56.29, 71.13% were female, and 55.6% had more than two comorbidities. Diabetes and hypertension were the most common causes of chronic renal disease. Male participants were more likely to die than females. The Charlson index was higher [6 (5 – 7)] in deceased patients than those who did not die [5 (3 - 7)]. Patients with lower hemoglobin and albumin levels were more likely to die. Also, calcium levels [9.05 (8.5 – 9.4)] were higher in deceased patients. 69.23% of patients who died used central venous catheter

Conclusions: The use of central venous catheters is an important risk of mortality in patients who receive hemodialysis therapy. Other factors associated with mortality in these patients are an elevated Charlson index, low hemoglobin, albumin, and high calcium levels. These results show the importance of an early assessment of the patient and the factors mentioned above.

PUB115

Case Report of Hemodialysis-Associated Thrombocytopenia

Samah S. Suleiman, Mohamedanwar M. Ghandour, Areeba Jawed. *Wayne State University, Detroit, MI.*

Introduction: Thrombocytopenia associated with hemodialysis is a rare complication that can be witnessed occasionally. Studies, however, showed that dialysis membranes could result in significant thrombocytopenia due to the role they play in activating the complement system. Herein, We present to you a case of polysulfone-dialyzer-induced thrombocytopenia in a patient with a previously normal platelet count.

Case Description: Our patient is a 44-year-old male with a past medical history of decompensated liver cirrhosis, who presented with hematemesis. Initial blood workup was remarkable for blood urea nitrogen of 25 mg/dL, Creatinine of 2.08 mg/dL. The patient was started on Ceftriaxone and Flagyl for the concern of spontaneous bacterial peritonitis in addition to pantoprazole drip, Octreotide drip, Norepinephrine, and vasopressin for hepatorenal syndrome. Due to worsening kidney function hemodialysis was initiated on day 18 of hospital admission using the Fresenius Optiflux 180 dialyzer with a synthetic polymer (electron-beam sterilized) membrane. The patient tolerated the first hemodialysis session without complications. However, on the next day, his platelet count decreased from 120,000 to 25,000. Workup was negative for other causes of thrombocytopenia. On the fourth hemodialysis session, the dialyzer was switched from the F180NR to Purema-Polyethersulfone dialyzer (gamma sterilized), after which the patient's platelet levels began to recover without any regression.

Discussion: Thrombocytopenia is a well-known complication of hemodialysis treatment, which results in platelet adhesion, aggregation, and activation. A post-dialysis platelet count decrease of more than 15% compared with predialysis values could identify dialysis-related thrombocytopenia. Verbeelen et al. showed that cellulose acetate dialyzer membranes could cause transient thrombocytopenia and platelet activation. In our patient's case, electron beam sterilization was used initially with the Optiflux 180 Polysulfone dialyzer, and the thrombocytopenia resolved when he was switched to the Purema-Polyethersulfone dialyzer that was gamma sterilized. This case of hemodialysis-associated thrombocytopenia in a new dialysis patient demonstrates that polysulfone dialysis membranes can variably affect platelet levels, despite previous evidence indicating that polysulfone membranes do not affect platelet counts.

PUB116

Frailty in Kidney Transplant Candidate Patients

Raquel B. Rico. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Frailty increase the risk of falls, cognitive impairment, hospitalization and mortality in patients both in dialysis and with kidney transplant. Incidence is more than 35% in dialysis patients.

Methods: We perform a single center and transversal study(2021) with patients in haemodialysis(HD) and peritoneal dialysis(PD) in kidney transplant waiting list. We analyze clinical and analytical characteristics. We used Frail scale, validated in patients with chronic kidney disease, for frailty.

Results: We include a total of 81 patients, 62 in HD and 19 in PD, 65.4% males, with a median age of 59 years. Median time in dialysis was 3 years(2-5), significantly lower in PD patients($p<0.001$). There was a 27.2% with a previous kidney transplant. Median time in waiting list was 21 months (9.5,3.4) significantly higher in HD($p=0.023$). We observe an acceptable control of calcium-phosphorus metabolism, anemia and nutritional state with low levels of inflammation markers. HD patients had significantly lower levels of prealbumin and higher levels of RCP. PD patients had more eritropoyetin and phosphorus chelators requirements. Frailty tase was 3.7%(2 women, 1 man), all in HD group. The 39.5% of patients were on prefrail status, 37.7% men and 22% with an age under 50. PD group had higher tase of fatigability 42.1%($p=0.005$) and prefraility 57.9%($p=0.004$).

Conclusions: Our group has low prevalence of fraility because there was selected patients for the kidney transplant, with relative low time in dialysis and waiting list. There was not fraility in PD because of a better nutritional state with lower inflamation. There higher tase of fatigability and prefraility can be explained by increased daily activity. HD tends to have more comorbility and inflamation. We should maintain follow up and control of the potentially frail patients, to optimice his functional reserve and pretransplantation status.

Atraumatic Splenic Rupture in a Patient on Apixaban and Clopidogrel

Pooja Patnaik, Pranav Sharma, Steve I. Khalil, Jonathan Lebowitz. *RWJBarnabas Health, New Brunswick, NJ.*

Introduction: Atraumatic splenic rupture (ASR) has an estimated overall mortality rate of 12.2% with 2.4% of cases occurring in patients on anticoagulation. Recently, more cases of ASR have been reported with the use of direct oral anticoagulants (DOACs). This is the first case of ASR in a patient on apixaban and clopidogrel.

Case Description: An 82-year-old woman with atrial fibrillation on apixaban, prior TIA on clopidogrel, and ESRD on hemodialysis presented with new, left-sided abdominal pain that radiated to her chest. There was no known prior abdominal trauma. Her abdomen was distended and diffusely tender with guarding. Hemoglobin was 8.7g/dL, platelets 240,000/μL, INR of 1.26, and lactate 8.8mmol/L. Her hypotension was not responsive to midodrine or NSS boluses, so she was initiated on IV norepinephrine. Over the next 12 hours, her hemoglobin dropped to 6.3g/dL, her lactate increased to 12.6mmol/L, and

her INR increased to 1.62. An urgent abdominal CT scan revealed splenic rupture and significant hemoperitoneum (Figure 1). An emergent exploratory laparotomy revealed splenic rupture and she underwent splenectomy. On pathologic examination, the spleen measured 12 x 6.5 x 1.9 cm with evidence of an organized splenic hemangioma.

Discussion: DOACs significantly reduce mortality from embolic complications in patients with atrial fibrillation but increase the risk of gastrointestinal bleeding. Additionally, patients on a DOAC with an add-on antiplatelet agent are 1.42 times more likely to have a major bleeding event than patients who do not receive add-on antiplatelet therapy. Furthermore, pharmacokinetic studies suggest that use of apixaban, even at recommended doses, may lead to supratherapeutic inhibition of factor Xa in patients with ESRD. Therefore, ASR should be suspected in any patient maintained on anticoagulation who presents with abdominal pain and shock, especially those who are taking both a DOAC and antiplatelet therapy. Bedside ultrasound showing free peritoneal fluid can aid in early diagnosis of these patients.

Adequacy of 4-Hour Sustained Low-Efficiency Dialysis Among Hospitalized Patients: A Retrospective Data Review

Mostafa Najim, Alaa Rahhal, Ahmed Mahfouz, Mhd Baraa Habib, Sara S. Hassen, Isra'a S. AlSheikh, Ashraf O. Ahmed, Haneen A. Toba, Mawahib A. Elhassan, Sumaya M. Alyafei, Amr M. Badr, Khaled M. Mahmoud. *Hamad Medical Corporation, Doha, Qatar*.

Background: Sustained low-efficiency dialysis (SLED) is a dialysis modality performed over 6-12 hours among hemodynamically unstable patients as it is characterized by a slower blood flow rate than intermittent hemodialysis. Conduction of 4-hour SLED may spare time and manpower for procedures needed in critical care units. However, the appropriateness of 4-hour SLED has not yet been evaluated.

Methods: We conducted a single-center retrospective observational study to explore the appropriateness of 4-hour SLED among critically ill patients admitted to Heart Hospital in Qatar from 1/06/2016 to 1/06/2020. Renal parameters, including blood urea nitrogen, serum creatinine, serum potassium, and serum bicarbonate were determined before and after each SLED session for all the patients who did up to ten SLED sessions during the index admission. The Wilcoxon signed-rank test was used to compare the variables before and after SLED sessions.

Results: Of the 297 patients included, 70% were male with a mean age of 64 years. The majority of patients were from the Middle East (65%), followed by 29% from Asia. Cardiogenic shock was the reason for hemodynamic instability in 45% of the study population, while mixed cardiogenic/septic shock was present in 10%. 4-Hour SLED resulted in a significant improvement in all evaluated renal parameters, as shown in Table 1.

Conclusions: The use of 4-hour SLED significantly improved renal parameters among critically ill patients, which warrants utilizing SLED shorter than 6 hours to preserve time for essential procedures in critical care units.

Table 1. Comparison of the renal parameters before and after 4-hour SLED (N= 297)

A Sliding PD Catheter: Caution on Repair of Pericatheter Hernias

Diala T. Khirfan,[1] Joven N. Tristeza,[1] Anil S. Paramesh,[3] Mihran V. Naljayan.[1,2] *[1]LSU Health New Orleans, New Orleans, LA; [2]DaVita Inc, Denver, CO; [3]Tulane University School of Medicine, New Orleans, LA.*

Introduction: Catheter migration is a common cause of catheter malfunction in peritoneal dialysis. Abdominal radiography is considered the standard of care to diagnose catheter migration. We are presenting a case where abdominal radiography failed to detect a migrated PD catheter. The catheter likely migrated due to a recurrence of repaired pericatheter hernia.

Case Description: A 56-year-old female with ESKD presented to the outpatient PD clinic with inflow and outflow failure. Four months after laparoscopic catheter insertion, she presented with PD catheter insertion site swelling. She underwent revision of the catheter where a pericatheter hernia at the peritoneal insertion site was found. The sac was sewn to incorporate the cuff, the old catheter was cut and tunneled to a new site. 6 months later, the patient presented with outflow failure and bulge at the catheter insertion site. Abdominal radiograph showed appropriate positioning of the catheter tip in the right lower quadrant. Laparoscopic surgery showed an incisional hernia at the previous peritoneal entrance site and no catheter in the peritoneal cavity. Incision of the bulge revealed a loculated subcutaneous fluid collection and the coils of the catheter. It appears that the hernia had pulled the catheter out of the abdominal cavity, and the peritoneum had sealed behind it, causing this loculated collection. The catheter was removed, the sac was resected, and the fascial defect was repaired. A new PD catheter was inserted on the other side.

Discussion: Pericatheter hernia can cause malposition of PD catheters. In this case, we believe the catheter suffered malposition due to the surgical technique employed in the initial surgery where the hernia sac had been sewn to the cuff. A plain posterior-anterior abdomen radiograph may be a useful tool in evaluating PD catheter position. However, in this case, despite the radiograph showing the tip in "appropriate position", the PD catheter migrated into the subcutaneous tissue. Other methods of identification for catheter placement like lateral abdominal x-rays, CT scan, or surgical exploration should be considered if catheter mispositioning is suspected

PUB120

Healthcare Perspective on Home Hemodialysis Use: Barriers and Interventions

Daphne H. Knicely, Emaad M. Abdel-Rahman. *UVA Health, Charlottesville, VA.*

Background: Home hemodialysis (HHD) has been available for several decades with known benefits, yet <2% of dialysis patients in the US use this modality. In 2019, an executive order directed the US Department of Health and Human Services to develop policies to target a goal of 80% of ESKD patients to either dialyze at home or be transplanted. Few studies are published to identify barriers and suggest solutions for more use of the HHD modality. Most published studies focused on surveying patients and nephrology trainees.

Methods: We surveyed the Nephrology team at the University of Virginia (UVA) about their experience with HHD. UVA has approximately 950 dialysis patients among all modalities, with 12 dialysis units located in central Virginia.

Results: Of 274 individuals receiving the survey, 139 responded (50.7%) including dialysis nurses (56.1%), dialysis technicians (15.1%), dieticians (7.9%), social workers (7.2%), nephrologists (10.1%) and nephrology fellows (3.6%). Both physicians and staff expressed extreme (36.8% and 40.0%) and somewhat comfort (52.1% and 40.8%) with HHD care. Physicians suggested the main barriers to HHD are patients-related (social barrier, lack of support, fear and lack of interest), inadequate electronic medical record, and insufficient patient/staff education. The staff further added inadequate home space for HHD, more frequent HHD (4-5 session/week) vs in-center HD (3 session/week), lack of patients' confidence to perform HHD and worrying about care partners burn. To help increase using HHD, faculty suggested better education of patients and trainees and early introduction of HHD to patients with pre-dialysis advanced CKD. The staff suggested policy changes to allow more catheter use, solo HHD, more involvement of the HHD nurse in the in-center HD unit and hospital setting, more physician education, and referral of eligible patients to the HHD unit or a transitional care unit. All forms of education were recommended by both physicians and staff including webinars, lectures, printed materials, hands-on education, short videos and fliers.

Conclusions: Improving access to HHD is possible. Overall, surveying physicians and staff provided more insight into modifiable barriers that could increase use of HHD. We would recommend all centers to survey physicians and staff to find better ways to meet the goals of this new executive order.

PUB121

CardioMEMS and Peritoneal Dialysis: Synchronizing Data to Provide Patient-Centered Care at Home: A Road to the Future

Julie A. Minser, Max Liebo, Kavitha Vellanki. *Loyola University Health System, Maywood, IL.*

Introduction: End stage renal disease patients are the highest risk populations for heart failure (HF), an estimated 36% with congestive heart failure at dialysis initiation. CardioMEMS is an FDA approved wireless pulmonary artery (PA) pressure monitoring device in New Yor Heart Association (NYHA)class III HF patients hospitalized during the previous year. Here, we present our experience with assessing ultrafiltration (UF) needs in peritoneal dialysis (PD) using CardioMEMS data. There are very few published reports of CardioMEMS in dialysis patients. We believe this is the first to report adjusting PD prescription using CardioMEMS recordings.

Case Description: A 61 yr old female with failing kidney transplant was initially referred to general nephrology clinic for impending dialysis needs. She had extensive cardiac history with ischemic cardiomyopathy, HF with ejection fraction of 25% and NYHA Class IIIB symptoms, CardioMEMS implantation a year prior and being evaluated for combined heart-kidney transplant. She also had symptomatic orthostatic hypotension at baseline. With a coordinated effort between surgery, cardiology and nephrology, she had a laparoscopic PD catheter placement and initiated on PD in-hospital. Her clinical course was complicated with pancytopenia, CMV viremia, acute decompensated heart failure and severe symptomatic gastroparesis raising concerns on whether she can continue PD. She was successfully discharged home on PD and home PD regimen adjusted to attain a

goal PA diastolic pressure of 18-20 mm Hg (Figure 1). Rehospitalizations were prevented and she eventually received a combined heart-kidney transplant 3 months later.

Discussion: Assessment of UF needs in dialysis patients with HF is fraught with multiple limitations leading to frequent rehospitalizations. In our patient, PA diastolic pressure readings from CARDIOMEMS were used as a guide in assessing UF needs and adjusting PD regimen. Our case illustrates that a coordinated multidisciplinary approach can provide patient centered care at home and improve outcomes.

PUB122

Development of a Registry for Peritoneal Dialysis at Yokohama City University and Affiliated Hospitals (Yokohama Bay-Shonan PD Registry)

Tomohiko Kanaoka, Sho Kinguchi, Kengo Azushima, Hiromichi Wakui, Kouichi Tamura. *Yokohama City University Graduate School of Medicine, Department of Medical Science and Cardiorenal Medicine, Yokohama, Japan.*

Background: Patient registry has become increasingly important as a strategy to promote clinical research and to improve the patient care. Yokohama City University Hospital is one of the leading hospitals in Kanagawa Prefecture, a representative and well-known urban area in Japan.

Methods: We started to construct a registry of peritoneal dialysis (PD) at Yokohama City University Hospital and 15 affiliated hospitals (Yokohama Bay-Shonan PD Registry) from the beginning of 2020. The categories of Yokohama Bay-Shonan PD Registry include an information including the age, sex, duration of PD, method of PD (continuous ambulatory PD, intermittent PD, or continuous cyclic PD), cause of end stage of kidney disease, prescription of renin-angiotensin system inhibitors (+/-), past history of heart disease (+/-), results of peritoneal function test, onset of new heart disease (+/-), onset of PD-related infection (+/-), and combination of hemodialysis (+/-).

Results: We collect data from each facility once a year. Only data of Yokohama City University Hospital were available for analysis this time, and total of 28 patients were registered at Yokohama City University Hospital. Mean age was 66.7 years old. Eleven patients were affected with PD-related infection, and 3 pateints discontinued PD (1 death, 1 pancreas cancer, and 1 PD-related infection).

Conclusions: We continue to collect data from each affiliated hospital and will expand the information recorded in the Yokohama Bay-Shonan PD Registry to find the persistence rate of PD and frequency of cardiovascular events for further analysis.

PUB123

Unusual Pathogen Causing Peritonitis in a Peritoneal Dialysis (PD) Patient

Rula A. Abdulrahman. *Stony Brook University, Stony Brook, NY.*

Introduction: Pantoea species causes infection in humans and are pathogenic to plants. Pantoea agglomerans are mostly isolated from human and was reported to cause peritonitis. We are describing a case of peritonitis in a PD patient, caused by Pantoea Calida (PC) and Pantoea Gaviniae (PG). There are few case reports about it causing bacteremia, meningitis infection in human but not peritonitis.

Case Description: 44 years old man on continuous cycling PD, has history of cardiomyopathy, was found to have cloudy effluent and was complaining of abdominal pain, nausea and diarrhea. Vitals signs: temperature 38 C, BP 126/80, PR 91. on exam: generalized abdominal tenderness. Effluent fluid analysis cell counts of 3408/µl. With 80% polymorph neutrophils. patient was prescribed intravenous antibiotics vancomycin and cefepime, then started on continuous cefepime intraperitoneal the next day, while effluent culture was pending. On day 5 patient was feeling better and the cell count dropped to 1996/µl, so was discharged home, Cefipime was continued intraperitoneally. 2 days after discharge, effluent was noted to be cloudy again and the cell count was 2948/µl. At this time decision was made to remove PD catheter for persistent peritonitis. Efflent Culture was consistent with PC & PG, susceptible to cefepime. Fungal culture remain negative. PD catheter was removed & Patient was started on hemodialysis. patient was treated with ceftazidime for 2 weeks. infection was treated. patinet chose to remain on hemodialysis.

Discussion: Peritonitis is a common and serious complication of PD. It is the major cause of death in around 16% of PD patients.it is reported that Pantoea agglomerans can cause peritonitis. Our patient had peritonitis caused by PC, PG which is a very rare finding. Despite treatment with appropriate antibiotic the symptoms persist and eventually PD catheter was removed, the patient was started on hemodialysis. Pantoea species have been isolated from soil, water, plant, seeds, fruits, and human body fluids. PG, and PC were isolated from infant formula. PC was isolated from dialysate of PD patients and from urine, although pathogenicity remain unknown. In our case the patient had sever peritonitis caused by Pantoea species, the way of transmission is unclear. We recommend further research and examining the dialysate fluid in certain population, aiming that such an infection can be prevented in future.

PUB124

The Effects of Location of Peritoneal Dialysis Training, In-Home vs. In-Center, on Peritoneal Dialysis Patients

Rajeev Chauhan,[1] Mallika Chauhan.[2] *[1]Renal Associates LLC., Columbus, GA; [2]New York Institute of Technology, Old Westbury, NY.*

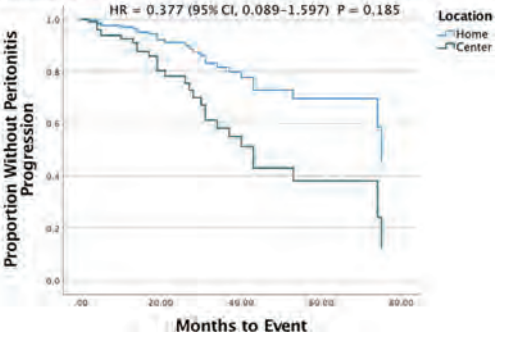
Background: The objective of this study is to investigate the relationship between peritonitis rates and whether peritoneal dialysis (PD) was taught in-center (n_1=104) or in-home (n_2=16) for 120 patients in a single center located in Southern Georgia. Preceding studies have assessed the link between peritonitis rates and demographic factors among PD patients. However, there is very limited research that examines the effects of peritoneal dialysis training location on a patient's chance of developing peritonitis.

Methods: This study is a retrospective analysis for data accumulated over a period of seven years. Subjects were categorized into two groups: one group's dialysis administrator received peritoneal dialysis training in their homes and the other group's dialysis administrator was trained in-center. The data collected includes gender, age, peritonitis occurrence, presence of family support to patient, and severity of comorbidities. The initial analysis was conducted by using a Fischer's test and Welch's t-test. Further investigation was done through a Cox hazards model to compare the influence of in-home and in-center training on peritonitis occurrence over time during PD.

Results: A hazard ratio (HR = 0.377) was utilized to compare the home trained group to the center trained group. The HR indicates that at any time during PD, patients who were home-trained had a 62.3% lower risk of peritonitis. The confidence interval includes one. Therefore, this result is not significant, and this finding is further verified by its p-value being over 0.05. Additionally, significance between peritonitis rate and location of training (P=0.352) could not be established and all models used to analyze each variable resulted in insufficient p-values and binary r-squared values.

Conclusions: Considering the use of unbalanced sample sizes and limited data, the results can be deemed misrepresentative of the general peritoneal dialysis patient population, this study finds that location of training, in-home versus in-center, may not be an accurate gauge of peritonitis risk in certain populations.

Figure 1. Time to Peritonitis for Home Trained Patients and Center Trained Patients



PUB125

Curious Rash

Parth Worah, Jingyin Yan, Sehrish Ali. *Baylor College of Medicine, Houston, TX.*

Introduction: Peritoneal dialysis (PD) involves infusing a solution into the peritoneal cavity via a catheter. PD provides removal of solute/fluids by using the peritoneal membrane as an exchange surface. Primary PD solutions are glucose containing. Glucose is not an ideal osmotic agent as it's easily absorbed; thereby attenuating the osmotic gradient driving ultrafiltration (UF). Icodextrin (ID) is an alternative to hyperosmolar glucose containing solutions. ID is an iso-osmolar solution consisting of a mixture of high molecular weight water-soluble polymers of glucose, isolated by the fractionation of hydrolyzed cornstarch. It's added when more UF is indicated and/or when patients are at an increased risk of hyperglycemia. Icodextren is generally well-tolerated; however, there have been reports documenting exfoliative rash from it. Our case describes biopsy proven spongiotic dermatitis on a patient who recently had ID added to her PD prescription.

Case Description: A 38-year-old female with past medical history of DM, HTN, and ESKD on PD for 1 year, presents with diffuse dry skin, pruritic rash and excoriations. This occured 4 days after changing her PD solution to ID. It worsened despite a 3 day course of steroids. Physical exam notable for diffuse superficial desquamation and excoriations. Labs showed mild leukocytosis with a neutrophil predominance. Upon removal of ID from the PD prescription, her symptoms improved and a slow resolution of the skin rash occured. Biopsy showed spongiotic dermatitis, consistent with eczematous/contact dermatitis.

Discussion: ID provides a continuous and longer osmotic gradient because it is absorbed through the peritoneal cavity slower than standard PD solutions. Therefore, ID is used to increase UF. A few case reports and studies documented rare hypersensitivity reactions and exfoliative rashes to ID in dialysis patients. The exact pathophysiologic mechanism is not fully understood, ID is slowly absorbed via the lymphatic system from the peritoneal cavity, and is rapidly hydrolyzed by amylase in maltose, which may cause pruritis. Hypersensitivity reactions may be caused by immune complex formation on the skin. Our case shows a case of spongiotic dermatitis caused by edema and exocytosis of lymphocytes. ID induced skin rashes typically resolves with discontinuation of ID, yet clinicians should remain attentive and consider these potential side effects in patients that develop skin rashes after being initiated on ID solution.

PUB126

Novel Combined Test for Osmotic Conductance to Glucose and Small Solute Diffusion Capacity in Peritoneal Dialysis

Karin E. Bergling, Giedre Martus, Carl M. Öberg. *Lunds Universitet, Lund, Sweden.*

Background: Peritoneal membrane small solute diffusion capacities and osmotic conductance to glucose (OCG) are key determinants of peritoneal dialysis treatment efficiency and patient outcomes. However, current peritoneal function tests for measuring these parameters are cumbersome, inaccurate, and time-consuming. Recently we developed an easy method to determine OCG on the basis of a single 1-h 4.25% glucose dwell (Fig. 1A). Here, we retrospectively assess the ability of the single dwell method to accurately determine also the diffusion capacity (PS) for creatinine.

Methods: Using a recently developed isocratic method, creatinine PS values were firstly determined on the basis of a single 1-h 4.25% dwell, and then validated against (reference) Three-pore model creatinine PS in a Bland-Altman analysis (n=28). Also, a simple equation was developed to convert between PS assessed using 1-hour dwells of 1.5% and 4.25% glucose fluid.

Results: Isocratic PS estimations based on the single 1-h 4.25% dwell correlated closely with the reference method (Fig. 1B) (r^2= 0.98), and had a mean difference of -0.6 ± 1.0 (1.96 SD) mL/min (Fig. 1C). The 1.5% glucose data showed higher variation, having a mean difference of -0.6 ± 3.9 mL/min and r= 0.81 (P <0.001).

Conclusions: The combined single dwell peritoneal function test shows promising estimation accuracy for both creatinine PS and OCG. The present retrospective findings need to be confirmed in a prospective clinical study.

PUB127

Troubleshooting Drain Pain: When Imaging Is Nondiagnostic

Toni Sabbouh, Salma Shaikhouni, Rachel Perlman, Richard D. Swartz. *University of Michigan, Ann Arbor, MI.*

Introduction: Catheter problems account for 17% of cases of PD failure forcing transition to HD. Drain pain is common when starting PD, and is typically attributed to catheter malposition, or the catheter abutting sensitive visceral tissue. We present 2 patients who experienced drain pain with a newly placed PD catheter and discuss our strategies to resolve it.

Case Description: Case 1: A 34 yo woman on PD had an uneventful US guided Tenckhoff catheter placement. She started experiencing significant pain with drains during weekly flushes. The effluent was clear and free of fibrin. An abdominal film showed the catheter in good position. Her pain persisted despite a regular bowel regimen. Ultimately, the patient was taken to the OR for revision. Laparoscopy revealed an adhesion of omentum ensnaring the catheter. The catheter was freed from the adhesion and sutured to the abdominal wall. The patient's pain resolved. **Case 2:** A 24 yo man on PD had uncomplicated laparoscopic placement of a Tenckhoff catheter. He experienced abdominal pain post-operatively, and significant pain with drain during his first flush. Cloudy fluid was noted but cell counts were not concerning for peritonitis. A CT peritoneogram showed the catheter in good position in the pelvis overlying the bladder. Laparoscopic exploration was pursued. This showed no significant adhesions or omentum. The catheter was manipulated away from bowel and secured to the abdominal wall. This resolved the patient's pain.

Discussion: Pain with dialysate drain is often due to catheter obstruction by omentum, bowel, bladder or the peritoneal membrane. Treatment of constipation or use of tidal fill volumes are initial strategies used to address this. When noninvasive methods fail to correct the issue, imaging can help identify tip migration or any adhesions. In the presented cases, we highlight how laparoscopy can be an important tool to salvage a PD catheter, and correct any mechanical obstacles complicating PD therapy.

PUB128

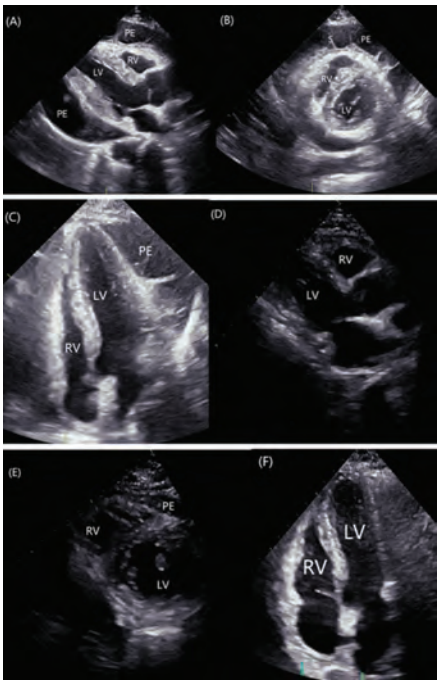
Hemorrhagic Pericardial Tamponade in a Peritoneal Dialysis Patient

Yihsin Chou, Chih-Ching Lin. *Taipei Veterans General Hospital, Taipei, Taiwan.*

Introduction: We report a case of hemorrhagic pericardial tamponade who was non-adherent to peritoneal dialysis with initial presentation of hypotension and syncope.

Case Description: A 46-year-old patient under peritoneal dialysis was hospitalized due to syncope, dyspnea on excertion and hypotension. He had high levels of BUN(~90 mg/dL) and creatinine(~20 mg/dL) in the past year. Low hemoglobin(7.9 g/dL) was found. Furthermore, chest radiograph revealed a round-head boot shape heart. Echocardiography revealed massive septated pericardial effusion with fibrinoid materials(Figure 1, A-C), which was difficult for echo-guided pericardiocentesis. He received pericardial window construction. More than 600 mL bloody effusion was drained. The pathology of pericardium revealed chronic fibrinoid pericarditis. After the operation, the patient's blood pressure increased from 90/60 mmHg to 130/100 mmHg. Follow-up transthoracic echocardiography revealed significant resolution of pericardial effusion and improvement of right ventricle compression(Figure 1,D-F).

Discussion: The traditional uremic pericarditis occurs within 8 weeks of renal replacement therapy. However, it can also develop in non-adherent and under-dialyzed patients with higher level of toxic nitrogenous metabolic end products, free radicals and increased endothelial permeability. Bleeding tendency due to platelet dysfunction can be caused by uremic toxin, anemia and von Willebrand factor dysfunction. Our patient presented with acute bleeding in a chronic inflammatory pericardial space, resulting in a rapid impedance to cardiac filling and decrease in cardiac output. Uremic pericarditis used to be a sign for initiation of dialysis in patient's with chronic kidney disease. It can also remind the clinician of reevaluating the patient's dialysis adequacy before any catastrophic complication such as cardiac tamponade.



PUB129

Abdominal Cocoon Syndrome in Peritoneal Dialysis

Julie G. van Baardwijk, Carlos Kuria, Joe N. Austin. *Christ Hospital, Cincinnati, OH.*

Introduction: Abdominal cocoon syndrome, also known as sclerosing encapsulating peritonitis (SEP), is a rare form of small bowel obstruction (SBO) resulting from peritoneal inflammation inducing formation of a fibrocollagenous membrane. Secondary (non-idiopathic) SEP is seen in patients on peritoneal dialysis, peritonitis, previous abdominal surgery, sarcoidosis, or tuberculosis. We present an interesting case of secondary SEP.

Case Description: A 54-year-old African American male with history of end-stage renal disease on hemodialysis (HD), sclerosing encapsulating peritonitis, recurrent SBO presented with weakness, failure to thrive and fecal drainage through his incision site. Because of his weakness, he had missed two HD sessions. Two and half weeks prior to presentation he was admitted for SBO and underwent ex-lap with lysis of adhesions, umbilectomy, small bowel enterotomy and drain placement to left lower quadrant abscess. He had been on peritoneal dialysis (PD) for about 20 years which was converted to HD due to interval development of intraperitoneal calcification consistent with SEP three years prior to presentation. On admission, potassium was 6.9. He was placed on empiric antibiotics and underwent emergent HD. CT scan of his abdomen demonstrated enterocutaneous fistula and extensive coarse intraperitoneal calcifications consistent with abdominal cocoon syndrome. There was also a left pelvic region abscess with tip of JP drain within the collection. He was evaluated by surgery with recommendations to treat with antibiotics and permanent cessation of oral intake. Abdominal wound cultures grew Escherichia coli. He was discharged with intravenous antibiotics and total parenteral nutrition (TPN).

Discussion: The exact etiology of SEP is unclear due to the rarity of this condition. Abdominal cocoon syndrome is an uncommon complication of chronic ambulatory peritoneal dialysis. It has an incidence of about 2% among patients undergoing PD. The incidence increases with PD duration and can be as high as 5-8% after 3 years. Mortality rates range as high as 50%. Patients can develop SEP while on peritoneal dialysis, but may also present later after renal transplantation or conversion to hemodialysis. The initial management includes removal of the PD catheter, bowel rest and TPN support. Additional treatment strategies include surgical management, steroids, immunosuppressive therapy and tamoxifen.

PUB130

Estimating Caloric Absorption on Peritoneal Dialysis: When Calories Matter!

Emily T. Dorman,[1] Rusty A. Keeney,[2] Melissa Roth,[2] Sandy Jilovec,[2] Lama A. Noureddine.[2] *[1]Iowa City VA Medical Center, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Most formulas that estimate calories absorbed from dialysate do not consider peritoneal dialysis (PD) modality and transport characteristics. We wanted to determine more accurately how many grams of carbohydrate and calories our patients were absorbing from dialysate based on the modality and transport characteristics of patients' peritoneal membrane.

Methods: Nursing staff entered patients' PET information into Baxter Sharesource to determine the membrane type. RDN reviewed patients' monthly dialysis logs to determine what percent dextrose solution was used, obtained patients' dialysis prescriptions from nursing staff, and entered different combinations into PD ADEQUEST software (Baxter Healthcare) to determine the grams of carbohydrates and calories absorbed. This is based on the kinetic formula ($1\text{-}D/D_0$ for dwell time) x initial glucose instilled = grams glucose absorbed. Patient education was provided to reduce fluid intake when using high dextrose solution along with education on minimizing the overall use of high dextrose solution to prolong the longevity of the peritoneal membrane. Grams of carbohydrate and calories were added to the chart to improve communication between departments.

Results: 23 adult patients on peritoneal dialysis were reviewed. Baseline characteristics included 12 females age 25-76, 11 males 32-87; 9 diabetics; 3 on CAPD, 20 on CCPD. Peritoneal membrane transport type included 1 low, 9 low average, 11 high average, and 2 high. PD prescriptions accounted for 37-217 grams of carbohydrates and 128-868 calories based on individual prescriptions (% dialysate used, transport properties, modality).

Conclusions: Quantifying the calories and grams of carbohydrates from the dialysate in peritoneal dialysis is easily accessible through PD ADEQUEST software and is extremely valuable to improve the care of diabetics with ESRD. This information can help optimize blood sugars and improve eligibility for transplant. Estimating caloric absorption on peritoneal dialysis is important for patients needing nutrition support to avoid over/underfeeding and should be considered in patients who struggle with obesity.

PUB131

A Central Venous Catheter That Cannot Be Dislodged Easily by a Confused Patient

Shuqin Mei. *Shanghai Changzheng Hospital, Shanghai, China.*

Introduction: The optional type of permanent access for hemodialysis among the elder is controversial. Reliable vascular access which can provide adequate blood flow is a prerequisite for hemodialysis. Exhausted vasculature, patient comorbidities, and life expectancy should be taken into consideration for whether it is worth to place an arteriovenous fistula (AVF)/arteriovenous graft (AVG). So the tunneled central venous hemodialysis catheter are both preferred choices for end-stage renal disease patients who have an urgent need for hemodialysis. But sometimes patients dislodged or pulled out central venous catheters by mistake or confused.

Case Description: A 75-year-old hemodialysis man with a history of multiple arteriovenous fistula operations was admitted to our clinic for the poor blood flow of 150ml/min. Although the AVF was historically known to be the ideal option for vascular access, the aging old man had no chance because of the poor vessel quality on both arms, and the tunneled hemodialysis catheter was optioned to be chosen. In view of the cerebral infarction induced intelligence obstacles of the patient, atypical tunnel of the catheter should be considered in case of the catheter pulled out by the patient unconscious. During the procedure without fluoroscopy, the guidewire entered the vessel smoothly after successful puncture into the right external jugular vein with the left lateral position of the patient. The exit of the tunnel was 5cm right to the middle of the spine at the level of the third thoracic which was out of reach of the patient and a cuffed hemodialysis catheter was eventually inserted through the peel-away sheath, and finally the catheter entered the vessel with satisfactory venous blood return. Hemodialysis was initiated with blood 200ml/min without any complication.

Discussion: To find a solution for confused or uncooperative patients, we conducted a different method. On the basis of our experience, we recommend clinicians consider using these techniques when placing a central venous catheter in a patient who is confused or uncooperative to prevents the patient from dislodging it. Although the back exit at the level of the third thoracic is better to avoid dislodging the central venous cathete comparing with the normal exit, it may uncomfortable when the patinet lying on bed or receiving hemodialysis treatment. Anyway, the best method is the right and suitable for the patient.

PUB132

Hemodialysis Catheters: the Good, the Bad and the Ugly

Jafar Alsaid. *Ochsner Medical Center - New Orleans, New Orleans, LA.*

Background: Over the past decades with all the efforts spent for fistula first, hemodialysis catheters are still used in more than 80% of patients for hemodialysis initiation. Moreover, up to 18 months after starting dialysis around 20% of the patient still have catheters as the main vascular access. Catheters are a vital component of our ESRD renal replacement care, and we need to learn more about them. This review covers all the evidence based data on HD catheters. "Knowing your enemy would give a leading step in winning the battle" *Art of War.*

Methods: Review of the current evidenced based and research including the CDC and NKF recommendation for utilization and care of HD catheters. This will be discussed to answer the following specific questions: What is the relation of Hemodialysis catheters with blood stream infection? What is the optimal practice in utilizing HD catheters? When, Where, How and Why? to use a dialysis catheter?

Results: Upon reviewing the evidence including the NKF and the CDC latest recommendation, the following answers were obtained for the above questions: There was a higher association between hemodialysis blood stream infection and catheters. The studies were retrospective with association. There was no prospective randomized controlled trail which showed a difference in the type of the access and the risk of hemodialysis blood stream infection. Tight infection control policy with full PPE for the staff and patients showed reduced risk of infection. This is needed during insertion or when using the catheter for hemodialysis. No randomized controlled trials were found. The hemodialysis catheters might be recommended in certain cases; elderly or short life expectancy and those with sever heart failure. Rt. IJ is the preferable insertion site. Ultrasound guided insertion is required with fluoroscopy for cuffed tunneled catheters.

Conclusions: With all the efforts spent to make the AV fistula as the first and main vascular hemodialysis access, we still have significant number of patients, specifically upon initiation of hemodialysis, using catheters as the main hemodialysis access. Taking care of the catheter utilization using high infection control protocols might be able to reduce the negative impact the catheters has on the blood stream infection rates. We need these catheter to save patient lives and we need to improve the way we are handling them.

PUB133

Vascular Access: A Screening Medical Device to Identify Patients at Risk for Access Dysfunction and Thrombectomy

Suha I. Moten,[1] Anis A. Rauf,[2] DeLynn Huff.[3] *[1]Midwestern University - Downers Grove Campus, Downers Grove, IL; [2]Nephrology Associates, Oakbrook, IL; [3]Vascular Access & Consulting, Lafayette, IN.*

Introduction: USRC Oakbrook has 13 dialysis stations for patients with end-stage kidney disease. The Medical Director wanted to improve patient outcomes by improving vascular access management. Vasc-Alert, an FDA-approved medical device, was used to screen for vascular access stenosis and provided reports with historical results upon initial staff training. Vasc-Alert was effective in identifying patients at risk for access dysfunction, which if left undetected can increase the risk for thrombosis.

Case Description: Initially, Vasc-Alert identified 9 patients on alert. 6 were deemed high risk. 4 patients were successfully referred for an angioplasty, but 2 patients thrombosed before referral. The remaining 3 alert patients were considered low risk. This report discusses 2 specific patients Vasc-Alert identified and proved intervention was needed. WA presented in March 2019 with no significant problems and met Kt/V. The patient was routinely on alert and later had longer post-bleeding time and plateauing lab data. Referred in April 2021 after Vasc-Alert training. The Kt/V and post-bleeding time significantly dropped. The patient has had no alerts and has been achieving adequacy. BP presented to USRC in January 2019 and had an angioplasty with minimal problems. Prior to thrombectomy in March 2021, BP was consistently on alert with no other clinical indicators of dysfunction. Clinical training for Vasc-Alert occurred two days prior to her clotting. There was insufficient lead time to refer based on Vasc-Alert data, but it is sufficient to deduce that Vasc-Alert successfully predicted future clotting.

Discussion: While USRC had an active vascular access management program, these 6 patients were not previously identified. The introduction of the Vasc-Alert surveillance helped focus on the patients at the greatest risk. While the recent 2019 KDOQI guidelines for vascular access discounted the use of surveillance devices from the prior 2006 guidelines, this case study indicates that surveillance devices can still be useful in helping busy staff focus on patients at high risk of complications. Vasc-Alert has successfully alluded to future problems and thus has the potential to improve diagnosis and treatment plans for patients with access dysfunction.

PUB134

Ambulatory Surgery for Vascular Access of Hemodialysis Patients: A Retrospective Observational Study

Xueqin Bian, Hong Ye, Wenjing Zhou, Yang Zhou, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: To demonstrate the clinical efficacy and safety of ambulatory surgery for vascular access of hemodialysis patients.

Methods: A total of 1845 hemodialysis patients receiving ambulatory surgery for vascular access from September 2017 through December 2020 were enrolled. The clinical characteristics, surgery procedures, safety, efficacy and cost were analyzed.

Results: The mean age was 57.1 years, 53.4% were male, and medium dialysis vintage was 61.9 months. The percentages of the existing vascular accesses of arteriovenous fistula (AVF), arteriovenous graft (AVG), tunnel-cuffed catheter (TCC) and non-cuffed catheter were 58.6%, 30.9%, 3.3% and 3.9%, respectively. The operation methods of ambulatory surgery was interventional surgery (82.3%), hybrid surgery (11.4%), TCC (4.1%) and digital subtraction angioplasty (1.3%). All of the surgery was successfully completed, and the primary patency rate was 100% at 30 days after the surgery. The average operation time was 68.3±10.6 minutes. The average duration of hospitalization was 17.7±6.3 hours. The average total cost of each hospitalization was 9121.3±2818.3 RMB including the operation fee of 2211.7±843.2 RMB and disposable medical material cost of 4587.6±2073.2 RMB.

Conclusions: Ambulatory surgery for vascular access of hemodialysis patients may help improve the efficiency of vascular access surgery.

PUB135

The Patency of Percutaneous Intervention-Treated Vascular Access for Hemodialysis Patients and Risk Factors for Recurrent Vascular Stenosis

Wenjing Zhou, Hong Ye, Xian Wu, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Stenosis is one of the main causes of dysfunction of vascular access for hemodialysis. Percutaneous transluminal angioplasty (PTA) has become a promising treatment. This study aimed to demonstrate the patency of percutaneous intervention-treated vascular access for hemodialysis patients in our dialysis center and to explore the risk factors for recurrent of vascular stenosis after PTA.

Methods: The general demographic information, complications, anthropometric parameters, ultrasonographic characteristics of internal fistula before operation, balloon diameter and stenosis opening pressure during operation, and corresponding vascular characteristics by ultrasound after operation were recorded. The patients were followed-up at 1, 3 and 6 months after operation, and follow-up every 6 months thereafter. The recurrent of stenosis and other fistula related complications were registered. Potential risk factors affecting the primary patency and postinterventional stenosis were analyzed.

Results: Among the 135 patients, 70 patients had arteriovenous fistula (AVF), the rests had arteriovenous graft (AVG). PTA was successfully operated in 90.37% of thr patients. Hematoma occurs in 5 patients during the operation. The primary patency rates at 1, 3, 6 and 12 months after operation were 97.78%, 84.4%, 62.96% and 45.93%, respectively. The larger peak systolic flow velocity ratio (PSVR) after PTA, smaller stenosis venous diameter before PTA, and older in age are risk factors for early recurrent of stenosis after PTA. Multivariate regression analysis showed that diastolic blood pressure > 88 mmHg and balloon diameter > 6mm were risk factors for recurrent of stenosis after PTA in patients with AVF. As for patients with AVG, the risk of recurrent of stenosis in patients taking antiplatelet medicine was 2.652 times than those without taking antiplatelet medicine (95% CI 1.393-5.047, P=0.003), suggesting that patients at hypercoagulable state may have a high risk of recurrent of stenosis.

Conclusions: The safety and efficacy of PTA for treatment of stenosis of vascular access is confirmed in this study. High diastolic blood pressure, balloon with larger diameter, elderly and antiplatelet medication are risk factors for recurrent of stenosis after PTA.

Funding: Government Support - Non-U.S.

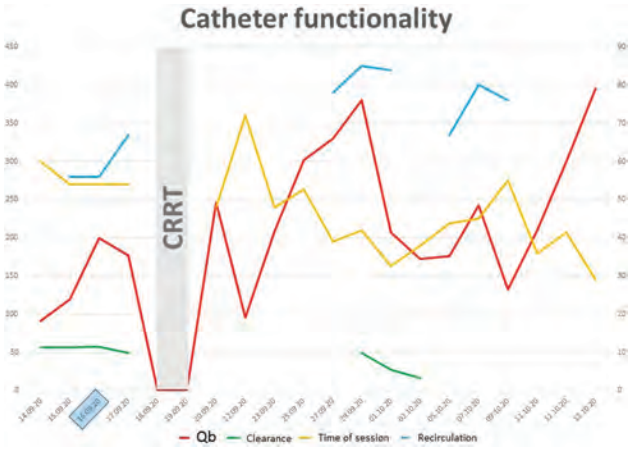
Successful Catheter Lock with Recombinant Tissue Plasminogen Activator as a Rescue Therapy in Hemodialysis Catheter Dysfunction in a Patient with Exhausted Vascular Access

María Guadalupe C. Núñez,[1] Salvador L. Gil,[1] Marcos G. Nava,[2] Lillana Pacchiano.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico.*

Introduction: Hemodialysis (HD) catheter complications are infection and occlusion. A catheter locking solution after HD sessions try to prevent them. Heparin and citrate has been used and the efficacy is successful in general population, but in patients with thrombophilia and exhausted vascular access could not have same effectiveness. Recombinant tissue plasminogen activator (rt-PA) has been used as an option.

Case Description: A 45 year-old women with ESRD due to collapsing glomerulophathy was taken to transplantation in 2 occasions with recurrence of glomerulopathy. She was maintained in peritoneal dialysis for 15 months, migrated to HDF due to refractory bacterial peritonitis. During next years she suffered from several catheter changes because of dysfunction and infections. Also, 2 arteriovenous fistulae did not work because of thrombosis, documenting elevated factor VIII, receiving anticoagulation. Then, central venous stenosis was documented and several femoral catheters were collocated, with infradialysis, increasing session time (240 to 270 min), using citrate locks, but blood flow pupm (Qb) diminished to 80 cc/min and she was hospitalized to perform an arteriovenous axilo-atrial graft placement presenting thrombosis. Finally, we use rt-PA to lock lumens, achieving an incremented Qb from 152.21 with citrate to 251.5 cc/min with rt-PA and substitution volume from 11.2 L to 33.56 L, respectively, but without improvement in recirculation rate (Figure 1). She was discharged, but after 2 days she died due to mesenteric ischemia.

Discussion: The options to treat a dysfunctional catheter in the setting of exhausted vascular access are limited with conventional lumen locks, the utility of rt-PA to prevent them in recently placement catheters has been demonstrated, but there is no description of the utility in cases like ours, to try to rescue an access to continue the therapy. We can improve the functionality of the vascular access, but the impact in substance clearance probably will not.



PUB137

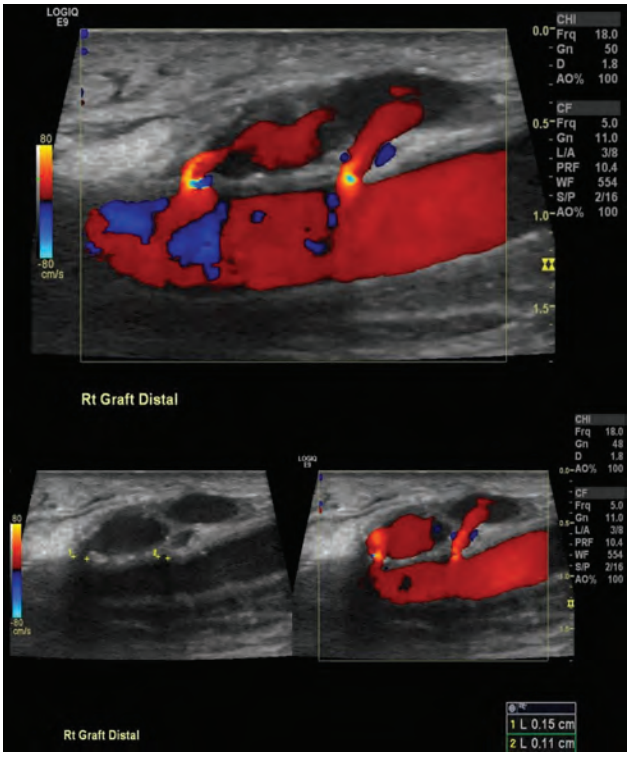
Unusual Ultrasound Graft Finding

Christy Gossett, Wisit Cheungpasitporn, Andrea G. Kattah, Fawad Qureshi. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: 42-year-old female with ESKD, dialysis dependent for 5 years, presented to ER feeling unwell and hyperkalemic to 6.8 mmol/L. Due for dialysis that morning but no missed dialysis sessions recently. Access is a right brachial artery to brachial vein loop graft created about 4 months ago. Graft had been difficult to cannulate with elevated pressures and pain requiring a decrease in blood flow rate or early treatment termination.

Case Description: Bruit, thrill and subcutaneous edema of the right arm overlying the graft noted. US revealed patent graft but unexpected findings of three adjacent fistulous communications between the distal loop graft and a superficially overlying subcutaneous branch of the right cephalic vein (figure 1). No surgical intervention recommended by Vascular Surgery. Repeat US done to mark patient's arm with cannulation sites resulted in successful cannulation and patient discharge. 1 month later, patient readmitted with similar presentation as markings not been preserved and cannulation challenges recurred. More extensive markings were created, identifying the overlying vein as well as cannulation sites. Patient refused further use of the graft and required central venous catheter placement.

Discussion: We describe an unusual case of difficult AV graft cannulation due to overlying cephalic vein. Cannulation improved with skin marking to guide cannulation, though due to impermanence of the markings, rehospitalization occurred and central catheter placement was required due to patient refusal to allow further graft cannulation. Early assessment of cannulation challenges with diagnostic US in patent dialysis fistulas or grafts may identify unexpected causes of cannulation. US and skin marking is a potential means of improving cannulation difficulties and avoid central catheter placement in unusual cases, such as described.



PUB138

Livestreaming in Instagram for the Kidney Health Promotion During Covid-19 Pandemic: Report of an Experience in Brazil

Juliana G. de Oliveira, Luisa Falcão Silva, Julia d. Barroso, Victor F. Costa, Lucas A. Mendes, Mirella N. Matos, Raul Victor L. Torres, Thaís A. Fontenele, Marcella Z. Martins, Geraldo B. Silva Junior. *Universidade de Fortaleza, Fortaleza, Brazil.*

Background: Chronic kidney disease (CKD) awareness is an important strategy to decrease its advance. The aim of this study was to describe livestreaming in Instagram during the World Kidney Day (WKD) 2021 in Brazil.

Methods: During the WKD 2021, the Renal Health project in Brazil carried out a week of health promotion online. Due to COVID-19 pandemic, which severely affected Brazil, all the activities were conducted online. From 1st to 11th March 2021, livestreaming sessions were carried out through the Instagram (@renal_health), with healthcare specialists and patients, discussing different aspects of CKD, with focus on the patients and the general audience. The followers could ask questions during the sessions and it was recorded to be accessed later (https://www.instagram.com/renal_health/channel/).

Results: A total of 3479 views were registered. The most viewed was the session about "resignifying life after dialysis", with 827 views, followed by "conservative treatment and lifestyle", with 549 views, and "kidney transplant and quality of life", with 537 views. There were 38 spontaneous feedbacks, most of them of compliments regarding the sessions. All sessions obtained a positive result from spectators, who posted compliments, such as "I loved the live, enlightening" and "congratulations on the subject, clear and highly enlightening language". Feelings about the impact of CKD were expressed: "these conversations with the interviewees are clearing my mind, as I also have kidney problems". Experiences that improved CKD knowledge could be shared: "I liked that the doctor said that it would be even better to have a transplant even before undergoing hemodialysis".

Conclusions: This experience evidence the importance of connecting with patients, using simple language, and the importance of digital means, including the Instagram, as a way of reliable health education. The true impact of COVID-19 on patients with CKD is yet to be known, but the nephrology community and health professionals as a whole should already be aware that patients are getting increasingly connected, and that is possibly the direction for the future.

Online CME Improves Clinician Understanding of Emerging Treatments for CKD-Anemia

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape Education, New York, NY.*

Background: We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologists (nephs) and primary care physicians (PCPs) related to emerging Hypoxia-Inducible Factor Prolyl Hyproxylase Inhibitors (HIF-PHIs).

Methods: The effect of an online, 30-minute, CME-certified 2-expert discussion was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and a paired samples t-test for overall and McNemar's test at the question level (5% significance level, P <.05) assessed educational effect. The activity launched January 5, 2021 and data were collected through March 25, 2021.

Results: In total, 354 nephs and 334 PCPs answered all pre-/post-assessment questions and were included in the study. Overall, 54% of nephs and 38% of PCPs improved their knowledge (P<.01 for both groups) 37% of nephs and 23% of PCPs demonstrated improvements at identifying dose requirement comparisons for inflamed vs noninflammed patients (P<.01 for both groups) 17% of nephs and 15% of PCPs demonstrated improvements at recognizing clinical trial data related to safety for emerging HIF PHIs (P=NS for both groups) 13% of nephs and 12% of PCPs demonstrated improvements at recognizing clinical trial data related to iron status for emerging HIF PHIs (P=NS for both groups) (P=NS for both groups) 54% of nephs and 46% of PCPs reported increased confidence in knowledge of HIF-PHIs in the treatment of anemia in patients with CKD who are iron replete or nonreplete Continued gaps: 35% of nephs and 54% of PCPs need additional education related to identifying dose requirement comparisons for inflamed vs noninflammed patients 56% of nephs and 70% of PCPs need additional education related to recognizing clinical trial data for emerging HIF PHIs 23% of nephs and 50% of PCPs need additional education related to recognizing clinical trial data related to iron status for emerging HIF PHIs

Conclusions: This study demonstrates the success of online, video-based 2-expert discussion on improving knowledge of nephs and PCPs related to HIF-PHIs for the treatment of anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

PUB140

Success of Online CME at Improving Nephrologist Understanding of Strategies to Reduce Progression of CKD

Amy Larkin, Kelly L. Hanley, Rita Moreira da Silva. *Medscape Education, New York, NY.*

Background: Clinicians need good clinical understanding of new strategies for reducing progression of CKD. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologists and primary care physicians (PCPs) related to use of SGLT2 inhibitors to reduce the progression of CKD.

Methods: The effect of an online, 30-minute, CME-certified 3 faculty roundtable discussion was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and a McNemar's test was conducted to assess significance at the question level (5% significance level, P <.05) assessed educational effect. The activity launched November 30, 2020 and data were collected through February 22, 2021.

Results: In total, 307 nephrologists and 224 PCPs answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation in both CME activities: 16% of nephrologists and 21% of PCPs demonstrated improvements at identifying clinical trial data for SGLT2 inhibitors in the reduction of CKD progression (P<.05 for both groups) 9% of nephrologists and 11% of PCPs demonstrated improvements at adjusting therapy in a patient needing enhanced renal protection (P<.01 for nephrologists, P=.05 for PCPs) 40% of nephrologists and 39% of PCPs had a measurable increase in confidence in knowledge of renal benefits of SGLT2 inhibitors Continued educational gaps: 27% of nephrologists and 41% of PCPs need additional education related to clinical trial data for SGLT2 inhibitors in the reduction of CKD progression

Conclusions: This study demonstrates the success of online, video-based roundtable panel discussion on improving knowledge of nephrologists and PCPs related to use of SGLT2 inhibitors to reduce the progression of CKD. Continued knowledge gaps were identified for future educational targets.

PUB141

Online Video-Based CME Successful at Improving Knowledge of Nephrologists Related to Mineralocorticoid Receptor Antagonists for CKD in Type 2 Diabetes

Amy Larkin, Kelly L. Hanley, Anne Le. *Medscape Education, New York, NY.*

Background: One goal of continuing medical education (CME) is improving knowledge related to mechanisms of action for new therapeutic options. We sought to determine if a video-based CME activity could improve the knowledge of nephrologists related to the mechanism of action of nonsteroidal mineralocorticoid receptor antagonists (MRAs) in the management of chronic kidney disease (CKD) in patients with type 2 diabetes (T2D).

Methods: The online CME activity consisted of a 30-minute, video-based presentation by 1 expert faculty using green screen technology to enhance the visual presentation related to mechanism of action. To measure outcomes, a repeated pairs pre-/post-assessment study design was used and a paired samples t-test for overall and McNemar's test at the question level (P <.05 is considered significant) assessed statistical significance. The activity launched in December 2020 and data were collected through March 2021.

Results: In total, 233 nephrologists answered all pre-/post-assessment questions and were included in the study. Improvements were seen after participation in the CME activity: Overall, 36% of learners improved their knowledge (P<.01) 19% of nephrologists demonstrated improvements at identifying mechanism of action of MR blockade in treating CKD in T2D (P<.01) 24% of nephrologists demonstrated improvements recognizing clinical differences in steroidal MRAs and nonsteroidal MRAs (P<.01) 30% had a measurable increase in confidence in managing CKD in T2D (P<.01) Continued educational gaps: 22% need additional education related to mechanism of action of MR blockade in treating CKD in T2D 33% need additional education related to clinical differences in steroidal MRAs and nonsteroidal MRAs

Conclusions: This study demonstrates the success of online, video-based presentation using green screen technology on improving knowledge of nephrologists related to mechanism of action of nonsteroidal MRAs in managing CKD in T2D. Continued knowledge gaps were identified for future educational targets.

PUB142

Success of Online CME Improving Nephrologists' Knowledge Related to Emerging Agents for Hepatorenal Syndrome

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape Education, New York, NY.*

Background: Clinicians need to understand clinical profiles of emerging agents in order to use safely and effectively when available to improve their patient management of HRS. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologists related to emerging treatments for HRS.

Methods: The effect of an online, 30-minute, CME-certified summary of a satellite symposium presented at the American Association for the Study of Liver Diseases (AASLD) 2020 annual meeting was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design, paired samples t-test for overall and McNemar's test at the question level (5% significance level, P <.05) assessed educational effect. The activity launched January 5, 2021 and data were collected through April 12, 2021.

Results: In total, 324 nephrologists answered all pre-/post-assessment questions and were included in the study. Matched learner data indicate that overall, 35% of responses improved from pre-to-post (P<.001) On a question-level: 12% of nephrologists improved at recognizing clinical trial data for an emerging treatment options for HRS 27% of nephrologists improved at acute kidney injury (AKI) in a patient with cirrhosis 5% of nephrologists improved at selecting the next step in treatment for a patient with HRS Overall, 58% of nephrologists had a measurable improvement in confidence in your knowledge of emerging treatment options for patients diagnosed with HRS-AKI, for an average confidence shift of +70%. Continued educational gaps: 35% of nephrologists did not recognize clinical trial data for an emerging HRS treatment option 16% of nephrologists did not recognize AKI in a patient with cirrhosis

Conclusions: This study demonstrates the success of an online summary from a satellite symposium on improving management of HRS by nephrologists. Continued knowledge gaps were identified for future educational targets.

PUB143

Online CME Is Successful in Prompting Performance Improvements Related to Hyperkalemia Management

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape Education, New York, NY.*

Background: We studied the effect of online education designed to improve the clinical performance of nephrologists, cardiologists, and NPs/PAs related to hyperkalemia management to enable/optimize RAAS inhibitor use.

Methods: The CME activity was a 30-minute online video roundtable panel discussion between 3 experts. Faculty discussion was reinforced with synchronized slides presenting supportive data. The impact of the education on performance outcomes was measured with a survey immediately post-education to assess planned changes in clinician practice as a result of participation in CME activity. Survey participants were contacted 8 weeks later to assess self-reported actual changes in practice. The activity launched October 6, 2020 and data were collected through April 30, 2021.

Results: A total of 275 clinicians completed the survey immediately post-education (91 nephrologists, 75 cardiologists, 109 NPs/PAs) 19% of nephrologists, 8% of cardiologists, and 4% of NPs/PAs treat >100 patients per month taking RAAS inhibitors 63% of nephrologists, 40% of cardiologists, and 42% of NPs/PAs are in private practice 44% of nephrologists, 64% of cardiologists, and 36% of NPs/PAs reported being in a suburban location 91% of respondents indicated an average of 3.2 planned practice changes each 28 cliniciansw completed the follow-up survey (12 nephrologists, 6 cardiologists, 10 NPs/PAs) Of those, 86% reported making an average of 3.9 changes in practice as a result of this activity. Changes in practice include: Consider a loop diuretic to increase potassium clearance and enhance volume management (67% nephrologists, 83% cardiologists, 50% NPs/PAs) Reviewing medications and diet to identify factors contributing to hyperkalemia (58% nephrologists, 83% cardiologists, 70% NPs/PAs) Controlling hyperkalemia with a novel potassium binder to optimize dose of RAASi (58% nephrologists, 33% cardiologists, 50% NPs/PAs) Using patiromer in patients on spironolactone to maintain normokalemia and allow for spironolactone continuation and dose uptitration, per the PEARL-HF Study (58% nephrologists, 33% cardiologists, 40% NPs/PAs).

Conclusions: The outcomes gathered in this assessment provide compelling evidence that participation in a 30-minute online video discussion among 3 experts prompted changes in practice to provide better hyperkalemia management to their patients.

PUB144

Success of Virtual Patient Simulation at Improving Diagnosis and Management of Chronic Hyperkalemia

Amy Larkin, Donald Blatherwick. *Medscape Education, New York, NY.*

Background: We sought to determine if virtual patient simulation (VPS)-based continuing medical education (CME) intervention could improve performance of nephrologists related to diagnosis and management of hyperkalemia.

Methods: The intervention comprised a patient presenting at two different time points in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions using a McNemar's test to determine *P* values. The activity posted October 30, 2020; initial data was collected through March 10, 2021.

Results: To date, 86 nephrologists completed the activity (all decisions within at least 1 case) and were included. Significant improvements were observed after CG: Initial visit: Diagnose CKD stage 3b: 34% absolute improvement (8% pre-CG vs 42% post-CG; P<.01) Diagnose hyperkalemia: 29% absolute improvement (8% pre-CG vs 37% post-CG; P<.01) Initiate a potassium binder: 36% absolute improvement (22% pre-CG vs 58% post-CG; P<.01) Initiate loop diuretic: 57% absolute improvement (5% pre-CG vs 62% post-CG; P<.01) Discontinue oral naproxen: 10% absolute improvement (85% pre-CG vs 95% post-CG; P<.01) Order patient education: 12% absolute improvement (50% pre-CG vs 62% post-CG; P<.01) Order nutritional counseling: 15% absolute improvement (50% pre-CG vs 65% post-CG; P<.01) Follow-up visit: Diagnose chronic hyperkalemia: 36% absolute improvement (4% pre-CG vs 40% post-CG; P<.01) Continue potassium binder: 9% absolute improvement (89% pre-CG vs 98% post-CG; P<.05) Continue loop diuretic: 11% absolute improvement (87% pre-CG vs 98% post-CG; P<.05) Order patient education: 13% absolute improvement (47% pre-CG vs 60% post-CG; P<.01) Order nutritional counseling: 17% absolute improvement (36% pre-CG vs 53% post-CG; P<.01)

Conclusions: VPS that immerses and engages specialists in an authentic and practical learning experience can improve evidence-based clinical decisions related to patient identification and management of hyperkalemia.

PUB145

Online CME Improves Clinician Understanding of Quality-of-Life Issues in Patients with Metabolic Acidosis

Amy Larkin, Donald Blatherwick, George Boutsalis. *Medscape Education, New York, NY.*

Background: We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologists (nephs) and primary care physicians (PCPs) related to quality of life issues in patients with metabolic acidosis and emerging treatments options.

Methods: The effect of an online, 30-minute, CME-certified 2-expert discussion was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design, paired samples t-test for overall and McNemar's test at the question level (5% significance level, P <.05) assessed educational effect. The activity launched November 4, 2020 and data were collected through January 27, 2021.

Results: In total, 416 nephs and 502 PCPs answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation in both CME activities: Overall, 44% of nephs and 53% of PCPs improved their knowledge (P<.01 for both groups) 8% of nephs and 25% of PCPs demonstrated improvements identifying signs of excess acid retention (P=NS for nephs, P<.01 for PCPs) 23% of nephs and 19% of PCPs demonstrated improvements identifying effect of increasing sodium bicarb in patients with CKD and metabolic acidosis (P=NS for nephs, P<.01 for PCPs) 26% of nephs and 30% of PCPs demonstrated improvements recognizing effect of emerging treatment for metabolic acidosis (P<.01 for both groups) 36% of nephs and 45% of PCPs had a measurable improvement in confidence discussing QOL concerns with metabolic acidosis (P<.01 for both groups) Continued educational gaps: 19% of nephs and 39% of PCPs need additional education related to identifying excess acid retention 42% of nephs and 55% of PCPs need additional education related to effect of increasing sodium bicarb in patients with CKD and metabolic acidosis 38% of nephs and 52% of PCPs need additional education related to data on emerging treatment options for metabolic acidosis

Conclusions: This study demonstrates the success of online, video-based 2-expert discussion on improving knowledge of nephs and PCPs related to QOL issues with metabolic acidosis and emerging treatment options. Continued knowledge gaps were identified for future educational targets.

Nephrology Best Practice, Integrating Healthcare Education, and CKD: A Qualitative Perspective

Shahid N. Muhammad.[1,2] *[1]The University of the West of England (UWE), England UK, Bristol, United Kingdom; [2]The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.*

Background: Education and information seeking is pinnacle for patients with Long-Term Conditions (LTCs) like Chronic Kidney Disease (CKD) to take ownership of health and disease and navigate healthcare between health sectors. Patient and Public Involvement (PPI) is key to help understand gaps in health education. 1) Involving patients between two support groups to help understand which topics and subjects are pertinent to CKD patients; 2) Involving patients to understand whether, retrospectively there has been an educational neglect in healthcare; and 3) To understand how healthcare and education for CKD patients could be more integrated.

Methods: Two PPI workshops were implemented (May and June 2019) after reviewing NIHR INVOLVE best practice guidelines. Fourteen (14) topic tags were applied over 1-month (March and April 2020) between the Renal Patient Support Group (RPSG) (est.2009) and the Kidney Disease and Renal Support (KDARs) (est.2014) for Kids platforms. Group disclaimers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice surrounding confidentiality and data protection.

Results: Thematic Analysis was used to highlight findings, according to over-arching themes having used Nvivo-12 software to code and help understand where there are healthcare educational inefficiencies. Five themes were identified through this study including 1) Using Different Mediums to Collect Qualitative Data and Understanding Healthcare; 2) Reliability and Validity of using the Internet to Collect Data; 3) Healthcare, Patient and Public Involvement and Maintaining Confidentiality through Online Methods to collect Qualitative Data; 4) Advantages, Disadvantages and Limitations to Online Data Collection and Peer Support Groups and 5) Using Qualitative Methodology to Understand Educational Needs for CKD Patients.

Conclusions: Wider Allied Health Professionals (AHPs) could increasingly find themselves taking on roles, particularly where involvement is increasingly dependent bridging educational gaps and 'alleviating misinformation' through technology and 'online spaces'. **Conclusion:** This is the first UK retrospective study that examines educational gaps between online paediatric and adult CKD patients close to two decades (16 years), and highlights where further PPI-focused research would help understand where healthcare requires investment.

PUB147

What, If Any, Are the Nephrology Health Educational Needs of CKD Patients: A Qualitative Inquiry

Shahid N. Muhammad.[1,2] *[1]The University of the West of England (UWE), England UK, Bristol, United Kingdom; [2]The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.*

Background: An estimated 15 million patients in England have at least one Long-Term Conditions with the prevalence of CKD rising. The characterization of CKD at all stages is an important part of its management and allows the initiation of appropriate treatments with the aim of slow progression of kidney disease. Providing up-to-date, accurate health education is pinnacle for patients to take ownership of healthcare. Patients require educational support as part of healthcare and help navigate understanding with different healthcare professionals. The aims and objectives of this research was to understand how CKD patients should be encouraged to take ownership of healthcare through education.

Methods: The theoretical framework for this research involved an Inductive Content Analysis (ICA) approach where essentially qualitative data collection and analyses will help understand what if any, are the health educational needs getting perspectives from CKD patients and Health Professionals (HPs). ICA is particularly effective to help understand analysis in linking theory, or framework.19 participants between 4 cohorts, that included 6 General Practitioner (GPs), 4 Healthcare Scientists (HS), and 6 CKD Patients (CKDPs) were recruited and participated in telephone interviews.

Results: Majority of CKDPs were in between CKD4 and CKD5. Interviews allowed participants to put forward views and understanding, relating to healthcare education. Topic guides were developed for participant cohorts with several themes to collect data through one-to-one telephone interviews. NViVo-12 software provided opportunity to classify and arrange transcript context and glean insight to develop overall conclusions. Nine (9) main themes and several sub-themes were identified when coding for healthcare professionals (HPs), and Nine (9) main themes and several sub-themes identified when coding qualitative data for patients (CKDPs).

Conclusions: There needs to be a coordinated effort between patients and professionals, to understand how CKD education is more integrated with healthcare, and especially wherein involvement is end-to-end. This exploratory study provides evidence applying research to public health. Every effort has been made to reduce biases and diminish disparities. Point of Care Education (POCE) could be an integrated through online spaces and linked to Electronic Patient Records (EPRs).

PUB148

Chronic Hyponatremia: Challenges in Diagnosis and Management

Shivangi Patel. *Atlantic Health System Inc, Florham Park, NJ.*

Introduction: Hyponatremia is manifestation of variety of disorders. Hyponatremia occurs as result of water intake exceeds greater than water excretion. Management becomes a challenge due to etiology and costly drugs.

Case Description: 46-year-old-male computer engineer who exercises 3 times a week, takes 25 grams of protein shake daily with no past medical history, not on meds, noted to have chronic sodium of ~ 126 mEq/L with stable BMI 26. His only complaint was mild fatigue. His exam was normal with a negative orthostatic. Labs: Sodium 126 mEq/L, Potassium 3.6 mEq/L, uric acid 2.8 mEq/L, Creatinine 0.65 mg/dL, Serum Osmolality 266 mOsm/kg, Urine sodium 72 mEq/L, Urine potassium 60.1 mEq/L, specific gravity 1.018, Urine Osmolality, 626 mOsm/kg H2O and Copeptin 6.2 pmol/L. Renal, adrenal, and thyroid function are normal. Imaging of brain, chest and abdomen is negative for pathology. He underwent colonoscopy with suprep which provided the least amount of volume load and Ure-Na prescribed to keep his serum sodium stable during the bowel prep. Max sodium achieved was 130 mEq/L after 30 g bid of Ure-Na. It was discovered later, his brother was noted to have serum sodium of 115 diagnosed at age 20 and maintained on sodium bicarb but was never tested genetically, nor achieved normal sodium levels.

Discussion: Labs were consistent with SIADH however he had undetectable copeptin level and negative workup for malignancy. Due to family history with negative workup for any other etiology, he likely has Nephrogenic Syndrome of Inappropriate Diuresis (NSIAD). NSIAD is caused by gain-of-function mutation in AVP receptor type 2 located on long arm of X chromosome (Xq28). Genetic confirmation for NSIAD is pending and if positive will need to test other family members. Management for chronic hyponatremia was challenging as fluid restriction was not realistic to adhere to as sugested by his high urine (Na+K) and high urine osmolality > 500mOsm/kg. Ure-Na was useful at time of bowel prep to avoid worsening of hyponatremia, however never achieved normal sodium even after 30 g bid Ure-Na. Vaptans were not tried as are more costly than Ure-Na and unclear efficacy in NSAID. Patient did not want to pay $80 of Urena, and he increased his protein intake to 75 g daily with fluid restriction 1.5 L/day, which maintained his sodium level at 130.

PUB149

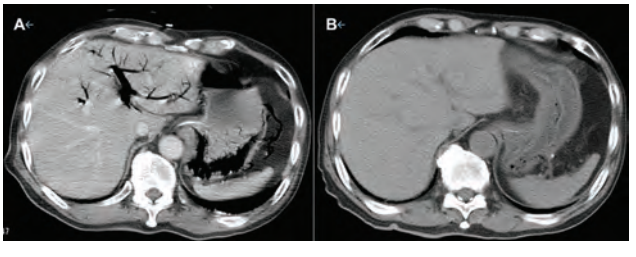
Spontaneous Regression of Hyperammonemic Encephalopathy, Lactic Acidosis, Gastric Mucosa Injury, and Hepatic Portal Vein Gas After Infusion of 5-Fluorouracil

Yoshihiro Nakamura.[1,2] *[1]Toyohashi-shi, Toyohashi, Japan; [2]Chubu Rosai Byoin, Nagoya, Japan.*

Introduction: 5-fluorouracil (5-FU) therapy is associated with hyperammonemic encephalopathy and lactic acidosis. 5-FU has a direct toxic effect on the gastric mucosa. Hepatic portal venous gas (HPVG) is caused by various factors including bowel necrosis and gastroduodenal ulcers.

