Conclusions: Black patients at a Midwestern medical center were receptive towards *APOL1* genetic testing and believed that testing would motivate changes in health-related behaviors. Ongoing research is needed to determine optimal patient-centered use of this emerging risk assessment tool.

Utility of Genetic Testing in Informing Management of Patients with Kidney Disease

Daniel W. Ross,[1] Kenar D. Jhaveri,[1] Laurel Kartchner,[2] Dinah Clark,[2] Kerry Gaj,[2] Deepa A. Malieckal.[1] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Natera, Inc., San Carlos, CA.*

Background: Early identification of monogenic causes of CKD through genetic testing can improve disease treatment, inform management and improve outcomes. Genetic testing can also be useful for families with a history of CKD to plan for the future, including appropriate identification of organ donors. Here we describe the use of genetic testing, with RenasightTM, an NGS-based >380 gene panel for kidney disease, to inform treatment for patients being treated for kidney abnormalities.

Methods: We performed a retrospective analysis of genetic test results using Renasight™ (NGS-based>380 broad kidney gene panel) at a large academic center over an 18-month period. After signed informed consent, broad genetic testing was performed on blood or saliva samples from 31 patients. Genetic testing results were then related to alterations in the management of treatment of these patients.

Results: In this cohort, 41.9% (13/31) were female with an average age 51 years. The most common demographic groups were African American and Caucasian (6 patients [19.4%], each). Nineteen patients (61.3%) underwent Renasight testing due to a CKD diagnosis, 5 (16.1%) due to nephritis/nephritic syndrome, 3 (9.7%) due to proteinuria/nephrotic syndrome, 1 (3.2%) due to thrombotic microangiopathy, 1 (3.2%) due to phosphorus metabolism disorder, and 1 (3.2%) due to hemochromatosis. Positive results were identified in 12.9% (4/31) of the patients in the *COL11A1, COL4A4,* and *APOL1* genes. Genetic testing results led to changes in management for 35.4% (11/31) of patients, confirmed diagnoses for 22.6% (7/31), provided additional diagnoses for 41.93% (13/31), and prompted family testing for 22.6% (7/31). For 4 patients with positive findings, test results impacted treatment management: 1 had transplant management impacted, 1 underwent biopsy to confirm Alport Syndrome, 1 had FSGS diagnosis confirmed and 1 underwent biopsy to confirm FSGS and initiated dialysis. Additionally, negative results led to alterations in management for 48.4% (15/31) of patients.

Conclusions: In this cohort at an academic practice, genetic testing informed nephrologists' management of their patients in multiple capacities. Negative results can rule out genetic causes of disease, and carriers and variants of uncertain significance (VUS) can inform family planning decisions and enable testing in family members.

PO1290

Early Experience with Broad-Panel Genetic Testing in Pre- and Post-Transplant Evaluation of Patients with Kidney Failure

Rupi K. Sodhi,[1] Amishi S. Desai,[1] Jongwon Yoo,[1] Divya J. Arwindekar,[1] Katya Brossart,[2] Hossein Tabriziani,[2] Sanjeev Akkina.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Natera, Inc., San Carlos, CA.*

Background: Genetic testing plays an important role in kidney transplantation (KT). Genetic assessment during the pre-KT workup enables more accurate estimation of the risk of recurrent kidney disease and informs treatment of recurrence living-related kidney donor selection. Testing with a broad genetic panel may be beneficial for patients with advanced disease. Here we describe an academic transplant center's early experience with a >380-gene kidney disease panel using NGS, with variant confirmation via orthogonal methods.

Methods: Twenty-six pre- and post-KT patients underwent genetic testing between June 2020 and April 2021. Patients ranged in age from 28 to 67 years, with a median age of 31 years. Genetic testing results were correlated to clinical histories, including biopsy (when available), ultrasound results, presence of proteinuria and hematuria, demographic factors, family history and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Positive findings were identified in 38.5% (10/26) of patients tested, in *TTR, COL4A3, COL4A4, COL4A5, COL11A1, INF2,* and *PKD1*. Two patients with a pathogenic variant in the *TTR* gene also had 2 *APOL1* risk alleles (G1 and/or G2). Genetic findings confirmed clinical disease in 1 individual, identified a subcategory of clinical disease in 2 individuals, reclassified disease in 3 individuals, and established a molecular diagnosis in 4 individuals. In this cohort, 8 individuals received a KT, of which 6 had no pathogenic variant identified. Of those 6, two had biopsy proven glomerular disease that recurred after early KT, implicating a non-inherited cause of renal disease. Identification of positive pathogenic variants in 75% (3/4) of patients evaluated for a living related donor transplantation, prompted evaluation of the intended donors.

Conclusions: Identification of patients awaiting KT who are at increased risk of a monogenic disease can result in a high yield via a broad-panel testing approach. The implications of a genetic diagnosis in this cohort are multifaceted, with potential to impact care and identify family members who may be at risk for kidney failure, and to enable early diagnosis and intervention.

PO1291

Early Experience with Broad-Panel NGS Testing for Kidney Disease in a Community Nephrology Setting

Tarek Darwish,[1] Katya Brossart,[2] Hossein Tabriziani.[2] *[1]Kansas City Kidney Specialists, Overland Park, KS; [2]Natera, Inc., San Carlos, CA.*

Background: Despite the increasing awareness of the value of incorporating genetic testing, its adoption in community nephrology settings is limited. Genetic testing can guide prognostication, targeted treatments, referral to specialists for extra-renal features, and identification of at-risk relatives. For individuals with kidney failure, additional testing can help assess the risk of recurrent kidney disease after transplant and evaluation of suitable living related kidney donors. Broad-panel testing can provide benefits over narrow panels based on clinical presentation.

Methods: Thirty-one patients with kidney disease completed genetic testing with the Renasight™ test (NGS-based >380-gene kidney disease panel) between October 2020 and April 2021. Median age of patients was 49 years (range: 28-78 years). Genetic testing results were correlated to clinical histories, demographic factors, family history (when available) and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Positive findings were identified in 22.6% (7/31) of patients tested in the *APOL1, PKD1, SLC2A9, COL4A4,* and *PKD2* genes (Table 1). Testing resulted in implications for prognosis in 85.7% (6/7) of patients and in changes in clinical management for 28.6% (2/7) of patients. Homozygosity or compound heterozygosity for the *APOL1* high risk alleles G1 and G2 was identified in 9.7% (3/31) of patients and were found primarily in African American patients.

Conclusions: In the community nephrology setting, the utility of genetic testing as part of the diagnostic workup is multifaceted. As compared to selection of a narrow panel based on clinical features, use of a broad panel that includes reporting of the *APOL1* high risk alleles has the additional benefit of identifying genetic causes of kidney disease with ambiguous or non-specific clinical findings.

Findings from Broad Panel Genetic Testing in Patients with Kidney Disease

Genes (# patients)	Associated Genetic Condition	Inheritance Pattern*
APOL1 (3)	Susceptibility to End-Stage Renal Disease & Focal Segmental Glomerulosclerosis 4	Complex
COL4A4 (1)	Alport Syndrome, COL4A4-Related	AD & AR
PKD1 (1)	Polycystic Kidney Disease 1	AD
PKD2 (1)	Polycystic Kidney Disease 2	AD
SLC2A9 (1)	Renal Hypouricemia 2	AD & AR

*Inheritance patterns: autosomal dominant (AD); autosomal recessive (AR); X-linked (XL)

PO1292

KIDNEYCODE: A Genetic Testing Program for Patients with CKD

Prasad Devarajan,[1] Kenneth V. Lieberman,[2] Xiangling Wang,[5] Bradley A. Warady,[3] Alex R. Chang.[4] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Hackensack Meridian School of Medicine, Nutley, NJ; [3]Children's Mercy Hospitals and Clinics, Kansas City, MO; [4]Geisinger Health, Danville, PA; [5]Cleveland Clinic, Cleveland, OH.*

Background: Knowledge about the genetic causes of chronic kidney disease (CKD) is one of the key gaps in global kidney research. Recent International Society of Nephrology recommendations encourage the adoption of genetic testing to provide precision medicine based on individual risk. A recent whole-exome sequencing study showed that genetic inheritance may be responsible for up to 10% of CKD diagnoses in adults, many of which may be previously undiagnosed or mis-diagnosed. Continued advances in DNA sequencing technology have made genetic testing applicable to routine clinical diagnoses.

Methods: K**ID**NEYCODE offers no-charge genetic testing for three rare forms of CKD: Alport syndrome (AS), focal segmental glomerulosclerosis (FSGS), and 2 forms of polycystic kidney disease: autosomal dominant polycystic kidney disease (ADPKD) due to *PKD2* mutations and autosomal recessive polycystic kidney disease. Invitae's renal disease panel includes 18 genes (*ACTN4, ANLN, APOL1, CD2AP, COL4A3, COL4A4, COL4A5, CRB2, HNF1A, INF2, LMX1B, MYO1E, NPHS1, NPHS2, PAX2, PKD2, PKHD1,* and *TRPC6).* Patients in the US with eGFR ≤ 90 mL/min/1.73m^2 plus hematuria or a family history of CKD, or with a known or suspected diagnosis of AS or FSGS are eligible for testing. Family members of those with suspected or known AS or FSGS are also eligible. All participants have access to genetic counseling follow-up at no additional charge.

Results: To date, the K**ID**NEYCODE program has results from 1389 genetic tests. Genetic variants were reported in 845 patients. Of those, 574 patients had 613 variants in *COL4A3, 4, or 5* genes (403 Pathogenic/Likely Pathogenic (P/LP), 210 Variants of Uncertain Significance (VUS)), 284 patients had 302 variants in genes associated with FSGS (55 P/LP, 247 VUS), 112 patients had 115 variants in *PKHD1* (15 P/LP, 100 VUS), and 22 patients had a variant in *PKD2* (7 P/LP, 15 VUS), and 75 patients had a VUS in *APOL1*.

Conclusions: Results from the K**ID**NEYCODE genetic testing program demonstrate that combining genetic testing with clinical presentation and medical history can improve accuracy of diagnosis in patients with hereditary CKD.

The Emerging Role of Whole-Genome Investigation to Identify Undetected Nephropathies: The HIDDEN Study

Andrew J. Mallett,[1,2] Amali Mallawaarachchi,[3,4] Zornitza Stark,[5,6] Cas Simons,[5] Catherine Quinlan,[5,6] Chirag Patel.[7] The KidGen Collaborative *[1]Townsville Hospital and Health Service, Townsville, QLD, Australia; [2]James Cook University, Townsville, QLD, Australia; [3]Garvan Institute of Medical Research, Darlinghurst, NSW, Australia; [4]Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [5]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [6]The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; [7]Royal Brisbane and Women's Hospital, Herston, QLD, Australia.*

Background: 5% of Australian and New Zealand patients commencing kidney replacement therapy have an uncertain kidney disease aetiology. New approaches and tools are required to resolve such diagnostic odysseys. WGS is an emerging diagnostic technology whose role in this setting is unclear. We sought to determine the diagnostic yield of clinical whole genome sequencing (WGS) in individuals with unexplained end stage kidney disease (ESKD).

Methods: Adult and paediatric patients reaching Chronic Kidney Disease Stage 5 before 51 years of age without an identified aetiology were prospectively recruited through an Australian national network of 18 clinics. Eligibility was determined by a national clinical committee based on pre-specified criteria. Clinically-accredited WGS analysis was undertaken with a curated "KidneyOme" virtual panel of genes associated with Mendelian kidney disorders. A genomic diagnosis constituted a KidneyOme result of pathogenic or likely pathogenic variant/s of appropriate zygosity.

Results: 168 individuals were referred (2018-2021) of whom 147 were approved and 104 consented. Of these, 40 (38.5%) were female and median age was 43yrs; 41 (39.4%) reached ESKD before 30yrs and 63 (60.6%) had undergone native kidney biopsy. Of 50 results returned to date, 7 (14%) were diagnostic, including both autosomal dominant (4/7) and recessive (3/7) inheritance patterns with 6/7 having a family history of CKD. A further 14/50 had variants of uncertain significance. One diagnosis was due to a copy number variation. The KidneyOme virtual panel curation of 384 genes is publicly available in PanelApp-Australia.

Conclusions: One in seven patients with ESKD of uncertain aetiology had an undetected underlying monogenic cause for their kidney disease. Application of KidneyOme with WGS has diagnostic utility and should be considered in younger patients with unexplained renal failure.

The Utility of an Inherited Kidney Disease Clinic Employing a Broad Range of Genomic Testing Platforms: Experience of the Irish Kidney Gene Project

Elhussein A. Elhassan,[1,3] Katherine A. Benson,[2] Susan L. Murray,[1,3] Kane E. Collins,[3] Edmund H. Gilbert,[3] Dervla M. Connaughton,[4,5] Claire Kennedy,[1] Mark A. Little,[6] Gianpiero Cavalleri,[3] Peter J. Conlon.[1,3] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland Department of Molecular and Cellular Therapeutics, Dublin, Ireland; [3]Royal College of Surgeons in Ireland, Dublin, Ireland; [4]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [5]Western University Division of Nephrology, London, ON, Canada; [6]Saint James's Hospital, Dublin, Ireland.*

Background: Inherited kidney diseases (IKD) are increasingly identified in adult patients. Here we demonstrate the diagnostic and clinical impact of evaluating patients with potential IKD in a dedicated IKD clinic (IKDC) utilising various genomic testing technologies (whole-exome sequencing, comprehensive gene-panel, and dedicated *MUC-1* sequencing) and immunostaining.

Methods: We undertook a prospective cohort study of adult patients referred to an academic medical centre with suspected monogenic cause as part of the Irish Kidney Gene Project (IKGP), between 2014 and 2020. Patients with chronic kidney disease (CKD) who had either a positive family history, extrarenal features, or had CKD of "unknown cause" (uCKD) were recruited from various centres across Ireland. We attempted to identify disease-causing variants and to assess the impact of the IKDC from diagnostic and clinical perspectives.

Results: During this period, genetic testing was performed for 677 adults (n= 501 families). The median age was 53 years (range, 18-93 years) and 73.9% participants had reported a family history of renal disease. We achieved a molecular diagnostic rate of 56.7 % (384/677). Among the identified disease-causing variants, PKD was the largest cohort (n= 183, 47.8% for *PKD1* and *PKD2),* while mutations in three other causative genes were most prevalent among the remaining identified 42 genes encompassing several Mendelian disorders; *MUC-1* (*n*=31, 8.1%); *COL4A5* (n=30, 7.8%); *UMOD* (*n*= 12, 3.3%). In the remaining 167 disease-causing variants, excluding PKD, the clinical diagnosis was confirmed in 60.5% and 18% of cases were reclassified. A molecular diagnosis was established in 27 (36.5%) patients with uCKD, implying the end of their diagnostic odyssey. Clinically, a diagnostic kidney biopsy was unnecessary in 13 (7.7%) patients based on the genomic testing, 80 (47.3%) had their treatment plan altered and further 76 (45%) patients had appropriate cascade testing.

Conclusions: The IKDC is a valuable resource and the implementation of a broad range of diagnostic platforms has a direct clinical and therapeutic impact on treatment of patients with CKD.

PO1295

Characterization of Patients with Alport Syndrome in the United States: A Retrospective Analysis of Medical Claims

Baris Deniz,[1] Aparna Singeetham,[1] Ishan Goradia,[2] Aishwarya Clarivate.[2] *[1]Reata Pharmaceuticals Inc, Irving, TX; [2]Clarivate Analytics US LLC, Philadelphia, PA.*

Background: Alport syndrome (AS) is a rare, hereditary genetic condition that often results in chronic kidney disease and may lead to early onset of end-stage kidney disease. The prevalence estimate in the literature is around 30,000-60,000 in the US. However, there are challenges with AS diagnosis (i.e. underdiagnosis and misdiagnosis), hence real-world patient population with AS diagnosis can be less than the prevalence estimates. This study is a retrospective analysis of medical insurance claims aimed to get a real-world estimate of the number of patients with a formal diagnosis of AS in the US, their disease characteristics, and treatment patterns.

Methods: A retrospective, observational cohort analysis was conducted, that leveraged DRG/Clarivate medical claims database, that integrates multi-payer and multi-plan data and covers >220 million annual patients in the US. Patients with at least one ICD-10 code (Q87.81) designated for AS in their medical history between October 2015 to September 2020 were considered diagnosed AS cases. Characteristics of patients and prescription data were analyzed descriptively. Patient interactions with health care professionals (HCP) within the last 24 months of the study window (i.e. October 2018 – September 2020) were used to determine the primary HCP responsible for patient management.

Results: The analysis identified total of 10,387 patients with at least one AS diagnosis code. Of the 42% of the population for whom chronic kidney disease (CKD) stage data were available, 44% had advanced CKD (IV & V). Adult or pediatric nephrologists were the primary HCPs for 59% of patients. Based on the prescription data, 21.6% (2,244 patients) were prescribed ACEs/ARBs, and 10.6% (1,101 patients) were prescribed CYP3A4 inhibitors.

Conclusions: The number of patients our study identified with AS diagnosis is lower than the commonly cited prevalence estimates in the US. The discrepancy can be explained by the fact that the database used covers a majority of but not the whole US population, and our study relies on real-world diagnoses.

Funding: Commercial Support - Reata Pharmaceuticals

AS Population (n)	CKD Stage (%)*				
	CKD I	CKD II	CKD III	CKD IV	CKD V
10,387	13%	11%	32%	17%	27%

* Staging data were available for 42% (4,404 pts) of the diagnosed population.

PO1296

Healthcare Resource Utilization by Patients with Alport Syndrome in the United States: A Retrospective Claims Analysis

Baris Deniz,[1] Sureka Gattu,[1] Mohit Mehra,[2] Justin W. Li,[2] Angela Yuan,[2] Samina Khan.[1] *[1]Reata Pharmaceuticals Inc, Plano, TX; [2]Trinity Partners LLC, Waltham, MA.*

Background: Alport syndrome (AS) is a rare and serious inherited form of chronic kidney disease (CKD) affecting as many as 60,000 persons in the US. In severe cases, patients develop end-stage kidney disease (ESKD) in their 20's. The health and economic burden associated with AS has not been well- characterized in the literature. This study aims to address this evidence gap.

Methods: A retrospective claims analysis (IBM MarketScan® Commercial Database) was conducted to assess the healthcare resource utilization (HCRU) by patients with AS in the US. Patients enrolled in a health plan for a minimum of six continuous months with at least 1 inpatient or 2 outpatient claims with the AS-specific ICD-10 code were considered to have a diagnosis of AS. Patients with AS were further segmented into CKD stages, where such information was available, to understand the impact of disease progression on HCRU. Patients with AS were age- and gender- matched to a comparator group without AS diagnosis in a 1:5 proportion. The analysis included commercial (medical and pharmacy) claims from 2015 to 2019.

Results: 851 patients with AS were identified, of which 518 also had a CKD diagnosis. The mean age was 33.3 years and 51% were males. 16.2% of patients were < 18 years old. Patients with AS required more healthcare services than the matched comparator group. 19.2% of patients with AS and CKD had at least 1 inpatient admission over the course of 6 months, versus 2.1% in the matched cohort; 100% had an outpatient or office visit, versus 61% in the matched cohort; and 26.7% had at least one emergency department visit, versus 6.6% in the matched cohort. The rate of HCRU increased with the increasing CKD stage, the highest utilization being observed in patients with advanced CKD. Approximately 25% of patients with AS were prescribed RAASi's, which is a commonly used treatment in eligible patients with AS.

Conclusions: Patients with AS were observed to utilize inpatient, outpatient, and emergency department services at higher rates than the comparator group, with high utilization largely driven by late-stage CKD. Consequently, delaying or preventing kidney disease may substantially reduce healthcare expenditures among patients with AS, particularly among patients with ESKD.

PO1297

Utilization of Broad-Panel Genetic Testing for Collagen Disorders of the Basement Membrane Disorders in Patients Requiring Kidney Transplantation

Rupi K. Sodhi,[1] Amishi S. Desai,[1] Jongwon Yoo,[1] Divya J. Arwindekar,[1] Katya Brossart,[2] Hossein Tabriziani,[2] Sanjeev Akkina.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Natera, Inc., San Carlos, CA.*

Background: Patients with advanced chronic kidney disease (CKD) are often misdiagnosed. Etiology of end-stage kidney disease (ESKD) significantly impacts the selection of candidates and donors for kidney transplant (KT), and post-KT management. Identification of a genetic etiology can reclassify disease and alter KT planning. Collagen disorders such as Alport syndrome present with heterogeneous phenotypes. However, a recently proposed classification system incorporates genetic variants into the diagnosis of this disease.

Methods: Twenty-two pre- and post-KT patients with a median age of 33 years (range: 26-67 years), completed genetic testing with Renasight™ (a NGS-based >380-gene kidney panel), between June 2020 and April 2021. Test results related to *COL4A* were correlated to clinical histories, including biopsy (when available), ultrasound results, presence of proteinuria and hematuria, demographic factors, family history and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Pathogenic or likely pathogenic variants in a type IV collagen gene were identified in 18.2% (4/22) of patients. All four patients had progressed to ESKD at the time of testing. One patient, with a variant in *COL4A3*, had a right nephrectomy and subsequently developed nephrotic range proteinuria. The second patient, with a variant in *COL4A4*, had genetic testing after a living related KT; the donor was subsequently referred for genetic counseling. The third and fourth individuals, brothers with a family history of CKD, for which the same familial *COL4A5* variant was identified, were both carriers of the *APOL1* G1 risk allele. One brother had biopsy-proven FSGS and did not respond to steroids.

Conclusions: Broad panel testing enables the identification of monogenic causes of CKD that can impact the selection of KT candidates and post-KT management. In this study, molecular diagnosis and genetic subtyping of type IV collagen disorders allowed providers to counsel patients on risk of disease recurrence and donor screening in potential living related donors. KT recipients with causal *COL4A3/4/5* variants have a low risk of recurrence in the allograft and will likely not require extensive therapy during after transplant.

PO1298

Genotype-Phenotype Analyses in Korean X-Linked Alport Syndrome: A Multicenter Study

Ji hyun Kim,[1] Hae Il Cheong,[3] Hee Gyung Kang,[2] Yo Han Ahn.[2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea.*

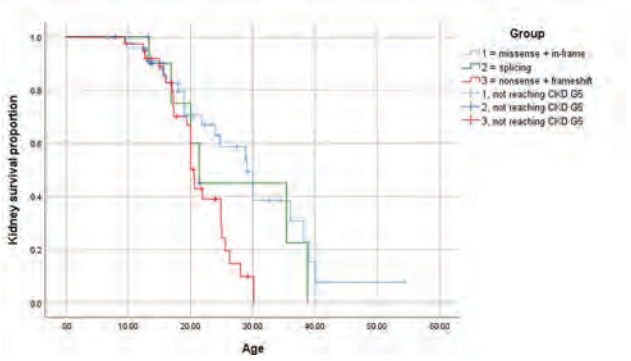
Background: X-linked (XL) inheritance, caused by *COL4A5* mutation, is most common in Alport syndrome (AS). Many clinical studies have elucidated the correlation between genotype and phenotype in male XLAS, whereas no association has been found in female XLAS. Here, we analyzed genotype-phenotype correlation in Korean XLAS.

Methods: This multicenter, retrospective study collected XLAS cases who had been diagnosed from 1985 to Jan 2021 in 13 tertiary centers of Korea. Sanger or next-generation sequencing were conducted in clinically suspected AS patients (male:female 96:42 from 121 Korean families) for genetic confirmation. We divided the cases into three groups according to the genetic variant types: 1=missense or in-frame mutations (n=46); 2=splicing mutations (n=12); 3=frameshift or nonsense mutations (n=38). Kidney survival was compared between the groups using Kaplan-Meier method.

Results: For male XLAS, median age of presentation was 5.1 years (yrs) and onset symptoms were gross hematuria (n=24), asymptomatic urinary abnormality (n=25) or nephrotic syndrome (n=19). At last follow-up, 54 (56.3%) patients had reached CKD G5 (median age 20.0 yrs)) and renin-angiotensin system inhibitors (RASi) were used in nearly all the patients. Hearing loss (HL) was present in 50%. Kidney survival rate was significantly different (median age of group 1, 29.0 yrs; group 2, 21.4 yrs; group 3, 20.6 yrs, p=0.014). HL showed a similar trend by mutant types (group 1, 32.6%; group 2, 58.3%; group 3, 68.4%; p=0.002). Female XLAS presented at median age of 3.0 yrs and 9 (21.4%) patients were reached CKD G5 at median age of 29.2 yrs. HL was present in 14.3%. Kidney survival was not significantly correlated with variant types.

Conclusions: There were strong genotype-phenotype correlation in male Korean XLAS. Both male and female XLAS showed similar results consistent with previous papers according to mutant types, but kidney survival rate was worse for all variant types, despite the appropriate use of RASi. These data could potentially be helpful of counseling in Korean families with XLAS.

Fig 1. Kidney survival proportion according to mutant types in X-linked male patients (p=0.014)



PO1299

Sparsentan, the Dual Endothelin Angiotensin Receptor Antagonist (DEARA), Improves Kidney Function and Life Span and Protects Against Hearing Loss in Alport Mice with Developed Renal Structural Changes

Dominic E. Cosgrove,[1] MichaelAnne Gratton,[2] Daniel T. Meehan,[1] Denise Vosik,[1] Jacob D. Madison,[1] Duane C. Delimont,[1] Gina C. Samuelson,[1] Diana Jarocki,[2] Radko Komers,[3] Celia P. Jenkinson.[3] *[1]Boys Town National Research Hospital, Omaha, NE; [2]Washington University, St. Louis, MO; [3]Travere Therapeutics Inc, San Diego, CA.*

Background: In Alport syndrome (AS), endothelin type A receptor activation is an important mediator of renal and inner ear pathologies. Sparsentan (SP) administered to COL4A3 $^{-/-}$ mice (AS mice) in prevention mode delayed increases in proteinuria, renal structural changes and hearing loss (HL). Whether these effects translate into preservation of glomerular filtration rate (GFR), increased lifespan (LS) and protection from HL in mice where renal pathology has initiated is unknown.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (WT-V or AS-V), 60 or 120 mg/kg SP (AS-SP60 or AS-SP120) starting at 4 weeks (W) of age or at 5, 6 or 7W. Baseline and 10W glomerulosclerosis (GS) were evaluated in kidney sections stained for fibronectin. GFR was measured using a transdermal device (Medibeacon) in mice treated from 4W. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8-8.75W in AS-V or AS-SP120 mice treated from 5W.

Results: SP begun at 4W abrogated the decline in GFR at 9W compared to AS-V mice (GFR μl/min mean ± SD; WT-V 159 ± 58 (n=6), AS-V 54.0 ± 30 (n=10), AS-SP60 148± 21 (n=6), AS-SP120 145 ± 42 (n=15); p<0.001 AS-V vs AS-SP60 or AS-SP120) and provided protection from GS in mice at 10W (P<0.01 AS-SP120 vs AS-V). For LS studies GS (mean % sclerotic glomeruli) prior to treatment in AS mice was 0 at 4W, 5.2% at 5W, 23.3% at 6W and 47.0% at 7W and SP120 extended median LS (MLS) when dosing began even in 5, 6 or 7W mice with detectable GS (MLS days; AS-V 67.5, AS-SP120 4W start 118.0, AS-SP120 5W start 89.0, AS-SP120 6W start 88.0, AS-SP120 7W start 83.0). SP120 begun at 5W improved post noise thresholds with prevention of HL at 16 (P<0.05) and 24 Hz (P<0.01) (Mean ± SD dB SPL 16 Hz; WT-V 5 ± 6.1, AS-V 23 ± 9.7, AS-SP120 11 ± 4.2).

Conclusions: SP prevents the decline in GFR in AS mice, extends LS and prevents noise-induced HL even in mice with developed renal structural changes. If these results are translated successfully into the clinic, SP may offer a novel treatment approach for reducing both renal injury and protecting hearing in AS.

Interim Analysis of the EAGLE Trial: An Open-Label Study to Assess the Long-Term Safety and Tolerability of Bardoxolone Methyl in Patients with Alport Syndrome

Pablo E. Pergola,[1] Gerald B. Appel,[2] Melanie Chin,[3] Bernard V. Fischbach,[14] Bertrand Knebelmann,[5] Kenneth V. Lieberman,[6] Colin J. Meyer,[3] Kandai Nozu,[4] David K. Packham,[7] Dana Rizk,[8] Arnold L. Silva,[9] Bruce S. Spinowitz,[10] Stuart M. Sprague,[11] Roser Torra,[12] Philippe Zaoui.[13] *[1]Renal Associates PA, San Antonio, TX; [2]Columbia University Irving Medical Center, New York, NY; [3]Reata Pharmaceuticals Inc, Irving, TX; [4]Kobe Daigaku, Kobe, Japan; [5]Structure Federative de Recherche Necker, Paris, France; [6]Hackensack Meridian School of Medicine, Nutley, NJ; [7]The University of Melbourne Medicine at Royal Melbourne Hospital, Parkville, VIC, Australia; [8]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [9]Boise Kidney and Hypertension Institute, Meridian, ID; [10]New York Presbyterian Queens Hospital, Flushing, NY; [11]NorthShore Medical Group, Evanston, IL; [12]Universitat Autonoma de Barcelona, Barcelona, Spain; [13]Centre Hospitalier Universitaire Grenoble Alpes, Grenoble, France; [14]Dallas Nephrology Associates, Dallas, TX.*

Background: Alport syndrome is a rare genetic disease affecting up to 60,000 persons in the US.

Methods: EAGLE (NCT03749447) is an ongoing, international, multi-center, open-label, extended access trial evaluating the longer-term safety and tolerability of bardoxolone methyl (bardoxolone) in patients with Alport syndrome who completed a prior qualifying clinical trial (CARDINAL Phase 2 and 3; NCT03019185). At baseline patients were 12 to 70 years old with eGFR 30 to 90 mL/min/1.73 m^2 and UACR ≤ 3500 mg/g. Patients receive bardoxolone daily and dose is escalated up to 20 mg or 30 mg (for patients with UACR > 300 mg/g).

Results: As of data cutoff (01/18/2021), 96 patients were enrolled in the EAGLE study, including 79 patients from CARDINAL Phase 3 (placebo: n=46, Bard: n=33), and 17 patients who received Bard in CARDINAL Phase 2. Mean age was 42 years, and 8 (8%) patients were <18. At baseline, mean eGFR was 58.2 ± 21.4 mL/min/1.73 m^2 and mean UACR was 183 ± 40 mg/g. Increases in eGFR were seen in patients who previously received placebo and initiated Bard treatment in EAGLE. Patients who previously received Bard for two years in CARDINAL also continued to experience mean eGFR increases in their third year of treatment. Bard has generally been well tolerated, with no deaths or drug-related severe adverse events (SAEs) reported in EAGLE to date. No drug-related cardiac SAEs were reported and no changes in blood pressure were observed. Nearly all (94%) adverse events were mild to moderate.

Conclusions: In EAGLE, Bard increased eGFR in patients with Alport syndrome, and increases observed in CARDINAL were sustained in the third year of treatment. To date, the longer-term safety profile of Bard is similar to that observed in the CARDINAL trial.

Funding: Commercial Support - Reata Pharmaceuticals

Mean ± SD eGFR Change (mL/min/1.73 m^2)	Week 12	Week 24	Week 48
Placebo to Bard (n=46)	*n=28* 12.4 ± 11.8	*n=14* 9.3 ± 14.7	*n=8* 8.4 ± 11.5
Bard to Bard (n=50)	*n=39* 8.8 ± 15.3	*n=30* 9.9 ± 14.0	*n=19* 7.3 ± 8.8

Integrated Analysis of the Efficacy and Safety of Bardoxolone Methyl in Patients with Alport Syndrome

Bradley A. Warady,[1] Rajiv Agarwal,[2] Sharon P. Andreoli,[3] Sripal Bangalore,[4] Geoffrey A. Block,[5] Arlene B. Chapman,[6] Melanie Chin,[7] Prasad Devarajan,[8] Keisha L. Gibson,[9] Angie Goldsberry,[7] Laura H. Mariani,[10] Colin J. Meyer,[7] Megan O'Grady,[7] Peter Stenvinkel,[11] Glenn M. Chertow.[12] *[1]Children's Mercy Hospitals and Clinics, Kansas City, MO; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [4]New York University Grossman School of Medicine, New York, NY; [5]US Renal Care, Plano, TX; [6]University of Chicago Division of the Biological Sciences, Chicago, IL; [7]Reata Pharmaceuticals Inc, Irving, TX; [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [9]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [10]University of Michigan Michigan Medicine, Ann Arbor, MI; [11]Karolinska Institutet, Stockholm, Sweden; [12]Stanford University School of Medicine, Stanford, CA.*

Background: Alport syndrome is a rare and serious inherited form of CKD. An integrated analysis of efficacy and safety was conducted from the CARDINAL Phase 2/3 (NCT03019185) and EAGLE (NCT03749447) trials of bardoxolone methyl (Bard) in patients with Alport syndrome.

Methods: The CARDINAL Phase 2 trial was open-label and enrolled 30 patients ages 12 to 60 years with Alport syndrome, baseline eGFR values 30 to 90 mL/min/1.73 m^2 and UACR ≤ 3500 mg/g. CARDINAL Phase 3 was an international, multi-center, double-blind, placebo-controlled trial with similar eligibility criteria and randomized 157 patients. EAGLE is an ongoing, open-label, extended access trial that is enrolling patients who completed CARDINAL Phase 2/3 trials.

Results: A total of 218 patients were included in the analysis (placebo: n=80, Bard: n=138). A majority (61%) of patients were female and receiving renin-angiotensin-aldosterone system inhibitor (83%). Mean age was 40 years, and 31 (14%) patients were <18 years old. Mean baseline eGFR was 60.4 and 62.3 mL/min/1.73 m^2 and the maximum duration of exposure was 3.2 and 1.9 years for Bard and placebo groups, respectively. The Bard group had significant increases in eGFR from baseline at the last on-treatment assessment (mean±SE: 3.37±1.21 mL/min/1.73 m^2; p=0.006). Significant decreases in eGFR were seen in the placebo group (mean ± SE: -8.30±1.58 mL/min/1.73 m^2; p<0.0001), resulting in a significant difference between groups after treatment withdrawal (p=0.03 vs placebo). Consistent with prior studies, common adverse events (AE) included muscle spasms, aminotransferase increases, and hyperkalemia. Discontinuations due to AEs were uncommon (9 % of Bard and 5% of placebo groups). Across all studies, no major cardiac events were observed and no changes in blood pressure were observed.

Conclusions: Consistent with individually reported prior trials, an integrated Alport syndrome analysis set showed that Bard preserved kidney function with significant on- and off-treatment eGFR benefits and was generally well tolerated by patients.

Novel Keap-Nrf2 Protein-Protein Interaction Inhibitor UBE-1099 Ameliorates the Severity of Experimental Alport Syndrome

Shota Kaseda,[1,3] Mary Ann Suico,[1] Sayaka Ogi,[2] Hidetoshi Sunamoto,[2] Hirohiko Fukiya,[2] Futoshi Nara,[2] Tsuyoshi Shuto,[1] Kazuhiro Onuma,[2] Hirofumi Kai.[1,3] *[1]Department of Molecular Medicine, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto City, Japan; [2]Pharmaceuticals Research Laboratory, UBE Industries, Ube city, Japan; [3]Program for Leading Graduate Schools "HIGO (Health life science: Interdisciplinary and Glocal Oriented) Program", Kumamoto University, Kumamoto, Japan.*

Background: Bardoxolone methyl is an electrophilic agent that induces Nrf2 activation by irreversibly and covalently binding to the cysteine residue of Keap1. Bardoxolone methyl has been shown to improve glomerular filtration rate (GFR) in clinical trials, and is attracting attention as a novel agent for chronic kidney disease. However, there is concern about long-term efficacy due to the unknown mechanism of GFR improvement and transient increase in albuminuria. Moreover, irreversible Keap1 inhibitors such as Bardoxolone methyl may covalently bind to other proteins in a non-specific manner and induce side effects due to off-target activities.

Methods: We developed a reversible Keap1 inhibitor that inhibits Keap1-Nrf2 protein-protein interaction (PPI) and evaluated its efficacy using Alport syndrome mice model (Col4a5-G5X). Development of Keap1-Nrf2 PPI inhibitor was performed by fluorescence polarization and Nqo1 induction test. The obtained novel compound UBE-1099 (30 mg/kg/day) and CDDO-Im (3, 10 mg/kg/day; rodent tolerable Bardoxolone methyl analogue) were orally administrated to Alport mice and efficacy was evaluated.

Results: UBE-1099 showed higher Nqo1 induction efficiency compared with CDDO-Im in mouse renal tissue. While CDDO-Im only improved inflammation pathology in Alport mice, UBE-1099 uniformly improved renal function (GFR and Plasma creatinine, but not albuminuria), podocyte injury, glomerulosclerosis, inflammation and fibrosis. Moreover, UBE-1099 treatment significantly prolonged the lifespan of Alport mice.

Conclusions: This study firstly revealed the efficacy of Keap1-Nrf2 PPI inhibitor for glomerulosclerosis. We will elucidate next the mechanism of renal pathology improvement, which may provide useful information for Nrf2 activators including bardoxolone methyl for clinical application.

Patient Global Impression of Change in Patients with Alport Syndrome in the CARDINAL Phase 3 Trial

Glenn M. Chertow,[1] Pablo E. Pergola,[2] Rajiv Agarwal,[3] Sharon P. Andreoli,[4] Gerald B. Appel,[5] Sripal Bangalore,[6] Geoffrey A. Block,[7] Melanie Chin,[8] Keisha L. Gibson,[9] Angie Goldsberry,[8] Kazumoto Iijima,[10] Lesley A. Inker,[11] Clifford E. Kashtan,[12] Bertrand Knebelmann,[13] Laura H. Mariani,[14] Colin J. Meyer,[8] Kandai Nozu,[10] Megan O'Grady,[8] Arnold L. Silva,[15] Peter Stenvinkel,[16] Roser Torra,[17] Bradley A. Warady.[18] *[1]Stanford University School of Medicine, Stanford, CA; [2]Renal Associates PA, San Antonio, TX; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [5]Columbia University Irving Medical Center, New York, NY; [6]NYU Langone Health, New York, NY; [7]US Renal Care, Plano, TX; [8]Reata Pharmaceuticals Inc, Irving, TX; [9]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [10]Kobe Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Kobe, Japan; [11]Tufts Medical Center, Boston, MA; [12]University of Minnesota Health, Minneapolis, MN; [13]Institut Necker-Enfants Malades, Paris, France; [14]University of Michigan Medical School, Ann Arbor, MI; [15]Boise Kidney and Hypertension Institute, Meridian, ID; [16]Karolinska Institutet, Stockholm, Sweden; [17]Universitat Autonoma de Barcelona, Barcelona, Spain; [18]Children's Mercy Hospitals and Clinics, Kansas City, MO.*

Background: Alport syndrome is a rare and serious inherited form of CKD affecting as many as 60,000 persons in the US with no specific therapies approved for its treatment.

Methods: An international, multicenter, double-blind, placebo-controlled, randomized Phase 3 trial (CARDINAL; NCT03019185) evaluated the safety and efficacy of bardoxolone methyl (Bard) in patients with Alport syndrome 12 to 70 years of age with baseline eGFR 30-90 mL/min/1.73 m^2 and UACR≤ 3500mg/g. As an exploratory endpoint, the trial assessed patient global impression of change (PGIC), a non-disease specific 7-point scale that asks patients to rate how much their illness has changed as very much/much/minimally improved (1, 2, and 3 pts), no change (4 pts), or minimally/much/very much worse (5, 6, and 7 pts) after 48 and 100 weeks of treatment.

Results: A total of 157 patients were randomized to Bard (n=77) or placebo (n=80). In addition to significant on-treatment and off-treatment increases in mean eGFR relative to placebo (between-group differences of 7.7 ± 2.1 [p=0.0005] at Week 100 and 4.3 ± 1.9 mL/min/1.73 m^2 [p=0.023] at Week 104, respectively), Bard improved PGIC scores relative to placebo (lower values) after 48 and 100 weeks. Categorical summaries also showed more patients randomized to bardoxolone (34%) reported their condition had improved compared to those on placebo (19%) after 100 weeks of treatment.

Conclusions: In CARDINAL, Bard significantly preserved eGFR in patients with Alport syndrome and also resulted in improvements in how patients evaluated their wellbeing.

Funding: Commercial Support - Reata Pharmaceuticals

	Placebo	Bardoxolone Methyl	Difference Between Groups
Week 48 Mean ± SE	3.76 ± 0.10	3.59 ± 0.12	-0.17 ± 0.149 (p = 0.26)
Week 100 Mean ± SE	3.90 ± 0.13	3.51 ± 0.14	-0.39 ± 0.186 (p = 0.04)

Treatment with Antisense-Oligonucleotide or Splicing Regulating Proteins for X-Linked Alport Syndrome Cases with Deep Intronic Variant

Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Sadayuki Nagai,[1] Yuya Aoto,[1] Nana Sakakibara,[1] China Nagano,[1] Kazumoto Iijima,[2] Kandai Nozu.[1] *[1]Kobe University Graduate School of Medicine, Pediatrics, Kobe, Japan; [2]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

Background: X-linked Alport syndrome (XLAS) is a hereditary progressive renal disease caused by mutation in *COL4A5*. Some cases of XLAS are caused by deep intronic variants which cause aberrant splicing and produce cryptic exon inclusion. Preventing translation of such cryptic exon has the potential to be an effective therapy. We reported that exon skipping therapy with antisense-oligonucleotide (ASO) was very effective in the XLAS mice model with a truncating mutation. However, an ASO needs very high sequence specificity and few patients can be treated by the same ASO. Therefore, we attempted to modify the splicing pattern not only by ASO but also by proteins important for splicing regulation. U2AF65 is one of the important splicing related proteins binding to polypyrimidine tracts promoting exonization. It has been reported that overexpression of the U2AF65 promotes or suppresses exonization in some circumstances.

Methods: We identified four cases of XLAS caused by the production of the same cryptic exon inclusion (r.[384_385ins385-764_385-617]) by different deep intronic variants: three cases (c.385-756C>G, c.385-749T>A and c.385-645T>A) were ours and 1 (c.385-719G>A) was a reported variant. For these cases, we introduced ASO that could skip cryptic exon. Moreover, using *in vitro* splicing evaluation system (minigene assay), we attempted to reduce the exonization of cryptic exon by overexpression of U2AF65.

Results: We succeeded in preventing the cryptic Exon insertion by introducing ASO treatment for patient's urine derived cells. In addition, in all patients, overexpression of U2AF65 in the minigene splicing analysis system successfully reduced the cryptic exon inclusion.

Conclusions: The cryptic exonization in deep intron region by nucleotide change is often difficult to identify, but there may be more such cases. In addition to ASO treatment, splicing related proteins such as U2AF65 has a potential for the treatment splicing abnormalities with splicing modifications.

Small Molecule APOL1 Inhibitors Block APOL1 Pore Function and Reduce Proteinuria in an APOL1-Mediated Kidney Disease Mouse Model

Brandon Zimmerman, Leslie Dakin, Anne Fortier. *Vertex Pharmaceuticals Inc, Boston, MA.*

Background: Two genetic variants of *APOL1* (G1 and G2) are associated with increased risk of kidney diseases. Current treatment options for APOL1-mediated kidney diseases are limited and do not address the underlying cause of disease. Here, we report the discovery of a series of novel small molecule APOL1 inhibitors, including the clinical candidate VX-147, that block APOL1 function *in vitro* and reduce proteinuria in a transgenic mouse model of kidney disease.

Methods: Microscale thermophoresis was used to assess binding of small molecule APOL1 inhibitors to recombinant APOL1 protein. HEK293 cells overexpressing APOL1 variants were used to quantify inhibition of APOL1-mediated cell death and ion flux. In addition, activity on APOL1 biological function was assessed using a trypanosome viability assay. Finally, changes in proteinuria following APOL1 inhibitor administration were assessed using a transgenic mouse model homozygous for the APOL1 G2 variant ($G2_{Hom}$).

Results: Small molecule APOL1 inhibitors showed binding to all three forms of APOL1 (wild-type, G1 and G2 variants). In cellular assays, APOL1 inhibitors prevented APOL1-mediated HEK293 cell death and inhibited APOL1-mediated ion flux. Addition of APOL1 inhibitors to trypanosome cultures rescued the parasites from APOL1-induced killing. The potency of VX-147 was consistent across the in vitro functional assays described above (EC_{50} of approximately 2nM). Finally, administration of IFNγ in $G2_{Hom}$ mice induced APOL1 expression, resulting in elevated urine albumin-to-creatinine ratios. Oral administration of VX-147 reduced proteinuria in IFNγ-induced APOL1 $G2_{Hom}$ mice by 74.1%.

Conclusions: Novel small molecule APOL1 inhibitors, including VX-147, bind recombinant APOL1 protein and inhibit its biological function, as demonstrated by trypanosome parasite rescue. These inhibitors block APOL1 pore function, as demonstrated by reduced APOL1-induced death and APOL1-induced ion flux of tetracycline-inducible APOL1 HEK293 cells. Administration of APOL1 inhibitors reduced APOL1-dependent proteinuria in an APOL1-mediated transgenic mouse model of kidney diseases. Taken together, our results strongly suggest small molecule APOL1 inhibitors, such as VX-147, target the underlying cause of disease, and have the potential to treat APOL1-mediated kidney diseases.

PO1306

Inhibition of Endoplasmic Reticulum Stress Signaling Rescues Cytotoxicity of Human APOL1 Risk Variants in Drosophila

Lea Gerstner, Mengmeng Chen, Lina L. Kampf, Julian Milosavljevic, Konrad Lang, Martin Helmstädter, Tobias F. Hermle. Hermle lab *Division of Nephrology, University Medical Center Freiburg, Freiburg, Germany.*

Background: Renal risk variants of the *APOL1* gene are associated with severe kidney disease, putting homozygous carriers at risk. *APOL1* G1- and G2-alleles likely represent gain-of-function (GOF) mutations as human subjects with *APOL1* null alleles have been found to be without renal anomalies. A wide range of mechanisms that are frequently in conflict have been described for *APOL1*-associated nephropathies.

Methods: The genetic tool-kit in *Drosophila* allows unique *in vivo* insights into disrupted cellular homeostasis. To perform a mechanistic analysis in this model, we expressed *APOL1* control and the GOF renal risk variants in the podocyte-like *Drosophila* nephrocytes and a wing precursor tissue.

Results: *APOL1* risk variant expression entailed elevated endocytic function of garland cell nephrocytes while processing of endocytic cargo and slit diaphragm morphology remained unimpaired. All APOL1 variants located to the endoplasmic reticulum (ER) and electron microscopy revealed significantly elevated ER swelling upon expression of risk variant G2-APOL1, indicating stimulation of ER stress. We employed *Drosophila* wing precursor tissue since this epithelial model enables unique recording of relative changes side by side within the same animal to study ER stress. Overexpression of the renal risk variants G1 and G2 caused a markedly stronger upregulation of PDI and apoptosis, while expression of wildtype *APOL1* resulted in milder upregulation. As a control, ER stress was absent upon deletion of 9 aa in the BH3 domain in the G2-APOL1 construct. We further confirmed *APOL1*-dependent ER stress by detection of chaperone induction and an *Xbp1*-reporter in the wing precursor. Both, genetic and pharmacological inhibition of ER stress abrogated apoptosis identifying ER stress as the essential factor of *APOL1*-induced cytotoxicity. This represents the first rescue of *APOL1*-associated cytotoxicity *in vivo*. Direct ER stress induction in nephrocytes phenocopied *APOL1* risk variant expression, supporting that ER stress underlies the gain-of-function in nephrocytes.

Conclusions: Our data reveal ER stress as the essential consequence of *APOL1* risk variant expression *in vivo*, indicating this pathway's central role in the pathogenesis of *APOL1*-associated nephropathies.

A Cohort Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) Started on SGLT-2 Inhibitors

Anthony J. Bleyer,[1,2] Kendrah O. Kidd,[1,2] Hannah C. Ainsworth,[1] Victoria C. Robins,[1] Abbigail Taylor,[1] Lauren Martin,[1] Alice Kim,[1] Venkata Sabbisetti,[3] Carl D. Langefeld,[1] Stanislav Kmoch.[2,1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; [3]Harvard Medical School, Boston, MA.*

Background: Sodium-glucose co-transporter-2 inhibitors (SGLT2i) have been shown to slow estimated glomerular filtration rate (eGFR) decline in chronic kidney disease (CKD) but have not been tested in patients with ADTKD. We performed a prospective nested cohort observational study and analyzed changes in eGFR and kidney injury marker 1 (KIM-1) in patients who were prescribed SGLT2i by their physicians.

Methods: We obtained baseline and follow-up laboratory studies at 1 week, 1 month, and 4 months after starting an SGLT2i and compared eGFR with baseline function. We also obtained information about adverse events.

Results: 12 individuals were started on SGLT2i by their physicians, with 10 on empagliflozin, 2 dapagliflozin. Table 1 shows the changes in eGFR and KIM-1. For patients with eGFR > 30, mean eGFR increased at 1 month by 3 ml/min. At four months, eGFR was 3 ml/min below baseline (-18.5% due to low baseline eGFR). For eGFR > 30, eGFR decline was 12% from baseline at one month and 8% from baseline at 4 months. Plasma KIM-1 was unchanged, but urinary KIM-1 increased by 100%. One patient stopped empagliflozin at his request after 8 weeks due to decline in eGFR of 14% from baseline. No other adverse events noted. Two patients have been treated for 6 months with stable eGFR

Conclusions: The change in eGFR after treatment with SGLT2i was consistent with prior studies of CKD. The plasma KIM-1 was unchanged, but the rise in urinary KIM-1 was very concerning. Further study is required to determine if these agents are beneficial in ADTKD. An additional 4 months of follow up will be presented at ASN.

Funding: NIDDK Support, Private Foundation Support

Changes in eGFR and KIM-1 in ADTKD Patients Taking SGLT2 Inhibitors

	Baseline	1 week	1 month	4 months
	Mean ± Standard Deviation [count]			
eGFR < 30 (ml/min/1.73m^2)	22.7±4.5 [3]	21.7±3.2 [3]	25.9±7.1 [2]	19.3±5.3 [2]
eGFR ≥ 30 (ml/min/1.73m^2)	42.2±12.1 [9]	37.7±11.2 [6]	34.9±10.5 [8]	34.7±8.6 [6]
Median Plasma KIM-1 (pg/ml)	195.72 [12]		203.74 [12]	-
Median Urine KIM-1 (pg/mg UCr)	2017.9		3395.1 [12]	-
	Percent Mean* Change from Baseline			
eGFR < 30 (ml/min/1.73m^2)	-	-4.1%	5.1%	-18.5%
eGFR ≥ 30 (ml/min/1.73m^2)	-	-5.9%	-11.6%	-7.9 %
Plasma KIM-1 (pg/ml)	-		1.1% [12]	-
Urine KIM-1 (pg/mg UCr)	-		103% [12]	-

*Mean was computed as the average change in eGFR for each individual (at time point), compared to their baseline measurement.

A Prospective Observational Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)

Kendrah O. Kidd,[1,2] Adrienne H. Williams,[1] Victoria C. Robins,[1] Abbigail Taylor,[1] Lauren Martin,[1] Alice Kim,[1] Martina Zivna,[2] Carl D. Langefeld,[1] Stanislav Kmoch,[2,1] Anthony J. Bleyer.[1,2] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Univerzita Karlova 1 lekarska fakulta, Praha, Czechia.*

Background: GFR decline in ADTKD due to UMOD or MUC1 mutations has not been well characterized. We have begun an international prospective cohort study to determine genetic and environmental factors associated with progression. We report here on early recruitment.

Methods: Patients with positive genetic testing for UMOD or MUC1 mutations prior to transplantation or starting dialysis are eligible. A baseline collection of health information, serum and urine biomarkers will be performed, with patients then followed longitudinally, with a serum creatinine measurement performed three times per year. There will be a nested cohort study of women who develop pregnancy during the study and patients started on ACE inhibition.

Results: Since March 2021, we have enrolled 57 patients in the prospective observational study, with 20 men, 35 women. The mean age of patients is 43.3 years, the mean baseline eGFR is 39.96 ml/min/1.73m^2. Table 1 shows baseline characteristics of patients enrolled in the study. No patients with CKD Stage 1 or 2 suffered from HTN, and only 39% of patients with CKD Stage 3 had HTN. Only 18% of patients were receiving ACE/ARB inhibition.

Conclusions: Despite significant CKD, there was a relatively low prevalence of HTN. Only 18% of patients were receiving ACE inhibition, indicating a potential therapeutic intervention. Please contact us if you have a patient who may be interested in participating in this prospective study (ableyer@wakehealth.edu).

Vasopressin Induces Urinary Uromodulin Secretion by Activating Protein Kinase A

Azuma Nanamatsu, Takayasu Mori, Fumiaki Ando, Taisuke Furusho, Shintaro Mandai, Koichiro Susa, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Urinary uromodulin, secreted by renal tubular cells, protects against urinary tract infections (UTIs) and kidney stones. In contrast, the intracellular accumulation of uromodulin is associated with hypertension and chronic kidney disease (CKD). In addition, uromodulin gene mutations cause autosomal dominant tubulointerstitial kidney disease (ADTKD-*UMOD*) via abnormal intracellular accumulation of uromodulin. However, the physiological stimuli for urinary uromodulin secretion remain largely unknown.

Methods: We investigated the acute effect of vasopressin/cAMP signaling on urinary uromodulin secretion in mice and in kidney epithelial cells stably expressing uromodulin. Additionally, we assessed the effect of vasopressin/cAMP signaling in kidney epithelial cells stably expressing mutant uromodulin, which causes ADTKD-*UMOD*.

Results: Desmopressin, a vasopressin type 2 receptor agonist, dramatically increased short-term tubular uromodulin secretion in mice. Immunofluorescence studies and ultracentrifugation-based polymerization assay suggested that desmopressin induced intraluminal polymeric filaments of uromodulin, indicating physiologically functional secretion. As a result of increased excretion, uromodulin abundance in the murine kidney was clearly reduced by desmopressin. In the cellular model, apical uromodulin secretion was increased in response to vasopressin/cAMP signaling, consistent with *in vivo* experiments. We also demonstrated that the response was dependent on cyclic AMP-dependent protein kinase (PKA) signaling pathway. We further showed that cAMP signaling induced excretion of mutant uromodulin. cAMP signaling suppressed PERK phosphorylation, which was upregulated by mutant uromodulin, implying cytoprotective effects.

Conclusions: Our work revealed vasopressin/cAMP/PKA signaling as a physiological stimulus of urinary uromodulin secretion. This finding may provide the basis for novel treatment strategies for UTIs, kidney stones, and potentially hypertension, CKD and ADTKD-*UMOD*.

PO1310

Standardizing HNF1B-Associated Disease

Johannes Muench,[1,2] Georgia Vasileiou,[4] Jan Kowald,[2] Jonathan de Fallois,[2] Marie Engesser,[2] Stefanie Weber,[3] Jan Halbritter,[2] Bernt Popp.[2] AG Nephrogenetics *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Universitat Leipzig, Leipzig, Germany; [3]Philipps-Universitat Marburg, Marburg, Germany; [4]Universitatsklinikum Erlangen, Erlangen, Germany.*

Background: Pathogenic variants in *HNF1B* are associated with a variety of inherited kidney diseases ranging from renal cysts and diabetes syndrome and CAKUT to autosomal dominant tubulointerstitial kidney disease. In addition, variable extrarenal manifestations were linked (MIM #189907). Although high throughput sequencing has advanced diagnostic variant detection, there is a lack of specific database analysis gathering both genotypic and phenotypic information from published and unpublished sources in order to establish valid genotype-phenotype correlations. By introducing a novel HNF1B database, we aim at gathering published and unpublished cases for identification of reliable variant-disease association analysis.

Methods: To standardize our own cohort and curate the clinical and genetic spectrum from the literature, we curated a list of 30 clinical features associated with HNF1B-disease based on HPO terms. Next, we developed a web-based application (available on curating. HNF1B.org) for comprehensive data input and analysis from patient histories or published literature within the time span from 1997 - 2020.

Results: We reviewed 968 individuals (152 publications) including 8.4% of prenatal cases and 45.0% of pediatric individuals (<18 years). Among *HNF1B* variants, we found 20.1% whole gene deletions (corresponding to 17q12 microdeletions), 2.3% gene duplications, 54.6% single nucleotide variants or small indels with the remainder represented by either small variants or incomplete/inaccurate descriptions. Reported phenotypes showed a vast variability with more accurate reporting in small case series or case reports. For example, renal function was not reported for 37.0% of cases while in 68.5% of cases with 17q12 microdeletion no neurodevelopmental phenotype was provided despite both phenotypes constitute hallmarks of *HNF1B*-associated disease.

Conclusions: To enhance the understanding of this multi system disorder, we will present out curation effort as an open source clinical and genetic database at HNF1B.org. Based on the literature and unpublished cohorts we will develop a recommendation for standardized reporting and selection scheme for genetic screening. Our effort exemplifies the curation efforts that are required for a better understanding of rare hereditary kidney diseases. The developed tools might serve as starting point for similar efforts.

PO1311

Treatment with 4-Phenylbutyrate Reduces Low-Molecular-Weight Proteinuria in a Clcn5 Knock-In Mouse Model for Dent Disease

Ana Perdomo-Ramirez,[1] Elena Ramos-Trujillo,[2,1] Glorian Mura Escorche,[2,1] Victor Garcia-Nieto,[1] Jose-David Machado,[2] Felix Claverie-Martin.[1] *[1]Hospital Universitario Nuestra Senora de la Candelaria, Santa Cruz de Tenerife, Spain; [2]Universidad de La Laguna, La Laguna, Spain.*

Background: Dent disease-1 (DD1) is a rare X-linked tubular disorder characterized by low-molecular-weight-proteinuria (LMWP), hypercalciuria, nephrolithiasis and nephrocalcinosis. This disease is caused by inactivating mutations in the *CLCN5* gene, which encodes the voltage-gated ClC-5 chloride/proton antiporter. ClC-5 is expressed predominantly in the kidney and participates in the acidification of proximal tubule endosomes. Currently, the treatment of DD1 is only supportive and focused in delaying disease progression. Our group has generated a C*lcn5* knock-in (KI) mouse that presents the main clinical manifestations of DD1 and carries the pathogenic mutation p.V523del, which causes partial ClC-5 retention in the endoplasmic reticulum. Here, we aimed to assess the ability of sodium 4-phenylbutyrate (4-PBA), a small chemical chaperone, to ameliorate DD1 symptoms in this mouse model.

Methods: Twelve-weeks old male *Clcn5* KI mice (n=50) and WT (n=33) littermates were divided into 2 groups, one was treated with 250 mg/kg/day of 4-PBA in drinking water, for 31 days, whereas the other group was given water without the drug for the same amount of time. Mice were placed in metabolic cages before and after treatment for 24h. Urinary β2-microglobulin and serum and urinary creatinine were measured by ELISA. Calcium and phosphate concentrations in urine were estimated using colorimetric kits. Water and food intake and 24-h urinary excretion were also measured, and mice body weights were monitored.

Results: We observed a significant reduction of β2-microglobulin urinary excretion in KI mice treated with 4-PBA compared to non-treated animals (p=0.0004). Glomerular filtration rate was also improved in treated mice (p=0.03). Urine production, urinary calcium and phosphate levels did not show differences compared with non-treated mice.

Conclusions: 4-PBA reduces LMWP in *Clcn5* KI mice, suggesting that this treatment could represent a promising therapeutic option for some DD1 patients.

PO1312

Long-Term Efficacy of Migalastat on Renal Function and Outcomes in Patients with Fabry Disease (FD)

Daniel G. Bichet,[1] Ulla Feldt-Rasmussen,[2] Roberto Giugliani,[3] Derralynn Hughes,[4] Eva Krusinska,[5] Biliana O. Veleva-Rotse.[5] *[1]Department of Medicine, Hôpital du Sacré-Coeur, University of Montréal, Montréal, QC, Canada; [2]Department of Medical Endocrinology and Metabolism, Rigshospitalet, National University Hospital, Copenhagen University, Copenhagen, Denmark; [3]Medical Genetics Service, HCPA, Department of Genetics, UFRGS, and INAGEMP, Porto Alegre, Brazil; [4]Lysosomal Storage Disorders Unit, Royal Free London NHS Foundation Trust and University College London, London, United Kingdom; [5]Amicus Therapeutics, Inc., Philadelphia, PA.*

Background: FD, caused by pathogenic *GLA* variants leading to functional deficiency of α-galactosidase A (α-Gal A), can eventually result in key organ damage. Preserving renal function and preventing Fabry-associated clinical events (FACEs) are important treatment goals. Approved therapies include enzyme replacement therapy (ERT) and the pharmacological chaperone migalastat. Stabilized renal function and FACE occurrence up to 30 mo have been reported in migalastat-treated adults with amenable *GLA* variants; here, we extend those analyses up to 8.6 yrs.

Methods: Integrated data from phase 3 clinical trials (FACETS, NCT00925301; ATTRACT, NCT01218659) and open-label extension studies (NCT01458119; NCT02194985) were used to evaluate the eGFR slope using linear regression in pts treated with migalastat for ≥2 yrs (n=78). Incidences of FACEs (predefined renal, cardiac, and cerebrovascular events) were assessed in all pts (N=97). Analyses were stratified by prior treatment and phenotype. Cox regression modeling was used to identify predictors of FACEs.

Results: eGFR remained stable for both ERT-naive and ERT-experienced pts who received migalastat for ≥2 yrs (median [min-max] duration: 5.9 [2.0-8.6]); the mean (SD) annualized rates of change in eGFR (mL/min/1.73 m^2) were –1.6 (3.1) and –1.6 (3.6), respectively. In male pts with the classic phenotype (classification based on multiorgan involvement and [ERT-naive only] α-Gal A level at baseline; n=25), mean (SD) rate of change in eGFR was –2.2 (4.4) mL/min/1.73 m^2. eGFR was also analyzed by baseline renal function and proteinuria levels. In all migalastat-treated pts (median duration: 5.1 yrs), the incidence of composite FACEs (per 1000 patient-years) was 48.3 (65.3 for

classic males) and incidence of renal events was 4.4 (14.5 for classic males). Lower baseline eGFR was a predictor of FACEs in classic males vs all others; however, rate of renal events was too low to analyze predictors.

Conclusions: Results demonstrate long-term efficacy of migalastat in stabilizing eGFR in pts with FD, including male pts with the classic phenotype. FACE incidence in pts receiving migalastat compared favorably to historic reports of ERT. The inverse correlation of eGFR with FACEs suggests the importance of early diagnosis and treatment to preserve renal function.

PO1313

Twenty-Year Renal Prognosis in Patients with Fabry Disease Who Underwent Enzyme Replacement Therapy

Akane Miura, Masahiro Okabe, Kotaro Haruhara, Izumi Yamamoto, Nobuo Tsuboi, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan*.

Background: The relationship between long-term renal prognosis and renal histopathology after enzyme replacement therapy (ERT) for Fabry disease (FD) has not been fully investigated.

Methods: Nine patients with FD from our hospital who had participated in a Japanese phase 2 study (August 2000–May 2001) on agalsidase β were eligible for this case-control study. They underwent repeated renal biopsy (before and six months after agalsidase β treatment), and the intra-renal amount of globotriaosylceramide (GL3) was measured at the same time points. Clinicopathological features were compared between the groups with or without developing end-stage kidney disease (ESKD).

Results: Seven patients were included in this study, because two were lost to follow-up. All were males, with a median age at the start of treatment of 30 [quartile 24.5, 31.5] years, and median serum creatinine level (s-Cr) of 1.1 [1.0, 1.2] mg/dL. The podocyte score (International Study Group of Fabry Nephropathy score system) improved in all patients after ERT from that evaluated before ERT. Interstitial fibrosis/tubular atrophy (IF/TA) worsened in three patients. The proportion of foamed tubules improved in five patients. Intra-renal accumulation of GL3 decreased six months after ERT in all patients. All patients continued to receive agalsidase β or agalsidase α after the phase II study. While four patients developed ESKD (median 6.7 years), three patients showed no exacerbation of renal function. The s-Cr level, age, and urinary protein excretion at the start of ERT were higher in the ESKD group. The decrease in the intra-renal accumulation of GL3 was not significantly different between the two groups, but the proportion of foamed tubules in the first biopsy and the degree of IF/TA in the second biopsy were higher in the ESKD group than in the non-ESKD group.

Conclusions: This study suggests that tubulointerstitial injury has a crucial role in the determination of renal prognosis and that earlier diagnosis and intervention in patients with FD may improve the renal prognosis. Further studies are needed on the relationship between tubulointerstitial injury and GL3 accumulation.

PO1314

Systems Analyses of Fabry Renal Transcriptome and Its Response to Enzyme Replacement Therapy (ERT) Identifies a Cross-Validated and Drugable ERT-Resistant Module

Oystein Eikrem,[1,2] Nicolas Delaleu,[2,4] Philipp Strauss,[2] Miroslav Sekulic,[5] Camilla Tøndel,[3,2] Rannveig Skrunes,[1,2] Sabine Leh,[9,2] Einar Svarstad,[1,2] Elena-Emanuela Rusu,[7] Ariana Gaspert,[6] Albina Nowak,[8] Andrea Rinaldi,[10] Hans-Peter Marti.[2,1] *[1]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [2]Department of Clinical Medicine, University of Bergen, Bergen, Norway; [3]Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; [4]2cSysBioMed, Contra, Switzerland; [5]Columbia University Department of Pathology and Cell Biology, New York, NY; [6]Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland; [7]Fundeni Clinical Institute, Bucharest, Romania; [8]Department of Endocrinology and Clinical Nutrition, University Hospital, Zurich and University of Zurich, Zurich, Switzerland; [9]Department of Pathology, Haukeland University Hospital, Bergen, Norway; [10]Institute of Oncology Research, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland*.

Background: Fabry nephropathy (FN) is a rare disorder caused by mutations in the alpha-galactosidase A gene that can, to a certain degree, be managed with enzyme replacement therapy (ERT). Via understanding the molecular basis of FN and ERT's long-term impact, we aim at providing a framework allowing selection of biomarkers and drug-targets.

Methods: Obtained from controls and two independent FN-cohorts, mRNA-isolates from archival kidney biopsies taken prior and up to 10 years of ERT, were subjected to RNAseq. Combining pathway-centered analyses with network-science allowed computation of transcriptional landscapes from glomeruli, proximal tubuli, distal tubuli and arteries and integration with existing proteome, interactome and drug::target data.

Results: Comparing transcriptional landscapes per cohort revealed high inter-cohort heterogeneity. Especially, with timely treatment initiation, FN seemed well controlled via ERT. Pathways consistently altered in both FN-cohorts pre-ERT vs. N_CTRLs were limited to glomeruli and arteries and commonly pertained to the same biological themes. While keratinization-related processes in glomeruli were sensitive to ERT, a majority of alterations, such as transporter activity and responses to stimuli, remained dysregulated or remerged despite of ERT. Inferring an ERT-resistant genetic module on this basis identified targets suitable for drug repurposing.

Conclusions: Kidney compartments' transcriptional landscapes comprehensively reflected differences in FN-cohort characteristics. With the exception of few key aspects, in particular concerning arteries, early ERT in classical Fabry patients could lastingly revert FN kidney-compartments' molecular state to closely match N_CTRLs. Thus, we identified and cross-validated ERT-resistant modules that, when leveraged with external data, allowed estimating their suitability as biomarkers and potential targets for adjunct treatment.

PO1315

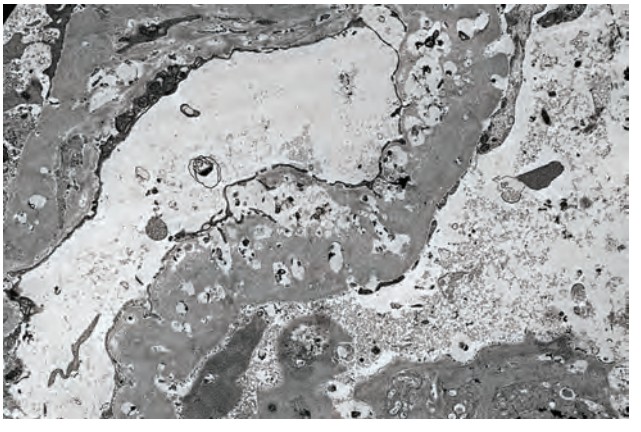
Resistant Focal Segmental Glomerulosclerosis (FSGS) due to Lecithin-Cholesterol Acyltransferase (LCAT) Deficiency: Is Early Gene Testing the Answer?

Moarij A. Qazi,[1] Huma Qazi,[2,1] Mary-Beth Roberts,[1] Richard A. Fatica,[1] Robert J. Heyka,[1] Xiangling Wang.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Army Medical College, Rawalpindi, Pakistan*.

Introduction: LCAT deficiency is a rare autosomal recessive disorder due to mutations in the *LCAT* gene presenting with corneal opacities, anemia, proteinuria, reduced HDL and CKD with progression to ESKD by the 4th- 5th decade. Electron microscopy (EM) is characteristic for abundant partially electron-dense and lucent deposits in the mesangium and basement membrane. Late diagnosis is not uncommon due to its rarity and nonspecific presentations in the early stages. Here we report a case of therapy resistant FSGS later uncovered as LACT deficiency confirmed by gene tests.

Case Description: A 49-year-old male presented to genetic nephrology clinic in 2020 with a clinical diagnosis of *LCAT* deficiency. In 2007, he had presented with hematuria, proteinuria with a serum creatinine of 2.4mg/dl, Hb 11 g/dL, albumin 2.4g/dL, total cholesterol 416mg/dL, HDL 14mg/dL and urine protein of 8.9g/d. Urine microscopy showed fine granular casts and dysmorphic RBCs. Kidney biopsy revealed FSGS with moderate tubulointerstitial fibrosis. EM showed some unexplainable intramembranous and subendothelial lucencies, which were thought to be sequela of prior immune mediated membranous glomerulonephritis. Patient failed treatment with months of steroids, oral cyclophosphamide and mycophenolate. Repeat biopsy in 2010 showed worsening of the prior findings. In 2011, corneal deposits led to a suspicion of LCAT deficiency. He progressed to ESKD in 2011 and kidney transplant in 2020. Genetic testing disclosed a homozygous nonsense variant c.321C>A (p.Tyr107*) in *LCAT* gene. A thorough genetic counseling included risk for his siblings and graft recurrence.

Discussion: LCAT deficiency can present with resistant or atypical appearing FSGS. This case emphasizes the need of early genetic assessment on suspicious biopsies or therapy resistant FSGS cases to timely diagnose and avoid unnecessary immunosuppression.



PO1316

ESKD due to Primary Hyperoxaluria Type I

Peter E. Thorne, Julia Lewis. *Vanderbilt University Medical Center, Nashville, TN*.

Introduction: Primary hyperoxaluria type I (PHT1) is a rare autosomal recessive disease (less than 3 cases per million population). Nephrolithiasis and nephrocalcinosis lead to progressive renal impairment and subsequent oxalate deposition in various tissues. We present a case of PHT1 diagnosed late in life and ultimately requiring definitive management with liver-kidney transplant due to rapid progression to end stage kidney disease.

Case Description: 55 year old male with history of renal calculi at birth, recurrent nephrolithiasis and PHT1 was hospitalized for acute kidney injury following 2 weeks of nausea and poor intake. His admission serum creatinine (Scr) was 11 from baseline of 3.5 four months before. He was diagnosed with PHT1 eight months prior via urinary oxalate measurement and genetic testing. He was started on low oxalate diet, calcium carbonate 1000mg with meals and pyridoxine 500mg daily. Ultrasound at admission notable for

diffuse increased echogenicity and bilateral non-obstructing calculi. Initial serum oxalate level was 63.5micromol/L and 24 hour urine oxalate level was 116mg/24hrs. Scr failed to improve with intravenous fluid administration and renal replacement therapy was initiated with goal serum oxalate level of <30micromol/L. Hemodialysis was performed daily for four hours with high flux membrane. Serum oxalate levels improved to nadir of 40micromol/L. Definitive therapy with simultaneous liver-kidney transplant was ultimately pursued.

Discussion: Our patient required intensive hemodialysis while awaiting liver-kidney transplant following late diagnosis of PHT1 and development of end stage kidney disease. Early diagnosis is key to reduce morbidity and mortality. Progressive kidney impairment leads to inability to excrete the increased oxalate produced by the liver and subsequent systemic deposition of oxalate including in the kidney causing multiorgan dysfunction. Hemodialysis removes oxalate but it is difficult to consistently reduce serum oxalate levels below goal given continued production of oxalate and rebound. Early treatment options include a trial of pyridoxine, hyperhydration, low oxalate diet and novel RNA inhibitors. Patients with advanced disease often require definitive management with liver-kidney transplant. Clinicians need to have a high index of suspicion for PHT1 as patients often go undiagnosed until advanced kidney disease or end stage kidney disease has developed.

PO1317

Real-World Healthcare Utilization and Clinical Markers Preceding Dialysis in Patients with Primary Hyperoxaluria (PH) in the United States

John Karafilidis,[2] Elnara Fazio-Eynullayeva,[1] Lisa Mucha,[2] Pamela B. Landsman-Blumberg,[1] Seth P. Kuranz.[1] *[1]TriNetX, Cambridge, MA; [2]Dicerna Pharmaceuticals Inc, Cambridge, MA.*

Background: PH is the accumulation of oxalate resulting in urolithiasis, nephrocalcinosis, chronic kidney disease (CKD), and eventually end-stage renal disease (ESRD) that usually requires dialysis. This study examined demographics, clinical characteristics, and healthcare utilization (HCU) among dialysis-treated PH patients during the time leading up to dialysis start.

Methods: This was a retrospective study of PH patients (ICD-10: E72.53) initiating dialysis (study entry), on or after October 1, 2018, in TriNetX Dataworks USA, a federated EMR network of 60+ million de-identified patients from 44 healthcare organizations (HCOs). Patient age, sex, race, comorbidities, CKD stage, kidney stone events (KSE), and HCU were examined at least 6 months prior to dialysis, through up to 5 years.

Results: The final study cohort included 47 patients: mean age of 59 years, 53% female, and 85% white. Only 47% had a recorded diagnosis of PH prior to dialysis, and 55% had a diagnosis of ESRD. During the 6 months immediately preceding dialysis, 91% of patients had ≥1 outpatient office visit, 17% ≥1 ED visit, and 53% ≥1 inpatient stay. HCU for the full study period showed 98% of patients had ≥ 1 physician office visit, 51% ≥1 ED visit, and 70% ≥1 inpatient stay (Figure 1). Patients with recorded KSE (n= 19; 40%) had a mean of 4 events during the study period. The frequency of KSEs doubled from 1 to 2 per person per year as patients neared dialysis. In the 6 months prior to dialysis, 70% of patients had CKD of stage III or higher recorded in their EMR.

Conclusions: In this real-world study, more than one-half of patients with PH were undiagnosed prior to initiating dialysis, according to the data reviewed. In addition, high rates of costly HCU, including ED visits and inpatient stays, were observed during the same timeframe. The number of KSEs increased over the study period, which may be indicative of worsening renal function due to PH prior to dialysis.

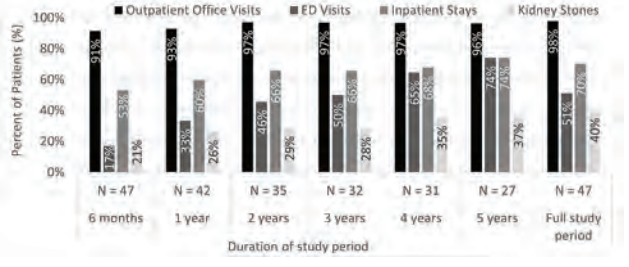
Figure 1: Resource utilization and clinical outcomes over the study period



PO1318

Association Between Longitudinal Plasma and Urine Oxalate and Time-to-Kidney Failure in Primary Hyperoxaluria Using Joint Models

Lisa E. Vaughan, John C. Lieske, Phillip Schulte. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The association between plasma oxalate (POX), urine oxalate (UOX) and the risk of kidney failure (KF) in patients with the rare disease primary hyperoxaluria (PH) is challenging to study due to small sample sizes and correlations among POX, UOX, and eGFR. To develop better KF models that simultaneously account for all 3 variables we used a novel statistical approach, joint models, modeling longitudinal biomarker processes (eGFR POX, UOX) and survival process (time-to-KF) jointly, using retrospective data from the Rare Kidney Stone Consortium PH registry.

Methods: Repeated eGFR, UOX, and POX after PH diagnosis were obtained from the registry. Time-to-KF was defined as time between PH diagnosis until transplantation, dialysis or eGFR<15 mL/min/1.73m^2. A multivariate joint model was fit with longitudinal sub-models for each biomarker and a survival sub-model for KF. Longitudinal sub-models employed linear mixed effects models with biomarkers on the log scale. Joint models share information between longitudinal and survival sub-models such that eGFR, UOX, and POX were time-dependent variables in the survival sub-model, specifically using subject-specific mean biomarker values. Models were adjusted for age and sex at diagnosis. Results were compared to last observation carried forward (LOCF) analyses.

Results: A total 166 patients (mean 5 POX and 7 UOX per patient) with 60 KF events during follow up were included. With LOCF, POX positively associated with KF risk, both unadjusted and adjusted for other biomarkers (hazard ratio (HR) = 1.14 per umol/L, 95%CI = 1.07, 1.22, p<0.001), while UOX was not associated with KF after adjustment. With joint modeling, POX and KF were not significantly associated after adjustment (HR = 1.12, 95%CI = 0.99, 1.30, p=0.08), while higher UOX was associated with lower KF risk (HR = 0.30 per mmol/1.73m^2/24h, 95%CI = 0.07, 0.92, p=0.04).

Conclusions: When modeling unevenly spaced longitudinal biomarkers and their association with KF, the LOCF time-dependent model makes implausible assumptions about steady-state biomarkers between observations. Implementation of a joint modeling framework allows flexible estimation of the association, which may impact conclusions. These novel methods can be used to inform patient-specific decisions about future KF risk, and the risk-benefit of novel treatment approaches.

PO1319

Modeling the Risk of Progression to Kidney Failure in Patients with Primary Hyperoxaluria Type 1 Treated with Lumasiran Relative to a Natural History Cohort Not Treated with Lumasiran

John C. Lieske,[1] Kristin C. Mara,[1] David S. Danese,[2] John M. Gansner,[2] Jiandong Lu,[2] Dawn S. Milliner.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Alnylam Pharmaceuticals Inc, Cambridge, MA.*

Background: In primary hyperoxaluria type 1 (PH1), the risk of kidney failure (KF) is positively associated with urinary oxalate (UOx) excretion. Lumasiran is an RNAi therapeutic to lower UOx levels in patients with PH1. We estimated the risk of progression to KF in patients with PH1 treated with lumasiran, relative to patients not treated with lumasiran.

Methods: A skewed-normal distribution of 24hr UOx values for patients with PH1 was simulated based on reported UOx values from the Rare Kidney Stone Consortium (RKSC) PH Registry among patients who were not in KF at diagnosis and did not receive lumasiran. Data from the ILLUMINATE-A trial of lumasiran were used to build a log-linear model of post-lumasiran treatment steady-state UOx as a function of baseline UOx. The distribution of steady-state, on-treatment UOx values for RKSC patients was then predicted by applying this model to the simulated 24hr UOx values of the RKSC cohort, considered as baseline. A risk model of KF as a function of 24hr UOx excretion, based on Kaplan-Meier curves of renal survival reported from the RKSC, was used to estimate the number of KF events/100 patients in the RKSC PH1 cohort, had all received lumasiran.

Results: The mean (SD) 24hr UOx excretion for the RKSC PH1 cohort was 2.2 (1.1) mmol/24hr/1.73m2 in the absence of lumasiran treatment and was predicted to decrease to 0.62 (0.17) mmol/24hr/1.73m2 in a model that simulated the effect of lumasiran administration (Figure 1). The predicted number of KF events/100 patients (95% CI) using the model for patients not treated with lumasiran at 10, 20 and 30 years, is 10 (4, 23), 32 (19, 50), and 42 (27, 59), respectively. In the model of lumasiran treatment, the estimated cumulative number of KF events/100 patients (95% CI) was 4 (1, 12) at 10 years and remained unchanged at 20 and 30 years.

Conclusions: This analysis predicts a long-term reduction in KF risk among PH1 patients treated with lumasiran, assuming prompt treatment at diagnosis.

Funding: Commercial Support - Alnylam Pharmaceuticals

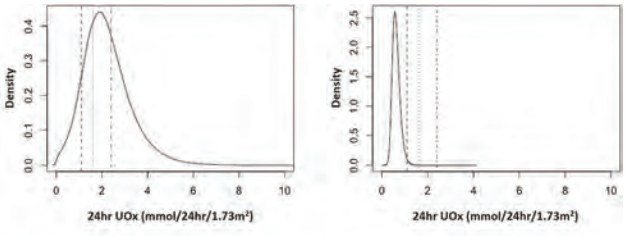

Figure 1. Simulated distribution of 24hr UOx excretion in patients from the RKSC not treated with lumasiran *(left panel)* and the predicted distribution of 24hr UOx excretion had all RKSC patients been treated with lumasiran *(right panel)*. Vertical dashed lines represent 24hr UOx excretion rates of 1.1, 1.6 and 2.4 mmol/24hr/1.73m^2.

PO1320

The Complex Landscape of Factor H and Factor I Rare Variants in Atypical Hemolytic Uremic Syndrome and C3 Glomerulopathy

Veronique Fremeaux-Bacchi,[1,2] Marie-Sophie Meuleman,[2] Paula Vieira-Martins,[1] Sophie Chauvet,[1] Fadi Fakhouri.[3] *[1]Assistance Publique-Hôpitaux de Paris, Paris, France; [2]INSERM U1138, Paris, France; [3]Lausanne University Hospital, Lausanne, Switzerland.*

Background: Complement genetics has been extensively studied to dissect the pathophysiology of atypical hemolytic uremic syndrome (aHUS) and C3 glomerulopathy (C3G) paving the way for highly tailored therapy. However, the assessment of each identified variant's contribution to disease pathogenesis remains a challenge in particular for rare variants detected in patients as well as in healthy individuals in the genome Aggregation Database (gnomAD). In this study we aimed to describe the rare variants in Factor H (CFH) and Factor I (CFI) genes identified in the French cohort of patients with aHUS and C3G.

Methods: We analyzed the distribution of the allele frequency (AF) of rare variants identified in 397 and 398 adult patients with a diagnosis of aHUS without coexisting disease and with C3G/Ig-mediated membranoproliferative glomerulonephritis (Ig-MPGN), respectively. We selected for this study variants with minor AF (MAF) below 0.1% in European healthy individuals.

Results: The frequency of patients with rare variants in CFH (108/398 vs 54/398) and CFI (33/397 vs 17/397) genes was higher in aHUS compared to C3G. A total of 148 variants were identified in CFH (n=98) and in CFI (n=50) genes. Among them, 9 were present in both diseases. We identified 43 (67%) and 20 (66%) novel variants in CFH in aHUS and C3G, respectively. Among them, 98% are pathogenic compared to 44% of the variants reported in gnomAD. The frequency of variants causing FH and FI deficiency is similar in both diseases (70% of the variants). The frequency of CFH variants identified in more than 1 patient is increased in aHUS compared to C3G (11/64 vs 2/30). We identified 12 (12/38; 31%) and 2 (2/12; 16%) novel variants in CFI in aHUS and C3G, respectively. Reported variants in CFI are more frequent in C3G than in aHUS (10/12 vs 26/38). The frequency of variants reported in gnomAD is higher in CFI (80%) compared to CFH (14%).

Conclusions: Our study indicates that novel pathogenic rare variants in complement genes is more frequent in aHUS than in C3G. However, half of the variants reported in gnamAD have a potential impact on gene function. Our results suggest that CFH variants are more damaging than CFI variants, and may contribute more significantly to the pathogenesis of both diseases, as compared to CFI.

PO1321

Phenotypic-Genotypic Relationship of Focal and Segmental Glomerulosclerosis (FSGS)

Ana M. Tato,[1] Noa Carrera cachaza,[2] Maria Garcia-Murias,[2] Amir Shabaka,[1] Clara M. Cases Corona,[1] Gema Fernandez Juarez,[1] Miguel A. Garcia-Gonzalez.[2] *[1]Hospital Universitario Fundacion Alcorcon, Alcorcon, Spain; [2]Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain.*

Background: FSGS can be of primary, secondary or genetic origin. The objective of our work is to establish in which patients with a histological diagnosis of FSGS a genetic etiology should be suspected

Methods: The study included adult patients with a histological diagnosis of FSGS and with either steroid resistant nephrotic syndrome (SRNS) or proteinuria without hypoalbuminemia in which secondary FSGS was ruled out. The presence of familial kidney disease was not an inclusion criterion. The genetic study was carried out by massive sequencing techniques (NGS) of the coding and flanking regions of the candidate genes associated with glomerular diseases.

Results: Out of 108 samples received, 80 patients met the inclusion criteria. We detected FSGS-related pathogenic genetic variants in 31 (39%) patients, finding no difference between those whose indication was steroid resistance (32 %) or proteinuria with normal albumin (58%). We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHS2 mutations were discovered in 7 (23%) patients. The remaining cases had variants affecting INF2, OCRL, HNF1B, WT2. All (3) black patients had high-risk APOL1 alleles. There were no differences between genetic and non-genetic causes in age, proteinuria, GFR, serum albumin, BMI, hypertension, diabetes, or family history. Hematuria was more prevalent among patients with genetic causes.

Conclusions: Genetic testing should be considered in FSGS patients in which a secondary cause has been excluded, to determine the patient's prognosis, treatment and perform familial screening.

Insight into the Pathophysiology of Hearing Loss and Renal Tubular Dysfunction Through Genetic Testing

Dylan H. West,[1] Jones Samuel.[1,2] *[1]Baton Rouge General Medical Center - Bluebonnet, Baton Rouge, LA; [2]Renal Associates of Baton Rouge, Baton Rouge, LA.*

Introduction: In this case report, we present a case of Type 3b Bartter's Syndrome associated with sensorineural hearing loss.

Case Description: A 69 year old caucasian female with a history of hypertension and osteoporosis presented to the emergency department with a worsening dry cough, altered mental status, and paresthesias. Physical examination was positive for Chvostek's sign and hearing loss bilaterally. Laboratory analysis was significant hypolcalcemia, hypokalemia, and hypomagnesemia. EKG on presentation displayed significant QT prolongation (QTc of 482 ms). The patient was treated for symptomatic hypocalcemia and initiated on calcium, potassium, and magnesium supplementation. 24 hour urine collection yielded: potassium and magnesium wasting and normal range calciuria. Parathyroid hormone was found to be inappropriately low in the setting of severe hypocalcemia but attributed to hypomagnesemia. Bartter's vs. Gittleman's was suspected, although profound hypomagnesemia suggested the latter. Renasight, a kidney gene panel employing next generation genome sequencing revealed a heterozygous variant in the basal chloride channel (CLCNKB), associated with Bartter's Syndrome Type 3/4B. This channel is found in the stria vascularis and can lead to sensorineural deafness. Hypoparathyroidism persisted in spite of adequate Magnesium, Vit D levels suggestive of primary hypoparathyroidism of autoimmune etiology.

Discussion: The positivity of CLCKNB heterozygous mutation suggested Bartter's Type 3/4B and this explained hearing loss and aided in the final diagnosis. Individuals who express both type A and B mutations present in infancy or antenatally. In a series of 115 patients w/ type B gene mutation, 26% had a Gitelman-like syndrome which includes late onset of age (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. Interestingly, the patient has persistent hypoparathyroidsism for which no genetic basis was identified such as the calcium sensing receptor mutation.

Whole-Exome Sequencing as a First-Line Diagnostic Tool in Bartter and Gitelman Syndromes

Francesca Becherucci, Viviana Palazzo, Luigi Cirillo, Benedetta Mazzinghi, Valentina Raglianti, Samuela Landini, Paola Romagnani. *Meyer Children's Hospital, Florence, Italy.*

Background: The clinical diagnosis of Bartter (BS) and Gitelman syndrome (GS) can be challenging, as they are rare and phenotypically overlapping. Thus, genetic testing represents the gold standard for the diagnosis. Next-generation sequencing is increasingly utilized in diagnostics and research of inherited tubulopathies. Sequencing of gene panels achieved high diagnostic yield and new insights into the phenotypic spectrum of these rare disorders. Whole-exome (WES) is not routinely performed for the molecular diagnosis of BS and GS. The aim of our study was to assess the diagnostic performance of WES in BS and GS, to establish genotype-phenotype correlations and to assess cost-effectiveness of this approach.

Methods: We performed WES in all consecutive patients referred for genetic testing with a clinical suspect of BS or GS. Variant prioritization was carried out according to ACMG guidelines. Clinical data were collected retrospectively.

Results: We enrolled 50 patients (22 males) with a clinical diagnosis of BS or GS. All the patients showed hypokalemic metabolic alkalosis at onset. The median age at clinical diagnosis was 7 years (range 0-67). WES showed pathogenic variants in 41/50 patients (82%). A dedicated analytic pipeline allowed us to identify copy number variations (CNVs) in 7/41 patients with a confirmed genetic diagnosis. In details, WES allowed us to confirm the clinical diagnosis in 33/50 patients and to change it 8 additional patients (6 patients from BS to GS, 2 patients outside the BS/GS spectum). Nephrocalcinosis was detected in 38% vs 8% of patients with a genetic diagnosis of BS and GS, respecively. Hypomagnesemia was similarly distributed among BS and GS patients (45% vs. 68%). Finally, patients with GS showed a median age at onset higher than patients with BS, but some overlap did exist, making differential diagnosis challenging at single-patient level.

Conclusions: The results of our study demonstrate that WES ensures a high diagnostic yield in patients with a clinical diagnosis of BS or GS, especially if coupled with analysis of CNVs. This approach showed to be useful in dealing with the phenotypic heterogeneity typical of these rare disorders, improving differential diagnosis by detecting phenocopies also outside the BS/GS spectrum.

PO1324

Examination of the Predicted Prevalence of Gitelman Syndrome by Ethnicity Based on Genome Databases

Atsushi Kondo,[1] Sadayuki Nagai,[1] Yuya Aoto,[1] Nana Sakakibara,[1] China Nagano,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Kazumoto Iijima,[2] Kandai Nozu.[1] *[1]Kobe University Graduate School of Medicine, Department of Pediatrics, Kobe, Japan; [2]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

Background: Gitelman syndrome is an autosomal recessive inherited salt-losing tubulopathy. It has a prevalence of around 1 in 40,000 people, and heterozygous carriers are estimated at approximately 1%, although the exact prevalence is unknown because most cases are thought to be asymptomatic or have nonspecific clinical findings. On the other hand, it has been reported that the non-specific symptoms can reduce the quality of life of patients, and in practice, we have often experienced cases where patients have suffered from these symptoms since childhood, but were not diagnosed and therefore not treated, and were diagnosed in adulthood. It could suggest that there are far more patients and carriers than expected.

Methods: We estimated the predicted prevalence of Gitelman syndrome based on multiple genome databases, HGVD and jMorp for the Japanese population and gnomAD for other ethnicities, and included all 274 pathogenic missense or nonsense mutations registered in HGMD Professional. The frequencies of all these alleles were summed to calculate the total variant allele frequency in *SLC12A3* which is the responsible gene for Gitelman syndrome. The carrier frequency and the disease prevalence were assumed to be twice and the square of the total allele frequency, respectively, according to the Hardy–Weinberg principle.

Results: In the Japanese population, the total carrier frequencies were 0.0948 (9.5%) and 0.0868 (8.7%) and the calculated prevalence was 0.00225 (2.3 in 1000 people) and 0.00188 (1.9 in 1000 people) in HGVD and jMorp, respectively. Other ethnicities showed a prevalence varying from 0.000012 to 0.00083.

Conclusions: These findings indicate that the prevalence of Gitelman syndrome in the Japanese population is higher than expected and that some other ethnicities also have a higher prevalence than previously been considered.

PO1325

An Off-the-Shelf CRISPR Gene Therapy Approach in Human Kidney Organoids

Nicole Vo, Catherine A. Macnary, Benjamin S. Freedman. The Freedman lab *University of Washington, Seattle, WA.*

Background: Gene therapy offers many opportunities to treat kidney diseases. Targeted, off-the-shelf therapeutics are needed for both loss-of-function (e.g. nephropathic cystinosis) and gain-of-function (e.g. APOL1) disease states. Kidney organoids are complex structures that resemble nephrons and can be used to develop gene therapy approaches. Commonly used gene transfer techniques, such as lentivirus and adeno-associated virus, are size limited, transient, or introduce DNA non-specifically into the genome. While targeted CRISPR gene editing is routinely used in 2D cell cultures, it has been challenging to use this powerful technique in intact organoids.

Methods: To achieve off-the-shelf gene transfer, organoids were transfected with Cas9 and gRNA ribonucleoprotein (RNP) complexes targeting the *AAVS1* safe harbor locus supplemented with knock-in cassettes encoding green fluorescent protein (GFP) or FLAG-tagged cystinosin (deficient in nephropathic cystinosis). Alternatively, to monitor gene knock-out, organoids expressing GFP from *AAVS1* were transfected with RNP and either one or two gRNAs to introduce indels in the coding sequence. Genome editing was detected three ways: by confocal microscopy, PCR, and next generation sequencing.

Results: GFP and cystinosin knock-in events in organoids were detected using microscopy and PCR. Immunofluorescence analysis revealed knock-in in proximal tubule epithelial cells (LTL^+). In knock-out experiments, live confocal microscopy indicated areas of GFP loss within kidney organoids treated with gRNA targeting GFP, but not with a scrambled guide. Mosaic patches of GFP knockout cells expanded over several days. Staining with nephron markers such as LTL and podocalyxin revealed knockout in both proximal tubule cells and podocytes. By next generation sequencing, the two-guide system produced larger deletions and was more efficient (20 % knockout), compared to single guide.

Conclusions: The strategy developed here is efficient for knocking in and knocking out genes in kidney epithelium. It uses commercially available reagents to perform CRISPR gene editing. sgRNA sequences or *AAVS1* knock-in templates can be customized to target or introduce any gene of interest at specific loci. This provides a platform for the development of off-the-shelf gene therapies for diverse kidney disease states.

PO1326

The Kidney Genome Atlas: A Resource to Understand APOL1 and Other Genetic Drivers of Adult Proteinuric Kidney Diseases

Eva Fast,[1] Thomas Soare,[1,2] Hari Somineni,[1,2] James Watkins,[1] Adam Tebbe,[1] Maria Lalioti,[1] Liron Walsh,[1] Matthias Kretzler,[3] Girish N. Nadkarni,[4] Rasheed A. Gbadegesin,[5] Jamie L. Wenke,[6] Daniel G. Macarthur,[9] Peter H. Mundel,[1,7] Thomas T. Tibbitts,[1,8] Michelle Penny.[1] *[1]Goldfinch Bio Inc, Cambridge, MA; [2]Insitro, South San Francisco, CA; [3]University of Michigan, Ann Arbor, MI; [4]Mount Sinai Health System, New York, NY; [5]Duke University School of Medicine, Durham, NC; [6]Nashville Biosciences, Nashville, TN; [7]Atlas Venture, Cambridge, MA; [8]Dogodan Therapeutics, Westford, MA; [9]Garvan Institute of Medical Research, Darlinghurst, NSW, Australia.*

Background: Chronic kidney disease (CKD) affects more than 30 million people in the US with African Americans being particularly at risk. There is an unmet need for pharmaceutical therapies that extend or, ideally, restore kidney function.

Methods: To guide genetically-driven drug development, we have established the Kidney Genome Atlas (KGA), which contains whole-genome sequences (>30X) from adult patients with Focal segmental glomerulosclerosis (FSGS), minimal change disease (MCD) and other, idiopathic, proteinuric disorders as well as public and technically matched controls. By implementing a rigorous quality control procedure, following the gnomAD pipeline, we obtained a high-confidence dataset for downstream analyses. Three genetically inferred ancestries (EUR, AFR, AMR) were included in association testing comparing 1400 cases, including 169 individuals with *APOL1* G1/G1, G2/G2 or G1/G2 high risk haplotypes (*APOL1*-HRH), with 14686 controls (including 485 *APOL1*-HRH individuals).

Results: Overall, our common variant cross-ancestry meta-analysis showed minimal impact of potential confounders, such as ancestry or sequencing center differences (lambda=1.03). Using summary statistics from our EUR analysis, we estimated a SNP heritability of 0.15 (SE = 0.028) in proteinuric diseases. Comparison to a recent CKD GWAS (Wuttke et al., 2019) indicated a weak positive genetic correlation (rg) of 0.097 (SE = 0.053). We identified the previously reported significant disease association of *APOL1*-HRH ($p=2x10^{-10}$) in our study. Recent in vitro data suggests amino acid in position 150 (rs2239785) is critical for the pathogenicity of *APOL1*-HRH (PO1986, ASN 2020) which we confirmed in our cohort of AFR ancestry individuals.

Conclusions: We have built a high-quality, multiethnic cohort that enables understanding of genetic drivers of polygenic proteinuric kidney disease. Future analysis including genetic modifiers of *APOL1* may provide opportunities for novel therapies and patient stratification.

PO1327

Effect of ApoL1 Genotype on Kidney Failure and eGFR Decline in Patients with All-Cause CKD

Mark Elliott, Maddalena Marasa, Enrico Cocchi, Junying Zhang, Atlas Khan, Krzysztof Kiryluk, Ali G. Gharavi. Gharavi Lab *Columbia University Irving Medical Center, New York, NY.*

Background: *ApoL1* risk variants G1 and G2 associate with an increased risk of kidney failure and a higher rate of eGFR loss. We assess the effect of *ApoL1* genotype in African American and Latino individuals with chronic kidney disease (CKD) in New York City.

Methods: *ApoL1* genotype determined by sequencing. CKD cases with high-risk *ApoL1* genotype (n= 242) were compared to CKD cases with a low-risk *ApoL1* genotype (n=885) and African ancestry per Admixture. Kaplan-Meier survival analyses assessed time to kidney failure followed by Adjusted Cox-proportional hazard model and competing risk regression against death both incorporating covariates. Linear mixed-effects modelling evaluated CKD-EPI $eGFR_{cr}$ decline rate using the same covariates.

Results: Cases with a high-risk *ApoL1* genotype reach kidney failure 10-15 years earlier than low-risk cases. G1/G1 reach kidney failure earliest, followed by G1/G2 and G2/G2 (Fig 1). These data are supported across multiple risk models (Table 1). Cases with a high-risk genotype have a higher eGFR decline rate than low-risk cases with a similar trend per specific genotype (Fig 2). The addition of self-declared or genetically defined ancestry did not confer additional risk.

Conclusions: High-risk *ApoL1* genotypes increase the risk of kidney failure at an earlier age, likely due to a higher eGFR decline rate. G1/G1 genotypes appear most affected and G2/G2 least.

Funding: Government Support - Non-U.S.

Table 1. Modelling Results by ApoL1 Genotype

ApoL1 Genotype	Age at Kidney Failure (Median, 95% CI, Years)	Unadjusted HR of Kidney Failure	Adjusted HR of Kidney Failure	Competing Risk HR of Kidney Failure	eGFR Decline Rate (mL/min/year)

PO1328

"APOL1-Plus" Genotypes in Patients with CKD

Darbey Raible,[1] Dinah Clark,[1] Fang Fang,[2] Jing Xie.[1] *[1]Natera, Inc., San Carlos, CA; [2]Fulgent Genetics, Temple City, CA.*

Background: Inheritance of homozygous or compound heterozygous *APOL1* G1 G2 risk alleles is associated with an increased risk of chronic kidney disease (CKD) including focal segmental glomerulosclerosis (FSGS). The *APOL1* high-risk genotype (HRG) is not completely penetrant; additional genetic and/or environmental factors are thought to be necessary for the development of CKD. While approximately 10% of individuals with CKD have causal variants when tested with exome-based next generation sequencing (NGS), few reports have examined co-occurrence of *APOL1* HRG alongside these variants. Here we examine the co-occurrence of *APOL1* HRG and additional genetic diagnoses ("*APOL1*-plus") using a broad NGS panel of CKD genes.

Methods: Clinical samples were analyzed via an NGS panel of >380 genes associated with isolated or syndromic CKD. Positive results had one pathogenic (P) or likely pathogenic (LP) variant in an autosomal dominant or X-linked gene, two P/LP variants in an autosomal recessive gene, or presence of two *APOL1* risk alleles.

Results: Among 1691 cases with positive results, 25% (n=430) had positive findings in *APOL1*. Other positive findings included variants in *PKD1/2* in 27% (456/1691) of cases, and in *COL4A3/4/5* in 22% (379/1691) of cases. Among positive cases, 7% (119/1691) had >1 positive result, including both dual (n=115) and triple diagnoses (n=4). *APOL1* HRG was present in 50% (59/119) of cases with multiple diagnoses, accounting for 3.5% of all positive cases and 14% of all *APOL1* HRG cases. Among the *APOL1*-plus cases, second positive findings were observed in *COL4A3/4/5* (29%; 17/59), *TTR* (29%; 17/59), and *PKD1/2* (15%; 9/59).

Conclusions: Dual diagnoses comprised 7% of all positive genetic testing results, with *APOL1* HRG present in half of these cases. Future studies are needed to understand how multiple genetic diagnoses, including those with *APOL1* HRG, impact disease presentation and progression. Dual *APOL1* and collagen IV-related diagnoses are of particular interest given the frequency of these glomerulopathies in the CKD population. Genetic testing via broad NGS panels can improve diagnosis and management of CKD and increased testing will contribute to an evolving understanding of genetic etiologies of CKD.

PO1329

Uncovering Mechanisms of Risk-Variant APOL1-Modulated Inflammatory Signaling in Macrophages

Esther Liu, Jennie Lin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: In the United States, Black Americans face a higher risk to develop CKD and progress to end stage kidney disease (ESKD) even after accounting for clinical and socioeconomic factors. Variants in the gene encoding for innate immunity factor Apolipoprotein L1 (APOL1) have been identified as risk factors for focal segmental glomerulosclerosis (FSGS) and HIV-associated nephropathy (HIVAN) in individuals with recent African ancestry. However, the role of immune cells in APOL1 nephropathy is not well understood. In this study we seek to understand the effect of risk variant APOL1 on macrophage function and inflammation.

Methods: Isogenic induced pluripotent stem cell (iPSC) lines expressing the G0, G1, and G2 variants of *APOL1* were generated through CRISPR/Cas9 gene editing. These iPSC lines were used to generate iPSC-derived macrophages (IPSDM). Peritoneal and bone marrow-derived macrophages (BMDMs) were collected from transgenic mice 14-18 weeks of age expressing G0, G1, and G2 variants of *APOL1*. Expression of *APOL1* in cultured iPSDMs, peritoneal macrophages, and BMDMs was induced with IFNγ (5 ng/mL).

Results: We observed that risk-variant *APOL1* expression results in higher *TNF* and *IL1B* gene expression by nine-fold and two-fold respectively, in G1 iPSDM ($P < 0.05$). In *APOL1* transgenic mouse peritoneal macrophages, oil red O staining revealed 2.83-fold increased neutral lipid accumulation ($N = 3$, $P < 0.01$) and 4.84-fold decreased efferocytosis capacity measured with flow cytometry ($N = 5$, $P < 0.05$) in G1 and G2 mice compared to G0. qRT-PCR analysis showed glycolysis genes to be increased in G1 iPSDM compared to G0. Additionally, G2 mouse BMDMs exhibit increased glycolytic rate compared to G0 both at baseline and under mitochondrial stress when *APOL1* was induced with IFNγ.

Conclusions: The findings in this study unveil some mechanisms by which risk-variant APOL1 modulates macrophage inflammatory phenotype and function, relevant to kidney disease progression.

A Multivariate Analysis of Genome-Wide Association (GWAS) Data to Identify Genes Associated with CKD

Amy J. Osborne, Agnieszka Bierzynska, Gavin I. Welsh, Moin Saleem, Ian C. Campbell. *University of Bristol, Bristol, United Kingdom.*

Background: Chronic kidney disease (CKD), a major public health burden, is characterised by a progressive loss of nephron function which leads to an impaired ability to filter the blood. Genome-wide association studies (GWASs) have identified single nucleotide polymorphisms (SNPs) and loci associated with the kidney function biomarkers estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN) by mostly univariate-based analyses. However, gene-based multivariate-SNP and multivariate-biomarker relationships have typically not been considered so far in this context. The purpose of this study was to highlight the additional insights gained from the statistical power of a multivariate-based approach to identify potential risk factor genes for CKD.

Methods: We used a multivariate statistical approach, canonical correlation analysis (CCA), to identify single nucleotide polymorphisms (SNPs) that showed significant correlation with estimated glomerular filtration rate (eGFR) and blood urea nitrate (BUN) taken jointly. Since attributes were in the form of three published GWAS summary statistics datasets, we used *metaCCA*. The SNPs were filtered using linkage disequilibrium-based pruning. For the significant SNPs and genes we identified, their functions, signalling pathways and cellular expression were investigated using gene set statistical enrichment analyses.

Results: For each of three published GWAS summary statistics datasets of both European and Japanese ancestry groups, we identified sets of 159, 246 and 181 protein-coding genes, respectively, that contained significant SNPs. Using gene set statistical enrichment analyses, these genes showed significant enrichment for kidney development processes, signalling pathways and kidney cell gene expression signatures. In addition, between all three datasets, we identified four significant genes (*CBLB, MACROD2, MECOM* and *SHROOM3)* that overlapped. Between two datasets, we identified a further four significant SNPs that overlapped.

Conclusions: By using a multivariate statistical approach, we have identified both previously reported and additional genes that contained SNPs statistically associated with kidney function. Overall, these findings provide new insights into SNPs and genes potentially involved in kidney function and CKD risk.

Rare Variants and Risk of ESKD: The Geisinger MyCode-DiscovEHR Study

Alex R. Chang, Bryn S. Moore, Gurmukteshwar Singh, Prince M. Anand, Natasha T. Strande, Tooraj Mirshahi. *Geisinger Health, Danville, PA.*

Background: Prior studies have reported that up to 1 in 10 patients with end-stage kidney disease (ESKD) have a diagnostic rare genetic variant but have lacked control groups.

Methods: Whole exome sequencing and electronic health records data from 147,750 participants in the Geisinger MyCode-DiscovEHR study, a health system-based cohort, were linked to the US Renal Data System to ascertain ESKD status and attributed cause. We compiled a list of variants in 80 autosomal or X-linked dominant (AD/XLD) genes used in commercial kidney genetics panels previously reported in Clinvar as pathogenic or likely pathogenic (P/LP) (minor allele frequency <0.01, any number of stars). We evaluated the association of these rare P/LP variants with risks of all-cause and cause-specific ESKD in logistic regression models adjusted for age and sex. Additional analyses were performed by subsets of kidney disease genes and by age of ESKD onset.

Results: Prevalence of previously reported rare P/LP variants in AD kidney disease genes was higher in participants with ESKD than those without ESKD (3.0% vs. 1.2%). Rare P/LP variants were most prevalent in congenital/cystic ESKD (12.6%), followed by ESKD attributed to genitourinary/nephrolithiasis disorders (4.9%), hypertension (4.3%), glomerular/vasculitis disorders (3.4%), and early onset diabetic ESKD (<60 years; 3.3%). By contrast, only 0.7% with later onset diabetic ESKD (60+ years) had rare P/LP variants. Individuals with rare variants were at increased risk of all-cause ESKD (OR 2.71, 95% CI: 1.99-3.70) (**Table**). When genes were grouped by specific categories, rare variants in cystic disease, Alport Syndrome, CAKUT, and FSGS gene panels were all associated with increased risk of ESKD.

Conclusions: Individuals in an unselected health system cohort with rare variants had substantially increased risk of ESKD, which was often attributed to hypertension or diabetes.

Genomic Disorders Are Associated with CKD Across the Life Span

Miguel Verbitsky,[1] Sarath Babu Krishna Murthy,[1] Maddalena Marasa,[1] Junying Zhang,[1] Atlas Khan,[1] Craig S. Wong,[7] Bradley A. Warady,[8] Susan L. Furth,[2] David R. Crosslin,[3] Robert P. Igo,[4] Sudha K. Iyengar,[4] Simone Sanna-Cherchi,[1] Krzysztof Kiryluk,[1] Afshin Parsa,[5] Harold I. Feldman,[6] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]University of Washington, Seattle, WA; [4]Case Western Reserve University, Cleveland, OH; [5]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [6]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [7]University of New Mexico School of Medicine, Albuquerque, NM; [8]University of Missouri Kansas City, Kansas City, MO*.

Background: Genomic Disorders (GDs), caused by pathogenic deletions and duplications (copy number variants, CNV) of large genomic regions of the genome, are a major source of genetic susceptibility for multiple developmental traits and are enriched in pediatric chronic kidney disease (CKD) patients. In the Chronic Kidney Disease in Children Study (CKiD) cohort 1, 4.5% participants carried a GD.

Methods: We extended our previous study in CKiD to cohort 2 and also examined the prevalence of GDs in adults with all-cause CKD enrolled in the Chronic Renal Insufficiency (CRIC, N = 3375), Columbia University CKD (CU-CKD, N=1146) and Family Investigation of Nephropathy and Diabetes (FIND, N=1318) cohorts, comparing them to 30746 controls. CNV calls were based on SNP microarrays and whole exome sequencing and annotated for known GDs. We also performed a phenome-wide association analysis of GDs in the Electronic Medical Records and Genomics (eMERGE, N=11971) cohort.

Results: We found 9/248 (3.6%) CKiD 2 pediatric participants with mild CKD carried a GD, replicating prior findings in pediatric CKD. We next identified GDs in 74/6,679 (1.1%) adult CKD patients in the CRIC, CU-CKD and FIND cohorts, compared to 165/30,746 (0.5%) GDs in controls (OR=1.6, $p=5x10^{-4}$). Recurrent known GDs in adult CKD patients comprised pathogenic CNVs in 1q21.1, 16p11.2, 17q12 and 22q11.2 loci. The 17q12 GD (renal cyst and diabetes syndrome) was most frequent, detected in 1:252 CKD cases with diabetes. In the phenome-wide analysis of the eMERGE cohort, dialysis was in the top three phenotypic associations with GD carrier status ($p<10^{-3}$), replicating the case-control association results. Other phenotypic associations for GDs in CRIC participants included lower serum Mg ($p=2x10^{-3}$) and lower educational achievement ($p=8x10^{-4}$).

Conclusions: GDs are significantly enriched in children and adults with CKD. Undiagnosed GDs can provide a molecular explanation for renal disease in both adults and children and represent hidden genetic links between CKD and other traits such as poorer neurocognitive performance. Systematic detection of GDs can enable a precise genetic diagnosis and inform prognosis and treatment.

