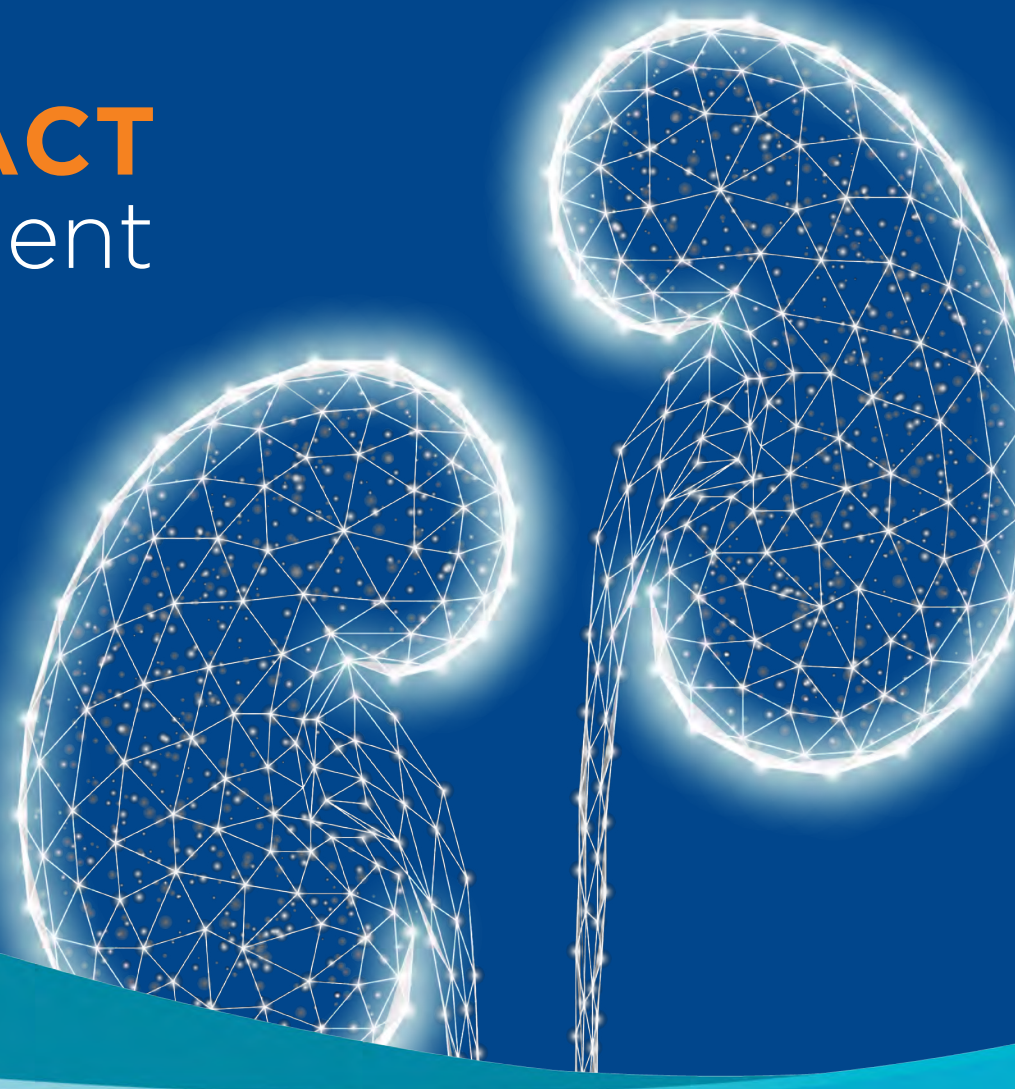
Kidney Week Edition

JASN

Journal of the American Society of Nephrology

ABSTRACT Supplement



KIDNEY WEEK 2021

Abstract Supplement

Abstract Publication
More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 32, 2021: Page(s).

Abstract Disclaimer and Copyright
This abstract issue of JASN® contains proprietary information belonging to the American Society of Nephrology. It is published as a service for the personal, noncommercial, and informational use only of the kidney community. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such materials within Kidney Week and other ASN publications or online postings does not constitute endorsement by ASN.

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

ASN General Information
Kidney Week Program and Presentations
The Kidney Week program, which can be found on the ASN website, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week to complete a disclosure form. Responses are listed on the ASN website.

TH-OR01

The Relationship Between Intravenous Fluid Administration and Renal Outcomes After Angiography

Qandeel H. Soomro,[1] Sonia T. Anand,[5] Steven D. Weisbord,[6] Martin P. Gallagher,[2] Ryan E. Ferguson,[4] Paul M. Palevsky,[3] James S. Kaufman.[4,1] *[1]New York University, New York, NY; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]Veterans Affairs Boston Healthcare System, Boston, MA; [5]VA Boston Health Care System Massachusetts Veterans Epidemiology Research and Information Center, Jamaica Plain, MA; [6]University of Pittsburgh, Pittsburgh, PA.*

Background: Contrast associated AKI (CA-AKI) may result in prolonged hospital stay and increased mortality. Fluids remain the mainstay for prevention. There is a lack of consensus on the optimal fluid rate and amount. Using the PRESERVE dataset, we studied the effect of peri-procedure fluid administration strategies on CA-AKI and 90-day need for dialysis, death, or a 50% increase in serum creatinine

Methods: We conducted a secondary analysis of 4993 of PRESERVE participants who received either IV saline or IV bicarbonate prophylaxis. Although fluid type was randomized, strategy of administration was at the discretion of the clinician. We divided the study group into quartiles by total fluid volume. Multivariable analysis was performed using logistic regression adjusting for age, history of heart failure, diabetes mellitus, left ventricular end-diastolic pressure, baseline glomerular filtration rate, procedure type, inpatient vs. outpatient status, and duration. We also tested for the interaction between fluid volume and duration of fluid administration categorized as <6 or ≥6 hours

Results: Compared to the highest quartile (Q4) of fluid volume, there was a significantly increased risk of the primary 90 day end point in quartile 1. There were no differences between quartiles 2 and 3 compared to quartile 4. There was no significant difference in the incidence of CA-AKI across the groups. The interaction between volume and duration of fluid administration was not significant

Conclusions: We found that fluid volumes <964 ml may be associated with an increased risk for the primary outcome although residual confounding cannot be excluded; and that administering higher volumes over a total duration of <6 hours seem to be equally protective. The utility of high volume, short duration fluid administration protocols will facilitate the safe performance of out-patient procedures.

	Quartiles of Total Fluid Volume			
	Q1 (N=1169)	Q2 (N=1165)	Q3 (N=1171)	Q4 (N=1166)

TH-OR02

AKI in Patients Treated with Immune Checkpoint Inhibitors

Shruti Gupta, David E. Leaf. ICPi-AKI Consortium *Brigham and Women's Hospital Department of Medicine, Boston, MA.*

Background: Data on immune checkpoint inhibitor-associated acute kidney injury (ICPi-AKI) are largely limited to single-center case series. We performed a multicenter study, the largest to date, to investigate risk factors, clinicopathologic features, outcomes, and survival in patients with ICPi-AKI.

Methods: We collected detailed data on 429 patients with ICPi-AKI and 429 controls who received ICPis contemporaneously but did not develop ICPi-AKI from 30 international sites. Multivariable logistic regression was used to identify predictors of ICPi-AKI and its recovery.

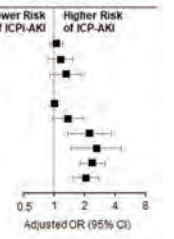
Results: ICPi-AKI occurred at a median of 16 weeks (IQR, 8-32) following ICPi initiation. Lower baseline eGFR, proton pump inhibitor (PPI) use, and prior or concomitant extrarenal immune-related adverse events (irAEs) were associated with a higher risk of ICPi-AKI (Figure A). Acute tubulointerstitial nephritis was the most common lesion on biopsy (125/151 biopsied patients [82.7%]). Hematuria, pyuria, and proteinuria were present in only 30-60% of patients with ICPi-AKI, and were more common in patients with greater severity of AKI. Renal recovery occurred in 276 patients (64.3%) at a median of 7 weeks (IQR, 3-10) following ICPi-AKI. Treatment with steroids was associated with higher odds of renal recovery (adjusted OR, 1.81; 95% CI, 1.01-3.27) (Figure B), particularly when initiated within 3 days of ICPi-AKI diagnosis (adjusted OR, 1.77; 95% CI, 1.01-3.13). Steroid use was also associated with a lower risk of death (adjusted HR, 0.52; 95% CI, 0.36-0.75). Of 121 patients rechallenged, only 20 (16.5%) developed recurrent ICPi-AKI.

Conclusions: Lower baseline eGFR, PPI use, and extrarenal irAEs are each independent risk factors for ICPi-AKI. Two thirds of patients have renal recovery following ICPi-AKI. Early treatment with steroids is associated with renal recovery and better overall survival.

A

Predictors of ICPi-AKI

Variable	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Age (per 10 years)	1.17 (1.04-1.31)	1.05 (0.92-1.21)
Male sex	1.16 (0.88-1.52)	1.15 (0.86-1.53)
Combination ICPi therapy	1.42 (1.01-1.98)	1.30 (0.90-1.87)
Baseline eGFR (ml/min/1.73m²)		
≥90 (REF)	1	1
60-89	1.54 (1.13-2.10)	1.36 (0.95-1.94)
45-59	2.48 (1.59-3.87)	2.23 (1.35-3.68)
<45	1.92 (1.74-4.89)	2.62 (1.47-4.65)
PPI use*	2.55 (1.92-3.40)	2.40 (1.79-3.23)
Prior or concomitant extrarenal irAEs**	2.19 (1.65-2.91)	2.07 (1.53-2.78)



B

Predictors of Renal Recovery after ICPi-AKI

Variable	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Age (per 10 years)	1.13 (0.95-1.34)	0.94 (0.75-1.18)
Male sex	1.81 (1.21-2.71)	1.45 (0.89-2.36)

Stage 3 AKI	0.29 (0.19-0.43)	0.36 (0.22-0.59)
Treated with corticosteroids***	1.56 (0.95-2.57)	1.81 (1.01-3.27)

TH-OR03

The Incidence and Risk Factors of AKI Among People with HIV on Antiretroviral Treatment

Anthony N. Muiru,[1] Erin Madden,[3] Rebecca Scherzer,[1] Chirag R. Parikh,[2] Chi-yuan Hsu,[1] Michael Shlipak,[1] Michelle M. Estrella.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Northern California Institute for Research and Education, San Francisco, CA.*

Background: The epidemiology of hospitalized acute kidney injury (AKI) among people with HIV (PWH) in the era of modern antiretroviral therapy for all PWH is not well-characterized.

Methods: We evaluated the incidence and risk factors for hospitalized AKI from 2005-2015 in a prospective study of PWH from the Johns Hopkins HIV Clinical Cohort. We defined hospitalized AKI as ≥0.3 mg/dL rise in serum creatinine (SCr) within any 48-hour period or 50% increase in SCr from baseline and assessed associations of risk factors with incident AKI using multivariate Cox regression models.

Results: Most participants (75%) were Black, 34% were female, mean age was 43 years and mean eGFR 106 mL/min/1.73 m^2. The incidence of AKI fluctuated annually, peaking at 40 per 1,000 person-years (PY) (95% CI: 22-69) in 2007, and reached a nadir of 20 per 1,000 PY (95% CI: 11-34) in 2010 (Figure). After multivariable adjustment, characteristics independently associated with AKI included Black race (HR=2.44; 95% CI: 1.42-4.20), hypertension (HR=1.61; 95% CI: 1.09-2.38), dipstick proteinuria >1+ (HR=1.78; 95% CI:1.06-2.97), history of AIDS (HR=1.82; 95% CI: 1.29-2.56), CD4 count <200 cells/mm^3 (HR=1.46; 95% CI: 1.02-2.07), and lower serum albumin (HR=2.87 per 0.1 mg/dL; 95% CI: 2.78-2.97).

Conclusions: In this contemporary cohort of PWH, the annual incidence of first AKI fluctuated during the study period. Attention to modifiable AKI risk factors and social determinants of health may further reduce AKI incidence among PWH.

Nephrotoxin Exposure and AKI: A Magnitude Assessment Using NINJA Methodology in the Adult Population

Benjamin R. Griffin,[1] Hermann Hounkponou,[1,2] Jason Misurac.[2] *[1]The University of Iowa Hospitals and Clinics, Iowa City, IA; [2]The University of Iowa Stead Family Children's Hospital, Iowa City, IA.*

Background: The Nephrotoxic Injury Negated by Just-in Time Action (NINJA) program was designed to identify pediatric patients with high exposure to nephrotoxic medications (NTMx) and to reduce rates of acute kidney injury (AKI). In children, this program resulted in a 23.8% reduction in NTMx-AKI. However, equivalent rates of NTMx-AKI in adults are largely unknown. We report rates of NTMX-AKI in adults through application of the NINJA screening tool in an adult population.

Methods: Adult non-ICU patients admitted to the University of Iowa hospital between January 1, 2019 and December 31, 2019 were included in this retrospective analysis. We excluded emergency department encounters, pregnant patients admitted for delivery, and patients with end-stage kidney disease. High NTMx exposure was defined per NINJA protocol as receiving ≥ 3 NTMx on one day or intravenous aminoglycoside or vancomycin for ≥ 3 days (list of NTMx previously published). Patient charts were screened daily by an automated NINJA algorithm for high NTMx exposure and for AKI, defined as a creatinine increase of ≥0.3 mg/dL or to 1.5x baseline. Patients could have more than one NTMx exposure or AKI episode if separated by 48 hours from resolution of a prior event. NTMX-AKI was defined as an AKI event occurring during or within 48 hours of a high NTMx exposure.

Results: There were 4,596/33,835 (13.6%) patients with at least one day of high-NTMx exposure, and 17,254/144,997 (11.9%) of hospital days met high NTMx exposure criteria. AKI of any etiology was seen in 3,398 (10%) of patients, of which 1,467 (43.2%) also had at least one day of high-NTMx exposure. In 943 of these 1467 cases (64.3%), NTMx exposure preceded AKI development, by a median of 5 days. There were 6,038 total exposures and 1,131 NTMx-AKI events, for an AKI rate of 18.7% following high NTMx exposure. Serum creatinine was checked on 89% of days on or within 48 hours of high NTMx exposure.

Conclusions: Rates of NTMx exposure in adults are substantial, accounting for 12% of all hospitalized patient-days. Rates of AKI following high NTMx exposure were 18.7%, suggesting that high NTMx exposure is a contributing factor in a large number of AKI cases. These findings support implementation of interventions like the NINJA program in adults in order to reduce rates of NTMx-AKI.

TH-OR05

Proton Pump Inhibitor Exposure and Risk of AKI after Cardiac Surgery

Hee Byung Koh,[1] Young Su Joo,[2] Hyung Woo Kim,[1] Wonji Jo,[1] Shinchan Kang,[3] Jong Hyun Jhee,[4] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Jung Tak Park.[1] *[1]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Uijeongbu Eulji University Medical Center, Uijeongbu, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Although postoperative acute kidney injury (AKI) is a serious and common complication of cardiac surgery, strategies for prevention are limited. A close link between proton pump inhibitor (PPI) usage and chronic kidney disease has been recently proposed. Therefore, the association between PPI exposure and AKI development after cardiac surgery was evaluated.

Methods: This retrospective study was conducted by analyzing two cohorts based on tertiary hospital-based electronic medical records and nationwide health insurance information. The Severance cardiac surgery cohort consisted of 6,555 patients aged ≥18 years who underwent cardiac surgery between May 2011 and September 2020. From the National Health Insurance Service-senior (NHIS-senior) cohort, 2,939 patients aged ≥60 years who underwent cardiac surgery between 2004 and 2015 were selected. Preoperative PPI exposure was defined as a PPI prescription record within 3 weeks before cardiac surgery. Primary outcome was AKI requiring dialysis (AKI-dialysis) and secondary outcomes were in-hospital mortality and hospital and intensive care unit (ICU) stay durations.

Results: In the Severance cardiac surgery cohort (mean age, 62.0 years; male, 60.1%) after propensity score matching, incident AKI-dialysis (5.5% vs. 3.2%, $P = 0.002$) and in-hospital mortality (4.7% vs. 3.2%, $P = 0.038$) were significantly higher among PPI-exposed than PPI non-exposed patients. In addition, median (IQR) hospital (17.0 [12.0-27.0] vs. 14.0 [11.0-19.0], $P < 0.001$) and ICU (3.0 [2.0-5.0] vs. [2.0-4.0], $P < 0.001$) stay durations were longer in patients exposed to PPI than in those who were not. Multivariable conditional logistic analyses revealed that PPI exposure was significantly associated with incident AKI-dialysis (OR, 2.20; 95% CI, 1.40-3.46) and in-hospital mortality (OR, 1.53; 95% CI, 1.03-2.27). The NHIS-senior cohort (mean age, 72.4 years; male, 58.7%) revealed comparable findings, showing that PPI exposure was significantly associated with incident AKI-dialysis (OR, 2.29; 95% CI, 1.60-3.29) and in-hospital mortality (OR, 2.25; 95% CI, 1.46-3.45).

Conclusions: Preoperative PPI exposure was associated with incident AKI in patients undergoing cardiac surgery, suggesting that PPI exposure could be a modifiable risk factor for AKI in these patients.

TH-OR06

Readmission and Mortality After AKI Hospitalization

Ivonne H. Schulman,[1] Duc Anh Ngo,[2] Kevin L. Chan,[1] Kevin C. Abbott,[1] Kenneth J. Wilkins,[1] Bryan Sayer,[2] Paul Eggers,[1] Jenna M. Norton,[1] Neha Shah,[1] Susan R. Mendley,[1] Afshin Parsa,[1] Jane S. Der,[2] Robert A. Star,[1] Paul L. Kimmel.[1] *[1]DKUHD, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; [2]DLH Corporation, Silver Spring, MD.*

Background: Acute kidney injury (AKI) associates with high morbidity/mortality, but we lack robust data to quantify short to long-term real-world outcomes after an AKI hospitalization. We derived a synthetic retrospective cohort of hospitalized AKI subjects from Optum Clinformatics, a large claims database, to quantify mortality and all-cause/selected rehospitalizations 90 days and 1 year after an AKI event.

Methods: All AKI hospitalizations between 1/2007 and 9/2020 who had >2 years of continuous enrollment free of AKI hospitalization were identified (n=594,509) from the Optum database and propensity score matched to 594,509 control subjects who were hospitalized for a non-AKI cause.

Results: Mean age (SD) of the AKI cohort was 74.1 (13.1) years and 47.6% were women, 73.7% were white, 14.1% were Black, 9.7% were Hispanic, and 2.5% were Asian, which was similar to the matched non-AKI cohort. 55.9% of AKI and 26.5% of matched non-AKI group were hospitalized in the 2 years before the index admission. 50.3% of AKI group had CKD and 34.9% had heart failure, similar to the matched non-AKI group. One-year unadjusted cumulative incidence of all-cause rehospitalization was higher in AKI vs matched non-AKI patients in the presence and absence of pre-existing CKD ($p<0.01$). Adjusting for baseline characteristics, AKI was associated with a higher rate of hospital readmission from any cause [Hazard ratio (HR) 1.77; 95%CI 1.75-1.80; death as competing risk], heart failure (HR 3.16; 95%CI 3.00-3.32), pneumonia (HR 1.64; 95%CI 1.54-1.75), sepsis (HR 3.06; 95%CI 2.92-3.21), and ESRD (HR 7.88; 95%CI 1.88-33.07) in the 90 days after discharge compared to the non-AKI group. Both crude and adjusted mortality rates were higher in the AKI group compared to the non-AKI at 90 (HR 3.04; 95%CI 2.98- 3.09) and 365 days (HR 2.39; 95%CI 2.36-2.42) and persisted when the groups were stratified by CKD status (vs without, $p<0.01$).

Conclusions: AKI hospitalization substantially increases the risk for subsequent death, hospitalization, heart failure, pneumonia, and sepsis compared to non-AKI hospitalization. These findings show novel interventions that mitigate the high burden of morbidity and mortality after an AKI hospitalization event are needed.

Cardiovascular Drug Use After AKI Among Hospitalized Patients with a History of Myocardial Infarction: A Population-Based Study

Alejandro Y. Meraz-Munoz,[1,2] Nivethika Jeyakumar,[13] Bin Luo,[13] William Beaubien-Souligny,[5] Rahul Chanchlani,[14,12] Edward G. Clark,[11,10] Ziv Harel,[1,2] Abhijat Kitchlu,[1,3] Javier A. Neyra,[6] Michael Zappitelli,[1,7] Glenn M. Chertow,[4] Amit X. Garg,[15,13] Ron Wald,[1,2] Samuel A. Silver.[8,9] *[1]University of Toronto, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada; [4]Stanford University, Palo Alto, CA; [5]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [6]University of Kentucky Medical Center, Lexington, KY; [7]The Hospital for Sick Children, Toronto, ON, Canada; [8]Queen's University, Kingston, ON, Canada; [9]Kingston Health Sciences Centre, Kingston, ON, Canada; [10]Ottawa Hospital, Ottawa, ON, Canada; [11]University of Ottawa, Ottawa, ON, Canada; [12]McMaster Children's Hospital, Hamilton, ON, Canada; [13]ICES, London, ON, Canada; [14]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [15]London Health Sciences Centre, London, ON, Canada.*

Background: Patients who survive an episode of acute kidney injury (AKI) are at increased risk of cardiovascular morbidity and mortality but may receive fewer cardioprotective drugs than patients without AKI. Our main objective was to evaluate the use of cardiovascular drugs after AKI among hospitalized patients with myocardial infarction (MI).

Methods: We conducted a population-based study of patients aged ≥ 66 years old with a prior history of MI, hospitalized from January 1, 2008, to March 31, 2017. We ascertained AKI using KDIGO serum creatinine criteria. We used propensity score matching to assemble a cohort of patients with and without AKI. The primary outcome was time to receipt of prescriptions for ACEi/ARB, beta-blocker, and statin (all 3 drugs) within one year of hospital discharge. We utilized proportional subdistribution hazards regression, accounting for the competing risk of death, to determine the cumulative incidence of receipt of cardiovascular drugs after AKI compared to patients without AKI.

Results: We identified 28,871 patients with AKI, of whom 21,452 were matched 1:1 to similar patients without AKI. Acute kidney injury was associated with a 7% (95% CI 5-9%) lower likelihood of receiving all 3 cardiovascular drug classes within one year of hospital discharge. This result was largely driven by a 13% (95% CI 11-15%) lower likelihood of ACEi/ARB prescription across all categories of AKI severity. Lower use of beta-blockers and statins was observed in severe AKI. Conversely, AKI was associated with more frequent use of loop diuretics (sHR=1.20, 95% CI 1.17-1.23) and mineralocorticoid receptor antagonists (sHR=1.22, 95% CI 1.15-1.28). The use of most medications stabilized at 3 months post-AKI.

Conclusions: In patients with a history of myocardial infarction, survivors of AKI were less likely to receive prescriptions for all 3 cardiovascular drug classes with strong evidence (ACEi/ARB, beta-blocker, and statin) and more likely to receive loop diuretics and mineralocorticoid receptor antagonists within one year of hospital discharge. Most medication changes stabilized at 3 months, indicating a critical timeframe to provide follow-up care.

TH-OR08

IMPROVE AKI: A Cluster-Randomized Trial of Team-Based Coaching Interventions to Improve AKI

Jeremiah R. Brown,[1] Richard J. Solomon,[2] Meagan E. Stabler,[1] Sharon E. Davis,[3] Kevin C. Cox,[1] Dax Westerman,[3] Chad A. Dorn,[3] James O'Malley,[1] Michael E. Matheny.[3] *[1]Dartmouth College Geisel School of Medicine, Hanover, NH; [2]University of Vermont College of Medicine, Burlington, VT; [3]Vanderbilt University, Nashville, TN.*

Background: Over 2 million people in the U.S. undergo cardiac catheterization procedures each year with acute kidney injury (AKI) occurring in up to 14% of all patients. However, orders are often not standardized to ensure adequate oral and intravenous fluids, reduced NPO time, and limited contrast dye dose across or within hospitals to prevent AKI. Therefore, we hypothesized that providing team-based coaching in a Virtual Learning Collaborative (VLC) would reduce post-procedural AKI incidence compared to Technical Assistance (TA), both with and without Automated Surveillance Reporting (ASR).

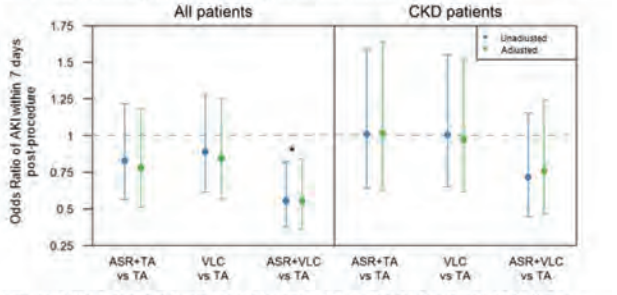
Methods: We conducted a 2x2 factorial cluster-randomized trial that randomized 20 hospitals to receive TA, TA+ASR, VLC, or VLC+ASR for 18-months. All sites received an AKI Prevention Toolkit that included AKI preventive strategies. We fit multilevel logistic models for AKI with site-level random effects to account for the clustered design.

Results: Across 20 randomized Veterans Administration medical centers, there were 4,517 patients including 1,153 patients with pre-existing chronic kidney disease (CKD) during the 18-month intervention phase of the trial. There were 510 AKI events (214 among CKD patients). In all patients, the VLC+ASR intervention cluster had a substantial reduction in AKI when compared to TA alone (aOR=0.55; 0.36, 0.84) mirrored by a strong yet non-significant effect among CKD patients (aOR: 0.76; 0.46, 1.24).

Conclusions: This implementation trial estimates that the combination of VLC with ASR reduces AKI by a highly significant 45% at an institution and is suggestive of a reduction among CKD patients. Therefore, the combined VLC with ASR team-based coaching intervention is an effective, scalable framework to establish aggressive prevention protocols to prevent AKI.

Funding: NIDDK Support

Figure 1. Multilevel logistic models for acute kidney disease with site-level random effects for all cardiac catheterization patients and those patients with chronic kidney disease.



Footnote: ASR: Automated Surveillance Reporting, TA: Technical Assistance, VLC: Virtual Learning Collaborative. The following patient features were included for adjustment: age, race, tobacco use, anemia, heart failure, CKD, diabetes, hypertension, and prior percutaneous coronary intervention. *In all patients, the VLC+ASR intervention cluster compared to TA alone showed a statistically significant reduction in AKI with an adjusted and unadjusted odds ratio of 0.55 [0.36, 0.84] and 0.56 [0.38, 0.82], respectively.

TH-OR09

Properties of Proenkephalin (penKid) in Septic AKI

Christian Nusshag,[1] Roman Szudarek,[2] Christoph Rupp,[2] Claudius Speer,[1] Florian Kälble,[1] Martin G. Zeier,[1] Florian Uhle,[2] Uta Merle,[3] Christian Morath,[1] Markus A. Weigand,[2] Thorsten Brenner.[2,4] *[1]Heidelberg University Hospital Department of Nephrology, Heidelberg, Germany; [2]Heidelberg University Hospital Department of Anesthesiology, Heidelberg, Germany; [3]Heidelberg University Hospital Department of Gastroenterology, Heidelberg, Germany; [4]Universitatsklinikum Essen, Essen, Germany.*

Background: Acute kidney injury (AKI) remains a serious complication in critically ill patients. The current definition of AKI continues to be based on changes in serum creatinine (SCr) and diuresis. However, neither SCr nor changes in diuresis provide an accurate estimate of true renal function. Proenkephalin (penKid) is a small and stable peptide derived from the same precursor molecule as encephalins. Recent evidence suggests that plasma PenKid concentrations more accurately reflect the true glomerular filtration rate than SCr. We therefore investigated the kinetic and diagnostic properties of penKid in critically ill patients with septic AKI.

Methods: In a secondary analysis of a prospective observational study, penKid levels were measured longitudinally in 200 patients with positive Sepsis-3 criteria. Plasma penKid levels were analyzed in relation to the severity and course of AKI and under renal replacement therapy. Area under the receiver-operating characteristic curve (AUC-ROC) analyses were performed.

Results: Sixty-two patients had no or mild AKI, 96 patients developed moderate or severe AKI without requiring RRT, and 42 patients developed RRT criteria or died within seven days after inclusion. Thirty-nine patients had transient AKI and 92 patients experienced persistent AKI or required RRT. Overall, penKid kinetics were more dynamic than SCr, and penKid courses preceded corresponding SCr courses by 48 h to 72 h. In patients without AKI, penKid levels generally remained below 50 pmol/L. Moreover, penKid levels discriminated well between transient and persistent AKI or the need for RRT. After 24 hours of sepsis therapy, the combination of SCr and penKid showed an improved AUC of 0.82 (95% CI 0.76-0.88) for predicting RRT or death compared with SCr or penKid alone (SCr: AUC 0.78, 95% CI 0.70-0.86; penKid: AUC 0.80, 95% CI 0.73-0.87). Interestingly, penKid courses were hardly affected by RRT and in some cases even increased under RRT.

Conclusions: Plasma penKid appears to indicate changes in renal function more dynamically than SCr and seems to provide additional diagnostic information on renal function. Remarkably, RRT appears to have little effect on plasma concentrations of penKid. Thus, penKid could allow assessment of renal function under RRT. Further research is needed to verify these results.

TH-OR10

Renal Outcomes After Chimeric Antigen Receptor T Cell (CAR-T) Therapy: A Single-Center Perspective

Rehan Ansari,[1] Ho Jun Lee,[1] Zhengyi Chen,[2] Arash Rashidi.[1] *[1]University Hospitals, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Background: Recently chimeric antigen receptor T-cell immunotherapy (CAR-T) has shown promise for refractory non Hodgkin lymphoma. While involving genetically engineered self T cells to express a synthetic receptor binding to tumor antigens, a great concern is the development of cytokine release syndrome (CRS). The release of cytokines can lead to vasodilation, decreased cardiac output, and intravascular volume depletion which may potentiate renal injury. Unfortunately a paucity of data exists of renal outcomes in patients treated with CAR-T, especially with chronic kidney disease (CKD). We aim to further elucidate renal outcomes in patients treated with CAR-T at our institution.

Methods: We reviewed the course of 39 adults who received CAR-T at our institution between July 2018 and May 2021. Baseline demographics (age, gender, comorbidites), and serum laboratory values were obtained. Primary outcomes compared the incidence of acute kidney injury (AKI), death and CRS between patients with and without CKD as defined by KDIGO (kidney disease improving global outcomes). Fisher's exact tests were used to calculate associations of univariate risk ratios. Multivariate survival analysis (COX model) was conducted for all outcomes, adjusting age, gender and death between patients with and without CKD.

Results: With an average age of 58.7 years (SD=10.5), 24 males and 15 females, 14/39 had mild CKD (GFR <90 ml/min/1.73 m^2) and 4/39 had moderate CKD (GFR <60 ml/min/1.73 m^2). CRS was observed in 22/39 (56%) and ICU care in 6/39 (15%) cases. Of the 9 AKI cases (6 class 1, 1 class 2, 2 class 3), 5 resolved, 2 progressed and 2 patients expired. There were a total of 10 deaths (8-678 days after CAR-T). Univariately, there was a correlation between underlying hypertension and AKI with death (RR (95% CI) = 3.4 (1.2, 9.8), P=0.04; RR (95% CI) = 5.0 (1.8, 13.9), p=0.004). ICU correlated with AKI (RR (95% CI) = 4.4 (1.6, 11.8), P=0.02), but there was no association between CRS and the development of AKI. Multivariate survival analysis didn't find any difference between patients with and without CKD.

Conclusions: Our findings did not show an increased risk of AKI or death in CKD patients treated with CAR-T. This supports the use of CAR-T in CKD patients, but with our small sample size, and lack of diverse ethnicities, more studies are needed to determine the safety of CAR-T therapy.

Treatment of Osteoporosis in CKD5D Patients Based on Bone Turnover: A Randomized Controlled Trial Showing Better Survival in Patients with Non-High Turnover

Hartmut H. Malluche, Florence Lima, Marie-Claude M. Faugere, Daniel Davenport. *University of Kentucky Medical Center, Lexington, KY.*

Background: Bone turnover in osteoporotic CKD5D patients (pts.) may be elevated (HTO), normal or low (Non-high turnover, NHTO). There is no information on a tailored approach to treatment based on bone turnover. In HTO, characterized by excessive resorption, it makes sense to use antiresorbers, while they should be avoided in NHTO.

Methods: 119 adult CKD-5D pts. with DXA t-scores < -1.0 were enrolled into this 12 month trial. Pts. were classified as NHTO or HTO based on race specific cutoff values of serum PTH. NHTO pts. were randomized into treatment (Trx) with teriparatide or standard of care (Ctrl) and HTO pts. into treatment with Alendronate or Ctrl. Demographic and clinical data, lab values, DXA and QCT total hip BMD, and MSQCT measurements of aortic calcium were obtained at baseline and 12 months. Outcomes were changes in BMD and aortic calcification (ΔAC). Declaration of Helsinki was followed. There were 48 NHTO and 71 HTO pts. The median total PTH was 183 (IQR 138-337) in the NHTO group and 669 (IQR 502-1068) in the HTO group. Treatment groups and turnover arms were well balanced relative to patient race (34% AA), sex (57% m), age (61.0 ±SD 12.5 y), dialysis vintage (4.7 ± 4.0 y) and DXA t-score (-2.9 ± 0.7). Throughout the study, 37 pts. withdrew due to transplantation and personal reasons.

Results: Bone loss was improved in treated NHTO pts. (Trx: +5.7 g/cm^3 ±SE 4.7 vs. Ctrl:-10.7 ±SE 4.7, p=.019) but not significantly in HTO pts. (Trx: +0.2 g/cm3 ±SE 5.7 vs. Ctrl: -3.5 ±SE 3.4, p=.577). ΔAC was higher in the HTO arm (NHTO: 4.5 ±SE 1.6 vs. HTO: 8.7 ±SE 1.4, p=.049) and lower in African Americans (AA: 3.6 ±SE 1.7 vs. White: 8.8 ±SE 1.4, p=.017). The multiv. ΔAC regression coefficient for HTO vs. NHTO was 5.0 HU (95% CI 0.9-9.2, p=.019) and for AA vs. Whites was -5.4 (95% CI -9.6–1.1, p=.013). In the NHTO group there were 0 deaths compared to 18% deaths in the HTO group (11 deaths, p = .005).

Conclusions: We demonstrate a benefit to teriparatide for management of osteoporosis in CKD5D pts. with PTH between 138-337 pg/mL. These same pts. had a significant survival benefit relative to the HTO pts. and had less progression of aortic calcification. African American CKD5D pts. experienced less progression of aortic calcification regardless of turnover status or treatment modality.

The Calcified Vasculature in CKD Secretes Signal Proteins That Inhibit Bone Mineralization

Maria L. Mace,[1,3] Eva Gravesen,[2,3] Søren Egstrand,[1,4] Anders Nordholm,[1,3] Marya Morevati,[1,3] Klaus Olgaard,[1,3] Ewa Lewin.[1,4] *[1]Rigshospitalet, Copenhagen, Denmark; [2]Dept of Pathology, Herlev Hospital, University of Copenhagen, Copenhagen, Denmark; [3]Kobenhavns Universitet, Copenhagen, Denmark; [4]Herlev Hospital, Herlev, Denmark.*

Background: Our group has recently demonstrated that CKD-induced vascular calcification impairs bone formation & mineralization in an *in vivo* model by transplanting calcified aortas from CKD rats into healthy recipients. Aim was to confirm our hypothesis of a direct crosstalk between the vasculature & bone in *in vitro* experiments.

Methods: Vascular calcification was induced in uremic Wistar rats. Normal aortas (NA) & uremic calcified aortas (CA) were incubated *ex vivo* or co-incubated with UMR-106 cell line (UMR). Media was measured for Wnt inhibitors sclerostin (Scl), Dkk1, SFRP4 & activin A (Act A). UMR-106 cell mineralization stained with Alizarin red. Signal pathways were analyzed by PCR and WB.

Results: CA completely inhibited mineralization in UMR-106 cells (Figure 1). Mineralization inhibitor osteopontin (OPN) mRNA & protein were highly upregulated in UMR+CA (OPN mRNA UMR+CA 25.50 [5.53-51.00], UMR+NA 2.78 [1.20-7.85], UMR 0.80 [0.39-5.49], p<0.001). Induction of OPN was abolished by LiCl. ANKH was upregulated in UMR+UA (2.95 [1.87-7.32], UMR+NA 1.75 [0.51-2.46], UMR 0.96 [0.49-2.15], p<0.01), whereas same levels of *Alpl* were found. Similar expressions of β-catenin protein & Wnt target genes *c-Myc* & *Ccnd1* were found. However, *Jun* was upregulated in UMR+NA & UMR+CA (UMR 0.94 [0.61-2.83] vs. UMR+NA 1.58 [1.18-2.29] vs. UMR+CA 1.98 [1.08-3.44], p< 0.01). The CA secreted large amounts of Scl (1936 [495-4400] vs. NA 31 [7-88] pg/ml, p=0.002), Dkk1 (353 [110-686] pg/ml vs. none in NA), and Act A (12158 [4712-18000] vs. NA 1838 [250-4146] pg/ml, p=0.002). NA & CA secreted SFRP4.

Conclusions: The present study confirms our hypothesis on a direct crosstalk between vasculature and bone. The uremic calcified aorta secretes signal molecules that inhibit bone mineralization.

HIF-PHI Have Direct Actions in Osteocytes: Implications for Anemia Treatment in CKD

Megan L. Noonan, Pu Ni, Emmanuel Solis, Rafiou Agoro, Sheng Liu, Erica Clinkenbeard, William R. Thompson, Jun Wan, Kenneth E. White. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients with CKD manifest overlapping oxygen sensing/endocrine dysfunction as osteocyte-produced FGF23 is highly elevated under prevailing anemia, however the cellular mechanisms driving FGF23 production are not understood. Our goal was to test the molecular context of osteocyte oxygen sensing, and the roles of these systems in FGF23 induction which can have severe effects on CKD bone disease.

Methods: A hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI; FG-4592, 'Roxadustat') was used to treat parent undifferentiated MSCs ('MPC2', mesenchymal progenitor cell clone 2) and 3-week differentiated osteocytes (Ocy), to mimic changes in cellular oxygen status *in vitro*, followed by ATACseq and RNAseq. Conditional Fgf23-KO mice were treated with FG-4592 *in vivo*.

Results: Following FG-4592 (50μM) treatment of MSCs and Ocy, unbiased RNAseq and Gene Ontology analysis validated Ocy enrichment for bone ossification/mineralization processes as well as revealed unforeseen pathways critical for oxygen and iron utilization. ATACseq showed that FG-4592 acutely (48 h) increased genome-wide chromatin accessibility, with HOMER motif analysis identifying highly significant enrichment in Ocy HIF-1α/β and -2α transcription factor binding motif accessibility (p<1e-33). In contrast, HIF motif accessibility in FG-treated MSC was unchanged, revealing a predisposition of Ocy to mediate oxygen responses. RNAseq (confirmed by qPCR) also showed significant upregulation of Fgf23 in FG-4592-treated Ocy cultures (logFC 5.8; FDR<0.001) but not in MSCs (logFC 0.08; FDR NS), and HIF1α inhibition completely suppressed Ocy Fgf23. Further, the iron chelator DFO increased Fgf23 (80-fold), which was dose-dependently reduced by holo-transferrin (p<0.001), underscoring direct effects of oxygen/iron on Ocy. In normal mice, FG-4592 injections induced plasma iFGF23 (450-900 pg/mL, p<0.001). In contrast, conditional *Fgf23* deletion from Ocy (flox-Fgf23/Dmp1-cre+) completely abolished this response despite similarly elevated plasma EPO (8,000-77,000 pg/mL, p<0.001) in both genotypes.

Conclusions: These data show Ocy are poised to respond to oxygen/iron via rapid genomic accessibility and transcriptional mechanisms, which together may drive Ocy biomineralization potential through FGF23 and thus have important implications for CKD-MBD.

Association of Genetically Predicted FGF23 with Heart Failure: A Mendelian Randomization Study

Cassianne Robinson-Cohen, Mindy Pike. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Multiple observational studies provide evidence of the role of FGF23 in the pathophysiology of heart failure, among individuals with CKD and in the general population. However, these studies suffer from many potential biases, e.g.confounding and reverse causation, limiting their ability to robustly identify causal associations. Mendelian randomization (MR) has emerged as a powerful study design to provide evidence supporting or refuting causality.

Methods: We performed a two-sample MR study to assess the causal association of FGF-23 with overall heart failure and heart failure subtypes. Instrumental variables were defined as independent SNPs associated with FGF23 genome-wide: rs17479566, rs11741640, rs9925837, rs17216707, and rs2769071. Summary-level data from the HERMES consortium and individual-level data from BioVU, was used to examine associations of the 5 SNPs with incident heart failure and subtype. We additionally developed an eGFR polygenic risk score based on CKD-GEN summary statistics, composed of SNPs associated with eGFR at $p<5 \times 10^{-3}$, and dichotomized the eGFR PRS at one SD below the mean.

Results: We found that genetically increased circulating FGF23 was significantly associated with higher risk of heart failure overall and with heart failure with preserved ejection fraction among individuals with genetically-predicted low eGFR (Table). Elevated FGF23 was not associated with reduced ejection fraction heart failure or preserved ejection fraction among individuals with higher genetically-predicted eGFR.

Conclusions: Our results provide evidence supporting a causal association between FGF23 and heart failure, particularly preserved ejection fraction heart failure, among individuals with low eGFR.

Funding: NIDDK Support

Mendelian Randomization Estimates for the Effect of FGF23 on Heart Failure and Subtypes

Outcome and data source	Number of HF Events	MR Estimate	
		Hazard Ratio (95%CI)	P-value
Heart failure, HERMES	47,309	1.25 (1.01, 1.55)	0.039
Preserved EF, BioVU			
Overall	12,900	1.23 (0.88, 1.72)	0.236
eGFR PRS <-1 SD	2,188	2.98 (1.31, 6.77)	0.009
eGFR PRS > -1 SD	10,712	1.02 (0.71, 1.48)	0.908
Reduced EF, BioVU			
Overall	2,928	0.89 (0.44, 1.83)	0.760
eGFR PRS <-1 SD	486	0.43 (0.08, 2.34)	0.326
eGFR PRS > -1 SD	2,442	1.04 (0.47, 2.28)	0.923

TH-OR15

The Spatial-Temporal Heterogeneity Dictating Kidney FGF23 Bioactivity as Identified by Single-Cell RNA Sequencing

Rafiou Agoro,[1] Jered Myslinski,[2] Pu Ni,[2] Danielle Janosevic,[2] Yamil Marambio,[1] Pierre C. Dagher,[2] Takashi Hato,[2] Kenneth E. White.[1,2] [1]*Indiana University School of Medicine Department of Medical and Molecular Genetics, Indianapolis, IN;* [2]*Indiana University School of Medicine, Department of Medicine, Indianapolis, IN.*

Background: FGF23 is critical for maintaining phosphate balance via interactions with renal FGFRs and Klotho (KL), and its effects on gene expression have been described at tissue levels. However, KL is expressed in multiple nephron cell types thus the full spectrum and spatial-temporal mechanisms dictating FGF23 bioactivity remain undefined.

Methods: A single cell RNA-seq approach was used to identify the dynamics of FGF23-mediated bioactivity. Kidneys were isolated from FGF23 (400ng/g)-injected C57BL/6 mice at 1, 4 and 12h, and single cell transcriptomics were analyzed.

Results: From libraries of 10,000 male/female kidney cells, 21 UMAP cluster enriched markers distinctly identified epithelial, endothelial, and immune cells. At baseline, *KL* mRNA had diffuse expression in proximal tubule (PT) S1-S3 cells, overlap in loop of Henle, and was more concentrated in distal/connecting tubule (DT/CNT). In response to FGF23, at 1h *Egr1*, other MAPK genes, and eIF2 signaling were increased, tracking with 80% of KL-positive PT and DT cells. The vitamin D 24-OHase (*Cyp24a1*) was the most up-regulated gene in PT-S1/S2 at 4h, whereas KL was reduced, and *Egr1* and vitamin D 1-alpha-OHase (*Cyp27b1*) were completely suppressed out to 12h. Pathway Analysis showed that most expressional changes were not cell type unique, including PT and DT up-regulation (8-20 fold) of TNF pathway member *Tnfrs12a*, supporting that FGF23 initially signals via common mechanisms but its function is defined by nephron-site specific gene expression. To segregate KL-dependent FGF23 responses in PT-S1, a critical FGF23 target, KL+ and KL- cells were subsetted. Of note, in response to FGF23, KL+ cells showed distinct clustering at each time point, whereas KL- cells remained indistinguishable, highlighting that temporal FGF23 responses drive unique and transient cellular identity. At later time points, PXR signaling was specific to PT, and Epithelial Remodeling and Actin-based Motility signaling to DT.

Conclusions: Kidney KL distribution was pinpointed at the single cell level, and we demonstrated that FGF23 bioactivity controls nephron segment-unique and -general transcriptional events that regulate mineral metabolism. Identification of these pathways is critical for the isolation of novel disease targets.

TH-OR16

Distinct Effects of FGF23, Iron and Phosphate on Mineral Metabolism and Kidney Function in Mice with CKD

Guillaume Courbon, Marta Martinez-Calle, Jadeah J. Spindler, Aline Martin, Valentin David. *Nortwestern University, Chicago, IL.*

Background: Elevated levels of fibroblast growth factor 23 (FGF23), hyperphosphatemia and iron deficiency are common complications of chronic kidney disease (CKD) and strong predictors of disease progression and death. We have previously found that administration of ferric citrate (FC), an iron-based, oral phosphate binder, to mice with CKD reduced dietary phosphate absorption and FGF23, increased iron stores, slowed CKD progression and prolonged survival. This suggests that FGF23, phosphate and/or iron play a major role in CKD progression.

Methods: To distinguish between the individual and combined effects of FGF23, phosphate and iron in CKD, we fed WT and Col4a3^{KO} mice (CKD model) from 4-10wks either control (Ctr), low iron (LI), low phosphate (LP), 1% carbonyl iron (CI) or ferric citrate (FC) diets. To further study the role of iron in CKD, we compared the effects of these diets to mice receiving iv ferric derisomaltose (FD) using biochemical, histological and RNAseq analyzes.

Results: CKD mice showed higher serum FGF23, PTH, phosphate and low calcitriol levels and administration of LI diet further accentuated these differences. Surprisingly, phosphate restriction in LP-CKD mice minimally reduced hyperphosphatemia and PTH levels and had no effect on FGF23. In sharp contrast, all iron containing diets reduced PTH and FGF23 levels. Surprisingly, similar effects were observed in mice receiving iv iron, suggesting that iron deficiency is a stronger predictor of FGF23 excess in CKD than hyperphosphatemia. Compared to Ctr-CKD mice, FC enriched diets showed the strongest potential to reduce FGF23 (-68%), and serum phosphate (-37%) and the only treatment to increase calcitriol (+220%). Biochemical, histological and RNAseq analyses also showed that only the combined reductions of phosphate and FGF23, and iron repletion, achieved by FC treatment, improved kidney function and slowed CKD progression. These benefits were fully reversed when FC-treated mice received a daily dose of 30ng/g of rFGF23 during 28 days. FGF23 administration increased renal inflammatory signaling and further accentuated CKD progression.

Conclusions: Our results suggest that combined corrections of FGF23, phosphate and iron slows CKD progression and suggest that FGF23 plays a major role in CKD progression independently of other disease modifiers.

TH-OR17

Critical Role of Osteopontin in Maintaining Urinary Phosphate Solubility in CKD

Kyle Jansson, Shiqin Zhang, Timothy A. Fields, Peter S. Rowe, Jason R. Stubbs. *University of Kansas Medical Center, Kansas City, KS.*

Background: The loss of functional nephrons dramatically increases tubular phosphate concentrations in residual nephrons to levels that exceed supersaturation. Osteopontin (OPN), a SIBLING protein expressed by epithelial cells of the distal nephron, is known to enhance calcium-phosphate solubility *in vitro*; however, the role of OPN in maintaining tubular mineral solubility in CKD remains undefined.

Methods: We used CKD mouse models to determine: (1) the expression and timing of kidney/urine OPN changes in relation to mineral metabolism and kidney function markers, (2) the differential effects of tubular injury and acute nephron reduction on OPN expression, (3) how OPN deficiency alters kidney mineral deposition in CKD, and (4) how neutralization of the mineral-binding (ASARM) motif of OPN alters kidney mineralization and injury in phosphaturic mice.

Results: OPN protein expression is markedly increased in all tubular segments in mouse models of cystic kidney disease (*pcy/pcy*), glomerulonephritis (*Col4a3*$^{-/-}$), and chronic tubulointerstitial injury (aristolochic acid). In *Col4a3*$^{-/-}$ mice with slowly progressive CKD, kidney OPN expression and urinary OPN:Cr increased before gross histologic changes in the kidney or a rise in BUN, serum Cr, FGF23 and PTH. Unilateral nephrectomy studies in wild-type mice proved that nephron reduction alone was sufficient to increase tubular OPN production. Induction of CKD in OPN-null mice fed a high phosphate diet led to severe nephrocalcinosis (**Figure 1**). Lastly, pharmacologic neutralization of the ASARM motif of OPN in phosphaturic (*Hyp*) mice resulted in severe nephrocalcinosis that mimicked OPN-null CKD mice.

Conclusions: Tubular OPN expression is increased in very early CKD and nephron loss alone is sufficient to induce these changes. OPN serves a key biological function to maintain tubular phosphate solubility in CKD.

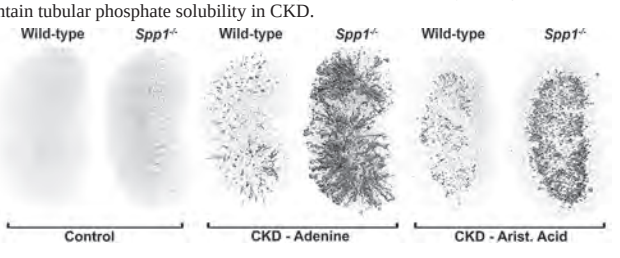

Figure 1. Induction of CKD in *Spp1*$^{-/-}$ (OPN-null) mice results in severe nephrocalcinosis. Whole kidney μCT images demonstrating severe nephrocalcinosis in *Spp1*$^{-/-}$ mice fed a high phosphate (1.1%) diet following CKD induction by either ingestion of 0.2% adenine or IP injections of aristolochic acid.

TH-OR18

Tenapanor Controls Serum Phosphorus and Reduces PTH and FGF-23 in Patients on Dialysis with Severe Secondary Hyperparathyroidism

Daniel E. Weiner,[1,2] David M. Spiegel,[3] Yang Yang,[3] David P. Rosenbaum.[3]
[1]Dialysis Clinic Inc, Boston, MA; [2]Tufts University School of Medicine, Boston, MA; [3]Ardelyx Inc, Fremont, CA.

Background: Secondary hyperparathyroidism (sHPT) is common in patients with chronic kidney failure, and most nephrologists treat parathyroid hormone (PTH) values >600 pg/mL. Hyperphosphatemia may directly contribute to sHPT, making the glands less responsive to therapy. Tenapanor is a first-in-class phosphate absorption inhibitor (PAI) that targets the paracellular pathway, the primary pathway of phosphate absorption.

Methods: The phase 3 PHREEDOM trial evaluated the safety and efficacy of tenapanor in patients on dialysis with hyperphosphatemia. Following washout from binders, patients whose serum phosphorus (sP) increased by 1.5 to ≥6.0 mg/dL were randomized. Those randomized to the tenapanor arm received tenapanor 30 mg PO BID for 26 weeks. Serum calcium (sCa), sP, PTH, and FGF23 were measured per protocol. This post-hoc analysis evaluates changes in PTH, FGF23, sP, and sCa among tenapanor-treated patients with baseline PTH >600 pg/mL and at least one post-baseline PTH measure (n=73).

Results: For the 73 participants with severe sHPT (defined as >600 pg/mL), the median baseline PTH was 766 pg/mL with a median absolute (percent) reduction of 280 pg/mL (34.0%) at week 26. Of these 73 patients, 31 had a recorded change in PTH-modifying medication during the treatment period, whereas 42 did not have any recorded change. Among those with medication changes, median PTH reduction was 231 pg/mL (26.9%); among those without changes, PTH reduction was 300 pg/mL (35.4%). Median baseline FGF23 was 15,275 ng/L with a median reduction of 3165 ng/L (40.7%) at the end of the treatment period. The magnitude of the median reductions was similar in the medication change and non-change subgroups (4278 ng/L [40.9%] and 2730 ng/L [38.7%], respectively). On average, sP decreased by 1.8 mg/dL (from 8.0±1.5 mg/dL at baseline), with similar changes in medication change and non-change subgroups (1.9 mg/dL and 1.8 mg/dL, respectively). sCa remained unchanged overall (0.2 mg/dL) and in the medication change and non-change subgroups (0 mg/dL and 0.3 mg/dL, respectively).

Conclusions: Tenapanor effectively lowers sP in patients on maintenance dialysis with severe sHPT and demonstrates that effective sP control with tenapanor improves both PTH and FGF23 concentrations.

TH-OR19

Initial Evaluation of High-Dose Extended-Release Calcifediol (ERC) in Patients with Stage 5 CKD on Hemodialysis (HD)

Stephen A. Strugnell,[1] Philipp Csomor,[2] Akhtar Ashfaq,[1] Charles W. Bishop.[1]
[1]OPKO Health Inc, Miami, FL; [2]Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: ERC has been approved since 2016 for treatment of secondary hyperparathyroidism (SHPT) in adults with stage 3-4 CKD and vitamin D insufficiency at weekly doses of 210 or 420 mcg (30 or 60 mcg/day). Conversion of calcifediol to calcitriol by CYP27B1 is thought to occur primarily in the kidney despite expression elsewhere, supporting a belief that normal serum levels of 1,25-dihydroxyvitamin D (1,25D) cannot be maintained with advancing CKD. A phase 2a study explored treatment of end-stage renal disease patients with SHPT requiring regular HD with high strength ERC (150 mcg/capsule). The goals of the study were to: (1) evaluate whether these patients could tolerate a high dose of ERC (900 mcg/week); (2) ascertain whether ERC could normalize serum total 1,25D in the absence of functional kidneys; and (3) determine whether ERC could reduce intact parathyroid hormone (iPTH).

Methods: Adults with stage 5 CKD on regular HD with iPTH ≥150 and <600 pg/mL and serum total 25-hydroxyvitamin D (25D) <30 ng/mL were enrolled from U.S. dialysis centers. Subjects underwent an 8-week washout from previous iPTH-lowering therapies and were randomized to 26 weeks of open-label treatment with ERC (300 mcg thrice weekly during HD) or matching placebo. Serum 25D, 1,25D, calcium (Ca) and phosphorus (P) and plasma iPTH were monitored at the start of HD on a weekly or bi-weekly basis.

Results: A total of 44 subjects were enrolled (33 on ERC and 11 on placebo). ERC-treated subjects attained mean (±SE) steady-state levels of 25D of 161±11 ng/mL vs 30±5.6 with placebo treatment without significant increases in serum Ca or P or the incidence of adverse events compared to placebo. Serum total 1,25D rose into the normal range (62.0±8.3 pg/mL) from undetectable or low baseline levels (10.6±1.5 pg/mL) in direct proportion to elevation of serum total 25D above 50 ng/mL. Significant decreases in iPTH were observed, in particular in patients reaching 25D levels exceeding 50 ng/mL.

Conclusions: ERC was well tolerated at 900 mcg/week, readily activated to calcitriol despite the lack of functional kidneys, and capable of suppressing elevated iPTH levels. These data suggest that extra-renal production of 1,25D can be sufficient to lower iPTH when serum 25D is gradually raised to high levels exceeding 50 ng/mL.

TH-OR20

Parathyroid-Specific Knockout of Core Circadian Clock Gene Bmal1 Increases Proliferation of the Parathyroid Gland in CKD

Søren Egstrand,[1,2] Maria L. Mace,[2] Marya Morevati,[2] Anders Nordholm,[1,2] Klaus Olgaard,[2,3] Ewa Lewin.[1,2] *[1]Herlev Hospital, Herlev, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, Copenhagen, Denmark.*

Background: Proper rhythms in metabolism, hormone secretion and cell cycle are maintained by a molecular circadian clock (CC) in the CNS as well as in peripheral tissues. The transcription factor *Bmal1* is a major component of the CC. We have previously shown that an internal CC operates in the parathyroid gland (PTG) and that it is disturbed in uremia. We constructed a PTG-specific *Bmal1* knockout mouse to investigate the function of the PTG clock in health and in CKD.

Methods: PTG-specific knockout of *Bmal1* was generated by crossing *PTHcre* mice with *Bmal1$^{flox/flox}$* mice (WT) giving rise to *PTHcre*; *Bmal1$^{flox/flox}$* (KO). Blood samples and PTGs were harvested at 4h interval. CKD was induced by feeding mice an adenine diet for 3 weeks. Gene expression was examined by qPCR, protein expression by western blot and proliferation by Ki-67 labeling. Circadian rhythmicity was assessed by cosinor analysis.

Results: BMAL1 protein was reduced by 77% in the PTGs of KO mice and circadian rhythmicity of *Bmal1* gene expression was abolished along with abolishment of rhythmicity of clock genes *Cry1* and *Cry2* and significant upregulation of clock genes *Per2* (p=0.01), *Cry1* (p<0.0001) and *Cry2* (p=0.0001), compared to WT. The disturbed clock in KO resulted in abrogated rhythmicity of clock-controlled cell cycle regulator *Wee1* (KO p=0.16, WT p=0.0016) and of regulators of parathyroid proliferation *Gcm2* (KO p=0.63, WT p=0.03) and *Gata3* (KO p=0.84, WT p=0.01). *Gata3* was upregulated compared to WT (p=0.01). Plasma PTH was significantly rhythmic in both KO and WT mice. In a basal condition the phenotype of KO mice was similar to WT, regarding weight, femur length, basal PTH levels and secretory response to hypocalcemia. Uremia significantly increased the PTG KI-67 labeling index in KO compared with WT (7.0% vs. 2.4%, p=0.036).

Conclusions: *Bmal1* knockout in the PTG resulted in disrupted rhythm of CC genes and a clock-controlled cell cycle regulator. The significant rhythms of regulators of parathyroid proliferation; *Gcm2* and *Gata3* found in PTGs of WT mice was absent in KO mice suggesting CC regulation of these genes. Increased KI-67 expression was found when PTGs of KO mice were challenged by CKD as compared to WT mice, indicating a key role of the CC in regulating the proliferation in the PTGs.

mTOR-Activating Mutations in RRAGD Cause Kidney Tubulopathy and Cardiomyopathy (KICA) Syndrome

Jeroen H. De Baaij,[1] Karl P. Schlingmann,[2] Francois Jouret,[3] Claudia Dafinger,[6] Pascal Houillier,[4,5] Max Liebau,[6] Rosa Vargas-Poussou,[7] Nine V. Knoers,[8] Martin Konrad.[2] *[1]Radboudumc, Nijmegen, Netherlands; [2]Universitatsklinikum Munster, Munster, Germany; [3]Universite de Liege, Liege, Belgium; [4]Assistance Publique - Hopitaux de Paris, Paris, France; [5]Centre de Recherche des Cordeliers, Paris, France; [6]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [7]Hopital Europeen Georges Pompidou, Paris, France; [8]Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Over the last decades, advances in genetic techniques have resulted in the identification of rare hereditary disorders of renal magnesium and salt handling. Nevertheless, ±20% of all tubulopathy patients remain without genetic diagnosis. Here, we explore a large multicentric patient cohort with a novel inherited salt-losing tubulopathy, hypomagnesemia and dilated cardiomyopathy (DCM).

Methods: Whole exome and genome sequencing were performed with various subsequent functional analyses of identified *RRAGD* variants in vitro.

Results: In 8 children from unrelated families with a tubulopathy characterized by hypomagnesemia, hypokalemia, salt-wasting, and nephrocalcinosis, we identified heterozygous missense variants in *RRAGD* that mostly occurred *de novo*. Six of these patients additionally suffered from DCM and a heart transplantation was performed in 3 of them. A dominant variant in *RRAGD* was simultaneously identified in eight members of a large family with a similar renal phenotype. *RRAGD* encodes GTPase RagD mediating amino acid signaling to the mechanistic target of rapamycin complex 1 (mTORC1). RagD expression along the mammalian nephron include the thick ascending limb and the distal convoluted tubule. The identified *RRAGD* variants were shown to induce a constitutive activation of mTOR signaling *in vitro.*

Conclusions: Our findings establish a novel disease phenotype combining kidney tubulopathy and cardiomyopathy (KICA) caused by an activation of mTOR signaling suggesting a critical role of Rag GTPase D for renal electrolyte handling and cardiac function.

Gitelman Syndrome Phenocopy Caused by Pathogenic Variants in Mitochondrial DNA

Daan Viering,[1] Karl P. Schlingmann,[7] Marguerite Hureaux,[2,8] Tom Nijenhuis,[6] Rosa Vargas-Poussou,[2,3] Nine V. Knoers,[4] Detlef Bockenhauer,[5] Jeroen H. De Baaij.[1] Molecular Physiology *[1]Radboudumc Afdeling Fysiologie, Nijmegen, Netherlands; [2]Assistance Publique - Hopitaux de Paris, Paris, France; [3]Centre de Recherche des Cordeliers, Paris, France; [4]University Medical Center Groningen, Department of Genetics, Groningen, Netherlands; [5]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [6]Radboudumc, Department of Nephrology, Nijmegen, Netherlands; [7]University children's hospital, Münster, department of General Pediatrics, Münster, Germany; [8]INSERM, Paris, France*.

Background: Gitelman syndrome (GS) is the most frequent hereditary salt-losing tubulopathy and is characterized by hypokalemic alkalosis and hypomagnesemia. GS is caused by biallelic pathogenic variants in *SLC12A3*, encoding the Na^+-Cl^- cotransporter (NCC) expressed in the distal convoluted tubule. Pathogenic variants in *CLCNKB, HNF1B, FXYD2* or *KCNJ10* may result in renal phenocopies of GS, as they can lead to reduced NCC activity. Nevertheless, ±10% of patients with a GS phenotype remain genetically unsolved.

Methods: After identification of mitochondrial DNA (mtDNA) variants in three families with GS-like electrolyte abnormalities, 155 families were investigated for variants in *MT-TI* and *MT-TF*, encoding the transfer RNAs for phenylalanine and isoleucine. Mitochondrial respiratory chain function was assessed in patient fibroblasts. In NCC-expressing HEK293 cells, mitochondrial dysfunction was induced to assess the effect on thiazide-sensitive $^{22}Na^+$ transport.

Results: Genetic investigations revealed four mtDNA variants in 12 families: m.591C>T (*n*=7), m.616T>C (*n*=1), m.643A>G (*n*=1) (all in *MT-TF*) and m.4291T>C (*n*=3, in *MT-TI*). Variants segregated with the phenotype and were near homoplasmic in affected individuals. Importantly, affected members of six families with an *MT-TF* variant additionally suffered from progressive chronic kidney disease (CKD). Kidney biopsies in two affected individuals showed abnormal mitochondria, especially in the distal tubule. Maximal mitochondrial respiratory capacity was reduced in patient fibroblasts, caused by dysfunction of oxidative phosphorylation complex IV. *In vitro* pharmacological inhibition of complex IV, mimicking the effect of the mtDNA variants, demonstrated an inhibitory effect on NCC phosphorylation and NCC-mediated sodium uptake.

Conclusions: Pathogenic mtDNA variants in *MT-TF* and *MT-TI* can cause a GS phenocopy. Genetic investigation of mtDNA should be considered in patients with unexplained GS-like tubulopathies. Moreover, pathogenic variants in *MT-TF* confer a significant risk for the development of CKD.

KS-WNK1 Translates the Potassium Ingestion State to NCC Activity and Expression

Jessica P. Bahena-López,[1,4] Maria Chavez-Canales,[2] Ju Hye Lee,[1] Adrian R. Murillo-de-Ozores,[1] Norma H. Vázquez,[2] David H. Ellison,[3] Maria Castañeda-Bueno,[1] Gerardo Gamba.[1,2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico; [2]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico; [3]Oregon Health & Science University, Portland, OR; [4]PECEM, UNAM, Mexico City, Mexico*.

Background: The physioilogical role of KS-WNK1 in the distal convoluted tubule is not yet elucidated. KS-WNK1 upregulates NCC through activation of WNK4-SPAK pathway. Under low potassium diet, in which NCC activity is increased, KS-WNK1 is required for the formation of WNK bodies. However, changes in plasma K^+ has not been observed in KS-WNK1 mice when compare to WT mice. We have recently shown that KS-WNK1 is highly sensitive to the CUL3-KLHL3 complex (JCI 2020) and its expression under control conditions is negligible, but it is increased under low potassium diet (AJP Renal 2021). In wild life, mammalians are exposed to cycles of no food and thus no K^+ consumption for days, followed by a vast meet and thus K^+ ingestion of in few hours. Because of the high sensitivity of KS-WNK1 expression to K^+ intake, we assessed the expression of KS-WNK1 and NCC-SPAK modulation using a model to imitate what occurs in wild life.

Methods: We exposed wild type (WT) and KS-WNK1-KO (KS-KO) mice to 10 days of zero K^+ diet (0KD), followed by high K^+ diet (5 %) to imitate what occurs in the wild. Groups of mice were sacrificed before the HKD and at 12 or 24 hours of HKD. Blood was taken for electrolyte analysis and renal proteins were subjected to western blot using anti NCC, phospho-NCC, SPAK, phospho-SPAK, WNK4, WNK1 and actin antibodies.

Results: At the end of 10 days of 0KD, serum K^+ was significantly lower in KS-KO mice than in WT mice (2.62±0.28 vs 3.40±0.22 mEq/L, $p<0.05$), while NCC phosphorylation was higher in the WT mice (1.00±0.32vs 0.58±0.06 a.u., $p<0.05$). At this point expression of KS-WNK1 was detected in WT, but not in KS-KO mice. In contrast, 24 hours after HKD, NCC expression and phosphorylation was not reduced in KS-KO mice, as ocurred in WT mice (WT 1.00±0.20 vs KS-KO 2.44±0.31, a.u., $p<0.01$ and 1.00±0.24 vs 3.07±0.56 mEq/l, $p<0.05$, respectively) and WT mice K^+ excretion was higher, since the plasma K^+ concentration was lower in WT than in KS-KO mice (6.02±0.62 vs 6.75±0.714 mEq/l, $p<0.001$).

Conclusions: Our data show that in WT mice during 0KD, activation of NCC was higher and after HKD, downregulation of NCC was more effective than in KS-KO mice. Thus, wild type mice are better suited to respond to extreme changes in potassium diet as those that probably occurs in wild life in mammals.

Role of WNK1 and WNK4 in Sensing Extracellular Potassium in Principal Cells to Modulate mTORC2-Dependent Activation of Epithelial Sodium Channel

Bidisha Saha,[1] Waheed Shabbir,[1] Enzo Takagi,[1] Mads V. Sorensen,[3] Deise C. Leite-Dellova,[1,2] David Pearce.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Universidade de Sao Paulo Faculdade de Medicina Veterinaria e Zootecnia, Sao Paulo, Brazil; [3]Aarhus Universitet, Aarhus, Denmark*.

Background: mTORC2 phosphorylation of SGK1 and consequent activation of ENaC is essential in the regulation of ion transport by principal cells (PCs) of the distal tubular system. We recently demonstrated that local K^+ concentration could be sensed by PCs to activate ENaC through mTORC2-SGK1 signaling, and suggested a role for WNK1 in this mechanism. However, the mechanistic basis of this regulation has not been explored. In DCT, WNK4 modulates NCC activity in response to extracellular K^+ in a kinase-dependent manner. Here we have explored the role of WNK1 and 4 in local sensing of extracellular K^+ and ENaC regulation in the mpkCCD cultured PC model.

Methods: We used CRISPR to generate $WNK1^{-/-}$ and $WNK4^{-/-}$ mpkCCD cells. WT and KO cells were grown on Transwell filters and adapted to 1 or 3 mM [K^+] on the basolateral side, followed by raising [K^+] to 5 mM in the presence or absence of WNK kinase inhibitor. Amiloride-sensitive current was measured by volt-ohmmeter as well as by patch clamp. Cells were processed for co-IP and immunoblot analysis.

Results: In WT mpkCCD cells, extracellular K^+ stimulated ENaC current concomitant with mTORC2-dependent SGK1 phosphorylation, Nedd4-2 phosphorylation and expression of cleaved ENaC. In WT cells, inhibition of WNK kinase activity by WNK463 had no significant effect on K^+-stimulated ENaC current or SGK1 phosphorylation, although SPAK phosphorylation was markedly reduced. In contrast, WNK1 deletion blocked the effect of extracellular K^+ on ENaC and SGK1 phosphorylation. Transfection of $WNK1^{-/-}$ mpkCCD cells with either WT or kinase-dead WNK1 restored K^+-stimulated SGK1 phosphorylation and ENaC activity. Furthermore, this effect was accompanied by greater association of SGK1 with both mTORC2 and WNK1 (WT or kinase-dead). WNK4 deletion and the recovery of WNK4 expression, had similar effects to WNK1 on SGK1 phosphorylation and ENaC current.

Conclusions: Our data support a scaffolding role for WNK1 and 4 that promotes mTORC2-SGK1 interaction and hence phosphorylation through a mechanism that does not require its kinase activity. Extracellular K^+, which has a well-established role to inhibit WNK-dependent SPAK phosphorylation, stimulates WNK1/4-SGK1 interaction, and assembly of an mTORC2-SGK1-WNK complex, resulting in enhanced SGK1 activity and ENaC activation in PCs

Comparative Effectiveness of Patiromer and RAAS Inhibitor Continuation vs. No Potassium Binder and Discontinued RAAS Inhibitors on Healthcare Resource Utilization and Cost Outcomes in Hyperkalemia

Steven G. Coca,[1] Christopher G. Rowan,[2] Paula J. Alvarez,[3] Ladan Golestaneh,[4] Nihar Desai.[5] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]COHRDATA, San Clemente, CA; [3]Vifor Pharma, Inc., Redwood City, CA; [4]Albert Einstein College of Medicine, Bronx, NY; [5]Yale University, Center for Outcomes Research and Evaluation, New Haven, CT*.

Background: Patiromer (PAT) is a sodium-free, non-absorbed potassium (K^+) binder approved for treatment of hyperkalemia (HK). The objective of the study was to estimate relative cost of treating Medicare Advantage patients (pts) with HK with different therapeutic strategies.

Methods: This retrospective, propensity score–matched cohort study utilized the de-identified Optum Clinformatics® Data Mart (from 2016 to 2019). Two HK cohorts were identified: 1) pts exposed to PAT+RAASi therapy; and 2) pts who discontinued RAASi therapy (DC RAASi). All pts had serum K^+ ≥5.0 mEq/L, HK diagnosis, and ≥6 mos insurance enrollment. Pts were propensity score matched on baseline characteristics. Relative healthcare spending rate (exposure contrast: PAT+RAASi vs DC RAASi [reference]) was analyzed at 3 mos using zero-inflated negative binomial regression. Cost outcomes included: total, inpatient, emergency department (ED), outpatient services, and outpatient pharmacy.

Results: Study cohorts included 464 pts (232 matched pairs). Overall, mean age was 74 yrs, 59% male, and 31% Hispanic. Pts had a mean of 5 comorbidities: CKD (95%), diabetes mellitus (73%), chronic heart failure (32%), cardiac arrhythmias (33%), and coronary artery disease (39%). At 3 mos, 168 pts (84 matched pairs) remained uncensored and were analyzed. Total healthcare spending rate for DC RAASi cohort was $15,344 vs $9135 (95% confidence interval, $6303, $13,241) for PAT+RAASi cohort over 3 mos ($P<0.01$; Figure) and was driven by marked reductions in outpatient and ED costs.

Conclusions: After 3 mos of PAT+RAASi therapy, relative total healthcare spending rate was 40% lower compared with pts not exposed to a K^+ binder who discontinued RAASi to manage HK in matched Medicare Advantage pts. Study Limitation: Potential exposure misclassification via RAASi dispensings from generic pharmacy programs.

Funding: Commercial Support - Vifor Pharma, Inc.

Outcome	DC RAASi ($) (reference)	PAT RAASi ($)	LCL ($)	UCL ($)	*P*-value
Total healthcare costs	15,344	9135	6303	13,241	0.006
Outpatient medical costs	8437	3852	2319	5752	0.000
Inpatient facility costs	22,943	6888	901	54,178	0.255
Emergency department costs	2600	1414	839	2385	0.022
Outpatient pharmacy dispensing costs	2170	4974	3635	8806	0.000

TH-OR26

Dietary Anion Prioritizes Pendrin Activation over Aldosterone

Seyedmohammadebrahim Tahaei,[1] Susan M. Wall,[2] Paul A. Welling.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Emory University School of Medicine, Atlanta, GA.*

Background: It is well established that the bicarbonate-chloride exchanger, Pendrin, is physiologically modulated in intercalated cells to maintain acid-base balance. Because Pendrin is also upregulated by aldosterone and angiotensin II to preserve intravascular fluid volume but is inhibited in high aldosterone states of dietary potassium-chloride loading, it has been suggested pendrin may be differentially regulated to help sculpt the distinct adaptive responses of aldosterone to volume contraction and hyperkalemia. Here, we challenge this hypothesis by investigating how Pendrin is modulated by dietary potassium salts.

Methods: C57/Bl6J male mice (2 month old) were randomized to matched control (2% KCl), high potassium bicarbonate (13.4% KHCO3), or high potassium chloride (10% KCl) diets (4 days). A separate cohort of mice was randomized to a switch anion diet protocol, whereby mice were first adapted to the high KHCO3 or the high KCl diet (4 days), and the response to changing the anion in the context of high potassium, high aldosterone was assessed at 24 and 48 hours. Aldosterone and plasma electrolytes were measured by standard methods. Kidney Pendrin mRNA and protein abundance were assessed by qRT-PCR and western blot, respectively.

Results: Dietary KCl and KHCO3 loading increased plasma potassium and aldosterone to the same extent but had opposite effects on pendrin abundance. KHCO3 loading increased pendrin, while dietary KCl loading inhibited it. Pendrin protein and transcript abundance decreased within 24 hours of switching the high KHCO3 diet to high KCl, and the response was coincident with an increase in plasma chloride and a decrease in bicarbonate. Switching the high KCl diet to high KHCO3 had the opposite response, increasing pendrin protein and transcript as plasma bicarbonate increased and chloride decreased. Neither anion switch protocol changed the extent of hyperaldosterone or hyperkalemia.

Conclusions: Pendrin regulation is prioritized by the dietary anion. Ingestion of an alkaline-rich, high potassium diet drives pendrin expression to prevent metabolic alkalosis, while pendrin is rapidly downregulated to limit hyperchloremic acidosis with consumption of a high KCl diet. We conclude pendrin is differently regulated depending on the potassium salt to control acid-base balance rather than to maintain K+ homeostasis.

Intracellular Water Shift and Disturbed Osmoregulatory Responses to High Sodium in Patients with Hereditary Multiple Exostosis

Jetta J. Oppelaar, Nienke M. Rorije, Rik H. Olde Engberink, Youssef Chahid, Naomi van Vlies, Hein J. Verberne, Bert-jan Van den born, Liffert Vogt. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Tissue Na^+ accumulation plays an important role in Na^+ homeostasis. During high Na^+ diet, negatively charged glycosaminoglycans (GAGs) facilitate extracellular Na^+ accumulation in various tissues. Patients with Hereditary Multiple Exostosis (HME) have a heterozygous loss of function mutation in a gene involved in heparan sulfate (HS) synthesis. HME patients may therefore respond differently to high Na^+ conditions with regard to Na^+ and water homeostasis.

Methods: We performed a randomized cross-over study in 7 male HME patients and 12 healthy controls, matched for age, body mass index, blood pressure and eGFR. All subjects followed randomized both an 8-day low Na^+ diet (LSD, <50mmol/d) and high Na^+ diet (HSD, >200mmol/d). After each diet, blood and urine samples were collected. Also, body fluid compartments measurements were performed by using the distribution curve of iohexol and ^{125}I-albumin.

Results: After LSD, body fluid volume distribution over total body water (TBW) was equal (Fig 1A). HSD resulted in a different distribution between groups (Fig 1B), while absolute TBW increase was not different (1.4 L vs 1.5 L, p=0.91). HME patients showed 3.9% ICFV expansion without concurrent changes in plasma effective osmolality (p=0.18). Whereas, in healthy controls, 23.0% IFV expansion was accompanied by increased plasma effective osmolality (p<0.01). HSD-induced changes in HS excretion were associated with ICFV change in healthy controls (Fig 1C).

Conclusions: HME patients, characterized by defective HS, show distinct body fluid composition and altered osmoregulation after HSD when compared to controls. The incapacity to expand IFV may reflect reduced extracellular Na^+ accumulation with reduced commensurate water. As a consequence, water shifts to the ICFV after hypertonic stress, indicating disturbed maintenance of a stable milieu intérieur. Our results underscore that intact HS synthesis is crucial for Na^+ homeostasis and fluid balance.

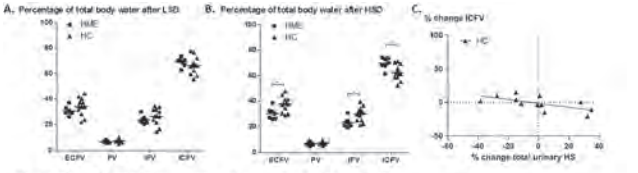

Fig 1.A. After LSD, body fluid compartments are similar divided over TBW.
B. After HSD the proportion of ICFV to TBW became higher in HME patients as compared to healthy controls (69.8L vs 62.5L ,p=0.01). Whereas, in healthy controls the proportion of ECFV to TBW was higher when compared to HME patients (30.2L vs 37.5L, p=0.01), which mainly resulted from a larger IFV compartment (23.2L vs 29.7L, p=0.01)
C. Linear regression graph showing the correlation between percentage change in total urinary NS and percentage change of ICFV in healthy controls, showed a significant negative correlation (r=-0.76, p<0.01).

TH-OR28

Renal Lymphatic Pumping Involves Interstitial Sodium Regulation of NKCC1 Transporter

Jing Liu, Jianyong Zhong, Elaine L. Shelton, Eric J. Delpire, Haichun Yang, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Sodium-potassium-chloride cotransporter 1 (NKCC1) is regulated by extracellular sodium and has recently been shown to modulate vascular dynamics contributing to hypertension. Previously, we showed that NKCC1 is expressed in renal lymphatic vessels of rats and in cultured human lymphatic endothelial cells (LECs). Since interstitial sodium retention is a hallmark of proteinuric injury and nephrotic syndrome, we examined whether high interstitial sodium environment affects expression of the NKCC1 transporter and alters pumping dynamic function of renal lymphatic vessels.

Methods: Puromycin aminonucleoside injected rats (PAN) served as a model of nephrotic syndrome and saline-injected rats served as control. *In vivo*, MRI was used to assess the renal sodium and water content. Renal lymph, which reflects the interstitial composition, was collected and sodium concentration analyzed. *Ex vivo*, contractile dynamics of isolated renal collection lymphatic vessels were studied in a perfusion chamber. Cultured LECs were used to assess the effects of high sodium on NKCC1.

Results: MRI revealed a significant elevation in the renal sodium and water content in PAN vs control rats. The renal lymph of PAN contained significantly higher sodium vs controls although the plasma sodium concentration was not different between the groups. *Ex vivo* studies revealed that high sodium environment decreased contractility of renal collecting lymphatic vessels. Immunostaining and PCR studies showed PAN injury increased NKCC1 expression in renal lymphatic vessels vs control. In cultured LECs, high sodium concentration increased mRNA and reduced phosphorylated NKCC1 protein as well as SPAK, an upstream activating kinase of NKCC1, and eNOS, a downstream link between LECs and smooth muscle cells. Like high sodium environment, furosemide, an NKCC1 inhibitor, showed a weaker effect on amplitude and ejection fraction in isolated renal lymphatics of PAN vs controls.

Conclusions: High sodium within the renal interstitium following proteinuric injury impairs the pumping function of renal lymphatic vessels through SPAK-NKCC1-eNOS pathway that may contribute to sodium and water retention and reduces lymphatic responsiveness to furosemide. We propose this dysfunctional pathway in lymphatic vessels is a novel mechanism of progressive edema in proteinuric kidney disease.

TH-OR29

A Novel Model of Hyperuricemia via Inducible Uricase Knock-Out

Victoria L. Halperin Kuhns, Allison C. Lane-Harris, Owen M. Woodward. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Hyperuricemia contributes to the development of kidney stones, chronic kidney disease, cardiovascular disease, metabolic syndrome, and gout. Classically, hyperuricemia was viewed as caused by an overproduction of urate (UA), underexcretion, or a combination of the two. Creating genetic animal models for overproduction type hyperuricemia is complicated because, unlike humans, mice express the enzyme uricase (*Uox*), which metabolizes UA. Previous models using germline *Uox* knock out resulted in significant juvenile mortality related to crystal induced nephropathy making longitudinal and transcriptional investigations difficult. Here we describe a novel inducible model of *Uox* inactivation (UOX-iKO) that surmounts previous challenges to begin to elucidate renal consequences of overproduction type hyperuricemia.

Methods: CRISPR-Cas9 was used to insert LoxP sites into the *Uox* gene of C57BL6J mice, then crossed with mice harboring a tamoxifen inducible Cre (*Gt(ROSA)26Sor*$^{tm1(cre/ERT2)Tyj}$). Male (M) and female (F) mice were induced at 9 weeks with tamoxifen or vehicle control and sacrificed after 2 weeks or followed longitudinally. RNA-Seq was performed on kidneys of 2 week induced and control mice, followed by DESeq2 and pathway analysis.

Results: Induced animals of both sexes showed significant increases in serum UA and urinary UA excretion 2 weeks after induction, increases that persisted for 10 weeks with no increase in mortality. RNA-Seq analysis revealed both sexes showed differential expression of inflammatory and other immune associated genes including renal injury markers *Lcn2* and *Stc1*, indicating subtle acute renal injury, even without changes in BUN. M mice demonstrated significant decreases in expression of UA transporter genes *Slc17a1* and *Slc17a3*, while F mice showed a significant increase in UA associated transcription factor *Hnf4a*. M but not F mice also had differential expression of genes involved in metabolic processes, while F but not M mice showed differential expression in signal transduction pathways including phospholipase C and toll-like receptor signaling.

Conclusions: The UOX-iKO mice cannot metabolize UA, and thus are an excellent model for overproduction of UA. These mice provide significant insights into the acute transcriptional changes occurring after UA increases, mechanisms of renal UA homeostasis *in vivo*, and new insights into hyperuricemia treatment.

TH-OR30

Factors Associated with Sex Differences in the Risk of Kidney Stones

Pietro Manuel Ferraro,[1] Eric N. Taylor,[2,3] Gary C. Curhan.[3] *[1]Università Cattolica del Sacro Cuore, Rome, Italy; [2]VA Maine Healthcare System, Augusta, ME; [3]Brigham and Women's Hospital Channing Division of Network Medicine, Boston, MA.*

Background: Kidney stone disease is a highly prevalent condition. Men are at higher risk of developing stones compared with women, however recent data suggest a changing epidemiology with women being relatively more affected than in the past. The reasons for such differences and changes over time are not clear.

Methods: We analyzed the association between sex and incident kidney stones using data from three large cohorts. Kidney stone incidence rates for men and women overall and across categories of age and calendar time were computed and hazard ratios (HRs) and 95% confidence intervals (CIs) generated with age-adjusted Cox proportional hazards regression models. Mediation analysis was performed to estimate the amount of excess risk for men explained by established risk factors, including waist circumference, history of high blood pressure, history of diabetes, use of thiazides, dietary intakes. Twenty-four hour urine composition was also examined.

Results: The analysis included data from 268,553 participants, contributing 5,872,249 person-years of follow-up, during which 10,302 incident stone events were confirmed. The incidence rate of kidney stones was 271 and 159 per 100,000 person-years for men and women, respectively. The age-adjusted HR for men compared with women was 2.32 (95% CI 2.20, 2.45). Part of the difference in rates was explained by the risk factors included in the analysis, mainly waist circumference and fluid intake. The risk of stones was consistently higher across categories of age among men compared with women (HRs ranging from 2.02 to 2.76). Regarding calendar time, the risk remained higher among men, but tended to decrease over time while it increased among women, resulting in a 48.1% decrease for after 2009 compared with before 1990. Supersaturations for calcium oxalate and uric acid were higher among men, primarily because of 26.3% higher urine oxalate, 16.3% higher urine uric acid, 23.5% higher urine phosphate and more acidic urine. Urine volume, citrate, oxalate and pH contributed significantly toward an increased risk among men.

Conclusions: The risk of kidney stones is higher among men compared with women. This difference is only partly explained by modifiable lifestyle risk factors; however, differences in urine chemistries explain a substantial fraction of the excess risk.

Deconvolution of Genetic Variation Using High-Quality Cis-Regulatory Elements Map of Kidney Cells

Seong Kyu Han,[1,2] Yoshiharu Muto,[3] Parker C. Wilson,[3] Benjamin D. Humphreys,[3] Matt G. Sampson,[1,2] Dongwon Lee.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Washington University in St Louis, St Louis, MO.*

Background: Genome-wide association studies (GWAS) have facilitated the discovery of disease- or trait-associated genetic variants that can ultimately lead to improved precision of clinical diagnosis and/or molecular pathogenesis in a translational medicine framework. However, identifying specific cell types within organs in which the GWAS variants exert their function remains a significant challenge, especially for the complex and heterogeneous kidney.

Methods: To tackle this, we constructed high-quality maps of *cis*-regulatory elements (CREs) for kidney cells to deconvolute GWAS variants for kidney-relevant phenotypes. Specifically, we devised a computational framework using a sequence-based predictive model that maximally detects CREs by identifying open-chromatin regions with marginal read-mappings but harboring CRE sequence features. We applied this method to kidney ATAC-seq data.

Results: Our high-quality CRE maps have enabled us to detect >100,000 CREs for podocytes, a key rare (<1%) cell type involved in kidney filtration function. Newly found CREs explained the significant proportion of SNP-heritability for a major kidney trait (Urinary Albumin-to-Creatinine Ratio (UACR); Pr[h_g^2]=9.3%). Heritability analysis using these CRE maps uncovered the differential contribution of specific cell types to two major kidney functional traits, UACR and estimated glomerular filtration rate (eGFR). As would be predicted from physiologic understanding, CREs for podocytes and proximal tubule cells (PT) had enriched proportion of SNP-heritability for UACR and eGFR, respectively (UACR: Pr[h_g^2]/Pr[SNPs]=6.8 for podocyte, 2.3 for PT; eGFR: Pr[h_g^2]/Pr[SNPs]=-1.9 for podocyte, 4.3 for PT. Moreover, we found the podocyte relevance of a known GWAS variant (rs17831251; OR=2.25, P=4.7×10^{-103}) on *PLA2R1* associated with Membranous Nephropathy. Our CRE map showed strong podocyte-unique CRE that overlaps with the index variant, suggesting that the index SNP is potentially the causal variant perturbing podocyte-specific transcriptional regulation of *PLA2R1*.

Conclusions: Taken together, we expect that the deconvolution of GWAS variants using the high-quality kidney CRE maps will provide cell-type relevance of GWAS variants on genetic effects not captured by single-cell RNA-seq alone.

Epistatic Interactions of APOL1 Modify the Association Between APOL1 and CKD in African and Hispanic Americans

Thi ha my Vy, Lili Chan, Ron Do, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Chronic kidney disease (CKD) is a major public health problem, and disproportionately effects racial and ethnic minorities. While the *Apolipoprotein L1 (APOL1)* locus has been identified as a significant genetic contributor to the disparities, only a minority of individuals with *APOL1* high-risk genotype develop kidney disease suggesting a major role for genetic and environmental modifiers. Prior genetic association studies studying gene/genetic variants interacting with *APOL1* were limited by small sample sizes and detected very few significant interactions.

Methods: In this study, we conducted a genome-wide single nucleotide polymorphism (SNP)x*APOL1* interaction analysis to identify SNPs that modify the association of *APOL1* high-risk genotypes with CKD in the largest minority cohort to date. Interaction analyses were conducted separately for four independent cohorts, 12,145 African Americans (AAs) and 16,580 Hispanic Americans (HAs) from the Population Architecture through Genomics and Environment (PAGE) Study and 6,827 AAs and 10,314 HAs from the Bio*Me* Biobank, followed by sample size based meta-analysis.

Results: Among the four cohorts, CKD cases and *APOL1* high-risk genotypes were observed with higher frequencies in AA (8.48% CKD and 11.99% *APOL1* in PAGE; 18.21% CKD and 13.90% *APOL1* in Bio*Me*) than in HA (3.40% CKD and 0.45% *APOL*1 in PAGE; 14.14% CKD and 1.69% *APOL1* in Bio*Me*). We tested about 28 million SNPs in our interaction analyses and identified 51 significant SNPs (P value < 1.0 x 10^{-6}) interacting with the *APOL1* locus across the genome (Figure 1). Of these, 28 SNPs were within a gene, and 14 out of the 28 SNPs were within the gene *PAIP2B* which has been showed to be involved in controlling translation and glucose homeostasis.

Conclusions: Although further biological validation is needed, our results provide early insights on the impact of genetic interaction on the association between *APOL1* and kidney disease.

Phenotypic Spectrum of COL4A3 Variants: The Geisinger MyCode/ DiscovEHR Study

Kaushal V. Solanki,[1] Bryn S. Moore,[1] Michelle N. Rheault,[2] Natasha T. Strande,[1] Ion D. Bucaloiu,[1] Alex R. Chang.[1] *[1]Geisinger Health, Danville, PA; [2]University of Minnesota Academic Health Center, Minneapolis, MN.*

Background: Patients with heterozygous *COL4A3* variants have been shown to be at increased risk of kidney disease, ranging from microscopic hematuria to focal segmental glomerulosclerosis (FSGS) and end-stage kidney disease (ESKD). Most studies of patients with *COL4A3* variants have focused on individuals presenting with more severe manifestations, and thus the full phenotypic spectrum remains unclear.

Methods: We used data from 174,418 participants in the Geisinger MyCode/ DiscovEHR study, an unselected health system-based cohort with whole exome sequencing and EHR data. We identified participants with *COL4A3* variants listed as pathogenic or likely pathogenic (P/LP) in ClinVar at minor allele frequency <0.01. Phenotypes were assessed using ICD diagnosis codes, linkage to the US Renal Data System, blood and urine laboratory data, and targeted chart review. Associations between

COL4A3 P/LP variants and Alport syndrome-related phenotypic features were assessed using logistic regression. Additional analyses were done comparing carriers and related non-carriers for the most common variant (p.Gly695Arg) observed in our cohort.

Results: There were 329 (0.2%) participants with a previously reported P/LP rare *COL4A3* variant. Individuals with a *COL4A3* variant (mean age 58.8 years) were at increased risk of ESKD (OR 3.79, 95% CI: 2.36-6.08), hematuria (OR 1.99, 95% I: 1.37-2.88), FSGS/renal sclerosis (OR 7.46, 95% CI: 3.31-16.84), and eGFR <60 ml/min/1.73m^2 (OR 1.46, 95% CI: 1.07-1.99) but not hearing loss. The most common P/LP variant was p.Gly695Arg with 161 heterozygous individuals in 58 families **(Table).** Compared to 123 related non-carriers, those with the p.Gly695Arg variant were at increased risk of hematuria (OR 3.44, 95% CI: 1.34-8.86), and ESKD (OR 12.39 (1.59-96.33; P=0.02). Two patients had a known family history of Alport Syndrome, and only 1 patient had been diagnosed using clinical genetic testing.

Conclusions: In an unselected health system cohort, we demonstrate that rare P/LP variants in *COL4A3* increase risks of hematuria, FSGS, and ESKD, and are undiagnosed in the vast majority of individuals.

The Genetic and Clinical Spectrum of Tubulointerstitial Kidney Disease and Associated Syndromes Revealed Through Whole-Genome Sequencing in the UK 100,000 Genomes Project

Gary Leggatt,[1,2] Christine Gast,[1,2] Rodney D. Gilbert,[3,2] Kristin Veighey,[4,2] Sarah Ennis.[2] *[1]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; [2]University of Southampton Faculty of Medicine, Southampton, United Kingdom; [3]Southampton Children's Hospital, Southampton, United Kingdom; [4]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom.*

Background: Tubulointerstitial kidney disease (TKD) is a heterogeneous group of monogenic disorders with progressive chronic kidney disease characterised by interstitial fibrosis, tubular atrophy and variable clinical manifestations. TKD includes recessive ciliopathies, autosomal dominant tubulointerstitial kidney diseases (ADTKD) and mitochondrial diseases. The Genomics England (GEL) project offered a unique opportunity to apply a novel discovery approach, synthesising the effect of common and rare variants using a whole-gene-based pathogenicity score (GenePy). This scoring system results in per gene-per person pathogenicity scores, with higher scores representing a higher mutational burden.

Methods: We applied the GenePy scoring system integrating patient zygosity, allele frequency, and deleteriousness metrics. We identified unrelated Europeans for a phenotype-genotype approach of 232 cases with TKD and 8,282 controls with no documented kidney phenotype. GenePy scores were generated for a discrete set of candidate genes for each individual. The highest decile GenePy scores were compared using a one-tailed Mann-Whitney U-test. We then took an unbiased genotype-phenotype approach by calculating GenePy scores for all 78,050 germline genomes. Individuals were ranked by gene score, and individuals with the highest scores were assessed for their phenotype.

Results: The difference in top decile scores between cases and the same proportion of controls was statistically significant for *PKD2* ($p=2.81\times10^{-6}$), *DNAJB11* ($p=3.56\times10^{-5}$), *XPNPEP3* (p=0.0083), *UMOD* (p=0.0015) and *CEP290* (p=0.034). Novel variants consistent with TKD were identified. The unbiased genotype-phenotype approach additionally revealed variants consistent with monogenic TKD in participants recruited for diverse reasons, including cancer.

Conclusions: Using a novel gene-level scoring system, we describe new gene variants associated with TKD and associated phenotypes. Patients were identified in non-kidney disease recruits demonstrating the benefit of an unbiased 'gene first' approach in large scale datasets such as the 100,000 Genomes Project.

A Glomerular Transcriptomic Landscape of APOL1 in Black Patients with Focal Segmental Glomerulosclerosis

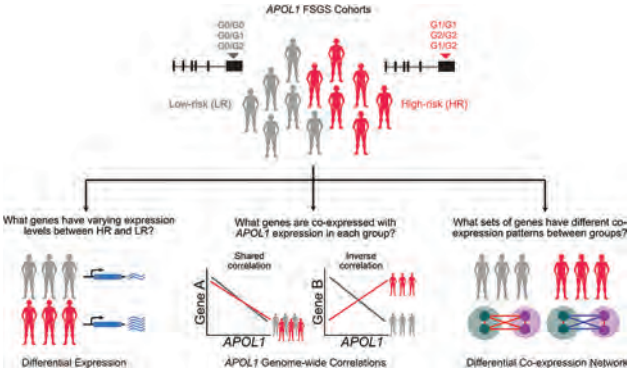
Michelle Mcnulty,[1] Damian Fermin,[2] Felix H. Eichinger,[2] Matthias Kretzler,[2] Martin R. Pollak,[3,4] David J. Friedman,[3,4] Matt G. Sampson.[1,4] Nephrotic Syndrome Study Network (NEPTUNE) *[1]Boston Children's Hospital, Boston, MA; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Apolipoprotein L1 (APOL1)-associated focal segmental glomerulosclerosis (FSGS) is the dominant form of FSGS in Black people. There are no targeted therapies for this condition, in part because the molecular mechanisms underlying APOL1's pathogenic contribution to FSGS are incompletely understood. Studying the transcriptomic landscape of APOL1 FSGS in patient kidneys is an important way to discover genes and molecular behaviors that are unique or most relevant to the human disease.

Methods: With the hypothesis that the pathology driven by the high-risk (HR) APOL1 genotype is reflected in alteration of gene expression across the glomerular transcriptome, we compared expression and co-expression profiles of 15,703 genes in 16 Black FSGS patients with a HR vs 14 with a low-risk ("LR") APOL1 genotype. Expression data from APOL1-inducible HEK293 cells and normal human glomeruli were used to pursue genes and molecular pathways illuminated in these studies.

Results: We discovered (1) increased expression of APOL1 in HR and nine other significant differentially expressed genes, including stanniocalcin (STC1), which has a role in mitochondrial and calcium-related processes, (2) differential correlations between HR and LR APOL1 and metabolism pathway genes, but similar correlations with extracellular matrix- and immune-related genes, (3) significant loss of co-expression of mitochondrial genes in HR FSGS, and (4) an NF-kB -down-regulating gene, NKIRAS1, as the most significant hub gene with strong differential correlations with NDUF family and immune-related genes.

Conclusions: Overall, differences in mitochondrial gene regulation appear to underlie many differences observed between HR and LR FSGS. All data are available for secondary analysis through the "APOL1 Portal" (http://APOL1portal.org).



TH-OR36

Therapeutic Potential of a CFTR Corrector to Mitigate Slowly Progressing Adult-Onset Polycystic Kidney Disease

Liudmila Cebotaru, Murali K. Yanda. *Johns Hopkins University, Baltimore, MD.*

Background: Autosomal dominant kidney disease is the most common dominant genetic renal disorder in humans leading to significant health care costs. It is associated with the slow but relentless formation of multiple renal cysts driven by cAMP-dependent fluid secretion leading to considerable patient morbidity.

Methods: We used a combination of MRI, Immunoblotting and Immunostaining to test VX-809 in a slowly progressing RC/RC mouse model, bearing the R3277C mutation

Results: At 6 months of age the RC/RC mice develop large renal cysts and impaired renal function. However, when treated with VX-809 between the ages of 6-8 months cyst area is reduced suggesting that VX-809 has shrunk already existing cysts (Fig. 1). Importantly, after 2 months of treatment their cyst size is approximately 50% less compared to untreated animals of the same age (8 months). The reduction in cyst size was accompanied by improved renal function. Colocalizations studies confirm that CFTR is localized predominately at the apical membrane in the 8-month-old untreated animals consistent with its role in Cl^- secretion. However, after treatment CFTR localization with the basolateral membrane increases approximately 4-fold, accompanied by an approximately 2-fold decrease in its apical colocalizing indicating that VX-809 alters the phenotype of the cysts to favor fluid absorption.

Conclusions: Demonstration of cyst reduction, improved renal function and generation of an absorptive phenotype increases the therapeutic potential of VX-809 as a treatment of ADPKD.

Funding: NIDDK Support

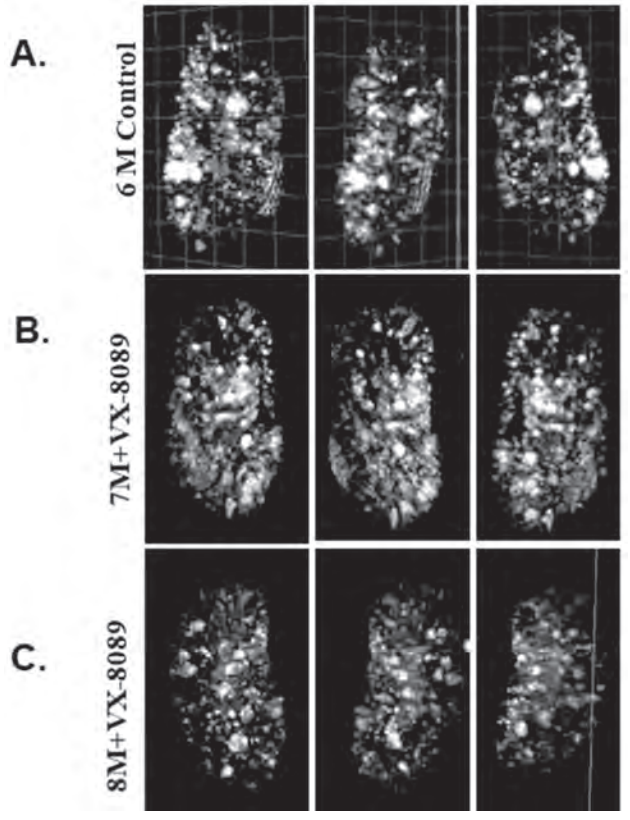


Fig 1: MRI images of mice kidneys Three sequential images are depicted. The animal depicted here (6M-Control) was allowed to develop cysts slowly over 6 months and then injected for one (B) and two months (C) with VX-809 (30 mg/kg) (8M+VX-809). **Note that** VX-809 shrinks the cysts between 6 and 8 months of age

TH-OR37

Comparative PKD1 and PKD2 Missense Variant Profiling Aids Molecular Diagnoses Across the ADPKD Spectrum and Reveals Common Pathomechanisms

Cynthia J. Sieben,[1] Vladimir Gainullin,[1,2] Christina M. Heyer,[1] Elizabeth K. Dillinger,[1] Ka Thao,[1] Ines Sturmlechner,[1] Peter C. Harris.[1] *[1]Mayo Clinic Research Rochester, Rochester, MN; [2]GeneDx, Gaithersburg, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the formation and growth of fluid-filled renal cysts, often leading to kidney failure. Typically, monoallelic *PKD1* or *PKD2* variants cause ADPKD, however, complex inheritance and a broad phenotypic spectrum also exist. The advent of genomewide variant screening has emphasized the importance of ADPKD molecular diagnostic methods to reliably determine the pathogenicity of variants of unknown significance (VUS).

Methods: Here, we developed a cell-based flow cytometry assay to assess the pathogenicity of *PKD1* and *PKD2* VUS. This assay utilizes localization of polycystin 1 (PC1; encoded by *PKD1*) to the apical plasma membrane, where formation of the PC1/PC2 complex (PC2; encoded by *PKD2*) is required for proper PC1 trafficking. Employing this assay, we have assessed 48 *PKD1* and 44 *PKD2* variants with predicted pathogenicity ranging from fully penetrant monoallelic, to incompletely penetrant biallelic, and likely benign variants.

Results: The majority of likely pathogenic monoallelic *PKD1* and *PKD2* missense variants perturb PC1 trafficking by >80%, with a correlation between the predicted penetrance (determined bioinformatically) and surface PC1. *In cis* monoallelic *PKD1* variants have an additive effect and perturb PC1 trafficking by 60-98%, whereas proposed biallelic *PKD1* variants exhibit variable impacts (0-70% perturbation; majority <60%). In contrast, likely benign variants have little or no impact. To understand mechanisms underlying aberrant PC1 trafficking, we evaluated defective protein folding under enhanced folding conditions (reduced culture temperature; 30°C). The majority of *PKD1* and *PKD2* monoallelic, and all *PKD1* and *PKD2* complex variants impact PC1 or PC2 folding, and can be partially or fully rescued at 30°C.

Conclusions: These studies describe a novel *in vitro* assay for determining *PKD1* and *PKD2* VUS pathogenicity, and highlight a continuum of allele penetrance across the ADPKD spectrum. This firmly establishes PC1 trafficking as a common *PKD1*/*PKD2*-mediated ADPKD pathomechanism, but suggests that other mechanisms account for a minority of variants. Further, demonstrated aberrant PC1 or PC2 folding suggests a role for chaperone therapy in ADPKD.

Funding: NIDDK Support

TH-OR38

The C-Terminal Tail of Polycystin 1 Rescues Cystic Phenotype in a Mitochondrial Enzyme-Dependent Fashion

Laura Onuchic,[1] Valeria Padovano,[1,2] Giorgia Schena,[1] Vanathy Rajendran,[1] Nikolay P. Gresko,[1] Ke Dong,[1] Xiaojian Shi,[1] Hongying Shen,[1] Stefan Somlo,[1] Michael J. Caplan.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Broad Institute, Cambridge, MA.*

Background: Approximately 85% of Autosomal Dominant Polycystic Kidney Disease (ADPKD) cases are caused by mutations in *PKD1*, which encodes polycystin-1 (PC1). PC1 is a large transmembrane protein that undergoes C-terminal cleavage, generating fragments (PC1-CTT) that translocate to mitochondria and nucleus. We find that PC1-CTT expression in an inducible PC1 KO ADPKD mouse model substantially rescues cystic phenotype and we elucidate mechanisms involved in this effect.

Methods: We generated BAC transgenic mice expressing a Flox-Stop 2HA-PC1-CTT inserted in the Rosa26 locus and crossed it with the inducible *Pax8rtTA; TetO-Cre; Pkd1$^{fl/fl}$* ADPKD mouse model. Doxycycline induction of these mice (*PC1-CTT*; *Pax8rtTA; TetO-Cre; Pkd1$^{fl/fl}$* on the C57BL6N background) leads to PC1-CTT expression in renal epithelial cells that lack full-length PC1. We applied MS-based proteomics and Co-IP techniques to identify PC1-CTT interactors and used MS-based metabolomics to identify mitochondrial differences associated with the observed phenotype.

Results: Compared to PC1 KO mice, PC1 KO mice expressing PC1-CTT have 3-fold lower kidney weight/body weight ratio (5.10% vs 14.85%, $p<0.0001$) and 3.6-fold lower BUN (32.7mg/dL vs 120.7mg/dL, $p=0.0008$), with both groups presenting comparable gender distributions. BUN levels in PC1-CTT-expressing ADPKD mice are comparable to those in WT controls. We show that PC1-CTT interacts with mitochondrial enzyme Nicotinamide Nucleotide Transhydrogenase (NNT) and confirm the importance of this interaction by crossing the same PC1-CTT expressing PC1 KO mice with NNT-deficient C57BL6J mice. These mice do not exhibit an improved cystic phenotype. Both *in vivo* and *in vitro*, PC1-CTT re-expression in the presence of NNT leads to increased mitochondrial mass, altered redox modulation, increased assembly of ATP synthase at a "per mitochondria" level as well as decreased tubular proliferation, suggesting potential mechanisms for the observed rescue. Finally, unbiased metabolomics reveals that PC1-CTT's ability to rescue the ADPKD metabolic profile is tied to the presence of NNT.

Conclusions: Expression of PC1-CTT and its interaction with NNT significantly rescues ADPKD renal phenotype. Considering its small size, PC1-CTT could be explored as a gene therapy approach for ADPKD.

Read-Through Therapeutics Reduce Cystogenesis in a Novel Cohort of CRISPR Base Edited ADPKD Organoids

Courtney E. Vishy,[1] Daniel Crawford,[2] Matthew Goddeeris,[2] Benjamin S. Freedman.[1] *[1]University of Washington, Seattle, WA; [2]Eloxx Pharmaceuticals, Waltham, MA.*

Background: In autosomal dominant polycystic kidney disease (ADPKD), truncating nonsense mutations are responsible for 40-50% of cases, with increased disease severity and limited treatment options. Eukaryotic ribosomal selective glycosides (ERSGs) allow read-through of premature stop codons to restore full-length proteins as a novel therapeutic approach. However, existing animal and kidney organoid models of ADPKD lack mutations amenable to read-through.

Methods: Human pluripotent stem cells were CRISPR base edited to introduce four specific nonsense mutations previously documented in ADPKD patients – *PKD1* R2430X and Q3838X and *PKD2* R186X and R872X. Mutations were confirmed by sequencing and protein changes by immunoblot. Mutant and isogenic control stem cells were differentiated into kidney organoids to determine if nonsense mutations conferred a cystic phenotype. Premature stop codon read-through potential was evaluated for impact on cyst formation and toxicity (live/dead staining and LDH release) over a period of two weeks using two unique ERSGs.

Results: Nonsense mutant clones of each targeted genotype were obtained with the desired single base pair mutation and lacked expression of full-length protein. Fewer than 5% of isogenic control organoids formed cysts compared to > 80% in untreated mutant organoids. Treatment of mutant organoids with ERSGs reduced cystogenesis to < 20% and slowed the rate of cyst expansion in a dose-dependent manner. Treatment associated toxicity was not significantly detected at efficacious doses.

Conclusions: CRISPR base editing enabled rapid generation of an ADPKD organoid cohort with patient targeted nonsense mutations. The data suggest that read-through by ERSGs is a viable therapeutic approach for reducing cystic burden in a large subpopulation of patients with ADPKD, supporting the advancement of ERSGs in human clinical trials.

Whole-Genome Sequencing Reveals the Genetic Architecture of Posterior Urethral Valves

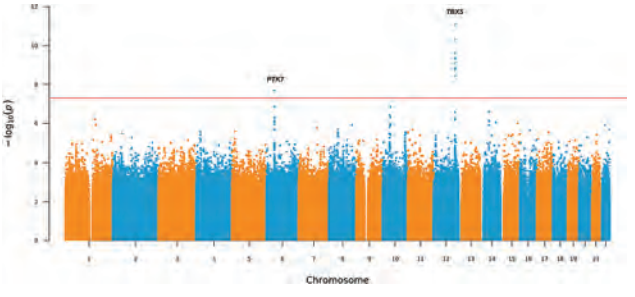
Melanie M. Chan,[1] Omid Sadeghi-Alavijeh,[1] Horia Stanescu,[1] Stefanie Weber,[2] Alina Hilger,[3,4] Adrian S. Woolf,[5] William G. Newman,[5] Detlef Bockenhauer,[1,6] Adam P. Levine,[1] Daniel P. Gale.[1] Genomics England Research Consortium *[1]University College London, London, United Kingdom; [2]Philipps-Universitat Marburg, Marburg, Germany; [3]Children's Hospital, University of Bonn, Bonn, Germany; [4]Universitatsklinikum Bonn Institut fur Humangenetik, Bonn, Germany; [5]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [6]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom.*

Background: Posterior urethral valves (PUV) are the commonest cause of childhood kidney failure and a major unmet clinical problem in pediatric nephrology. While usually sporadic, familial clustering and twin studies suggest a genetic component that is as yet unidentified. Using large-scale whole genome sequencing (WGS) we sought to understand the genetic architecture of PUV and identify key contributing genes.

Methods: We analysed WGS data from 132 unrelated PUV patients and 23,727 ancestry-matched unaffected controls from the 100,000 Genomes Project, seeking enrichment of common and rare single-nucleotide and structural variation (SV) on a genome-wide, per-gene, and cis-regulatory element basis.

Results: Exome-wide there was no significant enrichment of rare coding variation in any one gene. SV analysis identified an increased burden of rare inversions affecting CTCF-only cis-regulatory elements (P=2.0x10^{-5}; OR 2.1), but these did not affect any single genomic locus recurrently. GWAS of 17 million variants with minor allele frequency [MAF] > 0.001 revealed significant (P<5x10^{-8}) associations at two loci: 12q24.21 (P=7.8x10^{-12}; OR 0.4; MAF 0.37) and 6p21.1 (P=2.0x10^{-8}; OR 7.2; MAF 0.007), both of which replicated in an independent cohort of 398 European PUV patients. Bayesian fine mapping and *in silico* functional annotation mapped these loci to the transcription factor *TBX5* and planar cell polarity gene *PTK7*, respectively. Both are highly expressed in the embryonic mouse urethra and known to regulate development.

Conclusions: This work demonstrates that non-specific perturbations of broad regulatory networks and chromatin looping may be important in the pathogenesis of PUV. Furthermore, for the first time, two genetic loci for PUV are identified which map to the genes *TBX5* and *PTK7*, providing novel insights into the biological mechanisms underlying this complex disorder.



Manhattan plot for GWAS of 132 PUV patients and 23,727 unaffected controls.

Role of Hypertension in the Risk of Heart Failure in CKD

Sydney E. Hartsell,[1] Guo Wei,[1] Robert E. Boucher,[1] Adhish Agarwal,[1,2] James C. Fang,[1] Adam Bress,[1] Alfred K. Cheung,[1,2] Srinivasan Beddhu.[1,2] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Chronic kidney disease (CKD) is a risk factor for heart failure (HF), but the extent to which hypertension (HTN) contributes to development of HF in CKD is unclear.

Methods: We used the VA Informatics and Computing Infrastructure (VINCI) platform to identify a national cohort of veterans with prevelant CKD (two or more outpatient CKD-EPI eGFR <60 ml/min/1.73m^2 taken 60 days apart from January 2010 to December 2015). We used inpatient and outpatient ICD 9/10 codes to define HF admissions and incident HF through August 2018. We first related CKD stages at baseline with the time to HF hospitalizations and incident HF with adjustment for demographics and baseline comorbidity in a multivariable Cox regression. Next, we adjusted for baseline blood pressure (BP) and BP-lowering medications (BP meds). Finally, we conducted a time varying Cox regression model with 3-month averages of BP values and BP meds.

Results: Of the 915,038 veterans with prevelant CKD, we included 632,872 (69%) without known HF at baseline. Over about 3.5 million patient-years of follow up, 111,549 (18%) patients developed HF and 29,597 (5%) were hospitalized for HF. Compared to stage 3A CKD, more advanced CKD stages were significantly associated with HF incidence and admissions (Fig 1). Results were similar when adjusted for demographics only (incident HR 1.63 (95%CI 1.52-1.74); admission HR 2.28 (95%CI 2.05-2.53)) or with addition of comorbidities and atherosclerotic risk factors (Fig 1). Controlling for time-varying BP and BP meds significantly attenuated these hazard ratios (Fig 1). Results were similarly attenuated using baseline BP and BP meds (incident HR 1.06 (95% CI 0.99-1.13); admission HR 1.24 (95%CI 1.12-1.38).

Conclusions: Adjusting for HTN to a large degree attenuates the increased risk of HF observed in patients with CKD. Interventional trials targeting BP are needed to establish whether intensive BP control can reduce the risk of HF in CKD.

Prediction of Incident Heart Failure in CKD

Leila R. Zelnick,[1] Michael Shlipak,[7] Elsayed Z. Soliman,[8] Amanda H. Anderson,[2] Robert Christenson,[10] Mayank Kansal,[9] Rajat Deo,[3] Jiang He,[2] Bernard G. Jaar,[4] Matthew R. Weir,[10] Panduranga S. Rao,[5] Debbie L. Cohen,[3] Jordana B. Cohen,[3] Harold I. Feldman,[3] Alan S. Go,[6] Nisha Bansal.[1] *[1]University of Washington, Seattle, WA; [2]Tulane University, New Orleans, LA; [3]University of Pennsylvania, Philadelphia, PA; [4]Johns Hopkins University, Baltimore, MD; [5]University of Michigan, Ann Arbor, MI; [6]Kaiser Permanente Northern California, Oakland, CA; [7]University of California San Francisco, San Francisco, CA; [8]Wake Forest University, Winston-Salem, NC; [9]University of Illinois at Chicago, Chicago, IL; [10]University of Maryland School of Medicine, Baltimore, MD.*

Background: Heart failure (HF) is common in patients with chronic kidney disease (CKD); identifying high risk patients would guide clinical care. We assessed prognostic value of cardiac biomarkers and echocardiographic (echo) variables for HF prediction compared to a published clinical equation in the Chronic Renal Insufficiency Cohort (CRIC).

Methods: Among 2,146 CRIC participants without prior HF and with complete clinical, cardiac biomarker and echo data, we compared the discrimination of the 11-variable Atherosclerosis Risk in Communities (ARIC) HF prediction equation to cardiac biomarkers (N terminal brain natriuretic peptide, NT-proBNP, and high sensitivity troponin T, hsTnT) and echo measures (left ventricular mass, LVM, and ejection fraction, LVEF) to predict 10-year risk of HF hospitalization using Cox regression. We separately evaluated prediction of HF with preserved and reduced LVEF (LVEF ≥50% and <50%, respectively). We assessed discrimination with internally valid, 10-fold cross-validated C-indices.

Results: Participants had mean (SD) age 59 (11), eGFR 44 (16) mL/min/1.73m2, 53% men, and 43% Black; 268 incident HF hospitalizations occurred during 6.7 (SD 2.5) years of follow-up. The ARIC HF model with clinical variables had a C-index of 0.68 (**Table**). hsTnT alone (C-index 0.69) and LVM+LVEF (C-index 0.71) were comparable to the ARIC model, while NT-proBNP alone had better discrimination (C-index 0.72,

p=0.04). A model including cardiac biomarkers, echo, and clinical variables had a C-index of 0.78. Discrimination of HF with preserved LVEF was lower than for HF with reduced LVEF for most models (**Table**).

Conclusions: The ARIC HF prediction model for 10-year HF risk had modest discrimination among adults with CKD. NT-proBNP alone discriminated better than the ARIC model, and was comparable to models with echo variables. HF clinical prediction models specifically in adults with CKD are needed. Until then, use of NT-proBNP may be a low burden approach to predict HF in this population, and offers moderate discrimination.

Funding: NIDDK Support

Table. Discriminatory ability of models to predict incident heart failure (HF), compared with the published ARIC model

	Incident HF		Incident HFpEF		Incident HFrEF

Entries for ARIC clinical model are C-index and 95% bootstrap confidence intervals. All other entries are 10-fold cross-validated C-indices or difference in C-indices compared with ARIC clinical model, and 95% bootstrap confidence intervals. Bolded entries indicate statistical significance at the 5% level. ARIC clinical model predicts 10-year risk of HF from age, Black race/ethnicity, sex, heart rate, systolic blood pressure, use of antihypertensive medications, diabetes, coronary heart disease, current and former smoking, and BMI. HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction.

Risk of Subclinical-Cardiovascular Outcomes in Children with Ambulatory Hypertension: A Systematic Review and Meta-Analysis

Jason Chung,[1] Andrew Yu,[4] Abdulaziz A. Bamhraz,[2] Joycelyne E. Ewusie,[8] Arjun K. Pandey,[5] Mark Mitsnefes,[6] Rulan S. Parekh,[7] Janis M. Dionne,[3] Rahul Chanchlani.[2] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]McMaster Children's Hospital, Hamilton, ON, Canada; [3]BC Children's Hospital, Vancouver, BC, Canada; [4]University of Alberta Faculty of Science, Edmonton, AB, Canada; [5]McMaster University, Hamilton, ON, Canada; [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [7]The Hospital for Sick Children, Toronto, ON, Canada; [8]The Research Institute of St Josephs Healthcare Hamilton, Hamilton, ON, Canada.*

Background: Several studies have shown associations between childhood hypertension (HTN) and subclinical-cardiovascular outcomes (SCOs) such as left ventricular hypertrophy (LVH), increased pulse wave velocity (PWV) and increased carotid intima media thickness (cIMT). These data support the effect of elevated blood pressure (BP) in children leading to cardiovascular risk in adults; however, the association is not consistent in all studies. In this review, we investigate the prevalence of SCOs in children with HTN, diagnosed by ambulatory blood pressure monitoring (ABPM).

Methods: A systematic literature search was conducted on four electronic databases to include relevant full-length publications in English language, published abstracts and conference proceedings from Jan 1974 to Mar 2020. Article screening, data extraction and quality assessment were independently completed and verified by two reviewers. Primary outcomes included SCOs such as LVH, left ventricular mass index (LVMI), PWV and cIMT as per standard definitions. Meta-regression was done to adjust for the effect of body mass index (BMI) on LVMI.

Results: Of 8996 studies, 38 were included for analysis. SCO indices were significantly greater in those with HTN than those with normotension (NTN). Mean difference between the HTN and NTN group was 0.03mm (95% CI: 0.01, 0.05) for cIMT, 0.42 m/sec (95% CI: 0.25-0.6) for PWV, and 5.02$gm^{-2.7}$ (95% CI: 3.66-6.39) for LVMI. HTN group had 3-times higher odds of LVH (3.10 [95% CI: 1.65-5.82]). Meta regression showed that BMI had a significant influence on the mean differences in LVMI, with the mean difference in LVMI increasing by 0.81$gm^{-2.7}$ (95% CI [0.42, 1.19], $p < 0.001$) per unit increase in BMI.

Conclusions: Children with ambulatory HTN have a greater risk of SCOs. These findings emphasize the importance for children to have their BP within normal values.

Renal Revascularization Attenuates Myocardial Mitochondrial Damage and Improves Diastolic Function in Pigs with Metabolic Syndrome and Renovascular Hypertension

Alfonso Eirin,[1] Rahele A. Farahani,[1] Christopher M. Ferguson,[1] Xiang yang Zhu,[1] Hui Tang,[1] Kyra L. Jordan,[1] Ishran M. Saadiq,[1] Sandra Herrmann,[1] Alejandro R. Chade,[2] Amir Lerman,[1] Lilach O. Lerman.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]The University of Mississippi Medical Center, Jackson, MS.*

Background: Percutaneous transluminal renal angioplasty (PTRA) may improve renal and cardiac function in renovascular hypertension (RVH), but its effect on the biological mechanisms implicated in cardiac damage remains unknown. We hypothesized that restoration of kidney function by PTRA ameliorates myocardial mitochondrial damage and preserves cardiac function in pigs with metabolic syndrome (MetS) and RVH.

Methods: Pigs were studied after 16 weeks of MetS+RVH, MetS+RVH treated 4 weeks earlier with PTRA, and Lean and MetS Sham controls (n=6 each). Cardiac and renal function was assessed by multi-detector CT, whereas cardiac mitochondrial morphology and function, and injury pathways were assessed ex vivo.

Results: RVH induced renal and cardiac diastolic (albeit not systolic) dysfunction (Table). PTRA improved renal function but not RVH. It preserved myocardial mitochondrial structure and function, ameliorated oxidative stress and fibrosis (Fig.A), attenuated left ventricular remodeling (LVMM), and restored diastolic function (E/A ratio). Myocardial mitochondrial damage did not correlate with blood pressure but correlated directly with renal dysfunction (Fig.B).

Conclusions: Improved renal function by PTRA preserves myocardial mitochondria and enhances cardiac recovery regardless of RVH, underscoring reno-cardiac crosstalk in experimental MetS+RVH.

Baseline and Time-Updated Systolic Blood Pressure and Incident Cognitive Impairment in the Chronic Renal Insufficiency Cohort

Seda Babroudi,[1] Hocine Tighiouart,[1] Sarah J. Schrauben,[2] Jordana B. Cohen,[2] Jiang He,[3] Panduranga S. Rao,[4] Michael J. Fischer,[5] Mahboob Rahman,[6] Alan S. Go,[7] Chi-yuan Hsu,[8] Stephen M. Sozio,[9] Matthew R. Weir,[10] Mark J. Sarnak,[1] Kristine Yaffe,[8] Manjula Kurella Tamura,[11] David A. Drew.[1] *[1]Tufts Medical Center, Boston, MA; [2]University of Pennsylvania, Philadelphia, PA; [3]Tulane University School of Medicine, New Orleans, LA; [4]University of Michigan Michigan Medicine, Ann Arbor, MI; [5]University of Illinois Hospital and Health Sciences System, Chicago, IL; [6]University Hospitals, Cleveland, OH; [7]Kaiser Permanente Northern California, Oakland, CA; [8]UCSF Medical Center, San Francisco, CA; [9]Johns Hopkins Medicine, Baltimore, MD; [10]University of Maryland Medical System, Baltimore, MD; [11]Stanford University School of Medicine, Stanford, CA.*

Background: A linear relationship exists between systolic blood pressure (SBP) and cognitive impairment in the general population. Patients with chronic kidney disease (CKD) are at higher risk for hypertension and cognitive impairment. We therefore sought to investigate the relationship between SBP and cognitive impairment in patients with CKD.

Methods: Using data from the Chronic Renal Insufficiency Cohort Study, we investigated the association between baseline and time-updated SBP and incident cognitive impairment, defined as a mini-mental state (3MS) score < 80, during annual assessments using discrete hazards models that adjusted for demographics as well as cardiovascular and kidney disease risk factors.

Results: Mean (SD) age and eGFR (SD) by the CKD-Epi equation of the 3753 participants were 58 years (11), and 44 mL/min/1.73m^2 (15), respectively. Baseline cognitive impairment was present in 10.1% of overall participants (n = 365), and 5.4%, 9.5%, and 16.4% of participants with baseline SBP <120, 120-140, and ≥140 mm Hg, respectively ($p < 0.01$). There were 314 individuals who developed cognitive impairment during a median 6 years of follow-up. After multivariable adjustment, participants with higher baseline SBP were more likely to have incident cognitive impairment (hazard ratio (HR) [95%CI] = 1.09 [1.03, 1.16] per 10 mmHg higher SBP); this relationship was attenuated when using time-updated SBP (HR [95%CI] = 1.04 [0.99, 1.10]) (Table 1).

Conclusions: Among patients with CKD, elevated baseline SBP but not time-updated SBP was associated with incident cognitive impairment.

Influence of Baseline Diastolic Blood Pressure on the Effect of Lowering Systolic Blood Pressure on Mild Cognitive Impairment and Probable Dementia

Aditi Gupta,[1] Robert E. Boucher,[2] Guo Wei,[2] Mark A. Supiano,[2] Jeffrey M. Burns,[1] Sankar D. Navaneethan,[3] L Parker Gregg,[3] Jeff D. Williamson,[6] Nicholas M. Pajewski,[4] Srinivasan Beddhu.[5] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Utah Health, Salt Lake City, UT; [3]Baylor College of Medicine, Houston, TX; [4]Wake Forest University School of Medicine, Winston-Salem, NC; [5]The University of Utah School of Medicine, Salt Lake City, UT; [6]Wake Forest Baptist Medical Center, Winston-Salem, NC.*

Background: Lowering of systolic blood pressure (SBP) with already low diastolic blood pressure (DBP), can potentially decrease cerebral perfusion and worsen cognition. We examined the influence of baseline DBP on the effect of lowering SBP on incident mild cognitive impairment (MCI) and probable dementia (PD).

Methods: In this post-hoc analysis of the Systolic Blood Pressure Intervention Trial (SPRINT) study (N = 8562), we examined the effects of intensive (<120 mmHg) vs standard (<140 mmHg) SBP control on a composite, adjudicated outcome of MCI/PD across the range of baseline DBP in a spline Cox regression model. We also tested for interactions of baseline DBP on the effect of SBP goal on MCI/PD.

Results: Mean age was 68±9 years, 35% were women and 66% White. There were 640 MCI/PD events over 39,022 participant-years. Compared to standard SBP, intensive SBP control further lowered the DBP in those in the lowest baseline DBP tertile (Figure 1A) but also lowered the risk of MCI/PD (Table 1). While lower baseline DBP was associated with higher risk of MCI/PD (Table 1), there was no evidence that intensive SBP lowering increased the risk of MCI/PD in those with low baseline DBP (Figure 1B) with with baseline DBP x SBP goal interaction p = 0.37.

Conclusions: Intensive SBP lowering that further lowered DBP did not increase the risk of MCI/PD in those with low baseline DBP. The association of low baseline DBP with greater risk of MCI/PD is unlikely to be causal.

Funding: Other NIH Support - NIA

Table 1: Cox proportional hazard models for hazard ratios for MCI/PD for each 5 mmHg decrease in DBP and intervention.

	SBP intervention alone	DBP alone	Joint model
SBP intervention	0.80 (0.69, 0.94)		0.81 (0.69, 0.95)
Each 5 mmHg decrease in DBP		1.17 (1.13, 1.20)	1.17 (1.13, 1.20)

There was no interaction between baseline DBP and MCI/PD with the SBP intervention p=0.36

Changes in Aortic Compliance During Individualized Hypertension Management in CKD

Yossi Chait,[1] Brian H. Nathanson,[2] Daniel Schneditz,[3] Barbara A. Greco,[4,5] Michael J. Germain.[4,5] *[1]University of Massachusetts Amherst, Amherst, MA; [2]OptiStatum, Longmeadow, MA; [3]Medizinische Universitat Graz, Graz, Austria; [4]Renal and Transplant Associates of New England, Springfield, MA; [5]Baystate Medical Center, Springfield, MA.*

Background: The prevalence of hypertension (HTN) in chronic kidney disease (CKD) patients ranges from 60% to 90% with up to 50% having drug resistant hypertension.

Methods: Using a prospective pragmatic CQI initiative, we evaluated the effectiveness of a novel hypertension management (Study) with standard care (Control) in a cohort of patients with uncontrolled hypertension with and without chronic kidney disease. A pre-determined Study group algorithm, guided by hemodynamic data obtained using noninvasive bioimpedance-derived stroke volume measurements, was used for selecting and titrating antihypertensive medications based on state: vasoconstricted, hyperdynamic, and mixed. Hypertensive patients were assigned to groups at baseline, then followed for 4-6 months (endpoint). Aortic compliance was computed as the ratio of stroke volume (SV) over central pulse pressure (PP).

Results: There were 73 patients in Study group and 20 in Control. Baseline demographics and BP were similar in both groups (Table 1). Individualized hemodynamic guided management resulted in significantly greater reductions in mean SBP (24.2 vs. 14.5 mmHg, p = 0.010), DBP (12.8 vs. 7.3 mmHg, p = 0.031), and a greater proportion of patients achieving target BP (57.5% vs. 25.0%, p = 0.010). This was associated with more normalization of physiology at endpoint in the Study group (68.5% vs. 35.0%, p = 0.006). The change in compliance (endpoint-baseline) was statistically different only in Study Group A (Table 2). The correlation between the change in compliance and the change in SV was significantly different between groups (p= 0.021). In contrast, the changes in central PP were similarly correlated in both groups.

Conclusions: Hypertension management is more effective when guided by hemodynamic state. Greater decrease in BP is strongly associated with both hemodynamics normalization and compliance improvement, with the latter associated with increase in SV.

Regulation of Sodium Excretion and Blood Pressure by the Nuclear Factor of Activated T Cells 5 (NFAT5) in Renal Tubular Cells

Akiko Hiramatsu, Yuichiro Izumi, Yutaka Kakizoe, Masataka Adachi, Hiroshi Nonoguchi, Takashige Kuwabara, Masashi Mukoyama. *Department of Nephrology, Kumamoto University, Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: NFAT5 is an osmoprotective transcription factor, which is crucial for cell survival under hypertonic conditions such as those encountered in the renal medulla. Physiological role of NFAT5 in the kidney, however, is still obscure. We investigated the role of NFAT5 in renal tubules using renal tubular cell-specific NFAT5-knockout (KO) mice.

Methods: We crossed NFAT5 floxed mice with Pax8-rtTA/LC-1 mice to obtain mice with inducible and specific deletion of NFAT5 in renal tubular cells. To characterize the mice, urine and blood parameters and blood pressure of wild type (WT) and KO mice were examined at basal condition. Then, WT mice and KO mice were fed either a high-salt diet (HSD) or a regular-salt diet (RSD) for 4 weeks. The mRNA expression of sodium transporter-related genes in the kidney was examined by real-time PCR. Protein expression of the epithelial sodium channel (ENaC) in the membrane fraction was examined by Western blotting. Concentrations of urea and sodium in the renal medulla were measured.

Results: Compared to WT mice, KO mice exhibited polyuria (WT vs. KO: 2.0 ± 0.08 vs. 5.2 ± 0.18 ml/day) at basal condition. The serum sodium level was increased (151.8 ± 0.78 vs. 156.6 ± 0.45 mEq/L) and the urinary sodium excretion was decreased (498.7 ± 25 vs. 368.9 ± 15 mEq/gCr) in KO mice. Interestingly, the systolic blood pressure was significantly elevated in KO mice (97.4 ± 2.4 vs.114.9 ± 1.1 mmHg). mRNA expressions of AQP2 and UT-A1, a water channel and a urea transporter, respectively, were significantly decreased, while the expressions of ENaC were increased in KO mice. There was no significant difference in the plasma renin activity or aldosterone levels. The systolic blood pressure of KO mice fed HSD was significantly elevated earlier compared to WT mice fed HSD. ENaC protein levels were increased in KO mice fed HSD compared to WT. The urea concentration was lower and the Na concentration was higher in the medulla of KO mice than those of WT mice. HSD significantly increased the medullary Na concentration, but not the urea concentration in KO mice.

Conclusions: These results suggest that NFAT5 can regulate the urine concentration and sodium reabsorption in renal tubules, which could be important for body fluid homeostasis and blood pressure regulation.

Fluid Overload, 24-Hour Blood Pressure Patterns, and Their Association with Cardiovascular and Kidney Outcomes in CKD

Ye Eun Ko,[1] Jong Hyun Jhee,[2] Tae-Hyun Yoo.[3] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Gangnam Severance Hospital, Gangnam-gu, Seoul, Republic of Korea; [3]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Fluid overload is well-known risk factor for adverse cardiovascular and kidney outcomes in chronic kidney disease (CKD) patients. However, it is unclear whether fluid overload is associated with blood pressure (BP) patterns and their relationship to adverse clinical outcomes in CKD patients.

Methods: A total of 1,147 CKD (stage 1 to 5) patients were enrolled from the prospective observational cohort of CMERC-HI (Cardiovascular and Metabolic Disease Etiology Research Center-High Risk). The patients were classified into tertile based on fluid status defined as the extracellular water to total body water ratio (ECW/TBW) measured by bioelectrical impedance analysis; hypovolemic, euvolemic, and hypervolemic groups. BP patterns were assessed by 24-h BP measurements; dipper (nighttime BP fall 10-20%), extreme dipper (nighttime BP fall >20%), non-dipper (nighttime BP fall 0-10%), and reverse dipper (nighttime BP fall <0%). Primary outcome was composite of nonfatal myocardial infarction, nonfatal stroke, and all-cause mortality. The secondary outcome was progression of CKD (composite of at least 50% decrease in eGFR> 50% from baseline or eGFR <60 ml/min/1.73 m^2, or end-stage kidney disease).

Results: The mean age of study subjects was 59.9±12.2 years and 615(53.6%) were male. The hypervolemic group was associated with increased risk of reverse-dipping pattern (OR, 2.46; 95% CI, 1.30-4.64; *P*=0.01). During a median follow-up of 42.1 (41.3-42.9) months, the composite of cardiovascular events and CKD progression occurred in 42 (3.7%) and 345 (30.1%), respectively. The Kaplan-Meier analysis showed that hypervolemic group was associated with increased risk of cardiovascular events and CKD progression compared to hypovolemic group. In multivariable Cox analyses, hypervolemic group was associated with increased risk of cardiovascular events (HR, 4.44; 95% CI, 1.16-17.0; *P*=0.03). Moreover, hypervolemic group was associated with increased risk of CKD progression (HR, 2.47; 95% CI, 1.77-3.45; *P*<0.001). This increased risks of cardiovascular events and CKD progression with hypervolemic status were still consistent in patients with reverse-dipping pattern.

Conclusions: The increased risk of cardiovascular events and kidney disease progression in CKD patients with fluid overload can be explained by an association with a reverse-dipping BP pattern.

Galectin 3 and Air Pollution in Hypertensive Patients with and Without CKD

Hafsa Tariq,[2,1] Sadeer Al-Kindi,[2,1] Mahboob Rahman,[2,1] Jackson T. Wright,[2,1] Sanjay Rajagopalan,[2,1] Mirela A. Dobre.[2,1] *[1]University Hospitals, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Background: Air pollution is a major contributor to cardiovascular and kidney complications. The mechanisms linking air pollution with cardiorenal events are not well understood. We sought to assess whether Galectin 3 level, a marker of myocardial fibrosis and remodeling is associated with air pollution exposure in hypertensive patients with and without chronic kidney disease.

Methods: Satellite-derived PM2.5 measurements were linked with participants in the Systolic Blood Pressure Intervention Trial (SPRINT, Clinicaltrials.gov NCT01206062). A total of 1019 SPRINT participants with available Galectin 3 levels at study baseline and 24 months follow-up were included in these analyses. Multivariable linear regression models, adjusted for age, sex, race, eGFR, Framingham risk score, body mass index, and randomization assignment were built to assess the association between air pollution and Galectin 3 at baseline and longitudinal change at 2 years.

Results: The mean $PM_{2.5}$ was 9.6 μg/m^3, and the median (IQR) Galectin 3 level was 14.4 (11.5-18.0) ng/mL. In multivariable models, we found no association between $PM_{2.5}$ and baseline (β=-0.02, P=0.46) or longitudinal change (β=0.05, P=0.12) in Galectin 3. In the subgroup of participants with CKD (n=201), $PM_{2.5}$ was associated with change in Galectin 3 (β=0.21, P=0.002), which remained statistically significant after multivariable adjustments (β=0.23, P=0.003). In the overall cohort (n=1019), there was a significant interaction between $PM_{2.5}$ and eGFR with change in Galectin 3 (p-value for interaction=0.02), (Figure).

Conclusions: Air pollution may be associated with worsening myocardial fibrosis as evidenced by increasing levels of Galectin 3 in individuals with preexisting CKD. Further studies are needed to corroborate these findings with rigorous cardiac imaging studies.

Diagnostic Application of NanoString Gene Scores in Transplant Biopsies with Suspicious Features of Antibody-Mediated Rejection

Jack Beadle, Frederic J. Toulza, Michelle Willicombe, Candice A. Roufosse. *Imperial College London, London, United Kingdom.*

Background: Antibody-mediated rejection (AMR) is the leading cause of renal allograft loss, a diagnosis which is reached using the Banff Classification for Allograft Pathology. Biopsies that only partially fulfil the histological criteria for AMR, those with 'incomplete phenotypes', provide a challenge for diagnosis, prognosis and management. The Banff Molecular Diagnostics Working Group has designed a 758-gene panel for use with NanoString with the aim of developing a gene transcript signature to improve the diagnosis of AMR, but this has not been validated in biopsies with features suspicious for AMR, where its use may distinguish between cases that represent AMR from those that do not.

Methods: RNA was extracted from a retrospective cohort of 147 FFPE biopsies that were divided into three groups: biopsies that fulfilled the 2019 Banff Criteria for AMR ('AMR', n=34), those that would meet the criteria for AMR only in the presence of a validated gene signature ('AMRsusp', n=41), and biopsies that showed no features of AMR ('No AMR', n=72). Gene expression analysis of 758 genes in the Banff Human Organ Transplant panel was carried out using Nanostring® analysis. Gene expression was normalised using twelve housekeeper genes and internal positive-control normalisation

Results: Of the 758 genes, 134 were significantly different (with FDR set at 0.01) in biopsies which fulfilled the full Banff Criteria for AMR, compared to biopsies without features of AMR. Lasso regression was used to define a set of 37 up-regulated genes that were strongly predictive of AMR, and used to create an AMR Gene Score. A Reciever-Operating Characteristic demonstrated that the Gene Score was able to differentiate

between AMR and No AMR Cases (AUC 0.8742 ,95% CI 0.8095-0.9388, p<0.0001) and was used to develop a gene score cut-off, maximising sensitivity and specificity. In biopsies suspicious for AMR, but which did not complete the full diagnostic criteria, a high Gene Score was predictive of allograft loss, compared to biopsies with a low gene score (p=0.0065)

Conclusions: Nanostring analysis of gene expression in FFPE biopsy samples can be used to identify biopsies suspicious for AMR that are at higher risk of allograft loss, and may have a role in characterising cases that represent AMR, even in the abscence of full diagnostic criteria.

TH-OR52

Proteomics Reveals Extracellular Matrix Injury in the Glomeruli and Tubulointerstitium of Kidney Allografts with Early Antibody-Mediated Rejection

Sergi Clotet Freixas, Caitriona M. McEvoy, Chiara Pastrello, Max Kotlyar, Madhurangi Arambewela, Alexander Boshart, Sofia Farkona, Yun Niu, Yanhong Li, Andrzej Chruscinski, Rohan John, Ana Konvalinka. *University Health Network, Toronto, ON, Canada*.

Background: Antibody-mediated rejection (AMR) accounts for >50% of kidney allograft losses. AMR is caused by donor-specific antibodies (DSA) against HLA and non-HLA antigens in the glomeruli and the tubulointerstitium, which together with interferon gamma and tumor necrosis factor-alpha (TNFα), trigger graft injury. The reasons behind cell-specific injury in AMR remain unclear. Identifying compartment-specific proteome alterations may help uncover mechanisms of early antibody-mediated injury.

Methods: We studied 30 for-cause kidney biopsies with early AMR, acute cellular rejection (ACR) or acute tubular necrosis (ATN). We laser-captured microdissected glomeruli and tubulointerstitium and subjected them to unbiased proteome analysis.

Results: We found 107 glomerular and 112 tubulointerstitial proteins significantly differentially expressed in AMR vs. ACR. Similarly, 112 (glomeruli) and 124 (tubulointerstitium) proteins were regulated in AMR vs. ATN. Basement membrane and extracellular matrix (ECM) proteins were decreased in both compartments in AMR, compared with ACR and ATN. We verified decreased glomerular and tubulointerstitial LAMC1 expression, and decreased glomerular NPHS1 and PTPRO expression in AMR. Cathepsin-V (CTSV) was predicted to cleave ECM-proteins in the AMR glomeruli. We identified galectin-1, an immunomodulatory protein upregulated in AMR glomeruli and linked to the ECM. Examination of publicly available data revealed that galectin-1 is increased at the gene level in AMR. Anti-HLA class-I significantly increased CTSV expression, and galectin-1 expression and secretion, in human glomerular endothelial cells. We also studied glutathione S-transferase omega-1 (GSTO1), an ECM-modifying enzyme, increased in the AMR tubulointerstitium. GSTO1 expression was significantly increased in TNFα-treated proximal tubular epithelial cells.

Conclusions: Basement membranes are often remodeled in chronic AMR, and we demonstrated that this remodeling begins early in glomeruli and tubulointerstitium. Targeting ECM-remodeling in AMR may represent a new therapeutic avenue.

Single-Cell Profiling Reveals Sex-Based Transcriptional Programs in Healthy Human Kidney

Caitriona M. McEvoy,[1,2] Julia M. Murphy,[1,2] Lin Zhang,[3] Jessica A. Mathews,[1] Sergi Clotet Freixas,[1] James An,[1,2] Mehran Karimzadeh,[3] Delaram Pouyabahar,[2] Shenghui Su,[1] Bo Wang,[2] Gary Bader,[2] Sarah Q. Crome,[1,2] Ana Konvalinka.[1,2] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Vector Institute, Toronto, ON, Canada*.

Background: Single-cell transcriptomics provide unprecedented insight into disease states in the kidney, yet our understanding of the transcriptional programs of human kidney cells at homeostasis is limited by difficulty accessing healthy, fresh tissue. Sex-based dichotomy in human kidney cells remains unaddressed, but may underpin acute and chronic kidney diseases e.g. progressive diabetic kidney disease and IRI which exhibit a male preponderance.

Methods: We sequenced single-cell suspensions of 19 pre-implantation living donor biopsies (9 male, 10 female)(10X Genomics). Analyses were performed with Cellranger and Seurat in R. Sex-based transcriptomic differences were examined using varimax-rotated principal component analysis, machine learning approaches and differential expression analysis.

Results: 27677 high-quality cells forming 23 clusters were identified with several immune populations and all anticipated parenchymal populations. Individual kidney populations were examined for separation due to donor sex, with clear separation observed for the PT population alone using varimax-rotated principal component analysis (Fig1a). Machine learning identified the most discriminant subset of genes (Model1: 80 genes) that could correctly classify cell sex (AUC 0.98). 75 genes were differentially expressed between males and females (p-value <0.05, LogFC>0.25). Anti-oxidant metallothionein genes were increased in females. Pathway analysis revealed metabolism-related processes (oxidative phosphorylation, and the TCA cycle) as increased in males (Fig1B).

Conclusions: We report striking sex-based transcriptional differences in PT cells, suggesting higher baseline metabolic activity in males, and increased anti-oxidant metallothionein genes in females. These sex-based differences in PT gene expression may provide insights into the well-recognized, but previously unexplained sexual dimorphism observed in kidney diseases.

Figure 1: Identifying sex-biased gene expression in proximal tubule cells. (A) Varimax rotation of PCA components shows clear separation between PT cells from males and females **(B)** Depiction of top-ranking terms identified by GSEA analysis as being enriched in males and females respectively. Abbreviations: GSEA: Gene Set Enrichment Analysis; PT, proximal tubular NES, normalized enrichment score.

Vaccination with Class-Ib MHC Binding Synthetic Superagonist and Adoptive Transfer of Antigen-Specific CD8 Tregs Prolong Cardiac Allograft Survival in Alloantigen-Sensitized Hosts

John Y. Choi,[1,2] Hye-jung Kim,[3,2] Harvey Cantor,[3,2] Jamil R. Azzi.[1,2] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Dana Farber Cancer Institute, Boston, MA.*

Background: Previously, we showed Qa-1 (HLA-E in human) restricted regulatory CD8 T cells (CD8 Treg) are highly suppressive of follicular helper T cells (Tfh), and play a critical role in suppressing donor-specific antibodies (DSA) and antibody-mediated rejection (AMR). Alloreactive CD4 T cells upregulate Qa-1 in association with stress peptides such as FL9 that are recognized by CD8 Treg. Therefore, we hypothesized that vaccinating hosts with a superagonist that mobilizes CD8 Treg, and adoptive transfer of antigen-specific CD8 Treg may protect heart allografts from antibody-mediated injury.

Methods: We used a tetramer to sort FL9-Qa-1 specific CD8 T cells and sequenced their T cell receptors (TCR). We screened over 100 peptides synthesized with FL9 backbone and identified a superagonist that induces the strongest CD8 T cell response. We also generated FL9-Qa-1 TCR Transgenic mice (FL9-Tg mice). We then sensitized B6 hosts with Balb/c skin allograft with or without vaccinating with superagonist, AND with or without transferring CD8 T cells isolated from FL9-Tg. Following the sensitization with different treatments, each group received BALB/c heart allografts and was monitored for graft survival.

Results: The superagonist induced a strong CD8 Treg response that suppresses Tfh, activated B cells, plasma cells and DSA in vivo. Allograft retrieved from the treatment group showed less C4d deposit and attenuated graft injury. The treatment group also showed prolonged allograft survival; the superagonist and the adoptive transfer showed a synergistic effect.

Conclusions: Allo-sensitized, cardiac transplantation is a stringent model in which allografts undergo a robust process of AMR. While antibody-mediated graft injury in clinical transplantation is a major barrier to long-term kidney allograft survival, we believe the graft protection using the superagonist and antigen-specific CD8 Treg is biologically significant with a high translational potential. Further investigation is needed to maximize the efficacy of CD8 Treg therapy, such as co-administration of CD8 Treg-specific co-stimulator. In addition, we are investigating the human equivalent of FL9 peptide, and examining the potential unwanted toxicity of FL9-Qa-1 specific CD8 T cells on allografts.

Sodium-Glucose Cotransporter 2 Inhibitors in Kidney Transplant Recipients

Jeong-Hoon Lim,[1] Soie Kwon,[2] Hee Won Noh,[1] Soojee Jeon,[1] Hee-Yeon Jung,[1] Ji-Young Choi,[1] Sun-Hee Park,[1] Chan-Duck Kim,[1] Yong-Lim Kim,[1] Jung Pyo Lee,[2] Jang-Hee Cho.[1] *[1]Kyungpook National University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea*.

Background: The effect and safety of sodium-glucose cotransporter 2 inhibitors (SGLT2i) have not been investigated in kidney transplant recipients (KTRs) with diabetes. We evaluated the impact of SGLT2i in a multicenter cohort of diabetic KTRs.

Methods: A total of 2083 KTRs with diabetes were enrolled from six transplant centers in Korea. Among them, 226 (10.8%) patients prescribed with SGLT2i for more than 90 days. The primary outcome was a composite outcome of all-cause mortality, death-censored graft failure, and serum creatinine doubling. An acute dip in estimated glomerular filtration rate (eGFR) over 10% was surveyed after SGLT2i use.

Results: During the mean follow-up of 62.9 ± 42.2 months, the SGLT2i group had a lower risk of primary composite outcome than the control group in the multivariate and propensity score-matched models (Figure 1; adjusted hazard ratio [aHR], 0.52; 95% confidence interval [CI], 0.29–0.94; P = 0.031 and aHR, 0.46; 95% CI, 0.24–0.89; P = 0.022, respectively). Multivariate analyses consistently showed a decreased risk of serum creatinine doubling in the SGLT2i group. The overall eGFR remained stable without the initial dip after SGLT2i use. A minority (15.6%) of the SGLT2i users showed

acute eGFR dip during the first month, but the eGFR recovered thereafter (Figure 2). The risk factors for the eGFR dip were time from transplantation to SGLT2i usage and mean tacrolimus trough level.

Conclusions: SGLT2i improved a composite of all-cause mortality, death-censored graft failure, or serum creatinine doubling in KTRs. SGLT2i can be used safely and have beneficial effects on preserving graft function in diabetic KTRs.

The Role of Combined Gene Expression Profiling and Donor-Derived Cell-Free DNA to Diagnose Acute Rejection in Patients with Acute Allograft Dysfunction

Sookhyeon Park, Kexin Guo, Lihui Zhao, John J. Friedewald. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Gene expression profiling (GEP) has been used to monitor for subclinical acute rejection. Conversely, the majority of data with donor-derived cell-free DNA (dd-cfDNA) has been in patients with allograft dysfunction. We hypothesized that combining GEP and dd-cfDNA could improve the diagnostic performance to detect acute rejection in patients with acute allograft dysfunction.

Methods: We analyzed a total of 131 blood samples paired with kidney biopsies from patients (n=96) with 'for cause' biopsies in the CTOT 08 study. Blood samples were analyzed with the GEP and the dd-cfDNA assay. The area under the receiver operating characteristics (AUROC) was used for GEP and dd-cfDNA separately based on their continuous output variables, and for combining two assays with logistic regression.

Results: Of 131 blood samples, 50 and 81 cases were biopsy-proven clinical acute rejection and acute allograft dysfunction without rejection, respectively. In binary analysis, GEP showed a lower positive predictive value (PPV) at 0.54 to 0.64 from dd-cfDNA, but a higher negative predictive value (NPV) at 0.80 to 0.70. When both tests were positive, PPV increased to 0.68 (95% CI, 0.50-0.88). In cases when both tests were negative, NPV increased to 0.88 (95% CI< 0.78-0.96) (Table 1). Performance of GEP and dd-cfDNA on detection of antibody-mediated rejection and acute cellular rejection shown in Figure 1. The combined use of two assays showed similar AUROC, to 0.75 than GEP (0.74, p-value = 0.26) and dd-cfDNA (0.72, p-value=0.69).

Conclusions: Combined GEP and dd-cfDNA assay might improve the diagnostic performance of acute rejection in patients with acute renal allograft dysfunction.

Phase 3 Study of Maribavir (MBV) vs. Investigator-Assigned Therapy (IAT) for Refractory/Resistant (R/R) Cytomegalovirus (CMV) Infection Post-Transplant: Analysis of Kidney Recipients and Renal Safety

Fuad S. Shihab,[1] Robin K. Avery,[2] Emily Blumberg,[3] Abdolreza Haririan,[4] Jingyang Wu,[5] Aimee K. Sundberg.[5] *[1]University of Utah Health Care, Salt Lake City, UT; [2]Johns Hopkins University Division of Infectious Diseases, Baltimore, MD; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]University of Maryland, Baltimore, MD; [5]Shire Human Genetic Therapies, Inc., a Takeda company, Lexington, MA.*

Background: Risk of nephrotoxicity limits antiviral use for treatment (tx) of transplant recipients with CMV infection. We report efficacy (including sub-analysis of kidney recipients) and renal safety data from a phase 3 study of MBV vs IAT in patients (pts) with R/R CMV infection (NCT02931539).

Methods: Transplant recipients (≥12y) with CMV infection (screening plasma DNA≥910IU/mL) R/R to prior tx (failure to achieve>1$\log_{10}$ decrease in CMV DNA after≥14days±genotyped resistance) were randomized 2:1 MBV (400mg BID):IAT (val/ganciclovir, foscarnet[FOS], cidofovir) for 8wks. Primary endpoint:confirmed CMV clearance at end of Wk8 (plasma DNA<137IU/mL in 2 consecutive tests≥5days apart). Key secondary endpoint:CMV clearance and symptom control at end of Wk8 maintained through Wk16. Group differences were adjusted for baseline CMV DNA level+solid organ/hematopoietic cell transplant where applicable. Subgroup analysis of kidney recipients was conducted. Tx-emergent adverse events (TEAEs) were assessed (safety set).

Results: More MBV (randomized set: 235 MBV, 117 IAT[47 FOS]) pts achieved the primary (55.7% vs 23.9% IAT; adjusted difference[AD] 32.8%, 95% CI 22.8–42.7; **p<0.001**) and key secondary endpoint (18.7% vs 10.3% IAT; AD 9.5%, 95%CI 2.0–16.9; **p=0.013**). For kidney recipients (74 MBV, 32 IAT), 59.5% MBV vs 34.4% IAT pts achieved CMV clearance (AD 26.7%, 95%CI 7.5–45.9). Rates of TEAEs were similar between MBV and IAT (**Table**). Dysgeusia was the most frequent TEAE with MBV (37.2%, IAT 3.4% pts). Tx-related TEAE of increased immunosuppressant drug level was reported in 6% pts treated with MBV (IAT 0% pts). Renal and urinary TEAE rates were lower for MBV (17.1% pts) than IAT (26.7% pts[FOS 44.7% pts]). A lower proportion of pts had tx-related acute kidney injury (AKI) with MBV (1.7%) than IAT (7.8%[FOS 19.1%]). Pts in the IAT arm discontinued tx due to AKI (5.2% [FOS 12.8%]); no pts treated with MBV discontinued tx due to renal TEAEs.

Conclusions: Maribavir was superior to IAT for achievement of clearance of R/R CMV infection among transplant recipients, with consistent benefit in kidney recipients. Rates of renal TEAEs were lower with MBV than IAT.

Living in High Minority, Less English-Proficient Communities May Facilitate Living Donor Kidney Transplantation Among Asian Americans and Pacific Islanders

Alixandra C. Killian,[1] Brittany A. Shelton,[1] Paul A. Maclennan,[1] Marshall C. Mcleod,[1] Alexis J. Carter,[1] Rhiannon D. Reed,[1] Haiyan Qu,[1] Babak J. Orandi,[1] Vineeta Kumar,[1] Deirdre L. Sawinski,[2] Jayme E. Locke.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Living donor kidney transplantation (LDKT) racial disparities have increased. Living in linguistically isolated communities or areas with large minority populations has been associated with decreased access to transplant, but LDKT recipient-donor pairs are 95% racially concordant. The contemporary relationship between LDKT access and living in high minority, less English proficient communities is unknown.

Methods: The Scientific Registry of Transplant Recipients was utilized to identify adult, kidney-only transplant recipients (1/1/2018-12/31/2018). The Minority Status and Language Theme of the Centers for Disease Control and Prevention 2018 Social Vulnerability Index was linked to recipients' zip codes. Modified Poisson regression was utilized to evaluate likelihood of LDKT.

Results: Of the 18,950 kidney transplant recipients included in this study, 32% achieved LDKT. Black (adjusted relative risk (aRR): 0.60, 95% confidence interval (CI): 0.49-0.74) and Asian American and Pacific Islander (AAPI) recipients (aRR: 0.52, 95%CI: 0.39-0.70) were less likely to receive LDKT compared to White recipients. Overall, community minority status and language proficiency was not associated with LDKT (aRR: 1.01, 95%CI: 1.00-1.02), but the effect of this vulnerability measure varied by race. Among AAPI recipients only, living in higher minority, less English proficient communities was associated with increased likelihood of LDKT (ratio of aRR: 1.66, 95%CI: 1.12-2.47; Figure 1).

Conclusions: While all minority recipients had lower likelihood of LDKT, living in higher minority, less English proficient communities may be paradoxically advantageous for AAPI patients. Given LDKT racial concordance, living in areas with shared culture or language may facilitate LDKT access among AAPI.

Modifiable Risk Factors for New-Onset Hypertension After Live Kidney Donation

Yaerim Kim,[1] Eunjeong Kang,[2] Sehoon Park,[3] Yong Chul Kim,[4] Yon Su Kim,[4] Hajeong Lee.[4] *[1]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Ewha Women's University College of Medicine and Graduate School of Medicine, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Hypertension is a common comorbidity and also a risk factor for the development of end-stage kidney disease in living kidney donors. Herein, we aimed to evaluate the impact of exposure to overweight after donation on the development of new-onset hypertension.

Methods: A total of 6,581 donors and 13,350 controls were extracted from the national health insurance database between 2001 and 2018. Subjects took national health check-up 2 times and more were included. Controls were randomly extracted after matching with age, sex, date of donation, underlying hypertension and diabetes in the general population. Exposure to overweight and obesity was defined by body mass index (BMI) ≥23 kg/m^2 and ≥25 kg/m^2 during follow-up period. Overweight/obesity status was divided into 4 groups; 1) persistently no exposure, 2) exposure at only last health check-up, 3) persistently exposure in two times of health check-up, and 4) recovered from exposure at last health check-up. We used a multivariate logistic regression model to identify risk factors for new-onset hypertension.

Results: A total of 1,642 donors and 3,655 controls were finally included in the study. During 7.3±3.2 years, there were 142 (8.6%) and 253 (6.9%) subjects newly diagnosed with hypertension, respectively. After adjusted such variables showed significance in univariate analysis, kidney donation significantly increased risk for the development of hypertension (adjusted odds ratio [aOR] 1.53, 95% confidence interval [CI] 1.21-1.93). Persistent overweight significantly increased risk for the development of hypertension (aOR 3.53, 95% CI 2.07-6.35 vs. aOR 1.69, 95% CI 1.19-2.43), whereas recovered from overweight did not increase risk (aOR 1.61, 95% CI 0.36-5.1 vs. aOR 0.87, 95% CI 0.35-1.87) in kidney donor and controls, respectively. Exposure to persistent obesity significantly increased the risk for hypertension in both groups, but recovered from obesity still increased the risk in kidney donors (aOR 2.51, 95% CI 1.03-5.45) in contrary to the control (aOR 1.60, 95% CI 0.88-2.76).

Conclusions: Both exposures to overweight or obesity increased the risk for new-onset hypertension, but recovered from overweight or obesity showed different results in donors. Physicians need to be focused on counseling for reducing the modifiable risk factor such as for overweight during the follow-up period.

TH-OR60

A Mate Kidney Analysis to Determine the Impact of Preemptive Transplantation on Outcomes of High Kidney Donor Profile Index Deceased Donor Transplants

Justin Gill,[1,3] Matthew J. Kadatz,[1,2] James H. Lan,[1,2] Doris Tung Chang,[1] John S. Gill,[1,3] Jagbir Gill.[1,3] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]Vancouver Coastal Health Research Institute, Vancouver, BC, Canada; [3]Providence Health Care, Vancouver, BC, Canada.*

Background: There is an inadequate supply of kidneys for transplant. The kidney donor profile index (KDPI) combines donor factors into a percentile that summarizes the likelihood of deceased donor transplant failure. High KDPI kidneys are frequently discarded. Pre-emptive transplantation is associated with improved patient and graft survival, but it is unknown if this benefit is preserved with high KDPI kidneys.

Methods: Using the SRTR database, N = 7,232 donors were identified where one donor kidney was transplanted pre-emptively (before the recipient required dialysis) and the other was used non-pre-emptively (after the recipient has initiated dialysis). We compared all cause graft loss (ACGL), death censored graft loss (DCGL), and death with function (DWF) between the pre-emptive and non-pre-emptive recipients using univariable and multivariable time to event analyses adjusted for differences in recipient factors.

Results: Pre-emptive transplantation was associated with improved outcomes of ACGL, DCGL, and DWF (Fig 1). These results were consistent in the subgroup where the donor KDPI was >= 91%. Furthermore, the risk of ACGL with a pre-emptive transplant from a KDPI >= 91% donor (HR: 1.65, CI: 1.51 – 1.81) was similar to the risk of ACGL from a non-pre-emptive transplant from a KDPI 51-80% donor (HR: 1.57 CI: 1-48 – 1.66) (Fig 2).

Conclusions: In this mate kidney analysis, outcomes after a pre-emptive transplant were superior compared to a non-pre-emptive transplant, even among kidneys from donors with very high KDPI. Pre-emptive transplantation of high KDPI kidneys is an opportunity to safely increase the number of kidney transplants from the limited supply of deceased donor kidneys.

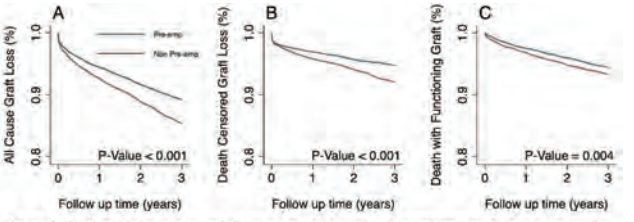

Figure 1: Kaplan-Meier curves of all cause graft loss, death censored graft loss and death with a functioning graft in a mate kidney cohort.

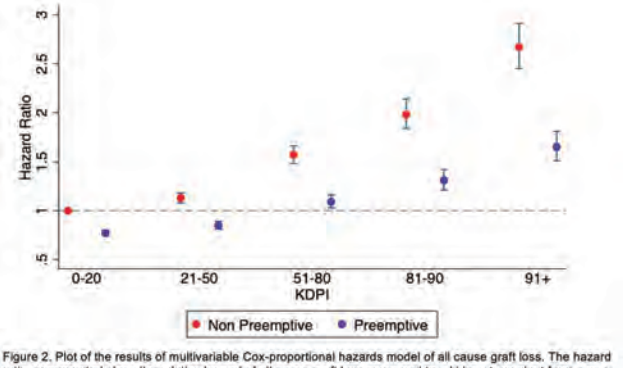

Figure 2. Plot of the results of multivariable Cox-proportional hazards model of all cause graft loss. The hazard ratios represented show the relative hazard of all cause graft loss compared to a kidney transplant from a non-pre-emptive donor with a KDPI of 0-20% (horizontal dotted line). The hazard ratios in blue represent the hazard ratio for a pre-emptive kidney transplant, while the hazard ratios in red represent the hazard ratio for a non-pre-emptive kidney transplant. The 95% confidence intervals are represented by the error bars.

Quantifying Individual-Level Uncertainty in GFR Estimation

Xiaoqian Zhu,[1] Seth Lirette,[1] Andrew D. Rule,[3] Tom Mosley,[1] Kenneth R. Butler,[1] Javed Butler,[1] Michael Hall,[1] Pradeep Vaitla,[1] James J. Wynn,[1] Neville R. Dossabhoy,[1] Eliseo Guallar,[2] Tariq Shafi.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Although the differences between estimated GFR (eGFR) and measured GFR (mGFR) are well-recognized, the magnitude and potential clinical implications of these differences at the individual level are not fully appreciated.

Methods: Using data from four US community-based cohorts with mGFR (total N=3,223), we calculated eGFR from serum creatinine alone ($eGFR_{CR}$) and cystatin and creatinine ($eGFR_{CYS-CR}$) using the CKD-EPI equations without race coefficients. Using quantile regression, we assessed eGFR's individual-level reliability by calculating a 95% prediction interval (PI), defined as the distribution of 95% of the observed mGFR values at a given eGFR. We also assessed eGFR's population-level reliability using standard metrics, including median difference (eGFR-mGFR). All GFR results are presented as ml/min/1.73m^2.

Results: The participants' median age was 61 years, 32% were Black, and 55% were female. The median mGFR was 68 (IQR, 46 to 88). At the population level, the median difference between $eGFR_{CR}$ and mGFR was small (1.4; 95% CI: 0.9 to 1.9). In contrast, the individual-level 95% PI of the $eGFR_{CR}$ was large, ranging from 53 to 120 at $eGFR_{CR}$ 90 and from 19 to 55 at $eGFR_{CR}$ 30 (Figure and Table). Substantial individual misclassification was also noted using $eGFR_{CR}$: 16% of individuals with $eGFR_{CR}$ <60 and 28% of those with $eGFR_{CR}$ <30 had mGFR above those thresholds. Results were similar for $eGFR_{CYS-CR}$.

Conclusions: A substantial individual-level discrepancy exists between eGFR and mGFR. The eGFR PI should be included with eGFR reporting. Some clinical decisions may need to be based on mGFR rather than eGFR.

Funding: Other NIH Support - NINR, NHLBI

Kidney Function Biomarkers Among American Indians (AI) and Hispanic Americans (HA)

Monica Moya Balasch, Christos Argyropoulos, Maria-Eleni Roumelioti. *University of New Mexico School of Medicine, Albuquerque, NM.*

Background: The NKF-ASN Task Force recommends that kidney function be estimated by an approach that is accurate introducing bias through racial adjustments. Use of multiple biomarkers may offer such an approach which we explored in a prospective community cohort of HA and AI in rural New Mexico.

Methods: Markers of kidney function, IDMS-Creatinine (SCr), chemiluminescence Beta-2 Microglobulin (B2M), Nephelometry-calibrated ELISA Cystatin C (CysC), inflammation, glucose tolerance, demographics, BUN/UACR from the baseline visit of the COMPASS cohort (PMID: 29486722), were analyzed by kernel-based machine learning methods.

Results: Cohort consisted of 172 individuals, 61% female, 30.2% AI, 54.7% HA, age 51.1 ± 18, SBP/BP 128 ±14.4/77.4 ± 11.5 mmHg, Height 1.7 ±0.1m, Weight 83 ± 20 kg, BUN 14±5 mg/dl, SCr 0.9 ±0.3 mg/dl, B2M 1.8 ± 0.5 mg/L, CysC 0.7 ± 0.2 mg/dl, UACR 43.8 ± 231 mg/g, hs-CRP 4.8 ± 6.7 mg/L, HbA1c ± 1.7 %. B2M was not associated with race/ethnicity/anthropometrics. CysC had the most non-kidney determinants [Table]. 75% of all log10 transformed values culustered together [Figure, yellow]. Ethnicity (p=0.02), HbA1c (p=0.03), hs-CRP (p=0.04) predicted discordance among the biomarkers (mauve).

Conclusions: Ethnicity, inflammation and diabetes increase discordance among kidney biomarkers. B2M was affected the least and should be strongly considered as a measure fulfilling the criteria for the NKF-ASN because its eGFR equation does not need adjustment for race or sex(PMID: 26362696)

Decline in Estimated Glomerular Filtration Rate (eGFR) Among Black Veterans After Removing the Race Coefficient: Results of the US Veterans Health Administration Electronic Health Records

Guofen Yan,[1] Keith C. Norris,[2] Robert Nee,[3] Julia J. Scialla,[1] Nan Hu,[4] Wei Yu,[1] Tom Greene,[5] Alfred K. Cheung.[5,6] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Walter Reed National Military Medical Center, Bethesda, MD; [4]Florida International University, Miami, FL; [5]University of Utah Health, Salt Lake City, UT; [6]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: In the US, Black Americans with CKD have faster kidney function decline than White peers. We examined whether this faster decline was also observed when the race coefficient was removed from eGFR calculation among US veterans.

Methods: eGFRs were calculated from serum creatinine measurements (excluding acute care settings) using the Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) and the CKD-EPI without the race coefficient (CKD-EPI-RACEout). We estimated eGFR slopes using quarterly averages of eGFRs for up to 8 years or until May 31, 2018 starting from the first quarter after CKD incidence (i.e., first eGFR<60 mL/min/1.73m^2 for >3 months). We used linear mixed-effects models with random intercept and slope, adjusting for age, sex, eGFR at CKD incidence, and CKD incidence year.

Results: From 2003-2017, 139,921 Black veterans had incident CKD defined by CKD-EPI-RACEout and 100,510 by CKD-EPI; and 636,598 White veterans by CKD-EPI, with median number of quarterly averages of eGFRs per patient of 8, 8, and 7, respectively. Overall, eGFR decline was greater among Blacks defined by CKD-EPI than Whites (-1.37 vs -0.84 mL/min/1.73m^2 per year, Table), consistent with prior findings. eGFR decline among Blacks by CKD-EPI-RACEout was attenuated (-1.07), but still greater than among Whites. In the two youngest groups, Blacks by CKD-EPI-RACEout still had about 2-fold larger decline versus Whites (Table).

Conclusions: Black veterans with CKD defined by eGFR without race coefficient still had faster kidney function decline following CKD incidence compared to White veterans, but the difference was attenuated. Use of eGFR without race coefficient may pick up earlier, less aggressive cases of CKD among younger Blacks and promote earlier prevention.

Funding: NIDDK Support

Slopes as eGFR decline per year (95% CI) with CKD-EPI with and without race coefficient

Race, Genetic Ancestry, and GFR Estimation: Findings from the CRIC Study

Chi-yuan Hsu,[1,4] Wei Yang,[5] Rishi V. Parikh,[4] Amanda H. Anderson,[2] Teresa K. Chen,[3] Debbie L. Cohen,[5] Jiang He,[2] Madhumita J. Mohanty,[9] James P. Lash,[6] Katherine T. Mills,[2] Anthony N. Muiru,[1] Afshin Parsa,[10] Milda R. Saunders,[11] Tariq Shafi,[7] Raymond R. Townsend,[5] Sushrut S. Waikar,[8] Jianqiao Wang,[5] Myles Wolf,[12] Thida C. Tan,[4] Harold I. Feldman,[5] Alan S. Go.[4,1]
CRIC *[1]University of California San Francisco, San Francisco, CA; [2]Tulane University, New Orleans, LA; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]Kaiser Permanente Northern California, Oakland, CA; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]University of Illinois at Chicago, Chicago, IL; [7]The University of Mississippi Medical Center, Jackson, MS; [8]Boston University School of Medicine, Boston, MA; [9]Wayne State University, Detroit, MI; [10]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [11]The University of Chicago Medicine, Chicago, IL; [12]Duke University, Durham, NC.*

Background: Inclusion of race in GFR estimating equations is undesirable. Prior studies have not examined replacing race with genetic ancestry.

Methods: We studied 1248 Chronic Renal Insufficiency Cohort (CRIC) Study participants with urinary ^{125}I-iothalamate clearance GFR (iGFR) measurements and complete data on self-reported race, genetic ancestry, serum creatinine (SCr) & cystatin C. Genotyping was conducted using the Illumina HumanOmni1-Quad v1.0 microarray. The cohort was split into development (2/3) and validation (1/3) samples. Using linear regression, we derived GFR estimating equations for iGFR using SCr or cystatin C, age, sex, and self-reported race or African ancestry. The derived equations were then applied to the validation sample. Equation performance was assessed using root mean squared error (RMSE), adjusted R^2, bias (iGFR - eGFR), and proportion of eGFR within 10% (P10) and 30% (P30) of iGFR.

Results: 539 participants were female and 458 self-identified as Black. Mean±SD age was 55.9±12.1 yr, iGFR 48±20 ml/min/1.73m^2, median [IQR] SCr was 1.5 [1.3-2.0] mg/dL, cystatin C 1.35 [1.09-1.71] mg/L. Median % African ancestry was 82.6% [74.5-88.3%] among those who self-identified as Black and 0.2% [0.1-2.0%] in those who did not. When using SCr to estimate GFR, incorporating vs omitting self-reported race yielded better performing estimates (**Table**). Incorporating genetic ancestry provided estimates of GFR similar to those incorporating self-reported race. Incorporation of race or ancestry was unnecessary when estimating GFR using cystatin C. A GFR estimating equation using cystatin C, age and sex performed comparably to an equation using SCr, age, sex, and race or ancestry.

Conclusions: Switching from SCr to cystatin C to estimate GFR yields comparably valid without needing to include either race or genetic ancestry.

Comparison of Estimated Glomerular Filtration Rate with and Without Race Adjustment on Associations with ESRD: The CRIC Study

Joshua D. Bundy,[1] Katherine T. Mills,[1] Amanda H. Anderson,[1] Wei Yang,[2] L. Lee Hamm,[3] Jing Chen,[1,3] Jiang He.[1,3] *[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Tulane University School of Medicine, New Orleans, LA.*

Background: Lower estimated glomerular filtration rate (eGFR) is strongly associated with higher risk of end-stage renal disease (ESRD). eGFR equations typically include adjustment for Black race, but this practice is controversial and the impact of its removal on associations with ESRD are unknown.

Methods: We included 3786 participants (mean age 57.8 years; 45.2% women; 41.8% Black) from the CRIC Study. ESRD was defined as initiation of dialysis or transplantation. We evaluated five CKD-EPI equations for calculating eGFR based on serum creatinine (SCr), cystatin C (CysC), and with or without race adjustment. We estimated associations and predictions of 5-year ESRD risk using Cox proportional hazards regression and the 4-variable Kidney Failure Risk Equation (KFRE), which includes age, sex, eGFR, and urinary albumin-to-creatinine ratio. Models were evaluated using measures of discrimination (AUC) and calibration (Brier score).

Results: Within 5 years after baseline, 642 participants developed ESRD and the cumulative incidence among Black and white/other participants was 22.5% and 15.4%, respectively. Across all eGFR equations, the KFRE was superior for prediction of 5-year risk of ESRD compared with eGFR alone among all participants (AUC range, 0.899-0.915 vs. 0.816-0.837 for eGFR alone; P<0.001). Among Black participants, the KFRE using creatinine-based eGFR without race adjustment improved calibration compared with the other equations (Figure).

Conclusions: The KFRE has superior discrimination for 5-year risk of ESRD compared with eGFR alone, regardless of whether race adjustment is employed. Removing the race adjustment for the creatinine-based CKD-EPI equation may improve prediction of 5-year risk of ESRD.

How Removing the Race Coefficient from eGFR Equations Impacts Racial Differences in CKD Progression Among People with HIV

Anthony N. Muiru,[1] Erin Madden,[2] Michael Shlipak,[1] Michelle M. Estrella.[1]
NA-ACCORD *[1]University of California San Francisco, San Francisco, CA; [2]Northern California Institute for Research and Education, San Francisco, CA.*

Background: The impact of removing the race coefficient from eGFR equations on racial differences in CKD progression in people with HIV (PWH) is unknown.

Methods: We included 69,125 PWH enrolled in the North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD) from Jan 1, 2005-Dec 31,2014. Baseline date was defined as the date of enrollment in NA-ACCORD or beginning of cohort eGFR observation window, whichever came last. Reported race was categorized as Black, White, or Other. We defined CKD stages in 2 ways: 1) Serum creatinine-based CKD-EPI eGFR equation, which assigns higher eGFR for Black persons; and 2) CKD-EPI eGFR without the race coefficient. We created Markov models to estimate 5-year probabilities of transitioning from the initial stage to worse CKD stages, with death as a competing event; the associations of race (Black vs White) with progression across CKD stages were evaluated.

Results: 31,298 PWH were Black, in whom baseline antiretroviral use and HIV suppression were less prevalent and hepatitis C infection, hypertension and diabetes were more prevalent compared with White participants (N=27,542). eGFR without the race coefficient reclassified 25% of Black PWH into a worse CKD stage at baseline. Those reclassified had a higher prevalence of CKD risk factors compared with Black PWH who were not reclassified. When modeled with the race coefficient, Black PWH had 23% lower risk of progressing from CKD stage 1 to 2, similar risk of progressing from stage 2 to 3 and 3-fold increased risk of progressing from stage 3 to 4, compared with White PWH. When CKD progression was modeled using race-free eGFR, Black PWH consistently had a higher risk of CKD progression compared with White PWH **(Table).**

Conclusions: Prior studies suggesting that Black PWH have lower risk than White individuals for early CKD progression but higher risk at later stages were likely biased by the race coefficient. Assigning higher kidney function for all Black individuals based on race systematically masks a subgroup of Black PWH who are at higher risk of CKD progression.

Funding: NIDDK Support

CKD progression	With Race Coefficient Hazard Ratio (95% CI)	Without Race Coefficient Hazard Ratio (95% CI)
Stage 1 to 2	0.77 (0.73,0.82)	1.26 (1.20,1.33)
Stage 2 to 3	0.99 (0.92,1.07)	1.08 (1.01,1.16)
Stage 3 to 4	2.93 (2.50,3.44)	1.61 (1.36,1.88)

Hazard ratio adjusted for calendar period (2005-2009 and 2010-2015), age, sex, History of AIDS, Hepatitis C, Diabetes, Hypertension, Cardiovascular disease, baseline viral load, and baseline eGFR.

GFR in the Era of Precision Medicine: The Importance of a Measured GFR in Onco-Nephrology

Francesco Trevisani,[1] Giulia Pegoraro,[2] Daniele Pugno,[2] Giulia Quattrini,[1] Federico Di marco,[1] Alessandra Cinque,[1] Arianna Bettiga,[1] Umberto Capitanio,[1] Andrea Salonia,[1] Giorgio Pizzagalli,[1] Francesco Montorsi.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Biorek S.R.L., Milano, Italy.*

Background: An accurate assessment of renal function in nephrological patients (pts) is of paramount importance Unfortunately, the most used method to measure GFR is represented by the estimated GFR(eGFR) which harbours a significant error in comparison to gold standards(mGFR). Aim of this study was to determine the extent of the error of eGFR compared to the mGFR in onco-nephrological pts.

Methods: A total consecutive cohort of 200 pts was collected to compare the eGFR formulas (MDRD, CKD-EPI 2012) with mGFR method(Iohexol Plasma Clearance). Cohort composition: 116 oncological pts(cases) and 84 functional diseases pts(controls) matched for baseline variables. The agreement between eGFR and mGFR was evaluated using bias, precision, accuracy, and total deviation index. The differences between cohorts were evaluated with Fisher's exact test and Chi-squared test and Wilcoxon rank sum test for continuous variables.

Results: Clinical data are reported in Table 1. The two matched cohorts displayed no statistical differences in term of clinical variables and agreement parameters(TDI, CCC and P30). Surprisingly, both groups harboured a non negligible errors in each CKD class with a huge discrepancy between the eGFR formulas and the gold standard method (Figure 1, 2), suggesting the great relevance of mGFR in the clinical decision making algorithm, both with two and one kidney.

Conclusions: The error in the classification of CKD stages using eGFR by formulas was too common in case and controls, with a poor agreement with mGFR in all CKD classes. The use of mGFR should be mandatory to obtain a tailored management in onco-nephrology.

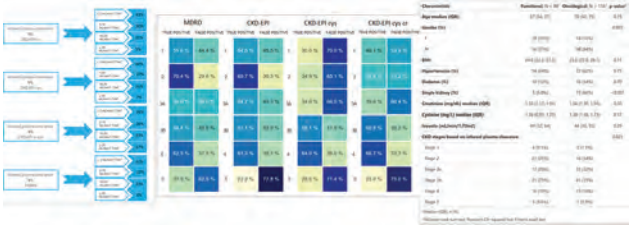

Figure on the left represent the percentages of pts with four different intervals of error. Figure on the right represent the classification of pts in CKD stages by eGFR. True positive represent subjects that were correctly classified from eGFR and false positive represent the cases that were not classified in the corresponding class. Table shows the clinical data of the population divided in two cohorts: functional and oncological pts.

TH-OR68

The Effect of Age on Performance of the Kidney Failure Risk Equation in Advanced CKD

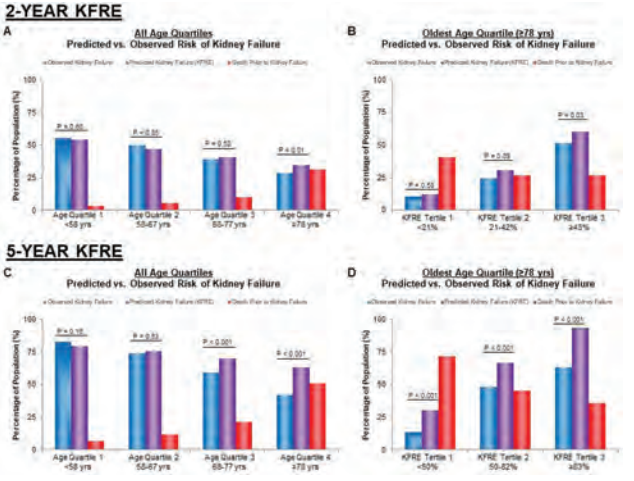
Gregory L. Hundemer,[1] Navdeep Tangri,[2] Manish M. Sood,[1] Ayub Akbari.[1] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Manitoba, Winnipeg, MB, Canada.*

Background: The Kidney Failure Risk Equation (KFRE) is a validated clinical tool used to predict progression from CKD to kidney failure. Concerns over risk overestimation have been raised with prediction models, such as the KFRE, where death is not treated as a competing event. Herein, we evaluated the effect of age (with which the competing risk of death would be anticipated to increase) on KFRE performance in advanced CKD.

Methods: All patients referred to the advanced CKD clinic at the Ottawa Hospital from 2010-2018 were divided into age quartiles: <58, 58-67, 68-77, and ≥78 years. Predicted vs observed rates of kidney failure were compared over 2- and 5-years. Predictive performance of the KFRE was determined by ROC curves (discrimination) and calibration plots. Cumulative incidence of kidney failure was compared between models that accounted for the competing risk of death and those that did not.

Results: The mean (SD) age and eGFR were 66 (15) years and 17 (6) mL/min/1.73m^2. The median (IQR) 2- and 5-year KFRE scores were 41% (22-64%) and 81% (55-96%), respectively. The KFRE overestimated the risk of kidney failure among the oldest age quartile (≥78 years) with absolute differences of 5.8% (P=0.01) and 21.6% (P<0.001) between predicted and observed risks over 2- and 5-years, respectively. The 2-year KFRE discrimination was reduced among patients ≥78 years compared with patients 58-67 years (P=0.03) and 68-77 years (P=0.03) though the difference was non-significant when compared with patients <58 years (P=0.06). The KFRE displayed adequate calibration across all age quartiles. The cumulative incidence of kidney failure was overestimated in models that did not account for the competing risk of death and this overestimation was more prominent with older age.

Conclusions: In older patients with advanced CKD at high risk of kidney failure, the KFRE overestimates risk and this overestimation relates to the increasing competing risk of death with older age.



TH-OR69

A Prediction Equation for Incident CKD Using Routinely Collected Data: The Kidney Disease Risk Equation (KDRE)

Manish M. Sood,[1] Stephanie Dixon,[2] Emily Rhodes.[1,2] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Institute for clinical and evaluative sciences, London, ON, Canada.*

Background: The identification of individuals at risk for incident CKD (eGFR < 60 ml/min, stage 3a) is an important first step for disease surveillance, monitoring, education and allocation of key therapies to reduce CKD progression. Despite recommendations, albuminuria measurements in appropriate individuals remains poor. As such, we set out to develop and validate a prediction equation for new onset CKD with and without an albumin creatine ratio (ACR).

Methods: Population-level administrative data cohort of 1,109,905 adults (>66 years old) from Ontario, Canada April 1, 2008 and December 31, 2017 with a minimum of 2 eGFR measures (one for baseline > 70 ml/min, one for outcome) were included. Prediction equations stratifying individuals with (n=191,690) and without (n=998,825) ACR were derived, internally validated by bootstrapping and externally validated in 122,144 (22,809 ACR, 99,335 non-ACR) individuals in Manitoba, Canada. The study outcome was a single eGFR measure < 60 mls/min/1.73 m^2 with up to 10 years follow-up. In additional analyses, we examined two eGFR measures < 60 mls/min and a single eGFR < 45 ml/min as study outcomes.

Results: Among individuals (54.5% women, mean age 64 SD 7, mean baseline eGFR 82 SD 8, median ACR 1 IQR 1-3), an eGFR < 60 ml/min occurred in 37.2% during the follow-up. The final model including up to 6 variables (age, sex, baseline eGFR, hemoglobin, time from hypertension and diabetes mellitus diagnosis) yielded a 5-year c-statistics of 0.77 (no ACR) and 0.78 (with ACR) with excellent calibration. Model performance was similar in additional analyses and in an external validation.

Conclusions: An equation incorporating readily available and routinely collected administrative data variables can accurately predict the onset of CKD with or without ACR.

TH-OR70

Tubular Secretion of Creatinine and Clinical Outcomes: The AASK Trial

Pranav S. Garimella,[1] Kevin M. Cummins,[3] Jennifer J. Gassman,[2] Francis B. Gabbai,[1] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]Cleveland Clinic, Cleveland, OH; [3]California State University Fullerton, Fullerton, CA.*

Background: Tubular secretion is a critical kidney function that is not routinely assessed. We evaluated the association of tubular secretion of creatinine calculated using the difference between either measured glomerular filtration rate (mGFR) or estimated GFR (eGFR) and 24-hour urine creatinine clearance (CrCl) with long-term clinical outcomes.

Methods: This prospective analysis of the African American Study of Kidney Disease (AASK) included 999 participants with baseline measures of iothalamate mGFR, creatinine based eGFR and 24-hour urine CrCl. Tubular secretion of creatinine was calculated in two ways as the difference between 1) CrCl and mGFR (mTS_{cr}); and 2) CrCl and eGFR (eTS_{cr}). The associations between mTS_{cr} and eTS_{cr} with incident end-stage kidney disease (ESKD) and cardiovascular disease (CVD) and all-cause mortality were evaluated using Cox regression.

Results: At baseline, the mean mGFR was 45.3 ml/min/1.73 m^2, and the mean CrCl was 49.3 ml/min/1.73 m^2. The mean (SD) mTS_{cr} and eTS_{cr} were 4.0 (14) and 6.5 (14) ml/min/1.73/m^2 respectively. Over 4.2 years of follow up there were 149 ESKD, 82 all-cause mortality, and 132 incident CVD events. Each 10 ml higher mTS_{cr} (HR 0.73, 95% CI 0.58-0.93) and each 10 ml higher eTS_{cr} (HR 0.59, 95% CI 0.44, 0.79) were associated with lower risk of ESKD, after adjustment for mGFR or eGFR, proteinuria, and other potential confounding factors (Table). Associations between mTS_{cr} or eTS_{cr} with lower risk of all-cause mortality or CVD events were not detected.

Conclusions: eTScr provides a measure of creatinine secretion similar to mTScr and is strongly associated with risk of ESKD, independent of GFR, proteinuria, or other risk factors. This allows for the incorporation of eTScr into epidemiological studies which may not have collected mGFR.

Role of Off-Target Ferrochelatase Inhibition in Vemurafenib Nephrotoxicity

Josie A. Silvaroli, Ji Young Kim, Navjot Singh P. Pabla. *The Ohio State University, Columbus, OH*.

Background: Complications linked with both cancer and anti-cancer therapeutics can trigger kidney injury. For targeted anti-cancer therapeutics, nephrotoxicity may occur because of on- or off- target mechanisms. In melanoma and other cancers with BRAF kinase activating mutations, targeted small molecule therapeutics such as vemurafenib, and dabrafenib have shown remarkable clinical benefits. However, recent clinical studies have shown that a significant number of patients that receive vemurafenib develop AKI through mechanisms that remain unknown. Here we have developed cell culture and murine models of vemurafenib nephrotoxicity to understand the causal mechanisms.

Methods: We established a murine model of vemurafenib toxicity through oral administration of 20 mg/kg vemurafenib in C57B6/J mice. We confirmed kidney damage and toxicity in these mice through measurement of blood urea nitrogen, serum creatinine, histological analysis, and TUNEL staining. Using the GGT-Cre strain we have also generated BRAF conditional knockout mice. To understand the role of ferrochelatase we used a hydrodynamic siRNA injection approach or heterozygous (+/fch) mutant mice. Control and gene knockout mice were treated with vemurafenib to examine the role of BRAF and FECH in vemurafenib nephrotoxicity.

Results: We found that BRAF gene deletion in tubular epithelial cells had no influence on vemurafenib-associated AKI. Instead, we found that inhibition of ferrochelatase (FECH), an enzyme involved in heme biosynthesis contributes to vemurafenib nephrotoxicity. FECH overexpression mitigated and conversely FECH knockdown increased the sensitivity to vemurafenib nephrotoxicity.

Conclusions: In the present study, we demonstrate that the mechanism for vemurafenib nephrotoxicity is not through the BRAF kinase inhibition, but instead occurs through off-target inhibition of FECH. Furthermore, these findings suggest that along with vemurafenib, other drugs that inhibit FECH activity might cause nephrotoxicity. Together, the present study describes the development of novel experimental models of vemurafenib nephrotoxicity and reveals the underlying off-target mechanisms that contribute to renal injury.

Kidney Tubule Polyploidization Is an Evolutionary Conserved Mechanism Required to Survive AKI

Letizia De Chiara,[1] Carolina Conte,[1] Maria Lucia Angelotti,[1] Giulia Antonelli,[1] Anna J. Peired,[1] Maria elena Melica,[1] Benedetta Mazzinghi,[2] Laura Lasagni,[1] Elena Lazzeri,[1] Paola Romagnani.[1,2] *[1]Universita degli Studi di Firenze, Firenze, Italy; [2]Azienda Ospedaliero Universitaria Meyer, Firenze, Italy*.

Background: Acute Kidney Injury (AKI) is characterized by a rapid deterioration of kidney function. Recently, we showed that tubular epithelial cells (TEC) respond to AKI by triggering polyploidy, a condition in which a normally diploid cell acquires additional sets of chromosomes. Polyploidy offers several advantages, but in the kidney the biological significance of polyploidization remains unclear. In this study we hypothesized that polyploidy 1) is the predominant cellular response during AKI and 2) is an adaptive stress response required to maintain a residual kidney function to assure survival.

Methods: To address these hypotheses, we employed in vivo transgenic models based on the Confetti reporter and the Fluorescence Ubiquitin Cell Cycle Indicator (FUCCI) technology in combination with YAP1 downregulation. Mice were subjected to unilateral ischemia reperfusion injury (IRI) or glycerol-induced rhabdomyolysis to induce AKI. Polyploid cells have been then characterized by single cell-RNA sequencing analysis, cell sorting, FACS analysis, super-resolution and transmission electron microscopy.

Results: After AKI, YAP1 is activated driving TEC polyploidization. Polyploid TEC increase in parallel to massive cell death triggered by AKI suggesting that polyploidization could be a means to escape cell death. Indeed, we found that polyploid TEC tend to accumulate genome instability and survive, while diploid TEC do not. Of note, virtually all dying cells were cycling cells based on the FUCCI reporter suggesting that TEC death occurred during the S or G2/M phase. As polyploid TEC increase immediately following AKI, they may be required to survive injury and damage by sustaining renal function. In order to evaluate the functional role of polyploid cells during AKI, we generated YAP1*ko* mice, where YAP1 is knocked-out specifically in TEC. Indeed, after AKI, YAP1*ko* mice showed a reduced number of polyploid cells, worsened kidney function and a dramatic reduction of mouse survival, proving that polyploidization is required to survive AKI.

Conclusions: In conclusion, we demonstrated that after AKI: 1) TEC accumulate genome instability and die or become polyploidy; 2) TEC polyploidy is essential to preserve residual kidney function allowing survival.

FR-OR03

Single-Cell and Spatial Transcriptomics Reveal Distinct Subpopulations of Kidney Resident Macrophages in AKI

Matthew D. Cheung, Elise Erman, Jeremie M. Lever, Anupam Agarwal, James F. George. *The University of Alabama at Birmingham, Birmingham, AL*.

Background: Macrophages are important in renal homeostasis and the response to acute kidney injury (AKI). Kidney resident macrophages (KRMs) are a unique, self-renewing $F4/80^{Hi}CD11b^{Int}$ population that originate from the fetal yolk sac and fetal liver during embryogenesis. Preliminary data suggests that the KRM population consists of a number of undescribed subpopulations with distinct functions, but the transcriptional signatures and spatial organization of these subsets in the kidney tissue remain unknown. Here, we combined scRNAseq and spatial transcriptomics to identify and localize KRM subpopulations during homeostasis and injury.

Methods: Fluorescence activated cell sorting was used to isolate KRMs from C57BL/6J mice without treatment and at one and six days after bilateral ischemia-reperfusion injury (BIRI). Single-cell RNA sequencing was performed using the 10X Genomics platform. For spatial transcriptomics, kidney sections were placed on 10X Visium Spatial Gene Expression slides, imaged, and then sequenced. scRNAseq and spatial gene expression data were integrated and analyzed using the R package, Seurat 4.0.

Results: UMAP plots of integrated data from injured and control mice revealed 6 major clusters of KRMs with unique transcriptional profiles. Spatial transcriptomics revealed that these clusters reside in distinct cellular compartments within the kidney. Following IRI, these subpopulations appear in cellular compartments distinct from those occupied in the controls. Gene ontology analysis (Biologic Process) indicated that the largest subpopulations changing location expressed transcripts associated with locomotion and chemotaxis. It also indicated that the transcriptomic profiles of each subpopulation were associated with distinct functions.

Conclusions: Transcriptionally distinct subpopulations of KRMs reside within specific kidney microenvironments and change location as a function of injury. Gene expression data suggests that they are physically migrating from one compartment to another. This indicates that resident macrophages in the kidney are not static with respect to transcriptional profiles and location. Therefore, further study of the temporal and spatial characteristics and signaling pathways of these subpopulations in the context of homeostasis and injury is warranted.

Proximal Tubule Pannexin 1 Channel Regulates Mitochondrial Function and Cell Death During AKI

Nabin Poudel, Nataliya Skrypnyk, Shuqiu Zheng, Christopher B. Medina, Eibhlin Goggins, Diane L. Rosin, Kodi S. Ravichandran, Mark D. Okusa. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Pannexin 1 (Panx1) channel serves as a conduit for release of small metabolites upon activation during cellular stress and injury. We have previously shown that pharmacological inhibition or genetic deletion of *Panx1* in mice prior to injury is protective against renal ischemia-reperfusion injury (IRI). How Panx1 contributes to acute kidney injury (AKI) is unknown. We hypothesized that Panx1 induces cell death by mediating both intracellular and extracellular events.

Methods: We performed IRI or cisplatin-induced AKI in a novel human Panx1 overexpressing mouse (*hPANX1*-Tg) and in proximal tubule specific Panx1 overexpressing mice (*hPANX1-Tg*^{PTEC}) and assessed plasma creatinine, renal expression of neutrophil gelatin associated lipocalin (*Ngal*), and acute tubular necrosis scoring. We challenged *PANX1* overexpressing murine proximal tubule-derived TKPTS cells with cisplatin and assessed cell death and mitochondrial changes. We next assessed the changes in mitochondria of kidneys from cisplatin challenged *hPANX1-Tg* animals.

Results: *hPANX1-Tg* mice had significant rise in plasma creatinine and expression of *Ngal* in the kidneys in both models of AKI compared to their littermate controls. Proximal tubule specific overexpression of hPANX1 also resulted in overt injury following IRI or cisplatin-induced AKI compared to littermate controls. *In vitro* studies showed that overexpression of PANX1 in TKPTS cells resulted in significantly higher cell death compared to controls during cisplatin challenge, which was associated with reduced mitochondrial biogenesis, mitochondrial function, increased mitochondrial ROS production, and altered mitochondrial quality control. Assessment of mitochondria in kidneys showed a significant reduction in Drp1 levels in kidneys from *hPANX1-Tg animals* compared to littermate controls after cisplatin challenge.

Conclusions: PANX1 overexpression results in overt renal injury during AKI that is in part mediated by reduced mitochondrial function and quality control in proximal tubules that facilitates proximal tubule cell death. These results provide strong rationale for the development of selective strategies to inhibit Panx1 in the prevention or treatment of AKI.

The Long Noncoding RNA GSTM3P1 Is Induced to Exacerbate Ischemic AKI by Antagonizing MicroRNA-668

Qingqing Wei, Jiliang Zhou, Zheng Dong. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: Long non-coding RNAs (lncRNAs) are a group of epigenetic regulators that may play important roles in kidney diseases, but the specific LncRNAs involved and the underlying mechanisms are poorly understood. We recently unveiled miR-668 as a potent protective microRNA in ischemic AKI (Wei Q et al. J Clin Invest 128:5448, 2018). By deep sequencing of mir-668-induced silencing complex, we have identified GSTM3P1, a lncRNA, as a potential interactor and regulator of mir-668.

Methods: The expression of GSTM3P1 and its mouse homologue gstm2-ps1 were examined in hypoxia-treated HK2 cells and in mouse kidneys after ischemic AKI. GSTM3P1 was overexpressed in renal cells for functional examination. Proximal tubule-specific gstm2-ps1 knockout mouse model was established to test its role in ischemic AKI in vivo.

Results: GSTM3P1/gstm2-ps1 was markedly induced in the early phase of ischemic AKI models both in vitro and in vivo. In HK2 cells, qPCR indicated a significant increase of GSTM3P1 at 3 hours after 1% O_2 treatment. In C57BL/6 mice, gstm2-ps1 was significantly induced in kidneys after 30 minutes of ischemia and 3 hours of reperfusion, which was also accompanied with the suppression of mir-668. In vitro, overexpression of GSTM3P1 led to more renal proximal tubular cell death after ATP depletion. GSTM3P1 overexpression in HEK cells caused significant decrease of the mature form of mir-668. A mir-668 binding site in GSTM3P1 was also confirmed by luciferase assay. We further generated kidney proximal tubule-specific gstm2-ps1 knockout (KO) mouse model. Compared to wild type littermates (WT), the conditional gstm2-ps1 KO mice were significantly protected from renal ischemia-reperfusion injury. Both blood urea nitrogen level [268.18±47.97 mg/dL (WT) vs 174.42±28.65 mg/dL (KO)] and the serum creatinine level [2.45±0.36 mg/dL (WT) vs 1.41±0.27 mg/dL (KO)] were remarkably decreased. Consistently, renal tubular damage and apoptosis were significantly suppressed in KO kidneys. KO kidneys also had lower tubular NGAL.

Conclusions: These results indicate that GSTM3P1/gstm2-ps1 is induced in ischemic AKI, and following induction it mediates tubular cell injury and death by interacting and antagonizing mir-668.

Novel Immune Checkpoint Molecule TIGIT Is Upregulated on Kidney CD4 T Cells and Mediates AKI in Mice

Sanjeev Noel, Kyungho Lee, Sepideh Gharaie, Johanna T. Kurzhagen, Hamid Rabb. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: T cells play important roles in acute kidney injury (AKI) but the molecular mechanisms are largely unknown. Our unbiased RNAseq analysis initially demonstrated increased mRNA expression of novel immune checkpoint molecule T cell immunoreceptor with Ig and ITIM domains (TIGIT) on kidney CD4 T cells after AKI. Here, we validated TIGIT expression on kidney T cells at protein level and investigated its effect on kidney T cell activation, function and AKI outcome.

Methods: C57BL/6J wild type (WT) mice underwent bilateral ischemia reperfusion (IR). TIGIT expression and effect on kidney T cell activation and cytokine expression was studied at baseline and after IR injury by flow cytometry in WT mice. TIGIT knockout (TIGIT KO) mice were used to assess effects on AKI. Human kidney at baseline and post ischemia for nephrectomy had CD4 TIGIT measured by flow cytometry.

Results: TIGIT expression increased significantly ($p<0.001$) on CD4 T cells in post IR kidneys compared to controls (15.0±1.5% vs 3.8±0.2%). Furthermore, TIGIT+ CD4 T cells from WT kidneys showed significantly increased expression of activation markers, CD25 (10.9±1.7% vs 2.4±0.2%, $p<0.001$), CD69 (14.5±1.4% vs 8.8±1.0%, $p<0.01$) and CD44 (93.9±1.5% vs 74.5±1.7%, $p<0.001$) compared to TIGIT- CD4 T cells. Intracellular cytokine analysis showed significantly increased IFNγ (50.4±3.4% vs 20.3±3.3%, $p<0.001$) and TNFα (55.7±5.0% vs 35.4±4.9%, $p<0.02$) expression by TIGIT+ CD4 T cells compared to TIGIT- CD4 T cell after IR injury in WT mice. TIGIT KO mice had significantly reduced SCr at 24h (2.1±0.2 vs 2.6±0.1 mg/dL; $p=0.03$) and 72h (1.3±0.3 vs 2.7±0.4 mg/dL; $p=0.02$) post IR compared to WT mice. At baseline, TIGIT KO mouse kidneys had significantly ($p=0.03$) reduced CD4 T cells compared to WT kidneys (59.2±1.7% vs 54.0±0.5%). CD4 T cells from ischemic human kidney had increased TIGIT expression compared to non-ischemic kidney (236.5±127.9 vs 24.75±19.4; $p=0.15$).

Conclusions: These data show that TIGIT expression increases on kidney CD4 T cells after ischemia in mice and humans. This correlates with increased CD4 activation and proinflammatory phenotype. Importantly, absence of TIGIT in mice reduced kidney dysfunction after AKI. TIGIT is a promising novel therapeutic target for AKI therapy and could also mediate other immune mediated kidney diseases.

FR-OR07

Compartment-Specific Role of Retinoic Acid Receptor Activation in AKI

Mark P. de Caestecker,[1] Min Yang,[1] Lauren N. Lopez,[2] Rachel Delgado,[1] Maya Brewer,[1] Leslie S. Gewin,[1] Haichun Yang.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California Davis, Davis, CA.*

Background: Retinoic acid receptors (RARs) are activated in proximal tubules (PT), collecting duct (CD), and renal macrophages (Møs) after ischemia reperfusion AKI (IR-AKI), and systemic RAR inactivation increases Mø-dependent injury after IR-AKI. However, the functional roles of RAR activation in different cellular compartments are unknown.

Methods: RARE-LacZ (RAR reporter); PEPCK-CRE; R26R-Dominant Negative RAR (PT-DNRAR); AQP2-CRE; DNRAR (CD-DNRAR); LysM-CRE; DN-RAR (Mø-DNRAR) underwent bilateral IR- and/or rhabdomyolysis-AKI (rhabdo-AKI). Injury and RARE-LacZ localization were evaluated by BUN, LacZ staining and IF. Renal Mø activation determined by FACS; primary PTEC proliferation and metabolic activity using Seahorse.

Results: RARs are more widely activated after rhabdo- vs. IR-AKI: ~90% in LTL or Kim1+ PTECs; ~5% in AQP2+ CD; ~2-3% in F4/80+ Møs; and <2% in THP1+ thick ascending limb. To evaluate RAR function, we performed IR- and rhabdo-AKI in PT-, CD- and Mø-DNRAR mice. AKI was less severe in PT-DNRAR mice: day 3 BUN in CRE- vs. +; rhabdo-AKI: 52.9 (11.2) vs. 29.1 (1.8); IR-AKI: 71.7 (8.8) vs. 38.4 (8.3) mg/dl, $p<0.005$. In contrast, Mø-DNRAR had more severe injury: IR-AKI, day 3 BUN CRE- vs. + 37.0 (2.9) vs. 63.1 (10.6), $p<0.05$. There was no difference in IR- or rhabdo-AKI severity in CD-DNRAR mice. Despite decreased injury, there was increased Kim1 and F4/80+ Møs after AKI, associated with decreased MLKL (necrosis) and increased Sox9 and Ki67 (de-differentiation and repair) in PT-DNRAR mice. FACS also showed decreased Ly6C inflammatory renal Møs after AKI. Uninjured PT-DN-RAR mice also had patchy increase in Kim1/Sox9+ PTECs; increased F4/80+ CD206+ reparative Møs; and PTECs from PT-DNRAR CRE+ mice were more metabolically active and proliferative than CRE- mice.

Conclusions: Inhibition of RAR in PTs protects against AKI by increasing reparative, metabolically active PTECs, and suppresses Mø activation, while inhibition of RAR in Møs exacerbates AKI. In contrast, inhibition of RARs in CDs does not affect the severity of injury. These findings indicate that RAR activation in different cellular compartments exert opposing effects on the severity AKI through distinct mechanisms, and provides the first evidence that dedifferentiated and inflammatory PTECs, recently described molecular signatures of failed repair, may be protective in AKI.

FR-OR08

Gasdermin D-Deficient Mice Are Hypersensitive to Necroptosis-Mediated AKI

Wulf Tonnus,[1] Alexia Belavgeni,[1] Francesca Maremonti,[1] Anne von Mässenhausen,[1] Jan U. Becker,[2] Christian Hugo,[1] Andreas Linkermann.[1] AG Linkermann *[1]Technische Universitat Dresden, Dresden, Germany; [2]Universitat zu Koln, Koln, Germany*.

Background: Within the last decade, a central role for regulated necrosis (RN) in the pathophysiology of renal ischemia/reperfusion injury (IRI) has been established. RN is an umbrella term for several RN subtypes. With respect to the kidney, necroptosis and ferroptosis are the best studied pathways. However, the role of pyroptosis, a highly inflammatory RN type dependent on the protein GSDMD (gasdermin D), during IRI remains unclear.

Methods: Acute kidney injury was induced by IRI or cisplatin application in wild type and GSDMD-ko mice. Furthermore, GSDMD/GSDME-dko mice were utilized in these models to broaden the biological understandings. Mechanistically, MLKL/GSDMD-dko mice (deficient for both necroptosis and pyroptosis) were generated and tested as l. Additionally, immunohistochemistry in murine and human kidney samples as well as experimental work in freshly isolated murine kidney tubules and cell culture were performed.

Results: We investigated gasdermin D- and gasdermin E-deficient mice in a well-established model of moderate IRI. Both strains showed more severe AKI than matched wildtypes as demonstrated by higher levels of serum creatinine and urea as well as more severe tubular damage. This effect was neither dependent on increased tubular cell death as measured by LDH release from freshly isolated murine tubules nor on increased infiltration by $CD3^+$ or $CD68^+$ cells. Based on previous studies, we speculated that pyroptosis-deficiency might promote necroptosis during AKI. To test this hypothesis, we generated MLKL/GSDMD-dko. In IRI, co-deletion of MLKL ameliorated the effects of pyroptosis-deficiency and led to reduced levels of serum creatinine and urea as well as reduced tubular damage compared to both wildtype and pyroptosis-deficient mice. Furthermore, we investigated whether this interaction of pyroptosis and necroptosis is transferable to other forms of AKI by utilizing cisplatin-induced tubular injury as a second model. Again, pyroptosis-deficient mice were more sensitive to AKI and could be protected by co-deletion of MLKL.

Conclusions: In summary, Gasdermin D and E appear to have protective roles in murine AKI as they help to reduce MLKL-mediated necroptosis. Our data are in striking contrast to previously published data (Miao et al., Kidney International 2019).

FR-OR09

ZFP24 Drives Sox9 Upregulation During AKI

Ji Young Kim, Josie A. Silvaroli, Navjot Singh P. Pabla. *The Ohio State University, Columbus, OH.*

Background: Sox9 is a member of the Sox family of transcription factors that have essential roles in cell-fate determination. In the normal adult kidneys, Sox9 expression is very low. During AKI, Sox9 is transcriptionally upregulated. Functionally, Sox9 plays a cytoprotective role during the early phase of AKI and facilitates repair during the recovery phase. Interestingly, the identify of transcription factor(s) that drive Sox9 upregulation during AKI remains unknown. Zinc finger protein ZFP24 belongs to the superfamily of SCAN-domain containing transcription factors. Outside the nervous system, ZFP24 is expressed in several tissues such as kidney, liver, heart, and spleen. However, its role in the kidney or its contribution to transcriptional regulation of Sox9 remains unknown.

Methods: To identify upstream transcriptional regulators of Sox9, we used RNAi mediated silencing of transcription factors and related genes (siRNA libraries from Dharmacon and Sigma, ~1900 genes) in BUMPT cells, followed by high-throughput-qPCR based examination of stress-induced (cisplatin) Sox9 gene induction. The primary and secondary screens in BUMPT and HK-2 cells identified ZFP24 as the key Sox9 regulatory gene. We then generated a conditional knockout mouse by crossing ZFP24 floxed mice with GGT1-Cre mice. The severity of renal injury (bilateral ischemia and cisplatin nephrotoxicity) was monitored in control and knockout littermates through measurement of blood urea nitrogen, serum creatinine, histological analysis, and biomarker analysis. To test promoter binding, we performed ZFP24 chromatin immunoprecipitation studies in renal tissues. Sox9 and its target gene upregulation was also monitored through qPCR and western blot analysis.

Results: We found that ZFP24 gene deletion in tubular epithelial cells increases the severity of ischemia and cisplatin-associated AKI. Importantly, ZFP24 gene ablation significantly suppresses injury induced Sox9 upregulation in tubular epithelial cells. Chromatin immunoprecipitation studies also demonstrated direct binding of ZFP24 to the Sox9 promoter region.

Conclusions: In the present study, we demonstrate that the transcription factor ZFP24 drives injury induced Sox9 upregulation. These studies establish ZFP24 as a critical regulator of kidney injury and recovery.

Cysteine Catabolism Is a Central Player in Diet-Induced Renal Stress-Resistance

Felix C. Koehler,[1,2] Chun-Yu Fu,[1] Martin R. Späth,[1,2] Karla J. Hoyer-Allo,[1,2] Katrin Bohl,[2] Heike Goebel,[1] Jan-Wilm Lackmann,[2] Franziska Grundmann,[1] Thomas Osterholt,[1] Claas Gloistein,[1] Joachim D. Steiner,[1,3] Adam Antebi,[3] Thomas Benzing,[1,2] Bernhard Schermer,[1,2] Volker R. Burst,[1] Roman-Ulrich Mueller.[1,2] *[1]Universitat zu Koln, Koln, Germany; [2]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany; [3]Max-Planck-Institut fur Biologie des Alterns, Koln, Germany.*

Background: Caloric restriction (CR) protects from acute kidney injury (AKI) in rodents. Translation of CR to the clinic is complex. Novel targeted dietary regimens modulating the dietary composition of macro- and micronutrients promise similar protective effects and increased translatability.

Methods: Six targeted dietary preconditioning protocols - fasting mimicking diet (FMD), ketogenic diet (KD), dietary restriction of branched chain amino acids (BCAA), SR80/100, two dietary regimens restricting sulfur containing amino acids (SAA) by 80 percent (SR80) or entirely (SR100), and CR - were systematically examined in a murine model of renal ischemia-reperfusion injury (IRI) to quantify diet-induced kidney protection. Shared mechanisms of dietary achieved renal resilience were deciphered using targeted metabolite and proteome profiling and confirmed in a human cohort of cardiac surgery patients adhering to a low-SAA diet.

Results: FMD, SR80/100 and CR efficiently protected from IRI-induced AKI quantified by kidney function, tissue damage and survival rates in mice. Preconditioning with KD yielded moderate benefits after IRI, whereas BCAA failed to protect from renal ischemic damage. Targeted metabolite and proteome profiling revealed overlapping changes in oxidative and hydrogen sulfide (H_2S)-dependent cysteine catabolism as a pivotal mechanism of kidney protection in response to FMD, SR80/100 and CR identifying sulfite as its central component. These diet-induced metabolic adaptions were confirmed in humans consuming a low-SAA diet.

Conclusions: FMD, SR80/100 and CR protect from IRI-induced AKI and show common metabolic patterns regarding cysteine catabolism. Importantly, these metabolic changes can be recapitulated in patients undergoing a low-SAA diet indicating a conserved metabolic response. Since FMD and low-SAA diets are feasible in humans our findings provide an important outlook towards novel protective strategies in the patient setting.

Deep Learning Uncovers Clinical Subphenotypes of Diabetic Kidney Disease Driven by Genetic Variation in Rac1 Pathway

Ishan Paranjpe, Xuan Wang, Nanditha Anandakrishnan, Weibin Zhou, Evren U. Azeloglu, John C. He, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Although diabetic kidney disease (DKD) is a leading cause of end stage renal disease, therapeutic development targeting causal pathways has been limited by disease heterogeneity. Integration of clinical data and genomics may uncover hidden DKD subphenotypes.

Methods: DKD patients from the Mount Sinai Bio*Me* Biobank were included. Using laboratory measurements, vitals, and clinical notes in a deep leaning framework (Fig 1 A,B) we performed unsupervised clustering, accounting for population structure. We then performed a genome wide association study comparing patients in each cluster with healthy controls.

Results: We identified two clusters (Fig 1C), M (mild, N = 972) and S (severe, N = 390). Cluster M had greater ESKD prevalence (16% vs 5%; p <0.001) and higher baseline serum creatinine (1.2 vs 1.1; p<0.001). Using exome sequencing, a missense variant in *ARHGEF18*, rs117824875, was significantly associated with DKD in cluster S, but not cluster M (OR = 7.7; $p = 9.56x10^{-8}$). This variant was also associated with DKD in an external cohort, UK Biobank (OR = 2.4, p =0.044). *ARHGEF18* knockdown in a diabetic zebrafish model induced whole body edema (Fig 1D). Stable overexpression of the rs117824875 mutant *ARHGEF18* transcript in a human podocyte cell line led to decreased cell viability (Fig 1E), actin cytoskeleton reorganization (Fig 1F) and induced *RhoA* and *Rac1* activation (Fig 1G). Mutant *ARHGEF18* transcripts exhibited slower ubiquitin mediated degradation (Fig 1H).

Conclusions: Integration of electronic health records with exome sequencing using deep learning uncovered DKD heterogeneity driven by a gain of function variant in *ARHGEF18. ARHGEF18* knockdown caused kidney failure in a zebrafish model. Mutant *ARHGEF18* was resistant to degradation and activated the *Rac1* pathway, suggesting pharmacological inhibition of *ARHGEF18* may be a therapeutic target by preventing *Rac1*mediated podocyte damage (Fig 1I).

Identifying Diabetic Kidney Disease Signatures in the Nuclei of the Tubular Epithelium Using a Novel Deep Learning Approach

Seth Winfree, Daria Barwinska, Niloy Talukder, Michael T. Eadon, Pierre C. Dagher, Mohammad A. Hasan, Tarek M. El-Achkar. KPMP *Indiana University School of Medicine, Indianapolis, IN*.

Background: Diabetic nephropathy (DN), a leading cause of end stage kidney disease (ESKD) is generally viewed as a glomerular disease. However, progression of DN towards ESKD correlates best with tubular pathology and fibrosis. Due to the spatial complexity of the human kidney, which includes many cell types, it is a challenge to capture the biology at the single cell level. While there is a growing body of information on the molecular phenotype of DN at the single cell level using omics approaches on dissociated tissue, there is little information on cellular changes in intact kidney tissue.

Methods: We used a 3D nuclei image-based deep learning approach to uncover spatially resolved single cell signatures of DN. 3D Imaging datasets were collected from fluorescently labeled human reference nephrectomy samples and biopsies from patients with DN. Using Volumetric Tissue Exploration and Analysis (VTEA) and cell-type markers, a 3D nuclei image dataset was generated from reference nephrectomies and used to train a custom Convolutional Neural Network (CNN). A second 3D nuclei image dataset was generated from images of biopsies taken from patients with DN and classified with the trained CNN.

Results: We generated a 3D nuclei image library from DN tissue secured from the NIDDK/Kidney Precision Medicine Project. We used our nuclei-based CNN classification of renal cells to uncover unique classes of renal epithelium and identify novel single cell image-based signature in DN. Using VTEA, we were able to spatially localize these novel classes of renal epithelium and assess correlation with injury and renal structures for a spatially resolved 3D nuclei image-based signature of DN.

Conclusions: Our work demonstrates that 3D nuclei images from renal cells allows for the identification of DN signatures. These data further suggest that in addition to glomeruli, the tubular epithelium plays a role in DN. Our work underlines the potential of using machine learning and deep learning approaches to automatically uncover new cell types which may emerge due to changes occurring in diabetes, while maintaining their spatial context. Thus, our work can provide insight into the cellular changes in intact kidney tissue during progression in DN.

Multi-Omics Identifies CERS6 and C16:0 Ceramide in Podocytes as Novel Therapeutic Targets for Diabetic Kidney Disease

Guanshi Zhang,[1,2] Dusan Velickovic,[3] Annapurna Pamreddy,[1] Viji Nair,[4] Blue Lake,[5] Manjeri A. Venkatachalam,[1] Matthias Kretzler,[4] Christopher R. Anderton,[1,3] Theodore Alexandrov,[5,6] Kumar Sharma.[1,2] for the KPMP Consortium *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX; [3]Pacific Northwest National Laboratory, Richland, WA; [4]University of Michigan, Ann Arbor, MI; [5]University of California San Diego, La Jolla, CA; [6]European Molecular Biology Laboratory, Heidelberg, Germany*.

Background: Dysregulated renal ceramide (Cer)/sphingomyelin (SM) metabolism has been reported in human and animal models of diabetic kidney disease (DKD). However, there have been limited investigations in understanding the roles of Cer/SM in the pathogenesis of podocyte dysfunction. To understand the role of sphingolipid metabolism in normal and diabetic kidneys, we integrated matrix-assisted laser desorption/ionization-mass spectrometry imaging (MALDI-MSI) data to single nucleus Droplet-based sequencing (snDrop-Seq) and single-cell RNA sequencing (scRNA-Seq) data for a network analysis of a tabulated list of 48 Cer/SM metabolism-related gene/enzymes.

Methods: Two MALDI-MSI platforms (QE-HFX and FTICR) were employed to characterize the lipid profile in normal human kidney tissues (n = 6; U. Michigan) *in situ* (spatial resolution: 20-30 μm). Same tissues were also processed by snDrop-Seq analysis for multi-omics data integration. To compare kidney scRNA-Seq profiles between DKD patients and healthy controls, patient kidney biopsies (n = 44) from an early DKD cohort were collected and 18 living donor (LD) biopsies were used as reference healthy tissues.

Results: Among 30 different cell types identified by snDrop-seq, we found that *CERS6* was specifically expressed in podocytes of the normal human kidney. Fluorescence microscopy analysis showed that CERS6 protein is co-localized with synaptopodin (a podocyte marker). In addition, MALDI-MSI data showed that the downstream C16:0 ceramide of CERS6 was specifically enriched in podocytes of normal human kidney biopsy tissues. scRNA-seq data of kidney biopsy tissues from LD controls and DKD patients showed that *CERS6* gene was exclusively enriched in podocytes of normal human kidney biopsies (LD), while no *CERS6* expression was detected in DKD biopsies, suggesting the potential role of CERS6 in regulating kidney functions.

Conclusions: This highlights the value of kidney atlas for healthy and diseased kidneys on the single cell levels of genes and metabolites in the kidney precision medicine. Multi-omics techniques could help identify novel therapeutic targets for different types of kidney diseases.

Integrated Multi-Omics Reveal the Complexity of TGF-β Signalling to Chromatin in Induced Pluripotent Stem Cell-Derived Kidney Organoids

Jessica L. Davis, Ciarán Kennedy, Shane Clerkin, Niall Treacy, Alison A. Murphy, Catherine Moss, Darrell C. Andrews, Thomas K. Dodd, John Crean. Crean lab *University College Dublin Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland.*

Background: Critical pathological features of diabetic kidney disease are now accepted to include dysregulation of epigenetic processes as evidenced by the observed differential methylation in patients with or without progressive disease. TGFβ resides at the centre of therapeutic approaches for the treatment of renal fibrosis, but few intervention studies have demonstrated clinical efficacy. Recently, we demonstrated a novel direct interaction between Smad3 and EZH2, the enzymatic component of the polycomb repressive complex 2 (PRC2) during cell fate specification.

Methods: Using the 10X Genomics platform, we performed single cell RNA-seq and -ATAC-seq on human iPSC-derived kidney organoids treated with the EZH2 inhibitor, GSK343, for 1 hour prior to treatment with TGFβ1 for 48 hours.

Results: Single cell RNA-seq analysis revealed that TGFβ1 treated organoids exhibited a similar fibrotic response to what is observed in human diabetic kidneys. Furthermore, TGFβ1 induced the differentiation of resident stromal cells into activated myofibroblasts, and this was accompanied by the upregulation of fibrotic genes such as α-smooth muscle actin and transgelin, consistent to what is observed *in vivo*. Single cell ATAC-seq of iPSC-derived kidney organoids treated with TGFβ1 revealed that TGFβ increases chromatin accessibility at all promoters, DNase I hypersensitive, and transcription start sites in all cell types present within the organoid. Furthermore, TGFβ1 increased chromatin accessibility at some enhancers and this was cell-type dependent. We have shown that pre-treatment with EZH2 inhibitor, GSK343, prevents TGFβ mediated increase in chromatin accessibility and inhibits the expression of the fibrotic marker, α-smooth muscle actin.

Conclusions: We propose that that the enzymatic function of the polycomb repressive complex is necessary for TGFβ1 induced increase in chromatin accessibility and its subsequent gene regulatory functions. Understanding the exact nature of how TGFβ cooperates with epigenetic complexes at the chromatin level will allow for a more comprehensive understanding of how changes in cell fate occur in developmental and pathological contexts. Manipulation of the association between Smad3 and EZH2 may be a useful therapeutic strategy for the resolution of renal fibrosis.

Spatial Mapping of Murine Diabetic Kidney Disease (DKD) Transcriptomics at Single-Cell Resolution

Eugene Myshkin,[1] Haojia Wu,[2] Savithri B. Kota,[1] Eryn E. Dixon,[2] Romer A. Gonzalez-Villalobos,[1] Thomas A. Natoli,[1] Dermot F. Reilly,[1] Benjamin D. Humphreys,[2] Maria chiara Magnone,[1] Matthew D. Breyer.[1] *[1]Janssen Research and Development LLC, Boston, MA; [2]Washington University in St Louis, St Louis, MO*.

Background: DKD is the major cause of kidney failure in the USA, yet the molecular pathogenesis of DKD and the spatial distribution of the transcriptomic response to injury is poorly characterized. Single cell RNA sequencing and cell clustering has been used on a limited basis in DKD to explore distinct cell-type transcriptomic responses. Here we applied *Multiplexed error-robust fluorescence in situ hybridization* (MERFISH) to anatomically validate snRNAseq cell clustering in diabetic mouse kidney.

Methods: MERFISH was used to localize a panel of 260 cell selective markers derived from single nuclear RNAseq clustering in frozen kidney sections from 3 murine models: C57BLKS db/m, db/db LacZ and db/db Renin-AAV.

Results: Each section contained ~100,000 cells. Single-cell gene expression profiling and cell identification by MERFISH allowed us to map the spatial organization of 11 major cell types: PTS1, PTS3, EC, DCT, Podo, DTL, injPT, PC, mTAL, cTAL, and fibroblasts. Podocyte cluster transcripts Cdkn1c, Dendrin, Sema3g, and EphA6 were specifically expressed in glomeruli and EphA6 and Sema3g were significantly increased in diabetes. Top PTS1 markers including Ppara, Slc7a9 and Slc5a2 exhibited superficial cortical localization whereas PTS3 markers Slc22a19, Acox2 and Kcnc3 were in the cortical/medullary region. Myh11 selectively labled JGA while Nos1 marked the macula densa. Endothelial (EC) markers including Egfl7, Cdh5, Ehd3, Plxnd1, Pi16, EphB4, exhibited distinct anatomic expression, with Ehd3 most highly expressed in glomeruli (**figure**), while Cdh5 and Plvap were low to absent in glomeruli and rather predominated in peri-tubular interstitium.

Conclusions: This application of MERFISH single cell spatial transcriptomics to murine diabetic kidney identified nephron specific cell clusters and confirmed anatomically separate gene expression patterns in PT and EC subpopulations.

Set7 Lysine Methyltransferase Influences Endothelial to Mesenchymal Transition in Experimental Diabetic Nephropathy

Assam El-Osta.[1,2] Human Epigenetics *[1]Epigenetics in Human Health and Disease Laboratory, Department of Diabetes, Central Clinical School, Monash University, Melbourne, VIC, Australia; [2]Department of Medicine and Therapeutics, The Chinese University of Hong Kong (CUHK), Hong Kong Institute of Diabetes and Obesity, CUHK, Li Ka Shing Institute of Health Sciences, CUHK, School of Biomedical Sciences, CUHK, Hong Kong SAR., Sha Tin, Hong Kong.*

Background: Diabetic nephropathy (DN) is the number one cause of renal failure with therapeutic options to prevent its progression limited. In response to hyperglycaemia, the lysine methyltransferase Set7 is known to regulate inflammation and fibrosis, however, its role in DN remains poorly understood. This study defines unique endothelial to mesenchymal transition in experimental diabetic nephropathy.

Methods: Set7$^{-/-}$ constitutive knockout mice were back crossed with ApoE$^{-/-}$ to accelerate DN. Streptozotocin (STZ) administration was used to induce diabetes with subsequent renal injury in Set7$^{-/-}$ApoE$^{-/-}$ mice over five consecutive days (referred now as diabetic Set7KO). Single cell RNA-seq (scRNA-seq) was used to identify the major renal cell types modified by hyperglycaemia. The selective inhibitor of the Set7 methyltransferase, PFI-2, was used to determine the generalizability in human proximal tubule cells (PTC), glomerular endothelial (GEN) and podocyte (PDC) cells.

Results: Diabetic Set7KO mice had improved urinary albumin excretion and glomerular pathology. Assessments of the transcriptome revealed endothelial-to-mesenchymal transition was predictive of diabetic injury using scRNA-seq. Gene expression changes dependent on Set7 regulation were identified in PTC, GEN, PDC and mesenchymal (MSC) cells. Network analyses of diabetic renal injury identified pathways dependent on Set7 involve respiratory electron transport (RET), rRNA processing, extracellular matrix organisation (EMO) and peroxisome proliferator activated receptor alpha (PPARa). Because scRNA-seq identified GEN, PDC and PTC populations as major cell types regulated by Set7 involved in diabetic injury, we extended studies to hyperglycaemic human renal cells using PFI-2, a pharmacological Set7 inhibitor. Pathways associated with diabetic injury in mice which are improved by genetic Set7 deletion closely correspond with Set7 inhibition using PFI-2 in human PTC, GEN and podocyte cells.

Conclusions: These findings support the rationale of targeting Set7 activity as a strategy for developing reno-protective therapies in diabetes. Our studies also show the MSC gene markers upregulated by diabetes in mice were attenuated in human GEN cells by PFI-2 and implicate Set7 in endothelial to mesenchymal transition.

PTEN-Induced Kinase 1 Exerts a Protective Effect in Diabetic Tubulopathy by Attenuating Necroptosis

So-young Lee, Min ji Sung, Hyeyun Jeong, Yu ho Lee, Hyun-Ju An, Ha Min Heui, Song Hee Lim. *CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea.*

Background: Mitochondria are cell generators that are critical to cell metabolism, survival, and homeostasis. Necroptosis, a programmed form of cell death mimicking features of apoptosis and necrosis, has emerging significance in various human disease. PTEN-induced serin/threonine kinase 1 (PINK1) is one of the core organizer of mitochondria quality control and contributes to mitochondrial homeostasis. We designed this study to explore the relationship of PINK1 and tubular cell necroptosis under high glucose conditions and investigate its effects on the progression of diabetic kidney disease.

Methods: Diabetes was induced with streptozotocin (STZ, 50mg/kg i.p. for 5 days) in male PINK1$^{+/+}$ and PINK$^{-/-}$ mice. Human renal proximal tubular epithelial cells (hRPTCs, HKC8) were subjected to low or high-glucose conditions (5mM, or 30mM D-glucose). PINK1-overexpressed (OE) HKC8 and primary renal tubular epithelial cells from kidneys of PINK1$^{+/+}$ and PINK$^{-/-}$ mice were used.

Results: PINK1$^{-/-}$ mice developed severer diabetic tubulopathy accompanied with much more albuminuria than PINK1$^{+/+}$ mice after induction of diabetes using STZ injection. More inflammatory and profibrotic cytokines were produced in the kidneys of diabetic PINK1$^{-/-}$ mice, eventually culminating in aggravated interstitial fibrosis. Dysmorphic and fissional mitochondria increased in the renal tubular cells of diabetic PINK$^{-/-}$ mice and lower levels of mitochondrial ROS and increased mitophagy were observed in PINK1 OE HKC8. We found that upregulation of PINK1 reduced necroptosis of renal tubular cells under high glucose conditions and mitigated the expressions of profibrotic markers. However, PINK1 deficiency was associated with amplified mitochondrial ROS production, exacerbated expressions of necroptosis regulator proteins, and profibrotic markers in hRPECs. Inhibitor of necroptosis and antioxidant attenuated the expressions of profibrotic and inflammatory proteins in HKC8 during treatment with high glucose media.

Conclusions: Our data suggest that PINK1 has roles in suppression of tubular cell necroptosis under high glucose conditions and exerts a protective effect in diabetic tubulopathy.

RTNA1 Mediates the Diabetic Kidney Disease Progression Through Endoplasmic Reticulum (ER) Mitochondrial Contacts in Renal Tubular Epithelial Cells

Fang Zhong,[1] Kyung Lee,[1] John C. He.[1,2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]James J Peters VA Medical Center, New York, NY.*

Background: Renal tubular epithelial cell (RTEC) injury contributes to kidney fibrosis and the progression of diabetic kidney disease (DKD), but the major risk factors contributing to RTEC injury in early DKD remain unclear. We previously showed that expression of reticulon 1A (RTN1A), an ER-associated protein, increases in RTEC in human and mice with DKD and contributes RTEC injury in vitro and in vivo through activation of ER stress. Here, we will further dissect the role and mechanism of RTA1A in RTEC injury in early DKD.