Case Description: A 79-year-old man was referred to the nephrology department owing to lactic acidosis. He had a history of hypopharyngeal carcinoma. Two days prior to the consultation, he was started on 300 mg of carboplatin and 4000 mg/m^2 of 5-FU as a continuous intravenous infusion. On the consultation day (day 1), he was experiencing confusion and had a GCS score of 11/15. There was a significant increase in NH_3 (>500 μg/dL) and lactate levels (19 mmol/L). Abdominal contrast-enhanced computed tomography (CT) showed HPVG and gastro-omental venous gas (Figure A). Subsequently, we performed an upper gastrointestinal endoscopy, which revealed acute ulcers with erythema. Infusion of 5-FU was stopped, and intravenous lansoprazole were started. Eight hours after onset, the patient gained a normal level of consciousness with a GCS score of 15/15. Lactic acidosis (4.2 mmol/L) and hyperammonemia (64 μg/dL) also improved. On day 2, CT showed no HPVG or gastro-omental venous gas (Figure B). A final diagnosis of lactic acidosis, hyperammonemic encephalopathy, gastric ulcers, and HPVG caused by 5-FU was made.

Discussion: In this case, a plausible explanation for the findings is that the two rare manifestations of adverse drug reactions due to 5-FU occurred simultaneously. First, hyperammonemic encephalopathy and lactic acidosis were caused by 5-FU. Hyperammonemic encephalopathy and lactic acidosis are rare adverse drug reactions to 5-FU. Second, 5-FU caused gastric mucosal injury; subsequently, gastric mucosal injury caused HPVG. HPVG was diagnosed after infusion of 5-FU and disappeared the following day. To the best of our knowledge, there are no reports of HPVG caused by venous infusion of 5-FU. This case suggests that 5-FU infusion causes gastric mucosa toxicity; therefore, we propose that gastric ulcers may cause HPVG.



PUB150

Methanol Poisoning Diagnosed by Brain MRI

Abhinaya Sridhar,[1,2] Viviam I. Becerra rivera,[1,2] Savneek S. Chugh.[1,2] *[1]Westchester Medical Center, Valhalla, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Methanol poisoning is deadly yet remains relatively common. Delays in diagnosis increases the risk of irreversible organ damage and death. In the absence of serum or urine levels, radiological findings may be useful in diagnosis. We report a unique case of methanol toxicity where we made the diagnosis based on characteristic brain MRI findings as timely serum or urine levels were unavailable.

Case Description: 81-year-old woman presented with altered mental status, poor appetite, lethargy and two episodes of vomiting en-route to the emergency room. On examination, her vital signs were normal but she was mildly agitated, oriented to person only. Initial blood work was significant for a low Bicarbonate level of 10mEq/L, Anion Gap 22, creatinine 0.81 mg/dL, serum Osmolality 403 mOsm/kg with calculated osmolality 296 mOsm/kg and Arterial Blood Gas (ABG) showing pH 7.29 and pCO2 24. Her CT head showed no acute changes with white matter microvascular ischemic disease. Because of high osmolar gap anion gap metabolic acidosis, patient was given intravenous Fomepizole. Overnight, her condition deteriorated requiring intubation and mechanical ventilation. Her repeat ABG showed worsening acidosis with pH 6.9 and pCO2 19. She was subsequently started on sodium bicarbonate drip. Further work up was negative for serum methanol, ethanol, salicylate, blood alcohol and 5-oxo-proline levels. Her acidosis gradually improved but her mental status continued to remain poor for which she had a brain MRI which showed extensive parenchymal brain abnormality, leukoencephalopathy and basal ganglia involvement reminiscent of acute methanol toxicity and thus a diagnosis was made. Unfortunately, her mental status remained poor and after consulting with palliative care, decision was made to prioritize patient comfort and terminal extubation.

Discussion: Characteristic MRI findings in methanol toxicity are high T2 signal suggestive of necrosis of lentiform nucleus with predilection for the putamen. There may be necrosis of lobar white matter with sparing of subcortical fibers and hemorrhagic transformation. Our patient had similar findings as well. An extensive ingestion history is crucial when evaluating high osmolar gap. However, in the absence of timely blood work and ingestion history, like in our patient, brain imaging with MRI may be integral to diagnosing methanol poisoning.

PUB151

Hypertonic Pseudohyponatremia with Seizures: A Treatment Dilemma

Neelam Jaju,[1,3] Mahendra L. Agraharkar.[2,3] *[1]Bhaskar Medical College and Bhaskar General Hospital, Yenkapally, India; [2]The University of Texas Medical Branch at Galveston, Galveston, TX; [3]Space City Associates of Nephrology, League City, TX.*

Introduction: Hyperosmolar hyperglycemic non ketotic syndrome (HHS) with seizures can cause brain damage and rapid correction of plasma sodium (pNa) and plasm glucose (pGL) can cause osmogenic demyelination (OD). If untreated it causes death due to cerebral edema. We lack guidelines for fluid and the rate of correction of hyponatremia in HHS. We describe a patient with hyponatremic seizure due to very high plasma glucose (pGL). Hyponatremia occurs with extracellular water shift and corrects as pGL improves as water shifts intracellularly. The seizures in HHS are due to high plasma osmolarity (pOsm) from high pGL. The protocols for HHS mandate saline infusion to repleat volume and simultaneous insulin infusion for pGL. Each infusion alone can correct pNa and pGL. We present a case of pseudohyponatremia with seizures and the dilemma we faced.

Case Description: A 55-yr-old female diabetic unwell for a few days had a seizure. She received levetiracetam on the way to the hospital where she was unconscious and volume depleted. Her pGL was 1452 mg/dl, pNa 115 mEq/L, HCo3 of 21 mg/dl and a pH 7.37. HHS was diagnosed as the plasma osmolality (pOsm) was 320 mOsm/kg. Her urine sodium was 42 mg/dl, osmolality was 448 mOsm/kg and no ketones. With infusion of saline and insulin her pNa was 123 mEq/L and 128mEq/L in 3 and 6 hours while pGL was 1158 and 709 mg/dl and pOsm 315 and 302 mOsm/Kg respectively. A 0.225% saline was infused to reduce correction rate and pNa was 128 mEq/L for 2 days while pGL continued to fall. She made a complete recovery in 6 days.

Discussion: HHS has greater mortality than DKA. HHS with seizures may get treated with vasopressin receptors antagonists (VRA) or hypertonic saline causing an acute rise in the pNa and pOsm enhancing OD. There are no guidelines for correcting HHS seizures with pseudohyponatremia. In our case we used hypotonic saline to slow down the correction rate. We feel that saline infusion alone corrects volume depletion and reduces pGL and pNa merely by the dilutional effect. Simultaneous infusion of saline and insulin may be unnecessary and can be harmful due to a precipitous drop. There is no role for VRA, hypertonic saline or medications in the management peudo hyponatremic seizures. We propose that pOsm should guide the correction rate rather than pNa or pGL and only saline may be used initially to avoid rapid correction and OD. The mortality may be due to rapid correction.

PUB152

Online Dysnatremia Correction Calculators: Consistency and Practice Guideline Adherence

Christina M. Yuan,[1] Maura A. Watson,[1] Benjamin M. Forster,[2] James D. Oliver.[1] [1]*Walter Reed National Military Medical Center, Bethesda, MD;* [2]*William Beaumont Army Medical Center, El Paso, TX.*

Background: Online calculators for sodium correction in dysnatremia are frequently used by non-nephrologists. We assessed 5 popular calculators which use the Androgue-Madais equation for practice guideline adherence and reproducibility in a theoretical 80 year old, 100 kg (72 inch) male.

Methods: Hypernatremia case: Na^+ 150 meq/L. *Guideline-based Rx*: Estimated water deficit 4.2 L. Replacement target 2.1 L in the first 24 hours, plus 1.5 L insensible losses. Infusate: 150 ml/hr D5W. **Hyponatremia case:** Na^+ 115 meq/L, euvolemic with acute/severe symptoms, normal serum K^+. *Guideline-based Rx:* Immediate treatment: 3% NaCl, 100 mL over 10 minutes up to 3 times; Na^+ increase ≤ 6-8 mEq/L in first 24 hours. Alternative using the Androgue-Madias equation: 3% NaCl at 32ml/hr, with frequent Na^+ determination.

Results: See Table. **On-line Calculators for Hypernatremia:** Water deficit calculated in 3 (range 3.6-4.3L). Insensible loss calculated in 1. Replacement target defaults: 140-145 mEq/L Na^+ at 10-24 hours. **On-line Calculators for Hyponatremia:** One discusses volume status, acuity, and symptoms. Only 2 indicate rapid correction should be used for severe symptoms. Default correction rate range: 6-12 mEq/L/day. Calculated rate of 3% NaCl: range 32-64 mL/hr. Only 1 calculator incorporated infusate K^+, and recommended Na^+ and infusate rate redetermination.

Conclusions: The 5 calculators correctly use the Androgue-Madias formula to determine infusate rate of hypertonic or hypotonic fluids in dysnatremia. However, defaults may yield rates that exceed safe correction rate; 4/5 had no discussion of chronicity, symptom severity, or need for frequent Na^+ determination/infusate rate recalculation. These may contribute to unexpected adverse outcomes. *The views expressed in this article are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or U.S. Government.*

Comparison of Online Calculator Results with Guidelines

Mass Poisoning from Ethylene Glycol at a US Military Base

Nina Shah, Benjamin M. Forster, Sarah Petteys, Scott B. Sullivan. *William Beaumont Army Medical Center, El Paso, TX.*

Introduction: Ethylene glycol (EG) poisoning occurs over 5000 times annually in the US, but a poisoning outbreak (3 cases within 72 hours) has not previously been reported. We describe on an EG poisoning outbreak in January 2021, presenting at William Beaumont Army Medical Center.

Case Description: Eleven soldiers presented to the emergency room over a twelve hour period after ingestion of an unknown alcohol, later identified as radar cooling fluid containing EG. Only the first two patients were symptomatic. Serum EG levels were not immediately available, therefore treatment decisions were based on surrogate markers (arterial pH, anion [AG] and osmolar [OG] gaps, serum bicarbonate [TCO2], lactate [Lac], and creatinine [sCr]).

Discussion: Two patients received immediate hemodialysis (HD) in combination with fomepizole (FOM) due to severe acidosis plus elevated OG and AG (Table). These patients developed acute kidney injury (AKI) with renal recovery occurring within a 3-week period. Two patients with elevated Lac received bicarbonate-based intravenous fluids (IVF) and FOM. Two patients received IVF only and required prolonged observation for worsening acidosis and/or AKI. Five patients with normal lab values were treated with IVF and observation. All patients received cofactors including thiamine and pyridoxine. All patients survived. The outbreak occurred in the setting of limited dialysis resources and FOM availability and in a community with widespread COVID-19 activity. Additional guidelines are needed to determine allocation of limited resources and optimal dialysis and FOM treatment course, and identify comorbid conditions which may prolong recovery. The views expressed in this article are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or U.S. Government.

Patient	pH/TCO2 (mEq/L)	Lactate (mmol/L)	AG (mEq/L)	OG (mOsm/kg)	AKI	EG (mg/dL)	FOM	HD

Unexplained Hyperkalemia

Nityasree Srialluri, Karla G. Carias Martinez, Elizabeth Kiernan, Jose M. Monroy-Trujillo. Hopkins Nephrology *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Hyperkalemia is a life-threatening emergency that warrants prompt evaluation and treatment. Evaluation should include ruling out falsely elevated potassium (K) levels that would otherwise lead to unwarranted and potentially harmful therapies.

Case Description: A 69-year-old male with mantle cell lymphoma presented with multifocal pneumonia, septic shock, and acute hypoxic respiratory failure. He had an acute kidney injury (AKI) with a creatinine of 2.4mg/dL from 1mg/dL due to ischemic acute tubular necrosis. CVVHD was started for oliguria and volume overload, with a prescription of blood flow rate 250ml/min, dialysis flow rate 2L/hr (at 25mL/kg), 4mmol/L of potassium, 1.5mmol/L of calcium, and 35mmol/L of bicarbonate. On day 5 of CVVHD, he was switched to a 3mmol/L (K) bath due to (K) of 5-5.3mmol/L. Labs also showed worsening lymphocytic predominant leukocytosis due to underlying cancer. The initial whole blood (K) was 6.9mmol/L. He received calcium gluconate, dextrose, and insulin, with whole blood (K) 3 hours later of 7.7mmol/L. EKG obtained twice did not show signs of hyperkalemia. Repeat (K) obtained from an arterial blood gas analyzer was 4.9mmol/L.

Discussion: Pseudohyperkalemia is an in-vitro phenomenon in which serum (K) exceeds plasma (K). It can occur in patients with severe leukocytosis, erythrocytosis, or thrombocytosis. Clinical consequences of hyperkalemia are absent, and aggressive management is unnecessary as in-vivo (K) levels are unchanged. Plasma (K) contains both serum and clotting factors, which is why plasma is collected in tubes with anticoagulants like heparin. With extreme leukocytosis, the white blood cell membrane is fragile and prone to lysis from heparin. The release of even a minute amount of (K) from cells can notably raise 'measured' extracellular (K). Both serum and plasma (K) samples can be affected, but the impact on plasma seems to be higher. As plasma (K) is higher than serum (K), it is termed "reverse pseudohyperkalemia". If suspected, a repeat whole blood (K) sample should be collected by a point of care (blood gas) analyzer that does not contain heparin. Early recognition of false (K) elevations is thus crucial to prevent detrimental interventions.

	Prior to CVVHD	Day 1	Day 3	Day 4	Day 5
Whole Blood Potassium (mmol/L)	4.6				8:30am: 6.9 mmol/L 11:00am: 7.7mmol/L
Serum Potassium (mmol/L)	5.5	5.3	5.0	4.9	5.1
White Blood Cell Count (K/cu mm)	78.48	78.19	84.94	104.48	149.28

PUB155

The Risks of the Administration of the Newly Introduced Potent Potassium Binders in Pseudohyperkalemia: Two Case Series

Macaulay A. Onuigbo. *University of Vermont College of Medicine, Burlington, VT.*

Introduction: Pseudohyperkalemia, first reported in 1955 by Hartmann and Mellinkoff, is a marked elevation of serum potassium in the absence of clinical evidence of electrolyte imbalance. Simultaneous serum potassium exceeds plasma potassium by >0.4 mmol/L. Pseudohyperkamlemia has mostly been associated with moderate to severe thrombocytosis or leukocytosis. Unmistakably, true hyperkalemia is potentially lethal. Nevertheless, inappropriate treatment of pseudohyperkalemia leading to severe hypokalemia is also life-threatening.

Case Description: Two patients with pseudohyperkalemia received inappropriate potassium binders: A 40-year-old African American male patient with sickle cell anemia with acute kidney injury, anion gap metabolic acidosis and true hyperkalemia subsequently developed pseudohyperkalemia secondary to post-sepsis thrombocytosis in the same hospitalization (Figure 1). He received over one week of sodium zirconium cyclosilicate before the diagnosis of pseudohyperkalemia was confirmed following the finding of a normal EKG with serum potassium of 6.7 mmol/L. A 77-year-old female with previously undiagnosed erythrocytosis and thrombocytosis from polycythemia vera had received over 3 months of Patiromer, for suspected renal tubular acidosis before the PCV was diagnosed and testing confirmed pseudohyperkalemia. Both potassium binders were promptly discontinued when pseudohyperkalemia was confirmed by simultaneous plasma versus serum potassium measurements. Subsequent potassium monitoring reverted to plasma potassium measurements only.

Discussion: Physicians must always give consideration to the plausibility of pseudohyperkalemia under appropriate clinical scenarios. One recurring mantra remains that true hyperkalemia in the absence of overt kidney dysfunction must always be viewed with circumspection and doubt. Iatrogenic life-threatening hypokalemia remains a real concern and must be avoided.

Symptomatic Hyponatremia and Possible Pulmonary-Renal Syndrome

Samuel A. Lazoff, Kambiz Kalantari. *University of Virginia, Charlottesville, VA.*

Introduction: Hyponatremia occurs in 15-30% of hospitalized patients and is associated with increased morbidity and mortality. Here we present a case of severe symptomatic hyponatremia, acute kidney injury, and dyspnea.

Case Description: A 59-year-old female with history of chronic obstructive pulmonary disease presented to the emergency department for recurrent falls and shortness of breath. She complained of confusion, difficulty with ambulation, and increased swelling in her bilateral arms/legs with 18 pound weight gain in one week. On examination she was hypotensive, tachycardic and tachypneic. There was jugular venous distention up the mid-neck, decreased breath sounds and 2+ pitting edema of all four extremities and the anterior abdominal wall. Laboratory results are shown in Figure 1. Chest X-ray showed bilateral infiltrates. Urine microscopy showed 20 – 30 erythrocytes, but no casts. She received multiple infusions of 3% NaCl and loop diuretics. Her mentation improved, but she eventually required kidney replacement therapy. Kidney ultrasound was unremarkable. Kidney biopsy showed hypercellular glomeruli and one cellular crescent. Immunofluorescence microscopy showed 1+ mesangial staining with IgA and C3 and electron microscopy showed mesangial immune deposits. She received pulse dose methylprednisolone and cyclophosphamide for treatment of rapidly progressive glomerulonephritis due to IgA nephropathy. She was then treated with continuous kidney replacement therapy with post filter 5% dextrose in water (D5W) replacement to avoid over correction of hyponatremia. She had a very high A-a gradient, but with aggressive ultrafiltration her respiratory status and oxygenation significantly improved. On hospital discharge, she had normal serum sodium concentration, but remained dialysis dependent.

Discussion: The severity of hyponatremia and a picture that suggested pulmonary renal syndrome were unusual. However, based on her response to treatment and further work up, her hyponatremia was related to severe volume overload. Her volume status stabilized with ultrafiltration and her serum sodium corrected appropriately by infusing D5W into the CKRT circuit, post-filter.

Initial Laboratory Values

Chronic Milk-Alkali Syndrome

Samantha M. Saggese, Manal Alotaibi. *Northwestern Memorial Hospital, Chicago, IL.*

Introduction: Milk-alkali syndrome is a common cause of hypercalcemia. Excessive calcium carbonate (antacid) consumption is a classic cause. We present a case of a 41 year old female with AKI, hypercalcemia and metabolic alkalosis due to dairy and supplemental vitamin D consumption.

Case Description: Our patient presented with abnormal labs (Table 1). She had no urinary frequency, abdominal pain, nausea, vomiting, constipation, or confusion on admission. She had mild pruritus and bilateral plantar foot pain and elbow pain. Her EKG was unremarkable. She received 2 liters of 0.9% saline and was started on continuous 0.9% saline intravenous fluids at 150 mL/hour upon admission. She drank a half-gallon of milk per day for the last two years. She consumed a Premier protein shake each morning with breakfast, which contains 50% of the daily value (DV) of calcium and 25% of the DV of Vitamin D. She rarely took antacids. She had a multivitamin containing 100% of the DV of Vitamin D and an additional Vitamin D supplement. Review of systems was positive for episodes of polyuria, urinary frequency, and dry mouth, for which she compensated with large volume fluid intake.

Discussion: Our patient was diagnosed with chronic milk-alkali syndrome. This syndrome is characterized by hypercalcemia, hyperphosphatemia, metabolic alkalosis, AKI and metastatic calcification. Hypercalcemia causes vasoconstriction, which decreases the glomerular filtration rate (GFR). It suppresses PTH secretion and leads to renal retention of phosphate. It activates the calcium-sensing receptor (CaSR) at the basolateral surface of Loop of Henle cells, inhibiting the Na-K-2Cl co-transporter, enhancing natriuresis and inducing volume depletion, which augments proximal reabsorption of calcium and bicarbonate. Alkalosis activates the pH-sensitive calcium channel, TRPV5, in the distal nephron, thereby contributing to calcium retention and hypercalcemia. Standard treatment is withdrawal of exogenous calcium and administration of intravenous normal saline. Furosemide is sometimes used in severe cases.

PUB158

An Unexpected Cause of Hypokalemia

Zainab Obaidi, Jose M. Monroy-Trujillo. *Johns Hopkins University, Baltimore, MD.*

Introduction: A case of Hyperemesis Gravidarum "HG" that presented with hypokalemia in the setting of starvation ketosis and metabolic alkalosis.

Case Description: A 25-year-old female (G3P3) 9 weeks pregnant presented with intractable nausea and vomiting since pregnancy. She noted 40 pounds unintentional weight loss and denied similar complaints in the past, diarrhea, fever, rashes or vaginal bleeding. She presented to the ER 2 days prior and was treated with promethazine suppository, metoclopramide, thiamine tablets and given 1-liter IVF and discharged home with metoclopramide and dicyclomine. (See table 1) She was readmitted 2 days later due to worsening symptoms (see table for labs). She received 2 liters IVF, famotidine, promethazine suppository and IV antiemetics. Nephrology was consulted for persistent hypokalemia after repletion with 120 meq of potassium chloride over 24 hours leading to potassium increase from 2.7 to 2.9. Magnesium was 1.5 and repleted. On day 3, labs were notable for metabolic alkalosis (see table for VBG) with concurrent respiratory alkalosis (expected pCO2=40+ 0.6x(27-24=3)=41 mmHg). Urine electrolyes noted on table 1. The urine potassium/urine creatinine ratio was high at 3.3 mmol/L indicating renal losses. She was discharged home once PO intake improved.

Discussion: Our patient initially presented with anion gap metabolic acidosis in the setting of starvation ketosis noted on her urinalysis. However, after receiving IVF her bicarbonate increased rapidly unmasking metabolic alkalosis with underlying respiratory alkalosis. The metabolic alkalosis was likely in the setting of her HG. However, urine studies did not correlate as urine chloride was elevated = 85 mmol/L likely in the context of potassium chloride repletion that increased urinary chloride excretion. This case highlights renal potassium losses due to: 1) Bicarbonaturia (urine pH 6) in the setting of metabolic alkalosis 2) Ketonuria (as urinary ketones bind to potassium increasing excretion in urine). It is important to account for unmeasured anions in the workup of persistent renal potassium wasting.

Lab values	Emergency visit	Day 1 of admission	Day 3 of admission

Successful Therapy for Life-Threatening Hyperkalemia with Isotonic Sodium Bicarbonate and No Dialysis

Vijayakumar Paramasivam, Daniel G. Gomez, Spencer Hodgins, Daniel L. Landry, Gregory L. Braden. *UMASS/Baystate, Springfield, MA*.

Introduction: Isotonic sodium bicarbonate (ISB) intravenously (iv) alone in acidotic pts was shown by K Schwarz, Circulation, 19:215, 1959 & Adler and Fraley in Kid Int, 12: 354, 1977 to cause up to a 3 mEq/L decrease in serum potassium (K) within 4 hours when 150-400 nM iv ISB was given. We treated a pt with a serum K of 9.8 mEq/L in sine wave EKG pattern who refused dialysis with ISB which brought her K to near normal in 14 hrs.

Case Description: A 90 yr old woman with Type 2 diabetes presented in sine wave, HR 30/min & systolic BP 80 mmHg with a K of 9.8 mEq/L. She ha3 mEq/Ld a baseline serum creatinine of 1.6 mg/dl with a K of 6.2 mEq/L & serum bicarbonate of 19 mEq/l. She was started on trimethoprim/sulfa 1 week earlier. Admission labs showed (mEq/L): Na 141, K 9.8, Cl 108, HCO3 13, serum creatinine 3.6 mg/dl, ph 7.2, UNa 43 mEq/L, UK 31 mEq/L, FE NA 1.8% & TTKG 0.5. The family & pt refused dialysis. She was given 3 amps of iv 10% calcium gluconate & her EKG converted to sinus rhythm. ISB (150 mEq of Na & bicarbonate/L) was started at 150 ml/hr along with sodium polystyrene resin 60 gm every 6 hours & 1 amp of Dextrose 50% (25 gm) followed by 10 U of reguiar insulin every 4 hrs. Labs in mEq/L showed: After 5 hrs: Na, 145 K 7.8, bicarb 16, glucose 156 mg/dl. After 10 hrs: Na135, K 6.8, Bicarb 20 glucose 185 gm/dl. After 14 hrs: Na 135, K 5.5, Bicarb 21 glucose 248 mg/dl, After 24 hrs: Na 142, K 3.3, Bicarb 28 glucose 157mg/dl, & TTKG .44.

Discussion: Our pt showed a 2 mEq/L decrease in serum K 5 h after a fast drip infusion rate of ISB giving 112 nM of ISB, a 3 mEq/l decrease after 225 nM ISB & 4.3 mEq/L after 315 nM ISB plus iv dextrose and regular insulin every 4 h. Sodium polystyrene resin works after 6 h and helped later lower the serum K. The low TTKG at the different times shows that increaed renal excretion did not account for the dramatic decrease in serum K. We Conclude: In acidotic pts ISB by continuous iv infusion along with q 4h iv dextrose and insulin can successfully reverse life threatning hyperkalemia without dialysis.

PUB160

An Interesting Case of Non-Anion Gap Metabolic Acidosis Secondary to Arginine Hydrochloride Infusion Therapy

Jiwanjot K. Narula, Kiran Shivaraj, Angela Y. Kim, Nadera Rahman, Amol Mittal. *Westchester Medical Center, Valhalla, NY*.

Introduction: Mitochondrial disorders are relatively common inherited disorders, the syndrome of mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) is a disorder characterized by hemiparesis, cortical blindness, or hemianopia, muscle weakness, seizures. Treatment of MELAS is critical, delay may result in cortical injuries, neurologic dysfunction and ultimately dementia. The pathophysiology involves reduced vasodilation. L-Arginine is a precursors to nitric oxide, which mediates vasodilation. Despite widespread use of arginine hydrochloride, there is limited understanding of its adverse effects, particularly metabolic acidosis.

Case Description: In our case report, we present a 60 year old male with MELAS who was brought in due to a 3 week progressive weakness, falls associate with poor appetite and failure to thrive. In the hospital, he became encephalopathic with RLL Aspiration pneumonia. Head CT showed ischemic changes. He was started on 30gm IV arginine HCl in 300ml of NS over 90 minutes. Day 1 of infusion, he developed hyperchloremic non anion gap metabolic acidosis with hyperkalemia. Due to hyperkalemia refractory to medical management and development of nonoliguric AKI due to ischemic ATN, the patient was started on CVVHD. His renal function recovered after two days with no further indications to continue dialysis, hypotension had also resolved with removal of vasopressor support.

Discussion: The pathogenesis of clinical features in MELAS has been attributed to the energy defect, causing dysfunction of the microcirculation thus poor perfusion. In our patient, who had hypoperfusion and encephalopathy, L-Arginine was the ideal treatment. The recommended infusion is standardized in adults. We suspect in our patient, the renal impairment resulted in the loss of renal excretion of bicarbonate combined with the relatively high arginine dose due to low body surface area resulted in severe acidosis. To prevent metabolic acidosis with the infusion of Arginine HCL, it should be dosed as per the BSA with close monitoring of the pH. The ability of the kidney to acidify the urine should be monitored by directly measuring the urine ammonia or the surrogate method like Urine anion gap or urine pH.

PUB161

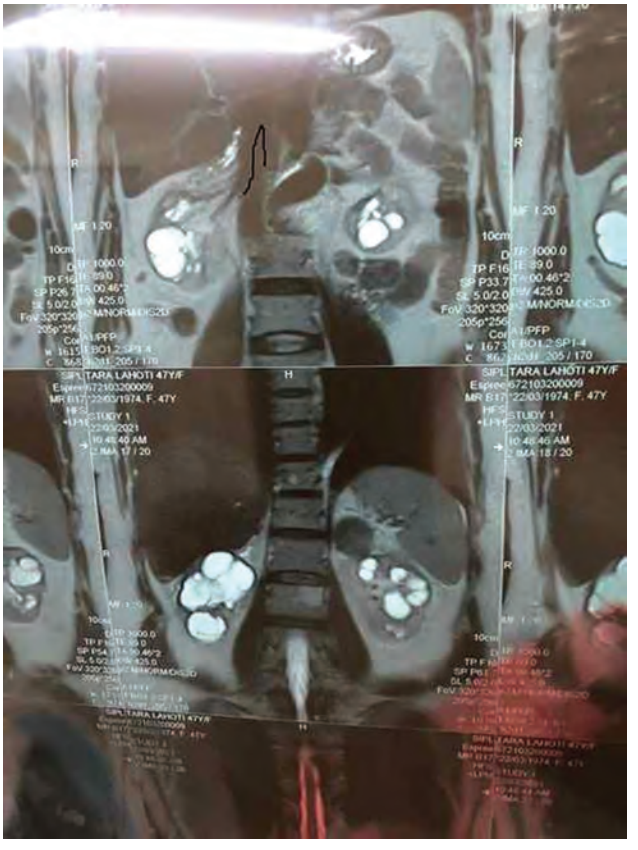
Adrenal Tumor Causing Hyperaldosteronism Leading to Kaliopenic Nephropathy, Nephrocalcinosis, and Nephrolithiasis

Blessy S. Bhalla, Rajesh K. Aggarwal. *Sribalaji Action Medical Institute, Pashim Vihar, New Delhi, India*.

Introduction: Nephrocalcinosis is of rare occurence in a patient with hyperaldosteronism. We report a case of hyperaldosteronism associated with cytsic renal disease, nephrocalcinosis and nephrolithiasis.

Case Description: 40 yrs lady hypertensive presented for evaluation of deranged renal parameters. She had nocturia, polyuria without over the counter, herbal medicine use. She was on antihypertensive drugs including telmisartan. Previous records showed persistent hypokalemia in the range of2 .7 to3 meq/l. BP160/100 mm of hg without any postural drop. Abg showed metabolic alkalosis. Her urinary osmolality was 184mosm/kg with urinary ph 5.5, 24 hour urine was 3.5 L urinary sodium 200meq, potassium160meq, chloride250meq, citrate30mg/day(>40 mg/d) creatnine800 mg/d(20mg/kg/day), calcium260mg/d(4mg/kg/d), uric acid300mg/d(170-1300mg/d), phosphate20 mmol/d(13-40 mmol/d) TTKG was 9.5. Her aldosterone to renin ratio 366.905(<15). An MRI abdomen showed bilateral normal sized cystic kidneys with wall calcification and nephrocalcinosis bilateral renal stones and left adrenal mass lesion of the size of 4.1x3.5 cms which was heterogenously hypointense on out of the phase sequencing suggestive of malignant etiologyand a lytic lesion in the L3 vertebrae. The patient has been advised adrenelactomy and has been started on tab spironolactone and potassium citrate.

Discussion: Although cystic renal disese is common occurence with chronic hypokalemia, nephrolithiasis and nephrocalcinosisis is rare. This patient had adrenal mass lesion with chronic hypokalemia. Nephrocalcinosis can be explained by increased sodium and calcium loss and decreased citrate loss and increased ammonia associated compliment activation due to chronic hypokalemia with hyperaldosteronism.



MRI abdomen showing bilateral cystic kidneys with calcification and left adrenal mass

PUB162

The Role of a Patient Navigator in Reducing Health Disparities in a Distal Renal Tubular Acidosis Decentralized Clinical Trial

Cynthia J. D'Alessandri-Silva,[1] Bradley P. Dixon,[2] Carol Ogg,[3] Maria A. Manso-Silvan,[3] Kimberley D. Cranstoun.[3] *[1]Connecticut Children's Medical Center, Hartford, CT; [2]Children's Hospital Colorado, Aurora, CO; [3]Advicenne, Nimes, France*.

Background: It is well documented that there are a multitude of health disparities that impede clinical trial enrollment in underrepresented racial and ethnic minorities. These disparities/barriers include systemic mistrust of the health system, deep-rooted fear of clinical trials, cultural and language barriers, as well as lack of education and socio-economic standing. Further compounding the complexities are decentralized clinical trials (DCTs) whereby patients may feel undervalued, unsafe, and less supported. Diverse trial participation is critical to understand therapeutic effectiveness in different populations; hence, the goal of the newly created role of industry-sponsored patient navigators will support the enriched enrollment and retention of a diverse and inclusive population in the ARENA2 trial for distal renal tubular acidosis (dRTA), a rare genetic disorder.

Methods: A patient navigation team was formed of English, Spanish, and French-speaking navigators with backgrounds in social services and education. Navigators received training about dRTA, clinical trials and ARENA2. The team collaborated to ensure all patient-facing materials aligned with relative cultural standards and reflected patient-friendly, appropriately translated lay terminology.

Results: The ARENA2 trial seeks to initiate enrollment June 2021 in the US and Canada. Navigators recorded native-language patient education videos about clinical trials, dRTA and ARENA2. Videos were uploaded to the ARENA2 website to inform

potential subjects and establish rapport. Native-language welcome packets that included information of the dedicated services and mapped out home care visits/expectations were created. Diverse and inclusive enrollment and retention rates will be compared to prior rare disease trials upon completion of the 12-week ARENA2 study.

Conclusions: Industry-sponsored, culturally sensitive, bilingual patient navigators are key stakeholders in clinical trials for rare disorders, especially DCTs, and can help reduce ethnic and racial disparities. The ARENA2 trial, will analyze and report on the patient navigator's unique role impacting trial enrollment and retention of Spanish and French speaking populations by addressing complex problems in underrepresented populations.

PUB163

The Prevalence of Hyperkalemia and Associated Risk Factors in a General Population

Xiaohong Fan, Wenling Ye, Jie Ma, Xuemei Li. *Peking Union Medical College Hospital, Beijing, China*.

Background: Hyperkalemia has been related to the risk of cardiovascular events associated mortality. The object was to determine the epidemiology of hyperkalemia and associated risk factors in a rural Chinese population.

Methods: We performed a cross-sectional study of 10,281 participants in China in 2014. All participants completed a questionnaire, physical examination, and collected venous blood to detect serum creatinine, and inorganic ions (potassium, etc.), First void morning urine was collected to detect the albumin-creatinine ratio(ACR) and urine potassium. Hyper- and hypokalemia were defined as serum potassium levels >5.0 mEq/L and <3.5 mEq/L, respectively.

Results: The mean age of the study population was 55.4±10.0 years; 47.1% were males. The crude prevalence of hyper-and hypokalemia was 9.3% and 0.3%, respectively. The subjects with hyperkalemia had higher urine potassium-creatinine ratio (4.4±2.6 vs. 3.7±2.5, P<0.001) and potassium excretion fraction(60.1±48.9 vs. 54.1±46.5, P<0.001). In multivariate analyses, the individuals with decreased eGFR<60ml/min/1.73m^2 had a 3.17-fold increase in the odds of having hyperkalemia. Hypertension, diabetes, and high low-density lipoproteinemia(LDL) were significantly associated with the increased risk of hyperkalemia. However, the female was negatively associated with hyperkalemia even after excluding those with decreased eGFR. The ACEI use was not found to be independently related to hyperkalemia.

Conclusions: The male and participants with hypertension, diabetes and high LDL had an increased risk of having hyperkalemia. Physicians should raise awareness of high-risk groups.

Factors associated with hyperkalemia in the general population

Factors	OR (95%CI) Overall	OR (95%CI) Excluding eGFR<60ml/min/1.73m2
Age (per 1 yr)	1.00(0.99-1.01)	1.01(0.99-1.01)
Gender (male vs. female)	1.19(1.03-1.36)	1.18(1.03-1.36)
BMI (per 1Kg/m2)	0.98(0.96-0.99)	0.98(0.96-1.00)
Hypertension	1.21(1.02-1.42)	1.20(1.01-1.42)
Diabetes	1.19(1.01-1.40)	1.18(0.99-1.39)
LDL (per 1mmol/L)	1.20(1.10-1.30)	1.21(1.11-1.32)
Decreased eGFR(<60ml/min/1.73m2)	3.17(2.08-4.84)	—-
Microalbuminuria(ACR>30mg/g)	1.17(0.95-1.44)	1.10(0.88-1.36)
ACEI/ARBs use	1.12(0.87-1.43)	1.06(0.82-1.38)

BMI: body mass index; LDL: Low-density lipoprotein; eGFR: estimated glomerular filtration rate; ACR: albumin-creatinine ratio; ACEI/ARBs: angiotensin-converting enzyme inhibitor/ Angiotensin receptor blockers.

A Suspected Case of Cerebral Salt Wasting (CSW) Syndrome in a Patient with Traumatic Subdural Hematoma: Revisiting a Long Debated Topic

Karim T. Attia, Jessica M. Greco. *The Ohio State University Wexner Medical Center, Columbus, OH*.

Introduction: It has long been debated whether CSW is a true entity causing hyponatremia in patients with central nervous system (CNS) pathology or whether the hyponatremia is actually secondary to SIADH while apparent salt wasting is due to underappreciated volume expansion. Literature agrees, for the most part, that CSW is a separate disease process and it has been mostly described in patients with aneurysmal subarachnoid hemorrhage. It has also been described in other forms of CNS pathology including traumatic brain injury, meningitis, and intracranial neoplasms. We present a unique case of symptomatic, severe hyponatremia and apparent renal salt wasting in a patient with subdural hematoma secondary to a traumatic head injury. It was transient and was successfully treated with hypertonic saline, mineralocorticoids, and salt tablets.

Case Description: A 30-year-old male with no significant past medical history presented to the hospital initially on 4/27/21 after a motorcycle accident that resulted in a subdural hematoma, minor cervical fractures, intraspinous ligaments strain, and lacerations. He was discharged on narcotic pain medications, gabapentin, and keppra for seizure prophylaxis. Serum sodium was 135mEq/L at the time of discharge. He returned on 5/5/21 after several days of feeling uncoordinated and having orthostatic symptoms. He was found to have evidence of volume depletion of physical examination. Computed tomography (CT) of the brain showed resolution of prior subdural hematoma. Serum sodium on admission was 115mEq/L. It later dropped to 112mEq/L post hydration with IV fluids composed of normal saline with 5% dextrose. Net sodium balance was calculated to be -60.4 mEq during that initial interval suggesting renal salt wasting. He eventually improved after several days of infusion with hypertonic saline, fludrocortisone, and salt tablets. His episode was transient as he maintained a normal serum sodium off hypertonic saline prior to discharge.

Discussion: We reexamined the proposed mechanisms behind CSW along with the different arguments for, and against it as a separate entity as they relate to this case. We also ecplored the key points of differentiation between CSW and SIADH while focusing on how they pertain to the management of these critically ill patients.

PUB165

Association of Serum Bicarbonate with Incident Gout in Patients with Advanced CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Thomas W. Ferguson,[3] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]MathurConsulting, Woodside, CA; [3]Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada*.

Background: Patients with CKD are at increased risk for gout and alkalinization solubilizes uric acid. We sought to determine if baseline bicarbonate or change in bicarbonate was an independent predictor of incident gout in patients with CKD stages 3-5.

Methods: Optum's de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values 12 to <30 mEq/L, 28-365 days apart, with data ≥1 year prior and ≥2 years of post-index or death within 2 years. Patients without pre-existing gout were followed for up to 11.5 years for diagnosed incident gout (ICD-9 or ICD-10 diagnosis codes 274.** excluding 274.11, M10.* or M1A). Cox proportional hazards models were used to examine predictors of incident gout, controlling for demographic characteristics as well as BMI, time-dependent change in serum bicarbonate; and baseline covariates eGFR, serum bicarbonate, hypertriglyceridemia, hypercholesterolemia, hyperuricemia, high c-reactive protein, hypertension, diabetes, obstructive sleep apnea, irritable bowel syndrome, inflammatory bowel disease, Charlson Comorbidity score, and prescriptions for thiazide diuretics or metoprolol. Death was similarly evaluated as a competing risk.

Results: 125,551/136,067 patients (92%) had no evidence of gout during the pre-index period. During the period up to 11.5-years of follow-up (median 4.2 years), the following covariates were most strongly associated with incident gout: male sex (HR 1.69, 95% CI:1.63-1.76), Black or Asian race (HR 1.52, 95% CI:1.44-1.60 and HR 1.47, CI:1.23-1.75), and hyperuricemia (HR 1.40, 95% CI:1.27-1.55). Hispanic ethnicity (HR 0.82, 95% CI:0.73-0.92), low-income status (HR 0.90, 95% CI:0.85-0.94), higher baseline eGFR (HR 0.98, 95% CI:0.979-0.983, and lower overall comorbidity burden (HR 0.98, 95% CI:0.97-0.99) were associated with a lower risk of gout. Baseline serum bicarbonate and time-dependent change in serum bicarbonate were not associated with incident gout.

Conclusions: In this longitudinal analysis of patients with CKD, serum bicarbonate was not associated with the development of gout.

PUB166

Hyponatremia in a Patient with Chyle Leak

Harish C. Nuthakki. *UT, Houston, TX*.

Introduction: Chylous ascites can cause a multitude of electrolyte abnormalities. Hyponatremia is not a very common presentation unlike hypernatremia in pts with chylous ascites. Here we present a case of hyponatremia in a patient with chylous ascites and the various management challenges we face while managing the hyponatremia.

Case Description: We present a case of a 75y old female with a history of papillary cancer of the thyroid status post thyroidectomy and left neck dissection, with worsening chyle leak from the surgical site with evidence of local recurrence of cancer with worsening left cervical lymphadenopathy. She presented with hypotension, which was treated by infusing 4L of normal saline over a period of 36 hours. She was also receiving 1.5L of free water daily with her tube feeds, which were 85% free water. On hospital day 3, she developed hypo-osmolar hyponatremia which reached the nadir over the next 48 hours, and nephrology was consulted. Patient's urine and serum studies showed a high ADH state and volume depletion. Her volume depletion is due to the chyle leak and she had concomitant high ADH state due to relapsing papillary thyroid cancer. Patient's chyle leak responded to IV octreotide and a low-fat diet with medium-chain triglyceride supplementation. The hyponatremia resolved with administration of oral sodium chloride tablets once the chyle leak was controlled.

Discussion: Patients with chylous ascites suffer volume depletion who can be a challenge to quantify secondary to the location of the leak. Excessive fluid administration, either isotonic or hypotonic can lead to severe life-threatening hyponatremia in these patients. Physicians should pay attention to the amount free water being administered through tube feeds in these pts with active malignancies as they are prone to high ADH states.

PUB167

SIADH-Related Hyponatremia due to a Non-Functioning Hemorrhagic Pituitary Adenoma

Saira Sajid, Katerina Hysi, Minesh Khatri, James Drakakis. *NYU Winthrop Hospital, Mineola, NY.*

Introduction: Determining the etiology of hyponatremia can be challenging. When euvolemic, one need consider a diagnosis of syndrome of inappropriate antidiuretic hormone (SIADH). This can be classified into two groups: ectopic production of ADH or release from the posterior pituitary gland related to disoders of the central nervous system, pulmonary disoders or drug administation. Mechanisms of posterior pituitary related hyponatremia are usually due to hypopituitarism or dysfunction of the pituitary adrenal axis. More rare, are reports of SIADH in patients with pituitary tumors and normal associated function. This is believed to be related to factors of mechanical stress.

Case Description: 39 year old female with no past medical history presented to the emergency department complaining of numbness and tingling of the bilateral upper and lower extremities. Serum sodium was found to be 122 mEQ/L. Urine osmolality 971 mOsm/kg and urine sodium 179 mmol/L. An initial CT scan showed fullness of the sella, possibly representing an underlying lesion. Subsequent MRI of the brain revealed a sellar/suprasellar lesion most consistent with a hemorrhagic pituitary adenoma. Neurohormonal axis proved to be intact and the tumor deemed non secreting. As such, the working diagnosis was SIADH caused by mechanical stress and inappropriate ADH release from the posterior pituitary. She was given a low dose (7.5 mg) of Tolvaptan with ensuing rapid correction of sodium, which required administration of DDAVP and D5W to slow down. Ultimately, salt tablets were started to help maintain an acceptable sodium range. Plan is for endoscopic transspenoidal resection of the pituitary mass.

Discussion: The clincal and laboratory features of this case were consistent with SIADH. There was hyponatremia, in the setting of euvolemia and high urine osmolality and urine sodium. Furthermore, the function of the pituitary gland remained normal on biochemical assessment. In such a scenario of increased ADH secretion, it is important to evaluate the anatomical interaction between the pituitary tumor and the hypothalamo-neurohypophysial system. The tumor may push the pituitary stalk upward leading to mechanical stress and the dislocated gland causing inappropriate ADH release. Such a description is a very rare occurence, but nevertheless need be considered as a cause of SIADH related hyponatremia.

PUB168

Hyponatremia and Hypothyroidism: Association or Causality?

Goutham Kondapi, Eric Krutel, Joel M. Topf. *Ascension St John Hospital, Detroit, MI.*

Introduction: Among the various etiologies of hyponatremia, one that is frequently called into question is hypothyroidism. Literature review repeatedly indicates that only the severe state of myxedema coma has shown a causality with hyponatremia. Data examining the incidence of hyponatremia in less severe hypothyroidism is conflicting; there is question as to whether there is any causality at all. Here we present a case of hyponatremia that is attributable to severe hypothyroidism without myxedema coma.

Case Description: 71-year-old female with a past medical history of hypothyroidism presented to the hospital following a fall and complaint of generalized weakness. Patient had a serum sodium of 111, initially thought to be SIADH given a low serum uric acid, urine sodium less than 20, and serum osmolality of 242. However, the patient had a TSH of 65.70 mcunits/mL with T4 less than 0.1 ng/dL. Patient was given normal saline with minimal sodium correction, and subsequently started on 2% NS with a DDAVP clamp. Patient was started on IV levothyroxine for treatment of her severe hypothyroidism. After 4 days of IV levothyroxine and hypertonic saline, her serum sodium reached 130, and she was discharged home on maintenance levothyroxine.

Discussion: The mechanism behind hypothyroid-induced hyponatremia is not well understood. Studies have suggested a hypothyroid state causes a decrease in cardiac output and peripheral vascular resistance, leading to decreased renal perfusion and decreased GFR. One study found that in patients with primary hypothyroidism before and after thyroid replacement, all had decreased GFR, with hyponatremia observed in greater than half the subjects. However, another study found hyponatremia to be uncommon in more short term hypothyroidism. Literature review has largely identified hypothyroidism-induced hyponatremia in myxedema coma. However, this patient presented not with symptoms suggestive of myxedema coma, but with an elevated TSH and no other attributable cause of her hyponatremia. Additionally, the low uric acid and urine sodium argue against a decrease in renal perfusion as the cause of ADH release. In summary, though some recent literature calls into question hypothyroidism causing hyponatremia, we present a case of profound hyponatremia in a patient with severe hypothyroidism without myxedema coma, which responded to treatment of her hypothyroidism as well as hypertonic saline.

PUB169

A Rare Case of Low-Dose Cyclophosphamide-Induced Symptomatic Hyponatremia

Saeid Karandish,[1] Tsering Dolkar,[2] Dawn Maldonado,[1] Ishita Bansal,[1] Maritza Brown,[1] Ayesha Mallick Imam.[1] *[1]Mount Sinai Health System, New York, NY; [2]Brookdale University Hospital and Medical Center, New York, NY.*

Introduction: We report a case of severe acute symptomatic hyponatremia with generalized tonic clonic seizures after the first cycle of adjuvant chemotherapy with cyclophosphamide.

Case Description: We present a case of 62-year-old woman who was diagnosed with breast cancer and underwent lumpectomy followed by first cycle of chemotherapy with cyclophosphamide, dexamethasone, and doxorubicin. She received low dose, 15 mg/kg or 1,030 mg IV Cyclophosphamide. On the day of chemotherapy her sodium was 144 mEq/L. The next day the patient had a seizure at home. While in the Emergency Department she had another witnessed seizure. On physical examination vital signs were normal, patient showed altered mental status with no focal deficits. Laboratory: Serum sodium 127 mEq/L, CBC was normal; LFT and other electrolytes were in a normal range. Her head CT was normal. Patient's urine osmolarity was 432 mmol/L and urine sodium was 116 mmol/L. These findings were suggestive of SIADH. Infusion of 300 ml of NaCl 3% and water restriction improved the symptoms and corrected hyponatremia within 24 hours.

Discussion: Hyponatremia is a known but rare complication of cyclophosphamide. Initially it was thought that only high doses of cyclophosphamide (>40 mg/kg) could induce hyponatremia. However, cases of low-dose cyclophosphamide (<20 mg/kg), have been reported, though uncommon. We report a rare case of low dose cyclophosphamide-induced symptomatic hyponatremia. Our patient's rapid decline of sodium could have precipitated the seizure. Using hypertonic saline, hyponatremia resolved, and symptoms improved without neurological deficits. Cyclophosphamide-induced hyponatremia was first reported by Moses et al demonstrating antidiuretic hormone-like effect of Cyclophosphamide to retain water. More recent studies suggest a direct toxic effect of cyclophosphamide or its metabolites on renal collecting tubules and/or an antidiuretic hormone-like activity of cyclophosphamide metabolites. Thus, development of SIADH has been accepted as one of the mechanisms for cyclophosphamide-induced hyponatremia. Thus, physicians should have a low threshold to suspect cyclophosphamide-induced hyponatremia which can be life threatening.

PUB170

Von Hippel-Lindau Syndrome (VHL) Associated with a Breast Tumor

Fatima Cheema, Dawn Maldonado, Maritza Brown. *Mount Sinai Health System, New York, NY.*

Introduction: We present a case of a woman who was incidentally found to have a breast tumor at the same time that she was found to have several other cysts and tumors, and was ultimately found to have Von Hippel Lindau syndrome (VHL). The breast tumor association has not yet been described in VHL.

Case Description: A 21-year-old female presented to another facility with dysphagia and bilateral upper extremity weakness. CT and MRI of the brain demonstrated multiple cysts in the spinal cord extending to the brain stem. Her renal ultrasound findings were read as polycystic kidney disease. The patient underwent C5-C7 laminectomy and resection of the largest intramedullary tumor. Pathology report revealed grade 1 hemangioblastoma. She presented to our hospital 3 months later for dyspnea and tachycardia, so CT angiogram of the chest was performed to rule out pulmonary embolism. It incidentally revealed a right breast mass measuring 3.5x2.7 cm, a 1.9 cm liver lesion, and innumerable sub-centimeter hypodense masses in both kidneys. The dyspnea was attributed to pneumonia and atelectasis from her post-operative recovery. A repeat renal sonogram at our facility demonstrated small kidneys, so the diagnosis of PCKD was questioned and re-evaluated. Genetic testing ultimately returned positive for VHL-1. Her breast mass was found to be a BIRADS-4A lesion on ultrasound, and core biopsy demonstrated a fibroadenoma.

Discussion: VHL is a rare autosomal dominant disorder characterized by the presence of multiple benign and malignant tumors and a pathogenic variant of the VHL gene. VHL is a tumor suppressor gene that inhibits hypoxia-inducible transcription factor, thereby inhibiting hypoxia-induced vascular growth. Loss-of-function mutations hence lead to tumor growth in multiple organs. Tumors associated with VHL include infratentorial hemangioblastomas, retinal hemangioblastomas, renal cysts and pheochromocytomas. It remains unclear whether her breast fibroadenoma was associated with VHL. However, the literature on VHL remains limited, so we may not yet know all potential lesions associated with VHL. We therefore present this case to contribute to the literature on possible VHL presentations.

PUB171

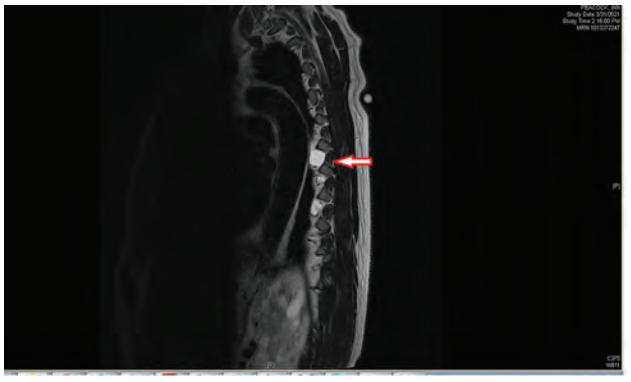
Perineural Cysts in Polycystic Kidney Disease

Kana R. Amari, Jennifer A. Tuazon. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

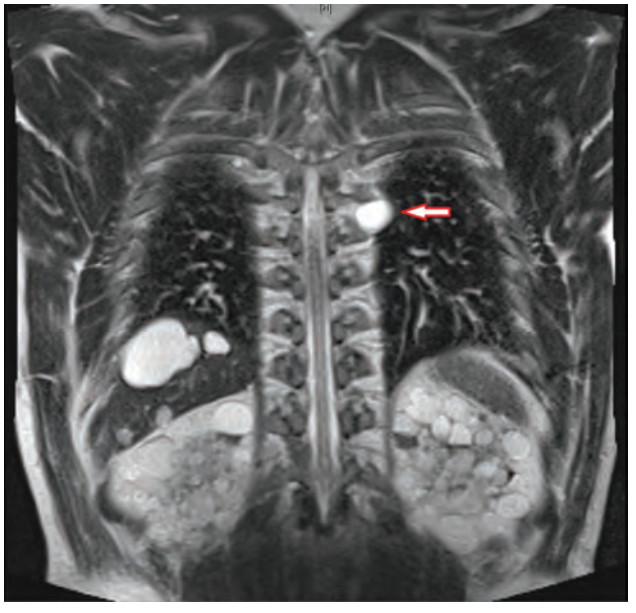
Introduction: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common hereditary kidney disease characterized by cyst formation in the kidneys and other organs. In the nervous system, arachnoid cysts have been found in ~8% of patients with spinal meningeal cysts being far less commonly reported.

Case Description: A 51 y.o. man presented to the Nephrology clinic for ADPKD. He underwent an MRI of the abdomen to calculate his total kidney volume. Incidentally found were multiple T2 hyperintense lesions in the intercostal spaces, most prominent in the left paraspinal midthoracic spine. A dedicated MRI of the thoracic spine was subsequently performed which further characterized the lesions to reflect perineural cysts.

Discussion: Perineural cysts are benign pouches filled with cerebrospinal fluid (CSF) located at the nerve root canals along the spine. Only a few cases of spinal meningeal cysts/perineural cysts have been reported in association with ADPKD. Most cases are asymptomatic, but variable nerve root or spinal cord compression may be present. Low-back pain, radiculopathy, and headache due to cerebrospinal fluid leakage may also occur, thus, such symptoms in a patient with ADPKD should warrant further investigation for this condition.



Perineural cyst in thoracic spine



PUB172

The Importance of Family History in Evaluating Persistent Microscopic Hematuria

Javad Najjar Mojarrab, Somto T. Nwaedozie, Syed M. Sajjad, Rebecca Blonsky. *Marshfield Clinic Health System, Marshfield, WI.*

Introduction: Alport syndrome (AS) is a condition caused by one or more mutations in *COL4A3-5* (1,2). These result in abnormal production of alpha chains 3, 4, and 5 of type IV collagen in the basement membranes of kidneys, cochlea, and eyes (2,3). Patients exhibit progressive glomerular disease that usually occurs with hematuria, sensorineural deafness, eye abnormalities, and/or leiomyomatosis (2-5). We present a case of presumed AS in a woman with persistent microscopic hematuria and preserved renal function.

Case Description: A 40-year-old woman with a history of Raynaud's syndrome and hypothyroidism was referred to nephrology for persistent microscopic hematuria. Hematuria was first noted in 2008 though renal function remained normal, and she had no significant proteinuria. Social history was non-revealing. The patient's family history was significant for multiple family members with End Stage Renal Disease (ESRD) requiring either dialysis or transplant. The patient underwent a renal ultrasound as well as serologic evaluation which were non-revealing. However, due to the patient's long history of hematuria in addition to her family history, a kidney biopsy was performed. Light microscopy and immunofluorescence were normal; however, electron microscopy demonstrated varying levels of basement membrane thickness. These findings are consistent with Alport syndrome. Genetic testing was performed to identify a mutation in type IV collagen but was unremarkable. Given the patient's family history, biopsy findings, and no identified pathogenic genetic variant, the patient will undergo whole exome sequencing.

Discussion: AS is generally an X-linked disease though other modes of transmission are possible (1-5). Patients with autosomal recessive and X-linked forms can have similar presentations with possible sensorineural hearing loss and visual abnormalities that are rare in patients with autosomal dominant forms. One of the most commonly observed renal manifestations of AS is persistent hematuria either microscopic or gross with the latter being very rare. Females with an X-linked form usually present with microscopic hematuria (4). AS is diagnosed by genetic testing and skin or renal biopsy. Genetic testing is preferred since it is highly accurate and non-invasive though cases of AS with no detectable mutations or copy number variants of *COL4A3-5* are reported (1,3).

PUB173

A Male Senior with Alport Syndrome in Digenic Inheritance of COL4A3 and 4A4

Shinichiro Koga. *Section for Nephrology and Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo, Japan.*

Introduction: Alport syndrome (AS) sometimes show positive in alpha 2 (a2(IV)) and 5 (a5(IV)) chains of type IV collagen in the glomerular basement membrane (GBM). This could illustrate with the facts that; 1) a5(IV) in basement membranes of Bowman corpuse and cortex are normally immunofluoroscent in 20 % of autosomal recessive AS (ARAS) patient **1)**; and 2) autosomal dominant AS (ADAS) as well as normal kidney are known to be positive in a5(IV).

Case Description: A 21-year-old Asian male senior ("the patient") was referred to nephrology outpatient clinic due to persistent microscopic hamatourina for over fifteen years. No apparent kidney abonormality was found in echogram so was observed till fourth grade of elementary school. Not only himself but his mother and elder brother had hematouria; this brother recently had complained of low-tone hearing loss. The patient had no ocular defect nor hearing loss; no hypertension, diabetes, nor hypercholesterolemia. Serum Cr 0.95 mg/dl; urine RBC 30-100/HPF, beta2-MG 42 microg/L, and UP/Cr 47.9 mg/gCr. LM of the kidney was near normal. The routine IF examination for Igs and complement components were negative. a2(IV) and a5(IV) were not lack in immunofluorescence staining. EM show 10% area of GBM had irregular thinning; No EDD in glomeruli. SPEEDI-KID version 3.0 **2)** next generation sequencing covered throughly 99.2 % genes, as well as COL4A3, 4A4, 4A5, and 4A6 genes. A known c.G469C,p.G157R **3)**, and a known c.T4793G,p.L1598R **4)** mutation was detected in COL4A3 gene. Novel c.G929A,p.R310Q was detected in COL4A4 gene. No mutation in 4A5 and 4A6 genes. The diagnosis of AS was made of persistent microscopic hematouria, type IV collagen gene mutations, and family history of nephritis. His mother also had a known D682G mutation in COL4A4 **3)**, as well as a known G157R mutation in COL4A3 **3)**. His elder brother has not been investigated so far.

Discussion: Two mutations in COL4A3 gene were located in another chromosome so indicated as having heterozygous compound mutations in COL4A3 gene of the patient. ADAS sometimes occur within a family; Its genetic manner, autosomal dominant, could differ symptoms among them. The patient had two individual gene mutations in COL4A3 and 4A4, which has severe clinical features as digenic inheritance **4)**. **References 1)** Pediatr Nephrol 2014;**29**:1535-44. **2)** Clin Exp Nephrol 2017;**21**:63-75. **3)** Plos One 2013;**8**:e71381. **4)** Pediatr Nephrol 2015;**30**:1459-65.

PUB174

A Rare Case of Gordon's Syndrome

Anne Marie Pop, Victoria Golas, Priya Gupta, Kelly M. Mercier, Michael S. Misuraca. *Beaumont Hospital - Farmington Hills, Farmington Hills, MI.*

Introduction: Pseudohypoaldosteronism type II (PHAII) or Gordon's Syndrome, is a rare inherited form of hypertension. It is characterized by hyperkalemia, metabolic acidosis, normal GFR, and a low renin state[2]. The first case was described in 1964[4] with only a few hundred cases being discovered since, making each diagnosis an important and unique discovery[3]. There are increasing studies investigating the alteration of genetic pathways leading to disease. In this case, a young male presents for persistent hyperkalemia and was diagnosed with Gordon's syndrome.

Case Description: A 33-year-old caucasian male presented to the emergency room with the chief complaint of abdominal pain. Family history is significant for a daughter who has a history of recurrent hyperkalemia of unknown etiology. Initial vital signs were within normal limits, including blood pressure. Labs revealed potassium of 6.4, a mild non anion gap metabolic acidosis, and serum creatinine of 1.26 with no prior diagnosis of chronic kidney disease. Urine potassium was 12.3 mmol/L and consideration of inappropriate renal retention of K was made. Cortisol and aldosterone levels were normal. Renin level was low at < 2.1pg/mL. He was treated with potassium binders as well as sodium citrate inpatient with improvement in hyperkalemia. Upon follow-up, hyperkalemia recurred despite an improved SCr of 0.9. Genetic testing revealed a variant in the WNK4 gene consistent with Gordon's Syndrome. The patient was started on 12.5 mg of hydrochlorothiazide and has missed all follow-up appointments to date.

Discussion: The discovery of this rare, inherited disorder has lead to the understanding of potassium and sodium handling along the distal convoluted tubule (DCT)[4]. The main disturbance involved is the activation of the thiazide-sensitive NaCl cotransporter (NCC) at the DCT[4]. Mutations in WNK1 and WNK4 genes were found to further increase the activity of the NCC as well as decrease surface expression of ROMK[1]. There are also findings that a chloride shunt is present[1]. It is with these studies that we have been able to identify the causation of pathogenesis and subsequent treatment. Our patient presents as a unique case as this autosomal dominant mutation was found later in life as well as being normotensive which can be present in ~20% of cases[3]. Regardless of presentation, one must consider this rare disorder as treatment can be lifesaving.

PUB175

Market Research Studies Across Primary Hyperoxaluria (PH) Subtypes: PH1, PH2, and PH3

Claudia Dallosso,[1] Donald P. Julien,[3] Guy Buckland,[3] Scott Hengst,[2] David Eckford,[2] Chris Okonis.[1] *[1]Dicerna Pharmaceuticals Inc, Lexington, MA; [2]Clarivate Analytics US LLC, Philadelphia, PA; [3]Collective Acumen, Greenwich, CT.*

Background: PH is a family of ultra-rare genetic disorders causing hepatic oxalate overproduction that can result in recurrent kidney stones, life-threatening kidney damage, and systemic oxalosis. There are 3 known subtypes of PH (PH1, PH2, and PH3). PH1 was the first subtype to be characterized and is the most studied. While PH2 and PH3 are less well understood, increasing evidence suggests that they have more severe clinical consequences than previously thought.

Methods: Several market research studies (table 1) were conducted to better understand PH disease burden across subtypes. All data are physician-reported. Copies of medical charts or genetic test reports were not provided for verification purposes.

Results: Across all studies, respondents reported a large subset of PH patients with moderate to severe renal disease. Specifically, the percentage of patients in CKD Stage 3 or worse was the following: — PH1: 87% (Study 1), 56% (Study 2), and 39% (Study 3) — PH2: 92% (Study 1), 68% (Study 2), and 55% (Study 3) — PH3: 83% (Study 1), 41% (Study 2), and 48% (Study 3) Stone burden was similar across PH subtypes: — Average of 3.24 (PH1), 3.92 (PH2) and 4.95 (PH3) stones in the last year (study 1) — 62% (PH1), 71% (PH2), and 61% (PH3) of patients with no renal impairment presented with 3 or more stones in 5 years (study 3). Nephrocalcinosis was reported in 48% (PH1), 61% (PH2), and 38% (PH3) of patients (study 1). The rate of hospitalizations and emergency room visits was comparable across PH subtypes: 63% (PH1), 64% (PH2), and 57% (PH3) (Study 1). Management of PH3 is qualitatively the same as PH1 and PH2. Hyperhydration, stone removal procedures, and vigilant monitoring of disease progression (study 3) are standard of care.

Conclusions: Results from these completed market research studies suggest that severe disease burden and progression is consistently reported across PH1, PH2, and PH3.

Improvement in Metabolic Control in Patients with Distal Renal Tubular Acidosis (dRTA) After Switching from Standard of Care to ADV7103

Valerie M. Panzarino,[1] Carol Ogg,[2] Maria A. Manso-Silvan,[2] Bradley P. Dixon.[3,4] *[1]University of South Florida, Tampa, FL; [2]Advicenne Pharmaceuticals, Paris, France; [3]University of Colorado Denver School of Medicine, Aurora, CO; [4]Children's Hospital Colorado, Aurora, CO.*

Background: Patients with dRTA present with hyperchloremic metabolic acidosis leading to poor growth as well as compromised bone and kidney health. Current standard of care (SoC) requires a multiple dose regimen with reported poor adherence which may render metabolic control difficult. We describe three patients switched from SoC to a prolonged-release galenic formulation of potassium bicarbonate and potassium citrate with twice daily dosing (ADV7103).

Methods: Three patients with clinically confirmed dRTA (18Y-M, 22Y-F, 16.5Y-F) enrolled in the ARENA2 Phase 3 study (NCT03644706) prior to COVID-19 interruption. Plasma bicarbonate and potassium levels were measured >12 months pre-study initiation on SoC, baseline screening, and 3, 6, & 12 months after participants were switched to ADV7103. Adverse events, palatability, patient satisfaction and adherence rates (estimated proportion of treatment effectively taken based on study drug retrieval) were also reported.

Results: All three patients demonstrated low plasma bicarbonate levels with SoC (< 22 mmol/L) 12 months prior to baseline screening. All patients receiving ADV7103 recorded normal plasma bicarbonate from 3 to 12 months after enrolment. Plasma potassium levels (3.0, 4.3 and 2.8 mmol/L respectively at baseline) were normal for the duration of the trial on ADV7103. One patient reported dyspepsia at 8 months on ADV7103 but resolved with symptomatic treatment. Palatability and patient satisfaction were greatly improved switching from SoC to ADV7103. Adherence rates by 12 months improved from average (50-75%) or good (75-90%) to excellent (>90%) for 2 patients and improved from poor (<50%) to good (75-90%) for one patient. One patient, an adolescent, reported a tremendous positive impact on growth velocity and lifestyle and is reluctant to return to SoC.

Conclusions: All patients maintained normal levels of plasma bicarbonate and potassium after switching from SoC to twice daily dosing with ADV7103. All three patients demonstrated better adherence with ADV7103 as compared to SoC. This small cohort of patients reported improved palatability and satisfaction with ADV7103 treatment as reasons for improved medication adherence and this increased adherence is believed to have had a direct impact on the overall metabolic control achieved throughout the study.

PUB177

A Curious Case of Isolated Glucosuria

Umair Khan, Wala Abusalah, Heather R. Lefkowitz. *Newark Beth Israel Medical Center, Newark, NJ.*

Introduction: Glucosuria exceeding 25 mg/dl is pathological and is known as frank glucosuria. Glucosuria can be grouped into two categories; defective absorption of glucose and overflow glucosuria. Conditions such as hyperthyroidism, pregnancy, fever, and exercise tend to decrease the renal threshold for glucose thereby resulting in glucosuria. Here we present a case of persistent isolated glucosuria likely due to primary renal glucosuria in a healthy 52-year-old female in the absence of any secondary etiology.

Case Description: A 52-year-old female was evaluated for incidental finding of glucosuria. She was a healthy individual with no history of diabetes mellitus or gestational diabetes, dysuria, polyuria or polydipsia, chronic kidney disease or kidney stones. Home medications included simvastatin, trazodone and a combined OCP. Hemoglobin A1c was mildly elevated at 5.9 with glucose of 121. Dipstick urinalysis showed pH of 5.5, specific gravity of 1.008 with trace glucosuria. In our workup, we were not able to identify any specific cause for our patient's glucosuria. Her HgbA1c was in the prediabetes range however multiple random blood glucose readings were normal. Based on the available information, we suspect that she might have rare genetic mutation in SLCA52 gene responsible for persistent glucosuria.

Discussion: Glucosuria in a non-diabetic patient is rarely observed in the general population. Primary renal glucosuria (PRG) is an autosomal dominant condition caused by a mutation in the SLC5A2 gene. A defect in this transporter disrupts the kidney normal function of maintaining glucose homeostasis. Based on a few case reports, PRG has not been associated with any renal dysfunction however polyuria, enuresis and later a mild growth and pubertal maturation on long term follow ups has been reported. In rare cases, episodic dehydration and ketosis during pregnancy and starvation have been reported. Few case reports have also linked isolated glucosuria to autoimmune diseases like Graves and undifferentiated connective tissue disease. Our case here emphasizes on the importance of monitoring isolated glucosuria in the general population. Majority of the patients presenting with glucosuria also have concomitant diabetes mellitus or chronic kidney disease, however glucosuria in the absence of comorbid conditions is a rare phenomenon which warrants further evaluation and close monitoring for worsening kidney function.

PUB178

Variants of MTHFR and FGG Genes Are Associated with Levels of Leptin but Not Adiponectin in Colombian Pediatric Lupus Nephritis

Gloria Garavito,[1] Luis Fang,[1] Nicole S. Pereira Sanandres,[1] Alex Dominguez-Vargas,[1,2] Gustavo Aroca Martinez,[3,2] Zilac Espitaleta,[3,2] Ana Moreno-Woo,[1] Antonio Iglesias,[4] Eduardo Egea.[1] Grupo de Inmunología y Biología Molecular *[1]Universidad del Norte, Barranquilla, Colombia; [2]Clinica de la Costa Ltda, Barranquilla, Colombia; [3]Universidad Simon Bolivar, Barranquilla, Colombia; [4]Universidad Nacional de Colombia, Bogota, Colombia.*

Background: Pediatric Systemic Lupus Erythematosus (pSLE) is a chronic autoimmune disease with unknown etiology. Pediatric Lupus nephritis (pLN) has a worse prognosis and morbidity. Leptin/adiponectin and SNPs in *MTHFR* and *FGG* genes are known to be risk factors that influence development of atheromatosis and cardiovascular disease. The aim of this study was to evaluate the association of serum leptin and adiponectin and SNPs of *MTHFR* and FGG genes in pLN Colombian Caribbean patients.

Methods: A case-control study (98/100) was carried out in Colombian children. The sample groups were selected from a pLN cohort by simple random sampling. Serum concentrations of leptin and adiponectin were determined by ELISA. SNPs in *MTHFR* (A1298C rs1801131) and *FGG* (C10034T-rs2066865) genes were genotyped by qPCR. p-values < 0.05 mean significant statistical

Results: Serum leptin and adiponectin levels were significantly increased in pLN patients (24.7%; 28.9%) compared to control group ($P < 0.001$; $P < 0.001$) respectively. There was no significant association between *MTHFR* rs1801131 or *FGG* rs2066865 SNPs and pLN neither in codominant (P=0.29; P=0.89) nor in allelic models (P=0.88; P=1), respectively. No association was observed between pLN, serum adipokines and *MTHFR*/*FGG* SNPs (*P=0.51; P=0.52)*, respectively. The AG genotype of *FGG* gene rs2228570 SNP was significantly associated with serum leptin levels (*P*=0,0161).

Conclusions: In our population, no association was observed between pLN with the SNP variants of the two gene systems studied nor between pLN and adipokines. However, results in this study found an association between the FGG polymorphism and categorized concentrations of leptin.

Magnitude of the Potential Screening Gap for Fabry Disease in Manitoba, Canada

Reid Whitlock,[1] David T. Collister,[1,2] Mohammad Nourmohammadi,[3] Clara Bohm,[1,2] Paul Komenda,[1,2] Navdeep Tangri,[1,2] Claudio Rigatto.[1,2] *[1]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [2]University of Manitoba Faculty of Health Sciences, Winnipeg, MB, Canada; [3]Covance Inc, Princeton, NJ.*

Background: Fabry disease is a rare disorder caused by deficient activity of -galactosidase A (GLA) and often leads to heart, kidney, and nerve damage. Fabry disease can be treated with enzyme replacement therapy, improving quality of life, but it often goes undiagnosed as neonatal screening programs suggest its true prevalence is much higher than what has been reported clinically. Given its low frequency, mass screening for Fabry disease is impractical. However, a targeted screening program of high-risk individuals may uncover previously unknown cases. Our objective was to use population-level administrative health databases to identify patients at high risk of Fabry disease.

Methods: We conducted a retrospective cohort study of all residents of Manitoba, Canada between 1998 and 2018. Using databases housed at the Manitoba Centre for Health Policy, we ascertained a cohort of patients without a diagnosis of Fabry disease who had at least one of the following high-risk conditions: idiopathic hypertrophic cardiomyopathy, ischemic stroke <45 years of age, kidney failure or proteinuria of unknown cause, peripheral neuropathy. We excluded patients with known contributing factors to these high-risk conditions, including, where appropriate, diabetes, hypertension, autoimmune diseases. cancer, glomerulonephritis, and polycsysitc kidney disease. Those who remained and did not have evidence of GLA testing were considered to have a 0.5-4.0% probability of having Fabry disease.

Results: A total of 145,466 individuals had at least one high-risk condition. Of those, 1,386 remained after applying exclusion criteria. Only 22 of 1,386 (1.6%) had GLA testing, leaving a screening gap of 1,364 individuals of which 932 were still alive and residing in Manitoba as of December 31 2018. We estimated that screening these individuals would yield between 4 and 37 new cases of Fabry disease.

Conclusions: Administrative health databases may be a useful tool to identify patients at higher risk of Fabry disease or other rare diseases. Further directions include designing a program to screen these individuals for Fabry disease.

PUB180

Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) with UMOD Gene Mutation as a Rare Cause of CKD in a Young Patient with Family History of ESRD

Saira Sajid, Katerina Hysi, Naveed N. Masani, James Drakakis. *NYU Winthrop Hospital, Mineola, NY.*

Introduction: Autosomal dominant tubulointerstitial kidney disease (ADTKD) is caused by mutations in the UMOD gene (ADTKD-UMOD). It is characterized by slowly progressive chronic kidney disease usually first noted in teen years and progressing to end stage renal disease (ESRD) between the third and seventh decades. Hyperuricemia and gout are hallmark features, presenting from an early age or developing over time. This is considered a rare and often underrecognized diagnosis and in fact, clincial features have been shown to poorly predict ADTKD-UMOD. As such, our case highlights the need for genetic testing to help define the etiology of renal disease guided by a relevant family history.