Genome-Wide Association Study in Mice Maps Susceptibility to HIV-Associated Nephropathy to the Ssbp2 Locus

Nicholas J. Steers,[1] Yask Gupta,[1] Vivette D. D'Agati,[1] Tze Yin Lim,[1] Anna Mo,[1] Judy Liang,[1] Kelsey O. Stevens,[1] Natalia D. Demaria,[1] Wan Yee Lam,[1] Lalitha Nagarajan,[2] Simone Sanna-Cherchi,[1] Ali G. Gharavi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]The University of Texas MD Anderson Cancer Center, Houston, TX*.

Background: To gain insight into the pathogenesis of collapsing glomerulopathy, a rare form of focal segmental glomerulosclerosis that often arises in the setting of viral infections, we performed a genome wide association study (GWAS) among inbred mouse strains using a murine model of HIV-1 associated nephropathy (HIVAN).

Methods: F1 hybrids were generated between HIV-1 transgenic mice on the FVB/NJ background and 20 inbred laboratory strains. Histology, BUN, proteinuria and urinary NGAL were assessed in the F1 hybrids. A GWAS in 366 transgenic F1 hybrids generated from these 20 inbred strains was performed.

Results: Six stains (A/J, C3H/HeJ, DBA/1J, KK/HlJ, WSB/EiJ, and LP/J) were highly sensitive to the Tg resulting in severe glomerulosclerosis, 9 strains (129S1/SvImJ, Balb/CJ, C57BL/6J, C57BL/6NJ, C57BL/10J, C57BL/J, C58/J, CAST/EiJ and NZB/BINJ) were resistant to the Tg resulting in limited to no glomerulosclerosis, and 5 strains (CBA/J, DBA/2J, NOD/ShiLtJ, NZO/HlLtJ and FVB/NJ) had intermediate glomerulosclerosis. Analysis of histology, BUN and urinary NGAL demonstrated a marked phenotypic variation among the transgenic F1 hybrids, providing strong evidence for host genetic factors in the predisposition to nephropathy. A GWAS identified a genome-wide significant locus on Chr. 13 and multiple additional suggestive loci. Cross annotation of the Chr. 13 locus, including single cell transcriptomic analysis of wild type and HIV-1 transgenic mouse kidneys, nominated *Ssbp2* as the likely culprit gene. *Ssbp2* is highly expressed in podocytes, encodes a transcriptional cofactor present in LDB1 containing complexes, and interacts with *LMX1B,* a known FSGS gene that requires LDB1 for optimal transcriptional activity. Consistent with these data, older *Ssbp2* null mice spontaneously develop glomerulosclerosis, tubular casts, interstitial fibrosis and inflammation, similar to the HIVAN mouse model.

Conclusions: These findings demonstrate the utility of GWAS in mice to uncover host genetic factors for rare kidney traits and suggest *Ssbp2* as susceptibility gene for HIVAN, potentially acting via the LDB1-LMX1B transcriptional network. Future studies will evaluate the role of *Ssbp2 in vitro* and in *Ssbp2* null mice.

Genetics Analysis of IgA Nephropathy-Discordant Monozygotic Twins

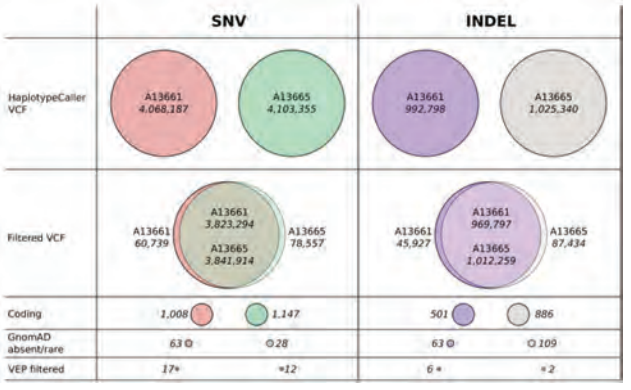
Enrico Cocchi,[1] Nicholas J. Steers,[1] Gerald B. Appel,[1] Maya K. Rao,[1] Licia Peruzzi,[2] Ali G. Gharavi.[1] Gharavi Lab. *[1]Columbia University, New York, NY; [2]Turin University, Turin, Italy*.

Background: Analysis of monozygotic twins can inform about the genetic and environmental basis of disease. We investigated monozygotic twins phenotypically discordant for IgA nephropathy (IgAN), in order to identify possible postzygotic variants that may provide further insights into IgAN pathogenesis.

Methods: We studied 5 pairs of discordant monozygotic twins, and their family members. Immunological analysis evaluated the in vitro secretion of IgA and Genome Sequencing (GS) was employed to identify germline and somatic variants.

Results: Culture of naïve B-cells and T-follicular like helper cells derived from the IgAN cases yielded 1.74 fold higher IgA production compared to cells from their corresponding healthy twins. Genetic analysis of the samples allowed to call ~4 mln (4,068,187 - 4,103,844) SNPs and ~1 mln (992,798–1,027,413) INDELs for each sample. Of those, ~60,000 (60,739–68,027) SNPs and ~50,000 (45,927–53,052) INDELs were discordant between twin pairs. Slightly lower rate were identified in the technical replicate (57,883 SNPs and 51.415 INDELs). Among discordant variants, only ~1,000 (986–1,147) SNPs and ~500 (401-886) INDELs were in coding regions. Further filtering for GnomAD AF, showed ~50 (43-68) SNPs and ~70 (53-109) INDELs had a minor allele frequency <0.0001, and of those just very few variants (9–22 SNPs and 2–7 INDELs) had potential impact on the gene function. We did not detect discordant variants in the same gene between the twin pairs.

Conclusions: Our analysis identified significant differences in IgA production demonstrating the role of the immune system and genetics in IgAN pathogenesis. Consistent with the literature, GS identified discordant variants between twins pairs, most of which are attributable to background errors in variant calling. Further analysis of twin-specific variants and gene sets may allow the identification of postzygotic variants that may be involved in IgAN pathogenesis.



Affected vs. Unaffected variant differences in one of the IgAN discordant twin pairs under analysis

PO1335

Primary AA Amyloidosis due to a chr11:18287683 T>C (hg19) Mutation in the SAA1 Promoter Linked to the Amyloidogenic SAA1.1 Haplotype

Jakub Sikora,[1] Dita Musalkova,[1] Petr Prikryl,[1] Hana Hartmannova,[1] Katerina Hodanova,[1] Helena Treslova,[1] Lenka Noskova,[1] Viktor Stranecky,[1] Milan Jirsa,[3] Martina Zivna,[1] Anthony J. Bleyer,[2,1] Ivan Rychlík,[4] Romana Rysava,[1] Stanislav Kmoch.[1,2] *[1]Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; [2]Wake Forest University School of Medicine, Winston-Salem, NC; [3]Institut klinicke a experimentalni mediciny Pracoviste laboratornich metod, Praha, Czechia; [4]Univerzita Karlova 3 lekarska fakulta, Praha, Czechia.*

Background: AA amyloidosis results from deposition of amyloid A (AA), a product of the proteolytic cleavage of serum amyloid A (SAA) proteins. Previously described AA amyloidosis has been due to increased production and deposition of serum amyloid A (SAA) proteins secondary to inflammatory conditions arising from infectious or metabolic causes. We describe for the first time a family with primary AA amyloidosis due to an isolated increase in production of AA protein.

Methods: A family was identified with autosomal dominant transmission of amyloidosis affecting 12 family members and associated with progressive chronic kidney disease (CKD) as well as other systemic manifestations of amyloidosis. Family members underwent measurement of serum SAA1 and whole exome sequencing with targeted sequencing. The luciferase reporter assay was used to determine promoter activity.

Results: Affected individuals developed proteinuria, CKD and systemic deposition of amyloid composed specifically of the SAA1.1 isoform. Affected individuals had a doubling of the SAA1 promoter activity and sustained elevation of serum SAA levels that segregated in an autosomal dominant pattern in 12 genetically affected and in none of 6 genetically unaffected relatives with a LOD score of >5. Genetic evaluation revealed a chr11:18287683 T>C (hg19) mutation in the SAA1 promoter linked to the amyloidogenic SAA1.1 haplotype that segregated completely with affected individuals. Tocilizumab had a beneficial effect when prescribed early.

Conclusions: A mutation in the SAA1 promoter linked to the amyloidogenic SAA1.1 haplotype led to a doubling of production of SAA1, leading to characteristic findings of amyloidosis. This is the first investigation to show that all manifestations of AA amyloidosis in humans are due solely to SAA overexpression. Idiopathic forms represent a significant and increasing proportion (15-20%) of all diagnosed cases of AA amyloidosis. Genetic screening of the SAA1 promoter should be pursued in individuals with AA amyloidosis without an obvious cause of systemic inflammation, especially if there is a positive family history. Contact ableyer@wakehealth.edu for genetic evaluation of familial amyloidosis.

PO1336

Genetic Testing in Focal Segmental Glomerulosclerosis (FSGS): Tale of Three Stories

Gaurav Rajashekar, Ying M. Chen. Washington University in St. Louis *Washington University in St Louis, St Louis, MO.*

Introduction: Genetic testing in kidney disease has improved our understanding of various etiologies of glomerular diseases. FSGS is a histopathological diagnosis with diverse causes and patterns of inheritance. Genetic testing in FSGS has unlocked a treasure of pathogenic mutations that are either limited to the kidney or represent a broader extra-renal manifestation. Here we present 3 biopsy proven cases of FSGS with different genetic polymorphisms and varied presentations.

Case Description: Case 1: 29-year-old female with scoliosis, hearing loss, right optic nerve coloboma presented with 1.5 g/day of proteinuria and normal renal function when she was 16 years of age. Kidney biopsy revealed FSGS with 90% foot process effacement. 13 years later, her renal function worsened, with serum creatinine 1.4 mg/dl (baseline 0.9 mg/dl), and urine protein creatinine ratio of 4 g/g. Her mother had undergone a kidney transplant assumed to be secondary to reflux nephropathy. Genetic testing showed PAX2 truncated mutation c.430>T p.Gln 144* which can lead to FSGS, optic nerve coloboma and papillorenal syndrome. Case 2: 21 year-old male with biopsy proven FSGS when he was 8 years old mentioned that his maternal grandfather suffered from unknown renal disease requiring dialysis and died in his 40's. Genetic testing revealed hemizygous, truncating p.W58* variant in the CLCN5 gene. Variants in CLCN5 gene can cause Dent's Disease manifesting later in life as proteinuria, nephrocalcinosis, hypercalciuria and renal failure. In addition he had variant of unknown significance NPHS1 designated p.T233A, and APOL1G2 risk allele predisposing him to develop FSGS. Case 3: 21 year-old male, born with genital ambiguity, perineal hypospadias, 46 XY karyotype was noted to have 14 g of proteinuria, low albumin and hypertension. Kidney biopsy revealed FSGS, abnormal glomerular basement membrane. Genetic testing was positive for heterozygous intronic variant of WT-1 and heterozygous missense variant of SMARCAL1 p.R820H which are pathogenic variants that cause renal failure due to defective podocyte development and dysfunction respectively.

Discussion: Genetic analysis for FSGS has become an important diagnostic tool in nephrology. We currently have over 50 genes that are known to be involved in FSGS. Reporting of different genetic variants and their occurrence is crucial to yield insight into our current understanding of FSGS.

PO1337

Whole-Exome Sequencing Reveals a Monogenic Cause of Disease in 26% of 335 Families with Steroid-Resistant Nephrotic Syndrome

Ronen Schneider,[1] Konstantin Deutsch,[1] Ana C. Onuchic-Whitford,[1,2] Kirollos Yousef,[1] Muhammad Y. Zahoor,[1] Camille H. Nicolas Frank,[1] Florian Buerger,[1] Shirlee Shril,[1] Michael J. Somers,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Steroid resistant nephrotic syndrome (SRNS) overwhelmingly progresses to end-stage renal disease. To date, more than 59 monogenic genes have been identified to cause SRNS. We previously detected causative mutations in 25% using whole exome sequencing (Warejko *CJASN* 13:53, 2018) and in 29.5% of patients with SRNS using targeted panel sequencing (Sadowski *JASN* 26:1279, 2015). However, whole exome sequencing (WES) has become more accessible, with the advantage of detecting not only known monogenic causes of SRNS, but also novel candidate NS-causing genes.

Methods: We employed whole exome sequencing (WES) to detect monogenic causes of SRNS in a large international cohort of 335 families with SRNS presenting before the age of 25 years.

Results: Samples were recruited from April, 1998 to December, 2018 (21 years). WES was performed at the Yale Center of Mendelian Genomics. First, we examined the WES data for mutations in 59 genes known to cause SRNS. In 87/335 families (26%), we identified mutations in 22 of the known genes. There were also 7 genes that were identified as phenocopies of SRNS e. g. *COL4A3*. In 58 families (17.3%), we have identified mutations in a potential novel candidate gene for SRNS. We found a 48.1% solve rate in individuals with high homozygosity by decent and 15.4% solve rate in non-homozygous individuals, recapitulating similar solve fractions to what has been previously published (Sadowski 2015; Warejko 2017).

Conclusions: This study confirms that ~26% of families with NS in our cohort are due to monogenic causes. WES is a viable way to diagnose the underlying cause of NS in children and young adults, and to suggest novel monogenic candidate genes of NS.

PO1338

Discovery of Podocyte-Specific Interaction Partners of the Nephrotic Syndrome-Associated Protein NOS1AP

David A. Ball, Florian Buerger, Friedhelm Hildebrandt, Amar J. Majmundar. *Boston Children's Hospital Department of Pediatrics, Boston, MA.*

Background: Recessive *NOS1AP* mutations are a novel Mendelian cause of nephrotic syndrome (NS) in humans and mice (Majmundar *Sci Adv* 2021). The NS patient mutation p.C143Y destabilizes the predicted structure of the NOS1AP phosphotyrosine-binding domain, impairs NOS1AP-dependent actin remodeling in immortalized podocytes, and causes abnormal kidney organoid glomerulogenesis. Here, we aimed to discover podocyte-specific NOS1AP interaction partners, which may mediate NOS1AP functions in the podocyte and whose binding is abrogated by the patient mutation p.C143Y.

Methods: Protein interaction data from candidate immunoprecipitation, mass spectrometry, and yeast two-hybrid studies were queried from the literature and public datasets (Orchard *NAR* 2014; Oughtred *Protein Sci* 2020; Szklarczyk *NAR* 2019). Gene expression was queried from kidney single cell mRNA sequencing (scRNAseq) datasets (Karaiskos *JASN* 2018; Menon *Development* 2018; Wang *Cell Rep* 2018; Wu *JASN* 2018). Protein interactions were validated by co-immunoprecipitation studies using tagged cDNA constructs.

Results: 85 putative NOS1AP-interacting proteins were identified from candidate interaction and proteomics studies. Six interacting proteins (of 85) demonstrated co-expression with *NOS1AP* in podocyte clusters from at least three out of four kidney scRNAseq datasets (% cell expression z-score > 1). Four of six candidates (FYN, GSN, SNTA1, HSPA12A) were cloned into expression vectors for interaction studies. SNTA1 and HSPA12A exhibited bi-directional co-immunoprecipitation with wildtype NOS1AP upon co-overexpression in a podocyte cell line. Co-immunoprecipitation was, similarly, observed with the NS patient mutant NOS1AP^{C143Y}.

Conclusions: Our results suggest NOS1AP is co-expressed with and can physically interact with SNTA1 and HSPA12A in podocytes. These proteins may mediate NOS1AP functions in podocyte biology.

Synuclein Alpha Accumulation Drives Lysosomal Dysfunction in Fabry Podocytopathy

Fabian Braun,[1] Ahmed Abed,[2] Mathias Woidy,[1] Oystein Eikrem,[3] Nicola Wanner,[1] Katharina M. von Cossel,[1] Soeren W. Gersting,[1] Ania C. Muntau,[1] Behzad Najafian,[4] Camilla Tøndel,[6] Michael Mauer,[5] Florian Grahammer,[1] Thorsten Eierhoff,[7] Hans-Peter Marti,[3] Victor G. Puelles,[1] Christoph Schell,[2] Tobias B. Huber.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Universitatsklinikum Freiburg, Freiburg, Germany; [3]Universitetet i Bergen Det medisinsk-odontologiske fakultet, Bergen, Norway; [4]University of Washington, Seattle, WA; [5]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [6]Haukeland Universitetssjukehus, Bergen, Norway; [7]Universitatsklinikum Munster, Munster, Germany*.

Background: Anderson-Fabry disease is an X-linked lysosomal disorder characterized by a multisystemic globotriaosylceramides (Gb3) accumulation due to reduced alpha-galactosidase activity (GLA). Podocyte injury is a major renal manifestation of Fabry disease. Recently, our data indicated Gb3 depletion to be insufficient in repairing podocyte damage seen in an *in vitro* model for Fabry disease. This project, therefore, focused on potential Gb3 independent mechanisms in Fabry podocytopathy.

Methods: We employed CRISPR/CAS9 to generate GLA knock out lines of immortalized human podocytes *in-vitro*. These cells were investigated by (ultra-) structural, transcriptome and proteome as well as functional analyses in the presence and absence of enzyme replacement therapy (ERT). The acquired data sets were integrated through network analysis and connectivity mapping. These data were complimented by the investigation of human biopsies taken sequentially before and after a period of ERT.

Results: We detected that enzyme replacement therapy (ERT) and Gb3 reduction failed to ameliorate signs of podocyte injury in patient biopsies. GLA knockout podocytes depicted high Gb3 levels that were fully reversed upon enzyme replacement. Still lysosomal dysfunction was significantly but not completely reversible with enzyme therapy. Proteomics suggested alpha-synuclein (SNCA) accumulation as a potential driver of lysosomal dysfunction. Transcriptomics-based connectivity mapping further revealed a potential anti-SNCA therapeutic effect of beta-adrenoceptor agonists. Indeed, genetic and pharmacological inhibition of this protein significantly improved lysosomal structure and function in Fabry podocytes beyond the effects of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry disease independent of Gb3 accumulation. The results offer new options for pharmacological strategies to target Fabry podocytopathy.

PO1340

Drosophila TBC1D8B Promotes Nephrin Endocytosis and Is Required for Endosomal Cargo Processing

Julian Milosavljevic, Camille Lempicki, Konrad Lang, Lina L. Kampf, Tobias F. Hermle. *Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany*.

Background: Mutations in *TBC1D8B* were recently identified as a monogenic cause of nephrotic syndrome. TBC1D8B interacts with nephrin and it was implicated as an inhibitory GAP protein for Rab11 which regulates endocytic recycling. However, the functional spectrum of TBC1D8B and its role in trafficking of nephrin remains poorly understood.

Methods: We generated and analyzed a stable genetic deletion of fly *Tbc1d8b* via CRISPR/Cas9. We successfully introduced a c-terminal HA-tag into the *Tbc1d8b* locus using microhomology-mediated end joining. For overexpression of murine *Tbc1d8b*-HA we further generated transgenic flies under control of GAL4/UAS. Endosomal cargo processing was assessed by sequential uptake of two tracers *ex vivo*.

Results: Germline expression of Cas9 and tandem *Tbc1d8b*-guide RNAs resulted in a stable genetic deletion spanning all functional domains while ending with a frameshift. Surprisingly, homozygous mutant animals were viable without any overt phenotype. However, analysis of the podocyte-like nephrocytes of these flies revealed mislocalization and partial loss of slit-diaphragm proteins with incomplete penetrance. This nephrocyte-restricted phenotype recapitulates the phenotype of human mutations that present exclusively with nephrotic syndrome. Overexpression of murine *Tbc1d8b*-HA in nephrocytes caused accumulation of endogenous fly nephrin in large vesicles while its binding partner Kirre (Neph1) was not affected. The vesicles containing fly nephrin co-localized with the late endosomal marker Rab7 and disappeared when silencing the early endosomal regulator *Rab5*. This suggests that mammalian Tbc1d8b specifically promotes nephrin endocytosis. To identify the endogenous subcellular localization of the fly Tbc1d8b we established a knock-in of a c-terminal HA-tag and noted partial co-localization with endosomal markers including Rab7. To investigate the functional role in the endolysosomal pathway we tracked the fate of two tracers sequentially applied *ex vivo*. A background of both, stable and conditional deletion of *Tbc1d8b* was associated with defective cargo processing.

Conclusions: Our findings implicate novel functional roles of Tbc1d8b beyond endocytic recycling: promoting nephrin endocytosis and facilitating processing of endosomal cargo.

Funding: Government Support - Non-U.S.

PO1341

Stable Genetic Deletion of Gapvd1 in Drosophila Results in a Nephrocyte-Restricted Phenotype

Konrad Lang, Julian Milosavljevic, Helena Heinkele, Lea Gerstner, Tobias F. Hermle. Hermle Lab *Universitatsklinikum Freiburg, Freiburg, Germany*.

Background: Mutations in the gene GAPVD1 cause of nephrotic syndrome in humans. GAPVD1 interacts with RAB5 and but the subcellular localization of GAPVD1 is unclear. Silencing of Gapvd1 the podocyte-like Drosophila nephrocytes by RNA-interference resulted in mislocalization of fly nephrin.

Methods: We generated conditional knockdowns and a stable genetic deletion of *Drosophila Gapvd1* by CRISPR/Cas9 and used microhomology-mediated end joing to introduce a genomic HA-tag into the Gapvd1 c-terminus. We performed a functional analysis of the novel fly models.

Results: We generated twin frameshift mutations at the second and third exons of the Drosophila Gavpd1 gene. Animals carrying these mutantion were homozygous viable without any overt phenotype. However, the podocyte-like nephrocytes revealed a severly altered slit diaphragm morphology with mislocalization of fly nephrin and the orthologue of NEPH1 and partial loss of both proteins from the surface. This phenotype was similar but considerably stronger than the phenotype observed by RNAi-mediated silencing. This suggests that the homozygous frameshift mutations result in a null allele. The phenotype was further confirmed by conditional CRISPR/Cas-mediated silencing using two different gRNAs. Deletion of *Gapvd1* in the Drosophila model thus results in a phenotype that manifests exclusively in disturbed slit diaphragms formation. This recapitulates the phenotype observed in human patients that was limited to nephrotic syndrome, supporting the use of Drosophila model for this genetic disease. To study the subcellular localization of Drosophila Gapvd1, we introduced an HA-tag into the c-terminus of the Gapvd1 locus. Immunofluorescence of nephrocytes derived from the knock-in lines showed co-localization of the protein with Drosphila Rab5, supporting that Gapvd1 primarily resides in early endosomes. We overexpressed human GAPVD1 in nephrocytes, that equally localized in early endosomes. Gain-of-function of the human gene entailed reduced tracer endocytosis in nephrocytes, suggesting a dominant negative effect.

Conclusions: We established suitable new Drosophila models to study the function of Gapvd1 in nephrocytes as an invertebrate podocyte model.

PO1342

Pathogenicity Assessment of Non-Glycine Missense Variants in COL4A5 Collagenous Domain

Yuya Aoto,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1,3] China Nagano,[1] Atsushi Kondo,[1] Sadayuki Nagai,[1] Nana Sakakibara,[1] Kazumoto Iijima,[2] Kandai Nozu.[1] *[1]Kobe Daigaku, Kobe, Japan; [2]Hyogo Kenritsu Kodomo Byoin, Kobe, Japan; [3]Manchester Metropolitan University, Manchester, United Kingdom*.

Background: *COL4A5*, which encodes type IV collagen α5 chain, is a causative gene of X-linked Alport Syndrome (XLAS). In triple-helical domain on collagen protein (collagenous domain), the amino acid strictly repeats glycine (Gly) in every third position, (Gly-Xaa-Yaa)n, and these Gly contribute to the stability of triple-helical structure. Because of this, within collagenous domain, most Gly missense variants are pathogenic, and most reported missense variants substitutes amino acids from Gly. However, several pathogenic missense variants other than Gly (non-Gly missense variants) have been reported and the mechanisms of disease onset by these variants are not clear until now. The aim of this current study is to investigate the pathogenicity of non-Gly missense variants in *COL4A5* collagenous domain.

Methods: We extracted 18 variants, 13 from the Human Gene Mutation Database and 5 identified in our cohort. Firstly, we conducted a functional splicing assay using a hybrid minigene analysis method to examine the existence of aberrant splicing. Then, variants not causing aberrant splicing were investigated for the characteristics including bioinformatics analysis.

Results: Seven out of eighteen (38.9%) non-Gly variants caused aberrant splicing and then, exhibited XLAS. In addition, three of these variants resulted in both exon skipping and normal splicing, and these three patients showed milder phenotypes. Five of the 12 variants not causing aberrant splicing were missense variants substituted from Proline (Pro) located at Yaa of (Gly-Xaa-Yaa)n. Pro at this position is hydroxylated and results in the stabilization of the triple-helix structure. Bioinformatics analysis showed that Pro missense variants decrease the structural flexibility. Two of the remaining variants were located in the interrupted domains, which are outside of the (Gly-Xaa-Yaa)n repeat. These interrupted domains are related to the flexibility of the collagen molecule or related to network in the basement membrane. Therefore, these 2 variants were considered to influence the triple-helix structure.

Conclusions: We revealed the new mechanisms showing pathogenicity of non-Gly missense variants in *COL4A5* collagenous domain.

Funding: Government Support - Non-U.S.

PO1343

A Human Missense Integrin-Linked Kinase Variant Negatively Regulates Murine Renal Branching Morphogenesis via mTOR Signaling

Xiangyue Hu,[1,2] Dana Kablawi,[1,2] Kirsten Y. Renkema,[3] Nine V. Knoers,[3] Norman D. Rosenblum.[1,2] *[1]Program in Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [3]Department of Genetics, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands.*

Background: Branching morphogenesis is critical to kidney development and the pathogenesis of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT). Identification of gene variants via genomic sequencing aims to elucidate molecular mechanisms underlying CAKUT. The pathogenic contributions of such variants are largely unknown; functional analyses are required to identify pathogenic mechanisms. Here, we identify pathogenic effects of a CAKUT-associated human missense variant of Integrin-Linked Kinase (*ILK*), a key regulator of renal branching morphogenesis, on ureteric branching.

Methods: Targeted gene panel sequencing was performed to identify gene variants. ILK-T173I function was investigated in mouse inner medullary collecting duct (mIMCD3) cells and mouse embryonic kidney explants transduced with lentivirus expressing ILK-T173I. Gene expression was analyzed by RNA microarray and validated by qPCR and Western analysis. Mutant mice with a *ILK*-c.518C>T point mutation were generated using CRISPR/Cas9. Morphogenic effects of ILK-T173I on ureteric branching were visualized using Hoxb7-driven fluorescent marker (MyrVenus) and quantitated by counts of ureteric bud tips and nephrons.

Results: An ILK missense variant, ILK-T173I, was identified in a CAKUT patient and her mother by targeted gene panel sequencing and verified by Sanger sequencing. mIMCD3 cells expressing ILK-T173I demonstrated dysregulated expression of AKT/mTOR target mRNAs, identified by RNA microarray and qPCR, and elevated levels of phospho-p70-S6Kinase, a mTOR target (n=3, P=0.03). Overexpression of ILK-T173I in embryonic kidney explants increased phospho-p70-S6Kinase expression (n=3, P=0.03) and decreased ureteric tip number by 50% (n=15, P=0.003), both of which were rescued by treatment with Rapamycin, an mTOR inhibitor (n=4, P=0.04). Knock-in mice in which ILK-T173I replaces the ILK-WT allele were characterized by low nephron number (n=6, P=0.04) and decreased ureteric branching (n=5, P=0.006), and increased expression of phospho-p70-s6Kinase (n=3, P=0.014). Treatment of mutant cultured embryonic kidney explants with Rapamycin rescued ureteric branching to levels observed in *Ilk*-WT mice.

Conclusions: Human *Ilk*-T173I variant decreases branching morphogenesis in a mTOR-dependent manner. Increased mTOR signaling disrupts mouse kidney development.

PO1344

Whole-Exome Sequencing Identifies FOXL2, FOXA2, and FOXA3 as Candidate Genes for Monogenic Congenital Anomalies of the Kidneys and Urinary Tract

Bixia Zheng,[1] Steve Seltzsam,[1] Chunyan Wang,[1] Luca M. Schierbaum,[1] Sophia Schneider,[1] Dervla M. Connaughton,[1] Nina Mann,[1] Velibor Tasic,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Department of Pediatrics, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Medical Faculty Skopje, University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of).*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the most common cause of chronic kidney disease in the first three decades of life. Variants in four Forkhead box *(FOX)* transcription factors have been associated with CAKUT. We hypothesized that other FOX genes, if highly expressed in developing kidney, may also represent monogenic causes of CAKUT.

Methods: We here performed whole exome sequencing (WES) in 541 families with CAKUT and generated 4 lists of CAKUT candidate genes: A) 36 *FOX* genes showing high expression during renal development, B) 4 *FOX* genes known to cause CAKUT to validate list A; C) 80 genes that we identified as unique potential novel CAKUT candidate genes when performing WES in 541 CAKUT families, and D) 175 genes identified from WES as multiple potential novel CAKUT candidate genes.

Results: To prioritize potential novel CAKUT candidates in *FOX* gene family, we overlapped 36 *FOX* genes (list A) with list C and D of WES-derived CAKUT candidates. Intersection with list C, identified a *de novo FOXL2* in-frame deletion in a patient with eyelid abnormalities and ureteropelvic junction obstruction, and a homozygous *FOXA2* missense variant in a patient with horseshoe kidney. Intersection with list D, identified a heterozygous *FOXA3* missense variant in a CAKUT family with multiple affected individuals.

Conclusions: We hereby identified *FOXL2*, *FOXA2* and *FOXA3* as novel monogenic candidate genes of CAKUT, supporting the utility of a paralog-based approach to discover mutated genes associated with human disease.

PO1345

Whole-Exome Sequencing Identifies Likely Deleterious Variants in 50 Families with Spina Bifida

Chunyan Wang,[1,2] Steve Seltzsam,[1] Bixia Zheng,[1,3] Chen-Han W. Wu,[1] Camille H. Nicolas Frank,[1] Kirollos Yousef,[1] Nina Mann,[1] Sophia Schneider,[1] Luca M. Schierbaum,[1] Dalia Pantel,[1] Jameela A. Kari,[4] Sherif M. El desoky,[4] Loai A. Eid,[5] Velibor Tasic,[6] Shirlee Shril,[1] Michelle A. Baum,[1] Carlos R. Estrada,[7] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital Department of Pediatrics, Boston, MA; [2]Children's Hospital of Fudan University, Shanghai, China; [3]Children's Hospital of Nanjing Medical University, Nanjing, China; [4]King Abdulaziz University, Jeddah, Saudi Arabia; [5]Dubai Hospital, Dubai, United Arab Emirates; [6]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [7]Boston Children's Hospital Department of Urology, Boston, MA.*

Background: Spina bifida (SB) is the second most common nonlethal malformation (1/1,000 of live births). Several lines of evidence indicate that SB can be of monogenic origin: i) its congenital nature; ii) familial occurrence; iii) it being part of the phenotypic manifestation of known monogenic syndromes; iv) the knowledge that specific master genes govern neural tube morphogenesis; v) and the existence of monogenic mouse models with SB. We hypothesized that whole exome sequencing (WES) enables identification of likely candidate mutations in a list of 170 candidate genes for SB that we generated, and may allow us to identify potential novel genes for SB.

Methods: We generated a list of 170 candidate genes of four categories: A) 33 known candidate genes from monogenic mouse SB models, B) 33 known candidate genes from human isolated SB, C) 70 known candidate genes from human syndromic SB, and D) 34 known candidate genes considered as risk factors for human SB. We evaluated WES data of 50 families with SB for likely deleterious variants in the 170 known candidate genes, and for potential novel monogenic causes of SB.

Results: Through systematic candidate gene analysis in combination with family-based unbiased evaluation in 50 SB families, we identified 16 likely deleterious variants in 170 SB candidate genes in 14/50 (28%) families: A) 5 variants (5 families) were identified in mouse candidate genes, B) 9 variants (7 families) were identified in human candidate genes for isolated SB, C) 1 variant (1 family) was identified in human syndromic candidate gene, and D) 1 variant was identified in human SB risk candidate gene. In addition, in 11 (22%) of SB families, we have identified mutations in a potential novel gene for SB.

Conclusions: In 28% of individuals with SB we identified likely deleterious variants in 170 candidate genes that we generated. Candidate genes that cause SB in mice can be considered as a potential human SB candidate gene. We additionally identified a potential novel gene in 22% of SB families.

PO1346

Pleiotropy of Congenital Anomalies of Kidney and Urinary Tract (CAKUT) Phenotypes in Human 16p11.2 Microdeletion Syndrome Is Recapitulated in Mouse Models of Tbx6 Deletion

Gregory B. Whittemore,[1,2] Jeremiah Martino,[1] Tze Yin Lim,[1] Yask Gupta,[1] Cathy L. Mendelsohn,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Vagelos College of Physicians and Surgeons, New York, NY.*

Background: We showed that 16p11.2 microdeletions are a major contributor to congenital anomalies of the kidney and urinary tract (CAKUT), and identified *TBX6* as the most likely culprit. It remains elusive what are the mechanisms by which gene dosage reduction causes CAKUT and what are the TBX6 downstream signaling pathways and targets.

Methods: We studied a *Tbx6* allelic series for gene dosage using two independent alleles: a null allele and a hypomorph allele. We conducted detailed phenotypic analysis of these models across early and late development. We generated gene expression data from E9.5 tailbud mesenchyme and conducted in silico binding site analyses.

Results: Phenotypic analysis showed recapitulation of the whole CAKUT spectrum observed in 16p11.2 patients (renal agenesis and hypodysplasia, hydronephrosis, and duplications of the collecting system) but also profound lower urinary tract defects (rectovesical fistula, persistent cloaca, defects of nephric duct insertion into the urogenital sinus, urethral malformations and failed insertion of the Müllerian ducts). These defects implicate an early effect of Tbx6 in urinary tract development. Tbx6 insufficiency also promoted the occurrence of ectopic neural tubes that impaired the reciprocal interaction between the ureteric bud and metanephric mesenchyme, providing additional mechanisms linking Tbx6 to CAKUT and its pleiotropy. Differential gene expression analysis coupled with supervised and unsupervised geneset enrichment identified somite development and Notch signaling. Binding site and motif enrichment analyses recovered known and novel targets in the Tbx6 interactome including Aldh1a2, Eya1, Fgfr2, Lfng, and Reln.

Conclusions: Phenotypic investigation coupled with gene expression and binding site analyses provides support for causality for TBX6 and CAKUT as well as its pleiotropy; provides a mechanistic reason for causation; and identifies pathways and targets regulated by Tbx6. The involvement of Notch signaling is interesting as mutations in *NOTCH2* cause Alagille syndrome, characterized by CAKUT and skeletal defects observed both in our *Tbx6* mouse models and in patients that carry the 16p11.2 microdeletion. These data implicate loss of TBX6-mediated regulation of Notch as critical to the development of CAKUT and spine defects.

Excess Burden of Rare Coding Variants in Mutation Intolerant Genes in Patients with Kidney Malformations

Hila Milo Rasouly,[1] Sarath Babu Krishna Murthy,[1] Gundula Povysil,[1] Maddalena Marasa,[1] Jeremiah Martino,[1] Velibor Tasic,[2] Enrico Fiaccadori,[5] Gian Marco Ghiggeri,[3] Giuseppe Masnata,[4] Simone Sanna-Cherchi,[1] Krzysztof Kiryluk,[1] Ali G. Gharavi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [3]Istituto Giannina Gaslini, Genova, Italy; [4]Azienda Ospedaliera Brotzu, Cagliari, Italy; [5]Universita degli Studi di Parma Dipartimento di Medicina e Chirurgia, Parma, Italy.*

Background: Renal hypodysplasia (RHD) is one of the most common cause of pediatric kidney failure. Although multiple causative genes have been identified, they only account for 10-15% of cases. The contribution of rare variants has not been systematically examined.

Methods: To evaluate the contribution of rare variants to RHD, we analyzed exome sequencing (ES) data in 1,265 unrelated RHD cases and 13,303 unrelated controls. We used gene-level burden analysis, comparing the proportion of cases and controls carrying rare variants per gene across 20 statistical models.

Results: We observed a 1.63-fold case enrichment for rare variants ($p= 1.5x10^{-6}$) in known genes associated with dominant forms of kidney diseases (165 cases versus 1,075 controls in 172 known genes), including *PAX2* ($7.6x10^{-8}$) and *HNF1B* ($5.6x10^{-6}$). All other known genes did not reach statistical significance (p-value>10^{-3}). Applying a similar approach, we observed a 1.35-fold case enrichment for rare missense variants ($p= 5.8x10^{-6}$) in genes constrained against missenses (misZ >3.09) and a 1.59-fold enrichment for rare protein truncating variants (PTV; $p= 2.4x10^{-9}$) in genes constrained against PTV (pLI>0.9 and oe lof upper<0.35). We particularly identified a 2.38-fold enrichment for PTV in 421 genes constrained against PTV, expressed in the mouse developing kidney (E15.5), and not known to be associated with human kidney disease ($p=1.4x10^{-6}$, Fig.). After curating publicly available databases, we identified at least 23 novel candidate genes, which will require validation in additional human cohorts or analysis of animal models.

Conclusions: We detected a significant excess of rare variants in mutation intolerant genes that are also expressed during early kidney development, suggesting the existence of many yet-to-be identified causal genes. However, owing to the high genetic heterogeneity of RHD, larger-scale investigations will be required to establish causality for individual genes.

Reverse Phenotyping Facilitates Disease Allele Calling in Whole-Exome Sequencing of Patients with Congenital Anomalies of Kidney and Urinary Tract (CAKUT)

Steve Seltzsam, Chunyan Wang, Bixia Zheng, Dervla M. Connaughton, Chen-Han W. Wu, Sophia Schneider, Luca M. Schierbaum, Shirlee Shril, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the leading cause of chronic kidney disease in children and young adults. To date, 174 genes are known to cause isolated or syndromic monogenic CAKUT. However, incomplete penetrance and broad phenotypic heterogeneity can impair disease allele identification, particularly in syndromic CAKUT. We hypothesized that the yield of a genetic diagnosis can be increased by combining whole exome sequencing (WES) with reverse phenotyping, in which the contributing physician is asked to examine a patient for signs/symptoms that may occur in the suspected clinical syndrome that results from the genetic variant detected by WES.

Methods: We conducted WES in an international cohort of 823 individuals with CAKUT from 732 unrelated families and evaluated WES data for variants in the 174 genes in which variants are known to cause isolated or syndromic CAKUT. In cases in whom the likely causative genotype suggested a syndromic phenotype that was not reported at enrollment, we conducted reverse phenotyping.

Results: In 84/732 (11.5%) families, we detected a likely causative variant consistent with an isolated or syndromic CAKUT phenotype. In 19 of the 84 families (22.6%) with detection of a likely CAKUT-causing variant, reverse phenotyping yielded syndromic findings, thereby strengthening the genotype-phenotype correlation.

Conclusions: We conclude that employing reverse phenotyping in the evaluation of (facultative) syndromic CAKUT genes by WES provides an important tool to establish a more valid and specific diagnosis mitigating the broad phenotypic and genotypic heterogeneity of CAKUT.

Broad Genetic Analysis Reveals Diverse Molecular Causes of Autosomal Dominant Tubulointerstitial Kidney Disease-Not Otherwise Specified (ADTKD-NOS)

Florian Wopperer,[1] Francesca Pasutto,[2] Michael S. Wiesener.[1] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Universitatsklinikum Erlangen Institut fur Humangenetik, Erlangen, Germany.*

Background: A particularly difficult group of diseases to diagnose are the Autosomal Dominant Tubulointerstitial Kidney Diseases (ADTKD). ADTKD is caused by mutations in one of at least five genes and leads to end-stage renal disease usually in mid adulthood. Families where no mutation can be found are therefore termed ADTKD-NOS (not otherwise specified), who are the focus of this study. Herein we investigated 45 families of our ADTKD-registry.

Methods: The study was approved by the institutional ethics committee (protocol number 251_18B). Detailed pedigree analysis and clinical characterisation of kidney diseases were performed, as well as evaluation of historical kidney biopsies, wherever available. Panel sequencing for all known ADTKD candidate genes was performed, followed by SNaPshot minisequencing for the dupC mutation of *MUC1*. Exome-Sequencing was performed on the HiSeq System 2500 (Illumina) after enrichment by TWIST human core technology (TWIST Bioscience). Initially, 560 genes associated with abnormal renal physiology (Human Phenotype Ontology, https://mseqdr.org/hpo_browser.php?12622, retrieved March 2020) were screened (here termed *nephrome*). If no disease-causing variants were detected, exome-wide analysis was performed.

Results: In 30 of the 45 registry families mutations in known ADTKD genes were found, most frequently *MUC1*. In the remaining 15 families diagnostic gene variants were either detected in the *nephrome* (4x *COL4A5*, 1x *COL4A4*x, 2x *INF2*, 1x *PAX2*) or the exome, where analysis yielded potentially disease associated variants in novel candidate genes for ADTKD. A list of these candidate genes in the respective families will be presented. All variants segregated within families.

Conclusions: In the great majority of our ADTKD registry families we were able to reach a molecular genetic diagnosis. However, a small number of families are indeed affected by diseases, which should in retrospect be seen as glomerular origin. Atypical clinical presentation, (seemingly) autosomal dominant pedigrees (i.e. *COL4*-associated disease) and sometimes decades since onset of disease and genetic evaluation have handicapped the classification towards ADTKD-NOS. The other families investigated by exome analysis have partly led to identification of promising novel candidate genes. However, functional studies will need to follow to determine if these variants are truly pathogenic.

PO1350

Prevalence of Autosomal Dominant Tubulointerstitial Kidney Disease in the German Chronic Kidney Disease (GCKD) Cohort

Bernt Popp,[1,2] Arif Ekici,[1] Karl X. Knaup,[3] Kai-Uwe Eckardt,[3,4] Mario Schiffer,[3] André Reis,[1] Michael S. Wiesener.[3] *[1]Institute of Human Genetics, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; [2]Institute of Human Genetics, University of Leipzig Hospitals and Clinics, Leipzig, Germany; [3]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [4]Department of Nephrology and Medical Intensive Care, Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Exome sequencing (ES) studies in chronic kidney disease (CKD) cohorts could identify pathogenic variants in ~10%. This implies underdiagnosis of hereditary CKD. Tubulointerstitial kidney diseases (TKD), showing no typical clinical/histologic finding but tubulointerstitial fibrosis, are particularly difficult to diagnose. Disorders associated with a tubulointerstitial phenotype include autosomal dominant TKD (ADTKD), mitochondrially inherited TKD (MITKD), nephronophthisis (NPHP) and Collagen4 (COL4) diseases.

Methods: We used a targeted panel (29 genes) and *MUC1*-SnaPshot to sequence 271 DNAs, selected by clinical criteria from 5,217 individuals in the GCKD (German CKD) cohort.

Results: We identified 33 pathogenic small variants. Of these 27 (81.8%) were in COL4 genes, the largest group being 15 *COL4A5* variants with 9 unrelated individuals carrying c.1871G>A, p.(Gly624Asp). We found three typical cysteine variants in *UMOD*, a novel missense, and a novel splice variant in *HNF1B* and the homoplastic *MTTF* variant m.616T>C. Copy-number analysis identified a heterozygous *COL4A5* deletion, and a duplication/deletion of *HNF1B*, respectively. Overall, we found pathogenic variants in 12.5% (34/271 individuals) and variants of unknown significance in 9.6%. This yield is high despite considering the targeted design and PKD1/2 exclusion. To explain this difference we compared our findings to the largest ES study in adults with CKD by random sampling. None of the 10,000 simulations resulted in an equal or higher yield (p<0.0001). Variant classification differences were excluded using automated ACMG classifiers.

Conclusions: Our study shows that >10% of individuals with certain clinical features carry disease variants in genes associated with TKD. COL4 genes constitute the largest fraction, implying that these are easily overlooked when applying clinical criteria for Alport syndrome. We also identified variants easily missed by some ES pipelines. Bioinformatic predictions paired with gold standard diagnostics for *MUC1* (SnaPshot) could not identify the typical cytosine duplication ("c.428dupC") in any individual of this

cohort, implying that ADTKD-*MUC1* is rare. Finally, our results indicate that the filtering criteria applied enriched for individuals with an underlying genetic disorder.

Funding: Government Support - Non-U.S.

Ultrabright Plasmonic-Fluor Nanolabel-Enabled Detection of a Urinary Endoplasmic Reticulum Stress Biomarker in Autosomal Dominant Tubulointerstitial Kidney Disease

Yeawon Kim,[1] Zheyu Wang,[1] Chuang Li,[1] Kendrah O. Kidd,[2] Yixuan Wang,[1] Bryce G. Johnson,[3] Stanislav Kmoch,[4] Jeremiah J. Morrissey,[1] Anthony J. Bleyer,[2] Jeremy S. Duffield,[5] Srikanth Singamaneni,[1] Ying M. Chen.[1] *[1]Washington University in St Louis, St louis, MO; [2]Wake Forest University School of Medicine, Winston-Salem, NC; [3]Pfizer Inc, New York, NY; [4]Univerzita Karlova, Praha, Czechia; [5]Prime Medicine, Cambridge, MA.*

Background: Autosomal dominant tubulointerstitial kidney disease (ADTKD)-*UMOD* is one of the most common non-polycystic genetic kidney disease, but it remains unrecognized due to its clinical heterogeneity and lack of screening test. Moreover, clinical feature being a poor predictor of the disease outcome further highlights the need for development of mechanistic biomarkers in ADTKD. However, low abundant urinary proteins secreted by thick ascending limb (TAL) cells, where uromodulin (UMOD) is synthesized, have posed a challenge on detection of biomarkers in ADTKD-*UMOD*.

Methods: We have utilized CRISPR/Cas9-generated mice with *Umod*-C147W mutation, analogous to human *UMOD*-C148W mutation, and ADTKD-*UMOD* patients to discover a novel endoplasmic reticulum (ER) stress biomarker. In addition, we have developed an ultrasensitive, plasmon-enhanced fluorescence-linked immunosorbent assay (p-FLISA) to detect the urinary biomarker in ADTKD patients by harnessing a newly invented ultrabright fluorescent nanoconstruct, termed "plasmonic fluor (PF)" (Nat Biomed Eng 2020).

Results: In the murine model and patients with ADTKD-*UMOD*, we find that immunoglobulin heavy chain-binding protein (BiP), an ER chaperone, was exclusively upregulated by mutant UMOD in TAL and easily detected by Western blot in the urine at an early stage of disease. However, even the most sensitive ELISA failed to detect urinary BiP in affected individuals. We therefore developed the ultrasensitive p-FLISA, which demonstrated that urinary BiP excretion was significantly elevated in ADTKD-*UMOD* patients compared with unaffected controls. Moreover, urinary BiP elevation was positively correlated with decline of kidney function in ADTKD-*UMOD* patients.

Conclusions: By developing the ultrasensitive p-FLISA, we have identified secreted BiP as a novel urinary ER stress biomarker with potential utility in risk stratification, prediction of disease progression and guidance of ER-targeted therapies in ADTKD.

PO1352

Genetic Analysis of a Brazilian Nephropathic Cystinosis Cohort Reveals Novel CTNS Variants Mostly of Non-European Origin

Maria H Vaisbich, Kelly Nunes, A. R Santos, Juliana C. Ferreira, F. M. Nunes, Andreia Watanabe, Luiz F. Onuchic. *Universidade de Sao Paulo, Sao Paulo, Brazil*.

Background: Nephropathic Cystinosis (NC) is a severe autosomal recessive disease caused by intralysosomal cystine deposition. Most *CTNS* variants have been described in Europe and North America, where a specific 57kb deletion (del) is the most frequent one. In this study, we seeked to characterize the *CTNS* variants and their genetic ancestry profiles in a NC Brazilian cohort, an admixed population.

Methods: 61 NC patients were studied, both sexes, ≤21 years old, followed at the University of Sao Paulo Medical Center. Mutation analysis was performed by gel electrophoresis and/or MLPA to assess the 57kb del, and NGS targeted sequencing. To characterize the genetic ancestry profiles, 48 patients were genotyped with a high-density SNP array. The average genomic ancestry was inferred using ADMIXTURE and the ancestry of the *CTNS* gene region using RFMIX.

Results: Two disease-causing variants were identified in 58/61 patients, followed by segregation analysis whenever possible. The detected variants included 9 previously reported and 7 novel ones. All previously reported variants were observed in European genomic segments, except the African ancestry-linked variant c.62-2A>G. Among the novel variants, 4 are in genomic segments of African origin (del exons 2,4,5; c.227delT:p.V76fs; c.T412C:p.W138R and c.A457T:p.K153X), 1 in Native American (c.16_19del:p.L6fs), 1 in a European-ancestry segment (c.*262_*266delinsCGGAC), and 1 could not be determined (c.158delC:p.W53fs). The highest allele frequencies were 57kb del (55.7%), c.C382T (14.0%), c.16_19del (7.4%) and c.611_613del (5.7%). Analyses of LD decay support that 57kb del, c.C382T and c.611_613del originated in Europe at least 1,750 years (250-3,750), 1,050 years (550-1,550) and 275 years ago (75-1,200), respectively, and suggest that c.16_19del likely originated in America 15,025 years ago (5,775-41,000).

Conclusions: 57kb del was the most frequent *CTNS* variant in this Brazilian NC cohort. However, given the admixed nature of the Brazilian population, novel variants with distinct ethnic origins were identified. Indeed, 5 of the 7 novel variants are located in chromosome segments of non-European ancestry. This finding raises the possibility that the novel non-European *CTNS* variants may be present in other South American and African populations.

PO1353

Adult Zebrafish as a Model to Study Renal and Extrarenal Manifestations of Cystinosis

Sante Princiero Berlingerio,[1] Junling He,[2] Sara Cairoli,[3] Bianca Maria Goffredo,[3] L.P.W.J. Van Den Heuvel,[1] Elena N. Levtchenko.[1] Pediatric Nephrology *[1]Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium; [2]Universiteit Leiden, Leiden, Netherlands; [3]Ospedale Pediatrico Bambino Gesu, Roma, Italy*.

Background: Cystinosis is a rare autosomal recessive disease caused by mutations in the CTNS gene, which encodes for the cystine transporter cystinosin leading to lysosomal cystine accumulation in all cells of the body, with kidneys being the first affected organs. The current treatment with cysteamine decreases the lysosomal cystine accumulation, but does not reverse the renal Fanconi syndrome, glomerular injury or loss of renal function. We have developed a zebrafish larvae model having truncating mutation in *ctns*, which recapitulates the kidney phenotype of cystinosis. However, long-term disease consequences in adult zebrafish have not been studied so far. In this study, we characterized the adult zebrafish model to evaluate the late effects of cystinosis on kidney and extra renal organs.

Methods: Cystinosis (*ctns*$^{-/-}$) zebrafish of 18 months and wild type (WT) zebrafish were studied. Histologic examinations of kidneys and extra-renal organs were performed. Cleaved caspase-3 staining was used to evaluate apoptosis in the kidney. Cystine accumulation was evaluated via liquid chromatography-mass spectrometry and toluidine blue staining. For the fertility studies, the number of total eggs and fertile eggs produced by breeding female and male *ctns*$^{-/-}$ zebrafish compared to WT zebrafish was evaluated.

Results: *ctns*$^{-/-}$ zebrafish show increased cystine level, glomerular hypertrophy and proximal tubular accumulation of hyaline-like eosinophilic droplets and vacuolated cytoplasm. Moreover, the cystinotic zebrafish exhibit increased cleaved caspase-3, indicating enhanced apoptosis in the proximal tubules. In addition, instead of the typical striped pattern, *ctns*$^{-/-}$ zebrafish present an altered melanin skin pigmentation, resulting in spotted skin. Lastly, male *ctns*$^{-/-}$ zebrafish show spermatogenic cysts enriched in spermatozoa, while female display increased percentage of unfertilized eggs.

Conclusions: The adult *ctns*$^{-/-}$ zebrafish model reproduces several phenotypes of cystinosis, such as altered glomerular and proximal tubular morphology, whole body cystine accumulation, impaired skin pigmentation and decreased fertility. Therefore, this model may be useful for studying long-term effects of cystinosis and for the development of new therapeutic strategies for correcting cystinosis, which is - up to now - incurable.

PO1354

Urine-Derived Kidney Progenitor Cells in Cystinosis: Potential for Disease Modeling and Ex Vivo Gene Therapy

Koenraad Veys,[1,2] Sante Princiero Berlingerio,[1] Tjessa Bondue,[1] Katharina Held,[1] Ahmed Reda,[1] Koen Theunis,[1] Pieter Baatsen,[1] Mirian C. Janssen,[3] Elisabeth A. Cornelissen,[3] Joris Vriens,[1] Francesca Diomedi-Camassei,[4] Rik Gijsbers,[1] L.P.W.J. Van Den Heuvel,[3,1] Fanny O. Arcolino,[1] Elena N. Levtchenko.[1,2] *[1]Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium; [2]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [3]Radboudumc, Nijmegen, Netherlands; [4]Ospedale Pediatrico Bambino Gesu, Roma, Italy*.

Background: Nephropathic cystinosis is an inherited multisystem lysosomal storage disorder caused by mutations in the *CTNS* gene. The kidney phenotype is characterized by excessive shedding of proximal tubular cells and podocytes into urine, development of renal Fanconi syndrome and progression to end-stage kidney disease. We hypothesized that, to compensate for epithelial cell losses, cystinosis kidneys undertake a regenerative effort, albeit maladaptive. We aimed to search for the presence of kidney progenitor cells (KPCs) in urine of cystinosis patients, and to explore the feasibility of *ex vivo* gene therapy.

Methods: We isolated undifferentiated cells from urine of cystinosis patients, characterized them as KPCs (Cys-uKPCs) and differentiated these to podocytes (Cys-uKPC-Podo) and proximal tubular epithelial cells (Cys-uKPC-PTEC) as shown by qPCR, RNA sequencing, immunostainings and specific functional assays. Complementation of *CTNS* in Cys-uKPCs was performed via lentiviral vector (LV) transduction.

Results: Cystinosis patients voided high numbers of undifferentiated cells in urine, of which specific clones expressed several kidney progenitor markers, showed a high level of self renewal, and could differentiate into functional podocytes and PTECs. RNA sequencing demonstrated distinctive transcriptomic signatures distinguishing Cys-uKPCs, Cys-uKPC-Podo and Cys-uKPC-PTEC. *Ex vivo* gene therapy using a gene addition approach with wild-type *CTNS* showed significant reductions of cystine levels and altered the perinuclear distribution of the LAMP1^{+} endo-lysosomal compartment.

Conclusions: Kidney progenitor cells are present in the urine of cystinosis patients. These cells can be isolated, differentiated to functional kidney epithelial cells and complemented with wild-type *CTNS* to improve the cellular phenotype. Cystinosis uKPCs are a novel tool for disease modeling, while we provided proof of principle of *ex vivo* gene therapy.

PO1355

Vascularized Kidney Organoids on Chip for Efficacy and Toxicity Testing of Somatic Genome Editing

Navin R. Gupta,[1,2] Kayla J. Wolf,[4] Krishna P. Maremanda,[3] Katharina T. Kroll,[4] Chengcheng Zhang,[1] Venkata Sabbisetti,[3] Jennifer A. Lewis,[4] Ryuji Morizane.[1,2] *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Harvard University Wyss Institute for Biologically Inspired Engineering, Boston, MA.*

Background: Somatic genome editing has therapeutic potential to cure inheritable disease. Clinical translation requires safety and efficacy analyses. DNA editing may be widely discrepant across species due to genomic differences, necessitating human tissue-based platforms. AAV-based delivery of DNA editing elements is under clinical investigation. If delivered systemically, the kidney may be particularly susceptible to genome editing owing to high blood flow. Kidney organoids have been generated from human stem cells through the co-induction of nephron, stromal, and endothelial progenitor cells that mature to form multicompartment human kidney tissue. We married organoid and organ-on-chip technologies to facilitate the maturation of nephron epithelia and the development of perfusable vascular networks to simulate systemic delivery of genome editing elements.

Methods: Using human recombinant growth factors and defined small molecules, kidney organoids were generated from male and female, embryonic and induced, stem cell lines. To test the efficacy of an AAV2-based delivery system, the tropism of varied capsids, 2/8/9, for kidney compartments was assessed under static and perfused conditions. The AAV receptor expression was evaluated by single nuclear RNA-seq.

Results: The greatest infectivity was with capsid protein 2, whose receptor of heparin sulfate proteoglycan is expressed in proximal & distal tubules and podocytes of kidney organoids by single cellular transcriptomics. Biomarker analysis demonstrated a statistically significant increase in tubular injury markers, KIM-1 and MCP-1, after infection with AAV2/2 as compared to other AAVs. Following treatment with AAV2/2CMVeGFP, the majority of LTL^+ and $CDH1^+$ tubular epithelia were GFP^+, while $PODXL^+$ podocytes were poorly infected. The optimal AAV serotype, MOI, and duration of infection under static conditions were applied to vascularized kidney organoids. Initial on-chip testing supports enhanced infectivity by live-cell monitoring and wholemount immunostaining, including AAV infection in GFP^+PODXL^+ podocytes.

Conclusions: We propose vascularized kidney organoids may simulate the systemic delivery of AAVs across kidney compartments, as a pre-clinical testing platform of the efficacy and safety of somatic cell genome editing.

Genotype and Phenotype Analysis in Patients with X-Linked Hypophosphatemia

Peong Gang Park,[1] Seon Hee Lim,[3] Yo Han Ahn,[2] Hee Gyung Kang,[2] Il-Soo Ha.[2] *[1]Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Uijeongbu Saint Mary's Hospital, Uijeongbu, Gyeonggi-do, Republic of Korea.*

Background: X-linked hypophosphatemia (XLH) is the most frequent form of hypophosphatemic rickets and is caused by mutations in the PHEX gene. We analyzed genotype-phenotype correlations in XLH patients with proven PHEX mutations.

Methods: PHEX mutations were detected in 57 out of 81 patients who clinically presented with hypophosphatemic rickets. The patients were grouped into nontruncating (n = 11) and truncating (n = 46) mutation groups; their initial presentation as well as long-term clinical findings were evaluated according to these groups.

Results: Initial findings, including presenting symptoms, onset age, height standard deviation scores (SDSs), and laboratory tests, including serum phosphate level and tubular resorption of phosphate, were not significantly different between the two groups (onset age: nontruncating mutation group, 2.0 years, truncating mutation group, 2.1 years; height SDS: nontruncating mutation group, -1.9, truncating mutation group, -1.8; serum phosphate: nontruncating mutation group, 2.5 mg/dL, truncating mutation group, 2.5 mg/dL). However, at their last follow-up, the serum phosphate level was significantly lower in patients with truncating mutations (nontruncating mutation group: 3.2 mg/dl, truncating mutation group: 2.3 mg/dl; P value 0.003). Additionally, 62.5% of patients with truncating mutations developed nephrocalcinosis at their last follow-up, while none of the patients with nontruncating mutations developed nephrocalcinosis (P value 0.008). Orthopedic surgery due to bony deformations was performed significantly more often in patients with truncating mutations (52.3% vs 10.0%, P value 0.038).

Conclusions: Although considerable inconsistency exists regarding the correlation of truncating mutations and their disease phenotype in several other studies, we cautiously suggest that there would be genotype-phenotype correlation in some aspects of disease manifestation after long-term follow-up. This information can be used when consulting patients with confirmed XLH regarding their disease prognosis.

PO1357

Childhood-Onset Nephrocalcinosis in Twins Caused By Biallelic Mutations in CYP24A1 Gene: A Long Journey to a Genetic Diagnosis

Xin Yee Tan, Mary-Beth Roberts, Saul Nurko, Xiangling Wang. *Cleveland Clinic, Cleveland, OH.*

Introduction: 24-hydroxylase deficiency is a rare autosomal recessive disorder caused by mutations in CYP24A1 gene, characterized by hypercalcemia, hypercalciuria and nephrolithiasis. Establishing a genetic diagnosis, while important to guide management and family counseling, can be challenging. We hereby report a case of twins with childhood-onset nephrocalcinosis and chronic hypercalcemia caused by biallelic mutations of CYP24A1, which took years to be diagnosed.

Case Description: A 26 year-old female presented for preconception evaluation for a history of childhood-onset nephrocalcinosis and chronic hypercalciuric hypercalcemia. Patient reported similar history in identical twin sister. They had exome sequencing (ES) eight years ago after negative genes panel test which revealed a heterozygous variant of unknown significance (c.1186C>T) in CYP24A1. A reanalysis of ES was performed four years ago which demonstrated no changes. Work up revealed hypercalciuric hypercalcemia, low 25(OH)vitamin D, elevated 1,25(OH)vitamin D and 24,25(OH) vitamin D, and suppressed PTH(fig.1). Ratio of 25(OH)D-to-24,25-(OH)2D, a new biochemical test for 24-hydroxylase deficiency, suggested biallelic mutations in CYP24A1 gene. ES reanalysis at this time reclassified the c.1186C>T variant as pathogenic and disclosed a novel intronic variant (c.544-17G>A) which was predicted to cause splicing pattern change with multiple silico algorithms. Parental tests confirmed these two variants were in trans configuration consistent with autosomal recessive inheritance pattern. A thorough counselling included low recurrence risk for her children while high risk for her to develop severe hypercalcemia during pregnancy. She has been closely monitored with low calcium and vitamin D diet, sun avoidance and adequate hydration during current pregnancy with no complications to date.

Discussion: CYP24A1 gene related hypercalcemia is rare and challenging to diagnose even with ES. This case suggests the benefits of ES regular reanalysis for clinically suspected patients with inconclusive genetic findings. The novel intronic mutation identified in this case broadens the genetics spectrum of 24-hydroxylase deficiency.

	Reference range	Results
Calcium *(mg/dl)*	8.5-10.2	9.5- 11.3 ↑
PTH *(pg/mL)*	15-65	4↓
25(OH) vitamin D *(pg/mL)*	31-80	27.1-29.1 ↓
1,25 (OH)vitamin D *(pg/mL)*	15-60	66.1 ↓
24,25 (OH) vitamin D *(pg/mL)*	<20	285 ↑

PO1358

Refractory Hypocalcemia with Recurrent Nephrolithiasis Related to a De Novo Gain-of-Function Mutation in the CaSR Gene

Xin Yee Tan, Leila Z. Khan, Xiangling Wang. *Cleveland Clinic, Cleveland, OH.*

Introduction: The calcium-sensing receptor (CASR) serves as the key calcium sensor in the maintenance of systemic calcium homeostasis. Gain-of-function mutations of CaSR-gene, mapped to Ala116-Pro136 region, causes autosomal dominant hypocalcemia and Bartter syndrome type V. Phenotypic manifestations include hypercalciuric hypocalcemia(mostly asymptomatic), hypoparathyroidism, paresthesias, tetany/ epilepsy, nephrocalcinosis/ nephrolithiasis, hypomagnesemia, ectopic and intracranial calcifications. Here we report a case of gravid female who experienced refractory hypocalcemia with recurrent nephrolithiasis related to a de novo gain-of-function mutation in the CASR gene.

Case Description: A 25 year-old G1P0 female at 20 weeks of gestation presented to genetic nephrology clinic due to refractory hypocalcemia. She was incidentally found to have asymptomatic hypocalcemia as part of prenatal evaluation. She was treated with calcium and calcitriol for four months while hypocalcemia persisted. Physical exam was unremarkable. As shown in **Table 1**, her total serum calcium had been persistently low despite calcium and Vitamin D supplementations, and she had low PTH, hyperphosphatemia, hypomagnesemia, and hypercalciuria. Genetic testing revealed a variant (c.398A>T,pGlu133Val) in CASR gene, with negative parental testing consistent with de novo mutation. Given this finding, calcium and calcitriol were discontinued. Renal ultrasound to assess stone burden showed bilateral renal calculi, which patient passed during delivery. Recurrent renal calculi were discovered on post-delivery follow up imaging, necessitating laser lithotripsy and left ureteral stent insertion.

Discussion: This case highlights the importance of early diagnoses by genetic testing which could guide the hypocalcemia management, as routine calcium and vitamin D supplementation exacerbates hypercalciuria and thus risk of nephrocalcinosis/ nephrolithiasis. c.398A>T,pGlu133Val mutation has been described in 1 family cluster of 3 patients with hypoparathyroidism and hypocalcemia to date. De novo mutation, unique to this case, was evidenced by negative parental testing.

	Reference range	Results
Calcium *(mg/dl)*	8.6-10	6.9- 8.0 ↓
Ionized calcium *(mmol/L)*	1.15-1.29	0.99 ↓
Phosphorus *(mg/dl)*	2.5-4.5	5-6.1 ↑
PTH *(pg/mL)*	18.5 -88	<6 -13.4 ↓
24 hour urine calcium *(mg/24H)*	< 200	546 ↑
Magnesium *(mg/dl)*	1.7-2.3	1.5-1.7 ↓

PO1359

TRPV4 Calcium Channel Activity Is Increased by With-No-Lysine Kinase 1 in the Collecting Duct Cells

Victor N. Tomilin, Kyrylo Pyrshev, Naghmeh Hassanzadeh Khayyat, Oleg L. Zaika, Oleh Pochynyuk. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Kidneys play a central role in regulation of potassium homeostasis and maintaining plasma K^+ levels within a narrow physiological range. Dietary K^+ load increases circulating levels of the mineralocorticoid aldosterone leading to kaliuresis via stimulation calcium-activated large conductive maxi-K^+ (BK) channel dependent K^+ secretion in the collecting duct cells. WNK1 and WNK4 (With-no-lysine) kinases, have been recognized to regulate K^+ balance, in part, by orchestrating BK-dependent K^+ secretion in the ASDN (aldosterone sensitive renal nephron). Ca^{2+}-permeable TRPV4 channel is essential for BK activation in the distal nephron, as we have recently demonstrated. Also of note, high K^+ diet increases TRPV4 activity and expression largely in an aldosterone-dependent manner.

Methods: Patch-Clamp; $[Ca_{2+}]_i$ imaging; Western blotting;

Results: In the current study, we aimed to test whether WNK1/4 contribute to regulation of TRPV4 by aldosterone. First we treatment of mpkCCDc14 cells with 1 μM aldosterone for 24 h it as expected, increased TRPV4-dependent Ca2+ influx approximately 2 fold. Inhibition of WNK1/4 with the pan-blocker of WNK, WNK463 (100 nM for 24h) decreased basal TRPV4 activity by approximately 30% and virtually abolished stimulation of TRPV4 by aldosterone. Similarly, WNK1 blockade with WNK-in-11 (400 nM, 24 h) produced comparable inhibitory effects on the basal and aldosterone-dependent TRPV4 activity as WNK463. Western blots performed on apical plasma membrane fraction from the same cells showed a complete block of the stimulatory effect of aldosterone after treatment with WNK-in-11 (400 nM, 24 h). Co-expression of TRPV4 and WNK1 into Chinese hamster ovary (CHO) cells increased the macroscopic TRPV4-dependent cation currents from 160±10 pA/pF to 250±22 pA/pF. In contrast, overexpression of TRPV4 with a dominant negative WNK1 variant (K233M) decreased the whole cell currents to 60±5 pA/pF suggesting both stimulatory and permissive roles of WNK1 in regulation of TRPV4.

Conclusions: Overall, we show that WNK1 is essential in controling of basal TRPV4 activity and its activation by aldosterone in collecting duct cells. We propose that this new mechanism is likely contributing to regulation of urinary K^+ levels to maintain systemic homeostasis.

PO1360

Cyclin M2 (CNNM2) Is Essential for Development and Systemic Magnesium Homeostasis

Gijs A. Franken,[1] Murat Seker,[2] Femke Latta,[1] Caro Bos,[1] Joost Hoenderop,[1] René J. Bindels,[1] Tilman Breiderhoff,[2] Karl P. Schlingmann,[3] Dominik Müller,[2] Jeroen H. De Baaij.[1] *[1]Radboudumc, Nijmegen, Netherlands; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Universitatsklinikum Munster, Munster, Germany.*

Background: Patients with mutations in the Cyclin M2 (*CNNM2)* gene display hypomagnesaemia and intellectual disability. CNNM2 is highly expressed in the distal convoluted tubule, where it is involved in renal magnesium (Mg^{2+}) reabsorption. However, the complete phenotypical spectrum of the CNNM2-related disorder remains unknown. We characterised a large patient cohort with novel *CNNM2* variants and used transgenic mouse models to investigate the role of CNNM2 in Mg^{2+} homeostasis.

Methods: The identified *CNNM2* variants were found in a cohort of hypomagnesaemic patients and characterised using $^{25}Mg^{2+}$ transport assays in HEK293 cells. In addition, *Cnnm2* deficient mice were developed using CRISPR/Cas9 technology and exposed to deficient or saturated Mg^{2+} diets for two weeks. Using metabolic cages, the 24-hour urinary and faecal excretion for Mg^{2+} was determined.

Results: Eleven patients were identified with novel dominant variants in CNNM2. Using $^{25}Mg^{2+}$ transport assays in HEK293 cells, seven variants showed decreased $^{25}Mg^{2+}$ transport compared to wild type. These pathogenic mutations resulted in decreased membrane expression of CNNM2. The phenotype of these patients was compared with those previously published. Patients with pathogenic *CNNM2* mutations had a mean plasma Mg^{2+} level of 0.54 ± 0.08 mmol/L. Neurological manifestations, such as seizures (79%), intellectual disability (92%) and speech difficulties (91%) were prevalent. Interestingly, obesity was often (80%) found. To elucidate the physiological function of CNNM2, we generated knockout mouse models. Approximately 30% of *Cnnm2*$^{-/-}$ embryos displayed exencephaly and all died shortly after birth. Both *Cnnm2*$^{-/-}$, *Cnnm2*$^{+/-}$ and *Cnnm2*$^{+/-}$ pups, and *Cnnm2*$^{+/-}$ adult mice showed decreased serum Mg^{2+} levels and increased Ca^{2+} levels, independent when fed with deficient or saturated Mg^{2+} diets. At basal level, adult *Cnnm2*$^{+/-}$ mice showed increased faecal Mg^{2+} and Ca^{2+} excretion compared to control.

Conclusions: CNNM2 is important for normal development and Mg^{2+} homeostasis, although the link remains elusive. Our mouse study suggests a putative role of CNNM2 in the intestine, which could have implications for the treatment of patients suffering from CNNM2 mutations.

PO1361

BCS1L Mutations Produce Fanconi Syndrome with Developmental Disability

Nana Sakakibara,[1] Sadayuki Nagai,[1] Yuya Aoto,[1] China Nagano,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Kazumoto Iijima,[2] Kandai Nozu.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

Background: Fanconi syndrome is a functional disorder of the proximal tubule, characterized by pan-aminoaciduria, glucosuria, hypophosphatemia, and metabolic acidosis. With the advancements in gene analysis technologies, several causative genes are identified for Fanconi syndrome. Several mitochondrial diseases cause Fanconi syndrome and various systemic symptoms; however, it is rare that the main clinical symptoms in such disorders are Fanconi syndrome without systematic active diseases like encephalomyopathy or cardiomyopathy.

Methods: We analyzed the patients clinically diagnosed with Fanconi syndrome of unknown cause. Patient-1 was a 3-year-old girl and Patient-2 was a 10-months-old boy. They were diagnosed with Fanconi syndrome based on renal tubular dysfunction, rickets, and elevated aspartate aminotransferase and alanine aminotransferase levels. They also had severe developmental disability and growth failure. Patient-1 had twin brothers who were diagnosed with Fanconi syndrome. GDF-15, a mitochondrial disease biomarker, was evaluated as an analysis of mitochondrial dysfunction. The following assays were also performed to confirm the pathogenicity of the novel mutations: oxygen consumption rate (OCR) of mitochondria, the activity of mitochondrial respiratory chain complexes.

Results: Whole-exome sequencing detected compound heterozygous *BCS1L* mutations, which cause mitochondrial respiratory chain complex III deficiency. In Patient-1, we identified missense mutation and frameshift mutation of *BCS1L*, c.268C>T, p.(Arg90Cys) and c.821del, p.(Pro274Argfs*26). These mutations have been reported previously. In Patient-2, we also identified novel missense mutations of *BCS1L*, c.167G>A, p.(Arg56Gln) and c.1195T>G, p.(Tyr399Asp). The level of GDF-15 was elevated in both patients; 1025.5 pg/mL in Patient-1 and 1152.1 pg/mL in Patient-2 (normal: <707.4 pg/mL). In Patient-2 skin fibroblasts, the activities of mitochondrial respiratory chain complexes were normal, whereas the OCR was significantly lower than that in the control.

Conclusions: Mitochondrial diseases with isolated renal symptoms are uncommon; however, this study indicates that mitochondrial respiratory chain complex III deficiency due to *BCS1L* mutations cause Fanconi syndrome with developmental disability as the primally indications.

PO1362

Expression of miRNA from Urinary Extracellular Vesicles in Patients with Gitelman Syndrome

Chih-Chien Sung, Shih-Hua Lin. *Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Gitelman syndrome (GS) is an inheritable renal tubule disorder with defect of sodium chloride cotransporter on distal convoluted tubule, resulting salt-losing, hypokalemia, hypomagnesemia and hypocalciuria. miRNA plays an important role in renal development and physical regulation. However, the miRNA expression from urinary extracellular vesicles (uEVs) in patients with Gitelman syndrome remains unclear.

Methods: miRNA profiling was conducted in uEVs obtained from 20 genetically confirmed GS patients and 20 healthy controls using small RNA sequencing.

Results: Principal component analysis revealed distinct miRNA expression pattern in GS patients (4 groups) compared with healthy controls (4 groups). The biological process from identified miRNA in uEVs included signaling transduction (24.3%), cell communication (22.6%), regulation of nucleobase, nucleoside, nucleotide and nucleic acid metabolism (18.4%), and transporter (7.7%). Comparing with healthy controls, differential expression of miRNA showed 18 upregulated miRNA (including has-miR-6825-5p, has-miR-4302, has-miR-4458) and 23 downregulated miRNAs (including has-miR-4740-5p, has-miR-4783-5p, has-miR-4508) in GS patients. Biological process conducted by DAVID (Database for Annotation, Visualization, and Integrated Discovery) using target genes from differential expressed up-regulated miRNAs were negative regulation of translation, positive regulation of transcription, and gene silencing by miRNA. Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis from upregulated miRNAs also revealed PI3K-Akt, MAPK, ErbB, aldosterone synthesis and secretion, TGF-β, aldosterone regulated sodium reabsorption, and calcium signaling pathways.

Conclusions: The expression of miRNA from uEVs in patients with GS could provide a physiological role in response to defect of NCC. Further validation and functional study will be performed.

Funding: Government Support - Non-U.S.

Infantile Hypercalcemia Associated with a Novel Homozygous Mutation in SLC34A1 Gene Encoding Sodium-Dependent Phosphate Transporter 2A

Mohamed Hassanein, Jordana Yahr, Mary-Beth Roberts, Xiangling Wang. *Cleveland Clinic, Cleveland, OH.*

Introduction: Early-onset and familial hypercalcemia often suggest a genetic etiology which is rare. Infantile hypercalcemia (IH) is a rare, autosomal recessive disorder that occurs due to mutations in the *SLC34A1* gene which encodes a sodium-dependent phosphate transporter 2A(NaPi-IIA) responsible for phosphate reabsorption in the kidney. We report an adult case who carried a clinical diagnosis of familial hypocalciuric hypercalcemia (FHH) since infancy, which is usually a benign condition characterized by autosomal dominant inheritance caused by mutations in calcium-sensing receptor (CASR) gene, while recently uncovered as IH related to a novel homozygous mutation in the *SLC34A1* gene.

Case Description: A 36-year-old Finnish male with a diagnosis of FHH presented to the genetics nephrology clinic for consultation regarding the recurrence risk for his children. He was diagnosed with FHH during infancy in Finland and has been treated with a low calcium diet. Family history was notable for a clinical diagnosis of FHH in his older sister. Physical exam was unremarkable. Labs showed mild hypophosphatemia and decreased glomerular filtration rate (69 mL/min/1.73m^2), with normal serum ionized calcium and intact parathyroid hormone. Twenty-four hour urine analysis revealed hypercalciuria 363 mg/d (normal <250), hypernatriuria 155 mmol/d (normal 50 – 150) and hypocitraturia 420 mg/d (normal >450). Kidney ultrasound showed bilateral medullary nephrocalcinosis. Genetic testing identified a novel homozygous variant in *SLC34A1* gene (c.1483C>T) and was negative in *CASR* gene. Family genetic studies revealed his affected sister is also homozygous for the same variant while his unaffected sister is only a carrier. With the new diagnosis, he was started on potassium citrate and chlorthalidone, and was reassured with the low recurrence risk for his children.

Discussion: Mutations in the *SLC34A1* gene lead to altered NaPi-IIA expression and reduced phosphate reabsorption, leading to hypophosphatemia. Secondary vitamin D activation leads to hypercalcemia, hypercalciuria, and nephrocalcinosis. We identified a novel mutation in the *SLC34A1* gene which broadens the genetic spectrum of IH. This case highlights the importance of early genetic testing for suspected hereditary hypercalcemia that may help improve its diagnosis and treatment.

PO1364

Characteristics and Genetic Defects of Systemic Lupus Erythematosus-Associated Thrombotic Microangiopathy

Cui Quexuan. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Thrombotic microangiopathy (TMA) is a life-threatening complication of systemic lupus erythematosus (SLE). However, the etiology of a considerable number of patients is still unclear and the best treatment is unknown. Sporadic reports suggest that the activation of complement pathway may play a role in SLE-TMA.

Methods: We prospectively enrolled 40 SLE-TMA patients in Peking Union Medical College Hospital, 14 patients with lupus nephritis (LN) and 38 patients with other types of TMA. The clinical data were collected. Peripheral blood concentrations of CFH, cCFB, soluble C5b-9, relative activity of complement pathway, ICAM1, VCAM1 and E-Selectin were measured by ELISA in SLE-TMA patients and control groups. Whole exome sequencing (WES) was performed to analyze the genetic variants in SLE-TMA patients.

Results: SLE-TMA mediated by ADAMTS13 inhibitors had severe nervous system involvement, but less kidney involvement and good response to plasma exchange. Among SLE-TMA with unknown etiology, patients with TMA confined to kidney had lighter hematological manifestations and lower serum creatinine level than SLE-aHUS ($p = 0.005$). Compared with SLE-aHUS, the concentration of CFH in SLE-TMA limited to kidney was higher ($p = 0.026$). The level of E-selectin in patients with SLE-TMA limited to kidney was significantly lower than that in SLE-aHUS patients with MAHA ($p = 0.016$). There was no significant difference in genetic susceptibility among SLE-aHUS, SLE-TMA limited to kidney and SLE-TMA with other causes. In SLE-TMA patients, thrombophilia variants may play a more important role than complement variants. Treatment response of SLE-TMA patients with variants is worse than those without variants. In serological test, VCAM1 level in SLE-TMA patients with complement related genetic variants was significantly higher than that in SLE-TMA patients without variants ($p = 0.001$). Patients with compound complement variants are more likely to detect abnormal level of complement factors.

Conclusions: SLE-TMA with unknown etiology can be divided into two subgroups with different severity according to the presence or absence of MAHA. The detection of complement factor and E-selectin may play a role in differentiating the two subgroups of SLE-TMA. The complement pathway is highly activated in patients with compound complement mutations, resulting in increased complement factors consumption.

PO1365

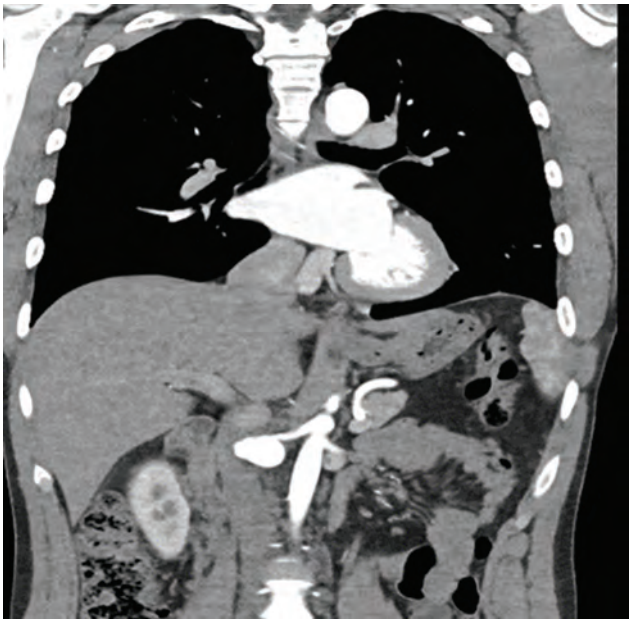
A Popping Renal Artery

Juan P. Portocarrero Caceres. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: The *COL3A1* gene encodes the collagen type III alpha chain, which forms the helical conformation. A mutation on this genec causes vascular Ehlers-Danlos syndrome (v-EDS), a life-threatening disease characterized by arterial fragility, vascular dissection or rupture, and organ perforation are the most common presenting signs in adults with vEDS (1).

Case Description: A 25-year-old man with history of bicuspid aortic valve, shoulder dislocation, chronic hemoptysis presented with severe left flank pain and syncope. A CT scan revealed a right retroperitoneal hematoma and aneurysms on the right renal artery (Image 1). Differential diagnosis were fibromuscular dysplasia, small vessel vasculitis and segmental arterial mediolysis (SAM). An extensive rheumatologic and vasculitis workup was negative. A collagen vascular disease was considered due to the history of bicuspid aortic valve and shoulder dislocation, and genetic testing was ordered. He underwent an urgent aorta-to-right renal artery bypass, and ligation of the aneurysm. Postoperatively, he developed hypotension. Abdominal imaging showed a new aneurysm on the superior mesenteric artery. Genetic testing results showed a *COL3A1 c.593 A* pathogenic variant, confirming vEDS. He now is treated with metoprolol succinate and spironolactone. His fathers genetic testing revealed possible mosaicism.

Discussion: vEDS is an uncommon but severe disease that needs a high degree of clinical suspicion. Patients usually present with unexplained pneumothorax, organ perforations and arterial ruptures. Little data exists about medical management, goals include mantaining low blood pressures (less than 120/80 mmHg). As well, patients should avoid contact sports and isometric exercises. Patients need constant imaging surveillance on the brain, neck, chest, abdominal and pelvic arteries.



PO1366

Mapping Genomic Regulation of Kidney Diseases and Traits at a Cell Type and Variant Level of Specificity

Christopher Benway, Michelle Mcnulty, Seong Kyu Han, Dongwon Lee, Matt G. Sampson. Nephrotic Syndrome Study Network (NEPTUNE) Consortium *Boston Children's Hospital, Boston, MA.*

Background: Although numerous genetically associated loci for kidney function and disease have been identified by genome-wide association studies (GWAS), determining the causal genes and functional variants remains a major challenge. Integration of GWAS results with other data types (such as expression quantitative trait loci [eQTLs]) can help identify causal and functional variants in a tissue- or cell-type specific manner. Further, analysis of disease tissue may uncover context-specific associations that may otherwise not be detectable.

Methods: We integrated eQTL data from micro-dissected glomerular (n = 240) and tubulointerstitial (TI) (n = 311) transcriptomes from individuals with nephrotic syndrome and summary statistics from two large trans-ethnic GWAS meta-analyses for estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR). We applied a Bayesian statistical framework for eQTL discovery and multi-SNP fine-mapping (TORUS/DAP). eQTL signals from each renal compartment were integrated with summary statistics to perform a gene-level probabilistic transcriptome-wide association study (PTWAS) and SNP-level co-localization (fastENLOC).

Results: We identified 5,526 glomerular and 9,742 TI eQTLs at < 5% FDR level. For eGFR, we identified 971 gene-trait pairs in the glomerulus and 1,816 gene-trait pairs in TI tissue that were significant (FDR < 5%). For UACR, we identified 194 and 340

significant gene-trait pairs in the glomerulus and TI tissue, respectively. In the SNP-level co-localization, we identified 46 TI and 3 glomerular co-localization signals (regional co-localization probability [RCP] > 50%) for eGFR, including known associations with *UMOD* and *FGF5* expression, as well as novel associations to *LARP4B* and *RRAGD* which can be attributed to single variants. We identified 7 TI and 16 glomerular co-localization signals (RCP > 50%) for UACR. In addition to replicating co-localization signals at *PRKCI* and *TGFB1* in glomerular tissue, we refined the co-localization signal at *PTH1R* to a single variant, rs6787229, which also co-localized with expression of *MYL3*.

Conclusions: Profiling and integrating renal compartment-specific eQTLs with kidney trait GWAS results in a probabalistic framework identified novel gene-trait associations and refined many known associations to a single variant.

PO1367

Factors Contributing to Decisional Conflict in Older Persons Facing Dialysis Decisions

Tramanh Phan, Janany J. Sabescumar, Sally Norton, Fahad Saeed. *University of Rochester, Rochester, NY.*

Background: Dialysis and conservative kidney management are the two main treatment options for elderly persons with end-stage-kidney disease who are ineligible for kidney transplantation. The high stakes of these decisions often force patients to choose between quality versus quantity of life. Thus, they face tremendous conflict while making dialysis decisions. This decisional conflict can adversely affect their mental health-related quality of life and leads to avoidable delays in decision making. Exploring factors contributing to dialysis decisional conflict in older persons with chronic kidney disease is critical.

Methods: Using a qualitative descriptive approach, we purposefully sampled a cohort of 10 patients; 5 with high scores on decisional conflict scale, and 5 with low scores. Patients met with a palliative care physician to discuss dialysis and these visits were audio-recorded. Audio recordings were transcribed verbatim and entered into MAXQDA for data management. Following an iterative process, 2 independent reviewers analyzed the transcripts for common themes contributing to decisional conflict.

Results: The mean age of patients was 83 years. We observed 3 themes in the data of patients with low decisional conflict: (1) clarity in values, (2) good current quality of life, and (3) strong therapeutic alliance with their nephrologist. In the high decisional conflict group, we observed 5 themes: (1) fear of: physical pain, complications from dialysis and its time commitment, loneliness, and losing independence, (2) concerns about being a burden to loved ones, (3) uncertainty about prognosis, (4) worries about transportation to and from dialysis, and (5) poor knowledge of treatment options.

Conclusions: Patients with high decisional conflict worried about their future quality of life, sense of burdensomeness, prognostic uncertainty, and issues related to transportation. They wished for detailed knowledge of treatment options. Future dialysis decision-making interventions should be tailored to identify each patient's unique needs, and incorporate details about treatment options and information about logistics of dialysis. Nephrologists need to discuss the expected quality of life and prognosis. Last, family involvement in these discussions and buy-in for or against dialysis may be helpful in mitigating the patient's sense of being a burden on their loved ones.

PO1368

Shared Decision-Making Among Older Adults with Advanced CKD

Rebecca Frazier,[1] Sarah Levine,[2] Hocine Tighiouart,[2] John B. Wong,[2] Tamara Isakova,[1] Susan Koch-Weser,[3] Elisa J. Gordon,[1] Daniel E. Weiner,[2] Keren Ladin.[3] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Tufts Medical Center, Boston, MA; [3]Tufts University, Medford, MA.*

Background: Older adults with advanced chronic kidney disease (CKD) face difficult, preference-sensitive decisions about dialysis. Although shared decision-making (SDM) can help align treatment with patient preferences and values, the degree to which older CKD patients experience SDM and associated factors remain unknown.

Methods: Using data from the Decision Aid for Renal Therapy Trial, we examined SDM in adults >70 years with non-dialysis CKD stage 4–5 from 4 sites in the US using the validated SDMQ9 measure, with scores scaled from 0-100 and higher scores reflecting greater SDM. We categorized predictors into demographic and clinical factors, cognitive factors (decisional perception and uncertainty), and behavioral and educational factors (resources supporting SDM). Multivariable linear regression assessed predictors of SDM.

Results: Among 350 participants, mean age was 78±6 years, 58% were male, 13% were Black, and 48% had diabetes. Mean SDMQ9 score was 52±28. Responses varied from 73% somewhat, strongly, or completely agreeing that "*My doctor told me that there are different options for treating my medical condition*," to just 41% agreeing that "*My doctor and I selected a treatment option together*" (Figure). In regression analyses, being "very well informed" about kidney treatment options (β=14.9, p=0.02), Black race (β=10.4, p=0.02), attended a dialysis class (β=8.3, p=0.02), diabetes (β=7.9, p=0.007), older age (β=5.2, p=0.04), lower eGFR (β=-2.4, p=0.02), and higher decisional certainty (β=1.5, p=0.002) were associated with higher SDMQ9 scores. In models evaluating behavioral/educational factors, dialysis class attendance (β=8.8, p=0.009) and care satisfaction (β=2.4, p=0.02) were associated with higher scores.

Conclusions: There is room for improvement in SDM for many older CKD patients who face preference-sensitive dialysis decisions. Being well-informed about treatment options, increased decision certainty, and dialysis options class attendance were associated with SDM, suggesting that education is critical to the SDM process.

A Qualitative Study of Patient-Clinician Dyads on Perceived Challenges to Shared Decision-Making About Treatment of Advanced CKD

Taylor R. House,[1,2] Aaron G. Wightman,[1,2] Abby R. Rosenberg,[1,2] Khaled Abdel-Kader,[3] Susan P. Wong.[1,4] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Hospital, Seattle, WA; [3]Vanderbilt University, Nashville, TN; [4]VA Puget Sound Health Care System Seattle Division, Seattle, WA.*

Background: An important step to implementation of shared decision-making for treatment of advanced CKD is acquiring a deeper understanding of its perceived challenges.

Methods: We performed a qualitative study using in-depth interviews with 29 patients aged ≥65 years with advanced CKD and 10 of their clinicians. We also reviewed patients' electronic health records and abstracted passages containing further information on treatment of their advanced CKD. We used thematic analysis to analyze interview transcripts and note passages and identify emergent themes reflecting their joint experiences with decision-making about treatment of their advanced CKD.

Results: Patients (age 73±6 years) were mostly men (66%) and Caucasian (59%). Of the clinicians (age 52±12 years, 30% male, 70% Caucasian) who participated in interviews, 4 (40%) were non-nephrologists. Four themes emerged from qualitative analysis: 1) *Competing priorities*: patients and their clinicians tended to differ on when to triage CKD and dialysis planning above other priorities; 2) *Focusing on present or future*: patients and their clinicians could be misaligned on their outlook on CKD, with patients being more focused on living well now; and clinicians, on preparing for dialysis and future adverse events; 3) *Textbook approach to CKD*: patients perceived their clinicians as taking a monolithic approach to CKD that was predicated on clinical practice guidelines and medical literature rather than their lived experience with illness, while clinicians were uncertain about how to incorporate patients' personal values and goals into decision-making; and 4) *Power dynamics:* while patients described cautiously navigating a power differential between themselves and their clinicians, clinicians seemed less attuned to these power dynamics.

Conclusions: Improving shared decision-making for treatment of advanced CKD will likely require efforts that explicitly reconcile the differences in mindset between patients and their clinicians on decision-making about treatment of advanced CKD and that address the power imbalances in their therapeutic relationship.

PO1370

Effect of Estimated Glomerular Filtration Rate on Survival in Patients ≥75 Years of Age at Dialysis Initiation

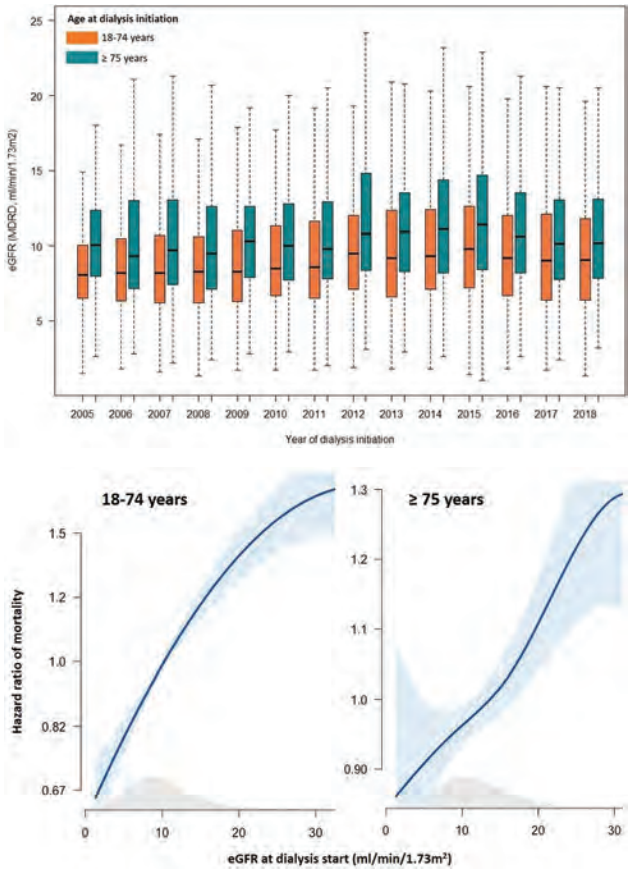
Aghiles Hamroun,[1,2] Linh Bui,[3] Sébastien Gomis,[1] François Glowacki.[1] *[1]Centre Hospitalier Universitaire de Lille, Lille, France; [2]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [3]Paris Saclay University, Paris, France.*

Background: Data regarding the prognostic impact of estimated glomerular filtration rate (eGFR) at dialysis start are discordant, and remain very scarce in elderly populations. The aim of this study is to explore whether the effect of eGFR on survival was similar in elderly incident dialysis patients compared with younger ones.

Methods: We included 4690 patients ≥75 years of age and 7045 patients 18-74 years of age starting dialysis between 2004 and 2018 from a French regional registry. Patients were followed until death or the end of 2019. Survival was assessed by Kaplan-Meier curves and the relative risk of death associated with eGFR (MDRD) was assessed by multivariate Cox regression analysis.

Results: The results showed an increasing trend of eGFR at dialysis start, which was also systematically higher in elderly patients (13.2 [10.1; 17.2] vs 11.2 [8.3; 14.9] ml/min/1.73m^2, p < 0.001) (Fig1). Overall, we found a significant dose-effect relationship between eGFR at dialysis initiation and mortality (HR = 1.33 [1.16; 1.51], 1.47 [1.29; 1.69], and 1.72 [1.49; 1.78] respectively for eGFR [5-10], [10-15], and > 15ml/min/1.73m^2, p for trend < 0.001). The same results were found in subgroup analyses according to age category (Fig2), with a significant interaction in favor of a stronger association in younger patients (p = 0.031).

Conclusions: In incident dialysis patients, our study shows a dose-effect relationship between higher eGFR at dialysis start and mortality, regardless of age category. This association seems to be even stronger in younger patients.



PO1371

Hospitalization Risk Among Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Connie Rhee,[1] Amy S. You,[1] Yoko Narasaki,[1] Csaba P. Kovesdy,[2] Dana B. Mukamel,[1] Susan T. Crowley,[3,4] Alejandra Novoa-Vargas,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center VolShop Memphis, Memphis, TN; [3]Yale University School of Medicine, New Haven, CT; [4]Veterans Health Administration, Washington, DC.*

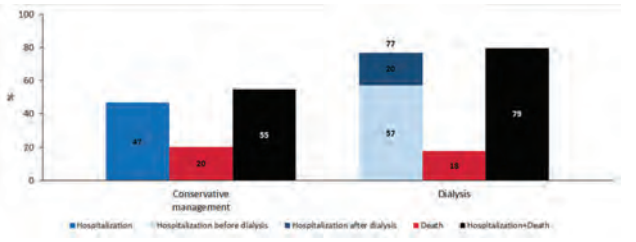
Background: Regarded as the default treatment option for advanced CKD, dialysis has been associated with frequent hospitalizations, functional decline, and loss of independence, particularly in the elderly and comorbid. While there is rising interest in conservative management (CM) as an alternative treatment option, this strategy remains underutilized. We sought to quantify differences in healthcare utilization in advanced CKD patients transitioning to dialysis vs. CM.

Methods: We compared hospitalization risk in 309,188 advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) treated with dialysis vs. CM from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. We examined hospitalizations within 2-yrs of the index eGFR (1st eGFR <25), which were parsed into pre- and post-dialysis transition hospitalizations in those treated with dialysis. We also examined the composite endpoint of hospitalization+death within 2-yrs of the index eGFR to account for death as competing event for hospitalization.

Results: In the overall cohort, 55% and 20% of patients experienced ≥1 hospitalization(s) and death, respectively, within 2-yrs of the index eGFR. Patients who transitioned to dialysis were more likely to be hospitalized vs. those treated with CM (77% and 47%), with a larger proportion of hospitalizations occurring pre- vs. post-dialysis transition in the former group (57% vs. 20%). While the proportion of deaths across dialysis vs. CM were similar (18% vs. 20%), the composite endpoint was more frequent in patients treated with dialysis vs. CM (79% and 55%).

Conclusions: In a national cohort of advanced CKD patients, while the proportion of death events was similar in those treated with dialysis vs. CM, patients who transitioned to dialysis had higher hospitalization risk. Further studies are needed to compare the components and effectiveness of CM vs. dialysis on CKD outcomes.

Funding: NIDDK Support



PO1372

Mortality Rates in a Nationally Representative Cohort of Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Amy S. You,[1] Kamyar Kalantar-Zadeh,[1] Yoko Narasaki,[1] Csaba P. Kovesdy,[2] Dana B. Mukamel,[1] Susan T. Crowley,[3,4] Alejandra Novoa-Vargas,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Yale University School of Medicine, New Haven, CT; [4]Veterans Health Administration, Washington, DC.*

Background: While dialysis has been the prevailing treatment paradigm in CKD patients progressing to ESRD, this treatment approach may not offer survival benefit nor improved quality of life in certain subgroups (elderly, multi-morbid). Hence, there is growing interest in conservative management (CM) as an alternative treatment strategy in advanced CKD.

Methods: We compared mortality rates in advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were categorized according to receipt of dialysis vs. CM, defined as those who did vs. did not receive dialysis within 2-yrs of the index eGFR (1st eGFR <25), with the former group parsed into late vs. early dialysis (eGFRs <15 vs. ≥15 at dialysis transition). Secondary analyses stratified the former group as late, intermediate, vs. early dialysis (eGFRs <5, 5-<10, vs. ≥10 at dialysis transition). Poisson regression was used to compare mortality rates across exposure groups.

Results: Among 309,188 advanced CKD patients, 60% vs. 40% of patients were treated with CM vs. dialysis, respectively. Patients who underwent CM vs. late dialysis had similar mortality, whereas those who underwent early dialysis had the highest mortality rates. In secondary analyses comparing CM and late vs. intermediate vs. early dialysis, a similar pattern was observed (140, 126, 141, vs. 158 deaths per 1000 person-yrs, respectively). In age-stratified analyses, compared to CM, all dialysis groups had higher mortality rates irrespective of timing of initiation in those <65 and ≥65 yrs old.

Conclusions: In a nationally representative cohort of advanced CKD patients, CM vs. late dialysis demonstrated similar mortality, whereas those who underwent early dialysis had the highest mortality rates.

PO1373

Continued Primary Care Use During the Transition to Kidney Failure with Renal Replacement Therapy (KFRT) Is Associated with Reduced Mortality Among Older Hemodialysis (HD) Patients

Raquel C. Greer,[1] JiYoon B. Ahn,[1] Laura Plantinga,[3] John Sperati,[1] Mara McAdams-DeMarco,[1] Kelly H. Beers,[2] Sandeep S. Soman,[4] Michael J. Choi,[5] Bernard G. Jaar.[1,6] National Kidney Foundation Education Committee *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Albany Medical College, Albany, NY; [3]Emory University, Atlanta, GA; [4]Henry Ford Hospital, Detroit, MI; [5]MedStar Georgetown University Hospital, Washington, DC; [6]Nephrology Center of Maryland, Baltimore, MD.*

Background: Primary care providers (PCPs) are responsible for addressing patients' comprehensive health needs. However, the provision of primary care during the KFRT transition and its contribution to clinical outcomes among in-center HD patients have not been well explored.

Methods: We quantified the associations between PCP use, mortality, and hospitalization among older (age≥67) incident (2008-2014) in-center HD patients using data from the United States Renal Data System. We defined patients' PCP use 1-year prior and 1-year post-KFRT as "continued" for PCP use pre- and post-KFRT; "initiated" for no PCP use pre-KFRT and PCP use post-KFRT; "discontinued" for PCP use pre-KFRT and no PCP post-KFRT; or "never used" as no PCP use pre- or post KFRT. We used Cox proportional hazard models and adjusted for confounding by using inverse probability weighting method to estimate hazard ratios (HRs) for all-cause mortality and first all-cause hospitalization up to 2 years post-KFRT.

Results: Among 111,424 patients, 57% had continuity of PCP care, 10% initiated PCP use, 10% discontinued PCP use, and 23% never used PCP care during the KFRT transition. Compared to those who never used primary care during the KFRT transition, those with continued primary care use had a 14% lower risk of mortality. Continued and initiated PCP care post-KFRT transition was associated with a 5-12% higher risk of hospitalization, respectively.

Conclusions: Continued primary care use during the KFRT transition was associated with lower mortality, but a higher risk of hospitalization. Additional studies are needed to determine the aspects of primary care that may be beneficial and which patients are most likely to benefit from continued PCP use.

Funding: Private Foundation Support

Hazard Ratios for All-Cause Mortality and First Hospitalization by Primary Use during KFRT Transition

	Never used	Discontinued	Initiated	Continued
	HR (95% CI)*	HR (95% CI)*	HR (95% CI)*	HR (95% CI)*
All-cause Mortality	Ref	1.01 (0.96-1.05)	0.97 (0.93-1.02)	0.86 (0.83-0.89)
First all-cause hospitalization	Ref	1.00 (0.98-1.02)	1.12 (1.10-1.15)	1.05 (1.03-1.06)

PO1374

Vascular Access Type and Survival Outcomes in Elderly Hemodialysis Patients

Marisa Roldão, Cátia R. Figueiredo, Rachele D. Escoli, Hernâni M. Gonçalves. *Centro Hospitalar do Medio Tejo EPE Unidade de Torres Novas, Torres Novas, Portugal.*

Background: The ideal vascular access for elderly hemodialysis (HD) patients remains widely debated. Limited life expectancy and lower arteriovenous access (AVA) maturation rates increase the likelihood of starting HD with a central venous catheter (CVC). The aim of the study was to evaluate the influence of vascular access type in survival outcomes for elderly HD patients.

Methods: Single-center retrospective cohort study of incident HD patients aged > 80 years from January 2010 to May 2021. Patients who recovered renal function or switched to another renal replacement therapy were excluded. Patients were categorized according to their vascular access at the beginning of dialysis: CVC or AVA. Baseline clinical and demographic data were compared among groups. Survival outcomes by the end of follow-up (31st May 2021) were analyzed using Kaplan-Meier survival curves and Cox's proportional hazards model. Statistical analysis was performed using SPSS (Version 23 for Mac OSX).

Results: The study included 99 patients: 48 (48.5%) were male, 44 (44.4%) diabetic, 60 (60.6%) had isquemic heart disease and 15 (15.2%) peripheral artery disease. Mean Charlson Comorbidity Index was 8.41±1.65 and mean age 85.14±3.98 years. Eleven patients (11.1%) were over 90 years old. Eighty patients (81%) started HD urgently as inpatients. The vascular access at dialysis start was a CVC in 75.8% (n=75) and an AVA in 24.2% (n=24). No statistical differences were found in age, gender, or comorbidities among groups. During a mean follow-up of 2.3 years, there were 64 deaths, 27 due to infections (12 access-related infections). All-cause mortality (HR [95% CI]: 1.92 [1.05-3.49], p=0.033) and infection-related mortality (HR: 5.87 [1.38-24.94], p=0.017) were significantly higher among patients who initiate HD with a CVC as compared to an AVA.

Conclusions: The ideal vascular access in elderly patients remains controversial. Our results suggest that patients who start HD with a CVC presented higher all-cause and infection-related mortality when compared with patients who start with an AVA. Our study supports the initiative "fistula first" however more studies are needed to confirm the observations.

PO1375

Predictors of Treatment Discussions in Geriatric Dialysis Patients Who Died

Laura Bywater,[1] Hannah Douglass-Molloy,[1] Matthew A. Roberts,[1,2] Lawrence Mcmahon,[1,2] Kathryn Ducharlet.[1] *[1]Eastern Health, Box Hill, VIC, Australia; [2]Monash University Faculty of Medicine Nursing and Health Sciences, Melbourne, VIC, Australia.*

Background: Geriatric patients on maintenance dialysis often have a high burden of symptoms and comorbidities with limited prognosis. Therefore, in the setting of declining clinical status, goals of treatment (GOT) discussions are important to inform illness expectations and balance the benefits and burdens of ongoing treatment. This study aimed to identify mortality risk factors that prompted nephrologists to have GOT discussions including dialysis withdrawal.

Methods: A cohort of 95 adult patients ≥65 years, cared for by Eastern Health (Victoria, Australia), who died between 1/1/2016-31/12/2019 was analysed using Fischer's exact tests to identify psychosocial variables associated with functional decline and mortality.

Results: Mean age was 78 (SD 7.3), with mean dialysis vintage 5 years and average 3.7 admissions in the 12 months preceding death. Mean Charleston comorbidity index (CCI) was 10 (SD 2.3), with hypertension 78%, T2DM (56%), IHD (56%), cardiac failure (51%), malignancy (34%), peripheral vascular disease (32%) and cognitive impairment (28%) major comorbidities. Almost one third (29%) of patients lived in a nursing facility, 74% used gait aids, and 55% needed assisted transport to dialysis. Median time between needing transport and death was 1.3 years [IQR 0.5, 2.2]. A GOT discussion in the preceding year was documented in 65% of patients, in renal clinics (37%) or on dialysis (12%). Median time between GOT discussion and death was 5 months [IQR 1, 11]. Discussions were more likely if patients had high comorbidity (CCI>5, 57% vs CCI<5, 8%, p<0.05) with no association between GOT discussions and patient age, dialysis vintage, functional status, or specific comorbidities. Advance care plans were completed in 26% and were more likely if a GOT discussion had already transpired (23%v4%, p<0.05), or the patient lived in a nursing facility (16 v12%, p<0.05). Deaths occurred in hospital (50%), hospice (19%), or at home (7%). Dialysis was withdrawn median 8 days before death [IQR 6, 11].

Conclusions: Older patients died with significant comorbidities and functional dependency, though only the former prompted GOT discussions. Despite a long-term relationship, nephrologists could improve documentation of future treatment planning with patients to promote patient centered end of life experiences.

PO1376

Nurse-Driven Advance Care Planning in a Hemodialysis Unit in a Veteran Population

Sam Tonthat,[1,2] Rebecca Yamarik,[2] Jocell Fernandez,[2] Jennifer Ballard-Hernandez,[2] Marysol Cacciata,[2] Pankaj Gupta,[2,1] Joline L. Chen.[2,1] *[1]University of California Irvine, Orange, CA; [2]Long Beach Veteran Affairs Healthcare System, Long Beach, CA.*

Background: Patients with end-stage kidney disease (ESKD) face difficult choices near the end of life. Advance care planning (ACP) allows patients and their providers to plan for treatments that align with patients' goals. In the US, only 6-35% of all ESKD patients have advance directives (AD). PREPARE is an interactive ACP website that helps patients complete AD and express their wishes regarding medical decisions. The goal of the study is to assess the feasibility and acceptability of using a nurse to facilitate ESKD patients to completing the PREPARE ACP during dialysis.

Methods: Inclusion criteria include patients without a documented AD within the past 3 years. Exclusion criteria are dementia/cognitive impairment, psychosis, deafness, or blindness. Pre and post engagement surveys were completed. Barriers related to navigating the PREPARE website were documented.

Results: Of 55 patients at the dialysis unit, 25 were eligible and 14 were enrolled. All participants are male with mean age of 69. All participants completed their AD within 1 dialysis treatment. In the pre-PREPARE questionnaire, using the Likert scale of 1 to 5 (1 for "not at all" to 5 for "extremely likely"), patients reported a mean score of 4.07 for readiness to talk about end-of-life care to a close family/friend, 4.23 for readiness to talk to a care provider, 4.46 for readiness to express wishes in writing, and 4.61 for readiness to sign official documentation. In the Post-PREPARE questionnaire, on a scale of 1 (very hard) to 10 (extremely easy), patients scored 7.61 for ease, 7.23 for comfortability, and 8.07 for helpfulness. Analysis of PREPARE AD showed that on a scale of 1 (AD goal mainly to extend life) to 5 (focus on the quality of life), the mean score is 3.06 suggesting that patients value both "extend life" and "maintain quality of life". Five patients expressed wishes for full care, 6 wanted a trial of resuscitation, and 3 requested DNR. Barriers to using PREPARE included patient difficulty navigating the website without help and using a laptop during dialysis when both hands are not always free.

Conclusions: Our study shows that PREPARE is a feasible method in facilitating ACP during dialysis, however, many patients needed assistance to complete the process. Future studies are needed to apply PREPARE and ACP wishes in the ESKD population.

PO1377

Dialysis Patients' Preferences on Resuscitation: A Cross-Sectional Study Design

Husam Alzayer,[1,5] Annette M. Geraghty,[2] Kuruvilla K. Sebastian,[3,5] Hardarsh Panesar,[4] Donal N. Reddan.[1,5] *[1]Galway University Hospitals, Galway, Ireland; [2]Mayo University Hospital, Castlebar, Ireland; [3]National University of Ireland Galway, Galway, Ireland; [4]Western University, London, ON, Canada; [5]Royal College of Physicians of Ireland, Dublin, Ireland.*

Background: End-stage kidney disease is associated with a 10-100-fold increase in cardiovascular mortality compared to age-, sex-, and race-matched population. Cardiopulmonary resuscitation (CPR) in this cohort has poor outcomes and is often followed by increased functional morbidity. Advance care planning (ACP) is an important aspect of patients' care that is often missed in chronic kidney disease (CKD) and there is growing support for its use. Nephrologists are often involved in end-of-life care decisions for their patients and frequent end-of-life care discussions can provide insight and valuable assistance to patients in the process of decision making.

Methods: 2-center cross-sectional study design. Adults > 18 years undergoing regular dialysis for more than 3 months were included. Patients with severe cognitive impairment or unable to understand discussion secondary to language barrier were excluded. After taking consent, a questionnaire was delivered during a structured interview during a routine dialysis session or clinic visit. Demographic data were collected and baseline Montreal Cognitive Assessment, Patient Health Questionnaire-9, Duke Activity Status Index, Charlson Comorbidity Index, and Willingness to Accept Life-Sustaining Treatment tool were used.

Results: 70 participants were included in this analysis representing a 62.5% response rate. There was a clear effect of treatment burden, nature of clinical outcome, and likelihood of the outcome on patients' preferences. Low-burden treatment resulting in return to baseline (vs death) was associated with 98.5% willingness to accept treatment and 94.2% if it was high-burden. When the outcome was severe functional or cognitive impairment then 54.3% and 71.5% would decline low-burden treatment, respectively. The response changed based on the likelihood of the outcome. In terms of resuscitation, 82.8% and 77.4% of the participants would be in favour of receiving CPR and mechanical ventilation, respectively, at their current health state. Over 94% of patients stated they had never discussed ACP while 59.4% expressed their wish to discuss this with their primary nephrologist.

Conclusions: ACP should be incorporated in managing CKD with an aim to improve communication and encourage patient and family involvement.