Methods: To assess the RTEC-specific role of RTN1A in the progression of DKD, we generated transgenic mice with tetracycline-inducible, RTEC-specific RTN1A overexpression (Pax8-rtTA;TRE-RTN1A). To assess the role of RTN1A in tubular injury in the setting of DKD, diabetes was induced in 8-week old transgenic mice with low-dose injections of streptozotocin (STZ). Also, we crossed the Pax8-RTN1A mice with diabetic OVE26. To delineate the molecular mechanisms of RTN1A-induced RTEC injury, we examined the RTN1A-interacting proteins by mass spectrometry. The role of RTN1A in regulation of ER-mitochondrial contacts (EMC) was assessed by measurement of both mitochondrial function and ER stress markers in the cultured RTEC and mice with RTN1A overexpression.

Results: We found that increased RTN1A expression in the RTEC induced significantly tubule-interstitial fibrosis and decline of renal function in both STZ and OVE26 diabetic mice with early DKD. We also demonstrated in vitro that RTN1A interacted with several mitochondrial proteins and RTN1A was enriched in the EMC. We showed that RTN1A overexpression in RTECs not only worsens ER stress but also induces mitochondrial dysfunction in RTEC in vitro and in vivo. As a novel mechnanism, we demonstrated that RTN1A interacts with mitochondrial hexokinase-1 (HK1) and competing for its interaction with voltage-dependent anion channel-1 (VDAC1). Disengagement of VDAC1 from HK1 subsequently results in the activation of apoptosis and inflammasome pathways, leading to RTEC injury and loss.

Conclusions: Our findings highlight the previously unrecognized role of ER-mitochondrial crosstalk in RTEC injury and progression of DKD and the importance of RTN1A-mediated EMC regulation in DKD pathogenesis.

Advanced Light Sheet Microscopy and 3D Image Analyses of Kidney Injury, Glomerulosclerosis, and Fibrosis in a Mouse Model of Diabetic Kidney Disease

Mette V. Østergaard, Urmas Roostalu, Stine T. Bak, Jacob L. Skytte, Niels Vrang, Jacob Hecksher-Sørensen. *Gubra Aps, Horsholm, Denmark.*

Background: Development of novel therapies for diabetic kidney disease (DKD) and other glomerulopathies is challenged by poor translatability of preclinical animal models. Novel biomarkers are sought to close this translational gap. Using 3D imaging techniques and advanced image analyses, we aimed to develop a method for quantification of kidney injury and fibrosis in a preclinical mouse model of progressive DKD.

Methods: Kidneys from hypertensive uninephrectomized db/db mice (reninAAV UNx db/db) and healthy controls were fixed and processed for whole-mount immunohistochemistry and light sheet microscopy (LSM) to assess and quantify tubular injury by KIM-1, and fibrosis and glomerulosclerosis by tenascin in the intact kidney. Using 3D image analysis, the distribution and intensity of KIM-1 and tenascin were determined. To correlate 3D imaging endpoints with DKD severity, kidney fibrosis and injury was characterized using standard methodologies including 2D histology.

Results: In reninAAV UNx db/db mice, tenascin was present in glomeruli as showed by its overlap with podocin. A sub-population of glomeruli with augmented tenascin intensity, but with no overlap of podocin was identified indicating that these glomeruli have global glomerulosclerosis and loss of podocytes. Tubulointerstitial tenascin was limited. These findings correlated with traditional histopathological assessment of glomerulosclerosis scoring and fibrosis quantification in PAS and collagen 3 stained kidney section, respectively. KIM-1 positive tubuli were also visualized in intact kidneys from reninAAV UNx db/db mice and showed a heterogenous pattern across the kidney.

KIM-1 was clearly localized to the proximal tubules and was also present in parietal cells in a subpopulation of glomeruli. These observations correlated with 2D IHC stains of KIM-1. Kidneys from healthy controls were KIM-1 negative in both 3D and 2D.

Conclusions: Development of advanced microscopy and 3D imaging technologies allows for assessment of kidney fibrosis and injury in the intact mouse kidney. Thereby, this 3D imaging technique can be used to support functional and 2D histological readouts in mouse models to improve their translatability in the study of disease mechanisms and drug discovery for DKD.

FR-OR20

Long Noncoding RNA lncMGC Mediates TGF-β-Induced Effects Related to Diabetic Kidney Disease via Nucleosome Remodeling Factors

Mitsuo Kato, Maryam Abdollahi, Sadhan Das, Zhuo Chen, Linda L. Lanting, Mei P. Wang, Rama Natarajan. *Arthur Riggs Diabetes & Metabolism Research Institute, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: microRNAs (miRNAs) and long noncoding RNAs (lncRNAs) play key roles in diabetic kidney disease (DKD). miR-379 megacluster of miRNAs and its host transcript lncMGC (lnc-megacluster) are regulated by transforming growth factor-β (TGFβ), increased in glomeruli of diabetic mice and promote features of early DKD. However, biochemical functions of lncMGC are unknown. Here we screened lncMGC-interacting proteins by in vitro-transcribed lncMGC RNA-pull down followed by mass spectrometry (MS). We also created lncMGC knockout (KO) mice by CRISPR-Cas9 editing and used mouse mesangial cells (MMC) from the KO mice to examine the effects of lncMGC on gene expression related to DKD, changes in promoter histone modifications and chromatin remodeling.

Methods: In vitro transcribed lncMGC RNA was mixed with lysates from HK2 cells (human kidney cell line). lncMGC interacting proteins were identified by MS. Candidate proteins were confirmed by RNA immunoprecipitation (RIP) and qPCR. Cas9 and guide RNAs were injected into mouse eggs to create lncMGC-KO mice. Wild type (WT) and lncMGC-KO MMC were treated with TGF-β and RNA expression (by RNA-seq and qPCR) and histone modifications (by chromatin immunoprecipitation) and chromatin remodeling/ open chromatin (by Assay for Transposase-Accessible Chromatin, ATAC-seq) were examined.

Results: Several nucleosome remodeling factors including SMARCA5 and SMARCC2 were identified as lncMGC interacting proteins by MS, and confirmed by RIP-qPCR. MMC from lncMGC-KO mice showed no basal or TGF-β-induced expression of lncMGC. Interestingly, several miRNAs in the miR-379 cluster were also reduced in lncMGC-KO MMC compared to WT MMC. Enrichment of histone H3K27 acetylation and SMARCA5 at the lncMGC promoter was increased in TGF-β-treated WT MMC but significantly reduced in lncMGC-KO MMC. ATAC peaks at the lncMGC promoter region as well as many other loci including *Col1a2*, *Col4a3*, *Col4a4* and *CTGF* were significantly lower in lncMGC-KO MMC than WT MMC.

Conclusions: lncMGC RNA interacts with several nucleosome remodeling factors to promote chromatin relaxation and enhance the expression of lncMGC itself and other genes including pro-fibrotic genes. Its epigenetic regulation in target kidney cells may contribute to DKD pathogenesis.

Impact of Medicare Bundled Dialysis Payment on Regional Racial Disparities in Home Dialysis Utilization

Virginia Wang,[1,2] Lindsay Zepel,[2] Cynthia Coffman,[1,2] Clarissa J. Diamantidis,[1,2] Sarah H. Scholle,[3] Matthew L. Maciejewski.[1,2] *[1]Durham VA Medical Center, Durham VA Medical Center, Durham, NC, US, hospital, Durham, NC; [2]Duke University, Durham, NC; [3]National Committee for Quality Assurance, Washington, DC.*

Background: The 2011 Medicare prospective payment system (PPS) for dialysis modestly increased access to home-based peritoneal dialysis (PD) and home hemodialysis (HHD) treatment modalities. To examine whether racial disparities in home dialysis use (PD and HHD) were affected, we compared regional change in home dialysis use by White and non-White dialysis patients over time.

Methods: We conducted a retrospective cohort study of dialysis facilities offering home dialysis to 1,098,579 patients with end-stage kidney disease (ESKD) in 2006-2016. Health care region was defined as hospital referral regions (HRR). Patients of non-Hispanic Black/African American, Hispanic, non-Hispanic Asian or Pacific Islander, or other race/ethnicity were grouped into a general category of non-White due to small numbers of home dialysis patients and small samples in some HRRs. For each HRR-year, we computed home dialysis utilization rates for White patients by dividing counts of home dialysis users by White users of any dialysis modality. We repeated this procedure to compute rates for non-White patients, and compared these rates using a generalized estimating equation (GEE) model with a negative binomial distribution, adjusting for regional ESKD provider and patient characteristics.

Results: The mean number of facilities offering home dialysis in each HRR increased from 15.6 in 2006 to 22.1 in 2016, with for-profit ownership (79.8% in 2006, 87.1% in 2016) and chain affiliation (82.3% in 2006, 91.7% in 2016) increasing over time. While average regional home dialysis utilization rates increased over time, disparities persisted with White patients having consistently higher home dialysis utilization than non-Whites in every year (19.5% vs. 12.9% in 2006, 26.2% vs. 17.8% in 2016, on average across HRRs). In adjusted analysis, region-level home dialysis use was one-third lower among non-White patients compared to White patients. Home dialysis disparities did not change following the 2011 Medicare payment reform (incidence rate ratio (IRR)=0.97, 95% CI=0.92, 1.02; p=0.29).

Conclusions: Racial disparities in home dialysis use persist after Medicare payment reform despite modest increases in dialysis facility availability and patient utilization. Targeted policy efforts are needed to reduce disparities in the use of home dialysis.

Real-World Analysis of Timing of Dialysis Transition and Mortality in a Nationally Representative Cohort of Advanced CKD Patients

Yoko Narasaki,[1] Connie Rhee,[1] Amy S. You,[1] Csaba P. Kovesdy,[2] Dana B. Mukamel,[1] Susan T. Crowley,[3,4] Alejandra Novoa-Vargas,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Yale University School of Medicine, New Haven, CT; [4]Veterans Health Administration, Washington, DC.*

Background: While there is substantial variation in the timing of the dialysis initiation in advanced CKD patients transitioning to ESRD, large population-based studies have observed a trend towards earlier dialysis transition over time. We sought to conduct a real-world analysis of the impact of timing of dialysis transition on mortality rates in a nationally representative cohort of advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days).

Methods: In advanced CKD patients transitioning to dialysis over 1/1/07-6/30/20, we examined the impact of timing of dialysis transition (defined by eGFR at the time of dialysis initiation) on mortality rates. Patients were identified from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were granularly categorized according to novel time-intervals of dialysis transition, defined as CKD stages 4B, 4C, 5A, 5B, and 5C (eGFRs 20-<25, 15-<20, 10-<15, 5-<10, and <5 at the time of dialysis transition, respectively). Poisson regression was used to compare mortality rates across exposure groups.

Results: Among 97,320 advanced CKD patients who transitioned to dialysis, 6%, 11%, 31%, 43%, and 9% initiated treatment at CKD stages 4B, 4C, 5A, 5B, and 5C. Patients who underwent incrementally earlier dialysis transitions experienced increasingly higher raw mortality rates: 118, 128, 141, 155, and 164 deaths per 1000 person-yrs for CKD stages 5C, 5B, 4C, and 4B. A similar trend was observed for Poisson model-based mortality rates in the overall cohort, as well as raw and model-based mortality rates stratified by age (<65 vs. ≥65 yrs).

Conclusions: In a real-world analysis of a nationally representative US cohort, incrementally earlier dialysis transitions demonstrated increasingly higher mortality rates. Further studies are needed to identify strategies optimizing survival in advanced CKD patients transitioning to dialysis.

Associations of Local Area Deprivation Index with Outcomes During the First Year of Maintenance Dialysis

Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1] Kirsten L. Johansen.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Clinical outcomes among patients undergoing maintenance dialysis are typically ascribed to non-modifiable patient characteristics and treatments. However, outcomes may be highly influenced by local socioeconomic conditions. We assessed whether the Area Deprivation Index (ADI), a composite measure of income, education, employment, and housing quality within 9-digit ZIP Code areas, is associated with the incidence of death and kidney transplantation during the first year of maintenance dialysis.

Methods: We analyzed United States Renal Data System Standard Analysis Files. The cohort included patients who initiated outpatient dialysis in 2014-2017; we retained patients with a 9-digit ZIP Code of residence, according to the Medicare Enrollment Database, as that code facilitated linkage to the ADI. Patients were followed from the initiation of outpatient dialysis to the earlier of death or kidney transplantation; patients were censored after one year of follow-up. We fit Cox models of death and kidney transplantation, including ADI decile (higher = more disadvantaged) and adjustment for age, sex, race/ethnicity, primary cause of end stage kidney disease, comorbidity, and dialysis modality.

Results: The cohort included 381,623 patients. Over 14% of patients resided in 9-digit ZIP Codes in the highest ADI decile. ADI deciles were linearly associated with adjusted hazards of death and kidney transplantation (table). The highest versus lowest ADI decile was associated with 20% higher rate of death and 72% lower rate of transplantation.

Conclusions: Increasing socioeconomic disadvantage in the local area was associated with higher rates of death and markedly lower rates of transplantation during the first year of dialysis.

Funding: NIDDK Support

	AHR of death	AHR of kidney transplant
ADI decile 1	1.00 (referent)	1.00 (referent)
ADI decile 2	1.01 (0.97-1.05)	0.83 (0.75-0.93)
ADI decile 3	1.04 (1.00-1.08)	0.77 (0.69-0.85)
ADI decile 4	1.06 (1.02-1.10)	0.73 (0.66-0.81)
ADI decile 5	1.09 (1.05-1.13)	0.70 (0.63-0.78)
ADI decile 6	1.10 (1.06-1.15)	0.57 (0.51-0.63)
ADI decile 7	1.12 (1.08-1.16)	0.50 (0.44-0.56)
ADI decile 8	1.14 (1.09-1.18)	0.42 (0.37-0.47)
ADI decile 9	1.18 (1.14-1.23)	0.38 (0.34-0.43)
ADI decile 10	1.20 (1.16-1.25)	0.28 (0.25-0.32)

Abbreviations: ADI, area deprivation index; AHR, adjusted hazard ratio.

Ultrafiltration Rate and Mortality in Hemodialysis: The Dialysis Outcomes and Practice Patterns Study (DOPPS)

Erin Flanagin,[1] Marcelo Lopes,[2] Keith McCullough,[2] Daniel E. Weiner,[1] Friedrich K. Port,[2] John Hartman,[6] Steven M. Brunelli,[3] Elke Schaeffner,[4] Kosaku Nitta,[5] Almudena Vega,[7] Eric W. Young,[2] Bruce M. Robinson.[2] *[1]Tufts Medical Center, Boston, MA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Davita Clinical Research, Minneapolis, MN; [4]Charite Universitatsmedizin Berlin, Berlin, Germany; [5]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [6]Visonex, Green Bay, WI; [7]Hospital General Universitario Gregorio Maranon, Madrid, Spain.*

Background: Fluid management is an essential component of hemodialysis (HD) practice. Both insufficient fluid removal and rapid ultrafiltration rate (UFR) are associated with higher cardiovascular and all-cause mortality risk, particularly in US populations, but it is uncertain whether adhering to a single UFR limit will mitigate this risk.

Methods: This retrospective cohort study includes 47,640 adult in-center HD patients from phases 4-6 of DOPPS (2009-2018) from the US, Japan, Australia, New Zealand, Russia, 7 European and 6 GCC countries. Mean UFR was calculated over one week occurring during the first four-month DOPPS data collection interval. Follow-up for all-cause mortality began after this interval. Risk was estimated using Cox models adjusting for DOPPS phase, country, years on dialysis, age, sex, race, 7 comorbidities, body mass index (BMI), catheter use, 5 labs, Kt/V, residual urine volume, and pre-HD session systolic BP.

Results: Mean UFR for the entire cohort was 8.3 (SD 3.8) ml/hr/kg and median follow up time was 1.3 (IQR 0.7-2.3) years. In adjusted analyses, compared to patients with mean UFR of 7 to <10 ml/hr/kg, those with higher UFR had greater risk of mortality: HR 1.09 (95% CI 1.03-1.17) for UFR 10 to <13 ml/hr/kg, HR 1.21 (1.09-1.33) for UFR of 13 to <15 ml/hr/kg, and HR 1.38 (1.24-1.55) for UFR >15 ml/hr/kg). Higher UFR was associated with a greater mortality risk for patients with higher weight or BMI (p-value <0.001 for both). DOPPS region did not modify the relationship between UFR and mortality despite differences in patient characteristics and HD practices across regions (p-value 0.67).

Conclusions: In a large international cohort, higher mean UFR, was associated with an increased risk of mortality. Patients with higher weight or BMI have a greater mortality risk from higher UFR, suggesting that a single UFR threshold to identify risk may not be equally beneficial for all patients.

Outcomes and Predictors Associated with Skin Sodium Concentration in Dialysis Patients

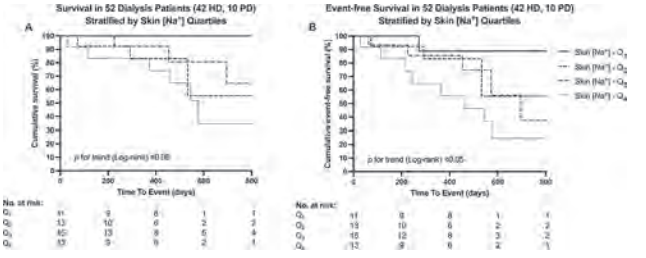
Fabio R. Salerno,[1,2] Alireza Akbari,[3,2] Sandrine Lemoine,[4,2] Guido Filler,[1,2] Timothy J. Scholl,[3,1] Christopher W. McIntyre.[1,2] *[1]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Robarts Research Institute, London, ON, Canada; [4]Universite Lyon 1 Faculte de Medecine Lyon-Est, Lyon, France.*

Background: Sodium-23 magnetic resonance imaging (^{23}Na MRI) allows the measurement of skin sodium concentration ([Na^+]). In patients requiring dialysis no data are available relating to the clinical outcomes associated with skin sodium accumulation or the determinants of increasing deposition.

Methods: This was an exploratory, observational study of adult hemodialysis (HD) and peritoneal dialysis (PD) patients. Participants underwent skin [Na^+] quantification with leg ^{23}Na MRI at the study beginning. Outcomes of interest were all-cause mortality and composite all-cause mortality and major cardiovascular adverse events (MACE) and were assessed. Cumulative total and event-free survival were assessed using the Kaplan-Meier survival function after stratification into Skin [Na^+] quartiles. Cox proportional hazards regression was used to model the association between Skin [Na^+] and outcomes of interest. Multiple linear regression was used to model the predictors of Skin [Na^+].

Results: 52 participants (42 HD, 10 PD) underwent the study procedures. Median follow-up was 423 days (*IQR*: 290-550). As shown in Figure 1, increasing Skin [Na^+] quartiles were associated with significantly shorter composite event-free survival (log-rank $\chi^2(1) = 4.733$, $p < 0.05$). Skin [Na^+] was significantly associated with all-cause mortality (univariate *HR* 1.059, *95% CI*: 1.014-1.107; sex-adjusted *HR*: 1.063, *95% CI*: 1.019-1.109) and composite all-cause mortality and MACE (univariate *HR* 1.054, *95% CI*: 1.017-1.092; sex-adjusted *HR*: 1.055, *95% CI*: 1.019-1.093). In multiple regression models, dialysate [Na^+], serum albumin and congestive heart failure were significantly associated with Skin [Na^+] in HD patients (R^2_{adj}=0.62).

Conclusions: Higher Skin [Na^+] was associated with worse clinical outcomes in dialysis patients and may represent a direct therapeutic target.



Kaplan Meier curves for overall survival (A) and event-free survival as a composite of all-cause mortality and major adverse cardiovascular events (B), after skin [Na^+] quartile stratification.

Itch Reduction with Difelikefalin Correlates with Improved Sleep Quality in Hemodialysis Patients with Pruritus

Daniel E. Weiner,[1] Sebastian Walpen,[2] Thilo Schaufler,[2] Isabelle Morin,[2] Warren Wen,[3] Frederique Menzaghi,[3] Sarbani Bhaduri,[4] Michael J. Germain.[5] *[1]Tufts Medical Center, Boston, MA; [2]Vifor Pharma Ltd, Glattbrugg, Switzerland; [3]Cara Therapeutics Inc, Stamford, CT; [4]Bhaduri Biotech Consulting, El Paso, TX; [5]Baystate Medical Center, Springfield, MA.*

Background: CKD–associated pruritus (CKD-aP) may impair sleep of hemodialysis (HD) patients. This analysis of a Phase 3 open-label study evaluated if itch reduction in HD patients treated with the investigational, peripherally restricted kappa opioid receptor agonist, difelikefalin (DFK), correlated with improved sleep quality.

Methods: 222 patients with moderate-to-severe CKD-aP received intravenous DFK 0.5 mcg/kg thrice weekly for up to 12 weeks. Change in itch intensity from baseline to week 12 was evaluated by weekly mean of the 24-hour Worst Itching Intensity Numerical Rating Scale (WI-NRS) score (range 0 [no itch] to 10 [worst itch imaginable]). Impact of pruritus on sleep quality was evaluated by the change from baseline to week 12 in weekly mean of the 24-hour Sleep Quality Questionnaire (SQQ) score (0 [did not interfere] to 10 [completely interfered]), and the sleep disability question score from the 5-D Itch (1 [never affects sleep] to 5 [delays falling asleep and frequently wakes me up at night]) at baseline and week 12. Spearman's correlation analysis was performed.

Results: At week 12, most patients achieved a ≥3-point reduction in WI-NRS (74%) and SQQ score (66%). Patients with a ≥3-point (vs <3-point) reduction in WI-NRS had greater reductions in mean SQQ score (–5.22 vs –1.53) and 5-D Itch sleep question score (–1.83 vs –0.78) from baseline to week 12. There was a strong correlation between changes in WI-NRS and SQQ scores from baseline to week 12 (r=0.78) (**Figure**) and a moderate correlation between changes in WI-NRS and 5-D Itch sleep question scores during this period (r=0.48). Week 12 SQQ and 5-D Itch sleep disability question scores were strongly correlated (r=0.64).

Conclusions: Itch reduction with DFK correlated with improvements in sleep quality as evaluated by the SQQ and 5-D Itch sleep disability question.

Fluid-Related Risk Factors of Peritoneal Dialysis Technique Failure

Jennifer E. Flythe,[1] Linda Ficociello,[2] Vidhya Parameswaran,[2] Michael A. Kraus,[2] Dinesh K. Chatoth,[2] Claudy Mullon,[2] Michael S. Anger,[2,3] Robert J. Kossmann.[2] *[1]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]Fresenius Medical Care, Global Medical Office, Waltham, MA; [3]University of Colorado, School of Medicine, Denver, CO.*

Background: Inadequate fluid management in peritoneal dialysis (PD) patients is associated with a higher risk of cardiovascular morbidity and mortality and may result in shortened PD technique survival (Van Biesen et al, 2019). In this analysis, we evaluated the associations between fluid-related clinical factors and PD technique failure within 1 year of treatment initiation.

Methods: Adult, ESKD patients who were newly prescribed PD for ≥ 120 days at Fresenius Kidney Care (FKC) facilities between 2017-2019 were included. Deidentified data were extracted from the FKC clinical data warehouse and evaluated within 120 days of treatment initiation. Crude and case-mix adjusted Cox regression models with competing risks (patient transfer to HD, death, and loss to follow-up) were used to evaluate the associations between fluid-related risk factors and PD technique failure.

Results: 15,854 automated PD patients (APD; age: 58 years; K_{RU}: 4.5 mL/min) and 1,547 manual PD patients (CAPD; age: 58 years; K_{RU}: 4.8 mL/min) were included. 53% of APD patients and 56% of CAPD patients had a PD technique survival ≥ 1 year, and all patients with urine volume ≤ 100 mL, systolic BP > 160 mmHg, history of cardiovascular events and hospitalizations, or weight change ≥ 2 kg between day 1 and day 120 of PD treatment had a higher risk of 1-year PD technique failure (Figure 1). Significant patient-reported risk factors included shortness of breath (APD only) and edema (APD and CAPD). Patients with a weekly Kt/V > 2 had half the risk of PD attrition at 1 year.

Conclusions: APD and CAPD patients with fluid-related complaints (shortness of breath and edema), history of cardiovascular morbidity and hospitalizations, hypertension, or weight change ≥ 2 kg within 120 days of PD initiation had a higher risk of technique failure within 1 year of PD initiation.

Mass Spectrometry-Based Proteomic Analysis of Adsorbed Molecules in a Hexadecyl-Immobilized Cellulose Beads Column for the Treatment of Dialysis-Related Amyloidosis

Suguru Yamamoto,[1] Keiko Yamamoto,[3] Yoshitoshi Hirao,[3] Shin Goto,[1] Tadashi Yamamoto,[3] Fumitake Gejyo,[2] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Niigata University of Pharmacy and Applied Life Sciences, Niigata, Japan; [3]Biofluid Biomarker Center, Niigata University, Niigata, Japan.*

Background: Dialysis-related amyloidosis (DRA) is a serious complication in CKD patients undergoing long-term hemodialysis (HD). β_2-microglobulin (β_2-m)-related amyloid deposition induces osteoarticular disorders including carpal tunnel syndrome. Direct hemoperfusion with a column containing hexadecyl-immobilized cellulose beads (HICB) is used to adsorb circulating β_2-m to inhibit the progression of DRA. As use of the column improves joint pain and physical functions; it is possible that the column adsorbs not only β_2-m but also other molecules associated with amyloidogenesis and inflammation.

Methods: We included 14 HD patients with DRA. Proteins were extracted from the HICB-containing column after treatment and identified using liquid chromatography-linked mass chromatography. We measured the adsorption rate of the proteins detected by proteomics, and compared it with those in the patients undergoing HD and hemodiafiltration (HDF). The amyloid tissue deposition in the carpal tunnel in the HD patients (n = 8) was corrected using laser microdissection and examined on liquid chromatography-linked mass chromatography. The protein profiles were compared between the HICB-containing column and the amyloid lesions.

Results: With high confidence criteria, 200 proteins adsorbed by the HICB were identified (e.g., β_2-m SIN, 193.8 ± 143.4; lysozyme SIN, 156.5 ± 47.8). After passing the HICB-containing column, the serum levels of several proteins were decreased as compared with those in the HD dialyzer and HDF hemofilter (e.g., adsorption rate of β_2-m, 80.5 ± 9.8% vs 38.0 ± 25.5% [HD] and 25.0 ± 14.6% [HDF], $p < 0.01$; lysozyme, 79.2 ± 10.9% vs 15.8 ± 18.8% [HD] and 10.0 ± 13.4% [HDF], $p < 0.01$). In the amyloid deposited in the carpal tunnel, 143 proteins were identified, of which 54 were also found in the HICB-containing column. Cellular protein metabolic process was one of major Gene Ontology pathways in the common proteins ($p = 1.05E-10$).

Conclusions: The HICB-containing column adsorbed various proteins in the HD patients with DRA, of which some were found in the lesions with amyloid deposition. The results suggest that direct hemoperfusion with the HICB-containing column contributes to the improvement of DRA by reducing the levels of related proteins.

Effects of NOS3 and Nitric Oxide Releasing Bionanomatrix Gel on Reducing Intimal Hyperplasia and Vascular Remodeling

Maheshika S. Somarathna,[1] Tatyana Isayeva Waldrop,[1] Patrick Hwang,[2] Hannah M. Northrup,[3] Isabelle D. Falzon,[3] Yan-Ting E. Shiu,[3] Ho-Wook Jun,[1,2] Timmy C. Lee.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Endomimetics, LLC, Birmingham, AL, Birmingham, AL; [3]University of Utah Health, Salt Lake City, UT.*

Background: An arteriovenous fistula (AVF) is the preferred type of vascular access in hemodialysis patients. However, nearly 60% of AVFs created develop AVF maturation failure due to venous intimal hyperplasia (IH) formation and poor vascular remodeling (VR). We hypothesize that the endothelial nitric oxide synthase (NOS3) system is critical for reduction of IH and outward VR and local nitric oxide (NO) delivery at the time of AVF creation can enhance AVF maturation

Methods: To explore the role of NOS3, AVFs were created in NOS3 -/-, NOS3 +/+ and NOS3 overexpression mice. To investigate the efficacy of NO gel, rat femoral AVFs were created and immediately after, therapy was applied on the anastomosis. Animals were sacrificed at 7 days following AVF creation to evaluate histomorphological changes. MRI based computational fluid dynamic simulations were performed to investigate hemodynamic changes

Results: As compared to the controls, overexpression of NOS3 can significantly 1) reduce venous IH 2) promote hemodynamic adaptation and VR by increasing venous cross-sectional area, reducing wall shear stress and vorticity through elevating cGMP levels. NO gel therapy had similar significant effects, including reduction of IH (P <0.0091, 70%). In addition, the NO treated group showed significant reduction in intimal α-SMA, vimentin, desmin and MCP-1 levels. Furthermore, slow degradation of NO-releasing gel resulted in prolonged release of NO during the AVF maturation process

Conclusions: NOS3-NO-cGMP system is a critical regulator of AVF remodeling. Thus NO-releasing gel has great potential to promote clinically successful AVF maturation

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

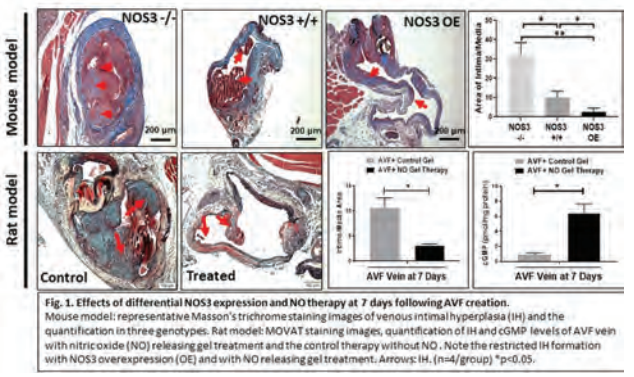

Fig. 1. Effects of differential NOS3 expression and NO therapy at 7 days following AVF creation.
Mouse model: representative Masson's trichrome staining images of venous intimal hyperplasia (IH) and the quantification in three genotypes. Rat model: MOVAT staining images, quantification of IH and cGMP levels of AVF vein with nitric oxide (NO) releasing gel treatment and the control therapy without NO . Note the restricted IH formation with NOS3 overexpression (OE) and with NO releasing gel treatment. Arrows: IH. (n=4/group) *p<0.05.

(A) Color maps of the fluid wall shear stress (FWSS) and vorticity. (B) quantifications of venous cross-sectional area, FWSS and vorticity. Box and whisker plots present data from the 25th to 75th percentile with whiskers extending to the 5th and 95th percentile. (n=3 for the control gel treated group and n=4 for the NO gel treated group). *p<0.05.

FR-OR30

The Transcriptomic Landscape of the Arteriovenous Fistula: The Postoperative Genetic Signature of Maturation Failure

Roberto I. Vazquez-Padron,[1,2] Miguel G. Rojas,[1] Marwan Tabbara,[1] Akshara Sree Challa,[1] Juan C. Duque,[1] Loay H. Salman,[3] Laisel Martinez.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]VA Miami Healthcare System, Miami, FL; [3]Albany Medical College, Albany, NY.*

Background: The molecular mechanisms contributing to arteriovenous fistulas (AVF) maturation or failure remain elusive, in part due to the scarcity of human postoperative biological data that may guide mechanistic and translational studies. The brachiobasilic AVF created in two stages overcomes this limitation and allows to collect vascular tissues representative of both outcomes at the time of transposition.

Methods: In this study, we compared the transcriptomic profiles of 40 postoperative AVF samples (20 matured and 20 failed) collected 4-6 weeks after access creation by bulk RNA sequencing.

Results: We identified 156 differentially expressed genes (DEG) between both outcomes (log_2FoldChange>1, FDR<0.05), including 101 protein-coding genes downregulated with failure and 11 protein-coding genes with higher expression in this group compared to AVF that matured. Gene set enrichment analysis (GSEA) indicated a suppression of responses to stress/stimuli and signal transduction pathways in AVF that failed. The main downregulated players include G protein-coupled receptors, metalloproteinases, and immunoregulatory chemokines. In contrast, upregulated transcripts in AVF that failed include a urea cell-surface transporter, a serotonin biosynthesis enzyme, and various extracellular matrix and cell adhesion proteins. A supervised machine learning algorithm (XGBoost) was applied to gene expression normalized counts to identify the best discerning features of AVF failure. The highest contributors to the decision tree by total gain were IL-10 and GPR183 (each downregulated 2.6 folds in AVF that failed and with an FDR significance level of $2x10^{-5}$). The area under the curve (AUC) in the logistic regression models for each of these genes is >90%.

Conclusions: In conclusion, this study identified for the first time a postoperative molecular fingerprint of AVF failure. These findings may allow us to pinpoint venous remodeling deficiencies that are responsible for this outcome and potentially correct them using targeted therapies.

Human PLA2R-Antibodies Induce Membranous Nephropathy in Minipigs

Linda Reinhard,[1] Thorsten Wiech,[1] Michaela Schweizer,[2] Catherine Meyer-Schwesinger,[1] Hermann-Josef Groene,[1,3] Elion Hoxha,[1] Rolf A. Stahl.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Universitatsklinikum Hamburg-Eppendorf Zentrum fur Molekulare Neurobiologie Hamburg, Hamburg, Germany; [3]Philipps-Universitat Marburg, Marburg, Germany.*

Background: PLA_2R is the main target antigen in patients with membranous nephropathy (MN). The pathogenicity of PLA_2R-antibodies (ab) in MN patients have so far not been proven. This study aimed to prove the pathogenicity of human PLA_2R-ab in MN, and to induce an active PLA_2R-dependend model of MN in minipigs.

Methods: In a first model, plasma and purified IgG from patients with PLA_2R-ab positive MN and healthy donors (negative control) were transferred into minipigs. In a second model, human PLA_2R-protein was used for active immunization of a minipig. We analyzed the PLA_2R-ab in serum, development of proteinuria as well as kidney tissues using immunohistochemistry, immunofluorescence, electron microscopy and "podocyte exact morphology measurement (PEMP)".

Results: After transfer into minipigs, the human PLA_2R-ab bound specifically to minipig PLA_2R in the glomeruli and induced all morphologic characteristics of human MN. Human PLA_2R-ab of the IgG4 subclass could be eluted from minipig glomeruli, showing that the antibodies were able to bind to PLA_2R in the absence of other human serum components. The active immunization of minipigs with human PLA_2R-protein led to the development of PLA_2R-ab, which recognized the N-terminal CysR-CTLD1-region, as well as the C-terminal CTLD7-8-region. Analyses of the kidney tissue revealed all morphologic characteristics of human MN, including a granular deposition of pig IgG and C3 along the glomerular basement membrane, as well as electron dense immune deposits, which were associated with effacement of podocyte food processes. Antibodies eluted from isolated glomeruli were able to bind human and minipig PLA_2R. The minipig developed moderate proteinuria. In contrast, no morphologic or clinical characteristics of MN were detectable in the control animal.

Conclusions: Human PLA_2R-ab induce MN in minipigs. Immunization of minipigs with PLA_2R-protein leads to the development of autoimmune PLA_2R-induced MN, which presents with activation of the complement system and all morphologic and clinical characteristics of human MN. These findings prove the pathogenicity of human PLA_2R-ab and fulfill Koch's postulate.

Chimeric Autoantibody Receptor (CAAR) T Cells as a Precision Therapy for Antigen-Specific B Cell Depletion in PLA2R Membranous Nephropathy

Aimee S. Payne, Baomei Wang, Silvio Manfredo-Vieira, Xuming Mao, Saar Gill, Jonathan Hogan. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Primary membranous nephropathy (MN) is an autoimmune disease caused by autoantibodies against podocyte antigens, leading to glomerular damage, nephrotic syndrome, and potentially end-stage renal disease requiring dialysis or transplant. Phospholipase A2 receptor (PLA2R) autoantibodies are found in 70-80% of primary MN patients, co-localize with PLA2R and IgG4 glomerular immune deposits, and correlate with disease activity, supporting their causative role in disease pathogenesis. B cell depletion with rituximab is an effective strategy for treatment of primary MN. However, patients often require repeat treatments for disease relapse or maintenance of remission, and infectious serious adverse events are observed in up to 6.2% of rituximab-treated patients, highlighting the need for therapy that induces durable disease remission without generalized immunosuppression. Chimeric antigen receptor T cells have proven clinical ability to induce long-term remission of B cell cancers. We have shown that autoantigen-based chimeric autoantibody receptor (CAAR) T cells cause DSG3-specific B cell depletion in animal models of mucosal pemphigus vulgaris (mPV) without detectable off-target toxicity, which has led to a phase 1 trial of DSG3-CAART in mPV (NCT04422912). This study extends the CAART approach to PLA2R MN.

Methods: CAARs comprising PLA2R immunodominant epitopes linked to CD137-CD3ζ cytoplasmic domains were expressed in primary human T cells and evaluated for specific cytotoxicity against anti-PLA2R target cells, adsorption of anti-PLA2R MN IgG, and potential off-target binding using luciferase assays, ELISA, and commercial membrane proteome arrays.

Results: PLA2R CAARs directed specific cytolysis of anti-PLA2R cell lines targeting major PLA2R MN epitopes in the cysteine-rich and C-type lectin 1 and 7 domains. PLA2R-CAART cells adsorbed 95-99% of anti-PLA2R IgG from MN patient plasma, indicating that PLA2R CAARs encompass the major autoantibody-binding epitopes in MN patients. Membrane proteome arrays screened with PLA2R CAAR extracellular domains did not identify off-target interactions.

Conclusions: CAAR T cells represent a novel strategy for targeted B cell depletion in PLA2R MN and may ultimately prove to be valuable for the treatment for a broad range of antibody-mediated diseases.

New Insights on the Role of C3a/C3aR1 Signaling in Membranous Nephropathy

Stefano Da Sacco,[1] Qi Zhang,[1] Kelly L. Budge,[2] Astgik Petrosyan,[1] Valentina Villani,[1] Roger E. De Filippo,[1] Laura Perin,[1] Paolo Cravedi.[2] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide. MN is characterized by the deposition of anti-podocyte-antibodies within the glomerular subepithelial space. While complement deposition and formation of membrane-attack-complex (MAC) are thought to play a crucial pathogenic role, the exact mechanism of injury in MN is still unclear. We have developed a novel glomerulus-on-a-chip system (GOAC) using human primary podocytes and glomerular endothelial cells (GEC) to study MN and assessed functional response to human MN serum, role of MAC formation and C3a/C3aR1 signaling in MN pathogenesis in addition to in vivo studies.

Methods: GOACs were cultured with serum containing either anti-PLA2R+ or THSD7A+ MN patients and from healthy individuals (as control). Functional response was assessed by albumin permeability assay. The mechanistic role of MAC and C3a/C3aR1 signaling pathway was assessed by immunofluorescence, functional analysis, PCR arrays and Western Blotting. Results were further confirmed in GOAC using podocytes$^{C3aR1-/-}$ and in vivo using THSD7A induced MN in balb/c mice.

Results: Following exposure to sera from MN patients, we have confirmed deposition of human lgG on podocytes and formation of MAC complex, accompanied by albumin leakage. MAC inhibition did not prevent albumin leakage while GOAC supplemented with C3aR1 antagonists as well as GOAC using podocytes$^{C3aR1-/-}$ were able to prevent glomerular filtration damage and albumin leakage. Efficacy of C3aR1 antagonists in preventing proteinuria was confirmed in mice injected with serum from patients with anti-thrombospondin Ab, substantiating our findings.

Conclusions: Using our microfluidic GOAC system in combination with in vivo animal models, we have found evidence that C3a/C3aR1 plays a dominant role in complement-mediated MN pathogenesis. Our results not only shed some light on the injury mechanisms in complement-mediated damage but could provide new avenues for the development of glomerulus-specific treatments.

FR-OR34

C3d-Targeted Factor H Achieves Potent Renal Complement Inhibition and Reduced Glomerular Injury Without Affecting Systemic Complement

Stefan Wawersik,[1] Fei Liu,[1] Sarah T. Ryan,[1] Kelly C. Fahnoe,[1] Jennifer Morgan,[1] David J. Salant,[3] Joshua M. Thurman,[2] Susan Kalled,[1] Shelia Violette.[1] *[1]Q32 Bio, Cambridge, MA; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Boston University Medical Center, Boston, MA.*

Background: Complement is critical to both the innate and adaptive immune systems, serving an essential role in pathogen response and as an effector of humoral immunity. This system is tightly controlled, and inappropriate activation can cause inflammation and organ injury. Consequently, inhibition has been pursued as a therapeutic strategy for rare complement-driven diseases. However, complement proteins exist in high abundance systemically and undergo rapid turnover, making effective chronic inhibition challenging. Furthermore, because of the complement system's essential role in immunity, systemic blockade raises the risk of infection in patients. As a result, substantial unmet need remains for safer and more effective anti-complement therapies, particularly for chronic diseases.

Methods: We designed a targeted fusion protein to inhibit complement activation in tissue while minimizing systemic blockade. ADX-097 is a humanized anti-C3d monoclonal antibody linked to five N-terminal consensus repeats of the complement inhibitor factor H (fH_{1-5}). We evaluated tissue targeting and both circulating and tissue PK and PD of a mouse ADX-097 surrogate, ADX-118, in $fH^{-/-}$ mice, which exhibit robust glomerular complement activation. We also examined disease-modifying efficacy of ADX-097 in the rat Passive Heymann Nephritis (PHN) model of membranous nephropathy.

Results: We demonstrate that our anti-C3d antibody binds high-density glomerular C3d deposits across a range of renal diseases, indicating that this binding could deliver fH_{1-5} locally. In $fH^{-/-}$ mice, a single subcutaneous dose of 1 mg/kg ADX-118 achieves >75% complement inhibition in glomeruli for at least 7 days post-dose while avoiding systemic complement blockade. A lower, 0.3 mg/kg dose achieves approximately 50% inhibition in glomeruli. In the rat PHN model, a single 1 mg/kg dose of ADX-097 inhibits glomerular complement and significantly reduces urine protein- and albumin-creatinine ratios, indicating potent disease-modifying efficacy.

Conclusions: These data provide proof-of-concept that targeting fH_{1-5} to deposited C3d results in potent, durable, and efficacious complement blockade in kidney while avoiding systemic complement inhibition.

Differentiating Steroid-Sensitive Minimal Change Disease and Primary and Secondary Focal Segmental Glomerulosclerosis: A Proteomics-Based Approach

Sethu M. Madhavan, Salem Almaani, John P. Shapiro, Anjali A. Satoskar, Isabelle Ayoub, Brad H. Rovin, Samir V. Parikh. *The Ohio State University, Columbus, OH.*

Background: Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) are common causes of nephrotic syndrome. Whether distinct molecular mechanisms are involved in the pathogenesis of MCD and FSGS remains unclear. We used proteomic studies in human kidney biopsies to characterize the differentiating molecular phenotype of steroid-sensitive MCD and primary and secondary FSGS.

Methods: Formalin-fixed paraffin-embedded kidney biopsies from patients with steroid-sensitive MCD (n=9), primary FSGS (pFSGS, n= 3), and secondary FSGS (sFSGS, n=4) were included. Patients with pFSGS had nephrotic syndrome and diffuse foot process effacement (FPE) in kidney biopsy. Patients with sFSGS were obese and had non-nephrotic range proteinuria, normal serum albumin and evidence of hyperfiltration and <80% FPE in kidney biopsy. Glomeruli were isolated using laser capture microdissection and HPLC MS/MS were performed using Orbitrap eclipse mass spectrometer. Paired *t*-test in the normalized data was used to compare the groups.

Results: 733 and 701 significant differentially expressed proteins were detected between MCD, and pFSGS and sFSGS respectively. Proteins regulating cell-cell and cell-matrix adhesion and differentiation (THY1, TRIP6, ACTN3, ACTN1, ITGA7, ITGB2, COL6A1, MMP9, FN1) were significantly upregulated in glomeruli of pFSGS compared to MCD. In the glomeruli of sFSGS, immune regulatory pathways predominantly from the complement system (C3, C5, C6, C8A, C8B, C8G, C9, CFHR1, CFHR5, CFH) were upregulated compared to MCD (**Figure 1**). FN1, EIF2AK4, MAP2K3, PHKB, INTS12, BET1 were the most significantly overexpressed proteins in pFSGS compared to MCD.

Conclusions: Proteomic signatures of glomeruli from primary and secondary FSGS are distinct from MCD. The differential upregulation of cell-cell, cell-matrix interacting proteins in pFSGS and immune regulatory proteins in sFSGS suggest distinct underlying pathogenic mechanisms. The causal role of novel molecules dysregulated in pFSGS compared to MCD needs to be investigated. A larger cohort of patient samples needs to be interrogated to validate the observation.

FR-OR36

Association of HLA-DPB1*04:01 and Maintenance of Remission in ANCA-Associated Vasculitis

Dhruti P. Chen,[1] Elizabeth A. McInnis,[1] Eve Wu,[1] Katherine G. Stember,[4] Susan L. Hogan,[1] Yichun Hu,[1] Candace D. Henderson,[1] Lauren N. Blazek,[1] Simon Mallal,[3] Eddie A. James,[2] J. Charles Jennette,[1] Dominic J. Ciavatta,[1] Ronald J. Falk,[1] Meghan E. Free.[1] *[1]University of North Carolina System, Chapel Hill, NC; [2]Benaroya Research Institute at Virginia Mason, Seattle, WA; [3]Vanderbilt University, Nashville, TN; [4]North Carolina Biotechnology Center, Research Triangle Park, NC.*

Background: Genome wide association studies identified HLA-DPB1*04:01 in ANCA vasculitis and observational studies suggest a biological role. We explored the interaction between HLA/PR3 peptide and association with clinical disease remission.

Methods: Peripheral blood mononuclear cells from patients with ANCA vasculitis and healthy controls with HLA-DPB1*04:01 were utilized for mRNA and protein expression assays. PR3 peptides associating with HLA-DPB1*04:01 were identified via *in silico* and *in vitro* assays. Antigen-presenting cells were analyzed for co-fluorescence of HLA-DPB1 and fluorescently tagged PR3 peptide. HLA/peptide multimers were used to identify autoreactive T cells.

Results: Carriers of HLA-DPB1*04:01 were less likely to maintain remission in PR3-ANCA vasculitis (adjusted hazard ratio for leaving remission 2.06 (1.01,4.20)), though similar effect was not observed in MPO-ANCA or the combined cohort. *In silico* predictions of HLA and PR3 peptide interactions showed strong affinity between $PR3_{225-239}$ and HLA-DPB1*04:01 and confirmed by *in vitro* assays. Expression of HLA-DPB1 did not differ among patients and controls. Circulating APCs analyzed by flow cytometry demonstrated higher fluorescence overlap between peptide and HLA among patients on therapy compared to healthy controls or patients in long-term remission off therapy (Figure). We also found that there is a dynamic autoreactive CD4+ T cell response.

Conclusions: Affinity between $PR3_{225-239}$ and HLA-DPB1*04:01 is reduced among patients in long-term clinical disease remission. These data suggest that the interaction is dynamic and that it could determine the subsequent immune response of T cell activation and maintenance of immunological remission. When HLA-DPB1*04:01 does present $PR3_{225-239}$ as an antigen, it is recognized by autoreactive T cells. The peptide-HLA interaction may be the link explaining why patients with PR3-ANCA and HLA-DPB1*04:01 are unable to maintain disease remission.

Funding: NIDDK Support

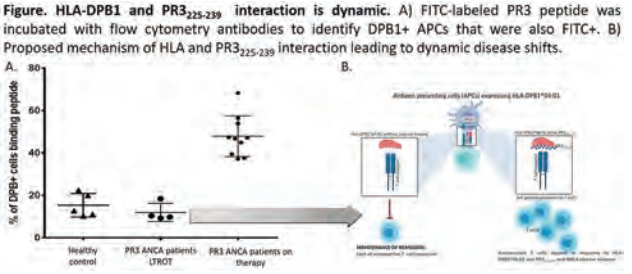

Figure. HLA-DPB1 and $PR3_{225-239}$ interaction is dynamic. A) FITC-labeled PR3 peptide was incubated with flow cytometry antibodies to identify DPB1+ APCs that were also FITC+. B) Proposed mechanism of HLA and $PR3_{225-239}$ interaction leading to dynamic disease shifts.

Leukotriene B4-BLT1 Axis Controls Neutrophil Accumulation via Fcγ Receptor-Dependent Leukotriene B4 Production in Experimental Glomerulonephritis

Ryotaro Shioda,[1,2] Airi Jo,[2] Maiko Nakayama,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Biochemistry, Juntendo University Graduate School of Medicine, Tokyo, Japan.*

Background: Eicosanoids are biologically active lipid mediators generated rapidly at sites of inflammation. Leukotrienes are one of the eicosanoids generated through the metabolism of arachidonic acid by 5-lipoxygenase and LTA_4 hydrolase. Although it is generally known that leukotriene B_4 (LTB_4) functions as a potent chemotactic factor for neutrophils via its receptor BLT1, the role of LTB_4-BLT1 axis on glomerulonephritis has not been clarified.

Methods: We used the nephrotoxic serum nephritis model, which mimics human glomerulonephritis. To investigate the effect of LTB_4-BLT1 axis on glomerulonephritis, we used BLT1-knock out (KO) mice. Specifically, serological and histological analyses were performed in acute and chronic phases. We used LC/MS/MS to measure LTB_4 in the kidney. To confirm LTB_4 production by neutrophils, we activated the Fcγ receptor of neutrophils by cross-linking with IgG.

Results: On day 7 after onset of nephritis, wild-type (WT) mice showed severe proteinuria, crescent formation accompanied by macrophage infiltration, which was markedly attenuated in BLT1-KO mice. Next, we examined neutrophil infiltration in glomeruli in acute phase; the number of neutrophils in glomeruli peaked at 6 hours after onset both in WT and BLT1-KO mice, but was markedly lower in BLT1-KO mice. Complement activity and chemokines were comparable in both groups. Then, we measured LTB_4 in the kidney and found that LTB_4 production occurred within an hour of onset, indicating a dominant effect of the LTB_4-BLT1 axis on early neutrophil infiltration. In vitro studies demonstrated that LTB_4 production was dependent on activation of Fcγ receptors. On day 1 after onset, BLT1-KO mice exhibited reduced proteinuria and attenuated endothelial damage. Furthermore, administration of BLT1 receptor antagonists after onset relieved nephritis, strongly indicating its therapeutic effect. Finally, BLT1-positive cells infiltrated glomeruli of patients with ANCA-associated vasculitis, suggesting that the LTB_4-BLT1 axis might play important roles in human glomerulonephritis.

Conclusions: Our results revealed that blockage of initial neutrophil infiltration by inhibition of the LTB_4-BLT1 axis mitigated nephritis and could counteract subsequent macrophage infiltration. The LTB_4-BLT1 might be a promising therapeutic target for glomerulonephritis.

FR-OR38

mTOR Activity of Macula Densa (MD) Cells Is a Major Determinant of Glomerular Structure and Function

Urvi Nikhil Shroff, Georgina Gyarmati, Audrey Izuhara, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Macula densa (MD) cells are paracrine regulators of renal hemodynamics and renin and were recently reported to feature a high rate of protein synthesis. Since the central regulator of protein synthesis is the mTOR pathway, the purpose of the present study was to examine the role of MD mTOR signaling in the maintenance of glomerular structure and function.

Methods: Inducible MD-specific mTOR gain-of-function (MD-mTOR^{gof}) mice were generated by crossing nNOS/CreERT2-mTmG and TSC2/fl mice. Protein synthesis activity *in vivo* at the single-cell level was quantified using O-propargyl-puromycin (OPP) fluorescence imaging and histological analysis in Sox2-tdTomato and MD-GFP mice. Glomerular filtration rate (GFR) was measured via transdermal detection of FITC-sinistrin plasma decay (MediBeacon) and renal blood flow (RBF) was quantified via intravital microscopy.

Results: Sox2-tdTomato mice and the OPP assay showed the highest protein expression in the MD among all renal cell types. Immunolabeling validated MD-specific TSC2 KO and upregulated pS6K in MD-mTOR^{gof} mice. MD-mTOR^{gof} significantly increased the overall rate of protein synthesis in MD cells (1.300±0.057) vs control (0.944±0.039). Physiological activation of MD cells by low salt diet further enhanced MD protein synthesis in both WT (1.365±0.055) and MD-mTOR^{gof} (1.482±0.056) mice, which was blocked by Rapamycin treatment. MD-enriched proteins such as CCN1, CCN3, Pappa2 and CxCl14 had significantly higher expression in response to MD-mTOR^{gof}. GFR was significantly elevated in MD-mTOR^{gof} mice compared to WT (1981±121.30 vs 1444±99.48 μL/min/100 g BW) with similar changes observed with respect to RBF based on single afferent (AA)/efferent arteriole (EA) blood flow, vessel diameter and glomerular tuft area measurements. COX2, mPGES1, renin, the length of basal MD cell processes (maculapodia) and MD cell number/plaque were also significantly increased in MD-mTOR^{gof} vs WT mice.

Conclusions: mTOR signaling is an important regulator of MD cell protein synthesis, proliferation, differentiation and paracrine signaling to the glomerulus via classic hemodynamic and novel, non-traditional glomerular tissue remodeling elements that may be therapeutically targeted to increase RBF, GFR and endogenous tissue remodeling in kidney diseases.

Extracellular Vesicles and Alport Syndrome: The Role of miR-93 in Modulating Glomerular Cell Biology

Laura Perin, Charmi Dedhia, Paola Aguiari, Astgik Petrosyan, Roger E. De Filippo, Sargis Sedrakyan. *Children's Hospital of Los Angeles, Los Angeles, CA.*

Background: miRNAs play important roles in the pathogenesis of various renal diseases miR-93 is a potent regulator of pathways responsible for glomerular damage like VEGF, TGFb, and Msk2. We have evidence that miR-93 is altered in the glomeruli of mice with Alport syndrome (AS, Col4a5-/-), and in glomeruli of AS patients. Here, we investigated the role of miR-93 in mesangial cells, podocytes, and glomerular endothelial cells (GEC) of mouse and human origin. We also used extracellular vesicles (EVs) derived from human amniotic fluid stem cells to assess their disease-modifying activity in vitro and in vivo by regulation of miR-93.

Methods: miR-93 expression was evaluated by qRT-PCR in mesangial cells, podocytes and GEC sorted from glomeruli of male and female WT and homozygous and heterozygous AS mice at different stages of disease (2m, 3.5m, and 5.5m) and in biopsies of AS patients. The role of miR-93-EVs was evaluated in vitro in human glomerular cells using $EV^{miR93-/-}$. The therapeutic effect of EVs was tested in vivo. RNA-seq analysis was performed in isolated glomeruli of EV-injected mice vs. controls.

Results: miR-93 expression differs between male and female mice along disease progression. In AS males, miR-93 level was significantly lower in GEC, but not in podocytes or mesangial cells vs. WT cells. miR-93 expression was downregulated in glomeruli and urine of AS patients. Expression of WT1 in PAN damaged human podocytes, of fibronectin and VEGF in damaged human GEC, and expression of PDGFRb in TGFb damaged mesangial cells were restored by miR-93 EV cargo transfer, unlike $EV^{miR93-/-}$. EVs showed amelioration of proteinuria and increased lifespan of treated mice. Transcriptomic analysis showed that WT male and female present differences in respiratory and metabolic pathways, extracellular matrix, and cell adhesion molecules. AS males injected with EVs showed improved gene modulations in metabolic function, extracellular matrix interaction, angiogenesis and fibrosis, important miR-93 targeted pathways.

Conclusions: Gender-specific variation in miR-93 expression in glomerular cells might indicate important differences in response to injury in progressive disease. EVs demonstrate great potential to restore lost miR-93 expression and its targets, thus presenting a targeted approach for the treatment of CKD.

Intravital Imaging Reveals Glomerular Capillary Enlargement and Endothelial/Immune Cell Activation Early in Alport Syndrome

Georgina Gyarmati,[1] Urvi Nikhil Shroff,[1] Audrey Izuhara,[1] Stefano Da Sacco,[1] Sargis Sedrakyan,[1] Paolo Cravedi,[3] Kerstin U. Amann,[2] Kevin V. Lemley,[1] Laura Perin,[1] Janos Peti-Peterdi.[1] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]Friedrich-Alexander-Universitat Erlangen-Nurnberg Medizinische Fakultat, Erlangen, Germany; [3]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: Alport syndrome (AS) is a rare genetic disorder caused by mutations in type IV collagen that lead to defective glomerular basement membrane, damage of the glomerular filtration barrier (GFB), and progressive kidney disease. While the genetics of AS is well known, the molecular and cellular mechanistic details of disease pathogenesis have been elusive, hindering the development of effective, specific, and mechanism-based therapies. Here we aimed to obtain direct visual clues on the major drivers of AS pathology by performing high-power intravital multiphoton microscopy (MPM) of the local kidney tissue microenvironment in a mouse model of AS, with translation to the human condition.

Methods: In vivo kidney MPM imaging of transgenic Alport mice (Col4α5 mutation) at 2 and 5 months of age was combined with urinalysis and histology. Endothelial glycocalyx was labeled with FITC-WGA, T cells with anti-CD3-Alexa594/CD44-Alexa488 antibodies, and plasma with Albumin-Alexa680. Animals received hyaluronidase (50U iv). AS patient renal biopsy specimens with minimal change disease controls were used for semithin and immunofluorescence histological analysis and single glomerular spatial proteomics (Nanostring).

Results: Severely distended glomerular capillaries and aneurysms were found in AS mice accompanied by numerous microthrombi, increased glomerular endothelial glycocalyx and immune cell homing, albumin leakage through the GFB, glomerulosclerosis and interstitial fibrosis by 5 months of age with an intermediate phenotype at 2 months. Histological and single glomerular spatial proteomics analysis of AS patient biopsies confirmed the presence of dilated glomerular capillaries, activated T cells, endothelial

injury and inflammation. Acute treatment of AS mice with hyaluronidase reduced excess glomerular endothelial glycocalyx and blocked immune cell homing and albumin leakage through the GFB.

Conclusions: We identified the central roles of glomerular capillary mechanical strain, endothelial and immune cell activation early in AS in both mice and humans that may be therapeutically targeted to reduce local tissue injury and improve kidney function.

Comparative Human and Mouse Kidney Transcriptomics Identify ELF4 as Potential Therapeutic Target

Hailong Hu, Xiangchen Gu, Julia Frederick, Jihwan Park, Rojesh Shrestha, Katalin Susztak. *Renal Electrolyte and Hypertension Division, Department of Medicine and Genetics, University of Pennsylvania, Philadelphia, PA.*

Background: Mouse models provide an excellent tool to study kidney disease pathogenesis, but little is known how well mouse models recapitulate molecular changes of human CKD.

Methods: Here we created four different mouse kidney disease models a) unilateral ureteral obstruction, b) folic acid injection c) tubular specific overexpression of Notch1 and d) podocyte specific overexpression of risk variant APOL1. We performed detailed phenotyping and molecular profiling by RNA Sequencing of mouse models. We also generated RNA Sequencing for 95 human kidney samples. We used the CRISPR technology to generate mice with ELF4 deletion. We used antisense oligonucleotides for test the therapeutic potential of ELF4 inhibition.

Results: Using comparative bioinformatics approaches we identified 1256 genes and 47 transcription factors that were commonly regulated in all mouse CKD and in patients with CKD. In particular we identified ELF3 and ELF4 transcription factors as they were elevated both in all mouse models and patient samples. Mice with genetic deletion of Elf4 was healthy at baseline and showed protection from FA and cisplatin induced kidney fibrosis and disease. We found that ELF4 is mostly expressed in immune cells and influenced inflammation. Therapeutic inhibition of ELF4 was tested by injection of Elf4, which showed similar protection of kidney disease.

Conclusions: Comparative transcriptomics identified Elf4 as one of the key conserved transcription factor in human and mouse CKD. Genetic deletion or pharmacological inhibition of Elf4 protected mice from fibrosis.

Proteome-Wide and Transcriptome-Wide Association Studies of Kidney Function

Pascal Schlosser,[1,2] Jingning Zhang,[3] Hongbo Liu,[8] Aditya L. Surapaneni,[4] Bing Yu,[5] Eric Boerwinkle,[5,6] Nilanjan Chatterjee,[3,7] Katalin Susztak,[8] Anna Kottgen,[1,2] Josef Coresh,[1,7] Morgan Grams.[1,7] *[1]Johns Hopkins University Department of Epidemiology, Baltimore, MD; [2]Institute of Genetic Epidemiology, Medical Center - University of Freiburg, Freiburg, Germany; [3]Johns Hopkins University Department of Biostatistics, Baltimore, MD; [4]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD; [5]The University of Texas Health Science Center at Houston, Houston, TX; [6]Baylor College of Medicine, Houston, TX; [7]Johns Hopkins University School of Medicine, Baltimore, MD; [8]Department of Medicine and Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.*

Background: Large-scale genome-wide association studies (GWAS) have implicated 424 loci associated with eGFR based on creatinine (eGFRcr), including 320 also associated with eGFR based on cystatin C (eGFRcys). However, the mechanisms by which genetic variation in these loci lead to differences in kidney function remain largely unknown. Combining genetic association statistics from GWAS of eGFR with those from the plasma proteome and gene expression in multiple tissues can reveal potentially causal genes and proteins affecting kidney function.

Methods: We applied proteome-wide association studies (PWAS) for eGFRcr and eGFRcys using summary-statistics from the CKDGen Consortium (EA, N_{eGFRcr}=1,004,041; $N_{eGFRcys}$=460,826) and 1,318 genetic plasma protein level prediction models developed in the Atherosclerosis Risk in Communities (ARIC) study (N=7,213 European American (EA) participants). Similarly, we conducted transcriptome-wide association studies (TWAS) based on prediction models developed in 49 human tissues (GTEx) and from 121 kidney tubule samples.

Results: We identified 62 proteins which were associated with eGFRcr and 42 with eGFRcys ($p<0.05/1,318$). Of these, 19 were associated with both kidney function measures in a directionally consistent manner, nominating novel gene annotations in 18 of the 19 genetically associated regions. The enzyme isopentenyl-diphosphate delta isomerase 2 (IDI2) showed the strongest associations (p_{eGFRcr}=4.8e-37, $p_{eGFRcys}$=1.0e-15). TWAS identified 1,799 and 845 transcripts for eGFRcr and eGFRcys, respectively ($p<0.05/235,763$). Of these, 544 were associated with both kidney function measures, including 13 of the 19 PWAS genes. There were also 27 identified in kidney tubule expression, including *DACH1* and *MANBA*, which were recently identified as contributors to kidney fibrosis.

Conclusions: We were able to consistently implicate 13 genes/proteins for eGFRcrea and eGFRcys across both PWAS and TWAS. Based on our human *in vivo* data these proteins are excellent candidates for downstream functional studies and for potential drug repurposing in the context of chronic kidney disease.

CTGF Aggravates the Oxidative Stress-DNA Damage-Cellular Senescence Sequence Following Renal Ischemia-Reperfusion Injury

Floris Valentijn,[1] Sebastiaan Knoppert,[1] Lennart Kester,[1] Raúl R. Rodrigues díez,[2] Laura Marquez-Exposito,[2] Roel Broekhuizen,[1] Roel Goldschmeding,[1] Marta Ruiz-Ortega,[2] Tri Q. Nguyen,[1] Lucas Falke.[1] *[1]Universitair Medisch Centrum Utrecht Afdeling Pathologie, Utrecht, Netherlands; [2]Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain.*

Background: Recent data suggest that AKI to CKD progression may be driven by cellular senescence evolving from prolonged DNA damage response following oxidative stress. Connective tissue growth factor (CTGF; CCN2) is a major contributor to CKD development and was found to aggravate DNA damage and the subsequent DNA damage response (DDR)-Cellular Senescence-Fibrosis sequence following renal ischemia reperfusion injury (IRI). Here, we investigated the impact of CTGF inhibition on the immediate (4 hours) and early (3 days) renal response to IRI.

Methods: We induced AKI by bilateral IRI in wild type and conditional CTGF-KO mice and euthanized the mice 4 hours and 3 days after reperfusion. We performed full transcriptome RNA sequencing to identify major dysregulated pathways and validated the findings by qPCR and immunohistochemistry.

Results: IRI resulted in upregulation of CTGF 4 hours and 3 days after reperfusion (Figure 1A,C). Four hours after reperfusion, CTGF-dependent differentially regulated genes were enriched in multiple signaling pathways related to oxidative stress and DNA damage. Consistently, decreased staining for γH2AX and p-p53 (Figure 1B) indicated reduced DNA damage response in tubular epithelial cells of CTGF-KO mice, although decline in kidney function, acute tubular damage score, and KIM1- and NGAL expression were not different. Three days after IRI, oxidative stress response markers (4HNE, nitrotyrosine, and Nrf2 target genes HMOX1 and NQO1), DDR markers (γH2AX-, p-p53, p21), and anti-apoptotic factors (Bcl-xL, HMGB1) were less elevated in CTGF-KO than in wild type mice.

Conclusions: Together, our observations suggest that CTGF inhibition might mitigate AKI to CKD progression by reducing oxidative stress induced DNA damage and the subsequent DDR-cellular senescence-fibrosis sequence response.

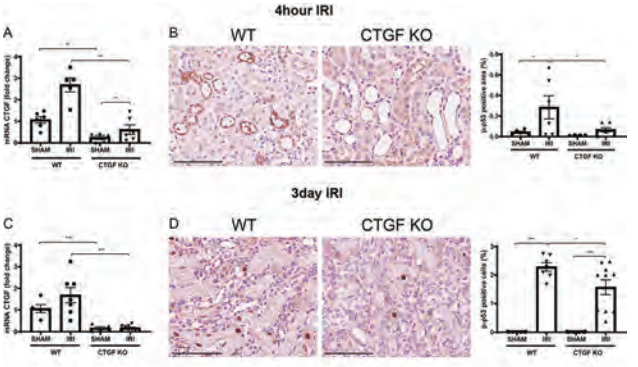

Figure 1. Near total deletion of CTGF resulted in reduced DNA damage induced p53 activation 4 hours and 3 days after IRI. (A, C) qPCR analysis showed that CTGF mRNA upregulation 4 hours (A) and 3 days (C) after IRI was decreased in CTGF KO mice compared with WT mice. (B, D) Cytoplasmic/membranous staining for phosphorylated p53 (p-p53) in the 4hour IRI model (B) and nuclear staining for p-p53 in the 3day IRI model (D) indicates that increased DNA damage induced p53 activation in IRI kidneys was decreased in CTGF KO mice compared with WT mice.

FR-OR44

Urinary mRNA Expression of Glomerular Podocyte Markers in Glomerular Disease and Renal Transplant

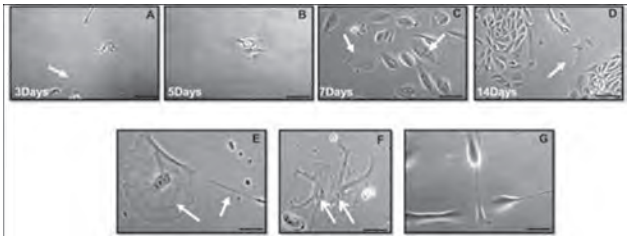
Silvia Armelloni,[1] Deborah Mattinzoli,[1] Masami Ikehata,[1] Carlo Alfieri,[1,2] Piergiorgio Messa.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: The search for urinary markers to monitor the progression of kidney disease is still ongoing and previous works have demonstrated the useful of quantifying mRNA expression of urinary cells. It is well known that in podocytes the slit diaphragm integrity and the function of the molecules shared with neuronal signaling pathways are essential for the maintenance of cell physiology. Our study focuses on the identification of the urinary mRNA expression of a panel of podocytes genes useful to identify possible biomarkers of glomerular pathology.

Methods: We studied the urine obtained from patients, native and renal transplant, affected by renal disease and undergone, with clinical indication, to renal biopsy (Rbx). We investigated the presence and the morphology of podocytes by immunocytochemistry and measured the expression of genes responsible for their structure and function by RTqPCR. We considered and applied possibly alternative methods to correct gene expression in respect to the total number of podocytes to compare different groups of patients.

Results: Our results demonstrate in urine the presence of podocytes with cytoskeletal alterations. Furthermore, we detected the increase of WT1 mRNA in the urine of both groups. After all kinds of normalization for the number of podocytes, there was a tendency to increase, compared to healthy controls, of the most of the tested genes; in particular, we obtained a significant rise of TRPC6 expression.

Conclusions: We suggest the expression of WT1 mRNA as a surrogate for quantifying podocytes in urine. We propose the increase of TRPC6 and GRM1 mRNA in urinary podocytes as a marker helpful to provide complementary information to Rbx. These genes are useful for monitoring actin cytoskeleton remodeling in podocytes that contributes to glomerular damage in course of renal disease.



Urinary cells culture. Podocytes are recognizable by their processes (A-E), a large cytoskeleton (A-C-D-E), by low duplication capacity (B) other than double nucleus (C-F) and processes trying to connect with those of other cells by synaptic-like structures (G)

FR-OR45

FKBP12 Interacts with 14-3-3 and Synaptopodin to Maintain Actin Cytoskeleton and Processes in Podocytes

Hidenori Yasuda, Yoshiyasu Fukusumi, Ying Zhang, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: FKBP12 is identified as a binding protein of Tacrolimus (Tac). We reported that FKBP12 is highly expressed in podocytes in kidney, and FKBP12 in podocytes is localized along the actin cytoskeleton. We also reported that FKBP12 is decreased in injured podocytes, and Tac ameliorates podocyte injury by restoring FKBP12 at the actin cytoskeleton (ASN 2019). However, the interaction of FKBP12 with actin-associated proteins and the molecular function of FKBP12 in podocyte are not elucidated yet.

Methods: The localization of FKBP12 with actin-associated proteins was analyzed by dual label immunostaining in glomeruli and human cultured podocytes. The subcellular distribution of FKBP12 was analyzed by western blot in the cultured podocytes. The interaction of FKBP12 with F-actin was analyzed by actin-binding assay with the cell lysate. The interaction of FKBP12 with the actin-associated proteins was analyzed by immunoprecipitation (IP) assay with the lysate of cultured podocytes and HEK293 transfected cells. The effect of FKBP12 siRNA and Tac treatment was analyzed in cultured podocytes.

Results: FKBP12 staining was co-localized with the actin-associated proteins 14-3-3β and synaptopodin (Synp) in glomeruli. The subcellular distribution of FKBP12 was similar to that of 14-3-3 in cultured podocytes. FKBP12 was co-localized and associated with F-actin in the podocytes. FKBP12 interacted with 14-3-3β in cultured podocytes. The IP assay with the HEK expression system also showed FKBP12 interacted with endogenous 14-3-3β. FKBP12 interacted with Synp in the HEK cells co-transfected with FKBP12 and Synp. The interaction of FKBP12 with Synp was not altered by the treatment of 14-3-3β siRNA. Tac enhanced the interaction of FKBP12 with Synp. The expression of 14-3-3β was decreased (63.0% to normal, $P<0.01$), the structure of F-actin is deranged (staining score, 2.0 vs. 2.9 of normal, $P<0.05$), and the process formation was impaired (40.4% to normal, $P<0.005$) in the podocytes treated with FKBP12 siRNA. Tac treatment to normal cells increased the expression of FKBP12 at F-actin in processes and enhanced process formation.

Conclusions: FKBP12 interacts with 14-3-3 and Synp to maintain the actin cytoskeleton and processes in podocyte. The enhanced interactions of FKBP12 with Synp and 14-3-3 by Tac treatment restores FKBP12 at actin cytoskeleton in podocyte.

Funding: Government Support - Non-U.S.

Soluble Flt1 Binds to Anti-Inflammatory Macrophages in the Kidney

Cleo C. Van Aanhold,[1] Lisa Landman,[1] Samiksha Sardana,[2] Kyra L. Dijkstra,[1] Jan A. Bruijn,[1] Cees van Kooten,[1] Hans J. Baelde.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Universiteit Utrecht, Utrecht, Netherlands.*

Background: Soluble Flt1 (sFlt1), a decoy receptor of VEGF ligands, is a key regulator of angiogenesis. High systemic levels of sFlt1 have been linked to the pathogenesis of preeclampsia. However, we have previously reported that treatment with low concentrations of sFlt1 ameliorates kidney damage and inflammation. Specifically, sFlt1 targets macrophages, suggesting that sFlt1 has nephroprotective immunomodulating effects. Here, we studied the presence of sFlt1 in human kidney diseases and investigated the expression and direct binding of sFlt1 to macrophages.

Methods: Renal biopsies of patients with various kidney diseases (IgA, LN, DN, FSGS, MCD) and pre-transplant control biopsies were stained for sFlt1, CD163 and CD68. Cultured macrophages were incubated with increasing concentrations of sFlt1-His, after which membrane binding was measured using flow cytometry. For this, THP-1 monocytes were differentiated with PMA and activated with IFN-γ+LPS or IL-4; primary macrophages were differentiated using GM-CSF or M-CSF.

Results: A patchy pattern of sFlt1 staining colocalizes with CD163/CD68-positive cells in tubulointerstitial areas and with CD68-positive cells in glomeruli. No quantitative differences in renal sFlt1 levels were observed in patients with kidney disease and controls. Flow cytometric analysis revealed that sFlt1 binds to PMA-differentiated THP-1 macrophages but does not bind to THP-1 monocytes. Activation with IFN-γ and LPS decreases sFlt1 binding to THP-1 macrophages. However, IL-4 activation of THP-1 macrophages strongly increases membrane sFlt1 binding. Furthermore, IL-4 activation upregulates sFlt1 mRNA expression in THP-1 macrophages. In primary macrophages, sFlt1 binding was higher in macrophages differentiated with GM-CSF compared to M-CSF.

Conclusions: Our results suggest that sFlt1, while typically associated with angiogenesis, binds to anti-inflammatory macrophages in the human kidney. Alternative activation of macrophages by IL-4 strongly induces sFlt1 production and increases direct binding of sFlt1 to the cell surface membrane. We infer that sFlt1 functions as an autocrine stimulus of anti-inflammatory macrophages, independent of its antiangiogenic properties. Since anti-inflammatory macrophages mediate repair after kidney injury, our work suggests the potential of sFlt1 as a therapeutic tool.

FR-OR47

Cytokines of Kidney Origin Are Retained in the Heart and Induce Cardiac Injury in CKD: A Renal-Cardio Axis

Alejandro R. Chade,[1] Tamer Mohamed,[2] Alfonso Eirin.[3] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]University of Louisville, Louisville, KY; [3]Mayo Clinic Minnesota, Rochester, MN.*

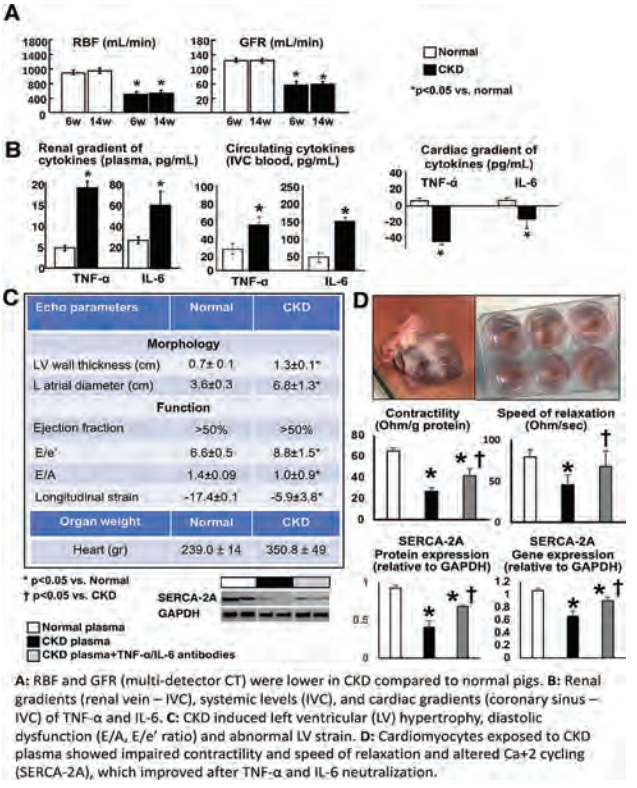
Background: Chronic kidney disease (CKD) is a major contributor to heart failure (HF), but the mechanisms underpinning CKD-induced HF remain to be fully elucidated. We hypothesize that inflammatory signaling from the kidney drives the development of cardiac injury in CKD.

Methods: CKD was induced in 4 pigs (bilateral renovascular disease and dyslipidemia) and observed for 14 weeks. Normal pigs served as controls. Renal hemodynamics (RBF, GFR) were quantified by multi-detector CT, and cardiac morphology and function by echocardiography. Renal vein, coronary sinus, and systemic blood was collected to quantify renal and cardiac gradients of TNF-α and IL-6. In a biomimetic heart culture system, pig heart slices were exposed to plasma from CKD or normal pigs and contractile/relaxation kinetics and sarcoplasmic-reticulum Ca^{+2} dynamics were investigated.

Results: Loss of renal function in CKD was accompanied by positive renal (renal release) and negative cardiac (cardiac retention) cytokine gradients, left ventricular (LV) hypertrophy, diastolic dysfunction (E/A, E/e' ratio) and abnormal LV strain. Cardiomyocytes exposed to CKD plasma showed impaired contractility and speed of relaxation, and altered Ca^{+2} cycling, which improved after TNF-α and IL-6 neutralization **(Figure)**.

Conclusions: This study supports a link between TNF-α/IL-6 inflammatory signaling from the kidney in causing cardiac dysfunction in CKD. Cardiac impairment *in vivo* was mirrored by altered cardiomyocytes kinetics and Ca^{+2} cycling after exposure to CKD plasma *in vitro*, supporting an inflammatory renal-cardio axis in CKD-to-HF pathophysiology.

Funding: Other NIH Support - NHLBI



A: RBF and GFR (multi-detector CT) were lower in CKD compared to normal pigs. **B:** Renal gradients (renal vein – IVC), systemic levels (IVC), and cardiac gradients (coronary sinus – IVC) of TNF-α and IL-6. **C:** CKD induced left ventricular (LV) hypertrophy, diastolic dysfunction (E/A, E/e' ratio) and abnormal LV strain. **D:** Cardiomyocytes exposed to CKD plasma showed impaired contractility and speed of relaxation and altered Ca+2 cycling (SERCA-2A), which improved after TNF-α and IL-6 neutralization.

FR-OR48

Computational Quantification of Interstitial Fibrosis and Tubular Atrophy (IFTA) for CKD Cases of the Kidney Precision Medicine Project

Brendon Lutnick,[1] Avi Z. Rosenberg,[11] Laura Barisoni,[2] Charles E. Alpers,[3] Yijiang Chen,[4] Andrew Janowczyk,[4] Anant Madabhushi,[4] Jose Torrealba,[13] Astrid Weins,[5] Isaac E. Stillman,[6] Leal C. Herlitz,[7] Luis Rodrigues,[12] Jonathan E. Zuckerman,[8] Sanjay Jain,[9] Ulysses G. Balis,[11] Kuang-Yu Jen,[10] Pinaki Sarder.[1] Kidney Precision Medicine Project *[1]University at Buffalo, Buffalo, NY; [2]Duke University, Durham, NC; [3]University of Washington, Seattle, WA; [4]Case Western Reserve University, Cleveland, OH; [5]Brigham and Women's Hospital, Boston, MA; [6]Harvard University, Cambridge, MA; [7]Cleveland Clinic, Cleveland, OH; [8]University of California Los Angeles, Los Angeles, CA; [9]Washington University in St Louis, St Louis, MO; [10]University of California Davis, Davis, CA; [11]University of Michigan, Ann Arbor, MI; [12]Universidade de Coimbra, Coimbra, Portugal; [13]The University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Quantification of interstitial fibrosis and tubular atrophy (IFTA) is critical in the evaluation of kidney diseases. In this study, our previously developed computational IFTA segmentation model was tested on an independent dataset of renal biopsy whole slide images (WSI) from Kidney Precision Medicine Project (KPMP) and compared to visual assessment.

Methods: A computational model for the IFTA segmentation was trained using 48 PAS stained WSIs from kidney biopsies obtained at three non-KPMP institutions. Twenty-six PAS WSIs from the KPMP chronic kidney disease (CKD) cohort were used as independent testing dataset. Quality control (QC) of the KPMP WSIs was performed using HistoQC, a previously developed QC tool for digital pathology images. Computationally derived percent IFTA scores were calculated using morphological processing to segment IFTA tissue regions in WSIs. Three KPMP pathologists independently estimated the percent IFTA on the same KPMP dataset. The pathologists' estimates and the computationally predicted percent IFTA values were compared pairwise using Pearson correlation.

Results: Computationally derived IFTA segmentations from select cases are shown in ***Fig. 1a.*** The Pearson correlation showed a high degree of agreement between both pathologists and the computational model. The pairwise correlations are shown in the confusion matrix in ***Fig. 1b.***

Conclusions: Computational segmentation of IFTA has the potential to add enhanced reproducibility, precision, and efficiency to clinical tasks such as the estimation of percent IFTA.

Funding: NIDDK Support

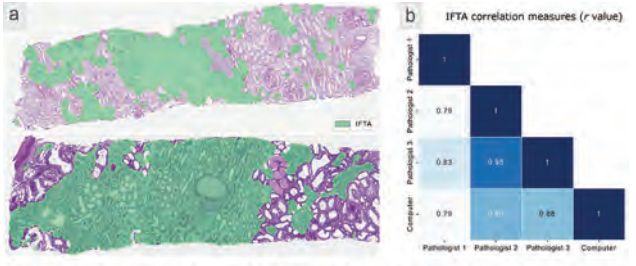


Figure 1. IFTA quantification results for KPMP renal biopsies. (a) Qualitative performance depicting segmented IFTA region in green overlaid on top of select KPMP CKD renal biopsies. (b) Pearson correlation measures comparing pathologists' visual assessment of IFTA and computationally quantified IFTA scores.

Complement Convertases in Glomerulonephritis: An Explainable Artificial Intelligence-Assisted Renal Biopsy Study

Thorsten Wiech,[1] Maria de las Mercedes Noriega,[1] Tilman Schmidt,[1] Sonia Wulf,[1] Timo Koch,[2] Philipp Marquardt,[2] Sergey Biniaminov,[2] Elion Hoxha,[1] Nicola M. Tomas,[1] Tobias B. Huber,[1] Peter F. Zipfel.[3] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]HS Analysis, Karlsruhe, Germany; [3]Leibniz-Institut fur Naturstoff-Forschung und Infektionsbiologie eV Hans-Knoll-Institut, Jena, Germany*.

Background: Complement activation is crucial in the pathogenesis of C3 glomerulopathy (C3GP). It is likely also involved in other forms of glomerulonephritis (GN), however, here, intensity, significance, and predominant activation pathways are less clear.

Methods: Proximity ligation assays (PLA) were used to visualize C3/C5 complement convertases in renal biopsies. Close proximity of C3b and Bb or C2 and C4b was interpreted as assembled alternative or classical/lectin C3/C5 convertases, respectively. For quantification we used deep learning based on explainable artificial intelligence (xAI) in a two-stage workflow: 1. detection of the glomeruli and 2. detection of the PLA signals. Signal densities were calculated as numbers of signals per glomerular area [signals/sqmm]. Cases of C3GP (n=10), immune complex-mediated membranoproliferative GN (IC-MPGN; n=10), IgA nephropathy (IgAN; n=10), postinfectious GN (PIGN; n=10), and membranous nephropathy (MN; n=10) were analyzed and compared with thin basement membrane disease (n=10) as control group, in which no local complement activity is expected.

Results: In C3GP and PIGN a clear predominance of the alternative convertase (mean 8410 and 14483 signals/sqmm) was detected as compared to the control group (mean 798 signals/sqmm) whereas IC-MPGN and MN cases showed higher densities of the classical/lectin convertase (3039 signals/sqmm and 5015 signals/sqmm) as compared to the control group (mean 176 signals/sqmm). Interestingly, cases with IgAN revealed increased densities for the alternative convertase (mean 2088 signals/sqmm) but only very slightly increased densities for the classical/lectin convertase (225 signals/sqmm).

Conclusions: This work shows the applicability of human-machine collaboration based on xAI to characterize and quantify local complement activity. The results reveal insights into the role of complement in the pathogenesis of different forms of glomerulonephritis. Moreover, it opens up the possibility to assess the local activity of the alternative and the classical/lectin pathway C3/C5 convertases in individual patients. Since several novel anti-complement agents are under clinical investigation, this method might become helpful for a more individual complement targeting therapy.

Cubilin Is a Novel Target Antigen in Anti-Brush Border Disease

Johann Morelle,[1,2] Tiffany Caza,[3] Hanna Debiec,[5] Olivier Devuyst,[6,1] Pierre M. Ronco,[4,5] Christopher P. Larsen.[3] *[1]Cliniques universitaires Saint-Luc, Brussels, Belgium; [2]Universite catholique de Louvain, Brussels, Belgium; [3]Arkana Laboratories, Little Rock, AR; [4]Hopital Tenon, Paris, France; [5]INSERM, Paris, France; [6]Universitat Zurich, Zurich, Switzerland*.

Background: Anti-brush border antibody disease (ABBA) is an autoimmune kidney disease that frequently progresses to kidney failure. It is characterized by proximal tubule damage, IgG-positive immune deposits along the tubular basement membrane (TBM), and circulating autoantibodies directed against the brush border. To date, the multiligand receptor megalin (also known as LDL receptor-related protein 2, LRP2) is the only target antigen associated with ABBA.

Methods: Here, we investigated a patient with LRP2-negative ABBA and applied mass spectrometry and confocal microscopy to identify a novel target antigen.

Results: A 75-year-old European female patient with past history of hypertension, type 2 diabetes and stage G3/A1 CKD was referred for rapid decline in kidney function (decrease in CKD-EPI estimated glomerular filtration rate from 37 to 16 ml/min per 1.73 m^2 over a few months). This was associated with new onset proximal tubule dysfunction, as attested by low molecular weight proteinuria and aminoaciduria. There was no evidence of monoclonal gammopathy, systemic autoimmune disease or exposure to environmental toxins, and serum cobalamin level was normal. The kidney biopsy revealed a protracted pattern of tubular injury, granular IgG deposits along the TBM, with a predominance of IgG1 subclass, and electron-dense deposits in the TBM on ultrastructural analysis. There was no light chain restriction. Although indirect immunofluorescence showed reactivity of the patient's serum against normal kidney brush border, consistent with the diagnosis of ABBA, immunofluorescence failed to detect LRP2 within TBM deposits. Protein G immunoprecipitation followed by mass spectrometry revealed cubilin (CUBN), another multiligand, endocytic-membrane glycoprotein of the proximal tubule, to be uniquely present within immune complexes eluted from frozen biopsy tissue. Confocal microscopy confirmed CUBN specifically colocalized with IgG in the TBM. Such colocalization was specific to the disease and not observed in other immune complex-mediated tubulointerstitial diseases, including LRP2 nephropathy, IgG4-related kidney disease, idiopathic hypocomplementemic interstitial nephritis, lupus nephritis, or polyomavirus nephritis.

Conclusions: CUBN is a novel target antigen in ABBA.

FR-OR51

The Effect of Dapagliflozin on Rate of Kidney Function Decline in Patients with CKD: A Prespecified Analysis from the DAPA-CKD Trial

Hiddo J. L Heerspink,[1,2] Niels Jongs,[1] Glenn M. Chertow,[3] Anna Maria Langkilde,[4] John McMurray,[5] Ricardo Correa-Rotter,[6] Peter Rossing,[7,8] David Sjostrom,[4] Bergur V. Stefansson,[4] Robert D. Toto,[9] David C. Wheeler,[10] Tom Greene.[11] *[1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Stanford University School of Medicine, Stanford, CA; [4]AstraZeneca, Gothenburg, Sweden; [5]University of Glasgow, Glasgow, United Kingdom; [6]The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; [7]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [8]University of Copenhagen, Copenhagen, Denmark; [9]UT Southwestern Medical Center, Dallas, TX; [10]University College London, London, United Kingdom; [11]University of Utah Health, Salt Lake City, UT*.

Background: Dapagliflozin reduced the risk of kidney failure in patients with chronic kidney disease (CKD) with and without type 2 diabetes in the DAPA-CKD trial (NCT03036150). This pre-specified analysis assessed the effect of dapagliflozin on the rate of change in estimated glomerular filtration rate (eGFR) slope.

Methods: DAPA-CKD randomized 4304 participants with urinary albumin-to-creatinine ratio (UACR) 200–5000 mg/g and eGFR 25–75 mL/min/1.73m^2 to dapagliflozin 10 mg or placebo once daily, added to standard care. We analysed eGFR slope using

mixed effect models with different slopes from baseline to Week 2 (acute change); Week 2 to end-of-treatment (chronic eGFR slope); and baseline to end-of-treatment at median 2.3 years (total eGFR slope).

Results: In the overall cohort, dapagliflozin compared to placebo slowed mean eGFR decline from baseline to end-of-treatment by 0.9 mL/min/1.73m^2/year (95% CI 0.6–1.3). Dapagliflozin compared with placebo caused an acute eGFR decline of 2.6 mL/min/1.73m^2 (95%CI 2.2–3.1) and 2.0 mL/min/1.73m^2 (95%CI 1.4–2.7), in patients with and without type 2 diabetes, respectively. Thereafter, dapagliflozin compared to placebo reduced the mean rate of eGFR decline by a greater amount in patients with type 2 diabetes (chronic eGFR slope mean difference 2.3 mL/min/1.73m^2/year [95% CI 1.9–2.6]) than in those without type 2 diabetes (1.3 mL/min/1.73m^2/year [95% CI 0.7–1.8]; interaction p=0.005). The effect of dapagliflozin compared to placebo on total slope in patients with and without type 2 diabetes was 1.2 mL/min/1.73m^2/year (95%CI 0.8–1.6) and 0.5 mL/min/1.73m^2/year (95%CI –0.1–1.0; interaction p=0.04), respectively. The total eGFR slope was steeper in patients with higher baseline HbA1c and UACR; the beneficial effect of dapagliflozin on eGFR slope was also more pronounced in patients with higher baseline HbA1c and UACR.

Conclusions: Dapagliflozin significantly slowed long-term eGFR decline in patients with CKD. The mean difference in eGFR slope between dapagliflozin- and placebo-treated patients was greater in patients with type 2 diabetes, with higher baseline HbA1c and higher UACR.

Phenome-Wide Association Study of Common Genetic Variants in SGLT2 and Health Disparities in Kidney Outcomes

Mona Mashayekhi,[1,2] Cassianne Robinson-Cohen,[1,2] Hua-Chang Chen,[1,2] Elvis A. Akwo,[1,2] Ran Tao,[1,2] Zhihong Yu,[1,2] Lee Wheless,[1,2] Cecilia P. Chung,[1,2] Adriana Hung.[1,2] *[1]Vanderbilt University, Nashville, TN; [2]Nashville VA, Nashville, TN.*

Background: SGLT2 inhibition represents one of the greatest therapeutic achievements of the last two decades, improving cardiovascular outcomes and slowing the progression of CKD to ESRD by 30% in patients with diabetes. Whether common genetic variants in *SGLT2* gene contribute to kidney disease progression and to health disparities in kidney disease is unknown.

Methods: We tested the association of two SNPs in the *SLC5A2* gene encoding SGLT2 with clinically diagnosed phenotypes in a phenome-wide association study in 428,438 whites and 114,536 non-Hispanic blacks (NHB)s from the Million Veteran Program. Using logistic regression adjusted for age, sex, and 10 principal components of ancestry, we regressed 250 phenotypes against the two SNPs (rs9934336; rs3116150), stratified by race and diabetes status. Minor allele frequencies for rs9934336 were 0.26 and 0.20 and for rs3116150 were 0.24 and 0.04 in White and non-Hispanic Black participants, respectively.

Results: The rs9934336 variant was associated with multiple kidney phenotypes in NHBs as shown in the table, while no associations of rs9934336 and kidney phenotypes were observed in whites. When stratified by diabetes, renal failure NOS remained significantly associated in diabetics, and anemia of CKD in non-diabetics. The rs3116150 variant was also associated with several kidney phenotypes in NHBs, while no associations were observed in whites. When stratified by diabetes, most of the associations of rs3116150 and kidney phenotypes remained.

Conclusions: Our study shows that SGLT2 variants are associated with CKD and ESRD in non-Hispanic blacks. This novel association with health disparities needs to be further evaluated. Mendelian randomization studies for *SLC5A2* variants are underway

Funding: Veterans Affairs Support

Effects of Daprodustat on Hemoglobin and Quality of Life in Patients with CKD: Results of the ASCEND-NHQ Randomized, Double-Blind, Placebo-Controlled Trial

Kirsten L. Johansen,[1] Alexander R. Cobitz,[2] Renato D. Lopes,[3] Ajay K. Singh,[4] Gregorio T. Obrador,[5] Borut Cizman,[6] Iain C. Macdougall,[7] Tony Okoro,[2] Michael Sprys,[2] Vivekanand Jha,[8,9] Shivinder S. Jolly,[10] Rubeen K. Israni,[2] Csaba P. Kovesdy,[11] David C. Wheeler.[12] *[1]Hennepin Healthcare, University of Minnesota, Minneapolis, MN; [2]GlaxoSmithKline, Collegeville, PA; [3]Duke Clinical Research Institute, Duke Health, Durham, NC; [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [5]Universidad Panamericana School of Medicine, Mexico City, Mexico; [6]GlaxoSmithKline, Collegeville, PA; [7]King's College Hospital, London, United Kingdom; [8]George Institute for Global Health, New Delhi, India; [9]Faculty of Medicine, Imperial College, London, United Kingdom; [10]Clinical Research Solutions Inc, Waterloo, ON, Canada; [11]University of Tennessee Health Science Center, Memphis, TN; [12]Department of Renal Medicine, University College London, London, United Kingdom.*

Background: Daprodustat (dapro) is a hypoxia-inducible factor prolyl hydroxylase inhibitor being developed for treating anemia of chronic kidney disease (CKD). In a Phase 3 trial in non-dialysis dependent (ND) CKD patients, we evaluated the effect of dapro vs placebo (PBO) on hemoglobin (Hb) and the SF-36 quality of life Vitality score (fatigue) over 28 weeks.

Methods: Adults with CKD stage 3–5, Hb 8.5–10.0 g/dL, transferrin saturation ≥15%, ferritin ≥50 ng/ml without recent rhEPO use were randomized 1:1 to dapro or PBO to maintain Hb 11–12 g/dL (NCT03409107). Primary endpoint was mean change in Hb between baseline (BL) and the evaluation period (mean over Wk 24–28). Principal secondary endpoints were 1) proportion with ≥1 g/dL increase in Hb, 2) mean change in SF-36 Vitality (fatigue) between BL and Wk 28. SF-36 Vitality responder (≥6 point increase) and blood pressure (BP) elevations were secondary endpoints. Superiority for all endpoints was tested (1-sided α=0.025).

Results: 614 ND-CKD patients were randomized. BL demographic characteristics were balanced; Hb was similar (9.73 g/dL dapro, 9.71 g/dL PBO). The adjusted mean difference (AMD) in change in Hb was 1.40 g/dL (95% CI 1.23, 1.56; P<0.001). A greater proportion on dapro had a ≥1 g/dL increase in Hb from BL (77% vs 18%; P<0.001). Adjusted mean (SE) SF-36 Vitality score increased by 7.3 (1.1) points (dapro) vs 1.9 (1.2) points (PBO); AMD at Wk 28 was 5.4 (95% CI 2.2, 8.6; P<0.001, Figure). 58% on dapro vs 40% on PBO were SF-36 Vitality responders (difference 13%; 95% CI 4%, 22%). While more BP elevations occurred in dapro vs PBO (32% vs 26%, p=0.07), dapro's overall effect on BP was similar to PBO. Rates of adverse events were similar (dapro 69% vs PBO 71%).

Conclusions: In patients with ND-CKD, dapro effectively increased Hb, significantly improved the vitality score (fatigue) and was well tolerated.

Integrated Efficacy and Safety of Bardoxolone Methyl in CKD

Laura H. Mariani,[1] Rajiv Agarwal,[2] Sharon P. Andreoli,[3] Sripal Bangalore,[4] Geoffrey A. Block,[5] Arlene B. Chapman,[6] Melanie Chin,[7] Prasad Devarajan,[8] Keisha L. Gibson,[9] Angie Goldsberry,[7] Colin J. Meyer,[7] Megan O'Grady,[7] Peter Stenvinkel,[10] Bradley A. Warady,[11] Glenn M. Chertow.[12] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [4]New York University, New York, NY; [5]US Renal Care, Inc, Plano, TX; [6]University of Chicago Pritzker School of Medicine, Chicago, IL; [7]Reata Pharmaceuticals Inc, Plano, TX; [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [9]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [10]Karolinska Institutet, Stockholm, Sweden; [11]Children's Mercy Hospitals and Clinics, Kansas City, MO; [12]Stanford University School of Medicine, Palo Alto, CA.*

Background: Bardoxolone methyl (Bard), an Nrf2 activator, has been studied in multiple CKD trials. To further characterize the safety and efficacy of Bard, we performed integrated analyses across all studies conducted with Bard in CKD.

Methods: Data from the following placebo-controlled trials, CARDINAL Phase 3 (NCT03019185) in 157 patients with Alport syndrome, TSUBAKI (NCT02316821) in 120 patients with T2DM and CKD, and BEACON (NCT01351675) in 2185 patients with T2DM and CKD, were pooled in a CKD Placebo-Controlled Set. An Overall Integrated Analysis Set included additional data from open-label Phase 2 studies.

Results: The CKD Placebo-Controlled Set included 2462 patients (1232 placebo, 1230 Bard). The median and maximum duration of exposure for the Bard group was 0.5 years and 1.9 years, respectively. The Overall Integrated Analysis Set included 3448 patients (1340 placebo, 2108 Bard) with a maximum Bard exposure of 4.8 years. In the CKD Placebo-Controlled Set, Bard significantly increased eGFR from baseline by 6.4±0.2 mL/min/1.73m^2 ($p<0.0001$) at the last on-treatment assessment while the placebo group had a significant decrease in eGFR (mean±SE:-1.1±0.2 mL/min/1.73m^2; $p<0.0001$). The eGFR increases with Bard were sustained four weeks after treatment withdrawal (1.5±0.2 mL/min/1.73m^2; $p<0.0001$ vs baseline and vs placebo). Fewer events in a composite of ESKD, ≥30% decline in eGFR, and eGFR <15 mL/min/1.73m^2 were seen in the Bard group (111 [9%]) compared to placebo (274 [22%]). The Overall Integrated Analysis Set showed similar results. Common adverse events (AEs) in both integrated sets included muscle spasms, decreased appetite, hypomagnesaemia and decreased weight. No serious AEs of cardiac failure were reported with Bard in CKD trials conducted after BEACON.

Conclusions: Across all studies in CKD, Bard preserved kidney function with on- and off-treatment eGFR benefits and was generally well tolerated. Studies in persons with CKD conducted after BEACON mitigated the risk for heart failure previously observed in patients with type 2 diabetes and Stage 4 CKD.

Renal Outcomes Associated with Direct Acting Antiviral Therapy in Patients with Hepatitis C Virus Infection

Fridtjof Thomas,[1] Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Keiichi Sumida,[1] Miklos Z. Molnar,[2] Elani Streja,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of Utah Health, Salt Lake City, UT; [3]University of California Irvine, Irvine, CA; [4]VA Memphis Medical Center, Memphis, TN.*

Background: Direct Acting Antiviral (DAA) agents are effective treatments for chronic Hepatitis C virus (HCV) infection, leading to sustained viral response in the majority of treated individuals. While HCV infection is associated with poorer renal outcomes in observational studies, the effect of DAA therapy on long term renal outcomes remains unclear.

Methods: We identified a national cohort of US Veterans with HCV infection based on positive quantitative RNA viral load testing and extracted data on any DAA therapy using pharmacy dispensation data. We examined the association of DAA therapy (compared to no DAA therapy) with the incidence of end stage kidney disease (ESKD) and the composite of ESKD or death, using time dependent Cox models adjusted for demographic characteristics, socio-economic characteristics including alcohol and illicit substance use, comorbid conditions and baseline kidney function and proteinuria.

Results: We identified 114,358 patients with HCV infection, of whom 58,045 (51%) received a course of DAA therapy between 2013-2018. The overall mean (SD) age at HCV diagnosis was 55.0 (7.5) years, 97% were male, 38% were African American, the mean (SD) eGFR was 92 (17) ml/min/1.73 m^2 and 8% had proteinuria. There were 497 ESKD events and 26,684 composite events over a median follow-up of 11.5 years. DAA therapy was associated with lower risk of ESKD and the composite event (multivariable adjusted HRs and 95%CI: 0.43, 0.31-0.61 and 0.62, 0.60-0.65) [table].

Conclusions: In a large national cohort of US veterans DAA therapy was associated with significantly lower risk of ESKD and the composite of ESKD or death, supporting the long term benefit on kidney function of HCV cure.

Funding: Veterans Affairs Support

FR-OR56

The Comparative Effectiveness and Safety of Direct Oral Anticoagulant (DOAC) and Warfarin Initiation in Adults with Atrial Fibrillation (AF) by eGFR Category

Min Jun, Martin P. Gallagher. KODIAC-AF Project Team *The George Institute for Global Health, Newtown, NSW, Australia.*

Background: There is ongoing uncertainty regarding the risk-benefit ratio of DOACs in patients with AF and CKD.

Methods: We conducted an international multicenter cohort study(2011-2018) using healthcare data from 5 jurisdictions across Australia (666 participants of the 45 and Up Study [among 267153 recruited in 2006-09] with data linked to hospital/laboratory data [by CHeReL] and the Medicare Benefits Schedule and Pharmaceutical Benefits Scheme data provided by Services Australia; all linked data accessed via SURE) and Canada (73876 patients in AB,BC,MB,ON; record linkage of provincial administrative/ laboratory data). We propensity score matched adults with a new dispensation of a DOAC (rivaroxaban, apixaban, dabigatran) or warfarin, who had AF and a recorded eGFR grouped as ≥60,45-59,30-44, <30ml/min/1.73m^2. Chronic dialysis or kidney transplant recipients were excluded. We assessed 2 composite outcomes within 1 year of initiating either therapy: ischemic (all-cause death, ischemic stroke or TIA) and bleeding (intracranial, gastrointestinal or other). We used Cox regression to estimate the hazard ratios (HRs[95%CI]) of outcomes across eGFR categories and summarized centre data in random effects meta-analysis.

Results: A total of 74542 eligible patients were included, among whom there were 6923(9.2%) ischemic and 1572(2.1%) bleeding events recorded. Across eGFR groups, DOAC initiation was associated with lower or similar risk for the ischemic outcome compared with warfarin initiation (pooled HRs[95%CI] for eGFR groups: 0.74[0.69-0.79], 0.76[0.54-1.07], 0.68[0.61-0.75] and 0.86[0.76-0.98], respectively). Similar results were observed for bleeding (0.75[0.65-0.86], 0.81[0.65-1.01], 0.82 [0.66-1.02], 0.71[0.52-0.99], respectively). There was no evidence of heterogeneity across jurisdictions except for eGFR 45-59ml/min/1.73m^2 for the ischemic outcome (I^2=77%).

Conclusions: In this cohort of AF patients initiating DOAC or warfarin, compared to warfarin, DOAC use was associated with lower or similar risk of both ischemic and bleeding outcomes independent of eGFR. Our results suggest DOAC therapy may have a favourable risk-benefit ratio in AF patients with non-dialysis dependent CKD that is similar to that seen in AF patients with preserved kidney function. Adequately powered randomized trials are needed to confirm these findings.

Funding: Government Support - Non-U.S.

Adiposity and Obesity-Related Metabolomics: The CRIC Study

Zihe Zheng,[1] Harold I. Feldman,[1] Amanda H. Anderson,[2] Eugene P. Rhee,[3] Casey Rebholz,[4] Wei Yang,[1] Sushrut S. Waikar,[5] Jesse Y. Hsu,[1] Rupal Mehta,[6] Sylvia E. Rosas,[7] Ana C. Ricardo,[8] Chi-yuan Hsu,[9] Jing Chen,[2] Vasan S. Ramachandran,[5] Robert G. Nelson.[10] CKD Biomarkers Consortium; CRIC Study *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Tulane University, New Orleans, LA; [3]Massachusetts General Hospital, Boston, MA; [4]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [5]Boston University, Boston, MA; [6]Northwestern University Feinberg School of Medicine, Chicago, IL; [7]Joslin Diabetes Center, Boston, MA; [8]University of Illinois at Chicago, Chicago, IL; [9]University of California San Francisco, San Francisco, CA; [10]National Institutes of Health, Bethesda, MD.*

Background: Obesity and adiposity are associated with progression and complications of CKD, partially by altering lipid metabolism and homeostasis. However, the phenotypic- and molecular-level mechanisms underlying these associations are not well understood. We identified adiposity/obesity related (AOR) CKD subgroups and examined potential mediation of CKD progression by plasma metabolites.

Methods: Among 1,529 CRIC participants with metabolomics data (Broad Institute) we applied consensus clustering with K-means on 20 adiposity-obesity and comorbidity parameters to identify CKD subgroups. We examined mediation effects by 634 plasma metabolites on the associations of patient subgroups with CKD progression using Aalen additive hazards models. For those statistically significant mediators, we estimated the HRs of CKD progression for each 2-fold increment in metabolite level using Cox model.

Results: We discovered 3 AOR CKD subgroups (groups with low obesity/diabetes risk, high obesity risk, and high diabetes risk) associated with CKD progression. 79 metabolites were significant mediators ($p<0.05$) for this subgroup-outcome association. After Bonferroni correction ($p<6.33\times10^{-4}$) and adjusting for eGFR, 11 metabolites were associated with a lower hazard and 9 with an increased hazard of CKD progression (**Table**). After additional adjustment for covariates, 4 metabolites remained statistically significantly associated with CKD progression.

Conclusions: We identified 3 clinically meaningful CKD subgroups driven by participant adiposity/obesity profiles and metabolites that mediated the association with the risk of CKD progression. Our findings provide insights into the pathophysiological link between obesity and CKD progression and may indicate potential therapeutic targets. Replication in other populations is needed.

[a] The significance of individual mediator metabolite association with CKD progression is based on the Cox model adjusted for eGFR, with Bonferroni corrected cut off of **p<0.05/79=6.33E-04**; (significant association in the fully adjusted model is bolded)
[b] CKD progression was defined as incident ESRD or ≥ 40% eGFR decline from baseline
[c] Model adjusted for age, gender, race/ethnicity, smoking status, eGFR, log(UPCR), systolic blood pressure, diabetes status, BMI, and CVD history
* Asterisk indicates that metabolites were measured with C8-pos liquid chromatography-mass spectrometry lipids measurement, otherwise metabolites were measured with hydrophilic interaction liquid chromatography for metabolites in positive ionization mode (HILIC-pos)

Abbreviation: HR, hazard ratio; CI, confidence interval; eGFR, estimated glomerular filtration rate; UPCR, 24-hour urine protein-to-creatinine ratio

FR-OR58

Association Between the Gut Microbiota and Kidney Function

Christoph Nowak,[1] Johan Arnlov.[1,2] GUTSY Research Consortium *[1]Karolinska Institutet, Stockholm, Sweden; [2]Hogskolan Dalarna, Falun, Sweden.*

Background: The human gut microbiota is composed of the bacteria, fungi and other microorganisms that live in the lower intestines in a symbiotic relationship with the host. Disruption of the gut microbiota has been associated with cardiovascular and metabolic diseases, but the association with kidney disease is still largely unknown.

Methods: We studied the composition and predicted function of the gut microbiota based on shotgun whole-genome sequencing of microbial DNA in fecal samples collected from 9,788 adults enrolled in the longitudinal, population-based Swedish SCAPIS cohort study. Linear regression adjusted for technical variables, age, sex, Shannon diversity index and (in sensitivity analysis) established kidney disease risk factors was used to identify associations between the log(x+1)-transformed relative frequencies of 1,900 metagenomic species and estimated glomerular filtration rate (eGFR). Additional sensitivity analyses included stratified analyses for gender, hypertension and diabetes mellitus. The Benjamini-Hochberg false discovery rate (FDR) multiplicity correction was used.

Results: We included 5,130 women (57.5±4.3 years) and 4,658 men (57.6±4.4 years). The mean eGFR was 86.5±11.3 for men, and 85.5±12.1 for women. Amongst all participants, 42% had an eGFR above 90, 39% had an eGFR between 75-90, 17% had an eGFR between 60-75, 2% had an eGFR between 45-60, and less than 0.1% had an eGFR below 45. In the age- and sex-adjusted model, we identified four bacteria that were associated with eGFR at an FDR < 0.05. Additional adjustment for kidney disease risk factors rendered one of the associations no longer significant. The kidney function-associated bacteria could be identified down to the species level and belonged to the Orders of *Eubacteriales* (two bacteria), *Coriobacteriales*, and *Veillonellales*. Gene set enrichment analysis indicated significant (FDR < 0.05) enrichment in 48 metabolic pathways.

Conclusions: In the largest gut microbiome association study of kidney function on healthy adults to date, we discovered four bacteria whose abundance was associated with glomerular filtration rate. The functional enrichment of kidney function-associated microbiota provides further insights into its possible role in kidney health.

Genetic Determinants of Serum Calcification Propensity and Mortality Risk in CKD

Amber de Haan,[1] Fariba Ahmadizar,[2] Peter J. Van der Most,[1,5] Zoha Kamali,[1,5] Alireza Ani,[1,5] Stephan J. Bakker,[1,5] Harold Snieder,[1,5] Maryam Kavousi,[2] Andreas Pasch,[4,3] Mark Eijgelsheim,[1,5] Martin H. De Borst.[1,5] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands; [3]Johannes Kepler Universitat Linz, Linz, Austria; [4]Calcisco AG, Bern, Switzerland; [5]Rijksuniversiteit Groningen, Groningen, Netherlands.*

Background: Serum calciprotein particle maturation time (T_{50}), a measure of calcification propensity, is associated with cardiovascular morbidity and mortality in patients with chronic kidney disease (CKD). Here, we aimed to identify genetic loci for serum T_{50} and examine whether these loci are linked with adverse outcomes.

Methods: We performed a genome-wide association study (GWAS) of serum T_{50} in 2,739 community-dwelling individuals of mostly European descent. Subsequently, we used the community-based Rotterdam study (RS) to examine the association between the identified variants and all-cause mortality in the general population and in a subgroup of CKD patients, applying multivariate logistic regression analysis.

Results: We identified three independent genome-wide significant single nucleotide polymorphism (SNPs), rs4917 ($p=1.72 \times 10^{-101}$), rs2077119 ($p=3.34 \times 10^{-18}$), and rs9870756 ($p=3.10 \times 10^{-8}$) in the *AHSG* gene encoding fetuin-A. The three SNPs together explained 18.3% of the variation in serum T_{50}. Quantitative trait locus analysis revealed that all three SNPs have effects detectable at blood protein level of fetuin-A. Associations with outcomes were studied in 8,556 RS participants (age 65.1±9.9 y, 57% female, 63% hypertension, BMI 27.3±4.2 kg/m^2), of whom 833 had CKD (age 75.5±8.7 y, 59% female, 85% hypertension, BMI 27.7±4.1 kg/m^2). The minor allele of rs9870756, linked with a reduced T_{50} and thus a higher calcification propensity, was significantly associated with a higher risk of all-cause mortality, both in the general population [OR (95% CI)=1.14 (1.00-1.30)] and in the CKD subgroup [OR (95% CI)=1.60 (1.05-2.42)]. In the fully adjusted model, the minor allele of rs9870756 was only associated with all-cause mortality in the CKD subgroup [OR (95% CI)=1.93 (1.21-3.08)]. The other two variants were not associated with all-cause mortality.

Conclusions: We identified three independent SNPs in the fetuin-A gene as strong genetic determinants of calcification propensity. The minor allele of rs9870756 was significantly associated with a higher risk of all-cause mortality in CKD patients. Our findings connect genetic susceptibility to calcification with adverse outcome in CKD patients.

Decision Aid for Renal Therapy (DART) Reduces Decisional Conflict and Improves Knowledge Among Older Adults with Advanced CKD: A Randomized Clinical Trial

Daniel E. Weiner,[1] Dena E. Rifkin,[2] Elisa J. Gordon,[4] Ana P. Rossi,[3] Hocine Tighiouart,[1] Sarah Levine,[1] Jack Degnan,[2] Brianna R. Kuramitsu,[4] Lexi Sewall,[7] Tamara Isakova,[4] Susan Koch-Weser,[5] Keren Ladin.[6] DART Research Team *[1]Tufts Medical Center, Boston, MA; [2]University of California San Diego, La Jolla, CA; [3]Piedmont Healthcare Inc, Atlanta, GA; [4]Northwestern University, Evanston, IL; [5]Tufts University School of Medicine, Boston, MA; [6]Tufts University, Medford, MA; [7]Maine Medical Center, Portland, ME.*

Background: For older adults, making decisions about kidney failure treatments is challenging, and dialysis may be inconsistent with life goals. Greater decisional conflict is associated with regret, poor outcomes, and worse satisfaction. The DART trial assessed the effectiveness of an interactive, web-based decision aid on decisional conflict and knowledge among older CKD patients facing dialysis decisions.

Methods: Randomized trial evaluating the web-based DART versus usual education, enrolling adults age 70+, English-fluent, with CKD stage 4-5 from 4 US sites. The primary outcome was change in decisional conflict scale (DCS) score from baseline to first follow-up (~ 3 months) compared using ANCOVA. The validated 16-question DCS (100 point scale; lower score indicates less decisional conflict) measures personal perception of uncertainty in choosing among treatment options and modifiable factors contributing to uncertainty. Twelve knowledge questions about CKD and treatment options were assessed at both visits.

Results: Among 363 participants, 180 were randomized to education and 183 to DART; 162 (89%) completed DART. Mean age was 78 years, mean eGFR was 23 mL/min/1.73 m2, 78% were white and 48% had diabetes. Groups were balanced at baseline. At first follow-up, DCS score improved significantly more among the DART group [mean difference 8.7 (5.2, 12.2)]. Results were similar across DCS subscales (Table). DART was also associated with a 7.2% (3.7, 10.7) greater improvement in knowledge.

Conclusions: DART reduced decisional conflict and improved knowledge among older adults facing kidney failure treatment decisions, emphasizing that the decision-making process for older adults with advanced CKD can be improved with use of this effective educational intervention. Identification of a Special Cell Type as a Determinant of the Kidney Tropism of SARS-CoV-2

Hongchun Lin, Xinxin Ma, Yuxiang Sun, Jun Song, Yongjie Li, Hui Peng. *The Third Affiliated Hospital of Sun Yet-sun University Department of Nephrology, Guangzhou, China.*

Background: Coronavirus disease-2019 (COVID-19) is an infectious disease caused by a novel discovered coronavirus, the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The kidney tropism of SARS-CoV-2 has been well-validated clinically and often leads to various forms of renal damage in COVID-19 patients. However, the underlying mechanisms and diagnostic approaches remain to be determined.

Methods: We interrogated the expression of virus-related host factors in single-cell RNA sequencing (scRNA-seq) datasets of normal human kidneys and kidneys with pre-existing diseases. We validated the results with immunohistochemistry and urinary proteomics of COVID-19 patients and healthy individuals. We also assessed the effects of genetic variants on kidney susceptibility using expression quantitative trait loci (eQTLs) databases.

Results: We identified a subtype of renal tubular cells, which we named PT-3 cells, as being vulnerable to SARS-COV-2 infections in the kidneys. PT-3 cells were enriched in viral entry factors and replication and assembly machinery, but lacked antiviral restriction factors. PT-3 demonstrated higher proportion of $ACE2^{+}$/$CTSB^{+}$ double positive cells compared with other PTECs (20.54% vs 2.24%). Immunohistochemistry confirmed positive staining of PT-3 cells marker SCL36A2 (according to single cell RNA-seq datasets) on kidney sections from COVID-19 patients and healthy individuals. Urinary proteomics confirmed that the protein levels of PT-3 markers, in addition to ACE2, CTSB, and restriction factors, were significantly increased in the urine of COVID-19 patients. We further found that the proportion of PT-3 cells increased in diabetic nephropathy but decreased in kidney allografts and lupus nephropathy, suggesting that kidney susceptibility varied among these diseases. We finally identified several eQTLs that regulate the expression of host factors in kidney cells.

Conclusions: We comprehensively characterized the expression patterns and expression levels of viral host factors in human kidney cells and identified PT-3 cells, a special subtype of PTECs that facilitates the SARS-CoV-2 invasion of the kidney. The detection of PT-3 cells markers in human urine may be used to assess the risk of renal infection during COVID-19.

Selective Tropism of SARS-CoV-2 in Genome-Edited Kidney Organoids Reveals Nephropathic and Therapeutic Effects

Louisa Helms, Benjamin A. Juliar, Jonathan Himmelfarb, Benjamin S. Freedman. *University of Washington, Seattle, WA.*

Background: Kidneys are critical target organs of SARS-CoV-2 infection and COVID-19 disease, but whether renal effects are due to direct infection via ACE2 or indirect damage to other organs is unknown. The added risk of pre-existing polycystic kidney disease and efficacy of proposed therapeutics are not yet clear and difficult to assess in patients, animals, or cells. Organoids provide a gene editable platform to assess SARS-CoV-2 kidney infection and its tropism, pathophysiology, and effects of COVID-19 therapeutics.

Methods: Kidney organoids were differentiated from control, *PKD2*$^{-/-}$, or *ACE2*$^{-/-}$ stem cells, and infected with WA1/2020 SARS-CoV-2 ± mNeonGreen transgene. Organoids were infected under BSL3 conditions with supernatant collected for plaque assays and analyzed with immunofluorescence or RNA was extracted. Remdesivir was added post infection, or *de novo* designed LCB1 Spike binder proteins were pre-incubated with SARS-CoV-2 prior to infection.

Results: SARS-CoV-2 specifically infected organoid proximal tubules, producing bulbous cells with disrupted markers. In *ACE2*$^{-/-}$ kidney organoids, viral replication was reduced by 85%. In *PKD2*$^{-/-}$ organoids, cyst-lining epithelial cells were infected at comparable levels to healthy controls. Remdesivir treatment reduced viral replication by 71.4%. Pre-incubation of LCB1 spike binder peptides prevented viral replication at ≥ 0.3 μM and significantly reduced detectable SARS-CoV-2 infection.

Conclusions: Proximal tubular kidney epithelium is susceptible to SARS-CoV-2 infection. ACE2 is the primary entry receptor for SARS-CoV-2 infection, but alternate pathways facilitate low levels of infection. PKD cysts can be infected comparably to controls. Remdesivir and LCB1 treatment can protect kidney epithelium from SARS-CoV-2 replication via distinct mechanisms. This work provides insight into susceptibility of kidneys to SARS-CoV-2 and the effectiveness of current and developing therapeutics for treating COVID-19.

The Spike Protein of the Causative COVID-19 Virus Induces Heme Oxygenase-1: Pathophysiologic Implications

Raman D. Singh,[1] Michael A. Barry,[2] Anthony J. Croatt,[1] Allan W. Ackerman,[1] Joseph P. Grande,[3] Anupam Agarwal,[4] Karl A. Nath.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Division of Infectious Diseases, Rochester, MN; [3]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; [4]The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.*

Background: Acute kidney injury (AKI) is both a consequence and determinant of outcomes in COVID-19. The kidney is one of the major organs infected by the causative virus SARS-CoV-2. The spike protein of SARS-CoV-2 is required for viral entry into cells and is present in the urine of patients with COVID-19 and AKI. The present study examined cellular effects that result from transfecting the spike protein of SARS-CoV-2 in HEK293 kidney cells.

Methods: HEK293-$ACE2^{+}$ cells stably overexpressing ACE2 were used. Codon optimized pcDNA encoding SARS-CoV-2 spike (7788bp) or empty vector (4033bp) plasmid was transfected using Lipofectamine LTX. For studies examining the effect of quercetin (an inducer of heme oxygenase-1, HO-1), full media containing quercetin or vehicle was added at 4-6 hours post transfection. mRNA and protein expression was assessed by quantitative real-time RT-PCR and western blot respectively. Syncytium formation was assessed by acquiring phase contrast images using Olympus CK40 microscope and the area covered by syncytia was measured using ImageJ software.

Results: HEK293-$ACE2^{+}$ cells expressed SARS-CoV-2 spike protein upon spike transfection. Such expression led to syncytia formation, the sloughing of sheets of cells, and focal denudation of the cell monolayer. Spike protein expression upregulated potentially nephrotoxic genes such as TNF-α, MCP-1, and ICAM1. Spike protein expression also upregulated potentially cytoprotective genes such as HO-1, as demonstrated by HO-1 mRNA and protein expression and relevant signaling pathways (p-Akt, p-STAT3, and p-p38) involved in inducing the HO-1 gene. Quercetin, a naturally occurring compound that induces HO-1, markedly reduced syncytia formation and spike protein expression.

Conclusions: These findings introduce a clinically relevant, spike protein-induced, in vitro model for the study of AKI in COVID-19. The major conclusions of the study are: 1) Spike protein expression in kidney cells provides a useful and timely model for the study of maladaptive and adaptive responses in these cells relevant to AKI observed in COVID-19; 2) spike protein expression in kidney cells upregulates HO-1; and 3) quercetin, an inducer of HO-1, may provide a clinically relevant/feasible protective strategy in AKI occurring in the setting of COVID-19.

A Novel Soluble ACE2 Protein Protects from Lethal SARS-CoV-2 Infection

Luise Hassler,[1] Jan Wysocki,[1] Ian A. Gelarden,[1] Anastasia Tomatsidou,[2] Haley Gula,[2] Vlad I. Nicolaescu,[2] Glenn Randall,[2] Anjana Yeldandi,[1] Daniel Batlle.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]The University of Chicago, Chicago, IL.*

Background: Severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) uses full-length angiotensin converting enzyme 2 (ACE2) as the main receptor to enter the target cells. A novel soluble ACE2 protein with increased duration of action and binding capacity to exert a decoy effect as a way to intercept SARS-CoV-2 from binding to membrane-bound ACE2 was generated. The protein was administered to a lethal mouse model of COVID-19 to examine its efficacy.

Methods: A human soluble ACE2 variant fused with a 5kD albumin binding domain (ABD) was linked via a dimerization motif hinge-like 4-cysteine dodecapeptide to improve binding capacity to the SARS-CoV-2. This novel protein (ACE2 1-618-DDC-ABD) was administered intranasally and intraperitoneally prior to viral inoculation and on the two following consecutive days. Infected animals were observed for weight, clinical score and mortality in a BSL-3 facility. Upon sacrifice, lung histopathology was evaluated, and viral loads were measured by plaque assay.

Results: Infected mice that received ACE2-1-618-DDC-ABD developed only moderate disease assessed by a clinical score, modest weight loss and lung histology. At 6 days, mortality was totally prevented in the treated group (figure), lung histopathology was markedly improved and viral lung and brain titers reduced or non-detectable. By contrast, in untreated animals, lung histology revealed extensive pulmonary alveolar hemorrhage and mononuclear infiltrates, and they all became severely ill and had to be euthanized by day 6/7 (figure).

Conclusions: This study demonstrates for the first time in vivo the preventative/therapeutic efficacy of a soluble ACE2 protein in a preclinical animal model.

Immunological Response in Dialysis and Kidney Transplant Patients with SARS-CoV-2 Infection

Stefania Affatato,[1] Federica Mescia,[1] Virginia Quaresima,[2] Chiara Fiorini,[2] Mario Gaggiotti,[2] Nicola Bossini,[2] Paola Gaggia,[2] Raffaele Badolato,[1] Luigi D. Notarangelo,[3] Marco Chiarini,[2] Francesco Scolari,[1] Federico Alberici.[1]
[1]Universita degli Studi di Brescia, Brescia, Italy; [2]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy; [3]National Institute of Allergy and Infectious Diseases Laboratory of Clinical Immunology and Microbiology, Bethesda, MD.

Background: Mortality for COVID-19 in dialysis(HD) and kidney transplant(TX) patients(pts) is 30%. In these pts the immunology of the disease has been poorly explored.
Methods: 32 HD or TX pts hospitalized for COVID-19 (COV), of which 13 with benign course(PosCOV) and 19 who died or developed ARDS(NegCOV), 10 controls(HC) and 12 HD/TX without COVID-19(PC), have been included. Lymphocytes subsets, dendritic cells(DC) and monocytes activation (MA) have been explored.
Results: COV showed lower counts of CD4+, CD8+, CD56+, CD19+, DC and higher counts of terminally differentiated CD19+ compared to HC and PC; CD4+, CD8+, CD19+ and MA were significantly lower in NegCOV than PosCOV. Compared to HD, TX showed lower CD56+, pDC and MA.
Conclusions: The COV group showed immunological alterations compared to HC and PC with deeper alterations of the innate immune system in TX pts with COVID-19.

Immune Monitoring of Kidney Transplant Recipients After SARS-CoV-2 mRNA Vaccination

Ayman Al Jurdi,[1,2] Rodrigo Benedetti Gassen,[1] Thiago J. Borges,[1] Frank E. Hullekes,[1] Isadora T. Lape,[1] Orhan Efe,[1,2] Areej saud a Alghamdi,[3] Poojan Patel,[2] John Y. Choi,[2] Zhabiz Solhjou,[2] Camille Kotton,[1] Jamil R. Azzi,[2] Leonardo V. Riella.[1]
[1] [1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Boston Children's Hospital, Boston, MA.

Background: There is limited data on the safety and efficacy of SARS-CoV-2 mRNA vaccines in kidney transplant recipients (KTRs).
Methods: We conducted a prospective, multi-center study of 58 adult KTRs receiving mRNA-BNT162b2 or mRNA-1273 vaccines to assess vaccine safety and efficacy. Primary outcome was biopsy-proven rejection within 3 months of vaccination. Secondary outcomes included adverse events, serum creatinine, proteinuria, donor-derived cell-free DNA (ddcfDNA) levels, and antibody and cellular immunity generation against SARS-CoV-2.
Results: Median age was 62 with 41% females. Median time post-transplantation was 48 months. Only one patient (2%) developed acute cellular rejection though patient had been recently converted to belatacept. There were no severe adverse events or deaths during follow-up. Two patients (3%) developed SARS-CoV-2 infection, one of whom required hospitalization. There was no significant change in serum creatinine, proteinuria or ddcfDNA during the study. Following vaccination, 36%, 25% and 20% of KTRs developed anti-spike, anti-S1 and anti-RBD antibodies. KTRs on mycophenolate-based and steroid-maintenance regimens were less likely to develop an anti-spike antibody response. 100% of KTRs with anti-spike and anti-RBD antibodies had a neutralizing response, compared to 44% in KTRs with anti-spike but without anti-RBD antibodies (RR 2.25, 95% CI 1.08-4.67). There was a significant increase in IFN-gamma spots per 10^6 PBMCs incubated with S1 peptides following vaccination (p=0.0143).

Conclusions: SARS-CoV-2 vaccination in KTRs was safe and associated with the generation of cellular immune response and in a third of patients with anti-spike antibody response. The degree of protection gained by these responses needs to be evaluated in future studies.

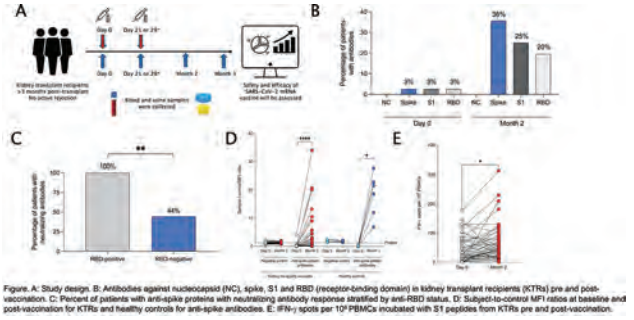

Figure. A: Study design. B: Antibodies against nucleocapsid (NC), spike, S1 and RBD (receptor-binding domain) in kidney transplant recipients (KTRs) pre and post-vaccination. C: Percent of patients with anti-spike proteins with neutralizing antibody response stratified by anti-RBD status. D: Subject-to-control MFI ratios at baseline and post-vaccination for KTRs and healthy controls for anti-spike antibodies. E: IFN-γ spots per 10^5 PBMCs incubated with S1 peptides from KTRs pre and post-vaccination.

SA-OR07

SARS-CoV-2 Vaccine Impact on COVID-19 Incidence in Maintenance Dialysis Patients

Eduardo K. Lacson,[1,2] Harold J. Manley,[1] Gideon N. Aweh,[1] Vladimir Ladik,[1] Jill M. Frament,[1] Caroline M. Hsu,[2] Dana Miskulin,[2] Daniel E. Weiner,[2] Doug Johnson.[1] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

Background: Maintenance dialysis patients are highly susceptible to SARS-CoV-2 and historically, when infected, >60% need emergency department or hospital care and mortality approaches 20% in 90 days. We evaluated the impact of vaccination against SARS-CoV-2 on incident COVID-19 cases in dialysis patients from 260 clinics in 28 states.

Methods: All adult maintenance dialysis patients without prior COVID-19 treated by Dialysis Clinic, Inc. who received one dose of vaccine were classified as "partially vaccinated" and at 14+ days after completing the manufacturer recommended series were classified as "fully vaccinated"; else were "unvaccinated". During the study period from 2/1/21 to 5/19/21, all new test-confirmed COVID-19 cases were documented. Every day at-risk for each patient was assigned to vaccination status and contributed to the denominator. Case rates per 10,000 days at-risk were compared using logistic regression.

Results: Among 13,717 eligible patients contributing 1,426,187 days at-risk, 327 new COVID-19 occurred. Only 4% were in fully vaccinated patients, with 25% in partially vaccinated and 70% in unvaccinated patients. Unvaccinated patients had 10-fold higher risk of COVID-19 than fully vaccinated patients (Table). Only 3 of 13 (23%) breakthrough cases were symptomatic, and 1 of 13 (8%) was hospitalized for COVID-19 with no deaths due to COVID-19. In contrast, 67 (29%) of unvaccinated and 34 (40%) of partially vaccinated patients were hospitalized for COVID-19, with 6 and 2 deaths, respectively.

Conclusions: Overall incidence of COVID-19 declined compared to rates prior to the study period. Regardless, there is marked risk reduction of incident COVID-19 for SARS-CoV-2 vaccinated maintenance dialysis patients, and most breakthrough infections were asymptomatic in fully vaccinated patients. These preliminary results support aggressive vaccination and a plan for maintenance of immunity to alleviate the devastating COVID-19 toll for dialysis patients.

COVID-19 Incidence from 2/1/21 to 5/19/21

Status	# Unique Patients*	Patient-Days at-Risk	# New COVID-19	new COVID-19/10,000 Pt-Days	Odds Ratio
Unvaccinated	3891	666,922	230	3.4	10.4 (6.9,18.2)
Partially Vaccinated	1112	366,775	84	2.3	6.9 (3.9,12.4)
Fully Vaccinated	8714	392,490	13	0.3	Reference

* Mutually exclusive status at the end of follow-up (may have contributed time at-risk in other statuses).

SA-OR08

Genetic Findings in COVID19-Positive Patients from a Cohort of Kidney and Liver Patients at Columbia University

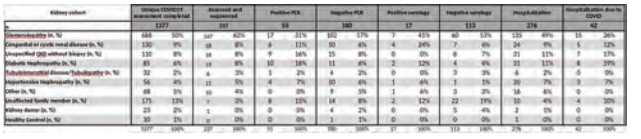
Enrico Cocchi, Maddalena Marasa, Mark Elliott, Jason Zheng, Jordann Lewis, Rafael Gras, Stacy E. Piva, Byum hee Kil, Debanjana Chatterjee, Vanna M. Nicasio, Maria M. Morban, Iman Ghavami, Judy Liang, Anna Mo, Kelsey O. Stevens, Gina Jin, Jung Soo Kim, Junying Zhang, Ali G. Gharavi. Gharavi Lab. *Columbia University, New York, NY.*

Background: Patients with preexisting chronic kidney (CKD) and liver disease and liver are more at risk from COVID-19, but reasons for variability in disease susceptibility and severity is still poorly understood. Given the high infection rate in New York City, we conducted a COVID-19 assessment survey in a cohort of CKD and liver patients previously consented into genetic studies.

Methods: Between March and August 2020, we completed 1601 unique IRB-approved COVID-19 assessment surveys. The survey covered COVID-19 symptoms, exposure risk, PCR and/or serology testing, and hospitalization. 298 of those patients were exome sequenced. We analyzed differences in COVID-19 PCR, serology and hospitalization rate and genetic analysis to identify possibly associated variants in the immune/coagulation pathways, suggested to be involved in COVID-19 susceptibility/severity by recent publicationw. We also analyzed variants based on the American College of Medical Genetics and Genomics (ACMG) guidelines for clinical annotation of genetic results

Results: Hispanic/Latino patients were more likely to have a positive COVID-19 PCR (Fisher Exact Test p: 0.01, 29.5% vs 16.7%), serology (Fisher Exact Test p: 0.02, 22.9% vs 9.7%) and hospitalization (Fisher Exact Test p: 0.01, 29.5% vs 16.7%). Patients with glomerulopathy had lower positive COVID-19 PCR tests (Fisher Exact Test p: 0.01, 14.7% vs 48.7%). Analysis of exome data identified an excess number of rare variants in genes in the immune dysregulation pathways among patients with positive COVID-19 PCR test, (fisher p: 0.01, 75% vs 18%). These results were mostly driven by rare variants in *CASP10,* which were more common among the Hispanic/Latino population.

Conclusions: We confirm that Hispanic/Latino ethnicity is a significant risk factor for positive COVID-19 PCR, serology and hospitalization. The analysis of the genetic mechanisms in immune/coagulation pathways identified an excess of rare variants in the *CASP10* gene, results that overlap with Hispanic/Latino ethnicity.



SA-OR09

APOL1 Risk Variants, AKI, and Death in Black Veterans with COVID-19

Adriana Hung,[1,2] Shailja C. Shah,[4,5] Alexander Bick,[1,2] Zhihong Yu,[1,2] Hua-Chang Chen,[1,2] Ran Tao,[1,2] Elvis A. Akwo,[1,2] Cecilia P. Chung,[1,2] Michael E. Matheny,[1,2] Katalin Susztak,[3] Cassianne Robinson-Cohen,[1,2] Sony Tuteja,[3] Edward D. Siew.[1,2] Million Veteran Program *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Nashville VA, Nashville, TN; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]University of California San Diego, La Jolla, CA; [5]San Diego VAMC, San Diego, TN.*

Background: Health disparities exist in rates of acute kidney injury (AKI) and death related to COVID-19. Black patients with two copies of apolipoprotein L1 (*APOL1*) variants G1 or G2 have significantly increased rates of renal disease. It is unknown whether *APOL1* is associated with an increased risk for AKI in COVID-19 infection.

Methods: We performed a retrospective study of 990 Black patients in the VA Million Veteran Program hospitalized with COVID-19 between March 2020 and January 2021. The primary exposure was having 2 *APOL1* risk variants (APOL1 high-risk group), compared to having 1 or 0 risk variants (*APOL1* low-risk group). The primary outcome was AKI. The secondary outcomes were AKI severity stages and death. We performed a subgroup analysis in individuals with eGFR> 60 ml/min/1.73m2.

Results: 392 (39.6%) patients developed AKI, 28 (7%) required dialysis and 122 (12.3%) died. Patients categorized as *APOL1* high-risk group had a significantly higher risk of AKI (adjusted odds ratio [OR] 1.98; 95% confidence interval [CI]: 1.29-3.05; p=0.002), higher AKI severity stages (OR 2.06; 95% CI: 1.39-3.04; p<0.001) and death (OR 2.15; 95% CI: 1.23-3.67; p=0.006). The association with AKI persisted in the subgroup with normal kidney function (OR 1.92; 95% CI: 1.15-3.22; p=0.01). Figure 1. shows the proportion of patients by AKI stages according to *APOL1* risk group.

Conclusions: *APOL1* renal risk variants were associated with higher risk of AKI, AKI severity, and death in Black Veterans hospitalized with COVID-19, even amongst individuals with prior normal kidney function. We identify a specific genetic contribution to COVID-19 health disparities.

Neutrophil Extracellular Traps and Endothelial Injury in COVID-19 Associated AKI

Naomi Pode shakked,[1,2] Brandon M. Henry,[1] Stefanie W. Benoit.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Neutrophil Extracellular Traps (NETs) release has been implicated in the pathomechanism underlying severe end-organ damage in COVID-19. While NETs are difficult to measure, cell free DNA (cfDNA) has been shown to be a surrogate measure for NETosis. The aim of this study was to determine whether circulating levels of cfDNA may be associated with development of acute kidney injury (AKI) in COVID-19.

Methods: Blood samples were collected prospectively in the emergency department from adult patients admitted to the hospital with COVID-19. cfDNA levels and serum biomarkers of AKI, thrombotic microangiopathy, and inflammation were correlated, as well as development of severe AKI defined by KDIGO SCr Stages 2+3 and need for renal replacement therapy (RRT).

Results: 51 patients were enrolled, median age 50.5 years (IQR 41-66). Age, race, coronary artery disease, heart failure, chronic kidney disease, and chronic liver disease were associated with severe AKI, while hypertension was protective. cfDNA levels were higher in those who developed severe AKI ($p<0.001$) and needed RRT ($p=0.020$) during hospitalization. cfDNA positively correlated with SCr, NGAL, cystatin C, neutrophil count, neutrophil-to-lymphocyte ratio, C3a, C5a, Scb5-9, IL-6, IL-8, IL-10, TNF-α, LDH, CRP, ferritin, fibrinogen, and negatively correlated with ADAMTS13/VWF ratio and lymphocyte count. In the multivariable logistic regression model adjusted for age, comorbidities, and SCr, one unit increase in cfDNA value was associated with a 4.6% increased odds of severe AKI (OR=1.046; p=0.040). Diagnostic performance of cfDNA is shown in Table 1.

Conclusions: Intravascular NETosis could be an important factor in development of microthrombosis and COVID-19 associated AKI. Further research is urgently needed to understand the role of NETosis in COVID-19 and evaluate therapeutic avenues.

Diagnostic Performance of cfDNA for COVID-19 AKI

	cfDNA Cut-Off (ng/mL)	Sensitivity	Specificity	AUC (95%CI)
Severe AKI	161.3	0.67	0.92	0.82 (0.67-0.97)
Need for RRT	142.0	0.75	0.77	0.76 (0.54-0.98)

SA-OR11

Identification of Molecularly Distinct Sub-Phenotypes in AKI and Association with Long-Term Clinical Outcomes

Pavan K. Bhatraju,[1] David K. Prince,[1] Sherry Mansour,[2] Talat Alp Ikizler,[3] Edward D. Siew,[3] Amit X. Garg,[4] Alan S. Go,[5] James S. Kaufman,[6] Paul L. Kimmel,[7] Steven G. Coca,[8] Chirag R. Parikh,[9] Mark M. Wurfel,[1] Jonathan Himmelfarb.[1] *[1]University of Washington, Seattle, WA; [2]Yale University, New Haven, CT; [3]Vanderbilt University, Nashville, TN; [4]Western University, London, ON, Canada; [5]University of California San Francisco, San Francisco, CA; [6]New York University, New York, NY; [7]The George Washington University Milken Institute of Public Health, Washington, DC; [8]Mount Sinai Health System, New York, NY; [9]Johns Hopkins University, Baltimore, MD.*

Background: AKI is a heterogeneous clinical syndrome with varying causes, pathophysiology and diverse clinical outcomes; however, staging AKI by serum creatinine does not fully capture underlying patient heterogeneity. Our goal was to identify AKI sub-phenotypes more tightly linked to underlying pathophysiology and long-term clinical outcomes.

Methods: We independently applied latent class analysis (LCA) and k-Means clustering to 29 clinical, plasma and urinary biomarker data measured during hospitalization to identify AKI sub-phenotypes in the ASSESS-AKI study. AKI sub-phenotype associations were examined with the composite of major adverse kidney events (MAKE), defined as incident or progressive chronic kidney disease, long-term dialysis, or all-cause death during study follow-up.

Results: Among 769 AKI patients both LCA and k-Means clustering identified two AKI sub-phenotypes. Class 1 was characterized by a higher prevalence of prior congestive heart failure and favorable blood inflammatory and urinary tubular injury biomarkers, while class 2 was characterized by higher rates of prior chronic kidney disease and less favorable biomarkers. After a median follow-up of 4.7 years, the risk for MAKE was higher with class 2 (HR 1.41; 95% CI, 1.08 to 1.84) compared with class 1 adjusting for demographics, hospital level factors and KDIGO Stage of AKI. The higher risk of MAKE among class 2 was explained by a higher risk of chronic kidney disease progression and dialysis (**Figure 1**).

Conclusions: In this analysis, we identify two molecularly distinct AKI sub-phenotypes with differing risk of long-term outcomes, independent of current criteria to risk stratify AKI. Future identification of AKI sub-phenotypes may facilitate linking therapies to underlying pathophysiology to prevent long-term sequalae after AKI.

Funding: NIDDK Support

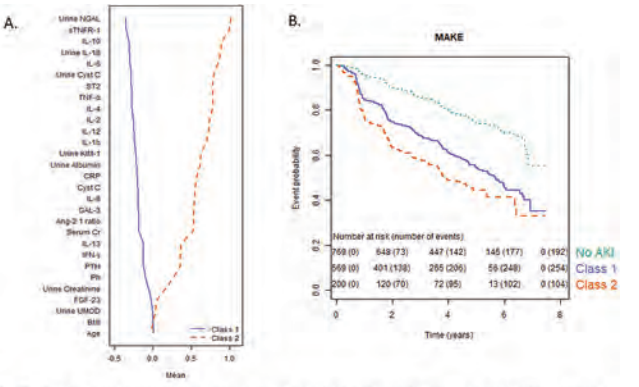

Figure 1a. 29 different continuous variables used in clustering analyses by AKI sub-phenotypes. Individual continuous variables were placed on a *z* scale with a mean of zero and standard deviation of one. Variables are presented from top to bottom in order of maximum separation between class 1 and 2.

SA-OR12

Association of Mild-to-Moderate AKI with CKD Progression Among Individuals with CKD: The CRIC Study

Anthony N. Muiru,[1] Jesse Y. Hsu,[2] Kathleen D. Liu,[1] Paul E. Drawz,[3] Ana C. Ricardo,[4] James P. Lash,[4] Jonathan J. Taliercio,[5] Edward J. Horwitz,[6] James H. Sondheimer,[7] Jing Chen,[8] Jiang He,[8] Lawrence J. Appel,[10] Alan S. Go,[9] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of Pennsylvania, Philadelphia, PA; [3]Regents of the University of Minnesota, Minneapolis, MN; [4]University of Illinois at Chicago, Chicago, IL; [5]Cleveland Clinic, Cleveland, OH; [6]The MetroHealth System, Cleveland, OH; [7]Wayne State University School of Medicine, Detroit, MI; [8]Tulane University School of Medicine, New Orleans, LA; [9]Kaiser Permanente, Oakland, CA; [10]Johns Hopkins Medicine, Baltimore, MD.*

Background: Observational studies have suggested that even mild episodes of AKI have a large effect on accelerating CKD progression (EJ See et al 2019;95:160-172). These seem inconsistent with clinical trials in which reducing AKI rate did not translate into reducing CKD risk (AX Garg et al JAMA 2014: 311:2191-8, SG Coca et al JASN 2016; 27: 2529-42). These differences may be due to incomplete control of important confounders such as proteinuria since proteinuria is both a strong risk factor for development of AKI and CKD progression.

Methods: To better address potential residual confounding, including confounding by pre-AKI proteinuria and pre-AKI eGFR slope, we quantified the independent association between an episode of mild-to-moderate AKI (identified using inpatient SCr measurements and staged using KDIGO guidelines) on eGFR trajectory (defined using outpatient research protocol measurements) in the prospective Chronic Renal Insufficiency Cohort (CRIC).

Results: Mean age of the 3150 CRIC participants included was 65 years, 44% were female, and 43% self-identified as Black. Mean baseline eGFR was 50 mL/min/1.73m^2, median urine protein-Cr ratio was 0.1g/g, and 54% had diabetes. 433 participants experienced at least one episode of AKI (68% stage 1; 24% stage 2). In linear mixed effects models, after controlling for demographics, pre-AKI proteinuria, pre-AKI eGFR slope, and time-updated diabetes mellitus, heart failure, SBP, and receipt of ACE-I/ARBs, an episode of AKI was not significantly associated with eGFR change (difference in mean eGFR at year 1 = -0.7 mL/min/1.73 m2, 95% CI -2.7 to 1.2 mL/min/1.73 m^2 95%, p=0.46). There was no detectable change in eGFR slope from before to after AKI (difference in eGFR slope = 0.1 mL/min/1.73 m^2 per year) (p=0.82 and 95% CI -0.7 to 0.8 mL/min/1.73 m^2 per year).

Conclusions: Prior observational studies showing an association between mild-to-moderate AKI and CKD progression may be exaggerated due to residual confounding. After accounting for key potential confounders hitherto not considered in published analyses, mild-moderate AKI was not independently associated with an absolute drop in eGFR nor eGFR slope after AKI.

Evidence for Kidney Involvement in an Acute Graft vs. Host Disease Model of Allogeneic Stem Cell Transplant (HSCT) in Non-Human Primates

Sangeeta R. Hingorani,[2] Edgar A. Jaimes,[3,1] Thangamani Muthukumar,[1] Surya V. Seshan.[1] *[1]Weill Cornell Medicine, New York, NY; [2]Seattle Children's Hospital, Seattle, WA; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Kidney injury is increasingly recognized as a significant cause of morbidity and mortality in recipients of HSCT. The frequency of kidney injury can be as high as 73% and among patients with kidney injury who require dialysis, mortality

approaches 100%. Acute graft-versus host disease (aGVHD) has emerged as an important risk factor for kidney injury in HSCT patients but whether the kidney itself is a target of aGVHD has not been established. In this study and utilizing a non-human primate model of HSCT we tested the hypothesis that the kidney undergoes inflammatory changes consistent with aGVHD.

Methods: For this study we used a non-human primate (NHP) model of allogeneic HSCT (allo-HCT) and aGVHD, in which a donor graft is transplanted into MHC haploidentical recipients pre-conditioned with myeloablative total body irradiation. Transplant recipients received no post-transplant immunosuppression, which enabled interrogation of the natural history of aGVHD. Apheresis was performed after G-CSF mobilization and an unmanipulated G-CSF mobilized apheresis product was transplanted into MHC haplo-identical transplant recipients in the allo-HCT cohort (N=3). As controls we used normal animals that did not undergo any intervention (N=4). NHP were euthanized one week after transplant and kidneys saved for histology and IHC (CD3, CD20, CD68, CD 56 and Granzyme B).

Results: As expected control kidneys had normal renal histology. In contrast, kidneys from allo-HCT recipients had evidence of mesangiolysis and tubulitis. By IHC we determined increased expression of $CD68^+$ monocyte lineage cells, Granzyme B^+ cytotoxic T lymphocytes and $CD\text{-}3^+$ T lymphocytes. There was no difference in the expression of $CD56^+$ NK cells while the number of $CD20^+$ B lymphocytes was lower in allo-HCT as compared to controls.

Conclusions: These studies demonstrate that aGVHD results in renal injury characterized by tubulitis and mesangiolysis and linked to increased infiltration by monocytes and T lymphoctes. These findings suggest that the kidneys are a target of aGVHD and may explain the high frequency of acute kidney injury post allo-HCT.

Serial Intravital Imaging of Ischemia-Reperfusion Injury Reveals the Dynamics of Tubular Injury and Repair

Luca Bordoni, Layla Pohl, Anders M. Kristensen, Hanne Kidmose, Donato Sardella, Ina M. Schiessl. Laboratory of Renal Cell Remodeling and Regeneration (The Schiessl-lab) *Aarhus Universitet, Aarhus, Denmark.*

Background: The kidney has a remarkable capacity to recover from acute kidney injury (AKI), but the involved dynamics of cellular damage and repair are incompletely understood. In this study, we investigated ischemia-reperfusion injury (IRI)-induced proximal tubule (PT) cell death and proliferation of the same renal cells over time using serial intravital 2-photon microscopy (2PM).

Methods: We performed 21 minutes IRI of the left kidney followed by abdominal imaging window implantation for serial imaging of the same tissue at 1 h and day 1, 2, 3, 4, 7, 14 and 21 after IRI. CycB1-GFP reporter mice identified proliferating cells by GFP-expression in S-G2-M cell cycle-stages.

Results: Necrotic tubular cell death, as detected by Propidium Iodide (PI)-staining, was primarily observed 1 h post IRI and mostly affecting PTs with 10.1±4.1 %, 12.3±3.8% and 1.9±.8% PI-positive nuclei per S1, S2 and distal tubule (DT)/collecting duct (CD) segments (Mean±SEM, n=8 each). From day 1, injured PTs shedded brushborder contents, which correlated with epithelial flattening and onset of proliferation (p=.002, r^2=.39). Tubular proliferation started day 1, peaked day 3 and was highest in S2 segments with 2.7±2%, 12.4±8.7% and 0.3±.9% (Mean±SEM, n=8 each) of GFP-positive nuclei per S1, S2 and DT/CD segments (p=.02. for S2 vs. S1 and p>.001 for S2 vs. DT/CD). While in S1 segments proliferation derived mainly from surviving cells in immediate proximity to PI-positive cells, in S2 segments also cells further distant from injured sites proliferated. We observed shedded cytosolic content from injured PT regions flowing downstream into previously PI-negative PTs, which spatially coincided with their proliferation one day after the appearance of shedded material in the lumen. By day 4, several PT segments revealed severe cast formation and epithelial vacuolization with nuclear karyolysis. 75% of the vacuolized tubule population reached full recovery before day 14 post IRI, while the remaining 25% failed to recover, resulting in nephron loss.

Conclusions: This is the first study to track IRI-induced injury and regeneration in the same renal cells over time. Our data uniquely links initial tissue damage to regenerative capacity of the renal PT in AKI and suggests distinct mechanisms for initiation of PT proliferation in S1 and S2 segments.

Genetic Validation of Hdac8 as a Therapeutic Target for AKI

Neil A. Hukriede,[1] Rachel Delgado,[2] Aneta J. Przepiorski,[1] Michael D. McDaniels,[1] Mark P. de Caestecker.[2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: We previously identified 4-phenylthiobutanoic acid (PTBA), which enhances repair in multiple models of AKI, and showed that histone deacetylase 8 (Hdac8) is a target of PTBA. Here, we show that loss of genetic deletion of Hdac8 protects against AKI in zebrafish, human kidney organoid and mouse models, and that Hdac8 mediates the efficacy of PTBA.

Methods: *hdac8*$^{sa14948/-}$ and wild type zebrafish were injected with gentamicin to induce AKI, treated +/- the PTBA prodrug, UPHD25, and AKI severity evaluated by survival, tubular proliferation, DNA damage response, and apoptosis with EdU, γH2AX, and TUNEL staining, respectively. Tamoxifen treated male UB-CRERT2; *Hdac8*$^{Y/LoxP}$ (Hdac8 KO) were evaluated over 28 days after severe ischemia reperfusion AKI (IR-AKI) by transdermal GFR (tGFR) and Sirius red staining for fibrosis. Hemin treated Hdac8 KO human kidney organoids were evaluated for injury and inflammatory markers.

Results: *hdac8*$^{-/-}$ zebrafish had enhanced survival after AKI compared to wild type controls associated with increased tubular cell proliferation, γH2AX expression, and reduced apoptosis. There was no improvement in survival in *hdac8*$^{+/-}$ mutant zebrafish with AKI, but when *hdac8*$^{+/-}$ mutants were treated with sub-therapeutic doses of UPHD25, they had improved survival. In mice, Hdac8 KO had increased tGFR at day 28 (CRE- vs. +, 495.1 (46.6) vs. 704.2 (77.1) ml/min/100gm, p<0.05), associated with reduced fibrosis in the outer medulla, and organoids showed a suppression of inflammatory markers.

Conclusions: Loss of Hdac8 reduced severity of injury and improves repair in models of AKI. Studies in *Hdac8*$^{+/-}$ mutants using sub-therapeutic doses of UPHD25 indicate that PTBA efficacy is mediated in AKI via Hdac8. Increased γH2AX expression with reduced apoptosis after AKI suggests that *hdac8*$^{-/-}$ null zebrafish preferentially uses mechanisms of DDR for repair. These data provide strong genetic evidence that Hdac8 is a valid therapeutic target for AKI; mediates PTBA effects; and suggest a potential mechanism by which Hdac8 deletion induces productive repair.

Loss of Proximal Tubular Krüppel-Like Factor 15 in Kidney Injury Is Detrimental Through Suppression of Fatty Acid Oxidation

Sian Piret, Ahmed A. Attallah, Yiqing Guo, Nehaben A. Gujarati, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

Background: Loss of fatty acid oxidation in the proximal tubule (PT) is a critical mediator of acute kidney injury (AKI) and eventual fibrosis. The transcription factor PPARα is a key regulator of fatty acid oxidation (FAO); however, *Ppara* knockout mice do not have kidney injury at baseline, suggesting that other important regulators remain to be described. Krüppel-like factor 15 is expressed in PT, downregulated in AKI, and with PPARα, regulates FAO in cardiomyocytes. Our aim was to investigate the role of PT KLF15 in AKI and fibrosis.

Methods: PT-specific *Klf15* knockdown (*Klf15*^{PTKO}) mice were generated by breeding *Klf15*$^{fl/fl}$ and *Pepck*-Cre mice. Kidney injury was induced using the PT-specific DNA damaging agent aristolochic acid I (AAI) or by ischemia-reperfusion (IR). Blood was collected for serum biochemistry, and kidneys harvested for histological and immunofluorescence analyses. Chromatin immunoprecipitation (ChIP) studies were undertaken to detect binding of KLF15 to FAO gene promoters. Primary PT cells were harvested from *Klf15*$^{fl/fl}$ mice and *Klf15* knocked out by infection with adenovirus-Cre (control = adenovirus-GFP), followed by qRT-PCR analysis and live cell metabolic assays using a Seahorse bioanalyzer. Gene expression and eGFR data for human CKD patients in Nephroseq were utilized for correlation analyses.

Results: PT KLF15 expression was downregulated in response to injury in control mice. *Klf15*^{PTKO} mice subjected to AKI using AAI or IR had significantly worse injury than *Klf15*$^{fl/fl}$ mice, as assessed by higher serum creatinine and urea nitrogen levels, exacerbated histopathological features, more extensive loss of mature PT brush borders, and increased fibrosis in AAI-treated mice. ChIP studies showed binding of KLF15 to the promoters of genes encoding key FAO enzymes CPT1A and ACAA2. Knockdown of *Klf15* in primary PT cells resulted in decreased expression of *Ppara, Cpt1a* and *Acaa2*. Live cell metabolic assays demonstrated that loss of *Klf15* compromised PT cellular metabolism, particularly the ability to utilize palmitate in FAO. *KLF15* expression positively correlated with eGFR and *PPARA* expression in human kidney biopsies with CKD.

Conclusions: PT KLF15 is a key regulator of FAO, and loss of KLF15 in kidney injury is detrimental through compromised FAO.

Single-Cell Transcriptomics Reveal Pyroptosis and Ferroptosis Inhibition Ameliorate Maladaptive AKI-to-CKD Progression and Epithelial-to-Immune Phenotype Switch

Michael S. Balzer,[1] Tomohito Doke,[1] Ziyuan Ma,[1] Matthew Palmer,[2] Katalin Susztak.[1] Susztak Lab *[1]Institute for Diabetes, Obesity and Metabolism, UPenn, Philadelphia, PA; [2]Department of Pathology and Laboratory Medicine, UPenn, Philadelphia, PA.*

Background: Following acute kidney injury (AKI) renal repair is possible to a certain extent. However, maladaptation to AKI leads to progression towards chronic kidney disease (CKD). Unwiring the incompletely understood processes driving both progression and repair might identify therapeutic targets to halt or reverse AKI-to-CKD progression.

Methods: Here we profiled transcriptomic changes at single-cell level over time in acutely injured kidneys of mice subjected to mild and severe bilateral ischemic reperfusion injury (IRI), modeling repair and maladaptation, respectively. Kidney function, structure, bulk and single-cell gene expression analyses were performed 1, 3 and 14d after ischemia. We used motif enrichment, trajectory, drug response pattern and cell-cell interaction analyses to define key drivers of failed and successful regeneration, finally informing *in vivo* experiments with 2 small molecules effectively ameliorating maladaptation.

Results: Long bilateral ischemia resulted in sustained renal failure (1-14d) and severe fibrosis at 14d, suggesting maladaptation, while after short ischemia early (1-3d) functional and structural impairment returned to baseline at 14d, suggesting repair. Analyzing 136,794 high-quality kidney cell transcriptomes, we uncover a maladaptive proximal tubule (PT) signature 14d after long IRI, characterized by sustained upregulation of pyroptosis and ferroptosis genes. We define the PT gene regulatory logic behind both regeneration and maladaptation, highlighting myeloid transcription factors (TFs) as novel potential drivers of AKI-to-CKD progression upstream of inflammasome effectors. Additionally, in cell-cell interaction analyses we show how PT cells acquire an immune phenotype during maladaptation. Finally, prompted by analyses of drug response transcriptional changes we show that inhibition of pyroptosis (VX765) and ferroptosis (liproxstatin) *in vivo* normalized single-cell transcriptomic kidney signatures despite severe IRI.

Conclusions: Using single-cell transcriptomics we reveal pyroptosis and ferroptosis as key druggable pathways of a detrimental PT signature associated with maladaptation to AKI and progression towards CKD, which was driven by TFs typically active in myeloid cells and characterized by a an epithelial-to-immune phenotype switch.

VEGF-R2 Signaling in Renal Interstitium Exacerbates Post-AKI CKD Progression

Takuto Chiba, Sunder Sims-Lucas. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: A dire consequence of acute kidney injury (AKI) is progression to chronic kidney disease (CKD). AKI patients are at more than twice the increased risk of progressive CKD that leads to excessive morbidity and mortality. Understanding the mechanisms by which AKI progresses to CKD is essential for establishing a new therapeutic target since no established therapy to date is available for. Peritubular capillary beds are significantly damaged during many types of AKI, which is closely associated with post-AKI CKD progression. Vascular endothelial growth factor (VEGF) is a well-defined angiogenic factor via its major receptor, VEGF receptor 2 (VegfR2). However, prior work from others demonstrated a role of VEGF as a negative regulator of pericyte function and vessel maturation. The functional implications of the VegfR2 signaling in renal interstitium remains poorly understood.

Methods: We generated genetic mouse models for renal stromal cells (RSCs)-specific loss-of-function of VegfR2 with constitutively expressed Foxd1-Cre (*VegfR2$^{RSC-/-}$*) as well as tamoxifen inducible Foxd1-Cre (*iVegfR2$^{RSC-/-}$*) to interrogate timing specific role of VegfR2 in renal interstitial cells in AKI-to-CKD. AKI/CKD models induced either by a renal ischemia/reperfusion injury (IRI) model or by low/dose repeated treatment of cisplatin were performed. Mice are monitored for the development of AKI and post-AKI CKD using serum chemistries and tissue analysis. Renal blood flow was evaluated with arterial spin labeling MRI (ASL-MRI).

Results: We found that *VegfR2$^{RSC-/-}$* mice have (I) reduced vascular injury and better blood flow post AKI, (II) are protected against AKI, and (III) have reduced AKI-to-CKD progression after renal IRI. Consistently, *VegfR2$^{RSC-/-}$* are protected against progression to CKD in a cisplatin AKI-to-CKD model. Mechanistically, it appears that the *VegfR2$^{RSC-/-}$* mice downregulate a maladaptive proliferation factor for pericytes, Thrombospondin-1 (TSP1). AKI triggers enhanced differentiation of a subpopulation of CD31+/ Foxd1+ cells, presumably caused by partial endothelial-mesenchymal transition (Endo-MT). Furthermore, *iVegfR2$^{RSC-/-}$* mice are significantly protected against renal IRI.

Conclusions: These data suggest that VegfR2 signaling in renal interstitial cells exacerbates renal IRI and its post-AKI CKD progression as well as cisplatin AKI.

Immune Cells as Drivers of Kidney Myofibroblast Formation and Fibrosis After Acute Cardiac Dysfunction

Kevin G. Burfeind,[1,2] Yoshio Funahashi,[2,1] Adam C. Munhall,[1,2] Mahaba B. Eiwaz,[1,2] Michael Hutchens.[2,1] *[1]Oregon Health & Science University, Portland, OR; [2]Portland VA Medical Center, Portland, OR.*

Background: Acute kidney injury (AKI) is a cause of chronic kidney disease (CKD). The AKI to CKD transition presents an opportunity for early intervention to prevent CKD. Myofibroblast formation is a hallmark of CKD. We have performed extensive mechanistic investigation in a translational model of AKI-CKD transition, cardiac arrest and cardiopulmonary resuscitation (CA/CPR), in which all animals develop CKD at 7 weeks. The purpose of this study was to identify potential immune drivers of myofibroblast formation.

Methods: Cardiac arrest was induced with potassium chloride in anesthesized intubated mice. Resuscitation was performed with epinephrine and chest compressions. Flow cytometry was used to profile the immune and mesenchymal landscapes during the AKI to CKD transition after CA/CPR (Fig. 1A). Kidney single nuclear RNA sequencing (snRNASeq) was performed at 1 day after CA/CPR, and CellChat was used to interrogate interactions between immune cells and myofibroblast precursors.

Results: Monocytes and natural killer cells increased in the kidney after CA/CPR (Fig. 1B). PDGFRB+ cells increased at 7 days (Fig. 1C), and immune cells colocalized with aSMA+ myofibroblasts after CA/CPR (Fig. 1D). snRNASeq revealed several distinct populations of kidney cells (Fig. 1E). High resolution subclustering combined with CellChat identified significantly upregulated interaction networks between immune cells and mesenchymal cells, including CD226 and CD96 signaling (Fig. 1E and F).

Conclusions: CA/CPR induces acute and lasting renal inflammation, which correlates with myofibroblast expansion. Lymphocytes communicate with myofibroblast precursors, revealing potential therapeutic targets.

Funding: Veterans Affairs Support

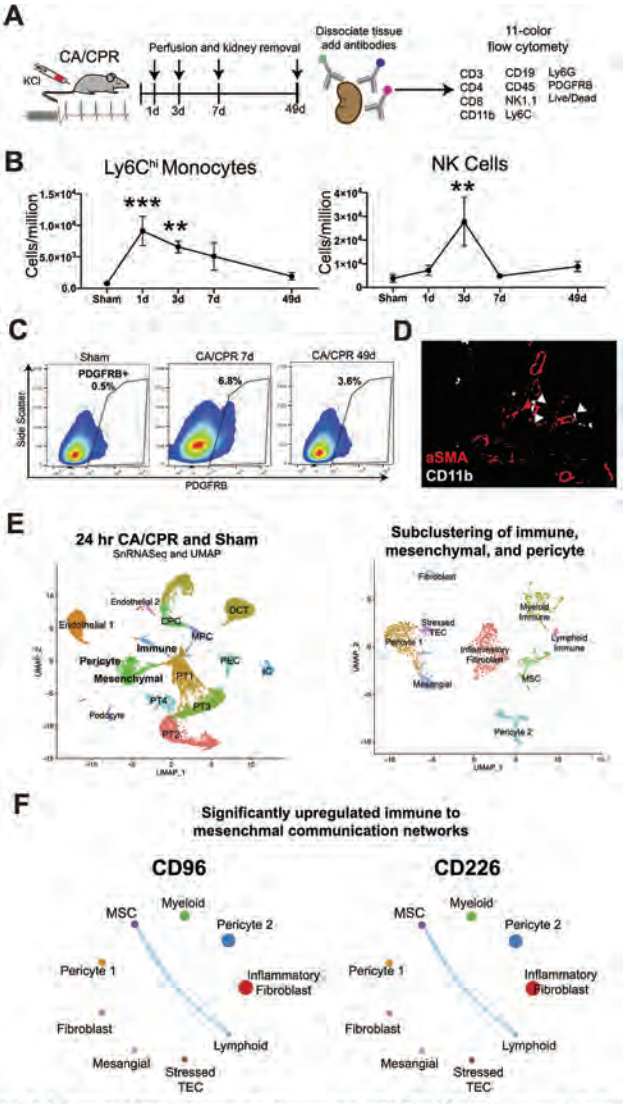

Figure 1. Assessing kidney immune and mesenchymal cells after CA/CPR. A) Workflow for flow cytometry analysis. B) Time course quantification of kidney Ly6C^{hi} monocytes and NK cells C) Quantification of PDGFRB+ (a marker for myofibroblasts and their precursors) cells in the kidney after CA/CPR. d = days after CA/CPR. D) Immunofluorescence images of alpha smooth muscle actin (aSMA), a key component of scar formation that is produced by myofibroblasts, and CD11b, a marker of myeloid cells, in the kidney after CA/CPR. Arrows denote myeloid cells in close proximity to aSMA+ cells. E) Umap clustering of cells isolated from whole kidney tissue. Clusters depict kidney cells from both vehicle and CA/CPR animals (*n*=2 kidneys and approximately 10,000 cells per group). PT = proximal tubule, IC = intercalated cells of the collecting duct, DCT = distal convoluted tubule, MPC = principal cells of the collecting duct of the medulla, CPC = principal cells of the collecting duct of the cortex, PEC = parietal epithelial cells. Right = Subclustering of immune and mesenchymal cells from panel A. TEC = tubular epithelial cell, MSC = mesenchymal stem cell. F) Circle plots depicting the immune to mesenchymal interaction networks identified. *n*=2-8/group. *P<0.05, **P<0.01, ***P<0.001 compared to sham in repeated measures one way ANOVA analysis.

SA-OR20

Differential Role of Endothelial Prolyl-Hydroxylase 1, 2, 3 in AKI

Ratnakar Tiwari, Si Young An, Pinelopi P. Kapitsinou. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Recently, we showed that pre-ischemic inhibition of endothelial cell (EC)-HIF Prolyl Hydroxylase 2 (*Phd2*) protects against kidney ischemia-reperfusion injury (IRI). However, the role of post-ischemic inactivation of *EC-Phd2* in kidney repair remains unclear. Further, recent single-cell RNA sequencing (scRNA-seq) data suggest a role for other *EC-Phd* isoforms (*EC-Phd1* and *EC-Phd3*) in oxygen sensing. Here, we wished to address the role of post-ischemic inactivation of *EC-Phd1*, *EC-Phd2*, and *EC-Phd3* in kidney repair.

Methods: Post-ischemic inactivation of EC-*Phd1* (*EC-Phd1^{KO}*), *Phd2* (*EC-Phd2^{KO}*), and *Phd3* (*EC-Phd3^{KO}*) was achieved by the *Cdh5(PAC)CreER* inducible system. To avoid compensatory effects between *Phds*, we generated mice with concurrent deletion of EC-*Phd1, 2,* and *3* (*EC-Phd123^{KO}*) and induced recombination after IRI. Analysis was performed on day 14 post-IRI.

Results: Post-ischemic inactivation of *EC-Phd1* or *EC-Phd2* failed to protect kidneys based on mRNA expression of kidney injury molecule 1 (*Kim1*) and profibrotic genes lysyl oxidase-like 2 (*Loxl2*), transforming growth factor-beta 1 (*Tgfβ1*), and smooth muscle actin (*Acta2*) and histopathological analysis (n=7-8). Surprisingly, the inactivation of *EC-Phd3* following IRI exacerbated kidney damage and fibrosis as indicated by increased expression of *Kim1, Tgf-β*, and *Acta2* and deposition of collagen (n=6-8; p< 0.05). Likewise, post-ischemic concurrent deletion of *EC-Phd123* increased kidney damage and fibrosis assessed by histopathological analysis and increased expression of profibrotic genes and collagen deposition (n=7-8, p<0.05), respectively, compared to *Cre*-controls. These changes were associated with significant worsening of renal function assessed by blood urea nitrogen level and transdermal GFR measurements (n=7, p<0.05). scRNA-seq data of the *EC-Phd123^{KO}* post-ischemic kidneys showed significant transcriptional alterations in the EC cluster compared to *Cre*- controls with prominent changes in metabolic genes. Significant transcriptional changes were also observed in tubular, fibroblast, and inflammatory cell clusters between the two genotypes.

Conclusions: Post-ischemic concurrent inactivation of *Phd1, 2*, and *3* significantly impaired renal function, induced fibrosis which was mainly driven by *EC-Phd3* inactivation. We delineated a critical role for EC-*Phd3* in post-ischemic AKI repair.

Finerenone and Kidney Outcomes in Patients with CKD and Type 2 Diabetes: Results from FIGARO-DKD

George L. Bakris,[1] Luis M. Ruilope,[2,3] Peter Rossing,[4,5] Stefan D. Anker,[6] Bertram Pitt,[7] Gerasimos Filippatos,[8] Nicole Mentenich,[9] Andrea Z. Lage,[10] Markus Scheerer,[11] Amer Joseph,[12] Rajiv Agarwal.[13] *[1]Department of Medicine, University of Chicago Medicine, Chicago, IL; [2]Cardiorenal Translational Laboratory and Hypertension Unit, Madrid, Spain; [3]CIBER-CV, Hospital Universitario 12 de Octubre, Madrid, Spain; [4]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Department of Cardiology (CVK) and Berlin Institute of Health Center for Regenerative Therapies, German Centre for Cardiovascular Research Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; [7]Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; [8]National and Kapodistrian University of Athens, School of Medicine, Department of Cardiology, Attikon University Hospital, Athens, Greece; [9]Statistics and Data Insights, Bayer AG, Wuppertal, Germany; [10]Cardiology and Nephrology Clinical Development, Bayer SA, São Paulo, Brazil; [11]Medical Affairs & Pharmacovigilance, Pharmaceuticals, Bayer AG, Berlin, Germany; [12]Cardiology and Nephrology Clinical Development, Bayer AG, Berlin, Germany; [13]Richard L. Roudebush VA Medical Center and Indiana University, Indianapolis, IN.*

Background: In the FIDELIO-DKD trial, finerenone reduced the risk of kidney outcomes in patients with predominantly advanced chronic kidney disease (CKD) and type 2 diabetes (T2D). FIGARO-DKD investigated the effects of finerenone in patients with less advanced CKD and T2D. The primary outcome of FIGARO-DKD was a cardiovascular composite; here we report the secondary kidney outcomes.

Methods: FIGARO-DKD (NCT02545049) was a randomized, double-blind, placebo-controlled phase III trial. Patients with T2D, urine albumin-to-creatinine ratio (UACR) ≥30–<300 mg/g and estimated glomerular filtration rate (eGFR) ≥25–≤90 mL/min/1.73 m^2 or UACR ≥300–≤5000 mg/g and eGFR ≥60 mL/min/1.73 m^2, optimized renin–angiotensin system blockade, and screening serum potassium ≤4.8 mEq/L were randomized to finerenone or placebo. The key secondary kidney outcome was an eGFR 40% composite of time to kidney failure, sustained ≥40% eGFR decline from baseline, or renal death. Another similar kidney composite endpoint, exchanging a sustained ≥40% eGFR decrease with a ≥57% decrease, and change in UACR from baseline to month 4 were pre-specified outcomes in the hierarchical testing strategy.

Results: In the 7352 patients included in the analysis, 62% of patients had baseline eGFR ≥60 mL/min/1.73 m^2 and 49% had baseline UACR <300 mg/g. Over a median follow-up of 3.4 years, 350 (9.5%) patients treated with finerenone and 395 (10.8%) patients with placebo had a 40% eGFR composite endpoint event (hazard ratio [HR]=0.87, 95% confidence interval [CI] 0.76–1.01; p=0.069). There was a clinically meaningful prolongation of the time to the 57% eGFR composite endpoint with finerenone (HR=0.77, 95% CI 0.60–0.99). Greater reduction in UACR at month 4 was observed with finerenone (ratio of least-squares means 0.68, 95% CI 0.65–0.70). Overall, the incidence of adverse events were similar between treatment arms.

Conclusions: In FIGARO-DKD, patients with stage 1–4 CKD and T2D, finerenone induced a pronounced reduction in albuminuria. Kidney composite outcomes observed were directionally similar to that seen among patients with more advanced kidney disease in the FIDELIO-DKD trial.

Finerenone in Patients with CKD and Type 2 Diabetes by SGLT-2i Treatment: The FIDELITY Analysis

Peter Rossing,[1,2] Gerasimos Filippatos,[3] George L. Bakris,[4] Stefan D. Anker,[5] Bertram Pitt,[6] Luis M. Ruilope,[7,8] Martin Gebel,[9] Markus Scheerer,[10] Luke Roberts,[11] Amer Joseph,[12] Rajiv Agarwal.[13] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [3]National and Kapodistrian University of Athens, School of Medicine, Department of Cardiology, Attikon University Hospital, Athens, Greece; [4]Department of Medicine, University of Chicago Medicine, Chicago, IL; [5]Department of Cardiology (CVK) and Berlin Institute of Health Center for Regenerative Therapies, German Centre for Cardiovascular Research Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; [6]Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; [7]Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research imas12, Madrid, Spain; [8]CIBER-CV, Hospital Universitario 12 de Octubre, Madrid, Spain; [9]Research and Development, Pharmaceuticals, Bayer AG, Wuppertal, Germany; [10]Medical Affairs & Pharmacovigilance, Pharmaceuticals, Bayer AG, Berlin, Germany; [11]Study Medical Experts, Bayer PLC, Reading, United Kingdom; [12]Cardiology and Nephrology Clinical Development, Bayer AG, Berlin, Germany; [13]Richard L. Roudebush VA Medical Center and Indiana University, Indianapolis, IN.*

Background: The aim of the FIDELITY analysis is to evaluate the efficacy and safety of finerenone, a novel, nonsteroidal, selective mineralocorticoid receptor antagonist, across the spectrum of patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) in the FIDELIO-DKD and FIGARO-DKD trials. Sodium-glucose co-transporter-2 inhibitors (SGLT-2is) are recommended for patients with CKD and T2D to reduce the risk of CKD progression, thus their combined use with finerenone is of interest. We report the pooled FIDELITY analysis of patients by SGLT-2i use.

Methods: This prespecified analysis combines patient-level data from the FIDELIO-DKD (NCT02540993) and FIGARO-DKD (NCT02545049) phase III, randomized, double-blind, placebo-controlled, multicenter clinical trials. Patients were randomized 1:1 to oral finerenone or placebo. Patients had T2D and either a urine albumin-to-creatinine ratio (UACR) ≥30–<300 mg/g and estimated glomerular filtration rate (eGFR) ≥25–≤90 mL/min/1.73 m^2, or UACR ≥300–≤5000 mg/g and eGFR ≥25 mL/min/1.73 m^2, with optimized renin–angiotensin system blockade. Efficacy outcomes included a cardiovascular (CV) composite endpoint of time to CV death, nonfatal myocardial infarction, nonfatal stroke, or hospitalization for heart failure, and a kidney composite endpoint of time to kidney failure, sustained ≥40% eGFR decline from baseline, or renal death.

Results: The FIDELITY analysis includes 13,026 patients. Approximately 7% of patients (n=877) received an SGLT-2i at baseline (finerenone: 6.7% [n=438]; placebo: 6.7% [n=439]). Compared with placebo, finerenone reduced the risk of the CV composite endpoint irrespective of SGLT-2i use at baseline (with SGLT-2i: hazard ratio [HR]=0.63, 95% confidence interval [CI] 0.40–<1.00; without SGLT-2i: HR=0.87, 95% CI 0.79–0.96; *p*-interaction 0.41), additional findings for efficacy outcomes, in addition to overall safety and hyperkalemia-related events by SGLT-2i treatment, will be presented.

Conclusions: FIDELIO-DKD and FIGARO-DKD comprise the largest cardiorenal outcomes program to date; therefore, combining the data for the SGLT2i subgroup in the FIDELITY analysis may provide further insights into the effects of receiving both finerenone and an SGLT-2i.

Sodium-Glucose Cotransporter 2 Inhibitors as Adjunct Therapy for Type 1 Diabetes and the Benefit on Cardiovascular and Renal Disease Evaluated by Steno Risk Engines

Elisabeth B. Stougaard,[1] Dorte Vistisen,[1] Frederik Persson,[1] Peter Rossing.[1,2] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Sodium–glucose cotransporter 2 inhibitors (SGLT2i) have beneficial cardiovascular and renal effects in persons with type 2 diabetes but no studies have shown whether this can be demonstrated in type 1 diabetes (T1D). We aimed to estimate the risk of cardiovascular disease (CVD) and end-stage kidney disease (ESKD) in persons with T1D with and without treatment with SGLT2i.

Methods: The study is based on 3,660 adults with T1D treated from 2001-2016 who fulfilled the inclusion criteria of age 30-75 years and an eGFR >45 ml/min/1.73 m^2. The Steno Type 1 Risk Engine was used to calculate 5-year cumulative risks of ESKD and in the subset of 3,284 (89.7%) without previous CVD at baseline, 5- and 10-year cumulative risk of CVD were estimated. The effect of SGLT2i was simulated by changing the recorded HbA_{1c} and systolic blood pressure (SBP) values in accordance with results from the DEPICT studies. Individual absolute change in HbA_{1c} and SBP was simulated as randomly drawn numbers from a normal distribution with mean (standard deviation (SD)) of -3.6 (0.9) mmol/mmol and -1.12 (2.8) mmHg. The recorded eGFR and albuminuria were changed in accordance with results from the Tandem studies; no change in eGFR and mean (SD) %-change in albuminuria of -23.7 (12.9).

Results: The SGLT2i induced change in the risk variables translated into an overall 5-year CVD relative risk reduction of 6.1% (95%CI 5.9,6.3), with up to 11.1% (10.0,12.2) in the subgroup with albuminuria. Similar results were seen for the 10-year risk of CVD. For the estimated 5-year risk of ESKD, we found an overall relative risk reduction of 5.3% (5.1,5.4) with up to 7.6% (6.9,8.4) in the subgroup with albuminuria.

Conclusions: Using the Steno T1 CVD and renal risk engine we estimated the risk of CVD and ESKD in persons with T1D with and without treatment with SGLT2i and found a substantial CVD and ESKD risk reduction, especially in the subgroup with albuminuria. Our model provides an estimate of benefit that may balance the risks associated with use of SGLT2 inhibition in T1D.

Renal Autologous Cell Therapy (REACT) for Type 2 Diabetic Kidney Disease: Preliminary Results with Renal Cortex Implantation

Joseph Stavas,[1,9] Maria E. Ferris,[10] Arnold L. Silva,[2] Randal K. Detwiler,[10] Steven G. Coca,[3] Anna M. Burgner,[4] Mark S. Segal,[5] Bijin Thajudeen,[6] Guido Filler,[7] George L. Bakris.[8] *[1]ProKidney, Raleigh, NC; [2]Boise Kidney and Hypertension, Boise, ID; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]University of Florida College of Medicine, Gainesville, FL; [6]Banner University Medical Center Tuscon, Tucson, AZ; [7]Western University, London, ON, Canada; [8]The University of Chicago Medicine, Chicago, IL; [9]Creighton University School of Medicine, Omaha, NE; [10]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Diabetic Kidney Disease (DKD) is the leading cause of kidney failure in the United States. REACT in preclinical trials demonstrated stability and improved kidney function without adverse effects. We present the 12 month findings of an ongoing Phase II multicenter randomized clinical trial (RCT) evaluating autologous homologous cell therapy on DKD progression in patients with stages 3a-4 DKD.

Methods: In this open label 1:1 RCT, 83 participants, 30-80 yrs, eGFR 20-50 ml/min/1.73m^2 were randomized to either REACT or a control group of standard of care. All patients had a kidney biopsy with renal progenitor cell isolation and expansion by cGMP. The treated group received two cell implants into the kidney cortex at six-month intervals with CT guidance. The control received standard of care treatment (SoC) including maximized hypertension, diabetes and comorbidity management. The primary endpoint is change in eGFR. The current analysis compares the mean eGFR and UACR of completers in each group at 12 months.

Results: No differences in Hgb or HbA1c were present between groups at baseline or 12 months. Annualized mean eGFR increased and UACR decreased in the treatment group from time of first injection to 12 months (Table). Major bleeding complications occurred in 1% of each group following biopsy or cell injections. There were no cell-related adverse events.

Conclusions: Preliminary findings indicate implantation of progenitor REACT into the renal cortex in DKD is safe and improved annualized eGFR and UACR. Further data will follow completion of the study.

Neuroblastoma Suppressor of Tumorigenicity 1 (NBL1) and Risk of Progression to ESKD in Diabetes

Hiroki Kobayashi,[1,3] Helen C. Looker,[2] Eiichiro Satake,[3] Robert G. Nelson,[2] Andrzej S. Krolewski.[1] *[1]Research Division, Joslin Diabetes Center; Department of Medicine, Harvard Medical School, Boston, MA; [2]Chronic Kidney Disease Section, National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ; [3]Division of Nephrology, hypertension and Endocrinology, Nihon University School of Medicine, Tokyo, Japan.*

Background: *TGF*-β-related signaling proteins have been implicated in the development of end-stage kidney disease (ESKD) in diabetes. Most of this evidence has come from cellular and animal studies focusing on individual proteins and, to date, no study has demonstrated the involvement of these proteins in the etiology of ESKD in humans.

Methods: Using aptamer-based SomaScan platform, 25 TGF-β-related circulating proteins including ligands, receptors, and inhibitors were measured in baseline plasma obtained from 4 different cohorts of 754 Caucasian and Pima Indian subjects; including 219 with Type 1 diabetes (T1D) and CKD stage 3 (CKD3) and 144 with T2D and CKD3, and 238 T1D subjects with CKD1,2 and 153 T2D Pima Indian subjects with CKD1,2. All patients were followed for 10 years to ascertain onset of ESKD.

Results: In logistic regression analysis, NBL1, FSTL3, RGMB, and TGF-β RIII were strongly associated with progression to ESKD in all cohorts (Table 1). In multivariable logistic regression analysis for 4 proteins and clinical variables, NBL1, a secreted BMP antagonist never before implicated in kidney diseases, was identified as the only protein very strongly and independently associated with progression to ESKD. Importantly, renal structural parameters, measured quantitatively in research kidney biopsies obtained from Pima Indian subjects, were strongly associated with circulating level of NBL1.

Conclusions: Our study did not find any associations with conventional TGF-β-related proteins but pointed to NBL1 as a very important factor in progression to ESKD. NBL1 is a novel strong biomarker for kidney disease progression, and regulation of this protein may become new therapeutic targets to retard progression to ESKD in diabetes.

Genome-Wide Association Study (GWAS) in the Million Veteran Program of Diabetic Kidney Disease (DKD) Highlights Biology of the Glomerular Basement Membrane (GBM) and Tubular Transporter in DKD

Adriana Hung,[1,8] Hua-Chang Chen,[1,8] Linda F. Fried,[3,2] Ran Tao,[1,8] Yan Sun,[4,5] Jin Zhou,[7,6] Peter Reaven,[6,7] Peter W. Wilson,[4,5] Lawrence S. Phillips.[4,5] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Pittsburgh VAMC, Pittsbrugh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Emory University, Atlanta, GA; [5]VA Medical Center Atlanta, Decatur, GA; [6]Phoenix VA Health Care System, Phoenix, AZ; [7]The University of Arizona College of Medicine Phoenix, Phoenix, AZ; [8]VAMC Nashville, Nashville, TN.*

Background: Diabetes is the most common cause of end-stage renal disease (ESRD) worldwide. Diabetic Kidney Disease (DKD) is defined by reduced kidney function and/or albuminuria. We here study the genetic determinants of DKD.

Methods: Our primary outcome was a composite of low estimated glomerular filtration rate (eGFR), or end-stage renal disease (ESRD). Cases had to meet criteria for diabetes for at least 5 years before the onset of DKD, while controls had to meet diabetes criteria for at least 7 years without DKD. Our secondary outcome was proteinuria/macroalbuminuria, no specific diabetes duration was required for the proteinuria cases. We conducted a large GWAS in 50,355 participants (21,273 cases) of European ancestry, and 18,144 (7,700 cases) of Non-Hispanic Blacks. Cases and controls were regressed onto additively coded genotypes imputed to a 1000 Genomes panel, with MAF>1%, adjusting for model 1: age, sex and 10 race/ethnicity-specific principal components and model 2: model 1 plus median HbA1c, BMI, and systolic blood pressure. Inverse-variance-weighted fixed-effects meta-analysis was conducted across race groups.

Results: Two loci reach genome-wide significance in the transethnic GWAS for low GFR or ESRD: rs113795872 (*CUBN*, p=9.8E-14), and rs71149134 (*UMOD*, p= 3.761 E-32). We replicated the association with the one variant in *COL4A3* reported as associated with DKD rs55703767 (p=0.02). Five loci that reach GWAS significant association with persistent gross proteinuria: *CUBN* (p=1.77 E-25), *UMOD* (4.5E-14), *CCD158* (8.17 E-10), *SHROOM3* (6.69 E-09), and *CEBPG* (1.5 E-08).

Conclusions: Our study found 5 genome-wide significant associations with different manifestations of DKD. Some of the involved genes play a role as a component of the glomerular basement membrane or renal tubular function and may represent targets for therapy.

Urinary Complement Proteome and 10-Year Risk of ESKD in Diabetes

Salina Moon,[1] Zaipul I Md Dom,[1,2] Amin Abedini,[3] Simon T. Dillon,[2,4] Katalin Susztak,[3] Monika A. Niewczas.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Our pilot urinary inflammatory proteomics identified enrichment in the Complement system in subjects with progressive diabetic kidney disease (DKD). Thus, we aimed to comprehensively evaluate the Complement proteome reflected by: i) relationships of urinary profiles with prospective ESKD risk, and ii) kidney tissue expressions in DKD.

Methods: Our prospective cohort study comprised 371 Joslin Kidney Study subjects with Type 1 (T1D) or Type 2 (T2D) Diabetes and an overt DKD (mean eGFR 45 mL/min/1.73m^2, ACR 1,075 mg/g). Our main outcome was 10-year ESKD risk. We measured 82 Complement proteins in baseline urine with aptamer proteomics; 8 were validated by

quantitative immunoassays. We evaluated kidney tissue expressions of the Complement system with aptamer proteomics in 23 subjects with an overt DKD and 10 controls.

Results: 160 (43%) subjects developed ESKD in 10 years. Multiple Complement proteins were associated with ESKD risk in Bonferroni-adjusted Cox models (risk per tertile change of the top protein, C5a: HR 4.2, $p<10^{-23}$; Fig. A). Cumulative 10-year risk for subjects with low levels of the top proteins built into Principal Component-based tertiles (PC) was 18%, vs. 78% for those with high levels (Fig. B). Accuracy of biostatistical and machine learning models built on the top proteins ranged from c=0.85 to 0.87. Quantitative measurements correlated with proteomics measurements and our outcome (median CFH in ESKD progressors: 214 vs. non-progressors: 8 ng/mg; $p<10^{-14}$). Of the top 10 urinary Complement proteins, 5 had increased renal expressions in subjects with DKD compared to controls. Renal expression of C3a featured the highest fold change, and CFH had the most significant association (Fig. C).

Conclusions: This study revealed robust associations of the urinary Complement proteome with 10-year risk of ESKD in subjects with T1D and T2D, with select correspondence in kidney protein expressions. These findings strongly suggest that the Complement system is an important driver of DKD progression.

Circulating Metabolites to Predict Renal Outcomes in CANVAS Type 2 Diabetes Mellitus Population

Manjula Darshi,[1] Eshetu Tefera,[2] Bin Gao,[2] Michele Weidner-Wells,[2] Dermot F. Reilly,[1] Craig Coorey,[3,4] Owen Tang,[5] Jean Yang,[6,7] Bruce Neal,[8] Clare G. Arnott,[8] Kenneth W. Mahaffey,[9] Vlado Perkovic,[8] Michael K. Hansen,[2] Ele Ferrannini,[10] Gemma Figtree.[5] *[1]Janssen Research & Development, LLC, Boston, MA; [2]Janssen Research & Development, LLC, Spring House, PA; [3]School of Medicine, Western Sydney University, Sydney, NSW, Australia; [4]Royal North Shore Hospital, St. Leonards, NSW, Australia; [5]Charles Perkins Centre, The University of Sydney; Dept of Cardiology, Royal North Shore Hospital; Cardiovascular Discovery Group, Kolling Institute of Medical Research, The University of Sydney; Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia; [6]Charles Perkins Centre, The University of Sydney, Sydney, NSW, Australia; [7]School of Mathematics and Statistics, The University of Sydney, Sydney, NSW, Australia; [8]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [9]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [10]Institute of Clinical Physiology, National Research Council, Pisa, Italy.*

Background: Albuminuria and eGFR are biomarkers for kidney disease progression but fail to explain all future risk. Additional biomarkers that better represent underlying disease pathophysiology may improve the prediction of progression from chronic kidney disease (CKD) to end stage renal disease (ESRD). We examined if baseline plasma metabolites predict renal outcomes in the Canagliflozin Cardiovascular Assessment Study (CANVAS) participants.

Methods: Plasma metabolites were assayed from a subset of the CANVAS study participants by HPLC (HILIC)-mass spectrometry using targeted assays. Forty-two metabolites were analyzed for association with the renal outcome (40% eGFR decline, end-stage kidney disease, or renal death) using Cox regression.

Results: We included 967 (22%) of the 4,330 CANVAS participants comprising 341 females (35%), mean age 63 ± 8 years, and BMI 33 ± 5 kg/m^2. All patients had T2DM with mean HbA1c 8.2 ± 0.9%, eGFR 75.5 ± 18.3 mL/min/1.73m^2, and median ACR (1Q, 3Q) 11.89 (6.5, 37.49). During a median follow-up of 5.6 years, 63 (6.5%) patients experienced a renal event. There were 10 metabolites significantly associated with the renal outcome (all P <0.05) when adjusted for age and gender (**Figure**) and treatment effect. In a fully adjusted model (age, gender, race, BMI, HbA1c, cholesterol, blood pressure, history of heart failure, baseline ACR and eGFR), arginine alone remained significant (P = 0.01).

Conclusions: Lower baseline plasma arginine levels are independently associated with high risk for renal events in patients with T2DM.

Uremic Solutes Are Associated with Cardiovascular Death in Diabetic Kidney Disease

Hima Sapa. CKD Biomarkers Consortium (BioCon) *Case Western Reserve University, Cleveland, OH.*

Background: Cardiovascular disease (CVD) is a major cause of mortality among people with diabetic kidney disease (DKD). The pathophysiology of CVD in DKD is not explained adequately by traditional CVD risk factors. Three small molecular weight, uncharged uremic solutes, asymmetric and symmetric dimethylarginine (ADMA, SDMA) and trimethylamine-N-oxide (TMAO) have been linked to CVD in ESKD. These solutes may be markers of CV mortality in non-ESKD DKD, as well as DKD progression to ESKD.

Methods: Uremic solutes in plasma and urine were assayed by mass spectrometry from a random subcohort of 555 REGARDS Study participants with diabetes and eGFR <60 ml/min/1.73m^2 at study entry. Plasma concentrations and urine:plasma (U/P) ratios of each solute were tested for association with CV mortality (primary outcome), all-cause mortality and incident ESKD (secondary outcomes). Cox regression models estimated the hazard ratios (HR) per $\log_2$ increment, adjusted for demographic and CVD risk factors, baseline eGFR and urine albumin to creatinine ratio (UACR).

Results: Mean (SD) baseline eGFR was 44 ± 12 ml/min/1.73 m^2, median (IQR) UACR was 32 (11, 203) mg/g. CV death, overall mortality and ESKD occurred in 120, 285 and 89 participants, respectively, during mean 6.2 years of follow-up. Higher plasma ADMA, and lower U/P ratios of all three solutes were associated with increased CV mortality (Table). Higher plasma concentrations and lower U/P ratios of all three solutes were significantly associated with all-cause mortality. Only higher plasma SDMA was associated with incident ESKD.

Conclusions: Higher plasma concentration and lower U/P ratio of ADMA were independently associated with CV and all-cause mortality in DKD. The strong associations of U/P ratios with CV mortality outcomes suggest a connection between renal clearance of uremic solutes and CVD pathogenesis.

Funding: NIDDK Support

Table 1. Association of plasma biomarkers and U/P ratios (per two-fold higher) with mortality and incident ESKD outcomes.

Biomarker	Continuous (log2)
Plasma ADMA	
Adjusted HR CV mortality (95% CI)	2.10 (1.07, 4.14)
Adjusted HR all-cause mortality (95% CI)	2.79 (1.79, 4.33)
Plasma SDMA	
Adjusted HR all-cause mortality (95% CI)	2.35 (1.66, 3.33)
Adjusted HR incident ESKD (95% CI)	2.07 (1.18, 3.63)
Plasma TMAO	
Adjusted HR all-cause mortality (95% CI)	1.14 (1.01, 1.30)
U/P ADMA	
Adjusted HR CV mortality (95% CI)	1.53 (1.23, 1.90)
Adjusted HR all-cause mortality (95% CI)	1.34 (1.17, 1.53)
U/P SDMA	
Adjusted HR CV mortality (95% CI)	1.69 (1.37, 2.09)
Adjusted HR all-cause mortality (95% CI)	1.37 (1.19, 1.58)
U/P TMAO	
Adjusted HR CV mortality (95% CI)	1.38 (1.21, 1.57)

Essential Branched-Chain Amino Acids and Ribonic Acid Are Associated with Cardiorenal Events in Type 1 Diabetes

Luis Felipe Ferreira Divino,[1] Tommi Suvitaival,[1] Viktor Rotbain Curovic,[1] Nete Tofte,[1,2] Kajetan Trost,[3] Ismo Mattila,[1] Simone Theilade,[1] Signe Abitz Winther,[1] Tine Hansen,[1] Marie Frimodt-Moller,[1] Cristina Legido-Quigley,[1] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Novo Nordisk A/S, Søborg, Denmark; [3]University of Copenhagen, Copenhagen, Denmark.*

Background: Diabetic kidney disease and cardiovascular disease (CVD) remain the leading causes of morbidity and mortality in diabetes despite recent advances in treatment. Further understanding of the underlying pathophysiology is needed. We investigated associations between serum metabolites and cardiorenal events.

Methods: The study comprised of 637 individuals with type 1 diabetes and various degrees of albuminuria. Non-targeted serum metabolomics was performed using two-dimensional gas chromatography coupled to time-of-flight mass-spectrometry. Longitudinal data on combined cardiorenal events (coronary events, peripheral arterial interventions, stroke, eGFR decline ≥30%, end-stage kidney disease and all-cause mortality) were obtained from National Danish Health registries and analyzed by Cox proportional hazards models. Adjustments included sex, baseline age, HbA_{1c}, mean arterial pressure, smoking, body mass index, statin treatment, p-triglycerides, total p-cholesterol, eGFR, albuminuria, previous CVD and correction for multiple testing by false discovery rate (FDR).

Results: Of the included participants, 55% were male and baseline mean age was 55 ± 13 years. 28% had macroalbuminuria, 25% microalbuminuria and 47% normoalbuminuria. The mean eGFR was 81 ± 26 ml/min/1.73m^2. A total of 75 metabolites were included in the analyses. Over a median (IQR) of 5.2 (4.8-5.7) years, 173 cardiorenal events were recorded. In adjusted analyses, ribonic acid was associated with a higher risk of cardiorenal events. (HR 1.4, CI [1.2-1.8], p_{FDR}=0.04). The essential branched-chain amino acids leucine (HR 0.8, CI [0.7-0.9], p_{FDR}=0.04) and valine (HR 0.8, CI [0.6-0.9], p_{FDR}=0.02) were associated with a lower risk of cardiorenal events.

Conclusions: In individuals with type 1 diabetes and various degrees of albuminuria, ribonic acid was associated with an increased risk of cardiorenal events and two essential branched-chain amino acids with a decreased risk, independently of relevant confounders. These findings might indicate important pathophysiology in the development of cardiorenal disease.

SA-OR31

Voclosporin Is Effective in Achieving Complete Renal Response in Severe Lupus Nephritis

Hanni Menn-Josephy,[1] Matt Truman,[2] Mary Palmen,[2] Paola Mina-Osorio.[2] *[1]Boston University School of Medicine, Boston, MA; [2]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: Voclosporin is a novel calcineurin inhibitor with a favorable metabolic profile and a consistent dose-concentration relationship. The Phase 3 AURORA 1 trial demonstrated that compared to mycophenolate mofetil (MMF) and low-dose steroids, adding voclosporin significantly increased complete renal response (CRR) rates in patients with lupus nephritis (LN). We report the results of a post-hoc analysis evaluating if the efficacy of voclosporin in patients with severe LN is similar to the overall population of AURORA 1.

Methods: Patients with systemic lupus erythematosus, biopsy-proven active LN (Class III, IV or V ± III/IV), and proteinuria of ≥1.5 mg/mg (≥2 mg/mg for Class V) were eligible to enroll in AURORA 1. Overall, 179 and 178 patients were randomized to the voclosporin (23.7 mg BID) and control arms, respectively. All patients received MMF (1 g BID) and low-dose oral steroids. Severe LN was defined as baseline UPCR ≥3 mg/mg with Class III or IV biopsy (± Class V) with active lesions. Renal function and serology were evaluated to ensure the population was representative of severe disease in clinical practice. CRR was defined as UPCR ≤0.5 mg/mg with stable renal function, use of low-dose steroids and no use of rescue medication.

Results: There were 76 and 72 patients in the voclosporin and control arms, respectively, with severe disease. Mean (SD) UPCR at baseline was 5.9 (2.4) mg/mg (Table 1). CRR at one year was 34.2% and 11.1% in the voclosporin and control arms, respectively (odds ratio 4.43, p=0.001; Figure 1).

Conclusions: In patients with severe LN, adding voclosporin to MMF and steroids results in statistically significantly higher CRR rates. This is clinically meaningful given that patients with severe disease are at higher risk of worse long-term outcomes and development of ESKD.

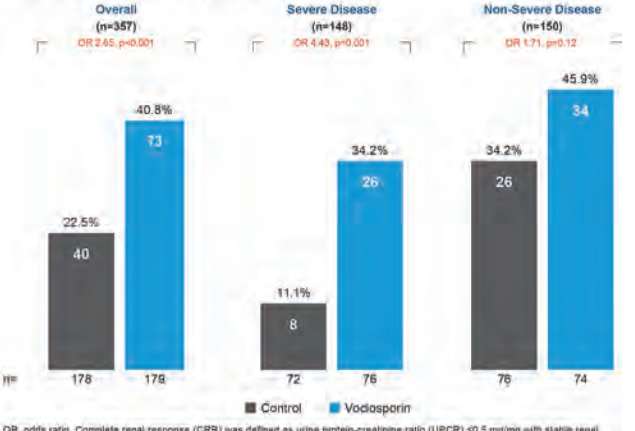
Funding: Commercial Support - Aurinia Pharmaceuticals Inc.

Table 1. Key Clinical Characteristics at Baseline and Week 52

Parameter	Baseline		Week 52	
	Severe Disease (n=148)	Non-Severe Disease (n=150)	Severe Disease (n=148)	Non-Severe Disease (n=150)
Time since LN diagnosis, years Mean (SD)	3.2 (4.1)	4.5 (5.8)		
eGFR,[a] mL/min/1.73 m^2 Mean (SD)	87.6 (29.5)	91.6 (29.8)	89.6 (32.8)	93.2 (29.8)
Serum creatinine, mg/dL Mean (SD)	0.9 (0.3)	0.9 (0.3)	1.1 (1.0)	1.0 (0.8)
UPCR, mg/mg Mean (SD)	5.9 (2.4)	2.1 (0.4)	2.3 (2.9)	1.0 (1.4)
Complement 3 Mean (SD), mg/dL Low <90 mg/dL, n (%)	77.9 (34.0) 96 (64.9)	86.6 (35.4) 80 (53.3)	97.6 (32.8) 52 (35.1)	96.5 (32.5) 58 (38.7)
Anti-dsDNA, IU/mL Mean (SD)	110.9 (129.3)	109.9 (129.9)	48.3 (60.7)	54.7 (83.2)

[a]Patients with baseline eGFR <45 mL/min/1.73 m^2 were excluded from the study. Anti-dsDNA, anti-double stranded DNA; eGFR, estimated glomerular filtration rate; LN, lupus nephritis; SD, standard deviation; UPCR, urine protein-creatinine ratio.

Figure 1. Complete Renal Response Rates at One Year



OR, odds ratio. Complete renal response (CRR) was defined as urine protein-creatinine ratio (UPCR) ≤0.5 mg/mg with stable renal function in the presence of low-dose steroids and no use of rescue medication.

SA-OR32

Effects of Belimumab (BEL) on Renal Outcomes in Patients (pts) with Relapsed and Newly Diagnosed Active Lupus Nephritis (LN)

Hans J. Anders,[1] Brad H. Rovin,[2] Ming Hui Zhao,[3] Ana Malvar,[4] Keiju Hiromura,[5] Angela R. Jones-Leone,[6] Tania González-Rivera,[6] Jennifer A. Gilbride,[7] Anuradha Madan,[6] Yulia Green,[8] David A. Roth.[6] *[1]Medizinische Klinik and Poliklinik IV, Klinikum der Universität München, Ludwig Maximilians University München, Munich, Germany; [2]Ohio State University Wexner Medical Center, Columbus, OH; [3]Peking University First Hospital, Beijing, China; [4]Organizacion Medica de Investigacion, Buenos Aires, Argentina; [5]Department of Nephrology and Rheumatology, Gunma University Graduate School of Medicine, Maebashi, Japan; [6]GlaxoSmithKline, Collegeville, PA; [7]GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom; [8]GlaxoSmithKline, Brentford, United Kingdom.*

Background: Despite standard therapy (ST) for LN, only 20–40% of pts achieve Complete Renal Response (CRR) at 0.5–1 year and 20–25% relapse in 3–5 years. The aim of this study was to assess effects of BEL on renal outcomes in relapsed and newly diagnosed pts with LN.

Methods: Post hoc analysis of the Phase 3, randomized, double-blind, 104-week BLISS-LN study (GSK BEL114054; NCT01639339). Pts with active LN received monthly intravenous (IV) BEL 10 mg/kg or placebo (PBO) + ST. Randomization was stratified by induction regimen: high dose corticosteroids (HDCS) + cyclophosphamide (CYC), followed by azathioprine + low-dose corticosteroids (LDCS), or HDCS + mycophenolate mofetil (MMF), followed by MMF + LDCS. We assessed Primary Efficacy Renal Response (PERR; uPCR ≤0.7; eGFR no more than 20% below pre-flare value or ≥60 ml/min/1.73m^2; no rescue therapy) and CRR (uPCR <0.5; eGFR no more than 10% below pre-flare value or ≥90 ml/min/1.73m^2; no rescue therapy) at Week 104 and time to renal-related event or death in relapsed vs newly diagnosed pts.

Results: Of 446 pts included in this analysis, 150 had relapse of LN and 296 were newly diagnosed. Positive effects of BEL vs PBO on PERR and CRR were noted in both subgroups and were numerically greater in relapsed vs newly diagnosed pts (**Table**). BEL-treated pts had a lower risk at any time of experiencing a renal-related event or death vs PBO in both subgroups (**Table**).

Conclusions: These data suggest BEL improved PERR and CRR rates more potently in relapsed pts, in which PERR and CRR were substantially less frequent compared with newly diagnosed LN.

Funding: Commercial Support - GSK

Table. Effect of BEL 10 mg/kg IV on PERR and CRR at Week 104 and time to renal-related event or death in newly diagnosed and relapsed pts with LN

	Relapsed		Newly diagnosed	
	PBO (n=75)	BEL 10 mg/kg IV (n=75)	PBO (n=148)	BEL 10 mg/kg IV (n=148)
PERR at Week 104, n (%)	17 (22.7)	27 (36.0)	55 (37.2)	69 (46.6)
OR (95% CI) vs PBO	2.31 (1.07, 5.01)		1.36 (0.85, 2.20)	
p-value	0.0331		0.2036	
CRR at Week 104, n (%)	8 (10.7)	17 (22.7)	36 (24.3)	50 (33.8)
OR (95% CI) vs PBO	3.11 (1.16, 8.31)		1.49 (0.88, 2.51)	
p-value	0.0237		0.1355	
Time to renal-related event or death*, n (%)	23 (30.7)	12 (16.0)	40 (27.0)	23 (15.5)
HR (95% CI) vs PBO	0.47 (0.23, 0.95)		0.55 (0.33, 0.93)	
p-value	0.0354		0.0242	

*Time to renal-related event or death is a composite endpoint defined as the first event occurring after Day 1 among the following: 1) death, 2) end-stage kidney disease, 3) doubling of serum creatinine, 4) renal worsening as evidenced by increased proteinuria and/or impaired renal function, or 5) renal disease-related treatment failure

OR, 95% CI and p-value are from a logistic regression model run within the subgroup level for the comparison between BEL and PBO with covariates of induction regimen (CYC vs MMF), race (Black African descent vs other), baseline uPCR, and baseline eGFR

HR, 95% CI and p-value from Cox proportional hazards model for the comparison between BEL and PBO adjusted for induction regimen (CYC vs MMF), race (Black African descent vs other), baseline uPCR, and baseline eGFR

CI, confidence interval; HR, hazard ratio; OR, odds ratio

SA-OR33

Antibodies Anti-Rituximab Do Not Affect Response to Rituximab in Idiopathic Nephrotic Syndrome

Andrea Angeletti,[1] Maurizio Bruschi,[1] Francesca Lugani,[1] Manuela Colucci,[2] Marina Vivarelli,[2] Francesco Emma,[2] Gianluca Caridi,[1] Enrico E. Verrina,[1] Gian Marco Ghiggeri.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Ospedale Pediatrico Bambino Gesu, Roma, Italy.*

Background: Previous studies reported how infusion of the chimeric anti-CD20 rituximab results in production of antibodies anti-rituximab, that may limit the efficacy of further infusions. Among other reasons, the reduced immunogenicity of fully humanized anti-CD20 antibodies should increase their efficacy. In a randomized clinical trial, we compared the efficacy of ofatumumab *vs.* rituximab in children and young adults with steroid dependent nephrotic syndrome. As secondary endpoints, we evaluated possible role of anti-CD20 rituximab.

Methods: We randomized 140 children treated with single infusion of rituximab or ofatumumab, with a follow up of 24 months. We measured anti-rituximab antibodies IgG at the enrolment in 64/140 (46%) patients who have previously received rituximab and at 6 months in patients in the rituximab arm. Median time of the previous rituximab was 36 (12-51) months before enrolment.

Results: As primary endpoint, ofatumumab was not superior to rituximab in maintaining remission (**Fig 1a**). Serum anti-rituximab IgG were undetectable at baseline in 64 participants who had previously received rituximab. Six months following rituximab infusion, anti-rituximab antibody levels increased in 14 (42%) of the 33/64 patients who were randomized in the rituximab arm (**Fig 1b**). Among patients with relapse in rituximab arm, the efficacy of a second infusion of rituximab, infused in accordance with the protocol, was not affected by the presence of anti-rituximab antibodies (**Fig 1c**).

Conclusions: Previous exposure to rituximab results in production of anti-rituximab antibodies, which persist for a limited time. Presence of circulating anti-rituximab antibodies does not affect response to rituximab in steroid dependent nephrotic syndrome.

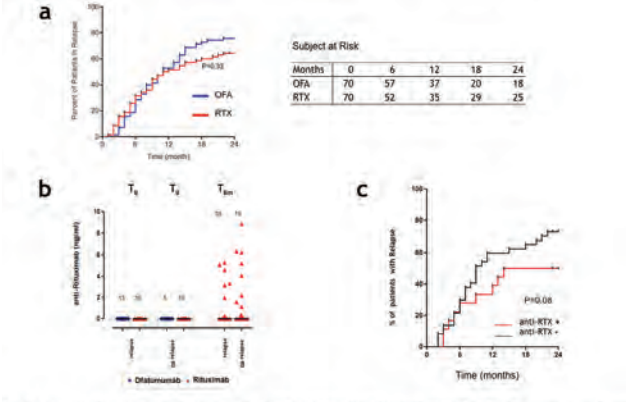


Figure 1. a) Relapse-free survival by treatment arm (Odds Ratio [OR] 1.06; 95% confidence interval [CI] 0.55 to 2.06). **b)** Circulating levels of anti-rituximab antibodies in patients receiving ofatumumab (blue) and rituximab (red) at the enrolment; the same cohort who received rituximab was tested 6 months after the infusion. **c)** Survival curve in patients in rituximab arm receiving a second infusion, with and without circulating anti-rituximab antibodies.

Glomerular Exostosin as a New Subtype and Activity Marker for Membranous Lupus Nephritis

Weixin Hu, Chengyu Wang, Yang Liu, Feng Xu, Zhihong Liu. *National Clinical Research Center for Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: Exostosin (EXT) expression has been shown to be related to membranous lupus nephritis (MLN). This study analyzed the distribution of EXT in MLN and its correlation with the activity, histological transformation and prognosis of MLN.

Methods: The renal biopsy specimens from MLN, other types of lupus nephritis (LN), other disease-related membranous nephropathy (MN), and PLA2R-related MN were included. EXT expression was detected by immunohistochemistry and was quantitatively determined by computer image analysis. The correlations between proteinuria and EXT expression, the differences between EXT-positive and EXT-negative MLN, and the relationship between pathological changes and EXT expression were analyzed by repeated renal biopsy.

Results: Of the 153 MLN, 47.7% were EXT positive; of the other types of LN, only 6.8% were EXT positive. The EXT-positive rates for Hashimoto's thyroiditis, Sjogren and HBV related MN were 16.7%, 10.0% and 10.0%, respectively. EXT was negative in psoriasis, mercury poisoning, tumor and GVHD or the PLA2R related MN. The EXT-positive rates in groups with 24-h urinary protein of <1 g, 1.0-2.9 g, 3.0g-4.9 g and ≥5.0 g were 32.3%, 39.6%, 50.0% and 68.4%, respectively (P=0.013), and EXT expression intensity was also positively correlated with proteinuria (r=0.78, P<0.001). When the EXT-positive was compared with the EXT-negative MLN, 24h urinary protein (P<0.001) and the proportion of massive subepithelial immune deposits (P<0.001) were higher, and the serum albumin (P<0.001), and CI (P<0.05) and renal tubular atrophy score (P<0.05) were lower. There were no significant differences in renal survival between the two groups. A total of 47 MLN (18 EXT-positive and 29 EXT-negative) underwent repeat renal biopsy after treatment or recurrence. For EXT-negative MLN, EXT remained negative in repeated biopsy regardless of pathological type (class V or class V+III/IV after transformation); for EXT-positive MLN, EXT became negative or EXT expression was reduced after renal remission, and as shown in repeated biopsy after recurrence: 62.5% of MLN without histological transformation were still EXT positive, but 80% of cases whose histological class became class V with III or IV were EXT negative.

Conclusions: Our study indicated that EXT expression in MLN could be used as a marker of diagnosis and activity, and a histological subtype marker of MLN.

Computationally Extracted Peritubular Capillary Shape Is Associated with Progression in Glomerular Diseases

Yijiang Chen,[1] Jarcy Zee,[2] Andrew Janowczyk,[1] Paula Toro,[1] Kyle Lafata,[5] Laura H. Mariani,[3] Lawrence B. Holzman,[2] Jeffrey B. Hodgin,[3] Anant Madabhushi,[1,4] Laura Barisoni.[5] *[1]Case Western Reserve University, Cleveland, OH; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]University of Michigan Michigan Medicine, Ann Arbor, MI; [4]Louis Stokes VA Medical Center, Cleveland, OH; [5]Duke University School of Medicine, Durham, NC.*

Background: In CKD models, the association between peritubular capillary (PTC) density and outcome has been demonstrated, but little is known about PTC pathomic features in glomerular diseases. We explored whether computer extracted features quantifying PTC shape and density can predict risk of progression (40% eGFR decline or kidney failure) in proteinuric diseases.

Methods: N=358 PAS-stained whole slide images from the NEPTUNE database were included: 133 Focal Segmental Glomerulosclerosis (FSGS), 55 IgA Nephropathy (IgAN), 109 Minimal Change Disease (MCD), and 61 Membranous Nephropathy (MN). The presence of segmental sclerosis (SS) further subclassified IgAN and MN. The kidney cortex was manually annotated, and a pre-trained deep learning model generated PTC segmentations (Fig. 1). Average PTC flatness (the PTC major and minor axis ratio) and cortical density (PTC pixels/unit cortical area) were digitally measured. Unadjusted Cox proportional hazards models were used to associate normalized PTC flatness and density with outcome across and within each disease, within cases with SS (FSGS, IgAN+SS, MN+SS) and w/o SS (MCD, IgAN w/o SS, MN w/o SS), and within gender and age.

Results: PTC flatness ≥0.469 significantly associated with a hazard ratio (95% CI) of progression of 1.99 (1.19-3.33) compared with normalized PTC flatness <0.469 (p=0.0109) (Fig. 1). PTC cortical density ≥ 0.135 associated with a hazard ratio (95% CI) of progression of 0.689 (0.398 – 1.19) compared with normalized PTC cortical density <0.135 (p=0.16). PTC flatness significantly associated with outcome in FSGS (p=0.045), in the presence of SS (p=0.022), in males (p=0.0138), and adults (p=0.016), but not in children, females, or patients w/o SS.

Conclusions: PTC flatness was significantly associated with progression in glomerular diseases, particularly in patients with SS. This association is age and gender dependent.

Funding: Private Foundation Support

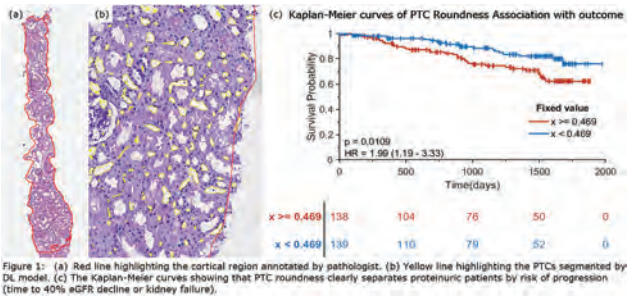

Figure 1: (a) Red line highlighting the cortical region annotated by pathologist. (b) Yellow line highlighting the PTCs segmented by DL model. (c) The Kaplan-Meier curves showing that PTC roundness clearly separates proteinuric patients by risk of progression (time to 40% eGFR decline or kidney failure).

Upregulated JAK-STAT Signaling and Augmented Potassium Efflux Characterize Induced Pluripotent Stem Cell-Derived Podocytes of Black Patients with APOL1-Associated FSGS

Opeyemi A. Olabisi, Somenath Datta, Karen Soldano, Sarah Nystrom. *Duke University School of Medicine, Durham, NC.*

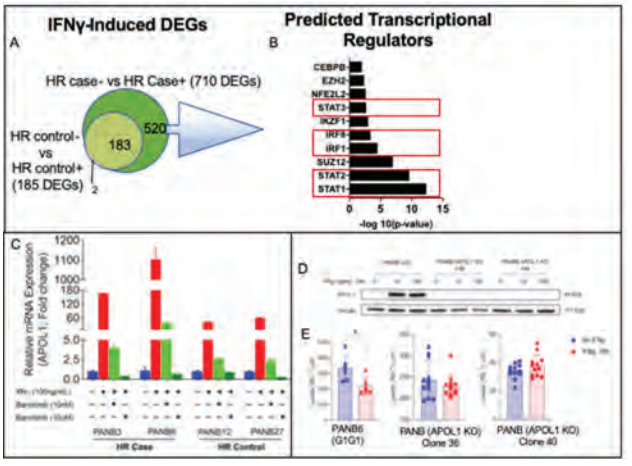
Background: High risk (HR) APOL1 genotypes account for 70% of excess risk of FSGS among Blacks. It is unknown why ~20% of carriers of HR APOL1 genotypes develop FSGS or other APOL1 nephropathies while 80% kidney disease-free. The possible role of genetic modifiers has been proposed. Also, the mechanism by which variants APOL1 cause podocyte injury is unknown. We previously reported that overexpression of variants APOL1 in HEK293 cells caused cytotoxic loss of cellular K^+. it is unknown if physiologic expression of APOL1 by IFNγ also causes K^+ loss in patient-derived podocytes.

Methods: We recruited Blacks with biopsy-proven FSGS (n=16) or with normal GFR and no proteinuria (n=20). 68.7% and 10% of FSGS cases and healthy controls carried HR APOL1 genotypes, respectively. Markers-confirmed iPSC-podocytes generated from 7 HR cases and 2 HR controls were treated or not with IFNγ followed by whole genome transcriptomics and measurement of cellular K^+. Additionally, APOL1-knockout iPSC-podocytes were generated using CRISPR-Cas9.

Results: Notably, the 520 differentially expressed genes (DEGs) unique to HR cases are transcriptionally regulated by JAK-STAT signaling (Fig. A-B). Consistent with this finding, IFNγ induces a higher expression of APOL1 in HR cases which was blocked by JAK1/2-specific inhibitor, Baricitinib (Fig C). Importantly, for the first time, we demonstrated that physiologic expression of variant APOL1 under its endogenous promoter causes significant loss of cellular K^+ in iPSC-podocyte of HR cases and was abolished by APOL1-knockout (Fig D-E).

Conclusions: JAK-STAT signaling may be an important modifier of APOL1-associated FSGS that upregulates APOL1 expression and function (K^+ efflux). Inhibition of JAK-STAT signaling and/or blockade of APOL1-mediated cation-transport may represent targeted therapeutic approach for APOL1-associated FSGS.

Funding: Other NIH Support - Common Fund (NIH Director's New Innovator Award)



IFNγ induces higher JAK-STAT signaling, APOL1 expression and Rb^+ efflux in iPSC-podocytes of HR cases. APOL1 KO blocks Rb^+ efflux.

Transcriptional Reprogramming by Wilms' Tumor 1 and FoxC2 Mediates a Repair Response During Podocyte Injury

Sandrine S. Ettou,[1,2] Mary E. Taglienti,[1] Valerie A. Schumacher,[1,2] Jordan A. Kreidberg.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Department of Surgery, Boston, MA.*

Background: We previously demonstrated a transcriptional response to injury in podocytes and identified WT1 as one of the most upstream transcription factors binding nearly all genes known to be crucial for maintenance of the glomerular filtration barrier. We now demonstrate that FoxC2 transcription factor is a major component of the response to injury, binding many of the same genes as WT1. Here, we focus on understanding WT1 and FoxC2 transcriptional mechanism in response to injury.

Methods: We used Adriamycin (ADR)-induced podocyte injury as a model for human Focal Segmental Glomerulosclerosis in mice and performed FoxC2 ChIP-seq from isolated podocytes. WT1 is required for the podocyte response to injury. Conditional *Wt1* knockout and *FoxC2* knockdown mouse models were used to decipher the transcriptional mechanism through which WT1 and FoxC2 regulate podocyte gene expression during injury, using transcriptomic approaches.

Results: WT1 is required for the podocyte response to injury. Indeed, the transient increased expression of podocytes genes in mice after injury, was abolished in the absence of *Wt1*. We found that FoxC2 was also actively involved during this response. By ChIP-seq, we detect 4214 FoxC2 binding sites before injury, rising to 12,532 after ADR. In contrast to WT1, that maintains a moderate degree of binding during the later stages of injury, FoxC2 binding is essentially absent. Using a set of 48 podocyte genes encoding components of the glomerular filtration barrier, ChIP-seq analyses demonstrated that WT1 and FoxC2 both acquire novel binding sites during the early stages of injury. One co-bound site is at the Wt1 transcriptional start site, where binding of both WT1 and FoxC2 increases dramatically after injury. Furthermore, WT1 and FoxC2 may be co-immunoprecipitated and knockdown of *Wt1* or *FoxC2* in immortalized podocytes demonstrated their mutual dependence for binding target genes.

Conclusions: Together, these results demonstrate that WT1 and FoxC2 mediate transcriptional reprogramming during podocyte injury. This transcriptional reprogramming may be initiated by the dramatic increased binding of WT1 and FoxC2 at the *Wt1* transcriptional start site after injury. Irreversible podocyte injury leading to FSGS may result from the nearly complete loss of FoxC2 binding to target genes during later stages of injury.

Cytosolic Phospholipase A2: A Drug Target in FSGS

Elif Erkan, Richard Chhaing, Andrew Potter. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is the most common glomerular cause of end stage kidney disease (ESKD) in children. The refractory nature of FSGS renders treatment of FSGS as one of the most difficult challenges in pediatric nephrology. A significant knowledge gap in understanding the mechanism of progression in FSGS hampers development of successful treatment strategies. We demonstrated that patients with FSGS present with a distinct urinary lipid profile characterized by increased fatty acids (FA) and lysophosphatidylcholines (LPC), metabolites of cytosolic phospholipase A2 (cPLA2). We propose that LPC and FA incites proinflammatory and proapoptotic response in podoctes and proximal tubule epithelial cells (PTECs). We hypothesize that increased cPLA2 activity induces apoptosis, fibrosis and progression in FSGS by harboring intracellular LPC and FA.

Methods: A bigenic model of FSGS was induced by mutation of Fyn and Cd2ap (Fyn–/–Cd2ap+/–) in podocytes. A second model of FSGS was generated by adriamycin injection in mice. Animals subjected to adriamycin were treated by intraperitoneal cPLA2 inhibitor (AACOCF3-4mM) versus saline for 6 weeks. Untargeted lipidomics was performed in urine and kidney lysates of FSGS mice by CSH-QTOF MS/MS. cPLA2 expression in podocytes and PTECs was investigated by RNA sequencing. Western blotting and immunofluorescence staining was utilized to examine cPLA2 expression.

Results: Lipid profiling revealed increased urinary LPC and FA and increased LPC levels in kidney lysates of FSGS mice reminiscent of human data. FSGS mice kidneys displayed increased cPLA2 activity in podocytes and PTECs. RNA seq data revealed upregulation of cPLA2 in podocytes and PTECs in FSGS mice. Treatment with AACOCF3 decreased proteinuria and ameliorated kidney dysfunction, FSGS pathology and tubulointerstitial fibrosis.

Conclusions: Our data strongly suggest that increased cPLA2 expression contributes to progression of FSGS by harboring production of proinflammatory and propapoptotic lipid metabolites. We propose that upregulated cPLA2 activity leads to podocytes and PTEC damage by perpetuating oxidative injury, apoptosis, inflammation and subsequent fibrosis in FSGS. We postulate that targeting cPLA2 pathway for drug development will improve outcomes in FSGS. Furthermore urinary lipid metabolite profile is a promising biomarker to monitor disease progression and treatment response in FSGS.

Glomerular 3D Co-Culture to Study Podocyte Disease Ex Vivo in a Personalized Manner

Victoria Rose, Nina Sopel, Alexandra Ohs, Christina Warnecke, Mario Schiffer, Janina Müller-Deile. *Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.*

Background: As a cause for glomerular disease, podocyte damage and related changes in the glomerular filtration barrier are typical findings. However, podocyte cell culture is challenging due to the inability of terminally end differentiated primary podocytes to proliferate and due to altered morphology and expression of cell-specific markers in immortalized podocytes. Besides, classical mono-cultures limit paracrine cell-cell-contact and communication by 2-dimensionality. To investigate cell-cell-interaction and to improve cell culture conditions we want to generate a 3D co-culture model of glomerular cells. Moreover, we want to study podocyte disease by personalizing the 3D co-culture model using patient-derived podocytes.

Methods: In order to generate 3D glomerular spheroids, immortalized differentiated podocytes, glomerular endothelial cells and mesangial cells were co-cultured in a hanging media droplet or via agarose microwells. Time laps experiments displayed spheroid formation and spheroids were characterized regarding extracellular matrix proteins and cell-specific marker expression by qPCR, histological sections, immunostainings and electron microscopy. Patient-specific podocytes and podocytes from healthy controls were generated from skin fibroblasts via reprogramming into human induced pluripotent stem cells (hiPSCs) and subsequent differentiation into hiPSC-podocytes.

Results: Spheroid formation could be imaged in time laps experiments and sectioning showed encapsulation of the spheroid. SEM could display the ultrastructure and produced extracellular matrix and collagen IV and laminin were quantified by immunostaining and qPCR. In the 3D model podocytes formed protrusions, shown by TEM, that were not seen in 2D. After reprogramming of fibroblasts, generated hiPSCs showed an increased expression of common pluripotency markers. Subsequently differentiated cells were positive for podocyte specific markers and developed distinct primary and secondary foot processes.

Conclusions: 3D co-culture is a model enabling paracrine cell-cell-contact and communication and providing better physiological conditions. Patient-specific hiPSC derived podocytes have the potential to personalize the 3D co-culture.

Anemia, Iron Deficiency, and FGF-23 in CKiD Study

Elizabeth Thomas,[1] Mark R. Hanudel,[1] Marciana Laster,[1] Isidro B. Salusky,[1] Susan L. Furth,[2] Bradley A. Warady.[3] *[1]University of California Los Angeles, Los Angeles, CA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Mercy Hospitals and Clinics, Kansas City, MO.*

Background: Fibroblast growth factor 23 (FGF23) is an important bone-derived hormone implicated in the pathogenesis of chronic kidney disease-mineral bone disorder (CKD-MBD), CKD progression, and CKD-associated cardiovascular morbidity. It has recently been demonstrated that anemia-related factors, specifically iron deficiency and erythropoietin, can also increase FGF23 production. The objectives were to determine whether anemia and/or iron deficiency are associated with increased FGF23 levels.

Methods: In the largest national pediatric CKD cohort (the Chronic Kidney Disease in Children (CKiD) Study), anemia, iron and FGF23 profiles were characterized in a cross-sectional analysis. Participants included children aged 1 month to 16 years old with mild to moderate CKD.

Results: In a cross-sectional analysis of 686 pediatric CKD patients (median (IQR) age 11 (8, 15) years, 62% male, 14% Hispanic), the median eGFR was 55 (41, 71) ml/min/1.73m^2, and the median age-related hemoglobin standard deviation score (SDS) was -1.1 (-2.3, 0.2). Anemic subjects had higher C-terminal FGF23 levels than non-anemic subjects (153 vs 103 RU/mL, p<0.0001). In bivariate analyses, log-transformed C-terminal FGF23 was inversely associated with hemoglobin SDS, serum iron, eGFR, and serum calcium and was positively associated with age-related phosphate SDS. In a multivariable linear regression model, log-transformed C-terminal FGF23 was inversely associated with hemoglobin SDS (see Table 1). Log-transformed intact FGF23 was not significantly associated with hemoglobin SDS or serum iron.

Conclusions: Decreased hemoglobin concentrations are independently associated with increased C-terminal FGF23 levels in pediatric CKD. Future analyses will assess relationships among longitudinal changes in hemoglobin SDS, iron parameters, and FGF23.

Elevated Load with Normal Mean in Pediatric Hypertension (HTN): What Does It Mean?

Fallon Campbell,[1] Shweta S. Shah,[2,1] Poyyapakkam Srivaths,[2,1] Katharine Sigler,[1] Alisa A. Acosta.[2,1] *[1]Texas Children's Hospital, Houston, TX; [2]Baylor College of Medicine, Houston, TX.*

Background: Current pediatric ambulatory blood pressure monitor (ABPM) guidelines define HTN as mean blood pressure (BP) ≥ 95th percentile for gender and age/height and load ≥ 25%. Those with a normal mean BP but elevated load are "unclassifiable." Adult ABPM criteria is based solely on mean BP using an absolute threshold. Applying pediatric versus adult ABPM criteria in adolescents has been a topic of research recently as the 2017 pediatric BP guidelines use adult norms to define clinic HTN in patients (pts) ≥ 13 years (yrs). However research on the utility of BP load in defining pediatric HTN is limited. We aimed to evaluate the significance of elevated BP load in "unclassified" pts by ABPM including association with left ventricular hypertrophy (LVH).