Case Description: 28 year old male with a past medical history of hypertension and serum creatinine 1.8 mg/dL presented for evaluation. Workup revealed small kidneys bilaterally (8.3 cm and 7.9 cm on right and left respectively) and lack of significant proteinuria or hematuria on urinalysis. Family history was very significant and included the patient's father, paternal grandfather and paternal uncle, all with ESRD having been on dialysis. Additionally, serum uric acid was noted to be 12.1 mg/dL. Genetic testing ultimately revealed a likely pathogenic variant in the UMOD gene associated with autosomal dominant tubulointerstitial kidney disease 1 (ADTKD1) also previously known as familial juvenile hyperuricemia nephropathy 1, glomerulocystic kidney disease with hyperuricemia and isosthenuria and medullary cystic kidney disease 2.

Discussion: ADTKD is a rare genetic kidney disease most commonly caused by mutations in the UMOD gene. It is characterized by early onset hyperuricemia and gout with development of slowly progressive renal failure with tubulointerstitial disease. There is usually no proteinuria or hematuria, and imaging may show medullay renal cysts. Pathogenic UMOD mutations cause protein misfolding, retention in the endoplasmic reticulum (ER) and mistargeting of uromodulin in the thick ascening limb of the loop of Henle. This results in tubulointerstitial damage via ER stress and reduced urinary uromodulin excretion. This case illustrates the lack of distintive clinical and diagnostic features of inherited interstitial kidney diseases, making them an underrecognized and underreported entity. Physican awareness and accurate family history can be of great benefit.

PUB181

Proteinuria Behind the Scenes: An Occult Diagnosis of Alport Syndrome in a Woman via Genetic Testing

Christopher Farmakis,[1] Muhammad R. Qureshi,[2] Roberto L. Collazo-Maldonado.[2] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Alport Syndrome is a rare disease amongst children and adults. The diagnosis is a clinical challenge for adult nephrologists. We illustrate a case demonstrating the use of genetic testing to confirm the diagnosis.

Case Description: The patient is a 23-year-old woman who presented with nephrotic syndrome. She was found to have proteinuria of 3.2 grams, glomerular hematuria, and a creatinine of 1.6 mg/dL. The patient endorsed a family history of End Stage Kidney Disease (ESKD) in her sister. A complete serologic work-up and renal ultrasonography were negative. Kidney biopsy was performed, which showed Focal Segmental Glomerular Sclerosis (FSGS) with diffuse foot process effacement. The patient was started on steroids and lisinopril. After 6 months, the patient did not improve. Genetic testing for Alport Syndrome was positive for the *COL4A4* mutation, confirming a diagnosis of autosomal Alport Syndrome despite a lack of classic symptoms.

Discussion: Alport Syndrome affects one in every 5000 to 10000 adult Americans and causes 0.2% of all ESKD cases in the United States. The pathophysiology involves a lamellated glomerular basement membrane with abnormal collagen IV composition. The majority (85%) of cases are inherited in an X-linked pattern via the *COL4A5* mutation. Autosomal recessive, and less commonly autosomal dominant, patterns are seen with mutations in the *COL4A3* and *COL4A4* genes. It is characterized by progressive renal failure, hematuria, hearing loss, and ocular abnormalities. Kidney biopsy in such patients has been reported to show FSGS, as in our patient. In the appropriate clinical context, the gold standard for diagnosis remains genetic testing. Treatment involves supportive care and RAAS blockade to slow the progression to ESKD. In 2021, the use of novel genetic testing can be more accessibly done in the clinic setting. These tests can uncover various renal pathologies which may otherwise have gone undiagnosed, as is what occurred in our case. Therefore, we believe the more routine use of genetic testing by nephrologists allows for better overall patient care.

PUB182

Genetic Testing to Help Navigate the Spectrum of Type IV Collagen Nephropathy

Katerina Hysi, Saira Sajid, James Drakakis. *NYU Winthrop Hospital, Mineola, NY.*

Introduction: Single gene mutations as an attributable cause of chronic kidney disease (CKD) are becoming increasingly elucidated. Those specifically recognized as being quite impactful involve type IV collagen. While these have been classically associated with Alport's syndrome, advances in genetics have permitted further understanding of the role type IV collagen plays in the pathogenesis of other causes of CKD. The spectrum of genetic hematuria syndromes spans entities ranging from thin basement membrane disease to X-linked Alport syndrome. There is wide variability in phenotype which depends on an interplay of sex, genotype and chromosome activation.

Case Description: 33 year old male with past medical history of excess BMI, and hypertension presented after routine UA displayed proteinuria and hematuria (serum creatinine 0.9 mg/dL). 24 hour study revealed proteinuria of 1.9 g per day and several repeat UAs had ongoing proteinuria and blood/RBC. Family history was significant for the patient's brother and father both with microhematuria. Kidney biopsy showed focal segmental & sclerosing glomerulopathy, perihilar variant (mild) with glomerulomegaly, diffuse GBM thinning (mean 230 nm) and rare GBM lamellations, most consistent with collagen IV nephropathy. Genetic testing revealed heterozygosity for a pathogenic deletion involving the COL4A4 gene, which is associated with both autosomal dominant and autosomal recessive Alport's syndrome.

Discussion: Thin basement membrane nephropathy (TBMN) is an entity within the spectrum of genetic hematuria syndromes which historically was considerated to be a benign hereditary condition characterized by thin basement membranes and microscopic hematuria without significant proteinuria or progressive kidney disease. Recent evidence and understanding of type IV collagen mutations has shown that the prognosis of TBMN may not always be so benign. In fact, 29% of patients heterozygous for mutations in COL4A3/4 develop CKD and 15% progress to ESRD. Phenotypes can be rather variable

along this genetic continuum and where TBMN specifically fits remains an area of ongoing discussion. Our case utilized genetic testing to confirm a deletion in the COL4A4 gene, after kidney biopsy findings were consistent with collegen IV nephropathy. The associated perhilar varient of FSGS and glomerulomegaly could be considered a risk factor for escalated CKD progression.

PUB183

MAGED2 Mutation with Bartter's Syndrome in Adult Patients

Geovani Faddoul, Swati Mehta. *Albany Medical Center, Albany, NY.*

Introduction: MAGED2 mutation is associated with a transient antenatal form of Bartter's syndrome that can be severe enough to lead to death.

Case Description: 43-year-old woman with a history of pituitary adenoma on cabergoline and levothyroxine, referred to nephrology for hypokalemia, hypocalcemia and hypomagnesemia dependent on replacement therapies, frequent lower extremity muscles cramping and weakness post exercise, with frequent ER visits for vomiting and hypokalemia. A diagnosis of Bartter versus Gitelman's syndrome was raised. Her Blood pressure on average is 90 systolic (80-100, asymptomatic). She noticed worsening LE edema and systolic up to 110 lately. Renin and aldo were elevated (36 and 51 respectively). FeNa was 0.03%, FeK of 6.76% and FeCa of 0.1%. The low urinary calcium (3mg/dl) was pointing towards a Gitelman's syndrome. MRI of the abdomen showed possible liver hemangioma, simple cyst of the left kidney and otherwise normal kidneys. As a kid, the patient had a constant craving for salt, had muscle cramping while sleeping, had lower extremity edema especially after puberty, and when she was 20 she would have a 9 lbs fluctuation in her weight in one day. Patient's mother had a pregnancy complicated by polyhydramnios and gave birth to a sister who suffered from nephrocalcinosis and died soon after birth. The patient has a daughter with an avid need to eat salt. She was started on spironolactone and enalapril which improved her edema, blood pressure and resolved the need for potassium. She remained on magnesium, calcitriol and calcium carbonate. Her recurrent vomiting improved after decreasing cabergoline. A genetic panel was order and revealed and X-linked MAGED2 heterozygous mutation, normally defined as variant of uncertain significance [P268L and c>T in exon 4]

Discussion: MAGED2 is linked to a transient form of antenatal Bartter's syndrome including nephrocalcinosis and symptoms resolve by 1.5 years of age. The mutation present in this patient however, is not described previously and is the first mutation of MAGED2 to cause a Bartter's syndrome that remains pathogenic at an adult age. This might be due to the fact that MAGED2 was described in relation to Bartter's syndrome in 2016 and the focus is on a pediatric population. Learning points: MAGED2 mutation can have a variable phenotype within the same family. MAGED2 mutation can cause Bartter's syndrome that is not limited to the perinatal period.

PUB184

Renal-Limited Thrombotic Microangiopathy in the Setting of Thrombomodulin Mutation

Kwon Soo Kim, Jean M. Francis, Andrea Havasi. *Boston Medical Center, Boston, MA.*

Introduction: Thrombotic microangiopathy is a pathological condition comprised of microvascular thrombosis involving any organ of the body leading to thrombocytopenia, Coombs-negative microangiopathic hemolytic anemia, and organ damage. Common causes of primary TMA are STEC-mediated hemolytic uremic syndrome, thrombotic thrombocytopenic purpura, and atypical hemolytic uremic syndrome. AKI secondary to TMA in severe Hypertension is not an uncommon scenario, however it is important to rule out primary TMA as a cause of Hypertension. Our case involves a very young male, who presented with elevated Creatinine and severe Hypertension, whose renal biopsy showed renal-limited TMA, with subsequent genetic panel showing Thrombomodulin mutation.

Case Description: This is a 29 year old African ancestry male with known history of Hypertension, diagnosed 1 year ago, not on any antihypertensive medication. Patient presented to the ED with chest pain with BP of 230/110 mm Hg. Blood work remarkable for serum Creatinine of 4.9, unknown baseline, K of 3 and serum bicarbonate of 27. Urinalysis remarkable for sterile pyuria with WBC of 100 and UPCR of 1.5 g/g Patient was admitted under the impression of hypertensive emergency. All the work up for secondary hypertension, including PRA/serum Aldosterone and Renal Doppler were negative. Serology work up for glomerulopathy including ANA, ANCA, Anti Cardiolipin Ab, Anti GBM Ab, HIV, Hepatitis, Anti PLA2R Ab, C3/C4 were negative. Renal fucntion has not improved despite hypertension management, and renal biopsy was performed, which showed findings suggesetive of severe TMA. Haptoglobin and LDH were not suggestive of presence of MAHA, Hemoglobin level and Platelet counts were never low. Genetic panel for aHUS was sent, which showed THBD mutation, for which Ravalizumab was initiated, with the plan of 3 to 6 months treatment with close monitoring of renal function.

Discussion: Though most patients with TMA will present with the hematologic abnormalities of MAHA and thrombocytopenia, there are some that never demonstrate those features and only present with acute renal injury and Renal-Limited TMA. High degree of suspicion of underlying dysregulation of alterenative pathway of complement is required, especially if patients do not improve with standard supportive care. Some of those mutations could present with Renal-Limited TMA without features of systemic TMA

PUB185

Endogenous Ouabain (EO) and Body Composition in Frail Subjects

Arianna Bologna,[1] Marta De Filippo,[1] Paolo Betti,[1] Marco Simonini,[2] Teresa Del Mastro,[1] Federico Persico,[1] Lorena Citterio,[2] Elisabetta Messaggio,[2] Laura Zagato,[2] Elena Brioni,[2] Chiara Lanzani,[2] Paolo Manunta.[2,1] *[1]Università Vita Salute San Raffaele, Milan, Italy; [2]IRCCS San Raffaele Scientific Institute, Milan, Italy.*

Background: The Na/K-ATPase is a highly selective receptor for cardiotonic steroids (CTS) such as ouabain and digoxin. At pharmacological concentrations used in the treatment of cardiac conditions, CTS modulate the ion-pumping function of Na/K-ATPase. At much lower concentrations, in the range of those reported for endogenous CTS in the blood, they stimulate hypertrophic growth of cultured cardiac myocytes through initiation of a Na/K-ATPase-mediated and reactive oxygen species (ROS)-dependent signaling.

Methods: As inflammatory mechanisms may be involved in the pathophysiology of hypertension and in endothelial dysfunction and atherosclerosis via reactive oxygen species, inflammatory and oxidative stress markers were studied in elderly frail subjects under basal condition.

Results: Males showed increased circulating EO (Male 189.8±8.22 vs Female 157.8 nM/L, p=0.0007adjusted for BMI, age, number of drugs taken). Mental health index was not associated with circulating EO levels contrary to what is reported in an experimental model. Conversely, a direct relationship between EO and muscle mass was observed (Pearson 0.236 p = 0.042).

Conclusions: We conclude that EO is a novel determinant of body composition in the presence of reduced renal function in elderly.

PUB186

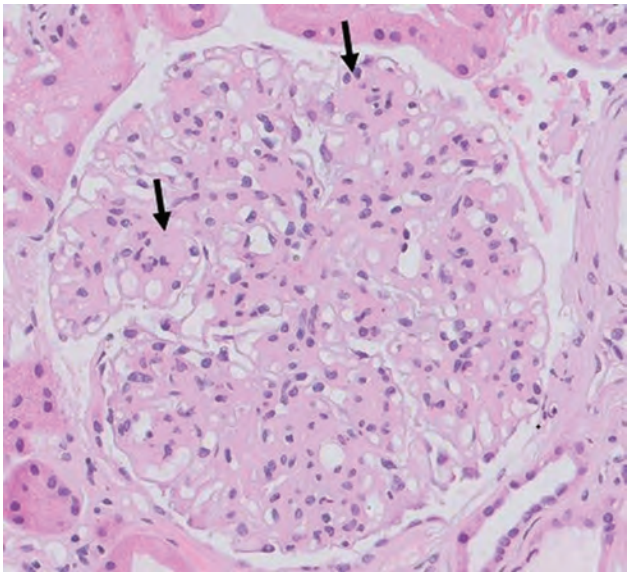
An Atypical Case of Nodular Glomerulosclerosis

Muhammad T. Baig,[1] Asish Thakkar,[2] Anjali A. Satoskar,[1] Udayan Y. Bhatt,[1] Salem Almaani.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Veterans Health Administration, Washington, DC.*

Introduction: Nodular glomerulosclerosis (NG) is a pathological lesion characterized by expansion of the mesangium and increased lobularity. They are typically found in diabetic nephropathy. Other conditions associated with NG include MPGN, paraproteinemias, and chronic ischemic lesions. In rare cases, the lesion may be idiopathic, (ING).

Case Description: The patient is a 67yo female with a medical history of chronic kidney disease, hypertension, hyperlipidemia, and tobacco use (quit 20 years prior). She has no history of diabetes and her most recent hemoglobin A1C value was 4.5. She presented to the hospital with dyspnea and worsening kidney function and nephrotic range proteinuria (3.9g/g). Her serological evaluation, which included SPEP, ANCA, ANA, hepatitis serologies, and serum complement proteins, were all unremarkable. Because of this, she underwent a kidney biopsy. Diffuse and nodular glomerular mesangial expansion was noted on light microscopic evaluation (arrows). She had evidence of advanced disease with 40% interstitial fibrosis and tubular atrophy. On electron microscopy, the patient had no discrete immune-type or organized deposits. She was noted to have a thickened GBM and diffuse podocyte foot process effacement. Unfortunately, she developed progressive renal dysfunction and was started on dialysis.

Discussion: NG is most commonly associated with diabetic nephropathy. However, nondiabetic NG can also be seen secondary to a number of conditions or as a primary condition, known as ING. Clinical risk factors for ING include obesity, hypertension, and tobacco use. Heavy tobacco use is one of the strongest risk factors. In the largest series published to date, the median tobacco consumption was 52 pack-years, and 43% of patients with former smokers, which demonstrate the importance of careful history-taking in identifying risk factors for this disease.



PUB187

Fibrillary Glomerulonephritis in a Patient with Long-Standing Hypertension, Proteinuria, and Advanced CKD: Not Everything Is Hypertension

Michael M. Samiratedu, Neda Shahoori, Yiqin Zuo, Jair Munoz Mendoza. *University of Miami School of Medicine, Miami, FL.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease that mostly affects patients in their fifth or sixth decade of life. Clinical manifestations include elevated creatinine, hypertension (HTN), hematuria, and proteinuria. FGN has been associated with monoclonal gammopathy, autoimmune diseases and viral infections. However, many of the cases ultimately have no precipitating factor identified.

Case Description: We present a case of a 65 years-old man with history of diabetes mellitus for 6 years without retinopathy, HTN and chronic kidney disease (CKD) who presented to our hospital with acute kidney injury after increasing dose of lisinopril for uncontrolled hypertension. Physical exam was unremarkable except for high BP 154/85 mmHg, and mild lower extremity edema. Laboratory studies revealed a serum creatinine of 4.13mg/dL (baseline 2.9 mg/dL, eGFR 22 ml/min/m^2), UPCR of 7.1 g/d, UA showed 10 RBCs and 3+ protein. No RBC on repeat UA. He was negative for Hepatitis B, C, and ANCA, anti-GBM, ANA, and anti-dsDNA Ab. C3,C4 were normal, SPEP showed no M spike, and elevated kappa/lambda ratio of 1.81 (89.7 / 49.6 mg/L). Renal biopsy revealed 20-30% interstitial fibrosis, diffuse, moderate to severe mesangial expansion by eosinophilic deposits with segmental mild increase in mesangial cellularity, polyclonal IgG-dominant smudgy mesangial staining with capillary loop extension with kappa/lambda light chain shift, and mesangial and subendothelial deposits with non-branching randomly arranged fibrils (7-21 nm). A Congo red stain was negative for amyloidosis. Immunohistochemical staining for DNAJB9 was positive, supporting the diagnosis of FGN.

Discussion: This case highlights the importance of pursuing a kidney biopsy in patients with worsening proteinuria and kidney function even without active sediment and negative work up for GN. In patients with long standing history of HTN, it is not uncommon to blame HTN as the cause of the CKD. However, diseases such as FGN although rare should always be considered as part of our differential diagnosis. Whether we should treat with immunosuppression or continue conservative management in this patient with advanced chronic kidney disease is debatable but knowing the diagnosis of FGN will certainly help to establish a better prognosis.

PUB188

Is This Primary or Secondary Membranous Nephropathy?

Rajan Regmi, Bianca Madrid. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: The definition and management of membranous nephropathy (MN) has rapidly evolved over the past decade, following the identification of PLA2R-Ab. A host of other target antigens have been discovered including thrombospondin type 1 domain-containing 7A, neural epidermal growth factor-like 1, and semaphorin-3B. Primary membranous nephropathy is considered to involve a humoral autoimmune response to a normal podocyte antigen, in the absence of known secondary etiologies including autoimmune diseases, infections, malignancies and certain drugs.

Case Description: We present a 72 Y male with medical conditions including HTN, pre-diabetes, grade 1 obesity, CAD, and remote history of laryngeal cancer, who presents to nephrology clinic for evaluation of lower extremity edema and proteinuria of 11 gms. Labs are consistent with nephrotic syndrome, and he is subsequently started on Furosemide and Lisinopril. His GFR is preserved with serum creatinine of 0.9 mg/dL. Additional work up includes HEP B/C, HIV, SPEP/UPEP/FLC, and ANA, which are negative but PLA2R-Ab is markedly elevated (PLA2R IFA positive with titer of 1:500 and PLA2R ELISA positive at 250.00 RU/mL). The patient refuses renal biopsy. In the absence of a biopsy, a mutual decision is made to treat the patient with rituximab. However, after two doses of rituximab 1g spaced two weeks apart, the patient fails to achieve clinical or biochemical remission within 6 months. The need for a biopsy is again discussed to further determine treatment options, and is eventually done. Biopsy suggests features of secondary MN, including mesangial expansion, intracapillary leucocytes on light microscopy (LM), IgG (1 and 3) and IgM, C3 and C1q deposits, absent PLA2R stain on immunoflourescence (IF), and subepithelial, intramembranous as well as subendothelial electron dense deposits on electron microscopy (EM). A thorough assessment for secondary causes of MN remains unremarkable. A CT head/neck, chest, abdomen, and pelvis is also obtained which does not reveal any malignancy.

Discussion: Although the biopsy findings are suggestive of a secondary MN, the significantly high titer of PLA2R-Ab have persisted. The patient is offered an alkylating agent based therapy, but has opted to enroll in an ongoing clinical trial on anti-CD 38 therapy. He remains under surveillance for possible secondary etiologies due to his biopsy findings, while awaiting his response to anti CD-38 therapy.

PUB189

Two Clinical Scenarios Leading to the Diagnosis of Staphylococcus Infection-Associated Glomerulonephritis

Varun Chalasani,[1] Parmjyot Singh,[2] Swati Arora.[1] *[1]Allegheny Health Network, Pittsburgh, PA; [2]Lake Erie College of Osteopathic Medicine, Erie, PA.*

Introduction: Historically, infection-associated glomerulonephritis (IAGN) has been associated with group A streptococcal infections. At this time, staphylococcus infection-associated glomerulonephritis (SAGN) has become more prevalent in developed countries. We describe two different patients and clinical scenarios, who merge at the diagnosis of SAGN.

Case Description: The first patient is a female in her 60s who had recently been treated for methicillin sensitive staphylococcus aureus (MSSA) bacteremia. Three weeks later she was admitted with heart failure exacerbation and started on diuresis. Labs showed creatinine of 2.22, from baseline of 0.9, and proBNP was 30,583. Her respiratory status improved, however her creatinine increased day by day, peaking at 6.9, and she became oliguric. Renal biopsy showed IgA dominant immune complex mediated diffuse segmental proliferative glomerulonephritis consistent with post-staphylococcal glomerulonephritis. Immunofluorescence showed granular mesangial staining for IgA and C3. She was started on hemodialysis and was discharged to inpatient rehab. The second patient is a 19 year-old female who was transferred for treatment of tricuspid valve endocarditis and methicillin resistant staphylococcus aureus (MRSA) bacteremia. After transfer her renal function worsened, with peak creatinine of 3.5 from a baseline of 0.6. She became oliguric and hyperkalemic, and hemodialysis was started. A few days later, she developed a necrotizing small vessel vasculitis and was treated with prednisone for presumed leukocytoclastic vasculitis. This resulted in improvement in her renal failure. After steroids were stopped her renal function again worsened. Renal biopsy showed diffuse segmental proliferative and necrotizing glomerulonephritis with crescent formation; immunofluorescence revealed granular mesangial and capillary staining for IgA and C3. Steroids were restarted with plans for a lengthy taper, and she was discharged a few days later.

Discussion: SAGN has become a prevalent cause of infection-associated glomerulonephritis. Clinicians should recognize the broad risk factors associated with SAGN as staphylococcus infections are exceedingly common. Including the more elusive differentials including SAGN can aid in providing appropriate and swift management with antimicrobials, and possible hemodialysis support.

PUB190

Something Out of Nothing: A Rare Case of Pulmonary Renal Syndrome with Pauci-Immune Glomerulonephritis and Diffuse Alveolar Hemorrhage with Negative Serologies

Lucas Wang, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Pauci-immune (PAN) crescentic glomerulonephritis (CrGN) is one the most common etiologies of rapidly progressive glomerulonephritis. PAN CrGN presents as CrGN with little or no immunoglobulin staining and negative serological workup aside from a positive antineutrophil cytoplasmic autoantibody (ANCA). Patients with PAN CrGN usually have underlying systemic small vessel vasculitis, but in rare cases, it is not associated with vasculitis or ANCA. ANCA-negative PAN CrGN is often isolated to the kidneys, but here we present a case in association with severe diffuse alveolar hemorrhage (DAH).

Case Description: A 66-year-old Hispanic woman with no significant medical history presented with four days of fatigue and dysphagia. On admission she was hypoxic on room air, and her physical exam was remarkable for crackles bilaterally. Initial laboratory results revealed anemia (5.2 g/dL), hyperkalemia (6.3 mmol/L), and AKI with serum creatinine of 4.5 mg/dL. Urinalysis showed dysmorphic RBCs and proteinuria. A computed tomography scan of the chest/abdomen/pelvis was obtained and revealed multifocal pulmonary consolidations. The patient developed hemoptysis and a bronchoscopy showed DAH. The ICU team proceeded to intubate her as the hemorrhage continued to worsen. Further workup revealed a positive ANA titer of 1:40, but otherwise negative serologies, including MPO-ANCA, anti-GBM, and anti-dsDNA. Kidney biopsy showed necrotizing CrGN with negative immunofluorescence. She was diagnosed with PAN ANCA-negative vasculitis with associated DAH and nephritis and was started on

pulse-dose steroids and IV cyclophosphamide. Afterwards, her creatinine began trending down and urine output improved. The patient was discharged with a regiment of daily oral cyclophosphamide and steroid taper.

Discussion: We present a unique case of pulmonary-renal syndrome with negative serologies including ANCA. Based on most recent results from PEXIVAS trial, plasmapheresis was not considered to be part of the treatment plan and not doing plasmapheresis did not affect outcome.

PUB191

A Case Report of ANCA-Negative Vasculitis Presenting with Pauci-Immune Glomerulonephritis

Khalid Elharrif,[1,2] Mica Alex,[2] Petersen Greti,[1] Ratha V. Kulasingam,[1] Hania Kassem.[2] *[1]Kern Medical Center, Bakersfield, CA; [2]The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: Crescentic glomerulonephritis (GN) is a severe form of GN characterized by a rapid decline in kidney function. Pauci- immune GN is one of the most common causes of rapidly progressive GN and is usually associated with positive antineutrophil cytoplasmic antibody (ANCA). We present a rare case of ANCA negative pauci- immune GN that was successfully treated with immunosuppression.

Case Description: A 17-year-old girl without significant PMH was admitted to the hospital with abdominal pain and diarrhea. She initially had dark colored urine but became anuric shortly thereafter. On admission, she had a blood pressure of 139/83 mmHg (98 percentile), Pulse of 87 bpm and Temp of 98.3 °F. Physical exam was unremarkable. Initial laboratory investigation revealed creatinine of 11.9 mg/dl. Urinalysis was positive for proteinuria and hematuria. Protein to creatinine ratio was 28 g/ g. Urine microscopy showed RBCs with dysmorphic features. ANA, ANCA and anti GBM antibodies were negative. C3 and C4 were normal. Viral serology was negative. Kidney biopsy was consistent with small vessel vasculitis with pauci-immune necrotizing GN. She has initially required dialysis for several sessions but her kidney function improved after we started her on steroids and cyclophosphamide with subsequent improvement of her condition.

Discussion: Pauci-immune crescentic glomerulonephritis is one of the most common causes of rapidly progressive glomerulonephritis. The majority of patients with pauci-immune had circulating ANCA. Some patients with pauci-immune crescentic glomerulonephritis lack ANCAs. There are recent studies about the association between anti LAMP 2 antibody and ANCA negative pauci-immune GN.

PUB192

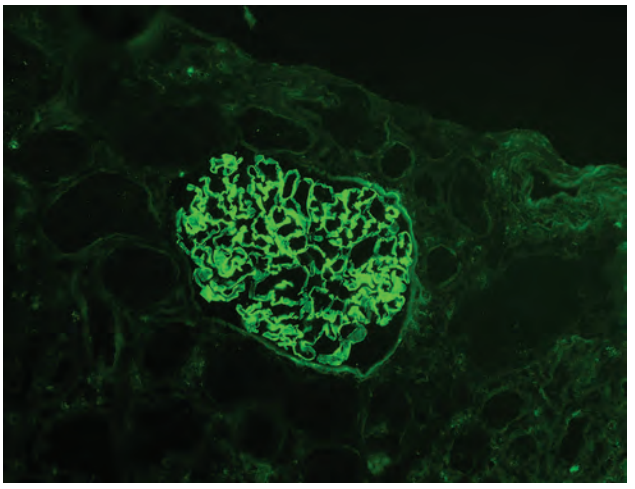
Atypical Presentation of Anti GBM Disease in an Elderly Woman with No Hematuria and Subnephrotic Proteinuria

Muralikrishna Gangadharan Komala,[1,2] Angela Bayly,[3] Ming-wei Lin.[3] *[1]Nepean Blue Mountains Local Health District, Penrith, NSW, Australia; [2]University of Sydney- Nepean Clinical School, Kingswood, NSW, Australia; [3]Westmead Hospital, Westmead, NSW, Australia.*

Introduction: Atypical anti GBM disease forms a small minority of patients in this rare and aggressive condition. Atypical disease usually presents with milder disease and typical histopathology and good prognosis. However, presentation without hematuria is unique.

Case Description: A 69-year-old lady with a background history of hyperlipidaemia, hypothyroidism and rheumatoid arthritis presented with a 4-week history of nausea and lethargy. She had been initiated on Pantaprazole and noted to have renal dysfunction with creatinine at 214 μmol/L 4 weeks later. She had no respiratory symptoms. Urine protein/creatinine ratio was elevated at 108 mg/mmol and she had leucocyturia and no hematuria. The vasculitic screen revealed positive anti GBM titre at 135 CU (QuantaFlash chemiluminescence assay; normal range <20CU). A renal biopsy revealed necrotising glomerulonephritis and distinctive linear IgG deposition on glomerular basement membrane. She underwent daily plasma exchange for one week and subsequently initiated on alternate daily exchanges. She was initiated on pulse Methylprednisolone 500 mg daily for three days followed by oral prednisolone 1 mg/Kg and oral cyclophosphamide 2 mg/Kg. Her renal function continues to improve with creatinine at 177 μmol/L.

Discussion: The initial presentation was suggestive of interstitial nephritis esopecially with the drug history. However, the anti GBM serology and the typical histopathological features were consistent with a diagnosis of anti GBM disease resulting in appropriate therapy. Hence the teaching points from this case are that anti GBM disease can present in an atypical manner and absence of hematuria does not rule out an aggressive glomerulonephritis and timely investigation with a renal biopsy and appropriate management can prevent end stage kidney disease.



Immunofluorescence with IgG antibody with linear staining of glomerular basement membrane

PUB193

IgA Nephropathy and Lupus Nephritis: A Subtype or a Separate Entity?

Gordon Wagler, Naman Trivedi, Mujahed M. Dauleh, Ali M. Zebi. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: The relationship between IgA nephropathy (IgAN) and lupus nephritis (LN) is controversial, some feeling the 2 can co-exist while others feel that IgAN could be a subtype of LN. We present a case of SLE that had features of IgAN on kidney biopsy which we treated as lupus nephritis resulting in recovery of renal function.

Case Description: A 51 year old female with undifferentiated connective tissue disease consistent with SLE was evaluated for AKI, proteinuria with protein to creatinine ratio of 5.76 grams, and microscopic hematuria. Lab investigation showed neg p-ANCA, c-ANCA, PLA2R Ab, DNA Ab, anti-GBM with normal C3 and slightly high C4. Around this time she was noted to have GI ulcers on scoping. Kidney biopsy was performed and sample was sent to Arkana lab. It showed 22 total glomeruli 2 of whicher were globally sclerosed, no segmental sclerosis or arteriolar hyalinosis, mild interstitial fibrosis and tubular atrophy, severe arterial intimal fibrosis, negative congo red stain for amyloid, and 1 glomerulus on toluidine blue stained sections. LM had crescents in 7/14 glomeruli. IF had 1/7 glomeruli that were globally sclerotic. There was 3+ amounts of mesangial deposits of IgA. 3+ amounts of lambda light chain and 2+ amounts of kappa light chain were seen in a similar pattern. Kappa and lambda light chains stained equally in small casts and in tubulointerstitial regions. EM showed mild effacement of foot processes. The mesangium was not expanded and there were a moderate number of mesangial electron-dense deposits. Pathology reported this as IgA–Crescentic glomerulonephritis and stressed that though an unusual pattern, it was consistent with diffuse class IV lupus nephritis. We treated her with Euro-lupus protocol using glucocorticoid and cyclophosphamide with good recovery of renal function.

Discussion: LN is a known complication of SLE and it normally has distinct characteristics on kidney biopsy. IgG deposits are commonly seen on IF in LN but IgA deposits are uncommon. Secondary forms of IgAN can present in patients who have mucosal infections or ulcerations which may have contributed to IgA deposition in our patient. Currently we do not have criteria to precisely differentiate whether these two entities (IgAN and LN) can co-exist. We feel our patient represents a distinct subtype of LN based on clinical history, biopsy findings and response to treatment.

PUB194

Hemoptysis in Mixed Cryoglobulinemia

Sonya M. Joshi, Mohamed Hassanein, Sujith R. Modugula, Leal C. Herlitz, Tarek Ashour. *Cleveland Clinic, Cleveland, OH.*

Introduction: Mixed cryoglobulinemia(MC) is a small vessel immune complex vasculitis caused by polyclonal cryoglobulin deposition in major end organs. Pathogenesis has been associated with viruses including hepatitis C and HIV, plasma cell dyscrasias, and connective tissue diseases. Clinical presentation varies but pulmonary manifestations are generally rare. We present a unique case of mixed cryoglobulinemia presenting with kidney, skin and lung involvement.

Case Description: A fifty-seven-year old female with a history of alcoholic cirrhosis, chronic kidney disease, diastolic heart failure was initially found to have a petechial rash during admission for syncope at an outside hospital. Her lab workup noted progressive acute kidney injury, cryoglobulin consisting of IgG kappa, polyclonal IgG and IgM lambda, low complement levels, positive rheumatoid factor, and negative HIV, hepatitis C, and ANCA. Skin biopsy revealed leukocytoclastic vasculitis. Kidney biopsy showed proliferative glomerulonephritis with necrotizing arteriolitis. She was treated with intravenous solumedrol for MC but developed hemoptysis followed by acute hypoxemic respiratory failure. Bronchoscopy with bronchoalveolar lavage(BAL) revealed thin bloody secretions in the right upper and middle lobe of the lung. Culture and gram stain

noted methicillin sensitive staph aureus(MSSA). Patient was given rituximab, antibiotics and was transferred to a tertiary center for consideration of plasmapheresis and bone marrow biopsy. Although course of antibiotics improved respiratory status, hemoptysis persisted raising suspicion for lung involvement of cryoglobulinemia. Patient's rash, kidney function, and hemoptysis improved with steroids and an additional rituximab dose. Patient did not undergo plasmapheresis. Bone marrow biopsy was negative for evidence of clonal plasma cell disorder.

Discussion: Pulmonary disease in MC includes cough, dyspnea, and rarely hemoptysis. Hemoptysis from diffuse alveolar hemorrhage (DAH) is documented as a clinical feature of cryoglobulinemia with an estimated incidence of 0.4– 4%.We report a case of mixed cryoglobulinemia with persistent hemoptysis despite antibiotics. No sequential BAL done to investigate DAH. MSSA pneumonia noted on BAL is likely a complication of immunosuppression with intravenous steroids. Our case is a valuable addition to the few cases of hemoptysis in MC described in the literature.

PUB195

Management of Infective Endocarditis-Related Glomerulonephritis

Syed Z. Ahmad, Shivangi Patel. *Morristown Medical Center, Morristown, NJ.*

Introduction: Antibiotics can be effective and curative if infective endocarditis (IE) infection is mild. However, in severe cases of IE, surgical intervention is necessary to restore integrity of heart value and to halt or cure IE related glomerulonephritis (GN).

Case Description: 28-year-old male with Crohn's disease, hepatitis C(viral load >10,000,000 IU/ml), admitted at an outside hospital (8/10-9/15) with creatinine (Cr) of 1.28 mg/dL (baseline Cr 0.83 mg/dL) after intravenous (IV) drug use resulting in methicillin-sensitive S. aureus tricuspid valve (TV) endocarditis with septic emboli to right shoulder, lung, and left hip. Renal biopsy: subendothelial and mesangial deposits with >60% foot process effacement consistent with membranoproliferative glomerulonephritis (MPGN). He was treated with IV oxacillin and no surgical intervention. Readmitted to our hospital on 9/19 with hypertensive urgency (173/123 mmHg), anasarca and gross hematuria. Labs:Cr 2.4 mg/dL (discharge Cr 2.09 mg/dL), WBC 17/nL, proBNP 30,000 ng/L, albumin 0.9 g/dL, and low C3 level. Urinalysis with hematuria and protein Ur/Cr Ur ratio 40 grams. C4, hemoglobin, liver function, platelet count, and coagulation were normal. ANCA and cryoglobulins were negative. Duplex of renal arteries and veins was negative for thrombosis. Serum Ascites Albumin Gradient (SAAG) score was 0.3 g/dL, not consistent with portal hypertension. Echo: severe TV regurgitation, moderate pericardial effusion, and global hypokinesis with an ejection fraction of 40% and 1.5 cm vegetation. He underwent TV DeVega annuloplasty. Hospital course complicated by hemorrhagic shock with acute tubular necrosis and right hemithorax requiring VATS. Outpatient follow up, 3 months later, he was on Coreg only with blood pressure (120/80 mmHg), albumin 3.8 g/dL, stable Cr 1.79 mg/dL, remains without edema and pending hepatitis C treatment.

Discussion: Despite~6 weeks of antibiotics and negative bacteremia, the persistent hypocomplementemia suggests failure to control the infection as seen by worsening renal function, hypertensive urgency, nephrotic proteinuria, and anasarca. By undergoing a repair rather than replacement of TV not only resulted in lower operative mortality but also achieved a higher long-term survival, both from cardiac and renal standpoint. MPGN was related to his IE and not hepatitis C as he had resolution of his proteinuria and stable Cr after his surgical intervention.

PUB196

Proliferative Glomerulonephritis with Monoclonal IgG Deposits (PGNMID) with Fibrillary Deposits Progressing to Macrophage-Driven Systemic Vasculitis: An Autopsy Case

Kazunori Karasawa, Kenichi Akiyama, Yoei Miyabe, Takahito Moriyama, Kosaku Nitta. *Tokyo Women's Medical University, Tokyo, Japan.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin (Ig) deposits (PGNMID) is a renal-limited glomerular disease characterized by disordered glomerular Ig deposits.

Case Description: Here, we report the case of a 62-year-old Japanese woman undergoing hemodialysis 5 years after PGNMID onset. After kidney failure, prednisolone treatment for managing PGNMID was discontinued. Thereafter, fever of unknown origin (FUO), multiple vascular occlusions in the brain, fingers, and retina were observed. Finally, the patient died of hemorrhagic cerebral infarction 8 months after kidney failure.

Discussion: Autopsy revealed the presence of subendothelial fibrillar deposits in differently sized vessels. Furthermore, electron microscopy revealed that macrophages phagocytosed the deposits and underwent autophagy. Liquid chromatography-mass spectrometry (LC/MS) analysis was performed to diagnose IgG1κ type PGNMID. Furthermore, MS revealed that the deposits contained an amyloidogenic protein, which was responsible for the systemic deposition and macrophage-driven systemic vasculitis, eventually resulting in FUO and vasoocclusive disease. Furthermore, macrophage-driven vasculitis in the present patient was suggested to be markedly influenced by pyroptosis, a form of pro-inflammatory cell death peculiar to phagocytes. Systemic PGNMID reported in the present case is a rare subtype of PGNMID.

PUB197

Urinary GADD45G Protein Excretion Predicts IgA Nephropathy Progression

Min-Jeong Lee, Jieun Park, Inwhee Park, Heungsoo Kim, Gyu Tae Shin. *Ajou University School of Medicine and Graduate School of Medicine, Suwon, Gyeonggi-do, Republic of Korea.*

Background: Growth arrest and DNA damage 45G (GADD45G) is a family of proteins involved in DNA damage response and cell growth arrest. We have previously shown that GADD45G promotes apoptosis leading to acute and chronic kidney injuries (KI 2008; Am J Nephrol 2009; PLoS One 2019). In this study, we show evidence that urinary GADD45G protein can predict progression of IgA nephropathy (IgAN).

Methods: IgAN patients were included in the study if they did not have acute kidney injury on the day of sample collection and had at least one follow up serum creatinine (SCr) measurement after renal biopsy. A 50% or greater increase of serum creatinine levels was used as an endpoint of deterioration of renal function. ELISA assay was performed using a Human GADD45G ELISA kit. Renal biopsy tissue was stained with a monoclonal mouse anti-GADD45G antibody.

Results: Forty-five patients were enrolled in this study whose renal biopsy revealed IgAN. Urinary GADD45G and urinary protein concentrations were 1.89±1.82 μg/g and 1.47±1.98 g/g, respectively. Urinary GADD45G showed a significant positive correlation with SCr-slopes and with urinary protein. The SCr-slope of the highest tertile group (above 1.95 μg/g) of urinary GADD45G was significantly higher than that of the lowest tertile group (below 0.90 μg/g). Urinary protein was significantly higher in the highest tertile group compared to the other tetile groups. Univariate Cox regression analysis showed that urinary GADD45G was significantly associated with deterioration of renal function. Kaplan-Meier test showed a significant difference in event-free survival for deterioration of renal function between patients with the highest urinary GADD45G tertile vs. the other tetile groups. The area under the receiver operating characteristics (ROC) curve indicated urinary GADD45G had a good performance in predicting renal outcome. The cut-off point of 1.67 μg/g was determined from the ROC curve. This cut-off point yielded a positive predictive value of 36.8% and a negative predictive value of 100%. Immunohistochemistry showed that GADD45G was expressed in all biopsy samples of IgAN whereas no staining was noted in normal control tissue. Staining was mainly detected in the cytoplasm of renal tubules.

Conclusions: In the present study, we showed that urinary GADD45G excretion is significantly associated with kidney disease progression in patients with IgAN.

PUB198

Expanding the Differential: Goodpasture's Disease in the Setting of the COVID-19 Pandemic

Abdullah Jalal. *Overlook Medical Center, Summit, NJ.*

Introduction: The 2020 COVID-19 pandemic was a challenging time in healthcare. Physicians struggled with limited resources, overwhelming patient volume and limited knowledge of COVID-19. During this period many hypoxemic patients with pulmonary infiltrates were empirically managed as COVID-19 patients. However, anchoring to COVID-19 diagnosis narrows differentials and potentially lead to missed diagnosis. Herein we highlight a case of delayed Goodpasture's disease diagnosis in the setting of COVID-19 pandemic.

Case Description: A 51 year old male was admitted for several days of malaise, diarrhea and decreased oral intake. On arrival the patient was hypothermic 88.6 °F, BP 122/67 mm Hg, SpO2 91% on room air. On exam he was encephalopathic, diffusely edematous with sonorous wheezes. Initial labs notable for (mEq/L): Na 135, K 7, Cl 107, low CO_2 8, significantly elevated BUN 184 and Cr 27.9. CT chest showed bilateral airspace opacities, renal ultrasound was unremarkable. Initial diagnosis was sepsis secondary to presumed COVID-19 infection despite several negative COVID tests. Emergent hemodialysis was complicated by hypotension and hypoxemia requiring intubation. The patient rapidly deteriorated requiring 3 vasopressors. Autoimmune serologies resulted several days later were negative (ANA, ANCA, C3, Anti-dsDNA Ab, Hepatitis B/C, HIV, SPEP with immunofixation) with the exception of positive anti-GBM IgG Ab (>8). Renal biopsy was unattainable given his tenuous clinical status; however, bronchoscopy performed revealed bloody aliquots consistent with alveolar hemorrhage. The patient was subsequently started on cyclophosphamide, pulse dose steroids and plasmapheresis. Respiratory status steadily improved allowing ventilator liberation. The patient underwent several more cycles of immunosuppression, plasmapheresis during hospitalization and was discharged after 80 days. 1 year later the patient remains dialysis-dependent.

Discussion: This case illustrates the unique challenges of diagnosing Goodpasture's Disease (GD), a rare immune complex-mediated small vessel vasculitis characterized by alveolar hemorrhage and renal insufficiency, during the COVID-19 pandemic. Similarities in their presentation (pulmonary infiltrates, hypoxemia, renal failure) led to our patient being initially treated for COVID-19. However, maintaining a broad differential is essential as the treatment for GD and COVID-19 are vastly different.

PUB199

The Alteration of Neutrophil Nuclear Morphology: A Potential Predictor for Corticosteroid Response in IgA Nephropathy

Reiko Muto, Sawako Kato, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: In patients with active IgA nephropathy (IgAN), immunosuppressive treatment using corticosteroid is widely used. It should be useful to detect a poor corticosteroid responder in advance. Neutrophils are the most abundant white blood cells (WBC) in circulation, representing a first line of defense from daily environmental insults. Recently, there have been reported associations between an alteration of neutrophil nuclear morphology and treatment responses in patients with infection, cancer, and autoimmune diseases. In these states, the neutrophil nuclear breaks down, then the nucleosome components extrude. The aim of study is whether an alteration of neutrophil nuclear morphology associates with poor corticosteroid response in IgAN.

Methods: We investigated IgAN patients starting corticosteroid therapy between July 2020 to March 2021. We excluded patients with apparent infection or cancer. We defined the alteration of neutrophil nuclear morphology as neutrophil blebs (NB) with Giemsa stain (Figure 1). The participants with NB greater than the median NB were grouped in the high-NB group and the rest were in the low-NB group.

Results: We enrolled five biopsy-proven IgAN patients; number of female, 4; median age, 51 [interquartile range (IQR): 41-57] years old; median WBC count, 7700 [IQR: 6100-9550] /mL; median eGFR, 58.5 [IQR: 56-69] ml/min/1.73m^2; median CRP, 0.06 [IQR: 0.01-0.64] mg/dL; median UP, 0.7 [IQR: 0.2-1.4] g/gCr; median NB, 53.2 [IQR: 37.6-69.2] % at baseline. The high-NB group showed the significantly decrease in UP than that low-NB group after 4 weeks from the initiation of corticosteroid therapy (p=0.0516). There was no differences in eGFR.

Conclusions: The alteration of neutrophil nuclear morphology could predict the response to corticosteroid therapy in IgAN patients.

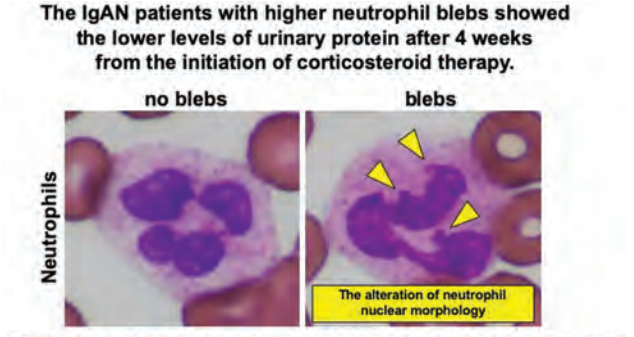


Figure1 The differences between neutrophils with no blebs and blebs

PUB200

Repeat Kidney Biopsy During Remission Induction in Crescentic C3-Dominant Glomerulonephritis

Samy Hakroush,[1] Bjoern Tampe.[2] *[1]Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany; [2]Department of Nephrology and Rheumatology, University Medical Center Göttingen, Göttingen, Germany.*

Introduction: C3 glomerulopathies are rare kidney diseases characterized by complement dysregulation in the glomerular microenvironment, resulting in complement C3-dominant depositions in kidney biopsy samples. To date, it remains elusive which histopathological lesions in C3-dominant glomerulonephritis (GN) are susceptible and effectively eliminated by aggressive immunosuppression and therapeutic plasma exchange (PEX) treatment or indicators of treatment response. In this report, we describe histopathological and ultrastructural findings in repeat kidney biopsies during remission induction with steroids, PEX and intensive protocol cyclophosphamide (CYC) in a case of severe crescentic C3 GN.

Case Description: We here report the case of a 53 years-old man with relapse of severe crescentic C3 GN and histopathological findings in repeat kidney biopsies during remission induction. Crescentic C3 GN developed within less than 2 weeks, associated with severe acute kidney injury. After initiation of aggressive immunosuppressive therapy including PEX treatment, dialysis treatment was still required based on clinical and laboratory markers of kidney injury. In a repeat biopsy after initiation of remission induction, no regression of previous observed crescentic GN was observed. However, no C3c was detectable, associated with an almost complete regression of previous observed ultrastructural deposits. Based on these observations, we continued aggressive remission induction and achieved partial recovery of kidney function with sufficient diuresis and discontinuation of dialysis treatment.

Discussion: Histopathological and ultrastructural findings in C3 GN may be helpful to conclude individual treatment response independent of clinical and laboratory markers of kidney injury and further emphasizes the value of repeat kidney biopsies in cases of severe crescentic C3 GN.

PUB201

Nile Red Fluorescence and Spectroscopy Reveal Unique Lipid Droplet Distribution and Physicochemical Changes in Glomerulonephritis

Jason T. Bau,[1,2] Wulin Teo,[1,3] Asha K. Swamy,[1,2] Adrienne S. Kline,[1] Hyunjae Chung,[1] Kevin R. Chapman,[1] Graciela Andonegui,[1] Daniel A. Muruve,[1,2] Peter K. Stys,[1,3] Justin Chun.[1,2] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]Division of Nephrology, Calgary, AB, Canada; [3]Division of Clinical Neurosciences, Calgary, AB, Canada.*

Background: Abnormalities in lipid deposition and lipid droplet (LD) accumulation have not been well established in glomerulonephritis (GN). Nile Red (NR), a well-known lipophilic stain for intracellular LDs, is a solvatochromic fluorophore that provides high-resolution spatial assessment of lipid distribution and chemistry. Solvatochromatic spectroscopy is a sensitive imaging modality with the potential to characterize the subtle, early changes in lipid chemistry associated with glomerular injury and disease.

Methods: A total of 72 kidney biopsies of histologically diagnosed glomerular diseases including minimal change disease, membranous nephropathy, primary FSGS, class IV lupus nephritis (LN), ANCA-associated vasculitis, and IgA nephropathy (IgAN), and healthy tissue controls were retrieved from the Biobank for the Molecular Classification of Kidney Disease. Quantitative spectral analysis of NR emission patterns were performed on NR-stained biopsies to generate unique physicochemical profiles for each type of GNl. Segmented regions of biopsies (glomeruli, tubules, and interstitial) were imaged using confocal microscopy allowing for LD quantitatation using an algorithm developed in MATLAB.

Results: Lipid droplet distribution greatly differed between the GN with IgAN and LN demonstrating the highest number LDs in glomeruli. By spectral analyses, control tissue showed significant differences in lipid polarity profile between histological compartments of the kidney (glomeruli, interstitium and tubules). Tubules consistently displayed more lipid rich domains compared to interstitial and glomerular regions. In diseased states, these patterns varied between GNs, with glomerular regions becoming more polar (for example in LN) and tubular regions (predominantly for IgAN). Within histologically identical disease types, we noted distinct populations based on lipid profiles, suggesting significant variance within GN.

Conclusions: Nile Red spectral analysis of human kidney tissue provides unique insights into lipid physicochemical changes in GN. Marked variance within identical disease types suggests that histological determinants of GNs are limited and sensitive techniques such as high-resolution imaging and spectroscopy can identify earlier changes in disease.

PUB202

ANCA Vasculitis: Detecting It Early

Kirtan Patel, Joe N. Austin. *The Christ Hospital Physicians Spine, Cincinnati, OH.*

Introduction: Renal limited vasculitis (RLV) is part of the spectrum of antineutrophil cytoplasmic autoantibody (ANCA) vasculitis and includes granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA). GPA and MPA present with kidney and pulmonary involvement. RLV tend to present later in the disease course given the lack of extrarenal symptoms that are seen with GPA and MPA. They can progress into having GPA and MPA with development of extrarenal manifestations. Here we present a case in which renal limited vasculitis is diagnosed early in its course.

Case Description: 54 year Hispanic male with no medical history was admitted with atrial fibrillation, acute heart failure, hyperthyroidism and melena. Patient had no history of recurrent sinus or respiratory infections. On exam, patient had a saddler nose deformity from an accident as a child and lower extremity edema. Creatinine (Cr) was 0.54 on admit and was also 0.54 in the emergency room one week prior. Urinalysis had large blood with >100 RBC/HPF and 30mg/dL protein. Patient was diuresed aggressively for 3 days with a furosemide drip and with a mild bump in creatinine from 0.73 to 1.16. The patient's renal function deteriorated even after losartan and furosemide were discontinued and nephrology was consulted when Cr was 2.23. Evaluation showed ongoing microscopic hematuria. Serologic studies were ordered and renal biopsy was performed. Biopsy showed pauci-immune necrotizing glomerulonephritis (GN) with crescents. C3 and C4 were low and C-ANCA and anti-proteinase 3 were strongly positive. Despite induction therapy with Solumedrol followed by weekly rituximab x 4 doses, renal function continued to decline. Due to aggressive clinical course, he was started on plasma exchange x 7 treatments. Despite interventions, he became oligo-anuric and required initiation of dialysis. Although he has had some recovery of renal function and is no longer oligo-anuric, he remains dialysis-dependent.

Discussion: Renal limited vasculitis is confirmed by kidney biopsy, and commonly shows necrotizing GN with crescents in the early stages. As the disease progresses, the lesions become more sclerotic. Untreated glomerulonephritis can progress to end stage renal disease within weeks. Treatment requires pulse methylprednisolone with 500 to 1000mg/day for three days followed by oral prednisone along with cyclophosphamide or rituximab. In rapidly decline in Cr continues, plasmapheresis is warranted.

PUB203

Unexpected Severe Thrombocytopenia Linked to Mixed C- and P-ANCA-Positive Vasculitis

Jesus D. Vega Colon. *Hospital Episcopal San Lucas, Ponce, PR.*

Introduction: The Anti-Neutrophil Cytoplasmic Autoantibody (ANCA)-associated vasculitis are a rare group of disorders that affect multiple organ systems with a peak age of 65-74 years. It encompasses several diseases including Granulomatosis with polyangiitis, Microscopic polyangiitis and Eosinophilic granulomatosis with polyangiitis. Few cases have been able to demonstrate the existence of mixed ANCA vasculitis related to severe refractory thrombocytopenia.

Case Description: We report a 74-year-old male with Past Medical History of Hypertension and Chronic Kidney Disease (CKD) Stage IV that came to our hospital complaining of fatigue and decrease urinary output since 5 days. Physical exam was remarkable for bilateral crackles and lower extremity edema. Initial labs showed evidence of anemia and thrombocytopenia of 5.8 g/dl and 66 $10^3/\mu L$ respectively. Multiple electrolytes abnormalities were found including acute kidney injury over CKD: serum creatinine 7.23 mg/dl (baseline: 3.85), marked azotemia BUN:101 mg/dL and metabolic acidosis: 13 mEq/L. Patient was admitted with diagnosis of volume overload to start emergent renal replacement therapy along with PRBC transfusion. Follow up labs revealed evidence of hemoglobin optimization (10.2 g/dl), improved azotemia (65 mg/dL) and metabolic acidosis (19.3 mEq/L). Further work-up sent by nephrology service showed evidence of high levels of Proteinase 3 ANCA antibodies: 4.9 U/ml and Myeloperoxidase ANCA antibodies: 96.4 U/ml. Decision was made to start induction therapy with Rituximab and high dose pulse IV steroids. Despite aggressive treatment, clinical course continued to deteriorate with thrombocytopenia reaching critical values of 19 $10^3/\mu L$. Other causes in the differential diagnosis were rule out such as Thrombocytopenia Purpura, Chronic lymphocytic leukemia, HIV, Hepatitis C, Thrombotic thrombocytopenia purpura, among others, which indicated an association between mixed ANCA vasculitis and severe thrombocytopenia.

Discussion: This case illustrates a routinely found inpatient lab abnormality not generally seen in this rare vasculitis type. It is important to keep a wide-ranging differential diagnosis in patients presenting with refractory thrombocytopenia concomitant to advance renal failure. Prompt identification and suspicion of ANCA vasculitis can lead to early start of induction therapy which can delay the progression to end stage kidney disease.

PUB204

Atypical Haemolytic Uremic Syndrome in Lung Transplantation and Treatment with Eculizumab: Our Experience

Raquel B. Rico. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Atypical haemolytic uremic syndrome (aHUS) is a clinical entity characterized by acute kidney injury, thrombocytopenia and microangiopathic hemolytic anemia. There are several cases of AHUS in non-renal solid organ transplants described in the literature, included lung transplant. Kidney and patient survival are compromised by this complication because of the lack of an effective treatment. Eculizumab is C5 complement factor specific blocker already administered in another kind of secondary aHUS with encouraging results

Methods: We analys six lung transplants in a retrospective single-center study between 2018-2020 who developed an aHUS and were treated with eculizumab. Clinical and analytical data were collected along the follow-up. Principal outcome was to explore haematologycal and renal response after treatment with eculizumab.

Results: We included a total of six patients(83% female) with a median age of 57 years at the time of transplantation. Induction and maintenance immunosuppressive therapy were based on tacrolimus, mycophenolate and prednisone. Baseline serum creatinine after lung transplantation was 1.1 mg/dl(0.9-2.4). Two patients developed an aHUS in the immediate post-transplant, one of them died because of surgical complications. Another four patients developed an aHUS 59 months(33-95) after transplantation. Previously of thrombotic microangiopathy, three patients were on treatment with everolimus instead of mycophenolate and two lung transplants have cytomegalovirus reactivation. At the aHUS onset, median serum creatinine was 4mg/dl(2.4-5-7) and acute dialysis was performed in 50% of patients. Median hemoglobin was 7.2g/dl(6.9-7.7), platelet count was 32x1000/μL(17-58), and DHL was 1343 U/L (581-1597)at the start of eculizumab despite having treated the trigger. After a median of 6 doses of eculizumab, the five surviving patients had haematologycal and renal response. No patients underwent chronic dialysis. Serum creatinine was 2.2 mg/dl(1.7-2.3), hemoglobin 9.8g/dl and platelet count 159x1000/μL at the end of follow-up.

Conclusions: AHUS is a critical complication in lung transplantation, shortly related with immunosuppressive therapy. Patients are at risk of end stage renal disease. Eculizumab treatment appears promising.

PUB205

Proliferative Glomerulonephritis with Monoclonal Immune Deposits: A Continued Treatment Conundrum

Ibrahim Khambati, Michael A. Mao. *Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Introduction: Proliferative Glomerulonephritis with Monoclonal Immune Deposits (PGNMID) is a rare entity characterized by abnormal light chain, heavy chain, or intact immunoglobulin deposits. Patients generally are Caucasian, female, >50 years-old, and present with renal dysfunction and nephrotic-range proteinuria. Pathogenesis involves clonal plasma or B-cells depositing abnormal monoclonal proteins into the kidneys. The clone however is rarely found, and this contributes to the lack of a standard treatment regimen.

Case Description: A 32-year-old Caucasian male with PMH of uncontrolled HTN, chronic microscopic hematuria, and anemia presented with hypertensive emergency (220/111 mmHg) and acute kidney injury (BUN: 58 mg/dl & SCr: 4.41 mg/dl). UA showed microscopic hematuria and proteinuria. 24-hr urine protein was 8.5 g/24hr. Renal US was unrevealing. Other studies were negative including autoimmune panel, SPEP, UPEP, C3/C4, serum FLC, anti-PLA2R, anti-THSD7A, illicit drug screen, endocrine (HgbA1c, renin, aldosterone, catecholamines) and infectious (hepatitis panel, HIV, antistreptolysin-O). A kidney biopsy showed a membranoproliferative pattern with cellular/fibrocellular crescents, 15% interstitial fibrosis, predominant lambda IgG3 and C3 granular capillary loop staining, and numerous subendothelial, mesangial and paramesangial immune complex deposits on EM. A bone marrow biopsy showed hypocellular marrow trilineage hematopoiesis. No clonal cells were identified. He was started on prednisone 80 mg x 4 weeks. Renal function deteriorated and so he was treated with Rituximab (4 doses, 375 mg/m2/dose; briefly interrupted by COVID-19 infection). Absolute CD20 count 4 weeks after this treatment showed 1 cell/mcl with no improvement in renal function or proteinuria.

Discussion: PGNMID is challenging to treat due to its rarity, and here we highlight a case without detectable clone or monoclonal protein in serum/urine that failed prior published effective treatment strategies. The reconstitution of CD20 cells shortly after treatment completion may suggest that a stronger dose or treatment is necessary to achieve clinical response. Daratumumab (a monoclonal anti-CD38 antibody) was recently studied in an open-label phase 2 study to treat 11 PGNMID patients, and this is our next step. Our case highlights the evolving treatment modalities of PGNMID.

PUB206

A Case of Class IV Diffuse Proliferative Lupus Nephritis in a Hispanic Woman with Underlying Systemic Lupus Erythematosus

Rosa White, Christine E. Loftis. *The University of Texas Rio Grande Valley - Edinburg Campus, Edinburg, TX.*

Introduction: Glomerulonephritis is the major cause of morbidity and mortality of SLE. Lupus nephritis is characterized by immune complexes deposition in the mesangium leading to complement activation resulting in hypocomplementemia. Studies show that up to 60% of adults with lupus develop renal involvement and it has been well established that Hispanic patients show poorer outcomes than Caucasians despite advances in treatment. Kidney biopsies are paramount in patients with an exacerbation of symptoms as it will establish a diagnosis, help to define treatment strategy, and determine response to treatment.

Case Description: A 41-yo-Hispanic-Woman with a PMH SLE without previous renal involvement, secondary Sjogren's hypertension, heart failure and NASH liver cirrhosis presented to the ER with worsening SOB, difficulty swallowing, and anasarca. Symptoms started two weeks prior and had progressively worsened. Patient was hypertensive, tachypneic, had positive JVD, wheezing in lung bases, +1 pitting edema in the lower extremities and hyperpigmentation of the skin on the face, neck and upper extremities. CXR showed pulmonary edema. Labs showed WBC 11.1, Hgb 10, plt 192, Cr 0.9, BUN 17, CO2 19, UA 3+ blood, 3+ proteinuria, negative LE, nitrates. BNP 1170. Other labs showed Protein/Cr > 2.000, ESR 94, CRP 4.5, ANCA negative, ANA 10, dsDNA 2.7, CENP antibody 0.9, Jo1 antibody 0.6, SCL 70 antibody <0.6, Smith antibody 3.1, SSA/RO 103, SSB/LA 0.9, UR1RNP 3.7, C3 54, C4 <5, RNA polymerase III Ab 37, Cardiolipin Ab IgM <12, Cardiolipin Ab IgG 14. HIV, Hepatitis C, and Hepatitis B were negative. Kidney biopsy showed class IV diffuse proliferative lupus nephritis with a component of Lupus anticoagulant. The patient was started on angiotensin receptor blocker, Prednisone 60 mg BID, Mycophenolate 1000 mg BID and Eliquis 5 mg BID.

Discussion: Kidney biopsies are imperative when establishing a cause of new onset proteinuria in a patient with history of SLE. Goal of treatment is to produce strong immunosuppression in order to reduce kidney inflammation in a timely manner and prevent flares, which decreases the long term risk of renal failure. Despite early recognition strategies and advances in treatment, Hispanic patients are likely to present with class IV or V lupus nephritis and are subsequently more likely to develop CRF compared to Caucasian patients.

PUB207

IgA Nephropathy (IgAN) and Focal Segmental Glomerulosclerosis (FSGS) in a Patient with Crohn's Disease (IBD) on Infliximab

Aulio E. Bustos, Michael D. Klein, Viviam I. Becerra rivera. Westchester Medical Center *Westchester Medical Center Health Network, Valhalla, NY.*

Introduction: IgA nephropathy and FSGS are common conditions which can coexist in the same patient either due to the nature of the underlying nephropathy, or to the use of anti-inflammatory agents. We present a case of IgAN and FSGS in a patient treated with anti-tumor necrosis factor-α therapy (aTNF-α) for IBD

Case Description: A 21-year-old male with diffuse IBD on semi-monthly Infliximab, presented with nephrosis manifesting as 4.2 grams proteinuria, hypoalbuminemia to 2.8 g/L, and hyperlipidemia. He had no complaints, was normotensive, and had a normal physical exam. Labs demonstrated BUN 15 mg/dl and Creatinine 0.8 mg/dl, normal complement C3 and C4, Urinalysis with 3+ protein, 1+ blood, 10 RBC/HPF, and 7 WBC/HPF. Renal biopsy showed extensive mesangial IgA deposits, diffuse foot process effacement, and tip variant FSGS in a single glomerulus. These findings presented diagnostic and therapeutic challenges since it was unclear whether the aTNF-α induced the FSGS, the IgAN, both, or neither

Discussion: IgAN is the most common nephritis in the developed world and is characterized by mesangial IgA deposition with varying degrees of proliferation. Primary FSGS is one of the most common patterns of nephrosis in adults. The use of aTNF-α for non-renal diseases, has been reportedly linked to the occurrence of FSGS, as well. Though there may be a link between the aTNF-α and the FSGS in our case, FSGS has also been reported in patients with IgAN, irrespective of aTNF-α use and may have prognostic significance. As for the IgA itself, a causal linkage between aTNF-α therapy and IgAN is tenuous as such reports may represent IgA deposition associated with the underlying condition such as ankylosing spondylitis or Crohn's disease This case is a rare example of combined pathology with IgAN and FSGS in a patient treated with aTNF-α that has an undefined primary cause. Despite the diffuse foot process effacement and evidence of FSGS lesions, we opted to treat this as drug induced nephropathy. We withheld the aTNF-α and are monitoring for recovery. We have a low threshold to initiate steroids for primary FSGS in the absence of near-term remission

PUB208

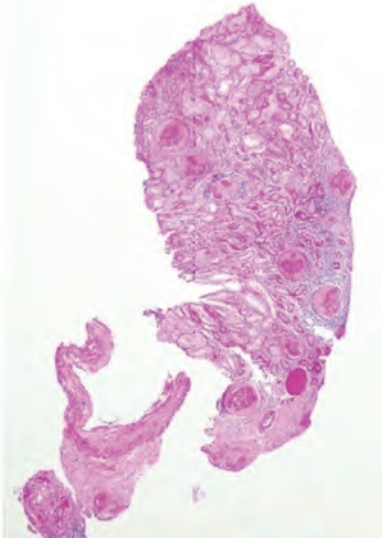
Double Positive Glomerulonephritis: A Disease Associated with Unfavourable Outcome Requiring Aggressive Treatment: A Case Report and Review of Literature

Marianna Napoli, Maria Mattiotti, Anita Campus, Carlo Stefanini, Olga Baraldi, Gisella Vischini, Benedetta Fabbrizio, Gaetano La Manna. *Universita di Bologna, Bologna, Italy.*

Introduction: Co-presentation with both ANCA and anti-GBM Ab is not unusual and associated with worst outcome (Tab.1); the prevalence of double-positivity in Good-Pasture Syndrome (GPS) is higher (30-38%) than in ANCA-associated vasculitis (AAV) (5-14%).

Case Description: A 70-year-old woman was admitted with a severe respiratory distress and AKI (stage 3) requiring urgent dialysis. Laboratory tests revealed high titer of ANCA (MPO >134 IU/ml, PR3 20 IU/ml) and anti-GBM Ab (54 IU/ml). Histopathological renal analysis showed chronical lesions (Fig. 1). Steroids, plasma-exchange and Rituximab were therefore administered. A sensible improvement of respiratory insufficiency, but no recovery of renal function was observed.

Discussion: Double-positive patients show hybrid features: the acute phase, similarly to GPS, is characterized by frequent lung hemorrhage, warranting plasma-exchange sessions; the subacute phase, like AAV, by high rate of recurrence, requiring a more intense and prolonged maintenance immunosuppressive regimen. Renal biopsy represents a useful diagnostic tool to establish chronicity degree and to speculate about pathogenethic contribution of each component. The worst renal outcome and higher risk of relapse require a careful follow-up.



10 glomeruli (8 global and 2 segmental sclerosed), 60-70% of tubulointerstitial fibrosis and moderate arteriolar intimal fibrosis (PAS stain 100x)

PUB209

A Rare Case of Severe AKI from Fibrillary Glomerulonephritis

Harshal Desai. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: Fibrillary glomerulonephritis (GN) is an uncommon disorder found on less than 1 percent of native kidney biopsies done worldwide. Due to its rare prevalence, the association of this disorder with other diseases is not fully understood. Here we present a case of a 60 year-old woman with a history of hypertension and untreated Hepatitis C who presented with acute oliguric kidney injury and was subsequently found to have biopsy proven fibrillary GN.

Case Description: 60 year-old woman with history of hypertension and Hepatitis C presented with shortness breath and back pains. Labs on admission showed an elevation in BUN and Cr to 121 mg/dL and 7.69 mg/dL respectively. Other findings included an elevated globulin gap of 4.6 g/dL and a urine dipstick with minimal proteinuria. Renal ultrasound was negative for obstruction and showed normal sized kidneys. Serum and urine protein electrophoresis with immunofixation revealed the presence of free monoclonal lambda light chains. Beta-2 microglobulin level was elevated to 12.4 mg/L. These clinical and laboratory findings raised suspicion for light chain cast nephropathy secondary to multiple myeloma and so renal and bone marrow biopsies were performed. Bone marrow biopsy showed no abnormal plasma cell clones, suggesting against a diagnosis of multiple myeloma. Furthermore, no lytic lesions were noted on skeletal survey. Renal biopsy showed findings consistent with fibrillary GN as well as acute pyelonephritis even though patient experienced no symptoms of urinary tract infection during the entirety of the hospitalization. She was started on intravenous antibiotics, and her renal function returned to near normal on day 14 of hospital stay. She was discharged home with appropriate Nephrology and Oncology follow up.

Discussion: Fibrillary GN is a poorly understood cause of renal failure. Treatment of the disorder is based on the underlying cause if one can be found. Approximately 30-50% of cases are associated with a hematological malignancy, autoimmune disease, monoclonal gammopathy, or Hepatitis C infection. For our patient, the renal biopsy failed to show monoclonal immunoglobulin deposits, suggesting that the most likely association was the underlying Hepatitis C. Also, the finding of acute pyelonephritis on the biopsy likely indicates an entirely separate (though still possibly related) disease process which probably also contributed to the renal injury.

PUB210

A Case of TAFRO Syndrome with Two Consecutive Renal Biopsies Following the Pathological Course of the Kidney

Noritoshi Kato,[1] Tomonori Hasegawa,[2] Reiko Muto,[1] Akihito Tanaka,[1] Yuka Sato,[1] Kayaho Maeda,[1] Kazuhiro Furuhashi,[1] Shoji Saito,[1] Tomoki Kosugi,[1] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Handa City Hospital, Nagoya, Japan.*

Introduction: Renal involvement of TAFRO syndrome consist of diffuse glomerular endothelial injury. But due to thrombocytopenia and deterioration of general condition, there are few reports on kidney biopsy results. We report a rale case of TAFRO syndrome with two consecutive renal biopsy which shows pathological time course of endothelial injury from acute to chronic phase.

Case Description: A 20-year-old female who presented with high fever, pleural effusion, ascites, thrombocytopenia, lymph node enlargement, and proteinuria around 1.0g/day. First, she was diagnosed as systemic lupus erythematosus and treated with prednisolone. But she showed poor response to the therapy. Then she was transferred to our hospital and received renal biopsy for definite diagnosis. The renal specimen showed no evidence of immune complex nephritis, but showed diffuse global swelling of endothelium and expansion of subendothelial space. TAFRO syndrome was diagnosed based on 3 major and 2 minor criteria. She was treated with oral prednisolone and tocilizumab, and once CRP titer became negative. But 3 weeks after first tocilizumab treatment, her CT images revealed worsening of ascites, lymph node swelling. CRP titer again became positive, and massive proteinuria appeared. We considered the situation as relapse of the disease and reduced the interval of tocilizumab doses. A second renal biopsy was performed two months after the first one to investigate the cause of the large amount of proteinuria. Interstitial fibrosis was observed in 15% of renal cortex. Glomeruli showed global collapse or focal segmental double contour. One glomerulus showed mesangiolysis and endocapillary hypercellularity. No thrombosis was observed on PTAH staining, and partial loss of CD31 staining was confirmed in a damaged glomerulus. Owing to the enhanced treatment, she achieved remission for one year.

Discussion: The pathological course of renal damage associated with TAFRO syndrome was observed at an interval of two months, and the second renal biopsy showed both active inflammation and advanced organic damage such as fibrosis of the interstitium and double contour, suggesting that solid anti-inflammatory treatment should be required from the beginning of the disease.

PUB211

Complement Inhibition with a Short Course of Eculizumab for Refractory Vasculitis

Miguel Uriol Rivera, Aina Obrador, Sonia Jimenez. *Hospital Universitari Son Espases, Palma de Mallorca, Spain.*

Background: Systemic vasculitis (SV) is a life-threatening disease and, in some cases, refractory to intensive multi-immunosuppressant drugs. Complement hyperactivation has gained interest in the pathogenesis of the SV. We report the efficacy of the short course of C5-inhibitor (eculizumab) in refractory cases of lupus nephritis (r-LN) and refractory ANCA-associated glomerulonephritis (r-AGN).

Methods: In this retrospective study, nine consecutive patients were included (r-LN:n=3 and r-AGN:n=6). All patients were previously treated with three or more drugs: corticosteroids(n=9), mycophenolate(n=9), rituximab(n=8), immunoglobulins(n=5), therapeutic plasma exchange (n=4), cyclophosphamide(n=1), and belimumab(n=1). Eculizumab was considered for use in off-label indication in patients with progressive renal deterioration (worsening creatinine, protein-to-creatinine ratio) or developing a high-risk lethal complication after the induction immunosuppressive therapy. The histologic lesson observed were: a) r-LN: Type VI (n=1), Type V (n=1), and type IV (n=1), and b) r-AGN: sclerotic (n=3), and malignant hypertension+/-thrombotic microangiopathy (n=1), in two patients who developed pulmonary haemorrhage, no renal biopsy was performed.

Results: Mean age (SD): 54(17) years. Median (min-max) of follow-up: 23(2-48) months. Overall, 2(22%) patients are in chronic renal replacement program (one r-AGN patient who was dialysis dependent at presentation, and presented a complement H mutation, and one r-LN within 12 months after the onset eculizumab). 8 patients showed hypocomplementemia. As a whole the mean (95%CI) eGFR (EPI-CKD), increased: 8.0 (-3.0 to 19.1) ml/min/1.73m2 (P = 0.13). In r-AGN, the mean (95%CI) eGFR increased :13(-1.8 to 28,25), P= 0.07; while in r-LN, a slight change was observed: -2.1(-24.8 to 20.59), P = 0.72. The median(p25-p75) protein-to-creatinine ratio decreased from 2.6 (1.6-5.5) to 0.6(0.4-1.2) mg/mg (P= 0.01). The eculizumab doses [median(p25-p75)] required in r-LN and rAGN patients were: 8400 (7800-10200) mg and 3150 (2475-5700) mg, respectively. No major side effects were recorded.