PO1378

Evaluation of a Concurrent Hospice-Dialysis Program for Patients with ESRD

Mayumi Robinson,[1] Natalie C. Ernecoff,[1] Erica M. Motter,[1] Keith Lagnese,[2,3] Robert Taylor,[4] Jane O. Schell.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]UPMC Family Hospice, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Dialysis Clinic Inc, Nashville, TN.*

Background: Most dialysis patients are hospitalized in the last month of life, nearly half of whom receive intensive care. Hospice financing poses a major barrier to hospice delivery to dialysis patients, increasing inequities for high-quality end-of-life care. The Concurrent Hospice-Dialysis Program aims to promote timely hospice services for dialysis patients with limited prognosis by offering concurrent hospice and dialysis.

Methods: We conducted a mixed methods study comprised of chart reviews and semi-structured interviews with 10 bereaved caregivers of deceased patients who were enrolled in the Concurrent Hospice-Dialysis Program and 13 clinicians who provided care as part of the program.

Results: Four major themes were identified: 1) Decisional distress regarding stopping dialysis; 2) The option to continue dialysis served as a psychological bridge to hospice; 3) Clear referral process, formal patient education, and care coordination between hospice and dialysis teams facilitated successful implementation; 4) Providing hospice and dialysis promoted goal-concordant care at end-of-life.

Conclusions: Bereaved caregivers and clinicians involved with the Concurrent Hospice-Dialysis Program found the program broadly acceptable and recommended it for patients on dialysis interested in hospice services. They offered suggestions for systematizing and disseminating the program.

Table 1. Key Themes

Theme	Representative Quote
Decisional distress regarding dialysis cessation	"The weight of stopping dialysis is so heavy that it takes so much time and planning and conversation to get a family [..] to see the benefit."
Psychological bridge	"Just knowing that it's an option [...] alleviates a lot of the fear and the sense of abandonment that can come with these really tough decisions."
Facilitator - care coordination	"We communicate far in advance. We set things up [...] so that we're prepared for what might happen. That is the best part of it."
Overall impression	"[...] it was really the best of all worlds." "I think the ones that have gone through this kind of program have done a lot better."

PO1379

Concurrent Hospice Dialysis: Perspectives on Dissemination

Erica M. Motter,[1] Mayumi Robinson,[1] Natalie C. Ernecoff,[1] Keith Lagnese,[2,3] Robert Taylor,[4] Jane O. Schell.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]UPMC Family Hospice, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Dialysis Clinic Inc, Nashville, TN.*

Background: In the United States, people receiving dialysis have traditionally been unable to enroll in hospice without ceasing dialysis treatments due to policy constraints. Therefore, these patients are often denied the full benefits of quality end-of-life care, either dying in hospitals or spending only a few days on hospice after dialysis is stopped. An alternative model would allow people living with end-stage renal disease (ESRD) to receive hospice services concurrently with dialysis treatments.

Methods: We implemented a concurrent hospice-dialysis program in one health system as proof of concept. In this project, we sought to build evidence for feasibility and program requirements for extending such programs to other settings across the country. We conducted semi-structured interviews with people living with ESRD, family caregivers, hospice and dialysis clinicians, and health system administrators from the Pittsburgh area and other regions in the U.S. Interviews elicited perceptions of strengths and weaknesses of a scalable concurrent hospice and dialysis program, including barriers and facilitators of implementation across various settings.

Results: We completed 25 interviews with 2 patients (8%), 3 caregivers (12%), 15 clinicians (60%), and 5 administrators (20%). Preliminary themes include important considerations: 1) Mechanisms and operational definitions for identification of eligible patients; 2) Procedures for decision-making conversations with patients and families; and 3) Protocols for communication between hospice and dialysis teams to coordinate care. Medicare policy and funding restrictions were also frequently discussed as barriers to the program.

Conclusions: Perspectives from patients, caregivers, clinicians and administrators describe critical implementation processes and resources for a successful concurrent hospice and dialysis program. These include the following: clear criteria for patient eligibility, consistent language to use when talking with patients and families, education for both hospice and dialysis teams, and a well-defined plan for care coordination between teams. Future evaluation of such programs may lead to policy change to make concurrent care broadly financially feasible.

PO1380

Dialysis for the Hospice Patient: A Paradoxical Challenge for Palliative Nephrology

Frank A. Portugal, Steve I. Khalil. *Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, NJ.*

Introduction: We present a case of a patient who developed anuric AKI who subsequently needed dialysis while patient and family were also simultaneously interested in hospice. Our case addresses the difficult conversation in prognosticating and how hospice eligibility for patients requiring dialysis can be challenging.

Case Description: A 63-year-old woman with hypertension and recently diagnosed metastatic pancreatic adenocarcinoma initially presented for intractable right hip pain and was admitted for emergent palliative radiation. She experienced rapid deterioration including septic and hemorrhagic shock and was managed in the ICU until she was later stabilized off pressors and downgraded to the floors. Unfortunately, she had further complications and quickly experienced anuric AKI from ischemic ATN as her serum creatinine rose from 0.8 to 4.9 mg/dL and became significantly volume overloaded with worsening acidemia. The decision was to start a trial of dialysis by family, but they also wanted hospice. Questions arose including prognosis and if patient could simultaneous be provided with dialysis during hospice. Given the current model of withdrawing from dialysis for hospice eligibility, the daughters agreed to transition their mother to hospice. The patient passed prior to leaving the hospital.

Discussion: We present a difficult scenario for the nephrologist as serious illness conversations remain incredibly challenging. We may opt to not take part in these conversations either due to time commitment, not viewing it as a primary responsibility, or not wishing to upset the patient and their families. Also, so much uncertainty in predicting prognosis makes it intimidating. Here, what also needed to be addressed were hospice benefits for the dialysis patient, if any existed. Usually, one is required to withdraw from dialysis to receive hospice care. There have been suggestions in providing a trial or "as needed dialysis" to focus on a patient-centered type of care but unfortunately that could potentially impact quality metrics and Medicare reimbursement for dialysis centers. As such, these ongoing challenges not only require collaboration between Nephrology and Palliative medicine but also changes at the national broader level.

PO1381

Kidney Palliative Care in Transplant Recipients with a Failing Allograft

Samantha L. Gelfand,[1] Naoka Murakami,[1] Joel T. Adler,[1] Joshua R. Lakin.[2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Dana-Farber Cancer Institute, Boston, MA.*

Background: Kidney transplantation provides longer survival and better quality of life than dialysis for patients with end-stage kidney disease. However, when allografts fail, navigating treatment options can be challenging as patients with allograft failure are older and sicker than when they were transplanted. Kidney palliative care, specialized interprofessional medical care working together with nephrology providers, providing communication, coordination, symptom management, and psychosocial support for seriously ill patients, has not yet been well-studied for those with kidney transplants.

Methods: We conducted a retrospective observational study comparing palliative care delivery, patient treatment choices, and clinical outcomes before and after creation of an inpatient kidney palliative care service (KidneyPal) at our institution. We included adult kidney transplant patients (age 18 or greater) who experienced allograft failure or death two years before and after the start of KidneyPal. Allograft failure was defined as imminent indication or chronic need for dialysis for more than 3 months.

Results: Fifty-four and fifty-nine patients were included before and after KidneyPal implementation, respectively. For the patients who experienced death with a functioning graft, inpatient palliative consultation frequency was similar before and after the creation of KidneyPal (40% and 33%, respectively). However, for the patients with allograft failure, palliative care consultation increased from 5.9% to 24.1%. Death in the ICU was common (15% vs. 17%), but death in hospice was more frequent (7% vs. 15%) after KidneyPal was created. While palliative care clinicians addressed code status, symptom management, and psychosocial issues throughout the study period, KidneyPal clinicians held more discussions about treatment options for allograft failure (20% vs. 41%). More patients chose dialysis as a time-limited trial or made a decision to forgo dialysis re-initiation after consultation with KidneyPal (3% vs. 17%).

Conclusions: Our observational study suggests that kidney palliative care may be useful in the context of allograft failure, particularly with regard to ensuring goal-directed shared decision making. Discussing prognosis, goals of care, and care options after graft failure are palliative skills that may be enhanced by collaboration with a specialty kidney palliative care team.

PO1382

Patient Perspectives on Frailty Status Evaluation During Kidney Transplant Assessment

Henry H. Wu,[1,2] Lyndsey Rushton,[1] Fiona Biggins,[1] Aimun K. Ahmed,[1,2] Alexander Woywodt.[1,2] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom.*

Background: The concept of frailty garnered attention within nephrology in recent years, given strong associations between frailty status and kidney disease outcomes. There is increased debate on formalizing frailty status evaluation during the early stages of assessment for potential kidney transplant recipients. Studies investigating patient perspectives on frailty and frailty status evaluation during transplant assessment are lacking.

Methods: We conducted a qualitative study using cognitive interviews in English for 25 patients aged 65-85 yrs awaiting initial transplant clinic assessment. The interview enquired on patient understanding of frailty, perspectives on the impact of frailty for transplantation outcomes and whether formalized frailty status evaluation during transplant assessment should be established. An inductive thematic analysis of interviews to identify themes reflecting participants' awareness, understanding and perspectives of frailty and frailty status evaluation in transplant assessment was performed.

Results: There were 14 Male and 11 Female participants and mean age was 69.6 yrs ± 3.4. Participants were mainly white (n=18) and native English speakers (n=20). 3 prominent themes were identified. 1) *Prerequisite awareness of the frailty syndrome and recognition of its strong associations with negative health outcomes.* Most participants understood frailty as a composite of declining physical function, reduced ability to perform daily activities and increased comorbidity status. 2) *Severe frailty status is associated with older transplant recipients.* Many participants felt worsened frailty status is correlated with older age, and older transplant recipients generally do more poorly. 8 participants recognized frailty may be independent of age in which older patients could be fitter transplant candidates compared to younger, frailer patients. *3) Universal support for a formalized screening program to evaluate frailty status during pre-transplant assessment.* All participants voiced support, to assist clinical decision-making on determining suitability for transplantation from an early stage.

Conclusions: Patient education initiatives should continue to expand awareness of frailty and its implications in transplantation. Further work is required to determine an optimal approach to formally evaluate frailty status during transplant assessment.

Differences in Frailty by Sex in Kidney Transplant Candidates

George L. Worthen,[1,2] Amanda J. Vinson,[1,2] Karthik K. Tennankore.[1,2] Frailty Assessments in Canadians being Evaluated for Transplant Study (FACETS) *[1]Dalhousie University, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada.*

Background: Frailty prevalence is higher in women, despite the observed protective effect of female sex on mortality in the general population. Understanding whether there are differences in perceived frailty by sex and the differential impact of frailty on outcomes for males versus females is crucial to avoid a sex disparity within the transplant assessment process.

Methods: We analyzed initial frailty assessments for patients enrolled in a multicenter prospective cohort study across 6 kidney transplant referral centers. Frailty was assessed using the Frailty Phenotype (FP; 3 of slowness, weight loss, low activity, exhaustion, and weakness), a Frailty Index (FI; including 37 variables across the domains of social function/cognition, function, mobility, and comorbidity), and the Clinical Frailty Scale (CFS, based on clinical judgement). Assessments were performed prior to or shortly after waitlisting. Prevalence of frailty as measured by the FP, FI, and CFS was reported. An unadjusted cox survival analysis (separately for males and females) was used to assess the effect of frailty on time to death or withdrawal from the waitlist among activated patients.

Results: A total of 767 unique patients had frailty assessments performed between 2016-2021. Patients were predominantly of male sex (64%), white race (82%) and had a mean age of 54+/-14. The prevalence of frailty for women was not significantly higher by the FP (16% vs 13%, p=0.15) or the FI (48% vs 46%, p=0.38), but was by the CFS (17% vs 12%, p=0.05). Among 325 activated patients, frailty by the CFS was significantly associated with death/withdrawal for men (HR 2.59; 95% CI 1.16-6.79) but not women (HR 1.41; 95% CI 0.48-4.18).

Conclusions: The prevalence of frailty was higher in females when measured by the CFS, but not by a transplant specific FI or the FP. Despite this, frailty was not significantly associated with mortality/withdrawal from the waitlist for female individuals, emphasizing the need to critically evaluate judgement based frailty assessments and their role in the transplant evaluation process.

PO1384

Changes in Cognition After Kidney Transplantation

Aditi Gupta,[1] Palash Sharma,[1] Rebecca J. Lepping,[1] Jonathan D. Mahnken,[1] William M. Brooks,[1] David K. Johnson,[2] Jeffrey M. Burns.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of California Davis, Davis, CA.*

Background: Longitudinal studies examining changes in cognition pre- to post-kidney transplantation (KT) are small, of short duration and do not include comprehensive neuropsychological (NP) testing or comparison with normative data.

Methods: We analysed pre- to post-KT cognition in 87 ESKD patients listed for KT and compared it to the National Alzheimer's Coordination Center (NACC) data. We used linear mixed models for longitudinal, repeated NP test measurements, adjusted for for age, practice effect, sex, race, transplant status, and level of education, and assessed cognition pre- to post-KT for our primary (Logical Memory I, II, and Digit Symbol tests) and secondary (Mini Mental State Exam (MMSE), Digit span, Category fluency for animals & vegetables, Trail making A & B) outcomes.

Results: Data from 87 ESKD patients (age 55.8±11.7 years) and 6974 controls (age 64.9±7.9 years) were analyzed. Pre-KT, ESKD patients had lower Logical Memory I & II, Digit Symbol, MMSE, Digit Span Backward, and Category Fluency of vegetables test scores (Table 1). There was no difference in scores of Digit Span forward, Category Fluency of animals, and Trail Making A & B between pre-KT ESKD patients and controls. Post-KT, Logical Memory I and II, and Category Fluency animals & vegetables improved, while Digit Symbol, MMSE, and Digit Span backward scores remained lower than controls (Table 1).

Conclusions: Not all cognitive abilities are affected in ESKD. While some test scores improve with KT, others do not. Further studies are needed to understand the mechanisms underlying cognitive impairment in ESKD and to explore interventions to mitigate them.

Funding: Other NIH Support - NIA

Patients Who Are Treated for Secondary Hyperparathyroidism Have a Lower Risk of Incident Dementia

JiYoon B. Ahn,[1] Aarti Mathur,[1] Dorry L. Segev,[1,2] Mara McAdams-DeMarco.[1,2] ERGOT *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Almost all patients with end-stage kidney disease (ESKD) have secondary hyperparathyroidism (SHPT). Elevated parathyroid hormone has been reported as a potential risk factor of cognitive impairment. We aimed to study whether the risk of dementia is improved when patients on dialysis receive treatment for SHPT.

Methods: Using data from the United States Renal Data System and Medicare claims, we studied older (aged≥66) ESKD patients without known pre-ESKD dementia who initiated maintenance dialysis in 2006-2016. SHPT treatment included vitamin D analogs, phosphate binders, cinacalcet or parathyroidectomy and was treated as a time-dependent treatments in the analysis. The study population was followed until transplant, death, end of Medicare coverage or administrative end date (12/31/2016), whichever came first. We used the Cox regression and adjusted for confounding using the inverse probability weighting method to examine the association of SHPT treatment and incident dementia.

Results: Of 189,433 ESRD patients, 65.1% received a treatment for SHPT during the study period. The rate of incident dementia was 11 per 100 person-years among patients with no SHPT treatment and 6 per 100 person-years among those with an SHPT treatment. Among patients on dialysis, the risk of incident dementia was lower after receiving treatment for SHPT compared with not receiving treatment for SHPT (adjusted hazard ratio=$_{0.60}0.62_{0.63}$) after adjusting for confounding.

Conclusions: Receiving treatment for SHPT was associated with a lower risk of incident dementia among older patients with ESKD. SHPT may need to be controlled among older ESKD patients considering the complications of SHPT including cognitive impairment and dementia.

Funding: NIDDK Support, Other NIH Support - NIAID, NIA

Table 1. Risk of incident dementia comparing patients with treatment for secondary hyperparathyroidism during dialysis with those without treatment among older end-stage kidney disease patients (n=189,433).

Kidney-Metabolic Risk Factors for Cognitive Impairment in Moderate CKD in the BRINK Study: Beyond eGFR and Albuminuria

Anne M. Murray,[1,2] David Tupper,[2,4] Cynthia S. Davey,[3] Ryan Mello,[2] Allyson Hart,[2] Kirsten L. Johansen.[2] *[1]The Berman Center for Outcomes and Clinical Research, Hennepin Healthcare Research Institute, Minneapolis, MN; [2]Hennepin Healthcare, Minneapolis, MN; [3]University of Minnesota Clinical and Translational Science Institute, Minneapolis, MN; [4]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Decreased kidney function is a risk factor for cognitive impairment (CI). We sought to identify kidney-metabolic biomarkers beyond eGFR and albuminuria associated with prevalent moderate to severe cognitive impairment (Mod/Sev CI) in a CKD cohort.

Methods: Community-dwelling non-dialysis participants aged ≥ 45 years with CKD (eGFR <60, in mL/min/1.73 m^2) were recruited from four health systems. We examined biomarkers including phosphorus, TNFαR1, PTH, calcium, total cholesterol, hemoglobin A1c%, bicarbonate (CO_2). A neuropsychological battery measured global and domain-specific cognitive performance. Logistic regression analyses estimated cross-sectional associations between kidney-metabolic measures and global and cognitive-domain-specific Mod/Sev CI at baseline, adjusted for eGFR, urinary albumin-creatinine ratio (UACR, in mg/g), demographics, and comorbid conditions.

Results: Among 436 CKD participants with mean age 70 years, 16% were Black, mean eGFR was 34 and median UACR. In adjusted models no kidney-metabolic biomarkers were significantly associated with global Mod/Sev CI. However, in cognitive-domain-specific analyses, low bicarbonate (CO_2 <20 mEq/L) was significantly associated with Mod/Sev impairment in memory [OR (95%CI): 3.04 (1.09, 8.47) P=0.03)] and with language [3.82 (1.12, 13.0; P=0.03). In addition, lower total cholesterol was associated with impaired executive function [1.12 per -10mg/dL (1.02, 1.23; P=0.02].

Conclusions: Low bicarbonate (acidosis) and lower cholesterol levels in older patients with CKD may be modifiable kidney-metabolic risk factors for Mod/Sev domain-specific CI in CKD. Longitudinal analyses are needed to determine whether low bicarbonate and low cholesterol are associated with cognitive decline.

PO1387

Targeting Sedentary Behavior in Older Adults: Subgroup Analysis of a Randomized Clinical Trial

Nikita Abraham,[1] Robert E. Boucher,[1] Guo Wei,[1] Jesse Christensen,[3,1] Sydney E. Hartsell,[1] Judy Carle,[1] Victoria Gonce,[1] Mark A. Supiano,[1] Kate Lyden,[2] Srinivasan Beddhu.[1,3] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]University of Massachusetts Amherst, Amherst, MA; [3]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Sedentary behavior (spending most of the awake hours in sitting/lying posture) is associated with increased mortality in CKD but few studies have examined the feasibility of interventions targeting sedentary behavior in older adults with CKD.

Methods: The Sit Less, Interact, Move More (SLIMM) Study was a 24-week RCT of an intervention to reduce sedenary duration with stepping duration in participants with CKD. Physical activity was measured using a mid-thigh accelerometer worn for 7 days before baseline and q4 weeks in standard of care (SOC) group (N=52) and baseline and q8 weeks in SLIMM group (N=54). Based on the accelerometry data, SLIMM group was provided instructions on reducing sedentary duration. In this post-hoc analyses, we used mixed effect models to compare the effects of the SLIMM intervention in participants age ≥ 70 (N =59) versus age < 70 (N=47).

Results: Age ≥ 70 group compared to age < 70 group had a higher % of Whites and lower % of stage3b-5 CKD (Table 1). While sedentary duration was similar, the older group had lower stepping duration, gait speed and 6-min walk distance (Table 1). In mixed models, there were no significant differences between SLIMM and SOC groups for sedentary (1, 95% CI -39 to 42 min/d) and stepping (-4, 95% CI -18 to 11 min/d) durations and the number of steps/day (-424, 95% CI -1669 to 820) in the age < 70 group. The corresponding numbers for the age ≥ 70 group for sedentary and stepping durations and the number of steps/d were -28, (95% CI -61 to 5 min/d), 13, (95% CI 1 to 24 min/d) and 1330, (95% CI 322 to 2338 min/d), respectively.

Conclusions: It is feasible to decrease sedenaray behavior In older adults with CKD.

Association of CKD Stages with Frailty Worsening or Death in Community-Dwelling Older Adults

Nina Mielke,[1] Alice Schneider,[1] Natalie Ebert,[1] Markus van der Giet,[1] Doerte Huscher,[1] Martin K. Kuhlmann,[2] Elke Schaeffner.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Vivantes Klinikum im Friedrichshain, Berlin, Germany.*

Background: Albumin-creatinine-ratio (ACR) and glomerular filtration rate (GFR) have been associated with prevalent and incident frailty. We analyzed the association of the KDIGO CKD stages and frailty status worsening or death in data of the Berlin Initiative Study (BIS).

Methods: Prospective population-based cohort study interviewing participants biannually with a standardized questionnaire. Frailty assessment according to Fried took place at the 3rd and 4th follow-up. Frailty worsening was defined as the transition within a two-year period from robust to prefrail or frail, or from prefrail to frail. Partial proportional odds regression analysis was used to analyze the association between KDIGO CKD stages and the ordinal outcome of no worsening, frailty worsening, or death.

Results: Of 1076 participants with 46% male and mean age 84.3 years, initially 48% were prefrail and 32% frail. After 2.1 (2.0-2.3) years of follow-up 188 (17.5%) had worsened and 111 (10.3%) died. Participants who died were older (88 vs. 83 yrs), were less physically active, had less muscle mass (calve circumference <31: 10% vs. 5%), and were more likely to be cognitively impaired; 92% had a GFR <60 mL/min/1.73m^2 and 59% had an ACR ≥30 mg/g compared to 72% and 24% in participants who did not worsen, respectively. Baseline characteristics of participants who worsened were similar to participants who did not worsen. In the multivariable[1] model participants in CKD stages G1,2/A2,3 and G3/A1 or higher had about 2-fold higher odds of frailty worsening than in CKD stages G1,2/A1. The odds for death increased remarkably with both higher CKD stage and increasing albuminuria. Wide confidence intervals are likely due to limited sample size/events. Additional adjustment for frailty baseline status did not alter the results.

Conclusions: In older adults, advanced CKD stages but also albuminuria independent of GFR were associated with 2-fold higher odds of frailty worsening independent of death.

Role of Klotho in Aging, Relationship with Frailty, Renal Function, and Body Composition

Paolo Betti, Marta De Filippo, Marco Simonini, Simone Fontana, Lorena Citterio, Elisabetta Messaggio, Patrizia Rovere Querini, Elena Brioni, Cristiano Magnaghi, Chiara Lanzani, Paolo Manunta. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Reduced expression of the Klotho protein has been associated with premature aging and increased mortality. Our aim is to evaluate the relationships between plasma Klotho levels and frailty, renal function and anthropometric parameters.

Methods: We enrolled a cohort of 1250 volunteers aged > 65 years (FRASNET Study) in recreation centers for the elderly, in hospital's outpatient clinic and in nursing homes. All the volunteers have signed informed consent and subjects with severe cognitive impairment were excluded (MMSE >18). We measured eGFR (CKD-EPI formula) and body composition by impedancemetry. Plasma Klotho was assayed by an ELISA kit on 194 samples. Frailty was classified according to Fried's criteria.

Results: A positive correlation between plasma Klotho and renal function (eGFR) was detected (fig 1). In agreement with what previously observed, in a younger population, we confirmed a reduction of klothemia in the sarcopenic patients (713 vs 791 pg/mL, p=0.0007 in patients with muscle mass <25th centile) and in patients with high visceral fat mass (fig.2). On the other hand, we did not observe different levels of plasma Klotho according to the frailty class or in relation to age.

Conclusions: In our elderly population, the plasma levels of Klotho do not correlate with age. Therefore, our results confirm the relevance of this biomarker in identifying pathological aging, in consideration of its association within the elderly population with CKD, abdominal obesity and sarcopenia (sarcopenic obesity). Klotho expression was demonstrated as an independent predictor of death in a follow up-study and was related to many diseases (e.g.: cognitive impairment, cardiovascular disease). The relation of plasma klotho levels and renal function is debated, and conflicting results have been published. Our findings evidenced a significative association of plasma Klotho with renal function and body composition.

Shrunken Pore Syndrome: Prevalence and Association with Mortality in a Population-Based Cohort of Elderly Women

Linnea Malmgren,[1,2] Fiona Mcguigan,[1] Anders Christensson,[1,2] Kristina Åkesson.[1,2] *[1]Lunds Universitet, Lund, Sweden; [2]Skanes universitetssjukhus Malmo, Malmo, Sweden.*

Background: Decreased kidney function results in lower clearance and increased plasma concentration of a GFR marker. So far creatinine has been the commonly used GFR marker but cystatin C becomes more common. Shrunken pore syndrome (SPS) is a recently identified kidney syndrome characterized by disturbed filtration of mid-sized molecules (5-30 kDa) compared to smaller ones (<0.9 kDa) (Fig1). Resulting in increased plasma levels of cystatin C (cysC) compared to creatinine. SPS is associated with increased risk of cardiovascular disease (CVD) and increased mortality risk. So far few data are available about SPS in population-based cohorts.

Methods: 75-yr old **women** (n=849) from the population-based Osteoporosis Prospective Risk Assessment (OPRA-) cohort, with follow-up after 5yr and 10yr were studied. eGFR was calculated with the CKD-EPI equation. SPS was defined as $eGFR_{cysC}$/$eGFR_{crea}$ ratio <0.6 and mortality risk (HR [95% CI]) estimated. Women with sarcopenia or on glucocorticoids were excluded.

Results: Almost 1 in 10 women (9%) had SPS at age 75 but at age 80 the majority of these women had increased their $eGFR_{cysC}$/$eGFR_{crea}$ ratio >0.6 (range from 0.6-1.0). Women with SPS had higher 10-yr mortality risk compared with ratios >0.9 (HR_{adj} 1.7 [95% CI, 1.1-2.6]). Table 1.

Conclusions: SPS defined as $eGFR_{cysC}$/$eGFR_{crea}$ ratio <0.6 is common in elderly women and associated with increased mortality. While longitudinal data indicate that the state may be reversible. Our results also confirm other studies and suggest that SPS may be a clinically applicable tool to assess mortality risk in the elderly.

Funding: Private Foundation Support, Government Support - Non-U.S.

Molecular Changes Associated with Type IV Collagen Switching in 1-Day-Old Alport Murine Glomeruli

Akanchaya Rana,[1,3] Sofia Farkona,[1,2] James W. Scholey,[1,2] Ana Konvalinka,[1,2] Moumita Barua.[1,2] *[1]Toronto General Research Institute, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]Institute of Medical Science, University of Toronto, Toronto, ON, Canada.*

Background: Alport syndrome (AS) is an inherited disorder caused by pathogenic variants in *COL4A3*, *COL4A4* or *COL4A5*, which encodes proteins that comprise basement membranes of the ear, eye and kidney glomerulus. Type IV collagen chains assemble as heterotrimers and during glomerular development, α1α2α1 (IV) is replaced by α3α4α5 (IV) within the developing glomerular basement membrane (GBM). This "switching" defines the starting point of disease in AS. We aimed to identify the molecular changes at the time of disease initiation in the developing glomeruli of Alport murine kidneys.

Methods: Immunofluorescence (IF) staining was done to identify the GBM distribution of type IV collagen chains in 1 day old *COL4A3* knockout (KO) and wildtype (WT) mice. Urine albumin to creatinine ratio (uACR) was also measured. Subsequently, glomeruli from 1 day old (P1) *COL4A3* KO and WT mice were isolated by cardiac injection of magnetic dynabeads that embolized to glomerular capillaries enabling their extraction from surrounding tissue. Protein was isolated and subjected to liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) analysis.

Results: IF localized type IV collagen α1 in the GBM, Bowman's capsule and mesangial matrix in both P1 KO and WT mice. Type IV collagen α5 was present in short segments of some developing GBM in P1 WT but was absent in KO mice indicating switching. uACR was increased in P1 KO (423.61±396.13 mg/mmol) compared to WT (128.67±69.86 mg/mmol) with a *p*-value of 0.02. LC-MS/MS identified >4300 proteins from glomerular isolates. In males, 2 and 15 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. In females, 543 and 978 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. Pathway analysis revealed alteration in collagen metabolic process, collagen biosynthesis, collagen formation and extracellular matrix organization.

Conclusions: Increased uACR in P1 KO mice showed disease onset at the time of type IV collagen switching. LC-MS/MS analysis revealed dysregulation of matrix turnover pathways in P1 KO mice, identifying potential molecular targets.

PTEN-Induced Kinase 1 Has Association with Renal Aging in the Context of Inflammatory Response

Hyeyun Jeong, Ha Min Heui, Min ji Sung, Yu ho Lee, Hyun-Ju An, Song Hee Lim, So-young Lee. *CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: Among several changes of aging-related human organ system, functional and structural deterioration of kidney is the most dramatic phenomenon, and the role of mitophagy has recently considered important in pro-aging process in CKD patients. PTEN-induced kinase 1 (PINK1), known to be associated with age-related diseases regulates mitochondrial dysfunction. To enhance understanding the function of PINK-1 on aging, we compared whole-kidney RNA sequencing between naturally aging mice (24-month-old) and PINK1 knock out aging mice.

Methods: Kyoto Encyclopedia of Genes and Genomes pathway analysis and gene ontology analysis were performed for gene expression analysis. To investigate the role of PINK1 on aging, we used Pink1-deficient mice and PINK1-overexpressing HKC8.

Results: Compared to naturally aging kidneys, PINK1 knock out aging mice showed prominent expression of the genes related to cytokines, immune system response, and inflammation (Fig 1). We also investigated the function of PINK1 on PINK1 (-/-) aging mice. PINK1 deficiency showed aggravated tubulointerstitial fibrosis on PAS staining (Fig2A), and the Urinary Albumin-Creatinine Ratio increased more prominently according to aging in PINK1 (-/-) mice (Fig2B). The Quantitative PCR analysis validated that the expression of genes associated with aging, fibrosis, and inflammation increased in PINK1 (-/-) mice compared to age-matched controls (Fig2C). Under treatment with H2O2, the expression of aging and pro-inflammatory marker decreased in PINK1-overexpressing HKC8 compared to naturally aging mice (Fig2D).

Conclusions: In conclusion, our results suggest that PINK1 deficiency contributes to renal aging process via proinflammatory change in the kidney.

TGF-β1/Smad Signaling in Glomerulonephritis and Its Association with Progression to CKD

Aglaia Chalkia,[1] Harikleia Gakiopoulou,[2] Panagiota E. Giannou,[1] Zoe Alexakou,[1] Athanasia Kapota,[1] Dimitris Kourniotis,[1] Dimitrios I. Petras.[1] *[1]Nephrology Department, Hippokration General Hospital, Athens, Greece; [2]1st Department of Pathology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.*

Background: Transforming growth factor-β1 (TGF-β1) is a multifunctional cytokine, with diverse roles in fibrosis and inflammation, which acts through Smad signaling in renal pathology. We intended to investigate the expression of TGF-β/Smad signaling in glomerulonephritis (GN) and to assess its role as risk factor for progression to chronic kidney disease (CKD).

Methods: We evaluated the immunohistochemical expression of TGF-β1, phosphorylated Smad3 (pSmad3) and Smad7 semi-quantitatively and quantitatively (computerized image analysis program has also been used) in different compartments of 50 renal biopsies with GN and the results were statistically analyzed with clinicopathological parameters. We also examined the associations among their expressions, the impact of their co-expression, and their role in progression to CKD.

Results: TGF-β1 expression correlated positively with segmental glomerulosclerosis (**p=0.025**) and creatinine level at diagnosis (**p=0.002**), while pSmad3 expression with interstitial inflammation (**p=0.024**). In glomerulus, concomitant expressions of high Smad7 and medium pSmad3 were observed to be correlated with renal inflammation, such as cellular crescent (**p=0.011**), intense interstitial inflammation (**p=0.029**) and lower serum complement 3 (**p=0.028**) and complement 4 (**p=0.029**). We also reported a significant association between pSmad3 expression in glomerular endothelial cells of proliferative GN (**p=0.045**) and in podocytes of non-proliferative GN (**p=0.005**). Finally, on multivariate Cox-regression analysis, TGF-β1 expression (**HR= 6.078; 95% CI 1.168-31.627; p=0.032**) was emerged as independent predictor for CKD.

Conclusions: TGF-β1/Smad signaling is upregulated with specific characteristics in different forms of GN. TGF-β1 expression is indicated as independent risk factor for progression to CKD, while specific co-expression pattern of pSmad3 and Smad7 in glomerulus is correlated with renal inflammation.

PO1394

ANCA Negative Medullary Angiitis

Tarun Kapoor, Daniel Birchmore, Mark Lusco, Juan Pablo Arroyo Ornelas, Gautam B. Bhave. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Medullary angiitis is a rare cause of renal failure. Most cases of medullary angiitis are found to be ANCA positive. We present a rare case of ANCA negative medullary angiitis with no identifiable secondary causes.

Case Description: A 55-year-old male with a medical history significant for uncontrolled diabetes complicated by retinopathy, Chronic kidney disease, HTN, and compensated cirrhosis of unclear etiology, presented to the hospital with shortness of breath and lower extremity edema. Initial workup revealed a creatinine of 7.6 (baseline creatinine 1.5 eighteen months earlier), and significant proteinuria estimated at 8.4g/day along with a urinalysis showing 3 RBC/high power field and 6 WBC/high power field. Serological workup including Hepatitis B/C, HIV, SPEP, serum free light chains, C3/C4, ANA, ANCA was negative. He underwent a renal biopsy revealing medullary angiitis with multifocal medullary hemorrhage with perivascular PMNs and eosinophils along with findings of long-standing diabetes and HTN. In the absence of IgA deposits, infection, or offending drugs, he was started on high steroids and treated similarly to ANCA positive medullary angiitis. His creatinine during the hospitalization peaked at 8.69 before and fell to 7.6 at discharge. He was continued to oral prednisone at discharge. Outpatient follow-up showed a decrease in Cr to 5.8 before slowing climbing back up to 8.5. He is currently maintained on an immunosuppressive regimen to help delay the initiation of renal replacement therapy.

Discussion: Medullary angiitis is a rare renal disorder that has largely been associated with ANCA positivity. ANCA negative medullary angiitis has been documented in the literature with a recent case series showing IgA nephropathy and recent antibiotics use to be the most common etiologies. This is one of the first case reports of ANCA negative medullary angiitis not associated with IgA nephropathy and recent antibiotic use. Currently, we have no standardized treatment options available for these patients. Given the rapid progression of the renal dysfunction, we decided to start our patient on high-dose steroids. Our patient had an initial improvement in his renal function with subsequent decline. However, treatment may have afforded time for AVF creation and patient education before the initiation of hemodialysis, which was the main goal of therapy.

PO1395

Calorie Restriction Ameliorates Obesity-Related Glomerulopathy in Adult Zebrafish

Evan Zeitler, J. Charles Jennette, Jennifer E. Flythe, Ronald J. Falk, John S. Poulton. *UNC Kidney Center, Chapel Hill, NC.*

Background: Obesity is a risk factor for chronic kidney disease. The mechanisms by which obesity results in kidney disease are understudied. Zebrafish are an attractive model animal for studying obesity due to their conserved biology and amenability to genetic screening. The effects of obesity on kidney function in zebrafish have not been reported.

Methods: Zebrafish were fed high-calorie and high-fat diets for 8 weeks. Kidneys were evaluated by light and electron microscopy, and the glomerular filtration barrier was assessed by fluorescent dextran permeability. We also tested the ability of calorie restriction to reverse obesity-related defects.

Results: Fish fed a high calorie diet developed glomerulomegaly, foot process effacement, GBM thickening, tubular enlargement (Figure 1) and ectopic lipid deposition after 8 weeks. High calorie feeding resulted in filtration barrier dysfunction. The observed effects resolved after 4 weeks of calorie restriction (Figure 2).

Conclusions: Our study reveals that obese zebrafish recapitulate key aspects of human pathology, and these defects can be reversed with calorie restriction. These findings establish zebrafish as a potential model for the study of obesity-related kidney disease.

Different Patterns of Renal Fibrosis Are Indicative of Independent Fibrogenic Causes in ANCA-Associated Glomerulonephritis

Samy Hakroush,[1] Michael Zeisberg,[2] Bjoern Tampe.[2] *[1]Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany; [2]Department of Nephrology and Rheumatology, University Medical Center Göttingen, Göttingen, Germany*.

Background: Renal fibrosis is a common manifestation and hallmark of a wide variety of chronic kidney diseases (CKD) appearing in different morphological patterns, suggesting different pathogenic causes or consequences. Renal fibrosis with focal injury usually presents with patchy fibrosis whereas diseases affecting renal parenchyma in a diffuse manner lead to a more diffuse fibrotic pattern. In the present study, we aimed to analyze renal fibrotic patters in association with the renal lesions which are considered to directly contribute to renal fibrogenesis in a cross-sectional study.

Methods: A total number of 112 renal biopsies with various renal pathologies including acute interstitial nephritis (AIN), ANCA-associated vasculitis (AAV), membranous GN, lupus nephritis, nephropathy due to hypertension, IgA nephropathy (IgAN), focal-segmental glomerulosclerosis (FSGS) and diabetic kidney disease (DKD) were retrospectively included between 2015 till 2020 in a cross-sectional study.

Results: We here provide evidence that tubulointerstitial fibrosis is either the consequence of nephron damage (dependent or independent of glomerular scaring) or the result of a primary interstitial injury (leading to a diffuse fibrotic interstitial remodeling). Our data also show that focal fibrosis correlated with glomerular damage and irreversible injury to nephrons, confirmed in experimental models of nephrotoxic serum-nephritis and folic acid nephropathy in mice. By contrast, diffuse fibrosis was specifically associated with interstitial inflammation independent of glomerular damage and nephron loss, confirmed in mice challenged with unilateral ureteral obstruction.

Conclusions: In conclusion, we here provide evidence that the majority of renal fibrosis seems to be the consequence of nephron loss and replacement scaring, representing incomplete tissue repair. By contrast diffuse fibrosis appears to be the result of primary interstitial inflammation and injury.

PO1397

Automatic Artificial Intelligence-Assisted Glomerulosclerosis Analysis in Mice Models with Glomerulopathy

Thomas Secher, Casper G. Salinas, Michael Christensen, Niels Vrang, Mette V. Østergaard. *Gubra, Hørsholm, Denmark.*

Background: Glomerulosclerosis (GS) is a hall mark pathological feature in glomerular diseases. In preclinical research, GS is recapitulated in a number of experimental mice models with glomerulopathy, and a cross model characterization of GS would add to our understanding of their translatability to human disease. Here, we report GS quantification using an objective and newly developed automated AI assisted image analysis strategy in three mice models with glomerulopathy.

Methods: AI-assisted GS scoring was performed in three mice models with glomerulopathy and to assess drug treatment effects: 1) Diabetic nephropathy in reninAAV-induced hypertensive uninephrectomized db/db mice (DN/HT). Mice received treatment with vehicle, lisinopril, empagliflozin or combination. 2) I.V. injection of nephrotoxic anti-GBM serum (NTS) and 3) Adriamycin (ADR) in healthy mice. Automatic AI-assisted GS scoring was performed as a two-step process on PAS stained kidney sections. Firstly, segmentation of all glomeruli and next, assignment of a GS score to each glomerulus using trained neutral networks. GS was classified on a five-point scale (GS0-GS4) according to the area of capillary tuft involvement.

Results: The automated AI-assisted scoring performed with high degree of accuracy and allowed for a large number of glomeruli to be evaluated pr. section (>100). We show that the mice models had very distinct GS profiles. The DN/HT model was most severely affected with highest average GS score (DN/HT: 2.5, NTS: 1.76, ADR: 0.68, control: 0.1) and the largest percentage of severely affect glomeruli, GS3+GS4 (DN/HT: 54.1%, NTS: 37.2%, ADR: 16.8%, control: 1.1%). The ADR model was the least affected and

NTS was intermediate. AI-assisted scoring was further validated by evaluating the effect of standard of care compounds in the DN/HT model. LIS and the combination treatment with EMPA significantly reduced the average GS score (LIS: 2.1, LIS+EMPA: 1.7).

Conclusions: We here demonstrate an automatic AI-assisted image analysis approach for obtaining GS scores in three mouse models with glomerulopathy, and we show that the models display very distinct GS profiles. An AI-assisted approach allows for rapid and reproducible quantification of GS and, as a tool, could help advance future research.

Increased Glomerular Parietal Epithelial Cell Expression of Cathepsins C and B in Anti-Thy1.1 Mouse Model of FSGS

Michael Merchant,[1] Michelle T. Barati,[1] Kenneth R. McLeish,[1] Jon B. Klein,[1,2] Bart Smeets.[3] *[1]University of Louisville School of Medicine, Louisville, KY; [2]VA Robley Rex Medical Center, Louisville, KY; [3]Radboudumc, Nijmegen, Netherlands.*

Background: Focal segmental glomerulosclerosis (FSGS) is characterized by replacement of glomerular capillaries by extracellular matrix (ECM). The collapsing FSGS (cFSGS) variant exhibits a poor prognosis and response to therapy. We recently reported that activated PECs migrate into glomerular tufts in human cFSGS and demonstrate increased cathepsins C and B expression. The absence of cathepsins B and C within normal glomerular tufts suggests these proteases may represent novel mediators of PEC-mediated glomerulosclerosis leading to collapse. We addressed the hypothesis that activated PECs migrate expressing cathepsins C and B migrate into glomerular PECs in a mouse model of cFSGS

Methods: Thy1.1 transgenic mice were injected with either saline (vehicle control) or anti-Thy1.1 antibody (19XE5; 1mg/mouse) to induce FSGS. Mice were sacrificed 4, 7, and 21 days after injection. Kidney sections were subjected to immunofluorescence staining for claudin-1, a marker of PECs, and cathepsin C or cathepsin B. Images were acquired by confocal microscopy.

Results: Claudin-1, cathepsin C, and cathepsin B co-localized to glomerular parietal epithelial cells lining Bowman's capsule in vehicle control mice. On day 4 after anti-Thy1.1 administration, claudin-1 staining showed migration of PECs into glomerular tufts in more than half of the glomeruli. Both cathepsin B and C staining co-localized to claudin-1 positive cells within glomerular tufts. PECs in the Bowman's capsule with hypertrophied morphology, suggesting activation, demonstrated increased expression of cathepsins C and B. Claudin-1 and cathepsins B and C co-localized within glomeruli on days 7 and 21 after anti-Thy1.1 administration, however, the number of stained cells per glomerulus and the percent glomeruli with positively stained cells in the glomerular tuft appeared decreased.

Conclusions: Glomerular PECs migrate into glomerular tufts and show increased expression of cathepsins C and B in the anti-thy1.1 model of cFSGS, recapitulating our findings in human cFSGS biopsies. The Thy1.1 mouse model of cFSGS can be used to define the role of PEC expression of cathepsins B and C in the pathogenesis of human cFSGS.

Effects of Enzymatic Cross-Linking and Increased Stiffness on Glomerular Basement Membrane and Podocyte Function

Dan Wang,[1] Nicholas J. Ferrell.[2,1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: The Glomerular basement membrane (GBM) is a critical component of the glomerular filtration barrier. Stiffening of the extracellular matrix is an important regulator of cellular function. How GBM stiffening affects podocyte function is not fully understood. This work aims to investigate the effect of GBM stiffening on molecular permeability and the podocyte function using a biomimetic in vitro model directly derived from kidney glomeruli.

Methods: Decellularized glomeruli isolated from porcine kidneys were pressure compacted on a Transwell membrane. GBM stiffness was tuned by crosslinking with transglutaminase (TG). The stiffness of the TG-crosslinked decellularized glomeruli was evaluated using a custom cantilever-based compression system Podocytes cultured on the TG crosslinked GBM were immunofluorescence stained with YAP, phalloidin and the nuclei were counterstained with DAPI. The diffusional molecular permeability was evaluated on native and TG crosslinked GBM with and without podocytes using FITC-Ficoll and AF488-BSA. Effects of GBM stiffening on gene expression of markers of podocyte differentation (NEPH1, WT1, Synaptopodin) were screened by qPCR.

Results: The stiffness of the decellularized glomeruli showed a dose-dependent increase after incubating with TG for 1 day and 4 days. On stiffer GBM, immunofluorescence imaging showed translocation of YAP to the podocyte nucleus. Passive molecular permeability of GBM was similar for native the TG crosslinked GBM. Podocytes cultured on both native and TG crosslinked GBM forms a stringent barrier to large molecules. qPCR results show an upregulation of differentiation markers as podocytes cultured on native and TG crosslinked GBM.

Conclusions: We developed a biomimetic in vitro model that fabricated directly from kidney tissue. mTG crosslinked glomeruli show a dose-dependent increase of stiffness. TG did not significantly effect the diffusive permeabilty of the GBM. GBM stiffness affects the YAP localization in the podocytes. The current in vitro model upregulates the gene expression of podocyte markers.

Effect of ANG-3070 in the Unilateral Ureteral Obstruction Mouse Model of Renal Fibrosis

Bert Oehlen, Jingsong Li, Kai Jiang, Latha Paka, Prakash Narayan, Itzhak D. Goldberg. *Angion Biomedica Corp, Uniondale, NY.*

Background: Tubulointerstitial inflammation and fibrosis are strong predictors of progression in all kidney diseases regardless of etiology. Receptor tyrosine kinases such as platelet-derived growth factor receptor (PDGFR) and discoidin domain receptors (DDRs), contribute to renal inflammation and fibrosis. ANG-3070 is an inhibitor of multiple tyrosine kinases receptors including PDGFR and DDR. This study evaluated whether ANG-3070 can slow the progression of fibrosis in the unilateral ureteral obstruction (UUO) mouse model of renal fibrosis.

Methods: Male mice were subjected to UUO and randomized to daily oral treatment with vehicle (n=15) or 100 mg/kg of ANG-3070 (n=15) for 10 days after UUO and then sacrificed. Control male animals were age-matched and were not subjected to UUO (n=10). At sacrifice, obstructed and control kidneys were collected and processed for renal damage by hematoxylin-eosin (H&E) staining and scoring (0-8, 0 no damage and 8 damage to >80% of kidney) by blinded observers. Collagen deposition and myofibroblast transformation was determined by quantitative image analysis of picrosirius red (PSR)-stained slides and slides stained for α-smooth muscle cell actin (αSMA), respectively.

Results: Animals treated with ANG-3070 had a statistically significant reduction in histological damage as compared to vehicle (Vehicle, 6.4 vs ANG-3070, 4.3; p-value <0.001) and the histological markers of fibrosis, PSR (% control, vehicle, 1458% vs. ANG-3070, 503%; p-value <0.001), and αSMA (% control, vehicle, 511% vs. ANG-3070, 248%; p-value <0.01) as shown in Figure 1.

Conclusions: Daily oral administration of 100 mg/kg ANG-3070 reduces renal damage and renal fibrosis in a mouse model of renal fibrosis induced by UUO.

Renal Outcome Using New Chronicity Scoring System in IgA Nephropathy: Nationwide Study in Korea

Donghyuk Kang,[1] Tae Hyun Ban,[2] Hyung Duk Kim,[1] Bumsoon Choi.[2] KOGNET group *[1]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [2]Catholic University of Korea Eunpyeong St Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea.*

Background: Many new grading systems of glomerulonephritis were proposed, recently. In 2019, new suggestion about standardized classification and reporting of GN is proposed by Mayo Clinic/Renal pathology society. Among the part of this new suggestion, grading the chronicity is an extremely important step and simple scoring system for chronic changes was devised. Therefore, the purpose of this study is predicting renal outcome with new chronicity grading system in IgA nephropathy (IgAN) patients.

Methods: 4,505 IgAN patients were enrolled from Korean GlomeruloNephritis Study Group (KoGNET) registry. Validation of Oxford classification, chronicity index with renal survival (End stage renal disease (ESRD), eGFR decrease rate of 50%, rate of renal function decline) were evaluated, followed by subgroup analysis according to chronic kidney disease (CKD) stages. Additional analysis between immunosuppressive therapy (IST) and chronicity index was performed, that chronicity index might help deciding initiation of IST.

Results: In validation of Oxford classification, both S and T scores were significantly associated with renal outcomes, but M and C scores were not. Multivariate linear regression analysis showed chronicity index was significantly associated with renal outcomes (P<0.05 for all). The severity of chronicity index was well correlated with renal outcomes in multivariate Cox regression analysis: minimal vs mild (HR, 1.95; 95% CI, 1.15 to 3.32; P=0.014), minimal vs moderate (HR, 2.98; 95% CI, 1.66 to 5.34; P<0.001), minimal vs severe (HR, 4.08; 95% CI, 2.27 to 7.35; P<0.001). Hypertension, eGFR, proteinuria and serum uric acid were also well correlated. In subgroup analysis,

chronicity index was still most powerful risk factor (P<0.05 for all) and they showed similar results to whole CKD stages. There was insufficient evidence to initiate IST according to chronicity index.

Conclusions: Among the known prognostic factors of IgAN, pathologic features were relatively abstract compared to other prognostic factors. But the chronicity index, presented as a simple integrated numeric scale, which is independently associated with renal outcome in IgAN, is more easily applicable in estimating renal outcome of IgAN patients.

PO1402

Comparison of Glomerular Proteomics Profiles of Healthy Human Kidney and Minimal Change Disease Identifies Distinct Targets and Pathways

Salem Almaani, Sethu M. Madhavan, John P. Shapiro, Anjali A. Satoskar, Isabelle Ayoub, Brad H. Rovin, Samir V. Parikh. *The Ohio State University, Columbus, OH.*

Background: Minimal change disease (MCD) is a common cause of idiopathic nephrotic syndrome and is characterized by diffuse podocyte foot process effacement. The pathogenesis of MCD remains unclear. We hypothesized that proteomics analysis of glomeruli could identify molecular markers that reflect the pathogenesis of MCD.

Methods: We included formalin-fixed paraffin-embedded kidney biopsies from patients with steroid-sensitive MCD (n=9) and normal donor kidneys (n=4). Glomeruli were isolated using laser capture microdissection and HPLC MS/MS was done using Orbitrap eclipse mass spectrometer. After data normalization, groups were clustered using principal component analysis (PCA) and compared by paired *t-tests*.

Results: PCA showed separate clustering of healthy glomeruli and MCD samples (**Figure 1**). Out of the 6729 unique proteins identified in MCD glomeruli, 1088 proteins were significantly differentially expressed compared to controls. Pathway analysis showed upregulation of complement pathway components (C1R, C1S, C1QA, C2, C3, C4A, C4B, C5, C7, C8B, C9) and downregulation of carbohydrate and amino acid metabolic pathway enzymes (FBP1, FBP2, ALDOC, ALDOB, AKR1A1, ALDH4A1, ALDH5A1, ACAT1). MCD glomeruli showed a significant reduction in expression of ECM proteins FREM2, FRAS1, CDHR2. Surprisingly, the expression of podocyte slit diaphragm-associated proteins (SYNPO, NPHS2, CD2AP) was not significantly altered in MCD compared to controls. We did not observe differential expression of MCD associated proteins, KANK, CFL1, CMIP. No peptides from SMPDL3b or ANGPTL4 were identified in MCD glomeruli.

Conclusions: Glomeruli from MCD showed differential proteomic signature compared to healthy human glomeruli. Activation of innate immune pathways including the complement system and loss of extracellular matrix and basement membrane-specific components in glomeruli of MCD are novel observations. The role of these markers in the pathogenesis of MCD needs to be investigated.

PO1403

Effects of ANG-3070 in a Mouse Model of Alport Syndrome

Latha Paka, Natalia Prakash, Kai Jiang, Prakash Narayan, Itzhak D. Goldberg. *Angion Biomedica Corp, Uniondale, NY.*

Background: Alport syndrome (AS) is a hereditary kidney disease that presents in childhood and progresses to end stage kidney disease (ESKD) in adolescence. There are no approved therapies. AS is caused by mutations in type IV collagen genes Col4a3, a4 or a5, that result in reduced structural integrity of the glomerular basement membrane, triggering activation of fibrogenic cytokines, including platelet derived growth factor (PDGF) and transforming growth factor beta (TGFβ1) causing proteinuric disease and fibrosis. We hypothesize that an antifibrotic therapy may decrease proteinuria-induced fibrosis, and evaluated ANG-3070, a novel tyrosine kinase inhibitor, in a Col4a3 knockout mouse model of AS.

Methods: After confirming the Col4a3 mutation by genotyping, 4-week-old male and female Alport mice were randomized to Vehicle (oral, twice-daily) or ANG-3070 (oral, 25 mg/kg, twice-daily) for 5 weeks (n=12/ group). Age-matched, wild-type mice were included (n=9) as a control. Animals were sacrificed after 5 weeks of treatment, after collecting spot urines to measure protein to creatinine ratio (PCR). Renal tissue was analyzed for hydroxyproline (HYP) content, by Western blot for tissue fibrotic markers, and for histopathology using hematoxylin-eosin (H&E) staining for renal damage score and picrosirius red (PSR) staining for fibrosis. All histological analyses were performed blindly by two independent observers using a 0-4 scale (0 being normal, 4 ≥ 75% injured or stained).

Results: ANG-3070 treatment reduced mortality (survivors; Vehicle: 8/12 vs ANG-3070: 12/12). In surviving mice, proteinuria was reduced (mg/ml; Vehicle 6.2 vs ANG-3070 3.1; p<0.05) along with PCR (mg/mg; Vehicle 11.1 vs ANG-3070 5.5; p<0.05). There was a reduction in renal damage (Vehicle: 2.6 vs ANG-3070: 1.2; p = 0.002) along with renal fibrosis (Vehicle 2.4 vs ANG-3070 1.2; p=0.001). When kidney lysates were evaluated, HYP content was reduced (μg/kidney; Vehicle, 132 vs ANG-3070, 57; p <0.002) along with fibrotic markers of collagen-1, TGFβ1, and α smooth muscle actin (αSMA) compared to Vehicle-treated Alport mice (p<0.05). Additionally, PDGFR expression was reduced (p<0.05).

Conclusions: Treatment with a novel tyrosine kinase inhibitor, ANG-3070, was efficacious in AS mice compared to Vehicle. ANG-3070 may represent a novel therapeutic for AS.

PO1404

Mesangial-Cell Activation by Circulating Immune Complexes Consisting of Galactose-Deficient IgA1 and IgG Autoantibodies from Patients with IgA Nephropathy

Zhi qiang Huang,[1] Xianwen Zhang,[2] Stacy D. Hall,[1] Lin Wang,[2] Yiping Chen,[2] Bruce A. Julian,[1] Jan Novak.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Long Hua Hospital, Shanghai, China.*

Background: We and others have shown that immune complexes from the circulation of patients with IgA nephropathy (IgAN) that contain galactose-deficient IgA1 (Gd-IgA1) can induce proliferation of mesangial cells (MC) in culture. Here, we assessed cellular responses and signal transduction in MC after stimulation with CIC.

Methods: Quiescent primary human MC were stimulated for 15 min at 37°C, with or without inhibitors, with circulating immune complexes (CIC) isolated from sera of patients with IgAN. Cell lysates were analyzed directly, or after immunoprecipitation (IP) with antibodies specific for integrin β1 or PDGFR-β, by SDS-PAGE/immunoblotting for IgA, IgG, phospho-ERK1/2, phospho-PEGFR-β, talin, and Axl.

Results: Cell lysates from MC stimulated with CIC and the corresponding IP products of integrin β1 contained IgA and IgG. Amounts of IgA and IgG were significantly reduced by an inhibitor of integrin α1β1 (obtustatin), but not by an inhibitor of integrin α5β1 (RGD), and partially inhibited by a tyrosine-kinase inhibitor (dasatinib). CIC induced phosphorylation of ERK1/2 that was inhibited by obtustatin, RGD, dasatinib, and a Chinese herbal medicine, ShenPing decoction (SP) that has been used to treat IgAN patients in China. Dasatinib and SP inhibited CIC-induced phosphorylation of PDGFR-β and Axl. In IP products of integrin β1 from CIC-activated MC, cytoskeleton-associated protein talin, known to activate ERK1/2, was associated with integrin β1. SP blocked binding of talin to integrin β1. In IP products of PDGFR-β, CIC induced association of integrin β1 with PDGFR-β, a process that may subsequently induce activation of MAP kinases. Dasatinib and SP inhibited this association.

Conclusions: Integrin α1β1 mediated activation of MC by IgA-IgG CIC; CIC activated multiple protein-tyrosine kinases in MC, leading to MAP kinase activation and cellular proliferation. Some of the inhibitors in this study may provide information about the mechanism of MC activation by the pathogenic CIC and, thus, inform development of future disease-specific therapeutic approaches.

PO1405

Effect of Mycophenolate and Rapamycin on Pro-Inflammatory and Pro-Fibrotic Mediators in Human Mesangial Cells

Chenzhu Zhang, Susan Yung, Tak Mao D. Chan. *Department of Medicine, The University of Hong Kong, Hong Kong, China.*

Background: A significant proportion of lupus nephritis (LN) patients develop chronic kidney disease. TGF-β1 expression is increased in renal biopsies from LN patients and it plays an important role in kidney fibrosis. We previously reported that mycophenolate and rapamycin inhibited pro-fibrotic processes in resident kidney cells in murine LN. We proceeded to investigate the effect of mycophenolate and rapamycin on inflammatory and fibrotic processes in human mesangial cells.

Methods: Growth-arrested human mesangial cells (HMC) were incubated with or without exogenous TGF-β1 (10 ng/ml), in the presence or absence of mycophenolic acid (1 μg/ml) or rapamycin (3 ng/ml), for up to 72 h. The effect on inflammatory and fibrotic processes was examined.

Results: TGF-β1 increased IL-6 and MCP-1 secretion, and α-smooth muscle actin, collagen and fibronectin expression, in a time-dependent manner, accompanied by increased ERK, mTOR and PI3K phosphorylation (*P*<0.05, for all). Constitutive IL-6 and MCP-1 secretion was mediated through PI3K phosphorylation, whereas IL-6 and MCP-1 secretion induced by TGF-β1 was mediated through PI3K, mTOR and ERK phosphorylation. Cell activation was mediated through PI3K and mTOR activation, while increased collagen and fibronectin expression was mediated through ERK, PI3K and mTOR. Mycophenolic acid inhibited the secretion of pro-fibrotic and pro-inflammatory cytokines, cell activation, and collagen and fibronectin expression, through suppressing ERK activation. Rapamycin inhibited similar processes through suppression of mTOR and ERK activation. Overall, the inhibitory actions of mycophenolic acid were comparable to that of rapamycin.

Conclusions: Mycophenolate and rapamycin both suppress pro-inflammatory and pro-fibrotic processes in mesangial cells by targeting signaling pathways that overlap partially.

PO1406

Collapsing FSGS Is Strongly Associated with Microvascular Injury

Nina A. Van de Lest, Kyra L. Dijkstra, Jamie S. Chua, Ron Wolterbeek, Jan A. Bruijn, Marion Scharpfenecker, Ingeborg M. Bajema. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Recent studies have suggested that the collapsing variant of focal segmental glomerulosclerosis (FSGS) might be a common secondary feature in renal disease influenced by microvascular injury. Here, we investigated glomerular and arteriolar microvascular injury in patients with collapsing FSGS, including primary FSGS and HIV-associated FSGS, and compared these lesions to patients with other variants of FSGS.

Methods: Biopsies of patients with FSGS were collected, including primary FSGS in native biopsies or transplant biopsies, as well as HIV-associated FSGS. Cases of FSGS secondary to renal diseases known to be caused by microvascular injury were excluded. We assessed all glomeruli in a biopsy for the presence of lesions associated with FSGS or ischemic injury, assessed microvascular lesions in glomeruli and arterioles, and studied interstitial lesions.

Results: We included 53 cases of FSGS, of which 19 cases with collapsing FSGS, 18 cases with FSGS not otherwise specified (NOS), 11 cases with FSGS tip, 3 cases with perihilar FSGS and 2 cases with cellular FSGS. Compared to other variants of FSGS, glomerular endothelial swelling of the vascular pole was more common in patients with collapsing FSGS (11% vs 0.0%; p=0.05). Associations between thrombotic injury and FSGS variant were not found. Arteriolar abnormalities were seen in 58% of collapsing FSGS and 38% of other variants of FSGS (p=0.17). When evaluating the concomitant occurrence of FSGS lesions and microvascular injury in individual glomeruli, we found that collapsing lesions and FSGS NOS lesions were associated with endothelial swelling in the same glomerulus (OR=22; p<0.001 and OR=3.8; p<0.01, respectively). Endothelial swelling was more common in glomeruli with collapsing lesions than glomeruli with FSGS NOS (OR=2.7; p=0.044). Collapsing FSGS was also associated with endocapillary hypercellularity (OR=4.3; p<0.001).

Conclusions: Here, we demonstrate that collapsing FSGS lesions are strongly associated with microvascular injury such as endothelial swelling and endocapillary hypercellularity, and often co-exist in the same glomerulus. In addition to collapsing FSGS occurring as a secondary phenomenon in renal microangiopathies, these results indicate that endothelial injury could also be involved in the pathophysiology of collapsing FSGS due to primary podocyte injury.

PO1407

Danhong Injection (DHI) Inhibits Lipopolysaccharide-Enhanced Cell Proliferation of Rat Renal Mesangial Cells via NF-κB Signaling Pathway

Hua Liu. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: To explore the mechanisms of DHI in the treatment of Mesangioproliferative glomerulonephritis (MsPGN), we investigated the effects of DHI on LPS-induced NF-κB activation and its downstream inflammatory mediators, such as ICAM-1, TGF-β1, iNOS and FN protein expression in rat MCs.

Methods: The rat MCs treated with different concentrations of DHI (0, 50, 100, 200, 500, 1000, and 2000 uL/L) for 12 h,then incubated with or without 100 ng/ml LPS for another 24 h. Then, cell proliferation was determined by CCK8. The MCs treated with low-dose DHI (250 uL/L), median-dose DHI (500 uL/L) and high-dose DHI (1000 uL/L) for 12 h or PDTC for 30 min before 24h treatment of LPS. Then the activation of NF-κB was detected by Western blot and immunofluorescence. The protein levels of ICAM-1, TGF-β1, iNOS and FN in rat MCs were detected by Western blot.

Results: DHI significantly suppressed LPS-induced cell proliferation by CCk-8 results (Fig 1). LPS stimulation resulted in a significant increment of p65 contents in nucleus and a decrement of p65 contents in cytoplasm in rat MCs compared with NC. PDTC and DHI exerted potent inhibitory effect on increasing expression of p65 in nucleus and decreasing in cytoplasm compared with LPS-treatment group. The inhibitory effect on NF-κB nuclear translocation of DHI was in a dose-dependent manner (Fig 2). The protein level of IκB-α in cytoplasm treated by LPS decreased significantly compared with that in control (Fig 3) and this decrement was significantly reversed by PDTC and DHI. In addition, the protein expression of ICAM-1, TGF-β1, iNOS and FN was also inhibited by PDTC and DHI (Fig 4).

Conclusions: DHI significantly repressed LPS-induced cell proliferation and FN expression in rat MCs through inhibiting the activation of NF-κB signaling pathway also its downstream inflammatory mediators.

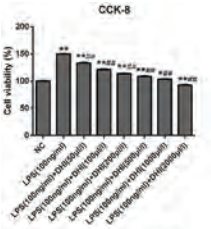

Fig 1 The results of CCK-8 revealed that DHI significantly suppressed LPS-induced cell proliferation

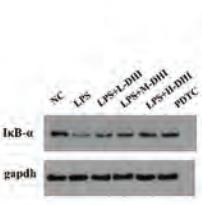

Fig 3 the protein level of IκB-α in cytoplasm treated by LPS

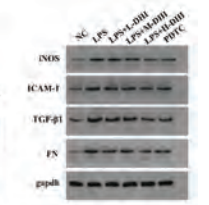

Fig 4 the protein expression of ICAM-1, TGF-β1, iNOS and FN treated by PDTC and DHI

PO1408

Effect of ANG-3070 in the Passive Heymann Nephritis Rat Model of Primary Proteinuric Kidney Disease

Christopher Pedigo, Zhijian Hu, Ping Zhou, Siobhan McCormack, Jingsong Li, Natalia Prakash, Anthony Pellicano, Prakash Narayan, Itzhak D. Goldberg. *Angion Biomedica Corp, Uniondale, NY.*

Background: Primary proteinuric kidney diseases (PPKD) as a group are an important cause of end-stage kidney disease (ESKD). Many receptor tyrosine kinases, including platelet-derived growth factor receptor (PDGFR), contribute to the progression of PPKDs to ESKD. ANG-3070 is a novel and proprietary inhibitor of multiple tyrosine kinases including PDGFR. This study evaluated the effects of ANG-3070 in a passive Heymann's nephritis (PHN) rat model of membranous glomerulopathy.

Methods: Male Sprague Dawley rats (300g) were administered anti-FX1A serum. Treatment groups included 15mg/kg ANG-3070 (n=11), Vehicle (n=11) and Sham (n=5). Animals were dosed orally, twice daily, for 12 weeks, and 24-hour urines were collected biweekly. At sacrifice, kidney tissue was harvested.

Results: Twelve-week treatment with orally dosed ANG-3070 significantly reduced the protein to creatinine ratio as compared to Vehicle (mg/mg; 5.3 vs 9.4; p<0.05). It also led to a significant reduction in total kidney hydroxyproline content (μg/kidney; 952 vs. 1416; p<0.05), indicating a reduction in fibrotic tissue. When periodic acid-Schiff staining from kidney sections were evaluated for glomerular damage by two blinded observers on a scale of 0 (normal/no injury) to 4 (severe injury), ANG-3070 significantly reduced glomerular damage (1.7 vs. 2.6; p<0.05), indicating a reduction in glomerulosclerosis. The evaluation of PDGFRβ levels from total kidney lysates by Western Blot indicated an increase in the Vehicle treated group compared to Sham (PDGFRβ/GAPDH; 2.6 vs 0.7, p<0.05). ANG-3070 treatment significantly reduced these levels when compared to Vehicle (PDGFRβ/GAPDH; 1.0 vs 2.6, p<0.05), which was comparable to the levels observed in the Sham group.

Conclusions: Twice-daily oral administration of the novel tyrosine kinase inhibitor ANG-3070 reduces proteinuria, renal fibrosis, glomerulosclerosis and PDGFRβ expression levels in a rat model of PHN. These data suggest ANG-3070 may be an effective treatment in PPKDs.

PO1409

A Rare Case of Immunotactoid Glomerulopathy Associated with Rheumatoid Arthritis

Ramon A. Seneriz,[1,2] Juanly N. Rodriguez,[1,2] Yiqin Zuo.[1,2] [1]*Jackson Memorial Hospital, Miami, FL;* [2]*University of Miami Health System, Miami, FL.*

Introduction: Immunotactoid glomerulopathy (ITG) is a rare disease that is characterized by nephrotic range proteinuria, hematuria, hypertension, and kidney failure. It is most commonly associated with hematologic disorders. Rarely it presents as a polyclonal process and associated with autoimmune disorders such as rheumatoid arthritis (RA).

Case Description: A 50-year-old woman with a medical history of rheumatoid arthritis without treatment who was recently diagnosed with hypertension (174/82 mmHg) with elevated serum creatinine (Scr 2.2mg/dL). She lost follow-up and returned to emergency department 5 months later complaining of worsening edema, fatigue, foamy urine, and joint pain for which she was taking NSAIDs daily. Further workup showed Scr of 3.0 mg/dL, proteinuria (urine protein to creatinine ratio 14 g/g), hematuria (5 RBCs/HPF), positive ANA (1:160), rheumatoid factor (140), and cyclic citrullinic peptide (30.4), negative for ANCA, dsDNA, cryoglobulins, Hepatitis B and C, HIV, SPEP, UPEP, and serum free light chains with normal complement levels. A renal biopsy showed diffuse thickening of the glomerular basement membranes with focal segmental endocapillary hypercellularity by light microscopy. There is polyclonal IgG-dominant smudgy/chunky capillary loop staining with mesangial extension with lesser IgM and C1q by immunofluorescence and numerous subepithelial deposits and occasional subendothelial deposits, which exhibit a microtubular substructure with hollow cores arranged focally in parallel arrays and measuring 11-72 nm with an average of 34 nm by electron microscopy. A Congo red is negative for amyloidosis. She was treated with low dose prednisone (10mg/day) for her RA. Upon follow up it was noted her Scr decreased to 1.4mg/dL but nephrotic range proteinuria persisted.

Discussion: ITG is a rare glomerulopathy. Determining the clonality and the underlying etiology is essential for the management. This case is associated with RA and presents as a polyclonal ITG. The exact treatment for this condition is unknown. Will continue following her closely as historically ITG caries a poor renal prognosis.

PO1410

Fibrillary Glomerulonephritis: A Rare Entity, Responsive to Rituximab

Ramya Bachu, Mujtaba Sarwar, Jahanzeb Khan, Sehrish W. Bukhari, Anum Syed, Heba Mousa, Fakhar Ijaz. *Baptist Health, Little Rock, AR.*

Introduction: Fibrillary glomerulopathy (FGN) is a rare proliferative type of glomerular disease with poor prognosis and limited therapeutic options. Literature review showed very few cases of FGN where Rituximab has been used.

Case Description: A 69-year-old Caucasian woman with a history of DM, HTN presented to the hospital with complaints of dyspnea and leg swelling. Lab work revealed BUN/Scr of 34/3.88 mg/dL (baseline Scr of 1.4 mg/dL, proteinuria (7,902 mg/dL). Renal biopsy was performed which showed fibrillary deposits as shown in the picture. Hepatitis panel and work up of malignancy including bone marrow biopsy was negative. She was started on Rituximab 1gm every 14 days for 2 doses. Pt initially required HD but with treatment her symptoms and Cr improved and was taken off HD. Most recent Cr was1.8.

Discussion: The diagnosis of FGN can only be established with kidney biopsy. Most of the patients present with renal insufficiency, nephrotic picture. Mostly idiopathic but can be associated with hepatitis C, dysproteinemia, autoimmune diseases and to lesser extent malignancies. The prognosis is very poor with very limited therapeutic options to date and optimal therapy remains to be ascertained. Rituximab has been used in few cases in literature showing good clinical response. Our patient tolerated and responded very well to Rituximab with significant improvement in kidney function and hence we propose the use of Rituximab in FGN.

PO1411

Renal-Limited Lupus Nephritis Misdiagnosed as Advanced CKD: Addressing the Need for Increasing Renal Biopsies in the Community Setting

Rajeev Chauhan,[1] Megha Kalia,[2] Katrina Hazim.[2] *[1]Renal Associates LLC., Columbus, GA; [2]Augusta University, Augusta, GA.*

Introduction: "Full-house" nephropathy is characteristic of lupus nephritis, but may be seen in patients without other evidence of SLE. Patient was presumed to have acute renal failure prior to renal biopsy and was placed on dialysis for chronic management of ESRD. Despite no extrarenal or clinical manifestations of SLE, renal biopsy revealed histopathology consistent with lupus nephritis.

Case Description: A 61-year old African American female presented to an outside hospital with complaints of mild abdominal pain, nausea, emesis, and diarrhea. Family history was positive for autoimmune disorders, including SLE and Sjogren's Syndrome. Initial lab work revealed creatinine 8.1 mg/dL, eGFR 7 mL/min, BUN 117 mg/dL, proteinuria, and hyperkalemia with potassium 5.2. Renal biopsy revealed collapsing glomerulopathy with "full-house" immune complex deposition without active glomerular lesions commonly seen with lupus nephritis. Evaluation was positive for anti-nuclear antibody (ANA), but anti-double stranded DNA (anti-dsDNA), serum immunofixation (IFE), hepatitis screen and HIV screen were negative. She was treated for lupus nephritis with a three-day course of Solu-medrol and continued on home peritoneal dialysis and oral prednisone. Renal function recovered with creatinine of 0.64 mg/dL and eGFR 116 mL/min/ leading to discontinuation of dialysis.

Discussion: Renal biopsy revealed collapsing glomerulopathy with "full-house" immune complex deposition without active glomerular lesions. Lupus nephritis is an immune mediated glomerulonephritis with characteristic histological pattern including "full house immunofluorescence" with glomerular deposits that stain for IgG with co-deposits of IgA, IgM, C3 and C1q. "Full-house" immune complex deposits are commonly seen in lupus nephritis, but are not pathognomonic. Nine adult cases of limited renal disease in absence of other evidence of SLE have been reported. Although there are no guidelines on treatment of lupus-like nephritis, all reported patients were treated with regimens of immunosuppressive agents and steroids. To date our patient has not developed additional manifestations of SLE and her renal function remains normal without signs of injury. We advocate for a lower threshold for performing renal biopsies as they can provide valuable information regarding disease diagnosis and treatment.

PO1412

Tissue MALDI-Mass Spectrometry Imaging Reveals the Potential Role of PLPP3 in Regulating Lysophosphatidic Acid Signaling in Aging Kidney

Li Liu,[1] Annapurna Pamreddy,[1] Jingli Gao,[1] Liang Min,[1] Hak Joo Lee,[1] Viktor Drel,[1] Wei Chen,[1] Hui Geng,[1] Ya guang Liu,[1] Balakuntalam S. Kasinath,[1] Kumar Sharma,[1,2] Guanshi Zhang.[1,2] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX.*

Background: Increasing evidence suggests that accumulation of lysophosphatidic acid (LPA) and aberrant activation of LPA signaling is implicated in various human diseases such as diabetic kidney disease. However, the role of LPA signaling in aging-related kidney injury remains elusive.

Methods: C57BL/6J male mice at 5 months (Control) and 24 months (Aging), N=10/group, were used in the current study. Kidney pathological changes were evaluated based on PAS-stained images and nephropathy markers including urinary albumin creatinine ratio (ACR) and kidney injury molecule-1 (KIM-1). Gene expression and protein levels of major enzymes/effectors involved in LPA metabolism and signaling were measured in kidney cortical tissues using standard RT-qPCR and western blotting approaches. Matrix-assisted laser desorption/ionization-mass spectrometry imaging (MALDI-MSI) was performed for spatial lipidomics analysis of lipids including LPA and other species in kidneys of aging mice and controls. MetaboAnalyst and GraphPad were employed for statistical analyses.

Results: Histological images showed that aging kidney developed glomerulosclerosis at the age of 24 months. Aging mice also had higher levels of urinary albumin, ACR, and KIM-1. Interestingly, both mRNA and protein levels of phospholipid phosphatase 3 (PLPP3), an enzyme that can dephosphorylate and inactivate the signaling functions of LPA, were lower in renal cortical tissues of aging mice. The gene expression level of LPA receptor 1 (*LPAR1*) was upregulated in aging renal cortical tissues. In addition, oscillations of gene expression and protein levels of enzymes involved in LPA metabolism/signaling, mitochondrial biogenesis, and mitochondrial dynamics were observed in aging kidneys. In the MALDI-MSI analysis, we found altered sphingolipid metabolism in glomeruli of mouse aging kidneys compared with controls. In particular, several LPA (e.g., LPA (16:0)) species were increased in aging glomeruli, suggesting the potential role of LPA signaling in the aging kidney.

Conclusions: These findings suggest that reduced PLPP3 contributes to the accumulation of LPA in glomeruli of aging kidneys. Activation of LPA signaling in glomeruli may play an important role in the pathogenesis of aging-related kidney injury.

Focal Segmental Glomerulosclerosis: A Rare Cause of Nephrotic Syndrome in Graft vs. Host Disease

Ian J. Da Silva Lugo, Juan C. Santiago-Gonzalez, Edilberto J. Ocasio Feliciano, Alexandra C. Pico-Ramirez, Yamiris Rodriguez, Krystahl Z. Andujar, Deniz E. Garcia, Ileana E. Ocasio Melendez. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Nephrotic syndrome (NS) is a very rare complication of allogeneic hematopoietic cell transplantation (HCT) and is usually associated with chronic graft versus host disease (GVHD). In such patients, membranous nephropathy and minimal change disease are the most frequently observed renal pathology. However, focal segmental glomerulosclerosis (FSGS) is an extremely uncommon etiology of NS in patients with HCT and GVHD. We herein describe a case of a patient with HCT and chronic GVHD who developed NS secondary to FSGS.

Case Description: A 24-year-old man with medical history of Sickle Cell Disease status post splenectomy and HCT, epilepsy, arterial hypertension and chronic GVHD with cutaneous and esophageal manifestations who presented to the emergency department with a one month of evolution progressive lower extremity edema and intermittent hematuria. Vital signs were remarkable for uncontrolled blood pressure. Home medications were lisinopril 20mg daily, levetiracetam 500mg twice daily and prednisone 10mg daily. Physical examination was remarkable for edema of the lower extremities, ascites, and cachexia. Laboratories revealed: BUN 35 mg/dL, serum creatinine 1.15 mg/dL, total protein 3.00 g/dL, serum albumin 1 g/dL, glucose 110mg/dL, total cholesterol 425 mg/dL, triglycerides 335 mg/dL, VLDL 67 mg/dL and LDL 316 mg/dL. Urine protein/creatinine ratio resulted in 30,000mg/g. Laboratory findings of hypoalbuminemia, hyperlipidemia, and nephrotic range proteinuria were consistent with NS. A renal biopsy was performed and revealed findings consistent with a diagnosis of FSGS, not otherwise specified. Partial remission of NS was achieved at 3 months of treatment with mycophenolate mofetil 500mg twice daily and prednisone 15mg twice daily.

Discussion: GVHD is a significant cause of morbidity and mortality in patients after HCT. Renal involvement can be a serious manifestation and prompt recognition is essential for adequate management and prevention of renal disease. FSGS is an extremely rare complication of HCT and very few cases have been reported in the literature linking FSGS to HCT. Further documentation of this phenomenon is important to further characterize the clinical and pathological features of this complication.

PO1414

Catastrophic COVID-19-Associated Nephropathy (COVAN) in an Asymptomatic Patient

Samer Akrawi, Toni Sabbouh, Khaled Janom, Panduranga S. Rao, Cathryn J. Lapedis. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Introduction: Glomerular lesions were reported in a minority of patients with COVID-19, with collapsing focal segmental glomerulosclerosis (FSGS) also called COVID-associated nephropathy (COVAN), This typically occurs in the setting of prominent COVID symptoms. We describe a COVAN occurring in an asymptomatic patient

Case Description: A 48-year-old, African American female patient who had CKD stage 3 a secondary to hypertension, with serum creatinine of 1.2 mg/dl and absent proteinuria at baseline, presented to the hospital for evaluation of an asymptomatic elevation of her serum creatinine to 9.9 mg/dl, discovered during a routine evaluation by her PCP. Her urine Protein/Creatinine was 6.15. Six weeks prior to her presentation, she endorsed 7 days of nausea and intermittent vomiting associated with non-bloody diarrhea without respiratory symptoms. Her GI symptoms has resolved on its own. She had multiple family members, including her husband and daughter, who had tested positive for COVID around the same time. Her nasal PCR for COVID was negative. She had not been vaccinated for SARS COVID. She has no family history of kidney disease; she denied IV drug use and had no risk factors for HIV. She was on Amlodipine for her hypertension. She was afebrile on admission with blood pressure of 170/80 mm Hg. She had 1+ pedal edema with an unremarkable physical exam. A percutaneous kidney biopsy was performed to evaluate the cause of her renal dysfunction. This showed collapsing FSGS. HIV and ANA were negative. A subsequent testing for COVID nucleocapsid and spike protein was positive. Results of APOL1 genotype is pending. She was started on high dose steroids and followed up as an outpatient.

Discussion: COVAN is increasing recognized as a serious complication of COVID. However, the typical presentation is in the setting of prominent respiratory involvement. Recognizing the minor fleeting symptoms of COVID preceding a catastrophic kidney disease and testing for it is an important in patients presenting with features of collapsing FSGS

PO1415

Siglec-9 Agonism Reduces ANCA-Mediated Neutrophil Responses In Vitro

Dana Kidder,[1] Kristine Nellany,[1] Catriona Walls.[2] *[1]NHS Grampian, Aberdeen, United Kingdom; [2]University of Aberdeen School of Medicine Medical Sciences and Nutrition, Aberdeen, United Kingdom.*

Background: Sialic acid-binding Ig-like lectin 9 (Siglec-9) is constitutively expressed on neutrophils and monocytes. The expression and potential role of siglec-9 in ANCA-associated vasculitis (AAV) is yet to be determined. We aimed to examine the expression of siglec-9 in patients with AAV and explore the impact of siglec-9 agonism on ANCA-mediated neutrophil responses *in vitro*.

Methods: Leukocytes and serum were isolated from peripheral venous blood of AAV patients and siglec-9 expression was measured by flow cytometry and ELISA, respectively. Immunohistochemistry was performed on kidney biopsies of AAV patients with AAGN and stained for siglec-9 and leukocyte markers. Functional studies were done using healthy donor neutrophils in the presence of ANCA and siglec-9 mAb to investigate its role in apoptosis and ROS production.

Results: We found increased serum siglec-9 expression in active AAV compared to remission AAV and a positive correlation with disease activity. Neutrophils and intermediate (CD14+/CD16+) monocytes from PR3-ANCA patients displayed higher siglec-9 expression compared to MPO-ANCA patients. Siglec-9 expression in AAGN was restricted to areas of active inflammation. We observed increased siglec-9 shedding in neutrophils following ANCA stimulation. Siglec-9 agonism in these neutrophils was associated with increased apoptosis and reduced ROS production compared to isotype control and unstimulated neutrophils.

Conclusions: Our study suggests that siglec-9 is expression correlates with disease activity in AAV. Our functional studies support a potential role for siglec-9 in modulating ANCA-mediated neutrophil responses. Further evaluation is required to determine the relevance of these findings on neutrophil-endothelial interactions.

The Proteinase 3-Alpha1-Antitrypsin Connection in PR3-ANCA Vasculitis

Maximilian Ebert,[1] Uwe Jerke,[1] Claudia Eulenberg-Gustavus,[1] Dieter E. Jenne,[4] Markus Bieringer,[2] Saban Elitok,[3] Kai-Uwe Eckardt,[5] Adrian Schreiber,[1,5] Alan D. Salama,[6] Ralph Kettritz.[1,5] *[1]Experimental and Clinical Research Center, Charité - Universitätsmedizin Berlin and Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; [2]Department of Nephrology, Helios Klinikum Berlin-Buch, Berlin, Germany; [3]Department of Nephrology and Endocrinology, Ernst von Bergmann Klinikum, Potsdam, Potsdam, Germany; [4]Institute of Lung Biology and Disease (ILBD), Comprehensive Pneumology Center (CPC), Helmholtz Zentrum, Munich, Germany; [5]Department of Nephrology and Medical Intensive Care, Charité - Universitätsmedizin, Berlin, Germany; [6]Department of Renal Medicine, University College London, Royal Free Hospital, London, United Kingdom.*

Background: PR3 is a major autoantigen in ANCA-associated vasculitis (AAV) and a neutrophil serine protease inhibited by alpha1-antitrypsin (AAT). Increased PR3 and decreased AAT were suggested as disease mechanism for PR3- but not MPO-AAV

Methods: We assessed PR3 and AAT in 100 AAV patients and 50 healthy controls (HC) and produced recombinant wt- and mut-AAT to study the effect on proteolytic PR3 activity, membrane PR3 (mPR3) by flow cytometry and surface plasmon resonance (SPR), and neutrophil activation.

Results: In active PR3- and MPO-AAV, plasma PR3 concentration increased approximately 5-fold and plasma AAT 1.8-fold shifting the PR3:AAT ratio significantly towards PR3. Both parameters normalized with remission. Notably, only one PR3-AAV remission patient showed strongly decreased plasma AAT. The PR3 neutrophil content was approximately 50% higher in active PR3- and MPO-AAV accompanied by increased PR3 transcription. The resulting total PR3 pool (plasma PR3 concentration x plasma volume + neutrophil PR3 x neutrophil number) was approximately 3-fold larger in active AAV and normalized with disease remission. In active PR3-AAV but not MPO-AAV, the total PR3 pool correlated with kidney injury, hemoglobin, and PR3-ANCA ELISA. Membrane-PR3 (mPR3) correlated negatively with plasma AAT in HC, was increased in AAV patients with a compromised plasma AAT correlation. Mechanistically, extracellular AAT dose-dependently reduced mPR3 by competing with PR3 for the PR3-presenting CD177 receptor. Consequently, AAT reduced neutrophil activation by PR3- but not MPO-ANCA. Neutrophils from AAV patients and HC showed similar mPR3 reduction with AAT. However, in contrast to HC plasma, neutrophil incubation in active AAV plasma increased the AAT concentrations required to lower mPR3, an effect that was recapitulated by adding inflammatory mediators to HC plasma. Finally, oxidative AAT modification resulted in less PR3 interaction and diminished mPR3 reduction

Conclusions: We found a strongly increased PR3 pool in active PR3-AAV and exclude decreased plasma AAT as the general underlying disease mechanism, as previously proposed. However, AAT controls mPR3 expression and subsequently PR3-ANCA induced neutrophil activation, suggesting adjunctive AAT administration may have beneficial effects in acute PR3-AAV

Funding: Government Support - Non-U.S.

PO1417

Serum Soluble CD206 Complements Urinary Soluble CD163 in Detecting Active ANCA-Associated Glomerulonephritis

Joop Aendekerk,[1] William F. Jiemy,[2] Inge M. Strating,[2] Gerjan J. Dekkema,[2] Jan-Stephan Sanders,[3] Coen A. Stegeman,[3] Mark A. Little,[4] Peter Heeringa,[2] Pieter van Paassen.[1] *[1]Department of Nephrology and Clinical Immunology, Maastricht University Medical Center, Maastricht, The Netherlands, Maastricht, Netherlands; [2]Department of Medical Biology and Pathology, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; [3]Department of Internal Medicine, Division of Nephrology, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; [4]Trinity Health Kidney Centre, Trinity Translational Medicine Institute, Dublin, Ireland, Dublin, Ireland.*

Background: Early detection of active glomerulonephritis (GN) in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is crucial to minimize renal damage, but accurate biomarkers are currently lacking. Urinary soluble CD163 (usCD163) has been shown as a potent biomarker for active ANCA GN. However, false negative rates can be as high as 29%. Here, we investigated whether serum soluble CD206 (ssCD206; macrophage mannose receptor), complements usCD163 in the detection of active ANCA GN.

Methods: Three independent cohorts (C1-Maastricht University Medical Center, C2-University Medical Center Groningen & C3-Trinity College Dublin) with available serum, urine, and renal biopsy samples (C1 only) were included. usCD163/creatinine (ng/mmol) and ssCD206 (ng/ml) were assessed by ELISA in urine and serum, respectively. The performance of usCD163 and ssCD206 to detect ANCA GN was assessed using receiver operating characteristics (ROC) curves. Biopsies from ANCA GN patients were immunohistochemically (IHC) stained for CD163 and CD206. Colocalization of CD163 and CD206 was assessed by immunofluorescence (IF).

Results: Patients (C1/C2/C3) had active ANCA GN (n=42/17/47), active non-renal AAV (n=3/3/12) or were in remission (n=4/8/38). Healthy controls (HCs; n=6/34/0) were included. usCD163 was significantly higher in active ANCA GN compared to active

non-renal AAV and remission in all cohorts, and healthy control urine in C1 (Kruskal-Wallis, $P<0.001$). ssCD206 was significantly higher in active ANCA GN compared to HCs in cohorts C1 & C2 (Kruskal-Wallis, $P\leq0.01$). usCD163 had a specificity of 100% in all cohorts, whereas sensitivity was 71 (C1), 88% (C2) and 64% (C3). The addition of ssCD206 increased the sensitivity to detect active ANCA GN in all cohorts to 83% (C1), 100% (C2) and 81% (C3). IHC revealed $CD163^+$ and $CD206^+$ cells in the kidneys of active ANCA GN patients (n=8). IF showed glomerular presence of $CD163^+CD206^-$ cells, whereas $CD163^+CD206^+$ and $CD163^-CD206^+$ cells were mainly found in the tubulointerstitium.

Conclusions: ssCD206 complements usCD163 and reduces false negative rates in the detection of active ANCA GN. Histological assessment revealed distinct glomerular and tubulointerstitial populations of $CD163^+$ and $CD206^+$ cells.

PO1418

Urine and Plasma Complement Ba Levels During Flares of Nephritis in Patients with ANCA-Associated Vasculitis

Salem Almaani,[1] Huijuan Song,[1] Meshora Suthanthira,[1] Christopher Toy,[7] Lynn A. Fussner,[1] Alexa S. Meara,[1] Haikady N. Nagaraja,[1] Nader A. Khalidi,[5] Christian Pagnoux,[3] Kenneth Warrington,[6] Paul Monach,[2] Peter A. Merkel,[4] Brad H. Rovin,[1] Daniel J. Birmingham.[1] Vasculitis Clinical Research Foundation *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Brigham and Women's Hospital, Boston, MA; [3]Mount Sinai Hospital, Toronto, ON, Canada; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]McMaster University, Hamilton, ON, Canada; [6]Mayo Foundation for Medical Education and Research, Rochester, MN; [7]Colorado State University System, Denver, CO.*

Background: The alternative complement pathway has been implicated in the pathogenesis of ANCA-associated vasculitis (AAV), however it is not clear whether activation of complement occurs systemically or in affected organs such as the kidney. This study measured levels of urinary and plasma complement fragment Ba (uBa and pBa respectively) at multiple timepoints in patients with AAV.

Methods: Ba was measured by ELISA in serial samples of urine (uBa) and plasma (pBa) from 20 AAV patients who developed a renal flare, 20 who developed a non-renal flare, and 20 in long-term remission. Changes in Ba levels were modeled using linear mixed effect models.

Results: Cohort characteristics are given in **Figure.1**. uBa levels increased at renal flare, but did not increase at non-renal flare, and remained stable in long-term remission (**Figure 2a**). pBa levels were stable over time in all groups (**Figure 2b**). uBa correlated with renal AAV activity measured as the renal component of the BVAS score (R^2= 0.33, p<0.01), but did not correlate with the overall BVAS score during renal flare (R^2= 0.13, p=0.12) or non-renal flare (R^2= 0.10, p=0.22).

Conclusions: Urine, but not plasma, Ba levels increase at the time of a flare of renal disease in AAV, suggesting intra-renal alternative complement pathway activation. uBa has the potential for use as a surveillance biomarker of renal vasculitis.

Funding: Other NIH Support - Supported by the Vasculitis Clinical Research Foundation

	Long-Term Remission (n=20)	Non-Renal Flare (n=19)	Renal Flare (n=21)	p-value

Figure 1. Patient demographics and disease characteristics.
Data depicted n (%); mean ± standard deviation; median (inter-quartile range) as appropriate.
Fisher's exact test used to compare group memberships and ANOVA used to compare continuous variables. Data obtained at flare visits for the non-renal flare and renal flare groups; and at the last visit for the long-term remission group.
ANCA: anti-neutrophil cytoplasmic antibody; cANCA: cytoplasmic ANCA; pANCA: perinuclear ANCA; PR3: proteinase 3; MPO: myeloperoxidase; BVAS: Birmingham Vasculitis Activity Score;
rBVAS: active renal disease per BVAS; eGFR: estimated glomerular filtration rate.

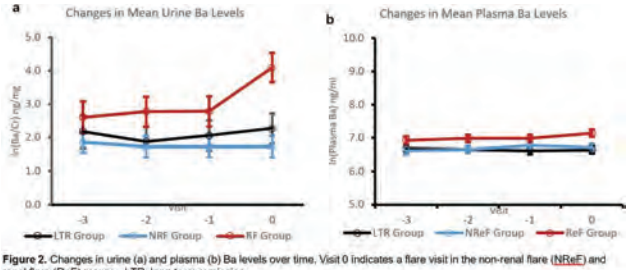

Figure 2. Changes in urine (a) and plasma (b) Ba levels over time. Visit 0 indicates a flare visit in the non-renal flare (NReF) and renal flare (ReF) groups. LTR: long-term remission.

PO1419

Alterations in Amino Acid and Lipid Metabolism in ANCA-Stimulated Monocytes

Emma Leacy,[1] Hania Khouri,[2] Gareth Brady,[1] Mark A. Little.[1] *[1]Trinity Translational Medicine Institute, Dublin, Ireland; [2]Agilent Technologies UK Ltd, Cheadle, United Kingdom.*

Background: Multiple metabolic pathways and intermediates are involved in inflammation. Altered immune cell metabolism is involved in the pathogenesis of autoimmune diseases such as anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). In particular, monocytes stimulated with ANCA show increased oxidative phosphorylation and glycolysis, with a more profound response to myeloperoxidase (MPO) ANCA than proteinase-3 (PR3). The aim of this work was to profile the metabolome of ANCA-stimulated primary monocytes.

Methods: Monocytes from healthy donors (n=24) were isolated and stimulated with monoclonal anti-MPO, anti-PR3 for 4 hours. Metabolites were extracted using an optimised extraction protocol and analysed by liquid chromatography–mass spectrometry (LC–MS). Targeted and untargeted analyses were carried out using Agilent MassHunter Profinder and Mass Profiler Professional. Cytokine production was measured by ELISA and flow cytometry was used to assess surface expression of MPO and PR3.

Results: Targeted metabolomic analysis showed increases in several amino acid and TCA cycle metabolites relative to unstimulated cells, notably phenylalanine, isomers leucine & isoleucine, and fumarate. Untargeted analysis confirmed alterations in amino acid and lipid metabolism in ANCA-stimulated monocytes (Figure 1). These metabolic differences did not correlate with the increased cytokine expression observed in anti-MPO-treated monocytes. Anti-PR3 stimulation did not induce major changes in metabolism or cytokine production. Monocytes expressed high levels of surface MPO and PR3, with MPO expression showing a significant inverse correlation with age.

Conclusions: Inflammatory and metabolomic activation of primary human monocytes occurs with anti-MPO, but not anti-PR3 stimulation. Early increases in amino acid and lipid metabolism are evident in anti-MPO treated cells. Further work is needed to validate these findings and determine their physiological relevance in AAV.

PO1420

LFA-1 (CD11a/CD18) and Mac-1 (CD11b/CD18) Are Important for Mediating Myeloperoxidase-ANCA Glomerulonephritis in a Preclinical Mouse Model

Shen-Ju Gou, Peiqi Hu, Hong Xiao, Yanglin Hu, Marco A. Alba, Ronald J. Falk, J. Charles Jennette. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Neutrophils play a critical role in the pathogenesis of necrotizing crescentic glomerulonephritis (NCGN) caused by anti-neutrophil cytoplasmic autoantibodies (ANCA). LFA-1 and Mac-1 are β2-integrins that have critical synergistic roles in neutrophil-mediated inflammation. In this study, we investigated the role of LFA-1 and Mac-1 in murine NCGN induced by mouse anti-mouse MPO, which is histopathologically indistinguishable from human ANCA NCGN.

Methods: Anti-MPO IgG was purified from sera of MPO knock out (KO) mice immunized with murine MPO. Mice with KO of LFA-1 or Mac-1, and normal wild-type C57BL/6j mice (WT B6) were injected i.v. with 50ug/g body weight anti-MPO IgG. Circulating anti-MPO IgG (MPO-ANCA) was monitored by ELISA. Proteinuria, hematuria and leukocyturia were monitored, and mice were sacrificed at day 6 and kidney tissue obtained for pathologic examination. MPO-ANCA-induced neutrophil activation was assayed *in vitro*.

Results: At day 6, WTB6 (n=8), LFA-1 KO (n=8) and Mac-1 KO (n=9) mice that received anti-MPO IgG had similar levels of circulating MPO-ANCA. All WT B6 mice developed hematuria and NCGN with mean 13.9% glomeruli with crescents and 5.3% with necrosis. In contrast, LFA-1 KO mice and Mac-1 KO mice had normal urine and substantially reduced NCGN (Table). *In vitro* assays showed that anti-MPO IgG caused similar activation of neutrophils from LFA-1 KO, Mac-1 KO and WT mice.

Conclusions: Depletion of LFA-1 or Mac-1 blocks MPO-ANCA induced NCGN in mice, thus both of these β2-integrins are required for ANCA disease induction. Depletion of LFA-1 or Mac-1 does not block MPO-ANCA induced neutrophil activation. These observations indicate that blockade of either of these β2-integrins abrogates MPO-ANCA NCGN by inhibiting the recruitment of neutrophils that is required to induce inflammatory vascular injury in ANCA disease. These data suggest that pharmacologic blockade of β2-integrins may have a therapeutic role in ANCA disease.

Drilling into a Potential Correlation Between ANCA-Associated Vasculitis and Natural Gas Wells

Devan Makati, James L. Akers, Khaled Shawwa, Rebecca J. Schmidt, Dinesh Kannabhiran. *West Virginia University Health Sciences Center, Morgantown, WV.*

Background: ANCA-associated vasculitis (AAV), a systemic necrotizing disease affecting small and medium blood vessels, is caused by antineutrophil cytoplasmic autoantibodies which target intracellular proteinase 3 (PR3) or myeloperoxidase (MPO). The incidences of PR3-AAV and MPO-AAV vary geographically with PR3-AAV most commonly reported in the United Kingdom and MPO-AAV the predominant type seen in Japan. Environmental exposure has been implicated in the pathophysiology of MPO-AAV. The aim of this study is to evaluate a potential relationship between AAV and environmental factors in north central West Virginia.

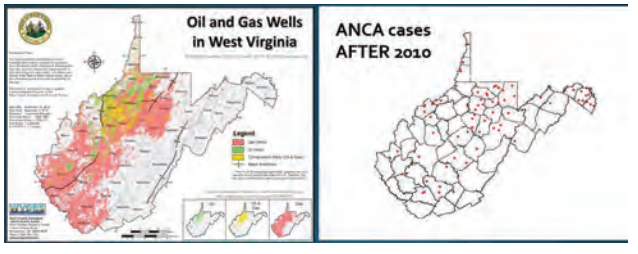
Methods: This is a retrospective cohort study of 212 patients diagnosed with AAV at West Virginia University and its affiliated hospitals from January 1, 1990 to December 31, 2019. Patients were mapped by zip code and prevalence of AAV assessed over time.

Results: The proportion of MPO-ANCA cases increased (37.5% before 2010 vs 71.7% after 2016 (p=0.008)) with a resultant increase in the prevalence of AAV overall after 2010 (Table). During this time, the production of natural gas through fracking increased with barrel production rising more than 5-fold after 2010. Regional heat mapping reveals that the increase in cases of AAV occurred in areas of increased fracking activity (Figure)

Conclusions: The increase in prevalence of MPO-ANCA AAV correlates temporally and geographically with escalations in fracking activity. These findings suggest that exposure to toxins from fracking could be operative in the pathophysiology of AAV and the increase in case numbers seen in north central West Virginia.

Prevalence of ANCA before and after 2010

Prevalence per 100,000	Before 2010	After 2010	p- value
Overall	4.84 (N=24)	11.73 (N=61)	<0.001
PR3-ANCA	3.25 (N= 16)	4.42 (N=21)	0.41
MPO-ANCA	2.24 (N=8)	7.66 (N=40)	<0.001



Pictured on the left is a map of all the gas fracking wells (pictured in red) and gas and oil fracking wells (pictured in yellow) (WVGES Maps and GIS Data Menu [wvnet.edu]). Pictured on the right is a map of the ANCA cases diagnosed after 2010.

PO1422

Maintenance of ANCA Vasculitis Remission by Intermittent Rituximab Dosing Based on B Cell Reconstitution vs. a Serologic ANCA Flare (MAINTANCAVAS)

Reza Zonozi,[1] Anushya Jeyabalan,[1] Pravarut Nithagon,[1] Karen A. Laliberte,[1] Frank B. Cortazar,[2] John Niles.[1] MGH Vasculitis and Glomerulonephritis Center (MGH VGC) *[1]Massachusetts General Hospital, Boston, MA; [2]New York Nephrology Vasculitis and Glomerular Center, Albany, NY.*

Background: ANCA vasculitis is caused by autoantibodies to proteinase 3 (PR3) or myeloperoxidase (MPO). Rituximab (RTX), an anti-CD20 monoclonal, is effective at induction and maintenance of remission. However, RTX is associated with adverse events; hypogammaglobulinemia, infections, and late onset of neutropenia. The ideal strategy for long-term maintenance of remission remains unknown.

Methods: This is an interim analysis of an open-label, single center, randomized, two-arm controlled trial (ClinicalTrials.gov Identifier: NCT02749292) to evaluate maintenance of remission strategies that provides the best relapse-free survival in patients with ANCA vasculitis at 36 months. We enrolled subjects with ANCA vasculitis on RTX-induced continuous B cell depletion for a minimum of two years to one of two arms as follows: intermittent B cell depletion with RTX re-dosing upon (1) B cell return (≥ 10 B cells/mm^3) or (2) upon a significant ANCA titer increase. The primary outcome was number of relapses defined by a Birmingham Vasculitis Activity Score (BVAS/WG) ≥ 2. Other outcomes, including serologic relapse and serious adverse events are not included in this analysis.

Results: From May 2016 to June 2021, 113 patients (mean age, 61 years; 48% women) were randomized, 57 to the ANCA arm and 56 to the B cell group. 52 patients were positive for anti-MPO, and 61 for anti-PR3. Relapse-free survival estimates at month 60 were 76% (95% CI, 62% to 86%) and 91% (95% CI, 74% to 97%) in the ANCA and B cell groups, respectively (hazard ratio of 3.85 (CI, 1.40 to 10.60) (P = 0.024 by logrank).

Conclusions: B cell driven RTX dosing appears to be highly efficacious at preventing relapses compared to ANCA titer driven dosing. Full trial analysis, including differences in adverse events, is needed to balance the benefit of reduced relapses against the infectious complications that may be associated with increased RTX use.

Pulsed Steroids Impede T Memory Cell Recruitment to the Kidney in Human and Experimental Crescentic Glomerulonephritis

Jan-Hendrik Riedel,[1] Tobias B. Huber,[2] Thorsten Wiech,[3] Christian F. Krebs,[1,4] Ulf Panzer.[1,4] *[1]III. Department of Medicine, Division of Translational Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Hamburg Center for Translational Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Despite undesirable side effects and understudied modes of action steroids still constitute a cornerstone of therapeutic regimes for autoimmune kidney diseases presenting as rapidly progressive glomerulonephritis (RPGN), e.g. anti-neutrophil cytoplasmatic antibody associated glomerulonephritis (ANCA-GN). However, if the rapid clinical effects of steroids are due to a direct impact on leukocytes, i.e. CD3$^+$ T cells, or mediated indirectly by attenuation of an inflammatory environment is still unknown.

Methods: Kidney biopsies of patients with ANCA-GN with and without pulsed steroids before biopsy were analysed by immunohistochemistry, flow cytometry and single cell RNA sequencing. Furthermore, corresponding studies were conducted in untreated or steroid pulsed mice with crescentic glomerulonephritis (cGN), respectively. Additionally, steroid effects were studied in mice lacking the glucocorticoid receptor specifically in T cells and in CD4$^+$ T cell transfer experiments in nephritic recombination activating gene 1 (RAG1) knockout mice.

Results: Combined high-dimensional single-cell analysis and IHC showed that intravenous steroid pulses rapidly reduced renal T-cell infiltrate in human ANCA-GN patients but did not significantly regulate the immune response of a specific T-cell subset (e.g., Th1, Th2, Th17, Treg). Almost identical effects were observed in a murine cGN model (nephrotoxic nephritis), including reduced glomerular crescent formation, after steroid pulse treatment. Functional studies using CD4+ T-cell-specific glucocorticoid receptor-deficient mice showed that T-cell reduction was not caused by T-cell-intrinsic factors. Mechanistically, we demonstrated in CD4+ T-cell transfer experiments that steroid-induced attenuation of intrarenal effector T cells in cGN was a consequence of reduced expression of the T-cell-attracting chemokines CCL5, CCL20, CXCL9, and CXCL10 by resident kidney cells, which was further confirmed by in vitro and ex vivo trafficking experiments.

Conclusions: Our findings demonstrate that pulse steriod therapy rapidly reduce renal T-cell infiltrate in human and murine cGN by inhibiting the production of T-cell-attracting chemokines by resident renal cells. In summary, we have identified a previously unrecognized therapeutic mechanism of steroids in immune-mediated glomerular disease.

Immune Checkpoint Molecule BTLA Attenuates Inflammation and Glomerular Damage in Experimental Glomerulonephritis

Paul Diefenhardt,[1,2] Marie Brand,[1,2] Thomas Schömig,[1,2] Bastian Trinsch,[1,2] Bernhard Schermer,[1,3] Paul T. Brinkkoetter,[1,2] Thomas Benzing,[1,3] Sebastian Braehler.[1,2] *[1]Uniklinik Koln, Koln, Germany; [2]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [3]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: An imbalance of pro- and anti-inflammatory signals in the kidney can result in irreversible damage and destruction of glomeruli leading to end stage kidney disease. Current treatment of the glomerulonephritis (GN) consists of unspecific, highly toxic immunosuppressive therapies with detrimental adverse effects. More specific therapies are therefore warranted. T Lymphocytes are not only key players in the nephrotoxic nephritis (NTN) model in rodents but also during GN in humans, representing potential targets for tailored therapies. As an immune checkpoint molecule, B and T lymphocyte attenuator (BTLA) is crucial in the regulation of T Lymphocyte activation and has been shown to mediate anti-inflammatory effects in other T cell-mediated disease models.

Methods: NTN was induced in BTLA knock out mice (BTLA-KO) and littermate controls. Regular urine analysis (ACR) was performed throughout the course of the disease. 14 days after NTN induction, blood, kidneys and spleens were harvested for further analysis. Histological assessment of the kidneys was used to evaluate the severity of NTN. Local immune response in the kidney and systemic immunity was analyzed via flow cytometry and qPCR.

Results: Wild type mice (WT) showed an increased BTLA expression on renal T cells and dendritic cells throughout the course of NTN. No immuno-phenotype was observed in unstimulated BTLA-KO and WT mice. However, BTLA-KO resulted in aggravation of NTN compared to WT. Quantification and characterization of renal immune cells revealed an increase in proinflammatory cells. Interestingly, especially T Lymphocytes were significantly expanded in BTLA-KO mice.

Conclusions: BTLA attenuates inflammation in experimental GN through suppression of proinflammatory T Lymphocytes. These results build the foundation of a checkpoint inhibitor based therapy of inflammatory glomerular disease.

PO1425

Collapsing FSGS or Crescentic GN or Both: A Diagnostic Challenge

Irshadjahan Malek, Harsharan K. Singh, Volker Nickeleit. *Division of Nephropathology, University of North Carolina, Chapel Hill, NC.*

Introduction: The finding of an ANCA associated necrotizing & crescentic GN with collapsing FSGS is a rarity with only few reported cases in literature.

Case Description: A 53-yr-old AA female was admitted to hospital with difficulty in swallowing, poor oral intake, hemoptysis & AKI superimposed on CKD-III with hx of HTN & use of NSAIDs. Urine analysis showed hematuria, proteinuria & UPC ratio of 4.15. Blood analysis showed S.Cr 8.7mg/dl, BUN 60mg/dl, Albumin 2.4gm/dl, positive MPO ANCA & ANA titers. By light microscopy 36 glomeruli were present, 20% showed cellular/fibro-cellular crescent formation with underlying tuft fibrinoid necrosis & 20% showed collapsing FSGS. ATI, moderate IF/TA & moderate to severe arteriosclerosis were present. EM showed global podocyte activation with foot processes effacement.

Discussion: Collapsing FSGS and ANCA associated GN can both present with abrupt onset AKI & proteinuria. No specific test exists to separate crescents from collapsing FSGS; therefore this daunting differentiation requires a high level of suspicion, often relegated to experience. Most useful morphologic features are summarized in table 1. In our case, AA race (possible $APOL_1$ risk variants) & underlying severe arterionephrosclerosis (ischemia) are the most likely etiologies for the collapsing FSGS.

Morphology	Collapsing FSGS	Crescentic GN
Tuft Collapse	++	-
Podocytes hyperplasia/hypertrophy	++	-
Parietal epithelial cell hyperplasia	-	++
Tuft fibrinoid necrosis	-	++
Fibrin in extra capillary space	+/-	++

PO1426

CD11b Activation Suppresses Pro-Inflammatory IL-1β in Myeloid Cells and Protects Against Lupus Nephritis

Veronica Villanueva, Xiaobo Li, Viviana Jimenez, Vineet Gupta. *Rush University Graduate College, Chicago, IL.*

Background: Lupus nephritis (LN) is a debilitating glomerular disease and a comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin CD11b/CD18, plays a critical role in cell signaling. Mutations in the ITGAM gene, encoding CD11b, are associated with LN and reduce integrin function. Interleukin-1β (IL-1β) is produced by myeloid cells as a proprotein and cleaved by caspase-1 where it mediates the inflammatory response. IL-1β is downstream of toll-like receptor and IL-1β receptor signaling. We previously showed that activation of CD11b suppresses TLR-dependent pro-inflammatory signaling. Here, we investigate if this mechanism includes control of IL-1β and/or if CD11b influences IL-1β by another mechanism, which may provide novel therapeutic options for proinflammatory diseases.

Methods: To investigate TLR-dependent signaling affected by CD11b activation, we utilized in vitro assays using primary macrophages. Cells were treated with TLR agonists, IL-1β protein, or IL-1β antibody and changes in protein expression was assessed by western blot and proinflammatory cytokine levels were assessed by ELISA. For complementary in vivo studies, we utilized our newly generated mouse model, where we incorporated a constitutively active CD11b point mutation (I332G) globally in mice to generate a model for CD11b activation – CD11b knock-in model. C57BL/6 wild type mice, CD11b knock-out, and CD11b knock-in mice were used to determine the effect of CD11b activation on circulating IL-1β levels.

Results: TLR-stimulation increased IL-1β levels in vitro and in vivo. Importantly, CD11b activation resulted in significantly reduced IL-1β levels in both systems, suggesting a novel mechanism for controlling inflammation in glomerular diseases. Additional mechanistic studies are on-going to define the exact molecular mechanism of action. Murine models of SLE and LN display significant decreases in IL-1β when CD11b is activated, both genetically or pharmacologically, showing potential protection against LN.

Conclusions: Using these models, we have identified a possible link between CD11b activation and IL-1β secretion in myeloid cells. These studies will provide understanding of the influence CD11b has on signaling pathways and inflammation associated with inflammatory diseases such as LN.

Deletion of Smad3 Worsens Lupus Nephritis by Promoting B Cell Activation

Wenqian Xu,[1,2] Jinhong Li,[1] Xiao Ru Huang,[2,4] Cheuk-Chun Szeto,[2] Tak Mao D. Chan,[3] Xueqing Yu,[4] Zhihua Zheng,[1] Hui Y. Lan.[2,5] *[1]Department of Nephrology, Center of Urology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; [2]Department of Medicine & Therapeutics, Li Ka Shing Institute of Health Sciences, and Lui Che Woo Institute of Innovative Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Department of Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; [4]Guangdong-Hong Kong Joint Laboratory for Immunity and Genetics of Chronic Kidney Disease, Guangdong Academy of Medical Science, Guangdong Provincial People's Hospital, Guangzhou, China; [5]The Chinese University of Hong Kong-Guangdong Academy of Sciences/Guangdong Provincial People's Hospital Joint Research Laboratory on Immunological and Genetic Kidney Diseases, The Chinese University of Hong Kong, Hong Kong, China.*

Background: TGF-β signaling has been shown to play a critical role in many autoimmune diseases. However, its regulatory role in lupus nephritis remains unknown, which was investigated in the present study in a mouse model of lupus nephritis (LN) in which Smad3 gene was deficient.