Methods: Retrospectively, pts 13-17 yrs with ABPM data between 9/2018 and 7/2019 were categorized by pediatric ABPM guidelines using only ABPM data. Data collected included gender, age, height, ABPM systolic and diastolic BP mean and load for 24hr, day, and night, and left ventricular mass index (LVMI). Unclassifiable pts were re-categorized to HTN or normal BP using the adult threshold for mean BP only. LVH was defined as LVMI > 51 g/m$^{2.7}$.

Results: 495 pts (335 M) had ABPM. 146 had HTN; 198 (121 M) were "unclassified." 52 pts with normal BP and 101 of unclassified pts had LVMI data. There was no significant difference in mean LVMI in pts with "unclassified" versus normal BP (41 vs 40 g/m$^{2.7}$ p=0.62) nor presence of LVH (11% vs 9.6% p =0.81). Of the 198 unclassified pts, 150 (76%) were re-categorized (re-cat) to HTN by adult criteria, and there was no difference in LVMI compared to pts re-cat to normal BP (42.6 vs 39.4 g/m$^{2.7}$ p=0.23). Pts re-cat to HTN, had significantly higher loads for night BP and 24 hr systolic BP compared to those with normal BP. However, there was no difference between the mean loads when comparing those with LVH versus no LVH.

Conclusions: For adolescents with a normal mean BP by pediatric criteria, elevated BP loads are not associated with LVH. Furthermore, applying adult criteria to define HTN would appropriately re-classify those with higher loads. Regardless, after re-classification, there is still no difference in LVMI. Applying adult ABPM standards for adolescents would simplify interpretation without sacrificing significance.

Using Electronic Health Record(EHR) Data to Evaluate Kidney Function Decline in Children with CKD

Caroline A. Gluck,[1] Amy Goodwin Davies,[2] Jill R. Mcdonald,[2] Mitchell Maltenfort,[2] Mark Mitsnefes,[3] Vikas R. Dharnidharka,[4] Bradley P. Dixon,[5] Joseph T. Flynn,[6] Michael J. Somers,[7] William E. Smoyer,[8] Alicia Neu,[9] Collin A. Hovinga,[12] Amy L. Skversky,[10] Thomas Eissing,[10] Andreas Kaiser,[10] Stefanie Breitenstein,[10] Susan L. Furth,[2,11] Christopher B. Forrest,[2,11] Michelle Denburg.[2,11] *[1]Alfred I DuPont Hospital for Children, Wilmington, DE; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Washington University in St Louis, St Louis, MO; [5]University of Colorado, Denver, CO; [6]Seattle Children's Hospital, Seattle, WA; [7]Boston Children's Hospital, Boston, MA; [8]Nationwide Children's Hospital, Columbus, OH; [9]Johns Hopkins Medicine, Baltimore, MD; [10]Bayer AG, Leverkusen, Germany; [11]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [12]Institute for Advanced Clinical Trials for Children, Rockville, MD.*

Background: This study utilized EHR data from pediatric centers to identify children with CKD and examine risk factors for kidney function decline.

Methods: We used PEDSnet, a network with EHR data from >7million children in 7 health systems, to identify children aged 1-18 yrs between 2009-2020 who met CKD

criteria: two eGFR<90 mL/min/1.73m² separated by ≥90 days without an intervening higher value. CKD progression was defined as composite outcome: eGFR<15 mL/min/1.73m², 50% eGFR decline, chronic dialysis, or kidney transplant. Subcohorts were based on CKD etiology: glomerular, non-glomerular or malignancy. We assessed impact of hypertension(HTN) (≥2visits with HTN code) and proteinuria (≥1 lab value ≥1+) within 2yrs of cohort entrance on outcomes.

Results: We identified 7395 children, median age 14.1yrs, 36% females, 23% blacks, median follow-up 4.2yrs. Median initial eGFR was 75.5 ml/min/1.73m²; 36% had proteinuria; 46 % had HTN. Children with glomerular CKD were more likely to reach outcomes (p<0.001). Children with HTN, proteinuria, or both were more likely to reach outcomes(p<0.001).

Conclusions: The EHR may be used to study large numbers of children with CKD. Risk factors for CKD progression were glomerular disease, HTN and proteinuria.

Risk Factors for Kidney Injury in Children with Solitary Functioning Kidney

Sander Groen in 't Woud, Nel Roeleveld, Wout Feitz, Michiel F. Schreuder, Loes F. van der Zanden. SOFIA study group *Radboudumc, Nijmegen, Netherlands.*

Background: Patients with a solitary functioning kidney (SFK) are at increased risk of kidney injury, for which several risk factors have been suggested. Large differences exist between previously reported cohorts, which hampers translation of these findings into clinical care. Our objective was to investigate the risk of and risk factors for proteinuria, high blood pressure, a decreased glomerular filtration rate (GFR), or use of antihypertensive medication in our nationwide study of children with SFK.

Methods: Children with congenital and acquired SFK were recruited in >30 hospitals throughout The Netherlands. Information on risk factors for and signs of kidney injury were collected from electronic patient files. Kaplan-Meier curves were used to estimate survival without signs of kidney injury and Cox regression was used to evaluate risk factors.

Results: Of 982 patients who provided informed consent, detailed clinical information was available from 898 (91%). After a median follow-up duration of 9.7 years, proteinuria was present in 118 patients (15%), high blood pressure in 184 (22%), and a GFR <60 ml/min/1.73m² in 23 (3.2%), while antihypertensive medication was used by 90 patients (9.8%). In total, 319 patients (36%) exhibited ≥1 sign of kidney injury and the median age at first sign of kidney injury was 4.4 year. Cumulative proportions of children with kidney injury were 20% at 5 years, 29% at 10 years, and 35% at 15 years of age. Kidney injury rates were higher in patients with a congenital cause of SFK compared to an acquired cause (odds ratio (OR) 1.6, 95% confidence interval (CI) 1.1-2.3), and in patients with unilateral renal agenesis compared to multicystic dysplastic kidney (OR 1.4, 95% CI 1.0-1.9).

Conclusions: Data from this largest SFK cohort so far indicate that one third of patients with SFK has one or more signs of kidney injury at 15 years of age. The cause of the SFK may influence the risk of kidney injury. Other risk factors will be investigated in our cohort to develop care strategies based on individual-patient risk profiles.

SA-OR45

Nephrotoxic Medications and Associated AKI in Hospitalized Neonates

Tahagod Mohamed, Hibo Abdi, Jacqueline K. Magers, Pavel A. Prusakov, Jonathan L. Slaughter. *Nationwide Children's Hospital, Columbus, OH.*

Background: Hospitalized neonates in the NICU are frequently treated with nephrotoxic medications (NM), a risk factor for acute kidney injury (AKI) which is associated with increased neonatal morbidity and mortality. Neonatal treatment with NM and subsequent AKI, especially in periviable neonates could be detrimental to nephrogenesis.

Methods: Multicenter retrospective analysis of hospital discharges (2005-2016) using the national Pediatric Hospital Information System database, including 49 pediatric hospitals across the U.S. Treatment with 37 NM in first 28 postnatal days across demographics and clinical variables, and relationship with AKI were evaluated.

Results: Of 192,229 neonates, 74% were treated with at least one NM, Figure 1. AKI prevalence was significantly higher in the NM group (aRR 3.68 [95% CI: 2.85, 4.75]), Figure 2. The aRRs of treatment were increased in <32-week, and <2000 g infants. NMs were prescribed to 90-95% of ≤ 28-week gestational age (GA) neonates. Most treatments with NM (95-98%) occurred in the first 3 postnatal days. IV aminoglycosides were the most frequent NM prescribed; 28% were treated with ≥ 4 calendar days. Most common diagnoses were infections (25%) and patent ductus arteriosus (20%).

Conclusions: The smallest and most immature preterm neonates are frequently treated with NM. the prevalence of AKI is higher in the NM treated group. The long-term implications of treatment with NM and subsequent AKI on nephrogenesis warrant attention in future studies.

Urinary VEGF as a Prognostic Biomarker of CKD in Premature Infants with Lung Disease

Michelle C. Starr,[1,2] Brian A. Halloran,[4] Robert Schmicker,[3] Patrick D. Brophy,[5] Patrick J. Heagerty,[3] Sandra Juul,[3] Stuart Goldstein,[6] Sangeeta R. Hingorani,[3] David J. Askenazi.[4] Preterm Erythropoietin Neuroprotection Trial Investigators
[1]Indiana University School of Medicine, Indianapolis, IN; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [3]University of Washington School of Medicine, Seattle, WA; [4]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [5]University of Rochester Medical Center, Rochester, NY; [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

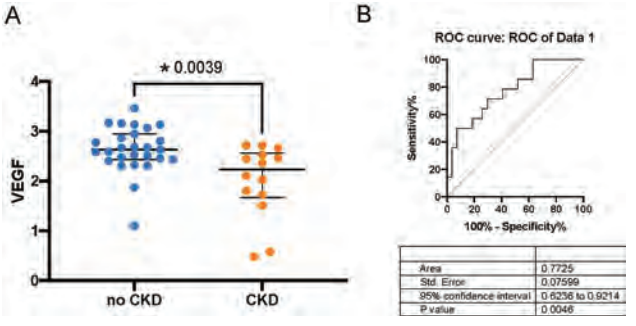
Background: Premature neonates are at risk for chronic kidney disease (CKD). Lung disease is an emerging risk factor for CKD in infants. Impaired angiogenesis may be implicated as it is required for both lung and kidney development, repair from injury, and perturbations contribute to CKD development. VEGF is a marker of angiogenesis. We hypothesize that urinary VEGF would be lower in infants with lung disease who go on to developed CKD.

Methods: Using data from the REPAIReD study (NCT01378273) an ancillary of the PENUT trial, we assessed urinary VEGF in 40 infants with severe lung disease defined by respiratory support or supplemental oxygen at 36 weeks post-menstrual age (PMA). We measured urinary VEGF at 30-34 weeks PMA. Our outcome measure was CKD at 22-26 months (estimated glomerular filtration rate <90 ml/min/1.73m^2). Urinary VEGF was determined with electro-chemiluminescent multi-analyte ELISA (Mesoscale). We compared values using Spairo-Wilk testing and ROC analysis with Youden's index.

Results: Fourteen infants (35%) developed CKD. Urinary VEGF at 30-34 weeks PMA was lower in infants that developed CKD (2.23 *vs*, 2.63 log pg/mL; p=0.004). The AUC for VEGF to predict CKD was 0.77 (95% CI 0.62-0.92, p=0.005). Using a likelihood ratio of 2.32, a threshold of 2.47 log pg/mL gives a sensitivity of 72% and specificity of 70%.(Figure 1)

Conclusions: In this small cohort of premature infants with severe lung disease, urinary VEGF levels were lower in premature infants who went on to developed CKD compared to similar neonates who did not develop CKD. Additional urinary VEGF analysis in this cohort is ongoing. Low urinary VEGF may be a marker of abnormal angiogenesis and vascular repair in the kidney. Our findings suggest that urinary VEGF may help predict CKD in premature infants with lung disease.

Funding: NIDDK Support



In infants with severe lung disease (A) those that develop CKD have lower urinary VEGF levels (p=0.004) and (B) urinary VEGF predicts CKD status with an AUC of 0.77 (p=0.005)

Hyperoxia Exposure in Neonatal Period Is Associated with Decrease in HB-EGF Expression in Mice Kidneys

Rishika P. Sakaria,[1] Catrina White,[1] Ahmed Abdelgawad,[2] Ajay J. Talati,[1] Kent A. Willis,[2] Amandeep Bajwa.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Background: Acute Kidney Injury (AKI) is common in preterm infants and may cause long-lasting renal damage. Hyperoxia exposure in the postnatal period has been linked to chronic kidney disease (CKD) in adulthood in survivors or preterm birth. The mechanism of hyperoxia-driven AKI in premature infants is not clearly understood. Activation of the epidermal growth factor receptor (*EGFR*) by EGF or heparin-binding EGF-like growth factor (*HB-EGF*) promote renal tubular proliferation and renal recovery in AKI. In contrast, activation of transcribing growth factor (*TGF-a*) signaling may lead to fibrosis and CKD. We hypothesize that hyperoxia exposure in neonatal mice leads to kidney injury via alteration in the expression of EGFR and its ligands.

Methods: Pups of C57BI/6J mice were exposed to hyperoxia (FiO2 0.85) and compared to littermate controls exposed to room air from postnatal days 3-10. One kidney from each pup was fixed in formalin and embedded in paraffin for histological analysis. The other kidney was snap frozen and RT-PCR was performed from the RNA isolated from this kidney.

Results: We analyzed renal tissues from 15 newborn mice (from 3 litters) exposed to hyperoxia and 5 mice (from 1 litter) exposed to normoxia. Relative mRNA levels of *HB-EGF* were significantly decreased in renal tissues of pups exposed to hyperoxia (mean:0.006 ± 0.001) compared to those exposed to normoxia (mean:0.012 ± 0.002) ($p < 0.05$). Both *EGFR* and *TGF-a* were not elevated in pups exposed to hyperoxia. Hyperoxia-exposed pups were also noted to have elevated *a-SMA* and fibronectin compared to the controls. *TGF*-β levels were also similar between exposed and non-exposed animals (Figure 1).

Conclusions: *HB-EGF* may contribute to hyperoxia-related renal injury in preterm neonates and may be a therapeutic target in these infants.

Identification of Molecular Mechanisms Regulating Mammalian Nephrogenesis Duration and Nephron Endowment

Alison E. Jarmas,[1,2] Praneet Chaturvedi,[1] Raphael Kopan.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Nephron endowment generated during development confers lifelong renal filtration function, and is established via nephron progenitor cell (NPC) interactions with the adjacent stroma and ureteric bud (UB). Two salient, incompletely understood features of nephrogenesis are (1) the coordinated cessation of nephrogenesis in independent niches and (2) a striking 10-fold variation in nephron number between kidneys from different individuals. Preterm births are associated with premature cessation of nephrogenesis and are consequently susceptible to early-onset chronic kidney disease (CKD) and end-stage renal disease (ESRD). We leverage multiple mouse models exhibiting consistent differences in nephron number to identify mechanisms promoting prolonged nephrogenesis and/or increased nephron endowment.

Methods: NPCs from mice with elevated nephron numbers and delayed cessation (Six2$^{TGC;\ Tsc1}$, herein *Tsc1$^{+/-}$*) were evaluated via single-cell transcriptomics, translatome profiling (bulk RNA-Seq of Rpl10a-associated transcripts), metabolic indicators (*in vitro* glycolysis assays and *in vivo* hypoxia studies), and immunofluorescence. Candidate genes emerging from the RNA analyses were validated with *in vivo* genetic models for nephron number and cessation timing phenotypes.

Results: Translatome analysis revealed age and genotype-dependent patterns in signaling pathway components that were not observed in the single cell transcriptome, including differential translation of Wnt antagonists over agonists (such as Rspondin-3) in *Tsc1$^{+/-}$* NPCs. Moreover, compared to postnatal day 0 niches, Wnt agonists are less robustly translated in younger (embryonic day 14) niches, resulting in high Fgf20 levels and low R-spondin levels promoting a self-renewal environment. Further, the selective differential translation observed in the *Tsc1$^{+/-}$* model was not associated with globally elevated mTORC1 activity or changes in cellular metabolic activities.

Conclusions: We propose a model in which the tipping point for nephron progenitor exit from the niche is controlled by the gradual increase in stability of Wnt/Fzd complexes in individual cells, enhancing the response to UB-derived *Wnt9b* inputs and driving differentiation. Consistent with this, loss of one *Rspo3* allele in nephron progenitors delayed cessation and increased nephron numbers *in vivo*.

Simultaneous Generation of Nephron and Renal Stroma via Progenitor Cell Replacement in Animal Fetus

Yatsumu Saito, Shuichiro Yamanaka, Kenji Matsui, Naoto Matsumoto, Tsuyoshi Takamura, Toshinari Fujimoto, Susumu Tajiri, Kei Matsumoto, Eiji Kobayashi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Tokyo, Japan.*

Background: To solve the organ transplant shortage by regenerative medicine, the whole kidney, including the renal stroma—which plays important roles in homeostasis, such as structural maintenance, hemodynamics, and kidney endocrine function—must be generated. Previously, we successfully generated a rat nephron using mouse kidney as a scaffold by replacing mouse nephron progenitor cells (NPCs) with rat NPCs. Therefore,

animal fetuses can potentially generate human kidneys. Herein, we applied progenitor cell replacement to stromal progenitor cells (SPCs) and to NPCs and SPCs to verify the simultaneous generation of renal stroma and nephrons.

Methods: We harvested the metanephroi of green fluorescent protein rats to extract dissociated single cells (DSCs) by enzymatic treatment. SPCs were extracted from these DSCs by cell sorting targeting the platelet-derived growth factor receptor alpha (PDGFRa)-positive fraction. NPCs were extracted by sorting integrin alpha 8-positive fractions from the PDGFRa-negative fraction. We injected the extracted SPC fractions and both NPC and SPC fractions in the nephrogenic zone of the metanephroi of Foxd1-iDTR mice (host SPC removal model) and Six2/Foxd1-iDTR mice (host NPC and SPC removal model), respectively. The metanephroi were organ cultured for 1 week or transplanted into the retroperitoneum of NOD/Shi-*scid*/IL-2Rγ^{null} mice and collected after 2 weeks for evaluation with immunofluorescence staining.

Results: In the SPC removal model, mouse SPCs were replaced with rat SPCs in vitro, and rat stroma was extensively generated in mouse kidneys in vivo. Rat SPCs differentiated into various stromal lineage cells, e.g., mesangial cells, interstitial fibroblasts, vascular pericytes, juxtaglomerular cells, and EPO-producing cells. In the two progenitor cell removal models, cap mesenchyme-like structures were formed with aggregated rat NPCs and SPCs around the mouse ureteric bud in vitro. Rat nephrons and renal stroma were generated in the mouse kidney in vivo.

Conclusions: SPC replacement helped generate heterogeneous rat renal stromal lineage cells in the mouse kidney. Simultaneous NPC and SPC replacement enabled the generation of nephrons and renal stroma between different species.

Crescents Derive from Single Podocyte Progenitors and a Drug Enhancing Their Differentiation Attenuates Rapidly Progressive Glomerulonephritis

Maria elena Melica, Giulia Antonelli, Maria Lucia Angelotti, Gianmarco Lugli, Carolina Conte, Letizia De Chiara, Fiammetta Ravaglia, Anna J. Peired, Benedetta Mazzinghi, Elena Lazzeri, Roberto Semeraro, Laura Lasagni, Paola Romagnani. *Universita degli Studi di Firenze, Firenze, Italy*.

Background: Rapidly progressive glomerulonephritis (RPGN) is characterized by crescent formation, which typically, is the consequence of diverse upstream pathomechanisms involving the specific activation of PEC, represente which represent in part renal progenitor cells (RPC). Similarities with stem cell of bone marrow prompted us to hypothesized that crescents result from clonal expansion of a single RPC, conceptually similar to monoclonal diseases originating from hematopoietic stem cells. We further hypothesized that drugs known to cure hematopoietic disease by enforcing their terminal differentiation could also attenuate crescentic glomerulonephritis.

Methods: We established a RPGN disease model in a conditional transgenic mouse based on the mT/mG and the Confetti reporter that allows lineage tracing of RPC. Mice were treated with drugs currently used in myeloproliferative disorders. Crescentic lesions were characterized by super-resolution STED microscopy. Single cell RNA sequencing of human renal progenitor cultures identify the immature progenitor subset-generating crescent in human.

Results: We observed that crescents originated from the clonal expansion of single RPC, thus suggesting a clonal stem cell disorder. Therefore, we administrated a series of drugs known to ameliorates myeloproliferative neoplasms to our mouse model. Treatment with one of the compounds induced a reduction in both proteinuria and crescent formation. 3D confocal microscopy and STED super-resolution imaging of glomeruli showed that this compound turned the uncontrolled hyperplasia of a immature PEC subset into a controlled differentiation into new podocytes restoring the injured glomerular filtration barrier. Single cell RNA of human renal progenitor cultures identified a new marker of the crescent-generating progenitor cells. Expression of this marker in biopsies of patients with RPGN associated with progression toward end stage kidney disease.

Conclusions: These results demonstrate that glomerular hyperplastic lesions derive from clonal amplification of a RPC subset and that shifting proliferation to podocyte differentiation reverses crescent formation and improves clinical outcome.

A Multimodal Single Cell and Spatial Atlas of the Human Kidney in Health and Disease Delineates Cell States Associated with CKD Outcomes

Sanjay Jain,[1] Blue Lake,[2] Rajasree Menon,[5] Seth Winfree,[4] Qiwen Hu,[3] Ricardo Melo ferreira,[4] Edgar A. Otto,[5] Daria Barwinska,[4] Kian Kalhor,[2] Michael J. Ferkowicz,[4] Abhijit S. Naik,[5] Evan Murray,[6] Sean Eddy,[5] James C. Williams,[4] Karol S. Balderrama,[6] Chirag R. Parikh,[7] Eric H. Kim,[1] Peter Kharchenko,[6] Joseph Gaut,[1] Jeffrey B. Hodgin,[5] Michael T. Eadon,[4] Pierre C. Dagher,[4] Tarek M. El-Achkar,[4] Kun Zhang,[2] Matthias Kretzler.[5] KPMP, HuBMAP *[1]Washington University in St Louis, St Louis, MO; [2]University of California System, San Diego, CA; [3]Harvard Medical School, Boston, MA; [4]Indiana University School of Medicine, Indianapolis, IN; [5]University of Michigan Michigan Medicine, Ann Arbor, MI; [6]Broad Institute, Cambridge, MA; [7]Johns Hopkins University, Baltimore, MD*.

Background: The knowledge of the complexity of cell types, states and their interactions during homeostasis or disease is needed to identify the mechanisms of kidney disease.

Methods: We have applied multiple single cell or nucleus omic assays (>400,000 nuclei/cells) that capture gene regulation, expression and their spatial relationships to a broad spectrum of healthy reference (35) and disease kidney tissues (50, AKI or CKD) to establish a robust atlas of the cellular diversity representing kidney function or dysfunction.

Results: We identified 100 cell clusters including rare and novel cell populations and their spatial locations spanning the entire kidney. Among these, we define cellular states associated with kidney injury alterations that represent cycling, adaptive or maladaptive repair and degenerative states, their associated regulatory factors, and genes and pathways underlying these transitions. Molecular signatures of these states permit their classification and spatial localization within injury neighborhoods, allowing discovery of intercellular signaling relevant to acute or chronic injury. Large scale 3D imaging linked glomerular, proximal tubule and thick ascending limb injured cells to an active immune response that is uniquely associated with tubular cells. The altered state gene signatures were negatively associated with a decline in eGFR in patients with chronic kidney disease in two separate cohorts.

Conclusions: This comprehensive molecular, cellular and spatial atlas serves as a benchmark to identify nascent and altered kidney cell states, define therapeutic targets in individual patient samples and engineer healthy kidneys.

Defining the Molecular Correlate of Arteriolar Hyalinosis in CKD Progression by Integration of Single-Cell Transcriptomic Analysis and Descriptor Scoring in KPMP and NEPTUNE

Rajasree Menon,[1] Edgar A. Otto,[1] Laura Barisoni,[2] Jeffrey B. Hodgin,[1] Matthias Kretzler.[1] for the Kidney Precision Medicine Project (KPMP) *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Duke University, Durham, NC*.

Background: Single cell RNA sequencing generates transcriptomic data at cellular resolution allowing the identification of cell-type specific transcript expression. We performed an integrated analysis of single cell data with descriptors from histopathology analysis of biopsy samples of CKD and AKI patients.

Methods: As part of Kidney Precision Medicine Project (KPMP), single cell analysis from 12 AKI and 15 CKD patients proceeded per KPMP guidelines (including normalization, scaling, clustering and cell-specific marker identification). Top 5000 highly variable genes expressed in the endothelial cluster identified at the low cluster granularity were analyzed using weighted co-expression network analysis. Next, the co-expressed gene sets were associated with descriptors from the histopathology analysis. A composite score was generated using the expression levels of genes for the modules that significantly correlated with the descriptors. For validation purposes, similar composite scores were also generated from tubular interstitial gene expression data of NEPTUNE cohort.

Results: The unsupervised clustering identified kidney cell clusters including glomerular, tubular and immune cell types. The weighted co-expression network analysis of endothelial genes showed a gene module significantly associated (adjusted $p < 0.02$) with arteriolar hyalinosis, one of the descriptors from the histopathology analysis; the genes in this module were enriched in the arteriolar endothelial cluster identified by high resolution clustering. KPMP CKD patients with the top composite scores had baseline eGFR < 60 (ml/min/1.73m2). In NEPTUNE, the endothelial scores significantly associated with low eGFR ($p < 0.0002$) and the composite endpoint of CKD progression (< 40% reduction eGFR or ESRD) indicating poor prognosis for the samples with high endothelial scores ($P < 0.0001$). Pathway analysis showed adipocytokine signaling as the top enriched pathway for this gene set.

Conclusions: Using integrated analysis of single cell expression data with histopathology descriptors, we identified an arteriola endothelial gene set linking arteriolar hyalinosis to CKD progression.

SA-OR53

Proteomic Characterisation of CKD Progression

Carlos Raul Ramirez Medina,[1] Nophar Geifman,[1] Philip A. Kalra,[1] Anthony Whetton,[1] Ibrahim Ali.[2] *[1]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [2]National Health Service England, Salford, United Kingdom.*

Background: Delaying or halting progression of chronic kidney disease (CKD) to established renal failure is a major goal of global health research. The mechanism of CKD progression among different CKD entities involves pro-fibrotic, pro-inflammatory and vascular pathways but current treatments are non-specific, with heterogeneity in terms of response and outcome. In depth phenotypic and proteomic data can help investigate differences between those CKD patients with rapid disease progression and those who remain stable after diagnosis.

Methods: Using eGFR slope analysis, 414 patients with a broad range of kidney disease aetiologies were divided into fast progressors (δGFR > -3 ml/min/yr; n=170) and stable patients (δGFR > 0 ml/min/yr; n=244); these composed our discovery cohort. Plasma samples were obtained, and interrogated for novel proteomic signals with SWATH-MS which enabled a digitised proteomic profile to be generated. For hypothesis testing, the t-test was used to identify differentially expressed proteins between our patient groups ($p<0.05$, after multiple testing corrections was considered statistically significant). Statistical analysis and machine learning approaches for discovery (Random Forest and Boruta Feature Selection) were performed using the computing environment R and additional software packages were obtained via the Bioconductor project.

Results: A SWATH map (on 414 patients with 943 proteins quantified) was generated and investigated in tandem with available clinical data in order to identify potential progression biomarkers. After differential expression analysis and supervised machine learning algorithms for feature selection, we identified a set of proteins that differentiate between our patient groups (AUC= 0.77). Baseline creatinine was not an accurate predictor of CKD progression (AUC=0.51). Functional enrichment analysis revealed platelet degranulation to be statistically important, suggesting a possible role for platelet function in then pathogenesis of CKD.

Conclusions: The in-depth proteomic characterisation of this large-scale CKD cohort is a step forward in generating mechanism based hypotheses that might then lend themselves to future drug targeting. Candidate proteomic biomarkers will be validated in samples from selected patients in other large CKD cohorts such as NURTuRE using a targeted mass spectrometric analysis.

SA-OR54

Capillaries Are Primary Targets in CKD and Tie2 Signaling Plays a Central Role in Disease Progression

Riikka S. Pietilä,[1] Susan E. Quaggin,[2] Christer Betsholtz,[3,1] Marie Jeansson.[3,1] *[1]Uppsala Universitet, Uppsala, Sweden; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Karolinska Institutet, Stockholm, Sweden.*

Background: Progressive renal diseases are associated with loss of peritubular capillaries, capillary rarefaction, but the underlying mechanisms are not well described. In both mouse models and patients, a decline in endothelial tyrosine kinase receptor (Tie2) signaling can be seen in CKD. We hypothesized that renal blood vessels through loss of Tie2 signaling upregulates Pdgfb that in turn act as a mitogen to activate pericytes and fibroblasts.

Methods: To investigate this, we utilized floxed alleles for *Tie2* and *Pdgfb* together with inducible endothelial specific Cre and lineage reporter. Additional lines (Pdgfra-H2b-GFP and Pdgfrb-GFP), were crossed into the line, resulting in reporters of myofibroblasts. Mice were subjected to an experimental model of CKD, the unilateral ureter obstruction model. Capillary density and fibrosis were evaluated at 1, 3, and 10 days after obstruction. A subset of mice was treated with an Tie2 activating antibody and evaluated the same way.

Results: Our studies show that loss of *Tie2* results in increased injury to peritubular capillaries and increased tubulointerstitial fibrosis in an experimental model of CKD. *Tie2* ecKO mice showed reduced capillary density, reduced fenestrations, and reduced vessel perfusion. Furthermore, treatment with an Tie2 activating antibody reduced both fibrosis and loss of capillaries if started at the time of injury, while endothelial specific knockout of *Pdgfb* only reduced fibrosis.

Conclusions: Our results suggest that capillaries are primary targets in CKD and that Tie2 regulation affects both capillary density and tubulointesrstitial fibrosis. Tie2 activating agents should be explored as therapies for patients with chronic kidney disease.

Autocrine Signaling of Sphingosine 1 Phosphate in Kidney Perivascular Cells Promotes Inflammation and Fibrosis

Shinji Tanaka,[1] Shuqiu Zheng,[1] Yugesh Kharel,[2] Diane L. Rosin,[2] Kevin Lynch,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate (S1P) is a sphingolipid that is produced inside the cell by the action of sphingosine kinase (SphK) 1 and 2. S1P is exported from cells by spinster homolog 2 (Spns2) or major facilitator superfamily 2b (Mfsd2b), and then acts on five G protein-coupled S1P receptors, S1P1 to S1P5, to affect various cellular functions. We recently showed that *Sphk2*$^{-/-}$ mice were protected from renal fibrosis when compared to wild type or *Sphk1*$^{-/-}$ mice (PMID: 27799486). We hypothesized that local S1P signaling in kidney perivascular cells affects the progression of kidney fibrosis.

Methods: Male *Foxd1Cre*$^{+}$ *Sphk2*$^{fl/fl}$, *Foxd1Cre*$^{+}$ *S1pr1*$^{fl/fl}$, *Foxd1Cre*$^{+}$ *Spns2*$^{fl/fl}$, and their littermate control mice were used. For unilateral ischemia-reperfusion injury (IRI), left kidney was clamped; right nephrectomy was performed at day 13. In the folic acid model, folic acid (250 mg/kg) was intraperitoneally injected. Mice were euthanized at day 14 to evaluate kidney fibrosis. Primary kidney perivascular cells were isolated from kidneys and used for *in vitro* studies.

Results: Both in the unilateral IRI and folic acid models, *Foxd1Cre*$^{+}$ *Sphk2*$^{fl/fl}$ and *Foxd1Cre*$^{+}$ *S1pr1*$^{fl/fl}$ mice demonstrated better kidney function (plasma creatinine/blood urea nitrogen), less kidney fibrosis (histology) with less macrophage infiltration, and suppressed expression of fibrosis-related genes (*Acta2*, *Col1a1*, *Col3a1*) in the kidneys compared with control. In *in vitro* studies, perivascular cells with *Sphk2* deficiency or *S1pr1* knockdown expressed less proinflammatory cytokines/chemokines, such as *Ccl2*, *Il6*, *Cxcl1*, after treatment with TLR2/4 agonists compared with control cells. We further identified Spns2 as the S1P transporter expressed in kidney perivascular cells. *Foxd1Cre*$^{+}$ *Spns2*$^{fl/fl}$ mice also showed protection against kidney fibrosis in the unilateral IRI model and *Spns2*-knockdown cells showed suppressed inflammatory signaling upon stimulation.

Conclusions: SphK2/S1P/Spns2/S1P1 axis enhances inflammatory signaling in perivascular cells on injury, which aggravates immune cell infiltration and subsequent fibrosis in the kidney.

CD153-CD30 Signaling Is Required for Age-Dependent Tertiary Lymphoid Tissue Expansion in the Kidney

Yuki Sato,[1,2] Akiko Oguchi,[1] Naoya Toriu,[1] Keisuke Taniguchi,[1] Takahisa Yoshikawa,[1] Takeshi Hosoi,[2] Makiko Kondo,[1] Shota Komidori,[1] Peter Boor,[3,4] Jürgen Floege,[4] Motoko Yanagita.[1,5] *[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]MIC TMKP, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Institute of Pathology, RWTH University of Aachen, Aachen, Germany; [4]Department of Nephrology, RWTH University of Aachen, Aachen, Germany; [5]Institute for the Advanced Study of Human Biology (ASHBi), Kyoto University, Kyoto, Japan.*

Background: The elderly show a reduced capacity for renal regeneration after acute kidney injury (AKI). We previously showed that, after AKI, aged, but not young, kidneys exhibit tertiary lymphoid tissues (TLTs), which underlie maladaptive repair in aged injured kidneys. TLTs facilitate lymphocyte activation and differentiation *in situ* and are involved in pathophysiology in various diseases. However, the cells and signals responsible for age-dependent TLT formation in the kidneys are still undefined.

Methods: We investigated immune cells in aged injured kidneys with TLTs, 45 days after ischemic reperfusion injury, utilizing scRNAseq and bulk RNAseq, combined with flow cytometry and reporter mouse analysis. We also investigated human kidney samples harboring TLTs.

Results: We observed accumulation of CD153^{+}PD-1^{+}CD4^{+} senescence-associated T (SAT) cells and CD30^{+}T-bet^{+} age-associated B cells (ABCs), within TLTs in aged kidneys. Both SAT cells and ABCs are unique age-dependent lymphocyte populations and have been demonstrated to contribute to the pathophysiology of autoimmune diseases and obesity. By scRNAseq, SAT cells were further divided into two subpopulations, peripheral helper-like T cells and IL10-producing T cells, both of which are specialized CD4^{+} T cell subpopulations with B cell helper functions. CD153 and CD30 were specifically expressed in SAT cells and ABCs, respectively, and their expression was confined within TLTs in aged injured kidneys. In kidney injury models, CD153 or CD30 deficiency reduced ABC numbers, resulting in attenuated TLT formation with less inflammation and fibrosis and better renal function. Mechanistically, SAT cells from CD30-deficient mice exhibited decreased expression of *Il21* and *Il10*, indicating CD153-CD30 signaling was required for SAT cells to acquire B cell helper functions. CD153-expressing cells were detected within TLTs in human kidneys, and human Tph/TFH-like cells and ABCs in chronically inflammatory organs also expressed CD153 and CD30, respectively.

Conclusions: These findings identify CD153-CD30 signaling between SAT cells and ABCs as a pivotal regulator of age-dependent TLT formation and suggest that targeting CD153-CD30 signal may be a valuable strategy for the prevention and treatment of kidney diseases in the elderly.

Persistent DNA Damage as a Driver of CKD and Tubular Cell Senescence

Rannar Airik,[1] Merlin Airik,[1] Yu Leng Phua.[2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC Children's Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is a frequent cause of progression to chronic kidney disease (CKD) in humans. Emerging studies have shown that the transition to CKD results from impaired tubular repair due to accumulation of unresolved DNA damage in kidney tubular epithelial cells. Here we identify Fan1, a DNA repair enzyme, as a critical regulator of AKI to CKD progression in response to genotoxic and obstructive kidney injury in mice.

Methods: *Ggt1-Cre* mice were crossed with *FAN1*$^{loxP/loxP}$ mice to inactivate *FAN1* expression in kidney proximal tubules. Kidney injury was induced by cisplatin administration (5 weekly injections of 2 mg/kg) or unilateral ureteral obstruction (UUO). Histological analysis was performed using hematoxylin and eosin, periodic acid–Schiff, or Masson's trichrome staining. Tubular cell senescence was demonstrated by β-galactosidase staining at pH 6.0. Primary human kidney proximal tubular cells were used for modeling FAN1 loss of function in cell culture. RNA-seq analysis was performed on cisplatin-treated *FAN1*-deficient kidneys. Roscovitine was administered to block cell cycle activity and reduce cellular injury in cisplatin-treated *FAN1* kidneys.

Results: Kidney proximal tubule cell-specific *FAN1* inactivation sensitized the kidneys to tubular injury characterized by massive DNA damage response (DDR) activity. We found that persistent DDR triggers tubular cell dedifferentiation, aberrant cell cycle entry and G2 arrest which ultimately led to a failed tubular repair, tubular cell senescence and induced interstitial fibrosis in *FAN1* kidneys. Transcriptional profiling of *FAN1* kidneys identified that unresolved DNA damage blocks the cell cycle progression in late G2 through p53-dependent p21 upregulation. G2 cell cycle exit in *FAN1*-deficient cells was reinforced by nuclear cyclin D1 accumulation and DNA re-replication which gave rise to polyploid karyomegalic cells. Adminstration of roscovitine effectively blocked cell cycle activity and the formation of karyomegalic cells in cisplatin-terated *FAN1*-deficient kidneys.

Conclusions: Collectively, our data demonstrate that intact DNA damage response (DDR) is critical for proximal tubule regeneration after renal injury, and that Fan1 is a key effector of the DDR pathway in this process. Blocking of cell cycle activity immediately after tubular cell injury may be beneficial to augment tubular repair in the kidney.

Kidney Tubule Polyploidization Drives CKD Progression After AKI

Letizia De Chiara,[1] Carolina Conte,[1] Maria Lucia Angelotti,[1] Giulia Antonelli,[1] Anna J. Peired,[1] Maria elena Melica,[1] Benedetta Mazzinghi,[2] Laura Lasagni,[1] Elena Lazzeri,[1] Paola Romagnani.[1,2] *[1]Universita degli Studi di Firenze, Firenze, Italy; [2]Azienda Ospedaliero Universitaria Meyer, Firenze, Italy*.

Background: Acute Kidney Injury (AKI) is characterized by a rapid deterioration of kidney function. In addition, AKI survivors frequently develop chronic kidney disease (CKD). The traditional concept of kidney function recovery after AKI is based on a widespread proliferative capacity of injured tubular epithelial cells (TEC), which however is incompatible with the high prevalence of CKD after AKI. We recently demonstrated that TEC respond to AKI not only by proliferation, but also by undergoing polyplodization i.e. acquire more than one pair of chromosomes. Physiologically, polyploidy offers several advantages such as rapid adaptation to stress, compensation for cell loss and enhanced cell function. However, as polyploid cells can provide functional restoration but not structural recovery they can potentially drive CKD progression

Methods: We employed in vivo transgenic models based on the Fluorescence Ubiquitin Cell Cycle Indicator (FUCCI) technology in combination with YAP1 overexpression or inhibition. In these models, mice were subjected to glycerol-induced rhabdomyolysis to induce AKI. Polyploid cells have been then characterized by single cell-RNA sequencing analysis, cell sorting, FACS analysis, super-resolution and transmission electron microscopy.

Results: After AKI, YAP1 is activated triggering TEC polyploidization. In YAP1 overexpressing mice, a sustained activation of TEC polyploidization after AKI reduces early acute function loss but aggravates fibrosis, senescence caused by AKI, and AKI to CKD transition. Indeed, healthy YAP1 overexpressing mice present a consistent decline of kidney function over time suggesting an association between increased polyploidy and CKD development. Isolation of polyploid cells proved that these cells transcribe pro-fibrotic and senescent factors thus confirming their role in CKD progression. Importantly, as polyploid TEC become detrimental over time, blocking YAP1-driven polyploidy in a time-dependent manner avoids CKD development in comparison to control mice.

Conclusions: Collectively, these data suggest that: 1) polyploid TEC are pro-fibrotic leading in the long run to CKD progression; 2) blocking polyploidization in the right window of opportunity, can successfully ameliorate CKD progression after AKI.

SA-OR59

Inhibition of Cadherin-11 Ameliorates Kidney Injury via Restored Expression of Alpha-1 Antitrypsin

Tessa Huffstater,[1] Michael A. Raddatz,[1,2] Lance A. Riley,[1] Leslie S. Gewin,[2] W. David Merryman.[1] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN*.

Background: Chronic kidney disease (CKD) represents a massive unmet clinical need, as the pharmaceutical options for treatment of renal injury are extremely limited. A recent study identified cadherin-11 (CDH11) as a potential biomarker for CKD. CDH11 is present in kidney biopsies and urine samples of CKD patients, and its expression is increased in CKD mouse models, but it's unclear whether it mediates CKD and could be a target for therapy.

Methods: We used three mouse models of CKD to evaluate the role of CDH11: aristolochic acid nephropathy (AAN), unilateral ureteral obstruction (UUO), and uninephrectomy/angiotensin II administration (Unx/AngII). In each of these models, we inhibited CDH11 genetically using transgenic mice and pharmacologically with the administration of a functional blocking antibody to CDH11. We also used de-identified electronic medical records (IRB 211049) to verify the clinical relevance of the proposed mechanism whereby CDH11 knockout improves kidney injury.

Results: We found that CDH11 is exclusively expressed in injured murine proximal tubules (PTs). PTs play a critical role in CKD, as they are both a target and mediator of chronic injury. In models of CKD, both genetic and pharmacologic CDH11 inhibition improves renal function (BUN and proteinuria), diminishes cytokine production (TGF-β1 and IL-6 expression), and reduces tubular injury (KIM-1 and histological analysis). RNAseq from AAN- and Unx/AngII-injured kidneys revealed that CDH11 knockout mice had significantly increased expression of alpha-1 antitrypsin (A1AT) compared to wild type controls. Additionally, siRNA knockdown of CDH11 in immortalized PT cells in vitro results in elevated expression of A1AT, confirming this mechanistic link. The protease inhibitor A1AT has been shown by others to promote PT survival in several kidney injury models. Using Cox proportional hazards models, we discovered that patients with A1AT mutations have increased incidence of CKD on a per-allele basis, with hazard ratios as high as 5.35.

Conclusions: These results identify CDH11 inhibition as a novel means of improving outcomes in murine CKD models and suggest an underlying mechanism of increased A1AT expression and enhanced PT survival. These findings advance our understanding of CKD and outline a potential new therapeutic strategy.

SA-OR60

SARA in the Kidney: Regulation of Cell Phenotype as a Potential Therapeutic Target in Renal Fibrosis

Vidhi Dalal, Xiaoyan Liang, Katia Corano Scheri, Tomoko Hayashida. *Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL*.

Background: Epithelial cells play an important role in renal fibrosis. After injury, podocytes and renal tubular epithelial cells (TECs) dedifferentiate. When dedifferentiated, podocytes detach from the glomerular basement membrane, while TECs stimulate surrounding cells to transdifferentiate into myofibroblasts, thus resulting in glomerulosclerosis and tubulointerstitial fibrosis respectively. Our laboratory has identified a protein called Smad Anchor for Receptor Activation (SARA) as a key factor for maintaining cellular phenotype in the face of fibrogenesis. Here, we aim to determine if SARA overexpression in podocytes and TECs can prevent their dedifferentiation and reduce fibrosis in mouse models of glomerular and tubulointerstitial disease.

Methods: SARA overexpression was driven either by Podocin-Cre in podocytes (SARA^{podo}) and Pax8-rtTA, tet-O-Cre in TECs (SARA^{TEC}) in mice. SARA negative littermates (Ctrl^{podo} and Ctrl^{TEC} mice) were used as controls. SARA/Ctrl^{podo} mice were treated with Adriamycin to induce podocyte injury and SARA/Ctrl^{TEC} mice with aristolochic acid (AA) to induce tubulointerstitial fibrosis. Urine, blood, and kidneys were harvested for histological and molecular analysis. Markers for fibrosis and injury were measured by qPCR. Podocytes were isolated by flow cytometry from SARA/Ctr^{podo} mouse kidneys

Results: SARA^{podo} mice showed less glomerulosclerosis histologically and less proteinuria than Ctrl^{podo} mice after Adriamycin treatment. Tubular cell injury markers (KIM1, Sox9, NGAL) tended to be lower in SARA^{TEC} mice compared to Ctrl^{TEC} after AA treatment, but did not reach statistical significance. No significant difference in expression of markers of fibrosis was observed. Gene expression profiles of podocytes isolated from SARA/Ctrl^{podo} mice are being analyzed by RNA sequencing. This will provide insight into the mechanisms by which SARA maintains cellular phenotype and protects against renal fibrosis.

Conclusions: SARA overexpression protects podocytes and TECs against injury. Elucidating the mechanisms by which SARA functions will help unearth new molecular targets for therapies directed at glomerulopathies.

Observational Evidence of NAD+ Biosynthetic Impairment and Urinary Metabolomic Alterations in COVID-Related AKI

Nathan H. Raines,[1] Matthew D. Cheung,[2] Landon S. Wilson,[2] Anupam Agarwal,[2] Stephen Barnes,[2] Samir M. Parikh.[1,3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]The University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Acute kidney injury (AKI) is a frequent extrapulmonary manifestation of COVID-19 and is associated with increased morbidity and mortality. We investigated alterations in the urine metabolome associated with AKI among patients with COVID-19, with the hypothesis that changes in nicotinamide adenine dinucleotide (NAD+) metabolism described in ischemic, toxic, and inflammatory AKI will be also associated with AKI in patients with COVID-19.

Methods: This is a case-control study among two adult populations with COVID-19: critically ill patients hospitalized in Boston, Massachusetts, and a general hospitalized patient population in Birmingham, Alabama. Cases had AKI stages 2 or 3 by Kidney Disease Improving Global Outcomes (KDIGO) criteria. Controls had no AKI by KDIGO criteria. Metabolites were measured by liquid chromatography - mass spectrometry.

Results: 14 cases and 14 controls were included from Boston, and 8 cases and 10 controls included from Birmingham. Urinary quinolinate to tryptophan ratio, an indicator which increases with impaired NAD+ biosynthesis, was higher among cases than controls at each location and pooled across locations (median [IQR]: 1.34 [0.59-2.96] in cases, 0.31 [0.13-1.63] in controls, unadjusted p = 0.0013; p=0.03 in analyses adjusted for age and sex). We identified alterations in tryptophan, nicotinamide, and other components of energy metabolism as well as decreases in purine metabolites which contributed to a

distinct urinary metabolomic signature that could reliably differentiate patients with and without AKI (supervised random forest class error: 1/14 for AKI and 1/14 for no AKI groups in Boston, 0/8 for AKI and 0/10 for no AKI groups in Birmingham).

Conclusions: Conserved urinary metabolic alterations spanning multiple biochemical pathways distinguish AKI vs. non-AKI in the context of COVID-related hospitalization at two large academic medical centers. AKI is further associated with derangements in NAD+ biosynthesis that suggest impaired energy metabolism in the kidney. Augmenting renal NAD+ by administering biosynthetic precursors may present a novel therapeutic opportunity to mitigate COVID-19 associated AKI.

Expression of SARS-CoV-2 Viral Protein ORF3A in Renal Tubular Epithelial Cells Induces Injury

Weibin Zhou,[1] Hong Cai,[1,2] Ya Chen,[1,2] Kyung Lee,[1] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [2]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China*.

Background: The coronavirus SARS-CoV-2 is the culprit of the COVID-19 pandemic. Acute kidney injury occurs frequently in COVID-19 patients and several lines of evidence suggest local infection of kidney cells by the virus. However, this remains controversial and it is unclear how the viral proteins of SARS-CoV-2 directly impact the health of renal tubular cells infected by the virus.

Methods: The viral protein ORF3A of SARS-CoV-2 was overexpressed in HK-2 renal tubular cell line and the pronephric tubule epithelia of transgenic zebrafish. The NF-kB and STAT3 signaling pathways and target gene expression were analyzed using quantitative RT-PCR and Western blots. The expression of the renal injury marker KIM-1 was also assessed by Western blots, quantitative RT-PCR and *in situ* hybridization. Protein interactions were studied by co-immunoprecipitation and Western blots.

Results: ORF3A augments both NF-kB and STAT3 signaling by enhancing the phosphorylation of the transcription factors and results in the expression of downstream target genes and subsequently increases the expression of kidney injury molecule 1 (KIM-1) in HK-2 cells. Mechanistically, ORF3A elevates the expression of Tripartite Motif-Containing Protein 59 (TRIM59), a ubiquitin E3 ligase, which forms a protein complex with ORF3A and STAT3. This in turn excludes the phosphatase TCPIP from binding to STAT3 and inhibits the dephosphorylation of STAT3. The transgenic zebrafish expressing ORF3A in renal tubular epithelia develop severe edema starting 48 hours post fertilization and *in situ* hybridization shows elevated kim-1 expression in the pronephric tubules, indicating that ORF3A induces renal injury in zebrafish in vivo.

Conclusions: These results demonstrate that overexpression of ORF3A is sufficient to injure renal tubular epithelial cells and uncover a previously unrecognized molecular mechanism underlying the deregulation of STAT3 activity by ORF3A that leads to renal tubular cell injury. Altogether, the results of this study support the notion that direct infection of renal epithelial cells by SARS-CoV-2 may contribute to the renal complications in COVID-19 patients.

Deciphering the Impact of Cytokine Storm on APOL1 Expression in Primary Human Glomerular Endothelial Cells

Sarah Nystrom, Somenath Datta, Karen Soldano, Opeyemi A. Olabisi. *Duke University School of Medicine, Durham, NC*.

Background: High Risk (HR) Apolipoprotein L1 (APOL1) genotypes are associated with collapsing glomerulopathy in the context of interferons (IFNs), HIV, systemic lupus erythematous (SLE), and SARS-CoV2 infection. Elevated circulating inflammatory cytokines, commonly referred to as "cytokine storm" are believed to play causal role in disease pathogenesis. Although the role of IFN and TNF in APOL1 induction has been described, it is unknown if other components of "cytokine storm" implicated in COVAN and lupus glomerulopathy also induce APOL1 expression. *In vitro* and animal studies show that expression of variant APOL1 is sufficient to cause glomerulopathy in dose-dependent manner. Therefore, it is important to establish if other components of "cytokine storm" regulate APOL1 expression in human glomerular compartment.

Methods: We evaluate the direct effect of cytokines implicated in the above diseases on APOL1 expression in primary human glomerular endothelial cells, a cell type with known significance in lupus and COVAN. We also screened these select cytokines using peripheral blood monocytes (PBMCs) from patient with SLE and HR APOL1 genotype.

Results: IFNs($\beta>\gamma>\alpha$) were the strongest drivers of APOL1 expression. Importantly, we also found that IL-6 increased APOL1 expression by 7 fold compared to control ($p<0.01$) in glomerular endothelial cells. Treatment with composite of all cytokines induced the most robust APOL1 expression. However, Jak 1/2-specific inhibitor, baricitinib, markedly attenuated this effect, with reduction in APOL1 expression from 800 fold down to 4 fold. Additionally, in PBMCs of a lupus patient with HR APOL1, IL-18 also showed significant upregulation of APOL1 expression.

Conclusions: Our data suggest that other cytokines beyond interferon may be important in the pathogenesis of COVAN, HIVAN, and APOL1-associated lupus collapsing glomerulopathy and that Jak-inhibitors may be a promising novel therapeutic in these cytokine-mediated APOL1 nephropathies.

Interferon-Activated Genetic Programs and a Novel Short Isoform of the SARS-CoV-2 Receptor ACE2 in the Kidney

Jakub Jankowski,[1,2] Hye kyung Lee,[1] Julia Wilflingseder,[2] Lothar Hennighausen.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Veterinarmedizinische Universitat Wien, Wien, Austria*.

Background: Severe COVID-19 causes cytokine storm, worsening patient prognosis and contributing to acute kidney injury (AKI) development. Genetic programs activated in the renal epithelium by cytokines like interferon, as well as those ablated by JAK inhibitors, like ruxolitinib, were previously not investigated in detail. Additionally, a short isoform of *ACE2, deltaACE2 (dACE2)*, of unknown function was recently identified as an interferon-stimulated gene, and it's presence, inducibility and regulation in the kidney was not explored.

Methods: We treated Human Primary Proximal Tubule (HPPT) renal epithelial cells with IFNa, IFNβ, IFNg, IL-1β and ruxolitinib and used RNA-seq to explore gene expression patterns. We performed GSEA analysis and compared this data to available AKI and renal COVID-19 datasets, as well as to other human interferon-treated tissues. We also measured mRNA expression of both *ACE2* isoforms by RT-qPCR before and after cytokine stimulation and identified changes in gene regulatory elements of the *ACE2* locus using ChIP-seq.

Results: RNA-seq analysis identified genes significantly induced by IFNα (746), IFNβ (1169), IFNγ (1280) and IL-1β (2142), mostly immunity related. We saw an overlap of 162 genes between IFNβ treatment and the post-AKI dataset and of only 35 with severe COVID-19. Comparison of kidney, lung and liver cells treated with IFNβ revealed a shared set of 153 genes and unique 685 renal genes. Using RT-qPCR we show 300- and 600-fold upregulation of *dACE2* mRNA by IFNα and IFNβ, respectively, while full length *ACE2* expression is almost unchanged. RNA-seq data revealed abundant fragment mapping to exons corresponding to *dACE2* compared to rest of the transcript. ChIP-seq analysis showed additional putative regulatory elements in *ACE2* locus, including intragenic enhancers and a *dACE2* promoter. JAK inhibitor ruxolitinib successfully ablated 79.5% (929) of genes induced by IFNβ in HPPT cells, including *dACE2*.

Conclusions: We generated and made available novel RNA-seq and ChIP-seq datasets for human renal proximal tubule cells stimulated with cytokines. We observed that type I interferons significantly upregulated only the short isoform of SARS-CoV-2 receptor *ACE2* and we linked it to JAK/STAT pathway, which may be an important factor in COVID-19 therapies using JAK inhibitors.

Single Cell Analysis Reveals Deeper Insight of the Gateway Cell Type for SARS-CoV-2 in Kidney

Yuxiang Sun, Hongchun Lin, Xinxin Ma, Qiang Huang, Hui Peng. *Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*.

Background: Kidney injury is one of the extrapulmonary injury manifestations of COVID-19. Due to the specific expression of SARS-CoV-2 receptor angiotensinase 2 (ACE2), renal tubular epithelial cells are the main target cells of SARS-CoV-2 during kidney infection, although studies have found that the evidence of SARS-CoV-2 infection of glomerular cells. However, detailed mechanism of SARS-CoV-2 infecting kidneys still needs to be identified. Since mice don't express ACE2, humanized organoids have become important carriers for studying the mechanism of viral infection in vitro. It is still unclear whether the existing kidney organoids are suitable for studying SARS-CoV-2 virus infection.

Methods: Data source: All scRNA-seq/bulk RNA-seq were downloaded from the Gene expression Omnibus. **ScRNA-seq analysis**: The scRNA-seq was analyzed using Seurat R package. **Cell communication analysis:** Cell communication was analyzed using CellPhoneDB and Cellchat R package. **SCENIC analysis:** Gene regulatory network was analyzed using SCENIC R package. **Bulk RNA-seq analysis**: We used MuSiC R package to deconvolute bulk RNA-seq data. **GSEA analysis:** GSEA was performed using clusterProfiler package.

Results: We mined the available scRNA-seq dataset of human adult kidneys (GSE140989, GSE131882), and identified a proximal tubule subgroup, PTv cells, is susceptible to SARS-CoV-2 infection. PTv cells are highly enriched a variety of factors related to viral infections (such as ACE2, DPP4, ANPEP, CTSB, TMPRSS2 etc.). Through cell communication and gene regulatory network analysis, we inferred that PTv cells are more active than other PT cells in terms of repairment, fibrosis, development, and reabsorption. Further by analysis in the datasets of GSE139061 and GSE126805, we found that the proportion of PTv increased during acute kidney injury, suggesting that PTv could be used to predict the progression of kidney injury. Analyzing human kidney organoid scRNA-seq data (GSE109718, GSE115986, GSE108291, GSE147863, GSE119561, GSE114802, GSE136314, GSE118184), we identified that the PTv widely present in kidney organoids, indicating that kidney organoids can be used in SARS-CoV-2 related research.

Conclusions: We revealed the characteristics of the PTv, a gateway cell for SARS-CoV-2 in kidney, and provided a molecular basis for the feasibility of renal organoids to study the renal tropism of SARS-CoV-2.

PO0006

Longitudinal Proteomic Characterization of AKI in Hospitalized COVID-19 Patients

Ishan Paranjpe, Ryan C. Thompson, Steven Ascolillo, Shan Zhao, Suraj K. Jaladanki, Evren U. Azeloglu, Alexander W. Charney, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) is a known complication of COVID-19 associated with increased in-hospital mortality.

Methods: We longitudinally measured serum levels of 4,497 proteins (SomaScan) in 437 COVID-19 patients at multiple timepoints along their hospital course and identified associations with AKI. Using single cell transcriptomic data from healthy human kidney specimens, we identified cell-specific kidney intracellular markers and quantified their leakage in sera from AKI patients. We also investigated whether serum proteomics improves AKI prediction.

Results: We identified 408 upregulated and 107 downregulated proteins in COVID-AKI (144 cases, 293 controls, FDR<0.05, Fig 1A). Downregulated proteins included coagulation cascade inhibitors (protein C, heparin cofactor 2) and platelet dysregulation markers (Fig 1B), including platelet factor 4 (PF-4). Given the role of PF-4 in heparin induced thrombocytopenia (HIT), we then retrospectively analyzed 4,035 COVID-19 hospitalizations and found a significant association of HIT suspicion with COVID-AKI (aOR = 12.6, p <0.001). Intracellular AKI associated proteins were enriched for markers of the Loop of Henle, descending vasa recta endothelium, and NK cells (Fig 1C), which all have low ACE2 (Fig 1D) and TMPRSS2 expression (SARS-CoV2 receptor and activator respectively), suggesting bystander damage within the kidney, not direct viral invasion likely drives COVID-AKI. Finally, a random survival forest model incorporating protein levels had lower prediction error for incident AKI than one using only clinical variables (Fig 1E).

Conclusions: The COVID-AKI serum proteome is characterized by dysregulated platelets with clinical evidence of HIT, improves prediction of incident AKI in a machine learning model and suggests inflammation mediated renal cell death, rather than direct viral invasion via the renal ACE2 receptor.

TIMP-2/IGFBP7 and N-Gal Are Strongly Associated with the Development of AKI in Patients with Severe Pneumonia Caused by SARS-CoV-2

Gustavo A. Casas-Aparicio, David Escamilla-Illescas. Departamento Investigacion Enfermedades Infecciosas - INER *Instituto Nacional Enfermedades Respiratorias, Cuidad Mexico, Mexico.*

Background: The cut-off points for the urinary kidney biomarkers (BM): TIMP2*IGFBP7 (Tissue Inhibitor of Metalloproteinase-2 *Insulin-Like Growth Factor Binding Protein-7 and Neutrophil Gelatinase associated lipocalin (NGal) in patients with AKI by SARS-CoV-2 are not defined.

Methods: Between May-August 2020 prospectively included patients with severe pneumonia caused by SARS-CoV-2 without AKI at the moment of enrollement. Fresh urine was collected at admission of critical care and was immediately frozen at -80 grades Celcius. NGal and TIMP-2*IGFBP-7 were measured in urine. We derived cutoffs based on sensitivity (S) and specificity (E) for predicting AKI using K-DIGO criteria of urinary kidney BM and some serum BM. The better cut-off of N-Gal and TIMP-2*IGFBP7 were used to construct Kaplan Meier curves to assess differences in the risk of AKI. We performed a logistic regression model for significant variables to AKI. The analysis was conducted by SPSS V25.

Results: We included 51 patients, 20 AKI and 31 matched controls. Hypertension in the AKI group was 50% vs 12.9% p=0.009. Mortality in the group with AKI was 8 (15.7%) vs 2 NO-AKI (3.9%) p=0.013. **Table 1** shows AUC of urinary and serum clinical BM for predicting AKI. TIMP2/IGFBP7 cut-off point of 0.2 ng/ml had S= 50%, E = 90%, and N-Gal 45 ng/ml had S=70.5%, E 80.6%. Survival curves for AKI were constructed after stratifying TIMP-2 IGFBP7 >0.2 vs <0.2 and N-Gal >45 vs <45 ng/ml, cut-off <0.2 of TIMP2*IGFBP7 had lower risk for AKI during (Log-rank test p = 0.002), lower risk for AKI was also observed with the cut-off <45 ng/ml for N-Gal (Log-rank test p = 0.001). Multivariate analysis indicated risk factor for AKI was higher when TIMP2*IGFBP7 >0.2 $(ng/ml)^2/1000$ (OR 10.29, 95% CI=1.26-83.60, **p=0.029**); and higher N-Gal >45 ng/ml (OR 5.57, 95% CI 1.00-30.87) **p=0.038.**

Conclusions: TIMP2*IGFBP7 and NGal in urine are excellent predictors of AKI in patients with severe pneumonia caused by SARS-CoV-2.

Funding: Government Support - Non-U.S.

AKI in a Mouse Model of COVID-19: Therapeutic Potential of a Novel Soluble ACE2 Variant

Luise Hassler,[1] Jan Wysocki,[1] Anastasia Tomatsidou,[2] Haley Gula,[2] Vlad I. Nicolaescu,[2] Isha Sharma,[1] Glenn Randall,[2] Yashpal S. Kanwar,[1] Daniel Batlle.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]The University of Chicago, Chicago, IL.*

Background: We have previously shown that in the ischemia reperfusion model of AKI kidney ACE2 activity decreases and that the administration of a shorter soluble ACE2 variant markedly attenuates AKI in terms of GFR and kidney histology (Shirazi et al, ASN 2019). Here, we report the effect of a novel ACE2 variant designed to prevent/treat SARS-CoV-2 in transgenic k18-hACE2 mice infected with a lethal viral dose.

Methods: In a BSL-3 facility, transgenic k18-hACE2 mice were infected intranasally with 2×10^4 PFU SARS-CoV-2. ACE2 1-618-DDC-ABD was administered intranasally and intra-peritoneally 1 hour prior to viral challenge as well as 24 and 48 hours afterwards for a total of 3 doses. Infected control animals received PBS at the same time-points. Kidneys were removed from all animals and examined by light microscopy (LM) histologically and for apoptosis, using PAS and TUNEL staining, respectively.

Results: In mice infected with SARS-CoV-2, variable degrees of AKI were found by LM with the following features seen in the few most severe cases: proximal tubule brush border loss (black arrows, figure 1A and B), cytolysis (red arrow, figure 1A), tubular basement membrane disruption (blue arrows, figure 1A and B) and apoptosis (white arrows, figure 1A, B, D and E). In animals treated with ACE2 1-618-DDC-ABD, survival was near 100% and proximal tubular kidney injury was absent or markedly attenuated with less proximal tubule injury (figure 1C) and minimal apoptosis (figure 1F). Glomeruli appeared ischemic (figure 1B, green arrow) but otherwise normal without evidence of thrombosis.

Conclusions: Kidneys from a transgenic mouse susceptible to SARS-CoV-2 infection, like patients with COVID-19, displays variable degrees of proximal tubular injury suggesting that this model can be useful to study AKI in COVID-19. Mice that received soluble ACE2 1-618-DDC-ABD protein were essentially protected from AKI suggesting a potential preventative/therapeutic role for soluble ACE2 in this otherwise pharmacologically untreatable devastating disease.

Kidney Injury Molecule 1 Is a Receptor for SARS-CoV-2 in Lung and Kidney

Yutaro Mori,[1] Takaharu Ichimura,[1] Corby Fink,[2] Philipp Aschauer,[3] Krishna Mohan Padmanabha Das,[3] Robert F. Padera,[4] Astrid Weins,[4] Gregory A. Dekaban,[2] Jimmy D. Dikeakos,[2] Mahmoud L. Nasr,[1,5] Joseph V. Bonventre.[1,5] *[1]Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Microbiology & Immunology, Schulich School of Medicine & Dentistry, Western University, London, ON, Canada; [3]Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School, Boston, MA; [4]Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [5]Division of Engineering in Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Coronavirus disease 2019 (COVID-19) caused by SARS-CoV-2 was first reported in Wuhan in 2019 and reached pandemic proportions. SARS-CoV-2-related respiratory failure and acute kidney injury (AKI) are major complications of infection. Kidney Injury Molecule-1 (KIM-1) is a scavenger receptor expressed by kidney epithelial cells and was previously reported to be a receptor for Hepatitis virus A. We hypothesized that KIM-1 is a receptor for SARS-CoV-2 and may play an important role in COVID-19 lung and kidney injury.

Methods: Human lung and kidney autopsy samples were immunostained and analyzed. Liposomal nanoparticles displaying the SARS-CoV-2 spike protein on their surface (virosomes) were generated. Virosome uptake by A549 lung epithelial cells, mouse primary lung epithelial cells and human kidney tubuloids (3D structures of kidney epithelial cells) was evaluated in the presences or absence of anti-KIM-1 antibody or TW-37, a small molecule inhibitor of KIM-1-mediated endocytosis that we discovered. Protein-protein interaction characteristics between purified SARS-CoV-2 spike protein and purified KIM-1 were determined using microscale thermophoresis. HEK293 cells expressing human KIM-1 but not angiotensin-converting enzyme 2 (ACE2) were infected with live SARS-CoV-2 or pseudovirions expressing the SARS-CoV-2 spike protein.

Results: KIM-1 was expressed in lung and kidney epithelial cells in COVID-19 patient autopsy samples. Human and mouse lung and kidney epithelial cells expressed KIM-1 and endocytosed spike-virosomes. Both anti-KIM-1 antibodies and TW-37 inhibited uptake. Enhanced KIM-1 expression by human kidney tubuloids increased virosome uptake. KIM-1 positive cells expressed less ACE2. Using microscale thermophoresis, the EC50 for interaction between KIM-1 and SARS-CoV-2 spike protein and the receptor binding domain were 56.2±28.8 nM and 9.95±3.10 nM, respectively. KIM-1-expressing HEK293 cells without ACE2 expression had increased susceptibility to infection by live SARS-CoV-2 and pseudovirions expressing spike when compared with control cells.

Conclusions: KIM-1 is a receptor for SARS-CoV-2 in the lung and kidney and thus, KIM-1 inhibitors such as TW-37 can be potential therapeutics and/or prophylactic agents for COVID-19.

PO0010

Regulation of SARS CoV-2 Host Factors in the Kidney and Heart in Rats with 5/6 Nephrectomy: Effects of Salt, ARB, Dipeptidyl Peptidase 4 Inhibitor, and SGLT-2 Blocker

Denis Delic,[1,2] Yingquan Xiong,[2] Shufei Zeng,[2] Xin Chen,[2] Chang Chu,[2] Ahmed A. Hasan,[2] Bernhard K. Krämer,[2] Thomas Klein,[1] Berthold Hocher.[2] *[1]Boehringer Ingelheim Pharma GmbH and Co KG Biberach, Biberach, Germany; [2]Universitatsklinikum Mannheim, Mannheim, Germany.*

Background: Host factors such as angiotensin-converting enzyme 2 (ACE2) and the transmembrane protease, serine subtype 2 (TMPRSS2) are important factors for SARS-CoV-2 infection. Clinical and pre-clinical studies demonstrated that RAAS-blocking agents can be safely used during a SARS-CoV-2 infection but it is unknown if DPP-4 inhibitors or SGLT2-inhibitors may promote COVID-19 by increasing the host viral entry enzymes ACE2 and TMPRSS2.

Methods: We investigated telmisartan, linagliptin and empagliflozin induced effects on renal and cardiac expression of ACE2, TMPRSS2 and key enzymes involved in RAAS (REN, AGTR2, AGT) under high-salt conditions in a non-diabetic experimental 5/6 nephrectomy (5/6 Nx) model. In the present study, the gene expression of *Ace2*, *Tmprss2*, *Ren*, *Agtr2* and *Agt* was assessed with qRT-PCR and the protein expression of ACE2 and TMPRSS2 with immunohistochemistry in the following experimental groups: Sham+normal diet (ND)+placebo (PBO); 5/6Nx+ND+ PBO; 5/6Nx+2% salt-diet (HSD)+PBO; 5/6Nx+HSD+telmisartan; 5/6Nx+HSD+linagliptin; 5/6Nx+HSD+empagliflozin.

Results: In the kidney the expression of *Ace2* was not altered on mRNA level under disease and treatment conditions. The renal TMPRSS2 levels (mRNA and protein) was not affected, whereas the cardiac level was significantly increased in 5/6 Nx rats. Intriguingly, the elevated TMPRSS2 protein expression in the heart was significantly normalized after treatment with telmisartan, linagliptin and empagliflozin.

Conclusions: Overall, our study indicated that there is no upregulation regarding host factors potentially promoting SARS CoV-2 virus entry into host cells when the SGLT2 inhibitor empagliflozin, telmisartan and the DPP4 blocker linagliptin are used. The results obtained in a preclinical, experimental non-diabetic kidney failure model need confirmation in ongoing interventional clinical trials.

ACE2 and TMPRSS2 Co-Localization in Proximal Tubules from Human Kidneys Obtained at Autopsy from COVID-19 Patients

Carla L. Ellis, Minghao Ye, Luise Hassler, Athar Baig, Jan Wysocki, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Studies at the single cell level have revealed that the localization of TMPRSS2 is in the distal nephron whereas ACE2 is in the proximal tubule. Since TMPRSS2 is a serine protease necessary for activation of the SARS-CoV-2 S spike protein after it binds to ACE2, this spatial separation would make it difficult to explain how SARS-CoV-2 can infect the kidney. The purpose of this study was to examine the localization of these proteins by immunofluorescence in the kidneys of patients who died from COVID-19.

Methods: Human kidney slides from a Northwestern COVID-19 repository were used after IRB approval. Slides from paraffin-embedded blocks were probed with different antibodies (ACE2, TMPRSS2, ACE, NBC-1, Aquaporin 2) for immunofluorescence studies. Mouse kidneys were also examined as additional controls.

Results: In mouse kidneys, TMPRSS2 was found in the brush border of proximal tubules and co-localized strongly with ACE2. Similarly, in human kidneys from patients who died from COVID-19, with or without AKI and from non-COVID-19 subjects, ACE2 and TMPRSS2 co-localized in the proximal tubule. TMPRSS2 and ACE2 also co-localized with ACE, a marker of the apical proximal tubule and to a lesser extent with NBC-1, a marker of the basolateral proximal tubule membrane. By contrast, TMPRSS2 and ACE2 did not co-localize with Aquaporin 2, a marker of principal cells in the collecting tubule.

Conclusions: In both mouse and human kidneys, ACE2 and TMPRSS2 co-localize in the proximal tubule. In kidneys from patients with COVID-19 with or without AKI obtained at autopsy, both proteins co-localized in the proximal tubule but not in the collecting tubule. Contrary to what was suggested from single-cell mRNA analysis, the co-localization of both proteins in the proximal tubule would make it possible for the SARS-CoV-2-ACE2 complex to be activated when coronavirus reaches the kidney.

PO0012

Plasticity of Neutrophil Subsets in ANCA Vasculitis and COVID-19

Aisling C. Ui Mhaonaigh,[1] Amrita Dwivedi,[1] Mark A. Little.[1,2] Renal Inflammation Group *[1]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Department of Clinical Medicine, Trinity Translational Medicine Institute, Dublin, Ireland.*

Background: A population of granulocytes appear in the PBMC layer of density separated blood and are termed Low Density Granulocytes (LDGs). These are seen in many conditions including cancer, sepsis, autoimmunity and pregnancy. We previously identified LDGs in acute and remission ANCA vasculitis (AAV) and hypothesise that these LDGs are also present in Covid-19 (C-19) and our aim is to phenotype these cells and determine whether LDGs are a disease specific cellular response to inflammation. Of particular interest is the expression of intracellular Arginase 1 (Arg-1), an enzyme linked to T cell suppression in many disease situations.

Methods: LDGs were isolated using a modified percoll preparation and analysed by both traditional and imaging flow cytometry, in patients with active and remission ANCA vasculitis, in patients with severe moderate and mild C-19 and in healthy controls. The phenotyping panel included CD14, CD15, CD16, CD10, CD33, CD62l. Intracellular Arg-1 was stained following permeabilisation with saponin.

Results: We identified extensive populations of LDGs in both AAV and Covid-19 peripheral blood. LDG levels are associated with disease severity. Arginase 1 is differentially expressed in neutrophil populations from AAV and C-19. In C-19 Arginase levels are correlated to disease severity suggesting that Arginase release may be associated with favourable outcome. Interestingly, all neutrophil fractions show lower levels of Arginase in C-19 patients whereas in AAV only LDGs have lower levels. Healthy controls have high Arginase expression.

Conclusions: Neutrophil subsets display disease specific responses in C-19 and AAV demonstrating their plasticity in inflammatory settings and warrant further investigation.

Plasma TNFR1 Predicts Major Adverse Kidney Events in Hospitalized Patients with COVID-19

Steven Menez,[1] Steven G. Coca,[2] Dennis G. Moledina,[3] Yumeng Wen,[1] Lili Chan,[2] Heather Thiessen Philbrook,[1] Wassim Obeid,[1] Evren U. Azeloglu,[2] Francis P. Wilson,[3] Chirag R. Parikh.[1] TRIKIC Consortium: Translational Research Investigating Kidney Outcomes in COVID-19 *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Yale University School of Medicine, New Haven, CT.*

Background: Patients hospitalized with COVID-19 are at risk for major adverse kidney events (MAKE). Predicting which patients will experience progression of disease and poor outcomes remains elusive. We sought to develop a biomarker-based risk model for predicting MAKE in patients hospitalized with COVID-19.

Methods: We applied least absolute shrinkage and regression methodology (LASSO) to a prospectively enrolled cohort of 432 patients admitted with COVID-19 who had

blood specimens collected (median 2 days [IQR 2-4 days] from admission) from March 2020-January 2021, at three large academic medical centers. Clinical variables and 26 plasma biomarkers were used as candidate features in the prediction models for the outcome of MAKE, defined as KDIGO stage 3 AKI, dialysis-requiring AKI, or in hospital mortality. Cross-validation was used for optimal shrinkage parameter selection and model AUCs were optimism-corrected using bootstrapping.

Results: MAKE occurred in 85 (20%) patients within 60 days of admission. Application of LASSO to the 26 biomarkers selected IL-12, IL-13, IL-6, Tie2, FLT1, NGAL, MCP1, YKL40, Ang1, Ang2, and TNFR1, which yielded an AUC of 0.88 (95% CI 0.85-0.91). Plasma TNFR-1 alone had an AUC of 0.88 (0.84,0.91). When LASSO was applied on the clinical variables and TNFR1, 4 clinical variables (age, black race, obesity, WHO COVID severity score) and TNFR1 were selected with an AUC was 0.88 (95% CI 0.87-0.89). Random Forest models of biomarkers and clinical variables had similar prediction performance. A cutoff of TNFR1 at 3005 pg/ml had a sensitivity of 69%, specificity of 89%, PPV of 60% and NPV of 92% for occurrence of MAKE over 60 days.

Conclusions: In this multi-center cohort study, plasma TNFR1 by itself produced a robust prediction for MAKE in patients hospitalized with COVID-19 that did not improve when combined with multiple clinical variables and was equivalent to combined inputs of 10 other plasma biomarkers.

PO0014

AKI in COVID-19: Risk Factors for Mortality and Estimating Burden Using an ARIMA Model

Kundan Jana, Kalyana C. Janga, Sheldon Greenberg. *Maimonides Medical Center, Brooklyn, NY.*

Background: Incidence of Acute Kidney Injury (AKI) among COVID-19 patients is 35%. Requirement for Renal replacement therapy (RRT) is estimated to be 15%-20%. We aimed to identify risk factors associated with mortality and need for RRT in COVID-19 patients with AKI. We also estimated burden of the pandemic on inpatient hemodialysis (HD) unit.

Methods: Inpatients above 18 years, diagnosed with COVID-19 on RT-PCR between March-June 2020 were included in the study. AKI was defined using KDIGO guidelines. Data collected included demographics, serum creatinine, time to AKI, comorbidities, albuminuria, need for RRT and intubation. All inpatient HD sessions from January 2016 to June 2020 were included to estimate burden of COVID-19. CVVHD, PIRRT and PD were excluded. Statistical analysis included logistic regression, ANOVA, z-test for proportions and Chi-square test. Interrupted time series analysis using Auto Regression Interference and Moving Average (ARIMA) was used to predict proportion of bedside HD sessions from January 2020.

Results: 1991 patients positive for COVID-19 on RT-PCR were included. 683 (34.2%) were found to have AKI. 185 patients (27.1%) required RRT. Mortality among AKI patients was 64.7%. Age (OR=1.04; CI 1.03 to 1.06), AKI after 1 week (OR=2.15; CI 1.06 to 4.35), albuminuria (OR=2.57; CI 1.11 to 5.93), need for RRT (OR=2; CI 1.26 to 3.19) and intubation (OR=4.6; CI 2.71 to 7.75) were the mortality risk factors. Albuminuria (OR=2.97; CI 1.04 to 8.46), CKD (OR=3.5; CI 1.67 to 7.34) and intubation (OR=7.8; CI 5.14 to 11.91) were the risk factors for RRT. Diabetes and hypertension did not increase mortality or the need for RRT. To estimate the burden of pandemic, 24086 HD sessions between Jan. 2016 to June 2020 were analyzed. Proportion of bedside HD was significantly higher in 2020 when compared to previous years ($p<0.01$) due to isolation protocols. ARIMA model showed a significant difference in the mean proportion of bedside HD sessions for 2020 between observed and expected values ($p<0.01$). Personnel requirement showed an extra burden of 870 nurse-hours with March-April accounting for 76%. This was due to increased number of bedside sessions requiring a 1:1 nurse-patient ratio as opposed to in unit sessions where nurse-patient ratio is 1:2.

Conclusions: Time to AKI, albuminuria and RRT are important risk factors for mortality in COVID-19 patients with AKI.

PO0015

Renal Comorbidities and New Acute Kidney Failure Drive Unfavorable Outcomes Among COVID-19-Positive Sickle Cell Trait Carriers

Sudha K. Iyengar,[1,2] Jessica Minnier,[3,4] Anurag Verma,[5,6] Shiuh-Wen Luoh.[7,8] Million Veteran Program COVID-19 Disease Mechanisms Working Group *[1]Louis Stokes Cleveland VA Medical Center, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Biostatistics Shared Resource, Knight Cancer Institute, Oregon Health and Science University, Portland, Portland, OR; [4]VA Portland Health Care System, Portland, OR; [5]Department of Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [6]Corporal Michael Crescenz VA Medical Center, Philadelphia, PA; [7]Division of Hematology and Medical Oncology, Knight Cancer Institute, Oregon Health and Science University, Portland, OR; [8]VA Portland Health Care System, Portland, OR.*

Background: The sickle cell trait (SCT) in the hemoglobin beta gene (HbS; rs334) affects millions of Americans, especially African Americans (AA; minor allele frequency [MAF]=7.8%) and Hispanic Americans (HA; MAF=1%). We investigated the impact of SCT on the severity and sequelae of COVID-19 infection in the Million Veteran Program (MVP). Pre-COVID diseases and laboratory findings present in electronic health records (EHR), as well as acute events following 60 days of COVID-19 infection, and their effect on COVID-19 mortality among SCT patients were examined.

Methods: COVID-19 clinical data on genotyped MVP participants (SCT^+ = 2,729, SCT= 129,848; $COVID^+$=13,841, $COVID^-$=118,736) was extracted from EHR. Outcomes analyzed were: severe disease (or mortality) vs. not severe (or survival). Ethnic-specific firth logistic regression for SCT was performed on European (EA), African (AA), Hispanic (HA) and Asian (ASA) groups, adjusting for sex, age, age^2, and 20 genetic principal components. Ethnic-specific phenome-wide association (PheWAS and LabWAS) for SCT captured 20+ years of comorbidities and historical laboratory values and was used to contrast effects of COVID-19. Multiple testing corrections were applied.

Results: HbS is associated with increased COVID-19 mortality in AA (N=3,749; OR=1.8 [1.14-2.84], p=0.01) with a similar trend in HA. PheWAS revealed significant associations of rs334 with phecodes for pulmonary embolism, chronic renal disease, diabetic kidney disease, hypertensive renal disease, gout, sickle cell disease/trait, and hemolytic anemia (FDR $p < 0.1$). After adjusting for SCT, past renal disease was significantly associated with higher COVID-19 deaths among AA. Increased incidence of acute kidney failure (AKF) and chronic kidney disease (CKD) were seen within 60 days of infection with COVID-19. We estimated direct and indirect effects of AKF or CKD in AA SCT carriers via a mediation framework. On average 20.7% (95% CI: 3.8% - 56.0%) of the total effect of SCT on COVID-19 death was found to be mediated through AKF, and that for CKD was 12.4% (95% CI: 0% - 63%).

Conclusions: SCT is associated with an elevated risk of mortality with COVID-19 infection. Both pre-existing chronic medical conditions and new acute events after COVID-19 may contribute to adverse COVID-19 outcomes with SCT.

Comparison of Mortality in Hospitalized COVID-19 Patients with AKI vs. ESRD

Karela B. Herrera-Enriquez,[1] Chris D'Adamo,[2] Nasir Alhamdan,[1] Tedine Ranich.[1] *[1]LifeBridge Health, Baltimore, MD; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Patients hospitalized with COVID-19 illness are at high risk for developing acute kidney injury (AKI) and have high mortality rates. Chronic kidney disease (CKD) and end stage renal disease (ESRD) are independent risk factors for COVID-19 disease severity and mortality. Our study compares mortality rates of hospitalized patients with COVID-19 illness who 1) develop AKI with baseline normal renal function, 2) develop AKI with baseline moderate-to-severe CKD stages 3 or 4, and 3) have ESRD.

Methods: Consecutive patients admitted with COVID-19 illness referred to Nephrology with AKI or ESRD on dialysis were included. Retrospective data collected included: Demographics, medical history including CKD stage, labs, O2 therapy, AKI diagnosis (KDIGO), and renal replacement therapy (RRT). Chi-square test was used to evaluate the unadjusted association between CKD stage and mortality. Multivariate logistic regression models were constructed to estimate associations between CKD stage and mortality adjusting for potential confounders.

Results: 166 patients were analyzed: 87 patients had AKI with baseline normal renal function (GFR > 60 ml/min (AKI-N), 41 patients had AKI on CKD Stage 3 or 4 (AKI-CKD3/4), and 38 patients had ESRD. Mechanical ventilation was used in 33[37.9%] AKI-N, 20[48.8%] AKI-CKD3/4, and 10[26.3%] ERSD patients, p = 0.069. Three [3.5%] AKI-N received iHD, and 9[10.3%] received CRRT/PIRRT. Six [14.6%] AKI-CKD3/4 received iHD and 7[17.1%] received CRRT/PIRRT. Of all AKI patients, 55.5% had Stage 3 AKI. 34[89.5%] ESRD patients received iHD and 2[5.3%] received PD. AKI-CKD3/4 were more likely to receive RRT than AKI-N, p = 0.035. Death occurred in 36[41.4%] AKI-N, 26[63.4%] AKI-CKD3/4, and 9[23.7%] ESRD patients, (p=0.001). Multivariate logistic regression modeling for mortality accounting for age, race, gender, diabetes mellitus, hypertension, obesity, and CHF revealed increased odds of mortality for AKI-CKD3/4 (OR=2.59, p=0.006) and decreased odds of mortality for ESRD patients (OR=0.5, p=0.001), compared to AKI-N.

Conclusions: COVID-19 patients with ESRD had less mortality than AKI-N, while AKI-CKD3/4 had higher mortality than both ESRD and AKI-N patients. Prospective studies to determine specific criteria for early initiation of RRT in COVID-19 AKI patients are warranted, as it may decrease mortality especially in those with baseline CKD 3/4.

PO0017

AKI Associated with COVID-19: Differences Between Previously Healthy Kidney Individuals and CKD Patients

Carlos G. Musso,[1,2] Gustavo Aroca Martinez,[2,3] Lil Geraldine Avendaño-Echavez,[2] Maria D. Velez-Verbel,[3] Stefani Chartouni Narvaez,[2] Sandra Y. Hernandez-Agudelo,[3] Mauricio Hinojosa,[3] Zilac Espitaleta,[2,3] Andres Cadena-Bonfanti.[2,3] *[1]Instituto Universitario del Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [2]universidad simon bolivar, Barranquilla, Colombia; [3]Clinica de la Costa Ltda, Barranquilla, Colombia.*

Background: Renal injury associated to COVID-19 has an incidence of 3-9%, which ranged from urinary abnormalities up to acute kidney injury (AKI-COVID19), which is mainly observed in critical care patients. The main risk factors for AKI-COVID19 appearance are: oncologic disease, sepsis, heart failure. However, it has not described if there are differences between AKI-COVID19 in patients with previously healthy kidney (AKI-NRF) and those with chronic kidney disease (AKI-CKD), thus we decided to explore it in patients who were assisted during the first pandemic wave (2020) in Clinica de la Costa, Barranquilla, Colombia

Methods: 572 patients with confirmed diagnosis of COVID-19 (PCR) were evaluated. Out of them 188 developed AKI and their epidemiological data, serum parameters, and functional status were recorded. Statistical analysis and comparison between AKI-NRF and AKI-CKD patients were performed

Results: From 720 individuals evaluated at the emergency room for suspicion of COVID-19, 572 of them were admitted with confirmed SARS-CoV-2 infection. Most of them were male (59%), median age 55 years, with hypertension (36%), obesity (23%), diabetes (18%), heart disease (5%), and COPD (9%). Almost all patients were robust (97%). 188 COVID-19 patients developed AKI (33%), although 149 (26%) presented a previous normal renal function (AKI-NRF), while 39 (7%) had CKD (AKI-CKD). Most of CKD patients (91%) developed AKI. There was a predominance of male gender, old age (≥ 60 years), frailty status (CFS ≥ 4), diabetes mellitus, obesity, COPD in AKI group (AKI-NRF and AKI-CKD subgroups) respect to NO AKI group (n: 380). The prevalence of hypertension and cardiac disease was significantly higher in AKI-CKD respect to AKI-NRF, and even higher respect to NO AKI. However, there was a tendency of higher mortality rate in AKI-NRF (69%) compared to AKI-CKD (56%). Even though, this trend did not reach statistical significance (p=0.09), mortality rate in AKI compared to NO AKI (16%) (p=<0.0001) did. D-dimer was slightly higher in AKI-NRF compared to AKI-CKD (p=0.06)

Conclusions: There was a trend to higher mortality rate and D-dimer levels in AKI-NRF individual compared to AKI-CKD patients

PO0018

AKI in Inpatients with COVID-19: Risk Factors and Mortality

Mauricio Ostrosky-Frid, Meredith C. McAdams, Pin Xu, Michael M. Li, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: AKI in hospitalized patients with COVID-19 is a common adverse complication. Our aim was to investigate risk factors associated with AKI and whether AKI in this setting is independently associated with in-hospital mortality at 30 days.

Methods: All adult patients admitted with a positive SARS-CoV-2 PCR between 3 /2021 to 1/2021 to nineteen hospitals who had a COVID-associated billing diagnosis and no history of ESKD or kidney transplant were included. AKI was defined according to the Kidney Disease Improving Global Outcomes guidelines. Risk factors associated with AKI were evaluated with univariable and multivariable logistic regression, and mortality was evaluated using Kaplan-Meier and Cox Proportional Hazards models.

Results: The study cohort included 9,681 patients, of which 3,666 (38%) met criteria for AKI. Compared with patients without AKI, patients with AKI were older [mean (SD) age 67 (16) vs. 60 (18) years], more likely to be male (58% vs. 47%), and more likely to be black (21% vs. 15%). Patients with AKI were also more likely to have diabetes mellitus (52% vs. 32%), hypertension (78% vs. 57%), CKD (55% vs. 17%), and coronary artery disease (20% vs. 11%). Patients with AKI were also more likely to be on ACEi/ARB on admission (51% vs. 37%), require mechanical ventilation (21% vs. 3.2%) or have higher WBC, hs-CRP, ferritin, D-dimer, and cardiac troponin). P-values were <0.001 for all of the aforementioned comparisons. Risk factors significantly associated with AKI in the multivariable model included age, sex, race, hypertension, CKD, diabetes, ACEi or ARB on admission, mechanical ventilation, WBC on admission, hs-CRP, ferritin, d dimer and troponin. Death occurred more frequently in patients with AKI (22.1%; n=811) than in those without (3%; n=178). Patient with AKI had higher mortality risk as compared to those without AKI, hazard ratio (HR) 3.08 (95% CI 2.56-3.71), that remained significant even after controlling for all variables associated with AKI, such as age, sex, race, comorbidities, inflammatory biomarkers, elevated troponin, and COVID-related treatments, HR 1.64 (95% CI 1.34-2.01).

Conclusions: Patients with COVID-19 who develop AKI have a higher mortality. We found risk factors associated with AKI in the setting of COVID, and that the increased mortality risk associated with AKI in COVID-19 is independent of these factors.

PO0019

Burdens of AKI and CKD Among COVID-19 Survivors

Yan Xie, Benjamin C. Bowe, Andrew K. Gibson, Evan Xu, Ziyad Al-Aly. *VA Saint Louis Health Care System Clinical Epidemiology Center, Saint Louis, MO.*

Background: COVID-19 is known to be associated with increased risk of acute kidney injury (AKI) during the acute phase of the infection. However, the burden of AKI and chronic kidney diseases (CKD) after the first 30 days of COVID-19 infection is not clear.

Methods: 181,384 COVID-19 patients from the United States Veterans Health Care System who survived the first 30 days of infection were enrolled and compared with 4,397,509 non-infected controls on burden of AKI and CKD at 6 months. Adjusted comparisons were conducted across severity of infection measured based on intensity of care received, and by subgroups based on age and pre-existing health conditions.

Results: With a median follow up of 150 (interquartile range: 115, 221) days, the adjusted excess burden of AKI due to COVID-19 was 6.07 (95% confidence interval: 5.46, 6.69) and excess burden of CKD was 7.19 (5.78, 8.55) per 1000 persons at 6 months. The excess burden of AKI increased with the severity of acute infection(excess burden 1.28 (0.68, 1.86), 28.11 (25.94, 30.26) and 73.18 (67.53, 79.02) per 1000 persons at 6 months for COVID-19 patients without hospitalization, hospitalized and admitted to intensive care units, respectively). The excess burdens of CKD were 1.66 (0.19, 3.08), 36.41 (31.71, 41.11) and 82.55 (71.93, 93.78) for those not hospitalized, hospitalized and admitted to intensive care units, respectively. The burden of AKI and CKD increased with increased age (≤60, 60-70, >70 years) and increased pre-existing health conditions (Charlson comorbidity index of 0, 1-3 and >3) (Table).

Conclusions: Our results suggest that COVID-19 survivors, including those without hospitalization or pre-existing health conditions, suffered burden of AKI and CKD after the first 30 days of the infection. We provide insight into the burdens of AKI and CKD by population groups; our estimates may help guide nephrology care for COVID-19 patients.

Funding: Veterans Affairs Support

Population		AKI Adjusted excess burden per 1000 persons at 6 months (95% Confidence interval)	CKD Adjusted excess burden per 1000 persons at 6 months (95% Confidence interval)
Overall		6.07 (5.46, 6.69)	7.19 (5.78, 8.55)
Age (years)	≤ 60	1.33 (0.81, 1.86)	0.87 (0.18, 1.57)
	60-70	6.36 (5.15, 7.69)	6.53 (4.02, 9.11)
	>70	12.32 (11.12, 13.58)	19.24 (15.43, 23.14)
Charlson comorbidity index	0	2.62 (2.14, 3.14)	3.60 (2.42, 4.75)
	1-3	8.87 (7.91, 9.88)	10.57 (8.08, 13.08)
	>3	25.07 (21.82, 28.42)	20.17 (13.92, 26.75)

Outcomes were ascertained from 30 days after COVID-19 infection until end of follow-up.
Excess burden estimated as the burden difference between COVID-19 and control groups per 1000 persons at 6 months.

PO0020

Association Between BMI and Risk of AKI in Hospitalized Patients with COVID-19

Natalia Cavin, Rosalba Y. Santana De Roberts, Tianying Li, Belinda Jim, Kisra Anis, Nidhi Varma, Naheed Ansari, Anjali Acharya. *Jacobi Medical Center, Bronx, NY.*

Background: Acute Kidney Injury (AKI) is a frequent complication in ICU patients with a negative impact on patient outcomes. High body mass index (BMI) is reported to be associated with a higher risk of AKI in critically ill patients. Obesity is also a risk factor for developing COVID-19 and for severe illness requiring hospital admission, mechanical ventilation and is associated with mortality

Methods: A multi-center retrospective cohort study was conducted on 2,716 electronic health records (EHR), (n=1,719 in first surge dates of 3/1/20 until 7/16/20), (n=997 in second surge dates of 10/15/20 until 2/28/21 with COVID-19. Patients without a recorded BMI value were excluded. AKI at admission was defined as the difference between first measured creatinine and nadir creatinine within the first 7 days of admission that was greater than 0.3 mg/dL[JB1]. The Chi-squared test was used to compare BMI as a categorical variable between AKI and non-AKI groups at admission. The Mann–Whitney U test was used for the same comparison when BMI was treated as a continuous variable. A p-value less than 0.05 is considered statistically significant.

Results: BMI was dichotomized to < 25kg/m^2 and >= 25 kg/m^2. The non-AKI group had a significantly higher percent of patients with BMI greater or equal to 25 kg/m^2 (80.2% vs. 73.7%, p = 0.0108). BMI was not found to be associated with either peak CRP or peak D-Dimer among AKI patients in both surges.

Conclusions: A direct relationship between BMI and AKI is well known, mostly from data that included surgical patients with multiple comorbidities and did not account for peri operative stress[JB1]. The proinflammatory state in obesity may lead to endothelial damage. In CKD and ESRD, obesity is paradoxically associated with a better prognosis. Few studies have shown an inverse relationship between BMI and AKI risk. High levels of lipoproteins in obesity is thought to lead to endothelial protection in the kidney vasculature. A 'pre-conditioning' effect of obesity attenuating against abrupt bursts of hyper-inflammation on renal vasculature has been shown. Altered adipokine and cytokine profiles produced by adipose tissue can exert protective effects by decreasing inflammation. We describe here the first study showing an inverse relationship between BMI and developing AKI at hospital admission in COVID-19.

PO0021

Association Between Inflammation Markers in Patients with SARS-Cov-2 with the Development and Severity of AKI

Claudia Delgado Astorga,[1] Miriam G. Nava-Vargas,[1] Jorge Andrade-Sierra,[2,1] Enrique Rojas-Campos.[3] *[1]Hospital Civil de Guadalajara Dr Juan I Menchaca, Guadalajara, Mexico; [2]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico; [3]Hospital de Especialidades del Centro Medico Nacional de Occidente IMSS, Guadalajara, Mexico.*

Background: Acute Kidney Injure (AKI) is a common complication associated with SARS-CoV2 infection. Sepsis, direct cellular injury due to the tropism of the virus, and systemic inflammation are mechanisms involved in its development.

Methods: Prospective Cohort from March-2020 to March-2021 including 200 patients ≥18 yrs with SARS CoV2 for RT-PCR. All patients with development of AKI (KDIGO classification) during their hospitalization were registered. Age, gender, hospitalization time, oxygen use, SOFA, APACHE II, BRESCIA, PAFI, Leukocytes, creatinine (CrS) andinflammation markers (procalcitonin, ferritin, RCP, LDH, D-dimer) were registered.

Results: The incidence of AKI was 40%, 77% were male, 64% had AKI 1 and 36% were AKIN 2 y 3. The use of higher supplemental oxygen, APACHE, BRESCIA, D-Dimer and procalcitonin at day 9 and 12 were associated with AKI. In a logistic regression analysis, risk factor to AKI was septic shock (RR; 1.7-117; *p*=0.013). Other results are shown in Table

Conclusions: Inflammatory markers (d-Dimer and procalcitonin) were associated with the development and severity of AKI but only septic shock was predictive of the development of AKI

Comparison of socio-demographic in patients with SARS CoV-2 and AKI

	AKI=80	No AKI=120	p

Impact of COVID-19-Associated AKI on Subsequent Development of CKD

Muner Mohamed,[1] Ashraf Dwal,[1] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]The University of Queensland Ochsner Clinical School, Herston, QLD, Australia.*

Background: There is paucity of data about post-hospital discharge kidney-related outcomes in individuals with COVID-19-associated acute kidney injury (CoV-AKI) during the pandemic. We hypothesized that patients who survive a hospital admission due to COVID-19 and AKI are at risk for acquiring residual chronic kidney disease (CKD) thereafter.

Methods: We conducted a retrospective observational study examining records of patients hospitalized at Ochsner Medical Center over a 3-month period (March-May 2020) with COVID-19 and diagnosis of AKI by KDIGO. We examined the rate of full recovery of AKI (serum creatinine value back to within 10% of baseline or < 1.2 mg/dL) at 9 months post-hospital discharge. Factors associated with recovery were assessed.

Results: Among 916 admissions due to COVID-19 within the study [220 (24%) to an intensive care unit], there were 226 (26%) cases of AKI, 98 of them (43%) with AKI-requiring dialysis (AKI-RRT). Patients with CoV-AKI had a median age of 67 (34-99) and 58% were men. Self-identified black race accounted for 65% of the cohort. Among those with CoV-AKI, there were 111 in-hospital deaths (49%). Of 115 patients with CoV-AKI who were discharged alive, 9-month follow-up data were retrieved in 97 (missing data in 18). Full recovery of kidney function was achieved by 76 (78%). Among those who progressed to residual CKD, 11 (11%) patients were declared to have end-stage kidney disease (ESKD) requiring dialysis. Baseline CKD stages 3-5 was associated with lower rate of full renal recovery [23/76 (30%) vs. 14/23 (61%); RR: 2.01, p=0.004)].

Conclusions: Full recovery from CoV-AKI was observed in ¾ of those who remain alive post-hospital discharge. About 1/10th of patients with CoV-AKI reached ESKD at intermediate-term follow-up. Preexisting CKD is associated with lower rate of recovery in CoV-AKI. These data do not seem to suggest that CoV-AKI is associated with greater risk for development of CKD compared to other forms of in-hospital AKI.

PO0023

Predictors of Recovery of Kidney Function Following AKI During Hospitalization for COVID-19

Sahitya Allam,[1] Bennett W. Wisner,[2] Abhijit Ravindran,[2] Kambiz Kalantari.[3] *[1]University of Maryland Medical System, Baltimore, MD; [2]University of Virginia School of Medicine, Charlottesville, VA; [3]University of Virginia, Charlottesville, VA.*

Background: Studies have shown that COVID-19 hospitalization is associated with severe AKI. However, determinants of kidney function recovery for these patients are not well studied.

Methods: We conducted a retrospective analysis of patients admitted to our institution from March 2020 to April 2021 with diagnoses of COVID-19 and AKI. Recovery of kidney function was defined as a discharge creatinine less than 0.3 mg/dL above baseline. Data on patients' demographics, comorbidities, AKI stage, ICU admission, and laboratory values were collected by chart review. Univariate analysis and a multivariate logistic regression model were used to identify factors associated with kidney recovery.

Results: Of 216 patients, the average age was 66.3 years and 56.0% were men. 62% of patients had recovery of kidney function by discharge. Univariate analysis identified congestive heart failure (CHF, p = 0.063), AKI-D (p < 0.001), AKI stage (p < 0.001), ICU admission (p < 0.001), and lower albumin (p = 0.040) as correlates of non-recovery at discharge. In the multivariate logistic regression model [(AUC: 0.732, 95% CI (0.664-0.800)], CHF (p = 0.010), AKI-2 (p = 0.011), AKI-3 (p = 0.001), and ICU admission (p = 0.006) remained associated with non-recovery (Table 1). Follow-up data, at a median of 64 days post-discharge, was available for 61% of the cohort (n = 131). Of these patients, 14% had new recovery after discharge, while 18% had no improvement compared to discharge. At 60 days post-discharge, 8.4% had new CKD. At discharge, 3% of all patients were dialysis dependent. Baseline CKD (p = 0.030) and CHF (p = 0.037) were associated with non-recovery at 60 days post-discharge.

Conclusions: History of CHF, severity of AKI, and ICU admission are predictors of non-recovery of kidney function in patients with COVID-19 and AKI.

Recovery from AKI Requiring Kidney Replacement Therapy in Critically Ill Patients with COVID-19

Caroline M. Hsu,[1] Shruti Gupta,[2] Hocine Tighiouart,[1] Nitender Goyal,[1] Anthony J. Faugno,[1] Asma Tariq,[1] David E. Leaf,[2] Daniel E. Weiner.[1] *[1]Tufts Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Acute kidney injury (AKI) requiring kidney replacement therapy (KRT) occurs in as many as one in five critically ill patients with COVID-19. Expanding on previous work by this group, we examined the association of clinical factors at the time of KRT initiation with the outcome of kidney recovery at hospital discharge, accounting for the competing outcome of death.

Methods: We used data from the Study of the Treatment and Outcomes in Critically Ill Patients with COVID-19 (STOP-COVID), a multicenter cohort study that enrolled adults with COVID-19 admitted to ICUs at 68 hospitals across the US from March 4 to June 22, 2020. Among those who acutely required KRT, the outcome of kidney non-recovery (continued dialysis dependence at hospital discharge) was explored with multinomial logistic regression, with kidney recovery (independence from dialysis at discharge) as the reference outcome and death as an alternate outcome. Exposures of interest included demographics, baseline medical status, and markers of illness acuity at the time of KRT initiation.

Results: Of 876 patients with AKI-KRT, 588 (67%) died, 95 (11%) survived to discharge and remained dependent on KRT, and 193 (22%) survived to discharge without KRT dependence. Patients with lower baseline eGFR had greater odds of kidney non-recovery, with OR 8.58 (95% CI: 3.03-24.28) among patients with eGFR ≤15 vs >60. Reduced urine output on the day of KRT initiation was also associated with kidney non-recovery, with OR 4.23 (95% CI: 1.61-11.15) for urine output <50 mL/day vs >500 mL/day (**Figure**).

Conclusions: Among critically ill patients with COVID-19 with AKI requiring KRT, lower baseline kidney function and reduced urine output at the time of KRT initiation are associated with kidney non-recovery.

Critically Ill Patients with COVID-19 and AKI: Clinical Characteristics and Outcomes

Christopher E. El Mouhayyar,[1,2] Jonathan Dewald,[1,2] Jose Cabrales,[1] Hocine Tighiouart,[3,4] Andrew H. Moraco,[1,2] Bertrand L. Jaber,[1,2] Vaidyanathapuram Balakrishnan.[1,2] *[1]Saint Elizabeth's Medical Center, Brighton, MA; [2]Tufts University School of Medicine, Boston, MA; [3]Tufts Medical Center, Boston, MA; [4]Tufts University, Medford, MA.*

Background: Acute kidney injury (AKI) is a well-recognized complication of COVID-19. In this retrospective cohort study, we describe the clinical characteristics and outcomes of patients with severe COVID-19 in 8 intensive care units (ICUs) during the first wave of the pandemic.

Methods: Demographic, clinical, laboratory characteristics, and outcome data, including need for renal replacement therapy (RRT), mechanical ventilation, mortality, and RRT dependence at discharge and at 3 and 6 months, were extracted from the electronic medical record (EMR) between March and July 2020. Using nadir-to-peak serum creatinine, AKI and its stages were defined by the KDIGO consensus. Group comparisons were performed using ANOVA and chi square tests.

Results: After excluding 20 patients with end-stage kidney failure, 479 patients with severe COVID-19 were included. Table 1 displays the characteristics and outcomes of the cohort stratified by AKI. 409 (89.2%) patients developed AKI, with 194 (42.3%) developing stage-3 AKI. Male gender, white race, obesity, and COPD were associated with higher stages of AKI severity. 83 patients (18.1%) required RRT of which 27 (32.5%) survived, and 12 (44.4%) remained dialysis-dependent at hospital discharge. Follow up at 3-months and 6-months indicated dialysis dependence in 5 (45.5%) and 4 (36.4%) of 11 patients (1 died), respectively.

Conclusions: AKI is highly prevalent in our cohort and peak serum creatinine occurs within 3 days of intubation. Long-term dialysis dependence is of concern and merits further study. Multivariable analyses are under way to identify factors that are associated with severe AKI, need for RRT and in-hospital death.

Increased Markers of Disease Severity in COVID-19 Patients with Hospital-Acquired vs. Community-Acquired AKI

Shashank Kailash,[1] Jose E. Navarrete,[2] Darya Hosein,[2] Frederic F. Rahbari-Oskoui,[1] Harold A. Franch.[1] Emory Renal COVID-19 Project *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University, Atlanta, GA.*

Background: The etiology of AKI in COVID-19 correlates strongly with age, comorbidities, and laboratory markers of disease severity. Outpatients with COVID-19 have different exposures that may cause AKI than hospitalized patients; thus, the etiology of AKI occurring before hospitalization [community-acquired AKI (CA)] may differ from those with hospital-acquired AKI (HA).

Methods: Excluding ESKD and hospital transfers, all COVID-19 PCR-confirmed cases admitted to 4 hospitals from 3/01/20 to 5/31/20 had data collected electronically through 7/31/20 including readmissions. Baseline C-EPI eGFR was determined by chart review for the period of 6 months prior to 5 months post-admission. AKI and recovery from AKI were scored using KDIGO staging. CA was defined as AKI with the highest level of creatinine (Cr) on admission, rising Cr on admission, or RRT started within 48 hours of admission without a subsequent AKI event after recovery. All AKI occurring > 48 hours was considered HA. To test which laboratory values correlated with CA or HA, we used a model adjusted for demographics, BMI, Elixhauser comorbidity index (ECI), and CKD stage.

Results: The table shows patients with HA and CA had similar demographics with only the ECI differing significantly. CA had less severe AKI, improved recovery to baseline, and lower mortality than HA. The lower mortality in CA was directly related to the lower stage of AKI. Within a given stage of AKI, mortality was not different between CA and HA. Recovery of renal function was significantly better in CA stage 1 vs. HA (8% vs. 26%, $p = 0.001$) but was not different for stage 2 or 3. In an adjusted model, higher

maximum dimers, ALT, AST, Bili, BNP, lactic acid, CRP, ferritin, LDH, neutrophils, troponin and lower minimum lymphocyte count were significantly associated with HA compared with CA. In contrast, on admission, only higher BNP, higher CRP, lower CPK and higher total CO_2 were associated with HA versus CA.

Conclusions: Compared to patients with CA, patients with HA had higher stages of AKI that correlated with higher mortality. They also had worsened recovery from stage 1 AKI and increased markers of COVID severity (except for CPK) in-hospital and on admission. We propose that factors other than COVID-19 disease severity led to CA, with volume and rhabdomyolysis as possible contributors.

PO0027

Hospital-Acquired AKI in COVID-19 Has a Similar Prognosis with or Without Prior Community-Acquired AKI

Kristy Linder,[1,2] Jose E. Navarrete,[1] Darya Hosein,[1] Frederic F. Rahbari-Oskoui,[1] Harold A. Franch.[1,2] Emory Renal COVID-19 Project *[1]Emory University, Atlanta, GA; [2]VA Medical Center Atlanta, Decatur, GA.*

Background: Recent meta-analyses suggest that Hospital Acquired AKI (HA) has a worse prognosis than Community Acquired AKI (CA). The effect of prior CA on HA in COVID-19 is largely unknown. COVID-19 case series that use lowest hospital creatinine (Cr) rather than outpatient baseline Cr may underestimate CA incidence.

Methods: Excluding ESKD and hospital transfers, COVID-19 PCR confirmed cases admitted to 4 hospitals between 3/01/20 & 5/31/20 had data collected through 7/31/20 including readmissions. Baseline Cr was adjudicated by manual review from 6 months prior until 5 months post admission. AKI and renal recovery were scored using KDIGO staging. CA is AKI with the highest Cr on admission, rising Cr from admission, or RRT in 48 hrs of admission. HA is AKIs occurring after >48 hrs. HA with CA (HA+CA) is AKI occurring in CA patients after renal recovery for > 48 hrs.

Results: AKI was present in 402 of 706 patients with COVID-19. HA+CA occurred in 63. Patients with HA+CA were older, had more comorbidities, lower eGFR, and lower admission albumin than patients with HA. Laboratory markers of COVID severity were similar in patients with HA or HA+CA and much worse than CA. Outcomes, including stage of AKI, renal recovery, ICU parameters, and mortality were similar in HA and HA+CA and much better in CA.

Conclusions: In COVID-19, HA + CA occurs in older patients with more comorbidities than HA but shares similar adverse disease markers and poor outcomes. We hypothesize that among older patients who recover from CA, those with severe disease markers are at risk for HA+CA.

Temporal Patterns in Incidence of AKI Associated with COVID-19 Using the National COVID Cohort Collaborative (N3C) Database

Farrukh M. Koraishy,[1] Siao Sun,[2] Chetan Potu,[2] Feifan Liu,[7] David H. Ellison,[4] Yongqun O. He,[3] Soko Setoguchi,[6] Rajiv Saran,[3] J. Brian Byrd,[3] Joel H. Saltz,[2] Sandeep K. Mallipattu,[1] Chirag R. Parikh.[5] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Stony Brook University, Stony Brook, NY; [3]University of Michigan, Ann Arbor, MI; [4]Oregon Health & Science University, Portland, OR; [5]Johns Hopkins University, Baltimore, MD; [6]Rutgers The State University of New Jersey, New Brunswick, NJ; [7]University of Massachusetts Medical School, Worcester, MA.*

Background: Acute kidney injury (AKI) is a common complication of patients hospitalized with coronavirus disease 2019 (COVID-19), however, the epidemiological studies are limited by single or few centers and short duration. How the incidence of COVID-19-associated AKI has changed over the last 18 months since start of the pandemic is not known.

Methods: We used the N3C enclave to collect data from 42 centers from all geographical regions of the United States of patients hospitalized with COVID-19 from December 2019 to May 2021. Unique patient visit occurrence ID data across various hospitalizations for each center was harmonized to uniformly collect information on serum creatinine (SCr), acute dialysis, end-stage kidney disease (ESKD) and transplantation. From a total of 127,223 patients hospitalized with COVID-19, 3,662 patients with pre-existing ESKD and 20,090 with < 2 measures of SCr were excluded. AKI and AKI stages were defined by KDIGO criteria. Baseline SCr was defined from the outpatient values before hospitalization when available or lowest inpatient value if not available. We analyzed how the incidence of in-hospital AKI changed over time (every 4-month period). Mann-Kendall Test was used to test for monotonic trends of the AKI incidence.

Results: Of the 103,471 patients hospitalized with COVID-19, 31,634 (30.6%) were diagnosed with AKI (mean age 63.3 years, 43.7% female, 32.4% non-white, and 19.5% Hispanic). 14,129 (13.7%) patients were diagnosed with AKI-1, 7,996 (7.7%) had AKI-2 and 9,509 (9.2%) patients had AKI-3 (6,285 [6.1%] without dialysis and 3,224 [3.1%] with dialysis). The incidence of 'all AKI' decreased from 38.8% in Dec 2019-March 2020 to 26.2% in March-May 2021 (p-value for trend = 0.086) and the incidence of AKI-3 declined from 15.5% to 6.5% (p = 0.086).

Conclusions: This is the largest and most nationally representative cohort of patients hospitalized with COVID-19 with the highest number of cases of AKI and of AKI-3 reported thus far. The incidence of COVID-19-associated AKI has shown a non-statistically significant decline during the past 18 months of the pandemic.

PO0029

AKI Prediction and Recovery in Hospitalized Patients with COVID-19

Meredith C. McAdams, Mauricio Ostrosky-Frid, Michael M. Li, Pin Xu, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: AKI is a complication in patients hospitalized with COVID-19 and is associated with poor outcomes. We aimed to develop predictive models for AKI development and recovery in patients hospitalized with COVID-19.

Methods: Patients with a positive SARS-CoV2 PCR admitted to 19 Texas hospitals from 3/13/2020-1/1/2021 were included. AKI presence and stages were determined using KDIGO guidelines. Individuals with AKI present on admission (POA) were excluded for predictive models. Patients were followed for 90 days to evaluate for renal recovery (serum creatinine ≤1.1 times baseline). Nested models for AKI were built using logistic regression: Model 1 included age, sex, race, smoking status, presence of hypertension (HTN), diabetes (DM), chronic kidney disease (CKD), coronary artery disease (CAD), and chronic heart failure (CHF), and use of ACEI/ARB; Model 2, added admission WBC, hs-CRP, and hemoglobin; Model 3, added ferritin and D-Dimer to Model 2 to assess for accuracy improvements. 10-fold stratified cross validation was done to evaluate model performance.

Results: Of 8392 patients, 2702 (32%) had AKI, of which 2281 (84%) recovered by 90 days: 92% of stage 1, 75% of stage 2, and 40% of stage 3 AKI, p for trend <0.001. After excluding AKI present on admission, 776 of 5671 developed AKI during the hospitalization. Percentages of AKI stages 1, 2 and 3 were 67%, 8%, and 25%. Overall, 152 (20%) of 776 required RRT. Patients with AKI were older, more likely to be male, black, and have hypertension, diabetes, coronary artery disease, congestive heart failure, and CKD. The interval improvement of each AKI predictive model was statistically significant, with last model AUC of 78.1 (95% CI 76.3%-79.9%) and all p<0.001. The final model had improvement in all metrics when compared to Models 1 and 2, with a sensitivity of 69%, specificity 76%, positive predictive value 32%, negative predictive value 94%, positive likelihood ratio 3.02, and negative likelihood ratio 0.40.

Conclusions: AKI is common among patients hospitalized with COVID-19, but a large proportion recover renal function by 90 days. Recovery rate is lower based on stepwise higher stages of AKI. Addition of inflammatory biomarkers to demographics and medical comorbidities can improve prediction of AKI in this patient population.

PO0030

Clinical Characteristics and Outcomes of COVID-19 Patients with AKI at Community-Based Hospital

Mariam Charkviani, Alisha Sharma, Kritika Yadav, Angkawipa Trongtorsak, Ekta Shrestha, Clio Musurakis, Amrit Devkota, Solab Chitrakar, Mina Sous, Shanmugha Vigneshwar Padmanabhan, Ki Seok Won, Emre C. Ozcekirdek, Ece Ozen, Drashti N. Antala, Elise Hyser. *AMITA Health Saint Francis Hospital Evanston, Evanston, IL.*

Background: The disease caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and later called Covid-19 has resulted in significant morbidity worldwide. The virus can cause various complications and affect many organ systems. Preliminary reports have shown that Acute Kidney Injury (AKI) is common in patients with Covid-19, however, outcomes of kidney injury in hospitalized patients, especially at the community-based hospitals are not well described. The aim of this study was to describe the incidence, severity, and outcomes of Covid-19 patients with AKI at the community-based hospital.

Methods: This was a single-center, retrospective observational cohort study. All patients (age ≥18) with positive by polymerase chain reaction testing for Covid-19 who required hospitalization were included in the study. Patients with End-Stage Kidney Disease and kidney transplants were excluded. We compared outcomes of patients with and without AKI. We used univariable and multivariable Cox regression model to evaluate the relationship between AKI and in-hospital mortality.

Results: 220 patients were included in the study. 89 (40%) patients developed AKI, of whom 6 (7%) required Kidney replacement therapy (KRT) and 131 (60%) did not develop AKI. In-hospital mortality of patients with AKI was markedly higher than patients without AKI. Among the patients with AKI, 39 (43.8%) experienced in-hospital death while in patients without AKI, 23 (17.5%) died (P<0.001). Unadjusted HR was 2.01 (CI 1.23-3.14; P<0.001). The risk of in-hospital death remained significantly high following adjustment for baseline demographics and comorbidities with adjusted HR 1.8 (CI 1.50-2.74, P=0.015). The median hospital length of stay of patients who were discharged alive differed based upon AKI status. Patients with AKI-KRT had the longest median length of stay (15.5 days IQR 8.5-23.7), followed by patients with AKI non-KRT (7 days, IRQ 5-14) and patients without AKI (6 days, IQR 4-10).

Conclusions: AKI is a common condition among patients hospitalized with Covid-19 and is associated with an increased risk of in-hospital mortality. It is important to consider this complication in the management of Covid-19 patients.

PO0031

Risk Factors for AKI and Mortality in COVID-19 in Western Mexico

Alejandro Garcia Rivera, Ríos C. Katia yuritzi, Arantxa K. Aguilar, Luz Yareli Villegas Gutierrez, Marcos A. Elias Lopez, Jesús A. Rico sánchez, Mónica L. Morales Guillén, Mauro G. Montemayor Villacobos, Roxana Villanueva Macedo, Hugo B. Espinoza, Ramon A. Soto Rodriguez, José J. Gutiérrez Hernandez, Omar H. Sanchez Vazquez, Jorge fernando Topete reyes, Renato Parra Michel, Rubén Lara Monterrubio, Mario Valdez Avendaño, Fabiola V. Rios Rios, Carolina R. Alvarez. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Especialidad en Nefrologia, Hospital General Regional No. 46 del IMSS, Guadalajara, Mexico.*

Background: Acute kidney injury (AKI) in COVID-19 is associated with disease severity. The aim of this study was to identify risk factors associated with the development of AKI and its clinical impact, such as need for RRT and mortality.

Methods: Retrospective cohort study of hospitalized adult patients COVID-19, with normal kidney function, from April to December 2020 in Western Mexico.

Results: 882 patients (60.8% men) with a mean age of 58.9y were included. 342 (38.8%) had a prior diagnosis DM, 412 (46.7%) HTN, 161 (18.3%) obesity, 59 (6.7%) heart diseases, 25 (2.8%) neurological disease, 47 (5.3%) lung disease. 216 (24.5%) smoking history. 270 patients (30.6%) developed AKI, 95 (10.77%) KDIGO stage 1, 44 (4.98%) stage 2, and 84 (9.52%) stage 3. 59 patients required RRT (6.23%), and 111 patients (12.6%) mechanical ventilation. Overall mortality was 30.6% (270 patients). Risk factors for mortality were: DM, HTN, neurological disease, age > 65 y, need for MV, and MAP < 65 mmHg, hyperNa, increased D-dimer or decreased HCO3 at admission. Risk factors for AKI were: DM, HTN, heart disease, age > 65 y, need for MV, and MAP < 65 mmHg, hyperNa, increased D-dimer or decreased HCO3 at admission. Image shows risk factors, ORs with CI.

Conclusions: A high incidence of AKI in the Mexican population compared to reports from other countries, with a significantly high risk for death.

PO0032

Follow-Up Study of Survivors of Stage 2 or 3 In-Hospital AKI with or Without COVID-19

Farrukh M. Koraishy, Imran Chaudhri, Kiran Munir, Euclid J. St Hill. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Acute kidney injury (AKI) is a hallmark of hospitalized patients with Coronavirus Disease 2019 (COVID-19) and associated with in-hospital mortality. Recent data suggests glomerular filtration rate (GFR) continues to decline after discharge in COVID-19 AKI survivors, but there are very few reports describing the long-term post-discharge outcomes.

Methods: This is an ongoing prospective study of 161 survivors of KDIGO stage 2 or 3 AKI who were admitted at Stony Brook Medicine (SBM) for COVID-19 between March-June 2020. 'CKD' was defined as patient's final outpatient serum creatinine (SCr) value remaining >10% or 50% above baseline (defined as the lowest SCr during hospitalization) and final GFR < 60 ml/min/1.73m^2. CKD was divided into 'incident' and 'progressive' based on baseline CKD status. We also investigated the readmission rate with and without AKI and post-discharge mortality. A comparison cohort of 66 AKI survivors concurrently admitted to SBM who tested negative for COVID-19 were also analyzed for all outcomes.

Results: COVID-19 AKI survivors were more likely to be non-White, Hispanic, have a lower prevalence of baseline CKD and greater severity of illness (mechanical ventilation, acute respiratory distress syndrome, vasopressor use and greater length of hospital stay) during hospitalization compared to COVID-19 negative survivors ($p \leq 0.01$). COVID-19 negative AKI survivors were more likely to have re-hospitalization ($p = 0.03$), although no difference was noted in re-hospitalization with AKI among the 2 groups. 29 out of 161 (18%) of COVID-19 positive AKI survivors died after their discharge from COVID hospitalization as compared to only 1 out of 66 patients (1.5%) of the COVID-19 negative AKI survivors ($p<0.001$). 42 (26.1%) of COVID-19 positive and 17 (25.8%) of the COVID-19 negative patients had a SCr and eGFR measure > 90 days after discharge. COVID-19 positive AKI survivors (11.9-19.0%) had no difference in the rate of incident or progressive CKD compared with COVID-19 negative AKI survivors (17.6%).

Conclusions: COVID-19 positive survivors of Stage 2 or 3 in-hospital AKI were more likely to have greater severity of illness during hospitalization and greater post-discharge mortality compared to COVID-19 negative AKI survivors. We did not find a difference in the rates of incident or progressive CKD at 10 months follow-up.

PO0033

Comparing COVID Acute Respiratory Distress Syndrome Patients on Extracorporeal Mechanical Oxygenation (ECMO) to Non-COVID Patients: Incidence and Effects of AKI

Kiran Shivaraj,[1] Abhinaya Sridhar,[1] Shruti Kore,[1] Demetrios Papademetriou,[2] George N. Coritsidis,[2] Savneek S. Chugh.[1] *[1]Westchester Medical Center, Valhalla, NY; [2]Elmhurst Hospital Center, Queens, NY.*

Background: AKI has historically plagued those with ARDS and during the pandemic especially so with large resultant mortality rates. During the past year those centers so equipped offered ECMO to treat severe COVID pneumonia. We compared the

non COVID ARDS requiring ECMO with patients with COVID pneumonia requiring ECMO. The aim of the study was to understand the difference in the renal outcomes and its effects of mortality and thereby help in prognostication.

Methods: This is a single center retrospective study where patients with COVID pneumonia needing ECMO in between March 2020 to April 2021 were compared with non COVID ARDS patients needing ECMO between April 2013 to April 2021. The 2 groups were compared and risk ratio calculated for the incidence of AKI, the need for Renal replacement therapy (RRT) and the mortality associated with it.

Results: After excluding the patients who did not meet the criteria, 26 COVID patients treated with ECMO were compared with 22 patients with non COVID ARDS treated with ECMO. The median age of COVID group was higher (48 years vs 36 years) and the median number of days needing ECMO for the COVID group was higher (13 days vs 31 days). Incidence of AKI and the AKI needing RRT were similar in the 2 groups. The overall mortality in patients with COVID pneumonia was higher. Patients with COVID who developed AKI had 1.32 times the risk of mortality, which increased to 1.62 when RRT was needed.

Conclusions: This is a first study comparing the renal outcomes of COVID ARDS requiring ECMO and non COVID ARDS requiring ECMO. Even though the median age and the median number of the days on ECMO were higher for the COVID group, surprisingly the incidence of AKI and those needing RRT were similar. But there was a significantly higher mortality when patients on ECMO developed AKI and even higher for those on RRT. This could be attributed to the cytokine storm seen with causing a multiorgan dysfunction which can manifest in the form of AKI. Presence of AKI needs to be identified early and can be used for the prognostication in COVID pneumonia.

Incidence of AKI	21/26 (80.7%)	16/22(72%)	1.12
AKI needing RRT	15/21 (71%)	11/16 (68%)	1.04
Overall Mortality	16/26 (61%)	9/22 (40%)	1.5
Mortality with AKI	12/21 (57.1%)	7/16 (43%)	1.32
Mortality on RRT	11/15 (73%)	5/11 (45%)	1.62
Median Age	48 yrs	36 yrs	
Median No. of days on ECMO	31 days	13 days	

PO0034

Rapid Deterioration or a Long Road to Recovery for COVID-19 Patients with AKI

Aruni Ratnayake,[1] Alexander Sarnowski,[1] Nicholas M. Annear,[1] Irina Chis Ster,[2] Debasish Banerjee.[1] *[1]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [2]St George's University of London, London, United Kingdom.*

Background: Global reports on the rates, risk factors and outcomes of acute kidney injury (AKI) with COVID-19 exhibit high variability. We evaluated all patients admitted with AKI to our centre where COVID-19 status was determined by PCR, and assessed risk factors for poor outcomes including death.

Methods: Retrospective study of all patients admitted with AKI between 13/03/2020 and 13/05/2020. All variables including COVID-19 status, demographics, co-morbidities and laboratory parameters were collected from electronic patient records. We used competing risk-regression models to assess association with mortality by subdistribution hazards ratio (SHR).

Results: Of 576 patients admitted with AKI, 257 (43.6%) were positive for COVID-19. Demographics and clinical characteristics of our cohort included: mean age 66.7 years, 58% male, 40.5% Caucasian, 56.3% hypertension, 33.1% diabetes. Overall 52.5% patients had AKI stage 1, 18.6% AKI stage 2, and 28.8% AKI stage 3. Patients with AKI stage 3 were 3.4 (95% CI 2.27-5.02) times more likely to be diagnosed with COVID-19 than those with AKI stage 1. Other factors associated with an increased likelihood of COVID-19 diagnosis adjusted for AKI stage were young age (p=0.004), non-Caucasian ethnicity (p=0.001), low lymphocyte count (p=0.002) and raised CRP, ferritin and D-dimer (p=0.001). Case fatality percentage of this cohort was 32.5% (10%, 19% and 35% mortality in COVID-19 negative patients with AKI stages 1, 2 and 3 respectively, compared with 33%, 52% and 71% in the COVID-19 positive counterparts). Patients with COVID-19 were 3.6 (95% CI 2.2-4.3) times more likely to die than those negative for COVID-19 (p<0.001). Furthermore, death in patients with COVID-19 and AKI stage 3 occurred rapidly, with 50% of patients dying within 10 days, 70% within 15 days and 95% within 21 days of admission. Those in the same group who survived had prolonged recovery, with 50% remaining inpatients in hospital for over 31 days.

Conclusions: In patients with AKI, those who were positive for COVID-19 was associated with severe AKI, younger age, non-Caucasian ethnicity, raised inflammatory markers, and suffered from high case fatality. Severity of AKI in conjunction with COVID-19 was associated with high and rapid death rates, or prolonged hospital admission with increased morbidity.

PO0035

Association of Endotoxemia with AKI in Critically Ill Patients with SARS-CoV-2 Infection

Sobia N. Khan,[1] Olena Bolotova,[1] Chris R. Gordon,[1] Sandeep K. Mallipattu.[1,2] *[1]Stony Brook University, Stony Brook, NY; [2]North Port VA Medical Center, North Port, NY.*

Background: AKI is frequently complicated by sepsis. Endotoxin (lipopolysaccharide), a component of the outer wall of gram-negative bacteria, has been investigated and acknowledged as one of the triggers of lethal shock during sepsis and drivers of cytokine storm. In studies, septic shock was present in 6.4% patients with severe COVID-19, but blood cultures and respiratory cultures were negative in 76%. Initial cohort study of COVID-19 patients from China showed 4.5% developed AKI, subsequent reports showed higher prevalence. While these data suggest that patients with COVID-19 are at risk for septic shock and AKI, mechanisms mediating these processes in the setting of severe coronavirus 2 (SARS-CoV-2) infection remain unclear.

Methods: We conducted a single-center, cross-sectional study in critically ill patients with COVID-19 to test the prevalence of endotoxemia and whether endotoxemia is associated with the development of AKI. Patients were recruited using criteria: Age ≥ 18yr, MODS ≥ 9, sepsis and intensive care unit admission, excluded if pregnant, requiring chronic dialysis or chronic immunosuppressive medications. Blood endotoxin activity (EA) measured in patients who met the criteria using the FDA-approved Endotoxin Activity Assay (EAA). EAA is a chemiluminescent bio-assay based on the oxidative burst reaction of activated neutrophils to complement coated LPS-IgM immune complexes. Patients divided into low (0.0 – 0.39 EA units), intermediate (0.40 – 0.59 EA units), high (≥ 0.60 EA units), and non-responder (NR) (patients whose neutrophils do not have the ability to respond to preformed immune complexes in the EAA) group based on measurements from the EAA.

Results: In this study, endotoxemia observed in 24/32 (75%) of our critically ill patients with COVID-19, despite only 2 patients having positive blood cultures for gram-negative organisms. The incidence of AKI was higher in the high EA group (7/14, 50%) as compared to intermediate EA group (1/10, 10%), p=0.01. The need for renal replacement therapy (RRT) was higher in the elevated EA group (4/14, 29%), with none of the patients in the intermediate group requiring RRT, p=0.008.

Conclusions: This study demonstrates the high prevalence of endotoxemia in critically ill patients with COVID-19, regardless of presence of bacteremia. We also observed that high EA was associated with AKI and the need for RRT.

PO0036

AKI in Extracorporeal Support

Santosh Subramanyam, Tammy Marshall, Enrique Gongora, Keith M. Wille, Ashita J. Tolwani. *UAB Hospital, Birmingham, AL.*

Background: Acute kidney injury (AKI) is common in critically ill patients receiving extracorporeal membrane oxygenation (ECMO). Use of continuous renal replacement therapy (CRRT) with ECMO may help optimize fluid balance and correct electrolyte abnormalities but may also worsen outcomes. The relationship between AKI, CRRT, and survival in ECMO patients remains poorly defined. The aim of this study was to evaluate AKI outcomes in the setting of ECMO support. We assessed factors that may influence AKI severity, as well as the safety of combined CRRT with ECMO

Methods: We performed a retrospective analysis of patients that received ECMO from 2018-2021 at a tertiary hospital, using a prospectively maintained database. All patients requiring CRRT received continuous veno-venous hemodiafiltration (CVVHDF). Data collected includes demographics, ECMO and CRRT parameters, anticoagulation, baseline kidney disease, baseline serum creatinine (sCr), ECMO and CRRT duration, hospital length of stay (LOS), complications (patient and device-related), and outcomes.

Results: To date, 16 ECMO patients with AKI have been analyzed. Mean age was 46.6 +/- 15.6 years. Eleven (68%) were male, and 50% were African American. ECMO indication included respiratory failure due to COVID-19 (43%), followed by respiratory failure from sepsis (19%). Initial ECMO modality was VV- in 75% and VA- in 25%. Mean baseline sCr and sCr at CRRT initiation were 1.3+/-1 mg/dL and 3.93+/-1.1 mg/dL, respectively. Mean ECMO duration was 30+/-37 days, and mean CRRT duration was 26+/–21 days. Elevated plasma hemoglobin (mean peak 103 mg/dL) levels occurred in 14 (88%) patients. Of 10 (63%) patient surviving to discharge, 3 (30%) were dialysis dependent. sCr at CRRT start did not influence CRRT duration: for sCr<4 mg/dL, mean CRRT duration was 37 days, and for sCr>4 mg/dL, mean CRRT duration was 20 days (p=0.21). Mean creatinine at discharge was 1.78+/-1.1 mg/dL.

Conclusions: Our results suggest that CRRT can be safely combined with ECMO to achieve satisfactory patient outcomes. Dialysis independence seems attainable in most patients; however, additional patient enrollment is underway to support this concept with a greater degree of confidence.

PO0037

RAAS Inhibition and Risk of AKI in COVID-19

Bethany Birkelo,[1] Amy Perkins,[2,1] Robert Greevy,[1,2] Sharidan Parr,[1,2] Adriana Hung,[1,2] Juan Pablo Arroyo Ornelas,[1] Michael E. Matheny,[1,2] Edward D. Siew.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Direct viral invasion of the kidney via ACE2 has been hypothesized as a mechanism of AKI in COVID-19 (COVID). The impact of RAASi on the risk of AKI in COVID is not known. We hypothesized that active use of RAASi preceding admission would be associated with a greater proportional risk of AKI in COVID than influenza (flu).

Methods: In this retrospective cohort, we compared the AKI incidence by RAASi status in 11,898 hospitalized Veterans with COVID or flu between Oct 1, 2019 and Sept 30, 2020. To control for confounding, propensity score weighting balanced baseline conditions, labs, and co-therapies in 4 exposure groups: RAASi users with COVID, non-users with COVID, RAASi users with flu, and non-users with flu. Weighted logistic regression estimated the main effects of RAASi and COVID, and their interaction.

Results: In flu, 7% of RAASi users had a stage 2-3 AKI vs 5% of non-users, a 2% increase (p=0.03). In COVID, 16% of RAASi users had a stage 2-3 AKI vs 12% of non-users, a 4% increase. While the absolute increase in AKI incidence for RAASi users vs non-users was greater in COVID patients vs flu, the difference was not statistically significant (p=0.66) and the RAASi association was proportionally smaller in COVID (see interaction in Table). Similar absolute differences were observed in stage 1-3 AKI (Table), and the interaction was also not statistically significant (p=0.66).

Conclusions: COVID was associated with a greater incidence of AKI than flu. RAASi was associated with an increased incidence of Stage 2-3 AKI in patients with COVID or flu. The proportional effect of RAASi was similar in COVID and flu patients. These findings do not support a disproportionate risk of AKI among RAASi users with COVID.

Funding: Veterans Affairs Support

AKI Incidence Rates and Odds Ratios in COVID and Flu by RAASi Status

	Stage 1-3 AKI	Stage 2-3 AKI
IR: No RAASi | Flu	25%	5%
IR: RAASi | Flu	28%	7%
IR: No RAASi | COVID	31%	12%
IR: RAASi | COVID	35%	16%
OR: COVID vs Flu | No RAASi	1.33 (1.12-1.58)	2.72 (1.89-3.92)
OR: RAASi vs No RAASi | Flu	1.16 (0.95-1.42)	1.60 (1.04-2.46)
OR: COVID by RAASi Interaction	1.06 (0.83 - 1.35)	0.90 (0.56-1.45)

IR: Incidence Rate, OR: Odds Ratio.

Rates and Stage 1-3 ORs are based on the entire weighted cohort. Stage 2-3 ORs are in the subset of Stage 2-3 and no AKI patients.

Dexamethasone Reduces AKI in Critical COVID-19 Patients

Noemi Del Toro-Cisneros, Juan M. Mejia, Adrián Esteban Caballero-Islas, Armando Jezael Martinez-Rueda, John Hernandez Flores, Jefferson A. Proaño Zamudio, Victor M. Sacoto, Megan Ashley N. Gerrard, Roque A. Comunidad Bonilla, Ricardo Correa-Rotter, Olynka Vega. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico.*

Background: More than 50% of severe COVID-19 patients develop acute kidney injury (AKI) and a high percentage of them will require renal replacement therapy (RRT). The aims of this study were to identify AKI prevalence and associated factors in patients with COVID-19 and invasive mechanical ventilation (IMV).

Methods: Prospective cohort analysis of all COVID-19 patients with IMV, admitted to our Institute in Mexico City (Mar 2020 - Jan 2021). AKI was defined according to KDIGO guidelines. Patients with CKD stages 4 or 5 were excluded. Demographic, clinical, laboratory, and treatment variables were registered. AKI development was analyzed by uni- and multivariate logistic regression, mortality by survival analysis.

Results: Of 552 COVID-19 patients, AKI was detected in 196 (35.5%). Among AKI; 80 (40.8%) were Stage 2, and 116 (59.2%) Stage 3. The incidence of each AKI stage was lower in patients treated with dexamethasone (DEXA, Fig. 1A) and decreased the requirement of RRT (30 vs 16, p=0.05). For the multivariate analysis, AKI was grouped into no AKI/Stage1 and Stage 2/3 AKI; DEXA treatment was associated with less AKI incidence (OR 0.34, 95%CI 0.23-0.51) and lower mortality in the adjusted Cox-regression analysis (Fig. 1B).

Conclusions: AKI is associated with increased mortality in COVID-19 patients with IMV. The use of DEXA is associated with lower AKI severity and lower mortality.

Table 1: Characteristics and in-hospital outcomes for AKI vs no AKI.

	All (N=552)	No-AKI (N=356)	AKI (N=196)	P value

PO0039

Volume Balance and AKI in Critically Ill Patients with SARS-CoV-2

Samantha Gunning, Ashley La, Anthony Hung, Daniel S. Rubin, Jay L. Koyner. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Evidence from the management of critically ill patients suggests restrictive volume management strategies and avoidance of volume overload improve ICU outcomes. Restrictive practices have been applied to the management of patients with SARS-CoV-2 (COVID-19), but data describing volume management and its associated outcomes in those with and without acute kidney injury (AKI) in this setting are lacking.

Methods: We conducted a single-center retrospective cohort study of ICU patients with COVID-19. 7-day cumulative volume balance from ICU admission in excess of -5% (negative balance) or +5% (positive balance) of ICU admission weight as well as AKI based on KDIGO guidelines were identified. Associations between volume balance, AKI and clinical outcomes (dialysis, mechanical ventilation, and inpatient mortality) were explored.

Results: 194 of 374 ICU admissions (51.9%) had AKI with 60 of 374 (194) (16.0%, 30.9% of those with AKI) requiring dialysis. 110 of 374 (29.4%) developed negative balance and 40 of 374 (10.7%) developed positive balance. Inpatient mortality was higher in those with AKI and negative balance (28%) and positive balance (35%) compared to those with neutral balance (16%) (p=0.039). Of the subjects with negative balance (Table), despite no difference in their net volume balance, inpatient mortality was significantly higher in those with AKI compared to those without AKI (p=0.048). Using the Kaplan-Meier estimator, patients with no AKI had no difference in inpatient survival when compared on the basis of volume balance (p=0.69). However, in those with AKI, inpatient survival was significantly lower for positive and negative volume balance compared to neutral balance (p=0.01).

Conclusions: Negative and positive volume balance are associated with higher inpatient mortality particularly in patients with AKI. Future research must investigate the impact of negative balance on morbidity and mortality in patients with and without AKI.

Outcomes of ICU Patients with Negative Balance by AKI Status

	AKI (N=68)	No AKI (N=42)	p-value
Cumulative 7-Day Fluid Balance (L), Median (IQR)	-6.1 (-7.7, -4.0)	-6.1 (-7.8, -5.3)	0.30
AKI-D	25 (37%)		
Mechanical Ventilation	29 (43%)	11 (26%)	0.081
Days of Mechanical Ventilation, Mean (SD)	5.4 (3.4)	6.3 (4.1)	0.50
Mortality	19 (28%)	5 (12%)	0.048

PO0040

Urinary Findings Reveal Dominant Tubular Injury in Hospitalized Patients with COVID-19

Avital Angel-Korman,[1,2] Adi Leiba.[1,2] *[1]Samson Assuta University Hospital, Ashdod, Israel; [2]Ben Gurion University, Faculty of Health Science, Beer-Sheva, Israel.*

Background: Renal manifestations during infection with SARS-CoV-2 are prevalent and include proteinuria and hematuria as well as acute kidney injury (AKI). Possible mechanisms of renal involvement with COVID-19 are acute tubular injury (ATI) due to cytokine storm, direct virus-induced tubulopathy or glomerular injury related to podocytopathy. However, a kidney biopsy or urine studies including direct urine microscopy have rarely been performed. Our aim was to examine the urinalysis, level of

protein excretion and microscopy findings in urine collected from hospitalized COVID-19 patients in order to better elucidate the nature of COVID-19 related kidney involvement.

Methods: We collected fresh urine samples from 92 patients admitted to the COVID-19 ward at Samson Assuta University Hospital in Israel. Urine samples were collected randomly, regardless of renal function or prior medical history. Urinalysis and urine chemistry were performed in addition to direct urine microscopy analyzed by an experienced nephrologist.

Results: Urine samples were collected from 55 men and 37 women, most of whom (64%) had severe COVID-19 at the time urine samples were obtained. AKI at different levels of severity was diagnosed in 37 patients (40%). Proteinuria and hematuria were present in 43% and 38% of urinalysis samples, respectively, suggesting glomerular involvement. Urine protein to creatinine and albumin to creatinine ratios were measured in 76 patients (83%). Median urinary albumin to protein ratio (UATPR) was very low –0.16, indicating a tubular origin of the proteinuria. Direct urine microscopy was performed on 58 samples, of which granular casts were detected in 43% (25 samples) and in 5 of them granular casts were spotted without evidence of AKI. Additionally, uric acid crystals and amorphous urate were found in 19 (33%) of microscopy samples. Median urine pH was 5.5 which likely contributed to precipitation of uric acid. Notably, urine sediment clues of either nephrotic or nephritic syndrome were absent in all examinees.

Conclusions: Urinary sediment findings and a very low UATPR support ATI as the main mechanism for kidney injury in COVID-19 patients. Acidic urine and uric acid crystals may have resulted from viral related ACE2 down regulation, enhanced angiotensin II and aldosterone mediated urinary acidification. Further studies are needed to shed light on COVID-19 related kidney involvement.

PO0041

Urinary Epidermal Growth Factor as a Protector in COVID-19 Patients with AKI

David Escamilla-Illescas, Gustavo A. Casas-Aparicio. *Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico.*

Background: Acute Kidney Injury (AKI) in hospitalized patients with infection by SARS-Cov-2 (COV-AKI) is a multifactorial syndrome with immune and inflammatory responses. Knowing the cytokine profile will help to understand the pathogenesis.

Methods: Single center, prospective study at the National Institute of Respiratory Diseases (INER), Mexico. Between May-August 2020 we included patients with severe pneumonia by Sars-Cov-2. We collected urine for citokines quantification with a Human Cytokine Magnetic 30-plex panel by Luminex, TIMP-2 and IGFBP7 by ELISA and N-Gal by Architect®. Clinical and laboratory data were gathered from medical file. We evaluated for AKI defined by the 23rd ADQI consensus with [TIMP2]x[IGFBP7] >0.3. We used $\chi 2$ and Mann Whitney-U test to compare groups. We calculated the area under the curve (AUC) for EGF, determined the best accuracy cut-off point and correlated EGF with NGAL, [TIMP2]x[IGFBP7] and GFR with a Spearman-rho. We did a univariate and multivariate logistic regression.

Results: We included 51 patients with 53 years-old median age and 58.8% men. Hypertension and D-dimer were higher in the AKI group. In the urinary citokines there were differences for RANTES as risk factor and EGF as protective factor. The analysis was consistent considering all the values and taking out the outliers. The AUC for EGF was 0.788 (p=0.01, 95% CI: 0.59-0.97), with the best accuracy cutoff of 4600 pg/mL. EGF showed correlation with NGAL ρ-0.62 (**p<0.01**), [TIMP2]x[IGFBP7] ρ-0.71 (**p<0.01**) and CKD-EPI GFR ρ+0.74 (**p<0.01**). EGF shows protective effects with statistically differences in the univariate and multivariate logistic regression *(Table 1)*.

Conclusions: Patients without AKI had more expression of uEGF; this cytokine could be involved in the renal protection against the development of COV-AKI. EGF has an inverse correlation with NGAL and [TIMP2]x[IGFBP7] and a positive correlation with the GFR.

The Assessment of Bronchoalveolar Lavage (BAL) Fluid Composition in Critically Ill Patients with and Without COVID-19 and AKI

Nay Seif, Richard G. Wunderink, Anand Srivastava, Pinelopi P. Kapitsinou. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Recent reports identified enrichment of T cells and monocytes in the BAL fluid of patients with COVID-19 pneumonia, in contrast to neutrophilia in patients with non-COVID-19 pneumonia, which suggests a distinct immunopathology. We evaluated whether AKI, an independent risk factor for adverse outcomes, modifies BAL cell composition in critically ill patients.

Methods: We retrospectively analyzed BAL specimens from 710 critically ill patients undergoing evaluation for pneumonia at an academic medical center from 3/2018-11/2020. Kruskal-Wallis tests compared distributions of BAL fluid % cell counts by COVID-19 and AKI status. Multivariable linear regression models tested the associations of COVID-19 status with the BAL fluid % cell counts. We tested for effect modification by AKI status. AKI was defined by the KDIGO criteria.

Results: Mean age was 60±15 years and median baseline serum creatinine was 0.8 [0.6–1.1] mg/dl. COVID-19 was positive in 34.5% and AKI occurred in 42.8% of patients. Figure 1A shows differences in BAL fluid cell composition by COVID-19 and AKI status. Highest % of neutrophils were in COVID-19(-) AKI(-) patients and lowest in COVID-19(+) AKI(-) patients. Macrophages, monocytes, and lymphocytes were highest in COVID-19(+) AKI(-) patients and lowest in COVID-19(-) AKI(-) patients. COVID-19(+) patients had a significantly lower % of neutrophils and a higher % of monocytes and lymphocytes after multivariable adjustment (Figure 1B). Patients who were AKI(+) had decreased % of neutrophils when COVID-19(-), while the opposite effect was noted for COVID-19(+) (P for interaction=0.007).

Conclusions: AKI may differentially modify the cell BAL fluid cell composition among patients with suspected pneumonia based on their COVID-19 status.

Funding: Private Foundation Support

Figure 1A

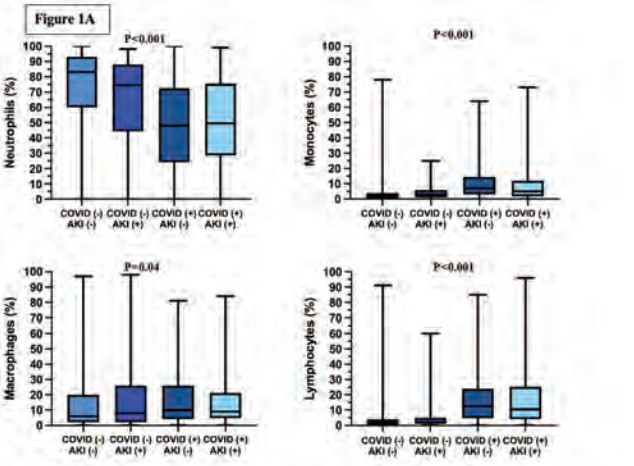

Figure 1B

BAL cell fluid composition	Beta Coefficient	95% Confidence Interval
Neutrophils	-19.4%	-24.2 – -14.8
Monocytes	5.5%	4.2 – 6.7
Lymphocytes	12.9%	10.9 – 15

Beta coefficient is for COVID-19(+) compared to COVID-19(-) after adjustment for age, sex, race, diabetes, congestive heart failure, malignancy, baseline kidney function, and AKI status

PO0043

Clinical Outcome and Antibody Response in COVID-19-Positive Pediatric Kidney and Liver Transplant Recipients

Efrat Talgam Horshi,[1] Yael Mozer Glassberg,[2,3] Orith Waisbourd-Zinman,[2,3] Liat Ashkenazi-Hoffnung,[2] Orly Haskin,[2,3] Shelly S. Levi,[2,3] Gilad Hamdani,[2,3] Daniel Landau,[2,3] Hadas Alfandary.[2,3] *[1]Assuta Ashdod Hospital, Ashdod, Israel; [2]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [3]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: The COVID-19 pandemic has profoundly impacted transplantation activity worldwide. Nevertheless, data on the clinical and laboratory features of SARS-CoV-2 infection in pediatric recipients of solid organ transplant (SOT) recipients are scarce.

Methods: We describe clinical and laboratory manifestations, including serologic response, and short-term outcomes of 25 pediatric recipients of SOT who tested positive for SARS-CoV-2 during the first nine months of the epidemic in Israel.

Results: The mean age was 15.2±4 years; 14 (56%) were kidney and 11 (44%) liver transplant recipients. Twenty-three (92%) of the patients were symptomatic. The most common symptoms were fever (44%), headache (44%), cough (40%), and fatigue (36%). Most (84%) had a mild disease. Two patients (8%), both kidney transplant recipients with additional comorbidities, had severe respiratory disease and required adjustments in their immunosuppression therapy. None were admitted to the pediatric intensive care unit or died, and all the patients fully recovered after a median of 27 [interquartile range 21-41] days. Significantly longer virus shedding time was found among kidney and pancreas transplanted recipients than among liver transplant recipients (35.1±9.8 vs.19.6±4.7 days, p=0.0005). Following a median of 7 (5-10.5) weeks after COVID-19 diagnosis, 3 (22%) reported residual symptoms, mainly fatigue; 22/23 (96%) had positive antibody responses.

Conclusions: Our study demonstrated that while the majority of pediatric recipients of SOT developed a mild disease with a positive serologic response, a relatively high percentage (8%) developed a severe disease. This emphasizes the need for close monitoring of this particular population, especially those with comorbidities.

PO0044

COVID-19 Seropositivity in New York ESKD Patients

Ranjeeta Chand, David M. Charytan, Lama Nazzal, Arnav Mishra, Mansi Mehta, Robert Holzman. NYU Grossman School of Medicine, Division of Nephrology, New york *New York University, New York, NY.*

Background: Patients on hemodialysis (HD) with COVID-19 infections have increased emergency room visits, hospitalization, and mortality. We evaluated COVID-19 seroprevalence in a dialysis organization in NYC.

Methods: We collected data on patients undergoing maintenance HD in four different units in Manhattan, New York. Data was collected regarding demographics, cause of kidney failure, time on dialysis, and insurance. Covid antibody was tested using the elecsys Anti-SARS-CoV-2 immunoassay. We performed univariate analysis using Chi square test and multivariate linear logistic regression models to identify variables associated with COVID-19 seropositivity.

Results: Seropositivity was detected in 108 (20.2%) out of the 535 patients tested. In univariate analysis, age, HD unit, race, institutionalized status, time on dialysis, and type of insurance were associated with seropositivity. In multivariate analysis race, age, time on dialysis were not associated with COVID seropositivity Patients uninsured, or those covered by medicaid, had a significantly higher likelihood of testing positive for COVID antibodies than patients covered by private insurance (OR, 8.02, P=0.05). In reference to the Chinatown unit, patients receiving treatment at the 34th Street unit (OR, 4.90, p=0.002) and the Lower Manhattan unit (OR, 3.42, p=.02) were more likely to test positive., Institutionalized patients were almost eleven times more likely to test positive for the antibodies than those not institutionalized (OR, 10.97, p<0.001). Race was not significantly associated with antibody positivity.

Conclusions: Our study showed increased prevalence of COVID-19 antibodies in Institutionalized and uninsured/Medicaid patients but no association with race suggesting socioeconomic status, is more important than race in determining the risk of COVID-19 infection in patients on maintenance dialysis.

PO0045

Prevalence and Dynamics of SARS-CoV-2 Nucleocapsid IgG in Kidney Transplant Recipients

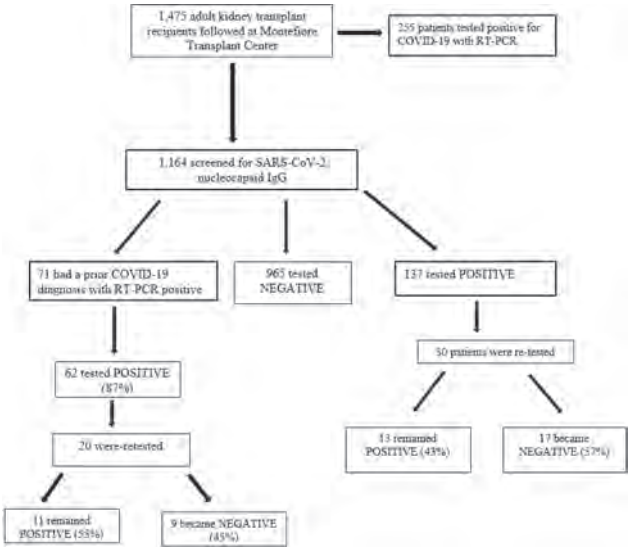
Yorg Al Azzi, Pablo Loarte Campos, Cindy T. Pynadath, Omar Alani, Harith Raees, Luz E. Liriano-Ward, Maria Ajaimy, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

Background: We aimed to investigate the prevalence and dynamics of SARS-CoV-2 IgG in kidney transplant recipients in the Bronx, New York, one of the epicenters of the pandemic

Methods: Between March 16 and May 5, 2021, 255 patients tested positive by SARS-CoV-2 RT-PCR. From May 3 to May 5, 2021, 1,164 patients were screened for SARS-CoV-2 IgG antibodies and 199 (17.1%) were tested positive (Figure).

Results: 62 of the 199 patients were previously diagnosed COVID-19 by RT-PCR, while the remaining 137 did not have significant symptoms and had not been previously tested by RT-PCR. Overall prevalence of COVID-19 diagnosis by RT-PCR and/or SARS-CoV-2 IgG in 1,348 patients tested were 29.1%. Seventy-one RT-PCR+ patients were screened for SARS-CoV-2 IgG antibody and 62 (87%) were positive at a median 106 days (81-168) A total of 50 patients of 199 who were previously tested positive for SARS-CoV-2 IgG (30 diagnosed with IgG and 20 with RT-PCR) were retested at a median time of 112 days (IQR: 81-121). Twenty-six patients (52%) became seronegative at a median time of 105 days (IQR: 84-141) from their first positive IgG. Nine of 20 (45%) patients who were diagnosed by RT-PCR became seronegative at a median time of 108 days (IQR: 81-168) from their first positive IgG while 17 of 30 (57%) patients who were initially diagnosed by a positive IgG, became seronegative at a median time of 121 days (IQR: 90-145) from the date of diagnosis.

Conclusions: In summary, 35% of kidney transplant recipients were asymptomatic or mildly symptomatic and developed SARS-CoV-2 IgG without requiring testing by RT-PCR. However, half of the patients who initially developed antibodies lose them over time raising the questions of lasting immunity against SARS-CoV-2 and how effective are those antibodies in preventing future infection.



PO0046

Kidney Outcomes in Long COVID-19

Benjamin C. Bowe,[1] Yan Xie,[1,2] Evan Xu,[1,2] Andrew K. Gibson,[1] Ziyad Al-Aly.[1,3] *[1]Veterans Health Administration, St. Louis, MO; [2]Saint Louis University, Saint Louis, MO; [3]Washington University in St Louis, St Louis, MO.*

Background: Early epidemiologic evidence has suggested that the coronavirus disease 2019 (COVID-19) increases the risk for subsequent disease even after its acute phase. We aimed to describe post-acute kidney disease sequalae of COVID-19.

Methods: In a cohort of 1726683 US Veterans identified from March 01, 2020 to March 15, 2021, we examined the risk of AKI, progression of kidney disease, ESKD, and MAKE following the acute phase of the infection (30 days) in those with COVID-19 (89216) compared to those without (1637467), using weighted survival regressions. Linear mixed models characterized intra-individual eGFR trajectory.

Results: In a cohort of US Veterans with a median follow up of 172 days (IQR: 133-281), those with COVID-19 were at a higher risk of AKI (aHR=1.94 (95%CI: 1.86-2.04)), eGFR decline ≥30% (1.29 (1.25-1.34)), eGFR decline ≥40% (1.44 (1.37-1.51)), eGFR decline ≥50% (1.62 (1.51-1.74)), ESKD (2.96 (2.49-3.51)), and MAKE (1.66 (1.58-1.74)). Compared to non-hospitalized Veterans without COVID-19, excess burden 6 months after infection was higher by severity of COVID-19 infection, including AKI (3.17, 45.21, and 74.19 per 1000 persons in those non-hospitalized, hospitalized, and admitted to ICU, respectively), eGFR decline ≥ 30% (3.01, 44.71, 72.23), and MAKE (2.01, 31.92, 79.13). COVID-19 was associated with an excess rate of decline in eGFR following the acute phase of the infection (-2.30, -7.68, -9.70 mL/min/1.73m^2/year in those non-hospitalized, hospitalized, and admitted to ICU).

Conclusions: COVID-19 is associated with increased risk of adverse kidney outcomes after the first 30 days of the infection; excess burden was higher in those with a more severe infection.

PO0047

COVID-19-Associated Kidney Injury: A Single-Center Community Experience of 684 Consecutive Patients

Dana Mueller,[1,2] Angela Pauline P. Calimag,[1,2] Anthony Guglielmi,[1,2] Caroline Youssef,[1,2] Spencer Deleveaux,[1,2] Vinay Raju,[1,2] Edgar V. Lerma.[1,2] *[1]Advocate Christ Medical Center, Oak Lawn, IL; [2]University of Illinois at Chicago, Chicago, IL.*

Background: Acute kidney injury associated with COVID-19 is poorly understood; majority of the published literature currently available in the United States comes from major academic institutions. This study aims to describe the epidemology and general outcomes of hospitalized patients with COVID-19 at a large tertiary community hospital.

Methods: This is retrospective descriptive study of the incidence of acute kidney injury for hospitalized patients with COVID-19 between March 1st - May 31st at a single-center community teaching hospital in Cook County, Illinois. Patients diagnosed previously with End Stage Renal Disease (ESRD) and kidney transplant recipients were excluded, as were incidental positives and multiple COVID-19 hospitalizations. Acute kidney injury (AKI) was defined by KDIGO criteria. Baseline creatinine (SCr) was defined as the median SCr from the previous 365 days until 7 days prior to admission. If no baseline SCr was available, admission SCr was used as the baseline. Results are descriptive.

Results: Of the 684 patients admitted the hospital with COVID-19 infections, 231 (33.8%) developed an AKI. Stage 1 129 (55.8%), Stage 2 36 (15.6%), Stage 3 66 (28.6%). Urine microscopy showed proteinuria 104 (45.1%), hematuria 129 (55.8%), leukocyturia 129 (55.8%); Median FE Na 0.3 [0.1 - 0.7] and FE Urea 21.1 [15.0 - 29.5].

Renal biopsy performed on four patients demonstrated acute tubular necrosis. Fifty-two (22.5%) patients received KRT; most commonly with CKRT in 26 (50%) or combination of CKRT and HD in 17 (32.7%). Median hospital day for initial dialysis was 5.0 [2.0 - 10.0]; mechanical ventilation 0.0 [1.0- 4.0], ECMO 1.0 [0 - 4]. LOC was significantly longer for AKI patients (overall 8.7 [4.8 - 17.3], No AKI 7.7 [4.0 - 12.7], AKI 15.0 [7.1 - 27.2] days p <0.01). Most common co morbidities were Type 2 diabetes and hypertension. D-dimer, LDH, CRP, procalcitonin and IL-6 were significantly higher. Upon discharge, 138 (59.7%) were discharged without KRT, whereas 12 (5.2%) patients required KRT. Nine (3.9%) went hospice, and 72 (31.2%) died. One patient was still admitted to the hospital.

Conclusions: Acute kidney injury is a poor prognostic indicator for patients with COVID-19. The mortality rates and outcomes of patients with AKI in this setting are comparable to previously published studies.

PO0048

Kidney Recovery Post Coronavirus Infection in Hospitalized Kidney Transplant Recipients: A Single-Center Observational Study

Adarsh Vijay, Gina L. Defelice, Kofi Atiemo, Hoonbae Jeon, Mary Killackey, Sixto G. Giusti, Anil S. Paramesh. *Tulane University School of Medicine, New Orleans, LA.*

Background: Kidney transplant recipients (KTR) are at an increased risk of severe disease and death caused by coronavirus-19 infection. There is a paucity of information on the evolution of graft function among hospitalized KTRs who overcome the infection.

Methods: The study included adult KTRs at a single transplant institute who were diagnosed with Coronovirus-19 virus and needed hospitalization between March 15, 2020 and January 15, 2021. We analyzed patient demographics, comorbid risk factors, and inpatient clinical course for patients that were able to recover from the infection. Kidney function was analyzed pre-infection, during initial hospitalization and up to 12 months post infection.

Results: We identified 48 kidney transplant recipients who were diagnosed with Coronavirus-19 infection during the study period. Eighteen KTRs among these needed hospitalization for symptoms of fever and respiratory distress. Four patients died of Coronavirus-19 infection related complications and were excluded from the study. The 14 remaining patients in the study were predominantly black (78%), with a median time since transplant of 4 years. 64% of the patients developed AKI, with an average peak serum creatinine of 2.64 mg/dl and GFR of 34. The mean serum creatinine and GFR of the group were 2mg/dl and 44 at baseline (prior to infection). This represented an increase in their serum creatinine and GFR of 34% and 29% respectively. The median follow-up post infection was 7.5 months. Serum creatinine and GFR were 1.83 mg/dl and 48 at 3 months, and 2.2 mg/dl and 40 at 6 months post infection. New onset proteinuria was noted in 5 out of the 14 patients (36%), with complete resolution of same in all at 3 months follow up. 75% patients with AKI had complete recovery at 3 month follow-up. The mean baseline GFR of patients who had incomplete recovery was 32. There was only 1 graft loss and this was in a patient who had chronic rejection and had a baseline Cr of 3.8 mg/dl at time of coronavirus-19 infection.

Conclusions: AKI is common among KTRs that are hospitalized with Covid-19 infection. Most of these recover, although we noted that patients with baseline lower kidney function (GFR < 32) and existing proteinuria had a lower recovery rate.

PO0049

Risk Factors for RRT and Mortality in Patients with COVID-19-Related AKI in São Paulo, Brazil

Carlos Augusto P. Almeida, Marcia Fernanda Arantes de Oliveira, Carla P. Sandoval Cabrera, Alexandre M. Teixeira, Jorge L. Espinosa Armijos, Eduardo d. Valle, Bernardo V. Reichert, Gabriel T. Sales, Igor Smolentzov, Fernando L. Strufaldi, Paulo R. Lins, Camila E. Rodrigues, Victor F. Seabra, Lucia Andrade. *University of Sao Paulo School of Medicine, Sao Paulo, Brazil*.

Background: In COVID-19, as in SARS, the degree of kidney injury can have major implications for the clinical outcomes. Early reports indicate that, among patients with COVID-19, AKI is common and is associated with worse outcomes. However, COVID-19-related AKI among ICU patients in Brazil has not been well described.

Methods: This was a retrospective observational study of the electronic health records of patients with COVID-19-related AKI admitted to the *Hospital das Clínicas* in the city of São Paulo, Brazil, between March and August of 2020. We applied only KDIGO criteria 2 and 3. We used logistic regression to analyze risk factors for the composite outcome of mortality or RRT.

Results: Among the 694 patients with COVID-19-related AKI, the mean age was 63 years and mortality was 66.4%; 41% needed vasoactive drugs, 66% needed mechanical ventilation, and 72% needed dialysis. Univariate analysis showed the following risk factors for mortality and RRT at admission: male sex; diabetes; CKD; vasoactive drug use; mechanical ventilation; acidemia; elevated lactate, magnesium, potassium, creatinine, C-reactive protein, creatine phosphokinase, total bilirrubin; proteinuria; hematuria; and increased fractional excretion of potassium (n=98) and sodium (n=110). The factors that remained significant in the multivariate analysis were male sex, vasoactive drug use, serum magnesium >2.5 mg/dL and oliguria (24-h urine output <500 mL).

Conclusions: In ICU patients with COVID-19-related AKI, in Brazil and elsewhere, in-hospital mortality is high. The exact mechanism by which hypermagnesemia increases mortality in such patients merits further study. Supported by FAPESP.

Risk factors for mortality or RRT in patients with COVID-19-related AKI in Brazil

	Univariate analysis	P	Multivariate analysis	P
	OR (95% CI)		OR (95% CI)	
Age, per year increase	1.01 (1-1.02)	0.13	1 (0.99-1.02)	0.66
Male sex	1.74 (1.15-2.62)	0.008	1.86 (1.2-2.9)	<0.01
Serum creatinine at ICU admission, per unit increase	1.12 (1.01-1.25)	0.004	1.03 (0.94-1.14)	0.61
Vasopressor use at admission	2.96 (1.71-5.43)	<0.001	4.07 (2.35-7.46)	<0.001
Serum magnesium > 2.5 mg/dL	3.54 (2.08-6.2)	<0.001	2.09 (1.1-4.36)	0.03
Oliguria	0.99 (0.99-0.99)	0.005	3.31 (1.83-6.44)	<0.001

PO0050

Mortality in an Emergency-Only Hemodialysis Population from COVID-19 in a Large Safety Net

Yao Yao,[1] Ravi D. Bhatia,[2] Lauren Kasper,[2] Sarah A. Johnson.[2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]Emory University, Atlanta, GA.*

Background: The COVID-19 pandemic has shown to disproportionately impact certain populations highlighting health, economic and social disparities. An especially vulnerable group is the emergency-only hemodialysis (EoHD) patient population at Grady Health System, 91% of whom are Hispanic with a median age of 52. This population initially included 102 EoHD patients followed from 4/2020 to 5/2021. A COVID screening protocol was developed to assess disease prevalence, and patients who tested positive were isolated and treated accordingly. The aim of this study is to estimate the mortality rate in this at-risk population.

Methods: From 4/2020 to 5/2021, COVID PCR tests were administered either as scheduled screenings or diagnostically if a patient presented with symptoms; patients testing positive were isolated per health department and hospital policy recommendations. In total 494 PCR tests were performed, and 444 were screening; each patient received an average of 4.8 tests. Hospital admissions, complications, and mortality data were collected and analyzed using statistical software.

Results: A total of 102 patients comprised the EoHD cohort at the onset of the study in 4/2020. Of this population, 58 (58%) patients tested positive for COVID and 19 (33%) of these COVID cases required hospitalization. The majority of positive cases (n = 32, 55%) were in asymptomatic patients and detected with screening tests while the remaining were diagnostic results. Eleven (11%) patient deaths occurred during the study, and two (2%) were attributed to COVID related complications. The remaining causes of death included hemorrhagic shock (1), cardiac arrest (1), heart failure (2), and unspecified, non-COVID related illnesses (5). The prevalence of COVID infection in patients who had diabetes and/or hypertension was non-significant (p-value = 0.2).

Conclusions: Amongst the EoHD population, the risk of COVID-19 is disproportionately high compared to the general population possibly due to chronic exposure to healthcare settings and socioeconomic disadvantages. One would expect the mortality from COVID to be higher in this cohort as compared to the general population due to ESRD and associated comorbid conditions. However, our results show that COVID attributable deaths in the EoHD population was 2%, which is comparable to the 1.8% mortality rate observed in the general U.S. population.

PO0051

Excess COVID and Non-COVID Mortality Among Patients with ESKD in 2020

Kirsten L. Johansen,[2,1] James B. Wetmore,[1,2] Eric D. Weinhandl,[1,3] David T. Gilbertson,[1] Yi Peng.[1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Hennepin Healthcare, Minneapolis, MN; [3]University of Minnesota Medical School Twin Cities, Minneapolis, MN.*

Background: Patients with ESKD are at high risk of mortality from COVID-19. The extent to which increased mortality in the ESKD population in 2020 was related to COVID-19 vs other causes in the setting of disruption of healthcare delivery is not clear.

Methods: We used the Death Notification Form (CMS-2746) to examine excess all-cause and COVID-related mortality in Jan through Aug of 2020 among the whole ESKD population and by race/ethnicity adjusting for age and comorbidity. We further examined causes of non-COVID-related mortality in 2020 compared with 2017-2019.

Results: All-cause mortality increased by 13.1% during Jan-Aug 2020 compared with mortality during the same period in 2017-2019. Peak overall and excess mortality occurred during Apr (Figure), when 14.7% of all deaths were attributed to COVID-19. COVID-related deaths declined to a nadir of 6.2% of all deaths in June and then increased again in Jul and Aug. Excess mortality was approximately twice as high among Black and Hispanic patients as among whites. Between Feb and Apr, there was substantial excess non-COVID mortality in addition to COVID mortality, whereas most excess mortality during May to Aug was related to COVID-19. There were 4310 excess deaths during Feb-Apr 2020. 1576 (37%) were due to COVID-19, and 517 (12%) were attributed to pneumonia. Thus, approximately half of the excess mortality was not due to COVID-19, including 1635 excess deaths due to cardiac arrest, cause unknown.

Conclusions: Patients with ESKD experienced substantial excess mortality in 2020 relative to prior years that affected Black and Hispanic patients disproportionately. Approximately half of the excess mortality was likely caused by COVID-19. There was also excess mortality in the early phase of the pandemic that was not attributed to COVID-19.

Number of overall and COVID-related deaths in 2020 vs 2017-2019

PO0052

Associations of Dialysis Modality and Setting with Incidence of COVID-19 Diagnosis and Hospitalization

Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1] Kirsten L. Johansen.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: The novel coronavirus 2019 (COVID-19) pandemic has resulted in substantial morbidity and mortality among patients undergoing maintenance dialysis. Patients performing home hemodialysis (HHD) or peritoneal dialysis (PD) may be able to minimize exposure to the community, thus lowering risk of COVID-19 infection. We assessed whether HHD and PD were associated with lower risks of COVID-19 infection and hospitalization, compared to in-facility hemodialysis (IHD).

Methods: We analyzed Medicare Parts A and B claims accrued during 2020. For each epidemiologic week from week 12 (beginning March 15) to week 37 (September 6), we identified patients with a Medicare-covered outpatient dialysis treatment during the preceding 7 days. We stratified patients into cohorts of IHD, HHD, and PD; we limited the IHD cohort to patients without residency in a skilled nursing facility during the 28 days preceding the epidemiologic week. During each week, we estimated the incidence of COVID-19 infection and COVID-19 hospitalization, per Medicare claims with ICD-10-CM diagnosis code U07.1. Using logistic regression with adjustment for demography, comorbidity, and state, we estimated odds ratios of outcomes during weeks 12-22, 23-33, and 34-37.

Results: Incidence of COVID-19 infection (figure) and COVID-19 hospitalization peaked twice: during weeks 14-16 and weeks 29-30. During weeks 12-22, adjusted odds ratios (AORs) of COVID-19 infection for HHD versus IHD and PD versus IHD were 0.55 (95% CI, 0.43-0.71) and 0.52 (0.46-0.58), respectively. During weeks 23-33, corresponding AORs were 0.63 (0.50-0.78) and 0.63 (0.57-0.69).

Conclusions: Both home dialysis modalities were associated with similarly lower risks of COVID-19 infection and hospitalization. Nephrologists and dialysis provider should consider counseling patients about potentially lower risk of infectious respiratory disease with home dialysis.

Understanding Dialysis Patient COVID-19-Related Mortality

Alvin H. Moss,[1] Annette Aldous,[2] Glenda Harbert,[3] Amanda C. Nicklas,[3] Dale Lupu.[3] *[1]West Virginia University Health Sciences Center, Morgantown, WV; [2]The George Washington University Milken Institute of Public Health, Washington, DC; [3]The George Washington University School of Nursing, Ashburn, VA.*

Background: Reported COVID mortality in dialysis patients is high and ranges from 15-25%. We reviewed data from a prospective 14-month study of seriously ill (SI) dialysis patients pre-COVID (May 2019-January 2020) and during COVID (February 2020-June 2020) to better understand COVID-related mortality in SI and not SI patients.

Methods: We recruited 10 dialysis centers (6 in NYC, 3 in Denver, CO, and 1 in Dallas, TX) with 1,507 patients. Dialysis staff screened patients monthly with the surprise question (SQ)—*Would I be surprised if this patient died in the next 6 months?*—and recorded outcomes. Those with a "No" response were identified as SI. A SQ "No" response is known to identify older patients with multiple comorbidities and an increased risk of early mortality. In this rolling population, we calculated the monthly mortality risk prior to and during COVID and determined the relative risk of death (RR) for SI compared to not SI during both periods. We also compared the increased mortality risk during COVID between patients dialyzed in NYC vs. Denver and Dallas and used logistic regression to determine whether COVID-19-related mortality differed by geographic region.

Results: Over 14 months, dialysis centers screened a monthly average of 1,342/1,507 (89.1%) patients and identified 274 (18.2%) as SI, with more consistent screening pre-COVID than during COVID (98.6% vs. 71.2%). Pre-COVID, the monthly mortality rate for SI patients was 2.8% and for not SI patients 0.4%, (RR 7.02, 95% CI, 4.76-10.44). During COVID, the monthly mortality rate for SI patients increased to 4.8% and for not SI to 1.5% (RR 3.19, 95% CI, 2.28-4.44). The absolute increase in monthly mortality risk from pre-COVID to COVID was greater for SI than for not SI patients, 2.0% vs 1.1%. The excess monthly mortality was higher in NYC (2.3% for SI and 1.2% for not SI) than in Denver and Dallas (1.3% for SI and 0.7% for not SI), but the difference was not significant (p = .12).

Conclusions: A "No" response to the SQ identified SI dialysis patients whose 5-month mortality during COVID increased to 23.9% (annualized rate 57.4%). For not SI, the 5-month mortality rate during COVID increased to 7.5% (annualized rate 18%). These findings underscore the importance of advance care planning not only for SI patients but also for all dialysis patients, who are particularly vulnerable to concurrent infections such as COVID-19.

PO0054

Temporal Trends in Mortality and Hospitalization Related to SARS-CoV-2 in Dialysis Patients in Québec (Canada)

Annie-Claire Nadeau-Fredette,[1,2] William Beaubien-Souligny,[3] Fabrice Mac-Way,[6] Remi Goupil,[4] Daniel Blum,[5] Rita Suri.[5] For the Quebec Renal Network Study Group *[1]Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada; [2]Universite de Montreal, Montreal, QC, Canada; [3]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [4]Hopital du Sacre-Coeur de Montreal Centre de Recherche, Montreal, QC, Canada; [5]McGill University Health Centre, Montreal, QC, Canada; [6]CHU de Quebec-Universite Laval, Quebec, QC, Canada.*

Background: In Canada, Quebec province was the most severely hit region during the first year of the SARS-CoV-2 pandemic. We aimed to compare characteristics and outcomes of dialysis patients during the first and second SARS-CoV-2 transmission surges in this province.

Methods: The QRN-COVID-HD study included adult dialysis patients from 13 units in Quebec, with SARS-CoV-2 PCR tests performed between Mar-Sept 2020 (1st wave) and Oct 2020-Feb 2021 (2nd wave). Crude and stratified rates of mortality, hospitalization and intensive care unit (ICU) admission within 90-day of SARS-CoV-2 positivity were calculated with mixed effect Poisson regressions. Adjusted predictors of 90-day outcomes were evaluated using mixed effect logistic regressions and negative binomial regressions (as appropriate).

Results: Over this 12-month period, 431 patients were infected with SARS-CoV-2 (211 1st wave; 220 2nd wave). Most characteristics (including age) were similar in the two waves although 2nd wave patients were less frequently living in long-term care facilities and had more diabetic nephropathy. Overall, 214 (50%) patients were hospitalized at least once and 214 (26%) died within 90-day of SARS-CoV-2 positivity, with 78% of hospitalizations and 84% of deaths directly attributed to SARS-CoV-2. Mortality and hospitalization rates were lower for 2nd compared to 1st wave patients. **Figure** In contrast, ICU admissions were similar in both waves (0.14, 95% CI 0.10-0.19 [1st] vs. 0.13, 95% CI 0.09-0.18 [2nd] per 100 pt-yrs). When adjusted for case-mixed differences, the 2nd wave remained associated with lower risk of mortality (OR 0.55, 95% CI 0.32-0.95), hospitalization (OR 0.45, 95%CI 0.28-0.71) and days in hospital (IRR 0.49, 95% CI 0.46-0.53), but similar risk of ICU (OR 0.73; 95% CI 0.39-1.37).

Conclusions: Dialysis patients with SARS-CoV-2 infections had more favorable clinical outcomes during the 2nd wave, which is consistent with observations in the general population and may be related to improved clinical care.

PO0055

COVID-19 Outcomes in Hospitalized Patients with CKD

Varsha V. Suresh,[1] Kay T. Khine,[1] Saif M. Borgan,[2] Francheska Castro,[1] Hiren Patel,[3] Abdo Asmar.[1] *[1]University of Central Florida, Orlando, FL; [2]Cleveland Clinic, Cleveland, OH; [3]Saint Louis University, Saint Louis, MO.*

Background: Current research revolving around Coronavirus Disease 2019 (COVID-19) has identified that patients with co-morbid illnesses are at risk for worse outcomes.

Methods: This is a retrospective study comprising an observational dataset of 149 hospitals that included hospitalized patients (n=9366) aged 18 and above with a Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) Polymerase Chain Reaction (PCR) positive result between January 1st, 2020 and May 29th, 2020. Main outcomes and measures included hospital length of stay, Intensive Care Unit (ICU) admission, ventilator dependency, development of Acute Kidney Injury (AKI) and in-hospital death. Baseline patient characteristics were recorded, including demographic variables and comorbidities.

Results: A total of 9,366 patients were included in the analysis, of which 4765 (50.8%) were males, with mean age of 55.4 years (SD=18.6). Patients with CKD (n=1092, 11.7%) had a significantly higher length of hospital stay (Mean of 10.5 vs 4.9 days), ICU admission rates (23.3% vs 13.0%), ventilator dependency (24.5% vs 9.3%), AKI (6.2% vs 1.9%) and in-hospital death (20.5% vs 5.9%). In a multivariable logistic regression model, in-hospital death was independently related to presence of CKD.

Conclusions: This study confirms the independent association between a personal history of CKD and poor outcomes among hospitalized patients with COVID19, including in-hospital death.

Table 1. Outcome analysis according to CKD status for hospitalized patients with COVID19 in an observational database (n=9366).

Outcome	CKD present (n=1092/9366)		CKD absent (n=8274/9366)		P-Value
	Number	Percent (%)	Number	Percent (%)	
In-hospital death	224/1092	20.5	487/8274	5.9	<0.0001
In-hospital death or discharge to hospice	308/1092	28.2	709/8274	8.6	<0.0001
Intensive care unit (ICU) admission	254/1092	23.3	1072/8274	13.0	<0.0001
Ventilator dependency	268/1092	24.5	765/8274	9.3	<0.0001
Development of Acute Kidney Injury (AKI)	68/1092	6.2	160/8274	1.9	<0.0001
Length of hospital stay	Mean 10.5 days (SD=14.3)		Mean 4.9 days (SD=7.0)		<0.0001
Length of ICU stay	Mean 14.8 days (SD=1.3)		Mean 14.1 days (SD=14.3)		0.54

PO0056

COVID-19 Among Hospitalized Patients with Kidney Disease: Experience at a Midwestern Medical Center

Krista L. Lentine, Seyedmahdi Pahlavani, Yasar Caliskan, Ariel A. Schnell, Nikolas E. Marino, Aberdeen X. Taylor, Usama Elewa, Marie D. Philipneri, Amy Mosman, Thanh-Mai N. Vo, Rosemary Ouseph, Sruthi Ainapurapu, Thomas R. Groll. *Saint Louis University School of Medicine, Saint Louis, MO.*

Background: Manifestations of novel coronavirus disease-2019 (COVID-19) range from minimal symptoms to organ failure and death. Preliminary studies suggest that acute kidney injury (AKI) is a common complication of COVID-19 and may predict adverse outcomes. Patients with chronic kidney diseases may be vulnerable to increased risk of serious COVID-19-related complications.

Methods: In this (ongoing) retrospective cohort study, we examined the characteristics, presentations, treatments, and outcomes of COVID-19 among hospitalized patients with AKI, dialysis-dependent end-stage kidney disease (ESKD-D) or kidney transplantation (KTx) at an urban, Midwestern tertiary center (3/19/2021–3/25/2021).

Results: Among 184 patients, 91 had AKI (49%), 51 CKD5-D (28%), and 42 patients were KTx recipients (23%). Monthly cases ranged from 6 in March to 35 patients in December 2020. Among the cohort, 61% were Black (including 50% AKI, 82% ESKD-D, and 57% KTx). Overall, 35% required mechanical ventilation, with highest use in the AKI group (51%). 48% of AKI patients required renal replacement therapy (RRT) and 9% treated with ECMO. Mechanical ventilation was lower among KTx recipients (12%) and 9% required RRT. The most common medical treatment was dexamethasone (48%). Mortality was 46% in the AKI and 23% in CKD5-D groups, but 2% among KTx recipients.

Conclusions: We observed high mortality associated with COVID-19 among hospitalized patients with kidney disease, especially in those with AKI. Public health and therapeutic studies should focus on mitigating COVID-19 disease transmission and optimizing outcomes in this vulnerable population.

Table. Characteristics, Treatments and Key Outcomes of Study Cohort

Decision-Making During Uncertain Times: A Qualitative Study of Kidney Patients, Care Partners, and Nephrologists During the COVID-19 Pandemic

Thalia Porteny,[1] Susan Koch-Weser,[2] Dena E. Rifkin,[3] Tamara Isakova,[6] Elisa J. Gordon,[6] John B. Wong,[5] Ana P. Rossi,[4] Daniel E. Weiner,[5] Keren Ladin.[1] DART Investigators *[1]Tufts University, Medford, MA; [2]Tufts University School of Medicine, Boston, MA; [3]University of California San Diego, La Jolla, CA; [4]Piedmont Healthcare Inc, Atlanta, GA; [5]Tufts Medical Center, Boston, MA; [6]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Older adults faced treatment decisions for kidney failure during the COVID-pandemic, despite high risk of hospitalization, intensive care, and death. Given heightened uncertainty, clinicians needed to adapt communication about risks, benefits, and treatment decisions during the COVID-19 pandemic. Understanding how to support decision-making during uncertain times can guide clinicians in future public health crises.

Methods: Qualitative study using semi-structured interviews (August-December 2020) with CKD stage 4-5 patients, age 70+, carepartners, and clinicians in Boston, Portland, Maine, San Diego, and Chicago. Thematic analyses were conducted.

Results: Among 76 participants (39 patients, 17 carepartners, 20 clinicians) 13 patients (33%) identified as Black, and 7 (18%) were receiving dialysis. Four themes characterized treatment decision-making during the COVID-19 pandemic: Difficulty communicatng risk: balancing hope with caution; Clinicians' increased support for home dialysis; Patient confidence in chosen modality; and Coping with uncertainty and isolation in CKD. Clinicians struggled to balance discussion of COVID-19 risks while preserving hope. Black patients reported fewer conversations about COVID-19 risks than White patients and had more unaddressed questions. Clinicians reported being more open to home dialysis than pre-COVID-19. While some patients expressed interested in conservative management, few clinicians offered conservative management as an option. All patients who had initiated treatment prior to COVID-19, irrespective of modality, believed that their treatment was safest and optimal during the pandemic. With few clinical converations incorporating COVID-19-specific risks, patients and carepartners struggled to cope, finding both in-person and telehealth visits safe but isolating.

Conclusions: Although clinicians struggled communicating about COVID-19 leaving patients with unadressed concerns, patients across modalities felt safe and confident in their treatment. Clinicians developed an openness to home dialysis, though few offered conservative management despite patient preferences. Research should examine optimal approaches to enhance communication and shared-decision making to prepare for future systemic challenges.

PO0058

Risk Factors for In-Hospital Mortality Among Patients Hospitalized with COVID-19 and ESKD

Jackson Heilbronn, Amir Abdi Pour, Giv Heidari-Bateni, Lida Gharibvand, Kwame B. Agyeman, Sahib D. Grewal, Mohammad Sharif, Sergio Infante, Mita Zahra E. Co, Sayna Norouzi. Loma Linda Medical Center *Loma Linda University, Loma Linda, CA.*

Background: End Stage Kidney Disease (ESRD) has been shown to be a risk factor for poor outcomes in the setting of COVID-19 infection. Our study aims to identify risk factors for mortality in ESRD patients hospitalized with COVID-19.

Methods: We conducted a retrospective analysis from March 1st, 2020 to January 31st, 2021 at Loma Linda University Medical Center. Inclusion criteria included patients admitted with diagnosis of COVID-19 and history of ESRD prior to admission. Risk factors for hospital mortality were identified with univariate and multivariate logistic regression methods.

Results: A total of 92 patients (age 59.9±13.7) were included in the analysis of which 21(18.6%) were deceased. Univariate analysis (Figure 1) demonstrated that age odds ratio (OR) with 95% confidence interval (CI) for mortality 1.05 (95% CI: 1.01-1.09, P= 0.03), Positive D-dimer OR = 6.3 (95% CI: 1.29-27.9, P= 0.02), ejection fraction less than 50% OR=1.08 (95% CI: 2.62-28.77, P= <.0001), and ferritin >300 ng/ml OR=1.02 (95% CI: 1.01-1.03, P= 0.04) were associated with increased risk of hospital mortality. Adjusted multivariate analysis demonstrated that only ejection fraction less than 50% was associated with increased risk of mortality (OR 9.9, 95% CI: 2.2-45.1, P <.01)

Conclusions: Age, elevated D-dimer, elevated ferritin and heart failure with reduced ejection fraction were identified as risk factors for hospital mortality of ESRD patients with COVID-19 infection.

Figure 1. Unadjusted Univariate Analysis

Variables	OR (95% CI)	P-Value

Risk Factors for In-Hospital Mortality Among Patients Hospitalized with COVID-19 and AKI

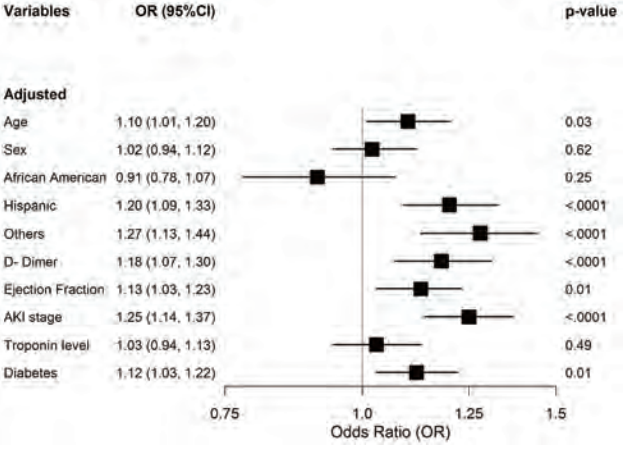
Sahib D. Grewal, Amir Abdi Pour, Giv Heidari-Bateni, Lida Gharibvand, Jackson Heilbronn, Mohammad Sharif, Mita Zahra E. Co, Kwame B. Agyeman, Sergio Infante, Sayna Norouzi. Loma Linda Medical Center *Loma Linda University, Loma Linda, CA.*

Background: Coronavirus disease- 2019 (COVID-19) has the highest mortality in patients with advanced age and those with pre-existing chronic medical conditions. Limited data, however, is available with regard to COVID-19 mortality in acute kidney injury (AKI). We aimed to identify risk factors associated with mortality in patients hospitalized for COVID-19 with AKI.

Methods: This is a retrospective cohort study conducted at Loma Linda University Medical Center (LLUMC) from March 1st, 2020 to January 31st, 2021. Inclusion criteria included patients admitted to LLUMC with diagnosis of COVID-19 and AKI during the admission based on the Risk Injury Failure Loss ESRD (RIFLE) criteria. Univariable and multivariable logistic regression models were utilized to explore risk factors associated with in-hospital mortality.

Results: A total of 320 patients (age 66.5 ± 14.4) were included in the analysis, of which 88 (28%) were deceased. Multivariable regression analysis (Figure 1) demonstrated that age greater than 70 had adjusted odds ratio (OR) with 95% confidence interval (CI) for mortality 1.10 (95% CI: 1.01, 1.20, p=0.03). An Ejection Fraction of less than 50% had OR=1.13 (95% CI: 1.03, 1.23, p=0.01), AKI-injury stage had OR=1.25 (95% CI: 1.14, 1.37, p=<0.001), positive D-dimer levels had OR=1.18 (95% CI: 1.07, 1.30, p=<0.001) and diabetes had OR=1.12 (95% CI 1.03, 1.22, p=0.01), all significant risk factors for mortality. In addition, Hispanics had a higher risk of mortality with OR=1.20 (95% CI 1.09, 1.33, p=<0.001) when compared to Caucasians.

Conclusions: Diabetes, age greater than 70, Hispanic background, Heart failure with reduced ejection fraction, AKI-injury stage, and positive D-dimer level are identified as risk factors associated with higher mortality amongst patient admitted with COVID-19 and AKI.



PO0060

Outcomes of COVID-19 Infection in Dialysis vs. Kidney Transplant Patients: A Nationwide Cohort Study from Qatar

Tarek A. Ghonimi, Abdullah I. Hamad, Mohamad M. Alkadi, Essa Abuhelaiqa, Rania A. Ibrahim, Shajahan J. Kadukkamoottil, Musab Elgaali, Muftah Othman, Hany E. Ismail, Karima Boubaker, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar*.

Background: COVID-19 infection carries a high burden and poor outcomes in patients who are immunosuppressed like kidney transplant or on dialysis. Our study aim is to compare outcomes between dialysis and kidney transplant patients infected with COVID-19 in the State of Qatar.

Methods: Retrospective cohort study reviewing medical, laboratory and radiographic data of all dialysis and kidney transplant recipients' patients in our national registry (between February and August 2020). Data collected from a national-based electronic medical record.

Results: 76 patients on dialysis patients had COVID19 vs 43 kidney transplants (p=ns). Kidney transplant patients with COVID19 tended to be younger than dialysis patients (52 vs. 58 years old, p=0.007), has less hypertension and more history of deep venous thrombosis. Clinical presentation did not differ between both groups with more asymptomatic in dialysis patients compared to kidney transplant patients (14.5% versus 2.3%, p=0.03). More patients died from COVID19 in the dialysis patients vs. kidney transplant patients (11 (14.5%) vs. only 1 (2.3%), p=0.034). Inflammatory markers were significantly higher in dialysis patients (IL6 peak and Ferritin) compared to kidney transplant patients.

Conclusions: Our national study showed similar incidence and severity of COVID19 in dialysis compared to kidney transplant in Qatar. Mortality and inflammatory markers were higher in dialysis patients.

One-Year Experience of COVID-19 Disease of 700 Chronic Dialysis Patients from Ecuadorian Highlands

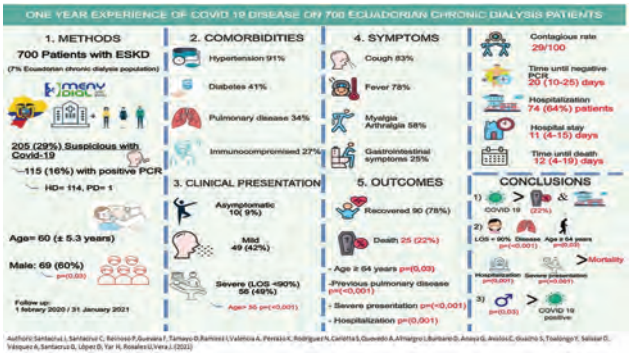
Juan C. Santacruz, Ana K. Vásquez Perez, Carlotta Sulbaran, Paulo Reinoso, Maria G. Santacruz, Angel C. Santacruz. *Clinica de los Riñones Menydial, Quito, Ecuador*.

Background: In December 2019, first Covid-19 disease cases were reported. The pandemic spread with 114.217.365 cases and 2.533014 deaths worldwide in March 2021, with 286.155 cases and 15.811 deaths in Ecuador. The aim of this work was to share COVID-19 disease impact on 700 chronic dialysis patients from Ecuadorian highlands, which represents almost 7% of Ecuadorian dialysis population, after one year of pandemic.

Methods: Observational-prospective-multicenter study on 700 Latin-American chronic dialysis patients of five different cities from Ecuadorian highlands. Patients were followed since February first, 2020 until 31 January 2021. Patients with COVID-19 symptoms were identified and diagnosis was made exclusively with positive nasopharyngeal swabs PCR testing. Oxygen saturation below 90% at presentation (LOS) classified disease presentation as severe, moderate if symptoms without LOS and asymptomatic if no symptoms. Hospital-stay, time until negative PCR, mortality and laboratory findings were collected.

Results: A total of 205 patients (29%) presented COVID-19 symptoms; 115 tested positive (16%), 60% were men (p=0.03), 25 subjects died (22%). Mortality was related with age above 64 years old, saturation < 90%, severe disease (p=0.03), previous pulmonary pathology and hospitalization (p=0.01). Hospitalization was needed in 74 patients (64%) with hospital stay 11 days (4-15), days until death during hospitalization of 12 days (4-19) and time until negative PCR 20 days (10-25). Symptomatic time was 16 days (11-26).

Conclusions: COVID-19 disease was more frequent in men and has added up to 22% of extra mortality to chronic dialysis population. Patients older than 64 years old, previous pulmonary pathology, LOS at presentation are at higher risk of mortality. Health care burden due to COVID-19 is high in dialysis population suggesting that vaccination programs must include dialysis patients and staff involved in their care to diminish mortality, infections and health care burden.



PO0062

Mortality in COVID-19 Patients with CKD with and Without Kidney Replacement Therapy in Western Mexico

Alejandro Garcia Rivera, Ríos C. Katia yuritzi, Arantxa K. Aguilar, Marcos A. Elias Lopez, Jesús A. Rico sánchez, Luz Yareli Villegas Gutierrez, Mario Valdez Avendaño, Fabiola V. Rios Rios, Mauro G. Montemayor Villacobos, Mónica L. Morales Guillén, Rubén Lara Monterrubio, Roxana Villanueva Macedo, José J. Gutiérrez Hernandez, Ramon A. Soto Rodriguez, Hugo B. Espinoza, Omar H. Sanchez Vazquez, Jorge fernando Topete reyes, Renato Parra Michel, Carolina R. Alvarez. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Especialidad en Nefrologia, Hospital General Regional No 46 del IMSS, Guadalajara, Mexico.*

Background: COVID-19 is a new disease of pandemic proportions. Currently, there are no reports on clinical outcomes in patients with CKD with and without KRT in the Mexican population. Our aim was to describe the clinical outcomes in patients with CKD.

Methods: Retrospective cohort study of hospitalized adult patients COVID-19 confirmed with RT-PCR, from April to December 2020 in a second-level hospital in Western Mexico. Information was obtained from medical records.

Results: 1012 patients were included, of which 130 patients (12.8%) had CKD (65.3% men), with a mean age of 53.8 years, 43.8% with Diabetes Mellitus and 82.3% with Hypertension. 84 patients (64.6%) were on KRT, within which 47 patients were on hemodialysis, 31 on peritoneal dialysis and 6 with a kidney transplant. 46 patients had no KRT, in stages ranging from KDIGO 3b to 5. 78.4%. 14 patients (10.7%) required mechanical ventilation. In our study, mortality among patients with normal kidney function was 30.6%. Regarding patients with CKD, patients on hemodialysis had a mortality of 25.5% (OR 0.74, 95% CI 0.39-1.5), patients on peritoneal dialysis had a mortality of 54.8% (OR 2.75, 95% CI 1.33-5.66), patients with CKD and no KRT had a mortality of 43.5% (OR 1.74, 95% CI 1.15-3.17).

Conclusions: In our population, an increased mortality was found in patients with CKD with and without KRT, highlighting the mortality of patients on PD.

African Americans Have Lower COVID-19 Mortality Risk Than Caucasians in CKD

Victoria Gonce,[1] Guo Wei,[2,1] Robert E. Boucher,[1] Nikita Abraham,[1] Sydney E. Hartsell,[1] Judy Carle,[1] Terrence S. Bjordahl,[3,1] Srinivasan Beddhu.[3,1] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; [3]Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.*

Background: In the general population, African Americans have increased mortality risk with COVID-19. However, this has not been well-studied in CKD population.

Methods: We analyzed a national Veteran cohort using data from the VA COVID-19 Shared Data Resource for COVID-positive patients (N=196,269) from 3/1/2020 - 3/9/2021. Diagnosis of COVID-19 was defined as a confirmed positive laboratory test result. Index date was defined as the date of first positive COVID-19 test or the first negative test for patients who never tested positive for COVID-19. Baseline eGFR was defined as at least one outpatient serum creatinine measurement obtained within two years before the index date or the average of the two closest serum creatinine measurements obtained within two years before the index date. We identified 58,743 patients with valid eGFR measurements. Of this cohort, 51,002 were African American or Caucasian. Mortality data were available for 50,830 patients. We used Cox regression models to compare COVID-19 mortality in African Americans versus Caucasians based on pre-COVID eGFR stratification.

Results: Of the COVID-positive patients with available eGFR and mortality data, baseline mean age was 60 ± 17 years, 24% African American, 76% Caucasian, and 21% with eGFR <60. There were 627 deaths among African Americans and 2,480 deaths among Caucasians. Average follow-up duration was 0.5 ± 0.3 years in African Americans and 0.4 ± 0.2 years in Caucasians. While there was no difference in mortality risk between African American and Caucasian Veterans without CKD, African Americans had lower mortality risk when compared to Caucasians in the CKD subgroup (Table 1).

Conclusions: In the CKD subgroup, African Americans have lower COVID-19 mortality than Caucasians. The reasons for this observation are unclear.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

Table 1. Risk of Mortality in African Americans versus Caucasians in COVID-19 by eGFR Groups

	Incidence Rate		HR* (95% CI)
	African American	Caucasian	
All eGFR groups	0.11	0.17	0.99 (0.90, 1.08)
eGFR ≥60	0.06	0.10	1.01 (0.88, 1.16)
eGFR 45 to <60	0.17	0.37	0.81 (0.68, 0.98)
eGFR <45	0.42	0.78	0.87 (0.74, 1.03)

*Model adjusted for demographics and comorbidities

PO0064

COVID-19 Among a Population of Predominantly American Indian and Hispanic American Kidney Transplant Recipients

Pooja Singh, Ashish Kataria, Christos Argyropoulos. *University of New Mexico School of Medicine, Albuquerque, NM.*

Background: COVID-19 leads to higher mortality among organ transplant recipients when compared to the general population.

Methods: In this study, 52 renal transplant recipients with COVID-19 were followed through 60 days from the date of initial diagnosis. We analyzed basic demographics, therapeutics used, and clinical outcomes among patients who survived and those who did not.

Results: Of the entire cohort, 53.8% were Hispanic Whites, 38.5% American Indian, and 5.8% were non-Hispanic Whites. 48% required hospital admission and 17% died, with 15% of deaths attributed to complications secondary to COVID-19. All those who died were either American Indian or Hispanic. Comorbidities among the non-survivors included hypertension (100%), chronic kidney disease (67%), diabetes (78%), and either being overweight or obese (100%). 89% had acute kidney injury and 56% required renal replacement therapy. Gender, blood type, and panel reactive antibody prior to transplant did not correlate with disease severity. There was no improvement in mortality during the fall/winter surge compared to the spring/summer surge, though therapies improved during the pandemic. None of the patients who received monoclonal antibody progressed to severe disease or died.

Conclusions: In conclusion, mortality with SARS-CoV-2 infection remains high among kidney transplant recipients, especially from ethnic minority groups. However, therapy with monoclonal antibody was associated with a reduced progression to severe disease and better outcomes. Therefore, it should be considered as a therapy in this high-risk group of patients if they satisfy the eligibility criteria listed by the Food and Drug Administration. Finally, further studies are needed to corroborate the findings from our study.

Prospective Study of COVID-19 in Patients Receiving Dialysis in Alberta Kidney Care South

Joanne Peterson,[1] Trinity A. Tam,[2] Victoria Riehl-Tonn,[2] Asha K. Swamy,[2] Sofia B. Ahmed,[2] Meghan J. Elliott,[2] Jennifer M. MacRae.[2] *[1]Alberta Health Services, Alberta Kidney Care South, Calgary, AB, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: People with kidney failure who are on facility-based hemodialysis (FBHD) are at high risk for COVID-19 infection due to inherent alterations in their immune system as well as the requirement to travel to a health care facility multiple times per week. In Alberta Kidney Care South, AKCS, public health measures and standardized screening of all patients entering clinics and HD units was initiated in March 2020 with COVID-19 testing of all patients who presented with a temperature, COVID related symptoms or a history of exposure to COVID-19.

Methods: All COVID-19 test results performed for AKCS patients are tracked in the electronic kidney database. We performed a 14-month prospective observational study (March 2020 to May 2021) to determine the incidence of confirmed COVID-19 infections, the prevalence of symptoms amongst COVID + patients and outcomes of hospitalization and death for FBHD, home hemodialysis (HHD) and peritoneal dialysis (PD) patients within the Alberta Kidney Care South program.

Results: We report on our preliminary results up to December 31, 2020. From a population of 1 329 patients, (931 FBHD, 102 HHD and 296 PD) 46(3.5%) patients were COVID positive. COVID-19 prevalence was 3.5% in FBHD (33/931), 4.4% in PD (13/296) and no HHD patients. The mean age of the cohort was 61 ± 16.5 years with 14(30%) female and comorbidities of hypertension 43(93%), diabetes 35(76%), coronary artery disease 16(35%) and heart failure 10(22%). COVID-19 testing was done for the following reasons: contact with a known COVID-19 person in 4(8.7%), resident of a long-term care facility in 3(6.5%) and for symptoms in 31(67%). The most common symptoms were fever (defined as T> 37.3C) with 20(43%), cough 10(22%) and sore throat 6(13%). Overall, 14 patients (30%) were admitted to hospital, 4 of whom went to the ICU and 5(11%) died. There were no differences in hospitalization between FBHD and PD (30% vs 31% respectively p = 0.971), ICU admissions (12% vs 0%, p=0.189) or death (12% vs 8 %, p=0.664).

Conclusions: The prevalence of COVID-19 amongst FBHD and PD patients was similar to the general population but with higher rates of hospitalization, ICU admissions and death. People on HHD appear to have very low rates of COVID-19 as compared to either PD or FBHD.

PO0066

Patients on Chronic Maintenance Hemodialysis with and Without COVID-19 Infection: Comparison of Baseline Characteristics and Mortality

Mujahed M. Dauleh, Muhammad Abdulbasit, Omar K. Salameh, Navin Verma, Amanda A. Karasinski, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: The COVID-19 pandemic has impacted nearly all aspects of the care of patients, particularly those with chronic conditions. There is a need for higher quality of evidence to better identify populations at risk, in various clinical situations. We analyzed the difference in demographic characteristics in patients with end stage kidney disease (ESKD) who were started on hemodialysis (HD) in 2020 and contracted COVID-19, with those who remained free of the infection in a large multicenter cohort.

Methods: We performed a retrospective multi-center cohort study using TriNetX Research Network database, a federate medical records network, to identify 7405 unique adult patients ≥ 18 years from 37 healthcare organizations (HCOs), mostly in the United States, for whom maintenance HD was initiated for ESKD between 1/1/2020 and 12/31/2020 (study period). From this group, we then identified patients who had a confirmed diagnosis of COVID-19 infection during the study period. We calculated the odds ratio (OR) and 95% confidence interval (CI) of mortality in the first three months of initiation of HD for the COVID group.

Results: 903 patients (from 33 HCOs) had a confirmed diagnosis of COVID-19 infection. Patients in the COVID-positive group were less likely to be white (p=0.019), and more likely to: —be of Hispanic/Latino ethnicity (p<0.0001), —have had a previously failed kidney transplant (p<0.0001) —have diabetes mellitus (DM) (<0.0001), and —have a BMI above 31 (p=0.003). A total of 628 patients died during the study period. After propensity matching, COVID exposure was associated with higher odds of mortality (OR: 2.32; CI: 11.66, 3.24). The survival probability at the end of 3 months was 84.4% for the COVID group, compared with 92.5% for the no-COVID group (p<0.0001).

Conclusions: During the study period, among the patients who were started on HD for ESKD, those who contracted COVID-19 infection were more likely to be Hispanic/Latino, less likely to be white, more likely to have a previously failed kidney transplant, more likely to have DM, and to have a BMI above 31. The COVID-positive group also had a higher mortality and a lesser 3-month survival probability compared to the control group.

PO0067

Kidney Transplant Patients with and Without COVID-19 Infection: Comparison of Baseline Characteristics and Outcomes

Omar K. Salameh, Muhammad Abdulbasit, Mujahed M. Dauleh, Ali M. Zebi, Gurwant Kaur, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: The COVID-19 pandemic has been associated with enormous impact on morbidity and mortality, particularly among individuals with chronic conditions and among patients on chronic immunosuppressive therapy. There is a need for higher quality of evidence to better identify populations at risk, in various clinical situations. We analyzed the difference in kidney transplant (KT) rejection, kidney transplant failure and mortality in patients who received a KT in 2020 and contracted COVID-19 with those who remained free of the infection, in a large multicenter cohort.

Methods: We performed a retrospective multi-center cohort study using TriNetX Research Network database, a federate medical records network, to identify 3773 unique adult patients ≥ 18 years, who had received a kidney transplant (KT) between 1/1/2020 and 12/31/2020 at 34 healthcare organizations (HCOs), mainly in the United States. From this group, we then identified patients who had a confirmed diagnosis of COVID-19 infection after KT. We calculated the odds ratio (OR) and 95% confidence interval (CI) of mortality, KT rejection, and KT failure in the two groups during the first 3 months after KT (study period).

Results: A total of 590 patients from 27 HCOs had a confirmed diagnosis of COVID-19 infection. Patients in the COVID group were more likely to be of Hispanic/Latino ethnicity (P < 0.0001). A total of 78 patients died during the study period. After propensity matching, COVID-19 exposure was associated with a higher odds of 3-month mortality (OR: 3.22; CI: 1.56, 6.62). The survival probability at the end of 3 months was 94.4% for the COVID group compared with 98.6% for the no COVID group (p<0.0001). Exposure to COVID-19 was also associated with a higher odds of KT failure (OR: 1.50; CI: 1.01, 2.20) during the study period. There was no statistically significant difference between the two groups regarding KT rejection during the study period.

Conclusions: During the study period, among the patients who received kidney transplant in 2020, those who contracted COVID-19 infection were more likely to be Hispanic/Latino, had higher mortality, were more likely to have KT failure and have less survival probability. There was no statistically significant difference between the two groups regarding KT rejection.

PO0068

Characteristics and Outcomes of Patients with COVID-19 Infection Requiring Extracorporeal Membrane Oxygenator with and Without Continuous Renal Replacement Therapy: A Single-Center Study

Dilraj S. Sekhon,[1] Richard Baker,[1] Karthikeyan Meganathan,[1] Prakash S. Gudsoorkar,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: Up to 1-in-3 cases of severe COVID-19 infection can cause respiratory failure sometimes necessitating extracorporeal membrane oxygenation (ECMO) support. Acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) is a common complication, yet risk factors & outcomes in these patients are not well studied.

Methods: A retrospective single-center study included 40 patients who received ECMO support for severe COVID-19 infection from Jan 20 to April 21. We extracted demographic, clinical, & laboratory variables on all patients. Primary outcome was hospital mortality; other recorded outcomes were total length of stay, ventilator, ECMO, & CRRT days, dialysis dependence at discharge. Group comparisons with & without CRRT were made by 2-sample Wilcoxon test for continuous variables & Fisher's exact test for categorical variables. Association of CRRT use & primary outcome was assessed by multivariable logistic regression (odds ratio (OR), 95% confidence interval (CI)).

Results: Overall cohort was 62.5% male, 32.5% black, with a median age of 51 years & BMI of 39.4. Thirty percent were diabetic & 42.5% were hypertensive. Of the 40 ECMO patients, 36 were on veno-venous, 2 on arterio-venous, & 2 utilized both veno- and arterio-venous circuits. 19/40 (47.5%) of ECMO patients required CRRT for AKI (3/19 patients CRRT was connected through the ECMO circuit). The median CRRT days were 20. Compared to those without CRRT, ECMO with CRRT patients needed a median of 19 ventilation days vs 15, 19 ECMO days vs 11, & 28 hospital days vs 32. Overall mortality was 50% (68.4% ECMO+CRRT vs 33.3% in others; p-value 0.0562). Logistic regression indicated that CRRT use in ECMO was associated with increased adjusted odds of death (6.37 OR, 1.12-36.19 95% CI). Of those who did not experience hospital mortality in the ECMO+CRRT group, 83% were dialysis-dependent at discharge.

Conclusions: Overall, extracorporeal support offers a meaningful bridge until organ recovery in severe COVID-19 infection. Despite necessitating ECMO, 50% of patients were able to be liberated from ECMO & survived. However once renal failure ensued, all patients required CRRT, which in turn predicted poor outcomes.

PO0069

Hypertension After Multisystem Inflammatory Syndrome in Children (MIS-C)

Jake R. Lehman,[1] Sareen Shah,[1,2] Christine A. Capone,[1,2] Christine B. Sethna.[1,2] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Cohen Children's Medical Center, Queens, NY.*

Background: MIS-C is an inflammatory condition in children associated with previous SARS-CoV-2 infection that has significant morbidity. Yet, long-term consequences of MIS-C remain unknown. The objective was to determine the prevalence of hypertension (HTN) and pre-HTN during the inpatient stay and post-hospitalization period in children diagnosed with MIS-C.

Methods: A retrospective study of children ≤18 years of age admitted to a tertiary center with MIS-C between 3/1/2020-2/28/2021 was performed. Children with a minimum of three documented outpatient blood pressures (BPs) were included. All available BPs were averaged and indexed (SBPi/DBPi) to the 95%ile for age, sex and height for the inpatient stay and post-hospitalization period. HTN was defined as mean SBPi or DBPi >1 during the inpatient stay and post-hospitalization period, or taking blood pressure medications for the diagnosis of HTN. Pre-HTN was defined as mean systolic or diastolic BP >90%ile for age, sex and height. Data were analyzed using paired tests and logistic regression.

Results: Among 66 children with MIS-C (mean age 9.4±4.6 years, 59.1% male, 21.2% Black, BMI z-score 0.48±2), 1.5% were hypertensive while hospitalized compared to 18.2% with post-hospitalization HTN (p<0.001). 4.5% were prehypertensive while hospitalized compared to 21.2% of MIS-C children post-hospitalization (p=0.003). Mean SBPi (0.91±0.13 vs. 0.86±0.06, p=0.03) and DBPi (0.87±0.13 vs. 0.77±0.09, p<0.0001) were significantly greater post-hospitalization compared to during hospitalization. In a multivariate model, Black race (OR 10.9 CI 1.6-75.2, p=0.02) and greater BMI z-score (OR 2.9 CI 1.2-7, p=0.02) were significantly associated with post-hospitalization HTN. Acute kidney injury (21.2%), inpatient steroids (86.4%), outpatient steroids (3%), vasoactive support (36.4%) and other clinical/demographic variables were not associated with post-hospitalization HTN (all p>0.05). After hospitalization, no MIS-C patients were started on antihypertensives for the management of HTN. No left ventricular hypertrophy was noted on echocardiography at six months post-hospitalization in those with HTN.

Conclusions: MIS-C appears to be associated with the development of post-hospitalization pediatric HTN and pre-HTN. Follow-up of children who have recovered from MIS-C requires careful BP monitoring and consideration of antihypertensive medication.

PO0070

The Role of Hypertension in Incidence and Morbidity of COVID-19: A One-Year Review in US Veterans

Elizabeth Cristiano,[1,2] Mariana Garcia-Touza,[1] Peter S. Wiegmann,[1] Mukut Sharma,[1] Virginia J. Savin,[1] Ram Sharma,[1] Vikas Singh,[1] Thomas Wiegmann.[1] *[1]Kansas City VA Hospital, Kansas City, MO; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: The discovery that ACE2 was a co-receptor of COVID-19 as well as early clinical findings induced interest in the role of hypertension (HTN) and its treatment with angiotensin converting enzyme inhibitors (ACEI) and angiotensin II receptor blockers (ARB) with regard to COVID-19 incidence and morbidity. We examined the effect of demographic and common risk factors of HTN and treatment with ACEI, ARBs, calcium channel blockers (CCB) and beta blockers (BB) in patients with COVID-19.

Methods: The VA COVID resource data combines hospital data, administrative and clinical record search results. The prevalence of HTN was defined by its presence in the last 2 years prior to COVID-19 testing. New event (incidence) was determined as occurrence within 60 days thereafter. ACEI and ARB, and CCB and BB were combined, basic demographic and risk factors were categorized for comparisons. Data sets were propensity matched, statistical analysis (SAS enterprise guide 7.1) used frequency distributions (chi square). The data was limited to the first year of collection.

Results: Of 1,305,466 veterans, we found positive tests (18.1%), HTN (56.9%), ACE or ARB (33.7%), and CCB or BB (15.4%). HTN and treatment had no effect on COVID-19 incidence (OR HTN 1.08, ACE/ARB 1.01, CCB/BB 0.94). White, male patients aged over 60 years predominated. Age, race, and smoking had no effect on incidence, but DM2 (OR 1.2) and higher BMI (OR 1.4) did. We then examined demographics and risk factors in the COVID-19 positive HTN population. Male gender (5.4), age > 60 years (7.5), race non-white (1.6), BMI >30 (2), smoker (2.8), and DM2 (11.8). In turn, these factors at most affected outcomes (OR) such as all-cause mortality (7.9), admissions (2.1), ICU admissions (2.5), and ventilator use (2.7) with the exception of BMI which was associated with improved outcomes (0.6). ACEI or ARB had no effect (< 1.1) while CCB or BB had a small effect (1.26) on outcome.

Conclusions: In conclusion, HTN and anti-hypertensive treatment had no effect on COVID-19 incidence. HTN is associated with age, race, smoking and a diagnosis of DM2. Treatment with ACEI or ARB has no effect on morbidity while CCB or BB had a small effect that deserves further evaluation.

PO0071

Initial Blood Pressure (BP) and COVID-19 (C19) Mortality

Tenzin Yangchen,[1] Farrukh M. Koraishy,[1] Rajeev Rohatgi.[2,1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Northport VA Medical Center, Northport, NY.*

Background: For C19 to infect epithelia, serine proteases cleave the spike protein to enhance its binding to ACE2 and entry into the epithelia. Since viral replication highjacks components of the renin-angiotensin system, investigators speculate that hypertension (HTN) is a risk factor for severe infection; however, it is uncertain whether high BP at presentation is a risk factor for mortality in C19 infection. Thus, we tested whether BP at presentation portends mortality in C19 positive (+) vs. negative (-) hospitalized patients.

Methods: Clinical/laboratory data from C19(+) and (-) hospitalized patients at Stony Brook Hospital (SBH) from March 2020 to July 2020 were included. The initial systolic BP (SBP) categorized patients into normotensive (SBP 90-139 mm Hg), stage 1 HTN (SBP 140-159 mm Hg) and stage 2 HTN (>160 mm Hg). Subjects with a mean arterial BP (MABP) <65 (hypotensive) were excluded and the remaining cohort was re-categorized into tertiles (T) of MABP (65-85 [T1], 86-97 [T2] and ≥98 [T3]).

Results: 4436 patients were admitted to SBH and 1591 diagnosed with and 2845 without C19. Mortality of C19(+) was 4.5-fold greater than C19(-) patients. Though the diagnosis of HTN was more prevalent among C19(+) (629/1591; 39.53%) vs. (-) (1014/2845; 35.64%; $p<0.05$) patients, the average presenting SBP and MABP was significantly lower in the C19(+) cohort ($p<0.05$). After excluding hypotensive patients, the mortality of stage 1 (33/271; 12.18%) and/or stage 2 (24/150; 16.00%) SBP cohorts did not differ from the normotensives (133/1112; 11.95%) in C19(+) patients. A similar finding was noted in the C19(-) patients. T2 tertile of MABP had the lowest mortality among C19(+) patients (56/562; 9.96%) and the T1 and T3 tertile of MABP had greater mortality at 15.31% (81/529) and 12.75% (58/455), respectively, than T2 ($p<0.05$). No difference in mortality was noted across the MABP tertiles of C19(-) cohort. Two multivariate (MV) regressions models evaluating mortality were studied each comparing T1 vs T2 or T2 vs. T3. In T1 vs T2 age, gender, albumin and T1 MABP significantly contributed to mortality while in T2 vs T3 age, gender, and first respiratory rate predicted mortality.

Conclusions: Univariate analysis of MABP suggests mortality is greater in T1 and T3 cohorts compared to T2; however, MV analysis implies that a low MABP (T1), but not high MABP (T3) is a significant predictor of mortality in C19 infection.

PO0072

SIADH with COVID-19-Induced Hemophagocytic Lymphohistiocytosis: A Case Report

Alissar El Chediak, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: The effects of COVID-19 on the body are still being unraveled as we learn more about this disease. Here we report a case of hyponatremia secondary to Syndrome of Inappropriate Antidiuretic Hormone secretion (SIADH) from COVID-19 induced hemophagocytic lymphohistiocytosis (HLH).

Case Description: A 47-year-old female with hypertension was admitted with COVID-19 infection. She had persistent fever, elevated inflammatory markers (ferritin: 6094 ng/ml, C-reactive protein: 217.1 mg/l, LDH 614 unit/L), and liver tests (ALP:275 unit/L, AST 106 unit/L, ALT 196 unit/L) and was thus diagnosed with COVID-19-associated HLH. Patient was treated with dexamethasone with resolution of fever but still had elevated CRP, ferritin, and LDH. She was discharged on a dexamethasone taper but returned just over a week later with malaise, brain-fog, and poor oral intake. Patient was then found to have severe hyponatremia with a serum sodium (Na) of 119 mmol/L and the following lab data: urine osmolality: 503 mOsm/kg, urine Na: 46, serum osmolality: 262 mOsm/Kg. Moreover, she had no edema on exam, nor did she display any signs of orthostatic hypotension. This was consistent with SIADH. Her medication list didn't include any medications that can cause SIADH. No hormonal disturbances were detected. She was given high dose steroids again and Intravenous Immunoglobulin for persistent fever and lack of clinical improvement. Meanwhile, despite treatment with urea and fluid restriction, her Na stayed in the low 120's. The decision was then made to start Interleukin-1 (IL-1) antagonist therapy. 1 day after the Interleukin-1 antagonist therapy was started, sodium started rising again by around 2 meq/day till it normalized.

Discussion: HLH has a wide range of causes including viruses but all can lead to a hyperinflammatory state. SARS-CoV-2 is known to cause a cytokine storm. Cases of COVID-19 associated HLH have been reported. The proposed mechanism of SIADH is related to the surge of interleukins associated with inflammation due to HLH induced COVID-19. Particularly, IL-6 is increased with both HLH and COVID-19. IL-6 can cause the release of ADH by stimulating the hypothalamic-pituitary-adrenal axis. Thus, hyponatremia can be found in patients with COVID-19. One way of addressing that is through Interleukin receptor antagonism. More data is needed to prove the efficacy of that therapy.

PO0073

Prevalence and Outcomes Associated with Hyperuricemia in Hospitalized Patients with COVID-19

Kinsuk Chauhan,[1] Pattharawin Pattharanitima,[1] Federica Piani,[2] Richard J. Johnson,[2] Jaime Uribarri,[1] Lili Chan,[1] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [2]University of Colorado Health, Aurora, CO.*

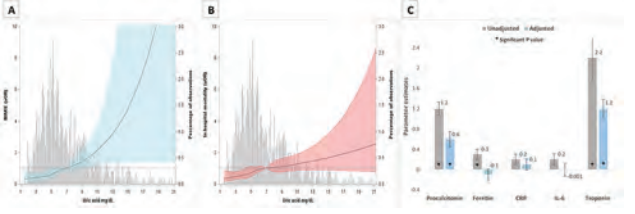
Background: COVID-19 can increase catabolism and result in hyperuricemia. Uric acid (UA) potentially causes kidney damage by alteration of renal autoregulation, inhibition of endothelial cell proliferation, cell apoptosis, activation of the pro-inflammatory cascade, and crystal deposition. Hyperuricemia in patients with COVID-19 may contribute to acute kidney injury and poor outcomes.

Methods: We included 834 patients with COVID-19 who were >18 years old and hospitalized for >24 hours in the Mount Sinai Health System and had at least one measurement of serum UA. We examined the association between the first serum UA level and major adverse kidney events (MAKE, defined by a composite of all-cause in-hospital mortality or RRT or 100% increase in serum creatinine from baseline), as well as markers of inflammation and cardiac injury.

Results: Among the 834 patients, the median age was 66 years, 42% were women, and the median first UA was 5.9 mg/dL (IQR 4.5-8.8). Overall, 52% experienced MAKE, and 32% died during hospitalization. After adjusting for demographics, comorbidities, and laboratory values, a doubling in serum UA was associated with increased MAKE (OR 2.5 per doubling, 95% CI 1.7-3.5) and in-hospital mortality (OR 1.7 per doubling, 95% CI 1.3-2.3) (**Figure A & B**). Serum UA levels were independently associated with a higher level of procalcitonin (β, 0.6; SE 0.2) and troponin (β, 1.2; SE 0.2) but was not associated with the serum ferritin, CRP, or IL-6 (**Figure C**).

Conclusions: In patients admitted to the hospital for COVID-19, higher UA levels were independently associated with MAKE and mortality in a dose-dependent manner. In addition, hyperuricemia was associated with higher procalcitonin and troponin levels.

Funding: Commercial Support - XORTX Therapeutics Inc.



A) & B) Association between serum UA and outcomes, MAKE (A) and in-hospital mortality (B) using restricted cubic spline models and mean serum UA (6.9 mg/dL) as a reference **C)** Association between serum UA and $\log_2$ transformed markers of inflammation and cardiac injury

PO0074

Association of Sodium Abnormalities with Outcomes in Hospitalized Patients with and Without COVID-19

Chetan Potu, Nisha Nataraj, Sandeep K. Mallipattu, Farrukh M. Koraishy, Leonard A. Arbeit. *Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Background: Several reports of serum sodium (Na) abnormalities have been reported in patients hospitalized with COVID-19. However, the association of Na abnormalities with hospital outcomes have not been well-described in patients with COVID-19 (C19 +v. especially in comparison to those who tested negative (C19 -).

Methods: This is a retrospective analysis of the first surge of COVID-19 (C-19) in patients who presented to our ED from December 2019 -June 2020, with a systemic viral illness. There were 5,289 patients from the Covid19 data set, 1,703 COVID+ patients and 3,586 Covid- patients. Based on a nasal swab PCR patients were divided into two groups: C19 + and C19 –. Na levels at the time of hospitalization were used to divide patients into three groups: hyponatremia(hypoN) (<135), normonatremia (normoN)(135-145) and hypernatremia(hyperN)(>145). In C-19 patients, hypoN and hyperN were compared to normoN using multivariable (MV) models adjusting for comorbidities to calculate odds/risk (O/R) ratios for outcomes.

Results: C19 + patients, had significant increased incidence of HypoN (26.7% vs 16.2%;); and HyperN (4.2% vs 1.3%) compared to C19 -ve (Figure 1). Non MV analysis, among C19 + patients, found both HypoN and HyperN were significantly associated with mortality compared to normoN. HypoN (compared to normoN) was also associated with higher admission rate to the ICU, acute respiratory distress syndrome (ARDS), and intubation.(Figure 2a; 2b)

Conclusions: Among patients admitted with acute viral illness, Na abnormalities on admission were more prevalent in patients with COVID-19 + compared to those who tested negative. COVID-19 + patients with abnormal admission Na concentrations had increased mortality when compared to Cov - patients. Covid + patients had increased morbidity measured by admission to the ICU, need for intubation, and ARDS. Abnormalities in sodium metabolism predicts a poorer result in Covid-19 care.

PO0075

Association of Obesity with 3-Month COVID-19-Related Mortality in ESKD Patients

Ekamol Tantisattamo,[1] Céline Imhof,[2] Luuk Hilbrands,[3] Kitty J. Jager,[4] Marlies Noordzij,[2] Priya Vart,[2] Kamyar Kalantar-Zadeh,[1] Ron T. Gansevoort.[2] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, California, United States, Orange, CA; [2]Department of Internal Medicine, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands., Groningen, Netherlands; [3]Department of Nephrology, Radboud University Medical Center, Nijmegen, The Netherlands., Groningen, Netherlands; [4]ERA-EDTA Registry, Department of Medical Informatics, Amsterdam University Medical Center, Amsterdam Public Health Research Institute, Amsterdam Public Health Research Institute, Amsterdam, The Netherlands., Amsterdam, Netherlands.*

Background: In the general population obesity is associated with increased risk of mortality. However, in ESKD patients obesity is associated with lower risk of mortality, particularly in dialysis patients (i.e. the obesity paradox). In COVID-19 patients, obesity exhibits a similar association with mortality as observed in the non-COVID-19 general population. Given the obesity paradox, we questioned the association of obesity with mortality in ESKD patients with COVID-19.

Methods: Data from the European Renal Association COVID-19 Database (ERACODA) were analysed. Association of BMI (kg/m^2), divided into: <18.5 (lean), 18.5-24.9 (normal weight), 25-29.9 (overweight), 30-34.9 (obese I) and ≥35 (obese II), with 3-month mortality was investigated using Cox proportional-hazards regression. Results were investigated for the total population and, dialysis patients and kidney transplant recipients separately.

Results: In 3160 ESKD patients (mean age: 65 years, male: 61%), 99 patients were lean, 1151 normal weight (reference group), 1160 overweight, 525 obese I and 225 obese II. During follow-up of 3 months, 28%, 20%, 21%, 23% and 27% of patients died in the lean, normal weight, overweight, obese I and obese II category, respectively. In fully adjusted model, the HRs for 3-month mortality were 1.65 (95% CI:1.10, 2.47), 1.07 (95% CI:0.89, 1.28), 1.17 (95% CI:0.93, 1.46) and 1.71 (95%CI:1.27, 2.30) in lean, overweight, obese I and obese II vs normal weight patients (Figure). Results were similar among dialysis patients and transplant recipients (p-interaction=0.99).

Conclusions: In ESKD patients with COVID-19, dialysis patients or kidney transplant recipients, obesity is associated with an increased risk of mortality at 3 months. This is contrary to obesity paradox generally observed in dialysis patients. There is need to investigate why in dialysis patients with COVID-19 the survival benefit of obesity is lost.

PO0076

Prevalence and Association of Dysnatremia with Outcomes in Hospitalized COVID-19 Patients

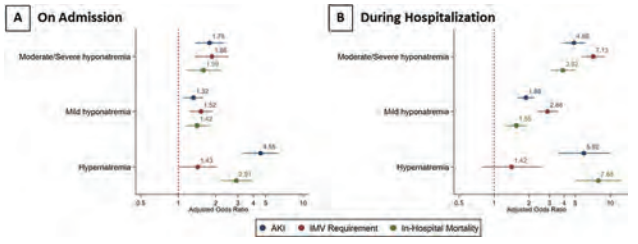
Pattharawin Pattharanitima, Kinsuk Chauhan, Steven G. Coca, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: Studies have reported both hypo and hypernatremia in patients hospitalized with COVID-19. We sought to examine the prevalence and association of dysnatremia with clinical outcomes among hospitalized COVID-19 patients at the Mount Sinai Health System.

Methods: We included 5,712 patients with COVID-19 who were ≥18 years old and hospitalized for ≥24 hours in the Mount Sinai Health System. Patients with ESKD, who received dialysis within the first 24 hours were excluded. We evaluated the association between serum sodium on admission (first level within 24 hours from admission) and the lowest serum sodium during hospitalization with AKI, IMV requirement, and in-hospital mortality using multivariable logistic regression models.

Results: The median age of patients was 67 (55-78) years, 57% were male, and median serum creatinine was 1.0 (IQR, 0.7-1.4) mg/dL. On hospital admission, 6% had moderate/severe hyponatremia (<130 mEq/L), 18% had mild hyponatremia (130-134 mEq/L), and 8% had hypernatremia (>145 mEq/L). After adjustment for demographics, comorbidities, and admission lab values, the adjusted OR for moderate/severe hyponatremia, mild hyponatremia, and hypernatremia on admission, compared to normal serum sodium, for in-hospital mortality were 1.59 (1.16-2.19), 1.42 (1.14-1.76) and 2.91 (2.16-3.93), respectively (**Figure 1A**). Dysnatremias during hospitalization were also associated with all three outcomes, except IMV requirement was not significantly associated with hypernatremia. (**Figure 1B**).

Conclusions: Both hypo- and hypernatremia on hospital admission and during hospitalization for COVID-19 were independently associated with AKI, IMV requirement, and in-hospital mortality. It is highly likely that dysnatremias are a marker for severity of illness and not causal for the adverse outcomes in COVID-19.



Forrest plots of the adjusted OR for AKI, IMV requirement, and in-hospital death among patients in 3 sodium categories on admission (A) and during hospitalization (B)

PO0077

The Role of CKD on Incidence and Morbidity of COVID-19: A One-Year Review in US Veterans

Mariana Garcia-Touza,[1] Elizabeth Cristiano,[1,2] Peter S. Wiegmann,[1] Vikas Singh,[1] Ram Sharma,[1] Mukut Sharma,[1] Virginia J. Savin,[1] Thomas Wiegmann.[1] *[1]Kansas City VA Hospital, Kansas City, MO; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: The Coronavirus disease 2019 (COVID-19) pandemic has greatly impacted the global community. With approximately 15% of the United States (US) population having chronic kidney disease (CKD), it is important to understand how COVID-19 interacts with CKD.

Methods: We used the VA COVID-19 resource data to examine the role of CKD on incidence and morbidity of COVID-19. The database combines standard hospital data, administrative and clinical record search results. CKD is defined in this system as having occurred at any time in the 2 years prior to the COVID-19 test, while new results (incidence) refer to 60 day period after positive test. Patients with chronic kidney failure (CKF2yrs) were excluded. We examined the effect of basic demographics and common risk factors on all-cause mortality, ICU admissions, ventilator use, and dialysis. Statistical analysis (SAS enterprise guide 7.1) used frequency distributions (chi square). The data was limited to the first year of collection.