Conclusions: The coadjuvant complement inhibition with eculizumab stabilized or increased renal function and decreased proteinuria significantly in refractory vasculitis. The short course of eculizumab seems to be highly effective in r-AGN, and also was associated with lower doses needed.

PUB212

Lupus Nephritis Presenting with Positive PR3-ANCA and Decreased ADAMTS13

Mujahed Abualfoul, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Lupus nephritis is a well-described entity. The simultaneous presence of ANCA abs is rare and is related to poor prognosis. Positive patients usually have MPO-ANCA. We present a case of biopsy-proven Class IV/V Lupus nephritis with PR3-ANCA and decreased ADAMTS 13 activity in an AA man.

Case Description: This 46-year-old AA man with no known past medical history presented to the ED for two weeks of SOB, leg, and scrotal swelling. He denies any associated symptoms. He denies using any other OTC medications and illegal drugs. On exam, vital signs were stable. He had 2+ pitting edema in LE bilaterally, scrotal and penile edema. Other systems were unremarkable. Labs were significant for Hg 5.1, Platelets 106, K 6.9, CO2 9, BUN 78, Cr 10.2, and Albumin 2.4. UA showed dysmorphic RBCs and proteinuria, and Urine protein/creatinine of 9. COVID-19 testing was negative. HIV1&2, RPR titer, hepatitis panel, rheumatoid factor, ASO screen were all negative. Renal U/S showed normal-sized kidneys and no hydronephrosis. ANA, ANA titer, and anti-dsDNA returned elevated at >10,1:640 and 9.9IU, respectively. PR3-ANCA was also positive, but MPO-ANCA negative. C3 and C4 at 0.4g/L and 0.14g/L, respectively. ADAMTS-13 activity decreased to 40%. The rest of the work-up was negative. Kidney biopsy confirmed lupus nephritis, Class IV, and V, with ~50% cellular crescents. Moderate to advanced interstitial fibrosis and tubular atrophy ~50%. EM showed two globally sclerotic glomeruli. IF showed a full-house with IgG, IgA, C3, C1q, kappa, and lambda. Unfortunately, kidney function did not recover, and hemodialysis was started, and he was treated with MMF, Methylprednisolone, and with plasma exchange.

Discussion: ANCA positivity, although not common, is a well-described entity but not understood in lupus nephritis patients. Most of these patients present with MPO-ANCA rather than PR3-ANCA. This subset of patients usually presents clinically differently with distinct histopathological features. Long-term follow-up in these patients is also needed to better understand this disease process in lupus nephritis patients.

PUB213

Novel Prognostic Marker of ANCA-Associated Glomerulonephritis: Is It C3?

Muhammad U. Aameish,[1,2] Milica Jovanovic,[1,2] Ashok P. Chaudhari.[1,2] *[1]Metropolitan Hospital Center, New York, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Antineutrophilic cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is known as a systemic vasculitis with unknown etiology. AAV has a predilection for affecting the respiratory tract and kidney parenchyma. Hypocomplementemia with low C3 levels at granulomatosis with polyangitis or Microscopic polyangitis diagnosis, may be responsible for worse survival and renal prognosis. We are reporting lowest C3 level in a patient of ANCA associated glomerulonephritis (GN) leading to rapidly deteriorating renal functions.

Case Description: A 78 years old female with history of Diabetes Mellitus complicated with retinopathy, hypertension, end stage renal disease on hemodialysis. She initially presented for workup of proteinuria and worsening renal functions. Her workup showed positive P-ANCA with low C3 levels. Patient did not consent for biopsy. Her kidney functions kept on worsening rapidly and she was started on hemodialysis within a period of two years from the onset of chronic kidney disease.

Discussion: The complement system has been proposed to play an important role in pathogenesis of AAV. A low C3 serum level in AAV patients at diagnosis is associated with worse long term patient and renal survival. When the kidneys are involved, AAV typically gives rise to rapidly progressive renal failure and necrotizing cresentic GN. The study by Augusto et al. showed evidence that even if serum C3 levels are within normal range low C3 values are associated with worst renal outcomes. Lower than normal C3 levels as in our patient could have more significance in terms of patients poor renal outcome even in the absence of biopsy. This raises a question, is C3 a novel independent prognostic marker for AAV?

A Case of Biopsy Proven Kidney Restricted AL Amyloidosis Leading to Diagnosis of Multiple Myeloma

Rutu Shah, Alexander Pennekamp, John Hergenrother. *The Christ Hospital Physicians Spine, Cincinnati, OH.*

Introduction: Monoclonal gammopathy is defined by presence of a monoclonal immunoglobulin in plasma, urine or both produced by clonal plasma cells. It could be associated with hematologic malignancy, smoldering, MGUS or a relatively new term monoclonal gammopathy of renal significance. We present a case of monoclonal gammopathy associated with renal damage leading to the diagnosis of multiple myeloma.

Case Description: A 69 year old male with history significant for hypertension, CAD, PVD presented to the office with bilateral lower extremity swelling extending up to his trunk and significant weight gain over the past month. Laboratory investigations revealed serum albumin of 2.6g/dl, cholesterol 300mg/dl, LDL 187mg/dl. Urine analysis revealed macroalbuminuria with a urinary protein-to-creatinine ratio of 14,314g/g in the setting of a normal serum Cr of 0.89. SPEP followed by serum immunofixation showed an M-spike which was difficult to quantitate. Kappa to lambda ratio was low at 0.06. Extensive work up to determine the etiology for nephrotic syndrome was performed which was followed by a kidney biopsy, showing lambda light chain deposition on immunofluorescence and positive birefringence of congo red stained material under polarized light. Electron microscopy showed haphazardly arranged fibrils and foot process effacement, consistent with amyloid deposition and nephrotic syndrome respectively. An echocardiography, skeletal survey and PET scan obtained to exclude any other organ involvement, were insignificant. Patient was referred to hematology-oncology and he underwent a bone marrow biopsy which showed 10-20% involvement by a plasma cell neoplasm. With the information gathered, the diagnosis of AL amyloidosis with multiple myeloma was made. The patient later underwent therapy with CyBorD whereafter his swelling improved.

Discussion: An unimpressive SPEP should not be ignored. In the setting of high clinical suspicion, work up should always be followed by kidney and bone marrow biopsy. About 12-15% of patients with renal AL amyloidosis have associated multiple myeloma which require treatment with chemotherapeutic agents. Even though our patient fits into the monoclonal gammopathy associated with hematologic malignancy, MGRS is an evolving topic which deserves considerable attention because many of these entities benefit from clonal based therapies.

PUB215

Hematuria and Proteinuria in a Patient of Cypriot Descent

Kelly V. Liang,[1] Brigid K. Ellis,[2] Michael B. Stokes,[5] Richard J. Smith,[3] Daniel P. Gale.[4] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Tower Health, Reading, PA; [3]The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; [4]University College London, London, United Kingdom; [5]Columbia University Irving Medical Center, New York, NY.*

Introduction: C3 glomerulonephritis (C3GN) caused by a mutation in complement Factor H-related protein 5 (CFHR5) is endemic in patients of Cypriot descent. CFHR5 nephropathy bears a striking resemblance to IgA nephropathy (IgAN). We present a case of CFHR5 nephropathy in a Cypriot patient who was initially diagnosed with IgAN and highlight the importance of family history, labs, renal biopsy, and genetic testing in diagnosis of CFHR5 nephropathy.

Case Description: A 22-year-old male of Cypriot and Greek descent presented in June 2019 with recurrent microscopic hematuria and proteinuria in the setting of upper respiratory tract and gastrointestinal illness. Blood pressure was 132/78 and he had no edema. Serum creatinine (SCr) was 1.6 mg/dL (SCr was 0.7 in 2012, 1.0 in 2018, and 1.3 in 2019). Urinalysis revealed microscopic hematuria and proteinuria. Spot urine protein/Cr ratio (UPCR) was 580 mg/g Cr. Serologic workup was unremarkable. He was diagnosed initially with IgA nephropathy. Due to slowly progressive renal dysfunction, a renal biopsy was performed in January 2020, which showed mild mesangial hypercellularity, segmental duplication of basement membranes, and glomerular C3 deposits. Immunofluorescence was negative for IgG, IgM, C1q, light chains, or fibrin. Electron microscopy revealed segmental mesangial, subepithelial, and subendothelial immune-type electron dense deposits with segmental duplication of glomerular basement membranes. He was diagnosed with C3GN. Genetic testing confirmed the CFHR5-CFHR5 fusion gene that has been causally linked to C3GN by a gain-of-function effect leading to overactivation of the alternative complement pathway. He was treated conservatively with Lisinopril 10 mg daily. Home blood pressures remain stable. SCr remains 1.5 to 1.9 mg/dL and UPCR remains 610 to 810 mg/g Cr.

Discussion: CFHR5 nephropathy is endemic in patients of Cypriot descent. Therefore, a high index of suspicion for CFHR5 nephropathy should be maintained in Cypriot patients presenting with nephritic syndrome. The presentation of CFHR5 nephropathy bears a striking similarity to IgAN. The main distinguishing features of CFHR5 nephropathy vs. IgAN are its familial nature and absence of IgA deposition. Therefore, family history, renal biopsy, and genetic testing for CFHR5 mutation are critical in establishing a diagnosis of CFHR5 nephropathy.

PUB216

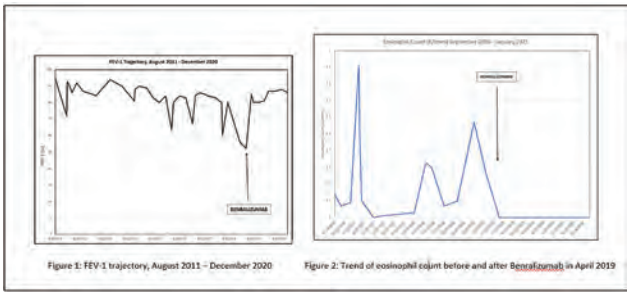
Benralizumab Monotherapy Substitution Therapy in Symptomatic Asthma Exacerbations of Eosinophilic Granulomatosis with Polyangiitis

Macaulay A. Onuigbo. *University of Vermont College of Medicine, Burlington, VT.*

Introduction: There is increasing interest in the use of the biologicals including anti-interleukin 5 and anti-interleukin 5 receptor antibodies in the management of steroid-resistant or steroid-dependent eosinophilic granulomatosis with polyangiitis (EGPA). Benralizumab, an anti-IL 5 receptor antibody is steroid sparing. We describe successful substitution Benralizumab montherapy in EGPA.

Case Description: In late 2005, a 38-year old male was diagnosed with multisystemic illness that included asthma, polyarthrits and nephrotic syndrome. Urine protein creatinine ratio was 11.6 (<0.11) mg/mg. He had 20.3% eosinophils (absolute count 1160 K/cmm) on his differential and erythrocyte sedimentation rate was 50 mm/hour. Standard serology/immunology work up was negative. Serum creatinine was slightly above recent baseline at 1.1 mg/dL and albumin was 2.3 mg/dL. A kidney biopsy demonstrated minimal change disease and EGPA was diagnosed. He achieved early remission with corticosteroids and IV cyclophosphamide and was later continued on combination prednisone and MMF. Nevertheless, he had repeatedly experienced severe asthma exacerbations, falls in FEV-1 and associated eosinophilia (Figure 1). In April 2019, he was started on Benralizumab, 30 mg subcutaneously every 4 weeks for 3 doses and thereafter every 8 weeks. His asthma symptoms resolved, eosinophil count promptly dropped to zero and he was weaned off mycophenolate mofetil and prednisone, 14 and 16 months, respectively, after starting Benralizumab (Figure 2). FEV-1 trajectory has been most impressive with Benralizumab monotherapy (Figure 1).

Discussion: We describe the successful Benralizumab substitution monotherapy in EGPA with eosinophilic asthma. We support calls for larger trials of the biologicals in EGPA.



Composite showing impact of Benralizumab montherapy on FEV-1 (Figure 1) and Eosinophil count (Figure 2) after its introduction in April 2019.

PUB217

Infection-Related Glomerulonephritis: Is It Only Related to Infection?

Ana C. Brás, Anna Lima, Afonso Santos, Rita Theias Manso, Patricia S. Carrilho, Karina Soto. *Hospital Professor Doutor Fernando Fonseca EPE, Amadora, Portugal.*

Background: Infection-related glomerulonephritis (IRGN) encompass a wide relationship between active bacterial infection and associated glomerular lesion. The treatment relies on eradication of infection. The role of immunosuppression (IS) is still in debate. We aimed to assess factors that could be related to kidney and patient outcomes in a series of IRGN patients.

Methods: Clinical and outcome data from patients >18y, with histologic and laboratory diagnosis of IRGN, were collected retrospectively. Pathologic patterns were reviewed and evidence of simultaneous infection was confirmed.

Results: Fifteen patients (12 male; mean age 70±10y) were included; 33% were diabetic and 33% had alcoholic habits. Median baseline eGFR was 78.7mL/min. All presented haematuria and proteinuria, 53% in nephrotic range. Median SCr at admission was 3.7mg/dL. C3 was decreased in 60% and IgA levels were elevated in 40%. The commonest infection site was skin (47%) and Staphylococcus aureus infection was the most prevalent. The most common pathologic patterns were mesangial (86.7%) and endocapillary proliferative GN (93.3%), 60% with crescentic proliferations. IF showed mesangial and capillary C3 deposits (93%), 60% of cases were IgA-dominant. All patients were treated with antibiotics and 73.3% underwent IS. All developed kidney dysfunction (median SCr 6.1mg/dL), 60% needing RRT. In hospital mortality was 20%. At discharge 26.7% remained RRT-dependent and 46.7% had AKD; only one patient presented total recovery. At 3mo of follow-up (n=12), one new patient had total recovery, 33.3% remained RRT-dependent and 66.7% had median eGFR 40.0mL/min. At 12mo (n=11) one patient died (unrelated cause); 36.3% remained with CKD, 36.3% maintained RRT and 27.3% maintained recovery. Data related outcomes regarding IS and IgA dominance showed that neither influence recovery. During follow-up a new episode of infection was detected in 50% of cases, most of them with AKI associated.

Conclusions: Overall IRGN had poor kidney outcome and it seems that treatment with IS did not improve that, although it is important to highlight that all patients IS-treated had more severe disease. Patients with IgA-dominant IRGN had better eGFR. Our results correspond to a small series of a single centre; therefore, future research is needed to better understand risk factors for outcomes.

PUB218

A Descriptive Study of the Demographic, Clinical, and Biopsy Findings at the Time of IgA Nephropathy (IgAN) Diagnosis

Saeed K. Shaffi, Darren W. Schmidt, Catherine Do, Christos Argyropoulos. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: In patients with IgAN, higher proteinuria, glomerulosclerosis, and tubular atrophy are associated with poor outcomes. We summarize the demographic, laboratory, and biopsy findings of an IgA nephropathy cohort from the US southwest.

Methods: We identified patients diagnosed with IgAN between 2002 to 2016 on whom data was available within 30 days of the biopsy. We summarized the data by calculating n (%), mean (SD), or median (IQR) as appropriate. We compared the clinical data at biopsy stratified on Oxford IgA nephropathy (MEST-C) classification.

Results: We identified 67 patients with IgAN (Figure 1). Approximately half of the cohort was female and most of the patients identified as Hispanic (40.3%) or Native American (22.5%). The mean biopsy age was 37.7 years with a median serum creatinine and spot urine protein to creatinine ratio of 2.35 mg/dl and 3.3 g/g, respectively. Most biopsies had segmental sclerosis (88.5%) and cortical tubular atrophy (62.3%). On the Oxford classification, patients' with M1, E1, and S1 lesions had a lower creatinine level and higher urinary RBCs and serum creatine compared to those with M0, E0, and S0 lesions, respectively (Figure 2a). T lesions were positively correlated with creatinine and proteinuria. The majority of the biopsies stained negative for C1q and positive for C3 on immunofluorescence (IF) microscopy (Figure 2b).

Conclusions: This IgA cohort was predominantly Hispanic or Native American. Most of the patients had established CKD, proteinuria, segmental sclerosis, and tubular atrophy at the time of the diagnosis. At the time of biopsy, higher T lesions were associated with an increased creatinine level and a trend towards increased proteinuria. On IF, C3 was

positive with a negative C1q pointing towards alternate and/or mannose-binding lectin complement pathway activity.

PUB219

Diabetic Nephropathy: A Great Mimicker or Mistaken Identity

Siddharth Bhayani,[1] Kavitha Vellanki.[2] *[1]University of Illinois Hospital and Health Sciences System, Chicago, IL; [2]Loyola University Health System, Maywood, IL.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) is often a challenging diagnosis due to wide spectrum of disease and difficulty in establishing a pathogenic link between monoclonal proteins and kidney disease. Here, we describe a biopsy 'proven' diabetic kidney disease in a non-diabetic patient, diagnosed as membranoproliferative glomerulonephritis (MPGN) years later with robust clinical response to treatment.

Case Description: A 68-year-old male with stage 3A-B CKD, hypertension and monoclonal gammopathy of uncertain significance (MGUS) was referred to renal clinic for second opinion on biopsy 'proven' diabetic kidney disease in 2013 despite never being a diabetic. A repeat kidney biopsy in 2020 for persistent proteinuria revealed MPGN with segmental subendothelial electron dense deposits (Figure 1). Unfortunately, IF was inconclusive due to inadequate sample. After ruling out other etiologies, he was treated as MGRS with velade and dexamethasone with excellent clinical response with improvement in renal function and resolution of proteinuria (Figure 2).

Discussion: This case brings up an interesting clinical question: could the original diagnosis of diabetic nephropathy be early changes related to MGRS and was it a mistaken identity? Serial kidney biopsies are rarely done in MGRS but could provide guidance as illustrated by our experience.

PUB220

AKI Associated with Anticoagulant-Related Nephropathy in a Newly Diagnosed IgA Nephropathy

Aglaia Chalkia, Athanasia Kapota, Georgios Agelis, Margarita Mpora, Dimitris Kourniotis, Zoe Alexakou, Katerina Damianaki, Dimitrios I. Petras. *Nephrology Department, Hippokration General Hospital, Athens, Greece.*

Introduction: Anticoagulant-related nephropathy (ARN) is a type of acute kidney injury (AKI) that may be caused by anticoagulation with warfarin and other anticoagulants. It is an underestimated cause of AKI with poor renal prognosis. AKI is probably resulting from glomerular hemorrhage and the characteristic pathologic findings consist of obstruction of renal tubules by red blood cell casts, which do not contain Tamm-Horsfall protein.

Case Description: A 58-year-old Caucasian man presented with AKI stage 3 (serum creatinine 5.9mg/dL) complaining of macroscopic hematuria. Two months ago, he underwent aortic valve replacement with a mechanical valve and he began taking acenocoumarol as an anticoagulant agent (serum creatinine 0.9mg/dL). He also presented INR 2.2, several dysmorphic erythrocytes in urinary sediment and 24-h urinary protein excretion 5g/day. The renal biopsy revealed mild mesangial hypercellularity, acute tubular necrosis with occlusive red blood cell casts and interstitial inflammation. The immunofluorescence presented mild mesangial deposits of IgA (2+) and C3 (1+). We consider that the cause of AKI was anticoagulant-related nephropathy rather than IgA nephropathy because there was no history of prior infection and the presence of numerous RBC tubular casts could not be explained just by these glomerular findings (mild mesangial proliferation, as well as mild deposits of IgA by immunofluorescence). Due to the severe interstitial nephritis, pos prednisolone 1mg/Kg/daily was added to his treatment, with a gradual reduction in 4 months and acenocoumarol was replaced by tinzaparin. After 1year renal function remains stable at creatinine level 2.5mg/dL, proteinuria <1gr/24h, without microscopic hematuria.

Discussion: This case report highlights an unusual severe cause of AKI "anticoagulant-related nephropathy", in which the majority of patients remains hemodialysis dependent. Patients with underlying glomerulopathies, associated with hematuria are predisposed to be risk factors. Considering the poor renal prognosis, it highlights the necessity for close vigilance of renal function, as well as, urine sediment in patients, who begin on anticoagulation, especially with pre-existing renal diseases, including glomerulopathies and those with glomerular hyperfiltration.

PUB221

Eculizumab for Treatment of Recurrent Pregnancy-Triggered Atypical Hemolytic-Uremic Syndrome with a Mutation in Complement 3: A Case Report

Yoei Miyabe,[1] Anna Nakai,[1] Kentaro Watanabe,[1] Kazunori Karasawa,[1] Noritoshi Kato,[2] Shoichi Maruyama,[2] Takahito Moriyama,[1] Kosaku Nitta.[1] Tokyo Women's Medical University Department of Medicine Division of Nephrology, Nagoya University Graduate School of Medicine Department of Nephrology *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan.*

Introduction: In atypical hemolytic-uremic syndrome (aHUS), thrombotic microangiopathy (TMA) often develops due to mutations in complement-related genes or autoantibodies to complement regulators. Anti-C5 monoclonal antibodies (eculizumab and ravulizumab) are expected to improve prognosis. However, the significance of genetic testing is unknown. We report a case of pregnancy-triggered aHUS that was successful with plasmapheresis and eculizumab administration.

Case Description: A 37-year-old Japanese female who had a twin pregnancy underwent a scheduled cesarean section at 37 weeks gestation. On the second day after her delivery, she developed thrombocytopenia, hemolytic anemia, and renal dysfunction. TMA was suspected, and plasma exchange (PE) was started on the 3rd day after her delivery, and steroid pulse was started on the 4th day, and then prednisolone 60 mg/day was administered. Since Shiga toxin-producing *Escherichia coli* in her stool was negative and both ADAMTS13 activity and inhibitor were normal, the patient was clinically

diagnosed with aHUS. Her clinical findings tended to improve, so PE was interrupted after eight times; however, aHUS relapsed due to a urinary tract infection 15 days after her delivery. We decided that eculizumab was necessary because of the relapse of aHUS due to the infection even under high doses of steroids. Eculizumab was administered 22 days after her delivery, and her clinical findings improved. After that, the pathogenic variant C3 p.Ile1157Thr was identified by genetic testing. Since aHUS due to C3 gene mutation has been reported to have a high recurrence rate, eculizumab administration was continued every two weeks.

Discussion: When thrombotic thrombocytopenic purpura (TTP) and aHUS are suspected in patients with TMA, PE should be started as soon as possible, and eculizumab administration should be considered when aHUS is diagnosed by ADAMTS13 testing. In the case of aHUS, genetic testing is essential because it enables the definitive diagnosis and the prediction of prognosis.

PUB222

Severe AKI: A Case of Histiocytic Glomerulopathy

Latoya N. Gayle, Nia Flemming, Janeen Grant, Deborah A. Fein. *Englewood Health, Englewood, NJ.*

Introduction: Histiocytic glomerulopathy(HGP) is a rare and potentially life-threatening cause of acute kidney injury(AKI) which can occur coincident with macrophage activation syndrome(MAS) or hemophagocytic lymphohistiocytosis(HLH). HGP has also been recognized secondary to viral infections and autoimmune diseases(AD). Early identification with renal biopsy(RB) to exclude other forms of rapidly progressive glomerulonephritis(GN) and to initiate prompt treatment is of utmost importance to improve outcomes. We present a case of AKI secondary to HGP in the setting of acute viral illness

Case Description: 52-year-old male with DM, HTN presented(Pre-Pandemic) with 4 days of fever, chills, myalgia with severe hand joint stiffness and pain. On exam, he had hand swelling and tenderness. Labs noted hemoglobin11.9, platelet(plt)69000, bicarbonate(CO2) 23, BUN 47, creatinine(Cr) 3.4 mg/dl, urinalysis(UA) with >1000mg protein, 11 red cells and 10 white cells. UA and Cr(0.8) was normal one year prior. Other tests noted a 24 hour urine protein of 4gm, TSat 12%, ferritin 295, ANA(1:320), anti ds-DNA 1:80, elevated EBV and Parvovirus IgM and IgG, positive EBV nuclear antigen, low C3<8(14-44), C4- 46(88-165), ESR 64 with negative cryoglobulin, hepatitis B, C, anti-GBM, RF, ANCA, urine immunofixation and serum protein electrophoresis. By day 2 of admission, he became oliguric with urine output(UO)<500cc/day, CO2 decline to 19 a hyperuricemia. RB demonstrated endocapillary histiocytes, endothelial cell swelling with mild IgM deposits and 80%foot process effacement. With supportive therapy (IV fluids, holding ACE, analgesics) his arthritis resolved. By day 4, UO increased, SCr improved to 1.5 and plt normalized. Anemia persisted and was treated with IV iron

Discussion: HGP has been reported secondary to acute viral illnesses and may be associated with MAS in the settings of AD and malignancies. When associated with MAS or HLH, multiorgan failure may be life threatening prompting early immunosuppressive treatment. Though rare, HGP should be considered in the differentials of acute GN prompting early renal biopsy. If clinical picture is severe, treatment with steroids and calcineurin inhibitors may be renal and life saving. In our patient, with a more benign course of HGP likely due to EBV, clinical improvement was rapid with supportive care alone. Without RB, appropriate treatment for other forms of GN, microangiopathic injury or vasculitis might have been delayed

PUB223

A Case of ANCA-Associated Vasculitis (AAV) in Patients with Systemic Sclerosis (SSc)

Manal Alotaibi, Veronica Zamora-Olivencia. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: AAV in patients with SSc has been reported rarely. As both diseases can present with renal involvement, diagnosis is challenging. We report the case of a 56 y.o. male with hx of SSc who was admitted for proteinuria AKI found to have biopsy-proven P-ANCA-associated crescentic glomerulonephritis.

Case Description: 56 YOM with PMH of SSc, recent hx of sinus and ear infection and progressive B/L SNHL who presented with systemic symptoms. He was seen by Rheumatology in 2013, found to have + ANA 1:1280 homogeneous, SCL-70 and low C3 and diagnosed with SSc. He has progressive bilateral hearing loss in the past five months with B/L ear discharge and otalgia S/P multiple Abx and steriod courses. On the admission, he was vitally stable. His labs are significant for Cre 13.77 mg/dl from Cre baseline 1.1 mg/dl. UA with hematuria, proteinuria, and pyuria with no casts. UPCR 4.93 mg/dl. Renal US showed with B/L renal enlargement and no hydronephrosis. He started on iHD urgently. Further labs were significant for + ANA 1:1280, SCL70, and MPO 595, C3 is low. Anti-GBM was negative. Hemolysis labs and peripheral smear were negative. A kidney biopsy showed severe allergic interstitial nephritis, focal necrotizing arteritis, and few lesions of focal crescentic glomerulonephritis. He treated with Solumedrol x 3 doses and then started on a Prednisone taper. He received his first dose of Rituximab in the hospital and ultimately had renal recovery. Of note, his hospital course was c/b peripheral parasethesia and EMG showed multiple mononeuropathies, consistent with a vasculitic polyneuropathy. He was discharged and received his second dose of Rituximab. His kidney function, UPCR and MPO titers continued to improve.

Discussion: His AKI is likely related to AAV with overlap SSc. He also has severe interstitial nephritis, which would indicate some drug induced trigger for AAV. There have been rare reports of patients with SSC with ANCA. However, the majority of these patients do not manifest AAV. Studies showed an association between ANCA positivity in patients with SSc and increased mortality and poor prognosis. These findings suggest that ANCA should be tested early in patients with SSc. AAV in SSc is rare with conflicting data about renal outcomes. Rapid recognition is essential for prompt initiation of treatment. Kidney biopsy is the gold standard diagnostic test.

PUB224

ANCA Negative, Yet Pulmonary Embolism Positive

Latoya N. Gayle, Deborah A. Fein. *Englewood Health, Englewood, NJ.*

Introduction: Pauci immunue glomerulonephritis(GN) with negative ANCA serology occurs in ~1/3 of pauci immune GN patients. ANCA negative patients are thought to have a lower incidence of extra-renal involvement but poorer renal prognosis than those who are ANCA-positive. We present a case of ANCA-negative Pauci-immune Rapidly Progressive GN(RPGN), returning 4 weeks after diagnosis with pulmonary embolism(PE)

Case Description: A 39-year-old male presented(pre-pandemic) with 2 weeks of fever and chills. For ~3 years, he has had intermittent arthralgia, dyspnea, facial and ankle swelling with gross hematuria and a 12lb weight gain 2 months prior to admission. Baseline creatinine(Cr) was 1.3(0.7-1.3mg/dl) a month prior. On admission Cr was 2.6, Alb 3mg/dl and Urinalysis noted protein 100mg/dl, RBC 20-30 and WBC 10-20. A 24 hour urine protein measured 8g/day. Serologies were positive for dsDNA1:10 and Antistreptolysin O, with negative ANA, ANCA, anti-GBM, SPEP, Hepatitis B, C, HIV and normal C3/C4. Renal sonogram noted normal sized kidneys with increased echogenicity. A renal Biopsy was done and Methylprednisolone pulse therapy commenced. His renal biopsy showed focal necrotizing and crescentic GN with negative IF, consistent with pauci-immune GN. Cr peaked at 3.6 and IV Cyclophosphamide was given. He was discharged on Prednisone with Rituximab given 2 weeks later.4 weeks after discharge, Cr improved to 1.3, however he represented with SOB, pleuritic chest pain and hemoptysis. CT chest revealed acute bilateral PE. Malignancy work-up and lower extremity dopplers were negative. He had normal IgG, A, M, antithrombin III, prothrombin gene analysis, protein C,S activity and factor X with negative Lupus anti-coagulant and antiphospholipid Ab. He was started, then discharged on Enoxaparin for anticoagulation

Discussion: Renal disease manifests as a pauci-immune GN in ANCA-Associated Vasculitis(AAV).~ 1/3 of patients with pauci immune vasculitis are ANCA negative. Whether these patients should be included in the spectrum of AAV or are a separate pathophysiologic mechanism is unknown. Our patient presented with RPGN and a PE after initial treatment despite negative ANCA panel and current evidence suggesting a lower incidence of other organ involvement. The presence of an underlying pulmonary vasculitis could not be excluded. We postulate that all patients with ANCA negative RPGN should be followed for additional organ involvement and further study of this patient population is warranted

PUB225

Autologous Mesenchymal Stromal Cell Therapy for Idiopathic Nephrotic Syndrome: The MESNEPH Study

Marina Vivarelli,[1] Mattia Algeri,[2] Norberto Perico,[3] Federica Casiraghi,[3] Francesco Emma,[1] Martino Introna,[4] Franco Locatelli.[2] *[1]Bambino Gesù Pediatric Hospital IRCCS Division of Nephrology, Rome, Italy; [2]Ospedale Pediatrico Bambino Gesu Dipartimento Oncoematologia Terapia Cellulare Terapie Geniche e Trapianto Emopoietico, Rome, Italy; [3]Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [4]Aziende Socio Sanitarie Territoriale Papa Giovanni XXIII, Bergamo, Italy.*

Background: Corticosteroids represent first-line treatment of idiopathic nephrotic syndrome (INS). However, 60-80% of patients present multiple relapses and require steroid-sparing immunosuppression with significant toxicity. New therapeutic approaches with a better safety profile are needed. Mesenchymal stromal cells (MSC) exert immunomodulatory functions, regulating cells of both adaptive and innate immune systems.

Methods: Approximately 20 patients (age-range 5-40 years) with multi-relapsing INS (≥2 relapses despite prednisone and/or ≥1 other immunosuppressive steroid-sparing agent) in remission will be recruited. After screening and informed consent, a bone marrow aspirate will be performed, followed by a 6-12 week MSC-expansion period during which oral immunosuppression will be maintained. Each patient will receive 2 intravenous infusions of 1-2x10^6/kg autologous MSCs 7 days apart. One month after the first infusion, all concomitant immunosuppressive therapy will be tapered and withdrawn. The observational phase will last 12 months after the first MSC infusion (Table 1). This is a prospective, phase 1 open-label non-randomized multicentric study evaluating the safety and efficacy of autologous bone-marrow derived MSC treatment in patients with severe frequently-relapsing or steroid-dependent INS.

Results: The study is ongoing, last patient visit is expected in July 2021.

Conclusions: The study will primarily assess the feasibility and safety of this approach for the treatment of severe INS. Secondarily, it will evaluate treatment effect on INS relapses, immunosuppressive therapy dose and toxicity, kidney function at baseline and 12 months after MSC infusion.

Safety and Efficacy of Avacopan (CCX168) in a Pediatric Patient with C3 Glomerulopathy

Marina Vivarelli, Maria Arena, Federica F. Zotta, Andrea Cappoli, Ines D. L'Erario, Marco Busutti, Francesco Emma. *Division of Nephrology and Dialysis - Bambino Gesù Pediatreic Hospital IRCCS, Rome, Italy*.

Introduction: C3 glomerulonephritis (C3GN) is a subtype of C3 glomerulopathy, characterized by alternative pathway complement activation and intense C3 immunofluorescence on renal biopsy. C5a is a potent pro-inflammatory mediator of the complement system, whose chemotactic effects are mainly mediated by the interaction with complement C5a receptor (C5aR) expressed on the cell surface. Avacopan is an orally administered selective inhibitor of C5aR.

Case Description: An 11-year-old female with biopsy-proven C3GN was initially treated with three intravenous (IV) boluses of methylprednisolone then tapered to oral prednisone (PDN) given with mycophenolate mofetil (MMF) and an angiotensin-converting enzyme inhibitor (ACE-i). Complete remission was achieved, PDN was stopped, and MMF and ACE-i were maintained. Twelve months following remission, due to relapse of proteinuria (urinary protein/creatinine ratio [UPCR] 1.19 mg/mg), a second course of PDN therapy was started and cyclosporin (CyA) was added to the therapy. A high level of C5b9 was found. Since the patient never achieved complete remission, she was enrolled in the ChemoCentryx ACCOLADE study, which was a randomized, double blind, placebo controlled study. Patients received avacopan or matching placebo for the first 26 weeks, followed by open-label avacopan in all patients for the following 26 weeks. At the end of the open-label phase, her UPCR was 2.09 mg/mg. Following avacopan, a progressive reduction of proteinuria of approximately 0.5 mg/mg was observed. In the last 4 weeks of the study, avacopan was discontinued, and an increase in proteinuria (UPCR 0.7 mg/mg) was observed, which continued to >1 mg/mg in the subsequent weeks. The patient also reported increased fatigue. After about 3 months, authorization for compassionate use of avacopan was obtained and the patient experienced improvement in her physical well-being and a reduction of proteinuria of approximately 0.5 mg/mg. CyA was discontinued, but it was rapidly reintroduced due to a transient increase of proteinuria. In the following months, proteinuria remained low despite the interruption of MMF. At the last follow up (+16 months from open-label start) UPCR was 0.29 mg/mg and the drug was well tolerated.

Discussion: To the best of our knowledge, this is the first report on the use of avacopan in a pediatric case of C3GN.

PUB227

Rituximab for Steroid-Dependent Minimal Change Disease in Adults

Lakshmi Kannan. *UVA Health, Charlottesville, VA.*

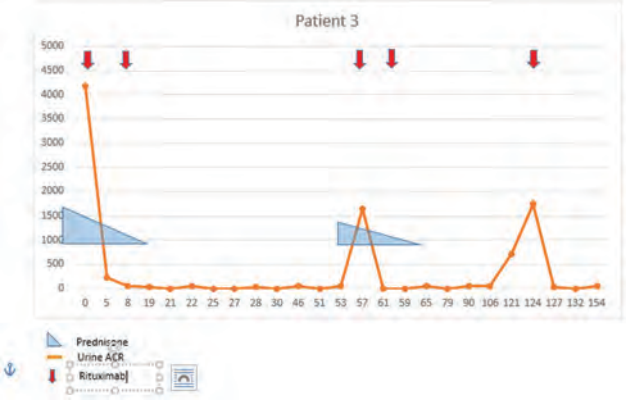
Introduction: Minimal change disease (MCD) accounts for 15% of adult nephrotic syndrome, out of which 25% have frequently relapsing nephrotic syndrome and 30% become steroid dependent. Here we report four cases of relapsing or steroid dependent MCD in adults who were treated with rituximab and their long term follow up.

Case Description: Retrospective chart review of 4 adult patients with relapsing or steroid dependent minimal change disease treated with rituximab at the University of Virginia with more than 6 months follow up following rituximab infusion.

Discussion: The table shows a summary of demographics and laboratory values for these patients. All four patients achieved complete remission and remained steroid free, at least 18 months following treatment with rituximab, although 2 had relapses that responded to another dose of rituximab. One case was treated with immunosuppressive drugs for decades and had developed several complications.

CLINICAL CHARACTERISTICS OF THE PATIENTS

	Patient 1	Patient 2	Patient 3	Patient 4
Sex	Female	Female	Male	Male
Age at diagnosis	78	69	5	22
Age at the time of rituximab infusion	80	69	22	23
Duration of follow-up	4 years	1 year	9 years	3 years
Serum Cr, presentation	1.2	3.6	1	1.5
Urine ACR (mg/g)	8600	11900	4200	4600
Previous Rx	-	-	Cyclosporine + Prednisone	-
Biopsy	Normal LM, severe foot process effacement on EM	Diffuse foot process effacement superimposed on arterionephrosclerosis	Normal LM, severe foot process effacement on EM	ATL mild mesangial expansion, mesangial IgA(3+), C3 (2+, IgM (2+, IgG (1+), severe foot process effacement on EM
Number of rituximab infusions	3	2	5	1
No. of relapses after rituximab	2	0	1	0
Duration of remission after last dose of rituximab	19 months	12 months	18 months	14 months



PUB228

Dapsone-Induced Methemoglobinemia in a Patient with Minimal Change Disease

Misha Varma, Khaled Shawwa. *West Virginia University, Morgantown, WV*.

Introduction: Dapsone is commonly used as a second line medication in treatment and prevention of pneumocystis pneumonia. Its use has been associated with life-threatening conditions, namely methemoglobinemia.

Case Description: A 34-year-old female presented to Nephrology clinic for evaluation of proteinuria in the setting of weight gain. She had 4 prior pregnancies with one complicated by HELLP and another by preeclampsia. A week prior to presentation, she reported waking up with significant swelling in her face and legs. She had a protein to creatinine ratio of 12 grams/gram of creatinine at her primary care's office. Her serum albumin was 1.9 gram/deciliter. Her other serological workup was negative or normal. Her hemoglobin A1C was 5.1%. The patient does not take NSAIDs or OTC medications. A kidney biopsy showed minimal change disease. Prednisone was started at 1mg/Kg along with Atovaquone for PCP prophylaxis. Patient had a prior history of anaphylactic reaction to Bactrim. Given COVID19 pandemic, Pentamidine administration has been restricted due to droplet isolation. Atovaquone was subsequently replaced with Dapsone due to poor palatability. The patient was hospitalized for worsening dyspnea with new oxygen requirement two weeks later. Her oxygen partial pressure at room air was 32 mmHg with a normal A-a gradient. She had lost 10 pounds and was no longer on diuretics. The patient was euvolemic on exam. An echocardiogram was unremarkable. A CTA of the chest to assess was negative for pulmonary edema and pulmonary embolism. The patient had new anemia (hemoglobin was 11.3 from a baseline of 14 g/dL). She did not have signs of hemolytic anemia (LDH, bilirubin, haptoglobin and peripheral smear were normal). Her methemoglobin levels were then tested given recent initiation of dapsone and were found to be elevated at 11.5%. Dapsone was consequently discontinued, and she was transitioned back to Atovaquone after taking it with food. Discontinuation of dapsone resulted in significant symptomatic improvement without further need of supplemental oxygen.

Discussion: Methemoglobinemia a is rare but serios adverse event of Dapsone. Teaching points: - Knowledge about options for PCP prophylaxis is essential when using high dose steroids in the treatment of glomerular diseases. - It is important to counsel and monitor patients being started on Dapsone for potential side effects (hemolytic anemia and methemoglobinemia).

PUB229

Kidney Function in Patients with Lupus Nephritis Followed Up for a Very Long Time

Isabelle Ayoub,[1] Bethany Wolf,[2] Betty Tsao,[2] Jim Oates,[2] Brad H. Rovin.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Medical University of South Carolina, Charleston, SC.*

Background: Most investigations of long-term kidney outcomes in patients with lupus nephritis (LN) focus on end-stage kidney disease (ESKD), but seldom on the proportion of patients left with chronic kidney disease (CKD). Both CKD and lupus are non-traditional risk factors for cardiovascular morbidity. We therefore looked at the development of CKD in a subset of LN followed for a very long time in an LN clinic.

Methods: A retrospective chart review was conducted in biopsy-proven LN patients followed for ≥10 years in a single-center, multidisciplinary LN clinic. Patients with CKD were defined as having an eGFR <60 ml/min/m^2, and those with ESKD as having an eGFR <15 ml/min/^{2} or requiring permanent kidney replacement therapy. eGFR was determined by the clinical laboratories the patients used and was race adjusted. Results were analyzed with descriptive statistics.

Results: 72 patients were followed for a median of 17.1 years (range 10 to 38.7) after LN was confirmed by kidney biopsy. The mean (± standard deviation, SD) age at diagnostic biopsy was 31.8±14.1 years. 21 patients were of African ancestry, 4 were Asian, and 47 were White. ESKD developed in 12 patients (16.7%) after a median of 14.6 years. At the time of last follow-up, 27 patients (37.5%) had CKD with a mean (±SD) eGFR of 40.4±13.0 ml/min/1.73m^2. Of the 27 patients who developed CKD, 21 experienced at least one episode of eGFR <50 ml/min/1.73m^2 that lasted for at least 6 months. Of the other 6 CKD patients, 4 (67%) had at least one 6 month (or longer) episode of proteinuria >3.5 g/d.

Conclusions: These data suggest that over 50% of LN patients may be at risk for developing ESKD or CKD if followed for 10 or more years. Almost all of these patients had sustained periods of kidney injury resulting in eGFR <50 ml/min/1.73m^2, nephrotic-range proteinuria, or both preceding ESKD or CKD. Immunosuppression may not be sufficient to prevent CKD in LN. These patients may benefit from intense anti-progression therapy.

PUB230

Staphylococcus aureus Infection-Related IgA Vasculitis with Kidney Involvement

Arun Rajasekaran, Amruta S. Nair, John W. Hunsicker, Ashita J. Tolwani. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: IgA Vasculitis (IgAV), a systemic small vessel vasculitis with IgA dominant/co-dominant immune deposits, is characterized by purpura, arthralgias, and kidney involvement (IgAV with nephritis; IgAV-N). *Staphylococcal*, including methicillin-resistant *Staphylococcus aureus* (MRSA), infection with glomerular IgA deposits known as IgA-dominant infection related glomerulonephritis (IgA-IRGN), is a variant of IRGN whose management remains controversial.

Case Description: A 46-year-old White male with diabetes, lumbar discitis with recurrent MRSA bacteremia, and normal kidney function [baseline SCr 0.7 mg/dl] presented with bilateral lower extremity palpable purpura and petechiae, polyarthralgia, diarrhea; without urinary complaints. Concomitant MRSA bacteremia without an adequate source (despite interrogation of lumbar hardware) or evidence of endocarditis was found. Skin biopsy revealed leukocytoclastic vasculitis with direct IF (+) for IgA, C3, and fibrin confirming IgAV. Urinalysis revealed nephritic sediment. Sr albumin was 2.3 g/dl; random UPCR was 3 g/g. Workup including lupus serologies, cryoglobulins, ANCAs, Anti-GBM, RF, ASO, Hepatitis B/C, HIV, paraproteinemia testing were negative. Complements were normal. SCr on admission was 0.8 mg/dl; peaked to 1.4 mg/dl on the 3rd hospitalization day likely in setting of contrast-related AKI, multifactorial ATN, and potential IgAV-N secondary to MRSA infection. He was started on IV vancomycin, IV methylprednisolone, IVIG, and dapsone. SCr returned to baseline on 5th day. Oral prednisone 60 mg/d with a rapid taper was started. Rash, kidney function, and proteinuria improved; hence a kidney biopsy wasn't pursued. Blood cultures turned negative; he was discharged on IV daptomycin/ceftaroline and prednisone taper X 6 weeks.

Discussion: Kidney histopathological features of IgA-IRGN are similar to those of IgAN/IgAV-N. Correct diagnosis is imperative as IgAN and IgAV-N likely necessitate immunosuppressive (IS) treatment, while initial IS can exacerbate infection in IgA-IRGN. In our patient, skin biopsy clinched diagnosis of IgAV, and was treated with IS given widespread systemic disease, and antibiotics, with rapid improvement of kidney function abating need for kidney biopsy. Individualized approach for the management of IgA-IRGN is therefore warranted.

PUB231

Treatment Dilemma of Immune Complex Deposition of Unclear Significance in Hypocomplementemic Urticarial Vasculitis Syndrome

Kara Kaplan, Rima Kang. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Hypocomplementemic urticarial vasculitis syndrome (HUVS) is a rare autoimmune disorder with recurrent urticaria, glomerulonephritis, and arthritis. Literature reports 50% or more of patients with HUVS have renal involvement that can be delayed up to a decade after diagnosis and portends a poorer prognosis. Treatment is aggressive immunosuppression.

Case Description: 36 year old female with HUVS diagnosed July 2020 and anxiety was admitted in April 2021 with HUVS flare and intermittent microscopic hematuria. Rheumatology and Dermatology followed. Vitals remained stable. Euvolemic with unremarkable exam, no rash. No signs of systemic lupus erythematosus. Creatinine 0.5mg/dL and hemoglobin 8-9mg/dL, at baseline. Urinalysis: moderate blood, RBC >20/hpf, no WBCs, no bacteria. 24 hour urine PCR 0.20. Renal ultrasound unremarkable. Urine sediment negative for dysmorphic RBCs or casts. Negative infectious workup. Glomerulonephritis workup: positive ANA 1:320 speckled, C3 64mg/dL, C4 18mg/dL, beta 2 glycoprotein IgM antibody 73.3 cu. Remainder of workup negative. Renal biopsy with scattered mild glomerular immune complex deposition, mildly thickened arteries but no active disease. Due to unclear significance of renal pathology and patient preference, no further immunosuppression pursued other than hydroxychloroquine with frequent lab monitoring. One month after discharge, HUVS skin manifestations worsened and she was started on mycophenolate mofetil 1000mg BID at the time of writing.

Discussion: There is a high rate of kidney involvement in HUVS. Early HUVS renal involvement can manifest as intermittent microscopic hematuria, such as this case. The patient also had rare immune complex deposition in HUVS. Renal biopsies may capture this early, subclinical disease. This can lead to a treatment dilemma of whether to wait for renal disease progression to become clinically significant or to treat subclinical disease with non-regimented immunosuppressants with the quandary of how to monitor therapy response, such as frequent renal biopsies. Renal biopsy monitoring is not ideal in all patients, especially those with anxiety; therefore, expectant monitoring was pursued. Due to the rarity of the disease, there is no standard treatment for HUVS renal involvement. More research is needed to determine optimal therapies, especially for subclinical disease.

PUB232

Treatment with Rituximab in Patients with Idiopathic Membranous Nephropathy: A Case Series and Literature Review

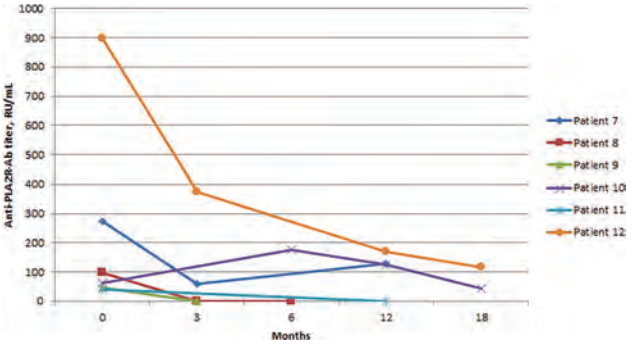
Soojee Jeon, Yong-Lim Kim, Chan-Duck Kim, Ji-Young Choi, Jang-Hee Cho, Hee-Yeon Jung, Jeong-Hoon Lim, Hee Won Noh, Sun-Hee Park. Division of Nephrology, Department of Internal Medicine, School of Medicine, Kyungpook National University Hospital *Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: Membranous nephropathy (MN) is a major cause of nephrotic syndrome in adults. This study aimed to evaluate the effect of rituximab (RTX) in patients with idiopathic MN (iMN) who have a high risk of progression.

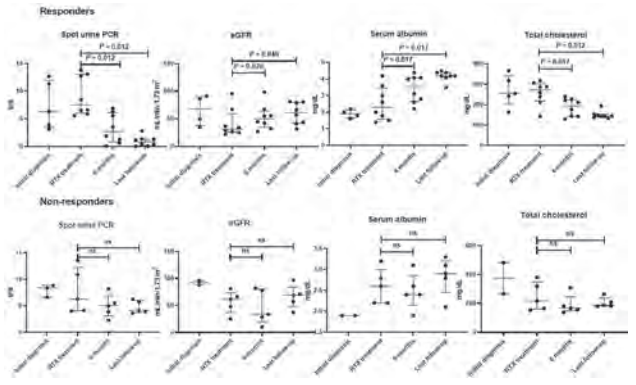
Methods: We retrospectively analyzed data of 13 patients with iMN, who received RTX treatments from January 2014 to July 2020. RTX was indicated in patients with iMN with severe proteinuria and decreasing estimated glomerular filtration rate (eGFR) in the previous 6 months despite other immunosuppressive therapy.

Results: The patients were predominantly male and with a mean age of 55.3 years, median eGFR, 37.0 mL/min per 1.73 m^2 (interquartile range [IQR], 26.3–66.5); serum albumin level, 2.6 g/dL (IQR, 1.9–3.1); and spot urine protein-to-creatinine ratio at baseline, 6.6 g/g (IQR, 5.7–12.9). In a median follow-up of 22 months, 8 patients (61.5%) achieved complete or partial remission. In responder group (n = 8), median eGFR increased from 31.5 to 61.5 mL/min/1.73m^2 (p = 0.049) and serum albumin level increased from 2.3 to 4.2 g/dL (p = 0.017) from RTX initiation to last follow-up. Antiphospholipase A2 receptor antibody (anti-PLA2R-Ab) was positive in 6 among 7 tested patients, which markedly decreased in responder group. There were no adverse events after RTX.

Conclusions: This study suggests that RTX is a safe and effective treatment option for patients with iMN who have a high risk of progression. Individualized therapy based on anti-PLA2R-Ab titer would be needed for better outcomes.



Changes in antiphospholipase A2 receptor antibody of each patient.



Changes in outcomes between responder group and non-responder group.

PUB233

Sometimes an Ultrasound Scan Before the Kidney Biopsy Is Enough: An Unexpected Case of Rapidly Progressive Renal Failure(RPRF)

Davide Raimondo,[1] Chiara Lanzani,[1] Alessandro Barruscotti,[1] Marta Vespa,[1] Paolo Manunta,[1,2] Giuseppe Vezzoli.[1,2] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy.*

Introduction: RPRF is a clinical diagnosis in patients with progressive renal impairment of short duration. The underlying etiology may be a primary renal disease or a systemic disorder. Early definitive diagnosis of RPRF is essential to reverse progression to end-stage kidney disease.

Case Description: Male patient, 64 yo, referred to us after hospitalization elsewhere for RPRF with nephritic-like syndrome. PMH: DM2 history. At age 58 (2015) aortic valve replacement with bioprosthetic valve for severe stenosis. HPI: after 4 months of persistent low-grade fever with a TIA, in March 2021 the patient referred to the ER for epigastric pain and fever. A worsening of renal function was found (creatinine 2.3 mg/dl). During hospitalization, further renal function worsening (creatinine 6.1 mg/dl) and a positive blood culture for E.faecalis treated with amoxi/clav. Renal biopsy was planned. On 03/26/21 the patient was admitted to our clinic, we detected creatinine 6.2 mg/dl, proteinuria <1g/day, normal serologic workout. Urinary sediment revealed dysmorphic erythrocytes. At abdominal ultrasound: kidneys of normal dimensions, hyperechoic, reduced cortico-medullary differentiation, normal vascular resistance. The same procedure revealed hypoechoic splenic lesions due to probable ischemia. On physical examination severe systolic heart murmur. Transesophageal echocardiogram showed an infective endocarditis on the prosthetic aortic valve, so renal biopsy was not performed because cardiac surgery was mandatory. He started antibiotic therapy with ceftriaxone and ampicillin, after 2 weeks renal function improved (3.8 mg/dl). On 05/04 he underwent valve substitution with a mechanical prosthesis. Discharged on 05/26 with creatinine 3.14 mg/dl.

Discussion: Clinical history and carefully evaluation of radiological and serological investigations are mandatory before kidney biopsy. Unfortunately without a renal biopsy it is not possible to have a precise diagnosis.

Etiopathogenetic hypotheses of our case nephropathy

	Present signs	Absent signs
Post-infectious glomerulonephritis	dysmorphic hematuria, proteinuria <3 g/day	15 days after infection onset, C3 consumption, oedema, hypertension
Rapidly progressive glomerulonephritis	dysmorphic hematuria, loss of renal function >50% in a short period, proteinuria <1g/day	ANCA pos, complement consumption, therapy needed for renal function improvement
IgA nephritis	dysmorphic hematuria, proteinuria <2 g/day, complement normal levels, hyperchromic urine	48h after respiratory or gastrointestinal infection onset, IgA high levels
Endocarditis-associated glomerulonephritis	microhematuria, moderate proteinuria, renal function improvement during antibiotic therapy	Rarely with rapidly progressive manifestations, complement consumption, circulating immune complexes, elevated rheumatoid factor, type III cryoglobulinemia
Septic embolization	hematuria, proteinuria <3g/day; marked loss of renal function, only partial improvement	No spontaneous improvement of renal function, embolism/indirect signs evidence

PUB234

A Case of Malignancy in NELL-1 Membranous Nephropathy

Neha Patel,[1] Amit K. Rajput.[2,1] *[1]TriHealth, Cincinnati, OH; [2]The Kidney & Hypertension Center, Cincinnati, OH.*

Introduction: The predominant target antigen for primary membranous nephropathy (MN) has been Phospholipase A2 receptor (PLA2R), which is present in approximately 70% of cases. Neural epidermal growth factor like 1 protein (NELL-1) was recently identified as one of four new antigens in a distinct type of primary MN. NELL-1 membranous nephropathy was found to be the first candidate antigen highly prevalent in malignancy associated MN, seen in nearly 33% of all cases. We will review a case of NELL-1 membranous nephropathy.

Case Description: A 54-year-old Caucasian female presented from her PCP's office with shortness of breath, left flank/lower back pain, and bilateral lower extremity edema for four days. Physical exam exhibited BP 170/99 mmHg, nontender cervical lymphadenopathy (LAD), left CVA tenderness, and 2+ pitting edema. Initial lab studies were significant for elevated D-dimer, hypoalbuminemia (Alb 1.7g/dL), and nephrotic range proteinuria (UPCR 13.5g). Imaging revealed bilateral subsegmental pulmonary emboli, a left renal vein thrombosis, and extensive bilateral LAD (axillary, supraclavicular, mediastinal, and left periaortic retroperitoneal). Given concerns for a podocytopathy due to a possible lymphoma, the patient underwent an unremarkable extensive serologic workup and a renal biopsy. Her biopsy revealed NELL-1 membranous nephropathy, with diffuse (3+) fine granular staining along glomerular capillary loops for NELL-1 and numerous subepithelial deposits with severe foot process effacement. The patient underwent a bone marrow biopsy, excisional right axillary/cervical lymph node biopsies, PET scan, infectious work up, and age-appropriate malignancy screenings, which were all non-diagnostic for a malignancy. Her biopsies showed reactive lymphadenopathy with concern for evolving B-cell lymphoproliferative disorder with plasmacytic differentiation. Given her biopsy findings and NELL-1 MN, the patient was treated with rituximab.

Discussion: NELL-1is a rare emerging subtype of MN that has been identified in both primary MN and malignancy associated nephropathy. A thorough malignancy workup is warranted in all patients diagnosed with NELL-1 MN. More research is needed in the association between NELL-1 and specific cancers, in hopes of guiding future treatments for this disease.

PUB235

Vitamin D Status and Its Association with PTH in 73645 Caucasian Outpatients

Xin Chen,[1,2] Chang Chu,[1,2] Cornelia Doebis,[3] Bernhard K. Krämer,[1] Volker V. Baehr,[3] Berthold Hocher.[1,3] *[1]Fifth Department of Medicine (Nephrology/Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Berlin, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Institute of Medical Diagnostics, IMD Berlin-Potsdam, Berlin, Germany.*

Background: 25-hydroxyvitamin D (25(OH)D) inhibits the synthesis of PTH. However, the limited size of clinical studies to date has only allowed a relatively crude analysis of the relationship between 25(OH)D and PTH.

Methods: We investigated this relationship in 73645 patients (Figure 1).

Results: The relationship between 25(OH)D and iPTH has three phases: an initial drop in iPTH (25(OH)D: 0~20 ng/ml); a horizontal phase (25(OH)D: 20~60 ng/ml): a final drop in iPTH (25(OH)D: ≥60 ng/ml). A Cox regression analysis of these three phases considering age, sex, 25(OH)D, calcium, phosphate, and creatinine showed that in the initial phase age (RR: 0.20 ; CI: 0.09~0.31, p<0.0001), sex (RR: 15.84; CI: 11.40~20.28; p<0.0001), 25(OH)D (RR: -1.73; CI; -2.22~-1.25; p<0.0001), and creatinine (RR: 45.52; CI: 42.87~48.16; p<0.0001) are independently correlated with iPTH, whereas in the second horizontal phase age (RR: 0.14 ; CI: 0.09~0.20, p<0.0001), sex (RR: 14.84; CI: 13.01~16.66, p<0.0001), calcium (RR: -10.73; CI: -17.81~-3.64; p=0.003), phosphate (RR: -19.19; CI: -23.46~-14.92; p<0.0001), and creatinine (RR: 46.36; CI: 45.30~47.41, p<0.0001) are relevant. In the third phase, only sex (RR: 17.94; CI: 5.38~30.50, p=0.005) and creatinine (RR: 42.07, CI: 35.39~48.74, p<0.0001) play a significant role. Analyzing the relation between iPTH and 1,25-dihydroxyvitamin D (1,25(OH)2D) in a subset of the study (N=2441) revealed that serum 1,25(OH)2D concentrations have no effect on iPTH concentrations in subjects with normal kidney function.

Conclusions: In conclusion, circulating 1,25(OH)2D does not contribute substantially to the regulation of iPTH in healthy subjects. Presumably, serum 25(OH)D that is converted to 1,25(OH)2D after megalin-mediated uptake in the parathyroid chief cells plays the critical role. The relationship between 25(OH)D and iPTH has three phases. Factors correlating independently with PTH in the different phases differ substancially. 25(OH)D is only relevant in the first initial phase.

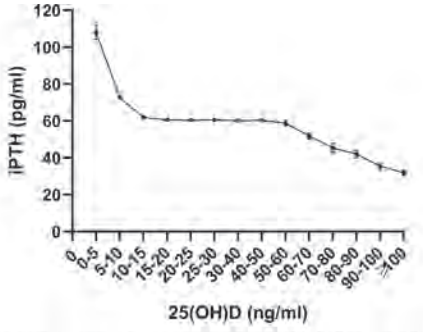


Figure 1. Relationship between serum 25(OH)D and iPTH (Mean ± SEM).

PUB236

Metabolic Features of Patients Older than 80 Years Receiving Total Parenteral Nutrition (TPN)

Richard L. Barnett, Kinjal Gosalia, Marian Glick-Bauer, Eric Klein. *Northwell Health, New Hyde Park, NY.*

Background: Advances in surgical and interventional techniques has extended the use of TPN in patients unable to receive enteral support. Metabolic abnormalities in "elderly" individuals receiving TPN has been reported > 65 yo but few focusing on > 80.

Reduced GFR, low muscle mass, and multiple comorbidities create unique management challenges. Use of a multidisciplinary approach as described may mitigate TPN associated electrolyte derangements and mortality. For this retrospective study we report some of the clinical parameters associated with "extreme" elderly patients receiving TPN.

Methods: A TPN team consisting of a nephrologist/intensist, abdominal/critical care surgeon, dietician and surgical PA met daily at 1030 to consider all referrals and create orders by 1230 for a TPN specialty pharmacist review followed by administration at 1730. 38 patients between 1/1/2019-12//15/2020 receiving CENTRAL parenteral nutrition (no PPN) were included. Metabolic complications of 1 or more times were reported.

Results: Baseline Characteristics (n=38) Gender: 45% male, 55% female Mean Age (range): 86 years (80-98 years) BMI <19 kg/m2: 18% BMI 30-39 kg/m2: 24% Severe Malnutrition: 66% HbA1c >6.5%: 5% GFR <60 mL/min/1.73m2: 34% TPN Characteristics Mean days on CPN (range): 14 days (4-39 days) Mean energy dose: 26.7 kcal/kg Mean protein dose: 1.7 gm/kg Caloric distribution: 26% protein, 50%CHO, 24% lipid Metabolic Complication%(n = 38) Hyperglycemia (blood glucose >200 mg/dL) 50%(19) Hypoglycemia (blood glucose <60mg/dl)3%(1) Hypertriglyceridemia (>400mg/dL)0%(0) Hypokalemia (<3 mEq/L)8%(3) Hypophosphatemia (<2 mg/dL) 18%(7) Hyponatremia (<135 mEq/L)63%(24) Hypernatremia (>145 mEq/L)24%(9) Low potassium (< 3.5 mEq/L) in 1st 2 days on TPN 32%(12) Low phosphorus (<2.5 mg/dL) in 1st 2 days on TPN 34%(13)

Conclusions: Expected "refeeding" hypo K and PO4 were observed but critical levels <2 and 1.5 respectively and early fatalities not encountered given daily monitoring and aggressive supplementation. Very frequent hyponatremia largely of the "SIADH Type" was mitigated by fluid restriction and/or high osmolar load. Na levels < 125 or >150 were not seen after initiation of TPN. We believe that a concerted multidisciplinary team approach is extremely useful in provision of the high risk "TPN medication".

PUB237

Comparison of the Triglyceride and Glucose Index in Predicting CKD Among Hypertensive Population: Six Southern China Community Cohorts

Hequn Zou. *Pinghu Hospital of Shenzhen University, Shenzhen, China.*

Background: Hypertension (HTN), as a major disease concern around the world that impacts middle-age and elderly population. We intend to explore the relationship between HTN and CKD through a new insulin-related index: Triglyceride and glucose index (TyG).

Methods: A cross-sectional cohort study of six populations in the southern coastal town of Wanzhai (Zhuhai, China) was carried out over 4 months. Group assignment criteria were: Systolic Blood Pressure (SP) ≥140mmHg with or without a Diastolic Blood Pressure (DP) ≥90mmHg or self-reported currently under treatment with anti-hypertensive medications for the hypertensive case group; while the control group population had normal blood pressure and no previous history of HTN. CKD was defined with the following criteria for diagnosis: urinary albumin/creatinine ratio (ACR)≥30mg/g with or without an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2.

Results: Lipid and glucose metabolic index TyG showed a correlation with the occurrence of CKD in the hypertensive population. In binomial logistic regression analysis, the risk of occurence of CKD was 1.503 (odds ratio) with the 95% confidence interval (CI) of each standard deviation of TyG lying between 1.127-2.003 (p<0.05). Area under the curve (AUC) of a receiver operating characteristic (ROC) was 0.5807 (p<0.001; 95% CI: 0.5337–0.6278), showing the utility of TyG as a prognosticator of CKD in people with HTN.

Conclusions: TyG may predict the prevalence of CKD occurence among hypertensive population of Southern China.

PUB238

Renal Artery Stenosis: Ticking Bomb

Shivangi Patel. *Morristown Medical Center, Morristown, NJ.*

Introduction: Untreated renal artery stenosis leads to poorly controlled and difficult to manage hypertension, congestive heart failure, and progression of renal disease. A high index of suspicion is essential for clinical diagnosis and to potentially reverse a condition with narrow time window.

Case Description: 82-year-old female with poorly controlled blood pressure, 27 pack year smoking history, quit 2007 was evaluated for worsening creatinine of 2.64 mg/dL, eGFR 16, 8/24/2020 (cr 1.29 mg/dL, eGFR 37,11/5/2019). Each time a RAAS antagonist was given, this would result in decreased renal function and would improve off it. Blood pressure 180/90, BMI 28, +2 edema. Labs: proBNP 9,317 pg/ml, LDL 137 mg/dl, Protein creatinine ratio 1.588 mg/g, 3+ dipstick. Serology for proteinuria was negative. Renal ultrasound: right kidney 8.7cm with cortical tissues are echogenic and markedly thin consistent with areas of atrophy and left kidney 10.5 cm with normal cortical thickness and echogenicity. Renal duplex: aortic velocity 95.4cm/s peak systolic, right renal artery 134.5cm/s peak systolic and left renal artery 386.8cm/s peak systolic. Resistive index right kidney average of 0.55 and left kidney 0.72. Renal artery to aortic velocity ratio 1.4 on right and 4.1 on left. Echo: moderate to severe concentric LVH, abnormal diastolic relaxation. After left renal artery stent placement, her creatinine was 1.31 mg/dL from 2.11 mg/dL. A month later after addition of losartan to carvedilol and Lipitor her creatinine was 1.2 mg/dl eGFR 42, protein creatinine ratio 745 mg/g with no edema, "more energy" and blood pressure 110/60.

Discussion: She has solitary left functioning kidney due to right renal atrophy. When RAAS antagonist was introduced her kidney function deteriorated demonstrating it was dependent on angiotensin, behaving as bilateral stenosis. She developed poorly controlled hypertension, edema, proteinuria, LVH and diastolic dysfunction. Combination of ultrasound and duplex showed a window of opportunity to intervene on viable kidney tissue with an atherosclerotic lesion. She was safely placed on ARB to further reduced her risk of progression of renal and heart disease.

Renal Artery Stenosis

PUB239

Epithelial Overexpression of Human ACE2 in Mice as a Model for Studying Renal Disease

Jacqueline M. Emathinger, Joshua A. Robertson, Jonathan W. Nelson, Susan B. Gurley. *Oregon Health & Science University, Portland, OR.*

Background: ACE2 is an integral part of the renin angiotensin system (RAS) and is highly expressed at the brush border of epithelial cells of the renal proximal tubule. Within the lumen, ACE2 is poised to metabolize angiotensin II and extinguish its effects as part of the counter-regulatory arm of the RAS. Use of transgenic mouse models has been essential in exploring the cardiovascular and renal functions of ACE2. Limitations in using mouse models for SARS was overcome by generation of mice expressing human ACE2 (hACE2) downstream of the keratin 18 promoter (K18-hACE2) by McCray *et al* 2007. K18-hACE2 mice express hACE2 in epithelial cells throughout the body and have proved valuable for the study of SARS-CoV and CoV2 viral infectivity and pathogenesis. Here, we investigate whether K18-hACE2 mice might serve as a unique tool with which to study the role of ACE2 in the intra-renal RAS.

Methods: We assessed ACE2 activity in urine collected from K18-hACE2 mice (obtained from Jax and bred in our own colony) and their wildtype littermates. Urine was collected over 24 hours in individual metabolic cages, and enzymatic activity was determined using an ACE2 activity assay. Duplicate samples tested for each animal.

Results: Our lab has a longstanding interest in the role of ACE2 in the kidney and our preliminary experiments demonstrate that K18-hACE2 mice have significantly increased ACE2 enzymatic activity in the urine compared to wildtype littermates (1597.0±379.74 vs 396.0±143.92, p=0.013).

Conclusions: The increased urinary ACE2 activity suggests that there are elevated levels of ACE2 reaching the kidney. While this seems most likely due to increased expression of renal epithelial ACE2, soluble ACE2 derived elsewhere and able to reach the lumen of the nephron must also be considered. Thus, K18-hACE2 mice with increased urinary ACE2 activity can serve as a model to examine the effect of ACE2 and the RAS on kidney diseases such as hypertension and acute renal injury.

PUB240

Nephrotic Syndrome Secondary to Paraneoplastic Syndrome of Leukemia

Jan P. Rosaly, Elizabeth Pabon-Vazquez. *Mayaguez Medical Center, Mayaguez, Puerto Rico.*

Introduction: Paraneoplastic glomerulopathies are rare manifestations of neoplastic disease that must be differentiated from iatrogenic renal injury. Nephrotic Syndrome is one of the most frequent presentations of paraneoplastic glomerulopathies. Such findings might serve to identify prognosis of disease course. It has been reported that solid tumors are associated with membranous nephropathy while lymphomas are associated with minimal change disease. While the incidence of paraneoplastic glomerulonephropathies in Chronic lymphocytic leukemia (CLL) is unknown and rare. CLL is one of the most common type of leukemia in Western countries. It is commonly observed in elderly patients but is hasn't been associated with renal gromeluropathies. Recent studies suspected that leukemic cells might have certain properties that lead to the development of nephrotic syndrome.

Case Description: This is the case of a 82 y/o male patient with past medical history of hypertension, hypothyroidism, and prostate cancer that presented to the hospital with complaints of edema. Associated symptoms were malaise, poor urinary output and nauseas. Physical examination was remarkable for generalized edema with pitting edema +2 on lower extremities. Initial laboratory work up was remarkable for findings of acute renal injury accompanied by oliguria and proteinuria +3. Despite foley placement and diuresis no major improvements on renal function was observed. Due to constant deterioration he was started on hemodialysis with adequate response but further work up for nephrotic syndrome was requested. ANCA and ANA was negative as well cryoglobulin. Complement such as C3 and C4 were within normal limits. Fat Pad biopsy was performed. Report was remarkable for changes suggestive of membranous

glomerulonephritis. In addition, due to sudden decrease in hemoglobin levels and elevated light kappa chains bone marrow biopsy was performed. Report was remarkable for changes suggestive of CLL.

Discussion: This case exhibits a patient that did not presented with symptoms or findings suggestive of CLL at the time of renal injury. Therefore, this case strongly underlines the importance of performing a bone marrow biopsy to patients that present with abnormal electrophoresis and immunofixation in order to detect lymphoproliferative disorder. Early detection can help to treat such disease at early stages and avoid further complications that might affect patient's prognosis.

PUB241

A Case of Immune-Complex-Mediated Glomerulonephritis Associated with Pembrolizumab

Marco A. Bonilla, Vanesa Bijol, Antonio Corona, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Immune checkpoint inhibitors (ICI) are changing the way we treat cancer. However, these agents have various systemic adverse events that may preclude their use and cause poor patient outcomes. ICI-associated acute kidney injury is an emerging complication of this treatment.

Case Description: An 80-year-old man diagnosed with metastatic adenocarcinoma of the lung with high PDL-1 expression was evaluated for new-onset proteinuria and elevation of serum creatinine. The patient had completed four cycles of carboplatin, pemetrexed, and pembrolizumab at the initial evaluation. His only complaint was foamy urine. Vital signs were remarkable for elevated blood pressure. The physical exam was unremarkable. Laboratory data showed serum creatinine of 1.8mg/dl (baseline of 1.18mg/dl, two months prior), blood urea nitrogen of 24mg/dl, and serum albumin of 3.3g/dl. Urinalysis showed proteinuria, and moderate blood with 9 RBC/HPF. A spot urine protein/creatinine ratio of 10.8 g/g. A kidney biopsy was performed, which showed immune complex-mediated glomerulonephritis, with a membranoproliferative and diffuse segmental endocapillary proliferative pattern of glomerular injury.

Discussion: Kidney immune-related adverse events occur in about 2-5% of patients receiving ICI therapy. Recently there has been increasing recognition of its association with glomerular diseases. Several differential diagnoses were considered that could have instigated these pathological findings. Ultimately, our team had a high clinical suspicion that they were associated with ICI therapy. After a multidisciplinary discussion, the decision was to hold pembrolizumab and start prednisone at a 1mg/kg dose. The patient responded well to therapy, was discharged home with prednisone taper; subsequent protein/creatinine ratio had a striking improvement to 1.8g/g. The serum creatinine was back to baseline. To our knowledge, this is the first case reported of pembrolizumab-associated immune-complex glomerulonephritis. Patients undergoing ICI therapy require close monitoring for potential kidney adverse events. Physicians must remain vigilant and should be able to recognize a potential glomerular injury from ICI therapy.

PUB242

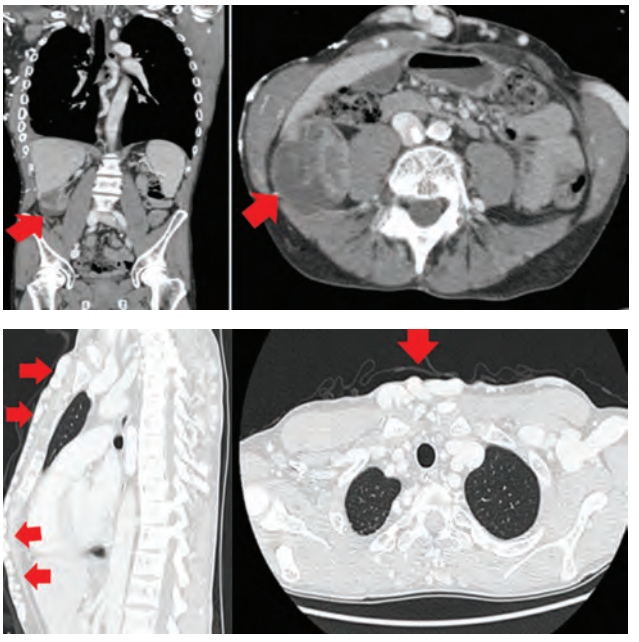
Renal Cell Carcinoma Incidentally Discovered in Native Kidney During Imaging for Superior Vena Cava Obstruction

Nihal Bashir. *Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.*

Introduction: Papillary RCC accounts for approximately 15 % of all kidney cancers, and these can be divided into type 1 and type 2 subtypes based on histopathologic features. As with clear cell cancers, papillary RCC originates from the proximal tubule, but these tumours are morphologically and genetically distinct malignancies. The initial information on their molecular pathogenesis was derived from cases arising in patients with hereditary forms of RCC.