Methods: To investigate the role of Smad3 in LN, we generated Smad3 knockout (KO) lupus mice by cross-breeding Smad3$^{+/-}$ mouse with B6.NZMSle1-3 lupus mice (C57BL/6J background) mouse. We then determined the regulatory role of Smad3 in the pathogenesis of LN and investigated the regulatory mechanisms of Smad3 in T cell and B cell activation and autoantibody production in Smad3 KO LN and Smad3 WT LN mice and B cells in vivo and in vitro.

Results: We successfully deleted the Smad3 gene from B6. NZMSle1-3 mice with unexpected findings that Smad3KO-LN mice developed much more severe LN with higher mortality rate (50%), higher circulating anti-dsDNA (60%), higher levels of serum creatinine (Cr, 30%) but lower creatinine clearance rate (Ccr, 20%), more severe glomerular necrosis (50%), massive renal immune complex deposition and complement activation, and progressive renal inflammation and functional injury. Mechanistically, we observed that lupus mice lacking Smad3 largely promoted Th1, Th2 and Th17 populations while suppressed Treg immune responses in the kidney. Unexpectedly, deletion of Smad3 largely increased macrophage inducible lectin-receptor (Mincle) expression by B220^{+} B cells (80%). Further studies showed that B cells lacking Smad3 were largely promoted Cytosine-phosphorothioate-guanine oligodeoxynucleotides (CpG ODN)-induced but failed to response to the inhibitory effect of TGF-β1 on Mincle-Syk-NFκB signaling, MHC II and CD86 expression, and autoantibody production. Importantly, silencing Mincle inhibited CpG ODN-induced Syk-NFκB signaling and IgG production by splenic B cells.

Conclusions: TGF-β/Smad3 signaling plays a protective role in LN by maintaining the balance of T cell immunity and B cell function. Loss of Smad3 worsens LN by shifting Treg to Th1, Th2 and Th17 and promoting B cell activation and autoantibody production via the Mincle-Syk-NFκB-dependent mechanism. Thus, outcomes from this study will be of great significance both scientifically and clinically.

PO1428

Intrarenal B Cells in Systemic Lupus Erythematosus Upregulate Na+-K+-ATPase to Facilitate Survival in a High-Sodium Environment

Irene Chernova, Joseph Craft. *Yale University, New Haven, CT.*

Background: The kidney is a unique microenvironment characterized by high sodium concentrations, yet susceptible to infiltration by lymphocytes in autoimmune diseases such as systemic lupus erythematosus. The effects of sodium-immune cell interactions on tissue injury in autoimmune disease and the mechanisms used by infiltrating lymphocytes to survive the high sodium environment of the kidney are not known.

Methods: We investigated the mechanisms utilized by B cells from lupus-prone mice to survive in a high Na^+ environment *in vitro* and *in vivo.* We also utilized biopsies from lupus nephritis patients to confirm our key findings.

Results: Here we show that numbers of kidney infiltrating B cells in murine lupus are significantly decreased when exposed to elevated sodium concentrations [Na^+] *in vivo* and that the expression of sodium potassium ATPase (Na^+-K^+-ATPase) correlates with the ability of infiltrating B cells to handle sodium stress. Pharmacological inhibition of Na^+-K^+-ATPase and a genetic knockout of the Na^+-K^+-ATPase gamma subunit, newly shown by us to be expressed in B cells, resulted in decreased kidney B cell infiltration and amelioration of proteinuria. Na^+-K^+-ATPase gamma subunit expression was also observed in renal B cells in human lupus nephritis.

Conclusions: These studies reveal that kidney-infiltrating B cells in lupus adapt to environmentally regulated sodium stress and identify Na^+-K^+-ATPase as a novel organ-specific therapeutic target in lupus nephritis.

Environmental Factors Influence Site and Magnitude of Myeloperoxidase and DNA Autoimmunity in BXSB Murine Lupus

Lanette Fee,[1] Robert M. Tighe,[1,2] Mary H. Foster.[1,2] *[1]Duke University, Durham, NC; [2]DVAMC, Durham, NC.*

Background: SLE is a systemic autoimmune disease with devastating clinical manifestations and complex origins linked to gene-environment interactions. To better understand the role of environmental factors, we exposed lupus-prone female mice to crystalline silica (Si) or vehicle (V) by oropharyngeal aspiration (OPA), mimicking an inhalational exposure compellingly linked to human autoimmunity. Si but not V exposed mice developed chronic lung inflammation, tertiary lymphoid structures (TLS), and elevated autoantibody (autoAb) levels. Si-exposed BXSB mice, a strain that develops vasculitis and glomerulonephritis, uniquely demonstrated elevated anti-myeloperoxidase (MPO) as well as anti-DNA Ig levels in bronchoalveolar lavage fluid (BALF). Herein we extend our studies in BXSB lupus to quantify local autoAb production and assess the impact of environmental co-exposure, using Toll-like receptor ligand (TLR-L) stimulation to mimic microbial infection.

Methods: BXSB mice were exposed to Si or V by OPA and organs harvested 2-3 months later. A subset of mice were injected with TLR4-L i.p. 1-2 days prior to harvest. Lung injury and TLS were quantified and autoAbs in serum, BALF, and cell culture supernatants (±TLR4 or TLR7/9 L) measured by ELISA; mean±SD.

Results: Si but not V exposed BXSB mice developed chronic lung injury (scores 5.0±4 vs 0.1±0.4) and lung TLS (counts 36±19 vs 0±0), n=13/grp, p<0.0001. Levels of anti-DNA and anti-MPO IgM and IgG in BALF and anti-DNA IgG in serum were elevated in Si vs V exposed mice (p<0.05, for each). Splenocytes produced little anti-MPO or anti-DNA Ig when cultured with medium and abundant anti-MPO IgM and anti-DNA IgM after TLR-L stimulation, regardless of Si vs V exposure (p=NS; n=13/grp). Anti-DNA IgG levels were higher from stimulated splenocytes of Si-exposed mice (OD 0.082±0.054 Si vs 0.035±0.011 V, TLR4-L, p=0.0009). Lung cells from Si but not V exposed mice produced abundant autoAb after TLR-L stimulation (OD 1.232±1.100 Si vs 0.025±0.043 V, anti-MPO IgM; OD 0.212±0.310 Si vs 0.001±0.001 V, anti-DNA IgG, TLR7/9-L, p<0.05).

Conclusions: Inhalational Si exposure enhances local and systemic autoimmunity in lupus-prone BXSB mice. Autoreactive B cells with diverse disease-relevant specificities, including anti-MPO and anti-DNA Ig, are recruited to the lungs, where they can be activated by co-exposure to exogenous or endogenous TLR-L.

Anti-SOD2 Antibodies in Lupus Nephritis as Second Wave Antibodies

Andrea Angeletti, Maurizio Bruschi, Francesca Lugani, Gianluca Caridi, Enrico E. Verrina, Gian Marco Ghiggeri. ZEUS Study *Istituto Giannina Gaslini, Genova, Italy.*

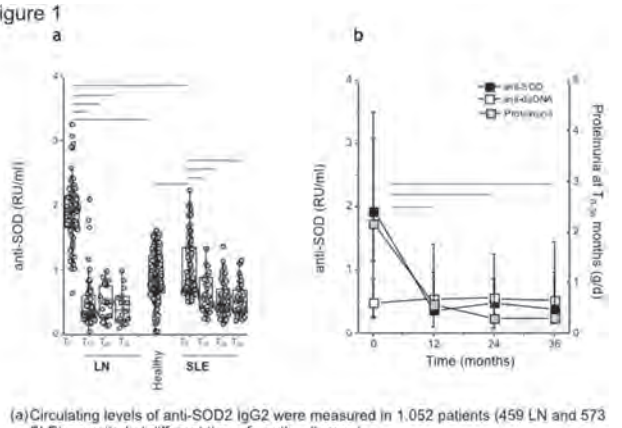
Background: Superoxide dismutase-2 (SOD2) is an enzyme with antioxidant action. Anti-SOD2 antibodies (anti-SOD2 IgG2) were recently described in the serum of subjects with Membranous Nephropathy, as antigens of a possible second wave injury. The presence of anti-SOD2 IgG2 correlated with worse outcomes in terms of response to treatment [1]. The presence and role of anti-SOD2 IgG2 in Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN), a secondary autoimmune glomerulonephritides, are to be clarified.

Methods: We measured serum levels of anti-SOD2 IgG2 (Homemade designed ELISA), every six months, in 1.052 patients (459 LN and 573 SLE) enrolled at different times from the diagnosis (i.e., 0-1 month, 2-12 m, 13-24 m, 25-48 m, 49-96 m, and >96 m). We also evaluated the main markers of the SLE activity, such as serum complement C3 and C4, ANA, ENA, anti-dsDNA and proteinuria. Of note, 91 LN and 130 SLE had a relevant follow-up of 36 months.

Results: As main characteristics, we report median age of 40 (IQR 28-54) years, the predominance of females (88%), disease activity (SLEDAI) of 4 (IQR 2-8). At the cross-sectional analysis, serum levels of anti-SOD2 IgG2 at T0 are significantly higher in LN than in SLE (**Fig 1a**). Considering LN, the serum levels of anti-SOD2 IgG2 at T0 were significantly higher than the other time points (**Fig 1a**). No correlation with the histological class of LN is reported. In LN, the reduction of anti-SOD2 IgG2 was in accordance with proteinuria. Anti-dsDNAs did not result as a valuable marker of disease activity (**Fig 1b**).

Conclusions: Circulating anti-SOD2 IgG2 are elevated in active LN. Serum levels of Anti-SOD2 IgG2, also considering the concomitant negative serum levels of anti-dsDNAs in all phases of LN, support the hypothesis of direct involvement of anti-SOD2 antibodies in LN as second wave antibodies that actively contribute to the manifestations of autoimmune glomerulonephritides.

Figure 1



(a) Circulating levels of anti-SOD2 IgG2 were measured in 1.052 patients (459 LN and 573 SLE), recruited at different times from the diagnosis.
(b) 91 LN and 130 SLE patients recruited at the time of the diagnosis were followed for 36 months. Anti-SOD2 and anti-dsDNA antibody levelsweredetermined every 6 months during the follow up. In both cases, antibodies were of the IgG2 isotype and levels were calculated as relative intensity value (RU/ml) given the absence of WHO international standards.

PO1431

Altered Propanoate Metabolism and gut Lachnospiraceae Composition in Lupus Nephritis Patients

Ji Eun Kim,[1] Ji In Park,[2] Hyo Eun Kim,[3] Jangwook Lee,[4] Hyunjeong Cho,[6] Dong Ki Kim,[3,5] Yon Su Kim,[3,5] Hajeong Lee.[3,5] *[1]Korea University Guro Hospital, Seoul, Republic of Korea; [2]Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; [3]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [4]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [5]Seoul National University, Gwanak-gu, Seoul, Republic of Korea; [6]Chungbuk National University Hospital, Cheongju, Chungcheongbuk-do, Republic of Korea.*

Background: There are growing evidence for the role of gut microbiota in the pathogenesis systemic lupus erythematosus (SLE), especially lupus nephritis (LN). Recently, high abundance of Ruminococcus gnavus belonging to the family Lachnospiraceae has been noticed in fecal sample of LN patients. However, the functional role of gut microbiota and its metabolic pathway which affect host metabolism in LN are less understood.

Methods: Shotgun sequencing of fecal samples from biopsy-proven LN patients and matched controls was performed. We used Kraken2 for taxonomic analysis and humann2 with customized KEGG database for genefamily analysis. Comparison of taxonomic abundance and genefamilies were assessed by Maaslin2.

Results: Control and LN group were included 24 and 20 patients, respectively. Both groups had similar age, sex, and eGFR. In the comparison of relative abundance of major species, Roseburia intestinalis, Butyricimonas faecalis, and Eubacterium eligens were significantly decreased while Ruminococcus gnavus was significantly elevated in LN group, respectively. Interestingly, 3 of these 4 species were included in the same Lachnospiraceae family showing a significantly different composition between the two groups (PERMANOVA p=0.042). Furthermore, we found 161 differentially expressed genefamilies including 65 metabolism-associated and 29 carbohydrate metabolism-associated genes. Considering Lachnospiraceae is known to play a role in propanoate (esters of propionate) formation, we further assessed the propanoate pathway (ko00640). As a result, LN patients revealed more prone to propanediol pathway rather than in succinate pathway in the propanoate pathway. This tendency was more pronounce in the contribution to the pduE gene by R. gnavus having well-known pathogenetic linkage with SLE.

Conclusions: LN patients showed altered propanoate metabolism associated with the differential species composition of Lachnospiraceae including R. gnavus. Functional role of this alteration on the pathogenesis of LN should be clarified by further investigations.

PO1432

Gut Microbiome Changes in NZBWF1/J Murine Lupus Nephritis

Tak Mao D. Chan, Jing Yu, Chi pang Tai, Susan Yung. *Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong.*

Background: Lupus nephritis is an important cause of acute kidney injury and chronic kidney disease. There is preliminary data that gut dysbiosis may be involved in the pathogenesis of lupus nephritis. We investigated gut microbiota burden in murine lupus nephritis.

Methods: Eight-week old NZBWF1/J mice were randomized to receive drinking water alone or containing ampicillin (1.0 mg/ml) and neomycin (0.5 mg/ml) for 18 weeks. Renal and colonic histopathology was examined, and intestinal mucosal permeability investigated with LPS-FITC. Quantitative changes in gut microbiota were assessed by 16S rRNA sequencing.

Results: Serum LPS and urea levels, and proteinuria were significantly lower in antibiotic-treated mice ($P<0.05$, for all). Histopathologic manifestation of active nephritis and podocyte foot process effacement were associated with increased LPS-binding protein, CD14 and TLR-4 expression in proximal renal tubular epithelial cells, and increased interstitial α-smooth muscle actin, fibronectin and collagen expression. Mice with active nephritis showed increased gut permeability to LPS-FITC given orally, and decreased ZO-1 expression in the colonic epithelium. 16S rRNA sequencing data showed that active nephritis was associated with a progressive decrease in Gram-positive bacteria phyla *Actinobacteria* and *Firmicutes* and increased Gram-negative bacteria phyla *Bacteroides* and *Proteobacteria*. Antibiotic treatment significantly decreased *Bacteroides*, which was associated with lower levels of serum LPS and urea, proteinuria, and ameliorated histopathologic features in the colon and kidney.

Conclusions: Murine lupus nephritis is associated with gut dysbiosis, which may contribute to the pathogenesis of nephritis progression.

PO1433

The Significance of Glomerular Galactose-Deficient IgA1 in Patients with Systemic Lupus Erythematosus (SLE)

Lihong Bu,[1] Bayardo I. Garay,[1] Youngki Kim,[1] Fm Lai,[4] Xin J. Zhou,[3] Patrick H. Nachman,[1] Cynthia C. Nast.[2] *[1]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Pathologists Bio-Medical Laboratories, Dallas, TX; [4]The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, China.*

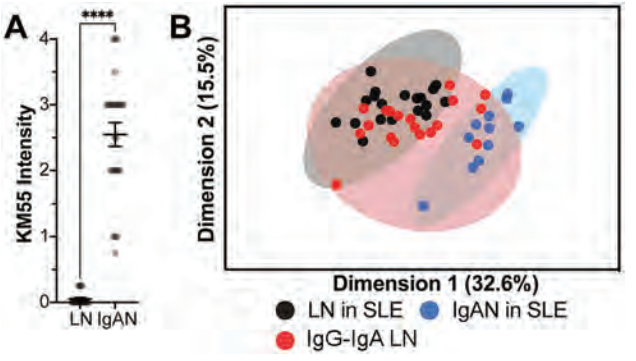
Background: Approximately 0.3% of end stage kidney disease in SLE patients is due to non-lupus nephritis. IgA nephropathy (IgAN) is rarely reported in SLE patients. As galactose-deficient IgA1 (Gd-IgA1) plays a key role in the pathogenesis of IgAN but not SLE, the aim was to investigate whether KM55, a Gd-IgA1 specific monoclonal antibody, might identify IgAN in patients with SLE.

Methods: Immunofluorescence (IF) staining of KM55 was performed on 77 native kidney biopsies from 25 non-SLE (IgAN or IgA vasculitis (IgAV)) and 52 SLE patients, the latter including lupus nephritis (LN) with IgG dominant full house staining (LN; n=20), IgAN without features of LN (IgAN; n=11), concurrent LN class V and IgAN (n=2), and LN with dominant/co-dominant IgA (IgG-IgA-LN; n=19). In SLE patients, principal component analysis was carried out on LN, IgAN, and IgG-IgA-LN cases.

Results: KM55 staining intensity >0.5 (trace) on a scale of 0-4 discriminates IgAN/IgAV from LN with a sensitivity of 1.00 [0.86-1.00] and specificity of 1.00 [0.82-1.00] ($p<0.0001$) (Fig 1). KM55 staining with mean 2+ intensity was detected in all SLE patients with lgAN and no features of LN. IgAN had no difference in KM55 intensity or distribution in non-SLE vs SLE patients. Mesangial KM55 staining was detected in cases with dual LN class V and IgAN. Of 19 IgG-IgA-LN biopsies, 9 (47%) showed positive KM55 staining in the same distribution as IgA.

Conclusions: Our results demonstrate that IF staining of KM55 is valuable in distinguishing IgAN from LN. In SLE patients, negative KM55 staining argues against the presence of IgAN while >0.5 (trace) KM55 staining with dominant/co-dominant IgA staining is suggestive of IgAN as the sole lesion or a co-occurring component of dual glomerulonephritis.

Funding: Other NIH Support - NHLBI [F30HL151138 to BIG]



A) KM55 staining intensity in LN and IgAN/IgAV. B) Principal component analysis shows LN with dominant/co-dominant IgA (IgG-IgA-LN; pink) with overlapping features with LN (grey) and/or IgAN (blue).

Tertiary Lymphoid Tissue Development Is Associated with Impaired Renal Function in Lupus Nephritis

Yuki Sato,[1,2] Makiko Kondo,[2] Shingo Fukuma,[3] Naoya Toriu,[2] Yoshifumi Ubara,[4] Motoko Yanagita.[2,5] *[1]Medical Innovation Center TMKP, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [4]Department of Nephrology, Toranomon Hospital, Tokyo, Japan; [5]Institute for the Advanced Study of Human Biology (ASHBi), Kyoto University, Kyoto, Japan.*

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE) and the pathophysiology is heterogenous. Recently, the careful assessment of not only glomerular but tubulointerstitial lesions has been proposed for more precise evaluation of the disease activity, which leads to better management. Tertiary lymphoid tissues (TLTs) are inducible ectopic lymphoid tissues formed in the kidney interstitium under chronic inflammation. Several studies have reported TLTs in LN, though the frequencies, clinical characteristics and relevance in LN have been undefined.

Methods: We examined the presence of TLTs in 205 kidney biopsy samples of patients with LN and investigated the clinical characteristics of patients with renal TLTs. TLTs were defined as organized T and B cell aggregates with sign of proliferation. Histological activity and damage at biopsy were calculated as the National Institute of Health (NIH) activity and chronicity indices (CI).

Results: 43 patients (21%) exhibited TLTs in the kidneys. There were no significant differences in ISN/RPS classification between LN patients with TLTs and those without TLTs. TLT development was not associated with disease activity indicators, such as SLEDAI, dsDNA titer, proteinuria, or complement factors, but it was associated with reduced eGFR (60.2 versus 83.8 ml/min/1.73m^2, P = 0.001) and higher histological kidney injury scores (P = 0.0038). A higher prevalence of TLTs was observed with age over 40 years old and non-treatment history of immunosuppressive drugs. Additionally, TLT development was associated with incidence of hypertension.

Conclusions: Association between TLT development and reduced eGFR and higher histological injury suggest the potential of TLTs as an additional histological marker for evaluation of LN disease activity. Dissociation between TLT development and SLE disease activity indexes such as SLEDAI and dsDNA antibody titers also suggest that TLTs development are, at least partly, independent of the severity of glomerulonephritis.

PO1435

New Drugs and Evolving Treatment Patterns in Lupus Nephritis: How Nephrologists and Rheumatologists Are Responding Differently to New Treatment Options

Tucker B. Hurtado, Jennifer Robinson, Ryan Rex. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: Early uptake and experience with recently approved lupus nephritis (LN) drugs belimumab and voclosporin reveal different perceptions, comfort levels, and prescribing intentions between nephrologists and rheumatologists.

Methods: Data were collected over four waves of research between February and May 2021 via online surveys with 50 US nephrologists and 50 US rheumatologists who are actively treating LN patients, followed-up with a subset of qualitative interviews.

Results: In a notable trend, rheumatologists deem more of their LN patients as candidates for belimumab, while nephrologists increasingly see their patients as better suited for voclosporin. Rheumatologists tend to rate belimumab higher overall than voclosporin, particularly on safety and tolerability, thanks to long term history with the product in SLE patients. Both physician types generally use belimumab as later-line therapy in mild-to-moderate LN, often to reduce steroid burden. It is generally used with at least one other advanced agent like an antimalarial, steroid, or MMF. Recently initiated patients are most often in CKD Stage 3, with proteinuria and fatigue. Nephrologists favor voclosporin, likely due to their familiarity with the CNI drug class. Both physician-types are using voclosporin even later-line than belimumab for moderate-to-severe LN patients given the drug's perceived quicker onset of action, efficacy, and steroid-sparing effect. Voclosporin is nearly always used concomitantly with advanced drugs like antimalarials, steroids, or MMFs. Rheumatologists appear to be initiating voclosporin most often in CKD Stage 2, while nephrologists are initiating most often in CKD Stage 3. Rheumatologists are the leading prescribers of belimumab, and currently have a slight edge with voclosporin patient initiations as well. Nephrologists are tending to wait longer to initiate, due to cost- and risk-benefit uncertainty compared to other options like tacrolimus. Rheumatologists currently view both drugs as a greater treatment advance than nephrologists; nephrologists believe voclosporin is more of an advance in LN treatment than belimumab.

Conclusions: Physician understanding and comfort level with belimumab and voclosporin MOAs are driving early use and perceptions of the two new LN drugs.

PO1436

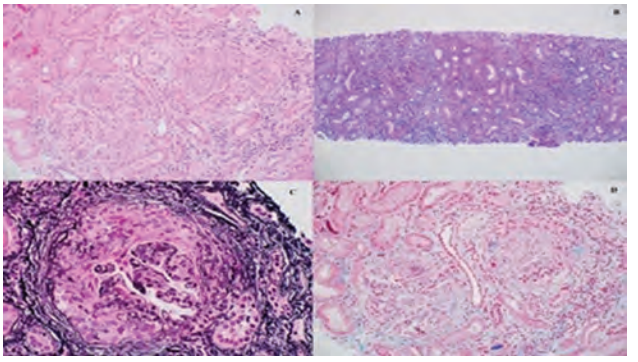
Treatment of Crescentic Lupus Nephritis with Voclosporin

Irshad Hussain,[1] Syed H. Bukhari,[1] Paul F. Shanley,[2] Ramya Bhargava.[1] *[1]State University of New York Upstate Medical University Division of Nephrology, Syracuse, NY; [2]State University of New York Upstate Medical University Department of Pathology, Syracuse, NY.*

Introduction: Crescentic glomerulonephritis (CGN) is a rare complication of Lupus nephritis (LN) and carries a worse prognosis. There is paucity of data regarding effective treatment options for CGN. We present a case of crescentic ANCA negative LN treated with voclosporin (VSN).

Case Description: 19-year-old African American female with 2-year history of Class II LN, treated with hydroxychloroquine 200 mg/day, prednisone 10 mg/day, mycophenolate mofetil 1 gm twice daily and Belimumab, presented with a 2-week history of anasarca and generalized bullous skin rash. On exam BP 126/78 mm Hg, HR 96/min, afebrile, RR 18/min, O2 saturation 97% on room air. Investigations revealed hemoglobin 9.2 g/dL, serum creatinine (SCR) 1.2 mg/dl (baseline 0.6), albumin 1.9 g/dL, hypocomplementemia, microscopic hematuria and proteinuria of 4.3 gm. A kidney biopsy showed diffuse crescentic immune complex LN and membranous LN (Figure 1). The patient received IV methylprednisolone 1gm for 3 days, however, became anuric, SCR peaked at 5 mg/dl and was commenced on hemodialysis and 7 sessions of plasma exchange. She was started on VSN 15.8 mg BID and after 10 days of therapy, SCR improved and dialysis was discontinued. On discharge, SCR was 2.0 mg/dl and proteinuria 0.9 gm. C4 normalized and C3 improved.

Discussion: There has not been any published case report of Crescentic LN being treated successfully with VSN. Given poor prognosis of CGN, early diagnosis and treatment is imperative. Our patient had rapid recovery of renal function and resolution of proteinuria following treatment with VSN. VSN may be effective in combination with plasma exchange in ANCA negative Crescentic LN. Larger studies with longer follow-up are needed to assess the efficacy of VSN in CGN.



A. H&E stain shows diffuse segmental endocapillary hypercellularity and glomeruli with cellular crescents (60%), segmental necrosis and subendothelial deposits. B and C. PAS and Silver stains show no glomerular basement membrane remodeling. D. Trichome stain with moderate interstitial fibrosis and tubular atrophy (35%).

PO1437

Healthcare Resource Utilization and Costs over 5 Years for a Systemic Lupus Erythematosus (SLE) Cohort Newly Diagnosed with Lupus Nephritis: Evidence from a US Administrative Claims Database

Christopher F. Bell,[1] Benjamin Chastek,[2] Bernie Rubin,[3] Shirley Huang.[1] *[1]US Value, Evidence and Outcomes, GlaxoSmithKline, Research Triangle Park, NC; [2]Optum, Eden Prairie, MN; [3]GlaxoSmithKline, Philadelphia, PA.*

Background: Lupus nephritis (LN) occurs in ~40% of adults with SLE. Despite the high burden of LN, current care management and utilization data are limited. This longitudinal study evaluated US healthcare resource utilization (HRU) and costs over 5 years in patients (pts) with SLE newly diagnosed with LN.

Methods: This retrospective cohort study (GSK Study 214102) used data from the Optum Research Database. Index date was the first claim with a renal diagnosis code indicating LN during the identification period (Aug 1, 2011–Jul 31, 2018). Inclusion criteria: age ≥18 years; ≥2 renal diagnosis codes during the identification period; ≥1 inpatient or ≥2 outpatient SLE diagnosis codes in the 12 months pre index; and continuous enrollment of ≥12 months pre and post index. HRU and costs for the cohort with 5 years of continuous enrollment post index are reported.

Results: Overall, 2159 pts met the study criteria (mean [standard deviation, SD] age, 58.5 [14.9] years; 86.7% female) and 335 had ≥5 years of continuous enrollment post index. HRU and costs were highest in the first year post LN diagnosis (**Figure**). Mean healthcare costs were $44,205 in Year 1 and ~$30,000/year in Years 2 through 5. Approximately 50% of patients incurred an inpatient stay in Year 1, with ~25% of patients hospitalized in each subsequent year.

Conclusions: Patients with newly diagnosed LN incur substantial HRU and costs, which were highest in the year of diagnosis. These data highlight the need for interventions to prevent renal worsening in SLE.

Funding: Commercial Support - GSK

PO1438

Association of TNIP1 Variants with Disease Severity and Progression and IP-10 Chemokine Levels in Lupus Nephritis Patients

David W. Powell,[1,2] Makayla Brady,[2] Michelle T. Barati,[1] Dawn J. Caster.[1] *[1]University of Louisville School of Medicine, Division of Nephrology, Louisville, KY; [2]Department of Biochemistry and Molecular Genetics, University of Louisville., Louisville, KY.*

Background: African American SLE patients experience higher rates of LN, increased progression to ESKD, and higher mortality when compared with white patients, but etiology for this disparity in unclear. We reported that a TNIP1 polymorphism, rs4958881, is a risk variant for lupus nephritis (LN) in African American patients. TNIP1 encodes the protein ABIN1, which negatively regulates the transcription factor NF-κB. Transgenic mice with impaired ABIN1 function (ABIN1[D485N]) spontaneously develop autoimmunity and LN. IP-10 is a pro-inflammatory chemokine and NF-κB target.

Increased tissue levels of IP-10 have been implicated in pathogenesis and as a diagnostic marker of LN, but the mechanism is unknown. The current project tested a hypothesis that LN severity and enhanced IP-10 levels are associated with the TNIP1 rs4958881 risk allele.

Methods: All endpoints were compared for LN patients w/wo TNIP1 variant rs4958881. LN pathology classifications were compared for 125 African American and 133 White American LN patients. Urine and serum IP-10 levels were measured in 33 LN patients using ELISA. Progression of disease was assessed and compared from follow up (mean = 3 yrs) for 33 LN patients. Urine, plasma, and kidney levels of IP-10 were compared in wildtype and ABIN1[D485N] mice.

Results: A higher percent of African Americans with Class IV LN had the TNIP1 variant (68%) versus 42% for Whites with Class IV and 93% of African American with Class V LN had the variant versus 38% for Whites with Class V. 26.3% of patients with the variant vs. 7.1% of patients without the variant reached the endpoint of doubling of creatinine or ESKD. Proteinuria at follow up was higher in variant (2800 mg/g) vs. non-variant (1175 mg/g) patients, suggesting refractory disease in variant patients. There were significantly higher levels of IP-10 in serum and urine from African American versus White LN patients and a trend for association in patients with the variant. Urine, plasma, and kidney levels of IP-10 were significantly enhanced in ABIN1[D485N] versus wildtype mice.

Conclusions: Our findings suggest that TNIP1 variant genotyping and IP-10 measurement could provide precision diagnostics for African American LN patients and that inhibition of NF-κB or neutralization of IP-10 is a promising personalized therapeutic direction for these patients.

Inflammatory Dendritic Cell and Th17 Polarization in Mouse Model of Lupus Nephritis

Latha Prabha Ganesan, Noushin Saljoughian, James M. Turman, Murugesan Rajaram, Brad H. Rovin, Wael Jarjour, Samir V. Parikh. OSU Nephrologist *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: We have recently identified inflammatory dendritic cells (InfDC) in human lupus kidneys. These cells are over expressed in LN patients compared to healthy controls. Knowledge on how the infDC interact with intra-renal T cells and their role in pathogenesis of LN kidney is crucially needed

Methods: We examined infDC and T cells in the kidneys of NZM 2410 (NZM), from proteinuric (prot-NZM) mice (proteinuria ≥300mg/dl) and pre-proteinuric NZM (pre-prot-NZM) mice by Immunofluorescence (IF). To quantitatively assess infDC and various T cells, we analyzed single cell suspensions obtained by enzymatic digestion followed by gentle MACS dissociation from prot-NZM kidneys and pre-prot-NZM kidneys by multi-color flow cytometry using specific markers for infDC and T cells.

Results: The immunofluorescence studies recapitulated the human LN robust infiltration of the infDC marked by FcRγ in the periglomerular and tubulointerstitium in prot-NZM compared to pre-prot-NZM. The infDC were also identified to be in close proximity to CD3+ T cells constant with an immunological synape. Further characterization by IF revealed infDC in mice LN were $FcR\gamma^+$, $MHCII^+$, $CD11c^+$, $CD163^-$, $CD11b^+$, $Ly6C^+$. Interestingly, 2 subtypes of infDC were identified in NZM mice, $FcR\gamma^+MHCII^+CD11c^+$, $CD11b^+$ and $FcR\gamma^+MHCII^+CD11c^-$, $CD11b^+$ and differentiated by the presence or absence of CD11c. Flow cytometry analysis of T helper cell phenotypes shows that Th17 expression, but not Th1 was upregulated significantly in prot-NZM compared to pre-prot-NZM in parallel to infDC.

Conclusions: Similar to human LN, infDC are abundant in prot-NZM LN kidneys compared to respective pre-prot NZM and healthy control kidneys; 2) infDC synapse with CD3+ T cells in LN kidneys; and 3) Th17 cells, but not Th1 cells, correlate with infDC's expression in LN kidneys. These data suggests that infDC regulate the intra-renal Th17 cell response in LN and contribute to IL-17 mediated kidney injury. Ongoing studies will examine if these infDC are necessary or sufficient to cause LN.

PO1440

SeqStain Is a Novel, Multiplex Imaging Method for Spatialomic Profiling of Human Kidney Tissues

Ishwarya Venkatesh, Anugraha R. Rajagopalan, Disha Varma, Vineet Gupta. Team SeqStain *Rush University Medical Center, Chicago, IL.*

Background: Chronic Kidney Disease (CKD) is the ninth leading cause of death in the United States, an emerging global health challenge affecting 10-15% of the population. Lack of reliable biomarkers precludes early diagnosis of CKD. The progression of CKD is known to be dictated by renal tissue changes. For instance in Diabetic Nephropathy, disease progression is accompanied by considerable changes to the glomeruli, reduced podocyte number, inflammation in the renal tissue, influx of immune cells that ultimately lead to tissue damage. Understanding these tissue-centered events on a deeper level is imperative for early diagnosis

Methods: To understand molecular and cellular composition of tissues and their relative organization in three-dimensional space, we developed a novel multiplex staining method called SeqStain. The SeqStain multiplex platform uses fluorescently labeled DNA oligonucleotides (termed "SeqStain antibodies") to stain while endonucleases are used to achieve gentle de-staining after each round. This methodology can fluorescently label primary antibodies, secondary antibodies and Fabs of secondary antibodies to efficiently analyze complex tissues. We generated a SeqStain multiplex panel with antibodies that would probe different histological regions relevant to the kidney

Results: Normal kidney was stained with SeqStain antibodies and de-stained using endonucleases. Using SeqStain methodology, we built >20-plex panel on kidney tissue and provided a simple, gentle and rapid technique for multiplex imaging. Strikingly, de-staining using the SeqStain method was rapid and removed ~99% of the signal in <1min without affecting tissue integrity. The method was implemented using a simple perfusion setup with readily available components, allowing staining of tens of antigens on a single tissue section. Alignment of images and their analyses provided spatialomic data on multiple cell types in tissue

Conclusions: The SeqStain method offers a gentle, easy-to-use, and effective multiplex imaging technique that provides a unique platform for obtaining spatialomic insights. SeqStain method can profile the CKD kidney tissues and comprehend the tissue-centered events that could play a role in disease progression. Currently, we are profiling the CKD tissues in multiplex staining experiments in comparison to healthy human kidney to generate spatial maps

PO1441

A Phase 1 Study to Evaluate the Safety, Tolerability, and Pharmacokinetics of AT1501

Steven Perrin. *Eledon Pharmaceuticals, Irvine, CA.*

Background: CD40L is a costimulatory receptor for CD40 found on T helper cells. Binding of CD40L on T cells to CD40 on antigen presenting cells induces downstream immune and inflammatory responses. Inhibition of CD40L signaling can abolish inflammation, prevent the progression of autoimmunity, and instill transplant tolerance. AT-1501 is a humanized anti CD40L antibody lacking Fc effector function and high affinity binding to CD40L. Purpose: Execute a phase 1 study of AT-1501 to assess safety, pharmacokinetics, and functional activity.

Methods: The study employed a placebo-controlled, sequential, dose-escalation design. 28 healthy subjects and 4 adults with ALS were enrolled. Five sequential ascending doses of AT1501 (0.5, 1, 2, 4, or 8 mg/kg) or placebo were administered by IV infusion. The primary endpoint was the safety and tolerability of AT1501. The secondary endpoint was to determine plasma pharmacokinetics (PK) and anti-drug antibody (ADA) responses to AT1501. An exploratory endpoint was to examine the ability of AT1501 to block an immune challenge in subjects who received a Keyhole Limpet Hemocyanin (KLH) challenge.

Results: Dose proportionality was achieved over the AT-1501 dose range of 0.5 to 8 mg/kg for C_{max} and AUC_{0-t}. The mean AT-1501 $t_{1/2}$ in healthy volunteers was 18 to 26 days. AT1501 had a safety profile comparable to placebo and was well tolerated in healthy subjects and subjects with ALS. 54% of subjects treated with AT-1501 had at least 1 TEAE and 62% of subjects treated with placebo had at least 1 TEAE. The most commonly reported TEAEs overall were headache, somnolence, and upper respiratory tract infection. There were no meaningful laboratory abnormalities, vital sign assessments, ECG assessments, or physical examination findings. Positive ADA responses to AT-1501 were observed in 6 of 30 subjects in the study. There was no dose dependence with respect to the incidence of positive ADA titers. ADA did not appear to affect AT-1501 plasma PK profiles or parameters suggesting they were not neutralizing. 8 mg/kg AT-1501 successfully blocked an immune response to KLH challenge in 2 of the 3 subjects tested.

Conclusions: Our results support further clinical development of AT-1501 for transplantation and autoimmune indications

PO1442

High Expression of Mincle in Intermediate Monocytes of Patients with Autoimmune Diseases

Shuping Li,[1] Lokyu Cheng,[1] Tianjiao Cui,[1] Lanyue Zhang,[1] Xiuxun Tian,[1] Zhizhuang J. Zhao,[2] Yun Chen,[1] Zhihua Zheng.[1] *[1]The Seventh Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China; [2]Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Macrophage-inducible C-type lectin (Mincle) is a transmembrane C-type lectin receptor that is predominantly expressed on macrophages' surface and recognizes a broad range of self and foreign antigens as part of innate immune sensing, thus playing a pivotal role in tailoring immune response. Mincle's function associates with its expression levels on immune cells' surfaces. However, the differential expression of Mincle in various types of immune cells between patients with autoimmune disease (AD) and normal controls (NCs) is yet to be examined, and its clinical relevance remains unclear. Therefore, this study aimed to investigate Mincle expression and distribution in different types of immune cells in patients with AD and NCs, and to explore the clinical relevance and potential mechanisms of Mincle expression levels in immune cells of peripheral blood in patients with systemic lupus erythematosus (SLE).

Methods: Mincle expression levels in leukocyte subgroups and monocyte subsets of peripheral blood from all participants were analyzed using flow cytometry and real time PCR, and the clinical characteristics of patients with SLE were collected for correlation analysis. Intermediate monocyte (IM) were co-cultured with naïve T cells, and the differentiations of naïve T cells were detected by flow cytometry.

Results: Mincle was expressed predominantly in myeloid cells, both in peripheral blood and cell lines. Moreover, monocytes expressed higher levels of Mincle than granulocytes in both patients with AD and NCs, and Mincle expression levels were higher in IMs of patients with AD, including patients with SLE, than in those of NCs;

however, Mincle was not differentially expressed in granulocytes, lymphocytes, classical monocytes, and nonclassical monocytes between the two groups. In addition, Mincle expression was positively correlated with immunoglobulin G and κ-LC levels in serum but negatively related to serological renal function index (serum urea and creatinine levels) in patients with SLE. IMs increase the differentiation of toward Th1, Th2 and Th17, but IMs decrease naïve T cells toward Treg.

Conclusions: High expression levels of Mincle in IMs were associated with elevated immunological indicators in patients with SLE. IM influences the differentiation of T cells in patients with SLE.

PO1443

Development of Kidney Resident and Recruited Macrophages

Nicholas J. Steers, Judy Liang, Kelsey O. Stevens, Anna Mo, Cathy L. Mendelsohn, Jonathan M. Barasch, Ali G. Gharavi. *Columbia University Irving Medical Center, New York, NY.*

Background: Macrophages are part of the phagocyte mononuclear system constantly replaced by the circulating blood monocytes. In the steady state, the myeloid cell compartment is highly heterogenous, and contains cells of different origins and functions. These cells include macrophages and dendritic cells, and each play important roles in tissue maintenance, including development, homeostasis, immunity and repair following tissue injury. The composition of kidney macrophages is not well known.

Methods: A multi-parameter flow cytometry approach was used to identify the resident and recruited macrophage population in the kidneys of male and female C57BL/6J mice aged -7, -21 and -84 days in the steady state. Resident and recruited macrophage populations were characterized based on 33 cell surface and intracellular markers.

Results: Both resident and recruited macrophages were identified in the kidneys of male and female mice aged -7, -21 and -84 days in the steady state. We observed two distinct resident macrophage populations in young mice (7 and 21 days old) but by 84-days, male and female mice displayed 4 and 5 resident populations, respectively. The resident macrophage population in 7-day old mice displayed low surface expression of MHC class II and began to shift to an increased expression of MHC class II at 21 days, and high MHC class II expression at 84 days. We detected three recruited macrophage populations in 7- and 21-day-old mice, and two populations by 84-days of age. The recruited macrophage population displayed low MHC class II at all ages in both sexes. Analysis of the global macrophage populations at 84 days of age revealed female mice had twice as many recruited compared to resident macrophages, whereas male mice had an equal distribution.

Conclusions: The data indicate a dynamic change in the kidney macrophage population, leading to an activated resident macrophage phenotype. The composition of macrophage populations also differs by sex and age. These data suggest each population plays a role in kidney homeostasis. Future studies will be directed towards elucidating the functions of each of the identified macrophage populations.

Activation of the Integrated Stress Response Regulates the Production of IL-17 in Tissue Resident Memory T Cells

Nariaki Asada, Pauline Ginsberg, Anna Kaffke, Anett Peters, Ning Song, Jan-Hendrik Riedel, Hans-Joachim Paust, Christian F. Krebs, Hans-willi Mittrücker, Ulf Panzer. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*.

Background: CD4-positive T cells produce cytokines and play a central role in immunity. Tissue-resident memory T (Trm) cells remain in organs after infection and contribute to efficient host defense by immediate production of cytokines, such as IL-17A. More recently, it was demonstrated that Trm cells also promote autoimmunity. Therefore, the regulation of cytokine production by Trm cells is of great importance to achieve efficient host defense without excessive inflammation. However, the control mechanisms of cytokine production by Trm cells are not well understood.

Methods: Human and mouse T cells including renal Trm cells were analyzed by single cell RNA sequencing (scRNAseq), polysome profiling combined with bulk RNA sequencing, RT-PCR, flow-cytometry, immunocytochemistry, and mRNA FISH. Mouse models for *Staphylococcus aureus* infection and crescentic glomerulonephritis were used to induce and study Trm cells *in vivo*.

Results: Combined scRNAseq, polysome profiling and tissue signature analysis of human and mouse tissue samples revealed that resting $CD4^+$ Trm cells in the kidney express *IL17A* mRNA but do not produce or secrete the cytokine protein without re-stimulation. Mechanistically, we demonstrate that the phosphorylation of eIF2a, a key feature of the integrated stress response (ISR) activation, resulted in recruitment of *IL17A* mRNA into stress granules, which are organelles crucial for regulating mRNA translation during ISR, thereby inhibiting mRNA translation in resting Trm cells. Finally, we show that re-stimulation of human renal Trm cells through T cell receptor resulted in eIF2a dephosphorylation, leading to efficient translation of *IL17A* mRNA and subsequent IL-17A secretion.

Conclusions: Tissue-resident memory $CD4^+$ T cells in the kidney express high levels of IL-17A cytokine mRNA. Under homeostatic conditions the cytokine mRNA is stored in stress granules and not translated into protein. In contrast, these Trm cells rapidly produce IL-17A upon re-stimulation. Our study identifies a novel mechanism of how “poised Trm17 cells” use the integrated stress response - stress granules pathway to regulate IL-17A cytokine mRNA translation. Dysregulation of this pathway might have a pathogenic role in chronic relapsing and remitting inflammatory diseases.

Differential Cell Cycle and Kinase Activation in IgA1-Producing Cells from IgAN Patients and Healthy Controls Mediated by Cytokine Stimulation

Colin Reily, Dana Rizk, Jan Novak. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Some cytokines increase production of galactose-deficient IgA1 (Gd-IgA1) in immortalized IgA1-producing cells derived from peripheral blood of patients with IgAN. Previous work has indicated dysregulated cytokine induced signaling may be responsible, but minimal work investigating the overlapping pathways has been performed. Using single-cell transcriptomics, we analyzed pathway responses in immortalized IgA1-secreting cells derived from IgAN patients and healthy controls (HC) before and after response to a mixture of cytokines.

Methods: A mixture of cytokines mimicking those produced by T-follicular helper (Tfh) cells (IL-4, IL-6, IL-21, CD40L; 50 ng/mL) was used to stimulate immortalized IgA1-producing cells for 30 min before single-cell transcriptomic analysis. Gd-IgA1 level was determined by lectin ELISA. Standard data processing using Seurat was performed along with Alteryx for IgA1 separation. Differential markers for genes in unstimulated and stimulated conditions were analyzed for pathway differences using the GSEA MSig database, and kinase-transcription factors were imputed using X2K analysis.

Results: Tfh cytokines mediated overproduction of Gd-IgA1 in IgAN cells but not HC. IgA1-secreting subpopulations were separated, and UMAP was used for unsupervised dimension reduction analysis. Within these UMAP groups, pathway analysis found multiple significant associations, including down-regulation of cell cycle processes ($FDR<6X10^{-25}$) in IgAN IgA1 cells compared to an increase in HC ($FDR<4.7X10^{-6}$) cells after Tfh cytokine stimulation. Analysis of imputed kinases changed in IgAN stimulated IgA1 cells compared to HC identified MAPK14 ($p<1X10^{-20}$ and AKT1 ($p<1.1X10^{-17}$), which have been associated with controlling *O*-glycosylation expression.

Conclusions: Significant changes in imputed kinases previously associated with *O*-glycosylation were found in IgA1-secreting cells in IgAN compared to HC in response to Tfh cytokine stimulation. When stimulated with cytokines, there were significant decreases in cell cycle and proliferation pathway responses in the IgA1-secreting cells from IgAN vs. HC samples. Further investigation is needed to determine the role of cell cycle and MAPK14 pathways in driving Gd-IgA1 overproduction mediated by cytokine stimulation.

Serum and Glomerular Complement Components as Biomarkers in the First South Asian Prospective Longitudinal Observational IgA Nephropathy Cohort (GRACE-IgANI)

Suceena Alexander,[1] Santosh Varughese,[1] Athul Thomas,[1] Jeethu J. Eapen,[1] Elenjickal E. John,[1] Anna T. Valson,[1] Vinoi G. David,[1] John Feehally,[5] Jonathan Barratt,[4] George John,[1,2] Marc M. Seelen,[3] Mohamed R. Daha.[3] *[1]Christian Medical College Vellore, Vellore, India; [2]Royal Brisbane and Women’s Hospital, Herston, QLD, Australia; [3]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [4]University of Leicester College of Life Sciences, Leicester, United Kingdom; [5]University of Leicester, Leicester, United Kingdom.*

Background: The **G**lomerular **R**esearch **A**nd **C**linical **E**xperiments- **IgA** **N**ephropathy in **I**ndians is a prospective longitudinal cohort. The study protocol has been published and is registered with WHO trial id: ISRCTN36834159. The role of serum and glomerular complement components in South Asian IgAN is unknown.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 192 (97%) patients completed 3 years. Serum complement C3 and C4 levels and glomerular C3d, C4d and C5b-9 by IHC were quantified at baseline in IgAN patients. Composite outcome (CO) was defined as ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m² or RRT/death.

Results: 195 patients (97%) completed 3 year longitudinal follow-up. Lower serum C3 was significantly associated with S1, T1/T2 according to the Oxford MEST grading and with global glomerulosclerosis (GS>33%) whereas higher C4 levels were associated S1 scores. Increased mesangial C3d deposition correlated with increased mean arterial pressure, proteinuria, decreased serum albumin, decreased eGFR and with GS>33%. Similar to C3d, increased mesangial C4d correlated with increased systolic blood pressure, decreased serum protein and decreased eGFR and with GS>33%. Mesangial deposition of C5b-9 did not have any clinical associations. Lower serum C3, higher serum C4 and incrased mesangial C3d was significantly associated with CO over three years.

Conclusions: Serum and tissue complements could be potential biomarkers for severity and progression n the GRACE-IgANI cohort. This requires furhter validation.

Immune Complexes Containing Galactose-Deficient IgA1 Deposit on Mesangium Through Damage to Endothelial Cells

Yuko Makita,[1] Hitoshi Suzuki,[2] Daisuke Nakano,[3] Toshiki Kano,[1] Akira Nishiyama,[3] Yusuke Suzuki.[1] *[1]Juntendo University Faculty of Medicine, Bunkyo-ku, Japan; [2]Juntendo University Urayasu Hospital, Urayasu, Japan; [3]Kagawa University, Kagawa, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). However, the pathogenic role of mesangial Gd-IgA1-containing immune complexes (ICs) remains unclear. The endothelial surface glycocalyx modulates microvascular function. Loss of the glomerular endothelial glycocalyx is known to be involved in albuminuria. Here, we examined whether the deposition of Gd-IgA1-containing ICs in the mesangium may lead glomerular endothelial cell dysfunction in this disease.

Methods: Gd-IgA1 and recombinant anti-glycan IgG were used to form ICs to inject into nude mice. The renal microvascular endothelial glycocalyx removal of the injected nude mice was evaluated by real-time glycocalyx imaging. Human renal glomerular endothelial cells (HRGECs) were used to assess the potential capacity of Gd-IgA1-containing ICs to activate endothelial cells.

Results: After co-culture of Gd-IgA1-containing ICs with HRGECs, mRNA expression levels of endothelial adhesion molecules (ICAM-1, VCAM-1 and E-selectin) were significantly upregulated (P<0.01). Expression levels of proinflammatory mediators (TNFα and IL-6) that are able to induce the expression of the adhesion molecules on endothelial cells were also increased (P<0.01). Nude mice injected with Gd-IgA1-containing ICs showed podocyte and endothelial injuries with IgA, IgG, and C3 co-deposition along the glomerular capillaries and in the mesangium. Moreover, albuminuria and hematuria were also induced. Real-time glycocalyx imaging showed that renal microvascular glycocalyx was decreased immediately after the injection of Gd-IgA1-containing ICs and then mesangial IgA deposition was increased.

Conclusions: Present data suggest that Gd-IgA1-containing ICs may induce glomerular endothelial injuries resulting in mesangial deposits.

PO1448

Immune Complexes in the Peripheral Blood of Patients with IgA Nephropathy Contain Polymeric Galactose-Deficient IgA1 Associated with IgG and Complement C3

Stacy D. Hall,[1] Sarah Coffee,[1] Nicolas Maillard,[1,2] Zina Moldoveanu,[1] Ellenore P. Craine,[1] Audra A. Hargett,[1] Dana Rizk,[1] Bruce A. Julian,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.*

Background: IgA nephropathy (IgAN) is an autoimmune disease wherein immune complexes (IC) consisting of IgA1 with some hinge-region *O*-glycans deficient in galactose (Gd-IgA1) and IgG autoantibodies deposit in the kidneys and induce injury. Although the glomerular immunodeposits are enriched for Gd-IgA1, not much is known about the distribution of different molecular forms of Gd-IgA1 in circulation.

Methods: Total serum IgA1 was isolated from 7 Caucasian and 10 African American patients with IgAN by jacalin -affinity chromatography. Different molecular forms of IgA1 were then separated by size-exclusion chromatography (SEC). Gd-IgA1 was detected by lectin ELISA. IgA1-IC were isolated by SEC from sera of 4 IgAN patients. Biological activity of the isolated IC was assessed measuring the proliferation of cultured primary human mesangial cells (MC). IgA1, IgG, and complement C3 were analyzed by SDS-PAGE/immunoblotting.

Results: Total serum IgA1 included monomeric and polymeric forms and IgA1 bound in IC. Monomeric IgA1 represented ~88-92% of total IgA1, whereas polymeric IgA1 represented ~8-12%. IgA1 in IC was the least abundant form, representing <0.4% of total IgA1. Relative representation of Gd-IgA1 was highest in IC, followed by polymeric forms, and lowest in monomeric forms. Gd-IgA1 in IC had minimally sialylated *O*-glycans, whereas polymeric and monomeric forms were substantially sialylated. Caucasian patients had higher content of Gd-IgA1 in polymeric and monomeric forms of IgA1 compared to those of African American patients (P<0.03 and P<0.05, respectively). IgA1-IC in sera of IgAN patients had molecular mass >700 kDa and stimulated proliferation of MC. These IC consisted of polymeric IgA1, IgG, and complement C3.

Conclusions: Biologically active IC in the circulation of IgAN patients contain polymeric, minimally sialylated Gd-IgA1 associated with IgG and C3. These findings support the pathogenic role of Gd-IgA1-IgG IC in IgAN.

Propensity of Immunoglobulin A Self-Aggregation via "Tailpiece" Cysteine 471 and Therapeutic Use of Existing Drug Cysteamine to Treat IgA Nephropathy

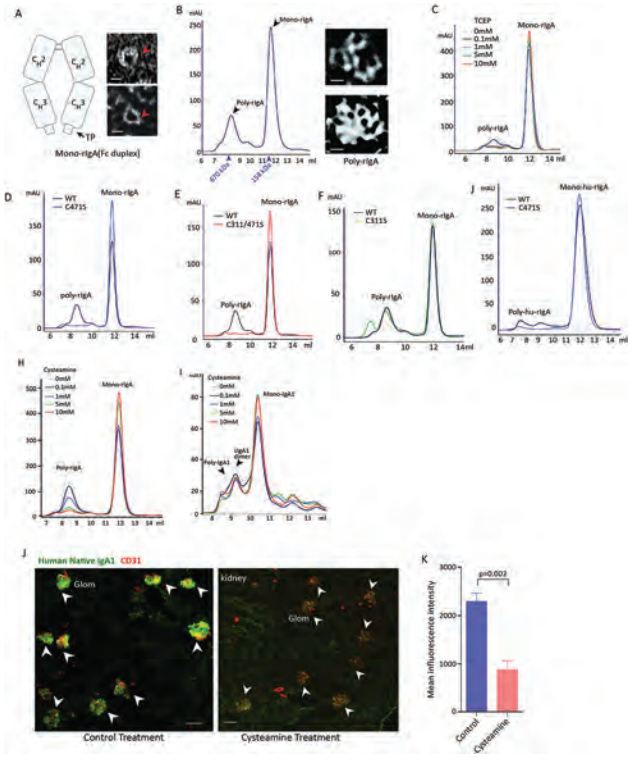
Xinfang Xie,[1,2] Li Gao,[3,2] Pan Liu,[2] Jicheng Lv,[4] Wanhong Lu,[1] Hong Zhang,[4] Jing Jin.[2] *[1]Department of Nephrology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China, Xi'an, China; [2]Department of Medicine-Nephrology and Hypertension, Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Department of Cardiology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [4]Renal Division, Department of Medicine, Peking University First Hospital, Beijing China; Institute of Nephrology, Peking University, Beijing, China.*

Background: IgA nephropathy (IgAN) is caused by deposition of circulatory IgA1 in the kidney. Hypo-galactosylated IgA1 has the propensity to form poly-IgA1 complexes that are prone to deposition. In IgA1 protein sequence, there are features required for the assembly of dimeric mucosal IgA1, including "tailpiece" Cys471 residue of the heavy chain in participating disulfide bonds with J-chain subunit in IgA1 dimer. In monomeric IgA1 with the absence of J-chain, this free Cys471 is susceptible to oxidation-induced disulfide with other IgA monomers.

Methods: Poly-IgA1 isolated from the plasma of IgAN patients was analyzed for intermolecular disulfide connections. Cysteine residues of Cys311 and Cys471 of IgA1 were mutated to determine their participation in IgA1-IgA1 disulfide bond formation. Cysteine-reducing drugs cysteamine and WR-1065 were tested for effects on IgA1 aggregation and on kidney deposition.

Results: High-molecular-weight IgA1 complexes were susceptible to reducing condition, suggesting disulfide-linkages in poly-IgA1 complexes. Mutagenesis confirmed Cys471's participation in IgA1 self-aggregation, which could be disassembled by aminothiol drugs cysteamine and WR-1065. Administration of cysteamine to murine models of IgAN reduced the level of IgA1 deposition in the glomerulus.

Conclusions: IgA1 tailpiece contributes to the propensity of IgA1 monomer to self-aggregate via intermolecular disulfide bonds. Our results revealed a novel molecular mechanism for aberrant formation of IgA aggregates, to which repurposed cystinosis drug cysteamine was efficacious in preventing renal IgA deposition.



'Tailpiece' Cysteine-471 involved in IgA self aggregation, cysteamine treatment lowers poly-IgA contents *in vitro* and its renal deposition *in vivo*.

PO1450

Structural Characterization of Autoreactive IgG Antibodies in the Context of IgA Nephropathy

Jordan Lingo, Barbora Knoppova, Stacy D. Hall, Jan Novak, Todd J. Green. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: IgA nephropathy (IgAN) is the most prevalent glomerulonephritis in the world. The pathology of IgAN is characterized by deposition of immune complexes in the kidneys. These complexes can trigger inflammation and mesangial cell proliferation in patients, where up to 40% of cases progress to renal failure. The pathogenic immunodeposits in kidneys of IgAN patients have been shown to contain IgA1, which has *O*-linked glycans in the hinge region of the heavy chain that are deficient in galactose (galactose-deficient IgA1; Gd-IgA1) and IgG autoantibodies to Gd-IgA1. Sequencing of IgG heavy chain variable regions from IgAN patients has identified a correlation between a serine residue, introduced by somatic hypermutation into the framework leading into the third hypervariable loop of the heavy chain, with an increased association of IgG autoantibodies with Gd-IgA1. We set out to understand how this single amino acid mutation affects the IgG Fab structure and antigen recognition with the aid of protein crystallography, reverse engineering, and binding studies.

Methods: Recombinant IgG constructs (rIgG) based on IgAN patient sample sequences and site-specific mutants were expressed in 293F cells and purified. Fabs were cleaved from IgG, purified, crystallized, and their protein structures determined. Binding differences between Gd-IgA1 and intact rIgGs were determined with ELISA-based experiments.

Results: Comparisons of rIgG Fabs structures derived from a healthy control patient and an IgAN patient showed conformational differences that possibly influence the recognition of Gd-IgA1. Using this structural data and bioinformatics to guide antibody design, we reverse engineered the IgG from a healthy patient control to modulate binding to Gd-IgA1. Site-directed mutagenesis and binding studies indicated that residues in our selected regions of the variable domains alter Gd-IgA1-IgG complex formation.

Conclusions: We have determined the structures of Fabs from IgGs that form complexes with Gd-IgA1, and we have further identified residues in the Fabs that are important for Gd-IgA1-binding. This knowledge could inform future strategies to inhibit pathogenic immune complex formation.

Histopathologic Association of Lambda Light Chain Predominance in IgA Nephropathy

Prasanth Ravipati,[1] Virginie Royal,[2] Lihong Bu,[1] Rebecca L. Freese,[1] Michelle N. Rheault,[1] Patrick H. Nachman.[1] CureGN Investigators [1]*University of Minnesota Twin Cities, Minneapolis, MN;* [2]*Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: A relative predominance of lambda (λ) over kappa (κ) light chain deposition has long be recognized in IgA Nephropathy (IgAN), which is unlike any other glomerular disease. The reason for this predominance is unknown but may be related to a purported predominance of λ chain expression by gut associated lymphoid tissue B cells. There is limited information regarding the histopathologic findings, if any, associated with predominant λ light chain deposition. Utilizing the CureGN IgAN cohort, we evaluated if predominant λ chain deposition was associated with histologic markers of disease activity by examining MEST characteristics and other variables.

Methods: We divided the CureGN IgAN cohort into two groups based on the intensity of light chain deposition by immunofluorescence. The λ dominant group (LD) was defined by a difference in intensity score of staining of λ minus κ ≥ 1+, and the λ-κ codominant group (KL) by a difference of λ minus κ < 1+. Fisher's exact test was used to compare the histopathologic changes between the groups with respect to M, E, S, T, scores, total crescents, percent (%) of globally sclerotic glomeruli, % of glomeruli with fibrinoid necrosis, degree of interstitial inflammation, and the intensity of IgG, C1q, and C3 staining.

Results: Among 695 IgAN patients, the kidney biopsy digital images of 269 patients were reviewed by CureGN pathologists and 234 patients had reported λ and κ staining intensity. Of these, 96 (41%) patients were classified as LD (including 7 patients (3%) with λ monotypic staining) and 138 (59%) classified as KL. The two groups did not differ significantly in age, sex, or race. Compared to the KL group, the LD group had a greater frequency of endocapillary hypercellularity (E1, 51.1% vs 36.3%, p=0.04) and IgG staining intensity ≥ 1+ (37.3% vs 21.9% ; p=0.01). There were no significant differences between groups with respect to any other histologic finding.

Conclusions: In IgAN, patients with predominantly λ mesangial deposition are more likely to have increased endocapillary hypercellularity and IgG deposition, two findings previously linked with greater histologic disease activity and possibly worse prognosis. Further studies are needed to elucidate if the predominance of λ chains represents a unique pathogenesis in a subset of patients, or if it imparts a more severe disease course.

Plasmacytoid Dendritic Cells from Murine IgA Nephropathy Have a Capacity to Enhance IgA Production Through TLR9/APRIL Signaling

Yusuke Fukao,[1] Hitoshi Suzuki,[1,2] Maiko Nakayama,[1] Toshiki Kano,[1,3] Yuko Makita,[1] Yusuke Suzuki.[1] [1]*Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan;* [2]*Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan;* [3]*Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan.*

Background: Our recent study revealed that chronic Toll-like receptor 9 (TLR9) stimulation induce a proliferation-inducing ligand (APRIL) expression on naïve B cells and such APRIL$^+$B cell may contribute to nephritogenic IgA production in IgA nephropathy (IgAN). On the other hand, APRIL from TLR9 activated dendritic cell (DC) is generally known to be involved in B cell maturation and IgA class switching. In this study, we evaluated IgA production through TLR9/APRIL signaling by DCs from murine IgAN.

Methods: Splenic B cells and DCs from grouped ddY (gddY) mice, which are known as the spontaneous IgAN model, and Balb/c mice were isolated using magnetic cell sorting system. In addition, DCs were further divided into three DC subsets; i.e., plasmacytoid DCs (pDCs), CD8+ conventional DCs (cDCs), and CD11b+ cDCs by cell sorter. We co-cultured these isolated DCs and B cells with or without CpG-ODN, a synthetic oligonucleotide TLR9 ligand, and IgA in the culture supernatants was measured by ELISA. We also measured the expressions of TLR9 and APRIL in each DC.

Results: The gddY-derived, but not Balb/c-derived, DCs could dramatically enhance IgA production by co-culture with B cells derived from both gddY and Balb/c mice, and further enhance under CpG-ODN stimulation. Moreover, pDCs from gddY mice strongly induced the IgA production in B cells, compared with cDCs. The expressions of APRIL and TLR9 in the pDCs were higher than those in cDCs.

Conclusions: Present findings suggest that the gddY DCs, especially pDCs, strongly enhance IgA synthesis from B cells through TLR9 and APRIL signaling.

PO1453

Targeted Release Formulation Budesonide (Nefecon) Selectively Reduces Circulating Levels of Chemokines Critical to Immune Cell Trafficking to Peyer Patches in IgA Nephropathy

Karen Molyneux,[1] David H. Wimbury,[1] Jasraj S. Bhachu,[1] Masahiro Muto,[2] Andrew M. Stone,[3] Jonathan Barratt.[1] [1]*University of Leicester, Leicester, United Kingdom;* [2]*Juntendo Daigaku, Bunkyo-ku, Japan;* [3]*Stone Biostatistics ltd, Crewe, United Kingdom.*

Background: Evidence supports a pivotal role of gut-derived chemokines in the direction of immune cell trafficking to the intestine in homeostatic and inflammatory conditions. It is well established that chemokines and their receptors control the influx

of T cells and B cells into Peyer's patches (PP). T-cell homing to the PP depends on CCR7 and its ligands, CCL19 and CCL21, whereas B-cell homing to PP depends on the coordinated signaling of CCR7, CXCR4, CXCR5 and CCR6. The PP are believed to be a major source of the poorly *O*-galactosylated IgA1 in IgA nephropathy (IgAN). The therapeutic potential of targeting PP was demonstrated in the Phase 2 NEFIGAN trial (NCT01738035), which assessed the safety and efficacy of a novel targeted-release investigational formulation of budesonide (TRF-budesonide [Nefecon]), designed to deliver budesonide to the PP-rich distal ileum in patients with IgAN. The trial comprised a 6-month run-in, 9-month treatment, and 3-month follow-up phase: 49 patients received Nefecon 16 mg/day, 51 patients received Nefecon 8 mg/day and 50 patients received placebo. Nefecon 16 mg/day, added to optimized renin–angiotensin system blockade, reduced proteinuria and stabilized eGFR in patients with IgAN. This study investigated whether Nefecon treatment altered serum levels of chemokines.

Methods: Serum levels of a panel of 20 chemokines were measured by Luminex. Changes in log-transformed levels of each biomarker with treatment were compared by one-way ANCOVA. Significance was p<0.05.

Results: A significant, dose-dependent modulation in serum levels of key chemokines directing T and B cell trafficking to the intestine (CXCL5), and more specifically to the PP (CCL11, CCL19, CCL20) was seen with Nefecon, which reversed on cessation of Nefecon. These observations paralleled significant reductions in the levels of soluble CD23, CD27 and CD30, and are consistent with our previous reports describing a dose-dependent reduction in BAFF, soluble BCMA, TACI, IgA–IgG immune complexes, secretory IgA and galactose-deficient IgA levels with Nefecon.

Conclusions: Nefecon, which targets the PP-rich distal ileum, modulates key chemokine signals which direct immune cell trafficking to the intestine in IgAN.

PO1454

The Dual Endothelin Angiotensin Receptor Antagonist (DEARA) Sparsentan Protects from Glomerular Hypercellularity and Associated Immune/Inflammatory Gene Network Activity in a Model of IgA Nephropathy

Colin Reily,[1] Zina Moldoveanu,[1] Tiziano Pramparo,[2] Stacy D. Hall,[1] Lea Novak,[1] Radko Komers,[2] Celia P. Jenkinson,[2] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Travere Therapeutics Inc, San Diego, CA.*

Background: IgA Nephropathy (IgAN) is an autoimmune glomerulonephritis wherein immune complexes (IC) composed of galactose-deficient IgA1 (Gd-IgA1; autoantigen) and Gd-IgA1-specific IgG autoantibodies (AuAb) deposit in the glomeruli (gli) and cause injury. In a mouse model of IgAN induced by IC formed *in vitro* from human Gd-IgA1 and a recombinant AuAb, we used whole-kidney RNAseq profiling to assess how Sparsentan (Sp) affects the gene expression of pathways dysregulated by IC.

Methods: IC were injected into ~7-week-old nude mice every other day for a total of 6 doses (n=5/group). Sp (60 or 120 mg/kg) or vehicle (V) were given by gavage once daily from the first day of IC injections. Negative-control mice received only V. Kidney tissue for histopathology and RNAseq was harvested on day 12. RNAseq raw data processed using DESeq2 identified differentially expressed genes. WGCNA was used for network-level profiling and to identify co-expressed genes associated with hypercellularity and Ki-67 positivity of gli. GSEA and X2K assessed changes at the pathway level and imputed correlated upstream cell-signaling networks. Pathway enrichment p-values were adjusted with FDR.

Results: Sp ameliorated IC-induced hypercellularity (P<0.01) and Ki-67-positive gli (P<0.05). WGCNA clustered genes into co-expressed modules associated with hypercellularity and Ki-67 positivity. GSEA-identified top-5 pathways were enriched for immune processes (FDR <1x10^-20), the top being cytokine signaling pathways. The expression pattern of 95% of the top module genes dysregulated by IC, was corrected by Sp. X2K analysis revealed correlated expression of top hub genes, kinases MAPK14, GSK3B, CSNK2A1 (z-score <1x10^-12) and transcription factors SP1 and RUNX1 (z-score <0.05), highlighting the role of the ERK1/2-SP1 axis known to regulate cell proliferation.

Conclusions: In a mouse model of IgAN, kidney transcriptomics revealed gene networks, enriched in immune/inflammatory functions, correlating with IC-induced hypercellularity. The top dysregulated genes were normalized by Sp and were linked to kinases and transcription factors with correlated functional activity. These data suggest a potential anti-inflammatory role for Sp in IgAN.

Treatment with Targeted Release Formulation Budesonide (Nefecon) Modulates the Complement System in Patients with IgA Nephropathy

Laura Pérez Alós,[1] Karen Molyneux,[2] Bengt C. Fellstrom,[3] Jonathan Barratt,[2] Peter Garred.[1] *[1]Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, Kobenhavn, Denmark; [2]University of Leicester, Leicester, United Kingdom; [3]Akademiska sjukhuset, Uppsala, Sweden.*

Background: The NEFIGAN trial (NCT01738035) evaluated the effect of a novel targeted-release investigational formulation of budesonide (TRF-budesonide [Nefecon]) in the treatment of IgA nephropathy (IgAN). Participants in this Phase 2b trial were randomly assigned placebo, Nefecon 8 mg or 16 mg/day, and samples were collected at baseline (0 months), at the end of the treatment (9 months) and at the end of the study (12 months). In this exploratory study we evaluated the effect of Nefecon treatment on the circulating levels and urinary excretion of a panel of complement components.

Methods: Plasma and urine levels of complement proteins (C4c, C3bc and soluble C5b-9) and ficolin-1, -2 and -3, MBL, CL-11, MASP-3, MAP-1 and PTX-3 were measured using in-house sandwich-ELISAs. Treatment differences between baseline, end of treatment and end of study were assessed by mixed-effects model analysis. The effect of the treatment correcting for the baseline was assessed by multiple linear regression. Significance: $p < 0.05$. Urinary proteins were adjusted for creatinine excretion.

Results: Circulating levels of MASP-3 were decreased in a dose-dependent manner after treatment (p=0.0313 Nefecon 8 mg/day, p=0.0080 Nefecon 16 mg/day). MBL/creatinine was significantly reduced in the urine by both doses of Nefecon compared with placebo (p<0.0001 Nefecon 8 mg and 16 mg/day). CL-11/creatinine levels were also significantly reduced in a dose-dependent manner after Nefecon administration (p<0.0411 Nefecon 8 mg/day, p<0.0095 Nefecon 16 mg/day). Complement activation markers and ficolin-3 levels were detectable in urine but levels remained unaltered.

Conclusions: Treatment with Nefecon modulates components of both the alternative (MASP-3) and lectin (MBL and CL-11) pathways of complement, two pathways known to be important in mediating kidney damage in IgAN. These initial observations warrant further investigation.

PO1456

Defining Cell Type Specificity of TNF Targets in Nephrotic Syndrome

Phillip J. McCown, Sean Eddy, Fadhl Alakwaa, Jennifer L. Harder, Jamal El Saghir, Wenjun Ju, Matthias Kretzler, Laura H. Mariani. Nephrotic Syndrome Study Network (NEPTUNE) *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Mechanistic, targeted therapies are needed for patients with FSGS and MCD, as diverse biological processes produce similar histologic injury patterns. Bulk transcriptomic data from kidney biopsy tissue can be used to find subgroups with shared molecular features, but cellular signaling networks need to be defined.

Methods: Consensus clustering was applied to bulk RNA sequencing data from the tubulointerstitial (TI) compartment of 220 participants from the NEPTUNE cohort, a study of children and adults with nephrotic syndrome enrolled at the time of kidney biopsy. Clusters were assessed for association with clinical outcome. Differential gene expression analysis was analyzed for enrichment of canonical pathways and functional groups between patient clusters. Nuclei were extracted from renal biopsies, processed, and quality control analyzed to remove low quality nuclei. Nuclei identity were assigned by comparisons of enriched genes in a cluster to previously identified cell type-specific gene profiles.

Results: One cluster of 59 patients was associated with a higher risk of loss of kidney function over time and observed TNF activation. To test the cellular source of the TNF pathway biomarker candidates, we performed snRNA-seq on 10 NEPTUNE biopsies, 5 with high TNF activity scores and 5 with moderate to low TNF activity scores in TI gene expression profiles. We pooled 45,175 nuclei into 15 clusters, which included all major kidney cell types. *TNF* expression was found in nuclei from immune clusters and in a proximal tubule and loop of Henle cluster. *TNFRSF1A* was universally expressed across cell clusters, while *TNFRSF1B* showed more restrictive expression. TNF targets *CCL2* and *TIMP1* had higher levels in all patients with activated TNF scores with maximal increase in epithelial cells (proximal and podocytes). Kidney organoids confirmed MCP1 (encoded by *CCL2*) and TIMP1 upregulation by TNF treatment.

Conclusions: TNF, TNF receptors, and TNF-responsive biomarkers reflect alterations in inflammatory and intrinsic kidney cell populations in patients with a TNF-associated signaling profile and are currently assessed as TNF target engagement biomarkers in a clinical trial of FSGS patients (NCT04009668).

Dysregulated T Cell Metabolomic Profile in Patients with Steroid-Resistant Nephrotic Syndrome

Chang-Yien Chan,[1,2] Liangjian Lu,[2] Sharon Teo,[2] Yaochun Zhang,[1,2] Kong Peng Lam,[3] Kar Hui Ng,[1,2] Hui Kim Yap.[1,2] *[1]National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [2]Khoo Teck Puat - National University Children's Medical Institute, Singapore, Singapore; [3]Agency for Science Technology and Research, Singapore, Singapore.*

Background: We have recently reported early relapse following rituximab in patients with minimal change disease was associated with baseline reduction in regulatory T-cells and T-cell hyporesponsiveness to activation, suggesting chronic T-cell activation. This study aimed to compare T-cell activation and characterise the metabolic alterations associated with T-cell hyporesponsiveness in patients with steroid-dependent (SDNS) and steroid-resistant nephrotic syndrome (SRNS) in relapse.

Methods: A total of 48 patients with childhood-onset SDNS (n=31) and SRNS (n=17) were recruited during relapse. T-cell activation assay was performed on whole blood while metabolomic profiling was performed on purified stimulated CD4 T-cell culture supernatants (n=23) using GC-MS/MS and analysed using Shimadzu Smart Metabolites Database. Differences in the metabolomic profile between SDNS and SRNS were identified using PLS-DA (SIMCA), and pathway analysis was performed using MetaboAnalyst 4.0. Metabolomic validation assay was performed using Glucose 6 Phosphate Dehydrogenase (G6DP) assay kit.

Results: SRNS patients had significant lower T-cell expression of CD69 (88±2.3% vs 91±3.1%, P=0.024) and IFNγ (1.9±0.73% vs 6.6±1.35%, P=0.016) compared to SDNS patients. PLS-DA modeling of the 93 metabolites identified in CD4 culture supernatants yielded one fitted component, in which 24% of the variability in metabolites measured (R^2X) could explain 58% of the variation in steroid-response (R^2Y). Of note, 85% of the metabolites tended to be lower in SRNS compared to SDNS patients. Pathway analysis of the 38 metabolites with VIP>1 implicated the biosynthetic pathways glyoxylate and dicarboxylate metabolism, ascorbate and aldarate metabolism as well as galactose metabolism (Benjamini-Hochberg P<0.05). Interestingly, the 2 metabolites with the highest VIP score have been implicated as downstream products in the pentose phosphate pathway and were reduced in SRNS compared to SDNS patients (P<0.001). G6DP activities in SDNS patients in relapse negatively correlated with T-cell expression of CD69 (r=-0.58, P<0.047).

Conclusions: We demonstrated that muted T-cells response to *in vitro* stimulation in SRNS patients was associated with metabolic quiescence, with dysregulated biosynthetic pathways including the pentose phosphate shunt.

Blocking the IL-1β/IL-1R1 Signaling as a Potential Therapy for Multidrug-Resistant Nephrotic Syndrome

Andrea Angeletti,[1] Francesca Lugani,[1] Gianluca Caridi,[1] Enrico E. Verrina,[1] Paolo Cravedi,[2] Gian Marco Ghiggeri.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: In idiopathic nephrotic syndrome (NS), Steroid-resistant patients with complete or partial resistance to the combination of prednisone and steroid sparing-agents are at high risk to progress to end-stage kidney disease. Considering the toxicities associated with chronic use of these drugs, alternative interventions are urgently needed. IL-1β/IL-1R1 has been recently suggested as a possible mechanism of complement-mediated progression of Focal Segmental Glomerulosclerosis.

Case Description: A 26-year-old white woman had FSGS (kidney biopsy) presenting with NS and kidney failure. Serum creatinine level was 1.6 mg/dL, urinary protein excretion 20.4 g/d and serum albumin 0.9 g/dL. She received methylprednisolone, 1g rituximab, and CNI with partial remission. Three months later, she presented relapse of NS and acute kidney failure requiring 5 HD: CNI was switched to MMF. Immunoglobulins IV were administered. After 3 months, serum creatinine was 5.1 mg/dL, urinary protein excretion was 18 g/d. Given the lack of improvement/worsening of proteinuria, wet started anakinra, the anti-IL-1R1 (subcutaneously, 2 mg/kg/d for the first week and then 4 mg/kg/d). After 1 year, serum creatinine is 3.4 mg/dL, urinary protein excretion is 5.2 g/d and serum albumin level was 1.3 g/dL. No side effects were reported (**Fig 1**).

Discussion: We administered Anakinra in MRNS due to FSGS and CKD Stage IV. After Anakinra, multiple ongoing immunosuppressive treatments were stopped. We acknowledge that Anakinra did not promote full disease remission, but it was associated with a significantly amelioration of the disease clinical. By slowing the rapid progression of kidney failure, the young patient better faced all future perspectives: a pre-emptive kidney transplant in case kidney function worsens is now available. In conclusion, our data indicate that Anakinra, by antagonizing IL-1β/IL-1R1 signaling, may represent a useful therapeutic option to prevent the progression of kidney injury in advanced forms of nephrotic syndrome.

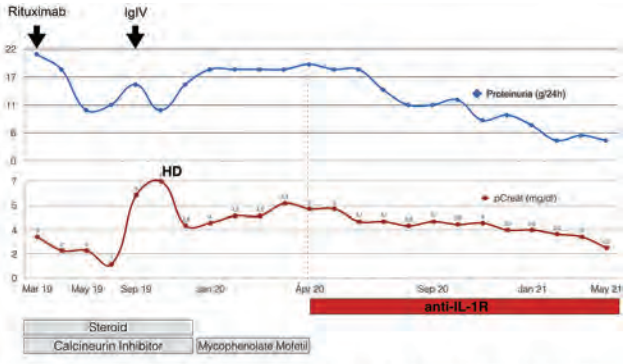

Figure 1. Proteinuria and serum creatinine course pre and post anakinra administration in 26-year-old white woman with Focal Segmental Glomerulosclerosis multidrug-resistant.

More Severe Mitochondrial Injury at the Time of Diagnosis Is Associated with Poor Prognosis in Minimal Change Disease

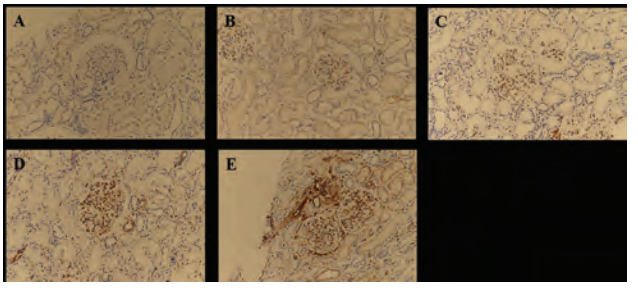
Byung chul Yu, Moo Yong Park, Soo Jeong Choi, Seung D. Hwang, Jin kuk Kim. *Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea.*

Background: We hypothesized that the pathogenesis of minimal change disease (MCD) may be associated with mitochondrial injury and that the degree of mitochondrial injury at the time of diagnosis may serve as a prognostic marker in MCD.

Methods: We retrospectively enrolled patients with MCD who were followed up for more than 5 years and IgA nephropathy (IgAN) patients as controls (n = 20 each). Focusing on the stimulator of interferon genes (STING) pathway activated by mitochondrial injury, immunohistochemical (IHC) staining for STING was performed on kidney tissue at the time of diagnosis. The IHC stain site and signal intensity for STING were analyzed. Time-averaged proteinuria (TA-proteinuria) was calculated as the average of the mean of proteinuria measurements were obtained by 24-hour urine collection every 6 months for each patient. A relapse after treatment was defined as proteinuria >3.5 g per 24 hours after complete or partial remission.

Results: In patients with IgAN and MCD, kidney tissue from 13 patients each showed positive IHC staining for STING. While various kidney structures including glomerulus and tubulointerstitium were stained in IgAN patients, the glomerulus was exclusively stained in MCD patients (Figure). MCD patients were divided into the high (n = 6) and low (n = 14) intensity subgroups according to the signal intensity based on 2+ and more or less, respectively. TA-proteinuria and frequency of relapses during the follow-up period were higher in the high intensity group than in the low intensity group (1.18 ± 0.54 vs. 0.57 ± 0.45 g/day, p = 0.022; and 0.72 ± 0.60 vs 0.09 ± 0.22 episodes/year, p = 0.022, respectively).

Conclusions: These findings suggest that more severe mitochondrial injury, as represented by a high signal intensity of IHC stain for STING at the time of diagnosis, could be used as a prognostic marker to predict poor prognosis in MCD.



IHC staining for STING on kidney tissue obtained from MCD patients (classified into negative (A), 1+ (B), 2+ (C), and 3+ (D) according to the signal intensity) and IgAN patient (E).

PO1460

Maturation of Decay Accelerating Activity Response Across the Natural History of C3 Glomerulopathy

Christopher Culek,[1] Richard J. Smith,[1,2] Carla M. Nester.[1,2] *[1]University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; [2]The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA.*

Background: C3 Glomerulopathy (C3G) is an ultra-rare complement-mediated renal disease characterized by dysregulation of the alternative pathway (AP) of complement. Dysregulation is often driven by a nephritic factor (C3Nef), an autoantibody to the C3 convertase (C3BbB) of the AP. We hypothesized that the properties of Nefs change

over time and that changes will be associated with changes in underlying complement dysregulation.

Methods: IgG was purified from normal human serum and from sera collected across six time points of a well characterized C3G patient. Using SPR (Biacore), the C3 convertase (C3bBb) was formed on a CM5 sensor chip. Purified test or control IgG was injected to form the Nef-C3bBb complex. The ability of native complement regulators to decay the Nef-C3bBb complex was assessed by injecting Decay Accelerating Factor (DAF), Complement Receptor 1 (CR1), Factor H (FH), or control reagent. Residual C3bBb was determined by the ratio of post- to pre-regulated convertase. Data were compared to time-associated complement biomarker results.

Results: The presence of Nef conferred resistance to the normal decay accelerating activity (DAA) by DAF, CR1, and FH. Resistance to DAA was highest in the earliest sample (S1, p= 0.0001), with a reduction in subsequent samples. This change was independent of Nef titer and coincident with reduced complement activity. Low DAF resistance was maintained in later samples, whereas CR1 and FH resistance gradually increased.

Conclusions: Nef-stabilized C3bBb resistance to native DAA proteins matures over time and is independent of Nef titer. Changes in response to regulators is accompanied by a relative change in underlying complement dysregulation as reflected by complement biomarkers. How this variance (in time and across regulators) impacts disease course and outcome in patients with C3G or whether the phenomenon represents a novel treatment target warrants further study.

C3 Glomerulonephritis with Nephritic Factor Treated with Rituximab

Hanny Sawaf, Georges Nakhoul, Ali Mehdi, Jonathan J. Taliercio. *Cleveland Clinic, Cleveland, OH.*

Introduction: C3 Glomerulonephritis (C3GN) is a well described cause of kidney disease that results from dysregulation of the alternative complement pathway. Kidney biopsy demonstrates a membranoproliferative pattern of injury and mesangial C3 staining with minimal or no staining of immunoglobulins on immunofluorescence. C3GN can be due to genetic mutations, autoantibodies against the alternative complement regulators, or monoclonal gammopathy. C3 nephric factor (C3NeF) is an auto-antibody that stabilizes C3 convertase which leads to an increase in activity of the alternate complement pathway. Steroids, mycophenolate mofetil (MMF), rituximab, and eculizumab have been used with varying results. We present a patient with biopsy proven C3GN with C3NeF who was successfully treated with rituximab after failing therapy with MMF.

Case Description: Patient is a 64-year-old male diagnosed with biopsy proven C3GN after being found with decreased kidney function with a peak creatinine of 1.97 mg/dL and nephrotic range proteinuria with a maximal urinary protein excretion of 4.3 g/d. Evaluation revealed low C3 and C4 at 60 mg/dL and 5 mg/dL respectively, negative monoclonal testing, and a C3NeF of 21 unit/mL (reference range 0). Patient was initiated on prednisone 60 mg/day with taper, MMF with a maximal dose 3 grams/day, and valsartan for 2 years with little improvement in clinical parameters. Therapy was switched to rituximab 1 gram on weeks 0, 2, 26. Within 3 months patient had; normalization of complements, negative C3NeF, 0.7 urine protein-to-creatinine ratio (UPCR), and serum creatinine 1.5 mg/dL. Since his initial rituximab regimen 2 years ago, he remains off maintenance therapy, with negative C3NeF, normal complements, 0.1 UPCR, and serum creatinine 1.04 mg/dL.

Discussion: C3GN was successfully treated with rituximab based on the disappearance of C3NeF and improvement in clinical parameters. Rituximab was chosen to target CD20 cells to halt the production of the C3NeF autoantibody. Laboratory response (complements and C3NeF) was seen within 3 months of initial rituximab dosing, and UPCR and serum creatinine required a longer follow up for a nadir. Reoccurrence of relapse is being monitored using serial C3NeF measurements. We believe that targeted B cell therapy should be considered in the treatment of C3GN cases which are C3NeF antibody mediated.

PO1462

Complement-Activated Polymorphonuclear Neutrophils Contribute to C3G Pathogenesis

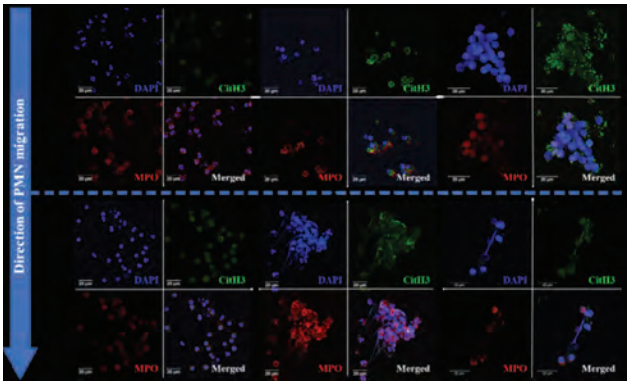
Maria Maqsood,[1] Noah A. Fine,[3] Carolina Ortiz,[1] Patrick D. Walker,[2] Christoph Licht.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Arkana Laboratories, Little Rock, AR; [3]University of Toronto, Toronto, ON, Canada.*

Background: C3G is caused by dysregulation of the complement alternative pathway, but there is a gap in the pathogenetic cascade from complement activation (intravascular space) to inflammation and complement deposition in the glomeruli (extravascular space). Recently, biopsies have shown the presence of (activated) polymorphonuclear neutrophils (PMNs) in C3G glomeruli indicating an underappreciated role for PMNs in C3G pathogenesis.

Methods: PMNs were investigated in a transwell chamber allowing for different environments. Conditions were chosen to resemble the intravascular space (top well; serum containing) versus extracellular space (bottom well; serum-free conditions). PMNs were stimulated in the top well via various agonists, including complement, and allowed to transmigrate to the bottom well where they were monitored for the formation of Neutrophil Extracellular Traps (NETs) via immunofluorescence and SYTOX assay. Circulating C3G patient PMNs were examined for priming via flow cytometry.

Results: Upon complement stimulation, PMNs showed evidence for priming in serum conditions (top well). PMNs travelled to the bottom well following chemoattractant fMLP where they then completed the process of NET formation (NETosis) in serum-free conditions (bottom well). Results were validated ex vivo using C3G patient PMNs and autologous serum (Figure). In addition, incubation of control PMNs in C3G patient serum revealed a correlation between serum-albumin levels and the degree of NET formation. C3G patient PMNs showed upregulation of CD11b compared to controls.

Conclusions: Assigning a pathogenetic role to PMNs in C3G identifies a new treatment and monitoring strategy with the potential for improved long-term outcomes and quality of life.



PMNs were seeded in the top well of a transwell system and allowed to transmigrate for 12 h. PMNs from both wells were stained for IF with DAPI (blue), Citrullinated histone 3 (CitH3; green) and Myeloperoxidase (MPO; red). Scale bar 20 um. 63x magnification.

PO1463

Differential Expression of Complement and Non-Complement Proteins in C3 Glomerulonephritis and Dense Deposit Disease

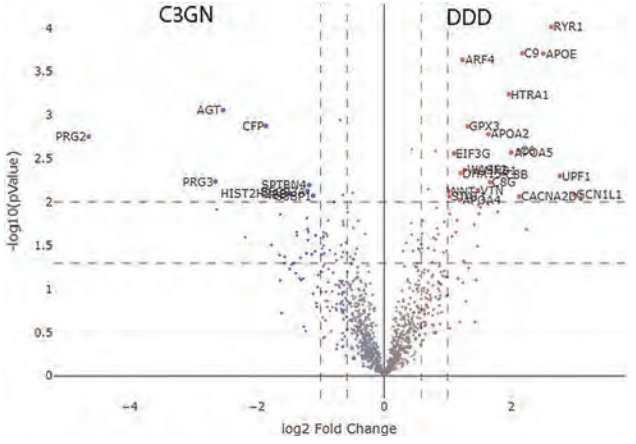
Sanjeev Sethi,[1] Benjamin J. Madden,[1] Fernando C. Fervenza,[1] Lilian M. Palma.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Universidade Estadual de Campinas, Campinas, Brazil.*

Background: C3 glomerulopathy comprising dense deposit disease (DDD) and C3 glomerulonephritis (C3GN) results from overactivation of the alternative pathway of complement. Mass spectrometry (MS) studies have previously shown accumulation of complement proteins in C3GN and DDD. However, complete MS analysis of non-complement proteins and comparison of complement proteins in C3GN and DDD has not been done.

Methods: We performed laser microdissection of glomeruli followed by MS in 12 cases each of biopsy-proven C3GN and DDD, and 6 control cases of time 0 transplant biopsies.

Results: Compared to the controls, C3GN showed increased intensity based absolute quantification (iBAQ) values of C3 (20-fold), C5 (52-fold), C6 (76-fold), C7 (90-fold), C8 (66-fold), C9 (30-fold), CFHR1 (146-fold) and CFR5 (65-fold). Similarly, DDD showed also increased iBAQ values compared to controls of C3 (26-fold), C5 (365-fold), C6 (473-fold), C7 (261-fold), C8 (353-fold), C9 (159-fold), and CFHR1 (73-fold). When DDD was compared to C3GN, there was a 2-5 fold increase in iBAQ values in C5, C6, C7, C8 and C9 ($p<0.001$), although there was no significant difference in C3. Among the non-complement proteins Apolipoprotein E (APOE) and A-II and V (APOA-II and V), Serine protease HTRA1, Ryanodine receptor 1 (RYR1), and Translational activator GCN1 were expressed 3-7 fold higher in DDD compared to C3GN ($p<0.001$). On the other hand, proteoglycan 2 and 3 (PRG2 and 3), angiotensin (AGT) and properdin (CFP) were expressed 2-5 fold higher in C3GN compared to DDD ($p<0.001$).

Conclusions: MS of C3GN and DDD show high iBAQ values of complement proteins. DDD shows a higher iBAQ vaules in terminal complement proteins compared to C3GN. In addition, proteins such as APOE and APOA II/V are increased in DDD compared to C3GN, while PRG2/3 and properdin are increased in C3GN compared to DDD suggesting a role for the proteins in the pathophysiology of C3GN and DDD.



Volcano plot showing differential expression of proteins in C3GN and DDD.

PO1464

Clinical and Histological Features of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits: A Single-Center Retrospective Study from China

Yifeng Wang, Xiaoye Zhu, Shaojun Liu, Jun Xue, Chuan-Ming Hao. *Huashan Hospital Fudan University, Shanghai, China.*

Background: PGNIMID is a new entity of monoclonal gammopathy affecting the kidney characterized by intact monoclonal immunoglobulins (mIg) deposits that result in membranoproliferative pattern of glomerular injury. In this study, clinical and histological of PGNMID cases were evaluated.

Methods: A total of 23 patients with biopsy-confirmed PGNMID in native kidney diagnosed between December 2015 to April 2021 were enrolled in this study. Clinical, histological, hematologic, and follow-up data were abstracted from the medical record.

Results: Of 23 cases, majority were male (65.2%), and the mean age was 49.5 years with 8 cases (34.8%) under 40 years old. At the time of biopsy, 19 cases had proteinuria with a mean 24h urine protein of 3.99g (0.28 to 8.96), 11 of 22 cases had nephrotic syndrome, and 18 of 22 cases had hematuria. The mean serum creatinine was 1.52mg/dL (0.6 to 7.8), 15 cases (65.2%) had eGFR<90 mL/min (CKD-EPI), and 4 cases had eGFR <60 mL/min. Eleven of 23 cases (47.8%) showed MPGN, 6 cases showed EPGN, 2 cases showed MesPGN, and 2 cases showed MN. By IF, 21 cases (91.3%) showed mIgG deposits (12 IgG3κ, 5 IgG1κ, 1 IgG1λ, 1 IgG3λ, and 2 IgGκ without determined subclass) and 2 cases (8.7%) showed mIgAλ deposits. All cases showed C3 co-deposits, and 6 of 18 cases (33.3%) had a low serum C3 level. EM revealed unorganized and granular deposits in the mesangial area (17 of 17), subendothelial area (15 of 17), and subepithelial area (12 of 17). Three of 4 cases whose eGFR<60 mL/min showed EPGN. SIFE showed mIg that matched the renal deposits in 2 of 13 cases (15.38%). After mean follow up of 3 months in 3 cases, 1 patient treated with bortezomib+ CTX+DXM and another patient treated with rituximab both achieved partial renal remission. But the third patient treated with rituximab had a persistent renal dysfunction. Of note, previous or concurrent infections by fungi, HIV, HBV, HPV or other undetermined pathogen, were observed in 5 cases (21.7%). We also found 1 patient with autoimmunity and another with malignancy.

Conclusions: Compared with previous reports, our PGNMID cases showed similar clinical and histological features. EPGN pattern seems to be associated with more severe renal function damage. Previous or concurrent infections, autoimmunity and malignancy were observed in 21.7% of cases.

PO1465

Diagnostic and Risk Factors for Deregulated Complement in Thrombotic Microangiopathy

Sjoerd Timmermans, Pieter van Paassen. Limburg Renal Registry *Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.*

Background: The syndromes of thrombotic microangiopathy (TMA) are diverse and represent severe endothelial damage caused by various etiologies. The early recognition of complement-mediated (C-)TMA is of utmost importance to select patients for complement inhibition. Whether or not clinicopathologic features at presentation can distinguish C-TMA from secondary TMA and/or predict the response to complement inhibition remains unknown.

Methods: Fifty-seven patients with TMA on kidney biopsy and a normal activity of von Willebrand factor cleaving protease were screened for deregulated complement using *ex vivo* C5b9 formation on the endothelium and genotyping. Massive *ex vivo* C5b9 formation and/or rare complement gene variants defined C-TMA. Clinicopathologic features that may distinguish C-TMA from secondary TMA were studied. Regression models were used to assess the prognostic value of chronic damage on kidney biopsy.

Results: C-TMA was diagnosed in 30 patients (coexisting conditions, n=26 [87%]), including 16 (53%) cases with rare complement gene variants; 27 patients had secondary TMA related to autoimmunity (n=13), hypertension (n=10), and other etiologies (n=4). Patients presented with acute kidney injury, while systemic hemolysis was uncommon in both groups (n/N=14/30 vs. n/N=6/27; P>0.05). C-TMA was linked to younger age (37 [±14] vs. 46 [±15] years; P=0.04), low plasma C3 (n/N=16/29 vs. n/N=3/22; P<0.01), and glomerular thrombosis (n/N=19/30 vs. n/N=8/27; P=0.02) as compared to secondary TMA; glomerular thrombosis, however, was common in patients with autoimmunity (n/N=6/13; P>0.05 vs. C-TMA). These characteristics, when combined, had a specificity and sensitivity for C-TMA of 100% and 33%, respectively. Eculizumab treatment was associated with clinical remission in C-TMA (n/N=12/14; P<0.01 vs. n/N=3/16 untreated patients). Morphologic features of chronic damage, i.e., glomerulosclerosis, interstitial fibrosis/tubular atrophy, and arteriosclerosis, did not predict prognosis; 5 out of 6 patients with C-TMA and moderate-to-severe chronicity scores treated with eculizumab recovered and/or improved kidney function.

Conclusions: Patients with TMA, low plasma C3, and glomerular thrombosis who present at younger age (i.e., <45 years) are at high risk for C-TMA. Although a kidney biopsy is often needed to detect the TMA, morphologic features of chronic damage cannot predict prognosis.

PO1466

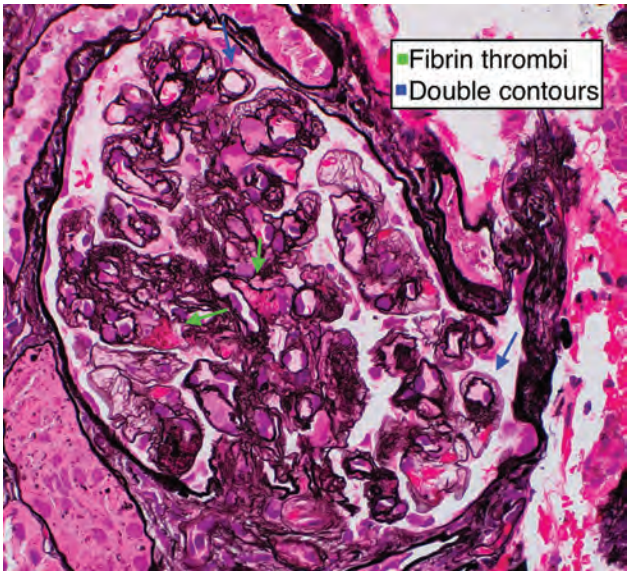
Limited Therapeutic Arsenal for the Thrombotic Microangiopathy Spectrum

Jesse E. Diaz Correa,[1] Joris M. Schuller,[2] Harold M. Szerlip.[1,2] *[1]Baylor University Medical Center at Dallas, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Thrombotic microangiopathy (TMA) is a common renal pathologic finding with an associated broad spectrum of clinical diseases. Complement-mediated TMA (C-TMA) is a frequently recognized cause of TMA due to uncontrolled complement activation. Terminal complement inhibitors such as Eculizumab have been shown to improve renal function in C-TMA. Multiple case reports have demonstrated a benefit in patients without identifiable complement disorder.

Case Description: 41-year-old Ethiopian female with a history of metastatic ovarian cancer treated with omentectomy, partial hepatectomy, salpingo-oophorectomy, splenectomy one year before admission was admitted for renal biopsy for evaluation of an increasing creatinine and proteinuria. Following her surgery she had been treated initially with paclitaxel and carboplatin and subsequently she had received bevacizumab and doxorubicin; the last doses of these latter agents were six months before admission. Four months prior to admission she developed new onset hypertension and her creatinine began to increase with subsequent development of nephrotic range proteinuria. All serologies were negative. Kidney biopsy demonstrated TMA. Despite the discontinuation of all chemotherapeutic agents and adequate blood pressure control, her creatinine continued to increase, peaking at 6.8 mg/dl 2 months after the biopsy She was started on Eculizumab with an improvement in creatinine to 3.49 mg/dL 2 months later.

Discussion: There are no randomized trials evaluating terminal complement inhibitors for c-TMA. The indication for these medications becomes even more unclear when we factor in drug-induced TMA, cancer-associated TMA, malignant hypertension, and other TMAs without readily identifiable complement disorders. More research on the use of genetic testing and complement inhibition is warranted for the entire spectrum of TMA.



PO1467

Hematopoietic Stem Cell Transplant Membranous Nephropathy Is Associated with Protocadherin FAT1

Sanjeev Sethi,[1] Benjamin J. Madden,[1] Samih H. Nasr,[1] Fernando C. Fervenza,[1] Mark Haas.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Membranous nephropathy (MN) is a common cause of proteinuria in patients with a hematopoietic stem cell transplant (HSCT). The antigen(s) responsible for MN in HSCT-associated MN is unknown.

Methods: We performed laser microdissection and mass spectrometry (MS/MS) of glomeruli of 230 cases of PLA2R-negative MN to detect novel proteins/antigens in MN. These included PLA2R-negative MN developing in the setting of HSCT and *de-novo* MN in the kidney transplant.

Results: We detected a novel protein Protocadherin FAT1 (FAT1) in 9 cases of PLA2R-negative MN. Of the 9 FAT1-associated MN cases, 7 patients followed HSCT and 2 followed kidney transplant (*de-novo* MN). HSCT was done for treatment of AML (5 cases), MDS (1 case) and essential thrombocytopenia (1 case). All 9 cases were negative for known antigens of MN including PLA2R, THSD7A, NELL1, PCDH7, NCAM1, SEMA3B and HTRA1. Baseline PLA2R spectral counts were detected in 7 of the 9 cases. The FAT1 total spectral counts ranged from 27 to 70 (mean 44.1 ± 13.1). FAT1 was not detected by MS/MS in 115 control cases that included time 0 transplant, minimal change disease, FSGS, diabetes and IgA nephropathy. FAT1 was also not detected in 28 cases of PLA2R-positive MN. No case of FAT1-associated MN was detected in a non-transplant setting. The mean age of patients with FAT1-associated MN was 56 ± 9.7 yrs, 7 patients were females and 2 were males. MN occurred 2.5 ± 0.8 yrs and 7.5 ± 1.2 yrs after HSCT and kidney transplant, respectively. The mean serum creatinine and proteinuria at kidney biopsy was 1.9 ± 1.2 mg/dL and 7.4 ± 5.4 gms/L, respectively. Kidney biopsy showed IgG (2-3+) and minimal C3 (0-1+) along glomerular capillary walls; electron microscopy showed stage II MN in 8 out of 9 cases.

Conclusions: FAT1 appears to be a unique protein found in MN developing in the setting of HSCT and *de-novo* MN following kidney transplant. Further studies to localize FAT1 on the glomerular basement membranes and detect circulating antibodies are ongoing.

Proteomic identification of FAT1 in 9 cases of PLA2R-negative MN. All 9 cases show large spectral counts of FAT1 and only baseline spectral counts of PLA2R. Case 3 and 5 are de-novo MN in kidney transplant, the remaining are following HSCT.

PO1468

Netrin G1 Is a Novel Target Antigen in Membranous Nephropathy

Linda Reinhard, Maya Machalitza, Thorsten Wiech, Nicoletta Ferru, Elion Hoxha, Rolf A. Stahl. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: PLA_2R is the main target antigen in membranous nephropathy (MN), representing 70-80% of cases. In the past years a number of confirmed, or potential target antigens, such as THSD7A, NELL1, HTRA1, Sema3B and PCDH7 have been reported, showing that the pathophysiology of PLA_2R-antibody (ab) negative MN represents a diverse repertoire of antigens with low frequency.

Methods: Western blot (WB) analysis was used to identify sera of MN patients with IgG4 specific signals binding to antigens in the membrane fraction of human glomerular extracts (HGE). Only sera which were negative for PLA_2R- and THSD7A-ab were used. IgG4-ab from the serum of an index patient was purified and used to immunoprecipitate the corresponding target antigen from the membrane fraction of HGE. The purified antigen in the eluate was identified by mass spectrometry. Recombinant protein was used to confirm the reactivity of patient sera by WB and identify other patients in a large cohort of MN patients. The deposition of the target antigen in the glomerular immune deposits was confirmed by immunohistochemistry (IHC).

Results: Using this approach, we identified Netrin G1 (NTNG1) as a novel target antigen in MN. NTNG1 is a 50 kDa secreted glycoprotein, which is attached to the cell surface by a GPI anchor (Fig. A, B). We identified NTNG1-ab in two out of 110 PLA_2R- and THSD7A-ab negative MN patients. A follow-up of 5 years was available for the index patient. During this time, both proteinuria and NTNG1-ab persisted while renal function was stable. Further, a granular positivity for NTNG1 along the glomerular capillary wall was confirmed in the kidney biopsy by IHC (Fig. C), but was undetectable in the negative control (PLA_2R-ab positive MN).

Conclusions: We report NTNG1 as a novel target antigen in MN, occurring with low frequency and expanding the repertoire of antigens in patients with MN. Its prevalence, pathogenetic and clinical roles remain to be defined.

Contactin 1: A New Antigen in Membranous Nephropathy Associated with Chronic Inflammatory Polyneuropathy

Domenico Santoro,[1] Elisa Longhitano,[1] Massimo Torreggiani,[2] Antonella Barreca,[3] Elisa Vegezzi,[5] Giorgina B. Piccoli,[2] Anna Mazzeo,[1] Massimo Russo,[1] Antonio Toscano,[1] Hanna Debiec,[4] Pierre M. Ronco.[4] *[1]Universita degli Studi di Messina, Messina, Italy; [2]Centre Hospitalier du Mans, Le Mans, France; [3]Azienda Ospedaliero Universitaria Citta della Salute e della Scienza di Torino, Torino, Italy; [4]INSERM, Paris, France; [5]Fondazione Istituto Neurologico Nazionale C Mondino Istituto di Ricovero e Cura a Carattere Scientifico, Pavia, Italy.*

Introduction: In recent years, several new antigens have been characterized in membranous nephropathy (MN), but those involved in association with demyelinating neuropathy remain elusive. Although several antibody specificities were identified in this group of autoimmune neuropathies with or without glomerular involvement, there is no evidence for the deposition of the relevant antibodies in glomeruli. We investigated a patient with such association.

Case Description: A 73 y/o woman was referred to the neurology department for weakness and ataxic gait. Romberg's manoeuvre was positive. On examination, thermal and nociceptive hypoesthesia and hypopallestesia were found. Electromyography demonstrated sensory-motor axonal polyneuropathy, compatible with a chronic inflammatory demyelinating polyneuropathy (CIDP). Blood tests showed normal kidney function (eGFR 73 ml/min) and hypoalbuminemia (2.89 g/dl); 24h proteinuria was 3.6 g/24h. Autoantibodies (ANA, ENA, DNA, LAC, anti-cardiolipin, ANCA) were undetectable, serum immunoglobulins and C3 and C4 complement components were normal. A kidney biopsy (KB) demonstrated a picture of MN. Anti-PLA2R antibody was negative in the serum and PLA2R and THSD7A antigens were not detected in the KB. Three CIDP-associated autoantibodies (anti-contactin 1 (CNTN1), anti-contactin associated protein 1 and anti-neurofascin) were tested by ELISA which revealed the presence of anti-CNTN1 at 1:100 serum dilution. CNTN1 antigen was revealed by immunohistochemistry in the subepithelial immune deposits in the patient's paraffin biopsy sections but not in control PLA2R-positive KB (figure 1).

Discussion: CNTN1 should be added to the armamentarium of antigens involved in MN and tested in PLA2R negative MN associated with CIDP. Further studies are needed to determine the prevalence of CNTN1-associated MN among patients with CIDP, and in those without CIDP and as yet unidentified antigen.

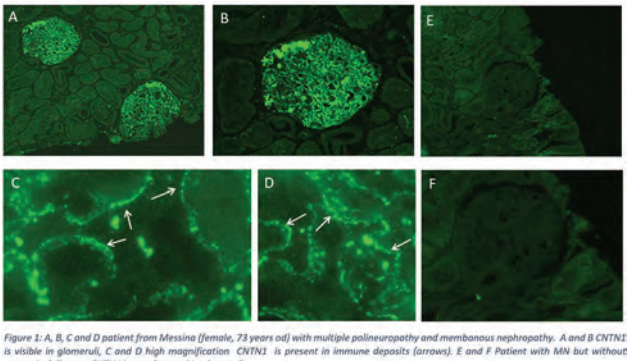

Figure 1: A, B, C and D patient from Messina (female, 73 years od) with multiple polineuropathy and membanous nephropathy. A and B CNTN1 is visible in glomeruli, C and D high magnification CNTN1 is present in immune deposits (arrows). E and F Patient with MN but without neurogical disease. CNTN1 is not detected in glomeruli

PO1470

Epitope Spreading and Immune Complex Rearrangement in Membranous Nephropathy

Olusola Sogbein, Marjan Afrouzian, Tina Kochar. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: We present a rare case of ANA and anti-dsDNA negative, anti-GBM positive lupus nephritis (LN) patient with two biopsies demonstrating LN Class III+V with possible immune complex (IC) rearrangement and/or epitope spreading (ES).

Case Description: A 62-year-old white male who presented with a year-long history of purpuric rash and hematuria. His hospital admission laboratory data is detailed in Table 1. The first renal biopsy showed crescents in 2/4 glomeruli with mild (+) granular and segmentally linear deposits by immunofluorescence (IF). The patient received cyclophosphamide, corticosteroids and one session of therapeutic plasma exchange due to rapidly worsening renal function and an initial presumptive diagnosis of anti-GBM disease. The second biopsy demonstrated no crescents but features of combined class III + V LN with IF findings suggestive of a full-house pattern with a change in the deposits from segmentally linear to pure granular. He began therapy with mycophenolate mofetil and prednisone resulting in a decrease in his UPCR from 2.3 to 0.3 mg/mg (complete remission) over the next four months and significant improvement in renal function.

Discussion: A link has been reported between anti-GBM histopathology and membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-dominant epitopes leading to propagation of autoimmunity. Circulating anti-GBM antibodies may continually stimulate the upregulation and alteration of anti-GBM epitopes leading to the development of granular deposits and membranous nephropathy. We believe our case suggests this possible pathogenic mechanism. More research is needed to improve understanding of the sequential change observed on immunofluorescence microscopy.

Laboratory Data

Laboratory Test	Result	Units	Reference Interval
White Blood Count	8.3	x10 3/mL	4.0-10.5
Hemoglobin	12.8	g/dL	14.0-18.0
Platelets	342	x10 3/mL	140-415
Creatinine	2.35	mg/dL	0.7-1.3
Complement - C3	39	mg/dL	88-201
Complement - C4	2	mg/dL	15-45
Anti-Neutrophil Antibody (ANA)	1:20		Titer < 1:40 (negative)
Double Stranded DNA Antibody (dsDNA Ab)	3.0	IU/mL	<30.0
Anti-Glomerular Basement Membrane (anti-GBM)	63	AU/mL	0-19
Urine Protein-to-Creatinine Ratio (UPCR)	2.3	mg/mg	<0.2

Generation of Anti-THSD7A Antibodies Using a Human Antibody Phage Display Library

Sarah Köllner,[1] Larissa Seifert,[1] Philip A. Heine,[2] Michael Hust,[2] Nicola M. Tomas.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Technische Universitat Braunschweig, Braunschweig, Germany.*

Background: Membranous nephropathy (MN) is an antibody-mediated autoimmune renal disease. In the majority of cases, autoantibodies target podocyte membrane proteins such as PLA2R1 and THSD7A. We could previously demonstrate that autoantibodies in THSD7A-associated MN cause disease and recognize several extracellular domains of the target antigen. However, it remains unclear how this antibody polyreactivity relates to disease pathogenicity. The aim of this study was the generation of anti-THSD7A antibodies using a human antibody phage display library for further diagnostic and pathomechanistic studies.