Results: The population consisted of 1,305,466 veterans. Of these, 235,857 tested positive (18.1%) and 140,143 (11.4%) had CKD. White, male patients aged over 60 years predominated (60.7%, 81.2%, 53.3%). These demographics had no significant effect on COVID-19 incidence. Hypertension (HTN), diabetes mellitus type 2 (DM2), and smoking were taken as risk factors. These were found to have little effect (OR 0.86 – 1.22) while BMI had more weight (1.41). In the positive population CKD was recorded in 28,420 (12%). In these patients, significant differences were associated with CKD, such as higher death rate (OR 4.05), ICU admission and ventilator use when compared to the total population (OR 1.24, 2.88 vs 1.25, 3.13). Need for acute dialysis was disproportionately greater(OR 36.75).

Conclusions: CKD had no effect on incidence of COVID-19. Once present it was associated with higher rates of ICU admission, ventilator use, need for dialysis and all-cause mortality. This calls for increased vigilance in our patients with CKD to prevent COVID-19 infection.

Funding: Veterans Affairs Support

PO0078

Association of the COVID-19 Pandemic with ESKD Incidence

James B. Wetmore,[1,2] Kirsten L. Johansen,[1,2] Jiannong Liu,[2] Yi Peng,[2] David T. Gilbertson,[2] Eric D. Weinhandl.[2] *[1]Hennepin Healthcare, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: How the COVID-19 pandemic altered ESKD incidence, dialysis initiation, and preemptive kidney transplantation is unknown.

Methods: Using Centers for Medicare & Medicaid Services data, we investigated the incidence of ESKD, dialysis initiation, and preemptive kidney transplantation by week during the first half of 2020. Using Poisson regression, we compared findings in 2020 to a forecast of 2020, had 2017-2019 historical trends continued, overall and by strata of age and race.

Results: Mean weekly counts of patients with new ESKD are shown in the **Figure**. Incidence of ESKD dropped dramatically in 2020 compared with the expected incidence, particularly during epidemiologic weeks 15-18 (April; incidence rate ratio [IRR] 0.75, 95% CI 0.73-0.78), before approaching pre-pandemic levels in weeks 23-26 (June; IRR 0.93, 0.90-0.95). Across age groups, the decrease was most pronounced during weeks 15-18 among individuals aged ≥75 years (IRR 0.69, 0.66-0.73, compared with individuals aged 45-64 years, IRR 0.80, 0.77-0.84). In terms of race, the decrease was least notable among non-Hispanic Blacks (IRR 0.85, 0.81-0.89) and was most pronounced in non-Hispanic Whites (IRR 0.72, 0.69-0.74) and Hispanics (IRR 0.73, 0.69-0.78). Dialysis initiation reached a nadir during weeks 15-18 (IRR 0.76, 0.74-0.78), and preemptive kidney transplantation decreased even more strikingly during this period (IRR 0.56, 0.46-0.67).

Conclusions: During the first wave of the COVID-19 pandemic in 2020, the number of patients starting treatment for ESKD fell to a level not observed since 2011. Changes in ESKD incidence and utilization of treatment modalities may reflect differential access to care.

Funding: NIDDK Support

Interim Analysis of the COSA Registry: COVID-19 Patients Treated with the Seraph® 100 Microbind® Affinity Filter

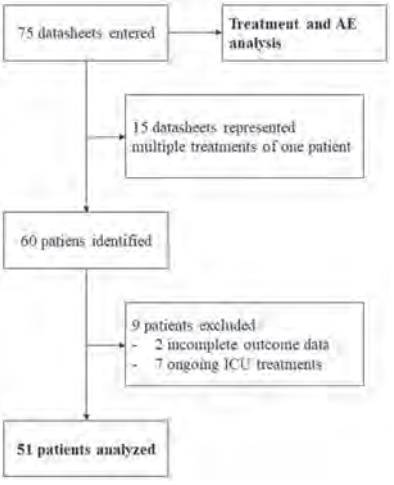
Julius Schmidt,[1] Michael Schmitz,[2] Jan T. Kielstein.[3] *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Stadtisches Klinikum Solingen, Solingen, Germany; [3]Academic Teaching Hospital Braunschweig, Braunschweig, Germany.*

Background: The Seraph®100 Microbind Affinity Blood Filter® is a hemofiltration device that is licensed for pathogen reduction in the blood that received an emergency authorization for the treatment of COVID-19 by the FDA. The aim of this registry was to evaluate safety and efficacy of Seraph 100 treatment for COVID-19 patients.

Methods: This is an online registry in which main patient charcteristics, treatment characteristics and outcome parameters of COVID-19 patients, treated with the Seraph100 can be documented without reimbursement.

Results: Seventy-five treatment sessions in 60 patients from 12 hospitals were documented in the registry (Fig 1). Overall mortality was 42.3%. Adverse events of the Seraph® 100 treatment were reported in 8 (10.6 %) of the 75 treatments. Eight (10.6 %) of all the procedures ended prematurely due to circuit failure. Non-survivor had a higher rate of bacterial superinfection, higher level of inflammatory laboratory markers (procalcitonin and ferritin) and higher d-dimer levels(Fig 2). While predicted mortality according to SOFA score in ICU patients was >80 %, the observed mortality was 47.6 %. In non-ICU patients, 4C score predicted a mortality of 31.4-34.9 % while the observed mortality was 22.2 %.

Conclusions: Seraph 100 treatment was well tolerated and circuit failure rate was significantly lower than reported for KRT in COVID-19 patients. Compared to the calculated mortality, the observed mortality in the registry was lower.



n	51	22	29

COVID-19 and CKD: An Overview of Reviews to Inform the World Health Organization Scientific Brief

Sara S. Jdiaa,[1] Razan Mansour,[2] Abdallah E. Alayli,[2] Archana Gautam,[2] Preston J. Thomas,[2] Reem Mustafa.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]The University of Kansas Health System, Kansas City, KS.*

Background: The World Health organization (WHO) declared COVID-19 as a global pandemic in March of 2020. Many studies have assessed the association between different comorbidities and COVID-19 outcomes. In this overview of reviews, we aim to summarize the association between CKD and different COVID-19 outcomes.

Methods: We performed a systematic search through Embase, PubMed, Epistemonikos, and Cochrane as well as preprint databases from January 1, 2020 to January 5, 2021. After searching systematic reviews, we updated the search by identifying primary studies published after August 2020, which was the date of last search in the reviews. We focused on systematic reviews and large primary studies. We followed the GRADE methodology to assess the certainty in effect estimates. Data was pooled based on random effects model.

Results: We included a total of 69 systematic reviews and 66 primary studies in our overview. We did not identify any systematic reviews that directly reports on CKD and the risk of contracting COVID-19. There was no convincing difference on the risk of acquiring COVID-19 infection in patients with and without CKD in primary studies (OR = 1.00, 95% CI 0.76-1.33). CKD is associated with higher risk of COVID-19 related mortality pooled hazard ratio (HR) 1.48 (95% CI 1.33-1.65) and pooled odds ratio (OR) 1.77 (95% CI 1.54-2.02)(moderate certainty), hospitalization pooled risk ratio (RR) 1.63 (95% CI 1.03-2.58) (moderate certainty) and disease severity pooled RR 1.56 (95% CI 1.3-1.86) (moderate certainty). Notably, the risk of COVID-19 attributed hospitalization and mortality were higher in patients with more advanced CKD stage.

Conclusions: Evidence consistently demonstrated an increased risk of mortality, hospitalization and disease severity in patients with CKD and COVID-19 infection. The results highlight the importance of recognizing patients with CKD as a high-risk group and of prioritizing these patients for COVID-19 prevention strategies including vaccination.

PO0081

Virtual Pediatric Systems: AKI in Pediatric COVID-19 Among North American Intensive Care Units

Rupesh Raina,[1,2] Ronith Chakraborty,[1,2] Siddhartha S. Singh,[1,2] Shefali Mahesh.[2] *[1]Cleveland Clinic, Akron, OH; [2]Akron Children's Hospital, Akron, OH.*

Background: There is a dearth of large-scale studies assessing the extent of Acute Kidney Injury (AKI) in pediatric COVID-19 patients. We aim to identify the epidemiology and associated risk factors of AKI in the pediatric COVID population through the Virtual Pediatric Systems (VPS) database.

Methods: We performed a retrospective analysis on 2,597 COVID-19 pediatric patients (≤ 24 years) in the VPS COVID-19 database including both males and females with a positive status of SARS-CoV-2 infection, ICU admission, and AKI diagnosis for the AKI group using ICD-10 codes. Variables included in the analyses covered demographics, diagnosis, lab order/results, treatment modalities, length of stay, and mortality. Categorical variables were summarized as percentages while continuous variables as medians. We utilized univariate analysis and multivariate linear regression to assess the differences between the patient group with AKI and those without.

Results: An AKI incidence of 10.7% (297/2597) was found within the pediatric cohort. The AKI group had a significantly higher median hospital length of stay (9.1 days vs. 5.1), PIM2 and PIM3 probability of death (1.2 vs. 0.96 and 0.99 vs. 0.78, respectively), and proportion of mortality (7.5% vs. 1.6%) in comparison to the non-AKI group. Similarly, the AKI group experienced higher rates of interventions in comparison to the non-AKI group such as vascular access (67.0% vs. 29.8%), airway/respiratory support (55.9% vs. 43.8%), renal support (5.4% vs. 0.4%), and cardio-respiratory support (2.9% vs. 0.8%).

Conclusions: AKI is a severe complication of COVID-19 in children and adolescents. Our study suggests a 4.7-fold increase in mortality in the COVID-19 AKI group. Pediatric COVID-19 patients should be monitored for AKI development and necessitate analyses on manifestations of COVID-19 to improve health outcomes.

PO0082

Changes in Timing and Preparedness for Dialysis Initiation in the Era of COVID-19

James B. Wetmore,[1,2] Kirsten L. Johansen,[1,2] Yi Peng,[2] Jiannong Liu,[2] David T. Gilbertson,[2] Eric D. Weinhandl.[2] *[1]Hennepin Healthcare, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: How the COVID-19 pandemic altered aspects of dialysis initiation, such as eGFR at initiation, selection of peritoneal dialysis (PD), and, in patients initiating hemodialysis (HD), use of a central venous catheter (CVC), is not fully understood.

Methods: We analyzed the most recently updated quarterly USRDS data available. Using Poisson and logistic regression, we studied weekly changes in eGFR at dialysis initiation, use of PD (versus HD), and use of incident CVCs, overall and by strata of race, during the first half of 2020 compared to a forecast of 2020, had 2017-2019 historical trends continued.

Results: Mean eGFR at dialysis initiation decreased by 0.33 mL/min/1.73 m^2 in weeks 19-22, compared with historical trends; non-Hispanic Black patients exhibited the largest decrease, at 0.61 mL/min/1.73 m^2. The odds of initiating dialysis with eGFR <10 ml/min/1.73m^2 were highest during weeks 19-22 (May; OR 1.14, 1.05-1.17), corresponding to an absolute increase of 2.9%. Although initiation of both HD and PD fell, PD fell less, such that the odds of initiating PD (versus HD) were 24% higher (OR 1.24, 1.14-1.34) in weeks 11-14. Odds of initiating HD with a CVC increased by 30% (OR 1.30, 1.20-1.41) in weeks 15-18, representing an absolute increase of 3.3%.

Conclusions: In the first half of 2020, eGFR at dialysis initiation fell, most prominently in non-Hispanic Blacks. During the initial wave of the pandemic, odds of utilizing PD, compared with HD, increased by nearly 25%, and odds of using a CVC at HD initiation increased by 30%.

An ISN-DOPPS Survey of the Global Impact of the COVID-19 Pandemic on In-Centre Haemodialysis Services

Ryan E. Aylward,[1,2] Brian Bieber,[3] Murilo H. Guedes,[5] Ronald L. Pisoni,[3] Elliot K. Tannor,[6] Gavin Dreyer,[7] Adrian Liew,[8] Valerie A. Luyckx,[4,2] Dibya Singh Shah,[9] Chimota T. Phiri,[10] Rhys D. Evans,[11] Vivekanand Jha,[12,13] Roberto Pecoits-Filho,[3] Bruce M. Robinson,[3] Fergus Caskey.[1] ISN DOPPS collaboration *[1]University of Bristol Medical School, Bristol, United Kingdom; [2]University of Cape Town, Rondebosch, South Africa; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Brigham and Women's Hospital, Boston, MA; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [7]Barts Health NHS Trust, London, United Kingdom; [8]Mount Elizabeth Medical Centre, Singapore, Singapore; [9]Tribhuvan University Teaching Hospital, Kathmandu, Nepal; [10]Queen Elizabeth Central Hospital, Blantyre, Malawi; [11]The University of British Columbia, Vancouver, BC, Canada; [12]The George Institute for Global Health, New Delhi, India; [13]Imperial College London, London, United Kingdom.*

Background: Haemodialysis units (HDUs) have had to rapidly adapt practices and policies to safely continue life-sustaining HD services during the COVID-19 pandemic. We aimed to describe the impact of COVID-19 in different parts of the world.

Methods: The Dialysis Outcomes and Practice Patterns Study (DOPPS) and International Society of Nephrology (ISN) collaborated to web-survey individual HDUs. Responses were obtained in three ways: (1) a survey of DOPPS sites in China (May/ June 2020), (2) a random sample (20 units if > 40 units/ country; all units if < 40) stratified by region and HDU census (November 2020 – March 2021), and (3) an open invitation via ISN's membership list and social media (March 2021). Responses were compared between the ten ISN regions.

Results: There were returns from 412 HDUs (46% public sector, 79% urban; 70% adult, 2% paediatric, 28% adult & paediatric) from 78 countries (9% low-, 24% lower-middle-, 28% upper-middle-, 39% high-income).

Conclusions: The COVID-19 pandemic has had a significant impact on dialysis services and staffing worldwide. Differences in uptake of policies and practices across regions have likely been because of variable access to resources to enable implementation of diagnostic testing algorithms and adequate supply of PPE to implement infection prevention and control recommendations. Guidance should be consistent, adaptable to (nearly) all situations and locations, and evidence based. Going forward, the operationalisation of vaccine programs should be incorporated into guidelines. Disruptions to dialysis services should be minimised, and resource provision (including vaccines) prioritised by policymakers and governments in future waves of COVID-19 and pandemics if we are to protect HD patients, staff, and services.

Dialysis facility COVID-19 related resources, practices, and outcomes, as reported unit manager at each participating site

PO0084

The New Era of COVID-19: The Rise of Telehealth, Trends to Home Dialysis, and the "New Normal"

Tucker B. Hurtado, Charisse Pearson-Bey, Jennifer Robinson. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: The objective of this study was to evaluate the impact of the COVID-19 pandemic to help conceptualize how patient care delivery, pharmaceutical representative interactions, conferences, and dialysis care may evolve.

Methods: Data was conducted between March 20, 2020 - March 31, 2021, providing coverage on the quickly evolving COVID-19 outbreak via online surveys. 50 nephrologists, neurologists, dermatologists, rheumatologists and gastroenterologists participated in each wave (total 250+) for 16 waves of research.

Results: Practice operation dynamics have changed due to the COVID-19 pandemic. Prior to 2020, 10% of practices were offering telemedicine, now nearly all (90%) offer virtual services. This migration has not come without challenges: 36% of physicians would prefer not to do telemedicine due to issues with patient access (60%), technology (53%) and their own reluctance to conduct new patient visits virtually (44%). The pandemic has created a high burnout among nephrologists compared to other specialties and nearly 20% would reevaluate their career choice if they could go back. Along with patient care, sales representative interactions have declined due to closed-door policies, with 51% of physicians reporting substantially lower or no engagements (virtual or in-person) compared to pre-COVID. Physicians are looking forward to resuming traditional in-person conferences, with 61% of vaccinated physicians planning to attend in-person if the option is available. COVID-19 has also significantly impacted HD patient care, with 66% of nephrologists reporting an outbreak among HD patients and/or staff. However, despite the obvious advantages of home care during the pandemic, only 34% of nephrologists indicated they were more likely to start a patient on a home modality due to the pandemic in March 2021 – versus 30% in March 2020. Despite their hesitancy, 80% of physicians agree the use of telemedicine will continue after the COVID-19 crisis has passed and estimate that ~20% of weekly visits will be virtual.

Conclusions: The pandemic has changed the delivery of patient care, evolving towards a more virtual model where possible – potentially creating physician burn out and interfering with the physician-patient relationship. The focus is now on the "new normal" post-COVID and the ongoing changes that will have on physicians.

PO0085

Analysis of the COVID-19 Pandemic in Home and In-Center Dialysis Populations

Alhaji Cherif,[1] Yuedong Wang,[2] Rachel Lasky,[3] Joanna Willetts,[3] Len A. Usvyat,[3] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]University of California Santa Barbara, Santa Barbara, CA; [3]Fresenius Medical Care North America, Waltham, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: While dialysis patients have a high risk of complications from COVID-19, in-center hemodialysis (ICHD) patients show lower SARS-CoV-2 reproduction rates when compared to the general population (Cherif, JASN 2021), possibly related to lifestyle and interventions to prevent SARS-CoV-2 spread. Here we expand the research to study the prevalence of COVID-19 in both home (PD/HHD) and ICHD patients.

Methods: We analyzed COVID-19 cases in PD/HHD and ICHD patients from the U.S. Fresenius Kidney Care (FKC) network, from March 1 to November 27, 2020. Patients were tested for SARS-CoV-2 (confirmed by RT-PCR) when showing signs compatible with COVID-19 or exposed to an infected person. We perform statistical analysis for inter-/intra-modalities, with continuous and categorical variables being expressed as the mean (standard deviation) and absolute (relative, %), respectively.

Results: We studied 263,223 patients (age 62.8±14.5 years, 57.7% males) receiving dialysis in the FKC network (87.3% ICHD; 12.7% PD/HHD). In the FKC network, 21,175 (8.05%) were infected with SARS-CoV-2. COVID-19 infection was more prevalent among ICHD (8.56%) vs. PD/HHD (4.49%) patients. Black had a significantly higher risk than other races for both ICHD (9.10%, $p < 0.0001$) and PD/HHD (5.13%, $p = 0.0038$), without a difference between modalities ($p = 0.1827$). While white ICHD patients did not have a different risk compared to others (8.52%, $p = 0.4105$), they had

a smaller risk when dialyzed at home PD/HHD (3.82%, $p < 0.0001$), and the difference between ICHD and PD/HHD was significant ($p < 0.0001$). Similar results are shown for other patients (**Tab.1**).

Conclusions: COVID-19 infection was more common among ICHD patients. To what extent this is related to lifestyle, travel to dialysis facilities or other aspects warrants further analyses.

Funding: NIDDK Support

Table 1: Demographics of hemodialysis patients with confirmed COVID-19 on November 27, 2020. The patients received ICHD and PD/HHD in the U.S. Fresenius Kidney Care network.

Perception of COVID-19 Risk Among In-Center Hemodialysis Patients

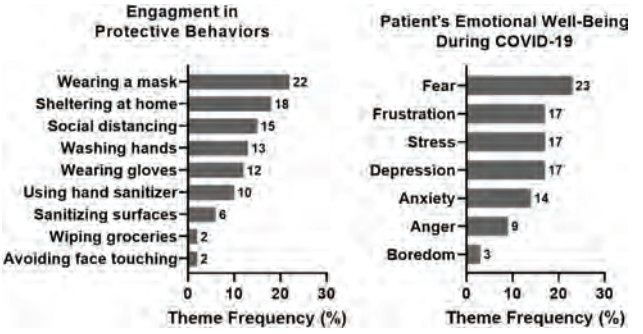
Ania Filus, Carlos G. Garcia Gonzalez, Steven M. Brunelli, Karen-Marie Eaton, Francesca Tentori. *Davita Clinical Research, Minneapolis, MN.*

Background: Dialysis patients are at high risk for severe complications related to COVID-19. The present study examined perception of risk of COVID-19 and its impact on behavior modification and emotional well-being among in-center hemodialysis (ICHD) patients during the recent COVID-19 pandemic.

Methods: In-depth, semi-structured telephone interviews were conducted between May and July 2020 with adult ICHD patients dialyzing at a large dialysis organization (LDO). Responses were analyzed using inductive thematic analysis. The reliability of categories was examined by an independent coder.

Results: A total of 41 LDO patients were interviewed. The median age was 63 years and 54% were female. Satisfactory inter-rater reliability was achieved for all identified themes (kappa = 0.70 - 0.99). We found that the COVID-19 pandemic caused a high level of worry among ICHD study subjects; 78% of those interviewed felt that they are at high risk of COVID-19. Consequently, subjects reported a high level of compliance with appropriate protective behaviors during the pandemic, such as wearing a mask, sheltering at home, social distancing, and frequent handwashing. The perception of the actual likelihood of contracting the virus during a hemodialysis session was relatively low ($M = 3.38$ on a 0 to 10 risk scale). The pandemic had no impact on self-reported adherence to dialysis treatment schedules, medications, or diet. However, subjects reported dominating emotions of frustration, fear, stress, depression, and anxiety.

Conclusions: The study subjects were aware of the risk of COVID-19 and seemingly increased compliance with protective behaviors as a consequence. It appears that the pandemic had a strong negative impact on the study subjects' emotional well-being and that additional support in this area might be beneficial.



PO0087

Feasibility of Infection Control Measures in Hemodialysis Units to Prevent Outbreaks of COVID-19: A Descriptive Study from Quebec

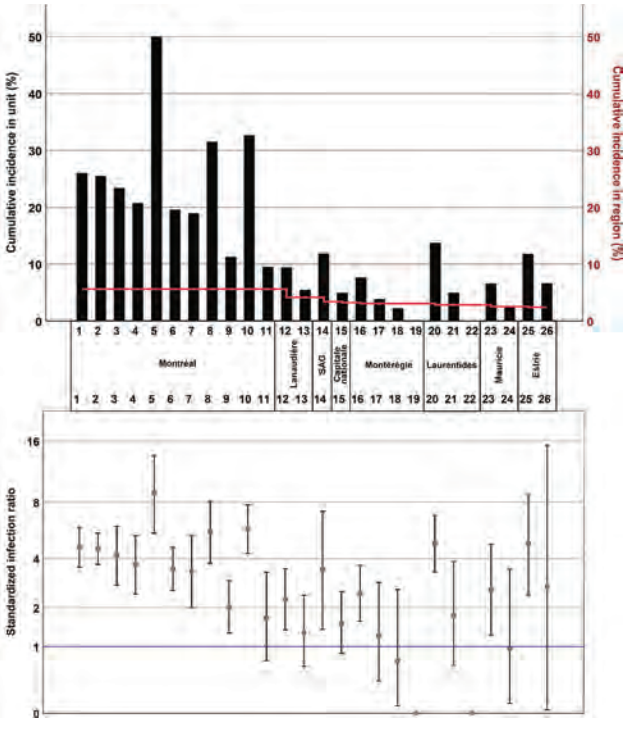
William Beaubien-Souligny,[1] Annie-Claire Nadeau-Fredette,[2] Marie-Noël Nguyen,[1] Norka Rios,[3] Marie-Line Caron,[1] Alexander Tom,[3] Rita Suri.[3,4] Quebec Renal Network *[1]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]Research Institute of the McGill University Health Centre, Montreal, QC, Canada; [4]McGill University, Montreal, QC, Canada.*

Background: In-center hemodialysis (HD) units pose the perfect conditions for COVID-19 transmission yet limited space and resources are obstacles to infection prevention and control (IPAC) measures. We aimed to describe IPAC measures implemented and document the infection rates within HD units during the first year of the pandemic.

Methods: We invited leaders of Quebec's HD units to collect information on IPAC measures from March 1st to June 30th 2020 and HD unit characteristics. Participating units were contacted again in March 2021 to collect information about the total number of cases. The cumulative infection rate of each unit was compared to the regional cumulative infection rate using a standardized infection ratio (SIR).

Results: Data was obtained from 38 units, representing 90% of Quebec's HD patients. 30% of units were perceived as crowded, and this was associated with objective distance measures between stations, which was much more likely to be <2m in units considered crowded (83.3% vs 19.2% $p<0.001$). IPAC measures regarding general prevention, screening procedures, physical distancing, and PPE use were implemented in 50% of units by 3 weeks and the remainder by 6 weeks. Data on cumulative infection rate was obtained in 26 units providing care to 3942 patients. The cumulative infection rate was disproportionally elevated in HD units compared to regional rates (Median SIR:2.68 IQR:1.58; 4.45)(Figure 1). No difference was noted in the SIR related to specific IPAC measures or to the physical characteristics of the units.

Conclusions: Hemodialysis units throughout Quebec were able to rapidly implement modified IPAC measures. Despite this, infection rates were disproportionally elevated.



PO0088

Safety and Efficacy of the Anti-COVID-19 Vaccination Practiced During the Hemodialysis Session

Gianmarco Lugli,[1,2] Giuseppe L. Spatoliatore,[2] Andrea Batazzi,[1,2] Silvia Pilo,[1,2] Alberto Rosati.[2] *[1]Universita degli Studi di Firenze, Firenze, Italy; [2]Ospedale San Giovanni di Dio, Firenze, Italy.*

Background: CKD patients represent a population at high risk of mortality from Covid-19. For 3 years, our hospital has been running a complete intradyalitic vaccination project (HBV, Hemophylus, Pneumococcus, Influenza) for hemodialysis patients during dialysis treatment. This study aims to evaluate the safety and the serological response of intradialysis anti-Covid19 vaccination.

Methods: 217 hemodialysis patients from 5 centers were vaccinated with Moderna (Fig. 1). Patients with a previous infection received only one dose. 10 patients (4.6%) refused the treatment. The administration took place one hour after the start of the dialysis session, and therefore with the session still in progress. 44 vaccinated patients, with no history of previous Covid19 infection, out of a total 80 dialysis patients, were selected on voluntary basis, in our HD-center, to measure and titrate the anti-RBD S1 antibodies of the virus spike antigen 14 days after the second dose.

Results: Of the 217 patients, 64.3% were male, with a mean age of 70 ± 14 years. 19 patients (8.7%) had mild adverse reactions at site of vaccine-inoculation. Neither serious adverse events nor intradialytic complications were recorded. Table 1 shows the characteristics of the 44 patients whose antibody titration was performed. Seroconversion was achieved in 41 patients (93.18%), anti-RBD S1 titer was 936,6 ± 661,7 UI/mL.

Conclusions: Our preliminary data form our study shows that intradialytic vaccination for Covid-19 is safe and effective and solves logistic problems in prophylaxis's management. This approach should be preferred in hemodialysis patients. We are planning to extend anti-RBD S1 antibodies monitoring of the Sars-Cov2 virus in all HD Centers involved in the study and to include Peritoneal Dialysis' patients.

PO0089

Assessing the Impact of a Renal Care Management Program on Disease Progression Prior to and During the COVID-19 Pandemic

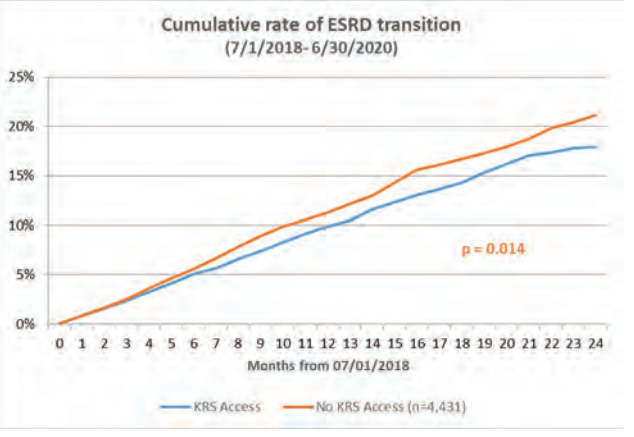
Ashley Crossman, Kevin Plosser, Rahul Dhawan, Wade M. Bannister. Optum Kidney Resource Services Team *Optum Inc, Eden Prairie, MN.*

Background: The transition to dialysis among chronic kidney disease (CKD) patients marks a significant change in health accompanied by increases in morbidity and health care costs. Delaying this transition means extending the patient's quality of life and cost savings. The effects of renal care management on the transition to dialysis and whether having access to the program impacts the risk of transitioning to dialysis as well as the timeline of transitioning to dialysis is necessary to study given the increased role of case management programs with the advent of the COVID-19 pandemic. Understanding the role of disease management programs provide direction for management programs across the globe

Methods: The design is a retrospective, cohort study of patients in the US drawn from a national claims database who were identified as having CKD 4 or 5 on July 1, 2018. The data was analyzed to determine whether program access affected the rate of transition to dialysis and the likelihood of transitioning to dialysis from 2018 to 2020.

Results: We followed the cohort of 7,992 participants (3,561 with access to Kidney Resource Services and 4,431 without access to Kidney Resource Services) during a two year period from 2018 to 2020. Those with access to Kidney Resource Services transitioned to dialysis later than those without access to the program. Further, after controlling for patient risk and characteristics, patients with access to the program had a 22 percent reduced risk of initiating dialysis compared to those without access.

Conclusions: Patients with stage 4 or 5 CKD who have access to renal care management have a reduced risk of transitioning to dialysis as well as a later transition to dialysis compared to CKD patients without access to renal care management. Further research is needed given the increased need for education during and post the COVID-19 pandemic to address social and clinical determinants of health.



PO0090

Stigma Syndemics and ESKD in Disenfranchised Urban Communities Fighting COVID-19

Insa M. Schmidt,[1] Lauren D. Stern,[1] Margaret Farr,[2] Nicole H. Nguyen,[2] Sushrut S. Waikar,[1] Merav Shohet.[2] *[1]Boston Medical Center, Boston, MA; [2]Boston University, Boston, MA.*

Background: Although COVID-19 is impacting all communities, the distribution of its harms is not equal. Poor, urban people of color with compromised health are particularly hard-hit. This study explores how patients with end-stage kidney disease (ESKD), living in underprivileged urban communities, manage their illness and treatment experiences and disease-associated stigmas in the face of COVID-19.

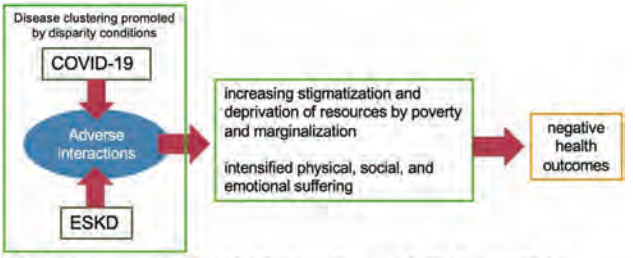
Methods: We used purposive sampling to enroll patients with ESKD at a safety net hospital in Boston, MA. 12 remote ethnographic interviews were conducted from December 2020 to June 2021. Interviews were recorded and transcribed, and data were analyzed using grounded theory and dimensional narrative analysis. We identified dominant themes reflecting the biosocial harms caused by ESKD as well as patients' sense of isolation and stigmatization before and during the COVID-19 pandemic.

Results: The mean age of patients was 56±14 years, 50% were female, and 90% self-identified as Black. Almost all patients reported adverse effects from dialysis treatment which leaves them depleted and precludes them from working. Facing the biosocial implications of dialysis, patients also experienced severe economic hardship which has been intensified by the COVID-19 pandemic. While many patients framed COVID-19 as "just one more thing" and denied increased stigmatization by others due to their potentially increased susceptibility to infection, male patients more frequently reported experiencing racial stigmatization and narrated it as contributing to and exacerbating their chronic illness and suffering.

Conclusions: Biosocial and environmental factors as well as institutional racism and stigmatization play significant roles in amplifying the burden of ESKD in patients of color who are now syndemically impacted by COVID-19 (Figure 1). A better understanding of

how these factors interplay will help to inform policy makers in alleviating tensions and structural conditions that impinge on patients' well-being and health outcomes.

Funding: Private Foundation Support



Model of stigma syndemics. Modified from Singer et al. (The Lancet, 2017).

PO0091

COVID-19 Vaccine Hesitancy and Uptake Amongst a Multiethnic Hemodialysis Population

Andrea Cove-smith, Sujanita Thyagarajan, Kieran Mccafferty, Suzanne H. Forbes, Heidy Hendra, Natasha P. O'Sullivan. *Barts Health NHS Trust, London, United Kingdom.*

Background: Broad adoption of vaccination against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is key to fighting the spread of Covid-19. Hemodialysis patients are at increased risk of exposure to SARS-CoV2 and associated with high morbidity and mortality if they contract Covid-19, therefore attaining high vaccination rates in dialysis patients is of utmost importance. The aim of this study was to establish the prevalence of vaccine hesitance across the multi-ethnic population of dialysis patients in North East London, and to assess whether vaccine uptake could be improved by offering vaccination in a familiar setting by trusted healthcare professionals.

Methods: Prior to the initiation of the hemodialysis vaccine programme, a survey was conducted of 837 in-centre haemodialysis patients to identify those willing to accept the vaccine. The vaccine was then offered to all haemodialysis patients during their dialysis attendance, by their dialysis team of nurses and nephrologists.

Results: Of 674 responses, 476 (71%) patients reported willingness to accept the vaccine. However only 41% of the 232 patients of Black ethnicity stated that they would accept the vaccine with 59% undecided or declined, compared to acceptance of 77% and 82% of the Asian and White patients respectively ($p<0.0001$). The actual acceptance rate was significantly higher in all ethnic groups than that predicted by the survey (82.2% uptake in total), with 71.5%, 86.0% and 89.3% in Black, Asian and White cohorts respectively ($p<0.0001$). In total, 59.1% of patients who responded 'no' in the initial survey, accepted the vaccine when offered on the unit.

Conclusions: Though vaccine hesitancy remains a concern, even in this particularly vulnerable patient group, our data show that uptake can be improved by offering Covid-19 vaccination in a familiar environment by a trusted healthcare team.

PO0092

Navigating Vaccine Hesitancy in a Hemodialysis Clinic

Kathleen Murphy,[1] Jean Lee,[2] Lauren Zanikos,[1] Lori L. Widenr,[1] Leonor V. Pareja,[1] Louise Enderle,[1] Christina Petyo,[1] Evetta C. Frazier,[1] Marie Clerge,[1] Othello Kwaidah,[2] Ziauddin Ahmed,[2] Crystal A. Gadegbeku,[2] Avrum Gillespie.[2] *[1]Dialysis Clinic Inc, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Background: Pre-vaccination, SARS-CoV2 infected 20% of our hemodialysis clinic with a 48% mortality. Vaccine access and hesitancy are significant barriers to vaccination among minority groups. Over 90% of our patients self-report as Black or African American, thus we created a multidisciplinary vaccine navigation program to optimize COVID-19 vaccination.

Methods: We surveyed the patients' vaccination attitudes before the vaccine was available. All care team members: patient care technicians, nurses, social worker, dieticians, and nephrologists were educated to provide the patients with the efficacy and safety of the vaccine. Our affiliate hospital had an mRNA vaccine clinic.

Results: Over 60% responded to the survey, 18% said they would decline vaccination and 39% were unsure. Figure 1 shows the growth of the percentage of patients receiving one and two doses of the vaccine. The first patient received a dose on 1/9/2021. On 1/28/21, the hospital vaccine clinic invited dialysis patients who used the hospital's services. On 2/4/21, we provided the hospital a complete list of patients. On 2/11/21, a vaccine hotline was implemented and a renal dietician became the dialysis clinic's vaccine navigator scheduling and tracking patients' vaccine appointments, avoiding conflicts with their dialysis times and coordinating transportation. Nurses documented vaccinations. A spreadsheet was emailed weekly to team members to track vaccinations and to remind patients of vaccine appointments. All of the staff discussed vaccination with patients who were hesitant or declining the vaccine. By 5/4/21, 89% of the patients had received at least one dose, 79% had received two doses.

Conclusions: Although many patients had vaccine hesitancy, the growth curves show the rapid adoption of the vaccine. The main barrier to the vaccine was access. Multidisciplinary care in the hemodialysis clinic can facilitate access to care and may be a model for navigating kidney transplantation.

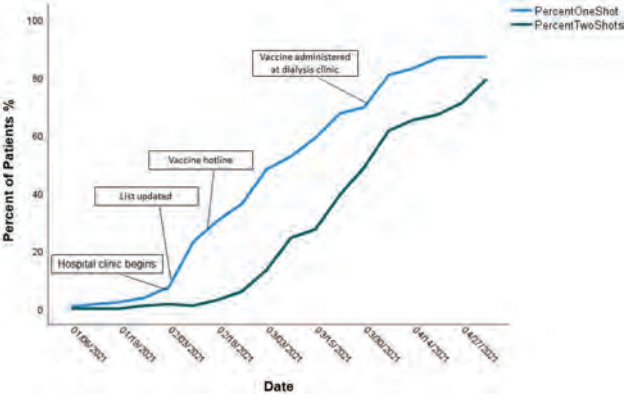


Figure 1

PO0093

Disparities in CKD Risks: Data from the CURE-CKD COVID-19 Sub-Registry

Susanne B. Nicholas,[1] Robert W. Follett,[1] Theona T. Tacorda,[1] Xiaoyan Wang,[1] Dennis Ruenger,[1] Panayiotis Petousis,[1] Bing Zhu,[1] Tyler A. Davis,[1] Davina J. Zamanzadeh,[1] Kenn B. Daratha,[2] Cami R. Jones,[2] Keith C. Norris,[1] Katherine R. Tuttle,[2] Alex Bui.[1] CURE-CKD *[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]Providence St Joseph Health, Spokane, WA.*

Background: The SARS-CoV-2 pandemic accelerated health disparities in chronic kidney disease (CKD). Here, we describe risk factors and access to care surrogates (area deprivation index-ADI) for clinical outcomes among SARS-CoV-2-tested patients in the CURE-CKD Registry.

Methods: We formed a COVID-19 Sub-Registry within CURE-CKD (1/1-6/30/2021; N=171,988) of patients with CKD, diabetes (DM)/pre-DM, or hypertension (HTN) with SARS-CoV-2 testing at UCLA Health (UCLA; N=17,884) and Providence St. Joseph Health (PSJH; N=154,104). Statistical analyses and fitted multivariable logistic regression models were adjusted for age and sex. The UCLA cohort included analyses for acute kidney injury (AKI), ADI (for poor housing, education, income), Charlson Comorbidity Index (CCI), and severe COVID-19 disease.

Results: Odds ratios (OR) of COVID-19 positivity for the combined UCLA + PSJH population, as well as OR of having severe COVID-19 disease in the UCLA cohort are presented (**Table**). OR[95%CI] for AKI were higher for ages ≥80 years (1.77[1.14-2.46]), ADI by state (1.12[1.06-1.18]), CKD (12.20[8.46-17.58]) and pre-existing DM (3.65[2.62-5.08]), $p<0.001$. In the UCLA CURE-CKD population, AKI was associated with severe COVID-19 ($r=0.26$) and ICU admissions ($r=0.29$). Mortality was associated with severe COVID-19 disease ($r=0.5$).

Conclusions: Non-White and/or LatinX race/ethnicity, ADI, CKD, DM, and older age were associated with higher risks of COVID-19 positivity, disease severity, and mortality in CURE-CKD. Efforts on viral screening, timely COVID-19 diagnosis, and optimal care delivery for patients with or at-risk for CKD are needed.

Funding: Private Foundation Support

Table: Results from the CURE-CKD COVID-19 Sub-Registry

		Odds Ratio (95% CI)	p-value
UCLA + PSJH Populations: Risk factors for COVID-19 Positivity			
Sex	Female vs. Male	0.85 (0.82-0.89)	<0.0001
Age (years)	>=80 vs. <60	1.42 (1.33-1.52)	<0.0001
	>=80 vs. 60-79	1.40 (1.31-1.50)	<0.0001
Race/ ethnicity	Latin vs. Non-LatinX	3.95 (3.69-4.22)	<0.0001
	Black vs. White	1.99 (1.84-2.16)	<0.0001
	Asian vs. White	2.03 (1.88-2.18)	<0.0001
	Hawaiian/Pacific Islander vs. White	2.33 (1.97-2.76)	<0.0001
Pre-existing	DM	1.08 (1.03-1.13)	0.003
	HTN	0.84 (0.80-0.88)	<0.0001
UCLA Health population: Risk factors for severe COVID-19			
Pre-existing conditions	CKD	3.71 (2.06-6.66)	<0.0001
	Myocardial infarction	3.55 (2.01-6.24)	<0.0001
	Pre-DM	0.33 (0.15-0.74)	0.007

PO0094

Beliefs About and Impact of the COVID-19 Pandemic on a Population of Inner City Kidney Transplant Recipients (KTRs)

Sae Morita, Galina Udod, Michael A. Goldberg, Stefan Hamaway, Perry A. Kerner, Ryan Harrington, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: The COVID-19 pandemic was especially stressful for indigent people with multiple health conditions. We examined beliefs and behaviors at the height of the pandemic in a population of inner-city KTRs.

Methods: 40 KTRs followed at our Center were surveyed by telephone including questions about behaviors, knowlege and attitudes regarding COVID-19 using yes/no or Likert scale answers as well as the Stress and Social Suppory and Health Beliefs Questionnaires.

Results: Mean age was 57±1.8yrs, with 22 males and 18 females, 27 (77%) Black, (4) White 11% and 8 (23%) other. Time since transplant 7.75±1.07yrs. 35% (9/26) felt difficulties were piling up so high that they could not overcome them.13% (4/31) reported it was more difficult to pay for medications and were more likely to skip doses to make them last longer (r=0.473, p=0.008). 75% (23) were afraid of COVID-19. 51% (17/33) were afraid of catching it from a family member, 54% (18) from a friend, 84% (26) limited any in person interactions, 44% (19) avoided leaving home for any reason and 45% (15) avoided going to any public spaces. Pts who reported being more afraid of COVID-19 were more likely to report poor health (r=-0.39, p=0.032), to report being afraid to leave their home (r=0.48, p=0.006), were more likely to have contacted their provider more than 4-6 times in the past two months (p=0.034), to state that their health was poor (r=-0.39, p=0.032), and to say that their condition keeps them from working (r=0.52, p=0.027). They also believed that eating Chinese food could increase COVID-19 risk (r=0.37, p=0.039).

Conclusions: In our population of inner-City KTRs: 1. Two thirds were afraid of COVID-19, including catching itfrom a friend or family member, and limited leaving their home. 3. They were also more likely to report poor health. contact their healthcare provider multiple times, as well as state their condition made it impossible to work and believe that one could catch COVID-19 from Chinese food. 4. Over 10% were financially stressed and skipped doses of medication to make them last longer and a third felt it difficult to cope overall. 5. Follow up will be necessary as the pandemic subsides to examine if there was a detrimental effect on graft survival due to multiple stressors that could affect adherence in this population.

PO0095

Barriers and Facilitators to Emotional Well-Being and Healthcare Engagement in COVID-19: A Qualitative Study Among Patients with Kidney Disease and Their Caregivers

Jia Hwei Ng,[1] Candice Halinski,[1] Devika Nair,[2] Michael A. Diefenbach.[1] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Vanderbilt University Department of Medicine, Nashville, TN.*

Background: Patients with chronic kidney disease (CKD) have disproportionately faced poor health outcomes during the coronavirus disease-19 (COVID-19) pandemic. Barriers and facilitators to patients' and caregivers' emotional well-being and healthcare engagement have not been deeply described, leaving a gap in interventions during future crisis settings.

Methods: We conducted a qualitative study among patients with CKD (stages 4-5), kidney failure, kidney transplantation, and their caregivers. Interviews were guided by Leventhal's Model of Self-Regulation that emphasized individual interpretations and emotional responses to health threats as determining factors of health behaviors. Interviews were audio-taped, transcribed, and analyzed thematically.

Results: Twenty-eight patients (median age 63, self-reported race: White 57%, Black 18%, Asian 1%, others 14%) and 14 caregivers were interviewed over six months. Barriers and facilitators related to patients' emotional well-being included 1) negative emotional responses (feelings of increased vulnerability, anxiety, social isolation, and depression); 2) coping behaviors (adaptive coping via self-preservation and emotion regulation; maladaptive coping via alcohol and unhealthy eating); 3) and the need for caregiver support for daily tasks. Barriers and facilitators to healthcare engagement included: 1) continued trust in the medical community (*" I put my faith in [my doctor's] knowledge"*); and 2) technology (telehealth was a facilitator to access for some but inadequate for multidisciplinary care *"[my] transplant evaluation was stopped…we could not go to the cardiologist")*. Caregivers reported higher burden compared to before the pandemic.

Conclusions: Patients and caregivers widely reported negative emotional reactions to enforced pandemic-related social isolation. Coping efforts were partially successful. Telehealth provided adequate access to kidney health services for some but was insufficient for those requiring multidisciplinary care. Lessons learned from the COVID-19 pandemic suggest that patients with kidney disease may benefit from psychosocial and multi-modal structural support to offset social isolation, reduce caregiver burden, and bolster access to multidisciplinary care during future crisis settings.

PO0096

Three-Month Clinical, Functional, and Mental Outcomes in Kidney Transplant Recipients Surviving COVID-19

Raphael Duivenvoorden,[1] Priya Vart,[2] Marlies Noordzij,[2] Augusto Cesar Soares dos Santos Jr,[3] Alex B. Zulkarnaev,[4] Casper F. Franssen,[2] Dirk R. Kuypers,[5] Erol Demir,[6] Hormat Rahimzadeh,[14] Julia Kerschbaum,[7] Kitty J. Jager,[12] Kultigin Turkmen,[11] Marc H. Hemmelder,[10] Marcel Schouten,[9] María L. Rodríguez-Ferrero,[13] Marta Crespo,[8] Ron T. Gansevoort,[2] Luuk Hilbrands.[1] *[1]Radboudumc, Nijmegen, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Hospital das Clinicas at Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [4]Moskovskij oblastnoj naucno-issledovatel'skij kliniceskij institut imeni M F Vladimirskogo, Moskva, Russian Federation; [5]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [6]Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey; [7]Medizinische Universitat Innsbruck Universitatsklinik fur Innere Medizin IV Nephrologie und Hypertensiologie, Innsbruck, Austria; [8]Hospital del Mar, Barcelona, Spain; [9]Tergooi, Hilversum, Netherlands; [10]Universiteit Maastricht, Maastricht, Netherlands; [11]Necmettin Erbakan Universitesi Meram Tip Fakultesi, Meram, Turkey; [12]Amsterdam Universitair Medische Centra, Duivendrecht, Netherlands; [13]Hospital General Universitario Gregorio Maranon, Madrid, Spain; [14]Sina Hospital, Tehran, Tehran, Islamic Republic of Iran.*

Background: Kidney transplant patients are at high risk for COVID-19 related mortality. However, limited data are available on longer term clinical, functional and mental outcomes in patients that survive COVID-19.

Methods: Data from adult kidney transplant patients that presented with COVID-19 between February 1st, 2020 and January 31st, 2021 were retrieved from the ERACODA database. Data from patients with complete data for vital status, hospitalization and/or ICU admission was used for this analysis.

Results: 912 patients were included with a mean age of 56.7 (±13.7) years. 26.4% were not hospitalized, 57.5% hospitalized, and 16.1% hospitalized and ICU admitted. Three-months survival was 82.3% overall and 98.8%, 84.2% and 49.0% resp. in each group. Three-months acute rejection, need for dialysis / CVVH at any time point, and graft failure occurred in the overall group in 1.0%, 2.6% and 1.8% resp., and in 2.1%, 10.6% and 10.6% of ICU admitted patients resp. Of the surviving patients 83.3% had reached their prior functional status within 3 months. Of patients that had not yet reached their prior functional status, it was expected that 79.6% still would do so within the coming year. 94.4% had reached their prior mental status. Of patients that had not yet reached their prior mental status, it was expected that 80% of patients would do so within the coming year.

Conclusions: In patients alive at three-months follow-up, graft loss was rare, and most patients had reached their pre-COVID-19 functional and mental status.

Table 1

Outcomes	Total	Not hospitalized	Hospitalized, no ICU	Hospitalized, ICU	p-value
Acute rejection, n (%)	5 (1.0)	2 (1.4)	2 (0.7)	1 (2.1)	0.57
Required dialysis / CVVH, n (%)	13 (2.6)	3 (2.1)	5 (1.7)	5 (10.6)	<0.001
Graft Loss, n (%)	9 (1.8)	1 (0.7)	3 (1.0)	5 (10.6)	<0.001
Reached pre-COVID-19 functional status, n (%)	375 (83.3)	123 (87.9)	235 (87.0)	17 (42.5)	<0.001
Reached pre-COVID-19 mental status, n (%)	425 (94.4)	134 (95.7)	260 (96.3)	31 (77.5)	<0.001

Clinical, functional, and mental outcomes in kidney transplant recipients three months after being diagnosed with COVID-19. Data of 487 patients were available for analysis of graft function related outcomes. Data of 450 patients were available for functional and mental status outcomes.

PO0097

Clinical, Functional, and Mental Outcomes in Hemodialysis Patients 3 Months After COVID-19 Diagnosis

Marc H. Hemmelder,[4] Marlies Noordzij,[1] Priya Vart,[1] Kitty J. Jager,[3] Raphael Duivenvoorden,[2] Alferso C. Abrahams,[5] David A. Arroyo,[6] Yuri Battaglia,[13] Robert Ekart,[12] Francesca Mallamaci,[7] João Oliveira,[10] Andrzej Z. Rydzewski,[9] Sivakumar Sridharan,[11] Liffert Vogt,[8] Casper F. Franssen,[1] Luuk Hilbrands,[2] Ron T. Gansevoort.[1] on behalf of the ERACODA Collaborators *[1]Dept. Internal Medicine, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [2]Dept. Nephrology, Radboud University Medical Center, Nijmegen, Netherlands; [3]ERA-EDTA Registry, Dept. Medical Informatics, Amsterdam University Medical Center, Amsterdam Public Health Research Institute, Amsterdam, Netherlands; [4]Dept. Internal Medicine, Division of Nephrology, Maastricht University Medical Center, Maastricht, Netherlands; [5]Dept. Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [6]Dept. Nephrology, Hospital General Universitario Gregorio Marañón, Madrid, Spain; [7]Nephrology, Dialysis and Renal Transplantation Unit, Grande Ospedale Metropolitano di Reggio Cal, Reggio Calabria, Italy; [8]Dept. Nephrology, Amsterdam University Medical Center, Amsterdam, Netherlands; [9]Central Clinical Hospital of the Ministry of Interior, Warsaw, Poland; [10]Centrodial, São João da Madeira, Portugal; [11]Dept. Nephrology, Lister Hospital, Stevenage, United Kingdom; [12]UMC Maribor, Clinic for Internal Medicine, Dept. of Dialysis, Maribor, Slovenia; [13]Dept. Nephrology, University Hospital St. Anna, Ferrara, Italy*.

Background: There is overwhelming evidence that hemodialysis (HD) patients are at high risk of death in the first month after developing COVID-19. However, less is known about their long-term mortality risk and functional and mental outcome. We aimed to assess these outcomes in a large cohort of HD patients 3 months after COVID-19 diagnosis.

Methods: From ERACODA, we included adult HD patients who presented with COVID-19 from February 1, 2020-January 31, 2021 and with complete data on vital status and hospitalization. Recovery of functional and mental status was estimated by the treating nephrologist. Logistic regression was used to calculate odds ratios (OR) with 95% confidence interval (95%CI) for the likelihood of reaching the pre-COVID-19 status.

Results: A total of 2,249 HD patients (mean age 67.5 ± 14.4 years) were included, of whom 1,087 (44%) were not hospitalized, 1,165 (48%) were hospitalized but not admitted to an ICU, and 197 (8%) were hospitalized and ICU-admitted. In these 3 groups, the survival probability at day 28 was 90%, 75% and 47%, and at 3 months 90%, 73% and 40%, respectively. For 854 patients who survived 3 months after COVID-19 diagnosis, data on functional and mental status was available. 743 (87%) reached their pre-COVID-19 functional status within 3 months. 111 patients had not yet reached this, but it was expected that 58% of them would do so within 1 year. Higher age (adjusted OR: 0.97; 95%CI: 0.96-0.99), higher frailty score (0.81; 0.70-0.93) and ICU admission (0.11; 0.05-0.26) were associated with a lower likelihood of reaching pre-COVID-19 functional status. Pre-COVID-19 mental status was reached by 803 (94%) patients. Higher frailty score (0.76; 0.65-0.89) and ICU admission (0.27; 0.11-0.67) were associated with lower likelihood of reaching prior mental status. For 56% of the 51 patients who had not yet reached their prior status, it was expected that they would do so within the coming year.

Conclusions: Three months after a COVID-19 diagnosis, most HD patients who were not admitted to the ICU were still alive. Furthermore, a vast majority had already reached their pre-COVID-19 functional and mental status at that time point.

PO0098

Anxiety in Patients with CKD During the COVID-19 Pandemic: Predictors and Consequences Among Chronic Renal Insufficiency Cohort (CRIC) Study Participants

Kirsten S. Dorans,[1] Julie A. Wright Nunes,[2] Douglas E. Schaubel,[3] Daohang Sha,[3] Mahboob Rahman,[4] Harold I. Feldman.[3] CRIC Study Investigators *[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]University of Michigan Medical School, Ann Arbor, MI; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Case Western Reserve University, Cleveland, OH*.

Background: Chronic kidney disease (CKD) is associated with anxiety and depression. Though the Coronavirus 2019 (COVID-19) pandemic has increased stressors on patients with CKD, assessments of anxiety, its predictors and consequences, including on virus mitigation behaviors are lacking.

Methods: From June to October 2020, we administered a survey about anxiety related to the COVID-19 pandemic to 1888 participants in CRIC. We examined associations of anxiety with demographics, clinical indices, health literacy, health-related behaviors and COVID-19 mitigation behaviors.

Results: Four anxiety-related constructs were assessed: one composite overall global anxiety construct and three sub-constructs: general anxiety, worry, mood/feelings. Construct scores had moderate to strong correlations with each other (0.48–0.89) and high internal consistency (Cronbach's alpha ≥0.81). In adjusted analyses, younger age, female gender, Hispanic ethnicity, cardiovascular disease, household income <$100,000, unemployment, and marginal or inadequate health literacy predicted higher anxiety. During the pandemic, higher global anxiety scores were associated with higher odds of eating less healthy foods, reduced physical activity, and weight gain as well as reporting always wearing a mask in public in the past week.

Conclusions: Several factors predict higher anxiety related to the COVID-19 pandemic. Although anxiety is typically thought to be an undesired outcome, in addition to being associated with less healthy behaviors, anxiety was associated with higher self-reported mask wearing. Our study indicates a need for interventions to support healthy behaviors and virus mitigation strategies, without provoking or worsening anxiety in patients with CKD.

Funding: NIDDK Support, Other NIH Support - National Institute of General Medical Sciences

Multivariable-adjusted logistic regression examining associations between overall anxiety composite score and self-reported behaviors.

	Odds Ratio	p value
In past week, always wear a mask in public	1.27	<0.001
In past week, always remain ≥6 feet apart from others not in household while in public	1.06	0.26
Since pandemic began, travel out of state/country	0.94	0.43

PO0099

Hand Sanitizer Overdose in the Era of COVID-19

Neeharika Mettupalli, Ashton N. Breithaupt, Alice Chedid. *The University of Tennessee Health Science Center College of Medicine, Memphis, TN*.

Introduction: Isopropyl alcohol is a common ingredient in hand sanitizers. Ingestion should be suspected if patient presents with high osmolar gap & pseudo renal failure without metabolic acidosis.

Case Description: 44 y/o female with h/o of HTN & hypothyroidism, brought to the ED for altered mental status. 2 bottles of hand sanitizers were found empty next to her. She was drowsy, unable to provide any further history. Vitals T- 36.7 C, HR 91, BP 124/84, RR 14, SaO2 97 on RA. Physical exam was unremarkable. Initial labs on admission: Serum creatinine 2.47, i-stat creatinine at 0.7, bicarb 24, AG 8, serum osmolality 341, osmolar gap of 57. Ethanol level was negative. Table1 outlines the patient's labs. Given normal bicarb, normal AG with very high osmolar gap, isopropyl alcohol ingestion was suspected. IV fomepizole was started, as some hand sanitizers contain methanol. Fomepizole was continued until osmolar gap closed. No dialysis was required. Methanol level was undetectable. Acetone level high 176. Isopropranol level high 49. Patient's mental status improved with supportive measures.

Discussion: Isopropanol ingestion presents with normal bicarb, normal AG with very high OG. Treatment is usually supportive. Clinicians should be aware of falsely elevated serum cr if measured via colorimetric method due to acetone's interference. Our case presents a new challenge added to numerous challenges physicians are facing in the COVID Era.

Federated Learning for AKI Prediction in COVID-19 Patients

Suraj K. Jaladanki, Akhil Vaid, Ishan Paranjpe, Aparna Saha, Karandeep Singh, Lili Chan, Benjamin S. Glicksberg, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Predictive models are trained on single-center data and are non-generalizable, and multi-center data pooling raises privacy concerns. Federated learning (FL) trains models by updating parameters from a central aggregator without sharing raw data. We used FL to predict acute kidney injury (AKI) in COVID-19 patients within 3 (AKI_3) and 7 (AKI_7) days of admission as a use case.

Methods: We selected 4035 COVID-19 patients admitted to 5 hospitals in New York City, after excluding patients with kidney failure, to train logistic regression and logistic regression with L1 regularization (LASSO) models through 3 approaches: local data, pooled data from all sites, and a FL method.

Results: Federated models outperformed local models as measured by area under the receiver operating characteristic curve (Figure 1, Table 1). SHAP plots indicate differences in feature importance between LASSO models in AKI_3 prediction (Figure 2).

Conclusions: FL has utility for developing accurate predictive models without compromising patient data.

Funding: NIDDK Support

ANCA-Associated Glomerulonephritis and Vasculitis Following COVID-19 Vaccination in a Patient with Giant Cell Arteritis

Nay Seif, Carla L. Ellis, Shikha Wadhwani. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: A 66-year-old man with history of hypertension, chronic obstructive pulmonary disorder, latent tuberculosis, and biopsy-proven giant cell arteritis (GCA) was admitted for fevers and intermittent headaches three weeks after receiving dose 2 of the Moderna COVID-19 vaccine.

Case Description: On admission, the patient was afebrile with normal vitals and unremarkable physical examination. He noted his GCA had been in remission off treatment for two years. Labs noted new-onset microscopic hematuria and proteinuria (1.5 g/24 hr) as well as serum creatinine (SCr) of 2.2 mg/dL from 1.4 ten days prior. His sedimentation rate and C-reactive protein were also markedly elevated (119 mm/hr and 105 mg/L). Given rapidly progressive glomerulonephritis, IV Solumedrol was given for 3 days (after infection was ruled out). A kidney biopsy showed pauci-immune, necrotizing, crescentic glomerulonephritis and small vessel vasculitis (Figure 1A & 1B). Serologies returned with positive p-ANCA and high-titer myeloperioxidase antibody, confirming the diagnosis of Microscopic polyangiitis (MPA). He was transitioned to oral Prednisone and given the first of two doses of IV Rituximab. One week post-biopsy his SCr was 1.8 mg/dL.

Discussion: Renal involvement by MPA in patients with GCA is rare but has been reported. This case is unique in its temporal relation to COVID-19 vaccination. There have been reports of crescentic IgA nephropathy as well as minimal change disease following COVID-19 vaccination but we are unaware of cases of de novo or recurrent vasculitis. While causality is difficult to prove, clinicians should closely monitor patients post-vaccination.

COVID-19 Pandemic Highlights Global Inequities in Chronic Hemodialysis Care: A DOPPS/ISN Survey

Elliot K. Tannor,[1] Brian Bieber,[2] Dibya Singh Shah,[3] Chimota T. Phiri,[7] Rhys D. Evans,[12] Ryan E. Aylward,[9,10] Murilo H. Guedes,[8] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Fergus Caskey,[9] Adrian Liew,[4] Valerie A. Luyckx,[11,10] Vivekanand Jha,[5] Roberto Pecoits-Filho,[2] Gavin Dreyer.[6] ISN DOPPS collaboration *[1]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Tribhuvan University Teaching Hospital, Kathmandu, Nepal; [4]Mount Elizabeth Medical Centre, Singapore, Singapore; [5]The George Institute for Global Health, New Delhi, India; [6]Barts Health NHS Trust, London, United Kingdom; [7]Queen Elizabeth Central Hospital, Blantyre, Malawi; [8]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [9]University of Bristol, Bristol, United Kingdom; [10]University of Cape Town, Rondebosch, South Africa; [11]Brigham and Women's Hospital, Boston, MA; [12]The University of British Columbia, Vancouver, BC, Canada.*

Background: Patients receiving chronic hemodialysis (HD) are highly vulnerable in all settings. It is unknown whether the COVID-19 pandemic has disproportionately affected the care of chronic HD patients in low (LIC) and low-middle income (LMIC) settings. This survey aimed to identify global challenges and inequities in HD care delivery during the COVID-19 pandemic.

Methods: The Dialysis Outcomes and Practice Patterns Study (DOPPS) and the International Society of Nephrology (ISN) conducted a global online survey of HD units (HDU). Sample HDUs included DOPPS sites in China, a random sample stratified by region and HDU population, and an open invitation via ISN's membership list. The survey assessed availability of COVID-19 diagnostics and personal protective equipment, the impact of COVID-19 on HD delivery and patient outcomes from COVID-19. Responses were stratified by country income according to World Bank classification.

Results: Responses were received from 412 HDUs across 78 countries (Table 1).

Conclusions: Striking global inequities were identified in access to COVID-19 diagnostics, infection prevention, and access to routine HD care during the pandemic. Higher apparent mortality in patients on chronic HD in LICs and LMICs is likely multifactorial, reflecting poorer access to the diagnosis and care of COVID-19, as well as greater disruptions to HD delivery. Urgent action is required to address these inequities, which disproportionately affect low-income settings, exacerbate pre-existing vulnerabilities and lead to worse outcomes.

		World Bank Country Income Classification			
	All	LIC	LMIC	UMIC	HIC
	n=412	n= 15 (4%)	n=111 (27%)	n=145 (35%)	n=141 (34%)
No or low availability of diagnostic PCR for COVID-19	13.2%	61.5%	21.5%	9.4%	4.6%
Availability of same-day diagnostic PCR test for COVID 19	34.4%	21.4%	13.2%	25.5%	59.5%
Severe shortage in respirator (N95) masks	13.9%	42.9%	23.8%	4.2%	10.1%
Use of face mask beyond manufacturer's shelf life	31.1%	50%	39.6%	29.1%	24.8%
Increase in patients with missed hemodialysis treatment	32.0%	64.3%	66.3%	30.4%	5.5%
Proportion of clinics reporting >30% mortality among hemodialysis patients who contracted COVID-19	26.2%	40.0%	33.3%	25.3%	19.8%

UMIC - upper middle income country; HIC - high income country; PCR - Polymerase Chain Reaction

Distribution of responses regarding resources, practices, and outcomes during the COVID-19 pandemic, by World Bank country income classification

PO0103

A Novel Approach to Identify Nonclinical Factors That Impact Outcomes in Dialysis Patients

Claire Ryan,[1] Scott Sibbel,[2] Janice Engel,[1] Amber Pace,[1] Steven M. Brunelli,[2] Ania Filus,[2] Francesca Tentori.[2] *[1]DaVita Inc, Denver, CO; [2]Davita Clinical Research, Minneapolis, MN.*

Background: Nonclinical factors heavily impact quality of life and outcomes in severely ill patients. In oncology, self-reported levels of distress are routinely assessed to identify patients with higher risk of adverse outcomes and possible interventions. While similar dynamics may be at play in dialysis, this type of screening is not part of the current standard of care. In order to potentially enhance a patient-centered and holistic approach to care, we tested the use of the distress thermometer (DT) among patients dialyzing at a large dialysis organization.

Methods: Between September 2019 and January 2021, social workers administered a dialysis-adapted version of the DT. Associations between DT scores and outcomes were assessed in logistic regression models adjusted for age, race, sex, and dialysis vintage. Models in in-center hemodialysis (ICHD) patients were also adjusted for vascular access type. Additionally, outcomes were compared between patients who selected specific items off the problems lists and those who did not select that specific problem.

Results: This analysis included data from 32,174 patients (N = 25,447 ICHD and N = 6727 peritoneal dialysis [PD]). The refusal rate was 11.4% and 4.7% among ICHD and PD patients, respectively (10.0% overall). The mean ± SD DT score was 3.22 ± 2.85 for all patients, 3.29 ± 2.87 for ICHD patients, and 2.96 ± 2.75 for PD patients. High DT scores (≥7) were associated with hospitalization among both ICHD (odds ratio [95% CI] = 1.22 [1.07-1.39]) and PD (1.51 [1.11-2.05]) patients and with greater risk of PD discontinuation (1.77 [1.38-2.25]). Problems attributed to transportation and housing were associated with greater risk of missing an in-center treatment (1.36 [1.23-1.50] and 1.37 [1.23-1.52], respectively). Physical problems were associated with increased risk for hospitalization among ICHD patients (1.08 [1.06-1.10]) and PD patients (1.07 [1.02-1.11]), and missed treatments among ICHD patients (1.03 [1.01-1.04]).

Conclusions: We found that a novel screening tool may be useful in identifying dialysis patients at high risk for adverse clinical outcomes. Moreover, specific responses on this tool may help identify specific problems that are driving this risk. Practices aimed at addressing such problems could have the potential to impact quality of life and clinical outcomes.

PO0104

Cutaneous Manifestations of COVID-19 Vaccine in ESRD Patients

Irtiza Hasan, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: COVID-19 vaccines including Pfizer (BNT16262) & Moderna (mRNA-1273) have been authorized for emergency use by FDA since late 2020. Although there are reported cases of cutaneous manifestation post mRNA based COVID vaccines, but literature is lacking for the same in patients with ESRD. Here we report two cases of generalized cutaneous manifestations in patients with ESRD.

Case Description: A 76-year-old female with DM, HTN, SLE (in remission) & CKD 5 was admitted with bilateral leg edema & generalized skin reaction 2 weeks post receiving 1st dose of Moderna vaccine. Skin manifestations included generalized macular & blistering lesions, painful ruptured vesicles & skin weeping. Skin biopsy revealed epidermal necrosis, neutrophilic spongiosis & negative DIF. The 2nd case was a 34-year-old male with DM, HTN & ESRD on PD who was admitted with inadequate PD due to membrane failure. Also complaint of itchy, painless maculopapular rash, which was initially localized following 1st dose of Moderna vaccine but became progressive & diffuse post 2nd dose. Biopsy was nonspecific with focal epidermal squamous atypia, overall negative DIF except C3 granular staining in basement membrane. Immunological tests failed to detect ab against infectious origin. Both cases denied oral or genital ulcers, new onset diarrhea, new medication, new sexual contact or recent travel. CBC were normal & other lab tests were negative for active immunological, autoimmune or other dermatologic disease. Both cases were considered to be related to cutaneous complication of COVID vaccine in patients with ESRD. The 1st case made significant improvement post start of hemodialysis (HD), oral & topical steroid. The 2nd case gradually improved post transition to HD & use of topical steroid.

Discussion: The majority of studies looked at skin reaction to COVID19 vaccine were in non-renal disease population & reported minor, self-limited manifestations, our case report highlights a more severe & generalized skin manifestation in ESRD. Associated factors may be related to difference in vaccine response in renal patients, alteration of immunogenic reaction in uremic environment or progression due to delayed healing & concomitant presence of edema in setting of inadequate dialysis. Clinical trials for Moderna vaccine didn't include participants with renal disease & hence insufficient to determine the pharmacology & side effect profile in this population.

PO0105

Glomerular Disease in Temporal Association to SARS-CoV-2 RNA Vaccination: A Series of 16 Cases

Tiffany Caza,[1] Christopher P. Larsen,[1] Patrick D. Walker,[1] Regan M. Seipp,[3] Hassan Amin,[4] Irina Vancea,[2] Mandolin S. Ziadie,[5] Nidia C. Messias,[1] Clarissa A. Cassol.[1] *[1]Arkana Laboratories, Little Rock, AR; [2]South Colorado Nephrology Associates, Pueblo, CO; [3]DuPage Medical Group, Naperville, IL; [4]The Kidney Group of Memphis, Memphis, TN; [5]Memorial Regional Hospital, Miramar, FL.*

Background: Vaccination is considered safe in patients with chronic kidney disease. However, given the ability to activate the immune system, immunizations carry a risk of inducing inflammatory disease flares. The mass vaccination for SARS-CoV-2 provides a unique opportunity to investigate potential vaccine-associated glomerular diseases.

Methods: Kidney biopsies from patients who presented with acute kidney injury (AKI) and/or nephritic/nephrotic syndrome within three weeks of SARS-CoV-2 vaccination were included in the study (n=16). Kidney biopsies were reviewed at a single center and clinical information was provided from nephrologists for clinicopathologic correlation.

Results: Sixteen patients with a new onset of kidney disease or flare within 3 weeks of SARS-CoV-2 vaccination were identified and all had glomerular disease on biopsy. Eleven patients had two vaccine doses prior to symptom onset. The patient cohort included 6 males and 10 females, with a mean age of 58 years. Biopsy diagnoses included IgA nephropathy (n=7), minimal change disease (n=4), ANCA-associated glomerulonephritis (n=3), membranous glomerulopathy (n=1), and diffuse lupus nephritis (n=1). Thirteen patients had co-morbid medical conditions, including hypertension (n=10), diabetes mellitus (n=4), autoimmune disease (n=5), and chronic kidney disease (n=4). The most common clinical presentation was AKI with concurrent nephritic or nephrotic syndrome (n=9), followed by nephritic syndrome with preserved kidney function (n=5), nephrotic syndrome with preserved kidney function (n=1), and isolated hematuria (n=1). Three patients with AKI required dialysis. A majority of patients had an elevated serum creatinine (mean 3.4 mg/dL), 14 had proteinuria (nephrotic range in 4), 11 had hematuria, and 10 had hypoalbuminemia (mean 2.9 g/dL). Six patients had antinuclear antibodies and 4 had a positive ANCA serology at the time of biopsy. Clinical follow-up is ongoing.

Conclusions: IgA nephropathy, minimal change disease, ANCA-associated glomerulonephritis, membranous glomerulopathy, and lupus nephritis were identified with temporal association with SARS-CoV-2 vaccination. In the setting of mass vaccination, causality is unclear, but a new onset of glomerular disease should be monitored as a potential adverse event.

PO0106

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposition (PGNMID) Associated with COVID-19

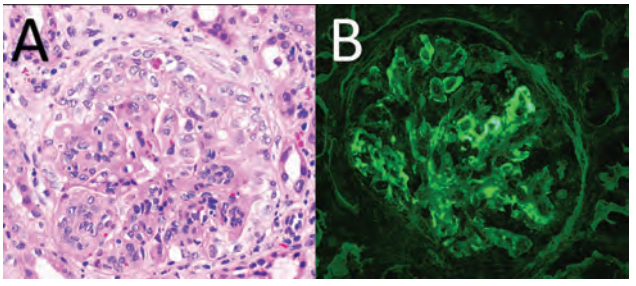
Julie Giannini,[1] Michelle Shieh,[1] Sara Combs,[1] Saeed K. Shaffi,[1] Nidia C. Messias,[2] J Pedro Teixeira.[1] *[1]University of New Mexico School of Medicine, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Renal disease in COVID-19 is often due to acute tubular injury but can include multiple glomerular lesions such as collapsing glomerulopathy. This is the first reported case of COVID-19-associated PGNMID.

Case Description: A 71-year-old woman with normal baseline creatinine (Cr) was admitted with COVID-19 and discharged on oxygen and dexamethasone (Dex). She improved but returned a month later with edema and nausea. She was found to have nephrotic syndrome, hematuria, and AKI (peak Cr 8.5 mg/dL) requiring HD. Kidney biopsy revealed PGNMID with clonal IgG3-kappa. SPEP, serum free light chains (sFLC), 24h urine UPEP, bone marrow biopsy with flow cytometry, fat pad biopsy, and PET-CT

were negative for monoclonal immunoglobulin (Ig) or cell line, amyloid, or malignancy. Though symptoms had long since resolved, she was still PCR-positive for SARS-CoV-2 on nasal swab. Upon discharge she was given cyclophosphamide (Cy). Her renal function improved (Cr 2.5) and she came off HD 2 weeks later. Her outpatient oncologist opted not to continue therapy. However, 2 months later she was readmitted with nausea, dyspnea, and anasarca with recurrent AKI (Cr 6.7) and nephrotic syndrome. HD was restarted. Repeat kidney biopsy [Figure] was noted to be a "carbon copy" of the first. SPEP, spot UPEP, and sFLC were again negative. She was started on Cy, bortezomib, and Dex with similar partial response (Cr <2.5).

Discussion: PGNMID is a rare type of monoclonal gammopathy of renal significance (MGRS) that often has no detectable extrarenal monoclonal Ig or cell line. MGRS and PGNMID, though usually not postinfectious, have been reported with other viruses (e.g., viral hepatitis, parvovirus-B19). However, though causality is unclear, this is the first case of MGRS reported in association with COVID-19.



Biopsy #2 yielded 32 glomeruli, 4 globally sclerotic, 4 with crescents, and rest with highly active proliferative GN (panel A, H&E 400x), with 20% interstitial fibrosis. IF showed granular deposition restricted to IgG3-kappa (panel B, IgG3 stain 400x).

PO0107

Minimal Change Disease with Severe AKI Following the Oxford-Astra-Zeneca SARS-CoV-2 Vaccine

Simon Leclerc,[1,2] Virginie Royal,[1,2] Caroline Lamarche,[1,2] Louis-Philippe Laurin.[1,2] *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Universite de Montreal, Montreal, QC, Canada.*

Introduction: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic has been associated with an increased mortality worldwide over the last year. Novel vaccines against SARS-CoV-2 offers new perspectives to control the virus. Major side effects of these vaccines, especially those affecting the kidney, appear to be uncommon. Although minimal change disease (MCD) has been reported three times following the Pfizer-BioNTech SARS-CoV-2 vaccine, no cases are described to our knowledge after the Oxford-AstraZeneca vaccine SARS-CoV-2 vaccine.

Case Description: A 71-year-old man known for dyslipidemia and a serum creatinine of 0.7 mg/dl presented with nephrotic syndrome and acute kidney injury 13 days after receiving the first injection of the Oxford-AstraZeneca SARS-CoV-2 vaccine. On admission, urine analysis revealed 2321 mg of protein per mmol of creatinine and significant hematuria as well as granular casts. His serum albumin and creatinine were 2.8 g/dl and 10.6 mg/dl, respectively. Polymerase chain reaction for SARS-CoV-2 was negative. A workup to exclude auto-immune disease, active infection and neoplasm was negative. A kidney biopsy was performed 4 days after admission and 17 days after vaccination. It showed minimal change disease with acute tubular injury. Steroid therapy was initiated. Hemodialysis was stopped 38 days after the start of therapy. At dialysis cessation, serum creatinine was 1.4 mg/dl with a marked decreasing in spot microalbuminuria.

Discussion: We suspect that this case of MCD might be related to the Oxford-AstraZeneca SARS-CoV-2 vaccine injection. To the best of our knowledge, this would be the first published case of MCD related to this vaccine. However, MCD has been described after other vaccines, including 3 cases after the Pfizer-BioNTech SARS-CoV-2 vaccine. The fact that MCD is now described with different types of SARS-CoV-2 vaccines argues on a potential mechanism not implying a direct effect of the vaccine itself, but a T cell process ignited by the vaccine that leads to podocyte injury. Since vaccination is the most promising way out of the current SARS-CoV-2 pandemic, millions of doses of vaccines will be administered around the world in a near future. Thus, nephrologists should be aware of this rare but reversible potential complication of COVID-19 vaccination.

PO0108

Focal Segmental Glomerulosclerosis (FSGS) Recurrence After mRNA COVID-19 Vaccine in a Young Adult with Kidney Transplant

Sonya B. Lopez, Jonathan D. Savant, Jennifer Hewlett, Lauren E. Galea, Rosanna Fulchiero, Benjamin L. Laskin, Christopher J. LaRosa, Bernarda Viteri, Sandra Amaral. *The Children's Hospital of Philadelphia, Philadelphia, PA.*

Introduction: Patient is a 21 year old Hispanic male with history of FSGS 8 years status post deceased donor kidney transplant. Other than one prior FSGS recurrence early post-transplant, which responded to plasmapheresis (PP) and rituximab, he maintained normal allograft function with stable, low level proteinuria on losartan 12.5 mg daily.

Case Description: Routine labs 1 day prior to COVID 19 mRNA vaccine series were stable with serum creatinine (sCr) 0.8 mg/dL, urine protein creatinine ratio (UPCR) 0.42 mg/mg (65 mg/dL of protein), and serum albumin 4.8 g/dL. Thirty-one days after the second COVID 19 vaccine, routine labs were significant for nephrotic range proteinuria with UPCR >6.21 mg/mg (>2500 mg/dL of protein), hypoalbuminemia (1.7 g/dL), and peak sCr of 1.3 mg/dL. Of note, he remained asymptomatic until 2 days prior to labs when noted to have periorbital and lower extremity edema associated with decreased urine output. Allograft biopsy revealed foot process effacement without definitive evidence of segmental sclerosis. Infectious workup including viral studies for SARS-CoV-2 were negative. He received methylprednisolone 1g IV for 3 days, thrice-weekly PP, rituximab 375 mg/m2 weekly x2, and an oral prednisone taper. During week 4 of PP concurrent with prednisone taper, the patient appeared clinically well with noted improvement in labs: UPCR 0.55 mg/mg, sCr 0.57 mg/dL, and serum albumin 3.5 g/dL. He is currently undergoing wean of PP and steroids.

Discussion: While there are isolated reports of new onset or recurrence of proteinuric kidney disease after an mRNA COVID-19 vaccine, to our knowledge, this is the first report of FSGS recurrence in a kidney transplant recipient. Although causality is not proven, the temporal relationship strongly suggests an association between the vaccine and the recurrence. Compared with prior reports, our patient presented somewhat later, ~1 month after dose #2 as compared to within 2 weeks after dose #1. Although the risk-benefit ratio of COVID vaccination for kidney transplant recipients remains favorable and vaccination is encouraged by national clinical guidelines, close monitoring after COVID vaccine for kidney transplant patients at risk for disease recurrence is warranted.

PO0109

IgA Nephropathy Post COVID-19 Vaccination

Prakrati C. Acharya,[1] Chirag Acharya,[3] Juan A. Medaura.[2] *[1]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [2]The University of Mississippi Medical Center, Jackson, MS; [3]LCCF, Hobbs, NM.*

Introduction: Inclusion of patients with kidney disease in COVID vaccine trials remains low. It is important to report association of disease exacerbation so that patients may undergo post vaccination monitoring. We hereby present a case of worsening IgA nephropathy temporarily associated with COVID vaccination

Case Description: 63-year-old Hispanic female with past medical history of hypertension, psoriatic arthritis presented to the hospital with gross hematuria for 6 weeks starting 3 days after 2nd dose of Pfizer COVID vaccine. Her PCP had sent her to ER 5 days after onset of hematuria as had noted a creatinine (Cr) of 1.6 with 3+ protein and >20 RBCs on urinalysis suspicious for nephritic syndrome. On review she had serum Cr of 0.5 about 4 months ago with no proteinuria or hematuria before. In the ER she was given antibiotics for urinary tract infection and outpatient referral for nephrology. She could not make the outpatient appointment and with continued gross hematuria for a month, she presented to the ER again where she was noted to have Cr of 10 mg/dl and urine protein:cr ratio of 7.3gm/gm. Renal imaging including CT urogram was normal. Renal biopsy showed IgA nephropathy, M1S0E0T1C1 with a fibrocellular crescent and acute tubular necrosis likely secondary to lyzed red cells in setting of multiple RBC casts in the tubules. She was put on 250 mg Solumedrol for 3 doses followed by 1 mg/kg of Prednisone with eventual downtrend in Cr to 4.5 in 15 days.

Discussion: There have been 2 cases reported in literature with known IgA nephropathy who developed gross hematuria post COVID 19 vaccination. SARS- COV 2 vaccines use nucleoside modified purified mRNA which does elicit higher neutralizing antibody titre and strong cluster of differentiation response leading to production of several proinflammatory cytokines. Thus, there is a concern that vaccines might exacerbate immune mediated glomerular diseases. IgA1 is involved in the pathogenesis of IgA nephropathy and patients with IgA nephropathy have higher than normal IgA1 response to other vaccines like influenza. Also while studying the antibody response to COVID 19 illness patients with IgA nephropathy are known to express higher IgA response compared to IgG and IgM along with reports of concurrent worsening of the glomerulonephritis. Nephrologists should closely follow patients with IgA nephropathy to establish the frequency of disease activation post vaccination.

PO0110

IgA Nephropathy After Receiving the Pfizer COVID-19 Vaccine: A Case Report

Lisa L. Roberts. *University of Rochester, Rochester, NY.*

Introduction: Here, we present a case of IgA nephropathy in a 22-year-old Caucasian woman with no comorbidities and prior COVID positive infection, after receiving the Pfizer vaccine for COVID-19. She initially presented to her primary care physician for an episode of gross hematuria two days after receiving the first Pfizer COVID -19 vaccine.

Case Description: She was asymptomatic for urinary tract infection, neither was she menstruating. Her renal functions were normal with a creatinine of 0.93 mg/dL. Urinalysis showed hematuria with > 50 red blood cells (RBC) per high-power field (HPF) and 2+ protein on the dipstick. She again experienced gross hematuria with > 50 RBC/HPF on urinalysis and proteinuria of 2.23g after receiving the 2nd Pfizer vaccine, at which time she was referred to the Nephrology department for further evaluation. We examined urine sediment which was significant for dysmorphic RBCs and rare granular casts. A renal biopsy showed that the majority of 14 glomeruli had global sclerosis on light microscopy, a diffuse increase of mesangium, and interstitial fibrosis with tubular atrophy. Immunofluorescence microscopy was positive for Immunoglobulin A (IgA), Lambda light chains, and anti-complement C3 antibodies. Electron microscopy revealed mesangial expansion and cellularity and peri-mesangial electron-dense deposits. These and other findings fit with the Oxford Classification of M1, S1, E0, T0, C0. Following

the biopsy, we prescribed Lisinopril 5 mg daily for control of proteinuria. We did not prescribe glucocorticoids due to the mild nature of the disease and lack of underlying inflammation. The patient continues to do well without symptoms. Her most recent labs show preserved renal function and spot proteinuria reduced to 1.3 g.

Discussion: The current case raises questions about the potential association of IgA Nephropathy with the COVID vaccine. One of several possible mechanisms includes an aberrant mucosal immune response to the initial SARS-COV-2 infection that she contracted in December 2020. This could have then predisposed her to IgA nephropathy after the administration of the vaccine. The virus' spike protein or other factors may trigger an aberrant mucosal immune IgA response which can then lead to the onset and progression of IgA nephropathy. Further case series are needed to establish a more definitive association of the COVID-19 vaccine with IgA nephropathy.

PO0111

IgA Nephropathy Flare Following COVID-19 Vaccination

Mohammad Hamza, Kelly H. Beers. *Albany Medical Center, Albany, NY.*

Introduction: IgA nephropathy is the most common cause of primary glomerulonephritis in people of Asian origin. It is characterized by mesangial deposition of IgA which activates Lectin and Alternative pathways that cause glomerular damage which results in hematuria and proteinuria. Untreated disease can progress to chronic kidney disease, and even end-stage kidney disease.

Case Description: We describe a case of a 28-year-old male of Chinese descent who has a biopsy-proven diagnosis of IgA nephropathy (Oxford classification M1 E0 S1 T0 C1). Patient was maintained on Losartan 100 mg daily with proteinuria under 500mg per day. He presented to the nephrology clinic for an urgent visit after he experienced gross hematuria in his urine following the second dose of his COVID-19 vaccination (Moderna). His first shot of the same vaccination was 28 days ago. After receiving his second dose, patient experienced high-grade fever (Tmax of 39F) and chills. Next morning, he again experienced high-grade fevers and on the same night, he experienced gross hematuria. On his visit to the clinic, patient was feeling back to normal. His vital signs were within normal limits. Physical examination did not reveal any crackles in his lungs or lower extremity edema. Workup revealed elevated hemoglobin in his urine with 10-20 RBCs per high power field with no WBCs. Spot urine analysis revealed urine protein-creatinine ratio of 828mg/g. A 24-hour urine collection was performed which revealed urine protein excretion to be 925 mg/24hr. All these findings were consistent with a flare of his well-established IgA nephropathy. Since patient's urine protein excretion was less than 1g/day, a decision was made to not start the patient on steroids and instead closely monitor the patient on his usual dose of Losartan 100 mg daily. Patient had not had any further complaints. He is to regularly follow up at our nephrology clinic.

Discussion: IgA nephropathy is seen in individuals with recent mucosal infection or after administration of mucosal vaccination as these phenomena result in elevated IgA secretion that can then deposit in the mesangium. Our case is unique in the sense that a non-mucosal mRNA vaccination caused IgA flare. This could indicate a possible mucosal response to COVID-19 vaccination which can be a possible mechanism as to how the vaccine protects against COVID-19. Further investigations are necessary to examine the link between the two.

PO0112

IgA Vasculitis with Renal Manifestations in a College-Aged Individual After COVID-19 Infection

Samuel A. Lazoff, Tushar Chopra, Emaad M. Abdel-Rahman. *University of Virginia, Charlottesville, VA.*

Introduction: IgA Vasculitis is one of the most common causes of primary glomerulonephritis, however there are very few cases reported in association with COVID-19. Approximately 20-50% of patients present with renal manifestations, such as IgA Nephropathy (IgAN). Here we present a case of rapidly progressing crescentic IgAN presenting after COVID-19 infection.

Case Description: A 19-year-old male presented to the emergency department with elevated creatinine after being seen in the rheumatology clinic. A timeline of the patient's symptoms is presented in Figure 1. The renal biopsy showed a rapidly progressing IgAN with 15% crescents, hence he was placed on Mycophenolate mofetil and prednisone. He was also placed on Lisinopril and low-salt diet for better control of blood pressure and fish oil for dyslipidemia. Despite aggressive immunosuppression and risk factor modification, his renal function has not improved and he continues to have nephrotic range proteinuria.

Discussion: COVID-19 is a coronavirus that enters the host cell via the ACE-2 receptor. In the kidney, ACE-2 is expressed in mesangial cells, podocytes, the parietal epithelium of Bowman's capsule, and the collecting ducts. Research suggests that the inflammatory environment from COVID-19 can activate or exacerbate immune mediated diseases in predisposed individuals. The mucosal immune response against COVID-19 might have contributed to the progression of IgAN in this patient. We plan on checking the SARS-CoV-2 anti-RBD IgA titer to see if there is a correlation between anti-RBD IgA levels and progression of kidney function. Also, the persistence of IgA antibody or memory B cells post-COVID 19 infections may have prognostic implications in advancing IgAN or even end-stage kidney disease. Although our patient has not been vaccinated, there have also been cases of patients with IgAN developing gross hematuria after receiving the mRNA COVID-19 vaccine. This suggests that the vaccine components may induce further activation of disease. This previously healthy patient is believed to have a severe and persistent case of IgAN in part due to his COVID-19 infection.

PO0113

A Biopsy-Confirmed Case of IgA Nephropathy Flare-Up with Gross Hematuria and AKI Following SARS-CoV-2 Vaccination Successfully Treated with Steroid Therapy

Shota Watanabe, Shuling Zheng, Arash Rashidi. *University Hospitals, Cleveland, OH.*

Introduction: The flare of immune-mediated disease (IMDs) following SARS-CoV-2 vaccination is a rare adverse event following immunization (AEFI). A few cases of suspected IgA nephropathy (IgAN) flare-up, causing gross hematuria without an increase in Cr, have been reported, and they all resolved without treatment. Here we report a biopsy-confirmed case of IgAN flare-up with AKI following mRNA-1273 vaccination, which was successfully treated with steroid therapy.

Case Description: A 54-year-old female with history of IgAN after strep throat infection that was diagnosed with renal biopsy in 2006. Other significant co-morbidity includes obesity (BMI 31.6), hypertension, and GERD. No prior documented infection with COVID-19. She was on enalapril 20mg daily, hydrochlorothiazide 12.5mg daily, and propranolol 120mg daily. Her baseline creatinine level was 1.2. Urinalysis was positive for 2+ protein, 3+ blood, and RBC 15 /HPF. The total urine protein to Cr ratio was 1.03. Two days after receiving the second Moderna mRNA-1273 vaccine, she developed gross hematuria, which resolved in 2 days. Follow-up Cr increased to 3.04 one week after receiving the second dose of vaccine. The urinalysis showed 1+ protein, 3+ blood, RBC 50/ HPF. The total urine protein to Cr ratio was 0.67. The renal ultrasound was unremarkable. Repeat kidney biopsy showed IgA mesangial deposition, focal segmental and focal global glomerulosclerosis, mild interstitial fibrosis and tubular atrophy, and mild arteriolar hyalinosis. The patient was started on prednisone 60mg daily. Shortly after she was started on prednisone, Cr level started getting better. In 3 weeks Cr level was down to 1.7.

Discussion: This is the first reported case of biopsy-proven IgAN flare-up after SARS-CoV-2 vaccination that caused AKI. Corticosteroid is an effective treatment, promptly improving Cr. IgAN exacerbation after SARs-Cov-2 vaccination should be closely monitored for frequency and consequence to further elucidate AEFI of the novel vaccine.

PO0114

New Diagnosis of Glomerulonephritis and Relapse of Prior Glomerulonephritis Post mRNA COVID-19 Vaccination

Nattawat Klomjit, Ziad Zoghby, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Messenger RNA COVID-19 vaccine is more effective than traditional vaccines due to superior immune activation. However, the impact of mRNA COVID-19 vaccine on glomerulonephritis (GN) is limited. We report 4 cases of patients who developed new or had relapse of GN post vaccination.

Case Description: Case 1: A 43-year-old male with prior COVID-19 infection and baseline serum creatinine (SCr) of 1.2 mg/dl received Moderna vaccine 9 months after recovering from COVID-19 infection. Two weeks after the 1st dose, SCr increased to 2.5 mg/dl. He received 2nd dose 2 weeks later and SCr 3 days after was 2.7 mg/dl. Urinalysis (UA) showed 21-30 RBC/hpf and 24 hr urine protein (UP) was 14.4 g/d. A kidney biopsy revealed IgAN with moderate interstitial nephritis. He was treated with prednisone and ramipril. Case 2: A 66-year-old male with atrial fibrillation with baseline SCr 1.1 mg/dl received 1st dose of Moderna vaccine and two weeks later SCr was 1.5 mg/dl. Eight weeks after the 2nd dose, SCr was 2.4 mg/dl. UA showed 51-100 RBC/hpf and 24 hr UP 1.2 g/d. A kidney biopsy revealed IgAN with acute tubular injury and RBC casts. He was treated conservatively. Case 3: A 29-year-old female with minimal change disease who had been in remission for 2 years, received 2 doses of Pfizer vaccine. Three weeks after the 2nd dose, she developed leg edema with albumin 2.2 g/dl, 24 hr UP 10 g/d, and SCr 0.6 mg/dl. A repeat kidney biopsy showed focal segmental glomerulosclerosis, tip variant. She was treated with prednisone and tacrolimus. Case 4: A 39-year-old male with PLA2R+ membranous nephropathy who was in remission and off immunosuppressive therapy for 1.5 years received 2 doses of Pfizer vaccine. Two weeks after the 2nd dose, he developed leg edema with SCr 1.1 mg/dl, albumin 2.0 g/dl, and 24 hr UP 8.7 g/d. Tacrolimus was re-initiated.

Discussion: New cases and relapse of GN can present shortly after mRNA COVID-19 vaccination. Messenger RNA COVID-19 vaccine may be associated with reactivation of known glomerulonephritis or unmask presence of previously undiagnosed GN such as IgAN possibly due to potent immune activation. However, mechanism remains unknown and additional studies are needed.

PO0115

Impact of the COVID-19 Pandemic on Kidney Diseases Requiring Renal Biopsy: A Single-Center Observational Study

Bjoern Tampe,[1] Samy Hakroush.[2] *[1]Nephrology and Rheumatology, University Medical Center Göttingen, Göttingen, Germany; [2]Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany.*

Background: The coronavirus disease-2019 (COVID-19) pandemic impacted healthcare services for kidney disease patients. Lockdown and social distancing were mandated worldwide, resulting in closure of medical services. The diagnosis of various kidney diseases may have been delayed during the COVID-19 pandemic because non-urgent tests and visits were postponed due to closure of medical services during the lockdown.

Methods: We here report the impact of the COVID-19 pandemic on a total number of 209 native kidney diseases requiring renal biopsy for diagnosis in a retrospective observational study from a tertiary hospital in Germany.

Results: The lockdown period in March and April 2020 primarily affected patients admitted to the normal medical ward with a compensatory increased rate of renal biopsies in the postlockdown phase. In addition, there was a shift towards more patients admitted with hemoglobinuria during the COVID-19 pandemic. This phenomenon of an increased number of patients with hemoglobinuria during the COVID-19 pandemic was specifically observed in a subgroup with hypertensive nephropathy requiring renal biopsy, not attributed to the COVID-19 lockdown period itself.

Conclusions: To our knowledge, this is the first report of identifying a subpopulation susceptible to closure of medical services during the COVID-19 pandemic and diagnostic delay of specific kidney diseases. Therefore, the COVID-19 pandemic should be regarded as a risk factor especially in patients with diseases other than COVID-19 primarily admitted to the normal medical ward.

PO0116

Tip Lesion Variant of Focal and Segmental Glomerulosclerosis (FSGS): A Case Report in a Patient with COVID-19

Rita S. Afonso, Ana Cabrita, Ana P. Silva. *Centro Hospitalar do Algarve EPE, Faro, Portugal.*

Introduction: Acute kidney injury (AKI) is a common complication of SARS-CoV-2 infection. Published cases report acute tubular injury as the most common pathologic finding in these patients. Glomerular disease has been reported in a minority of patients, with collapsing focal segmental glomerulosclerosis being the most common. Nonetheless, the existing evidence is sparse and inconclusive. The authors present a case of a patient diagnosed with a tip lesion variant of focal and segmental glomerulosclerosis (FSGS) and concomitant SARS-CoV-2 infection.

Case Description: A 43-year-old African woman, with no known past medical history, presented to the emergency department with a 6-day history of fatigue, headache, cough, hypoageusia, myalgia, dyspnea, nausea and vomiting. Laboratory tests confirmed SARS-CoV-2 infection. Despite fluid therapy, there was an elevation of serum creatinine from 1.1 to 1.6mg/dl and the urinalysis was positive for protein (4) and blood (2). The urinary sediment revealed 3 red blood cells per high-power field. The urinary protein/creatinine ratio was approximately 13 g, subsequently confirmed with a 24-hour urine collection (13445 mg/24hours). All immunological tests were negative with the exception of hepatitis B serology (positive for HBV past infection). Renal ultrasonography showed a right kidney of 106 mm and a left kidney measuring 99 mm with important reduction of corticomedullary differentiation. After cure criteria for COVID-19, the proteinuria was 1022 mg/24h. The kidney biopsy revealed a tip lesion variant of focal and segmental glomerulosclerosis (FSGS). Low dose angiotensin converting enzyme inhibitors were started but no corticotherapy due to spontaneous regression of proteinuria. The patient returned home 20 days after hospitalisation. After 1 month, serum creatinine levels and 24-hour urine protein decreased to 1.1 mg/dl and 1060 mg, respectively.

Discussion: To our knowledge, this is the first case report of a patient with tip lesion variant of focal and segmental glomerulosclerosis (FSGS) possibly associated with COVID-19 disease. More data from kidney biopsies will further elucidate about pathologic processes associated with kidney injury and glomerular involvement in SARS-CoV2 infection.

PO0117

Cause or Not: IgA-Dominant Infectious-Related Glomerulonephritis in a Patient Infected with COVID-19

Alexander Borrero-Arvelo,[1] Lisa M. Sebastian,[2] Roberto L. Collazo-Maldonado.[2] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: IgA dominant infectious related glomerulonephritis (IGAD-IRGN) is an uncommon variant of IRGN. It has been mostly associated with S.aureus infections. In the COVID Era, thre has been one case of IGAD-IRGN related to COVID. This is a case of IGA-IRGN in a patient infected with COVID-19.

Case Description: 51 y/o male with no previous medical history who presented with a 3 day history of generalized swelling. Patient had no known medical problems and was not taking any medications. He reported drinking 3 beers daily. Denied any recent illness or sick contacts. At ED, the patient was found with anasarca and uncontrolled blood pressure. Initial blood tests showed normal renal function with hypoalbuminemia (2.9g/dL). U/A showed active sediments and nephrotic range proteinuria of about 4 g/day. Proteinuria workup was done, including serologic workup. Labs were remarkable for elevated ESR (105), low C4 (12), normal C3 (95) and elevated RF (44). ANA, HIV, HCV, light chain ratio, cryoglobulins and ANCA were negative. UPIEP showed faint IgG kappa. CXR showed hazy interstitial opacities with a perihilar distribution. Pre-biopsy COVID molecular testing came back positive. He was diuresed aggressively and received losartan for BP control. A kidney biopsy was performed and revealed MPGN pattern with IF strongly positive for IgA in addition to weaker staining for C3, and IgG. EM showed subendothelial humps with few mesangial and subepithelial deposits. The diagnosis of IgA-dominant immune complex-mediated glomerulonephritis consistent with IRGN was made.

Discussion: IGA-IRGN is a rare variant of IRGN that has been mostly associated with S. aureus infections. In this case, the recent COVID-19 infection in this patient could reasonably explain the finding of IGAD-IRGN on kidney biopsy. IGAD-COVID-related GN has been reported only once in the literature. Up until recently, most cases of COVID related kidney injury have been associated to ATN and collapsing FSGS. A immunohistochemistry test for COVID in kidney tissue was sent, which is pending at the time of this submission. If confirmed positive, this could be the second confirmed case COVID related IGAD-IRGN. It is important for nephrologists to include IGAD-IRGN in the differential diagnosis in a COVID patient with nephrotic syndrome. Renal Biopsy is of utmost importance for diagnosis.

PO0118

De Novo Henoch Schönlein Purpura (HSP) Post Kidney-Pancreas Transplant Triggered by COVID-19 Infection

Mingyue He, Iris J. Lee, Ilay Rakhman, Serban Constantinescu. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: Histologic recurrence of immunoglobulin A (IgA) nephropathy after transplant is common, however, de novo development of HSP is rare post-kidney transplant. We describe a case of HSP with cutaneous and renal allograft findings, triggered by COVID-19 (SARS-CoV-2) infection.

Case Description: A 53-year-old African American (AA) male with history of ESRD secondary to diabetic nephropathy, underwent simultaneous pancreas-kidney transplant. Three months later, he presented with rash on the upper and lower extremities, hand and wrist pain, acute kidney injury and new onset nephrotic syndrome with 6.6g proteinuria and microscopic isomorphic hematuria. He had detectable SARS-CoV-2 RNA in the nasopharyngeal specimen and mild multifocal pneumonia treated with steroids and Remdesivir. Serologic work-up for nephrotic syndrome was negative. A skin biopsy demonstrated leukocytoclastic vasculitis. Renal allograft biopsy showed membrane proliferative and sclerosing glomerulonephritis with dominant IgA staining by immunofluorescence, consistent with IgA nephropathy. He received pulse dose steroids with improvement in kidney graft function and reduction of his proteinuria to 0.6 g four months after steroid treatment.

Discussion: We postulated that our patient developed de novo HSP and nephrotic syndrome as a result of COVID- 19 infection. Podocytopathy and nephrotic syndrome linked to viral infection have been well described, particularly in AA patients with high-risk APOL1 genotype. Key cytokines known to be elevated in COVID19 infection can drive autoimmune responses, such as interferon and IL-6. Cytokine release, uncontrolled activation of both innate and adaptive immune cells, along with genetic variants likely predispose patients to the development of glomerular disease mediated by various immune mechanisms. Published biopsy series consistently demonstrate acute tubular injury as the most common renal manifestation of COVID-19, however, new onset autoimmune diseases such as IgAN may also be triggered by COVID infection. HSP can be a rare complication of COVID-19, and also rarely occurs post-transplant. Glomerular disease and systemic autoimmunity should be recognized as a complication of COVID-19, regardless of the presence or absence of pulmonary findings.

PO0119

COVID-19 Infection in Kidney Transplant Recipients: A Single-Center Case Series of 10 Cases from Dominican Republic

Denazir Atizol Rodriguez,[1] Nathalí E. Bencosme,[1] Anthony J. Gutierrez,[1,2] Annette G. Garcia Delgado,[1] Eliana Dina-Batlle.[2,1] *[1]Pontificia Universidad Catolica Madre y Maestra Facultad de Ciencias de la Salud, Santiago De Los Caballeros, Dominican Republic; [2]Hospital Metropolitano de Santiago, Santiago de los caballeros, Dominican Republic.*

Introduction: The coronavirus disease 2019 (COVID-19) has caused tremendous impact globally due to the significant morbidity and mortality caused by this virus. It is currently known that the probability of becoming seriously ill from this disease is higher in older adults, in people with pre-existing comorbidities, and those with a suppressed immune state. Therefore, transplant patients are not the exception. Considering the importance of this topic and the scarce information on the outcome of this type of patient, especially in Latin America, this series of cases is focused on our experience with 10 kidney transplant patients hospitalized for COVID-19.

Case Description: The age range of the patients was 41 to 68 years, where 8 of these were men. The most common admission symptoms were fever (80%), dyspnea (70%), myalgia/arthralgia (50%), and headache (50%). The most prevalent laboratory findings were lymphocytopenia and increased inflammatory markers such as D-dimer, LDH, procalcitonin, erythrocyte sedimentation, and ferritin. General management included supportive treatment, statins, and antithrombotic therapy, while the specific treatment options were hydroxychloroquine, antivirals, corticosteroids, intravenous ig, tofacitinib, and convalescent plasma. All the patients improved and were discharged. Two of them went to the ICU and only one required mechanical ventilation. The majority of the patients (70%) remained with their baseline immunosuppression without dose reduction or suspension.

Discussion: kidney transplant recipients are more susceptible to infections, along with increased disease severity. At the same time their immunosuppressed state may reduce the inflammatory response following this type of infection. Decisions were based on stopping or attenuating the viral load and the systemic inflammation caused by this virus, but at the same time protecting against acute allograft rejection and the coinfection with other pathogens. Our findings suggest that the use of statins and antithrombotic prophylaxis in all hospitalized transplant patients may be beneficial to reduce the risk of mortality in patients with COVID-19 infection. Also, the maintenance of immunosuppressive therapy was not associated with worse outcomes.

PO0120

ANCA Vasculitis Presenting as Hemoptysis Post COVID-19 Infection

Surya Manivannan, Koyal Jain. *University of North Carolina System, Chapel Hill, NC.*

Introduction: COVID-19 infection has been suggested to be a trigger for a de-novo autoimmune response. This case represents one of a few reported cases of ANCA-vasculitis developing after a COVID infection.

Case Description: A 41-year-old female with a history of chronic sinusitis (not vasculitis related), obesity, right pulmonary sequestration, and mild COVID-19 infection 1-month prior manifesting as only mild cough with loss of taste and smell, was admitted with a 2-week history of progressive cough productive of blood-tinged sputum and lower extremity neuropathy. CTA of her chest showed air space opacities in right lower lobe concerning for bacterial superinfection in a host with altered pulmonary architecture. She was treated for presumed community acquired pneumonia. A week later, she presented with worsening hemoptysis and respiratory failure requiring intubation, which escalated quickly to needing extracorporeal membrane oxygenation (ECMO). Extensive bilateral airspace infiltrates due to diffuse alveolar hemorrhage and a PR3-ANCA level of 175 U/ml were strongly suggestive of a new diagnosis of ANCA-vasculitis (granulomatosis with polyangiitis). Her renal function remained normal, and urine sediment had no findings to indicate an ongoing concurrent nephritic process. She was given high dose pulse intravenous steroids, recombinant factor VII, 7 sessions of daily plasma exchange, intravenous tranexamic acid, and 1 dose of Cytoxan 500 mg/m2. She briefly had clinical improvement and required decreased ECMO support, but unfortunately, she later developed worsening pulmonary hemorrhage and hypotension, which was attributed to acute respiratory distress syndrome and thrombocytopenia, as opposed to immune mediated capillaritis. After 2 weeks of treatment, she was terminally decannulated.

Discussion: This is a rare case of ANCA-vasculitis likely triggered by COVID-19 infection. The presence of peripheral neuropathy indicates that she probably had extrapulmonary manifestations of vasculitis, although she had no evidence of renal involvement. This case report demonstrates that a high index of suspicion is needed for a new diagnosis of ANCA-vasculitis in patients with a prior history of COVID-19 infection to allow for prompt diagnosis and appropriate management.

PO0121

Deep Learning for Subphenotype Identification in COVID-19-Associated AKI

Suraj K. Jaladanki, Sergio Dellepiane, Akhil Vaid, Ishan Paranjpe, Karandeep Singh, Lili Chan, Steven G. Coca, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) is common in COVID-19 and associated with increased adverse outcomes. COVID-associated AKI (COVID-AKI) pathophysiology is heterogenous, and deep learning may discover subphenotypes.

Methods: We used data from 5 New York City hospitals from adults admitted between March '20-March '21 with COVID and AKI, excluding patients with kidney failure. An autoencoder compressed 58 features containing comorbidities, the first laboratory values and vital signs within 48 hours of admission for unsupervised *K*-means clustering. Outcomes were mortality, dialysis, mechanical ventilation, and ICU admission.

Results: We identified 1634 patients with COVID-AKI and discovered 3 subphenotypes. Subphenotype one had 576 patients (35%); two had 635 patients (39%), and three had 423 patients (26%) (Table 1). Subphenotype three had the lowest median blood pressures, highest median BMI, and highest rates of all outcomes. (Figure 1)

Conclusions: There are distinct subphenotypes in COVID-AKI indicating the heterogeneity of this condition.

Funding: NIDDK Support

Table 1. Demographics of COVID-Associated AKI Subphenotypes.

	Overall	Subphenotype 1	Subphenotype 2	Subphenotype 3	P-value
N (%)	1634	576 (35.3%)	635 (34.1%)	423 (25.6%)	
Age, median (IQR)	73.0 [63.0,83.0]	74.0 [63.0,84.0]	75.0 [65.0,83.0]	69.0 [59.5,78.0]	<0.001
Female, n (%)	936 (57.3)	324 (56.2)	318 (50.1)	294 (69.5)	<0.001
Race, n (%)

An ISN-DOPPS Survey of the Global Impact of COVID-19 Pandemic on Home Peritoneal Dialysis Services

Rehab B. Albakr,[1] Brian Bieber,[2] Ryan E. Aylward,[3,4] Fergus Caskey,[3] Gavin Dreyer,[5] Rhys D. Evans,[6] Murilo H. Guedes,[7] Vivekanand Jha,[14,15] Valerie A. Luyckx,[8,4] Roberto Pecoits-Filho,[2] Chimota T. Phiri,[9] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Dibya Singh Shah,[10] Elliot K. Tannor,[12] Adrian Liew,[11] Jeffrey Perl.[13] ISN DOPPS collaboration *[1]University of Toronto, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Bristol Medical School, Bristol, United Kingdom; [4]University of Cape Town, Rondebosch, South Africa; [5]Barts Health NHS Trust, London, United Kingdom; [6]The University of British Columbia, Vancouver, BC, Canada; [7]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [8]Brigham and Women's Hospital, Boston, MA; [9]Queen Elizabeth Central Hospital, Blantyre, Malawi; [10]Tribhuvan University, Kirtipur, Nepal; [11]Mount Elizabeth Medical Centre, Singapore, Singapore; [12]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [13]St. Michael's Hospital, Toronto, ON, Canada; [14]The George Institute for Global Health, New Delhi, India; [15]Imperial College London, London, United Kingdom.*

Background: Home dialysis may be able to minimize SARS-CoV2 exposure risks. The pandemic may have introduced unique challenges related to supply disruption and care delivery changes. We sought to assess the global burden of COVID-19 on peritoneal dialysis units (PD) and understand PD unit practice changes during this time.

Methods: The Peritoneal Dialysis/Dialysis Outcomes and Practice Patterns Study (PDOPPS/DOPPS) and International Society of Nephrology (ISN) administered a web-based survey (1) to dialysis units selected based on a random sample stratified by region (November 2020 – March 2021), and (2) to an open invitation via ISN's membership list and social media (March 2021). Responses were compared across 10 ISN regions.

Results: Returned surveys included 167 PD facilities across 52 countries. Changes in several care domains including clinic communication and frequency, labwork frequency, method of communication, masking policies, changes in handling of PD effluent among infected individuals, PD supply disruption, access to methods of PD catheter insertion and frequency of new patient training are highlighted (table).

Conclusions: Variability exists in routine PD care, and the availability and use of PPE, disruption in PD supplies among the different regions reflecting the availability of the resources and infrastructure differences. LMIC tended to be more severely impacted—this gap needs to be addressed in anticipation of future pandemics for treatment continuity. Although remote technology use among PD patients to communicate with their physicians has increased during the pandemic, optimal communication frequency, methods and schedule of routine bloodwork needs to be better elucidated.

Table: Change in PD facility practices from before the COVID-19 pandemic by ISN region, as reported by medical directors at each participating site

		ISN Region

Modifications in procedures for handling of effluent in COVID-19 positive patients	29%	33%	34%	33%	40%	22%	14%	0%	38%	50%	24%

a. Restricted to facilities with some pre-pandemic laparoscopic use
b. Restricted to facilities with some pre-pandemic non-surgical percutaneous (skin,) procedure use
c. Includes masking during all exchanges or masking only if patient is symptomatic

Hence, work-up to exclude nephritic syndrome was requested. Reports were remarkable for positive p-ANCA and presence of MPO antibodies. Workup for GBM antibodies came back negative. Patient was started on intravenous steroids. Renal biopsy showed evidence of ANCA mediated pauci immune GN with crescents. Further on, she was transitioned to oral steroids and Rituxan where improvement of renal function was observed.

Discussion: While ANCA associated GN in SARS-CoV-2 is rare, the incidence of COVID19 cases is on the rise. The incidence of other potential complications are yet to be identified. Thus, it is important to understand and study the disease's pathophysiology to extrapolate possible complications. This will assist in the early detection of disease and help improve patient's prognosis. Also, will prevent development of chronic repercussions in patient's renal function.

PO0123

Comparison of Rates of AKI Between Two COVID-19 Surges in Hospitalized Patients in the Bronx

Bruna Taveras Garcia,[1] Maria V. Avendano,[1] Tianying Li,[1] John D. Wagner,[2] Natalia Cavin,[1] Rosalba Y. Santana De Roberts,[1] Kisra Anis,[1] Naheed Ansari,[1] Belinda Jim,[1] Nidhi Varma,[1] Sneha Chelimeda,[1] Anjali Acharya.[1] Jacobi Renal Group *[1]Jacobi Medical Center, Bronx, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Background: The incidence of AKI in COVID 19 is very variable across the world. In New York City it was as high as 36% in a large series in early 2020. However, the incidence of AKI during the second surge between Oct of 2020 to early 2021 is unknown. In this study, we compared these two COVID-19 periods for the incidence of AKI amongst hospitalized patients.

Methods: This was a multi-center, retrospective cohort study of patients hospitalized with COVID-19 between March 1st and July 16th 2020 (n=1,719), and between October 15th 2020 and February 28th 2021(n=997) in two NYC public hospitals, (total n= 2,716). Patients < 18 years, with End Stage Kidney Disease or a kidney transplant were excluded. Chi-squared test and Fisher's exact test were used to compare the clinical characteristics of the patients. A p-value less than 0.05 was considered statistically significant.

Results: The baseline clinical characteristics and demographics of the two surges were similar. The incidence of AKI as defined by KDIGO criteria, during admission decreased from 28.7% in the first surge to 18.6% in the second surge ($p<0.0001$). This trend was seen both at encounter level too as shown below. For laboratory characteristics, more patients with hypernatremia and with peak CRP > 50 (Ref range: <50) presented in the first surge than the second surge ($p<0.0001$). No differences in the peak potassium and peak D-Dimer, or ICU admission rates were seen between two surges. However, significantly more AKI patients in the first surge were on mechanical ventilation as compared to the second surge ($p=0.0196$).

Conclusions: To our knowledge this is the first comparison reported between rates of AKI in hospitalized patients with COVID-19 during two different surge periods. The difference may be related to less severe disease during the second surge, though ICU admission rate was the same. Better care established by the time of the second surge and improved therapeutics such as early use of anti-viral agents, corticosteroids, and anticoagulation may have contributed to better outcomes. Improvement in care of COVID-19 in the second surge may have contributed to a decline in the incidence of AKI. Future studies are needed to see if this trend towards lower AKI incidence continues.

PO0124

COVID-19-Induced P-ANCA-Associated Nephritic Syndrome in a Woman Without Respiratory Involvement

Jan P. Rosaly, Elizabeth Pabon-Vazquez, Bryan L. Pagan rivera. *Mayaguez Medical Center, Mayaguez, Puerto Rico.*

Introduction: Infection with severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) has affected our population worldwide leading to a global pandemic. The most common manifestation was infection to the lungs leading to respiratory failure. As the infection continued to spread, other complications started to emerge. Studies have identified involvement of other organs such as heart and kidneys. It has been observed that patients with severe infection are debuting with renal failure. The most common lesion is acute tubular necrosis (ATN) but other causes such as endotheliitis, nephrotic syndrome and glomerulonephritis (GN) have been observed. ANCA associated GN is a rare manifestation of SARS-CoV-2 infection that must be differentiated from ATN. Only two cases of ANCA associated vasculitis have been reported. They were both male and presented with ANCA associated GN responsive to immunosuppressive therapy.

Case Description: Case of a 65 year old female patient with medical history of asthma and dyslipidemia presented to the hospital with complaints of recurrent painless hematuria. Physical examination was unremarkable. Initial laboratory work up was remarkable for acute kidney injury accompanied by the presence of pyuria, hematuria and proteinuria. There was evidence of leukocytosis and anemia. PCR test for COVID19 came back positive. Renal imaging showed thickening of the urothelium at the renal pelvis with parenchymal echogenicity. After multiple efforts there was no significant improvement.

PO0125

AKI Secondary to Atypical Hemolytic Uremic Syndrome Caused by COVID-19

Rahul R. Abraham, Hugo Akabane. *LSU Health Shreveport, Shreveport, LA.*

Introduction: Atypical Hemolytic Uremic Syndrome(aHUS) can be triggered by viral infections. So far there has been little data on COVID 19 infection-causing aHUS. We present one such case of acute kidney injury(AKI) secondary to aHUS with COVID-19 infection and its outcome.

Case Description: A 55-year-old woman presented with altered mental status and shortness of breath from 2-3 days. The patient tested positive for the COVID-19 virus. Labs showed creatinine of 4.8g/dl from a baseline of 0.8g/dl, with a hemoglobin of 8.9g/dl and a platelet count of 20,000/uL. Peripheral smear showed evidence of a large number of schistocytes and thrombocytopenia. Haptoglobin and reticulocyte counts were 28mg/dl, reticulocyte count 3.8% respectively. In view of her symptoms and laboratory findings, there was high suspicion for Thrombotic thrombocytopenic purpura (TTP). Her PLASMIC score was 6. Treatment with plasma exchange therapy (PEX) and steroids was initiated but there was no significant clinical improvement. An ADAMSTS13 level was sent prior to the initiation of PEX and resulted at 65%, ruling out the diagnosis of TTP. Due to lack of evidence of TTP eculizumab was started for suspected aHUS. She responded remarkably well (within days) with mentation returning to baseline, hemoglobin stabilizing, platelet slowly trending towards normal and peripheral smear, labs showing no signs of hemolysis, and an improvement in her RFP. At 5 month follow-up, the patient eventually progressed to end-stage renal disease had to be placed on regular dialysis.

Discussion: AHUS is a rare variety of thrombotic microangiopathy(TMA) which results in a classic triad of Coombs negative hemolytic anemia, renal injury, and thrombocytopenia. aHUS has a mortality rate of 25%. 50% of patients eventually progress to ESRD or have irreversible brain damage. Multiple triggers have been identified including various non-enteric infections, viruses, drugs, malignancies, transplantation, pregnancy, and other underlying medical conditions. At the time of writing this case report, there is only one other case report of COVID-19 virus-induced aHUS resulting in AKI. In aHUS renal damage is thought to be caused by microthrombi formation in the kidney vasculature. Endothelial damage is further escalated by anaphylatoxins produced by complement activation. aHUS induced AKI is an alternate mechanism for COVID -19 to cause AKI requiring eculizumab for optimal treatment.

PO0126

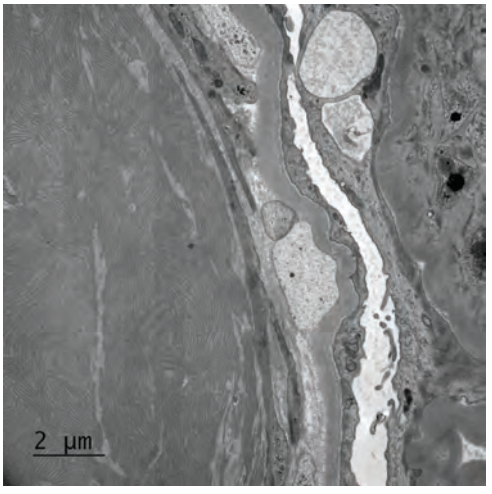
Cryoglobulinemia in the Setting of COVID-19 AKI

Emily L. Ward, Gunjan Garg. *University of Louisville, Louisville, KY.*

Introduction: COVID19 is due to SARS-CoV-2 a single stranded RNA virus with respiratory and epithelial cell targets. As COVID19 has reached pandemic proportions, complicating AKI is common. Pathogenesis is varied and multifactorial but acute tubular injury is most common. Glomerular pathology is possible but not well defined.

Case Description: 66YOM with HTN, Stage III CKD, & COVID19 hypoxemic respiratory failure complicated by AKI & nephritic syndrome. Cr peaked at 5mg/dL. He required CRRT for volume overload & acidosis. Labs showed low C3 & type I cryoglobulinemia. IgGλ monoclonal protein on SPEP. Extensive cryoglobulinemic GN on renal bx with IgGλ immunofluorescence. Negative Congo red stain. Microtubular deposits indicative of cryoglobulins on EM. He received pulsed solumedrol then 5 sessions of PLEX. Renal recovery with good urine output, dialysis discontinued. Cr down to 2.2mg/dL post PLEX.

Discussion: Cryoglobulinemia is due to cold immunoglobulin precipitation. Type I is associated with malignancy or hematologic disease and Types II & III have infectious triggers. Our patient had Type I IgGλ cryoglobulinemia without evidence of malignancy. BM bx had 10% abnormal plasma cells, perhaps due to plasma cell dyscrasia of cryoglobulinemia. A prior case series reported COVID19 incident MGUS. Patients had monoclonal IgGλ or IgGκ but no mentioned renal injury. They hypothesized gammopathy due to immune hyperactivation. Expounding, our patient's renal manifestations fit a Hemophagocytic Lymphohistiocytosis pattern so we hypothesize they are due to COVID19 associated hyperinflammation and cytokine release. Our case illustrates the benefit of biopsy to identify additional treatment options and the reality that timely biopsy can't always be safely obtained. In COVID19 patients respiratory or hematologic status can make biopsy unsafe which may limit defining associated glomerular pathology.



PO0127

Antibody and T Cell Reactivity Response After SARS-CoV-2 BNT162b2 mRNA Vaccine in Hemodialysis Patients: A Single-Center Experience from Sweden

Jan Melin,[1,2] Maria K. Svensson,[1,2] Bo Albinsson,[1,2] Karlis Pauksens.[1,2] *[1]Akademiska sjukhuset, Uppsala, Sweden; [2]Uppsala Universitet, Uppsala, Sweden.*

Background: The immune system is affected by uremia. Patients with end-stage kidney disease (ESKD) on hemodialysis treatment (HD) are vulnerable to infections, may have suboptimal response to vaccination and are at increased risk of contagious infections due to many health care contacts. They also have a high mortality from Covid-19 infection.

Methods: In 50 patients (mean age 69.4 years, 62% men) with ESKD and HD at Uppsala Academic Hospital, Sweden, administration of vaccine began in late Dec 2020 and the immune response was followed up four months later, in April/May 2021. IgG antibody test against Covid-19 (SARS-CoV-2) was performed against the nucleocapsid antigen (anti-N), positive only after illness, and against Spike antigen (anti-S) positive both after illness and after vaccination (quantitative method in routine diagnostics at the department of microbiology, Uppsala). T-cell reactivity testing against the Spike protein using ELISPOT technology measuring Interferon-gamma activity was performed at ABC-labs, Solna.

Results: Out of 50 patients IgG antibodies to anti-S were detected in 37 (74%), 5 (10%) had a limit response and 8 (16%) were negative after two doses of vaccine. T-cell responses were detected in 29 (58%) and in 21 (42%) no response was detected. Of the 37 patients with antibody responses to anti-S, 25 (68%) also had a measurable T-cell response, 2 (40%) of 5 with limit value for antibody response and 2 (25%) of 8 had no antibody response. 27 (54%) had both an antibody and T-cell reactivity response. IgG antibodies to anti-N indicating a previous Covid-19 disease after 2 doses of vaccine were detected in 7 (14%) patients. 3 patients (6%) had tested PCR-Covid-19 positive before vaccination, 2 (4%) became positive between doses one and two. 4 (8%) had positive tests after two injections and all of them developed a mild disease.

Conclusions: A majority of patients with ESKD and HD develop a B- and/or T-cell response after vaccination against Covid-19 but approx. 20 % had a very limited immunological response. In a clinical setting it is justified to measure the antibody response after vaccination to identify patients are not protected and where to need to take other measures to protect them from infection. In these patients, a third vaccine dose with another type of vaccine could be justifyable.

PO0128

COVID-19 mRNA Vaccine-Associated Autoimmunity Presenting as Minimal Change Disease and Membranous Nephropathy

Kenar D. Jhaveri,[1] Vanesa Bijol,[1] Rimda Wanchoo,[1] Keith H. Keller,[2,5] Mariam P. Alexander,[4] Astrid Weins.[2,3] *[1]Northwell Health, New Hyde Park, NY; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Broad Institute, Cambridge, MA.*

Background: Vaccine-triggered complications, including autoimmune diseases and minimal change disease (MCD), were reported during recent COVID-19 vaccine rollout. Anti-nephrin autoantibodies were described in nephrotic syndrome (NS) with kidney biopsy (Kbx)-proven MCD. Therefore, we examined patients with COVID-19 vaccine-associated NS for anti-nephrin autoantibodies.

Methods: 5 patients presenting with nephrotic-range proteinuria 1-3 weeks after COVID-19 vaccine and a KBx were identified (3 Pfizer/BioNTech, 2 Moderna). Past medical history and lab tests including serum creatinine (sCr), urine protein-to-creatinine ratio (UPCR), and serological workup were recorded. KBx were routinely evaluated by light microscopy (LM), immunofluorescence microscopy (IF), and electron microscopy (EM), followed by confocal examination of relative IgG and nephrin localization in all patients; serological studies for anti-nephrin antibodies using human glomerular extract and recombinant nephrin extracellular domain were performed using plasma available on 2 patients.

Results: In all patients, sCr was 0.5-1.2 mg/dl and UPCR 4.5-7.6 g/g. 1 patient had MCD in remission diagnosed 6 months prior; others had no relevant PMH. All workup was negative, except low positive ANA in 2 patients. On KBx, diagnosis of MCD was made in 4 and stage I membranous nephropathy (MN) in 1 patient(s) (serum albumin 2.0-2.4g/dl in MCD and 3.6g/dl in MN patient(s)); all had mild chronic changes. All 4 MCD patients had fine granular punctate podocyte staining for polyclonal IgG colocalizing with nephrin by IF and diffuse FPE by EM; in 1 patient plasma was saved during NS and was serologically positive for anti-nephrin. The MN patient had 3+ fine granular IF staining for polyclonal IgG and PLA2r along GBMs with sparse superficial subepithelial electron-dense deposits on EM, and was serologically negative for anti-nephrin. All MCD patients were successfully treated with oral glucocorticoids, while the MN patient was monitored closely under RAAS blockage.

Conclusions: COVID-19 mRNA vaccines can trigger de-novo or relapsing anti-nephrin- and PLA2r-mediated NS, thus adding both autoimmune-mediated podocytopathies to vaccine-induced complications. Temporal association is essential for diagnosis; prompt accurate diagnosis benefits treatment and response.

Real-World Effectiveness and Immunogenicity of BNT162b2 in Dialysis Patients

Scott Sibbel,[1] Katherine L. Mckeon,[1] Jiacong Luo,[1] Karl Wendt,[1] Adam G. Walker,[1] Rachael Lazar,[2] Meredith L. Zywno,[2] Jeffrey J. Connaire,[1] Francesca Tentori,[1] Amy Young,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: BNT162b2 (Pfizer/BioNTech) is a SARS-CoV-2 vaccine that received an emergency use authorization from the US Food and Drug Administration. Clinical trials in the general population demonstrated that BNT162b2 reduced risk of COVID-19 by 95%, however, dialysis patients were not represented in these trials. Here, we estimated the effectiveness and SARS-CoV-2 antibody response among real-world dialysis patients who were vaccinated with BNT162b2.

Methods: Patients included in this analysis were adults dialyzing at a large dialysis organization. For the effectiveness analysis, patients who began a BNT162b2 vaccination series (January-March 2021) were matched (with replacement) to up to 4 previously unvaccinated controls based on age, diabetes status, sex, race, body mass index, date of first vaccine, US state of residence, and prior known COVID-19 diagnosis. Vaccine effectiveness was estimated by calculating the hazard ratio (HR) for time to polymerase chain reaction confirmed infection between vaccinated and unvaccinated patients over 3 follow-up intervals: days 1-21, 22-42, and ≥43 after first dose of vaccine. Immunogenicity was measured in a subset of consented patients who completed the 2-dose BNT162b2 vaccination schedule. Blood samples were collected approximately 28 days after the second dose of BNT162b2, and indirect chemiluminescence immunoassays were used to measure immunoglobulin G (IgG) antibodies against SARS-CoV-2. Samples with a reading of >1 arbitrary unit (AU) were considered IgG+.

Results: We identified 12,169 patients who received BNT162b2 and were matched to 44,377 unvaccinated controls. The HRs and 95% confidence intervals (CI) were 0.84 (0.68, 1.03), 0.61 (0.40, 0.93), and 0.21 (0.13, 0.35) during 1-21, 22-42, and ≥43 days postvaccination, respectively. Among the 344 patients with postvaccination antibody measurements, 98.0% (95% CI: 95.2%-99.2%) were IgG+ (median: 63.3 AU of IgG).

Conclusions: Our results indicate that BNT162b2 is effective in preventing SARS-CoV-2 infection in dialysis patients. Moreover, antibodies to SARS-CoV-2 were detected in nearly all patients vaccinated with BNT162b2 in whom antibodies were measured.

PO0130

Early Humoral Responses of Hemodialysis Patients After COVID-19 Vaccination with BNT162b2

Claudius Speer, Louise Benning, Christian Nusshag, Florian Kälble, Paul Schnitzler, Martin G. Zeier, Christian Morath, Caner Süsal, Katrin Klein. *University of Heidelberg, Heidelberg, Germany.*

Background: Patients receiving hemodialysis are at high risk for both SARS-CoV-2 infection and severe COVID-19. A life-saving vaccine is available, but sensitivity to vaccines is lower in dialysis patients. Little is yet known about antibody response after COVID-19 vaccination in this vulnerable group.

Methods: In this prospective study, we included 22 dialysis patients and 46 healthy controls from Heidelberg University. We measured anti-S1 IgG with a threshold index for detection >1, neutralizing antibodies, and antibodies against different SARS-CoV-2 fragments 17–22 days after the first and 18–22 days after the second dose of BNT162b2.

Results: After the first vaccine dose, 4/22 (18%) dialysis patients compared with 43/46 (93%) healthy controls developed positive anti-S1 IgG, with a median (IQR) anti-S1 IgG index of 0.2 (0.1–0.7) compared with 9 (4–16), respectively. SARS-CoV-2 neutralizing antibodies exceeded the threshold for neutralization in 4/22 (18%) dialysis patients compared with 43/46 (93%) in healthy controls, with a median (IQR) percent

inhibition of 11 (3–24) compared with 65 (49–75), respectively. After the second dose, 14/17 (82%) of dialysis patients developed neutralizing antibodies exceeding the threshold for viral neutralization and antibodies against the receptor-binding S1-domain of the spike protein, compared to 46/46 (100%) of healthy controls, respectively. The median (IQR) percent inhibition was 51 (32–86) compared to 98 (97–98) in healthy controls.

Conclusions: Patients receiving long-term hemodialysis show a reduced antibody response to the first and second doses of the mRNA vaccine BNT162b2. The majority (82%) develop neutralizing antibodies after the second dose, but at lower levels than healthy controls.

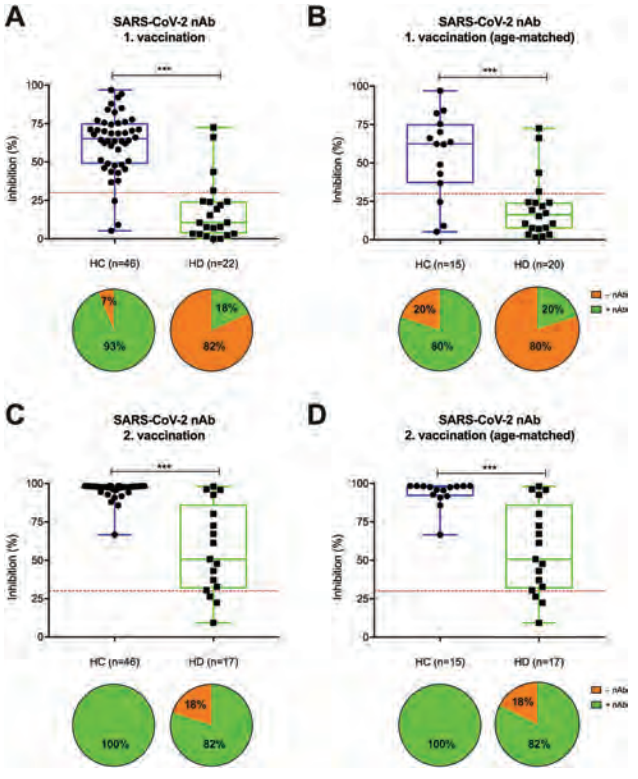

Figure 1

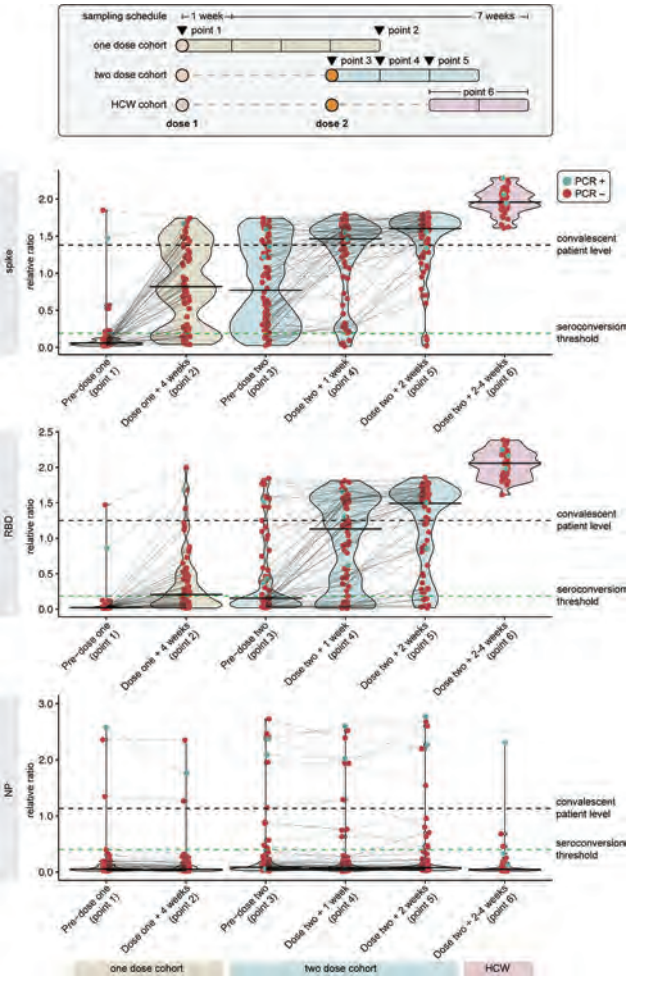

Figure 1: SARS-CoV-2 IgG Spike, RBD, and NP Antibody Response Following One Versus Two Dose BNT162b2 Vaccine in Hemodialysis Patients.

PO0131

Humoral Response to the BNT162b2 Vaccine in Hemodialysis Patients

Kevin Yau,[1] Kento T. Abe,[2] Jeffrey Perl,[1] David M. Naimark,[1] Christopher T. Chan,[1] Matthew J. Oliver,[1] Karen Colwill,[2] Anne-Claude Gingras,[2] Michelle A. Hladunewich.[1] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada.*

Background: Hemodialysis (HD) patients have high mortality from COVID-19 and immunity following vaccination remains uncertain. This study evaluated SARS-CoV-2 antibody response in HD patients following BNT162b2 COVID-19 vaccination compared to health care workers (HCW) and convalescent serum.

Methods: This single centre observational cohort study enrolled 142 HD patients and 35 HCW receiving the BNT162b2 vaccine. SARS-CoV-2 IgG antibodies to the spike protein (anti-spike), receptor binding domain (anti-RBD), and nucleocapsid protein (anti-NP) were measured in 66 HD patients receiving one vaccine dose, 76 HD patients receiving two vaccine doses, and 35 HCW receiving two vaccine doses.

Results: In HD patients receiving a single BNT162b2 dose, seroconversion occurred in 53/66 (80%) for anti-spike and 35/66 (55%) for anti-RBD by 28 days post dose, but only 15/66 (23%) and 4/66 (6%), respectively attained a robust response defined as reaching the median level of anti-spike and anti-RBD in convalescent serum. In patients receiving two doses of BNT162b2 vaccine, seroconversion occurred in 69/72 (96%) for anti-spike and 63/72 (88%) for anti-RBD by 2 weeks following the second dose while 52/72 (72%) and 43/72 (60%) reached median convalescent serum levels of anti-spike and anti-RBD. In HCW, 35/35 (100%) exceeded median levels of anti-spike and anti-RBD in convalescent serum 2-4 weeks post second dose.

Conclusions: This study found poor immunogenicity 28 days following a single dose of BNT162b2 vaccine in HD patients, supporting adherence to recommended vaccination schedules, and avoiding delay of the second dose in this population.

PO0132

Comparative Effectiveness of Ad26.COV2.S vs. BNT162b2 for the Prevention of SARS-CoV-2 Infection Among Dialysis Patients

Steven M. Brunelli,[1] Scott Sibbel,[1] Gilbert Marlowe,[1] Jeffrey A. Giullian,[2] David B. Van Wyck,[2] Francesca Tentori.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Elsewhere, we have demonstrated that the BNT162b2 vaccine (Pfizer/BioNTech) is highly effective in reducing risk of COVID-19 among real-world dialysis patients. Because individual vaccines may be differentially available (and acceptable) to patients, it is important to understand the comparative effectiveness of other agents, such as Ad26.COV2.S (Janssen).

Methods: This was a retrospective real-world comparative effectiveness study comparing two vaccination strategies ("use Ad26.COV2.S" versus "use BNT162b") among adult patients dialyzing at a large dialysis organization. Patients receiving Ad26.COV2.S were matched 1:1 to those initiating a BNT162b2 series based on age, race, US state of residence, calendar week of first vaccine receipt, and prior history of COVID-19. Follow-up time began the day after the first vaccine dose. The outcome of interest was the comparative rate of polymerase chain reaction-confirmed SARS-CoV-2 infections considered over 3 follow-up intervals: days 1-21, 22-42, and ≥ 43 post vaccination.

Results: There were 2683 matched pairs of patients who received a first dose of each vaccine. During days 1-21, the incidence rate was 1.26 infections per 1000 patient-weeks (pt-wks) among BNT162b2 recipients and 1.26 among Ad26.COV2.S recipients (incident rate difference [IRD]: 0.00; 95% confidence interval [CI]: -1.10, 1.10). During days 22-42, the incidence rate was 0.93 infections per 1000 pt-wks among BNT162b2 recipients and 0.40 among Ad26.COV2.S recipients (IRD: -0.50; 95% CI: -1.40, 0.30). After day 43, the incidence rate was 0.50 infections per 1000 pt-wks among BNT162b2 recipients and 0.50 among Ad26.COV2.S recipients (IRD: 0.00; 95% CI: -0.8, 0.8). Results were nearly identical when considering only patients without a prior history of COVID-19.

Conclusions: In a large contemporary cohort of dialysis patients, a "use Ad26.COV2.S" strategy versus a "use BNT162b2" strategy would be expected to yield no difference in additional cases of SARS-CoV-2 infections. Given similar effectiveness, vaccine allocation should be based on availability and logistical considerations.

PO0133

Predictors of Response to SARS-CoV-2 Vaccines Among Maintenance Dialysis Patients

Caroline M. Hsu,[1] Daniel E. Weiner,[1] Gideon N. Aweh,[2] Harold J. Manley,[2] Vladimir Ladik,[2] Jill M. Frament,[2] Dana Miskulin,[1] Doug Johnson,[2] Eduardo K. Lacson.[1,2] *[1]Tufts Medical Center, Boston, MA; [2]Dialysis Clinic Inc, Nashville, TN.*

Background: Vaccines against SARS-CoV-2 are highly effective in the general population; however, their efficacy may be diminished in maintenance dialysis patients, a population particularly vulnerable to COVID-19. We assessed vaccine response in a national sample of maintenance dialysis patients.

Methods: Using retrospective clinical data, we assessed seroresponse to vaccine among maintenance dialysis patients cared for at 130 Dialysis Clinic, Inc (DCI) facilities. Via a clinical protocol available to early vaccinating facilities, antibodies against SARS-CoV-2 spike antigen were semi-quantitatively assessed beginning with the monthly blood draw at least two weeks after completion of a SARS-CoV-2 vaccine series. Vaccine response was defined as a titer ≥2 U/L, and logistic regression analysis was used to identify characteristics associated with response. Patients with history of COVID-19 prior to antibody assessment were excluded.

Results: Among 1,352 patients, 996 (74%) had a serologic response. Serologic response differed significantly by vaccine type: 314/386 (81%) among BNT162b2/Pfizer recipients, 615/655 (94%) among mRNA-1273/Moderna recipients, and 67/311 (22%) among Ad26.COV2.S/Janssen recipients. Age greater than 75, lack of hepatitis B immunity, immune-modulating medication, lower serum albumin, and COPD were associated with vaccine non-response (**Figure**).

Conclusions: Serologic response to mRNA vaccines is robust among chronic dialysis patients, and the use of mRNA vaccines should be promoted aggressively in this vulnerable population. High rates of non-response to the Janssen vaccine warrant further study. Future research should evaluate the potential role for boosters and whether seroresponse corresponds with protection from COVID-19.

Humoral Responses to Single-Dose BNT162b2 mRNA Vaccination in Dialysis Patients Previously Infected with SARS-CoV-2

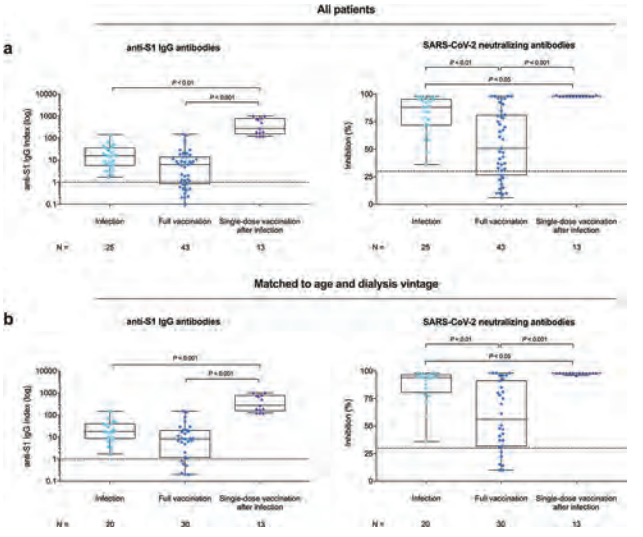
Claudius Speer, Christian Nusshag, Florian Kälble, Katrin Klein, Caner Süsal, Paul Schnitzler, Martin G. Zeier, Christian Morath, Louise Benning. *University of Heidelberg, Heidelberg, Germany.*

Background: Seroconversion rates following infection and vaccination are lower in dialysis patients compared to healthy controls. There is an urgent need for the characterization of humoral responses and success of a single-dose SARS-CoV-2 vaccination in previously infected dialysis patients.

Methods: We performed a dual-center study with 43 dialysis patients after BNT162b2 vaccination and 25 dialysis patients after PCR-confirmed COVID-19. Single-dose vaccination was performed in 13 previously infected patients. Anti-S1 IgG, neutralizing antibodies, and antibodies against various SARS-CoV-2 epitopes were measured 6 weeks after the first vaccination or onset of COVID-19 and 3 weeks after single-dose vaccination.

Results: Previously infected patients without vaccination showed a significantly higher neutralizing capacity than patients vaccinated twice (median (IQR) percent inhibition 88.0 (71.5–95.5) vs. 50.7 (26.4–81.0); P=0.018). After one single vaccine dose, infected individuals generated 15- to 34-fold higher levels of anti-S1 IgG than age- and dialysis vintage-matched patients after infection or two-time vaccination with a median (IQR) index of 274 (151–791) compared to 18 (8–41) and 8 (1–21) (for both P<0.001). With a median (IQR) percent inhibition of 97.6 (97.2-98.9), the neutralizing capacity of SARS-CoV-2 antibodies was significantly higher in previously infected patients compared to other groups (for both P<0.01). Bead-based analysis showed high antibody reactivity against various SARS-CoV-2 spike protein epitopes after single-dose vaccination in previously infected patients.

Conclusions: Single-dose vaccination in previously infected dialysis patients induced a strong and broad antibody reactivity against various SARS-CoV-2 spike protein epitopes with high neutralizing capacity.



PO0135

Anti-Spike Antibody Responses in Hemodialyzed Patients Vaccinated with Anti-COVID-19 BNT162b2 mRNA Vaccine

Iolanda Godinho,[1] Ana rita Abrantes,[1] Marie-Louise L. Bergman,[2] Lígia A. Gonçalves,[2] Nádia Duarte,[2] Patricia C. Borges,[2] Ana Brennand,[2] Vanessa C. Malheiro,[2] Paula G. Matoso,[2] Onome Akpogheneta,[2] Jocelyne Demengeot,[2] Carlos Penha-Gonçalves,[2] Marco A. Marques,[3] Estela Nogueira,[1] Pedro A. Cruz,[1] Andre L. Weigert.[1] *[1]Davita Óbidos, Óbidos, Portugal; [2]Instituto Gulbenkian de Ciencia, Oeiras, Portugal; [3]Affidea Portugal, Lisboa, Portugal.*

Background: Patients under hemodialysis are at higher risk of developing severe complications upon SARS-CoV-2 infection and were prioritized in the Portuguese vaccination campaign.

Methods: We performed a longitudinal analysis of antibody responses upon vaccination with BNT162b2 mRNA (Pfizer/BioNTech, Comirnaty) in a cohort of 156 hemodialyzed patients. Direct ELISA was used to quantify IgG, IgM and IgA anti-full-length Spike antibody levels against calibrated sera from naturally infected patients at three points: day of the first vaccine dose (t0); 3 weeks later (day of the second dose, t1), and 3 weeks after the second inoculation (t2) for 143/156 patients. Anti-n was also measured in t0 and patients anti-n positive were excluded.

Results: We observed that 90.9% of the patients developed anti-spike IgG antibodies after the second vaccine dose (t2). Seroconversion was remarkably low at t1 after the first vaccine dose with only 29.4% of patients developing anti-spike IgG antibodies. In addition to positivity, the second vaccine dose markedly increased IgG antibody levels. IgA levels were also higher at t2 with 83.9% of the patients achieving positivity while IgM positivity only reached 29.4%. Age showed a significant negative effect on the humoral response at t2 for anti-Spike IgG and for IgM, particularly over 60 years. Further analysis revealed that nine patients under immunosuppression therapies showed significantly lower humoral response along the vaccine schedule (p=0.005 at t1; p=0.008 at t2). Interestingly, the inability to develop anti-HBs antibodies upon hepatitis B vaccination frequently found in hemodialyzed patients was not correlated with lack of responsiveness to SARS-CoV-2 vaccination.

Conclusions: The large majority hemodialyzed patients showed a significant humoral response to BNT162b2 mRNA vaccination, but a sizable proportion of patients showed low antibody levels when compared to responses in the general population (medRxiv 2021.03.19.21253680).

Age Group (years)	27-49	50-59	60-69	70-79	80-89	90-93
IgG (median)	2.27	2.09	2.07	1.84	2.00	0.54
IgG (IQR)	(2.1-2.4)	(1.9-2.3)	(1.8-2.2)	(1.6-2.2)	(1.6-2.2)	(0.38-1.9)

PO0136

How Well Do Hemodialysis Patients Respond to the BNT162b2 mRNA COVID-19 Vaccine?

Fernando Carrera,[1] Joana S. Costa,[1] Luciano Pereira,[1] Marco A. Marques,[2] Belarmino Spencer,[1] Francisco Ferrer.[1] *[1]DaVita Kidney Care, Leiria, Portugal; [2]Affidea Laboratory, Lisbon, Portugal.*

Background: Hemodialysis patients as well as healthcare workers are considered to be in a high-risk category for SARS-CoV-2 infection and a priority for vaccination.

Methods: In a single-center out-patient hemodialysis unit, 46 healthcare workers and 216 patients were vaccinated simultaneously with BNT162b2 (BioNTech-Pfizer) vaccine. They received two doses, 21 days apart. The primary objectives were to evaluate the safety and efficacy of the vaccine.

Results: There were no major adverse events in either group. Lymphadenopathy was reported by some health workers. All (100%) individuals in the healthcare workers group developed a positive antibody response (anti-S IgG) after the second dose compared with 91.7% of patients. Among patients there was a significant negative correlation between anti-S levels and age after both, the first dose (R= -0.176, p=0.01) and the second dose (R= -0.193, p=0.005); there was also a significant negative correlation between anti-S and Charlson Comorbidity Index adjusted for age after both, the first dose (R= -0.150, p=0.028) and the second dose (R= -0.163, p=0.018). Finally, a negative correlation between anti-S and Body Mass Index was found after the first dose (R= -0.140, p=0.04). No correlations were found with dialysis vintage, Kt/V, or diabetes.

Conclusions: Following vaccination, patients had a significantly lower anti-S response than healthcare workers. Age, Charlson Comorbidity Index and Body Mass Index negatively impacted the humoral response. However, with more than 91% response we believe that vaccination can be recommended strongly in the hemodialysis population.

PO0137

Real-World Effectiveness and Immunogenicity of mRNA-1273 in Dialysis Patients

Katherine L. Mckeon,[1] Scott Sibbel,[1] Jiacong Luo,[1] Karl Wendt,[1] Adam G. Walker,[1] Rachael Lazar,[2] Meredith L. Zywno,[2] Jeffrey J. Connaire,[1] Francesca Tentori,[1] Amy Young,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: mRNA-1273 (Moderna) is a SARS-CoV-2 vaccine that received an emergency use authorization from the US Food and Drug Administration. Clinical trials in the general population demonstrated that mRNA-1273 reduced risk of COVID-19 by 94.5%, however, dialysis patients were not represented in these trials. Here, we estimated the effectiveness and SARS-CoV-2 antibody response among real-world dialysis patients who were vaccinated with mRNA-1273.

Methods: Patients included in this analysis were adults dialyzing at a large dialysis organization. For the effectiveness analysis, patients who began an mRNA-1273 vaccination series (January-March 2021) were matched (with replacement) to up to 3 previously unvaccinated controls based on age, diabetes status, sex, race, body mass index, date of first vaccine, US state of residence, and prior known COVID-19 diagnosis. Vaccine effectiveness was estimated by calculating the hazard ratio (HR) for time to polymerase chain reaction confirmed infection between vaccinated and unvaccinated patients over 3 follow-up intervals: days 1-21, 22-42, and ≥43 after first dose of vaccine. Immunogenicity was measured in a subset of consented patients who completed the full, 2-dose mRNA-1273 vaccination schedule. Blood samples were collected approximately 28 days after the second dose of mRNA-1273, and indirect chemiluminescence immunoassays were used to measure immunoglobulin G (IgG) antibodies against SARS-CoV-2. Samples with a reading of >1 arbitrary unit (AU) were considered IgG+.

Results: We identified 23,037 patients who received mRNA-1273 and were matched to 64,243 unvaccinated controls. The HRs and 95% confidence intervals (CI) were 0.96 (0.79, 1.16), 0.51 (0.34, 0.75), and 0.27 (0.17, 0.42) during 1-21, 22-42, and ≥43 days postvaccination, respectively. Among the 329 patients with postvaccination antibody measurements, 96.0% (95% CI: 93.3%-97.9%) were IgG+ (median: 100.5 AU of IgG).

Conclusions: Our results indicate that mRNA-1273 is effective in preventing SARS-CoV-2 infection in dialysis patients. Moreover, antibodies to SARS-CoV-2 were detected in nearly all patients vaccinated with mRNA-1273 in whom antibodies were measured.

PO0138

Fewer ESKD Dialysis Patients (pts) Reach Antibody (AB) Levels Consistent with Neutralizing Titers When Vaccinated with Ad26.COV2.S Compared with mRNA COVID-19 Vaccines

Jeffrey Mulhern,[1] Amit Fadia,[2] Ruchir S. Patel,[3] Linda Ficociello,[4] Joanna Willetts,[4] Ines Dahne-Steuber,[5] Claudy Mullon,[4] Josephine Delisi,[5] Curtis D. Johnson,[5] Chance Mysayphonh,[4] Robert J. Kossmann,[4] Michael S. Anger,[4] Jeffrey L. Hymes.[4] *[1]Baystate Medical Center, Baystate Medical Center, Springfield, MA, US, academic/hospital, Springfield, MA; [2]Arizona Kidney Disease and Hypertension Center, Tuscon, AZ; [3]Desert Kidney Associates, Casa Grande, AZ; [4]Fresenius Medical Care, Global Medical Office, Waltham, MA; [5]Spectra Laboratories, Spectra Laboratories, Milpitas, CA, US, corporate/medsupport, Milpitas, CA.*

Background: The COVID-19 viral vector (VV) vaccine's single dose and routine storage requirements may be preferred to the mRNA-based vaccine's 2 doses and low temperature storage requirements. We report an interim analysis of a quality improvement project performed at 2 Arizona dialysis clinics comparing the AB response to VV vaccine with mRNA vaccine in ESKD pts.

Methods: Pts received either the VV vaccine (Ad26.COV2.S) administered in the dialysis clinic or mRNA vaccines (BNT162b2, mRNA-1273) administered in the community. AB response was assessed with remnant blood and a semi-quantitative chemiluminescent assay for IgG directed against the receptor binding domain of the SARS-CoV-2 spike antigen. Values >7.0 Index produce plaque reduction neutralization test (PRNT50) titers greater than 1:80 dilution recommended by the FDA standard for measuring neutralizing titer.

Results: AB response was evaluated at an average of 22 days post vaccination (≥14 days post Ad26.COV2.S or post 2nd mRNA vaccine). 36/45 pts (80%) who received the VV vaccine failed to develop an AB index >7 after ≥14 days post vaccine compared to 5/31 pts (16%) who received an mRNA vaccine (84% achieved AB index >7); all 5 pts had no prior COVID-19 history. Of pts receiving the VV vaccine with prior history of COVID-19, 22% of pts had AB index <8 after 14 days post vaccine. 41 pts receiving the VV vaccine had additional AB measurements in the next 14-37 days (ave 26 days after prior measure). In 34 pts with no prior history of COVID-19, 3 pts achieved AB index >7 in the recent sample and had previously been < 1 (n=1) or 1-7 (n=2), bringing the total number with AB > 7 from 2 to 5 (15%). AB levels remained unchanged in pts with a prior history of COVID-19 (n=9). No demographic or laboratory differences were observed.

Conclusions: Our data support the contention that the available VV-based vaccine against the SARS-CoV-2 virus is not effective in producing AB response in most ESKD pts especially when compared to an mRNA counterpart. If AB indices predict immunity and other studies support our findings, alternative vaccination strategies in ESKD pts vaccinated with VV vaccines is needed.

PO0139

Humoral Response to Pfizer BNT162b2 in Peritoneal and Hemodialysis Patients: A Comparative Study

Rui A. Duarte, Marisa Roldão, Cátia R. Figueiredo, Francisco Ferrer, Hernâni M. Gonçalves, Flora Sofia, Ivan A. Luz. *Centro Hospitalar do Medio Tejo EPE Unidade de Torres Novas, Torres Novas, Portugal.*

Background: Generalized immunization against COVID19 has become the cornerstone in prevention of Sars-CoV-2. Maintenance dialysis patients (MDP) are at higher risk of both exposure and mortality. Efficacy and security of Pfizer BNT 162b2 vaccine is well documented for the general population, but not in MDP, particularly in peritoneal dialysis (PD) patients. This study aims to compare humoral response between HD and PD patients.

Methods: Observational prospective study including MDP on HD or PD program from a Portuguese middle-sized Nephrology Center, who received Pfizer-BNT162b2. Specific anti-Spike IgG was measured as arbitrary units per milliliter (AU/mL) on two separate occasions, corresponding to the first and second doses' humoral response. The two groups were compared both for absolute value and number of non-responders (NR) after both inoculations. Demographic data was also obtained and compared.

Results: Of 73 patients enrolled, 67 were eligible for the final study: 42 HD and 25 PD patients. PD group developed significantly higher antibody titers both after first (Med 5.44 vs 0.99; p<0.01) and second dose (Med 170.43 vs 65.81; p<0.01). HD status was associated with non-responding after the first dose (Phi=0.383; p<0.01), but not after the second one (p=0.08). Age, Charlson Comorbidity Index and dialysis vintage were lower in the PD group (p<0.01; p=0.02; p<0.01, respectively).

Conclusions: This study demonstrated a better humoral response to immunization with Pfizer BNT162b2 in PD patients, when comparing to HD patients, after both inoculations. Both groups showed substantial humoral response after just one dose of the vaccine. Older age and higher comorbidity burden may explain the relative immunogenicity deficit.

PO0140

Time-Dependent Evolution of IgG Antibody Levels After First and Second Dose of mRNA-based SARS-CoV-2 Vaccination in Hemodialysis Patients: A Multicenter Study

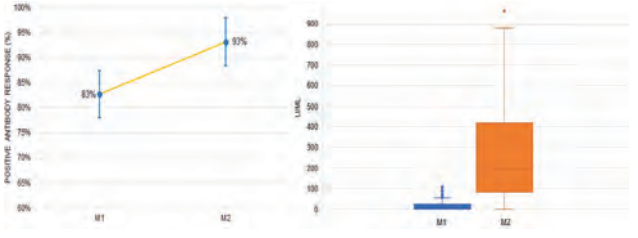
Carla Alexandra R. Santos Araujo,[1,2] Pedro Mota Veiga,[3,4] Mário João P. Santos,[5] Lidia Santos,[6,7] Catarina Romãozinho,[6,7] Carlos Lucas,[1] Mónica T. Silva,[6] Maryluz L. Duarte,[5] Mathias Haarhaus,[1,8] Michael Haase,[1,9] Fernando Macario.[1]
[1]Diaverum Renal Services Group, Lund, Sweden; [2]Unit of Cardiovascular Development and Research; Faculty of Medicine of Porto, Porto, Portugal; [3]Polytechnic Institute of Viseu, School of Education, Viseu, Portugal; [4]NECE Research Unit in Business Sciences, University of Beira Interior, Covilhã, Portugal; [5]Unilabs Portugal, Porto, Portugal; [6]Diaverum Portugal, Sintra, Portugal; [7]Department of Nephrology, Hospital and University Center of Coimbra, Coimbra, Portugal; [8]Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [9]Medical Faculty, Otto-von-Guericke University Magdeburg, Magdeburg, Germany.

Background: Vaccination programs are essential for the containment of the COVID-19 pandemic, which has affected significantly the hemodialysis population. Early reports suggest a reduced immunologic response to COVID-19 vaccines in dialysis patients, in spite of a high degree of seroconversion. We aimed to identify risk factors for a reduced efficacy of an mRNA vaccine in a cohort of hemodialysis patients.

Methods: In a multicenter study, including 294 Portuguese hemodialysis patients from multiple centers who had received 2 doses of BNT162b2 with a three week interval, IgG-class antibodies against the SARS-CoV-2 spike protein were determined 3 weeks after the first dose (M1) and 6 weeks after the second dose (M2). The threshold for seroconversion was 10UR/mL. Demographic and clinical data was retrieved from a quality registry. Adverse events were registered using a questionnaire.

Results: At M2, seroconversion was 93.1% with a median antibody level of 197.5U/mL (1.2-3237.0) and a median increase of 180.0U/mL (-82.9-2244.6) from M1. Age (beta -8.9; 95%CI: -12.88 to -4.91; p<0.0001), ferritin >600ng/mL (beta 183.93; 95%CI: 74.75 to 293.10; p=0.001) and physical activity (beta 265.79; 95%CI: 30.7 to 500.88; p=0.03) were independent predictors of SARS-Cov-2 antibody levels after two vaccine doses. Plasma albumin >3.5g/dL independently predicted the increase of antibody levels between both doses (OR 14.72; 95%CI: 1.38 to 157.45; p=0.03). Only mild adverse reactions were observed in 10.9% of patients.

Conclusions: The COVID-19 vaccine BNT162b2 is safe and effective in hemodialysis patients. Besides age, iron status and nutrition are possible modifiable modulators of the immunologic response to COVID-19 mRNA vaccines.



Positive IgG spike protein antibody response and antibody levels after BNT162b2 vaccination, just before (M1) and six weeks after (M2) the second administration of the vaccine.

PO0141

Antibody Response to COVID-19 Vaccine in Peritoneal Dialysis (PD) Patients: A Single-Center Study

Shab E Gul Rahim,[1] Sri Lekha Tummalapalli,[1,2] Gabriel Stryjniak,[1] Supriya Gerardine,[1] Vesh Srivatana.[1,2] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Background: In initial published reports of dialysis patients, response to COVID-19 vaccination tends to be lower as compared to general population. To date, these studies were primarily focused on hemodialysis (HD) patients. We studied the factors associated with COVID-19 vaccine humoral response in PD patients.

Methods: Our research setting was a single-center academic institution in New York City. We included patients on PD who received the COVID-19 vaccine. Response was assessed at a median of 4 weeks after completing the full vaccination series by measuring semiquantitative COVID-19 spike protein total antibody (Ab) level using a chemiluminescent sandwich immunoassay. Chi-squared tests for categorical variables and Wilcoxon rank-sum tests for continuous variables were used to compare characteristics among patients who did and did not have an Ab response.

Results: Of 111 patients on PD in our center, 64 (58%) received COVID-19 vaccine as of April 2021 and had Ab levels checked. A total of 60/64 (94%) of patients had a positive Ab response and 4/64 (6%) did not mount a response. IgG levels in positive responders were a median of 11.5 (interquartile range, 1.9 – 20). Lower Kt/V was associated with a positive Ab response (p = 0.045) and type of vaccine was associated with an Ab response (p = 0.028). Age, BMI, diabetes, hypertension, lymphocyte count, or residual Kt/V were not statistically significantly associated with Ab response to the vaccine (Table 1).

Conclusions: In conclusion, the vast majority of patients on PD developed positive Ab response to the COVID-19 vaccine. While a small sample size limited our statistical power, our results show promising COVID-19 vaccine effectiveness among patients on PD.

Table 1. Characteristics of patients on PD by COVID-19 Ab response

Variable	Total Sample (n = 64)	Antibody Response to COVID-19 Vaccine (n = 60)	No Antibody Response to COVID-19 Vaccine (n = 4)	p-value
Age	64 [52.5 – 72.5]	64 [51.5 – 73]	63 [59.5 – 64.5]	0.77
Body mass index (BMI)	26.2 [23.3 – 30.1]	26.1 [23.1 – 30.5]	28.5 [26.6 – 29.5]	0.53
Diabetes	16 (25%)	14 (23%)	2 (50%)	0.23
Hypertension	60 (94%)	56 (93%)	4 (100%)	0.59
Absolute lymphocyte count (x 10^3 per µL)	1.1 [0.9 – 1.7]	1.1 [0.9 – 1.6]	1.5 [1 – 1.9]	0.48
Total Kt/V	2.04 [1.75 – 2.4]	1.96 [1.73 – 2.26]	2.49 [2.44 – 2.93]	0.049
Residual Kt/V	0.38 [0 – 0.72]	0.37 [0 – 0.64]	0.75 [0.35 – 1.56]	0.18
COVID-19 Ab Positive prior to Vaccine	11 (17%)	11 (18%)	0 (0%)	0.89

PO0142

Breakthrough COVID-19 Infection in Hemodialysis Patients Following mRNA-1273 (Moderna) Vaccine Administration

Nicholas Fuca,[2] Lili Chan,[2] Kirk N. Campbell,[2] Aisha Shaikh.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Patients on maintenance hemodialysis are highly susceptible to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. We recently reported that 95% (58/61) hemodialysis patients developed anti-receptor binding domain (RBD) IgG antibody following the 2-dose Moderna vaccine administration. The incidence of breakthrough COVID-19 infection in hemodialysis patients following vaccination is not known.

Methods: All hemodialysis patients (n=61) received the 2-dose Moderna vaccine series. Anti-RBD IgG titer was measured at 1-, 2-, 4- weeks after the 1st vaccine dose. The 2nd vaccine dose was administered 29±3.9 days after the 1st dose. Anti-RBD IgG titer was measured at 1-week following the 2nd vaccine dose. Nasal swabs were performed every 2-weeks to detect SARS-CoV-2 RNA as part of routine surveillance. Additionally, nasal swab tests were performed if patients exhibited signs or symptoms suggestive of COVID-19. Patients were followed for 2-months following the 2nd vaccine dose administration.

Results: Three patients tested positive for SARS-CoV-2 RNA following vaccination. Of these 3 patients, 2 patients tested positive at day-7- and at day-12 following the 1st vaccine dose respectively. Both these patients presented with symptoms of fever and dyspnea, and both had undetectable anti-RBD IgG titer at the time of COVID-19 diagnosis. A third patient tested positive for SARS-CoV-2 RNA on routine nasal swab surveillance test at day-40 following the 2nd vaccine dose administration. At the time of the test, the patient had a positive anti-RBG IgG titer. The patient remained asymptomatic and had an uneventful course. Viral genome analysis revealed that the infection was due to the B.1.526 SARS-CoV-2 variant, also known as the New York variant.

Conclusions: Breakthrough COVID-19 infections were rare in fully vaccinated hemodialysis patients up to 2-months following the Moderna vaccine administration. One case of SARS-CoV-2 breakthrough infection was due to the B.1.526 variant.

PO0143

Rapid Decline in Antibody Levels After Initial High Response in ESKD Patients Vaccinated with mRNA COVID-19 Vaccines

Jeffrey Mulhern,[1] Linda Ficociello,[2] Joanna Willetts,[2] Ines Dahne-Steuber,[3] Claudy Mullon,[2] Josephine Delisi,[3] Curtis D. Johnson,[3] Chance Mysayphonh,[2] Robert J. Kossmann,[2] Michael S. Anger,[2,4] Jeffrey L. Hymes.[2] *[1]Baystate Medical Center, Springfield, MA; [2]Fresenius Medical Care, Global Medical Office, Waltham, MA; [3]Spectra Laboratories, Milpitas, CA; [4]University of Colorado, School of Medicine, Denver, CO.*

Background: Vaccine unresponsiveness and rapid AB level decline after successful vaccination have been barriers to antiviral strategies in ESKD populations. We report an interim analysis of a quality improvement project characterizing the temporal AB response to COVID-19 vaccination across 7 dialysis clinics in MA.

Methods: Chronic dialysis pts received 2 doses of mRNA vaccine at prescribed intervals. AB response was measured in remnant blood with semiquantitative chemiluminescent assay detecting IgG AB directed against receptor binding domain of S1 subunit of SARS-CoV-2 spike antigen (Siemens); AB index ≥1 was considered reactive. AB index >7 produce plaque reduction neutralization test (PRNT50) titers >1:80 dilution recommended by FDA standard for measuring neutralizing titer.

Results: 211 pts received the 2-dose mRNA vaccine (mRNA-1273, 1 given BNT162b2). On average (ave) AB peaked at day 19 post 2nd vaccine; peak index was >7 for 97% of pts. Pts with AB peak >7 had higher serum albumin vs pts with AB peak ≤ 7 (3.8 vs 3.4 g/dl). Among pts with AB measured after peak AB index (n=188),

ave AB index decreased by 125 (46% reduction) over an ave 46 days. Ave decreases from peak were 51% in pts with no prior COVID-19 history (n=162) and 20% in pts with COVID-19 history (n=26); illustrated in subset with ≥5 AB measurements ≥ 45 days post 2nd vaccine dose (n=114, Figure). No symptomatic COVID-19 cases were reported.

Conclusions: mRNA-1273 is a highly reactive vaccine producing reactive AB in all, and >7 index in 97% of vaccinated ESKD pts. However, if AB index confers immunity, blunted and rapid decline of circulating AB may place ESKD pts at risk of future COVID-19 infection. Monitoring post-vaccination AB levels may be important for ESKD pts (especially hypoalbuminemic pts) and may guide future vaccination requirements.

PO0144

Immunogenic Response of Hemodialysis Patients to COVID-19 Vaccine: A Multicenter Study

Avital Angel-Korman,[1,2] Tal Brosh-Nissimov,[1,2] Adi Leiba.[1,2] *[1]Samson Assuta University Hospital, Ashdod, Israel; [2]Ben Gurion University, Faculty of Health Science, Beer-Sheva, Israel.*

Background: The use of the mRNA-based vaccine BNT162b2 against COVID-19 has shown great success preventing SARS-CoV-2 infection in the general population. Limited data exist regarding its effectiveness in patients requiring dialysis. Dialysis patients have reduced immune response following different types of vaccines including Hepatitis B vaccine. We aimed to asses humoral response and the factors associated with it in a large and diverse maintenance hemodialysis (MHD) patient population.

Methods: SARS-CoV-2 Anti-spike, anti-nucleocapsid and neutralizing antibody (Ab) levels of 424 MHD patients from 13 nationally spread dialysis units in Israel were compared with 155 control subjects (dialysis patients' family members and dialysis units health care workers). Patients' history, dialysis treatment details and Hepatitis B Ab (HBsAb) levels were obtained from dialysis units medical records.

Results: Our study included 400 MHD patients and 141 controls (58% males, 42% females), excluding 24 MHD and 14 control samples from anti-N positive cases, signifying previous SARS-CoV-2 infection. Anti-S antibodies developed in 89.3% of MHD patients and 99.3% of controls, ($p<0.01$) after a median time of 82 and 89 days from second vaccine dose for MHD and controls, respectively. Median anti-S titer was significantly lower in MHD patients compared with controls (median 194, IQR 118-242 vs. 69, IQR 33-119; $p<0.001$) and correlated well with the level of neutralizing Ab titers in the study group as compared to control group (median 16, IQR 8-64 vs. 256, IQR 64-516; $p<0.001$, respectively). Notably, age was higher in MHD patients than controls (median 72, IQR 63-80 vs. 49, IQR 38-58, $p<0.01$) which likely contributed to the association with anti-S titers ($p<0.01$, $r=0.44$) as well as neutralizing Ab titer levels ($p<0.01$, $r=0.42$). Sex, dialysis vintage and etiology of ESRD were not significantly associated with anti-S positivity or titer levels. Interestingly, there was a significant correlation, between anti-S and HBsAb positivity ($p<0.01$) though campatability was low ($r=0.18$).

Conclusions: MHD patients have lower seroconversion rate, lower anti-S and neutralizing Ab levels after BNT162b2 vaccination. HBsAb levels may potentially be used as a marker for estimating the level of humoral response following COVID-19 vaccine. To our knowledge this is the largest cohort of MHD patients studied thus far.

PO0145

Extremely Low Humoral Immune Responses to BNT162b2 Vaccine in Nursing Home Residents Undergoing Hemodialysis

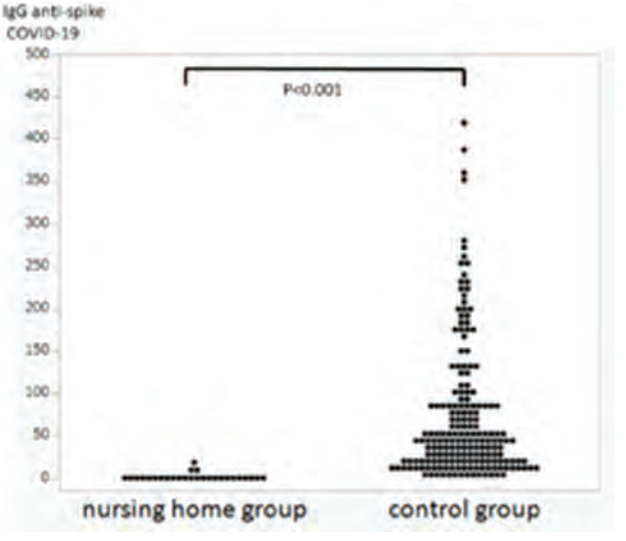
Mineaki Kitamura,[1,2] Takahiro Takazono,[2] Tomoya Nishino,[2] Satoshi Funakoshi.[1] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Daigaku Igakubu Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan.*

Background: As coronavirus disease 2019 (COVID-19) can cause lethal outcomes in hemodialysis (HD) patients, they should be protected effectively by vaccination. HD patients are known to have a weak immune response to vaccines, and the seropositive rate three week after first vaccination (BNT162b2 Pfizer) is around 35%. However, its efficacy among elderly HD patients remains unknown. We aimed to evaluate spike antibody levels of nursing home residents on long-term maintenance HD after the BNT162b2 vaccine, comparing those of health care workers.

Methods: Between April and May 2021, HD patients from a nursing home (nursing home group) and health care workers (the control group) who received BNT162b2 were included. Those with a prior history of COVID-19 were excluded. IgG anti-spike against COVID-19 were measured by Elecsys Roche (cut off index <1.0) 3 weeks after the first injection.

Results: The study included 27 nursing home residents on HD and 191 care workers, and 2 care workers were excluded due to a prior history of COVID-19. The nursing home group were 84±9 years old and 41% male, and the median of HD vintage was 51 months (IQR 28-119), and the control group were 45±14 years old and 29% male. Only 6 patients in the nursing group were confirmed as seropositive (22%), whereas the rate of responder in the control group was 99% ($p<0.001$). Notably, the IgG levels of 20 patients in the nursing home group were under the detectable level (<0.4). In contrast, the median of the IgG levels in the control group was 42 (IQR 18-87). Moreover, the prevalence of adverse reactions, such as developing fever, in the nursing home group was low compared to the control group ($p<0.001$)

Conclusions: The seropositive rate after BNT162b2 in elderly HD patients was quite low owing to poor immune responses. To prevent a COVID-19 outbreak in nursing homes, IgG levels against COVID-19 in elderly residents on HD should be paid attention to.



PO0146

No Antibody Response to Viral Vector SARS-CoV-2 Vaccine but Subsequent Conversion After COVID-19 Infection in an ESKD Patient

Ruchika Chhibar, Niti Madan, Andrew I. Chin. UC Davis, Division of Nephrology *University of California Davis School of Medicine, Sacramento, CA.*

Introduction: ESKD patients generally have low response rate to vaccines. Early data suggests that viral vector SARS-CoV-19 vaccine is less effective than its mRNA counterparts. This case illustrates AB non-response to a viral vector based SARS-CoV-19 vaccine (Janssen) with subsequent AB response to mild clinical COVID-19 in an ESKD patient.

Case Description: 84 year old male on HD for 12 years. He had a prior response to the Hepatitis B vaccine with a recent titer >10 IU/L. SARS-CoV-19 AB (IgG AB to the spike protein) was being checked monthly as part of an observational cohort. SARS-CoV-19 AB was (-) 1 month prior to receiving a viral vector-based vaccine. The AB was rechecked 1 month after the vaccine and remained (-). He was soon after admitted for GI bleed and tested positive for COVID-19 by PCR nasal swab on routine hospital screening. On discharge, he was asymptomatic but was hypoxemic requiring oxygen. 17 days after hospital discharge, SARS-CoV-19 by nasal PCR remained positive and AB titer was detectable at 1.3 U/L. Both were checked again 1 week later, viral PCR remained (-) with further increase in AB to 2.3 U/L. A titer of >2.0 U/L has been reported as protective. He was no longer hypoxemic by that time.

Discussion: SARS-CoV-19 AB was measured longitudinally in this elderly HD patient. AB titer to the spike protein was negative 4 weeks after receiving a viral vector-based SARS-CoV-19 vaccine. He was relatively immunocompetent based on prior AB response to Hepatitis B vaccination. He became SARS-CoV-19 AB (+) 2.5 weeks after mild COVID-19 infection. Most studies on SARS-CoV-19 vaccination in ESKD have focused on mRNA vaccines, which show a reasonably high AB conversion rate after the second injection. We do not know if lack of detectable spike protein AB after vaccination necessarily precludes resistance to infection, nor do we know if this patient's eventual seroconversion was due only to his COVID-19 infection or simply a slow response to the vaccine. There is evidence in the general public that efficacy of the viral vector-based SARS-CoV-19 vaccine may be lower than that of mRNA vaccines. With ESKD patients more susceptible to infection and less able to mount AB's to vaccines, this case supports the use of mRNA SARS-CoV-19 vaccines preferentially in the ESKD population if AB seroconversion is the targeted intermediary outcome.

PO0147

ESKD Immunoglobulin Response at 3 Months Post COVID-19 Vaccination

Devasmita Choudhury,[1,2] Lampros S. Karageorge,[1] Alia Hasan.[1] *[1]SAlem Veterans affairs medical Center, Salem, VA; [2]Virginia Tech Carilion School of Medicine, Roanoke, VA.*

Background: End stage kidney disease (ESKD) patients (pts) remain at high risk for COVID 19 infection. Inadequate post infection antibody response is reported in 10-11% of pts[1]. Current data is limited on ESKD post vaccination (vac)[2] We report 3-month (mo) post vac response of ESKD pts receiving 2 doses of either Moderna or Pfizer vaccines.

Methods: Twenty- six of 42 stable ESKD pts completed 2 doses of either Moderna or Pfizer vaccination at Salem VAMC or at their nursing home facility during mo 01/02-2021. 17/42 were not vaccinated (7 declined, 2 with COVID 19 infection, 6 acutely hospitalized) during that time. Antibody immune response testing using ADVIA Centaur COV2G automated 2-step sandwich immunoassay using indirect chemiluminescent technology and designed to detect the SARS-CoV-2 surface spike protein receptor binding domain (S1RBD) was completed in 05/2021. Measures obtained included reactivity to total SARS CoV-ab (IgM+ IgG) and IgG separately.

Results: Please see table 1 for results

Conclusions: ESKD vaccine response to COVID 19 after 3months was 96% for total immunoglobulin response (IgM and IgG) and 87.5% for total IgG antibody response compared to no reactivity in those nonvaccinated patients. Age and presence of diabetes did not significantly affect immune response. Approximately 12.5 % of patients had nonreactivity to IgG antibody after 3 months. Patients not developing an IgG response by 3 mo were found to have underlying immunosuppressive disease. ESKD with COVID 19 infection maintained IgG reactive response 3 months after active disease. Nonreactivity was seen in those neither infected nor vaccinated, suggesting that these patients have likely not been exposed to COVID 19 viral infection.

Funding: Veterans Affairs Support

PO0148

The SARS-CoV-2 Vaccine Response in ANCA-Associated Vasculitis

Sam Kant,[1] Srekar Ravi,[2] Duvuru Geetha.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Florida Atlantic University, Boca Raton, FL.*

Background: The development of efficacious vaccines against COVID-19 is an overarching achievement of modern medicine. This efficacy, however, may not be achieved in patients on immunosuppression. We looked to ascertain humoral response and tolerability of these vaccines in patients with ANCA associated vasculitis(AAV) treated with B-cell depleting agents

Methods: AAV patients who completed 2 doses of BNT162b2 or mRNA-1273 or a dose of JNJ-78436735, subsequently screened for spike protein antibody against SARS-CoV-2 were included in the study. Clinical details, demographics and immunosuppression regimes were ascertained, with primary outcome being humoral response to SARS-CoV-2.Statistics included Fischer's exact test and Wilcoxon rank sum test.

Results: Forty-eight patients with a mean age of 67y(35% female) completed vaccine series with BNT161b2(n=19), mRNA-1273(n=25) and JNJ-78436735(n=4). Vaccine associated side effects occurred in 27% of patients after 1st dose, with 39% after the 2nd dose. Spike protein antibody was tested at a median of 31 days after vaccination- 30(61%) patients had demonstrable antibody. All patients (n=44) other than 4 post-transplant patients, were treated with Rituximab- only 17/44(39%) developed an antibody response. In the setting of rituximab treatment, absence of seroconversion post vaccination was associated with vaccine type, duration elapsed since last rituximab dose (figure 1), low IgM level and absence of B-cell reconstitution (all stastically significant). Two patients without serologic response had severe COVID–19 infection

Conclusions: This data demonstrates that majority of patients treated with rituximab lack demonstrable serologic response, with risk of severe COVID-19 infections despite vaccination. Confirmation of B-cell reconstitution before vaccination may have a bearing on serological conversion. It is imperative that authorities consider these factors while designing vaccination schedules and provide recommendations for booster doses in this vulnerable population

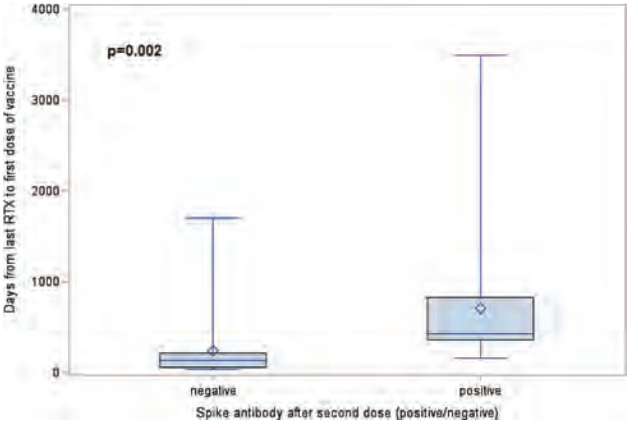

Fig 1

PO0149

Durability of SARS-CoV-2 Spike Antibody Levels in Dialysis Patients After COVID-19 Infection

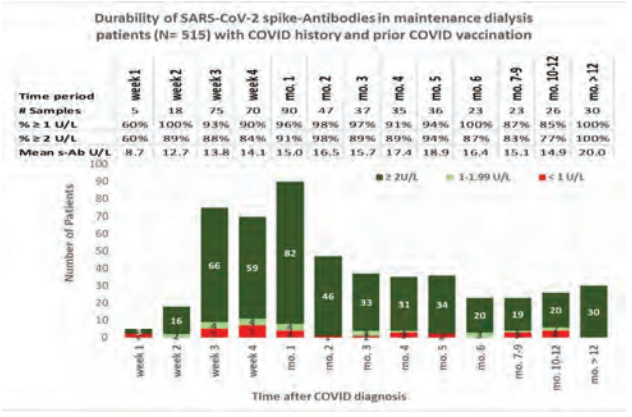
Harold J. Manley,[1] Caroline M. Hsu,[2] Gideon N. Aweh,[1] Daniel E. Weiner,[2,1] Jill M. Frament,[1] Vladimir Ladik,[1] Doug Johnson,[1] Eduardo K. Lacson.[1,2] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts University School of Medicine, Boston, MA.*

Background: Durability of SARS-CoV-2 receptor-binding domain spike antibody (RBD s-Ab) levels among patients receiving dialysis after COVID-19 [WDE1] is unknown[EL2] beyond 6 months. We describe the persistence (index value ≥ 1 and ≥ 2 U/L) of semi-quantitative RBD s-Ab levels in dialysis patients over 14 month period.

Methods: All maintenance dialysis patients (≥18 years old) within Dialysis Clinic, Inc. 260 clinics in 28 states with COVID-19 infection history and RBD s-Ab levels determined between Jan 1 and May 23, 2021 were included. On the day of RBD s-Ab level determination, patient demographics (age, sex, race, modality, ESKD vintage) and days since COVID-19 diagnosis were determined. Patient RBD s-Ab levels obtained after COVID-19 vaccination were excluded.

Results: A total of 515 patients, mean age 62±14 years, 57% male, 46% White, 94% HD and vintage 4.6±4.4 years[EL1], [HJM2] had 835 RBD s-Ab levels assessed at a median of 59 days (range 0-422 days) post COVID-19 diagnosis. RBD s-Ab levels were assessed 1, 2 or ≥3 times in 64%, 18% and 18% patients, respectively. Only 32 (6.2%) patients had undetectable RBD s-Ab on the last draw. A cross sectional summary of the last available RBD s-Ab levels suggests that titers remain detectable for long duration (Figure[EL3] [HJM4]). In patients (N=186; 36%) with multiple RBD s-Ab levels (mean 28±15; median 28 days between levels), subsequent values were higher, lower [EL5] [HJM6] or unchanged 7%, 16% and 77% of time[EL7], respectively.

Conclusions: Most maintenance dialysis patients sampled developed SARS-CoV-2 RBD s-Ab after COVID diagnosis, and durability extends up to 14 months. Further elucidation of longitudinal RBD s-Ab values post-COVID-19 infection as well as after completing vaccination for SARS-CoV-2 is needed.



PO0150

COVID-19 Vaccine and Multiple Viral Infection: Cross-Reaction?

Jose Rivera Sepulveda, Elizabeth Pabon-Vazquez. *Mayaguez Medical Center, Mayaguez, Puerto Rico.*

Introduction: The COVID-19 pandemic has brought a lot of challenges in the medical and educational field. Every day, new facts and knowledge are published about the pathophysiology, treatment, and prognosis of COVID-19 patients. In addition, community response to vaccination and vaccine side effects has been one of the major talking points in social media. The general public wants to fully understand if the vaccine really provides immunity and possible side effects of its use.

Case Description: Under this premise, a 36 y/o female patient with a past medical history of type 2 diabetes mellitus, hypertension and obesity came to emergency department 2 days after she received the second dose of Moderna COVID-19 vaccine, and developed non-quantified fever, general malaise, vomiting and watery diarrhea. Associated symptoms were scattered non-blanching maculopapular rash from head to shoulders to mid back and abdomen, pustules inside ear and decrease urine output. Patient was unable to urinate for at least 48hrs. Laboratory bloodwork was remarkable for hyponatremia, hypochloremia, high anion gap metabolic acidosis and creatinine clearance of 18ml/min. Hepatic enzymes were more than five times elevated, and total bilirubin was elevated as well. Urinalysis reported proteinuria, positive leukocytes esterase, few calcium oxalate crystals and many urate amorphous sediment. Patient was convinced that symptoms were related to COVID-19 vaccination. Etiology of symptoms remained unclear at admission, for that reason she was admitted and received isotonic IV fluids. Further laboratory bloodwork reported elevated LDH, creatinine kinase and hypertriglyceridemia. In addition, infectious disease workup was performed, in which HAV, VZV, EBV, CMV IgM were positive. Patient received inpatient supportive care for five days. Renal function normalized, rash improve and the patient was discharged home with close follow up.

Discussion: There are different reasons that could explain patient's acute kidney injury. From dehydration to sepsis is the spectrum of differential diagnosis in this patient. The renal function recovery after hydration, clearly suggest pre-renal injury. Viral infection could be the primary reason of her dehydration. However, the event of vaccination, could not be completely ruled out. Was the vaccine a catalyst for viral infection? Or was the vaccine a confounder in this patient's renal failure?

PO0151

Five-Month Impact of Tozinameran (BNT162b2) Vaccine on Kidney Transplant and Dialysis Patients: Serology and Clinical Outcomes

Michal Dranitzki Elhalel,[1,2] Keren Tzukert,[1,2] Irit Mor yosef levi,[1,2] Ido Burstain,[1,2] Hadass Pri Chen,[1,2] Yonatan Oster,[3,2] Dana G. Wolf,[3,2] Iddo Z. Ben-Dov.[1,2] *[1]Hadassah Hebrew University Medical Center, Department of Nephrology and Hypertension, Jerusalem, Israel; [2]Faculty of Medicine, Hebrew University, Jerusalem, Israel; [3]Hadassah Hebrew University Medical Center, Department of Clinical Microbiology and Infectious Diseases, Jerusalem, Israel.*

Background: Dialysis-treated (DT) and kidney transplant (TX) patients face higher morbidly and mortality risks than the general population during COVID-19 pandemic. Determining humoral response and associated COVID-19 morbidity after vaccination will guide risk assessment and changes in vaccination policy in this vulnerable population.

Methods: Prospective cohort study up to 5 months follow-up after Tozinameran or SARS-CoV-2 infection. Primary outcomes: qualitative and quantitative anti S1/S2 antibody (ABs) and disease rates during follow up. Anti-SARS-2 IgG ABs were quantified using LIAISON SARS-CoV-2 S1/S2 IgG (DiaSorin) immunoassay in serum of TX, DT and treating team at our hospital. Demographics and clinical data were collected from participants files.

Results: 174 DT patients (40% women, age 65±15 years) 253 TX patients (33%, 53±14 years) and 71 control participants (65%, 44±14 years) were recruited. 3 months or more after vaccination we detected anti S1/S2 ABs in 81% of DT (95%CI, 72-90%), 43% of TX (95%CI, 29-57%) and 100% of controls. After COVID-19 respective rates were 94% (95%CI, 83-100%), 75% (95%CI, 60-90%) and 100%. Quantitative titers were in line with qualitative ones. Predictors of negative serology were older age, diabetes, cancer history, lower lymphocyte count and lower vitamin D. Peritoneal dialysis predicted higher titers compared to hemodialysis. In TX, hypertension and higher levels of immnosupression predicated lower titers. Vaccination was associated with fewer subsequent COVID-19 infections (HR=0.23, 95% CI 0.05-0.99, p<0.05). Higher antibody titers associated with fewer events, HR 0.41/unit increase in $\log_{10}$ titer (p<0.05).

Conclusions: Patients with ESRD, particularly TX, mounted delayed and diminished antibody response to vaccination, and lesser response was associated with more infections. Thus, measures to protect non-responsive patients are urgently required.

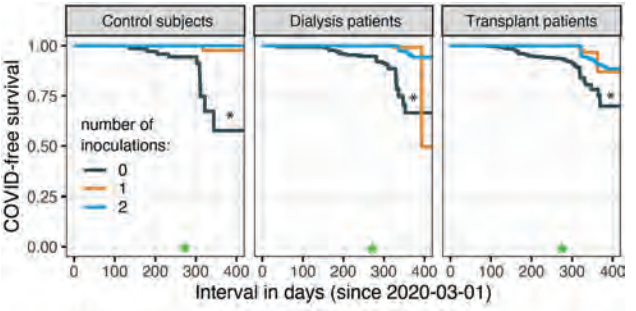


Figure: KM curves depicting COVID-19 infections according to vaccination status in all participants separated by study group. Vaccination began at ~day 270 (green symbol). * denotes p<0.05 for the comparison between 2 and 0-1 inoculations.

PO0152

Antibody Response Post SARS-CoV-2 Vaccination in Kidney Transplant Recipients

Maria Butiu, Nicolae Leca, Ramasamy Bakthavatsalam. *University of Washington, Seattle, WA.*

Background: This project aims to analyze the proportion of patients who did not develop antibodies following COVID-19 vaccination and to ensure that the immune stimulation secondary to the vaccine is not associated with clinical rejection and DSA development.

Methods: Samples collected from COVID-19 vaccinated kidney transplant recipients from 3/1/21-4/26/21 were tested for DSA and COVID-19 antibodies using a multi-antigen detection Luminex platform (BioRad). The following were tested: receptor binding domain IgG, spike 1 IgG, spike 2 IgG, nucleocapsid IgG.

Results: 94 patients were included in this study. 57% had no antibodies post second dose of COVID-19 vaccination. This number decreased to 52% when looking at samples collected >2 weeks after the final vaccine dose. Of all positive patients, 19% showed evidence of previous COVID-19 infection based on nucleocapsid positivity, which if excluded from the cohort analysis, lead to a higher rate of patients not responding to the vaccine. We did not observe a correlation between antibody positivity and demographics or clinical characteristics. Only 2 patients developed new DSA post-vaccination(avg MFI 1600). No episodes of clinical rejection were noted. 10 patients provided multiple samples, of which 5 had positive antibodies with an average decrease of 17 U/mL for S1 IgG per week.

Conclusions: When excluding patients previously infected with COVID-19, the rate of positive antibody formation post vaccine is 35%. More research needs to be done to understand the correlation of antibody response and protection against COVID-19 infection.

Comparison of Safety and Outcomes Related to Remdesivir Use Among Dialysis Patients Hospitalized with COVID-19

Kirollos E. Zaki, Cheng-Wei Huang, Hui Zhou, Joanie Chung, David C. Selevan, Mark P. Rutkowski, John J. Sim. *Kaiser Permanente Southern California, Los Angeles, CA.*

Background: Use of remdesivir in the treatment of dialysis patients with Coronavirus Disease 2019 (COVID-19) has been limited due to inconclusive data regarding safety outcomes among patients with severe renal impairment. For this reason, the FDA has not recommended remdesivir use in patients with eGFR < 30 ml/min per 1.73 m^2. We sought to evaluate outcomes among dialysis patients with COVID-19 who received remdesivir in a real-world setting.

Methods: We conducted a retrospective study of patients on hemodialysis or peritoneal dialysis hospitalized with COVID-19 between 5/1/2020 - 1/31/2021 within the integrated health system of Kaiser Permanente Southern California. Patients with a COVID-19 International Classification of Diseases (ICD)-10 code: U07.1 and laboratory confirmed SARS-CoV-2 infection within 14 days prior to admission date to two days after admission date were included. The primary endpoint was 30-day all-cause mortality. Secondary endpoints were intensive care unit (ICU) stay, and evidence of acute liver injury defined as AST and/or ALT values >5x upper limit of normal.

Results: A total of 486 patients (407 hemodialysis and 79 peritoneal dialysis) met inclusion criteria. Among those, 112 patients (23%) were treated with remdesivir, with median treatment time of 4 days (IQR: 2-5). Mean age was 63.8 years with 63.8% male and 63.0% Hispanic patients. There were 80.2% of patients who received treatment with steroids during hospitalization. Relative risk (RR) for all-cause 30-day mortality was 0.74 (95% CI: 0.52-1.05) in remdesivir treated patients compared to untreated patients. Acute liver injury occurred in 1.8% and 2.4% of remdesivir treated and untreated patients, respectively. ICU admissions occurred in 14.3% of remdesivir treated and 16% of untreated patients.

Conclusions: Among dialysis patients hospitalized with COVID-19, treatment with remdesivir was not associated with worse outcomes in terms of liver injury or ICU admission, and demonstrated a trend (26% lower risk) toward decrease in 30-day mortality, though no statistical significance was found due to insufficient power.

PO0154

Outcomes Associated with Tocilizumab Use in Patients with COVID-19 Infection Complicated by Severe AKI Requiring Continuous Renal Replacement Therapy

Muriel Ghosn, Nizar M. Attallah, Fadi A. Hijazi, Rakesh Madhyastha, Sudeendra S. Gupta, Wasim El Nekidy. *Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates.*

Background: The percentage of critically ill amongst COVID-19 infected patients stands at 5%. The incidence of acute kidney injury in those patients varies according to risk factors. A little is known about the use of Tocilizumab in patients with severe acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT)

Methods: This is a retrospective study of 22 COVID-19 patients. Patients were between 18 and 80 years old, had proven COVID-19 infection, were admitted to the ICU between April 1 and July 15, 2020, received CRRT and Tocilizumab parenterally. Other therapies included antivirals, hydroxychloroqine and convalescent plasma. We reported biochemical outcomes related to cytokine storm as well as clinical outcomes; Those included ventilator dependence, renal outcomes, length of hospital stay and mortality

Results: 21 out of 22 patients were males. Median age was 56 years. 14 patients had hypertension and 13 had diabetes mellitus. All patients had cytokine storm on admission (elevated IL-6 and CRP levels). At the completion of the follow up (average 44.4 days), 20 out of 22 patients experienced improvement in IL-6 and CRP levels. 11 patients died. 13 experienced improvement in oxygen requirements including 9 who were succesfully extubated. 13 were still on CRRT (including 10 patients who died) while 9 patients became dialysis independent (5 had complete recovery of kidney function and 4 developed chronic kidney disease). There was no reported side effect from using tocilizumab

Conclusions: Tocilizumab can be considered in critically ill COVID-19 patients with severe AKI and cytokine storm. No dose adjustment is needed in patients on CRRT. Further studies are required to confirm our results.

Safety of Bamlanivimab Monotherapy Administered in Dialysis Centers to Hemodialysis Patients for COVID-19

Katherine L. Mckeon,[1] Scott Sibbel,[1] Karl Wendt,[1] Nicole Macioce,[2] Francesca Tentori,[1] Steven M. Brunelli,[1] Irina Goykhman,[2] George R. Aronoff.[2] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Bamlanivimab (Eli Lilly) is an intravenously administered monoclonal antibody that was granted an emergency use authorization (EUA) by the US Food and Drug Administration for the treatment of mild to moderate COVID-19 on 09 Nov 2020.

On 16 Apr 2021, the EUA was revoked over concerns of resistance among SARS-CoV-2 variants. Between 01 Jan and 16 April 2021, physicians at DaVita dialysis clinics were able to order bamlanivimab (700 mg) treatment during dialysis for nonhospitalized hemodialysis patients who tested positive for SARS-CoV-2 infection and met the eligibility criteria. Here, we report safety data among dialysis patients who received bamlanivimab as a monotherapy for COVID-19.

Methods: Bamlanivimab was administered intravenously as a single dose over the course of 60 minutes during a regularly scheduled hemodialysis session. All patients were monitored for at least 1 hour after bamlanivimab administration. All facilities were required to have emergency medications on-site, and staff were trained to identify and treat potential reactions. A serious adverse event was considered if a patient developed anaphylaxis or any condition requiring use of an epinephrine injection (1:10,000 IM) or albuterol, was sent to the emergency department, or was hospitalized after bamlanivimab administration. An adverse event was considered if a patient developed fever, chills, hives, rash, hypotension, headache, nausea, fatigue, dizziness, angioedema, muscle pain, or throat irritation.

Results: 264 patients with newly diagnosed SARS-COV-2 infections received a single dose of bamlanivimab at DaVita. Among all patients who received the drug, 46% were female and the mean age was 60 years. On average, patients were followed for 64 days postinfusion. There were 0 adverse events or serious adverse events documented in the 1-hour postadministration observation window.

Conclusions: Bamlanivimab was found to be safe in dialysis patients.

Patients	264
Days postadministration, mean ± SD	63.5 ± 23.9
Age, years, mean ± SD	60.3 ± 14.4
Female sex, n (%)	121 (45.8)
Severe adverse events within 1-hour postadminstration, n (%)	0 (0.0)
Adverse events within 1-hour postadminstration, n (%)	0 (0.0)

PO0156

Intravenous Immunoglobulin: Answer to COVID-19?

Walaa S. Dabbas, Ruchi H. Naik, Zahraa F. Hajjiri, Sajid Q. Ansari. *University of Illinois at Chicago, Chicago, IL.*

Introduction: Traditionally intravenous immunoglobulin (IVIG) has been used for immunodeficiency disorders. It has been also used in certain autoimmune and infectious diseases. IVIG has several immunomodulatory and anti-inflammatory effects. Here, we are reporting a case where IVIG was used for BK viremia in a patient with COVID-19 pneumonia who showed dramatic recovery of COVID-19 symptoms and laboratory parameters.

Case Description: Our patient is a 55-year-old African American male who received simultaneous pancreas and kidney transplant in April 2019 with induction immunosuppression with thymoglobulin and was on chronic immunosuppression with Tacrolimus and Mycophenolic mofetil. His Post-transplant course was complicated by BK viremia and presumed BK nephropathy after 2 months. His immunosuppression was gradually tapered off but his viremia was persistent despite being off Mycophenolate and low target goal of Tacrolimus. Patient partially responded to high dose IVIG so we decided to continue monthly high dose IVIG with daily Leflunomide. Later in April 2021, patient was admitted with COVID-19 symptoms with normal oxygen saturation at room air. His clinical condition worsened over the following 4-5 days in the form of hypoxic respiratory failure requiring high flow oxygen supplements and Acute Kidney injury (AKI) with nephrotic range proteinuria and gradual rising inflammatory markers. Patient was about to be transferred to the Intensive Care Unit as his clinical condition was worsening and refractory to the traditional treatment with steroid and antibiotics. On day 10 he received his monthly due dose of IVIG therapy (0.5 gm/kg of body weight for 4 consecutive days). His COVID symptoms started to improve from day 2 of the treatment. His inflammatory markers were dramatically down trended over the next 3-4 days post IVIG. He was discharged home with oxygen therapy (3L/min) by the day 5 post treatment with IVIG with recovering AKI.

Discussion: Few international studies have reported that initiation of high dose IVIG as adjuvant treatment for COVID-19 disease in selected patients may result in early clinical and laboratory recovery. The studies are limited due to the small sample size and patient selection criteria. Although our patient exhibited dramatic recovery, randomized clinical trial needs to be done to explore more about effect on COVID-19 pneumonia and COVID-19 associated AKI.

PO0157

CytoResc, or CytoSorb for COVID-19 Patients with Vasoplegic Shock: A Prospective Randomized Pilot Study

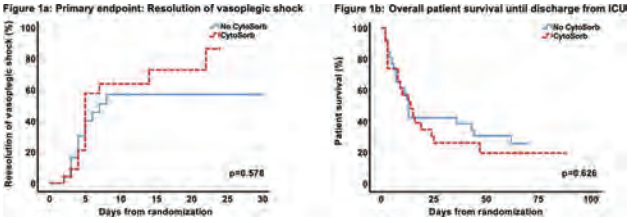
Helena Stockmann, Philipp Thelen, Mareen Pigorsch, Kai-Uwe Eckardt, Philipp Enghard, Lukas J. Lehner. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Several observations indicate a hyperinflammatory state in severely ill COVID-19 patients as target for therapeutic interventions. The aim of this study was to investigate the effect of extracorporeal cytokine elimination by CytoSorb on COVID-19 associated vasoplegic shock.

Methods: In this prospective randomized pilotstudy patients with vasoplegic shock requiring norepinephrine >0.2 µg/kg/min, CRP >100 mg/L and indication for kidney replacement therapy were randomized 1:1 to receive CytoSorb treatment for 3-7 days or standard of care. The primary endpoint was time until resolution of vasoplegic shock (freedom of vasopressor therapy for at least 8 hours to sustain a MAP ≥65mmHg). Data were analyzed using Cox-regression and Kaplan-Meier curves.

Results: From November 2020 - March 2021 50 patients were enrolled. Of these 23 patients received CytoSorb treatment, 26 patients received standard of care and 1 patient had to be excluded due to withdrawal of informed consent. The median age was 61 (IQR 58-65) years in the CytoSorb group and 66 (IQR 60-71) years in the control group. Patients were predominantly male (CytoSorb 91.3% vs. control 76.9%). Comorbidities and indicators for disease severity were well balanced. The primary endpoint was reached in 13/23 patients (56.5%) in the CytoSorb and 12/26 patients (46.2%) in the control group after a median of 5 (IQR 4-5) and 4 days (IQR 3-5), respectively (Figure 1a). The Cox-regression analysis for the primary endpoint showed no statistically significant difference between the groups with and without adjustment for the predefined additional variables age, gender, ECMO-therapy or time from beginning of shock until study inclusion. ICU-mortality was high with 18/23 (78%) deaths in the CytoSorb and 19/26 (73%) deaths in the control group (Figure 1b).

Conclusions: In this pilot trial in severely ill COVID-19 patients CytoSorb treatment did neither lead to a faster resolution of vasoplegic shock as compared to standard of care, nor was it associated with altered mortality.



PO0158

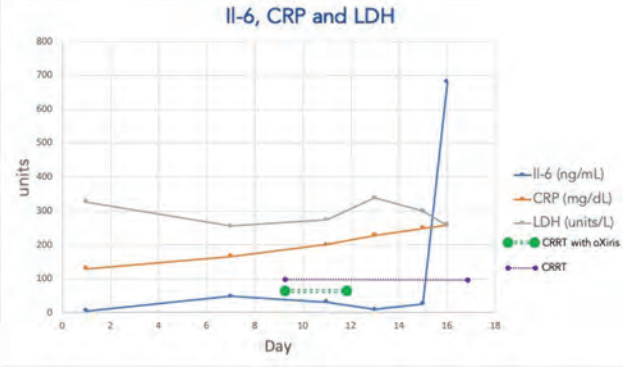
CRRT with the oXiris Filter Attenuates IL-6 in a Patient with Severe COVID-19

Jennifer C. Tang, Thanh Cao. *Keck Hospital of USC, Los Angeles, CA.*

Introduction: SARS-CoV-2 infection can result in ARDS and multiorgan dysfunction. The pathophysiology underlying Covid-19 includes a hypercoagulable state and a cytokine release storm with upregulation of IL-6, IL-10, and TNF-alpha, which are associated with ICU admission, ARDS, AKI, and increased mortality. While there are no proven treatments for this cytokine storm, tocilizumab, has shown promise in studies against severe Covid-19, suggesting that cytokine removal via blood purification products like oXiris may help achieve immune homeostasis.

Case Description: A 70-year-old male status post DDRT in 2016 presented with fevers, malaise, and dyspnea. He tested positive for SARS-CoV-2 and was admitted requiring high-flow nasal cannula with a rate of 50L/min and FiO2 of 90%. Urinalysis revealed pyuria, hematuria, and proteinuria. Labs revealed a creatinine of 2.4 and a BUN of 61 as well as a CRP of 130, ESR of 65, D-dimer of 1048, LDH of 325, ferritin of 3891, and IL-6 of 5.6 consistent with severe Covid-19. An ultrasound of his allograft kidney was normal. The patient then went into PEA arrest and was intubated with decreasing urine output, therefore was initiated on CRRT with an oXiris filter for 48 hours followed by a M150 filter. His P/F ratio increased and his IL-6 and SOFA score decreased while on the oXiris filter, however both CRP and LDH increased. After switching filters, the patient's P/F ratio quickly declined with a rapid increase of IL-6. Ultimately, the family decided to withdraw care.

Discussion: The oXiris filter could potentially manage the cytokine storm seen in Covid-19 as it is the only filter shown to remove cytokine and endotoxins, improve renal function, and have antithrombogenic properties as it is grafted with heparin. It is an AN69-based oXiris membrane treated on the inside with a high concentration of polyethyleneimine (PEI) binding cytokines and endotoxins. Given the impact of Covid-19, more studies must be done to assess if oXiris may serve as an effective treatment.



Graph demonstrating Day of Admission vs IL-6, CRP, and LDH.

PO0159

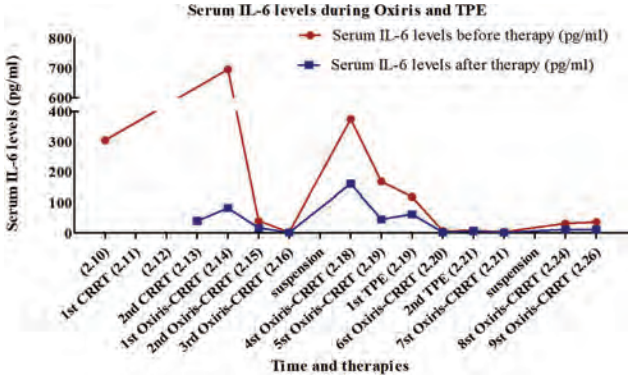
Blood Purification in a Critically Ill COVID-19 Patient with Cytokine Storm: A Case Report

Wenya Cao. *Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Introduction: Cytokine storm syndrome (CSS) is a common and severe cause of mortality among critically ill COVID-19 patients. BPTs, especially continuous renal replacement therapy (CRRT), may work by removing cytokines and blocking the cascade of inflammation and thus preventing the progression of CSS. However, the efficacy of Blood purification therapies (BPTs) in patients with complications of CSS but without AKI(Acute kidney injury) is still controversial.

Case Description: We report the case of a 66-year-old female who had severe COVID-19 without AKI. After admission, the patient's condition progressed rapidly to severe respiratory failure and heart failure, and she had been treated with venous-venous extracorporeal membrane oxygenation (VV-ECMO). Meanwhile, the level of interleukin-6 (IL-6) increased rapidly and reached 304.8 pg/ml. Although there was no kidney impairment in our patient, CRRT was initiated to reduce the levels of cytokines in circulation, while the decrease in IL-6 in serum and dialysate was not significant. Oxiris-CRRT was then introduced and there was a significant decline in serum levels of IL-6 after 3 Oxiris-CRRT sessions. However, when we stopped Oxiris-CRRT after the third treatment, the serum levels of IL-6 were elevated again 12 hours after the suspension of Oxiris-CRRT Subsequently. Therefore, the patient received 6 additional Oxiris-CRRT sessions until the serum IL-6 levels of 2.67 pg/ml. After 144 days of hospitalization, including 2 CRRT sessions, 9 Oxiris-CRRT sessions and 2 therapeutic plasma exchange (TPE) sessions, she completely recovered (shown in Fig. 1).

Discussion: In our patient, BPTs, especially Oxiris-CRRT, showed unique superiority and application value in the clearance of excess plasma cytokines, promoting a smooth recovery, which suggests that even if AKI does not occur, it is beneficial to use BPTs to prevent the progression of CSS in COVID-19 patients.



IL-6 levels gradually decreased to normal levels after 9 sessions of Oxiris-CRRT and two sessions of TPE.

PO0160

COVID-19 vs. Bloodstream Purification: A Targeted Therapy

Sean Barnett. *Brooke Army Medical Center, Fort Sam Houston, TX.*

Background: The use of bloodstream purification has been well studied in bacteremia but the emergence of COVID found a new target. Using blood purification in the fight against COVID we have found a potential treatment for viremia and pneumonia, cytokine storm and decompensation, and superinfections in COVID. When used at the appropriate time, blood purification has the potential to prevent further organ injury.

Methods: The following case series is an individual clinical observation of patients withing the PURIFY NIH funded clinical trial.

Results: 28M w/o significant PMHx, transferred to BAMC for ECMO due to severe COVID. He initially improved, but decompensated with MRSA bacteremia, was ECMO/CRRT and quadruple pressor dependent. He was treated with the Seraph for bloodstream purification and was off all vasopressors within 6 hours. He recovered, and was ultimately discharged without ECLS depdence. 64 M w/ CAD and CKD was admitted for mild COVID PNA requiring minimal o2. On hospital day 9-11 he decompensated ultimately requiring intubation and vasopressor support with AKI and oliguria. He was treated with the Seraph for 16 hours and was off vasopressors within 10 hours, urine output recovered within 24 hours, he was extubated in 48 hours and discharged from the ICU after 96 hours. 52 M w/ CKD/COPD/CHF/CAD admitted for mild COVID PNA, decompensated on day 12, required intubation / vasopressor support / CRRT, treated for 24 hours on CRRT with the Seraph Filter and was off vasopressors with returning renal function within 24 hours. 64 M w/ CKD/CHF/CAD admitted for NSTEMI and cardiogenic shock, found to be non-obstructive and likely viral cardiomyopathy due to COVID. He was started on dobutamine / levophed and IABP. Due to oliguria he was treated with CRRT and Seraph for blood purification. Within hours he was off vasopressors, no longer needing IABP after 24 hours, and ultimately recovered renal function within 48 hours.

Conclusions: While further study is needed, the use of blood purification for specific targets in COVID appears to have incredible benefits. Due to documented pathogen removal (bacteria/fungi/virions) it is likely beneficial treatment for any bloodstream infections, but especially in the susceptible COVID population it seems to have miraculous benefit. The Seraph also appears to mitigate organ injury from the cytokine storm in COVID due to attenuation of the cytokine storm.

Funding: Other U.S. Government Support

PO0161

Hemoperfusion with Seraph® Filter Late in the Course of Severe COVID-19 Pneumonia

Yahya R. Ahmad, Javier A. Neyra, Taha Ayach. *University of Kentucky Medical Center, Lexington, KY.*

Introduction: Severe COVID-19 infection is often associated with uncontrolled cytokine response and a milieu of circulating inflammatory markers. Cytokine adsorption with viral binding of SARS-CoV-2 has been utilized in severe COVID-19 cases under emergency use authorization by the FDA. Evolving observations of its use showed reduction in inflammatory markers; improvement in hemodynamics; reduction of vasopressor requirements and oxygen support; and avoidance or reduction of time on mechanical ventilation. We report a case of hemoperfusion utilizing the Seraph® filter as a last resource in a patient with life-threatening COVID-19 infection.

Case Description: A 37-year old female with a diagnosis of morbid obesity (BMI 60 kg/m^2) presented to the University of Kentucky hospital with acute respiratory failure from COVID-19 pneumonia. The patient required ICU care, mechanical ventilation and eventually extracorporeal mechanical oxygenation (ECMO) on day 5 of her hospital stay. Despite aggressive COVID-19 management, her condition gradually worsened. On day 15 of her hospital stay, extracorporeal sorbent hemoperfusion via Seraph® filter was delivered through PrismaFlex® in tandem with the ECMO circuit. Her serum IL-6 levels dropped from 154 pg/ml to 29 pg/ml, and C-reactive protein from 317 mg/L to 294 mg/L within 2 hours of treatment completion. She had intermittent fevers up to 40C, especially in the 48 hours prior to treatment which resolved right away with hemoperfusion and she remained afebrile for the next 72 hours. There was, however, no significant change in her hemodynamics and overall clinical status and the patient remains on ECMO and mechanical ventilation at the time of this report (Day 34).

Discussion: This case exemplifies that hemoperfusion therapy delivered late in the course of severe COVID-19 disease is still effective in decreasing circulating inflammatory markers, but may not be effective in significantly and positively affecting clinical outcomes. Although circulating inflammatory markers could be used to guide eligibility for hemoperfusion therapy, timing of hemoperfusion should be considered in clinical trials to effectively test the potential of this intervention to ameliorate clinical outcomes in susceptible populations.

PO0162

Direct Hemoperfusion Using a Polymyxin B-Immobilized Polystyrene Column for COVID-19

Daisuke Katagiri, Minami Suzuki, Emi Sakamoto, Takahito Niikura, Eisei Noiri, Hideki Takano. *National Center for Global Health and Medicine, Department of Nephrology, Tokyo, Japan.*

Background: The involvement of increased cytokine levels in severe COVID-19 has been noted, and anti-inflammatory therapy including corticosteroids or anti-human interleukin (IL)-6 receptor monoclonal antibody is expected to be effective in such patients. Direct hemoperfusion using a polymyxin B-immobilized polystyrene column (PMX) is a treatment that selectively adsorbs endotoxins; it is also expected to adsorb a variety of endogenous substances.

Methods: The patients (N=22) included were those whose respiratory samples tested positive for SARS-CoV-2 upon real-time reverse transcription-polymerase chain reaction (RT-PCR) and underwent PMX during hospitalization at National Center for Global Health and Medicine, Tokyo, Japan between January 30 2020 and April 30, 2021. PMX was considered when an image of pneumonia consistent with COVID-19 was obtained on chest CT and the P/F ratio was less than 300. Demographic data, information on clinical symptoms, and laboratory data were collected.

Results: On day 15 of first PMX treatment, disease severity decreased in 63.6 % of the patients. P/F ratio increased and there was a downward trend in urine β2-microglobulin on days 4 and 8. Cytokine level measurement pre- and post-PMX revealed a downward trend in interleukin-6 levels and decreased levels of the factors involved in vascular endothelial injury, including vascular endothelial growth factor. There were 43 PMX, of which nine and five caused an increase in inlet pressure and membrane coagulation, respectively. When the membranes coagulated, the circuitry needed to be reconfigured.

Conclusions: PMX is expected to become a therapy to address medical needs and prevent the exacerbation from moderate to severe condition in COVID-19.

PO0163

Plasma Exchange to Treat Patients with Severe COVID-19

Christian Nusshag,[1] Christian Morath,[1] Claudius Speer,[1] Florian Kälble,[1] Martin G. Zeier,[1] Monica Boxberger,[3] Anna E. Schulze Schleithoff,[3] Markus A. Weigand,[2] Uta Merle.[3] *[1]Heidelberg University Hospital Departement of Nephrology, Heidelberg, Germany; [2]Heidelberg University Hospital Departement of Anesthesiology, Heidelberg, Germany; [3]Heidelberg University Hospital Deparement of Gastroenterology, Heidelberg, Germany.*

Background: The clinical spectrum of coronavirus disease 2019 (COVID-19) ranges from asymptomatic infection to critical illness and death in up to 89% of mechanically ventilated patients. Therefore, new therapeutic strategies are needed. Recent evidence

suggests a multi-level inflammatory syndrome in some of the most critically ill patients with overlapping features of other hyperinflammatory or autoimmune diseases. Thus, plasma exchange (PE) has become a subject of controversy as potential therapy in these patients. Here, we report the results of the so far largest cohort of critically ill COVID-19 patients treated with PE.

Methods: All critically ill COVID-19 patients treated with PE at Heidelberg University Hospital were analyzed between April and December 2020. Disease course and outcomes were compared with a standard care control group matched for age, sex, and disease severity. Changes in laboratory and clinical parameters were studied longitudinally. Kaplan-Meier and Cox regression analyses were performed.

Results: In total, 28 critically ill COVID-19 patients were treated with an average of 3 PE procedures per patient. No relevant complications occurred during PE therapy. Inflammatory markers and biochemical indicators of end-organ damage and endothelial activation were significantly reduced during PE. These laboratory changes were accompanied by normalization of body temperature, improved pulmonary function, and reduced vasopressor demand. Most importantly, the laboratory and clinical improvements were maintained after the last PE. In contrast, most parameters in the control group did not improve significantly over seven days, although baseline clinical and laboratory parameters were comparable in both groups. Kaplan-Meier analysis showed improved 30-day survival in the PE group compared to the control group (67.9% vs. 42.9%, p=0.044). In a multivariable analysis, the hazard ratio for death was 0.27 (95% CI 0.11-0.68, p=0.005) with PE versus standard care.

Conclusions: Our data further suggest that PE represents a potential therapeutic strategy for a subset of severe COVID-19 cases. The observed PE-related effects appear to go beyond a purely artificial improvement in blood parameters and may indicate a reversal of the complex COVID-19 immunopathology. Randomized controlled trials are urgently needed.

PO0164

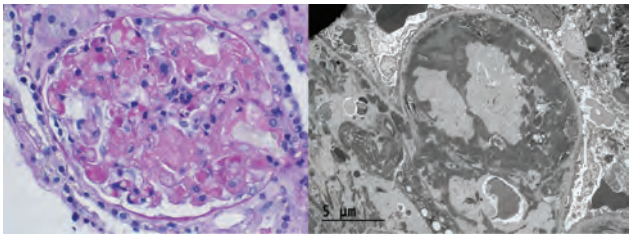
COVID-Related Renal Thrombotic Microangiopathy: Role of Plasma Exchange

Janame J. Kottey, Niraj K. Yadav, Rama Kethineni, Sarah Gilligan, Martin C. Gregory, Tahir Zaman, Marc Barry, Adhish Agarwal, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: The most common COVID-19 associated glomerular diseases are COVID associated nephropathy (COVAN) and Thrombotic Microangiopathy (TMA). Other less common glomerular diseases associated with COVID reported are antineutrophil cytoplasmic antibody (ANCA) vasculitis, anti-glomerular basement membrane (Anti GBM) antibody disease, podocytopathies, and IgA nephropathy. We report a case of TMA due to COVID-19 infection.

Case Description: A 67-year-old woman with asthma was admitted for COVID related respiratory failure and was noted to have acute kidney injury with anemia and thrombocytopenia. She was hypertensive and urine analysis was notable for hematuria and proteinuria. ANA, ANCA, Anti GBM, Coombs, ADAMTS13, disseminated intravascular coagulation panel, serum immune fixation and free light chains, cryoglobulins, and infectious work up were unrevealing. Complement C3 and C4 were low, lactate dehydrogenase and bilirubin were high, haptoglobin was undetectable, and schistocytes were seen on peripheral smear which raised concern for thrombotic microangiopathy. Renal function deteriorated rapidly with ensuing anuria prompting initiation of dialysis. Kidney biopsy confirmed acute thrombotic microangiopathy. She was started on plasma exchange (PLEX) for COVID related thrombotic microangiopathy and she started producing urine with rapid improvement in creatinine (Cr) after two treatments. Cr was down to 3.11mg/dL from a peak of 7.45 mg/dL after PLEX and normalized at discharge. The patient is currently being monitored with renal panel and complete blood picture every three months, as an outpatient.

Discussion: COVID is known to cause TMA that is presumed to be secondary to endothelial dysfunction and complement activation. There are no standard guidelines for treatment. Terminal complement blockade was not used in our patient. Our case demonstrates the efficacy of PLEX in the treatment of COVID related TMA. Early recognition and treatment is crucial and may reduce morbidity and mortality.



PO0165

Sustained Low-Efficiency Dialysis vs. Continuous Renal Replacement Therapy in Critically Ill COVID-19 Patients

Essa Abuhelaiqa, Mohamad M. Alkadi, Saifatullah Khan, Awais Nauman, Muftah Othman, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

Background: Acute kidney injury among patients with COVID-19 infection is a poor prognostic indicator. There is limited evidence to guide the nephrology community if there are any risk or advantages of using sustained low-efficiency dialysis (SLED) or continuous renal replacement therapy (CRRT). We aim to evaluate the clinical outcomes of COVID-19 patients receiving renal replacement therapy in the intensive care unit (ICU).

Methods: This is a retrospective chart review of adult patients with COVID-19 admitted to ICU in the state of Qatar who had 1)acute kidney injury and 2)received renal replacement therapy between February to August of 2020. We evaluated clinical characteristic, severity of illness, mortality, and renal outcomes at 30 days.

Results: Among 127 patients with acute kidney injury requiring dialysis in ICU, 16 patients were on CRRT, 68 patients were on SLED, and 43 patients were on combination. We did not observe significant difference among age, gender, ethnicity or baseline creatinine. Most common indication for indication of dialysis was volume overload followed by acidosis in all three groups with serum creatinine of 264umol/L vs 499umol/L vs 351umol/L in CRRT, SLED and CRRT+SLED, respectively. Inflammatory markers, Pressore requirement and APACHE II score were similar between all groups. 30-day Survival was 23%, 50% and 9%. Among 34 patients on SLED who survived, 6 were dialysis dependent post COVID-19 infection.

Conclusions: Acute kidney failure in critically ill COVID-19 patients is associated with high mortality. A lower mortality, but high morbidity is observed in patients receiving SLED in critical care setting. Further investigation of SLED in COVID-19 should be considered.

PO0166

Detection of SARS-CoV-2 in Dialysis Effluent on a Peritoneal Dialysis Program in Mexico City: Four Cases

Diana P. Morales, Daniel Rodriguez, Elva Arellano Escalante, Andreé M. Tirado Hernández, Joaquin Gonzalez Monroy, Maria Guadalupe Suarez. *Hospital General "Dr. Darío Fernández Fierro", Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

Introduction: Since the rapid spread of the COVID 19 pandemic, it is crucial to identify possible sources of transmission of the SARS-COV-2 virus in order to perform procedures safely. There has been interest to identify the presence of SARS-CoV-2 in different compartments including peritoneal compartment. SARS-CoV-2 was detected by reverse transcriptase-polymerase chain reaction (RT-PCR) in dialysis effluent on a few single cases while other authors have reported negative results. Peritoneal membrane pores have a diameter of 20-40 nm while the SARS-CoV-2 virion diameter is between 60 to 140 nm, theoretically the virion could reach the peritoneal cavity by hematogenous diffusion or through the dialysis catheter after contact contamination.

Case Description: We report dialysis effluent findings of four patients, two women and two men, with an age range of 35 to 64 years and different comorbidities including: diabetes mellitus, hypertension and obesity. They were diagnosed with COVID-19 using RT-PCR assay on nasopharyngeal samples or by tomography findings. RT-PCR samples of peritoneal effluent were obtained with a length of stay on peritoneal cavity of 6 hours, without centrifugation of the sample. Three patients were positive for presence of SARS-CoV-2 on nasopharyngeal sample and dialysis effluent, while the fourth patient was negative in both samples despite having tomography findings suggestive of COVID-19 infection. It should be noted that in the 3 patients that had a positive RT-PCR on both nasopharyngeal and peritoneal effluent, samples were obtained within the first 7 days following the onset of symptoms associated with COVID-19 and on the fourth patient the peritoneal effluent sample was obtained 12 days after initial symptoms. All patients presented with acellular peritoneal fluid. No abdominal symptoms were reported.

Discussion: Presence of SARS-CoV-2 on peritoneal fluid continues to be a subject of debate. Peritoneal effluent sample-drawing procedure has not been standardized, which may explain the inconsistent results noted by different authors. The positive results of the RT-PCR for SARS-CoV2 on peritoneal effluent must be confirmed on a larger sample. Although based on a small group, these findings should prompt to consider these fluids as potentially infective.

PO0167

A Comparison of Clotting Rate During Hemodialysis in COVID-19 Patients Receiving Anticoagulant vs. No Anticoagulant in an Inpatient Setting

Vincent M. Campion, Wina Yousman, Elvira González, Preethi Subramanian, Golnaz Vahdani, Waseem Albasha, Sangeetha Murugapandian, Bekir Tanriover. *Banner University Medical Center Tuscon, Tucson, AZ.*

Background: Anticoagulant use during hemodialysis is a standard practice in both outpatients and inpatients setting. In an inpatient setting with heightened acuity of illness, the potential for bleeding attributable to anticoagulant is concerning. Hospitals have started applying an anticoagulant free HD protocol with success. COVID-19 patients showed a degree of systemic hypercoagulability with unique features, including a consumptive disseminated intravascular coagulation coexisting with hyperfibrinolysis and increased bleeding risk. Maintaining circuit patency and avoiding bleeding risk has been challenging. Data regarding anticoagulant in COVID-19 patients who received hemodialysis is limited. This study's primary objective is to compare hemodialysis clotting rate in COVID-19 patients who received anticoagulant versus those without anticoagulant.

Methods: Retrospective chart review for all COVID-19 patients who received hemodialysis at Banner Medical Center Tucson Campus Between November 2020 and January 2021. Primary outcome was clotting rate during hemodialysis. CRRT was excluded.

Results: 330 total patients observed, 56% sessions in the ICU unit and 44% in the medicine unit. 57% were AKI and 43% were ESRD. Anticoagulant use was 38.5% (heparin IVP during hemodialysis was 12%, continuous systemic heparin was 16% and others (warfarin, DOAC, Argatroban, etc) was 11%). Clotting rate was 12%. Other characteristics can be seen on the table 1. There was no difference in the clotting rate between group with anticoagulant versus without anticoagulant (8% vs.15%, p value 0.06). Multivariable logistic regression for clotting outcome showed that compared to no-anticoagulation, systemic heparin continuous infusion decreased clotting by 83% (OR 0.17, 95% CI 0.04- 0.77, p-value=0.02) and others anticoagulant decreased clotting by 91% (OR=0.09, 95% CI 0.01-0.85); compared to AV fistula, temporary dialysis catheter increased clotting by 2.9x (OR 2.9, 95% CI 1.10-7.44, p-value=0.03); and every 10 increase in platelet count increased clotting by 4% (OR 1.04, 95% CI 1.01-1.07, p value =0.01)

Conclusions: No anticoagulation and temporary catheters carry high risk for clotting in patients with COVID undergoing iHD. Continuous heparin should be considered.

PO0168

Divergence Between Serum Creatinine and Cystatin C in Estimating Glomerular Filtration Rate of Critically Ill COVID-19 Patients

Yanan Liu, Peng Xia. *Peking Union Medical College Hospital, Dongcheng-qu, China*.

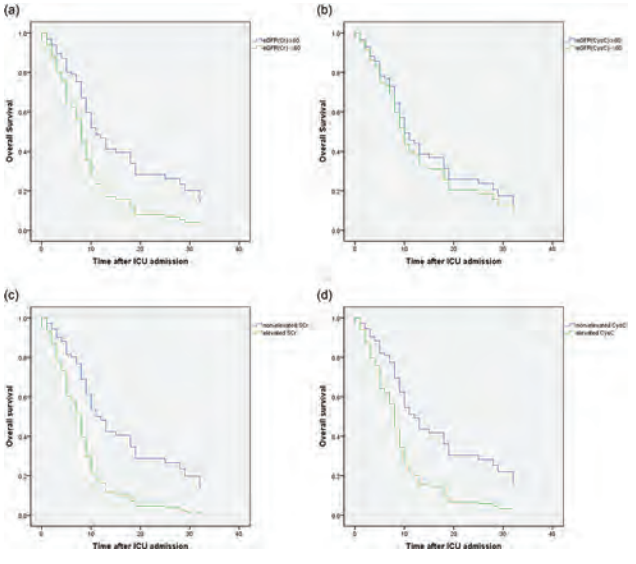
Background: The clinical use of serum creatine (sCr) and Cystatin C (CysC) in kidney function evaluation of critically ill patients has been in continuous discussion. The values of estimated glomerular filtration rate calculated by sCr(eGFRcr) and CysC (eGFRcysc) of critically ill COVID-19 patients were investigated in this study.

Methods: This is a retrospective, single-center study of critically ill patients with COVID-19 admitted in Intensive Care Unit (ICU) at Wuhan, China. Control cases were moderate COVID-19 patients who were matched in age and sex at a ratio of 1:1. The eGFRcr and eGFRcysc were compared. The association between eGFR and death were analyzed in critically ill cases. The potential factors leading to the divergence between eGFRcr and eGFRcysc were explored.

Results: A total of 76 critically ill COVID-19 patients were concluded. The mean age was 64.5±9.3 years and the male : female ratio was 49:27. At ICU admission, their eGFRcr (85.45 (IQR 60.58-99.23) ml/min*1.732m^2) were much higher than eGFRcysc (60.6 (IQR 34.75-79.06) ml/min*1.732m^2). About 50% of them showed eGFRcysc < 60 ml/min/1.73 m2 while 25% showed eGFRcr < 60 ml/min/1.73 m^2 (c^2=10.133,P=0.001). This divergence was not observed in control group. The potential factors influencing the divergence included serum interlekin-6(IL-6)level, tumor necrosis factor(TNF-α) level as well as APACHEII. Reduced eGFRcr (<60 mL/min/1.73 m2) was associated with death(HR=1.939,95%CI 1.078-3.489, P=0.027).

Conclusions: The eGFRcr was higher than eGFRcysc in critically ill cases. The divergence might be affected by the inflammatory condition. Reduced eGFRcr predicted in-hospital death. In these patients, we advocate for caution when using eGFRcysc.

Funding: Private Foundation Support



The Kaplan-Meier survival curves for critically ill patients divided by reduced eGFRcr (a), reduced eGFRcysc (b), elevated sCr(c) and elevated CysC (d).

PO0169

Serum Sodium and Patient Symptoms in COVID-19 Hospitalizations

Timothy E. Yen, Andy Kim, Henry Rutherford, Saee Ratnaparkhi, Ann E. Woolley, Finnian R. McCausland. *Brigham and Women's Hospital, Boston, MA.*

Background: Disorders of serum sodium (SNa) are common in hospitalized patients with COVID-19 and associated with longer length of stay and inpatient mortality. However, the association of SNa with patient-reported outcomes is not clear.

Methods: The Brigham and Women's Hospital COVID-19 Registry is a prospective cohort study of consecutive, adult patients admitted with confirmed SARS-CoV-2 infection (n=809). We examined the association of SNa (continuous and tertiles) at admission with: 1) patient symptoms obtained from detailed chart review; and 2) in-hospital mortality using unadjusted and adjusted logistic regression models. Covariates included demographic data and comorbidities. Only index admissions were considered.