Case Description: 37-year-old male patient with recurrent FSGS post renal transplantation currently on dialysis. He had aneurysmal AV dialysis fistula and he had CT Scan to evaluate superior and inferior vena cava obstruction which picked up a large complex heterogeneous well-defined mass arising from the lower pole of the atrophic right kidney highly suspicious for renal cell carcinoma (image 1). CT venogram showed chronic obstruction of SVC. This has resulted in extensive varicosed collateral veins in the anterior lateral chest wall and abdominal walls (image 2). The dilated collaterals drain into the femoral veins bilaterally. The patient undergone SVC angioplasty followed by elective right Nephrectomy. The renal mass histology showed Type II papillary renal cell carcinoma, G3. No extrarenal extension or renal sinus invasion identified.it was graded as pT1b pNx (AJCC 8th edition). As per EUA Guidelines for CT scan control at 6 months, 1 year, 2 years, 3 years then every 2 years for 10 years.

Discussion: Treatment approach For localized disease, the general approach to treatment of localized in clear and non-clear cell renal cell carcinomas. Surgical resection offers the best chance of cure.



PUB243

Immune Checkpoint Inhibitor (ICPI)-Associated Hypopituitarism Presenting as Severe Hyponatremia

Amer A. Belal, Chintan V. Shah. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: ICPI has improved the prognosis for patients with advanced malignant disease. However, as their use increases, it is important to be aware of their potential side effects that require prompt attention. Here, we report a case that presents with life-threatening severe hyponatremia from secondary adrenal insufficiency as the first sign of hypopituitarism secondary to ICPI therapy.

Case Description: A 67-year-old man with a past medical history significant for metastatic clear cell type renal cell carcinoma, status post radical right nephrectomy, and adrenalectomy. He was found to have a metastatic lesion to his lungs and was initially treated with Pembrolizumab along with Axitinib for almost one year. 5 months later, He was found to have a metastatic necrotic mass in the right renal fossa and was started ipilimumab/nivolumab x 4 cycles followed by maintenance monthly nivolumab. Almost 4 months after being initiated on ICPI therapy and almost 3 weeks after the last dose, labs showed severe hyponatremia with serum sodium of 115 mmol/L with serum osmolality of 249 mmol/L. Clinical examination was suggestive of euvolemia. Urine osmolality of 510 with Urine sodium of 59 was consistent with the diagnosis of the syndrome of inappropriate antidiuretic hormone release (SIADH). Further workup included 8:00 AM cortisol of 0.5 mcg/dl increasing up to 9.3 mcg/dl in two hours after Cosyntropin 250 mcg IV stimulation along with inappropriately normal levels of ACTH of 18.4 pg/ml suggestive of secondary adrenal insufficiency. Additionally, relatively low TSH (with low free T4) along with low LH were suggestive of pituitary insufficiency. FSH and prolactin were within normal range. MRI brain was without any evidence for pituitaritis. No laboratory or clinical evidence for hypoaldosteronism. The patient was treated with the addition of hydrocortisone and levothyroxine. Follow-up labs at one month showed serum sodium of 132 meq/L.

Discussion: This case is an excellent illustration that hyponatremia in the patients receiving checkpoint inhibitors could be from hypocortisolemia. Extensive work up to detect pituitary insufficiency should be considered in such cases as hyponatremia could present as the initial sign of pituitary insufficiency.

PUB244

TMA Associated with Hypereosinophilic Syndrome

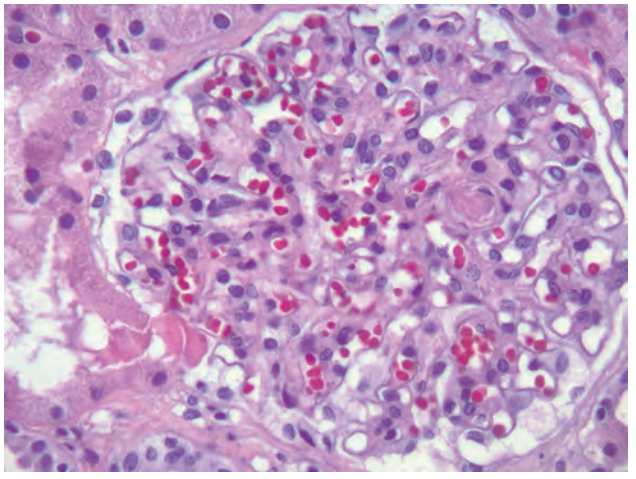
Jose L. Henao, Kenneth M. Ralto, Matthew J. Trainor, Vijay Vanguri. *University of Massachusetts System, Worcester, MA.*

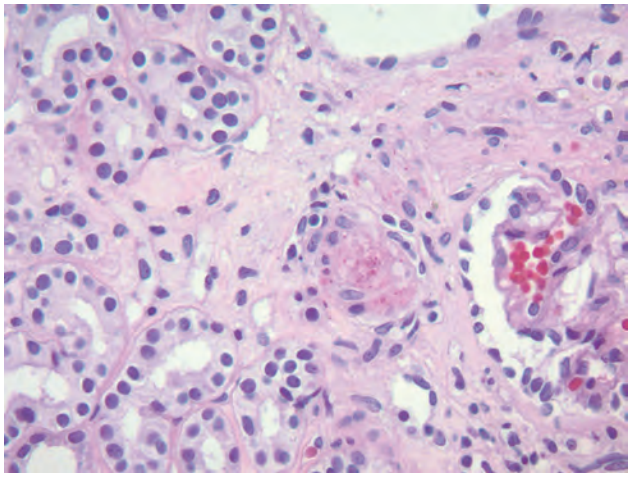
Introduction: Thrombotic microangiopathy (TMA) is a rare but serious form of renal injury that can be a manifestation of an array of conditions, including malignancies. Here we illustrate a case of renal TMA due to hypereosinophilic syndrome associated with PDGFRA gene rearrangement.

Case Description: A 29 year-old male presented with endocarditis-like features and findings of myocarditis on cardiac MRI. He was found to have AKI with creatinine up to 2.0 mg/dL, six months prior his creatinine was 0.96 mg/dL. Laboratory data was notable for peripheral eosinophilia, sub-nephrotic range proteinuria, and urine sediment showed many dysmorphic red blood cells. FISH testing showed FIP1L1-PDGFRA fusion rearrangement. A kidney biopsy was performed which revealed an acute TMA with

focal glomerular capillary thrombosis, multifocal arteriolar thrombosis, and arteriolar fibrinoid necrosis (Figures 1, 2). The patient was started on imatinib with improvement of creatinine to 1.75 mg/dL.

Discussion: Hypereosinophilic syndrome with PDGFRA mutation has been associated with renal TMA in only a few reported cases. It has been hypothesized that eosinophil granule proteins lead to the endothelial injury and platelet activation that precipitates this form of renal injury. This case highlights the importance of early diagnosis of AKI in these patients and the need for prompt treatment.





PUB245

Deep Analysis of AKI and CKD in Allogeneic Stem Cell Transplantation: A Big Data Approach

Nicole Brueder,[1] Jan T. Kielstein,[2] Catherina Lueck,[1] Elke Dammann,[1] Luca-Marie Heinze,[1] Victoria Panagiota,[1] Sophia Koehler,[1] Hans Laser,[1] Svetlana Gerbel,[1] Michael Stadler,[1] Matthias Eder,[1] Gernot Beutel.[1] HON Circle of the iCHOP initiative (www.ichop.eu) *[1]Hannover Medical School Enterprise Clinical Research Data Warehouse, Hannover, Germany; [2]Academic Teaching Hospital Brunswick, Clinic for Nephrology, Rheumatology and Blood Purification, Brunswick, Germany*.

Background: Acute kidney injury (AKI) is a common complication in allogeneic stem cell transplantation (ASCT). Although it is thought that in the majority of patients this injury is short lived in some patients, the damage persists for more than 3 months progressing into chronic kidney disease (CKD). So far, just a few publications have shown robust data based on larger patient populations. The aim of this project is to analyze the incidence and severity of AKI in ASCT and the transition into CKD.

Methods: Between 2000 and 2019, 1,401 patients underwent ASCT in our clinic. For 1,099, a detailed history of creatinine (n=184,056) could be extracted from the Clinical Data Warehouse. The classification of AKI was carried out in accordance with creatinine criteria of KDIGO classification at the respective stages (AKI 1, 2, 3). For AKI, an increase in serum creatinine of ≥ 0.3 mg/dl (26.5 micromol/l) within 48 hours or an increase in serum creatinine to ≥1.5 times baseline was used. Persistence of impaired renal function beyond day 90 was defined as CKD. An algorithm was programmed for the analysis of the big data and classification of the AKI / CKD. Retrospectively, the results were validated by a colour-coded representation of renal function.

Results: Between January 1, 2000 and December 31, 2019, 184,056 creatinine levels were enriched for 1,099 patients for the period from day -42 before to day +118 after ASCT. The overall incidence of AKI was 87% (n=956). 782 (71%) Patients have shown an AKIN 1, 145 (13%) an AKIN 2 and 29 (3%) an AKIN 3. During the observation period 122 (11%) patients died. For 32% (204/644) the transition to CKD has been observed.

Conclusions: AKI after ASCT is the rule and not the exception. As the vast majority of patients show AKIN 1 it might be often clinically overlooked. However early intervention might mitigate the development of long term renal impairment. Automated detection (AKI alert systems) as well identification and avoidance of factors contributing or aggravating injury (e.g., conditioning, immunosuppression, perfusion, inappropriate dosing of drugs) might minimize long-term renal complications in ASCT.

PUB246

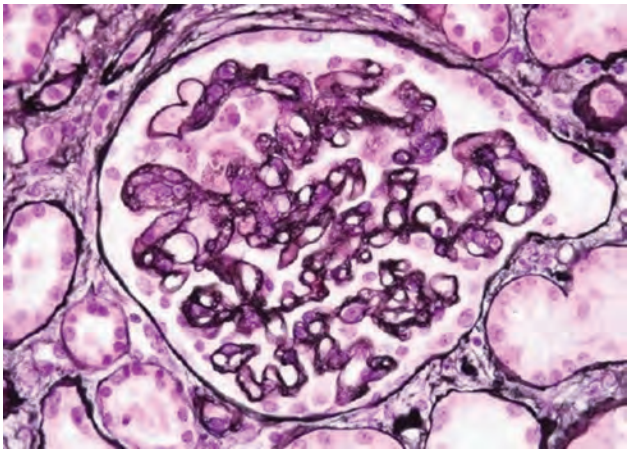
Gemcitabine-Induced TMA: A Rare Side Effect Associated with High Mortality: A Case Report of Partial Response to Eculizumab

Maria Mattiotti, Marianna Napoli, Anita Campus, Carlo Stefanini, Gisella Vischini, Olga Baraldi, Benedetta Fabbrizio, Gaetano La Manna. *Universita di Bologna, Bologna, Italy*.

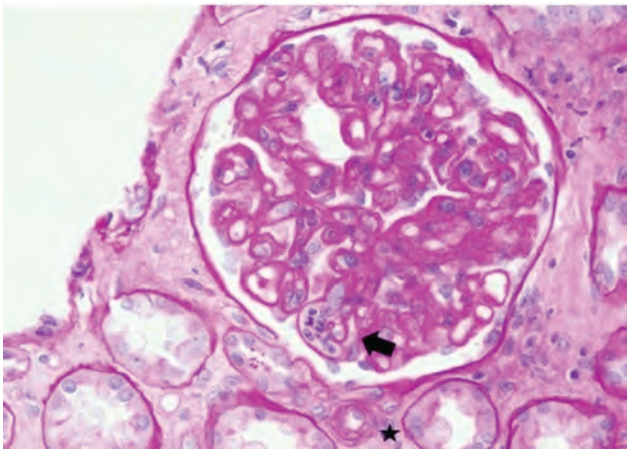
Introduction: Thrombotic Microangiopathy (TMA) is a well-known complication in cancer, and it could be secondary to neoplasm itself or to its treatment. Gemcitabine-induced TMA is rare, but associated with high mortality rate and negative renal prognosis.

Case Description: A 71-year-old woman treated with Gemcitabine for recurrence of endometroid carcinoma developed a rapid progressive kidney injury, hypertension and pulmonary edema. Laboratory tests revealed signs of TMA. Histological analysis showed both acute and chronic TMA signs (Fig. 1). Upon suspicion of GiTMA, antiblastic therapy was discontinued and, in order to prevent complement activation, Eculizumab was administered. According to literature, a sudden improvement of blood count was observed. Because of worsening of renal function, dialytical treatment was started. Histologically chronical lesions were documented (Fig.2).

Discussion: GiTMA is mostly misdiagnosed, because blood count instability and renal impairment could recognised multiple triggers in neoplastic patients. An early diagnosis enables drug withdrawal and complement system inhibition: the only measures that seem to be associated with increased survival and a better renal outcome.



Focal mesangiolysis, glomerular basement membrane reduplication (Silver Jones stain; 400x)



Mesangiolysis, endocapillary proliferation (arrow), glomerular basement membrane reduplication; arteriole (asterisks) free from TMA signs (PAS stain; 400x)

PUB247

Electrolyte Disorders Associated with the Use of Immune Checkpoint Inhibitors: A Single-Center Cohort

Swetha Rani Kanduri,[1] Nicholas J. Carbajal,[1] Karthik Kovvuru,[1,2] Aldo E. Torres Ortiz,[1] Luis A. Matute Trochez,[1] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.*

Background: Electrolyte imbalances have been reported in association with exposure to immune check point inhibitors (ICI). However, the incidence of these disorders has not been widely established. Herein, we report a single center experience on the incidence of electrolyte abnormalities associated with ICI therapy as well as risk factors associated with their development.

Methods: We conducted a retrospective review of medical records searching for patients who received ICI over a 10-yr period at Ochsner Health. Demographic and clinical characteristics were extracted up to 1 year post ICI treatment. Common Terminology for Cancer Adverse Events version 5.0 criteria were used to grade the severity of electrolyte abnormalities. Risk factors were examined by logistic regression.

Results: A total of 102 patients were identified. The mean age was 64 ± 11 years, 43% women, 82% of white race. Pembrolizumab was the most commonly used ICI (46%), followed by nivolumab (26%) and atezolizumab (15%). The mean baseline glomerular filtration rate is 58 ml/min. ICI was more frequently administered to patients with lung cancer (47%). The incidence of hyponatremia (<134 mEq/L) and severe hyponatremia (<124 mEq/L) were 17% and 2%, respectively. Hypocalcemia (<8.4 mg/dL) was observed in 7%, whereas 11% experienced hypomagnesemia (<1.5 mg/dL) and 3% hypokalemia (<3.4 mEq/L). Melanoma was found to be numerically associated with hyponatremia, but not statistically significant (OR 3.1, 95% CI 0.7-14.8). White race was associated with 3 times greater risk of hyponatremia with ICI therapy (OR 3.5, 95% CI 1.2- 9.9). Although co-administration of cisplatin, underling chronic kidney disease and use of SSRI are known risk factors associated with hyponatremia, those variables were not associated with hyponatremia in our cohort, suggesting that hyponatremia secondary to use of ICI could be mediated by a mechanism independent of those variables.

Conclusions: Exposure to ICI is associated with the development of electrolyte imbalances. In our study, white race was identified as factor having 3 times higher odds of hyponatremia. Further studies are needed to examine race and other factors and the risk of hyponatremia in patients treated with ICI.

PUB248

Spontaneous Tumor Lysis with Normal Electrolytes

Ayesha Mallick Imam, Carlos J. Gonzalez Gonzalez, Dawn Maldonado, Ismail Omran, Aaron S. Stern, Stephen C. Ward, Maritza Brown. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Tumor lysis syndrome (TLS) leading to renal failure can occasionally occur prior to treatment in highly proliferative hematological malignancies. We present a case of AKI due to spontaneous TLS without the typical antecedent electrolyte derangements normally expected with TLS.

Case Description: A 76-year-old male with no prior medical history presented to the emergency room with abdominal pain and weight loss. CT scan revealed a gastric mass, ascites and abnormal liver consistent with cirrhosis. Gastric biopsy revealed diffuse large B cell lymphoma. He initially had a bland UA and a slight increase in baseline creatinine. The primary team treated him for hepatorenal syndrome with no response. His renal function rapidly deteriorated and he became anuric. A follow up UA showed protein and blood. Although the uric acid (UA) was 13.7 mg/dL, the phosphorous and potassium remained in their normal ranges leading us away from a diagnosis of TLS and toward the possibility of a rapid progressive glomerulonephritis. On biopsy the renal tubules contained calcium oxalate and calcium phosphate crystals with vacuolization of the tubular epithelial cells and tubular changes consistent with prior uric acid crystal deposition. The glomeruli were normal. At this point the uric acid level had risen to 25 mg/dl. Rasburicase was initiated and the patient eventually recovered renal function.

Discussion: In TLS, tumor cells lyse and release their intercellular electrolytes and purines (which are metabolized to uric acid) leading to elevated potassium, phosphorus and uric acid. Rarely the potassium and phosphorus can be normal. Our patient had renal failure further limiting the excretion of potassium and phosphate, making the normal levels of these electrolytes especially notable. Identifying the mechanism of normokalemia and normophosphatemia in spontaneous TLS may give us insight on how to diagnose it earlier, thus leading to earlier treatment.

PUB249

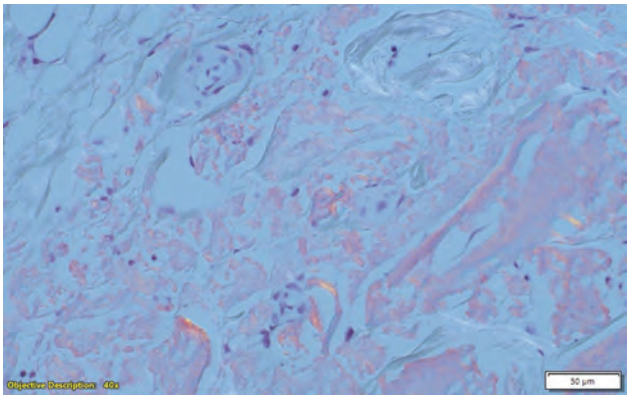
Bladder Amyloidosis as a Rare Cause for Hematuria

Nihal Bashir. *Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.*

Introduction: Urinary tract amyloidosis involvement can mimic transitional cell carcinoma, with haematuria and irritative symptoms. Bladder amyloidosis has slow progression to systemic disease. More than 50% of bladder amyloidosis can be diagnosed as bladder carcinoma. Histological examination with congo-red stain remain important. Tests like bens-johns proteins serum electrophoresis, abdominal fat biopsy and serum amyloid P component can help to differentiate primary and secondary amyloidosis.

Case Description: 60 yo male, presented with on and off frank haematuria with TURB done 9 years ago. CT Contrast enhanced images confirmed an enhancing polypoidal soft tissue density/wall thickening of the bladder wall projecting within the lumen on the right lateral aspect along the bladder base, suspicion of malignancy was high so patient underwent Transurethral bladder tumour resection for solid tumour in the bladder trigone.

Discussion: Tumour biopsy showed extensive deposition of faint eosinophilic material in lamina propria, basement membrane, and submucosa and focally in muscularis propria with formation of chunky separate pieces present in artificially created spaces. Extensive deposition is also seen in the wall of blood vessels focally. The material was diffusely positive for Congo red stain with apple-green birefringence, consistent with amyloid. Immunohistochemical staining for kappa and lambda light chains was performed and shows dual positivity of the amyloid material, but with stronger staining on the lambda side, suggestive for AL type. SPEP Elevated beta globulins. UPEP and immunofixation showed glomerular Proteinuria selective for albumin&negative Bence Jones protein. Creatinine ranged between 111 – 144 micromole/L. the patient had negative investigations for systemic amyloidosis. The patient was advised to start colchicine, but he was not compliant with medication or follow up. No other pathology would explain his haematuria.



PUB250

Pattern of Renal Diseases Detected on Renal Biopsy at Pakistan Institute of Medical Sciences (PIMS) Islamabad

Muhammad Sajid R. Abbasi,[1] Rukhsana Manzoor,[2] Khawar Sultan.[3] *[1]Pakistan Air Force, Islamabad, Pakistan; [2]Kulsum International Hospital, Islamabad, Pakistan; [3]Pakistan Institute of Medical Sciences, Islamabad, Pakistan.*

Background: Renal biopsy is an important tool for evaluation and diagnosis of glomerular, vascular, tubulointerstitial and genetic kidney diseases. It helps in determining the stage of disease, making treatment protocol and predicting prognosis as well Purpose of the study is to find out pattern of renal diseases diagnosed on renal biopsies.

Methods: This is retrospective analysis done from February 2012 to April 2018. This data was taken from pathology department of Pakistan Institute of Medical sciences Islamabad Pakistan. These were adult patients above 18 years who underwent percutaneous renal biopsy due to some clinical indications. Their data was analyzed for spectrum of kidney disease on renal biopsy

Results: Total biopsies were 254. Most common lesions were glomerular lesions. Among them primary forms were found. Most common GN found was Membranous Nephropathy (14%), second most common lesion was Focal segmental glomerulosclerosis (FSGS) (12.5%) followed IgA Nephropathy (10.6%) Membranoproliferative glomerulonephritis MPGN (9.1%). Most common secondary glomerular lesion was found was Lupus Nephritis (7.8%). Other lesions were chronic kidney disease (12.5%), Interstitial fibrosis with tubular atrophy (IFTA) (5.9%)., Rapidly progressive GN (5.9%), Renal cortical necrosis (4.3%), Acute tubular necrosis (ATN) (4.3%), IgM Nephropathy 2%, chronic tubulointerstitial disease (TID) (2.4%), Diabetic Kidney disease (DKD) (2%) Minimal Change Disease (2%), Amyloidosis AA (1.2%), HTN (0.8%), pos-streptococcal GN (0.8%), Postinfectious GN (0.4%), diffuse proliferative GN (0.4%). In young patients' glomerular lesions were common whereas in middle age and elderly Chronic tubulointerstitial diseases and DKD were the common lesions.

Conclusions: In review of renal biopsies most common histological lesion found was membranous nephropathy (12.5%) followed by focal segmental glomerulosclerosis (FSGS) (12.5%) and IgA Nephropathy (10.6%).

PUB251

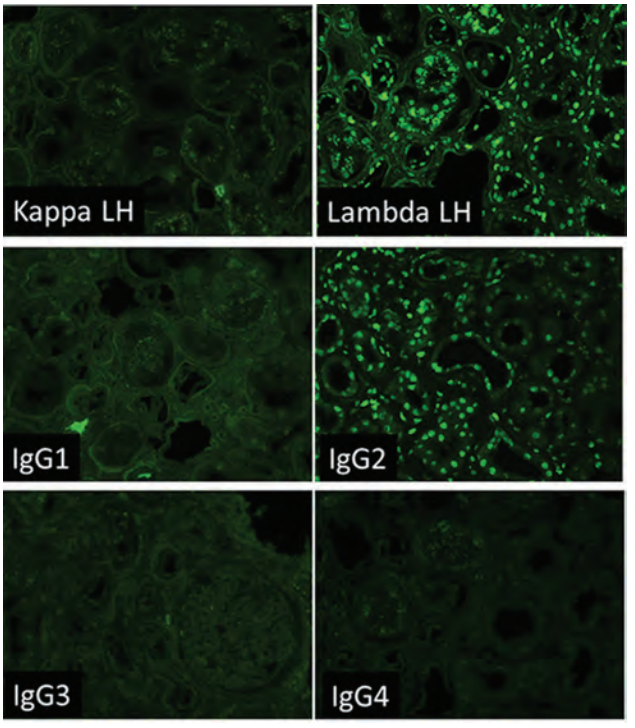
Can Antinuclear Antibody (ANA) Be Monoclonal? A Case Report of Unusual Immunofluorescence Findings in a Patient with Monoclonal Gammopathy of Uncertain Significance (MGUS)

Mohankumar Doraiswamy,[1] Brian Mussio,[3] Anjali A. Satoskar,[1] Laura Biederman,[1,2] Galina Mikhalina,[4] Sergey V. Brodsky.[1] *[1]The Ohio State University, The Ohio State University, Columbus, OH, US, academic, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH; [3]Hypertension Nephrology Consultants Inc., Columbus, OH; [4]Rochester Regional Health Nephrology, Rochester, NY.*

Introduction: Nuclear staining by immunofluorescence in a kidney biopsy is often seen in patients with positive ANA in the serum. These ANA are usually polyclonal, but herein we report an unusual finding by immunofluorescence of IgG2 lambda monoclonal nuclear staining in a patient with MGUS.

Case Description: The patient is a 72-year-old Caucasian male with a history of diabetes mellitus type 2 (hemoglobin A1c is 6.1%) who was recently treated with hydralazine, and he was found to have positive ANA (homogenous pattern, > 320), but after discontinuation of hydralazine the ANA decreased to 21. He had positive P-ANCA (positive MPO, 4) and negative C-ANCA (negative PR3). Also he has positive anti-double-stranded DNA. His serum creatinine was 1.7 mg/dl (1 mg/dl baseline), proteinuria 0.34 gm/24h. He did not have monoclonal protein in the urine, but in the serum by immunofixation there was IgG lambda monoclonal protein (two monoclonal bands were noted). He has elevated serum both kappa and lambda light chains with normal kappa-to-lambda light chain ratio. Kidney biopsy showed acute tubular necrosis (ATN), moderate chronic kidney injury and there was no evidence of immune complex deposition, monoclonal immunoglobulin deposition or amyloid. Immunofluorescence showed positive nuclear staining for IgG (IgG2 subclass only) and lambda but not kappa light chain (Fig 1). These findings raise the possibility that his ANA are of monoclonal origin.

Discussion: Our case demonstrates the unique pattern of IgG2 lambda monoclonal nuclear staining by immunofluorescence in the patient with MGUS. The prevalence of this type of findings is not well studied.



PUB252

The Use of Bone Wax to Position and Secure the Kidney for Intravital Analysis in Mice Using an Abdominal Imaging Window

Hanan Chweih, Isis Thomas, Courtney J. Haycraft, Mandy J. Croyle, Bradley K. Yoder. *The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: Intravital imaging is a powerful technique for evaluating inflammatory processes, cell migration, tubule and blood flow, cyst development, and injury and repair responses in vivo in live kidneys. Combining this with the use of an abdominal imaging window (AIW) allows for long-term in vivo visualization. However, the challenge has been preventing the kidney from repositioning in the AIW over the course of the study. Previous methodology utilized a cyanoacrylate adhesive to attach the kidney to the window or gauze placed under the kidney to stabilize it against the window, thus facilitating the acquisition of images. In our hands, both approaches cause scaring and fibrosis that have complicated our analysis. Here we compare a bone wax approach to secure the kidney with that of gauze.

Methods: AIW implantation surgery was done on 8 to 10 week old wild type mice and the kidneys were positioned and secured in the window using sterile gauze or bone wax (n=4 each).

Results: Our results show that sterile gauze can cause adhesion reactions with the surrounding tissue, including the kidney, making it difficult to visualize and image the kidney for more than 3 days post window insertion. In addition there are inflammatory reactions, and the kidney frequently adhered to the AIW coverslip preventing imaging of cell movements, cilia responses, and flow within the renal tubule. Bone wax is an inert and malleable substance that is used for bone recovery surgeries and therefore should not result in an intense inflammatory response. In contrast to the results obtained with sterile gauze, using bone wax to secure placement of the kidney in the window resulted in a far less inflammatory reaction and reduced adhesions and fluid accumulation within the window. Using bone wax, we can now easily follow the kidney for 2 - 3 weeks after surgery with minimal complications.

Conclusions: We conclude that bone wax is a superior approach for long-term intravital renal imaging. The longer time frame provided by using bone wax for longitudinal renal visualization will allow us to evaluate the initiation and expansion of cysts, to image renal injury responses and cell movements, and to analyze tubule flow and cilia responses.

Renal Tuberculosis: An Uncommon Presentation of a Common Disease: Case Report

Raúl A. Suc Valenzuela,[1,2] Hernan D. Rancho Malchic,[1,2] Mario Sierra,[1] Gylari M. Calderón,[4] Rodolfo A. Moreno,[3] Luis D. Gónzalez Patzan.[5] *[1]Internal Medicine Department, Guatemalan Military Medical Center, Guatemala, Guatemala; [2]Mariano Gálvez University, Guatemala, Guatemala; [3]Nephrology Department, Guatemalan Military Medical Center, Guatemala, Guatemala; [4]Pathology Department, Guatemalan Military Medical Center, Guatemala, Guatemala; [5]Infectious Disease Department, Guatemalan Military Medical Center, Guatemala, Guatemala*.

Introduction: Guatemala is an endemic country for tuberculosis (TB) with 3 500 cases per year, 85% correspond to pulmonary presentation. Genitourinary tuberculosis is uncommon, it is considered a severe form of extrapulmonary TB; it is secondary to infection with Mycobacterium tuberculosis complex with a long-standing dysuria, sterile pyuria, fever and consumptive symptoms. We present the case of an atypical renal TB having hematuria and fever as the only clinical features.

Case Description: A 54-year-old Guatemalan male came to the emergency room with a history of intermittent fever during the last year that worsens in the last 2-weeks. He lived in a rural area at the southern-coast of Guatemala. No previous medical history, no pets at home. The fever was between 38.3-40º (100-104ºF) with no predominant pattern during the day. On admission, normal vital signs, dehydrated with no other sign or symptom at physical examination. Initial laboratories with WBC 6 500, Hb 13gr/dl, SCr 0.86mg/dl, BUN 15mg/dl, normal LFTs and electrolytes. Chest X-ray with no evidence of pneumonia or other pulmonary disease. Urinalysis with microscopic hematuria with >30 RBCs per hpf, 40% of dysmorphism; no WBC in three consecutive urinary test. Urinary protein-creatine ratio15mg/g. Negative urine culture. ANA, ANCAs, C3, C4 were negative. Infectious disease tests were negative (FilmArrayâ, TORCH, blood culture, SARS-Cov2, HIV, HBV, HCV, lumbar puncture). Considering hematuria from urological origin we perform a uro-CT which was negative for kidney stones, masses or other anatomical abnormalities. Urine Ziehl-Nielsen stain was negative but with a positive result for acid fast bacilli in urine Kinyoun stain (figure 1). A multidrug therapy was started with isoniazid, pyrazinamide, ethambutol, rifampicin. Forty-eight hours later the fever disappeared until discharged.

Discussion: Renal TB has a prevalence of 10% worldwide and 20% in Latin-America mainly from pulmonary origin. The reported cases have higher prevalence in developing countries, male gender, immunosuppressed state as in HIV infection and post transplanted. It is an under diagnosed disease that can lead to CKD. The diagnosis of renal TB must be considered in patients with dysuria, hematuria, pyuria with negative urinary cultures.

PUB254

Real-Time Percutaneous Kidney Biopsy Experience: Is There a Change in the Trend of Complication?

Rotimi Oluyombo,[1,2] Peter S. Topham.[3] *[1]Norfolk and Norwich University Hospital, Norwich, United Kingdom; [2]Federal Teaching Hospital, Ido-Ekiti, Nigeria; [3]Leicester General Hospital, Leicester, United Kingdom*.

Background: Percutaneous kidney biopsy (PRB) is essential in establishing diagnosis and guides in the treatment of renal diseases. The procedure of kidney biopsy has evolved through technique and procedural refinements. Bleeding and its consequences are the most concerning complications of kidney biopsy. This is a UK renal centre experience to report the post-kidney biopsy bleeding complications.

Methods: We included all patients (inpatient and day case) who underwent PRB between January 2014 and Dec 2016. Biopsy was performed using a 16-gauge biopsy needle with a spring-loaded trigger device. Pre-biopsy parameters such as Blood pressure, haemoglobin, platelet counts and coagulation studies of patients were recorded. Data on kidney biopsy outcome were collected retrospectively. Bleeding complications were macroscopic hematuria, drop in haemoglobin requiring blood transfusion or requiring intervention radiology. Statistical analysis was performed.

Results: A total of 458 kidney biopsies were carried out with 58.9% male and 53.1% as day case. There was a 2.4% technical failure and 96.9% histological adequacy. Indications for kidney biopsy were acute kidney injury (37.1%), nephrotic syndrome (24.5%), proteinuria (17.7%) and hematuria (8.2%). Histopathology diagnoses were IgAN (12.2%), pauci-immune glomerulonephritis (10.4%), tubulointerstitial nephritis (9.3%), FSGS (7.6%), diabetic nephropathy (7.1%) and membranous glomerulonephritis (6.4%). Bleeding episodes were seen in 19(4.3%) with 3(0.6%) having haematoma and 1(0.2%) inpatient had embolisation. Day case (2.1%) compared to in-patient (6.8%) kidney biopsy and platelet count (>150 x 10^9) had less bleeding complication ($p< 0.05$). Mean serum creatinine is higher among in-patient kidney biopsy (361.93 ±216.41 vs. 151.21 ± 94.26, p= 0.005). In-patient kidney biopsy were older, had lower hemoglobin and higher INR ($p< 0.05$). Lower mean hemoglobin (104.42 ± 15.39 vs. 115.35 ± 21.03, p=0.025) and higher mean serum creatinine (413 ± 288.41 vs. 242.16 ± 185.72, p=0.005) were reported in those who had hematuria. We reported no nephrectomy or death.

Conclusions: We report a low post kidney biopsy bleeding complication. Day-case procedure has a lower rate of kidney biopsy bleeding complication when compared to in-patient kidney biopsy.

PUB255

Variation in Interpretation of 24-Hour Ambulatory Blood Pressure Monitoring (ABPM) in Children with Confirmed or Suspected Hypertension (HTN) by Canadian Pediatric Nephrologists and Cardiologists

Isabella Stefanova,[1] Abdulaziz A. Bamhraz,[2] Anne Fournier,[6] Kevin Harris,[5] Guido Filler,[3] Damien G. Noone,[4] Janis M. Dionne,[5] Rahul Chanchlani.[2] *[1]McMaster University, Hamilton, ON, Canada; [2]McMaster Children's Hospital, Hamilton, ON, Canada; [3]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [4]Sick Kids Foundation, Toronto, ON, Canada; [5]BC Children's Hospital, Vancouver, BC, Canada; [6]Universite de Montreal, Montreal, QC, Canada*.

Background: ABPM is more accurate compared to a single office-based blood pressure (BP) measurement. However, it is unclear how physicians interpret ABPM and make management choices, especially where evidence supporting recommendations is limited. This survey's goal is to study ABPM interpretation variation by HTN category and disease among pediatric nephrologists and cardiologists.

Methods: Survey content included physician demographics, ABPM indications, interpretation, and management. The same questions were asked of all respondents, except kidney-related conditions which were only shown to nephrologists.

Results: The survey was sent to 196 physicians, with 69 (35.2%) responses. Most respondents were age 45+, in practice for 11+ years and university-based. Table shows significant differences in ABPM interpretation for BP load, isolated systolic and diastolic HTN, and between nephrologists and cardiologists for different conditions (not all data included in abstract table). Rates of HTN treatment are lower than guidelines recommendations.

Conclusions: There is significant practice variation among physicians in ABPM interpretation and management. Gaps in guidelines create ambiguity regarding management decisions for different ABPM parameters. A more protocolized approach may help to standardize practice.

Initiation or alteration of antihypertensive treatment with respective ABPM parameters in various conditions

ABPM Parameter	Condition	Nephrologists (n=32)	Cardiologists (n=37)
Isolated systolic hypertension	Essential hypertension	19 (59.4%)	14 (37.8%)
	Congenital heart disease	27 (53.1%)	13 (35.1%)
	CKD stage 1-4/dialysis/kidney transplant	23 (71.9%)	n/a
	Renovascular hypertension	21 (65.6%)	
Isolated diastolic hypertension	Essential hypertension	9 (28.1%)	11 (29.7%)

An Electronic Health Record (EHR) Algorithm to Identify Patients with Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Eric Benz,[1] Amy Goodwin Davies,[1] Hanieh Razzaghi,[1] Lisa M. Guay-Woodford,[3] Charles Bailey,[1,2] Erum A. Hartung.[1,2] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Children's National Hospital, Washington, DC*.

Background: ARPKD is an important cause of pediatric chronic kidney disease, hepatic fibrosis, and portal hypertension. Its rarity makes it difficult to collect larger-scale natural history data and to identify patients for clinical trials.

Methods: We developed an EHR-based algorithm to identify ARPKD patients at a single site in PEDSnet (v3.9, 1/2009-7/2020), a national pediatric learning health system. A training/testing cohort consisted of 50 clinician-confirmed ARPKD patients and 150 non-ARPKD controls (enriched for patients with cystic/dysplastic diagnoses). A random forest was implemented to classify patients as cases and non-cases, with variable importance permutation-based, with high performance (precision 98%, recall 94%). The algorithm was applied to a denominator of 45,186 patients with either a nephrology visit, a GI visit + a liver diagnosis, or a NICU visit to classify patients as cases or non-cases. Two clinicians blinded to model case classification used a standardized form to review 97 patients with ≥1 ARKPD diagnosis (not included in original training/testing cohort) and classify them as ARPKD or non-ARPKD.

Results: The key model selection features were number of visits with an ARPKD diagnosis code and presence of a hepatic fibrosis diagnosis code. Table 1 shows patient characteristics. Of 97 patients reviewed, clinicians excluded 5 as indeterminate, and classified 56 as non-ARPKD and 36 as ARPKD [positive predictive value (PPV) of ≥1 ARPKD diagnosis 39%]. The algorithm identified 23 true positives, 17 false positives,

13 false negatives, and 39 true negatives; model performance: sensitivity 64%; specificity 70%; PPV 58%; negative predictive value (NPV) 75%.

Conclusions: An EHR-based algorithm improves PPV for identifying patients with ARPKD compared to diagnosis code alone and has relatively good NPV for excluding ARPKD in non-ARPKD patients with an ARPKD diagnosis code in their chart. Further chart reviews of incorrectly classified patients will allow algorithm refinement to improve performance.

Nitromethane Fuel Toxicity Causing False Elevation of Serum Creatinine

Vimal Master sankar raj, Megan Narula, Joanna Hrabia. *University of Illinois College of Medicine at Peoria, Peoria, IL.*

Introduction: Nitomethane along with methanol is a common component of model airplane fuel, rocket fuel and race car fuel. Reports of nitromethane exposure causing falsely elevated creatinine by its interference with the Jaffe reaction analysis has been reported in adult literature with limited pediatric data being available.

Case Description: 12 year old male with past medical history significant for major depressive disorder on prozac, H/o medium chain acyl-CoA dehydrogenase (MCAD) deficiency on a low fat diet and levocarnitine. Patient had prior admissions for self-harm and presented after ingesting about a mouthful of Torco race fuel. On initial evaluation in outlying ER, he was hemodynamically stable with heart rate of 97 per minute, respiratory rate of 16/min with saturations of 97% on room air and BP recorded at 130/67. Initial lab check showed a normal creatinine at 0.69 mg/dl. Patient was transferred to our hospital for administration of fomepizole as methanol is a main component of Torco race fuel. On arrival, repeat labs in 5 hours showed an increase in creatinine to 1.73, which slowly started coming down to 1.39, 48 hours into admission. He remained normotensive through the course of stay and further studies including urine studies for protein came back normal. No azotemia and blood urea nitrogen remained normal at 13-15 mg/dl through the length of stay. Cystatin -C levels done on hospital transfer returned normal at 0.68 mg/L. With serum methanol levels returning negative, patient was transferred to inpatient psychiatry ward.

Discussion: This is a pediatric case report on Torco race fuel ingestion in which the ingredient nitromethane ($CH_3 NO_2$) caused a false elevation of serum creatinine. The standard assay for creatinine uses the Jaffe reaction, where interaction happens between creatinine and alkaline picrate. Nitromethane by its reactive methyl component interacts with alkaline picrate producing a cromophore that closely resembles the creatinine picrate complex, causing false elevation of creatinine. Enzymatic assay of creatinine, which is not widely used will not get affected by nitromethane. False elevation of creatinine in a patient with methanol and nitromethane ingestion can force the physician to do unnecessary procedures such as dialysis and should be kept in mind.

PUB258

Long-Term Renal Outcomes of Congenital Ureteropelvic Junction Obstruction

Alexandra Stewart, John S. Thurlow, Stephen W. Olson, Brent L. Lechner, Sarah Khan, Erin D. Parker, Maura A. Watson, Christina M. Yuan, Robert Nee. *Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Congenital ureteropelvic junction obstruction (UPJO) is often diagnosed in adulthood. Current literature is lacking in evaluation of long-term renal outcomes for adult patients with UPJO.

Methods: We queried service members diagnosed with UPJO from the U.S. Military Health System electronic health records. We assessed demographic, laboratory, radiology, stenting/pyeloplasty and outcome data. We assessed the impact of intervention regarding development of chronic kidney disease (CKD) with estimated glomerular filtration rate (eGFR)<60ml/min/1.73m$^{2)}$, hypertension (HTN) (blood pressure >130/80mmHg), and changes in renal excretory function on radionuclide scans.

Results: We identified 108 individuals diagnosed with congenital UPJO; mean follow-up of 7 years. 55% had right-sided, 40% left-sided and 5% bilateral UPJO. Mean age at diagnosis was 25 years (n=10 at <18 years; n=98 at ≥ 18 years); 95% male; 69% White, 15% Black. At diagnosis, mean BP was 130/78 mmHg; mean eGFR 86ml/min/1.73m^2; and 22% had proteinuria ≥ 30mg/dL. 85.2% had pyeloplasty and 23.4% had lone stent placement. 14% developed eGFR<60 ml/min/1.73m2. 9.5% of patients with intervention developed stage 3 CKD vs. 21.4% of those without intervention (p=0.42). Intervention was not associated with development of HTN in adjusted logistic regression analysis (OR 0.30, 95% CI 0.08-1.20). Intervention significantly reduced the proportion of patients with delayed cortical excretion and T½ emptying time with right-sided UPJO only (Table).

Conclusions: Approximately 14% of our young adult cohort with congenital UPJO developed CKD. Intervention improved cortical excretion and T½ emptying time with right-sided UPJO only. The views expressed are those of the authors and do not reflect official policy of the Dept of the Army/Navy/Air Force, Dept of Defense, or US government.

Variables	Pre Procedure	Post Procedure	P value
Left sided and bilateral UPJ obstruction			
Kidney size (ultrasound), cm (n=8)	13.1	12.7	0.22
Differential function (%) (n=35)	42.6	43.1	0.83
Delayed cortical excretion	18/33 (55%)	11/30 (37%)	0.06
T½ emptying time (Lasix scan), min (n=28)	24.1	22.8	0.78
Right sided and bilateral UPJ obstruction			
Kidney size (ultrasound), cm (n=11)	13.0	12.1	0.08
Differential function (%) (n=41)	39.0	38.6	0.77
Delayed cortical excretion	22/41 (54%)	16/44 (36%)	0.01
T½ emptying time (Lasix scan), min (n=31)	33.2	20.0	0.018

Prevalence of Secondary Hypertension in Children with a New Diagnosis of Hypertension: A Meta-Analysis

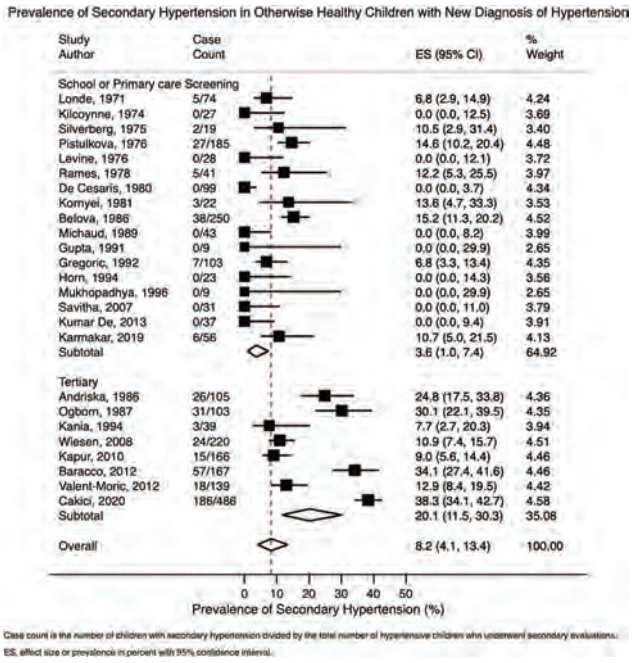
James Nugent, Chelsea R. Young, Melissa C. Funaro, Lama Ghazi, Francis P. Wilson, Jason H. Greenberg. *Yale University School of Medicine, New Haven, CT.*

Background: Secondary hypertension (HTN) in children is associated with an increased risk of end organ damage and treatment resistance. For asymptomatic children with HTN identified on screening, the prevalence of secondary HTN is unknown.

Methods: MEDLINE, EMBASE, Web of Science, and Cochrane Library were searched for studies reporting rates of secondary HTN in children aged 0-19 years who underwent evaluation for HTN. We identified studies that diagnosed HTN based on at least 2 outpatient blood pressure readings and included children without any known comorbidities associated with HTN. Two authors independently extracted the study-specific prevalence of secondary HTN in children with HTN of unknown cause. Prevalence estimates were pooled in random effects meta-analysis.

Results: For the 18 prospective and 7 retrospective studies included, there was a median of 56 (range, 9-486) participants with HTN in each study. Although studies applied different diagnostic criteria for HTN, 20 of 25 studies used a blood pressure percentile-based approach. The pooled prevalence of secondary HTN was 8.2% (95% CI: 4.1-13.4%). Studies conducted in primary care or school settings reported a lower prevalence of secondary HTN (3.6% [95% CI: 1.0-7.4%]) than studies conducted in referral clinics (20.1% [95% CI: 11.5-30.3%]). When stratified by study setting, there were no significant subgroup differences according to study design, participant age range, HTN definition, blood pressure device, or study quality.

Conclusions: The low prevalence of secondary HTN in otherwise healthy children with a new diagnosis of HTN reinforces current guidelines to avoid extensive diagnostic testing for secondary causes in most hypertensive children ≥6 years old.



PUB260

Building the Bridge Between Pediatric and Adult Nephrology: A Quality Improvement (QI) Approach for Health Care Transition (HCT)

Sahar Siddiqui,[1,2] Cortney T. Zimmerman,[1,2] Constance M. Wiemann,[1,2] Sai Kaumudi Saridey.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: HCT from pediatric to adult-focused care in patients with renal disease continues to be difficult, we know that an inadequate HCT process can lead to poor patient outcomes. Various studies have demonstrated utilization of a HCT clinic as a means to improve communication and satisfaction between adolescents/young adults (AYA) and providers. This abstract highlights a QI approach conducted in the pediatric nephrology department of a children's hospital in collaboration with adult nephrology providers at an affiliate hospital in the Southwestern USA.

Methods: A dedicated transition team was created at the pediatric nephrology section which participated in transition needs assessment (Fig. 1). Part of this assessment involved surveys to pediatric faculty (n = 14), who rated the current transition process. A pilot group of patients was proposed to lead this effort with initiation of a novel form of transition clinic; 2-step transition clinic to tackle lack of a dedicated transition clinic. This clinic provides patient interaction with their renal providers and multi-disciplinary support in at least two different health care settings, pediatrics followed by adult.

Results: Multiple barriers were identified by initial needs assessment including lack of standardized transition procedure. Ease of transition was rated as 2.5 out of 5 (a 5 being easiest transition). During this endeavor, our team was able to build a framework for HCT along with strengthening ties with our adult colleagues. We collected surveys from patients at the time of 2-step transition clinic (n= 10) which was overall reassuring however 50% of the patients felt "somewhat ready for transition" highlighting the need for better transition preparedness.

Conclusions: The needs assessment underscores areas to target for intervention. We propose that implementation of the new standardized process including our 2-step transition clinic will result in enhanced patient satisfaction and HCT outcomes with potential areas for improvement.

PUB261

Clinicopathological Characteristics of Focal Segmental Glomerulosclerosis (FSGS) in a Pediatric Patient Population

Kenneth V. Lieberman,[1] Clint Abner,[2] Kerime Ararat,[2] Patrick D. Walker,[2] Amin Yakubu,[3] Martin C. Bunke.[4] *[1]Hackensack University Medical Center, Hackensack, NJ; [2]Arkana Laboratories, Little Rock, AR; [3]Genesis Research, LLC, Hoboken, NJ; [4]Travere Therapeutics Inc, San Diego, CA.*

Background: FSGS is a major cause of steroid resistant nephrotic syndrome and is a major cause of end stage renal disease in children. FSGS may progress to chronic kidney disease if untreated, however, treatment is only ameliorative. Few studies are available that characterize the histological and clinical features of FSGS in pediatric patients (pts) at time of kidney biopsy.

Methods: A retrospective cohort study was performed within the Arkana Biopsy database (January 1, 2016 to May 31, 2020) among pediatric pts who met the following study criteria: ≤17 years of age, ≥1 FSGS positive biopsy, and no prior kidney transplant. Outcomes evaluated included clinical and histologic characteristics.

Results: Of 3,157 renal biopsies performed among pts ≤17 years during the study period, 167 (5.3%) FSGS cases were identified, and 164 pts evaluated met study criteria. In this sample, 44.5% were female and mean (SD) age at biopsy was 11.4 (4.8) years. About one third of pts were White (33.5%), 25.6% African American, 12.2% Hispanic and 1.2% Asian. Median (Q1 - Q3) urine protein to creatinine ratio/24-hour urine protein for 61.0% of patients with available data was 3.0 (1 - 9) g/g, and approximately a third of pts (34.2%) had a diagnosis of hypertension. The majority of pts had absent/no comment indicated for arteriosclerosis (82.3%) and arteriolosclerosis (90.9%) and nearly half of FSGS pts (49.4%) had severe foot process effacement (≥80%). The most common FSGS type was "not otherwise specified" (71.3%), while 13.4% of pts had tip lesion, followed by perihilar (8.5%) and collapsing (6.7%) FSGS. Approximately 25.0% of pts had 0% interstitial fibrosis and tubular atrophy (IFTA), 52.4% had 1-<25% IFTA, 17.1% had IFTA 25%-<50% and 4.9% had IFTA ≥ 50%. Most pts (79.3%) exhibited <25% glomerular sclerosis while 9.2% had ≥50% GS.

Conclusions: FSGS in this pediatric population was associated with low degrees of glomerular sclerosis, interstitial fibrosis and tubular atrophy, but severe foot process effacement was common. When comparing to data reported in a companion abstract in adult pts with FSGS, the lower levels of sclerosis and fibrosis observed in these pediatric FSGS pts, suggest that early and effective intervention could potentially aid long term renal survival.

Impact of Hypertension on Health-Related Quality of Life in Childhood-Onset Systemic Lupus Erythematosus

Kristianna A. Singh, Marietta De guzman, Alisa A. Acosta, Cortney T. Zimmerman, Scott E. Wenderfer. *Baylor College of Medicine, Houston, TX.*

Background: Childhood oneset SLE can significantly impact Health-related quality of life (HRQOL) due to disease manifestations and its associated therapies. Hypertension is another chronic disease that can impact the HRQOL in children despite its "silent nature." In cSLE, secondary HTN can occur in up to 70%, due to nephritis and/or medications (i.e. steroids). We aim to assess the impact of HTN on HRQOL in patients diagnosed with active SLE aged 7-18 years in the Texas Children Hospital (TCH).

Methods: A total of 10 subjects met inclusion criteria: diagnosis of SLE as determined by a Pediatric Rheumatologist, age 7-18 years, new onset disease or flare from 11/2020 to 4/2021. Subjects were excluded if unable to complete the questionnaire, BMI >32, or eGFR<60. We classified hypertension using ambulatory BP monitoring (ABPM). HRQOL was measured by both patient and parent proxy using disease-specific SMILEY© (Simple Measure of Impact of Lupus in Youngsters) tool. We used Jamovi software to analyze demographic data.

Results: Median age was 17 (IQR 13-18) years. HTN was diagnosed in 40% by casual BP measurement and 70% by ABPM. Median Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score was 13(10-18). Median SMILEY score was 60 (57-64). While there was no clinically significant differences in the parent report scores, patients with attenuated nocturnal BP dipping had lower child reported scores (Table1). Child reported SMILEY© scores correlated inversely with Mean 24hr systolic and diastolic load (r=-0.7, -0.9), mean wake SBP and DBP load (r=-0.7, -0.7), and sleep DBP load (r=-0.76).

Conclusions: In cSLE, ambulatory BP patterns significantly impact HRQOL. These initial conclusions suggest that HTN may impact HRQOL in cSLE.

Table 1 Median SMILEY© scores stratified by nocturnal BP dipping status at enrollment.

	ABPM Diagnosis	All=10 (IQR)	Normal Dipping (N=5)	Attenuated Dipping (N=5)	Absolute Mean Difference (SED)
Child Report	Global HRQoL	4 (3-4)	4	4	0 (0.3)
	Global SLE	3(3-4)	3	4	-1(0.1)

Parenteral Iron and Erythropoietin Effects on FGF-23 and Cardiac Function in Young Dialysis Patients

Wacharee Seeherunvong, Sethuraman Swaminathan, Chryso P. Katsoufis, Marissa J. Defreitas, Jayanthi Chandar, Carolyn L. Abitbol, Michael Freundlich. *University of Miami School of Medicine, Miami, FL.*

Background: Elevated fibroblast growth factor 23 (FGF23) levels are associated with left ventricular hypertrophy (LVH) and diastolic dysfunction (DD). Recent preclinical and adult studies have shown that parenteral iron (Fe) supplementation and erythropoietin (EPO) may increase FGF23 production and circulating levels. Whether treatment with EPO or Fe could increase FGF23 levels and adversely contribute to LVH and DD in pediatric patients maintaining hemodialysis (HD) remains largely unknown.

Methods: Adolescents (n=20, median age 16 years) maintained on HD (average dialysis vintage 30 ± 17 months) were studied. All were treated with EPO, with or without concomitant parenteral Fe sucrose and all received intravenous paricalcitol for secondary hyperparathyroidism. C-terminal FGF23 (cFGF23), biochemical markers, and sequential echocardiograms (conventional and tissue Doppler, ECHO) were analyzed longitudinally twice, 6 months apart. LV dimensions, including IVST (interventricular septal thickness) and markers of diastolic function with peak early (E), late (A) diastolic flow velocities, and corresponding mitral annular velocities (Em, Am) were measured, and adjusted to Z-scores according to age and gender.

Results: Whereas the cumulative average EPO dose was similar in Fe-treated and untreated patients (10,056 ± 5,445 and 10,818 ± 7,935 Units/week/6 months, respectively), the initial and final cFGF23 levels remained similarly elevated in both groups. Prevalence of DD improved from 22% to 12% during the study period. LogFGF23 values correlated with Am (r= -0.7) and Em/Am (r= 0.7) Z-scores (both $p<0.05$) in Fe-treated patients. The doses of EPO and Fe did not correlate with markers of diastolic function, but EPO correlated with the IVST Z-score (r= 0.7, $p<0.05$). The cumulative paricalcitol dose did not correlate with markers of diastolic function but inversely correlated with IVST Z-score (r= -0.5, $p<0.05$)

Conclusions: Treatment with EPO, irrespective of parenteral Fe supplement, hemoglobin, and ferritin levels did not result in consistent elevations of cFGF23 levels. While the FGF23 levels correlated with worsen markers of diastolic function, the overall prevalence of DD improved overtime. The administration of paricalcitol may have contributed to the improvement of DD and the LVH.

Is It Time to Update the Age-Specific Pediatric Normative Serum Creatinine Ranges?

Vimal Chadha, Uttam Garg, Uri S. Alon. *Children's Mercy Hospitals and Clinics, Kansas City, MO.*

Background: Diagnosis of abnormal kidney function is routinely based on serum creatinine (SCr) value. SCr in children increases with growth and normative values therefore vary with age. However, due to lack of availability of large number of blood samples from healthy children, most laboratories combine the SCr reference ranges in up to 5-year age group blocks, resulting in an upper limit that can be 2.3 to 2.6 times higher than the lower limit for that age block. As a result, a child with subnormal kidney function (GFR < 90 mL/min/1.73m2) who is near or at the younger end of the age in a specific age group block, can still have SCr value below the upper limit of reference range and thus will remain unflagged on the reported result. This may result in a missed diagnosis of decreased kidney function. Similarly, a diagnosis of acute kidney injury (SCr increase >1.5 above baseline) can also be missed as the increased SCr value can still fall within the reference range for that age group. In research studies, missing baseline creatinine values are customarily back calculated from eGFR equations with a presumed GFR of 120 mL/min/1.73m2. Our objective was to calculate age specific SCr reference ranges for children 2 – 18 years, and copmpare them with current age group block reference ranges.

Methods: We used bedside Schwartz equation (eGFR = height*0.413/SCr, where 0.413 is the constant k) to calculate estimated creatinine (eCr) = height*0.413/GFR. We calculated the eCr reference ranges by inserting 3rd percentile for height and GFR of 120 mL/min/1.73m2 for the lower limit, and by inserting 97th percentile for height and GFR of 90 mL/min/1.73m2 for the upper limit. Height values for respective ages were obtained from the CDC reference charts.

Results: The calculated theoretical reference ranges are shown in the Table. The upper limit of eCr values are only 1.6 times higher than the lower limit in contrast to the current reference ranges where the upper limit is 2.3 to 2.6 times higher than the lower limit for its age group block.

Conclusions: We believe that by switching from age group blocks to age specific normal SCr ranges the possibility of missing subnormal kidney function will be minimized. The calculated values need to be further validated.

Are Mutations in the Alpha-Hydroxy Acid Oxidase (HAO1) Gene Not as Harmless as Described?

Bernd Hoppe,[1] Luisa Averdunk,[3] Kathrin Buder,[2] Cristina Martin Higueras.[1] *[1]German Hyperoxaluria Center, Bonn, Germany; [2]University Childrens Hospital Zurich, Zurich, Switzerland; [3]University Childrens Hospital Düsseldorf, Düsseldorf, Germany.*

Introduction: Alpha-hydroxy acid oxidase (*HAO1*) catalyzes the oxidation of glycolate into glyoxylate in hepatic peroxisomes. Patients with homozygous *HAO1* mutations have massively elevated urinary glycolate excretion (Uglyc), but are said to be clinically asymptomatic.

Case Description: We present three pediatric patients, who either developed clinical sequelae, here urolithiasis (UL), or surprisingly had hyperoxaluria. First patient now 10 years of age, developed UL at age 6 years, which was treated by lithotripsy (stone analysis: 100% whewellite). Currently, he has 2 small stones in left kidney. Recent 24 h urine excluded elevated urinary oxalate excretion (UOx, 0.35-0.43), but high glycolate UGlyc (3.34-4.78 mmol/1.73m^2/d). His grandfather also had recurrent UL, but normal Uox and Uglyc. Patient 2 was 6 months of age at diagnosis of elevated Uox and Uglyc (1.37 and 7.01 mmol/1.73m^2/d, respectively). He has 3 relatives with a history of UL, elevated Uox/creatinine ratio was found in 2/3, and in the boys mother. Genetic evaluation for primary hyperoxaluria (PH) was negative. In patient 3 screening for organic acids detected elevated Uox: 1.56 and Uglyc: 7.04 mmol/1.73m^2/d. Genetic testing for PH was negative. Vitamin B6 though let to decline in Uox. Uglyc remained significantly elevated. Homozygous (family) mutations in *HAO1* were found also in parents, sister and in newborn brother. Father and sister also had elevated Uox (1.09 and 0.92) and Uglyc (4.19 and 4.75 mmol/1.73m^2/d). The newborn has a massively elevated Uglyc/creatinine ratio, but no hyperoxaluria.

Discussion: In the contrary to current understanding, patients with *HAO1* mutations can express a renal phenotype. We do not have an adequate explanation for UL in patient 1, as only Uglyc is elevated and no other risk factor is found. GO inhibition is used as therapeutic target in patients with PH1, which reduces Uox, but elevates Uglyc. Even more problematic to explain is the significant hyperoxaluria in patients 2 and 3 (after excluding secondary reasons). Therefore, the link between *HAO1* (loss of function) mutations and UL, or hyperoxaluria, respectively, clearly needs further clarification.

PUB266

Characterization of Adolescents with Persistent Albuminuria in a Region with a High Prevalence of ESRD of Unknown Etiology

Jose M. Arreola Guerra, María T. Tiscareño Gutiérrez, Ana L. Reza Escalera, Andrea Natalia A. Nájera, Dulce María Macias-Díaz. *Centenario Hospital Miguel Hidalgo, Aguascalientes, Mexico.*

Background: We report high prevalence of ESRD of unknown etiology. Affected group was between 20 and 30 yo. We screen adolescents for chronic kidney disease (CKD).

Methods: Pts with Albuminuria-creatinuria ratio (ACR) ≥30 mg/gr or GFR ≤75 ml/min were reevaluated. Ultrasound (US) and tomography were performed. Renal bx was performed in pts with persistent albuminuria (PA).

Results: We include 482 pts, mean age 13.3(±1.5), 53.9% were male. We detect 17 pts (3.53%) with PA. US did not show abnormalities. 16 bx were performed.(Table1)

Conclusions: The characteristics of the biopsies are suggestive of established histological damage. Potential genetic and contaminants should be searched.

More Than "Getting High," Be Aware of Cannabis-Induced AKI: A Report of Two Pediatric Cases

Ashley L. Dojcsak,[1] Victoria S. Cox,[1] Sai Sudha Mannemuddhu.[2,3] *[1]Lincoln Memorial University, Harrogate, TN; [2]East Tennessee Children's Hospital, Knoxville, TN; [3]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

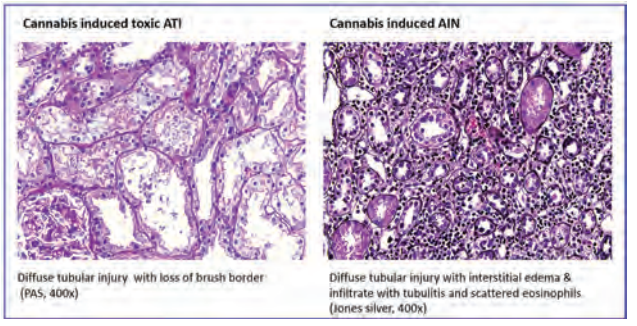
Background: Cannabinoids (synthetic > natural) can have deleterious effects on kidneys. We report 2 cases of cannabis-induced acute kidney injury (AKI) with acute tubular necrosis (ATN) and acute interstitial nephritis (AIN).

Methods: Case Series

Results: Two adolescents were cared for in 2021, presented with elevated serum creatinine (S. Cr). At presentation S. Cr was 1.7- 5.4 mg/dL, peaked at 5.4-6.6 mg/dL. Both patients developed acidosis. Patient 2 had hypokalemia, hypophosphatemia, and hypomagnesemia. Urine drug screen was positive for cannabinoids. Both patients admitted to using natural cannabis predominantly and smoking cannabis joints daily for a few weeks- a month prior to admission. Urinalysis showed proteinuria, leukocyturia, heme+ without RBCs in urine, hyaline casts. Renal bladder sonogram: echogenic kidneys. Kidney biopsy revealed ATN in patient 1 and AIN in patient 2 (Fig2). ATN was managed conservatively, while the patient with AIN received steroids. Both patients responded well with improvement in kidney function.

Conclusions: Though the endocannabinoid system (ECS) has been found to play a beneficial role in renal homeostasis and improvement of tubular cell survival; long-term stimulation and alterations to the ECS can lead to kidney damage as reported here. It is interesting to note that 2 patients predominantly used natural cannabis and reported that they assumed that natural cannabis is safe. A thorough history including drug use should be obtained in cases of AKI, particularly where the cause is not apparent and AKI does not improve with hydration. Awareness of this could lead to early diagnosis, management, and appropriate counseling, which might potentially decrease kidney damage and scarring.

		Patient 1	Patient 2
Age (yrs)		16	15
Ethnicity		Caucasian	Caucasian
Gender		Male	Male
Drug usage		Cannabis joints & synthetic cannabis	Cannabis joints & synthetic cannabis
S. creatinine (mg/dL)	At admission	1.7	5.4
	Peak	5.4	6.6
	At discharge	1.4	3.1
Serum Electrolytes	Potassium	Low-normal	low
	Magnesium	normal	low
	Phosphorus	normal	low
	Bicarbonate	low- normal	low
Serum complement (mg/dL)		C3: 112, C4: 13.4	C3: 167, C4: 31.8
CBC			Normal WBC count. No eosinophilia
Urinalysis		2+ protein, 2+ blood, 8 RBCs/HPF, 10 WBCs/HPF, no glucose or casts	SG 1.006, pH 6.5, 1+ protein, trace blood, 1 RBCs/HPF, 35 WBCs/HPF, 1+ Glucose, 1+ ketones, 4 hyaline casts
Kidney & bladder sonogram		Isoechoic kidneys (RT 12.0 cm, LT 12.1 cm)	Hyperechoic kidneys (14 cm each)
Biopsy	diagnosis	Severe toxic ATN	Acute interstitial nephritis
	LM	diffuse dilation and vacuolization involving 80-90% tubular profiles. Normal glomeruli.	Diffuse (70-80%) lymphocyte predominant AIN with edema & scattered tubulitis with scattered eosinophils (up to 20) involving ~30% tubules. Normal glomeruli.
	EM	2+ global granular mesangium with segmental chunky capillary loop deposits for C3	No immune complex staining.
	IF	Mild increase on GBM thickness. No subepithelial or subendothelial or mesangial deposits. No TBM immune complex deposits.	Normal GBM without any sub epithelial or sub endothelial deposits. Interstitium shows edema, lymphocytes, with deposits along TBM.
Management		Conservative. - Ionotropic PRN for about a week. - Fluid restriction followed by generous fluid intake.	- Solumedrol 1g IV daily x 3 days → daily prednisone 60 mg x 4 weeks. - Magnesium, Potassium, Bicarbonate supplementation temporarily. - Correction of Vitamin D deficiency
Effects on other organs		Seizures at presentation that resolved after admission. EEG normal. Not on anti-epileptic medications.	Cannabis hyperemesis syndrome
Outcome		Discharged to out of state hospital	Follow up and complete recovery



PUB268

Involvement of Succinate Dehydrogenase (SDH) in Deceased Kidney Donors' Inflammation

Elena Guillen-gomez,[1] Irene Silva,[1] Carla G. Solana,[1] Jordi Vilardell,[1] Brenno D. Astiarraga,[2] Sonia Fernandez-Veledo,[2] Francisco Caballero,[3] Jesus L. Cebrecos,[3] Carme Facundo,[1] Yolanda Arce,[1] Lluis Guirado,[1] Montserrat M. Diaz Encarnacion.[1] *[1]Fundació Puigvert, Institut Investigació Biosanitaria SantPau, University Autonomous of Barcelona (UAB), REDinREN, Fundación Renal Iñigo Álvarez de Toledo (FRIAT), Barcelona, Spain, Barcelona, Spain; [2]Department of Endocrinology and Nutrition, Hospital Universitari de Tarragona Joan XXIII, Institut Investigacio Sanitaria Pere Virgili (IISPV), Tarragona, Spain, CIBERDEM–Instituto de Salud Carlos III, Madrid, Spain, Tarragona, Spain; [3]Hospital de la Santa Creu i Sant Pau, Universitat Autonoma de Barcelona, Barcelona, Spain, Barcelona, Spain.*

Background: Succinate is a Krebs cycle intermediate that is converted to fumarate by succinate dehydrogenase (SDH). SDH activity depends indirectly on the oxygen availability. In deceased renal donation, hypoxia associated to ischemic process can increase renal succinate formation and induce the infiltration of immune cells producing TNF-α, increasing inflammation, renal epithelial apoptosis, as well as leukocyte recruitment, binding and migration, which can lead to renal graft damage. Moreover, increased levels of IL-1β promoting inflammation. We aim to demonstrate that succinate pathway is an important player in early and late inflammation in deceased kidney transplants.

Methods: Relative gene expression of SDH complex genes (SDHA, SDHB, SDHC and SDHD), HIF-1a and inflammatory factors were quantified by qPCR in RNA samples from deceased donors. Succinate levels were measured in serum from deceased kidney donors at the time of donation.

Results: Circulating succinate levels in serum from deceased donors were significantly higher than in healthy volunteers ($p=0.002$). In kidneys samples from deceased donors, gene expression of all four subunits of SDH complex were downregulated before transplantation ($p<0.001$ for all of them) whereas HIF-1α was increased compared to living donors ($p<0.001$). SDHA, SDHB and SDHD gene expression at 4 months after kidney transplant is positively correlated with graft renal function (CKD-EPI). In kidneys from deceased and living donors, SDHA, SDHB and SDHD are negatively associated with recruitment (MCP-1), adhesion (ICAM-1) and activation (IL-1β) of monocyte.

Conclusions: Our results indicate that low gene expression of SDH in kidneys from deceased donors could result in reduced activity of SDH that would reduce the ability to transform succinate to fumarate resulting in succinate accumulation, increasing inflammation that can influence on kidney transplantation outcomes.

PUB269

Lymphoproliferative Disease After Kidney Transplantation: Describing Our Experience

Raquel B. Rico. *Hospital 12 de Octubre, Madrid, Spain.*

Background: Post-transplant lymphoproliferative disorders (PTLD) are one of the most common malignancies in kidney transplant (KT) recipients. Immunosuppressive therapy and Epstein Barr Virus (EBV) play a main role in their pathogenesis.

Methods: In this study we retrospectively analyze the characteristics, clinical evolution and treatments of a group of KT recipients performed between 1986 and 2020 in a single center.

Results: We included 31 patients (64.5% males). Polycystic kidney disease was the most frequent cause of renal failure. Before KT a 6.5% of the patients presented another malignancy, 10% were EBV seronegative and one received immunosuppressive therapy secondary to his primary disease. Mean age at KT was 43±12 years. 68% of the KT came from brain-dead donors. The most frequent immunosuppressive regime consisted in tacrolimus, mycophenolic acid and prednisone (61.3%). Basiliximab and Timoglobulin were used in the same proportion for the induction therapy (22.6%). Before PTLD appearance the immunosuppressive therapy was reduced in the 54.8% of the recipients. 13% of them presented acute allograft rejection. The majority of PTLD were diagnosticated between 2016 and 2020. Median time to develop PTLD was 13 years. 54.3% of the patients presented with extranodal involvement. Although all the patients positivized EBV serology, 60% of them had undetectable EBV viral load. The main therapeutical strategy after PTLD consisted in a reduction of the immunosuppressive

therapy. In this way, 28.6% of the recipients was treated with monotherapy with a calcineurin inhibitors and 21.5% with monotherapy with a mTOR inhibitor. In other hand 16.7% received a combination of tacrolimus with a mTOR inhibitor. Rejections were not observed in our group and all the patients presented a preserved kidney function at the end of follow up. Four recipients died because of PTLD. The remaining 27 presented a complete response or stabilization of the disease.

Conclusions: Most of the PTLD were detected between 2016-2020. The time from transplantation to PTLD appearance was long, being EBV viral load negative in the majority of the cases. Graft survival after chemotherapy and reduction of immunosuppressive therapy was excellent, with a low risk of rejection and a good prognosis for hematologic disease. It is possible that a reduction in immunosuppression in selected patients could prevent the development of PTLD.

PUB270

Shorter Antibody-Mediated Rejection-Free Survival in Persistence Preformed DSA vs. Clearance After Kidney Transplantation: A Single-Center 10-Year Experience in Thailand

Theerachai Thammathiwat,[1,2] Suwasin Udomkarnjananun,[1,3] Yingyos Avihingsanon,[1,3] Kearkiat Praditpornsilpa,[1,3] Natavudh Townamchai.[1,3] *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Naresuan University Faculty of Medicine, Phitsanulok, Thailand; [3]Excellence Center for Solid Organ Transplantation King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Preformed donor specific anti-HLA antibodies (pre-KT DSA) is one of the leading causes of post kidney transplant antibody mediated rejection (ABMR). Decrease level of pre-KT DSA by pre-transplant desensitization is one of the best available methods to lower risk of ABMR after transplantation. Post-transplant follows up of DSA to determine the persistence or clearance of DSA should reflect transplant outcomes. This study aimed to compared outcomes between patients who have persistence and patients who have clearance of DSA after kidney transplantation.

Methods: This retrospective cohort enrolled pre-KT DSA positive (CDC-AHG negative) kidney transplant recipients (KTR) at King Chulalongkorn Memorial Hospital from 2009 to 2018. Post-transplant DSA was tested by Luminex single-antigen assays and divided patient in to two groups 1) DSA clearance (<1000 MFI) and 2) DSA persistence (>1000 MFI). The outcomes were evaluated that comprise biopsy-proven acute rejections, including acute antibody-mediated rejection (ABMR) and acute T cell-mediated rejection (TCMR), subclinical or borderline rejections, and graft loss and mortality. Complications following KT and other associated risks were also assessed.

Results: There were 47 KTR enrolled. The mean pre-KT DSA (MFI) level was 931.37. Sixty percent of patients underwent pre-transplant desensitization. The median follow-up time was 5.7 years after transplant. The persistence DSA group (n=17) had higher rate of ABMR than DSA clearance group (n=30), with hazard ratio (HR) of 4.47 (95% CI, 1.48 – 13.45, p=0.008). Factors associated with persistence DSA include the recipient's age of over 40 years old, higher number of HLA A/B/DR mismatch, and lower tacrolimus levels at six months.

Conclusions: DSA should be monitored in kidney transplant patient with pre-KT DSA. The persistence of pre-KT DSA after kidney transplantation is associated with higher rate of ABMR. Surveillance allograft biopsy should be performed in patient with persistence DSA for early detection of rejection.