Methods: In the antibody phage display technology, antibody fragments are displayed on the phage particle and the corresponding gene fragment encoding the antibody fragment is packaged in the phage particle. A selection process called panning enables the selection of antibody fragments against virtually any target structure *in vitro*. In this project, a naïve antibody gene library was used to select binders to the extracellular part of human and mouse THSD7A. Binders were sequenced, cloned into scFv-Fc format - an IgG like format - and produced in HEK293 cells. Binding of scFv-Fc to human and mouse THSD7A was investigated using Western blot, ELISA and indirect immunofluorescence testing (IFT). Epitope regions were mapped using an ELISA.

Results: Four binders (SAK79-B1, SAK78-C12, SAK78-E6, SAK78-F8) could be obtained. While SAK78-F8 exclusively bound human THSD7A, the other binders reacted with both human and murine THSD7A in Western blot, ELISA and IFT. A domain-specific ELISA revealed binding of SAK78-C12, SAK78-E6 and SAK78-F8 to the regions d8_d9, d1_d2 and d6_d7, respectively. SAK79-B1 did not react with any domain combination, but showed strong binding to murine and human d1_d21. We suspect a conformational epitope that is not conserved in the coated domain fragments. SAK78-C12 and SAK78-E6 were succesfully cloned into human IgG subclass backbones IgG 1-4.

Conclusions: Antibody phage display represents a powerful method to generate recombinant antibodies. The antibodies selected in our study show different binding characteristics *in vitro*. *In vivo* binding characteristics, pathogenicity and potential as a diagnostic tool, e.g. to stain THSD7A in patient biopsies, need to be determined.

A Comparison of aPLA2Rab Assays on Treatment with Cyclophosphamide and Steroids

Coralien Vink- van Setten,[1] Anne-Els van de Logt,[1] Alexander Kühnl,[2] Jack F. Wetzels.[1] *[1]Radboudumc, Nijmegen, Netherlands; [2]EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany.*

Background: Anti-PLA2r antibodies (aPLA2r) are present in ~75% of patients with primary membranous nephropathy (MN). A qualitative immunofluorescence test (IIFT) allows accurate detection of aPLA2r, additionally ELISA and ChLIA provide quantitative analysis. Sensitivity of the two latter methods after start of immunosuppressive therapy is not well studied.

Methods: We retrieved stored samples of patients with aPLA2R associated MN, who were treated with cyclophosphamide and steroids(CP), collected at baseline and 8 weeks after start of therapy. Assays were performed by the EUROIMMUN researchlab, Lübeck, Germany. All samples were analysed by IIFT, ELISA and ChLIA. We categorized ELISA results to cut-off values used in literature: 2, 14, and 20 RU/ml resp.

Results: We included baseline samples of 50, and 8 week samples of 51 patients. At baseline, all patients tested IIFT positive; ELISA test was positive in 94% or 98% of samples using cut-off values of 20 RU/ml or 14 RU/ml resp., indicating high sensitivity. Agreement between IIFT and ChLIA was 100%. After 8 weeks on CP, 37/51 patients had immunological remission by IIFT. ELISA test results are given in Table1. In the IIFT positive samples collected after 8 weeks, ELISA titers were < 20RU/ml or < 14 RU/ml in 9/14 and 5/14 patients respectively, suggesting lower sensitivity. All IIFT negative samples had ELISA titers < 14 RU/ml. When analysing IIFT negative patients with ELISA titer <2 U/mL (N=23) vs. 2-14 U/mL (N=14), persistent immunological and clinical remission was better in the first group (74% vs 58%), however not statistically different. With ChLIA only 4/51 (8%) had different results (2 IIFT+/ChLIA-, 2 IIFT-/ChLIA+); resulting in a sensitivity of 86% and a specificity of 95%, when compared to IIFT.

Conclusions: Using immunological remission as treatment target, as described here after 8 weeks of CP, requires evaluation of the applied assay for this purpose. Of the examined quantitative methods, ChLIA demonstrated the highest agreement with IIFT. ELISA titers below the recommended cut-off for initial diagnosis still show a tendency towards the clinical outcome, which could be investigated by further studies.

Funding: Commercial Support - EUROIMMUN researchlab, Lübeck, Germany

	ELISA titer	<2	2-14	14-20	>20	Sum
Baseline samples (total 50)	IIFT + / ChLIA +	0	1	2	47	50

PO1473

The Classical Pathway Triggers Pathogenic Complement Activation in Membranous Nephropathy

Larissa Seifert,[1] Gunther Zahner,[1] Naemi C. Hickstein,[1] Sarah Köllner,[1] Catherine Meyer-Schwesinger,[1] Dominik Kylies,[1] Anna Borodovsky,[2] Peter F. Zipfel,[3] Victor G. Puelles,[1] Ulf Panzer,[1] Tobias B. Huber,[1] Thorsten Wiech,[1] Nicola M. Tomas.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Alnylam Pharmaceuticals Inc, Cambridge, MA; [3]Leibniz-Institut fur Naturstoff-Forschung und Infektionsbiologie eV Hans-Knoll-Institut, Jena, Germany.*

Background: Membranous nephropathy (MN) is characterized by severe proteinuria, circulating autoantibodies against podocyte antigens such as PLA2R1 and THSD7A, and glomerular deposition of IgG and complement components (CCs). However, the pathways triggering the complement cascade (classical, alternative or lectin) and the significance of local glomerular complement action for podocyte damage and proteinuria are poorly understood.

Methods: Complement activation was investigated in 20 biopsies from patients with PLA2R1- and THSD7A-associated MN using immunofluorescence and proximity ligation assays to visualize the assembly of CCs/convertases. Experimental autoimmune MN (EAMN) was established in 12-week-old BALB/c mice by immunization with THSD7A. Anti-THSD7A antibodies, proteinuria, serum parameters, and histological signs of MN were analyzed. The role of the complement system was studied by induction of EAMN in *C3*$^{-/-}$ mice. The efficacy of complement-targeted treatment was evaluated by weekly injection of a C3-silencing siRNA after the onset of proteinuria.

Results: The assembly of the classical/lectin convertase was identified in 19/20 MN biopsies, which was accompanied by detection of IgG and C1q in the majority of cases. The alternative convertase and MBL deposits were detected in fewer cases. Upon immunization, mice developed clinical and histopathological features of MN. Proteinuria ranged from mild to severe nephrotic syndrome and histopathological features included granular glomerular deposition of IgG and CCs including C1q and C3 as well as loss of the integral podocyte proteins neph1 and nephrin. Strikingly, severe disease with ascites was prevented in *C3*$^{-/-}$ mice and overall proteinuria was reduced in comparison to WT littermates. Finally, treatment with C3-silencing siRNA after the onset of proteinuria attenuated disease.

Conclusions: The complement system is dominantly activated via the classical pathway in MN patients. Experimental data in the first autoimmune model involving an antigen that is pathogenically relevant in patients suggest complement-targeted treatment as a promising strategy for MN patients with severe disease, but also hint at a role of complement-independent mechanisms in the pathogenesis of MN.

PO1474

Positive PLA2R Detection by Mass Spectrometry but Negative PLA2R Staining on Immunofluorescence Microscopy

Sanjeev Sethi, Benjamin J. Madden, Ladan Zand, Fernando C. Fervenza. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Detection of PLA2R along the glomerular basement membranes by immunofluorescence (IF) studies using antibodies directed against PLA2R is considered the gold standard for diagnosis of PLA2R-positive MN on the kidney biopsy. Laser microdissection of glomeruli followed by mass spectrometry (MS) of PLA2R-positive MN also detects high total spectral counts of PLA2R confirming the IF studies. However, correlation of PLA2R-negative MN cases by both IF and MS has not been done.

Methods: We performed laser microdissection and mass spectrometry in 230 cases PLA2R-negative MN in search of novel proteins that may represent new target antigens in PLA2R-negative MN. All 230 cases were negative for PLA2R by IF staining.

Results: We detected high total spectral counts of PLA2R in 8 (3.5%) of the 230 PLA2R-negative MN cases by IF. The mean total spectral count of PLA2R in the 8 cases was 57 (range 24 to 83, SD ± 25.0) (Figure 1). This is comparable to the mean total spectral counts in PLA2R-positive MN (57.7 ± 23.7). The baseline mean total spectral count of PLA2R in 6 time zero transplant biopsies (control cases) was 6. Interestingly, all subtypes of IgG were present in the 8 cases that were postivie for PLA2R by MS with IgG1 being the dominant (total spectral count 57 ± 16.9) followed by IgG3 (50.0 ± 11.5), IgG4 (46.3 ± 18.1) and IgG2 (39.3 ± 11.4). On kidney biopsy, 3 of the 8 cases showed findings for secondary autoimmune MN such as C1q positivity or full house Ig staining. Electron microscopy showed stage I MN in 2 cases, stage II MN in 5 cases and stage III in 1 case. Clinical details at presentation were as follows: 3 females and 5 males, mean age 53.6 years (± 20.7), mean serum creatinine 1.38 mg/dL (± 0.6), and mean proteinuria 6.8 gms/24 hours (± 6.2).

Conclusions: IF is negative for PLA2R-staining in a small (3.5%) number of PLA2R-postive MN. These cases can be detected by MS. Thus, MS is an alternative to IF staining and the new gold standard to detect PLA2R on the kidney biopsy.

MS studies showing high total spectral counts of PLA2R in 8 cases that were PLA2R-negative by IF. Baseline mean levels of PLA2R in 6 controls (Ctrls) are shown in first column.

PO1475

Can the Use of the Serum Anti-PLA2R Antibody Negate the Need for a Renal Biopsy in Primary Membranous Nephropathy?

Omar S. Ragy, Vilma Rautemaa, Durga Anil K Kanigicherla, Patrick Hamilton. *Manchester Metropolitan University, Manchester, United Kingdom.*

Background: Since the emergence of the anti-PLA_2R antibody test, nephrology practice has not changed dramatically, and most nephrologists are still relying on performing a kidney biopsy in diagnosing membranous nephropathy. In this study, we sought to examine how anti-PLA_2R antibody tests using ELISA can be utilized in clinical practice.

Methods: We have conducted a retrospective analysis for 187 patients between 2003 and 2020 correlating their renal biopsy findings with their anti-PLA_2R antibody test when performed. We have recorded all patient's demography, urine protein creatinine ratios, serum albumin, and treatment commenced whether using RAS blockade or immunosuppression treatment. Using a statistical analysis model, we have calculated the positive and negative predictive values of the anti-PLA_2R ab test carried out during that period.

Results: The mean levels of anti-PLA2R antibody titer in primary membranous nephropathy were 217 RU/ml, whereas the mean level was only 3 RU/ml for both secondary membranous nephropathy and other diagnoses. The majority of our cohort who had a positive anti-PLA_2R antibody test had a confirmed renal biopsy diagnosis of primary membranous nephropathy with a PPV of 97.3%. Also, we found that the test sensitivity was 75.5%. On the other hand, we found that the NPV was 79.8% and the specificity was 97.8% at a level of >20 RU/ml

Conclusions: The anti-PLA_2R antibody test is a highly specific test for diagnosing membranous nephropathy. Experience from our center supported by some evidence from the literature suggests that we can rely solely on a positive test without the need to perform a renal biopsy. More prospective trials are required to further validate that notion.

PO1476

Complement Activation and Suppression Profile Reveals Distinct Subtypes in C3 Glomerulonephritis

Nicholas J. Steers, Kelsey O. Stevens, Judy Liang, Anna Mo, Debanjana Chatterjee, Jason Zheng, Iman Ghavami, Rafael Gras, Maria M. Morban, Xueru Mu, Stacy E. Piva, Vanna M. Nicasio, Maddalena Marasa, Andrew S. Bomback, Pietro A. Canetta, Jai Radhakrishnan, Gerald B. Appel, Ali G. Gharavi. *Columbia University Irving Medical Center, New York, NY.*

Background: The complement pathway is an innate immune defense mechanism, and uncontrolled activation can cause damage to host tissues including the kidney. C3GN is characterized by deposits in the glomerulus made up entirely of complement C3 protein without the presence of immunoglobulins.

Methods: The activity of the alternative complement pathway (ACP) was determined in serum derived from C3GN patients, IgA Nephropathy (IgAN) and Polycystic Kidney Disease (PKD) and heathy controls (HC) by measuring the lysis of rabbit red blood cells (rRBC). Complement factor H (CFH) was added to the serum of C3GN patients to establish if CFH is capable of inhibiting the ACP in C3GN.

Results: Analysis of the ACP using the serum of C3GN, IgAN, PKD patients and healthy controls can be calculated by the lysis of rRBC. The percent lysis at specified time points (5, 10 and 15 minutes) was calculated using the maximal lysis for each sample. Serum from C3GN patients result in more significant lysis (one way ANOVA $P < 0.01$) at 5 and 10 minutes (22.9% ± 11% and 42.7% ± 12%, respectively) compared to HC (7.1% ± 3% and 21.7% ± 6%, respectively), IgAN (10.9% ± 7% and 27.3% ± 15%, respectively) and PKD (8.6% ± 6% and 24.4% ± 12%, respectively). However, at 15 minutes, there were no significant differences in the lysis of the rRBC between these groups, suggesting that the ACP is more rapidly activated in C3GN patients, leading to faster depletion of C3. Addition of CFH to the serum of C3GN patients reduced the ACP activity to control levels in 6 out of 14 patients. We did not detect CFH specific antibodies in the serum of patients who did not respond to CFH, indicating additional mechanisms are involved with the rapid activation of the ACP in C3GN.

Conclusions: The ACP is rapidly activated by the serum of C3GN patients compared to other kidney diseases and HC. Although the addition of CFH to the serum reduced the ACP activation comparable to controls in 42% of C3GN patients, not all the serum samples responded to CFH. Future work may elucidate additional mechanisms of the continued ACP activation in C3GN patients and have implications for therapy of these patients.

PO1477

Preexisting Autoimmune Dysregulation Unmasks a Role for Silica Dust Exposure in Nephrotropic Autoantibody Production

Lanette Fee,[1] Robert M. Tighe,[1,2] Mary H. Foster.[1,2] [1]*Duke University, Durham, NC;* [2]*DVAMC, Durham, NC.*

Background: Pathogenic autoantibodies (autoAb) promote severe glomerulonephritis in ANCA vasculitis and lupus. Genetic susceptibility and environmental exposures, particularly inhalation of silica (Si) dust, are implicated in dysregulated autoimmunity and are targets for therapeutic intervention. Using a mouse reporter system expressing a regulated nephrotropic autoAb transgene (Tg) targeting basement membrane (BM) and instilling Si by oropharyngeal aspiration (OPA), we demonstrated that central B cell tolerance and anergy to BM are preserved in multiple lupus strains despite induction of lung inflammation and ectopic lymphoid tissue. Nonetheless, Si exposure increased local and systemic anti-DNA Ig levels in wildtype (WT) B6 and lupus mice, suggesting subversion of alternative regulatory checkpoints. Herein we leverage the aberrant M7 anti-BM Tg lineage that demonstrates partial escape from tolerance and evidence of glomerular Ig deposition to study the interaction of Si exposure with preexisting defects in autoreactive cell regulation.

Methods: M7 Tg mice (WT at Ig light chain, or LC, locus) were exposed to Si or vehicle (V) by OPA, organs harvested at 5-6 weeks, and cells cultured ±Toll-like receptor ligand (TLR-L). To restrict Ig specificity, a subset of mice (Tg/KI) was bred to heterozygosity for the Vk8/Jk5 V8R Ig LC knock-in. Tg autoAb were measured by ELISA; mean OD±SD.

Results: Presence of serum Tg autoAb and induction of high levels of autoAb by TLR-L-stimulated splenocytes (OD 2.612±0.49, TLR7/9, vs 0.063±0.03, medium, $p<0.0001$) confirmed Tg phenotype, and bronchoalveolar lavage fluid cell counts confirmed exposure (237.1±130 vs 1.8±1.7, x1000, Si vs V, $p<0.05$). Among Tg/WT mice, more autoAb were produced by TLR7/9-stimulated lung cells from Si vs V exposed mice (OD 0.131±0.15, Si, vs 0.032±0.01, V, $p<0.05$), indicating that Tg B cells recruited by Si exposure contribute to local autoAb production. Among Si-exposed mice, Tg autoAb levels were higher in Tg/W vs Tg/KI mice: OD 1.239±0.47 for TLR4-L stimulated splenocytes, Tg/W, vs 0.515±0.13, Tg/KI, $p<0.05$.

Conclusions: An autoAb reporter system reveals that anti-BM autoreactive lymphocytes that escape tolerance can be recruited to the lung after exposure to inhaled silica dust. Anti-BM cell activation by superimposed stimuli, such as TLR-L, can lead to secretion of nephrotropic autoAb.

PO1478

Characteristics of Membranous Nephropathy Patients with IgG and IgA Co-Deposits on Capillary Wall

Guan Yi, Qionghong Xie, Ruiying Chen, Shaojun Liu, Lingyun Lai. *Huashan Hospital Fudan University, Shanghai, China*.

Background: Membranous nephropathy (MN) is characterized by immune deposits on glomerular capillary wall, predominantly IgG. There have been several reports of MN combined with IgA nephropathy with features of IgA immunofluorescence staining in the glomerular mesangium. However, we found that IgA can also be deposited on the capillary wall with IgG. This study aimed to investigate the prognostic, clinical and renal histopathological characteristics of adult MN patients with IgG and IgA co-deposits on capillary wall.

Methods: A retrospective study was conducted in biopsy-proven MN patients of our renal department during January, 2007 to May, 2020. Clinical data were collected at time of biopsy and the latest followed-up. Pathological parameters included immunofluorescence staining, pla2r staining, membranous Churg's stages, sclerosis, crescent, focal segmental sclerosis lesion, chronic tubulointerstitial injury and et al. Indirect immunofluorescence experiment was conducted in 293T cells transfected with pla2r plasmid.

Results: Out of 531 cases diagnosed with MN, 53 patients have moderate IgA deposit on capillary walls with IgG. 19 cases were determined to be secondary MN, which were 10 cases of autoimmune disease, 4 cases of Hepatitis B, 3 cases of kidney transplation, 1 case of chemical explosure and 1 case of AL amyloidosis-associated secondary MN. 31 Idiopathic MN patients with both IgA and IgG depositing along capillary wall were followed up for a median interval of 49months (interquartile-range, 17-82) and 3 withdrew. 3 (9.8%) patients progressed to ESKD or death, 2 (6.5%) patients had their eGFR declined by half, 11 (35.5%) patients had no remission and 15 (53.6%) patients underwent immunosuppressive therapy. 72.4% idiopathic MN patients with IgA deposit were pla2r associated. Indirect immunofluorescence study revealed that both IgG and IgA isoform of anti-pla2r autoantibody in MN patients' serum.

Conclusions: IgA and IgG could be co-depositing along glomerular capillary wall in MN patients, secondary causes should be screened with cation. IgA and IgG type of autoantibodies linked to MN co-existed in serum of idiopathic MN patients, whose prognosis might be poor.

PO1479

Humanistic Burden of Rare Kidney Diseases; Understanding the Impact of FSGS and IgAN on Patients and Caregivers: The HONUS Rationale and Study Design

Justyna Szklarzewicz. HONUS Advisory Board Members and HONUS Study Team *University Hospitals of Leicester NHS Trust, Leicester, United Kingdom*.

Background: While both Immunoglobulin A Nephropathy (IgAN) and Focal Segmental Glomerulosclerosis (FSGS) conditions have been shown to be associated with significant clinical and economic burden to healthcare systems, less is known about the humanistic burden associated with these diseases. Here we describe the **H**umanistic Burden **o**f Rare Kid**N**ey Diseases: **U**nderstanding the Impact of FSGS and IgAN on Patients and Caregivers **S**tudy (HONUS), which aims to elucidate the impact of these conditions.

Methods: HONUS is being designed in consultation with patient and clinical community members as a multi-national, cross-sectional survey recruiting adult patients, caregivers (care-partners) and parents/care-partners of youth with FSGS or IgAN. Participants complete a comprehensive survey covering demographic and clinical information, health-related quality of life (HRQoL), and the impact these diseases have on education, career, employment, relationships, mental wellbeing, personal finances, lifestyle, and fear and uncertainty for the future.

Results: Humanistic burden considers the impact of illness on patient HRQoL, activities of daily living, caregiver health and HRQoL, and is commonly quantified in population health context as Disability- or Quality-Adjusted Life Years (DALYS or QALYS). Quantifying humanistic burden is foundational for value assessment of new therapeutic options, but also has broader benefits. For patients and care-partners, insights can validate and support individual experiences and coping. For patient advocacy groups, information can be used to raise awareness, facilitate education and develop resources for affected families. For the clinical community, evidence supports patient/family communication, education of the broader clinical community and contributes to informed decision making. For industry, data supports value assessments and ensures the patient and care-partner voice is heard. This begins with engagement of patient and clinical community members at inception of study design, ensuring the right elements are included in the study, the design fits with the evidence generation goal, and results are disseminated in a comprehensive and useful way.

Conclusions: HONUS will provide evidence quantifying the humanistic burden of FSGS and IgAN from patient and care-partner perspectives.

PO1480

Mystery Cryoglobulinemic Glomerulonephritis Treated with Rituximab

Mohamed Hassanein, Hanny Sawaf, Leal C. Herlitz, Michael Lioudis. *Cleveland Clinic, Cleveland, OH.*

Introduction: Cryoglobulinemic Glomerulonephritis (GN) is characterized by the deposition of immunoglobulins (IG), also known as cryoglobulins (CG), in the kidney. We report a case of idiopathic mixed cryoglobulinemic GN treated with rituximab and prednisone.

Case Description: A 42-year-old tri-athlete with a history of pediatric meningitis with hydrocephalus requiring placement of a ventriculoperitoneal shunt presented with lower extremity swelling limiting his ability to exercise. He denied non-steroidal anti-inflammatory drug and illicit drug use, and was not on any prescribed medications. Laboratory workup showed serum creatinine: 1.2 mg/dL (normal 0.7 – 1.2), serum albumin: 2.1 mg/dL (normal 3.9 – 4.9), CG: 140 μg/mL (normal 0 – 50), C3: 39 mg/dL (normal 86 – 166), C4: 7 (normal 13 - 46), and a urine protein to creatinine ratio (UPCR) 5.9 g/g. Kidney biopsy showed diffuse proliferative GN with polyclonal IgM deposits consistent with mixed cryoglobulinemic GN (figure 1). An infectious workup, including human immunodeficiency virus (HIV), viral hepatitis, blood and urine culture, and a lumbar puncture were unremarkable. Computed tomography of the chest, abdomen, and pelvis revealed splenomegaly. Echocardiogram and bone marrow biopsy were non-diagnostic. He was treated with rituximab and prednisone with normalization of CG, C3, and C4, a reduction in UPCR to 0.5 g/g and return to full exercise capacity five months later.

Discussion: Mixed cryoglobulinemic GN is a rare disorder caused by polyclonal deposition of IG in the kidney. Autoimmune disease, hematological malignancies, and infectious etiologies such as endocarditis, HIV, and viral hepatitis should be ruled out prior to immunosuppressive therapy. Our patient elected to proceed with treatment due to his poor quality of life and evidence of end-organ involvement. Although workup for hematological malignancies was unremarkable, it is unclear if his splenomegaly could be reflective of an underlying indolent lymphoma, which could have simultaneously responded to rituximab treatment.

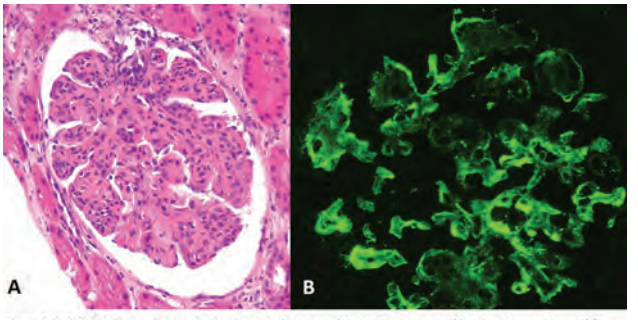

Figure 1. A: H & E stain showing lobular hypercellularity suggestive for membranoproliferative glomerulonephritis, B: Immunofluorescence showing polyclonal IgM kappa and lambda staining.

PO1481

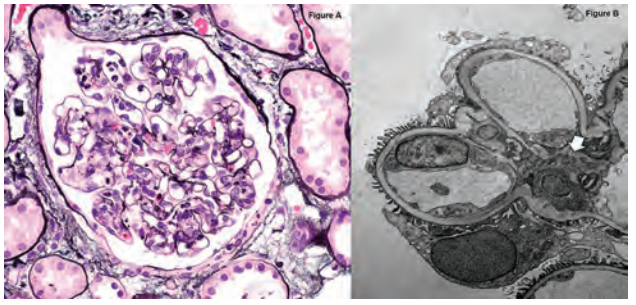
Does SARS-CoV-2 Activate the Alternative Complement Pathway? A Case Report of C3-Dominant Proliferative GN in a Patient with SARS-CoV-2 Infection

Jahanzeb Khan,[1] Sehrish W. Bukhari,[2] Muhammad G. Alam.[1,2] *[1]Baptist Health Medical Center - North Little Rock, North Little Rock, AR; [2]Kidney Care Center, Little Rock, AR.*

Introduction: C3-glomerulopathy is a rare kidney disorder due to dysregulation of the alternative complement pathway. C3 glomerulonephritis (C3GN) has been associated with a variety of diseases including connective tissue disorders and infections. Here we present the first case report of C3GN in a patient with SARS-CoV-2 infection.

Case Description: A 54-year-old man with no known renal disease presented to the hospital with fever, cough, dyspnea and worsening edema. His SARS-CoV2 PCR test was positive and he was treated for COVID-19 pneumonia. His blood cultures remained negative and no bacterial infection was identified. He was also noted to have worsening renal function with a peak serum creatinine of 3.9 mg/dL. His serologies including Hep B, Hep C, HIV, ANA, ANCA, RF, and Cryoglobulins were all negative. His serum complement levels were low. A renal biopsy was performed. Light microscopy showed mild mesangial and endocapillary hypercellularity (Figure A). IF revealed mesangial and endocapillary wall staining positive for C3. Electron microscopy confirmed electron dense deposits of C3 (Figure B).

Discussion: Several mechanisms have been suggested in the pathogenesis of SARS-CoV-2 related tissue injury including classical and alternate compliment pathways. C3GN is rare renal disorder due to dysregulation of alternate complement pathway. C3GN is characterized by mesangial deposits, endocapillary hypercellularity under light microscopy, and C3 deposits in mesangial and endocapillary wall on IF, in the absence of other significant findings. We present the first case report of C3GN in a patient with SARS- CoV-2 infection. Although this case does not establish a cause-effect relationship, but does raise the possibility of activation of the alternative complement pathway in SARS-COV-2 infection.



Light microscopy showed mild mesangial and endocapillary hypercellularity (Figure A). Electron microscopy confirmed electron dense deposits of C3 (Figure B).

PO1482

Vancomycin-Induced Thrombotic Microangiopathy: A Rare Association

Gaurav Rajashekar, Anuja Java. Washington University in St. Louis *Washington University in St Louis, St Louis, MO.*

Introduction: Thrombotic microangiopathies (TMAs) are life-threatening conditions characterized by hemolytic anemia, thrombocytopenia and AKI. Drug-induced TMA (DITMA) is a diagnostic challenge because specific tests to identify a drug etiology are not available.

Case Description: A 40 yr-old female with history of neurofibromatosis type 2 underwent resection of a T10-11 schwannoma. The surgery was complicated by wound dehiscence which was treated with incision and drainage followed by intravenous vancomycin and cefazolin. The next day, she developed fever, altered mental status and a diffuse purpuric rash (Fig 1). Labs showed anemia (Hgb, 6.2 g/dl), thrombocytopenia (PLT, 15 k/µl), elevated LDH and anuric AKI requiring dialysis. C3 and C4 were low. Coombs test was negative. She subsequently developed disseminated intravascular coagulation and elevated liver enzymes. Skin biopsy revealed a leukocytoclastic vasculitis with IgG and complement deposition within vessel walls. Given the concern for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Treatment with prednisone and plasmapheresis was initiated which led to improvement of renal function, mental status and hematologic parameters within 48 hrs. Renal biopsy confirmed TMA. ADAMTS-13 activity and complement genetic testing came back normal. Unfortunately, later during the hospitalization, she developed acute respiratory failure leading to cardiac arrest.

Discussion: This is a rare case of vancomycin-induced TMA. We speculate the mechanism is immune-mediated given the presence of low complement levels (although we did not test for vancomycin-dependent antibodies). Patients with immune-mediated DITMA present with sudden onset of severe systemic symptoms after a short exposure to the implicated drug. Greater awareness with improved methodology for diagnosis of DITMA is critical for clinicians evaluating such patients. Recognition of DITMA and documentation of the drug etiology are essential for patient safety.

Diffuse purpuric rash

PO1483

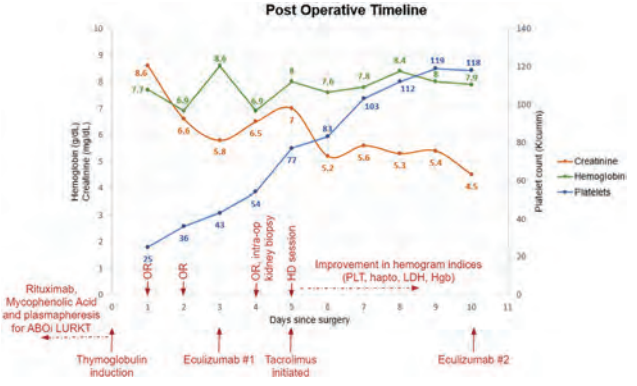
Post-Transplant Thrombotic Microangiopathy due to a Pathogenic Mutation in Complement Factor I

Sana J. Shaikh, Maryam Saleem, Anuja Java. *Washington University in St Louis, St Louis, MO.*

Introduction: Thrombotic microangiopathy (TMA) is characterized by hemolytic anemia, thrombocytopenia, and AKI. Atypical hemolytic uremic syndrome (aHUS) is a classic complement-mediated TMA that occurs when genetic variants in complement proteins result in a dysregulated complement system. Genetic variants in complement Factor I (*CFI*) have been reported in 5–15% of patients with aHUS.

Case Description: 28-year-old African American man with ESKD secondary to biopsy-proven PLA2R-positive membranous nephropathy underwent a 2/2/1 mismatch ABO incompatible living-unrelated kidney transplantation. Induction immunosuppression included methylprednisolone and Thymoglobulin. Post-op course was complicated by bleeding and he was taken back to the OR on POD 1. Labs showed anemia (Hgb 7.7 g/dL), thrombocytopenia (PLT 25 k/µl), low haptoglobin (< 10 mg/dL), high LDH (580 Units/L), low C3 and normal C4. ADAMTS-13 activity and coagulation profile were normal. Graft function was delayed. This raised concern for a TMA. Tacrolimus was not initiated. Allograft biopsy performed on POD 4 confirmed the diagnosis. Eculizumab was administered, resulting in resolution of thrombocytopenia and hemolysis, and gradual renal recovery. Genetic testing for complement revealed a 'variant of uncertain significance' in *CFI* (Iso357Met). This variant is located in the serine protease domain of Factor I which contains the catalytic site. Functional analysis of the variant using recombinant proteins revealed that it had defective complement regulatory activity. This work established that the *CFI* variant was deleterious and thus defined the etiopathogenesis of TMA in the patient.

Discussion: This is a case of de novo post-transplant aHUS due to a pathogenic complement mutation, likely triggered by transplant surgery. Our strategy of recombinant protein production followed by detailed functional assessment defined the functional repertoire of the variant protein and provided critical guidance relative to the underlying pathophysiology and appropriate therapeutic regimen.



PO1484

Cryoglobulinemic Vasculitis in a Patient with Known Thrombotic Microangiopathy

Sanjay Gadi,[1] Eugene P. Rhee,[3] Veronica E. Klepeis,[3] Janewit Wongboonsin.[2,4] *[1]Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Introduction: Acute kidney injury (AKI) is a ubiquitous presentation, but thrombotic microangiopathy (TMA) and cryoglobulinemia are uncommon causes that are not easily diagnosed. We highlight a case of AKI that was found to be cryoglobulinemic vasculitis, an unexpected diagnosis in a patient with history of TMA.

Case Description: A 68-year-old female was diagnosed with giant cell arteritis, with temporal artery biopsy showing inflammation of the adventitia consistent with small vessel vasculitis. She received prednisone and tocilizumab. 6 months later, she was admitted for hypertensive crisis with thrombocytopenia and schistocytes, with creatinine (Cr) elevation to 3.5 from baseline of 1.0. Renal biopsy showed TMA. Tocilizumab was discontinued. She was transitioned to eculizumab, eventually resulting in renal recovery (Cr 1.5) after 1.5 months. However, she continued to feel poorly and returned to the hospital, where she was found to have Cr 4.0. Physical exam was significant for hypertension and tender retiform purpura. Urine studies were consistent with cellular casts. Dermal biopsy showed dermal necrosis but no intravascular thrombi. Renal biopsy ultimately revealed cryoglobulin deposition, resulting in a diagnosis of cryoglobulinemic vasculitis. She was treated with prednisone, rituximab, and cyclophosphamide with good renal response, and discharged with Cr 2.4.

Discussion: The finding of cryoglobulin on this patient's renal biopsy was subtle, causing a near-miss in her diagnosis. Her history and repeat clinical evidence of TMA further confounded her presentation. Therefore, when TMA is on the differential, workup should also evaluate for cryoglobulinemia. Her prior diagnosis of GCA also acted as a confounder, though absence of panarteritis and large vessel involvement on temporal artery biopsy may have hinted at underlying systemic vasculitis. While eculizumab is a standard therapy for TMA, there is limited evidence for its use in treating cryoglobulinemic vasculitis. This patient's positive renal response to eculizumab supports the potential role of complement inhibitors in treating cryoglobulinemia. It remains possible that the patient could have had TMA and cryoglobulinemia concurrently, with renal biopsy during this presentation only capturing the latter. Therefore, further research into the role of complement inhibitors for cryoglobulinemia is needed.

PO1485

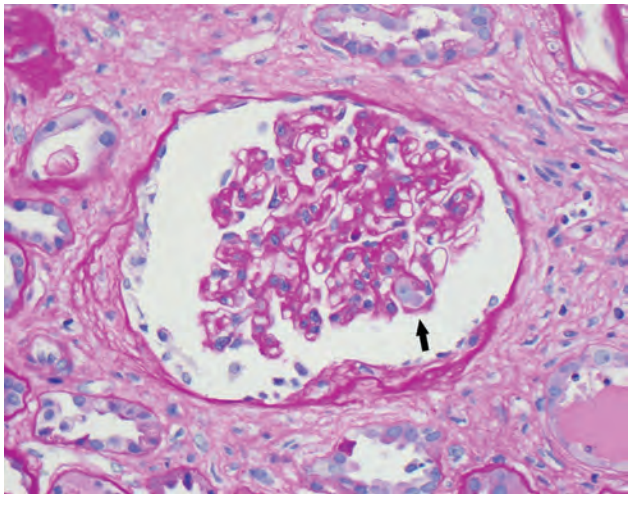
Minimal Change Disease as a Novel Manifestation of Cytomegalovirus

Andrew Lee, Hsiao L. Lai, Abdullah Thayyil, Reginald I. Obi. ECU Nephrology and Hypertension *East Carolina University Division of Health Sciences, Greenville, NC.*

Introduction: Cytomegalovirus (CMV) infection is typically asymptomatic among the immunocompetent or can cause a mononucleosis. Among immunosuppressed patients common presentations are colitis, hepatitis, encephalitis, retinitis and even Guillian-Barre syndrome. This case is a rare disseminated presentation of CMV manifesting as acute glomerulopathy.

Case Description: A 67 year-old female with past medical history of lupus, rheumatoid arthritis, and Sjogrens syndrome on maintenance steroids presented with a prolonged cough, joint swelling, shortness of breath and rash consistent with livedo reticularis. She developed worsening weakness in the arms and legs. High dose IV steroids were initiated for presumed rheumatoid vasculitis. Nephrology was consulted for worsening renal function with urine protein to creatinine ratio of 42 g, later requiring hemodialysis for volume management. Work up for nephrotic range proteinuria including hepatitis B/C, HIV, SPEP, UPEP, and complement screen was unrevealing. Renal ultrasound demonstrated an 11.7 cm right kidney and 14 cm left kidney. Renal biopsy demonstrated diffuse podocyte effacement and large atypical mononuclear cells within the glomerulus. No immune deposits seen on electron microscopy. Immunohistochemical staining confirmed glomerular CMV. Six weeks after starting treatment with ganciclovir and tapering steroids, CMV viral load was undetectable and renal function recovered to baseline.

Discussion: CMV involvement of the kidney is unusual aside from tubulointerstitial nephritis. Rare cases of collapsing glomerulopathy and focal segmental glomerular sclerosis are found in literature. We report a novel presentation of CMV glomerulopathy with minimal change disease and renal failure. To prevent tissue invasive CMV in a chronically immune suppressed patient one needs to maintain clinical suspicion for infectious pathogens and perform tissue biopsy.



PAS of glomerulus showing giant cell

PO1486

Minimal Change Disease Following the mRNA-1237 Vaccine in a Kidney Transplant Recipient

Juanly N. Rodriguez, Shobana Sivan, Mariella O. Goggins. *University of Miami School of Medicine, Miami, FL.*

Introduction: Kidney transplant recipients (KTR) are susceptible to post-transplant glomerulopathies. Minimal change disease (MCD) seen rarely. Few cases have been reported post-immunization, recently with the Pfizer-BioNTech vaccine against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report a case of *de novo* MCD after mRNA-1273 vaccine in a deceased donor KTR, with sudden onset nephrotic syndrome (NS) and acute kidney injury (AKI) a week after the first dose.

Case Description: 45-yo woman with history of ESKD from lupus nephritis, underwent DDKT on 09/2019 from a 20-yo Caucasian male, kidney donor profile index 16%, calculated panel reactive antibody 0%. Complicated by delayed graft function. On day 27 post-transplantation serum creatinine (Scr) improved to 0.8 mg/dl. Maintenance immunosuppression tacrolimus and mycophenolic acid. 11 months post-KT contracted COVID-19 pneumonia, managed conservatively. 6 months later developed anasarca 4 days post-mRNA-1273 vaccine. Initial Scr 2.10 mg/dl, urine analysis 4 + protein / 2 RBCs, urine protein to creatinine ratio (UPCR) 9.6 g/g, albumin 2.1 g/dl consistent with NS. SARS-CoV-2 PCR negative. Positive IgG antibody, titer 3.87 s/co (0-0.99), tacrolimus 4.7 ng/ml. Normal C3/C4 levels, anti-DNA antibody 5 IU/m. Allograft biopsy showed mild tubulitis and interstitial nephritis on light microscopy (LM), immunofluorescence negative for C4d, electron microscopy with moderate foot process effacement and no electron dense deposits, suspicious for MCD. Prednisone 1mg/kg/day was started. 4 weeks later UPCR 1.12 g/g, Scr 0.8 mg/dl and albumin 3.3 g/dl.

Discussion: This is a seropositive SARS-CoV-2 KTR from previous COVID-19 pneumonia who developed NS and AKI following the mRNA-1273 vaccine. Biopsy consisted with MCD. Immunogenicity to mRNA vaccines in transplant recipients is blunted after the first dose but higher in seropositive patients. Timing from vaccine exposure to development of MCD ranges from days to months, our patient mounted an immune response in 4 days. The acute tubular injury seen in LM is atypical, unclear if this is a cell mediated process from allograft rejection or part of the pathogenesis post-immunization. In cases of AKI with NS, days to weeks following either class of mRNA vaccine a prompt initiation of steroids and further investigation with kidney biopsy is warranted.

PO1487

COVID-19-Associated Collapsing Focal Segmental Glomerulosclerosis During Pregnancy in a Woman with Lupus Nephritis

Ramchandani Santosh, Syed Aown, Sharon E. Maynard. *Lehigh Valley Health Network, Allentown, PA.*

Introduction: Lupus nephritis (LN) is a common clinical entity in patients with systemic lupus erythematosus (SLE). LN is classified on the basis of renal biopsy findings. We present a woman with a history of LN who was diagnosed with COVID and AKI during pregnancy. Kidney biopsy showed collapsing FSGS and class V LN with APOL1 gene mutation.

Case Description: A 32-year-old G4P0212 African American female presented to a multidisciplinary Nephrology Maternal-Fetal Medicine program at 12 weeks gestation for management of LN in pregnancy. She was diagnosed with SLE at age 8, previously treated with rituximab and belimumab for rash, and other extrarenal manifestations. Three years prior, she was diagnosed with LN Class 3 + Class V treated with MMF with partial remission. She was switched from MMF to azathioprine at pregnancy diagnosis. She was diagnosed with COVID 4 days prior to the telemedicine office visit with GI symptoms and fever and admitted to the hospital. Her creatinine was 3.9 mg/dl, increased from the prior baseline of 1.3 mg/dl. Urinalysis showed proteinuria, and 24-hour urine collection contained 13.6 grams of protein. Her renal function continued to worsen despite intravenous fluid administration. Laboratory results included anti-Ds DNA titer 1:80, C3 61 mg/dl (90-180 mg/dL), and C4 34 mg/dl (10 -40 mg/dL). Kidney biopsy revealed class V LN and FSGS potentially related to COVID. As per biopsy finding and ethnicity, we sent APOL1 genetic analysis which came back positive. Treatment was started with IV steroids. The creatinine peaked at 4.7 mg/dl on hospital day 8 and subsequently improved. She did not require RRT and was continued on her maintenance IS. Unfortunately, she had fetal demise at 18 weeks 3 days of gestation with stable renal function.

Discussion: This is a case of COVID-associated FSGS in a pregnant woman with a history of LN. The initial impression included prerenal azotemia, LN flare, and COVID-associated kidney injury. Serologies were consistent with an LN flare, but renal biopsy showed both class 5 LN and FSGS potentially related to COVD. Kidney biopsy should be considered in pregnant patients with hematuria, proteinuria, to rule out alternative etiologies, even when LN is suspected on clinical grounds. The threshold of RRT is very narrow in pregnancy and requires increasing dialysis frequency for adequate pregnancy outcomes.

PO1488

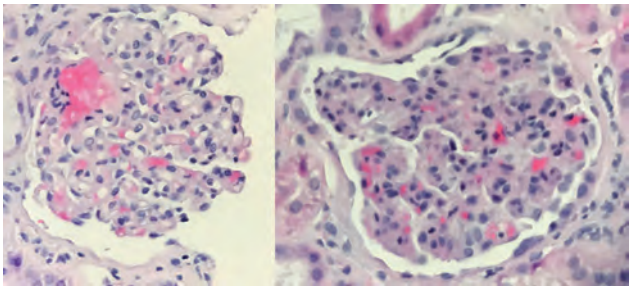
Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis (SAPHO) Syndrome and IgA Nephropathy

Jake N. Cho,[1,2] Grant Oakley,[1,2] Gary DiPerna,[1] Michael C. Akom.[1] *[1]Maine Medical Center, Portland, ME; [2]Tufts University School of Medicine, Boston, MA.*

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common form of glomerulonephritis (GN). It is characterized by IgA-dominant or codominant immune deposits within glomeruli, classically caused by poorly galactosylated immunoglobulin A1 that trigger autoantibodies. Other forms of IgA nephropathy include IgA vasculitis with nephritis (Henoch-Schönlein purpura) and secondary forms arising from chronic liver disease, chronic infections and neoplasms.

Case Description: Patient is a 50 year old female with anemia, hypothyroidism and chronic joint pain who presented for rising creatinine and hematuria. Baseline creatinine was 0.9 mg/dL but increased to 1.8 mg/dL within 2 months. She follows with a rheumatologist for polyarthralgias and hives where labs showed rheumatoid factor of 18 IU/mL, CRP elevated to 125 mg/L, sedimentation rate of 81 mm/hr but normal complement levels and negative ANA titers. Workup for lymphoma or myelodysplasia was negative and she was eventually diagnosed with SAPHO syndrome. Her urinalysis showed active sediment with mixed WBC/RBC casts, dysmorphic RBCs and nephrotic range protein to creatinine ratio of 7.4 g/g Concerning for a rapidly progressive GN, she was admitted to nephrology for expedited biopsy.

Discussion: Labs were negative for pauci-immune GN, phospholipase A2 receptor antibody, hepatitis panel and blood cultures. Kidney biopsy showed a membranoproliferative pattern of injury with IgA dominant GN and diffuse endocapilllary proliferation. This case may represent a rare association between SAPHO and IgA nephropathy which has only been reported in a few case reports. For the proteinuria, she was started on lisinopril and for the IgA, she was given pulse dose steroids and maintenance prednisone. Her creatinine has stabilized to 1.4 mg/dL and urine protein to creatinine ratio has also improved.



Kidney biopsy for IgA case depicting membranoproliferative pattern of glomerular injury in patient with SAPHO syndrome

PO1489

Crescentic Pauci-Immune Glomerulonephritis in a Patient with Sickle Cell Anemia and Cocaine Abuse

Marimar Contreras Nieves. *Stanford Medicine, Stanford, CA.*

Introduction: Levamisole is an anthelminthic agent and a common contaminant found in cocaine. It has been linked to ANCA-associated vasculitis with cutaneous, and more rarely, renal and pulmonary manifestations. This is the case of a patient with sickle cell anemia and cocaine abuse presenting with acute kidney injury (AKI) and nephrotic-range proteinuria, initially attributed to sickle cell nephropathy, but with kidney biopsy revealing pauci-immune glomerulonephritis, demonstrating the importance of having a high level of suspicion in patients with known cocaine use.

Case Description: A 58-year-old male with history of sickle cell anemia, CKD Stage 3, hypertension, and cocaine abuse, was admitted for epididymitis and found to have AKI. He presented with testicular pain, as well as right knee and back pain. Initial work up revealed a creatinine of 2.45 mg/dL, from baseline of 1.8 mg/dL. Urine toxicology was positive for cocaine. His urine studies were consistent with intrinsic renal disease. He received red blood cell exchange transfusion, but he continued with worsening renal function following the procedure. His 24-hr urine collection revealed 6.2 g proteinuria. Extensive workup included normal C3 and C4, positive rheumatoid factor, negative UPEP, free kappa/lambda light chain ratio 1.8, negative HIV and anti-HCV, hepatitis B immunity, negative c-ANCA, but positive p-ANCA and anti-MPO. Patient chronically smoked cocaine, sometimes cut with levamisole, which is associated with vasculitis. A kidney biopsy was performed, with pathology showing a pauci-immune necrotizing and crescentic glomerulonephritis, transmural arteritis, and sickle cell nephropathy. He was treated with pulse dose steroids and rituximab, followed by maintenance prednisone and additional doses of rituximab after discharge. His renal function improved, but did not return to baseline, which could have been due to his degree of kidney injury and ongoing cocaine use after discharge.

Discussion: This case demonstrates the importance of keeping a broad differential diagnosis in the evaluation of AKI and nephrotic-range proteinuria in sickle cell anemia, particularly in the setting of cocaine use and its known association with levamisole. Although sickle cell nephropathy could have explained this patient's presentation, a broader workup was key to arrive to the correct diagnosis, and therefore prompt treatment.

PO1490

A Case of Rapid Progressive Glomerulonephritis Associated with Disseminated Gonococcal Infection

Safa Osman, Nihal M. Ali, Pradeep Vaitla, Franco H. Cabeza Rivera. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Disseminated gonococcal infection (DGI) results from bacteremic spread of the sexually transmitted pathogen, Neisseria gonorrhoeae. Direct and immunological damage of multiple organs can be seen. We are reporting a case of sterile DGI with RPGN as part of the initial presentation.

Case Description: A 60-years old male with a 5-year history of seronegative spondyloarthropathy, hypertension, heart failure, poor dentition who presented to the hospital with shortness of breathing, diarrhea, joint pain, and palpable purpura ongoing for several weeks. Work-up revealed severe anemia and rapidly progressive acute renal failure (Baseline creatinine unknown, peaked at 7.2 mg/dl on admission), urine showed 9.3 g of proteinuria, hematuria, and pyuria. Serological w/up showed low C3 with normal C4, ASO, ANA, ANCA and anti GBM. Negative HIV, hepatitis B, C, syphilis serologies, monoclonals and cryoglobulins. Skin biopsy showed leukocytoclastic vasculitis which improved with steroids. Kidney biopsy showed crescentic glomerulonephritis (GN) with 10% IFTA likely due to infectious GN (RPGN). Patient completed 3-day course of solumedrol but left before cyclophosphamide could be initiated. A week later he presented with persistent hematuria and oliguria. Echocardiogram showed tricuspid endocarditis and leaflet perforation. Blood cultures were negative. Patient started on vancomycin and Rocephin for culture negative endocarditis. Extensive infectious disease workup, metagenomics test showed Neisseria gonorrhea as the cause of endocarditis. Kidney function improved. Due to disseminated GC and concern for complement deficiency, he was referred to Adult Immunology clinic.

Discussion: DGI is estimated to occur in up to 3 percent of patients infected with N. gonorrhoeae. The probability that a localized gonococcal infection will spread to joints and other tissues depends upon specific host, microbial, and possibly immune factors. RPGN is unusual presentation, the immunopathogenesis is uncertain but immunological and hypersensitivity damage is postulated based on the frequent lack of N. gonorrhoeae growth from blood, skin, and synovial fluid cultures during disseminated infection. Congenital or acquired complement deficiencies (C5, C6, C7, or C8) predispose to DGI as a result of decreased complement-mediated killing of N. gonorrhoeae.

PO1491

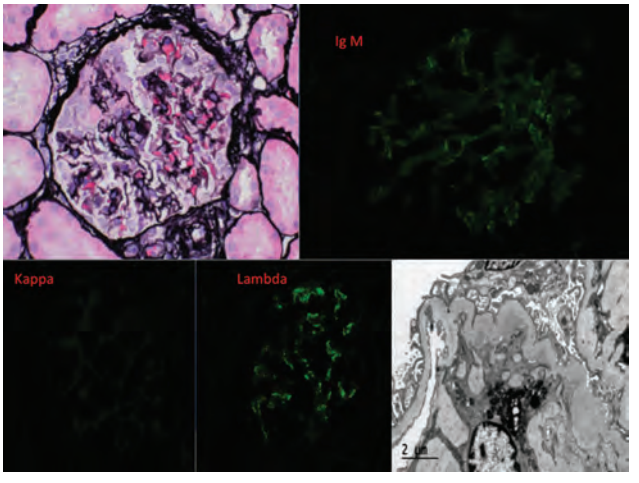
Proliferative Glomerulonephritis with Monoclonal IgM Deposits in ANCA Vasculitis

Rama Kethineni, Marc Barry, Monica P. Revelo Penafiel, Janame J. Kottey, Niraj K. Yadav, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobin deposition (PGNMID) is a rare entity of unclear etiology that can be occasionally associated with an underlying hematological malignancy. We report a case of PGNMID in a patient with ANCA vasculitis.

Case Description: A 78 yr old female with hypertension presented with a history of recurrent sinusitis over 6 months that was treated with steroids and antibiotics. She had progressive weight loss, fatigue, cough, and dyspnea. Chest X-ray was normal prompting a CT chest, which showed bilateral pulmonary nodules. Her creatinine was 0.96mg/dL. Urine analysis was notable for hematuria. Antineutrophil cytoplasmic antibodies were positive at 1: 640 with myeloperoxidase Abs IgG of 199. Serum protein electrophoresis showed a normal pattern with no monoclonal spike on immunofixation electrophoresis. Her Kappa/Lambda light chain ratio was normal at 1.04, infections were ruled out, and cryoglobulin was not detected. She was started on prednisone 60 mg and had a renal biopsy. Renal biopsy showed focal segmental necrotizing glomerular lesions, mesangial hypercellularity with deposition of IgM with lambda light chains restriction on immunofluorescence and occasional mesangial and subendothelial granular electron densities on electron microscopy. She was referred to hematology for concern with monoclonal gammopathy of renal significance and had a negative evaluation on serological tests, bone marrow biopsy and PET CT scan. She was treated with Rituximab. Her creatinine had remained stable with resolution of hematuria and respiratory symptoms.

Discussion: PGNMID is an immune complex glomerulonephritis that is occasionally associated with a hematological malignancy. The pathophysiology remains elusive and treatment can be challenging. We present a case of PGNMID with monoclonal IgM with light lambda chain restriction with an unusual association with ANCA vasculitis.



PO1492

A Case of ANCA-Associated Vasculitis (AAV) in Mixed Connective Tissue Disease (MCTD) Manifesting as Pulmonary Renal Syndrome

Samira Z. Chandra, Michelle W. Krause. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Newly diagnosed microscopic polyangiitis (MPA) with positive anti-MPO in the background of MCTD is quite uncommon. Not every patient with positive Anti-MPO titers develops clinical manifestations of microscopic polyangiitis. Prompt diagnosis and early intervention is necessary to prevent end organ damage.

Case Description: 56-year-old malnourished AAF with history of MCTD (diffuse systemic sclerosis and SLE since 2005), restrictive lung disease, recurrent URI, CKD stage 3, diastolic heart failure with moderate MR, and pulmonary hypertension was transferred to ICU for worsening pneumonia and acute on chronic kidney injury. Admission serum creatinine was 2.6mg/dl (baseline s. creat 2.0mg/dl) which increased to 4.7 mg/dl during the hospital course. Lab was significant for Hgb 6.3 gm/dl, ESR 120 mm and CRP 30. Non-contrast CT chest showed bilateral interstitial opacities with superimposed consolidation. Evaluation for infectious etiologies and malignancies were negative. Bronchoscopy was concerning for diffuse alveolar hemorrhage. UA was positive for large blood with proteinuria >200mg/dl. Vasculitis work up came back positive for p- ANCA (1:1280) and anti-MPO 4 AU/ml (reference range <19) but negative for anti-PR3 and anti-GBM antibody. Renal biopsy revealed focal crescentic and necrotizing glomerulonephritis with

severe interstitial fibrosis and tubular atrophy indicating MPA. Patient was treated with pulse steroid and plasma pheresis initially, later received Rituximab. Patient improved clinically with therapy. Later, serum creatinine plateaued around 3.6 with eGFR 15.6 indicating patient's CKD had progressed to advanced CKD stage 4/ 5.

Discussion: Though the presence of AAV is not common in MCTD, this case illustrates the importance of considering AAV for worsening pulmonary and renal function in overlap syndrome. Microscopic polyangiitis is one of the most common cause of pulmonary- renal syndrome, often manifested as diffuse alveolar hemorrhage and RPGN. Prompt diagnosis and early intervention can dramatically improve the patient outcome.

PO1493

Nephrotic Range Proteinuria due to ANCA-Associated Vasculitis in a Diffuse Systemic Sclerosis Patient: A Rare Presentation

Pranav Sharma, Steve I. Khalil, Jonathan Lebowitz. *Rutgers University New Brunswick, New Brunswick, NJ.*

Introduction: Scleroderma renal crisis (SRC) is a severe complication of SSc and typically presents with new-onset hypertension and a reduction in renal functioning. Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a rare co-occurrence with SSc. We present a rare case of diffuse systemic sclerosis who presented with features of SRC and AAV with nephrotic range proteinuria without significant renal failure.

Case Description: The patient is a 32-year old woman with diffuse systemic sclerosis complicated by pulmonary fibrosis who had been treated with Mycophenolate mofetil but she discontinued treatment in order to conceive. She reports having an uncomplicated pregnancy without proteinuria or hypertension, but she delivered 7 weeks early. After delivery, she began experiencing weakness of her lower extremities and given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil. She had improved but few weeks later (3 months after delivery), she was readmitted with hypertensive encephalopathy in setting of suspected scleroderma renal crisis. She also developed a rash and swelling in her legs after her pregnancy. Her urinalysis was remarkable for proteinuria and numerous RBCs and quantification of the urine protein revealed nephrotic range proteinuria (4.6 g/24 hours) but her serum creatinine (0.6 mg/dl) remained normal. She was found to be positive for antinuclear antibodies, rheumatoid factor, myeloperoxidase antibodies, MPO-ANCA (> 8.0 IU/mL). Her complement levels were within normal limits. She underwent a renal biopsy, which revealed an acute necrotizing vasculitis consistent with AAV.

Discussion: Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

PO1494

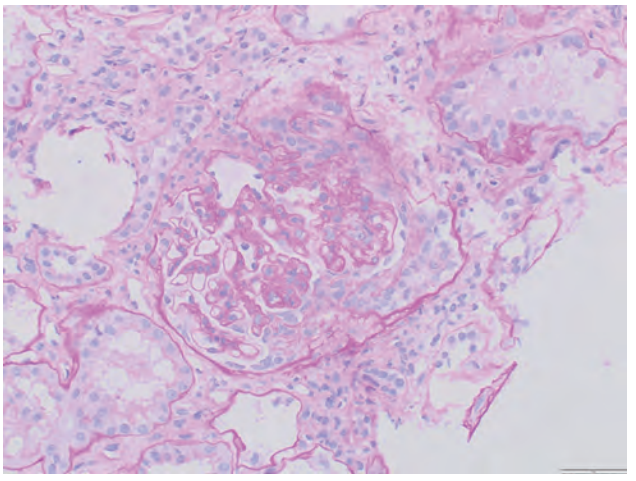
Filgrastim-Induced ANCA-Associated Glomerulonephritis in the Presence of Membranous "Full House Nephropathy"

Avital Angel-Korman,[1] Adi Leiba.[1,2] *[1]Assuta Ashdod Hospital, Ashdod, Israel; [2]Harvard Medical School, Boston, MA.*

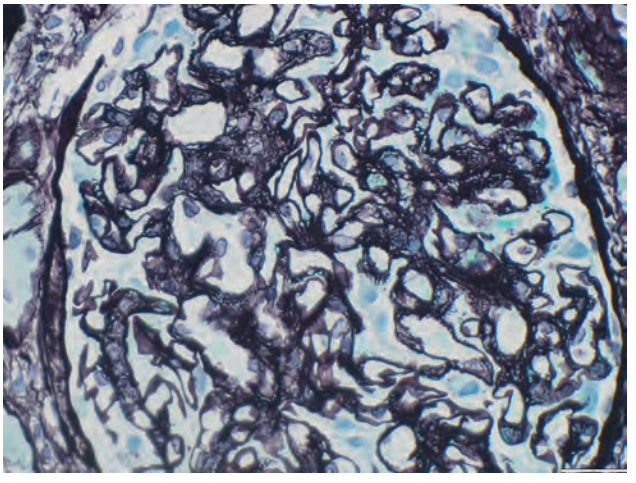
Introduction: G-CSF is commonly used to stimulate progenitor cell collection for bone marrow transplantation . We present a seemingly healthy altruistic bone marrow donor who developed glomerulonephritis secondary to G-CSF treatment.

Case Description: A 34-year old man presented after altruistic bone marrow donation. During G-CSF treatment he developed headache, epistaxis, painless macrohematuria and AKI (creatinine- 2.91mg/dL). Seven years and one year prior to this event he had similar presentations of macrohematuria, AKI and proteinuria . In between episodes he had persistent microhematuria . At this admission, Myeloperoxidase antibodies (MPO) were found to be elevated to 97 IU/ml. all other serologies were unremarkable. A kidney biopsy revealed glomeruli with cellular crescents (Figure 1). Capillary loop "spikes" were seen on silver staining (Figure 2). On immunofluorescence, there was a "full house" granular pattern. PLA2R and IgG4 stains were negative. Electron Microscopy revealed mainly subepithelial electron dense deposits. His current creatinine, without immunosupression, is 1.19 mg/dL.

Discussion: G-CSF induced ANCA associated glomerulonephritis developed on top of silent membranous "full house nephropathy ". Bone marrow donors should be asked about prior glomerulopathies and screened for proteinuria and hematuria before bone marrow donation is authorized.



A glomerulus showing a cellular crescent (PAS stain x100)



By silver stain, spikes are identified (Silver stain x400)

PO1495

Ivermectin-Induced ANCA Vasculitis

Shuchi Pandey,[1] Hemant Magoo,[1] Ashish Verma,[1] Sudhir Perincheri.[2] *[1]Saint Vincent Hospital, Worcester, MA; [2]Yale-New Haven Hospital, New Haven, CT.*

Introduction: Ivermectin is an antiparasitic agent that has demonstrated antiviral potential against HIV1, Dengue, Zika viruses and most recently, COVID-19. But the rampant self-medication and off-label use for COVID prophylaxis in some countries is cause for concern. Here, we present what may be the first reported case of ANCA-associated vasculitis(AAV)from Ivermectin use.

Case Description: A 56-year male with no significant past medical history presented with dark urine, epistaxis, conjunctival redness, arthralgias, and malaise. His mother was on dialysis for the past few years for ESRD of unknown etiology. For several months, he had been taking Ivermectin imported from Peru for COVID prophylaxis per family advice. He was on no other medications. His creatinine, normal at baseline, was now 4.5mg/dL. He had hematuria, 3g/d proteinuria, dysmorphic RBCs and RBC casts. Serum C3, C4, ANA, anti-dsDNA, anti-GBM, hepatitisB&C screen, SPEP&UPEP were negative. Atypical and p-ANCA were negative, but c-ANCA was 1:640. Kidney biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis. He soon developed pulmonary hemorrhages. Ivermectin was discontinued. He received prednisone 1mg/kg, 3 biweekly doses of intravenous cyclophosphamide, 10 doses of plasmapheresis, and was initiated on dialysis. Four weeks later, he has no epistaxis or pulmonary hemorrhages and is off oxygen. He does remain dialysis-dependent.

Discussion: Drug exposure can trigger ANCA formation against myeloperoxidase(MPO) and, less commonly, proteinase 3(PR3). Drug-associated AAV can't be discerned from primary AAV based on clinical and pathological findings. Clues suggesting drug-associated AAV include a temporal relationship of symptom onset with suspected drug, a high ANCA titer, and positive autoantibodies like elastase and lactoferrin. Drug-associated AAV has a better prognosis than its primary counterpart, with symptoms often resolving with drug withdrawal. Though this may not suffice in cases with pulmonary and renal involvement, outcomes in drug-associated AAV remain comparable even with shorter induction and often no maintenance regimens. Commonly implicated drugs are hydralazine, levamisole-contaminated cocaine, propylthiouracil, allopurinol.

Although no case of Ivermectin-induced AAV has been reported, we recommend a high index of suspicion as prompt cessation of the offending drug can significantly improve prognosis in drug-associated AAV.

PO1496

Myeloperoxidase-ANCA and Takayasu Arteritis Overlap Syndrome Presenting as Rapidly Progressive Glomerulonephritis

Salvador L. Gil, Juan P. Rivas de Noriega, Gibber A. Oxlaj, Sebastian E. Toledo, Brian R. Garibay Vega, Virgilia Soto. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Introduction: The spectrum of vasculitides is classified according to the size of the vessels involved and the clinical and histopathological findings. The simultaneous involvement of Takayasu arteritis and myeloperoxidase-ANCA vasculitis is extremely rare

Case Description: A 12-year-old female with no previous medical history. In the last three years the patient developed lower limb claudication and unexplained intermittent fever. In recent weeks she developed edema and oliguria, she was admitted in another hospital where she was started on renal replacement therapy. Large vessel involvement was suspected so a contrast enhanced CT was ordered and was compatible with Takayasu arteritis. The patient was referred to our hospital for evaluation. During nephrology assessment she was found to have acute kidney disease with massive proteinuria (16 g/g), so work up was directed towards rapidly progressive kidney disease. Percutaneous kidney biopsy was performed, and it revealed pauci-immune crescentic glomerulonephritis. ANCA and glomerular basement membrane antibodies were ordered, with a positive MPO-ANCA result. She was then started on IV methylprednisolone pulses and 5 cycles of plasma exchange therapy. After this, rituximab was started on a weekly basis. The patient has not recovered kidney function and is still dependent on hemodialysis therapy, pending to finish the final two rituximab doses.

Discussion: This an extremely rare case which highlights the diagnostic and therapeutic difficulties in patients presenting with overlap clinical and serological features of different forms of systemic vasculitis.

Granulocyte Colony Stimulating Factor-Associated Vasculitis: Adding Fuel to the Fire

Nilam Patel, Ahmed Siddiqui, Pravir V. Baxi. *Rush University Medical Center, Chicago, IL.*

Introduction: Granulocyte colony-stimulating factor (G-CSF) is commonly used with chemotherapy to stimulate bone marrow production and prevent neutropenia. Although usually well tolerated, G-CSF can exacerbate underlying autoimmune diseases with the development or progression of glomerulonephritis (GN). We present a case of pauci-immune necrotizing GN that developed in a patient with rheumatoid arthritis (RA) after receiving G-CSF therapy.

Case Description: A 61 y/o man with ampullary adenocarcinoma and RA without prior renal involvement presented with AKI. One week prior to admission he had received his 5th cycle of FOLFOX and a first dose of G-CSF. His creatinine (Cr) was 4.8 mg/dL from a baseline of 0.9 mg/dl. His urinalysis was notable for hematuria and urine protein-creatinine ratio (UPC) of 5.2 g/g. Workup showed: +p-ANCA (1:320), +anti-histone Ab, + SSA and +ANA (1:1280 speckled pattern). A renal biopsy revealed necrotizing GN with necrosis or crescents in 75% of the glomeruli (Fig 1). There was no evidence of immune-deposits c/w pauci-immune GN. He received steroids and rituximab for induction. His Cr peaked at 6.0 mg/dl but improved down to 1.1 and UPC improved to 0.6 g/g after 3 months.

Discussion: G-CSF is used to prevent neutropenia and reduce infection risk by activating mature neutrophils and preventing neutrophil apoptosis. G-CSF can also have inflammatory effects including the release of proinflammatory cytokines and tissue infiltration by activated neutrophils with the potential of end-organ damage. In patients with a preexisting GN or an autoimmune disease (eg RA, SLE), G-CSF administration can exacerbate or even initiate a de-novo GN. Pauci-immune GN is a rare but well established complication of RA. In our case, the almost immediate temporal relationship between the development of the GN and the G-CSF administration supports G-CSF as etiologic. This case demonstrates the importance of considering the possible renal complications and need for close monitoring while giving G-CSF in patients with autoimmune diseases.

PO1498

Spontaneously Resolved Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits

Salma Shaikhouni, Alexandra M. Peirce, Andrea L. Oliverio, Laura H. Mariani. *University of Michigan, Ann Arbor, MI.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is thought to be a progressive disease, with early studies showing 38% of patients with persistent renal dysfunction and 22% progressing to ESKD within a 30 month follow up period. We present two cases of PGNMID who achieved spontaneous remission without directed therapy.

Case Description: Case 1: A 53 yo woman with hypertension and diabetes presented for evaluation of proteinuria with UPCR 3.86 g/g and normal creatinine. She was asymptomatic, but had an upper respiratory infection 1 month prior. Serologic evaluation for nephrotic range proteinuria was unrevealing. Renal biopsy showed PGNMID with IgG λ light chain deposits. Serum paraprotein was not detected. Bone marrow biopsy showed no concern for malignancy. UPCR decreased to 0.63 within 4 months with no treatment but an ACEi. Case 2: A 53 yo man with primary biliary cholangitis presented with edema and new hypertension. He was found to have AKI with SCr 1.83 mg/dL, UPCR of 12.9 g/g, and microscopic hematuria. While serum autoimmune markers were notable for mildly elevated anti-dsDNA (75 IU/mL), normal C3 and low C4 (8 mg/dL), renal biopsy revealed PGNMID with IgG λ light chain deposits. A low titer IgM κ was detected in the serum. The patient had diffuse lymphadenopathy on imaging, and two excisional biopsies showed reactive follicular hyperplasia. Bone marrow biopsy was normal. UPCR decreased to 1.23 g/g within 2.5 months of presentation and SCr down to 1.22 without any therapy.

Discussion: These unique cases demonstrate that PGNMID is likely a heterogeneous disease whose pathogenesis and natural history is poorly understood. We hypothesize that an infectious antigen or autoantigen may induce clonal proliferation of B-cells and the formation of transient monoclonal antibodies leading to complement activation and proliferative glomerulonephritis. When the stimulus is controlled, the associated immune response is regulated. Our patients did not require any immunomodulatory therapy, contrary to most recent case series. Recognition of the potential for spontaneous remission in PGNMID has important implications on treatment paradigms for this emerging diagnosis.

PO1499

PLAR2-Positive Membranous Nephropathy: A Renal Manifestation of Scleromyxedema

Alexander Hlepas, Casey N. Gashti, Roger A. Rodby. Rush Nephrology *Rush University Medical Center, Chicago, IL.*

Introduction: Scleromyxedema (SMX) is a rare primary cutaneous mucinosis that usually occurs in association with a monoclonal gammopathy. Systemic manifestations may involve the musculoskeletal, cardiovascular, gastrointestinal, pulmonary, nervous and renal systems and may lead to significant morbidity and mortality. Renal manifestation has been reported, but histopathologic description of renal involvement has been vague and histopathologic classification has not been implemented. Therapeutic management of the renal disease has included plasmapheresis and cyclophosphamide, but the roles of each of these is not determined.

Case Description: We report a case of a 53-year-old male with SMX and monoclonal gammopathy who developed renal manifestation of sclerodermoid disease. His skin manifestations of SMX had been previously controlled with intravenous immunoglobulins (IVIG) until he developed presumed central nervous system involvement manifestating as an isolated seizure. He failed a series of treatments including lenalidomide, melphalan, and bortezomib. He subsequently underwent an autologous stem cell transplant with initial improvement in cutaneous manifestations for 6 months but experienced a relapse thereafter. In addition, he developed acute kidney injury associated with minimal proteinuria (<1000 mg). A kidney biopsy demonstrated thrombotic microangiopathy (TMA) and tissue phospholipase A2 receptor antibody (PLAR2) positive membranous nephropathy. Ravulizumab was instituted but had to be abandoned as the patient was hospitalized on two occasions with fever and culture negative pulmonary infiltrates after each infusion. Alternatively, he was treated with intravenous cyclophosphamide, oral prednisone and plasmapheresis with improvement in skin disease and stabilization of proteinuria and renal function.

Discussion: Renal manifestations of SMX are poorly defined and treatment is unknown. Membranous nephropathy has been rarely reported in SMX, but PLA2R status has not been available. Most cases focus on treatment of the underlying monoclonal

gammopathy but outcomes with conventional therapy remain poor. We report a patient with SMX who developed TMA and PLA2R positive membranous nephropathy who failed clone directed therapy but was successfully treated with IV Cytoxan (an accepted option for PLA2R+ MGN), steroids and plasmapheresis.

PO1500

Pemphigus Vulgaris and PLA2R-Associated Membranous Nephropathy: Two IgG4-Related Diseases in the Same Patient

Camila L. Costa,[1] Matheus R. Correia,[2] Luis H. Sette,[3] Denise M. Costa,[3] Camila B. Oliveira,[3] Maria Alina G. Cavalcante,[3] Lucila Maria Valente,[3] Gisele Vajgel.[3] *[1]Hospital dos Servidores do Estado de Pernambuco, Recife, Brazil; [2]Hospital Getulio Vargas, Recife, Brazil; [3]Universidade Federal de Pernambuco, Recife, Brazil.*

Introduction: The relationship between bullous skin diseases and glomerulopathies has been increasingly recognised. Other bullous diseases were previously reported in association with membranous nephropathy (MN), but the association between MN and pemphigus vulgaris (PV) has not been reported in the literature yet.

Case Description: A 39-years-old smoker woman presented with trunk blisters and worsened mouth ulcers after stopping the treatment for MN. One year before she had nephrotic syndrome and the kidney biopsy was positive for anti-PLA2R and IgG4 (and negative for THSD7A) in the immunohistochemistry (IHQ). Serum anti-PLA2R was negative. Four months earlier she was started on cyclosporine, but stopped it due to mouth ulcers. She had nephrotic range proteinuria, no edema, when the painful blisters spread out on the trunk, back, limbs, scalp as well as ulcers in the oral cavity and oesophagus. The diagnosis of PV was confirmed by skin and oesophagus biopsy and IHQ showed the presence of IgG4 subclass antibody in the epithelial tissue. She received pulse and oral steroids along with azathioprine for the PV. The skin lesions were slowly healing and no more new blisters have appeared.

Discussion: The humoral auto-immune response in pemphigus produces anti-desmoglein 1 and 3, both IgG4. Desmogleins are responsible for adhesion in stratified squamous epithelia, when damaged produces to the blistering eruptions. There is a genetic predisposition between PV and MN, with HLA-DQA1, HLA-DRB1 and the thrombospondin gene (*THSD7A*). Environmental factors such as smoking and air pollution could act as a second trigger for the development of auto-immune diseases. PLA2R can be expressed in the bronchiolar tissue and in macrophages of the lung, however there is no evidence of histological damage in the pulmonary tissue. Although we found no description on the expression of PLA2R in the skin, in an attempt to find a common antigen for both diseases, we did search for anti-PLA2R in the skin, but it was negative. In conclusion, this is the first described case of association of pemphigus vulgaris and PLA2R-associated MN, both IgG4-related conditions that involve the production of different autoantibodies directed to skin and kidney antigens.

PO1501

A Case of an Elderly Woman with Membranous-Like Glomerulopathy with Masked Monoclonal IgG Deposits Whose Renal Biopsy Revealed Renal Cell Carcinoma

Sho Nishikawa, Naoki Takahashi, Sayu Morita, Kazuhisa Nishimori, Sayumi Sakashita, Sachiko Fukushima, Kenji Kasuno, Masayuki Iwano. *Fukui Daigaku Igakubu, Yoshida-gun, Japan.*

Introduction: Membranous-like glomerulopathy with masked monoclonal IgG deposits (MGMID) is a recently described form of glomerulopathy with a unique histopathology reported by Larsen et.al. The pattern is characterized by subepithelial and/or mesangial immune deposits that are “masked”, to immunoglobulin staining by routine immunofluorescence but strongly stained for IgG and kappa light chain after protease digestion. Patients with MGMID are commonly young females and have a vague history of autoimmune diseases such as low titer antinuclear antibodies.

Case Description: A 65-year-old woman was referred to our hospital with urinary protein (0.80 g/gCr) and microscopic hematuria. Serum antinuclear antibody, rheumatoid factor, and M-protein were negative and serum C3 and C4 were normal. Plain CT showed no neoplastic lesions in the kidney, and a renal biopsy was performed. Part of kidney biopsy tissue contained clear cell renal carcinoma (RCC). Light microscopy revealed increased mesangial matrix and partial thickening and double contour of the basement membrane. Immunofluorescence examination of the frozen sections was negative for IgG and C3. Electron microscopy revealed electron dense deposits in both the subepithelium and mesangium (Churg classification stage II). After proteinase digestion, paraffin-embedded sections were stained again, and IgG and kappa light chain were strongly positive in granular pattern along the basement membrane (IgG subclass: IgG1>IgG4). Staining for anti-PLA2r/THSD7A antibody was negative, and staining for anti-serum amyloid P antibody was positive. Based on the above, this patient was diagnosed as MGMID. Subsequently, she underwent a partial nephrectomy for RCC, and her urinary protein decreased significantly.

Discussion: Although most patients with MGMID are young women (<40 years), this patient was an elderly woman with RCC. IgA nephropathy and membranous nephropathy have been reported as glomerular lesions associated with RCC. In this case, the proteinuria decreased after RCC resection, suggesting that RCC may be related to the development of MGMID in elderly patients, although the details are unknown. This is the first case of MGMID in Japan.

PO1502

Granulomatous Interstitial Nephritis: A Rare Cause of AKI

Karla G. Carias Martinez,[1] Nityasree Srialluri,[1] Gabriel A. Giannini,[2] Jose M. Monroy-Trujillo.[3] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University Department of Pathology, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD.*

Introduction: Granulomatous interstitial nephritis is a rare finding identified in < 1 % of native kidney biopsies. The most frequent etiology is drug related followed by systemic granulomatous conditions.

Case Description: 54-year-old African American male with diabetes, obesity, CKD stage 3 with a baseline Creatinine of 1.4 mg/dL and history of remote sarcoidosis was admitted with epididymo-orchitis treated with multiple antibiotic regimens including beta lactams; complicated with MRSA bacteremia and AKI with a creatinine peak of 3 mg/dL. Laboratory studies showed: Normal complement levels, serum calcium of 8.4 mg/dL with normal ACE level and urinalysis with no protein 9 WBC/HPF and 10 RBC/HPF. CXR showed prominent bilatral hila and patchy infiltrates. Renal Biopsy was done and revealed granulomatous interstitial nephritis, focal glomerulonephritis (GN) consistent with infectious related GN with focal acute tubular injury and atrophy with interstitial fibrosis. Image 1 shows giant cells on PAS. Patient was started on prednisone 40 mg daily for 2 weeks and subsequent taper. Was referred to the sarcoidosis clinic due to his remote history and found to have multisystemic granulomatous disease affecting the pulmonary, hepatic and ymphatic systems.

Discussion: Granulomatous interstitial nephritis (GIN) is an uncommon histologic diagnosis. It is known to be associated with antibiotic use and granulomatous disorders like sarcoidosis. The incidence of renal sarcoidosis ranges from 7-17 % manifesting as GIN or with renal damage due to altered calcium homeostasis. Corticosteroids are considered the mainstay of therapy.

PO1503

Monoclonal Gammopathy in a Patient with Lupus Nephritis: A Case Report

Waseem Albasha, Ankita Ashoka, Erika R. Bracamonte, Bijin Thajudeen. *Banner University Medical Center Tuscon, Tucson, AZ.*

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) has known associations with many disorders, including inflammatory and connective tissue disorders. Systemic lupus erythematosus (SLE) is not traditionally considered to have an association with MGUS. However, a few studies and case reports have emerged that have suggested an association between MGUS and SLE. We describe herein a case of a patient who was newly diagnosed with lupus nephritis but also was found to MGUS.

Case Description: A 53-year-old gentleman with a history of hypertension presented to the hospital with blurry vision and bilateral lower extremity rash. He was found to have acute kidney injury (creatinine 1.67 mg/dl), microscopic hematuria (21-50 RBCs/HPF), proteinuria (24 hour urine protein 1,148 mg/day), and low complements (C3 50 mg/dl, C4 7 mg/dl, and CH50 13 U/ml). Kidney biopsy confirmed focal proliferative glomerulonephritis with full-house immunofluorescence staining and three cellular crescents, consistent with class III lupus nephritis. Interestingly his ANA and double-stranded DNA serologies were negative. Serum immunofixation was positive for an IgM lambda type monoclonal gammopathy. Bone marrow biopsy showed 2.1% plasma cells. Hematology/oncology was consulted and diagnosed him with MGUS. Incidentally, he was found to have type I cryoglobulinemia as well, with cryoglobulin immunofixation positive for IgM kappa type. The patient was given high-dose steroids, transitioned to prednisone, and started on mycophenolate mofetil. A t two months of treatment creatinine was 1.1 mg/d, proteinuria improved to 300 mg/gm creatinine.

Discussion: The pathophysiologic mechanism that has been suggested for the development of MGUS in patients with lupus is dysregulation in B cell populations and immunoglobulin production. Lupus is known to produce hyperactivity in B cells and a

polyclonal increase in gamma globulins. It is likely that in some patients with lupus, B cell regulation becomes impaired in a way that allows a clonal, but not necessarily neoplastic, an expansion that results in increased production of paraproteins, leading to MGUS. This case adds to the literature showing that there indeed may be an association between MGUS and lupus.

PO1504

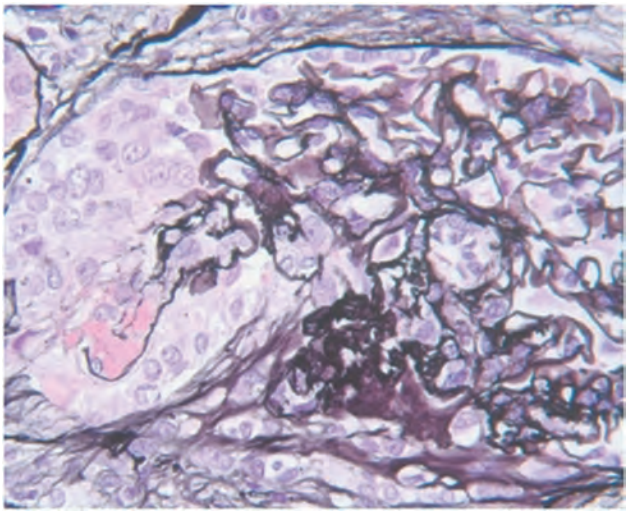
Bartonella Henselae Infective Endocarditis (BHIE): A Rare Cause of Pauci-Immune Necrotizing GN (PINGN)

Muhammad A. Shahzad, Ami Purohit, Stephen M. Korbet. *Rush University Medical Center, Chicago, IL.*

Introduction: Bartonella is the commonest cause of culture negative endocarditis. While, Infection Related GN (IRGN) can mimic pauci-immune vasculitis, the majority of cases of BHIE have been immune complex (IC) mediated. We present a rare case of BHIE related PINGN. Timely recognition of this atypical presentation led to appropriate medical therapy.

Case Description: A 33 yo M with HIV on HAART and recent tooth extraction was admitted with a severe headache due to a sub arachnoid hemorrhage from a ruptured right anterior cerebral artery mycotic aneurysm. TEE showed a vegetation on the aortic valve (AV). Blood cultures were negative. Initial SCr was 3.3 mg/dl and urinalysis had 2+ protein, 3+ blood with 29 RBC/hpf and a UPro/Cr ratio was 1.7 g/g. The C4 was low (10.2 mg/dL) and PR3-ANCA elevated-4.0 (NL <3.5 U/mL). The Bartonella henselae IgG titer was elevated-1:2,560 (NL <1:320). Renal biopsy revealed pauci-immune necrotizing GN (Figure) with no evidence of IC deposition. BHIE associated PINGN was diagnosed and treatment with doxycycline, ceftriaxone and gentamicin initiated. The AV was replaced and was positive for BH by PCR. After a prolonged course of antibiotics the SCr improved to 2.5 mg/dl.

Discussion: B henselae associated GN is a rare cause of PR3-ANCA positive GN with only 6 cases previously reported. By immunofluorescence, 4 cases were immune complex mediated with 2 cases having a pauci-immune necrotizing GN. We present only the 3rd case of B henselae associated PR3-ANCA and pauci immune necrotizing GN. The PR3-ANCA may be induced through B-cell activation after release of PR3 from neutrophils. Ruling out B henselae IE in cases of PINGN is critical in guiding management as this diagnosis leads to the initiation of antibiotics and avoids inappropriate treatment with immunosuppressive agents.



PO1505

Atypical Hemolytic Uremic Syndrome and Systemic Lupus Erythematosus-Dermatomyositis Overlap: A Challenging Scenario

Yelena R. Drexler, Juanly N. Rodriguez. *University of Miami School of Medicine, Miami, FL.*

Introduction: Overlap syndromes are rare disorders wherein at least two systemic autoimmune diseases meet diagnostic criteria. We present a case of atypical hemolytic uremic syndrome (aHUS) in a patient with systemic lupus erythematous (SLE) and anti-melanoma differentiation-associated gene 5 antibody (anti-MDA5) dermatomyositis (DM) overlap.

Case Description: A 45-year-old woman with SLE diagnosed 8mo prior, treated with belimumab and prednisone, developed proximal muscle weakness, violaceous erythema of eyelids, neck, hands and feet with ulcers. Three weeks later, she presented with abdominal pain, shock and respiratory failure. Testing showed WBC 19,200/uL, lipase >600 and ionized calcium 0.47 mmol/L; acute kidney injury (BUN 64 mg/dL, SCr 2.4 mg/dL); anemia (Hb 7.1 g/dL); and thrombocytopenia (PLT 24,000). CT showed pancreatitis and omental nodularity. Given oliguria and hypocalcemia despite high-dose calcium infusion, she initiated renal replacement therapy. Further workup showed low C3 level 42, C4 level 7, elevated anti-dsDNA Ab 237 IU/ml and UPCR 2.2 g/g; haptoglobin <10, LDH 1,371 U/L, Positive direct Coombs, schistocytes on smear and ADAMTS13 activity 18%. Due to autoimmune vs microangiopathic hemolytic anemia, received pulse methylprednisolone and IVIG without improvement. She then started eculizumab. Within 7d, LDH decreased to 772, haptoglobin increased to 79 and platelets normalized. Further workup revealed elevated creatine kinase 1,271 U/L, aldolase 17 U/L, AST 566 U/L with normal ALT and positive anti-MDA5 and transcription intermediary factor 1-gamma (TIF-1γ) Abs, meeting criteria for DM. Patient continued eculizumab and prednisone. Eventually developed invasive aspergillosis and expired.

Discussion: We report a case of SLE–DM overlap with anti-MDA5 and TIF-1γ Abs complicated by aHUS and severe hypocalcemia in the setting of pancreatitis. The cutaneous manifestations are typical of MDA5-associated DM. Our patient did not develop interstitial lung disease, exemplifying range of variation from case to case. The presence of anti-TIF-1γ confers a 6-fold increased malignancy risk; finding of omental nodularity in this case would warrant further investigation. aHUS as a complication of SLE-DM overlap is rare, with mortality risk up to 52%. AKI, infection and low C3 are associated with highest mortality. Prompt diagnosis, high clinical suspicion and early initiation of eculizumab resulted in a rapid response.

PO1506

Anti-LRP2 Nephropathy in a Patient with Chronic Lymphocytic Leukemia

Derek Tran,[1] Chien-Wen Yang,[2] Avantika Israni,[1] Abdallah Sassine Geara,[2] Al J. Lee.[1] *[1]St Mary Medical Center, Langhorne, PA; [2]Penn Medicine, Philadelphia, PA.*

Introduction: Anti-LRP2/anti-Brush Border nephropathy is a newly identified autoimmune tubulointerstitial nephritis triggered by circulating antibodies to low-density lipoprotein receptor-related lipoprotein 2 (LRP2). We present a case of anti-LRP2 nephropathy in a patient with chronic lymphocytic leukemia (CLL).

Case Description: A 74-year-old Caucasian male patient known to have CLL presented following a fall with a forearm laceration. At presentation, he had acute renal failure (sCr of 5.04 mg/dL) and severe thrombocytopenia (platelets of 11,000/u). Additional evaluation showed positive ANA and p-ANCA. The patient had proteinuria of 1754 mg/g of creatinine. The kidney biopsy showed moderate interstitial fibrosis and tubular atrophy involving 30-40% of the renal cortex. The tubular epithelium showed reactive-appearing nuclei as well as cytoplasmic thinning with loss of the proximal tubular brush border. Immunofluorescence showed IgG (3+) and C3 (3+) for the glomeruli capillary and the TBM. There was focal staining of the brush borders by IgG with positive LRP2 stain in the TBM. Electron microscopy revealed numerous subepithelial electron-dense deposits. The serum anti-LRP2 antibody titer was 1:100. The patient was started on dexamethasone and rituximab with improvement of the thrombocytopenia. Plasmapheresis was prescribed for 5 sessions, the creatinine continued to worsen (sCr of 7.73 mg/dL), and the anti-LRP2 titer did not improve. The patient is being transitioned to renal replacement therapy.

Discussion: The mechanism that links the ABBA disease with lymphoproliferative disease is still unknown. The current reported cases suggest an association between direct lymphoma renal infiltration, progression of the lymphoproliferative disease and the presence of the ABBA disease. However, in our reported case, the patient's underlying CLL was stable without evidence of renal infiltration. The poor response to treatment in this case is consistent with the poor outcomes of many anti-LRP2 reported cases. The renal biopsy on this patient also showed membranous glomerulonephritis. We presented a case with anti-LRP2 nephropathy/ABBA disease with concurrent CLL without evidence of kidney infiltration which responded poorly to immunosuppression therapy. The prognosis of ABBA associated paraneoplastic syndrome with underlying CLL warrants future investigation.

PO1507

Black Tar Heroin and AA Amyloidosis

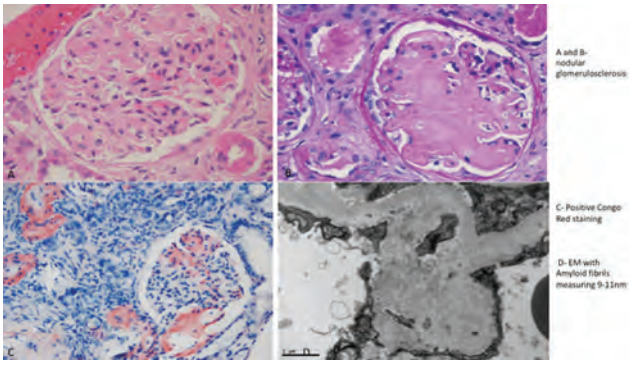
Rama Kethineni, Monique E. Cho, Monica P. Revelo Penafiel, Olesya Ilkun, Janame J. Kottey, Niraj K. Yadav, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: AA amyloidosis due to deposition of serum amyloid A protein occurs as a secondary reaction to chronic inflammatory disease, chronic infections, and familial period fever syndromes. We present a case of AA amyloidosis secondary to chronic black tar Heroin use in the Intermountain West.

Case Description: A 61 yr. old Caucasian female with a history of Hepatitis C, IV Heroin use presented with bilateral leg pain, swelling, and abdominal distension. Examination was significant for ulceration in lower extremities with purulent blisters. Notable lab data include Hemoglobin of 8.2 g/dl, potassium of 6 meq/L, calcium of 10.6 mg/dl, BUN of 90 mg/dl, creatinine of 2.9 mg/dl, serum albumin of 2.1 g/dl, and ESR of 129 mm/hour. She had a urine protein to creatinine ratio of 12.3 g/g. Abdominal US revealed enlarged liver and normal renal echogenicity. The quantification of HCV RNA by polymerase chain reaction was negative, and her complement levels were within normal range. Cryoglobulin was also negative with a kappa/lambda light chain ratio of 1.33. Serum protein electrophoresis showed decreased albumin and immunofixation electrophoresis showed a faint band in IgG kappa suggestive of a specific immune response or an early monoclonal protein. Renal biopsy showed non-AL amyloid deposition involving glomeruli, and arteries. Mass spectrometry performed at Mayo Clinic Laboratories confirmed renal involvement by Amyloidosis, AA (serum amyloid A)-type.

Discussion: "Black tar heroin" has increasingly been identified as a risk factor for AA Amyloidosis. Impurities in heroin promote vascular sclerosis and lead to the use of injection into muscle and skin. The suppurative infections that follow stimulate

the production of serum amyloid A protein with subsequent deposition in the kidney leading to nephrotic syndrome and end stage kidney disease. Greater awareness of this complication may help prevention in areas with increased black tar heroin use.



Renal biopsy

PO1508

Guselkumab-Associated Severe AKI from Collapsing Glomerulopathy

Varun Madireddy, Deepa A. Malieckal, Boonyanuth N. Maturostrakul, Philip S. Yune, Vanesa Bijol, Hitesh H. Shah. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Collapsing glomerulopathy (CG) has been commonly associated with viral infections, mainly HIV. Several medications have also been associated with CG. We present the first case of Guselkumab-associated rapidly progressive AKI from CG and acute tubular injury.

Case Description: 86-year-old African American female with history of HTN, RCC with left nephrectomy, CKD, CHF, and psoriasis (on Guselkemab treatment since 2018) presented to our hospital for worsening bilateral LE edema and AKI. On presentation, Scr was elevated at 3.75 and serum albumin was WNL (3.5). Three weeks prior to presentation, Scr was elevated but stable at 1.77 on outpatient labs. Of significance, pt. received Guselkemab injection one week prior to presentation. During hospital stay, UA was significant for proteinuria and hematuria. Spot urine total protein-to-creatinine ratio (TP/CR) was significantly elevated at 13.7. Of note, spot urine TP/CR was 1.6, four months prior to presentation. There was no right hydronephrosis or renal vein thrombosis seen on imaging. Serological tests including ANCAs, HBsAg, Hep C ab, HIV, RVP, COVID-19 PCR, Parvovirus B19 PCR, and CMV PCR were all negative. Patient initially received diuretic therapy for LE edema. Kidney biopsy performed during hospital stay showed CG and acute tubular injury. Electron microscopy examination of kidney biopsy specimen was significant for extensive effacement of podocyte foot processes and rare tubuloreticular inclusions in endothelial cell cytoplasm. Scr rapidly worsened to 7.98 and HD treatment was initiated. Our patient was also initiated on daily high dose oral corticosteroid therapy.

Discussion: Guselkumab, an IL-23 blocker is FDA approved for the treatment of plaque psoriasis and active psoriatic arthritis. A case of Ustekinumab (IL-23/IL-12 inhibitor) associated FSGS (after 2 years of treatment) has been reported in the literature. Our patient while on chronic Guselkumab treatment developed rapidly worsening AKI and CG, a week following the last dose of Guselkumab. We believe that in absence of any additional known risk factors, Guselkumab was responsible for AKI and CG in our patient. Our patient currently remains dialysis dependent. Clinicians should be aware of this very rare but potential association.

PO1509

Proteinuria and Hematuria, an Unfamiliar Side Effect of Statin Therapy

Marco B. Thierry,[1,2] Daniel Varela,[1,2] Mourad Alsabbagh,[2] Sergio A. Trevino Manllo,[2] Salil Mangi.[1] [1]*The University of Texas Rio Grande Valley, Edinburg, TX;* [2]*DHR Health, Edinburg, TX.*

Introduction: Statins are among the most commonly prescribed medications worldwide, and have a relatively mild side effect profile. We describe a rare manifestation of statin therapy, with proteinuria and microscopic hematuria.

Case Description: A 53-year old Hispanic lady with a history of proteinuria and hematuria for 1 year with negative Urologic workup was referred to nephrology for further evaluation. Patient complained of foamy urine. Her only medication was rosuvastatin 40 mg. Initial UA showed 2+ protein and 5-10 RBC/HPF. Lab work - BUN 16, creatinine 1.0 mg/dL, albumin 4.8 mg/dL, Urine Protein Creatinine Ratio 2.1 g/g creatinine. Serologies were negative and complement levels were normal. Patient was started on ARB and a low sodium diet for proteinuria. Proteinuria persisted and renal biopsy was recommended with suspicion of IgA nephropathy. Biopsy showed mild glomerular and tubular interstitial chronic injury likely secondary to arteriosclerosis. There was no immune complex deposition and no evidence of thin basement membrane disease. Genetic workup was negative for Alport's syndrome. Because of the rare association of Rosuvastatin with urinary abnormalities, we decided to hold patient's Rosuvastatin. Only three days later the patient reported that foamy urine had resolved. Repeat UPCR showed 99 mg protein/g creatinine. Hematuria also decreased to 0-2 RBC/HPF.

Discussion: Proteinuria is one of the lesser known side effects of statin therapy. It was initially found in the clinical development programme for Rosuvastatin, where it was found that the 80 mg dose caused proteinuria in 12% of patients. Furthermore, a comprehensive review of the renal effects of rosuvastatin, found that 1.2% of patients taking 40 mg of rosuvastatin developed 2+ proteinuria, and 0.3% developed 2+ proteinuria and 1+ hematuria. Our case highlights a rare manifestation of Rosuvastatin induced urinary abnormalities, which improve after stopping the drug. This should be kept in mind for patients on Rosuvastatin with negative workup for proteinuria and hematuria, before a renal biopsy is pursued.

PO1510

Rituximab for Membranous Nephropathy in a Patient with Sjögren Syndrome and Mixed-Connective Tissue Disease

Joshua D. Pollock, Maurice I. Khayat. *Madigan Army Medical Center, Tacoma, WA.*

Introduction: Membranous nephropathy (MN), a cause of nephrotic syndrome, is characterized by the deposition of immune complexes in the glomerular basement membrane with resultant subepithelial "spikes" visualized under light microscopy. Although often a primary disease process, several secondary etiologies exist, including Sjögren's syndrome (SS) and mixed-connective tissue disease (MCTD). Treatment typically targets the underlying condition. Despite rituximab's demonstrated efficacy in MN, MCTD and SS, case reports for specific treatment of MN secondary to these conditions have primarily described regimens of systemic corticosteroids with or without cyclophosphamide.

Case Description: A 54-year-old-male was diagnosed with MN on renal biopsy in 2001. Despite features suggestive of a secondary etiology (tubulo-reticular structures, mild cellular increase by light microscopy, mesangial deposits, and irregular distribution of deposits by EM), both his initial presentation and subsequent relapse in 2010 responded to antiproteinuric therapy alone. Following treatment-resistent relapse, cyclophosphamide and prednisone were initiated in 2019 without improvement. A secondary evaluation was significant for strongly positive anti-ribonucleoprotein and anti-SSA antibodies with negative serologies for systemic lupus erythematosus. The patient reported only mild polyarthralgia and sicca symptoms. Following rheumatology consultation and salivary gland biopsy the patient was diagnosed with MCTD and SS. Rituximab 1000 mg on day 0 and 14 was administered, with partial remission noted 4 months following therapy. Complete remission was achieved 8 months following therapy and has been sustained for 13 months. His extrarenal symptoms of MCTD and SS have also resolved.

Discussion: Rituximab is a well-described treatment for primary MN, MCTD and SS. However, there is a paucity of literature evaluating its use in MN as the specific renal manifestation of MCTD and SS. This case illustrates the potential role for rituximab as an effective treatment for membranous nephropathy secondary to SS and MCTD when deciding on immunomodulatory therapy. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.

PO1511

A Rare Case of Concurrent Glomerulonephritis and Autoimmunity

Janany J. Sabescumar, Rickinder Grewal, Hae Yoon Grace Choung. *University of Rochester, Rochester, NY.*

Introduction: We report a rare case of necrotizing and crescentic glomerulonephritis in the setting of Streptococcus mitis bacteremia.

Case Description: A sixty-one year old man with a history of hypertension, hyperlipidemia, and non-insulin-dependent diabetes presented to the emergency room with progressive lower extremity edema and dyspnea with tea-colored frothy urine. Initial workup revealed bilateral pulmonary edema and acute kidney injury with a serum creatinine of 1.84 mg/dL (0.8 mg/dL 6 months prior) with 9.18 grams proteinuria and an active urine sediment. He was initially diuresed for decompensated heart failure but further workup revealed hypocomplementemia and positive ANCA/proteinase-3 (PR3) antibody. A kidney biopsy revealed membranous glomerulonephritis (MGN) with focal endocapillary proliferative features and focal crescents with fibrinoid necrosis with positive PLA2R immunostaining and serum PLA2R IgG antibody testing revealing a titer of 1:2560. An echocardiogram revealed reduced left ventricular ejection fraction with a mobile aortic valve vegetation. Blood cultures obtained on admission ultimately grew Streptococcus mitis and he underwent aortic valve repair. Despite completion of a full antibiotic course, his creatinine remained impaired with nephrotic-range proteinuria and elevated serum PLA2R titers. Repeat renal biopsy revealed membranous glomerulonephritis and he was started on immunosuppression for treatment of PLA2R-associated MGN.

Discussion: Peri-infectious PLA2R-associated MGN and ANCA-associated glomerulonephritis appears to be a rare. While his proliferative ANCA-mediated glomerulonephritis was likely related to the infectious endocarditis, the relationship to the PLA2R-positive MGN remains unclear. We hypothesize that host immune response to infectious agents lead to an autoimmune process resulting in glomerulonephritis. It is possible that in addition to a genetic predisposition ("first hit"), a "second hit" which begins with activation of the innate immune response by an infectious agent leading to autoimmunity through various mechanisms including defective immune regulation, molecular mimicry, epitope spreading, and autoantigen complementarity.

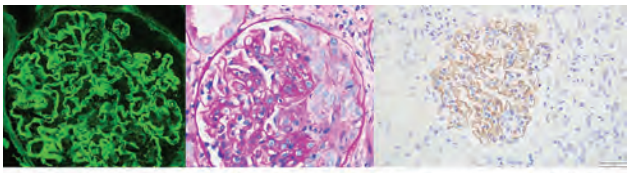


Figure (right to left) Immunofluorescence microscopy shows 3+ granular global glomerular capillary wall staining. Segmental cellular crescent (periodic acid-Schiff, original magnification x400), and Electron microscopy shows extensive stage I to 2 subepithelial electron dense deposits (original magnification x 10000)

PO1512

C2 Deficiency Associated with Severe Recurrent ANA-Negative Lupus and Microangiopathy

Maria Llanos, Daniel Marino, Sanjay K. Menon, Kotresha Neelakantappa, Michael Malekan. *NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.*

Introduction: Deficiencies in the classical complement pathway have been associated with the development of systemic lupus erythematosus (SLE) and lupus-like disease in 10-20% of affected patients. In fact, SLE patients deficient in classical complement present at an earlier age, with severe manifestations and a worse prognosis. Several mechanisms have been described to explain these immune phenomena including impaired clearance of immune complexes, impaired handling of apoptotic cells, or changes in regulation of cytokines. Here, we present a case of a young female with ANA-negative lupus presenting with dyspnea and acute renal failure responsive to immunosuppressive therapy found to have C2 Complement deficiency.

Case Description: 44 year old female with sickle cell trait, ANA-negative SLE, ESRD due to biopsy-proven class IV lupus nephritis briefly requiring HD, pulmonary HTN, presented with signs of fluid overload, acute on chronic renal failure in the setting of malignant hypertension. Labs revealed thrombocytopenia of 52 with a creatinine of 2.66 (prior 1.61), hypocomplementemia and undetectable CH50 levels concerning for acute flare of SLE and an underlying functional complement deficiency. Low haptoglobin and peripheral smear with schistocytes raised concerns for microangiopathy. Hospital course was complicated by encephalopathy and possible CNS involvement of lupus. Renal biopsy confirmed chronic sclerosing immune complex glomerulonephritis with minimal activity. The patient responded well to high dose corticosteroids, plasma exchange and mycophenolate mofetil. Final serology confirmed persistent C2 complement deficiency.

Discussion: There is a well-studied link between immune-complex mediated disease and complement deficiency. Of these, C2 deficiency is the most common. In our case, a C2 deficiency was found in the setting of ANA-negative SLE with severe clinical manifestations. Our case raises the question of whether testing to exclude underlying complement deficiency is particularly indicated in patients with ANA-negative SLE. It also remains to be seen whether clinical manifestations of microangiopathy are prevalent in these patients, and whether therapeutics targeting complement may be effective in their treatment.

PO1513

De Novo IgA Vasculitis Following Exposure to SARS-CoV-2 Immunization

Terrance Wickman,[1] Muner Mohamed,[1] Agnes B. Fogo,[2] Juan Carlos Q. Velez.[1,3] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]The University of Queensland, Saint Lucia, QLD, Australia.*

Introduction: Immunizations have been previously described as potential triggering events for the development of certain glomerular diseases. However, there is paucity of reports of occurrence of glomerular diseases developing after exposure to a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccine.

Case Description: A 50-yearl-old man presented to a nephrology clinic for evaluation of persistent proteinuria. Six weeks prior to evaluation, the patient had reported developing a new rash approximately 2 weeks after receiving the first dose of a SARS-CoV-2 vaccine (Pfizer®). The rash was treated by his primary care provider with topical and oral corticosteroids, leading to partial improvement of the skin lesions. Three weeks after the first vaccine injection, the patient received his scheduled second vaccine injection. Within 2 days, the rash reappeared. This time, the lesions were more severe in nature, with a violaceous papular rash involving his lower legs and with some areas progressing to blisters. He also reported myalgias and arthralgias. A skin biopsy was performed and revealed IgA-dominant leukocytoclastic vasculitis. After completion of 2 weeks of oral corticosteroids, a urinalysis revealed proteinuria and a consultation to nephrology was requested. On examination, healing papules were noted on his legs but otherwise exam was normal. Serum creatinine was 0.9 mg/dL. Microscopic examination of the urinary sediment revealed acanthocytes. A urine protein-to-creatinine ratio (UPCR) was 1.1 g/g. Serum complements were normal and all pertinent serology was negative. A kidney biopsy was performed and light and immunofluorescence microscopy findings showed an IgA nephropathy. UPCR decreased to 0.7 g/g and rash completely subsided.

Discussion: The clinical presentation and pathological findings in this case strongly suggest that SARS-CoV-2 vaccine (Pfizer®) can trigger a clinical syndrome compatible with Henoch-Schönlein purpura. The recurrence of the rash following re-exposure to the vaccine injection (second dose) argues for a definite causal association by Naranjo criteria.

PO1514

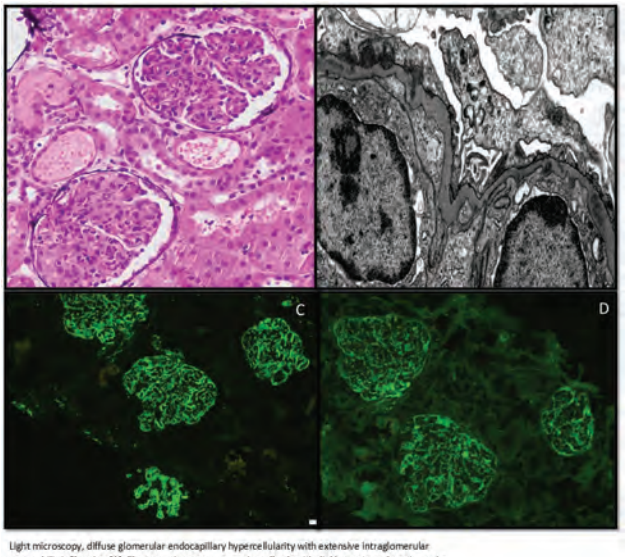
Postinfectious Glomerulonephritis Complicated by Complement-Positive Coombs Autoimmune Hemolytic Anemia

Elizabeth A. Armstrong, Christian Hanna, Mary E. Fidler, Cheryl L. Tran. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Postinfectious glomerulonephritis (PIGN) is the most common cause of GN in children. Mild normocytic anemia is often noted during the acute illness and is usually thought to be secondary to hemodilution from fluid overload and/or depressed erythrocytes production. Here, we describe a case of PIGN and autoimmune hemolytic anemia in a pediatric patient.

Case Description: A 3-year-old girl presented with 5 days of gross hematuria, fatigue, and decreased urination. Laboratory evaluation revealed elevated potassium at 5.4 mmol/L (normal range 3.6-5.2 mmol/L), creatinine 3.04 mg/dL (0.19-0.49 mg/dL), and blood urea nitrogen 98 mg/dL (7-20 mg/dL), low hemoglobin (Hb) 8.4 g/dL (11.4-14.3 g/dL) and normal platelet count. Urinalysis showed numerous red blood cells (RBCs) and nephrotic range proteinuria. Bilirubin, lactic dehydrogenase, and haptoglobin were normal. Direct antiglobulin test (DAT) was positive for monospecific C3, and negative for IgG. Peripheral blood smear revealed mild RBC polychromasia and occasional helmet cells. Several hours after admission, her Hb dropped acutely to 6.3 g/dL requiring blood transfusion. Complement proteins C3 and C4 were low at <6 mg/dL (75-175 mg/dL) and 5 mg/dL (14-40 mg/dL), respectively. DNase-B Antibody was normal and dsDNA antibody was negative. A kidney biopsy revealed findings consistent with PIGN **(Image 1).** She received acute hemodialysis for the first 48 hours after admission for worsening hyperkalemia, uremia, anuria, and edema. Her Hb remained stable and did not require additional blood transfusions.

Discussion: Our case of concurrent PIGN and autoimmune hemolytic anemia is exceptionally rare. This unique association may explain the anemia that is often seen in PIGN. We suggest that PIGN cases with anemia should have a DAT performed.



Light microscopy, diffuse glomerular endocapillary hypercellularity with extensive intraglomerular neutrophilic infiltration **(A).** Electron microscopy, several small subepithelial hump type deposits and a few intramembranous deposits **(B).** Immunofluorescence, C3-dominant coarse granular glomerular basement membrane and mesangial positivity **(C)** with accompanying significant staining for IgG **(D).**

PO1515

Hydralazine-Induced ANCA Vasculitis and Lupus Nephritis

Ankita Ashoka, Golnaz Vahdani, Waseem Albasha, Erika R. Bracamonte, Preethi Subramanian, Iyad S. Mansour, Amy Yau. *Banner University Medical Center Tuscon, Tucson, AZ.*

Introduction: Hydralazine is a common antihypertensive drug, but drug induced glomerulonephritis (DI-GN) is observed in 5-10% of the population on hydralazine after three years of therapy. We present a case of rapidly progressive glomerulonephritis due to hydralazine.

Case Description: 65-year-old female with a history of hypertension, diabetes mellitus, and chronic kidney disease presented for altered mental status. Her serum creatinine (SCr) three months and two years prior were 2.3 mg/dl and 0.9mg/dl respectively. On presentation, her SCr was 12.7 mg/dL, and she was started on hemodialysis. During her hospitalization, she had persistent hemoptysis with worsening dyspnea, skin rash, and oral ulcers (Fig 1, 2). Work up revealed hematuria, low complement levels, positive histone antibody and ANCA titers, and negative double stranded DNA antibody (Table 1). Skin biopsy showed small and medium vessel vasculitis. Kidney biopsy revealed class 3 and 5 lupus nephritis with full house immunofluorescence staining and active cellular crescents (Fig 3). Review of her medications included hydralazine 25 mg three times a day for three years, and she was diagnosed with hydralazine induced glomerulonephritis and systemic vasculitis. She was given pulse steroids and cyclophosphamide with improvement in extrarenal manifestations, but no renal recovery.

Discussion: Hydralazine has been known to cause DI-GN since the 1950s, and it can manifest with features of pauci-immune glomerulonephritis and lupus nephritis. Drug induced vasculitis has a high incidence of renal involvement compared to drug induced systemic lupus erythematosus, however both entities have multiple auto-antibodies and ANCA positivity. The use of hydralazine has increased over the years due to trials demonstrating mortality benefit in heart failure. There is no consensus on the treatment, but discontinuing the offending agent, early diagnosis, and immunosuppressant therapy may result in favorable prognosis.

Table 1

Complement 3	76 mg/dL (90-180)
Complement 4	17 mg/dL (16-47)
Antinuclear antibody immunofluorescence and titer	Positive, titer of 1:320
Anti-histone antibody immunofluorescence	Positive (8.9 U)
dsDNA Antibody	Negative
ANCA immunofluorescence	Positive
MPO	Positive
PR3	Negative
pANCA titer	1:640

PO1516

Chicken or the Egg Causality Dilemma: Primary ANCA Vasculitis Complicated by Infective Endocarditis (IE) vs. IE Leading to ANCA Vasculitis

Benjamin P. Catanese, Ayesha Anwaar, Shuchi Anand. *Stanford Health Care, Stanford, CA.*

Introduction: As the cases of infective endocarditis increase in the Unites States it is important to recognize the associated complications. Glomerulonephritis is a well-recognized but not fully understood consequence. Immune complex deposition is the most common etiology but ANCA-mediated kidney injury is increasingly described and even less understood.