Results: Mean age was 60 years, 48% were male, and 35% had diabetes. The most frequent symptoms were cough (64%), fever (60%) and shortness of breath (46%). In adjusted models, higher SNa (per mmol/L) was associated with lower odds of GI symptoms (OR 0.96; 95%CI 0.93-0.99), higher odds of confusion (OR 1.08; 95%CI 1.40-1.13) and higher odds of in-hospital mortality (OR 1.06; 95%CI 1.02-1.11). Compared with the lowest tertile, the highest tertile of SNa was associated with a lower odds of GI symptoms and anosmia/ageusia, and higher odds of confusion and in-hospital mortality (Table 1).

Conclusions: In this prospective cohort study of hospitalized patients with COVID-19, hypernatremia is associated with higher odds of confusion and in-hospital mortality, but lower risk of GI symptoms and anosmia. The presence of dysnatremia may help identify higher-risk patients with COVID-19 and prompt ascertainment of patient symptoms, both of which may improve patient-centered approaches to care.

Table 1

Variable	Frequency	SNa (mmol/L)	SNa Tertiles

PO0170

Lower CD3 and CD4 Counts in Kidney Transplant Recipients Who Did Not Respond to COVID-19 Vaccination

Yorg Al Azzi, Harith Raees, Levi G. Cleare, Yi Bao, Pablo Loarte Campos, Luz E. Liriano-Ward, Cindy T. Pynadath, Maria Ajaimy, Omar Alani, Liise-anne Pirofski, Enver Akalin. *Montefiore Medical Center, Bronx, NY*.

Background: Kidney transplant recipient's response rate to COVID-19 vaccination is reportedly less than 54% after the 2nd dose, significantly lower than general population and dialysis patients, reported as between 85-90% and 95-100%, respectively.

Methods: We studied SARS-CoV-2 anti-spike IgG levels in our kidney transplant recipients after their COVID-19 vaccination using the OrthoV IgG platform.

Results: 69 kidney transplant recipients received a SARS-CoV-2 vaccine (47 Pfizer, 20 Moderna and 2 Johnson and Johnson) at a median 36 months after transplantation (range, 3 months to 22 years). 61% were male, 39% Black, 29% Hispanic with a median age of 60 (range 22-82). 72% were deceased-donor kidney transplant recipients. 23 patients had previous history of COVID-19 diagnosed by SARS-CoV-2 PCR and/or anti-nucleocapsid antibody and 21 of those patients (91%) developed anti-spike IgG after 1st or 2nd dose with a median level of 13.2 (11.2-16.2). 46 patients without history of previous COVID-19, 17 (37%) developed anti-spike IgG at a median of 28 days (range 10-72) after the second vaccine dose with a median level of 5.7 (1.22-15.4). Patients who didn't develop anti-spike IgG tended to be older, of African-American descent, on MMF > 1 g/day, have lower CD3 and CD4 counts.

Conclusions: In summary, most kidney transplant recipients without history of COVID-19 did not produce anti-spike IgG after being fully vaccinated and it is associated with augmented immunosuppression, lower T cell counts, African-American race and older age.

Mean eGFR (SD), mL/min	53 (42)	71 (67)	0.32

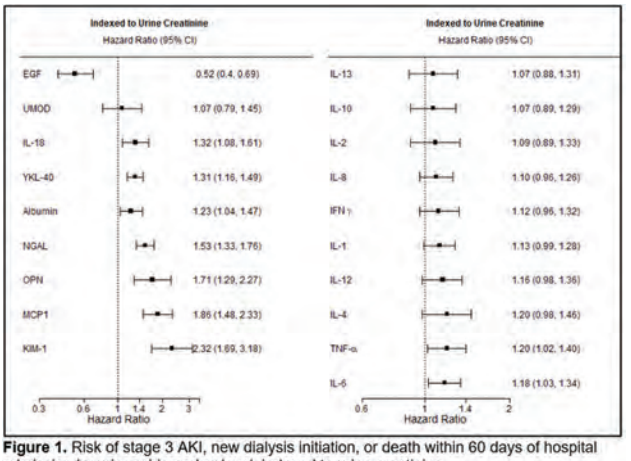

Figure 1. Risk of stage 3 AKI, new dialysis initiation, or death within 60 days of hospital admission by urinary biomarker level, indexed to urine creatinine.

PO0171

Prognostic Significance of Urinary Biomarkers in Patients Hospitalized with COVID-19

Steven Menez,[1] Dennis G. Moledina,[2] Heather Thiessen Philbrook,[1] Francis P. Wilson,[2] Wassim Obeid,[1] Michael Simonov,[2] Yu Yamamoto,[2] Celia P. Corona villalobos,[1] Crystal Chang,[1] Brian T. Garibaldi,[1] William Clarke,[1] Shelli Farhadian,[2] Charles Dela Cruz,[2] Steven G. Coca,[3] Chirag R. Parikh.[1] TRIKIC Consortium: Translational Research Investigating Kidney Outcomes in COVID-19 *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Yale University School of Medicine, New Haven, CT; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) is common in patients with COVID-19 and associated with poor outcomes. Urinary biomarkers have been associated with adverse kidney outcomes in other settings and may provide additional prognostic information in patients with COVID-19.

Methods: We evaluated 19 urinary biomarkers of injury, inflammation, and repair in patients hospitalized with COVID-19 at 2 academic medical centers between April and June 2020. We associated biomarkers with a primary composite outcome of KDIGO stage 3 AKI, requirement for dialysis, or death within 60 days of admission. We also compared various kidney biomarker levels in the setting of COVID-19 versus other common AKI settings.

Results: Out of 157 patients, 24 (15.3%) experienced the primary outcome. Two-fold higher levels of neutrophil gelatinase-associated lipocalin (NGAL) (HR: 1.53; 95% CI: 1.33-1.76), monocyte chemoattractant protein (MCP-1) (HR: 1.86; 95% CI: 1.48-2.33), and kidney injury molecule-1 (KIM-1) (HR: 2.32; 95% CI: 1.69-3.18) were associated with highest risk of the primary outcome. Higher epidermal growth factor (EGF) levels were associated with a lower risk of the primary outcome (HR 0.52; 95% CI: 0.40-0.69). Individual biomarkers provided moderate discrimination and biomarker combinations improved discrimination for the primary outcome.

Conclusions: Urinary biomarkers are associated with severe kidney complications in patients with COVID-19 and provide valuable information to monitor kidney disease recovery and progression.

PO0172

Urine Test Predicts Kidney Injury and Death in COVID-19

Katherine Xu, Ning Shang, Abraham D. Levitman, Alexa Corker, Satoru Kudose, Andrew Yaeh, Jacob Stevens, Sumit Mohan, Rosemary V. Sampogna, Vivette D. D'Agati, Krzysztof Kiryluk, Jonathan M. Barasch. *Columbia University Irving Medical Center, New York, NY.*

Background: Kidney injury is a common feature of COVID-19 infection, but serum creatinine (SCr) is not a sensitive or specific marker of kidney injury. We hypothesized that measurement of molecular markers of tubular injury can diagnose COVID-19 associated kidney injury and predict a poor prognosis.

Methods: This is a prospective cohort study of 444 consecutive COVID-19 patients in a New York City Emergency Department recruited in March and April, 2020. Urine and blood were collected simultaneously at hospital admission (median time of day 0, IQR 0-2 days) and within 1 day of a positive SARS-CoV-2 test in 70% of patients. Urine NGAL and KIM-1 assays were blinded to clinical data. Primary outcomes included the diagnosis of Acute Kidney Injury (AKI) as defined by AKIN criteria, as well as its duration and severity. Secondary outcomes included death, dialysis, shock, respiratory failure, and length of hospital stay. Kidney biopsies from COVID-19 patients were examined for biomarker gene expression.

Results: Elevated urinary NGAL (uNGAL) levels were associated with SCr based AKI (267±301 vs. 96±139 ng/mL, P=1.6x10^{-10}). uNGAL level >150 ng/mL had 80% specificity and 75% sensitivity to diagnose AKIN stage 2 AKI or higher. Higher uNGAL levels were associated with sustained AKI [aOR per SD of uNGAL (95%CI): 2.67 (1.81-4.06), P=1.8x10^{-6}], need for dialysis (aOR: 3.67 (1.89-7.57), P=2.2x10^{-4}), shock (aOR: 1.64 (1.26-2.15), P=2.9x10^{-4}), prolonged length of stay (aHR: 1.22 (1.09-1.36), P=4.8x10^{-4}), and death [aOR=1.62 (1.19-2.24), P=2.5x10^{-3}], independent of baseline SCr and pre-existing co-morbidities. These associations were also preserved after adjusting for proteinuria measured in the same urine sample. NGAL is typically transcribed by distal nephron segments but in COVID-19 kidney biopsies with widespread histopathologic acute tubular injury (ATI), NGAL mRNA expression included proximal tubules.

Conclusions: Elevated uNGAL in patients admitted with acute COVID-19 was associated with the development of AKI, increased severity and duration of AKI, the degree of histopathological acute tubular injury, shock, prolonged hospitalization, need for dialysis, and death.

PO0173

Readmissions After AKI in Colorectal Carcinoma Are Associated with Adverse Outcomes: Findings from the National Readmission Database

Victor E. Prado,[1] Miguel Salazar.[2] *[1]University of Cincinnati, Cincinnati, OH; [2]Cleveland Clinic, Cleveland, OH.*

Background: Acute kidney injury (AKI) is common in critically ill cancer patients with poor outcomes. Colorectal carcinomas (CRC) are frequently associated with AKI, due to complications of disease or treatment. AKI in CRC remains a well-known but under-represented topic in current literature. We aim to analyze and quantify the impact, healthcare burden, readmission rates and predictors of metastatic CRC with AKI.

Methods: We conducted a retrospective cohort study of the 2017 National Readmission Database (NRD) of adult patients readmitted within 30 days after an index admission for AKI with a concomitant diagnosis of CRC. ICD 10 codes were used to identify diagnoses and procedures.

Results: A total of 2,239 patients with metastatic colorectal cancer were admitted with AKI. The 30-day readmission rate was 27.9%. Main causes for readmission were sepsis, progression of malignancy, hypovolemia and recurrent AKI. Readmitted patients were associated with higher in-hospital mortality (0.1% vs. 1.5%; p<0.01), mechanical ventilation need (4.7% vs 1.5%; P<0.01) and chronic kidney disease (CKD) diagnosis (44.6% vs 36.1%; P<0.01). The total health care in-hospital economic

burden of readmission was $32.3 million in total charges and $7.8 million in total costs. After adjusting for age and comorbidities, independent predictors of readmission were disposition against medical advice, HIV, CKD, and sepsis. Preventive factors for readmission were found to be radiation therapy and peripheral parenteral nutrition.

Conclusions: AKI in metastatic CRC has a high rate of readmissions, with poor outcomes in morbidity, mortality and costs making it a significant healthcare burden. Among common causes of readmission, potentially targetable causes include hypovolemia and sepsis while among readmission predictors, CKD and sepsis warrant further attention. Abovementioned preventive predictors consolidate the importance of combination therapy and supportive care in CRC.

Predictors of Readmissions

Variable	Adjusted odds ratio (95% confidence interval)	P value
Comorbidities		
HIV	2.95 (1.58-5.49)	<0.01
CKD	1.46 (1.10-1.93)	<0.01
Radiation therapy	0.59 (0.14-0.39)	<0.01
In-Hospital Complications		
Sepsis	2.19 (1.01-4.84)	0.05
In-Hospital Procedures		
Peripheral parenteral nutrition	0.33 (0.07-0.56)	<0.01

PO0174

Risk for AKI in the Outpatient Setting

Daniel P. Murphy,[1] Scott Reule,[2] David M. Vock,[1] Paul E. Drawz.[1] *[1]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [2]Minneapolis VA Health Care System, Minneapolis, MN.*

Background: Risk-factors for acute kidney injury (AKI) in the hospital have been well studied. Yet, tools for identifying outpatients at high risk for AKI are not available.

Methods: A development cohort for modelling risk of AKI without concurrent or subsequent hospitalization was defined by repeated primary care encounters in an urban healthcare system. An external validation cohort was similarly defined in the Veterans Health Administration. Logistic regression with bootstrap sampling for backward stepwise covariate elimination was used to develop a model for outpatient AKI in an 18-month outcome period. The model was then transformed into two binary tests to identify high-risk patients: one for research and another for clinical care.

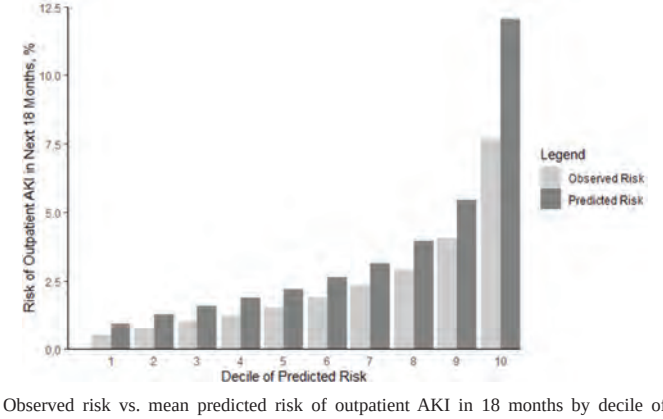
Results: Outpatient AKI occurred in 4611 of 152,371 (3.0%) and 115,744 of 4,864,576 (2.4%) patients in the development and validation cohorts, respectively. The model C-statistics were 0.72 (95% CI: 0.71-0.73) and 0.72 (95% CI: 0.72-0.72) in the development and validation cohorts. The research test had sensitivity of 0.21 (95% CI: 0.21-0.21) and specificity of 0.95 (95% CI: 0.95-0.95). The clinical test, with a lower test-positivity threshold, had sensitivity of 0.49 (95% CI: 0.49-0.50) and specificity of 0.81 (95% CI: 0.81-0.81).

Conclusions: The outpatient AKI-risk prediction model performed well in both continuous and binary forms.

Performance in the validation cohort of two binary tests for outpatient AKI in 18 months

Statistic	Research Test	Clinical Test
Threshold for test-positivity (a)	≥9.5% (b)	≥4.5% (b)
Sensitivity	0.210 (95% CI: 0.208-0.213)	0.494 (95% CI: 0.491-0.497)
Specificity	0.952 (95% CI: 0.951-0.952)	0.806 (95% CI: 0.806-0.807)
Positive predictive value	0.096 (95% CI: 0.094-0.097)	0.058 (95% CI: 0.058-0.059)
Negative predictive value	0.980 (95% CI: 0.980-0.980)	0.985 (95% CI: 0.985-0.985)
Percent of cohort "positive" by the test	5.2%	20.0%

(a) Derived in the development cohort (b) P <0.001 for predicting outpatient AKI in the validation cohort



Observed risk vs. mean predicted risk of outpatient AKI in 18 months by decile of predicted risk in the validation cohort.

PO0175

Additive Harmful Effects of AKI and Acute Heart Failure on Mortality in Hospitalized Patients

Hyung Eun Son,[1,2] Eunji Baek,[1] Ji Young Ryu,[1,2] Jong Cheol Jeong,[1,2] Dong-Wan Chae,[1,2] Seung Seok Han,[2,3] Sejoong Kim.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Organ crosstalk between kidney and heart has been suggested. This study aimed to investigate the additive effect of both conditions on mortality.

Methods: We retrospectively recruited 102,721 hospitalized patients for 5 years. Acute kidney injury was diagnosed with serum creatinine-based criteria, and acute heart failure with International Classification of Diseases code, within two weeks after admission. Primary outcome was all-cause mortality.

Results: Among the 5,316 (5.2%) patients who died, 20.5% died within 1 month. Hazard ratio for 1-month mortality was 23.25 in patients with both conditions, 13.47 for acute kidney injury only, and 2.76 for acute heart failure only. The relative excess risk of interaction was 8.01, and it was more prominent in patients aged <75 years, and those without chronic heart failure.

Conclusions: Acute kidney injury and acute heart failure had a detrimental additive effect on short-term mortality in hospitalized patients.

Results of analyses on interaction, where AKI and AHF are the two exposures of interest to mortality within 1 month

Clinical Trajectories of AKI and Clinical Outcomes in Acute Decompensated Heart Failure

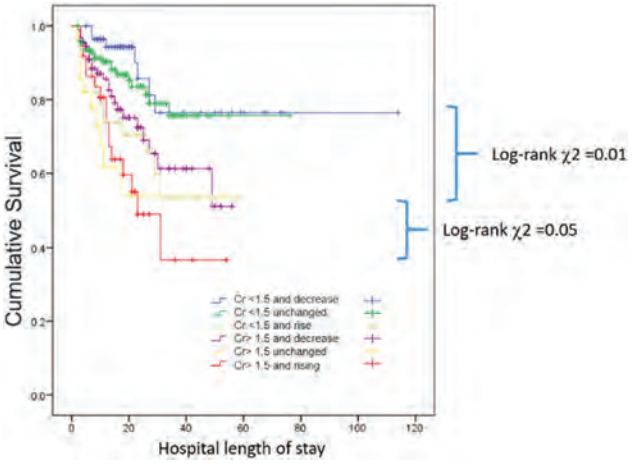
Octavio R. Garcia-Flores, Armando Vázquez-Rangel. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: Cardiorenal syndrome (CRS) is a pathophysiologic disorder of the heart and kidneys, with both acute and chronic dysfunction. CRS type 1 is characterized by an acute cardiac disease leading to AKI.

Methods: This is a retrospective cohort study from Jan 2017 to Dec 2018 in 3rd level center in Mexico City. The objective was to describe the incidence and outcome of AKI in patients with CRS type 1. We divide AKI's trajectory into: ascending and descending AKI, also we used a creatinine (Cr) cut-off point of 1.5mg/dl and identified 6 trajectories. We used a Logistic regression analysis (LRA) for in-hospital mortality and length of stay.

Results: 404 patients were included. Mean age 58.9 ±16.5 years, 60% were men, 27% had DM, 45% had hypertension. The incidence of AKI was 60.9% and mortality was 22%. Severe AKI in 25.5%, 36 (8.9%) required kidney replacement therapy. The incidence of ascending AKI was 29.7% and mortality In this group was 46.7%. AKI's six trajectories are shown in Figure 1. In LRA for the whole cohort, PASP >40mmHg (OR 4.82 CI 2.0-11.6 p=<0.001), NT-proBNP >10000 (OR 3.26 CI 1.61-6.57 p= 0.001), ascending AKI (OR 4.08 CI 2.11-7.88 p=0.04) were associated with mortality. In LRA for ascending AKI, BUN/Cr ratio >25 (OR 1.59 CI 1.00-2.54 p=<.001) and neutrophil/lymphocyte ratio (NLR) >6.5 (OR 2.64 CI 1.65-4.23 p=<0.001) were associated with in-hospital mortality.

Conclusions: The incidence and mortality of AKI in patients with decompensated heart failure is high. Patients with ascending AKI had a significant increase in mortality and descending AKI had a better prognosis. Different Cr trajectories indicate different outcomes, the group of patients who at the time of admission had Cr >1.5mg/dl and presented a rise during hospitalization had a worse outcome. NLR>6.5 and BUN/Cr ratio >25 are predictors of mortality.



PO0177

National Epidemiology of Community-Acquired AKI

Clarissa J. Diamantidis,[1,2] Lindsay Zepel,[2] Matthew L. Maciejewski,[2,3] Erin E. Burks,[1] M. Alan Brookhart,[2] C. Barrett Bowling,[1,3] Virginia Wang.[2,3] *[1]Duke University Department of Medicine, Durham, NC; [2]Duke University Department of Population Health Sciences, Durham, NC; [3]Durham VA Health Services Research and Development, Durham, NC.*

Background: Community-acquired acute kidney injury (CA-AKI) is AKI that develops outside of the hospital and is the most common form of AKI globally. National estimates of CA-AKI in the US are absent due to lack of integrated health data and limited availability of outpatient lab data. In this study, we leverage data from the Veterans Health Administration (VA) to estimate CA-AKI incidence and risk factors.

Methods: We constructed a retrospective cohort using national VA administrative and lab data to assess the cumulative CA-AKI incidence among active VA primary care users in 2013-2017. Veterans who did not have recorded outpatient serum creatinine (SCr) and those with a history of severe kidney disease (≥ Stage 5 or kidney transplant) were excluded. CA-AKI was defined as ≥ 1.5 fold relative increase in outpatient SCr or inpatient SCr (≤ 24 hours from admission), from a reference value defined as the preceding outpatient SCr ≤ 12 months prior. A Cox model was used to estimate the association between CA-AKI risk and baseline variables capturing socio-demographics and comorbidities, accounting for repeated measurements among Veterans.

Results: Of approximately 2.5 million eligible Veterans in each analysis year, the cumulative incidence of CA-AKI was approximately 2% each year and declined slightly over time (2.0, 2.0, 2.0, 1.9, and 1.6% in 2013-2017, respectively). Of these, 79% were Stage 1 AKI, 15 % were Stage 2, and 6% were Stage 3 across all years. Only 26% of CA-AKI was observed in the inpatient setting. Veterans with CA-AKI (vs. no CA-AKI) more likely to be older, male, Black race, with greater comorbidity. After adjustment, increasing age, female sex, Black race, Hispanic ethnicity, diabetes, heart failure, hypertension, alcohol use, HIV/AIDs, metastatic cancer, and sickle cell anemia were all associated with increased CA-AKI risk (HR >1.15).

Conclusions: CA-AKI affects approximately 1 of every 50 US Veterans and is most common in the outpatient setting, with less than a third observed in the inpatient hospital setting. Reliance on inpatient evaluation of AKI likely results in significant under-recognition and missed opportunity to prevent and manage the substantial long-term consequences of AKI.

PO0178

National Practice Patterns in the Care of Pediatric AKI Survivors

Anna E. Williams,[1] Erin E. Burks,[1] David T. Selewski,[2] Rasheed A. Gbadegesin,[1] Clarissa J. Diamantidis.[1] *[1]Duke University Hospital, Durham, NC; [2]Medical University of South Carolina, Charleston, SC.*

Background: Acute kidney injury (AKI) affects 5-10% of all children admitted to the hospital and is associated with adverse outcomes such as increased risk of recurrent AKI, incident and progressive chronic kidney disease (CKD) and death. However, few guidelines exist to optimize post-AKI care. In this study, we surveyed pediatric nephrologists to determine their practice patterns in the care of AKI survivors.

Methods: We administered an email survey to members of the Pediatric Nephrology Research Consortium (PNRC) throughout the US & Canada. Participants were asked questions regarding their practice characteristics, frequency of care of post-hospital AKI survivors and perceptions regarding provider roles in post-AKI outpatient care. Participants were also asked questions regarding the content of their AKI care, patient counseling and disease monitoring.

Results: Of the 52 respondents, most practiced in an academic setting (96%) for <20 years (83%) and reported caring for >10 AKI survivors each year (69%). The majority of respondents (64%) felt pediatric nephrology should always be involved in AKI follow-up care; 33% felt only for ≥ Stage 2 AKI. Most (73%) felt nephrology care was no longer needed when clinical concerns resolved; 60% when eGFR returns to normal; 46% when urine protein/creatinine (UPC) ratio is normal. Most respondents listed professional conferences (79%) and peer-reviewed articles (87%) as information sources. For mild AKI, 60% of participants repeated a creatinine test after 1 month following discharge; 25% reported checking within 1 week of discharge. In severe AKI, tests were repeated within 1 week (67%). Most reported measuring blood pressure, serum creatinine & UPC at follow-up (>90%). Respondents endorsed counseling patients on risk of recurrent AKI (69%), incident hypertension (92%), incident CKD (81%) and NSAID avoidance (85%). Overall, 90% of respondents felt comfortable managing AKI follow-up in pediatric patients.

Conclusions: Pediatric nephrologists were generally confident in their ability to counsel and manage pediatric AKI survivors. Most felt AKI care required pediatric nephrology input and reported providing education about AKI consequences. Whether primary care providers endorse similar confidence and co-management perceptions requires further study.

PO0179

AKI Stage Is a Poor Predictor of Long-Term Cardiovascular Outcomes

Benjamin R. Griffin,[1,2] Jason Wachsmuth,[1] Masaaki Yamada,[1,2] Meenakshi Sambharia,[2] Saket R. Girotra,[1,2] Eli Perencevich,[1,2] Heather Reisinger,[1,2] Mary V. Sarrazin,[1,2] Diana I. Jalal.[1,2] *[1]Iowa City VA Medical Center, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Trials to improve long-term outcomes in post-AKI patients have enrolled patients primarily based on AKI stage; however, whether AKI stage is a reasonable predictor of cardiac morbidity and mortality is unknown. We developed predictive models for MACE readmissions in post-AKI patients and determined the utility of AKI stage within these predictive models.

Methods: VHA patient data for inpatient admissions was obtained between 2013 and 2018. AKI was defined as a creatinine increase of ≥0.3 mg/dL from baseline. The primary outcome was subsequent hospitalization for congestive heart failure (CHF), myocardial infarction (MI), or stroke (MACE), with follow-up of at least 2 years. Over 50 variables were considered for inclusion in the final model. Bootstrap modeling was used to determine the outcomes of 100 stepwise regressions using random sampling with replacement. Variables included in more than 60 were included in a final model using Cox regression censored for mortality. If not selected, AKI stage was forced into the model. Due to the association between cardiac disease and the primary outcome, and in order to evaluate risk factors for de novo cardiac disease, separate models were constructed for patients with and without pre-existing cardiac disease.

Results: A total of 241,781 Veterans with AKI were included. AKI stage did not meet selection criteria for either model. In patients without pre-existing cardiac disease, the final model included age, sodium, bilirubin, chronic lung disease (CLD), complicated diabetes mellitus (CxDM), atrial fibrillation (A-Fib), and proteinuria. AKI stage 3 (HR 1.12, CI 1.08-1.16) compared to AKI stage 1 was a weak predictor of subsequent MACE events. Similarly, in patients with prior cardiac disease, the final model included age, blood urea nitrogen, white blood count, CHF, MI, CLD, CxDm, A-Fib, cardiomyopathy, cardiac device, sleep apnea, complicated hypertension, valvular disease, major electrolyte abnormalities, and proteinuria. AKI stage 3 was again a weak predictor (HR 1.065, 1.03-1.10).

Conclusions: While AKI stage is commonly used to enroll patients into AKI survivorship clinics, it was not found to be a strong independent predictor of MACE events among post-AKI Veterans. Our findings may inform risk stratification for post-AKI follow up.

PO0180

Urinary Oxygen Partial Pressure to Monitor AKI Risk

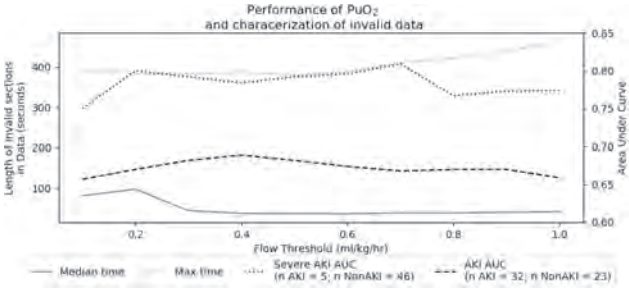
Lars Lofgren, Kai Kuck, Natalie Silverton. *University of Utah Health, Salt Lake City, UT.*

Background: In a prior study, we showed that patients who developed acute kidney injury (AKI) had lower mean urinary oxygen partial pressure (PuO_2) following cardiopulmonary bypass (CPB). However, PuO_2 is unreliable when urine flow is low and little is known about the distribution of urine flow intraoperatively. The objective of this research was to determine the distribution of the length of sections of unreliable PuO_2 data due to low flow.

Methods: Following IRB approval and informed consent, a device that measures PuO_2 and urine flow was placed in cardiothoracic surgery patients. PuO_2 and urine flow (sampled at 1 Hz) were deemed not reliable when urine flow was below a threshold. Patients who did not meet a percent valid data threshold were excluded. Mean PuO_2 following CPB and the maximum and median length of sections of invalid data were calculated. Data were generated for a percent valid data threshold of 30 % and urine flow rate thresholds of 0.1 to 1 mL/kg/hr at 0.1 increments. Patients who met the KDIGO criteria for AKI were compared to non-AKI patients. In addition, patients with Stage 2 or 3 AKI based on the KDIGO serum creatinine criteria were assigned to the Severe AKI group and were compared to patients with stage 1 or no AKI. The area under the curve (AUC) of a receiver-operator (ROC) plot of mean PuO_2 estimating AKI development was calculated for each comparison.

Results: AUC was 0.69 for AKI when the flow threshold was 0.4 ml/kg/hr. The average for all patients of the median and maximum length of invalid data was 37 seconds and 387 seconds, respectively. For Severe AKI, the AUC was 0.81 for a flow threshold of 0.7 ml/kg/hr. As the maximum length of invalid data sections increases the AUC decreases.

Conclusions: Sections of unreliable PuO_2 data are sufficiently short and do not significantly impact the performance of PuO_2 as a marker of AKI when a urine flow threshold is used to filter the data. The data demonstrate the feasibility of measuring PuO_2 to monitor AKI risk during cardiothoracic surgery. Further research is needed to determine if intraoperative PuO_2 can reduce the incidence of AKI.



AUC of mean PuO2 and distribution of length of invalid data sections

PO0181

Serum Trace Metal Changes Could Potentially Indicate Kidney Damage in Rats with Cisplatin-Induced Kidney Injury

Yuji Hotta,[1] Natsumi Tomita,[1] Yuko Yamamoto,[1] Aya Naiki-Ito,[2] Akimasa Sanagawa,[1] Masahiro Kondo,[4] Tomoya Kataoka,[3] Satoru Takahashi,[2] Kazunori Kimura.[3,1] *[1]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [3]Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [4]Department of Pharmacy, Nagoya City University Hospital, Nagoya, Japan.*

Background: Cisplatin (CDDP), a widely used anticancer drug, is known to exhibit nephrotoxic adverse effects. Nephrotoxicity is a dose-limiting toxicity. Therefore, the early detection of cisplatin-induced nephrotoxicity is crucial. Certain trace metals reportedly change with kidney injury, although their relationship with CDDP-induced kidney injury remains unclear. Therefore, in this study, we investigated the trace metal changes after cisplatin treatment in rats.

Methods: Eight-week-old male Wistar-ST rats were divided into a control and a CDDP group (n = 6 for both), treated intraperitoneally with saline or CDDP 3 mg/kg, respectively. On day 0 and 5, we took serum samples and measured the SCre and BUN levels. The kidneys were obtained on day 5 and subjected to histological studies using HE staining. The serum samples were used for the comprehensive measurement of nine different trace metal types (Mn, Fe, Co, Ni, Cu, Zn, As, Se, and Mo) by ICP-MS. The statistical analysis was performed using Student's *t*-test.

Results: The SCre and BUN levels significantly increased in the CDDP group compared with those in the control group ($P<0.01$). The HE staining showed that the proximal tubular injury in the CDDP group was severe compared to that in the control group. Three out of nine serum trace metals, Co, Ni and Cu, were significantly high in the CDDP group compared with those in the control group ($P<0.01$).

Conclusions: Co, Ni, and Cu increased after the CDDP treatment. The measurement of such elements could be useful for the detection of CDDP-induced nephropathy.

PO0182

Identifying Factors Associated with Clinically Adjudicated Drug-Induced AKI in Children

Zaid Yousif,[1] Stuart Goldstein,[2] David T. Selewski,[3] Michael Zappitelli,[4] David J. Askenazi,[5] Patrick D. Brophy,[6] Il-Soo Ha,[12] Vivekanand Jha,[10] Nadine M. Benador,[1] Alyssa A. Riley,[7] Ayse Akcan Arikan,[9] Li Yang,[11] Kar Hui Ng,[8] Sucheta M. Vaingankar,[1] Ravindra L. Mehta,[1] Linda Awdishu.[1] DIRECT Investigators *[1]University of California San Diego, La Jolla, CA; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Medical University of South Carolina, Charleston, SC; [4]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [5]University of Alabama at Birmingham, Birmingham, AL; [6]University of Rochester Medical Center, Rochester, NY; [7]The University of Texas at Austin, Austin, TX; [8]National University of Singapore, Singapore, Singapore; [9]Baylor College of Medicine, Houston, TX; [10]The George Institute for Global Health UK, Oxford, United Kingdom; [11]Peking University First Hospital Department of Nephrology, Beijing, China; [12]Seoul National University Children's Hospital, Seoul, Republic of Korea.*

Background: Drug-induced acute kidney injury (DI-AKI) affects up to 33% of hospitalized children. Clinical adjudication of DI-AKI is challenging since AKI is multifactorial. We report clinical variables that influence ascertainment of DI-AKI cases and inter-rater reliability (IRR) of existing causality assessment tools (CAT) for adverse drug events.

Methods: We analyzed data from the DIRECT study, an international, multi-center, observational cohort study of clinically adjudicated pediatric cases of AKI stage 2 associated with nephrotoxic medication (NTMx) exposure. Each case was adjudicated by two pediatric nephrologists using CAT. A third adjudicator acted as the tiebreaker. IRR was calculated using Krippendorff's alpha. We developed variables to capture exposure to NTMx and serum creatinine trends. We constructed a multivariable logistic regression model with clinically adjudicated DI-AKI as the outcome and clinical variables as predictors.

Results: 115 (86.5%) out of 133 children were adjudicated as DI-AKI. The mean age was 12.2 ± 4.5 years, and the most frequent NTMx: vancomycin (43.6%), piperacillin/tazobactam (32.3%), and non-steroidal anti-inflammatory drugs (18.8%). AKI risk factors were comparable between clinically adjudicated DI-AKI and Not DI-AKI groups. Past medical history of malignancy, increased vascular capacity (i.e., sepsis or hypotension), and severe AKI treated with dialysis made DI-AKI adjudication less likely. Longer duration from the start of drug exposure to AKI onset made DI-AKI adjudication more likely. The IRR of the Liverpool ($ka = 0.35$) and the Naranjo ($ka = 0.31$) CAT were poor.

Conclusions: DI-AKI adjudication is a complex and multifactorial process. Current CAT appear to be unreliable. Development of CAT specific to DI-AKI is needed to perform robust outcomes research.

Funding: Other NIH Support - International Serious Adverse Events Consortium, National Library of Medicine (Grant #T15LM011271).

PO0183

Clinically Distinct Subtypes of AKI on Hospital Admission Identified by Machine Learning Consensus Clustering

Michael A. Mao,[1] Charat Thongprayoon,[2] Jose L. Zabala-Genovez,[2] Kianoush Kashani,[2] John J. Dillon,[2] Vesna D. Garovic,[2] Wisit Cheungpasitporn.[2] *[1]Mayo Clinic's Campus in Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Patients with acute kidney injury were clustered at hospital admission into clinically distinct subtypes using an unsupervised machine learning approach. Mortality risk was assessed among these distinct clusters.

Methods: Consensus clustering analysis was performed on demographics, principal diagnoses, comorbidities, and laboratory data on 4,289 hospitalized adult patients with acute kidney injury at admission. The standardized difference of each variable was calculated to identify each cluster's key features. We assessed the association of each cluster with hospital and one-year mortality.

Results: Consensus clustering analysis identified four distinct clusters. There were 1,201 (28%) patients in cluster 1, 1,396 (33%) patients in cluster 2, 1,191 (28%) patients in cluster 3, and 501 (12%) patients in cluster 4. Figure 1 illustrates cluster differences. Figure 2 highlights associated increased mortality in clusters 2, 3, and 4.

Conclusions: Our study demonstrated the use of machine learning consensus clustering analysis to characterize a heterogenous cohort of patients with acute kidney injury on hospital admission into four clinically distinct clusters with different associated mortality risks.

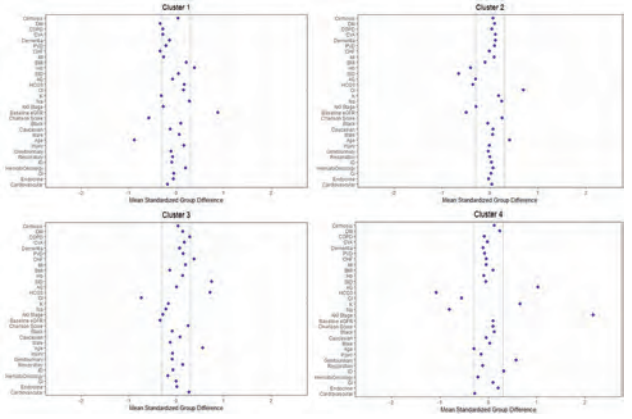


Figure 1: Standardized differences across clusters

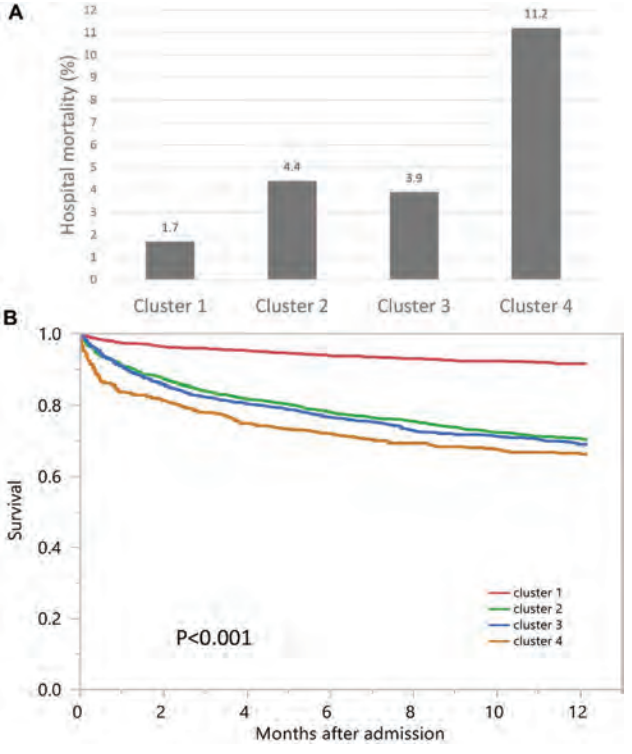

Figure 2: Hospital and One-Year Mortality among Different Clusters with Admission AKI

PO0184

Severe Kidney Injury Requiring Continuous Renal Replacement Therapy: Correlation of Mean Platelet Volume with Mortality at Multiple Time Intervals

Sean Pickthorn, Nathaniel Hocker, Lewis Mann, Ravinandan Venkatasubramanian, Meenakshi Sambharia, Jonathan Nizar, Benjamin R. Griffin. *The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Platelet decreases after continuous renal replacement therapy (CRRT) initiation are common and associated with increased mortality. Platelet activation during CRRT due to shear forces and membrane interactions may be associated with subsequent platelet loss. The degree of platelet activation can be approximated with mean platelet volume (MPV), as activated platelets undergo degranulation which increases their size. While MPV values at CRRT initiation correlate with mortality, MPV changes following CRRT initiation are unknown. We hypothesized that MPV would increase following CRRT initiation and correlate with mortality.

Methods: Adult patients admitted to the University of Iowa between January 1, 2019 and December 31, 2020, were included in this retrospective analysis. Patients were excluded if they survived <48 hours while on CRRT, or if fewer than two values were available for MPV. MPV was collected at the time of CRRT initiation and at 24, 48, and 72 hours. The primary outcome evaluated was in-hospital mortality. The final regression models were adjusted for age, sex, race, illness severity, and days of CRRT therapy.

Results: A total of 190 patients (81 survivors and 109 non-survivors) were included. MPV was significantly higher at each timepoint (24, 48, and 72 hours) in the full cohort compared to CRRT initiation, and increased by a greater amount over time in non-survivors than survivors. MPV at 72 hours was independently associated with in-hospital mortality after adjustments for covariates (OR 1.76, CI 1.15-2.69, p=.01).

Conclusions: MPV increased after CRRT initiation, especially in non-survivors, and MPV at 72 hours was independently associated with in-hospital mortality. These findings suggest that platelet activation temporally related to CRRT initiation may play a role in platelet loss and mortality in this population. Future studies will evaluate more direct measures of platelet activation in patients on CRRT and the impact of platelet activation blocking agents in this population.

PO0185

Recovery After AKI: Goals of an AKI!Now Workgroup

Samuel A. Silver,[1] Emaad M. Abdel-Rahman,[2] Jorge Cerda,[3] Leslie S. Gewin,[4] Javier A. Neyra,[5] Anitha Vijayan,[6] Erin F. Barreto.[7] AKI!Now *[1]Queen's University, Kingston, ON, Canada; [2]University of Virginia, Charlottesville, VA; [3]Albany Medical College, Albany, NY; [4]Vanderbilt University Medical Center, Nashville, TN; [5]University of Kentucky, Lexington, KY; [6]Washington University in St Louis, St Louis, MO; [7]Mayo Clinic Minnesota, Rochester, MN.*

Background: The American Society of Nephrology recently established the AKI!Now initiative. AKI!Now aims to promote excellence in the prevention and treatment of AKI by transforming the delivery of AKI care to improve clinical and patient-centered outcomes. Herein, we describe the focused efforts of AKI!Now on "recovery after AKI."

Methods: Three core objectives were identified in the domain of AKI recovery: 1. To determine areas of priority for mechanistic research focused on recovery after AKI. It is expected that these would include a variety of experimental models suitable for various AKI etiologies and disease severities. 2. To benchmark existing strategies to care for patients after AKI including integrated insights from primary care providers, nephrologists, other subspecialty health care professionals. 3. To facilitate implementation and testing of interventions designed to limit short- and long-term complications of AKI and promote recovery. Dialysis dependent and independent AKI survivors should both be considered for these interventions and clinical trials.

Results: The AKI!Now initiative will highlight and clarify challenges and opportunities to improve care after AKI. This work will also inform who is followed after AKI and by whom (i.e., primary care and/or nephrology), options for care delivery (i.e., in-person versus telehealth), and potential practices to improve outcomes (i.e., role of ACEi/ARB and SGLT2 inhibitors after AKI, physical/cognitive rehabilitation). The stakeholder relationships formed, including those with patients, healthcare professionals, industry, and academia, will facilitate a collaborative research and practice agenda necessary to understand and outline best practices after AKI.

Conclusions: Survivors of AKI are a high-risk and growing population, and AKI is associated with worse long-term outcomes than an acute myocardial infarction. However, how to care for patients after AKI remains ill-defined with substantial practice variation. This represents an opportunity for the "recovery after AKI" workgroup of AKI!Now to provide leadership by raising awareness and promoting strategies focused on equitable and effective post-AKI care throughout the American Society of Nephrology and wider nephrology community.

PO0186

Exploration of the Mitochondria Genes Alteration in AKI

Shensen Li, Qingqing Liu, Haiyan Shen, Bingquan Deng, Wenwen Li, Changchun Cao. *Sir Run Run Hospital Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is one of the most common complications in clinic, especially in critical ill patients. Recently, the fundamental function of mitochondria in acute kidney injury and repair have gradually been noticed while the mechanism still unclear. Therefore, we aimed to identify the change pattern of mitochondria alteration associated gene in AKI through Gene Expression Omnibus (GEO) database analysis and AKI animal model verification.

Methods: A total of 1893 genes involved in mitochondria function and metabolism were screened from Gene Ontology (GO) database and defined as GO terms in mitochondria metabolism. Meanwhile, 2 studies invested transcriptome differences in renal ischemia reperfusion injury (GSE98622 and GSE99703) were extracted from GEO database. By crossing GO terms and 2 datasets from GEO database, 69 and 62 mitochondria metabolism genes were identified in GSE98622 and GSE99703 separately. Among which, 23 genes were overlapped in 2 datasets and verified by real-time PCR in 2 kinds of AKI model (ischemic renal reperfusion injury model and cisplatin induced AKI model).

Results: Through GO and KEGG enrichment analysis, these differentially expressed genes (DEGs) were allocated to peroxisome, butanoate metabolism, arginine and proline metabolism, neurotrophin signaling pathway and metabolic pathways. Protein-protein interaction analysis demonstrated that Hao2, Acsm3, Amacr, Aadat may play vital roles of mitochondrial regulation in AKI. The results of real-time PCR shown that 3 genes were significantly increased in both two kinds of AKI model (Arg2, Clu, Lgals3) and 12 genes were decreased (Aadat, Acsm3, Agps, Ak4, Amacr, Bdh1, Gatm, Hao2, Isoc2b, Mpv17l, Nat8f1, Nudt19), while others were not altered in animal model or had no consistency changes between 2 kinds of AKI model.

Conclusions: We have identified 23 DEGs were associated with mitochondria metabolism in I/R AKI by using bioinformatic technology. Among these genes, GO and KEGG analysis suggests that the DEGs are mainly enriched in lipid metabolism, amino

acid metabolism pathway and tightly associated with peroxisome. Furthermore, 15 DEGs were revalidated in kidney of two kinds of AKI mouse model (I/R AKI and Cisplatin-AKI).

Funding: Government Support - Non-U.S.

PO0187

Artificial Intelligence in AKI: Goals of an AKI!Now Workgroup

Javier A. Neyra,[1] Jay L. Koyner,[2] Stuart Goldstein,[3] Neesh I. Pannu,[4] Kianoush Kashani,[5] Karandeep Singh,[6] Shina Menon,[7] Danielle Soranno,[8] Girish N. Nadkarni,[9] Azra Bihorac.[10] *[1]University of Kentucky Medical Center, Lexington, KY; [2]University of Chicago Pritzker School of Medicine, Chicago, IL; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]University of Alberta, Edmonton, AB, Canada; [5]Mayo Clinic Minnesota, Rochester, MN; [6]University of Michigan, Ann Arbor, MI; [7]Seattle Children's Hospital, Seattle, WA; [8]Children's Hospital Colorado, Aurora, CO; [9]Icahn School of Medicine at Mount Sinai, New York, NY; [10]University of Florida, University of Florida, Gainesville, FL, US, academic, Gainesville, FL.*

Background: In 2019, the American Society of Nephrology established *AKI!Now,* a collaborative initiative to promote excellence in the prevention, diagnosis, and treatment of Acute Kidney Injury (AKI). Here, we describe the ongoing efforts of the *AKI!Now* workgroup focused on Artificial Intelligence (AI) to improve the quality, accessibility, affordability, and equity of AKI care.

Methods: The workgroup has outlined objectives in 3 key domains: *1. Patients*. Input in designing and implementing fair and equitable AI tools and identifying clinical scenarios based on personal and caregiver experience that could be improved with AI *2. Clinicians*. Input in the design, value, and implementation of fair and equitable AI tools and identifying clinical uncertainties that may benefit from new AI tools *3. Researchers*. Evaluation of current AI tools, with a focus on removing implicit bias; development of novel, feasible, and effective AI tools to address gaps identified by patients and clinicians; and development and implementation of AI methods along with novel sensors for more sensitive assessment of kidney function and injury to advance the science of AKI

Results: This project, with involvement from a multi-disciplinary group of stakeholders, will yield efficient and effective use of AI for quality improvement in AKI care. Specific deliverables include 1) Risk-stratification and prediction tools; 2) Intelligent alert tools; 3) Decision support for bundled care compliance; 4) Decision support for implementing pragmatic clinical trials, among others. Importantly, this work will fill gaps in validating available AI tools and develop many desired AI tools that do not exist. These coordinated efforts are expected to deliver highly useful AI tools that could improve AKI care, research and reduce associated costs.

Conclusions: The *AKI!Now* workgroup on AI is committed to improving value care in AKI and encourages engagement and collaboration with patient, provider, researcher, and industry stakeholders. We seek to improve the care provided to the growing and susceptible AKI population, along the entire lifespan.

PO0188

Incidence of AKI in Individuals Treated with Lithium

Gisli Gislason,[1] Olafur S. Indridason,[2] Engilbert Sigurdsson,[4,1] Runolfur Palsson.[3,1] *[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Division of Nephrology, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [3]Internal Medicine Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [4]Mental Health Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Lithium has been linked to acute kidney injury (AKI) at toxic blood levels but the risk of AKI has otherwise not been well studied. Interestingly, lithium has been shown to protect against tubular injury in experimental AKI models. The aim of the study was to examine the risk of AKI in individuals treated with lithium.

Methods: This was a retrospective cohort study of all individuals treated with lithium in Iceland in 2003–2018. A control group comprised patients with affective disorders (ICD 10 codes F30-F39) attending the outpatient clinic of the Mental Health Services at Landspitali–the National University Hospital in 2014–2016, who had never used lithium. Clinical and laboratory data, including ICD-9 and ICD-10 codes and serum creatinine (SCr) values, were obtained from nationwide electronic medical records. Individuals with <2 SCr values available were excluded. AKI was defined using the SCr component of the KDIGO criteria. Multivariable logistic regression was used for the analysis.

Results: The lithium-treated group consisted of 2682 individuals, of whom 2310 (86.1%) were included in the study. Of those, 297 (12.9%) developed AKI. Of 1426 individuals in the control group, 1218 (85.5%) were included and 97 (8.0%) developed AKI. Lithium use was not an independent risk factor for AKI (OR 0.93, 95% CI, 0.72–1.20; Table). When lithium users were analyzed separately, lithium intoxication (OR 2.34, 95% CI, 1.33–4.09), duration of lithium therapy (OR 1.01, 95% CI 1.00–1.01) and mean lithium concentration (OR 1.22, CI, 1.14–1.30) were all significant risk factors for development of AKI.

Conclusions: Our findings suggest that lithium use does not affect the incidence of AKI after controlling for important covariates. However, lithium intoxication, time on lithium therapy and blood lithium concentration are associated with increased risk of AKI.

Healthcare Analytics with Time-Invariant and Time-Variant Feature Importance to Predict Hospital-Acquired AKI

Horng-Ruey Chua,[1,3] Kaiping Zheng,[5] Liangjian Lu,[2] Graeme Maclaren,[4,3] Hui Kim Yap.[2,3] National University Health System Academic Informatics and Innovation Office *[1]National University Hospital, Department of Medicine, Division of Nephrology, Singapore, Singapore; [2]Khoo Teck Puat - National University Children's Medical Institute, Singapore, Singapore; [3]National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [4]National University Hospital, Department of Cardiothoracic and Vascular Surgery, Singapore, Singapore; [5]National University of Singapore, School of Computing, Department of Computer Science, Singapore, Singapore.*

Background: Acute kidney injury (AKI) develops in 4% of inpatients and is a marker of clinical deterioration and nephrotoxicity. AKI onset is highly variable in hospital which makes it difficult to time biomarker assessment in patients for preemptive care. We applied machine learning to electronic health records and predict hospital-acquired AKI by a 48-hour lead time, with aim to create an AKI surveillance algorithm that is deployable in real-time.

Methods: The data was sourced from 20,732 case-admissions in 16,288 patients over one year in our institution. We enhanced our bidirectional recurrent neural network with a novel time-invariant and time-variant module to capture clinical features temporal to AKI in cases. Time-series features included laboratory parameters that preceded a 48-hour prediction window before AKI onset; the latter's corresponding reference was the final in-hospital serum creatinine performed in cases without AKI.

Results: The cohort was of mean age 53(±25) years, of whom 29%, 12%, 12%, and 53% had diabetes mellitus, ischemic heart disease, cancers, and baseline eGFR <90 mL/min/1.73m^2, respectively. There were 911 AKI episodes in 869 patients. We derived and validated an algorithm in the testing dataset with an AUROC of 0.81 (0.78–0.85) for predicting AKI. At a 15% prediction threshold, our model generated 699 AKI alerts with 2 false positives for every true AKI and predicted 26% of AKIs. A lowered 5% prediction threshold improved the recall to 60% but generated 3,746 AKI alerts with 6 false positives for every true AKI.

Conclusions: We generated an accurate algorithm from electronic health records through machine learning that predicted AKI by 48 hours prior. The prediction threshold could be adjusted during deployment to balance an optimal recall with alert-fatigue, while its precision could be augmented by better-timed AKI biomarker assessment in the high-risk cohort identified.

Urine Biomarkers of AKI in Extremely Low Gestational Age Neonates: A Case-Control Study

David J. Askenazi,[1] Brian A. Halloran,[1] Robert Schmicker,[2] Patrick J. Heagerty,[2] Sandra Juul,[2] Stuart Goldstein,[3] Sangeeta R. Hingorani,[4] Meagan Reagan.[1] *[1]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [2]University of Washington School of Medicine, Seattle, WA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Seattle Children's Hospital, Seattle, WA.*

Background: Urine biomarkers hold promise to diagnose and differentiate AKI. In premature neonates, biomarker evaluation must address normative gestational age (GA) differences.

Methods: We performed a case-control study from neonates enrolled in the Preterm Erythropoietin Neuroprotection Trial (PENUT) to evaluate differences in urine obtained in the first postnatal week between cases and controls. Twenty (N=20) neonates with severe AKI (Stage 2 or 3) were matched with 2 controls (N = 40) who did not have AKI, had the same GA week (rounded down to the nearest week), gender, and BW (+/- 50 g), without replacement. Biomarkers were analyzed on multi-analyte electro-chemiluminescent or single colorimetric ELISA kits. Biomarker were run in duplicates; the average concentration was converted to $\log_{10}$. Days were grouped into day 0-3, 4-6, 7-9, with day of birth was defined as day 0. For each biomarker, the average pairwise difference between cases and controls was calculated. To account for multiple measurements, a linear mixed model framework was employed incorporating a random intercept for match, random effects across day, and a day case status interaction term. The predicted mean differences (95% CI) between cases and controls for each measurement time frame are compared and reported in the figures.

Results: Demographic characteristics were similar between those with and without AKI. The association with case status was modified by day (interaction p-values <0.05) for (Albumin, Clusterin, Creatinine, Cystatin C, epithelial growth factor (EGF), kidney injury marker-1 (KIM1), neutrophil gelatinase associated lipocalin (NGAL), FGF23, Ghrelin, IGFBP7, IL15, MCP1, TIMP2, VEGFA). Figures show a forest plot of the predicted mean differences (case minus control) at days 1 (0-3), 5 (4-6), and 9 (7-9) for each of 21 urine biomarkers. Urine albumin (day 1), EGF (day 1), creatinine (day 5 and 9), Cystatin C (Day 9), KIM-1 (day 9), IL-15 (day 9), and VEGFa (day 5) were significant differences between cases and controls.

Conclusions: Several urine biomarker concentrations differed in extremely low gestational age neonates with severe AKI *vs.* control. Further evaluation of these biomarkers is needed before clinical utility can be addressed.

Funding: Other NIH Support - Recombinant Erthropoietin for Protection of Infant Renal Disease (REPaIReD) Study is an NIH NIDDK funded (R01 DK103608) ancillary study designed to look at kidney outcome in patients enrolled in the Preterm Erthropoietin Neuroprotection Trial (PENUT Trial) which is an NIH NINDS funded (U01 NS077953, U01 NS77955) trial. The clinicaltrials.gov identifier is NCT01378273.

PO0191

Predictors and Outcomes of Post-Left Ventricular Assist Device AKI

Omar K. Salameh, Muhammad Abdulbasit, Mujahed M. Dauleh, Ronald P. Miller, Gurwant Kaur, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Left ventricular assist device (LVAD) is used to treat advanced heart failure as a bridge to orthotopic heart transplant (OHT) or as destination therapy in patients who are not OHT candidates. With limited donor availability and significant improvement in LVAD outcomes, the number of patients with LVAD implantation as destination therapy has increased. With increased LVAD use, the number of adverse events and complications are expected to increase. Acute kidney injury (AKI) is a frequent complication after LVAD implantation and is associated with high mortality. We studied the predictors of Post-LVAD AKI and the association between AKI and mortality, as well as between AKI and receiving an OHT.

Methods: We conducted a retrospective multi-center study using TriNetX Research Network database, a federated electronic medical records, to identify 486 patients from 24 healthcare organizations from the United States, with no underlying chronic kidney disease (CKD) who had an LVAD implanted between 1/1/2010 and 12/31/2019. Of these, 116 (23.9%) had developed AKI within the first month of the procedure. The baseline characteristics of this group were compared with the 370 patients who had not developed AKI during the first month after LVAD placement.

Results: There was no statistically significant difference between the two groups in regards to age at time of LVAD placement, sex, or ethnicity. Black race was associated with a higher odds of developing AKI (Odds Ratio [OR]: 1.70; 95% Confidence Interval [CI]: 1.11, 2.59). The two co-morbidities most significantly associated with AKI during the first month after LVAD placement were: persistent atrial fibrillation (OR: 3.33; CI: 1.35, 8.22), and a body mass index (BMI) > 50 (OR: 3.86; CI: 2.21, 6.75). During the first year after LVAD placement, 73 patients died and 37 patients received OHT. There was no statistical difference in one-year mortality or likelihood of undergoing an OHT within a year between the AKI and non-AKI groups.

Conclusions: In patients with no underlying CKD, black race, persistent atrial fibrillation, and BMI above 50 increase the likelihood of post-LVAD AKI. Development of AKI post-LVAD implantation in these patients is not associated with changes in one-year mortality or likelihood of receiving an OHT.

PO0192

AKI in COVID-19 Patients and History of Cancer: Role of D-Dimer as a Potential Risk Factor

Supriya Gerardine,[1] Edgar A. Jaimes,[2] Andriy Derkach,[2] Insara Jaffer Sathick,[2] Victoria Gutgarts,[2] Sheron Latcha,[2] Ilya Glezerman.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: New York City (NYC) was the epicenter of the coronavirus disease 19 (COVID-19) pandemic in the United States in the Spring of 2020. Complications of severe COVID-19 infection included ARDS, thrombotic events and acute kidney injury (AKI). Patients with co-morbidities such as diabetes mellitus, heart failure, chronic kidney disease and cancer had higher mortality rates. The rate of AKI in NYC was between 37%-46% in hospitalized patients. In this study we determined the role of coagulation activation as assessed by D-Dimer as a risk factor for AKI in COVID-19 patients with history of cancer.

Methods: We used the MSKCC electronic medical records to obtain patient data. We included all patients above 18 years of age who were hospitalized at MSKCC for COVID-19 infection and had a confirmed positive RT-PCR nasopharyngeal swab test for SARs-CoV2 between March 1, 2020 to May 1, 2020. Patents with ESRD on dialysis were excluded.

Results: We had a total of 361 patients with COVID-19 infection who were hospitalized and of these 25.7% (93/361) required admission to the intensive care unit (ICU). AKI developed in 9% (33/361) of patients and of these 69% (23/33) developed AKI after ICU admission. 26 patients who developed AKI had D-dimer levels checked and 88.4% of these patients had an elevated D-dimer vs 34.5% (67/194) positivity rate for patients with no AKI (p= 1.4e-7). D-dimer and AKI association shown in Figure 1.

Conclusions: The rate of AKI in our population was significantly lower than in general population despite having history of active or treated cancer as a comorbidity. The majority of patients developed AKI after admission to the ICU. An elevated D-dimer was noted in 88.4% of patient who developed AKI and were tested for it. This could make D-Dimer a risk marker for AKI in cancer patients with COVID-19.

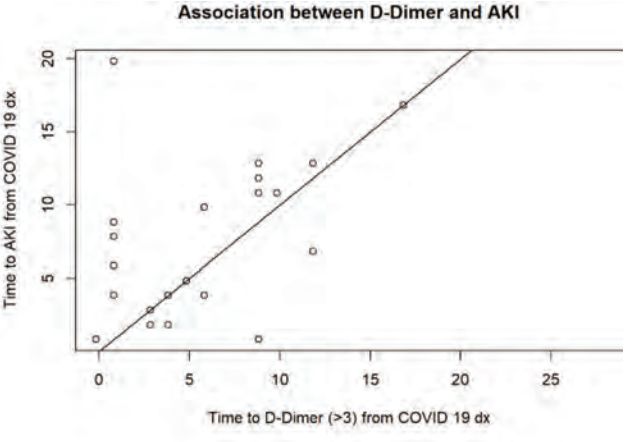

Fig 1.Association between time to elevated D-Dimer and time to AKI after COVID-19 diagnosis.

PO0193

Associations of RAS Inhibitor Suspension During AKI with Mortality in Hospitalized Patients

Ana carolina N. Tome,[1] Marcelo Lopes,[2] Daniela Santos Menezes Lopes,[3] Rodrigo J. Ramalho,[1] Emerson Q. Lima.[4] *[1]Hospital de Base, Sao Jose do Rio Preto, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Universidade Federal da Bahia, Salvador, Brazil; [4]Faculdade de Medicina de Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil.*

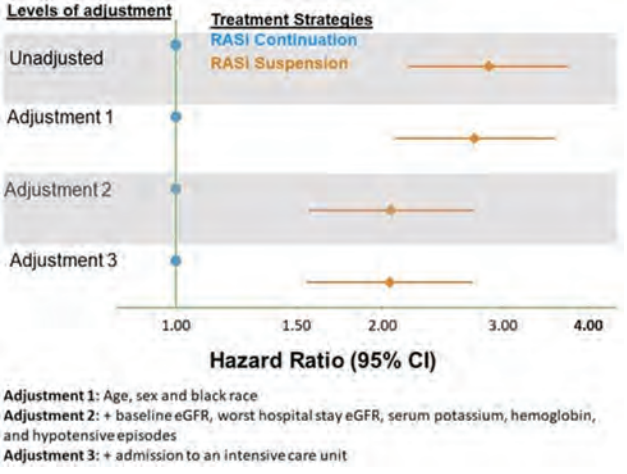
Background: Blockade of the renin-angiotensin system may slow disease progression and prevent mortality in patients with chronic kidney disease. However, it is unclear whether RASi can increase the risk of developing AKI and its complications in hospitalized patients. The aim of the study is to compare mortality of patients with AKI who have discontinued RASi to those who maintained its use.

Methods: We analyzed data from a cohort of hospitalized patients identified by an AKI alert based on KDIGO creatinine criteria, who were on a RASi. From January to December, 2018, suspension of RASi medications was defined by the lack of its prescription until 3 days after AKI alert in their electronic health records. Cox models were used to test the association of RASi suspension with all-cause mortality, adjusting for possible confounders: age, sex, race, baseline and worst achieved GFRs, potassium, hemoglobin levels and episodes of hypotension during the hospitalization.

Results: During hospitalization 1253 patients were on a RASi. After the AKI alert, 493 remained and 760 suspended its use. The median [IQR] follow-up time was 11.9 [7.20-20.8] days. Patient characteristics were similar across treatment strategies. In the suspended group more patients needed dialysis (13% vs 4%) and were admitted to intensive care units (66% vs 55%); mean potassium levels were consistent across groups

(4.45 mg/dL (0.72) vs 4.39 mg/dL (0.67) for the patients who remained on RASi). There was a strong association of RASi suspension with death as shown in the figure.

Conclusions: Among patients with AKI, the strategy of suspending RASi resulted in a twofold higher death rate than for those who remained on the medication, even after adjustment for possible confounders. These findings suggest that an individualized approach to RASi therapy may be warranted in the hospitalized patient with AKI.



Adjustment 1: Age, sex and black race
Adjustment 2: + baseline eGFR, worst hospital stay eGFR, serum potassium, hemoglobin, and hypotensive episodes
Adjustment 3: + admission to an intensive care unit

PO0194

External Validation of Simple Postoperative AKI Risk (SPARK) Classification in Noncardiac Surgery: The NARA-AKI Cohort Study

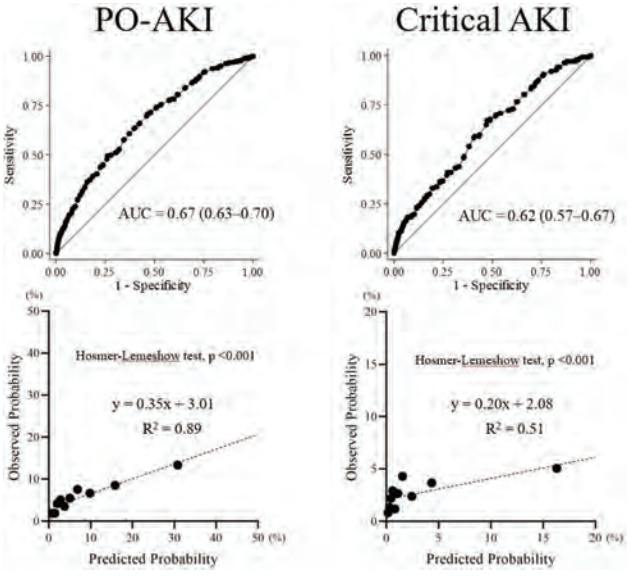
Masatoshi Nishimoto,[1] Miho Murashima,[2] Maiko Kokubu,[3] Masaru Matsui,[3] Masahiro Eriguchi,[1] Ken-ichi Samejima,[1] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1]
[1]Nara Kenritsu Ika Daigaku, Kashihara, Japan; [2]Nagoya Shiritsu Daigaku, Nagoya, Japan; [3]Nara-ken Sogo Iryo Center, Nara, Japan.

Background: The aim of the present study was to externally validate Simple Post-operative AKI Risk (SPARK) index which was developed to predict post-operative acute kidney injury (PO-AKI) in non-cardiac surgery.

Methods: In a retrospective cohort study, adults with non-cardiac surgery under general anesthesia were included. Those with obstetric or urological surgery, estimated glomerular filtration rate (eGFR) <15 mL/min/1.73 m^2, pre-operative dialysis, expected surgical duration <1 hour, and missing data for analyses were excluded. The exposures of interest were risk factors for AKI included in SPARK index, and outcomes were PO-AKI and critical AKI. The discrimination and calibration of SPARK index were examined with receiver operating characteristic curves and calibration plots, respectively.

Results: Among 5135 subjects, 303 and 137 developed PO-AKI and critical AKI, respectively. Subjects in our cohort were older, and baseline eGFR was lower compared to SPARK cohort. In addition, the proportion of subjects with comorbidities was higher. The incidence of PO-AKI and critical AKI increased as the scores of SPARK index increase. However, areas under the curves for PO-AKI and critical AKI were both suboptimal, and the calibration was poor (Figure). Higher age, diabetes mellitus, expected surgical duration, emergency surgery, renin-angiotensin-aldosterone system blockade use, and hyponatremia included in SPARK index were not associated with PO-AKI in our cohort, resulting in overestimation of predicted probability of AKI in our cohort.

Conclusions: SPARK index is useful in identifying subjects at high risk for developing AKI pre-operatively. However, predicted probability might not be accurate in cohorts including older subjects with more comorbidities.



PO0195

A Risk Score for Major Adverse Kidney Events One Year After AKI

Benjamin C. Bowe,[1,2] Hong Xian,[2] Steve E. Rigdon,[2] Yan Xie,[1,2] Ziyad Al-Aly.[1,3]
[1]Veterans Health Administration, St. Louis, MO; [2]Saint Louis University, Saint Louis, MO; [3]Washington University in St Louis, St Louis, MO.

Background: Epidemiologic evidence suggests that those with AKI are at increased risk of post-AKI kidney disease, higher hospital resource utilization, and deathI. However, literature to support identification of those most at risk of these outcomes is limited. Here we pilot predicting risk of post-AKI MAKE.

Methods: In a cohort of 4.2 million United States Veterans, risks of MAKE within a year of discharge associated with an AKI were detailed using survival regression with inverse probability of treatment weighting. Risk factors for MAKE including demographics, clinical characteristics including diagnoses, medication use, and laboratory tests, as well as hospitalization parameters among those with an AKI were examined, and then a risk score was developed and evaluated following the Framingham Heart risk score algorithm.

Results: In the year after dischrarge form a hospitalization, compared to those without an AKI, those with an AKI were at an increased risk of a subsequent AKI (HR=1.47; 95% CI=1.45-1.49), incident eGFR less than 60 ml/min/1.73 m^2 (1.23; 1.22-1.24), eGFR decline >30% (1.69; 1.67-1.71), receipt of kidney replacement therapy (2.41; 2.28-2.51), and MAKE (1.24; 1.23-1.25). Results were consistent in Fine and Gray competing risk models. Among those with an AKI, predictors of MAKE included age, albuminuria, bicarbonate, blood pressure before and during hospitalization, cardiovascular disease, cancer, chronic lung disease, dementia, diuretic use, baseline eGFR, hematocrit level, NSAID use, obesity, platelet count, pneumonia, serum creatinine trajectory during hospitalization, surgeries, and urinary tract infection. A risk score constructed using these predictors achieved an area under the curve (*AUC*) of 0.72, where corresponding probabilities of having a MAKE within a year of discharge ranged from 7.3% to 59.9% at the lowest and highest risk score values experienced in the cohort. Comparatively, use of KDIGO stage alone marginally predicted future risk of MAKE (0.52). Calibration plots suggested that models were well calibrated.

Conclusions: Use of EHR resulted in a moderate ability to identify those at increased risk of post-AKI MAKE. Further research is needed in identifying those who may benefit from post-AKI care.

Funding: Veterans Affairs Support, Private Foundation Support

PO0196

The Association of Metabolic Acidosis with AKI in Patients with CKD: A Retrospective Cohort Study in Two Cohorts

Antonia Zhu,[1] Reid Whitlock,[2] Thomas W. Ferguson,[1,2] Mohammad Nourmohammadi,[2] Paul Komenda,[1,2] Claudio Rigatto,[1,2] Clara Bohm,[1,2] Nancy L. Reaven,[3] Susan E. Funk,[3] Navdeep Tangri.[1,2] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Seven Oaks General Hospital, Winnipeg, MB, Canada; [3]Strategic Health Resources, La Canada, CA.*

Background: Metabolic acidosis in patients with chronic kidney disease (CKD) results from a loss of kidney function. It has been associated with more rapid CKD progression, all-cause mortality, and other adverse outcomes. Whether metabolic acidosis is associated with a higher risk of acute kidney injury (AKI) remains unknown.

Methods: We conducted a retrospective cohort study in 2 North American cohorts (US EMR cohort and Manitoba Claims cohort) using electronic health records and administrative data of patients with CKD Stages G3-G5. The primary exposure was metabolic acidosis (serum bicarbonate between 12 and <22 mEq/L), and the primary

outcome of interest was the development of AKI (defined using ICD-9 and 10 codes at hospital admission or a laboratory-based definition based on KDIGO guidelines). We applied Cox proportional hazards regression models adjusting for common demographic and clinical characteristics.

Results: In both cohorts, metabolic acidosis was associated with AKI: HR 1.565 (95% CI 1.518 – 1.613) in the US EMR cohort and HR 1.652 (95% CI 1.578 – 1.729) in the Manitoba Claims cohort. The association was consistent when serum bicarbonate was treated as a continuous variable, and in multiple subgroup and sensitivity analyses including those adjusting for albuminuria.

Conclusions: Metabolic acidosis is associated with a higher risk of AKI in patients with CKD. AKI should be considered as a safety outcome in studies of treatments for patients with metabolic acidosis.

Chikungunya Fever: A Trigger for Different Renal Disorders

Denise M. Costa,[1] Camila B. Oliveira,[1] Gisele Vajgel,[1] Maria Alina G. Cavalcante,[1] Joyce S. Lages,[2] Precil D. Neves,[3] Natalino Salgado Filho,[2] Lucila Maria Valente,[1] Gyl Barros-Silva.[2] *[1]Universidade Federal de Pernambuco, Recife, Brazil; [2]Universidade Federal do Maranhao, Sao Luis, Brazil; [3]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Prevalence of chikungunya fever (CHIK)-related kidney injury (KI) is variable, but data are scarce and limited to the acute phase of the disease. Necropsies performed in fatal acute cases of CHIK show that viral RNA can be found in renal tissue, but clinical and histopathological aspects poorly characterized. This study aimed to describe renal histopathological features and to detect viral antigens in renal tissue in patients affected by CHIK in different phases of infection.

Methods: This was an exploratory study, conducted between 2016 and 2020. Patients followed in six nephrology reference centers due to KI with onset after different phases of CHIK infection were evaluated. These patients had hematuria, proteinuria and/or renal dysfunction after a common history of CHIK infection and were referred for renal biopsy. Viral antigens were investigated by electron microscopy, immunohistochemistry and PCR in renal tissue.

Results: Sixteen patients (aged 10-59years) had KI 0.5 to 24months after CHIK, with predominance of glomerular lesions. Initial creatinine ranged from 0.2 to 22.3mg/dl (median 3.9mg/dl; IQR 1.0-5.5). Proteinuria and hematuria were initially detected in 94% and 81% of patients, respectively. Histopathological findings comprised diagnoses of focal segmental glomerulosclerosis (FSGS) (3), class IV lupus nephritis (3), crescentic glomerulonephritis (2), atypical hemolytic uremic syndrome (aHUS) (2), pauci-immune vasculitis (1), PLA2R-positive membranous nephropathy (2), collapsing glomerulosclerosis (CG) (2). One patient was diagnosed with collagen IV-related nephropathy in renal biopsy performed due to macroscopic hematuria after CHIKV infection. No viral antigens were detected in renal tissue. The 2 patients with aHUS included in the study carry heterozygosis mutations associated with increased risk of developing the disease. *APOL1* high-risk genotypes were identified in 2 patients with CG (G1/G2 and G2/G2) and 1 patient with FSGS (G1/G2). Nine (56%) patients progressed to chronic kidney disease after a median follow-up of 12 months.

Conclusions: Our findings reveal the potential of CHIK virus to directly cause and/or trigger KI. These effects can be translated into a variety of renal lesions potentially with significant severity.

PO0198

Risk Factors and Outcome Variables of Cardiorenal Syndrome Type 1 from the Nephrological Perspective

Daniel Patschan. *Medical School of Brandenburg, Brandenburg, Germany.*

Background: In cardiorenal syndrome (CRS) type 1, acute cardiac failure or acute decompensation of chronic heart failure causes acute kidney injury (AKI). Every individual AKI episode increases the risk for chronic kidney disease (CKD) in the long-term. In this study we aimed to evaluate epidemiological characteristics and outcome variables of CRS type 1 individuals from the nephrology perspective.

Methods: The study was performed in a restrospective, observational manner. All AKI patients treated at the Brandenburg Hospital of the Medical School of Brandenburg between january and december 2019 were screened for diagnostic criteria of CRS type 1. Endpoints were in-hospital death, need for dialysis, and renal recovery.

Results: During the screening, a total number of 1,189 subjects were diagnosed with acute kidney injury according to KDIGO. One-hundred ninety-eight (198 - 16.6%) out of these patients were assigned to the diagnosis CRS type 1. The overall in-hospital mortality was 19.2%. Non-survivors were not older than survivors. Nine point six (9.6) % of the patients required dialysis due to AKI, respective individuals were significantly older (84.6 +/-1.4 vs. 77.6 +/-0.7 years; p=0.002). Complete recovery of kidney function was observed in 86 individuals (43.4%), incomplete recovery occurred in 55 patients (27.8%), fifty-seven patients (28.8%) did not revover at all. Age-related differences were not identified. Sixty-four (32.2%) demission letters did not contain any cardiorenal diagnosis at all, nephrology follow-up recommendations were given in only 8%.

Conclusions: The incidence of CRS type 1 is high (~16% of all in-hospital AKI subjects) and the mortality is higher than the average mortality of AKI in general. At the same time complete recovery of kidney function occurs less frequent. The kidney-related follow-up management of CRS type 1 needs to be significantly optimized in order to improve the long-term outcome of affected patients.

PO0199

An Automated, Open-Source Program to Standardize AKI Definition from Time-Stamped Creatinine Data

Ishan Saran, Abinet M. Aklilu, Yu Yamamoto, Aditya Biswas, Francis P. Wilson. *Yale University School of Medicine, New Haven, CT.*

Background: Though KDIGO guidelines specify a definition for AKI based on changes in serum creatinine, operationalizing this definition with real-world data requires multiple assumptions that leads to variation across studies. A standardized AKI flagging tool may increase inter-study validity.

Methods: We develoepd AKIFlagger, an open-source computational tool built in Python, R, and as a web application which implements a standardized AKI definition based on KDIGO guidelines while allowing for variational definitions of baseline creatinine. We applied the AKIFlagger to a dataset of patients hospitalized with COVID-19 while permuting various operational implementations of the guidelines.

Results: We demonstrate that subtle changes in definition can have a large impact on estimates of AKI prevalence and outcomes. Compared to a rolling window approach, using a baseline definition that leverages outpatient creatinine values and or imputes those values based on an eGFR back-calculation increases the size of captured patient populations by 20.7% and 57.1%, respectively. We characterize the predictive value of the different methods of identifying AKI by determining the sensitivity and specificity for stage progression and progression to death or dialysis. The approaches span sensitivities from 0.18 to 0.20 and specificities from 0.90 to 0.95 for stage progression, and sensitivities from 0.71 to 0.85 and specificities from 0.62 to 0.76 for progression to death.

Conclusions: Subtle differences in the definition of AKI can lead to drastic differences in which patient populations are captured by the definition. A standard mechansim to implement the KDIGO criteria is necessary for the field to accurately advance both clinical and basic science research. This standardized tool can be used by researchers to ensure definitions are uniform across studies.

Community-Acquired AKI: A Prospective Case-Control Study

Telma H. Ragnarsdóttir,[1,2] Margret Kristjansdottir,[1] Gisli Gislason,[2] Vicente Sanchez-Brunete,[4] Margret O. Tomasdottir,[2,3] Olafur H. Samuelsson,[5] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Internal Medicine Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [3]Heilsugaesla, Reykjavik, Iceland; [4]Department of Emergency Medicine, Landspitali–the National University Hospital of Iceland, Reykjavik, Iceland; [5]Department of Geriatric Medicine, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) represents an abrupt decline in kidney function occurring over hours or days. While hospital-acquired AKI has been extensively studied, data on community-acquired AKI are scarce. The aim of this study was to examine the incidence and causes of AKI among patients presenting to the emergency department (ED).

Methods: This was a prospective case-control study in which serum creatinine (SCr) of all individuals admitted to the ED of Landspitali–The National University Hospital were examined for the presence of AKI. We present data from January 1 until March 3, 2020 and May 19 until September 21, 2020. The study was paused between these periods due to the COVID-19 epidemic. All patients who met the KDIGO criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex and time of ED admission. Participants answered questions about their medical history and use of medications, including over-the-counter (OTC) drugs. Medical records were reviewed with regard to medical history. Logistic regression was used to identify factors associating with AKI.

Results: A total of 372 persons with AKI were identified, 315 (85%) of whom participated in the study. The mean (±SD) age of AKI cases and controls was 66.6±16.1 years and 66.3±16.2 years, respectively; 46% of cases and controls were female. AKI cases were significantly more likely than controls to have used non-steroidal anti-inflammatory drugs (NSAIDs) (31.1% vs 22.2%, p=0,003) in the week preceding the ED visit, particularly OTC NSAIDs (24.7% vs 16.2%, p=0.001). In the logistic regression analysis, AKI was associated with vomiting (OR 2.40 95%CI 1.74-3.35), diarrhea

(OR 1.35, 95%CI 1.00-1.84), diabetes (OR 1.66, 95%CI 1,17-2,35) and NSAID use (OR 1.60, 95%CI 1.18-2.23), but a statistically significant relationship was not observed for use of ACE inhibitors/angiotensin receptor blockers or diuretics, or a history of hypertension, vascular disease or chronic kidney disease.

Conclusions: These results suggest that volume depletion and the use of NSAIDs play a major role in the development of AKI in the community setting. Frequent use of OTC NSAIDs is a concern and should be addressed in light of serious adverse effects.

Serum Proteomics Identifies Protein Alterations After Platinum-Based Chemotherapy

Shensen Li, Qingqing Liu, Haiyan Shen, Wenwen Li, Changchun Cao. *Sir Run Run Hospital Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is a common complication after platinum-based chemotherapy. However, the mechanisms mediating this process remain to be fully understood. Our object was to invest serum proteins variations among patients after receiving platinum-based chemotherapy to provide more evidence of the pathophysiology of chemotherapy induced AKI.

Methods: In this study, serum samples from 10 patients underwent chemotherapy were used and samples before therapy were used as control. Serum proteins were extracted and submitted for LC-MS/MS. Peptides were analyzed for spectral count quantitation. The classification and enrichment analysis of these factors were based on Gene Ontology and Kyoto Encyclopedia of Genes and Genomes.

Results: An overview of GO enrichment showed that organization biogenesis, response to stimulus and immune system process were significantly changed after chemotherapy. Protein binding and transporter activity were the main differences of molecular function in the GO assignments. KEGG analysis revealed that several pathways were highly enriched including infectious disease, immune system, transport and catabolism. After narrowing down the targets and compared with the control status, top 5 significantly up-regulated proteins were HBD, HBB, HBG2, HBA1, TNC and top 5 down-regulated proteins ADAMTS13, FLT4, HRNR, MINPP1 and KRT9. These proteins were mostly involved in immune regulation, cellular component and organization biogenesis.

Conclusions: The serum proteomic is distinct after platinum-based chemotherapy. Inflammation and extracellular related proteins were involved in renal disease.

Funding: Government Support - Non-U.S.

PO0202

Markers of Kidney Tubule Cell Function and Future Risk of Infection-Associated AKI

Alexander Bullen,[1,2] Orlando M. Gutierrez,[3] Dena E. Rifkin,[1,2] Joachim H. Ix.[1,2] *[1]VA San Diego Healthcare System, San Diego, CA; [2]University of California San Diego, La Jolla, CA; [3]The University of Alabama at Birmingham School of Medicine Huntsville, Huntsville, AL.*

Background: Novel biomarkers can quantify kidney tubular functions including proximal tubule reabsorption (alpha 1 microglobulin [a1m]), and tubule protein synthesis (uromodulin [umod]). We have previously reported that abnormalities in these markers at times of health predicted future risk of AKI secondary to volume depletion. Association between tubular function markers and other causes of AKI are uncertain.

Methods: We identified 474 individuals within the REGARDS study who had in-patient admissions for infections and developed AKI (≥ KDIGO stage 1) during 3.8 years follow-up. Cases were matched (1:1) by age, sex, race, and time from baseline to hospital admission to individuals admitted with infection but without AKI. We used stored urine specimens from REGARDS baseline to measure a1m (ELISA) and umod (immunoassay), as well as NGAL (immunoassay) as a marker of tubule injury. Conditional logistic regression evaluated odds of AKI.

Results: Mean age was 70 ± 8 years, 44% were female, 38% were black. Mean baseline eGFR among cases and controls was 71 and 78 mL/min/1.73m^2, respectively and mean albuminuria was 241 vs. 69 mg/g, respectively. Cases were more likely to be taking ACEi, ARB, and NSAIDs. Most had state 1 AKI (92.7%). Higher urine a1m and higher urine umod levels were each associated with higher AKI risk but these associations were attenuated in final models. Results were similar with NGAL (Table). Results were also similar when examining KDIGO stage 2 or greater AKI vs. controls.

Conclusions: At times of health, urine a1m and UMOD are not independently associated with future risk of infection-associated AKI.

Funding: Veterans Affairs Support

Association of tubule cell function markers and future risk of infection-associated AKI

Biomarker (per 2-fold higher)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
a1m	1.49 (1.38, 1.61)	0.97 (0.86, 1.09)
Umod	1.22 (1.04, 1.42)	1.24 (1.00, 1.54)
NGAL	1.60 (1.43, 1.78)	1.01 (0.89, 1.17)

Adjusted for age, urine creatinine, diabetes, SBP, DBP, ACE, ARB, or NSAID use, and baseline eGFR and urine albumin.

PO0203

Circulating Endotoxin Levels Correlate with Kidney and Mortality Outcomes in Critically Ill Patients

Chang Kyung Kim, Sobia N. Khan, Fabliha Fairuz, Sandeep K. Mallipattu, Sian Piret. *Stony Brook University, Stony Brook, NY.*

Background: Among the critically ill, sepsis is a common cause of acute kidney injury (AKI). Endotoxin is a component of gram negative bacterial cell walls, and is a potent trigger of AKI in sepsis, but may also be present in non-bacteremic patients. Our aim was to determine correlations between endotoxin levels and AKI and mortality outcomes in incident critically ill patients.

Methods: Patients were recruited from those admitted to intensive care units (ICUs) who were over 18, and who did not have end-stage renal failure requiring dialysis, or were on chronic immunosuppressive medications. Blood endotoxin activity (EA) was measured using the FDA-approved chemiluminescent EA Assay. Blood EA was measured on days 1, 4 and 8 of admission to ICU, and results either categorized as low (0.0-0.39), intermediate (0.4-0.59) or high (≥0.60), or used as a continuous variable in Spearman correlation analysis. Kidney parameters and dispositions were obtained from electronic medical records. AKI was defined as per KDIGO guidelines.

Results: A total of 35 patients were recruited between November 2020 and April 2021, with 4 testing positive for gram negative bacteria. Initial EA levels were 6 (17%), 10 (29%) and 19 (54%) patients with low, intermediate, and high levels, respectively. During the study, 14 patients' EA levels changed such that their categorization either went up (4) or down (9), whilst one patient alternated between intermediate and high levels. When stratified by presence of AKI, no patients with low EA (0/6) developed AKI, whilst 9/13 (71%) of patients with AKI had high EA versus 8/20 (40%) of non-AKI patients who had high EA. All of the patients with low EA were discharged, whereas 3/10 (30%) and 4/18 (22%), respectively, of those with intermediate and high EA expired. When analyzed as a continuous variable, there was a significant positive correlation between initial EA and initial sCr ($r = 0.56$, $p<0.001$). Furthermore, there was a significant correlation between the rates of changes in EA and sCr over time ($r = 0.47$, $p<0.05$).

Conclusions: Endotoxin levels on admission to ICU correlated with kidney function, presence of AKI, and mortality. Changes in EA over time also correlated with changes in kidney function, suggesting that EA may be a potential biomarker in critically ill patients.

PO0204

Incidence of Hypophosphatemia During Continuous Renal Replacement Therapy: Baseline Data for a Quality Improvement Initiative

Juarez R. Braga,[1] Luis A. Juncos,[1,2] Nithin Karakala.[1,2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR.*

Background: Hypophosphatemia is common among critically ill patients on continuous replacement therapy (CRRT). And low serum phosphorus is associated with difficulty to wean off from mechanical ventilation, longer hospital stays, and death. Our objective was to determine the incidence of hypophosphatemia among individuals receiving CRRT before implementing a phosphate replacement protocol as part of a quality improvement initiative.

Methods: We conducted a retrospective study of electronic health records from the University of Arkansas for Medical Sciences to identify consecutive adults diagnosed with acute kidney injury who received CRRT for at least 24 hours between May 2014 and September 2018. Laboratorial measurements of serum phosphorus collected while on CRRT were examined and hypophosphatemia was defined as levels <2.5 mg/dL.

Results: A total of 685 unique participants received CRRT between 2014 and 2018. On average, 13.2 individuals were started on CRRT every month. Of 685 individuals, 446 were on CRRT for at least 24 hours for a total of 3,328 treatment days. The median number of days on CRTT was 4.3 (2.1-9.2). Those 446 individuals had 2,709 measurements of serum phosphorus. In total, 192 (43%) individuals were diagnosed with hypophosphatemia which occurred with a median time of 63.0 hours after initiation of CRRT. Hypophosphatemia developed in 25% of individuals within the first 2 days after starting dialysis.

Conclusions: Hypophosphatemia occurred frequently, and the incidence peaked at day 3. Although there is no ideal protocol about how to replace phosphate, our findings suggest that replacement should begin early after initiation of CRRT.

PO0205

AKI in Kuwait: Incidence, Causes, Management, and Outcomes – A Prospective Observational Study

Ali AlSahow,[1] Anas M. Al Yousef,[2] Bassam A. Alhelal,[3] Heba Al Rajab,[8] Ahmed Alqallaf,[5] Yousif Bahbahani,[6] Monther M. Alsharekh,[4] Basem Said,[1] Mohamed A. Osman,[8] Ahmed M. Mazroue,[2] Ali S. Abdelzaher,[4] Alaa T. Abdelmoteleb,[5] Gamal Nessim,[6] Emad Abdallah,[3] Rajeev K. Malhotra.[7] *[1]Al Jahra Hospital, Al Jahra, Kuwait; [2]Amiri Hospital, Kuwait City, Kuwait; [3]Al Adan Hospital, Kuwait, Kuwait; [4]Chest Diseases Hospital, Kuwait, Kuwait; [5]Jaber Al Ahmed Al Jaber Al Sabah Hospital, Surra, Kuwait; [6]Mubarak Al-Kabeer Hospital, Safat, Kuwait; [7]All India Institute of Medical Sciences, New Delhi, India; [8]Farwaniya Hospital, Farwaniya, Kuwait.*

Background: Little is known about AKI epidemiology, causes, management and outcome in Kuwait. We report that.

Methods: Demographics, comorbidities, treatment and 4 weeks outcome data for nephrology referrals for AKI in 7 public hospitals from 1/Jan-30/Apr/2021 prospectively collected and analyzed

Results: Total number of AKI referrals was 1298, that is 3.3% of hospital admissions. Community acquired cases were 12.5%. Males were 57%, mean age 64 (52% > 65), and Kuwaiti citizens 65%. DM affected 71%, HTN 74%, and cardiac disease 36% of patients. Mean baseline eGFR before AKI was 62. Baseline eGFR < 60 seen in 52%, and those compared to patients with eGFR > 60, had mean baseline eGFR of 35 (vs 90), were older (68 vs 60 with 61% above age 65 vs 41%), 81% had DM (vs 60%), 85% had HTN (vs 63%), 46% had cardiac disease (vs 24%). Cause of AKI was pre-renal / ischemic ATN in 87%, COVID-19 related in 8%, contrast-associated in 6%, drug-induced AIN in 5% of cases. Many had more than one possible cause. Sepsis was most common precipitating factor seen in 67% then volume depletion in 50%. Many had more than one factor. IV fluids used in 73% (less in lower eGFR group), IV diuretics in 46% (more in lower eGFR group), IV vasopressors in 40% (less in lower eGFR group) and steroids in 33%. KRT needed in 33%, more in patients who used diuretics or vasopressors. Volume overload and electrolytes / acid-base disorders were most common indication (75% and 79% respectively). CKRT was modality of choice in 85%, however, in 52% of CKRT, conventional HD not used due to lack of dialysate source in some sites. At 30 days, mean eGFR was 42%, with complete recovery in 34%, and 38% failed to recover at all. Death occurred in 31%, 55% had baseline eGFR > 60, and 50% of deaths occurred while still on KRT. Non-survivors were older and had higher use of vasopressors. AKI associated mortality in 25% of total hospital mortality and in 31% of ICU / CCU mortality.

Conclusions: AKI is common. Most cases hospital-acquired. Use of resources (medications, critical care, KRT) and rates of mortality are high. Kuwaiti citizens represent 1/3 of the population and 2/3 of AKI cases and almost 70% of deaths.

PO0206

AKI in the Month of Ramadan

Ali AlSahow,[1] Omar M. Alkandari,[5] Anas M. Al Yousef,[2] Bassam A. Alhelal,[3] Heba Al Rajab,[4] Basem Said,[1] Ahmed M. Mazroue,[2] Mohamed A. Osman,[4] Zeyad A. Elhusseini.[3] *[1]Al Jahra Hospital, Al Jahra, Kuwait; [2]Amiri Hospital, Kuwait City, Kuwait; [3]Al Adan Hospital, Kuwait, Kuwait; [4]Farwaniya Hospital, Farwaniya, Kuwait; [5]Mubarak Al-Kabeer Hospital, Safat, Kuwait.*

Background: Fasting in Ramadan from dawn to sunset is one of Islam's 5 pillars. Islamic lunar calendar is 11 days shorter than Gregorian solar calendar, so the start of Ramadan changes every year and hours spent on fasting vary from 12 hours in Australia, to 21 hours in Sweden, with most countries have 11-16 hours of fasting on average. Patients with certain medical illness are exempted from fasting, however, many such patients partake in fasting. The long hours of fasting may be a risk factor for AKI in certain populations. We assess AKI in Ramadan.

Methods: Demographics, comorbidities, treatment, and 4 weeks outcome data for all nephrology consultation for AKI in 4 public hospitals in Kuwait during Ramadan of 2021 (13/April-12/May/2021) prospectively collected and analyzed. We compare AKI in people fasting prior to admission to non-fasting.

Results: Total number of AKI cases in Ramadan was 158, 55% males, mean age 64, and 61% were Kuwaiti citizens. Community acquire cases were 15%. DM affected 75%, HTN 72%, and cardiac disease 25% of patients. Median baseline eGFR before AKI was 66.5. Baseline eGFR < 60 seen in 43%, and those compared to patients with eGFR > 60, had median baseline eGFR of 37.5 (vs 92), were older (69 vs 62), 87% had DM (vs 66%) and 87% had HTN (vs 61%). Cause of AKI was pre-renal / ischemic ATN in 69%, COVID-19 related in 17%. Many had more than one possible cause. IV fluids used in 76%, IV diuretics in 39%, IV vasopressors in 31%, and steroids in 21.5%. KRT needed in 27%. Volume overload and electrolytes / acid-base disorders were most common indication (21% and 19% respectively and 15% had more than one indication. Death within 30 days occurred in 11.4%. Of the total, 24% were fasting before admission, with mean age of 56 (compared to 63 for non-fasting). No significant difference in baseline eGFR between fasting and non-fasting, nor in use of IV fluids, IV diuretics, or IV vasopressors. Dialysis needed in 21% of the fasting group, not significantly different from non-fasting group. Mortality rates were lower but not statistically significant in the fasting group (8% vs 12.5%).

Conclusions: AKI affect both fasting and non-fasting population similarly, with no increased risk of need for dialysis or mortality.

PO0207

Seventy-Two Cases of Metformin-Associated Lactic Acidosis (MALA): Clinical Presentation and Evolution Analysis

Jose M. Pena Porta, José F. Gascó, Almudena Castellano, Paula Juárez Mayor, Ana Coscojuela Otto, Pablo J. Inigo Gil, Rafael Alvarez lipe. *Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain.*

Background: MALA is a complication that continues to occur today. It is important to collect large series of cases to better understand the clinical presentation and evolution of this condition.

Methods: We collected the MALA cases (diagnostic criteria: pH ≤ 7.5; lactate ≥ 5 mmol / L) in a 700-bed tertiary hospital during the period January 2010-December 2020. We analyzed the clinical factors and laboratory tests associated with the presentation of the condition, as well as mortality.

Results: 72 cases were registered (38 men; 52.8%). Average age 76.03 ± 10.37 years. Metformin serum levels were available in 46 patients (mean: 26.41 ± 17.87 mcg / ml; toxic if > 5 mcg / ml). Mean length of stay 11.61 ± 9.7 days. Average Charlson comorbidity index 5.7 ± 1.8 points. Ingested milligrams / day of metformin: 1788.89 ± 395.8. 29 patients had a history of chronic kidney disease (CKD) (40.3% of the total). Cases in the context of acute kidney injury (AKI): 70 (97.2% of the total; 7 KDIGO stage 1 cases, 6 stage 2, 57 stage 3). 90.2% were AKI of prerenal origin. 26 patients required admission to the ICU (36.1%). 10 cases received hemodiafiltration, 26 cases hemodialysis. Mean analytical parameters: pH 7.10 ± 0.19; Lactate 10.12 ± 5.3 mmol / l; bicarbonate 10.94 ± 5.3 mmol / l; GAP anion 27.23 ± 7.6 mmol / l; pCO2 31.9 ± 12.22 mmHg; potassium 6.25 ± 1.42 meq / l; hemoglobin 11.51 ± 2.3 g / dl. Overdose occurred in 17 cases (23.6%). The statistical analysis detected the existence of a linear association between: metformin and peak creatinine levels (Spearman's r 0.48, p = 0.001); metformin levels and pH (Spearman's r -0.37, p = 0.000); metformin and lactate levels (Pearson's r 0.42, p = 0.004); potassium and pH levels (Spearman's Rho 0.35, p = 0.003); Charlson index and number of active drugs (Pearson's r 0.38, p = 0.001). 17 patients died (mortality 23.6%). A multivariate logistic regression model detected pH (OR 0.003; 95% CI 0.00-0.380) and peak creatinine (OR 0.706; 95% CI 0.49-1.008) as the variables independently associated with mortality.

Conclusions: Virtually all cases occurred in the context of severe AKI, the majority of prerenal origin. Mortality was 23.6%. It is necessary to warn patients taking metformin of the clinical situations potentially inducing AKI (especially dehydration).

PO0208

An Analysis of Risk Factors for AKI in Patients with Decompensated Cirrhosis: A 4-Year Retrospective Study, 2012-2015

Youjun Xu, Lianxin Luo, Fangfang Zhou, Lina Han, Yixin Chen, Yi Lu, Qun Luo. *Department of nephrology, HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.*

Background: Acute kidney injury (AKI) is a common complication in advanced liver diseases. So prevention of AKI occurence in patients with cirrhosis might improve their outcomes. We aimed to determine the risk factors for AKI in patients with decompensated cirrhosis.

Methods: We conducted a retrospective analysis, which was a 4-year study involving 945 patients. AKI was diagnosed based on 2012 Kidney Disease Improving Global Outcomes (KDIGO) criteria. The clinical and demographic data of AKI group was compared with other patients by univariate and multivariate regression analyses.

Results: The incidence of AKI in decompensated cirrhosis was 17.7%. Compared with patients without AKI, patients with AKI had higher white blood cell (WBC) count, longer prothrombin time (PT), higher total bilirubin (TBil), higher serum creatinine (SCr) and higher blood urea nitrogen (BUN), but having lower alanine aminotransferase (ALT), lower albumin, lower cholinesterase (ChE), lower estimated glomerular filtration rate (eGFR), lower total cholesterol (TC), lower triglyceride (TG) and lower serum sodium concentration. But no significant differences in platelet (PLT) count and International Normalized Ratio (INR). In the multivariate logistic regression analysis, hypertension (odds ratio [OR]:3.647, 95% confidence interval [CI]:1.546-8.606, *P*=0.003), upper gastrointestinal bleeding (OR:4.957, 95%CI:2.177-11.286, *P*<0.001), SCr(OR:1.019, 95%CI:1.003-1.035, *P*=0.019), WBC(OR:1.147, 95%CI:1.032-1.275, *P*=0.011), PT(OR:1.097, 95%CI:1.004-1.198, *P*=0.04) and eGFR (OR:0.958, 95% CI:0.934-0.983, *P*=0.001) were independent risk factors for occurrence of AKI in patients with decompensated cirrhosis.

Conclusions: We observed that hypertension, upper gastrointestinal bleeding, SCr, value of WBC count, length of PT and eGFR were independently associated with the development of AKI in patients with decompensated cirrhosis. It is, therefore, necessary to apply early intervention in patients with the risks of AKI.

PO0209

Admission Platelet Count Is an Independent Predictor of AKI

Benjamin R. Griffin,[1] Kelly Miell,[2] Eli Perencevich,[1,2] Heather Reisinger,[1,2] Mary V. Sarrazin,[1,2] Marin R. Schweitzer,[2,1] Diana I. Jalal.[1,2] *[1]The University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA.*

Background: Thrombocytopenia is a recognized marker of disease severity that is associated with higher mortality in patients with sepsis-associated acute kidney injury (SA-AKI). It is plausible that thrombocytopenia is also a predictor of SA-AKI development due to the characterisitic microvascular dysfunction seen in this disease state, but human studies are lacking. In this analysis, we evaluated admission platelet counts and SA-AKI rates in a large VA database of patients with methacillin-resistant staph aureus (MRSA) bacteremia.

Methods: We evaluated patients admitted to 124 VA Hospitals who developed MRSA bloodstream infections during a hospitalization from 2007-2014. Patients were excluded if platelet counts or creatinine values were not available on 2 or more days. Predictor variables were platelet counts <150 and <100 at admission. Primary outcome was the development of in-hospital AKI, defined as a platelet increase of 0.3 mg/dL over 48 hours, or an increase of 1.5x baseline within 7 days. Cox proportional hazard modeling was used to determine the association between predictors and primary outcome, and covariates were chosen using forward stepwise regression. Potential covariates evaluated for inclusion were age, race, admission laboratory values, comorbidities, antibiotic agents, infection location, healthcare utilization prior to admission, and surgical intervention, among others.

Results: A total of 6,765 patients were included, of which 2,656 (39.3%) developed AKI during admission. At admission, 1,633 (24.1%) and 757 (11.2%) had platelet counts <150 and <100, respectively. AKI rates in these pateints were 44.1% and 46.2%, respecitvely. Hazard ratios for AKI were 1.17 (CI 1.07-1.28) in patients with platelets <150, and 1.24 (CI 1.10-1.39) in patients <100.

Conclusions: Platelet counts of <150 and <100 at admission were found to be independent predictors of subsequent SA-AKI development in a large database of patients with MRSA bacteremia. These findings may inform future studies in the prevention and prediction of AKI development.

PO0210

AKI!Now: Defining Excellence in the Prevention of and Care for Patients with AKI

Jorge Cerda,[1] Samir M. Parikh,[2] Jay L. Koyner,[3] Anitha Vijayan,[4] Stuart Goldstein,[5] Kathleen D. Liu,[6] Marlies Ostermann,[7] Anupam Agarwal,[8] Mark D. Okusa.[9] AKI!Now Initiative of the American Society of Nephrology
[1]Albany Medical College, Albany, NY; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]University of Chicago Pritzker School of Medicine, Chicago, IL; [4]Washington University in St Louis, St Louis, MO; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [6]University of California San Francisco, San Francisco, CA; [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [8]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [9]University of Virginia Medical Center, Charlottesville, VA.

Background: ASN is committed to define excellence in AKI prevention and care to transform management, reduce morbidity, mortality and improve long-term outcomes. AKI!Now addresses a set of well-defined objectives to achieve those goals.

Methods: The AKI!Now initiative has developed a broad education program that bridges the continuum from basic investigation to clinical studies focused on early recognition, intervention, and effective therapies with a patient-centered focus

Results: *Workgroups and tasks*: **Basic Science: AKI-Specific Early Interventions**: Leverage basic science discoveries to innovate in AKI prevention, diagnosis, and treatment; develop a centralized research portal; promote AKI research and translational initiatives; create a roadmap to facilitate discovery and novel interventions; and enhance communication within the community. **AKI Recognition and Clinical Interventions**: **Artificial Intelligence (AI):** Design fair and equitable AI tools among physicians and researchers; and provide expert input on pathways to implement AI tools in all clinical contexts. **Post-AKI Recovery**: Identify mechanisms of repair to identify treatment strategies to accelerate recovery; prevent adverse outcomes and identify areas of priority research; promote comparative effectiveness research benchmarks; develop, test, and promote strategies to build capacity for post-AKI care. **Public Awareness and Education:** Leverage existing and develop novel education processes for health professionals and patients and multiple resources including the AKI!Now Compendium, focusing on AKI recognition, management, and recovery; collaboratively emphasize the role of continuous quality improvement in AKI recognition and care, and include patients and families in the healing process.

Conclusions: AKI is common, serious, under-recognized across the life span, and associated with severe risk of progressive adverse outcomes. Education at all levels; use of AI to improve pattern recognition, prevention, and management; development of novel specific therapies through better understanding of AKI mechanisms; and appropriate post-AKI recovery care will alleviate the severe short- and long-term individual and societal AKI impacts.

PO0211

Diagnosing and Staging AKI in the Absence of a Baseline Serum Creatinine Value

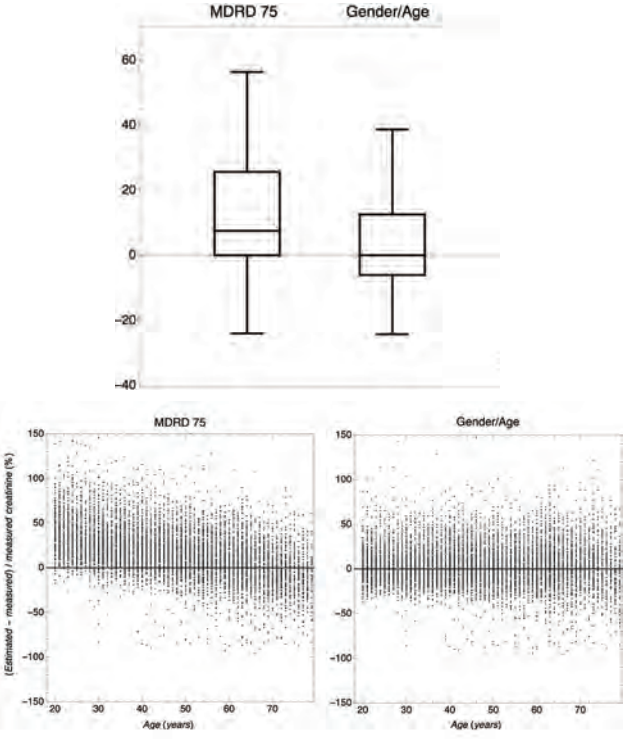
Florian Buchkremer, Stephan Segerer. *Kantonsspital Aarau, Division of Nephrology, Aarau, Switzerland.*

Background: AKI is commonly diagnosed and classified from changes to serum creatinine according to the 2012 KDIGO criteria. When baseline creatinine is missing, the guideline recommends to back calculate it from an assumed MDRD-GFR of 75ml/min/1.73m2. We describe an alternative method.

Methods: From NHANES 2015-2018 data we calculated distribution of serum creatinine values for the adult US population as a whole, and for gender, age and weight subgroups. We then assessed mean values in an external validation cohort (NHANES 2011-14) for performance to predict baseline creatinine in comparison to back calculated MDRD values.

Results: Relative differences between back calculated MDRD and measured creatinine values in the validation cohort show a median bias of +8% and an interquartile precision range of 0% to +26% (Fig 1). Accuracy is rather low, with P15 and P30 values at 42% and 71%. In contrast, our gender/age-based estimation eliminates bias to 0 % and improves precision, interquartile range of -6% to +13% (Fig 1). P15 increases to 58%, P30 to 86%. The relative differences show a clear age dependency for MDRD, that is not present in our gender/age-based estimation (Fig 2). Adding weight categories did not significantly improve our predictions.

Conclusions: We describe a simple method to estimate missing baseline creatinine values for assessing acute kidney injury. Compared with the current standard approach our method shows no bias, more precision and improved accuracy in predicting baseline creatinine on a population level.



PO0212

Premenopausal Age in Females Is Associated with Protection from Development of Postoperative AKI

Jamie Privratsky,[1] Matt Fuller,[1] Karthik Raghunathan,[1,4] Tetsu Ohnuma,[1] Raquel Bartz,[1] Rebecca A. Schroeder,[1,4] Thomas M. Price,[1] Martin I. Sigurdsson,[2,5] Michael R. Mathis,[6] Bhiken I. Naik,[3] Vijay Krishnamoorthy.[1]
[1]Duke University School of Medicine, Durham, NC; [2]Landspitali, Reykjavik, Iceland; [3]University of Virginia, Charlottesville, VA; [4]Durham VA Medical Center, Durham, NC; [5]Haskoli Islands, Reykjavik, Iceland; [6]University of Michigan, Ann Arbor, MI.

Background: Acute kidney injury (AKI) is one of the most common forms of perioperative organ injury. Preclinical and clinical studies examining the influence of sex on AKI have yielded conflicting results. The objective of our study was to determine the association of sex hormones on postoperative AKI. We hypothesized that pre-menopausal-aged females would display lower incidence of postoperative AKI than males of similar age; and the protection would be lost in post-menopausal-aged females.

Methods: This was a retrospective observational study of the Multi-center Perioperative Outcomes Group database. We reviewed surgical patients at 46 institutions between 2013-2019. Our primary exposure was an interaction between age younger or older than 50 years and sex. Our primary outcome was development of AKI by KDIGO criteria. A mixed effects multivariable logistic regression was used to determine the association of sex hormone status with postoperative AKI. Secondary analyses consisted of ascending age groupings over 40 years.

Results: After excluding patients with CKD5 and cardiac, transplant, urologic and obstetric procedures, among 390,382 patients undergoing index surgeries, 25809 (6.6%) developed postoperative AKI. In the adjusted model, the lowest risk of AKI was in women under 50 (OR 1.0), with higher risk in men under 50 (OR 1.90 [1.79, 2.01]; p<.0001), women over 50 (OR 1.51 [1.43, 1.59]; p<.0001), and men over 50 (OR 2.06 [1.96, 2.17]; p<.0001). In the secondary analysis, risk of AKI gradually increased in women as they aged, whereas men had very little change in risk based on age (Fig. 1).

Conclusions: Younger females display a lower risk of postoperative AKI that gradually increases with age. These results suggest that female sex hormones might protect against AKI. To explore this possibility, we are examining the risk of postoperative AKI in patients receiving sex hormone replacement or antagonism at time of surgery.

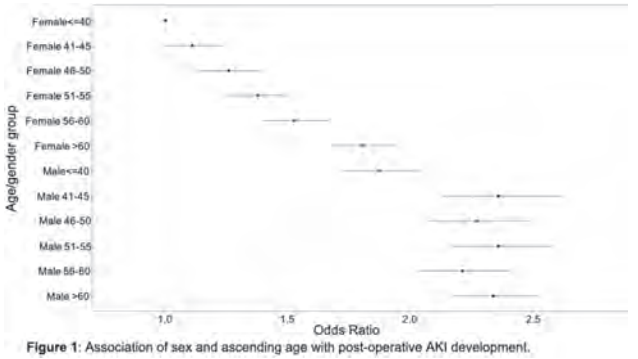


Figure 1: Association of sex and ascending age with post-operative AKI development.

PO0213

Phenotyping Inpatient AKI by Serum Creatinine Trajectory

Benjamin C. Bowe,[1,2] Yan Xie,[1,2] Hong Xian,[2] Steve E. Rigdon,[2] Ziyad Al-Aly.[1,3] *[1]Veterans Health Administration, St. Louis, MO; [2]Saint Louis University, Saint Louis, MO; [3]Washington University in St Louis, St Louis, MO.*

Background: Clinical guidelines for risk stratification of acute kidney injury (AKI) do not fully consider characteristics of changes in serum creatinine that may be informative for future risk of adverse outcomes. Identification of patient groups that display distinct patterns in trajectory of SC during an AKI may enhance risk stratification.

Methods: Latent trajectory model identified trajectory patterns of SC in a cohort of United States Veterans hospitalized with AKI. Trajectories and outcome profiles were used to establish AKI phenotypes. Risk factors for phenotypes were examined, and phenotype discrimination in short-term outcomes was assessed vis-à-vis KDIGO stages.

Results: In a cohort of 360,560 US Veterans with a hospitalization with an AKI, we identifyied 6 phenotypes representing distinct patterns in trajectory of SC during hospitalization. Compared to a trajectory with mild changes in SC (59.4% of cohort), moderate (23.1%), and more severe changes (8.7%) with moderate recovery were associated with decreasing odds of non-recovery in SC by discharge (OR=0.52 and 0.25 respectively), higher odds of receipt of kidney replacement therapy (KRT) (3.8 and 13.8) and death within 30-days of hospitalization (1.8 and 2.5). Those whose SC continued to rise during hospitalization (3.86%) had the lowest odds of recovery (OR=0.02) and highest odds of mortality (8.0). Phenotype with highly increased SC with incomplete recovery (2.81%), or very dynamic change in the first few days of hospitalization (2.15%), were associated with higher odds of KRT (57.3 and 89.4, respectively) and lower odds of recovery (0.08 and 0.11). A prior history of chronic kidney disease, albuminuria, and prior AKI, as well as major in-hospital events including sepsis, admission to ICU, and mechanical ventilation, were associated with trajectories with worse outcomes. Discrimination in future outcomes during course of hospitalization suggested that as the hospitalization progressed, phenotypes increasingly provided more information on risk of future outcomes (*C*-statistic: 0.72, recovery; 0.87, KRT; 0.62, death) than KDIGO stages (0.62, recovery; 0.75, KRT; 0.59, death).

Conclusions: Our results suggest that leveraging EHR data to profile changes during the occurrence of AKI in kidney function may enhance risk stratification of AKI patients during the course of the hospitalization.

PO0214

Provider Acceptance of Electronic AKI Alerts in a Cardiac Surgery ICU

Ankit Sakhuja,[1] Nada Mohamed,[1] Donnie B. Goodiwn,[1] Rebecca L. Neely,[1] Chris Cook,[1] Charles J. Mullett,[1] Gordon S. Smith,[1] John A. Kellum.[2] *[1]West Virginia University, Morgantown, WV; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Electronic acute kidney injury (AKI) alerts can improve the rates of detection of AKI, though their effect on improving patient outcomes has been variable. Their focused utilization in cardiac surgery patients, a population at a high risk for both AKI and its complications, is likely to lead to more consistent improvement in outcomes. We implemented AKI alerts in the cardiac surgery ICU of a tertiary care, high volume cardiac surgery center starting July 2020. As electronic alerts can be disruptive to the workflow and lead to alert fatigue, we surveyed health care providers in our cardiac surgery intensive care unit (ICU) regarding their acceptance of these electronic AKI alerts.

Methods: Our AKI alerts used a previously validated logic to trigger an alert when serum creatinine increase by 0.3mg/dL or more within last 52 hours. They were implemented as passive alerts in the EPIC electronic medical record. Alerts were situated in the EPIC storyboard and provided information in the format "Possible AKI Stage X", with the option to get more information by hovering over the alert. The alerts were set to disappear if no further increase in creatinine by at least 0.3mg/dL was noted in next 52 hours. We emailed a validated survey regarding alert usefulness to providers 6 months into the alerts implementation to assess their acceptance.

Results: Out of 19 ICU providers (7 intensivists and 12 advanced practice providers) all but one responded to the survey. 7/18 (38.8%) providers reported that they recognized AKI earlier due to the alert. 16/18 (88.9%) shared that they re-dosed or discontinued medications earlier due to the AKI alert. Majority of participants also reported earlier management of volume status (72.2%), avoidance of iv contrast use (72.2%) and point of care ultrasound use (77.8%) in response to the alert. 15/18 (83.3%) reported satisfaction with the way AKI alerts are displayed and overall satisfaction with the AKI alerts. 16/18 (88.9%) providers reported satisfaction with the duration the alert is displayed for.

Conclusions: Among providers taking care of patients at high risk for AKI, the electronic AKI alert well received. A follow up survey is planned to assess the changes in longitudinal perception of the AKI alert.

PO0215

Kratom, an Herbal-Induced Cholestatic Liver Failure, Leads to Cholemic Nephropathy Requiring Liver Transplant and Hemodialysis

Thuy Le, Adrian J. Baudy. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Kratom, an herbal supplement, has opioid-like and stimulant effects. Its recreational misuse has increased in the United States (US). Its alkaloid compounds consist primarily of mitragynine and 7-hydroxymitragynine and are metabolized in the liver. Reports have shown many side effects, notably confusion, seizures, coma, and hyperbilirubinemia. Hepatic injury presents as cholestatic liver injury, which has a consequence on renal function. Patients with hyperbilirubinemia, bile casts damage the nephron directly and is known as bile cast nephropathy, a rare or underdiagnosed pathology. We present a case of Kratom usage that play a role in causing cholestatic liver failure, leading to cholemic nephropathy and liver transplant and hemodialysis.

Case Description: A 26-year-old woman with history of Kratom usage presented with complaint of 5-days of abdominal distention and pain, jaundice, and heavy mucosal bleeding. Laboratory testing revealed Na^+ 123 mmol/L, BUN 84 mg/dL, Cr. 6.9 mg/dL, AST 104, ALT 31, total bilirubin 32 mg/dL and ALP 124 units/L, WBC 27.8, platelets 109, and H/H 7.2/20.7, INR 2.23. There was no serology evidence of viral infection. Tylenol and alcohol level were unremarkable. Urinalysis positive for bile acid cast. Abdominal ultrasound and Computed Tomography findings are consistent with liver cirrhosis. She underwent liver transplantation and required hemodialysis due to acute renal failure from profound hyperbilirubinemia.

Discussion: Bile cast nephropathy represents a wide spectrum of disease, ranging from mild reversible to irreversible needing dialysis. It occurs when total bilirubin levels >20mg/dL**,** exceeding the binding capacity of albumin to bilirubin. It causes tubular obstruction and injury, oxidative damages, and ATPase activity. Most of the damage occurs in distal tubules but can occur in the proximal tubules. While kratom has stimulant and opioid-like effects, its use can be hazard to health. There are currently no treatment guidelines for bile cast nephropathy. In irreversible nephropathy in cirrhotic patient, patient may be evaluated for both liver and kidney transplant. Renal replacement therapy has no role in treating bile cast nephropathy directly. Clinicians should keep cholemic nephropathy as a differential diagnosis in patient with hyperbilirubinemia and be aware of the increasing consumption of kratom in the US.

PO0216

Dietary Hyperuricemia Causes Nephropathy in a Cancer Patient

Aliasger A. Ali,[1] Harini Bejjanki,[2] Jaya Kala.[1,2] UT Houston/MD Anderson *[1]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Hyperuricemia is associated with several diseases including kidney disease. Everyday drinks (sodas/juices) have very high fructose content, contributing to hyperuricemia through various mechanisms. Here we present a case of a cancer patient with Acute Kidney Injury (AKI) secondary to hyperuricemia in the setting of a sudden high intake in fructose rich drinks.

Case Description: A 49-year-old Asian man with history of myelofibrosis, coronary artery disease and chronic kidney disease stage 2, was admitted for AKI. He was recently admitted for septic shock due to scrotal abscess and discharged to a nursing home for wound care. He endorsed recent high intake of sodas and juices, due to dislike of food at the nursing home. His creatinine at previous admission was 1.1–1.4 mg/dl (similar to his baseline). His urinalysis (UA) routinely did not show uric acid crystals, and uric acid levels were within reference range. One week prior to admission, his creatinine was 1.97 mg/dl and UA showed occasional uric acid crystals. At current admission, creatinine was 3.02 mg/dl with uric acid level of 23.3 mg/dl, and UA showed uric acid crystals. He received 3 doses of 3 mg Rasburicase (9 mg total) the first day, after which uric acid level improved to 6.4 mg/dl, and creatinine dropped to 2.14 mg/dl. Three days later his creatine improved to 1.76 mg/dl, and repeat UA did not show uric acid crystals. A week after discharge, his creatinine was at baseline and uric acid level was normal. By the time visual examination of urine could be done, uric acid level had normalized.

Discussion: It is known that fructose is the only carbohydrate that increases uric acid levels. Fructose-induced hyperuricemia results from an increased degradation of purine ribonucleotides and causes increased purine synthesis. Hyperuricemia is common in patients with hematological malignancies with or without chemotherapy. Our patient had a hematological malignancy and endorsed drinking large amounts of soda and juice. Given many patients drink fructose rich drinks daily, it is imperative that the dangers of this dietary habit are highlighted, both to physicians and patients. Cancer patients can benefit from nutrition education and dietary modifications prior to and during chemotherapy to avoid hyperuricemia and renal failure. Dietary counselling can help avoid need for hospitalization as well as use of expensive uric acid lowering agents.

PO0217

Turmeric-Associated Oxalate Nephropathy

Shuchi Pandey,[1] Deetu Simh,[1] Hemant Magoo,[1] Ashish Verma,[1] Helmut G. Rennke.[2] *[1]Saint Vincent Hospital, Worcester, MA; [2]Brigham and Women's Hospital Division of Renal Pathology, Boston, MA.*

Introduction: Turmeric contains Curcumin which has anti-inflammatory properties that may be beneficial in patients with osteoarthritis, hyperlipidemia, pruritus, and Rheumatoid Arthritis. Thus it's a popular herbal supplement. Here we present a rare case of severe acute kidney injury (AKI) due to calcium oxalate nephropathy in a patient with heavy turmeric consumption.

Case Description: An asymptomatic 69 year male with no significant past medical/surgical history was evaluated for a spike in Creatinine from 1.2 to 3.1mg/dl over a few months. There was no history of drug/NSAID use, contrast exposure, or other nephrotoxins. He did mention taking Turmeric 2g daily for the past 2 years. There was no personal or family history of nephrolithiasis. Urine sediment was bland. Serum C3, C4, ANA, ANCA, anti-GBM, anti-dsDNA, hepatitis B&C screen, SPEP&UPEP were negative. Kidney Biopsy revealed widespread calcium oxalate deposition in tubules(Renal Oxalosis-Hyperoxaluria) with diffuse acute tubular injury. Turmeric was discontinued, but the patient soon started on dialysis. 24h urine oxalate was elevated; serum oxalate was also high at 14micromol/L. Genetic testing(AGXT mutation) for primary hyperoxaluria(PH) is pending, but lack of recurrent nephrolithiasis or nephrocalcinosis or systemic oxalate deposition and only marginally high S.oxalate make PH less likely.

Discussion: Although many herbal remedies have shown promising results, these supplements often evade the rigorous standards that conventional therapies are subject to. Turmeric has long been used for anti-inflammatory & analgesic benefits and recently was publicized as an immunity booster and studied for prophylactic and therapeutic use in COVID. Compelling evidence for its efficacy comes from osteoarthritis trials, but recommendations for safe daily allowances aren't elucidated. Contrarily, turmeric has demonstrated increased urine oxalate excretion, a known cause of oxalate stones and, presumably, oxalate deposition in tubules. Hyperoxaluria mainly occurs secondarily in malabsorption syndromes. Loss of oxalate-degrading gut flora from antibiotics contributes and PH, a disorder of oxalate overproduction, is a rare cause. Several factors can interplay, but the contribution of oxalate-rich food like spinach, starfruit, and in this case, turmeric is indisputable. We recommend a high suspicion index and a thorough medication review in patients with severe AKI.

PO0218

Chronic Tubulointerstitial Nephropathy and Nephrotic Range Proteinuria in a Patient with an Underlying Eating Disorder

Khawaja A. Bashir, Boonyanuth N. Maturostrakul, Antonio Corona, Vanesa Bijol, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Eating disorders in particular atypical anorexia nervosa; binge eating/purging type, have been reported as an established cause of CKD with chronic tubulointerstitial nephritis as a prominent histopathological feature seen on kidney biopsy.

Case Description: A 40-year-old woman with hypertension, generalized anxiety and an eating disorder was referred to our clinic for new onset nephrotic range proteinuria and elevated serum creatinine (SCr). Patient endorsed remote NSAID use without any recent use. Physical exam notable for uncontrolled hypertension and bilateral lower extremity edema. SCr was elevated at 2.33 mg/dl, higher than 1.6 mg/dl two months prior to evaluation. Urinalysis showed proteinuria and trace hematuria but was otherwise unremarkable. Spot urine TP/CR was elevated at 9.4 gm/gm. Serologic work up including PLA2R antibody levels, ANA, ANCAs, Hep B surface antigen were negative. Serum immunofixation did not reveal any monoclonal bands. Renal sonogram showed bilateral echogenic kidneys with no renal artery stenosis or hydronephrosis. Of note, patient presented with severe hypokalemia (2.2 mmol/L) and hypomagnesemia (0.8 mg/dl), which were found to be chronic. Electrolyte derangements were attributed to purging disorder in the past, however she adamantly denied active purging or diuretic/laxative abuse. She also denied taking any herbal medications. A kidney biopsy showed widespread fibrosis and advanced global and segmental glomerulosclerosis (more than 50% of gloemruli) with diffuse chronic tubulointerstitial nephropathy (TIN). The tubules also revealed microcystic dilatation with several simple cysts. CKD and TIN were most likely secondary to underlying eating disorder. Lithium exposure can have a similar pattern on histology, however there was no history of lithium use as confirmed by prior providers. Given the chronicity, she was initiated on dialysis. A Renasight genetic test revealed no genetic abnormalities explaining the above findings

Discussion: Diffuse TIN with glomerulosclerosis and widespread fibrosis can be associated with anorexia nervosa. Clinicians should be aware of the potential implications of kidney disease in patients with eating disorders. Early recognition and referral to Nephrologists can help improve outcomes by preventing irreversible kidney damage.

PO0219

BK Polyomavirus Nephritis in a Low-Risk Native Kidney: A Case Report

Maryam Saleem, Charbel C. Khoury. *Washington University in St Louis, St Louis, MO.*

Introduction: BK viremia has increased prevalence in solid organ transplant, particularly renal transplant recipients. BK nephropathy in native kidney is rare, but has been reported after hematopoietic stem cell transplant (HSCT).

Case Description: 74-year-old male with Grade 2 Follicular lymphoma (in complete remission for 2 years after obinutuzumab, bendamustine, & venetoclax), complicated by hypogammaglobinemia receiving IVIG (IgG 751mg/dL) & chronic lymphopenia (absolute lymphocyte 152 cells/uL) who was evaluated for acute kidney disease. Patient's baseline creatinine was around 0.8 mg/dL & progressively rose to 4mg/dL over a period of 6 months despite IV hydration for intermittent mild diarrhea. Urinalysis had no proteinuria or hematuria. Serologic workup for systemic lupus erythematosus and other autoimmune disease, monoclonal gammopathy, sarcoid was unrevealing. Kidney biopsy revealed polyomavirus nephritis with acute tubular injury & severe interstitial fibrosis with tubular atrophy. Serum BK PCR showed 1.3 million copies. The patient continued on IVIG increasing the frequency to every 3 weeks and started on a course of fluoroquinolones but with ultimate progression to chronic kidney disease.

Discussion: BK virus infections in immunocompetent individuals typically occur early in childhood (asymptomatic or mild respiratory illness). Following primary infection, BK virus remains in a latent state in the urothelium & renal tubular epithelial cells. Most cases of BK Polyomavirus nephritis occur in renal transplant recipients. Risk factors for BK Polyomavirus nephritis in native kidneys include non-renal solid organ transplant as well as HSCT, chronic lymphocytic leukemia, AIDS, and congenital dysgammaglobulinemia. Clinical presentation is nonspecific and includes varying degrees of renal failure without fever, leukocytosis, hematuria or proteinuria. Incidence of renal failure is dependent on the degree of glomerular inflammation caused by proinflammatory cytokines, influx of immune effector cells, BK virus lytic replication, and lysis of renal tubular epithelial cells that can lead to renal fibrosis. Treatment agents include leflunomide, cidofovir, fluoroquinoles and IVIG but the success has been limited. This case highlights that BK nephropathy may develop in the native kidney other than HSCT. Chronic lymphopenia & hypogammaglobinemia likely predisposed our patient despite his ongoing infusion of IVIG.

PO0220

Interaction of Blood Urea Nitrogen and Tryptophan in Predicting Mortality in a Trauma-Induced Model

Pragya Singh,[1] Daniel Montemayor,[1] Annapurna Pamreddy,[1] Viktor Drel,[1,2] Jiwan J. Kim,[1] Jingli Gao,[1] Hongping Ye,[1] Jae Hyek Choi,[3] Kevin K. Chung,[3] Andriy Batchinsky,[3] Kumar Sharma.[1,2] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX; [3]United States Army Institute of Surgical Research, San Antonio, TX.*

Background: Multiple Organ Failure (MOF), often precipitated by Acute Respiratory Distress Syndrome (ARDS) brought on by trauma-induced injury, is a significant cause of death in military and civilian life. Furthermore, in ARDS, Acute Kidney Injury (AKI) is the most frequent organ failure affecting almost 50% of the patients, increasing the mortality rate. Therefore, understanding the molecular difference between survivors and non-survivors can significantly reduce the mortality burden.

Methods: A porcine MOF model (n =17) was developed using pulmonary contusion injury at Dr. Batchinsky's laboratory. In this model, n=10 are survivors, and n=7 are non-survivors with mortality at 3, 6, and 9 hours. Serum was employed for Amino acid metabolites using the Zip-Chip platform for mass spectrometry. A Cox proportional hazard analysis was employed to quantify the association of survival with the metabolite concentration. Serum blood urea nitrogen (BUN) was measured using the assay kit, and baseline BUN was correlated with baseline tryptophan level using a linear model.

Results: In survival analysis, survivors and non-survivors were partitioned by the mean metabolite concentration. The group with increased tryptophan concentration had a better chance of survival than the group with a reduction of tryptophan from the baseline. Furthermore, when associating the tryptophan level with the BUN, there is an opposite trend between the two groups. In the survivors, higher tryptophan is positively associated with increased BUN, whereas in the non-survivors, there is a negative correlation indicating that lower tryptophan coupled to high BUN increases the risk of mortality. Additionally, linear regression model showed a significant association of tryptophan and BUN with survivors and non-survivors.

Conclusions: Survival analysis indicated that a decrease in serum tryptophan level is a strong risk factor for mortality. Since tryptophan metabolism is associated with renal failure in AKI settings, we investigated serum tryptophan association with BUN. Non-survivors have a strong negative association of tryptophan with BUN, suggesting that combination of BUN and tryptophan could improve mortality risk prediction in early time-point in trauma-induced model.

PO0221

Performance of Validated Indices for Risk of Death for Patients with AKI Requiring Dialysis: A Systematic Review and Meta-Analysis

Bjoerg Thorsteinsdottir,[1] Atieh Pajouhi,[1] Madugodaralalage Dona K. Gunaratne,[1] Molly A. Feely,[1] LaTonya J. Hickson,[1] Allyson Hart.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hennepin Healthcare, Minneapolis, MN.*

Background: Acute kidney injury (AKI) requiring renal replacement therapy (RRT) is associated with high morbidity and mortality. Multiple mortality indices have been developed, however, the most optimal index for predicting survival in AKI requiring RRT is unknown. **Objective:** To assess performance of validated mortality indices for patients with AKI requiring RRT.

Methods: Design, setting, participants and measurements: Systematic review and meta-analysis following the PRISMA guidelines. Multiple databases (MEDLINE, Embase, Central Register of Controlled Trials, Cochrane, and Scopus) were searched from inception to Jan 31 2019. **Selection Criteria:** Studies evaluating the performance of validated mortality indices in adult AKI patients requiring RRT were included. Studies not separating AKI patients requiring RRT or used validated indices only as covariates were excluded. Articles were screened and data extracted in duplicate. Risk of bias was assessed using the PROBAST tool. Pre-planned random effects meta-analysis was performed stratified by index, population, renal specific vs. general mortality index, and predictive window.

Results: Of 10,115 articles screened, 37 (2 development, 21 validation and 14 combined) were included totaling 35 different indices tested in 11,142 patients. Average age was 60.8 years with 34.6% women. Predictive windows ranged from ICU to 60-day survival. The most used indices were APACHE II, Liano, SOFA, and SAPS II. Meta-analysis by index showed overall discrimination area under the curve (AUC) of 0.69 (95% CI 0.67-0.71) with high heterogeneity (I^2 =82.37) with highest AUC for APACHE III 0.73(0.66-0.8) Liano 0.73(0.68-0.78) and MODS 0.71(0.62-0.80).

Conclusions: There is insufficient discrimination and heterogeneity in the performance of prognostic indices for AKI requiring RRT. Additional studies are needed to optimize mortality prediction in this population.

PO0222

Detection and Diagnosis of AKI in the Emergency Department

Margret Kristjansdottir,[1] Telma H. Ragnarsdóttir,[1,2] Gisli Gislason,[2] Vicente Sanchez-Brunete,[3] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Internal Medicine Services, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland; [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [3]Department of Emergency Medicine, Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) represents an abrupt decline in kidney function occurring over hours or days and is associated with inferior clinical outcomes. In recent years, new definitions of AKI based on changes in serum creatinine (SCr) have gained acceptance, but awareness by primary care and emergency physicians may still be limited. The aim of this study was to use diagnosis codes to examine the detection of AKI among patients who presented to the emergency department (ED).

Methods: This was a prospective case-control study in which SCr of all individuals admitted to the ED of Landspitali–The National University Hospital in Reykjavik were examined by the research team for the presence of AKI. We present data from January 1 until March 3, 2020, from May 19 until September 21, 2020 and from February 1 until May 1, 2021. The study was paused between these periods due to COVID-19 outbreaks. All patients who met the KDIGO criteria for AKI were invited to participate. Clinical information and ICD-10 diagnoses were obtained from participants and from electronic medical records. ICD-10 codes N17 (acute kidney failure) and N19 (unspecified kidney failure) were used as indicative of a confirmed AKI diagnosis.

Results: A total of 527 cases of AKI were identified, 445 (84%) of whom participated in the study. The mean (±SD) age of AKI cases was 67.2±16.8; 47% were female. Of the AKI cases, 104 (23.4%) had a documented diagnosis of AKI in the ED. No difference was found between women and men (20.9% and 23.9%, respectively; p=0.85) and no difference was observed between different age groups (18-49 years 23.9%, 50-69 years 21.7% and >70 years 21.7%). Of 39 (8.7%) participants with pre-existing diagnosis of chronic kidney disease (CKD), 38.5% had a documented AKI diagnosis compared with 21.9% of those without history of CKD (p=0.003). Participants with stage 3 AKI had a documented diagnosis in 48.0% of cases, 25.2% of those with stage 2 AKI and 15.1% of cases with stage 1 AKI.

Conclusions: AKI appears to be seriously underdiagnosed in the ED. While multiple factors may affect the use of diagnosis codes, lack of awareness of recent AKI guidelines among emergency physicians may play an important role. Measures must be taken to improve the diagnosis and documentation of AKI in the ED.

Funding: Government Support - Non-U.S.

PO0223

Risk Factors for AKI in the Intensive Care Unit

Ian J. Da Silva Lugo, Carla I. Colon Nunez, Eric Miranda, Ileana E. Ocasio Melendez. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Background: Acute Kidney Injury (AKI) is defined by a sudden decrease in glomerular filtration rate. It currently represents a global public health issue as it is associated with short and long-term morbidity and mortality. In the Intensive Care Unit (ICU) there is an overall incidence of AKI ranging from 20-50% and a mortality rate from 15-60%. Its development leads to increased length of stay and costs. The main objective of this proposed study is to identify risk factors associated with the development of acute kidney injury in a community hospital and a tertiary hospital in Puerto Rico. Also, to investigate if there is a relationship between AKI, length of stay and mortality.

Methods: This retrospective case control study included patients 18 years of age or older admitted to the ICU between January 2015 to December 2016. Patients with chronic kidney disease (CKD) stage 4 or 5, maintenance renal replacement therapy (RRT), or AKI before ICU admission were excluded. The population was divided between patients with AKI and patients without AKI. AKI was diagnosed according to KDIGO criteria. Demographic (age, gender) and clinical data (comorbid conditions, APACHE II score, sepsis or septic shock, vasopressors status, mechanical ventilation, creatinine levels, urine output, nephrotoxic drugs, RRT use, and mortality) was collected from medical records.

Results: Among 121 patients included (median age 54.40, 50% male), 44.6% were diagnosed with AKI and 3.31% underwent RRT. All 7 patients with diagnosed Chronic Obstructive Pulmonary Disease (COPD) had AKI during ICU stay (p-value 0.0024). Diuretics, aminoglycosides, and amphotericin B had a statistically significant relationship with AKI (p-value 0.012, 0.002, and 0.050 respectively). Mechanical ventilation, vasopressor use, sepsis or septic shock and mortality also had a statistically significant relationship with AKI (p-value 0.013, 0.002, 0.018 and <0.0001 respectively).

Conclusions: In our study AKI had a statistically significant association with COPD, diuretics, aminoglycosides, amphotericin B, mechanical ventilation, vasopressors, sepsis or septic shock and mortality. Nephrotoxic agents described as statistically significant are modifiable risk factors to be considered in their administration. This study aids in the characterization of an epidemiologic pattern on ICU patients for future applicability.

PO0224

Evaluation of Chosen Biochemical Parameters in Diagnosis of AKI in Course of Burn Disease

Wojciech Klimm,[1] Katarzyna Szamotulska,[2] Agnieszka Wozniak-Kosek,[1] Stanislaw Niemczyk.[1] *[1]Wojskowy Instytut Mediczny, Warszawa, Poland; [2]Instytut Matki i Dziecka, Warszawa, Poland.*

Background: Burn disease after severe thermal injury often causes multi-organ damage, included AKI. Diagnosis of AKI based on standard renal biomarkers seems to be not optimum, because of its too late beginning. The aim of the study is evaluation of non-renal biochemical parameters as early prognostic factors of AKI in this group of patiens (pts).

Methods: 33 adult pts; 11(33,3%) females, 33(66,7%) males; were hospitalised after severe burn injury. Mean age was 48,3(±18,8) years. None of the pts presented symptoms of chronic kidney disease. Biochemical parameters - platelets count (PLT); serum concentration of albumin (ALB), sodium (Na), potassium (K), urea (U), creatinine (Cr); glomerular filtration ratio (GFR), serum activity of asparagine transaminase (AST) and creatine phosphokinase (CK); blood gas tests and urine sodium excretion - were measured at each patient once daily till 7th day. The results were presented as a mean value with standard deviation or median with interquartile range. AKI criteria were based on RIFLE/AKIN scale. Relationship between parameters and AKI risk were analysed with chi-square test and presented as relative risk (RR) with 95% confidence level, p-value significant level was <0,5.

Results: Biochemical symptoms of AKI were confirmed in 15 (60,6%) pts. AKI developed at the beginning of hospitalisation, on the1st day – 10 (30,3%) pts and 2rd day – 4 (12,1%) pts. Non-normative levels of biomarkers were reported in the same time: low PLT count - average 91,6(±42,7) x10^9/l in 5 (15%) pts; low ALB concentration – avg. 2,4(±0,7) g/dl in 32 (97%) pts; high K concentration – avg. 6,1(±0,7) mmol/l in 14 (42,4%) pts; high activity of AST – avg. 73(40,5÷141,5) U/l in 21(63,6%) pts and CK – avg. 429,0(242,0÷4720,0) U/l in 21 (63,6%) pts and metabolic acidosis with low pH - avg. 7,22(±0,08) in 19 (57,6)%, pts. The significant relationship between parameters and the risk of AKI was confirmed: high activity of CK (RR 2,86; p=0,047) and AST (RR 2,73; p=0,034), and low concentration of ALB (RR 2,63; p=0,012).

Conclusions: AKI is a frequent and important problem in burned patients, occurred in the first days after injury as a part of multi-organ dysfunction. Non-renal biochemical parameters as serum concentration of ALB, activity of CK and AST can be useful early biomarkers of AKI after massive burn injury.

PO0225

Intravenous Administration of Vitamin B Complex Improves Renal Recovery in Patients with AKI

Rolando Claure-Del Granado,[1,2] Ariana Torrico Salinas.[1,2] *[1]Hospital Obrero No 2 - CNS, Cochabamba, Bolivia, Plurinational State of; [2]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of.*

Background: Preclinical studies have identified NAD^+ augmentation as a potential strategy for the prevention and treatment of AKI. NAD^+ is the final metabolized form of vitamin B3 (niacin). Since there is no availability of niacin in the country; we tested if I.V. vitamin B complex (vitamin B1, B6 and B12) could improve renal recovery in patients with AKI. By oxidation, vitamin B6 (pyridoxine) through the pathway of pentose phosphate lead to the formation of NADPH an analog of NAD^+.

Methods: We conducted randomized, blind, placebo-controlled study in hospitalized patients with AKI (NCT04893733). During the study I.V. vitamin B complex or placebo was given twice a day for 5 consecutive days. For AKI management in each patient, a protocol-based approach was used (STOP AKI protocol from the ISN 0by25 trial https://doi.org/10.1371/journal.pmed.1003408). We evaluated if vitamin B complex could improve renal recovery and if it could reduce *de novo* CKD incidence or CKD progression.

Results: From September 2020 to May 2021, 191 patients were enrolled in this ongoing RCT with 160 patients completing the follow-up by day 7 and 91 patients completing the follow-up by 3 months. Peak sCr was higher in patients randomized to vitamin B complex (2.8 ±1.2 vs. 2.2 ±1.3 mg/dl; p = 0.006). A higher pecentage of patients randomized to vitamin B complex arm had severe AKI (stage ≥ 2) 74% vs. 43% randomized to placebo; p = 0.011. The drop in sCr values by day 7 was higher in the vitamin B complex group (1.01 vs. 0.65 mg/dl; p < 0.001). No differences were found in the percentage of patients with complete recovery (54.3% vs. 45.6%; p=0,268), partial recovery (25.9% vs. 25.3%; p = 0.930) and non-recovery (19.8% vs. 29.1%; p = 0,168). At 3 months, the incidence of *de novo* CKD and CKD progression was not different in both arms (23.9% vs. 20%; p = 0.652 and 28.2% vs. 26.6%; p = 0.865 respectively). No difference was found in mortality rate at day 90 (vitamin B complex 31.1% vs. placebo 28.2%; p = 0.544).

Conclusions: The administration of vitamin B complex could potentially accelerate renal recovery in patients with AKI by day 7, reducing the percentage of patients who will not recover renal function after an AKI episode. No differences were found in terms of CKD progression or de novo CKD. The preliminary data of our ongoing study warrants future studies to validate these findings.

PO0226

GDF-15 Predicts In-Hospital Mortality of Critically Ill Patients with AKI Requiring Continuous Renal Replacement Therapy: Results from a Prospective Randomized Controlled Trial

Jeong-Hoon Lim,[1] Hee Won Noh,[1] Soojee Jeon,[1] Sejoong Kim,[2] Hee-Yeon Jung,[1] Ji-Young Choi,[1] Sun-Hee Park,[1] Chan-Duck Kim,[1] Yong-Lim Kim,[1] Jang-Hee Cho.[1] *[1]Kyungpook National University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: Growth differentiation factor-15 (GDF-15) is a stress-responsive cytokine that is positively associated with inflammation. This study evaluated the association between GDF-15 and in-hospital mortality among patients with severe acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: Among the multicenter prospective CRRT cohort between 2017 and 2019, 66 patients whose blood sample was available were analyzed. Patients were divided into three groups according to the GDF-15 concentrations. In-hospital mortality was compared using Cox proportional hazards regression model.

Results: The mean age was 67.7 ± 14.3 years and 47 (71.2%) were male. The median GDF-15 level was 7865.5 pg/mL (496.9 pg/mL in the healthy control patients). Baseline characteristics were not different among tertile groups except the severity scores (Acute Physiology and Chronic Health Evaluation II [APACHE II] and Sequential Organ Failure Assessment [SOFA]) and serum lactate level, which were higher in the third tertile. After adjusting for confounding factors, the patients with higher GDF-15 had significantly increased risk of mortality (second tertile: adjusted hazards ratio [aHR], 3.67; 95% confidence interval [CI], 1.05–12.76; *P*=0.041; third tertile: aHR, 6.81; 95% CI, 1.98–23.44; *P*=0.002). Furthermore, GDF-15 predicted in-hospital mortality (area under the curve, 0.710; 95% CI, 0.585–0.815) better than APACHE II and SOFA scores (Figure 1).

Conclusions: Serum GDF-15 concentration was elevated in AKI patients requiring CRRT, higher in more severe patients. GDF-15 is a better independent predictor for in-hospital mortality of critically ill AKI patients than the traditional risk scoring system such as APACHE II and SOFA scores.

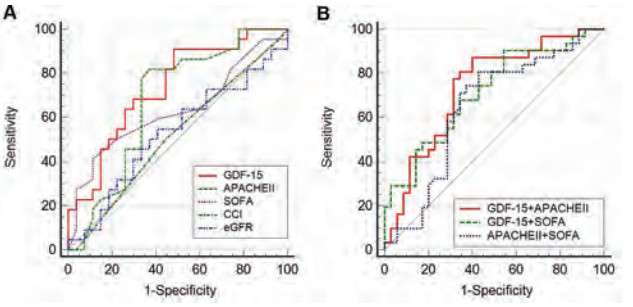

Figure 1. Receiver operating characteristic curves of prognostic predictors for in-hospital mortality.

PO0227

The Effect in Renal Function and Vascular Decongestion in Type 1 Cardiorenal Syndrome Treated with Two Strategies of Diuretics: A Randomized Trial

Jonathan Chavez,[1,2] Natashia L. Gongora,[1,2] Manuel Arizaga Napoles,[1,2] Guillermo Garcia-Garcia,[1,2] Ramon Medina,[2] Guillermo Navarro Blackaller,[2] Juan Gómez Fregoso.[1,2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

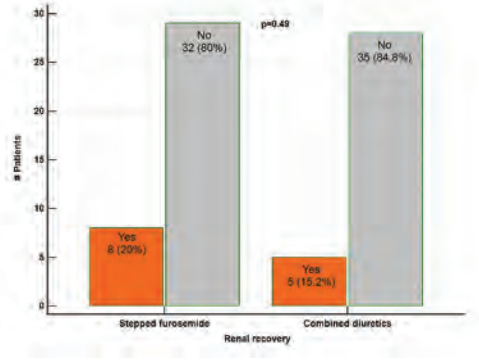
Background: In cardiorenal syndrome 1 (CRS1), is probable that sequential blockage of the renal tubule with combined diuretics (CD) will obtain similar benefits compared with stepped-dose furosemide (SF)

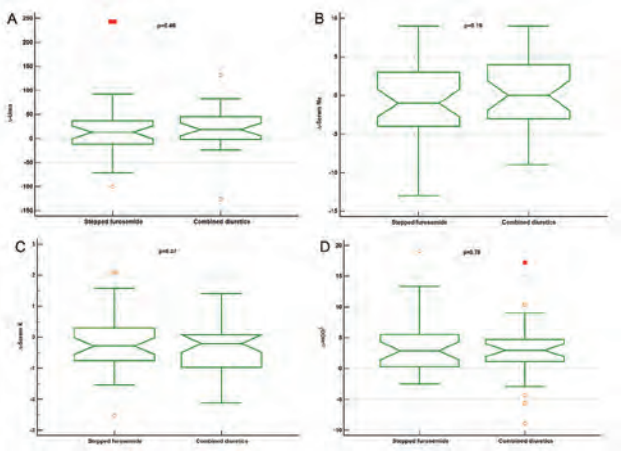
Methods: In a double-blind randomized controlled trial of CRS1 patients were allocated 1:1 to SF or CD. The SF group received a continuous infusion of furosemide 100mg during the first day, with daily incremental doses to 200 mg, 300 mg and 400 mg. The CD group received a combination of diuretics, including 4 consecutive days of oral chlorthalidone 50 mg, spironolactone 50 mg and infusion of furosemide 100 mg. The objectives were to assess renal function recovery and vascular decongestion.

Results: From July 2017 to February 2020, 80 patients were randomized, 40 to SF and 40 to CD group. Groups were similar at baseline and had several very high-risk features. Their mean age 59 ± 14.5 years; 37 were men (46.2%). Primary endpoint occurred in 20% of the SF group and 15.2% of the DC group (p = 0.49). All secondary and exploratory endpoints were similar between groups. Adverse events occurred frequently (85%) with no differences between groups (p = 0.53).

Conclusions: In patients with SCR-1 and a high risk of resistance to diuretics, the use of CD compared to SF offers the same results of renal recovery, diuresis, vascular decongestion and adverse events, and it can be considered an alternative treatment.

Figure 2. Primary endpoint Renal function recovery (*sCr return to baseline value*) in 80 patients with cardiorenal type 1 syndrome according to allocation groups.





PO0228

Restriction of Sulfur-Containing Amino Acid Intake for Prevention of AKI in Cardiac Surgery: UNICORN, a Randomized, Controlled, Double-Blinded Trial

Thomas Osterholt,[1] Claas Gloistein,[1] Polina Todorova,[1] Ingrid Becker,[3] Katja Arenskrieger,[1] Ramona Melka,[1] Felix C. Koehler,[1] Thomas Benzing,[1,2] Roman-Ulrich Mueller,[1,2] Volker R. Burst,[1] Franziska Grundmann.[1]
[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [3]Institute of Medical Statistics and Computational Biology, University of Cologne, Cologne, Germany.

Background: Acute kidney injury (AKI) can result in short- and long-term complications and increased mortality. Nonetheless, preventive and therapeutic strategies are lacking. Protein restriction has been shown to protect from organ failure in mice and this protection depended on restriction of sulfur-containing amino acids (SAA). The UNICORN study aims to evaluate the impact of restricting SAA intake by replacing milk-derived dietary protein by collagen prior to cardiac surgery on AKI.

Methods: In this single-center, randomized, controlled, double-blinded trial 115 patients scheduled for cardiac surgery, were assigned in a 1:1 ratio into a LowS group (SAA depleted formula diet) or a regular formula diet (control group, CG) for 7 days prior to surgery. The primary endpoint was incidence of AKI within 72 hours after surgery (KDIGO), secondary endpoints included increase of serum creatinine at 24h, 48h and 72h as well as safety parameters. Quantitative variables were analyzed with t-test or nonparametric methods, while categorical variables were evaluated by means of Chi-Square or Fisher's test.

Results: Baseline characteristics: LowS serum creatinine 1.0 mg/dl[0.34] vs. CG 0.85 mg/dl[0.42]; LowS 77% male vs. CG 54%; age: LowS 67y[IQR: 13] vs. CG 69y[12], body weight: LowS 88 kg[20] vs. CG 78kg[18], crossclamp time: LowS 67min[32] vs. CG 68min[35]). Patients in the LowS group had a 77,6% reduction in SAA as compared to CG. There was no difference in the primary endpoint between the groups (LowS AKI incidence 23% vs. CG 16%; p=0.37). Likewise, no differences were observed with respect to secondary endpoints (AKI during hospitalization, creatinine at 24h, 48h, 72h after surgery). Subgroup analysis focusing on age, gender, body mass index and markers of organ damage did not reveal any between-group differences.

Conclusions: In this first-in-humans translational clinical trial, dietary SAA restriction before cardiac surgery did not result in a lower incidence of AKI. However, larger studies are needed to confirm this finding.

PO0229

Use of Peritoneal Dialysis for the Treatment of AKI Was Associated with Lower Risk for 30-Day All-Cause Mortality During the COVID-19 Surge

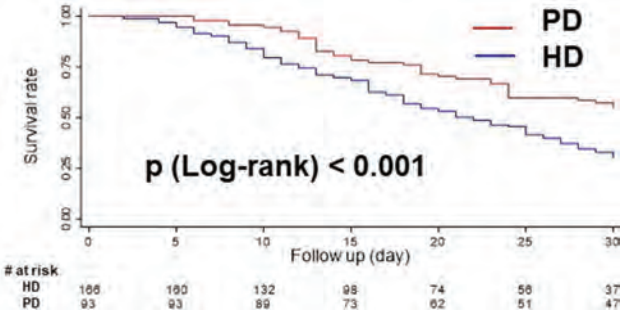
Maryanne Sourial,[1,2] Anirudh R. Gone,[1] Jaime Uribarri,[4] Nina J. Caplin,[5] Vesh Srivatana,[3] Shuchita Sharma,[4] Daniil Shimonov,[6] Michael Chang,[1] Wenzhu Mowrey,[2] Rochelle Dalsan,[2] Kaltrina Sedaliu,[1] Swati Jain,[1] Michael J. Ross,[1,2] Wei Chen.[1,2] New York City PD Consortium
[1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Rogosin Institute, New York, NY; [4]Mount Sinai Health System, New York, NY; [5]NYU Langone Health, New York, NY; [6]Weill Cornell Medicine, New York, NY.

Background: To offset resource constraints that limited the capability to deliver hemodialysis (HD) during the COVID-19 surge, nephrologists in New York City (NYC) rapidly incorporated peritoneal dialysis (PD) for the treatment of acute kidney injury (AKI), which was rarely used in the United States. This study aims to compare the in-hospital all-cause mortality between AKI patients who received PD versus HD during the COVID-19 pandemic.

Methods: In a retrospective observational study, we collected data on 259 patients with AKI who required kidney replacement therapy (KRT) in four medical centers of NYC during the Spring 2020. Patients who had ever received PD were included in the PD group (n=93), and patients who only received intermittent HD or continuous KRT were included in the HD group (n=166). Kaplan-Meier survival curves, log-rank test and Cox regression were used to compare survival between PD and HD groups.

Results: For the entire cohort, the mean age was 61±11 years; 31% were women; 96% had confirmed COVID-19. Median follow up was 21 days (IQR 12-30). Mortality was lower in PD group compared to HD group (43% vs. 60%, p=0.01). Time-dependent analyses showed that PD group was at a lower risk for mortality compared to HD group (p<0.001 for Log-rank test; Figure). After adjusting for age, sex, BMI, comorbidities, oxygenation on admission, mechanical ventilation, prone positioning, steroid use and C-reactive protein, the PD group remained to have a lower risk of mortality compared to the HD group with a HR of 0.45 (95% CI: 0.27-0.77, p=0.003).

Conclusions: Compared to HD, the use of PD for the treatment of AKI was associated with lower mortality in this cohort of patients treated during the COVID-19 pandemic in the Spring of 2020. Our findings demonstrate that rapid implementation of PD for the treatment of AKI was feasible and may be lifesaving.



PO0230

Association of an AKI Follow-Up Clinic with Patient Outcomes and Care Processes: A Propensity-Matched Cohort Study

Samuel A. Silver,[1] Neill Adhikari,[2] Nivethika Jeyakumar,[4] Ziv Harel,[3] Stephanie Dixon,[4] Bin Luo,[4] Edward G. Clark,[5] Javier A. Neyra,[6] Chaim Bell,[3] Ron Wald.[3]
[1]Queen's University, Kingston, ON, Canada; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]Western University, London, ON, Canada; [5]Ottawa Hospital, Ottawa, ON, Canada; [6]University of Kentucky, Lexington, KY.

Background: Survivors of AKI are at higher risk of chronic kidney disease and death, but few patients see a nephrologist following hospital discharge. Our objectives were to determine whether an AKI Follow-up Clinic is associated with changes in care processes and a reduction in major adverse kidney events in comparison to survivors of AKI who received usual care.

Methods: We identified all patients ≥ 18 years of age who survived a hospitalization with AKI from February 1, 2013 to September 30, 2017 and visited our hospital's AKI Follow-up Clinic within 6-months of hospital discharge. We used propensity scores to match each patient to 4 patients in the region who received usual care. We randomly assigned the control group index dates to ensure these patients were alive and could have received follow-up care. The primary outcome was time to a major adverse kidney event, defined as death, chronic dialysis, or CKD (newly sustained eGFR < 60mL/min/1.73m^2 or a sustained decrease in eGFR ≥ 25% from baseline). We also measured processes of care after AKI, which included nephrologist visits and serum creatinine/proteinuria testing.

Results: We matched 170 AKI Follow-up Clinic patients to 680 patients who received usual care. Approximately 75% in each group had KDIGO stage 2-3 AKI, with similar mean eGFR [SD] at baseline (64.6 [25.1] versus 64.2 [27] mL/min/1.73m^2) and hospital discharge (49.6 [24.6] versus 49.0 [28.1] mL/min/1.73m^2). The AKI Follow-up Clinic group had more nephrology visits per patient-year (1.4 [3.1] versus 0.7 [1.5]), with a greater proportion completing serum creatinine (94% versus 84%) and proteinuria (49% versus 25%) tests within 90-days of hospital discharge. Care in the AKI Follow-up Clinic was not associated with time to a major adverse kidney event (HR=0.90, 95% CI 0.72-1.13), but it was associated with a decreased risk of death (HR=0.55, 95% CI 0.37-0.82).

Conclusions: The AKI Follow-up Clinic was not associated with a decreased risk of major adverse kidney events, possibly due to an increased risk of CKD from more serum creatinine testing. The association with reduced mortality warrants confirmation in randomized controlled trials.

Funding: Government Support - Non-U.S.

PO0231

Risk Factors for Long-Term Mortality Following AKI

Benjamin R. Griffin,[1,2] Jason Wachsmuth,[1] Masaaki Yamada,[1,2] Meenakshi Sambharia,[2] Saket R. Girotra,[1,2] Eli Perencevich,[1,2] Heather Reisinger,[1,2] Mary V. Sarrazin,[1,2] Diana I. Jalal.[1,2] *[1]Iowa City VA Medical Center, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Acute kidney injury (AKI) occurs in over 20% of hospitalized patients and is associated with increased long-term mortality. The purpose of this study is to identify risk factors for mortality following a hospitalization with AKI in US Veterans.

Methods: AKI was defined as a creatinine increase of ≥0.3 mg/dL at or after admission to a VA hospital between 2013 and 2018. The primary outcome was mortality, with follow-up ranging from 2-7 years. Over 50 variables were considered for inclusion in the final model, including demographics, comorbidities, and laboratory data. Bootstrap modeling was used to determine the outcomes of one hundred stepwise regressions using random sampling with replacement, and those included in more than 60 of the 100 models were evaluated in a final model using Cox regression. Given that over a quarter of post-AKI mortality is due to cardiac disease, separate models were constructed for patients with and without pre-existing cardiac disease at baseline.

Results: A total of 241,781 Veterans with AKI were included. There were 47,390 deaths out of 139,144 (34%) in the non-cardiac group, and 54,384 deaths out of 102,637 (53%) in the cardiac disease group. The final Cox regression models for each population are given in **Table 1**. Harrell's Concordance values were 0.67 and 0.66, respectively. Cardiac comorbidities were major predictors of mortality in the cardiac group. Notably, kidney metrics such as admission creatinine and discharge creatinine were not selected for inclusion, and AKI stage was not a strong predictor in the non-cardiac model where it was included.

Conclusions: We report factors in AKI survivors that predict long-term mortality among US Veterans. Mortality was significantly higher in the cardiovascular disease group, and cardiovascular history was a major risk factor. Variables related to creatinine values or AKI stage were not strong predictors of mortality.

PO0232

The Clinical Characteristics of Inpatients with AKI and the Risk Factors for Progression to CKD

Lingling Xu, Yang Zhou, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: To explore the incidence of AKI in hospitalized patients and demonstrate the distributions and clinical characteristics of AKI and the risk factors for progression to CKD.

Methods: Medical records of inpatients were acquired from Nanjing Health Information Platform from January 1 to December 31, 2019. A total of 20258 patients with 2 or more serum creatinine records during one single hospitalization were enrolled. We analyzed the distribution, clinical features, and associated risk factors of AKI. A prospective cohort of 999 AKI patients was followed up for a medium of one year. Multivariable logistic regression was used to analyze the risk factors for the progression from AKI to CKD and a risk predictive model was established accordingly.

Results: Among the enrolled patients, 2194 (10.8%) developed AKI in this study. The prevalence of AKI in medical department, surgical department and ICU were 9.1%, 10.5% and 27.9%, respectively. Compared with the non-AKI group, there were more men and elderly in the AKI group. Patients with AKI were more likely to be complicated with diabetes, hypertension, and CKD. The baseline serum creatinine, uric acid, fasting blood glucose and inflammatory biomarker in AKI group were significantly higher than those in non-AKI group. On the contrary, those with AKI had lower blood lipids, albumin and hemoglobin. The presence of AKI predicted a significant increase in hospitalization cost, duration and all-cause mortality. Furthermore, 110 individuals (11.0%) progressed to CKD in the prospective cohort. Age, AKI stage, hypertension, baseline serum creatinine, uric acid and hemoglobin were found to be independent risk factors for progression to CKD. A risk predictive model of progression from AKI to CKD was established with an area under the ROC curve of 0.822 (95%CI 0.788 ~ 0.877, $P < 0.001$).

Conclusions: Age, AKI stage, baseline serum creatinine, hypertension, hyperuricemia and hypo-hemoglobinemia were independent risk factors for the progression of CKD in AKI patients. Predictive model established using these variables can help us screen those high-risk populations.

PO0233

Reduction of Intraoperative Nephrotoxic Antimicrobial Exposure Can Decrease the Severity of Stage of AKI and Improve Renal Recovery in Patients Undergoing Heart Transplantation

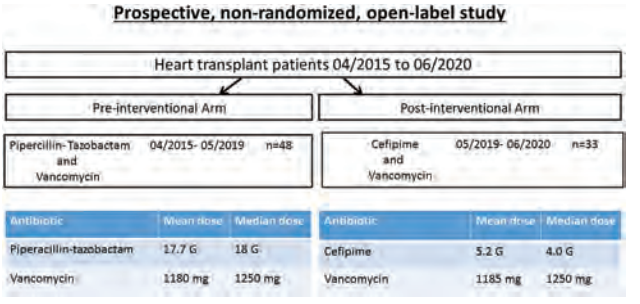
Blaithin A. McMahon, Syed M. Quadri. *Medical University of South Carolina, Charleston, SC.*

Background: Acute Kidney Injury (AKI) is very common complication post-heart transplant with a reported incidence of approximately 47-76%. Antibiotic combinations, such as piperacillin-tazobactam and vancomycin can cause nephrotoxicity and AKI especially in high doses. The mechanism for this nephrotoxicity is not clear. The purpose of this study was to evaluate the impact of reducing intraoperative nephrotoxic antibiotic exposure on the rate of Acute Kidney Injury and renal recovery in adult patients undergoing heart transplantation.

Methods: This is a single-center prospective study design of all adult patients undergoing heart transplants at Medical University of South Carolina between 4/12/2015 to 5/1/2020. In 06/20/2019, as part of a quality improvement effort to reduce our AKI rate, we changed empiric intraoperative antimicrobial coverage from piperacillin-tazobactam to cefepime while continuing vancomycin use. We collected data using the electronic health record. AKI severity and recovery were extracted for patients exposed to piperacillin-tazobactam and vancomycin or cefepime and vancomycin. AKI was identified using KDIGO serum creatinine criteria. Renal recovery was defined as 25% improvement in serum creatinine within 7 days. We assessed rates of nephrotoxin exposure and KDIGO AKI rates in all heart transplant inpatients for at least 4 years pre-intervention and almost 1 year post-intervention.

Results: While the overall rate of AKI remained the same after the intervention, the rates of severe stage 3 AKI decreased by 32%. Recovery of AKI prior to hospital discharge improved 4-fold in the intervention group (24.0% vs 6.0 %, $P < 0.05$). There was a trend towards less readmissions at 6 months with the intervention group (48.6% vs. 65.9%; p=0.117).

Conclusions: Reduction of nephrotoxic antimicrobial exposure can decrease the severity of heart transplant-related AKI and improve AKI recovery rates.



PO0234

Clinical Trajectories of AKI in Hospitalized Patients

Tezcan Ozrazgat-Baslanti, Tyler J. Loftus, Azra Bihorac. *University of Florida, Gainesville, FL.*

Background: In surgical sepsis patients, AKI trajectory subgroups have unique physiologic signatures of immunologic and endothelial dysfunction, suggesting potential utility for targeted, therapeutic interventions. It is unknown whether the same phenomena occur among all hospitalized patients. Our objectives are to understand the baseline characteristics of patients who will develop distinct AKI trajectories, determine differences in clinical outcomes, resource use, and long-term survival by AKI trajectory groups defined by persistent kidney injury and renal non-recovery on, and assess the relative importance of AKI severity, duration, and recovery on survival.

Methods: We performed a retrospective study of 156,699 patients admitted to a quaternary care academic hospital between January, 2012 and August, 2019. We used Kidney Disease Improving Global Outcomes and Acute Dialysis Quality Initiative criteria to stage AKI and classify patients as having no AKI, rapidly reversed AKI, persistent AKI with renal recovery, or persistent AKI without renal recovery. Clinical outcomes, resource use, and long-term survival rates were compared among AKI trajectory groups. Cox proportional-hazards regression was used to assess associations between AKI trajectories and time to death while controlling for demographics, Charlson comorbidity score, and provision of mechanical ventilation and ICU admission for two days or greater.

Results: Fifteen percent (54,212/355,678) of the encounters developed AKI. Fifty-eight percent (31,500/54,212) of AKI episodes rapidly reversed within 48 hours; among patients with persistent AKI, two-thirds (14,122/22,712) did not have renal recovery by discharge. One-year mortality was significantly higher among patients with persistent AKI (35%, 7,856/22,712) compared to patients with rapidly reversed AKI (15%, 4,714/31,500) and no AKI (7%, 22,117/301,466). Persistent AKI without renal recovery was associated with approximately five to six fold increased mortality compared to no AKI group, with adjusted hazard ratios of 4.7 and 6.2 for mild and severe AKI.

Conclusions: Among hospitalized patients, persistent AKI and the absence of renal recovery are associated with increased health care resource use and decreased short- and long-term survival. Early identification of patients at increased risk for persistent AKI may facilitate the provision of targeted treatments.

Funding: NIDDK Support

PO0235

Incidence and Prognosis of Different Stages of Acute Kidney Disease: A Single-Center Retrospective Cohort Study

Yu-Wei Chen,[1,2] Mei-Yi Wu,[1,3] Mai-Szu Wu.[1,3] *[1]Division of Nephrology, Department of Internal Medicine, Shuang Ho Hospital, Taipei Medical University, New Taipei City, Taiwan; [2]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [3]TMU Research Center of Urology and Kidney, Taipei Medical University, Taipei, Taiwan.*

Background: The 16th Acute Disease Quality Initiative (ADQI) recommends that the definitions and staging criteria for acute kidney disease (AKD) be congruent with the stage of AKI. To delineate the prognostic values of the AKD staging system, we constructed a large retrospective cohort and evaluated the disparate outcomes among patients with different stages of AKD.

Methods: This study was a retrospective cohort study including 4,741 adult AKI patients in a single tertiary medical center from 2015 to 2018, with at least 1 serum creatinine measurement between 7 to 90 days after AKI. The 16th ADQI recommendations were used to estimate the proportion of patients at different AKD stages (Figure 1). All patients were followed up for 1 year (study end date, Dec 31st, 2019) to analyze risk factors associated with eGFR decline, initiation of dialysis and in-hospital mortality.

Results: Among the 4,741 AKI patients included in the cohort, AKD stages 1-3 after AKI was common (53% in the CKD group and 51% in the non-CKD group). In the logistic regression model adjusted for demographics and comorbidities and after a 1-year follow-up, AKD stages 1/2/3 (AKD stage 0 as reference group) were associated with higher risks of eGFR decline (AKD stage: Odds ratio, 95% Confidence Interval [95% CI], AKD 1: 2.14, 1.65-2.79; AKD 2: 2.64, 2.01-3.47; AKD 3: 2.90, 2.29-3.66), initiation of kidney replacement therapy, (AKD stage: Odds ratio, 95% CI, AKD 2: 1.88, 1.39-2.53; AKD 3: 8.72, 7.07-10.76), and in-hospital mortality (AKD stage: Odds ratio, 95% CI, AKD 1: 1.79, 1.47-2.18; AKD 2: 3.23, 2.65-3.94; AKD 3: 5.59, 4.69-6.67).

Conclusions: Staging criteria for AKD identified AKI patients at higher risk of kidney function decline, dialysis, and mortality. AKD patients with a more severe stage need to receive intensified care.

PO0236

The Quality of Discharge Summaries After AKI

Cameron Giles, Milica Novakovic, Wilma M. Hopman, Samuel A. Silver. *Queen's University, Kingston, ON, Canada.*

Background: Patients who survive acute kidney injury (AKI) are at increased risk of hospital readmission, chronic kidney disease (CKD), and death. However, most patients are unaware they experienced AKI, emphasizing the importance of high-quality communication between inpatient and outpatient health care providers. Our objectives were to determine how often different elements of AKI were mentioned in discharge summaries and to identify predictors of discharge summary quality after AKI.

Methods: We performed a retrospective chart review of 300 randomly selected discharge summaries from 2015 to 2019. We included 150 hospitalizations before and after introduction of a post-AKI clinic in August 2017, with 50 patients from each Kidney Disease Improving Global Outcomes (KDIGO) AKI stage. We assessed each discharge summary for 10 elements, including AKI course and follow-up recommendations. We used multivariable logistic regression to determine predictors of discharge summary quality.

Results: The median number of AKI elements mentioned was 4/10 (IQR, 2-6). Follow-up with nephrology was documented for 33 (11%) patients. AKI-specific recommendations for labs and medication changes were noted in 66 (22%) and 80 (27%) discharge summaries, respectively. The odds of having a higher quality discharge summary (AKI elements ≥4/10) were greater for every increase in baseline creatinine (Cr) of 25 umol/L (OR, 1.86; 95% CI, 1.42-2.43); intrarenal etiology (OR, 2.33; 95% CI, 1.23-4.41); increased AKI severity (stage 3 or kidney replacement therapy (KRT)) (OR, 6.85 and 4.39; 95% CI, 2.83-16.59 and 1.53-12.58, respectively); inpatient nephrology consultation (OR, 10.53; 95% CI, 4.82-22.98); and discharge Cr ≥100% above baseline (OR, 4.88; 95% CI, 1.80-13.26). Discharge summary quality did not improve with the introduction of a post-AKI clinic (OR, 0.76; 95% CI, 0.44-1.31).

Conclusions: Overall discharge summary quality in AKI survivors is poor, improving modestly for patients with baseline CKD, intrarenal etiology, severe AKI, higher discharge Cr, and inpatient nephrology involvement. Most discharge summaries are missing key post-AKI elements, including Cr trajectory and AKI-specific follow-up recommendations, even in patients receiving KRT. These gaps suggest an opportunity exists to improve discharge summary quality and communication post-AKI, especially for patients not assessed by nephrology as inpatients.

PO0237

Risk of Renal Recovery Post Dialysis-Requiring AKI in Critically Ill Transplant Patients Receiving Calcineurin Inhibitors

Blaithin A. McMahon,[1] Maria C. Browne,[1] Dariush Liske-Doorandish,[1] Keisuke Okamoto.[2] *[1]Medical University of South Carolina, Charleston, SC; [2]Nara Daigaku, Nara, Japan.*

Background: The use of the calcineurin inhibitors has led to major advances in the field of transplantation, with excellent short-term graft outcomes. However, these agents are associated with chronic nephrotoxicity and long-term may lead to ESRD. The purpose of this study was to assess the risk of renal recovery at 3 months in critically ill transplant and non-transplant patients who required continuous renal replacement therapy (CRRT) (AKI-D).

Methods: This is a single center retrospective study aimed to assess differences in renal recovery from AKI-requiring dialysis (AKI-D) in both non-transplant patients (CNI - patients) and transplant patients taking calcineurin inhibitors (CNI + patients). Our study was undertaken from 02/2017 to 07/2019 at the Medical University of South Carolina, and our analysis included 153 critically ill patients who received CRRT for AKI-D. Non-renal recovery from AKI-D was defined as ESRD as per KDIGO guidelines. We performed a Cox Hazard Risk Model to asess risk of CNI use on renal recovery at 3 months adjusted for transplant status, mortality at 28 or 90 days, age, sex, hypertension, DM, APACHE score and initial number of vasoactive medication used at that time of CRRT initiation.

Results: CNI users had 61% lower risk of developing end stage kidney disease compared to non-CNI users at 90 days (HR 0.49, p = 0.49, CI 0.07 -3.69) although this risk was not statistically significantly. Interestingly, there was a statistically significant lower rate of 28-day and 90-day mortality in the critically ill transplant AKI-D cohort (21% and 37%, p< 0.05) when compared to the critically ill non-transplant AKI-D cohort (57% and 61%, p<0.05), respectively (see figure)

Conclusions: Even in this small retrospective cohort analysis, critically ill AKI-D patients requiring CNI agents did not have a statistically significant higher rate of ESRD despite CNI use and was associated with a lower 28- and 90-day mortality. More research is required to study the relationship between CNI use on renal recovery.

Outcomes by Transplant Recipient (Yes) vs. Non-Transplant Recipients (No)

Factor	No	Yes	p-value
N	133	20	
Dialysis-free at 2 weeks post-CRRT initiation	24 (37%)	7 (44%)	0.61
Dialysis-free at 4 weeks post-CRRT initiation	33 (50%)	9 (60%)	0.80
Development of CKD at 30days	19 (45%)	4 (44%)	0.97
Development of CKD at 90days	17 (36%)	3 (33%)	0.89
Mortality During Hospitalization	73 (55.7%)	4 (21.1%)	0.005
28-day Mortality	74 (56.5%)	4 (21.1%)	0.003
survival28, mean (SD)	16.669211 (10.908638)	24.578947 (7.1671767)	0.003
90-day Mortality	78 (60.8%)	7 (36.8%)	0.049
survival90, mean (SD)	46.082966 (40.613281)	73.8125 (23.612696)	0.010

PO0238

Outpatient Dialysis Prescription as Predictor and Modifiable Factor for Outcomes of Patients with Dialysis-Requiring AKI

Emaad M. Abdel-Rahman, Ernst Casimir, Genevieve R. Lyons, Jennie Z. Ma, Jitendra K. Gautam. *UVA Health, Charlottesville, VA.*

Background: Patients with acute kidney injury requiring hemodialysis (AKI-D) have poor prognosis. Beginning January 1, 2017, End Stage Kidney Disease (ESKD) facilities were allowed to furnish dialysis services to AKI-D patients. Identifying modifiable predicators of AKI outcomes will allow better care of patients with AKI-D.

Methods: Patients with AKI-D discharged for outpatient hemodialysis (HD) to one of 11 University of Virginia dialysis units from 1/1/2017 to 12/31/2019 (n=274) were followed for up to 6 months. Multinomial logistic regression was used to estimate association between clinical and dialysis factors and outcomes: recovery (patient off dialysis), ESKD, or death at 3 and 6 months. Dialysis data from the first 28 days were analyzed.

Results: Patients were 42% female, 67% Caucasian with mean age 62.8 ± 15.4 years. Comorbidities included diabetes mellitus (42%), hypertension (78%), congestive heart failure (18%), coronary artery disease (27%), prior AKI episode (36%) with pre AKI eGFR 33.8 ± 29.1 ml/min. Median (IQR) number of dialysis sessions was 11 (6-16), lasting 3.6 ± 0.6 hours. Patients declared ESKD had more median drops in blood pressure (BP) (16) than those who recovered (9) or died (10). At 90 days post start of outpatient HD, 45% recovered, 45% were declared ESKD and 9.9% died. Two more patients recovered, 2 patient died with one patient who was initially off HD was declared ESKD by 180 days. Patients with more frequent BP drops had increased odds ratio (OR) of ESKD compared to patients in the lowest quartile. Adjusted odds ratios (95% CIs) for ESKD were 3.8 (1.4 – 9.7, p<0.01) and 2.7 (1.1 – 7.2, p=0.05) for patients in 3rd and 4th quartiles, respectively, adjusting for prior AKI, age, baseline eGFR, hypertension, and UF rate. The magnitude of drop in mean arterial blood pressure was not associated with ESKD or death. Net ultrafiltration (UF) (Liters) and UF rate (ml/kg/hour) were associated with ESKD. OR (95% CIs) 1.6 (1.0 – 2.53, p=0.05) and 1.2 (1.0 – 1.3, P <0.01) respectively.

Conclusions: Optimizing dialysis prescription and close monitoring of outpatient dialysis for patients with AKI-D is crucial and may improve outcomes of these patients

PO0239

Exploratory Diagnostic and Prognostic Biomarkers in Adults with Atypical Hemolytic Uremic Syndrome (aHUS): Analysis of the Phase 3 Study of Ravulizumab (NCT02949128)

Tobin J. Cammett, Katherine Garlo, Ellen E. Millman, Kara Rice, Susan Faas. *Alexion Pharmaceuticals Inc, Boston, MA.*

Background: Validated biomarkers for diagnosis and monitoring of patients with complement-mediated thrombotic microangiopathy (CM-TMA) are not clinically available. Characterization of biomarkers in patients with aHUS, a form of CM-TMA, may inform diagnosis, treatment decisions and monitoring for patients with other types of CM-TMA.

Methods: Using data from the phase III study of ravulizumab (terminal C5 complement inhibitor) in adults with aHUS (NCT02949128), baseline (BL; prior to treatment) serum, plasma and urine biomarker levels in patients were compared with levels in healthy volunteers (HV), and evaluated for associations with kidney function (e.g. estimated glomerular filtration rate [eGFR] and urine protein/creatinine [Cr] ratio [UPCR]) at BL and 26 weeks post-treatment initiation. Regression coefficients and p-values (two-sided t-test) are reported.

Results: This analysis included 55 patients: median age 39 (range 19–76) years; 67% female; 53% White, 27% Asian. Specific BL biomarkers were elevated compared with HV, and associations between BL biomarker levels and both BL eGFR and BL UPCR were identified (Table 1). BL plasma complement factor Ba was associated with eGFR changes after 26 weeks of ravulizumab treatment, while urine sC5b-9, sC5b-9/Cr, Ba and Ba/Cr were associated with UPCR changes after 26 weeks of treatment.

Conclusions: The complement biomarkers Ba (plasma and urine) and sC5b-9 (urine) were associated with kidney function in patients with aHUS at baseline and over 26 weeks of treatment with anti-C5 therapy. Such biomarkers demonstrate diagnostic potential in CM-TMA and may predict renal response to terminal complement inhibition.

Urinary Follistatin: A Novel Biomarker for Monitoring the Severity of AKI

Izumi Nagayama,[1] Daisuke Nagata,[2] Hajime Hasegawa,[1] Akito Maeshima.[1] Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, 1981 Kamoda, Kawagoe, Saitama 350-8550, Japan *[1]Saitama Ika Daigaku Sogo Iryo Center, Kawagoe, Japan; [2]Jichi Ika Daigaku, Shimotsuke, Japan.*

Background: Activin A, a member of the TGF-beta superfamily, which was absent in normal kidney, was increased in the ischemic rat kidney and negatively regulates the repair process of the kidney after injury. However, the role of follistatin, an endogenous antagonist of activins, in the kidney is unknown. To address this issue, we examined the localization of follistatin in normal and ischemic rat kidney, and measured urinary follistatin in both rats and human with AKI.

Methods: Using vascular clamps, renal ischemia was induced for 45 min in 8-week-old male Wistar rats. Localization of follistatin in the kidney and urinary follistatin was examined by immunostaining and ELISA, respectively. Renal tissues of Nephrectomized kidney was used as normal human kidney (Approved number A18-150). Patients with AKI (n=98) and healthy adults (n=10) were enrolled in this study (Approved number A18-081 and A18-089). Serum and urinary follistatin was measured by ELISA. Correlations of urinary follistatin with other clinical parameters were analyzed.

Results: Follistatin was localized in renal tubules of normal rat kidney. Follistatin-expressing cells were positive for NCC and uromodulin, but were negative for AQP1 or AQP2. In contrast, follistatin expression was increased in the inner medulla of the kidney after renal ischemia. Urinary follistatin, undetectable in normal rats, was significantly increased with a peak at 24 h after renal ischemia. Consistent with normal rat kidney, follistatin was localized in renal tubules of normal human kidney. Urinary follistatin, undetectable in healthy adults, was significantly increased in patients with AKI (0.0 ± 0.0 vs. 433.6 ± 190.0 pg/mL, p< 0.05) and was positively correlated with the severity of AKI. Urinary follistatin was significantly increased in patients requiring renal replacement therapy compared to those who did not (911.7 ± 428.3 vs. 94.4 ± 40.0 pg/mL, p< 0.05). There was a significant correlation of urinary follistatin with urinary protein, alpha1-microglobulin, NGAL, but not with serum follistatin.

Conclusions: Follistatin, which is localized in the distal tubules of normal kidney, become detectable in the urine of AKI patients. Urinary follistatin may reflect the severity of acute tubular damage.

PO0241

RBT-1 Safety and Cytoprotective Response Biomarkers in Healthy Volunteers and Subjects with CKD

Bhupinder Singh,[1] Stuart Goldstein,[4] Navdeep Tangri,[2] Richard A. Zager.[3] *[1]University of California Irvine, Irvine, CA; [2]University of Manitoba, Winnipeg, MB, Canada; [3]University of Washington, Seattle, WA; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: RBT-1 (stannous protoporphyrin [SnPP] with iron sucrose [FeS]) is a novel drug designed to precondition organs to prevent acute injury via activation of Nrf2, anti-inflammatory, and iron sequestering pathways. Pretreatment with RBT-1 in several animal models of acute kidney injury (AKI) has demonstrated protection from AKI in conjunction with upregulation of cytoprotective proteins. Here, we report results of a Phase 1b study of RBT-1 that assessed safety and cytoprotective response biomarker induction in healthy volunteers and subjects with stage 3 and 4 chronic kidney disease (CKD).

Methods: Fifty-four (54) subjects (18 healthy volunteers and 36 subjects with CKD) were enrolled and received a single IV dose of RBT-1 (9, 27, 45, 63, or 90 mg SnPP with 240 mg FeS). Plasma heme oxygenase-1 (HO-1), interleukin-10 (IL-10) and ferritin were selected as surrogate measures of organ protective activity. Safety was assessed through Day 29, and cytoprotective response biomarkers were assessed through 168 hours post-dose.

Results: RBT-1 was well tolerated in both healthy volunteers and subjects with CKD. The most common treatment-emergent adverse event was photosensitivity reaction (a known reaction to SnPP), which occurred in 15 subjects (27.8%) and was more commonly observed in the higher dose groups (63 and 90 mg SnPP/240 mg FeS). Photosensitivity was transient and generally mild in intensity. No serious adverse events were reported. RBT-1 induced dose-dependent, statistically significant increases in cytoprotective response biomarkers in both healthy volunteers and subjects with CKD. Peak increases from baseline in healthy volunteers and subjects with CKD were: 386% and 402% for HO-1, respectively; 99% and 332% for IL-10, respectively; and 1552% and 469% for ferritin, respectively.

Conclusions: RBT-1 is well tolerated with a similar safety profile in healthy volunteers and subjects with CKD Stage 3 or 4 and elicits a biomarker response in humans that is associated with RBT-1-mediated organ protection in animal models of AKI. The positive safety and biomarker efficacy data provide a strong scientific basis to study RBT-1 as an AKI prevention strategy in patients undergoing elective cardiac surgery.

PO0242

IL-17 Levels Are Higher in Patients with AKI and Associate with Mortality and Major Adverse Kidney Events

Jason A. Collett,[1] Victor M. Ortiz-Soriano,[2] Xilong Li,[3] Alexander H. Flannery,[2] Robert D. Toto,[3] Orson W. Moe,[3] David P. Basile,[1] Javier A. Neyra.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Kentucky Medical Center, Lexington, KY; [3]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Inflammatory markers of AKI have garnered attention for having potential to be sensitive biomarkers for AKI prognosis. We demonstrated that TH17 cells are increased in ICU patients diagnosed with AKI vs. those without AKI. The main objective of this study was to examine the association of serum IL-17 with mortality and major adverse kidney events (MAKE) in critically ill patients with and without AKI.

Methods: Multicenter prospective study of 299 critically ill patients with AKI stage 2 or above, and matched ICU patients without AKI. Blood samples were collected within 48 hours after AKI diagnosis (n=153) or within 48 hours of ICU admission in those without AKI (n=146). Serum IL-17a was measured using extremely sensitive ELISA (S-Plex technology; Meso Scale Discovery). Logistic regression was used to examine the association of IL-17 levels with hospital mortality and MAKE at 90 days post-discharge (composite of death, need of renal replacement therapy or inability to recover at least 70% of baseline eGFR).

Results: Patients in the highest tertile of IL-17 were more severely ill than those in lower tertiles, including more frequent AKI (73% vs. 47% vs. 33.3%, p <0.001), more frequent mechanical ventilation (63% vs. 48% vs. 44.4%, p=0.021), and higher APACHE-II scores (19 vs. 15.5 vs. 14, p<0.001). Moreover, patients in the highest tertile of IL-17 had higher rates of inpatient mortality (26% vs. 8% vs. 9.1%, p<0.001) and MAKE-90. In multivariable models, patients in the highest tertile (vs. lowest tertile) had increased risk of hospital mortality (aOR 2.80, 95%CI 1.09-7.20) and MAKE-90 (aOR 3.51, 95%CI 1.72-7.14). Concordant results were obtained when IL-17 was analyzed as a continuous variable.

Conclusions: Higher levels of IL-17 during acute illness were independently associated with hospital mortality and MAKE-90 in critically ill patients with and without AKI. Further studies are needed to validate the use of IL-17 as a surrogate pathobiologic and prognostic marker in this susceptible population.

Serum Renin and Major Adverse Kidney Events in Critically Ill Patients: A Multicenter Prospective Study

Alexander H. Flannery,[1] Victor M. Ortiz-Soriano,[2] Xilong Li,[3] Fabiola Gianella,[3] Robert D. Toto,[3] Orson W. Moe,[3] Prasad Devarajan,[4] Stuart Goldstein,[4] Javier A. Neyra.[2] *[1]University of Kentucky College of Pharmacy, Lexington, KY; [2]University of Kentucky College of Medicine, Lexington, KY; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Preliminary studies have suggested that the renin-angiotensin system (RAS) is activated in critical illness and associated with mortality and adverse kidney outcomes. We sought to assess in a larger, multicenter study the relationship between serum renin and Major Adverse Kidney Events (MAKE) in intensive care unit (ICU) patients.

Methods: Prospective, multicenter study at two institutions of patients with and without acute kidney injury (AKI). Blood samples were collected for renin measurement a median of 2 days into the index ICU admission (T1) and 5-7 days later (T2). The primary outcome was MAKE at hospital discharge, a composite of mortality, kidney replacement therapy, or reduced estimated glomerular filtration rate to ≤ 75% of baseline.

Results: Two hundred and eighty patients were enrolled with available blood samples for analysis. Patients in the highest renin tertile were more severely ill overall, and serum renin was significantly higher at both time points in patients with AKI, those who experienced MAKE, and those who died (Fig. 1). In multivariable logistic regression, this initial measurement of renin (T1) was significantly associated with MAKE: third renin tertile OR 2.33 (95% CI 1.01-5.44) and second renin tertile OR 2.51 (1.08-5.80) in reference to the first renin tertile. Similar results were noted for renin's association with hospital mortality. The association of renin with MAKE events in survivors was not statistically significant. The trajectory of the renin measurements between T1 and T2 was distinct when comparing death vs. survival, but not when comparing MAKE vs. those without.

Conclusions: In a broad cohort of critically ill patients, serum renin measured early in the ICU admission is associated with MAKE events at discharge, particularly mortality.

Urinary Epidermal Growth Factor and CKD Progression: The ASSESS-AKI Study

Steven Menez,[1] Heather Thiessen Philbrook,[1] David G. Hu,[1] Wassim Obeid,[1] Pavan K. Bhatraju,[8] Talat Alp Ikizler,[2] Edward D. Siew,[2] Vernon M. Chinchilli,[10] Amit X. Garg,[3] Alan S. Go,[4,5] Kathleen D. Liu,[4] James S. Kaufman,[6] Paul L. Kimmel,[7] Jonathan Himmelfarb,[8] Steven G. Coca,[9] Chirag R. Parikh.[1] ASSESS-AKI Consortium *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Vanderbilt University School of Medicine, Nashville, TN; [3]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [4]University of California San Francisco, San Francisco, CA; [5]Kaiser Permanente, Oakland, CA; [6]New York University Grossman School of Medicine, New York, NY; [7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [8]University of Washington, Seattle, WA; [9]Icahn School of Medicine at Mount Sinai, New York, NY; [10]Penn State College of Medicine, Hershey, PA.*

Background: Acute kidney injury (AKI) and chronic kidney disease (CKD) are interconnected syndromes with AKI recognized as a risk factor for CKD incidence or progression. However, biomarkers of repair or resilience, such as epidermal growth factor (EGF), may help better inform this risk, given the limitations of serum creatinine (sCr) in the setting of AKI.

Methods: We enrolled 1,538 hospitalized patients prospectively in the multi-center Assessment, Serial Evaluation, and Subsequent Sequelae of Acute Kidney Injury (ASSESS-AKI) Study. We measured urinary epidermal growth factor (uEGF) from samples at 3 months post-discharge. The primary outcome was a composite of CKD incidence, progression, or development of end-stage kidney disease (ESKD). We also evaluated change in estimated glomerular filtration rate (eGFR) over time by EGF quartile.

Results: 299 (20%) patients developed the primary outcome at a median of 4.3 years follow-up. Patients in the fourth quartile of uEGF had higher eGFR at baseline and at 3-month follow-up compared to those in quartiles 1-3, as well as significantly lower albuminuria. Each 2-fold higher uEGF level was significantly associated with decreased risk of the composite outcome (HR 0.65; 95% CI: 0.59-0.71). This association remained robust after adjustment for demographic factors, baseline kidney function, urinary albumin, and other urinary biomarkers of injury and inflammation (aHR 0.65, 95% CI: 0.54-0.79). Patients in uEGF quartile 1 had the fastest decline in eGFR (-5.6% per year), compared to patients in uEGF quartiles 2-4 (-3.2, -2.8, -2.3% per year, respectively).

Conclusions: Urinary EGF is a marker of repair after kidney injury, and higher levels of uEGF after discharge are associated with reduced risk of CKD and progression to ESKD in hospitalized patients with and without AKI.

Funding: NIDDK Support

Table 1. Association of kidney outcomes by urinary EGF level at 3-month follow-up

Urine EGF at 3-month follow-up	Range	CKD Incidence, Progression or ESKD				% Change in eGFR over time

Dicarbonyl L-Xylulose Reductase (DCXR) as Surrogate for "Muddy" Brown Granular Casts and Diagnostic Biomarker for Acute Tubular Injury

Vipin Varghese,[1] Akanksh Ramanand,[1,3] Frank C. Abbruscato,[1] Patrick E. O'Reilly,[4] Colin Suplee,[4] Alison Bland,[4] Benjamin A. Neely,[5] Luis A. Matute Trochez,[1] Lyndsey R. Buckner,[2] Michael G. Janech,[4] Juan Carlos Q. Velez.[1,3] *[1]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Biorepository Unit, Ochsner Clinic Foundation, New Orleans, LA; [3]The University of Queensland Ochsner Clinical School, Herston, QLD, Australia; [4]Department of Biology, College of Charleston, Charleston, SC; [5]National Institute for Standards and Technology, Charleston, SC.*

Background: Detection of abundant "muddy" brown granular casts (MBGC) during microscopic examination of the urinary sediment (MicrExUrSed) is pathognomonic of acute tubular injury (ATI). Because hospital laboratories do not optimally report MBGC, nephrologists have to independently perform MicrExUrSed. Thus, a diagnostic test to identify MBGC without performance of MicrExUrSed could be clinically useful. Unlike most AKI biomarker discovery approaches, we hypothesized that MBGC-enriched urinary sediment (MBGC-sedi) contains unique proteins that could serve as biomarkers of ATI.

Methods: MicrExUrSed was performed in specimens from patients with acute kidney injury (AKI) seen for nephrology consultation with a suspected etiology of ATI. Specimens from 3 patients containing numerous MBGC (>10 per low power field in >50% of slide) were collected, subjected to low speed centrifugation (100g), proteolytically digested and analyzed by nano-LC tandem mass spectrometry. Identified proteins were quantified by normalized spectral abundance factor (NSAF). Proteins were identified by MASCOT and accepted at <1% false discovery. Presence of proteins in casts was verified by immunofluorescence (IF) and western blotting (WB).

Results: A total of 242 proteins were significantly more abundant in MBGC-sedi specimens respect to the supernatant ($p<0.05$). Among the identified proteins unique to the MBGC-sedi, we selected dicarbonyl L-xylulose reductase (DCXR) as a candidate ATI biomarker because it was the protein with the lowest p value for MBGC-sedi specificity ($p=0.00012$, per NSAF) and only identified in MBGC-sedi. To validate the proteomics, in a separate set of MBGC-sedi specimens from patients with AKI due to ATI ($n = 10$), presence of DCXR was probed by WB and detected in 6 of 7 cases, and DCXR localization within MBGC by IF was verified in 3 of 3 cases.

Conclusions: DCXR is abundant in MBGC-sedi and may be a biomarker of ATI as an etiology of AKI. DCXR is an enzyme expressed in the kidney, primarily localized in proximal tubuli, absent in glomeruli. At the cellular level, DCXR is involved in metabolic and osmotic stress detoxification. We conclude that urinary DCXR is a potential target molecule for ATI diagnosis.

Preoperative Plasma TNFR1, TNFR2, and KIM-1 and Long-Term Adverse Events After Cardiac Surgery: The TRIBE-AKI Study

George Vasquez-Rios,[1] Dennis G. Moledina,[2] Eric McArthur,[3] Sherry Mansour,[2] Steven Menez,[4] Heather Thiessen Philbrook,[4] Michael Shlipak,[5] Jay L. Koyner,[6] Amit X. Garg,[7] Chirag R. Parikh,[4] Steven G. Coca.[1] TRIBE-AKI Consortium *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University School of Medicine, New Haven, CT; [3]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [4]Johns Hopkins University, Baltimore, MD; [5]University of California San Francisco, San Francisco, CA; [6]University of Chicago Pritzker School of Medicine, Chicago, IL; [7]London Health Sciences Centre, London, ON, Canada.*

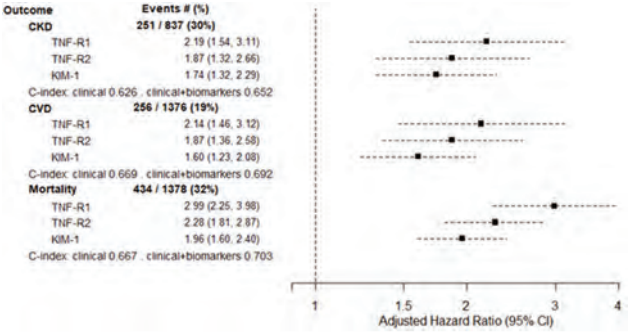
Background: Plasma TNFR1, TNFR2, and KIM-1 have been associated with CKD progression in ambulatory patients with/without diabetes. However, their role as predictors of long-term outcomes and their ability to discriminate such outcomes compared to clinical parameters prior to cardiac surgery is unknown.

Methods: Prospective, multicenter cohort study of high-risk adults undergoing cardiac surgery (2007-2010). We assessed the association between pre-operative levels of TNFR1, TNFR2, and KIM-1 (natural log-transformed) and long-term mortality, CKD (incidence/progression), and cardiovascular (CV) events. We also examined the potential effect modification of DM status on the relationship between these biomarkers and outcomes. C-statistic analysis was used to quantify the discriminatory ability of the biomarkers beyond the clinical model.

Results: 1378 participants (69.1% male) with a mean age: 71.9 ± 9.7, were followed for a median of 5.6 (IQR 4.3-8.6) years. 434 (31.5%) died within the study timeframe, 251 (30%) developed CKD, & 256 (19%) had CV events. After adjustment for covariates, each natural log increase in biomarker concentration was associated with mortality [adjusted HR: TNFR1, 3.0 (95% CI 2.3-4.0); TNFR2, 2.3 (95% CI 1.8-2.9); KIM-1, 2.0 (95% CI 1.6-2.4)]. Similar effect sizes were seen for all 3 biomarkers in their association with CV & CKD events (**Figure 1)**. Baseline DM status did not modify the association between biomarkers and clinical outcomes. The addition of all 3 biomarkers improved discrimination for the 3 outcomes.

Conclusions: Preoperative plasma TNFR1, TNFR2, and KIM-1 were independently associated with long-term outcomes after cardiac surgery and improved discrimination compared to standard clinical models. Pre-operative plasma biomarkers may serve with timely risk-stratification and planning to prevent clinical sequela.

Funding: Other NIH Support - NIH/NHLB institute



HRs were adjusted for age, sex, race, pre-op clinical & kidney-related parameters.

PO0247

Preoperative Biomarkers and Mortality Risk After Cardiac Surgery

Caroline Liu,[1] Steven Menez,[2] Dennis G. Moledina,[4] Heather Thiessen Philbrook,[2] Eric McArthur,[3] Wassim Obeid,[2] Sherry Mansour,[4] Amit X. Garg,[3] Chirag R. Parikh,[2] Steven G. Coca.[1] TRIBE-AKI Consortium *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [4]Yale University School of Medicine, New Haven, CT.*

Background: Cardiac surgery patients are at an increased risk for developing adverse outcomes. Preoperative blood and urine biomarkers may help stratify cardiac surgery patients at high risk for mortality.

Methods: The TRIBE-AKI study enrolled 1526 patients undergoing cardiac surgery in the USA and Canada from 2007-2010 and was randomly split into a training and test dataset (70:30). A total of 32 plasma and 17 urine biomarkers were measured preoperatively. The primary outcome was 3-year mortality. Random forest (RF) and LASSO logistic regression models were used to identify top biomarkers. Logistic regression models with the highest performing biomarkers and the Society of Thoracic Surgeons (STS) risk calculator were evaluated and the discriminatory ability was assessed in the test dataset.

Results: Death by 3 years occurred in 163 of the 1526 (10.7%) patients. LASSO logistic regression models retained the STS score and 6 plasma biomarkers (Troponin, IL-6, KIM1, NT-proBNP, TNFR1, YKL-40). The top 6 biomarkers identified by random forest were plasma KIM-1, TNFR1, eGFR, TNF-R2, hsTNT, and urine IL-8. In logistic regression models, the AUC in the test dataset for the STS clinical model was 0.68 (0.61, 0.76) and increased to 0.72 (0.65, 0.79) with the addition of 8 plasma and 2 urine biomarkers (plasma Troponin, IL-6, KIM-1, NT-proBNP, TNFR1, YKL-40, hFABP, TNFR2, and urine IL-8 and albumin; $p=0.24$).

Conclusions: The addition of biomarkers improved discrimination for 3-year mortality prediction minimally beyond clinical characteristics alone. The clinical utility of measurement of biomarkers pre-operatively prior to cardiac surgery is suspect.

PO0248

Considerations in Controlling for Urine Concentration in Performance of Biomarkers of AKI

Yumeng Wen,[1] Heather Thiessen Philbrook,[1] Dennis G. Moledina,[2] James S. Kaufman,[8] William B. Reeves,[9] Nasrollah Ghahramani,[7] Talat Alp Ikizler,[3] Alan S. Go,[4] Kathleen D. Liu,[5] Jonathan Himmelfarb,[10] Edward D. Siew,[3] Paul L. Kimmel,[6] Chi-yuan Hsu,[5] Chirag R. Parikh.[1] ASSESS-AKI Investigators *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Yale University School of Medicine, New Haven, CT; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Kaiser Permanente Northern California, Oakland, CA; [5]University of California San Francisco School of Medicine, San Francisco, CA; [6]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [7]Penn State College of Medicine, Hershey, PA; [8]New York University, New York, NY; [9]The University of Texas at San Antonio, San Antonio, TX; [10]University of Washington, Seattle, WA.*

Background: Urine biomarkers are often indexed to urine creatinine (UCr) to control for urine concentration. Whether the biomarker-outcome associations are altered using this or other approaches, such as indexing to urine osmolality (UOsm), in AKI patients has not been examined.

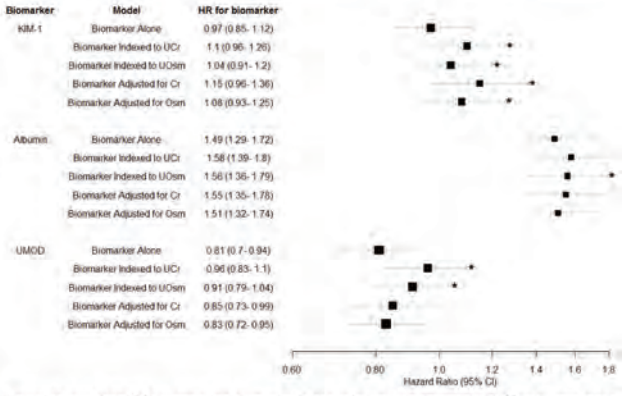
Methods: We studied 769 hospitalized patients with AKI enrolled in the multicenter prospective Assessment, Serial Evaluation, and Subsequent Sequelae in Acute Kidney Injury (ASSESS-AKI) Study. Using Cox proportional hazards regression, we assessed urine biomarkers' associations with a composite outcome of incident chronic kidney disease (CKD) and CKD progression using four approaches to account for urine concentration: indexing to UCr or UOsm and adjusting for UCr or UOsm as covariates.

Results: 207 (27%) participants developed composite CKD outcome at median follow-up of 4.7 years. UCr and UOsm during hospitalization were inversely associated with developing CKD (HR 0.84, 95% CI 0.73-0.96 for UCr; HR 0.81, 95% CI 0.71-0.93 for UOsm). Figure 1 shows the hazard ratio of urine biomarkers collected during hospitalization with the composite CKD outcome using the four approaches to account for urine concentration. The association between urine kidney injury molecule-1 (KIM-1), albumin and CKD strengthened after indexing to or adjusting for UCr or UOsm, but uromodulin's (UMOD) inverse association with CKD was blunted after indexing to UCr or UOsm.

Conclusions: UCr and UOsm, potential markers for tubular health, are both associated with lower risk of developing CKD in hospitalized AKI patients. Indexing to UCr or UOsm strengthens the biomarker- CKD associations for urine KIM-1 and albumin, but attenuates UMOD's inverse association with CKD.

Funding: NIDDK Support

Figure 1. Hazard ratio of urine KIM-1, albumin and UMOD collected during hospitalization in AKI patients with composite CKD outcome using different approaches to account for urine concentration.



* p value less than 0.01 comparing biomarker's association with composite CKD outcome when urine creatinine or osmolality is accounted for versus biomarker alone.
All urine measurements were converted to log-2 base normally distributed Z score.

Clinical Factors Affecting Continuous Renal Replacement Therapy Circuit Life Span

Jae seok Kim, Hanwul Shin, Kim Yoojin, Jun Young Lee, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. *Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.*

Background: CRRT is a useful dialysis modality in hemodynamically unstable patients. But despite use of anticoagulants, clotting of CRRT circuit frequently occurs, which reduces the efficiency of dialysis. In the study, we aim to investigate the clinical factors contributing to CRRT circuit clotting.

Methods: The medical records of total 119 critically ill patients requiring CRRT were reviewed retrospectively. We investigated the clinical factors affecting the time from CRRT start to first dialysis circuit clotting, and the proportion of dialysis circuit changes due to clotting to total circuit changes during entire CRRT periods.

Results: Un-tunneled femoral hemodialysis catheter had a shorter time to first circuit clotting (22.8 vs. 32.1 hours, p=0.013), and a higher rate of circuit clotting (69.3 vs. 52.6 %, p=0.043) than jugular catheter. The time to first circuit clotting had a negative correlation with norepinephrine dosage (r= -0.335, p=0.002) and serum creatinine level (r= -0.402, p<0.001), while it had a positive correlation with arterial blood ionized calcium (r=0.273, p=0.017). In multiple regression analysis, it was confirmed that high norepinephrine dosage and high serum creatinine contributed to circuit clotting, and of which serum creatinine was the most significant contributing factor to circuit lifespan (Table 1). During entire CRRT periods, the proportion of dialysis circuit changes due to clotting was well negatively correlated with the time to first circuit clotting (r= -0.460, p<0.001), and total duration of CRRT application (r= -0.306, p=0.006). However, neither transfusion nor CRRT parameters such as blood flow and filtration fraction had no relationship with circuit survival.

Conclusions: Conclusively, in regard to CRRT circuit lifespan, femoral hemodialysis catheter, high norepinephrine dosage, and especially high serum creatinine level contributed to CRRT circuit clotting.

CRRT Dose Variation Across Multiple ICUs: A Single-Center Study

Dariush Liske-Doorandish,[1] Keisuke Okamoto,[2] Maria C. Browne,[1] Ruth C. Campbell,[1] Blaithin A. McMahon.[1] MUSC Nephrology CRRT QI *[1]Medical University of South Carolina, Charleston, SC; [2]Nara Kenritsu Ika Daigaku Fuzoku Byoin, Kashiwara, Japan.*

Background: Continuous Renal Replacement Therapy (CRRT) is increasingly a cornerstone of critical care provision in Intensive Care Units (ICUs) but variation in utilization and differences in culture of practice impact percentage of dose delivered, bearing on outcomes. Efforts to establish timing for initiation, modality, and type of anticoagulation continue, but standardizing local practice may be a more feasible route to improvement, through establishing standards across units and measuring adherence to those standards.

Methods: Our single center quality improvement study aimed to assess differences in CRRT utilization, clotting events, percent CRRT dose delivered, and other contributors to differences in CRRT delivery. This initial study is part of a long-term quality improvement project to identify routes to improve CRRT dose delivery and further evaluate CRRT modalities best suited to different ICU environments. We tracked "clotting events," "filter life," and "percent dose delivered," to assess unit specific practice patterns and outcomes. Our study was undertaken from 02/2017 to 07/2019, and includes 150 ICU patients who received CRRT across our system's 5 adult ICUs.

Results: We found CRRT delivery ranging from 92.7% to 96.4% of prescribed dose across our ICUs, with 12,745 hrs of CRRT delivered out of 13,575 hrs CRRT prescribed, and a weighted mean of ~7.8 hrs undelivered CRRT per patient for all patients in the study; average <0.05 hrs undelivered CRRT/patient/day. Undelivered CRRT ranged from 3.4 hrs/patient in the Medical ICU to 13.1 hrs/patient in our Cardio Vascular ICU; the use of a smaller French catheter size for the patients on a specialty surgical ICU, and interruptions for surgical procedures, accounted for the greatest deviation from the mean for undelivered CRRT; significant inter-unit variability of delivered CRRT dose per patient was also noted.

Conclusions: Increased clotting events and decreased percent dose delivery were associated with the use of smaller catheters, and significant variation in average undelivered hours of CRRT per patient across the different units, both of which highlighted the need for shared institutional standards and more frequent measuring of adherence to those standards to improve overall CRRT delivery.

Prediction of the Clinical Outcomes in Patients with CRRT Using Body Composition Monitoring: A Machine Learning Approach to a Multi-center Cohort Study

Kyung Don Yoo,[1,4] Junhyug Noh,[5] Jung Nam An,[7] Seon Ha Baek,[8] Shin-Young Ahn,[9] Harin Rhee,[12] Eun Young Seong,[12] Jang-Hee Cho,[10] Dong Ki Kim,[11,6] Sejoong Kim,[3,6] Jung Pyo Lee.[2,6] *[1]Ulsan University Hospital, Ulsan, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [4]University of Ulsan College of Medicine, Songpa-gu, Seoul, Republic of Korea; [5]Lawrence Livermore National Laboratory, Livermore, CA; [6]Seoul National University College of Medicine, Seoul, Republic of Korea; [7]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [8]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea; [9]Korea University Guro Hospital, Seoul, Republic of Korea; [10]Kyungpook National University, Daegu, Daegu, Republic of Korea; [11]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [12]Pusan National University Hospital, Busan, Republic of Korea.*

Background: Fluid balance is a critical predictor of patient outcomes with severe acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT). However, accurate assessment and application of fluid balance monitoring for predicting clinical outcomes in these patients were inconclusive.

Methods: In a multicenter cohort study, a total of 784 patients with severe AKI requiring CRRT were recruited, and body composition monitoring (BCM) using InBody® was performed on patients who started CRRT at nine tertiary hospitals in Korea from 2017 Nov to 2019 Nov. The comparison for sequential changes of total body water was performed between the survivor and non-survivor groups using mixed-effects linear regression analysis. Machine learning algorithms were used for the modeling to predict mortality.

Results: Of the 784 patients (mean age: 63.5 years), 521 (66.4%) were male. The mean APACHE II score was 29.2 ± 10.3 in the non-survivor group and 26.5 ± 9.0 in the survivor group. There were no significant differences in the volume status assessed by body weight and BCM at baseline. After adjusting for confounding factors, the survivor group had a marginal benefit from fluid balance in a mixed-effects linear regression (p=0.074). From a range attribute of the decision tree model for predicted mortality, platelet count was found in the first node in the late mortality group (survival duration > 60 days). Patients with survival duration under 60 days showed increased mortality, according to the SOFA score, serum sodium, bilirubin, and target clearance in a decision tree model (AUC=0.957)(Figure 1).

Conclusions: These machine learning approaches showed that conventional parameters for predicting clinical outcomes were interrelated as notable risk factors for mortality augmented by BCM in CRRT patients.

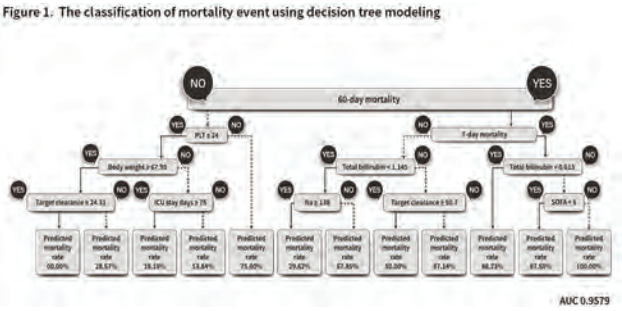

Figure 1. The classification of mortality event using decision tree modeling

PO0252

Optimal Cefepime Dosing Regimens in Obese Critically Ill Patients with AKI Receiving Continuous Renal Replacement Therapy

Dhakrit "Jesse" Rungkitwattanakul,[1] Andrew A. Yabusaki,[1] Kuang-Heng Hsiao,[1] Kendra Getaw,[1] Taniya Charoensareerat,[2] Weerachai Chaijamorn.[2] *[1]Howard University College of Pharmacy, Washington, DC; [2]Siam University, Bangkok, Thailand.*

Background: Cefepime can be removed by continuous renal replacement therapy (CRRT) due to its pharmacokinetics. Physiologic alterations in obesity and critical illness commonly impact the pharmacokinetics of antibiotics and may result in suboptimal dosing. The information regarding drug dosing in this population is relatively limited. The objective of our study is to determine the appropriate dosing of cefepime in obese critically ill patients receiving continuous renal replacement therapy (CRRT).

Methods: All necessary pharmacokinetic and pharmacodynamic parameters from obese critically ill patients were obtained to develop one-compartment mathematical models with first-order elimination. Obesity is defined as a body mass index (BMI) greater than 30 kg/m^2 according to WHO classification. Cefepime concentration-time profiles were calculated to determine the efficacy based on the probability of target attainment (PTA) of both pharmacodynamics targets of 70% T> MIC and 70% T> 4MIC for Gram-negative infections. A group of 10,000 virtual patients was simulated and tested using Monte Carlo simulations for each dose in the models. The optimal dosing regimens or the "successful dose" were defined as the lowest daily dose that achieved target PTA in at least 90% of the virtual patients.

Results: Our results showed the highest FDA-recommended dosing of cefepime at 2000 mg every 8 hours for patients receiving CRRT with an effluent rate of 25 mL/kg/h cannot achieve at least 90% of PTA for Gram-negative infection due to pseudomonas aeruginosa with an MIC of 8 mg/L. In addition, when a higher effluent rate of 35 mL/kg/h and an aggressive pharmacodynamic targets were applied, the % PTA decreased. The successful dose (3000 mg loading dose on day 1 followed by 2500 mg every 8 hours) was far exceeded the maximal FDA-approved doses.

Conclusions: Using cefepime in obese critically ill AKI patients receiving CRRT with traditional dosing of 2000 mg every 8 hours cannot be recommended as an empiric therapy due to suboptimal efficacy. The MIC target and replacement fluid rate directly impact the pharmacodynamic outcome.

PO0253

Molecular Adsorbent Recirculating System (MARS) Therapy and Outcomes at Mayo Clinic Florida: A Single-Center Experience

Mahnoor M. Khan, Lyle W. Baker, LaTonya J. Hickson, Christopher L. Trautman. *Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Background: Molecular adsorbent recirculating system (MARS) is an extracorporeal multi-integrative system, combining the processes of continuous veno-venous hemodiafiltration (CVVHDF) and adsorption, that provides rescue support in fulminant hepatic failure. The use of albumin dialysate within the circuit provides effective removal of circulating toxins which accrue from hepatic failure. Our primary aim was to characterize a cohort of patients who received MARS therapy and renal events, given limited data to date.

Methods: Patients initiating MARS in a tertiary care setting from January 2010 through December 2020 were assessed for treatment indications, transplantation, renal replacement therapy (RRT), renal recovery, and death. Data was collected using the REDCAP software.

Results: During the study period, 49 adult patients (67.3% female; 75.0% White; median age 55 years) received MARS therapy during the study period. Indications included hepatic encephalopathy (55.1 %), primary dysfunction of liver transplant (14.3%), bridge to liver transplant (HRS) (12.2%), acute intoxication or overdose (i.e. acetaminophen) (8.2%), and intractable pruritis in cholestasis (2.0%). A majority (73.4%) of patients received 3 or more MARS treatments (median 3; range 1-10). Following MARS, nearly three-fourths (71.4%) of the cohort required Continuous veno-venous hemofiltration (CVVH) due to acute kidney injury. However, 37.1% recovered renal function prior to discharge. 23 (46.9 %) patients died prior to hospital discharge. Twenty (40.8%) patients received liver transplant during hospitalization. Among those who received liver transplant, a majority (75%) required RRT post transplantation.

Conclusions: MARS therapy though most commonly provided for hepatic encephalopathy is associated with high morbidity and acute kidney failure requiring CVVH. About half may recover renal function sufficient to come off renal replacement therapy but mortality rates are high for all MARS patients.

PO0254

The Temporal Relationship Between Ultrafiltration and Mortality in Continuous Renal Replacement Therapy

Nathaniel Hocker, Sean Pickthorn, Lewis Mann, Ravinandan Venkatasubramanian, Meenakshi Sambharia, Jonathan Nizar, Benjamin R. Griffin. *The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: In acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT), studies suggest that higher ultrafiltration rate (to a point) is associated with reduced mortality, but fluid gain is associated with increased mortality. However, the impact of the timing of net ultrafiltration rate (NUF) on mortality is unknown. Here we evaluated whether the relationship between NUF and mortality is mediated by temporal factors.

Methods: Adults requiring CRRT at the University of Iowa from 2019-2020 were included. Patients were excluded if they survived less than 48 hours on CRRT. Cumulative fluid volume was collected at CRRT initiation and at 24, 48, and 72 hours after initiation. NUF was calculated for each day on therapy by taking the difference in cumulative volume between timepoints and dividing by patient weight. The primary outcome was in-hospital mortality. Covariates were age, gender, BMI, illness severity, CRRT days, volume at CRRT initiation, and comorbidities.

Results: A total of 200 patients met inclusion criteria. Neither NUF from CRRT initiation to 24 hours, nor NUF from 48 to 72 hours, differed significantly between survivors and non-survivors. Strikingly, however, NUF from 24 to 48 hours was strongly statistically associated (**Table 1**), and remained independently associated after adjustments for covariates.

Conclusions: A temporal relationship was observed between NUF and in-hospital mortality in AKI-CRRT patients. NUF from 24-48 hours was a strong predictor of mortality, but outside of this interval no association was observed. Modern fluid resuscitation strategies emphasize the importance of timing and of appropriate de-resuscitation. A similar paradigm may be advisable in CRRT, but further studies are needed.

Table 1. Net ultrafiltration rate by day in survivors and non-survivors

In-hospital Mortality		NUF*: Initiation to 24 Hours	NUF*: 24 to 48 Hours	NUF*: 48 to 72 Hours
Survivors (N=85)	Median, mL/kg/day	5.4	14.2	6.5
	Interquartile Range, mL/kg/day	-10.3 to 17.7	-0.1 to 27.1	-1.0 to 22.8
Non-Survivors (N=115)	Median, mL/kg/day	-0.3	2.4	1.7
	Interquartile Range, mL/kg/day	-20.1 to 14.2	-17.3 to 14.8	-7.4 to 16.7
Total (N=200)	Median, mL/kg/day	1.3	6.6	4.7
	Interquartile Range, mL/kg/day	-13.4 to 16.1	-9.6 to 19.3	-5.6 to 19.6
P-value		.28	.001	.56

* By convention, positive NUF means greater fluid loss, and negative NUF mean an overall fluid gain;

NUF - net ultrafiltration

PO0255

Kinetic Estimated Glomerular Filtration Rate May Be a Useful Tool to Guide Hemodialysis Discontinuation

Eduardo d. Valle, João Lucas M. Gorzoni, Isabela C. Salgado, Vanessa O. Gomes, Charles M. Junior, Marcia Fernanda Arantes de Oliveira, Nadia Guimaraes- Souza, Bernardo V. Reichert, Victor F. Seabra, Lucia Andrade, Igor Smolentzov, Camila E. Rodrigues, Jose M. Vieira jr. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: There are no objective criteria for the discontinuation of renal replacement therapy (RRT) in patients who have acute kidney injury (AKI). It is unknown if Kinetic Estimated Glomerular Filtration Rate (KeGFR) can be used as assessment of renal recovery in patients who underwent RRT.

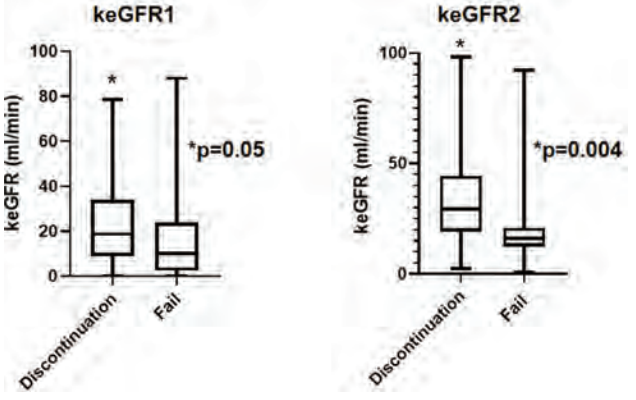
Methods: All critical patients in Hospital das Clínicas during September 2020 to May 2021 who started hemodialysis due to AKI and remained free of RRT for at least 2 consecutive days were included. Patients who stopped RRT due to decision for exclusive palliative care or hemodynamic instability were excluded. Patients were divided in two groups: Success group (free from RRT for 7 consecutive days after their last RRT session) and failure group. Discontinuation day was defined as the second day without RRT. Variables were expressed as median (25th and 75th percentile) and categorical data as percentage. Mann Whitney test was used. Statistical significance was defined as $p<0.05$.

Results: 72 patients were enrolled. COVID19, ischemia-reperfusion and sepsis were the main causes of AKI (37%; 28,7%; 24,6%, respectively), with no difference in prevalence between groups. Success group (n=47) presented higher KeFGR on the day of discontinuation (keGFR1) and in the day after (keGFR2) when compared to failure group (n=25): KeGFR1: Success: 18.76ml/min vs. failure: 10.21ml/min, p=0.05. KeGFR2: Success: 29.38ml/min vs. failure: 16.03ml/min, $p<0.05$. Success group had lower non-

renal SOFA score at discontinuation (4 vs. 6; p<0.05) and higher urine output (1600 vs. 725; p<0.05) when compared to failure group. There was no difference in diuretic use.

Conclusions: KeGFR is higher in patients who succeed in stopping RRT and it may be an useful tool for decision-making. Supported by FAPESP.

Funding: Government Support - Non-U.S.



PO0256

Survival Comparison Between Continuous Venovenous Hemodiafiltration (CVVHDF) and Continuous Venovenous Hemofiltration (CVVH) for Septic AKI

Mun Jang. *Yemidam Hospital, Cheonjusi, Republic of Korea.*

Background: The mortality rate of septic acute kidney injury (AKI) remains high despite improvements in renal replacement technology. Adding dialysis to continuous veno-venous hemofiltration (CVVH) can increase survival in these patients, although hemofiltration leads to better clearance of inflammatory mediators in sepsis than hemodialysis. We tested whether continuous veno-venous hemodiafiltration (CVVHDF) is more effective than CVVH with the same net effluent according to body weight in intensive care unit (ICU) patients with septic AKI.

Methods: CVVHDF was performed using a Prismaflex (©Baxter International, Deerfield, IL, USA) with a blood flow rate (BFR) of 150 ml/min at a dialysate flow rate 20 ml/kg/hour, in addition to a replacement fluid flow rate of 20 ml/kg/hour. In contrast, the replacement fluid flow rate of CVVH was 40 ml/kg/hour. The patient's removal rate was individually adjusted by attending staff based on clinical status.

Results: In this prospective randomized pilot study, 100 patients were assigned to CVVH (n=47, M:F=25:22, age 64±15 years) or CVVHDF (n=49, M:F=30:19, age 65±11 years). Baseline characteristics including age, sex, body weight, serum creatinine, blood urea nitrogen (BUN), beta-2 microglobulin, Acute Physiology and Chronic Health Evaluation (APACHE) II and Sequential Organ Failure Assessment (SOFA) scores did not vary between the two groups. There were no significant differences in the reduction ratios of serum creatinine, BUN, beta-2 microglobulin, APACHE II and SOFA scores between the two groups. Seven-, 28-, and 60-day survival also did not vary.

Conclusions: In conclusion, CVVH and CVVHDF led to similar clearance of waste products and survival at the same net effluent in this study. Future large-scale randomized prospective studies will be needed to confirm these results in critically ill patients with septic AKI.

Outcomes by treatment groups

	CVVHDF group	CVVHF group	p-value
Total CRRT days	8.5±8.9	7.4±8.0	0.57
Total ICU days	15.8±18.2	15.8±15.5	0.99
Renal recovery at hospital discharge (%)	31	20	0.29
Survival (%)			
7 days	67	70	0.82
28 days	47	45	1.00
60 days	31	25	0.64

CRRT, continous renal replacement therapy; CVVHDF, continous veno-venous hemodiafiltration; CVVHF, continous veno-venous hemofiltration; ICU, intensive care unit.

Systematic Review of the Effects of High-Volume High-Flow (HVHF) in Pediatric Sepsis

Rupesh Raina,[1,2] Ronith Chakraborty,[1,2] Siddhartha S. Singh,[1,2] Nikhil Nair.[1] *[1]Cleveland Clinic, Akron, OH; [2]Akron Children's Hospital, Akron, OH.*

Background: Pediatric sepsis is a significant public health issue. This condition is exacerbated by the presence of excess serum creatinine and inflammatory cytokines that lead to deleterious effects upon the body. The current standard of care involves the use of continuous kidney replacement therapy to remove harmful cytokines until the body returns to homeostasis. In order to promote faster clearance and reduced stay in the ICU, high volume high flow has been posited as a potential new modality of choice. However there is a paucity of studies to fully elucidate its benefits.

Methods: A literature search was done using PubMed/Medline and Embase. Keywords used while conducting the literature search were, "hemofiltration OR haemofiltration OR hemodiafiltration" AND "high-volume". The literature was reviewed by two independent reviewers, who independently assessed the quality of randomized controlled trials by using the Cochrane risk of bias tool for RCTs And Newcastle Ottawa Scale (NOS) for assessing the quality of non-randomized controlled trials. Data was combined from studies with similar design.

Results: The primary endpoint of all cause mortality was found to be reduced by 40% across all of the pooled studies. For secondary endpoints, significant reductions of serum creatinine were found after 24 and 48 hours of use compared to the current standard of care. Additionally, duration of ICU stay and treatment course was found to be significantly shorter in HVHF patients than the current standard of care. Finally the rate of adverse effects were analyzed and there was no difference in the proportion of patients developing hypokalemia, hyperkalemia, hypernatremia or hyponatremia. The proportion of patients developing hyperglycemia was higher in patients undergoing HVHF whereas the proportions of patients developing bleeding was significantly less in patients undergoing HVHF. One study reported a total number of adverse events between the two groups which were significantly lesser in patients undergoing HVHF.

Conclusions: HVHF shows promise as a modality to treat pediatric patients with sepsis. In order to confirm the benefits of this modality, future studies need significantly more patients for analysis.

PO0258

AKI and Hospital-Acquired Sepsis in Critically Ill Children: A Retrospective Single-Center Study

Cassandra L. Formeck,[1,2] Robert Feldman,[1] Andrew D. Althouse,[1] John A. Kellum.[1,3] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA.*

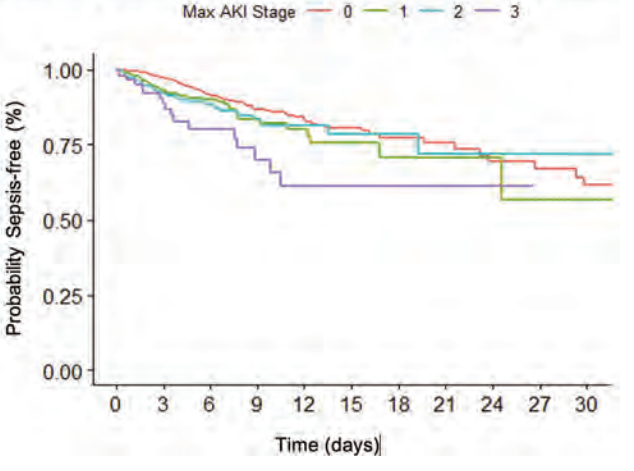
Background: Acute kidney injury (AKI) is common among critically ill children and is associated with an increased risk for de novo infection, however little is known about the temporal relationship between AKI and risk for subsequent infection. The objective of this study was to describe the risk of developing hospital-acquired sepsis over time following AKI onset.

Methods: We conducted a single-center retrospective cohort study of critically ill children admitted to the pediatric and cardiac ICUs at a tertiary pediatric care center in the United States. The cohort included children, ages birth to 18 years, without a diagnosis of chronic kidney disease, primary immunodeficiency, or sepsis within the first 48 hours of hospital admission. The relationship between the primary exposure (AKI) and primary outcome (development of hospital-acquired sepsis) was assessed using Cox proportional-hazards models using AKI as a time-varying covariate.

Results: Among the 5695 children included in the study, hospital-acquired sepsis was more common in the 1153 children that developed AKI (n=117, 10.7%) than in the 4542 children that did not develop AKI (n=210, 4.6%). Over a median follow-up of 3.1 days, the development of AKI was associated with an increased risk for development of hospital-acquired sepsis with an adjusted HR of 1.41 (95% CI 1.11-1.80, p=0.005). The median time from AKI onset to sepsis was 2.6 days (IQR 1.5 – 4.7). Among the 117 children who developed hospital-acquired sepsis following AKI (from 48 hours after hospital admission through hospital discharge or 30 days), 80.3% of children developed sepsis within 7 day and 96.6% within 14 days of AKI onset.

Conclusions: AKI is an independent risk factor for de novo infection. Children with AKI are at highest risk for developing hospital-acquired sepsis within 14 days following AKI onset.

Figure 1. Adjusted probability of hospital-acquired sepsis according to maximum stage of AKI by Kaplan-Meier Analysis.



PO0259

Disseminated Intravascular Coagulation Is Associated with AKI in Pediatric Severe Sepsis

Ayse Akcan Arikan,[1,2] Michael P. Smaglick,[1] Vinod Vijayan,[1] Curtis E. Kennedy,[1] Brady S. Moffett,[2] Poyyapakkam Srivaths,[1] Trung C. Nguyen.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Exact mechanism of pediatric septic acute kidney injury (AKI) remains unknown. Coagulation pertubations like disseminated intravascular coagulation (DIC) are frequent in sepsis and associated with organ dysfunction. The link between DIC and septic AKI has not been adequately explored in pediatric patients.

Methods: Single center cohort study of pediatric patients with severe sepsis Jan 2017-Apr2018. Primary outcome was AKI (per Kidney Disease Improving Global Outcomes creatinine criteria), primary exposure was DIC (per International Society of Thrombosis and Haemostasis criteria).

Results: 287 patients were enrolled, median age 7.3 (IQR 1.6-14.5) years; 58% had AKI, 34% had DIC. Pediatric risk of mortality score was 8 (IQR 4-13), 57% were mechanically ventilated and 67% were on vasopressors. DIC prevalence was 52% in AKI pts vs 19% in no AKI pts (p<0.001). DIC score was higher in AKI (4.27 (IQR3.85- 4.67) vs 2.25 (IQR1.92- 2.58) in no AKI (p<0.001)). In adjusted analysis controlling for severity of illness, mechanical ventilation, and vasopressor use, DIC presence (aOR 2.6 (95%CI 1.45-4.67)) and DIC score (aOR 1.33 (95% CI 1.17-1.51)) were both independently associated with AKI.

Conclusions: DIC is very common in pediatric septic AKI. Severity and presence of DIC are both independently associated with septic AKI. Mechanistic contribution of coagulation perturbations to septic AKI and identification of potential modifiable factors require further study.

PO0260

Midterm Renal Outcomes and Renal Recovery in Pediatric Continuous Renal Replacement Therapy

Sameer Thadani,[1] Dana Y. Fuhrman,[3] Claire Hanson,[3] Joseph A. Carcillo,[3] Poyyapakkam Srivaths,[1] Ayse Akcan Arikan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Most pediatric continuous renal replacement therapy(CRRT) outcome studies focus on crude mortality. Recent data highlighted incomplete recovery and dialysis dependency in pediatric acute kidney injury treated with dialysis. We described midterm outcomes and renal recovery in pediatric CRRT.

Methods: Multicenter cohort study between 2/14-2/20. Primary outcome was Major Adverse Kidney Events at 90 days(MAKE90), secondary outcome was renal recovery (noMAKE90 in survivors).

Results: 419 patients received CRRT for 9 days (IQR3-21) (age 93 mo (17-180), 51% male). PELOD2 was 9(7-14), 55% were ventilated, 67% were on vasoactives. 276(66%) patients had MAKE90 (61% dead, 21% dialysis dependent, 18% persistent renal dysfunction). ICU admission reason, peak mean airway pressure, thrombocytopenia, and leukopenia were associated with MAKE90. Urine output at CRRT start was independently associated with renal recovery, each ml/kg/h was associated with 47%(95%CI 12-235%) increased odds of renal recovery.

Conclusions: Majority of pediatric CRRT patients develop MAKE90. Worse lung disease requiring higher respiratory support is independently associated with MAKE90, while admissions for metabolic/endocrine reasons are more likely to survive with intact renal function. Urine output at CRRT start is an independent predictor of renal recovery among pediatric CRRT survivors.