PUB271

Angiosarcoma in a Kidney Transplant Recipient with Fibrillary Glomerulonephritis

Mohammad Atari, Jessica Friedman, Anil S. Paramesh, Sixto G. Giusti. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Kidney transplant recipients are at increased of developing malignancy. Angiosarcomas (AS) are aggressive tumors arising in either blood or lymphatic vessels. Fibrillary glomerulonephritis (FGN) has been described in the setting of malignancies. Here we present a case of metastatic angiosarcoma that developed in a patient with a history of end-stage kidney disease (ESKD) secondary to FGN.

Case Description: A 66-year-old female with ESKD secondary to FGN underwent a five-antigens mismatch living unrelated donor kidney transplant with thymoglobulin and methylprednisolone induction. Pre-transplant workup showed no malignancy. Immunosuppression included tacrolimus, mycophenolic acid, and prednisone. Three months post-transplant, she had a scalp lesion diagnosed as eczema, which improved partially with topical steroids. Four months post-transplant, the lesion increased in size and developed abdominal discomfort with distention. Imaging showed widespread lymphadenopathy, numerous liver lesions, splenomegaly, and ascites. An excisional lymph node biopsy from the neck revealed AS. She developed acute kidney injury with gross hematuria. Urine microscopy revealed numerous intact RBCs but no other abnormal findings. Due to volume overload with low serum albumin (2 g/dl), she was given intravenous albumin and furosemide, and her creatinine improved. Tacrolimus and mycophenolate were stopped, and sirolimus was started. Weekly paclitaxel was initiated, but she developed febrile neutropenia and deconditioning after the second dose, for which she opted out for further chemotherapy. Nine months post-transplant, follow-up showed dramatic clinical improvement with complete resolution of scalp lesions. Imaging showed markedly decreased conspicuity of low attenuation observations in the liver and a marked decrease in mesenteric and retroperitoneal lymphadenopathy. Kidney function remained at baseline.

Discussion: Angiosarcoma is a rare yet aggressive tumor with a poor prognosis in kidney transplant recipients. Here, the dramatic response may have resulted from lowering immunosuppressive drugs and starting chemotherapy. However, the anti-angiogenic activity of mTOR inhibitors is a possible explanation. Most reported AS cases developed from arteriovenous fistulas in kidney transplant patients. This is the first case of AS with FGN with an unexpected dramatic improvement.

PUB272

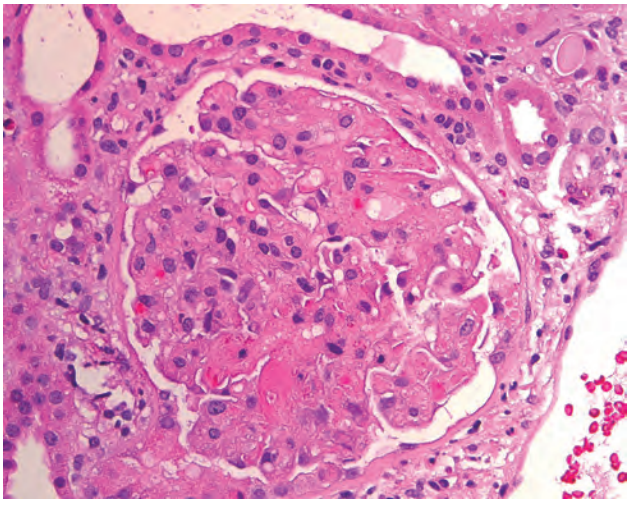
Recurrence of Scleroderma Renal Crisis After Kidney Transplantation

Juan P. Portocarrero Caceres, Cybele Ghossein, Yashpal S. Kanwar. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Diffuse cutaneous Systemic Sclerosis (dcSSc) is a disease of generalized inflammation, vascular damage, and organ fibrosis. Scleroderma Renal Crisis (SRC), one of the most devastating complications of dcSSc occurs in 5-20% of patients and leads to end stage renal disease (ESRD) 20-50% of the time. SRC is characterized by malignant hypertension and acute kidney injury (AKI). Thrombotic microangiopathic anemia (TMA) and heart failure (HF) can also be seen. SRC patients with ESRD can undergo kidney transplantation (KT) with excellent graft survival. Recurrence of SRC in KT is very rare presumably because the renal vasculature is from a donor kidney without dSSc. We report a case of SRC in a patient post KT

Case Description: A 52-year-old male-to-female transgender patient with a history of ESRD due to SRC, who had a living unrelated KT 2 months prior to admission is admitted hypertension and pulmonary edema. She was found to have HF with reduced ejection fraction (37%) a new pericardial effusion and AKI. Kidney biopsy showed arterioles with thickened walls, bland arteriolitis with semi occlusive changes. She was diuresed and discharged home. She returned 2 weeks later with microangiopathic hemolytic anemia, thrombocytopenia, and worsening kidney function. Repeat kidney biopsy was consistent with TMA. Given her clinical presentation and her biopsy findings, a presumptive diagnosis of SRC was made. The patient was also found to have an antibody-mediated graft rejection. She received captopril, multiple sessions of PLEX, eculizumab, and belatacept, without response. She was initiated on dialysis where she remains today.

Discussion: SRC post KT is unusual but should be considered in the differential of AKI in the right clinical setting. Active dcSSc disease, use of steroids and calcineurin inhibitors may increase the risk of post transplant SRC



PUB273

Kidneys with Kidney Donor Profile Index (KDPI) >85% Can Be Used Successfully in Older Recipients

Muna Alnimri. *University of California Davis, Davis, CA.*

Background: Kidneys with KDPI>85% have high discard rate approaching 50%, transplanted elderly patients over the age of 55 have lower risk of all cause mortality and death caused by cardiovascular disease compaired to their counterparts on dialysis .We present one year clinical outcomes of High KDPI > 85% kidneys when transplanted in elderly recipients.

Methods: Retrospective analysis of kidneys with KDPI >85% transplanted in UC Davis Medical Center between 1/1/ 2016 and 12/30/2018

Results: 67 patients received kidneys with KDPI >85% between 1/1/2016 and 12/30/2018, 77.5% were males, 52.2% diabetics, mean recipient age was 64.3years, 41.8% developed delayed graft function staying on dialysis for a mean of 17 days, 82% were alive after one year, 3 kidneys failed 81.5 % of kidneys were functioning after one years with amean creatinine of 1.4mg/dl.

Conclusions: KDPI >85% kidneys can be used successfully in older kidney recipients avoiding dialysis exposure and expanding the donor pool

PUB274

Risk Factors and Outcomes of BK Viremia Among Deceased Donor Kidney Transplant Recipients Based on Donor Characteristics

Isabel C. Breyer, Ban E. Dodin, Arjang Djamali, Margaret R. Jorgenson, Neetika Garg, Fahad Aziz, Maha A. Mohamed, Didier A. Mandelbrot, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: BK polyomavirus (BKV) and BKV nephropathy (BKN) are common infections among kidney transplant recipients (KTR). Risk factors and outcomes based on donor characteristics remain largely unknown, although some studies suggest BKV is donor derived. In particular, outcomes based on concordance or discordance for BKV among pairs of deceased donor KTRs receiving sister kidneys are unknown.

Methods: This was a retrospective study including all adult deceased donor KTRs at our center between 01/2014 and 12/2019 in which both donor kidneys were transplanted to two different recipients. Recipient pairs from each donor were divided into three groups based on concordance or discordance for BK viremia between the pair: "no BK-group" if neither KTR developed BKV, "discordant" if one KTR developed BKV but not the other and "concordant" if both KTRs developed BKV. Acute rejection (AR), graft failure and BKN were outcomes of interest.

Results: Of 578 KTRs, 336 (58%) were in no BK-group, 176 (30%) were discordant and 66 (11%) were concordant. Donors in the concordant group were younger, had lower KDPI, were less likely to be DCD, and had lower cPRA. Most of the recipient baseline characteristics were similar in all groups. In a multivariate analysis (MA) adjusting for significant factors, KTRs who had a donor with a higher BMI (HR: 0.97; 95% CI: 0.95-0.99; p=0.009) were less likely to develop BKV and those who received depleting induction were more likely to develop BKV (HR: 1.77; 95% CI: 1.26-2.51; p=0.001). There was no difference in the rate of AR, death censored graft failure (DCGF) or BKN among the groups. In MA, concordance was not associated with AR (HR: 0.83; 95% CI: 0.51-1.34; p=0.45), DCGF (HR: 1.77; 95% CI: 0.42-7.50; p=0.43) or BKN (HR: 1.02; 95% CI: 0.51-2.03; p=0.96). By K-M survival analysis, uncensored and DCGF were signficiantly lower in the concordant group (p=0.009 and 0.04 respectively), but not after removing grafts that failed within one year post-transplant. There was no difference in AR or BKN across the groups.

Conclusions: In this large study of 578 deceased donor KTRs, we identified donor BMI and depleting induction to be associated with BKV. Interestingly, concordance or discordance for BKV was not associated with detrimental outcomes.

PUB275

Risk of Rejection, Graft Failure, and Patient Death After Knee or Hip Replacement Surgery in Kidney Transplant Recipients

Ban E. Dodin, Isabel C. Breyer, Fauzia Osman, James D. Alstott, Fahad Aziz, Neetika Garg, Maha A. Mohamed, Didier A. Mandelbrot, Arjang Djamali, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: There remains a large debate about the timing of hip and knee replacement surgery (joint replacement) in the context of patients with end-stage renal disease (ESRD). Few studies have assessed the surgical complications of knee and hip joint replacement surgery after kidney transplantation; however, there is a paucity of data regarding risk-factors leading to joint-replacement surgery, as well as transplant outcomes. More studies are needed to assess the risk factors of joint replacement on transplanted kidneys in patients with ESRD.

Methods: This was a retrospective study analyzing all adult kidney transplant recipients (KTRs) at our university hospital who underwent hip or knee replacement between 2001 and 2017. Among KTRs with multiple joint replacements, only the first surgery was included. Risk factors for joint replacement and the incidence of rejection and graft survival were compared to controls using incidence density sampling at a 1:3 ratio based on the post-transplant interval.

Results: A total of 101 KTRs underwent joint replacement surgery during the study period. Although we attempted to select controls at a 1:3 ratio, this was not possible in all cases. However for each case, at least one control was selected, resulting in a total of 281 controls. The mean interval from KT to joint replacement was 3.9 ± 3.1 yrs. Patients needing joint replacements were older at time of KT (56 ± 11.7 yrs vs 50.7 ± 12.9, p <0.011) and White (94.1% vs 84%, p=0.01). In regression analysis, only older age was associated with an increased risk of needing joint replacements (HR: 1.04; 95% CI: 1.01-1.06; p =0.001). In multivariable analyses, the need for joint replacement was not associated with patient death (HR: 0.79, 95% CI: 0.52-1.18, p=0.25), death-censored graft failure (HR: 0.87; 95% CI: 0.48-1.56; p=0.64) or rejection (HR: 1.59; 95% CI: 0.77-3.29; p=0.21).

Conclusions: Our observational study suggests that hip or knee joint replacement after kidney transplantation is not a risk factor for acute rejection, graft failure, or patient death. Further studies are required to determine the risks of complications after joint replacement surgery.

PUB276

Transmitted Renal Hypouricemia in Living Donor Kidney Transplantation: A Case Report and Literature Review

Takamasa Miyauchi,[1,2] Maho Terashita,[1] Masatomo Ogata,[1] Marie Murata,[1] Kiyomi Osako,[1] Naohiko Imai,[1] Yuko Sakurai,[1] Hideo Sasaki,[1] Yuki Ohashi,[3] Kimiyoshi Ichida,[3] Yugo Shibagaki,[1] Masahiko Yazawa.[1] *[1]Sei Marianna Ika Daigaku Byoin, Kawasaki, Japan; [2]Daini Hattori Clinic, Koto-ku, Japan; [3]Tokyo Yakka Daigaku, Hachioji, Japan.*

Introduction: Hypouricemia in kidney transplant (KT) recipients is rare since they usually have subnormal kidney function and/or use calcineurin inhibitors. Recently, hypouricemia has gained more interests due to recent progress in understanding of the role of uric acid transporters, and its recognition of renal hypouricemia (RHUC) as a disease, which often complicates kidney stones and exercise-induced acute kidney injury (EIAKI). We report a case of RHUC that developed in a recipient from a living donor with hypouricemia. Besides, we reviewed the previous literature on RHUC among KT recipients/donors for preventing potential complications.

Case Description: A 73-years-old Japanese man underwent KT, and the donor was his wife who had hypouricemia [serum uric acid (S-UA): 0.6 mg/dL]. Nine months after KT, the recipient's S-UA was low (1.5 mg/dL) with serum creatinine (S-Cr) of 1.56 mg/dL, and fractional excretion of UA (FEUA) was high (59.7%; normal <10%), indicating RHUC. Regarding the donor's information, S-Cr, S-UA, and FEUA were 0.95 mg/dL, 1.0 mg/dL, and 54.5%, respectively. To investigate further on the pathogenesis of RHUC in both the recipient and the donor, we performed genetic tests. The donor had a homozygous mutation of W258X in the *SLC22A12* gene and the recipient had a wild type of W258X.

Discussion: We eventually found 5 reports and 6 cases of RHUC in KT from a literature review based on past case reports on MEDLINE. According to the literature review, the incidence of urinary stone and EIAKI in either KT recipients or donors with RHUC were not determined due to a small number of patients in previous studies. However, we should focus on preventing these complications based on the evidence obtained from the general population, since both the recipient and the donor have a single kidney with significant hypouricemia, which potentially can be high risk for these complications. RHUC in donors transmits in recipients, which raise the caution for potential kidney stones or EIAKI in both recipients/donors after KT.

PUB277

Utilization of Donor-Derived Cell-Free DNA and Total Cell-Free DNA to Inform Treatment Decisions in a Pancreas Transplant Recipient with COVID-19 Infection and Active Rejection

Ty Dunn,[1] Kerry Gaj,[2] Behdad Besharatian,[1] Robert R. Redfield,[1] Mary Kaminski,[1] Heather Wade,[2] Philippe Gauthier.[2] *[1]Penn Medicine, Philadelphia, PA; [2]Natera, Inc., San Carlos, CA.*

Introduction: Donor derived cell-free DNA (dd-cfDNA) is an established noninvasive biomarker for immunologic rejection of donor tissue in organ transplant recipients. The Prospera™ test, a SNP-based mmPCR methodology, evaluates dd-cfDNA levels as a fraction of total cfDNA. Atypical elevations in total cfDNA, as seen in immunologic responses, could affect the assessment of active rejection (AR). dd-cfDNA has been analyzed in patients undergoing kidney transplants, however, early data suggests that dd-cfDNA behaves similarly following pancreas transplant. Here we present the clinical course of a pancreas transplant recipient with COVID-19 infection for whom, serial dd-cfDNA testing was performed.

Case Description: A 51-year-old female received a deceased donor pancreas transplant in August, 2020. The patient was maintained on a triple immunosuppressive (IS) therapy regime, had stable amylase and lipase levels and no episodes of rejection. Six months later, the patient received the first dose of a COVID-19 vaccine, and the second dose three weeks later. The patient's spouse was diagnosed with COVID-19 and soon after, the patient had elevated pancreatic enzymes, 156 and 199 (prior labs 67 and 27) and presented with elevated temperature (100.4 F), cough, fatigue, loss of taste, diarrhea, myalgias and rhinorrhea. The patient was determined to have COVID-19 with a severity score of 2. IS was reduced and monoclonal ab therapy was initiated. dd-cfDNA fraction was 1.38%, indicated high-risk for AR, with corresponding total cfDNA elevated 10.2 multiples of the median (MoM). The patient was treated with Methylprednisolone 500 mg with a PO Prednisone tail. Three weeks later, the patient was negative for COVID-19 and IS was resumed. The dd-cfDNA fraction at this time was 1.59%, and total cfDNA decreased to 1.1 MoM. Subsequent weekly Prospera tests indicated dd-cfDNA fractions of 1.03%, 0.54%, and 0.81% with total cfDNA levels of 1.4 MoM, 1.3 MoM, and 0.94 MoM.

Discussion: Measurement of dd-cfDNA can guide IS management in pancreas transplant recipients with COVID-19 undergoing AR. Viral infections and anti-rejection therapies can influence total cfDNA. Thus, continued monitoring of both total and dd-cfDNA are needed to identify a true response to therapy.

PUB278

No Benefit of Prophylactic Surgical Drainage in Combined Liver and Kidney Transplantation: Our Experience

Paolo Vincenzi. Miami Transplant Institute, Liver/GI Transplant Surgery and Kidney/Pancreas Transplant Surgery *Miami Transplant Institute, Miami, FL.*

Background: Contrasting results have emerged from limited studies investigating the role of prophylactic surgical drainage in preventing wound morbidity after liver and kidney transplantation. This retrospective study analyzes the use of surgical drain and the incidence of wound complications in combined liver and kidney transplantation.

Methods: A total of 55 patients aged >18 years were divided into two groups: the drain group (D) (n= 35) and the drain-free group (DF) (n= 20). Discretion to place a drain was based exclusively on surgeon preference. The primary outcome was the development of superficial/deep wound complications during the study follow-up. Secondary outcomes included the development of delayed graft function (DGF) of the transplanted kidney, primary non function (PNF) and early allograft dysfunction (EAD) of the transplanted liver, graft failure, graft and patient survival, overall postoperative morbidity rate and length of hospital stay.

Results: With a median follow-up of 14.4 months after transplant, no difference in the incidence of superficial/deep wound complications, except for hematomas, in collections size, intervention rate, PNF, EAD, graft failure and patient survival, was observed between the 2 groups. Significantly lower level of platelets, higher INR values, length of hospital stay, DGF and morbidity rates were reported postoperatively in the D group. Preoperative hypoalbuminemia and longer CIT were included in the propensity score for receiving a drain and were associated with a significantly higher rate of developing a hematoma post-transplant.

Conclusions: Absence of the surgical drain did not appear to adversely affect wound morbidity compared to the prophylactic use of drains in renal transplant patients during CLKTx.

Albumin Preceding Simple Plasma Exchange in ABO-Incompatible Kidney Transplantation

Toshihide Naganuma, Yoshiaki Takemoto, Yoshikazu Kuroki, Tomoaki Iwai, Junji Uchida. Department of Urology, Osaka City University *Osaka Shiritsu Daigaku - Abeno Campus, Osaka, Japan.*

Background: In Japan, where very few deceased donor kidney transplants are performed, approximately 30% of living donor kidney transplants are ABO-incompatible. In these patients, pre-transplant antibody removal by apheresis is generally performed in addition to immunosuppressive therapy. Clinical problems include side effects such as allergic reactions, which are known to frequently occur in conventional plasma exchange (PEx) using fresh frozen plasma (FFP). In this study, we performed PEx using 5% albumin as the replacement fluid in the first half of the procedure followed by FFP.

Methods: PEx starting with albumin replacement fluid was performed in ABO-incompatible kidney transplant recipients (5 patients; 22 sessions). Of the total replacement volume (1.5 plasma volume), 5% albumin was used in the first half, and FFP in the latter half. The incidence of side effects was compared with that of recipients who underwent conventional PEx using FFP (18 patients; 39 sessions). We also studied the changes in coagulation factors before and after PEx using albumin.

Results: The incidence of side effects was significantly higher in recipients who underwent PEx using only FFP (29/39 sessions; 74.4%) compared to that of recipients who underwent PEx using albumin (6/22 sessions; 27.3%) (p<0.001). Among recipients who underwent PEx using albumin, there were only two sessions in which the patient had side effects including skin rash, redness, and itching, which were frequently observed in recipients who underwent PEx using FFP. The median [IQR] of fibrinogen and factor XIII removal rate was 31.6 [27.5, 42.5] and 31.0 [18.0, 44.4] %.

Conclusions: Recently, it has been reported that type AB soluble ABO substances (SAS) neutralizes ABO antibodies. In conventional PEx using FFP, antigen-antibody reaction of SAS and ABO antibodies is thought to induce allergic reactions. Our results suggested that there were fewer allergic reactions in recipients who underwent PEx starting with albumin replacement fluid, because ABO antibodies were removed by albumin first, making it difficult for SAS contained in FFP to react with ABO antibodies. In addition, because there was a slight decrease in the amount of coagulation factors using this method, studies should be made to determine the optimal ratio of albumin to use as the replacement fluid.

PUB280

Post-Transplant Nephrocalcinosis: A Single-Center Case Series

Aileen Wang, Vivek Charu, Colin R. Lenihan. *Stanford University School of Medicine, Stanford, CA.*

Background: Nephrocalcinosis is characterized by multifocal renal tubular and interstitial calcifications. Few studies describe the correlates and outcomes of post-transplant nephrocalcinosis. The goal of this study was to describe the characteristics of patients with nephrocalcinosis diagnosed on kidney transplant biopsy at our center.

Methods: We searched all adult kidney transplant biopsy reports between January 2010 and May 2021. We excluded biopsies performed on a non-functioning transplant kidney and with a concurrent acute rejection or glomerulonephritis diagnosis. We identified 13 patients with nephrocalcinosis as a principle histological diagnosis.

Results: Patient characteristics and laboratory findings are shown in Table 1. Mean age was 49±13 years, 69.2% were male and 53.8% Caucasian. Time from transplant to biopsy was 15±18 months. Post-transplant nadir creatinine was 1.25±0.55 mg/dL. Creatinine at the time of biopsy was 1.9±0.72 mg/dL. Creatinine measured at mean of 28 months post-biopsy was 1.89±0.61mg/dL. Pre- and post-transplant parathyroid hormone levels were 1516±1192 and 264±190 pg/mL respectively. 4 patients underwent post-transplant parathyroidectomy for a parathyroid adenoma in all cases. 7 and 9 patients were prescribed cinacalcet pre- and post-transplant respectively. Hypocitraturia was found in all 5 patients with available urine studies.

Conclusions: Long dialysis vintage, markedly elevated pre-transplant parathyroid hormone level, and cinacalcet use were common in patients with post-transplant nephrocalcinosis. Further study is required to identify risk factors and treatments for post-transplant nephrocalcinosis.

PUB281

Adenovirus and Clostridium difficile Coinfection in a Kidney Transplant Recipient

Katherine Rizzolo, Scott Davis. *University of Colorado, Denver, CO.*

Introduction: Adenovirus infection is associated with AKI (hemorrhagic cystitis, tubulointerstitial nephritis, or obstructive uropathy), fevers, and non-glomerular hematuria. Severe adenovirus infections are rare in solid organ transplants, manifesting within the first year of transplant. In this case, we report fever, AKI, and hematuria one year post kidney transplant due to co-infection of *Clostridium difficile* and adenovirus.

Case Description: 65 yo male status post deceased donor kidney transplant one year prior presented with five days of diarrhea and fever. Blood work revealed an acute kidney injury (AKI) from a baseline serum creatinine of 1.5 mg/dL to 2.3 mg/dL. He was found to be *Clostridium dificile* toxin positive and started on PO vancomycin and IV fluid. On hospital day 4, he began having high grade fevers to 40C, worsening creatinine to 5.9 mg/dL, and gross hematuria despite resolution of diarrhea. Urine microscopy revealed non dysmorphic red blood cells. Adenovirus blood and urine PCR returned positive >1 million copies/mL. Remainder of workup was negative. Biopsy was unable to be performed due to persistent bowel overlying the kidney. Tacrolimus was reduced to target a range of 4-7 ng/mL, mycophenolate was discontinued, prednisone was increased to 20 mg.

He received 5 days of 400 mg/kg IVIG with declining levels of adenovirus and resolution of fevers. Adenovirus became undetectable after four months and creatinine stabilized to 1.3 mg/dL

Discussion: This is the first case reported to our knowledge of *Clostridium difficile* coinfection with adenovirus. It is unclear whether the coinfection we report is due to viral immunomodulation or over-immunosuppression, further research will be needed in this area. Detection methods include direct antigen detection, molecular methods, viral culture, or histopathology. Kidney biopsy reveals acute tubular injury, necrosis, interstitial nephritis with pleiomorphic infiltrate, viral cytopathic changes. Treatment is reduction of immunosuppression; refractory cases may be treated with cidofovir, ribavirin, or IVIG. IVIG was used for our patient given its good safety profile compared with antiviral therapies, and theoretical rationale for reducing immunosuppression.

PUB282

Evaluation of Longitudinal Laboratory Data in Clinical Decision Support for Renal Allograft Longevity

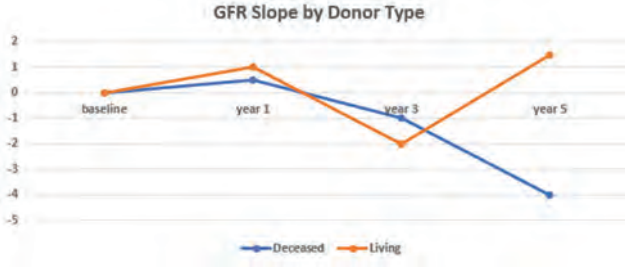
Marcus Garcia,[1] Monique Dodd,[1] Teofilo Borunda Duque,[1] Namita Singh,[2] Christos Argyropoulos.[2] *[1]TriCore Reference Laboratories, Albuquerque, NM; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Renal transplant is considered the preferred treatment for kidney failure. Pre- and post-transplant monitoring is a key factor influencing allograft longevity. The aim was to assess the value of longitudinal laboratory data for early identification of allograft dysfunction within the renal transplant population in NM.

Methods: This was a retrospective observational study evaluating lab data from Tricore Reference Laboratories for renal transplant patients, age 18-75, in NM between 1/1/10 and 12/31/10. TriCore is the largest lab in NM, serving the University of New Mexico (public) and Presbyterian (private) Hospitals. Following the standard of care clinical guidelines for identification of risks associated with renal allograft rejection, we evaluated estimated glomerular filtration rates (eGFR) for living and deceased allografts post-transplant over a 5-year period. Other labs such as urine protein excretion, complete blood count, comprehensive metabolic panel, hemoglobin A1C, immunosuppressive therapy, biopsy results, and history of ICD10 code (Z94.0) were also evaluated.

Results: A total of 575 patients were identified; 82.4% (474) and 17.5% (101) received allograft from deceased or living donor, respectively. Patients at risk for allograft dysfunction due to age were 15% (86) at <35 and 19% (108) at >65 years of age, respectively and 44% (85) required biopsy. eGFR was evaluated to determine allograft function over time (Figure 1). Average eGFR showed a reduction by 4 ml/min/1.73m^2 over a 5-year period in the deceased donor group and a 1.5 ml/min/1.73m^2 increase over a 5-year period in living donor group. There was a 3 ml/min/1.73m^2 reduction between year 1 and 3 in the living donor group.

Conclusions: Preliminary data results noted that allograft function declines in a linear pattern. This study demonstrates the value of longitudinal clinical laboratory data in the assessment of renal allograft longevity. Assessment of risk factors and care gaps enables early identification of allograft rejection and can ultimately improve patient outcomes.



PUB283

Kidney Transplant in African Americans and Associated Risk of Inferior Allograft Survival

Peter E. Umukoro, Muhammad S. Yaqub, Asif A. Sharfuddin, Oluwafisayo O. Adebiyi. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Inferior allograft outcomes have been previously reported among African Americans (AA) compared to non-African Americans (non-AA) in the intermediate and long terms. When these inferior allograft outcomes start to occur between AA and non-AA is unclear. Some have attributed loss of medicare insurance at 3 years post transplantation as responsible in part for these disparities in allograft outcomes between AA and non-AA. Our objective was to evaluate how soon after transplantation do AA begin having worse graft/survival outcomes compared to non-AA focusing on the short term as soon as 1 year post transplantation period. We hypothesized that there would be no difference between AA and non-AA in graft survival and function, acute rejection rates, and patient survival 1 year after a kidney transplant.

Methods: This is a single center retrospective cohort. 2096 study participants, mean (SD) age 51 (14.4) years, with 456 (21.8%) participants being AA who received a kidney alone transplant between 2005 - 2016 and were followed up for one year. We compared patient/graft survival and function at 1 year; 1-year rates of biopsy-proven acute rejection in AA versus non-AA. We used Cox proportional hazards models to estimate hazard ratios.

Results: No differences were observed in patient survival/surviving graft function. Graft survival with HR of 2.56 (95% CI: 1.03 – 6.35, p<0.04) and one-year acute rejection with HR of 1.73 (95% CI: 1.35 – 2.21, p<0.01) were worse in AA compared to non-AA after adjusting for age, sex, diabetes and donor type.

Conclusions: In this sizeable cohort with ethnic diversity, AA were at higher risk for worse graft outcomes even in the early post-transplant period compared to non-AA. Further studies evaluating factors including socio-economic determinants of health are needed to mitigate against poorer allograft outcomes.

Comparison of Allograft/Patient Survival at one year between African Americans and non-African Americans

Outcome	Hazard Ratios (HR)	95% Confidence Interval of HR	p-value
Death Censored Graft Failure At 1 Year	2.56	1.03 – 6.35	0.04
Graft Failure or Death at 1 Year	1.62	0.91 – 2.88	0.10
Acute Rejection Within 1 Year	1.73	1.35 – 2.21	<0.01
Patient Survival at 1 Year	1.17	0.54 – 2.53	0.69

All models were controlled for age at transplant, sex, diabetes (yes/no) and donor type (living donor versus deceased donor)

PUB284

Assessment of Donor-Derived Cell-Free DNA for Allograft Rejection in Kidney Transplant Patients More Than 1 Year from Transplant: Implications for Clinical Management

Mike Morgan, Sarah McCormick, Philippe Gauthier. *Natera, Inc., San Carlos, CA.*

Background: Detection of acute rejection in patients more than a year from kidney transplant (KT) relies on monitoring kidney function tests such as serum creatinine (SCr), BUN, protein:creatinine reactions and periodic assessment of donor specific antibody levels. Unfortunately, these metrics are lagging indicators of rejection and other injuries that may contribute to declining allograft function over time. In this setting, regular monitoring of donor-derived cell-free DNA (dd-cfDNA) can enhance the nephrologists's ability to detect and monitor acute changes in the allograft and to detect early injury caused by immunosuppression (IS) non-adherence. Here we examined the results of the Prospera™ test, a non-invasive single nucleotide polymorphism-based mmPCR methodology to evaluate dd-cfDNA levels, that was performed on patients >1 year from KT.

Methods: We contacted clinics with high-risk Prospera test results (dd-cfDNA >1%) for patients >1 year from KT. Based on the clinical follow-up, we classified the results as rejection, other injury, IS non-adherence or chronically elevated dd-cfDNA for an unknown reason.

Results: We identified 403 patients with Prospera tests performed between 366 and 14,554 days post-KT with a median time of 1445 days. Among test results, the median dd-cfDNA fraction was 2.19% (range: 1-20.73). Clinical follow-up was available for 115 cases with biopsy-matched results available for 24. Biopsy revealed rejection in 33.3% (8/24) of the cases: ABMR (62.5%, 5/8) and TCMR (37.5%, 3/8). An additional 8 biopsies showed pathological findings consistent with other allograft injury including diabetic/hypertensive nephropathy, BK nephropathy, interstitial fibrosis and tubular atrophy and other injury not classified as rejection. Elevated dd-cfDNA test results in patients without biopsy were attributed to IS non-adherence in 4 cases, as assessed by the physician, and to viral infection (1 CMV, 3 BK virus) in the remaining 4 cases. These findings resulted in referral to the transplant center for 3 patients, treatment for rejection for 1 patient, and serial testing and increased monitoring for 16 patients.

Conclusions: These findings provide real-world data that supports Prospera's utility in identifying allografts at high-risk for injury in patients more than 1 year from transplant.

PUB285

Subclinical Rejections on Kidney Transplant Recipients After COVID-19

Enzo C. Vasquez jiménez,[1,2] Bernardo Moguel,[1] Cesar Flores Gama.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto de Seguridad Social del Estado de Mexico y Municipios, Toluca, Mexico.*

Background: The outcomes after COVID-19 and the associated immunosuppressive agents modification in kidney graft is unknown. We evaluated the presence of de-novo DSA and histopathologic findings in a group of kidney recipients after COVID-19 infection

Methods: Kidney recipients recovered from COVID 19 infection from March 31, 2020 to December 8, 2020 in a single transplant center in Mexico were enrolled. Four weeks after COVID-19 diagnosis, DSA and kidney graft biopsy were performed.

Results: A total of 20 kidney transplant recipients were enrolled. Immunosuppressive regimen was modified in 60% of patients, the most common modification was MMF reduction or withdrawn (35%). Allograft biopsy revealed that 70% had rejection; 20% were classified as active chronic rejection, 15% active ABMR, 20% mixed ABMR/TCMR rejection, 10% borderline for acute TCMR and 5% acute TCMR. Among allografts diagnosed with rejection, 57% were considered as subclinical. All borderline for acute TCMR and active ABMR with dnDSA were subclinical

Conclusions: The unusually high rate of acute rejections and the high number detected without allograft dysfunction in recipients recovered from COVID-19 should be an alert to others transplant centers to monitorize alloimmune response after COVID-19

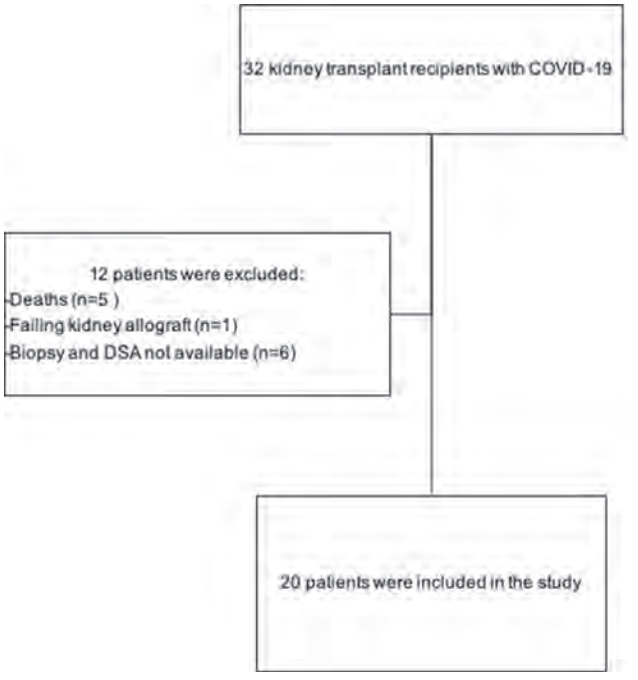


Figure 1. Study flowchart of kidney transplant recipients recovered from COVID-19.

One-Year Follow-Up of Delayed Graft Function in Renal Transplant Patients Performed in Private Hospitals in the State of México, México

Armando Armenta,[2] Eduardo Mancilla,[2,3] José S. Aburto,[2,1] Jesús R. Pérez,[2,1] José R. González,[2,4] Marco S. Escalona,[2] Marcela E. Abasta,[5,2] Armando Armenta Alvarez,[3,2] Hirepan Armenta,[3,2] Delfilia Valle,[2,1] Andrea Armenta,[2] Guillermo Mondragón.[6,2] *[1]SSA, Toluca, Mexico; [2]Toluca Hospital, Toluca, Mexico; [3]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [4]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; [5]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [6]IMTSC, Cuernavaca, Mexico.*

Background: Renal graft function delay (GFD) is defined as the need for dialysis in the first week after kidney transplantation (KT). The most common cause is acute post-ischemia tubular necrosis (ATN-pi). The survival reported in the literature of kidney grafts (KG) after one year with ATN-pi is about 89% for CDKT and 95% for LDKT. We report the evolution of KT made from May 1994 to December 2019 in two private hospitals in the City of Toluca, State of Mexico.

Methods: The data were obtained from the clinical records and were analyzed with student t-test and Chi2 for continuous or categorical variables respectively. The results are expressed as means with standard deviation, accepted as significant value of $p < 0.05$. SPSS 11.5 statistical program was used.

Results: We perform 28 KT: Male 19 (68%), Female 9 (32%). Age 36.5±14.89 years old (yo). Haemodialysis Pre-KT 22 (78.6%), CAPD pre-KT 6 (21.4%). Cause of CKD: Unknown 19 (68%), Diabetic Nephropathy 5 (17.9%), Others 4 (14.2%). LDKT 13 (46.4%), CDKT 15 (53.6%). The ATN-pi showed up 11 (39.3%), of these 10 with DCKT (90.9%) and 1 LDKT (9.1%). 0 HLA 23 (82.1%), 1 HLA 5 (17.9%). *Evolution post-KT RG function (with SCr mg/dl):* SCr one week post-KT ATN-pi 3.9±1.98 vs No ATN-pi 1.48±0.5 (p 0.0001). SCr one month post-KT ATN-pi 1.47±0.27 vs No ATN-pi 1.18±0.35 (p 0.02). SCr Three months Post-KT ATN-pi 1.25±0.3 vs No ATN-pi 1.13±0.26 (p NS). SCr six months post-KT ATN-pi 1.18±0.18 vs No ATN-pi 1.18±0.3 (p NS). SCr twelve months post-KT ATN-pi 1.25±0.16 vs No ATN-pi 1.18±0.24 (p NS). RG working one year after KT was 28 (100%). *Risk factors associated with the development of ATN-pi:* Male 10/11 with ATN-pi vs 12/13 No ATN-pi (p 0.03) (RR 8.8). DCKT 10 with ATN-pi vs 5 No ATN-pi (p 0.001) (RR 24). *Receptor age;* KT ATN-pi 43.9±12.73 yo vs No ATN-pi 32.11±14.97 yo (p 0.03). Diabetic Nephropathy ATN-pi 4 vs No ATN-pi 1 (p 0.04) (RR 9.1). Cold ischemia time with ATN-pi 14.7±4.9 hours vs No ATN-pi 5.7±8.4 hours (p 0.001). No other risk factors were found.

Conclusions: In our study sample, the incidence of Renal Graft function delay was 39.3%. ATN-pi was the only cause of GFD. The patient's survival and renal graft to a follow-up year was 100%.

PUB287

Challenges Treating Discordant Rejection in Simultaneous Kidney Pancreas Transplant (SPKT)

Fizza Abbas, Linyuan Wang, Arpita Basu. *Emory University, Atlanta, GA.*

Introduction: Discordant rejection in SPKT are uncommon wih limited data on outcomes. We present 2 cases of severe discordant acute rejections of the pancreas presenting early post-transplant (PTx).

Case Description: Patient 1 46-year-old lady underwent SPKT. 4 months PTx she was admitted, with abdominal pain and elevated pancreatic enzymes. CT abdomen was suggestive of transplant pancreatitis. She was treated for presumed pancreas rejection with IV Solumedrol. She was re-admitted 10 days later with significant rise in amylase and lipase. Pancreas biopsy showed moderate acute cellular rejection treated with IV solumedrol and ATG. Patient was readmitted 1 week later with elevated pancreatic enzymes and additional ATG was administered. In the following months while pancreatic enzymes normalized, she developed hyperglycemia needing insulin therapy. 9 months Ptx she is on an oral hypoglycemic agent. **Patient 2** 35-year-old lady underwent SPKT. 9 months PTx she was admitted with fever, elevated pancreatic enzymes elevation and acute kidney injury. Kidney biopsy showed no rejection. CT abdomen showed transplanted pancreatitis. She was treated for presumed pancreas rejection with IV Solumedrol. Patient was readmitted 4 days later with worsening pancreatic enzyme elevation. Pancreas biopsy showed severe acute cellular rejection which was treated with ATG. 12 months Ptx, pancreas and kidney allograft function are normal, however, blood sugars are elevated and being monitored without medications.

Discussion: Treatment of discordant acute pancreas rejection is difficult, particularly with congruent viremia. Large studies assessing allograft and patient outcomes post discordant rejection is needed to better care for this cohort.

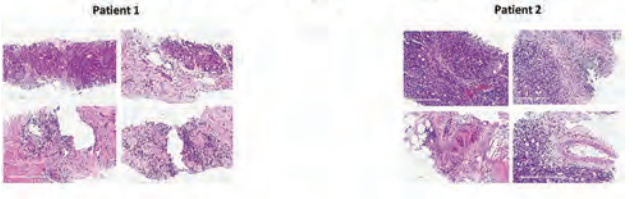
Figure 2. Pancreas Biopsy Pathology Findings



Findings:
- Acute Cellular Rejection, at least moderate
- Multifocal acinar inflammation with acinar cell injury
- Moderate septal inflammation
- Multifocal venulitis
- Mild intimal arteritis

Findings:
- Acute Cellular Rejection, severe
- Diffuse lobular inflammation (prominent neutrophils) with focal early necrosis
- Venulitis
- Arteritis with focal early fibrinoid necrosis
- Foamy arteriopathy

PUB288

Light Chain Deposition Disease (LCDD) Recurrence Post Kidney Transplant

Joel O. Adewuyi, Alfonso Santos, William L. Clapp. *University of Florida Health, Gainesville, FL.*

Introduction: Advanced Renal disease from LCDD does benefit from renal transplant but allograft survival may be shortened by LCDD recurrence. We report a case to support this

Case Description: 57-yr old male with history of multiple myeloma status post autologous peripheral blood stem cell transplantation (PBSCT) and ESRD due to IgG Kappa LCDD who got a diseased donor kidney transplant (DDKT) and developed recurrence of LCDD. Patient evaluated 4 years prior for creatinine 3.43mg/dL, proteinuria 7.4g/day, kappa light chain(KLC) 118.2mg/dL, lambda light chain(LLC) 13.8mg/dL, K/L ratio 8.5, serum protein electrophoresis (SPEP) with M-spike in gamma region, UPEP showed selective glomerular proteinuria, urine immunofixation with 2% of total urine protein being IgG kappa. Kidney biopsy showed:diffuse tubular and glomerular basement membrane staining for kappa light chain (KLC) 3+, weak basement membrane staining for IgG and albumin 1+, moderate -severe fibrosis, negative amyloid. Bone marrow biopsy: 30-40%, hypocellularity, atypical plasmacytosis, plasma cells with CD138 + up to 5% of marrow cellularity, CD56 +, and KLC restricted. Had 3 cycles of chemotherapy with partial response and autologous PBSCT to achieve complete response 1. Two years later, bone marrow and Kidney biopsies showed evidence of disease relapse. Had another cycle of chemotherapy and salvage PBSCT, follow up bone marrow biopsy negative for plasma cell abnormality. Started on PD due to worsening renal function. Allograft biopsy 9 months post DDKT done due to elevated serum creatinine and proteinuria showed recurrent LCDD (tubular basement membrane thickening and mesangial expansion with nodular accentuation, 3+ Linear staining for KLC, negative for lambda, focal glomerular staining for albumin 1+, Electron dense fine granular deposits along glomerular basement membrane) similar to native kidney biopsy prior to PBSCT. SPEP with M -spike 0.4 g/dl, K/L elevated at 11. He was started on chemotherapy for LCDD recurrence. Renal Allograft failed at 10 months post-DDKT and patient retuned to Hemodialysis

Discussion: This case illustrates that renal allograft survival is reduced in LCDD patients no matter the treatment used to achieve sustained hematologic response and this supports the need for more studies to establish the pathophysiologic mechanisms underlying LCDD recurrence in renal allograft which may serve as therapeutic targets

PUB289

Hypoalbuminemia Is a Risk Factor for Invasive Fungal Infections and Worse Outcomes in Infected Kidney Transplant Recipients

Aniruddha Srivastava, Fauzia Osman, Aahad N. Khan, Margaret R. Jorgenson, Neetika Garg, Fahad Aziz, Maha A. Mohamed, Didier A. Mandelbrot, Arjang Djamali, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Serum albumin is a marker of overall health status. It is unknown if kidney transplant recipients (KTRs) with hypoalbuminemia are at an increased risk of invasive fungal infection (IFI) specifically, blastomycosis, coccidiosis, histoplasmosis, aspergillosis, and cryptococcus.

Methods: In this retrospective observational cohort study, all adult KTRs transplanted between 01/01/2001 and 12/31/2017 were included with serum albumin measured 3-6 months before selected IFIs and compared to matched controls using incident density sampling. KTRs were stratified into three pre-infection albumin levels: normal albumin ≥4.0 g/dL, mild hypoalbuminemia 3.0-<4 g/dL, and significant hypoalbuminemia <3.0 g/dL. Incidence models per 100 person-years and Cox proportional hazards were used to compare outcomes between groups.

Results: 113 KTRs with IFI and 348 controls were included in the study. Mean serum albumin level at the time of IFI was 3.1±0.62 gm/dl. The majority of infected KTRs had aspergillus (48.7%) followed by endemic fungal and cryptococcus infections. Infected KTRs were older at transplant (56±11 vs 53±14 years, p=0.02) with a higher incidence of delayed graft function (23.9% vs 5.8%, p<0.001). Basiliximab induction was more common in those with IFI (55.8% vs 47.4%, p=0.02). Calcineurin-inhibitor maintenance immunosuppression prevailed overall, but differed (85.9% vs 96.9%, p<0.001). Infected KTRs had lower serum albumin level with 7.1% normal, 50.4% mild, and 42.5% significant hypoalbuminemia; while in controls 18.7% had normal, 75.9% mild and only 5.5% significant hypoalbuminemia (p<0.001). The incidence rate of IFIs among normal, mild, and significant hypoalbuminemia was 3.6/100, 8.7/100, and 29.3 person-years, respectively. After multivariate analysis, mild hypoalbuminemia (HR: 2.2, 95%CI: 1.02-4.7) and significant hypoalbuminemia (HR: 5.0 95%CI: 2.3-11.2) had a significantly higher risk of IFI than normal albumin. A similar pattern of mortality and graft failure with hypoalbuminemia after IFI was observed.

Conclusions: These results suggest that hypoalbuminemia is associated with an increased risk of IFI as well as subsequent graft loss and mortality.

PUB290

Incident Fractures in Kidney Transplant Recipients: A Nationwide Cohort Study

Da won Kim,[1] Jaeseok Yang,[2] Myoung soo Kim,[3] Jeong hoon Lee,[4] Jin seok Jeon,[5] Hye Eun Yoon.[1] *[1]Catholic University of Korea, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [4]Myongji University, Seodaemun-gu, Seoul, Republic of Korea; [5]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea.*

Background: Increased fracture incidence is a challenging issue among kidney transplantation recipients (KTRs). This study investigated the incidence, location, and predictors of fracture following kidney transplantation (KT).

Methods: Data were obtained from the Korea Organ Transplantation Registry, a nationwide cohort study of KTRs. A total of 5403 KTRs who received KT between January 2014 and June 2019 were included. We estimated incidence rates and risk factors of fracture using Kaplan-Meier method and Cox proportional hazard model.

Results: At median follow-up of 31.6 (18.1 – 46.8) months, 79 patients developed incident fracture. The cumulative incidence of fracture was 2.23% at 5 years. The most frequent locations of fracture were foot (26.3%) and leg (25.0%). Older recipient age [hazard ratio (HR) = 1.038, 95% confidence interval (CI), 1.011 - 1.067; P = 0.007] and diabetes mellitus (HR = 2.404, 95% CI, 1.383 – 4.180; P = 0.002) at baseline were associated with higher risks for fracture after KT, while the use of anti-thymocyte globulin as induction therapy (HR = 0.233, 95% CI, 0.073 – 0.748; P = 0.014) and higher calcium * phosphorous product at 6 months post- transplantation (HR = 0.950, 95% CI, 0.906 – 0.995; P = 0.032) were associated with a lower risk of fracture.

Conclusions: The first 5 years after KT were associated with risks of peripheral skeleton fractures. Recipients' age, diabetes mellitus, induction therapy, and post-transplant calcium/phosphorus interaction may explain the risk. These results define the need of further studies to evaluate the reason for the fracture risks of KTRs.

PUB291

Outcome of 313 Czech Patients with IgA Nephropathy After Renal Transplantation

Dita Maixnerova,[1] Petra Hruba,[2] Michaela Neprasova,[1] Kamila Bednarova,[2] Miloslav Suchanek,[3] Vladimir Tesar,[1] Ondrej Viklicky.[2] *[1]Dept. of Nephrology, General Teaching Hospital, 1st Faculty of Medicine, Prague 2, Czechia; [2]Institute of Clinical and Experimental Medicine, Prague, Czechia; [3]University of Jan Evangelista Purkyně in Ústí nad Labem, Usti nad Labem, Czechia.*

Background: The recurrence of IgA nephropathy (IgAN) after kidney transplant is often with the range among 20 – 35 %. The main aim of our study was to evaluate the risk factors affecting the course of the disease after renal biopsy of native kidney and kidney transplant.

Methods: We evaluated clinical parameters and histological findings at the time of biopsy of native kidney and after kidney transplant in 313 Czech patients with IgAN during the follow up of 26 years. Logistic regression model, hypothesis test on binomial distribution and Kaplan-Meier survival curves were used for statistical analysis.

Results: Histologically verified recurrence of IgAN was confirmed in 23 individuals (46.0 %) of the total number of 50 (16.0 %) patients with IgAN with irreversible graft failure. Microscopic hematuria was detected just in 31 patients (62.0%) with graft failure. 10-years renal survival was unfavourable in patients with histologically confirmed recurrence of IgAN and microscopic hematuria in comparison with patients with recurrence of IgAN without microscopic hematuria. Using hierarchial clustering method patients with graft failure were divided into two groups according to the time from kidney transplant to graft failure (11.2 versus 6.1 years) which excellently correlated with the distribution of two groups based on the time from the renal biopsy of native kidney to end stage renal disease (5.9 versus 0.4 years). Body mass index, proteinuria, microscopic hematuria, histological evaluation of fibrosis and crescents at the time of renal biopsy of native kidney were confirmed for the differentiation into two groups.

Conclusions: The presence of microscopic hematuria together with histological verified recurrence of IgAN were confirmed to be unfavourable predictors of renal survival in our cohort of 313 Czech patients after kidney transplant (P<0.001). Higher age of donor kidney transplant, histological verified recurrence of IgAN, antibody mediated rejection and the onset of microscopic hematuria and proteinuria till one year after kidney transplant were confirmed for worse graft survival in multivariate Cox regression analysis in patients with original diagnosis of IgAN in native kidney biopsy.

PUB292

Symptoms and Occurrence of Hepatitis E in Solid-Organ Recipients: A Single-Center Experience of the Last Five Years

Sandra E. Hasmann, Stephan Kemmner, Julia Krappe, Bruno Meiser, Carola Grinninger, Nikolaus Kneidinger, Reinhart Zachoval, Michael Fischereder. Nephrology department, Transplantation Center *Ludwig-Maximilians-Universitat Munchen Medizinische Fakultat, Munchen, Germany*.

Background: The Hepatitis E virus (HEV) can be found worldwide and the transmission is mainly fecal-oral. In Germany, transfection occurs especially from pork or beef, where genotype 3 is predominant. While most infections are asymptomatic, under immunosuppressive therapy a chronic (and fatal) course of Hepatitis E is possible. Regular testing is often missing due to lack of experience. Therefore, we retrospectively evaluated all solid-organ transplant patients in our tertiary care center with a positive diagnosis of Hepatitis E in the last five years.

Methods: All solid-organ recipients with positive HEV-RNA replication in the blood in the last 5 years were retrospectively analysed regarding disease manifestation, immunosuppressive therapy, and course of HEV infection. HEV-IgG or IgM alone were not sufficient for diagnosis.

Results: From 2015 to 2020 14 solid-organ transplant patients (4x kidney, 5x heart, 4x liver, 1x lung) were diagnosed with HEV in our center. All patients showed elevated transaminases before diagnosis. In total 3 patients experienced abdominal pain, two presenting with acute liver failure. Overall, HEV infection occurred after a median of 8.6 years after transplant, however 3 patients developed HEV within the first year after transplantation. The transmission path remained uncertain in all cases. Blood transfusions were never associated. Contaminated and/or undercooked meat was the most likely cause, especially as none of the patients were vegetarian. Regarding immunosuppressive therapy, 92 % (N=13) had a tacrolimus based regimen combined with either mycophenolic acid or m-Tor inhibitor. No significant differences between the two could be found. 10 out of 14 patients were treated with Ribavirin because of either persistent HEV-RNA or because of the severe course of the disease. In 4 patients HEV infection disappeared without specific treatment due to the reduction of immunosuppressive therapy. One patient developed a chronic HEV infection, which resolved after Ribavirin therapy.

Conclusions: HEV is a common cause of elevated transaminases in solid-organ recipients and should be considered for differential diagnosis. Therefore, we suggest a more precise instruction – even years after transplantation – regarding cooking rules.

PUB293

Vancomycin Nephrotoxicity Causing Renal Transplant AKI

Luan D. Truong, Sean Hebert, Ngoentra Tantranont. *The Houston Methodist Hospital, Houston, TX*.

Introduction: Nephrotoxicity is a rather frequent side effect of vancomycin treatment. Attributes of vancomycin nephrotoxicity (VN) are well documented including its clinical manifestations and renal morphologic changes. However, VN has not been documented as the cause of acute kidney injury in the renal transplant setting.

Case Description: We herein reported the first three such cases. In each of these cases acute kidney injury developed concurrently with vancomycin treatment and resolved after its cessation. As compared with the general population VN in the renal transplant setting displayed some unusual clinical behaviors. Its development was rather capricious, being noted in some treatment episode, but not others even in the same patient. Acute kidney injury developed gradually in conjunction with a protracted vancomycin treatment, in contrast to a precipitous course in the non-transplant setting. However, renal transplant biopsies showed typical features of VN in each case

Discussion: VN is an exceptional but now well documented causes of acute kidney injury in renal transplant recipients. VN in this setting may display some atypical features setting it apart from that in the general population. However, renal transplant biopsy changes are characteristic and are amenable to a definitive diagnosis

PUB294

A Qualitative Exploration of Patient-Provider Communication Challenges After a Kidney Transplant

Melika Dastgheib, Renad F. Aser, Pearse O'Malley, Noor A. Kaabi, Mahdiba Chowdhury, Rabail Siddiqui, Tibyan Ahmed, Heather Ford, Beth Edwards, Istvan Mucsi. Multi-Organ Transplant Program and Division of Nephrology *University Health Network, Toronto, ON, Canada*.

Background: Kidney transplantation is a life-altering treatment, but symptoms and drug side effects persist for many patients post-transplant. Effective communication with the healthcare team (HCT) is key to address these, yet research shows patients find that challenging. Ineffective communication may lead to inadequate assessment and management of symptoms. Although communication is among patients' top research priorities, less than 5% of articles in the two leading transplant journals address it. To fill this gap, we conducted a qualitative exploration of communication challenges from recipients' perspective.

Methods: Within a larger study, we used Qualitative Description methodology to understand the quality of communication between patients and HCT post-transplant. Purposive recruitment was done via flyers (Jun-Dec2020). Patients with significant cognitive impairment or insufficient English were excluded. In-depth, semi-structured, individual interviews were recorded and transcribed verbatim. Directed content analysis framed the iterative development of codes.

Results: 7 recipients (4 males, ages 51-75, 4-15.5 years post-transplant) and 1 caregiver participated. Findings indicate a range of experiences, from regular contact with HCT to little perceived opportunity to communicate in-between clinic visits. Compared to pre-transplant care, communication was less frequent and many patients felt isolated, making it difficult for them to know where and how to seek information and support. Instead, patients relied on searching for information online, visiting family doctors or the emergency room. Some used phone/voicemail to reach HCT, but these were not always timely or efficient. Patients also raised the need for HCT to consider the uniqueness of each patient and their broader context, in addition to quantitative measures, in assessing their health. The diverse communication experiences also relate to patients' comfort with self-advocacy. While some proactively initiate conversation, others are more reserved.

Conclusions: Communication challenges between kidney transplant recipients and HCT contribute to feelings of isolation and difficulties navigating post-transplant life. Tailoring communication to individual preferences may improve patient-centered care.

PUB295

CMV-Associated Thrombosis in a Kidney Transplant Recipient

Young C. Hsu,[1,2] Lin Wang,[1,2] Thanh Cao,[1,2] Neeraj Sharma.[1,2] *[1]University of Southern California, Los Angeles, CA; [2]Keck Hospital of USC, Los Angeles, CA.*

Introduction: Cytomegalovirus (CMV) infection is a common infectious complication after kidney transplantation. Indirect effects of CMV infection include an increased risk of secondary infections, increased risk of acute rejection and chronic allograft dysfunction. However, it is not well known that CMV may also increase the risk of venous and arterial thrombosis. Here we present a case of acute deep venous thromboembolism associated with acute CMV disease in a kidney transplant recipient.

Case Description: A 64 year old male presented with 4 weeks of sore throat, cough, subjective fevers, and fatigue. 3 weeks prior, he presented to an outside hospital with flu-like symptoms and complaints of right calf pain. Imaging showed the right leg with totally thrombosed posterior tibial and peroneal veins as well as acute partially thrombosed popliteal vein. The patient was subsequently admitted to the hospital and found with a CMV PCR of 35,900 IU/ml, after which he underwent an esophagogastroduodenoscopy (EGD) and colonoscopy with biopsies confirming CMV in the lower esophagus consistent with CMV esophagitis. IV ganciclovir treatment was initiated with appropriate response seen.

Discussion: CMV belongs to the herpesvirus family that establishes latent infection following a primary infection. For patients who are CMV seropositive, the risk of CMV reactivation is highest in the setting of systemic immunosuppression. CMV infections may present with a wide array of syndromes ranging from meningoencephalitis to enteritis/colitis and hepatitis. In addition, CMV infection has been associated with thromboembolic events. Kidney transplant recipients show a high prevalence of thrombotic events compared with the general population. In short, acute CMV infection should be considered as a risk factor for venous thromboembolism. Therefore, diagnosis of acute CMV infection in patients with an acute thrombosis should redefine the thrombotic event as provoked rather than unprovoked, limiting the duration of anticoagulation treatment.

PUB296

Comparison of the Efficacy and Safety Between Anti-Thymocyte Globulin vs. Basiliximab in Deceased Donor Kidney Transplantation: A Multicenter Cohort

Suyeon Hong,[1,2] Chul Woo Yang,[1] Byung ha Chung,[1] Woo Yeong Park,[3] Kyubok Jin,[3] Seungyeup Han.[3] *[1]The Catholic University of Korea, Seoul St.Mary's Hospital, Seoul, Seoul, Republic of Korea; [2]The Catholic University of Korea, Uijeonbu St.Mary's Hospital, Uijeonbu, Gyeounggido, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea*.

Background: Induction immunosuppressant is decided upon the condition of deceased donors and recipients in deceased donor kidney transplantation (DDKT). Although anti-thymocyte globulin (ATG) is preferred in immunologically high risk patients, there has no clear evidences for the efficacy and safety of induction agent in DDKT. This study aims to compare the efficacy and safety between ATG and basiliximab (BSX) based on donor characteristics in DDKT.

Methods: A total of 724 kidney transplant recipients (KTRs) from 3 transplant centers were enrolled and ATG-DDKT group was 252 and BSX-DDKT group was 472. We investigated the impact of induction therapy based on donor age of 60, donor kidney with acute kidney injury (AKI) and kidney donor profile index (KDPI) score of 65% on post-transplant clinical outcomes in delayed graft function (DGF), acute rejection (AR), infectious complications, allograft and patient survivals.

Results: ATG-DDKT group had poor donor condition and highly sensitized recipients than BSX-DDKT group. DGF did not show statistically significant differences according to induction agent in terms of elderly/young donor, AKI/non-AKI, and high-KDPI/low-KDPI subgroups. Acute rejection and infection rate did not show meaningful differences. Death-censored allograft survival and patient survival rate between induction agents were also statistically irrelevant.

Conclusions: Our results suggest that though ATG was more frequently applied to poor donor condition and highly sensitized recipients, ATG was not inferior to BSX not only in aspect of survival rate but also DGF, AR and infection aspects. Therefore, as an induction agent, ATG should be considered in preference to BSX, especially in high-risk DDKT.

Longitudinal Urine Inflammatory Profile During Renal Transplantation

Elizabeth Spiwak, Corina Nailescu, Andrew L. Schwaderer. *Indiana University School of Medicine, Indianapolis, IN.*

Background: In the year 2020, more than 5,000 living donor kidney transplants were performed in the United States. Kidney transplant recipients are subjected to several types of immunosuppressants in order to prevent rejection of the graft. Over-immunosuppression increases the risk of infectious complications and these patients require a delicate balance. Inflammatory profiles from the urine can help identify which biomarkers may guide clinicians in balancing over vs. under-immunosuppression.

Methods: Urine samples were obtained from 12 kidney donor-recipient pairs at a pre-operative visit ~1 week prior to or at time of transplant and then for the recipients, ~3 months following transplantation. The urine samples were analyzed using inflammatory urine biomarker profiles (Mesoscale Discovery). Urine levels were then normalized to urine creatinine values. Differences were noted between groups using the mixed-measures ANOVA, corrected for multiple comparisons with the Tukey test to get adjusted p-values.

Results: Results are presented in the figure, but it was identified that eotaxin urine levels were higher in post-transplant samples compared to donor samples; interleukin-15 levels were higher in pre-transplant samples compared to both donors and post-transplant samples; GM-CSF levels were higher in pre-transplant samples compared to their donors; and interleukin-6 levels were higher in pre-transplant samples compared to their post-transplant samples.

Conclusions: The urine inflammatory profile evolves over the transplant course between donors, pre-transplant recipients and transplant recipients. Although the transplant itself is typically accepted as a pro-inflammatory event, levels of biomarks in the urine tend to decrease post-transplant. Immunosuppression regimens may influence inflammatory profiles and warrant further investigation.

A Study of Outcomes of Renal Transplantation from Deceased Donors in a Tertiary Care Centre from Southern India

Vishnu K. Kotha. nephrology NP1 UNIT *Nizam's Institute of Medical Sciences, Hyderabad, India.*

Background: In India, there are large number of end stage renal disease patients awaiting renal transplantation. Deceased donor reanl transplantation(DDRT) is one possible solution to this. So this study aimed to determine the outcomes of DDRT.

Methods: Total 126 DDRT recipients in a tertiary care hospital in southern India, between 2013 and 2020 were taken in to the study and the outcomes were retrospectively analysed.

Results: Out of 339 renal tranplants, 126(37%) were DDRT in the study period. Mean age at transplant was 38.3 years.77.7% were males and 22.3 % were femlaes. 73.8% patients received basiliximab, 26.2% received antithymocyte globulin for induction. Steroids, calcineurine inhibitors and mycophenolate mofetil were used for maintenance immunosupression. Over a mean follow up of 3.6 years, patient and graft survival rates were 85% and 92,6%, respectively, with a median serum creatine of 1.32 mg/dl. The incidence of delayed graft function(DGF) was 54.3%. The incidence of slow graft function was 33.4%. The incidence of immediate graft function was 12.3%. Prolonged cold ischaemia time was risk factor for DGF. Mean cold ischemia time was 4.2 hours.

Conclusions: Outcomes of DDRT showed successful results. So DDRT has a potential to expand donor pool and shorten the waiting list for renal transplantation. Increasing public awareness and good communication and a well trained team of transplant coordinators can help in improving the number of organ donations.

PUB299

Pressure Natriuresis and Diuresis Are Differentially Regulated Depending on Age and Sex

Yang gyun Kim, Sangho Lee, Ju young Moon. *Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: The renal capacity for handling salt and water is linked to hypertension. This study aimed to clarify the sex- and age-related natriuretic and diuretic differences in blood pressure (BP) regulation.

Methods: We analyzed two datasets: one from the E-SPECIAL trial, which evaluated the effect of a low-salt diet (LSD) on lowering albuminuria in 235 patients with nondiabetic chronic kidney disease, and the other from the Korean Genome and Epidemiology Study (KoGES), including 4,937 subjects.

Results: In the E-SPECIAL trial, BP was lower in premenopausal women (Pre) than in younger men (Y), and the gap disappeared between postmenopausal women (Post) and older men (O). LSD decreased urine sodium in Y, Post, and O but did not mitigate urine sodium in Pre. A positive correlation between BP and urine sodium was

observed only in the younger groups (Pre, Y). Urine volume was greater in Pre than in Y, and urine concentration was reciprocally lower in Pre than in Y. Urine volume was positively correlated with BP in Pre and negatively associated with BP in other groups. Urine volume and urine sodium were the most decisive factors for predicting BP in Pre. In the KoGES, BP was lowest in Pre. Urine sodium increased in Pre compared with Post, although sodium intake was not different. The correlation between BP and urine sodium augmented in younger groups (Pre, Y).

Conclusions: The pressure-natriuretic and pressure-diuretic responses were well conserved in Pre and mitigated in Post. Augmented natriuresis and diuresis might contribute to lower BP in Pre.

PUB300

Misoprostol-Induced Pulmonary Edema in a Pregnant Woman with ESKD Undergoing Induction of Labor Following SARS-CoV-2 Infection

Kelly H. Beers, Swati Mehta, Geovani Faddoul. *Albany Medical College, Albany, NY.*

Introduction: Misoprostol can induce pulmonary edema in patients with end stage kidney disease (ESKD) undergoing induction of labor (IOL). Careful monitoring and interdisciplinary care is required in these complicated patients with tenuous respiratory status. We present a case of misoprostol-induced pulmonary edema in a pregnant women with ESKD requiring hemodialysis (HD) who may have been at higher risk of adverse effects due to recent SARS CoV-2 infection.

Case Description: A 21-year-old woman at 34 weeks, 6 days gestation in her first pregnancy and ESKD due to IgA nephropathy on home hemodialysis (HHD) was admitted for IOL. She had been hospitalized at 21 weeks gestation with severe SARS CoV-2 infection requiring ICU stay. She recovered and was discharged on HHD 6 hours, 6 days weekly. She required 2L supplemental oxygen upon discharge for a total of 7 weeks. Her BUN was maintained < 35mg/dl throughout her pregnancy. Prior to IOL, patient was euvolmic with oxygen saturation of 96% on room air, and patient was at her dry weight. IOL was initiated with two doses of vaginal misoprostol, 25mcg per dose, first dose at 8:37PM then another at 12:38AM. At 3AM she developed flash pulmonary edema. Her oxygen saturation dropped to 90% and B lines were seen in the apex of both lungs on point of care ultrasound. No clinical or laboratory signs of pre-eclampsia were found. Patient required urgent dialysis with 2L of fluid removal while she was in early labor, with resolution of symptoms. Given her tenuous fluid status, it was decided to perform primary cesarean section, which resulted in the birth of a healthy infant.

Discussion: Misoprostol has been identified as a possible cause of pulmonary edema in at least two cases of otherwise healthy asymptomatic patients. This is first report of misoprostol causing flash pulmonary edema in a patient with ESKD. Other prostaglandin analogues have been reported to cause pulmonary edema, and the FDA lists edema and myocardial infarction among possible cardiovascular adverse effects of misoprostol. We hypothesize that our patient was at higher risk of development of adverse effects due to her recent severe SARS CoV-2 infection.

PUB301

Predictors of Readmission in Patients with Advanced CKD and Colon Cancer: A Nationwide Analysis

Victor E. Prado,[1] Miguel Salazar.[2] *[1]University of Cincinnati, Cincinnati, OH; [2]Cleveland Clinic, Cleveland, OH.*

Background: It is well-documented that chronic kidney disease (CKD) and colorectal cancer (CRC) have an almost reciprocal effect, with CKD associated with development of CRC and viceversa. We attempt to explore predictors that increase the risk for 30-day readmission rates in patients with CRC and conconcomitant CKD.

Methods: A retrospective study of the 2017 National Readmission Database of adult patients readmitted within 30 days after an index admission for CRC with a concomitant diagnosis of CKD 4 and greater. We aim to identify 30-day readmission rate, mortality, healthcare related utilization resources, and independent predictors of readmission.

Results: A total of 5,678 patients with CKD were admitted with a diagnosis of CRC. The 30-day readmission rate was 28.3%. Main causes for readmission were sepsis, acute kidney failure (AKI), recurrent malignant or metastatic disease and pericarditis. Readmitted patients were more likely to be female (39.9% vs 37.1%; P=0.05), obese (15.2% vs 11.8%; P<0.01), develop AKI (37.6% vs 29.4%; P<0.01) and ileus (12.4% vs 8.7%; P<0.01). Readmission was associated with higher in-hospital mortality rate (1.5% vs. 0.1%; P<0.01), hypertension (2.2% vs 4.1%; P<0.01), and hemodialysis requirement (32.7% vs 36.4%; P=0.03). The total health care in-hospital economic burden of readmission was $104 million in total charges and $25.1 million in total costs. Independent predictors of readmission were prolonged length of stay, pleural effusion, and alcohol abuse. Factors preventative of readmission were younger age and disposition to a skilled nursing facility.

Conclusions: Readmissions in patients with CRC and comorbid advance stages of CKD (4 & 5) is associated with high morbidity and health care burden. Through this study we identified risk factors that can be targeted to help reduce this burden. Controlling these factors could help reduce re-admission rates and thus reduce morbidity and mortality. Similarly, focus on proper disposition planning can greatly improve outcomes.

Predictors of Readmissions

Variable	Adjusted odds ratio (95% confidence interval)	P value
Comorbidities		
Hypertension	0.73 (0.40-1.33)	<0.01
Obesity	0.88 (0.71-1.09)	<0.01
In-Hospital Complications		
Iron deficiency anemia	1.08 (0.88-1.32)	<0.01
Ileus	0.86 (0.66-1.12)	<0.01
Pleural effusion	1.40 (1.07-1.82)	<0.01

PUB302

Urinary Dickkopf-3 (DKK3) Uncovers Unapparent Progressive Kidney Injury in Patients with Chronic Obstructive Pulmonary Disease: An Etiological Study and Experimental Validation

Stefan J. Schunk, Danilo Fliser, Thimoteus Speer. *Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany.*

Background: Chronic kidney disease (CKD) and chronic obstructive pulmonary disease (COPD) represent global public health problems with high disease-related morbidity and mortality. However, the interaction between both diseases remains unclear.

Methods: In a novel murine model, cigarette smoke (CS)-induced lung injury was combined with a CKD model (CS-CKD model). In 2,314 patients of the prospective multi-center COSYCONET study, urinary Dickkopf-3 (DKK3), a renal tubular stress marker, was quantified. The association between urinary DKK3 and trajectories of FEV_1 and estimated glomerular filtration rate (eGFR), exercise capacity, risk of exacerbation, and mortality was determined (follow-up 37.1 months).

Results: In the CS-CKD model, CKD was associated with higher systemic and pulmonary inflammation, and the combination of CKD and CS significantly aggravated kidney inflammation as well as fibrosis and increased renal expression of DKK3. Abrogation of *Dkk3* attenuated kidney injury and pulmonary inflammation alike. In COPD patients, higher urinary DKK3 was associated with rapidly declining FEV_1 (OR 3.36, P<0.0001), higher risk for exacerbation, lower 6-minute walking distance, and higher all-cause mortality (HR 1.49, P=0.015). Importantly, higher urinary DKK3 was also associated with declining eGFR during follow-up (OR 2.23, P=0.0005). Neither eGFR nor proteinuria were associated with lung or kidney dysfunction during follow-up.

Conclusions: In summary, the present study identified a strong pathophysiological link between lung and kidney dysfunction, which is at least partially mediated by DKK3. Urinary DKK3 allows identification of COPD patients at increased risk for deteriorating pulmonary and kidney function as well as adverse outcomes. These patients might particularly benefit from preventive therapeutic strategies as a personalized-medicine approach.

PUB303

Outpatient Treatment Patterns of Hyperkalemia in the United States: The Design and Initial Findings from ZORA, an Observational Study

Eva Lesén,[1] Abiy Agiro,[2] Alaster Allum,[3] Jonatan Hedberg,[1] Mina Khezrian,[3] Krister Järbrink.[1] *[1]AstraZeneca, Gothenburg, Sweden; [2]AstraZeneca US, Wilmington, DE; [3]AstraZeneca, Cambridge, United Kingdom.*

Background: Hyperkalemia (HK) is a potentially life-threatening disorder due to alterations in cardiac conduction, which may result in arrhythmias and sudden death. Potassium binders is a key pillar in the outpatient treatment of HK, but conventional binders, including sodium polystyrene sulfonate (SPS), are generally poorly tolerated, lack palatability and have limited long-term efficacy – with suboptimal use as a consequence. New potassium binders (patiromer and sodium zirconium cyclosilicate [SZC]) with a more beneficial tolerability profile have become available, but contemporary real-world evidence on outpatient treatment patterns including these new therapeutic options is scarce. **Purpose**: To describe the characteristics and treatment patterns among patients with outpatient potassium binder treatment in the US.

Methods: This is an observational study including patients who filled an outpatient prescription for SPS, patiromer or SZC between 1 Jan 2018 and 30 Jun 2020, as identified in HealthVerity claims data linked with Quest Diagnostics laboratory data. Patient characteristics and binder treatment patterns will be described using standard descriptive statistics and survival analysis.

Results: The data set includes a random sample of 20,000 patients with a filled prescription for SPS, and approximately 20,000 patients with a filled prescription for a new binder (patiromer or SZC), over a data capture period of 30 months for patiromer and 12 months for SZC. Analyses on patient characteristics (such as demographics, HK severity, comorbidities, treatment history etc.) and their associations with outpatient treatment choice, as well as binder treatment patterns and trends over time, are ongoing and will be presented.

Conclusions: This study will identify important insights into the characteristics and binder treatment patterns among US patients with HK, and provide useful guidance to improve adherence to guidelines and optimize patient care.

eGFR calculation Without the Race Coefficient Obscures Obesity-Related Glomerulopathy in Female Adolescents

Dana Bielopolski,[1] Ohad S. Bentur,[1] David M. Charytan,[2,3] Jonathan N. Tobin.[4]
[1]The Rockefeller University, New York, NY; [2]NYU Langone Health, New York, NY; [3]New York University Grossman School of Medicine, New York, NY; [4]Clinical Directors Network Inc, New York, NY.

Background: Obesity is more prevalent among minorities, increasing the risk for cardio-renal morbidity. We explored interactions between race, body mass index (BMI), and the risk of hyperfiltration associated with Obesity Related Glomerulopathy (ORG).