Case Description: A 65 year old male presented with acute onset dysarthria, left facial droop, left sided weakness, and dizziness. 5 months prior he was diagnosed with PR3+ ANCA vasculitis after presenting with 18 lbs weight loss, purpura, anemia, hematuria and sub nephrotic proteinuria. He was treated with methotrexate and a steroid taper, which finished one week prior to the current presentation. Admission vitals were: 145/74 mmHg, heart rate of 90 bpm, afebrile, and 100% oxygen saturation on room air. Lab work revealed: hemoglobin of 10.7 K/uL, creatinine of 1.17 mg/dl (baseline 0.9), low C3: 81 mg/dL, positive PR3 (>8.0), positive c-ANCA (1:128), negative MPO and p-ANCA, and UA: 3+ blood, negative protein, and 11-20 WBC. MRIs of the brain and heart revealed numerous acute and subacute infarcts and severe mitral regurgitation respectively, concerning for small vessel vasculitis, and he was started on high dose steroids. Discovery of streptococcus mutans bacteremia was a surprise. Suspicion was raised that the ANCA vasculitis may have been a consequence of underlying sub-acute endocarditis rather than a primary disease hence a kidney biopsy was planned and he was discharged on steroids and IV antibiotics. Kidney biopsy confirmed the diagnosis of ANCA-mediated endocarditis-associated glomerulonephritis with the presence of glomerulosclerosis with fibrocellular/fibrous crescents, segmental fibrinoid necrosis but no obvious immune deposits on light microscopy. Granular deposits in the mesangial and capillary wall stained for C3, IgM, IgA, kappa and lambda. He underwent 6 weeks of ceftriaxone and mitral valve replacement. His renal function is mildly impaired; he is recovering neurologically.

Discussion: Endocarditis-associated GN typically requires treatment of the underlying infection without immunosuppression, but when the injury is primarily ANCA-mediated, this presents a unique challenge in that end-organ damage from vasculitis may not improve without immunosuppression.

PO1517

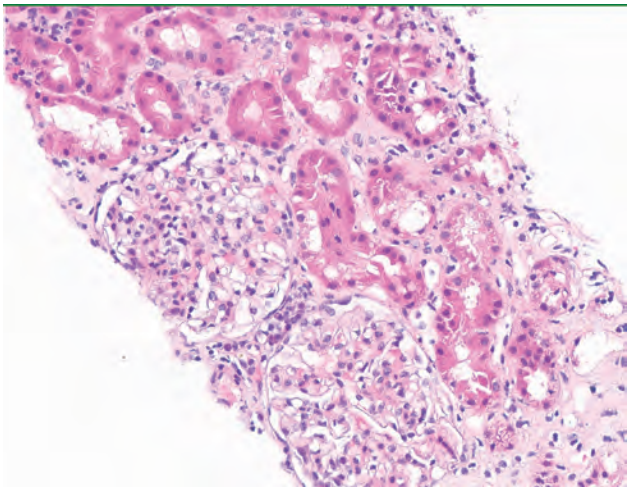
Crescentic Glomerulonephritis in Sjögren Syndrome

Jake N. Cho,[1,2] Danielle Jamison,[3] Grant Oakley,[1,2] Gary DiPerna.[1] *[1]Maine Medical Center, Portland, ME; [2]Tufts University School of Medicine, Boston, MA; [3]Maine Nephrology Associates PA, Portland, ME.*

Introduction: Sjogren's syndrome (SS) is an infiltrative autoimmune disorder involving the parotid, lacrimal and salivary glands causing sicca syndrome. Kidney involvement is variable and most often results in tubulointerstitial nephritis. Glomerular disease is infrequent with MPGN and membranous nephropathy being most prevalent pathologically.

Case Description: Patient is a 21 year old female with SS, hypothyroidism and asthma who was being evaluated for fever and fatigue. Lab evaluation revealed acute kidney injury (AKI) with creatinine rising from 1.0 to 1.8 mg/dL over several weeks. Echocardiogram was concerning for mobile echodensity at the tricuspid valve, but transesophageal echo showed no abnormalities and evaluation for infection was negative. CT showed extensive prominent lymph nodes in the chest, abdomen, and pelvis but lymph node biopsy showed benign reactive hyperplasia without neoplasm. Renal ultrasound showed normal sized kidneys. Urinalysis was positive for trace proteinuria and sediment revealed dysmorphic RBCs. She was started on high dose prednisone and hydroxychloroquine for possible lupus nephritis but due to diagnostic uncertainty and unresolved AKI, kidney biopsy was performed.

Discussion: Kidney biopsy demonstrated plasma rich interstitial nephritis with severe tubulitis consistent with SS. Interestingly, the biopsy showed 3 active cellular crescents out of 21 glomeruli with focal crescentic GN. Tubulointerstitial nephritis is the most common renal pathology in primary SS leading to renal tubular acidosis, impaired concentrating ability and proximal tubule defects. GN in SS is rare but has been associated with membranoproliferative GN, membranous nephropathy and cryoglobulinemic GN. Crescentic GN was unexpected and the treatment plan was adapted to taper the prednisone, start on Mycophenolate Mofetil and trial on Rituximab.



Light microscopy for renal biopsy of Sjogren's case depicting interstitial nephritis and crescentic glomeruli

PO1518

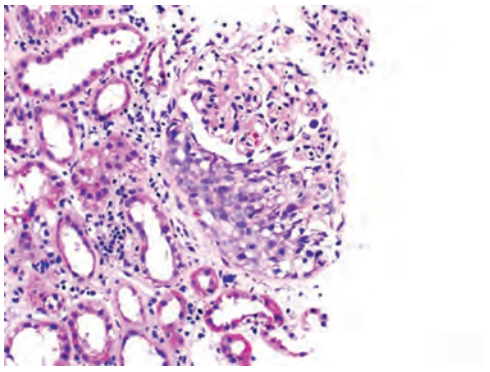
Crescentic Glomerulonephritis and Membranous Nephropathy: A Case Report of a Rare Overlap

Mohamedanwar M. Ghandour, Zeenat Y. Bhat. *Wayne State University, Detroit, MI.*

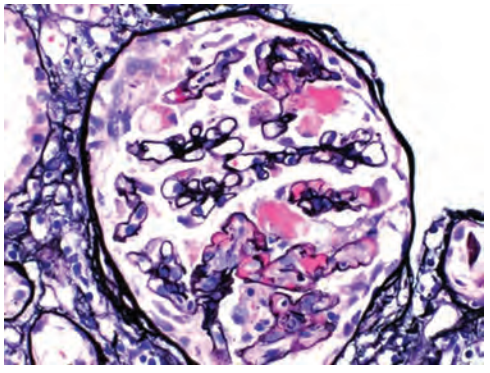
Introduction: Membranous nephropathy (MN) is a disease that affects the basement membrane of the glomeruli of the kidney resulting in proteinuria. The concurrent incidence of vasculitic glomerulonephritis and MN in the same patient is unusual. Herein, we report a case with this unusual combination.

Case Description: Our patient is a 53-year-old Hispanic male with a past medical history of tobacco use, type 2 diabetes mellitus, and hypertension who presented with hematuria and was found to have nephrotic range proteinuria and renal impairment. Blood workup revealed positive ANCA serology, which led to a renal biopsy that showed crescentic vasculitis in addition to membranous nephropathy. The patient was started on intermittent hemodialysis (HD) and treated initially with intravenous (IV) pulse steroids; subsequently, oral prednisolone and IV cyclophosphamide was initiated. The patient remained HD dependent at the time of discharge with the resolution of hematuria. A follow-up with an outpatient nephrology clinic was arranged.

Discussion: Membranous nephropathy complicated by crescentic glomerulonephritis has a more aggressive clinical course and decline in renal function compared to MN alone which can lead to initiating renal replacement therapy. However, immunosuppressive drugs can result in significant improvement of renal function if started early enough.



Light microscopy shows diffuse cellular crescent formation



Light microscopy shows a glomerulus with focal segmental fibrinoid necrosis

PO1519

Unmasking a Case of Membranous-Like Glomerulopathy with Masked IgG-κ Deposits

Alissa Ice, Darren W. Barefield. *Louisiana State University Health Sciences Center, Baton Rouge, LA.*

Introduction: Membranous-like glomerulopathy with masked IgG-κ deposits (MGMID) is a recently described, exceedingly uncommon entity of glomerular immune-complex deposition requiring antigen retrieval on formalin-fixed paraffin-embedded tissue. We report a rare case of MGMID in a young female with newly diagnosed APLA.

Case Description: An 18 year old female with no medical history presented with left leg swelling. Vital signs were normal and an enlarged, discolored left lower extremity was appreciated on exam. Initial laboratory results were remarkable for Cr 0.78 mg/dL, albumin 2.3 g/dL, platelets 128,000/μL, PTT 87.1 s, INR 1.02, and hematuria and proteinuria on UA. Imaging demonstrated an extensive acute DVT. Additional studies revealed positive APLA, unremarkable bone marrow and flow cytometry analyzes, and negative autoimmune panel. Hepatitis panel, ANCA, anti-PLA2R, serum free light chains, and serum and urine immunoelectrophoreses were normal. Furthermore, she was found to have 7.2 g of protein on 24 hour collection and biopsy results consistent with MGMID. She was discharged on a prednisone taper and losartan and later initiated on tacrolimus with stable renal function and improved proteinuria after six months.

Discussion: MGMID was first described in 2014 by Larsen et al found predominantly amongst young female patients with autoimmune phenomena with variable clinical progression regardless of the treatment. Similar to this case, subepithelial and mesangial deposits [A], predominant C3 on IF [B], SAP positivity [C], and IgG-κ deposits [D] appear to be characteristic [see figure]. Given these findings in the absence of the antigen-retrieval step, pathology misclassifcation as infection-associated glomerulonephrtis, membranous nephropathy, or C3 glomerulonehritis can significantly impact prognosis and treatment. Therefore, it is important to consider this additional step in pathology analysis in certain clinical presentations.

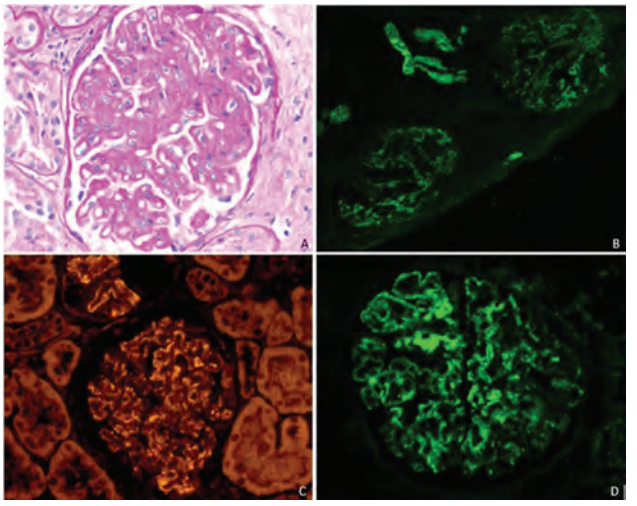


Figure 1: Pathology

PO1520

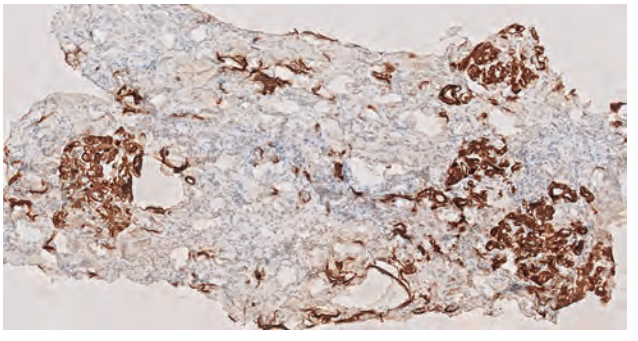
A Case of Secondary Renal Amyloidosis Associated with HIV

Dawn Maldonado, Ismail Omran, Carlos J. Gonzalez Gonzalez, Ayesha Mallick Imam, Arpita Joshi, Saeid Karandish, Majd Al Shaarani, Fadi E. Salem, Aaron S. Stern, Ishita Bansal, Maritza Brown. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Secondary amyloidosis is known to be associated with multiple chronic infections and inflammatory conditions including rheumatoid arthritis, inflammatory bowel disease, systemic lupus erythematosus, and tuberculosis. HIV has not yet been established as a known association. We present a case of secondary amyloidosis associated with well-controlled HIV with no history of other potential etiologies.

Case Description: A 71-year-old man with hypertension and well-controlled HIV for 40 years (viral load undetectable and last CD4 917) was referred to the renal clinic for acute kidney injury and heavy proteinuria. He had complained of leg swelling and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8. Serologic work-up was unrevealing; PLA2r, complements, hepatitis serologies, ANA, ANCA, A1C, SPEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

Discussion: Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.



Positive SAA staining

PO1521

Renal Cell Carcinoma Presenting as Henoch-Schönlein Purpura with AKI and Leukocytoclastic Vasculitis in Adults

Ashton N. Breithaupt, Neeharika Mettupalli, Stacy A. Johnson, Alice Chedid. *The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Introduction: Henoch-Schonlein purpura (HSP) is a small vessel vasculitis characterized by IgA tissue deposition. HSP presenting in adults is often the result of an underlying malignancy.

Case Description: A 60-year-old man with history of HTN, CVA, DMII, recent COVID-19 infection, presented for 2 week history of petechiae on bilateral upper and lower extremities. Skin biopsy findings were compatible with leukocytoclastic vasculitis (LCV). Patient on admission was also found to have AKI with creatinine 2.1 mg/dl, microscopic hematuria, and sub-nephrotic range proteinuria with urine protein/creatinine ratio of 2.66 g/g. Kidney biopsy findings were consistent with IgA dominant glomerulonephritis. Given multi-system involvement, patient was diagnosed with Henoch-Schonlein Purpura. Given unusual presentation with extreme of age, there was concern for malignancy. CT scan chest abdomen pelvis was performed which revealed a solid and septated 8.3 cm exophytic mass on the superior pole of left kidney. A partial left nephrectomy was performed with pathology report consistent with clear cell renal carcinoma. Patient's hematuria, proteinuria and skin rash resolved with surgical intervention. Creatinine remained stable in the 1.6-1.8 mg/dl range on discharge.

Discussion: Henoch-Schonlein purpura (HSP) is generally seen in the first decade of life. There have been a few cases of HSP presenting in adults due to underlying solid organ malignancies including renal cell carcinoma (RCC). Our case illustrates the importance of evaluating adults presenting with clinical findings of HSP for underlying malignancy. Treatment of underlying malignancy will improve vasculitis symptoms including renal parameters.

Exophytic and sepatated mass within superior pole of left kidney (Figure 1).

PO1522

A Case of Necrotizing Crescentic Glomerulonephritis due to ANCA Vasculitis and Fibrillary Glomerulonephritis

Munahal Nasim,[1] Faizan Babar.[2] *[1]Nishtar Medical College and Hospital, Multan, Pakistan; [2]Nephrology Associates Lexington, Lexington, KY.*

Introduction: Fibrillary Glomerulonephritis is a rare disorder thought to be idiopathic in nature. Cases of fibrillary GN have been assoicated with malignancy, monoclonal gammopathy, autoimmune disease, or infection. We present a unique case of fibrillary GN with pauc-immune cresentic GN due to Myeloperoxidase antibody (MPO) vasculitis.

Case Description: A 77 year old lady with history of well controlled diabetes, hypertension, congenital deafness, presented with weakness, fatigue & weight loss for four weeks. She was noted to have severe anemia with Hemoglobin of 6.6 g/dl, and presumed acute kidney injury. Her labs on admission were remarkable for creatinine 2.5mg/dl (unclear baseline creatinine), eGFR 25ml/min, potassium 5.3, Bicarbonate 16, Sodium 128. Urinalysis showed large blood and 1+ protein. The serological workup was positive for P ANCA 1:640, C ANCA 1:640, MPO ab and negative for PR-3 ANA, SPEP, Free light chain ratio, HIV, Hepatitis panel. Endocscopy and Colonoscopy was negative for any obvious bleeding. Patient underwent renal biopsy which showed 7 out of 15 glomeruli with early fibrocellular crescents with fibrinoid necrosis, along with healing phase of necrotiizing arteritis. Immunoflourescence didn't show any preferrential staning for immunoglobulin, kappa or labmda. Electron microscopy showed messangial mild non branching randomly arrayed thick fibrils with no immune complex type deposits. EM findings were confirmed by positive DNAJB9 stain. Patient received treatment with pulse dose steriods, two doses of rituximab 1 gm 14 days apart and continued on prednisone for slow taper with good renal response. Due to the findings of Fibrillary GN addition workup for lymphoproliferative disorder was done Whole body CT scan was negative but flow cytometry testing still pending.

Discussion: We present a unique case of fibrillary GN and pauci-immune crescentic GN with positive MPO antibodies. The significance of fibirillary deposits in this setting is unclear and usually not seen with pauci-immune crescentic GN. Fibrillary GN is a very rare diagnosis mostly thought to be idiopathic in nature. This unique presentation of fibrillary GN with ANCA vasculitis questions the current pathogensis fibrillary GN and overall renal prognosis in association with glomerular pathologies like ANCA vasclitis

PO1523

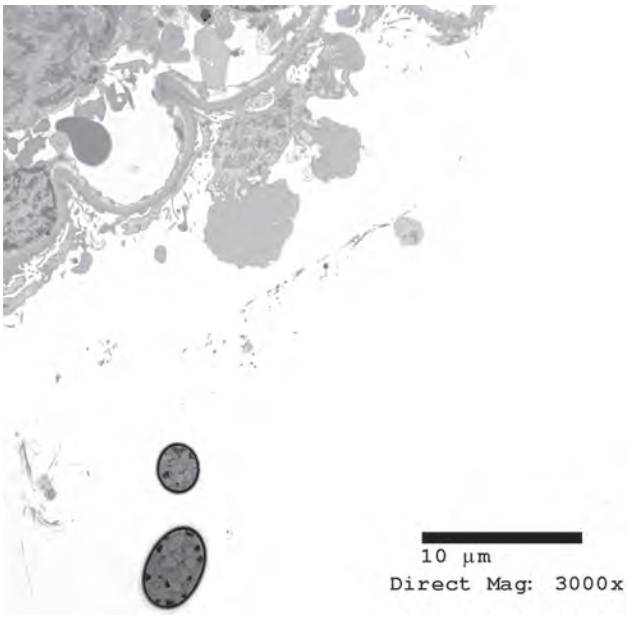
An Unexpected Clue in the Urinary Space: The Overlap Between IgA Predominant Staphylococcus aureus-Associated Glomerulonephritis and IgA Nephropathy: A Case Report

Luise J. Froessl,[1] Luan D. Truong,[2] Justin Merszei.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Houston Methodist Hospital, Houston, TX.*

Introduction: There is significant histological overlap between IgA nephropathy (IgANP) and IgA predominant Staphylococcus-aureus associated glomerulonephritis (IgASAAGN). [1] [1] Satoskar et al., "Staphylococcus Infection-Associated Glomerulonephritis Mimicking IgA Nephropathy," November 2006.

Case Description: Kidney biopsy was performed in a 60 yo male for an unexpected decline in kidney function. IgASAAGN was diagnosed on histology and foreign particles that were consistent with staphylococci were noted in the urinary space on electron microscopy. The patient was found to have methicillin-sensitive staphylococcus aureus (MSSA) pneumonia. Two months later, after a second decline in kidney function, IgANP was diagnosed on repeat kidney biopsy.

Discussion: This patient is diagnosed with two distinct conditions on pathology samples that show very similar histological findings. The presence of SA in the urinary space is a previously unreported finding. SA infection is known as the initiating factor for the development of IgASAAGN. Recent studies have also suggested SA cell envelope antigens as a new candidate for the induction of IgANP and antigens have been colocalized with IgA deposits in the glomeruli of affected patients. [2] SA infection and IgA deposition seem to play an essential role in the pathogenesis of both conditions, and the consideration that they may be two extremes of a disease spectrum could be considered. If the role of SA in the development of IgA nephropathy is confirmed, it may be of interest to explore the role of anti-staphylococcal antibiotics in the treatment regimen of IgANP. [2] Koyama et al., "Staphylococcus Aureus Cell Envelope Antigen Is a New Candidate for the Induction of IgA Nephropathy."



Staphylococcus aureus in the urinary space

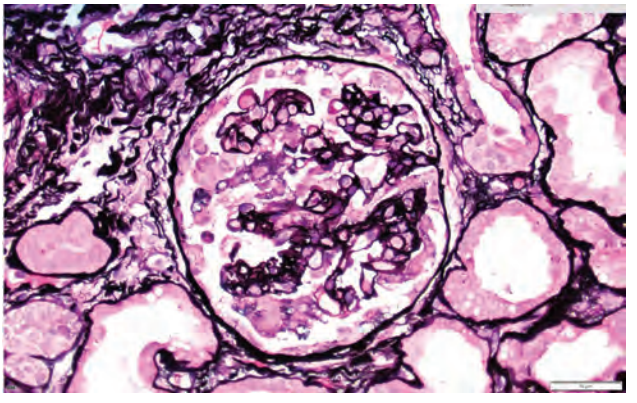
The Collapsing Variant of FSGS in a Patient with Hemophagocytic Lymphohistiocytosis due to an Aggressive T Cell Lymphoma

Manal Alotaibi, Akansha Agrawal, Carla L. Ellis. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Collapsing FSGS is a histologic renal lesion, most often seen in patients with HIV infection. We report a rare case of collapsing FSGS in a patient with HLH due to T-cell lymphoma

Case Description: A 50 years old lady with a PMH of SLE who was admitted to the hospital with fatigue. She was diagnosed with hepatosplenic T-cell lymphoma and HLH. She received multiple coures of chemotherapy with a good response. During the course of hospitalization, she developed oliguric AKI with rising serum creatinine to 2 mg/dl from baseline 0.8 mg/dl with nephrotic range proteinuria of 9g/24hrs. Immunological workup was significant for high ANA titer 1:1280 but with normal complements C3 and C4, and negative anti-double strand DNA, anti-smith, anticardiolipin IgG, anti-GBM, and ANCA antibodies. Infectious workup was negative for HIV, syphilis, and hepatitis B and C. Kidney ultrasound showed normal-sized kidneys without hydronephrosis. She then underwent a renal biopsy, which revealed the collapsing variant of FSGS, characterized by glomerular collapse with overlying podocyte hypertrophy. The biopsy additionally showed the absence of tubuloreticular inclusions or electron dense deposits by electron microscopy. Immunofluorescence showed largely negative/baseline staining. Her renal function was improved by the time of discharge with serum Cr 0.9 mg/dl and improving in proteinuria.

Discussion: Collapsing FSGS can be associated with a variety of causes. It was seen frequently in patients with HIV infection. Other etiologies include non-HIV infections (e.g., CMV, parvovirus B19), drugs (e.g., pamidronate, interferon), lupus nephritis, diabetes mellitus, and genetic factors. Collapsing FSGS has been described with HLH in a few reported cases, which are mostly related to lymphoma. The renal involvement is believed to be caused by T cell activation and cytokine storm resulting in podocyte injury.



Jones Silver Stain at 40 x magnification: A glomerulus shows collapse of the glomerular tuft with overlying podocyte hypertrophy and hyperplasia.

PO1525

Diagnostic Dilemma: Glomerular Linear IgG Deposit with Negative Anti-GBM Antibody

Sonali Gupta,[1] Meenakshi Sambharia,[1] Danniele G. Holanda,[1] Elyas Safar,[2] Y-Chen Huang.[1] *[1]The University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Blessing Hospital, Quincy, IL.*

Introduction: Linear deposition of IgG along glomerular basement membrane (GBM) is hallmark of anti GBM glomerulonephritis. Subclass IgG 3 deposition is seen predominantly in these cases. Rare atypical anti-GBM cases have been described in literature as rare, indolent, no pulmonary involvement and undetectable antibodies. We describe a case of atypical anti GBM, four days after mRNA COVID vaccine.

Case Description: A 77-year-old male with history of hypertension presented with hypertensive emergency and acute kidney injury 4 days after first COVID vaccine (mRNA). Workup revealed sCr 2.6 mg/dl (1.5 mg/dl 1 month back), 3+ blood and 3+ protein by UA, normal C3, C4, ANA 1: 160, spot urine protein: creatinine- 2.2, serum albumin- 4g/dl. anti ds-DNA, ANCA and anti-GBM antibody was negative so was Hepatitis panel andHIV. Serum electrophoresis was negative for monoclonal protein. He did not have any pulmonary symptoms and CXR was negative for acute pathology. Renal biopsy was performed. LM: mild to moderate nodular mesangial expansion, mildly increased mesangial cellularity and focal segmental nodular mesangial sclerosis. IF showed positive linear global capillary loop staining with IgG (2+), with kappa (1+) and lambda (2+) co-staining. Trace mesangial IgM and granular C3 (trace1+) are also noted in the peripheral capillary loops. EM showed diffuse foot process effacement. Few subepithelial, intramembranous and mesangial electron dense deposits were seen. Additional IgG subclasses IF showed positive linear glomerular staining for IgG1 (3+), IgG2 (1+), IgG4 (1+), negative for IgG3.

Discussion: Although no definitive active glomerular crescents or necrotizing lesions were seen, positive linear IgG staining in the glomerular capillary loops was concerning for atypical anti-GBM disease in setting of negative antibody and negative IgG3A study looking at 20 atypical anti-GBM patients found that 1 year patient and renal survival was 93% and 85% respectively. A few patients in this study had biopsy findings of DFPE and sub-epithelial deposits like ours. There have been few reports of COVID vaccine unmasking glomerulonephritis. However, it needs further investigation.

PO1526

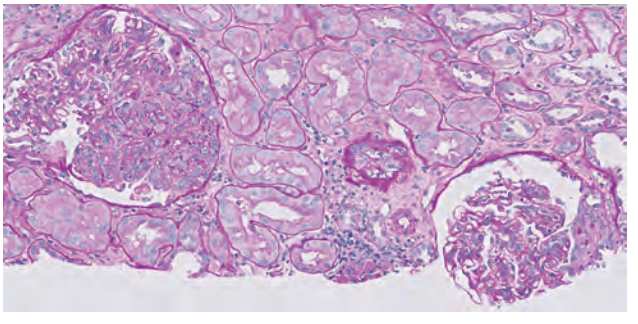
Rapidly Progressive Glomerulonephritis due to Crescentic IgA Nephropathy in the Setting of HIV

Fatima Cheema, Dawn Maldonado, Saeid Karandish, Carlos J. Gonzalez Gonzalez, Ismail Omran, Ayesha Mallick Imam, Temi-Ete I. Ediale, Majd Al Shaarani, Fadi E. Salem, Aaron S. Stern, Maritza Brown. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: In patients with HIV-related kidney diseases, the most widely recognized histological abnormality is focal segmental glomerulosclerosis (FSGS). Less commonly found is IgA nephropathy in HIV patients, which tends to have a chronic stable course. We report a case of crescentic IgA nephropathy and FSGS in a patient with rapidly progressive glomerulonephritis and newly diagnosed HIV.

Case Description: A 34-year-old transgender woman with a history of alcohol use disorder presented with a petechial rash and lower extremity edema for 1 week, and was found to have a new diagnosis of HIV with an elevated creatinine. CD4 count was 143 and viral load was 103,774, and she was started on renally-dosed dolutegravir, abacavir and emtricitabine. Creatinine on admission was 1.27 mg/dL (baseline 0.7), and increased over the next several days to 5.3. Urine microscopy revealed dysmorphic RBCs and granular casts, with spot urine protein:creatinine 2.3. Renal biopsy demonstrated crescentic IgA nephropathy (Oxford classification M1 E1 S1 T1 C2) with concomitant FSGS (NOS subtype). Cellular crescents were seen in 4/7 glomeruli (figure 1), mesangial and endocapillary hypercellularity in all non-sclerotic glomeruli, and FSGS in 2/7 glomeruli. Immunofluorescence showed strong granular segmental mesangial staining for IgA (3+) and C3 (3+), and was otherwise negative. She was started on pulse-dose steroids (methylprednisolone 500mg x 3 days followed by 1 mg/kg x 2 weeks), as well as plasmapheresis every other day for 5 sessions. Her renal function had not improved by the time of discharge.

Discussion: To our knowledge this is the first reported case of IgA-induced RPGN in the setting of newly diagnosed HIV. A few prior case reports describe stable IgA nephropathy in individuals with HIV, suggesting that there may be some unifying pathogenesis. This case highlights the need for investigation of this potential mechanism, which may help determine the optimal therapy for IgA nephropathy and IgA-induced RPGN in the setting of HIV.



PO1527

Features and Outcomes of Patients with C1q Nephropathy in the NEPTUNE and CureGN Cohorts: Comparisons to Minimal Change Disease and Focal Segmental Glomerulosclerosis

Scott E. Wenderfer,[1,2] Maria Larkina,[3] Mir Reza Bekheirnia,[1,2] Clarissa A. Cassol,[4] Carmen Avila-Casado,[5] Laura Barisoni,[6] William E. Smoyer,[7,8] Laura H. Mariani.[3] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX; [3]University of Michigan, Ann Arbor, MI; [4]Arkana Laboratories, Little Rock, AR; [5]University Health Network, Toronto, ON, Canada; [6]Duke University, Durham, NC; [7]Nationwide Children's Hospital, Columbus, OH; [8]The Ohio State University, Columbus, OH.*

Background: Predominant immunostaining for C1q distinguishes a subset of patients with primary glomerular disease. C1q nephropathy (C1qN) has been proposed but not universally accepted as a distinct glomerular disease. This study describes clinical characteristics and short-term outcomes of patients meeting the provisional CureGN definition of C1qN, including comparisons to patients with minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) without C1qN.

Methods: MCD and FSGS patients with C1qN were identified from the Cure Glomerulonephropathy Network (CureGN) and NEPTUNE cohorts. Comparisons were made to MCD and FSGS patients without C1qN, based on age, disease, and time since kidney biopsy, using 5-to-1 matching. We performed cross-sectional analyses of clinical and treatment data at enrollment and a longitudinal analysis of disease course.

Results: A total of 42 patients met the provisional CureGN definition for C1qN (16 adults >18yo, 11 teens 12-18yo, and 15 children <12yo), including 15 with MCD and 27 with FSGS. Those with C1qN were more commonly female (60 vs 49%, p=0.2) and black (34 vs 27%, p=0.4). At enrollment, those with and without C1qN had comparable kidney function (eGFR 90 vs 88 mL/min/1.73m^2, p=0.8). Individuals with C1qN were equally likely to have been treated with steroids or other immunosuppressive therapy (76 vs 81%, p=0.4) and to have ever achieved complete remission of proteinuria (defined as uPCR <0.3) (54 vs 65%, p=0.2). Median time to last follow-up was 3.1 yrs (IQR 1.9, 4.4) from enrollment and 4.8 yrs (IQR 3.3, 6.5) from biopsy date. While proportions with kidney failure were higher for FSGS compared to MCD (14 vs 1%, p=0.01), they were similar between patients with and without C1qN (7 vs 10%, p=0.6). There was a trend towards steeper GFR slope in C1qN patients (-4.8 vs -0.2 mL/min/yr, p=0.06).

Conclusions: FSGS and MCD patients with and without C1qN have comparable demographics and short-term outcomes in CureGN and NEPTUNE. Outcomes do not appear to be biased by differences in immunosuppressive therapies. Further interrogation of genetic and molecular profiles between patients with and without C1q immunostaining on biopsy may be more informative.

PO1528

Morphologic Descriptors Most Predictive of Clinical Outcomes in Minimal Change Disease and FSGS

Jarcy Zee,[1] Qian Liu,[4] Abigail R. Smith,[4] Laura H. Mariani,[2] Jeffrey B. Hodgin,[2] Brenda W. Gillespie,[2] Laura Barisoni,[3] Lawrence B. Holzman.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Michigan, Ann Arbor, MI; [3]Duke University, Durham, NC; [4]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Previous studies applying the NEPTUNE Digital Pathology Scoring System (NDPSS) uncovered the value of kidney tissue features for clinically relevant patient subcategorization. This study aims to identify histologic and ultrastructural descriptors most predictive of clinical outcomes in NEPTUNE patients.

Methods: 39 glomerular, 9 tubulointerstitial, 2 vascular, and 20 ultrastructural descriptors were quantified using the NDPSS on 39 MCD, 61 MCD-like, and 124 FSGS NEPTUNE digital kidney biopsies. Outcomes included time from biopsy to disease progression (kidney failure or ≥ 40% eGFR decline with eGFR <90) and first complete remission (CR) of proteinuria (UPCR <0.3). Relative importance of descriptors for prediction of outcomes was obtained from random forest models, without adjusting for clinical features.

Results: The mean age, eGFR and UPCR at biopsy for the total 224 participants was 28.8, 85.2, and 5.4, respectively. Model performance was excellent (predictive discrimination= 0.902 for disease progression and 0.853 for CR). Most predictive descriptors included conventional (e.g., global sclerosis or segmental sclerosis, and interstitial fibrosis/tubular atrophy) and unconventional features [Fig]. Top 10 predictors included inflammation, podocyte abnormalities, and acute tubular injury for both outcomes; deflation, interstitial foam cells, and collapse for disease progression; and endothelial cell abnormalities, hyalinosis, and periglomerular fibrosis for CR.

Conclusions: Most predictive descriptors of proteinuric glomerulopathies reflected structural changes in various renal compartments. Reporting these descriptors should be standardized to guide the subcategorization of proteinuric glomerular diseases and improve targeted clinical care.

Natural History of Focal Segmental Glomerulosclerosis (FSGS): The UK National RaDaR Idiopathic Nephrotic Syndrome Cohort

Moin Saleem,[1,2] Jonathan Barratt,[3,4] Fiona E. Braddon,[5,12] Kevin Carroll,[11] Ulysses A. Diva,[8] Maryam Afzal,[1,2] Bruce M. Hendry,[8] Alex Mercer,[10] David Pitcher,[5,12] Retha D. Steenkamp,[5,12] A. Neil Turner,[9] Daniel P. Gale.[6,7] *[1]University of Bristol, Bristol, United Kingdom; [2]Bristol Royal Hospital for Children, Bristol, United Kingdom; [3]University of Leicester, Leicester, United Kingdom; [4]Leicester General Hospital, Leicester, United Kingdom; [5]UK Renal Registry, Bristol, United Kingdom; [6]Royal Free Hospital, London, United Kingdom; [7]University College London, London, United Kingdom; [8]Travere Therapeutics Inc, San Diego, CA; [9]University of Edinburgh, Edinburgh, United Kingdom; [10]JAMCO Pharma Consulting, Stockholm, Sweden; [11]KLC Statistics Ltd, Cheshire, United Kingdom; [12]The Renal Association, Bristol, United Kingdom.*

Background: Idiopathic FSGS is an important cause of proteinuric renal disease leading to ESKD. Here we describe the natural history of FSGS using the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RaDaR-INS) Cohort, including retrospective and prospective data from 3907 patients with nephrotic syndrome (NS) not attributable to glomerulonephritis or systemic disorders recruited from 107 adult and paediatric kidney units across the UK since 2010.

Methods: Participants included those with biopsy-proven or monogenic FSGS and ≥12 mo. observation from baseline. Patients with ESKD (CKD stage 5 or on renal replacement therapy) at or prior to baseline were excluded. Baseline date was defined as first database occurrence of renal biopsy, primary renal diagnosis, NS symptoms, PCR ≥1 g/g, or initiation of immunosuppression. Renal survival was defined as absence of ESKD or death with survival time calculated from baseline to last follow-up.

Results: Of 786 FSGS patients meeting eligibility, median baseline age was 28 yrs (IQR 9-49) with paediatric patients representing 38% of the study population. Median proteinuria at baseline was 5.9 g/g (IQR 3.3-11.0; n=140), while mean eGFR was 163 mL/min/1.73m^2 (SD 47; n=69) and 71 mL/min/1.73m^2 (SD 32; n=103) for children and adults, respectively. Median follow-up duration was 9.7 yrs (IQR 5.7-16.1) with ESKD/death events occurring in 46% of patients (1% death). Kaplan-Meier survival curves of children and adults show 50% renal survival probability of 16 years & 12 years, respectively (Figure 1).

Conclusions: The RaDaR-INS Cohort represents a large study population with lengthy follow-up data. These analyses indicate rapid progression and poor outcomes, highlighting a need for effective treatments for patients with FSGS.

PO1530

Proteinuria End Points and Associations with Renal Survival in FSGS: Analysis of the UK National RaDaR Idiopathic Nephrotic Syndrome Cohort

Moin Saleem,[1,2] Jonathan Barratt,[9,10] Fiona E. Braddon,[3,12] Kevin Carroll,[11] Ulysses A. Diva,[6] Bruce M. Hendry,[6] Alex Mercer,[7] David Pitcher,[3,12] Retha D. Steenkamp,[3,12] A. Neil Turner,[8] Daniel P. Gale.[4,5] *[1]University of Bristol, Bristol, United Kingdom; [2]Bristol Royal Hospital for Children, Bristol, United Kingdom; [3]UK Renal Registry, Bristol, United Kingdom; [4]Royal Free Hospital, London, United Kingdom; [5]University College London, London, United Kingdom; [6]Travere Therapeutics Inc, San Diego, CA; [7]JAMCO Pharma Consulting, Stockholm, Sweden; [8]University of Edinburgh, Edinburgh, United Kingdom; [9]University of Leicester, Leicester, United Kingdom; [10]Leicester General Hospital, Leicester, United Kingdom; [11]KLC Statistics Ltd, Cheshire, United Kingdom; [12]The Renal Association, Bristol, United Kingdom.*

Background: In patients with FSGS, severity of proteinuria (PU) at onset and during follow up is associated with renal failure. In this study, we tested for associations between defined PU endpoints and renal survival in patients with FSGS from the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RaDaR-INS) Cohort.

Methods: A total of 225 biopsy-proven or monogenic FSGS pts met study eligibility criteria, including a nephrotic PU value (≥3.5 g/g), a follow-up PU within 6-12 mo. and no ESKD (eGFR <15 mL/min/1.73m^2 or on renal replacement therapy) or death prior to first PU follow-up. Baseline pertains to first nephrotic PU value (T0 for survival analyses). Applied PU responder/non-responder definitions are described (Table 1). Time to ESKD/death was analysed using accelerated failure time modelling of the Weibull distribution.

Results: Within 6-12 mo. from baseline, 63% of patients achieved complete or partial remission (CR/PR), while 37% were non-responders (NR). Applying the FSGS partial remission of PU endpoint (FPRE) and including CR patients, 49% met this definition (CR/FPRE-R), while 51% were FPRE-NR. A higher probability for survival was observed among patients achieving remission definitions (Figure 1), extending median time to ESKD/death by ≈8 years for CR/PR vs NR, and ≈17 years for CR/ FPRE-R vs NR (Table 1) independent of initial PU level. Further analyses are ongoing.

Conclusions: Achieving partial or complete remission of PU is associated with clinically meaningful increases in time FSGS patients are alive and free from ESKD.

PO1531

Clinicopathological Characteristics of Adult Patients in the United States with Focal Segmental Glomerulosclerosis (FSGS)

Katherine R. Tuttle,[1] Clint Abner,[2] Kerime Ararat,[2] Patrick D. Walker,[2] Amin Yakubu,[3] Martin C. Bunke.[4] *[1]University of Washington, Spokane, WA; [2]Arkana Laboratories, Little Rock, AR; [3]Genesis Research, LLC, Hoboken, NJ; [4]Travere Therapeutics Inc, San Diego, CA.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common histopathologic lesion of glomerular injury in patients with nephrotic syndrome. These analyses characterize clinical and histological features of FSGS in adults at time of kidney biopsy.

Methods: A retrospective study was performed using data from the Arkana Biopsy Database (January 1, 2016 to May 31, 2020) in patients that met study criteria, which included: ≥18 yrs, ≥1 FSGS positive kidney biopsy, and no prior kidney transplant, and available data on race/ethnicity. Outcomes included clinical and histologic characteristics. eGFR was calculated using CKD-EPI-creatinine equation without race modifier.

Results: Of 64,105 adult kidney biopsies performed during the study period, 2,065 (3.2%) FSGS positive cases were identified and 1,482 pts (71.8%) evaluated met study criteria. Demographic characteristics included: 56.2% male, 55.1% White, 32.1% African American (AA), 7.7% Hispanic and 3.4% Asian. Overall mean (SD) age at biopsy was 49.0 (17.2) with older ages in Whites (52.8 (17.3) yrs) and younger ages in Hispanics (39.4 (15.8) yrs). Mean urine protein to creatinine ratio was similar by race/ethnicity (range 5.1-6.0 g/g). Asians were more frequently biopsied at eGFR Stage 4 (32.7%) compared to other race/ethnicity groups: AAs (29.0%), Whites (23.1%), and Hispanics (18.7%). The highest rates of ≥50% global glomerular sclerosis (GS) were observed in AAs (31.1%) and lowest in Whites (14.6%). Whites (51.9%) and AAs (39.7%) exhibited the highest rates of severe foot process effacement (≥80%), while interstitial fibrosis and tubular atrophy ≥50% was more common in AAs (34.6%) compared to Hispanics (27.2%), Asians (17.7%) or Whites (14.7%). Of all FSGS types, "not otherwise specified" was most common across all race/ethnicity groups (range 64.2-75.4%). Among other FSGS types, tip lesion was most frequent in Whites (21.5%) and collapsing was most frequent in AA patients (12.4%).

Conclusions: Non-White patients are more frequently diagnosed with FSGS at later CKD stages with advanced GS. Strategies to improve earlier awareness and detection of FSGS are needed to allow effective intervention before severe kidney damage has occurred.

Funding: Commercial Support - Travere Therapeutics

PO1532

Long-Term Outcomes of Patients with Focal and Segmental Glomerulosclerosis Treated with Tacrolimus

Mukunthan Srikantharajah,[1] Thomas M. Connor,[2] Jeremy B. Levy,[1] Stephen P. McAdoo,[1] Megan Griffith.[1] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.*

Background: Tacrolimus (TAC) is used to treat Focal and Segmental Glomerulosclerosis (FSGS). Prolonged treatment is often required and there is little data on long-term outcomes.

Methods: This is a retrospective study of 29 patients who received TAC as first line immunosuppression for nephrotic syndrome (NS) secondary to FSGS from December 2007- January 2020 at our institution.

Results: Mean follow up was 59.6 months (12– 144). The mean age at diagnosis was 42 years (range 18-85). 52% were Male. 59% were White, 10% Black, 21% Asian, 3% Chinese, 7% Other. Baseline mean eGFR was 64.4ml/min (18-90). 23/29 (79%) obtained complete (CR) or partial remission (PR) of NS, at a mean time of 5.09 months (range 1-31 months). 6/29 (21%) did not enter remission with TAC. 2/6 subsequently achieved

remission with CyP and prednisolone/rituximab. 7/23 (30%) patients who achieved remission with TAC had at least one relapse. 4/7 after stopping TAC, 1/7 during TAC wean and 2/7 with therapeutic TAC levels. 4/7 were treated by restarting or increasing TAC, 1/7 also had steroids added, 1/7 received rituximab (achieving remission) and 1/7 was not further treated with immunosuppression. 4/4 restarted with TAC monotherapy reachieved remission. 16/23 (70%) patients did not relapse and 7 of these remain off TAC and in remission (mean follow up of 92.6 months). At 1 year, the mean eGFR was 67.4 ml/minute (21-90). 1/29 patient developed end-stage kidney disease (ESKD) at 2 months. This patient had not responded to TAC. 16 patients have 5-year-follow up. The mean eGFR was 66.5 ml/minute (11-90). 1 further patient developed ESKD (this patient had not responded to TAC nor subsequent immunosuppression). 4 patients have 10-year follow-up. The mean eGFR was 80.8 ml/minute (67-90). 3 further patients developed ESKD. 1/3 had achieved PR, 1/3 had achieved CR but had multiple relapses despite re-treatment and 1/3 had CR but defaulted from follow up, presenting with ESKD 6 years later.

Conclusions: The long-term data from this study suggests tacrolimus can be effective in both achieving and maintaining remission of NS in FSGS. CR is associated with good long-term outcomes in most patients although relapse can occur and long term careful follow up is required. Non-responders have a worse outcome, although some patients do respond to alternative immunosuppression.

PO1533

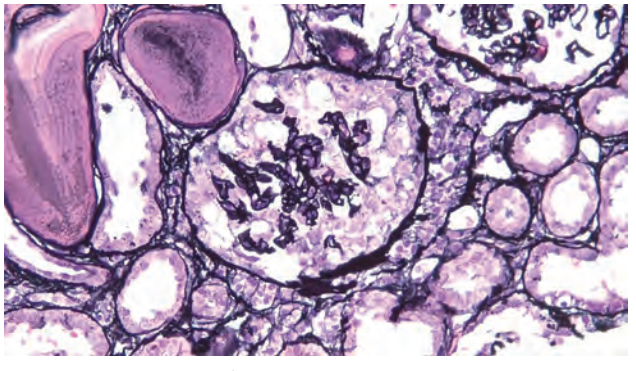
Collapsing FSGS in a Patient with Acute Myeloid Leukemia and Prior COVID-19 Infection

Surya Manivannan, Stephanie S. Pavlovich, Irshadjahan Malek, Koyal Jain. *University of North Carolina System, Chapel Hill, NC.*

Introduction: Collapsing focal segmental glomerulosclerosis (c-FSGS) has been independently associated with COVID-19 infection, acute myeloid leukemia (AML), and apolipoprotein L1 (APOL1) risk variants. We describe a patient with homozygous APOL1 G1 risk allele and AML who developed renal failure due to c-FSGS and acute tubular injury.

Case Description: A 25-year-old male with a history of mild asthma and COVID-19 infection 1 month prior presented with a 3-week history of severe fatigue, weight loss, persistent dyspnea, and fevers. He was found to have leukopenia, thrombocytopenia, an acute kidney injury, and nephrotic range proteinuria. The patient was diagnosed with AML by bone marrow biopsy (BMBx). At presentation, his serum creatine was 2.8 mg/dL, which rapidly increased to 6.9 mg/dL over 2 weeks. Urine protein:creatinine ratio (UPCR) was 3.4g/g on admission. Renal biopsy demonstrated c-FSGS (Figure) and diffuse acute tubular injury. He was treated with standard remission induction therapy for AML with 7+3 therapy (7-day continuous infusion of cytarabine, daunorubicin on days 1-3, and high dose steroids). High dose steroids were continued for c-FSGS treatment with plan for a slow taper over several months. Within a few days of starting 7+3 treatment, his renal function began to improve. His 14-day BMBx demonstrated a hypocellular marrow consistent with complete remission. After 1 month, his creatine improved to 1 mg/dL, along with improvement in his serum albumin. Repeat UPCR is pending.

Discussion: COVID-19 is associated with immunologic alterations precipitating c-FSGS, especially in patients with APOL1 high risk alleles. Additionally, FSGS has been reported in AML, but the etiology behind glomerular pathologies in AML is unclear and likely multifactorial. Studies have indicated immunologic dysregulation related to leukemia, as well as viral-related etiologies. The trigger for c-FSGS in our patient is uncertain.



Light microscopy demonstrated focal and segmental glomerulosclerosis with global and segmental collapse.

PO1534

Role of LDL-Apheresis in Management of Glucocorticoid-Resistant Minimal Change Disease

Dharika P. Shah, Alka A. Tyagi, Jason Prosek, Eshetu L. Obole. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Minimal Change Disease (MCD) is described as diffuse podocyte foot process effacement on kidney biopsy, resulting in nephrotic proteinuria, >3 grams/day. Glucocorticoids (GC) are the mainstay of therapy and most patients achieve complete remission in a few months. 7-12% patients, however, have GC-resistance and thus limited treatment options. Often, they are suspected of having focal segmental glomerulosclerosis (FSGS) due to biopsy sampling error. We present a challenging case of GC-resistant MCD, managed with immunosuppression, and ultimately lipid (LDL) apheresis.

Case Description: An otherwise healthy 20-year-old male presented for sudden onset lower extremity swelling and 10-pound weight gain. Work up including ANA, C3, C4, p-ANCA, c-ANCA, serum and urine immunofixation and renal ultrasound were unremarkable. Notably, LDL was 390 mg/dL, proteinuria of 9 grams/day and serum creatinine (Scr) of 0.96 mg/dL. Kidney biopsy revealed diffuse podocyte effacement, consistent with MCD. He was treated with oral prednisone 1 mg/kg/day and diuretics for several weeks with minimal symptomatic improvement and had worsening kidney function, Scr 1.5 mg/dL and proteinuria of 36 grams/day. Unfortunately, he also contracted COVID-19 disease prior to second kidney biopsy. Repeat kidney biopsy revealed acute tubular necrosis along with widespread podocyte effacement, without sclerotic lesions, ~10% interstitial fibrosis and tubular atrophy. He was empirically treated with tacrolimus for FSGS. However, proteinuria continued to worsen and peaked at 83 grams/day. Ultimately diagnosed as GC-resistant MCD, he was weaned off steroids, he was referred for LDL-apheresis therapy. He is maintained on tacrolimus and LDL apheresis with symptomatic improvement, still has significant proteinuria of 67 grams/day and advanced chronic kidney disease (CKD).

Discussion: The exact pathophysiology of nephrotic syndromes is unclear, mechanisms of T-cell dysfunction causing production of glomerular permeability factor and nephrotoxic hyperlipidemia have been described. In cases of GC-resistant diseases, immunosuppression has only been partially successful. LDL-apheresis has a role in the management of such nephrotic syndromes, thought to reduce circulating lipid induced disruption of podocyte integrity, and help prevent decline of kidney function and decrease proteinuria as seen in this patient.

PO1535

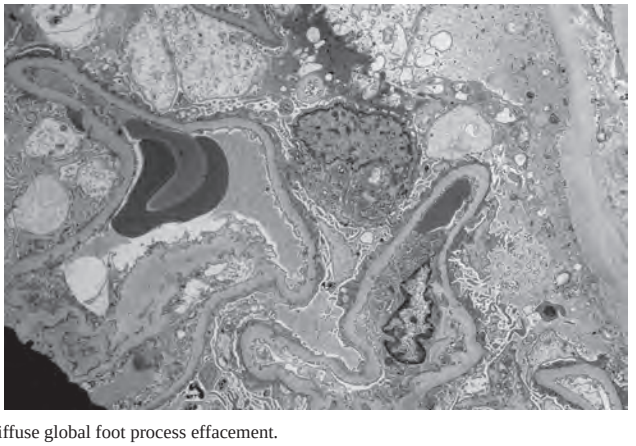
Infliximab-Associated Minimal Change Disease in an Adult with Ulcerative Colitis

Kisan P. Thakkar, Surya Manivannan, Irshadjahan Malek, Koyal Jain. *University of North Carolina System, Chapel Hill, NC.*

Introduction: Tumor necrosis factor-alpha (TNF-α) inhibitors are increasingly utilized for the treatment of several autoimmune conditions. They have been associated, in rare cases, with renal complications. We report a patient who developed minimal change disease (MCD) and interstitial nephritis while being treated with infliximab (IFX) for ulcerative colitis (UC).

Case Description: A 48-year-old male with a history of primary sclerosing cholangitis, liver transplant 8 years prior, psoriasis, and UC well-controlled on monthly IFX presented with a one-week history of lower extremity swelling, dyspnea, and weight gain. He was found to have rapidly progressive renal failure and nephrotic syndrome. Laboratory data showed a serum creatinine of 11mg/dL up from 1mg/dL 3-weeks prior and urine protein:creatinine ratio (UPC) of 11g/g. Renal biopsy demonstrated acute interstitial nephritis (AIN) on light microscopy. Electron microscopy revealed global podocyte activation and foot process effacement, consistent with MCD (Figure). He continued to become progressively oliguric despite escalating doses of diuretics and received two days of hemodialysis due to volume overload. After a total of 7 days of high dose steroids, his urine output increased and hemodialysis was stopped. IFX was discontinued due to the association of TNF-α inhibitors with MCD and AIN. After a month of prednisone, his creatine improved to 1.6 mg/dL and UPC improved to 0.3g/g.

Discussion: This is the first report of IFX associated MCD. Although IFX has been associated with IgA nephropathy, crescentic glomerulonephritis, renal artery occlusion, membranous glomerulopathy, and AIN in patients with spondyloarthritis spectrum diseases, no reports exist in the literature regarding MCD. However, several case reports of Etanercept, another TNF-α inhibitor, associated with MCD exist. TNF- α inhibitors are implicated in immunoregulatory effects in the kidney, which are not well understood.



Diffuse global foot process effacement.

PO1536

Anti-Phospholipase A2 Receptor Antibody Levels in Asian Patients with Primary Membranous Nephropathy: A Territory-Wide Study

Desmond Y. Yap, Irene Yam, Michelle Lam, Hemlata Bisnauthsing, Tak Mao D. Chan. *University of Hong Kong, Hong Kong, Hong Kong*.

Background: Different cut-off values of anti-phospholipase A2 receptor (anti-PLA2R) antibody for differentiating between primary membranous nephropathy (PMN) and secondary membranous nephropathy have been reported. The optimal anti-PLA2R levels to reflect disease activity states in Asian patients with PMN remain undefined.

Methods: We conducted a territory-wide study in Hong Kong to investigate the serum anti-PLA2R levels in Chinese patients with PMN during 2017-2020. Anti-PLA2R levels were measured by commercial ELISA kits (EuroImmun, Germany) in serum samples collected from biopsy-confirmed PMN patients during active disease or remission, and their predictive values for active PMN were evaluated.

Results: Forty hundred and six serum samples from 320 PMN patients were analysed. 319 samples were obtained during active disease and 87 during disease remission. Anti-PLA2R titres during active disease were significantly higher than that during remission (95.1±235.0 RU/mL vs. 1.9±3.9 RU/ml respectively, p<0.001). Using 20 RU/ml as cut-off, the sensitivity (SN) and specificity (SP) for predicting active disease were 39% and 98% respectively [AUC 0.68, p<0.001; positive predictive value (PPV) and negative predictive value (NPV) were 98% and 30% respectively]. Using 10 RU/mL as cut-off, the SN and SP for diagnosing active PMN were 46% and 95% respectively [AUC=0.71, p<0.001; PPV and NPV were 97% and 32% respectively]. Anti-PLA2R titres correlated with urine protein-to-creatinine ratio and 24-hr urine protein levels (r= 0.32 and 0.37 respectively, p<0.001 and <0.001).

Conclusions: Anti-PLA2R showed good SP and PPV prediction for active PMN in Chinese patients, and correlated with severity of proteinuria. A lower threshold (≥10 RU/mL) may show improved SN for predicting active PMN in Asian patients.

PO1537

Qualitative and Quantitative Dosage of the Anti M-Type Phospholipase A2 Receptor Autoantibody: One-Year Experience in Quebec's Reference Center

Simon Leclerc,[1,2] Karim Benkirane,[1,2] Caroline Lamarche,[1,2] Jean-Philippe Lafrance,[1,2] Annie-Claire Nadeau-Fredette,[1,2] Virginie Royal,[1,2] Vincent Pichette,[1,2] Louis-Philippe Laurin.[1,2] *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Universite de Montreal, Montreal, QC, Canada*.

Background: Dosage of the M-type phospholipase A2 receptor antibodies (anti-PLA2R) is now an essential tool for diagnosis and management of primary membranous nephropathy (MN). Since October 2018, Hôpital Maisonneuve-Rosemont (HMR) has been designated as Quebec's reference center for serum anti-PLA2R antibody testing by the *Institut National d'Excellence en Santé et Services Sociaux* (INESSS), the regulatory body on drugs and tests usage in Quebec.

Methods: All patients who had a serum anti-PLA2R antibody testing performed at HMR from October 1st, 2018 to October 1st, 2019 were included in the study. Serum anti-PLA2R antibodies were screened by a qualitative test, followed by a quantitative test if the results were undetermined or positive. We calculated sensitivity, specificity, predictive value, and likelihood ratio for both tests, using kidney biopsy findings as the gold standard.

Results: In the province of Quebec, a total of 1690 tests were performed among 1025 patients during the study year. A small proportion of these patients (8%) were followed at HMR. Patients tested at HMR and in the rest of Quebec had similar characteristics. Test validity was only characterized for patients tested at HMR. Sensitivity and specificity were, respectively, 58% and 100% for the qualitative test, and 71% and 100% for the quantitative test. The combined net sensitivity was 42% and the net specificity, 100%. The net positive and negative predictive value were 100% and 84% respectively, whereas the net negative likelihood ratio was 0.58.

Conclusions: Serum anti-PLA2R antibody testing was widely used in Quebec during its first year of availability. In one of the biggest real life cohort described, the test performed as previously described in the literatur. Moreover, the two-step approach that was used at HMR, using a qualitative test before a quantitative test if needed, appears to be an efficient way to avoid quantitative testing in negative patients and to better characterize undetermined results on immunofluorescence.

PO1538

Clinical Relevance of NELL1 Antibodies in Patients with Membranous Nephropathy

Linda Reinhard, Benedikt Krümpelmann, Thorsten Wiech, Rolf A. Stahl, Elion Hoxha. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: NELL1 was identified as a potential novel target antigen in membranous nephropathy (MN). Here, we studied the association of NELL1-antibody (ab) with treatment response and prognosis in a large cohort of MN patients.

Methods: Circulating NELL1-ab were detected by Western blot in a prospective cohort of 87 PLA_2R- and THSD7A-ab negative MN patients, 130 PLA_2R- or THSD7A-ab positive MN patients and 116 control patients with a biopsy-proven GN other than MN. Clinical follow-up included treatment, remission or relapse of proteinuria and development of kidney function.

Results: NELL1-ab were identified in 18 (21%) patients with PLA_2R- and THSD7A-ab negative MN but none of the control cohorts' patients. We identified NELL1-specific IgG1, IgG2, IgG3 and IgG4 subclasses in the serum of 12 (67%), 7 (39%), 11 (61%) and 15 (83%) NELL1-ab positive patients, respectively. NELL1-ab positive patients were significantly (p<0.05) older compared to PLA_2R-ab positive patients or MN patients without known target antigen (median age 70 vs 58 vs 58 years). Within 6 months of MN diagnosis, a malignant tumor was identified in 2 (11%) NELL1-ab positive, 7 (6%) PLA_2R-ab positive, 3 (50%) THSD7A-ab positive and 7 (10%) MN patients without known target antigen. 14 NELL1-ab positive patients were observed over a median follow-up of 75 months. One patient presented with eGFR < 30 ml/min due to severe hypertensive and diabetic kidney damage and developed ESKD after 69 months. All other 13 patients had a remission of proteinuria. 12 (92%) patients had a complete remission, although only 4 patients received an immunosuppressive therapy. Remarkably, of the 9 untreated patients with complete remission of proteinuria, 4 patients had persisting NELL1-ab in the circulation over the whole observation period and 2 patients reached complete remission of proteinuria before NELL1-ab disappeared. Renal function was stable in NELL1-ab positive patients but showed a more pronounced decline in NELL1-ab negative patients.

Conclusions: NELL1-ab positive MN patients had slightly more often a malignant tumor, but also were significantly older compared to PLA_2R-ab positive patients. Overall, NELL1-ab positive patients had a good prognosis. The presence of NELL1-ab in the serum did not show a close association with disease outcome.

PO1539

Non-Pathogenetic THSD7A Antibodies in a Patient with No Membranous Nephropathy

Linda Reinhard,[1] Cindy Thomas,[2] Maya Machalitza,[1] Erik Lattwein,[2] Lothar S. Weiß,[1] Jan Vitu,[3] Thorsten Wiech,[1] Rolf A. Stahl,[1] Elion Hoxha.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany; [3]Medizinisches Versorgungszentrum Hamburg-Sinstorf der MVZ gGMbH der PHV, Hamburg, Germany*.

Background: PLA_2R- and THSD7A-antibodies (ab) are considered to be specific for the diagnosis of membranous nephropathy (MN). There is a controversial discussion whether the detection of circulating PLA_2R- or THSD7A-ab is sufficient to diagnose MN, without the need of a kidney biopsy.

Methods: Circulating THSD7A-ab were detected and their specificity evaluated by an indirect immunofluorescence test (IIFT), reducing, non-reducing and native Western blot techniques as well as a live cell assay. The kidney biopsy was investigated by immunohistochemistry and electron microscopy.

Results: A patient presented with high level proteinuria and was tested positive for THSD7A-ab using IIFT. Except for the diagnosis of diabetes mellitus, the medical history of the patient was unremarkable. Because of persistent proteinuria and a decline of kidney function, a kidney biopsy was performed, showing the diagnosis of diabetic nephropathy and excluding MN. A detailed biochemical characterization of the THSD7A-ab was performed to clarify these discrepancies between the serological and histomorphological findings. The circulating THSD7A-ab from the serum of the patient bound to recombinant THSD7A in the IIFT, co-localizing with THSD7A in co-immunofluorescence staining experiments and reacted with purified THSD7A in reducing WB analyses. However, these antibodies did not bind THSD7A derived from human glomerular tissue in any experimental condition (reducing, non-reducing, native). Moreover, the circulating THSD7A-ab did not recognize recombinant THSD7A under native conditions in the native Western blot or live cell assay. In contrast, THSD7A-ab from MN patients recognized native THSD7A in all experiments.

Conclusions: We show for the first time the existence of non-pathogenetic THSD7A-ab, which are not able to bind THSD7A *in vivo* and can hence not induce MN. Nevertheless, their presence can be detected by different assays, leading to false-positive results for pathogenic circulating THSD7A-ab. In cases of low THSD7A-ab positivity in IIFT, findings from different diagnostic tests such as kidney biopsy, Western blot analyses and live cell assays should be integrated in making a safe diagnosis of THSD7A-ab positive MN.

PO1540

Urinary NPHS2-mRNA in Relation to Glomerular and Tubular Damage Markers in Patients with Membranous Nephropathy

Bartholomeus T. van den Berge,[1,2] Anne-Els van de Logt,[1] Jitske Jansen,[2,3] Bart Smeets,[2] Johan Van der vlag,[1] Jack F. Wetzels,[1] Rutger J. Maas.[1] *[1]Radboudumc Afdeling Nierziekten, Nijmegen, Netherlands; [2]Radboudumc Afdeling Pathologie, Nijmegen, Netherlands; [3]Radboudumc Afdeling Kindergeneeskunde, Nijmegen, Netherlands*.

Background: Measurement of podocyte-specific mRNA in patients' urine samples has been proposed as a novel tool to monitor podocyte loss in glomerular disease, and may have prognostic value. In our hospital, we routinely measure timed urinary excretion of high- and low-molecular weight proteins as prognostic markers in patients with membranous nephropathy (MN). Here, we investigated the relationship between *NPHS2*-mRNA and high- and low-molecular weight proteins in patients with MN.

Methods: We included 35 patients with MN (80% male, median age 67, median eGFR 63). *NPHS2*-mRNA was measured in urinary pellets as described by Wickman *et al.* (JASN 2013). Normal values of urinary *NPHS2*-mRNA were obtained in spot urine samples of 19 healthy controls.

Results: Clinical characteristics and results of urinary measurement are shown in Table 1. Mean urinary *NPHS2*-mRNA/creatinine ratio (UPodCR) was 64 fold higher in patients with MN versus healthy controls. UPodCR showed weak but significant correlations with urinary IgG excretion and proteinuria selectivity index (Figure 1), but not with total proteinuria or eGFR (Table 1).

Conclusions: Urinary excretion of *NPHS2*-mRNA correlated significantly with protein markers of glomerular damage in patients with MN. However, correlations were weak. Prospective studies are needed to evaluate if urinary *NPHS2*-mRNA excretion holds independent prognostic value.

Table 1. Characteristics of patients with membranous nephropathy (N=35)

Characteristic		Correlations with UPod
Serum creatinine (µmol/L)	102 (82-124)	0.02 (0.37)
Selectivity index (%)	19.8 (12.7-23.2)	0.12 (0.05)
UAlb (g/g creat)	3.0 (2.2-5.1)	0.02 (0.47)
UIgG (mg/g creat)	143.2 (74.3-332.0)	0.14 (0.03)
Ualpha-1m (mg/g creat)	45.7 (25.3-67.6)	0.03 (0.32)
Ubeta-2m (mg/g creat)	1.6 (0.3-4.0)	0.07 (0.14)
UPod (ng/g creat)	4.4e-4 (1.6e-4-1.6e-3)	

Continuous variables are expressed as Median (interquartile range). Correlations are expressed in Spearman's R2 (p-value). UAlb = Urinary albumin, UPod = Urinary NPHS2 mRNA.

Urine Biomarkers Predict Treatment Response in the MENTOR Study

Prapa Pattrapornpisut,[1,2] Sarah M. Moran,[4] Gary Bader,[8] Changjiang Xu,[8] Paul C. Boutros,[6] Fernando C. Fervenza,[7] Sean Barbour,[3] Daniel C. Cattran,[1,5] Heather N. Reich.[1,5] for the MENTOR investigators *[1]University Health Network, Toronto, ON, Canada; [2]Bhumirajanagarindra Kidney Institute, Bangkok, Thailand; [3]The University of British Columbia, Vancouver, BC, Canada; [4]Queen's University, Kingston, ON, Canada; [5]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [6]University of California Los Angeles, Los Angeles, CA; [7]Mayo Clinic Minnesota, Rochester, MN; [8]University of Toronto, Toronto, ON, Canada*.

Background: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. The outcome of patients with MN is highly variable and clinical parameters do not reliably identify which patients will respond to immunosuppressive therapy (IS). In the MENTOR trial >40% of subjects did not achieve complete or partial remission (CR/PR) of proteinuria by 12 months despite IS with rituximab or cyclosporine, exposing them to unnecessary IS and portending potentially poor prognosis. We evaluated whether a panel of urinary molecular markers of kidney inflammation and fibrosis improves the ability to identify treatment responders in the MENTOR trial beyond clinical data alone.

Methods: We measured the abundance of 55 urinary cytokines, metalloproteases and their inhibitors at the time of randomization in 104 subjects using a Luminex-based multiplex assay. The primary outcome of interest was achievement of CR/PR at 12 months.

Results: Patients achieving CR/PR had significantly higher CrCl (94.25 ±31.42 vs 75.17 ± 28.52 mL/min/1.73m^2, p=0.002) and lower anti-PLA2R titre (168.5 IQR 20.5,341 vs 549 IQR 115.5,1345 U/mL, p= 0.0002) at baseline. Stepwise selection identified 3 clinical variables (CrCl, PLA2R, treatment) and 8 urinary proteins (IL9, IL10, GM-CSF, VEGF-A, TGFα, MMP2, MMP3, MMP10) associated with CR/PR. A model including the clinical and molecular variables improved discrimination of patients who are predicted to achieve CR/PR compared to a model containing clinical variables alone (ANOVA test p-value = 1.30x10^{-5}, AUC 0.81 ± 0.096 vs. 0.70 ± 0.109).

Conclusions: In summary, measurement of a panel urinary molecular markers improves the ability to predict remission at 12 months in patients with MN. Improved prediction of patients resistant to standard therapy using non-invasive markers has potential to offer more individualized treatment, to spare unnecessary treatment toxicity and to identify patients who may benefit from trials of novel therapeutic agents.

Figure: Receiver operating characteristic (ROC) curves for the prediction models selected by stepwise regression.

Use of Urinary Proteins as Predictors of Response to Immunosuppressive Treatment in Membranous Nephropathy

Lagu A. Androga,[1] Jason K. Viehman,[1] Shane A. Bobart,[3] Lisa E. Vaughan,[1] John C. Lieske,[1] Ladan Zand,[1] Eddie L. Greene,[1] Sanjeev Sethi,[1] Daniel C. Cattran,[2] Fernando C. Fervenza.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Cleveland Clinic Florida, Weston, FL.*

Background: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in adults. Prognosis is defined by remission in proteinuria. Response to immunosuppression agents such as calcineurin inhibitors and rituximab vary. While the presence of anti-PLA2R antibodies may help to guide prognosis and treatment strategies, further identifying biomarkers that could refine treatment decision would be useful. Using data from the MENTOR trial (NEJM 2019), we evaluated whether 24-hour total urinary protein, urinary albumin, immunoglobulin M (uIgM), immunoglobulin G (uIgG), and urinary alpha 1 microglobulin (uα1m) at baseline could be used to predict response to immunosuppressive therapy at 12 months in patients with MN.

Methods: Logistic regression models were used to study the relationship between baseline urinary proteins with patients' treatment outcomes by treatment drug (rituximab or cyclosporine). The treatment outcome was defined as patients achieving either complete (CR; <0.3g/24 hours) or partial remission (PR; >0.3-<3.5g/24 hours) of proteinuria at 12 months.

Results: In both cyclosporine and rituximab arm, all urinary proteins exhibited a decline from baseline to 12 months post treatment. However, none of the baseline urinary proteins were found to be significantly associated with treatment response at 12 months (p>0.05 for all). Results were similar when restricted to patients with positive anti-PLA2R at baseline.

Conclusions: Baseline measures of the urinary albumin, uIgM, uIgG, and uα1m are not predictors of patients going into CR or PR at 12 months after treatment with rituximab or cyclosporine.

Table 1: Odds ratio of urinary protein predicting CR or PR at 12 months in patients treated with Rituximab or Cyclosporine (Fully Adjusted model)

Urinary Protein	Treatment Group	All Patients		Anti-PLA2R Antibody Positive Patients	
		Odds Ratio (95% CI)	p-value	Odds Ratio (95% CI)	p-value
α1M, per 10 mg / 24hr	Rituximab	1.018 (0.946, 1.096)	0.631	1.024 (0.939, 1.117)	0.591
	Cyclosporine	1.009 (0.950, 1.072)	0.767	1.006 (0.935, 1.082)	0.873
Albumin, per 100 mg / 24hr	Rituximab	0.996 (0.982, 1.011)	0.596	0.995 (0.978, 1.013)	0.577
	Cyclosporine	0.992 (0.978, 1.006)	0.270	0.990 (0.973, 1.007)	0.257
IgM, per 10 µg / 24hr	Rituximab	1.014 (0.984, 1.045)	0.369	1.015 (0.983, 1.047)	0.365
	Cyclosporine	1.012 (0.988, 1.036)	0.334	1.011 (0.986, 1.037)	0.388
IgG, per 100 mg / 24hr	Rituximab	0.988 (0.923, 1.057)	0.718	0.972 (0.901, 1.050)	0.472
	Cyclosporine	0.958 (0.909, 1.009)	0.101	0.941 (0.881, 1.004)	0.067

PO1543

APOL1 High-Risk Genotype Is Associated with Worse Renal Outcomes in Black Patients with Membranous Nephropathy

Dhruti P. Chen, Candace D. Henderson, Claudia Aiello, Yichun Hu, Susan L. Hogan, Ronald J. Falk. *University of North Carolina System, Chapel Hill, NC.*

Background: Black patients have a higher propensity for progression to end-stage kidney disease (ESKD) and this disparity persists in glomerular diseases studied thus far. Genetic variants in the Apolipoprotein L1 (*APOL1)* gene contribute to kidney disease burden in those with African ancestry. To date, there are no data on the role of *APOL1* risk alleles in outcomes among black patients with membranous nephropathy (MN).

Methods: Sanger sequencing for *APOL1* risk allele genotyping was completed on patients of African-American ancestry (self or clinician reported) with diagnosis of MN enrolled in the Glomerular Disease Collaborative Network (GDCN) or Cure Glomerulonephropathy Network (CureGN) with DNA samples available were included.

White patients from CureGN were included for comparison. Data from CureGN or chart abstraction for GDCN patients were used to determine demographics, diagnosis, disease onset, and ESKD (dialysis initiation or transplantation). Fisher's exact, Wilcoxon rank, and Kaplan-Meier curves with log rank tests were used to evaluate differences between high risk (2 variants) and low risk (0/1 variant) and white population.

Results: There were 106 African American patients with diagnosis of MN in our study. Of these, 15 patients (14%) were high risk (two risk alleles of *APOL1*) and the remaining 91 patients (86%) were low risk (0/1 risk alleles of *APOL1*). Data were available for 493 white patients. Hazard ratio for composite outcome of ESKD/death was 4.21 (95% CI 1.54,11.51) among African Americans (high risk vs. low risk) and 6.37 (95% CI 2.74, 14.80) compared to white population. Time to endpoint was significantly faster in those with high risk *APOL1* genotype (Figure), p<0.0001.

Conclusions: High-risk *APOL1* genotype in African Americans is associated with faster time to ESKD/death compared to low-risk AA or white patients with MN.

PO1544

Treatment-Resistant Membranous Nephropathy in a Patient with NPHS2 Mutation

Ioana Ailincai, Gabriela Lupusoru, George C. Costea, Georgiana Fratila, Oana Ion, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania*.

Introduction: Membranous nephropathy (MN) is one of the most frequent causes of nephrotic syndrome (NS) in adults. NPHS2 gene encodes podocin, a protein of the slit diaphragm that is essential for recruitment of nephrin into the lipid rafts and for maintaining the glomerular filtration barrier. Recessively transmitted mutations in NPHS2 cause familial forms of steroid-resistant NS that progress to end-stage renal disease (ESRD).

Case Description: A 37-year-old male was referred to our clinic with NS and hypertension. Admission labs showed creatinine of 3 mg/dl, serum albumin of 3 g/dl, proteinuria of 20 g/d and microscopic hematuria (30 cells/µl). Immunological testing – ANA, ANCA, anti-C1q, anti-GBM – was negative, C3 and C4 were normal. Kidneys appeared normal on ultrasound examination. A renal biopsy was performed. Light microscopy revealed 19/23 glomeruli with global sclerosis and 4/23 glomeruli with thickening of GBM, podocyte hypertrophy and segmental sclerosis; there was also diffuse tubular atrophy, interstitial fibrosis and arteriolar hyalinosis. Electron microscopy showed subepithelial electron dense deposits with spike formation, with granular capillary loop staining for IgG4 in immunofluorescence. The histopathological diagnosis was stage II MN associated with diffuse glomerulosclerosis secondary to hypertension. In the meantime, the anti-PLA2R antibodies returned positive (titer 1/320). Therapy was started with Rituximab 1000 mg; a second dose was administered after 14 days. Despite treatment, NS persisted and kidney function worsened; hemodialysis was initiated 6 months after the diagnosis. One year later, the patient's 16-year-old son was diagnosed with NS, resistant to steroids. Genetic testing identified NPHS2 c.947C>T p.(Pro316Leu) heterozygous mutation in the family; the son was also heterozygous for c.3447dup, p.(Val1150Cysfs*39) in KANK1, inherited from the mother.

Discussion: Recent data suggest an important role of genes in the pathogenesis of MN; NPHS1 polymorphisms are associated with low remission rate after treatment and high disease progression. Our patient has a heterozygous mutation in NHPS2, resulting in abnormal signaling through the nephrin-podocin complex and podocyte disfunction. Therefore, it is very probable that in this case of primary MN genetics played a major role in treatment resistance and progression to ESRD.

PO1545

Primary Membranous Nephropathy Flare After COVID-19 Vaccination

Kelly V. Liang, Elizabeth C. Kurtz, Matthew Pittappilly, Syeda B. Ahmad, Marta I. Minervini. *University of Pittsburgh, Pittsburgh, PA.*

Introduction: Primary membranous nephropathy (MN) is most commonly due to phospholipase A2 receptor antibodies (PLA2R Ab). It is unclear whether the COVID-19 vaccine can trigger flares of glomerular diseases such as primary MN. We present a patient with MN and metastatic breast cancer who developed nephrotic syndrome after receiving her second mRNA-1273 COVID-19 vaccine with positive PLA2R Ab by ELISA suggesting MN flare.

Case Description: A 62 year old female with history of Stage IIIB T3N3M1 ER/PR positive HER-2 negative metastatic left breast invasive ductal carcinoma, hypertension, hyperlipidemia, and primary MN presented with bilateral leg edema, dyspnea, and proteinuria 2 weeks after COVID-19 vaccination. She had previous proteinuria of 7029 mg/24hr in August 2018 with PLA2R Ab 128 RU/mL in October 2018. She underwent modified radical mastectomy in September 2018 followed by adjuvant chemotherapy in November 2018, after which PLA2R Ab decreased to <2 RU/mL in February 2019 and urine protein/Cr ratio (UPCR) decreased to 1094 mg/g Cr in April 2019. She was diagnosed with metastatic breast cancer and started anastrazole transiently. She received mRNA-1273 COVID-19 vaccines in late January and February 2021. In March 2021, she presented with bilateral leg edema, dyspnea, and bilateral pleural effusions. Urinalysis had >1000 protein, 24hr urine protein 11.2 g, Cr 1.6 mg/dL, and PLA2R Ab 787 RU/mL. Renal biopsy showed immune complex-mediated glomerulopathy with positive PLA2R, consistent with primary MN stage II-III. Glomerular basement membrane deposits were strongly positive for IgG4. Electron microscopy showed numerous subepithelial and occasional intramembranous electron-dense immune-type deposits. She was treated with lisinopril and furosemide followed by rituximab in May 2021. Prior to rituximab PLA2R Ab was 342 RU/mL and UPCR was 8671 mg/g Cr.

Discussion: There is insufficient data on the risk of flare after COVID-19 vaccine in glomerular diseases. There have been a few case reports of primary MN and minimal change disease after COVID-19 vaccine as well as MN after influenza vaccine. Our case of primary MN flare after COVID-19 vaccine adds support to a potential association between SARS-CoV-2 antigens and loss of tolerance to the PLA2R antigen. Close follow-up of patients with primary MN and other glomerular diseases after COVID-19 vaccination is warranted.

PO1546

Primary Membranous Nephropathy Concurrent with ANCA-Positive Crescentic Glomerulopathy in a Hispanic Man

Leonardo Pozo Garcia,[1,2] Daniel Varela,[1,2] Steffi Sathiyaraj,[1,2] Mourad Alsabbagh,[2] Sergio A. Trevino Manllo,[3] John Manllo.[3] *[1]The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; [2]DHR Health, Edinburg, TX; [3]South Texas Kidney Specialists, McAllen, TX*.

Introduction: Primary membranous nephropathy (MN) is a common cause of glomerular disease in adults usually presenting with nephrotic syndrome. Crescents are an unusual finding in MN, its presence suggests a concomitant disease process, such as pauci-immune anti-neutrophil cytoplasmic antibody-related (ANCA) glomerulonephritis (GN).

Case Description: A 36-year-old Hispanic man presented with a 1-week history of worsening lethargy. Examination revealed an obese Hispanic man with rales on lung auscultation and lower-extremity edema. Laboratory results showed a serum creatinine (sCr) 8.8 mg/dL, BUN of 54 mg/dL. Urinalysis revealed 4+ protein, 25-50 red blood cells per hpf. Spot urine protein creatinine ratio (UPCR) was 19 g/g, p-ANCA titer 1:640. Urine toxicology screen was positive for cocaine. Other serologies and imaging were unremarkable. Renal biopsy showed MN with PLA2R positive staining as well as necrotizing and crescentic glomerulonephritis. Interstitial fibrosis and tubular atrophy were seen only in 10% of the sample. Management was initiated with a pulse of steroids followed by a taper, and renally dosed oral cyclophosphamide. The patient was initiated on hemodialysis due to uremic symptoms and volume overload. Three months after initiation of therapy, urine output significantly improved. Laboratory data showed: a 24 hours urine creatinine clearance of 31 ml/min, sCr 2.9 mg/dL, and UPCR 5.3 g/g. Patient was euvolemic. Hemodialysis was discontinued.

Discussion: MN and ANCA GN are distinct manifestations of renal injury with different clinical, laboratory, and pathology findings. Our case highlights an individual with both entities. We hypothesize that the patient's renal findings of p-ANCA and crescentic GN were likely associated with levamisole adulterated cocaine in the background of primary MN. The patient discontinued cocaine use after our discussions. We decided to treat the patient's MN with immunosuppressive therapy. Fortunately, the patient has responded favorably to our management with significant improvement in renal function.

PO1547

Clinical-Pathological Features of Podocyte Infolding Glomerulopathy

Ling Hong,[1,2] Lin Wang,[3] Zhihua Zheng,[1] Wenfang Chen.[2] *[1]Department of Nephrology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; [2]Department of Pathology,The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [3]Department of Renal Pathology, Guangzhou Kingmed Diagnostic Laboratory Ltd, Guangzhou, China*.

Background: Podocyte infolding glomerulopathy (PIG) is characterized by presence of microstructural aggregates originated from cytoplasmic infoldings of podocytes in the glomerular basement membrane (GBM). Few PIG cases have been reported and the significance of this morphology is still unclear. This study aims to elucidate the incidence, clinical-pathological features and prognosis of PIG.

Methods: Renal biopsies with PIG features from January 2018 to December 2020 in Kingmed Diagnostic Laboratory were reviewed. Patients were divided into three groups according to their clinical and pathological findings.

Results: Among 87452 biopsies, 116 (1.37‰) cases were found to have features of PIG and 61 patients among them had complete clinical data and follow-up information. Most PIG cases were accompanied with other glomerular diseases, among which were 39 cases (63.9%) with lupus nephritis (Group PIG-LN), 14 cases (23%) with other glomerulonephritis such as membranous nephropathy, focal segmental glomerulosclerosis (FSGS) and IgA nephropathy (Group PIG-GN). Only 8 cases (13.1%) presented with pure PIG with absence of immunoglobulins and complement deposits. In the PIG-LN group, most patients revealed presence of immunoglobulin deposits, with IgG in 84.6% of the patients, C3 in 74.4% and C1q in 69.2%. Similarly, electron dense deposits were seen in PIG-LN (61.5%) and PIG-GN (57.1%) in accordance with immunofluorescence. There is no significant difference in levels of proteinuria, hematuria and creatine among the three groups. Most patients in PIG-LN group showed increased ANA tier (100%) and decreased C3 level (84.6%). The patients in the pure PIG group showed more sensitivity to glucocorticoid therapy and got a significantly higher complete remission rate (75%) than those in group PIG-LN (53.8%) and group PIG-GN (14.3%).

Conclusions: PIG is a special type of podocyte injury, which is either a separate disease entity or concomitant with other GN, among which LN is the most frequent one. Patients with pure PIG tend to be more sensitive to glucocorticoid therapy compared with those coincide with other GN.

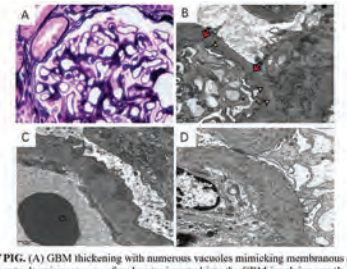

Figure 1. Different degree of PIG. (A) GBM thickening with numerous vacuoles mimicking membranous nephropathy; (PASM, ×600); (B) Mild PIG showing a few cytoplasmic processes of podocytes inverted into the GBM involving mostly the superficial area of GBM (C) Moderate PIG showing irregular GBM thickening with numerous podocytes cytoplasmic fragments extending into nearly half of the GBM; (D) Severely thickened GBM with a large number of cytoplasmic protrusions of podocytes involving the whole GBM layer.

Different degree of PIG.

PO1548

Baseline Characteristics of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits in the International Kidney Registry Consortium (K-REG)

Ghazal Z. Quinn,[1] Sandra Susanibar-Adaniya,[1] Stacey Lau,[2] Radhakrishna R. Kallem,[2] Jonathan Hogan.[1] The International Kidney Registry Consortium (K-REG) and the International Kidney and Monoclonal Gammopathy (IKMG) Research Group *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Proliferative glomerulonephritis with monoclonal Ig deposits (PGNMID) is a monoclonal gammopathy of renal significance-associated lesion unique for low rates of paraprotein and clone detection. Prognosis is poor with 30% of patients progressing to ESKD, but recent data suggest improved outcomes with clone-directed therapy regardless of clone-detection status. Here, we present the baseline kidney and hematologic characteristics of patients with PGNMID from the International Kidney Registry Consortium (K-REG).

Methods: PGNMID cases were identified retrospectively by K-REG sites. Baseline demographic, clinical, kidney biopsy, hematologic and treatment data were analyzed and stratified by presence or absence of clone detected, as well conservative vs. non-specific immunosuppression vs. clone-directed therapy prescribed.

Results: 134 patients from 15 sites in 3 countries with PGNMID were included, 13% of which had been included in previously published studies. The mean age was 57 (SD 17) years, 49 % of whom were female and 72% Caucasian. The median baseline eGFR was 35 (IQR 21-52) ml/min/1.73m^2 and median proteinuria 3.9 (IQR 1.5-7.2) g/day. IgG kappa was the most common involved paraprotein (61%). 30% of patients had a detectable circulating paraprotein by SPEP or sIFE and 11% by UPEP or uIFE. 75% of patients underwent a bone marrow biopsy. Overall, a clone was detected in 19% of patients. There were no significant differences in age, sex, race, baseline eGFR, or proteinuria based on clone or paraprotein-detection status. Clone-directed therapy was prescribed in 55% of patients, non-specific immunosuppression to 15% of patients and conservative therapy in 40% of patients. Clone-directed therapy was prescdribed in 82% of patients with a detectable clone vs. 52% of patients without a detectable clone(p=0.011).

Conclusions: In this large series of PGNMID, a minority of patients had detectable clone. Baseline demographic and clinical characteristics were not different based on clone-detection status but treatment varied significantly based on clone-detection status. Additional analyses of the K-REG cohort will provide insight into renal and hematologic responses.

PO1549

Kidney Outcomes in Biopsy-Proven Thrombotic Microangiopathy with Eculizumab Therapy

Mohammad A. Sohail,[1] John R. Sedor,[2] Susana Arrigain,[2] Jesse D. Schold,[2] Leal C. Herlitz,[2] Ali Mehdi.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Background: There are limited long-term data on kidney outcomes in eculizumab-treated patients with biopsy-proven thrombotic microangiopathy (TMA). We report our experience of using eculizumab in patients with primary (genetic/antibody mediated) TMA, secondary TMA syndromes associated with antiphospholipid syndrome (APS) or systemic lupus erythematosus (SLE), as well as TMA of undetermined etiology.

Methods: We reviewed adult patients with kidney biopsy-proven TMA treated with eculizumab between 2014-2019. Transplant recipients, pregnant patients and those with scleroderma, shiga-toxin related hemolytic uremic syndrome or thrombotic thrombocytopenic purpura were excluded. Kidney response to eculizumab at 26 weeks for patients not on kidney replacement therapy (KRT) and for those requiring KRT at the time of or within 1 week of initiation of eculizumab, was defined as an increase in eGFR of 15 ml/min/1.73m^2 and liberation from KRT respectively. Death within 26 weeks was considered lack of response.

Results: We collected data on 16 patients (primary TMA [n=3]; secondary TMA including SLE [n=3] and APS [n=4]; TMA of undetermined etiology [n=6]). The median time from biopsy diagnosis to treatment initiation was 3.0 days (IQR:-1.0,10.0) and the median duration of therapy was 303 days (IQR:160,604). 13 patients (81%) required KRT at the time of initiation of eculizumab. 4 patients died during follow up, 2 of whom died within 26 weeks. 6 (37.5%) patients exhibited kidney response to eculizumab, 5 of whom required KRT when therapy was started. 2 of 3 patients who did not need KRT initially eventually progressed to end-stage kidney disease after 1 and 5.5 years from treatment initiation. 3/6 patients (50%) and 3/8 patients (37.5%) with mild and moderate interstitial fibrosis and tubular atrophy (IFTA) on biopsy respectively responded to therapy, whilst those with severe IFTA (n=2) showed no response.

Conclusions: Although eculizumab use has been expanding rapidly for primary and secondary TMA syndromes, our data depicts a suboptimal kidney response, which appears independent of the need for KRT at treatment initiation. Severity of IFTA may be a predictor of kidney response to eculizumab. We suggest that more data is needed on long-term kidney outcomes with eculizumab across TMA syndromes before universally adopting this expensive therapeutic strategy.

PO1550

Recurrence of Atypical Hemolytic Uremic Syndrome After Kidney Transplantation: A Prospective Cohort Study

Caroline Duineveld, Romy N. Bouwmeester, Kioa L. Wijnsma, Nicole Van De Kar, Jack F. Wetzels. CUREiHUS study group *Radboudumc, Nijmegen, Netherlands.*

Background: Since 2016, aHUS patients in the Netherlands are treated with a restrictive treatment protocol. Withdrawal of eculizumab is considered after a treatment period of three months. Furthermore, kidney transplantations in aHUS patients are performed without eculizumab prophylaxis, with initiation of eculizumab in case of post-transplant recurrence. This restrictive treatment protocol is monitored in the CUREiHUS study. Here, we present the CUREiHUS study results for kidney transplant patients.

Methods: All kidney transplant patients who received eculizumab therapy for a suspected aHUS recurrence, and who were included in the CUREiHUS study (after informed consent), were evaluated.

Results: In the period from January 2016 until October 2020 we included 15 (F 12, M 3; median age 42y, range 24-66) patients with suspected aHUS recurrence after kidney transplantation. Patients were classified as high (N=8) or moderate (N=7) recurrence risk. The time-interval to recurrence showed a bimodal distribution. Seven patients presented early after transplantation (median 3 m, range 0.3-8.8), with typical aHUS features: rapid eGFR loss and laboratory signs of TMA. Eight patients presented late (median 46m, range 18-69) after transplantation. Of these, 3 patients showed typical aHUS features, while in 5 patients no laboratory evidence of TMA was seen, and only a gradual eGFR loss. Treatment with eculizumab resulted in disappearance of TMA and improvement/stabilization of eGFR in 14 patients. Withdrawal of eculizumab was thus far proposed in 10 patients, and successful in only 5. Median follow-up after recurrence is 29 months (range 3-53 months). At last follow-up median eGFR was 32.0 ml/min/1.73m2 (range 7-80), considerably less than eGFR before recurrence (54.3 ml/min/1.73m2, range 22-103).

Conclusions: Patients with aHUS who develop recurrence after kidney transplantation do not fully recover kidney function. The major cause is treatment delay due to late recognition of disease recurrence in patients who present with a “creeping creatinine”. Discontinuation of eculizumab is often unsuccessful.

PO1551

A Case of Thrombotic Microangiopathy from an Intra-Abdominal Abscess

Sindhuri Prakash-Polet, Lusine Nahapetyan, Raphael J. Rosen, Satoru Kudose, Russell J. Crew. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Infection mediated thrombotic microangiopathy (TMA) has a high mortality with many patients requiring kidney replacement therapy. Recognition of TMA can be difficult in the setting of sepsis as clinical abnormalities can overlap. We report a case of TMA from complicated diverticulitis and polymicrobial intra-abdominal abscess.

Case Description: A 25 year old non-vegetarian man presented with generalized abdominal pain, fatigue, chills and intermittent epistaxis. He was found to have severe acute renal failure with Coombs positive hemolytic anemia, thrombocytopenia, high fibrinogen, high PT/PTT, low ADAMTS13 activity (15%) and ADAMTS13 inhibitor. Further workup showed sigmoid diverticulitis with a large intra-abdominal and small intrahepatic abscess which was culture positive for *Streptococcus anginosus* (an oral microbe with proclivity to abscess formation) and *Escherichia coli*. Shiga toxin was not tested. Kidney biopsy revealed acute TMA. Drainage of the abscess and treatment with antibiotics resolved the systemic features of TMA. Renal recovery was protracted and the patient required dialysis for three months, with a last sCr of ~2mg/dl.

Discussion: Infection mediated TMA is an important third subgroup of thrombotic microangiopathy. The mechanism of injury is likely due to the concerted effort of both bacteria. *E.coli* produced shiga toxin causes direct damage to the endothelial cells, worsened by the incorporation of non-human sialic acid from dairy and meat, increasing toxin affinity to endothelial cells and injury. *S.anginosus* produces an exotoxin that can lyse erythrocytes and platelets allowing IgM binding to the exposed Tn antigen, leading to the coombs positivity observed. There is decreased hepatic synthesis of ADAMTS13 in sepsis, and ADAMTS13 autoantibodies are reported in *Ecoli* mediated TMA. Given high fatality rate, prompt recognition and treatment of the underlying infection is pivotal as ongoing infection propagates microangiopathy. Severe features of TMA can develop during the clinical course necessitating intensive treatments such as plasmapheresis. As infection can be a frequent trigger of TMA among patients with complement abnormalities, patients should undergo genetic testing of the regulatory genes involved in the complement system.

PO1552

Characteristics and Outcomes of Immune-Complex Membranoproliferative Glomerulonephritis and C3 Glomerulonephritis in Japan: A Retrospective Analysis of Data from the Japan Renal Biopsy Registry

Naoki Nakagawa,[1] Sawako Kato,[2] Shoichi Maruyama,[2] Ichiei Narita,[3] Yoshitaka Isaka.[4] Committee for Renal Biopsy and Disease Registry of the Japanese Society of Nephrology *[1]Asahikawa Ika Daigaku, Asahikawa, Japan; [2]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [3]Niigata Daigaku Igakubu Igakuka Daigakuin Ishigaku Sogo Kenkyuka, Niigata, Japan; [4]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan*.

Background: The reclassification of membranoproliferative glomerulonephritis (MPGN) into immune-complex mediated MPGN (IC-MPGN) and C3 glomerulopathy (C3G) based on immunofluorescence findings in kidney biopsies has provided insights into two distinct diseases. C3G is further classified into dense deposit disease and C3 glomerulonephritis (C3GN) based on electron micrographic findings. Although these diseases have poor outcomes, limited Japanese literature confined to small, single-center cohorts exist on these diseases.

Methods: We retrospectively analyzed 81 patients with MPGN type I and III from 15 hospitals in the Japan Renal Biopsy Registry (J-RBR) to compare demographic, clinical characteristics and treatment outcomes of patients with IC-MPGN to those with C3GN.

Results: Of the 81 patients reviewed by immunofluorescence findings in kidney biopsies, 67 patients had IC-MPGN and 14 patients had C3GN. Age at diagnosis, systolic and diastolic pressures, proteinuria, impaired renal function, and hypoalbuminemia were significantly higher in patients with IC-MPGN than in those with C3GN. About 80% of the patients in both groups were treated with immunosuppressive therapy. At last follow-up (median 4.8 years), complete remission rate of proteinuria was significantly higher in patients with C3GN (64.3%) than in those with IC-MPGN (29.9%; P = 0.015). The renal survival rate was lower in patients with IC-MPGN when compared to C3GN (73.1% vs. 100%; log-rank, P = 0.031). Systolic blood pressure and renal function at baseline were independent predictors of progression to end-stage kidney disease.

Conclusions: The overall prognosis of patients with C3GN is more favorable than for patients with IC-MPGN.

Funding: Government Support - Non-U.S.

PO1553

Early Recurrence of C3 Glomerulopathy (C3G) in the Allograft

Yonatan A. Peleg, Shelief Robbins-Juarez, Jae Hyung Chang, Russell J. Crew, David J. Cohen, Geoffrey K. Dube, Syed A. Husain, Sumit Mohan, Heather K. Morris, Ibrahim Batal, Andrew S. Bomback. *Columbia University Irving Medical Center, New York, NY*.

Background: C3G encompasses both C3 glomerulonephritis (C3GN) and Dense Deposit Disease (DDD), a rare group of kidney diseases associated with alternative complement pathway dysregulation that commonly recurs in the allograft. How early recurrence occurs is underexplored.

Methods: We reviewed cases of recurrent C3G in the allograft at CUIMC. Protocol biopsies were encouraged for transplanted C3G patients (PTS) at 6 months if a for-cause biopsy (bx) had not already been performed. Median (range) reported.

Results: 13 PTS (9 C3GN, 4 DDD) were included (**Table 1).** 6 PTS (46%) had previous allografts fail due to C3G recurrence. Age at transplant was 32 years (18-71). Time from transplant to histologic recurrence was 54 days (5-472). 4 PTS (31%) had bland urine at first recurrence. 7 PTS (54%) had histologic recurrence at first allograft bx, 15 days (5-56) after transplant. After 2.3 years (0.33-10.1), 11 PTS (85%) remained with functioning allografts; 5 PTS (46%) had creatinine > 2 mg/dl. 2 DDD PTS had allograft failure. 6 PTS (43%) had acute T cell mediated rejection. 2 PTS received eculizumab-both were without clinical recurrence.

Conclusions: This series highlights earlier histologic recurrence of C3G in the allograft than previously reported, partly due to protocol bx. Many PTS were without urinary abnormalities. At last follow up, majority of PTS had significant transplant CKD and 2 lost their allografts. Future study is needed to better understand if early detection of recurrence, coupled with anti-complement therapies, improves outcomes.

Summary of Clinicopathologic Course After Histologic Recurrence

Patient ID	Transplant Type	Native Disease	Days to Histologic Recurrence	Protocol vs For Cause	Immunosuppression at Histologic Recurrence	Serum Creatinine (SCR) at Biopsy (mg/dl)	LM Findings at First Recurrence	Most Severe LM Findings on Follow Up	Most Severe Rejection on Follow Up	Allograft outcome	Eculizumab at last follow up	Follow Up Time OR Time to Allograft Failure (Years)
1	DDKT	DDD	24	For Cause	Tacrolimus, IVIG, Mycfortic	2.0	Mild Mesangial Proliferative	Mild Mesangial Proliferative	3A ACR	SCR 2.2, No hematuria, No proteinuria	Yes	3.2

PO1554

C3 Glomerulopathy in Children and Adolescents

Yael Borovitz,[1] Hadas Alfandary,[1,2] Amit Dagan,[1,2] Orly Haskin,[1,2] Daniel Landau,[1,2] Miriam Davidovits.[1,2] *[1]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel*.

Background: C3 glomerulopathy (C3G) has been classified as a glomerular complement mediated disease with predominant C3 deposits almost a decade ago. Data regarding clinical course, treatment options and long term prognosis in children and adolescents is still scarce. The aim of the study was to retrospectively describe a single tertiary center's experience with C3G in the pediatric population, and correlate presentation, pathology, complement findings, response to treatment and disease prognosis.

Methods: A retrospective cohort study. Patients presented with C3G by the age of 18 years compromised the study group. All cases underwent kidney biopsy at presentation. Repeated kidney biopsy was performed on a need basis, in native or transplanted kidneys. Definition of C3G was based on the 2013 consensus guidelines. Patients underwent complement workup and genetic tests. Treatment regimen was not uniform.

Results: 17 patients were diagnosed with C3 glomerulopathy. Features of Dense deposit disease (DDD) were found in 8 patients, C3 glomerulonephritis in 6 patients. For 3 patients EM was not available. Mean age at diagnosis was 12.7 years (range 1.9 – 17.3). 6 girls and 11 boys. Median follow up 4.4 years (range 1.1-20.9). Treatment modalities ranged from ACE inhibitors and Angiotensin receptor blockers to corticosteroids, Mycophenolate Mofetil, Plasmapheresis, Rituximab and Eculizumab. Only 2 (12%) patients achieved complete remission. 4 (23%) patients reached end stage renal failure and had kidney transplantation. All of them had disease recurrence in the transplanted kidney. Complement workup was positive for C3Nef in 6 patients, C4Nef in 2 patients, C5Nef in 2 patients, factor H antibodies in 2 patients. Genetic testing was positive in one patient. Elevated creatinine at presentation, severe proteinuria, DDD in kidney biopsy– were correlated with worse prognosis.

Conclusions: Understanding the pathophysiology of C3G as a complement mediated disease has progressed during the past years. Still no guidelines exist regarding treatment and prognosis in the pediatric population. Our cohort presented a wide variability in disease course and presentation. Further understanding of the correlation between exact complement abnormality and C3G prognosis is warranted, especially now when new complement system blockers may become available.

PO1555

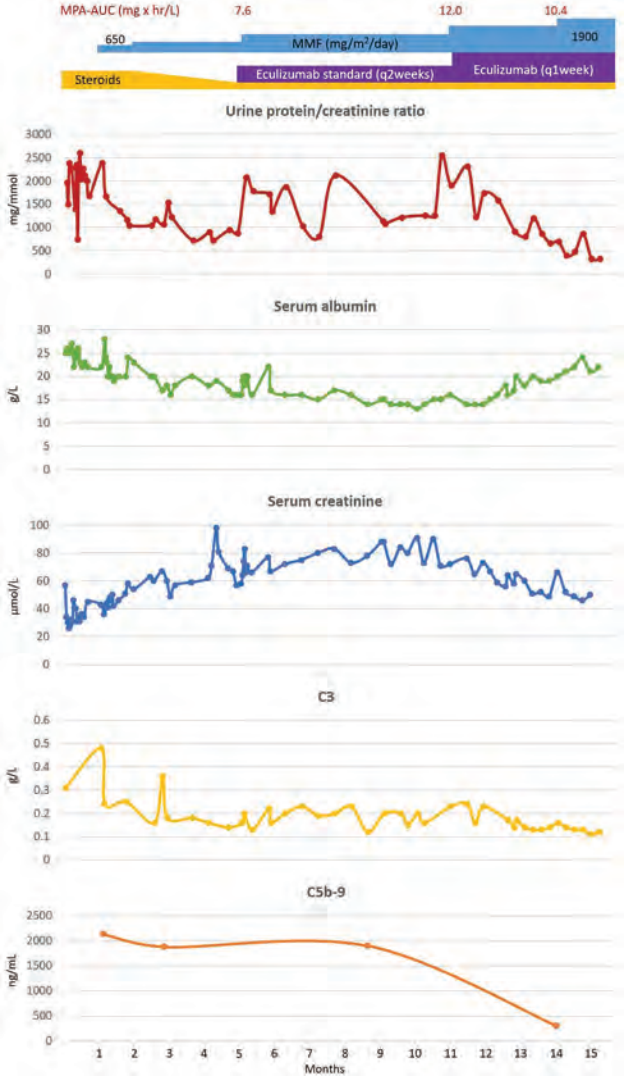
Utilizing Pharmacokinetic Studies to Optimize Therapy in a Child with C3 Glomerulonephritis and Nephrotic Syndrome: A Precision Medicine Approach

Magdalena Riedl Khursigara, Damien G. Noone, Seetha Radhakrishnan, James A. Tjon, Rose Chami, Rulan S. Parekh, Valerie Langlois, Christoph Licht, Chia Wei Teoh. *The Hospital for Sick Children, Toronto, ON, Canada.*

Introduction: C3 glomerulonephritis (C3GN) is caused by complement alternative pathway dysregulation, has no definitive treatment and is characterized by progression to ESRD. Terminal complement blockade has successfully been used especially in patients with elevated C5b-9 levels.

Case Description: We describe a 6 year old boy with C3GN, who presented with nephrotic syndrome, severe hypertension (4 anti-hypertensive medications) and acute kidney injury. Complement C3 level was 0.12 g/L (normal 0.8-1.5) with pos C3NeF and elevated C5b-9 levels (2135, normal <239ng/ml). Despite 6 months of treatment with steroid and MMF, he had ongoing nephrotic syndrome and worsening kidney function. He commenced on standard Eculizumab dosing. Despite 6 months of therapy, he had persistent severe hypertension, nephrotic syndrome requiring weekly albumin/furosemide infusions and worsening kidney function. Complement C3 levels remained low with elevated C5b-9 levels, suggesting sub-optimal terminal complement inhibition due to urinary loss. We confirmed sub-therapeutic plasma concentrations of eculizumab as free plasma eculizumab levels were low on day 7 (9, normal >99 ug/ml) and undetectable on days 10 and 14 post-infusion. Eculizumab frequency was subsequently increased to weekly with MPA-AUC guided adjustment of MMF dosing. Since then, his kidney function, C5b-9 levels (297ng/ml) and nephrotic syndrome improved significantly, leading to discontinuation of albumin/furosemide and anti-hypertensive medications.

Discussion: Use of pharmacokinetic studies can aid in individualized eculizumab treatment in C3GN patients with ongoing proteinuria and who failed to respond to standard dosing.



PO1556

Remission of C3 Glomerulonephritis with Rituximab

Akilandanayaki Angamuthu, Fatima Batool, Neethu Gopisetti, Imara Dissanayake, Ji Young Shin. *Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: C3 glomerulonephritis (C3GN) is rare form of glomerulonephritis. It is diagnosed primarily by kidney biopsy with immunofluoroscence showing deposits of C3 along the basement membranes. It differs from dense deposit disease with absence of the pathognomonic deposits on electron microscopy (1). There are no radomized trials to guide therapeutic decisions. Spontaneous and treatment-associated complete remissions are rare.

Case Description: 69-year-old female with history of well controlled hypertension on amlodipine was sent to hospital with elevated creatinine of 2.52 (unknown baseline) with positive ANA - 1:320 titer. Patient was asymptomatic with negative family history of kidney disease. She denied taking NSAIDs. Serum creatinine on admission was 3.05 mg/dl. Urinalysis showed numerous RBCs with 2 g of proteinuria in the 24-hour urine collection. P- ANCA was positive. All other pertinent serologies were negative including complements, C- ANCA, MPO, PR3. Renal ultrasound revealed medical renal disease. Renal biopsy was performed and preliminary reports showed crescentic glomerulonephritis. Pulse dose steroids was started followed by oral prednisone. In addition, Rituximab was started weekly. Final biopsy confirmed C3GN. Patient did not require dialysis and renal function significantly improved after 4 doses of rituximab to serum creatinine of 1.5 mg/dl.

Discussion: In C3GN with rapidly progressive glomerulonephritis (crescents on biopsy), treatment is not well established. Most patients are treated with steroids in combination with either cyclophosphamide or Mycophenolate mofetil (2). Rituximab was used in some case reports (3). In our patient, since P-ANCA was positive and preliminary biopsy showed crescents, Rituximab was started immediately after pulse dose steroids. Patient did not require dialysis, due to good response and remission. Rituximab is a promising treatment option for C3GN. PO1557

Myeloperoxidase Immunohistochemical Staining and Response to Eculizumab in a Pediatric Patient with Dense Deposit Disease

Neal B. Blatt, Larysa T. Wickman, Ping L. Zhang. *Beaumont Health, Royal Oak, MI.*

Introduction: Previous studies have demonstrated residual complement mediated deposits in repeat renal biopsies of patients with C3 glomerulopathies (Dense deposit disease (DDD) and C3 glomerulonephritis) following eculizumab treatment despite clinical improvement. With the residual complement deposition, it is often difficult to determine whether there is a reduced complement mediated endothelial cell injury. Herein, we report the use of myeloperoxidase (MPO) immunohistochemical staining to show decreased glomerular endothelial cell injury in a pediatric patient with DDD on chronic eculizumab therapy.

Case Description: Our patient was diagnosed with DDD by renal biopsy when he was 5 years old after presenting with a serum creatinine of 5.2 mg/dL, a urine protein to creatinine ratio of 2.5, and a complement C3 level of 50 mg/dL. Functional complement testing showed the presence of C3 and C5 nephritic factors. He was treated with eculizumab (600 mg every 2 weeks) and azathioprine, and over the course of 6 months, his serum creatinine, proteinuria, and complement C3 levels returned to normal. After weaning the frequency of his eculizumab infusions, he experienced a flare of DDD 15 months after initial presentation with a serum creatinine of 3.6 mg/dL, urine protein to creatinine ratio of 7, and complement C3 level of 76 mg/dL. He was re-dosed with eculizumab (600 mg every 2 weeks) with a rapid response to treatment. He had normalization of his serum creatinine to pre-flare levels within 6 months. Since then he has been maintained on eculizumab infusions (600 mg every 4 weeks) along with mycophenolate mofetil. A second kidney biopsy was performed after 3 years of treatment with eculizmab to evaluate response to treatment. The biopsy showed some residual features of dense deposit disease including C3 complement deposition. To evaluate if eculizumab blocked complement mediated injury on glomerular endothelial cells, MPO staining of his initial and repeat biopsy was performed: his initial biopsy revealed diffuse endothelial staining for MPO along glomerular endothelium and the repeat biopsy showed either no MPO staining or weak MPO staining in the glomerular endothelium.

Discussion: In this case, we find that MPO immunohistochemical staining may be useful for monitoring the response to complement blockade in patients with DDD.

PO1558

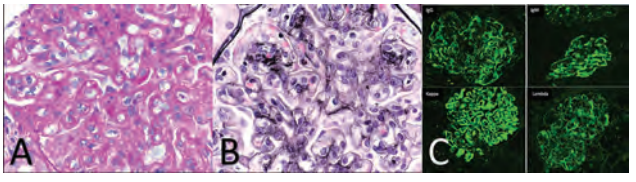
Pregnancy-Associated Membranoproliferative Glomerulonephritis (MPGN)

Pamela C. Vasquez Buitron,[1] Saeed K. Shaffi,[1] Zhi Xu,[1] Michael B. Kuperman,[2] J Pedro Teixeira.[1] *[1]University of New Mexico School of Medicine, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Nephrotic syndrome (NS) in pregnancy is rarely due to MPGN. We present a case of MPGN in pregnancy for which no other cause was found.

Case Description: A 33-year-old G1P0 woman develops hypertension and proteinuria at 12 weeks gestation followed at 21 weeks by NS (7.5g/24h proteinuria, albumin 1.1 g/dL), AKI with creatinine (Cr) 1.1 mg/dL (up from 0.6), hematuria, and mildly elevated AST and ALT. C4 is low (5.9 mg/dL). SPEP and UPEP detect monoclonal IgG kappa with serum light chain ratio 5.1. ANA, anti-dsDNA, cryoglobulins, C3 nephritic factor, and serologies for hepatitis B and C, *T. pallidum*, and HIV are negative. Renal biopsy [figure] reveals MPGN. After counseling, she opts to end the pregnancy. Cr, AST, ALT, and hematuria rapidly normalize, but the proteinuria at first persists. Immunosuppression is offered, but she declines. The proteinuria slowly falls to <0.7 g/g Cr with supportive care and telmisartan over a year. Apart from low C4, an atypical hemolytic uremic syndrome (aHUS) panel is negative. Genetic testing for aHUS is also negative (heterozygous mutation in DGKE and heterozygous deletion in CFH R1-CFH R3). HLA analysis shows B35 and B51 alleles. C4d staining later performed on the biopsy is strongly positive.

Discussion: As in this case, NS in pregnancy is associated with an increased risk of complications such as superimposed preeclampsia. The etiology of this MPGN case is unknown, with no clear infectious or autoimmune cause. The C4d deposition and negative aHUS testing suggest a defect in the classic complement pathway. The paraprotein may or may not be involved as, though the immune complex deposition was polyclonal, monoclonal IgG-kappa has been rarely reported to activate complement in other autoimmune disorders. Regardless of mechanism, we speculate this MPGN case was triggered by pregnancy as it improved after the pregnancy with supportive care alone.



Biopsy yielded 20 glomeruli, with mesangial and endocapillary hypercellularity (A, PAS stain), mild tubular injury, and minimal fibrosis/glomerular sclerosis. Silver stain (B) showed diffusely thickened capillary walls with double contours. IF (C) was positive for IgG, IgM, kappa, and lambda.

PO1559

Comparing and Contrasting Glomerular Disease Patients: A Real-World Analysis Showing Demographic, Clinical, and Treatment Differences Across More Than 1,000 Patients

Tucker B. Hurtado, Ryan Rex, Jennifer Robinson. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: One-half of nephrologists selected glomerular diseases as their leading area of interest in nephrology in 2020. These rare and often-idiopathic disorders are seen as particularly challenging to manage, but an influx of promising pipeline drugs may offer new treatment options in the not-so-distant future.

Methods: 1,112 glomerular disease patient records were collected in collaboration with 290 US nephrologists via HIPAA-compliant, online chart review tool between December 20, 2020 – February 16, 2021.