AKI and Mortality in Patients Prescribed Immune Checkpoint Inhibitor Therapy

Megan L. Baker,[1] Yu Yamamoto,[1] Mark A. Perazella,[1] Chirag R. Parikh,[2] Francis P. Wilson,[1] Dennis G. Moledina.[1] *[1]Yale University Department of Internal Medicine, New Haven, CT; [2]Johns Hopkins Medicine, Baltimore, MD.*

Background: In patients on immune checkpoint inhibitor (ICI) therapy, acute kidney injury (AKI) is relatively common, and can occur from tubular injury or pre-renal azotemia unrelated to ICI use, or from off-target immune activation resulting in acute interstitial nephritis (AIN). The association of AKI and its specific etiologies with mortality is not known.

Methods: In participants initiated on ICI between 2013-2019, we tested the association of serum creatinine-based AKI with mortality up to 1 year after therapy initiation using Cox proportional hazard models controlling for demographics, comorbidities, cancer type, severity, therapy, and baseline laboratory values. In patients with AKI, we tested the association of AKI severity, AKI duration, and, using a validated risk score, AIN risk with mortality.

Results: Of 2,207 patients initiated on ICI therapy, 549 (25%) developed AKI. Mortality rate was higher in those who developed AKI (905 vs. 445 per 1000 person-years). AKI was independently associated with higher mortality [adjusted HR, 2.18 (95% CI, 1.38-3.45)] and this hazard was highest in the first month after AKI [9.7 (7.8-12.1)] and progressively diminished to the background rate by four months. Among patients with AKI, mortality was higher in those with severe AKI [2.03 (1.01-4.11)] and longer duration AKI [2.58 (1.01-6.60)], but lower in those with the highest likelihood of AIN [adjusted HR highest vs. lowest tertile, 0.07 (0.02-0.29)].

Conclusions: We noted that occurrence of AKI was independently associated with higher mortality in patients treated with ICI. Among patients with AKI, mortality was higher in those with severe AKI and longer duration AKI, but lower in those with features suggestive of AIN.

PO0262

Sodium-Glucose Cotransporter 2 Inhibitors and the Risk of AKI in Older Adults with Type 2 Diabetes

Min Zhuo,[1,2] Julie M. Paik,[2,3] Deborah J. Wexler,[4] Joseph V. Bonventre,[2] Seoyoung C. Kim,[2] Elisabetta Patorno.[2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital Department of Medicine, Boston, MA; [3]VA New England Geriatric Research Education and Clinical Center, Boston, MA; [4]Massachusetts General Hospital, Boston, MA.*

Background: We compared the association of AKI with the initiation of a sodium-glucose cotransporter-2 inhibitors (SGLT-2i) to the initiation of a dipeptidyl peptidase 4 inhibitor (DPP-4i) or a glucagon-like peptide 1 receptor agonist (GLP-1RA) in adults aged ≥ 66 years with type 2 diabetes (T2D).

Methods: In this nationwide cohort study, we used Medicare fee-for-service from 2013 to 2017 to identify older adults with T2D. SGLT-2i initiators were 1:1 propensity score (PS)-matched to DPP-4i or GLP-1RA initiators, in two pairwise comparisons. More than 100 variables were used in the PS model, including demographic characteristics, comorbid conditions, medication use, and health care utilization. The primary outcome was a hospital discharge diagnosis of AKI in the primary or secondary position. Cox proportional hazards regression models were used to generate hazard ratios (HRs) in PS-matched groups.

Results: A total of 68,130 and 71,477 SGLT-2i new users were PS-matched to new users of DPP-4i or GLP-1RA (**Table**), respectively. The risk of AKI was lower in the SGLT-2i group than the DPP-4i group (HR 0.71, 95% CI 0.65-0.76) or the GLP-1RA group (HR 0.81, 95% CI 0.75-0.87), over a median follow-up of 181 days.

Conclusions: Among older adults with T2D, initiating an SGLT-2i was associated with a reduced risk of AKI compared to initiation of a DPP-4i or GLP-1RA.

Table. Selected baseline characteristics of SGLT-2i versus DPP-4i and SGLT-2i versus GLP-1RA cohorts after PS-matching

Characteristic	SGLT-2i versus DPP-4i (Cohort 1, n=68,130 pairs)		SGLT-2i versus GLP-1RA (Cohort 2, n=71,477 pairs)	
Age, mean (SD), years	71.9 (5.1)	71.8 (5.2)	71.9 (5.1)	71.9 (5.2)

White	56,252 (82.6%)	56,245 (82.6%)	59,366 (83.1%)	59,070 (82.6%)
Acute kidney injury	2,225 (3.3%)	2,225 (3.3%)	2,977 (4.2%)	2,997 (4.3%)
Chronic kidney disease stages 3-5	5,525 (8.1%)	5,498 (8.1%)	8,237 (11.5%)	8,306 (11.6%)
Hypertension	62,857 (92.3%)	62,760 (92.1%)	66,464 (93.0%)	66,512 (93.1%)
Diabetic nephropathy	7,155 (10.5%)	7,046 (10.3%)	9,561 (13.4%)	9,647 (13.5%)
Heart failure	7,481 (11.0%)	7,520 (11.0%)	8,771 (12.3%)	8,788 (12.3%)
Combined comorbidity index (CCI), mean (SD)	1.2 (2.0)	1.2 (2.0)	1.5 (2.1)	1.5 (2.1)
Metformin	53,142 (78.0%)	53,319 (78.3%)	53,957 (75.5%)	53,925 (75.4%)
Insulin	19,153 (28.1%)	18,988 (27.9%)	22,904 (32.0%)	22,818 (31.9%)
GLP-1RA (cohort 1) or DPP-4i (cohort 2)	8,137 (11.9%)	7,595 (11.1%)	26,527 (37.1%)	26,787 (37.5%)
Renin-angiotensin-aldosterone system (RAAS) inhibitors	54,088 (79.4%)	53,823 (79.0%)	57,506 (80.5%)	57,846 (80.9%)
Endocrinologist visit	12,949 (19.0%)	12,520 (18.4%)	15,744 (22.0%)	15,871 (22.2%)
Nephrologist visit	2,955 (4.3%)	2,947 (4.3%)	4,280 (6.0%)	4,341 (6.1%)

Characteristics were measured during the 365 days before treatment initiation, standardized differences < 0.1

PO0263

Urine Sediment Examination: Comparison Between Laboratory-Performed vs. Nephrologist-Performed Microscopy

Adam Fawaz,[1] Elias Bassil,[1] James F. Simon,[1] Susana Arrigain,[1] Jesse D. Schold,[1] Remy Daou,[2] Ali Mehdi,[1] Jonathan J. Taliercio,[1] Georges Nakhoul.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Universite Saint-Joseph, Beirut, Lebanon.*

Background: Urinalysis is a commonly performed diagnostic test in clinical laboratories and automated urine technology is becoming the standard for providing urinalysis data to clinicians. Time constraints, and use of automated technology has resulted in clinicians no longer performing their own urine sediment exam. We believe that there is a critical value in performing this important unappreciated skill to improve patient care.

Methods: Using our Electronic Medical Records, we identified 140 adult in-patients with acute kidney failure that had urine microscopy with sediment analysis performed both by the laboratory and by a nephrologist within 72 hours of each other. We performed a chart review to determine the following: number of RBCs (≤ 5 or > 5 HPF), number of WBCs (≤ 5 or > 5 HPF), presence of casts (<1 or ≥ 1 LPF), type of casts (hyaline, fine granular, coarse granular, muddy brown, WBC casts, RBC casts and mixed cellular casts), and presence of dysmorphic RBCs. We used Kappa statistics to evaluate agreement between urine microscopy by lab versus by nephrologist reviews.

Results: The reported agreement was moderate for RBCs with 79% of samples in agreement (Kappa 0.54 – 95% CI: 0.39, 0.69), fair for WBCs with 74% of samples in agreement (Kappa 0.39 – 95% CI: 0.23, 0.54), and there was no agreement for casts (Kappa 0). Nephrologist detected 8 dysmorphic RBC's (Kappa 0) while the laboratory did not detect any. Additionally, the laboratory only detected hyaline and fine granular casts, while the nephrologist reported coarse Granular / muddy brown casts, RBC and WBC casts.

Conclusions: Urine sediment exam is an important procedure that provides evaluative information about kidney disease. In our study, we report a disagreement between laboratory vs. nephrologist performed analysis, notably for the recognition of structures that can provide important information in the diagnosis of acute tubular ischemia and glomerulonephritis. This highlights the importance of clinicians continuing to perform sediment exam.

Cast Group – lab review	Cast Group – nephrologist review					
Frequency	No	Hyaline or FG	CG or MBC	RBC	WBC	Total
No casts	22	25	23	0	2	72
Hyaline or FG cast	16	22	23	1	3	65
CG or MB cast	0	0	0	0	0	0
RBC cast	0	0	0	0	0	0
WBC cast	0	0	0	0	0	0
Total	38	47	46	1	5	137
Kappa 0.02 (95%CI:-0.08, 0.11)						

FG: Fine granular; CG: Coarse Granular; MB: Muddy Brown; RBC: Red Blood Cell; WBC: White blood cell

PO0264

Accuracy of Nephrologist Performed Urine Microscopy in Predicting Pathologic Diagnosis in Patients with AKI

Adam Fawaz,[1] Elias Bassil,[1] James F. Simon,[1] Susana Arrigain,[1] Jesse D. Schold,[1] Remy Daou,[2] Jonathan J. Taliercio,[1] Ali Mehdi,[1] Georges Nakhoul.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Universite Saint-Joseph, Beirut, Lebanon.*

Background: Urinalysis is a commonly performed diagnostic test in clinical laboratories and automated urine technology is becoming the standard for providing urinalysis data to clinicians. Time constraints, and automated technology reporting has resulted in a decline in clinicians performing their own urine sediment exam. We hereby look at the diagnostic accuracy of sediment suggested diagnoses in predicting the respective pathologic diagnoses

Methods: Using our Electronic Medical Records, we identified 33 adult patients with acute kidney injury with documented nephrologist performed urine microscopy and a kidney biopsy within one week of the sediment analysis. We performed chart review to ascertain the suggested diagnosis based on urine sediment analysis and compared it to the respective pathologic diagnoses identified on the subsequent kidney biopsy. We categorized the sediment findings into four categories: Bland, suggestive of acute tubular injury (sATI), suggestive of glomerulonephritis (sGN), and suggestive of acute interstitial nephritis (sAIN). Pathologic findings were categorized into ATI, GN, and AIN.

Results: The cohort demographics consisted of 18 (54.6%) male patients, 23 whites (69.7%), and a mean age of 56.6 years. Sediment analyses was bland in 6 patients (8.45%) with 5 (15.15%) sATI, 22 (66.67%) sGN, and no sAIN cases. All 5 cases with sATI on sediment analysis showed ATI on the kidney biopsy. Similarly, all 22 cases with sGN on the sediment had a pathologic diagnosis consistent with GN on the biopsy. Of the 6 patients with bland sediment analyses, 3 showed ATN pathologically while the other 3 had GN on the kidney biopsy

Conclusions: Urine sediment examination remains an important test than can provide important information about kidney disease. Our data shows 100% agreement between sediment analyses suggestive of ATI or GN and the pathologic diagnoses. This is important in patients in whom a kidney biopsy might be contraindicated precluding the luxury of a pathologic diagnosis. While a suggestive sediment analysis seems to carry a high predictive value, the negative predictive value of a bland sediment was low however. Overall, we believe urine sediment analysis is an important skill for the nephrologist with important patient care implications.

PO0265

Histopathological Confirmation of Acute Tubular Injury in Patients with "Muddy Brown" Granular Casts in the Urinary Sediment

Vipin Varghese, Akanksh Ramanand, Juan Carlos Q. Velez. *Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Microscopic examination of the urinary sediment (MicrExUrSed) can be a useful tool in the differentiation of acute kidney injury etiology. In particular, "muddy brown" granular casts (MBGC) are thought to be pathognomonic for acute tubular injury (ATI). However, the ability of MBGC to predict biopsy-proven ATI has not been formally examined. Thus, we hypothesized that the identification of MBGC by MicrExUrSed can accurately predict a histopathological diagnosis of ATI.

Methods: In a single-center prospective study, we selected cases of patients seen in nephrology consultation who had a urine specimen subjected to MicrExUrSed as part of the clinical evaluation. Within this cohort, we identified cases in which a kidney biopsy was performed within 2 weeks of the MicrExUrSed. Presence of MBGC in those cases was determined. We assessed the performance of identification of MBGC for the diagnosis of biopsy-proven ATI. Sensitivity, specificity, negative predictive values (NPV), and positive predictive values (PPV) of MBGC to diagnose ATI were determined.

Results: Among 371 patients in whom MicrExUrSed was completed, 49 underwent kidney biopsy and were included. Mean age was 61 years, 38% were women. White race accounted for 59% and black race accounted for 33%. Mean serum creatinine was 3.4 mg/dL. Biopsy diagnosis was ATI in 36 (73%) and non-ATI in 13 (27%). Among the 36 cases of biopsy-proven ATI, concomitant glomerular pathology was present in 19 (53%). The sensitivity of MBGC for biopsy-proven ATI diagnosis was 78% (95% CI 61-90%), while the specificity was 100% (95% CI 75-100%). The PPV of MBGC for ATI diagnosis was 100% (95% CI 100%) and the NPV was 62% (95% CI 47-93%).

Conclusions: Our data demonstrate that MBGC on MicrExUrSed are pathognomonic for ATI confirmed by kidney biopsy – with high PPV and specificity of 100%. While MBGC reflect ATI, concomitant glomerular pathology can be present in patients with MBGC in the urine sediment.

PO0266

Feasibility of Point-of-Care Solid Organ Doppler for Assessing Emergency Department Patients with AKI

Forrest F. Lindsay-McGinn, Christy Moore, Jeffrey A. Kramer, Nova Panebianco, Felipe Teran, Nathaniel C. Reisinger. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Acute kidney injury (AKI) in the emergency department (ED) portends worse in-hospital outcomes for patients. Point-of-care ultrasound (POCUS) can assist with volume assessment, which is critical to diagnose the underlying cause of AKI. We describe clinical and ultrasonographic characteristics of patients with AKI using a

POCUS protocol that examines hepatic, portal and interlobar renal vein spectral Doppler assessment previously described as the Venous Excess Ultrasound (VExUS) protocol which was found to predict AKI after cardiac surgery.

Methods: This is a prospective convenience sample of adult patients presenting to an academic, urban emergency department found to have AKI from September 2020 to May 2021. US images were obtained and interpreted by an US fellowship trained emergency medicine physician under the guidance of a certified vascular US technician. Spectral Doppler assessment of hepatic, portal, and interlobar renal veins were obtained. Hepatic vein dopplers were considered abnormal if the D wave was greater than the S wave. Portal vein Dopplers were considered abnormal if the pulsatility index was greater than 30%. Interlobar renal vein dopplers were considered abnormal if there was phasisity. The diagnosis of AKI was established by Kidney Disease Improving Global Outcomes criteria. The institutional review board approved this study.

Results: Thirty-seven patients were included. Median age was 63 and average BMI 29. 15 experienced stage 1 AKI, 5 had stage 2 AKI, 17 had stage 3 AKI. 7 required dialysis. 36 had an assessment of their inferior vena cava (IVC). 15 had an IVC >15mm with less than 50% respiratory collapse. Of the 15 patients with plethoric IVC assessments, 11 had interpretable hepatic vein Dopplers, 4 were abnormal. 14 had interpretable portal vein Dopplers, 6 were abnormal. 13 had interpretable interlobar renal vein Dopplers, 4 were abnormal. The most common reasons for uninterpretable Dopplers were difficulty holding expiration, arrhythmias and liver cirrhosis or masses.

Conclusions: Our study describes the feasibility of a POCUS assessment using solid organ spectral Doppler for emergency department patients with AKI. Further research is required to understand the test characteristics solid organ spectral Doppler for assessment of this population.

PO0267

Utility of a Point-of-Care Ultrasound Volume Assessment for Emergency Department Patients with AKI: A Pilot Study

Forrest F. Lindsay-McGinn, Christy Moore, Jeffrey A. Kramer, Nova Panebianco, Felipe Teran, Nathaniel C. Reisinger. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Acute kidney injury (AKI) identified in the emergency department (ED) portends worse in-hospital outcomes for patients. Point-of-care ultrasound (POCUS) for AKI is recommended to rule out obstructive uropathy but does not routinely include volume assessment, which may be informative regarding the underlying cause of AKI. POCUS evaluation of heart and lungs has proven to be useful in assessing intravascular volume status in patients on dialysis and with heart failure. This study aims to describe the clinical and ultrasonographic characteristics of patients with AKI using a POCUS volume assessment.

Methods: This is a prospective convenience sample of adult patients presenting to an academic, urban ED found to have AKI from September 2020 to May 2021. Ultrasounds were performed using 8-point lung, 5-point cardiac, kidney and bladder views. The diagnosis of AKI was established by Kidney Disease Improving Global Outcomes criteria. US images were obtained and interpreted by an US fellowship trained emergency medicine physician. The institutional review board approved this study.

Results: Thirty-seven patients were included. 22 were African American and 20 were male. Median age was 63 and average BMI was 29. Eight had documented CKD, 15 had diabetes, 24 had hypertension and 13 had heart failure. Prior to ultrasound assessment, 24 patients were assessed as hypovolemic, 4 as euvolemic, and 9 as hypervolemic by their emergency physician. Fifteen experienced stage 1 AKI, 5 had stage 2 AKI, and 17 had stage 3 AKI. Seven required dialysis during their admission. Two were found to have a bladder outlet obstruction and 4 were found to have bilateral, moderate to severe hydronephrosis. Thirty-seven had a left ventricular ejection fraction (EF) assessment, 21 had an EF >55%, 10 had an EF 30-55%% and 6 had an EF <30%. Four had right ventricular dilation. Thirteen had bilateral pulmonary B-lines suggestive of pulmonary edema. Thirty-six had an assessment of their inferior vena cava (IVC) and 15 had an IVC >15mm with less than 50% respiratory collapse.

Conclusions: Our study describes the findings of a POCUS volume assessment of ED patients with AKI. Abnormal cardiac and lung findings were common and may be a useful adjunct to IVC, kidney and bladder assessment alone.

PO0268

Addition of High-Dose Furosemide to Norepinephrine During Treatment of Hepatorenal Syndrome Type 1 Augments Diuresis and Does Not Halt Kidney Function Recovery

Kasra Tayebi,[1,2] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]The University of Queensland Ochsner Clinical School, Herston, QLD, Australia.*

Background: Withdrawal of diuretics is recommended as a first intervention in patients with cirrhosis who present with acute kidney injury (AKI) to eliminate prerenal factors. Moreover, diuretics are considered potential trigger for hepatorenal syndrome type 1 (HRS-1). As a result, diuretics are rarely utilized once the diagnosis of HRS-1 is made due to concerns for aggravating the clinical course. We hypothesized that after a prerenal state is ruled out and HRS-1 is diagnosed and properly treated with a vasoconstrictor, i.e., the mean arterial pressure (MAP) is effectively raised, use of diuretics is safe and effective

Methods: We search records of patients hospitalized at Ochsner Medical Center over a 3 year period who received intravenous (IV) furosemide (FURO) while receiving IV norepinephrine (NE) as a vasoconstrictor specifically for treatment of AKI due to HRS-1. We assessed the change in urine output (UOP) and the trajectory of serum creatinine (sCr) values before and after the initiation of NE and before and after the addition of FURO.

Results: A total of 19 patients with HRS-1 received IV FURO [median duration: 2 (1-8) days); median dose: 160 (80-240) mg boluses q6-24 h)] added to IV NE during the study period. Median age was 52 (31-69) years; 89% white race, 53% women, median MELD score 32 (22-41). At the time of initiation of FURO, median sCr was 3.8 (1.7-7.9) mg/dL. Before initiation of any therapy, the median UOP was 275 (10-695) ml/day. NE alone led to a median increase in UOP to 530 (200-2150) ml/day (p=0.013). Addition of FURO to NE induced a subsequent increase in median UOP to 2045 ml/day (p<0.0001), i.e., median gain in UOP of 1605 ml/day. Fifteen (79%) patients treated with NE+FURO [w/median MAP rise 15 (11-24) mmHg] either maintained or improved the sCr trajectory consistent with kidney recovery and not needing dialysis. The magnitude of NE-induced rise in MAP significantly correlated with the average UOP achieved during the days of combined NE+FURO therapy (R=0.48, p=0.03).

Conclusions: In patients with HRS-1 who are adequately treated with NE and achieved an optimal MAP increment, addition of high-dose IV FURO enhances diuresis without negatively affecting recovery of kidney function.

PO0269

Responsiveness to Vasoconstrictor Therapy in Hepatorenal Syndrome Type 1

Jason R. Ledoux,[1] Swetha Rani Kanduri,[1] Juarez R. Braga,[2] Kasra Tayebi,[3] Destiney A. Mundy,[1] Kevin Scharwath,[1] Kateryna A. Poole,[1] Catherine Wentowski,[1] Juan Carlos Q. Velez.[3,1] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]University of Arkansas for Medical Sciences, Little Rock, AR; [3]The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.*

Background: We previously reported that raising mean arterial pressure (MAP) during treatment of hepatorenal syndrome type 1 (HRS-1) with vasoconstrictors (VC) is associated with improvement in kidney function. However, the optimal MAP target and factors associated with response to VC remain unclear.

Methods: Records from hospitalized patients with HRS-1 treated with VC without shock were reviewed. We selected those who achieved ≥ 5 mmHg rise in MAP within 48 hours. We examined the relationship between the mean MAP achieved during the 1st 72 hours of VC therapy and the change in kidney function at 7-14 days as determined by serum creatinine (sCr). The primary (1ry) endpoint was > 30% reduction in sCr without need for dialysis or death at day 14. Secondary (2ry) endpoint was change in slope of sCr from positive (worsening) to negative (improving) by day 7.

Results: A total of 74 patients with HRS-1 treated for 2-7 days with either midodrine/octreotide (n=28) or norepinephrine (n=46) were included. Median age was 53 (IQR 46-60), 41% were female and 47% had alcoholic cirrhosis. At start of VC, median MAP was 70 mmHg (IQR 66-73) and median sCr was 3.8 mg/dL (IQR 2.6-4.9). When analyzed based on tertiles of mean MAP increment (5-9, 10-14, ≥ 15 mmHg), there was a significant trend for greater reduction in sCr with greater rise in MAP (ANOVA, p<0.0001). When analyzed based on tertiles of achieved absolute MAP (65-74, 75-84, ≥ 85 mmHg), there was a non-significant trend for greater reduction in sCr with higher absolute MAP (p=0.06). The 1ry and 2ry endpoints were met by 25 (34%) and 42 (57%) patients, respectively. By multivariate logistic regression analysis, mean MAP rise in 1st 72 hrs had an OR 1.18 (95% CI 1.04-1.34; p=0.012) for meeting the 1ry endpoint and an OR 1.22 (95% CI 1.07-1.40; p=0.003) for the 2ry endpoint. Neither age, sex, MELD score, baseline sCr nor baseline MAP were predictive of any endpoint.

Conclusions: Greater magnitude of rise in MAP with VC therapy in HRS-1 is associated with greater improvement in kidney function. Targeting an increment of MAP ≥ 15 mmHg may lead to favorable kidney-related outcomes. No other demographic or clinical variables predicts response to VC therapy, highlighting the need for biomarker development.

PO0270

Rates of In-Hospital Decongestion and Association with Cardiovascular Outcomes Among Patients Admitted for Acute Heart Failure

Wendy I. McCallum,[1] Hocine Tighiouart,[1] Jeffrey M. Testani,[2] Matthew Griffin,[2] Marvin Konstam,[1] James Udelson,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Yale University School of Medicine, New Haven, CT.*

Background: Decongestion is an important goal in the management of acute heart failure (HF) among patients with heart failure with reduced ejection fraction (HFrEF), but whether the rate of decongestion is associated with cardiovascular (CVD) outcomes is unknown.

Methods: Using data from the Efficacy of Vasopressin Antagonism in Heart Failure Outcome Study With Tolvaptan (EVEREST) trial, we used multivariable Cox regression models to evaluate the association between the rate of in-hospital change in assessments of volume overload, including b-type natriuretic peptide (BNP), N-terminal prob-type natriuretic peptide (NT-proBNP) and clinical congestion score (0-12), as well as change in hemoconcentration including measures of hematocrit, albumin and total protein with risk of the trial's primary endpoint of a composite outcome of CVD mortality or HF hospitalization.

Results: Among 3500 patients with median 10 month follow-up, 1369 (39%) experienced the composite outcome of CVD mortality or HF hospitalization. There were no differences in baseline kidney function between those in the quartile of most rapid decongestion compared to least rapid (mean eGFR 59±23 vs 57±23 ml/min/1.73m^2, respectively). Overall, despite in-hospital eGFR decline with decongestion (-0.2 ml/min/1.73m^2 per day), faster decongestion was associated with decreased risk of both CVD mortality and HF hospitalization (Table).

Conclusions: Among patients with HFrEF admitted for HF, achievement of faster rates of decongestion is associated with reduced risk of CVD mortality and HF hospitalization. Whether this suggests that either more rapid decongestion provides cardiovascular benefit, or whether the ability to rapidly decongest is a proxy for a healthier individual, remains to be further evaluated.

		Quartile 1. Least rapid decongestion	Quartile 2	Quartile 3	Quartile 4. Most rapid decongestion
Volume Overload	BNP	1.00 (1.00, 1.00)	0.69 (0.57, 0.83)	0.62 (0.51, 0.75)	0.46 (0.37, 0.58)
	NT-proBNP	1.00 (1.00, 1.00)	0.98 (0.79, 1.21)	0.78 (0.62, 0.98)	0.52 (0.40, 0.68)
	Congestion Score	1.00 (1.00, 1.00)	0.92 (0.79, 1.08)	0.88 (0.75, 1.04)	0.91 (0.77, 1.09)
Hemoconcentration	Hematocrit	1.00 (1.00, 1.00)	0.90 (0.77, 1.06)	0.82 (0.70, 0.97)	0.71 (0.60, 0.84)
	Albumin	1.00 (1.00, 1.00)	0.96 (0.83, 1.13)	0.82 (0.70, 0.97)	0.75 (0.63, 0.88)
	Total Protein	1.00 (1.00, 1.00)	0.90 (0.77, 1.05)	0.88 (0.74, 1.03)	0.71 (0.59, 0.84)

*Adjusted for: age, sex, race, randomization group (tolvaptan vs placebo), body mass index, medication use (angiotensin converting enzyme inhibitor or angiotensin II receptor blocker, mineralocorticoid receptor antagonist), ejection fraction, New York Heart Association functional class, systolic blood pressure, eGFR at discharge and respective baseline biomarker level

Abbreviations: BNP, b-type natriuretic peptide; NT-proBNP: N-terminal pro b-type natriuretic peptide; HF, heart failure

PO0271

Effect of Intensive vs. Standard Blood Pressure Targets on AKI and Subsequent Cardiovascular Outcomes and Mortality

Paul E. Drawz,[1] Nicholas M. Pajewski,[2] Nayanjot Kaur Rai,[1] Kristin M. Lenoir,[2] Areef Ishani.[1] *[1]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [2]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Using linked electronic health record (EHR) data, this study evaluated the effect of intensive vs. standard blood pressure (BP) treatment in SPRINT on acute kidney injury (AKI) and whether incident AKI was associated with cardiovascular disease (CVD) and mortality.

Methods: Inpatient AKI was defined by a) serious adverse event (SAE) reports based on diagnosis codes and admission and discharge notes and b) a 50% or ≥0.3mg/dl increase in creatinine using EHR labs. Outpatient AKI was defined by a 50% increase in creatinine using EHR labs, compared to the most recent creatinine measured in trial follow-up. Cox regression was used to evaluate the effect of intensive BP lowering on the incidence of AKI, and to examine the time-varying association between incident AKI and CVD and mortality.

Results: 3321 participants (1690 intensive vs 1631 standard) had linked EHR data. The mean age was 69 years, 23% were female, and 29% were black. More inpatient AKI events were identified using EHR labs (162 intensive vs 137 standard) as compared to SAE reporting in the trial (87 intensive vs 56 standard). Outpatient AKI similarly occurred more frequently with the inclusion of EHR labs (216 intensive vs 156 standard). Intensive treatment was associated with an increased risk for inpatient AKI based on SAE reports (HR 1.48, p=0.02) and for outpatient AKI (HR 1.36, P=0.004), but not for inpatient AKI based on EHR labs (HR 1.16, P=0.21). Irrespective of the definition, the incidence of AKI was associated with increased risk for all-cause mortality in adjusted analyses, but not with incident CVD. Despite this increased risk, intensive treatment reduced the risk of all-cause mortality (HR 0.57, P<0.001) in this subset of SPRINT participants.

Conclusions: Lab based ascertainment of AKI, facilitated by the EHR, may be more sensitive and less biased than traditional SAE reporting, particularly for open-label trials and for capturing more frequent outpatient AKI events. Given that inpatient and outpatient AKI were associated with increased risk for all-cause mortality, identifying ways to prevent AKI may reduce mortality even further with intensive BP lowering.

PO0272

Fostering Scientific Innovation to Impact AKI: A Roadmap from the AKI!Now Basic Science Workgroup

Samir M. Parikh,[1,2] Anupam Agarwal,[3] Amandeep Bajwa,[4] Sanjeev Kumar,[5] Sherry Mansour,[6] Mark D. Okusa,[7] Jorge Cerda.[8] AKI!Now Basic Science Workgroup *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]The University of Texas Southwestern Medical Center, Dallas, TX; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [5]Cedars-Sinai Medical Center, Los Angeles, CA; [6]Yale University School of Medicine, New Haven, CT; [7]University of Virginia, Charlottesville, VA; [8]St. Peter's Health Partners, Albany, NY.*

Background: The American Society of Nephrology convened a new initiative in 2020, *AKI!Now*, to promote excellence in the prevention and treatment of acute kidney injury (AKI). *AKI!Now*'s interests are broad, spanning molecular and cell biology research through provider education and patient advocacy. Here we describe current efforts of *AKI!Now*'s Basic Science Workgroup to foster innovation in the prevention, diagnosis, and treatment of AKI by leveraging fundamental discoveries. Both in hospitals and the community, the incidence of AKI is high and increasing worldwide. For the individual patient, severe AKI is a life-altering event with profound future consequences. At the societal level, AKI is increasingly recognized as a major public health burden.

Methods: We propose the following goals to promote collaborative and inclusive discovery research that could translate more effectively to our patients:

Results: (1) to develop a centralized portal that provides a living resource for the research community and access to open data sources; (2) to lower entry barriers for researchers interested in AKI by developing interactive educational content; (3) to promote greater collaboration between AKI basic researchers, translational investigators, and researchers in other fields; (4) to articulate a preclinical roadmap that facilitates the development of novel interventions; and (5) to enhance communication around AKI innovation by fostering an open and vibrant community of patients, researchers, clinicians, and other stakeholders.

Conclusions: State-of-the-art medical care of AKI patients remains reactive and supportive. No targeted treatment has yet been identified to prevent this syndrome or hasten the recovery to health. Lowering barriers for new entrants and increasing opportunities for collaborations across a wide spectrum of stakeholders may help promote a culture of innovation to impact AKI.

PO0273

Telenephrology (TN) vs. Face-to-Face (F2F) Visits: A Comparison of Inpatient Nephrology Outcomes and Provider Perspectives

Lagu A. Androga, Priya Ramar, Rachel H. Amundson, Andrea G. Kattah, Bjoerg Thorsteinsdottir, Ziad Zoghby, Lindsey M. Philpot, Robert C. Albright. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Clinical outcomes, patient, and provider perspectives on inpatient synchronous telenephrology care remain largely unstudied. In this retrospective study, we compared outcomes in patients who received inpatient synchronous TN plus F2F (cases) versus only F2F (controls) at two Mayo Clinic Health System (MCHS) community hospitals

Methods: Hospitalized adults who had nephrology consults from 3/1/2020 to 2/28/2021 were classified in several diagnoses groups. Logistic regression was used to assess 30-day mortality, readmissions, and hospital transfers. Penalized regression was used in the case of rare events. Negative binomial regression was fit to account for overdispersion in length of hospital stay data. Unadjusted and Adjusted odds ratio with 95% confidence intervals were calculated. We used structured surveys to evaluate the perspectives of non-nephrology hospital providers and tele-nephrologists

Results: A total of 850 patients were included. Mean age was 69 years, 59% were male and 93% white. Cases were more likely to get dialysis after a TN consult; OR: 1.80 (1.00, 3.22). Other outcomes were not statistically different (Table 1). Both non-nephrology hospital providers and tele-nephrologists reported the most frequent reasons for consults were AKI, ESRD, electrolytes, or acidosis. Tele-nephrologists preferred video consults (82%) to phone for communication. More than half (64%) of tele-nephrologists spent less time on TN compared to F2F consults. Non-nephrology hospital providers were very satisfied 10 (48%) and satisfied 6 (29%) with TN response time, and most felt TN was as safe as F2F (67%) and provided them enough information to make patient care decisions (76%)

Conclusions: Outcomes for in-hospital nephrology consults were similar between telenephrology plus face-to-face and face-to-face. Non-nephrology hospital providers and tele-nephrologists had favorable opinions for TN and most thought it is as safe as F2F consults

Table 1: Hospitalized Patient outcomes comparing TN plus F2F versus F2F consults

Outcome	Unadjusted Odds ratio (95% Confidence Interval)	p-value	Adjusted Odds ratio (95% Confidence Interval)*	p-value
Hospital transfer	1.13 (0.36, 3.54)	0.83	1.19 (0.37, 3.82)	0.77
Length of stay	0.94 (0.83, 1.05)	0.27	0.94 (0.84, 1.06)	0.34
30-day Readmission	0.86 (0.53, 1.39)	0.53	0.97 (0.61, 1.52)	0.88
Death within 30 days	0.94 (0.62, 1.42)	0.76	0.90 (0.58, 1.40)	0.63
Dialysis	1.24 (0.88, 1.74)	0.23	1.24 (0.79, 1.94)	0.36

PO0274

Renal Cytosolic Phospholipase A2 Mediates AKI in Humans

Evans O. Asowata,[1,2] Fynn N. Krause,[3] Simone Romoli,[1] Stephanie Ling,[4] Jennifer Y. Tan,[4] Barbara Musial,[1] Margaret M. Huang,[2] Krishnaa T. Mahbubani,[2] Julian L. Griffin,[3] Pernille B. Laerkegaard Hansen,[5] Kourosh Saeb-Parsy,[2] Kevin Woollard.[1] *[1]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [2]Department of Surgery, School of Clinical Medicine, University of Cambridge, Cambridge, United Kingdom; [3]Department of Biochemistry, University of Cambridge, Cambridge, United Kingdom; [4]Clinical Pharmacology & Safety Science, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [5]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: Increasing evidence suggests that cytosolic phospholipase A2 (cPLA2) and prostaglandin E2 (PGE2) drive the progression of various forms of kidney disease. Whether renal cPLA2-dependent PGE2 production significantly contributes to the progression of acute kidney injury (AKI) in humans is currently unknown. We compared the lipidomic and metabolomic profile of kidneys from deceased transplant organ donors with or without AKI and used molecular and tissue culture techniques to investigate the role of cPLA2-PGE2 pathway in AKI.

Methods: Kidneys with or without AKI were collected from deceased human transplant organ donors (non AKI: 10 kidneys from 7 donors and AKI: 12 kidneys from 8 donors). We used LC-MS and mass-spectrometry imaging (MSI) to investigate the abundance of relevant metabolites, RT-PCR and Western blotting were used to examine the levels of lipid enzymes and PGE2 levels were investigated by ELISA. To determine whether cPLA2-PGE2 pathway mediates AKI, we stimulated RPTEC and human kidney organ culture using interleukin-1β (IL-1β) and cPLA2 inhibitor and investigated changes in kidney injury markers.

Results: To validate this human model of AKI, kidney injury (KIM-1 and NGAL) and inflammatory (IL-1β and IL-6) markers were significantly higher in kidneys collected from donors with AKI compared to kidneys collected from donors without AKI. Lipidomics showed significantly lower levels of phosphatidylcholine (PC) species (PC 29:1, 31:1, 32:4 and 35:5) and MSI showed significantly higher abundance of arachidonic acid and prostaglandins in kidneys from donors with AKI. Kidneys from donors with AKI demonstrated significant upregulation of cPLA2 mRNA and protein, and higher levels of PGE2, compared to kidneys without AKI. cPLA2 inhibitor significantly reduced PGE2 and kidney injury markers in IL-1β-stimulated RPTEC and human kidney organ culture model.

Conclusions: Lipidomics, MSI and molecular data identify changes in the PC-cPLA2-PGE2 pathway in human kidneys obtained from AKI donors. The inhibition of cPLA2 ameliorates kidney injury *in vitro* suggesting that this enzyme is a key driver of AKI in humans.

PO0275

Quantitative Proteomics Analysis Identifies Novel Markers of AKI, CKD, and AKI-to-CKD transition in Human Kidneys

Sethu M. Madhavan,[1] John P. Shapiro,[1] Michael T. Eadon,[2] Tarek M. El-Achkar,[2] Pierre C. Dagher,[2] Emilio D. Poggio,[3] Robert D. Toto,[4] Chirag R. Parikh,[5] Francis P. Wilson,[6] Krzysztof Kiryluk,[7] Brad H. Rovin,[1] Samir V. Parikh.[1] Kidney Precision Medicine Project (KPMP) *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Indiana University Purdue University at Indianapolis, Indianapolis, IN; [3]Cleveland Clinic, Cleveland, OH; [4]The University of Texas Southwestern Medical Center, Dallas, TX; [5]Johns Hopkins University, Baltimore, MD; [6]Yale University School of Medicine, New Haven, CT; [7]Columbia University, New York, NY.*

Background: The etiology of AKI is multifactorial and is associated with in-hospital mortality and progression to CKD. Molecular phenotypes that are shared across AKI, CKD and the transition are unclear but may characterize common injury mechanisms that can be targeted for kidney preservation. We hypothesize that molecular interrogation of the kidney tubulointersitium (TI) will identify proteomic signatures that reflect AKI, AKI to CKD transition and CKD progression.

Methods: Frozen kidney biopsies from 4 CKD and 3 AKI patients obtained from recruitment sites in the Kidney Precision Medicine Project were used for this study and compared to nephrectomy controls (n=4). TI was isolated using laser microdisseciton and recovered proteins were submitted for HPLC MS/MS proteomic analysis using Orbitrap eclipse mass spectrometer. Label-free quantification and global normalization of spectral count data was performed to determine changes in protein expression.

Results: Protein signatures demonstrating cell proliferation and migration (MAP1B, PPFIBP1, RASAL1, NT5C2, PITPNM1, S100A4, XRN1, MNDA, SRM, MAMDC2) and extracellular matrix regulatory proteins (VCAN, POSTN, TNC, PXDN, ITGB6, THBS2, FBLN5, COLGALT1) were upregulated in AKI while cell-cell adhesion and extracellular matrix expansion (COL7A1, POSTN, FBLN5, ELN, VCAN, FERMT3, A1BG, MRC1, CP, STAB1, TIMP3, ITIH3, MFAP4, TNC), cell proliferation (MAP1B, PTPRC, NIBAN1, FUBP1, S100A, PPFIBP1, ARHGDIB) and inflammation markers (C2, SAMHD1, IL16, C7) were upregulated in CKD compared to controls. Overall, 57% and 28% of up- and downregulated proteins in AKI, were shared in CKD and may reflect AKI to CKD transition.

Conclusions: Proteomic analysis of the TI identified known and novel markers specific to AKI and CKD. Additionally, activation of common inflammatory and extracellular matrix remodeling proteins in AKI and CKD settings suggests that unified pathways activated in the TI could underlie AKI to CKD progression. The causal role of these candidate markers in the pathogenesis of AKI and CKD needs to be better defined, but if validated, targeting these pathways could help arrest tissue injury and limit disease progression. This work is ongoing.

PO0276

Leishmania infantum-Induced Acute on Chronic Interstitial Nephritis

George Vasquez-Rios,[1] Luis F. Sanchez Russo,[1] Sergio Dellepiane,[1] Fadi E. Salem,[2] Lili Chan,[1] Tonia K. Kim.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Leishmania is an exceedingly rare yet important cause of acute and chronic interstitial nephritis (CIN) that can lead to severe renal dysfunction, necessitating dialysis if unaddressed.

Case Description: A 53-year-old man presented with a progressive rash, cyclic fevers, 20 kg weight loss over 1 year, and prominent hepato-splenomegaly. He resided in Russia and had traveled to South Asia and Africa multiple times. Due to compressive symptoms and pancytopenia, the patient underwent splenectomy and lymph node biopsy which yielded *Leishmania infantum* (Figure 1A). In our institution, he was oliguric and hypertensive. Labs showed Na 129, K 5.3, HCO_3 8.8, BUN 144, Cr 12.6 mg/dL (baseline Cr 0.8 last year), and elevated LFTs. UA showed ATN casts. 24-hour urine protein was 1.8 grams. SPEP/UPEP and K/L ratio were normal. Due to concerns for AIN, CIN, infectious GN vs. amyloidosis, a kidney biopsy was pursued after HD initiation. Biopsy revealed chronic active tubulointerstitial nephritis associated with marked interstitial plasma cell infiltrates and moderate fibrosis without evidence of glomerular disease (Figure 1B). Amphotericin B was started. Steroids were not initiated given moderate fibrosis and risk for blunting response against Leishmania. His rash and LFTs improved rapidly yet, he required HD 3 times a week at discharge. 9 weeks after amphotericin initiation, his HD requirement is now reduced to twice weekly and pre-HD creatinine levels continue to decrease.

Discussion: Leishmaniasis is a rare cause of kidney injury in the US. CIN is the most common underlying pathology in these patients. A high index of suspicion in the appropriate clinical context is necessary to institute timely interventions to prevent long-term sequelae. Patients with visceral leishmania and kidney dysfunction should be evaluated for interstitial nephritis as a potential cause when alternative etiologies have been ruled out.

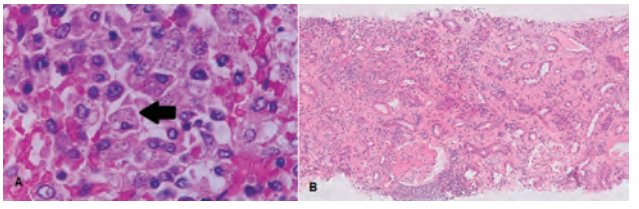

Figure 1: A. Lymph node with Leishmania amastigotes seen as a cytoplasmic organisms in macrophages (arrow) **B.** Kidney biopsy shows diffuse active interstitial inflammation with a background of interstitial fibrosis and frequent tubular injury (H&E).

PO0277

Too Much of a Good Thing: A Case Report of Suspected Acute Tubular Necrosis Potentiated by Hypervitaminosis D

Kevin V. Benavente,[1] Meghna P. Peesapati,[1] Mark Knox.[2] *[1]Marian University College of Osteopathic Medicine, Indianapolis, IN; [2]Hilo Medical Center, Hilo, HI.*

Introduction: While Vitamin D deficiency is prevalent in the United States, vitamin D toxicity remains a rare pathology. More novel is the incidence of acute kidney injury facilitated by calcitriol toxicity, with a Pubmed search yielding less than twenty results, a majority of which come from foregin journals. Tubular injury propagated by calcitriol has been demonstrated both in vivo, and from biopsies in even fewer case reports.

Case Description: A middle age man presented to the ED after routine labs demonstrated an acute kidney injury approximately four times his baseline creatinine, with mildly elevated hypercalcemia. Creatinine was within normal limits 1 year prior. Workup for his hypercalcemia revealed a markedly elevated 25 vitamin D >480, exceeding the quantifiable limit of the lab equipment. The patient reported a two week history of vitamin D supplementation of approximately 210,000 IU daily. Even with stabilization of his hypercalcemia, fluid resuscitation, and cessation of his supplements, the patient did not recover his baseline kidney function at discharge, nor at follow-up three months later. The patient had no medical history predisposing him to chronic kidney disease, with labs non-contributory for any other nephritic or nephrotic process, but suggesting an intrinsic, tubular pathology. With other etiologies essentially ruled out, in the setting of recent consumption of massive amounts of Vitamin D, the diagnosis of ATN secondary to hypervitaminosis D was suspected.

Discussion: Hypercalcemic AKI, at calcium levels as high as 19.9 mg/dL, typically resolves with treatment within 1-2 weeks; this patient failed to resolve, suggesting an additional insult. In calcitriol-induced AKI, toxicity of excess free Vitamin D metabolites exceeds the capacity of neutralizing vitamin D binding proteins. In vitro, calcitriol potentiates ATP depletion, and cytotoxicity of renal tubular cells even in the absence of hypercalcemia. In vivo, excess calcitriol exacerbates cellular azotemia by 2-3 times even with only modest hypercalcemia. Similar case reports describe biopsy evidence of tubular injury caused by vitamin D toxicity, with recovery of baseline creatinine taking between 3 months to 2 years. As incidence of vitamin intoxication increases, vigilance toward the harms of these supplements are important to recognize in healthy patients presenting with AKI.

PO0278

An Unusual Case of Tubulointerstitial Nephritis with Uveitis (TINU) Syndrome Associated with Alendronic Acid

Toni Sabbouh, Benjamin R. Wagner, Samer Akrawi, Cathryn J. Lapedis, John T. Ludwig. *University of Michigan, Ann Arbor, MI.*

Introduction: Tubulointerstitial nephritis and uveitis (TINU) syndrome is rare; while no etiology is identified, in 50% in the remaining it is typically seen with autoimmune or infectious diseases, and medications (nonsteroidal antiinflammatory drugs (NSAIDs)). Bisphosphonate nephropathy has been described causing renal lesions such as collapsing focal segmental glomerulosclerosis, acute tubular necrosis, or very rarely tubulointerstitial nephritis. To the contrary, bisphosphonates are known to cause a variety of ocular side

effects, including uveitis. To our knowledge, TINU syndrome has not been reported with bisphosphonate use.

Case Description: 77 year-old female with a history of hypertension on lisinopril, osteoporosis on alendronic acid for 2 years, baseline creatinine of 0.7 mg/dl, was admitted for worsening renal function. On labs obtained 3 weeks prior to presentation, her creatinine was 1.46 mg/dl. Around that time, she was being treated for an "iritis" episode. Despite holding her lisinopril and alendronate, her creatinine was found to be 3.53 mg/dl 1 day prior to admission. Patient was stable and her exam was unremarkable. Review of system was positive for frothy urine. She denied NSAIDs or antibiotics use. Labs revealed a non-anion gap acidosis and a creatinine of 3.2 mg/dl. Urinalysis showed sterile pyuria and microscopic hematuria; urine protein-creatinine ratio was 1.97. Renal ultrasound was unremarkable. Her autoimmune, infectious, and monoclonal gammopathy workups were negative. A renal biopsy revealed a lymphocytic predominant severe interstitial nephritis with focally destructive tubulitis and edema. During her admission, she developed recurrence of her ocular involvement and was diagnosed with anterior uveitis by ophthalmology. As a result, a diagnosis of TINU syndrome secondary to alendronic acid use was made. Patient was started on 1 mg/kg of daily prednisone and discharged after 5 days of hospitalization. Her creatinine was 1.82 mg/dl 1 week later, and 0.98 mg/dl 3 weeks later.

Discussion: Association of Bisphosphonates use and TINU syndrome has not been reported. Prompt recognition of this rare complication and drug discontinuation are crucial to the management. In our patient, since discontinuation of medication did not improve her renal function, we treated her with steroids, with excellent response.

PO0279

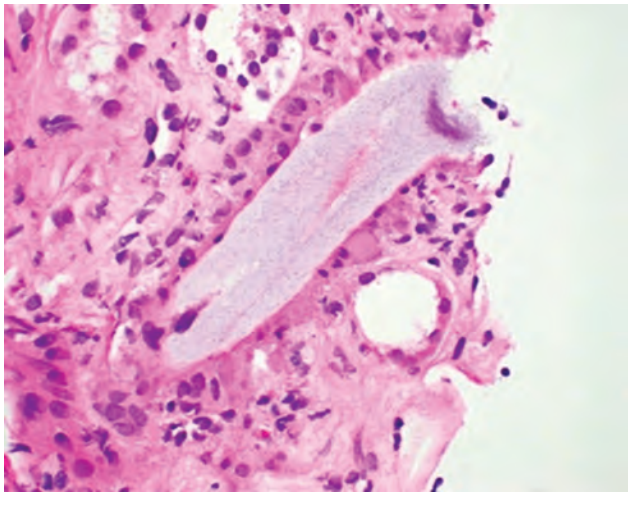
AKI Associated with Hydrophilic Polymer Embolism: A Case Report

Alejandro J. Ruiz Toledo,[1,2] Nima Hosseinian,[1,2] Maryam Qadir.[3] *[1]UCF/HCA Healthcare GME, Greater Orlando, Orlando, FL; [2]Department of Internal Medicine, University of Central Florida College of Medicine, Orlando, FL; [3]Orlando VA Healthcare System, Orlando, FL.*

Introduction: Minimally invasive endovascular procedures have become increasingly popular. Technology has improved, allowing the use of hydrophilic polymers to coat surgical tools such as catheters, guidewires, and sheaths to reduce vasospasm and trauma to vessels. However, a complication of using hydrophilic polymers is embolization of the material to distal small arteries, causing ischemia of organs such as the lung, brain and kidneys. Although hydrophilic polymer embolization has recently increased in recognition, only a few cases of renal embolization have been reported.

Case Description: Here we present the case of a 73-year-old male with history of peripheral artery disease and no previous diagnosis of kidney disease who was admitted to the hospital due to acute oliguric acute kidney injury (AKI), four weeks after undergoing an endovascular aneurysm repair with aorto-uni-iliac stent, right femoral endarterectomy and right femoral-popliteal bypass. Laboratory work-up such as complement levels, viral and antibody serologic testing were unremarkable. His hospital course was complicated by anuria, hyperkalemia and hyperphosphatemia. Kidney biopsy (figure 1) showed a foreign material consistent with a hydrophilic polymer embolism, as well as histiocytes with similar ingested foreign material, along with atheromatous emboli, and mild to moderate interstitial fibrosis. Treatment was supportive, including renal replacement therapy (RRT), with improvement in kidney function to the point of having adequate urinary output, no electrolyte derangements and no further need for RRT at discharge.

Discussion: In this case report, we compare our findings to other reported cases of hydrophilic polymer emboli to increase awareness of this under-recognized cause of organ dysfunction.



H&E stain showing arteriole occluded by hydrophilic polymer emboli.

PO0280

A Nutty Case of Oxalate Nephropathy

Nandakishor Kapa,[1] Kuang-Yu Jen,[1] Lana Gafter,[2] Nasim Wiegley.[1] *[1]University of California Davis Medical Center, Sacramento, CA; [2]Summit Nephrology Medical Group, Inc., Roseville, CA.*

Introduction: Oxalate nephropathy occurs when considerable amounts of calcium oxalate crystals deposit in the renal parenchyma. Excessive dietary intake of oxalate-rich foods (including some associated with healthy eating) in otherwise healthy individuals can lead to secondary oxalate nephropathy. We report a case of severe AKI related to excessive nut consumption.

Case Description: A 41-year-old man with history of Hashimoto's disease and pancytopenia presented to the hospital with 1 week of nausea and vomiting. Evaluation showed AKI with elevated serum creatinine (19.9 mg/dL), BUN (229 mg/dL), hematuria, and proteinuria (urine protein/creatinine ratio 1.6 gm/gm). Serologic workup showed mildly elevated kappa/lambda ratio (3.52) and low C3 (71mg/dL) but was otherwise unremarkable. Serum uric acid was high at 11.6 mg/dL. Renal ultrasound revealed normal kidney size with increased parenchymal echogenicity and punctate echogenic foci bilaterally. A renal biopsy was performed demonstrating widespread oxalate deposition with associated interstitial inflammation and tubular injury. Further history revealed no recent medications, infections, or ingestions, but did uncover a high intake of nuts (~1 pound) daily over the prior 1 year due to their perceived health benefits. He remained hemodialysis dependent on hospital discharge.

Discussion: Secondary oxalate nephropathy can result from increased enteric oxalate availability from dietary consumption. Diagnosis can be delayed when a review of diet and supplements is deferred. It is therefore essential to obtain a detailed dietary and pharmacologic history, particularly in all patients with unexplained kidney disease. Treatment is supportive including decreasing the high oxalate culprit foods in the diet.

PO0281

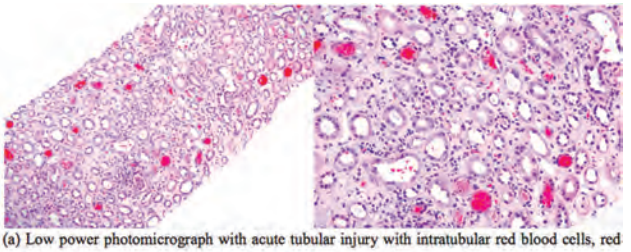
Case Report of Rivaroxaban-Induced Anticoagulant-Related Nephropathy

Remy Fadel,[1,2] Raiya Habib,[4] Patrick D. Walker,[3] Paul A. Alfino,[1,2] Joel D. Murphy,[3] Ayesha Kaleem.[1,2] *[1]North Florida Regional Medical Center, Gainesville, FL; [2]University of Central Florida, Gainesville, FL; [3]Arkana Laboratories, Little Rock, AR; [4]Dow Medical College, Karachi, Pakistan.*

Introduction: Anticoagulant related nephropathy (ARN) is still an under recognized etiology of acute kidney injury (AKI). There are no guidelines for ARN treatment to date and the literature consists mostly of case reports. While early detection of AKI remains the most important treatment, discontinuing the offending agent and antidote administration are also crucial. Other measures utilized include administering fluids and urine alkalinization to minimize red cell precipitation.

Case Description: Our patient is a 63-year-old Hispanic male treated with Rivaroxaban for atrial fibrillation. He started experiencing increased hemorrhaging with progressive worsening kidney function over two months. His serum creatinine (sCr) increased to 3.35mg/dL from 0.83mg/dL. Initial work up only revealed hematuria on a urinalysis. Serologies including auto-immune and hepatitis panels were negative. Subsequently, a renal biopsy done revealed chronic IgA nephropathy and acute tubular injury with prominent RBC casts and intratubular red blood cells. This was suggestive of ARN in the absence of glomerular dysfunction. The causative agent was held and a bicarbonate infusion was initiated. The patient's renal function improved with a most recent sCr of 1.5 mg/dL consistent with an estimated glomerular filtration rate (eGFR) of 50 ml/min/1.73m^2 improved from 19, approximately 7 months after initial treatment.

Discussion: Our case provides another example of ARN and highlights the therapeutic measures utilized. ARN has previously been shown to hasten CKD progression with increased mortality. Early identification and therapeutic management can lead to considerable renal recovery as seen in our patient's case. More studies are needed to further clarify the pathophysiology of ARN and to investigate potential treatments.



(a) Low power photomicrograph with acute tubular injury with intratubular red blood cells, red blood cell casts (hematoxylin and eosin, original magnification x 100). (b) High power photomicrograph with severe acute tubular injury and intratubular fresh red blood cells, red blood cell casts (hematoxylin and eosin, original magnification x 200).

PO0282

The Answer Is in the Urine

Kirtan Patel, Justin M. Berger, Kyle Schwarz, John Hergenrother. *The Christ Hospital Physicians Spine, Cincinnati, OH.*

Introduction: Ethylene glycol toxicity carries significant morbidity. Prompt recognition and treatment prevents mortality. Given time needed for confirmatory laboratory testing, high suspicion should be raised in cases of anion gap metabolic acidosis. Here we present a case of ethylene glycol toxicity diagnosed with simple urine microscopy.

Case Description: The patient is a 48-year-old male presented in an obtunded state. Laboratory evaluation was notable for a severe metabolic acidosis with a CO2 <5 mmol/L on basic metabolic panel. Anion gap was unable to be calculated but was at least 27. Serum labs were: Sodium 139 mmol/L, potassium 4.9 mmol/L, chloride 108 mmol/L. Glucose level 144 mg/dL Creatinine 1.14mg/dL and BUN 16 mg/dL, Lactic acid 7.63 mmol/L. ABG showed a pH of 7.14, pCO2 of 11 mmHg, pO2 of 114 mmHg, pHCO3 of 3.6 mmHg, and calculated base excess of -25.0. Measured serum osmolality was 321 mOsm/kg. Calculated serum osmolality was 292 mOsm/kg indicating an osmolar gap of 29 mOsm/kg. White blood cell count was 39.0 x10^3/uL. Ethanol level was <10mg/dL. Volatile acid labs were sent. Unfortunately, these labs required send out to another facility to run which resulted in significant delay. Due to high suspicion of toxic volatile substance ingestion, Fomepizole was administered and a urine sample was viewed under the microscope. Needle shaped crystals were noted to be present. Patient underwent 1 session of hemodialysis and significantly improved clinically. Ethylene glycol level, drawn prior to hemodialysis, came back at 24.9 mg/dL. He received 4 additional doses of fomepizole. He also received high dose thiamine and pyridoxine to enhance the metabolism of ethylene glycol. Labs drawn the following morning resulted in an undetectable ethylene glycol level.

Discussion: Toxic ingestion needs to be considered in any obtunded patient. Workup should include careful assessment of acid-base status and osmolar gap. Prompt Treatment may need to be initiated prior to confirmatory lab results. Simple methods including urine microscopy and fluorescing the urine with Wood's lamp can assist a prompt diagnosis. In our case, crystalluria was present. A teaching point is that the crystals need not be the classic "envelope shape" as a six-sided needle-like structure often occurs as noted in our patient. While labs may confirm the diagnosis, the answer can be found in the urine.

PO0283

AKI: Rare Side Effect of Pemetrexed

Junaid M. Alam, Aswin Srinivasan, Haris Ahmed, Branden C. Wilson, Brotee Rahman. *HCA, Kingwood, TX.*

Introduction: Pemetrexed was approved by FDA in 2004 to treat local or advanced metastatic non-small cell lung cancer. It works by disrupting folate dependent processes and in turn preventing cell replication. Folate deficiency leads to increased pemetrexed toxicity. We report a rare and deleterious case of acute kidney injury associated with pemetrexed toxicity.

Case Description: 63-year old male with PMH of stage IV non-small cell lung cancer and HTN presented with acute onset of skin desquamation of his facial, groin and buttocks regions along with severe mouth pain and odynophagia. The chemotherapy regimen was changed from pembrolizumab to pemetrexed two days prior. Severe odynophagia limited his oral intake. His BP on arrival was 86/60 and was fluid resuscitated. CBC was unremarkable except for platelet count of 56,000/uL and absolute neutrophil count of 372 cells/uL. CMP demonstrated BUN of 38mg/dL and serum Creatinine of 4.2mg/dL. His baseline Creatinine one month prior to presentation was .6. MRI of his abdomen was unremarkable. Initial treatment included aggressive fluid hydration, a granulocyte colony stimulating factor (TBO-Filgrastim) and empiric IV antibiotics given the severe neutropenia. Additionally, 5mg of folic acid intravenously was started to counter the anti-folate effects of pemetrexed. Increase in oral intake was encourage and pemetrexed was discontinued. His Creatinine returned to baseline within a few days. After resolution of mucositis, odynophagia and skin desquamation, he was discharged back home with changes to his chemotherapy regimen.

Discussion: Pemetrexed is a second line agent that has been used to treat 84% of the second most common cancer in both men and women in the US. The most common adverse reactions are fatigue, skin desquamation, nausea, stomatitis, neutropenia and pharyngitis. A significantly less common adverse effect is AKI that can occur and if not identified can lead to acute renal failure. In our patient, his AKI is thought to be multifactorial from pre-renal due to decreased oral intake and intrinsic due to the toxicity of pemetrexed. Although aggressive fluid administration is imperative, the anti-folate effects of pemetrexed must be reversed with folic acid in order to prevent the patient from going onto dialysis. Prompt recognition of this adverse effect can lead to suitable treatment and recovery of his kidney function.

PO0284

An Unusual Presentation of Type 1 Cryoglobulinemic GN in Monoclonal Gammopathy of Undetermined Significance (MGUS)

Heedeok Han, Teena Zachariah, Raphael J. Rosen, Dominick Santoriello. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Type I cryoglobulinemia can develop in the setting of monoclonal gammopathy of undetermined significance (MGUS) and can have renal involvement in a third of cases. We present an unusual case of Type I cryoglobulinemic glomerulonephritis (GN).

Case Description: An 83-year-old woman with a history of IgG Kappa MGUS presented with decreased urine output and nausea. During the previous six months, the patient was hospitalized three times for acute kidney injury (AKI) requiring dialysis. Two renal biopsies had been performed during those admissions, which showed GN with scant immune deposit. One glomerulus had intraluminal staining for IgG and Kappa suggesting Type 1 Cryoglobulinemic GN secondary to her MGUS (Figure 1, A-C). She declined chemotherapy at the time, however, each time her renal function improved spontaneously and she was discharged without requiring dialysis. In the ED, her blood pressure was 182/69 but her vitals were otherwise normal. The physical exam was unremarkable. Labs were notable for sodium 122 meq/L, potassium 5.2 meq/L, creatinine 4.5 mg/dL, albumin 3.4 g/dL, low C3 and C4, and positive MPO-ANCA. The urinalysis showed 50 red blood cells, 15 white blood cells, and random urine protein > 2000mg/dL. Other serologic and infectious labs, including serum cryoglobulin, were negative. The renal ultrasound was normal. The patient's renal function worsened and was started on dialysis. This time the patient agreed to chemotherapy and immunosuppression with the aim to prevent further recurrences of AKI. The patient was started on clone-directed therapy with cyclophosphamide, bortezomib, and dexamethasone. Plasma exchange therapy was also performed for the clearance of light chains. The patient's renal function improved and she was discharged without requiring dialysis. Her two-month follow up creatinine was 1.08mg/dL.

Discussion: This case of type 1 cryoglobulinemic GN is unusual in that the patient developed cyclical but self-resolving episodes of AKI-D that was successfully treated with clone-directed therapy.

PO0285

A Case of Renal Papillary Necrosis in the Setting of Acute Pyelonephritis and Chronic NSAID Use

Arjun L. Kalaria, Michael Heslin, Michael A. Nalesnik, Blaise W. Abramovitz. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Introduction: Renal papillary necrosis is an ischemic process that affects the renal papillae and inner medulla leading to acute kidney injury. Most common causes include diabetes mellitus often with urinary tract infection, sickle cell anemia, and analgesic use. It is histologically delineated by coagulative necrosis of the renal papilla and medullary pyramids, and potentially acute liquefactive necrosis in the presence of infection. We report a case of renal papillary necrosis in the setting of acute pyelonephritis and chronic NSAID use.

Case Description: A 59-year-old Caucasian male with a history of hypertension, irritable bowel syndrome, hyperlipidemia who presented with 4 days of vomiting, diarrhea, decreased urinary output, and generalized weakness. He endorsed twice daily use of naproxen for the past couple months. Physical examination only notable for dry mucous membranes. Initial work-up demonstrated serum creatinine of 12.7 mg/dL (baseline 1.0 mg/dL), serum sodium level of 123 mmol/L, serum potassium level of 7.4 mmol/L, blood urea nitrogen 147 mg/dL, WBC count 30.5 x10^9/L, and urinalysis with pyuria, microscopic hematuria, and proteinuria. Further work-up showed urine culture

with pan-sensitive Escherichia coli, sub-nephrotic proteinuria, and complete serologic work-up only positive for serum protein electrophoresis. CT abdomen/pelvis without contrast did not demonstrate any hydronephrosis. A native kidney biopsy was performed and revealed diffuse tubulointerstitial inflammation with prominent intratubular white cell casts and areas of confluent parenchymal necrosis consistent with acute pyelonephritis leading to renal papillary necrosis. He completed a 7-day course of ceftriaxone for E. coli urinary tract infection and eventually required hemodialysis with no signs of kidney recovery upon discharge.

Discussion: Renal papillary necrosis is a rare disease entity and is underdiagnosed due to its variable clinical presentation. Unfortunately, it could have potentially fatal outcomes if undiagnosed, which is evident upon reviewing the current literature. By presenting this case, we highlight this unique presentation of renal papillary necrosis in a non-diabetic individual and urge clinicians to have a high index of suspicion and subsequently a low threshold for kidney biopsy to establish a diagnosis and improve patient outcomes.

PO0286

A Rare Case of Evans Syndrome with Systemic Lupus Erythematosus and Pulmonary Nocardiosis

Reddappa Venkata Sai Rakesh Kanipakam. *Brown University, Providence, RI.*

Introduction: Evans syndrome (ES) is a rare autoimmune disorder characterized by the simultaneous or sequential development of autoimmune hemolytic anemia (AIHA) and immune-mediated thrombocytopenic purpura (ITP). The exact pathophysiology is unknown but is initiated by having autoantibodies attacking body's own red blood cells and platelets.

Case Description: 20-year-old male with history of autoimmune dysregulation including SLE (diagnosed when he was 13), Evan's Syndrome, class 5 lupus nephritis presented to the Hospital for difficulty breathing, dry cough and 30-pound weight loss. He was admitted to ICU for acute hypoxic respiratory failure requiring intubation. His lab work showed anemia, thrombocytopenia, AKI, ANA+, low C3, C4, elevated LDH, high uric acid, UA showing 3+ blood and 6 grams of proteinuria. A chest CT on admission also noted extensive LAD, splenomegaly, ground glass opacities and interstitial prominence in lungs. He underwent a lung biopsy which showed DAH. The patient was also treated with pulsed steroids, plasmapheresis and Cytoxan. He also had MSSA bacteremia treated with antibiotics and rehab course complicated with pulmonary nocardiosis.

Discussion: Although ES is an extremely rare case, it is important to keep broad differentials as renal dysfunction is common from different pathologies. Usually the most common cause of AKI associated with ES is ATN from intravascular hemolysis and had widespread intratubular hemoglobin casts but it is essential to consider other etiologies as in our case of previous lupus flare.

PO0287

Acute Myositis Complicated by Rhabdomyolysis in Setting of COVID-19 Infection in a Patient on Rosuvastatin: A Case Report

Anand Kumar, Anjali Muraleedharan, Yasir Lal. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: Viral illnesses are uncommon cause of rhabdomyolysis and AKI. A few cases of rhabdomyolysis have been reported with Covid-19 infection previously. However, Covid-19 presenting solely with rhabdomyolysis in absence of respiratory symptoms is rare. There is also paucity of data supporting steroids use in such cases. We present a case of COVID-19 related rhabdomyolysis who recovered in response to steroid therapy.

Case Description: This is a 78-year-old female with history of dyslipidemia and chronic kidney disease III who presented with generalized weakness and myalgias. Home medications included Rosuvastatin. She was diagnosed with Covid-19 virus. Rosuvastatin was held, however her myalgia muscle weakness worsened, and she was no longer able to stand without support. She denied fever, chills, rash, or respiratory symptoms. At presentation, physical exam revealed diffuse muscle tenderness and diminished strength: 1/5 and 2/5 in proximal bilateral lower and upper extremities respectively. WBCs 11.13, K 5.7, Cr 5.72, ANA, HMG CoA reductase antibody assay and myositis panel (SSA-52, SSA-60, Smith/RNP antibodies, anti-SMRNP, anti-SSA, anti-SSB, & RF) were negative. CK 14, 085 U/L, granular and muddy brown casts on urine microscopy. Lower extremities MRI showed bilateral muscular edema, EMG was consistent with myopathic changes. Muscle biopsy revealed scattered necrotic and regenerating fibers, diffuse type 2 fiber atrophy, and mild neurogenic changes, consistent with rhabdomyolysis. Immunohistochemistry showed rare perivascular B lymphocytes and plasma cells. CK continued to rise and peaked at 89,303 U/L. At that point steroid therapy was initiated. This resulted in a significant improvement in CK and creatinine over the next few days.

Discussion: Viral myositis leading to rhabdomyolysis and AKI as the primary presentation of Covid-19 infection is uncommon. In our case, a short course of steroids, resulted in quick recovery. Early recognition and diagnosis followed by intervention can prevent further muscle and renal damage and can shorten hospital stay and related morbidity significantly. Cureus. 2020 Oct; 12(10): e11186.Ankalesaria et al. Solís, J. G. et al. *The American journal of tropical medicine and hygiene, 103*(3), 1158–1161

PO0288

AKI Induced by Oral Semaglutide Leading to Metformin-Induced Lactic Acidosis

Allyson K. Halderman, Madhu Kandarpa. *Kettering Health Network, Dayton, OH.*

Introduction: Lactic acidosis is a known complication of metformin treatment, especially in the context of elevated creatinine. This is a patient on chronic metformin therapy who developed actue kidney injury and lactic acidosis after intiaition of semaglutide.

Case Description: a 77-year-old male with a history of non insulin dependent type 2 diabetes, hypertension and hyperlipidemia brought in for altered mental status. Patient had been prescribed metformin for years without any complications. Vitals: temp 91.2 F, BP 81/72, RR 25, spO2 98% on room air. Physical examination was unremarkable including no edema however was oliguric. On admission patient had a Na 130 mmol/L, Potassium 6.1 mmol/L, Chloride 76 mmol/L, CO2 5 mmol/L, Anion gap 49 mmol/L, Blood Urea Nitrogen 65 mg/dL, Creatinine (Cr) 6.4 mg/dL (baseline Cr 1.3 mg/dL), lactic acid 22.4 mmol/L and a Venous blood gas pH of 6.8, Ammonia 245 umol/L with normal liver enzymes, COVID PCR negative. CT Abdomen without contrast and Chest x-ray did not show any acute process. Treatment: Patient was admitted to Intensive Care Unit, Semagliptide and Meformin discontinued. He was started on Continuous Renal Replacement Therapy (CRRT) then transtioned to conventional hemodiaylsis. Patient made remarkable recovery. At the time of discharge patient was off diaylsis with Cr 1.1 mg/dL.

Discussion: Semaglutide is a glucagon-like peptide 1 receptor agonist (GLP-1 agonist). GLP-1 agonist's have gained popularity in the outpatient setting for management of Type 2 diabetes mellitis. They carry a low side effect profile including reduced risks of hypoglycemia compared to older treatments. Acute kidney injury requiring diaylsis is listed as a possible adverse reaction, it is rare, usually occurring in the setting of acute dehydration. Reports of AKI requiring dialysis in available studies show incidences near that present in the placebo groups. The high acuity of disease that occurred in the above patient was compounded by metformin toxicity. Many future patients prescribed semaglutide will be on metformin. Information such as this could require physicians to use extra caution as they prescribe this medication combination, especially in the elderly and those at risk for dehydration. Futher studies needed to evaluate possible interval labortory monitoring when patients are initated on this medication combination.

PO0289

Staphylococcus aureus-Associated Infection-Related Glomerulonephritis (IRGN) in an Elderly Male

Iman S. Khan,[1] Alice J. Tao,[1] Justin E. Grenet,[1] Emiliy S. Smith,[1] Steven Salvatore,[1] Jeffrey I. Silberzweig.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Introduction: IRGN commonly occurs in children following Streptococcal upper respiratory tract or skin infections. However, more cases are now being described in adults with symptoms ranging from microscopic hematuria to dialysis dependence. Herein, we describe a case of IRGN in an elderly male in association with a heel ulcer.

Case Description: An 88-year-old man with hypertension, chronic kidney disease stage 3 (baseline creatinine (Cr) 1.6-1.8 mg/dL), rheumatoid arthritis & peripheral artery disease presented with a Cr of 8 mg/dL. 3 weeks prior to presentation, he was hospitalized for a right heel abscess, treated with doxycycline for 5 days & discharged with a Cr of 1.84 mg/dL. Wound cultures grew methicillin sensitive Staphylococcus aureus, E. coli & coryneform bacteria. 7 days after discontinuing doxycycline, he developed oliguria & a pruritic rash on his chest & arms & was readmitted. Urinalysis revealed >50 RBCs, >50 WBCs, 100 protein & few bacteria without casts. Urine protein to Cr ratio was 3.3 g/dL, fractional excretion of sodium was 4.4% & eosinophil count 6.8%. Additional labs included C3 64 mg/dL, C4 32.8 mg/dL & ANA 1:320, with speckled pattern. ESR was 46 mm/hr & CRP was 3.3 mg/dL, with negative blood & urine cultures. Renal ultrasound showed bilateral echogenic kidneys without hydronephrosis. Recent antibiotic use, rash, peripheral eosinophilia & acute kidney injury suggested acute interstitial nephritis. He was started on prednisone 1mg/kg/day. Hemodialysis (HD) was initiated for volume overload & uremic encephalopathy. His kidney function did not improve with prednisone & a renal biopsy was performed. Pathology revealed diffuse exudative glomerulonephritis, prominent C3-only staining, active interstitial inflammation, & subepithelial deposits consistent with IRGN. Despite improved respiratory status with HD, his mental status deteriorated, kidney function did not recover & he died on the 20th day of admission.

Discussion: While prognosis for IRGN is excellent in children with nearly 95% recovery; about half of affected adults become dialysis dependent. Our case is unique as it (a) highlights the need for a high index of suspicion for IRGN in an adult patient recovering from infection & (b) implores nephrologists to have a low threshold to perform a renal biopsy when noticing lack of improvement of AKI.

PO0290

Continuous Renal Replacement Therapy: A Reversible Cause of Thrombocytopenia

Megan E. Goff, Blaithin A. McMahon. *Medical University of South Carolina, Charleston, SC.*

Introduction: Thrombocytopenia is frequently encountered in critically ill patients. Whether present on admission or acquired during hospitalization, inadequate platelet counts are an independent risk factor for patient morbidity and mortality in the Intensive

Care Unit. Continuous renal replacement therapy is a lesser known cause of acquired thrombocytopenia.

Case Description: In this retrospective case series, four patients that developed thrombocytopenia while receiving continuous renal replacement therapy (CRRT) in the Intensive Care Unit were evaluated. The temporal relationship between onset of thrombocytopenia, timing of CRRT, and subsequent trend in platelet counts were analyzed. The patients had a variety of risk factors for thrombocytopenia including septic shock, presence of chronic kidney disease, mechanical support therapies, and anticoagulation with heparin. Despite these characteristics and interventions, each of the patients demonstrated a pronounced drop in platelet count within 72 hours of initiating CRRT, with a subsequent improvement in platelet count following cessation of CRRT.

Discussion: Thrombocytopenia is a complication of critical illness that, in extreme cases, can lead to further cost and resources to evalute and possibly delay necessary intervention. In patients requiring renal replacement therapy, clinicians must be cognizant that continuous modalities are a potential source of thrombocytopenia. Nephrologists are responsible for knowing all potential adverse outcomes of the procedure of dialysis. Educating other health team members of these risks is part of that responsibility.

Data

Hours since CRRT initiation	Platelet Count Patient 1 (per microL)	Platelet Count Patient 2 (per microL)	Platelet Count Patient 3 (per microL)	Platelet Count Patient 4 (per microL)

PO0291

Successful Utilization of Hemodialysis for Treatment of Vancomycin Nephrotoxicity

Tushar Thakur, Mingyue He, Waqas Ahmad Khan, Ziauddin Ahmed, Iris J. Lee. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: Vancomycin is frequently used as empiric antimicrobial therapy for septic shock. At supratherapeutic levels, vancomycin can potentially cause nephrotoxicity. Nephrotoxicity often resolves on discontinuing the medication, but recovery may be prolonged and injury severe, requiring dialysis. The role of hemodialysis is limited, and evidence suggests that standard membrane dialysis provides poor clearance. However, the current use of high flux dialysis can eliminate vancomycin faster, promoting quicker renal recovery.

Case Description: A 49-year-old female admitted for septic arthritis received vancomycin 1.5g q8h and piperacillin/tazobactam. After two days, she developed an oliguric acute kidney injury (AKI). Urine sediment revealed few tubular cells without casts. Vancomycin trough level was 42 ug/ml, and the random level was 101.3ug/ml. We suspected vancomycin toxicity, and for quicker clearance of the drug, we initiated high flux dialysis. She received five sessions of HD, and her random vancomycin level dropped to 18 ug/ml. Gradually her urine output improved with resolution of AKI.

Discussion: Discerning vancomycin nephrotoxicity can be a challenge as higher vancomycin levels can result from decreased GFR from AKI. The rise of creatinine coexisting with elevated vancomycin levels and the absence of an alternative explanation for renal injury supports the diagnosis of vancomycin nephrotoxicity. The odds of developing vancomycin nephrotoxicity are three times higher when combined with piperacillin/tazobactam. Incidence of AKI increases with higher daily dosage (>4g vancomycin/day), higher trough levels (>15 mg/L), and longer treatment time (>1 week). Treatment is aimed at discontinuation of the drug. In severe AKI, with oliguria and poor clearance, strikingly elevated serum vancomycin levels may further escalate the risk of renal injury. In our case, the use of HD to increase the clearance of vancomycin may have expedited renal recovery. Faster removal of vancomycin with HD should be considered in patients with severe AKI.

PO0292

Atypical Hemolytic Uremic Syndrome: A Case Report

Neethu Gopisetti, Akilandanayaki Angamuthu, Fatima Batool, Daranee Chewaproug, Imara Dissanayake. *Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: Thrombotic microangiopathy is a pathological condition comprised of microvascular thrombosis involving any organ of the body leading to thrombocytopenia, Coombs-negative hemolytic anemia, and end-organ damage. The most common forms of thrombotic microangiopathies are Shiga toxin-producing Escherichia coli mediated hemolytic uremic syndrome, thrombotic thrombocytopenic purpura, and atypical hemolytic uremic syndrome. The atypical hemolytic uremic syndrome occurs due to genetic and acquired mutations in complement regulatory factors and to complement activation factors in the immune system, mainly the alternative pathway. Clinical manifestations and outcomes differ with the prevalent mutations of the patient. Currently, available treatment modalities are therapeutic plasma exchange and a monoclonal antibody against C5, eculizumab.

Case Description: 43-Year-Old African American female with past medical history hypertension and Diabetes presented with 2-day history of altered mental status. On presentation, she has BP 264/133. Her blood investigations showed acute kidney disease, thrombocytopenia, hemolytic anemia with negative Coombs's test. Coagulation profile was normal. Schistocytes were noted on peripheral smear. Received plasmapheresis for concern of Thrombotic thrombocytopenic purpura with no clinical improvement. Initiated on hemodialysis. Adams TS 13 level returned at 27%, ruling out Thrombotic thrombocytopenic purpura. Genetic complement testing was sent on the patient and was initiated eculizumab for presumed Atypical hemolytic uremic syndrome. After giving eculizumab patient's mental status improved and recovered renal function, came off dialysis. Genetic complement testing is negative however, next generation sequencing revealed no coverage for the CFHAI and' CFHRS genes which may be a risk factor for FH autoantibody development and needs further testing

Discussion: Conclusion: The atypical hemolytic uremic syndrome is a rare disease entity requiring a high index of suspicion to diagnose. It is a diagnosis of exclusion. Early diagnosis with prompt treatment will render a better outcome. The atypical hemolytic uremic syndrome needs to be considered in all patients with thrombotic microangiopathy. PO0293

A Tricky Diagnosis of Complement-Mediated Thrombotic Microangiopathy

Fehlin Stone, James D. Oliver, Maura A. Watson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Complement-mediated thrombotic microangiopathy (C-TMA) is caused by inappropriate activation of the alternative complement pathway, usually leading to acute kidney injury (AKI), microangiopathic hemolytic anemia (MAHA), and thrombocytopenia (TCP). Renal biopsy is normally not indicated for diagnosis.

Case Description: A 22 year-old black male was admitted for hypertensive emergency with blood pressure (BP) of 240/140 mmHg, vision loss, and AKI. Ocular exam showed bilateral Frisén Grade IV papilledema. Serum creatinine (sCr) was 4.9 mg/dL (baseline 1.1 mg/dL two years prior) with 4 g proteinuria. Urine microscopy had dysmorphic red blood cells with hyaline and granular casts. Platelet count, hemoglobin, LDH, and haptoglobin were normal. Records showed several years of untreated hypertension; family history was unremarkable. Complement, hepatitis/HIV, ANA, ANCA, anti-GBM, and cryoglobulins were normal. Secondary hypertension workup was negative for endocrine and macrovascular disease. He was treated with antihypertensives and his vision corrected over several days. Renal biopsy showed >50% glomerular obsolescence and 35% interstitial fibrosis/tubular atrophy, with focal arteriolar narrowing and bloodless glomeruli concerning for a subtle TMA. Genetic testing showed a homozygous deletion of CFHR3-CFHR1, confirming C-TMA. Factor H autoantibodies were negative. Therapy was begun with eculizumab, an anti-C5 monoclonal antibody. BP decreased to 120-150/65-90 mmHg and sCr improved to 2.9 mg/dL. He was later switched to ravulizumab for less frequent dosing.

Discussion: This was an atypical presentation of C-TMA without the usual diagnostic clues of TCP or MAHA. Renal biopsy was essential in the eventual diagnosis confirmed by genetic testing. The associations between the genetic variants of C-TMA and specific clinical presentations warrants further investigation. *The views expressed are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense or the United States Government.*

PO0294

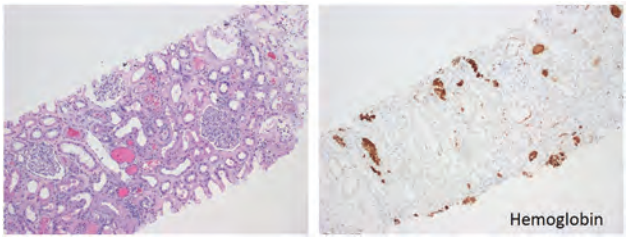
Hemolytic Anemia, Thrombocytopenia, and Kidney Injury Associated with Cardiac Procedure: A Diagnostic Dilemma

Saiyed W. Ali,[1] Kuang-Yu Jen,[2] Shubha Ananthakrishnan,[1] Nasim Wiegley.[1] *[1]University of California Davis Department of Internal Medicine, Sacramento, CA; [2]University of California Davis, Davis, CA.*

Introduction: Acute intravascular hemolysis is a rare complication of ventricular septal defect (VSD) closure devices; however, profound thrombocytopenia is not typical. We present a case of hemolysis, thrombocytopenia, and kidney failure in a patient with recent VSD closure device placement. Although hemoglobin cast nephropathy (HCN) was considered, the patient was also newly started on ticagrelor, which has been associated with thrombotic microangiopathy (TMA). A biopsy was required for ultimate diagnosis.

Case Description: A 79-year-old woman with recent myocardial infarction (MI) underwent percutaneous coronary intervention and initiation of dual antiplatelet therapy with ticagrelor and aspirin. Subsequently she developed VSD and underwent transcatheter VSD closure device placement. Pre-procedure labs showed normal hemoglobin and platelet levels, but following the procedure she developed progressively worsening jaundice, dark urine, anemia and thrombocytopenia. Peripheral smear revealed numerous schistocytes. ADAMTS-13 activity was 27%, and serotonin release assay was negative. She required initiation of hemodialysis due to anuria. A kidney biopsy was performed, which showed widespread acute tubular injury with hemoglobin casts and without findings of TMA. Hemolysis spontaneously resolved after a few days. The patient remained dialysis dependent at the time of discharge.

Discussion: Intravascular hemolysis can be a rare complication of intracardiac devices as a result of high-velocity turbulent blood flow through the device or a residual shunt causing mechanical erythrocyte fragmentation. HCN can develop as a consequence of intravascular hemolysis. This case was complicated by the recent initiation of ticagrelor, which is associated with TMA. Differentiating between HCN and TMA required a kidney biopsy after careful planning due to ongoing cytopenias.



H&E and Immunohistochemical staining of Hemoglobin casts

PO0295

Patient with Refractory Acquired Thrombotic Thrombocytopenic Purpura Treated with a Novel Agent Caplacizumab

Pranav Sharma, Jonathan Lebowitz. *Rutgers The State University of New Jersey, New Brunswick, NJ.*

Introduction: Acquired or immune-mediated TTP is characterized by thrombocytopenia and anemia caused by autoantibody mediated inhibition of the von Willebrand factor (vWF) cleaving protease, ADAMTS13. This results in a microangiopathic hemolytic anemia and severe thrombocytopenia, resulting in tissue ischemia, multiorgan failure, and, potentially, death. Up until now, treatment for TTP included therapeutic plasma exchange (TPE) and immunosuppression. Recently, caplacizumab, the first targeted nanobody based therapeutic agent that prevents adhesion of platelets to vWF, has been approved for use in acquired TTP. We present a case of acquired TTP that was refractory to high dose, steroids, therapeutic plasma exchange (TPE) and rituximab but responded well to caplacizumab.

Case Description: A 53-year-old man with HIV, complicated by cryptococcal meningitis and PCP pneumonia, intermittent confusion, headache, and multiple falls, presented with anemia, thrombocytopenia, an elevated LDH, and a peripheral blood smear with numerous schistocytes with acute kidney injury with an initial serum creatinine of 1.7 mg/dl which peaked up to 5.5 mg/dl. Further testing revealed a positive ADAMTS13 inhibitor with high titer of 3.4 and less than 5% ADAMTS13 enzyme activity, consistent with TTP. He was treated with high dose steroids, TPE, and rituximab but did not respond. He was initiated on caplacizumab on hospital day 14 and by day 18 his platelet counts began to normalize and mentation improved. He suffered only mild epistaxis as a side effect from caplacizumab. In span of few days, his neurologic symptoms resolved and he was discharged home to complete thirty days of caplacizumab treatment. At the time of follow up, he remained well and continued to have normal ADAMTS13 activity. Kidney function improved post caplacizumab to 0.8 mg/dL.

Discussion: Although conventional therapy has reduced the mortality of TTP, it is not always effective and there are fair number of cases refractory to conventional treatment. Caplacizumab, the first nanobody-based therapeutic agent, has shown marked efficacy in treating TTP and its complications and is a therapeutic option for patients with refractory TTP.

PO0296

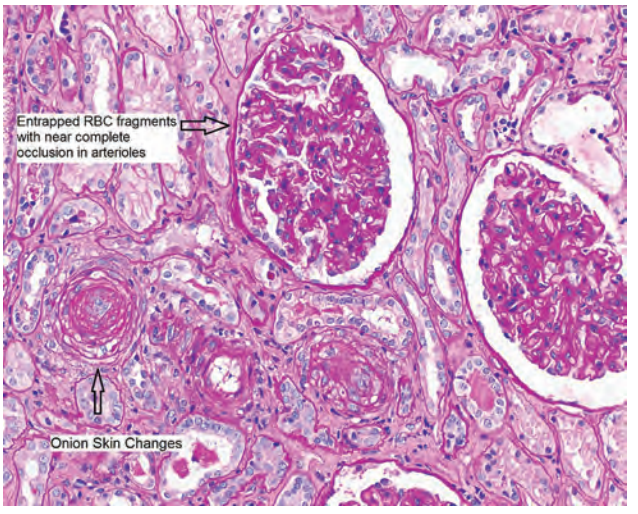
Use of Eculizumab in Thrombotic Microangiopathy (TMA) Associated with PM/SCL100 and 75 and RP 155 Antibody-Positive Autoimmune Overlap Syndrome with Renal Crisis

Jahanzeb Khan,[1] Heba Mousa,[1] Mujtaba Sarwar,[1] Ramya Bachu,[1] Anum Syed,[1] Sehrish W. Bukhari,[2,1] Fakhar Ijaz.[1,2] *[1]Baptist Health Medical Center - North Little Rock, North Little Rock, AR; [2]Kidney Care Center, Little Rock, AR.*

Introduction: TMA with associated PM/SCL100 & 75 and RP 155 antibody positive Autoimmune Overlap Syndrome with renal crisis has a very poor prognosis and limited therapeutic options. Use of Eculizumab has been reported in only a few cases in literature.

Case Description: A 44 years old female with hypertension and Raynaud's phenomenon presented with hypertensive emergency, recent sclerodactyly, hemolytic anemia, thrombocytopenia and renal failure. Routine serum markers including DsDNA Ab, complements, ANCA, SSA, SSB, Scl 70 Ab, Anti-centromere Ab, RNA polymerase 3 Ab, U-3 RNP Ab, lupus anticoagulant, beta 2 glycoprotein Ab and ADAMTS-13 were all negative. Pulse Steroids and plasmapheresis were initiated due to concern of aHUS. Renal biopsy showed onion skinning of arterioles with near complete occlusion of arterioles as shown in the figure. ACEI was added. Later she was found to have positive PM/SCL 100 & 75 and RP 155 antibodies. She was started on Eculizumab secondary to poor hematological response to the above measures. Our patient showed improvement of her thrombotic microangiopathy which helps to support the use of this drug in this rare disorder.

Discussion: Very limited theraputic options are available for cases of Autoimmune Overlap Syndrome. Our use of Eculizumab; an anti-CD5 monoclonal antibody, also supports the benefits of blocking the activation of the classical complement pathyway which may suggest the underline mechanism in this disease process.



PO0297

AKI and Collapsing Focal Segmental Glomerulosclerosis in an Immunocompetent Patient with Cytomegalovirus and COVID-19 Infection

Milton Ray, Sudhanshu Jain, Suhaib A. Andrabi, Marco Ramos. *Harlem Hospital Center, New York, NY.*

Introduction: Collapsing Glomerulopathy is a morphological variant of focal segmental glomerulosclerosis (FSGS) characterized by rapidly progressive renal failure and nephrotic range proteinuria. CMV-associated renal infections are usually seen in post-transplant and immunocompromised patients. We present a case of severe collapsing FSGS and acute CMV infection in an immunocompetent host.

Case Description: A 19-year-old woman with HbSS sickle cell disease and infrequent vaso occlusive crisis was hospitalized with febrile illness. During hospitalization she developed non-oliguric acute kidney injury (AKI) and volume overload and started on intermittent hemodialysis. Chest x-ray showed cardiomegaly, pulmonary venous congestion, infiltrates and bilateral pleural effusions. 24h Urine protein was 17,291 mg/24h. Urine and serum myoglobin were elevated. Relevant investigations include positive CMV IgM, CMV PCR 7000 international unit(s)/ml, positive mycoplasma IgM. SARS-CoV-2 RT-PCR & NAT were negative but antibodies were positive. A diagnosis of COVID associated Multisystem inflammatory syndrome in children (MIS-C) was made and she received methylprednisolone. She received piperacillin/tazobactam, azithromycin, ganciclovir, meropenem, and linezolid for CMV infection and pneumonia. Renal biopsy revealed collapsing FSGS, moderate and acute tubular injury, interstitial edema, focal tubular microcysts and podocyte effacement. Renal function improved after ganciclovir therapy and hemodialysis was discontinued. Prednisone and losartan were started for persistent proteinuria.

Discussion: Active CMV infection in immunocompetent hosts is uncommon. The mechanism of CMV associated with collapsing FSGS is unclear as direct viral infection is not always seen on biopsy. CMV is not routinely tested for in immunocompetent patients and should be considered in AKI and nephrotic syndrome with multi-system involvement. Our patient had lung infiltrates and rhabdomyolysis which could be explained by CMV infection. Anti-viral therapy may be effective. As opposed to primary collapsing FSGS steroids are not routinely needed. Some patients have persistent proteinuria and nephrotic syndrome may respond to steroids, with tacrolimus in refractory cases. It is unclear if prior COVID infection or MIS-C contributed to activation of CMV infection and FSGS.

PO0298

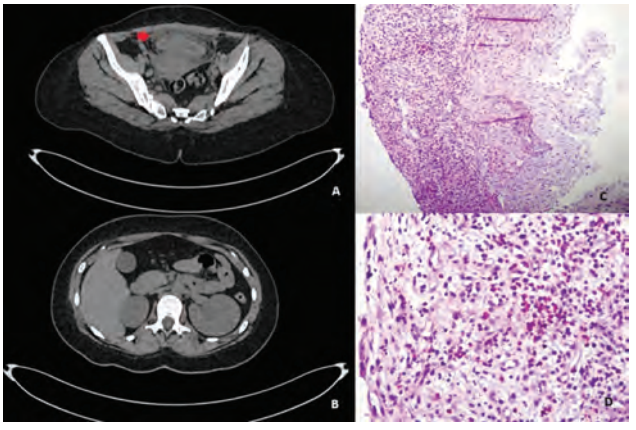
Bilateral Hydronephrosis: An Unusual Presentation of a Rare Disease

Osama S. Ouda. *Abu Dhabi Health Services Co, Abu Dhabi, United Arab Emirates.*

Introduction: Eosinophilic cystitis is a rare disease. Prevalence is equal among gender in adult patients. Patients commonly present urinary frequency, dysuria, hematuria, suprapubic pain and urinary retention. Association with history of allergy and urinary tract infection is variable.

Case Description: 26 years old female presented with bilateral flank pain and dysuria. Labs showed high creatinine and urinalysis was suggestive of a urinary tract infection. CT of the abdomen and pelvis showed bilateral hydronephrosis with no stones (Image A). Diffuse circumferential wall thickening of urinary bladder with extensive perivesical fat stranding (image B). Cystoscopy was performed which revealed diffuse edematous bladder wall including both ureteric orifices. Bilateral retrograde studies confirmed that the obstruction is at the ureteral orifices. JJ stents were inserted bilaterally. Bladder biopsies were taken. Histopathology of the biopsies(image A and B) show denuded urothelium with underlying chronic inflammatory cell infiltrate rich in eosinophils consistent of eosinophilic cystitis. The renal function improved after the procedure. The patient was discharged on antihistamine and a tapering dose of steroid. On follow up, JJ stents were removed and retrograde studies showed normal flow through the ureteral orifices. Serum creatinine is back to baseline and dysuria improved on three months follow up.

Discussion: Eosinophilic cystitis is a rare disease. Association with history of allergy and urinary tract infection is variable. Radiological finding are usually consistent with thickened bladder wall. In a case series of 10 Chinese patients, only one patient had bilateral hydronephrosis. Medical treatment is mainly by non-steroidal anti-inflammatory drugs, corticosteroids, anti-histamines and antibiotics. Surgical modalities of treatment include transurethral resection of the lesions, partial cystectomy or total cystectomy. Response to different modalities of treatment is variable.



PO0299

Treatment of FSGS and Hemophagocytic Syndrome with Tocilizumab

Daniel W. Shields, Michael Dore, Richard A. Plasse. *Naval Medical Center Portsmouth, Portsmouth, VA.*

Introduction: Hemophagocytic syndrome (HPS) is a rare and often life-threatening condition characterized by an overreaction of the immune system. HPS has a variety of triggers including: malignancy, infection, and rheumatologic conditions. Clinically, it is characterized by acute fever, cytopenia, lymphadenopathy, hepatosplenomegaly, intravascular coagulation, hyperferritinemia, and elevated liver associated enzymes. We present a case of reactive HPS complicated by focal segmental glomerulonephritis (FSGS) secondary to a febrile gastrointestinal illness in an otherwise healthy 36 year old male.

Case Description: A 36 year old male presented to the ER with a 3 day history of fevers, nausea, vomiting, and diarrhea. Labs demonstrated hyponatremia to 126 and acute renal injury. He was admitted for presumed viral gastroenteritis and treated supportively. He then developed elevated liver associated enzymes and pancytopenia. An infectious work up was unrevealing. Flow cytometry was negative for lymphoma or leukemia. Ferritin was elevated at 4450 ng/ml. A bone marrow biopsy demonstrated hemophagocytosis. He then developed multiple pulmonary embolisms, lower extremity edema, new onset ascites, and nephrotic range proteinura. A renal biopsy showed diffuse podocyte effacement with rare Focal Segmental Glomerulosclerosis (FSGS) with collapsing features and no immune complexes. His IL-2 soluble receptor was elevated at 2710 µg/mL. He was diagnosed with HPS, started on prednisone 1 mg/kg then transitioned to tocilizumab.

Discussion: The pathogenesis of HPS is excessive activation and proliferation of T lymphocytes and macrophages leading to phagocytosis of hematopoietic cells in the bone marrow and hypersecretion of proinflammatory cytokines causing multi organ dysfunction. Due to the difficulty in diagnosis, the Hscore was developed to estimate the probability of HPS. Our patient's Hscore was 209 equating to an 88-93% probability. Renal dysfunction occurs in ~16% of patients with HPS with symptoms ranging from hyponatremia to renal failure. Nephrotic syndrome is most commonly due to collpasing FSGS. Case reports have demonstrated the use of tocliziumab in the treatment of FSGS from other etiologies, but treatment of HPS and FSGS has not been reported. Our patient had resolution of his nephrotic syndrome with immunosuppressive therapy with steroids and remain in remission on tocilizumab.

PO0300

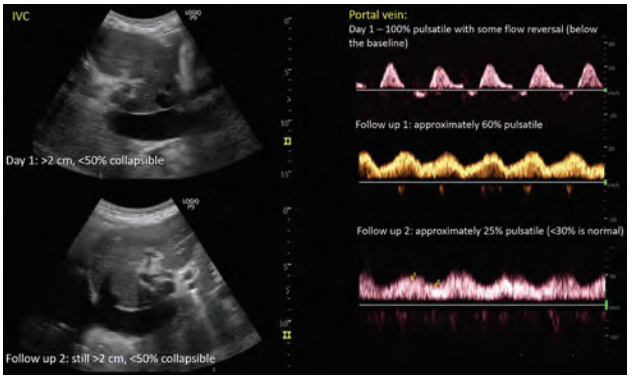
Transition of Portal Vein Doppler Waveform with Improving Venous Congestion: A Case Study

Totini S. Chatterjee, Abhilash Koratala. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: The diagnostic accuracy of physical examination, weight, laboratory parameters such as BNP is limited for the assessment of fluid status. Point-of-Care Ultrasonography (POCUS) is emerging as a valuable bedside tool for evaluation of hemodynamics at the bedside. Herein, we present a case which illustrates the practical utility of portal vein Doppler.

Case Description: A 78-year-old woman with a history of heart failure (HF) with reduced EF (<20%) and pulmonary hypertension was brought to the hospital for altered mental status. She was found to have acute kidney injury (AKI) with a serum creatinine of 2.2 mg/dL (baseline ~1.1) and urinalysis was suggestive of UTI. Urine sodium and chloride were <20 mmol/L. Antibiotic therapy was started; AKI was presumed to be secondary to volume depletion as her diuretic regimen was recently intensified. There was no significant weight gain. Admitting physician noted mild pedal edema and no jugular venous distension. NT-pro-BNP level was 8118 pg/mL (last available value 10,537). 1 liter of isotonic fluid was administered, and diuretics were held. Her metal status eventually improved; nephrology consulted for AKI. POCUS-assisted physical examination demonstrated severely impaired left ventricular systolic function, a D-shaped left ventricle suggestive of pressure and volume overload and a plethoric inferior vena cava (IVC) suggestive of elevated right atrial pressure. Portal vein Doppler waveform was pulsatile with intermittent flow reversal consistent with severe venous congestion. Based on these findings, diuretic therapy was restarted. Serum creatinine improved to 1 mg/dL at discharge. While IVC continued to be dilated, portal vein waveform showed consistent improvement during the course of decongestive therapy [Fig.1].

Discussion: While IVC POCUS is relatively easy to perform, it maybe chronically dilated in patients with pulmonary hypertension. Portal vein Doppler offers an additional datapoint to assess the severity of venous congestion and monitor the efficacy of decongestive therapy.



PO0301

Skin Biopsy in Diagnosis of Acute Interstitial Nephritis

William J. Assante,[1,2] Jiwanjot K. Narula,[1,2] Sanjeev Gupta,[1,2] Bo Li.[1,2] *[1]Westchester Medical Center Health Network, Valhalla, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Acute Interstitial Nephritis (AIN) is a common cause of Acute Kidney Injury (AKI). It is often caused by drugs, systemic diseases, and infectious diseases. The diagnosis is elusive, as the triad of fever, rash, and peripheral eosinophila is rarely seen. Other diseases, such as atheroembolic renal injury, could present similarly. Hallmark findings on urinalysis (leukocytes, WBC casts) and urine eosinophils are also non-specific. Hence, a definitive diagnosis only comes from renal biopsy. The case presents a patient with AKI and rash, highlighting the utility of skin biopsy in diagnosing AIN as an alternative to renal biopsy.

Case Description: A 72 year old female with a history of hypertension and chronic kidney disease was treated with Keflex in-hospital for a urinary tract infection. Within four days of beginning the medication, she developed a maculopapular rash on the trunk, back, and extremities with AKI (creatinine rose to 3.05 mg/dL, while creatinine on admission around baseline of 1.9 mg/dL). Keflex was discontinued and replaced with Ciprofloxacin. Urinalysis had 2+ proteinuria and 3+ hematuria with 113 red blood cells and 24 white blood cells. Urine eosinophils was positive. Autoimmune workup was unremarkable. Renal ultrasound showed kidneys of normal size and echogenicity. The patient began empiric prednisone 60 milligrams daily. Dermatology performed a skin biopsy showing inflammation consistent with drug eruption. Immunostaining was unremarkable. Meanwhile, the patient's creatinine began to improve after treatment and reached baseline by discharge. The rash also began to improve.

Discussion: AIN is a very common cause of AKI, particularly in the hospital setting. Current lab tests used for workup are neither sensitive nor specific for the disease, often rendering AIN a clinical diagnosis. A definitive diagnosis requires tissue sampling, traditionally via renal biopsy. However, the procedure has particular risks, such as retroperitoneal bleed. In this case, skin biopsy showed inflammation characteristic of drug eruption in a patient with AKI and rash correlating in time with initiation of an antibiotic, lending credence to the diagnosis of AIN. Therefore, in patients with suspected AIN involving skin rash, skin biopsy could prove to be a safer mode of tissue sampling for diagnosis, averting the complications traditionally associated with renal biopsy.

PO0302

Oxandrolone-Induced Acute Tubular Necrosis

Cesar Zambrano, Valentina Celis, Ayoola O. Olayiwola, Susana Barreiro Sacco. *Mount Sinai Medical Center, Miami Beach, FL.*

Introduction: Oxandrolone is an anabolic-androgenic steroid (AAS) indicated as adjunctive therapy to promote weight gain in chronic wasting conditions. It is also used off-label by many sports and bodybuilding enthusiasts to increase muscle mass. Common adverse effects include transient elevations in transaminase levels and reduction in HDL cholesterol level. Mostly, kidney complications occur after long-term administration. Renal disorders range from a mild, reversible rise in serum creatinine and BUN to irreversible CKD and FSG. We hereby present a case of acute tubular necrosis in the setting of Oxandrolone use.

Case Description: A 30-year-old previously healthy male presented to the ED with complaints of nausea and vomiting. He reported intentional caloric restriction and intense exercise over the past month, along with using under-the-counter oral Oxandrolone. Labwork revealed AGMA and ketosis (CO2 17.2mmol/L, AG 24.4 mmol/L, β-hydroxybutyrate 48.97 mg/dL) elevated Creatinine (2.8 mg/dL). Glucose, LFTs and CPK were WNL. UA revealed Ketones, Protein 100 mg/dL, RBC 10-25. US and CT of abdomen and pelvis were unremarkable. He was started on IVF and anti-emetics with resolution of symptoms and starvation ketoacidosis. Renal function, however, progressively worsened. BUN/Cr < 20, FeNa 1.4% and no improvement with IVF was consistent with intrarenal etiology. Further work up revealed low C3, normal C4, negative ANA, ANCA, GBM Ab, dsDNA Ab, ASO, LAC, Cryoglobulin, Hepatitis B and Hepatitis C serology. Kidney biopsy was performed given rapid deterioration of renal function with creatinine peak at 6.06. Histology, Immunofluorescence and Electron Microscopy revealed ATN with unremarkable glomeruli. Kidney function gradually improved after 8 days, and patient was discharged in stable condition with follow up with nephrologist.

Discussion: Use of AAS has risen into a worldwide substance abuse problem. Although renal damage secondary to AAS use is rare, they have been demonstrated to cause glomerular damage as FSGS. Tubular injury, however, has only been seldomly reported in the setting of AAS use. Given the rise of uncontrolled use of AAS and the rarity of this type of injury in an otherwise young and healthy population, it is important to inquire further on a possible direct causal relationship. Increased compound risk with commonly coexistent excess creatine and protein intake should also be considered.

PO0303

Pregnancy and Hereditary Thrombotic Thrombocytopenic Purpura: A Case Report

Sarah Abdel Massih, Jason M. Kidd. *Virginia Commonwealth University Health System, Richmond, VA.*

Introduction: Pregnancy and postpartum have been recognized as periods of high risk for development of thrombotic microangiopathy (TMA). We report a case of hereditary thrombotic thrombocytopenic purpura (TTP) unmasked by pregnancy.

Case Description: A previously healthy 32-year-old Caucasian female G1P1 24 weeks pregnant presented with urinary frequency, dark urine and diarrhea for 1-2 weeks. On initial presentation, blood pressure was at 153/96 mmHg. Labs were significant for a rapidly dropping Hgb with hemolysis, thrombocytopenia with a platelet count of 11, mild transaminitis, and a rising serum creatinine with no antecedent history of renal disease (table 1). Unfortunately, an ultrasound revealed intrauterine fetal demise. She received 2 units of platelets and underwent an uneventful delivery. Following delivery, all parameters including Hgb, platelets and Cr improved (table 1). Two days post-delivery, ADAMTS-13 level returned at <2%. She was started on high dose prednisone and received 4 sessions of plasmapheresis. ADAMTS-13 antibody was later found to be negative.

Discussion: TTP is caused by deficiency of ADAMTS-13 metalloproteinase which cleaves the Von Willebrand factor. Low activity of ADAMTS-13 (20-40%) is seen in patient with preeclampsia, eclampsia, HELLP syndrome and pregnancy associated hemolytic uremic syndrome. The enzyme level will decrease to less than 20% only in pregnancy associated TTP. Though TTP in the general population is mostly immune in nature, 24% of cases of pregnancy associated TTP are hereditary. Delivery has been shown to achieve rapid remission in many cases. Most authorities recommend initiation of plasmapheresis with TMA and pregnancy when platelet count is less than 30 with later addition of steroids when the diagnosis of TTP is confirmed. The response rate to treatment is 80-90%. Immune TTP may reoccur in future pregnancies but hereditary TTP has a 100% risk of relapse with future pregnancies making it essential to differentiate the two entities for appropriate management of future conceptions which requires plasma exchange starting early in pregnancy.

Table 1

	Pre-delivery	Post-delivery	Post-plasmapheresis
Hb (mg/dL)	13.9-->6.9	8.2	11.2
Platelets x10^9/L	11	69	521
LDH (U/L)	1616		
Haptoglobin (mg/dL)	<8		238
Cr (mg/dL)	2.5-->3.7	2.65	1

PO0304

No Tears, Frothy Urine, and Lots of Antibodies: Sjögren Syndrome Presenting as Tubulointerstitial Nephritis

Jason Lofters, Nia Flemming, Oluwafeyi F. Adedoyin, Ro-Kaye A. Simmonds, Lena Makartian. *Englewood Health, Englewood, NJ.*

Introduction: Sjogren's syndrome(pSS) is a systemic autoimmune disease that primarily affects the exocrine glands. Renal involvement is a common finding among patients however, in select patients, worsening renal function precedes these symptoms. Associated pSS renal pathologies include tubulointerstitial nephritis (TIN), glomerulonephritis and renal tubular acidosis. Here we present an unusual case of a patient with worsening renal function as a primary presentation of Sjogren's syndrome.

Case Description: 52 year old woman with no medical illnesses presented with renal impairment and retrospectively reported fatigue, 18lbs weight loss, loss of appetite as well as dry mouth, dry eyes and dysphagia. Labs: Hb 9.4g/dL, BUN 24mg/dL, Cr 1.91mg/dL and random urine protein/creatinine ratio of 2.12mg/g without microscopic hematuria. ESR 94 mm/hr, RF 175 IU/mL and positive ANA with a speckled pattern and titre of 1:1280, normal C3/C4 levels, normal dsDNA, negative hepatitis B&C, negative basement membrane IgG antibodies, negative c-ANCA and p-ANCA. Renal ultrasound showed normal sized kidneys with normal echotexture and renal biopsy revealed interstitial nephritis with moderate to severe activity and mild chronicity. She was diagnosed with tubulointerstitial nephropathy secondary to primary Sjogren's syndrome and was started on 1mg/kg of prednisone along with topical agents for sicca symptoms. After 2 months labs revealed Hb 12.3g/dL, Cr 1.43mg/dL, ESR 22 mm/hr and urine protein/creatinine ratio of 0.358mg/g. She has subsequently been started on a prednisone taper to which she has responded well.

Discussion: TIN is associated with a number of systemic illnesses inclusive of pSS. Renal disease in pSS is as high as 42%, with TIN accounting for approximately 10-20% of cases. TIN usually presents after the initial diagnosis of pSS but in our patient it occurred concurrently with the diagnosis. The renal involvement in pSS is usually chronic and it typically shows monolymphocytic TIN with minimal glomerular involvement. However, there is a wide range of renal pathology including TIN to MPGN, membranous nephropathy, and focal crescentic GN. Even though renal impairment does not typically precede pSS it is imperative to biopsy as early as possible so that treatment can be initiated to prevent chronic disease.

PO0305

Excess Vitamin C Leading to Hyperoxaluria and AKI

Katherine Julian, Catherine Abendroth, Ali M. Zebi, Amanda A. Karasinski, Rohit Jain. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: Secondary hyperoxaluria is caused by increased ingestion of oxalate or oxalate precursors, increased oxalate enteric absorption due to fat malabsorption, or changes in intestinal microflora and can manifest as end stage renal disease or hypothyroidism.

Case Description: A 55-year-old female with history of hyperparathyroidism and hypothyroidism (not med compliant) presented with myxedema coma secondary to uncontrolled hypothyroidism. Initial workup revealed elevated potassium (7mmol/L), BUN (194mg/dL), SCr (35mg/dL) and TSH (>100uIU/mL). She was given IV levothyroxine, IV liothyronine, insulin, calcium gluconate and hydrocortisone, and started hemodialysis in the setting of acute kidney injury (AKI) with no known underlying CKD, nephrolithiasis or nephrocalcinosis. Autoimmune, gastrointestinal, and hepatobiliary AKI etiologies were ruled out. A renal biopsy revealed renal oxalosis (Fig 1). Investigation of possible secondary causes of renal oxalosis revealed consumption of large quantities of vitamin C in hopes of preserving her health during the COVID-19 pandemic. The patient remained dependent on hemodialysis was discharged on levothyroxine 150mcg sublingual daily followed by nephrology and endocrinology. At time of discharge, TSH remained >100 uIU/mL, but free T4 was 0.86 ng/dL without any hypothyroid symptoms. High dose vitamin C consumption was discontinued.

Discussion: The combination of severe hypothyroidism resulting in myxedema coma and the excessive intake of vitamin C, a precursor for oxalate stones in the kidney, resulted in AKI. However, we believe the severe hypothyroidism was a result of medication noncompliance vs manifestation of systemic oxalosis. We recommend considering secondary oxalosis in cases of dialysis-dependent AKI in the setting of high dose vitamin C consumption or increased exogenous oxalate ingestion and confirming this diagnosis with renal biopsy.

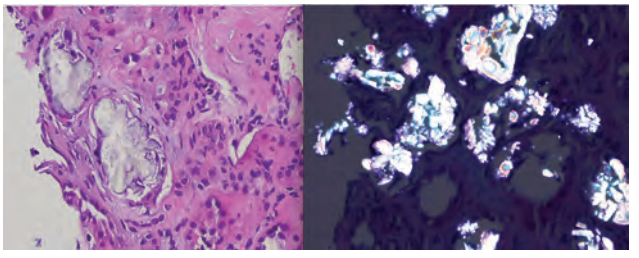


Figure 1: Left: Rhomboid shaped calcium oxalate crystals distending renal tubule with attenuated and disruption of epithelial lining. Right: Calcium oxalate crystals characteristically birefringent under polarized light microscopy.

PO0306

Candida parapsilosis Endocarditis Presenting as Acute Glomerulonephritis: A Case Report

Tai Truong, Devin Lee, Martin Sedlacek. *Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.*

Introduction: Candida species is an uncommon cause of left sided endocarditis that traditionally associated with high morbidity rate. In a few rare cases, Candida endocarditis has been reported as a cause of infection related GN. Here, we described a case of Candida parapsilosis endocarditis that presented as acute glomerulonephritis.

Case Description: A 52 y.o Caucasian female with history of antiphospholipid syndrome, intravenous drug use history on suboxone who presented with 3 weeks of dyspnea, LE edema and tea colored urine. She was found to have elevation in creatinine to 3.6mg/dL from baseline of 1.08mg/dL. There was no history of fever, chill, night sweats, weight loss. There was a dime sized healing ulcer on the thigh. Due to her high risk thrombotic history, she received heparin for anticoagulation. A urine dipstick showed >300 protein and 3+ blood. A spot urine protein to creatinine ratio was 4.5. The urine sediment showed granular and hyaline casts, many RBC of normal morphology and rare acanthocytes. The C3 level was mildly decreased at 60 and C4 level normal at 14. She had

mildly elevated ANA at 1:80 and negative double strand DNA, smooth muscle antibody level, PR3/MPO and extractable nuclear antigen antibody including SSA/SSB, RnP, Scl-70 and Jo-1 antibody level. A CRP was 33 and ESR was 47. Blood cultures revealed Candida parapsilosis. MRI spine with inflammatory changes of L4-L5 suggesting osteomyelitis. Patient received micafungin but remained persistently fungemic. A TEE revealed a large mitral valve vegetation. While under evaluation for mitral valve surgery, she suffered from a large right MCA stroke and deceased within 48 hours from brain herniation. No autopsy performed due to family's request.

Discussion: Fungal associated GN is a rare clinical entity that usually mentioned only as a foot note in textbooks. The mechanism of kidney injury is likely immune complex deposition. Given the high mortality rate with Candida endocarditis and its associated complications, heightened clinical suspicion and early aggressive treatment with antifungal and surgery are important. Corticosteroid in one case report improved renal function indicating a possible role in patients with controlled infection.

PO0307

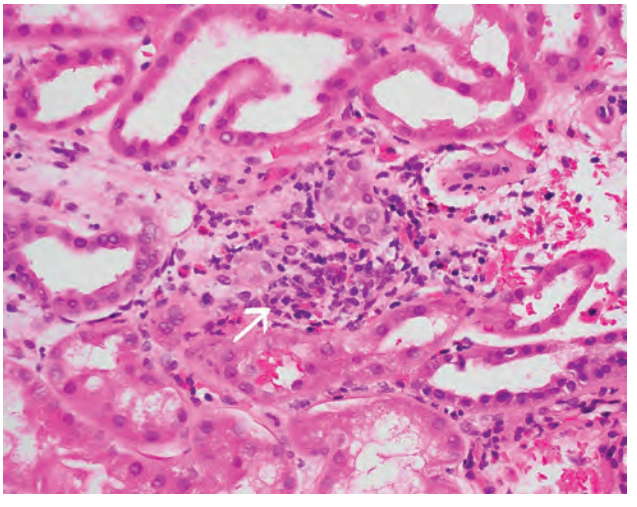
Linezolid-Associated Interstitial Nephritis

Varsha V. Suresh,[1] Mario A. Mendoza Sanchez.[2] *[1]University of Central Florida, Orlando, FL; [2]Orlando VA Healthcare System, Orlando, FL.*

Introduction: Acute Interstitial Nephritis (AIN) accounts for 15-27% of renal biopsies performed for Acute Kidney Injury (AKI). Drug induced AIN remains the most common cause. We present a case of Linezolid induced AIN, a rare entity.

Case Description: Elderly male patient with type 2 diabetes, hypertension and normal renal function was initiated on linezolid for osteomyelitis. Two weeks later, he reported a maculopapular rash on his arms and chest. Labs were significant for a serum creatinine (Scr) of 3.8mg/dl. Immunological and infectious work up for AKI was unremarkable. Scr continued to increase to 7.2mg/dl and absolute serum eosinophil count was 1800 cells/microliter. Interstitial nephritis was suspected and empiric prednisone was initiated. Renal biopsy showed Acute Tubular Injury with Interstitial Nephritis and moderate interstitial fibrosis. The AIN was associated with several eosinophils, and was consistent with a drug induced reaction. Linezolid was stopped, and the patient continued a steroid taper with which SCr improved to 2.0mg/dl and remained stable. The patient did not meet diagnostic criteria for DRESS (Drug Rash with Eosinophilia and Systemic Symptoms) as he had no other systemic involvement, and the rash was not associated with desquamation or infiltration.

Discussion: This patient developed a rash and interstitial nephritis after the initiation of linezolid. He reported no Non-Steroidal Anti-Inflammatory Drug (NSAID) intake and was on vancomycin and piperacillin- tazobactam for less than 48 hours, during which renal function remained stable. Linezolid associated Interstitial Nephritis is rare, and only 4 cases have been reported in the literature. As the prevalence of Methicillin Resistant Staphylococcus Aureus increases, we must be wary of this complication before initiating treatment. Renal function must be monitored, and prompt initiation of steroids can ensure improvement of renal function.



Pathology showing acute interstitial nephritis with eosinophils

PO0308

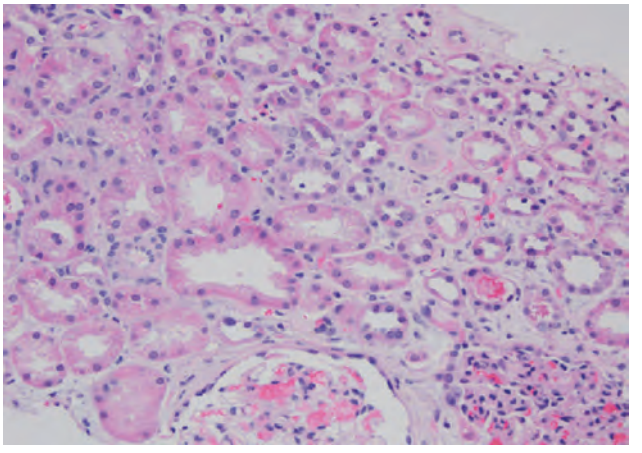
Rifampicin: An Infrequent Cause of AKI

Niraj K. Yadav, Janame J. Kottey, Rama Kethineni, Zachary Drury, Monica P. Revelo Penafiel, Adhish Agarwal, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Rifampicin is used to treat Mycobacterium infection. Hypersensitivity reaction to rifampicin resulting in acute kidney injury (AKI) is infrequent. Here we describe rifampicin hypersensitivity in a patient presenting with AKI who was treated for Mycobacterium marinum infection.

Case Description: A 43 year old male was treated with Rifampicin for Mycobacterium marinum infection 3 years ago. He recently injured his hand and took two pills of Rifampicin leftover from 3 years ago to prevent another infection. He took them about 12 hours apart and a few hours after taking the second pill he developed severe nausea, vomiting, flank pain and dark colored urine. He presented to emergency department and labs showed elevated LDH(lactate dehydrogenase) and bilirubin, thrombocytopenia, anemia and elevated creatinine. He was transferred to our hospital for further management. Upon arrival creatinine was 7.5mg/dl. Bilirubin had normalized and haptoglobin was in normal range. ADAMTS13 level was 56%. Peripheral smear did not show schistocytes. He underwent kidney biopsy which showed moderate acute tubular injury and focal thrombotic microangiopathy. It was determined that he had AKI from type 2 hypersensitivity to Rifampicin. His creatinine continued to worsen to 18mg/dl before improving. He did not require renal replacement therapy. On follow up three weeks later, his creatinine had improved to 1.7mg/dl.

Discussion: Rifampicin hypersensitivity can manifest with hepatitis, hemolytic anemia and AKI. It is most often seen when the drug is re-administered or used intermittently. The outcome of AKI is usually favorable after discontinuation of the drug, with most patients achieving full recovery within 90 days. As the hypersensitivity reaction is infrequent, prompt recognition and withdrawal of drug is important to prevent irreversible injury.



Renal biopsy showing Acute Tubular Injury.

PO0309

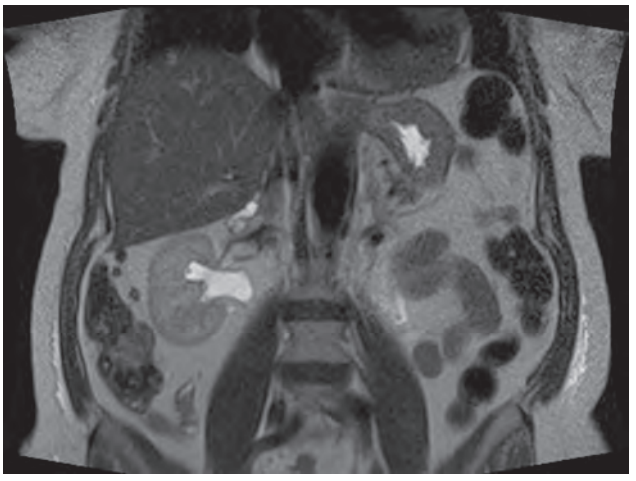
Hypertension Secondary to Obstructive Retroperitoneal Fibrosis

Bindu S. Dindu, Moeed Ahmed, Sangeeta Mutnuri, Mohammed Nazmul. *Creighton University School of Medicine, Omaha, NE.*

Introduction: Retroperitoneal fibrosis (RPF) has been known to cause ureteral compression leading to obstructive nephropathy. This case details RPF presenting as hypertensive emergency with acute on top of chronic kidney disease.

Case Description: A 62-year-old female with stage 3 chronic kidney disease and essential hypertension (HTN) presented to the emergency room with headache and elevated blood pressure (BP) of 200/121 mm Hg. Physical exam was significant for trace lower edema. Labs showed elevated creatinine at 13.8 (1.08 two months prior) and hyperkalemia, potassium at 5.8. Urine analysis was unremarkable. MRI revealed bilateral hydronephrosis and a soft tissue mass encasing the aortal bifurcation, abutting the ureters concerning for RPF vs. lymphoma. Subsequent MAG 3 showed significantly compromised left renal function. A foley was placed, returning 4.7 liters of urine in 24 hours. Her BP and headache improved with clonidine and nicardipine over the next 48 hours. Upon normalization of her BP and creatinine, patient was discharged. On follow up, CT guided biopsy of her mass confirmed RPF. Extensive workup for etiology was unrevealing, making a diagnosis of idiopathic RPF. Post discharge, a left ureteral stent was placed and repeat imaging after 3 months showed spontaneous regression of the mass with resolving hydronephrosis. The stent was removed, and the patient opted to pursue mycophenolate mofetil therapy to manage her RPF.

Discussion: Rarely detailed in medical literature, RPF induced secondary HTN has been proposed to be mediated by the tubuloglomerular feedback and renin angiotensin and aldosterone axis. Imaging can play a key role in diagnosing RPF. Whilst relieving obstruction can quickly resolve HTN in these patients, glucocorticoids and other immunosuppressive therapies can manage long-term progression.



Soft tissue mass encasing the distal abdominal aorta and aortic bifurcation, measuring 2.3 cm by 5.2 cm by 9.2 cm

PO0310

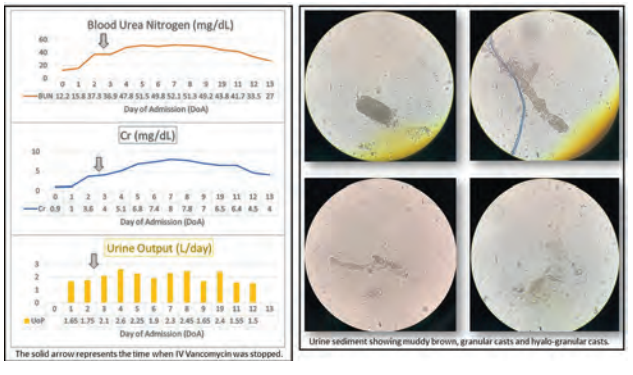
Precipitous AKI: A Unique Form of AKI by Vancomycin

Sheikh B. Khalid,[1] Javaria Mahmood.[2] *[1]Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan; [2]Shalimar Medical and Dental College, Lahore, Pakistan.*

Introduction: Vancomycin-associated acute kidney injury (VA-AKI) is a well-known entity. With improvement in formulations of vancomycin (vanc), its incidence has decreased, however it remains a risk factor of AKI especially when used in combination with other nephrotoxic agents. We present a case of VA-AKI that represents a unique pattern of kidney injury, known as "precipitous AKI".

Case Description: A 23-yr-old male presented to the emergency room with fever & body aches for 1 day. He was getting chemotherapy for acute lymphocytic leukemia; last received cyclophosphamide 10 days ago. He was tachycardic. Physical exam was unremarkable. His absolute neutrophil count was $0.5x10^3$ cells/µl. He was admitted & started on IV vanc & Piperacillin/Tazobactam. On the 4th day of admission (DoA), he developed AKI with rise in blood urea nitrogen (BUN) and creatinine (Cr) to 37mg/dL and 3.6mg/dL, (baseline of 12mg/dL & 0.9mg/dL) respectively. Urine sediment showed granular casts suggestive of tubular injury. Vanc was stopped; until then he had received a cumulative dose of 5grams. Cr peaked to 8mg/dL on the 8th DoA. The rise in BUN was discordant which only rose to 52mg/dL. The patient never developed oliguria either. His BUN and Cr improved thereafter and he was discharged. The BUN and Cr were normal on repeat testing done 2 weeks later.

Discussion: Precipitous AKI is the term coined by Velez et al. which appears to be the first description of this entity. To our knowledge, only a handful of cases have been reported. It is seen in patients who receive high cumulative dose of vancomycin and manifests as rapid rise in Cr (more than 2.5mg/dL in a day) while in other causes of AKI the rise of Cr is between 1-1.5mg/dL. The relative rise in BUN does not match that of Cr. The patients do not develop oliguria, & cystatin C is usually normal:. These observations support the notion that glomerular filtration is not affected, and is postulated to be caused by tubular toxicity that effects the tubular secretion of Cr. Further studies are needed however.



PO0311

Atypical Hemolytic Uremic Syndrome Secondary to Homozygous CFHR1-CFHR3 Mutation

Jad Tabbara, Mohamed Hassanein, Xiangling Wang, Evamaria Anvari. *Cleveland Clinic, Cleveland, OH.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a disease of complement dysregulation characterized by microangiopathic hemolytic anemia, thrombocytopenia, and multisystem end organ damage commonly affecting the kidneys. About two thirds have identifiable genetic abnormalities. Mutations cannot be identified in 30% of the time. A strong association has been observed between anti-FH autoantibodies and a homozygous deletion of *CFHR1* and *CFHR3*. Factor H autoantibodies can impair complement regulation, resulting in aHUS. We report a case of aHUS secondary to a homozygous CFHR1 – CFHR3 mutation.

Case Description: A 35-year-old gentleman with no significant past medical history presented with acute worsening of his kidney function of unclear etiology (creatinine 2.5mg/dL). Kidney biopsy was performed showing thrombotic microangiopathy without evidence of vasculitis. Two days post-biopsy, he developed acute weakness and slurred speech. MRI of the brain was compatible with multiple acute cerebral infarcts. Initial laboratory values were nonspecific but follow up labs showed evidence of hemolysis with worsening renal function (creatinine 3.8 mg/dL) and thrombocytopenia (platelet count 120,000 from 283,000 per microliter). Further workup showed undetectable haptoglobin, elevated lactic acid dehydrogenase, low C3 levels and normal ADAMS-T13 activity. Given high index of suspicion for aHUS and the absence of other causes of thrombotic microangiopathy, he was started on eculizumab. After 6 doses his renal function improved and repeat MRI showed improving cerebral vasculopathy suggesting that the process was likely thrombotic. The aHUS susceptibility panel was positive for a homozygous *CFHR3-CFHR*1 gene deletion with elevated Factor H autoantibody 74.2 mg/dl (normal 37-68 mg/dl). The patient's renal function stabilized with complete neurologic recovery. He remains on maintenance dose of eculizumab.

Discussion: Atypical HUS is an rare cause of thrombotic microangiopathy. Many cases have identifiable genetic mutations that lead to dysregulation of alternative complement pathway. Delayed or inappropriately treated cases lead to increased morbidity and mortality. Early screening for aHUS related genetic mutations in patients with acute kidney injury and microangiopathic hemolytic anemia is essential for prompt diagnosis of aHUS and help guide treatment duration.

PO0312

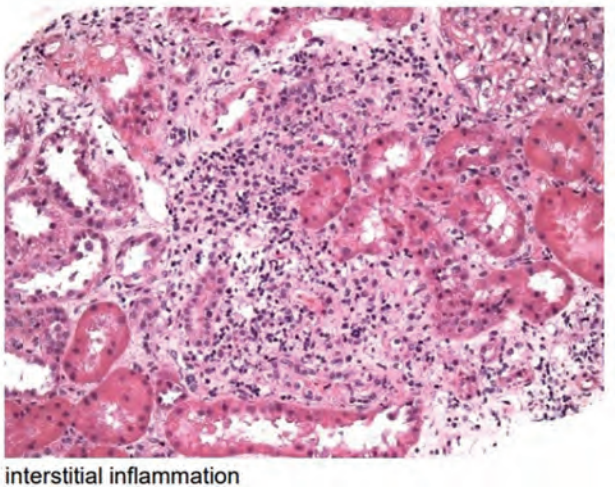
A Rare Case of Concomitant Acute Interstitial Nephritis (AIN) and HIV-Associated Nephropathy (HIVAN)

Aditi Bhardwaj, Raja Jadav, Jorge Tirado, Laith Alzyood, Jamil Ibrahim, Ahmed Abdurham, Bessy Suyin Flores Chang. *St Barnabas Hospital, Bronx, NY.*

Introduction: HIVAN is characterized by collapsing focal segmental glomerulosclerosis (FSGS), the most common cause of renal dysfunction in HIV patients. Whereas AIN causes only 10% of renal dysfunction in HIV patients and it is usually caused by drugs, infections, or dysimmune syndromes but not as a direct consequence of HIV infection. AIN caused by HIV itself is a rare phenomenon, with only one reported case in the literature. We present a case of AIDS presenting itself as acute renal failure secondary to AIN and HIVAN

Case Description: 51-year-old male with a history of hypertension presented with abdominal discomfort, loss of appetite, and dark brown urine for one week. He denied medication use. Initial laboratory values of serum potassium 8.9 mEq/L, serum creatinine 18 mg/dL, serum bicarbonate 12 mEq/L. CT Abdomen showed no hydronephrosis. He underwent urgent hemodialysis for refractory hyperkalemia. Urinalysis showed pyuria with WBC clumps, and microalbumin-to-creatinine ratio of 27g/dL. Further workup revealed HIV-1 positive with a CD4 count of 5/mL and viral load of 2,680,000 copies/mL. Anti-retroviral therapy was started. Kidney biopsy was consistent with acute intestitial nephritis and collapsing FSGS. IV pulse steroids started for 3 days then oral prednisone with gradual improvement in the clinical status. Unfortunately, his clinical status deteriorated with an acute respiratory failure requiring intubation with multiorgan failure and refractory septic shock that resulted in demise

Discussion: AIN in HIV is rare with few case reports having been published in the literature. In this case, pulse dose steroids were use for treatment with a very limited response. Our aim is to remind physicians that AIN can be found in HIV with or without glomerular disease. More data is needed to establish treatment guideliness and monitor patient closely for treatment response.



PO0313

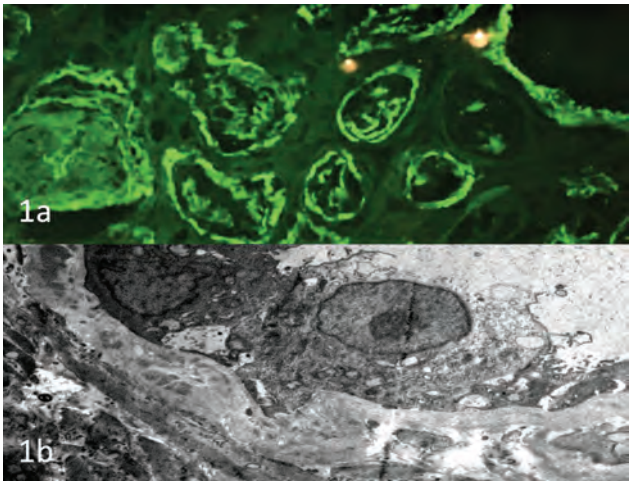
Unexplained AKI: Never "Brush" Off the Role of a Renal Biopsy

Chintav Shah,[1] Roger A. Rodby,[2] Umbar Ghaffar.[1] [1]*University of Arkansas for Medical Sciences, Fayetteville, AR;* [2]*Rush University Medical Center, Chicago, IL.*

Introduction: Anti-Brush Border Antibody Disease (ABBAD) is a rare condition typically seen in elderly individuals and presents with acute kidney injury (AKI) and sub-nephrotic proteinuria. Patients often progress rapidly to ESKD despite treatment.

Case Description: A 73-y/o man with a PMH of HTN, a-fib and CKD (serum creatinine SCr 1.5 mg/dl 4 mo ago and 2.3 mg/dl 2 mo ago) was found to have a SCr of 3.2 mg/dl. His medications were tamsulosin, apixaban, losartan and metoprolol tartrate. He denied NSAID usage. His vital signs were normal and his physical exam was unremarkable. His urinalysis was significant for 2+ protein without blood. He had an elevated urine protein/Cr ratio at 1.5 g/g. Serological and infectious workups were negative. A renal ultrasound was normal. A renal biopsy demonstrated 50% global sclerosis with remaining glomeruli normal. There was moderate interstitial fibrosis and tubular atrophy. The immunofluorescence and electron micrographs are shown in Fig 1a and 1b. Specific IF staining for lipoprotein-related protein 2 (LRP2) was positive in the tubular basement membrane (TBM), consistent with a diagnosis of ABBAD. Because of his advanced age he was treated with 60 mg of prednisone alone with no improvement.

Discussion: ABBAD occurs from formation of IgG antibodies against low density lipoprotein-related protein 2 (LRP2) megalin which deposit on the tubular BM of the PCT. Because it is so rare, (<20 cases) little is known about the treatment with rare responses to prednisone and cytotoxic agents. It is unknown if rituximab is effective. ABBAD can recur in a renal transplant. Early diagnosis and aggressive immunotherapy would seem prudent. This approach requires a low renal threshold for biopsy in AKI. It is however unknown if early treatment can alter the typical abysmal renal outcome.



1a) IF showing segmental staining with IgG along the tubular basement membrane. 1b) EM showing electron dense deposits along the tubular basement membrane.

PO0314

Vitamin C, CKD, and Roux-en-Y; A Dangerous Combination

Darren W. Schmidt,[1] Nidia C. Messias,[2] Saeed K. Shaffi.[1] [1]*University of New Mexico School of Medicine, Albuquerque, NM;* [2]*Arkana, Little Rock, AR.*

Introduction: Patients who have undergone bariatric procedures can be at increased risk for acute kidney injury (AKI) due to oxalate nephropathy; therefore, it is important that there is an awareness of other risk factors for this condition in this patient population. In particular, high doses of vitamin C should be avoided.

Case Description: A 74-year-old female, who had a Cr of 0.8 mg/dl a year prior, with a history of Roux-en-Y gastric bypass surgery in 2016, recurrent nephrolithiasis, and an atrophic right kidney was advised to go to the hospital after outpatient laboratory data revealed a Cr of 8.7 mg/dl. The patient had been taking Vitamin C 1000 mg daily. An initial evaluation did not reveal an etiology of AKI and her renal function did not improve with 48 hours of IV fluids. Hemodialysis was initiated for uremic symptoms. The patient underwent a biopsy (Figure 1) which showed severe acute tubular injury, mild interstitial fibrosis and tubular atrophy, and significant tubular calcium oxalate crystal deposition. At the time of discharge, she had poor creatinine clearance and remained on hemodialysis.

Discussion: AKI related to oxalate nephropathy can be viewed as a confluence of pre-disposing conditions, risk factors, and exposures. Any single case may have one or more of these issues; this case is remarkable in that it encompasses multiple factors: 1. A pre-existent history of calcium oxalate stones, 2. A markedly atrophic right kidney, with a suspicion of chronic kidney disease and a reduced excretory capacity, 3. Prior Roux-en-Y gastric bypass resulting in increased absorption of oxalate, 4. Supplemental vitamin C intake, 5. Pyridoxine deficiency which limits the body's ability to "detoxify" oxalate. Unfortunately, oxalate nephropathy is associated with poor renal outcomes; therefore, patients with multiple risk factors for this condition should be appropriately counseled and closely monitored.

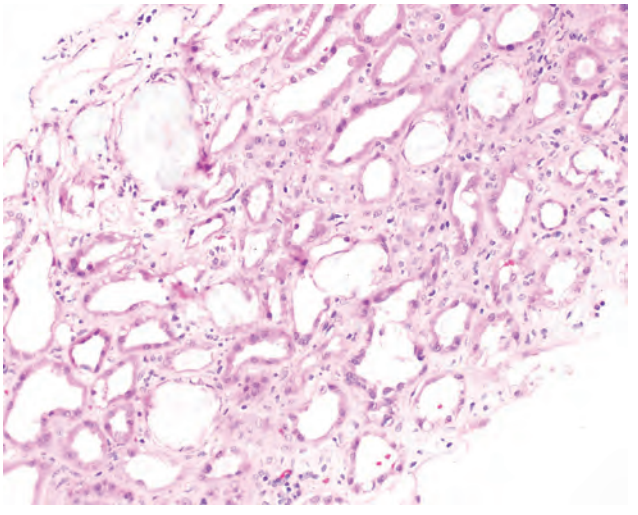


Figure 1: H & E stain

PO0315

Lamotrigine-Induced Acute Interstitial Nephritis

Indraneel Reddy, Abhay D. Patel, Rupesh Raina, Ron Jones. *Summa Health System, Akron, OH.*

Introduction: Medications such as penicillins, cephalosporins, vancomycin, ibuprofen, and ketorolac are the most common cause of acute interstitial nephritis (AIN), accounting for more than 75% of cases. Recently, antiepileptic drugs such as lamotrigine have been reported to cause AIN. Here, we report a case of a 39-year-old female who was on lamotrigine and admitted to the hospital with abdominal pain and acute renal failure.

Case Description: A 39-year-old female with a history of Hepatitis C, history of meth and heroin abuse, overactive bladder, hypothyroidism, and bipolar disorder presented to the emergency department with a week of abdominal pain. In the emergency department, she complained of nausea, constipation, and five days of hematuria. The patient was admitted after labs showed BUN/Cr of 48/3.69. Two weeks prior to presentation, she was started on lamotrigine 100 mg daily, which was held upon admission. Patient was started on IV fluids but her condition acutely worsened with thrombocytopenia, anemia, and leukopenia. She was started on methylprednisolone 500 mg IV daily due to concern for AIN vs vasculitis. Her blood and urine cultures resulted positive for E. coli, and she was subsequently started on IV ceftriaxone. The patient underwent a left kidney biopsy demonstrating AIN without crescentic glomerulonephritis, which was likely an allergic reaction secondary to lamotrigine use. Her biopsy also showed neutrophilic infiltration, likely secondary to pyelonephritis. She was discharged in stable condition on prednisone oral 20 mg daily.

Discussion: In summary, we present an adult patient on lamotrigine who was admitted due to acute renal failure. There have only been four reported cases of AIN induced by lamotrigine use. The patients had few commonalities other than lamotrigine use, but notably half of them were being treated for bipolar disorder. Our patient had a history of drug abuse with uncertainty on last use, which could represent another cause of

her AIN. After cessation of lamotrigine and treatment with methylprednisolone 500 mg IV, her kidney function improved. Renal biopsy confirmed AIN. Our case is significant because it substantiates the use of corticosteroids for management of lamotrigine-induced AIN.

PO0316

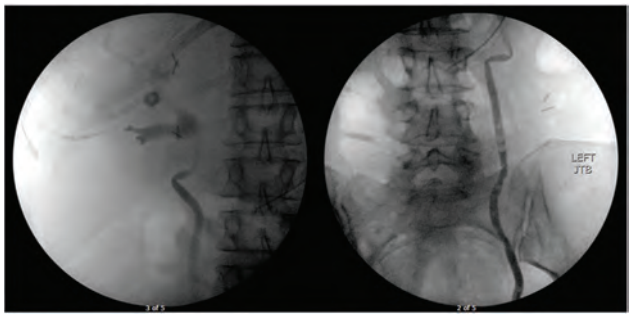
A Case of Abrupt Anuria from Bilateral Kinked Ureters

Hanny Sawaf, Eiftu Haile, Anne M. Huml. *Cleveland Clinic, Cleveland, OH.*

Introduction: Urinary tract obstruction is a well-known cause of reversible AKI. In patients with 2 functioning kidneys, bilateral ureteral obstruction is rare and unilateral ureteral obstruction rarely causes anuria and often does not result in a noticeable worsening of renal function. Here we describe a case of abrupt anuria and severe AKI secondary to bilaterally kinked ureters resembling parenchymal renal failure.

Case Description: A 58-year-old female with metastatic epithelioid mesothelioma underwent debulking peritonectomy, bilateral salpingioopherectomy, and omentectomy with hyperthermic intraperitoneal chemotherapy with cisplatin at 50 mg/m^2. Bilateral ureteral catheters were placed preoperatively to avoid ureteral injury during surgery. The catheters were removed on post-operative day (POD) 0. Post-operative course was initially uncomplicated with stable renal function and more than 2L urine output a day. On POD 2, she was noted to have abrupt anuria despite the presence of a functioning foley catheter. Her creatinine increased from 0.7 mg/dL to 2.3 mg/dL. Renal ultrasound revealed normal sized, echogenic kidneys with mild bilateral hydronephrosis. A CT cystogram with contrast was negative for a urinary leak. On POD 3, she remained anuric. At this point there was concern for a dense ATN caused by cisplatin and initiation of renal replacement therapy was considered. Given a high degree of suspicion for ureteral obstruction, the patient underwent cystoscopy with bilateral retrograde pyelogram revealing significant bilateral ureteral kinking (see image). Bilateral ureteral stents were placed with brisk urine output noted intraoperatively and her renal function improved back to baseline.

Discussion: Obstruction can occur at any point in the urinary tract but tends to only cause anuric AKI with an obstruction below the level of the bladder for patients with 2 functioning kidneys. Obstruction at the level of the ureter generally does not cause anuric AKI except in rare bilateral cases. This case may represent reflex anuria in the setting of a combination of post-operative bilateral ureteral spasm, edema, and kinking.



PO0317

Acute Interstitial Nephritis Secondary to Cocaine Use

Andrea Broka, Marjorie M. Flores chang, Carlos E. Arias Morales, Ahmed Abdurham, Jamil Ibrahim, Bessy Suyin Flores Chang. *SBH Health System, Bronx, NY.*

Introduction: Renal failure resulting from cocaine use disorder is well documented with etiology ranging from rhabdomyolysis, vasculitis, thrombotic microangiopathy and rarely acute interstitial nephritis, although unclear underlying mechanisms

Case Description: 33-year-old African American female with history of bipolar disorder alcohol, crack, cocaine use disorder presented with generalized fatigue and dyspnea for the past 4 days requesting inpatient detox. Home medications were ziprasidone, trazadone, topiramate. No recent history of nonsteroidal anti-inflammatory drugs, antacids or antibiotics. Family history was positive for hypertension only. On exam, vitally stable but, she was lethargic, with fluctuating sensorium and attention, with painful, deep linear nonbleeding lesion on oral mucosa and oliguric. Rest of exam was unremarkable. Her initial work up showed elevated blood urea nitrogen (BUN) 215 mg/dL and serum creatinine (SCr) 19.3 mg/dL, serum bicarbonate of 14 mEq/L, leukocytosis 19.2 x10^3 cells/uL with neutrophilia, normal eosinophil count and elevation of liver enzymes. Creatine phosphokinase was 782, peaked at 2574 and down trending the next day. Urinalysis showed large blood with more than 182 red blood cells/ HPF, 27 white blood cells/HPF, and moderate leukocyte esterase. Protein to creatinine ratio 1.12. Urine drug screen was positive for cocaine. Ultrasound kidney was unremarkable. A panel for autoimmune disease, hepatitis, and human immunodeficiency virus was negative. Initial assessment was acute kidney failure, likely acute tubular necrosis in the setting of cocaine use. She underwent emergent hemodialysis (HD) with improvement on her mental status. Renal biopsy showed diffuse acute tubulointerstitial nephritis, acute tubular injury, focal myoglobin casts and arteriosclerosis with negative immunofluorescence. She was started on IV methylprednisolone 1 g/daily for 3 days and then switched to oral prednisone 1 mg/kg for 8 weeks. HD was discontinued, urine output improved, with complete renal recovery on outpatient follow up

Discussion: We believe that AIN must be in the differential when treating patient with AKI and recent cocaine use, treatment must be started as earlier as possible to prevent progression to chronic kidney disease with fibrosis

PO0318

Uric Acid Crystallopathy Associated with Trimethoprim/Sulfamethoxazole (TMP/SMX) Use in a Patient with Gout

Mengting Qiu,[1] Mengyao Tang,[2,3] David B. Mount.[2,4] *[1]Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]VA Boston Health Care System Boston Vet Center, Boston, MA.*

Introduction: The commonly used antibiotic trimethoprim/sulfamethoxazole (TMP/SMX) is known to cause AKI. AKI induced by TMP/SMX can occur through various mechanisms, such as acute interstitial nephritis, crystalluria, acute tubular necrosis, and "pseudo"-AKI due to inhibition of proximal tubular secretory organic cation transporters by TMP. Here, we present a patient with a history of gout found to have AKI secondary to uric acid crystallopathy in the setting of TMP/SMX treatment.

Case Description: A 69-year-old male with a history of gout, heart transplant, and CKD3a secondary to calcineurin inhibitor toxicity was initiated on inpatient TMP/SMX treatment for *Pneumocystis jirovecii* pneumonia (PJP), with starting dose of 15mg/kg/day orally. 3 days later, creatinine was 3.2 mg/dL, from baseline of 1.6 mg/dL; cystatin C was 4.1 mg/L with an eGFR of 12. Urinalysis revealed pH of 5 and 4+ uric acid crystals. Serum uric acid level was 11.7 mg/dL, with an elevated fractional excretion of uric acid at 17%. Of note, the patient had been off urate-lowering therapy since heart transplant, and had had 3 gout flares in the 6 months prior to presentation. Because TMP/SMX is the preferred treatment for PJP, it was continued. He was given IV bicarbonate to alkalinize his urine; uric acid crystals were no longer present on repeat UA the next day. He was also given rasburicase, which lowered serum uric acid to <0.4 mg/dL. Creatinine began to downtrend 1 week after rasburicase therapy, reaching baseline levels about 3 weeks later, while still on TMP/SMX.

Discussion: Uric acid crystallopathy, uricosuria, and hypouricemia associated with SMX and/or TMP have been previously reported in the literature. It is hypothesized that SMX may inhibit uric acid reabsorption in the proximal tubule, increasing fractional excretion. TMP has also been shown to be uricosuric. Studies to determine whether SMX and TMP inhibit heterologously-expressed urate transporters are ongoing. Patients with a history of gout and a high baseline serum uric acid level may be at higher risk of kidney injury from uric acid crystallopathy when administered TMP/SMX. Thus, it seems appropriate to check serum uric acid levels before initiating TMP/SMX therapy in patients with gout. If serum uric acid level is elevated, concomitant urate-lowering therapy may be renoprotective.

PO0319

Pseudo AKI: When the Kidney Biopsy Doesn't Match the Creatinine

Abebech J. Waktola, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Elevated Creatinine (Cr) without AKI can be seen due to increased production of Cr, interference with the assay, decreased tubular secretion of Cr and urine ascites. We report a patient who presented with pseudo AKI due to delayed urine leak after prostatectomy.

Case Description: A 53-year-old male with PMH of hypertension, mixed connective tissue disease and prostate cancer was admitted to an outside hospital 6 weeks after prostatectomy due to AKI noted during post op follow up visit. He had abdominal pain for which he was taking naproxen, nausea and oliguria. Labs showed a Cr 6.58 mg/dl (baseline 1.1 mg/dl), proteinuria, hematuria and pyuria. A CT of his abdomen showed fluid in his pelvis and no hydronephrosis. His Cr worsened despite supportive care. Serologic testing was unremarkable and a renal biopsy revealed mild acute tubular injury and glomerulomegaly. His Cr improved to 5 mg/dl with foley catheter placement and he was discharged. He presented to our ED two days later with worsening symptoms. Labs revealed his Cr had worsened to 10.8mg/dl and BUN was 103 mg/dl. He had hyperkalemia, metabolic acidosis, hyponatremia and hyperphosphatemia. A repeat CT of his abdomen revealed fluid in the retropubic space and free fluid in peritoneum concerning for an anastomotic leak. Static cystogram confirmed a leakage from the vesicourethral anastomotic site into the retropubic space. A drain was placed in retropubic space and a foley catheter was maintained. He was discharge with resolution of symptoms, drain and foley catheter in place with Cr of 1.1mg/dl and normal electrolytes.

Discussion: Vesicourethral anastomotic urinary leak is reported in 8.6-13.6% of cases after laparoscopic prostatectomy and most cases present within 8 days after surgery. Patients usually present with symptoms due to urine leak resulting in peritonitis, paralytic ileus and pseudo AKI. Pseudo AKI is a rare condition with biochemical evidence of AKI in the absence of structural kidney damage or injury. It can be seen following genitourinary surgery, blunt abdominal injury or radiation therapy leading to urine ascites. Urine ascites causes reverse auto peritoneal dialysis characterized by flux of small molecules from collected peritoneal urine to blood. Nephrologists should have a high degree of suspicion for pseudo AKI in patients who present with oliguria, ascites and biochemical evidence of AKI following genitourinary surgery.

PO0320

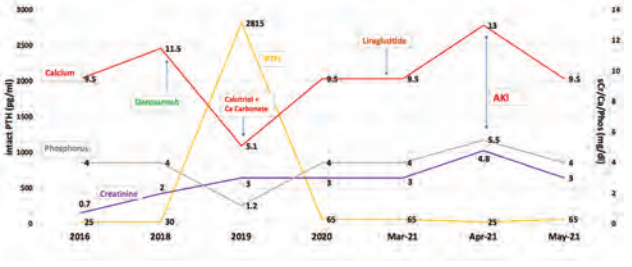
Liraglutide-Induced Hypercalcemia with AKI

Nilam Patel, Muhammad A. Shahzad, William L. Whittier. *Rush University Medical Center, Chicago, IL.*

Introduction: Iatrogenic hypercalcemia from Vitamin D analogues and Calcium supplements is well-described. We present a patient who develped AKI and hypercalcemia on stable doses of these agents in CKD after being started on Liraglutide. This diabetic agent is a GLP-1 agonist, used for weight loss and glycemic control. We postulate the decreased gastric and intestinal motility caused by Liraglutide as the cause of increased enteric absorption and bioavailability of CaCO3 + Calcitriol leading to hypercalcemia-induced AKI.

Case Description: A 60 YO man with PMH of DM-2, Obesity and Multiple Myeloma (MM) presented for evaluation of AKI on CKD. He had CKD stage 3b due to MM with a b/l sCr of 3 mg/dl. Two years prior, he developed severe symptomatic hypocalcemia after treatment with Denosumab for osteolytic lesions. He was started on Calcitriol 1 mcg QD and CaCO3 2000 mg TID with stable serum Calcium, phos, iPTH and Cr for the next two years. He presents now with fatiguability, paresthesias and weight loss, one month after being started on Liraglutide by his PCP. Labs: serum Cr 4.3 mg/dl (b/l 3 mg/dl), Ca 13 mg/dl (b/l 9.5 mg/dl), Phos 5.5 mg/dl, iPTH 25 pg/ml. AKI was deemed secondary to hypercalcemia and thus Liraglutide, Calcitriol and CaCO3 were discontinued with resolution over two weeks (Fig 1).

Discussion: Liraglutide improves glycemic control and reduces weight by slowing gastric and intestinal motility inducing early satiety. It modifies the enteric absorption of drugs and can increase the bioavailability of lipophilic drugs such as Calcitriol. Longer contact with gastric acidic pH can potentially render agents more lipophilic with increased absorption. In our case, the temporal relationship between Liraglutide and onset of hypercalcemia, in a patient previously stable on unchanged doses of Calcitriol and CaCO3, suggests increased enteric absorption of calcitriol and calcium induced by the GLP-1 agonist. We suggest close monitoring and potential reduction of Calcitriol and CaCO3 dose prior to starting gastroparetic agents like Liraglutide. Further studies are recommended to better elucidate the pharmacokinetics of Calcitriol and Liraglutide.



PO0321

Recreation with a Concerning Diagnosis

Sobia N. Khan, Heesuck Suh. *Stonybrook University Hospital, Stony Brook, NY.*

Introduction: Sarcoidosis is a systemic granulomatous disease of unknown etiology, characterized by non-necrotizing/non-caseating granuloma. The diagnosis of sarcoidosis requires stepwise approach to identify organs that may be affected and are amenable to biopsy, exclusion of other causes of granulomatous histopathology with special stains for mycobacteria and fungi, documentation of involvement of at least one additional organ system, and exclusion of other multisystem granulomatous diseases.

Case Description: A 73-year-old male with history of chronic kidney disease stage II serum creatinine 1.4mg/dl, T2DM, hypertension, history of lymphoma presented to the clinic. He was noted to have a black ink tattoo on his shoulder, present for > 40 years. Blood work showed wbc 8.66, H/H 12.8/39.8, platelets 210, BUN/Cr 34/2.86, GFR 21, Na 139, K 3.6, Hco 26, Ca 10.9, P 3.5, Mg 2.2, Hgba1c 6.3%, Ua +protein. Follow up: Further work up for hypercalcemia and acute kidney injury showed Ca 11.2, iPTH 10.2, PTHrP 4.7, 1, 25 vit D 78.2, vit D 41, ACE 84, SPEP/UPEP: no monoclonal gammopathy. CXR negative for hilar lymphadenopathy. Renal ultrasound normal size kidneys with mild echogenicity. Chest CT showed calcified enlarged left lower cervical, supraclavicular, chest wall and axillary lymph nodes and reticular asymmetric mild pleural thickening. He underwent axillary lymph node biopsy which showed granulomatous lymphadenitis, with extensive infiltration by pigment laden macrophages, multiple non-caseating granuloma with foreign body type giant cell, some with intracellular pigment particles staining. Staining was negative for any mycobacterial or fungal organism, melanoma cocktail had negative staining, the immunostains showed increased background due to pigment. The differential included non-infectious granulomatous lymphadenitis and sarcoidosis.

Discussion: Our patient had a tattoo placed > 40 year ago and developed non-caseating granuloma with extensive infiltration by pigment laden granuloma. In an unexplained case of hypercalcemia in the setting of granulomatous histopathologic finding containing tattoo pigment, it is prudent to consider the diagnosis of sarcoidosis. Granulomatous reaction to tattoo pigment histologically can be sarcoidal or foreign body type. These sarcoidal granuloma usually involve the tattooed skin and may represent first manifestation of systemic sarcoidosis.

PO0322

Rifampin-Induced Hemolysis Resulting in Pigment Nephropathy

Gilda M. Portalatin,[1] Shruti Shettigar,[1] Sushma Medikayala,[1] Leal C. Herlitz,[2] Surafel K. Gebreselassie,[1] Shane A. Bobart.[1] *[1]Cleveland Clinic Florida, Weston, FL; [2]Cleveland Clinic, Cleveland, OH.*

Introduction: Rifampin is an antibiotic that is a key component of multidrug regimens used to treat mycobacterial infections. The toxicity profile including hepatotoxicity is relatively well known, however some other complications including hemolysis, is a rare side effect. Pigment nephropathy is an abrupt decline in renal function as a consequence of the toxic action of endogenous heme-containing pigment on the kidney. We present a case of pigment nephropathy in the setting of rifampin-induced hemolysis requiring renal replacement therapy.

Case Description: A 74 year old female with a history of bronchiectasis, cavitary lung lesion due to pulmonary nocardiosis, mycobacterium avium-intracellulare infection (MAI) and atrial fibrillation presented with multi-organ dysfunction and anuria while recently restarting rifampin, azithromycin and ethambutol for the treatment of MAI infection. Key laboratory findings were a serum creatinine of 3.7 mg/dL and BUN 62 up from a baseline creatinine of 0.65 mg/dL with severe thrombocytopenia, platelet count 36 k/μL and hemoglobin of 10.4g/dL. This coupled with liver dysfunction evidenced by INR 1.4, indirect bilirubin 6.2 mg/dL, AST 1311 U/L, ALT 506 U/L, elevated lactate dehydrogenase 2074 U/L, low haptoglobin 16 mg/dL, gave an initial suspected diagnosis of thrombotic microangiopathy (TMA). Peripheral blood smear revealed few schistocytes. Negative ADAMTS13 antibody and a low PLASMIC score guided us not to initiate plasmapharesis. Serological work up including ANA, dsDNA, ANCA were negative, while C3 was low at 76 mg/dL and C4 14 mg/dL. The patient remained anuric and was initiated on hemodialysis. As the platelet count improved, she underwent kidney biopsy showing diffuse acute tubular injury with prominent pigmented casts. Immunofluorescence was negative without any evidence of TMA. After approximately two months of dialysis, renal function recovered back to serum creatinine of 1.14 mg/dL and the patient no longer required hemodialysis.

Discussion: Rifampin induced hemolysis is rare complication but can mimic TMA and cause renal dysfunction due to pigment nephropathy. Nephrologists should be aware of this possible rare complication of rifampin therapy.

PO0323

Paraneoplastic Manifestations of Mantle Cell Lymphoma

Chantelle Harry,[1] Shivangi Patel,[1] Judy A. King.[2] *[1]Morristown Medical Center, Morristown, NJ; [2]Louisiana State University, Baton Rouge, LA.*

Introduction: Mantle cell lymphoma (MCL) is a rare and aggressive form of Non Hodgkins Lymphoma. Pathological patterns involving extra nodal sites are either the result of lymphoid infiltration or secondary mechanisms such as immune complex deposition triggering paraneoplastic disease, that can be revealing of the underlying pathology.

Case Description: 58-year-old Hispanic male with a history of hypertension, hyperlipidemia presented with nontender, nonpruritic rash from buttocks down that evolved from a petechial scattered rash into a maroon-colored, palpable purpura. He had no associated fever, chills, abdominal symptoms, or weight loss. Labs were notable for WBC 13.3/nL, Hgb 11 g/dL, Platelets 100/nL, Creatinine 2.3mg/dL (Creatinine 1 mg/dL 6/25/2019), AST/ALT 87/70 U/L, ESR 50 mm/hr, CRP 69 mg/L and urinalysis with large blood and 4-10 RBCs, Protein/Creatinine Ratio, Urine 0.34 mg/dL. RUS showed normal size kidneys and 19.5 cm spleen. Patient received 1-gram IV Methylprednisone for presumed IgA nephropathy. Complement levels were low, not consistent with IgA Nephropathy leading to a negative serological workup for infectious disease and secondary glomerulonephritis. Renal biopsy showed immune complex mediated GN with C1q positivity and diffuse foot process effacement. CT scan of abdomen showed splenomegaly with markedly enlarged lymph nodes throughout the abdomen and pelvis. Further outpatient workup was positive for skin biopsy with leukocytoclastic vasculitis. Lymph node biopsy was positive for Ki-67 of 70%, cyclin D1 along with chromosomal analysis positive for t(11:14) confirming mantle cell lymphoma. He was enrolled in a research study which includes Rituxan, bendamustine and high dose cytarabine.

Discussion: Developing a rash led the patient to seek medical attention. Combination of rash, hematuria and abnormal creatinine presumed a diagnosis of IgA nephropathy, however both skin and renal biopsy showed immune complex mediated pathology representing paraneoplastic disease. Further workup revealed splenomegaly and lymphadenopathy (LAD) eventually diagnosing MCL. MCL classically presents with B cell symptoms and LAD, but it is important to recognize that extra-nodal manifestations can unmask and lead to an earlier diagnosis and treatment. Management of MCL also treated his paraneoplastic pathology as seen by improved renal function and no recurrence of rash.

PO0324

Page Kidney Secondary to Ruptured Mycotic Pseudoaneurysm of Renal Artery: An Unusual Complication of Infective Endocarditis

Ebubechukwu Ezeh, Saad Ullah Malik, Zachary S. Higginbotham, John L. Saylor, Ghassan Bandak. *Marshall University Joan C Edwards School of Medicine, Huntington, WV.*

Introduction: Mycotic pseudoaneurysms of renal artery following infective endocarditis are uncommon and their rupture is the most feared complication. This can lead to subcapsular hematoma and development of Page kidney, an uncommon cause of secondary hypertension and renal dysfunction. We present a unique case of ruptured

mycotic pseudoaneurysm of the renal artery that resulted in subcapsular hematoma and Page kidney in an intravenous (IV) drug user.

Case Description: A 36-year-old female IV drug user presented with fever and hemoptysis. She denied history of kidney disease or preceding trauma. Admission blood pressure was 116/61 millimeter of mercury. Initial serum creatinine was 1.6 milligrams per deciliter (mg/dl) and hemoglobin (Hb) was 12 grams per deciliter (g/dl). Renal ultrasound was unremarkable. She was found to have septic emboli on computed tomography (CT) of the chest, and methicillin-resistant Staphylococcus aureus (MRSA) grew in her blood cultures. Patient was diagnosed with infective endocarditis based on Duke's criteria. She was started on IV antibiotics. On the third day of admission, she developed severe right flank pain and hematuria. She had worsening acute kidney injury and was started on hemodialysis. She was persistently hypertensive and progressively anemic. Hb dropped to 6.5 g/dl requiring transfusion of packed red cells. CT abdomen showed a new aneurysm and a large subcapsular hematoma of the right kidney. The bleeding pseudoaneurysm of the superior pole branch of the right renal artery was embolized by interventional radiology. She subsequently improved and no longer required hemodialysis. Plasma renin activity level returned elevated at 12.26 nanograms per milliliter per hour (reference 0.16-5.83).

Discussion: Renal artery aneurysm has a reported incidence of 0.1%. Subcapsular hematoma from rupture of mycotic pseudoaneurysm is a very rare complication of infective endocarditis. Page kidney is a hyperreninemic phenomenon that results from the renal ischemia secondary to external compressive forces from subcapsular hematoma. Elevated renin level and activation of the renin-angiotensin-aldosterone system usually occurs, as in our patient. For this reason, angiotensin converting enzyme inhibitors and relief of external compression are great treatment options in these patients.

PO0325

A Case of AKI with ANCA Vasculitis Associated Retroperitoneal Fibrosis

Leanne Brown,[1] Nickolas Coombs,[1] Christine B. Vigneault.[2] *[1]University of Connecticut School of Medicine, Farmington, CT; [2]Greater Hartford Nephrology, Bloomfield, CT.*

Introduction: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) refers to a group of multi-system autoimmune small vessel diseases that can give rise to a broad array of clinical signs and symptoms. ANCA-associated retroperitoneal fibrosis (RPF) is an exceptionally rare condition characterized by fibroinflammatory changes in the retroperitoneal space. Most RPF cases are idiopathic, or can be secondary to other medical conditions, the rarest association is with AAV. We present a case of ANCA-associated RPF in a patient with recurrent acute kidney injury (AKI).

Case Description: A 57-year-old male with a history of reactive arthritis presented to the hospital with acute left-lower quadrant abdominal pain and found to have AKI due to obstruction by a soft tissue nodule on the left pelvic sidewall with mild-moderate hydronephrosis. He underwent left ureteral stent placement and his hydronephrosis resolved. Left iliac lymph node pathology was consistent with RPF. He was started on high-dose prednisone with resolution of his AKI. Steroids were tapered after repeat imaging 6 weeks later showed a decrease in the size of the soft-tissue nodule. He subsequently had a series of repeat admissions to the hospital with fevers, hypotension, shortness of breath, and recurrent AKIs. Each time, he was treated with antibiotics and stress-dose steroids with resolution of his symptoms. He was advised to return to the hospital as his symptoms progressed to include hemoptysis and epistaxis. He was found to have proteinase-3 antibodies (PR-3) consistent with granulomatosis with polyangiitis and was started on rituximab.

Discussion: RPF in association with AAV is an extremely rare condition with very few cases documented in the literature. RPF is an uncommon collagen vascular disease characterized by inflammation of the retroperitoneal space which can produce obstruction notably affecting the abdominal aorta, iliac arteries and ureters. Mostly idiopathic, RPF can be associated with vasculitis, medications, infection, and neoplasms. As highlighted in this case, AAV should be considered with a recently diagnosed RPF and recurrent AKI. A hallmark is improvement of symptoms with steroids. This is important with reference to patient outcomes as delayed treatment, especially when renal disease is present, portends a higher risk of end stage renal disease and early mortality.

PO0326

Runaway Kidneys: First Case of Bilateral Herniated Kidneys in a Ventral Hernia

Areeba Jawed, Samah S. Suleiman. *Wayne State University School of Medicine, Detroit, MI.*

Introduction: Kidney herniation is extremely rare and typically seen in the setting of congenital defects. A handful of case reports have described traumatic thoracic herniation, postoperative renal transplant herniation and one report of postoperative incisional herniation. In this case report, we discuss the first case of bilateral kidney herniation into a ventral abdominal wall hernia.

Case Description: 58-year-old male with a significant history of CKD stage IIIb, hypertension, large abdominal wall hernia, hypothyroidism presented to the Emergency Department with complains of abdominal pain and diarrhea. Vital signs were unremarkable and physical exam was pertinent for morbid obesity (BMI 0kg/m2) and a non-reducible ventral hernia. Labs revealed serum creatinine of 4.77 mg/dL with a prior baseline of 1.9-1.8 mg/dL. CT scan without contrast showed a massive ventral hernia containing pancreas, bilateral kidneys and loops of bowel forming pannus overlying the right anterior pelvic wall. Persistent mild hydronephrosis without a definitive obstructive mass, obstruction might be caused by tethering of the proximal ureter to this large ventral hernia. No improvement in renal function was noted despite fluid resuscitation and Foley catheter placement. Urology was consulted and patient was taken for cystoscopy with bilateral retrograde pyelograms and left diverting single-J ureteral stent insertion. His renal function improved remarkably following relief of obstruction and serum creatinine down trended to 2.87mg/dL at discharge. Patient was scheduled to follow up with nephrology and urology at discharge

Discussion: Kidney herniation is very uncommon and usually, only mobile structures, such as the small intestine and omentum are seen in ventral hernias. We postulate that mechanical forces related to obesity and prior surgeries played a role in the herniation of both kidneys which are normally firmly anchored in the retroperitoneum.

PO0327

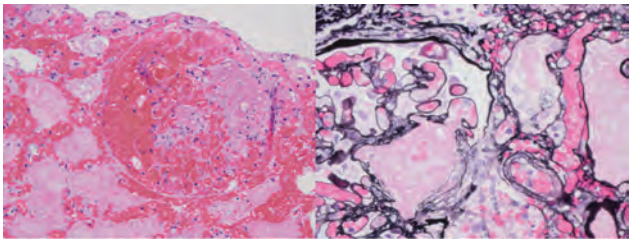
IV Immunoglobulin Triggering Renal Cortical Necrosis

Janame J. Kottey, Niraj K. Yadav, Rama Kethineni, Divya Raghavan, Fuad S. Shihab, Monica P. Revelo Penafiel, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Renal cortical necrosis is a rare cause of acute kidney injury mostly seen in infants and young women with obstetric complications accounting for >50% of cases. Intravenous immunoglobulin (IVIG) is used for treatment of various conditions and one of the complications associated with its use is thromboembolism. We report the case of a patient that developed thrombotic microangiopathy with renal cortical necrosis after receiving IVIG.

Case Description: A 50-year-old man with Alport syndrome status post renal transplant in 2008 complicated by nasal Natural Killer T-cell lymphoma in 2017, had cutaneous recurrence in 2020 and was started on treatment with Brentuximab. He subsequently developed Immune Thrombocytopenic Purpura (ITP) and was started on pulse steroids, Rituximab, and IVIG. He was admitted for sudden onset of anuric renal failure after receiving the first dose of IVIG. He was off antimetabolite since diagnosis of NK/T-cell lymphoma in 2008 and Tacrolimus was held after he developed thrombocytopenia raising concern for allograft rejection. The patient was started on dialysis. Evaluation including C3, C4, ANA, anti-GBM antibodies, ANCA, rheumatoid factor, cryoglobulins, HIV, Hepatitis B and C, blood and stool cultures, stool Shiga toxin, echocardiogram, CMV PCR, peripheral smear, BK virus, ADAMTS 13, and DSA were unremarkable. He underwent renal biopsy that showed extensive cortical necrosis and thrombotic microangiopathy. A follow up ultrasound showed no blood flow to the kidney allograft. He did not had renal recovery and was discharged on outpatient dialysis.

Discussion: Thrombosis is a well-known complication of IVIG. IVIG increases blood viscosity and reduced blood flow promoting thrombogenesis. This can manifest as acute coronary syndrome, stroke, or venous thromboembolism. In our patient, it has manifested as thrombotic microangiopathy with cortical necrosis. IVIG, although, a very useful drug in treatment of various medical conditions should be used with caution, ensuring adequate hydration while monitoring baseline viscosity in patients at risk of hyperviscosity, prior to administration.



PO0328

Renal Failure due to Bilateral Renal Artery Stenosis

John Janosevic,[1] Maria Fernanda Martinez Lopez,[2] Danielle Janosevic.[3] *[1]Hunter College, New York, NY; [2]Universidad Iberoamericana, Santo Domingo, Dominican Republic; [3]Indiana University School of Medicine, Indianapolis, IN.*

Introduction: We present a patient with renal failure and accelerated hypertension while on a chronic, stable dose of an angiotensin-converting enzyme inhibitor (ACEI) due to progression of renal artery stenosis (RAS).

Case Description: A 73 year-old Caucasian male with DM2, HLD, CKD2 was referred for evaluation of resistant HTN. Initial visit, blood pressure (BP) was controlled on stable doses of metoprolol XR 50 mg qd, amlodipine 10 mg qd, hydrochlorothiazide 25 mg qd and lisinopril 40 mg qd. Ultrasound revealed bilateral 11 cm kidneys, left proximal RAS with peak systolic velocities (PSV) of 2.6 m/s, globally elevated resistive indices (RI) >0.83-0.86. Given controlled HTN, stable renal function with baseline Scr range of 1.1-1.2, he was conservatively managed with above medications and statin. On 4 month follow up, BP 160-200/60s, despite stable medication doses and compliance, unexplained elevated Scr 2.1 mg/dL. Given suspicion of RAS progression, renin and aldosterone level were drawn measuring 3000 pg/ml (6 mo prior 1800) and 16 ng/dl (prior 12), respectively. Patient underwent renal artery duplex with noted bilateral RAS: >60% diameter reductions and RI averaging 0.85. ACEI was promptly discontinued and within 48 hours, the patient's Scr improved to 1.5, and he underwent CT-Angiogram (CTA) abdomen to determine if intervention needed. CTA noted bilateral moderate ostial RAS (left 50%, right 30%) due to progression of atherosclerotic calcifications. At follow up, Scr normalized to 1.2, BP controlled on amlodipine 10 mg qd and carvedilol 3.125 mg BID. Given the resolution of uncontrolled resistant HTN, and return to baseline Scr, renal artery stenting was not pursued and the decision remained continued monitoring.

Discussion: ACEI are indicated as effective anti-HTN therapy in unilateral RAS. However, when accelerated hypertension and/or renal failure occurs while on an ACEI in an elevated risk individual with RAS, a high index of suspicion for RAS progression must be entertained and the ACEI promptly discontinued. Individuals at risk for progression of atherosclerotic lesions are elderly individuals, especially those with HLD and DM. Elevated renin levels and Scr, which were rapidly obtainable during our clinic visit, were suggestive of pronounced renal ischemia and prompted quick action of ACEI discontinuation, definitive imaging and overall clinical improvement.

PO0329

The Role of KYNU in Mediating Sex Dimorphism of AKI

Weiyuan Gong, Chuan-Ming Hao. *Fudan University, Shanghai, China.*

Background: Acute kidney injury (AKI) is a disorder that is associated with high mortality and a high risk for development of chronic kidney disease. It is well documented that female gender is associated with relative resistance to kidney injury, the underlying mechanism is incompletely understood. Mounting evidence suggests that NAD^+ levels are associated with enhanced tolerance of kidney to injury, and exogenous supplement of NAD^+ precursor NMN alleviate AKI. The present study examined NAD^+ synthesis pathways and their association with gender related susceptibility to AKI.

Methods: IRI AKI model was performed on 8 weeks old wild-type C57BL/6J female and male mice, bilateral renal pedicles were clamped for 22 minutes. The animals were euthanized 48 hours after reperfusion. Prepubertal (3 weeks old) wild-type C57BL/6J female or male mice were ovariectomized or castrated respectively and were euthanized after 5 weeks for renal KYNU expression analysis. The metabolites of NAD^+ de novo pathway were examined by HPLC.

Results: Following IRI, female mice had less severe kidney injury, manifested as lower BUN and Cr levels, lower kidney injury marker (NGAL) expression and alleviated tubule damage. Further study revealed renal KYNU, but not other enzymes involved in the NAD^+ synthesis pathways, was 5 fold higher in female mice compared to male at age 8 weeks, despite that it is comparable between female and male mice at age 7 days. Prepubertal oophorectomy in female mice did not significantly decrease renal KYNU expression, in contrast, prepubertal castration of male mice increased renal KYNU levels to that seen in female, demonstrating KYNU is regulated by testosterone other than estrogen. HPLC result showed no difference in the metabolites concentration between male and female mice under physiological condition, however, following IRI, 3-HAA and QA concentration, which are precursors for NAD^+, were significantly upregulated in the female urine but remained unchanged in the male urine, so as QA concentration in the female kidney, suggesting kynurenine pathway is more activated in the female kidney under AKI condition, which may contribute to NAD^+ synthesis and improve AKI.

Conclusions: We propose a KYNU-dependent mechanism, which contributes to the relative renoprotection of female after IRI by regulating renal NAD^+ level. NAD^+ de novo synthesis pathway may be a potential target for IRI-AKI treatment.

PO0330

β-Estradiol Protects from Ferroptosis and Explains the Higher Sensitivity of Murine Male vs. Female Kidney Tubules to Acute Tubular Necrosis

Alexia Belavgeni,[1] Anne von Mässenhausen,[1] Wulf Tonnus,[1] Francesca Maremonti,[1] Cloudy Meyer,[1] Christian Hugo,[1] Joel M. Weinberg,[2] Andreas Linkermann.[1] *[1]Universitatsklinikum Carl Gustav Carus, Dresden, Germany; [2]University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: In several preclinical models of acute kidney injury (AKI), male mice are known to exhibit a higher sensitivity compared to females, but mechanistic insights to explain this observation have been lacking over decades. Acute tubular necrosis (ATN) is a common feature of AKI the sensitivity to which might explain this long-standing obstacle.

Methods: Isolated murine kidney tubules were assessed with cell death assays (e.g. LDH release assay).

Results: Here, we demonstrated in isolated murine kidney tubules that spontaneous ATN is a regulated event. While tubules isolated from combined necroptosis- and pyroptosis-deficient mice ($MLKL/GSDMD^{DKO}$) did not show different LDH release levels compared to control, inhibition of ferroptosis by the ferroptosis inhibitor ferrostatin 1 (Fer-1) significantly protected wild type tubules. Importantly, we detected less spontaneous necrosis in female versus male tubules. While female tubules exhibited resistance to LDH release, male tubules were sensitive but could be protected by co-incubation with Fer-1. Tubular sex specific differences could not be explained by potential pro-ferroptotic effects of testosterone but rather by anti-ferroptotic effects of β-estradiol.

Conclusions: In summary, while these data confirm the involvement of ferroptosis in spontaneous tubular necrosis, we identify β-estradiol as a general inhibitor of ferroptosis. This anti-ferroptotic effect explains the difference in sensitivity toward ATN of renal tubules of male and female mice.

PO0331

Pharmacological Validation of HDAC8 as a Therapeutic Target for AKI

Donna M. Huryn,[1] Keith E. Long,[1] Michael D. McDaniels,[1] Rachel Delgado,[2] Zoe Vaughn,[1] Prema C. Iyer,[1] Veronika Sander,[3] Alan J. Davidson,[3] Mark P. de Caestecker,[2] Neil A. Hukriede.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]The University of Auckland, Auckland, New Zealand.*

Background: Treatment for acute kidney injury (AKI) remains a significant unmet medical need and there are few validated targets on which to base therapeutic interventions and drug discovery programs. Our work has revealed histone deacetylase 8 (HDAC8) as a promising new candidate.

Methods: Known potent, selective HDAC8 inhibitors, as well as negative control compounds within the same scaffold, were evaluated in gentamicin-induced AKI in zebrafish (zfAKI), reperfusion injury AKI (IRI-AKI) in mouse, and in human kidney organoid-derived tubule cells subjected to hypoxia.

Results: Known potent, selective HDAC8 inhibitors such as PCI-34051, tetrahydroisoquinoline hydroxamic acids and an isoindolyl amide were effective in the zf AKI assays, while control compounds (i.e. HDAC8 inactive compounds of the same scaffold) were not effective. Testing of PCI-34051 in the IRI-AKI mouse model showed improvements in kidney function markers (BUN, tGFR) and while there was no significant reduction in renal fibrosis as measured by Sirius red staining, expression of the renal fibrosis markers *Collagen 1a1* and *LoxL2* were reduced. Further evaluation of PCI-34051 and the isoindolyl amide in primary renal epithelial cells from human kidney organoids showed that HDAC8 inhibition is associated with a pronounced suppression of inflammatory cytokine genes, providing one mechanism to explain their *in vivo* efficacy.

Conclusions: Our data supports that pharmacological inhibition of HDAC8 ameliorates AKI injury in multiple *in vivo* models and validates this target as a promising therapeutic lead to treat AKI.

PO0332

Class IIa Histone Deacetylase Inhibition Blunts AKI by Suppressing Apoptosis, Enhancing Autophagy, and Promoting Cellular Proliferation in Mice

Jialu Li,[1] Chao Yu,[1] Shougang Zhuang.[2,1] *[1]Shanghai East Hospital, Shanghai, China; [2]Rhode Island Hospital, Providence, RI.*

Background: Expression and function of histone deacetylases (HDACs) vary with cell types and insults. Our recent studies have shown that class IIa HDACs contribute to renal fibrosis chronically, but their roles in acute kidney injury (AKI) remain unknown.

Methods: In this study, we examined the effect of TMP269, a potent and selective class IIa HDAC inhibitor on folic acid (FA) and ischemia/reperfusion (I/R) -induced AKI in mice.

Results: Protein levels of four class IIa HDAC isoforms (4, 5, 7, 9) were increased in the kidney of folic acid (FA) and ischemia/reperfusion (I/R)-induced AKI, with HDAC4 being more abundant. Administration of TMP269, a potent and selective class IIa HDAC inhibitor, reduced expression of HDAC4 and increased expression of acetyl-histone H3. This was coincident with improved renal function, reduced tubular injury and less apoptosis, and enhanced tubular cell proliferation. Mechanistical studies showed that

TMP269 treatment inhibited FA or I/R -induced p53 acetylation and phosphorylation, as well as caspase-3 cleavage and Bax expression. In contrast, TMP269 increased expression of Bcl-2, an anti-apoptotic protein and PCNA. TMP269 was also effective in promoting cellular autophagy as indicated by increased expression of Atg7, Beclin-1 and LC3II. Moreover, class IIa HDAC inhibition resulted in the restoration of E-cadherin and upregulation of BMP7 and klotho, two renoprotective proteins.

Conclusions: These results indicated that activation of class IIa HDACs, in particular, HDAC4, contributes to AKI and renal tubular apoptosis, while targeted inhibition of class IIa HDACs protects against AKI through a mechanism associated with reduced apoptosis and enhanced autophagy and cellular regeneration.

PO0333

Distinct Spatiotemporal Dynamics of Damaged Proximal Tubular Epithelial Cells After Mild and Severe AKI in Mice

Shintaro Ide,[1] Yoshihiko Kobayashi,[1] Kana Ide,[1] Sarah A. Strausser,[1] Savannah Herbek,[1] Lori L. O'Brien,[2] Steven D. Crowley,[1] Laura Barisoni,[1] Aleksandra Tata,[1] Purushothama rao Tata,[1] Tomokazu Souma.[1] *[1]Duke University School of Medicine, Durham, NC; [2]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Clinical and preclinical studies revealed that damage to proximal tubular (PT) epithelial cells after severe acute kidney injury (AKI) is a critical mechanism underlying the development of chronic kidney disease (CKD). Recent advancements of single-cell RNA sequencing (scRNA-seq) approach identified that PT cells adopt heterogeneous molecular states after injury and contribute to maladaptive repair. However, their cell fate after mild versus severe AKI remains poorly understood.

Methods: Single-cell transcriptomics and genetic fate-mapping approaches were used in a mouse model of unilateral ischemia-reperfusion injury (IRI) to investigate PT cell dynamics after short (20 min) and prolonged ischemia (30 min). For scRNA-seq analyses, we analyzed a total of 18,258 cells from the damaged kidneys harvested on 6 hours, and 1, 7, and 21 days after 30 min ischemia and the homeostatic normal kidneys. We used Seurat's integration and label transfer to create the integrated dataset. To infer the dynamic cellular process during injury and repair, we used two computational tools (Monocle 3 and Velocyto).

Results: Our single-cell mouse atlas of maladaptive repair shows that PT cells develop a molecularly distinct, pro-inflammatory state following injury. These cells are characterized by reduced expression of homeostatic genes (ex. *Lrp2*, *Slc34a1*) and enrichment of genes associated with kidney development (ex. *Sox9*, *Cdh6*) and kidney injury (ex. *Vcam1*, *Havcr1*). Gene ontology analysis of these cells revealed high enrichment of pro-inflammatory signaling. Our genetic fate-mapping using a *Sox9IRES-CreERT2; Rosa26-tdTomato* mouse line showed these inflammatory PT cells transiently appear after short ischemia and return to their original state without inducing fibrosis. However, they accumulate and contribute to persistent inflammation after prolonged ischemia.

Conclusions: Our single-cell transcriptomic and genetic fate-mapping approaches identify that the accumulation of inflammatory PT cells after severe injury underlies the maladaptive repair process. Future studies of how this pathologic cell state persists and contributes to inflammation will inform us to develop novel therapeutic approaches for AKI and its transition to CKD.

PO0334

Cisplatin AKI: Localization of Cell State Injury Clusters with Spatial Transcriptomics

Judith Maddatu,[1] Ricardo Melo ferreira,[1] Yinghua Cheng,[1] Blue Lake,[4] Rajasree Menon,[2] Matthias Kretzler,[2] Sanjay Jain,[3] Michael T. Eadon.[1] the KPMP Consortium *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Washington University in St Louis School of Medicine, St Louis, MO; [4]University of California San Diego, La Jolla, CA.*

Background: Human acute kidney injury (AKI) is a multifactorial process and severity varies between individuals. The murine cisplatin model is a replicable example of AKI with limited confounding variables. We determined the pathways and injury markers dysregulated across the nephron in cisplatin AKI. We localized relevant human cell state signatures with spatial transcriptomics (ST) to determine which were most prevalent in cisplatin AKI and where these cells reside.

Methods: Six 129S6-SVE mice received vehicle or cisplatin (0.5 mg/g). After 72 hours, mouse kidneys were harvested and preserved for histology, single cell sequencing (scRNAseq), and ST. Gene mapping was completed with Cell Ranger 5.0.1 (scRNAseq) or Space Ranger 1.2.0 (ST). Human scRNAseq data was downloaded from kpmp.org, clustered by cell state (injured, adaptive, degenerative, transitioning, cycling, or reference) and mapped to mouse orthologs in Enembl database. Seurat clustered and integrated scRNAseq data as well as performed spatial mapping. Visualizations were created with R Studio.

Results: Cisplatin mice had increased BUN and tubular atrophy. scRNAseq identified 32 cell clusters, merged across common cell types. Cell cycle genes (*Cdkn1a*) were upregulated across epithelial cell types, but injury markers (*Lcn2* and *Spp1*) were only upregulated in the distal nephron. A novel cluster of dedifferentiated injured cells was identified and defined by cell cycle markers, *Lcn2* and *Spp1*, suggesting a distal nephron origin despite dedifferentiation. *Cdkn1a* was upregulated in ST across all cell types, but the novel injury cluster mapped only to the outer renal cortex. From the 6 identified human cell states, the adaptive epithelial state was found to be upregulated in cisplatin mice.

Conclusions: This study localizes the differential effects of cisplatin across the nephron. It adds support to the human injury cell states defined from scRNAseq of heterogenous human samples, showing their relevance in a well-defined AKI model.

Cell Interaction Dynamics in Human AKI Revealed by Single-Cell Transcriptomics

Yoshiharu Muto,[1] Yuhei Kirita,[1,2] Benjamin D. Humphreys.[1] *[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]Kyoto Furitsu Ika Daigaku, Kyoto, Japan.*

Background: Single cell transcriptomic maps of human AKI have not been reported, in part due to the difficulty of obtaining tissue. Acute kidney injury (AKI) is characterized by dynamic changes in cellular interactions among epithelia, stroma and inflammatory cells across the acute injury, repair and failed repair spectrums. Single cell transcriptomic technology is ideally suited to unravel the spectrum of cell states and interactions during injury and repair.

Methods: We performed snRNA-seq on 4 human AKI samples (2M and 2F, mean age = 60y, mean sCr = 4.6 mg/dl) and 5 control samples (3M and 2F, mean age = 55.8y, mean sCr = 1.07 mg/dl). Nuclear preparations were processed using 10x Genomics 3′ v3 Chromium kits and sequenced by NovaSeq. Reads were counted with CellRanger and analyzed with Seurat.

Results: After quality control and doublet removal, 62,649 nuclei (18 clusters) were identified in the dataset. GLI1^{high} fibroblasts were enriched in AKI, suggesting hedgehog signaling pathway activation. Among ligands, DHH expression was specifically up-regulated in the ADAMTS6^{high} endothelial subset in AKI, suggesting that AKI-induced endothelial stress may activate fibroblast reprogramming for myofibroblast proliferation. Comprehensive ligand-receptor analysis suggests secreted proteins including TRAIL from injured epithelium signaling to endothelium, driving DHH expression and subsequent myofibroblast proliferation. We define the transcriptomic signature of failed-repair PT in human AKI and show that this is similar to that of primary cultured RPTEC, validating primary RPTEC as a model of failed repair. Indeed, TNFa treatment of RPTEC drove expression of the full complement of failed repair PT marker genes, suggesting a critical role for NFKB activation in human PT injury and repair.

Conclusions: This is the first single cell transcriptomic atlas of human AKI. It reveals a novel PT-endothelium-myofibroblast signaling loop coupling PT injury to endothelial injury and ultimately interstitial fibrosis. This TRAIL and DHH dependent intercellular signaling cascade suggests a molecular mechanism for the AKI to CKD transition.

Unraveling Single-Cell Responses in Human AKI

Christian Hinze,[1,3] Christine Kocks,[2] Janna Leiz,[1,3] Nikos Karaiskos,[2] Anastasiya Boltengagen,[2] Christopher Skopnik,[1,4] Jan Klocke,[1,4] Jan-Henderik B. Hardenberg,[1] Helena Stockmann,[1] Inka Gotthardt,[1] Benedikt Obermayer,[5] Laleh Haghverdi,[2] Emanuel Wyler,[2] Markus Landthaler,[2] Victor M. Corman,[6] Jonas Busch,[7] Wolfgang Schneider,[8] Birgit Rudolph,[8] Nina Himmerkus,[9] Markus Bleich,[9] Kai-Uwe Eckardt,[1] Philipp Enghard,[1] Nikolaus Rajewsky,[2] Kai M. Schmidt-Ott.[1,3] *[1]Department of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin, Berlin, Germany; [2]Berlin Institute for Medical Systems Biology, Max Delbrueck Center in the Helmholtz Association, Berlin, Germany; [3]Max Delbrueck Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; [4]Deutsches Rheumaforschungszentrum, an Institute of the Leibniz Foundation, Berlin, Germany; [5]Berlin Institute of Health at Charité – Universitätsmedizin, Core Unit Bioinformatics, Berlin, Germany; [6]Institute of Virology, Charité-Universitätsmedizin, Berlin, Germany; [7]Department of Urology, Charité-Universitätsmedizin, Berlin, Germany; [8]Department of Pathology, Charité-Universitätsmedizin, Berlin, Germany; [9]Institute of Physiology, Christian-Albrechts-Universität, Kiel, Germany.*

Background: Acute kidney injury (AKI) is frequently observed in critically ill patients and is associated with a poor prognosis. AKI has recently moved into the focus of interest during the SARS-CoV-2 pandemic as high rates of AKI have been reported in severe COVID-19. We aimed to delineate cell type-specific molecular phenotypes associated with human AKI, including COVID-associated AKI.

Methods: We analyzed human kidney tissues using histology and single-nuclei RNA sequencing. Samples included kidney biopsies obtained within 2 hours post mortem from patients who succumbed to critical illness with and without evidence of AKI. Samples also included tumor-adjacent normal kidney tissues obtained during surgeries. AKI cases included patients with severe courses of COVID-19 (COVID AKI) and patients with other types of critical illness associated with systemic inflammation (Non-COVID AKI). Post-mortem kidney tissues obtained 30 min, 1 hour and 2 hours after death from a brain-dead patient without AKI were analyzed to assess the impact of post-mortem effects.

Results: Single-nuclei sequencing from kidney tissues yielded data of high transcriptional depth, which allowed transcriptome-based identification and de-novo spatial reconstruction of kidney cells. Principal component and differential gene expression analyses indicated that the presence of clinically confirmed AKI was the primary driver of global kidney transcriptomes and that different molecular subtypes of AKI existed. In contrast, the sampling time post-mortem and the presence of COVID-19 had minor effects. Subclustering analyses of different kidney cell types identified subclasses of cells representing injured kidney tubular cells, which were marked by distinct biomarker expression and expression signatures signifying intrinsic responses to inflammation, an induction of epithelial-to-mesenchymal transition, and an upregulation of hitherto unrecognized novel receptor-ligand pairs.

Conclusions: We provide the first cell type-specific molecular atlas of human AKI, revealing unanticipated disease subtypes and cell type-specific injury patterns.

PO0337

Human Kidney Proximal Tubule-on-a-Chip to Model Acute Hypoxic Tubular Injury in AKI

Sefa B. Çam,[1] Bulent Altun,[2] Petek Korkusuz.[1] *[1]Hacettepe University, Faculty of Medicine, Dept. of Histology and Embryology, Ankara, Turkey; [2]Hacettepe University Faculty of Medicine Dept. of Nephrology, Ankara, Turkey.*

Background: Acute kidney injury (AKI), with high mortality, is a serious public health issue. Hypoxic injury in proximal tubules (PT) sets the course of ischemic AKI. Microfluidic organ-on-a-chip technology mimics 3D kidney structures in vitro. We asked if AKI-related hypoxic injury may be modelled on a microfluidic 3D PT system comprising human epithelial cells and extracellular matrix (ECM).

Methods: A 2-lane microfluidic device without membrane was set to model 3D PT. Human PT epithelial cells (HK-2) were cultured with K-SFM media against ECM. Hypoxic conditions was designed as 1% O_2, 5% CO_2 and 94% N_2 in humidified multi-gas incubator. Tubular injury was assessed by immunofluorescence (IF) labelling and barrier integrity assay for 48 hours.

Results: Proximal tubules formed successfully at normoxia by phase contrast microscope. Hypoxia increased tubular leakage by 6-fold for 20 kDa (Fig. 1B, p=0.001) and 4-fold for 155 kDa molecules (Fig. 1C, p=0.001) compared to normoxia on 24h. Leakage for 20 kDa molecules remained 2-fold high compared to normoxia on 48h (Fig. 1B, p=0.001). Leakage for 155 kDa molecules restored with similar data as normoxia (Fig. 1C, p=0.268) on 48h. IF data supported impairment of the barrier.

Conclusions: In this study, a novel human kidney PT-on-a-chip was designed and successfully optimized for real time-modelling acute hypoxic tubular injury in AKI. Our human PT-on-a-chip mimics reversible tubule injury of clinical AKI more accurately compared to severe animal tubular damage models and presents a reliable and adjustable platform for testing potential therapeutic interventions. Hacettepe University Research Fund financially supported this work (TSA-2020-18383).

PO0338

Mechanisms of Nucleophosmin-Mediated Regulated Cell Death During Renal Ischemia

Zhiyong Wang, Andrea Havasi, Steven C. Borkan. *Boston Medical Center, Boston, MA.*

Background: Nucleophosmin (NPM) is a protein chaperone that potentiates Bax-mediated cell death during ischemic AKI by an unknown mechanism. In contrast, heat shock protein 70 (Hsp70) is a potent anti-apoptotic agent that promotes renal cell survival and preserves organ function. In this study, we characterize for the first time the intracellular events in which NPM and Hsp70 compete to regulate cell survival during ischemic stress.

Methods: Hsp70 wild type (WT) or Hsp70 mutants either restricted to the cytosol (Hsp70 985A) or unable to enter the nucleolar region (Hsp70 M45) were selectively over-expressed in primary murine proximal tubule epithelial cells (PTEC) harvested from Hsp70 null mice. Hsp70 expression, NPM nuclear translocation, NPM de-oligomerization, NPM-Bax complex formation, T95 phosphorylation responsible for NPM translocation, and cell survival were measured.

Results: Equivalent, selective over-expression of the hsp70 proteins significantly improved cell survival after ischemic stress in the following rank order: WT > M45 > 985A (each $P < 0.05$ vs. control). Only Hsp70 members with nuclear access (WT and M45) inhibited T^{95} NPM phosphorylation that mediates NPM translocation and reduced cytosolic NPM accumulation. Neither WT nor the Hsp70 mutants inhibited stress-induced NPM de-oligomerization. In contrast, WT > 985A > M45 Hsp70 significantly improved survival in Hsp70 null PTEC that expressed a cytosol-restricted NPM mutant, interacted with cytosolic NPM, and reduced NPM-Bax complex formation required for mitochondrial injury and cell death. Hsp70 knockout prevented the cytoprotective effect of suppressing NPM in ischemic PTEC and also increased cytosolic NPM accumulation after acute renal ischemia *in vivo*, emphasizing the protective effects of Hsp70 on NPM-mediated renal cell toxicity.

Conclusions: These observations identify key steps that mediate NPM toxicity during ischemia-induced cell death: (**1**) nuclear NPM de-oligomerization, (**2**) NPM translocation into the cytosol and (**3**) cytosolic NPM-Bax complex formation. Hsp70 promotes renal cell survival during ischemic acute kidney injury partly by inhibiting two of these toxic events in distinct cell compartments: nuclear NPM translocation and NPM-Bax interaction in the cytosol. Renal cell survival during ischemic AKI is substantially improved by interfering with events that render NPM toxic.

Limonin Protects Against AKI by Targeting ERK Signaling

Xianke Zhou, Xue Hong, Dier Li, Menghua Zhong, Haiyan Fu. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Renal Division, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Acute kidney injury (AKI) is characterized by tubular cell injury, vascular dysfunction, and inflammation. As a key pathological event, sustained inflammation in AKI plays a critical role in accelerating disease progression. In the clinic, there are no effective therapeutic strategies to prevent AKI by thus far. We previously reported, Limonin, a member of the class of compounds known as furanolactones possesses potent anti-inflammatory effects in multiple auto-immune diseases. Whether Limonin could serve as a candidate to preserve renal function after AKI remains unclear.

Methods: Kidney ischemia-reperfusion injury (IRI) was employed to induce AKI in mice. Limonin was pretreated in mice two days before IRI. A molecular docking study and thermal shift assays were performed to determine the binding capacity between Limonin and key targets. *In vivo* and *in vitro* molecular experimental pathology studies were applied.

Results: After ischemic AKI, pretreatment of Limonin preserved kidney functions, ameliorated tubular injury, and repressed inflammation in the diseased kidneys, compared to the vehicles. In structure, we identified Limonin has active binding sites for 38 significant target proteins, including ERK. A molecular docking study demonstrated a high binding affinity between ERK2 and Limonin, which was confirmed by the temperature- and dose-dependent cellular thermal shift assays. *In vivo*, we further revealed that Limonin activated ERK signaling pathway and then promoted tubular cell proliferation and reduced cell apoptosis after AKI. *In vitro*, blockade of ERK signaling abolished the abilities of Limonin in preventing tubular cell apoptosis under hypoxia conditions.

Conclusions: Our results indicated that Limonin is a novel ERK activator. Its therapeutic effect on murine AKI paved a new avenue for AKI intervention in the clinic.

Connecting Extracellular Vesicle Transfer RNA to Oxidative Stress in Injured Kidneys

Sang-Ho Kwon, Byung Rho Lee. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: While urine-based liquid biopsy has recently expanded to the analyses of cell-free extracellular nucleic acid, the potential of transfer RNA (tRNA) encapsulated within extracellular vesicles as a new class of urine biomarkers for kidney injury has not been explored.

Methods: Using rat renal ischemia-reperfusion and tubular cell injury models, we tested if extracellular release of tRNA encapsulated in extracellular vesicles responds to kidney injury and determined the mechanism of tRNA packaging into extracellular vesicles under oxidative stress.

Results: We detected a set of tRNAs present in urine that was packaged inside extracellular vesicles. We then identified extracellular vesicle-loaded tRNAs differentially released after ischemia-reperfusion injury and oxidative stress, in a reproducible manner. Next, we determined post-transcriptional methylation of these tRNA as a response to oxidative stress present in extracellular vesicle tRNAs. Mechanistically, oxidative stress decreases tRNAs loading into intracellular vesicles, mobilizes tRNAs to endosomes destined to extracellular vesicles, suppresses release of extracellular vesicles from the cell surface, and induces Maf1-mediated transcriptional repression of the tRNAs, all of which affect the availability of tRNAs in the cytoplasm.

Conclusions: Our data support that decreased release of non-fragmented tRNAs via extracellular vesicles reflects oxidative stress of kidney tubules, which might be a new source of urine biomarkers for ischemic kidney injury and could lead to rebalance protein translation in response to oxidative stress.

Inhibition of miR-155 Ameliorates AKI by Protecting Telomeres and Reducing DNA Damage of Renal Tubular Cells

Qing Yin,[1] Bin Wang,[1,2] Bi-Cheng Liu.[1,2] *[1]Southeast University, Nanjing, China; [2]Southeast University Zhongda Hospital, Nanjing, China.*

Background: Acute kidney injury (AKI) is associated with significant morbidity and mortality, and currently there is no therapy to prevent or treat established AKI. miR-155 is significantly up-regulated in diabetic nephropathy, IgA nephropathy, bilateral renal ischemia-reperfusion injury (IRI) or drug-induced AKI. However, the molecular mechanism of miR-155 in AKI remains to be studied.

Methods: We subjected miR-155$^{-/-}$ mice and wild-type controls, as well as human proximal tubule cells, to cisplatin-induced AKI models. We assessed kidney function and injury with standard techniques and measured telomere by the fluorescence in situ hybridization.

Results: The expression level of miR-155 was upregulated in both cisplatin-induced AKI mice model and cisplatin-treated HK2 cells. Inhibition of miR-155 expression protected cisplatin-induced AKI both in vivo and in vitro. Compared with wild-type mice, miR-155$^{-/-}$ mice had reduced mortality, improved renal function and pathological damage after cisplatin intervention. Moreover, inhibition of miR-155 expression decreased cells apoptosis and suppressed DNA damage. Additionally, we found that miR-155 efficiently regulates TRF1 expression by targeting a partially conserved sequence motif in the TRF1 3′UTR. Inhibition of miR-155 enhanced the expression of TRF1 and reduced the telomere DNA damage induced by cisplatin. In addition, CDK12 had also been identified as a novel target of miR-155. Inhibition of miR-155 increased the expression of CDK12, and reduced DNA damage and maintain genome stability.

Conclusions: We demonstrated that inhibition of miR-155 ameliorates AKI involving the targeting and regulation of TRF1 and CDK12, indicating a novel regulatory mechanism and elucidating a potential target for cisplatin induced AKI treatment.

Evaluation of Urinary NHE3 in Rats with AKI

Anni Xie,[1,2] Zhiyun Ren,[1] Mingda Liu,[1] Yanting Yu,[1,2] Xiaoyan Wang.[1,2] The Core Laboratory for Clinical Research *[1]The Core Laboratory, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China; [2]Department of Nephrology, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injuries (AKIs), caused by hypovolemia, ischemia-reperfusion, or nephrotoxins, are concerned with high morbidity and mortality. Urinary Na/H exchanger isoform 3 (NHE3) has been demonstrated as a noninvasive marker of acute tubular necrosis. However, the ideal diagnostic biomarker in AKI is still lacking.

Methods: In order to determine the potential role of urinary NHE3 in early diagnosis of AKI, we evaluated the exosome NHE3 in daily urines from rat models of AKIs including low NaCl (0.01%) plus candesartan (1mg/kg/day, IP) for 7 days, ischemia/reperfusion (ischemia for 40min, referfusion for 2h) and cisplatin (20mg/kg for 7 days) in Sprague Dawley rats (male, 2-3 months old, 4-7 rats per group). Urine exosomes were isolated by a series of centrifuges including ultracentrifuges (17k xg, 4°C, 10min;200k xg, 4°C, 1 hr).

Results: NHE3 levels (western blotting) were increased at day 1, which was 1 day before serum creatinine increased in low NaCl/candesartan rats and reperfusion rats (day1) relative to controls. They were also increased in cisplatin rats at day 2 (1 day before serum creatinine increased). Furthermore, NHE3 in original urines from 6 patients diagnosed with AKI (Scr 249.83 ±166.93 umol/L) and 6 volunteers with normal renal function (Scr 68.67±13.20umol/L) were assessed without ultracentrifuge isolation. NHE3 was increased remarkably in AKI patients (333±28, % of controls) compared with volunteers (100±30, %, t-test, $P<0.05$).

Conclusions: Our results in rats and patients suggest that assessment of urine NHE3 may be a potential non-invasive biomarker for early detection of various acute kidney injuries.

Tubular β-Catenin Ameliorates AKI by Restoring Mitochondrial Biogenesis

Hongyu Li,[1] Joseph C K Leung,[1] Loretta Y.Y. Chan,[1] Bin Li,[1,2] Wai Han Yiu,[1] Sydney C. Tang.[1] *[1]University of Hong Kong, Hong Kong, Hong Kong; [2]Sun Yat-sen University First Affiliated Hospital, Guangzhou, China.*

Background: Renal tubular β-catenin signaling plays a protective role in acute kidney injury (AKI), but the underlying mechanisms remain unclear. Mitochondrial dysfunction is responsible for the pathogenesis of AKI. This study aims to investigate the role of β-catenin activation on mitochondrial biogenesis in tubular cells upon AKI and its underlying mechanism.

Methods: Loss- and gain-of-β-catenin function was established in mice with tubular cell-specific β-catenin stabilization (TubCat mice) and knockout (TubCatKO mice). Septic and aseptic AKI was induced by exposure to LPS or ischemia/reperfusion, respectively. Kidney injury was examined by NGAL immunohistochemical staining. Markers of mitochondrial biogenesis were determined by Western blot, real-time quantitative PCR and immunofluorescence staining. Signaling cascade was examined by Western blot.

Results: Compared to the controls, TubCat mice under septic and aseptic AKI had significantly alleviated kidney injury and enhanced mitochondrial biogenesis as indicated by (i) reduction of NGAL positive tubules; (ii) restoration of mitochondrial mass protein TOMM20 and mitochondrial biogenesis molecules PGC-1α and NRF1; (iii) increasing co-localization of PGC-1α and β-catenin in renal tubules and (iv) increasing FOXO3 signaling against septic and aseptic injury. Consistently, kidney injury, and mitochondrial dysfunction were aggravated in TubCatKO mice versus their control littermates.

Conclusions: In both septic and aseptic AKI, tubular β-catenin stabilization restores mitochondrial homeostasis through the FOXO3/PGC-1α signaling pathway. **Funding:** General Research Fund (HKU 17119818), RGC Collaborative Research Fund (Ref: C7018-16G) and Hong Kong Society of Nephrology Research Grant (2019)

PO0344

CB11: Mitochondrial Effects in Renal Proximal Tubular Cells

Joshua D. Crossman,[1,2] Rick G. Schnellmann.[1,2] *[1]The University of Arizona Department of Pharmacology and Toxicology, Tucson, AZ; [2]The University of Arizona BIO5 Institute, Tucson, AZ.*

Background: Oxidative stress and mitochondrial dysfunction are characteristic of many acute and chronic conditions such as acute kidney injury and chronic kidney disease. Renal proximal tubular cells (RPTC) are mitochondria-dense, dependent on oxidative phosphorylation, and are particularly susceptible to injury. Identifying compounds that induce mitochondrial biogenesis (MB) is of increasing importance for the treatment of renal diseases associated with metabolic dysfunction. We investigated the effects of 1-butyl-3-hydroxy-3-[2-oxo-2-(pyridin-2-yl)ethyl]-1,3-dihydro-2H-indol-2-one, (CB11), on MB, mitochondrial dynamics, antioxidant response, and apoptosis in RPTC using a model of oxidant-induced injury.

Methods: In primary cultures of renal proximal tubular cells, we used uncoupled oxygen consumption rate (FCCP-OCR), transmission electron microscopy, immunoblotting, oxidant-induced injury with tert-butyl hydroperoxide (TBHP), and flow cytometry.

Results: CB11 (0.1 nM) treatment increased FCCP-OCR and mitochondria number after 24h. CB11 exposure decreased expression of fusion protein Mfn1 at 1 and 10 nM concentrations. CB11 had no effect on fusion proteins Mfn2 or OPA1 or phosphorylation of fission protein Drp1 at serine residues S637 or S616. Expression of Nrf2 protein decreased with no effect on Nrf2-regulated antioxidant response proteins (e.g. NQO1, GSTM1, GSR1, GPX2). Following a 24h pretreatment with CB11, TBHP-induced injury at 1h was evaluated. CB11 exposure did not prevent the loss of monolayer confluence at 1h post-injury. However, daily exposure prevented further loss of confluence at 48, 72, and 96h. No significant change in apoptosis, as measured by annexin-V positive cells (AnnV+), was seen in control or CB11 exposed samples 48h post-injury. TBHP-induced injury increased AnnV+, while exposure of CB11 did not attenuate AnnV+.

Conclusions: CB11 represents a new and highly potent inducer of MB with a unique signaling pathway in RPTC. Our data reveal that CB11 pretreatment does not prevent oxidant-induced cell death but acts as a RPTC protectant. Future studies will test this compound in AKI and CKD models.

FDA-Approved Drug Lasmiditan Stimulates Mitochondrial Biogenesis and Promotes Recovery of Vasculature and Renal Function After Ischemia-Reperfusion Injury in Mice

Kevin A. Hurtado,[1,2] Jaroslav Janda,[1,2] Rick G. Schnellmann.[1,2] *[1]The University of Arizona College of Pharmacy, Tucson, AZ; [2]The University of Arizona BIO5 Institute, Tucson, AZ.*

Background: Acute kidney injury (AKI) is induced by multiple mechanisms (e.g. ischemia/reperfusion (I/R), drugs, sepsis) and results in tubular and vascular dysfunction. Mitochondrial dysfunction is a key mediator of injury and recent studies have shown that pharmacological-induced mitochondrial biogenesis (MB) can provide renal recovery. Activation of the 5-HT_{1F} receptor has been demonstrated to induce MB in the mouse kidney and the absence of said receptor results in greater renal injury from I/R, demonstrating the importance of the 5-HT_{1F} receptor in the kidney. The goal of this study was to test the efficacy of the potent, selective, and FDA-approved 5-HT_{1F} receptor agonist lasmiditan in a mouse I/R-induced AKI model.

Methods: Male mice were subjected to I/R-induced AKI. After 24 h, serum creatinine was measured and I/R mice were divided into two groups and dosed with lasmiditan (0.3 mg/kg) or vehicle. Daily dosing was continued until euthanasia at 144 h. Electron microscopy was used to measure mitochondrial number. Serum creatinine was measured. Vascular leakage was determined using Evan's blue dye and tight junction proteins. Mitochondrial proteins and KIM-1 were measured using immunoblot analysis.

Results: Treatment with lasmitidan increased renal cortex mitochondrial number by 33%. Serum creatinine levels were similar between the I/R+vehicle group and I/R+lasmiditan group at 24 h. At 144 h, serum creatinine markedly decreased by 72% and KIM-1 decreased by 50% in I/R+lasmiditan group compared to I/R+vehicle group, respectively. PGC-1α and electron transport chain complexes IV and V were restored in I/R+lasmiditan group. Vascular permeability increased 2.5-fold in the I/R+vehicle group and was restored to control levels in the I/R+lasmiditan group. The tight junction proteins occludin, ZO-1, and Claudin 5 decreased in the I/R+vehicle group and was restored to control levels in the I/R+lasmiditan group.

Conclusions: In this study we demonstrate that FDA approved lasmiditan restores mitochondrial function and renal and vascular function after I/R injury in mice. Lasmiditan could be repurposed for the treatment of AKI in humans.

Treprostinil Improves Mitochondrial Dynamics and Reduces Oxidative Stress During Renal Ischemia-Reperfusion Injury in Rats

Meiwen Ding,[1] Evelyn Tolbert,[2] Mark Birkenbach,[2] Reginald Y. Gohh,[2] Nisanne S. Ghonem.[1] *[1]University of Rhode Island, Kingston, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Renal ischemia-reperfusion injury (IRI) is a major factor that contributes to acute kidney injury (AKI). Mitochondria enriched in renal proximal tubular cells are particularly susceptible to IRI-induced oxidative stress. Currently, there is no treatment for IRI available. We recently demonstrated the efficacy of treprostinil (Remodulin®), an FDA-approved prostacyclin analog, in reducing AKI during bilateral rat renal IRI. This study investigates the role of treprostinil in improving mitochondrial dynamics and reducing oxidative stress during rat renal IRI.

Methods: Male Sprague Dawley rats were subjected to 45 minutes of bilateral renal ischemia followed by 1-72 hours reperfusion. Placebo or treprostinil (100 ng/kg/min) was administered subcutaneously via an osmotic mini-pump. Blood and kidney tissue were collected for analyses.

Results: Treprostinil significantly reduced renal injury and peak elevated serum creatinine from 24- to 6-hours post-reperfusion compared to placebo-treated animals. PAS staining revealed that treprostinil markedly reduced epithelial cell necrosis and partially attenuated apical brush border loss at 6 hours post-IRI vs. placebo, with near reconstitution of normal histology by 48-hours post-reperfusion. Also, treprostinil restored renal antioxidant levels, including catalase, superoxide dismutase activity, and glutathione content vs. placebo ($p<0.001$). In parallel, treprostinil improved the mRNA expression of *Nqo1* and *Gclc*, that encode NAD(P)H dehydrogenase [quinone] 1 and glutamate-cysteine ligase catalytic subunit (Gclc) to 45% ($p<0.05$) and 52% ($p<0.01$) of sham at 48-hour post-IRI vs. placebo. Treprostinil reduced the renal mitochondrial fission proteins Drp1 and Mff by 61% and 44% relative to placebo ($p<0.001$) and restored the protein expression of mitochondrial fusion marker Sirt3 along with the mRNA expression of *Mfn1, Mfn2,* and *Opa1* to that of sham (vs. placebo, $p<0.0001$).

Conclusions: Treprostinil reduced renal oxidative stress as well as Drp1-mediated mitochondrial fission and upregulated Sirt3-mediated mitochondrial fusion, thereby improving renal mitochondrial dynamics and protecting against renal IRI. These results support the clinical investigation of treprostinil as a viable therapy to reduce renal IRI.

PO0347

A Mitochondrial Cardiolipin Targeting Peptide Ameliorates Kidney Oxidative Damage

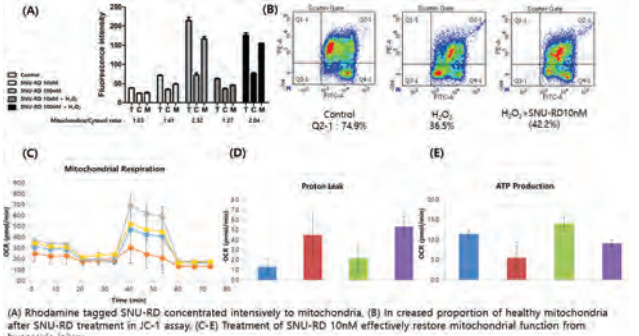
Soie Kwon,[1] Semin Cho,[1] Jong joo Moon,[1] Kyu hong Kim,[1] Jae Wook Lee,[2] Dong Ki Kim,[1] Yon Su Kim,[1] Seung Hee Yang.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]National Cancer Center, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Mitochondria is a major organelle of adenosine triphosphate production and O2 consumption. Also, kidney is mitochondria abundant organ. Many mitochondria-targeting agents were developed, though there is no single agent approved in clinical practice. We investigate renoprotective effect of newly invented mitochondrial cardiolipin targeting peptide, the SNU-RD, in hypoxic condition.

Methods: Based on our experience that dimer formation by bisulfate bond of cell penetrating peptide accelerate cell permeability, we synthesized 15 candidate tetra-peptides which target inner mitochondrial membrane specific phospholipid, the cardiolipin. After cell viability, distribution and mitochondrial functional test, we selected best candidate and tentatively named as SNU-RD. As hypoxic damage, bilateral ischemia-reperfusion injury (IRI) and primary cultured human proximal tubular epithelial cells (hPTECs) with H_2O_2 were chosen. Wild-type mice were divided into four groups: sham, IRI, IRI with low dose or high dose SNU-RD. After SNU-RD treatment with various concentration (10nM, 100nM, 1000nM), high dose H_2O_2 stress was done. Mitochondrial function was tested and mitochondrial oxygen consumption rate (OCR) was measured.

Results: In IRI, serum BUN and creatinine were significantly decreased without SNU-RD dose dependency. Pathologic findings (NGAL and cytochrome C) were improved. Also, mitochondrial anti-oxidative enzyme (NQO-1, SOD-1), ATP6 and IL-10 mRNAs were over-expressed after SNU-RD treatment. Cell viability was increased with dose dependently decrease of early and late apoptosis. IL-1ß, IL-18, p16 and p21 mRNA were dramatically down-regulated. When traced by rhodamine, SNU-RD was intensively distributed to mitochondria then cytoplasm. In JC-1 assay, ratio of healthy mitochondria was increased with SNU-RD. Basal and maximal OCR were most recovered from SNU-RD 10nM.

Conclusions: Mitochondrial cardiolipin targeting peptide, SNU-RD can protect kidney from hypoxic injury by restoring mitochondrial function.



(A) Rhodamine tagged SNU-RD concentrated intensively to mitochondria. (B) In creased proportion of healthy mitochondria after SNU-RD treatment in JC-1 assay. (C-E) Treatment of SNU-RD 10nM effectively restore mitochondrial function from hyperoxic injury

PO0348

Regulation of Mitochondrial Metabolism in T-Regulatory Cells by Programmed Cell Death Protein 1 in AKI

Murat Dogan, Vikram Sabapathy, Rajkumar Venkatadri, Christopher O'Neill, Sandhya Xavier, Didier Portilla, Rahul Sharma. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: The T-regulatory cells (Tregs) are important for suppressing inflammation and for resolution of injury during acute kidney injury (AKI). Absence or blocking of programmed cell death 1 (PD-1) mitigates the Treg-mediated protection in AKI. The mechanisms, however remain unknown. Here we test the hypothesis that PD-1 regulates mitochondrial metabolism of Tregs during AKI.

Methods: Bilateral renal ischemia reperfusion injury (IRI) was used to investigate the role of PD-1 function in Tregs. Adoptive transfer of splenic $CD4^+CD25^+$ Tregs isolated either from wild-type (WT) or PD-1-/- Foxp3-GFP mice was performed into recipient mice 1h or 24h prior to IRI. Renal structure and function was assessed by plasma creatinine, *Kim1* and *Ngal* expression, histopathology and flow cytometry. Mitochondrial

metabolism of isolated Tregs was assessed *ex vivo* using Seahorse Metabolic Flux Analyzer and staining with mitochondrial dyes (TMRE and Mito-ROS) for mitochondrial membrane potential and ROS production respectively, as well as by RT-PCR for genes related to mitochondrial dynamics. Scanning Electron microscopy (SEM) was performed on isolated Tregs to image mitochondrial morphology followed by ImageJ™ analyses.

Results: Contrary to the WT, adoptive transfer of PD-1$^{-/-}$ Tregs was unable to protect the recipient mice from IRI-induced AKI. The oxygen consumption rate (OCR), a measure of oxidative phosphorylation, was significantly reduced in PD-1$^{-/-}$ Tregs at baseline and under maximal respiration as compared to WT. PD-1$^{-/-}$ Tregs also had reduced mitochondrial mass, lower mitochondrial membrane potential, and greater mitochondrial ROS production than WT Tregs. Further, the expression of *Pgc1a, Nrf1, Brf2, Tfam, Drp1, Mfn1, Mfn2 and Mff* was also significantly reduced in the PD-1$^{-/-}$ Tregs. Importantly, compared to Tregs from age and sex-matched WT mice and as measured using SEM and ImageJ™, the mitochondria in Tregs from PD-1$^{-/-}$ mice were fewer in number and had lower average pixel area.

Conclusions: The data suggest that PD-1 regulates mitochondrial function and dynamics of Tregs and this is critical for protection from AKI and other inflammatory diseases.

Intraflagellar Transport Protein 88 Deficiency in Proximal Tubular Cells Exaggerates Cisplatin-Induced Injury by Suppressing Autophagy

Shixuan Wang, Zheng Dong. *Augusta University, Augusta, GA.*

Background: Primary cilia are widely regarded as specialized sensors in differentiated cells that have been implicated in the regulation of cell proliferation, differentiation, and viability. We previously showed that shortening of primary cilia sensitizes cultured kidney tubular cells to cisplatin-induced apoptosis. IFT88 is an essential component for ciliogenesis and maintenance.

Methods: To study the effect of proximal tubule-specific IFT88 ablation on cisplatin-induced acute kidney injury (AKI), we took advantage of conditional IFT88 knockout mice to study how differently cisplatin affected renal function in knockout mice and age- and sex-matched wild type ones. Furthermore, we used cultured cells to examine whether autophagy was involved.

Results: It was found that more severe AKI occurred in IFT88 knockout mouse than controls. Mechanistically, cisplatin stimulated autophagy in kidney tubular cells as an intrinsic protective mechanism. However, renal autophagy was severely impaired in IFT88 knockout mouse. In cultured HK-2 cells, cisplatin induced more apoptosis when IFT88 was knocked down. Tat-beclin 1 peptide, a specific autophagy activator, could partially prevent IFT88-associated cell death during cisplatin treatment, although cilium length was not improved significantly.

Conclusions: These results indicate that defective autophagy in IFT88-deficient kidney cells and tissues contributes to the exaggerated AKI following cisplatin exposure.

Urinary UDP-Glucose as a Novel Actionable Biomarker of Dehydration-Induced AKI

Maria A. Battistone,[1,2] Alexandra Mendelsohn,[1,4] Dennis Brown,[1,2] Sylvie Breton.[1,3] *[1]Massachusetts General Hospital Division of Nephrology, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Universite Laval, Quebec, QC, Canada; [4]Tufts University School of Medicine, Boston, MA.*

Background: People working in ”extreme” conditions such as sugar cane workers, firefighters, and military personnel are subjected to significant dehydration. Prolonged episodes of dehydration may result in acute kidney Injury (AKI). AKI is associated with inflammation and is usually diagnosed only after the kidneys have gone through significant and often irreversible damage. We showed that the P2Y14 receptor mediates renal inflammation leading to AKI following ischemia-reperfusion-injury. P2Y14 is activated by the danger molecule UDP-glucose (UDP-Glc). Here we hypothesized that UDP-Glc is released by damaged cells throughout the body after dehydration-induced stress. UDP-Glc is filtered by the kidney and concentrated in collecting ducts where it activates P2Y14 in intercalated cells. This would trigger renal inflammation and contribute to dehydration-associated AKI.

Methods: Mice were subjected to water deprivation for 24, 48 and 72 hours. Kidney function was assessed via serum creatinine (SCr), blood urea nitrogen (BUN) and urine albumin. To study proximal tubule (PT) damage, aquaporin 1 (AQP1) localization was analyzed by immunofluorescence (IF). Urinary UDP-Glc concentration was measured by LC-MS, and renal recruitment of immune cells by flow cytometry and IF.

Results: Mice that were subjected to dehydration showed body weight loss. Water deprivation induced elevations in SCr and BUN after 48 and 72 hours, relative to control. Dehydration also promoted albuminuria and the redistribution of AQP1 from the plasma membrane into the PT cell body indicating PT injury. An increase in urinary UDP-Glc concentration, and renal recruitment of macrophages (CD64+F4/80+) were detected at 48 and 72 hours of dehydration. In particular, infiltration of CD11c-positive renal macrophages after dehydration was observed.

Conclusions: This study supports the hypothesis that UDP-Glc, released by damaged cells during severe dehydration, induces the renal recruitment of inflammatory macrophages leading to PT injury. Blocking the UDP-Glc/P2Y14 pathway represents, therefore, a new therapeutic avenue for the attenuation of dehydration-induced renal inflammation and dysfunction. In this context, urinary UDP-Glc is a promising actionable biomarker for dehydration-induced AKI.

Role of Collagen Receptors in Radiation-Induced Nephrotoxicity

Anis Ahmad,[1] Jumana Afaghani,[1] Junwei Shi,[1] Saba Ansari,[1] Jin Ju Kim,[1] Yan Shi,[1] Sandra M. Merscher,[1] Alan Pollack,[1] Youssef Zeidan,[2,1] Alessia Fornoni,[1] Brian Marples.[1,3] Radiation Oncology *[1]University of Miami School of Medicine, Miami, FL; [2]American University of Beirut (AUB) School of Medicine, Beirut, Lebanon; [3]University of Rochester Medical Center, Rochester, NY.*

Background: Radiation therapy represents a severe late complication for cancer patients and induces radiation nephropathy (RN). Collagen receptors Discoidin domain receptor 1 (DDR1) and integrin α2 are involved in the pathogenesis of renal fibrosis. However, the mechanisms is largely unknown. We hypothesized that radiation therapy (RT)-induced collagen I accumulation in podocytes activates DDR1, integrin α2, and matrix metalloproteinases (MMPs) signaling leading to changes in the laminin and collagen homeostasis in GBM thus inducing RN.

Methods: 10–14-weeks old C57BL/6 male and female mice kidneys received a single dose (SD) 4Gy, 10Gy, and 14Gy or fractionated dose (FD) 6Gyx5 and 2Gyx24 X-irradiation. Kidney function parameters (estimated glomerular filtration rate (eGFR), urinary albumin-to-creatinine ratio (ACR), serum BUN and creatinine), histopathological changes (determined by H&E, Periodic Acid-Schiff (PAS), Picrosirius red (PSR)), gene expression analysis (by nanostring), ultrastructural changes (by transmission electron microscopy (TEM), were measured at 10- and 20-weeks post-SD and FD.

Results: IHC and nanostring data showed a significant upregulation of Col I, pDDR1, and integrin α2 expression ($p<0.001$) and reduction in integrin α1 ($p<0.001$) in kidney cortices 10 and 20 weeks post-SD and FD. Western blot and gene expression analysis showed that several MMPs expression increased significantly in a dose and time-dependent manner in cultured human podocytes and mouse kidney cortex post-RT. Significant reductions were seen in collagen type IV (Col4A3, Col4A4, Col4A5), laminin α5β2γ1 (LM-521) and a substantial increase in the expression of collagen type I (Col1A1, Col1A2), collagen type IV (Col4A1, Col4A2), laminin α1β1γ1 (LM-111) and laminin α2β1γ1 (LM-211) in radiated mice kidney cortex ($p<0.001$). TEM data demonstrated time and dose-dependent increases in GBM thickness and foot process width ($p<0.001$). Significant increases in fibrosis (PSR), mesangial expansion (PAS), ACR in association with decreased podocyte number and eGFR 20 weeks post SD and FD were observed.

Conclusions: Our data suggest that targeting collagen receptors (DDR1 and integrin α2) with specific small molecule inhibitors and genetic or pharmacological induction of integrin α3 may prevent the RN.

Leucine Metabolism and Ketone Bodies Role in AKI

Afaf Saliba, Jana Tumova, Jiwan J. Kim, Kumar Sharma. Center for Renal Precision Medicine, Lab of Dr. Kumar Sharma *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Renal ischemia reperfusion (IR) results in injury caused by dynamic process that includes inflammation and extensive cell death. The increase in oxidative stress appears to play a great role in the inflammatory process causing acute kidney injury (AKI) during IR. Oxidative stress activates p53 and promotes cell death. On the other hand, ketones, were shown to decrease oxidative stress and are renal protective under different pathological conditions including AKI. Acetoacetate, one of the major ketone bodies, is a product of leucine catabolism. The means through which ketone bodies could play a protective role still requires further understanding. Computational studies in our lab have uncovered a link between mouse double minute 2 homolog (MDM2), which is a direct inhibitor of p53, and methylcrotonyl-CoA carboxylase 2 (*MCCC2*), which encodes a mitochondrial enzyme essential for leucine and isovaleric acid catabolism.

Methods: To explore amino acid metabolism and ketone bodies role in AKI we analyzed gene expressions in kidney cortex of mice that have undergone 35 minutes of renal ischemia followed by 24h of reperfusion. Moreover, to further investigate a connection between MDM2 and MCCC2, we knocked-down MDM2 in human kidney 2 (HK2) cells using small interfering RNA (siRNA) transfection at 2 concentrations (100nM and 200nM). Cells were harvested 48 hours post-transfection for mRNA and protein analysis.

Results: Renal ischemia- reperfusion increased levels of p53 and HIF1-alpha consistently with previous studies. Intriguingly, we also got significant decrease in MCCC2 mRNA (n=6) in IR-mice compared to sham operated mice (n=5). Preliminary data from MDM2 knock-down HK2 cells also show p53 upregulation, increased cell death and MCCC2 downregulation. These results are observed both at the mRNA and protein levels at 200nM MDM2 siRNA.

Conclusions: Though preliminary, our data show a consistent decrease in MCCC2 expression at the mRNA levels under AKI provoked by IR. This novel finding could be a steppingstone towards deciphering important pathways in AKI that involve oxidative stress related cell death and dysregulated amino acid. metabolism.

Targeting Polycomb Repressive Complex 2 Protects Against Cisplatin-Induced AKI in Mice

Tingting Li,[1] Chao Yu,[1] Shougang Zhuang.[2,1] [1]*Shanghai East Hospital, Shanghai, China;* [2]*Rhode Island Hospital, Providence, RI.*

Background: Our previous studies have shown that blocking EZH2 (Enhancer of Zeste Homolog 2), a catalyzing subunit of polycomb repressive complex 2 (PRC2) with histone methyltransferase activity, protects against acute kidney injury (AKI). The role and mechanism of the entire PRC2 in AKI remain undefined. In this study, we investigated the involvement of PRC2 in the pathogenesis of AKI following cisplatin exposure.

Methods: A potent and selective PRC2 inhibitor EED226 was used to evaluate the effect of loss of PRC2 catalytic activity on renal function and tubular cell injury as well as activation of key apoptotic signaling pathways and expression of renoprotective proteins in a murine model of cisplatin-induced AKI.

Results: Administration of EED226 improved renal function, attenuated renal pathological changes, and reduced renal tubule injury and apoptosis in a murine model of cisplatin-induced AKI. In cultured renal epithelial cells, treatment with either EED226 or EED siRNA also reduced apoptosis. Mechanistically, EED226 treatment inhibited cisplatin-induced phosphorylation of p53 and fox3a, two transcriptional factors associated with apoptosis, and prevented downregulation of expression of Sirt3 and PGC-1α, two proteins that contribute to mitochondrial protection. Moreover, EED226 also enhanced renal tubular cell proliferation and suppressed inflammatory responses and phosphorylation of STAT3 and NF-κB, two transcriptional factors associated with inflammation.

Conclusions: These results indicate that targeted inhibition of PRC2 can improve renal function and promote the survival and proliferation of renal tubular cells through mechanisms associated with inhibition of p53 and fox3a signaling pathways and preserved expression of Sirt3 and PGC-1α.