Methods: We created a cohort of women and girls ages 12-21 from the New York area using their longitudinal electronic health records (EHR). Glomerular filtration rate (GFR) was estimated in two ways: I) using the standard age recommended formulae, and II) eGFRr –without a race-specific coefficient. Multivariate logistic regression was used to analyze the relative contribution of risk factors for ORG associated hyperfiltration, defined by a threshold of ≥135ml/min/1.73m^2.

Results: 7315 Black and 15,102 non-Black women and girls were evaluated for kidney function in parallel to body measures. Hyperfiltration was more frequent in Black compared to non-Black individuals when using standard eGFR but was lower after eliminating the race-specific coefficient. Black race was independently associated with hyperfiltration with standard eGFR calculation (OR=3.43, 95% CI 2.95-3.99) but the association was reversed when estimated by eGFRr (OR=0.56, 95% CI 0.45-0.70). Risk of hyperfiltration was higher for Black individuals across all BMI strata with standard eGFR estimates, but when estimated as eGFRr hyperfiltration filtration risk was reduced for overweight (OR =0.70 95% CI 0.54-0.89) and obese (OR=0.47, 95% CI 0.37-0.60) participants.

Conclusions: Estimated CKD prevalence among Black adolescents and young adults increases following removal of the race coefficient while fewer have evidence of obesity associated hyperfiltration. In the CKD range of GFR we should consider a gradual increase in the race coefficient to avoid underestimation of obesity related glomerulopathy in the high normal range of GFR

Inside CKD: Projecting the Global Clinical Burden of CKD Using Patient-Level Microsimulation

Juan Jose Garcia Sanchez,[2] Claudia S. Cabrera,[5] Joshua Card-Gowers,[4] Steven J. Chadban,[1] Timothy Coker,[4] Stephen Nolan,[2] Albert J. Power,[6] Lise Retat,[4] Navdeep Tangri,[3] Juan Vesga,[4] Laura Webber,[4] Michael Xu.[4]
Inside CKD *[1]Royal Prince Alfred Hospital Department of Neurology and Stroke, Camperdown, NSW, Australia; [2]AstraZeneca UK Ltd, Cambridge, United Kingdom; [3]University of Manitoba Faculty of Health Sciences, Winnipeg, MB, Canada; [4]HealthLumen Ltd, London, United Kingdom; [5]AstraZeneca, Gothenburg, Sweden; [6]North Bristol NHS Trust, Westbury on Trym, United Kingdom.*

Background: Chronic kidney disease (CKD) affects ~10% of the global population and disease progression is associated with increased risk of cardiovascular events, renal replacement therapy (RRT) and premature death. The trajectory of CKD and related costs are critical considerations for public health and policy planning. Using country-specific, patient-level microsimulations, *Inside CKD* models the global clinical and economic burden of CKD from 2021 to 2026.

Methods: We used the *Inside CKD* microsimulation to project the clinical burden of CKD in Canada, the UK and the US. We constructed a virtual *general* population for each country using national survey data and relevant published literature. Data inputs included country demographics and the prevalence of CKD, RRT, comorbidities, and complications. CKD stages were defined as discrete health states consistent with Kidney Disease: Improving Global Outcomes (KDIGO) 2012 recommendations. We conducted model validation and calibration using established methods for health economic modelling. Analyses from additional countries in the Americas, Asia-Pacific and European regions are underway.

Results: Preliminary results show that the prevalence of CKD stages 1–5 is projected to increase from 13.35% to 14.22% in Canada, from 13.48% to 13.98% in the UK, and from 14.88% to 15.57% in the US from 2021 to 2026 (**Table**). The number of patients receiving RRT annually is projected to increase from 42 064 to 47 582 in Canada, from 69 796 to 75 051 in the UK**,** and from 797 638 to 823 050 in the US, between 2021 and 2026 (**Table**).

Conclusions: *Inside CKD* projects that the prevalence of CKD will continue to rise in Canada, the UK and the US over the period 2021–2026 with a corresponding increase in the annual RRT burden. These data demonstrate that CKD continues to pose a significant global challenge to public health and demonstrates the continued need for national policies aimed at early intervention.

Peer Support as an Intervention for Kidney Disease: A Systematic Review

Jennifer Taylor, Supritha Prasad, Talar Markossian, Holly J. Kramer. *Loyola University Chicago, Chicago, IL.*

Background: Peer support may help improve chronic kidney disease (CKD) self-management because patients who share experiences can provide unique resources including patronage, encouragement and advice unlike any provider. The objective of this systematic review is to assess the published data on peer support as an intervention to improve health outcomes for patients with CKD.

Methods: This systematic review was guided by the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P). The electronic search for studies was done using Medline, Psychological Information Database (PsychINFO), Cumulative Index to Nursing and Allied Health Literature (CINAHL), Cochrane Central Register of Controlled Trials and Web of Science Core Collection. Medical Subject Heading (MeSH) terms and free text terms were modified as appropriate into each database. Eligibility criteria was based on the Problem or Population, Interventions, Comparisons, Outcomes and Study design (PICOS) framework. Study quality was evaluated using the Effective Public Health Practice Project (EPHPP) Quality Assessment Tool for Quantitative Studies and the Mixed Methods Appraisal Tool (MMAT).

Results: A total of 319 articles were identified and10 clinical trials, 8 observational studies, and 1 mixed method study met inclusion criteria. Clinical trials showed medium to high quality while observational studies showed medium to low quality. The mixed-methods study showed high quality. Studies covered a broad range of CKD stages and problems relating to kidney disease. Only 2 articles of low quality focused on peer support as an intervention to slow CKD progression.

Conclusions: This systematic review shows a need for more research on peer support -especially for peer support as an intervention to slow CKD progression.

Funding: Private Foundation Support

PUB307

Risk of Pulmonary Emboli in Patients with Renal Failure

Abhishek Pulla, Arslan Zahid, Jonathan Paul, Stephanie Besser, Mary S. Hammes. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: There are 2 million cases of deep vein thrombosis and 200,000 deaths due to pulmonary emboli (PE) each year in US. The LITE study showed a relative risk of 2.1 (95% CI 1.5-3.0) for venous thromboembolic events in advanced renal failure with limitations as patients with ESRD were not included, renal function at time of event was not defined, and no definition or clot burden or cardiac function. The objective of the current study was to characterize the thrombotic event and details of cardiac function in patients who develop PE, stratifying for renal failure along with determination if demographic data or medical history can predict the outcome or severity of a PE.

Methods: This was a retrospective review conducted at a single-center in an urban community. Charts were reviewed from patients who were referred to the Pulmonary Emboli Response Team (PERT) for treatment of a PE. Demographic data, medical history, and labs including serologic markers of renal and cardiac were reviewed. Patients were stratfied based on renal function. Controls had an eGFR > 60 ml/min as compared to patients with AKI or a history of CKD. PE severity was defined by 2019 ESC guidelines with the most severe classification (4) having hemodynamic instability. Cardiac parameters reviewed included echocardiograms and CT scans.

Results: Charts were reviewed for 170 patients who were admitted for a PE with PERT team activation between 2017 through 2020. There were 45 patients included with AKI; 37 with Stage 3 CKD; 20 with Stage 4-6 CKD; 69 in the control group defined as a eGFR of > 60 mL/min. The control group was younger with a lower incidence of coronary artery disease and hypertension ($p < 0.05$). Mortality associated with a PE was statified for renal function with a higher in-hospital mortality in patients with AKI and advanced CKD when compared to controls (p=0.052). Logistic regression was performed to ascertain the relationship of the severity of the PE and renal failure with an OR 9.2 SE 6.97 (95% CI 2.1-40.6) p = 0.003. Patients had a 9-fold increased risk of PE Severity Class 4 if they had renal failure when compared to controls.

Conclusions: Patients with advanced CKD or AKI tend to have a higher PE severity with increased in-hospital mortality. Efforts to triage and agressively treat patients with renal failure who present with PE may improve outcomes.

PUB308

Effects of Air Pollutants on Mortality of Patients with CKD Living in Green Spaces in Seoul, Korea: A Large Observational Study

Jiyun Jung,[1] Jangwook Lee,[1] Yong Chul Kim,[2] Jung Pyo Lee,[2] Yon Su Kim,[2] Sung joon Shin,[1] Jae Yoon Park.[1] *[1]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Owing to increasing air pollution, the association between green spaces and health outcomes has become a global health concern. The relationship between air pollution and the survival of patients with chronic kidney disease while considering residential greenness remains to be elucidated

Methods: Time-varying survival analysis was conducted to investigate the association between long-term exposure to air pollutants ($PM_{2.5}$, PM_{10}, NO_2, SO_2, CO, and O_3) and mortality in 29 602 chronic kidney disease patients living in residential environments with low and high green infrastructure. Low and high green infrastructure was defined as continuous (0.3, 0.35, and 0.4) and percentile (50%, 75%, and 90%) thresholds using satellite data derived average normalized difference vegetation index within 250 m and 1250 m around the residence.

Results: During the average 6.14 ± 3.96 observation period, 3 863 (14%) deaths occurred. The effect of exposure to air pollution on mortality was stronger in the low index group compared to the high index group. Particularly, SO_2 was significantly associated with increased mortality risk in the low index group regardless of the threshold. Consistent results were observed in the co-pollutant models

Conclusions: Exposure to high greenery significantly reduced the mortality risk associated with air pollution. Our results emphasize the need for creating environmental infrastructure considering green spaces.

PUB309

Impact of Inpatient Educational Programs on Mortality After the Introduction of Dialysis Therapy

Keisuke Yoshida,[1] Yohei Kita,[1] Wei Han,[1] Sayaka Shimizu,[2] Yugo Shibagaki,[1] Tsutomu Sakurada.[1] *[1]Sei Marianna Ika Daigaku, Kawasaki, Japan; [2]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan.*

Background: Although inpatient educational programs (IEPs) for non-dialysis-dependent chronic kidney disease (CKD) have been reported to slow disease progression, its effect on prognosis after the introduction of dialysis therapy is unclear.

Methods: Consecutive patients who started to dialysis therapy between January 1, 2011 and December 31, 2018 were included in this study. The patients were divided into two groups according to whether or not they received IEPs before dialysis introduction, and their background characteristics were compared. The survival rate for each group was calculated using the Kaplan-Meier method and compared by the log-rank test. Furthermore, the hazard ratio (HR) adjusted for confounding factors associated with mortality(age, sex, BMI, CCI, eGFR, albmin, ADL, smoking, welfare patient and emergency hospitalization) was calculated using a Cox regression analysis.

Results: Of the 489 subjects (mean age 68 years, 71.0% male), 129 patients (26.4%) received IEP. Compared with the non-IEP group, the IEP group had higher serum albumin ($p < 0.001$) and lower total cholesterol levels ($p = 0.0078$), and the proportion of patients with independence in their daily living activities was high ($p = 0.005$). The median observation period was 3.8 years, and 153 people (31.3%) died. The 5-year survival rates[A1] [A2] [A3] were 81.0% and 61.4% in the IEP and non-IEP groups, respectively ($p = 0.015$). From the Cox regression analysis,[A4] [A5] [A6] the HR for the IEP group was 0.56 (95% CI 0.36–0.88).

Conclusions: IEPs for CKD patients were associated with a more favorable prognosis after induction of dialysis.

PUB310

The Prevalence of Adverse Childhood Experiences in Adults with CKD

Kira Clark, Amira Al-Uzri. *Oregon Health & Science University, Portland, OR.*

Background: Adverse childhood experiences (ACE) are traumatic events of physical and emotional neglect and abuse, sexual abuse, household dysfunction, caregiver instability, community violence, and collective trauma. Previous research shows the prevalence of ACEs is higher in people with chronic disease, but limited data is available on the prevalence of ACEs in people experiencing chronic kidney disease (CKD).

Methods: This case-control study used the Adverse Childhood Experiences International Questionnaire to compare the ACE prevalence of people diagnosed with CKD (case) to people without CKD (control). ACE scores consisted of 13 trauma sub-types and were coded on a scale from 0-13 for an overall score. Fisher's exact test determined the difference between groups within a 95% confidence interval. Logistic regression examined group differences for each ACE sub-type and adjusted for sociodemographic confounders.

Results: The analysis included 34 people with CKD and 29 controls. Subjects were predominantly female (66.7%), white (84.1%), had a college degree (73.0%), were employed full-time (54.0%), and had a *M* age of 36.1 (± 8.6) years old. Subjects with CKD were diagnosed around 25.5 (± 13.6) years old with a mean eGFR of 38.5mL/min/1.73m^2. ACE scores for CKD ($M = 6.7$, $SD = 3.2$) compared to control group ($M = 5.0$, $SD = 2.4$) demonstrated significantly higher ACE scores, $t(61) = 2.4$, $p = .02$. People with CKD had a higher prevalence in 11 of the 13 ACE trauma sub-types with the highest reported categories including bullying (91.2%), emotional abuse (82.4%), physical abuse (70.6%), household violence (70.3%), and caregiver mental illness (64.7%). Statistically significant ($p < .05$) differences in prevalence occurred with exposure to emotional neglect, caregiver mental illness, and sexual abuse. Odds ratios for having a CKD diagnosis were significant ($p < .05$) for emotional neglect (*OR*; 8.84), caregiver mental illness (*OR*; 4.81), sexual abuse (*OR*; 4.52), and bullying (*OR*; 5.55).

Conclusions: This pilot research indicates that adults with CKD experienced every trauma sub-type of ACEs and at higher frequencies than a control population. Cumulative exposure to ACEs and experiencing specific trauma sub-types increased the odds of having a CKD diagnosis. Further research is needed to explore how ACEs affect disease occurrence and management of people with CKD.

PUB311

Increased Mortality due to Uranium-Associated Renal Disease Has Not Been Observed in Uranium Workers: A Meta-Analysis

Andrew M. Horvit, Donald A. Molony. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Studies in animal and human populations have suggested nephrotoxic effects of uranium exposure, but little statistical synthesis of the data has been done. This study aims to update and expand on existing meta – analyses of mortality due to renal disease by evaluating multiple uranium – exposed populations. This study also aims to further evaluate the effect of uranium exposure on renal biomarkers.

Methods: PubMed, Embase, Web of Science, and Trip Database were searched through September 2020. Studies that reported Standardized Mortality Ratios (SMR) for kidney cancer and chronic nephritis/nephrosis in uranium – exposed humans were identified. Studies that reported data for urine protein excretion, glomerular filtration rate, urine β2-microglobulin (BMG), and urine N-acetyl-β-glucosaminidase (NAG) between high uranium exposure and control groups were also identified. The Mantel – Haenszel Method was used for all SMR analyses. Inverse Variance with Mean Differences (MD) was used for all biomarker analyses. Random Effects Models were used for all analyses.

Results: 25 studies were included in the analyses. The mortality studies were exclusively occupational exposures and were divided into a uranium miner/miller subgroup and a factory/nuclear worker subgroup. Exposure subgroups were not created for the biomarker analyses due to an insufficient number of studies. Mortality analyses of kidney cancer and chronic nephritis/nephrosis irrespective of exposure group demonstrated an SMR of 0.93 (95CI: 0.82 – 1.05) and 0.82 (95CI: 0.70 – 0.96), respectively. The subgroup analyses demonstrated similar mortality deficits. The MD analysis of urine BMG (3.41, 95 CI: -5.21 – 12.03) showed higher levels in the high exposure group.

Conclusions: Uranium workers are not at increased risk of death due to renal disease. The current literature is limited to only occupational exposures, thus future community – based studies are needed to fully elucidate the effects of uranium exposure on morbidity and mortality due to renal disease by alleviating the presence of a "healthy worker effect". In the workers studies, non-cancer related renal disease may be under recognized

as a contributor to morbidity / mortality. The BMG analysis suggests there are possible nephrotoxic effects of uranium exposure, though more studies are needed to improve precision.

PUB312

Nephrology eConsultation: A Progress Update

David S. Levy, Rickinder Grewal, Monica L. Ranaletta, Stephanie Lempke, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Given the high demand for nephrology consultation at the University of Rochester, with an average of 30 - 40 new outpatient consult requests per week, based on the AAMC (Association of American Medical Colleges) Project CORE (Coordinating Optimal Referral Experiences) model, we developed an eConsultation program for primary care providers (PCPs) across the University's health network to receive subspecialty advice in a prompt and efficient manner in lieu of formal face-to-face nephrology consultation.

Methods: Here, we report our experience with time and value-based metrics of our eConsultation program from September 2019 through March 2021. eConsult requests were placed by PCPs for renal-related issues such as mild to moderate acute kidney injury, CKD, electrolyte disturbances, and proteinuria. The nephrologist electronically communicated with the PCP who then conveyed the subspecialty recommendations with their patient.

Results: Between September 2019 and March 2021, 338 eConsult requests were received, averaging 17.8 eConsults/month. Of these, 47% were deemed medically appropriate and completed, 34% were converted to in-person visits and 4% were declined. The majority – 63% of eConsults were completed between 11 - 20 minutes, 35% were completed between 5-10 minutes, and only 2% required more than 20 minutes to complete the consult. From a financial perspective, between September 2019 and March 2021, the nephrology eConsult program has generated over $6500 in revenue, translating to ~$38 per encounter, the equivalent of 0.7 wRVUs. From an access standpoint, eConsults were generally completed within 1-2 business days whereas the average wait time for an in-person consultation from referral creation was 33.8 ± 3.7 days.

Conclusions: Our nephrology eConsultation program has provided timely and remote subspecialty guidance for PCPs within our University's health network and has overall been well-received by patients and PCPs. This model has the ability to decrease wait time for more complex patients requiring in-person consultation thereby improving the overall quality of care we provide to all of our patients, while still maintaining, if not improving, financial feasibility. Further expansion of the program to involve non-University affiliated PCPs may further improve the program's ability to provide prompt quality care and better access for patients in more remote areas.

PUB313

eGFR Trajectory and Risks of Cardiovascular Events and ESKD in CKD Patients

Kohei Ohori, Maiko Kokubu, Masaru Matsui. *Nara Prefecture General Medical Center, Nara, Japan.*

Background: Growing evidence has shown the eGFR level is an established predictor of cardiovascular events, but the association of eGFR trajectory with cardiovascular and renal events remained limited.

Methods: We conducted a retrospective cohort study on 276 CKD patients in whom at least two measurements of eGFR levels to calculate eGFR slope were confirmed. Patients were divided into two groups according to the below and above cut-off values of eGFR slopes for outcomes using ROC curve. Outcomes are cardiovascular events defined as heart failure requiring hospitalization, revascularization for IHD and PAD, stroke or sudden death, and renal events defined as ESRD or baseline eGFR decline of > 30%.

Results: In total, the median (IQR) age of participants was 68 (56~77) years and 176 (64%) were male. The median (IQR) levels of baseline eGFR were 33 (20~48) mL/min/1.73m^2 with the median eGFR slope of -5.2(-0.85~-9.5) mL/min/1.73m^2/yr. During the study period, 92 cardiovascular events and 89 renal events occurred. Crude Kaplan-Meier analysis showed participants with lower eGFR slopes had higher probabilities of cardiovascular and renal events with statistical significances (p<0.001 and p<0.001, respectively). In the fully adjusted model, having lower eGFR slopes were associated with HRs (95%CIs) for cardiovascular and renal events of 1.71 [1.08-2.70] and 1.79 [1.09-2.93], respectively.

Conclusions: These data suggest not only current eGFR but also eGFR trajectory is an independent risk factor for cardiovascular and renal events in CKD patients.

PUB314

Baseline Renal Characteristics and Trial Design for MIRROR RCT, Randomized Trial of Pegloticase with or Without Methotrexate for Uncontrolled Gout

John K. Botson,[1] Naval G. Parikh,[2] Stephen Ong,[3] Dan T. La,[4] Karon Locicero,[5] Jeff R. Peterson,[6] Suneet Grewal,[7] Paul M. Peloso,[8] Stephen M. Sainati,[8] Katie L. Obermeyer,[8] Kenneth G. Saag,[9] John Tesser,[10] Amar Q. Majjhoo,[11] Michael E. Weinblatt.[12] *[1]Orthopedic Physicians Alaska, Anchorage, AK; [2]Napa Research Center, Pompano Beach, FL; [3]MD Medical Research, Oxon Hill, MD; [4]Medvin Clinical Research, Tujunga, CA; [5]GCP Clinical Research, Tampa, FL; [6]Western Washington Arthritis Clinic, Bothell, WA; [7]East Bay Rheumatology Medical Group, Inc., San Leandro, CA; [8]Horizon Therapeutics plc, Deerfield, IL; [9]University of Alabama, Birmingham, AL; [10]Arizona Arthritis & Rheumatology Associates, P.C., Phoenix, AZ; [11]Clinical Research Institute of Michigan, LLC, St. Clair Shores, MI; [12]Brigham and Women's Hospital, Boston, MA.*

Background: Twenty four percent of patients with gout[1] and 49% of patients with uncontrolled gout (UCG)[2] patients have CKD. Pegloticase (a pegylated recombinant uricase which rapidly dissolves urate) is associated with a 42% response rate,[3] however preliminary evidence suggests co-therapy with immunomodulation such as methotrexate (MTX) may increase this response.[4] The ongoing MIRROR randomized controlled trial (RCT) directly compares pegloticase w/wo MTX for UCG. We describe study design and baseline renal characteristics.

Methods: Enrolled patients had a serum urate [SU]≥7 mg/dL, urate lowering therapy failure/intolerance, AND visible tophi, recurrent flare, or chronic gouty arthropathy. Chronic immunosuppression, eGFR<40 ml/min/1.73m^2, and G6PD deficiency were key exclusion criteria. Patients who tolerated a 2-wk 15 mg/wk oral MTX run-in were randomized 2:1 to receive MTX or placebo (PBO). After a 4-wk MTX or PBO period, patients began 52 wks of pegloticase with weekly MTX or PBO. Primary endpoint is 6-month response rate (% patients with SU<6 mg/dL for ≥80% during Month 6).

Results: 42 US sites randomized 152 adults (54.7±12.6 yrs, 89% men, BMI 32.6±6.5 kg/m^2) with UCG (SU 8.9±1.6 mg/dL, 13.9±10.7 yr gout history, 68% with clinical tophi). 21% had prior kidney stones. Mean eGFR was 69.7±17.8 ml/min/1.73m^2 with 32% having eGFR<60 ml/min/1.73m^2. Gout burden became more severe as CKD stage increased, as indicated by Physician Global Assessment, Health Assessment Questionnaire (HAQ), and affected joint count.

Conclusions: Key baseline renal demographics demonstrate heavy gout disease burden and suggest UCG impacts patients with advanced CKD more severely. **References** 1. Clinical Outcomes Associated with Systemic Lupus Erythematosus (SLE) in the 5 Years Prior to ESKD Diagnosis

Christopher F. Bell, Amy Guisinger, Shirley Huang. *GlaxoSmithKline, NC 27709, NC.*

Background: Lupus nephritis affects up to 38% of patients (pts) with SLE, many of whom may progress to ESKD.[1] Despite high disease burden, data on clinical characteristics of pts with SLE in the years leading to ESKD diagnosis are limited. This study describes and compares the clinical outcomes of pts with SLE in the 5 years prior to ESKD diagnosis.

Methods: This retrospective analysis (GSK Study 215295) of United States administrative claims data (from IBM MarketScan database) included adult pts with SLE newly diagnosed with ESKD (International Classification of Diseases codes ICD-9/10) from March 2012 to December 2018. Study results focus on clinical outcomes in pts with 5-year continuous enrollment pre ESKD diagnosis.

Results: Of 1356 pts with SLE and ESKD identified, 81.8% were female; mean (standard deviation, SD) age was 46.7 (12.3) years. Of these pts, 616 had 5 years of continuous enrollment pre ESKD. Over the 5-year period pre ESKD, mean (SD) Quan-Charlson Comorbidity score increased from 1.8 (1.5) in Year 5 to 3.1 (2.0) in Year 1 prior to ESKD. The proportion of pts with severe disease also increased from 31.3% in Year 5 to 51.1% in Year 1 pre ESKD, and more pts experienced SLE flares (80.5% in Year 5 and 94.8% in Year 1 pre ESKD), particularly severe flares (Year 5: 11.9%; Year 1: 33.1%). Renal outcomes worsened each year for the 5-year period (**Figure**).

Conclusions: Prior to ESKD diagnosis, pts with SLE had high disease burden, particularly renal-related, which increased in the years leading to ESKD.

Gout in Advanced CKD Patients: Prevalence and Impact on Patient Health

Leonard Stern,[1] Richard J. Johnson,[2] Payam Shakouri,[3] Amod Athavale,[4] Karim R. Masri,[5] Brian LaMoreaux,[6] Brad Marder,[6] Sreedhar A. Mandayam.[7] *[1]Columbia University Irving Medical Center, New York, NY; [2]UCHealth University of Colorado Hospital, Aurora, CO; [3]Advanced Kidney Care, Poughkeepsie, NY; [4]Trinity Life Sciences, Waltham, MA; [5]Bon Secours Rheumatology Center, Richmond, VA; [6]Horizon Therapeutics plc, Deerfield, IL; [7]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Gout is associated with higher mortality risk,[1] multiple comorbidities,[1-3] and decreased quality of life.[3] Impaired renal function increases gout risk,[4] but gout prevalence and impact on advanced CKD patients have not been thoroughly described. This study reports health burden of gout in CKD patients under the care of nephrologists.

Methods: Nephrologists provided chart data on random Stage 3-5 CKD patients. Criteria to identify gout in this study: gout listed as comorbidity, urate-lowering therapy (ULT) use, or visible tophi/gout flare noted. Uncontrolled gout (UCG) was defined as serum urate >6 mg/dL with visible tophi, ≥2 flares in past year, or ≥1 swollen/tender joint. Gout prevalence was examined and patients with and without gout were compared.

Results: 111 physicians reported on 746 patients (55% male, 56.2±18.3 yrs, BMI: 31.4±10.9 kg/m^2) with Stage 3-5 CKD (duration: 4.0±4.8 yrs, eGFR: 32.2±15.5 ml/min/1.73 m^2). 173 (23%) met gout criteria, with highest frequency in Stage 3b and 4 (both 28%). Of gout patients, 13% had UCG, 29% had no formal gout diagnosis, and 38% were not using a ULT. Compared to those without gout, gout patients more often sought acute medical care (30% vs 7% in prior yr) and, at presentation, more often had urination changes (15% vs 7%) and shortness of breath (21% vs 14%; all p≤0.02). Gout patients had more diagnoses of CKD-mineral bone disorder, ischemic heart disease, CHF, peripheral vascular disease, and chronic pain. Compared to controlled gout patients, UCG patients more often had pulmonary hypertension, joint issues, chronic pain, febuxostat use, and colchicine use.

Conclusions: 1 in 5 advanced CKD patients had gout, of which 13% had UCG. Gout highly impacts advanced CKD patients, with increased healthcare utilization and higher cardiovascular and bone/joint comorbidity. Patients with uncontrolled gout have an even higher health burden and more frequent colchicine use (26%), which has worse toxicity profile in CKD patients. Among CKD patients, gout is common, impactful, and requires careful screening and collaborative management. **References** 1. Choi HK, Curhan G. *Circulation* 2007;116:894-900 2. PUB317

Claims-Based Evaluation of Pegloticase Use in Gout Patients with a History of Kidney Transplant

Craig Alan Shadur,[1] Karim R. Masri,[2] Brad Marder,[3] Claudia C. Vesel,[3] Brian LaMoreaux.[3] *[1]Kidney Physicians, PC, Des Moines, IA; [2]Bon Secours Mercy Rheumatology Center, Richmond, VA; [3]Horizon Therapeutics plc, Deerfield, IL.*

Background: Kidney transplant (KT) recipients have a high occurrence of gout due to reduced GFR and medications associated with hyperuricemia. Impaired renal function and drug interaction concerns can make it challenging to effectively lower urate in this population. Pegloticase (pegylated recombinant uricase) rapidly metabolizes urate and has known efficacy for managing uncontrolled gout. However, clinical trials excluded organ transplant recipients and few cases of use in transplant recipients have been reported. This study examined pegloticase use in KT patients with uncontrolled gout in a large claims database.

Methods: The IQVIA database was used to identify pts with a history of KT (≥1 CPT or ICD 9/10 code) receiving ≥1 pegloticase infusion. The number and type of concomitant immunosuppression (IMS) prescriptions within 3 mo prior to/during pegloticase use were collected and the number of pegloticase infusions was evaluated. Pts were excluded if they returned to dialysis before the first pegloticase infusion because of graft failure or rejection.

Results: 91 pts were identified between 2015 and 2020. Pts with reported demographics (n=85) were predominately male (81%) and 58±11 yrs old at the time of first pegloticase infusion. The most common comorbidities were hypertension (84%), hyperlipidemia (48%), anemia (46%), type 2 diabetes mellitus (40%), and heart failure (34%). Compared to 1st pegloticase claim, the 1st transplant code was 2.6±1.7 yrs (mean ± SD) earlier and 1st gout code was 2.1±1.7 yrs earlier. 61 pts (67%) had a tophaceous gout code. Transplant IMS medication codes were available for 67 pts (74%), with the majority receiving tacrolimus (n=34), mycophenolate mofetil (n=33), and/or cyclosporine (n=29). Pts received a mean of 13±16 pegloticase infusions (median: 8; Q1, Q3: 4, 15), with 38% receiving ≥12 infusions and 20% receiving ≥20 infusions.

Conclusions: This real-world dataset demonstrated that KT patients with uncontrolled gout are being treated with pegloticase. A main consideration with pegloticase efficacy is potential development of anti-drug antibodies (ADAs). Given that solid-organ transplant patients are on IMS medications to preserve their grafted organ, this likely contributed to prevention of ADAs indicated by the longer average duration of therapy compared to other real-world pegloticase datasets.

PUB318

Safety of Pegloticase with Immunomodulation Co-Therapy: Literature Review

Jeff R. Peterson,[1] Nathan Roe,[2] Howard M. Kenney,[3] Abdul A. Abdellatif,[4] Brian LaMoreaux.[2] *[1]Western Washington Medical Group Arthritis Clinic, Bothell, WA; [2]Horizon Therapeutics plc, Deerfield, IL; [3]Arthritis Northwest, Spokane, WA; [4]Baylor College of Medicine, Division of Nephrology, Houston, TX.*

Background: Gout occurs frequently among Chronic Kidney Disease (CKD) patients. Pegloticase therapy for uncontrolled gout does not require renal adjustments and is effective across all stages of CKD. Efficacy can be limited by development of anti-drug antibodies, which also increase the risk of infusion reactions (IR). A recent study reviewed publications on pegloticase with immunomodulating (IMM) co-therapy and demonstrated an increased response rate compared to the pivotal trials; however, aggregate safety data from the literature has not been reported.[1] The purpose of this study is to report IR prevalence and adverse events (AEs) of interest in publications which have evaluated the co-prescription of IMM with pegloticase.

Methods: Studies of pegloticase (q2w) use with concurrent IMM were identified in a search of PubMed and abstracts from professional society meetings (2012-2020). AEs were extracted and reported including IRs, gout flares, and infections. Gout flares and infection occurrence were not described in all studies, therefore, only studies where occurrence was specifically addressed were included.

Results: 10 publications were identified using IMM with pegloticase consisting of 82 total patients. Methotrexate was the most common IMM co-therapy. Due to the frequency of CKD in gout patients, other IMM agents were frequently used, including mycophenolate mofetil, leflunomide, azathioprine, and cyclosporine. All reports included serum urate monitoring to evaluate the ongoing efficacy of pegloticase. 3/82 (3.7%) patients experienced an IR during pegloticase treatment (total of 3/955 [0.3%] of infusions). Severity was described for 2 of the 3 IRs and were listed as mild. No instances of severe IR or anaphylaxis were reported. Gout flares as a % of patients were reported for 3 studies and occurred in 25/34 (72.2%). Among the 10 publications, 2 clinical studies reported details on infections. In these 2 studies (n=36), 5 infections occurred.

Conclusions: Pegloticase administered with IMM co-therapy had a low rate of mild IRs with no anaphylaxis reported. This study demonstrates that in addition to established improvements in pegloticase efficacy, the use of IMM co-therapy with pegloticase results in a favorable response rate and safety profile with low rate and severity of IRs. **References** 1. Prediction of Mortality Among Patients with CKD: A Systematic Review

Panupong Hansrivijit,[1] Kriti Lnu,[1] Angkawipa Trongtorsak,[4] Max Puthenpura,[3] Charat Thongprayoon,[2] Wisit Cheungpasitporn.[2] *[1]UPMC Pinnacle, Harrisburg, PA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Drexel University College of Medicine, Philadelphia, PA; [4]AMITA Health, Evanston, IL.*

Background: Chronic kidney disease (CKD) is a common medical condition with an increasing prevalence. To date, several clinical characteristics have been shown to be associated with mortality in CKD patients from regression analyses. However, the accuracy of mortality prediction has not been clearly elucidated. Thus, we aimed to demonstrate the predicting factors for mortality among CKD patients by utilizing the area under the receiver operating characteristic curve [AUC] analysis.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched through January 2021. Inclusion criteria were: 1) observational studies; 2) populations were non-transplant CKD at any stage; and 3) results were presented with AUC analysis with 95% confidence interval. AUC of 0.70-0.79 is considered acceptable, 0.80-0.89 is considered excellent, and more than 0.90 is considered outstanding.

Results: A total of 18 studies (n = 14,579) were included in the systematic review. 832 patients had non-dialysis CKD and 13,747 patients had dialysis-dependent CKD (2,160 hemodialysis, 370 peritoneal dialysis, and 11,217 non-differentiated mode of dialysis). Of 24 mortality predicting factors, none were deemed outstanding for mortality prediction. 7 factors were excellent predictors for mortality (NT-proBNP, BNP, soluble urokinase plasminogen activator receptor [suPAR], augmentation index, left atrial reservoir strain, C-reactive protein, and systolic pulmonary artery pressure). 17 predictive factors were in the acceptable range; two of which were echocardiographic factors (Image 1).

Conclusions: Several factors were predictive of mortality among CKD patients. Most of these factors could be identified by echocardiography, which may serve as an practical tool for mortality prediction in this population.

AUC range	Interpretation	Predicting factors (AUC)	Subjects
≥ 0.90	Outstanding	–	–
0.80-0.89	Excellent	NT-proBNP (0.83)	HD

Utilization of Renin Angiotensin Aldosterone System Inhibitors in Cardiorenal Syndrome Patients: An Experience from the Middle East

Yosef Manla, Feras Bader, Fahad Alsindi, Medhat Soliman, Wasim El Nekidy, Amir R. Malik, Nizar M. Attallah. *Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates*.

Background: Renin-angiotensin-aldosterone system inhibitors (RAASi) have demonstrated undisputed cardio-nephroprotective merits. However, RAASi are underused in patients with cardiorenal syndrome (CRS) due to various reasons. Therefore, we aim to explore RAASi utilization in heart failure (HF) patients according to renal function and determine predictors of not receiving RAASi in CRS patients.

Methods: We included HF patients (n=235) with 12-month follow-up in our outpatient HF clinic. Data on patient characteristics were collected by retrospective chart review. We compared HF patients with eGFR<60 (CRS) vs. those with HF and eGFR≥60 (non-CRS) using appropriate testing methods. Predictors of not receiving RAASi in CRS patients at 12-month follow-up were assessed using multivariable logistic regression.

Results: At baseline, 77 (32.8%) of HF patients had CRS. Patients in the non-CRS group had a significantly higher rate of RAASi use compared to the CRS group (84.2% VS. 54.5%, p<0.001). After a follow-up of 12 months, there was a significant proportional increase in RAASi receivers within each group (table), with no significant between-group difference in increase (6.9% vs.7.8% p=0.8). On multivariable logistic regression including age, gender, diabetes, baseline serum creatinine (Scr), and distance from clinic; only baseline Scr predicted not receiving RAASi at follow-up (OR:1.07, per 0.1 mg/dl increase, 95%CI [1.01-1.17], p=0.02), and a significant trend was noticed with distance from clinic (OR:1.01, per 1 mile increase, 95%CI [0.998-1.02], p=0.09).

Conclusions: While RAASi are underutilized in CRS patients, a multidisciplinary team approach considering CKD stage and patient demographics can increase their use and impact treatment plans and outcomes in this population.

Table.1 Characteristics of HF patients with CRS vs. those without CRS.

Variable	CRS HF patients (n=77)	Non-CRS HF patients (n=158)	P-value
Age (years)	64.3 ±11.2	54.6 ±16	<0.001
Male gender	70%	62.7%	0.2
Ischemic heart disease	58.4%	36.7%	0.002
Hypertension	87%	64.5%	<0.001
Hyperlipidemia	75.3%	59.5%	0.02
Diabetes mellitus	72.7%	47.5%	<0.001
Atrial fibrillation	33.8%	25.3%	0.2
Smoking	37.6%	32.9%	0.5
Ejection fraction%	36.6 ±14.4	31.9±13.5	0.01

Renal Function Outcomes at 5 Years from Radical and Partial Nephrectomies in Normal Renal Function Patients: An Insidious Tale of Failed Renal Hyperfiltrations

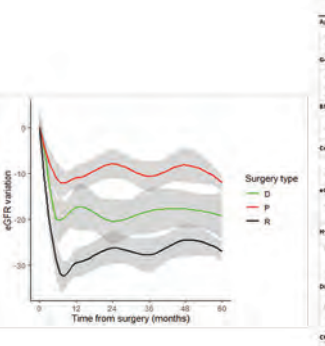
Francesco Trevisani,[1] Federico Di marco,[1] Matteo Floris,[2] Francesco Trepiccione,[3,4] Giuseppe Rosiello,[1] Antonello Pani,[2] Giovambattista Capasso,[3,4] Caterina Vitagliano,[3,4] Giacomo Mascia,[2] Francesco Fiorio,[1] Alessandra Cinque,[1] Arianna Bettiga,[1] Alessandro Larcher,[1] Umberto Capitanio,[1] Andrea Salonia,[1] Francesco Montorsi.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Ospedale Giuseppe Brotzu, Cagliari, Italy; [3]Universita degli Studi della Campania Luigi Vanvitelli Dipartimento di Scienze Mediche Traslazionali, Napoli, Italy; [4]Biogem, Institute of biology and genetics, Avellino, Italy*.

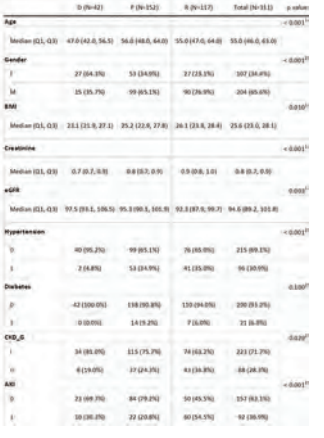
Background: CKD represents a major postoperative long-term complication in renal surgery, both in radical (RN) than in partial nephrectomy (PN). Aim of our study was to compare the eGFR decay over time from pre-operative time surgery to 5 years follow up in RN and PN in normal renal function pts.

Methods: A multicentric cohort-study of 269 consecutive pts who underwent RN or PN due to the presence of a kidney mass was enrolled. A group of 42 kidney living donors was considered as control. We evaluated eGFR variation at the pre-surgical value, hospital dismissal, 6,12,24,36,48,60 months. eGFR categories were created according to K-DIGO system. Comparisons between groups were performed using Kruskal-Wallis ranks sum test for numerical variables and Pearson's Chi square test for categorical variables

Results: Descriptive analysis is reported in table1. Two-way Anova underlined a significative difference for the type of surgery(p<0.001). The analysis showed the presence of a variation over time of the eGFR(p<0.001) that depends also on the surgery type(p<0.001). Post-hoc analys showed: at 6-12-24-36-48-60 months RN groups always had a mean decay higher(p<0.001) in respect to PN. In respect to living donor, oncological RN had a mean decay higher (p=0.02) at all time points, except at 24 months, when the donor group had a decay higher(p=0.005) by 13.1 (5.8,20.4)(figure1)

Conclusions: RN and PN harbor a solid risk of post-operative CKD even in normal renal function pts. RN pts tend to vicariate the acute loss of nephfron mass with an increase of eGFR over time, while PN renal function remains stable in time without hyperfiltration





PUB322

Outcomes of Educational Initiatives for Advanced CKD

Asheen Zariat, Ali W. Rizvi, Patricia Khalil. *Allegheny Health Network, Pittsburgh, PA.*

Background: Timing of kidney replacement therapy (KRT) and transplant referral in chronic kidney disease (CKD) G4 and G5 is a difficult topic. The COVID-19 pandemic has disrupted nearly all aspects of healthcare, including the process of KRT plan. This study examined if the addition of a Transition Coordinator (TC) improved KRT transition plan despite the pandemic.

Methods: Retrospective descriptive study examining patients at single academic practice with eGFR <20 that completed CKD educational program (CKDEP). Control Group: 5/1/19-1/31/20 with in-person CKDEP, no TC. Intervention Group (IG): 5/1/20-1/31/21 with virtual or in-person CKDEP with addition of TC. TC called patient monthly to assess barriers to KRT planning, assist with scheduling, and communicate with Nephrologist. "Success" was defined as having a KRT plan. Failure was defined as either urgent start dialysis via dialysis catheter (DC) or patients without KRT plan.

Results: CG had n=15 while IG had n=47. Both groups were evenly distributed with age, average eGFR (15). The CG had slightly higher rates of urgent starts and patients without KRT plan compared to IG (Table 1). Patients were referred for Vascular access +/- Transplant 20% (3) in CG and 23% in IG. PD +/- Transplant was chosen in 6.7% (1) of CG and 36% (17) of IG. Success and Failure rates were similar in both groups (Table 2).

Conclusions: Despite the pandemic, there was no overall change in rate of failure (urgent start or lack of KRT plan), however, individual decreases in these groups were noted. This could indicate that TC may improve outcomes when the pandemic is controlled. Increased interest in PD was noted which could indicate greater understanding via follow up provided by TC.

Table 1. Percentage of Urgent KRT vs no KRT plan due to intervention

	Control group (2019-2020) (%)	Intervention group (2020-2021) (%)
Urgent start KRT	2 (13.3%)	4 (8.5%)
No KRT plan	2 (13.3%)	8 (17.0%)
Total	15	47

Table 1

Control Group Outcomes

	Frequency	
Failure	4	26.7%
Success	11	73.3%

Chronic Hematuria Increases Chronic Kidney Injury and Epithelial Mesenchymal Transition in 5/6 Nephrectomy Rats

Sergey V. Brodsky, Min Xiao, Ajay kumar Medipally, Laura Biederman, Anjali A. Satoskar. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Chronic kidney disease (CKD) is a common outcome of many kidney diseases. Interstitial fibrosis and tubular atrophy (IFTA) is a histologic hallmark of CKD. Hematuria is a common symptom in many human kidney diseases. Free hemoglobin may affect tubular epithelial cells by generating reactive oxygen species (ROS). Epithelial mesenchymal transition (EMT) of the tubular epithelial cells has been shown to play an important role in the IFTA development. The aim of this study was to determine the effects of chronic hematuria on the CKD progression in 5/6 nephrectomy (5/6NE) rat model of CKD.

Methods: 5/6NE rats were treated with oral warfarin (0.5 mg/kg/day) or vehicle (control). Animals were monitored for 26 weeks, prothrombin time (PT), serum creatinine (SCr) and hematuria were measured weekly. Stainings for iron, trichrome and EMT markers were performed on the remnant kidneys, ROS were detected in the kidneys by protein carbonyl assay at the end of the study.

Results: Warfarin treatment resulted in a PT increase 1.5-2.5 times from control, increase in hematuria and serum creatinine. Histologically, warfarin-treated animals had more iron-positive tubular epithelial cells and increased IFTA as compared to control (42.9±17% vs 18.3±2.6%), Fig 1. ROS were increased in the kidney in warfarin-treated rats. The number of tubules that show evidence of EMT was significantly higher in warfarin-treated 5/6NE as compared to control 5/6NE rats.

Conclusions: Chronic hematuria results in increased iron-positive tubular epithelial cells, EMT and more prominent IFTA in CKD rats. Our data suggests an important role of chronic hematuria in the progression of CKD.

Inhibition of Old Astrocyte Specifically Induced Substance (OASIS) in Myofibroblasts Suppressed Kidney Fibrosis

Ayaha Yamamoto,[1] Masanori Obana,[1] Yoshiaki Miyake,[1] Shota Tanaka,[1] Makiko Maeda,[1] Kazunori Imaizumi,[2] Yasushi Fujio.[1] *[1]Osaka Daigaku, Suita, Japan; [2]Hiroshima Daigaku, Higashihiroshima, Japan.*

Background: Although kidney fibrosis is a critical event for the onset of renal failure, molecular mechanisms are not fully understood. Previously, we found that Old astrocyte specifically induced substance (OASIS), a transcription factor, exacerbated kidney fibrosis in part by increased bone marrow stromal cell antigen 2 (Bst2), using conventional knockout mice; however, the cell specificity of OASIS function in kidney fibrosis remains to be elucidated. In this study, we focused on the role of OASIS in myofibroblasts to elucidate novel mechanisms of kidney fibrosis.

Methods: OASIS expression in human kidneys was examined by immunohistochemistry with anti-OASIS and α-SMA antibodies. Cultured myofibroblasts were treated with AEBSF, an inhibitor of OASIS activation. In addition, C57BL/6 mice were intraperitoneally injected with AEBSF for 9 consecutive days starting 2 days before unilateral ureteral obstruction (UUO) surgery. To examine the effects of OASIS in myofibroblasts on kidney fibrosis, myofibroblast-specific OASIS knockout (cKO) mice were subjected to UUO. Day 7 after UUO, kidney fibrosis was examined by Sirius Red staining, hydroxyproline assay and immunofluorescence analysis. Isolated murine myofibroblasts were treated with TGF-β1 for 24 hours and chromatin immunoprecipitation assay was conducted to test whether OASIS directly regulates the transcription of Collagen I and Bst2.

Results: OASIS was increased in myofibroblasts in human fibrotic kidneys. AEBSF suppressed OASIS activation in myofibroblasts and reduced kidney fibrosis after UUO. Importantly, kidney fibrosis was attenuated in OASIS cKO mice compared with control mice (Sirius Red positive area (%): Control-contralateral;2.4±0.9, Control-UUO;23.4±2.9, cKO-contralateral;3.1±1.0, cKO-UUO;18.8±2.0, n=9-11). In addition, OASIS cKO mice showed reduced number of Ki-67-positive proliferative myofibroblasts in fibrotic kidneys. Finally, mRNA levels of Collagen I and Bst2 was decreased in the kidneys of OASIS cKO mice after UUO and OASIS directly bound to the promoter region of these genes in murine kidney myofibroblasts.

Conclusions: OASIS in myofibroblasts contributes to the development of kidney fibrosis. Suppression of OASIS signaling in myofibroblasts could be a novel therapeutic strategy against fibrotic kidney disease.

PUB325

Salvianolic Acid C Activates PPAR Signaling Pathway and Ameliorates Renal Fibrosis in Obstructive Kidneys

Junyan Lin, Ming Wu, Dongping Chen, Chaoyang Ye. *Shuguang Hospital, Shanghai, China.*

Background: Salvianolic acid C (SAC) is a component of Danshen, a widely used herbal medicine for the treatment of renal cardiovascular diseases. Renal interstitial fibrosis is a common pathway of all kinds of chronic kidney diseases progressing to the end stage of renal diseases. We aimed to study the effect of SAC on renal fibrosis and explore its underlining mechanisms.

Methods: After sham or unilateral ureteral obstruction (UUO) operation, 20-25g male c57 mice were treated with vehicle or SAC (10mg/kg) for 14 days. Moreover, normal rat kidney interstitial fibroblast (NRK-49F) cells were treated with various concentrations of SAC (10 mM to 100 mM). Protein samples from *in vivo* and *in vitro* experiments were collected to assess renal fibrosis.

Results: Treatment with SAC reduced the deposition of interstitial matrix proteins in UUO kidneys as shown by Masson staining. The expression of Fibronectin, collagen-I and α smooth muscle actin (αSMA) were increased in UUO induced fibrotic kidneys, which were down-regulated in SAC treated UUO kidneys. In parallel, treatment with SAC reduced the expression of fibronectin and αSMA in NRK-49F cells. RNA sequence analysis showed that multiple genes belong to the PPAR (peroxisome proliferator-activated receptor) signaling pathway were up-regulated by SAC treatment in UUO kidneys.

Conclusions: SAC inhibits renal fibrosis in obstructed kidneys possibly through activation of the PPAR signaling pathway.

PUB326

Role of PAR-1 in Immune Activation and Tubulointerstitial Fibrosis During AKI-to-CKD transition

Sarah W.Y. Lok, Wai Han Yiu, Loretta Y.Y. Chan, Joseph C K Leung, Sydney C. Tang. *University of Hong Kong, Hong Kong, Hong Kong.*

Background: The high-affinity thrombin receptor protease-activated receptor-1 (PAR-1) has been recognized as a therapeutic target for cardiovascular intervention. Emerging evidence suggests that the coagulation cascade is activated in the kidney interstitium during AKI. Yet, the role of PAR-1 signaling in AKI to CKD transition remains largely unexplored.

Methods: We investigated the effect of PAR-1 deficiency in a longitudinal kidney fibrotic murine AKI to CKD transition model. PAR-1$^{-/-}$ and wild type mice underwent unilateral ischemia-reperfusion injury (UIRI) for 7, 14 and 28 days. Uninephrectomy of the contralateral kidney was performed one day before sacrifice to assess renal injury.

Results: After 14 or 28 days of UIRI, BUN was significantly lower in PAR-1$^{-/-}$ vs wild type mice. PAR-1$^{-/-}$ mice showed diminished kidney fibrosis with reduced ECM accumulation and expression of fibronectin, α-smooth muscle actin and collagen via TGF-β/Smad signaling after UIRI. Macrophage infiltration and inflammation was alleviated in PAR-1$^{-/-}$ ischemic kidneys in which macrophage M1-polarization and its secretory cytokine TNF-α were attenuated.

Conclusions: PAR-1 deficiency confers renoprotection by suppressing M1 macrophage activation, inflammatory and profibrotic responses during AKI and its subsequent transition to CKD. **Funding:** Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 05163596), Research Grants Council of Hong Kong (General Research Fund, grant no. 17118720), and Hong Kong Society of Nephrology/HK Kidney Foundation Research Grant 2018.

PUB327

Increased Serum ApoCIII Levels in CKD Patients May Underlie the Impaired Delivery of Cholesterol to Hepatocytes and Increased Cardiovascular Disease (CVD) Risk

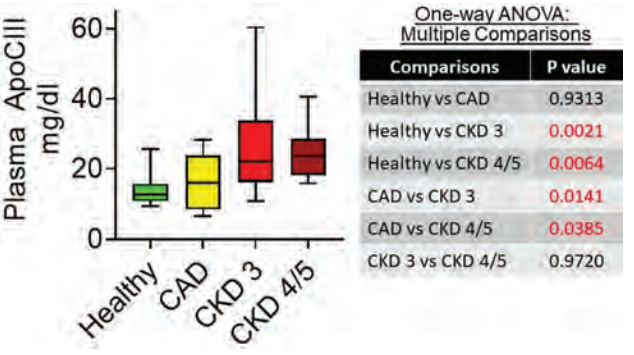
Graham T. Gipson,[1] Siddhartha S. Ghosh,[1] Todd W. Gehr,[1] Sarah Bu,[1] Jing Wang,[1] Shobha Ghosh.[1,2] *[1]Virginia Commonwealth University, Richmond, VA; [2]VA Richmond Medical Center, Richmond, VA.*

Background: Increased CVD risk underlies the mortality in CKD patients but the underlying mechanisms are not completely defined. We reported earlier that the serum from CKD patients displayed an impaired ability to deliver cholesterol to hepatocytes demonstrating a likely defect in hepatic elimination of cholesterol (as bile acids and biliary cholesterol) returning to the liver from the peripheral tissues via lipoproteins (e.g., VLDL or HDL). Apolipoprotein C-III (ApoCIII) is associated with VLDL and HDL and, not only inhibits lipoprotein lipase and hepatic lipase, but inhibits the uptake of VLDL and HDL by hepatic lipoprotein receptors. Herein we examined the hypothesis that impaired ability of serum from CKD subjects to deliver cholesterol to hepatocytes was associated with increased serum ApoCIII.

Methods: ApoCIII levels were determined by ELISA in serum samples from 32 patients with CKD [stage 3 (N=15) and stage 4+5 (N=17)], 15 patients with established CAD and 15 healthy subjects from our earlier study. One-way ANOVA with Multiple group comparisons was used to determine significance of observed differences.

Results: While ApoCIII levels in healthy subjects and patients with established CAD were not significantly different, significantly higher ApoCIII levels were seen in patients with CKD 3 and CKD 4/5 (See Figure) compared to healthy subjects as well as compared to patients with CAD. This is consistent with the reported decrease in hepatocyte uptake of lipoprotein cholesterol from serum of CKD patients.

Conclusions: Circulating ApoCIII, the catabolism of which is related to kidney function, is increased in CKD and likely impairs the ability of VLDL and HDL uptake by hepatocytes. Using ApoCIII transgenic mice, the mechanistic details are currently under investigation.



One-way ANOVA: Multiple Comparisons

Comparisons	P value
Healthy vs CAD	0.9313
Healthy vs CKD 3	0.0021
Healthy vs CKD 4/5	0.0064
CAD vs CKD 3	0.0141
CAD vs CKD 4/5	0.0385

Omega-3 Polyunsaturated Fatty Acid Attenuates Uremia-Induced Brain Damage in Mice

Kang Wook Lee, Youngrok Ham, Dae Eun Choi, Jin Ah Shin, Jin young Jeong, Soo hyun Han, Haet Bit Hwang, Eu Jin Lee, Kiryang Na. *Chungnam National University School of Medicine, Daejeon, Republic of Korea.*

Background: Researchers have increasingly demonstrated the relationship between renal impairment and cognitive impairment. Omega-3 polyunsaturated fatty acid (ω3-PUFA) plays an important role in preserving nerve function. However, neuroprotective effects of ω3-PUFA against uremic condition remain unclear. We are to identify brain damage caused by uremic toxicity and determine the protective effects of ω-3 PUFA against uremic toxin.

Methods: We induced uremic condition with renal ischemia reperfusion (IR) injury. 10 weeks male C57BL/6 mice and Fat-1 mice were used for IR injury. 3 days after IR injury, blood, brain and kidney tissue were collected for analysis.

Results: The results showed that Ki67 and neuronal nuclei (NeuN) decreased in the brain of uremic mice as compared to wt mice brain, but increased in the ω-3 PUFA–treated uremic mice and the brain of uremic Fat -1 mice as compared to the brain of uremic mice. The pro-apoptotic protein expressions were increased, whereas anti-apoptotic protein expression decreased in the brain of uremic mice as compared to wt mice brain. However, apoptotic protein expression decreased in the ω-3 PUFA–treated uremic mice and the brain of uremic Fat -1 mice as compared to the brain of uremic mice. Furthermore, the ω-3 PUFA–treated uremic mice and brain of uremic Fat-1 mice protein expression of p-PI3K, p-PDK1, and p-Akt were increased as compared to the brain of uremic mice.

Conclusions: In conclusion, we confirm that uremic toxin damages the brain and causes cell death. ω-3 PUFA may play a role in reducing neuronal injuries through PI(3) K-Akt signaling.

The TESTING Study: Steroids vs. Placebo in High Risk IgA Nephropathy

Vlado Perkovic,[2] Jicheng Lv,[1,2] Muh Geot Wong,[2,3] Michelle A. Hladunewich,[4] Vivekanand Jha,[5,6] Helen Monaghan,[2] Hong Zhang.[1] The TESTING Study Group *[1]Renal Division, Peking University First Hospital, Beijing, China; [2]The George Institute for Global Health, University of New South Wales, Sydney, NSW, Australia; [3]Renal Medicine, Royal North Shore Hospital, St Leonards, Sydney, NSW, Australia; [4]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [5]The George Institute for Global Health India, New Delhi, India; [6]Imperial College, London, United Kingdom.*

Background: The Therapeutic Evaluation of STeroids in IgA Nephropathy Global (TESTING) study assessed the effects of oral methylprednisolone compared to placebo on major kidney outcomes and safety in IgAN.

Methods: This investigator-initiated, double-blind randomized trial included people with IgAN, proteinuria ≥1g/day and eGFR 20-120 mL/min/1.73m^2, following ≥3 months of optimized background care including RAS blockade. Participants were randomized 1:1 to methylprednisolone (0.6-0.8 mg/kg/day, maximum 48 mg/day, for 2 months then weaning by 8mg/day/month) or to matching placebo. In 2016, due to an excess of serious infections in the steroid arm, the methylprednisolone dose was reduced (0.4 mg/kg/day, maximum 32 mg/day, weaning by 4 mg/day/month) and *pneumocystis jirovecii* prophylaxis added. The primary endpoint was the composite of 40% eGFR decline or kidney failure (dialysis, transplantation or death due to kidney disease) with prespecified secondary and safety outcomes.

Results: In total, 503 participants (mean age 38 years, 39% female, mean eGFR 61.5 mL/min/1.73m^2, proteinuria 2.46 g/day) were randomised to methylprednisolone (257) or placebo (246), including 262 to the full dose and 241 to the reduced dose protocols. Over 4.2 years average follow up, methylprednisolone reduced the risk of the primary outcome by 47% (event rate 7.0 vs 11.8/100 patient years, HR 0.53, 95% CI 0.39-0.72, p <0.0001), and ESKD by 41% (HR 0.59, CI 0.40-0.87, p=0.008). The reduction in risk was seen across both dose protocols (p heterogeneity 0.11): full dose HR 0.58 (95% CI 0.41-0.81), reduced dose HR 0.27 (95% CI 0.11-0.65). Serious adverse events were more frequent with steroids compared to placebo (28 vs 7 patients, p=0.0004), particularly with the full dose (22 vs 4, p=0.0003) vs the reduced dose regimen (6 vs 3, p=0.50).

Conclusions: Steroids reduce the risk of major kidney outcomes and kidney failure in people with high risk IgAN. The incidence of serious adverse events is increased mainly with high dose therapy. **joint first (JL MW)/senior authors (HZ VP)*

Randomized Controlled Trial Comparing 3- vs. 6-Months Initial Prednisone Therapy in Young (<4-Year-Old) Children with Nephrotic Syndrome

Aditi Sinha, Pankaj Hari, Arvind Bagga. Nephrotic Syndrome Study Group *Pediatrics, All India Institute of Medical Sciences, New Delhi, India.*

Background: While recent RCTs suggest no role for prolonged (>2-3 months) initial corticosteroid therapy in NS, subgroup analysis in 2-studies suggests its association with reduced frequency of subsequent relapses in children <4-6 yr-old. This multicenter open-label trial examines the efficacy & safety of 3-months versus 6-months prednisone therapy during the first episode of NS in patients <4-yr-old [CTRI2015/06/005939; NCT03141970].

Methods: Following ethics approval & parental consent, 172 consecutive patients (1-4 yr-old) were enrolled at onset of idiopathic NS during 2015-19. After 6-wk daily & 6-wk alternate day (AD) initial prednisone therapy, they were randomized (1:1) to either tapering prednisone on AD for 12-wk or no therapy. Relapses were treated with prednisone 2 mg/kg/d till remission, then on AD for 4-wk. Outcomes, based on intention-to-treat analysis during 2-yr follow up, include the proportion of patients with relapse or frequent relapses, time to first relapse, cumulative steroid dose & adverse effects. Based on a prior RCT, at 80% power & α=0.05) 78 patients were required per group to show 30% higher sustained remission with 6-mo therapy.

Results: Baseline features in the groups were similar **(Fig 1)**. Despite trends favoring 6-mo therapy, proportions of patients in sustained remission & frequent relapses at 1- & 2-yr, time to relapse (HR 0.75; 95%CI 0.53-1.06) or frequent relapses (HR 0.78; 0.52-1.18), and relapse rates were similar **(Fig 1, 2)**. The rates of adverse events were similar.

Conclusions: Prolonged initial prednisolone therapy does not significantly alter the disease course in young children with NS.

Funding: Government Support - Non-U.S.

Effect of Avacopan, a Selective C5a Receptor Inhibitor, on Kidney Function in Patients with ANCA-Associated Vasculitis

David R. Jayne,[1] Peter A. Merkel,[2] Pirow Bekker,[3] Annette Bruchfeld,[4,5] Duvuru Geetha,[6] Alexandre Karras,[7] John Niles.[8] *[1]University of Cambridge, Cambridge, United Kingdom; [2]University of Pennsylvania, Philadelphia, PA; [3]ChemoCentryx Inc, San Carlos, CA; [4]Linkopings universitet, Linkoping, Sweden; [5]Karolinska Institutet, Stockholm, Sweden; [6]Johns Hopkins University, Baltimore, MD; [7]Hopital Europeen Georges Pompidou, Paris, France; [8]Massachusetts General Hospital, Boston, MA.*

Background: Patients with anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis and renal disease have a poor prognosis. The effect of avacopan, an oral C5a receptor inhibitor, on renal function is described.

Methods: The ADVOCATE Phase 3 trial randomized patients to receive avacopan or prednisone taper on a background of either cyclophosphamide (followed by azathioprine) or rituximab. Primary endpoints were remission at Week 26 and sustained remission at Week 52. Secondary objectives included evaluation of kidney function.

Results: At Week 52, the difference in eGFR recovery in patients with eGFR <60 mL/min/1.73 m^2 and/or urinary abnormalities at baseline between avacopan and prednisone treatment groups was 5.5 mL/min/1.73 m^2 (95% CI [1.4, 9.6], p<0.01) **(Figure1A)**. Improvement in eGFR with avacopan was most prominent in patients with eGFR <30 mL/min/1.73 m^2 at baseline, when by week 52, the least squares mean (LSM) increase in eGFR was 13.7 (avacopan group) vs. 8.2 mL/min/1.73 m^2 (prednisone group) (p<0.01) **(Figure 1B)**. Among patients with CKD Stage 4 at baseline: in the avacopan group (n=52), 26 (50%) improved 1 stage and 3 (5.8%) improved 2 stages; in the prednisone group (n=48), 21 (44%) improved 1 stage and 1 (2.1%) improved 2 stages (p=0.32). Avacopan was also associated with more rapid reduction in proteinuria and hematuria. Urinary albumin:creatinine ratio improved 40% within the first 4 weeks of treatment with avacopan vs. no change in the prednisone group (difference -40, 95% CI [-53, -22]).

Conclusions: In ADVOCATE, patients with ANCA-associated vasculitis in the avacopan group had greater recovery of kidney function compared to patients in the prednisone group, especially among patients with CKD Stage 4 and those with eGFR <60 mL/min/1.73 m^2 and/or urinary abnormalities at baseline.

ILLUMINATE-C, a Single-Arm, Phase 3 Study of Lumasiran in Patients with Primary Hyperoxaluria Type 1 and CKD Stages 3b-5, Including Those on Hemodialysis

Mini Michael,[1] Jaap Groothoff,[2] Hadas Shasha-Lavsky,[3] John C. Lieske,[4] Yaacov Frishberg,[5] Eva Simkova,[6] Anne-Laure A. Sellier-Leclerc,[7] Arnaud Devresse,[8] Fitsum Guebre Egziabher,[9] Sevcan A. Bakkaloglu,[10] Chebl Mourani,[11] Rola Saqan,[12] Richard F. Singer,[13] Richard G. Willey,[14] Bahru A. Habtemarian,[14] Ishir Bhan,[14] Tracy McGregor,[14] Daniella Magen.[15] *[1]Department of Pediatrics, Texas Children's Hospital, Houston, TX; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [3]Pediatric Nephrology Unit, Galilee Medical Center, Nahariya, Israel; [4]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [5]Division of Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [6]Al Jalila Children's Specialty Hospital, Dubai, United Arab Emirates; [7]Hopital Femme Mere Enfant, Bron, France; [8]Division of Nephrology, Cliniques universitaires Saint-Luc, Bruxelles, Belgium; [9]Nephrology and Renal Function Unit, Groupement Hospitalier Edouard Herriot Service de soins palliatifs, Lyon, France; [10]Department of Pediatric Nephrology, Gazi Universitesi, Ankara, Turkey; [11]Pediatrics, Hotel-Dieu de France Hospital, Beirut, Lebanon; [12]Pharmaceutical Research Center, King Abdullah University Hospital, Ramtha, Jordan; [13]Canberra Health Services, Garran, ACT, Australia; [14]Alnylam Pharmaceuticals Inc, Cambridge, MA; [15]Pediatric Nephrology Institute, Rambam Health Care Campus, Haifa, Israel.*

Background: Primary hyperoxaluria type 1 (PH1) is a rare genetic disorder characterized by hepatic overproduction of oxalate, leading to progressive kidney disease. As kidney function declines, oxalate elimination is compromised and plasma oxalate (POx) increases, leading to systemic oxalosis. In CKD stages 3b–5, elevated POx is directly related to the pathophysiology of oxalosis and reduction of POx is a relevant clinical trial endpoint. We present results from the 6-month primary analysis period of ILLUMINATE-C, a single-arm, phase 3 study to evaluate lumasiran, an RNAi therapeutic which inhibits oxalate production, in patients with PH1 and impaired kidney function.

Methods: Key inclusion criteria: genetically confirmed PH1 diagnosis, eGFR≤45 mL/min/1.73m^2, POx≥20 µmol/L (upper limit of normal=12 µmol/L). Cohort A: patients who did not require dialysis or kidney transplantation at study start. Cohort B: patients on hemodialysis. Primary endpoints: percent change in POx from baseline to Month (M) 6 (cohort A); percent change in pre-dialysis POx from baseline to M6 (cohort B).

Results: Twenty-one patients enrolled, 6 in cohort A and 15 in cohort B. The baseline mean (SD) POx was 64.7 (41.3) µmol/L in cohort A and 108.4 (29.5) µmol/L in cohort B. In cohorts A and B, respectively, lumasiran led to 33.33% (95%CI:–15.16, 81.82) and 42.43% (95%CI:34.15, 50.71) least-square mean reductions in POx from baseline to M6 (averaged across M3-6). Lumasiran also demonstrated a reduction in urinary oxalate (cohort A). The most common adverse events (AEs) related to lumasiran were injection-site reactions, all of which were mild. There were no serious or severe AEs related to lumasiran nor deaths of patients that received lumasiran. There were no treatment discontinuations or study withdrawals.

Conclusions: Lumasiran resulted in substantial reductions in POx in PH1 patients with CKD 3b-5, with an acceptable safety profile through M6. Changes of this magnitude in POx may impact long-term clinical outcomes, including those related to systemic oxalosis, which will be evaluated in the extension period of the study.

FR-OR65

Long-Term Results of the Ellipsys Percutaneous Fistula for Hemodialysis

Jeffrey E. Hull,[1] William C. Jennings,[2] Randy I. Cooper,[4] Rajeev Narayan,[5] Neghae Mawla.[3] *[1]Richmond Vascular Center, Richmond, VA; [2]Surgery, The University of Oklahoma - Tulsa, Tulsa, OK; [3]Dallas Nephrology, Dallas, TX; [4]Southwest Kidney Institute Central Phoenix, Phoenix, AZ; [5]San Antonio Kidney Disease Center, San Antonio, TX.*

Background: The Pivotal Multicenter Trial of Ultrasound Guided Percutaneous Arteriorvenous Fistula (pAVF) Creation for Hemodialysis (Ellipsys Pivotal Trial) demonstrated the early safety and efficacy in a two-stage procedure with creation followed by maturation of proximal radial artery fistula for hemodialysis. The long-term outcomes through 5 years were evaluated to demonstrate fistula use, durability, and complications.

Methods: Prospective data from Ellipsys Pivotal Trial was combined with chart review to obtain a median follow-up of 50 (12 to 60) months. Review included fistula use, secondary procedures, and complications. The initial procedures and follow-up were performed in the office based lab (OBL).

Results: The percutaneous fistula (pAVF) was successfully used in 92.2% (83/90) of patients undergoing hemodialysis. Non-use of pAVF occurred in 22.4% (24/107) patients: 5 pAVF not created, 5 abandoned, 8 deaths, 1 transplant, 1 pre dialysis, 2 lost to follow-up, 1 catheter, 1 peritoneal dialysis. Procedures performed per patient per year (PPPY) to maintain function and patency was 0.93 (362/391) over 5 years with 2.63 in the first year, and then declining to 0.25, 0.57, 0.18, 0.24 in years 2-5. Access complications the location and treatment are listed in Table 1. Kaplan-Meier (KM) analysis demonstrated secondary patency of 89.5%, 88.4%, 88.4%, 85.6%, and 82.0% at years 1-5. Functional patency was 97.5%, 97.5%, 97.5%, and 91.8% at years 1-4 after two-needle cannulation.

Conclusions: Percutaneous fistulae created by interventionalist in the office based lab have provided durable access for hemodialysis through 5 years with a high rate of fistula use, and low rates of secondary procedures and complications.

Dole,[15] Lata Kler,[16] Amy M. Meadowcroft,[17] Lin Taft,[15] Xinyi Zhu,[18] John McMurray.[19] On behalf of the ASCEND-D authors *[1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]KJC Statistics Limited, Stockport, United Kingdom; [3]UNSW Sydney, Newtown, NSW, Australia; [4]Brigham and Women's Hospital, Boston, MA; [5]The George Institute for Global Health India, New Delhi, India; [6]Hennepin Healthcare, Minneapolis, MN; [7]Duke University, Durham, NC; [8]King's College Hospital, London, United Kingdom; [9]Universidad Panamericana, Ciudad de Mexico, Mexico; [10]Boston University, Boston, MA; [11]University Hospital, Wuerzburg, Germany; [12]University College London, London, United Kingdom; [13]Medical University of Silesia, Katowice, Poland; [14]GlaxoSmithKline, Durham, NC; [15]GlaxoSmithKline, Collegeville, PA; [16]GlaxoSmithKline, Middlesex, United Kingdom; [17]GlaxoSmithKilne, Raleigh, NC; [18]GlaxoSmithKline, Stevenage, United Kingdom; [19]University of Glasgow, Glasgow, United Kingdom.*

Background: The Anemia Studies in Chronic Kidney Disease (CKD): Erythropoiesis via a novel prolyl hydroxylase inhibitor Daprodustat (ASCEND) phase 3 program investigated efficacy and safety of daprodustat.

Methods: The program included 2 event-driven, cardiovascular outcomes trials (CVOTs) in non-dialysis (ASCEND-ND) and dialysis (ASCEND-D) patients comparing daprodustat with conventional ESAs. Non-inferiority (NI) co-primary endpoints included mean change in hemoglobin (Hb) between baseline and evaluation period (avg over weeks 28–52; NI margin: -0.75 g/dL) and time to first adjudicated major adverse CV event (MACE; NI margin: 1.25). Principal secondary endpoints, adjusted for multiplicity, included superiority assessments of MACE, MACE + thromboembolic events, MACE + hospitalization for heart failure and average monthly intravenous iron dose up to week 52 in ASCEND-D and time to progression of CKD in ASCEND-ND. Three smaller trials also reported adjudicated MACE but were not designed for formal MACE evaluation.

Results: 8169 patients were randomized across the 5 trials, with ~14,200 person-years (PY) of follow-up in CVOTs. The co-primary NI Hb objective was met in both CVOTs (adjusted mean treatment difference [95%CI]: ASCEND-D 0.18 [0.12-0.24] g/dL, ASCEND-ND 0.08 [0.03-0.13] g/dL). The co-primary NI MACE endpoint was also met (hazard ratio [95%CI]: ASCEND-D 0.93 [0.81-1.07], ASCEND-ND 1.03 [0.89-1.19]). No principal secondary endpoints met superiority. CVOT rates of treatment emergent adverse events were similar between daprodustat and ESA groups. Figure shows program-level first adjudicated MACE rates per 100 PY (intent-to-treat); MACE rates for ASCEND-NHQ (N=614) were 4.9% for daprodustat and 6.2% for placebo).

Conclusions: CVOTs demonstrated daprodustat was non-inferior to ESA for Hb efficacy and MACE and was well-tolerated. CV safety was generally consistent across treatment groups in the other studies.

EMPEROR-Preserved: Empagliflozin and Outcomes in Heart Failure with a Preserved Ejection Fraction and CKD

Faiez Zannad,[1] Bettina J. Kraus,[2] Cordula Zeller,[3] Stuart Pocock,[4] Milton Packer,[5] Gerasimos Filippatos,[6] João Pedro Ferreira,[7] Stefan D. Anker,[8] Javed Butler.[9] EMPEROR-Preserved Trial Committees and Investigators *[1]Université de Lorraine, Inserm INI-CRCT, CHRU, Nancy, France; [2]University Hospital, Wuerzburg, Germany; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Birkendorfer, Germany; [4]London School of Hygiene and Tropical, London, United Kingdom; [5]Baylor Heart and Vascular Institute, Dallas, TX; [6]Attikon University Hospital, Athens, Greece; [7]CHRU Nancy - Hopitaux de Brabois, Nancy, France; [8]Charité Medical School, Berlin, Germany; [9]University of Mississippi, University Park, MS.*

Background: In EMPEROR-Preserved, empagliflozin reduced cardiovascular death and heart failure hospitalizations and slowed the progressive decline in glomerular function in heart failure and a preserved ejection fraction (HFpEF), with or without diabetes. We explored the effect of empagliflozin on cardiovascular and kidney endpoints, across the spectrum of kidney function.

Methods: 5988 patients were randomized, of whom 3198 (53%) had prevalent chronic kidney disease (CKD) (eGFR<60ml/min/1.73m^2 or an UACR>300mg/g). The key outcomes were (1) a composite of cardiovascular death or hospitalization for heart failure; (2) total hospitalizations for heart failure, and (3) eGFR slope. The median follow-up was 26 months.