Results: Chart audits reveal ~8% of nephrologists' patient populations have a glomerular disorder. Of that group, 26% have IgAN, 26% have FSGS, and 3% have Alport's Syndrome, among other conditions. IgAN patients are typically middle-aged, white males, in the middle-to-upper class and often present with hypertension, hyperlipidemia, and/or obesity. FSGS patients are mostly middle-aged, black males, in the lower-to-middle class and often present with hypertension, hyperlipidemia, obesity, and/or edema. Alport Syndrome patients tend to be younger (18-49), white males, in the lower-to-middle class and present with hypertension, hearing loss, and sometimes ocular abnormalities. Of the three conditions, FSGS patients are most heavily prescribed steroids and advanced therapeutics like MMFs, cyclophosphamide, and Acthar Gel and are least likely to be deemed "optimally managed" by their nephrologist. Alport patients are much less likely to receive steroids and are most likely to be seen as optimally managed. Interestingly, despite the value of ACEi/ARB therapy, 42% of IgAN patients were not on therapy at referral, with FSGS and Alport close behind. Nephrologists are trialing SGLT2is across conditions, with up to one-in-ten patients currently on the drug. A diagnosis for Alport Syndrome may take several months or even years after referral to determine (unlike IgAN and FSGS where it usually takes under four months). Alport is also the least likely of the three diseases to be diagnosed via kidney biopsy. Patient referrals are often deemed "late" by nephrologists, but particularly with the faster-progressing FSGS and IgAN.

Conclusions: Deeper understanding of key comparative differences among rare glomerular diseases may aid physicians in developing strategies for diagnosis and treatment.

PO1560

Glomerular Diseases in Flanders: Overview of the FCGG Biopsy Registry

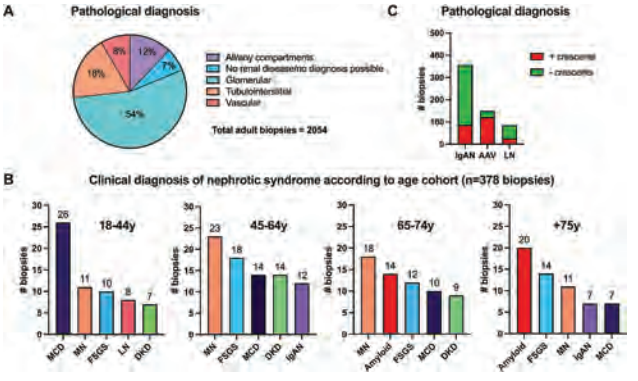
Dries Deleersnijder,[1] Wim Laurens,[2] Johan M. De Meester,[2] Amélie Dendooven,[3] Ben Sprangers.[1] *[1]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [2]AZ Nikolaas, Sint-Niklaas, Belgium; [3]Universitair Ziekenhuis Gent, Gent, Belgium.*

Background: High-quality population-based registries on glomerular diseases are required for epidemiological study and new trial design. The FCGG (Flemish Collaborative Glomerulonephritis Group) database is a population-based registry that has been including data on all native kidney biopsies performed in Flanders since 2017 (Northern part of Belgium) covering a population of approximately 6.5 million inhabitants.

Methods: Clinical data and nephrological diagnosis according to the ERA-EDTA Coding system for Primary Renal Disease are collected together with pathological data including primary and secondary pathological diagnoses according to the Mayo Clinic/Renal Pathology Society Consensus Guideline 2016. Here, we describe the main results of the first three years of the registry.

Results: From 2017 until 2019, 2178 biopsies were included, of which 5.7% were performed in the pediatric population. Median age (IQR) was 59 years (42-71). Biopsy incidence proportion was 130 biopsies p.m.p. per year in the adult population. Glomerular disease was present in 54% of the adult biopsies (Fig. 1A). IgA-nephropathy (IgAN) was the most frequently diagnosed disease in adults (17.3% of total, 30.2% of glomerular subcategory). The etiologies of the nephrotic syndrome differed across age categories, with membranous nephropathy (MN) being most frequently diagnosed in the total group of adult nephrotic patients (Fig. 1B). IgAN and pauci-immune glomerulonephritis (AAV) were the two most important causes of the nephritic syndrome in adults. A crescentic pattern of injury was most frequently diagnosed in adults with AAV, lupus nephritis (LN) and IgAN (Fig. 1C, crescents in 82%, 31% and 24% of biopsies, respectively).

Conclusions: The FCGG database is a valuable population-based registry that characterizes the epidemiology of glomerular disease in Flanders. These results are relevant to the clinician, will enable disease subgroup analyses and are useful to set up observational or interventional trials in patients with glomerular disease.



PO1561

CureGN Pediatric Glomerulopathy: Identifying Pathologic Molecular Signatures in Glomerulopathy with Quantitative Proteomics

Timothy Cummins,[1] Michael Merchant,[1] Laura H. Mariani,[3] Wimal Pathmasiri,[4] Susan J. Sumner,[4] William E. Smoyer,[5,6] Jon B. Klein.[2,1] *[1]Kidney Disease Program and Clinical Proteomics Center, University of Louisville School of Medicine, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY; [3]University of Michigan School of Medicine, Division of Nephrology, Ann Arbor, MI; [4]University of North Carolina at Chapel Hill Nutrition Research Institute, Kannapolis, NC; [5]Nationwide Children's Hospital, Columbus, OH; [6]The Ohio State University, Columbus, OH.*

Background: Glomerular disease is a leading cause of end stage kidney disease with related treatment costs placing a significant burden on healthcare systems worldwide. Immunosuppressive glucocorticoids are a primary therapeutic approach yet can be ineffective in nearly 50% of patients. In this study we tested the hypothesis that the pediatric urinary proteome would contain unique protein signature that predict treatment response vs. resistance in glomerular diseases.

Methods: We performed proteomic analyses of serial clinically, histologically phenotyped and biopsy-confirmed pediatric urine samples from children with 3 glomerulopathies (MCD, FSGS and IgAN) to identify putative mechanistic differences between glomerular disease pathology and treatment responsiveness. 434 patient urine samples were analyzed by LC-MS/MS, and subsequently 1119 unique proteins were identified using MaxQuant and Scaffold-5 Q+ applying strict FDR (1%) with 2 peptide identification required. Protein lists were analyzed by clinical category (urine protein) using MetaboAnalyst 5.0 to perform univariate and multivariate statistical analysis, volcano plot, and heatmap visualization of protein clusters.

Results: Our analysis indicates specific and unique protein/molecular signatures separating MCD, FSGS and IgAN with respect to disease status and pathological diagnosis. Univariate analysis indicated that at least 62 proteins were significantly different in complete remission vs. proteinuric patients across all pathologies. Multivariate analysis showed significant contributions by several proteins to identify disease state and pathology. Heatmap analysis identified protein signatures that are differentially abundant across the 3 distinct glomerulopathies.

Conclusions: Pediatric glomerular disease and disease activity are associated with unique urine proteomes and if confirmed will lead to further identification of important biomarkers. We are currently performing validation of a subset of proteins as biomarkers to determine if they are diagnostic and predictive of treatment response.

The Thromboembolism Among Hospitalized Patients with Different Types of Chronic Glomerulonephritis: A Retrospective Study Spanning 18 Years from a Single Tertiary Hospital

Xiaohong Fan, Jie Ma, Xuemei Li. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Chronic kidney disease is associated with hypercoagulability and platelet dysfunction. However, data on thromboembolism associating different types of chronic glomerulonephritis (CGN) are less.

Methods: We conducted a retrospective analysis using the database of hospitalization with CGN in Peking Union Medical College Hospital (PUMCH), China from 2000 through 2017. The tenth revision from the International Classification of Diseases (ICD-10) codes of discharge diagnosis was used to identify types of thromboembolism and 6 kinds of glomerulonephritis including lupus nephritis (LN), systemic vasculitis (AAV), Henoch-Schönlein purpura nephritis (HSPN), IgA nephritis (IgAN), idiopathic membrane nephropathy (IMN), minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS). Cochran-Armitage trend test and Logistic regression were used for analysis.

Results: Between 2000 and 2017, there were 15,714 hospitalizations with the aforementioned CGN. Their mean age was 51.7±19.8 years and 39.4% were males. The annual prevalence of overall thromboembolism increased steadily from 1.6% in 2000 to 6.6% in 2017 in a dose-response manner (p for trend <0.001). Among all thromboembolism cases, 49.8% had venous thromboembolism and 31.7% had a pulmonary embolism. The prevalence of thromboembolism in IgAN, FSGS, MCD, IMN, HSPN, LN, and AAV were 0.6%, 2.4%, 2.6%, 5.89%, 2.2%, 4.4%, and 5.3%, respectively. The patients with thromboembolism had a 2.30-fold increased risk of death (95%CI 1.53-3.46) after adjustment for age and gender. In multivariate analyses adjusted for multiple confounders such as gender, hypertension, diabetes, cardiovascular disease, cerebrovascular disease, heart failure, chronic obstructive pulmonary disease, infection, LN (OR 8.15; 95% CI 5.25-12.65), IMN (OR 6.93; 95% CI 4.39-10.92), AAV (OR 4.53; 95% CI 2.66-7.72), MCD (OR 4.42; 95% CI 2.56-7.61), HSPN (OR 4.05; 95% CI 2.33-7.03), and FSGS (OR 3.18; 95% CI 1.56-6.49) were significantly associated with the increased risk of thromboembolism compared with IgAN.

Conclusions: In the present study, chronic glomerulonephritis, particularly lupus nephritis, idiopathic membrane nephropathy, and systemic vasculitis were independently associated with an increased risk of thromboembolism.

PO1563

Identification and Validation of Infection-Related Acute Care Events in Patients with Glomerular Disease

Dorey A. Glenn,[1] Jarcy Zee,[2] Anisha R. Hegde,[1] Candace D. Henderson,[1] Michelle M. O'Shaughnessy,[7] Andrew S. Bomback,[3] Keisha L. Gibson,[1] Larry A. Greenbaum,[5,6] Sarah Mansfield,[8] Yichun Hu,[1] Laura H. Mariani,[4] Ronald J. Falk,[1] Susan L. Hogan,[1] Michelle Denburg,[9] Amy K. Mottl.[1] *[1]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Columbia University, New York, NY; [4]University of Michigan, Ann Arbor, MI; [5]Children's Healthcare of Atlanta Inc, Atlanta, GA; [6]Emory University School of Medicine, Atlanta, GA; [7]University College Cork, Cork, Ireland; [8]Arbor Research Collaborative for Health, Ann Arbor, MI; [9]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Infections are an important contributor to morbidity and mortality in glomerular disease (GD). Accurate identification of infections using real world clinical data would support the conduct of observational studies examining infection risk, but standard approaches are labor-intensive. We sought to derive and test the validity of diagnosis-code based algorithms to identify infection-related acute care events (ACEs) within a large cohort of children and adults with GD.

Methods: CureGN is a prospective multi-center cohort study of patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, or IgA Nephropathy. We describe the sensitivity, specificity, and positive and negative predictive values (PPV/NPV) of four infection diagnosis code lists using manually curated infectious and non-infectious ACEs (hospitalization or emergency department visit) as the gold standard. We then validate the best performing code list within a more contemporary CureGN cohort, using multi-site adjudication of medical records.

Results: In the development phase, the optimal performing combination of diagnosis codes were those used by CureGN coordinators combined with those described by Sahli et al. (PPV 78%, 95% CI 73-83%) (Table 1). Using this code list, 265 infectious and 1231 non-infectious ACEs were identified among 2599 CureGN participants in the validation phase, of which 124 were randomly selected and adjudicated. The PPV and NPV for the final code set were 87% (95% CI: 75-99%) and 83% (95% CI: 72-93%) respectively.

Conclusions: Diagnosis codes can be used to accurately identify infection-related ACEs among patients with GD. Future studies should validate our findings in other GD cohorts and for specific infection types of high-severity or burden.

Patients with Glomerular Disease Are at Very High Risk of TB Infection Compared to the General Population

Heather M. Gunning,[1] Mark Canney,[1,2] Yuyan Zheng,[1] Jonathan Hogan,[3] Sean Barbour.[1,4] *[1]BC Provincial Renal Agency, Vancouver, BC, Canada; [2]Department of Medicine, University of Ottawa and the Ottawa Hospital Research Institute, Ottawa, ON, Canada; [3]Division of Nephrology, University of Pennsylvania, Philadelphia, PA; [4]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada.*

Background: Advanced kidney disease is a known risk factor for active TB disease; however this risk has not been studied in patients with glomerular disease (GN). We sought to determine the incidence of TB disease in patients with GN and to explore the risk associated with immunosuppression (IS) treatment.

Methods: A population-level cohort was created using a centralized kidney biopsy registry (2000-2012) of all GN cases in British Columbia, Canada: IgA nephropathy (IgAN) n=857, focal segmental glomerulosclerosis (FSGS) n=564, ANCA-GN n=404, lupus nephritis (LN) n=360, membranous nephropathy (MN) n=398, minimal change disease (MCD) n=191, and other GN (n=305). TB disease was ascertained by linkage to administrative databases. High TB incidence was defined as >30/100,000 person years (PY) consistent with the definition used in first-world countries. Incidence rates were standardized to the general population to generate standardized incidence ratios (SIR, 95% CI). Hazard ratios were calculated using Cox proportional hazards regression.

Results: During a median follow-up 6.2 years, there were 41 cases of TB disease. TB incident rate was 197.4/100,000PY, and was higher in patients with LN vs. other types of GN (403.0/100,000PY, p<0.05). TB incidence in patients with GN was 23-fold higher than the general population (SIR 23.4, 16.8-31.7), and was high in both Canadian and foreign-born patients (range 124.1-579.6/100,000PY). TB incidence was higher during periods of IS use (282.4 vs. 147.9 per 100,000PY, p<0.05), and most cases (80.5%) had IS exposure prior to TB diagnosis. Time from IS to TB disease was highly variable, with median 3.9 years but 24% of TB cases occurred within 1 year. Reduced kidney function and higher proteinuria were also associated with increased TB risk (Table).

Conclusions: Patients with GN have a high risk of TB disease, irrespective of GN type or country of origin. TB disease can occur within months of starting IS, suggesting that all GN patients should be screened for latent TB early in their disease course.

The Impact of Obesity on Glomerulonephritis: A Multicenter Cohort Study of Kidney Biopsy over 40 Years

Tae-bum Kim,[1] Hyeon-Jin Min,[1] Young-Bin Son,[1] Jonghyun Lee,[1] Myung-Gyu Kim,[1] Sang-Kyung Jo,[1] Won-Yong Cho,[1] Eun Hui Bae,[2] Jieun Oh,[3] Shin-Young Ahn,[1] Sewon Oh.[1] *[1]Korea University Medical Center, Seoul, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Gwangju, Republic of Korea; [3]Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea.*

Background: Worldwide obesity has increased by almost three times between 1975 and 2020. Many studies reported that obesity related kidney disease was also increasing, and most of them were focal segmental glomerulosclerosis (FSGS). However, little was known about the prevalence and outcome of other type of glomerulonephritis (GN) in obese patients.

Methods: A total of 14,833 adult patients who underwent kidney biopsy and had body mass index (BMI) were identified in 18 tertiary hospitals during 1979-2018. Obesity was defined as BMI≥30 kg/m^2. We analyzed the prevalence of specific forms of glomerulonephritis in obese patients and effect of obesity on mortality and end stage kidney disease (ESKD).

Results: Obese patients in glomerular disease have increased about 12.8-fold over 40 years between 1979-1988 (0.6%) and 2009-2018 (7.7%). In GN patients with obesity, prevalence of IgA nephropathy (IgAN) is the most common (33.7%) followed by FSGS (13.3%), minimal change disease (MCD) (10.8%), membranous nephropathy (10.6%), diabetic nephropathy (DMN)(6.0%), lupus nephritis (LN) (2.7%), and hypertensive nephropathy (HT-N) (2.6%). The prevalence of FSGS (HR 1.60, 95%CI 1.24-2.06), DMN (HR 1.46, 95%CI 1.01-2.12) and HT-N (HR 2.14, 95% CI 1.29-3.54) were significant higher in obese patients compared than non-obese patients. Obesity had a 1.39-fold increased risk for ESKD progression during 93.8±0.8 months follow up in total patients (95%CI 1.11-1.73). Obesity had higher risks for progression of ESKD in MCD (HR 2.48, 95%CI 1.02-6.04) and LN (HR, 3.28, 95% CI 1.30-8.31). In patients with FSGS, DMN, and HT-N, obesity was not associated with ESKD. Obesity was not associated with mortality in GN patients although obesity was related to mortality only in MCD patients (HR 2.48, 95% CI 1.02-6.04).

Conclusions: Obesity rates are increasing in GN patients. The prevalence of FSGS, DMN, and HT-N are significantly higher in obese patients although IgAN is the most common form of GN. Obesity had significant risks for progression of ESKD in patients with GN, especially MCD and LN patients.

PO1566

Obesity at Time of Diagnosis Is Associated with Proteinuria in Glomerular Disease

Evan Zeitler, Yichun Hu, Caroline J. Poulton, Lauren N. Blazek, Amy K. Mottl, Jennifer E. Flythe, Susan L. Hogan. *UNC Kidney Center, Chapel Hill, NC.*

Background: Obesity is an established risk factor for chronic kidney disease (CKD). The relationship between obesity and glomerular disease outcomes is not well studied.

Methods: We evaluated a cohort of adult patients with biopsy-proven IgA nephropathy, focal segmental glomerulosclerosis (FSGS), ANCA-associated vasculitis (ANCA), or membranous nephropathy (MN) between January 2014 and June 2020, with follow up through April 2021. We categorized body mass index (BMI) at time of biopsy as <25 kg/m2, 25 kg/m2≥BMI<30 kg/m2 or ≥30 kg/m2. We used Fisher's exact and Kruskal-Wallis tests to compare baseline characteristics between groups and a proportional hazards model to evaluate factors associated with CKD progression to kidney replacement therapy (KRT). We used the sign rank test to compare Kaplan-Meier curves of KRT-free survival.

Results: The cohort included 153 patients: 77 (50%) male with median age 50 (IQR 38-65) years and median BMI 28 (IQR 24-34) kg/m2. Compared to patients with lower BMIs, patients with BMI >25 kg/m2 had higher median urine protein to creatinine ratios (uPCR) (p=0.02, Table 1). In univariate analyses, factors associated with progression to KRT were: blood pressure (p = 0.01), uPCR (p <0.01), and lower eGFR (p<0.001). BMI at biopsy was not associated with CKD progression, adjusted HRs (95% CIs): BMI 25≥BMI<30 kg/m2 - 1.09 (0.42-2.83); BMI ≥30 kg/m2- 1.54 (0.68-3.52). Logrank p-value for KM curves was 0.004, with paired uPCR values imparting the greatest distinction between curves (data not shown).

Conclusions: Among glomerular disease patients, BMI was associated with proteinuria, but not with progression to KRT.

Funding: NIDDK Support

Baseline Characteristics Across BMI Groups

When to Biopsy Type 2 Diabetes Mellitus (DM2)

Haridian Sosa Barrios,[1,2] Victor Burguera,[1,2] María García,[1,2] Ana Saiz,[1,2] Javier Villacorta Perez,[1,2] Guillermo F. Conde,[1,2] Milagros Fernandez-Lucas,[1,3] Maite Rivera Gorrin.[1,3] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Instituto Ramon y Cajal de Investigacion Sanitaria, Madrid, Spain; [3]Universidad de Alcala de Henares Facultad de Medicina y Ciencias de la Salud, Alcala de Henares, Spain.*

Background: DM2 patients may have diabetic (DN) or non-diabetic renal disease (NDRD) and a histological diagnosis is needed. There is no clear consensus on when to biopsy, but a predictive model was recently published(1).

Methods: Aim: Assess NDRD prevalence, histology and apply the predictive score in our cohort. **Methods**: Retrospective analysis of native kidney (NK) biopsies performed in our center from 2016 to 2020. Data collected included DM history, retinopathy, peripheral vascular disease (PVD), insulin prescription, proteinuria, BMI and hematuria >10 cells/HPF. A score >3 was highly suggestive of DN and would preclude renal biopsy (RB).

Results: 62 of 274 NK RB's had DM, 66.1% males with a mean age of 64±13.7 (range 23-83). Mean estimated glomerular filtration rate (MDRD4) was 41.4±26.5 ml/min/1.73m^2 (range 6-98) with mean BMI 27.9 (range 18-41). Mean proteinuria was 4453 mg/g (range 4-36249) and 51.6% had microhematuria. 51.6% had a DM history >10 and 28.3% < 5 years since diagnosis. 82.3% did not have retinopathy, 11.3% had neuropathy and 48.4% were on insulin. 27.4% had PVD, 6.5 % ischaemic cardiomyopathy (ICD) and 3 had a previous stroke. RB indications: 21 nephrotic syndrome, 2 nephritic syndrome, 6 proteinuria-hematuria, 18 non nephrotic proteinuria, 7 renal impairment and 8 AKI. Histology: 22 had DN (38.6%), 35 NDRD (61.4%) and insufficient in 5. NDRD included crescentic glomerulonephritis, membranous, FSGS, chronic tubulointertitial nephritis, ATN, IgA GN, minimal change, amyloid, hiperfiltration, glomerular sclerosis and chronic inespecific lesions. Longstanding DM (>10 y), retinopathy, neuropathy and PVD were independent predictors of DN (p value 0.02, 0.01, 0.001 and 0.001). Neither hematuria, nephrotic range proteinuria nor ICD were significant. Score: Patients with a score>3 had DN except 2 (oxalate crystals and cast nephropathy). 70.2% with a score<3 had NDRD and 84% of those with <1 did not have DN.

Conclusions: 61.4% do not have DN and NDRD is underdiagnosed. The score had excellent correlation with DN and could be efficient on RB decision making process in these patients. Validation in multicentric studies is desirable. 1.García-Martín F. et al. When to perform renal biopsy in patients with type 2 diabetes mellitus? Predictive model of non-diabetic renal disease. 10.1016/j.nefro.2019.07.005

PO1568

Year of Life Lost due to Premature Death from Glomerulonephritis in Thailand

Chitimaporn Janphram, Suchin Worawichawong, Sarinya Boongird, Umaporn Udomsubpayakul, Montira Assanatham, Chagriya Kitiyakara. *Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: The contribution of Glomerulonephritis (GN) on mortality is not fully known. The impact of each GN subtype on premature mortality can be measured by calculating the year of life lost (YLL), which takes into account the age at which deaths occur. Therefore, this study aimed to estimate premature mortality in GN using the average YLL.

Methods: In this retrospective study, we estimated the average YLL in each glomerular disease. The YLL is the difference between age at death and the standard life expectancy of an individual at the same age. To calculate YLL, we retrieved data from Ramathibodi Hospital Glomerular Registry during January 2011 to December 2020 and national data of standard life expectancy 2020. Individual deaths and date were obtained from the National Death Registry office. The average YLL is obtained by dividing total YLL by the total patients in each GN type. GN were categorized into primary GN (IgA nephropathy (IgAN), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MGN) and minimal change disease (MCD)), and secondary GN (lupus nephritis(LN), ANCA-GN, infection related GN (iGN) or MPGN, and diabetic nephropathy (DN).

Results: A total of 1,022-kidney biopsies was performed. The median follow-up time was 67 (IQR 45, 92) months. Age for GN patients was 43.9 ± 16.7 years and 44.8 % males. The total and average YLL of all GN were 4741.9 years and 4.64 years, respectively. The average YLL for secondary GN (n = 391) was higher than primary GN (n = 469) being 7.31 vs 2.23 years ($p < 0.05$). DN (n= 97) had average YLL at 9.76 years followed by LN (n = 243) at 7.1 years. The average YLL (years) for primary GN were: FSGS (n=125), 2.52 years; MGN (n=106), 2.32; IgAN (n=164), 2.26; and MCD (n=74) 1.57.

Conclusions: GN causes premature mortality with secondary GN being associated with higher premature death than primary GN. DN and Lupus nephritis have the highest YLL. This study provides useful information on the impact of GN for prioritization of public health policies intervention.

PO1569

The Significance of Hematuria in Primary Proteinuric Glomerular Disease Outcomes

Dorota Marchel,[1] Maria Larkina,[1] Damian Fermin,[1] Jennifer Lai Yee,[1] Debbie S. Gipson,[1] Andrew S. Bomback,[2] Pietro A. Canetta,[2] Amy K. Mottl,[3] Rulan S. Parekh,[6] Manish K. Saha,[3] Matt G. Sampson,[4] Howard Trachtman,[5] Richard A. Lafayette,[7] Laura H. Mariani.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Columbia University, New York, NY; [3]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [4]Boston Children's Hospital, Boston, MA; [5]NYU Langone Health, New York, NY; [6]The Hospital for Sick Children, Toronto, ON, Canada; [7]Stanford University, Stanford, CA.*

Background: Hematuria is associated with the incidence and progression of CKD. The study aims were to assess the prevalence of hematuria in a large cohort of proteinuric glomerular disease and assess the association between hematuria and kidney-related outcomes.

Methods: Hematuria was assessed at first reported study urinalysis in patients with MN, MCD, and FSGS in NEPTUNE and CureGN cohorts with >24 months of follow-up. Hematuria was defined as small, moderate, or large blood on urinary dipstick and no hematuria was negative or trace blood. Multivariable Cox proportional hazards models were fit for time to composite outcome (ESKD or 40% decline in GFR and eGFR <60) and proteinuria remission (UPCR <0.3 mg/mg).

Results: 1,108 adults and children were included. 412 (37%) patients had FSGS, 389 (36%) had MCD, and 307 (28%) had MN. 745 (67%) participants were positive for hematuria at first urinalysis. Those who had hematuria vs. those without at first urinalysis were more likely to have an underlying diagnosis of MN (37% vs 23%), be older (34 vs 25 years), have shorter time since biopsy (128 vs 315 days) and higher UPCR (3.6 vs 0.8). Patients with hematuria had higher rates of the composite outcome and lower rates of complete remission (Figure 1). After adjusting for diagnosis, age, sex, UPCR, eGFR, time since biopsy, and cohort, hematuria was associated with a higher hazard of reaching the composite outcome (HR 1.39 [1.05, 1.84], p-value 0.02) and lower hazard of reaching proteinuria remission (HR 0.71 [0.55-0.91], p-value 0.006).

Conclusions: Hematuria is prevalent among patients with podocytopathic disease not classically considered nephritic. There was an independent association between hematuria and worse kidney related outcomes. The underlying mechanisms warrants further investigation and include genetic predisposition, structural alterations in the glomerular basement membrane, and tubular toxicity from heme pigment.

Vacuolated Denatured Casts Are a Distinct Type of Urinary Casts Associated with Severe Nephrotic Glomerulopathy

Akanksh Ramanand,[1] José A. Poloni,[2] Abhirup Sarkar,[3] Ana P. Giolo Franz,[4] Juan Carlos Q. Velez.[1] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]Universidade do Vale do Rio dos Sinos, Sao Leopoldo, Brazil; [3]Suraksha Diagnostics, Kolkata, India; [4]Hospital de Clinicas de Passo Fundo, Passo Fundo, Brazil.*

Background: Urinary casts identified through microscopic examination of the urinary sediment (MicrExUrSed) constitute clinically useful elements for the diagnosis of acute and chronic kidney pathologies. Granular, waxy and cellular casts are well characterized. However, a unique type of casts containing non-polarizable lipoid-like granules immersed within a lightly granular cast matrix is occasionally found. These casts have been labeled as vacuolated denatured casts (VDC). The clinical significance of VDC is not known. Herein, we present a case series of patients with specimens containing VDC.

Methods: We utilized an educational social media platform (Twitter) to probe for individual cases of VDC. We surveyed known educators who frequently post microphotographs of MicrExUrSed asking for filed cases of identification of VDC. Demographic and clinical characteristics were extracted and representative images were compiled for correct identification of VDC.

Results: Four urine microscopists (2 from South America, 1 from India, 1 from USA) contributed to the case series. A total of 12 cases were identified. Images were carefully reviewed to confirm identity of VDC. Median age 53 (27-78), 80% men, 50% had type 2 diabetes mellitus. Median serum creatinine at the time of MicrExUrSed was 3.6 (1.7-5.5) mg/dL. All (100%) patients had 3+ protein by urinary dipstick. Urine protein-to-creatinine ratio was in the nephrotic range in all 5 cases with available value [median 10.2 (3.3-11.8) g/g]. Concomitant findings included hematuria (58%), waxy casts (67%), granular casts (80%), fatty casts (42%) and renal tubular epithelial cells (58%). Histopathological diagnosis was available in 10 cases: 3 diabetic glomerulopathy, 3 focal segmental glomerulosclerosis, 2 transplant glomerulopathy, 1 membranous nephropathy and 1 advanced arterionephrosclerosis. Greater than 25% interstitial fibrosis was present in 6/10 (60%) cases.

Conclusions: VDC are a distinct type of casts that can be found in specimens of patients with advanced proteinuric glomerulopathy. The specific origin and composition of these casts remains unknown and requires further study.

PO1571

Detection of Urinary Acanthocytes for the Diagnosis of Glomerulonephritis

Akanksh Ramanand,[1,2] Swetha Rani Kanduri,[1] Vipin Varghese,[1] Sarah P. Rosenbloom,[1] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.*

Background: Acanthocyturia is a specific indicator of glomerulonephritis (GN). However, it is reported that the sensitivity of acanthocyturia for the diagnosis of GN is merely around 50%. Examiner expertise is expected to affect the ability to identify urinary acanthocytes. Thus, we hypothesized that in a well-equipped laboratory with proficient observers, the sensitivity of acanthocyturia for the diagnosis of GN can be improved.

Methods: In our institution, we have established a prospective data collection of individuals seen in nephrology consultation who had urine specimen subjected to microscopic examination (MicrExUrSed) as part of the clinical evaluation. Within this cohort, we identified cases in which a kidney biopsy was performed within 2 weeks of the MicrExUrSed. We assessed the performance of acanthocyturia in the diagnosis of biopsy-proven GN. Acanthocyturia reflects glomerular hematuria caused by forms of glomerular disease characterized by injury to the endothelium, mesangium, glomerular basement membrane or blood vessel, but not injury to the podocyte that classically presents with proteinuria. Therefore, podocytopathies were grouped with other diagnoses (tubular, interstitial, etc.) as non-GN

Results: Among 390 patients with MicrExUrSed, 70 underwent kidney biopsy and were included. Mean age was 55 years, 50% were women. White race accounted for 52% and self-identified black race for 39%. Mean serum creatinine was 4.2 mg/dL. Biopsy diagnosis was GN in 27 (39%) and non-GN in 43 (61%). The sensitivity of acanthocyturia for GN diagnosis was 74% (95% CI 53-89%), while the specificity was 86% (95% CI 72-95%). Five of 6 false positive cases had diabetic nephropathy. The positive predictive value of acanthocyturia for GN diagnosis was 77% (95% CI 61-88%) and the negative predictive value 84% (95% CI 73-91%). Acanthocyturia was predominantly detected in pauci-immune GN and IgA nephropathy, with both diagnoses accounting for 14 of the 19 (74%) cases. The hospital laboratory did not report acanthocyturia in any case and misreported it as "yeast" in 2 cases.

Conclusions: With optimal proficiency, the sensitivity of acanthocyturia can be significantly greater than previously reported. Because hospital laboratories do not report it, attempting identification of urinary acanthocytes by nephrologists should be encouraged.

Feasibility and Acceptability of Home Urinalysis Monitoring Using a Smartphone Application

Daniella Levy Erez,[1,2] Hannah C. Derwick,[1] Susan L. Furth,[1] Lance S. Ballester,[1] Jonah Mink,[3,4] Stephanie Omuemu,[3] Michelle Denburg.[1] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [3]Healthy IO, Tel Aviv, Israel; [4]Ben Gurion University Faculty of Health Sciences, Beer Sheva, Israel.*

Background: Monitoring proteinuria in patients with kidney disease is of crucial importance given its implications for long term disease progression and clinical management. As part of efforts to encourage test adherence, leveraging technology to provide a clinical grade urinalysis result from a home test can greatly enhance the clinical experience for patients, caregivers and providers.

Methods: Children and young adults (5-21 yrs old) at a single pediatric center participated. Caregivers or patients (>12yrs) completed a brief survey and then received a home urinalysis kit by mail. The Healthy.io smartphone app uses advanced computer vision to assess the urinalysis dipstick using the smartphone camera. Families downloaded the app through a text message link and performed a home urine test followed by a survey about their experience. Urine results immediately appeared in the app for patients and accessed by the study team through a secure portal. Patient satisfaction was compared between the new app and current practice (home albustix or a urine sample brought to clinic) using Wilcoxon rank test with a p value <0.05. Free text responses were analyzed to identify themes related to the app experience.

Results: 103 children, 63 (61%) male, median age 10.9 yrs. (IQR 7.8-14.2) were enrolled. Primary diagnosis included: 47 (46%) glomerular disease, 48 (47%) non-glomerular disease and 8 (8%) kidney transplant recipients. 101(98%) patients were satisfied with the smartphone app compared to 41(40%) patients who were satisfied with the current practice P<0.0001. (Table 1) Patients' free text comments were divided into themes in table 2.

Conclusions: The Healthy.io home urine testing app received very high rates of satisfaction among patients and caregivers compared to current practice and holds great potential to enhance patient-centered care.

Proliferative Glomerulonephritis in a Patient with NK Cell Lymphocytosis

Hannah Angle, Jia Yi, Koyal Jain. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) occurs in patients with non-malignant lymphoproliferative disorders who present with kidney injury secondary to monoclonal immunoglobulin deposition.[1] We present a rare case of proliferative glomerulonephritis (PGN) likely due to NK cell lymphocytosis.

Case Description: A 57-year-old male with NK lymphocytosis and HTN presented with progressively worsening oliguric renal failure (creatinine 1.1 to 6.2 mg/dL over 3 months) and elevated lambda free light chains (FLC) with a κ/λ ratio of 0.06 (κ=3.14, λ=52.58). Urine sediment showed numerous dysmorphic RBCs and granular casts. Renal biopsy (limited specimen) revealed PGN with polyclonal-IgG-dominant deposition and background of moderate interstitial fibrosis and tubular atrophy. Although obvious monoclonal lesions were absent and the PGN may have been coincidental, there was concern for a potential paraneoplastic GN induced by NK lymphocytosis or, less likely, MGRS. Thus, patient was treated with Cyclophosphamide-Bortezomib-Dexamethasone (CyBorD). However, due to worsening kidney function patient was started on hemodialysis, hoping for potential renal recovery. Despite significant hematologic response (plasma cell burden <1%), chemotherapy was discontinued after 7 months due to lack of renal improvement and worsening medication side effects.

Discussion: This case suggests a potential rare cause of PGN with polyclonal-IgG-dominant deposition due to NK cell lymphocytosis. This is the first case to describe a potential association between them. Additionally, while the patient did have a hematologic response to the CyBorD, there was no renal recovery. Although the PGN may have been coincidental, CyBorD therapy should have had some effect while treating PGN. This suggests a potentially aggressive form of the disease resulting in end-stage kidney disease within 3 months in our patient. It also brings up the question of whether it was the presence of NK cell lymphocytosis that worsened the renal prognosis. Such cases are extremely difficult to treat and likely have a poor prognosis. Reference: Leung, N., *et al.* The evaluation of monoclonal gammopathy of renal significance: a consensus report of the International Kidney and Monoclonal Gammopathy Research Group. *Nat Rev Nephrol* **15,** 45–59 (2019). https://doi.org/10.1038/s41581-018-0077-4

PO1574

A Sporadic Case of Fibronectin Glomerulopathy in Which Mass Spectrometry Was Indispensable for the Diagnosis

Rie Kunitomo, Takahisa Kawakami, Kiyotaka Nagahama, Satoru Hibino, Kazuhito Fukuoka, Yoshinori Komagata, Shinya Kaname. *Kyorin University, Tokyo, Japan.*

Introduction: Fibronectin glomerulopathy (FG) is an autosomal-dominant hereditary disease, which is caused by deposition of mutated fibronectin (FN). The immunostaining of FN is decisive for the diagnosis. We present a case of FG, in which FN was not detected with immunostaining and the detection of FN with mass spectrometry determined the diagnosis.

Case Description: A 60-year-old female with non-functional right kidney with calculi, 5-year history of proteinuria and 2-year history of hypertension presented with pretibial and palpebral edema. There was no family history of kidney diseases. Physical examination was significant for blood pressure of 176/98 mmHg and the edema. Laboratory test showed serum creatinine of 2.53 mg/dL, serum albumin of 2.3 g/L, urinary protein 5.8 g/day, and slight urinary glomerular RBCs. Anti-nuclear antibody, monoclonal protein, cryoglobulin, HCV, or hypocomplementemia was not detected. Open biopsy was performed. Light microscopy showed lobular glomeruli with mesangial expansion with PAS-positive material. Immunoglobulins, including κ and λ light chains, and complements were not deposited. Electron microscopy showed massive mesangial deposits with fibrillary structure. However, Congo red staining and immunostaining of DNAJB9 and fibronectin (IST-4 and IST-9) were all negative. Finally, the analysis of microdissected glomeruli with liquid chromatography/mass spectrometry (LC/MS) revealed abundance of FN, demonstrating the diagnosis of solitary FG.

Discussion: FG is caused by deposition of the soluble form of FN from serum, rather than the insoluble form produced by resident cells. Therefore, immunostaining with the monoclonal antibody IST-4, which can detect soluble FN, is usually positive in FG, while that with IST-9, which binds only to cellular FN, is negative. Although IST-4 staining was negative in the reported case, FN was detected with LC/MS. This might be due to a structural change of FN in the deposits, which hindered the binding of IST-4 antibody to FN. Furthermore, it was also confirmed that LC/MS is a powerful method to identify characteristics of unexplained glomerular deposits.

PO1575

To Treat or Not to Treat? Therapeutic Challenges in a Case of Advanced Renal Sarcoid

Catherine Larned, John S. Thurlow, Maura A. Watson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Use of potentially toxic therapy in patients with low chance of renal recovery is clinically challenging. Kidney biopsy with significant interstitial fibrosis and tubular atrophy (IFTA) and reduced estimated glomerular filtration rate (eGFR) suggests unlikely recovery. We describe a patient with advanced IFTA who recovered substantial kidney function with treatment.

Case Description: A 55-year-old man was diagnosed with pulmonary and renal sarcoidosis. Renal biopsy at diagnosis showed granulomatous interstitial nephritis with non-caseating granulomas and 20% IFTA. Prednisone was started but was discontinued by the patient for onerous side effects. Serum creatinine (SrCr) stabilized at 1.5-1.8 mg/dL. He returned two years later with SrCr 5.8 mg/dL (eGFR 12 ml/min/1.73m2). Urinalysis was bland. Serum calcium was 10 mg/dL, phosphorus 4.0 mg/dL and intact PTH 20 pg/mL. He lacked pulmonary or systemic symptoms to merit empiric treatment, and he was hesitant to receive steroids due to prior side effects. Given new concurrent diagnosis of a monoclonal gammopathy and sclerotic bone lesions, repeat renal biopsy was performed that showed granulomatous interstitial nephritis and 50% IFTA consistent with sarcoid. Despite concern for lack of recoverable kidney function due to high chronicity and reduced eGFR, treatment with high-dose prednisone was started based on the unknown time course of recurrence in a relatively young active patient. SrCr improved to 3.0-3.2 mg/dL (eGFR 23-25ml/min/1.73m2). He was compliant with steroid taper and his renal function remained stable. The gammopathy was not renally significant and sclerotic bone lesions were attributed to sarcoidosis.

Discussion: In this patient with active sarcoidosis, presenting with eGFR 12 ml/min/1.73m2 and 50% IFTA on biopsy, it would be reasonable to presume limited benefit and defer steroid treatment, especially given patient reluctance. However, there was significant recovery with treatment. This should prompt reconsideration of the prognostic value of renal pathology in sarcoidosis, especially in view of known heterogenous involvement. *The views expressed are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, or the United States government.*

PO1576

Clinicopathological Characteristics of Adult IgA Nephropathy: A Retrospective Cohort Study

Dawn J. Caster,[1] Clint Abner,[2] Kerime Ararat,[2] Patrick D. Walker,[2] Amin Yakubu,[3] Martin C. Bunke.[4] *[1]University of Louisville, Louisville, KY; [2]Arkana Laboratories, Little Rock, AR; [3]Genesis Research, LLC, Hoboken, NJ; [4]Travere Therapeutics Inc, San Diego, CA.*

Background: IgA nephropathy (IgAN) is the most common form of primary glomerular nephropathy and a leading cause of chronic kidney disease (CKD). These analyses characterize clinical and histological features of IgAN in adults at time of kidney biopsy.

Methods: A retrospective study of clinical and histologic characteristics was performed in patients (pts) ≥18 yrs of age with ≥1 IgAN positive kidney biopsy without prior kidney transplant reported from Arkana Laboratories (Jan 1, 2016-May 30, 2020). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-Epi equation without race modifier. All results are at the time of biopsy.

Results: Of 67,262 kidney biopsies performed during the study period, 4,384 (6.5%) IgAN positive cases met the study criteria and were included, of which, 62.7% were male, 49.6% White, 5.1% African American, 5.3% Hispanic, 5.6% Asian and 34.4% Unknown/ Other race/ethnicity. Mean (SD) age at biopsy was 47.7 (16.6) yrs. Urine protein to creatinine ratio/ 24-hour urine protein data were available for 52.4% of pts and the median (Q1-Q3) was 3.0 (1.0 – 5.0) g/g. Additionally, 65.2% of pts had hypertension, 63.1% had known hematuria, 25.7% had severe arteriosclerosis, 15.8% had severe arteriolosclerosis, and 27.2% and 20.9% of patients had CKD stage 3 and 4, respectively. The mean (SD) eGFR was 42.4 (32.1) mL/min/1.73m^2. Immunofluorescence, sclerosis, and fibrosis characteristics are presented in Table 1.

Conclusions: The large proportion of pts diagnosed at CKD stage ≥3 and high MEST-C scores for S and T suggest significant disease duration at the time of biopsy. Earlier intervention may be of value to prevent ESKD.

Funding: Commercial Support - Travere Therapeutics

Natural History of IgA Nephropathy: Analysis of a UK National RaDaR IgA Nephropathy Cohort

Jonathan Barratt,[1,2] Moin Saleem,[3,4] Fiona E. Braddon,[5] Kevin Carroll,[12] Ping He,[9] Bruce M. Hendry,[9] Alex Mercer,[11] David Pitcher,[5,6] Retha D. Steenkamp,[5,6] A. Neil Turner,[10] Daniel P. Gale.[7,8] *[1]University of Leicester, Leicester, United Kingdom; [2]Leicester General Hospital, Leicester, United Kingdom; [3]University of Bristol, Bristol, United Kingdom; [4]Bristol Royal Hospital for Children, Bristol, United Kingdom; [5]UK Renal Registry, Bristol, United Kingdom; [6]The Renal Association, Bristol, United Kingdom; [7]Royal Free Hospital, London, United Kingdom; [8]University College London, London, United Kingdom; [9]Travere Therapeutics Inc, San Diego, CA; [10]University of Edinburgh, Edinburgh, United Kingdom; [11]JAMCO Pharma Consulting, Stockholm, Sweden; [12]KJC Statistics Ltd, Cheshire, United Kingdom.*

Background: Primary IgA nephropathy (IgAN) is the most common form of glomerulonephritis and a major cause of renal failure. Here we describe the natural history of IgAN using the UK National Registry of Rare Kidney Diseases (RaDaR). Since 2013, patients with biopsy-proven IgAN and eGFR <60 mL/min/1.73m^2 or proteinuria ≥1g/24h have been enrolled into RaDaR from 107 adult and paediatric kidney units across the UK, including retrospective and prospective data. Patients with systemic vasculitis or pre-existing liver disease were excluded.

Methods: Baseline date was defined as first occurrence of renal biopsy, primary renal diagnosis or symptom presentation. Patients were grouped into those with ESKD (CKD stage 5 or renal replacement therapy) at or prior to baseline (ESKD group) and those without ESKD at baseline with ≥12 months follow-up (CKD group). For survival analyses, ESKD or death was applied with survival time calculated from baseline to last follow-up.

Results: In the ESKD group (n=326), median age at first dialysis (56% of patients) and kidney transplant (7%) was 38 yrs (IQR 29-50). In the CKD group (n=1838), median baseline age was 39 yrs (IQR 28-50) with paediatric onset of disease comprising 6%. Baseline median urine PCR was 1.5 g/g (IQR 0.6-3.2; n=356) and mean eGFR was 58 mL/min/1.73m^2 (SD 32; n=440). Median follow-up was 9.2 years (IQR 5.1-16.3) and ESKD/death occurred in 53% of patients (<1% death). Kaplan-Meier survival curves of paediatric and adult patients show 50% survival probability of 24 & 10 years, respectively (Figure 1).

Conclusions: RaDaR contains a large cohort with long follow up enabling detailed investigation of the natural history of IgAN. These results indicate associations between rapid disease progression and poor outcomes, highlighting a need for effective treatments for patients with IgAN with renal impairment or >1g/24h proteinuria.

Symptom Burden Among Immunoglobulin A Nephropathy (IgAN) Patients in a US Real-World Setting

Robert M. Perkins,[1] Carolina A. Aldworth,[2] Raymond Przybysz,[1] Jim P. Doherty,[2] Stephen W. Olson,[1] Aneesh T. George,[3] Jaydeep Das,[3] Rachel Studer.[2] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Novartis Pharma AG, Basel, Switzerland; [3]Novartis Healthcare Pvt. Ltd., Hyderabad, India.*

Background: Immunoglobulin A nephropathy (IgAN) is the most prevalent chronic glomerulonephritis and 15-40% of patients will progress to end stage kidney disease (ESKD) within 10-20 years of diagnosis. The symptom burden by eGFR and proteinuria levels has not been well described in IgAN and is presented here.

Methods: This is a descriptive, retrospective study of adult (≥ 18 years) patients in de-identified Optum® Electronic Health Records (2007-2019). Pre-processed physician notes were used to select patients with at least two IgAN records without any secondary or negative notion. Patients without a record of renal biopsy, valid eGFR and proteinuria

levels, or with a history of ESKD/kidney transplant were excluded. The demographic and clinical characteristics, including symptoms up to 12 months before and up to the 1st record of IgAN are presented here; these symptoms were stratified by eGFR and proteinuria levels.

Results: The final cohort consisted of 846 patients with a mean age of 48.5 years; 57.7% were male and 7.0% Asian. Proteinuria levels of ≥1 g/day were found in 35.7% of patients. The median eGFR was 39.0 ml/min/1.73m^2, median creatinine was 1.8 mg/dL, and 20.8% of patients had severe deterioration of kidney function (eGFR <15). Overall, more patients in higher chronic kidney disease (CKD) stages experienced any given symptom but this trend was not as consistent for higher proteinuria levels.

Conclusions: Our study found that a considerable proportion of patients experienced pain, fatigue and edema. Except in a few instances, all symptoms increased with lower eGFR levels but this trend was less apparent for proteinuria. Our overall findings suggest that a relatively large proportion of IgAN patients, even those with preserved kidney functions could be experiencing substantial symptomatic burden and this warrants further investigation.

Clinical Outcomes of Kidney Diseases Diagnosed in Active Duty Service Members

Trevor W. Tobin, John S. Thurlow, Robert Nee, Christina M. Yuan. *Walter Reed National Military Medical Center, Bethesda, MD.*

Background: There are no studies that have reported glomerular disease prevalence and looked at the overall healthcare outcomes following renal biopsies in active duty soldiers. We aimed to determine the prevalence of renal diseases amongst the soldiers biopsied at out hospital and determine the outcomes for these individuals as a result of their diagnoses.

Methods: In this retrospective study, we evaluated the results of all native renal biopsies performed at Walter Reed National Military Medical Center from 2005 to 2020. We used this data to determine the prevalence of patients who progressed to have ESKD (End Stage Kidney Disease), renal transplantation, creatinine doubling, proteinuria greater than 3.5 grams/day, medical evaluation board (MEB), and death. The AHLTA and JLV EMR systems were used to collect data on the patients who met our inclusion criteria. After the data was collected, chi squared tests were performed and Kaplan Meier Curves were created for analysis.

Results: Among 169 patients (mean age =32 years old; 79% male; 48% white; 37% black; 7% Hispanic; 4% Asian; 3% pacific islander; 2% other), the most common indication for renal biopsy was for concomitant hematuria and proteinuria (31%) and the most common histologic diagnosis was IgA Nephropathy (23%). The mean time of follow up was 7.3 years. 11% progressed to ESKD, of whom 87% received a kidney transplant (10% overall). Approximately one third progressed to proteinuria greater than 3.5 grams per day and 5% died.

Conclusions: We identified IgA Nephropathy as the dominant histologic diagnosis in our patients undergoing renal biopsy between 2005 and 2020. Despite our patients being largely young and healthy individuals, renal biopsy identified severe disease with over 10% of patients progressing to ESKD and 5% mortality.

PO1580

Clinicopathological Features, Risk Factors, and Outcomes of Immunoglobulin A Nephropathy Associated with Hepatitis B Virus Infection

Jiachuan Xiong. *Xinqiao Hospital, Chongqing, China.*

Background: Hepatitis B virus (HBV) infections are associated with an increased risk of kidney diseases. However, the effects of HBV infection on the prognosis of immunoglobulin A nephropathy (IgAN) are unclear.

Methods: A total of 838 patients with biopsy-confirmed IgAN were enrolled in this retrospective cohort study. The patients were categorized into either affected by IgAN and HBV infection (HBsAg-IgAN) or by primary IgAN with no sign of HBV infection (P-IgAN). A 1:1 propensity-score matching was performed between the two groups, followed by a Kaplan–Meier survival analysis, to compare the prognoses, and a Cox regression analysis, to identify factors influencing the HBsAg-IgAN outcomes.

Results: A total of 176 pairs of patients were successfully matched. A significant difference in the systolic blood pressure and urea, serum creatinine, uric acid, and 24-h urine protein levels was observed between the groups. A renal pathological analysis also revealed a significant difference in the mesangial hypercellularity between the groups. During a median follow-up period of 2.4 years, Kaplan–Meier analysis also revealed a significant difference in the renal survival between the groups. Furthermore, multivariate Cox analysis confirmed that HBV infection is an independent risk factor for IgAN progression (hazard ratio [HR] 2.096; 95% confidence interval [CI] 1.091–4.026). Finally, the HBsAg-IgAN patients who received treatment with renin–angiotensin–aldosterone system inhibitors had a better overall prognosis than those who received immunosuppressive therapy and antiviral treatment.

Conclusions: Our results indicate that the clinicopathological features and outcomes of patients with IgAN differ significantly between those with and without HBV infection, and that HBV is an independent risk factor for IgAN progression.

PO1581

Factors Associated with ESKD in Mexican Patients with IgA Nephropathy: A Single-Centre Retrospective Cohort Study

Daniela Xavier, Guadalupe Ramos De Jesus, Octavio R. Garcia-Flores, Bernardo Moguel. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis in the world among patients undergoing renal biopsy. To standardize the histological findings, the Oxford Classification (OC) has allowed clarifying kidney lesions that confer potential risk of progression. The aims are describe the factors associated with ESKD and treatment implemented in Mexican patients with IgAN.

Methods: We conducted a single-center, retrospective cohort study in a tertiary hospital in Mexico City, patients with biopsy-proven IgAN and followed up for at least 2 years and examined the relationship between clinical parameters and OC to predict the risk of ESKD after biopsy. We used age and sex adjusted Cox proportional hazards models to study the association of the predictor variables (MEST-C, global glomerulosclerosis and proteinuria > 1g/day) with the incidence of ESKD. The HRs were expressed with 95% confidence intervals (95% CI).

Results: 35 patients were included, mean age 37.2±15.2 years, 60% were female, mean eGFR and proteinuria at biopsy were 60.8± 34.6 ml/min/1.73m2 and 3.4± 4.0 g/day respectively. ESKD or eGFR decline by ≥50% as compared to baseline occurred in 10 patients (28.6%) in of follow-up of 2 years. The eGFR at 24 months post-biopsy 59.1± 39.6 ml/min/1.73m2. 18 patients received immunosuppressive treatment and 24 received prednisone. The distribution of MEST-C lesions were: M1-35(100%), E1-20(57.1%), S1-33(94.3%), T1-15(42.9%) and T2-5(7.5%), C1-11(31.4%) and podocytopathic features in 5 (14.3%). Of the MEST-C components, only T2 was significantly associated with ESKD (HR 4.66, 95% CI 0.8 to 27.1). After adjusting for confounding variables global glomerulosclerosis >50% (HR 1.92 [1.02-3.58], p=0.001) and new Oxford classification system (O-grade) grade III (HR 2.79 [0.89-8.58], p=<0.001) were independently associated with ESKD.

Conclusions: There are no reports in Mexico of clinical characteristics and outcomes of IgA nephropathy. This study demonstrates that IgA nephropathy was more common in young adults and women and that the progression to ESKD or the global glomerulosclerosis >50% is similar to the reported in the literature. IFTA >50%, and O-grade III were associated with the development of ESKD in Mexican population.

PO1582

External Validation of Two New IgA Risk-Prediction Tools in a Norwegian Cohort

Yngvar Lunde Haaskjold,[1] Njål Lura,[1] Rune Bjoerneklett,[1,2] Lars S. Bostad,[1,2] Thomas Knoop.[1,2] *[1]Haukeland Universitetssjukehus, Bergen, Norway; [2]Universitetet i Bergen, Bergen, Norway.*

Background: Recently two prediction tools for IgA nephropathy (IgAN) have been developed combining clinical and histopathological parameters. Barbour and colleagues developed the *International IgAN Prediction Tool*, to predict the risk for 50 % decline in estimated glomerular filtration rate (eGFR) or end stage renal disease (ESRD) up to 80 months after diagnosis. Schena and colleagues developed the *IgA Nephropathy Clinical Decision Support System (CDSS)*, using artificial neural networks (ANN) to estimate the risk for ESRD. In the present study we aim to externally validate both prediction tools using a Norwegian cohort with long-term follow-up.

Methods: We included 306 patients with biopsy-proven primary IgAN. Histopathologic samples were retrieved from the Norwegian Kidney Biopsy Registry and reclassified according to the Oxford classification. The probability of the primary outcome, ESRD, was calculated by plotting the data from our cohort into the respectively online tools. The predicted outcome probabilities from the models were handled as a prognostic index in the validation analysis. We used principles for external validation of prognostic models: discrimination (concordance statistics), calibration (cox models and survival estimates), and model fit (akaike information criterion).

Results: Mean patient follow-up was 16.5 years, and a total of 61 (20%) patients reached ESRD. The cumulative dynamic time dependant receiving operating characteristics (tdROC) analysis showed no difference between the models with an area under curve (AUC) of 0.88 and 0.85 at 15 years for Barbour and Schena respectively. Integrated AUC (iAUC) at 20 years was 0.79 for Schena and 0.75 Barbour (p =0.2). Incident dynamic ROC-analysis at 5 and 20 years showed no significant difference in Scena's tool (AUC 0.80 and 0.74 respectively, p=0.08), but there was but there was a significant decrease in Barbour's tool (AUC 0.80 and 0.65 respectively, p<0.001). Concordance index was 0.85 for Barbour, and 0.82 for Schena (p=0.03).

Conclusions: Both prediction tools perform well and could become helpful tools for clinicians to identify patients at risk. Barbour's tool seem to loose prognostic discriminative value at a faster rate than Schena's over time.

PO1583

International IgA Nephropathy Network (IIgANN) Risk Prediction and Longitudinal Outcomes in the First South-Asian Prospective IgA Nephropathy Cohort (GRACE-IgANI)

Suceena Alexander,[1] Santosh Varughese,[1] Athul Thomas,[1] Jeethu J. Eapen,[1] Elenjickal E. John,[1] Anna T. Valson,[1] Vinoi G. David,[1] Mohamed R. Daha,[2] George John,[1,3] John Feehally,[5] Jonathan Barratt.[4] *[1]Christian Medical College Vellore, Vellore, India; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [4]University of Leicester College of Life Sciences, Leicester, United Kingdom; [5]University of Leicester, Leicester, United Kingdom.*

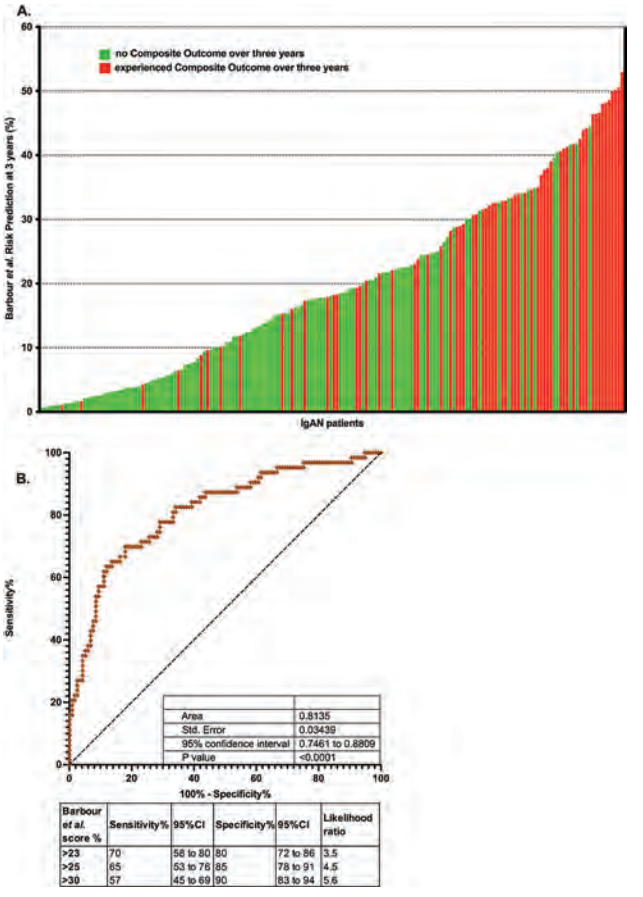
Background: The **G**lomerular **R**esearch **A**nd **C**linical **E**xperiments- **IgA N**ephropathy in **I**ndians is a prospective longitudinal cohort registered with WHO trial id: ISRCTN36834159. The performance of the IIgANN risk prediction score (Barbour *et al.*) has not been assessed in South Asian IgAN.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 195 patients (97%) completed 3 year longitudinal follow-up. Of these, 180 patients had complete Oxford MEST-C score at baseline. Composite outcome (CO) was defined as ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m2 or RRT/death.

Results: The median predicted 3-year risk of a 50% decline in eGFR or ESKD using the IIGANN risk prediction tool was 18.1% (IQR 7.4–31.2) at baseline. The minimum score was 0.64% and the maximum was 53%. Short course IS was used in 146/201 (73%) of patients. 72 patients (36.9%) experienced CO over 3 years. The median risk in patients with favourable outcome was 13.15% (IQR 4.2–21.7) and in those with CO was 32.2% (IQR 19.6–41), *P* <0.0001 (Figure A). The area under the ROC curve for detecting CO was 0.81 (95% C.I. 0.74 to 0.88, *P* <0.0001) (Figure B). The specificity for predicting CO for percentage risk score >23 was 80% (95% C.I. 72 to 86), and >30 was 90% (95% C.I. 83 to 94).

Conclusions: IIgANN predicted 3-year risk score >23% has good specificity for predicting CO over 3 years. Overall the score seems to be underestimating the actual CO over 3 years in the GRACE-IgANI cohort. This requires further validation.

Funding: Government Support - Non-U.S.



Barbour *et al.* 3 year prediction score and actual Composite Outcome over 3 years in GRACE-IgANI cohort.

PO1584

IgA Nephropathy Histopathology and Long-Term Renal Prognosis

Nora C. Maddy, Robert Nee, Sarah M. Gordon, Stephen W. Olson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Background: The Oxford Classification established the mesangial hypercellularity (M), Endocapillary hypercellularity (E), segmental sclerosis (S), Tubulointerstitial fibrosis (T), and crescents (C) score as an important prognostic tool for IgA nephropathy (IgAN). However, these studies did not investigate the impact of complement 3 (C3) immunofluorescence (IF) staining or interstitial inflammation (iI) on long term renal outcomes, nor evaluate an ethnically diverse population which included African Americans.

Methods: We queried the military health system (MHS) by ICD-9/10 codes to identify potential IgA nephropathy cases. We then reviewed the electronic medical record to find those with biopsy-proven IgA nephropathy. Prespecified clinical data was collected to include MEST-C scores, iI, and C3 IF. Primary outcomes included >50% decline in estimated glomerular filtration rates (eGFR), chronic kidney disease (CKD) with eGFR <60ml/min/1.73m2, and end-stage kidney disease (ESKD).

Results: 172 patients were identified with a mean follow-up of 11 years. Mean age was 32 years; 77.9% male; 64.5% White, 9.9% Black, and 12.2% Asian/Pacific Islanders. C3 IF ≥2+ was significantly associated with ESKD (p=0.03) and >50% decline in eGFR (p=0.02). iI ≥ 15% was significant for ESKD (p=0.003), CKD (p=0.01), and >50% decline in GFR (p=0.01). T and C scores were significant for ESKD, CKD, and >50% decline in GFR (all p<0.001). S score was significant for ESKD (p=0.022) and CKD (p=0.009). E score was significant for CKD (p=0.003). M score was not significant for any of the primary outcomes.

Conclusions: We present histopathology associated long term renal outcome data for the most ethnically diverse IgAN cohort with the longest follow up to date in such a population. Our data suggests that degree of C3 staining on IF and amount of interstitial inflammation could augment the prognostic accuracy of the MEST-C score. In addition, it supports the theory that IgA immune complexes activate the alternative complement pathway which drives significant interstitial inflammation ultimately resulting in tubular atrophy and interstitial fibrosis. **Disclaimer**: The views expressed are those of the authors and do not reflect official policy of the Department of the Army/Navy/Air Force, Department of Defense, or United States government.

PO1585

Severity of Arterial and Arteriolar Sclerosis in IgA Nephropathy and Effects of Renin-Angiotensin System Inhibitors on Its Prognosis

Naoko Sugiura, Takahito Moriyama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: IgA nephropathy (IgAN) patients often suffer from renal arterial intimal thickening (AIT) and arteriolar hyaline (AH) however, it is unclear whether these features are associated with a poor prognosis. This study aimed to analyse whether treatment with renin-angiotensin system inhibitors (RASI) improves those patient's survival.

Methods: This retrospective cohort analysis included total 871 patients with IgAN, grouped according to the absence or presence of AIT (Study 1; AIT0: n=415, AIT1: n=268) or AH (Study 2; AH0: n=405, AH1: n=354). The clinical, laboratory, and histological backgrounds of the patients were analyzed along with their 20-year renal prognosis. In the AIT1 and AH1 groups, the effect of renin-angiotensin system inhibitors (RASI) on renal prognosis after making adjustments for the background was analyzed and risk factors for progression were also analyzed.

Results: IgAN patients with AIT1 or AH1 had significantly higher age, blood pressure, body mass index, total cholesterol, uric acid levels, and proteinuria than patients with AIT0 or AH0. They also had more marked histologic findings, decreased renal function, and lower survival rates (AIT: 62.2% vs. 83.4%, p<0.0001; AH: 63.5% vs. 85.4%, p<0.0001). Multivariate Cox regression analysis considering with clinical and histological findings and treatments revealed AIT and AH as an independent factor for disease progression (AIT1: hazard ratio (HR), 1.98, p=0.017; AH1: HR, 2.12, p=0.014). The renal survival rate was significantly higher in IgAN patients with AIT1 or AH1who were treated with RASI than in those who were not treated with RASI after background adjustments (AIT1: 71.1% vs. 50.4%, p=0.023; AH1: 76.4% vs. 39.5%, p=0.006). RASI was found to be an independent factor in the prevention of progression, by multivariate Cox regression analyses (AIT1: HR, 0.40, p=0.014; AH1: HR, 0.42, p=0.007).

Conclusions: AIT and AH are associated with serious clinical, laboratory and histological findings and a poor prognosis. RASI was found to improve renal prognosis of those patients.

PO1586

Intensity of Glomerular Galactose-Deficient IgA1 Deposition Can Be a Marker of Disease Activity in IgA Nephropathy

Maiko Nakayama,[1] Hitoshi Suzuki,[1,2] Yusuke Fukao,[1] Mingfeng Lee,[1] Toshiki Kano,[3] Yuko Makita,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; [3]Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the development of IgA nephropathy (IgAN). Recently, it was reported that Gd-IgA1 specifically deposit on glomeruli of primary IgAN using Gd-IgA1-specific monoclonal antibody (KM55 mAb). However, the association between the intensity of Gd-IgA1 deposition and clinical parameters and histological severity are not clarified.

Methods: We performed immunostaining with KM55 mAb on paraffin sections of 141 patients diagnosed with IgAN at Juntendo University Hospital. We quantified the intensity of glomerular Gd-IgA1 by Image-J software, and analyzed its association with histological findings. We also analyzed the association of intensity of glomerular Gd-IgA1 deposition with creatinine, serum/urinary level of Gd-IgA1, and proteinuria.

Results: In all 141 patients with primary IgAN, glomerular Gd-IgA1 deposition was positive. We divided patients into tertiles according to the amount of Gd-IgA1 deposition by the Image-J software (low, middle, and high groups). The level of proteinuria in the high-intensity group was significantly higher than that in the other two groups (low vs high; $P<0.05$, middle vs high; $P<0.05$). Moreover, the level of urinary Gd-IgA1 was also higher in the high-intensity group (middle vs high; $P<0.05$). The percentage of acute lesions such as cellular crescents was significantly higher in the high-intensity group (low vs high; $P<0.05$).

Conclusions: Present study suggested that high intensity of glomerular Gd-IgA1 deposition is associated with histological severity, especially acute lesions. Thus, glomerular Gd-IgA1 staining can be considerable index for therapeutic intervention.

PO1587

Segmental Necrotizing/Crescentic Glomerulonephritis (SNGN) in IgA Nephropathy (IgAN): A Single-Center Experience

Nirali B. Ramani, William L. Whittier, Stephen M. Korbet. *Rush University Medical Center, Chicago, IL.*

Background: The presence of SNGN on renal biopsy generally portends a poor prognosis with rapidly progressive disease. We evaluate the presentation and outcomes of pts with IgAN to determine if the presence of SNGN portends a poorer prognosis in this pt population.

Methods: Biopsies done at Rush University Medical Center from 1992-2019, found IgAN in 73 pts in whom follow-up (FU) was available. SNGN was seen in 26 pts (36%). Clinical, laboratory, histologic features at biopsy, treatment and outcome data (doubling of SCr and ESKD) were collected retrospectively. Pts with and without SNGN were compared. Data is presented a mean±SD and a P value of <0.05 was significant.

Results: At biopsy there was no difference in age (42±16 vs 43±17 yrs), gender (54% vs 43% male), race or SCr (1.7±1.1 vs 1.6±1.1 mg/dl) in pts with compared to those without SNGN. Pt with SNGN had higher systolic BPs (140±14 vs 131±17 mmHg, P 0.02) and higher UPro/Cr ratio (2.8±2.7 vs 1.7± 1.7 g/g, P 0.04). All 15 SNGN pts tested were ANCA negative. The percent of glomeruli with global (GS)+segmental (SS) sclerosis (32±25 vs 38±28%) and interstitial fibrosis+tubular atrophy (IFTA) (22±20 vs 23±22%) was similar for those with vs without SNGN. In pts with SNGN, only 15% had lesions involving >25% of glomeruli. FU was similar on average (7±6 vs 8±7 yrs) in pts with and without SNGN and treatment with ACEi/ARBs was similar (88 vs 100%). A larger proportion of pts with SNGN were treated with immunosuppressive agents (69 vs 21%, P 0.003). At FU, doubling of SCr (25 vs 22%), ESKD (19 vs 21%) and renal survival at 10 yrs (80 vs 76%) were similar in pts with and without SNGN. In both groups, pts that progressed to ESKD had a higher proportion of glomeruli with GS+SS (SNGN: 63±16 vs 24±21%, P 0.002 and No SNGN: 64±27 vs 31±24%, P 0.002) and IFTA (SNGN: 47±19 vs 16±16%, P 0.006 and No SNGN: 41±27 vs 17±18%, P 0.01). In pts with SNGN, the proportion of glomeruli with SNGN was similar in those with and without ESKD (16±14 vs 18±17%).

Conclusions: In pts with IgAN, the presence of SNGN is frequently seen but does not alter prognosis. This may be the result of <25% involvement with SNGN lesions in the majority of our pts and more aggressive treatment in pts with SNGN. The presence of advanced GS+SS and IFTA at biopsy were most associated with progressive kidney disease rather than SNGN.

PO1588

Novel Scoring System Based on the Oxford Classification Indicating Steroid Therapy Use for IgA Nephropathy

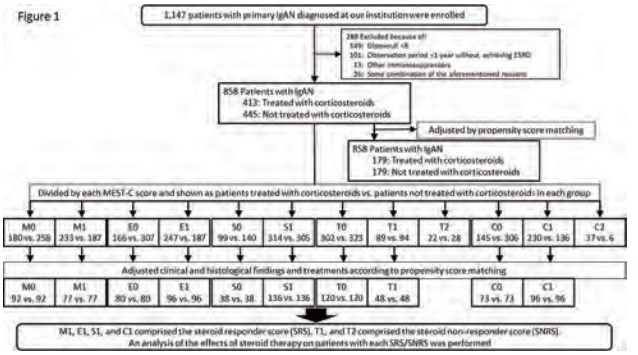
Takahito Moriyama, Eri Kasama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: The Oxford classification identifies predictors of the renal prognosis for IgA nephropathy (IgAN); however, it has been unclear about usefulness for deciding the management approach. We analyzed the clinical utility of this classification for indicating steroid therapy.

Methods: The effects of steroid therapy on the long-term prognosis for all 858 IgAN patients and patients divided with M0, M1, E0, E1, S0, S1, T0, T1, T2, C0, C1 and C2 scores according to the Oxford classification (M, mesangial hypercellularity; E, endocapillary hypercellularity; S, segmental sclerosis; T, tubular atrophy/interstitial fibrosis; and C, crescents) were examined using Kaplan-Meier analysis and Cox regression analysis. The steroid responder score (SRS) and steroid non-responder score (SNRS) were determined using the obtained results. The effects of steroid therapy on renal prognosis according to the combination of the total SRS and SNRS for IgAN were analyzed using Cox regression analysis.

Results: Steroid therapy improved the 20-year renal survival rates in all IgAN patients (steroid (+): 75.5% vs. steroid (-): 61.7%, p=0.025) and patients with M1, E1, S1, C1, and T0 scores. We recognized the total score of M1, E1, S1, and C1 scores (0–4 points) as the SRS and that of T1 and T2 scores (0–2 points) as the SNRS. Multivariate Cox regression analysis revealed that steroid therapy improved the long-term renal prognosis in IgAN patients with higher SRS and lower SNRS (SRS4/SNRS0: hazard ratio [HR], 0.08 and p=0.008; SRS3/SNRS0: HR, 0.05 and p=0.025; SRS4/SNRS1: HR, 0.11 and p=0.007), but not in IgAN patients with lower SRS (0–3)/SNRS1 and any SRS/SNRS2.

Conclusions: Patients with M1, E1, S1, and C1 scores responded to steroid treatment; contrarily, those with T1 and T2 scores did not. A higher SRS was a useful indicator for steroid therapy. Nevertheless, prevention of progression in IgAN patients with SNRS was difficult with steroid therapy.



PO1589

Remission of Hematuria Is Associated with Favorable Prognosis in IgA Nephropathy

Kyung Ho Lee, Young seung Oh, Moo Yong Park, Soo Jeong Choi, Jin kuk Kim, Seung D. Hwang, Byung chul Yu. *Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea*.

Background: Recent studies have shown that remission of hematuria is associated with favorable clinical outcomes in patients with immunoglobulin A nephropathy (IgAN). The current study was conducted to compare the long-term clinical outcomes between patients with remission of hematuria and those with persistent hematuria using the stricter but intuitive definition of "remission of hematuria" than that used in previous studies.

Methods: This retrospective, multicenter, observational study was conducted using a cohort of patients diagnosed with IgAN through kidney biopsy at three tertiary hospitals. A total of 403 patients who had been followed up for more than 3 years and who underwent regular check-ups at intervals of at least 6 months were enrolled. Hematuria remission was defined as the presence of hematuria for at least 3 months after biopsy for diagnosis but with no RBC per high-power field observed in the urine under the microscope for at least 2 years thereafter.

Results: The mean annual rate of eGFR decline was lower in the remission of hematuria group than in the persistent hematuria group (-1.51 ± 2.86 vs. -2.60 ± 3.18 mL/min/1.73 m^2/year, p = 0.002). In the remission of hematuria group, the mean annual rate of eGFR decline decreased after hematuria disappearance (from -1.28 ± 7.06 to 0.09 ± 0.29 mL/min/1.73 m^2/year, p = 0.016). Multivariable analysis revealed remission of hematuria as an independent predictor of a 50% reduction in kidney function (hazard ratio, 0.55; 95% CI, 0.33 to 0.99). Renal survival, defined as a 50% reduction in kidney function, was better in the remission of hematuria group than in the persistent hematuria group (p = 0.030). However, free of ESRD was not significantly different between the two groups (p = 0.079).

Conclusions: In this study, which used a more rigorous but intuitive definition of hematuria remission than that used in previous studies, patients with remission of hematuria showed favorable kidney prognosis. This new definition for remission of hematuria could be used as a prognostic marker in actual clinical practice.

Comparison of renal outcomes between the two groups

Variable	Remission of hematuria (n=100)	Persistent hematuria (n=303)	p-value
Mean annual rate of eGFR decline (mL/min/1.73 m2/year)	-1.51 ± 2.86	-2.60 ± 3.18	0.002
50% Reduction in kidney function, no. (%)	17 (17.0)	62 (20.5)	0.45
ESRD, no. (%)	10 (10.0)	37 (12.2)	0.559

PO1590

Reduction of Urinary Levels of Lectin Pathway Complement Components in an IgA Vasculitis Patient After MASP-2 Inhibition with Narsoplimab

Laura Pérez Alós,[1] Katrin Scionti,[2] Karen Molyneux,[2] Jonathan Barratt,[2,3] Peter Garred.[1] *[1]Rigshospitalet, Copenhagen, Denmark; [2]University of Leicester, Leicester, United Kingdom; [3]Leicester General Hospital, Leicester, United Kingdom*.

Background: A young female suffering from IgA vasculitis was treated with 4 mg/kg weekly infusions of narsoplimab (a MASP-2 inhibitor) for 12 weeks. MASP-2 is considered the key activator of the lectin pathway (LP) by cleaving C4 and C2, after the binding of LP pattern recognition molecules to its ligands. Inhibition of MASP-2 is predicted to decrease complement activation in complement-mediated kidney diseases. In this exploratory study we measured the levels of different LP complement components to evaluate the influence of narsoplimab on complement activation.

Methods: Urine levels of complement activation markers (C4c, C3bc and soluble C5b-9) and serum and urine levels of ficolin-1, -2 and -3, MBL, CL-11, MASP-3, MAP-1 and PTX-3 were measured using sandwich-ELISAs. Urine samples were subjected to LC/MS-MS. Correlations between LC/MS-MS and sandwich-ELISA were conducted using simple linear regression and Spearman's rank correlation coefficient. Significance: *p* value < 0.05. Urine proteins were adjusted for creatinine excretion and expressed as specific protein/creatinine ratio.

Results: C4c/creatinine ratio, ficolin-3/creatinine ratio and C3bc/creatinine ratio levels were decreased 75%, 58% and 29%, respectively, from baseline to the end of the treatment; while levels of MBL and CL-11 remained stable during the treatment. C4c/creatinine ratio levels were significantly correlated to LC/MS-MS C4 data (R^2: 0.5059; Spearman r: -0.5824, *p*=0.0402). Circulating levels of complement components in serum were unaltered during treatment. Soluble C5b-9, ficolin-1, -2, MASP-3 and MAP-1 were undetectable in urine and PTX-3 was undetectable in both urine and serum.

Conclusions: This is the first report describing the effect of narsoplimab on urinary complement levels in a complement-mediated kidney disease. Our data suggest a decrease in local complement activation with narsoplimab treatment. Further studies are ongoing to evaluate the use of urine as a non-invasive, inexpensive and readily accessible resource to monitor responses to complement-directed treatments.

PO1591

Identification of Urinary Diagnostic Biomarker for IgA Nephropathy by Lectin Microarray

Yasuhiro Onishi,[1] Koki Mise,[1,2] Haruhito A. Uchida,[1] Hitoshi Sugiyama,[1] Jun Wada.[1] *[1]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]The University of Texas MD Anderson Cancer Center, Houston, TX*.

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis and the pathogenic roles of aberrantly glycosylated IgA1 have been reported. The glycan abnormalities are mediated by the alterations of glycan processing enzymes, such as decreased activity of β-1,3-galactosyltransferase (C1GALT1). However, it is unexplored whether the detection of urinary glycosylation changes contributes to the diagnosis of IgAN.

Methods: We measured the urinary glycan signals bound to 45 lectins on LecChip in the 493 patients with renal biopsy-proven kidney diseases at Okayama University Hospital from December 2010 to September 2017. To evaluate the diagnostic performance, we added the urinary glycan signals to the diagnosis model with the reference standard, *i.e.*, the presence of hematuria, 24 hr urinary protein excretion, and concentration of serum IgA.

Results: The inclusion of 6 lectins showed a significant improvement of the models; *Amaranthus Caudatus* (ACA) with the difference of AUC 0.038 [95%CI, 0.019 - 0.058, P < 0.001], *Agaricus Bisporus* (ABA) 0.035 [95%CI, 0.015 - 0.055, P < 0.001], *Maackia Amurensis* (MAH) 0.035 [95%CI, 0.015 - 0.054, P < 0.001], *Maackia Amurensis* (MAH) 0.035 [95%CI, 0.015 - 0.054, P < 0.001], *Maclura Pomifera* (MPA) 0.021 [95% Cl, 0.006 - 0.037, P = 0.006], *Jacalin* 0.019 [95%Cl, 0.004 - 0.034, P = 0.012], and *Lycopersicon Esculentum* (LEL) 0.016 [95%Cl, 0 - 0.032, P = 0.045]. All 6 lectins demonstrated reduced signals in IgAN patients and 3 lectins (ACA, ABA, MAH) showed false discovery rate (FDR) below 0.05. In 3 lectins, each signal plus reference standard showed good model fitting associated with the improvement of AIC. By decision curve analysis, there was a 3.45% net benefit by adding urinary glycan signals to ACA at the pre-defined threshold probability of 40%.

Conclusions: The reduction of Gal(β1-3)GalNAc (T-antigen), Sia(α2-3)Gal(β1-3) GalNAc (Sialyl T), and Sia(α2-3)Gal(β1-3)Sia(α2-6)GalNAc (disialyl-T) was suggested by binding specificities of 3 lectins. C1GALT1 and COSMC were responsible for the biosynthesis of these glycans, and they were known to be downregulated in IgAN. The urinary glycan profile may be useful for the identification of diagnostic marker for IgA nephropathy.

Urinary Transferrin and IgG Are Significant and Early Markers of Tubulointerstitial Lesions in Patients with IgA Nephropathy

Elena Saganova, Olga Galkina, Vasiliy Sipovskii. *Pervyj Sankt-Peterburgskij gosudarstvennyj medicinskij universitet imeni akademika I P Pavlova, Sankt Peterburg, Russian Federation*.

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis and is a frequent cause of end-stage renal disease. There is a pressing need to identify suitable noninvasive biomarkers in IgAN, to aid with diagnosis, treatment decisions, prediction of the histological lesions and disease progression. Our aim was to assess diagnostic value of urinary transferrin and IgG excretions in prediction of morphological lesions in patients with IgAN.

Methods: 37 patients [19 female, age Me 33 (25; 48) years] with biopsy proven IgAN and without acute kidney injury, infectious diseases, severe heart failure, respiratory insufficiency, cancer were included in the study. 24-hour urinary excretions of transferrin (uTr), IgG (uIgG) were measured by immunoturbidimetric method. Tubulointerstitial fibrosis (TIF), tubular atrophy (TA) were assessed semi-quantitatively (0-lesions absent; 1-mild focal tubular and interstitial lesions; 2-moderate tubular and interstitial lesions; 3-diffuse tubular and interstitial lesions). All patients consistently were separated into two groups according to the degree of each morphological lesion (TIF or TA): "mild" (TIF or TA grade 0 or 1) and "severe" (TIF/TA grade 2-3).

Results: uTr, uIgG positively correlated (p<0,05) with TIF (r=0,38, r=0,43) and TA (r=0,38, r=0,45), respectively. We did not find correlations between uTr, uIgG and glomerulosclerosis. Using ROC-analysis all patients were separated in two groups using uTr or uIgG according to the degree of morphological lesions ("mild" or "severe") (Figure 1). We also found that all cut-off values of uTr, uIgG corresponded to the level of urinary protein excretion not more than 1,25 g/24hour.

Conclusions: Our data shows that uTr and uIgG can be used as markers of early tubulointerstitial lesions in patients with IgA nephropathy with mild protein excretion (<1,25 g/24hour).

Funding: Government Support - Non-U.S.

Precision Medicine Approach Identifies Patients with IgA Nephropathy at Risk for Progression Using Endothelin Activation Signatures

Viji Nair,[1] Wenjun Ju,[1] Sean Eddy,[1] Marvin Gunawan,[2] N. E. Olson,[2] Joyce Wu,[2] Jennifer H. Cox,[2] Andrew J. King,[2] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Chinook Therapeutics Inc, Vancouver, BC, Canada.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis globally, with up to 40% of patients at risk of progressing to ESKD. Endothelin (ET) A receptor activation results in mesangial cell (MC) activation, proteinuria, inflammation, and fibrosis, all considered hallmarks of IgAN progression, suggesting the potential for therapeutic benefit of ETA antagonists. The aim of our study was to identify intra-renal transcriptional signatures of ET-activation to stratify patients at high risk of IgAN progression

Methods: We used two approaches to establish a transcriptional signature of ET-activation. First, using a targeted approach, an ET-activation network was generated using three publicly available datasets, produced a geneset of 60 transcripts to create an activity score which was assessed in kidney biopsy profiles in patients with IgAN (n= 25) from the European Renal cDNA Bank (ERCB). In addition, an ET-activation signature was also generated experimentally via RNAseq profiling of primary human MCs simulated with ET1 (4nM) +/- the selective ETA antagonist atrasentan (1nM, 25nM, n=3/group). Pairwise differential gene expression and gene set enrichment analysis (GSEA) was performed.

Results: The targeted analysis showed that the ET-activity score correlated with increased proteinuria (r=0.42, p=0.05) and decreased eGFR (r=-0.47, p=0.02) in patients with IgAN. The transcript network showed enrichment in endothelial and mesangial cell clusters in renal single cell RNASeq profiles. Differential expression analysis identified the ET gene network was reversed by atrasentan in MCs (25nM, n=780 genes, q£0.05). GSEA in MCs revealed up-regulation of cell proliferation, inflammatory and fibrotic networks, with ET1 treatment, which were blocked by atrasentan.

Conclusions: We generated an ET-activation score using a systems biology approach to stratify patients with IgAN. Intra-renal ET-activation signatures were associated with progression, providing additional support for the therapeutic potential of ETA receptor blockade in IgAN patients at high risk of progression. Ongoing work is focused on optimizing the signature, extending findings to additional cohorts and identifying mechanistic biomarkers

NR3C1 Polymorphisms in Membranous and IgA Nephropathies

Michał Pac,[1] Natalia Krata,[1] Beata Kaleta,[2] Barbara Moszczuk,[1,2] Aleksandra Wyczalkowska-Tomasik,[1] Julia Prystupa,[1] Krzysztof Kiryluk,[3] Krzysztof Mucha.[1,4] *[1]Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; [2]Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Poland; [3]Department of Medicine, Columbia University, College of Physicians and Surgeons, New York, NY; [4]Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland.*

Background: In other diseases (ex. asthma and pemphigus vulgaris) *NR3C1* single nucleotide polymorphisms (SNPs) were associated with glucocorticoid (GC) treatment outcomes. The aim of the study was evaluation of the frequency of *NR3C1* (SNPs) in adult membranous (MN) and IgA (IgAN) nephropathies biopsy proven patients.

Methods: We analyzed *NR3C1* SNPs: rs6198, rs41423247 and rs17209237 in 39 MN patients (mean age 42,9±14,22 y.; 14 ♀), 39 sex- and age-matched and 35-unmatched IgAN patients (mean age 33,5±12,3 y.; 34 ♀) and 39 sex- and age-matched and 136-unmatched healthy controls (mean age 48,7±17,9 years; 89 ♀) using RT-PCR and GWAS methods. The results were tested for Hardy-Weinberg equilibrium (control group; p>0,05) and compared between MN, IgAN and controls and within MN and IgAN between GC-resistant and -sensitive and GC-dependent and -independent groups using the χ^2 with Yate's correction test.

Results: The frequency of the minor C allele of rs6198 SNP was significantly increased in MN (p<0,05) and IgAN (p<0,05) compared to controls; and in GC-resistant MN (p<0,05), GC-resistant (p<0,05) and GC-dependent (p<0,05) IgAN. The rs6198 SNP genotypes were unequally distributed among GC-resistant MN (p<0,05), GC-resistant (p<0,05) and GC-dependent (p<0,05) IgAN. The frequency of the major A allele of rs17209237 was significantly increased in GC-sensitive (p<0,05) and -independent (p<0,05) IgAN. There was a disequilibrium in rs17209237 SNP distribution among GC-sensitive IgAN (p<0,05). The minor C allele was significantly more frequent among MN (p<0,05) and IgAN (p<0,05) relapse patients and there was rs6198 genotypes distribution inequality for these both groups (p<0,05; p<0,05).

Conclusions: Rs6198 and rs17209237 alleles and genotypes have different distribution between MN and IgAN and controls; and between patients differently responding to the GC treatment. Results indicate that they predict GC treatment outcomes and therefore should be further investigated for their potential prognostic value.

PO1595

A Rare Case of Paraneoplastic IgA Nephropathy in the Setting of Renal Cell Carcinoma

Alka A. Tyagi, Mohankumar Doraiswamy, Sethu M. Madhavan. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Paraneoplastic nephropathy can present in patients with malignancy. Renal cell carcinoma (RCC) is the most common urologic malignancy; there is a paucity of reported paraneoplastic nephropathies associated with this condition. As such, we present an intriguingly unique case of nephrotic range proteinuria in the setting of recurrent, metastatic renal cell carcinoma.

Case Description: An 81-year-old male with history of recurrent metastatic RCC, solitary kidney after a nephrectomy, with stage III chronic kidney disease (CKD) presents with newly worsening renal function. In a 3-month span, his creatinine (Cr) rose from 1.35 mg/dL up to 4.6 mg/dL, which prompted further evaluation. He had reported taking daily nonsteroidal anti-inflammatory drugs along with his ACE-inhibitor. Urinalysis showed microscopic hematuria with random urine protein/creatinine ratio resulted 16 g/g and renal ultrasound was unrevealing. Other serologic tests at the time were notable for C3 134 mg/dL, C4 32 mg/dL, negative ANA, negative C-ANCA. Of note, he had suffered an E. coli and MRSA UTI, clostridium difficile infection, and was treated for pneumonia with anti-microbials. A renal biopsy was obtained with pathology significant for IgA-dominant mesangial and capillary wall immune complex deposition with only segmental and weak C3 (Oxford score was reported as M1, E1, S1, T0, C0). Because of the weak C3, in spite of the patient's history of recent infections, a secondary para-neoplastic IgA nephropathy was favored. He was treated with Nivolumab plus Ipilimumab with improvement in serum Cr improved to 2.23 mg/dL in the following 3 months after starting immunotherapy and remained stable in one-year follow up.

Discussion: Acutely worsening renal function and nephrotic range proteinuria in the setting of malignancy prompts investigation into a paraneoplastic nephropathy. As in this case, secondary IgA mesangial nephropathy can rarely present with RCC. This association is scarce and furthermore there is a lack of understanding of the development of this glomerulopathy. Treatment of the underlying malignancy has shown to improve and preserve renal function. Further investigation into the immune-pathophysiology can help drive the development of further treatment strategies.

PO1596

Circulating and Depositing Glomerular Antibodies: A Concurrence or Coexistence

Deepthi Ayanavelli, Dhanalakshmi Vurum. *ESIC Medical College and Hospital Hyderabad, Hyderabad, India.*

Introduction: Anti-GBM disease is a systemic autoimmune disorder characterized by circulating IgG antibodies (rarely IgA and IgM), may coexist with pauci-immune antineutrophil cytoplasmic autoantibody-positive glomerulonephritis and membranous glomerulopathy. The concurrent or sequential presentation of anti-GBM disease with IgA nephropathy has been rarely described.

Case Description: We herein report a case of 31-year-old female who had presented with sudden onset of breathlessness, pedal oedema for 15 days and oliguria for 5 days with 1 episode of haematuria. There were no arthralgias, oral ulcers, alopecia, skin rash, sore throat and diarrhoea. Her marital life was of five years with no history of conception or abortions. On examination she had mild pedal edema and her BP was 180/130mm Hg. Blood investigations revealed haemoglobin 9.5g/dl, urea 209 mg/dl, serum creatinine of 17mg/dl. Urine microscopy showed 3+protein and plenty of RBC and protein creatinine ratio 4.3g/g. Serologic test results were strongly positive for IgG anti-GBM antibody (73.97 units) by ELISA; serum C3 and C4 levels were normal. Other serologic tests for ANA, Anti ds DNA antibody, rheumatoid factor, cryoglobulinemia, hepatitis B and C, and ANCA were negative. Kidney biopsy showed 6 glomeruli of which 2 were sclerosed, 2 with cellular crescents, one with fibrocellular crescent and the other fibrous crescent. Interstitium filled with infiltrate of lymphocytes and tubules showed red cell casts. Vessels were unremarkable. IF showed mesangial granular staining with IgA (3-4+), C3c (2+); and kappa (3+) and lambda (3+) light chains. The patient was initiated on hemodialysis and treated with three pulses of IV methylprednisolone followed by pulse cyclophosphamide. Plasmapheresis was done as there were cellular crescents in the biopsy. Patient progressed to ESRD and continuing on hemodialysis.

Discussion: Presentation of IgAN along with anti GBM without linear deposition on renal biopsy but with positive anti GBM titers makes this case interesting. The association of anti-GBM disease with IgA nephropathy could be a coexistence as IgAN is most common glomerular disease or these IgA mesangial deposits might have role in the pathogenesis of triggering GBM antigens and formation of antibodies in this case.

PO1597

Early Predictors for Stable Kidney Function in Lupus Nephritis

Juan M. Mejia-Vilet, Megan Ashley N. Gerrard, Roque A. Comunidad Bonilla, Luis E. Morales-Buenrostro. *National Institute of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, Mexico.*

Background: Early prediction of outcomes in LN is essential to adjust LN treatment. The aim of this study was to evaluate the early course of laboratory parameters and their association with long-term stability of kidney function.

Methods: We studied 433 patients from our local LN cohort recruited between 2008 and 2017. All patients had >36 months follow-up and complete evaluation at LN flare, 3-, 6-, and 12-months of follow up with hemoglobin, creatinine, 24h-proteinuria, albumin, anti-dsDNA-Ab, complement C3 and C4 fragments. The main outcome was stable kidney function defined as eGFR within 25% of the best eGFR attained in the first 12 months of treatment. Each variable was evaluated individually by ROC curves and in association with other variables. The change in area under the curve (AUC) was analyzed with De Long's test.

Results: Median follow up was 73 months (IQR 51-101). Kidney survival was 90% and 81% at 3- and 5-years, respectively. Stability of kidney function was 77% and 65% at 3- and 5-years, respectively. The predictive performance of each parameter varied with the timepoint where evaluated (Table). Serum albumin and hemoglobin AUCs improved from baseline to the 3- and 6-month timepoint. Proteinuria and eGFR AUCs improved at each timepoint up to the 12-month timepoint. C3, C4, and anti-dsDNA-Ab level did not improve at any timepoint vs. baseline. The best predictor of 36-month eGFR stability was proteinuria <1.0g/g by 12 months. The sum of proteinuria plus eGFR provided the best combined AUC at each timepoint (Figure 1).

Conclusions: Early course of albumin, hemoglobin, and serological parameters does not improve prediction for stable kidney function in LN. The predictive performance of each biomarker improves over time. The combination of proteinuria and eGFR remains the best predictor of kidney outcomes.

	eGFR	Proteinuria	Hematuria	Hemoglobin	Albumin	dsDNA-Ab	C3	C4
At flare	0.694	0.599	0.504	0.549	0.520	0.524	0.558	0.539
3 months	0.742	0.673	0.529	0.659	0.605	0.552	0.531	0.510
6 months	0.768	0.750	0.515	0.683	0.633	0.599	0.548	0.511
12 months	0.799	0.834	0.581	0.702	0.677	0.601	0.620	0.503

Table 1. Area under the curve (AUC) of the evaluated parameters to predict stable kidney function by 36 months.

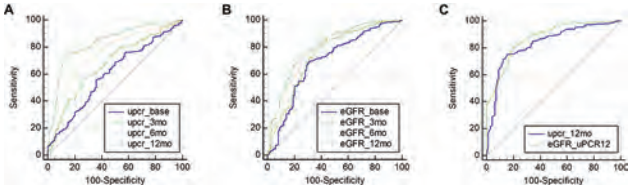

Figure 1. ROC curves of proteinuria (A), eGFR (B), and the sum of proteinuria plus eGFR (C) to predict stable kidney function by 36 months.

PO1598

Long-Term Outcomes of Lupus Nephritis in a Single Tertiary Care Center in South India

Srinivasa N. Kinjarapu, Swarnalatha Guditi, Siddharth Herur. *Nizam's Institute of Medical Sciences, Hyderabad, India.*

Background: Lupus nephritis (LN) is a frequent and severe manifestation of SLE, a risk factor for chronic kidney injury and end-stage renal disease in SLE we evaluated the clinical presentation and outcome with various treatment regimens in patients with lupus nephritis

Methods: A retrospective study in 50 patients with biopsy proven LN [class III (12), class IV(11), class V(4), class III+IV(10), class III+V(7), class IV+V(6)] treated with IVMP for 3 days followed by monthly CYC for 6 months and oral corticosteroids 0.5-1mg/kg with tapering to 10mg/day at the end of 6th month as induction protocol. AZA or MMF as maintenance regimen based on clinician discretion. Clinical presentation, histopathological (LM+IF) features, treatment regimen, treatment response and renal relapse and out comes were evaluated.

Results: Patients had a mean follow up of 3.6 years, clinical presentation nephrotic N.S (36%), nephritic Nes (24%), RPGN (16%), nephritic-nephrotic NS-NeS (12%), AKI (12%).patients who had RPGN and AKI presentation had crescentic GN and high chronicity index.46% attained complete remission(C.R), 28% attained partial remission, 26% did not respond to treatment(N.R) at the end of induction.15 and 8 patients out of 23 who attained complete remission were initiated on MMF and AZA as maintenance regimen respectively, 13/15 in MMF group and 7/8 in azathioprine.patients continued to be in C.R at the end of 2 years, In patients who attained partial remission 5 on MMF, 5 on AZA, 4 on quarterly pulse doses of cyclophosphamide, 3/5 patients on MMF had C.R, 2/5 on AZA had C.R, 2/4 on quarterly pulse doses of CYC had C.R. 6 out of 13 non responders were not given maintenance regimen as patients progressed to CKD at the end of 6 months. 4/7 patients who did not respond to CYC as induction were treated with MMF, 2 patient were treated with rituximab and one with triple immunosuppression(tacrolimus+MMF+corticosteroids) ,1 patient who treated with MMF and 1 patient who treated with rituximab attained partial remission, no patient attained complete remission at the end of 2 years

Conclusions: Induction regimen with cyclophosphamide is non inferior when compared to various other induction regimen in LN. Quartely pulse dose of CYC has no better out comes when compared to AZA and MMF as maintenance. Non responders at the end of 6 months of induction does not have better outcomes at the end of 2 years

PO1599

The Relationship Between Renal Flares and Continuity of Medical Care in Patients with Lupus Nephritis

Loulwa Alsharhan,[1] Insa M. Schmidt,[2] Ramon Bonegio,[2] Michael R. York,[2] Christina Lam,[2] Monica Crespo-Bosque,[2] Sushrut S. Waikar,[2] Hanni Menn-Josephy.[2] *[1]Kuwait Ministry of Health, Safat, Kuwait; [2]Boston University, Boston, MA.*

Background: African American and Hispanic patients with lupus nephritis (LN) are known to have worse clinical outcomes compared to those of white patients, with higher prevalence of severe inflammatory nephritis, higher rates of doubling creatinine, End Stage Kidney Disease (ESKD) and death. In this study, we characterized the frequency and severity of renal flares of patients treated in our lupus nephritis clinic.

Methods: Patient demographics are presented as mean ±SD; student t-tests were used when appropriate; Chi-square tests were used to determine differences in the number of renal flares and the number of missed appointments (dichotomized into 0 vs. >=1).

Results: Between 2005–2019, a total of 116 patients with Lupus Nephritis treated at the multidisciplinary lupus clinic in a safety net hospital in Boston, MA were enrolled in our study. 23.3% of patients (n=27) self-identified as white or Asian and non-Hispanic (group 1); 76.7% of patients (n=89) self-identified as Black, African American and/or Hispanic (group 2). Patients' demographics and disease characteristics were similar between the two groups. Over the duration of the study, 59.5% of patients (n=69) did not experience any flare, and 40.5% of patients (n=47) experienced ≥1 flares. Of the patients that experienced ≥1 flares, 89% (n=42) missed one or more appointments over the course of the study. The rate of missed appointments in group 2 was significantly higher than the one observed in group 1 (85.4% vs. 48.1% respectively, p≤0.001).

Conclusions: This study represents one of the largest cohorts of patients with lupus nephritis with consistent, longitudinal, long term follow up. We found that in our black, African American and/or Hispanic patient population, there was a significant association between renal flares and missed appointments. In our safety net hospital setting, missed appointments frequently represents patients' inability to access care due to various challenges including lack of sick days at work, transportation challenges, access to certain technologies and language barriers. When looking to reduce racial and ethnical health care disparities, we should design interventions that are aimed at removing key barrier to health care access.

PO1600

Collapsing Glomerulopathy Can Worsen Prognosis in Lupus Nephritis

Jia Yi, Vimal K. Derebail, Susan L. Hogan, Caroline J. Poulton, Lauren N. Blazek, Koyal Jain. *University of North Carolina System, Chapel Hill, NC.*

Background: Collapsing glomerulopathy (CG) conveys a poor renal prognosis and is characterized by podocytopathy with segmental or global collapse of the capillary walls. While it can be idiopathic, it is often seen in association with other viral, drug, and autoimmune conditions including lupus nephritis (LN). This retrospective study describes features and clinical outcomes of 16 patients with SLE and biopsy proven CG.

Methods: Using our Glomerular Disease Collaborative Network registry, we performed retrospective chart review on patients with systemic lupus erythematosus and CG on kidney biopsy with or without an LN lesion from 2000 - 2021. For patients with multiple biopsies, the first biopsy with GC was identified as the incident biopsy. We defined poor renal outcome as reaching a renal endpoint of serum creatinine doubling, chronic dialysis initiation, or renal transplantation. Patients were characterized by baseline demographics, laboratory results, serologies, interstitial fibrosis, and medications.

Results: We identified 16 patients with mean age of 33 years at incident biopsy. Most were female (87.5%) and black (87.5%). Mean serum creatinine (Sr Cr) was 3.1mg/dL and mean proteinuria by 24-hour urine collection or spot urine protein:creatinine ratio was 7.12g. Excluding 2 patients with limited follow-up, 11 of 14 (78.6%) patients had poor renal outcomes. These patients were similar in age (mean 33 years) and were also majority female (90.1%) and black (90.1%). In this group, mean Sr Cr was 3.53mg/dL and proteinuria was 3.69g. This group had significant interstitial fibrosis and tubular atrophy (IFTA) with 71.4% moderate and 28.6% severe IFTA. They reached renal endpoint in 4.5 years (average). Of 3 patients who did not have a renal end point, mean Sr Cr was 1.83 mg/dL with less IFTA noted on biopsy. Treatment options varied with most receiving mycophenolate or cyclophosphamide.

Conclusions: This descriptive project confirmed that CG was associated with poor renal prognosis in LN; the majority of the patients required dialysis, proceeded to transplantation, or had doubling of serum creatinine during follow up. Despite treatment with standard of care agents, outcomes remained poor. Patients who had worse Sr Cr at presentation or severe IFTA had worse outcomes.

PO1601

Serological Activity in Pure Membranous Lupus Nephritis in a Predominantly Black Population

Levard G. Roberts, Aakriti Arora, Hilton Mozee, Jason Cobb. *Emory University, Atlanta, GA.*

Background: Clinically significant kidney disease is estimated to occur in nearly 60% of patients with systemic lupus erythematosus (SLE). A majority of these patients develop proliferative disease, however 10-15% develop a non-proliferative form of disease known as membranous lupus nephritis (LN) (Class V lupus nephritis). These patients typically present with significant proteinuria. Austin et al. reported 7% of patients with low complements levels and 21% with elevated anti-dsDNA levels. In this study we assess serological activity (C3, C4, anti-dsDNA) of pure membranous LN in a predominantly black patient population

Methods: Kidney biopsy log from 2010 – 2017, and a retrospective chart review was completed. We excluded any patients with proliferative disease (active or chronic). We analyzed serological activity (C3 level, C4 level & anti-dsDNA) at time of renal biopsy and again at 24 weeks.

Results: Of the total 101 patients with pure membranous LN, we had 54 patients with sufficient follow-up data. 52 of the 54 patients were female with an average age of 35.5; 92.5% (50 of 54) were black. At time of kidney biopsy, low C3 and low C4 was found in 54% and 41% of patients respectively. Whereas an elevated anti-dsDNA was identified in 39% with 20% having the classic triad of low C3, low C4 and elevated anti-dsDNA. When compared to 24 weeks (roughly end of induction therapy) low C3 and low C4 was found in 37% and 24% of patients respectively. Whereas an elevated anti-dsDNA was identified in 31% with 13% have the combination of low C3, low C4 and elevated anti-dsDNA

Conclusions: In this predominantly black population of pure membranous LN the majority of patients did not have the classic triad of low complements and elevated dsDNA (20% at time of diagnosis/biopsy). Compared to others looking at pure membranous we did find higher rates of low complements and elevated anti-dsDNA at time of diagnosis (54% with low C3 initially). Possibly due to our unique urban patient population which is >90 percent black; i.e. more severe SLE. Despite the majority of patients not having the classic triad of low C3, low C4, and elevated anti-dsDNA, clinical providers must be diligent in assessing the need for kidney biopsy in SLE and non-SLE patients as serological activity does not correlate with biopsy findings. Earlier treatment correlates with improved prognosis.

PO1602

Role of Kidney Biopsies in Systemic Lupus Erythematosus Patients: Clinicopathologic Correlation

Lorenz Leuprecht, James M. Chevalier, Thangamani Muthukumar, Surya V. Seshan. *Weill Cornell Medicine, New York, NY.*

Background: Lupus nephritis (LN) affects >50% of the patients with systemic lupus erythematosus (SLE) and is a major cause for morbidity and mortality. The diagnosis of LN as well as the extent and severity of renal involvement are assessed via kidney biopsy. However, appropriate clinical indications for a kidney biopsy are not well defined in adults, nor is the predictability of the clinical presentation. Therefore, a clinicopathologic correlation of patients with SLE and presumed SLE who underwent a kidney biopsy is conducted.

Methods: We evaluated a total of 134 biopsy samples from 123 patients with either SLE or presumed SLE at the time of biopsy that were obtained during a 10-year period at a large medical center in New York City. 11 patients underwent a biopsy twice during that period. Laboratory, and clinical data were also collected retrospectively via chart review.

Results: 86% of the patients were female, 31% African American, 21% White, and 11% Asian. The mean age at the time of the biopsy was 36.2±12.6 years, the mean serum-creatinine 1.45±1.28 mg/dl, and the mean urinary protein excretion 3.86±3.43 g/d. 97% of the biopsy samples had evidence of LN, with the majority showing either Class IV+V (29%) or Class V (33%). About 13% had findings other than LN, such as TMA, focal collapsing features of the glomeruli, diabetic nephropathy, or possible ANCA vasculitis, with or without evidence of LN. Additionally, in patients of 65% of the biopsy samples, eGFR was ≥60 ml/min/1.73 m^2, and 29% (38/132) had a negative urine dipstick for blood. Complement levels were low in 88/128 instances, and anti-dsDNA was positive in 57% of the instances (n=127). When comparing all proliferative forms of LN (n=74) with Class V alone (n=44), patients with a proliferative form were younger, had a higher creatinine, higher proportion of hematuria, anti-dsDNA positivity, low complements, as well as a proteinuria level ≥1 g/d.

Conclusions: We conclude that normal serum-creatinine values may not preclude significant kidney pathology in SLE patients and those with proliferative forms of LN may have a negative urine dipstick for blood (16%), normal complement levels (14%), and/or a negative anti-dsDNA test (29%) around the time of the biopsy. Furthermore, patients with SLE may have other morphologic findings correlating with clinical renal presentation, instead of LN.

PO1603

Rituximab for Severe Recurrent Proliferative Lupus Nephritis After Kidney Transplantation: Pondering a Rare Case

Rui Song, Mingyue He, Ilay Rakhman, Serban Constantinescu, Iris J. Lee. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: Severe histologic recurrence of lupus nephritis (LN) post-kidney transplant(KTX) is extremely rare on standard transplant immunosuppression. Severe recurrence shortens allograft survival, yet treatment guidelines post-KTX are lacking.

Case Description: A 52-year-old African American (AA) man with ESRD secondary to LN underwent a second KTX from a deceased donor. He had a prior living-unrelated KTX with graft failure due to mixed rejection without LN recurrence. For the second KTX, he received Thymoglobulin induction and maintenance immunosuppressive regimen: Enteric-coated mycophenolate sodium (EC-MPS), Tacrolimus, Prednisone, with immediate graft function (nadir creatinine 1.4mg/dL). He developed leukopenia requiring a reduction of EC-MPS to 360mg twice daily. He developed nephrotic range proteinuria 6 months post-KTX but had stable allograft function, bland urine sediment, normal complements, and negative anti-dsDNA antibodies. Despite inactive serologies, allograft biopsy revealed diffuse proliferative sclerosing and crescentic LN (ISN/RPS class IV). Due to persistent leukopenia, Rituximab was chosen over commonly-used Cyclophosphamide (CYC) for therapy. He received intravenous Methylprednisolone (3000 mg) and Rituximab 800mg (375 mg/m2) for 4 doses. Complete B-cell depletion was maintained for 3 months. His proteinuria decreased from 6.9 g/g to 1.2 g/g, and renal allograft function remained stable.

Discussion: Severe recurrent LN post-kidney transplant is rare and can present atypically. Negative serologic markers, bland urine sediment and lack of LN recurrence on the first KTX did not rule out LN recurrence on the second kidney allograft. In our case, only the presence of persistent progressive proteinuria warranted allograft biopsy. AA ethnicity and reduction of EC-MPS were risk factors, which highlights the significance of full transplant maintenance therapy to prevent recurrent LN. B cell plays a pivotal role in LN pathogenesis. Rituximab targets CD20+ B cells and has been successfully utilized for refractory LN. It has a more favorable toxicity profile compared to CYC which has been the conventional treatment for clinically significant LN post-KTX. We propose Rituximab as a better treatment option for severe recurrence of LN post-KTX.

PO1604

Influenza Vaccination in Systemic Lupus Erythematosus (SLE): Effectiveness, Efficacy, Safety, Utilization, and Barriers

Jackie Jia Lin Sim,[1] Cynthia C. Lim.[2] *[1]National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [2]Singapore General Hospital, Singapore, Singapore.*

Background: Influenza infections increase morbidity and mortality among immunocompromised individuals with SLE and lupus nephritis. Yet, they are highly preventable through vaccination. We aimed to describe the effectiveness, efficacy, safety, utilization and barriers to influenza vaccination in SLE so that targeted strategies can be implemented to improve vaccination rates.

Methods: We conducted a systematic review and meta-analysis of all published and unpublished studies up to 19 May 2021 via PubMed, Embase, Cochrane, WHO Clinical Trials, and ClinicalTrials.gov, which reported on our desired outcomes relating to influenza vaccination in SLE and lupus nephritis.

Results: Of 726 articles screened, 44 studies (14779 patients) were included. 9 studies reported on effectiveness, 20 studies on efficacy, 24 studies on safety, 12 studies on utilization, and 4 studies on barriers to influenza vaccination. Renal involvement or lupus nephritis was present in 20.9%. The majority were female (90.8%). The mean age was 41.3 years (95% CI 36.8-45.7), mean disease duration was 10.91 years (95% CI 7.10-14.72), and mean SLEDAI score was 4.15 (95% CI 3.18-5.12). Individuals who received influenza vaccination were less likely to develop pneumonia (relative risk, RR 0.38, 95% CI 0.08-1.86, p=0.23), acute bronchitis (RR 0.21, 95% CI 0.09-0.48, p=0.0002), and viral respiratory infections (RR 0.36, 95% CI 0.21-0.64, p=0.0005). Pooled seroconversion and seroprotection rates were 56.6% and 68.2% for H1N1, 56.7% and 73.7% for H3N2, and 46.8% and 69.9% for B influenza strains. Mean SLEDAI scores did not change significantly after vaccination. Flares occurred in 20.3%, while local and systemic adverse events occurred in 20.5% and 26.6%, respectively. Only 39.1% of SLE patients were currently vaccinated against influenza. Meta-regression showed that vaccination rates were significantly associated with increasing GDP of the country (p=0.002) and increasing mean years of disease duration (p=0.02). The most common barriers to vaccination were concerns over the safety or efficacy of the vaccine (37.2%), lack of doctor recommendation (23%), and having experienced side effects of other vaccines previously (13%).

Conclusions: Influenza vaccination is effective and safe in SLE and lupus nephritis. Targeted strategies are required to overcome barriers to improve influenza vaccination uptake.

PO1605

Lupus Nephritis in a Patient with Autoimmune Hepatitis: A Case Report

Soo H. Kae,[1] Erin Lawlor,[1] Sankar N. Niranjan.[2] *[1]UConn Health, Farmington, CT; [2]Greater Hartford Nephrology, Bloomfield, CT.*

Introduction: Overlapping of autoimmune hepatitis (AIH) and lupus nephritis (LN) is a rare entity, only occurring in 1-2.6% of AIH cases, and is difficult to diagnose due to the overlap of autoimmune features. Only a few case reports have been reported in the literature.

Case Description: 61-year-old male with established remote diagnosis of AIH well controlled on azathioprine on routine urinalysis had new-onset proteinuria (5 g/day) and hematuria. Renal biopsy showed membranoproliferative glomerulonephritis (MPGN) pattern on light microscopy with "full house" on immunofluorescence consistent with class IV renal-limited LN. He was treated with steroids and mycophenolate mofetil with remission of proteinuria and improvement in renal function.