Kidney Protection by Caloric Restriction Depends on De Novo NAD+ Synthesis Activation

Martin R. Späth,[1,2] Karla J. Hoyer-Allo,[1,2] Martin Höhne,[1,2] Christina Lucas,[3] Susanne Brodesser,[2] Jan-Wilm Lackmann,[2] Katharina Kiefer,[2] Felix C. Koehler,[1,2] Torsten Kubacki,[1] Franziska Grundmann,[1] Thomas Benzing,[1,2] Bernhard Schermer,[1,2] Volker R. Burst,[1] Roman-Ulrich Mueller.[1,2] [1]*Department II of Internal Medicine, University hospital of Cologne, Cologne, Germany;* [2]*Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany;* [3]*Syft Technologies GmbH, Darmstadt, Germany.*

Background: In clinical practice, targeted measures for the treatment of acute kidney injury (AKI) are lacking. In mouse models, AKI by ischemia-reperfusion injury (IRI) can be reduced effectively through preconditioning protocols using hypoxia (HP) or caloric restriction (CR). In previous transcriptome analyses of murine kidneys after HP or CR, we identified *Kynu* as a common downstream target. The kynureninase encoded by *Kynu* is one of the key enzymes in tryptophan metabolism and the aim of this work was to further characterize the role of KYNU in the protection of AKI.

Methods: CRISPR-cas9 based non-homologous end joining (NHEJ) resulted in a KYNU-deficiency in C57Bl6 mice. This was followed by basal (e.g. biometry, kidney function) and special (e.g. kidney function 24h after renal IRI with or without HP/CR) phenotyping of the KYNU-deficient ($KYNU^{null}$) mice in comparison to wildtype littermates ($KYNU^{wt}$). The changes in the murine transcriptome, proteome and tryptophan metabolism mediated by HP and CR were then investigated before and after renal IRI. Finally, confirmatory analyses of the CR-mediated changes in the tryptophan metabolism of human blood samples were carried out.

Results: NHEJ resulted in a nonsense mutation in *Kynu* exon 2 and various protein analyses (e.g. Western blot and immunohistochemistry) confirmed the KYNU-deficiency. In the basal phenotyping and 24 h after IRI, $KYNU^{null}$ mice showed no differences from $KYNU^{wt}$ mice. However, the protection mediated by HP was no longer detectable in $KYNU^{null}$ mice and after CR the $KYNU^{null}$ mice showed significantly worse AKI than the $KYNU^{wt}$ littermates. Analyses of the transcriptome, proteome and tryptophan metabolism showed that KYNU is necessary for CR-mediated maintenance of nicotinamide adenine dinucleotide levels (NAD+) by inducing *de novo* NAD+ synthesis. The changes in *de novo* NAD+ synthesis identified in murine blood and induced by CR can also be recapitulated in human blood samples.

Conclusions: The CR-mediated induction of *Kynu* results from an increased activity of the *de novo* branch of NAD+ synthesis, which can also be recapitulated in humans. This finding offers new options for targeted therapeutic measures for the treatment of AKI.

PO0355

De Novo NAD+ Biosynthesis May Promote AKI Resistance

Amanda J. Clark,[1] Samir M. Parikh.[2,3] [1]*Boston Children's Hospital, Boston, MA;* [2]*Beth Israel Deaconess Medical Center, Boston, MA;* [3]*The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Acute kidney injury (AKI) is a wide-spread, costly condition with no treatment. Renal energy metabolism impairment is a key feature of AKI. Nicotinamide adenine dinucleotide (NAD+) plays a critical role in maintaining ATP and regulating energy metabolism. It is produced from three pathways: dietary tryptophan, niacin, and NAD+ recycling. Ischemic AKI suppresses de novo NAD+ biosynthesis from tryptophan, including the bottleneck enzyme, quinolinate phosphoribosyl transferase (QPRT). QPRT +/- mice have worse AKI after ischemia-reperfusion (IRI). It is unknown if these disturbances are specific to ischemia, whether QPRT suppression contributes to AKI, or if restoration of this minor NAD+ pathway may be sufficient to improve AKI.

Methods: Nephron-specific conditional QPRT over-expressing mice were created (Pax8-rtTA, tetO-QPRT, iNephQPRT). Cisplatin was administered to induce AKI. Parallel AKI was induced in QPRT +/- and QPRT +/+ mice. QPRT expression was measured via qPCR. AKI severity was assessed with serum biochemistries and histology.

Results: Toxic AKI suppressed QPRT mRNA proportionally to AKI severity (Fig C,D). QPRT +/- mice were more susceptible to toxic AKI (Fig A). Conversely, iNephQPRT mice exhibited protection against AKI (Fig B).

Conclusions: QPRT suppression is necessary for severe nephrotoxic injury, and renal tubular QPRT augmentation is sufficient to ameliorate injury. Given that de novo NAD+ synthesis is considered a minor contributor to steady-state NAD+ balance, these results provide striking evidence of this pathway's importance to renal health during acute stress. Further, these findings implicate de novo NAD+ biosynthesis suppression as a pathogenic event in a mechanistically distinct context compared to IRI. Elucidating the regulation of QPRT and NAD+ homeostasis may be critical to understanding AKI physiology and developing novel therapies.

Lack of Gb3 Elevated Renal Tubular Injury in a Mouse Model of Aristolochic Acid Nephropathy

Yang Liu,[1,2] Songhai Tian,[1,2] Hatim Thaker,[1,2] Jie Zhang,[1,2] Shan Wu,[3] Min Dong.[1,2] Dong Lab [1]*Boston Children's Hospital Department of Urology, Boston, MA;* [2]*Harvard Medical School Department of Surgery and Department of Microbiology, Boston, MA;* [3]*Jilin University, College of Basic Medical Sciences, Department of Pathology, Changchun, China.*

Background: Globotriaosylceramide (Gb3) is a glycosphingolipid serving as the receptor for Shiga toxin (Stx) and is responsible for mediating binding of Stx onto kidney tissues. However, the normal physiological function of Gb3 in kidney remains unknown. Under normal circumstances, Gb3-knockout (KO) mice (A4GALT (α-1, 4-galactosyltransferase) knockout) showed no obvious physical and chemical abnormalities. Gb3 is known to be mainly distributed in proximal renal tubule and collecting duct epithelial cells in C57 mouse strain, and aristolochic acid (AA), which has nephrotoxic properties, can cause the necrosis in proximal renal tubule epithelial cells. Here we examined whether Gb3 plays a role in AA-induced kidney damage and repair by comparing renal function and pathological changes of wild type (WT) versus A4GALT KO mice after AA challenge.

Methods: WT and A4GALT KO C57 mice were intraperitoneally injected with AA 5mg/kg/d for a total of 8 days. Mice general status and body weight were monitored. The urine, blood, kidney and bladder tissues of the mice were collected on the 9th day to determine the function and pathological changes.

Results: Compared with WT C57 mice, A4GALT KO mice were more sensitive to AA. From day 5 of administration, A4GALT KO mice began to show significant weight loss. On day 9, More severe renal tubular injury pathological changes, significantly increased urine leukocytes and ketones were detected in A4GALT KO mice. The proliferation of bladder transitional epithelial cells was significantly increased in AA treated WT and A4GALT KO C57 mice, accompanied with fibrin deposition, vascular dilatation and a small amount of inflammatory cell infiltration in the bladder compared with that in the untreated group. There was no significant difference in bladder changes between WT and A4GALT KO groups after AA administration.

Conclusions: Our findings uncovered that Gb3 is protective in AA-mediated renal tubular necrosis and its presence reduces kidney injury. We will further explore its specific mechanism in the following study.

PO0357

The Effect of Ischemia-Reperfusion Injury on Nuclear-Reduced Glutathione Levels in Kidneys from Old Female Lewis Rats

Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

Background: The purpose of the study was to determne the effect of ischemia/reperfusion injury (IRI) on nuclear reduced glutathione (GSH) levels in kidneys from old rats. GSH is the major antioxidant inside cells, and a decrease in GSH levels would contribute to the damage caused by free radicals that are elevated in IRI. There is limited information on the effect of IRI on nuclear GSH levels.

Methods: Anesthetized old female Lewis rats (22 months of age) were used in the study. The left and right renal pedicles was clamped for 60 min, followed by 60 min of reperfusion in the Experimental Group (n=5). The kidneys were then harvested, separated into cortex and medulla, and homogenized. Kidneys in the Control Group (n=5) were not subjected to IRI before being harvested. The nuclear fractions were isolated using differential centrifugation, and GSH levels were measured using a spectrophotmetric assay. The water contents of the cortex and medulla were determined to allow GSH levels to be expressed as nmol/ g kidney dry weight. A Student's T test was used to compare the groups, and statistical significance was determined at $p < 0.05$. All data shown as X ± SEM.

Results: Nuclear GSH levels were significantly decreased in both the kidney cortex and medulla of the Experimental Group when compared to the Control Group. Nuclear GSH levels in the cortex decreased by **28%**, with nuclear GSH being **535 ± 56 nmol/g kidney dry wt** in the Control Group, and decreased to **385 ± 23 nmol/g kidney dry wt** in the Experimental Group exposed to IRI. Nuclear GSH levels in the medulla decreased by **54%**, with nuclear GSH being **676 ± 72 nmol/g kidney dry wt** in the Control Group, and decreased to **309 ± 29 nmol/g kidney dry wt** in the Experimental Group exposed to IRI.

Conclusions: After 60 min of ischemia, nuclear GSH levels in rat kidney cortex and medulla did not return to normal levels after 60 min of reperfusion. The results suggests that the nucleus is experiencing major oxidative stress and damage caused by free radicals in IRI, and this may be contributing to the renal dysfunction seen in IRI.

PO0358

Metabolomics Reveals the Efficacy of Limonin on Mitigating Cisplatin-Induced AKI

Xi Zeng, Xianke Zhou, Yadie Xiang, Yudan Chen, Haiyan Fu. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Renal Division, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: In the clinic, acute kidney injury (AKI) is one of the most severe cisplatin side effects, limiting its use in cancer therapy. Our previous study demonstrated that Limonin, a triterpenoid compound extracted from citrus, alleviated cisplatin-induced AKI. However, the involved mechanisms remain largely unknown. In this study, we elucidated how Limonin mitigates cisplatin-induced AKI from a new perspective, metabolomics.

Methods: A total of 30 mice were divided into three groups: Sham, Cisplatin + vehicle, and Cisplatin + Limonin. Limonin was administrated once daily *via* oral gavage started 3 days before cisplatin injection. At 72 h after cisplatin injection, kidney tissues were collected for metabolomics. Metabolomics was performed using Trace 1310 Gas Chromatograph equipped with an AS 1310 autosampler connected to a TSQ 8000 triple quadrupole mass spectrometer.

Results: After AKI, Limonin significantly preserved serum creatinine and blood urea nitrogen levels and ameliorated kidney tubular injury, compared with vehicles. Kidney samples were then subjected to metabolomics. A total of 302 metabolites were detected. The principal component analysis indicated that these metabolites could be well separated, reflecting the changes of metabolite distribution after treatment of Limonin. Multivariate statistical analysis further identified 34 endogenous differentially expressed metabolites within three groups. Intriguingly, phenylalanine, tyrosine and tryptophan biosynthesis, phenylalanine metabolism, and linoleic acid metabolism were the top disturbed metabolic pathways amid the AKI repair process. These metabolic pathways are tightly correlated with oxidative stress, inflammatory response, and energy metabolism. Specifically, Limonin reduced Linoleic acid content, a major metabolite in the linoleic acid metabolism pathway in the AKI kidneys. Downregulation of Linoleic acid subsequently inhibited the synthesis of arachidonic acid. It ultimately influenced the abundance of metabolites in the tricarboxylic acid cycle to exhibit its protective role of Limonin in mitigating AKI.

Conclusions: Our data suggested that Limonin mitigates cisplatin-induced AKI through alternating multiple metabolic pathways.

Role and Regulatory Mechanism of Adropin in AKI by Regulating PDK4

Mingcheng Huang,[1,2] Shan Jiang,[1,2] Keping Wu,[1,2] Xiaohua Wang,[1,2] Yan Lei,[1,2] Xiuxun Tian,[1,2] Lanyue Zhang,[1,2] Yu Liu,[1,2] Tianjiao Cui,[1,2] Zhihua Zheng.[1,2] *[1]Sun Yat-Sen University, Guangzhou, China; [2]Department of Nephrology, Kidney and Urology Center, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China, Shenzhen, China.*

Background: Oxidative stress and inflammation are the important biological mechanisms of the development of ischemic Acute kidney injury (AKI). Pyruvate Dehydrogenase Kinase 4 (PDK4) is a key enzyme in the process of glucose oxidation, which can inhibit glucose oxidation. Adropin, a secreted protein encoded by Energy Homeostasis Associated (ENHO) gene, is involved in the pathogenesis and pathological process of metabolic and inflammatory diseases and other diseases, can inhibit oxidative stress and inflammation, but its mechanism is unclear in AKI.

Methods: *In vitro*, HK2 cells were incubated with rotenone to mimicked Ischemia Reperfusion Injury (mIRI) and treated with Adropin, the changes of mitochondrial membrane potential, indicators of autophagy, antioxidant protein, ROS levels and PKD4 were detected. *In vivo*, we established AKI model with IRI, and Adropin was given intravenously to detect the changes of renal injury indexes, antioxidant protein (SOD2), Adropin and PKD4 in mice.

Results: 1. Adropin up-regulated the antioxidant enzyme SOD2 and decreased the ROS level in HK-2 cells with mimicked Ischemia Reperfusion Injury. 2. The expression of PDK4 was significantly up-regulated and SOD2 was down-regulated in AKI mice induced by IRI. With the treatment of Adropin, the expression of SOD2 was up-regulated, and renal injury was alleviated.

Conclusions: Adropin can reduce the production of ROS by down-regulating the expression of PDK4 and up-regulating SOD2, thus alleviating renal injury in AKI.

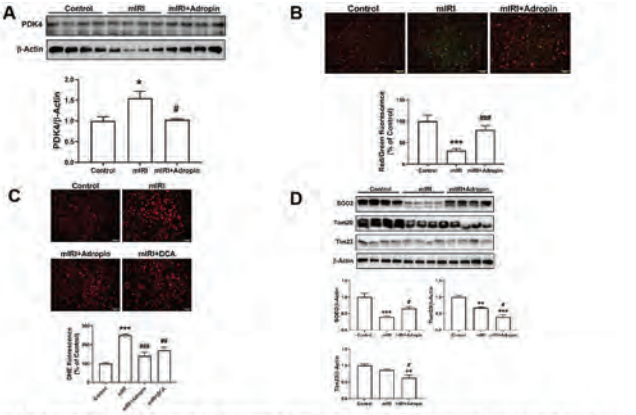

Fig.1 The method of ATP depletion by incubating a sugar-free medium containing rotenone (100 mol/L) in HK-2 cells to MIRI in vitro. The expression of PDK4, mitochondrial ROS, membrane potential, indicators of autophagy and SOD2 in HK2 cells with the treatment of Adropin were detected.

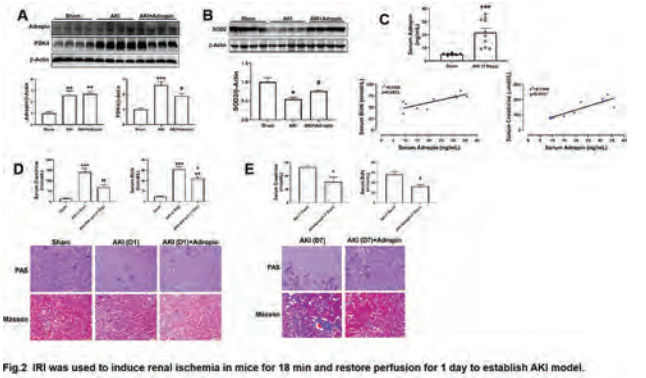

Fig.2 IRI was used to induce renal ischemia in mice for 18 min and restore perfusion for 1 day to establish AKI model. The expression of PKD4, SOD2 and renal injury indexes and changes after intravenous administration of adropin.

PO0360

Targeting Myeloid Ferritin Heavy Chain (FtH) in Rhabdomyolysis-Induced AKI

Kayla R. Mccullough, Mauhaun Taheri, Matthew C. Hudson, Amie Traylor, Subhashini Bolisetty. *Division of Nephrology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) is defined as an abrupt decrease in kidney function and significantly impacts mortality. During rhabdomyolysis, muscle injury leads to release of myoglobin, causing an increased heme/iron delivery to the kidney, leading to AKI. Iron exacerbates oxidative stress and causes cell death. Kidneys respond to increased iron by inducing ferritin heavy chain (FtH) expression. FtH is a ferroxidase

that converts ferrous iron into ferric form. Distinct myeloid populations promote injury and depletion of macrophages protect against rhabdomyolysis. Myeloid cells express high levels of FtH and mediate iron recycling. Therefore, we tested the hypothesis that myeloid FtH confers protection against rhabdomyolysis-induced AKI.

Methods: To induce rhabdomyolysis, female mice (10-12 weeks) deficient in myeloid FtH ($FtH^{Lysm-/-}$) and floxed controls ($FtH^{fl/fl}$) were deprived of water for 16 h and administered 50% glycerol via intramuscular injection into hindlimbs (7.5 or 11 ml/kg body weight). Mice were harvested at 1-, 3-, or 7-days post-glycerol. Kidney function and injury were evaluated by serum creatinine, and kidney injury marker 1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL) expression, respectively. Kidneys were analyzed for markers of cell injury/death (KIM-1, calcium-binding protein A8 (S100A8)), cleaved caspase 3 (CC3) and TUNEL positivity and fibrosis.

Results: Rhabdomyolysis led to a significant loss in kidney function and an increase in kidney injury (NGAL and KIM-1) in all groups of mice. However, at 7 days, while these markers returned to baseline in $FtH^{Lysm-/-}$ mice, there was a persistent tripling of creatinine and elevated KIM-1 levels only in $FtH^{fl/fl}$ mice. This was associated with increased activation of JNK, and markers of cell death. Additionally, $FtH^{fl/fl}$ kidneys expressed higher levels of aSMA and collagen when compared to $FtH^{Lysm-/-}$ kidneys. This was associated with increased expression of TGFb and Gal-3, which mediate myofibroblast activation and promote fibrosis.

Conclusions: Our findings demonstrate that while myeloid FtH deletion does not impact acute injury following rhabdomyolysis, it mitigates injury progression and promotes recovery. Current studies are aimed at using single cell RNA sequencing approaches to identify key pathways that are activated during the resolution phase following rhabdomyolysis.

Nicotinamide Retains Klotho Expression and Ameliorates Rhabdomyolysis-Induced AKI

Wenjun Lin. *Department of Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China, Shanghai, China.*

Background: Acute kidney injury is a severe complication of rhabdomyolysis. Inflammation plays a critical role in the pathogenesis of rhabdomyolysis-induced AKI. Nicotinamide, a form of vitamin B3 and a precursor of nicotinamide adenine dinucleotide, has been shown potent anti-inflammation effects. Klotho is a tubular highly expressed renoprotective protein. Therefore, we explored the effect of nicotinamide on rhabdomyolysis-induced AKI and the underlying mechanisms.

Methods: We used glycerol-induced rhabdomyolysis mice model to observe the effect of nicotinamide on kidney injury. Western blot, chromatin immunoprecipitation and small interfering RNA were used to evaluate the role of Klotho in nicotinamide-related renoprotection.

Results: The results showed that nicotinamide attenuated kidney injury in rhabdomyolysis. Moreover, nicotinamide effectively blocked the recruitment of NF-kB, NCoR and HDAC1 to the promoter of Klotho and preserved Klotho expression. More importantly, renoprotection effect of nicotinamide was abrogated when Klotho was knockdown by small interfering RNA.

Conclusions: Our study demonstrates that Klotho preservation is essential for the renoprotection effect of nicotinamide and provides a new preventive strategy for rhabdomyolysis-induced AKI.

Defective Clearance of Nucleic Acids Exacerbates AKI

Rajkumar Venkatadri, Murat Dogan, Vikram Sabapathy, Saleh Mohammad, Rahul Sharma. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Extracellular nuclear DNA and RNA released from dying cells can act as damage associated molecular pattern (DAMP) to trigger inflammatory pathology during acute kidney injury (AKI). Cell-free or cytoplasmic DNA can activate immune cells through the interferon stimulatory DNA (ISD) pathway to contribute to tissue damage. We aimed to understand immune dysregulation due to defective DNA clearance in the setting of murine AKI models. To study direct effect of defective DNA clearance in AKI, we utilized Three prime repair exonuclease (TREX1) deficient mice.

Methods: C57BL/6J (B6) mice or bone marrow derived macrophages (BMDM) were treated with poly I:C (pIC) to mimic elevated nucleic acid DAMPs. Bilateral ischemic reperfusion injury (IRI) or treatment of TREX1 deficient (TREX1 KO and TREX1 D18N) and STING KO mice with cisplatin (Csp), which causes DNA damage-induced AKI, was employed. Renal function was assayed using plasma creatinine (PCr) and blood urea nitrogen (BUN) levels. Levels of proinflammatory cytokines (IFNg, TNFa), renal injury markers (*Kim1* and *Ngal)* and pro-inflammatory genes (*Il1b, Mx1, Nos2, Ifi44, Tnfa* and *Il6)* were measured by Flow cytometry, ELISA and RT-PCR. H&E-stained kidney sections were used to assess renal injury.

Results: Treatments of wildtype (WT) B6 mice with pIC upregulated proinflammatory cytokines leading to a Th1 predominance, indicative of excessive inflammatory predisposition. Csp and IRI induced significantly higher injury and dysfunction in TREX1 deficient (TREX1 KO and TREX1 D18N) mice. Kidney injury markers *Kim1* and *Ngal* were also significantly elevated along with elevated proinflammatory cytokines. The TREX1 D18N mice subjected to IRI also exhibited upregulated recently activated ($CD4^{+}CD69^{hi}$) and elevated T effector memory ($CD4^{+}CD44^{+}CD62L^{lo}$) phenotype confirming immune dysregulation. CD4 T cells in TREX1 D18N mice also had reduced levels of the anti-inflammatory cytokine IL-10. Interestingly, STING KO and TREX1 D18N-STING double KO mice also had exacerbated injury levels indicating the role of uncleared DNA and the cGAS-STING DNA sensor pathway in AKI as a result of TREX1 deficiency.

Conclusions: The study presents evidence of the role of TREX1 and uncleared DNA to cause immune dysregulation in AKI and supports employing approaches that can target DNA scavenging to counteract the burden of AKI.

Heme Oxygenase 1 Is a Key Player in Arsenical-Induced AKI

Amie Traylor,[1] Ritesh Srivastava,[1] Stephanie Esman,[1] Jasim Khan,[1] Anna A. Zmijewska,[1] Bini Mathew,[2] Laurence M. Black,[1] Mark J. Suto,[2] Mohammad Athar,[1] Anupam Agarwal.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Southern Research, Birmingham, AL.*

Background: Arsenicals, such as Lewisite, are a class of warfare vesicants that cause immediate and painful blistering of the skin and mucous membranes upon contact. Systemic absorption of arsenicals results in "Lewisite shock," which is characterized by hypovolemia due to capillary damage, and multi-organ dysfunction. There is an ongoing risk of exposure from arsenical weaponization, but accidental exposures from underground storage of these compounds in several countries including the US, Italy, Russia, and Japan also pose a risk. Molecular mechanisms of arsenical-induced injury

involve oxidative and endoplasmic reticulum (ER) stress, inflammation, and cell death. We have previously reported that a single cutaneous exposure to arsencials causes acute kidney injury (AKI) in mice as evidenced by increased serum and urinary biomarkers of AKI. Intrarenal heme oxygenase-1 (HO-1), a protective anti-oxidant enzyme, is also upregulated as a response to injury in addition to ATF4 and CHOP, molecules involved in regulation of ER stress and cell death.

Methods: To interrogate the precise role of HO-1 in arsenical-induced AKI, we exposed HO-1 knockout mice (HO-1$^{-/-}$) and wild-type controls to phenylarsine oxide (PAO), an analog of Lewisite that is commonly used due to the restricted use of this vesicant. Employing *in vitro* techniques, we further tested the efficacy of a novel small molecule inducer of HO-1, SR-37618 after PAO treatment.

Results: Our data show that HO-1 deficiency results in worse kidney damage post-PAO exposure, suggesting it is a targetable enzyme for intervention. Utilizing a novel small molecule inducer of HO-1 created in collaboration with Southern Research, we demonstrate that 1 hour pre-treatment with SR-37618 diminishes PAO-induced ATF4 and CHOP expression in HEK-293 cells.

Conclusions: While further studies to assess the efficacy of SR-37618 in mouse models are ongoing, the data presented here provide evidence that HO-1 induction by SR-37618 is protective against arsenical-induced AKI. Moreover, small molecule inducers of HO-1 could potentially serve as a novel therapeutic for intervention in other forms of AKI.

Quantitative Systems Toxicology (QST) Modeling of Drug-Induced Acute Proximal Tubule Epithelial Cell Injury and Associated Renal Hemodynamic Responses

Yeshitila Gebremichael, Nader Hamzavi, Jeffrey L. Woodhead, Sergey Ermakov, Brett A. Howell. *DILIsym Services, Inc., a Simulations Plus company, Research Triangle Park, NC.*

Background: Renal proximal tubule epithelial cells (RPTEC) are vulnerable to drug-induced toxicities which often result in acute kidney injury (AKI). Drug toxic effects range from mild sub-lethal RPTEC injuries to cellular death via multiple cellular damage mechanisms. At the systems level, decline in glomerular filtration rate (GFR) is a common manifestation of AKI. The complexity of pathophysiological responses (cellular, neurohormonal, hemodynamic) that lead to impaired filtration pose a challenge for reliable prediction of AKI. QST modeling is a promising method for translating cellular-level renal damage to clinical manifestations of AKI.

Methods: We developed RENAsym, a QST model of drug-induced AKI that includes key cellular injury mechanisms and renal hemodynamic responses. At the cellular level, RENAsym represents RPTEC life cycle, bioenergetics, and immune responses to renal toxicity. *In vitro* assays were used to parameterize key cellular injury mechanisms. At the systems level, RENAsym model represents renal function and feedback mechanisms including tubuloglomerular feedback (TGF) and renin-angiotensin-aldosterone systems (RAAS). RENAsym was employed to characterize the renal hemodynamic responses of drug induced RPTEC injury in humans treated with cisplatin.

Results: At the cellular level, urinary biomarkers such as KIM-1 and αGST were used to represent cellular injury and death following cisplatin exposure. RENAsym was able to capture the elevations in KIM-1 and αGST. The model also captured GFR decline and demonstrated that it occurs due to 1) increased Bowman's pressure, 2) reduced intraglomerular pressure caused by vascular effects due to RAAS activation and TGF mechanisms, and 3) lower renal perfusion pressure from excess sodium and water excretion. The model quantitatively relates cellular injury and biomarker changes with renal hemodynamic responses.

Conclusions: RENAsym represents kidney function at cellular and organ levels in healthy and pathologic states caused by toxic drug effects. By describing drug induced cellular injury and subsequent hemodynamic changes it can predict clinical responses during AKI.

Elastin-Like Polypeptide Vascular Endothelial Growth Factor (ELP-VEGF) Improves Renal Function and Decreases Inflammation Following Ischemia-Reperfusion Injury in Mice

Jason A. Collett,[1] Md Mahbub Ullah,[1] Purvi Mehrotra,[1] Alejandro R. Chade,[2] Gene L. Bidwell,[2] David P. Basile.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]The University of Mississippi Medical Center, Jackson, MS.*

Background: Acute Kidney Injury (AKI) represents a significant clinical concern and significant risk factor for the development of chronic kidney disease (CKD). AKI is associated with impaired renal function, increased inflammation and microvascular congestion, damage and loss. A fusion protein between the elastin-like polypeptide biopolymer and human VEGF-A_{121} (ELP-VEGF) efficiently targets the renal vasculature and promotes vascular protection and angiogenesis, while potentially altering inflammatory processes. However, it is unknown if ELP-VEGF administration following ischemia-reperfusion mitigates injury, facilitates vascular protection and hastens repair.

Methods: Male C57BL/6 mice were subjected to unilateral ischemia (I/R) for 25 minutes. Post-ischemic animals were treated daily with either vehicle or ELP-VEGF (10ug/kg bw; i.p) at reperfusion, and every 24 hours for 7 days. Serum creatine (sCre) and BUN were collected 24 hours and 7 days following ischemia to assess renal function. At day 7, kidneys were harvested for analysis of infiltration of inflammatory cells by FACS and measurement of peritubular capillary density by immunofluorescent staining.

Results: Increases in BUN following unilateral I/R were significantly attenuated in the ELP-VEGF treated group compared with vehicle at both 24 hours (66% vs. 15%) and 7 days (49% vs. 19%) following ischemia ($p<0.05$). I/R significantly reduced the number of CD31+ endothelial cells in the injured kidney of the vehicle-treated mice compared with sham ($p<0.05$), and ELP-VEGF attenuated that reduction. ELP-VEGF also attenuated the pro-inflammatory response following I/R, with significant reductions in total number of infiltrating mononuclear cells ($p<0.05$). In ELP-VEGF treated mice, there was a significant reduction in Th17 cells (CD4+IL17+; 408236 vs. 182277 cells/g kidney: CD8+IL17+; 484483 vs. 99391 cells/g kidney), DC/Macrophages (12404078 vs 4764147 cells/g kidney) and B cells (16201335 vs. 7641714 cells/g kidney) compared with vehicle treated rats ($p<0.05$).

Conclusions: ELP-VEGF represents a novel reno-protective therapeutic compound related to its anti-inflammatory and renovascular protective effects.

Inhibition of PFKFB3 Alleviates Cisplatin-Induced AKI

Lu Wen,[1,2] Qingqing Wei,[2] Zheng Dong.[2] *[1]Central South University, Changsha, China; [2]Augusta University Department of Cellular Biology and Anatomy, Augusta, GA.*

Background: Metabolism and its reprogramming may have influence on acute kidney injury (AKI) and subsequent kidney repair. 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase 3 (PFKFB3) is an important rate-limiting enzyme in glycolysis. Recently, PFKFB3 has gained substantial interest as an attractive target for cancers and pulmonary hypertension therapy. However, the role of PFKFB3 in AKI remains poorly understood.

Methods: To investigate the role of PFKFB3 in cisplatin nephrotoxic AKI, we established stable PFKFB3 knockdown rat renal tubular cell lines (RPTC) and generated the kidney proximal tubule-specific PFKFB3 knock-out mice by crossing PFKFB3-floxed mice with PEPCK-CRE mice. PFKFB3-knockdown and wild-type RPTC cells were treated with 20μM cisplatin for 24h *in vitro*, while PFKFB3 knock-out or wild type male mice of 8-10 weeks were intraperitoneally injected with 30 mg/kg of cisplatin *in vivo*.

Results: PFKFB3 was up-regulated in cisplatin-induced AKI models both *in vitro* and *in vivo*. In the mouse model, deficiency of PFKFB3 reduced cisplatin-induced kidney injury and improved renal functions. Moreover, genetic and pharmacological inhibition of PFKFB3 in RPTC cells suppressed cisplatin-induced apoptosis. In addition, phosphorylated Erk1/2, phosphorylated p38 and phosphorylated NF-κB were decreased in PFKFB3 knockdown RPTC cells compared to the vector group.

Conclusions: These results indicate that PFKFB3 is a key mediator of renal tubular injury in cisplatin-induced AKI and may be an effective therapeutic target for alleviating cisplatin nephrotoxicity in chemotherapy.

Cilastatin Inhibits Renal Myoglobin Endocytosis and AKI Following Rhabdomyolysis

Jessica F. Hebert, Kevin G. Burfeind, Megan N. Nickerson, Yoshio Funahashi, Mahaba B. Eiwaz, Tahnee Groat, Michael Hutchens. *Oregon Health & Science University, Portland, OR.*

Background: Muscle-derived myoglobin, a renal toxin, causes rhabdomyolysis-induced acute kidney injury (AKI) via megalin-mediated endocytosis into proximal tubule cells (PTs). Endocytosis kinetics and inhibition are poorly understood. We characterized myoglobin uptake *in vivo*, hypothesizing cilastatin, a putative megalin inhibitor, would prevent endocytosis akin to megalin knockouts.

Methods: Procedures in wild-type (WT) male C57BL/6 mice and inducible, PT-specific megalin-deleted mice (iMegKO) were approved by OHSU or PVAMC IACUC. FITC-myoglobin (FMb) and cilastatin (200 mg/kg) were injected retroorbitally. Experimental rhabdomyolysis (ER) was induced via intramuscular injection of 50% glycerol (8 mL/kg). Glomerular filtration rate (GFR) was measured 24h later, and immunofluorescence and single-cell RNASeq were performed on renal tissue.

Results: FMb was observed in PTs 15 min post-injection in control mice; in iMegKO mice, FMb puncta were nearly absent ($p<0.0001$). FMb puncta were reduced in cilastatin-treated WTs without ER vs vehicle controls ($p=0.0012$). iMegKO prevented AKI following ER, with 24h GFR 5x control ($p<0.001$). Cilastatin injection did not affect GFR in iMegKO ($p=0.89$), but had a significant effect on ER-induced AKI in wild-type mice: GFR was 8x vehicle ($p=0.03$) while PT uptake of endogenous myoglobin decreased ($p<0.05$). A composite score of endocytosis related genes (endoscore) showed significant alterations (Figure 1).

Conclusions: Megalin interference prevents ER-induced AKI by reducing myoglobin endocytosis; cilastatin recapitulates the effect in a megalin-inhibitory fashion. Alteration of endocytosis-related genes confirms this process is critical in rhabdomyolysis, and may suggest additional therapeutic targets. Future studies will also include cilastatin delivery timing, dosage, and formulation.

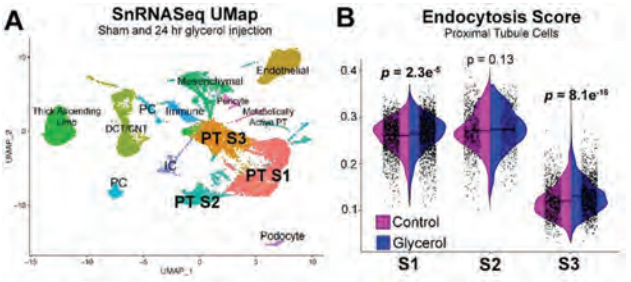

Figure 1. Kidney SnRNASeq after RIAKI. A) Umap clustering of cells isolated from whole kidney tissue 24 hrs after glycerol or vehicle injection (n=2 kidneys and approximately 10,000 cells per group). Data generated in Seurat V4 using Rstudio. PT = proximal tubule, PC = principal cells of the collecting duct, IC = intercalated cells of the collecting duct. DCT = distal convoluted tubule. B) Split violin plots of different PT segments depicting "endocytosis score", generated by calculating average expression of 657 genes in gene ontology term "endocytosis" (GO:0006897). Line = median endocytosis score of all cells within group. P values generated from student's t-test.

PO0368

PKM2-Specific Deletion in Myeloid Cells Ameliorates Renal Impairment by Alleviating Metabolic Changes in CaOx-Induced AKI

Orestes Foresto-Neto,[1,2] Tâmisa S. Honda,[1] Magaiver A. Silva,[1] Ingrid K. Watanabe,[1] Paulo J. Basso,[1] Iris C. Jesus,[1] Ana R. da Silva,[2] Marcos A. Cenedeze,[2] Meire I. Hiyane,[1] José C. Alves-Filho,[1] Roberto Zatz,[1] Alvaro Pacheco-Silva,[2] Niels O. Camara.[1,2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: Macrophages are plastic cells and can polarize towards pro- or anti-inflammatory phenotype. PKM2 catalyzes the last step of glycolysis, which is a crucial metabolic pathway for activation of macrophages. We investigated whether deletion of PKM2 in myeloid cells would interfere with renal metabolism and exert protection in calcium oxalate (CaOx) crystal-induced acute kidney disease (AKI).

Methods: Myeloid-specific PKM2-knockout mice ($PKM2^{fl/fl}$;LysM-Cre^{+}) and their Cre-negative littermates ($PKM2^{fl/fl}$) underwent AKI by a single i.p. injection of NaOx (100mg/kg) and 3% NaOx in drinking water for 24hr before sacrifice. Expression of PKM2 in bone marrow-derived macrophages was assessed by FACS. Serum creatinine, blood urea, renal CaOx crystal deposition (Pizzolato staining), IL-6, NGAL, KIM-1, HK2, CPT1a and CPT2 mRNA expression (quantitative PCR), macrophage number/phenotype (FACS), and lactate levels were all measured.

Results: In $PKM2^{fl/fl}$, intrarenal CaOx deposition impaired renal function, as well as increased the expression of IL-6, NGAL, KIM-1 and HK2 and the levels of lactate in kidneys compared to healthy controls ($p<0.05$). Renal expression of CPT1a and CPT2 did not differ among groups. $PKM2^{fl/fl}$;LysM-Cre^{+} exhibited similar deposition of crystals but less impairment of renal function, inflammation/injury and renal lactate content ($p<0.05$). The number of F4/80+CD11b+ cells in kidneys were similarly elevated by CaOx in both $PKM2^{fl/fl}$ and $PKM2^{fl/fl}$;LysM-Cre^{+}, while pro-inflammatory macrophages (Ly6C+CD206-) were significantly reduced in PKM2;LysM-Cre^{+} mice ($p<0.01$).

Conclusions: Pro-inflammatory macrophages rely mainly on glycolysis in oxalate induced-AKI. Deletion of PKM2 in myeloid cells partially prevents renal metabolic changes and inflammation/injury. FAPESP (2019/02893-9 and 2017/05264-7), CNPq and CAPES (Financial Code 001).

Tubular MPC1 Deletion Protects from Glycerol-Induced Kidney Injury

Adam J. Rauckhorst,[1] Aaron A. Simoni,[2] Gabriela Vasquez Martinez,[2] Robin L. Bolek,[2] Prerna Rastogi,[1] Navjot Singh P. Pabla,[4] Douglas R. Spitz,[1] Eric Taylor,[1] Diana Zepeda-Orozco.[2,3] *[1]The University of Iowa Healthcare, Iowa City, IA; [2]Nationwide Children's Hospital, Columbus, OH; [3]The Ohio State University Wexner Medical Center, Columbus, OH; [4]The Ohio State University, Columbus, OH.*

Background: Pyruvate fuels mitochondrial oxidation, scavenges H_2O_2, and regulates the glutathione and thioredoxin dependent antioxidant systems. Acute kidney injury (AKI) results in damaging oxidative stress and metabolic disruptions that are lessened upon pyruvate treatment. The specific mechanism by which pyruvate protects against AKI is unknown. We hypothesize that the Mitochondrial Pyruvate Carrier 1 (MPC1), which controls the cellular fate of pyruvate, plays a central role in AKI and injury recovery.

Methods: MPC1 was disrupted in tubular epithelial cells by generating $Pax8^{Cre+/-}Mpc1^{f/f}$ (Tub-MPC1-KO) mice and was tested against $Mpc1^{f/f}$ (Tub-MPC1-WT) littermates. 13C-tracer and steady state metabolomics were performed in 4 hour-fasted mice. Rhabdomyolysis-induced AKI was initiated by injecting 10 ml/kg of 50% glycerol into the hind limb of Tub-MPC1-WT vs Tub-MPC1-KO mice and we evaluated toxicity and kidney function prospectively.

Results: 13C enrichment into TCA cycle intermediates demonstrated decreased glucose-driven PDH- and PC-dependent pyruvate metabolism in Tub-MPC-KO mice. At steady state, this fueled adaptations in carbohydrate, fatty acid, and amino acid metabolism. Interestingly, pathway analysis identified glutathione metabolism as significantly altered in Tub-MPC1-KO. Glutathione biosynthetic precursors were decreased and NADPH/NADP was increased in Tub-MPC1-KO kidney. This implies that the renal redox environment was potentially primed to be better able to respond to renal oxidative stress. To test this idea, rhabdomyolysis-induced AKI was initiated by injecting Tub-MPC1-WT and Tub-MPC1-KO mice intramuscularly with glycerol. Following AKI, Tub-MPC1-KO mice lost less weight and had significantly decreased serum cystatin C and BUN compared to Tub-MPC1-WT mice.

Conclusions: *In vivo* disruption of tubular MPC1 results in metabolic changes that favor a reduced cellular environment and protects from glycerol induced AKI.

Ginsenoside Rg3 Attenuates Ischemia Reperfusion-Induced Renal Injury in Mice via Induction of Autophagy Flux

Jin Ah Shin, Dae Eun Choi, Jin young Jeong, Haet Bit Hwang, Soo hyun Han, Eu Jin Lee, Youngrok Ham, Kiryang Na, Kang Wook Lee. *Chungnam National University School of Medicine, Daejeon, Daejeon, Republic of Korea.*

Background: Ginsenoside Rg3 (Rg3) has been shown as protective effects via various mechanism. However, the reno-protective effect and the role of autophagy are not clearly evaluated. This study investigate Rg3 induces autophagy flux and reduces renal cell death in renal ischemia reperfusion injury (IRI).

Methods: C57Bl/6 mice were divided into the following groups: sham; Rg3 treated sham; saline treated IRI mice; Rg3 treated IRI mice. Kidneys and blood were collected 24h after operation of mice (sham and IR operation). Renal function, kidney histology, and the protein expression of autophagy signals were evaluated.

Results: In IRI mice, the levels of BUN and s-Cr were increased, compared to sham. The Rg3 treatment decreased the BUN and s-Cr in IRI mice. In addition, Rg3 treatment decreased the renal injury score including the renal tubular cell detachment and necrosis in IRI mice. Rg3 treated IRI mice showed significantly less oxidative stress and autophagy impairment, greater amounts of LC3 and Beclin-1, lower amounts of p62, and higher levels of renal ATP6E compared to saline treated IRI mice. Rg3 treatment also increased phosphorylation of AMPK in IRI mice kidney.

Conclusions: Rg3 has renoprotection against renal IR injury via enhancement of autophagy flux.

PO0371

A Novel Immunomodulatory Peptide Suppresses Inflammatory Macrophages and Mitigates AKI

Chih-Wei Chu, David Yang, Ssu-Wei Hsu, Ching-Hsien Chen. *University of California Davis, Davis, CA.*

Background: Monocytes/macrophages are known to play a critical role in the pathogenesis and progression of acute kidney injury (AKI), as large numbers of monocytes are recruited to the kidney and differentiate into pro-inflammatory macrophages (M1 phenotype) after injury. Although targeting macrophages has emerged as a promising therapeutic strategy for AKI, the effective treatment is still limited. We previously identified a novel peptide, the MPS peptide, which targets the signaling molecule myristoylated alanine-rich C-kinase substrate (MARCKS), a central inducer of M1 macrophages. In this study, we have employed this novel peptide to determine if MARCKS inhibition reduces kidney injury.

Methods: High-dimensional single-cell mass spectrometry was used to reveal immune profiling in an AKI mouse model. Both commercial macrophage cell lines and primary macrophages isolated from peripheral blood mononuclear cells were utilized in this study for gene expression analysis. In vitro and in vivo inflammatory activities of the MPS peptide were confirmed by Western blots, real-time reverse transcription-polymerase chain reaction (RT-qPCR), flow cytometry, ELISA cytokine assays, and immunohistochemistry.

Results: Analysis of the single-cell RNA sequencing data has identified that the immune microenvironment of injured kidneys is associated with the expansion of monocytes/macrophages, particularly M1 macrophages. We next show that an elevated abundance of phospho-MARCKS in macrophages upon cisplatin treatment and this increase occurred in parallel with an increase of M1 markers as well as upregulation of inflammatory cytokines and markers of nephrotoxicity in cisplatin-exposed kidneys. Mechanistically, we demonstrate that MPS peptide had an inhibitory effect on cisplatin-induced phospho-MARCKS, p65 phosphorylation, and NF-κB activation in macrophages. Targeting of MARCKS phosphorylation using MPS peptide not only downregulated kidney-infiltrating M1 macrophages but also suppressed levels of serum creatinine and blood urea nitrogen in mice exposed to cisplatin.

Conclusions: Our results suggest that MARCKS phosphorylation is a novel NF-kB activator in pro-inflammatory macrophages and also presents a proof of concept for the use of MPS peptide as a renal protection agent for AKI.

PO0372

Renal NG2-Expressing Cells Have Phagocytic Activity and Facilitate Renal Recovery After Ischemic Injury

Daisuke Nakano, Wararat Kittikulsuth, Akira Nishiyama. *Kagawa University, Kagawa, Japan.*

Background: Pericytes play an important role in the recovery process after ischemic injury of many tissues. Brain pericytes in the peri-infarct area express macrophage markers in response to injury stimuli and are involved in neovascularization. In the kidney, nerve/glial antigen 2 $(NG2)^+$ pericytes have been found to accumulate after renal injury. However, the role of accumulated $NG2^+$ cells in injured kidneys remains unknown.

Methods: A reversible ischemic reperfusion model, we found that renal $NG2^+$ cells were increased in injured kidneys and expressed macrophage markers (CD11b or F4/80) on day 3 after reperfusion.

Results: Isolated $NG2^+$ cells from ischemia/reperfusion (I/R) kidneys also had phagocytic activity and expressed anti-inflammatory cytokine genes, including mannose receptor and IL-10. These macrophage-like $NG2^+$ cells did not likely differentiate into myofibroblasts because they did not increase α-SMA expression. Intravenous transfusion of renal $NG2^+$ cells isolated from donor mice on day 3 after reperfusion into recipient mice on day 1 after I/R surgery revealed that $NG2^+$ cell-injected mice had lower plasma blood urea nitrogen, reduced KIM-1 mRNA expression, ameliorated renal damage, and reduced cellular debris accumulation than PBS-injected mice on day 5 after reperfusion.

Conclusions: In conclusion, these data suggest that renal $NG2^+$ cells have an M2 macrophage-like ability and play a novel role in facilitating the recovery process after renal I/R injury.

PO0373

The Role of Renal Hmgcs2 in Fasting and Bacterial Inflammation

Andrea H. Venable, Kyle C. Feola, Lauren Elizabeth Lee, Sarah C. Huen. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The purpose of inflammatory anorexia during states of acute illness, such as sepsis, remains incompletely understood. We have found that glucose supplementation during bacterial sepsis suppresses ketogenesis and increases mortality, suggesting a potential protective effect of fasting metabolism. Gene expression analysis of the liver and kidney during fasting and after lipopolysaccharide (LPS) challenge, to model sterile bacterial inflammation, revealed that *Hmgcs2*, the rate-limiting enzyme of ketogenesis, is suppressed in the liver while upregulated in the kidney during LPS sepsis. This expression pattern differs from fasting, during which *Hmgcs2* is induced in both the kidney and liver. The significance of renal *Hmgcs2* upregulation during bacterial inflammation is unclear.

Methods: Liver-specific *Hmgcs2* knockout mice *(Alb-CreERT2; Hmgcs2fl/fl*), kidney-specific knockout mice (*Six2-Cre*; *Hmgcs2*$^{fl/fl}$), *Ppara*$^{-/-}$, and wild-type C57BL/6J mice were fed *ad libitum*, fasted or injected i.p. with 10 mg/kg LPS. Plasma was analyzed for lipids and ketones. Livers and kidneys were harvested for RNA and protein analysis.

Results: In wild-type mice, circulating ketones increase during fasting and LPS sepsis. While not expressed in the fed state, HMGCS2 protein is induced in the proximal tubules in a PPARa-dependent manner during both fasting and LPS sepsis. Liver-specific *Hmgcs2* deletion results in a significant attenuation of circulating ketones during fasting and LPS sepsis, while kidney-specific *Hmgcs2* deletion has no effect. Preliminary data show that the loss of *Hmgcs2* in the kidney results in an increase in KIM1 protein, a marker indicative of kidney injury, up to 48 hours after LPS injection.

Conclusions: It is well-established that the liver is the main source of circulating ketones. Our data support this notion and demonstrate that although fasting and LPS sepsis induce an upregulation of renal HMGCS2, the expression of this enzyme in the kidney does not appear to contribute to circulating ketones. Our data suggest that while renal HMGCS2 does not produce systemic ketones, it may be important for mitigating kidney injury during LPS sepsis.

Head-to-Head Comparison of Two SGLT-2 Inhibitors on AKI Outcomes in a Rat Ischemia-Reperfusion Model

Chang Chu,[1,2] Denis Delic,[3,1] Yingquan Xiong,[2] Ting Luo,[5] Ahmed A. Hasan,[1] Shufei Zeng,[1,2] Mohamed M. Gaballa,[1] Xin Chen,[2] Thomas Klein,[3] Saban Elitok,[4] Bernhard K. Krämer,[1] Berthold Hocher.[1] *[1]Universitatsklinikum Mannheim, Mannheim, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Boehringer Ingelheim International GmbH, Biberach, Germany; [4]Klinikum Ernst von Bergmann gGmbH, Potsdam, Germany; [5]Jinan University First Affiliated Hospital, Guangzhou, China.*

Background: The CREDENCE trial testing canagliflozin and the EMPA-REG OUTCOME trial testing empagliflozin suggest different effects on acute kidney injury (AKI). Since the diagnosis of AKI was made in these studies usually based on changes of serum creatinine (sCr) although changes of sCr may reflect the mode of action of SGLT-2 inhibitors.

Methods: We analyzed both drugs in a rat AKI model (ischemia-reperfusion injury (IRI) model) focusing on established morphological and biochemical AKI markers. Four groups were analyzed: sham, IRI+placebo, IRI+canagliflozin, IRI+empagliflozin.

Results: Urinary glucose excretion was comparable in both treatment groups indicating comparable SGLT-2 inhibition. Comparing GFR surrogate markers after IRI (sCr and BUN). At all investigated time points after IRI, sCr and BUN were higher in the IRI+canagliflozin group than placebo-treated rats, whereas the empagliflozin group did not differ from the placebo group. IRI led to tubular dilatation and necrosis. Empagliflozin was able to reduce that finding whereas canagliflozin had no effect. Renal expression of KIM-1 increased after IRI and empagliflozin but not canagliflozin normalized KIM-1 expression (Figure). IRI reduced urinary microRNA-26a excretion. Empagliflozin but not canagliflozin was able to restore normal levels of urinary miR-26a.

Conclusions: In conclusion, our study confirmed the observations made in the CREDENCE and the EMPA-REG OUTCOME trials. The empagliflozin effects on KIM-1 and miR-26a might indicate beneficial regulation of inflammation and innate immune response. Our data should stimulate clinical studies analyzing whether empagliflozin is a preferable SGLT-2 inhibitor in patients at high AKI risk.

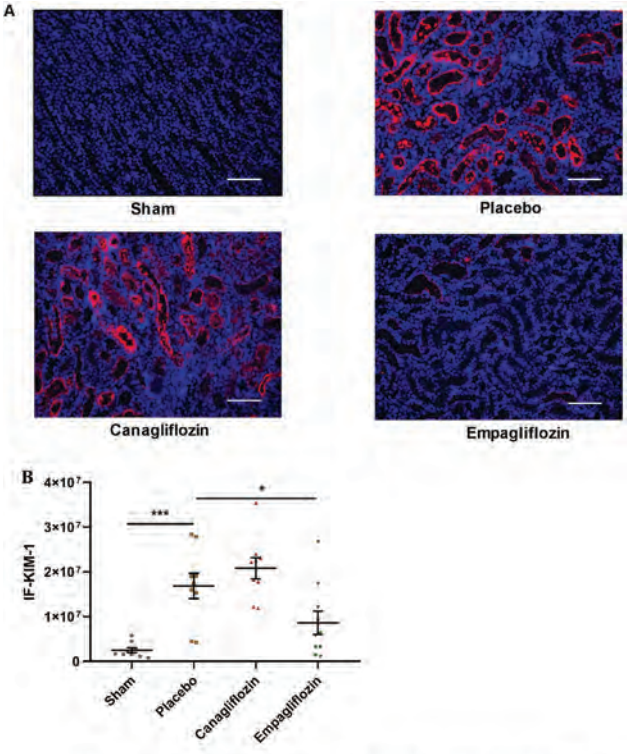

Figure 1. KIM-1 expression in kidney tissue. (A) Representative microphotographs from kidney sections of each treatment group. (B) KIM-1 expression in kidney tissue, n-values: sham (n = 9), placebo (n = 9), canagliflozin (n = 9), empagliflozin (n = 10). Values shown are means ± SEM. *p<0.05; **p<0.01; ***p<0.001; ****p<0.0001, significantly different as indicated; one-way ANOVA followed by least square method post-hoc test. Scale bars = 100 µm.

PO0375

Modeling Sepsis in Human Kidney Organoids: Cell-Free Hemoglobin-Induced Cytotoxicity Is Attenuated by Ascorbate or Acetaminophen

Julie Bejoy,[1] Justin M. Farry,[3] Lorraine B. Ware,[1] Julie A. Bastarache,[1,2] Lauren E. Woodard.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]US Department of Veterans Affairs, Nashville, TN; [3]Vanderbilt University, Nashville, TN.*

Background: Sepsis-associated acute kidney injury (AKI) is associated with high morbidity and mortality. Cell-free hemoglobin (CFH) is released into the circulation of patients with severe sepsis and higher levels are independently associated with mortality. CFH is toxic to HK-2 cells, suggesting that CFH can directly injure the renal tubular epithelium. Treatment with ascorbate (Vitamin C) or acetaminophen provides protection from CFH-induced toxicity in endothelial cells. Therefore, we sought to generate a model of sepsis-induced AKI in human kidney organoids in which to study CFH-targeted AKI treatments.

Methods: We cultured human kidney organoids from fibroblast-derived human induced pluripotent stem cells (hiPSCs) by the Takasato protocol, with optimization. We then treated mature human kidney organoids with CFH (1 mg/ml) for 48 hours and evaluated cell toxicity, viability, reactive oxygen species (ROS), and mitochondrial fragmentation. To study the protective effects, CFH-exposed organoids were co-treated with ascorbate (200 uM) or acetaminophen (1000 uM) for 48 hours.

Results: The kidney organoids expressed the expected kidney cell type markers ECAD (distal tubule), GATA3 (collecting duct), LTL (proximal tubule) and NEPHRIN (Glomeruli) at Day 21 (n=3). CFH treatment resulted in ROS production in 80% of cells within organoids compared to 5% in control group (n=3). Analysis by Lactate Dehydrogenase showed CFH treatment increased toxicity by 30% in organoids and and analysis by MTT (tetrazolium dye) assays showed reduced viability [by 70% within

organoids compared to control group (n=3)($p<.005$). LDH assay also revealed that the addition of ascorbate or acetaminophen attenuated the impact of CFH on organoids by decreasing the toxicity by ~23% within the organoids (p value<.0001).

Conclusions: Human kidney organoids can be used to model sepsis-induced AKI. CFH treatment induced toxicity and reduced viability of the human kidney organoids. Both ascorbate and acetaminophen had protective effects on CFH-induced organoid injury.

Pulsed Ultrasound Reduces Oxidative Stress-Induced Disruption of Epithelial Barrier in Sepsis-AKI

Shuqiu Zheng, Diane L. Rosin, Junlan Yao, Nabin Poudel, Shinji Tanaka, William Nash, Mark D. Okusa. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Oxidative stress disrupts epithelial junctions leading to increased paracellular permeability and kidney dysfunction. We previously showed that pulsed ultrasound (pUS) reduced inflammation and kidney injury. We hypothesized that pUS mitigates renal injury by maintaining epithelial tight junctions. Here, we utilized lipopolysaccharide (LPS) induced sepsis to create acute kidney injury (S-AKI) in a mouse model and RAW 264.7 cells to investigate the effects of pUS on the epithelial tight junction barrier and renal macrophages.

Methods: C57/BL/6 mice received pUS 24 hrs before LPS treatment. The parameters of pUS therapy followed the protocol previously published by us (PMID: 23907510). Following pUS treatment, mice received a single injection of LPS (5 mg/kg, ip). Animals were euthanized at increasing time intervals for measurement of mRNA expression and kidney imaging. Kidney histopathological changes were observed by using PAS staining. Co-staining with TUNEL and cleaved caspase-3 was used to assess kidney injury. For in-vitro assays, RAW cells were seeded onto 4-well plates and incubated for 24 hrs at a density of 5×10^5 per well. Cells were treated with LPS (100 ng/mL) in serum-free DMEM for 2 hrs.

Results: LPS induced kidney injury and apoptosis, as observed by PAS and TUNEL staining, was attenuated by pUS. Co-staining with PSD95 (postsynaptic scaffolding density protein 95) and ZO-1 (zonula occludens-1) showed both were expressed in kidney. LPS also induced a significant loss of PSD95 accompanied by a reduced mRNA expression of nuclear factor erythroid 2-related factor 2 (NRF2) and activated macrophages. The structural changes, extent of loss of PSD95 and NRF2, as well as macrophage infiltrate were all partially reversed by prior pUS treatment. In cultured RAW cells, pUS upregulated the expression of NRF2 and heme oxygenase-1 (HO-1), and attenuated CD68-positive macrophage signals.

Conclusions: pUS protected kidneys from LPS-induced S-AKI by preserving antioxidant NRF2 expression and attenuating oxidative stress-induced disruption of epithelial tight junctions.

Hypertensive Diabetic Kidney Disease Increases the Severity of Experimental AKI

Anna Menshikh,[1] Rachel Delgado,[1] Maya Brewer,[1] Min Yang,[1] Chris R. Kennedy,[2] Haichun Yang,[1] Mark P. de Caestecker.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Ottawa, Ottawa, ON, Canada*.

Background: Patients with diabetic kidney disease (DKD) are at increased risk of severe AKI and adverse outcomes. Since DKD may alter cellular and therapeutic responses in AKI, there is a need to establish a model to evaluate the mechanisms and therapeutics of AKI in the context of DKD. These studies address this deficiency by characterizing AKI in transgenic mice with renin-induced hypertension and progressive DKD.

Methods: Hypertensive male transgenic TThRen (TR+) mice, which over-express renin in the liver, were treated +/- streptozotocin to induce diabetes (DM). Tail cuff BP; urinary albumin/creatine ratio (ACR); BUN; and transdermal GFR (tGFR) were measured from 11-31 wks in DM and non-diabetic (ND) cohorts. After optimizing renal pedicle clamp times in DM (19 mins) vs. ND mice (24 mins) to induce similar injury after ischemia-reperfusion AKI (IR-AKI), mice underwent bilateral IR-AKI at 32 wks, followed by serial BP, BUN, ACR and tGFR measurements over 8 wks.

Results: ND and DM TR+ mice had increased albuminuria (31wk ACR, mg/mg: ND TR - vs. +, 17.7 (2.0) vs. 498.2 (325.2), $p<0.0001$; DM TR – vs. +, 136.7 (50.3) vs. 1028 (420.3) $p<0.01$), with no significant difference between DM and ND TR+ mice. BP was elevated in TR+ mice, with no difference between DM and ND mice, but there was a decrease in tGFR in DM TR+ vs. ND TR+ over time (2 way ANOVA, $p<0.05$). After IR-AKI, DM TR+ mice had more severe injury than DM TR- mice (e.g.: day1 BUN, mg/dl: DM TR- vs. +, 56.7 (8.6) vs. 95.1 (11.8), $p<0.01$), but there was no difference in severity of injury in ND TR- and + mice. This was associated with a progressive increase in albuminuria, but after 14 days, no difference in tGFR in DM TR- vs. + mice, and no change in albuminuria or tGFR in ND TR- vs. + mice up to 8 weeks after IR-AKI.

Conclusions: Hypertensive DM and ND mice develop albuminuria, but only hypertensive DM mice develop reduced tGFR consistent with progressive DKD. After optimizing renal pedicle clamp times to induce similar injury, only hypertensive DM mice had increased injury and progressive nephropathy after IR-AKI, as determined by increased albuminuria, compared with non-hypertensive DM and both hypertensive and non-hypertensive ND controls. This model mimics human disease as there is increased injury and progressive DKD after IR-AKI mice with pre-existing DKD.

Kidney-Specific Intestinal Alkaline Phosphatase (IAP) in Transgenic Mice Protects Lipopolysaccharide (LPS)-Induced Inflammation and Renal Failure

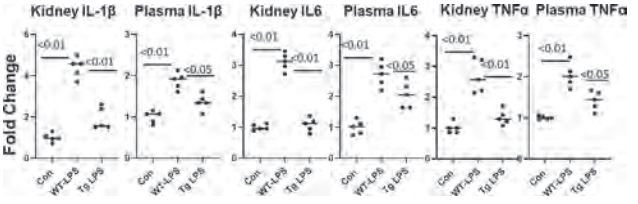
Siddhartha S. Ghosh, Graham T. Gipson, Joshua M. Kang, Shobha Ghosh, Todd W. Gehr. *Virginia Commonwealth University Medical Center, Richmond, VA.*

Background: LPS is a major player in septic AKI. However, LPS can be dephosphorylated to an inactive form by IAP. We generated kidney specific IAP transgenic mice (Tg) mice to test whether the targeted increase in IAP can decrease inflammation and improve renal function.

Methods: Tg mice were developed in C57Bl6 background using human chimeric IAP under the control of villin promoter making them kidney specific albeit some expression was also observed in the intestine. The 3′ prime end of the transgenic codon had a cmyc tag to distinguish human IAP from resident mouse IAP. Tg and non-transgenic littermates (Wild type, WT) were given 10 mg/kg LPS. Wild type control (Con) received saline. Renal function tests, plasma BUN creatinine, proteinuria, and albuminuria were performed. Plasma, Kidney, and liver were harvested after 12 hours for western blots and ELISA. Electron microscopy (EM) was done to evaluate podocytes.

Results: Serum creatinine and BUN were 2.5 and 3 fold higher in WT compared to Con ($p<0.01$), the increases were attenuated in Tg ($p<0.05$). In WT proteinuria and albuminuria were 3 and 5 fold higher than Con ($p<0.05$) these were attenuated in Tg ($p<0.05$). Cytokines (IL-1β, IL-6, and TNFα) in the liver, kidney, and plasma of WT after LPS injection was 2 to 4-fold higher than Con. However, in the liver of Tg+LPS, only TNFα was significantly reduced. Plasma and kidney cytokines of Tg+LPS were significantly lower than WT+LPS (Fig). The reduction of cytokines in the kidney of Tg+LPS was more profound than the plasma of TG+LPS. Podocyte effacement in Tg mice was less severe than WT. We could detect cmyc in plasma and kidney in Tg mice.

Conclusions: This study shows targeted increase of IAP in the kidney can abate LPS mediated deterioration of renal function, inflammation, and podocyte effacement. IAP has been shown to be released after LPS administration perhaps as a protective mechanism. An increase in plasma cmyc after LPS injection indicate that human IAP could have been secreted in the blood from the kidney or intestine. This may have decreased the inflammatory burden in the plasma.



Fold changes in cytokines

PO0379

Pretreatment with Low-Dose Lipopolysaccharide Attenuates Ischemia Reperfusion-Induced Vascular Congestion Through Vasoconstriction of the Outer Medulla During Reperfusion

Sarah C. Ray, Paul O'Connor. *Augusta University, Augusta, GA.*

Background: Vascular congestion in the renal outer medulla (OM) is common in acute tubular necrosis caused by ischemia and has been shown to promote tubular injury. Evidence from our laboratory suggests that vascular congestion originates in the renal venous vessels during ischemia and backfills the outer-medullary circulation with red blood cells (RBCs) during the reperfusion phase. We have previously reported that pretreatment with low dose lipopolysaccharide (LPS) attenuates ischemia reperfusion (IR) induced vascular congestion, however the mechanisms mediating this effect remain unknown. In the current study, we hypothesized that pretreatment with LPS prevents vascular congestion by limiting early reperfusion of the OM capillaries following ischemia.

Methods: To test this hypothesis, male WKY rats (12wks) were pretreated (i.p) with 1mg/kg LPS (n=6) or saline control (n=7) daily for 3 days. Rats were then anesthetized, and Transonic Laser Doppler probes were inserted in the cortex and OM. Regional kidney blood flow was then measured over 10 minutes of baseline, 45 minutes of renal artery clamping and 30 minutes of reperfusion.

Results: There were no differences in baseline blood flow between rats pretreated with low dose LPS or control ($p_{treat}=0.51$). The return of blood flow to the cortex was gradual ($p_{time}<0.0001$), reaching a plateau following 10 minutes of reperfusion in both groups ($p_{treat}=0.98$). The return of blood flow to the OM, however, rapidly returned to baseline levels within 1 minute of reperfusion only in control animals (1 min: 0 to 0.43AU). In contrast, OM blood flow returned slowly in LPS treated rats (1 min: 0 to -0.08AU) and did not return to baseline levels during the 30-minute reperfusion period ($p_{interaction}=0.01$).

Conclusions: Our data indicate that LPS pre-treatment, paradoxically, slows the early reperfusion of the renal OM through regional vasoconstriction. We speculate this effect attenuates medullary congestion by allowing RBCs in the shared venous circulation to clear. These findings support the hypothesis that backfilling of the renal medullary circulation before cortical reperfusion is restored, is responsible for the development of vascular congestion. New therapeutics focused on renal hemodynamics after ischemia may prevent much of the injury associated with acute kidney injury.

Dexamethasone Attenuates Kidney Ischemia Reperfusion Injury in SD Rats by Mediating M1 Macrophage Cytokine Production

Nataliya Skrypnyk, Henriette Frikke-Schmidt, David W. Frederick, Kamal Albarazanji, Gavin Lewis, Jianying Liu, Lili Guo, Qiu Li, Raul Camacho, Li-Jun Ma, Andrea R. Nawrocki, George Ho, Matthew M. Rankin, Rong Meng, Alessandro Pocai, Seunghun P. Lee. *Janssen Global Services LLC, Titusville, NJ*.

Background: Published evidence suggests a beneficial effect of adjunctive corticosteroid therapy on time of withdrawal from ventilation and time in ICU, as well as a faster reversal of septic shock. Studies in rodent models of acute kidney injury (AKI) have demonstrated a protective role of dexamethasone (Dexa), however its mechanism in attenuation of AKI is not clearly understood. Because M1 macrophages play role in the early stage of sepsis and ischemic kidney injury by producing proinflamatory cytokines contributing to AKI progression, we investigated the effect of Dexa during AKI on M1 polarized macrophages and kidney tubular epithelial cells.

Methods: Bilateral kidney Ischemia Reperfusion (IR) (30 minutes) was performed in 20 male SD rats (n=10/group). Dexa (3mg/kg) was injected IP 30 min before IR. Plasma creatinine, BUN and transcutaneous glomerular filtration rate (tGFR) were evaluated as readout for kidney function. Plasma cytokines were measured at 4 and 24h after IR using a Luminex Multiplex Assay. The human monocytic cell line THP1 was differentiated for 72h after a 4h pulse of 20 ng/mL PMA and then polarized to M1 phenotype in the presence or absence of Dexa. Macrophage-conditioned keratinocyte media was then collected and transferred to HK-2 cells (a human kidney tubular epithelial line) in a hypoxic chamber (0.2% O2) for 48 hrs. Apoptosis of HK-2 cells was evaluated by determining Casp3/7 activity.

Results: Pretreatment of rats with Dexa reduced plasma creatinine (2 vs 1 mg/dL), BUN (121 vs 96 mg/dL) and increased tGFR (0.5 vs 0.8 mL/min) at 24h post IR. Plasma cytokines known to be produced by M1 macrophages such as IL-1β and keratinocyte-derived chemokine (KC) were significantly reduced at 4h while MCP-1 was reduced 4 and 24h after IR. HK-2 cells treated with conditioned media obtained from M1 macrophages in the presence of Dexa and hypoxic conditions showed reduced casp3/7 activity.

Conclusions: Our data demonstrate that Dexa has a renoprotective effect in SD rat with IR-induced AKI. The observed beneficial effect of Dexa seems to involve an indirect anti-apoptotic effect on tubular epithelial cells and potentially a reduction of cytokine production by M1 macrophages.

PO0381

IL-33/ST2 Alarmin Signaling Axis in Myeloid Cells Regulates Kidney Injury

Vikram Sabapathy, Gabrielle Costlow, Nardos T. Cheru, Airi Price, Rajkumar Venkatadri, Murat Dogan, Saleh Mohammad, Rahul Sharma. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Macrophages are a heterogeneous class of cells that play a vital role in inflammation, repair and fibrosis post-injury; however, their role in early and late phases of injury is not well understood. IL-33 is a nuclear-localized alarmin cytokine that is released upon tissue damage and signals through IL-1 receptor-like 1 (IL1RL1 or ST2). ST2 is expressed in a variety of cells, including myeloid cells. The role of IL-33/ST2 in regulation of macrophages in ischemia reperfusion injury (IRI) is unclear. Here, we studied the role of $ST2^{+}$ macrophages using acute and chronic IRI models.

Methods: For myeloid cell-specific deletion of ST2, $ST2^{fl/fl}$ mice were crossed with LysM-Cre mice. Bilateral IRI (26min renal pedicle clamping and 24 hours reperfusion) was used to model acute kidney injury (AKI). Unilateral IRI (24min) was used for chronic injury studies. Contralateral nephrectomy was performed on day-13 post-IRI and the mice were euthanized 24hrs later for analyses. The structure and function of kidneys were probed using flow cytometry, histology, immunohistochemistry, quantitative gene expression, and biochemical analyses. The *in vitro* analyses were performed using peritoneal and bone-marrow-derived macrophages.

Results: Although global ST2 deficiency in mice showed reduced renal injury, it is challenging to ascertain the contribution of different cells involved in the inflammation and fibrosis process. Preliminary metanalysis of single cell RNA seq data indicated high expression of ST2 on renal macrophages. Therefore, we performed acute and chronic IRI studies on myeloid-cell specific deletion of ST2. Interestingly, loss of ST2 on myeloid cells also resulted in attenuation of acute renal injury. In vitro, efferocytosis assays on both peritoneal and bone-marrow derived macrophages demonstrated that loss of ST2 on macrophages resulted in a decrease in functional phagocytosis of apoptotic cells. Intriguingly, results from the chronic injury model showed that the absence of myeloid-ST2 resulted in exacerbated injury and fibrosis and a significant reduction in the immunoregulatory cells and cytokines.

Conclusions: The data suggest that ST2 signaling in macrophages is essential not only for the regulation of inflammation early on after injury but is also critical for immune-mediated resolution of injury in later stages.

Curcumin Protects Lipopolysaccharide (LPS)-Induced AKI in Cirrhotic Mice

Graham T. Gipson, Todd W. Gehr, Shobha Ghosh, Siddhartha S. Ghosh. *Virginia Commonwealth University Medical Center, Richmond, VA.*

Background: Cirrhotic patients frequently develop AKI in a variety of settings one of which is spontaneous bacterial peritonitis (SBP). Alteration in intestinal permeability associated with cirrhosis leads to leakage of inflammatory materials from the gut to circulation, aggravating AKI. Using our published model of AKI with cirrhosis and LPS injection mimicking SBP we show that curcumin improves hepatic and renal function by ameliorating alteration in intestinal permeability.

Methods: 12 weeks biweekly oral gavage (1ml/kg) of carbon tetrachloride (CCl4) in mice induced cirrhosis. AKI was precipitated by injecting 2 mg/kg IP LPS one day before culling. The dose of LPS, chosen after careful titration, precipitated AKI only in cirrhotic mice. Animals were divided into four groups control (CO), CCl4, CCl4+LPS (CCl4+L), CCl4+LPS+Curcumin (CCl4+L+CU). CCl4+L+CU received 100 mg/kg CU for 12 weeks. FITC-dextran was administered a day before culling orally and blood levels assessed to determine intestinal permeability. Blood, urine, liver, and kidney were harvested to measure various parameters.

Results: BUN and creatinine of CCl4 and CCl4+L were significantly higher than CO however, a significant decrease of urinary sodium (50±8%, $p<0.01$) and urine output (70±9%; $p<0.01$) was seen only in the CCl4+L group. Liver injury markers SGOT and SGPT were significantly high in CCl4 and were even higher in CCl4+L. CU treatment (CCl4+L+CU) significantly improved all the liver and renal functions. Inflammasome markers NFkB, caspase 1, and IL-1β in the liver and kidney of CCl4 were significantly higher than the control which was further augmented in the CCl4+L group. There was a significantly increased absorption of FITC-dextran and decreased expression of tight junction proteins ZO 1 and claudin in the jejunum and ileum of CCl4 and CCl4+L cohorts suggesting increased intestinal barrier permeability. Curcumin treated, CCl4+L+CU group had decreased expression of inflammasome markers, decreased absorption of FITC-dextran, and increased expression of intestinal tight junction proteins.

Conclusions: Although curcumin has a significant anti-inflammatory property its systemic anti-inflammatory effect is limited by its poor bioavailability. We posit that curcumin by mitigating intestinal permeability reduces inflammatory burden in the circulation which helps in preserving liver and kidney function.

PO0383

Identification of Hub Genes and Pathways of Ischemia-Reperfusion Injury and AKI by a Bioinformatics Method

Ruilian You, Zhige Heyang, Yixin Ma, Hua Zheng, Jianfeng Lin, Peili Ji, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China*.

Background: Ischemia/reperfusion injury (IRI) is the most common cause of acute kidney injury (AKI). However, mechanisms underlying the rapid loss in kidney function and tissue injury are not fully elucidated. We aimed to explore the potential crucial genes and pathways involved in the pathogenesis of IRI/AKI by the bioinformatics method.

Methods: We extracted two gene expression profiles (GSE87024 and GSE34351) from the GEO database of wild-type mice and the early onset of the IRI-AKI. Differentially expressed genes (DEGs) were identified from the two expression profiles, enriched with its gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways of the DEGs. Then we applied Gene set enrichment analysis (GSEA) methods to detect the potential crucial gene sets, the string network to identify PPI, and Cytoscape with plug-ins to find the hub genes and modules. We also used the robust rank aggregation (RRA) to the combined DEGs of the two datasets and analyzed the target genes for miRNA/TF, drug-gene interaction networks to find the potential therapeutic targets.

Results: We extracted a total of 239 and 384 DEGs in GSE87024 and GSE34351 separately, with the 73 same DEGs. GO and KEGG enrichment analysis of the DEGs and GSEA revealed that the significant pathways involve MAPK signaling pathway, IL-17 signaling pathway, and TNF signaling pathway. RRA analysis detected a total of 27 common DEGs. We identified JUN, ATF3, FOS, EGR1, HMOX1, DDIT3, JUNB, NFKBIZ, PPP1R15A, CXCL1, ATF4, and HSPA1B as hub genes. A total of 23 miRNAs interacted with the target genes and interact with curcumin, staurosporine, and deferoxamine by the drug-gene interaction networks analysis.

Conclusions: Our study focused on the early IRI-AKI by firstly adopted RRA analysis to combine DEGs in different datasets, identified hub genes and pathways. We further detected the potential therapeutic targets of the IRI-AKI such as curcumin and staurosporine.

PO0384

Resident Macrophages Limit IL-6 generation to Protect Against Septic AKI

Jamie Privratsky,[1] Jiafa Ren,[1] Hélène Fradin,[1] Xiaohan Lu,[1] Benjamin T. Morris,[1] Tomokazu Souma,[1] Steven D. Crowley.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]Durham VA Medical Center, Durham, NC.*

Background: The most common cause of acute kidney injury (AKI) in critically ill patients is sepsis. There are currently no treatments for septic AKI. Intra-renal macrophages include both tissue-resident ($CD11b^{mid}$, $F480^{hi}$) and infiltrating ($CD11b^{hi}$, $F480^{lo}$) populations. The role of resident and infiltrative macrophages in septic AKI pathogenesis remains unclear. As resident macrophages are reported to contribute to tissue repair following injury, we hypothesized that selective depletion of resident macrophages would worsen septic AKI.

Methods: Resident macrophages were selectively depleted via diphtheria toxin injection in *CD11cCre(+)/CX3CR1$^{dtr/wt}$* (RM KO mice) compared to *CD11cCre(-)/CX3CR1$^{dtr/wt}$* (RM WT) mice. RM WT and RM KO mice were subjected to sham or cecal ligation and puncture (CLP) sepsis. Kidney injury was assessed by serum creatinine and histologic injury scoring. Cytokine mRNA and protein levels in the serum and kidney were measured by RT-PCR and ELISA. Fluorescent cell-sorting and single cell RNA sequencing were used to profile gene expression following CLP in various intra-renal cell lineages.

Results: After CLP, resident macrophages expressed high levels of anti-inflammatory genes including interleukin 1 receptor antagonist (IL1rn), known to suppress IL6 generation. Compared to RM WT mice, RM KO mice displayed worsened septic AKI at 24 hours as measured by serum creatinine (0.17 +/- 0.08 vs 0.41 +/- 0.17 mg/dl, p<0.001-Fig. 1) and histologic injury (median injury score 0 vs 1, p=0.02). Furthermore, RM KO mice elaborated higher circulating and kidney IL-6 levels. In turn, anti-IL6 therapy ameliorated septic AKI in RM KO mice (Fig. 1).

Conclusions: Resident macrophages protect against septic AKI by limiting IL6 generation. Production of anti-inflammatory IL1rn by resident macrophages may limit tissue damage by constraining IL-6 generation in the septic kidney.

Untargeted Lipidomics Reveals the Potential Mechanism of Ferroptosis in HK-2 Cells Treated with Iohexol

Fangfang Zhou, Lianxin Luo, Yixin Chen, Yi Lu, Qun Luo. *HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China, Ningbo, China.*

Background: The purpose of this study was to explore significantly different lipid markers that may be involved in the potential mechanism of ferroptosis in CIN.

Methods: Lipids were extracted from HK-2 cells (HK2-NC group), HK-2 cells treated with 100mg I/ml iohexol for 6 hours (HK2-I6 group) and HK-2 cells co-treated with iohexol and Ferrostatin-1(a potent and selective inhibitor of ferroptosis, Fer-1) (HK2-I6+FeI group) according to MTBE method. An Untargeted Relative uantitative lipidomics based on ultra-high performance liquid chromatography-Orbitrap mass spectrometry was used, combined with the lipids Search software (Thermo Scientific).

Results: In our study, the Principal Component Analysis(PCA) and orthogonal partial least squares analysis(OPLS-DA) models were performed to explore the difference in lipid metabolites between the four groups. Both the PCA score plot and the OPLS-DA model revealed lipid differences, with a clear separation of metabolites between the HK2-I6 and HK2-NC groups, HK2-I6+FeI and HK2-I6 groups. The heat map result showed 132 lipid variations of HK2-I6 group compared to the HK2-NC group, and 170 lipid variations of HK2-I6+FeI group compared to the HK2-I6 group. Among the varied lipid species (HK2-I6 group vs. HK2-NC group), 35 out of 42 PC, 8 out of 10 PS, two out of three SM, and all the 6 LPC increased with statistical significance, while 38 out 39 TG, 16 out of 17 PE, and all the 9 Cer, 2 CerG2, 1 GM, 1 LPI, 2 PG decreased significantly. Among the varied lipid species (HK2-I6+FeI group vs. HK2-I6 group), 35 out of 36 PE, 19 out of 36 PC, 3 out of 5 PS, and all the 50 TG, 15 SM, 5 PI, 5 PG, 6 Cer, 2 CerG1, 2 CerG2, 2 CerG3, 2 LPE increased with statistical significance. According to multivariate statistical analysis, PC(20:3/22:6), LPC(18:0), and PC(44:10), etc. were clearly increased in HK2-I6 group, while these lipid species were significantly decreased after Fer-1 treatment. Cer(d18:1/18:0), Cer(d18:2/24:1), and TG(18:0/18:1/22:2), etc. were clearly decreased in HK2-I6 group, while these lipid species were significantly increased after Fer-1 treatment.

Conclusions: This study revealed that increased PC, decreased PE and TG may involved in the potential mechanism of ferroptosis in the HK-2 cells treated with iohexol.

PO0386

CRISPR-Induced Knockout of Ubiquitin Ligase Cullin 3 in Human Proximal Tubule Cells

Turgay Saritas,[1] Lu Chen,[1] Susanne Ziegler,[1] Nazanin Kabgani,[1] Christoph Kuppe,[1] Jürgen Floege,[1] James A. McCormick,[2] Rafael Kramann.[1] *[1]University Hospital RWTH Aachen, Aachen, Germany; [2]Oregon Health & Science University School of Medicine, Portland, OR.*

Background: We have shown earlier that kidney-specific deletion of Cullin 3 (Cul3) causes proximal tubule injury and fibrosis, but the mechanism is still unclear. Cul3 is essential for the ubiquitination and thus degradation of many critical proteins in several organs. This study aims to generate a Cul3-deficient human proximal tubule cell line using the CRISPR-Cas9 system. This model will allow us to understand the mechanistic role of Cul3 in the human proximal tubule.

Methods: $CD10^+$ proximal tubule cells were isolated by cell sorting from healthy human kidney cortex of a nephrectomy specimen. The primary proximal tubule cells were cultivated and then immortalized using SV40LT and HTERT. Using different CRISPR/Cas9 approaches, Cul3 knockout clones were aimed to achieve. The most successful approach is depicted in the results section.

Results: The Cul3-specific guide RNA was cloned into pL-CRISPR.EFS.GFP using BsmBI restriction digestion. Lentiviral particles were produced by transient co-transfection of HEK293T cells with lentiviral transfer plasmid, packaging plasmid psPAX2 and VSVG packaging plasmid pMD2. G using TransIT-LT. Viral supernatants were collected 48–72 h after transfection, clarified by centrifugation, supplemented with 10% FCS and polybrene and sterile filtered. Cell transduction was performed by incubating the $CD10^+$ cells with viral supernatants. eGFP-expressing cells were single-cell sorted into 96-well plates. Expanded colonies were assessed for mutations with mismatch detection assay: gDNA spanning the CRISPR target site was PCR amplified and analyzed by T7EI digest. To determine specific mutation events on both alleles within the clones grown, the PCR product was subcloned into the pCR 4Blunt-TOPO vector. Minimum 6 colonies per CRISPR-clone were grown and sent for sanger sequencing. Results from qPCR and western blot confirmed Cul3 knockout. The clones were sent out for bulk RNA sequencing to reveal differentially regulated genes upon Cul3 deletion.

Conclusions: Cul3 is a major upstream player in different cell signaling pathways. This study will show the role of Cul3 in the proximal tubule of human kidney.

Role of Megalin and Sex in AKI-CKD Transition due to Cardiorenal Syndrome Type 1

Yoshio Funahashi,[1,2] Jessica F. Hebert,[1,2] Kevin G. Burfeind,[1,2] Adam C. Munhall,[1,2] Megan N. Nickerson,[1,2] Tahnee Groat,[1,2] Michael Hutchens.[1,2] *[1]Oregon Health & Science University, Portland, OR; [2]VA Medical Center Portland, Portland, OR.*

Background: Cardiorenal syndrome type 1 (CRS-1) is acute kidney injury (AKI) due to rapid worsening of cardiac function. The megalin-mediated endocytic system is an important component of renal function which may influence AKI and which likely influences development of chronic kidney injury (CKD). As part of investigating AKI-CKD transition after CRS-1, we tested whether megalin deletion affects the severity of CRS-1 and consequential CKD.

Methods: Male and female proximal tubule-specific inducible megalin deletion mice (iMegKO, LRP2 fl/fl NDRG1-CreERT2) received tamoxifen (150 mg/kg) for 5 days, 16 days before cardiac arrest and cardiopulmonary resuscitation (CA/CPR). 24 hours after CA/CPR, glomerular filtration rate (GFR), cystatin c, KIM-1 were measured and urine proteins were characterized. Immunofluorescence and immunoblotting were performed to quantify acute and chronic renal injury, fibrosis, and megalin expression.

Results: Tamoxifen only induced deletion of megalin in cre+ mice. Urine protein and urine albumin were increased by proximal tubule-specific megalin deletion, primarily low-molecular weight proteins. Specific megalin ligands including RBP-4 were elevated in the urine. At baseline, GFR of iMegKO mice was higher than control mice (p<0.001 by student's t-test, n=11-12/group). CA/CPR variables, including time to resuscitation and epinephrine dose were not different between groups (p>0.05 by one-way Anova, n=9-13/group). Body weight-corrected urine volume at 24 hours after CA/CPR or 49 days after CA/CPR were not different between iMegKO mice and cre- littermate control mice, both in male and female groups (p>0.05 by one-way Anova; for 24h analysis, n=5-9/group, for 49day analysis, n=2-3/group). GFR at 24 hours and 49 days after CA/CPR was not different in iMegKO mice compared with littermate control mice (p>0.05 by one-way Anova; for 24h analysis, n=5-6/group, for 49day analysis, n=2/group). In female, iMegKO didn't mediate GFR at 24 hours or 49 days after CA/CPR (p>0.05 by one-way Anova; for 24h analysis, n=2-3/group, for 49day analysis, n=3/group).

Conclusions: iMegKO causes low molecular weight proteinuria, of specific megalin ligands. GFR of iMegKO and control is different at baseline, but not different by 24h or 49days after CA/CPR in male and female.

Spatially Resolved Transcriptomics Reveal Temporal Dynamics of Gene Expression Changes in a Model of Female AKI

Eryn E. Dixon, Haojia Wu, Parker C. Wilson, Yoshiharu Muto, Benjamin D. Humphreys. *Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Preclinical studies of acute kidney injury (AKI) have focused on male rodents leaving a substantial gap in our understanding of AKI in females. Single cell transcriptomic studies are remarkably powerful, but the loss of positional information with tissue dissociation handicaps our interpretation. Therefore, we applied the 10X Genomics spatial transcriptomic solution, Visium, to investigate interactions between cell types in their physiological orientation during injury.

Methods: We performed bilateral ischemia reperfusion injury (Bi-IRI) on female C57BL/6J mice. Kidneys were collected at acute and late injury timepoints. The efficacy of IRI cross-clamp was validated by transdermal GFR measurements using FITC-sinistrin. Sequencing libraries were created from flash frozen kidney tissues, sequenced by NovaSeq, and integrated with corresponding images using SpaceRanger.

Results: New analytic pipelines SPOTlight and Giotto, enriched with gene expression data from our previously published single cell RNA transcriptomic atlas of mouse injury, significantly enhanced the visualization and resolution of spatial data in our female Bi-IRI model. Spatial libraries detected 16,856 unique genes across all injury timepoints. Integration with scRNAseq increased resolution of specific underrepresented cell types, such as macrophages, T cells, and fibroblasts. Key visualization tools demonstrated changes in the temporal and spatial expression of differentiation markers, including Krt20 and Vim, after injury. Spatial interaction analyses of macrophages and T cell related genes, such as Lyn and Tmem30b, revealed dynamic cell type interaction changes in addition to specific interactions with a proinflammatory and pro-fibrotic proximal tubule injury-induced cell state. We prioritized cell-cell interactions based on physical proximity and validated these results by immunofluorescence. We curated an online data visualization tool to provide broad access of this dataset to the community.

Conclusions: We present the first comprehensive spatial transcriptomic atlas for a female mouse model of AKI along a time course after ischemic injury. We leveraged this spatial transcriptomic dataset to investigate cell type interaction changes, revealing previously unknown cellular dynamics of macrophages and T cells in the proximal tubule.

Single-Cell Sequencing of Immune Cells in AKI and Renal Fibrosis

Bnar Talabani, Chia-Ter Chao, Donald Fraser, Philip R. Taylor. Myeloid Cell Biology Group ; Welsh Kidney Research Unit *Cardiff University School of Medicine, Cardiff, United Kingdom.*

Background: Immune responses help determine outcome following acute kidney injury (AKI) and Chronic Kidney Disease (CKD) progression. Single Cell RNA Sequencing (scRNAseq) provides an unparalleled opportunity to uncover heterogeneity and provide new mechanistic understanding in AKI-CKD. We have performed scRNAseq of immune cells at specific timepoints mimicking human disease pathology in models of AKI and renal fibrosis.

Methods: Kidneys were harvested from three mice at each time point (*Figure 1*) mimicking disease states in AKI/CKD. Using a cell sorting strategy, CD45+ cells were isolated from whole kidneys and libraries were prepared on the 10X Genomics platform. ScRNASeq was performed using the Illumina NextSeq 550 System. We conducted Genome mapping using Cellranger and zUMIs and downstream expression analysis was carried out using R and Seurat.

Results: 21,734 CD45+ve Cells were sequenced in total. Analysis of gene expression profiles delineated transcriptomic profiles in distinct sub-clusters of immune cells across disease states. Comparison of these demonstrated dynamic changes in immune cell compositions, recruitment and patterns of gene expression, in line with an immune response, to AKI, recovery and fibrosis. Heterogenous clustes of macrophages were seen in disease states, revealing an inverse pattern of gene expression when comparing AKI-recovery and AKI-fibrosis.

Conclusions: ScRNASeq has enabled unbiased profiling of gene expression in disease states important in AKI-CKD. We have identified a novel mechanistic target which we are currently pursuing in knock-out gene experiments that impact macrophage phenotype, that we hypothesise, impacts recovery. This presents an exciting opportunity to study the mechanism of renal fibrosis following AKI.

Funding: Private Foundation Support

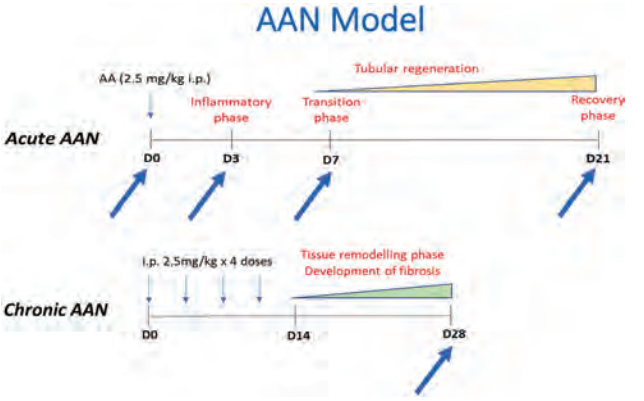

Figure 1: A schematic diagram of aristolochic acid nephropathy (AAN). Acute AAN represents AKI and chronic AAN represents CKD. Blue arrows represent time points at which kidneys were harvested and scRNASeq of CD45+ immune cells performed.

An Improved Protocol for the Isolation and Monoculture of Primary Murine Renal Peritubular Endothelial Cells to Enhance Long-Term Phenotypic Retention

Austin D. Thompson,[1,2] Jaroslav Janda,[1,2] Rick G. Schnellmann.[1,2] Rick G. Schnellmann's Lab [1]*The University of Arizona College of Pharmacy, Tucson, AZ;* [2]*The University of Arizona BIO5 Institute, Tucson, AZ.*

Background: Acute kidney injury (AKI) is often followed by a persistent reduction in mitochondrial function, microvasculature (MV) dysfunction/rarefication, and tubular injury/necrosis. While the functional restoration of the renal MV is crucial, the mechanisms by which MV angiogenesis improves renal recovery remain understudied. Unfortunately, primary cultures of renal microvascular endothelial cells (RMEC) exhibit variability in purity and outgrowth, and undergo phenotypic losses in monocultures. Thus, we focused on refining the isolation and phenotypic retention of monocultured mouse renal peritubular endothelial cells (MRPEC).

Methods: MRPEC were initially isolated using the method of Zhao et al (2014). MRPEC were then subjected to a second round of CD146+ magnetic bead purification. Twice purified MRPEC (TP-MRPEC) were seeded in cloning cylinders within 35mm culture dishes precoated with fibronectin or gelatin, and incubated overnight at 37°C with 5% CO2 in ScienceCell™ EC media. Cloning cylinders were removed the next day, and media was changed every 24h. After 48h, cells were placed onto a circular rotor in a 37°C incubator. After 10 days, purity and phenotype were assessed by flow cytometry analysis using a CD146-PE+ antibody (Biolegend™) and confirmed by immunofluorescent (IF) staining of endothelial markers VE-Cadherin and CD31.

Results: Brightfield micrographs revealed that TP-MRPEC seeded in cloning cylinders increased seeding density, promoted faster outgrowth, and preserved MRPEC morphology. MRPEC seeded onto fibronectin exhibited faster outgrowth; however, MRPEC seeded onto gelatin reduced morphological variability. MRPEC placed onto a circular rotor set to ~45rpm enhanced endothelial cell polarization and paracrine signaling. Flow cytometry analysis revealed that standard MRPEC had an average PE+ purity of ~76% compared to the IgG isotype and unstained controls. Conversely, TP-MRPEC average purity was ~93% (N=5, T(x)=829.09). Immunofluorescence staining confirmed high levels of CD-31 and VE-Cadherin 10 days after isolation (EVOS-M500).

Conclusions: In conclusion, we have developed a modified MRPEC isolation and cell monoculture protocol that enhances the uniformity, purity, and long-term phenotypic retention of primary MRPEC monocultures.

PO0391

Modeling Kidney Injury and Repair in Kidney Organoids Reveals an Intrinsic Repair Mechanism

Navin R. Gupta,[1,2] Takuya Matsumoto,[2] Ken Hiratsuka,[1,2] Pierre Galichon,[3] Tomoya Miyoshi,[3] Koichiro Susa,[3] Narihito Tatsumoto,[4] Michifumi Yamashita,[4] Ryuji Morizane.[1,2] [1]*Massachusetts General Hospital, Boston, MA;* [2]*Harvard Medical School, Boston, MA;* [3]*Brigham and Women's Hospital, Boston, MA;* [4]*Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Kidneys have the capacity for intrinsic repair, preserving kidney architecture with return to a basal state following tubular injury. When injury is overwhelming or repetitive, that capacity is exceeded and incomplete repair results in scar tissue replacing normal kidney parenchyma. Loss of nephrons correlates with reduced kidney function, which defines chronic kidney disease (CKD) and confers significant morbidity and mortality to the worldwide population. Despite the identification of pathways involved in intrinsic repair, limited treatments for CKD exist, in part due to the limited throughput and predictivity of animal studies.

Methods: hPSC-derived kidney organoids were subject to repeated cisplatin injury twice weekly from differentiation days 49 to 63. Samples were harvested following each injury for immunostaining and qPCR to determine transition from intrinsic to incomplete repair. Single nuclear sequencing (snRNAseq) of pooled samples of control, intrinsic repair, and incomplete repair were compared to similar data sets of mouse UUO and IRI, and human rejecting kidney transplant. Transcriptomic results were validated with fibrotic human kidney biopsy samples by immunostaining. Targeted drug screening was conducted in kidney organoids to promote intrinsic repair for the identification of novel therapeutic candidates.

Results: snRNA-seq from kidney organoids identified 159 differentially expressed genes and 29 altered signal pathways during intrinsic repair. Tubular atrophy and the induction of scar-forming myofibroblasts correlates with reduced expression of homology-directed repair genes in injured tubular cells, a finding supported by single cellular transcriptomics in models of obstructive, hemodynamic, and immune-mediated kidney injury, as well as biopsy samples of patients with fibrotic kidney disease. We identified FANCD2/RAD51-mediated repair as a critical determinant governing the transition between intrinsic and incomplete repair and identified a novel therapeutic target for the prevention of CKD onset and progression following AKI.

Conclusions: Our findings demonstrate the utility of kidney organoids in determining novel pathologic pathways, conducting mechanistic studies of human kidney disease and identifying druggable targets through translational studies.

Acetylcholine Receptor Agonist Reduces Acute Lung Injury After Renal Ischemia-Reperfusion Injury by Acting on Splenic Macrophages

Daiki Goto, Soichiro Nagata, Yoshitaka Naito, Takamasa Iwakura, Shinsuke Isobe, Tomoyuki Fujikura, Naro Ohashi, Akihiko Kato, Hideo Yasuda. First Department of Medicine *Hamamatsu Ika Daigaku, Hamamatsu, Japan*.

Background: Acute kidney injury (AKI) has been reported to contribute to development of acute lung injury (ALI) via proinflammatory response. Although the inflammation caused by AKI directly might affect the lungs, this inflammation has been exacerbated by splenectomy. Macrophages with α7 nicotinic acetylcholine receptor(α7nAChR), which play a central role in the cholinergic anti-inflammatory pathway (CAP), are abundant in the lung and spleen. We hypothesized that CAP could reduce ALI after AKI. The objectives of this study were to determine 1) whether AChR agonist could reduce ALI after AKI, and 2) which macrophages in the lung or spleen, could contribute to the improvement of ALI by AChR agonist.

Methods: AKI was induced in C57BL/6 male mice by unilateral ischemia-reperfusion injury (IRI) with contralateral nephrectomy. The α7nAChR selective agonist, GTS-21 was administered in three experimental settings: 1) splenectomy, 2) splenic macrophage deletion via intravenous administration of clodronate liposomes, 3) alveolar macrophage deletion via intratracheal administration of clodronate liposomes. The lung neutrophil infiltration and evans blue dye (EBD) leakage were assessed as lung injuries.

Results: GTS-21 significantly reduced lung neutrophil infiltration (23.04±3.30 vs 11.69±2.38/HPF, p<0.0001) and EBD vascular leakage (13.54±5.32 vs 8.04±3.25μg/g lung tissue, p<0.01) after renal IRI. In splenectomized mice, GTS-21 did not reduce lung injuries after renal IRI. (neutrophil infiltration: 46.39±16.65 vs 37.54±12.91/HPF, p=ns, EBD vascular leakage: 23.30±8.88 vs 22.18±10.41μg/g lung tissue p=ns). In mice depleted of splenic macrophages, GTS-21 did not reduced lung injuries after renal IRI(neutrophile infiltration: 37.03±10.54 vs 34.36±11.61/HPF, p=ns, EBD vascular leakage: 34.78±20.55 vs 49.92±39.83μg/g lung tissue, p=ns). In mice depleted of alveolar macrophages, GTS-21 significantly reduced lung injuries after IRI (neutrophil infiltration: 21.00±7.52 vs 12.93±3.64/HPF, p<0.05, EBD vascular leakage: 13.86±4.59 vs 9.74±2.25μg/g lung tissue, p<0.05).

Conclusions: AChR agonist reduces acute lung injury after renal IRI by acting on splenic macrophages.

PO0393

Macrophage Heterogeneity in Progression and Regression Phages of Cisplatin-Induced AKI Mice Model: A Single-Cell RNA Sequencing Study

Shensen Li, Bingquan Deng, Qingqing Liu, Haiyan Shen, Wenwen Li, Changchun Cao. *Sir Run Run Hospital Nanjing Medical University, Nanjing, China*.

Background: Immune cells, especially innate immune cells, play an important role in the pathogenesis of AKI. However heterogeneous of macrophage (M) and its dynamic change during progression and regression of cisplatin induced AKI (cis-AKI) remain uncertain.

Methods: 8-week-old male C57BL/6 mice were randomly divided into sham, cis3d and cis7d groups (Fig.1A). Single-cell analysis were conducted based on 10×Chromium platform. Differentially expressed genes were analysed.

Results: 36 cell clusters were identified and integrated into 11 cell types according to cell-specific markers in murine kidneys (Fig.1B). 4 clusters were identified as macrophage (Fig.1C). Cluster 4 ($Cx3cr1^+$M) was defined as embryonic derived renal resident macrophage (EMRM) for its high expression of F4/80, Cd74, Cx3cr1 (Fig.1D). Cluster 15 ($Itgam^+$M) was defined as recruit M due to its high expression of Itgam (Fig.1D). Cluster 26 ($Cd74^+$M) was defined as bone marrow derived resident macrophage according to its high expression of Cd74 (Fig.1D). Cluster 30 ($Cx3cr1^+Mki67^+$M) was the proliferation subset of EMRM (Fig.1D). The proportion of $Itgam^+$MΦ was increased in the injury stage, and restored in repair stage (Fig.1E). Resident-M ($Cx3cr1^+$M, $Cd74^+$M and $Cx3cr1^+Mki67^+$M) slightly decreased in injury period and recovered in the repair period (Fig.1E). KEGG analysis showed $Itgam^+$M mainly enriched in apoptosis and damage-related pathway, while $Cx3cr1^+$M and $Cd74^+$ enriched in phagocytosis and antigen presentation pathway (Fig.1F).

Conclusions: A total of 4 clusters were classified as M, while recruit-M and resident-M shown opposite dynamic trends in the injury and repair stages. KEGG analysis demonstrated that recruit-M may dominant injury phage while resident-M contribute to regression phages in cis-AKI.

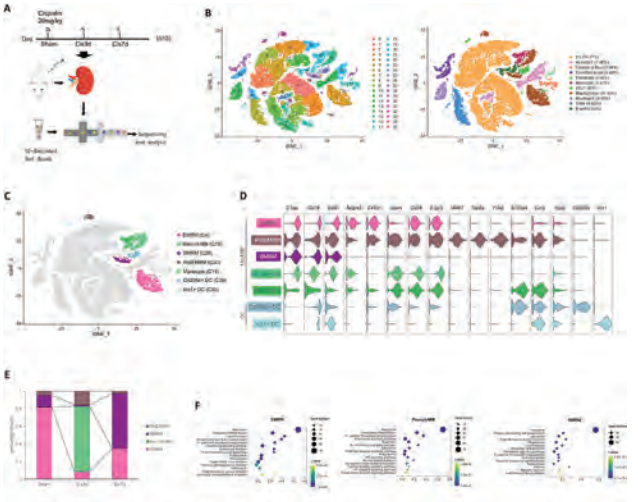

Figure 1. (A) Schematic diagram of current single-cell RNA sequencing study. 8-week-old male C57BL/6 mice underwent 20mg/kg cisplatin intraperitoneal injection and were harvest 3 days later (cis3d) or 7 days later (cid7d). Sham group underwent same amount of saline intraperitoneal injection and harvest 3 days later. (B) scRNA-seq analysis identifies discrete renal cell types in AKI and sham operated mice. tSNE plots of cell cluster(left) and cell types(right) of 36,735 cells from libraries pooled from mice of sham (n=3), cis3d (n=2) and cis7d (n=3) groups were shown. (C) tSNE plot of pooled myeloid cells annotated by cell type. (D) Violin plots showing the expression levels of selected marker genes in each cluster. (E) Relative proportions of each cells clusters of mono-macrophage at each time point. (F) KEGG pathway analysis showing the top 15 riched pathways of DEGs in EMRM (left), recruit-M? (middle), BMRM (right). T Cell Metabolic Reprogramming and Effect of Glutamine Blockade in Ischemic AKI

Kyungho Lee, Elizabeth A. Thompson, Chirag H. Patel, Sepideh Gharaie, Johanna T. Kurzhagen, Sanjeev Noel, Phillip M. Pierorazio, Barbara S. Slusher, Hamid Rabb. *Johns Hopkins University, Baltimore, MD*.

Background: T cells play an important role in the pathogenesis of AKI. Metabolic programming of T cells regulates T cell function, is a rapidly emerging field, and has not been studied in detail during AKI. We aimed to elucidate dynamics of T cell metabolism as well as the effect of blocking glutaminolysis on ischemic AKI.

Methods: We induced ischemic AKI with 30 min ischemia followed by reperfusion in C57B6 mice and harvested kidneys and spleens at multiple early time points including during ischemia. Human nonischemic and ischemic kidney tissue was obtained from nephrectomy cases. T cells were isolated and analyzed by a flow cytometry-based immune-metabolic assay with interrogating metabolic programs. The data was evaluated by computational multidimensional analyses with machine learning. The glutamine antagonist JHU083, which targets T cell metabolism, was injected intraperitoneally and effects on AKI were evaluated.

Results: Unbiased high-dimensional analyses identified a distinct T cell subset with reduced expression of mitochondrial VDAC1 and phospho-S6 ribosomal protein (pS6) in postischemic kidneys. H3K27Me3 expression, regulated by TCA cycle, drove the segregation of ischemic kidney T cells from those of nonischemic kidneys in both humans and mice. Splenic T cells from post-AKI mice showed higher expression of GLUT1, hexokinase II (HKII), and CPT1α, indicating upregulation of glycolysis and fatty acid oxidation. Blocking glutamine uptake by JHU083 treatment attenuated renal injury at 24h (plasma creatinine 1.7±0.8 vs 1.0±0.5 mg/dL, *P*=.03) and enhanced expression of pS6 (normalized MFI 0.38±0.07 vs 0.47±0.06, *P*<.01) and HKII (0.31±0.04 vs 0.41±0.05, *P*<.01), compared to vehicle-treated mice. Activation and proliferation were reduced in CD4 (CD44, 67±5 vs 56±6%, *P*<.01; Ki67, 59±9 vs 51±6%, *P*=.03) and CD8 T cells (CD44, 61±11 vs 41±11%, *P*<.01; CD69, 25±7 vs 18±4%, *P*=.02; Ki67, 61±13 vs 48±12%, *P*=.04) but increased in double-negative T cells (CD44, 94±2 vs 96±1%, *P*=.04; CD69, 61±8 vs 72±7%, *P*<.01; Ki67, 79±9% vs 91±3%, *P*<.01) from post-AKI kidneys of the JHU083-treated group.

Conclusions: T cells undergo distinct metabolic reprogramming during ischemic AKI. Reconstitution of metabolism by targeting the T cell glutamine pathway could be a promising therapeutic approach for AKI.

IRF8-Dependent Type I Conventional Dendritic Cells (cDC1s) Control Post-Ischemic Inflammation and Mildly Protect Against Post-Ischemic AKI and Disease

Li Na,[1,2] Stefanie Steiger,[2] Chenyu Li,[2] Chongxu Shi,[2] Zhihua Zheng,[1] Hans J. Anders.[2] *[1]The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China; [2]Klinikum der Universitat Munchen, Munchen, Germany*.

Background: Post-ischemic acute kidney injury and disease (AKI/AKD) involve acute tubular necrosis and irreversible nephron loss. Mononuclear phagocytes including conventional dendritic cells (cDCs) are present during different phases of injury and repair, but the functional contribution of this subset remains controversial. Transcription factor interferon regulatory factor 8 (IRF8) is required for the development of type I conventional dendritic cells (cDC1s) lineage and helps to define distinct cDC1 subsets.

Methods: Unilateral ischemia reperfusion injury (IRI) was induced in mice by 25 mins' kidney pedicle clamping. Organ harvest was taken from healthy state, day 1 (IRI-1D) and day 7 (IRI-7D) after IRI. Time point D0 represents healthy state.

Results: We identified one distinct subset among mononuclear phagocyte subsets according to the expression patterns of CD11b and CD11c in healthy kidney and lymphoid organs, of which IRF8 was significantly expressed in the $CD11b^{low}CD11c^{high}$ subset that mainly comprised cDC1s. Next, we applied a *Irf8*-deficient mouse line (*Irf8*$^{fl/fl}$*Clec9a*^{cre} mice) to specifically target *Clec9a*-expressing cDC1s *in vivo*. During post-ischemic AKI/AKD, these mice lacked cDC1s in the kidney without affecting cDC2s. The absence of cDC1s mildly aggravated the loss of living primary tubule and decline of kidney function, which was associated with decreased anti-inflammatory Tregs-related immune responses, but increased T helper type 1 (T_{H1})-related and pro-inflammatory cytokines, infiltrating neutrophils and acute tubular cell death, while we also observed a reduced number of cytotoxic $CD8^+$ T cells in the kidney when cDC1s were absent.

Conclusions: Together, our data show that IRF8 is indispensable for kidney cDC1s. Kidney cDC1s mildly protect against post-ischemic AKI/AKD, probably via suppressing tissue inflammation and damage, which implies an immunoregulatory role for cDC1s.

PO0396

Myeloid Heparin-Binding Epidermal Growth Factor-Like Growth Factor (HB-EGF) Protects Against Ischemic AKI

Shirong Cao, Yu Pan, Aolei Niu, Yinqiu Wang, Ming-Zhi Zhang, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN*.

Background: Epidermal growth factor receptor (EGFR) activation plays an important role to mediate recovery of epithelial integrity following ischemic acute kidney injury (AKI) and subsequent development of interstitial fibrosis when recovery is incomplete. EGFR can be activated by a family of ligands. The ligand responsible for EGFR activation after AKI has not been previously identified. In response to various stimuli, EGFR can be transactivated by its ligand, HB-EGF. The present study examined the potential role of myeloid HB-EGF in recovery from ischemic AKI and subsequent development of fibrosis.

Methods: Wild type (WT, HB-EGF$^{f/f}$) or LysM-Cre; HB-EGF$^{f/f}$ (myeloid HB-EGF$^{-/-}$) mice (male, 8 weeks old, C57BL/J background) were uninephrectomized, immediately followed by unilateral ischemia-reperfusion with renal pedicle clamping for 31.5 min. Mice were sacrificed at different time points after ischemic AKI. Renal myeloid cells were isolated with a mixture of CD11b and CD11c microbeads.

Results: Compared to WT mice, LysM-Cre; HB-EGF$^{f/f}$ mice had delayed functional recovery after ischemic AKI. At 28 days after AKI, myeloid HB-EGF-/- mice had more severe persistent kidney damage, indicated by higher KIM-1 mRNA and protein levels. Myeloid HB-EGF-/- mice also had more renal immune cell infiltration, including macrophages, neutrophils, and lymphocytes. The myeloid HB-EGF-/- mice exhibited more renal fibrosis, as indicated by quantitative Sirius red and Masson's Trichrome staining and increased mRNA and protein levels of profibrotic and fibrotic components including α-SMA, collagen I, collagen IV, IL-11, fibronectin, and PDGFRβ. The myeloid HB-EGF-/- mice also had increased renal ER stress as indicated by increased CHOP. In renal myeloid cells from WT mice, HB-EGF mRNA levels were increased by 10 fold at 2 h after ischemic AKI. Immunofluorescent staining demonstrated increased HB-EGF expression in myeloid cells and increased phosphor-EGFR in the proximal tubule epithelial cells.

Conclusions: Early HB-EGF upregulation in myeloid cells in response to ischemic injury may promote functional and structural recovery after ischemic AKI, possibly due to stimulation of epithelial cell proliferation via EGFR activation.

circBNC2 Inhibits Renal Fibrosis Through Regulating G2/M Cell Cycle Transition

Peng Wang. *Division of Nephrology, Nanfang Hospital, Southern Medical University, State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Guangzhou, China*.

Background: Emerging evidence indicates that AKI is a causative factor for subsequent development of chronic kidney disease (CKD). G2/M cell cycle arrest of TECs promotes AKI to CKD progression, but the regulation of G2/M cell cycle arrest of TECs is largely unclear. Circular RNAs (circRNAs), a class of noncoding RNA, are recently found to be dysregulated in tubular epithelial cells (TECs) during renal ischemia/reperfusion (I/R) injury. However, the effects and underlying mechanisms of circRNAs in the progression of renal fibrosis are largely unrevealed.

Methods: Mild-AKI (20 min- IRI) and severe-AKI (40 min-IRI) were performed in C57BL/6 mice. The expression of circRNA were analyzed in the freshly isolated tubules from these mice by RNA-seq. One of the dysregulated circRNA, circBNC2 were identified and analyzed by Northern blot, FISH and real-time qPCR in HK2 cells, mouse primary TECs and in mouse kidney. HK-2 cells were exposed to hypoxia as *in vitro* model. To study the function of circBNC2, we used the CRISPR-Cas9 genome editing system to specifically knocked out circBNC2 in HK2, while circBNC2 was overexpression by plasmid. To study the function of circBNC2 *in vivo*, we applied adeno-associated virus (AAV)-based circBNC2 overexpression in C57BL/6 mice 3 weeks before performing IRI model. G2/M cell cycle arrest and pro-fibrotic cytokine expression were evaluated in HK2 and primary TECs. Renal fibrosis was evaluated in mouse kidney sections.

Results: The un-biased sequencing showed significant down-regulation of circBNC2 in TECs from severe-IRI mice, as compared to the TECs from mild-IRI mice and control mice. Knockout circBNC2 in HK2 and primary TECs led to G2/M cell cycle arrest and pro-fibrotic cytokines expression. While overexpression of circBNC2 decreased hypoxia-induced G2/M cell cycle arrest of TECs. Preventative overexpression of circBNC2 *in vivo* ameliorated 40 min-IRI induced renal fibrosis.

Conclusions: Our results showed that circBNC2 regulated G2/M cell cycle transition of TECs and might be served as a therapeutic target for AKI-progressed CKD.

PO0398

Ischemia Reperfusion Activation of Kidney HDAC1 Results in Interstitial Fibrosis

Kelly A. Hyndman, Luciano D. Mendoza, Ariana S. Ramos, Kaitlyn Aldaz. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL*.

Background: Following a kidney ischemic event the chromatin remodeling enzyme, histone deacetylase-1 (HDAC1), is activated in many cell types of the kidney including fibroblasts/pericytes. Pharmacological inhibition of HDACs can attenuate ischemia-reperfusion-injury (IRI) mediated interstitial fibrosis. In this study, we tested the hypothesis that fibroblast/pericyte HDAC1 activation promotes interstitial fibrosis.

Methods: Tamoxifen inducible, fibroblast/pericyte HDAC1 knockout (KO) mice (HDAC1$^{Fl/Fl}$; Col1a2-CreEr) and littermate controls (HDAC1$^{Fl/Fl}$) were used. Male and female mice (8-10 wks of age) were given tamoxifen i.p. and IRI or sham surgery was performed after a 2-week tamoxifen washout period. A mild, 18 min, bilateral, warm IRI model was used and samples collected over 4 weeks. Additional groups of mice underwent unilateral ureteral obstruction (UUO) for 48 h. In vitro experiments with kidney fibroblast cells (NRK49F) overexpressing HDAC1 were used for RNA-sequencing studies.

Results: HDAC1 KO was confirmed in myofibroblast cells by co-immunolocalization of HDAC1 and platelet-derived growth factor receptor beta or a-smooth muscle actin (α-sma) in the kidneys of IRI mice. 24 h post ischemia there was a tripling of plasma creatinine (PCr) in all IRI mice, regardless of sex or genotype. 2- and 4-weeks after IRI, PCr were similar to sham values for all mice. However, the male control IRI mice had significant interstitial fibrosis but this was attenuated in the KO male IRI mice. The female mice, regardless of genotype, had very mild kidney damage and interstitial fibrosis at 4 weeks. The UUO male KO mice had reduced α-sma abundance compared to control male mice. Transcriptomes of NRK49F cells overexpressing HDAC1 had 15 genes upregulated (0.1% of the genes sequenced) and 64 genes downregulated (0.5%). Upregulated genes included *C3, Bmp6, Cxcl12, and Fzd1*. Downregulated genes included *Ccl4, Ifnb1*. Gene Ontology analysis determined significant enrichment in the regulation of Wnt signaling and innate immune response activating signal transduction.

Conclusions: For male mice, fibroblast/pericyte HDAC1 activation leads to pro-fibrotic programming of the myofibroblast and interstitial fibrosis. Future studies will determine the specific epigenetic pathways that may be significantly changed by HDAC1 activation leading to maladaptive interstitial fibrosis.

PO0399

Endothelial and Not Proximal Tubule Epithelial Pannexin 1 Plays a Critical Role in Fibrosis Progression After AKI

Nabin Poudel, William Nash, Nataliya Skrypnyk, Shuqiu Zheng, Eibhlin Goggins, Mark D. Okusa. *University of Virginia School of Medicine, Charlottesville, VA*.

Background: Activation of pannexin-1 (Panx1) channels during acute kidney injury (AKI) and Panx1-mediated release of tissue messengers facilitates the recruitment and activation of immune cells to the site of injury. Lack of *Panx1* in the proximal tubules (PT) or in the endothelial cells (EC) significantly reduces AKI. Metabolites released from Panx1 affect a number of biological processes that regulate inflammation and cellular metabolism. Thus, we investigated the role of PT or EC Panx1 during AKI to chronic kidney disease (AKI-CKD) transition by inducing deletion of Panx1 from PT or EC before or after an established AKI.

Methods: AKI was induced by unilateral ischemia-reperfusion injury (IRI), folic acid, or bilateral IRI. Cell-type specific deletion of Panx1 was achieved by injecting tamoxifen before or after AKI to Panx1 floxed (*Panx1*$^{fl/fl}$) animals expressing either PT (*SLC34a1*^{GCE}) (provided by B. Humphreys, Washington University) or EC (*Cdh5*^{CreER}) specific inducible Cre-recombinase to generate either PT (*SLC34a1*^{GCE}*Panx1*$^{-/-}$) or EC

(*Cdh5^{CreER}Panx1$^{-/-}$*) specific Panx1 knockout animals. Kidneys were analyzed for extent of fibrosis by measuring mRNA expression of fibrotic markers and Masson's trichrome staining and for immune cell infiltration by flow cytometry.

Results: Deletion of Panx1 before AKI globally, in PT, or in EC attenuated renal fibrosis. Deletion of *Panx1* after AKI did not alter the extent of fibrosis in *SLC34a1^{GCE}Panx1$^{-/-}$* animals compared to *SLC34a1$^{+/+}$Panx$^{fl/fl}$* controls that received tamoxifen, however, deletion of *Panx1* after AKI significantly increased fibrosis in *Cdh5^{CreER}Panx1$^{-/-}$*compared to *Cdh5^{CreER}Panx1$^{fl/fl}$* controls. Tamoxifen itself did not alter the extent of fibrosis. Flow cytometry revealed robust immune cells recruitment including neutrophils, macrophages, dendritic cells, and T-cells in injured kidneys post-AKI. While there was no significant difference in other immune cell proportions at day 3 and day 7 post AKI, *Cdh5^{CreER}Panx1$^{-/-}$* animals had a significantly higher CD103-positive dendritic cell population at day 10 post AKI.

Conclusions: Our data show that while Panx1 from PT or EC play crucial role during AKI, Panx1 from EC is vital for limiting extent of fibrosis during AKI-CKD potentially by releasing metabolites that regulate immune cell function and fibrosis/repair.

Apoptotic Exosome-Like Vesicles Aggravate Inflammation and Renal Injury After Ischemia-Reperfusion

Imane Kaci,[1,2] Shanshan Lan,[1,2] Hyunyun Kim,[1,2] Annie Karakeussian Rimbaud,[2] Francis Migneault,[2] Julie Turgeon,[2] Natalie Patey,[3,1] Mélanie Dieudé,[2,1] Marie-Josee Hebert.[2,1] *[1]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [2]Centre Hospitalier de l'Universite de Montreal Centre de Recherche, Montreal, QC, Canada; [3]Centre Hospitalier Universitaire Sainte-Justine Centre de Recherche, Montreal, QC, Canada*.

Background: Ischemia-reperfusion injury (IRI) is a common cause of acute kidney injury (AKI) and chronic kidney disease (CKD). Mounting evidence suggests that damage to microvascular peritubular capillaries (PTC) is a critical determinant of CKD transition after IRI. We previously identified anti-LG3/perlecan autoantibodies in patients with CKD, as a negative prognostic factor for long-term renal function after AKI. We also showed that a new class of extracellular vesicles produced by apoptotic endothelial cells (ApoExo), characterized by the LG3 autoantigen, active 20S proteasome and a specific pattern of immunogenic RNAs, can prompt the production of anti-LG3. Here, we test the hypothesis that ApoExo drive renal inflammation after renal IRI leading to anti-LG3 production, defective microvascular repair and loss of renal function.

Methods: ApoExo were purified by sequential ultracentrifugation from serum-free media conditioned by apoptotic murine endothelial cells. Renal IRI in mice was performed with renal artery clamping for 30 minutes and contralateral nephrectomy. ApoExo were injected twice every other day before IRI and thereafter up to eight injections, and end-points were assessed at day 21 post-IRI. Interstitial inflammation was assessed with immunohistochemistry for CD3 and IL-17A. PTC rarefaction, complement activation and myofibroblasts accumulation were monitored by immunohistochemistry for MECA-32, C4d and α-SMA. Circulating anti-LG3 levels were measured by ELISA.

Results: ApoExo injection enhanced tubular damage and interstitial inflammation with increased CD3$^+$ lymphocytes infiltration and IL-17A staining (p=0.004 and p=0.002, respectively). PTC rarefaction, C4d deposition and interstitial accumulation of α-SMA$^+$ cells were also increased in ApoExo treated mice (p=0.01, p=0.009 and p=0.04, respectively) as were anti-LG3, which correlated strongly and positively with PTC-C4d deposition and myofibroblasts accumulation (r=0.86, p=0.007 and r=0.75, p=0.03, respectively).

Conclusions: Collectively, these results identify ApoExo as novel regulators of inflammation after renal IRI, driving anti-LG3 formation, complement activation and fibrosis. These results suggest that autoimmune pathways triggered by ApoExo can contribute to microvascular rarefaction and renal fibrosis.

The Brain-Gut-Kidney Axis in the Development of Cognitive Dysfunction Following AKI

Young Eun Choi, Jihyun Yang, Ko Yoon Sook, Lee Hee Young, Yina Fang, Sewon Oh, Myung-Gyu Kim, Won-Yong Cho, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Republic of Korea*.

Background: Although epidemiological studies suggest that long-term survivors of dialysis requiring AKI show increased prevalence of dementia, its underlying mechanisms remain uncertain. Based on recent data showing kidney-gut crosstalk mediated by immune modulation in acute kidney injury (AKI), we hypothesized that gut dysbiosis and aberrant gut immune response might contribute to the cognitive dysfunction following AKI.

Methods: Thirty min ischemia/reperfusion injury (IRI) was performed in C57/BL6 mice, cognitive dysfunction, histological damage including blood-brain barrier (BBB) disruption and inflammation, gut microbiome and immune cell activation were determined at 6 months after IRI.

Results: Glomerular filtration rate showed complete recovery of renal function at 6 months after IRI. However, in the open field behavior test, IRI mice traveled shorter distance and walked more slowly compared to sham, suggesting the development of cognitive dysfunction long after kidney IRI. Evans blue dye extravasation showed disrupted BBB and the number of microglial cells, amyloid-beta deposits increased in the brain in IRI mice. Principal coordinate analysis of gut microbiome in IRI was clearly distinguished from that of sham. Despite no difference in alpha-diversity, relative increase of abundance of bacterial families of Saccahrimonas, Erysipelotrichaceae, Bacteroidaceae, Lactobacillaceae while decrease of Lachnospiraceae and Prevotellaceae were the hallmark of dysbiosis. Flow cytometry of gut immune cells showed a significantly increased percentage of IL-17A+CD4+ cells in small intestine, whereas percent CD25+CD4+ Tregs decreased significantly in colon, showing the gut immunity moving toward inflammation long after AKI.

Conclusions: This is the first animal study that showed the development of structural brain injury and cognitive dysfunction long after AKI. Given that the important role of dysbiosis in various neurologic diseases, presence of dysbiosis and gut inflammation at 6months after IRI might contribute to the development of long-term neurologic sequelae of AKI. Targeting the gut might be a novel therapeutic target for prevention of long-term adverse outcomes in AKI patients.

PO0402

Probiotics Supplementation Protects the Transition from AKI to CKD in Aged Mice via the Kidney-Gut Axis

Myung-Gyu Kim, Yina Fang, Ko Yoon Sook, Lee Hee Young, Jihyun Yang, Sewon Oh, Sang-Kyung Jo, Won-Yong Cho. *Korea University Anam Hospital, Seoul, Republic of Korea*.

Background: Several epidemiological studies have reported that acute kidney injury (AKI) is more frequent in the elderly and they often progress to chronic kidney disease (CKD). Chronic inflammation has recently been reported as an important mechanism mediating CKD progression after AKI in the elderly. This study investigated how kidney and intestinal crosstalk is involved in exacerbation of inflammation in AKI and whether microbial targeted therapy could modulate the transition from AKI to CKD in aged mice.

Methods: In young and aged C57BL/6 mice, 25min bilateral ischemia reperfusion injury (IRI) was applied, and then colon inflammation, histological changes and intestinal barrier integrity were compared for 28 days post-IRI. To determine the role of the microbiome on kidney-gut crosstalk, we analyzed microbiome from feces in young and aged mice and examined the effects of probiotics supplementation.

Results: M1 predominant inflammation was observed in the kidneys of aged mice compared to young mice for 28 days after IRI. Interestingly, this intrarenal inflammatory milieu in aged mice was similarly observed in the colon on day3 post IRI. The increased inflammatory cytokines in the colon were accompanied by an increase in TUNEL-positive apoptotic colon epithelial cells, resulting in increased intestinal permeability in aged mice for 28 days. The AKI-induced "leaky gut" also showed a strong positive correlation with high TNF-α expression in mesenteric lymph nodes. Microbiome analysis revealed changes in Lactobacillus and Bifidobacterium in aged mice at the genus level. To clarify the role of the microbiota, probiotics were administered for 2 months during the AKI recovery period. We observed that administration of Bifidobacterium (B. longum + B. bifidum) altered intestinal Th17/Treg balance and improved kidney inflammation, but not intestinal leakage. They finally resulted in improvements in GFR and kidney fibrosis, suggesting that kidney-gut crosstalk in aged mice makes an important contribution to AKI to CKD transition.

Conclusions: Our study suggests that exacerbation of chronic inflammation through the kidney-gut axis is an important mediating mechanism of the transition from AKI to CKD in the elderly. Therefore, strategies to modulate the microbiota are considered promising to improve outcomes in elderly AKI.

The Proteomic Landscape of Liver After AKI

Yuan Gui,[1] Yanbao Yu,[2] Dong Zhou.[1] *[1]University of Connecticut School of Medicine, Farmington, CT; [2]University of Delaware, Newark, DE*.

Background: Acute kidney injury (AKI) was traditionally viewed as an 'innocent bystander' in various critical illnesses that reflected disease severity in the clinic. Emerging evidence suggests that AKI is an independent protagonist that may cause acute diseases in other organs such as the liver. Thus far, the mechanisms of hepatic dysfunction in patients with AKI have not been well described. We have previously characterized the kidney proteome changes after septic AKI. Here, we further described the proteomic landscape of the liver and assessed the reno-hepatic communications after septic AKI.

Methods: Cecal ligation and puncture procedure was employed to construct the sepsis-induced AKI model. A high-resolution accurate mass-based quantitative proteomics approach was applied.

Results: After septic AKI, alanine aminotransferase (ALT) levels were markedly induced in serum at day 2, while it then dropped, approaching the baseline at day 7, reflecting the process of liver damage and repair. PAS staining exhibited a consistent trend in liver morphological changes. To understand the molecular mechanisms in AKI-caused liver injury, we examined the global proteome and phosphoproteome of the liver on day 2 and day 7 after AKI using a recently developed ultrafast and economic filter-based sample processing approach. We collectively quantified a total of 1,673 proteins and 1,219 phosphosites in the liver. The principal component analyses indicated that the liver's completely distinct protein expression patterns between day 2 and day 7 after AKI. The network analyses revealed that oxidation-reduction and metabolic processes are the top changed pathways in liver injury and repair. In the meantime, we identified a wide range of differential proteins in the liver after AKI, including Cyp7b1, cyp1a2, Hemopexin, Acss2, Orm1, Steap 4, and Haptoglobin. These proteins were further validated by western blot and immunostaining. Of particular interest, Steap4, a member of the six transmembrane epithelial antigen of the prostate, was significantly upregulated in the liver but not in the kidney upon septic AKI, suggesting a tissue-specific inflammatory response.

Conclusions: Our results implied that describing the liver's proteomic landscape after AKI would help understand reno-hepatic crosstalk, and Steap4 may serve as a potential candidate to monitor AKI-caused liver injury in the clinic.

PO0404

COX-2-EP4-MafB Axis Protects Against Renal Fibrosis in Mice with Renal Ischemic Injury

Yu Pan,[1,2] Shirong Cao,[1] Juan Pablo Arroyo Ornelas,[1] Andrew S. Terker,[1] Yinqiu Wang,[1] Aolei Niu,[1] Suwan Wang,[1] Xiaofeng Fan,[1] Raymond C. Harris,[1] Ming-Zhi Zhang.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Shanghai Jiao Tong University, Shanghai, China.*

Background: The mammalian kidney is easily injured by ischemic or toxic insults but can often recover functional and structural integrity. Innate immunity is involved in both the injury and recovery processes, and its maladaptive response causes delayed recovery and development of kidney fibrosis. Cyclooxygenase 2 (COX-2) plays an essential role in antiinflammatory and tissue-reparative M2 polarization of macrophages, the major renal myeloid cells. Renal macrophage COX-2 increases after ischemic acute kidney injury (AKI). The current study investigated the role of renal macrophage COX-2 in ischemic AKI and subsequent development of fibrosis.

Methods: We developed myeloid COX-2-/- mice (CD11b-Cre; COX-2$^{f/f}$), myeloid EP4-/- mice (CD11b-Cre; EP4$^{f/f}$), and myeloid MafB-/- mice (LysM-Cre; MafB-/-). The animals were uninephrectomized, immediately followed by unilateral ischemia-reperfusion with renal pedicle clamping for 32 min.

Results: Following ischemic AKI, COX-2 was selectively increased in renal macrophages as indicated by colocalization with CD68, and myeloid COX-2-/- mice exhibited delayed renal recovery and increased tubulointerstitial fibrosis, in association with augmented proinflammatory cytokines in isolated renal macrophages. In bone marrow derived monocytes, PGE2 is the major COX-2-mediated arachidonic acid metabolites and acts primarily via EP4 receptors. Myeloid EP4-/- mice mimicked the effects seen with myeloid COX-2-/- mice in response to ischemic AKI. We found that myeloid EP4 activation induced expression of MafB, a master transcription factor, to upregulate antiinflammatory genes and suppress proinflammatory genes in macrophages. Selective myeloid MafB deletion recapitulated the effects seen with myeloid COX-2 or EP4 deletion, with delayed recovery and increased kidney fibrosis. Mice with myeloid deletion of COX-2, EP4, or MafB had similar impairment of renal macrophage efferocytosis.

Conclusions: These studies show that COX-2/EP4-dependent MafB expression mediates renal macrophage antiinflammatory and pro-resolving polarization and identify a previously unknown mechanism by which myeloid COX-2 inhibition exacerbates acute and chronic kidney injury, a finding that is relevant to understanding detrimental effects of NSAIDs in the setting of renal dysfunction.

Subcutaneous Adipose Stromal Cell-Derived Secretome Improves Renal Function and Inflammation in Established AKI

Md Mahbub Ullah,[1] Jason A. Collett,[1] Dmitry Traktuev,[2] Michael E. Coleman,[3] David P. Basile.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Florida, Gainesville, FL; [3]Theratome Bio, Inc, Indianapolis, IN, IN.*

Background: Previous studies demonstrated that human adipose derived stromal cells (ASC) attenuated the development of acute kidney injury (AKI) and preserved vascular density, when administered in the suprarenal aorta immediately following ischemia reperfusion (IRI). Recently, stem cell derived secretome, has received attention for the potential treatment of renal disease. We hypothesized that cell-free, concentrated fraction of ASC-derived secretome would improve renal function in a well-established rat model of AKI.

Methods: Male Sprague Dawley rats underwent bilateral IRI-40 min to induce AKI. 24 hours later, renal function was evaluated (serum creatinine; SCre) and rats were randomized into vehicle or secretome-treated groups. Rats received subcutaneous (SQ) injection either secretome (2 mg/kg in 1 ml) or saline (1 ml) on day 1 and day 3 post IRI. After 5 days of IRI, kidneys were collected for further analysis.

Results: At 24 h post IRI, SCre levels were 3.3±0.2 mg/dl in vehicle treated rats and 3.1±0.1 mg/dl in secretome treated rats (P=0.31). SCre level significantly (P=0.03) decreased in secretome treated ratscompared to the vehicle treated rats across 5 days study period. After 24 h administration of first secretome injection, there was a significant reduction of SCre level (27.8%, P>0.001) in secretome treated rats compared to their baseline. There was a significant increase of infiltration of dendritic/macrophage cells following IRI which was significantly reduced in secretome group (IRI; 1.2 X10^6 vs. secretome; 5.0 X10^5 cells/g kidney; p<0.05). Additionally, there was a significant reduction of TH-17 cells (CD4+IL-17+) following secretome treatment compared to vehicle group (secretome: 2.0 X10^4 vs. IRI: 4.6 X10^4 cells/g kidney; p<0.05). Kidney tissue stained with periodic acid-Schiff reagent shown secretome treatment improved the degree of tubular damage following IRI.

Conclusions: These data indicate that SQ injection of secretome following established AKI hastens recovery of renal function and reduces infiltration of renal inflammatory cells. Thus, secretome might represent a useful option to treat AKI.

The Role of Disrupted Iron Metabolism in AKI: Targeting Iron Trafficking via the Hepcidin-Ferroportin Axis in Renal Proximal Tubules

Abdul A. Soofi,[1] Jeffrey A. Beamish,[1] Greg R. Dressler,[1] Mawieh Hamad.[2] *[1]University of Michigan, Ann Arbor, MI; [2]University of Sharjah, Sharjah, United Arab Emirates.*

Background: Acute Kidney injury (AKI) and iron-related disorders remain major clinical challenges associated with significant morbidity and mortality. Ferroportin (FPN) is an iron exporter, identified as a modulator of iron balance. Hepcidin binds to FPN, causing its internalization and degradation. Though FPN and Hepcidin are expressed in proximal tubule cells (PTCs) of the mouse kidney, their role in the pathogenesis of AKI is unclear. Through this work, we hope to determine if modulation of iron homeostasis by selective depletion of hepcidin or FPN in PTCs alters the response to AKI.

Methods: We generated PTCs-specific Hepcidin1 and Ferroportin (FPN) knockout (KO) by selectively expressing Cre in PTCs and confirmation with a red-green reporter (mT/mG; Pepck-cre) allele. We subjected these mice to either the Folic Acid induced injury model or the ischemia-reperfusion injury models of AKI. Serum samples were collected at 2, 7, 14, 21, and 28 days after injury and BUN, creatinine, iron, and ferritin level were measured. Kidney tissues were collected at each time point for histology, iron deposition, immunohistochemistry, RNA isolation, and immunoblot analysis.

Results: Conditional KO mice were generated and deletion of Hepcidin1 and FPN specifically in PTCs was confirmed at the DNA and protein levels. Mutant young adult mice showed no gross morphology phenotype. However, both mutant strains developed pronounced iron deposition in PTCs measured with DAB-enhanced Perls stain for iron which further increased following injury. After AKI, mutant mice failed to recover and regenerate damaged tubules leading worsening interstitial fibrosis, necrosis, and ferroptosis compared with wild type mice of the same genetic background. Markers of fibrosis, ferroptosis, and levels of ferritin will be quantified in serum and kidney tissue.

Conclusions: Our preliminary data indicate that disrupting iron trafficking in PTCs by manipulating the expression of FPN and hepcidin increases AKI severity and impairs recovery. These findings may offer new insights into the role of iron metabolism in AKI and illuminate new therapeutic strategies for progressive kidney disease and other syndromes of iron overload.

PO0407

Noncanonical Wnt5a/CD146 Signaling Drives Renal Fibrosis by Activating Transcriptional Factor Snail in AKI

Xiaomei Li, Jiejun Wen, Junjie Jia, Qunzi Zhang, Ting Zhou, Ying Fan, Niansong Wang. *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Acute kidney injury (AKI) with severe and persistent kidney cell injury will more likely progress to permanent damage, progressive fibrosis and chronic kidney disease (CKD). However, the exact cellular and molecular mechanisms mediating the progression of AKI to CKD remain incompletely understood. We recently reported that Wnt5a promotes renal tubular inflammation in diabetic nephropathy by binding to CD146 through noncanonical Wnt signaling. Snail, which expressed in the precursors of the renal epithelial cells, can induce partial epithelial-to-mesenchymal transition and drive renal fibrosis in mice. Here, we investigated whether modulation of Wnt5a expression during AKI would contribute to the progression to CKD.

Methods: To examine whether Wnt5a mediated CD146/JNK pathway was involved in AKI, we determined the expression of Wnt5a and CD146 in the kidneys of AKI patients. Wnt5a knockdown mice underwent either unilateral ureteral obstruction (UUO) or ischemia reperfusion injury (IRI) was established to assess whether the loss of Wnt5a attenuated renal injury. *In vitro*, HK-2 proximal tubule cells were subjected to oxygen glucose deprivation (OGD) to mimic the ischemia-reperfusion injury. More over, HK-2 cells were transfected a wnt5a small interfering RNA (siRNA) to reduce the expression of Wnt5a to further confirm the role of Wnt5a/CD146 signaling in the kidney injury.

Results: Increased expression of Wnt5a and CD146 were found in the kidney sections of patients with AKI, which was associated with the severity of kidney injury and the progression to CKD. In an Wnt5a-knockdown mouse model subjected to UUO or IRI, Wnt5a ablation significantly ameliorated kidney cell injury and renal fibrosis development. Mechanistically, Wnt5a promoted the phosphorylation of JNK and the activation of snail in UUO and IRI models. Silencing Wnt5a with small interfering RNA (siRNA) attenuated the activation Wnt5a/CD146 signaling and the expression of snail in HK-2 cells with oxygen glucose deprivation (OGD).

Conclusions: Together, our data suggest that noncanonical Wnt5a/CD146 signaling may be an important determinant in the severity of AKI. Through the activation of snail, it drives the renal fibrosis and promotes the progression to CKD.

Funding: Government Support - Non-U.S.

PO0408

Hyperactivation of CDK5 Promotes Proximal Tubule Cell Dedifferentiation and Interstitial Fibrosis in CKD

Kensei Taguchi, Bertha C. Elias, Craig R. Brooks. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) effects ~15% of the world's population. Recently, we demonstrated that Cyclin G1 (CG1) regulates proximal tubule cells (PTCs) G2/M arrest and promotes fibrosis. CG1 is known to act through Cyclin dependent kinase 5 (CDK5), which regulates cell cycle exit and homeostasis in differentiated cells. Under

normal conditions, CDK5 activity is kept in check by p35; however, during cellular stress p35 is cleaved to p25, leading to hyperactivation of CDK5, a leading driver of many neurodegenerative diseases. The aim of the current study is to determine if CG1 induced hyperactivation of CDK5 plays a pathological role in PTCs dedifferentiation and profibrotic signaling.

Methods: A novel CDK5/p25 inhibitor, Glixx, was utilized to inhibit hyperactivation of CDK5. Protocol 1; Aristolochic acid nephropathy (AAN) and low-dose cisplatin model were conducted as AKI-to-CKD model by repeated doses of AA and cisplatin in 8 to 12-week-old male wild-type (WT) and CG1 globally knockout mice (CG1KO). Protocol 2; To investigate the effect of CDK5 hyperactivation, unilateral ureter obstruction (UUO) was conducted with administration of Glixx. Protocol 3; CDK5 was overexpressed in cultured PTCs. Protocol 4; Primary PTCs of WT and CG1KO mice were co-incubated with AA in the presence or absence of Glixx or roscovitine, a selective CDK inhibitor.

Results: AAN and low-dose cisplatin induce phosphorylation and activation of CDK5 in wild-type but not CG1KO kidneys. Expression and cleavage of p35 to p25 is also reduced in CG1KO PTCs compared to wild-type. Inhibition of CDK5 or CDK5/p25 interaction (hyperactivation) prevents dedifferentiation and profibrotic cytokine secretion in AA treated primary PTCs. Overexpression of either CG1 or CDK5 induces upregulation of dedifferentiation and profibrotic markers, which can be reversed through inhibition of CDK5. In vivo, inhibition of CDK5/p25 binding reduces fibrosis and prevents PTC dedifferentiation following UUO.

Conclusions: CG1 expression induces hyperactivation of CDK5 in PTCs. Inhibition of CDK5 or CDK5/p25 binding prevent CG1 induced dedifferentiation, profibrotic cytokine secretion and fibrosis. Targeting the CG1/CDK5 pathway is a potential therapeutic target for inhibiting AKI-to-CKD transition.

PO0409

Clearance of Chronic Senescent Tubular Cells by ABT263 After Ischemic AKI Halts the Progression of Established Fibrosis and Restores Tubular Regeneration

Man J. Livingston, Zheng Dong. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: Emerging studies from aging models demonstrate that increased senescent cell load causes kidney dysfunction and removal of senescent cells by senotherapeutics may rejuvenate aged kidneys for renoprotection. Senescent cells also accumulate in the kidney during maladaptive repair after AKI. However, the pathological role of cellular senescence in post-injury kidney and the therapeutic significance of targeting senescence to treat fibrosis during AKI to CKD transition remain less understood.

Methods: To induce post-ischemic kidney fibrosis, 10 to 12-week-old C57/BL6 mice underwent 30-minute unilateral or 22-minute bilateral renal ischemia followed by reperfusion for 2 weeks. The mice were then treated with either vehicle or ABT263 at 50 mg/kg/day, daily i.p. injection, 5 days/week for 2 weeks. One week after the completion of ABT263 treatment, the morphology and function of the fibrotic kidneys were examined.

Results: Following ischemic AKI, senescent cells accumulated in renal tubules, as indicated by upregulation of p16 and SASP factors, increased tubular staining of SA-β-gal, and induction of γ-H2AX nuclear foci. This injury-induced tubular senescent phenotype was accompanied by persistent interstitial fibrosis. Compared with vehicle treatment, ABT263 significantly eliminated senescent tubular cells and partially suppressed the progression of post-ischemic kidney fibrosis. Along with fibrosis resolution, ABT263 also reduced the infiltration of macrophages in interstitial tissues and attenuated the chronic expression of KIM-1 in injured proximal tubules, therefore creating a pro-regenerative environment for tubular repair. As a result, the number of Ki67-positive tubular cells was promoted and tubular expression of LTL was restored to some extent as well, indicating increased tubular proliferation and redifferentiation. Consistent with the morphological findings, renal function, as assessed by BUN, serum creatinine and eGFR, was also improved in mice treated with ABT-263.

Conclusions: These results support the pathological role of tubular injury-induced accumulation of senescent cells in fibrotic repair after AKI. Targeting these chronic senescent cells by senolytic drugs may represent a therapeutic strategy to reverse maladaptive tubular repair and to halt AKI to CKD progression.

PO0410

Defects in KIM-1-Mediated Phagocytosis Do Not Predispose to AKI in Humans

Rita Suri,[1] Ji Yun Lee,[2] Matthew Ban,[3] Bradly Shrum,[2] Ola Z. Ismail,[2] Qingyong Xu,[4] Robert A. Hegele,[2,3] Lakshman Gunaratnam.[2,5] *[1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada; [2]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [3]Robarts Research Institute, London, ON, Canada; [4]University of Pittsburgh, Pittsburgh, PA; [5]Lawson Health Research Institute, London, ON, Canada.*

Background: Phagocytosis of dying cells is critical for homeostasis and tissue repair. During renal injury, upregulation of kidney injury molecule-1 (KIM-1) transforms kidney epithelial cells into phagocytes which engulf apoptotic and necrotic cells. A mutation that impairs KIM-1 phagocytic function (mucin domain deletion) resulted in worse kidney dysfunction after ischemia-reperfusion-injury (IRI) in mice, but this has not been studied in humans.

Methods: We expressed three common mucin domain nonsynonymous variants (rs12522248, rs45439103, rs6149307) of the human KIM-1 gene (*HAVCR1*) in human kidney cells. To test if impaired KIM-1-mediated phagocytosis predisposes to kidney dysfunction after IRI, we genotyped 627 consecutive kidney donors and assessed risk of delayed graft function in recipients.

Results: Cells expressing these variants exhibited markedly reduced phagocytosis of apoptotic and necrotic cells, compared to cells expressing *wild type* KIM-1; rs6149307 showed the most severe defects (<5% phagocytosis vs. *wild type*). Surprisingly, the risk of delayed graft function in recipients of donor kidneys homozygous for rs6149307 was not significantly increased compared to recipients of donor kidneys with one or no copies (adjusted relative risk 1.0 [0.7-1.3]). Analysis of rs12522248 and rs45439103 yielded similar resutls.

Conclusions: Contrary to murine models, these results suggest severe defects in KIM-1-mediated phagocytosis do not predispose to acute kidney dysfunction after IRI in humans.

PO0411

Mechanistic Modeling of Kidney-Injury Molecule 1 (KIM-1) as a Biomarker for Cisplatin-Induced AKI

Nader Hamzavi, Yeshitila Gebremichael, Jeffrey L. Woodhead, Sergey Ermakov, Brett A. Howell. *DILIsym Services Inc. A Simulations Plus Company, Research Triangle Park, NC.*

Background: Kidney Injury Molecule 1 (KIM-1) is a specific and sensitive biomarker for drug-induced acute kidney injury (AKI) prediction. Cisplatin-induced injury of the renal proximal tubular epithelial cells (RPTEC) has been characterized using KIM-1 in both *in vivo* and *in vitro* studies. Despite growing interest in clinical use of KIM-1 as a key biomarker for AKI diagnosis, a mechanistic model of KIM-1 that accurately predicts the kinetics of KIM-1 is still lacking. We developed a mechanistic model of KIM-1 as part of a quantitative systems toxicology (QST) model to predict urinary KIM-1 in rats treated with cisplatin.

Methods: We developed a mechanistic model of KIM-1 within the framework of RENAsym, a QST model of drug-induced AKI that incorporates key cellular injury mechanisms and renal hemodynamics. The KIM-1 model represents the early shedding of KIM-1 arising from the loss of brush borders during sub-lethal injury of RPTEC followed by the marked expression of KIM-1 in dedifferentiated cells in regenerating proximal tubules (Ichimura et al. 1998). The model is integrated with the RENAsym to capture RPTEC injury and regeneration following toxic renal injury.

Results: RENAsym was used to simulate the response of urinary KIM-1 in rats treated with cisplatin. The model parameters were fitted to data from rats treated with 2.5 mg/kg cisplatin (Gebremichael et al. 2017). The magnitude and time profile of KIM-1 were captured by the model. The KIM-1 model was also analyzed using data obtained from rats treated with single doses of 1 and 5mg/kg of cisplatin, and it can recapitulate the dose-dependent responses of urinary Kim-1.

Conclusions: Mechanistic model of KIM-1 was developed to quantitatively predicted cisplatin-induced AKI. The model recapitulated the urinary KIM-1 data obtained from rats treated with cisplatin. Human data will be used in the future for model validation.

PO0412

The Role and Mechanism of DcR2-Positive Failed Repair Cells in AKI

Jia Chen, Yani He. *Daping Hospital, Army Medical University, Chongqing, China.*

Background: Acute kidney injury (AKI) is a common clinical emergency and critical illness. The regeneration and repair of renal tubular cells determine the prognosis of AKI. Our previous study found that decoy receptor 2 DcR2, a senescent marker, was specifically expressed renal tubules and did not have the ability to proliferate in AKI, suggesting DcR2 may be associated with repair of tubular cells. This study aims to investigate the role and mechanism of DcR2-positive tubular cells in AKI.

Methods: The DcR2-GFP lineage trace mice, KSP-creDcR2f/f and GGT1-creDcR2f/f mice and Ischemia-Reperfusion (I/R) Injury models were constructed. Confocal analysis the co-expression of DcR-GFP and proximal tubular markers(AQP1, Villin), distal markers (AQP2), failed repair markers (Vcam1, Dcdc2), proliferative markers (Ki-67, Edu, PCNA), Kim1, differentiated markers (pax2, sox9, six2), senescent markers (P16, P21, SA-β-gal) and fibrotic markers (a-SMA, collagen I, Fibronectin). And wild type (WT) mice and DcR2 CKO mice were used to compar the degree of renal tissue, functional damage and tubular repair after I/R injury. Furthermore, quantitative proteomics analyzed the downstream molecules of DcR2 in renal tissues from WT-AKI and CKO-AKI, and validated studied were done.

Results: The DcR2-GFP were mainly expressed proximal tubular cells in AKI. DcR2-GFP positive cells were co-expressed failed repair markers, senescent markers and co-localization with fibrotic markers. And DcR2-GFP positive cells were not expressed Kim1, proliferative and differentiated markers. The levels of Scr, BUN and renal injury scores were significantly lower in GGT1-creDcR2f/f -AKI than that of WT-AKI. Meanwhile, the area of renal fibrosis and fibrotic markers expression was decreased. However, the above phenomenon of KSP-creDcR2f/f–AKI were not obviously improved. Additionally, quantitative proteomics and validated studies showed HMGCS2, a key enzyme for Ketone Synthesis, was increased in GGT1-creDcR2f/f mice compared with WT. And the levels of urinary and serum β-hydroxybutyrate were higher in GGT1-creDcR2f/f mice.

Conclusions: DcR2-positive tubules were failed-repair cells in AKI. And DcR2 promotes failed repair of tubular cells through regulating the expression of HMGCS2 then affects the metabolism of β-hydroxybutyrate, suggesting that DcR2 may be a potential intervention target during the progression of AKI.

Mini-Pulse and Fast-Tapering Corticosteroids in Acute Tubulointerstitial Nephritis Related to Immune Checkpoint Inhibitors: Testing a Treatment Scheme

Raquel B. Rico. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Acute tubulointerstitial nephritis (ATIN) is the most common lesion seen on kidney biopsy related to immune check-point inhibitors (ICI) in oncological patients. Clinical and laboratory features as well as risk factors are well known, albeit non-specific in predicting the underlying renal lesion. Corticosteroid-based therapy has proven to be effective, however, the optimal duration of treatment has not yet been established.

Methods: We conducted a retrospective single-center study to evaluate a treatment scheme with low-dose corticosteroids in patients diagnosed with ICI-related ATIN between 2017-2021. Extrapolating our treatment scheme for acute interstitial nephritis, we administer pulses of methylprednisolone (2 mg/kg/day for 3 consecutive days) followed by prednisone 1mg/kg/day with rapid-tapering until total withdrawal 2 months after treatment onset. The main outcome was to assess renal response during follow-up.

Results: We included a total of 8 patients (87.5% males) with a median age of 66.5 years and diagnosis of metastatic disease in all cases. Three patients had urothelial cancer, two had renal cell carcinoma and lung cancer, and one had hepatocellular carcinoma. Monotherapy as first- or second-line treatment with PDL-1 and PD-1 inhibitors was employed in 62.5 and 37.5% of the cases, respectively. Baseline serum creatinine (SCr) was 1.1 mg/dl(0.82-1.5), three patients had chronic kidney disease and six patients were on treatment with proton pump inhibitors. Acute kidney injury presented 13.5 weeks after starting ICI therapy. The median highest SCr was 3.2 mg/dl(2.5-5) and one patient required acute dialysis. Urinalysis alterations were present in all patients (proteinuria in 50%, hematuria in 75%, and sterile pyuria in 87.5%). Complete renal response was observed in all cases, except for one patient who showed a partial response. ICI rechallenge was not applied to any patient and no ATIN recurrences were documented after corticosteroids discontinuation. Two patients died due to oncologic disease progression. Median follow-up was 12.5 months(2.5-27.5).

Conclusions: Our treatment scheme with fast-tapering corticosteroids was effective for inducing renal response in ICI-related ATIN, without evidence of relapses.

PO0414

Contralateral Nephrectomy Stimulates Proliferation of Renal Epithelial Progenitor Cells After Unilateral Ischemia

Lies Moonen,[1] Elena Lazzeri,[2] Anna J. Peired,[2] Carolina Conte,[2] Paola Romagnani,[2] Patrick D'Haese,[1] Benjamin A. Vervaet.[1] Laboratory of Pathophysiology *[1]Universiteit Antwerpen Laboratorium voor Pathofysiologie, Wilrijk, Belgium; [2]Universita degli Studi di Firenze Dipartimento di Scienze Biomediche Sperimentali e Cliniche Mario Serio, Firenze, Italy.*

Background: Acute kidney injury is a global health concern and important risk factor for the development of chronic kidney disease. Crucial for successful renal recovery after AKI is the proliferation of surviving tubular epithelial cells. We established a murine model in which functional and histological recovery of a kidney, injured by ischemia, is enhanced by removal of the contralateral kidney, i.e. nephrectomy-induced recovery. The epithelial reparative response in this unique model has not been investigated, yet can provide new insights in the inherent regenerative potential of the renal epithelium.

Methods: AKI was induced in two different mice strains by left unilateral ischemia/reperfusion (UIRI) after which either right nephrectomy (Nx) or no Nx was performed on day 3. In $R26R^{tdTomato}$ mice kidney-to-body-weight ratio, renal function (serum creatinine) and fibrosis (Sirius Red histology) were measured at week 6. Additionally, renal tissue of PAX2/Confetti mice was processed to study clonal expansion by lineage pattern analysis of $PAX2^+$ renal epithelial progenitor cells at day 28.

Results: When no Nx was performed after UIRI, a significant decrease in left kidney-to-body weight ratio along with increased fibrosis and functional loss were observed in the injured kidney at week 6 compared to controls. However, when Nx was performed, renal function and mass were preserved. During spontaneous repair after UIRI (i.e. without Nx) clonal analysis in PAX2/Confetti mice revealed a significant increase in clone size frequency from mainly monoclonal $PAX2^+$ progenitor cells in controls to an increased number of multicellular clones. When Nx was performed after UIRI, this clonal expansion was further significantly stimulated. Likewise, the percentage of PAX2+ cells stimulated to divide (i.e. clonogenicity) was significantly higher when Nx was performed after UIRI (42%) as compared to when no Nx was performed (28%).

Conclusions: Nx overcomes loss of renal mass and function after UIRI. This enhanced recovery is at least established by increased clonogenicity and enhanced clonal expansion of renal progenitor cells that surpasses that of spontaneous repair after UIRI. Getting insight in the signaling mechanisms by which nephrectomy achieves this response may open new therapeutic research avenues.

PO0415

Long Noncoding RNA Neat1 Promotes Tubular Epithelial Cells Apoptosis to Facilitate the Progression of AKI to CKD

Tongtong Ma,[1] Peng Wang.[2] *[1]Department of Critical Care Medicine, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Division of Nephrology, Nanfang Hospital, Southern Medical University, State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Guangzhou, China.*

Background: The severity and frequency of acute kidney injury (AKI) determine if the injury leads to chronic kidney disease (CKD). A growing number of research shows that the injury of tubular epithelial cells (TECs) is the driving force during chronic progression of AKI. However, there are limited knowledge about the role of lncRNAs in the progression of AKI.

Methods: To screen out the candidate lncRNA in the progression of AKI to CKD, 8-week old C57BL/6 mice were subjected to mild-AKI (20 min-ischemic reperfusion injury) and severe-AKI (40 min- ischemic reperfusion injury). RNA-sequencing was performed with the isolated tubules from mild- or severe- AKI mouse. The expression of a candidate lncRNA Neat1 was evaluated by FISH, Northern blot and real-time qRT-PCR in HK2 cells and mouse kidney tissues. To study the biological function of Neat1 *in vitro*, CRISPR-Cas9 was used to knock out Neat1, while Neat1 was ectopic overexpressed by lentivirus. HK2 cells were cultured in anoxic environment as the *in vitro* model to study the function of Neat1. RNA pull down was performed to screen out the microRNAs that bound to Neat1. Knocking down Neat1 *in vivo* was performed by injecting Adeno-associated virus serotype 9 (AAV9) particles carrying siRNA targeting Neat1. Flow cytometer was used to calculate the apoptotic cells under each treatment. TUNEL was applied to evaluated the apoptotic TECs in kidney sections.

Results: The expression of Neat1 was upregulated in the tubules from severe AKI mouse, as compared to mild AKI mouse. Knocking out Neat1 inhibited hypoxia-induced HK2 cells apoptosis while overexpression of Neat1 enhanced the apoptosis of HK2 cells *in vitro*. Furthermore, knockdown of Neat1 *in vivo* reduced the apoptosis of TECs and improved the kidney functions of IRI mice.

Conclusions: Our results showed that LncRNA neat1 regulated apoptosis of TECs and might be served as a therapeutic target to ameliorate AKI.

PO0416

Effects of Proton Pump Inhibitors (PPIs) on Renal Vascular Reactivity in Cirrhotic Rats

Chiao-Lin Chuang.[1,2] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

Background: Hepatorenal syndrome is, a lethal complication of cirrhosis, defined as renal hypoperfusion resulting from intense renal vasoconstriction. Vascular dysregulation such as ET-1 and nitric oxide (NO) might be the contributing factor. Proton pump inhibitors (PPIs) are widely used for peptic ulcer. Although generally safe, recent studies reported that PPIs decreased NO production, leading to reduction of arterial relaxation. The prevalence of gastric ulcer in cirrhotic patients is higher than healthy controls. The impact of PPIs on renal vascular responsiveness in cirrhosis is worth to be studied.

Methods: Liver cirrhosis was induced in S-D rats by common bile duct ligation (CBDL). Sham-operated (SHAM) rats were surgical controls. On the 29th day after surgery, in-situ renal perfusion was performed. In acute treatment study, rats were randomized to receive Krebs solution or Esomeprazole (30 mM) incubation for 1h before renal perfusion. In chronic treatment study, rats were randomly received oral distill water or Esomeprazole (3.6 mg/kg/d) for 28 days.

Results: The were no significant changes in renal vascular reactivity to ET-1 after acute (Fig. A) and chronic (Fig. B) PPIs treatment in CBDL rats. Chronic PPIs treatment had no significant effects on systemic hemodynamics and renal function but decreased hemoglobin in both SHAM and CBDL rats (Table).

Conclusions: In conclusion, PPIs showed no renal vascular effects. The mechanisms of lower hemoglobin following PPIs treatment need further analysis.

Table. Hemodynamic and biochemistry data

	SHAM-DW	SHAM-PPIs	CBDL-DW	CBDL-PPIs

Hospitalized AKI Is Associated with Long-Term Increases in TNFR1 and TNFR2: Findings from the CRIC Study

Ian Mccoy,[1] Jesse Y. Hsu,[2] Joseph V. Bonventre,[3] Chirag R. Parikh,[4] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of Pennsylvania, Philadelphia, PA; [3]Brigham and Women's Hospital, Boston, MA; [4]Johns Hopkins University, Baltimore, MD.*

Background: Evaluation of plasma biomarkers before and after AKI may yield valuable insights into the pathogenesis of progressive CKD after AKI. Markers of endothelial inflammation and injury, Tumor Necrosis Factor Receptors 1 and 2 (TNFR1 and TNFR2), are associated with progressive CKD, but it is unknown whether an episode of hospitalized AKI may cause long-term changes in these biomarkers.

Methods: Among participants in the prospective Chronic Renal Insufficient Cohort (CRIC), episodes of hospitalized AKI were identified using acute changes in inpatient serum creatinine values (peak/nadir ≥1.5). For each AKI hospitalization, we found the best matched non-AKI hospitalization (unique patients) using the following pre-hospitalization criteria: estimated glomerular filtration rate (eGFR), urine protein/creatinine ratio, duration between hospital discharge and next CRIC visit (max 1 year), diabetes, age, sex, and duration between hospital admission and prior CRIC visit (max 2 years). We measured plasma levels of TNFR1 and TNFR2 using banked plasma samples collected at CRIC study visits before and after the hospitalization. Biomarkers were measured using a customized U-Plex assay on a MesoScale Device.

Results: Study participants who did and did not have AKI were well matched (**Table**). Pre-hospitalization TNFR1 and TNFR2 levels were also similar. AKI was associated with greater increases in TNFR1 ($p<0.01$) and TNFR2 ($p<0.01$).

Conclusions: Hospitalized AKI was associated with increases in plasma TNFR1 and TNFR2 months after the hospitalization.

Can Urinary Biomarkers at AKI Predict Progression to CKD?

Jennifer R. Charlton,[1] Teng Li,[2,3] Yanzhe Xu,[2,3] Teresa Wu,[2,3] Kimberly Deronde,[1] Kevin M. Bennett.[4] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]Arizona State University, Tempe, AZ; [3]Arizona State University-Mayo Center for Innovative Imaging, Tempe, AZ; [4]Washington University in St Louis, St Louis, MO.*

Background: Acute kidney injury (AKI) can cause permanent structural changes and progressive chronic kidney disease (CKD). If kidney function normalizes after AKI, it is difficult to distinguish who will progress to CKD. We evaluated urinary biomarkers from mice at the time of AKI and correlated them to a range of structural features derived from histopathology and cationic ferritin enhanced-MRI (CFE-MRI) in the kidney later in life. We investigated whether these biomarkers at AKI could predict future progression to CKD.

Methods: Adult male mice were injected with folic acid (AKI) or $NaHCO_3$ (controls), (n=8/grp) and urine was collected after 4 days. Biomarkers were measured using the Cytokine Array Q1000 (Ray BioTech). Mice received CF 12 wks after AKI and kidneys were imaged *ex vivo* using a 7T MRI. Structural metrics were derived by CFE-MRI (N_{glom} and aV_{glom}) and histology (proximal tubule (PT) content, atubular glomeruli (ATG), and scarred area).

Results: We performed a univariate analysis comparing the AKI and controls. Using hierarchical edge bundling, there were 19 connections between the urinary biomarkers and structural metrics at 12 wks and 7 connections in the control group (Fig 1A). EGF, OPG, TARC and TNF RII (correlation>0.8, Fig 1B) were correlated to structural metrics in AKI and only IGFBP-6 was correlated to the structural metrics in controls. We developed predictive models using the 13 urinary markers in Fig 1B. The best model predicted mean aV_{glom} (r^2=0.67), %ATG (r^2=0.50) and PT content (r^2=0.47).

Conclusions: Urinary biomarkers, alone or in combination, may provide noninvasive predictive markers for progression to CKD after AKI. We identified 13 urinary biomarkers that appear to predict structural changes in the kidney 12 weeks after AKI and may serve as candidate biomarkers to predict outcomes in patients.

The Kidney Produces a Non-Polymerizing Form of Uromodulin That Associates with Reduced Risk of AKI

Radmila Micanovic, Kaice A. LaFavers, Kavish R. Patidar, Shehnaz Khan, Tarek M. El-Achkar. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Uromodulin (Tamm-Horsfall protein, THP) is a glycoprotein uniquely produced in the kidney. It is released by cells of the thick ascending limbs (TAL) apically in the urine, and basolaterally in the renal interstitium and systemic circulation. Processing of mature urinary THP, which polymerizes into supra-molecular filaments, requires cleavage of an external hydrophobic patch (EHP) at the C terminus. However, THP in the circulation is not polymerized, and it remains unclear if non-aggregated forms of THP exist natively in the urine. We propose that an alternative processing path, which retains the EHP domain, can lead to a non-polymerizing form of THP.

Methods: We have generated an antibody that specifically recognizes THP with retained EHP (THP+EHP). Liquid chromatography, mass spectrometry and C terminal sequencing were performed to delineate potential sites of enzymatic cleavage of immunoprecipitated THP+EHP. Immunofluorescence confocal microscopy was used to localize this isopform in the human kidney. Finally, we finally developed a customized ELISA to measure THP+EHP and used it on urine and plasma samples from a small cohort of patients hospitalized with liver cirrhosis.

Results: Using native and denaturing Western blots, we established the presence of THP+EHP in the urine in a non-polymerized native state. Proteomic studies confirmed the identity of THP+EHP and suggested that enzymatic cleavage occurred at Arg615, which is one amino acid beyond the GPI anchoring site. In the human kidney, THP+EHP predominantly co-localized with urinary THP in TAL cells, but it was also detected, at lower levels, in other tubular segments. In a cohort of patients with liver disease, admission urinary THP+EHP, but not total THP, was significantly lower in patients who subsequently developed acute kidney injury during hospitalization. THP+EHP was also detected in the plasma, albeit at very low concentrations.

Conclusions: Our findings uncover novel insights into uromodulin biology by establishing the presence of an alternative path for cellular processing. Our proof-of-principle findings in patients warrant further investigations to establish the utility of THP+EHP as a sensitive biomarker of kidney health and susceptibility to injury.

Air Pollution Aggravates Ischemia-Reperfusion-Induced AKI in Mice

Antonio C. Parra,[1] Alessandra Tammaro,[2] Mariana Graner,[1] Lucas Yuji Umesaki Itto,[1] Jesper Kers,[2] Joris Roelofs,[2] Mariana Veras,[1] Camila E. Rodrigues,[1] Sandrine Florquin,[2] Talita R. Sanches,[1] Lucia Andrade.[1] *[1]Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Department of Pathology, Amsterdam UMC, Amesterdam Infection & Immunity Institute, University of Amsterdam, Amsterdam, Netherlands.*

Background: The biggest city in Latin America is São Paulo (SP), where disorganized urbanization has had a negative impact on air quality and vehicle emissions are the main source of fine particulate matter ($PM_{2.5}$). Epidemiological studies have linked $PM_{2.5}$ exposure to an increased risk of CKD. The mechanisms mediating the adverse health effects of $PM_{2.5}$ include epigenetic changes, oxidative stress and inflammation. The role of $PM_{2.5}$ in AKI has yet to be described. We hypothesized that $PM_{2.5}$ exposure would aggravate renal ischemia/reperfusion (I/R) injury in mice.

Methods: In temperature-/humidity-controlled chambers within an ambient particle concentrator, animals were exposed to a concentrated $PM_{2.5}$ stream ($PM_{2.5}$) or to high-efficiency particulate air-filtered clean air (CA). Mass concentrations of PM were measured with an airborne particulate monitor, and the target dose was 600 μg m^{-3}/day (equivalent of the daily exposure in SP). After 12 weeks, some $PM_{2.5}$ and CA mice underwent bilateral 30-min clamping of the kidney hila and subsequent reperfusion. All studies were performed 48 h after I/R. Groups: CA, $PM_{2.5}$, CA+I/R and $PM_{2.5}$+I/R. Data are mean±SEM.

Results: Renal TLR4 protein expression was higher in CA+I/R and $PM_{2.5}$+I/R than in CA and $PM_{2.5}$ (128±2.1 and 146±2.0 vs. 97.5±2.1 and 98.0±0.9%; P<0.05), also being much higher in $PM_{2.5}$+I/R than in CA+I/R (P<0.05). Manganese superoxide dismutase levels were higher in $PM_{2.5}$+I/R than in CA+I/R, AF and $PM_{2.5}$ (146±12 vs. 99±3.6, 102±3.9 and 96±2.8; P<0.05).

Conclusions: $PM_{2.5}$ aggravates I/R-induced AKI by decreasing renal Klotho protein, leading to increased renal TLR4 expression and inflammatory cell infiltration. (FAPESP, NWO)

Proteogenomic Effects of Environmental and Uremic Toxin Acrolein on Mouse Kidneys

Sanjana Rane, Shunying Jin, Susan M. Isaacs, Michelle T. Barati, Michael Merchant, Jianmin Pan, Shesh Rai, Sanjay Srivastava, Madhavi J. Rane. *University of Louisville, Louisville, KY.*

Background: Acrolein is present in the environment, water, food and is a uremic toxin endogenously produced through lipid peroxidation and polyamine oxidation. Its mechanism of action involves cellular thiol reactivity and glutathione depletion-induced oxidative stress. However, direct effects of acrolein on kidneys are not known. The current study conducted RNA-seq and proteomic analysis on mouse kidneys exposed to acrolein.

Methods: C57BL/6 mice were subjected to filtered-air (control) or inhaled-acrolein (1.0 ppm), 6h/day, 5 days/week for 12 weeks. Total-RNA and kidney homogenates from all mice were subjected to RNA-seq and proteomic analysis. Immunoblotting, H&E and Sirius-Red staining of kidneys was performed.

Results: RNA-seq analysis detected activation of profibrotic pathways including TGFb/TGFbR/SMAD3/TEAD4/Autotaxin and down-regulation of anti-fibrotic pathways including STAT5A/FGF21/PPARb/IL-22. Proteomic analysis identified fibrotic pathways, activation of oxidative stress, mitochondrial dysfunction, proteasomal degradation, apoptosis, and inflammatory pathways. Proteomic analysis demonstrated acrolein-decreased expression of antioxidant proteins, non-erythroid hemoglobin and glutathione synthetase (GSS), targets of transcription factor Nuclear Factor-Erythroid derived-2 (NF-E2). Accordingly, acrolein decreased renal NF-E2 expression and increased cleaved caspase-3 and profibrotic connective tissue growth factor (CTGF) expression. H&E staining demonstrated damaged tubules while Sirius-Red staining demonstrated increased collagen deposition in kidneys of acrolein exposed mice. Over-expression of NF-E2 in immortalized human renal proximal tubule (HK-11) cells, inhibited acrolein-induced CTGF expression and caspase-3 cleavage.

Conclusions: Our studies demonstrate activation of oxidative stress, apoptotic and profibrotic pathways in acrolein treated kidneys. Chronic exposures of acrolein may lead to progressive fibrosis-induced End Stage Renal Disease (ESRD). *In vivo* modulation of NF-E2 expression may slow-down progressive fibrosis-induced ESRD.

Impaired Renal Hemodynamic Reserve Following Ischemic AKI Is Associated with Inflammation and Capillary Rarefaction and Reversed by Retrograde Hydrodynamic Isotonic Fluid Delivery

Md Mahbub Ullah, Jason A. Collett, Robert L. Bacallao, David P. Basile. *Indiana University School of Medicine, Indianapolis, IN.*

Background: We have previously shown that retrograde hydrodynamic delivery of isotonic fluid (HIFD) improved renal function in established AKI between 24-48 hours following ischemia and reperfusion injury (IRI). This improvement was associated with decreased inflammation and vascular congestion and improved microvascular perfusion. However, it is unknown whether HIFD results in sustained effects on renal hemodynamic reserve and CKD progression

Methods: Male Sprague Dawley rats underwent left unilateral IRI-35 min with right unilateral nephrectomy to induce AKI. 24 hours later, serum creatinine (SCre) was measured and rats received either HIFD via the renal vein or 0.5ml of isotonic saline into the vena cava (VC) as control. After 5 weeks, renal hemodynamic responses were assessed in response to i.v. L-arginine infusion (450 mg/kg/hr) in anesthetized rats. Kidneys were evaluated for further analysis

Results: At 5 weeks of recovery from surgery, baseline renal blood flow (RBF) and renal vascular resistance (RVR) were similar in the experimental groups (sham-, HIFD-, and VC-treated rats). Following 40 minutes of arginine infusion RBF increased similarly in both the sham group and the I/R HIFD group (22.6% and 19.8% compared to their corresponding baseline value (P<0.001). However, I/R-VC treated rats showed an impaired response to arginine infusion relative to the sham group (P<0.001). As expected, RVR to blood flow was decreased significantly by 14% and 17% in sham operated and HIFD treated rats compared to their corresponding baseline respectively. In the kidney, HIFD treatment attenuated recruitment of inflammatory CD4+IL17+ cells (777659 vs. 417609, p<0.05), as assessed by flow cytometry compared to the VC-treated rats. Peritubular capillary density in medulla, measured by cablin immunofluorescence, was significantly reduced by (41%) in VC-treated rats compared to sham group. HIFD treatment significantly improved capillary density after 35 days of IRI

Conclusions: HIFD treatment shown improved impaired renal blood flow response to arginine infusion following 35 days IRI. This is associated with improved capillary density and attenuated infiltration of CD4+IL17+ cells. This data shows that HIFD treatment has long-term protective effects following I/R injury

Evidence for a Critical Role of ARNT Homodimerization in Renal Regeneration and Attenuation of Fibrosis

Michael Zeisberg, Bjoern Tampe. *Georg-August-Universitat Gottingen, Gottingen, Germany.*

Background: Based on the organ-spanning effectiveness of ischemic preconditioning we hypothesized that underlying mechanisms could be utilized to aid the kidney in realizing its endogenous regenerative capacity and to circumvent kidney fibrosis. Previous studies implied that ARNT, also known as HIF1beta, plays an important role independent of HIF1alpha in ischemic preconditioning. Here we aimed to explore the mechanisms underlying the reno-protective activity of ARNT and to exploit these mechanisitc insights for novel therapeutic strategies.

Methods: ARNT homodimerization in vivo and in vitro was studied by mass spectrometry, immunoprecipitation, proximity ligation assays, native gel analysis and the use of mutant ARNT variants. Control of ARNT expression was studies by use of qRT PCR, immunoblot and promoter assays. To study impact of ARNT homodimerization in vivo we utilzed mure models of UU and CCl4-induced liver fibrosis.

Results: We provide evidence that transcriptional induction of ARNT by administration of FK506 or Tacrolimus enhances renal regeneration and attenuates fibrosis in mice. This effect is not realized when ARNT is targeted by administration of in vivo morpholinos. We demonstrate that the protective effect of ARNT is only realized when it forms homodimers. ARNT homodimers acts as transcription factor on ALK3 and the protective effect of ARNT homodimers is not realized when ALK3 is lacking. We identify that ARNT dimerization decision to form homodimers is controlled by phosphorylation of a critical serine 77 amino acid. ARNT Ser77 phosphorylation is controlled by PP2A. The PP2A inhibitor LB100 enhances Ser77 phosphorylation, ARNT homodimer formation and attenuates fibrosis in the kidney. Combination of GPI1046 (to induce ARNT transcription) and LB100 (to enhance ARNT homodimers) has additive effect to protect against fibrosis in kidney and liver.

Conclusions: Increased intracellular ARNT levels through enhanced transcription and augmented homodimerization through phosphorylation of ARNT Ser77 are pre-requisites to realize the reno-protective activity of ARNT. Utilization of this dual mechanism through combination therapy has potential to protect the kidney.

PO0424

TGF-βR1-Mediated Tubular Injury and Cell Death Requires Recruitment of Inflammatory Cells via CCL5

Emelie Lassen,[1] Liping Yu,[1] Krisztian Stadler,[2] Ilse S. Daehn.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Pennington Biomedical Research Center, Baton Rouge, LA.*

Background: Activation of the TGFβ signaling pathway plays an important role in both AKI and CKD pathogenesis. We have previously shown that ligand-independent activation of TGFβR1 in proximal tubules results in rapid epithelial cell injury and death, as well as immune cell infiltration. This study aims to determine the drivers and mechanism of epithelial cell injury.

Methods: *In vivo* studies were performed in transgenic Pax8Tgfbr1 mice with proximal tubular activation of TGFβR1 signaling by +/- doxycycline (Dox) chow. Immortalized proximal tubular epithelial cells (PTECs) from Pax8Tgfbr1 mice were treated with Dox and with activated spleen derived leukocytes. Cell death was determined by TUNEL or AnnexinV/PI staining, lipid-derived free radicals by electron paramagnetic resonance (EPR) spin resonance spectroscopy and *in vivo* spin trapping, and mitochondrial superoxide was determined by mitoSOX. Gene and protein expression were determined by RT-PCR, western blotting and immunofluorescence.

Results: Canonical TGFβ signaling induced by Dox was confirmed in Pax8Tgfbr1 mice and in isolated PTECs cells by increased Tgfbr1 gene expression and phospho-SMAD2 or nuclear translocation of SMAD2/3. Markers of tubular cell injury and inflammation were prominent in kidney sections from Pax8Tgfbr1 mice after 5 days of Dox. There was also increased oxidative stress and cell death after 5 days. TGFβR1 signaling activation in cultured Pax8Tgfbr1 PTECs did not induce cell death, but showed an increase in CCL5/RANTES expression, a chemokine involved in recruitment of several immune cell types, among them monocytes and T-cells. PTECs co-cultured with leukocytes isolated from spleens resulted in mitochondrial oxidative stress and cell death of PTECs. Cell death and mitochondrial oxidative stress was ameliorated by a mitochondrial superoxide scavenger in co-cultured PTECs.

Conclusions: Our studies show that induction TGFβR1 signaling in tubular epithelial cells triggers recruitment of inflammatory cells which mediate mitochondrial stress and cell death.

Kidney-Draining Lymph Node Fibrosis Following Unilateral Ureteral Obstruction

Xiaofei Li,[1] Jing Zhao,[1] Stefan G. Tullius,[1] Su Ryon Shin,[1] Jonathan Bromberg,[2] Vivek Kasinath,[1] Reza Abdi.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Although the primary organ has been the subject of intense investigation in the field of organ fibrosis over the past several decades, the presence of lymph node fibrosis due to persistent activation of the immune response in its partner organ remains largely unknown. Previously, we demonstrated that activation of the immune response following ischemia-reperfusion injury and crescentic glomerulonephritis in the kidney was associated with extracellular matrix (ECM) production by fibroblastic reticular cells (FRCs) of the kidney-draining lymph node (KLN). Here, we sought to determine whether FRCs in the KLN become similarly fibrogenic following unilateral ureteral obstruction (UUO) of the kidney.

Methods: We subjected 6–8-week-old C57BL/6J mice to UUO for 2, 7, and 14 days. We examined the microarchitecture of the kidney and KLN by immunofluorescence staining at each timepoint, and we quantified immune cell populations in the KLN by flow cytometry. The contralateral kidney unaffected by UUO and its partner KLN were used as controls.

Results: We found through immunofluorescence staining that FRCs increased production of ECM fibers and remodeled the microarchitecture of the UUO KLN, contributing to fibrosis that mirrored the changes in the kidney. We also observed by flow cytometry that the populations of $CD11b^+$ macrophages, $CD11c^+$ dendritic cells, and activated $CD4^+$ and $CD8^+$ T cells were significantly higher in the UUO KLN than the KLN draining the unaffected contralateral kidney.

Conclusions: These findings for the first time highlight the association between fibrosis both in the kidney and the KLN during UUO, and they lay the groundwork for future studies that will investigate more deeply the mechanisms behind KLN fibrosis.

The Irradiation-Induced Renal Ischemic Preconditioning Is Blunted by the Oral Administration of the Anti-Angiogenic Agent Sunitinib

Badr Khbouz,[1] Pascal Rowart,[2,1] François Lallemand,[1] Poma Laurence,[1] Jean-Marie H. Krzesinski,[1] Francois Jouret.[1] Laboratory of Translational Research in Nephrology (LTRN) - GIGA Institute *[1]Universite de Liege Faculte de Medecine, Liege, Belgium; [2]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Whole-body irradiation has been suggested to induce renal ischemic preconditioning(RIP) in mice, possibly via angiogenesis. First, we comprehensively investigate the pathways involved in renal irradiation. Next, we assess the functional impact of renal irradiation applied before renal ischemia/reperfusion(I/R) injury. Finally, we test whether Sunitinib-mediated inhibition of the angiogenesis prevents irradiation-associated RIP.

Methods: Exp1: Renal irradiation(8.56 Gy) was performed in male C57bl/6 mice(n=10). One month later, total kidney RNA was extracted from irradiated and control(n=5) mice for comparative RNA-Seq. Exp2: After renal irradiation, the right kidneys were removed, and the left kidneys undergo ischemia(30min)/reperfusion(48h) at Days 7-14-28 post irradiation(n=8). Exp3: Following the same protocol of I/R at Day14, 3 groups were compared(n=8): 1/irradiation; 2/irradiation and gavage with Sunitinib from Day2 to 13; 3/control group without irradiation or gavage.

Results: Exp1: RNAseq showen up-regulation of angiogenesis signalling pathways. Expressions of angiogenesis markers(CD31, VEGF) showed an increase at both mRNA and protein levels in irradiated kidneys($p<0.01$). Exp2: Following I/R, Blood Urea Nitrogen(BUN) and Creatinine(SCr) levels were lower in the irradiated mice compared to controls: (BUN: 86.2±6.8 vs. 454.5±27.2mg/dl; SCr: 0.1±0.01 vs. 1.7±0.2mg/dl, $p<0.01$). The renal infiltration by CD11b-(187±32 vs 477±20/mm^2) and F4-80-positive cells(110±22 vs 212±25/mm^2) was reduced in the irradiated group. VEGF and CD31 expression was increased in irradiated kidneys at both mRNA and protein levels($p<0,01$). Exp3: One-way analysis of variance followed by Tukey's test showed that, following I/R, BUN and SCr levels were lower in the irradiated group compared to controls(BUN: 106.1±33.6 vs. 352.2±54.3mg/dl; SCr: 0.3±0.13 vs. 1±0.2mg/dl), and in irradiated group compared to the irradiated-exposed group to Sunitinib(BUN: 106.1±33.6 vs. 408.4±54.9mg/dl; SCr: 0.3±0.12 vs. 1.5±0.3mg/dl; $p<0.01$).

Conclusions: Renal irradiation induces the activation of angiogenesis in mice. Renal irradiation leads to RIP, with preserved renal function and attenuated inflammation post I/R. Exposure to the anti-angiogenic drug Sunitinib post-irradiation prevents the irradiation-induced RIP.

Inhibition of 12/15 Lipoxygenase (12/15 LOX) Improves Renal Recovery and Function Post Ischemia-Reperfusion in Male Spontaneous Hypertensive Rats (SHR)

Riyaz Mohamed, Paul O'Connor, Jennifer C. Sullivan. *Augusta University, Augusta, GA.*

Background: Acute kidney injury (AKI) due to ischemia-reperfusion (IR) is a serious and frequent complication with high mortality rates. The mechanisms mediating renal IR injury leading to increased risk of later developing cardiovascular and renal diseases in either sex remain poorly understood, although elevated 12/15-LOX activity has been reported to contribute to the progression of numerous kidney diseases. The goal of the current study was to test the hypothesis that enhanced activation of 12/15-LOX leading to impaired recovery post-IR.

Methods: 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral IR (n=6/group). Additional male SHR were randomized to receive vehicle or the specific 12/15-LOX inhibitor ML355 (30 mg/kg i.p.; n=5/group) 1 hr prior to sham/IR and every other day up to 7 days post-IR. Blood and urine were collected from all rats 24 hrs and 7 days after IR; kidneys were harvested 7 days post-IR for biochemical, histological, and Western blot analysis.

Results: IR increased plasma creatinine (Pcr) and blood urea nitrogen (BUN) in both male and female SHR compared to respective sham controls at 24 hrs (P_{IR}=0.0001; P_{sex*IR}=0.2). At 7 days post-IR, Pcr and BUN remained elevated in male SHR but returned to baseline levels in females (Pcr: P_{IR}=0.03; P_{sex}*$_{IR}$=0.04; BUN: P_{IR}<0.05; P_{sex}*$_{IR}$=0.05). Histological examination of kidneys 7 days post-IR showed greater tubular damage (P_{IR}=0.0003, P_{sex}*$_{IR}$=0.0019) and renal cell death (P_{IR}=0.001; P_{sex}*$_{IR}$=0.001) in male vs. female SHR. Delayed recovery of renal function in male SHR was associated with activation of renal 12/15-LOX (P_{IR}<0.05; P_{sex}*$_{IR}$=0.008), increased lipid peroxidation (P_{IR}=0.008; P_{sex}*$_{IR}$=0.018), and ER stress (P_{IR}=0.05; P_{sex}*$_{IR}$=0.01) compared to sham-controls. Pre-treatment of male SHR with ML355 reduced IR-induced lipid peroxidation (P_{IR*TxT}=0.02) and ER stress (P_{IR*TxT}=0.05), prevented IR-induced tubular damage (P_{IR*TxT}=0.02) and tubular cell death (P_{IR*TxT}=0.04), and improved renal function (Pcr: P_{IR*TxT}=0.0067; BUN: P_{IR*TxT}=0.042) compared to vehicle-treated IR males 7 days post-IR.

Conclusions: In conclusion, our data demonstrate that enhanced activation of 12/15-LOX contributes to impaired renal recovery post-IR via ER stress and cell death in male SHR.

The Immunomodulatory Effect of LMWF5A on Infiltrating Immune Cells Supports Its Clinical Use for AKI

Elizabeth Frederick,[1] Melissa Hausburg,[2,4] Gregory Thomas,[1] David Bar-Or.[2,3] *[1]Ampio Pharmacueticals, Englewood, CO; [2]Swedish Medical Center, Englewood, CO; [3]St. Anthony Hospital, Lakewood, CO; [4]Trauma Research LLC, Englewood, CO.*

Background: Infiltrating immune cells are critical to acute kidney injury (AKI) pathogenesis. They are activated to clear cellular debris, secrete pro-inflammatory mediators, and drive leukocyte recruitment, with a subsequent switch to produce anti-inflammatory mediators that promote tissue repair. However, dysregulated, continuous, or excessive immune activation can result in further tissue damage. The <5kDa low molecular weight fraction of human serum albumin (LMWF5A) has anti-inflammatory/pro-resolution effects. This *in vitro* study aimed to evaluate the ability of LMWF5A to treat AKI by examining its effects on immune cells relevant to AKI.

Methods: Peripheral blood mononuclear cells (PBMC) were treated with vehicle control or LMWF5A and activated with lipopolysaccharide (LPS), LPS + interferon (IFN) γ, or interleukin (IL)-4 + IL-13. Media and total RNA were collected at 24h. Secreted molecules were analyzed using multiplex cytokine arrays or prostaglandin E2 (PGE2) ELISA, and differential gene expression was determined by mRNAseq. Data were then subjected to *in silico* interrogation of known AKI signaling pathways and comparison to public datasets featuring human AKI samples.

Results: Cytokine release by PBMC was significantly modulated by LMWF5A treatment. While cytokine profiles differed depending on stimulant, the most highly downregulated cytokines included C-X-C chemokine ligand 10, IFNγ, IL-10, IL-12, IL-17, monocyte chemoattractant protein (MCP)-1, and MCP-3 (n=3; p≤0.05), which have been implicated in AKI. In addition, the release of PGE2, which has been proven to be beneficial to kidney injury, was potentiated with LMWF5A treatment. *In silico* secretome and transcriptome analysis of LMWF5A-treated PBMC displayed predicted inhibition of pathways known to drive AKI, notably IFN and IL-17 signaling. Further, comparison to public human AKI biopsy data revealed that pathways activated by AKI were predicted to be significantly inhibited in LMWF5A-treated PBMC.

Conclusions: These data reflect the ability of LMWF5A to reduce inflammatory cytokines and shift the immune response towards resolution. Moreover, global regulation of pathways activated by AKI in kidney tissue are predicted to be inhibited by LMWF5A. This preliminary study suggests a potential role for LMWF5A as an effective AKI therapeutic.

Mutation of Regulatory Phosphorylation Sites in PFKFB2 Does Not Affect Metformin's Protective Effects Against Renal Fibrosis

Geoffrey Harley,[1] Marina Katerelos,[1] Kurt Gleich,[1] Peter F. Mount,[1,2] David A. Power.[1,2] *[1]Austin Health, Heidelberg, VIC, Australia; [2]The University of Melbourne Austin Clinical School, Heidelberg, VIC, Australia.*

Background: Metformin has been shown to have protective effects in mouse models of renal fibrosis via its effects on fatty acid oxidation but the contribution of glycolysis to this effect is unclear. 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase (PFKFB) is a key regulator of glycolysis in the kidney and is not believed to have an effect on fatty acid oxidation. We aimed to determine if modification of glycolysis has a critical role in metformin's protective effects against renal fibrosis.

Methods: Mice with inactivating mutations of the phosphorylation sites in PFKFB2 (PFKFB2 KI mice) were generated, which is predicted to reduce the ability to increase the rate of glycolysis following stimulation. These were compared with wild-type controls. Mice were administered metformin via drinking water and a unilateral ureteric obstruction (UUO) model was used. The degree of fibrosis was assessed by Western blot and RT-PCR.

Results: In the PFKFB2 KI mice treated with metformin, there was decreased fibrosis following UUO as assessed by Western blot for fibronectin ($p<0.05$) and RT-PCR for alpha-SMA, collagen-3 and F4.80. There was no significant difference between WT and PFKFB2 KI mice treated with metformin in regards to the degree of fibrosis following UUO in any of the Western blot or RT-PCR parameters that were measured.

Conclusions: These data show that inhibition of the regulation of glycolysis by PFKFB2 does not prevent metformin from having protective effects against renal fibrosis in a UUO model.

Scaffold Protein Na+/H+ Exchanger Regulatory Factor 1 (NHERF1) Protect Tenofovir-Induced Nephrotoxicity by Regulating Na+/Pi Cotransporter (Npt) and Intracellular Phosphorus Balance

Tiantian Ma, Xiaoxiao Shi, Bingbin Zhao, Jiaying Li, Peili Ji, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Tenofovir disoproxil fumarate (TDF) could cause proximal tubular (PT) dysfunctions and eGFR decline with mitochondria damages. PDZK1, MAP17, and NHERF1 are scaffold proteins that influence the localization and function of membrane proteins. We tried to investigate the changes of both membrane-associated proteins and proximal tubular transporters in TDF-induced nephrotoxic model.

Methods: C57/BL6 mice (n = 8) were gavaged daily with 10mg/kg/d, 50mg/kg/d of TDF for 8 weeks. The human renal tubular epithelial cells (HK-2) were grown and received 24 to 72 h exposure to 0–128 μM TDF or vehicle. NHERF1 was overexpressed in HK-2.

Results: Chronic TDF administration to mice resulted in swollen and exfoliated tubular epithelial cells, brush border cilia lodging and dissolving, and serum creatinine elevation ($P<0.05$, mean 10.23±2.683 vs. 27.18±18.41) compared to the control group. The protein expressions of scaffold protein NHERF1, Na+/Pi cotransporter (Npt), and sodium-glucose cotransporter type 2 (SGLT-2), but not PDZK1 and MAP17 were decreased in the kidneys of TDF-treated mice and cells. The intracellular phosphorus concentrations decreased dose-dependent with TDF concentration and the exposing time, companies with down-regulated Npt expressions. ATP levels reflected mitochondrial functions were also decreased with a time and dose-dependent exposure of TDF. NHERF1 overexpressing cells are well resistant to transporter damage and mitochondrial damage caused by TDF.

Conclusions: NHERF1 protects the TDF-induced AKI by Npt, intracellular phosphorus, and mitochondria dysfunction pathway.

PO0431

Renal Papillary Function and Repair After Reversible Ureteral Obstruction

Mark P. de Caestecker, Rachel Delgado, Maya Brewer, Min Yang, Haichun Yang. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Models of reversible UUO (R-UUO) have provided insight into the mechanisms of repair in the renal cortex, but little is known about the mechanisms or extent of renal papillary repair after reversal of obstruction. Here we characterize long-term functional and structural papillary repair in a new mouse model of R-UUO.

Methods: Vascular clamps are placed on the L ureter, removed on day 7, and a R nephrectomy (Nx) performed on day 17. We evaluated serial BUN; transdermal GFR (tGFR); urinary osmolarity (OSM) after water restriction; histology and fibrosis; tubules, interstitium, and capillaries by IF with segment-specific markers, markers of repair, and lineage analysis with Six2-CRE; R26R-td Tomato reporter mice to assess repair of nephronic epithelium.

Results: At clamp removal (day 0) all mice had hydronephrosis. 60-80% survived 48hrs after Nx, and day 14 BUN in Nx vs. R-UUO+Nx was 18.5 (0.9) vs. 42.6 (8.5) mg/dl, $p<0.001$, indicating reversal and consistent injury. tGFR was reduced at day 28 (991.0 (46.6) vs. 569.8 (82.6) ml/min/100gm, $p<0.001$), reversed by day 84, with decreased urinary OSM up to day 84 (3525 (106.9) vs. 1718 (175.7) mOsm/L, $p<0.0001$). There was cortical fibrosis from 0-84 days. Fibrosis increased day 0>28 in the papilla but was absent by day 84. There was papillary necrosis days 0-3; repopulation of tubular structures starting day 7 with disorganized tubulointerstitial repair by day 28 but normal histology by day 84. There was loss of AQP1 (descending thin limb, DTL) and AQP2 but not LTL staining (distal collecting duct, CD) days 3>28. AQP1 and 2 were restored by day 84, but there was a reduction in capillary density by CD31 staining days 14>84. Lineage analysis showed persistent Six2 lineage in the papilla at day 28, indicating effective repair of AQP1- DTL. There was a marked increase in Ki67+ Six2 lineage and LTL+ CD cells days 3-7 after reversal, but no expression of the de-differentiation marker, Sox9, in the papilla.

Conclusions: There is robust, Sox9-independent repair of tubules in the papilla that is initially disorganized but ultimately restores tubular organization after R-UUO. Despite this, a persistent defect in urinary concentrating capacity associated with decreased papillary capillary density, suggests that despite robust tubular repair, disorganized vascular integrity results in long-term papillary dysfunction after R-UUO.

PO0432

The Susceptibility Mechanism of AKI in Cirrhosis Through Regulation of miR-599 Mediated by SIRT1 rs4746720 Polymorphism

Yixin Chen, Fangfang Zhou, Youjun Xu, Yi Lu, Qun Luo. *HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.*

Background: Previous study has confirmed that SIRT1/PGC-1α signaling pathway might be involved in the pathogenesis of acute kidney injury (AKI) in cirrhosis. This study aimed to analyze the association between *SIRT1* single nucleotide polymorphism (SNP) and the risk of AKI in cirrhosis in a Chinese Han population, and to further explore the molecular mechanism of *SIRT1* SNP *in vitro*.

Methods: A total of 29 patients in AKI group and 87 patients in control group were selected from a Chinese Han population. Genotypes of *SIRT1* rs4746720 and rs2273773 were detected by SnaPshot technology. Bioinformatics softwares predicted that miR-599 might bind to the rs4746720 loci within *SIRT1* 3′UTR. The dual luciferase reporter vectors pmir-GLO-SIRT1-3′UTR-T/C were constructed and respectively co-transfected with miR-599 mimic or NC into HK-2 cells. The overexpression recombinant plasmids pcDNA3.1-SIRT1-T/C were further constructed and respectively co-transfected with miR-599 mimic, miR-599 inhibitor or NC into HK-2 cells, and the expression of miR-599 and SIRT1/PGC-1α/NRF1/TFAM were detected by qRT-PCR and Western blot.

Results: There was no significant association between *SIRT1* SNP and the risk of AKI in cirrhosis (P>0.05). But stratified analysis based on risk factors showed that in the subgroup of hepatic encephalopathy, *SIRT1* rs4746720 polymorphism was significantly associated with the risk of AKI in cirrhosis (OR=6.00, 95%CI: 1.22-29.48, P=0.027). Analysis of liver and kidney function showed that Scr and BUN of TT genotype of *SIRT1* rs4746720 was significantly higher than that of CC+CT genotype in the AKI group, and eGFR was significantly lower than that of CC+CT genotype (P<0.05). Dual luciferase reporter vectors showed that rs4746720 T allele of *SIRT1* could increase the binding of miR-599, which resulted in significantly reduced luciferase activity (P<0.001). Overexpression recombinant plasmids showed that rs4746720 T allele of *SIRT1* could mediate the binding of miR-599, which resulted in significantly reduced expression of SIRT1 and its downstream pathway (P<0.05).

Conclusions: The rs4746720 polymorphism in *SIRT1* 3′UTR may be associated with the risk of AKI in patients with cirrhosis. The rs4746720 T allele of *SIRT1* may mediate the binding of miR-599, affect the expression of SIRT1 and its downstream pathway.

PO0433

RAP Inhibits Proximal Tubule Endocytosis and Protects Against Gentamicin-Induced Nephrotoxicity

Ruben M. Sandoval, Mark C. Wagner, Shiv Pratap S. Yadav, Silvia B. Campos-bilderback, Bruce A. Molitoris. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The proximal tubule (PT) reabsorbs and concentrates filtered nephrotoxins by clathrin mediated (CME) and fluid phase mediated (FPE) endocytosis, leading to PT injury and AKI. The molecular chaperone RAP (Alpha-2-macroglobulin receptor-associated protein) a 39kDa protein inhibits LDL receptor family members ligand binding, including megalin. Our hypothesis was that RAP would inhibit megalin mediated CME, but not FPE, and reduce gentamicin nephrotoxicity.

Methods: We utilized daily injections of gentamicin (100mg/Kg, IP) in a uninephrectomy CKD model in Munich Wistar Fromter rats with a baseline serum creatinine (sCr) of 0.80 ± 0.23. Gentamicin was given with or without RAP (40mg/Kg, IV) to evaluate RAP's impact on function, sCr, 24 hr urinary creatinine clearance and proteinuria, and endocytosis, 2-photon microscopy to determine FPE i.e. 10 kDa Cascade Blue dextran, and Megalin mediated CRE, i.e. albumin, endocytosis.

Results: RAP injections markedly reduced S1 PT albumin uptake over 60 minutes (80%), dextran (67%) and gentamicin (62%) in normal rats in a rapid and fully reversible fashion. In rats treated with or without RAP, daily gentamicin treatment resulted in elevated serum Cr by day 5 (1.4 ± 0.2 vs 3.1 ± 0.4mg/dl, p<0.01) and day 6 (1.5 ± 0.5 vs 5.4 ± 0.8mg/dl, p<0.01). CrCl decreased on day 6 to 0.49 ± 0.16 ml/min vs 0.09 ± 0.07 ml/min and urinary protein increased to 488 mg/ml/100gm wt vs 2,512 mg/ml/100 gm wt in RAP treated and untreated rats, respectively.

Conclusions: These results indicate RAP treatment induced reductions of both CME and FPE PT endocytosis suggesting a link between megalin and FPE. Clinically, RAP may have direct relevance to preventing the harmful nephrotoxic effects of gentamicin treatment, and likely other nephrotoxins, especially in individuals more susceptible to aminoglycoside injury. Future studies will need to explore whether reductions in ototoxicity are also prevented.

PO0434

Role of Protease-Activated Receptor 1 (PAR1) in Glomerular Filtration Barrier Integrity

Sergey V. Brodsky,[1] Ajay kumar Medipally,[1] Min Xiao,[1] Mohankumar Doraiswamy,[1] Bryce A. Kerlin.[2,1] *[1]The Ohio State University, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: Protease-activated receptors (PARs) play a significant role in the regulation of angiogenesis and fibrosis. Their role in the regulation of glomerular filtration barrier (GFB) function is incompletely elucidated. We had demonstrated that PAR1 inhibition with SCH79797 results in glomerular hemorrhage and acute kidney injury in the 5/6 nephrectomy rats (5/6NE), effects similar to those of a direct thrombin inhibitor (dabigatran) and mimic features of anticoagulant-related nephropathy in humans. The aim of the current study was to investigate potential synergistic effects of dabigatran with PAR1 inhibition or agonism in 5/6NE.

Methods: Three weeks after surgery 5/6NE rats were treated with dabigatran (150 mg/kg/day) alone or with PAR-1 inhibitor SCH79797 (1.0 mg/kg/day and 3.0 mg/kg/day) or PAR1 activation peptide, TFLLR-NH2 (0.25 mcmol/kg/day and 0.5 mcmol/kg/day). Serum creatinine (SCr), activated partial thromboplastin time (aPTT), and hematuria were measured daily; kidney morphology was evaluated at the end of the study.

Results: As expected, treatment with PAR1 modulators did not alter the anticoagulant effects of dabigatran and did not prolong aPTT when used alone. Both SCH79797 and TFLLR-NH2 aggravated increased SCr levels induced by dabigatran in a dose-depended manner in the 5/6NE. Interestingly, both PAR1 activation peptide and PAR1 inhibition increased SCr in 5/6NE when used alone (Fig 1). Neither SCH79797 nor TFLLR-NH2 significantly affected dabigatran-induced hematuria in 5/6NE. Morphologically, 5/6NE treated with dabigatran, SCH79797 and TFLLR-NH2 alone or in combination, had red blood cell casts in the tubules and acute tubular epithelial cell injury.

Conclusions: PAR1 homeostasis is necessary to maintain GFB integrity in 5/6NE. Pharmacological activation or inhibition of PAR1 results in glomerular hematuria and acute kidney injury in 5/6NE. These effects are similar to those of dabigatran-mediated thrombin inhibition in 5/6NE, suggesting that the thrombin-PAR1 signaling axis is important to GFB function.

Renal GPNMB Is Highly Upregulated in Rodent Models of AKI and Is Further Elevated with Pharmacological AMPK Activation

Jenson Qi, Henriette Frikke-Schmidt, German Aleman Muench, Li-Jun Ma, Kamal Albarazanji, Nataliya Skrypnyk, Zheng Huang Devine, Lili Guo, Alessandro Pocai, James Leonard. *Janssen Research and Development LLC, Spring House, PA.*

Background: Glycoprotein nonmetastatic melanoma B (GPNMB) is highly expressed in macrophages. GPNMB is an AMP-activated protein kinase (AMPK) up-regulated gene in whole bloods. GPNMB deficient mice fail to undergo repair and injury resolution following kidney ischemia reperfusion injury (IRI). Here we investigated GPNMB expression in the rat IRI and mouse cisplatin AKI models with or without an AMPK activator treatment. We also characterized GPNMB expression in human proximal epithelial cells, M1 and M2 macrophages.

Methods: RPTEC and HK2 cells were exposed to hypoxia for 24 h. GMCSF- or MCSF- primed human M1 or M2 macrophages were isolated from human LeukoPaks. Male SD rats were subjected to 40 min of bilateral renal ischemia. Kidneys were harvested 2 days after IRI. Male C57B mice were administered with a single injection of cisplatin. Kidneys were harvested 72 h after cisplatin injection.

Results: In human proximal epithelial HK2 and RPTEC cells, an AMPK activator treatment resulted in a dose-dependent increase of GPNMB mRNA. Significant increase of GPNMB mRNA was observed in HK2 and RPTEC cells cultured in hypoxic versus normoxic conditions. We also demonstrated that AMPK activation increased IFNγ and LPS-induced GPNMB secretion in human M2 but not M1 macrophages. After a single oral administration of an AMPK activator in normal mice or rats, a robust induction of GPNMB mRNA in the whole blood was seen starting 3 h and lasting up to 22 h. We found that GPNMB mRNA was expressed at low levels in the kidneys of normal mice or rats. GPNMB mRNA was markedly up-regulated following IRI in the kidneys at 48 h.

In a mouse cisplatin-induced AKI model, a dramatic increase of GPNMB mRNA was observed in the kidneys. Pharmacological activation of AMPK in both AKI models resulted in further increase of renal GPNMB.

Conclusions: GPNMB mRNA is highly up-regulated in the kidneys of rat IRI and mouse cisplatin AKI models and is further elevated after an AMPK activator treatment. GPNMB is a gene marker for AMPK activation in tubular epithelial cells, M2 macrophages, and whole bloods. Our results support that GPNMB could modulate macrophages polarization which may be involved in inflammation and immune response, contributing to injury and repair post AKI.

Loss of Stimulator of Interferon Genes (STING) Pathway Does Not Protect the Kidney Against Acute Injury or Inflammatory and Fibrotic Pathways Induced by Folic Acid

Henriette Frikke-Schmidt, Hani Jouihan, George Ho, Alessandro Pocai, Lisa Norquay. *Janssen Research and Development LLC, Spring House, NJ.*

Background: Acute kidney injury (AKI) greatly increases the risk for developing chronic kidney disease (CKD), but it is currently not well understood how this progression from injury to inflammation and fibrosis takes place. Recently it was discovered that with injury, damaged mitochondria in the kidney can leak mitochondrial DNA into the cytosol, where it activates the cyclic GMP-AMP synthase (cGAS) stimulator of interferon genes (STING) pathway causing inflammation and fibrosis. To explore the significance of this pathway in the setting of AKI and CKD transition we induced folic acid nephropathy in mice with no detectable STING activity and evaluated them for kidney function and inflammatory/fibrotic gene expression 7 days after administration.

Methods: 23-week-old Goldenticket (Gt)mice (no detectable STING protein due to a missense mutation) and age matched wild type (WT) littermate controls were injected with 250 mg/kg of folic acid. Seven days later plasma, urine, and kidneys were collected for analysis of plasma creatinine, blood urea nitrogen (BUN) and urinary albumin creatinine ratio (uACR). 8 mice were used for both WT and Gt vehicle groups and 11 mice were used for WT and Gt groups treated with folic acid.

Results: In WT control mice folic acid treatment significantly elevated plasma creatinine from 0.27±0.06 to 0.62±0.33mg/dl, BUN levels from 25.1±3.1 to 66.8±21.0mg/dl, and uACR more than doubled from 21.5±13.4 to 53.5±64.3ug/mg. This effect was not statistically different from what was observed in Gt mice (plasma creatinine increasing from 0.25±0.04 to 0.53±0.20mg/dl, BUN increasing from 20.9±1.9 to 54.7±21.1mg/dl, and uACR increasing from 15.9±13.8 to 140.2±313.5ug/mg with folic acid, respectively). Kidney gene expression for genes involved in fibrosis (*Tgf-β*, *Col1a1*), inflammation (*Tnf*, *Il6*, *Il1b*), and apoptosis (*Bax*, *Trp53*) were all elevated with folic acid treatment. Only *Il6* which is a direct effector gene of STING, was significantly decreased in the folic acid treated Gt mice as compared to the folic acid treated WT controls.

Conclusions: Ablation of STING did not protect kidney function, nor did it impact fibrotic or inflammatory gene expression. Our data suggest that the cGAS/STING pathway is not involved in the development of AKI and in the transition to CKD in the folic acid nephropathy model.

Extracellular Matrix Protein 1 Organized Microenvironment Keys to Kidney Repair After AKI

Yuan Gui, Dong Zhou. *University of Connecticut School of Medicine, Farmington, CT.*

Background: In AKI, the kidney tubule is well-known as the epicenter of damages, yet little attention has been paid to changes in the microenvironment and associated repair processes. Amid this process, the extracellular matrix (ECM) is the principal organizing component for microenvironment construction and tubule repair, serving as a scaffold for remodeling. How ECM interacts with its surrounding materials to dictate the prognosis of AKI remains unclear in the field.

Methods: Kidney ischemia-reperfusion injury was employed to induce AKI in mice. *In vivo*, *in vitro*, and *ex vivo* translational experiments and quantitative proteomic analyses were performed.

Results: Quantitative proteomics revealed that extracellular matrix protein 1 (ECM-1) was the earliest activated matrix protein in ischemic AKI kidneys. Immunostaining revealed that ECM-1 was predominantly expressed in the activated kidney fibroblasts. In cultured fibroblast, knockdown ECM1 markedly repressed cell activation and proliferation, as assessed by the decreased expression of α-SMA, vimentin, PDGFR-β, and PCNA. *Ex vivo*, knockdown ECM1 in the decellularized AKI kidney scaffold directly reduced its capacities in promoting the proliferation of the seeded tubular cells. *In vivo*, loss of ECM1 caused elevated serum creatinine levels, more severe morphologic changes, and reduced inductions of α-SMA, vimentin, and PDGFR-β than the controls after AKI. By using affinity-purification mass spectrometry, we identified a vital mechanism that ECM1 could bind to an essential tubule-derived growth factor protecting against AKI, sonic hedgehog (Shh). *In vitro*, we confirmed that recombinant ECM1 promoted tubular cell proliferation and Shh expression.

Conclusions: Our finding implicated that ECM1 created a favorable microenvironment by interacting with Shh to promote AKI recovery.

TNF Drives AKI-to-CKD Transition Downstream of Proximal Tubule EGFR

Mai Abdelmageed, Eirini Kefalogianni, Akshayakeerthi Arthanarisami, Fatima Zohra Khamissi, Jeffrey J. Atkinson, Andreas Herrlich. *Washington University in St Louis, St Louis, MO.*

Background: Inflammation is a key driver of fibrosis and progression of human chronic kidney disease (CKD), often caused or worsened by acute kidney injury (AKI-to-CKD transition). Sustained epidermal-growth-factor-receptor (EGFR) activation in injured proximal-tubule-cells (PTC) is strongly pro-inflammatory and has emerged as a key paradigm in AKI-to-CKD transition and CKD progression. Whether the key Type 1 inflammatory cytokine tumor-necrosis-factor (TNF) has a role in CKD progression and how TNF relates to the PTC-EGFR pathway is unknown.

Methods: We compared mice treated with control, TNF-inhibition (etanercept, TNF-scavenger), EGFR-inhibition (erlotinib, EGFR-kinase-inhibitor) or their combination in an AKI-to-CKD bilateral renal-ischemia-reperfusion model.

Results: TNF- or EGFR-inhibition did not affect initial kidney injury, but significantly overlapped in reducing kidney injury-upregulated cytokines and equally strongly reduced kidney fibrosis, while combination treatment had no additive effect, suggesting EGFR and TNF act in the same fibrosis pathway. TNF exerted its profibrotic effects downstream of PTC-EGFR, as TNF-inhibition did not affect tubular EGFR activation *in vivo*. Consistent with this, TNF-PTC-KO did not reduce inflammation or fibrosis, suggesting that PTC-derived TNF does not contribute to profibrotic PTC-EGFR activation. Kidney single-cell-RNAseq analysis identified macrophages, dendritic cells and T cells, but not PTC, as dominant TNF sources after AKI. Only EGFR-inhibition, but not TNF-inhibition significantly blocked injury-induced kidney ingress of macrophages, however, macrophage numbers where equal one month after AKI independent of treatment. Thus EGFR-inhibition reduces ingress and accumulation of TNF-producing proinflammatory and profibrotic immune cells whereas TNF-inhibition mechanistically largely acts by neutralizing their proinflammatory and profibrotic activities.

Conclusions: Our work provides mechanistic background to motivate examination of TNF pathway inhibition in human AKI or CKD.

PO0439

Antioxidant Prevents Deleterious Heart-Kidney Cross-Talk in a Novel Experimental Model of Cardiorenal Syndrome due to Isolated Right Heart Failure

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

Background: Since recognition of CRS, most studies have investigated left heart failure and CRS due to isolated RVF is under recognized. However, renal dysfunction is an independent predictor of death and hospitalization in RVF. To examine experimental models of CRS improve our understanding of the pathophysiology of RV-Kidney interaction and enable us to explore new therapeutic modalities.

Methods: In a alkaloid (ALK) injection induced CRS in rats we investigated whether antioxidant prevents deleterious interactions of RV-Kidney in CRS. Rats were treated with an antioxidant, 1 wk pre & post-ALK injection. At 3 and 4 wks post-ALK injection, serial echocardiography was performed to monitor cardiac function. RV systolic pressure (RVSP), RV hypertrophy (RVH), RV function, RV levels of superoxide dismutase (SOD), catalase, glutathione peroxidase (GSHPx) and lipid peroxidation (LPX) were measured. After sacrificing animals, hearts and kidneys were removed for histopathology.

Results: At 4 weeks, ALK-induced CRS resulted in increased mortality, RVSP, RVH, and LPX in RV myocardium accompanied RVF as well as the kidney. Antioxidant enzymes activities including SOD and GSHPx were decreased in RV and the kidney. Kidney histopathology with Periodic acid-Schiff (PAS) staining demonstrated tubular epithelial denudation, a marker of ATN that was not seen at 3 weeks post-ALK injection. This excludes renal toxicity of the alkaloid. Antioxidant treatment prevents not only ALK-induced CRS and decreased oxidative stress but also increased the SOD and GSHPx levels in the RV myocardium and the kidney.

Conclusions: A reduction in oxidative stress by antioxidant may explain the prevention of ALK-induced CRS. Thus, targeting oxidative stress may lead to the development of novel therapies for CRS and antioxidants as an adjuvant therapy may be beneficial.

PO0440

Inability to Increase Fatty Acid Oxidation Worsens AKI and Impacts the Benefit of Metformin

Geoffrey Harley,[1] Marina Katerelos,[1] Kurt Gleich,[1] David A. Power,[1,2] Peter F. Mount.[1,2] *[1]Austin Health, Heidelberg, VIC, Australia; [2]The University of Melbourne Austin Clinical School, Heidelberg, VIC, Australia.*

Background: Energy metabolism is critical to the pathogenesis of ischaemic acute kidney injury (AKI) - its role in nephrotoxic AKI is less understood. Fatty acid oxidation (FAO), the kidney's most important energy source, is regulated by acetyl-CoA carboxylase (ACC). Metformin increases FAO by increasing phosphorylation of ACC. We aimed to determine whether regulation of FAO affects the outcome of nephrotoxic AKI.

Methods: Cisplatin AKI was induced in ACC knockin (KI) mice, which have mutations of ACC phospho-sites that disrupt FAO regulation, and compared to wild-type (WT) controls. A primary tubular epithelial cell (TEC) culture model of cisplatin toxicity was used to further study the findings.

Results: ACC KI mice demonstrated more severe cisplatin-AKI versus WT as assessed by day 2 serum urea (ACC KI 40.5±11.6 mM vs WT 27.2±7.6 mM, p <0.005) and creatinine (ACC KI 0.09±0.03 mM vs WT 0.06±0.03 mM, p <0.05). Western blot for neutrophil gelatinase associated lipocalin (NGAL) was increased 9.3±2.1 fold in ACC KI compared to 3.3±3.4 fold in WT (p<0.0001 for ACC KI vs WT). WT and ACC KI TEC cultures exposed to cisplatin revealed increased apoptosis in ACC KI, as assessed by increased cleaved caspase-3 (cCasp3) (p<0.0001). In TECs, metformin was protective against cisplatin mediated apoptosis, however this was diminished in ACC KI cells (cCasp3 reduced 49.5%) versus WT cells (cCasp3 reduced 72%) (p=0.03 for ACC KI vs WT).

Conclusions: Severity of nephrotoxic AKI is dependent on maintaining regulation of FAO. Metformin reduces cisplatin-AKI severity by its ability to increase FAO.

Caloric Restriction Reduces the Pro-Inflammatory Eicosanoid 20-HETE to Protect from AKI

Karla J. Hoyer-Allo,[1,2] Martin R. Späth,[1,2] Susanne Brodesser,[2] Katrin Bohl,[2] Torsten Kubacki,[1] Katharina Kiefer,[1,2] Felix C. Koehler,[1,2] Franziska Grundmann,[1] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Volker R. Burst,[1,2] Roman-Ulrich Mueller.[1,2] *[1]Uniklinik Koln, Cologne, Germany; [2]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany*.

Background: Acute kidney injury (AKI) is a frequent complication in the clinical setting and associated with significant morbidity and mortality. Preconditioning with short-term caloric restriction (CR) is highly protective against kidney injury in rodent ischemia-reperfusion-injury (IRI) models, but the underlying mechanisms are unknown hampering clinical translation. The aim of this work was to further characterize possible mechanisms of protective effects of preconditioning.

Methods: 14-week-old male and female C57Bl6 wild-type mice underwent no preconditioning serving as a control group (CR) or four weeks of a calorie-restricted diet as a method of preconditioning prior to IRI. Afterwards, we compared control animals with animals after CR by phenotyping (histology, urea).

Results: We examined the molecular basis of CR-mediated protection to elucidate the principles of renal stress resistance. Analysis of an RNAseq dataset after CR identified *Cyp4a12a* – a cytochrome exclusively expressed in male mice - to be strongly downregulated after CR. Renal IRI robustly induced AKI in male mice and damage could be markedly attenuated by pre-treatment with CR. In females, the damage was significantly less pronounced and preconditioning with CR had only little effect. Tissue concentrations of the metabolic product of *Cyp4a12a*, 20-Hydroxyeicosatetraenoic acid (20-HETE), were significantly reduced by CR. Conversely, intraperitoneal supplementation of 20-HETE in preconditioned males partly abrogated the protective potential of CR.

Conclusions: Our findings provide an insight into the mechanisms underlying renal organ protection and implicate 20-HETE as a target of CR-based preconditioning. Understanding the mediators of preconditioning is an important pre-requisite for moving towards translation to the clinical setting.

The MLL1/WDR5 Complex Contributes to Cisplatin-Induced Renal Epithelial Death by Promoting p53-mediated E-Cadherin Repression

Chunyun Zhang,[1] Yingjie A. Guan,[1] George P. Bayliss,[1] Shougang Zhuang.[1,2] *[1]Rhode Island Hospital, Providence, RI; [2]Shanghai East Hospital, Shanghai, China*.

Background: The mixed-lineage leukemia 1 (MLL1)/WD-40 repeat protein 5 (WDR5) complex is a methyltransferase deemed a positive regulator of histone H3 lysine 4 trimethylation (H3K4me3) and functions as an oncogenic factor in many cancer types. The role of the MLL1/WDR5 complex in acute kidney injury (AKI) and renal epithelial cell death is still unclear. In this study, we investigated the role and mechanism of this complex in the apoptosis of renal epithelial cells following cisplatin exposure.

Methods: Cultured mouse kidney proximal tubular (TKPT) cells were exposed to cisplatin in the presence or absence of MM102, a MLL1/WDR5 protein–protein interaction inhibitor or small interfering RNAs (siRNA) specific targeting MLL1 or WDR5.

Results: Expression of MLL1, WDR5 and H3K4me3 as well as phospho-p53 and cleaved caspase 3 were increased whereas that of E-cadherin was decreased in cultured TKPT cells exposed to cisplatin in a time dependent manner. Inhibition of the MLL1/WDR5 complex with MM102 or siRNA-mediated silencing MLL1 or WDR5 attenuated cisplatin induced cleavage of caspase 3 and cell death, which was coincident with downregulation of p-p53 and preservation of E-cadherin expression. Inhibition of p53 by pifithrin-α also alleviated cisplatin-induced cell death and restored E-cadherin expression in TKPT cells with or without MM102 treatment. In contrast, activation of p53 by Nutlin potentiated TKPT cell death and E-cadherin repression. Moreover, siRNA mediated silencing of E-cadherin attenuated the protective effect of MM102 following cisplatin treatment while expression of p-p53 was not affected. Finally, we found that pharmacological inhibition of MLL1/WDR5 reduced cisplatin-induced phosphorylation of ataxia-telangiectasia mutated protein, ataxia telangiectasia and Rad3-related protein, checkpoint kinase 1 (Chk1), checkpoint kinase 2 (Chk2) and γ-H2AX, which are activated in response to DNA damage and associated with p53 transcriptional activation.

Conclusions: These data suggest that the MLL1/WDR5 complex may contribute to cisplatin-induced apoptosis of renal tubular epithelial cells by promoting p53-mediated E-cadherin repression following DNA damage. Targeting the MLL1/WDR5 complex may have a therapeutic potential for the treatment of cisplatin-induced AKI.

Comparison of Inflammatory Responses in Sepsis-Induced AKI Mouse Models and Response to Dexamethasone

Matthew M. Rankin, George Ho, Rong Meng, Nataliya Skrypnyk, Gavin Lewis, Rohit Rajoria, Andrea R. Nawrocki, Raul Camacho. *Janssen Research and Development LLC, Spring House, PA.*

Background: AKI occurs in the majority of patients with severe sepsis and contributes to high morbidity and mortality. Despite the frequency of AKI, the underlying mechanisms of renal injury during sepsis are not fully understood, and no approved therapies to prevent or reverse this condition. Systemic and local inflammatory responses play a large role in the development of sepsis induced acute kidney injury (S-AKI).

Methods: To develop novel treatments for patients with S-AKI, animal models of polymicrobial sepsis are used; the most widely reported models being cecal ligation puncture (CLP) and cecal slurry (CS). We compared the acute (24h) renal function and inflammatory response of these two models, as well as the ability of dexamethasone (dexa) to prevent the development of S-AKI.

Results: CLP significantly reduced renal function, with increased plasma creatinine (0.18±0.11 mg/dL), blood urea nitrogen (BUN, 81.11±12.88 mg/dL), and increased inflammatory markers IL-6 (127±73 ng/mL), TNF-α (176±33 pg/mL), and IL-1β (164±141 pg/mL) compared to sham animals. Dexa (8 mg/kg) significantly decreased BUN but did not significantly decrease plasma creatinine or the inflammatory markers. Dexa (2.5mg/kg) had no significant effects on renal functional markers or circulating cytokines. CS significantly increased plasma creatinine (0.7±0.1 mg/dL), BUN (103±20 mg/dL), cystatin C (2443±947 ng/mL), IL-6 (124±63 ng/mL), TNF-α (134±39 pg/mL) compared to basal levels. Dexa treatment (2.5 mg/kg) significantly decreased creatinine, cystatin C, IL-6, TNF-α, and IL-1β. In this study, we have shown the CS model elicits a more robust increase in AKI and inflammatory measurements than the CLP model, with reduced variability. It also responds to a greater extent to the same dose of dexa. Our results suggest that the CS model may be provide a better window with less variability compared to the CLP model, to test novel treatments for S-AKI.

Conclusions: We have shown the CS model elicits a more robust increase in AKI and inflammatory measurements than the CLP model, with reduced variability. It also responds to a greater extent to the same dose of dexamethasone. Our results suggest that the CS model may be provide a better window with less variability compared to the CLP model, to test novel treatments for S-AKI.

PO0444

Prohibitin Ligand FL3 Protects Renal Proximal Tubular Cells Against ATP-Depletion-Induced Injury

Xun Zhou,[1,2] Zheng Dong.[1,2] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]Augusta University Department of Cellular Biology and Anatomy, Augusta, GA.*

Background: FL3 is a synthesized ligand of prohibitins, a family of proteins located on and important for mitochondrial inner membrane. FL3 has been reported to protect neurons and cardiomyocytes by regulating mitochondrial function. Whether FL3 can protect kidney cells against cell stress remains unknown. This study aims to evaluate the effect of FL3 on ATP-depletion-induced cell death in renal proximal tubular cells (RPTCs).

Methods: RPTCs were pre-treated with 50nM FL3 for 3 hours and incubated with 10mM azide in glucose-free Krebs-Ringer bicarbonate solution for 3 hours to induce ATP depletion. The cells were then returned to a normal cultured medium for recovery. Cells were also exposed to the same concentration of FL3 throughout the ATP depletion and recovery phases. Mitochondrial changes including mitochondrial fragmentation, Bax translocation, cytochrome C release, prohibitin complex breakdown, OPA1 and OMA1 proteolysis were examined immediately after azide treatment; whereas apoptosis events including apoptotic morphology and caspase activation were examined after 2 hours of recovery.

Results: RPTCs with azide-induced ATP depletion developed apoptotic morphology, caspase 3 activation and PARP cleavage, which were suppressed by FL3. Mitochondrial fragmentation and membrane leakage of cytochrome C were increased in RPTCs during ATP depletion. FL3 suppressed mitochondrial fragmentation and inhibited mitochondrial injury. Under cell stress, the large prohibitin ring complex was disrupted to medium and small complexes, releasing OMA1 to cleave the inner membrane fusion protein OPA1. FL3 treatment decreased both the small prohibitin complex and the activation of OMA1. FL3 also partially prevented the degradation of the long isoforms of OPA1 during ATP depletion.

Conclusions: FL3 can protect against ATP-depletion-induced injury in renal tubular cells, likely through the regulation of mitochondrial dynamics.

PO0445

Mechanisms of Aristolochic Acid I (AAI)-Induced Proximal Tubule Cell Injury

Rohit Upadhyay, Vecihi Batuman. *Tulane University School of Medicine, New Orleans, LA.*

Background: Aristolochic acids (AAs) are naturally occurring polyaromatic nitrogen compounds extracted from certain plants that were used to treat various diseases for centuries until their nephrotoxicity and carcinogenicity began to be recognized. Aristolochic acid I (AAI) is potentially one of the main pathogenic compounds and has been demonstrated to have nephrotoxic, carcinogenic, and mutagenic effects. Previous studies have indicated that AAI acts mainly on proximal renal tubular epithelial cells however investigation into the mechanisms of AAI-induced proximal tubule cell damage are still warranted.

Methods: Human kidney proximal tubule cells (PTCs; HK2 cell line) were exposed to AA1 at different time/dose conditions *in vitro*. Cell proliferation, ROS generation, NO production, m-RNA/ protein expressions and mitochondrial dysfunction was checked in HK2 cells after treating them with AA1.

Results: We found that AA1 treatment decreased HK2 cell proliferation significantly at 24hrs with 40μM concentration. AA1 exposure increased ROS generation and decreased NO production significantly. Furthermore, gene/ protein expression studies demonstrated activation of innate immunity (TLRs 2,3, 4 and 9, HMGB1), inflammatory (TNFA, IL6, IL18 and TGFB) and kidney injury (LCN2, KIM1) markers. In addition, our results indicated AA1 induced epithelial-mesenchymal transition (EMT) as well as mitochondrial dysfunction in HK2 cells.

Conclusions: AA1 treatment caused injury to proximal tubule cells (HK2) through ROS-HMGB1/mt DNA mediated TLRs activation and inflammatory response.

PO0446

AMPK Activation Alleviates TNF-α Induced Human Umbilical Vein Endothelial Cell Monolayer Permeability Increase

Zheng Huang Devine, Alessandro Pocai, James Leonard. Cardiovascular & Metabolism *Janssen Research and Development LLC, Spring house, PA.*

Background: The abnormal structure and function of the renal microvasculature contributes to acute kidney injury (AKI) pathophysiology by reducing regional blood flow especially in the outer medulla. AKI results in marked increases in local and systemic cytokine levels. IL-1α, IL-6, and TNF-α orchestrate various inflammatory reactions increasing endothelial permeability due to loss of endothelial monolayer and alteration of endothelial cell-cell junctions. AMP-activated protein kinase (AMPK) has been reported to play a protective role in vascular function, mainly through eNOS phosphorylation, inhibition of ROS formation and stimulating mitochondrial biogenesis. In addition, AMPK has been reported to regulate the assembly and disassembly of epithelial tight junction. **Objectives:** Our aims were to investigate whether a direct small molecule AMPK activator could preserve endothelial cell monolayer integrity when challenged by TNF-α treatment, and to investigate the potential mechanisms.

Methods: Structural and functional integrity of human umbilical vascular endothelial cells (HUVECs) monolayer was evaluated by measuring permeability, and caspase 3/7 activity was measured to reflect apoptotic cell death. TNF-α was used to induce injury. AMPK activation was confirmed by measurement of pACC. Data were analyzed using 1-way ANOVA.

Results: 10, 30, and 100 ng/ml TNF-α significantly induced HUVEC monolayer permeability after 24 hr treatment, with 11.2-, 8.1-, and 8.1-fold increases, respectively. Direct allosteric AMPK activator (CpdA) protected against permeability induced by 24 hr of 100 ng/ml TNF-α treatment, with a maximum reduction of 57.6% permeability at 3 mM. SB 203580, a p38 MAPK inhibitor, decreased the permeability by about 62.5%. 100 ng/ml TNF-α treatment for 24 hr increased apoptosis by 2.8-fold. CpdA treatment significantly protected cells from apoptosis in a dose dependent manner. TNF-α treatment for 6 hr increased HUVEC permeability (~6.4-fold), which was reduced (40.6% reduction) by CpdA treatment. Cells incubated with CpdA maintained their shape and cell-cell contacts and showed less intercellular gaps when compared to those treated with DMSO vehicle control.

Conclusions: AMPK activation alleviated endothelial leakage, potentially via decreasing apoptosis and maintaining cell-cell contacts. Our data supports AMPK activation as a novel therapeutic approach for AKI.

PO0447

SGLT-2 Inhibitor Dapagliflozin Does Not Improve Severe Ischemia-Reperfusion-Induced AKI

Jana Tumova, Jiwan J. Kim, Manjeri A. Venkatachalam, Kumar Sharma. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Acute kidney injury (AKI) is defined by a rapid decline in the kidney function, occurs in approximately 5-20% hospitalized patients and is associated with high mortality. Renal ischemia-reperfusion (IR) injury is a leading cause of AKI. Despite intensive research and progress in understanding the pathophysiological mechanisms, IR-AKI remains a critical problem without any effective treatment available. Dapagliflozin is a novel antidiabetic drug from the class of sodium-glucose cotransporter 2 (SGLT2) inhibitors that reduce glucose reabsorption in renal proximal tubules. SGLT2 inhibitors have been recently suggested to cause protection even in renal injury conditions beyond diabetes, such as AKI. In our work, we aimed to test the effectivity of dapagliflozin in decreasing kidney injury in a mouse model of severe IR-AKI.

Methods: We developed a mouse model of severe IR-AKI. C57BL/6J males underwent 35 minutes of renal ischemia by bilateral clamping of renal pedicles followed by 24h of reperfusion. The levels of blood urea nitrogen (BUN) and plasma creatinine at 24h after reperfusion were high but all mice undergoing IR surgery survived. Histological analysis showed severe tubular injury in the outer stripe of outer medulla. Mice undergoing IR surgery were divided into groups and received either no treatment, 1 mg/kg dapagliflozin, 10 mg/kg dapagliflozin or vehicle only administered by oral gavage 24h and 1h before the onset of ischemia. BUN and other parameters of kidney function were assessed 24h after reperfusion.

Results: In our preliminary data oral administration of dapagliflozin did not prevent kidney function decline in the model of severe IR-AKI. The BUN levels in plasma at 24h after reperfusion were not significantly different in groups of mice undergoing IR surgery. This is in contrast to previously published study[1] where, however, less severe model of IR-AKI with 27 minutes of renal ischemia was used.

Conclusions: Dapagliflozin did not improve severe IR-AKI. We hypothesize that dapagliflozin may be effective in improving less severe kidney injury, however, lacks effectivity in more severe cases of AKI. In our future studies, we would like to test the ability of dapagliflozin to prevent kidney injury at different stages of IR-AKI. [1]Chang et al. *PLoS One*. 2016;11(7):e0158810.