Results: Patients with prevalent CKD had a higher rate of CV and kidney events. Overall, empagliflozin reduced the risk of cardiovascular death and hospitalization for heart failure by 21% (p<0.001), reduced total hospitalizations for heart failure by 27% (p<0.001) and significantly slowed the yearly decline in eGFR (Difference: 1.36 mL/min/1.73 m2 per year, p<0.001). In this present CKD subgroup analysis, all three benefits were seen consistently in patients with and without CKD (figure) and were apparent even in patients with severe impairment (eGFR from 20 to 30ml/min/1.73m^2). Empagliflozin was well tolerated regardless of the level of baseline kidney function.

Conclusions: In patients with HFpEF, empagliflozin reduced serious heart failure events and slowed the decline in glomerular function, regardless of the presence or absence of CKD and across a broad spectrum of baseline kidney function.

Chlorthalidone for Hypertension in Advanced CKD (CLICK): A Randomized Double-Blind Trial

Rajiv Agarwal,[1,2] Arjun D. Sinha,[1,2] Andrew E. Cramer,[1] Mary Balmes-Fenwick,[1] Jazmyn H. Dickinson,[1] Fangqian Ouyang,[1] Wanzhu Tu.[1] *[1]Medicine, Indiana University School of Medicine, Indianapolis, IN; [2]Medicine, Richard L Roudebush VA Medical Center, Indianapolis, IN.*

Background: Hypertension, a common risk factor for both cardiovascular disease and chronic kidney disease (CKD), remains poorly controlled, especially among patients with advanced CKD.

Methods: The chlorthalidone (CTD) in chronic kidney disease (CLICK) study was a placebo-controlled, double-blind, randomized control trial of CTD versus placebo in patients with advanced CKD. Here, patients with stage 4 CKD and poorly controlled hypertension as confirmed by 24-hour ambulatory BP monitoring were randomly assigned to either placebo or CTD 12.5 mg daily in a 1:1 ratio stratified by prior loop diuretic use. The primary end point was the change in 24-hour systolic ambulatory BP from baseline to 12 weeks and was multiply imputed for missing data. Secondary outcome measures were the change from baseline to 12 weeks in the following measures: urine albumin to urine creatinine ratio, NT-pro BNP, plasma renin, plasma aldosterone, and total body volume. Long term follow up was planned for 3 years. An NHLBI-appointed DSMB had trial oversight.

Results: Of the 160 randomized, 140 patients (88%) completed the 12 weeks of double-blind exposure phase. Mean 24-hour ambulatory BP at randomization was 140.1 (8.1)/72.8(9.3) mmHg in the placebo group and 142.6 (8.1)/74.6 (10.1) mmHg in the CTD group. The adjusted change from baseline to 12 weeks in 24-hour systolic blood pressure was -0.5 (95% CI, -3.5 to 2.5) mmHg in the placebo group and -11.0 (95% CI, -13.9 to -8.1) mmHg in the CTD group. The between group difference was -10.5 (95% CI, -14.6 to -6.4: p<0.0001) mmHg. Compared to placebo, the urine albumin to urine creatinine ratio in the CTD group at 12 weeks was 50% lower (95% CI, 37% to 60%). CTD also induced changes in NT-proBNP, renin, aldosterone and total body volume were directionally consistent with a diuretic effect. Following randomization, hypokalemia, reversible increases in serum creatinine, hyperglycemia, dizziness, and hyperuricemia occurred more frequently in the CTD group.

Conclusions: In summary, this trial showed that treatment with CTD could effectively treat poorly controlled systolic hypertension in patients with advanced CKD. The reduction in albuminuria points to an early effect of target organ protection. (funded by National Institutes of Health NHLBI R01 HL126903; registration number NCT02841280)

Activated Vitamin D for the Prevention of AKI in Critically Ill Patients

David E. Leaf,[1] Sushrut S. Waikar.[2] *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Boston University Medical Campus, Boston, MA.*

Background: Decreased circulating levels of active vitamin D metabolites, including 25-hydroxyvitamin D (25D) and 1,25-dihydroxyvitamin D (1,25D), are common in critically ill patients, and lower levels are independently associated with a higher risk of AKI. Administration of 25D and 1,25D attenuates AKI in animal models. Randomized trials of vitamin D in critically ill patients have focused on inactive precursors (e.g., cholecalciferol), which may not be efficiently converted into 25D and 1,25D in this setting.

Methods: We conducted an NIH-funded, 3-arm, double-blind, randomized clinical trial using high doses of 25D and 1,25D in 150 critically ill patients at high risk of AKI. Patients were randomly assigned in a 1:1:1 ratio to receive 25D (oral calcifediol, 400µg on day 1 and 200µg on days 2-5), 1,25D (oral calcitriol, 4ug daily for 5 days), or placebo. The primary outcome was a composite global rank endpoint of death, dialysis, or relative average increase in serum creatinine within 7 days.

Results: Among the 150 patients enrolled, the median age was 65 years (IQR, 52-72), 61% were male, 83% were intubated, and 57% were receiving vasopressors at randomization. The median time from ICU admission to randomization was 1 day (IQR, 1-2). Median levels of 25D and 1,25D at randomization were 17 ng/ml (IQR, 10-26) and 27 pg/ml (IQR, 18-39), and increased to 57 ng/ml (IQR, 53-67) and 91 pg/ml (IQR, 66-122) in the 25D and 1,25D groups, respectively. Neither the primary nor secondary endpoints differed between groups (**Table**). Longitudinal plasma and urinary KIM-1 levels were also similar between groups. No safety concerns were identified.

Conclusions: Administration of activated vitamin D metabolites did not improve renal outcomes among critically ill patients.

Funding: NIDDK Support

PO2523

SCD Treatment in COVID-19 ICU Patients with ARDS and AKI Is Safe and May Improve Clinical Outcomes

Lenar T. Yessayan,[1] Javier A. Neyra,[2] Angela Westover,[1] Balazs Szamosfalvi,[1] H. David Humes.[1,3] *[1]Nephrology, University of Michigan, Ann Arbor, MI; [2]Nephrology, University of Kentucky, Lexington, KY; [3]SeaStar Medical, Denver, CO.*

Background: ICU patients with COVID-19 with acute respiratory distress syndrome (ARDS) on mechanical ventilation (MV) and acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) have very high mortality rates. Elevation of certain inflammatory mediators, including IL10 and soluble interleukin 1 receptor-like 1 (sST2), predict mortality in COVID-19 patients and declines as patients recover. Previous data have shown that treatment with a selective cytopheretic device (SCD) improves clinical outcomes in ARDS and severe AKI by removing proinflammatory leukocytes from circulation and reducing plasma levels of inflammatory cytokines. The aim of this feasibility study was to evaluate the safety and early efficacy of SCD treatment (Tx) in ICU COVID-19 patients with ARDS on MV and AKI requiring CRRT.

Methods: 22 subjects were enrolled and treated with SCD for ≤10 days. 5 patients were treated less than 96 hours due to family's request for withdrawal of care. Patients were previously treated with remdesivir and corticosteroids. All but one patient were on both MV and CRRT with 10 patients on extracorporeal membrane oxygenation (ECMO). A subgroup of 8 patients was further evaluated with plasma inflammatory biomarkers and cell sorting/cytometric analysis (CSCA) of circulating neutrophils and monocytes. Clinical outcomes of SCD-treated patients were compared to untreated control patients on CRRT and mechanical ventilation in a contemporaneous, prospective observational data set (CRRTnet).

Results: Patients completed the study between September 2020 and July 2021. Mean age was 53±17 years (19-79). No device-related serious adverse events were reported. 60-day mortality in the SCD treated group was 11/22 (50%) vs.11/13 (85%) in the control group. CSCA demonstrated SCD removed the most activated circulating neutrophils (CD11b, CD10) and monocytes (CD11b, CD14). SCD Tx reduced baseline plasma levels of IL10 (12±9 pg/ml to 2±1, $p<0.02$) and sST2 (212±70 pg/ml to 88±74, $p<0.02$), as well as reducing plasma IL6 and MCP (Monocyte Chemotactic Protein)-1 levels.

Conclusions: SCD treatment is safe in ICU COVID-19 patients with ARDS on MV and AKI requiring CRRT. In this feasibility study, mortality rate was substantially lower than a concurrent control group, suggesting clinical benefit.

PO2524

Effect of Clinical Decision Support with Audit and Feedback for Prevention of AKI in Coronary Angiography and Intervention: Stepped Wedge Cluster Randomized Trial

Matthew T. James,[1] Bryan J. Har,[1] Benjamin D. Tyrrell,[2] Peter D. Faris,[4] Zhi Tan,[1] John Spertus,[3] Stephen B. Wilton,[1] William A. Ghali,[1] Merril L. Knudtson,[1] Neesh I. Pannu,[2] Scott Klarenbach,[2] Michelle M. Graham.[2] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [3]University of Missouri, Columbia, MO; [4]Alberta Health Services, Calgary, AB, Canada.*

Background: Contrast-associated acute kidney injury (CA-AKI) is a common complication of coronary angiography and percuateous coronary intervention (PCI). We evaluated whether the incidence of CA-AKI was reduced with an intervention including clinical decision support with audit and feedback.

Methods: In this cluster-randomized, stepped-wedge trial conducted in Alberta, Canada, we randomly assigned all invasive cardiologists to various start dates for an intervention that included education, point-of-care computerized clinical decision support on contrast volume and IV fluid targets, and repeated audit and feedback related to these processes for CA-AKI prevention. The eligible study population included adults ≥18 years of age, not receiving dialysis, with a predicted risk of CA-AKI >5%, who received non-emergency coronary angiography or PCI. The primary outcome was incidence of AKI based on the KDIGO serum creatinine criteria. Analyses were performed according to the intention-to-treat principle, using mixed-effect models to account for clustering in the data.

Results: Of 34 physicians randomized, 3 retired prior to randomization, and the remaining 31 received the intervention. There were 7,087 procedures performed in 6,449 eligible patients; mean (SD) age 70.2 (10.7) years, 2,292 (32.3%) female, mean (SD) eGFR 62.7 (22.4) mL/min/1.73m^2. The proportion of procedures where the desired contrast volume limit was exceeded was reduced from 41.0% to 29.2% ($p<0.01$), while the proportion who received hemodynamically guided IV fluids increased from 35.3% to 42.0% ($p<0.01$) with the intervention. The incidence of CA-AKI was significantly reduced, from 9.2% (280 events/3,036 procedures) before the intervention to 8.2% (334 events/4,051 procedures) with the intervention (time adjusted odds ratio, 0.74; 95% CI, 0.58 to 0.94). There was no statistical evidence of effect modification by age, sex, comorbidity, or baseline CA-AKI risk.

Conclusions: An intervention combining education, clinical decision support, and audit and feedback resulted in less contrast dye use, greater intravenous fluid administration, and reduced the incidence of CA-AKI following coronary angiography and PCI.

Background: Higher levels of serum magnesium (Mg) are associated with lower risk of cardiovascular (CV) events in patients with CKD and Mg prevents vascular calcification (VC) in animal models of CKD. We hypothesized that oral Mg supplementation would slow the progression of VC in CKD.

Methods: In a randomised, double-blind, placebo-controlled, parallel group, clinical trial we recruited 148 patients with an eGFR between 15 and 45 mL/min and randomised them to oral Mg hydroxide 15 mmol twice daily or matching placebo for 12 months. We excluded kidney transplant recipients. The primary endpoint was the between-groups difference in coronary artery calcification (CAC) score after 12 months adjusted for baseline CAC score (ANCOVA).

Results: Seventy-five subjects were randomised to Mg and 73 to placebo. Median eGFR was 25 mL/min at baseline. Mg treatment significantly increased plasma Mg ($p < 0.001$). CAC scores were not significantly different between the two groups after 12 months (mean difference 0.01%, 95% CI –13.5% to 15.6%; $p = 0.991$). A prespecified subgroup analysis of subjects with CAC > 0 at baseline did not significantly alter the main results (mean difference 4.0%, 95% CI –5.4% to 14.3%). Thirty-two subjects randomised to Mg treatment experienced gastrointestinal side effects compared to 11 subjects randomised to placebo. There were five deaths and six CV events in the Mg group, compared to two deaths and no CV events in the placebo group.

Conclusions: Mg supplementation did not slow the progression of VC in CKD, despite a significant increase in plasma Mg. There were more deaths and CV events in the Mg group compared to placebo, although the trial was not powered to investigate these endpoints.

REDUX: A Multicenter, Open-Label Study of DM199 (Recombinant Human Tissue Kallikrein-1) in Patients with Stage 2 or 3 CKD

Harry W. Alcorn,[1] Arnold L. Silva,[2] Zachary L. Yablon,[5] Neal A. Patel,[3] Billy T. Hour,[4] Paul W. Crawford.[6] *[1]DiaMedica Therapeutics, Minneapolis, MN; [2]Boise Kidney & Hypertension Institute, Meridan, ID; [3]Elixia LLC, Royal Palm Beach, FL; [4]Kidney Consultants Medical Group, Northridge, CA; [5]Florida Kidney Physicians, Fort Lauderdale, FL; [6]Associates in Nephrology, SC, Chicago, IL.*

Background: DM199 is a recombinant form of the endogenous human tissue kallikrein-1 protein (KLK1) that by selectively releasing bradykinin-mediated nitric oxide, prostaglandins and other anti-inflammatory mediators to increase renal blood flow, and reduce inflammation, oxidative stress, and fibrosis in the kidney and elsewhere. The safety, efficacy, pharmacokinetics, and pharmacodynamics of DM199 is being evaluated in an open-label, Phase 2 study of patients with chronic kidney disease (CKD).

Methods: Here, enrolling three cohorts of patients all with stage 2 or 3 CKD: 1) non-diabetic African Americans with hypertension (AA/CKD); 2) patients with IgA nephropathy (IgAN); and 3) patients with type 2 diabetes mellitus with hypertension (DKD). Patients were assigned to receive subcutaneous DM199 2 or 5 mcg/kg twice weekly for 95 days. Primary endpoints were safety and tolerability, kidney function (eGFR, urine:albumin creatinine ratio [UACR], blood pressure), and plasma and urine pharmacokinetics of DM199 (and KLK1).

Results: At an interim analysis conducted June 2021, 62 patients had completed the study, and data were available for 56 patients, 12 in the AA/CKD cohort, 16 in the IgAN cohort, and 28 in the DKD cohort. Results are in the Table. DM199 was well tolerated across all cohorts, with no DM199 related severe adverse events (AEs) or discontinuations due to drug-related AEs. AEs were generally mild to moderate in severity, with the most common being local injection site irritation that resolved.

Conclusions: These data provide clinical validation of the meaningful biologic activity of the recombinant KLK1 (DM199) and support the potential of achieving clinical benefit in patients with CKD. Enrollment is continuing in the AA/CKD and IgAN cohorts.

Association of Urine Albumin-to-Creatinine Ratio and Its Early Change with Cardiorenal Outcomes in FIDELIO-DKD: A Mediation Analysis

Rajiv Agarwal,[1] Stefan D. Anker,[2] Bertram Pitt,[3] Luis M. Ruilope,[9,10] Peter Rossing,[8,11] Meike D. Brinker,[4] Amer Joseph,[4] Robert Lawatscheck,[4] Charlie Scott,[5] Gerasimos Filippatos,[6] George L. Bakris.[7] *[1]Richard L Roudebush VA Medical Center, Indianapolis, IN; [2]Berlin Institute of Health Center for Regenerative Therapies, Berlin, Germany; [3]University of Michigan Michigan Medicine, Ann Arbor, MI; [4]Medical Affairs & Pharmacovigilance, Bayer AG, Berlin, Germany; [5]Bayer plc, Reading, United Kingdom; [6]School of Medicine, Department of Cardiology, Attikon University Hospital, Athens, Athens, Greece; [7]The University of Chicago Medicine, Chicago, IL; [8]Steno Diabetes Center Copenhagen, Steno Diabetes Center Copenhagen, Gentofte, Denmark; [9]Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research imas12, Madrid, Spain; [10]CIBER-CV, Hospital Universitario 12 de Octubre, Faculty of Sport Sciences, European University of Madrid, Madrid, Spain; [11]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: The selective, nonsteroidal mineralocorticoid receptor antagonist finerenone slowed chronic kidney disease (CKD) progression and improved cardiovascular (CV) outcomes in patients with CKD and type 2 diabetes (T2D) in FIDELIO-DKD (NCT02540993). Previous studies have shown that treatment-induced urine albumin-to-creatinine ratio (UACR) reduction correlates with kidney and CV benefits. Here, we investigate the association of UACR and its early change with the magnitude of cardiorenal protection.

Methods: Patients (N=5674) with T2D, UACR ≥30–≤5000 mg/g and estimated glomerular filtration rate (eGFR) 25–<75 mL/min/1.73 m² receiving optimized renin–angiotensin system blockade were randomized 1:1 to finerenone or placebo. Key outcomes included a kidney composite of time to kidney failure, sustained ≥40% or ≥57% eGFR decline from baseline, or renal death, and a CV composite of time to CV death, nonfatal myocardial infarction, nonfatal stroke, or hospitalization for heart failure. Outcomes were assessed using cubic-basis splines including UACR at baseline and change in UACR from baseline to month 4 as continuous variables. Mediation analyses were performed to determine the proportion of change in UACR to month 4 contributing to the kidney and CV benefits of finerenone.

Results: Finerenone was associated with a 31% greater reduction in the UACR from baseline to month 4 than placebo (ratio of least-squares mean change from baseline, 0.69; 95% confidence interval 0.66–0.71). Overall, the risk of adverse kidney and CV outcomes increased as UACR at baseline increased. Reduction in UACR from baseline to month 4 was also associated with a reduction in risk for kidney outcomes. Mediation analyses indicated a variable proportion of the kidney and CV benefits observed with finerenone could be explained by early change in UACR.

Conclusions: Finerenone resulted in early reductions in UACR in patients with T2D and CKD that are associated with its beneficial effects on kidney and CV outcomes. We will discuss early changes in UACR as a biomarker of subsequent finerenone-associated cardiorenal benefit.

Dapagliflozin and Kidney Outcomes in Hospitalized Patients with COVID-19 Infection: Results from the DARE-19 Randomized Controlled Trial

Hiddo J. L Heerspink,[1,2] Remo Furtado,[3,5] Otavio Berwanger,[5] Gary G. Koch,[4] Felipe Martinez,[6] Omar Mukhtar,[7] Subodh Verma,[8,9] Samvel B. Gasparyan,[11] Fengming N. Tang,[10] Sheryl L. Windsor,[10] Joan Buenconsejo,[11] Russell L. Esterline,[11] Jan Oscarsson,[11] Philip D. Ambery,[11] Anna Maria Langkilde,[11] Mikhail Kosiborod.[2,10] *[1]University Medical Center, University of Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Instituto do Coracao do Hospital das Clinicas da FMUSP, Sao Paulo, Brazil; [4]Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Academic Research Organization-Hospital Israelita Albert Einstein, Academic Research Organization-Hospital, Sao Paulo, Brazil; [6]National University of Córdoba, Córdoba, Argentina; [7]Experimental Medicine and Immunotherapeutics Division, Department of Medicine, University of Cambridge, Cambridge, United Kingdom; [8]Division of Cardiac Surgery, Keenan Research Centre for Biomedical Science, Li Ka Shing Knowledge Institute of St Michael's Hospital, Toronto, ON, Canada; [9]Department of Surgery and Department of Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada; [10]Saint Luke's Mid America Heart Institute, Kansas City, MO; [11]Late-stage Development, CVRM, Biopharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: Hospitalized patients with COVID-19 infection are at high risk of acute kidney injury (AKI) and renal replacement therapy, especially in the presence of chronic kidney disease (CKD). The DARE-19 trial showed that in hospitalized patients with COVID-19, treatment with dapagliflozin (DAPA) vs placebo resulted in numerically fewer patients experiencing organ failure or death, although these differences were not

statistically significant. We performed a pre-specified secondary analysis of DARE-19 to determine the efficacy and safety of DAPA on kidney outcomes in the overall population and by CKD status.

Methods: The DARE-19 trial randomized 1250 hospitalized patients (231 [18.5%] had eGFR <60 mL/min/1.73m^2) with COVID-19 and cardiometabolic risk factors to DAPA or placebo. Dual primary outcomes (time to new or worsened organ dysfunction or death, and a hierarchical composite endpoint of recovery [change in clinical status by Day 30]), and the specific kidney outcome (composite of AKI, renal replacement therapy or death), as well as safety were assessed in patients with baseline eGFR <60 and ≥60 mL/min/1.73m^2.

Results: The effect of DAPA vs placebo on the primary prevention outcome (hazard ratio [HR] 0.80 [95%CI 0.58, 1.10]) and primary recovery outcome (win ratio 1.09 [95%CI 0.97, 1.22]) was consistent across eGFR subgroups (p for interaction 0.98 and 0.67, respectively). The effect on the composite kidney outcome (HR 0.74 [95%CI 0.50, 1.07]) was also consistent in eGFR subgroups (p for interaction 0.44). There were numerically fewer AKI events with DAPA in patients with eGFR<60 ml/min/1.73m^2 (HR 0.71 [95%CI 0.29, 1.77]) and ≥60 ml/min/1.73m^2 (HR 0.69 [95%CI 0.37, 1.29]). DAPA was well tolerated in patients with eGFR <60 and ≥60 mL/min/1.73m^2.

Conclusions: The effects of DAPA on primary and secondary outcomes in hospitalized patients with COVID-19 were consistent in those with/without CKD. DAPA was well tolerated and did not increase the risk of AKI in patients with/without CKD.

Maintaining Operational Excellence During the COVID-19 Pandemic in the FLOW Trial

Richard E. Pratley,[1] George L. Bakris,[2] Willem A. Bax,[3] Heidrun Bosch-Traberg,[4] Kenneth W. Mahaffey,[5] Peter Rossing,[6,7] Katherine R. Tuttle,[8] Jack Lawson,[4] Camilla Møntegaard,[4] Alfredo Wassermann,[9] Johannes F. Mann.[10] *[1]AdventHealth Translational Research Institute, Orlando, FL; [2]The University of Chicago Medicine, Chicago, IL; [3]Northwest Clinics, Alkmaar, Netherlands; [4]Novo Nordisk A/S, Søborg, Denmark; [5]Stanford University School of Medicine, Palo Alto, CA; [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [7]Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [8]University of Washington and Providence Health Care, Spokane, WA; [9]FEPREVA, Buenos Aires, Argentina; [10]KfH Kidney Center, Munich, Germany.*

Background: The FLOW trial is a multicenter, international, randomized, phase 3b kidney outcomes trial of once-weekly subcutaneous semaglutide vs placebo, both added to standard-of-care, in >3,500 people with type 2 diabetes and chronic kidney disease. The trial is guided by a steering committee with academia and industry representatives and a global expert panel (GEP). The coronavirus disease 2019 (COVID-19) pandemic has presented major challenges for running clinical trials, with restrictions for trial sites impacting recruitment and retention. Once the extent and hazards of COVID-19 were apparent, regular impact assessments were done to quickly identify and mitigate challenges to the conduct of the trial. Here, we report the timing of mitigation strategies in the FLOW trial and the relationship to recruitment during the pandemic.

Methods: The primary focus was to ensure participant and staff safety and no undue risk of COVID-19 exposure, as well as data integrity, recruitment and retention. These aims were met by implementing protocol amendments, guidance documents for trial sites and local support from GEP members, through strategies such as replacing face-to-face visits with phone and home visits, remote monitoring, alternative trial drug dispensing and allowing for co-participation in COVID-19 trials **(Figure)**.

Results: After the mitigation strategies were employed in response to the COVID-19 pandemic, the FLOW trial recruitment was completed according to schedule **(Figure)**. To date, no participants have withdrawn from the FLOW trial due to COVID-19.

Conclusions: After the rapid identification and implementation of mitigation strategies and efforts of the steering committee and GEP, the FLOW trial successfully recruited the planned number of participants on time and avoided withdrawals due to COVID-19.

Funding: Commercial Support - Novo Nordisk A/S

Background: FIDELITY, a prespecified meta-analysis of FIDELIO-DKD and FIGARO-DKD, evaluates the efficacy and safety of finerenone across a spectrum of patients with chronic kidney disease (CKD) and type 2 diabetes (T2D).

Methods: FIDELITY combines individual patient data from FIDELIO-DKD (NCT02540993) and FIGARO-DKD (NCT02545049). Eligible patients were adults with T2D and CKD (urine albumin-to-creatinine ratio [UACR] ≥30–<300 mg/g and estimated glomerular filtration rate [eGFR] ≥25–≤90 mL/min/1.73 m^2, or UACR ≥300–≤5000 mg/g and eGFR ≥25 mL/min/1.73 m^2), treated with optimized renin–angiotensin system blockade. Efficacy outcomes included a composite kidney outcome of time to first onset of kidney failure (end-stage kidney disease [ESKD] or sustained eGFR <15 mL/min/1.73 m^2), sustained ≥57% decrease in eGFR from baseline over ≥4 weeks, or renal death.

Results: In 13,026 patients, over 3.0 years' median follow-up, finerenone reduced the risk of the kidney composite outcome by 23% vs placebo (HR=0.77; 95% CI 0.67–0.88; *P*=0.0002); consistent benefits were observed across baseline eGFR and UACR subgroups ($P_{interaction}$ 0.62 and 0.67, respectively). Compared with placebo, finerenone led to a nominally significant reduction in the incidence of all nonfatal components of the kidney composite outcome, including a 20% lower risk of ESKD (chronic dialysis or kidney transplant; HR=0.80; 95% CI 0.64–0.99; *P*=0.04). Finerenone caused an initial drop in eGFR vs placebo (least-squares [LS] mean change in eGFR slope from baseline to month 4, –3.3 vs –1.0 mL/min/1.73 m^2) but slowed long-term eGFR decline (LS mean change in eGFR slope from month 4 onwards, –2.5 vs –3.7 mL/min/1.73 m^2/year). The incidence of adverse events was similar between groups. The incidence of permanent discontinuation due to hyperkalemia in finerenone and placebo recipients with an eGFR <60 mL/min/1.73 m^2 was 2.4% and 0.8%, respectively, and 0.6% and 0.3% in those with an eGFR ≥60 mL/min/1.73 m^2.

Conclusions: FIDELITY demonstrates robust kidney benefits and safety of finerenone in patients with T2D across the spectrum of CKD severity.

PO2532

ACCESS (NCT02513303): A Phase 3 US Multicenter Randomized Controlled Trial Evaluating Efficacy of a Perivascularly Delivered Sirolimus Formulation (Sirogen™) for Improving Hemodialysis AVF Outcomes

Maria V. DeVita,[1] Nelson P. Kopyt,[2] Osman Khawar,[3] Naveen K. Atray,[4] Nirav Gandhi,[5] Kendra S. Hendon,[6] Robert I. Lynn,[7] Sriram Iyer.[8,9] On behalf of the ACCESS Trial Investigators *[1]Medicine, Lenox Hill Hospital, New York, NY; [2]Lehigh Valley Health Network, Allentown, PA; [3]Balboa Nephrology Medical Group, San Diego, CA; [4]Capital Nephrology Medical Group, Sacramento, CA; [5]West Anaheim Medical Center, Anaheim, CA; [6]Parkwest Medical Center, Knoxville, TN; [7]Albert Einstein College of Medicine, Bronx, NY; [8]Cardiology, Lenox Hill Hospital, New York, NY; [9]Vascular Therapies, Cresskill, NJ.*

Background: Lack of a prophylactic therapeutic for improving AV **F**istula **S**uitability for **D**ialysis (FSD) is an unmet need. Sirolimus delivered locally to the vessel wall is a clinically proven anti-proliferative. Advancing age, female gender & comorbidities like coronary artery disease (CAD) are known risks for AVF maturation.

Methods: The Full Analysis Set (FAS) included 243 pts randomized 1:1; 125 Sirogen 118 Controls; 174 ESRD 69 CKD; 205 RCF 38 BCF. End points: Clinical FSD: AVF use with 2 needles with mean Qb ≥300 ml/min (2N/300) for at least 2/3rd of the HD sessions during a 30-day period starting day 150 (FSD6; Primary Endpoint) or day 330 (FSD12). Ultrasound FSD: outflow vein diameter ≥6mm, Qa ≥500ml/min; criteria used if CKD pt. was not on HD by day 150 or 330. Secondary Patency (SP): Fistula survival without abandonment; Fistula Maturation (FM): AVF use for 3 consecutive 2N/300 HD sessions.

Results: Age subgroup analysis provides explanation supported by data for endpoint results shown in Table. 2/3rd of randomized pts were <65y (lower risk). In ESRD pts ≥65y clear evidence of Rx effect (Figs 1,2); RCF outcomes were even more compelling. Exceptional control performance in <65y group masked treatment effect. No evidence of Rx failure. No safety concerns.

Conclusions: 1. No differences in prespecified endpoints 2. Demographic differences & risk imbalance (bias favored controls) motivated a *post hoc* age subgroup analysis a. <65y: Control overperformance (not Rx failure) negated endpoint differences & influenced overall outcomes b. ≥65y: Maturation Benefit (FM) is significant & durable (FSD12, SP) 3. Confirmatory Trial is planned

PO2533

Incremental HD in the US: A Multicenter Pilot Controlled Trial

Mariana Murea,[1] Kamyar Kalantar-Zadeh,[2] Gregory B. Russell.[3] *[1]Internal Medicine, Nephrology, Wake Forest University School of Medicine, Winston-Salem, NC; [2]University of California Irvine, Irvine, CA; [3]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Incremental HD—twice-weekly initiation followed by thrice-weekly HD—is uncommonly prescribed in the US. We conducted a pilot trial to assess the feasibility and safety of incremental-start HD.

Methods: Adults with eGFR ≥5.0mL/min/1.73m² and urine volume ≥500mL/day initiated on maintenance HD at 14 centers were randomly assigned to twice-weekly HD and adjuvant pharmacologic therapy (loop diuretics, sodium bicarbonate, patiromer) for 6 weeks, then transitioned to thrice-weekly HD (incremental HD) (n=23) vs continued thrice-weekly HD (conventional HD) (n=25). Intervention was embedded in usual care.

Results: Adherence to assigned HD schedules and serial timed urine collection was 96% and 100%, respectively, in both groups. Two patients in incremental group switched to thrice-weekly HD in <6 weeks (Figure). There were fewer hospitalizations and deaths in incremental group (Table 1). Between-group differences in % change from baseline to week 26 in urine volume and renal average urea and creatinine clearance favored incremental HD (Table 2).

Conclusions: Incremetnal HD is feasible. Larger multicenter clinical trials are indicated to determine the efficacy and safety of incremental HD with longer twice-weekly HD periods.

Funding: Commercial Support - Vifor Inc.

Table 1

Serious adverse events	Incremental HD (n=21)	Conventional HD (n=22)
Total number of patients hospitalized	11	12
Total number of hospitalizations	19	33
Cumulative hospitalization rate, per person-year (95% CI)	1.06 (0.95 - 1.16)	1.84 (1.70 - 1.98)
Length of hospital stay, days, median (1st - 3rd quartile) (per hospitalization, per person)	2.0 (2.0 - 5.0)	5.0 (2.5 - 6.5)

Table. Difference in estimated percent change in residual kidney function parameters between groups

Outcome	Week 1 to Week 6		Week 6 to Week 12		Week 1 to Week 12		Week 1 to Week 24	
	Difference (95% CI)	P	Difference (95% CI)	P	Difference (95% CI)	P	Difference (95% CI)	P
Urine volume, mL/day	21.7 (-0.9, 44.3)	0.059	2.2 (-42.4, 46.8)	0.92	24.5 (0.1, 48.8)	0.049	51.0 (-0.7, 102.8)	0.053
Urea clearance, mL/min/1.73m²	2.4 (-5.4, 9.5)	0.93	-7.0 (-58.3, 41.4)	0.77	26.1 (-34.7, 74.8)	0.46	7.6 (-67.6, 82.9)	0.84
Creatinine clearance, mL/min/1.73m²	-13.6 (-63.7, 36.5)	0.59	14.0 (-36.1, 64.1)	0.58	7.6 (-59.9, 35.8)	0.73	38.6 (-62.3, 139.5)	0.44
Average urea and creatinine clearance, mL/min/1.73m²	3.2 (-34.1, 40.5)	0.86	-0.5 (-46.1, 45.1)	0.98	-2.7 (-48.4, 43.0)	0.90	57.9 (-22.6, 138.4)	0.15

Data are presented as mean (95% confidence interval). Difference was calculated as % change in least squares mean parameter in incremental HD group – % change in least squares mean parameter in conventional HD group. P value and estimate for difference in change between groups modeled through mixed-effects linear regression analysis.

A Randomized, Double-Blind, Phase 2 Study to Evaluate the Tolerability, Feasibility, and Efficacy of AKST1210 in Patients on Hemodialysis with ESRD and Cognitive Impairment

Seema Garg, Eva Czirr, Katie Koborsi, Anthony Kalife, Esther Rawner. *Alkahest Inc, San Carlos, CA.*

Background: Cognitive impairment is frequently observed in many end-stage renal disease (ESRD) patients undergoing hemodialysis (HD). Since this protein is not effectively cleared with standard HD, beta-2 microglobulin (b2M) is highly elevated in ESRD patients and data in mice has shown that b2M is a potential driver of cognitive impairment and synapse loss. Based on robust preclinical data, a clinical study was initiated to assess safety, tolerability, and feasibility of utilizing AKST1210, an extracorporeal b2M-selective adsorbent column, during HD in patients with ESRD and cognitive impairment (ESRD-CI).

Methods: The study inclusion criteria were adults ≥ 40 years of age on HD for > 12 months and a Montreal Cognitive Assessment (MoCA) score ≥ 16 and ≤ 23. Participants were randomized 1:1 to receive HD 3 times a week for 12 weeks with either AKST1210 (escalating size every 4 weeks) or no column. The primary objective was to assess the safety of AKST1210 as evaluated by the incidence of treatment-emergent adverse events (TEAEs) and serious adverse events (SAEs). Secondary objectives included tolerability of procedures as assessed by participant compliance and retention as well as changes from baseline in b2M levels, activities of daily living (ADL), and cognitive assessments.

Results: Of 36 patients screened, 22 were randomized, 20 completed through end of treatment, and 19 completed the study. Thirty-four of 36 patients screened met the MoCA eligibility criteria. Preliminary review of safety data indicate AKST1210 is safe and well tolerated in this study population based on a low incidence of TEAEs and SAEs, adherence to study procedures, and completion of the treatment period in greater than 90% of participants. Analysis of the secondary and exploratory endpoints related to change from baseline in cognitive function, ADL, and b2M levels will be presented.

Conclusions: Assessment and treatment of cognitive impairment in patients with ESRD remains an unmet need. Treatment with AKST1210 provides a safe and tolerable intervention targeting removal of b2M, a potential driver of cognitive impairment. Further investigation with AKST1210 to better understand efficacy related to cognitive impairment, ADL, and quality of life is warranted.

PO2535

Enhancing Decongestion in Cardiorenal Syndrome by Renal Negative Pressure Diuresis: A First in-Human Experience

Amir Kazory,[1] Alex M. Parker,[3] Vincent G. Bird,[3] Brittany McMichael,[2] David A. Baran.[2] *[1]Medicine-Nephrology, University of Florida College of Medicine, Gainesville, FL; [2]Sentara Healthcare Inc, Norfolk, VA; [3]University of Florida, Gainesville, FL.*

Background: Inadequate decongestion is the driver of adverse outcomes in acute decompensated heart failure (ADHF). Accumulating data points to renal venous congestion as the key mechanism underlying cardiorenal syndrome and diuretic resistance. Herein, we present the initial experience with a novel device that utilizes negative pressure in the renal pelvis to enhance diuresis (i.e. renal negative pressure diuresis [rNPD]).

Methods: rNPD involves endoscopic delivery of a ureteral catheter. Its proximal portion is placed in the renal pelvis to deliver controlled negative pressure via a specially designed vacuum pump. Patients with ADHF and diuretic resistance underwent rNPD for 24 hours. Several parameters including GFR, urine output, and natriuresis were measured 24 hours before and 24 hours after rNPD (72-hour study period).

Results: The current proof-of-concept study includes 3 patients from 2 centers meeting strict inclusion and exclusion criteria. Mean serum creatinine levels were 1.86 and 1.82 mg/dL before and after intervention respectively. rNPD resulted in a significant improvement in net fluid balance from -198 to -1775 ml/24 hours (an almost 8-fold effect) [figure-1] and a 156% increase in urinary sodium excretion (from 148 to 378 mmol/24 hours). No complications were observed.

Conclusions: After successful animal studies, this proof-of-concept study is the first in-human experience confirming the salutary impact of applying negative pressure in the renal pelvis of patients with ADHF and diuretic resistance. rNPD resulted in an impressive improvement in net negative fluid balance associated with exponential increase in natriuresis without any notable adverse effect.

Iptacopan, a Novel Oral Complement Factor B (FB) Inhibitor, Significantly Reduces Proteinuria and C3 Deposit Scores in Native and Transplanted Kidneys C3 Glomerulopathy (C3G) Patients

Edwin K. Wong,[1] Carla M. Nester,[2] Teresa Cavero escribano,[3] Alexandre Karras,[4] Moglie Lequintrec-Donnette,[5] Liz Lightstone,[6] Ute Eisenberger,[11] Maria Jose Soler,[7] Andrea Biondani,[9] Frederique Chaperon,[9] Kenneth M. Kulmatycki,[9] Julie M. Milojevic,[9] Prasanna Kumar Nidamarthy,[8] Nicholas Webb,[9] Guido Junge,[9] Giuseppe Remuzzi.[10] *[1]Freeman Hospital, Newcastle upon Tyne, United Kingdom; [2]University of Iowa Hospital and Clinics, Iowa, IA; [3]Hosp 12 de Octubre, Madrid, Spain; [4]AP-HP, Hôpital Européen Georges Pompidou, Paris, France; [5]Hopital Lapeyronie, Montpellier, France; [6]Imperial College Healthcare NHS Trust, London, United Kingdom; [7]Nephrology Department Hospital Universitari Vall d Hebron, Barcelona, Spain; [8]Novartis Healthcare Pvt Ltd, Hyderabad, India; [9]NIBR, Basel, Switzerland; [10]Centro Ricerche Cliniche per Malattie Rare Aldo e Cele Daccò Villa Camozzi, Bergamo, Italy; [11]Universitätsklinikum Essen, Essen, Germany.*

Background: C3G is a rare, inflammatory KD caused by genetic mutations or auto-AB that dysregulate the complement system. With no approved therapies, progression to ESRD is frequent. Iptacopan is a new, highly selective oral LMW inhibitor of FB, a key complement alternative pathway (AP) protease. We report final Ph2 data [NCT03832114] for iptacopan in pts with native or recurrent C3G post kidney Tx.

Methods: Adults with biopsy-proven (Bx), native (CoA) or recurrent C3G post KTx (CoB) received iptacopan for 12 wks (W). CoA had proteinuria >1g/24h despite ACEi/ARB, and all had low C3 levels. Primary endpoints (pEP) were reduction in UPCR from baseline (BL) to W12 for CoA; change in C3 Deposit Score (DS) for CoB. Pts were invited to continue iptacopan in a long-term extension trial [NCT03955445].

Results: All pts (N=16/11 in CoA/B) completed the trial. BL mean age 26.1/34.5 yrs; geo-mean UPCR (24h) 401.9/36.2 g/mol; mean eGFR 70.1/52.2 mL/min in CoA/B; median C3 DS 3.0 in CoB. Iptacopan was well tolerated without any drug-related serious AE. CoA pEP met with -45% in UPCR from BL to W12 (p=0.0003) [**Fig 1A**]. CoB pEP met with significant reduction in C3 DS in kidney Bx from BL to W12 (p=0.0313) [**Fig 1B**]. A profound and sustained inhibition of the AP [**Fig 1C**] and normalization of C3 levels were observed [**Fig 1D**]. eGFR was stable with mean change from BL to W12 of +1.04 mL/min.

Conclusions: Treatment with iptacopan 200 mg bid in patients with native or recurrent C3G was well tolerated and resulted in statistically significant and clinically important reduction of UPCR, normalization of C3 levels, stabilization of eGFR, and significant reduction in histologic C3 DS in follow-up kidney Bx. Iptacopan is now tested in a pivotal Ph3 trial APPEAR-C3G [NCT04817618].

Erickson,[4] Mangalee R. Fernando,[13] Sheryl L. Foster,[5] Adriana Gregory,[4] Imad A. Haloob,[10] Carmel Hawley,[6] David W. Johnson,[6] Timothy L. Kline,[4] Vincent W. Lee,[1] Maureen A. Lonergan,[12] Elaine Pascoe,[6] Anna M. Rangan,[2] Simon D. Roger,[7] Kamal Sud,[11] Vicente E. Torres,[4] Sundareswari V. Adinarayanan,[8] David Harris.[1] On behalf of the PREVENT-ADPKD clinical trial investigators *[1]Michael Stern Laboratory for Polycystic Kidney Disease, Westmead Institute for Medical Research, Westmead, NSW, Australia; [2]The Charles Perkins Centre, The University of Sydney, Sydney, NSW, Australia; [3]Dept of Renal Medicine, Saint George Hospital, Kogarah, NSW, Australia; [4]Translational PKD Center, Mayo Clinic Minnesota, Rochester, MN; [5]Dept of Radiology, Westmead Hospital, Westmead, NSW, Australia; [6]Australasian Kidney Trials Network, Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [7]Renal Research, Gosford Hospital, Gosford, NSW, Australia; [8]Dept of Nephrology, John Hunter Hospital, New Lambton Heights, NSW, Australia; [9]Dept of Renal Medicine, Sir Charles Gairdner Hospital, Nedlands, WA, Australia; [10]Department of Renal Medicine, Bathurst Hospital, Bathurst, NSW, Australia; [11]Dept of Renal Medicine, Nepean Hospital, Penrith, NSW, Australia; [12]Dept of Renal Medicine, Wollongong Hospital, Wollongong, NSW, Australia; [13]Renal Medicine, Prince of Wales Hospital, Sydney, NSW, Australia.*

Background: Arginine vasopressin (AVP) promotes kidney cyst growth in autosomal dominant polycystic kidney disease (ADPKD). Increasing water intake to reduce urine osmolality and AVP release is hypothesized to slow kidney cyst growth in ADPKD.

Methods: In this multi-center, open-label, parallel-arm randomized controlled 3-year trial adults with ADPKD and Mayo Subclass 1B to 1E and an estimated glomerular filtration rate (eGFR) of ≥30 mL per minute per 1.73m^2, were randomized to water intake prescribed to reduce 24-hour urine osmolality to ≤270 mOsm/kg or *ad libitum* water intake irrespective of urine osmolality. The primary endpoint was the annualized rate of change in the height-corrected total kidney volume (Ht-TKV).

Results: One hundred and eighty-four patients, with a mean 24-hour urine osmolality of 423±178 mOsm/kg and median 24-hour urine volume of 2.3L/day (IQR:1.8-3.1L/day) at baseline, were randomized to either *ad libitum* water intake (92 patients) or prescribed water intake (92 patients). Over 3 years the mean treatment differences between the *ad libitum* water and prescribed water intake groups for 24-hour urine osmolality and 24-hour urine volume were -91 mOsm/kg (95% CI –127 to -54 mOsm/kg;P<0.01) and 0.6L/day (95% CI 0.4 to 0.9L/day;P<0.01) respectively. The proportion of patients with 24-hour urine osmolality <300 mOsm/kg for >50% of timepoints was 52%. There was no difference in the percentage annualized rate of change in Ht-TKV between the groups (*ad libitum* water intake: 7.8% per year, 95% CI, 6.6 to 9.0%; prescribed water intake: 6.8% per year, 95% CI 5.8 to 7.7%; P=0.18). The decline in eGFR from baseline to 3 years, changes in other secondary endpoints, discontinuation rates and adverse events were comparable between the two groups.

Conclusions: In ADPKD patients with a median baseline urine volume of 2.3L/day with Mayo subclass 1B to 1E, prescribed water intake was a safe intervention which achieved target urine osmolality in half of the patients but did not change the progression of total kidney volume over 3 years compared to *ad libitum* water intake.

PO2538

PHYOX2: Nedosiran Reduced Urinary Oxalate Excretion in Patients with Primary Hyperoxaluria

Michelle A. Baum,[1] Craig B. Langman,[2] Pierre Cochat,[3] John C. Lieske,[4] Shabbir H. Moochhala,[5] Shuzo Hamamoto,[6] Hiroyuki Satoh,[7] Chebl Mourani,[9] Gema Ariceta,[11] Aniruddha Amrite,[8] Bernd Hoppe.[8,10] *[1]Boston Children's Hospital, Boston, MA; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Hopital Femme Mere Enfant, Bron, France; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Royal Free Hospital, London, United Kingdom; [6]Nagoya Shiritsu Daigaku, Nagoya, Japan; [7]Tokyo Toritsu Shoni Sogo Iryo Center, Fuchu, Japan; [8]Dicerna Pharmaceuticals Inc, Lexington, MA; [9]Hotel-Dieu de France Service d'Hematologie-Oncologie, Beirut, Lebanon; [10]Rheinische Friedrich-Wilhelms-Universitat Bonn, Bonn, Germany; [11]Vall d'Hebron Hospital Universitari, Barcelona, Spain.*

Background: Primary hyperoxaluria (PH) is a family of 3 ultra-rare genetic disorders characterized by hepatic oxalate overproduction leading to hyperoxaluria, recurrent calcium oxalate kidney stones, nephrocalcinosis, and often, kidney failure. Nedosiran is an investigational RNA interference (RNAi) therapy that reduces overproduction of oxalate by inhibiting hepatic lactate dehydrogenase (LDH). Results from PHYOX2, the pivotal trial of nedosiran in 35 participants with PH1 or PH2 are reported here.

Methods: See Table

Results: PHYOX2 achieved its primary and key secondary endpoints. Nedosiran resulted in a 57.5% greater daily average reduction in urinary oxalate (Uox) excretion AUC (based on D90 to D180 AUC) compared to placebo (p<0.0001). Among participants given nedosiran, 50% achieved and sustained normal or near-normal Uox at 2 or more consecutive visits after D90 compared to 0% given placebo (p=0.0025). Uox was significantly reduced in the PH1 cohort (Figure; post hoc analysis). The results in the PH2 cohort (5 nedosiran, 1 placebo) were inconsistent; only 2 out of 5 participants given nedosiran showed reduction in Uox between D90 and D180. The most common AEs were mild, self-resolving injection site reactions. There were 3 SAEs (1 in nedosiran; 2 in placebo).

Conclusions: Nedosiran was well-tolerated and resulted in a clinically and statistically significant sustained reduction in Uox excretion compared to placebo, with robust efficacy in the PH1 subtype. The heterogeneity of response in the smaller PH2 cohort was inconsistent with prior clinical experience and warrants further investigation.

Funding: Commercial Support - Dicerna Pharmaceuticals, Inc.

Design	Phase 2, randomized, placebo-controlled, double-blind trial (NCT03847909)
Key inclusion criteria	Genetically confirmed PH1 or PH2; Age ≥ 6 years; 24-hr urinary oxalate (Uox) excretion ≥ 0.7 mmol (per 1.73 m^2 in age < 18 years); eGFR ≥ 30 mL/1.73 m^2
Demographics	Safety population: Nedosiran (n=23; PH1=18; PH2=5); Placebo (n=12; PH1=11; PH2=1) Mean age: Nedosiran (n=23): 23.7 years; Placebo (n=12): 23.6 years Efficacy population (mITT*): Nedosiran (n=22; PH1=17; PH2=5); Placebo (n=12; PH1=11; PH2=1) [*participants with at least 1 efficacy assessment after Day 90]
Nedosiran dosing (subcutaneous, once monthly X 6 months)	• Ages ≥ 12 + weighing ≥ 50 kg: 170 mg • Ages ≥ 12 + weighing < 50 kg: 136 mg • Ages ≥ 6 to < 12: 3.5 mg/kg (not exceeding 136 mg)
Primary endpoint	Percent change from baseline in 24-hr Uox excretion as assessed by area under the curve (AUC) from Day 90 (D90) to Day 180 (D180)
Key secondary endpoint	Proportion of participants reaching normalization (< 0.46 mmol; upper limit of assay normal-ULN) or near-normalization (≥ 0.46 to < 0.60 mmol; 1.3XULN) of 24-hour Uox excretion on at least 2 consecutive visits, starting from D90

Effect of Avacopan, a Selective C5a Receptor Inhibitor, on C3G Histologic Index of Disease Chronicity

Andrew S. Bomback,[1] Leal C. Herlitz,[2] Huibin Yue,[3] Priyanka Punit Kedia,[3] Thomas J. Schall,[3] Pirow Bekker.[3] *[1]Columbia University Irving Medical Center, New York, NY; [2]Cleveland Clinic, Cleveland, OH; [3]ChemoCentryx Inc, San Carlos, CA.*

Background: Complement 3 Glomerulopathy (C3G) is a rare kidney disorder with no approved treatment presenting with proteinuria, hematuria, renal insufficiency, and/or hypertension.

Methods: In the randomized, double-blind, placebo-controlled ACCOLADE study, patients were randomized 1:1 to receive avacopan 30 mg twice daily (n=28) or placebo (n=29) for 26 weeks; thereafter (still blinded as to original treatment) consenting patients (25 each in avacopan and placebo groups) received avacopan for another 26 weeks. The C3G Histologic Index (C3HI) was used to evaluate changes in kidney histology. C3HI of Disease Activity, measuring acute glomerular inflammation, was the primary efficacy measure; change in the C3HI of Disease Chronicity, measuring chronic indices such as fibrosis, was a secondary endpoint.

Results: Mean baseline C3HI of Disease Chronicity was 4.7 and 4.2 (out of 10) in the avacopan and placebo groups, respectively. Mean % change from baseline in the C3HI of Disease Chronicity (greater score denotes greater fibrosis progression) through week 26 was 31.7% with avacopan (N=26) vs 57.5% with placebo (N=26); change of 0.8 vs 1.6, respectively, P=0.04 **(Table 1)**. Subsequent assessment of paired biopsies from weeks 26 and 52 (in 17 and 16 patients, avacopan and placebo, respectively) revealed that patients continuously on avacopan had a similar rate of change in the second 26 weeks vs. the first 26 weeks (14.4% vs 12.6%), while patients who switched from placebo to avacopan for the second 26 weeks showed a significant improvement inflection (-2.3%; P=0.0083, **Figure 1**).

Conclusions: Avacopan attenuated C3G progression. The change in C3HI of Disease Chronicity was lower with avacopan compared to placebo and also improved in patients who switched from placebo to avacopan.

Funding: Other U.S. Government Support, Commercial Support - ChemoCentryx

Background: Until now there are no approved specific therapy for IgA nephropathy. Telitacicept is a novel fusion protein composed of transmembrane activator and CAML interactor (TACI) and the Fc portion of IgG, which targets and neutralizes B lymphocyte stimulator (BLyS) and a proliferation-inducing ligand (APRIL). This phase II study evaluated the efficacy and safety of telitacicept compared with placebo, when added to standard therapy in patients with IgAN with high risk for progression

Methods: In this randomized, double-blind, placebo-controlled trial, we enrolled patients with proteinuria ≧ 0.75g/day despite optimal supportive care, who were randomized 1:1:1 to receive subcutaneous telitacicept at 160 mg, 240 mg or placebo weekly for 24 weeks. The primary endpoint was a change in 24-hour proteinuria at week 24; key secondary endpoints included change in eGFR.

Results: Overall 44 participants were randomized in this study: placebo (14) and telitacicept 160mg (16) and 240mg (14). A consistent, dose-dependent reduction in serum IgA(Figure 1A), IgG and IgM were observed through Week 24. Telitacicept therapy was associated with a 49% decrease from baseline in mean proteinuria (change in proteinuria vs placebo -0.88; 95% CI-1.57~-0.20; p=0.013) received 240mg, and 25% reduction but non-significantly in 160mg arm (-0.29; -0.95~0.37; p=0.389) (Figure 1B). Estimated GFR remained stable over time (Figure 1C). TEAEs were reported similar in all groups. TEAEs were mild or moderate in severity, with no severe TEAEs reported.

Conclusions: Telitacicept reduced proteinuria in patients with IgA nephropathy with high risk. This effect is indicative of a reduced risk of future kidney progression.

Funding: Commercial Support - Remegen, LTD

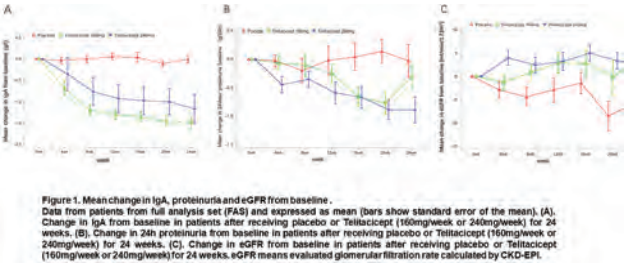

Figure 1. Mean change in IgA, proteinuria and eGFR from baseline.
Data from patients from full analysis set (FAS) and expressed as mean (bars show standard error of the mean). (A). Change in IgA from baseline in patients after receiving placebo or Telitacicept (160mg/week or 240mg/week) for 24 weeks. (B). Change in 24h proteinuria from baseline in patients after receiving placebo or Telitacicept (160mg/week or 240mg/week) for 24 weeks. (C). Change in eGFR from baseline in patients after receiving placebo or Telitacicept (160mg/week or 240mg/week) for 24 weeks. eGFR means evaluated glomerular filtration rate calculated by CKD-EPI.

Figure 1. Mean change in IgA, proteinuria and eGFR from baseline

PO2541

Long-Term Phase 2 Efficacy of the MASP-2 Inhibitor Narsoplimab for Treatment of Severe IgA Nephropathy

Richard A. Lafayette,[1] Kevin Carroll,[2] Jonathan Barratt.[3] On behalf of the ALC Steering Committee *[1]Stanford University, Stanford, CA; [2]KJC Statistics Ltd., Cheshire, United Kingdom; [3]University of Leicester, Leicester, United Kingdom.*

Background: IgA nephropathy (IgAN) is a glomerular disease in which the lectin pathway of complement is activated following mesangial deposition of IgA immune complexes. Narsoplimab (OMS721) inhibits mannan-binding lectin-associated serine protease-2 (MASP-2), the effector enzyme of the lectin pathway.

Methods: A staged Phase 2 study (NCT02682407) enrolled adult patients with severe IgAN. Substudy 1 was a single-arm open-label study of 12 weekly IV infusions of narsoplimab and tapered corticosteroids. In substudy 2, corticosteroid-free patients were randomized 1:1 to receive weekly IV narsoplimab or vehicle infusions for 12 weeks followed by open-label extension. The primary endpoint was safety and tolerability of narsoplimab. Key secondary endpoints were 24-hour urine protein excretion (UPE) and estimated glomerular filtration rate (eGFR) assessed by time-weighted average regression analysis after up to 35 months follow-up. Patients from the Leicester Renal Unit IgA Nephropathy Registry with similar disease burden and matched baseline UPE and eGFR values were used as the comparator group.

Results: This high-risk population with advanced IgAN at enrollment had a median disease duration of 6.9 yrs (range 0.4–27.5). Baseline risk factors included hypertension (10/12, 83%), obesity (7/12, 58%; median BMI 32.5 kg/m^2; range 24.4–44.3), excessive proteinuria (median UPE of 4.2 g/24 hr; range 1.5–11.9), and kidney dysfunction (median eGFR of 40.8 mL/min/1.73m^2; range 25.4–76.5). 12 patients participated in the dosing extension phase and were followed for a median of 22 months. Patients received median 1 course of 12 weekly doses of narsoplimab per year (range 0.7–2.5 courses), with 58% (7/12) receiving ≤1 course per year. eGFR rate of decline was 5.2 (±2.1) mL/min/yr vs 8.6 (±3.7) mL/min/yr in the Leicester IgAN control cohort, suggesting better eGFR stability in the patient population. Over 3 years, eGFR improved in 25% (3/12) of patients. UPE decreased 38% from baseline through the follow-up period. Narsoplimab was well tolerated with no treatment-related serious adverse events reported.

Conclusions: In this Phase 2 study, narsoplimab was well tolerated. Treatment in patients with severe IgAN resulted in proteinuria reduction and better renal protection via eGFR stability relative to a matched comparator group.

PODO: Phase 2 Study of PF-06730512 in Focal Segmental Glomerulosclerosis (FSGS) - Results from First Interim Analysis

Stephen Berasi,[1] J. B. Copley,[1] Donal Gorman,[2] Chay Ngee Lim,[1] Tara Moorehead,[1] Daniel I. Levy,[3] Susan Hwang,[1] Molly Geraghty,[4] Joel M. Henderson,[4] David J. Salant,[4] Weining Lu.[4] *[1]Pfizer Inc, Cambridge, MA; [2]Pfizer Inc, Cambridge, United Kingdom; [3]Pfizer Inc, Collegeville, PA; [4]Boston University School of Medicine, Boston, MA.*

Background: Focal segmental glomerulosclerosis (FSGS) is characterized by proteinuria and a histologic pattern of glomerular lesions including scarring and podocyte foot process effacement. ROBO2/SLIT2 signaling destabilizes the slit diaphragm and reduces podocyte adhesion to the glomerular basement membrane. This clinical trial evaluates efficacy and safety of ROBO2/SLIT2 inhibition with the ROBO2 fusion protein, PF-06730512, in patients with FSGS.

Methods: PODO (ClinicalTrials.gov NCT03448692) is an open-label, Phase 2a, multicenter trial in adults with FSGS, enrolling 2 cohorts (~22 each) with IV infusions of high or low dose PF-06730512 once every 2 weeks for 12 weeks. Inclusion criteria include confirmed biopsy FSGS diagnosis, suboptimal response with 1 and up to 3 drugs, eGFR ≥45 ml/min/1.73 m^2 (30–45 recent biopsy), and UPCR >1.5 g/g. Exclusion criteria include collapsing FSGS, ≥50% tubulointerstitial fibrosis, and organ transplantation. The primary endpoint is change from Baseline to Week 13 in 24-hour UPCR; secondary endpoints include safety, changes in eGFR and UPCR over time (Weeks 5, 9, 13), and PF-06730512 serum concentration. Interim analyses were pre-specified. A biopsy substudy to evaluate podocyte foot process width changes is also included.

Results: The first interim analysis occurred after approximately half of the first cohort subjects completed Week 13. Modelled LS mean reduction in UPCR was 35% at Week 13 and statistically significant reductions were also observed at Week 9 and in

ad hoc analysis Week 21. Exploratory data from the biopsy substudy may be presented. No safety signals have been identified for PF-06730512.

Conclusions: In this interim analysis (n=9), a significant mean reduction in UPCR was observed in FSGS subjects after 12 weeks of treatment with PF-06730512. PF-06730512 thus far is safe and well-tolerated.

Serum Aldosterone and Urine Electrolytes Dynamics in Response to DASH Intervention: An Inpatient Mechanistic Study

Dana Bielopolski,[1] Adam Qureshi,[1] Andrea Ronning,[1] Jonathan N. Tobin,[1,2] Rhonda Kost.[1] *[1]The Rockefeller University, New York, NY; [2]Clinical Directors Network Inc, New York, NY.*

Background: The Dietary Approaches to Stop Hypertension ("DASH diet") is a proven intervention to treat hypertension and is as effective as one antihypertensive drug. Despite years of research the precise understanding of its mechanism of action is lacking. We designed a translational trial to elucidate the biological pathway leading from nutritional change, through hormonal response, variations in urine electrolytes to blood pressure (BP) reduction.

Methods: A single center interventional trial. Stage 1 hypertensive otherwise healthy volunteers were admitted for 14-days, transitioning from American style diet to the DASH diet. Data were collected daily for vital signs, blood (chemistry) and urine (electrolytes). On days 1 and 10, participants completed 24-hour ambulatory blood pressure monitoring (ABPM) and 24-hour urine collections.

Results: 9 volunteers completed the protocol (7 men, 8 Black participants). Serum Aldosterone increased from day 0 (mean 8.3, range 2.8-18.9) to day 5 (mean 17.8, range 10.2-27.2) after intervention, and decreased on day 11 (mean 11.5, range 4.8-18.2) despite continuous exposure to the diet (p-value= 0.001). Urine ([Na]/[K]) electrolytes ratio (Picture 1) decreased from a mean of 3.5 before intervention on day 1 to 1.16 on day 4. BP reductions on 24-hour ABPM from day 1 to 10 were observed for the entire period, and during both sleep and awake recordings.

Conclusions: Shifting from a high-sodium/low-potassium diet to the opposite leads to serial physiological changes that are governed by Aldosterone and result in blood pressure reduction. Clinicians should follow urine electrolytes ratio to assess adherence to nutritional recommendations.

Early Changes in Estimated Glomerular Filtration Rate Post-Initiation of Empagliflozin in EMPEROR Heart Failure Trials

Faiez Zannad,[1] João Pedro Ferreira,[2] John Gregson,[3] Sibylle J. Hauske,[4] Bettina J. Kraus,[5] Michaela Mattheus,[4] Javed Butler,[6] Gerasimos Filippatos,[7] Christoph Wanner,[5] Stefan D. Anker,[8] Stuart Pocock,[3] Milton Packer.[9] EMPEROR-Preserved Trial Committees and Investigators *[1]Université de Lorraine, Inserm INI-CRCT, CHRU, Nancy, France; [2]CHRU Nancy - Hopitaux de Brabois, Nancy, France; [3]London School of Hygiene and Tropical, London, United Kingdom; [4]Boehringer Ingelheim, Ingelheim, Germany; [5]University Hospital, Wuerzburg, Germany; [6]University of Mississippi School of Medicine, Jackson, MS; [7]Attikon University Hospital, Athens, Greece; [8]Charité Medical School, Berlin, Germany; [9]Baylor Heart and Vascular Institute, Dallas, TX.*

Background: Sodium glucose co-transporter 2 inhibitors (SGLT2i) may induce a early post-initiation eGFR decrease which does not impact the SGLT2i benefits in patients with diabetes. The occurrence, characteristics, determinants, and clinical significance of eGFR change among patients with heart failure are yet to be described. We report here the results in EMPEROR-Reduced, with reduced ejection fraction (HFrEF). Results of EMPEROR-Preserved, in 5,988 patients with preserved ejection fraction (HFpEF), a trial which just terminated, will be reported at the ASN meeting. The aim is to describe eGFR change from baseline to week 4 (as % of change relative to baseline) and assess its impact in EMPEROR-Reduced.

Methods: Landmark analyses (week 4) were performed assessing the risk of outcomes across tertiles of eGFR change.

Results: eGFR change was available in 3547 patients out of 3730 (95%). Empagliflozin induced a leftward distributional shift of early eGFR changes with more patients with an initial eGFR decline. In the empagliflozin group, applying multiple adjustment methods, the risk of cardiovascular and renal outcomes was not increased in patients in whom early post treatment initiation eGFR decreased as compared to patients in whom it increased or did not change. However, in the placebo group, patients in whom early post treatment initiation eGFR decreased had a higher risk of sustained worsening kidney function compared to patients in whom eGFR increased.

Conclusions: In EMPEROR-Reduced, modest post treatment initiation eGFR decrease was observed more frequently with empagliflozin than with placebo. Only in patients taking placebo eGFR decrease was associated with a higher risk of sustained worsening kidney function. Any post-empagliflozin initiation decrease in eGFR did not deprive patients from benefiting from empagliflozin therapy. Full results of these analyses in EMPEROR Reduced as well as results of similar analyses in EMPEROR-Preserved, with preserved ejection fraction (HFpEF) will be reported at the time of the meeting.

AKI and Outcomes Following an Acute Myocardial Infarction

Finnian R. McCausland,[1,2] Martina M. McGrath,[1,2] Ebrahim Barkoudah,[1,2] Brian Claggett,[1,2] Karola Jering,[1,2] Eldrin F. Lewis,[6] Mariya Tokmakova,[3] Peter Van Der Meer,[4] Yinong Zhou,[5] Marc A. Pfeffer.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Medicinski universitet-Plovdiv, Plovdiv, Bulgaria; [4]Rijksuniversiteit Groningen, Groningen, Netherlands; [5]Novartis Pharmaceuticals Corp, East Hanover, NJ; [6]Stanford University, Stanford, CA.*

Background: Development of acute kidney injury (AKI) is a poor prognostic factor among patients with coronary artery disease. We evaluated the frequency of AKI and its association with adverse kidney and cardiovascular (CV) outcomes in patients with an acute myocardial infarction (AMI) in the PARADISE-MI trial.

Methods: In this randomized, double-blind, active controlled, event-driven trial, 5,661 patients with AMI were assigned to receive sacubitril/valsartan or ramipril, with no run-in. Key exclusions were baseline eGFR <30mL/min/1.73m^2, pre-existing heart failure (HF), and clinical instability. AKI was defined as an increase in serum creatinine ≥0.3mg/dL from baseline to day 7. Multivariable Cox regression models were fit to examine the association of AKI with the kidney composite (persistent ≥50% reduction in eGFR relative to baseline, end-stage renal disease, or renal death) and CV composite outcome (CV death, first HF hospitalization, or outpatient HF).

Results: AKI occurred in 275 (5.3%) of 5,207 patients with available data, over a median follow up of 1.8 years. Patients with AKI were more likely to be older, Asian, have higher SBP, diabetes, prior stroke, atrial fibrillation, STEMI without reperfusion in 24 hours, pulmonary congestion, higher Killip class, to be taking diuretics and have lower baseline eGFR (66 vs 72 mL/min/1.73m^2), compared to those without AKI. AKI was more frequent among those taking sacubitril/valsartan than ramipril (6.0 vs 4.6%). AKI was associated with a higher adjusted risk of the kidney composite outcome (HR 8.4; 95% CI 3.9 to 17.9), which occurred in 37 (0.7%) of the 5,207 participants. There was no evidence for effect modification by randomized treatment (P-interaction=0.71). AKI was not significantly associated with the CV composite (HR 1.23; 95% CI 0.90 to 1.68), which occurred in 585 (11.2%) of 5,207 participants.

Conclusions: In patients with AMI, AKI is associated with higher risk of the composite kidney outcome, which occurred in only 0.7% of individuals, and did not differ according to randomized treatment.

Effect of Empagliflozin on Kidney Biochemical and Imaging Outcomes in Patients with Type 2 Diabetes, or Prediabetes, and Heart Failure with Reduced Ejection Fraction (SUGAR-DM-HF)

Matthew M. Lee,[1] Sarah Allwood-Spiers,[2] Pauline Hall Barrientos,[2] Kirsty Wetherall,[1] Alex Mcconnachie,[1] Paul Welsh,[1] Giles Roditi,[1] Steven Sourbron,[3] Aleksandra Radjenovic,[1] John McMurray,[1] Pardeep Jhund,[1] Mark C. Petrie,[1] Naveed Sattar,[1] Patrick B. Mark.[1] SUGAR-DM-HF Investigators *[1]University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [3]The University of Sheffield, Sheffield, United Kingdom*.

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors reduce the risk of worsening kidney function in patients with diabetes, and heart failure with reduced ejection fraction (HFrEF). We explored the mechanisms underlying this benefit using magnetic resonance imaging (MRI).

Methods: We designed a multicenter randomized, double-blind, placebo-controlled trial to investigate the renal effects of empagliflozin in patients with left ventricular ejection fraction (LVEF) ≤40% and type 2 diabetes or prediabetes. Patients were randomized 1:1 to empagliflozin 10 mg once daily or placebo. Pre-specified exploratory outcomes included change from baseline to 36 weeks in kidney MRI biomarkers: kidney blood flow measured by a) arterial spin labelling (pCASL) and b) magnetic resonance renography (MRR), T1, apparent extracellular volume (aECV), volume.

Results: We randomized 105 patients: mean age 68.7 [SD 11.1] years, 77 (73%) male, 82 (78%) diabetes, mean eGFR 67 [22] mL/min/1.73m², mean urinary albumin:creatinine (uACR) 73 [277] mg/g. Compared with placebo, empagliflozin reduced right whole kidney (WK) and right cortex (Cx) pCASL by 27 (95% CI, -49 to -5; *P*=0.017) and 27 (-51 to -4; *P*=0.024) mL/100mL/min respectively, reduced right WK aECV by 4.2 (-7.8 to -0.7; *P*=0.02) %, and reduced urinary sodium concentration by 15 (-26 to -4; *P*=0.009) mmol/L. Similar results were seen for left WK pCASL, left Cx pCASL and left WK aECV. There were no between-group differences in MRR, kidney T1, total kidney volume, eGFR, uACR or fractional sodium excretion.

Conclusions: Empagliflozin reduced kidney blood flow measured by pCASL, but not by MRR, in patients with HFrEF and type 2 diabetes or prediabetes. Reduction in kidney blood flow may be a mechanism by which SGLT2 inhibitors reduce the risk of worsening kidney function in HFrEF.

Vitamin K1 Retards Progression of Cardiovascular Calcifications in Hemodialysis Patients: The VitaVasK Trial

Turgay Saritas,[1] Sebastian D. Reinartz,[1] Thilo Krueger,[2] Pieter Evenepoel,[3] Michel Y. Jadoul,[4] Christoph Kopp,[9] Markus Ketteler,[5] Peter Stenvinkel,[6] Ralf Westenfeld,[7] Stephanie Wied,[1] Robert Siepmann,[1] Ralf-dieter Hilgers,[1] Leon J. Schurgers,[8] Jürgen Floege.[1] *[1]University Hospital RWTH Aachen, Aachen, Germany; [2]DaVita, Geilenkirchen, Germany; [3]University Hospitals Leuven, Leuven, Belgium; [4]Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; [5]Robert-Bosch-Krankenhaus GmbH, Stuttgart, Germany; [6]Karolinska Universitetsjukhuset i Huddinge, Huddinge, Sweden; [7]Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany; [8]Universiteit Maastricht, Maastricht, Netherlands; [9]Universitatsklinikum Erlangen, Erlangen, Germany*.

Background: Cardiovascular calcifications are prevented by matrix Gla protein (MGP), a protein activated by vitamin K. As HD patients exhibit marked vitamin K deficiency, the VitaVasK trial (EudraCT No.: 2010-021264-14) analysed whether vitamin K1 supplementation affects progression of coronary artery calcifications (CAC) and thoracic aortic calcifications (TAC) in these patients.

Methods: This prospective, open-label, multicenter trial randomized patients with preexisting CAC to continue on standard care or to additionally receive 5 mg vit K1 orally thrice weekly. Primary end points were progression of TAC and CAC volume scores in CT scans during 18 months. Repeated linear mixed effects models assessed the treatment effect after adjusting for study site.

Results: Of 60 randomized patients, 20 dropped out for reasons unrelated to vit K1, resulting in 23 control and 17 vit K1 patients. The trial was stopped early due to low recruitment rate. TAC progressed significantly between baseline and 18 months but its progression was reduced by a mean of 56% in the vit K1 compared to the control group at 18 months (p=0.039) (**Table**). CAC significantly progressed within the control group, but not within the vit K1 group. Progression at 18 months was lower by an average of 68% in the vit K1 group compared to the control group (p=0.072). Inactive dp-ucMGP in plasma was elevated at baseline, confirming vit K deficiency. Levels at 18 months were 110±40% of baseline in controls but rapidly dropped in the vit K1 group to 27±12% at 18 months. No treatment-related adverse events were noted.

Conclusions: Despite early termination, this randomized trial identifies a highly effective mode of correcting the vit K deficiency in chronic HD patients. Our intervention is potent, safe and cost-effective to reduce progression of cardiovascular calcification in this high-risk population.

Attenuated COVID-19 Severity in the MDR-101 MLK MERCURY Tolerance Study

Sam Kant,[1] Sanjeev Akkina,[2] William S. Asch,[3] Daniel C. Brennan.[4] *[1]Johns Hopkins University Hospital, Baltimore, MD; [2]Loyola University Health System, Maywood, IL; [3]Yale University School of Medicine, New Haven, CT; [4]Medeor Therapeutics, San Franscisco, CA.*

Background: Transplant recipients are at high risk for COVID-19 infection and associated complications. This risk has correlated with use of immunosuppression. We describe an ongoing Phase 3 trial of a regimen to induce tolerance via mixed chimerism and functional tolerance with withdrawal of immunosuppression, and course of COVID-19 in patients participating in this study.

Methods: This is a prospective randomized multicenter open label-controlled trial to achieve sustained withdrawal from immunosuppression for 24 months without evidence of rejection, with enrollment of 30 patients with a 2:1 randomization of investigational and control patients. The investigational product MDR-101 (consisting of donor derived CD34+ hematopoietic stem and progenitor cells and a specified dose of CD3+ T cells) is administered post total lymphoid irradiation (TLI), 11 days post kidney transplantation with rabbit-anti-thymoglobulin induction and maintenance immunosuppression with prednisone for the first 10 days and mycophenolate mofetil on days 11-39 only. A calcineurin inhibitor (CNI) taper is initiated in those subjects who achieve a 6 month or greater period of persistent mixed hematopoietic chimerism (comprising at least 5% donor cells) coupled with the absence of de novo donor specific antibody (dnDSA), graft versus host disease (GVHD), transplant kidney loss, or biopsy proven acute rejection (BPAR) on a for cause or transplant kidney protocol biopsy.

Results: Two patients in the active arm developed COVID-19 (patient 1 at day 57 and patient 2 at 651 post enrollment; prior to introduction of vaccines). The COVID-19 infection in patient 1 presented with myalgias with minimal respiratory symptoms that did not warrant supplemental oxygen or mechanical ventilation. A prolonged course of myalgias persisted for 3 months despite resolution of the infection, with eventual tapering of CNI at day 186 post engraftment. Patient 2, completely off immunosuppression, presented only with mild URI symptoms that resolved without any sequalae.

Conclusions: Induction of tolerance with concomitant withdrawal of immunosuppression may aid not only in reduction in adverse effects of immunosuppressive drugs, but immune reconstitution to attenuate severity of COVID-19. Further larger studies are required to ascertain this effect in a larger population.