PO0448

Establishment and Evaluation of a Primary Human Renal Tubular 3D Spheroid Model for AKI and CKD

Lifeng Wang,[1,2] Yougang Zhai,[1] Lili Guo,[1] Rong Meng,[1] Li-Jun Ma,[1] Seunghun P. Lee,[1] Alessandro Pocai.[1] *[1]Janssen Research and Development LLC, Spring House, PA; [2]Janssen Global Services LLC, Titusville, NJ.*

Background: The proximal tubule of the nephron is a prime site for tubular injury due to its high energy requirements and its dependence on oxidative metabolism to meet its energy needs. Our understanding of the central role of mitochondrial abnormalities and alterations in metabolism in both acute and chronic kidney injury has steadily improved with potential targets to improve mitochondrial dysfunction that occurs in AKI and in AKI to CKD transition. Two-dimensional (2D) monolayer cultures and rodent animal models are unable to fully recapitulate clinical drug response, hence 3D models are being developed to provide a physiologically relevant condition.

Methods: Here, we developed a primary human renal tubular 3D spheroid culture and established a cisplatin-injury model for therapeutic target evaluation. Human primary renal tubular cells (RPTEC) seeded in ULA plates showed aggregation after 4 hours and formed initial spheroids after 4 days and the primary cells can be cultured over 5 weeks without major physiological changes.

Results: In 3D setting, gene expression of tubular markers was significantly induced/ restored close to the human tissue level comparing to 2D culture (*AQP1, OAT, LRP2, PEPT2, SLC12A1*, etc.) suggesting a more physiologically relevant condition. As NAD+ level is a critical factor to maintain mitochondria functionality in tubular cells, we evaluated genes involved in *de novo* NAD synthesis pathway and observed increased

expression in 3D- vs. 2D culture (*AFMID, KMO, KYNU, HAAO, ACMSD, NMNATs*, etc.). Moreover, since TGF-β is activated in AKI and is involved in AKI to CKD transition, we confirmed that TGF-β treatment repressed *de novo* NAD pathway gene expression, suggesting a possible link to the decrease of *de novo* NAD+ in the cells producing TGF-β. Lastly, In our cisplatin-induced tubular cell injury model in 3D spheroid, cisplatin induces the dose-dependent increase of cell apoptosis associated with dose-dependent reduction of total cellular NAD+ and GSH.

Conclusions: Taken together, our 3D primary human spheroid model restored key marker gene expression and recapitulated in vivo response to the TGF-β treatment and cisplatin-induced injury, which provide a physiological and pathophysiological relevant tool and translational model to enable the quick screening and evaluation of therapeutic targets for AKI and CKD.

PO0449

Succinylation of Metabolic Enzymes Protects Against AKI

Katherine Pfister,[1] Sunder Sims-Lucas.[1,2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) is an increasingly prevalent outcome of hospitalizations, affecting up to 50% of ICU patients in America. Kidney function depends on the metabolic activity of Renal Proximal Tubule Epithelial Cells (RPTECs). To understand AKI pathology, we focused on a class of proteins that affect posttranslational modifications of major proteins, and especially the deacylase Sirtuin 5 which is highly expressed in RPTECs. Our previous studies indicate that knockout of this protein has a protective role in RPTECs post AKI which presents the exciting possibility of clinical translation in preventing or ameliorating any long-term damage from AKI.

Methods: Through independent pathway analysis and mass spectrometry we attributed the major protective effect of Sirt5 knockout to be succinylation of key mitochondrial and peroxisomal proteins, leading to a metabolic shift from mitochondrial Fatty Acid Oxidation (FAO) to peroxisomal-dependent FAO. To test this hypothesis in a less invasive manner than genetic knockdown, we used the mitochondrial FAO inhibitor Etomoxir and the peroxisomal stimulator Benzifibrate. In both cases we found a significant reduction in the kidney injury marker NGAL after ischemia-like injury.

Results: We postulate that the switch to more peroxisomal-mediated fatty acid oxidation is protective due to a decrease in the Reactive Oxygen Species. To promote this shift, we investigated the effects of supplementing the mouse diet with medium-chain fatty acids (10% dodecanedioic acid) pre or post ischemia-reperfusion-injury (IRI). Mass spectrometry of the succinylation signature of murine kidneys after diet treatment was similar to that of the Sirt5 KO mice, suggesting a functional phenocopy. We have preliminary evidence that there is less oxidative stress when the dodecanedioic acid diet is administered pre- or post-injury and there is less overall damage to the proximal tubule epithelia.

Conclusions: The data from these experiments suggest a simple but effective diet treatment could reduce the burden of AKI cases.

Efficacy and Safety of Roxadustat in Patients with Anemia of Dialysis-Dependent CKD (DD-CKD) Treated Continuously for ≥3 Years

Chuan-Ming Hao,[1] Neera K. Dahl,[2] Stefan Tham,[3] Marcelo Orias,[2] Roberto Pecoits-Filho.[4] *[1]Huashan Hospital Fudan University, Shanghai, China; [2]Yale University School of Medicine, New Haven, CT; [3]Clinical Research, AstraZeneca, Gothenburg, Sweden; [4]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, is in development in the US for chronic treatment of anemia of CKD. This pooled *post hoc* analysis explored outcomes in DD-CKD patients (pts) treated with roxadustat for ≥3 years (y).

Methods: Pts were randomized to open-label roxadustat (n=1943) or epoetin alfa (EPO; n=1947) for up to 4y in 3 Phase 3 DD-CKD trials (ROCKIES, SIERRAS, HIMALAYAS). Intravenous iron was given per local care for EPO and limited to need for roxadustat. Data were analyzed in pts treated continuously for ≥3y, regardless of rescue therapy use. P values are exploratory. Adverse events (AEs) were assessed.

Results: Overall, 288 roxadustat and 360 EPO pts were treated for ≥3y; of these, 95% and 94% completed treatment. Baseline (BL) values for roxadustat vs EPO were generally balanced: mean age 55 vs 57y, mean hemoglobin (Hb) 9.8 vs 9.7 g/dL, dialysis modality was predominantly hemodialysis (94% vs 93% pts), median dialysis vintage 21.9 vs 17.4 months. Over Weeks (wk) 28–52, change in Hb from BL was greater with roxadustat vs EPO (+1.3 vs +1.0 g/dL; P<0.001) and proportion of pts with Hb ≥10 g/dL was higher (95% vs 85%). To wk 156, roxadustat maintained higher Hb vs EPO, with 11% increase in mean roxadustat weekly dose from wk 25–28 vs 20% increase in mean EPO weekly dose (Figure). Need for red blood cell (RBC) transfusion appeared less with roxadustat vs EPO (11% vs 16% pts). Serious AE rates with roxadustat vs EPO were 18.0 vs 16.9 per 100 pt-exposure years, respectively.

Conclusions: In DD-CKD pts who remained on treatment for ≥3y, Hb stability with roxadustat was achieved with minimal dose change and less need for RBC transfusion vs EPO. Safety was comparable with roxadustat vs EPO.

PO0451

Efficacy and Safety of Roxadustat in Patients with Anemia of Non-Dialysis-Dependent CKD (NDD-CKD) Treated Continuously for ≥2 Years

Roberto Pecoits-Filho,[1] Neera K. Dahl,[2] Stefan Tham,[3] Marcelo Orias,[2] Chuan-Ming Hao.[4] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Yale University School of Medicine, New Haven, CT; [3]Clinical Research, AstraZeneca, Gothenburg, Sweden; [4]Huashan Hospital Fudan University, Shanghai, China.*

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, is in development in the US for chronic treatment of anemia of CKD. This pooled *post hoc* analysis explored outcomes in NDD-CKD patients (pts) treated with roxadustat for ≥2 years (y).

Methods: Pts were randomized to double-blind roxadustat (n=2391) or placebo (PBO; n=1886) for up to 4y in 3 Phase 3 NDD-CKD trials (OLYMPUS, ALPS, ANDES). Oral iron was administered without restriction; intravenous (IV) iron was limited to rescue therapy. Data were analyzed in pts treated for ≥2y, regardless of rescue therapy use. P values are exploratory. Adverse events (AEs) were assessed.

Results: Overall, 789 roxadustat and 392 PBO pts were treated for ≥2y; of these, 87% and 85% completed treatment. Baseline (BL) values for roxadustat vs PBO were not balanced due to more discontinuation in PBO prior to 2y: mean hemoglobin (Hb) 9.2 vs 9.3 g/dL, 59% vs 78% of pts had hypertension, 56% vs 60% of pts had diabetes, mean eGFR 21 vs 24 mL/min/1.73 m^2. Change from BL Hb was greater with roxadustat vs PBO over Weeks (wk) 28–52 (+2.0 vs +0.5 g/dL; P<0.001), with differences seen from wk 4, and proportion of pts with Hb ≥10 g/dL over wk 28–52 was higher (95% vs 32%). Roxadustat maintained Hb ~11 g/dL to wk 100 (Figure). Mean roxadustat weekly dose increased by 11% from wk 25–28 to wk 97–100. Rescue therapy need (22% vs 34% pts), including red blood cell (RBC) transfusion (13% vs 18% pts), was less with roxadustat vs PBO; IV iron use was 9% for both. Serious AEs rates with roxadustat vs PBO were 20 vs 17 per 100 pt-exposure years, respectively.

Conclusions: In NDD-CKD pts who remained on treatment for ≥2y, roxadustat maintained Hb ~11 g/dL with minimal dose change and less need for rescue therapy, including RBC transfusion, than PBO.

PO0452

Number Needed to Treat with Roxadustat to Avoid One Transfusion or Intravenous Iron Administration in Anemia of Non-Dialysis-Dependent CKD

Roberto Pecoits-Filho,[1] Carol A. Pollock,[2] Anjay Rastogi,[3] Robert Provenzano,[4] Rachel Lai,[5] Tyson T. Lee,[5] Lynda Szczech.[5] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Sydney, Sydney, NSW, Australia; [3]University of California Los Angeles, Los Angeles, CA; [4]Wayne State University, Detroit, MI; [5]FibroGen Inc, San Francisco, CA.*

Background: Red blood cell (RBC) transfusion is the most common anemia treatment for non-dialysis-dependent chronic kidney disease (NDD CKD), but risks alloimmunization, which may delay or preclude kidney transplantation, and is associated with adverse events. Intravenous (IV) iron is recommended for poor response to oral iron, but requires travel to clinics. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor for anemia. It stimulates a coordinated erythropoietic response, increasing plasma endogenous erythropoietin levels and reducing hepcidin.

Methods: Data were pooled from 3 pivotal, randomized, phase 3 studies of roxadustat vs placebo NDD CKD populations. A phase 3 study of roxadustat vs darbepoetin alfa in NDD CKD was also analyzed. The number of patients needed to treat (NNT) with roxadustat for 1 year to avoid 1 RBC transfusion was calculated by taking the reciprocal

after subtracting the RBC transfusion annualized event rate in the roxadustat arm from the event rate in the placebo arm. The same analysis was done for RBC transfusion and IV iron incidence rates.

Results: Treating 4 patients with roxadustat vs placebo for 1 year is estimated to avoid 1 RBC transfusion. Treating 7 patients with roxadustat vs placebo for 1 year is estimated to avoid 1 patient needing 1 RBC transfusion, and treating 37 patients with roxadustat vs placebo is estimated to avoid 1 patient needing IV iron (Table). Rates of RBC transfusion (hazard ratio [HR]: 1.3 [95% CI 0.79, 2.11; p=0.3]) were comparable between roxadustat and darbepoetin alfa in the additional analyzed study, and a lower proportion of patients on roxadustat vs darbepoetin alfa required IV iron therapy use (HR: 0.45 [95% CI: 0.26, 0.78; p=0.004]).

Conclusions: In the pooled NDD CKD population, the NNTs to prevent RBC transfusion were low and indicative of patient benefit. Roxadustat reduced rates of RBC transfusions and IV iron use compared to placebo.

Funding: Commercial Support - FibroGen, Inc. and AstraZeneca

Table: Number needed to treat with roxadustat vs. placebo to avoid 1 RBC transfusion, 1 patient needing an RBC transfusion, and 1 patient needing IV iron

	Roxadustat arm rate	Placebo arm rate	Absolute risk reduction (ARR)	Relative risk reduction (RRR), %	1/ARR
RBC transfusion event (per 100 PFY)	15.5	45.5	30.0	65.9	3.3
RBC transfusion incidence (per 100 PEY)	6.1	20.4	14.3	70.1	7.0
IV iron usage, % patients	2.1	4.8	2.7	56.3	37.0

PEY: patient-exposure years, PFY: patient follow-up years

PO0453

Effects of Roxadustat in Patients with Dialysis-Dependent CKD (DD-CKD) Across All Baseline (BL) Hemoglobin (Hb) Values

Sunil Bhandari,[1] Carol A. Pollock,[2] Stefan Tham,[3] Anjay Rastogi.[4] *[1]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; [2]The University of Sydney, Sydney, NSW, Australia; [3]Clinical Research, AstraZeneca, Gothenburg, Sweden; [4]University of California Los Angeles, Los Angeles, CA.*

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, increases Hb by stimulating endogenous erythropoietin synthesis and improving iron bioavailability. This pooled *post hoc* analysis evaluated the efficacy and safety of roxadustat in patients (pts) with DD-CKD across all available BL Hb values.

Methods: Pts were randomized to open-label roxadustat (n=1943) or epoetin alfa (EPO; n=1947) in 3 Phase 3 DD-CKD trials (ROCKIES, SIERRAS, HIMALAYAS). Across trials, Hb eligibility criteria were <10 or 8.5–12 g/dL at final screening. EPO and intravenous (IV) iron were given per local care for the EPO group; for roxadustat, dose was titrated to Hb 11±1 g/dL and IV iron limited to need. Pooled subgroup analyses were performed by selected Hb values (g/dL: <8.0, ≥8.0–<9.0, ≥9.0–<10, ≥10.0) at BL (mean of up to 4 pre-randomization values) regardless of study rescue therapy use. Adverse events (AEs) were assessed.

Results: Pt study discontinuation rates were similar across BL Hb ranges (Table). Pts with lower BL Hb had less time on dialysis (Table), suggesting pts incident to dialysis. At BL, pts with Hb <9 g/dL had the lowest weekly ESA doses, but by Weeks (wk) 49–52 their weekly ESA doses were highest (Table). Pts with BL Hb <8 g/dL received on average ~1 mg/kg/wk more roxadustat dose at wk 49–52 than pts with BL Hb ≥10 g/dL (Table). Rates of serious AEs (SAEs) and treatment-emergent SAEs per pt-exposure year were comparable for roxadustat vs EPO and appeared more common in pts with higher BL Hb (Table).

Conclusions: DD-CKD pts with more severe anemia at BL required more IV iron during the study. Roxadustat was effective and had comparable tolerability to EPO across all BL Hb studied.

Funding: Commercial Support - AstraZeneca, Astellas, and Fibrogen

Effects of Roxadustat in Patients with Non-Dialysis-Dependent CKD (NDD-CKD) Across All Baseline (BL) Hemoglobin (Hb) Values

Carol A. Pollock,[1] Sunil Bhandari,[2] Stefan Tham,[3] Anjay Rastogi.[4] *[1]The University of Sydney, Sydney, NSW, Australia; [2]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; [3]Clinical Research, AstraZeneca, Gothenburg, Sweden; [4]University of California Los Angeles, Los Angeles, CA.*

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, increases Hb by stimulating endogenous erythropoietin synthesis and improving iron bioavailability. This pooled *post hoc* analysis evaluated the effects of roxadustat in patients (pts) with NDD-CKD across all available BL Hb values.

Methods: Pts were randomized to double-blind roxadustat (n=2391) or placebo (PBO; n=1886) in 3 Phase 3 NDD-CKD trials (OLYMPUS, ALPS, ANDES). Hb eligibility criteria were ≤10 g/dL at final screening, study drug dose was titrated to Hb 11±1 g/dL. Oral iron was administered without restriction; intravenous (IV) iron was limited to rescue therapy (IV iron, red blood cell [RBC] transfusion or ESA). Pooled subgroup analyses were performed by selected Hb values (g/dL: <8.0, ≥8.0–<9.0, ≥9.0–<10, ≥10.0) at BL (mean of up to 4 pre-randomization values) regardless of study rescue therapy use. Adverse events (AEs) were assessed.

Results: Pts with lower BL Hb had higher study discontinuation rates and lower BL eGFR (Table). Across BL Hb ranges over Weeks (wk) 28–52, BL change in Hb and proportion of pts with Hb ≥10 g/dL were greater with roxadustat vs PBO (Table). Pts with BL Hb <8 g/dL were treated with ~2 mg/kg/wk more mean roxadustat dose at wk 49–52 than pts with BL Hb ≥10 g/dL (Table). IV iron or RBC transfusion need was less with roxadustat vs PBO and with higher BL Hb (Table). Lower rates of serious AEs (SAEs) and treatment-emergent SAEs per pt-exposure year were observed with increased BL Hb (Table).

Conclusions: NDD-CKD pts with more severe anemia had worse kidney function, required more treatment including RBC transfusion and experienced more SAEs than pts with less severe anemia. Roxadustat improved anemia vs PBO across all BL Hb studied.

Roxadustat in Elderly Patients with Anemia of CKD

Carol A. Pollock,[1] Robert Provenzano,[2] Anjay Rastogi,[3] Roberto Pecoits-Filho,[4] Cameron S. Liu,[5] Lynda Szczech.[5] *[1]University of Sydney, Sydney, NSW, Australia; [2]Wayne State University, Detroit, MI; [3]UCLA, Los Angeles, CA; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]FibroGen, San Francisco, CA.*

Background: Elderly patients with anemia of chronic kidney disease (CKD) typically have several comorbidities requiring polypharmacy, but slower drug metabolism than younger patients. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that promotes coordinated erythropoiesis and increased iron availability. We explored roxadustat treatment in elderly (≥65 years) vs younger (<65 years) patients in dialysis-dependent-(DD) and non-dialysis-dependent-(NDD) CKD populations.

Methods: Data were pooled from pivotal phase 3 studies of roxadustat vs placebo (stage 3-5 NDD-CKD) and vs epoetin alfa (DD-CKD). Data were analyzed for patients <65 and ≥65 years old. The primary endpoint in the overall trials was mean change from baseline (CFB) in hemoglobin (Hb), weeks 28-52, regardless of rescue therapy. Least square mean difference (LSMD) was determined between treatments. Secondary endpoints were transfusion rate per 100 patient-exposure years (NDD and DD) and change in mean IV iron use (DD). Adverse events were monitored during treatment + 28 days post treatment (NDD and DD).

Results: In NDD (N=4277) and DD (N=3590) populations, the majority were female (NDD) or male (DD) (Table). Baseline Hb levels were higher in elderly vs younger patients (Table). Age did not affect improvements in Hb, but mean CFB was greater in elderly vs younger in DD and NDD patients (Table). Transfusion rates were lower in younger vs elderly DD patients and in elderly vs younger NDD patients (Table). Trends in mean IV iron use were lower with roxadustat vs epoetin alfa and similar among age groups (Table). Roxadustat was well tolerated, regardless of age (Table).

Conclusions: Roxadustat was effective and well tolerated, regardless of age, in patients with anemia of CKD.

Roxadustat Effectively Treats Anemia in Dialysis-Dependent CKD (DD-CKD) Patients with Ferritin ≥500 ng/mL

Pablo E. Pergola,[1] Steven Fishbane,[2] Chaim Charytan,[3] Stefan Tham,[4] Simon D. Roger,[5] Elizabeta Nemeth.[6] *[1]Renal Associates, San Antonio, TX; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [3]NewYork-Presbyterian/Queens, Flushing, NY; [4]Clinical Research, AstraZeneca, Gothenburg, Sweden; [5]Renal Research, Gosford, NSW, Australia; [6]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, increases hemoglobin (Hb) by increasing erythropoietin and improving iron bioavailability. This pooled *post hoc* analysis evaluated roxadustat vs ESA in DD-CKD patients (pts) with high ferritin.

Methods: Pts were randomized to roxadustat (n=1943) or epoetin alfa (EPO; n=1947) in 3 Phase 3 DD-CKD trials (ROCKIES, SIERRAS, HIMALAYAS). Ferritin was ≥100 ng/mL at entry. EPO and intravenous (IV) iron were given per usual care for EPO; for roxadustat, dose was titrated to Hb 11±1 g/dL and IV iron limited to keep ferritin ≥100 ng/mL and transferrin saturation (TSAT) ≥20%. Pooled subgroup analyses were performed by baseline (BL) ferritin ≥500 ng/mL. P values are exploratory.

Results: At BL, 963 roxadustat and 937 EPO pts had ferritin ≥500 ng/mL: median (min-max) 838 (502-5186) vs 855 (501-4577) ng/mL. Roxadustat vs EPO BL values were balanced for mean age (56 vs 57 years), mean Hb (9.9 g/dL), and median hepcidin (305 vs 301 µg/L), serum iron (68 vs 66 µg/dL) and TSAT (34% vs 33%). Through Week (wk) 52, roxadustat maintained Hb ~11 g/dL with minimal weekly dose change; EPO maintained Hb ~10.5 g/dL with dose increases (Figure). Ferritin reduction from BL was greater with roxadustat vs EPO at wk 20 (-249 vs -202 ng/mL; P=0.01) and to wk 52 (Figure). For roxadustat vs EPO, serum iron (1.6 vs -10.7 µg/dL) and transferrin (0.35 vs 0.01 µg/dL) increased at wk 20 and hepcidin (-88 vs -51 µg/L) reduced at wk 24 (all P<0.01). IV iron use was less with roxadustat vs EPO (29% vs 37% pts).

Conclusions: In DD-CKD pts with high ferritin, EPO pts had lower Hb and impaired iron mobilization despite increased IV iron use and EPO dose. Roxadustat drove ferritin reductions and increased serum iron and transferrin, with minimal dose change, and is an alternative to ESA for DD-CKD pts with high ferritin.

Iron-Related Outcomes in Patients with Dialysis-Dependent CKD Randomized to Vadadustat vs. Darbepoetin Alfa

Wolfgang C. Winkelmayer,[1] Steven Fishbane,[2] James A. Tumlin,[3] Youssef M. Farag,[4] Wenli Luo,[4] Robert Anders,[4] Christine Solinsky,[4] Dennis Vargo,[4] Mark Koury.[5] *[1]Baylor College of Medicine, Houston, TX; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]Emory University School of Medicine, Atlanta, GA; [4]Akebia Therapeutics Inc, Cambridge, MA; [5]Vanderbilt University Medical Center, Nashville, TN.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for treatment of anemia due to chronic kidney disease (CKD).

Methods: We conducted 2 global phase 3, randomized, open-label, active-controlled, noninferiority trials (INNO$_2$VATE) comparing once-daily oral dosing of VADA with the erythropoiesis-stimulating agent darbepoetin alfa (DA) in patients with anemia and incident (N=369) or prevalent (N=3554) dialysis-dependent (DD) CKD. Inclusion criteria: serum ferritin ≥100 ng/mL and transferrin saturation (TSAT) ≥20%. Safety and efficacy results of the INNO$_2$VATE trials were previously reported. Here we report iron-related outcomes, including the changes in mean serum hepcidin, ferritin, total iron-binding capacity (TIBC), iron, and TSAT from baseline to the primary (wk 24–36) and secondary (wk 40–52) evaluation periods.

Results: A total of 1958 patients received VADA and 1965 received DA. VADA treatment was associated with greater decreases in mean hepcidin and ferritin, and increases in TIBC from baseline to the primary and secondary evaluation periods (**Table**). Mean serum iron decreased more in the DA than the VADA group from baseline to wk 24–36 and 40–52. Oral and intravenous iron use was similar in the 2 treatment groups throughout both studies. Similar results were seen in the non–DD-CKD populations (PRO$_2$TECT studies).

Conclusions: The observed relative decreases in hepcidin and ferritin and the increase in TIBC are consistent with a VADA-induced facilitation of iron mobilization from intracellular stores that support erythropoiesis.

Funding: Commercial Support - Akebia Therapeutics, Inc., and Otsuka Pharmaceuticals Development and Commercialization, Inc.

Table. Changes From Baseline in Iron-Related Parameters

	Primary Evaluation Period (wk 24–36)				Secondary Evaluation Period (wk 40–52)

PO0458

Associations Between Hepcidin and Laboratory Measures of Iron and Inflammation in Patients with Anemia and CKD Not on Dialysis in the Roxadustat Global Phase 3 Program

Steven Fishbane,[1] Robert Provenzano,[2] Cameron S. Liu,[3] Tyson T. Lee,[3] Khalil G. Saikali,[3] Lynda Szczech.[3] *[1]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY; [2]Wayne State University, Detroit, MI; [3]FibroGen, Inc., San Francisco, CA.*

Background: Hepcidin is the master regulator of iron homeostasis. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates coordinated erythropoiesis in part by reducing hepcidin. We investigated the associations between hepcidin levels and select laboratories in anemic patients with non-dialysis-dependent chronic kidney disease (NDD-CKD) in the roxadustat studies.

Methods: This exploratory analysis used data from 3 similarly designed pivotal phase 3 studies (OLYMPUS, ANDES, and ALPS) of roxadustat vs. placebo in anemic patients with stage 3-5 NDD-CKD. Quintiles of baseline (BL) hepcidin levels and change from baseline (CFB) in hepcidin were evaluated for associations with select labs at BL and changes at weeks 20-28. Multivariate regression to hepcidin was performed at BL and after treatment using full analysis set.

Results: 2717 patients were assessed (1630 roxadustat, 1087 placebo). BL hepcidin (range 0.75 to 808.2 μg/L) was analyzed by quintile regardless of treatment group. Patients with higher BL hepcidin were observed to have a lower hemoglobin (Hb), lower eGFR, higher C-reactive protein (CRP), higher serum iron, higher ferritin, lower total iron binding capacity (TIBC), and higher transferrin saturation (TSAT) compared to lower BL hepcidin groups (Table). Further analysis of these relationships using multivariate regression models with minimalized AIC score model selection criteria showed that BL hepcidin (log-transformed) was significantly associated with the following BL parameters (log-transformed) in the descending order of importance (+/- indicated the direction): ferritin(+), TIBC(-), eGFR(-), albumin(+), Hb(-). The mean (SD) CFB in hepcidin at week 24 was -23.1 (86.0) μg/L in the roxadustat group vs. +12.3 (87.8) μg/L in the placebo group. Hepcidin associations after treatment will also be presented.

Conclusions: Baseline hepcidin was strongly associated with iron parameters like serum ferritin but not other known factors, such as CRP, in NDD-CKD patients with anemia.

Funding: Commercial Support - FibroGen, AstraZeneca, Astellas

PO0459

Associations Between Hepcidin and Laboratory Measures of Iron and Inflammation in Incident Dialysis Patients with Anemia Enrolled in the Roxadustat Global Phase 3 Program

Robert Provenzano,[1] Steven Fishbane,[2] Cameron S. Liu,[3] Tyson T. Lee,[3] Khalil G. Saikali,[3] Lynda Szczech.[3] *[1]Wayne State University, Detroit, MI; [2]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY; [3]FibroGen, Inc., San Francisco, CA.*

Background: Hepcidin is the master regulator of iron homeostasis. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates coordinated erythropoiesis in part by reducing hepcidin. We investigated the associations between hepcidin levels and select laboratories in incident dialysis (ID) patients with anemia.

Methods: This exploratory analysis used data from three similarly designed, pivotal, phase 3 studies (ROCKIES, HIMALAYAS, and SIERRAS) of roxadustat vs. epoetin alfa in anemic patients with dialysis-dependent chronic kidney disease (CKD). Patients on dialysis for 2 weeks to ≤4 months prior to randomization (defined as ID) were included in the analysis. Quintiles of baseline (BL) hepcidin levels and changes from baseline (CFB) in hepcidin were evaluated for associations with select labs at BL and changes at weeks 20-28. Multivariate regression to hepcidin was performed at BL and after treatment using full analysis set.

Results: 1297 ID patients were assessed (646 roxadustat, 651 epoetin alfa). BL hepcidin (range 5 to 1118.7 μg/L) was analyzed by quintile regardless of treatment arm. Patients with higher BL hepcidin were observed to have higher C-reactive protein (CRP), higher serum iron, higher ferritin, lower total iron binding capacity (TIBC), and higher transferrin saturation (TSAT) compared to lower hepcidin groups (Table 1). Further analysis of these relationships using multivariate regression models with minimalized AIC score model selection criteria showed that BL hepcidin (log-transformed) was significantly associated with the following BL parameters(log-transformed) in the descending order of importance (+/- indicated the direction): ferritin(+), TIBC(-), albumin(+), CRP(+), iron(+). The mean (SD) CFB to week 24 in hepcidin was -63.47 (121.8) μg/L in the roxadustat group vs. -34.84 (141.6) μg/L in the epoetin group. Hepcidin associations after treatment will also be included in the presentation.

Conclusions: Baseline hepcidin was strongly associated with baseline iron parameters and CRP in ID patients with anemia of CKD.

Comprehensive Safety Profile of Vadadustat from Global Phase 3 Clinical Trials

Rajiv Agarwal,[1] Dennis Vargo,[2] Wenli Luo,[2] Christine Solinsky,[2] Glenn M. Chertow.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for treatment of anemia due to chronic kidney disease (CKD).

Methods: We pooled safety data from 4 global phase 3, randomized, open-label studies evaluating VADA vs darbepoetin alfa (DA) in patients from 2 dialysis- and 2 non–dialysis-dependent CKD trials (INNO$_2$VATE and PRO$_2$TECT, respectively) who received ≥1 dose of study drug. We summarized treatment-emergent adverse events (TEAEs) by MedDRA system organ class (SOC) and preferred term (PT). We retrieved AEs of special interest (AESIs) using Standardized MedDRA Queries and analyzed as groups of PTs (medical topics).

Results: A summary of TEAEs by treatment group is provided (**Table)**. The most common in the VADA and DA groups by SOC were infections and infestations (50.8%, 52.7%), gastrointestinal disorders (40.2%, 35.2%), metabolism and nutrition disorders (34.6%, 36.2%), and injury, poisoning and procedural complications (29.5%, 30.7%). The most common drug-related TEAEs in the VADA group were the PTs of diarrhea (2.2%) and nausea (1.2%), leading to study drug discontinuation in 0.4% and 0.2% of patients, respectively. The most frequent serious AEs (SAEs) in the VADA and DA groups occurred in the SOCs for infections and infestations (23.3%, 24.0%) and renal and urinary disorders (18.6%, 18.1%). TEAEs leading to death in the VADA and DA groups were cardiac arrest (1.7% in each group), end-stage kidney disease (1.8%, 1.3%), and cardio-respiratory arrest (0.9%, 1.0%). AESIs (>10%) in the VADA and DA groups were hypertension (18.0%, 21.0%), congestive heart failure (10.3%, 11.5%), and hyperkalemia (9.9%, 11.9%), all of which were more frequent with DA.

Conclusions: VADA exhibited a TEAE safety profile generally comparable to DA.

Funding: Commercial Support - Akebia Therapeutics, Inc., and Otsuka Pharmaceuticals Development and Commercialization, Inc.

Table. Summary of TEAEs in Pooled Phase 3 Studies of VADA (safety population)

	INNO$_2$VATE		PRO$_2$TECT		Total	
n (%)	VADA N=1947	DA N=1955	VADA N=1739	DA N=1732	VADA N=3686	DA N=3687
Any TEAE	1712 (87.9)	1739 (89.0)	1565 (90.0)	1553 (89.7)	3277 (88.9)	3292 (89.3)
Any drug-related TEAE	176 (9.0)	73 (3.7)	195 (11.2)	101 (5.8)	371 (10.1)	174 (4.7)
Drug-related SAE	30 (1.5)	31 (1.6)	36 (2.1)	24 (1.4)	66 (1.8)	55 (1.5)
Drug-related TEAE leading to discontinuation	44 (2.3)	5 (0.3)	29 (1.7)	6 (0.3)	73 (2.0)	11 (0.3)

Vadadustat, an Oral HIF-PHI, Is Not Associated with Increased Risk of Neoplasm in Patients with Anemia due to CKD

Rajiv Agarwal,[1] Dennis Vargo,[2] Wenli Luo,[2] Christine Solinsky,[2] Glenn M. Chertow.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) that stimulates endogenous erythropoietin and red blood cell production. The downstream effects of the transcription of HIF-responsive genes prompted our investigation of the risk of malignancy in patients with chronic kidney disease (CKD) receiving VADA in four global phase 3 trials.

Methods: We examined reports of adverse events (AEs) and serious AEs (SAEs) suggestive of neoplasms according to Standardized MedDRA Queries (preferred terms [PTs]) from four phase 3, randomized, open-label trials evaluating VADA vs darbepoetin alfa (DA) in patients from the two dialysis-dependent (DD) and two non–dialysis-dependent (NDD) CKD (INNO$_2$VATE and PRO$_2$TECT, respectively) who received ≥1 dose of study drug. Patients with a history of active malignancy within two years prior to or during screening were excluded from the trials, except for those with treated basal

cell carcinoma of the skin, curatively resected squamous cell carcinoma of the skin, or cervical carcinoma in situ. Malignancies are reported here as events per 100 patient-years (PY).

Results: In total, 3686 patients were exposed to VADA and 3687 to DA for a median of 56.7 wk (25%, 75th percentile range 31.9–91.7 wk) and 70.0 wk (39.9–102.1 wk); 54.6% and 64.2% patients were exposed for ≥52 wk and 18.9% and 24.1% for >104 wk, respectively. Malignancies in the VADA and DA treatment groups were 2.1 events/100 PY and 2.7 events/100 PY, respectively (relative risk [RR], 0.81; 95% confidence interval [CI], 0.64–1.03). Specifically, malignancies in patients with NDD-CKD were 2.7 vs 3.0 events/100 PY (RR, 0.89; 95% CI, 0.65–1.21), and in patients with DD-CKD were 1.5 vs 2.4 events/100 PY (RR, 0.72; 95% CI, 0.50–1.03), for VADA vs DA, respectively. In both studies, no pattern was observed for any specific type of malignancy, including renal cell carcinoma in patients with DD or NDD CKD.

Conclusions: VADA was not associated with an increased risk of neoplasms compared with DA in patients with anemia and CKD.

PO0462

Assessment of Thromboembolic Events with Vadadustat vs. Darbepoetin Alfa for Treatment of Anemia in Patients with Non-Dialysis-Dependent CKD

Peter A. McCullough,[1] Wenli Luo,[2] Robert Anders,[2] Dennis Vargo,[2] Patrick S. Parfrey.[3] *[1]Baylor University Medical Center at Dallas, Dallas, TX; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Memorial University of Newfoundland, St. John's, NL, Canada.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for treatment of anemia due to chronic kidney disease (CKD). Two recently completed global phase 3, open-label, randomized (1:1), sponsor-blind, noninferiority trials (PRO_2TECT) compared the safety and efficacy of VADA with that of darbepoetin alfa (DA) in adult patients with non–dialysis-dependent (NDD) CKD. One of the studies (NCT02648347) was in 1751 patients previously untreated with an erythropoiesis-stimulating agent (ESA). The other study (NCT02680574) was in 1725 ESA-treated patients. The primary safety endpoint of the PRO_2TECT trials was time to first major adverse cardiovascular event (MACE; a composite of all-cause mortality, nonfatal myocardial infarction, and nonfatal stroke), prespecified as a pooled event-driven analysis of both trials. As previously reported, the hazard ratio (HR; VADA:DA) for MACE was 1.17 (95% confidence interval [CI], 1.01–1.36), which did not meet the prespecified noninferiority margin of 1.25.

Methods: Here we describe the prespecified pooled analysis of the secondary safety endpoints of time to first thromboembolic event, including (1) any thromboembolic event (a composite of events of vascular access thrombosis, arterial thrombosis, deep venous thrombosis [DVT], and pulmonary embolism [PE]), (2) arterial thrombosis, DVT, or PE, and (3) venous thromboembolic events (DVT or PE).

Results: A total of 1739 patients received VADA and 1732 received DA in these two studies. A first thromboembolic event occurred in 33 patients (1.9%) in the VADA group and 38 (2.2%) in the DA group (HR [95% CI]: 0.88 [0.554–1.408]; *P* value of Gray's test=0.569). For arterial thrombosis, DVT, or PE, there were 21 (1.2%) and 25 (1.4%) patients with events, respectively (HR [95% CI]: 0.86 [0.480–1.544]; *P*=0.569), and for venous thromboembolic events, there were 18 (1.0%) and 23 (1.3%), respectively (HR [95% CI]: 0.80 [0.430–1.485]; *P*=0.445). Vascular-access thrombosis was reported as <1.0 event/100 patient years in both the VADA and DA groups.

Conclusions: In the phase 3 PRO_2TECT trial in patients with anemia and NDD-CKD, the rate of thromboembolic events was similar between the VADA and DA groups.

Funding: Commercial Support - Akebia Therapeutics, Inc., and Otsuka Pharmaceuticals Development and Commercialization, Inc.

PO0463

Thromboembolic Events with Vadadustat vs. Darbepoetin Alfa for Anemia Treatment in Patients with Dialysis-Dependent CKD

Patrick S. Parfrey,[1] Wenli Luo,[2] Brad Maroni,[2] Robert Anders,[2] Dennis Vargo,[2] Peter A. McCullough.[3] *[1]Memorial University of Newfoundland, St. John's, NL, Canada; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Baylor University Medical Center at Dallas, Dallas, TX.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for treatment of anemia due to chronic kidney disease (CKD). Two recently completed global phase 3, open-label, randomized (1:1) noninferiority trials ($INNO_2$VATE) compared the safety and efficacy of VADA with that of darbepoetin alfa (DA) in adult patients with dialysis-dependent (DD) CKD. One trial randomized 369 patients with incident DD-CKD (Correction/Conversion trial; NCT02865850) and the other trial randomized 3544 patients with prevalent DD-CKD (Conversion trial; NCT02892149). The primary safety endpoint of the $INNO_2$VATE trials was time to first major adverse cardiovascular event (MACE; a composite of all-cause mortality, nonfatal myocardial infarction, and nonfatal stroke), prespecified as a pooled event-driven analysis of both trials. As previously reported, the pooled MACE risk (hazard ratio [HR]; VADA:DA) was similar between the VADA and DA groups (0.96; 95% confidence interval [CI], 0.83–1.11), which met the prespecified noninferiority margin of 1.25.

Methods: Here we describe the prespecified pooled analysis of the secondary safety endpoints of time to first thromboembolic event, including (1) any thromboembolic event (a composite of events of vascular access thrombosis, arterial thrombosis, deep venous thrombosis [DVT], and pulmonary embolism [PE]), (2) arterial thrombosis, DVT, or PE, and (3) venous thromboembolic events (DVT or PE).

Results: A total of 1947 patients received VADA and 1955 received DA in the 2 studies. A first thromboembolic event occurred in 169 patients (8.7%) in the VADA group and 148 (7.6%) in the DA group (HR [95% CI]: 1.20 [0.959–1.493]; *P* value of Gray's test=0.161). For arterial thrombosis, DVT, or PE, the number of patients with events was 26 (1.3%) and 32 (1.6%), respectively (HR [95% CI]: 0.86 [0.509–1.444]; *P*=0.462), and for venous thromboembolic events, there were 19 (1.0%) and 28 (1.4%), respectively (HR [95% CI]: 0.71 [0.400–1.269]; *P*=0.206). Vascular-access thrombosis was reported as 6.6 events/100 patient years in both the VADA and DA groups.

Conclusions: In the phase 3 $INNO_2$VATE trial in patients with anemia and DD-CKD, the rate of thromboembolic events was similar between the VADA and DA groups.

PO0464

Vadadustat for Treatment of Anemia in Patients with Dialysis-Dependent CKD Receiving Peritoneal Dialysis

Glenn M. Chertow,[1] Neil Boudville,[2] Pradip Chowdhury,[3] Carlos Gonzalez,[6] Laura Kooienga,[7] Wenli Luo,[4] Brad Maroni,[4] K. Adu Ntoso,[5] Dennis Vargo,[4] Kai-Uwe Eckardt.[8] *[1]Stanford University School of Medicine, Stanford, CA; [2]The University of Western Australia Medical School, Perth, WA, Australia; [3]Peritoneal Dialysis Center of America, Montebello, CA; [4]Akebia Therapeutics Inc, Cambridge, MA; [5]Pennsylvania Nephrology Associates, Philadelphia, PA; [6]PIH Health Inc, Whittier, CA; [7]Colorado Kidney Care, Denver, CO; [8]Charité – Universitätsmedizin Berlin, Berlin, Germany.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for treatment of anemia due to chronic kidney disease (CKD). In two recently completed global phase 3 trials in patients with dialysis-dependent CKD (DD-CKD) ($INNO_2$VATE), VADA was noninferior to darbepoetin alfa (DA) for the primary safety endpoint (time to first major adverse cardiovascular event [MACE: a composite of all-cause mortality, nonfatal MI, and nonfatal stroke]) and the primary and secondary efficacy endpoints (correction/maintenance of hemoglobin [Hb]). Here we describe safety and efficacy of VADA compared to DA in the subgroup of patients receiving peritoneal dialysis (PD).

Methods: We conducted two randomized (1:1), phase 3, global, open-label, sponsor-blind, parallel-group active-controlled noninferiority trials ($INNO_2$VATE) comparing VADA vs DA to determine safety and efficacy in patients with anemia of DD-CKD receiving dialysis (either PD or hemodialysis). The prespecified primary safety endpoint was time to first MACE, defined as all-cause mortality or nonfatal myocardial infarction or stroke. The primary and key secondary efficacy endpoints were the mean change in Hb from baseline to wk 24–36 and from baseline to wk 40–52, respectively, in each trial. We assessed the incidence of treatment-emergent adverse events (TEAEs). The efficacy endpoints and TEAE analyses were conducted post hoc.

Results: Of the 3923 patients randomized in the 2 $INNO_2$VATE trials, 309 were receiving PD (VADA, N=152; DA, N=157). Among patients receiving PD, MACE rates were similar in the VADA and DA groups (25/152 [16.4%] and 27/157 [17.2%], respectively). The least-squares mean difference in change in Hb from baseline was –0.10 g/dL (95% CI: –0.33, 0.12) to wk 24–36 and –0.19 g/dL (95% CI: –0.43, 0.05) to wk 40–52. Primary and key secondary efficacy endpoints met the prespecified noninferiority margin of –0.75 g/dL. The incidence of overall TEAEs was 88.2% vs 95.5% and of serious TEAEs was 52.6% vs 73.2% in the VADA and DA groups, respectively.

Conclusions: Among patients receiving PD in the $INNO_2$VATE phase 3 trials, safety and efficacy of VADA were comparable to DA.

Daprodustat Is Noninferior to Darbepoetin Alfa in Treating Anemia in Incident Dialysis Patients

Ajay K. Singh. for the ASCEND-ID Study Group *Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Daprodustat (Dapro) is a hypoxia-inducible factor prolyl hydroxylase inhibitor that is being evaluated as an alternative to conventional erythropoiesis stimulating agent (ESA) therapy. Treatment with Dapro in incident dialysis dependent (ID) patients (pts) that are at high risk for co-morbidity and mortality has not been examined previously. This Phase 3 trial evaluated the efficacy and safety of Dapro vs darbepoetin alfa (Darbe) in the ASCEND-ID (NCT03029208) study.

Methods: Pts who started on hemodialysis (HD) or peritoneal dialysis (PD) were randomized to Dapro or Darbe to maintain hemoglobin (Hb) at 10–11 g/dL in an open-label (sponsor-blind) 52-week study. Eligible pts were ≤3 months from initiation of HD or PD, ESA naïve or of limited ESA exposure, Hb 8–11.0 g/dL, and iron replete. Primary endpoint tested non-inferiority of Dapro vs Darbe (analysis of covariance) for mean change in Hb between baseline (BL) and Evaluation Period (EP) in weeks 28–52. Secondary endpoint included IV iron use.

Results: 312 pts from 14 countries were randomized; of those, 81% started on HD and 31% had an unplanned dialysis start. Overall 99% (155/157) pts on Dapro and 97% (151/155) on Darbe completed the study. Major BL characteristics were balanced, except age (mean 53.7 y vs 55.8 y) and history of heart failure (16% vs 22%) in Dapro vs Darbe, respectively. Hb measurements from EP are shown below. Mean (SD) Hb in EP was 10.5 (1.0) g/dL and 10.6 (0.9) g/dL (Dapro vs Darbe). There was no significant difference in mean (SE) monthly IV iron use 145 (10.9) mg vs 125 (11.0) mg (Dapro vs Darbe). Rescue treatment was the same in both groups (3%). While the number of subjects with worsening of hypertension (24% Dapro vs 19% Darbe) was numerically higher, the overall effect of dapro on BP was similar to Darbe. Rates of AEs were similar (76% Dapro vs 72% Darbe).

Conclusions: In a high-risk incident dialysis population, Dapro was non-inferior to Darbe in maintaining Hb in the target range. Dapro was well tolerated and appears to be a safe alternative to Darbe.

Funding: Commercial Support - GlaxoSmithKline

Mean Difference in Hb Change from BL in Dapro vs Darbe groups

Hb analysis Weeks 28–52	Population	Arm	n/N (%)	Adjusted mean Hb (g/dL) difference (95% CI)*
Post-randomization (observed and imputed)	ITT	Dapro Darbe	157/157 (100) 155/155 (100)	–0.10 (–0.34, 0.14)
Evaluable	ITT	Dapro Darbe	133/157 (85) 133/155 (86)	–0.20 (–0.43, 0.04)
Evaluable	PP	Dapro Darbe	77/77 (100) 101/101 (100)	–0.12 (–0.38, 0.14)

*Non-inferiority was declared when the lower boundary of the 95% CI for the treatment difference was greater than the prospectively defined non-inferiority margin of 0.75 g/dL.
ITT, intent-to-treat PP, per-protocol

Suboptimal Treatment of Anemia in CKD Non-Dialysis Patients: What Role Will HIF-PH Inhibitors Play?

Jennifer Robinson, Meghan Staudt, Tucker B. Hurtado. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: The purpose of this study was to understand the real-world patient presentation and treatment priorities for CKD non-dialysis patients, focusing on the treatment of anemia of CKD.

Methods: Using a HIPAA-compliant, online chart audit tool, nephrologists (n=183) submitted de-identified clinical and non-clinical demographic information for 1,030 non-dialysis patients with CKD (eGFR<60) in Fall 2020. This independent, retrospective patient chart audit collected data beginning at the time of patient referral and concluded with details from the most recent visit.

Results: As CKD progresses so too does the prevalence of anemia, with nearly six-in-ten CKD Stage 5 patients identified by their physicians as having anemia. However, while anemia is a common comorbidity in CKD non-dialysis patients, physicians tend to deprioritize the disease when consulting with these patients in their offices. When asked about topics discussed during their most recent patient visit, anemia falls behind other topics such as hypertension, weight and diet, and quality of life. Although anemia is less of a priority, more than 60% of patients did have a hemoglobin test ordered at their most recent visit, indicating that physicians are monitoring hemoglobin levels somewhat regularly to help keep track of potential anemia. More than one-half of CKD non-dialysis patients treated with ESAs have a hemoglobin level below 10.0 g/dL; however, the most common reason for non-treatment in patients with levels between 9.0 and 9.9 g/dL is that the hemoglobin is "not low enough", indicating physicians are waiting until hemoglobin is substantially low before starting treatment with ESAs. HIF-PH inhibitors are a novel class in development for the treatment of anemia, and nephrologists express a willingness to use the agents in their CKD non-dialysis patients who are not currenlty treated (45% Stage 3, 52% Stage 4 and 60% Stage 5). More than one-half (58%) would also be willing to switch ESA-treated non-dialysis patients to a HIF-PH inhibitor once they are approved, indicating there is a large opportunity for this class to have an impact on the treatment of anemia.

Conclusions: Enhanced communication with non-dialysis patients about anemia, as well as earlier detection and intervention with novel HIF-PH inhibitors, could lead to better anemia outcomes.

PO0467

Renal Injury Biomarkers Are Elevated in Acute Hepatic Porphyria

Simina Ticau,[1] Kristina Yucius,[1] Alexandre Karras,[2] Eliane Sardh,[3] Laurent Gouya,[4] Amy Simon,[5] Anna Borodovsky.[1] *[1]Alnylam Pharmaceuticals Inc, Cambridge, MA; [2]Department of Nephrology, Hopital Européen Georges Pompidou, APHP, Paris, France; [3]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [4]CRMR Porphyries, Hôpital Louis Mourier, APHP, Paris, France; [5]Beam Therapeutics, Cambridge, MA.*

Background: Acute hepatic porphyria (AHP) is a group of rare genetic diseases caused by defects in enzymes in the heme biosynthesis pathway. Acute intermittent porphyria (AIP) is the most common subtype. In patients with AHP, accumulation of heme pathway intermediates, delta-aminolevulinic acid (ALA) and porphobilinogen (PBG), lead to acute attacks and long-term complications including hypertension and chronic kidney disease which is present in 30-60% of patients with biochemically active AIP. Chronic high excreters (CHE) are a group of patients that carry a genetic mutation and have elevated levels of ALA and PBG but are not experiencing acute attacks.

Methods: Proteomic analysis (Olink® platform) was used to measure 1196 proteins in plasma from consenting AHP patients with recurrent acute attacks (>90% AIP) in the EXPLORE natural history study, the ENVISION Phase 3 study, and CHE patients in the ALN-AS1-001 Phase 1 study at baseline. A separate cohort of healthy controls, age- and gender-matched to EXPLORE patients was also analyzed. Linear regression accounting for age, and sex was used to determine the proteins that were significantly different between AHP patients or CHE patients and controls.

Results: 212 plasma proteins were significantly different between healthy controls and patients with AHP. Two proteins with the largest effect sizes, kidney injury molecule-1 (KIM1; 3.4-fold; p-value= 8.0e-13) and matrix metalloproteinase-7 (MMP7; 5-fold; p-value= 1.5e-25) were previously described as biomarkers of renal injury. Three additional kidney injury biomarkers (neutrophil gelatinase-associated lipocalin, cystatin C (CST3) and chitinase-3-like protein 1) showed significant elevations in patients with AHP. Moderate to strong correlations were observed between each of these biomarkers and eGFR (correlation coefficients -0.33 to -0.54). AHP patients with a diagnosis of renal disease demonstrated significantly higher levels of each of these biomarkers than patients without such a diagnosis (p-values <0.01). KIM1, MMP7, and CST3 were also significantly elevated in CHE patients compared to controls.

Conclusions: Renal injury biomarkers may aid in diagnosing and managing kidney disease in patients with AHP suffering from recurrent acute attacks as well as chronic high excreters.

PO0468

A Contemporary View of Erythropoietin-Stimulating Agent Switching: Determining a Dose Conversion Ratio (DCR) from IV Epoetin Alfa to IV PEG-Epoetin Beta and SC Epoetin Beta to Preserve Haemoglobin Control in Haemodialysis Patients

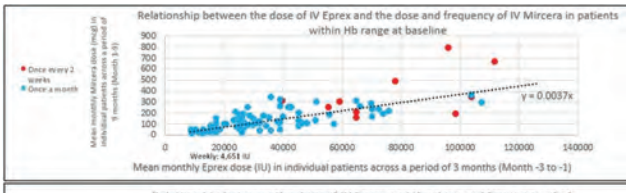
Lee White,[1] Rhys Williams,[1] Mark Gumbleton,[2] Justine Jenkins,[2] Greta Llyr,[2] Laura A. Galloway,[2] Christopher Brown,[2,1] Ashraf I. Mikhail,[1] Owain Brooks.[1] *[1]Swansea Bay University Health Board, Port Talbot, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom.*

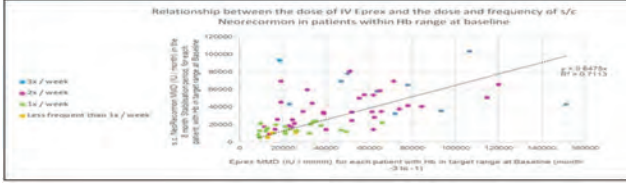
Background: Recent studies, such as PIVOTAL, in haemodialysis show the benefit of adequate iron repletion, including reduction in ESA dose. This study aims to determine the DCR to maintain Hb stability in a contemporary HD cohort, switch from IV epoetin alfa (Eprex®), to sc epoetin beta (Neorecormon ®) or IV PEG-epoetin beta (Mircera®).

Methods: This observational study from a UK single-centre analysed Hb stability and ESA requirements in 260 HD patients on IV epoeitin alfa, who switched to sc epoetin beta (n=118) or IV PEG-epoetin beta (n=142). Data from a 3 mth Baseline period were compared to a 9 mth post-switch Evaluation period. The DCRs were are calculated using Evaluation dose / Baseline dose. The target Hb was 100-120g/L. Iron requirements were determined from TSAT, Ret-He and Ferritin.

Results: The mean Hb, Hb in target, ESA dose, frequency and DCR were: For IV PEG-epoetin beta group 109g/L, 75%, 10418 iU/wk, 3/wk, at baseline;109g/L, 81%, 181mcg/mth, 1/mth, at evaluation; resulting DCR 1mcg:249iU. For sc epoetin beta 111g/L, 74%, 9717IU/wk, 3/wk, at baseline; 111g/L, 88%, 7528 iU/wk, 2/wk, at evaluation; resulting DCR of 0.8. At these DCRs the Hb stability was maintained throughout the study. Sub-group analysis for baseline Hb in the PEG-epoetin beta group were 1:255 (Hb in range), 1:239 (Hb below range), 1:253 (Hb above range).

Conclusions: These data show that the DCR of 0.8 for epoetin IV to sc, with a reduction in frequency for sc, is in keeping with published literature and product license. The DCR of 1mcg:249iU for PEG epoetin-beta IV: epoetin alfa IV is higher than the typical 1mcg:200iU reported in the literature. These dose conversion data will benefit clinicians wishing to switch ESA, and provide insight into the bio-equivalencies and reduced administration frequencies into any logistical or costing model.





PO0469

Anemia Care of Hemodialysis Patients: A National Study from Qatar

Abdullah I. Hamad, Nadiya N. Khan, Hany E. Ismail, Fatma A. Ramadan, Sahar Aly, Vimala K. Lonappan, Fadumo Y. Yasin, Mariamma Thomas, Rania A. Ibrahim, Fadwa M. Al-Ali. *Hamad Medical Corporation, Doha, Qatar.*

Background: Achieving anemia targets in dialysis patients is hard. Challenges like cost, compliance and erythropoietin stimulation agents (ESA) resistance can hamper anemia management. We established a new national anemia nurse manager model to improve care of anemia in dialysis patients in the State of Qatar. Key drivers of the new model are summerized in Figure below. We studied the effects of this program in improving anemia care in hemodialysis patients.

Methods: We did a retrospective study (IRB 01-20-158) to evaluate effectiveness of anemia nurse manager program in achieving anemia targets (percentage of patients with hemoglobin (Hg) in target (optimal range of 10-12g/dL)) and avoid extreme Hg (high (>13 g/dL) or low Hg (<9 g/dL) to avoid complications. We also studied effect of this model on ESA dosing. Our study included all adult ambulatory hemodialysis patients in the State of Qatar. Study duration was from July 2018-February 2020. Data was extracted from the Qatar national electronic medical rocord system.

Results: Our ambulatory HD patients increased from 535 to 575 during study duration. Age was 59+/-11 years with 59% male gender. Patients were mostly from the Middle East area 82% with 11% from South Asia and 5 % from East Asia. There was a significant improvement in patients with target Hg 10-12 g/dL (from 66% in July 2018 to 78% in February 2020, p=0.00001). Patients with extreme Hg were maintained at very low level throughout the study period (Hg<9 of 3.7% +/- 0.9% and Hg >13 of 4% +/- 0.7%). ESA dose was steady without much fluctuations (Darbepoietin 42.2+/-3.73 mcg/week and Mircera 149+/-18 mcg/month).

Conclusions: Our study showed that the new anemia care model improved anemia targets (Hg in range and low percentage of extreme Hg). ESA dose was steady during study period. Based on this result, we are implemnting similar models in different clinical areas in dialysis to improve patient care.

Anemia Treatment Patterns and First-Year Cardiovascular Outcomes in Incident ESKD Patients Undergoing Hemodialysis (2015-2018)

Eric D. Weinhandl,[1,2] William Eggert,[1] Jeffrey Petersen,[3] Yunji Hwang,[3] David T. Gilbertson.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Amgen Inc, Thousand Oaks, CA.*

Background: The first months of maintenance hemodialysis are characterized by a relatively high rate of death and by correction of anemia—mean hemoglobin (Hb) among incident end stage kidney disease (ESKD) patients is only 9.3 g/dL (source: 2020 USRDS Annual Data Report)—so it is hypothesized that new anti-anemia treatments could be utilized to improve outcomes. We assessed Hb, erythropoiesis-stimulating agent (ESA) dosing, and major adverse cardiac event-plus (MACE+) incidence during the first year of hemodialysis (HD), among users of either epoetin alfa (EPO) or darbepoetin alfa (DARB).

Methods: We analyzed United States Renal Data System Standard Analysis Files. The cohort comprised patients with newly diagnosed ESKD between 1 Jan 2015 and 30 Sep 2018 and whose primary modality was HD. We retained patients who used either EPO or DARB during the first month of HD, per CROWNWeb data. We followed patients until the earliest of kidney transplant, death, the end of the first year of ESKD, or 30 Sep 2019. During follow-up, we tabulated mean Hb and weekly ESA dose, by month. Among patients with Medicare coverage, we estimated the incidence of MACE+, as defined by death, myocardial infarction, stroke, or hospitalization for heart failure.

Results: Among 251,342 incident ESKD patients who initiated both HD and ESA treatment, 130,736 and 50,197 used EPO and DARB, respectively. Among EPO users, mean Hb was 9.9 g/dL in month 1 and between 10.6 and 10.7 g/dL thereafter. Mean weekly doses of EPO were 13,064 IU in month 1; 10,922 IU in month 4; 10,212 IU in month 7; and 9756 IU in month 10. Among DARB users, mean Hb was between 9.9 g/dL in month 1 and between 10.4 and 10.6 g/dL thereafter. Mean weekly doses of DARB were 39.3 mcg in month 1; 33.5 mcg in month 4; 32.5 mcg in month 7; and 31.7 mcg in month 10. Among EPO and DARB users, the cumulative incidence of MACE+ was 28.7% at 6 months and 49.1% at 12 months.

Conclusions: Anemia treatment among incident HD patients using either EPO or DARB is characterized by a brief increase in Hb, reaching a plateau of 10.5 to 10.7 g/dL, and steadily declining ESA doses during the first year. The incidence rate of MACE+ remains higher during the early versus late part of the first year. Real-world data are useful when evaluating benefits and risks of new anti-anemia treatments.

PO0471

Contemporary Anemia Treatment in Prevalent Patients Undergoing Hemodialysis

Eric D. Weinhandl,[1,2] William Eggert,[1] Jeffrey Petersen,[3] Yunji Hwang,[3] David T. Gilbertson.[1] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Amgen Inc, Thousand Oaks, CA.*

Background: Anemia treatment remains a major area of focus in the management of maintenance dialysis patients. We assessed hemoglobin (Hb) and erythropoiesis-stimulating agent (ESA) dosing among hemodialysis (HD) patients with records in CROWNWeb, a national reporting system that captures data from all prevalent patients undergoing maintenance dialysis, regardless of whether patients carry Medicare coverage.

Methods: We analyzed United States Renal Data System Standard Analysis Files. For each calendar month from January 2015 to September 2019, we identified adult (age ≥18 years) patients who underwent HD during the entire month and whose CROWNWeb records included a valid measurement of single-pool *Kt/V*. In each patient-month, we identified Hb and ESA treatment (agent [epoetin alfa, darbepoetin alfa, or pegylated epoetin beta] and monthly cumulative dose). Subsequently, we tabulated the distribution of Hb in each month, incidence of 3-month and 6-month series with Hb <10.0 g/dL; utilization of ESAs, overall and by agent; and mean weekly ESA dose, by agent.

Results: Among 878,883 patients in the study period, 7.2% of patient-months had Hb <9.0 g/dL, 15.2% had Hb 9.0-9.9 g/dL, 35.3% had Hb 10.0-10.9 g/dL, 28.5% had Hb 11.0-11.9 g/dL, and 13.9% had Hb ≥12.0 g/dL. The prevalence of Hb <9.0 g/dL was relatively higher with age 18-44 years, Black race, and female sex. Among all 6-month series of Hb measurements, 5.8% had Hb <10.0 g/dL for 3 consecutive months and only 2.0% had Hb <10.0 g/dL for 6 consecutive months. Approximately 76% of patients received an ESA in each month. In 2019, 34% used epoetin alfa, 9% used darbepoetin alfa, and 33% used pegylated epoetin beta. Mean (median) weekly doses were 10,562 (7727) IU for epoetin alfa, 35.9 (23.0) mcg for darbepoetin alfa, and 33.6 (23.0) mcg for pegylated epoetin beta.

Conclusions: Between 2015 and 2019, despite substantial flux in the mix of ESAs used, distributions of hemoglobin and ESA doses among patients undergoing HD were stable, with only a small percentage of patients experiencing persistently low hemoglobin.

PO0472

Estimating Long-Term Survival Rates in Patients with Anaemia of Non-Dialysis-Dependent CKD: An Expert Elicitation

Juan Jose Garcia Sanchez,[1] Johannes Nicolaas Martinus Ouwens,[2] Bart J. Willigers,[1] Andrew Briggs,[3] Oliver Darlington,[5] Purav R. Bhatt,[4] Eric T. Wittbrodt,[4] Marvin Sinsakul,[4] Susan Grandy,[4] Hiddo J. L Heerspink,[7] Carol A. Pollock,[6] Roberto Pecoits-Filho,[8,12] Navdeep Tangri,[9] Csaba P. Kovesdy,[10] David C. Wheeler.[11] *[1]AstraZeneca PLC, Cambridge, United Kingdom; [2]AstraZeneca AB, Mölndal, Sweden; [3]London School of Hygiene & Tropical Medicine, London, United Kingdom; [4]AstraZeneca, Wilmington, DE; [5]Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; [6]The University of Sydney, Sydney, NSW, Australia; [7]The University of Groningen, Groningen, Netherlands; [8]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [9]The University of Manitoba, Winnipeg, MB, Canada; [10]The University of Tennessee Health Science Center, Memphis, TN; [11]University College London, London, United Kingdom; [12]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Clinical trials for the treatment of anemia of CKD provide mortality data. Cost-effectiveness analyses of new treatments require survival extrapolations over a lifetime time horizon. An expert elicitation was conducted to obtain estimates of long-term survival probabilities for patients with anemia of non-dialysis dependent (NDD) CKD.

Methods: Literature searches were used to identify clinical trials and observational studies that included patients with anemia of NDD CKD aged ≥ 18 years, that had > 500 participants per study arm and that reported all-cause death incidence and/or survival Kaplan–Meier (KM) curves. Study data were extracted and collated. KM curves were extrapolated to 20 years by calculating standardized mortality ratios (SMRs) compared to age- and sex-adjusted general population lifetables. A summary of relevant data was presented to six CKD experts. After an elicitation training, the experts made a judgment on the 10th, 50th and 90th percentile of 10- and 20-year survival of patients with anemia of NDD CKD. The individual judgments were combined into an overall assessment.

Results: From the literature, all-cause death incidence in patients with anemia of NDD CKD was 3.5–39.4 per 100 patient-years (five studies). From SMR-extrapolated KM curves, estimated survival at 10 and 20 years was 30–57% and < 1–13%, respectively (three studies; median age of 80 and 68 years in two studies, and mean age of 66 in the third). The aggregated elicited survival values were 50% (80% confidence interval [CI]: 34–64%) at 10 years and 21% (80% CI: 8–36%) at 20 years.

Conclusions: The elicited survival estimates could be used to model long-term survival and complement results from other extrapolation methods to inform and validate cost-effectiveness analyses. Long-term survival extrapolations are also likely to support patients and physicians with treatment decisions.

The Effect of a Patient Blood Management Program on Renal Outcome in Patients with CKD

Hyeon-Jin Min, Tae-bum Kim, Young-Bin Son, Jonghyun Lee, Jihyun Yang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho, Sewon Oh. Division of Nephrology, Department of Internal Medicine, Korea University Anam Medical Center *Korea University Medical Center, Seoul, Republic of Korea.*

Background: Transfusion burden is high in CKD patients to treat anemia. However, transfusions had risks including volume overload, alloimmunization, blood stream infections and thromboembolism. We evaluated the effect of a monitoring program to identify appropriate transfusions in CKD patients.

Methods: Based on the guidelines of the Korean Society of Blood Transfusion, Korea University Anam Medical Center developed a verification program to assess the adequate indication of transfusion (patient blood management(PBM)) in August 2018. We analyzed 1,192 CKD patients admitted to the department of nephrology from August 2016 to July 2020. Patients were divided into two groups: patients who admitted before the implementation of PBM (pre-PBM(n=592)) and after the implementation of PBM (post-PBM(n=600)).

Results: The amount of blood transfused was 628 units in pre-PBM group and 443 units in post-PBM group. The patients who received more than 2 units was significantly lower in post-PBM group (20.1% vs. 13.5%, p=0.002). There were no differences in the administered doses of erythropoietin and iron between the groups. Although hemoglobin(Hb) (10.5±2.0 vs. 10.3±2.2) were not different between the two groups at admission, Hb levels were significantly lower in post-PBM group at discharge (10.4±1.8 vs. 10.1±2.0, p=0.010) and 6 months after admission (11.5±1.9 vs. 11.1±2.0, p=0.007). Kaplan-Meier analysis showed a survival benefit of CKD progression (≥50% increase in serum creatinine) (p<0.001) and percutaneous coronary intervention (p=0.030) in the post-PBM group. The incidence of end stage kidney disease or mortality was not different between groups. In multivariate analysis, PBM was associated with lower risk for CKD progression (HR of 0.587; 95% CI 0.416-0.830).

Conclusions: Patient blood management program may reduce inappropriate RBC transfusion. Implementation of PBM was associated with lower risk of CKD progression in hospitalized CKD patients.

PO0474

Ferric Pyrophosphate Citrate (Triferic® AVNU): Alternate Intravenous Dosing Strategies Compared to Continuous Infusion over 3 Hours

Raymond D. Pratt. *Rockwell Medical Inc, Wixom, MI.*

Background: Ferric pyrophosphate citrate injection (FPC-IV) is an iron replacement product to maintain hemoglobin by intravenous infusion over 3 to 4 hours. The aim of this study was to investigate FPC-IV pharmacokinetics and confirm safety of alternate dosing strategies.

Methods: An open-label, randomized, multiple period single dose study was conducted in 23 CKD-5HD patients to establish the equivalence of doses between FPC-IV as a 3-hour infusion using the on-machine syringe pump and 5 alternate dosing strategies. The treatments were A) Baseline FPC-IV 6.75 mg Fe/3 hours (approved rate); B) FPC-IV 3.38 mg Fe bolus injections at t=0 and t=3 hours; C) FPC-IV 6.75 mg Fe bolus injection at t=0 hours over 0.5 - 5 min. and D) FPC-IV 2.25 mg Fe bolus injections at t=0, t=1.5 and t=3 hours and E) FPC-IV 6.75 mg Fe by infusion using a spring-driven syringe pump with flow restrictive tubing to deliver 2 mL/hr]. Blood samples were obtained to assess total iron (Fe_{tot}), transferrin bound iron (TBI), transferrin saturation (TSAT) and iron binding capacity (TIBC).

Results: The results for TSAT (Fig.1) track the administration group. FPC-IV was generally well tolerated in all treatments. There was transient flushing and abdominal discomfort of mild to moderate severity associated with treatment C (bolus injection of FPC over 0.5-5 min.) experienced by 15 of 16 patients. All symptoms spontaneously resolved over 2 to 5 minutes and no adverse events or intolerance was reported with any other treatment.

Conclusions: The results of this study demonstrate that FPC-IV can be safely administered as a continuous infusion over 2.5 to 4 hours or as IV bolus administration of 1/2 or 1/3 of the total dose at intervals during the course of dialysis. Bolus administration of the entire dose is not recommended due to the transient intolerance associated with the rapid administration. The study expands the dosing strategies for the administration of FPC.

Funding: Commercial Support - Rockwell Medical Inc.

Ferric Pyrophosphate Citrate (Triferic® AVNU) Injection: Alternate Intravenous Dosing Using a Spring-Driven External Infusion Pump

Abdul A. Abdellatif,[1,2] Raymond D. Pratt.[3] *[1]Clear Lake Specialties, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Rockwell Medical Inc, Wixom, MI.*

Background: Ferric pyrophosphate citrate injection (FPC-IV) is an iron replacement product to maintain hemoglobin by intravenous infusion (IV) over 3 to 4 hours. Some hemodialysis (HD) centers cannot use HD system syringe pumps for drug administration. We investigated the use of a spring-driven syringe pump to infuse FPC IV into the pre-or post dialyzer blood lines.

Methods: An open-label, study was conducted in 12 HD patients at 6 treatments. FPC-IV (6.75mg Fe/4.5 mL) was drawn up into 20 mL syringes. The syringe was attached to a flow-restrictor tubing 2 mL/hr (nominal rate) and then attached to the the pre-Dialyzer blood line port or to the venous drip chamber. The syringe was placed in the chamber of the FreedomEdge® Pump (FP) and the pump activated. Blood for serum iron (sFe) and transferrin saturation (TSAT) was collected pre-hemodialysis and immediately post infusion.

Results: FP Delivery of FPC took an average of 134 ± 31.7 minutes (Range 71 to 195 min). The mean increment in sFe pre- to post infusion was 202 ± 73.7 µg/dL. The pump set up, including loading the syringe, took an average of 109 ± 42.7 sec (Range: 48 to 251 sec.). The incremental sFe in this study is compared to the dialysate and IV FPC infusions over 3 hours in Figure 1. The sFe was rapidly cleared with no increase in pre-dialysis sFe. FPC-IV was well tolerated with no reported adverse events.

Conclusions: The results of this study demonstrate that FPC-IV can be safely administered as a continuous infusion using a spring-driven pump (FP) over 71 to 195 minutes. The increment in sFe is slightly greater than the 3 or 4-hour FPC infusions due to the shorter administration time. A spring-driven infusion pump to administer FPC IV is well-tolerated and a suitable alternative to use of the Hemodialysis machine syringe pump.

Association Between Serum Indices of Iron Metabolism and Cardiovascular Morbidity in Patients with Pre-Dialysis CKD

Takeshi Hasegawa,[1] Takahiro Imaizumi,[2] Kenta Murotani,[5] Takayuki Hamano,[3] Hirotaka Komaba,[4] Naohiko Fujii,[6] Masafumi Fukagawa.[4] *[1]Showa Daigaku, Shinagawa-ku, Japan; [2]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [3]Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan; [4]Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan; [5]Kurume Daigaku, Kurume, Japan; [6]Hyogo Kenritsu Nishinomiya Byoin, Nishinomiya, Japan.*

Background: The optimal ranges of serum iron markers are uncertain in predialysis chronic kidney disease (CKD) patients. Therefore, we aimed to investigate the association between serum indices of iron metabolism and the incidence of CVD events in patients with predialysis CKD using the CKD-Japan Cohort (CKD-JAC) data.

Methods: We prospectively followed 1,550 CKD patients aged 20-75 years with an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m2 for a mean of 4.21 years. We set serum transferrin saturation (TSAT) and ferritin levels as the main exposures to be tested. Our main outcome measures were any of the CVD events including congestive heart failure (CHF) identified at each facility and adjudicated by the independent cardiac function evaluation committee. Multivariable Cox proportional hazards regression models were employed to examine the association between serum TSAT or ferritin levels with time to events. All models were stratified by facilities and adjusted for potential confounders. We also applied the multivariable fractional polynomial interaction (MFPI) approach to investigate whether serum TSAT or ferritin levels are the effect modifier of the association between iron supplementation and the outcomes.

Results: In the overall cohort, 208 (13.4 %) patients developed CVD events (including 97 CHF) during the follow-up period (26.6 events/1000 person-year). The incidence rate of CVD events was the highest in the TSAT < 20% category (33.0 events/1000 person-year). Compared to patients in the TSAT > 40% category, those in the TSAT < 20% category demonstrated an increased risk of CVD events (adjusted hazard ratio (AHR): 1.86, 95% confidence interval (CI): 1.06-3.26) and CHF events (AHR: 2.82, 95% CI: 1.15-6.89), respectively. There was no association between serum ferritin levels and the risk of CVD or CHF events. MFPI analyses showed a reduced risk of CVD in patients receiving iron supplementation only in patients with TSAT < 20% (P for interaction=0.02).

Conclusions: Maintaining TSAT > 20% could be effective to reduce the risk of developing CVD events (especially CHF) in patients with predialysis CKD. Our analyses also suggest that iron-deficient patients with predialysis CKD may benefit from iron supplementation for reduced risk of CVD events.

PO0477

Serum Erythroferrone and Serum Hepcidin 25 Are Associated with CKD

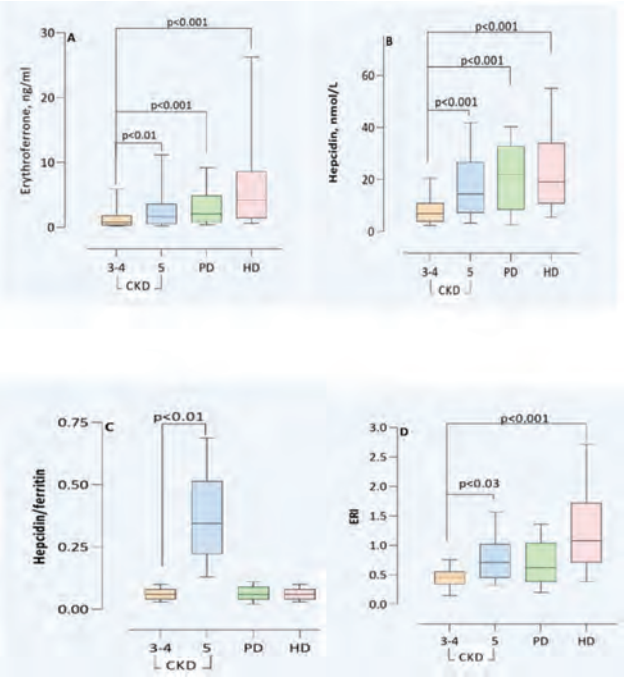
Kristin Danielson Pistis, Abdul Rashid T. Qureshi, Peter Stenvinkel, Bengt Lindholm, Peter F. Barany. *Karolinska Institutet Institutionen for klinisk vetenskap intervention och teknik, Huddinge, Sweden.*

Background: Erythroferrone is a recently discovered hepcidin suppressor expressed in erythroblasts in response to erythropoietin (EPO) with the downstream effect of increased iron availability. In light of the central role of hepcidin-25 in the pathogenesis of anemia, we determined serum erythroferrone, serum hepcidin-25, the hepcidin/ferritin ratio, and the ESA hyporesponsivess index (ERI) in different stages of chronic kidney disease (CKD).

Methods: Erythroferrone was determined by ELISA in 602 CKD patients (97 CKD 3-4, 220 CKD 5 non-dialysis patients, 76 prevalent peritoneal dialysis (PD) patients, and 209 prevalent hemodialysis (HD) patients. The ERI was calculated as follows: ESA dose (international units) per kg/haemoglobin level (g/L) per week. Differences in levels of erythroferrone (ng/ml), hepcidin-25 (nmol/L), the hepcidin ferritin ratio, and ERI between stages of CKD were assessed by non-parametric ANOVA.

Results: Serum erythroferrone and serum hepcidin-25 increased with increasing CKD stage and was higher in patients with CKD 5, in PD patients, and in HD patients as compared to patients with CKD 3-4 (Figure A, B). When levels of hepcidin-25 were corrected for serum ferritin levels (hepcidin/ferritin ratio), only patients in CKD 5 had higher levels as compared to patients in CKD 3-4 (Figure C). Estimated ERI was higher in CKD 5 and HD patients as compared to CKD 3-4 patients (Figure D). The high tertile of erythroferrone in CKD 5 was associated with worse clinical outcome. No significant association with clinical outcome was observed in other cohorts.

Conclusions: Serum erythroferrone, serum hepcidin and ERI were linearly associated with deteriorating renal function. We found significant association of erythroferrone to all-cause mortality in CKD 5 patients.



PO0478

Cardiorenal Anemia Syndrome in Heart Failure Patients with Reduced vs. Preserved Ejection Fraction: An Insight from the Middle East

Yosef Manla, Feras Bader, Shahrukh Hashmani, Hussam Ghalib, Wasim El Nekidy, Fadi A. Hijazi, Nizar M. Attallah. *Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates.*

Background: Patients with cardiorenal syndrome (CRS) have an increased risk of developing anemia, resulting in cardiorenal anemia syndrome (CRAS), which can lead to worsening renal and cardiac functions. This gets more complicated when multiple systemic conditions co-exist, such as in heart failure with preserved ejection fraction (HFpEF). To better understand the interplay between anemia, the heart, and the kidney, we aim to explore patients' characteristics of CRAS within different heart failure (HF) phenotypes, in the Middle East Region.

Methods: We included HF patients having stage 3-5 CKD (n=230) at their first visit to our HF clinic from October 2015 to January 2019. Patient characteristics were collected by a retrospective chart review. A comparison was made between HFrEF and HFpEF in CRAS patients in terms of baseline characteristics and iron deficiency anemia surrogates using appropriate parametric or non-parametric (for skewed variables) testing methods, and a p-value< 0.05 was considered statistically significant.

Results: Among 230 patients with cardiorenal syndrome, 138 (60%) of patients had anemia (Hb<120 g/L). There was no significant difference in the prevalence of anemia in the HFrEF- CRS group vs. HFpEF- CRS group (57.4% vs. 66.2%, p=0.2). When comparing HFrEF- CRAS patients with HFpEF- CRAS patients, the HFpEF group were more likely females, had lower hemoglobin, and higher rates of cardiovascular co-morbidities (Table). Furthermore, there was no significant difference in iron deficiency parameters between the two groups.

Conclusions: In this part of the world, where cardio-renal-metabolic conditions are highly prevalent, the prevalence of anemia among CRS patients is comparable to western countries and it was comparable among HFpEF and HFrEF CRS patients

Table. Baseline characteristics of patients with cardiorenal anemia syndrome according to their heart failure phenotype

Variable	HFrEF- CRAS patients (n=93)	HFpEF- CRAS patients (n=45)	P-value

Hypersensitivity Reaction to Epoetin-Alfa: A Therapeutic Challenge

Saiyed W. Ali, Brian Y. Young, Nasim Wiegley. *University of California Davis Department of Internal Medicine, Sacramento, CA.*

Introduction: Use of erythropoiesis stimulating agents (ESA) prevent the need for recurrent blood transfusions in patients with advanced kidney disease. Rarely, patients can have allergic reactions to the ESA components which can range from pruritic rash to fatal angioedema. We report a case of delayed-type hypersensitivity reaction (DTH) due to epoetin-alfa (EPO). Cross-reactivity between molecular structures of various agents raises a therapeutic challenge.

Case Description: A 78 year old man with anemia in the setting of chronic kidney disease stage 4 secondary to diabetes mellitus was initiated on EPO 10,000 units per month. He developed an urticarial rash in the back and chest after the first dose, which gradually worsened after receiving the second dose. Review of recent history was negative for any other new medication or chemical exposure. He underwent skin biopsy which showed dermatitis with eosinophils supporting a drug reaction. EPO was discontinued with resolution of the rash. Given known risk of cross-reactivity between various ESA molecules, he was subsequently referred to an allergist for desensitization protocol, followed by successful re-introduction of ESA therapy.

Discussion: Currently, ESA remains the treatment of choice for anemia of kidney disease, in order to limit need for blood transfusions. ESA-related DTH reactions can be due to excipients such as polysorbate, as well as the structural subunits of erythropoietin. Cross-reactivity has been reported between different ESA structures, which raises a therapeutic challenge in the care of such patients. Clinicians should consider desensitization, which can lead to successful re-introduction of ESA therapy.

Modified outpatient 17-day EPO desensitization protocol

Day	Dose (IU)
1	100
1	200
4	400
4	800
10	1,600
12	3,200
15	6,400
17	10,000

Doses were administered every 48–72 h

Urticarial Rash on back

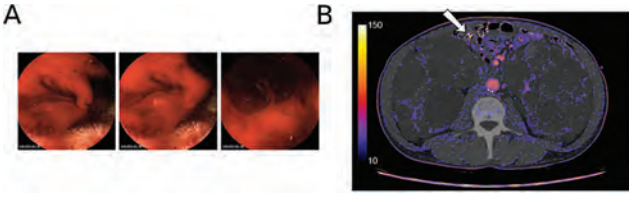
An Unusual Cause of Anaemia: Duodenal Compression by Polycystic Kidneys

Maithili Mehta, Fiona Duthie, Eoin D. O Sullivan. *Royal Infirmary of Edinburgh, Edinburgh, United Kingdom.*

Introduction: We report a rare case of gastrointestinal bleeding due to extrinsic compression and shearing of bowel in a patient with autosomal dominant polycystic kidney disease (ADPKD).

Case Description: A 52-year-old male presented with progressive dyspnoea and melaena over one week. He was noted to have an eGFR of 9 ml/min/1.73 m^2, giant polycystic kidneys and a family history of ADPKD. A diagnosis of ADPKD was made and he was commenced on peritoneal dialysis. He was noted to have mitral regurgitation and hypertension. His haemoglobin at presentation was 39 g/L and his blood film revealed ovalocytes, without evidence of haemolysis. Haematinics were suggestive of iron deficiency. While uraemic at presentation, he had no other notable risk factors for bleeding. Upper GI endoscopy and colonoscopy were both unremarkable. He was treated with red cell transfusion, intravenous iron and commenced on an erythropoiesis-stimulating agent. He presented on four subsequent occasions over an 8 month period with recurrence of severe anaemia and melaena. A capsule endoscopy suggested bleeding at the duodenal-jejunal flexure, however no source was visualised. The cause of the bleeding was revealed by double balloon enteroscopy which demonstrated extrinsic compression of the scope at D3. Review of imaging confirmed this was due to a large right renal cyst. Ongoing tranexamic acid and lanreotide treatment has reduced the frequency of bleeds. While a nephrectomy would potentially provide a definitive solution to the underlying cause, this caries substantial risk and would need to be carefully coordinated with his mitral valve repair.

Discussion: While peptic ulcer disease is slightly increased in ADPKD, this is the first description of mechanical trauma to bowel by polycystic kidneys resulting in severe recurrent GI bleeding. **Teaching points** 1. Giant polycystic kidneys can rarely compress small bowel and cause GI bleeding 2. Correlation of advanced endoscopy such as double balloon enteroscopy with radiology may be required to make the diagnosis 3. Tranexamic acid and lanreotide may reduce bleeding.



Enteroscopy (A) and CT (B) show compression point.

Targeted Literature Review (TLR) Exploring Adherence to Treatments, with Potential to Extrapolate to Patients with Anemia of CKD

Ana filipa Alexandre,[1] Mahmood Ali,[2] Alison Lawrence,[3] Jan McKendrick.[3] *[1]Astellas Pharma Europe B.V., Leiden, Netherlands; [2]Astellas Pharma Europe Ltd, Addlestone, United Kingdom; [3]PRMA Consulting, Fleet, United Kingdom.*

Background: Adherence to long-term treatment for chronic diseases, e.g. anemia of CKD, is problematic. Adherence to a patient's preferred treatment is critical to successful CKD management. We explored: availability of published best practice guidance for long-term disease; how analog scenarios from healthcare teams and patients provide learnings about treatment adherence and persistence; patient preferences; and how to measure adherence-related outcomes.

Methods: We conducted a TLR of analog scenarios where an oral therapy was introduced in a setting with injectable/subcutaneous therapy as standard of care. Embase and Cochrane searches included administration route, dosing frequency and titration, from 2016–2020. Searches were limited to literature reviews and clinical guidelines for adults with chronic disease from 10 countries.

Results: Of 1421 papers identified, 85 were relevant. Inspection of these papers revealed that non-adherence may be intentional or non-intentional, and can be linked to numerous factors, e.g. polypharmacy, treatment regimen complexity, number of daily tablets, lengthy treatment duration, and patient beliefs about treatment. Intentional non-adherence may link to patients' motivations/beliefs, and non-intentional non-adherence may link to patients' skill/ability to take a medicine. Regimen complexity can be influenced by drug dosage form, product characteristics, dosage schemes, specific additional instructions (e.g. fixed-time daily dosing), patient characteristics and administration errors. Discrete choice experiments and conjoint analyses provide robust means of measuring patient preferences, but evidence is conflicting of preference for injectable vs oral treatments, which is relevant to anemia of CKD management. Accurately documenting evidence of medication ingestion/administration is difficult. While several methods exist for assessing treatment adherence and persistence, no gold standard was identified.

Conclusions: In a competitive treatment setting, there remains significant opportunity to support patients in their treatment choice. Identifying best practice models of treatment adherence, persistence and measuring patient outcomes may prove important for differentiating between treatments.

PO0482

Iron-Related Outcomes in Patients with Non-Dialysis-Dependent CKD Randomized to Vadadustat vs. Darbepoetin Alfa

Mark Koury,[1] Pablo E. Pergola,[2] Prabir Roy-Chaudhury,[5] Youssef M. Farag,[3] Wenli Luo,[3] Robert Anders,[3] Christine Solinsky,[3] Dennis Vargo,[3] Wolfgang C. Winkelmayer.[4] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Renal Associates PA, San Antonio, TX; [3]Akebia Therapeutics Inc, Akebia Therapeutics Inc, Cambridge, MA, US, corporate/pharma, Cambridge, MA; [4]Baylor College of Medicine, Houston, TX; [5]UNC School of Medicine - W. G. (Bill) Hefner VA Medical Center, Salisbury, NC.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for treatment of anemia due to chronic kidney disease (CKD).

Methods: We conducted 2 global phase 3, randomized, open-label, sponsor-blind, active-controlled, noninferiority trials (PRO_2TECT) comparing once-daily oral dosing VADA with the erythropoiesis-stimulating agent (ESA) darbepoetin alfa (DA) in 1751 patients with non–dialysis-dependent CKD (NDD-CKD) not previously ESA treated and in 1725 NDD-CKD patients previously ESA treated. Inclusion criteria included serum ferritin ≥100 ng/mL and transferrin saturation (TSAT) ≥20%. Safety and efficacy results were previously reported. Here we report iron-related outcomes, including the changes in mean serum hepcidin, ferritin, total iron-binding capacity (TIBC), iron, and TSAT from baseline to the primary (wk 24–36) and secondary (wk 40–52) evaluation periods (PEP and SEP).

Results: A total of 1741 patients received VADA and 1735 received DA. VADA treatment was associated with greater decreases in mean hepcidin, ferritin, and TSAT, and increases in TIBC from baseline at PEP and SEP (**Table**). A small increase in serum iron was seen in the VADA group as was a decrease in the DA group from baseline to PEP and SEP. Oral and IV iron use was similar in the 2 treatment groups throughout both studies.

Conclusions: Treatment with VADA resulted in relative decreases in hepcidin and ferritin and increases in TIBC and serum iron. Decreases in TSAT should be interpreted in light of a greater increase in TIBC than that of serum iron. These changes are consistent with a VADA-induced increase in iron mobilization from extracellular stores that support erythropoiesis.

Funding: Commercial Support - Akebia Therapeutics, Inc., and Otsuka Pharmaceuticals Development and Commercialization, Inc.

Elevation in Red Cell Distribution Width (RDW) Is a Risk Factor for Future Hyponatremia and Hypokalemia

Hiroshi Tanaka. *Mihara Sekijuji Byoin, Mihara, Japan.*

Background: Elevation in red cell distribution width (RDW), a marker of size variance in red blood cells, recently has been reported to predict mortality, future cardiovascular events, and faster CKD progression. Putative mechanisms in RDW elevation include factors such as inflammation, aging, oxidative streess or malnutrition. It has not been clearly reported whether elevation in RDW has any significant impact on future electrolyte metabolism.

Methods: A hospital-wide study with all the laboratory data for a period of 4 years and 2 months was conducted. First, for each patient, hemoglobin (Hb) measurements of the initial 365 days were retrieved and the maximum RDW was obtained. Then the latest measurements of serum sodium (Na) and potassium (K), at least 365 days apart from the initial Hb and RDW measurement, were obtained. Prevalence and odds ratio (OR) of hyponatremia and hypokalemia were calculated for each quartile of RDW. Statistical analysis was performed with R 3.6.0 on Ubuntu and with Microsoft Excel.

Results: A total of 5,537 patients were included in the study. Hb ranged from 7.7 to 20.2 (median 13.4) g/dL, MCV 55.7-124.5 (93.1) fL, and RDW 10.1-34.6 (12.7)%. Hyponatremia (<130 mEq/L) was observed in 2.65%/1.10%/0.49%/0.71% in patients in each quartile of RDW (from high to low; chi-squared, P <0.001); Patients in the highest quartile of RDW had hyponatremia with OR of 3.80 when reference was set to the lowest quartile of RDW. Hypokalemia (<3.5 mEqL) was observed in 6.99%/4.02%/2.17%/1.89% in each quartile of RDW (chi-squared, P <0.001); Patients in the highest quartile of RDW had OR of 3.90 as the reference at the lowest quartile of RDW. Likewise, in patients with the highest quartile of RDW, more severe hyponatremia (<125 mEq/L) and hypokalemia (<3.0 mEq/L) were seen in 0.61% (OR 2.59) and 1.49% (OR 19.2), respecively.

Conclusions: Elevation in RDW is a risk factor for future development of hyponatremia and hypokalemia

PO0484

IL-6 Inhibitor Ziltivekimab Increases Serum Hemoglobin and Iron Biomarkers in Patients with CKD Stage 3–5: A RESCUE Trial Analysis

Pablo E. Pergola,[1] Michael Davidson,[2] Matt Devalaraja,[4] Milana Ivkovic,[3] Nicklas J. Johansen,[3] Dominic S. Raj,[5] Birgitte F. Sode,[3] Katherine R. Tuttle,[6] Vlado Perkovic.[7] *[1]Renal Associates PA, San Antonio, TX; [2]University of Chicago, Chicago, IL; [3]Novo Nordisk A/S, Søborg, Denmark; [4]Nipuna Therapeutics, Wilmington, DE; [5]George Washington University School of Medicine, Washington, WA; [6]University of Washington and Providence Health Care, Spokane, WA; [7]UNSW Sydney, Sydney, NSW, Australia.*

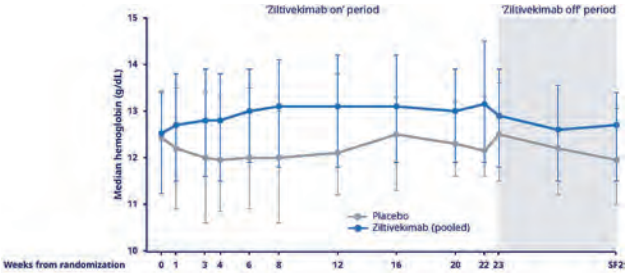
Background: Interleukin-6 (IL-6)-mediated inflammation causes functional iron deficiency and anemia in patients (pts) with chronic kidney disease (CKD). IL-6 inhibitor, ziltivekimab, reduced inflammation markers (RESCUE trial; NCT03926117) and improved anemia and serum albumin in hemodialysis pts (NCT02868229). We examined the effect of ziltivekimab on serum hemoglobin (Hb) and iron homeostasis in pts with CKD stage 3–5 in the RESCUE trial.

Methods: Changes in anemia markers from baseline (BL) to Week 12 were assessed in pts (CKD stage 3–5, high-sensitivity C-reactive protein ≥2 mg/L) treated with ziltivekimab 7.5, 15 or 30 mg vs placebo (PBO). The intention-to-treat population was analyzed using a mixed model for repeated measurements (no adjustment for multiplicity). Analysis by BL Hb level (<11 or ≥11 g/dL) was conducted.

Results: In the RESCUE trial overall, mean age was 66 years, median Hb 12.5 g/dL at BL (N=198, ziltivekimab; N=66, PBO). Ziltivekimab increased Hb from BL to Week 12 vs PBO (p<0.001 for each dose; Figure/Table), with numerically greater increases with ziltivekimab vs PBO in pts with BL Hb <11 g/dL than pts with BL Hb ≥11 g/dL (Table). Ziltivekimab increased serum iron levels (p<0.0001), total iron-binding capacity and transferrin saturation (both p<0.01) vs PBO. No major safety concerns were reported.

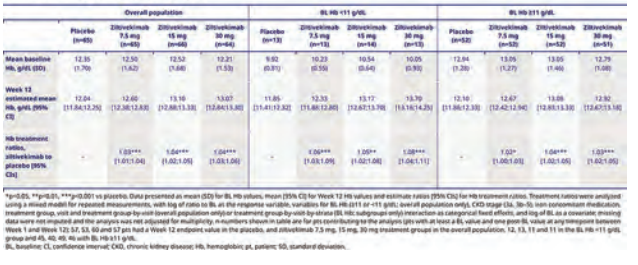
Conclusions: Ziltivekimab improved levels of Hb, serum iron and other iron biomarkers vs PBO in pts with CKD stage 3–5. By reducing inflammation and improving functional iron deficiency, ziltivekimab may improve anemia in pts with CKD.

Funding: Commercial Support - Novo Nordisk



Data are presented as median values and interquartile ranges (error bars) due to data distribution. Ziltivekimab data include pooled 7.5, 15 and 30 mg doses. n-numbers shown below the graph are for patients contributing to the analysis at that timepoint. SF2, safety follow-up 2 (11 weeks after last dose).

Table: Mean hemoglobin at baseline and Week 12



*p<0.05, **p<0.01, ***p<0.001 vs placebo. Data presented as mean (SD) for BL Hb values, mean (95% CI) for Week 12 Hb values and estimate ratios (95% CIs) for Hb treatment ratios. Treatment ratios were analyzed using a mixed model for repeated measurements, with log of ratio to BL as the response variable, variables for BL Hb (<11 or ≥11 g/dL; overall population only), CKD stage (3a, 3b–5), iron concomitant medication, treatment group, visit and treatment group-by-visit (overall population only)or treatment group-by-visit-by-strata (BL Hb; subgroups only) interaction as categorical fixed effects, and log of BL as a covariate; missing data were not imputed and the analysis was not adjusted for multiplicity. n-numbers shown in table are for pts contributing to the analysis (pts with at least a BL value and one post-BL value at any timepoint between Week 1 and Week 12); 57, 53, 60 and 57 pts had a Week 12 endpoint value in the placebo, and ziltivekimab 7.5 mg, 15 mg, 30 mg treatment groups in the overall population, 12, 13, 11 and 11 in the BL Hb <11 g/dL group and 45, 40, 49, 46 with BL Hb ≥11 g/dL.

Sodium-Glucose Cotransporter 2 Inhibitors and Anemia Among Diabetic Patients in Real Clinical Practice

Miho Murashima, Atsuki Ide, Minamo Ono, Masashi Mizuno, Taisei Suzuki, Takayuki Hamano. *Nagoya Shiritsu Daigaku, Nagoya, Japan.*

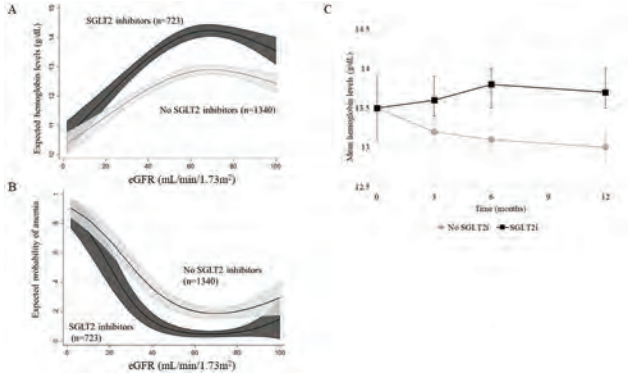
Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) were reported to increase hemoglobin levels in short-term clinical trials. Whether it is also true in real clinical practice is unknown.

Methods: This is a retrospective cohort study. Inclusion criterion was diabetics who visited our outpatient clinic from January 2019 to August 2020. Exposure of interest was the use of SGLT2i. Outcomes were hemoglobin levels. For the cross-sectional analyses, non-linear regression models were fitted with restricted cubic splines to investigate the association between hemoglobin levels and estimated glomerular filtration rate (eGFR) for users and non-users of SGLT2i. For the case-control study, cases (anemia defined as hemoglobin <12 g/dL for men, <11g/dL for women or the use of erythropoiesis stimulating agents) and controls were matched by age, sex, and eGFR.

Results: Among 2063 diabetics, 723 were on SGLT2i. In the cross-sectional analyses, hemoglobin levels were higher among SGLT2i users compared with non-users at eGFR >15 mL/min/1.73m^2. For the case-control study, 197 cases and controls were

matched. Conditional logistic regression showed that the use of SGLT2i was associated with significantly lower prevalence of anemia (OR: 0.35 [0.21-0.58]). Adjusted mean differences (95% CIs) in hemoglobin levels between users and propensity score-matched non-users of SGLT2i were 0.7 (0.3-1.0) g/dL at 6 months. Among SGLT2i users, odds of increase in 6-month hemoglobin were similar across eGFR categories except for eGFR <15 mL/min/1.73m^2.

Conclusions: The use of SGLT2i was associated with higher hemoglobin levels and lower prevalence of anemia in real clinical practice.



PO0486

Pro-Inflammatory Signaling Alters Hematopoiesis in Anemic Mice

Jane J. Thomas, Guillaume Courbon, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Iron deficiency anemia (IDA) is a common complication of Chronic Kidney Disease (CKD), associated with accelerated disease progression and death. IDA is the direct result of low circulating iron and total body iron stores, which are unable to meet the demands of erythropoiesis. To date, the effects of low iron bioavailability and anemia on hematopoiesis at the single cell level remain unexplored.

Methods: To investigate the effects of IDA on hematopoiesis, we fed three-week old mice a control or an iron deficient diet for 3 weeks. As expected, mice fed on a low-iron diet developed IDA, evidenced by low hematocrit count and severely reduced hemoglobin. We next analyzed the developing hematopoietic progenitors and identified molecular markers that are predictive of the cell differentiating status using single cell RNA sequencing of bone marrow (BM) and peripheral blood (PB) cells from control and IDA mice.

Results: We found that IDA increased the number of hematopoietic stem cells and restricted erythroid progenitors in BM and in PB. In contrast, IDA disrupted terminal erythroid differentiation, and particularly the differentiation of orthochromatic erythroblasts into reticulocytes. Compared to control mice, orthochromatic erythroblasts from IDA mice differentiated into an "alternate" reticulocyte cluster, overabundant in BM but quasi-absent in PB. Analysis of differentially expressed genes showed that iron deficiency increased pro-inflammatory signaling and resulted in the expression of pro-apoptotic markers in this alternate cluster, including the expression of *Ddit3* (+12 fold), *Trib3* and *Atf4* (+13 fold). The effects of IDA were not restricted to the erythroid lineage. IDA reduced the number of differentiated myeloid cells such as macrophages and neutrophils. Importantly, cells from IDA mice showed increased BM megakaryopoietic differentiation and higher number of circulating megakaryopoietic cells in PB. In contrast, IDA reduced lymphoid differentiation and thus, lowered the number of mature B cells, highlighting the importance of iron in adaptive humoral immune responses.

Conclusions: In aggregate, our data suggest that iron deficiency anemia alters hematopoiesis through inflammation-induced expansion of progenitors and apoptotic signaling in mature cell populations. Our results might help develop targeted therapies in CKD patients to correct anemia and improve outcomes.

ASCEND-TD: A Randomized, Double-Blind, Active-Controlled Study of Daprodustat Administered Three Times Weekly in Hemodialysis Patients

Daniel W. Coyne,[1] Ajay K. Singh,[2] Renato D. Lopes,[3] Christine K. Bailey,[4] Tara L. Dimino,[4] Chun Huang,[4] Jeffrey J. Connaire,[5] Anjay Rastogi,[6] Sung gyun Kim,[7] Marcelo Orias,[8] Sapna Shah,[9] Vickas Patel,[4] Alexander R. Cobitz,[4] Christoph Wanner.[10] *[1]Division of Nephrology, Washington University School of Medicine, St. Louis, MO; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Duke Clinical Research Institute, Duke Health, Durham, NC; [4]GlaxoSmithKline, Collegeville, PA; [5]Davita Clinical Research, Minneapolis, MN; [6]Division of Nephrology, Department of Medicine, UCLA, Los Angeles, CA; [7]Department of Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; [8]Sanatorio Allende, Córdoba, Argentina; [9]King's College Hospital NHS Trust, London, United Kingdom; [10]University of Würzburg, Würzburg, Germany.*

Background: Daprodustat (dapro) is a hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated for the treatment of anemia of chronic kidney disease (CKD). This study evaluated the efficacy and safety of dapro administered three-times-weekly (TIW) vs recombinant human erythropoietin (rhEPO) for in-center prevalent hemodialysis (HD) patients.

Methods: This double-blind study (NCT03400033) randomized (2:1) HD patients with a baseline hemoglobin (Hb) of 8–11.5 g/dL already on rhEPO to dapro TIW (n=270) or rhEPO (n=137) for 52 weeks. A dosing algorithm aimed to maintain Hb between 10–11g/dL. The primary endpoint was a mean change in Hb in the evaluation period (EP; Weeks 28–52). The principal secondary endpoint was average monthly intravenous (IV) iron dose. Other secondary endpoints included blood pressure (BP) and Hb variability.

Results: Baseline characteristics in 407 randomized patients were balanced between the dapro and rhEPO groups. Dapro TIW was non-inferior to rhEPO for mean change in Hb (model-adjusted mean treatment difference [dapro-rhEPO] -0.05; 95% CI: -0.21, 0.10). In the EP, mean (SD) Hb was 10.45 (0.549) g/dL and 10.51 (0.849) g/dL for dapro and rhEPO groups, respectively. However, 80.0% in the dapro group were responders (mean Hb during EP in the analysis range [10–11.5 g/dL]) vs 63.6% in the rhEPO group, with a difference of 16.5% (one-sided nominal p=0.0007 after adjustment for region). Mean monthly IV iron dose was not statistically significantly lower with dapro vs rhEPO. While fewer BP elevations occurred with dapro vs rhEPO (one-sided nominal p=0.0093), the overall effect of dapro on BP was similar to rhEPO. In general, safety findings were comparable between treatment groups, with the incidence of treatment-emergent adverse events similar between dapro (75%) and rhEPO (79%).

Conclusions: Dapro was non-inferior to rhEPO in Hb response and was well-tolerated. Dapro administered TIW using the protocol employed in this study is a viable alternative to rhEPO in prevalent HD patients with anemia of CKD.

Stabilization of Hypoxia-Inducible Factors Leads to Profound Epigenetic Changes in Primary Human Tubular Cells

René Krüger, Mario Schiffer, Johannes Schödel, Stephanie Naas. *Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.*

Background: Pharmacological stabilization of Hypoxia-inducible factors (HIFs) to induce erythropoietin expression presents a novel therapeutic approach to treat patients with renal anemia. Whereas general effects of HIFs on the transcriptome are well studied, insights in HIF-mediated alterations at the epigenetic level remain limited. The epigenetic landscape determines cellular identity and may be shaped by environmental factors such as hypoxia via HIF. In this study, we aim at generating a genome-wide atlas of the tubule-specific chromatin landscape while investigating the epigenetic plasticity of regulatory DNA elements provoked by HIF stabilization.

Methods: Primary tubular cells (PTC) were isolated from tumor nephrectomy specimens. We performed unbiased analyses of chromatin structure and HIF DNA-interactions using the Assay for Transposase Accessible Chromatin followed by sequencing (ATAC-Seq) and Chromatin Immunoprecipitation DNA-Sequencing (ChIP-seq), respectively. These epigenetic data sets were complemented with transcriptome information gained by RNA sequencing.

Results: ATAC-seq data generated in PTC obtained from four different individuals were combined to create a genome-wide landscape of chromatin accessibility comprising approx. 110 000 consensus regions. We validated cellular identity by benchmarking these sites against publicly available epigenomic data sets provided by ENCODE. Further characterization of chromatin activity was achieved by integration of ChIP-seq data for the histone mark H3K27ac. Pharmacological stabilization of HIF resulted in a remarkable change of chromatin accessibility yielding several hundred differentially open regions. Alterations of the chromatin coincided with HIF-binding events and HIF-mediated changes in mRNA expression suggesting a functional role for HIF in shaping chromatin accessibility in renal tubular cells.

Conclusions: Our genome-wide atlas of chromatin accessibility and activity in primary tubular cells represents a valuable reference data set for the investigation of tubule-specific features. Furthermore, our comprehensive approach allows for in-depth analysis of favourable as well as adverse epigenetic effects of HIF stabilizers in human tubular cells.

PO0489

Triferic (Ferric Pyrophosphate Citrate, FPC) Maintains Hemoglobin and Reduces Total IV Iron Requirement: Results from a Mid-Sized Dialysis Organization (MDO) Pilot Observational Analysis

Samuel L. Shull, Marc L. Hoffman. *Rockwell Medical Inc, Wixom, MI.*

Background: Triferic is approved as an iron (Fe) replacement product to maintain hemoglobin (Hb) in adult patients (pts) receiving chronic hemodialysis (HD). Randomized clinical trial data have demonstrated that FPC maintains Fe stores and Hb while reducing IV Fe usage with a safety profile similar to placebo. We now report the first 8 mos of an independent MDO's experience using FPC for all HD patients (pts) during a pilot implementation at 14 clinics.

Methods: FPC was added to centrally delivered liquid bicarb to provide 110 μg Fe/L dialysate. All patients received FPC at each HD. Anonymized prospective data were provided between Sep 2020—Apr 2021. Clinics added FPC into their anemia mgmt. practices per existing protocols and standards of care (SoC). Supplemental IV Fe, up to a max of 1000 mg Fe/mth, was administered according to a protocol based on serum ferritin and TSAT values. At baseline, the ave. utilization of IV Fe was 197 mg/pt/mo. During the first 3 mos of FPC, clinics saw a modest 23% reduction of IV Fe (151mg/pt/mo)). A new Fe mgmt. protocol was released specifically designed to guide IV Fe use in conjunction with FPC; this was adopted by 9 clinics while 5 clinics chose to maintain their SoC.

Results: Within 3 mos of initiation of the new protocol, Fe utilization in this group decreased by 81%, conversely Fe utilization increased by 19% in the SoC group. During this period, Hb remained stable in both groups (+/- 0.2 g/dL from baseline). Concurrent with these changes Mircera® (-epoetin beta) dose remained stable in the SoC group but was reduced 37% (from post-adoption baseline) in the new group.

Conclusions: Additional clinics continued to adopt the new protocol over time. Taking into account the staggered adoption of the protocol, after 8 mos, the aggregate Fe utilization across all 14 clinics was reduced by 51% and trending lower. Mircera dose was stable (decreased 5%) and Hb remains stable. This observational study demonstrates that FPC is a well tolerated replacement for IV Fe when administered to all patients in a HD unit. The findings of this real-world observational study align with pivotal clinical trials and previously reported real-world evidence in terms of reduction of IV Fe use and maintenance of Hb.

Automated Tubular Morphometric Analysis in Kidney Biopsies

Brandon Ginley,[1] Neil S. Kavthekar,[1] Nicholas Lucarelli,[1] Briana A. Santo,[1] Kuang-Yu Jen,[2] Pinaki Sarder.[1] *[1]University at Buffalo, Buffalo, NY; [2]University of California Davis, Davis, CA.*

Background: Tubular atrophy is prevalent in kidney disease. We automated tubular morphometric analysis and applied it to diabetic nephropathy (DN) and transplant biopsies.

Methods: Tubules (n = 302696) were segmented with a convolutional panoptic network (***Fig. 1***) from 57 native DN and 30 transplant surveillance renal biopsies. Distributions of digitally quantitated tubular diameter and basement membrane (TBM) were evaluated with respect to chronic kidney disease (CKD) stage and interstitial fibrosis and tubular atrophy (IFTA) severity.

Results: The trends in ***Fig. 2*** show that generally, as CKD and IFTA increase, tubular diameter decreases and TBM average width increases, with the DN trend being more prominent. However, significant distribution heterogeneity is observed.

Conclusions: High-throughput computation can be leveraged to automate morphometric analysis of tubules. Further data mining using a similar approach may reveal novel features that may have diagnostic or prognostic benefit.

Funding: NIDDK Support

A Computational Pipeline for Estimating Renal Histologic Primitives

Pinaki Sarder,[1] Yijiang Chen,[2] Brandon Ginley,[1] Avi Z. Rosenberg,[3] Andrew Janowczyk,[2] Brendon Lutnick,[1] Nicholas Lucarelli,[1] Charles E. Alpers,[4] Sanjay Jain,[5] Stephanie Grewenow,[4] Becky Steck,[7] Laura Barisoni,[6] Anant Madabhushi,[2] Ulysses G. Balis.[7] Kidney Precision Medicine Project *[1]University at Buffalo, Buffalo, NY; [2]Case Western Reserve University, Cleveland, OH; [3]Johns Hopkins University, Baltimore, MD; [4]University of Washington, Seattle, WA; [5]Washington University in St Louis, St Louis, MO; [6]Duke University, Durham, NC; [7]University of Michigan, Ann Arbor, MI.*

Background: While a number of image segmentation approaches exist for digital pathology, in this study, we aimed to combine three complementary tools for enhanced quality assessment and segmentation of histologic primitives on kidney biopsy images. Specifically, we evaluated the integrated image analysis approach on two chronic kidney disease (CKD) renal tissue biopsy WSI cases from the curated Kidney Precision Medicine Project (KPMP) database.

Methods: HistoQC, an established tool for automated quality control (QC) of digital pathology images, eliminated staining and image artifacts from the biopsies. Next, two complementary computational tools were interfaced. HAIL (Human-AI-Loop), a supervised convolutional neural network, was used to isolate renal co mpartments (i.e., glomeruli, vessels, interstitium, and tubules). HAIL output was used to gate the training process of the second algorithm, VIPR (Vectorizing spatially-Invariant Pattern Recognition), a kernel-based, high-dimensional textural classifier capable of extracting distinct histopathological features as distinct sub-regions, ultimately allowing for the generation of a resulting pixel-level classification of all tissue compartments.

Results: The integrated pipeline precisely classified tubular basement membrane, brush border, nuclei, nucleoli, and tubular epithelial cytoplasm from CKD WSIs in a manner consistent with subject matter expert opinion for region fractionation, when resultant segmentation images were manually reviewed (***Fig. 1***).

Conclusions: We have shown the potential of our pipeline for image curation, and segmentation and sub-characterization of renal histologic primitives.

A 3D Vascularised Tubule Model Improves the Phenotype of Cultured Cells

Miguel Carracedo,[1] Sanlin Robinson,[2] Babak Alaei,[1] Maryam Clausen,[1] Ryan Hicks,[1] Graham P. Belfield,[1] Annette Bak,[1] Jennifer A. Lewis,[2] Pernille B. Laerkegaard Hansen,[1] Julie Williams.[1] *[1]AstraZeneca PLC, Mölndal, Sweden; [2]Harvard University, Wyss Institute, Boston, MA.*

Background: Modelling proximal tubule physiology and pharmacology is essential for mechanistic studies and drug discovery. As a consequence, a plethora of models have been developed. Despite this no comparative study between monocultures, co-cultures and 3D models has been reported. In this study we aimed to understand the differences of proximal tubule epithelial cells (PTECs) and glomerular endothelial cells (HGECs) alone or in co-culture when grown in static non-coated, static matrix-coated and 3D flow matrix-coated conditions.

Methods: We cultured PTECs under physiological flow in a 3D channel embedded within an engineered extracellular matrix (ECM) that is colocalised with an adjacent channel lined with HGECs to mimic a peritubular capillary. After a period of maturation under continuous flow, both cell types were harvested for RNAseq analyses.

Results: Our results revealed that PTECs' transcriptional profile is highly dependent on the matrix on which these cells are cultured, as well as the application of flow. Endothelial cells however demonstrated greater phenotypic plasticity, being affected by matrix, flow and co-culture. The transcriptional profile of PTECs grown on a non-coated surface presented an enrichment of inflammatory markers such as TNF-a, IL6 and CXCL6, resembling that of diseased tubular biopsies. This inflammatory effect was not seen in PTECs grown on a matrix, and the growth conditions of matrix under flow further resembled the transcriptional profile of healthy tubular biopsies. Unsurprisingly the presence of flow modulated the expression of kidney signature genes including drug/solute transporters. Likewise, HGECs' transcriptional profile more closely resembled the profile of in vivo glomerular cells when grown on a matrix under flow.

Conclusions: In conclusion, PTECs and HGECs grown under different culture conditions present considerable transcriptional profile changes; being enriched in inflammatory pathways when grown on a non-coated surface, but closely resembling *in vivo* homeostatic profiles when grown with matrix and/or flow. These findings guide future selection of translatable models investigating renal physiology and pharmacology.

Recreating Renal Function in a Human Glomerulus and Proximal Tubule Microphysiological System

Stephanie Y. Zhang, Gretchen Mahler. *Binghamton University Thomas J Watson School of Engineering and Applied Science, Binghamton, NY.*

Background: Preclinical tests for pharmaceutical discovery extensively rely on static, 2D cultures and animal models. While these methods are commonly used, they poorly represent human responses due to the lack of architecture and physiological stimuli (2D culture), and human cells (animal models). Kidney microphysiological systems (MPS) better support renal function with controlled, 3D fluidic platforms, and serve as valuable tools in determining renal toxicity to new drugs. Current kidney MPS model individual regions of the nephron (glomerulus and proximal tubule or PCT) but fail to incorporate multiple filtration and reabsorption interfaces. Our study established a 7 day tri-culture of podocytes, endothelial, and PCT epithelial cells in a glomerulus and PCT MPS with key functional features.

Methods: The MPS consisted of: T-Junction, glomerulus housing (GH), and PCT chip. Media from the bloodstream flowed into the T-Junction, splitting 10% of flow to GH. The GH had a polyethersulferone membrane with human endothelial cells (HUVECs) and podocytes (CIHP-1) seeded at 10^5 cells/cm^2 on opposing sides. Connected to GH, PCT polycarbonate chip housed 10^5 cells/cm^2 of human PCT cells (HK-2) and outputs primary filtrate. At shear stress of 0.7-1.5 dyne/cm^2, velocity flow was measured based on daily filtrate output. Glomerular filtration was tested by challenging the system with 0.1 mg/mL of FITC-human serum albumin (FITC-HSA). PCT reabsorption was tested using fluorescent glucose analog (2-NBDG). Cultures were starved for 2 hrs, and later treated with media containing 200 mg/mL of 2-NBDG for 2 hrs. After 7 days of exposure, cell membranes were stained and imaged for F-actin, VE-cadherin, ZO-1, and nephrin.

Results: At a total pump flowrate of 45.3 μL/min, 17.7 μL/min (± 5.08 μL/min) exited as filtrate and 27.6 μL/min (± 7.63 μL/min) recirculated in the bloodstream. In the MPS, average daily filtrate output was 0.016 mL/min, filtration of FITC-HSA in the MPS was over 90%, and glucose output in the filtrate supported PCT reabsorption. Confocal images displayed cell type-specific protein expression.

Conclusions: Filtering of HSA, glucose reabsorption, and marker expression in the MPS indicates a physiological representation of renal filtration and reuptake in a human glomerulus and PCT. Our glomerulus and PCT MPS is a relevant preclinical tool for testing drug candidates for kidney toxicity.

PO0494

Renal Proximal Tubule Chip (RPTC) for Disease Modeling and Drug Toxicity Testing

Leslie Donoghue, Arushi Kotru, Alfredo J. Guzman, Palaniappan Sethu. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Tissue chips are an emerging technology in disease modeling and screening therapeutics to address discrepancies between animal models and human clinical trials. They utilize tissue engineering, fluid mechanics, and biomaterials to replicate in vivo architectures and functions of complex organs and tissues. For the renal proximal tubule (PT), there are currently limited options in terms of human cell types, scalable platforms for evaluation of drug toxicity, and tissue engineered solutions where the complexity of the PT is accurately modeled.

Methods: We developed both 2D and 3D versions of the RPTC which incorporates immortalized human renal PT epithelial cells (hRPTEC-TERT1) under static and perfused conditions (i.e. physiological pressure, shear stress, and stretch). Additionally, we have begun generating peritubular vascular networks using a co-culture of human umbilical vein endothelial cells (hUVECs) and human dermal fibroblasts (hDFs) in gelatin methacryloyl (GelMA). These models were then used to investigate the effect of pressure and flow on nephrotoxicity by introducing drugs with known levels of toxicity. Our initial evaluations have been limited to non-invasive measurements such as transepithelial electrical resistance (TEER) and pro-inflammatory soluble factors, and ICC.

Results: Compared to static controls, hRPTEC-TERT1 subjected to fluid shear demonstrate that culture under physiologically relevant forces results in cytoskeletal reorganization, establishment of barrier function (adherens and tight junctions) and increased expression of transporters like aquaporin 1 and mechanosensors like α-tubulin. Additionally, noninvasive readouts such as TEER indicate the greater integrity of the renal proximal epithelium. Lastly, after 7 days, we can form dense microvascular networks to mimic the surrounding peritubular capillary networks which can actively reabsorb solutes from the glomerular filtrate. This network will enable us to test drugs in an environment where both reabsorption and secretion functions of the tubule are replicated.

Conclusions: These results provide preliminary evidence of our ability to subject hRPTEC-TERT1 to in vivo like flow conditions and demonstrate that replication of biomechanical cues from fluid flow significantly enhances the attainment of an in vivo–like phenotype which enhances the relevance of our in vitro models.

Modeling Ischemia-Reperfusion in a High-Throughput Tubular/Microvascular Co-Culture-on-a-Chip

Erin M. Shaughnessey,[1,3] Samuel H. Kann,[2,3] Lauren D. Black,[1] Joseph L. Charest,[3] Else M. Vedula.[3] *[1]Tufts University, Medford, MA; [2]Boston University, Boston, MA; [3]Draper, Cambridge, MA.*

Background: Ischemia-reperfusion (IR) is a major cause of acute kidney injury (AKI). IR involves a period of inadequate perfusion that deprives highly metabolic kidney epithelia of nutrient and waste exchange impacting tissue structural integrity.

Methods: We demonstrate the potential of the PREDICT96 (P96) platform as a tool for examining tubule cell responses to IR. The oxygen-impermeable construction and robust pumping capabilities of P96 enable comparison of simulated IR and control conditions on a single culture plate. Here, primary human renal proximal tubule epithelial cells and human microvascular endothelial cells were cultured in adjacent microfluidic channels for 5 days under physiological fluid shear (0.07 Pa) to establish confluent layers. Subsequently, a portion of the tissue replicates underwent simulated IR consisting of 3 days of static conditions followed by 2 days of physiological flow. Transepithelial electrical resistance (TEER) was measured daily, and all tissues were fixed after 10 days in culture for structural characterization via immunofluorescence confocal microscopy.

Results: TEER measurements highlighted a transient increase in barrier function (relative to control tissues) in response to the onset of ischemia, followed by a reduction in integrity over subsequent days that persisted through reperfusion. IR tissues exhibited primary cilia that were on average less abundant but roughly double the length of those exhibited by control tissues. This is consistent with previous observations of cilia lengthening among IR-injured kidney epithelia in vivo. IR tissues also displayed nuclear staining for β-catenin suggestive of a proliferative response to injury.

Conclusions: The described model has significant potential to clarify mechanisms of IR injury in the kidney.

Funding: Other U.S. Government Support

Niacin Supplementation Increases In Vitro Apicobasal Volume Transport and Oxygen Consumption by Proximal Tubule Cells

Kuniko Hunter,[1] Rachel C. Evans,[2] Harold D. Love,[2] Samir M. Parikh,[3] H. David Humes,[5] Shuvo Roy,[4] William H. Fissell.[2] The Kidney Project
[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]University of California San Francisco, San Francisco, CA; [5]University of Michigan, Ann Arbor, MI.

Background: Renal tubule cells are energetically demanding as they consume ATP to transport salt and water within the kidney. In vitro, renal tubule cells have an attenuated glycolytic phenotype described as cell culture stress. We hypothesized that Krebs cycle intermediates might be rate-limiting for ATP-dependent transport. We tested the influence of supplemental niacin as a source for NAD+/NADH on mitochondrial oxygen consumption.

Methods: Primary human renal tubule epithelial cells (HREC) were seeded on polystyrene tissue culture plates and cultured with normal (2 mg/L) or high niacin (4mg/L). After two weeks of treatment, cell oxygen consumption (OCR) and extracellular acidification rates (ECAR) were assessed using a Seahorse XFe96 analyzer. Respiratory inhibitors oligomycin (2μM), CCCP (2μM), rotenone (0.5μM), antimycin A (0.5μM) and 2-deoxyglucose (2-DG, 50mM), and glucose (10mM) were used to probe mitochondrial and non-mitochondrial respiration. Statistical differences between control and experimental groups were estimated by two-tailed Student's t-test. Results are considered significant at p<0.05. Cells from the same lot were seeded on permeable supports and cultured with an inhibitor of TGF-b receptor 1 and low or high niacin concentrations. Apicobasal volume transport was measured gravimetrically.

Results: High-dose niacin was associated with increased oxygen consumption compared with normal dose niacin (225 vs 157 uMol/min, p < 0.01), and with increased transport (187 +/- 83 vs 87 +/- 2.8 uL/cm2/day; p < 0.0004).

Conclusions: Our observation that mitochondrial oxygen consumption increased with addition of supplemental niacin supports the hypothesis that Krebs cycle intermediates may be rate-limiting in tubuel cell function. The significant increase in apicobasal transport with added niacin suggest that some of the dysfunctional phenotype induced by cell culture stress may be mitigated by nutritional supplementation.

PO0497

Microenvironmental Influences on 3D Embedded and Bioprinted Induced Renal Tubular Epithelial Cells (iRECs)

Ludovica Rizzo,[1] Kevin Tröndle,[3] Michaela Bühler,[2] Roman Pichler,[2] Soeren S. Lienkamp.[1,2] *[1]Universitat Zurich, Zurich, Switzerland; [2]Universitatsklinikum Freiburg Abteilung Innere Medizin IV Nephrologie und Allgemeinmedizin, Freiburg, Germany; [3]Albert-Ludwigs-Universitat Freiburg Institut fur Mikrosystemtechnik, Freiburg, Germany.*

Background: Conventional cellular models of renal tubular origin only partially maintain their functional properties. Recent advances in 3D culture techniques and bioprinting technology promise to improve physiological conditions by reconstituting the tissue architecture in vitro. We previously described that direct reprogramming with a defined lentiviral cocktail of four transcription factors (Hnf1b, Hnf4a, Pax8, Emx2) can convert fibroblasts to induced renal tubular epithelial cells (iRECs). We analyzed how the microenvironment influences behavior, expression profile and the cellular function of iRECs to determine their utility for bioprinting applications.

Methods: iRECs were subjected to manual pipetting and inkjet bioprinting methods, embedded in three ECM-like microenvironments (Matrigel, Fibrin and Collagen I), and two culture media (DMEM and REGM). Morphology and viability of multicellular structures were assessed at several time points after seeding. Moreover, RNA-Seq was carried out to describe differentially regulated genes, and their protein products analyzed via immunofluorescence.

Results: iRECs showed high viability and biocompatibility with dispensing methods and bioinks. However, the morphology of multicellular aggregates was dramatically influenced by the microenvironment (e.g. they formed smaller spherical aggregates in Matrigel, but elongated tubule-like structures in Collagen I). Transcriptomic analysis revealed differentially expressed signature genes in each of the used biomaterials. For example, expression of apical endocytic machinery components was elevated in Matrigel embedded cells. In contrast, transcripts of ECM components showed strongest expression in the Fibrin condition. In addition, the tubule segment identity of iRECs was altered by the microenvironment. Microdispensing (drop on demand) bioprinting achieved perfusable tubule-like structures.

Conclusions: The design of specific tubule microenvironments for reprogrammed kidney tubule cells can be tailored to better reflect physiological conditions and to the desired purpose of vitro applications. This will facilitate the use of appropriate biomaterials to optimize the construction of biomimetic kidney tubule models at scale.

PO0498

Biomimetic Thin Film Scaffolds Support Renal Cell-Based Filtration and Reabsorption

Thomas F. Gallegos, Charles Klassen. IVIVA Medical *IVIVA Medical, Woburn, MA.*

Background: End stage renal disease affects millions of patients worldwide. Allotransplantation is the only curative treatment, yet it is only accessible to a fraction of patients. Hemodialysis does not adequately replace lost renal function. Engineered kidney replacing devices could be an alternative, however, excepting native extracellular matrix, no biologic scaffolding system to support cell-based filtration and absorption has yet been developed.

Methods: Biomimetic thin film scaffolds were fabricated by 3D printing, embedding, and leaching opposing networks of sacrificial material across 5μm thick microporous biologic membranes. The separate channel systems were co-seeded with primary glomerular microvascular endothelial cells and immortalized podocytes (glomerular grafts, N=3), or human umbilical vein endothelial cells and immortalized proximal tubule epithelial cells (tubular grafts, N=4) to recapitulate glomerular and proximal tubule anatomy and physiology.

Results: Scaffolds supported cell engraftment, polarization, and barrier formation in vascular and epithelial channels, and enabled filtration and reabsorption. Acellular scaffold vascular perfusion at 30mmHg resulted in a flow rate of 5.82mL/min/cm 2 (N=9), producing filtrate at 8.01μl/min/cm 2 of membrane. Confluent glomerular grafts produced filtrate at a rate of 3.76μL/min/cm 2 (48h, N=3). At 1 week, mature tubular grafts retained 96.8% of Inulin-FITC in the tubular epithelium (N=3). At maturity, glucose was transported into the vascular channel at a 24 hour rate of 0.11mg/mL/cm 2 (N=4).

Conclusions: Biomimetic thin film scaffolds support formation of perfusable 3D tissues and higher level renal cell based functions such as filtration and reabsorption in vitro. At scale, cellular constructs could enable fabrication of a fully biologic implantable renal replacement device.

Funding: Other U.S. Government Support

Figure 1. Recent developments in transplantable biologic and artificial filtration devices. Transplantation is the only permanent ESRD treatment while mechanical filtration requires ongoing treatments. Fully biological organ replacement devices are a long sought after therapeutic.

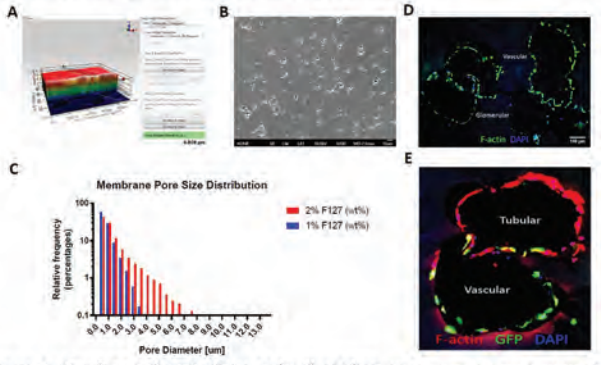

Figure 3. Membrane characteristics and cell seeding. (A) Membrane thickness is assessed by optical profilometry. (B) Porosity is imaged using SEM and can be quantified using image analysis techniques (Fiji/ImageJ). Stained histological sections show cells lining the channels glomerular and proximal tubular scaffolds. Podocytes and primary GMECs are shown by F-actin in green (D) and in HUVECs and PTECs in red (E). The HUVECs are GFP+.

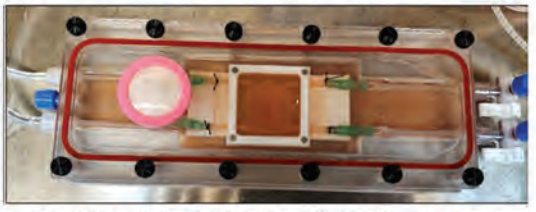

Figure 4. Perfusion culture of cellularized scaffolds in bioreactors. Scaffolds were cultured with separate perfusion into the vascular and epithelial channels. The cell seeded constructs were cultured for up to two weeks.

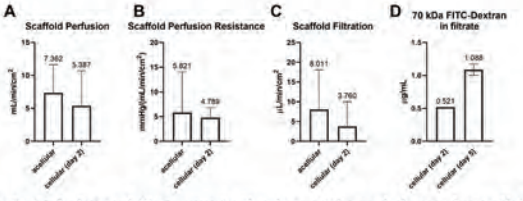

Figure 5. Perfusion and filtrate production in acellular and glomerular scaffolds. (A) PBS perfusion at 30mmHg pressure flowed through acellular (N=4) and glomerular (N=3) scaffolds at 7.3 and 5.3 mL/min/cm². Glomerular scaffolds (N=3) had slightly lower resistance to perfusion than acellular scaffolds (N=9) (B) but produced less than half of the filtrate into the epithelial channel (C). (D) At 2 (N=1) and 5 days (N=3) high molecular weight dextran at 1µg/mL was perfused through the vascular channels of glomerular cell seeded scaffolds. At 2 days, the filtrate macromolecular concentration was less than input, while at 5 days macromolecular concentration of filtrate matched input. Graphs represent means ± SD.

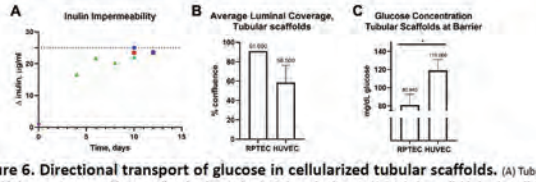

Figure 6. Directional transport of glucose in cellularized tubular scaffolds. (A) Tubular scaffolds become impermeable to small molecules at about 10 days of culture in N=3 tubular scaffolds (each scaffold a separate color). Fluorescent inulin at 25µg/mL in the tubular channel did not move into the vascular channel, while it quickly came to equilibrium in acellular scaffolds (N=1, purple triangle day 0). Delta inulin is epithelial channel concentration minus vascular channel concentration. (B) Luminal coverage of epithelium was nearly complete (N=2). (C) At inulin impermeability glucose was transported from the epithelial channel to the vascular channel, deviating from the initial concentration of 100mg/mL in each channel (N=4), P=0.0495 in a paired T-test. Graphs represent means ± SD.

Tunable Stiffness Amino Functionalized Polyacrylamide-Based Hydrogels for Renal Cell Tissue Culture

Harold D. Love,[1] Shuvo Roy,[2] William H. Fissell.[1] The Kidney Project
[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Francisco, CA.

Background: Tunable stiffness polyacrylamide (PA) based hydrogels have been utilized for tissue engineering studies. PA gels require functionalization for cell attachment. Reagents such as sulfo-SANPAH or acrylic acid NHS ester are often used to attach protein to the gel surface. However, these methods do not provide adequate binding to maintain cell attachment for studies involving fluid shear stress or long-term culture. In order to produce PA gels with uniform surfaces and robust cell attachment, we tested gels incorporating N-(3-Aminopropyl) methacrylamide (APMA) to create a positively charged polylysine-like biocompatible surface.

Methods: APMA was substituted in varying amounts in PA mixes previously reported to produce gels with expected stiffnesses of 2.6 kPa or 40 kPa. Gels were produced by free radical polymerization under nitrogen, using TEMED (1:300) and 10% ammonium persulfate (1:100). Gels were cast on glass coverslips soaked overnight in 2M NaOH, dried and treated with a 5% solution of 3-aminopropyltrimethoxy silane in isopropanol, then 1% glutaraldehyde. Gels were sterilized with 70% ethanol for 30 minutes, and then placed in sterile PBS. Different amounts of APMA were tested using primary human renal tubule cells (Lonza). The elastic modulus of the modified gels was measured using an Electroforce 3100 mechanical analyzer.

Results: Cells attached rapidly to gels in standard medium with 10-20% APMA substitution at both stiffness levels, and maintained excellent attachment for at least 6 weeks, under both static and shaking conditions. Cells proliferated on gels until confluent. Higher APMA amounts were less effective with softer gels. Cells initially attached to 5% APMA gels, but detached after 2-3 days. The addition of APMA decreased the stiffness of the softer gels by ~25%, while it increased by ~25% for the harder gels.

Conclusions: Primary human renal tubule cells were found to attach rapidly and robustly to polyacrylamide hydrogels containing 10-20% APMA. Cells proliferated well on APMA based gels, and remained attached for at least 6 weeks, even under fluid shear stress (~2 dyn/cm2). We conclude that the addition of APMA to PA gels provides a very simple and reproducible method of functionalizing PA gels for renal cell attachment, and allows for the testing of soft, tissue-like substrates under physiological fluid flow conditions.

Canonical TGF-β Signaling Mediates Renal Tubule Epithelial Cell Differentiation In Vitro

Kuniko Hunter,[1] Harold D. Love,[2] H. David Humes,[4] Shuvo Roy,[3] William H. Fissell.[2] The Kidney Project
[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of California San Francisco, San Francisco, CA; [4]University of Michigan, University of Michigan, Ann Arbor, MI, US, academic, Ann Arbor, MI.

Background: Transforming growth factor-β (TGFβ) initiates multiple signaling pathways involved in the regulation of epithelial cell fate and cell plasticity. Here we identify canonical TGFβ signaling as a critical regulator of renal tubule epithelial cell membrane transporter expression in vitro.

Methods: Primary human renal tubule epithelial cells (HREC) were cultured on permeable supports on an orbital shaker. After two weeks in culture, cells were supplemented with TGFβ receptor I (TβR1) inhibitors SB431542 or A8301, Smad3 inhibitor SIS3, PI3K inhibitor LY294002, Rapamycin, p38 MAPK inhibitor SB203580, Takinib (2nM), Trametinib. After four weeks, apicobasal fluid transport and gene expression by RT-PCR was measured. Statistical differences were estimated by two-tailed Student's t-test in MatLab.

Results: Canonical TGFβ inhibitors SB431542 and A8301 increase apicobasal fluid transport, while Smad3 inhibitor SIS3 does not. Non-canonical TGFβ inhibitors LY294002, Rapamycin, SB203580, Takinib, Trametinib do not increase apicobasal fluid transport. SB431542 and A8301 suppress Snail1 transcription, while SIS3 does not. SB431542 and A8301 increase AQP2 transcription, while SIS3 does not, and have a greater effect on NHE3 transcription.

Conclusions: Increased inhibitable transport by renal tubule cells in vitro appears to be mediated by canonical TGF-β signaling. The lack of response to SIS3 suggests that Smad2, ratehr than Smad3, is responsible.

TGF-β Mediates In Vitro Renal Tubule Cell Fatty Acid Oxidation

Kuniko Hunter,[1] Rachel C. Evans,[2] Harold D. Love,[2] H. David Humes,[4] Shuvo Roy,[3] William H. Fissell.[2] The Kidney Project *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of California San Francisco, San Francisco, CA; [4]University of Michigan, Ann Arbor, MI.*

Background: Renal tubule cells (HREC) are energetically demanding due to their role transporting solutes., but undergo a shift toward glycolysis and away from oxidative phosphorylation of fatty acids in vitro. We identified Transforming Growth Factor-β (TGFβ) as a critical modulator of HREC differentiation. Here, we find that TGFβ inhibition increases HREC fatty acid oxidation.

Methods: Primary HREC were seeded on polycarbonate Transwells or polystyrene Seahorse XFe96 tissue culture plates. Cells were supplemented with AMPK activator metformin, TGFβ receptor I inhibitor SB431542, or a combination of both. After four weeks, cell oxygen consumption (OCR) and extracellular acidification rates (ECAR) were assessed using a Seahorse XFe96. Glutamine oxidation inhibitor BPTES, fatty acid oxidation inhibitor etomoxir, and glucose oxidation inhibitor UK5099 were used to probe HREC substrate utilization. Gene expression was measured using RT-PCR. Statistical differences were estimated by two-tailed Student's t-test. Results are considered significant at $p<0.05$.

Results: MET and SB43 stimulate transcription of electron transport chain Complexes I, II, IV, and V. Control and MET OCR did not respond to inhibitors. MET cells have diminished basal OCR and decreased ECAR in response to BPTES. SB43 increases basal OCR and cellular responses to UK5099 and etomoxir, implying increased glucose and fatty acid oxidation. SB43 increases transcription of fatty acid transporter CD36 and fatty acid oxidation genes FABP1, CPT1, and CPT2.

Conclusions: Inhibition of TGFβ increases in vitro transcription of mitochondrial genes and oxidative phosphorylation of fatty acids by HREC.

Investigating the Use of Smartwatch-Based Self-Assessments to Monitor Fluid Consumption of Hemodialysis Patients

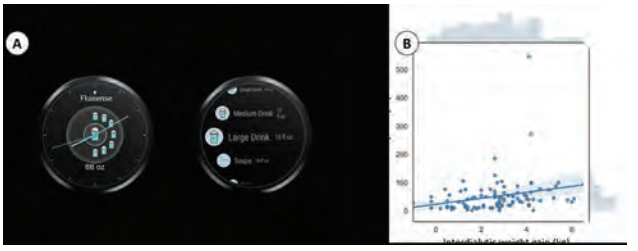
Mehdi Boukhechba, Mingyue Tang, Brendan T. Bowman, Jamie M. Zoellner, Emaad M. Abdel-Rahman. *University of Virginia, Charlottesville, VA.*

Background: Fluid intake control is a bedrock component of treatment for End Stage Kidney (ESKD) Patients, but continues to be a major challenge for patients, healthcare providers, and organizations. The ramifications of poor fluid control include increased mortality and morbidities, frequent hospitalizations and increased total cost of care. The goal of this work is to investigate the feasibility of leveraging self-assessments based on smartwatches to monitor fluid consumption of ESKD patients.

Methods: ESKD patients on hemodialysis (n=11) were given an Android smartwatch with an in-house developed app pre-installed (Fluisense, available on Android play store). Patients were asked to log their fluid intake through the app by choosing from a list of predefined volumes each time they consume any liquid. The app computed and displayed the self-reported daily volume intake to help patients monitor their own fluid consumption (Figure 1-A). Patients received text messages twice a day (9am and 8pm) to remind them to use the watch. We also recorded patients' weights before and after each of the thrice weekly dialysis sessions. The sum of self-reported interdialytic fluid intake was computed and compared against the interdialytic weight gain recorded in the clinic.

Results: Patients recorded fluids in 214 days out of 259 total days (i.e., 83% compliance rate). The average self-reported interdyalitic fluid consumption is 51 oz +/- 64, and the average interdialytic weight gain is 2.67 kg +/- 1.56. We found a moderate but significant correlation between the self-reported fluid volumes and the interdialytic weight gain ($r=0.363$, $P<0.001$, $r2=0.06$).

Conclusions: Leveraging smartwatches for the self-assessment of fluid intake is a promising solution for fluid monitoring of ESKD patients. This can be related to the ease of utilization of this technology and the ecological validity of its measurements given they are collected close to when they happen, reducing recall biases. In the future, we will leverage low-burden sensor data to monitor patients' fluid intake continuously and unobtrusively.



PO0503

Heterogeneous Local Hemodynamics in Rat Arteriovenous Fistula with Sildenafil Treatment

Hannah M. Northrup,[1] Yan-Ting E. Shiu,[1,2] Savanna Cahoon,[1] Isabelle D. Falzon,[1] Maheshika S. Somarathna,[3] Timmy C. Lee.[3,4] *[1]University of Utah, Salt Lake City, UT; [2]SLCVA, Salt Lake City, UT; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Birmingham VA, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) maturation failure is an unmet clinical need. Aberrant blood flow is thought to impair AVF remodeling, but previous literature has largely focused on hemodynamics averaged over the entire AVF. We hypothesize that hemodynamics is not uniform and thus any treatment's effect size is not uniform in AVF. We used the PDE5A inhibitor sildenafil and performed MRI-based computational fluid dynamics (CFD) to test our hypotheses.

Methods: Femoral AVFs were created in young male Sprague-Dawley rats. Sildenafil was given daily starting at 14 days before AVF creation and continuing for 21 days, at which time rats underwent MRI. MRI scans were used for measuring cross-sectional lumen area (CSA), and for CFD to derived flow rate, wall shear stress (WSS), oscillatory shear index (OSI), and vorticity. Results were split into 4 zones: 0-5, 5-10, 10-15, and 15-20mm away from the anastomosis.

Results: Sildenafil treated rats had significantly larger CSA, flow rate, WSS, OSI and vorticity than control rats in all zones ($p<0.05$)(Fig. 1). In both groups: (1) While flow rate remains constant in all zones, CSA increased from 0-5 to 15-20 zone. (2) Velocity, WSS and vorticity were the highest in the 0-5 zone, and each parameter drops significantly thereafter. (3) OSI increases at the 5-10 zone and then decreases gradually.

Conclusions: Sildenafil increased CSA and hemodynamics parameters in AVF. The magnitudes of increases are heterogenous along the AVF. Thus, the effect size of sildenafil on AVF remodeling and the association between hemodynamics and AVF remodeling depends on location. Increased knowledge of local hemodynamics and effect size may lead to treatments to improve AVF maturation.

Effects of Smoothing Methods on Hemodynamic Assessment of a Human Arteriovenous Graft

Brayden Fairbourn,[1] Hannah M. Northrup,[1] Ha D. Le,[1] Yan-Ting E. Shiu,[1,2] Alfred K. Cheung.[1,2] *[1]The University of Utah, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Aberrant hemodynamics contribute to the formation of neointimal hyperplasia in arteriovenous grafts (AVG) for hemodialysis, but the detailed hemodynamic environment in an AVG is unclear. Computational fluid dynamics (CFD), while a useful tool for hemodynamic analysis, is influenced by lumen geometry. 3D vascular lumens reconstructed from medical images must be smoothed to remove surface deformities and improve their uniformity before being used in CFD. We investigated whether different smoothing methods may cause different hemodynamic analysis results.

Methods: MRI scans were performed on a dialysis patient's AVG and then used to reconstruct a 3D AVG lumen, on which four smoothing methods were applied that vary in their uses of interpolation, unconstrained smoothing, and additional surface smoothing (Fig 1A, B). The four smoothed lumens were used in the same CFD protocol to calculate velocity, wall shear stress (WSS), and oscillatory shear index (OSI). Results from different methods were compared using standard deviation (SD) and relative standard deviation (RSD = SD/mean x 100%) (Fig 1C).

Results: All methods give similar AVG lumen areas (RSD<3%). Although velocity has RSDs of 6-9%, their SDs are <0.1 m/s, and thus the differences are not considered biologically significant. Along the same line, all methods do not give biologically significant differences in OSI, as the SDs are <0.01. However, different smoothing methods give very different WSS, with RSD >12% and large SDs.

Conclusions: A variety of smoothing methods can be used to create AVG lumen reconstructions for CFD and hemodynamic analysis. These different methods can lead to significantly different WSS values. Therefore, researchers should consider the smoothing techniques used to characterize the hemodynamic environment in an AVG.

Transdermal Glomerular Filtration Rate Measurement in Conscious Pigs Using the Novel Fluorescent Tracer Agent Relmapirazin

Sabine Neudecker,[1] Daniel Schock-Kusch,[1] Jochen Friedemann,[1] Marlene Jostock,[3] Yury Shulhevich,[1] Dzmitry Stsepankou,[1] Jesse Ross-Jones,[1] James R. Johnson,[2] Thomas E. Rogers,[2] Ivan R. Riley,[2] Jeng-Jong Shieh,[2] Jim M. Harr,[2] Richard B. Dorshow.[2] *[1]MediBeacon GmbH, Mannheim, Germany; [2]MediBeacon Inc., St. Louis, MO; [3]mfd Diagnostics, Wendelsheim, Germany.*

Background: Transdermal measurement of glomerular filtration rate (tGFR) using a miniaturized fluorescence detector ("TGFR Mini Monitors") in combination with a fluorescent exogenous GFR tracer agent is a common technique to measure kidney function in the preclinical setting, most commonly employed with rodents. However, larger animals are used in translational research on the way to human applications. The employ of an exogenous tracer agent in the preclinical setting which will also be amenable for seamless transition to human use would enhance the applicability of the preclinical data to clinical data.

Methods: The renal function of three healthy pigs (35-40 kg) was measured for 3 consecutive days. The novel fluorescent exogenous tracer agent Lumitrace™ (relmapirazin) was used in combination with two TGFR Mini Monitors per animal (MediBeacon, Germany). Excretion kinetics were measured transdermally, as well as in plasma, over the course of 4 hours. After attachment of the devices on the animal's skin, relmapirazin was administered intravenously. Seventeen blood samples were collected to measure plasma pharmacokinetics.

Results: The slopes of the single-exponential decay of the plasma kinetics and the transdermal kinetics of relmapirazin are in agreement (Slope 0.97; R^2=0.57). No statistical differences were detected using a paired t-test.

Conclusions: The collected data supports the suitability of the TGFR Mini Monitor to measure relmapirazin excretion kinetics in pigs, thus providing an important tool for translational research of GFR in larger animals.

Modeling Rare Human Tuberous Sclerosis Complex-Associated Kidney Angiomyolipomas In Vivo with Induced Pluripotent Stem Cell-Derived Renal Organoid Xenografts

Dario R. Lemos. Lemos Lab *Brigham and Women's Hospital, Boston, MA.*

Background: Currently there are no animal models of renal angiomyolipoma (AML) for the study of tumor mechanisms *in vivo*. This is partly due to the fact that biallelic inactivation of *TSC1* or *TSC2* during development causes embryonic lethality, while previous attempts to ablate *TSC1* or *TSC2* by means of tissue-specific Cre-mediated recombination have not succeeded in recapitulating the lesions.

Methods: We induced nephric differentiation of isogenic *TSC2*$^{-/-}$, *TSC2*$^{+/-}$, and *TSC2*$^{+/+}$ human iPSCs derived from a TSC patient, under three-dimensional tissue culture conditions for 21 days. Next we transplanted the resulting renal organoids under the kidney capsule of immunodeficient RNU Nude rats. We next tested the a novel formulation for delivery of the mTOR inhibitor rapamycin using nanocarriers, on xenograft growth and ablation.

Results: Orthotopically transplanted *TSC2*$^{-/-}$ AML organoids displayed significantly higher growth rate compared to *TSC2*$^{+/-}$ or *TSC2*$^{+/+}$ kidney organoids, at Day 14 post-transplantation. Histological analysis of organoid xenograft tissues using antibodies against human nuclear antigen (HNA) or the human isoform of Lamin A/C (hLamin A/C), revealed prominent presence of human AML-like cells expressing smooth muscle and melanocyte markers in *TSC2*$^{-/-}$ but not in *TSC2*$^{+/-}$ or *TSC2*$^{+/+}$ organoid xenografts, indicating that the myomelanocytic phenotype of *TSC2*$^{-/-}$ AML organoids was maintained *in vivo*. mTOR activation was observed in ACTA2^{+} PMEL^{+} cells of *TSC2*$^{-/-}$ AML organoid graft cells, but not in the adjacent normal rat tissue or in *TSC2*$^{+/+}$ or *TSC2*$^{+/-}$ organoid xenografts, indicating that metabolic activation in the absence of TSC2 was consistent with xenograft growth. The rat kidney critically provided vascularization, supporting the growth of *TSC2*$^{-/-}$ organoids, and promoting the proliferation of AML cells. In our drug testing experiments, 3mg/kg rapamycin delivered orally significantly slowed *TSC2*$^{-/-}$ organoid xenograft growth, while local injections of low-dose rapamaycin-loaded nanoparticles resulted in organoid AML cell apoptosis and xenograft abrogation after 7 days, without affecting the rat kidney.

Conclusions: *TSC2*$^{-/-}$ hiPSC-derived AML organoid xenografts recapitulate key features of human TSC-associated AML *in vivo* with a high degree of anatomical and molecular fidelity. This model can be used to study tumor mechanisms and to test new therapies.

Functional Maturation of Kidney Organoid Tubules: Mechanosensitive Ca2+ Signaling

Rolando Carrisoza-Gaytan,[1] Joanne Soong,[1] Basil G. Hanss,[6] Katharina T. Kroll,[2,3] Ken Hiratsuka,[5] Navin R. Gupta,[5] Ryuji Morizane,[5,4] Jennifer A. Lewis,[3,4] Lisa M. Satlin.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Pediatrics, New York, NY; [2]Harvard University John A Paulson School of Engineering and Applied Sciences, Cambridge, MA; [3]Harvard University Wyss Institute for Biologically Inspired Engineering, Boston, MA; [4]Harvard University Harvard Stem Cell Institute, Cambridge, MA; [5]Harvard Medical School Department of Medicine, Boston, MA; [6]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: When grown under static conditions, kidney organoids derived from human pluripotent stem cells exhibit glomerular- and tubular-like structures. However, static organoids possess an "immature" gene expression profile and their vascular development is limited (Homan et al., 2019; Takasato et al., 2015). As the technology for culturing organoids advances, aiming to promote terminal differentiation, the need to better characterize their physiological function has become a priority. To begin to functionally phenotype static organoids, we focused on characterizing mechano-induced changes in intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) and signaling pathways in tubules isolated from maturing static organoids.

Methods: Tubular structures, microdissected from organoids between 21-57 d of culture, were microperfused in vitro or affixed to the base of a specimen chamber, and loaded with Fura-2 AM (20 μM) to measure $[Ca^{2+}]_i$. Digital ratio imaging was performed in individually identified cells by epifluorescence microscopy using commercial software.

Results: The average baseline $[Ca^{2+}]_i$ in microperfused tubules was 189±13 nM (n=6). A rapid increase in $[Ca^{2+}]_i$ was observed when tubules were subject to luminal filling, sufficient to cause circumferential stretch and turbulent flow, reaching values of 404±186 and 719±78 nM in organoids at 40 and 57 d of culture, respectively (n=3, p≤0.002 vs. baseline). Luminal flow-induced increases in $[Ca^{2+}]_i$ were not detected in tubules isolated from organoids <40 d in culture (n=3). Mechanosensitive *Piezo1* channels contribute to the flow-induced $[Ca^{2+}]_i$ response in the fully differentiated distal tubule (Carrisoza-Gaytan et al., EB 2019). Nonperfused organoid tubules exposed to basolateral *Piezo1* activator Yoda 1 (20 μM) exhibited increases in $[Ca^{2+}]_i$ from 110±36 to 272±114 nM (24-31 d in culture; n=4, p≤0.00001) and from 130±36 to 504±197 nM (43-67 d in culture; n=4, p≤0.002).

Conclusions: These preliminary results are consistent with a maturational increase in flow/stretch-sensitive Ca^{2+} channels, including *Piezo1*, and/or associated signaling pathways, in tubules of static organoids in culture.

PO0508

Human Primary Renal Tubuloids as Tools for Pathophysiology and Nephrotoxicity Assessment

Keisuke Sako, Yutaro Mori, Takaharu Ichimura, Joseph V. Bonventre. *Brigham and Women's Hospital, Boston, MA.*

Background: Kidney organoids derived from human induced pluripotent stem cells can be used to study pathophysiology and nephrotoxicity using human kidney tissue. We have developed an efficient alternative way to generate homogeneous epithelial-like structures from kidney tissue derived from patients.

Methods: Human primary renal tubular epithelial cell (hRTEC) cultures were generated using non-tumor cells from partially resected human kidneys for renal cancer. Primary cells were cultured on ultra-low attachment plates for several days. The cells were then transferred into media containing matrigel, hepatocyte growth factor, fibroblast growth factor-2 and 5% fetal bovine serum. Tubuloids were treated with multiple nephrotoxicants. Morphological changes and KIM-1 expression were evaluated. Functional assays to characterize permeability and selective cellular absorption by tubuloids were conducted using fluorescent inulin and albumin. Co-culture experiments of tubuloids with bEnd.3 endothelial cells were performed.

Results: hRTEC tubuloids were generated based on the method above. We have generated a library of hRTECs derived from 25 patients. Tubuloids had polarized expression of cell surface markers, LTL, KIM-1 (apical) and Na-K-ATPase (basolateral). It took only a week to establish hRTEC cultures from patient kidneys and 2-4 weeks to form tubuloids from hRTECs. Cisplatin and palmitate-bound albumin altered the 3D structure of tubuloids. Treatment with aristolochic acid increased KIM-1 expression in a dose-dependent manner. Functional assays revealed that tubuloids reabsorb albumin from the apical side and release it into basolateral side, while being impermeable to inulin. Coculture of tubuloids and bEnd.3 cells resulted in formation of 3D capillary-like structure of bEnd.3 cells around tubuloids.

Conclusions: We generated renal tubuloids using hRTECs derived from patients. This strategy can recapitulate pathophysiology, enable nephrotoxicity screening of human kidney tissue and offers an additional approach to personalized kidney medicine.

PO0509

Nephrotoxicity Assessment with Human Kidney Tubuloids Using Spherical Nucleic Acid-Based mRNA Nanoflares

Christian Wiraja,[1,2] Yutaro Mori,[1] Takaharu Ichimura,[1] Jangsun Hwang,[2] Chenjie Xu,[3,2] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Nanyang Technological University, Singapore, Singapore; [3]City University of Hong Kong, Kowloon, Hong Kong.*

Background: Drug-induced nephrotoxicity represents an important cause of acute kidney injury with associated patient morbidity and mortality and is often responsible for termination of drug development, after extensive resource allocation. Current platforms for testing nephrotoxicity are limited and require disruptive end-point molecular assays. We have paired a 3D human kidney tubuloid system which phenocopies kidney proximal tubules with spherical nanoflare (NF) mRNA nanosensors to achieve facile, real-time assessment of drug nephrotoxicity.

Methods: Primary human tubuloids were generated from tubule cells isolated from patients' kidney tissue and cultured in 3D matrigel settings using serum-free media. NF nanosensors targeting kidney injury molecule-1 (KIM-1) mRNA and GAPDH mRNA were assembled and used to label tubuloids through overnight incubation. KIM-1 NF signal on tubuloids were monitored over time following drug exposure through fluorescence microscopy imaging. Quantitated NF signals were compared with quantitative polymerase chain reaction (qPCR) to verify the accuracy of NF signals.

To demonstrate utility, the proposed NF-tubuloid platform was applied to screen the nephrotoxicity of 10 representative anti-cancer drugs.

Results: Specificity of KIM-1 NF sensors were demonstrated by studying a cell line constitutively expressing KIM-1 mRNA and adenovirus-transfected tubuloids. NF ability to thoroughly label kidney tubuloids and report tubular injury were evaluated by applying several concentrations of aristolochic acid and cisplatin, two well-known nephrotoxicants. Compared against its respective mRNA expression from qPCR, quantitated NF fluorescence showed a positive linear correlation with R^2=0.931, indicating its accurate representation of tubuloid status. Finally, the platform was used to facilitate nephrotoxicity screening of anti-cancer drugs, with significant tubuloid KIM-1 upregulation induced by 5-fluorouracil and paclitaxel.

Conclusions: We demonstrated the utilization of NF nanosensors to monitor injury on human kidney tubuloids. This platform enables facile and personalized nephrotoxicity assessment *in vitro*.

Physiological Replication of the Glomerulus Using a Triple Culture Microphysiological System

Seyedramin Pajoumshariati,[1] Lorna Ewart,[2] Raymond Luc,[2] Ville J. Kujala,[2] Samantha Peel,[1] Heather Weber,[1] Pernille B. Laerkegaard Hansen,[1] Julie Williams.[1] *[1]AstraZeneca PLC, Mölndal, Sweden; [2]Emulate Inc, Cambridge, MA.*

Background: The glomerulus is a complex structure highly adapted for its function. A true representation of the in vivo cell-cell/ECM interactions, which provide the semi-permeable filtration barrier, is essential to interrogate physiological and pathophysiological processes and for understanding the impact of novel therapies.

Methods: We have developed a human microphysiological system with high fidelity to glomerular physiology and structure. For the first time the three resident cell types (glomerular endothelial cells (GECs), induced pluripotent stem cell (hiPSC)-derived podocytes and mesangial cells (MCs)) reside in a relevant 3D structure under flow conditions. Analysis was performed on the individual cell types using both transcriptomics (NGS) and high content imaging to shed light on the impact of each cell type on its neighbors. Inulin and albumin permeability assays (fluorescent) were performed to evaluate the integrity of the glomerular barrier.

Results: Transcriptomic analyses demonstrated crosstalk between cells in our microfluidic tri-culture system. An influence of MCs was observed on both podocytes and GECs. For GECs, MCs increased tight junction proteins (CLDN7) and for podocytes there was modulation of cell cycle control (WDR70). The differentiation of podocytes in the chip was able to regulate matrix and cell adhesion in MC (COL6A3, ITGA2) and influence angiogenic signals in GEC (KDR, THBS1). Analysis of pathways expressed in cells in the less complex comparator systems showed that they displayed transcriptomic signals akin to human disease phenotypes (comparison with signatures found in Nephroseq). Imaging showed increases in maturation markers such as synaptopodin in podocytes in triculture. Permeability assays revealed that as cell maturity increased barrier function improved and the passage of molecules was selectively hindered.

Conclusions: Our tri-culture model provides a highly physiologically relevant tool to study healthy glomerular function. This will enable improved understanding of the mechanisms underlying glomerulopathies and improved qualification of new therapies.

Biomimetic Platform for Quantitative Drug Screening of Podocyte Cytoskeletal Dynamics and Morphology

Smiti Bhattacharya,[1,2] Jonathan C. Haydak,[2] Alan Stern,[2] Robert Wiener,[2] Nicholas J. Wong,[2] Stefanie Defronzo,[2] Ravi Iyengar,[2] Ronald Gordon,[2] Kevin D. Costa,[2] John C. He,[2] James C. Hone,[1] Evren U. Azeloglu.[2] *[1]Columbia University, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Foot process effacement is driven by dysregulation of cytoskeletal dynamics. Currently, there are no drugs that primarily target the podocyte cytoskeleton due to dearth of *in vitro* model systems. To address this limitation, we designed a 3D drug discovery platform with a morpho-mimetic milieu that allows high-throughput quantitative measurements of drug-induced cytoskeletal changes in podocytes.

Methods: Immortalized human podocytes were differentiated on micropatterned surfaces fabricated via photolithography. High-resolution microscopy including confocal, TIRF, SEM and atomic force microscopy (AFM) were used to characterize morphometric and biophysical properties. Protein expression was quantified using automated immunofluorescence, cell proliferation via EdU, and basal motility via fluorescent live-cell imaging. High-throughput analytical capabilities of the system were tested with cytoskeletal dose response against puromycin aminonucleoside (PAN).

Results: Cells cultured in 3D micropatterns for up to 14 days show a significant reduction in morphometric variability compared to unpatterned controls. During differentiation, micropatterned podocytes achieve cell cycle arrest faster and more robustly with reduced motility. Furthermore, the increased speed and the extent of cell cycle arrest is also observed in low serum, suggesting that the effects of morpho-mimetic culture are independent from biochemical stimuli. AFM elastography shows primarily a peripheral distribution of stiff actin fibers in micropatterned podocytes, mimicking *in situ* conditions. A cohesive cytoskeletal dose response was observed against PAN in the micropatterned cells only.

Conclusions: 3D micropatterns increase the speed and efficiency of podocyte differentiation while reducing cell-to-cell variability by up to 5-fold. Through its increased reproducibility, our automated system allows for quantitative *in vitro* study of podocyte morphology, cytoskeleton and biomechanics in response to drugs and pathogens with high fidelity and reproducibility.

Funding: NIDDK Support, Other U.S. Government Support

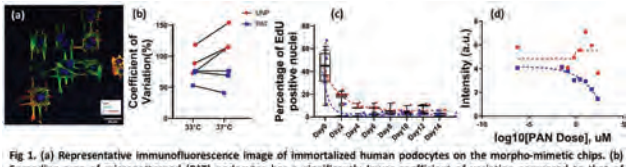

Fig 1. (a) Representative immunofluorescence image of immortalized human podocytes on the morpho-mimetic chips. (b) Spreading area of micropatterned (PAT) podocytes has a significantly lower coefficient of variation compared to that of unpatterned control (UNP) cells.(c) A more rapid decrease in cell division was observed during differentiation for PAT vs. UNP (2.1 ± 1.3 days vs. 6.4 ± 1.8 days) with a significantly lower number of dividing cells at the differentiated state (2.6 ± 1.8% vs. 5.4 ± 4.1%). (d) PAN dose response for cellular actin expression in UNP was mostly indiscernible due to high variability whereas it was clearly visible and quantifiable in PAT.

PO0512

Monitoring Mitochondrial Dynamics Within a Kidney-on-Chip Platform for Investigating Disease Progression and Potential Therapeutics

Samuel H. Kann,[1,2] Erin M. Shaughnessey,[1,3] Xin Zhang,[2] Else M. Vedula,[1] Joseph L. Charest.[1] *[1]Charles Stark Draper Laboratory Inc, Cambridge, MA; [2]Boston University, Boston, MA; [3]Tufts University, Medford, MA.*

Background: The kidneys rely on an abundant number of mitochondria to produce energy to drive key functions, such as fluid/electrolyte balance. Mitochondrial dysfunction has been linked to the progression of renal diseases including acute kidney injury and diabetic nephropathy. Thus, the mitochondria are a key target for therapeutic development. Kidney-on-chip platforms provide a dynamic *in vivo*-like tissue culture environment to investigate renal pathophysiology. Yet, it is difficult or impossible to investigate mitochondrial dynamics due to lack of real-time measurements. Here, we present a sensor integrated kidney-on-chip platform with real-time cell oxygen consumption rate (OCR) readouts for monitoring the dynamics of mitochondrial function.

Methods: Human primary renal proximal tubule epithelial cells (hRPTEC) were cultured in PREDICT96 (P96), a high-throughput organ-on-chip platform. Integrated optical- based oxygen sensors enabled measurement of dissolved oxygen. Flow was turned off to measure decreases in oxygen and compute OCR. hRPTEC were treated with mitochondrial inhibitors Oligomycin and Antimycin A and un-coupler FCCP. OCR was measured prior to and following the drug treatments.

Results: hRPTEC basal OCR was monitored under flow at 70 uL/min over a 10 day culture period. OCR decreased by 58% and 39% following treatment with Antimycin A and Oligomycin, respectively, and increased 64% following treatment with FCCP (**Fig.1**).

Conclusions: We demonstrated real-time and label-free monitoring of drug-induced shifts in mitochondrial respiration within a high-throughput kidney-on-chip platform. Our work enables new investigations into mitochondrial dynamics in response to nephrotoxic agents or disease progression, as well as potential therapeutics that target the mitochondria.

Demonstrating Preclinical Proof of Concept of an Implantable Bioartificial Kidney (iBAK)

Caressa Chen,[1] Ana Santandreu,[1] Charles Blaha,[1,4] Nathan Wright,[1] Jarrett Moyer,[1] Eun jung Kim,[1] Francisco J. Baltazar,[1] Benjamin W. Chui,[1] Tariq M. Haniff,[1] Paul R. Brakeman,[1] Shant M. Vartanian,[1] H. David Humes,[3] William H. Fissell,[2,4] Shuvo Roy.[1,4] The Kidney Project *[1]University of California San Francisco, San Francisco, CA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of Michigan Michigan Medicine, Ann Arbor, MI; [4]Silicon Kidney LLC, San Francisco, CA.*

Background: An implantable bioartificial kidney (iBAK) would provide continuous and convenient treatment while overcoming the challenges of dialysis and renal transplant. We previously demonstrated small-scale operational versions of an immunoprotective renal tubule cell-containing bioreactor and a pumpless hemofilter utilizing biomimetic silicon nanopore membranes (SNM). Here we report the successful integration of bioreactor and hemofilter components into an iBAK prototype that demonstrated operational feasibility in swine.

Methods: Designs of the bioreactor and hemofilter were optimized using computational fluid dynamics. Porcine renal (LL-CPK1) cells were cultured on collagen-coated Transwell® (Corning) membranes and inserted into the bioreactor. A hemofilter containing SNM with ~10 nm-wide pores was connected to the bioreactor in series through the hemofilter blood outlet and bioreactor blood inlet. The iBAK was implanted into the retroperitoneum of a healthy Yucatan mini-pig, with anastomoses from the hemofilter blood inlet and bioreactor blood outlet to the iliac artery and vein, respectively, and the bioreactor ultrafiltrate outlet connected to the bladder. The pig did not receive systemic anticoagulation or immunosuppression. After 3 days, patency was assessed via angiogram and the device was explanted for further analysis. Cell viability was assessed using a LIVE/DEAD™ Cell Viability Assay (Invitrogen).

Results: The iBAK was successfully assembled and implanted with no procedural complications. Post-operatively the pig did not demonstrate signs of seroma/hematoma, thromboembolism, infection, or other adverse reactions. 3 days after implant, the device was patent. Ultrafiltrate was noted at both implant and explant, with a flow rate of 0.28 uL/min measured at explant. Cells demonstrated ~80% viability, relative to *in vitro* controls. No gross thrombi or protein films were observed on the SNM.

Conclusions: We successfully integrated hemofilter and bioreactor components to create a small-scale iBAK. The hemofilter generated ultrafiltrate from blood while the bioreactor sustained renal cells and delivered ultrafiltrate ("urine") to the bladder. This feasibility study will guide future development of a clinical-scale iBAK.

PO0514

A 20-lb Portable Continuous Renal Replacement Therapy (PCRRT) Machine Battery Operated Using 300 mL Fluid: CRRT Anywhere, Any Time

Victor Gura.[1,2] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: CRRT is challenging due to needing large amounts of sterile fluids excessive labor and cost. Prescribed treatment is frequently interrupted when patients are transported out of the ICU for tests and procedures. Hence the unmet need for a light and portable battery operated CRRT machine that uses less fluids and nursing labor and can be used anytime at any place, including during procedures or transportation.

Methods: The machine connects to a central venous catheter and blood is heparinized and propelled through the blood compartment of a 0.6 sqm dialyzer and recirculated back to the central vein. 300 ml of sterile 0.45 N is circulated into the dialysate compartment of the dialysate. Calcium, magnesium, and sodium bicarbonate are added to the dialysate. Potassium and other additives may also be added. Blood and the dialysate are propelled by a double channel pulsatile pump. The volume of fluid removal is controlled by a volumetric separate pump. The spent dialysate coming out of the dialyzer is circulated through sorbents that regenerate the dialysate allowing for the use of only 300 ml of fluid instead of 30 liters, or more, of sterile fluid. Spent dialysate coming out of dialyzers during treatment of renal failure patients and with added urea, creatinine and lactic acid was circulated through the sorbent canisters. Lactate, urea, creatinine, and electrolytes were measured in the dialysate after recirculating through the sorbents.

Results: Urea, creatinine, potassium, and lactate were undetectable in the dialysate after it recycled through the sorbent canisters.

Conclusions: Less sterile fluid and less nursing labor, make it cost-effective. Current machines weigh more than 100 pounds, and have a large footprint, making it impossible to use them out of the ICU, or during ambulance or helicopter transportation. This machine, weighs 20 pounds, is battery powered and uses 300 ml of sterile fluid. The size and weight, and sterile fluid requirements allow uninterrupted use in ICU, on a stretcher, during ambulance or aircraft transportation.

PO0515

High Sodium Reduced the Expression of PTH1R and Klotho by Inhibiting 1,25 (OH)2D3 Synthesis

Huaizhou You, Jie Gu, Jialin Shi, Jing Chen. *Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: The proximal tubule is not only the sensing site of sodium and phosphorus, but also the main place for the synthesis and metabolism of 1,25 $(OH)_2D_3$. Sodium may share the sensing mechanism with phosphate in proximal tubule epithelial cells, whether sodium cooperates with phosphate, or it plays an independent role in the regulation of phosphorus homeostasis remains unknown. In this in vitro study, we were to investigate the effects of high sodium on the synthesis and function of active vitamin D and local phosphorus regulation in proximal tubular epithelial cells.

Methods: Human proximal tubule epithelial (HK-2) cells were treatment with different concentrations of sodium/phosphorus. The expressions of 1α-OHase (Cyp27b1) and 24-OHase (Cyp24a1) were determined by RT-PCR and Western Blot respectively. LC/MS and ELISA were used to detect the levels of 1,25 $(OH)_2D_3$. Intracellular Ca2+ ([Ca2+]i) was detected with the Ca2+ indicator dye Fura-4. Chromatin samples were immunoprecipitated with antibodies against PTH1R and klotho.

Results: High sodium decreased the expression of 1,25 $(OH)_2D_3$ through reducing 1α-OHase and 24-OHase in HK-2 cells. Sodium phosphorus transporter inhibitor (PFA) and sodium hydrogen transporter inhibitor (Caliporide) increased the expression of 1α-OHase and 24-OHase, while ouabain decreased their expressions. High sodium intervention increased intracellular calcium concentration, and chelating extracellular calcium reversed high sodium induced 1α-OHase and 24-OHase expression. High sodium reduced the expression of PTH1R and klotho, combined use of PFA and Caliporide significantly increased the gene and protein expressions of PTH1R and klotho, while ouabain intervention further decreased their levels. Vitamin D receptor agonists significantly increased the recruitment of VDR to the VDRE of PTH1R and klotho promoter, thus increased the expression of PTH1R and klotho.

Conclusions: High extracellular sodium can not only lead to a decrease in the synthesis of active vitamin D in the proximal tubules, but also affect the gene regulation of 1,25 $(OH)_2D_3$/VDR, and significantly reduce the expression of PTH1R and Klotho. It suggests the influence of high sodium diet on mineral metabolism and the core role of vitamin D in kidney mineral metabolism.

PO0516

Enhancement of In Vitro hPTH1-84 Bioactivity by hPTH38-84 and hPTH45-84

Kittrawee Kritmetapak,[1,2] Louis A. Losbanos,[1] Jolaine M. Hines,[1] Ravinder Singh,[1] Rajiv Kumar.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Khon Kaen University, Nai Mueang, Thailand.*

Background: Recent research using high resolution mass spectrometry demonstrates that serum concentrations of full-length parathyroid hormone (hPTH1-84) and its fragments (hPTH28-84, 34-77, 34-84, 37-77, 37-84, 38-77, 38-84, and 45-84) are increased significantly in CKD patients with an eGFR of ≤17-23 mL/min/1.73m^2 (Kritemetapak *et al.* Clin Chem. 2021 Mar 6:hvab013. doi: 10.1093/clinchem/hvab013. Online ahead of print.PMID: 33693557). Information about the bioactivity of these newly discovered hPTH fragments is lacking.

Methods: Recombinant hPTH1-84 was synthesized in *Escherichia coli* and purified by immobilized metal-ion affinity chromatography. hPTH28-84, hPTH38-84, and hPTH45-84 were synthesized by solid phase peptide synthesis. The identity of hPTH1-84 and hPTH fragments was confirmed by mass spectrometry. To determine whether different-sized hPTH fragments modulate the bioactivity of hPTH1-84, we studied their effects on the generation of the cellular second messenger, cAMP, which mediates the intracellular signaling of hPTH1-84, in murine preosteoblasts (MC3T3-E1) *in vitro*. Forskolin, an adenylyl cyclase activator, was used as a positive control for cAMP production. All experiments were performed in triplicate.

Results: In MC3T3-E1 cells, cAMP increased to 28.5±5.5, 64.4±9.9, 91.5±11.6, 114.6±15.5, and 109.1±6.5 pmol/mL 30 minutes after treatment with 1, 3, 10, 50, and 100 nM,hPTH1-84. The same concentrations of hPTH28-84, hPTH38-84, and hPTH45-84 had no effects. When hPTH1-84 was added to cells concurrently with 100 nM hPTH38-84 or hPTH45-84 in 1:100, 3:100, 1:10, 1:2, and 1:1 molar ratios, cAMP responses to hPTH1-84 increased by 65.3% (95% CI, 63.2% to 67.4%; $P<0.01$) in the presence of hPTH38-84 and increased by 77.0% (95% CI, 65.2% to 88.8%; $P<0.01$) in the presence of hPTH45-84. hPTH28-84, added concurrently with PTH1-84, did not enhance cAMP generation in MC3T3 cells.

Conclusions: The small hPTH fragments, hPTH38-84 and 45-84, but not hPTH28-84, enhance the hPTH-induced generation of cAMP in MC3T3-E1, suggesting a novel biological role and a novel mechanism of action for these PTH fragments in osteoblast-like cells. It is plausible that *in vivo* these fragments may enhance the activity of full-length PTH by novel mechanisms. These findings may partly explain the discrepancy between PTH levels and bone histology in patients with CKD.

PO0517

Bone Expression of Sclerostin in CKD and Dialysis Patients

Marciana Laster, Renata C. Pereira, Lauren V. Albrecht, Isidro B. Salusky. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Sclerostin, a 22-kDa glycoprotein secreted by osteocytes, negatively regulates bone formation through the inhibition of the Wnt/β-Catenin pathway. In patients with CKD, circulating sclerostin correlates negatively with bone formation but the impact of bone expression of sclerostin requires further investigation.

Methods: 87 pediatric patients with CKD underwent iliac crest bone biopsy with the quantification of sclerostin bone expression using immunohistochemistry (IHC). Subjects with circulating sclerostin values at the upper and lower extremes of each population (n=6 CKD and n=6 dialysis) underwent staining with two β-catenin antibodies that recognize the phosphorylated/unphosphorylated states.

Results: The median (IQR) age of the cohort was 17 (14, 20) and 39% had pre-dialysis CKD (Table). Significant correlations between IHC sclerostin and bone histomorphometry were limited to the dialysis group: IHC sclerostin correlated with bone formation rate (r=-0.34, p=0.02) and osteoid thickness (r=-0.3, p=0.03). In the sub-group undergoing β-catenin staining, dialysis patients demonstrated low bone staining of sclerostin independent of circulating sclerostin. CKD subjects with high circulating sclerostin levels (ranging from 58 to 110 pmol/L) demonstrated increased sclerostin staining in osteocytes when compared with CKD patients with lower serum sclerostin (ranging from 30 to 36 pmol/L). Phosphorylated β-catenin staining was higher and unphosphorylated β-catenin levels lower in bone tissues with high circulating sclerostin.

Conclusions: Together, these data support a model whereby high levels of circulating sclerostin from osteocytes contributes to altered bone remodeling through aberrant Wnt signaling activity in CKD and may provide a rationale to target therapeutic strategies using monoclonal antibodies towards sclerostin.

The Essential Role of miRNA in Maintaining an Intact Parathyroid in the Adult

Alia Hassan,[1] Rachel Levin,[2] Yael Fisher,[1] Justin Silver,[1] Iddo Z. Ben-Dov,[1] Tally Naveh-Many.[1] *[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Jerusalem College of Technology, Jerusalem, Israel.*

Background: miRNA are small noncoding RNAs with vital roles in homeostasis and development. Dicer mediates the final step of miRNA maturation. To study the roles of miRNA in the parathyroid, we generated parathyroid specific Dicer knockout (PT-*Dicer*$^{-/-}$) mice, to specifically delete parathyroid miRNA. The PT-*Dicer*$^{-/-}$ mice had normal serum PTH levels, but failed to increase PTH when stressed by hypocalcemia or kidney failure, unlike control mice and patients. We now show that in addition to parathyroid stimulation, miRNA are central to maintaining intact parathyroid glands throughout life.

Methods: We generated PT-*Dicer*$^{-/-}$ and control mice expressing YFP (Yellow Fluorescent Protein) in the parathyroid by cre lox recombination, to track parathyroid cells by fluorescence microscopy. Histological slides from P0 (day of birth) and older mice were immunostained. qRT-PCR and Western blots were performed on thyroid tissue that includes the embedded parathyroids.

Results: Surprisingly, adult PT-*Dicer*$^{-/-}$ mice had no YFP positive parathyroid glands detected by fluorescence microscopy, as opposed to easily detected intact glands in controls. However, the glands were present immediately after birth in P0 and P1 *Dicer*$^{-/-}$ mice. At P0 and P1 there were increased levels of the cleaved caspase-3 apoptotic marker in cells co-expressing PTH and the parathyroid transcription factor GCM2. From P3 to P12, there was a gradual loss of parathyroid glands in PT-*Dicer*$^{-/-}$ mice, with the left gland disappearing last. qRT-PCR of thyroid RNA, containing the parathyroid when present, showed reduced expression of PTH mRNA in adult PT-*Dicer*$^{-/-}$ mice, compared to controls. PTH levels were also decreased in thyroid extracts as determined by Western blots. There was no change in thymus PTH mRNA that has been proposed to provide an auxiliary source of PTH.

Conclusions: Mice that do not express miRNA in the parathyroid lose their parathyroid glands after birth, indicating that miRNA are not essential for parathyroid embryonic development by rather postnatally, for maintaining intact parathyroid glands. In the absence of parathyroid glands in adult PT-*Dicer*$^{-/-}$ mice, an additional source for PTH other than cells in the thyroid or thymus contributes to normal basal serum PTH that cannot be stimulated by hypocalcemia or uremia.

PO0519

PTH Suppression Improves Cortical Bone Parameters in Aging Mice with CKD

Samantha P. Tippen, Corinne E. Metzger, Elizabeth A. Swallow, Spencer Sacks, Matthew R. Allen. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Chronic kidney disease (CKD) and aging are each independently associated with higher risk of fracture due to significant loss of bone mass and quality. In CKD, cortical thinning and cortical porosity are driven by elevated parathyroid hormone (PTH) and directly linked to increased fracture risk in CKD patients. Overlaying CKD and aging produces cortical porosity that is higher than either condition alone. Previously, we discovered potent suppression of PTH in rodents with CKD infilled existing pores; however, it is unknown if aged bone may react similarly given attenuated osteoblast function. The goal of this study was to assess the impacts of PTH suppression on cortical porosity in young and aging CKD mice.

Methods: Male C57Bl/6J mice were used at 16 and 66 weeks of age. CKD was induced via dietary adenine (AD, 0.2% for 6 weeks + 2 weeks of maintenance on control diet). Control mice were fed normal control diet for the duration of the study. After 8 weeks of CKD induction, calcium water was provided for 4 weeks to suppress PTH (n=8/group). Outcome measures included biochemical assays and bone architecture via μCT.

Results: Aging AD mice had more than six-fold higher PTH levels than age-matched controls and more than two-fold higher PTH levels than young AD mice. Administration of calcium water led to lower PTH in both young AD and aging AD mice, 85% and 82%, respectively. Regardless of age, AD mice showed lower cortical bone area (~32%) and cortical thickness (32-40%) versus age-matched controls; mice given calcium water had higher cortical bone area (11%, 8%) and cortical thickness (20%, 10%) compared to untreated age-matched AD. Due to large variability, there were no statistical differences in cortical porosity between groups, although porosity did trend lower in both calcium water-treated young AD (-74%) and aging AD (-29%) groups compared to age-matched controls.

Conclusions: These data demonstrate the beneficial impact of PTH suppression on cortical bone in young and aging animals; however, PTH suppression alone may not be enough to sufficiently reduce cortical porosity, particularly in aging bone. This lays the groundwork for future studies to assess clinically available therapies of PTH suppression and their efficacy in reducing cortical porosity in a broad spectrum of CKD patients.

Calcimimetics Alter Periosteal and Perilacunar Bone Matrix Properties in Early CKD

John G. Damrath,[1] Sharon M. Moe,[2] Joseph M. Wallace.[3] *[1]Purdue University Weldon School of Biomedical Engineering, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University Purdue University at Indianapolis School of Engineering and Technology, Indianapolis, IN.*

Background: Chronic kidney disease (CKD) patients have an elevated fracture risk due to hyperparathyroidism, cortical porosity, and reduced bone material quality. Calcimimetic drugs are used to lower PTH in dialysis patients, but their impact on bone matrix quality in early CKD remains unknown. We hypothesized that tissue-level bone quality is altered in early CKD and that calcimimetic treatment improves bone quality.

Methods: Male Cy/+ rats fed a casein-based diet undergo progressive CKD with mineral and bone disorder. 18-week-old rats (stage 3 CKD, N=12) were treated with the calcimimetic KP-2326 (0.6 mg/kg i.p. 3x/wk). N=12 normal littermates (NL) and untreated CKD rats received the casein diet to control mineral intake. Calcein was administered 4 and 14 days prior to sacrifice at 28 weeks (stage 4 CKD). Blood was drawn and femora were harvested for MicroCT and 4-point bending. Femur sections were cut and polished for colocalized Raman spectroscopy and nanoindentation. Colocalization was run in fluid in periosteal bone using calcein as a guide and in concentric ellipses around osteocyte lacunae.

Results: PTH was 284% higher in CKD vs NL and KP reduced PTH by 92% vs CKD. Neither CKD nor KP altered cortical porosity and KP did not improve structural mechanical properties vs CKD. In new periosteal bone, CKD reduced carbonate substitution by 20% and elastic modulus by 15% vs NL while KP increased mineral crystallinity by 4% vs NL and restored elastic modulus to NL levels. In perilacunar bone, KP reduced carbonate substitution and increased elastic modulus and hardness vs CKD.

Conclusions: This study demonstrates that CKD and KP alter bone matrix composition and material properties on the tissue level prior to structural changes such as cortical porosity. The perilacunar data suggests that osteocytes may actively alter their surrounding matrix in CKD and that calcimimetics may help prevent these changes prior to a decline in bone structural integrity.

Funding: NIDDK Support, Other NIH Support - NIAMS, Veterans Affairs Support

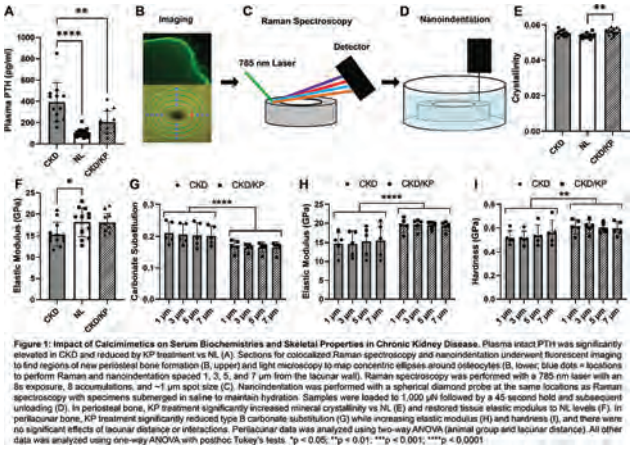

Figure 1: Impact of Calcimimetics on Serum Biochemistries and Skeletal Properties in Chronic Kidney Disease. Plasma intact PTH was significantly elevated in CKD and reduced by KP treatment vs NL (A). Sections for colocalized Raman spectroscopy and nanoindentation underwent fluorescent imaging to find regions of new periosteal bone formation (B, upper) and light microscopy to map concentric ellipses around osteocytes (B, lower; blue dots = locations to perform Raman and nanoindentation spaced 1, 3, 5, and 7 µm from the lacunar wall). Raman spectroscopy was performed with a 785-nm laser with an 8s exposure, 8 accumulations, and ~1 µm spot size (C). Nanoindentation was performed with a spherical diamond probe at the same locations as Raman spectroscopy with specimens submerged in saline to maintain hydration. Samples were loaded to 1,000 µN followed by a 45 second hold and subsequent unloading (D). In periosteal bone, KP treatment significantly increased mineral crystallinity vs NL (E) and restored tissue elastic modulus to NL levels (F). In perilacunar bone, KP treatment significantly reduced type B carbonate substitution (G) while increasing elastic modulus (H) and hardness (I), and there were no significant effects of lacunar distance or interactions. Perilacunar data was analyzed using two-way ANOVA (animal group and lacunar distance). All other data was analyzed using one-way ANOVA with posthoc Tukey's tests. *p < 0.05; **p < 0.01; ***p < 0.001; ****p < 0.0001

Integrated Transcriptomic and Proteomic Analyses for the Characterization of Oxyphil Cells in Patients with Uremic Secondary Hyperparathyroidism

Jianping Mao. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Calcitriol and calcimimetics are the most powerful treatments for secondary hyperparathyroidism (SHPT); however, the mechanisms leading to calcitriol or calcimimetic resistance in oxyphil cell–predominant SHPT are unknown. Here we used transcriptomic RNA-seq and tandem mass tag (TMT) proteomic techniques to characterize oxyphil cells by comparing the differences between chief and oxyphil cell nodules of parathyroid glands in patients with uremia.

Methods: Transcriptomic and proteomic analyses were performed on chief and oxyphil cell nodules collected from uremic patients. We sought to verify the expression of differentially expressed genes (DEGs), and detect the expression of mitochondrion-associated proteins (voltage-dependent anion channel 1 (VDAC1) and mitochondrially encoded cytochrome c oxidase II (MT-CO2)), proliferation-related proteins (proliferating cell nuclear antigen (PCNA) and cyclinD1), parathyroid-specific factors (parathyroid hormone (PTH) and glial cells missing homolog 2 (GCM2)), and SHPT-regulating factors (vitamin-D receptor (VDR), calcium-sensing receptor (CaSR), and Klotho). The mitochondrion microstructure and mitochondrial DNA (mtDNA) copy number were measured to assess the mitochondrial mass. Freshly excised parathyroid tissues were incubated *in vitro* to detect PTH secretion levels.

Results: Compared to chief cell nodules, the most marked expression increases in oxyphil cell nodules were for proteins involved in mitochondrion-associated components and a series of metabolic processes. The mitochondria number, mtDNA content, and protein levels of VDAC1 and MT-CO2 were significantly increased in oxyphil cell nodules. Moreover, oxyphil cell nodules expressed PTH and GCM2, and exhibited lower protein levels of PCNA and Cyclin D1 but higher synthesis and secretion level of PTH. The protein expression of VDR, CaSR, and Klotho were significantly downregulated in oxyphil cell nodules.

Conclusions: Oxyphil cells characterized by enrich mitochondria in patients with uremic SHPT were parathyroid-derived and showed higher synthesis and secretion of PTH but lower expression of SHPT regulators than chief cells, which may contribute to the pathophysiology of SHPT and the treatment resistance to calcitriol and calcimimetics.

The Calcimimetic KP-2326 Alters the Gut Microbiota in a Rat Model of CKD-MBD

Annabel Biruete,[1] Tzu-Wen L. Cross,[2] Shruthi Srinivasan,[1] Kalisha O'Neill,[1] Henriette De loor,[3] Pieter Evenepoel,[3] Neal X. Chen,[1] Kelly Swanson,[4] Sharon M. Moe.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Purdue University, West Lafayette, IN; [3]Katholieke Universiteit Leuven, Leuven, Belgium; [4]University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: CKD-MBD therapies, including diet and phosphate binders, can alter the gut microbiota. However, it is unknown if calcimimetics alter the gut microbiota and their derived uremic toxins.

Methods: Cy/+ rats, a slowly progressive rat model of CKD-MBD (CKD hereafter, n=13) and normal littermates (NL, n=8) consumed a diet with 0.7% phosphorus from 18 wk of age (~ 60% of NL glomerular filtration rate (GFR)) to euthanasia at 28 wk of age (~30% of NL GFR). An additional CKD group received the pre-clinical form of etelcalcetide, KP-2326 (CKD+KP; 0.6 mg/kg IP 3 times/wk, n=13) for a total of 10 wk starting at 18 wk of age. DNA was extracted from cecal samples, the V4 region of the 16S rRNA gene was sequenced via Illumina MiSeq, and data were analyzed via QIIME2. Indoxyl sulfate (IS), p-cresyl sulfate (PCS), and trimethylamine-N-oxide (TMAO) were quantified by ultra-performance liquid chromatography-tandem mass spectrometry.

Results: CKD or KP did not affect α-diversity, or diversity within samples. B-diversity, or diversity between samples, assessed by unweighted UniFrac distances was different across all groups (PERMANOVA p=0.001; q<0.013 between groups). Weighted UniFrac distances (presence/absence + abundance), differed between NL vs. CKD and CKD vs. CKD+KP (q<0.04), and there was a trend between NL and CKD+KP (q=0.07). At the phyla-level, CKD rats had a lower relative abundance of Firmicutes than NL (60.6±9.4% vs. 68.7±3.4%, p=0.03), but CKD+KP rats were comparable to NL (67.9±4.5%, p=0.96). Bacteroidetes relative abundance was higher in CKD vs. CKD + KP (22.1±5.3 vs. 17.7±3.2%, p=0.03). Several bacterial genera that were lower in CKD were comparable to NL rats with KP, including *Allobaculum, Bifidobacterium,* and *Blautia.* Similarly, CKD rats had a higher relative abundance of the mucin-degrader *Akkermansia* compared to NL, and while KP had a lower relative abundance, it remained higher than NL. Despite the gut microbial changes, IS, PCS, and TMAO levels were higher in the CKD and CKD+KP compared to NL rats (p<0.05).

Conclusions: KP-2326 changed the gut microbial composition without altering the levels of gut-derived uremic toxins. As the calcium-sensing receptor is expressed along the gastrointestinal tract, future studies should explore the effect of calcimimetics on host-microbe interactions.

A New Physiological Model to Study Regulation of SLC26A6-Mediated Oxalate Transport in Mouse and Human Intestinal Tissue

Madeleine J. Schorr,[1] David Holthaus,[3] Valeria Fernandez Vallone,[4] Robert B. Thomson,[2] Harald Stachelscheid,[4] Peter S. Aronson,[2] Felix Knauf.[1,2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Yale University School of Medicine, New Haven, CT; [3]Robert Koch Institut, Berlin, Germany; [4]Berlin Institute of Health, Berlin, Germany.*

Background: Intestinal organoids have great utility in studying stem-cell self-organizing properties. However, barrier and transport functions cannot be determined readily in three-dimensional (3D) cultures. We converted 3D intestinal organoids to two-dimensional monolayers (2D) and studied oxalate transport physiology via the oxalate transporter SLC26A6. Furthermore, we investigated the response of intestinal organoids to high oxalate concentrations.

Methods: Mouse and human adult stem cell-derived 3D culture systems were grown onto 2D monolayers. Cell differentiation was compared by gene expression and western blotting. Plasma membrane transport was examined in mouse and human monolayers with radioactively labeled substrates. Monolayers were exposed to soluble oxalate and cell death was measured by Caspase-3 activation and lactate dehydrogenase (LDH) release.

Results: We demonstrate that 2D intestinal monolayers maintained the gene expression profile of 3D organoids. Furthermore, murine and human intestinal organoids demonstrated high Cl-oxalate exchange transport activity that was 4,4-diisothiocyanostilbene-2,2-disulfonic acid (DIDS)-sensitive. Chloride-oxalate exchange was abrogated in murine organoids deficient for Slc26a6, resulting in intracellular oxalate accumulation, Caspase-3 activation and LDH release.

Conclusions: We conclude that 2D intestinal organoid cultures are suitable *in vitro* models to study oxalate transport from mice and humans. Using these models we demonstrate that Slc26a6-mediated chloride-oxalate exchange protects from intracellular oxalate accumulation and cell death.

Optimization of Oxalobacter formigenes-Derived Small Peptides with Therapeutic Potential for Hyperoxalemia, Hyperoxaluria, and Related Kidney Stones

Hatim A. Hassan, Altayeb Alshaikh, Jonathan Zerweck. *The University of Chicago, Chicago, IL.*

Background: Most kidney stones (KS) are composed of calcium oxalate, and very small increases in urine oxalate enhance the stone risk. Besides KS, oxalate also potentially contributes to CKD progression and CKD - and ESRD-associated cardiovascular diseases, emphasizing the need for plasma and urinary oxalate lowering therapies, and enhancing the bowel's ability to secrete oxalate may effectively do so. We previously discovered *Oxalobacter*-derived secreted factors stimulating oxalate transport by human intestinal Caco2-BBE (C2) cells and reducing urinary oxalate excretion in hyperoxaluric mice by inducing colonic oxalate secretion. We identified the small peptides P8 and P9 as the major secreted factors and they have significant therapeutic potential for hyperoxalemia and hyperoxaluria. Natural peptides are often not suitable therapeutics due to rapid degradation by proteolytic enzymes, and P8 & 9 peptides have multiple enzymatic cleavage sites.

Methods: Described under Results.

Results: To optimize P8 & 9 peptides and make them resistant to proteolytic degradation, there were subjected to the following structural modifications. N-terminal acetylation (P8-Ac & P9-Ac), C-terminal amidation (P8-Am & P9-Am), retroinverso (P8-RI & P9-RI), and replacing several glycine and lysine sites with PEG6 (P8-P & P9-P) & ornithine (P8-O & P9-O), respectively. All of these modified peptides stimulated oxalate transport by C2 cells similar to the native P8 & 9, except P9-RI (47.3% less functional) and P8-RI (nonfunctional). The native and modified peptides were then treated with different enzymes (trypsin, proteinase K, and colonic lavage fluid [CLF: mimics the colonic environment]) to evaluate the impact of such modifications using LC-MS and/or HPLC in an *in vitro* stability assay. Native and modified (P8/9-Ac, P8/9-Am, & P8/9-P) peptides were completely degraded by the above enzymes. P8-O and P9-O have improved stability (~57-80%) against trypsin, but they were fully degraded by proteinase K and CLF. Importantly, P9-RI is completely resistant to degradation by the above enzymes.

Conclusions: P9-RI is the most stable optimized peptide, but is less functional compared to native P9. Studies are ongoing to evaluate its *in vivo* therapeutic effects in lowering plasma and urinary oxalate levels in hyperoxalemic and hyperoxaluric mice.

Leaky Intestinal Epithelium Causes Hyperoxaluria in CA-MLCK Mice

Hatim A. Hassan,[1] Mohamed Elfatih Bashir,[1] Altayeb Alshaikh,[1] Daniel Y. Jung,[1] Jerrold R. Turner,[3] John R. Asplin.[2] *[1]The University of Chicago, Chicago, IL; [2]Litholink Corporation, Chicago, IL; [3]Harvard Medical School, Boston, MA.*

Background: Most kidney stones are composed of calcium oxalate, and very small increases in urine oxalate enhance the stone risk. The intestine plays a crucial role in oxalate homeostasis, and intestinal oxalate absorption is largely passive and paracellular. To evaluate whether enhanced intestinal paracellular permeability can increase urinary oxalate excretion, mice with augmented small and large intestinal paracellular leak (transgenic mice expressing intestinal constitutively active myosin light chain kinase = CA-MLCK) were used.

Methods: Described under Results.

Results: CA-MLCK mice have significantly higher (1.27-fold) urine oxalate compared to controls (μM/mg creatinine; Controls = 10.15±0.48; CA-MLCK = 12.86±0.65), reflecting that primary intestinal barrier dyscfuntion is sufficient by itself to cause hyperoxaluria. This 27% increase in urinary oxalate concentration is significant since minor increases enhance the stone risk. To see if the observed hyperoxaluria is due to enhanced passive paracellular intestinal oxalate absortion, jejunal and ileal tissues were isolated from control and CA-MLCK mice and mounted in Ussing chambers, and unidirectional ^{14}C-oxalate and ^{3}H-mannitol absorptive fluxes were assessed. CA-MLCK mice have signifincatly higher ileal ^{14}C-oxalate (1.65-fold) and ^{3}H-mannitol (1.70-fold) absorptive fluxes. CA-MLCK also have a statistically insignifcant higher jejunal ^{14}C-oxalate (1.31-fold) absorptive flux. To determine whether enhanced intestinal oxalate absorption is also active *in vivo* as observed *ex vivo,* control and CA-MLCK mice were orally gavaged with a single dose of ^{13}C-oxalate, followed by urine collection x 6 h. CA-MLCK mice have a statistically insignifcant higher (1.40-fold) ^{13}C-oxalate excreted in the urine compated to Controls in preliminary studies, suggesting that they absorbed higher amount of the administered ^{13}C-oxalate, which is likely due to the underlying intestinal barrier dysfunction leading to enhanced passive paracellular oxalate absorption.

Conclusions: CA-MLCK mice have significant hyperoxaluria due to mechanisms including enhanced small intestinal passive paracellular oxalate absorption. These findings are of significant interest since they provide new understanding into the role of leaky intestinal epithelium and hyperoxaluria, a feature of diseases such as obesity, DM, IBD, and celiac disease.

Transcriptomic Mapping of the Human Kidney Papilla Reveals Myeloid Immune Activation and Matrix Remodeling Pathways in Stone Disease

Victor Hugo Canela,[1] William S. Bowen,[1] Ricardo Melo ferreira,[1] Blue Lake,[3] Kun Zhang,[3] Sanjay Jain,[2] Michael T. Eadon,[1] James C. Williams,[1] Tarek M. El-Achkar.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Washington University in St Louis, St Louis, MO; [3]University of California San Diego, La Jolla, CA.*

Background: The role of the kidney papilla in the pathophysiology of stone disease remains unclear. The aim of this study was to identify the cellular and molecular determinants of nephrolithiasis by molecular mapping of the stone forming papilla using integrated single nuclear and spatial transcriptomics.

Methods: Renal papillary biopsies were obtained from Calcium oxalate (CaOx) stone formers and reference non-stone formers. Tissue sections were prepared according to Visium (10x Genomics) spatial transcriptomic protocol. Single nucleus RNA sequencing from papillary frozen sections was used to spatially map the signature of specific cell types within the tissue. Data analysis and visualization were performed in R (seurat, ReactomePA, ClusterProfiler) and Loupe browser. In-situ mapping of cell distribution and pathway activation were quantified using 3D immunofluorescence imaging. The levels of select proteins in urine samples were quantified by ELISA.

Results: Genes and pathways associated with reactive oxidative stress, myeloid immune activation and extracellular matrix (ECM) remodeling were significantly upregulated in CaOx biopsies relative to non-stone forming reference. Spatial transcriptomic localized the signature of specific cell types and demonstrated the increased expression of genes from those pathways such as FOS, JUN, SOD2, CCL2, SPP1, MMP7/9 and MGP, particularly in areas within or adjacent to mineralized regions in the stone forming papillae. 3D immunofluorescence imaging confirmed the observed activated stress response and myeloid immune activation using phospo-c-JUN and CD68 staining, respectively. Additionally, the activation of myeloid and ECM remodeling pathways was validated by increased levels of MMP7 and MMP9 in the urine of patients with stone disease compared to healthy controls.

Conclusions: Using integrated transcriptomic and imaging approaches, we demonstrate that the papilla of stone patients is an active site of myeloid immune activation, oxidative stress and matrix remodeling. This immune active state had a molecular profile comparable to atherosclerotic disease. Our studies also uncover potential novel markers for screening and activity assesment of important pathogenic pathways in stone patients.

Assessment of Vascular Calcification Using Micro-CT Quantification in a Vitamin D Rat Model

Firas Bassissi,[1] David Sabador,[3] Marc Blasco Ferrer,[1] Guillermo Garaulet Perez,[3] Maria del mar Perez,[1] Miquel D. Ferrer,[1,2] Francisca Mulero,[3] Carolina Salcedo.[1] *[1]Sanifit Therapeutics, Palma, Spain; [2]Universitat de les Illes Balears, Palma, Spain; [3]Centro Nacional de Investigaciones Oncologicas, Madrid, Spain.*

Background: Micro-computed tomography (micro-CT) scanning could be an alternative technique of both visualization and quantification of calcium content in vessels. Our aim was to standardize the micro-CT calcium quantification methodology and evaluate its reliability in a rat model of calcification.

Methods: Six Sprague-Dawley rats were induced by three consecutively daily subcutaneous administrations of 150 klU/kg vitamin D3 and sacrificed 5 days after induction. Three of the rats were subcutaneously treated with 60 mg/kg SNF472 (G1), an inhibitor of calcification, and the rest were treated with saline (G2). One additional rat was not induced nor treated and served as negative control. Micro-CT was performed in aorta and femoral arteries with an isotropic resolution of 45 μm, 400 projections collected in one full rotation of the gantry in 10 min, x-ray tube at 80 kV and 150 μA. A phantom made of a laser cut aluminum skeleton was scanned with the same protocol to simulate bone. After the image analysis, the vessel samples were digested (1:1 HNO_3:$HClO_4$) and total calcium was quantified using an inductively coupled plasma atomic emission spectrometry (ICP-AES).

Results: The threshold for calcium detection was established at 153.8 Hounsfield Units (HU). Rats treated with vitamin D presented more calcium deposits than the control and SNF472 treated rats (7.6 ± 6.1 HU in G2 vs 3.3 ± 3.2 HU in G1). The volume of calcium deposits in femoral samples was similar between groups. The quantification of calcium by ICP-AES brought similar results in aorta (>50% inhibition with SNF472 treatment) but not in femoral samples, as in this tissue increased calcium content was quantified in vitamin D-treated rats when compared to the control rat. A significant correlation was obtained between the calcium deposits quantified by micro-CT and the total calcium quantified by ICP-AES.

Conclusions: The threshold-based quantification method by micro-CT can be a useful and reliable tool to evaluate vascular calcification and the efficacy of inhibitors of vascular calcification in rat models, especially in large-diameter vessels such as aorta.

The Effect of the Warfarin-TG2-MVs Axis in Vascular Calcification

Yuqiu Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Warfarin is a common anticoagulant drug. How to effectively reduce vascular calcification induced by warfarin while ensuring its anticoagulant effect is an urgent problem to be solved. Previous studies have found that warfarin enhances the expression and activity of transglutaminase 2 (TG2) in vascular smooth muscle cells (VSMCs), which mediates communication between cells and extracellular matrix (ECM). Matrix vesicles (MVs) are the center of hydroxyapatite crystal precipitation, which is released to ECM and interacts with ECM protein to initiate mineralization and form calcification core. This study observed the role of warfarin-TG2-MVs axis in vascular calcification by culturing VSMCs in vitro.

Methods: VSMCs were cultured in normal or osteogenic medium (OM) and stimulated with 10 μm warfarin for 3-14 days. The expressions of SM22α, Runx2, ALP, OPN and OPG were detected by RT-PCR, Western blot. Alizarin red and von Kossa staining were performed to evaluate calcification, and calcium content was determined. Meanwhile, the expression and activity of TG2 were detected. Differential centrifugation was used to extract MVs and evaluate their release. Type I collagen was coated in the culture dish to determine the calcification of MV-collagen.

Results: Warfarin stimulation promoted transdifferentiation of VSMCs, that the expression of osteogenic factors Runx2, ALPL and OPN were increased, while the expression of SM22α and calcification inhibitor OPG were decreased. When using OM, the above trend was more obvious. Alizarin red and von Kossa staining were performed when the cells were cultured for 14 days. The results of calcium staining in the warfarin intervention group were all positive. Warfarin promoted the expression and activity of TG2, and it gradually increased with the extension of the intervention time. The same amount of cells were cultured for 7 days under different stimuli, and the medium was changed every other day. Then, the supernatant was collected for differential centrifugation. The amount of MVs produced by the warfarin and OM group was significantly higher than that of other groups, and the ability to mineralize of MVs in type I collagen was increased.

Conclusions: Warfarin increased the expression and activity of TG2, promoted the release of MVs from VSMCs, and further cross-linked ECM to aggravate vascular calcification.

PO0529

Uremic Milieu Exacerbates Muscle Regeneration After Muscular Injury in Mice

Takaaki Higashihara, Hiroshi Nishi, Masaomi Nangaku. *The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan.*

Background: In our life, skeletal muscle injuries occur not only in strenuous exercises but also in daily activities with unexpected excessive muscle contraction. In general conditions, injured muscles are repaired to normal structure, and muscle functions are rescued. However, whether this repair process is affected in the uremic milieu has not been fully elucidated yet.

Methods: In C57BL6 male mice fed with normal diet or 0.2% adenine-conjugated diet, the muscle injury was induced by intramuscular injection with vehicle (PBS) or barium chloride ($BaCl_2$) in tibialis anterior (TA) muscles. Then, we evaluated the TA muscle wet weight, histology, muscle strength, and marker gene expressions of $Pax7^+$ satellite cells and macrophages playing a pivotal role in muscle regeneration. We also treated differentiating mouse skeletal myoblasts with a representative uremic toxin, indoxyl sulfate (IS), and evaluated the cell morphology and marker gene expressions.

Results: In adenine-induced CKD mice, the $BaCl_2$-injected TA muscle showed reduction of muscle wet weight, muscle fiber size, instantaneous muscle strength, and Pax7 gene expression compared to control mice. Furthermore, the gene expression of DLL1 and Notch2 regulating the Pax7 expression, CCL5 accelerating the migration of macrophages, and cell surface markers of M1/2 macrophages (CD206, CD163, and CD86) also decreased in the injured muscle of CKD mice. Treatment of murine C2C12 myoblast with IS led to not only the myotube atrophy but also smaller number of nuclei per myotube. The gene expression of Pax7, DLL1, and CCL5 increased during the C2C12 myoblast differentiation, but IS treatment deteriorated these expressions as seen in vivo experiments.

Conclusions: Uremic milieu deteriorated muscle regeneration with the decline of gene expression associated with satellite cells and macrophages.

PO0530

Indoxyl Sulfate Induces Cardiomyocyte Hypertrophy via FGF23-FGFR4 Signaling Pathway

Hiroshi Kishimoto,[1] Toshiaki Nakano,[1] Shunsuke Yamada,[1] Kumiko Torisu,[1] Masanori Tokumoto,[3] Masatomo Taniguchi,[2] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Fukuoka renal clinic, Fukuoka, Japan; [3]Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

Background: Both fibroblast growth factor 23 (FGF23) and indoxyl sulfate (IS) have been reported to relate with left ventricular hypertrophy (LVH) in patients with chronic kidney disease (CKD), but their inter-relationship remains unknown.

Methods: To induce LVH, 8-week-old-male C57BL/6J mice were fed high phosphorus diet after heminephrectomy for the induction of FGF23 and administrated with continuous subcutaneous dose of 100mg/kg IS per day for 4 weeks, and half of them were treated with continuous intraperitoneal administration dose of 7.5 mg/kg H3B-6527 (H3B), a fibroblast growth factor receptor 4 (FGFR4)- inhibitor. Moreover, rat cardiac myoblast (H9c2, 2-1) cells were incubated with 0, 0.25 or 1.0 mM IS and collected after 24 and 72 hours for RT-PCR and western blotting, respectively.

Results: IS promoted cardiac hypertrophy, and inhibition of FGFR4 reduced heart weight and left ventricular wall thickness in IS groups ($p < 0.05$). There was no significant difference in serum FGF23 level among experimental groups, but the expressions of FGF23 protein and mRNA in the heart were markedly increased in IS-injected mice compared to control mice ($p < 0.05$). In cultured H9c2 cells incubated with IS, intact FGF23 protein expression and phosphorylation of FGFR4 were elevated in cell lysate, but intact FGF23 protein level in the media didn't change. The mRNA levels of β-myosin heavy chain (βMHC), α-smooth muscle actin (αSMA), brain natriuretic peptide (BNP), polypeptide N-acetylgalactosaminyltransferase 3 (Galnt3), and FGF23 were significantly up-regulated ($p < 0.05$), but collagen I was not.

Conclusions: IS increased intact FGF23 protein expression and activated FGF23-FGFR4 signaling in cardiomyocyte, leading to LVH, and FGFR4 inhibition suppressed IS-induced LVH.

PO0531

Hyperphosphatemia Contributes to Skeletal Muscle Atrophy in the Absence and Presence of CKD

Kylie Heitman,[1] Brian A. Czaya,[2] Isaac D. Campos,[1] Christopher Yanucil,[1] Dominik Kentrup,[1] David G. Westbrook,[1] Seth Bollenbecker,[1] Stefanie Krick,[1] Christian Faul.[1] *[1]The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; [2]University of California Los Angeles, Los Angeles, CA.*

Background: Chronic Kidney Disease (CKD) is a public health epidemic and associated with elevated serum levels of phosphate (hyperphosphatemia) as well as skeletal muscle atrophy, and the interconnection is poorly understood. Elevated phosphate (Pi) has direct effects on smooth muscle cells and induces vascular calcification. We wanted to test if Pi directly induces atrophy in skeletal muscle cells. Furthermore, we analyzed skeletal muscle on a functional, histological and molecular level in three models of hyperphosphatemia – two CKD models, i.e. mice with global deletion of collagen 4a3 (Col4a3-/-) and wildtype mice receiving an adenine-rich diet, as well as wildtype mice on a high Pi diet with normal kidney function. Finally, we determined the effect of a low Pi diet on skeletal muscle in Col4a3-/- mice.

Methods: C2C12 myotubes were treated with 1-5 mM Pi for 24 hours, followed by qPCR expression analysis of atrophy genes (atrogenes), including MT1, Trim63, and Fbox32. Furthermore, we studied Col4a3-/- mice receiving normal chow or a 0.2% Pi diet at 10 weeks of age. We also analyzed C57Bl/6 mice receiving an adenine-rich (0.2%) diet for 14 weeks or a 3% Pi diet for 3 months. We analyzed grip strength, hindlimb area by MRI, muscle wet weight, cross-sectional area of individual muscle fibers immuno-labeled with anti-laminin by fluorescence microscopy, and expression levels of atrogenes by qPCR.

Results: Pi treatments increased the expression levels of atrogenes in C2C12 myotubes. In the three mouse models, grip strength and cross-sectional area of myofibers were significantly reduced, and the expression levels of atrogenes were significantly elevated when compared to respective controls. Additionally, the two CKD models showed significant reductions in muscle weight and hindlimb area. Administration of a 0.2% Pi diet protected Col4a3-/- mice from developing skeletal muscle atrophy.

Conclusions: Elevated Pi induces myotube atrophy in vitro. Mouse models with hyperphosphatemia develop skeletal muscle atrophy in the presence and absence of CKD, and a low Pi diet protects the skeletal muscle in CKD mice. Pharmacological approaches targeting Pi uptake or excretion, or inhibition of Pi's direct actions on tissues might alleviate various CKD-associated pathologies.

Renal FGF-23 Resistance by Phosphate Leads to NaPi-2a Internalization via Activated PiT-2/ERK1/2 Signaling in Proximal Tubule

Beatrice Richter,[1] Stefanie Walter,[1] Isabel Vogt,[1] Roland Schmitt,[2] Dieter Haffner,[1] Maren Leifheit-Nestler.[1] *[1]Hannover Medical School Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover, Germany; [2]Hannover Medical School Department of Nephrology and Hypertension, Hannover, Germany.*

Background: The bone-derived hormone fibroblast growth factor (FGF) 23 targets the kidney to promote urinary phosphate (Pi) excretion by activating the FGFR1/Klotho/ERK1/2 signaling in renal proximal tubule (PT) cells. This reduces type II sodium phosphate cotransporters NaPi-2a and NaPi-2c in the apical brush border membrane (BBM) lowering serum Pi levels. In vitro data show that under high extracellular Pi, the type III sodium-dependent phosphate transporters PiT-1 and PiT-2 activate ERK1/2 in bone cells. Moreover, Pi-regulated osseous FGF23 secretion is facilitated via PiT-2. Here we aim to analyze Pi versus FGF23 regulated Pi transport in the setting of high phosphate load in renal PT cells.

Methods: We subject C57BL/6N male mice to increased dietary Pi load (0.8% vs. 2%) for 6 months to determine phosphate homeostasis and analysing kidneys by qPCR, immunoblot and histology. In addition, we study cultured renal PT cells treated with phosphate or FGF23 to examine the activation of downstream signaling events and

expression levels of specific target genes. Furthermore, we determine if co-treatment with the phosphate transporter inhibitor Foscarnet blocks the observed effects.

Results: A 2% Pi diet promotes the elevation of plasma FGF23 levels in mice. Despite reduced TRP, increased FEPi and urine Pi levels, the serum Pi levels are still enhanced. In animals fed a 2% Pi diet, we observed reduced renal *NaPi-2a* mRNA expression. Immunofluorescence staining revealed internalization of NaPi-2a from the apical BBM due to the high dietary Pi load. This is confirmed by analysing BBM vesicles. Interestingly, mice on 2% Pi diet have a diminished renal Klotho expression, but unaltered Fgfr1 expression. PiT-2 expression is increased and accumulated in the basolateral membrane of PT. In cultured PT cells, Pi enhanced *PiT-2* expression. The Pi-mediated increase in ERK1/2 phosphorylation was blocked by Foscarnet co-treatment.

Conclusions: Hyperphosphaturia might be a result of PiT-2/ERK1/2-mediated downregulation of NaPi-2a stimulated by Pi itself. Our study indicates these Pi-mediated effects may be independent of FGF23. We postulate that high dietary Pi load causes a resistance of renal FGF23/Klotho signaling.

PO0533

Recurrence of Hypophosphatemia Despite FGF-23 Reduction in Dmp1 Knockout Mice

Xueyan Wang,[1] Jadeah J. Spindler,[1] Guillaume Courbon,[1] Marta Martinez-Calle,[1] Wenhan Chang,[2] Jian Feng,[3] Valentin David,[1] Aline Martin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of California San Francisco Department of Medicine, San Francisco, CA; [3]Texas A&M University, Dallas, TX.*

Background: Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone produced by bone. Hypophosphatemic rickets diseases, such as X-linked hypophosphatemia (XLH) and autosomal recessive hypophosphatemic rickets (ARHR), are associated with FGF23 excess, impaired skeletal growth and osteomalacia. Treatment with FGF23 blocking antibody has shown great promise to improve serum phosphate (Pi) levels and bone mineralization in XLH. Further studies need to determine if blocking FGF23 is efficacious in the long term and in other diseases associated with FGF23 excess, including ARHR.

Methods: We deleted *Fgf23* in osteocytes using a *Dmp1*-cre in wild-type (WT) and Dmp1 knockout ($Dmp1^{KO}$) mice. We studied the bone and mineral phenotype of WT, $Fgf23^{cKO}$, $Dmp1^{KO}$ and $Dmp1^{KO}/Fgf23^{cKO}$ mice at 12 and 20 weeks of age.

Results: $Fgf23^{cKO}$ mice showed a 40% reduction in serum intact FGF23 levels and a 25% increase in Pi levels (vs. WT), confirming successful deletion. As expected, DMP1 deficiency in $Dmp1^{KO}$ mice induced significant elevations in serum FGF23 levels (+15-fold) and PTH levels (+5-fold), phosphaturia, hypophosphatemia, rickets and osteomalacia (vs. WT). At 12 and 20 weeks, osteocyte specific deletion of *Fgf23* in $Dmp1^{KO}$ mice partially corrected FGF23 levels (-80%), PTH levels (-50%), and ameliorated the bone phenotype (+50% in femur length and bone mineral density) (vs. $Dmp1^{KO}$). Partial reduction of FGF23 levels was sufficient to fully correct serum Pi levels in 12 week-old (NS vs. WT), but not in 20 week-old $Dmp1^{KO}/Fgf23^{cKO}$ mice which showed recurrent hypophosphatemia despite nearly normal FGF23 levels. In contrast, phosphaturia persisted in $Dmp1^{KO}/Fgf23^{cKO}$ mice at 12 and 20 weeks (vs. $Dmp1^{KO}$), suggesting that lowering FGF23 and PTH is insufficient to prevent phosphaturia in $Dmp1^{KO}$ mice.

Conclusions: These data suggest that in $DMP1^{KO}$ mice, hypophosphatemia is only partially responsible for the bone defects and that blocking FGF23 might not be sufficient to prevent hypophosphatemia in the long term.

PO0534

Linking CKD with COPD: Kidney-Lung Cross-Talk and the Role of Phosphate and FGF-23 in the Bronchial Epithelium

Seth Bollenbecker, Molly Easter, Jarrod W. Barnes, Christian Faul, Stefanie Krick. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Dysregulation of phosphate homeostasis and increased circulating FGF23 levels are associated with chronic kidney disease (CKD); however, their role in pulmonary pathology remains poorly defined. Hyperphosphatemia is associated with increased mortality in patients with chronic obstructive pulmonary disease (COPD). Human bronchial epithelial cells (HBECs) are key effector cells in the pathogenesis of COPD, making them essential for assessing the comorbid association of COPD with CKD. Smoking is the leading cause of COPD and dramatically accelerates kidney disease occurrence. We have previously shown that FGF23 can directly affect the COPD bronchial epithelium. With the goal of improving outcomes for patients with concomitant CKD and COPD, we aimed to study the effects of phosphate, FGF23, and cigarette smoke on HBECs and their underlying mechanisms.

Methods: HBECs were treated with 1 to 5 mM sodium phosphate, FGF23, and/or cigarette smoke extract (CSE). Expression levels of proinflammatory cytokines, including interleukin (IL)-1β, IL-6, and IL-8 were analyzed by RT-qPCR. Concentration of these cytokines in the conditioned media was also quantified via enzyme-linked immunosorbent assay. In addition, wild type and FGFR4 knockout ($FGFR4^{-/-}$) mice were fed a high phosphate diet for a total of three months or exposed to cigarette smoke for three weeks. Lung tissue was then analyzed by western blotting and RT-qPCR.

Results: Increased phosphate concentrations induced an inflammatory response in HBECs, which was further exacerbated by the addition of CSE but attenuated by FGF23 treatment. Furthermore, mice on a high phosphate diet showed increased FGF23 and IL-6 levels in their lung. The increase in IL-6 was not observed in the $FGFR4^{-/-}$ mice. Subacute cigarette exposure led to an increase in IL-1β and IL-8 in total lung tissue, which was abrogated in the $FGFR4^{-/-}$ mice.

Conclusions: Our in vitro data suggest that CKD-associated hyperphosphatemia may increase cigarette smoke induced airway inflammation, whereas our in vivo data demonstrates a role of both phosphate and FGF23 signaling in mediating lung inflammation. In summary, our results show that in CKD, there seems to be kidney-lung crosstalk with both FGF23 and phosphate as mediators of an inflammatory airway response, which seems to be mediated by FGFR4.

Plasma Biomarkers of Mineral and Bone Disorder in ADPKD Patients Treated with Tolvaptan

Matteo Bargagli,[1,2] Nasser Dhayat,[3] Manuel Anderegg,[3] Uyen Huynh-do,[3] Pietro Manuel Ferraro,[1,2] Daniel G. Fuster.[3] *[1]U.O.C. Nefrologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [2]Università Cattolica del Sacro Cuore, Rome, Italy; [3]Division of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland.*

Background: Autosomal-dominant polycystic kidney disease (ADPKD) is characterized by a unique bone and mineral phenotype. Patients affected by ADPKD show parathyroid hormone (PTH) resistance, a better-preserved cortical bone mass, higher sclerostin levels, lower bone turnover and total alkaline phosphatase compared to other chronic kidney disease (CKD) aetiologies. To date, the association between tolvaptan administration, plasma biomarkers of mineral and bone disorder (CKD-MBD) and bone mineral density has not been investigated.

Methods: We conducted an analysis of patients enrolled in the Bern ADPKD registry, a prospective observational cohort study. Plasma parameters for CKD-MBD and 24-hour urine analyses were performed at baseline and every 12 months thereafter. DEXA scans were obtained at baseline and after 3 years. Multivariable fixed-effects regression models adjusted for age, sex, BMI, eGFR, urinary sulfate excretion (a marker of acid intake) and NGIA (a marker of alkali intake) were applied to study changes in CKD-MBD parameters and bone mineral density associated with tolvaptan treatment.

Results: A total of 167 participants (56 with and 111 without tolvaptan treatment) were included in the analysis. Median follow-up time was 24.5 months. After adjusting for potential confounders, tolvaptan treatment was associated with a significantly reduced plasma PTH (β -14.84; 95%CI, -28.61 to -1.07; p=0.04), increased total plasma calcium (β 0.05; 95%CI, 0.01 to 0.09; p=0.01), plasma magnesium (β 0.02; 95%CI, 0.00 to 0.04; p=0.03) and femoral but not lumbar bone mineral density (β 0.10; 95%CI, 0.01 to 0.19; p=0.04 and β 0.22; 95%CI, -0.04 to 0.08; p=0.49, respectively). In contrast, tolvaptan treatment was not associated with changes in plasma phosphate, ionized calcium, TmP/GFR, serum intact fibroblast growth factor 23, plasma alkaline phosphatase, blood pH or serum 1,25(OH)2 and 25(OH) vitamin D.

Conclusions: Tolvaptan treatment is associated with changes in mineral metabolism parameters and increased bone mineral density at the femoral neck. Long-term prospective studies are needed to assess the impact of tolvaptan on fracture risk.

Call for Harmonization of the Histomorphometric Reference Ranges for Bone Turnover in Renal Osteodystrophy

Hanne S. Joergensen,[1,2] Patrick D'Haese,[3] Geert J. Behets,[3] Etienne Cavalier,[4] Pieter Evenepoel.[1,5] on behalf of the EUROD initiative of the CKD-MBD working group of the ERA-EDTA *[1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]Aarhus Universitetshospital, Aarhus, Denmark; [3]Universiteit Antwerpen, Antwerpen, Belgium; [4]Universite de Liege, Liege, Belgium; [5]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium.*

Background: Knowledge of bone turnover helps guide fracture preventive treatment in patients with chronic kidney disease (CKD). Bone histomorphometry remains the gold standard to assess bone turnover, while non-kidney retained bone biomarkers are considered a valid, but imperfect alternative. Published reports show marked variation in the histomorphometric reference values of bone turnover. Our aim was to investigate the impact of different diagnostic cutoffs on the categorization of bone turnover in a CKD population.

Methods: 199 patients with successful bone biopsies before or after kidney transplantation were categorized for bone turnover according to diagnostic cut-offs as published by Salusky *et al* and Malluche *et al*, recently published normative histomorphometric data by Recker *et al*, as well as population-based normal ranges for bone-specific alkaline phosphatase (BsAP), tartrate-resistant acid phosphatase type 5b (TRAP5b), and trimeric procollagen type I N-terminal propeptide (Intact PINP; all IDS-iSYS).

Results: Major differences in the distribution of bone turnover categories were seen depending on the reference method used, for both kidney transplant candidates (n = 80, Figure) and recipients (n = 119, data not shown). Compared to the categorizations based on biochemical bone turnover markers, the bone biopsy diagnosis was skewed towards lower bone turnover when using cut-offs as proposed by Salusky or Malluche.

Conclusions: These findings call for harmonization and calibration of bone histomorphometry for the categorization of bone turnover. This will require a collaborative effort to first, construct a repository of bone histomorphometric data from healthy controls across ages, sexes, and ethnicities, and second, to reach a consensus on the diagnostic cut-offs for bone turnover in renal osteodystrophy.

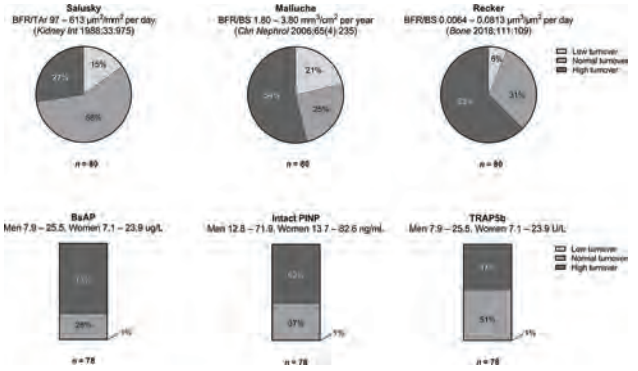

Figure Distribution of bone turnover by different references in kidney transplant candidates with chronic kidney disease stage 5-5D

Effects of Patiromer on Serum Phosphate over 4 Weeks of Treatment in Hyperkalemic Patients with Hyperphosphatemia: Pooled Analysis of the AMETHYST-DN, OPAL-HK and TOURMALINE Trials

David A. Bushinsky,[1] Murray Epstein,[2] Jeffrey J. Budden,[4] Jinwei Yuan,[4] Philip A. Kalra.[3] *[1]University of Rochester School of Medicine and Dentistry, Rochester, NY; [2]University of Miami School of Medicine, Miami, FL; [3]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [4]Vifor Pharma Group, Redwood City, CA.*

Background: Elevated serum phosphate (sP) is associated with increased mortality in non-dialysis CKD. KDIGO guidelines suggest elevated sP should be lowered into the normal range: 2.5–4.5 mg/dL. Patiromer is a non-absorbed, sodium-free, potassium (K^+) binder that uses calcium as the exchange ion which, when released, likely binds to intestinal phosphate. We conducted a *post-hoc* analysis of pooled data from AMETHYST-DN, OPAL-HK and TOURMALINE to evaluate patiromer's effect on sP over 4 weeks in patients with sP>4.5mg/dL.

Methods: Eligible patients had CKD and hyperkalemia (HK; serum K^+ [sK^+]>5.0 mEq/L). Prescription of phosphate binders was not allowed. Hyperphosphatemia subgroup was defined as baseline sP>4.5mg/dL. Patients in the analysis received ≥1 dose of patiromer (8.4–33.6 g/day to start) and had ≥1 post-baseline sP assessment. Mean (± SD) changes from baseline in sP, sK^+, serum magnesium and serum calcium at weeks 2 and 4 were evaluated.

Results: 86/578 (15%) patients had baseline sP>4.5mg/dL: 56% were male, mean (SD) age was 63.9 (10.5) years, 84% had diabetes, mean (SD) eGFR was 25.9 (17.2) mL/min/1.73m^2 and 76% had stage 4/5 CKD. Mean (SD) baseline sP and K^+ were 5.0 (0.5) mg/dL and 5.5 (0.4) mEq/L, respectively. At 2 or 4 weeks of patiromer treatment, both mean sP and sK^+ levels decreased into the normal range (**Table**). Most frequent adverse events (AEs) were constipation (8/86; 9%) and diarrhea (6/86; 7%); most cases were mild or moderate in severity. AEs leading to study discontinuation occurred in 3/86 (4%) patients.

Conclusions: Patiromer decreased both sP and sK^+ into the normal range in patients with elevated sP and sK^+. Patiromer was well tolerated with mild/moderate gastrointestinal events. The ability of patiromer to normalize sP may be therapeutically useful in hyperkalemic patients with CKD and hyperphosphatemia.

Circadian Changes in Serum Phosphate Among Patients with ESKD on Hemodialysis

Charles Ginsberg,[1] Lindsay M. Miller,[1] Norma J. Ofsthun,[2] Lorien S. Dalrymple,[2] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Serum phosphate concentrations are known to have a circadian rhythm in healthy adults and in CKD, with a nadir in the late morning and a peak in the afternoon. Circadian changes in serum phosphate concentrations among persons on chronic hemodialysis may have important treatment implications, as serum phosphate concentrations are a therapeutic target in these patients.

Methods: We assessed serum phosphate concentrations in 118,440 persons with ESKD treated with in-center hemodialysis at Fresenius Kidney Care centers across the United States in July 2017. We used linear regression to assess the relationship between time of day and serum phosphate concentrations. We assessed unadjusted models and models adjusting for age, sex, race, region, weight, diabetes and use and dose of vitamin D analogs, calcimimetics and phosphate binders.

Results: The cohort had mean age 63 ± 13 years, 44% were female, 53% were white and 33% were black. The mean serum phosphate concentration was 5.3 ± 1.5mg/dl. In both the unadjusted and fully adjusted models, serum phosphate concentrations varied over the day with a peak at 6:00 pm and a nadir at 10:00 am (p<0.001). In the unadjusted model the difference from peak to nadir was 0.6mg/dl. This difference was attenuated in the fully adjusted model to 0.2 mg/dl (Figure).

Conclusions: In a large and diverse cohort of adults with ESKD treated with hemodialysis, serum phosphate concentrations varied depending on the time of day in which serum phosphate levels were measured. Thus, the target serum phosphate range for patients treated with hemodialysis should account for when serum phosphate is being measured.

Association of Combined Urinary Fractional Excretion of Phosphate and Serum FGF-23 with Adverse Events in Moderate and Advanced CKD: An Analysis from the CRIC Study

Luís C. Mendonça,[1] Miguel Bigotte Vieira,[2] João Sérgio Neves.[1] *[1]Centro Hospitalar Universitario de Sao Joao, Porto, Portugal; [2]Nephrology Department, Hospital Curry Cabral, Centro Hospitalar Universitário de Lisboa Central, Lisboa, Portugal.*

Background: High levels of FGF23 are associated with adverse events in CKD. The urinary fractional excretion of phosphate (FePi) might modify this association, although data are limited in moderate and advanced CKD. We investigated the association of combined FePi and serum FGF23 with mortality, renal and cardiovascular events in patients with prevalent CKD 2-4.

Methods: Patients from the Chronic Renal Insufficiency Cohort (CRIC) were divided into four groups according to the median of FePi and FGF23: 1) low-FePi/low-FGF23, reference group; 2) high-FePi/low-FGF23; 3) low-FePi/high-FGF23; 4) high-FePi/high-FGF23. Primary outcomes were: incident heart failure; a composite atherosclerotic cardiovascular disease (ASCVD) outcome of myocardial infarction, ischemic stroke or peripheral artery disease; CKD progression; and all-cause mortality. The association of groups with the longitudinal outcomes was assessed through unadjusted and adjusted Cox proportional hazards models.