Discussion: Our patient met systemic lupus erythematosus (SLE) criteria via 2019 ACR guidelines with positive ANA (1:320 with dual speckled and nuclear pattern) and renal biopsy results. He did not have any other systemic or constitutional findings. Although he had hypocomplementemia and thrombocytopenia, these were not scored due to his liver disease. He had indeterminate anti-dsDNA levels but later became consistently negative with therapy. Our patient's rather unique disease course and mixed autoimmune features show the challenges in diagnosis of overlapping AIH and LN. In patients like ours who do not exhibit other systemic signs of SLE, renal biopsy might be the only way to establish diagnosis. Hence, prompt clinical suspicion by the clinician is important in diagnosis and subsequent delivery of treatment. Further case reports will be beneficial in raising awareness of the overlapping of AIH and LN.

PO1606

Delayed Clinical Manifestation of Biopsy-Proven Thrombotic Microangiopathy in a Patient with Lupus Nephritis: A Case Report

Najia Idrees,[1] Madeline A. Dilorenzo,[1] Joshua S. Hundert,[2] Jean M. Francis,[1] Hanni Menn-Josephy.[1] *[1]Boston Medical Center, Boston, MA; [2]South Shore Hospital, Weymouth, MA.*

Introduction: Complement-mediated thrombotic microangiopathy (c-TMA) involves unregulated complement activation due to inherited or acquired mutations in complement regulatory proteins. Immune complex formation, an important component of lupus nephritis (LN) pathogenesis, can over activate the complement system leading to c-TMA in the kidneys. Findings of c-TMA in LN patients have been associated with end-stage kidney disease (ESKD) or death in up to 50% of patients.

Case Description: 32-year-old female, with a history of lupus and ISN/RPS class III LN since 2017 and recent stroke, was evaluated at our lupus clinic for LN flare with worsening kidney function, increased proteinuria and low complements. A repeat kidney biopsy showed focal proliferative and membranous LN (ISN/RPS class III and V) and a component of TMA. She received standard of care treatment for LN with methylprednisolone and cyclophosphamide, due to past mycophenolate therapy failure. Kidney function and proteinuria improved and complement levels normalized. Three weeks later, she was admitted with hemorrhagic shock secondary to renal subcapsular hematoma, stabilized with PRBC transfusions. After one week, she again developed worsening anemia, worsening thrombocytopenia and oliguric acute kidney injury with diuretic resistant anasarca prompting intubation and initiation of hemodialysis. Hemolysis panel revealed a low haptoglobin, high LDH and schistocytes on peripheral smear. Serum complements were low. Due to high suspicion of c-TMA, she received weekly eculizumab followed by eculizumab every 2 weeks. Three weeks later, her hemoglobin and platelets improved and LDH decreased. Her urine output improved and she was able to come off of hemodialysis. She remained with stage 3b CKD.

Discussion: In patients with LN, severe renally-limited TMA can present without systemic manifestations. In our patient, hematologic signs of TMA appeared only 4 weeks after her initial biopsy-proven TMA, and after clinical improvement of her LN. This highlights the importance of monitoring LN patients with asymptomatic renally-limited TMA closely, and treating them promptly once they develop clinical features of active TMA. Anti-complement therapy with eculizumab is shown to be effective in these patients.

PO1607

Clinical Course of Crescentic Glomerulonephritis in Singapore

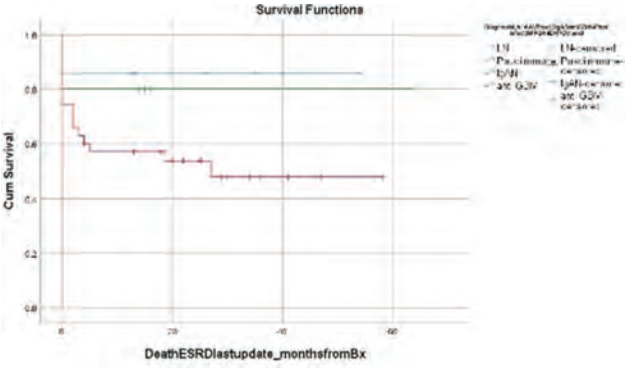
Tung Lin Lee, Hui Zhuan Tan, Irene Y. Mok, Jason Choo Chon Jun, Cynthia C. Lim. *Singapore General Hospital, Singapore, Singapore.*

Background: Crescentic Glomerulonephritis (GN) is histologically representative of severe glomerular damage, and commonly manifests as rapidly progressive glomerulonephritis (RPGN). We report our center's experience with Crescentic GN over a 5 year period.

Methods: Retrospective cohort study of biopsy-proven glomerulonephritis with ≥10% crescents diagnosed between November 2015 and January 2021 in an academic medical center nephrology unit. Primary outcome was time to death or end stage renal failure (ESRF).

Results: We evaluated 50 patients (36% male), median age 64.7 years (IQR 51.2, 72.4) with crescents in 37.5% (17.4, 54.3) of the glomeruli sampled. At presentation, 70% had acute kidney injury with median serum creatinine 278 (118, 537) μmol/L and 26% required dialysis. The most frequent diagnoses were pauci-immune GN including ANCA-associated vasculitis (70%), lupus nephritis (14%), IgA nephropathy (10%) and anti-GBM disease (4%). At 6 months, the majority (94%) had received immunosuppressants including methylprednisolone (66%), prednisolone (88%), cyclophosphamide (70%), rituximab (12%), mycophenolate mofetil (36%) and plasma exchange (30%). Remission was achieved in 44%. Median follow up was 29.5 (19.8, 48.2) months. End Stage Renal Failure (ESRF) occurred in 32% at 0 (0, 2) months and death occurred in 18% at 5 (1, 23) months. ESRF and/or death occurred in 22 patients (44%). Survival was best for lupus nephritis (log rank p = 0.03) among the most common diagnoses (Figure 1). Multi-variable analysis (stepwise) found that pre-biopsy serum creatinine was independently associated with the primary outcome (HR 1.02, 95% CI 1.01–1.03 per 10 μmol/L increase) after adjusting for age, diabetes, crescents and histological diagnosis.

Conclusions: Despite the majority of patients receiving treatment, a significant proportion (44%) still reached the primary outcome of death and ESRF. Novel and efficacious treatment options are therefore needed to improve the outcomes and prognosis of patients with such a debilitative condition.



PO1608

Clinical Characteristics and Outcomes of Severe ANCA-Associated Renal Disease in a Multiethnic Urban Population

Allison J. Leonard,[1] Shilpa Arora,[2] Ambarish Athavale.[1] *[1]John H Stroger Hospital of Cook County, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.*

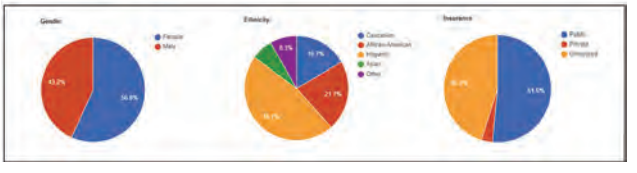
Background: To study the clinical characteristics, treatment and outcomes of ANCA vasculitides patients in an inner-city county hospital.

Methods: Retrospective study of 60 patients with biopsy-proven ANCA glomerulonephritis and a minimum follow-up of 6 months (median, IQR 23, 29 months) were included. Demographic and clinical information including pathology data, treatment and outcomes were collected. Multivariate regression analyses were done to study predictors of outcomes of estimated Glomerular Filtration Rate (eGFR) at 6 months and End Stage kidney Disease (ESKD).

Results: Patients represented an ethnically diverse population (Figure 1) with baseline characteristics as shown in Table 1. Mean age (SD) at diagnosis was 57.4 (13.7). Almost all patients (59/60, 98.3%) presented with hematuria and 17/60 (28.3%) had nephrotic-range proteinuria. Extra renal involvement most commonly pulmonary was seen in 35/60 (58.3%) patients. 44/60 (73.0%) had crescents and nearly all had interstitial fibrosis and tubular atrophy (IFTA) (median, IQR 30%, 56%). Most patients were induced with cyclophosphamide (49/60, 81.7%) and 16/60 (26.7%) received plasma exchange. eGFR (mean±SD) at baseline and 6 months follow up were 20.8±19.4 and 43.5±23.0 respectively. 15/60 (25%) patients progressed to ESKD. On multivariate linear regression analysis, age (B -0.5), IFTA (B -27.7) and baseline eGFR (B 0.3) predicted eGFR at 6 months and IFTA (OR, 95% CI, 111.5, 1.1-11907.7) and eGFR at 6 months (OR 0.9, 95% CI 0.8-1.0) were associated with ESKD (P <0.05) on multivariate logistic regression analysis. Ethnicity, ANCA type or titer, crescents on biopsy and treatment received did not predict eGFR at 6 months or ESKD.

Conclusions: In this cohort of patients with severe ANCA glomerulonephritis IFTA and baseline eGFR were the most significant predictors of eGFR at 6 months follow up which in turn was associated with progression to ESKD.

Figure 1: Patient Demographics



Patient Demographics

Serology	MPO n (%)	41/60 (70.7%)
	PR3 n (5)	15/60 (25.9%)
	Mean ANCA titer (95% CI)	69.46 (38.14-100.78)
Renal function	Baseline mean creatinine (95%CI)	4.93 (3.65-6.22)
	Baseline mean eGFR (95% CI)	20.80 (15.79-25.80)

Table 1: Baseline Characteristics

PO1609

Long-Term Outcome in Patients with ANCA-Associated Vasculitis (AAV): The Monocentric Experience of Brescia

Chiara Salviani,[1] Gina A. Gregorini,[1] Gianluca Tedoldi,[2] Federico Alberici,[1,2] Francesco Scolari.[1,2] *[1]Nephrology Unit, ASST Spedali Civili di Brescia, Brescia, Italy; [2]Universita degli Studi di Brescia, Brescia, Italy*.

Background: Renal involvement in AAV is common, ranging between 80 and 90%; of note, up to 40% of patients (pts) with renal involvement will develop End-Stage Renal Disease (ESRD). We explored prognostic factors of renal and overall long-term survival in AAV pts with renal involvement.

Methods: Monocentric, retrospective study, including all pts with clinical or histological diagnosis of AAV with renal involvement followed at our Unit from 1990 to 2019, with follow-up (f-u) ≥12 months.

Results: We identified 281 patients. Median f-u was 75 months (IQR 33-141). Most pts were classified as MPA (71%), followed by GPA (26%) and eosinophilic granulomatosis with polyangiitis (3%). ANCA were positive in 97% (anti-MPO in 66%, anti-PR3 in 31%). At onset, median creatinine was 3.5 mg/dl (IQR 1.9-6.7) and proteinuria 1.1 g/24h (IQR 0.5-2); 20% of pts required haemodialysis (HD), with subsequent recovery of renal function in 55% of them. Induction therapy consisted of oral corticosteroids for all pts, with iv pulses >1g in 38% of cases; plasma-exchange in 27%; cyclophosphamide in 57% and rituximab in 33% of pts. Relapses were experienced in 31% of pts, with renal flares in 20%. Renal survival was 87%, 79% and 73% at 1,5 and 10 years, respectively. At multivariate Cox regression analysis, clinical diagnosis of MPA (HR 5.116, CI 3.437-7.408, p<0.0001) and HD requirement at onset (HR 13.469, CI 9.050-19.504, p<0.0001) were predictors of ESRD. Overall survival was 90%, 77% and 56% at 1, 5 and 10 years, respectively. Most deaths were due to infections (33%), followed by cardiovascular (CV) diseases (20%) and malignancies (13%). At multivariate Cox regression analysis, age (HR 5.724, CI 3.846-8.288, p<0.0001) and HD requirement at onset (HR 2.902, CI 1.949-4.202, p<0.0001) were predictors of mortality.

Conclusions: Despite several therapeutic advances, AAV with renal involvement are still characterised by poor prognosis, especially in pts requiring HD at onset and of older age; infection, CV diseases and malignancies were the main causes of death.

PO1610

Predicting Outcomes in ANCA-Associated Vasculitis Using a Complete National Cohort

Dominic P. Mcgovern, Jennifer S. Lees, Colin C. Geddes, Emily Mcquarrie, Kate I. Stevens. The Scottish Renal Biopsy Registry *The Glasgow Renal and Transplant Unit, Glasgow, United Kingdom*.

Background: Outcomes in ANCA vasculitis remain difficult to predict & therapeutic decision-making can be challenging. We aimed to establish if a renal risk score (RRS) could predict outcomes.

Methods: The Scottish Renal Biopsy Registry is a complete national dataset of all biopsies performed in Scotland. Those who had a first renal biopsy between 2014 & 2017 with evidence of ANCA vasculitis were included. Demographic data & outcomes were recorded. RRS was calculated. Each patient was categorised according to % of normal glomeruli, % of tubular atrophy/interstitial fibrosis & eGFR (CKD-EPI) at time of biopsy. Individual scores were summated & patients defined as low, medium or high risk. Cox proportional hazard models were created for survival to ESKD, relapse & death, stratified by risk group.

Results: Two-hundred & forty-six patients with biopsy proven ANCA vasculitis were identified. Fifty percent (n=123), 46% (n=112) & 5% (n=11) were stratified as low, medium & high risk respectively. Fifty-two percent (n=129) were male & mean age at biopsy was 66.7±12.2 years. Mean eGFR was lower in the high-risk category (8.6±6.1 'v' Low risk 45.7±26.0 ml/min/1.73m^2, p<0.001) & proteinuria was higher (405 (IQR 170-767) 'v' Low risk 81 (IQR 41-155) mg/mmol, p<0.001). Thirty-seven percent (n=91) were PR3 antigen positive. Eighteen (n=7%) patients experienced pulmonary haemorrhage; representation similar across all risk categories. Those categorised as medium or high risk were more likely to receive plasma exchange & or haemodialysis at presentation (p<0.001) compared with the low risk category. Overall, 16% (n=40) of patients relapsed with a trend to higher risk of relapse in the low risk group (27% of these patients, p=0.05). Thirty seven (15%) patients developed ESKD. Cox proportional hazard model for development of ESKD shows that those in high risk category were more likely to reach ESKD (adj HR 78.4, 95% CI 14-438.4, p<0.001).

Conclusions: A simple RRS, using routinely reported data, in patients with renal biopsy proven ANCA vasculitis can help to predict development of ESKD. It may also be predictive of future relapse in those with a lower RRS. The RRS could inform monitoring & treatment decisions. A unique strength of this data is that it is based on a complete national dataset making it less susceptible to bias from regional variations in practice.

PO1611

ANCA-Associated Crescentic Glomerulonephritis (AAV-GN) in Patients with Chronic Lymphocytic Leukemia (CLL): A Case Series

Lagu A. Androga, Mariam P. Alexander, Marta I. Casal Moura, Kari Rabe, Sameer Parikh, Nelson Leung, Fernando C. Fervenza, Andrea G. Kattah. *Mayo Clinic Minnesota, Rochester, MN*.

Background: Previous case reports have identified an association between CLL and AAV-GN. However, information on the clinical and pathologic characteristics and long-term outcomes of AAV in the setting of CLL have not been well described.

Methods: We queried medical records and research databases of CLL and AAV subjects seen at our institution to identify patients with diagnoses of CLL and AAV-GN from 1990-2020. We analyzed patient demographics, AAV-GN, CLL specific characteristics, treatments, and outcomes. Kidney biopsies were also reviewed.

Results: We identified 12 patients with AAV-GN and CLL. The mean age at diagnosis was 65 years (48, 80) for CLL and 68 years (57, 80) for AAV-GN. 5 patients were diagnosed with CLL prior to AAV-GN, 4 the same month, and 2 developed CLL >3 years after AAV-GN. At the time of AAV-GN diagnosis, all had acute kidney injury, with a median serum creatinine (SCr) of 1.9mg/dL (SD 3.2). Other organs involved included lungs (n=3), skin (n=1), and eyes/ encephalitis (n=1). 9 patients p-ANCA-MPO and 2 had c-ANCA-PR3 and one with an indeterminate ANCA but had PR3. On light microscopy, all had crescents, no vasculitis of the arteries, but 9 patients had focal lymphoid infiltrates without a formal diagnosis of CLL in the kidneys. On immunofluorescence 6/12 had trace to 1+ of IgA, 5/12 with IgG and 4/12 with C3. 5/12 of the biopsies had mesangial deposits and majority (1 with diffuse and 7 with mild–moderate) had foot process effacement. All patients received treatment for AAV (9 with rituximab, and 3 with cytotoxic drugs). Renal outcomes were favorable with 11 patients showing an improvement or stabilization in SCr. One patient (p-ANCA MPO antibodies) developed end stage kidney disease, and 3 patients died, two from CLL and the other from heart failure.

Conclusions: In this case series of patients with CLL and AAV GN, the vast majority had had p-ANCA MPO, suggesting that the two conditions have either a common underlying lymphocyte dysfunction or that CLL is a predisposing factor to the development of AAV. Anti-CD20 monoclonal antibody therapy was most commonly used, and it led to remission of AAV-GN.

PO1612

Kidney Biopsy Chronicity Grading in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis

Marta I. Casal Moura, Fernando C. Fervenza, Ulrich Specks, Sanjeev Sethi. *Mayo Foundation for Medical Education and Research, Rochester, MN*.

Background: Kidney biopsy is valuable for prognostic assessment of renal outcomes in antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) with glomerulonephritis (AAV-GN) but the impact of chronic changes is not determined.

Methods: A retrospective cohort study of MPO- or PR3-ANCA positive patients with AAV and active renal disease. We applied the Mayo Clinic Chronicity Score (MCCS), validated and evaluated its implications on outcome prediction in AAV-GN.

Results: We analyzed 329 patients with kidney biopsies available to score. The extent of chronicity was graded by MCCS as (i) minimal – 102 (31.0%), (ii) mild – 106 (32.2%), (iii) moderate – 86 (26.1%), and (iv) severe – 35 (10.6%). The MCCS grades correlated with the degree of renal function impairment at presentation (mean eGFR: 48.3 vs. 29.2 vs. 23.7 vs. 18.5 mL/min/1.73 m^2, p<0.0001). Higher degrees of the individual components of the MCCS (glomerulosclerosis, interstitial fibrosis, tubular atrophy and arteriosclerosis) were associated with lower median eGFR (p<0.0001) and decreased event free (kidney failure (KF) and death) survival (p=0.002, p<0.0001, p<0.0001 and p=0.017, respectively). Patients with lower MCCS grades recovered renal function more frequently (p<0.0001). Increasing MCCS grades were associated with decreased renal recovery (p=0.001), more frequent events and shorter time to KF (p<0.0001), KF and death (p<0.0001), and death (p=0.042), independently of remission-induction treatment used (CYC or RTX). The MCCS stratified renal outcomes for each MCCS grade and can be used in clinical practice as a cut-off for KF prediction (MCCS≥4).

Conclusions: Chronic changes on kidney histology independently predict renal function, outcomes and response to treatment in AAV-GN.

PO1613

The Effect of Cumulative UVB Dose on ANCA-Associated Vasculitis

Jennifer Scott,[1] Enock Havyarimana,[2] Albert Navarro-Gallinad,[1] Jason Wyse,[1] Jos van Geffen,[3] Antonia Buettner,[1] Tamara Wanigasekera,[1] Louis J. Aslett,[4] Neil Basu,[2] Lina Zgaga,[1] Mark A. Little.[1] Trinity Health Kidney Centre, Trinity College Dublin, Ireland *[1]The University of Dublin Trinity College, Dublin, Ireland; [2]Institute of infection, immunity and inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom; [3]Royal Netherlands Meteorological Institute (KNMI), De Bilt, Netherlands; [4]Department of Mathematical Science, University of Durham, Durham, United Kingdom*.

Background: ANCA-associated vasculitis (AAV) has a relapsing-remitting course but the precise triggers of onset and relapse are unknown. The potential effect of ultraviolet B (UVB) radiation on disease phenotype and activity, mediated by vitamin D (vitD), has been proposed, given the marked incidence variation of AAV phenotypes and serotypes with latitude. Using a well-validated vitD proxy (cumulative-weighted

UVB dose (CW-D-UVB) at wavelengths that induce vitD synthesis) we hypothesized that prolonged periods of low ambient UVB are associated with an increased risk of GPA phenotype and AAV relapse in this subgroup.

Methods: The UKIVAS (n=1994) and Irish Rare Kidney Disease (RKD) (n=439) registries were used (total n=2433). Inclusion criteria: i). definite AAV diagnosis, ii). positive proteinase-3 (PR3) or myeloperoxidase (MPO) serology and/or positive histopathology. Logistic regression was used to investigate the relationship between latitude, CW-D-UVB and AAV phenotype/serotype in the entire cohort. A multi-level model was then applied to examine their effect on AAV relapse risk in the RKD subgroup.

Results: CW-D-UVB varied across seasons and latitudes. There was no relationship between latitude/CW-D-UVB at disease onset and AAV phenotype/serotype. MPA, MPO-ANCA, older age and rituximab maintenance were protective against relapse. There was no association between CW-D-UVB and relapse risk, even when examining phenotype specific risk (table 1).

Conclusions: We found no association between cumulative UVB, a validated vitD proxy, and AAV phenotype, ANCA serotype nor AAV disease activity in a genetically homogeneous cohort. These findings cast doubt on the role of vitD in AAV disease activity.

Random effects:	Variance (SD)
Patient ID	0.75 (0.86
Fixed effects:	**OR (95% CI, p)**
CW-D-UVB (kJ/m2)	1.20 (0.87 - 1.66, 0.28)
Not MPA (Ref: MPA)	1.69 (0.95 - 2.98, 0.07)
Age at diagnosis (years)	0.72 (0.58 - 0.90, 0.003)
Gender (male)	0.89 (0.58 - 1.37, 0.60)

Multi-level model investigating the association between CW-D-UVB and AAV relapse

PO1614

A Severe Presentation of Systemic Lupus Erythematosus (SLE) and ANCA-Associated Vasculitis (AAV) Overlap Syndrome

Jaclyn Khil, Thuy M. Nguyen, Sijie Zheng. *Kaiser Permanente Oakland Medical Center, Oakland, CA.*

Introduction: An increasingly recognized overlap syndrome (OS) of lupus nephritis and ANCA positive crescentic glomerulonephritis is rare and presents treatment challenges. It's not clear whether to treat as LN or ANCA vasculitis. Here we describe a severe presentation of OS, the subsequent management and positive outcome.

Case Description: A 42 y.o. woman with no PMH presented with 3 weeks of cough, dyspnea, fever, malaise, AKI and hypoxia. Her hgb was 6.3 g/dL and creatinine 17.4 mg/dl (normal 1.5 years prior). UA showed large hgb and >182 RBCs and UPCR 5.72 g/g. Serologies were significant for elevated DsDNA, RNP ab, Smith ab and positive ANA with low complement levels. MPO ab was elevated to >8.0 (<=0.9) and anti GBM negative. Cardiolipin ab was elevated but beta 2 glycoprotein ab and lupus anticoagulant ab were negative. Chest CT showed multifocal opacities. She was urgently started on hemodialysis and solumedrol 1g for 3 days then prednisone 60mg daily. On day 2 of admission she underwent renal biopsy. Her course was complicated by hemoptysis and bronchoalveolar lavage showed diffuse alveolar hemorrhage (DAH). She was initiated on plasmapheresis. Biopsy demonstrated necrotizing crescentic GN with immunofluorescence showing full house pattern and complex deposits with strong ANA staining of nuclei. Given the biopsy results and serologies the patient was diagnosed with LN/AAV overlap. The patient was started on Cytoxan 750mg monthly administration. She completed 7 daily sessions of plasmapheresis and renal function recovered sufficiently to stop dialysis. Two months after discharge, her renal function continued to improve with her most recent creatinine down to 2 mg/dl.

Discussion: LN and AAV overlap is rare and there are no guidelines regarding management of these patients. This case stresses the importance of having a high suspicion of LN/AAV when a young, female patient presents with new onset renal failure and DAH. The patient benefited from early, aggressive treatment targeting both disease processes including early initiation of high dose steroids. Secondly, plasma exchange should be initiated emergently with severe presentation, including DAH. Plasmapheresis did not reduce incidence of ESKD in PEXIVAS trial, however, we suspect in this case it contributed to the good outcome. Lastly, little is known about outcomes in these patients, but this is an example of a severe presentation with a positive outcome.

PO1615

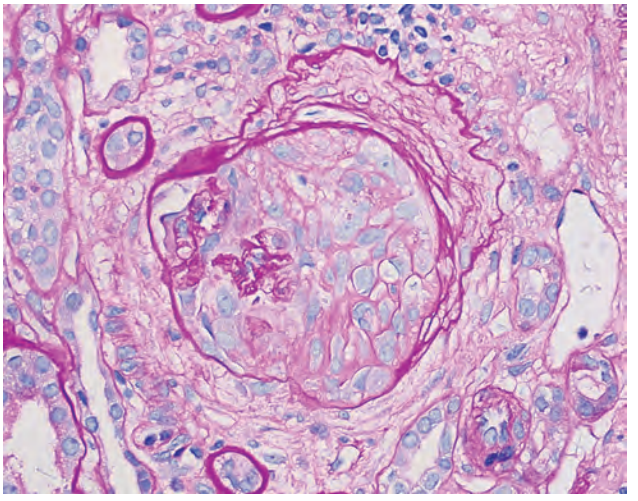
Pauci-Immune Crescentic Glomerulonephritis Associated with Pulmonary Coccidioidomycosis

Elvira González, Erika R. Bracamonte, Amy Yau. *Banner University Medical Center Tuscon, Tucson, AZ.*

Introduction: Coccidioidomycosis is an endemic fungal infection in the southwestern United States There are around 150,000-300,000 cases annually, of which 60% occur in the state of Arizona. Most patients are asymptomatic. 40% have primary pulmonary involvement and present with dyspnea and fatigue. A minority (around 1%) have extrapulmonary dissemination with unknown incidence of renal involvement.

Case Description: We report a 70-year-old immunocompetent patient with CKD (baseline creatinine of 1.2 mg/dL) recent diagnosis of pulmonary coccidioidomycosis presenting with AKI due to ANCA negative pauci-immune crescentic GN. Our patient was referred to nephrology for worsened renal function, creatinine of 1.7 mg/dL. He was diagnosed with pulmonary coccidioidomycosis 3 months prior and started on fluconazole 400 mg daily. Due to concern for disseminated coccidioidomycosis, underwent a renal biopsy showing minimally active pauci-immune crescentic GN (Fig 1). Complement levels were normal, ANCA immunofixation, anti-MPO and anti-PR3 titers were negative. He was initiated on prednisone 60 mg daily with appropriate supportive therapy and gradually tapered over the following three months with partial improvement to his creatinine to 1.5 mg/dL from a peak of 1.9 mg/dL (Fig 2).

Discussion: This is the third known reported case of pauci-immune crescentic GN associated with coccidioidomycosis, and one of a handful of case reports describing pauci-immune crescentic GN in patients with chronic fungal infections. Our case highlights the importance in understanding the pathogenesis and prognosis of chronic fungal infections and GN.



PO1616

Infective Endocarditis Associated Pauci-Immune GN: Look Before You Leap

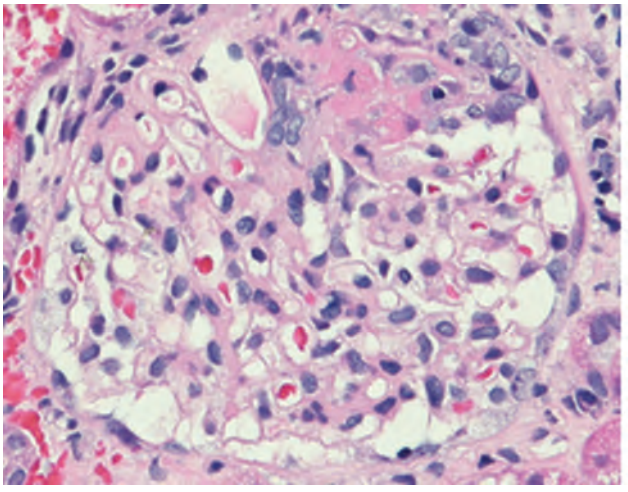
Stephanie S. Pavlovich, William C. Bennett, George Terinte-Balcan, Gerald A. Hladik, Koyal Jain. *University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Introduction: Small vessel vasculitis has a broad array of potential etiologies. A patient with known cryoglobulinemia due to hepatitis C (HCV) presenting with fever, glomerular hematuria and leukocytoclastic vasculitis because of endocarditis illustrates the importance of a judicious diagnostic evaluation.

Case Description: 41-year-old male with a history of HCV and intravenous drug use presented with confusion, migratory arthralgias and receptive aphasia over 3 months. 1 month prior to admission he was diagnosed with HCV-related type III cryoglobulinemia and started on therapy with glecaprevir/pibrentasvir. On exam he had a temperature of 38.4°C, petechial rash, receptive aphasia and systolic murmur. Laboratory data showed creatinine 1.23mg/dL, CRP 45.1mg/L, rheumatoid factor 15.9 IU/mL, type III cryoglobulins, PR3-ANCA 49.6U/mL and normal complement levels. Skin biopsy showed leukocytoclastic vasculitis. MRI of the brain showed foci of hemosiderin deposition consistent with vasculitic lesions. Blood cultures grew *E. faecalis* and echocardiogram showed a mitral valve vegetation. Kidney biopsy showed pauci-immune necrotizing GN

and diffuse ATN. As creatinine worsened (peak 2.66mg/dL), mycophenolate (MMF) was added after resolution of bacteremia following iv antibiotics. 1 week after stopping antibiotics, he was readmitted with AKI, nephritic syndrome, and recurrent *E. fecalis* bacteremia. MMF was stopped and antibiotics restarted with improvement in creatinine (1.40mg/dL) and urine sediment.

Discussion: This is a rare case of PR3-ANCA vasculitis due to *E. faecalis* endocarditis. A kidney biopsy and high index of suspicion is crucial in diagnosing pauci-immune GN in patients with preexisting vasculitis. Absence of hypocomplementemia raised suspicion for a superimposed process. This case highlights the importance of a careful evaluation in patients presenting with vasculitis despite appropriate treatment of a preexisting vasculitic syndrome.



PO1617

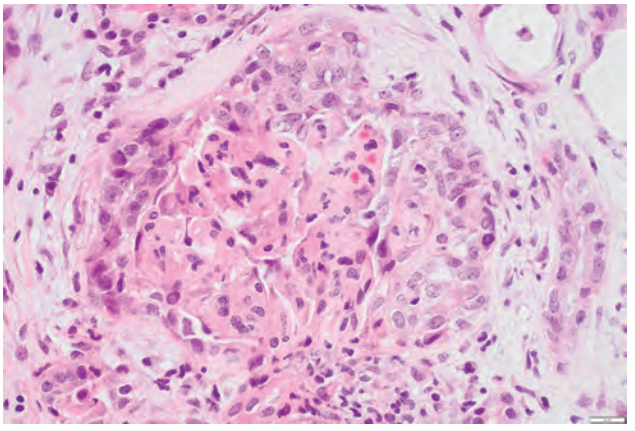
A Rare Case of Crescentic Glomerulonephritis, Diffuse Proliferative Class IV Lupus Nephritis, and Collapsing Glomerulopathy in a COVID, P-ANCA, and Myeloperoxidase-Positive Patient

Ajay B. Ganglam, Fatima Batool, Ronald Miick, Daranee Chewaproug, Mauricio A. Pedroza. *Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: An unusual case of Diffuse Class 4 Lupus Nephritis, along with Collapsing Glomerulopathy from asymptomatic COVID infection

Case Description: 42 year old Asian female presented with painless hematuria, anasarca, reduced hearing, and eye redness over a month. She had empiric antibiotics and steroids prior to admission. On admission, she was hypertensive with anasarca. Labs revealed AKI creatinine of 2.5 mg/dl, proteinuria of 11 grams, and serum albumin 1.9 gm/dL. Urine analysis showed dysmorphic RBCs, RBC casts. Ultrasound showed 12 cm kidneys bilaterally. She had normal complements and DS DNA, anticardiolipin and lupus anticoagulant negative. ANA, anticentromere antibody, COVID, PANCA, MPO all positive. Kidney biopsy showed crescentic glomerulonephritis, diffuse proliferative glomerulonephritis Class IV, collapsing glomerulopathy, full house pattern on IF. EM showed sub endothelial, mesangial, and para mesangial deposits, diffuse podocyte foot process effacement, corona virions in endothelial cells. The patient did not have any COVID symptoms and was treated with pulse steroids, MMF induction, hydroxychloroquine, and ACE I. Serum creatinine improved to 1.33 mg/dl, proteinuria improved to 5.6 grams. Her eye redness and hearing impairment resolved.

Discussion: This is a rare case of diffuse class IV lupus nephritis with normal complements, DS DNA, and full house pattern on IF. She tested positive for COVID, was asymptomatic, and was able to start treatment. Corona virions and podocytopathy was noted on EM. Improvement in proteinuria, serum creatinine, albumin, and resolution of anasarca were used to monitor response to treatments. Complements and DS DNA could not monitor disease activity. Thus, clinicians should not rely purely on serologies for diagnosis but should pursue kidney biopsy for definitive diagnosis and treatment. Patients may have atypical presentations.



PO1618

Schistosomiasis in a Patient on Rituximab for ANCA-Associated Glomerulonephritis

Milica Jovanovic,[1,2] Muhammad U. Aameish,[1,2] Donald I. Baumstein,[1,2] Ashok P. Chaudhari.[1,2] *[1]Metropolitan Hospital Center, New York, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Rituximab and glucocorticoids induce remission in ANCA associated vasculitis with renal involvement. Rituximab induces B-cell depletion and influences T-cell immunity, which predispose patients to serious infectious complications. We present a case of schistosomiasis in a patient on rituximab for Pauci Immune Glomerulonephritis (GN) associated with ANCA vasculitis.

Case Description: A 39 years old female from Honduras with history of sero-negative arthritis, acute kidney injury with pauci immune, focal necrotizing and diffuse crescentic GN on kidney biopsy and P-ANCA positive, was treated on rituximab and glucocorticoids. Ten months later, while in remission she presented with nausea, vomiting, obstipation and abdominal pain. Her labs showed, Hgb: 10.4g/dl, WBC: 6780/mcl, Eosinophils 25%, Cr: 0.7mg/dl, H. Pylori: Positive. Guaic negative. Stool negative for ova/parasites. Endoscopy showed non-bleeding erosive gastropathy with scattered punctate ulcerations in the duodenum. On biopsy diffuse acute and chronic inflammation, focal cryptitis, erosion of mucosa, Schistosoma Mansoni ova in glands of stomach, duodenum and jejunum were noted. CT brain negative for cysticercosis. CT chest showed calcified granulomas in right middle lobe and right lower lobe. On reevaluation she admitted to consuming snails. Rituximab maintenance therapy was not continued because of schistosomiasis. She was admitted for a multidisciplinary approach. Renal function remained stable protein/creatinine ratio 0.8, Myeloperoxidase negative . Patient was started on Praziquantel 1.2 g tid and prednisone 60 mg for 5 days which was followed by another cycle after 4 weeks to treat any remaining adult schistosomes. Repeat EGD and colonoscopy with multiple biopsies to ensure eradication of schistosomiasis before resuming rituximab is planned.

Discussion: Our case emphasizes the need to consider parasitic infections when starting patients from endemic areas on immunosuppressive therapy. Schistosomiasis can involve multi-organ systems and can lead to potentially debilitating and fatal complications such as liver fibrosis, portal hypertension, hypersplenism, esophageal variceal bleeding, GN and nephrotic syndrome. Detailed history for dietary habits and lifestyle is important. Serology, antigen detection or other diagnostic tools can be used when the suspicion is high.

PO1619

Porcine Desiccated Thyroid Extract Associated Dual Positive ANCA Vasculitis

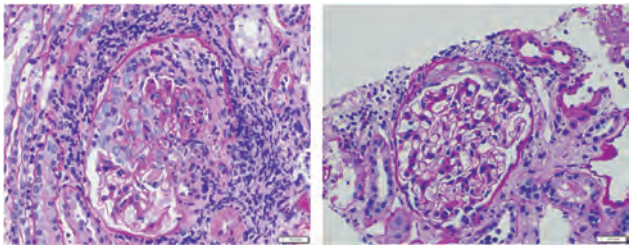
Nandakishor Kapa, Niti Madan, Mingyu Cheng, Nasim Wiegley. *University of California Davis Medical Center, Sacramento, CA.*

Introduction: Among medications used for thyroid disorders associated with small vessel vasculitis, the most well-known is propylthiouracil. However, there have been no reported cases of ANCA-associated vasculitis (AAV) with desiccated thyroid replacement hormones. We report the first case of drug-induced ANCA vasculitis presumed to be associated with porcine desiccated thyroid supplementation (Armour Thyroid).

Case Description: A 43-year-old Caucasian woman with Hashimoto's thyroiditis and bipolar disorder presenting with 1 month of generalized fatigue, subjective fevers, and foamy urine was found to have acute kidney injury with creatinine (Cr) peaking at 3.80 mg/dL from baseline 1.0 mg/dL. She recently started desiccated thyroid supplementation prior to the onset of symptoms. Urinalysis revealed active sediment with hematuria and subnephrotic proteinuria with 24-hour urine protein 1.1 gm/day. Serologic testing was notable for MPO Ab IgG positive >8.0 AI and PR3 Ab IgG positive > 6.4 AI. Further serologic workup, including anti-histone Ab, was negative. Kidney biopsy revealed features consistent with pauci-immune glomerulonephritis with cellular and fibrocellular crescents, mild interstitial inflammation and tubulitis, and mild arteriosclerosis and hyaline arteriosclerosis. She was not taking any other known medications associated with drug-induced vasculitis. She received pulse dose steroids with taper per the PEXIVAS trial

protocol and Rituximab therapy per the RAVE trial protocol. Cr improved (1.6 mg/dL) after induction therapy with persistent mild proteinuria at <500 mg/g at 6 months. Dual MPO and PR3 positivity persisted until Rituximab completion, after which only MPO positivity continued.

Discussion: It is well known that anti-thyroid medications can cause drug-induced AAV. However, this renal limited AAV case with desiccated thyroid supplementation suggests clinicians should also be aware of AAV as a possible adverse consequence of thyroid supplementation. Management should include discontinuation of the offending agent and consideration of immunosuppression with standard induction regimens based on disease severity.



PO1620

Renal Survival in Anti-Glomerular Basement Membrane Disease

Lauren Floyd,[1] Anna S. Li,[2,3] Nina Brown,[4] Helen Alderson,[4] Silke R. Brix,[2,3] Ajay P. Dhaygude.[1] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [3]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [4]Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

Background: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Presentation with severe kidney dysfunction in need of renal replacement therapy (RRT) often results in end stage kidney disease (ESKD). Reliable predictors of kidney survival are needed.

Methods: Retrospective analysis of patients with anti-GBM disease from the North West of England.

Results: Seventy patients with GBM nephritis were identified, 20 patients presented double positive for anti-neutrophil cytoplasmic (ANCA) and GBM antibodies (28.57%). Median age was 64 years (Interquartile range 43 – 76 years). 39 patients were female (55.7%). Median kidney function at presentation was an estimated glomerular filtration rate of 593 ml/min (eGFR, IQR 419.75 – 835.75 ml/min). Sixty patients required RRT at presentation, and twelve of these patients recovered sufficient kidney function to withdraw RRT (25.5%). Median follow up was 41 months (IQR 11 - 77.5), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was numerically higher but not significantly different in patients that required dialysis initially and recovered residual function compared to patients that remained dialysis dependent, and no cut-off was detected (p=0.25). Patients with presenting eGFR as low as 2 – 3 ml/min recovered function.

Conclusions: Timely aggressive therapy to salvage kidney function is crucial. Better predictors of outcome are needed to optimise management in GBM vasculitis.

PO1621

Validation of the Renal Risk Score in Anti-GBM Disease

Anna S. Li,[1,4] Lauren Floyd,[3] Nina Brown,[2] Helen Alderson,[2] Ajay P. Dhaygude,[3] Graeme T. Reid,[4] Silke R. Brix.[1,4] *[1]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [2]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [3]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [4]Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: Anti-glomerular basement membrane (GBM) disease is a rare immune mediated kidney lesion of an aggressive nature often resulting in end stage kidney disease (ESKD). Clinical and histological variables predicting outcome are needed to individualise therapy and improve outcome.

Methods: We performed a retrospective multicentre analysis and investigated the Renal Risk Score (RRS) proposed in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis for its prognostic value in anti-GBM disease. We used the published cut-offs for percentage of normal glomeruli (N0 > 25%, N1 10 - 25%, N2 < 10%), estimated glomerular filtration rate (eGFR, G0 > 15 ml/min/1.73 m2, G1 ≤ 15 ml/min/1.73 m2) and a simplified cut off for tubular atrophy and interstitial fibrosis (T0 ≤ mild to moderate, T1 ≥ moderate). We assigned points to each parameter (N1 = 4, N2 = 6, G1 = 3, T1 = 2 points) and patients to risk groups, low (0), intermediate (2 - 7), and high risk (8 - 11 points).

Results: Seventy patients with GBM nephritis were identified, 20 patients presented double positive for ANCA and GBM antibodies (28.57%). Median age was 64 years (Interquartile range, IQR 43 – 76 years). 39 patients were female (55.7%). Median eGFR at presentation was 593 ml/min (IQR 419.75 – 835.75 ml/min). Median follow up was 41 months (IQR 11 - 77.5 months), and fifty patients developed ESKD (71.42%). Forty-seven biopsies were available for scoring. Four patients were low risk, and none developed ESKD (0%). Eight patients belonged in the medium risk group, and five of these developed permanent kidney-failure (62.5%). Of 35 patients in the high-risk group, 30 patients developed ESKD (85.7%). Three patients had the highest score of 11 points, and none remained dialysis independent (100%). The risk groups differed in renal survival (p<0.001).

Conclusions: Low percentage of normal glomeruli, higher grade of tubulointerstitial damage and severe kidney failure are associated with poor outcome in anti-GBM disease. Combining these variables, the Renal Risk Score accurately predicted kidney survival in anti-GBM disease.

PO1622

Anti-Glomerular Basement Membrane Disease in Pregnancy

Anna S. Li,[1,2] Shahid Abdullah,[2] Iren Szeki,[2] Silke R. Brix.[1,2] *[1]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Introduction: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated inflammation resulting in organ- and life-threatening disease. Presentation during pregnancy presents an additional challenge to preserve organ function and life of the unborn child.

Case Description: We report the case of a 23-year-old woman, 18 weeks pregnant, presenting with haemoptysis and acute kidney injury. Her chest X Ray demonstrated multilobar consolidation with perihilar prominence consistent with pulmonary haemorrhage. Her blood tests detected an anaemia (Hb 51 g/L) and kidney failure (eGFR 17 ml/min). Her GBM antibody was 30.3 AI. She received daily plasma exchange (PLEX) for 7 days until her GBM antibody normalised. Additionally, she was commenced on 1gram of cyclophosphamide, and following her plasma exchange sessions she received 1gram of rituximab. Her acute kidney injury progressed (eGFR 13 ml/min), and renal replacement therapy was initiated to manage fluid overload and for foetal health. She remained 8 days in the high dependency unit on high flow oxygen therapy due to respiratory failure due to her diffuse alveolar haemorrhage needing daily transfusions to maintain her haemoglobin. Daily gynaecology reviews were performed. Post rituximab, PLEX was recommenced after 72 hours and continued daily for another week with 13 sessions in total. The patient stabilised, renal replacement therapy was discontinued, and she was discharged after a hospital stay of 27 days. Her baby was delivered via caesarean section due to the development of preeclampsia at week 28 gestation. Twelve months later, patient and baby are healthy with normal development per percentile, and patient's kidney function has recovered with a current eGFR of 86 ml/min.

Discussion: Timely and aggressive therapy is crucial to salvage kidney function in anti-GBM disease. Here, we present a case of a pregnant patient highlighting that a certain amount of cyclophosphamide is acceptable in life-threatening maternal conditions. Additionally, we demonstrate the possibility to significantly reduce cyclophosphamide in anti-GBM disease by adding in rituximab.

PO1623

Itolizumab, a Novel Anti-CD6 Therapy, in Systemic Lupus Erythematosus Patients: Interim Safety Results from the Phase 1b EQUALISE Dose-Escalation Study

Chaim Putterman,[1] Richard Furie,[2] Jai Radhakrishnan,[3] Vandana S. Mathur,[5] Krishna R. Polu,[5] Stephen Connelly,[5] Joel M. Rothman,[5] Cherie T. Ng,[5] Leslie Chinn,[5] Maple M. Fung,[5] Dolca Thomas,[5] Kenneth Kalunian.[4] *[1]Yeshiva University Department of Medicine, Bronx, NY; [2]Northwell Health, New Hyde Park, NY; [3]Columbia University, New York, NY; [4]University of California San Diego, La Jolla, CA; [5]Equillium, Inc, La Jolla, CA.*

Background: CD6 is a co-stimulatory receptor predominantly expressed on T cells. The CD6 ligand, ALCAM, is expressed on antigen presenting cells, epithelial and endothelial cells. Itolizumab (ITO) is a humanized IgG1 monoclonal antibody that binds CD6 and blocks ALCAM interaction to inhibit T cell activation and trafficking.

Methods: EQUALISE is an open-label Phase 1b 2-part study evaluating the safety, pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity of subcutaneous doses (SC) of ITO (0.4 to 3.2 mg/kg). Part A enrolled adults with active or inactive SLE who received ≥1 SLE treatment. Treated subjects received ITO SC Q2 weeks x 2. Part B, which evaluates ITO in subjects with active proliferative Class III/IV LN for 24 weeks, is currently enrolling (NCT04128579).

Results: Part A enrolled 34 subjects: 0.4 mg/kg (n=6), 0.8 mg/kg (n=7), 1.6 mg/kg (n=7), 2.4 mg/kg (n=6), and 3.2 mg/kg (n=8). Similar baseline characteristics were noted across cohorts. The mean age was 51, with 94% female, 74% white and ~11 years since SLE diagnosis. C3 and C4 were within normal ranges. Mean eGFR was 98 ml/min/1.73m2 and the median UPCR was 91 mg/g (range 48-1505). SC dosing of 0.4 mg/kg to 2.4 mg/kg (n=26) was well tolerated, with 38% reporting an AE, predominantly mild injection site reactions, with no SAEs reported. >85% of 3.2 mg/kg subjects reported an AE, the most common was injection site reactions, with 2 non-treatment related SAEs reported in 1 subject (hypotension, syncope). 4 3.2 mg/kg subjects (50%) discontinued treatment after 1 dose voluntarily. In all cohorts, there were no notable changes in vital signs or labs, except for transient declines in lymphocyte counts without clinical sequelae. PK and PD results show dose-proportional increases in ITO exposure and rapid and dose-dependent decreases in CD4 cell surface expression of CD6.

Conclusions: 2 SC doses of ITO up to 2.4 mg/kg SC in SLE subjects were well tolerated; with less tolerability to the 3.2 mg/kg dose, as 50% discontinued after 1 dose. The data support continued evaluation of ITO in SLE/LN. The ongoing EQUALISE Part B assesses ITO safety and efficacy in Class III/IV LN patients.

Funding: Commercial Support - Equillium, Inc

PO1624

Itolizumab, a Novel Anti-CD6 Antibody, in Systemic Lupus Patients with Proteinuria: An Interim Subgroup Analysis from EQUALISE, a Phase 1b Study

Chaim Putterman,[1] Richard Furie,[2] Jai Radhakrishnan,[3] Vandana S. Mathur,[5] Krishna R. Polu,[5] Stephen Connelly,[5] Joel M. Rothman,[5] Leslie Chinn,[5] Nuwan Nanayakkara,[5] Maple M. Fung,[5] Cherie T. Ng,[5] Dolca Thomas,[5] Kenneth Kalunian.[4] *[1]Yeshiva University Department of Medicine, Bronx, NY; [2]Northwell Health, New Hyde Park, NY; [3]Columbia University, New York, NY; [4]University of California San Diego Health Sciences, La Jolla, CA; [5]Equillium Inc, La Jolla, CA.*

Background: CD6 is a co-stimulatory receptor that is expressed on T cells. The CD6 ligand, ALCAM, is found on antigen presenting cells, as well as epithelial and endothelial cells. Itolizumab (ITO), a humanized IgG1 monoclonal antibody that binds CD6 and inhibits the interaction of CD6 and ALCAM, inhibits T cell activity and trafficking. ITO is being evaluated as a treatment for systemic lupus erythematosus (SLE) and lupus nephritis (LN).

Methods: EQUALISE (NCT04128579) is a Phase 1b US study of ITO in SLE patients with and without active proliferative LN. Part A enrolled SLE patients (N = 34) who had received ≥ 1 SLE treatment but did not have active proliferative LN. Patients received 2 open-label doses of 0.4 to 3.2 mg/kg each SC on Day 1 and Day 15 with follow up through Day 57.

Results: A subgroup analysis of 16 subjects with Baseline (mean of screening and Day 1) urine protein/creatinine ratio (UPCR) > 100 mg/g was performed. Mean age was 55, 94% were female; 81% white and the mean years since SLE diagnosis was approximately 11. Mean baseline eGFR was 95 ml/min/1.73m2 and UPCR was 272 mg/g (range 100-1505). On Day 29, a geometric mean decrease in UPCR of ~45% was observed in these 16 subjects with greater decline seen for subjects with higher Baseline UPCR values. By Day 57, 6 weeks post treatment the decrease was ~34% from Baseline (Figure). Notable is one subject (1.6 mg/kg dose) who had significant Baseline UPCR of 1505 mg/g, by Day 29 the UPCR had declined to 974 mg/g, and at Day 57 declined to 857 mg/g. SC treatment was well tolerated. Of the 6 subjects who had a total of 12 treatment-emergent adverse events (AEs), 4 were from the 3.2 mg/kg cohort. All AEs were mild or moderate in severity.

Conclusions: Patients with SLE and mild baseline proteinuria tolerated ITO treatment well. EQUALISE Part B will further explore the safety and efficacy of ITO in LN patients.

Adding Low-Dose CYC to RTX Combined with a Tailored RTX Maintenance Regimen Seems to Favor Stable Remission in Severe ANCA Vasculitis

Renee Ysermans, Matthias H. Busch, Joop Aendekerk, Pieter van Paassen. *Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands.*

Background: Rituximab (RTX) and cyclophosphamide (CYC) are effective remission-induction therapies in ANCA-associated vasculitis (AAV). High dose CYC is however considered toxic, whereas RTX monotherapy may increase the risk of relapse, depending on the choice of maintenance therapy and baseline disease severity. Particularly with renal involvement, stable remission will favor prognosis. In this respect, adding low dose CYC to RTX could be superior to RTX alone. We checked this premise by retrospectively analyzing our data derived from a pragmatic, clinical approach in patients with severe AAV.

Methods: Between 2007 and January 2019, 246 patients with severe active AAV, needing remission-induction therapy, were screened and 62 patients were included. Remission-induction consisted of either RTX (1000mg two times) or RTX-CYC (1000mg RTX and 15mg/kg CYC intravenously, two times). Corticosteroid tapering was identical in both groups. RTX during the maintenance phase was tailored according to either CD19+ B cell repopulation (≥5 cells/ µl) and/or a rise in ANCA level, combined with clinical symptoms, without signs of a major relapse. Primary outcome variables were major relapse rate and adverse events at 2 and 5 years, compared with the log-rank test.

Results: 28 patients received RTX only and 34 patients received RTX-CYC. Disease presentation, severity of disease (BVAS), and laboratory parameters (serum creatinine, CRP, and total IgG) at baseline were similar. Renal involvement was more prevalent in the RTX-CYC patients (85.3%) as compared to RTX only (60.7%) ($P = 0.028$). Relapse rates within 2 years were significantly higher in the RTX only group (n=7 in RTX only, n=1 in RTX-CYC, $P = 0.015$), whereas the number of patients receiving RTX maintenance and the number of infusions did not differ. After 5 years, however, relapse rates did not differ (n=9 in RTX only, n=7 in RTX-CYC). The rate of infections, hypogammaglobulinemia, end stage renal disease, malignancies, and mortality did not differ after 2 and 5 years.

Conclusions: Adding low dose CYC to RTX is safe and may favor the prevention of major relapses in patients with severe AAV, predominantly with renal involvement. Future prospective studies are needed to examine the role of reconstituted B cells and ANCA features to better define tailor-made treatment decisions.

Preferences Regarding Treatment with Plasma Exchange for ANCA-Associated Vasculitis: An International Patient Survey

David T. Collister,[1] Alfred Mahr,[8] Mark A. Little,[2] Reem Mustafa,[6] Lynn A. Fussner,[3] Alexa S. Meara,[3] David R. Jayne,[4] Peter A. Merkel,[7] Michael Walsh.[5] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]Tallaght University Hospital, Dublin, Ireland; [3]The Ohio State University, Columbus, OH; [4]University of Cambridge, Cambridge, United Kingdom; [5]McMaster University, Hamilton, ON, Canada; [6]University of Kansas Medical Center, Kansas City, KS; [7]University of Pennsylvania, Philadelphia, PA; [8]Kantonsspital Sankt Gallen, Sankt Gallen, Switzerland.*

Background: Patient preferences regarding plasma exchange (PLEX) for ANCA-associated vasculitis (AAV) are uncertain. We sought to elicit patient preferences regarding the use of PLEX in AAV.

Methods: An online survey was circulated via national vasculitis and kidney patient networks. Respondent characteristics were collected and information regarding PLEX in AAV was provided including its minimal effect on mortality. One year risks of end stage kidney disease (ESKD) and serious infections with and without PLEX in AAV were presented across 5 serum creatinine categories: 150, 250, 350, 450 and 600µmol/L. For each scenario, participants were asked: "If they were a patient with a new diagnosis or relapse of AAV, would they choose treatment with PLEX (yes or no) given its absolute risk reduction in ESKD, but absolute risk increase in serious infections?" Multilevel multivariable logistic regression was performed to identify independent predictors of choosing treatment with PLEX.

Results: There were 549 responses. The mean age of respondents was 57.4 (SD 14.5) years, 72.3% were female, and respondents were from the United States (58.1%), United Kingdom (23.7%), Canada (14.0%), and other countries (4.2%). The majority had AAV (86.7%). 190/549 (34.6%) would always choose PLEX and 87/549 (15.8%) would always decline PLEX across the baseline risks of ESKD or serious infections presented. Independent predictors for choosing PLEX included age (OR 0.98, 95% CI 0.96-0.99 per 1 year increase), country (United Kingdom OR 2.73, 95% CI 1.20-6.21), diagnosis (individuals with vasculitis other than AAV were more likely), previous dialysis (OR 3.34, 95% CI 1.37-8.16), previous PLEX (OR 5.13, 95% CI 2.50-10.49), and increased baseline risk of ESKD (Cr 350 and 450µmol/L only).

Conclusions: One third of participants would always choose treatment with PLEX across the 5 scenarios presented. The decision to choose PLEX is influenced by age, country, previous dialysis, and the baseline risk of ESKD and serious infections. Patient values and preferences are needed to inform shared decision-making regarding PLEX in AAV.

PO1627

Maintenance of Remission and Risk for Relapse in Myeloperoxidase Positive Antineutrophil Cytoplasmic Antibody-Associated Vasculitis with Kidney Involvement

Marta I. Casal Moura,[1] Shahrzad Tehranian,[1] Shane A. Bobart,[1,2] Ladan Zand,[1] Eddie L. Greene,[1] Sanjeev Sethi,[1] Ulrich Specks,[1] Fernando C. Fervenza.[1] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Cleveland Clinic, Cleveland, FL.*

Background: Optimal time of remission-maintenance therapy in patients with MPO-ANCA associated vasculitis (MPO-AAV) is not established. Defining clinical and laboratory parameters to guide safe withdrawal of maintenance immunosuppression is required in order to mitigate the risk of relapse.

Methods: A retrospective cohort study of all patients followed at the Mayo Clinic with MPO-AAV (MPA and GPA) and kidney involvement. Relapse rate, correlation with MPO-ANCA status and remission-maintenance strategy were characterized.

Results: We analyzed 159 MPO-ANCA positive patients with active kidney involvement. A total of 66 (41.5%) patients had at least 1 relapse. MPO-ANCA patients who became and remained seronegative did not relapse (HR 0.032, [95%CI, 0.001-0.970], p=0.048). MPO-ANCA reappearance after seronegative conversion was associated with increased relapse risk at 24 months (HR 3.651, [95%CI, 1.114-11.966], p=0.012). Immunosuppression was withdrawn in 80 (50.3%) and this was predicted by persistent MPO-ANCA seronegative conversion (OR 3.028, [95%CI, 1.262 – 7.268], p=0.013). In patients who withdrew remission-maintenance therapy, 32 (40.0%) relapsed (in comparison with 34 relapses [43.0%] in those who maintained immunosuppression, p=0.697). ENT involvement (OR 6.095 [95%CI, 1.280 – 29.010], p=0.023) and MPO-ANCA reappearance (OR 9.248, [95%CI, 3.126 – 27.361], p<0.0001), were independent predictive factors for relapse after withdrawal.

Conclusions: Our results suggest that patients who seroconverted and remain MPO-ANCA negative are at lower risk of relapse: remission-maintenance treatment might be withdrawn without an additional risk of relapse. MPO-ANCA reappearance after seronegative conversion is a risk factor for relapse at 24 months. Serial MPO-ANCA determinations are useful to guide clinical decisions on remission-maintenance treatment strategies.

PO1628

Renal Histological Biomarkers and Response to Different Induction Regimens in ANCA-Associated Glomerulonephritis: The REASSESS Study

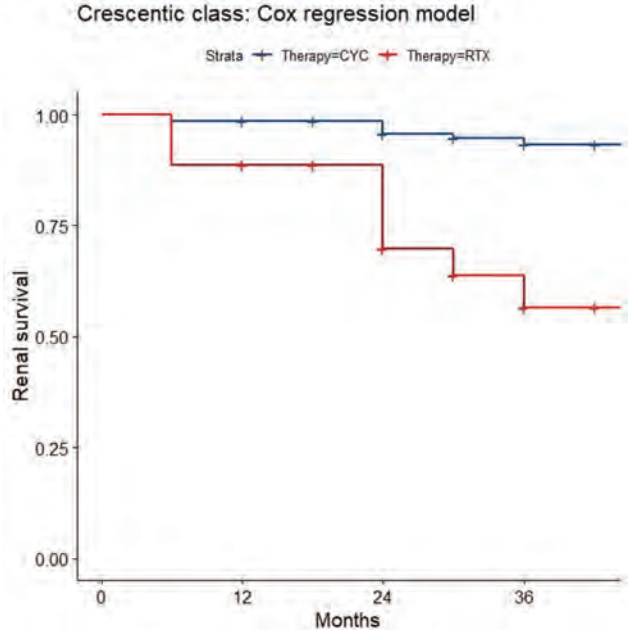
Martina Uzzo,[1] Jennifer Scott,[7] Alice A. Guerini,[2] Stefania Affatato,[2] Rosanna Lacetera,[1] Andreas Kronbichler,[9] Iva Gunnarsson,[10] Marco Allinovi,[3] Gaetano La Manna,[4] Mario Cozzolino,[5] Annette Bruchfeld,[11] Federica Mescia,[2] Federico Pieruzzi,[1] Stephen P. McAdoo,[6] Renato A. Sinico,[1] Matija Crnogorac,[12] Francesco Scolari,[2] Mark A. Little,[7] David R. Jayne,[8] Federico Alberici.[2]
[1]Department of Medicine and Surgery, University of Milano-Bicocca and ASST Monza, Milan, Italy; [2]Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy; [3]Nephrology, Dialysis and Transplantation Unit, Careggi University Hospital, Florence, Italy; [4]Dialysis and Renal Transplant Unit, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy; [5]Department of Health Sciences, Renal Division, ASST Santi Paolo e Carlo, University of Milan, Milan, Italy; [6]Imperial College London, London, United Kingdom; [7]The University of Dublin Trinity College, Dublin, Ireland; [8]University of Cambridge, Cambridge, United Kingdom; [9]Medizinische Universitat Innsbruck Department fur Operative Medizin, Innsbruck, Austria; [10]Karolinska Universitetssjukhuset, Stockholm, Sweden; [11]Linkopings universitet, Linkoping, Sweden; [12]Department of Nephrology and Dialysis, Agram Special Hospital, Zagreb, Croatia.

Background: The role of kidney biopsy on ANCA-associated vasculitis (AAV) is still debated: despite its significant prognostic value, whether it has an impact on the induction regimen choice has not been explored yet.

Methods: 323 AAV patients with biopsy-proven renal involvement were collected retrospectively from eleven centers and stratified according to the histopathological characteristics at the kidney biopsy and the induction regimen employed.

Results: The median follow-up time was 36 months; the eGFR was 19 ml/min/1,73m^2; 53% were MPO-ANCA and 41% PR3-ANCA. 58% were treated with Cyclophosphamide (CYC), 18% with Rituximab (RTX) and 24% with RTX-CYC. According to the *Berden* classification, 24% biopsies were classified as Focal, 31% as Crescentic, 33% as Mixed and 12% as Sclerotic. Renal remission rate at 6 months and relapse-free survival were comparable in the different groups. In the unadjusted survival analysis with the K-M curve, patients in the Crescentic group treated with RTX had a shorter ESRD-free survival compared to the CYC group (p=0.033) and the RTX-CYC one (p=0.044). This was confirmed with a Cox regression analysis adjusted for sex, age, ANCA type, AAV diagnosis, creatinine and proteinuria when comparing the RTX group with the CYC one (HR 8.30 [95% CI 1.64-42.01], p=0.011).

Conclusions: Response rates and relapse risk were comparable in the overall cohort and in each histopathological subgroup. The ESRD-free survival in the Crescentic class was shorter in the RTX group compared to the CYC one.



PO1629

ANCA Vasculitis Induction Management in the COVID-19 Pandemic: Results of an International Retrospective Cohort Study

Antonio Salas,[1] Duvuru Geetha.[2] ANCAITCOV *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Department of Medicine, Baltimore, MD.*

Background: Induction therapy for severe ANCA-associated vasculitis (AAV) combines glucocorticoids (GC) with either rituximab (RTX) or cyclophosphamide (CYC). The coronavirus 2019 disease (COVID-19) pandemic has increased concern around using aggressive immunosuppression; whether this concern has impacted AAV management is unknown. Here, we report treatment regimens and outcomes of patients with active AAV receiving induction immunosuppression during the first wave of the pandemic.

Methods: We retrospectively studied AAV patients with new or relapsing disease receiving remission induction therapy during the first wave of the COVID-19 pandemic across sites in the US, UK and Europe. Primary outcome was achievement of complete remission at 6 months.

Results: Of 191 patients with a mean age of 65 years old, 52% were female and a majority (89%) were Caucasian. Standard induction was deployed across all sites. Out of the US, UK, and European patient populations, the US used higher GC pulses leading to a higher average cumulative GC dose for remission induction (4153 mg, 2174 mg, 3408 mg, respectively, p<0.001) and had the highest proportion of patients given RTX induction therapy (64%; p=0.005). Complete remission was achieved in 90% of patients. Improvement in kidney function at 6 months was similar with all treatment regimens (6 ml/min^2 increase, p=0.68). Sixteen patients were diagnosed with COVID-19 and had similar exposures to CYC and RTX. There were no differences in remission rates, ESKD or death when stratified by induction therapy type.

Conclusions: Induction immunotherapy practices differ across the world, but specialists continued their standard management during the COVID-19 pandemic. AAV outcomes or rates of COVID-19 infection were not influenced by different induction regimens.

Treatment differences and 6M remission among different cohorts

Treatment variables	Entire cohort	United States	United Kingdom	Europe	P-value
Use of pulse GCs, n (%)	117 (61); n=191	35 (80); n=44	44 (53); n=83	38 (59); n=64	0.013
Mean (SD) cumulative dose of IV pulse methylprednisolone in mg	930 (981); n=175	1658 (1243); n=43	730 (755); n=74	647 (733); n=58	<0.001
Mean (SD) cumulative GC for remission induction in mg	2962 (1841); n=171	4153 (2427); n=35	2174 (1229); n=83	3408 (1642); n=53	<0.001
RTX use only, n (%)	84 (44); n=191	28 (64); n=44	28 (34); n=83	28 (44); n=64	0.005
CYC use only, n (%)	49 (26); n=191	5 (11); n=44	23 (28); n=83	21 (33); n=64	0.037
RTX and CYC, n (%)	49 (26); n=191	10 (23); n=44	28 (34); n=83	11 (17); n=64	0.066
Remission at 6 months, n (%)	160 (90); n=178	37 (90); n=41	64 (85); n=75	59 (95); n=62	0.164

Non-Sucrose Containing IV Immunoglobulin in ANCA Vasculitis Has No Adverse Effects on Renal Function

Renee Ysermans, Matthias H. Busch, Joop Aendekerk, Pieter van Paassen. *Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands.*

Background: Intravenous immunoglobulin (IVIG) has proven to be effective as an immunomodulator in several autoimmune and inflammatory diseases, including antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Moreover, in the era of B cell-depleting therapies, secondary immunodeficiencies are common, urging suppletion by IVIG. Reported adverse effects are generally mild in nature. However, concerns have been raised about the safety profile of IVIG in relation to renal function. IVIG associated kidney injury is proposed to be mainly related to sucrose stabilized products. Non-sucrose containing alternatives are available and increasingly used. We therefore aimed to analyze the safety of non-sucrose containing IVIG with regard to renal function in patients with AAV.

Methods: AAV patients of the Maastricht University Medical Center were retrospectively analyzed for dynamics of serum creatinine levels before and after IVIG using the Wilcoxon signed rank-test. Subanalyses were performed with regard to the presence of ANCA-associated renal disease and IVIG indication. In addition, correlation analysis was conducted to evaluate the relation between serum creatinine change and cumulative IVIG dose during a 1year follow-up.

Results: 36 with 49 courses of IVIG were included in the short-term and 54 patients with 70 courses of IVIG were included in the long-term analysis. No significant differences were found between serum creatinine levels before and after IVIG in the short-term (median [IQR], 132 [88-159] and 125 [86-173] mmol/L, P = 0.380), with a median follow-up of 16 days after the initial IVIG infusion, and the long-term (median [IQR], 104 [86-147] and 110 [90-152] mmol/L, P = 0.077), after 1 year. One patient with active AAV and renal involvement had a reversible serum creatinine increase >30% 6 days after IVIG. Subanalyses showed no significant changes in serum creatinine levels with regard to renal involvement and IVIG indication. There was no association between serum creatinine change and cumulative IVIG dose 1 year after the initial IVIG infusion (P = 0.667).

Conclusions: This study shows no short-term and long-term deleterious effects on renal function in response to treatment with non-sucrose containing IVIG in patients with AAV.

PO1631

Efficacy and Safety of a Combination Treatment of Mycophenolate Mofetil and Corticosteroid in Advanced IgA Nephropathy: A Multi-center, Prospective Study

Chan-Young Jung,[1] Sang Youb Han,[2] Beom seok Kim.[1] *[1]Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea; [2]Inje University Ilsan Paik Hospital, Goyang, Republic of Korea.*

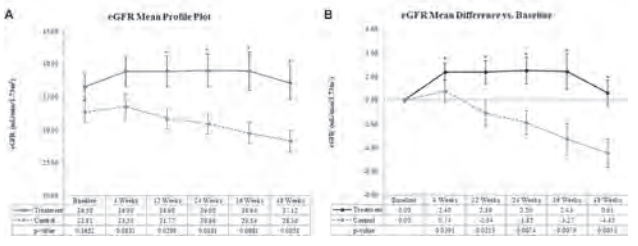
Background: It remains unclear whether immunosuppressive agents are effective in patients with IgA nephropathy (IgAN). We sought to determine the efficacy of mycophenolate mofetil (MMF) and corticosteroid combination therapy in patients with advanced IgAN.

Methods: We conducted a multicenter, randomized, placebo-controlled, parallel group study of a 48-week administration of MMF and corticosteroids in biopsy-proven advanced IgAN patients with an estimated glomerular filtration rate (eGFR) between 20-50 mL/min/1.73m^2 and a urine protein-to-creatinine ratio (UPCR) greater than 0.75g/day. The primary outcome was complete (UPCR<0.3g/day) or partial remission (reduction of UPCR >50% compared to baseline) at 48 weeks.

Results: Of the 48 randomized patients, complete and partial remission rates were higher in the MMF and corticosteroid combination therapy group (29.1% vs. 5.0%, *P*=0.05). In contrast to the combination therapy group, eGFR in the control group significantly decreased from 36 weeks onwards, resulting in a final adjusted mean change of -4.39 ± 1.22 mL/min/1.73m^2 (*P*=0.002). The adjusted mean changes at 48 weeks were 0.62 ± 1.30 and -5.11 ± 1.30 mL/min/1.73m^2 (*P*=0.005) in the treatment and control groups, respectively. The amount of UPCR was also significantly different between the two groups, where the adjusted mean difference was -0.47 ± 0.17 mg/mgCr in the treatment group and 0.07 ± 0.17 mg/mgCr in the control group (*P*=0.04). Overall adverse events did not differ between the groups.

Conclusions: In patients with advanced IgAN with a high risk for disease progression, combination therapy of MMF and corticosteroid appears to be beneficial in reducing proteinuria and preserving renal function.

Fig. 2



PO1632

Pharmacodynamic and Clinical Responses to BION-1301 in Patients with IgA Nephropathy: Initial Results of a Ph1/2 Trial

Jonathan Barratt,[1] Billy T. Hour,[4] Brian S. Schwartz,[2] Bess Sorensen,[2] Suzanne E. Roy,[2] Colleen L. Stromatt,[2] Margaret MacDonald,[2] Aaron N. Endsley,[3] Jeannette Lo,[2] Alan Glicklich,[2] Andrew J. King.[2] *[1]University of Leicester, Leicester, United Kingdom; [2]Chinook Therapeutics Inc, Seattle, WA; [3]Certara LP, Princeton, NJ; [4]Amicis Research Center, Northridge, CA.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis globally, with up to 45% of patients at risk of progressing to ESKD. The initiating step in IgAN pathogenesis is the excess production of galactose-deficient IgA1 (Gd-IgA1), resulting in the formation of immune complexes that cause kidney inflammation and damage. A Proliferation-Inducing Ligand (APRIL) is elevated in IgAN patients and correlated with higher levels of Gd-IgA1 and proteinuria, and lower eGFR. BION-1301 is a novel monoclonal antibody targeting APRIL. Here we present interim results from Part 3 of a Phase 1/2 study that characterizes the safety, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary activity of BION-1301 delivered by IV administration in patients with IgAN.

Methods: Part 3 of this Phase 1/2 study (NCT03945318) is an ongoing multicenter, multicohort, open-label study in up to 40 IgAN patients. In Cohort 1, BION-1301 is dosed at 450mg IV every 2 weeks for up to 12 months. Key objectives of the study include safety and the characterization of PK, PD, immunogenicity and changes in proteinuria. Key eligibility criteria include: (1) urine protein ≥0.5 g/24h or baseline UPCR ≥0.5 g/g, (2) stable/optimized dose of ACE-I/ARB or ACE-I/ARB intolerant and (3) biopsy-verified diagnosis of IgAN within the past 10 years.

Results: Preliminary results from the first 5 patients show BION-1301 is well tolerated with no serious adverse events and no adverse events leading to discontinuation to date. BION-1301 drives durable reductions in serum free APRIL, Gd-IgA1, IgA and IgM, with a lesser reduction in IgG. A clinically meaningful reduction in 24-hour UPCR was observed within 3 months. Updated data in all IV treated patients, along with mechanistic response kinetics, will be presented at the meeting.

Conclusions: BION-1301 is a novel anti-APRIL monoclonal antibody being developed as a potential treatment for patients with IgAN. BION-1301 offers disease modifying potential by directly targeting the pathogenesis of IgAN. Promising early biomarker and clinical activity support the continued development of BION-1301 in IgAN.

PO1633

Atrasentan Exhibits a Consistent, Predictable Pharmacokinetic Profile Among Healthy Asian Adults

Anjay Rastogi,[1] Jicheng Lv,[2] David A. Catanzaro,[3] Vince Tong,[3] Yusuke Suzuki.[4] *[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]Peking University First Hospital, Beijing, China; [3]Chinook Therapeutics Inc, Seattle, WA; [4]Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Background: Atrasentan, a potent and selective endothelin-A receptor antagonist, is under investigation for reducing proteinuria and preserving kidney function in IgA nephropathy and other glomerular diseases. Two phase 1 studies evaluated the pharmacokinetics (PK) and safety of atrasentan in healthy adults of Chinese (Study M11-521) and Japanese (Study M11-522) parentage.

Methods: Study M11-521 was an open-label, randomized (for single-dose regimens), single-center study of single and multiple doses of atrasentan in 36 healthy Chinese adults. Single doses of atrasentan tablets (0.5, 1, or 1.5 mg) were administered in Part I, and multiple once-daily doses of atrasentan 1.5 mg were administered in Part II. Study M11-522 was a double-blind, randomized, placebo-controlled, single-center study of single doses of atrasentan (0.5, 0.75, or 1.25 mg) in 36 healthy Japanese adults. Blood samples were collected for analysis of plasma PK parameters, including the area under the plasma concentration-time curve (AUC) and the maximum observed plasma concentration (C_{max}).

Results: In Study M11-521, atrasentan AUC increased proportionally with dose in the 0.5 mg to 1.5 mg dose range, and C_{max} increased proportionally with dose in the 1 mg to 1.5 mg dose range. No statistically significant differences were observed in either the dose-normalized AUC_∞ for the comparison of the 1.5 mg and 0.5 mg dose groups ($P \geq 0.260$) or the dose-normalized C_{max} for the comparison of the 1.5 mg and the 1 mg dose groups ($P = 0.279$). In Study M11-522, a linear increase in atrasentan mean AUC_∞ was observed across the 0.5 to 1.25 mg dose range; dose-normalized mean AUC_∞ did not show any statistically significant difference across the doses ($P = 0.735$). Atrasentan was generally well tolerated. No clinically significant vital signs, electrocardiogram activity, or laboratory measurements were observed, and no apparent significant differences among the dose regimens were found with respect to safety.

Conclusions: Dose-proportional increases in AUC were observed across the studied range, which includes the 0.75 mg dose being studied in ongoing clinical trials. These data support the safety and tolerability of atrasentan and suggest a consistent and predictable PK profile among patients of Asian descent.

Randomized Clinical Study to Evaluate the Effect of Personalized Therapy on Patients with Immunoglobulin A Nephropathy (IgAN)

Francesco P. Schena,[1,2] Giovanni Tripepi,[3] Daniela I. Abbrescia,[2] M. Rossini,[4] Carlo Manno,[1] Hiddo J. L Heerspink.[5] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Fondazione Schena, Bari, Italy; [3]CNR-IFC, Reggio Calabria, Italy; [4]Ospedale Consorziale Policlinico, Bari, Italy; [5]Dept Clinical Pharmacy and Pharmacology, Groningen, Netherlands.*

Background: IgAN is the most common biopsy-proven glomerulonephritis in the world. Approximately 40% of IgAN patients reach end-stage kidney disease (ESKD) 20 years after their kidney biopsy. The high prevalence of ESKD shows that IgAN has a high economic impact in the countries because renal replacement therapy is costly. Moreover, the disease's onset in the second and third decades of life represents a social challenge because young adult patients are very active and highly productive in the workplace. This challenge is one more reason to move from a generalized therapy for all patients to a personalized therapy. Many randomized controlled trials (RCTs) have been conducted, stratifying IgAN patients based on the laboratory findings (serum creatinine, estimated glomerular filtration rate (eGFR) and daily proteinuria). In contrast, data from the kidney biopsy has been used only for clinical diagnosis. **Aim**. We have designed a RCT to study personalized therapy in biopsy-proven IgAN patients with active and chronic renal lesions.

Methods: Our clinical study of IgAN (CLIgAN) is a multicentre, prospective, controlled and open-label randomized clinical trial based on patient's stratification at the time of their kidney biopsy. The trial has been registered in ClinicalTrials.gov (NCT 04662723). We will consider, first, the type of renal lesions followed by serum creatinine values, eGFR and proteinuria. Primary and secondary end points have been established. Second, we will determine whether personalized therapy can slow the decline of the renal function and delay the ESKD.

Results: We will enroll 132 IgAN patients with active renal lesions (66 patients per arm) in the first RCT (ACIgAN). They will receive corticosteroids combined with renin-angiotensin system blocker (RASB) or RASB alone. Two hundred ninety-four IgAN patients with chronic renal lesions at high or very high risk of chronic kidney disease (147 patients per arm) will be enrolled in the second RCT (CHRONIgAN) in which they will receive sodium-glucose cotransporter -2 inhibitor (SGLT2-i) combined with RASB or RASB alone.

Conclusions: Using this approach we hypothesize that patients could receive personalized therapy based on renal lesions to ensure that the right drug gets to the right patient at the right time.

PO1635

Enhanced Efficacy of Corticosteroid Therapy by Tonsillectomy in IgA Nephropathy

Keita Hirano,[1,2] Tetsuya Kawamura,[2] Kentaro Koike,[2] Nobuo Tsuboi,[2] Takashi Yokoo,[2] Yusuke Suzuki.[3] *[1]Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; [2]The Jikei University School of Medicine, Minato-ku, Japan; [3]Juntendo University Faculty of Medicine, Bunkyou-ku, Japan.*

Background: Efficacy of corticosteroid therapy in IgA nephropathy may vary among countries or races. Nowadays, the strategy to enhance efficacy of corticosteroid therapy is desired. In 2014, our randomized controlled trial demonstrated that corticosteroid therapy combined with tonsillectomy had superior anti-proteinuric effect than that of corticosteroid therapy alone (Nephrol Dial Transplant. 2014). However, the benefit of combining corticosteroid therapy with tonsillectomy for long-term renal survival was uncertain. Therefore, in a Japanese nationwide prospective cohort dataset, we aimed to evaluate whether the benefit of corticosteroid therapy may increase when it was combined with tonsillectomy, or not.

Methods: Patients were registered between April 1, 2005 and August 31, 2015 at 44 facilities throughout Japan. The primary outcome was a 50% increase in serum creatinine from baseline or dialysis induction. Two interventions were focused in the present study: corticosteroid with or without tonsillectomy. Survival analysis was adjusted with baseline clinicopathological parameters including eGFR, proteinuria, hematuria, RAS inhibitor use and MEST-C score in Oxford classification.

Results: Enrolled 991 patients showed 75.4 ml/min as mean eGFR and 0.58 g/day as median level of proteinuria. Among them, 634 (64.0%) and 425 (42.9%) patients received corticosteroid therapy and tonsillectomy, respectively. During the median follow up of 5.5 years, 87 patients (8.8%) reached primary outcome. Adjusted hazard ratio (HR) of corticosteroid therapy for primary outcome in patients with tonsillectomy was 3-fold favorable than that in those without tonsillectomy (HR 0.18, 95% confidence interval [CI] 0.06-0.65, versus HR 0.59, 95%CI 0.34-1.01; P value for interaction between corticosteroid therapy and tonsillectomy 0.060).

Conclusions: Enhanced efficacy of corticosteroid therapy by tonsillectomy in IgA nephropathy was confirmed in a Japanese nationwide prospective cohort.

The Potential Role of Monthly Corticosteroid Pulse in IgA Nephropathy

Arisa Kobayashi,[1,2] Keita Hirano,[1,2] Nobuo Tsuboi,[2] Takashi Yokoo.[2] *[1]Japanese Red Cross Ashikaga Hospital., Ashikaga, Japan; [2]The Jikei University School of Medicine, Minato-ku, Japan.*

Background: The risk of corticosteroid therapy may be underestimated in IgA nephropathy (IgAN). Previous studies provided that a fifth part of patients was older than 60 years and the rate of diabetes mellitus (DM) was increased in IgAN. The novel corticosteroid therapies with not losing benefit and reduced risk of corticosteroid are desired. Here, we aimed to determine whether monthly corticosteroid pulse is non-inferior in proteinuria remission and superior in blood glucose control to standard corticosteroid therapy or not.

Methods: Design: Retrospective, non-inferiority study. Participants: Adult patients with IgAN received intervention described below between 2013 and 2020. Intervention: Monthly corticosteroid pulse alone for 6 months versus standard corticosteroid therapy having oral corticosteroid for 6 months and three times of pulse corticosteroid in the same 6 months (Lancet 1999). Outcomes: The primary outcome was proteinuria remission (<0.3g/day) at 1 year and we prespecified 0.67 in odds ratio (OR) as non-inferiority margin. The secondary outcome was safety of blood glucose care, which was defined by less than 0.3 in change of hemoglobin A1c% between baseline and 6 months.

Results: The enrolled 83 patients (22 patients >60 years old and 11 patients with DM) showed median proteinuria 0.93g/day and mean eGFR 60.5ml/min at baseline. There was no significant difference in proteinuria remission between the two groups but including the non-inferiority margin (16/21[76.2%] versus 38/62[61.3%], adjusted OR 4.10, 95%CI 0.47 to 36.1). The safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19/21[90.5%] versus 35/62[56.5%], adjusted OR 14.2, 95%CI 2.02 to 98.9).

Conclusions: Compared to standard corticosteroid therapy, the current study showed that monthly corticosteroid pulse did not reach the statistical requirements for a proven non-inferiority on proteinuria remission, but significantly exhibited safety outcome in the control of blood glucose. Prospective larger studies are needed to determine the role of monthly corticosteroid pulse in IgAN.

PO1637

The Beneficial Effects of Renin-Angiotensin System Inhibitors on IgA Nephropathy with Global Sclerosis

Eri Kasama, Takahito Moriyama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: In IgA nephropathy (IgAN), global sclerosis has been recognized as one of the risk factors for progression, because it induces glomerular hypertension and hyperfiltration in the remained glomeruli. The reno-protective effects of renin-angiotensin system inhibitors (RASI) are considered to decrease glomerular hypertension and hyperfiltration, but their effectiveness in IgAN with global sclerosis has been unknown.

Methods: Of the 871 IgAN patients diagnosed at our institution, we classified them into three grades by the ratio of global sclerosis (G) against whole glomeruli [G0 (n=225): none, G1 (n=455): at least one but <25%, G2 (n=191): ≧25%]. We compared each clinical background and 20-year prognosis. Then, we examined the effect of RASI initiated during follow-up period on the long-term prognosis in patients with G1+G2 and in patients with G2 by Kaplan-Meier analysis and Cox regression analysis. To adjust the background characteristics between patients treated with or without RASI, propensity matching score was performed.

Results: The age, blood pressure, proteinuria, renal function, and histological findings were significantly severer with increasing grade in G0, G1, and G2, and 20-year renal survival rate was 83.5%, 75.0% and 54.4% in patients with G0, G1, and G2, respectively (p<0.001). After propensity matching between patients treated with or without RASI, 366 patients in G1+G2 and 90 patients in G2 were eligible for the evaluation. The 20-year renal survival rate was significantly higher in the patients with RASI than in the patients without RASI (G1+G2: 84.5% vs. 50.9%, p<0.001, G2: 63.8% vs. 33.5%, p=0.037). In multivariate Cox regression analysis considering clinical and histological findings and treatment, RASI was an independent factor to prevent progression in patients with G1+G2 and G2 (G1+G2, hazard ratio: 0.39, 95% confidence interval: 0.25-0.62, p<0.001; G2, hazard ratio: 0.35, 95% confidence interval: 0.19-0.66, p=0.001).

Conclusions: In this study, global sclerosis was associated with severer clinical and histological findings, and poor prognosis. However, RASI initiated during follow up period was found to improve renal prognosis in IgAN with at least one global sclerosis.

PO1638

Atacicept Reduces Serum Gd-IgA1 by Quartiles in IgAN Patients

Jonathan Barratt,[1] James A. Tumlin,[2] Celia J. Lin,[3] Yusuke Suzuki,[4] Marshall W. Fordyce,[3] Gerald B. Appel.[5] *[1]University of Leicester, Leicester, United Kingdom; [2]Emory University, Atlanta, GA; [3]Vera Therapeutics, Inc., South San Francisco, CA; [4]Juntendo Daigaku, Bunkyo-ku, Japan; [5]Columbia University Irving Medical Center, New York, NY.*

Background: Gd-IgA1 plays a central role in IgAN pathogenesis. Higher Gd-IgA1levels are independently associated with a greater risk of renal function deterioration that differ per Gd-IgA1 quartile. The Ph2a JANUS trial was the first to show substantial Gd-IgA1 reduction with atacicept in IgAN patients (pts). This analysis investigated whether atacicept could reduce Gd-IgA1 level by quartile and therefore potentially mitigate the poor prognosis of IgAN based on Gd-IgA1.

Methods: The JANUS study enrolled 16 IgAN pts with persistent proteinuria. Pts were randomized to atacicept 25mg, 75mg, or placebo (PBO). Gd-IgA1 was assessed at baseline (BL), wks 4, 12, 24, 48, and 72. At BL, pts were divided into 4 equal groups according to the quartiles of Gd-IgA1 distribution and assessed at each timepoint. A separate cohort of ~150 IgAN pts from the Univ of Leicester was used as a reference population for quartile determination.

Results: In IgAN pts, dose-dependent reductions in Gd-IgA1 were observed for up to 72 wks with atacicept (Fig 1). For pts in the highest quartile all 3 of 3 in the PBO group had no significant change over 48-72 wks, while all 4 of 4 in the atacicept highest quartile group had significant reductions. PBO pts transiently increased or decreased Gd-IgA1 levels by 1 quartile, atacicept 25 mg stably reduced Gd-IgA1 levels by 1 quartile in 2/6 (33%) pts and atacicept 75 mg stably reduced Gd-IgA1 levels by at least 1 quartile in 4/5 (80%) pts and by 2 quartiles in 3/5 (60%) pts. These results were generally consistent when using quartiles determined by the larger reference Univ of Leicester population.

Conclusions: In IgAN pts atacicept demonstrated a durable and substantial reduction in Gd-IgA1 in a dose dependent manner up to 72 wks. A stable 2 quartile decrease in Gd-IgA1 levels was observed in the atacicept 75 mg arm. The ongoing Ph2b ORIGIN trial evaluating up to atacicept 150 mg in IgAN pts will help determine how reduction of Gd-IgA1 translate to renal function.

Mean percent change in Gd-IgA1 over time

PO1639

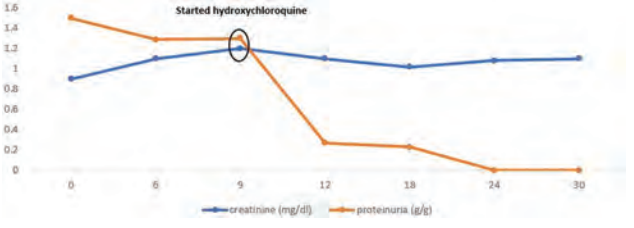
Remission of IgA Nephropathy with Hydroxychloroquine

Hafsa Tariq,[1] Jagmeet S. Dhingra.[2] *[1]University Hospitals, Cleveland, OH; [2]MetroHealth Medical Center, Cleveland, OH.*

Introduction: IgA nephropathy is the most common form of glomerulonephritis in the world. Treatment options include blockade of renin-angiotensin-system (RAS) as the first line of therapy. Steroids may be beneficial in refractory cases, however, can result in several adverse effects. Data regarding use of immunosuppression is inconclusive. Combination of RAS inhibition and hydroxychloroquine has shown to reduce proteinuria in recent studies, though, complete remission with long term use has not been described. We report the case of a 46-year-old Asian female with IgA nephropathy, who was treated with maximally tolerated RAS inhibition and hydroxychloroquine for about 24- months resulting in complete remission of proteinuria and hematuria.

Case Description: The patient was referred to nephrology for evaluation of hematuria and proteinuria (1.5g/g, Serum creatinine 0.9mg/dl). Serological work-up was negative. She was initiated on angiotensin receptor blocker (ARB) and underwent kidney biopsy which confirmed IgA Nephropathy. There were 8 glomeruli with 20-25% sclerosis, mild to moderate chronic tubulointerstitial nephritis and fibrosis, no crescents, mild mesangial proliferation and hypercellularity with IgA staining 3+. She did not have any significant improvement in proteinuria despite maximally tolerated ARB (losartan 100 mg daily) therapy for three months. Her kidney function also declined, creatinine 1.2mg/dl. Hydroxychloroquine 200mg daily was then initiated along with regular eye exams and hepatic function tests. Repeat workup in three months showed improvement in proteinuria to 0.2g/g and creatinine 1.1mg/dl. She was continued on the same regimen for about 24-months, with recent work-up showing complete resolution of proteinuria and hematuria.

Discussion: As per our literature review, this is the first reported case of IgA nephropathy treated with RAS inhibition and hydroxychloroquine over a span of almost two years resulting in complete remission. Hydroxychloroquine can be considered, in select cases, as an alternative to steroid therapy in refractory proteinuria.



Trend of serum creatinine and spot proteinuria measurement

PO1640

Long-Term Follow-Up Study of Immunosuppressive Therapy in IgAN Patients with CKD Stage 3 and 4

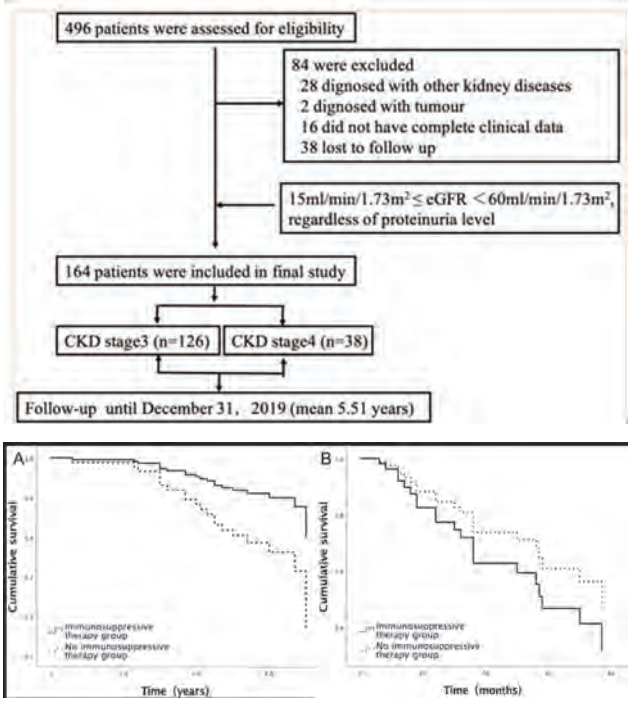
Yuehui Ni. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: The benefits of immunosuppressive therapy in patients with IgAN remain controversial, especially for those with more severe renal pathology and reduced renal function.

Methods: A total of 496 primary IgAN patients were screened between 2012 to 2014. Patients were divided to 4 groups according to CKD stage and the treatment. The primary endpoints were doubling of creatinine, progression to ESRD or death. The secondary endpoint was decrease in eGFR. Subgroup analysisof CKD3 immunosuppressive treatment group was conducted to explore the factors affecting the prognosis after treatment.

Results: 164 patients were enrolled and mean follow-up time was 5.5 years. There were 126 patients in CKD3 stage and 38 patients in CKD4 stage. Immunosuppressive therapy significantly improved prognosis in patients with CKD stage3 (HR 0.435[95% CI 0.200-0.944];p=0.035), but no difference for CKD stage4(p=0.364). Subgroup analysis showed baseline eGFR(OR 0.909[95%CI 0.834-0.991];p=0.031), serum IgG level(OR 0.809 [95%CI 0.658-0.995];p=0.045) were associated with primary outcome and loop necrosis (OR 0.189[95% CI 0.050-0.709], p=0.014), proportion of crescents (OR 0.200[95% CI 0.100-0.521], p=0.003), interstitial fibrosis>50%(OR 5.490[95% CI 1.323-22.727]) were associated with secondary outcome. Remission within 1 year could be an indicator of good long-term prognosis (HR 0.555[95%CI 0.296-0.759; p=0.035]).

Conclusions: For IgAN patients with CKD stage3, immunosuppressive therapy should be actively applied under the general treatment, but for patients with CKD stage4, it should be carefully. Patients with good renal function, more acute lesions of renal pathology would have a better prognosis after immunosuppressive therapy. Patients who achieved remission within 1 year would have better long-term prognosis.



PO1641

An International Delphi Survey on IgA Nephropathy: Results from the DEFINE Physicians Study

Marina Vivarelli,[1] Jürgen Floege,[2] Jonathan Barratt,[3] Rosanna Coppo,[4] Richard A. Lafayette,[5] Jai Radhakrishnan,[6] Brad H. Rovin,[7] David T. Selewski,[8] Vladimir Tesar,[9] Marcello Tonelli,[10] Heather N. Reich.[11] *[1]Bambino Gesù Pediatric Hospital Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS), Rome, Italy; [2]Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany; [3]University of Leicester, Leicester, United Kingdom; [4]Regina Margherita Hospital, Turin, Italy; [5]Stanford University, Stanford, CA; [6]Columbia University Medical Center, New York, NY; [7]The Ohio State University Wexner Medical Center, Columbus, OH; [8]Medical University of South Carolina, Charleston, SC; [9]Charles University, Prague, Czechia; [10]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada; [11]University Health Network and University of Toronto, Toronto, ON, Canada.*

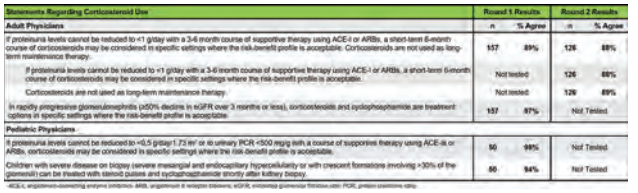
Background: It is unclear whether treatment guidelines for patients with IgA nephropathy (IgAN) are uniformly applied in clinical practice. The DEFINE: Physicians initiative sought to describe the opinions of nephrologists about the pathophysiology, diagnosis, and optimal management of adult and pediatric patients with IgAN.

Methods: A 2-round Delphi survey was distributed to nephrologists in Canada, France, Germany, Italy, Spain, the UK, and the US. A 1-9 Likert scale (9=strongly agree) was used to score statements. Consensus was defined as median and mean score ≥7, and ≥75% of participants scoring agreement (ie, score 7-9). Feedback collected in Round 1 was used to revise statements not achieving high consensus (≥90% agreement) for retesting in Round 2. Moderate consensus was defined as 75-89% agreement.

Results: In Round 1, 207 participants with a median clinical experience of 18 years (range, 5-49) rated 19 statements about IgAN. Half (50%) of participants worked in nonacademic settings. All statements met criteria for moderate or high consensus after the second round. Notably, a statement on corticosteroid therapy in adult patients reached moderate consensus after Round 1 and was divided into 2 parts in Round 2 (Figure 1). Both revised statements reached levels of agreement similar to the original statement. In contrast, a statement on corticosteroid and cyclophosphamide use in adults with rapidly progressive glomerulonephritis and 2 statements on corticosteroid therapy in pediatric patients reached high consensus in Round 1 (Figure 1).

Conclusions: High consensus regarding clinical decisions and the importance of controlling proteinuria in IgAN was observed in this Delphi survey. Although the level of consensus related to corticosteroid use was lower for adult patients vs pediatric patients, the level of consensus was relatively high for both groups.

Funding: Commercial Support - Travere Therapeutics, Inc.



Statements Regarding Corticosteroid Use	Round 1 Results		Round 2 Results	
Adult Physicians	n	% Agree	n	% Agree
If proteinuria levels cannot be reduced to <1 g/day with a 3-6 month course of supportive therapy using ACE-I or ARBs, a short-term 6-month course of corticosteroids may be considered in specific settings where the risk-benefit profile is acceptable. Corticosteroids are not used as long-term maintenance therapy.	157	89%	126	88%
If proteinuria levels cannot be reduced to <1 g/day with a 3-6 month course of supportive therapy using ACE-I or ARBs, a short-term 6-month course of corticosteroids may be considered in specific settings where the risk-benefit profile is acceptable.	Not tested		126	88%
Corticosteroids are not used as long-term maintenance therapy.	Not tested		126	89%
In rapidly progressive glomerulonephritis (≥50% decline in eGFR over 3 months or less), corticosteroids and cyclophosphamide are treatment options in specific settings where the risk-benefit profile is acceptable.	157	87%	Not Tested

Long-Term Effectiveness of Low-Dose Prednisone Treatment in Relapses of Steroid-Sensitive Minimal Change Disease

Irene Martin Capon,[1] Elizabeth R. Viera,[1] Eduardo Gutierrez-martinez,[2] Milagros Fernandez-Lucas,[1] Javier Villacorta Perez.[1] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Treatment of relapses of steroid-sensitive minimal change disease (SMCD) involves administration of high doses of prednisone for several weeks, implying significant pharmacological toxicity. In a previous pilot study, the efficacy of treatment with low doses of prednisone for the treatment of relapses in these patients was demonstrated.

Methods: Retrospective analysis of SMCD relapses treated with low doses of prednisone in two centers, was performed, and the response to treatment, the time to reach remission and the free-time of relapse was studied, comparing it with previous relapses of the same patients treated with standard doses of steroids.

Results: 85 relapses in 21 patients with SMCD were analyzed. The median age of patients was 35 years (IQR 18-53), with 62% being male. The mean proteinuria at relapse debut was 5.37 ± 4.11 g/g, serum albumin 2.47 ± 0.94 gr/dL and creatinine 0.86 ± 0.35 mg/dL. Thirty-six relapses (42.3%) were treated with low doses of prednisone (LDP) and compared with 49 previous relapses (57.6%) of the same patients, treated with high doses of prednisone (HDP). The mean initial prednisone dose in relapses treated with LDP and HDP was 0.45 ± 0.1 mg/kg and 1.00 ± 0.3 mg/kg, respectively (p=0.001). The mean cumulative dose of prednisone in relapses treated with LDP and HDP was 1771 ± 1303 mg and 3894 ± 2134 mg respectively ($p < 0.001$). There were no differences in treatment duration between relapses treated with low and high corticosteroids doses (124 days vs 153 respectively; p=0.2). All patients achieved complete remission after steroid treatment. Mean time to remission was 18.4 days for relapses with LDP and 17.1 days for HDP ($p = 0.6$). The mean free time to relapse after treatment with low doses was 12.6 months vs 10.9 months for those treated with high doses ($p = 0.6$).

Conclusions: Among SMCD patients, treatment of relapses with low doses of prednisone (0.5 mg/kg) is effective and safe, allowing to minimize cumulative steroid doses and derived toxicity.

PO1643

DEFINE Physicians: An International Delphi Survey to Identify Consensus in the Care of Patients with FSGS or Idiopathic Nephrotic Syndrome

Marina Vivarelli,[1] Keisha L. Gibson,[2] Debbie S. Gipson,[3] Manuel Praga,[4] Heather N. Reich,[5] Michiel F. Schreuder,[6] Vladimir Tesar,[7] Marcello Tonelli,[8] Jack F. Wetzels,[9] Jai Radhakrishnan,[10] Jürgen Floege.[11] *[1]Bambino Gesù Pediatric Hospital Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS), Rome, Italy; [2]School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of Michigan, Ann Arbor, MI; [4]Complutense University, Investigation Institute Hospital 12 de Octubre, Madrid, Spain; [5]University Health Network and University of Toronto, Toronto, ON, Canada; [6]Amalia Children's Hospital, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands; [7]Charles University, Prague, Czechia; [8]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [9]Radboud University Medical Center, Nijmegen, Netherlands; [10]Columbia University Medical Center, New York, NY; [11]Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany.*

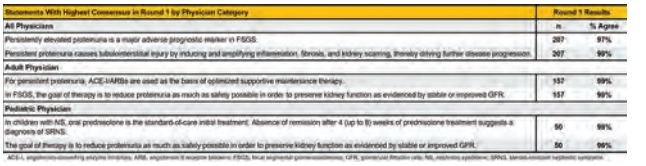
Background: The extent to which real-world practice aligns with guidelines for management of focal segmental glomerulosclerosis (FSGS) and pediatric idiopathic nephrotic syndrome (INS) is unknown. The DEFINE: Physicians project sought to describe physicians' opinions on the pathophysiology and optimal management of FSGS/INS in real-world settings.

Methods: DEFINE: Physicians was a 2-round Delphi survey that recruited nephrologists from North America and Europe. A total of 22 FSGS/INS statements were scored using a 1-9 Likert scale (9=strongly agree). Consensus was defined as median and mean score ≥7, and ≥75% of participants scoring agreement (ie, score 7-9). Statements not achieving high consensus (≥90% agreement) in Round 1 were revised and retested in Round 2.

Results: This study involved 207 adult and pediatric nephrologists. Median clinical experience was 18 (range 5-49) years; 103 participants (50%) worked in nonacademic settings. In Round 1, 21 statements met consensus criteria and 7 statements not achieving high consensus were revised or divided into multiple parts, creating 11 revised statements for testing in Round 2. In Round 2, 9 of 11 statements met at least moderate consensus. Round 1 statements with high consensus described prognostic significance of proteinuria and disease management (Figure 1). Controversial statements retested in Round 2 pertained to distinction between primary and secondary FSGS in adults, and to management of frequently relapsing INS in children (Figure 2).

Conclusions: The level of consensus in this Delphi survey was high for statements on treatment decisions and the importance of proteinuria control. The main area where high consensus was not reached pertained to differentiation between primary and secondary FSGS and managing frequently relapsing INS in children, suggesting that these areas require further research.

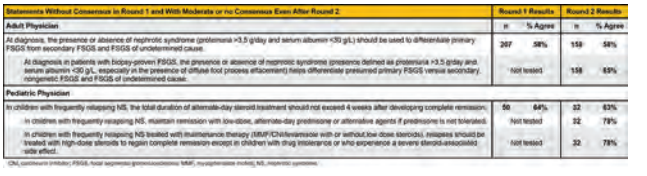
Funding: Commercial Support - Travere Therapeutics, Inc.



Statements With Highest Consensus in Round 1 by Physician Category	Round 1 Results	
All Physicians	n	% Agree
Persistently elevated proteinuria is a major adverse prognostic marker in FSGS.	207	97%
Persistent proteinuria causes tubulointerstitial injury by inducing and amplifying inflammation, fibrosis, and kidney scarring, thereby driving further disease progression.	207	99%
Adult Physician		
For persistent proteinuria, ACE-I/ARBs are used as the basis of optimized supportive maintenance therapy.	157	99%
In FSGS, the goal of therapy is to reduce proteinuria as much as safely possible in order to preserve kidney function as evidenced by stable or improved GFR.	157	99%
Pediatric Physician		
In children with NS, oral prednisolone is the standard-of-care initial treatment. Absence of remission after 4 (up to 8) weeks of prednisolone treatment suggests a diagnosis of SRNS.	50	99%
The goal of therapy is to reduce proteinuria as much as safely possible in order to preserve kidney function as evidenced by stable or improved GFR.	50	96%

ACE-I, angiotensin-converting enzyme inhibitors; ARB, angiotensin II receptor blockers; FSGS, focal segmental glomerulosclerosis; GFR, glomerular filtration rate; NS, nephrotic syndrome; SRNS, steroid-resistant nephrotic syndrome

Figure 1



Statements Without Consensus in Round 1 and With Moderate or no Consensus Even After Round 2	Round 1 Results		Round 2 Results	
Adult Physician	n	% Agree	n	% Agree
At diagnosis, the presence or absence of nephrotic syndrome (proteinuria >3.5 g/day and serum albumin <30 g/L) should be used to differentiate primary FSGS from secondary FSGS and FSGS of undetermined cause.	207	58%	159	58%
At diagnosis in patients with biopsy-proven FSGS, the presence or absence of nephrotic syndrome (presence defined as proteinuria >3.5 g/day and serum albumin <30 g/L, especially in the presence of diffuse foot process effacement) helps differentiate presumed primary FSGS versus secondary, nongenetic FSGS and FSGS of undetermined cause.	Not tested		159	63%
Pediatric Physician				
In children with frequently relapsing NS, the total duration of alternate-day steroid treatment should not exceed 4 weeks after developing complete remission.	50	64%	32	63%
In children with frequently relapsing NS, maintain remission with low-dose, alternate-day prednisone or alternative agents if prednisone is not tolerated.	Not tested		32	78%
In children with frequently relapsing NS treated with maintenance therapy (MMF/CNI/levamisole with or without low dose steroids), relapses should be treated with high-dose steroids to regain complete remission except in children with drug intolerance or who experience a severe steroid-associated side effect.	Not tested		32	78%

Safety and Efficacy of ANG-3070 in Patients with Primary Proteinuric Kidney Disease: A Phase 2 Study Design

Jai Radhakrishnan,[1] Shakil Aslam,[2] John F. Neylan,[2] Dana Rizk,[3] Howard Trachtman.[4] *[1]Columbia University Irving Medical Center, New York, NY; [2]Angion Biomedica Corp, Uniondale, NY; [3]University of Alabama at Birmingham, Birmingham, AL; [4]NYU Grossman School of Medicine, New York, NY.*

Background: Primary proteinuric kidney diseases (PPKDs) are among the leading causes of End-Stage Kidney Disease (ESKD). Receptor tyrosine kinases like PDGFR, DDR1, DDR2 are thought to play a role in the progression of PPKDs to ESKD. ANG-3070, a selective oral tyrosine kinase inhibitor, has demonstrated beneficial effects in chronic kidney disease animal models. **Objective**: Describe the design of a proof-of-concept study of ANG-3070 in the treatment of PPKD patients with persistent proteinuria while on standard of care (SOC).

Methods: A 12-week, randomized, double-blind, placebo-controlled study enrolling 100 patients with biopsy-proven PPKD and persistent proteinuria, ≥ 1 g/day, while on the SOC including maximum tolerated RAAS inhibitors. Patients will be randomized 1:1:1:1 to 200 mg or 400 mg once-daily or 300 mg twice-daily of ANG-3070 or placebo (Fig.1).

Results: The primary endpoint is the percentage change in 24-hr urinary protein at Week 12. Key secondary endpoints evaluated at week 12 include percentage change in 24-hr urinary albumin, number of patients with complete remission in proteinuria (24-hr urinary protein < 300 mg), number of patients with partial remissions in proteinuria (24-hr urinary protein reduction of ≥ 50% from the baseline and a 24-hr urinary protein < 3.5 g/day if the baseline 24-hr urinary protein > 3.5 g), number of patients with ≥ 50% reduction in 24-hr urinary protein from the baseline, and number of patients with ≥ 50% reduction in 24-hr urinary albumin from baseline. An independent data monitoring committee will review safety throughout the study.

Conclusions: This Phase 2 study will provide data about the safety and efficacy of ANG-3070 in PPKD patients that will inform the design of a Phase 3 study.

PO1645

Transcutaneous Auricular Vagus Nerve Stimulation (taVNS) for the Treatment of Pediatric Nephrotic Syndrome (NS)

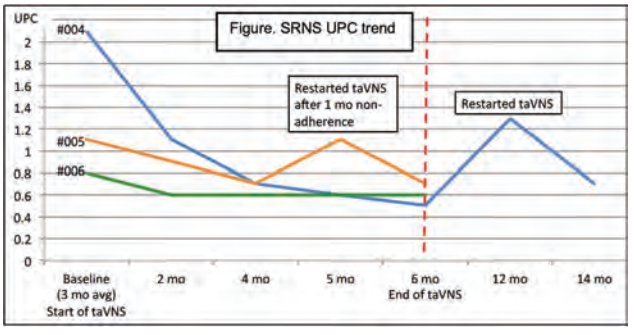
Christine B. Sethna,[1,2] Kumail Merchant,[1] Stavros Zanos,[2] Timir Datta-Chaudhuri,[2] Pamela Singer,[1] Laura J. Castellanos,[1] Rachel Frank.[1] *[1]Steven and Alexandra Cohen Children's Medical Center, New Hyde Park, NY; [2]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.*

Background: Children with NS, especially those with frequent relapses (FRNS) or steroid resistance (SRNS), are exposed to prolonged courses of immunosuppressant medications with side effects and variable efficacy. There is an urgent need to identify novel and safe therapies to treat pediatric NS. taVNS modulates the immune system via the cholinergic anti-inflammatory pathway and has become a therapy of interest for treating immune-mediated illnesses. The objective was to conduct an open-label early feasibility study of taVNS therapy for pediatric NS.

Methods: Children with FRNS (≥2 relapses in previous 6 months) or SRNS (no remission after 4 weeks of steroids) were enrolled. Participants with FRNS were in remission and off immunosuppression (off steroids >14 days and other immunosuppression >3 months). SRNS patients were on a stable regimen of medications for 6 months prior to enrollment. Participants performed taVNS therapy 5 minutes daily for 6 months with a TENS 7000 unit. taVNS was delivered to the auricular branch of the vagus nerve via the left cymba concha. Cytokine levels were compared using the Wilcoxon test.

Results: Seven participants (3 FRNS, 3 SRNS, 1 genetic congenital nephrotic syndrome [CNS]) had a median age of 7 years (range 3-17) and 63% were male. FRNS participants remained relapse-free during the study period (two continued taVNS at 9 and 13 months and remained in remission). SRNS participants had a 25-76% reduction in urine protein to creatinine ratio (upc) compared to baseline (Figure). Upc decreased (13.7%) in the participant with CNS but remained in nephrotic range. All but one participant (non-compliant) had a reduction in TNF-α (7.33pg/mL vs. 5.46pg/mL, p=0.03). No adverse effects were reported.

Conclusions: taVNS prevented NS relapses in FRNS, reduced proteinuria in SRNS, and reduced TNF-α levels without any adverse effects, suggesting taVNS as a promising therapy for pediatric NS. A larger, randomized clinical trial is needed to confirm these findings.



PO1646

A Study Comparing Rituximab and Modified Ponticelli (MP) Regimen in Primary Membranous Nephropathy(PMN)

Abhishek Kumar, Arpita Ray Chaudhury, Saugat D. Gupta, Sriranjan Mukherjee, Moumita Sengupta. IPGMER Nephrology *Institute of Postgraduate Medical Education and Research, Kolkata, India.*

Background: The study was designed in December 2018 when the Gemritux trial had established Rituximab as an alternative to MP regimen in the treatment of PMN. So we designed a study comparing Rituximab and MP Regimen.

Methods: We allocated 35 adults with PMN and proteinuria >3.5 gm/day in a 3:2 ratio to MPregimen or Rituximab 375mg/m^2 on days 1,8,15 and 22.The primary outcome was complete or partial remission(CR+PR)at 6 and 12 months in the 2 groups. The other findings included trends of 24 hr urine protein, albumin, creatine and seriousadverse events at 6 and 12 months in both groups.

Results: At 6 months, 12 of 21 patients (57.14%) allocated to MP Regimen and 5 of 14 patients (35.71%) allocated to Rituximab experienced remission(CR+PR) (odds ratio [OR], 2.4; 95% CI, 0.596 -9.670, p value 0.10). At 12 months, 14 of 21 patients (66.66%) allocated to MP Regimen and 10 of 14 patients (71.43%) allocated to Rituximab experienced remission(CR+PR) (odds ratio [OR], 0.8; 95%CI, 0.184-3.487, p value 0.383). Serious adverse events occurred in 15% of patients receiving Rituximab and in 24% receiving the MP Regimen.

Conclusions: We found No Statistically Significant difference betweenRituximab and the Modified Ponticelli Regimen in the treatment of membranous nephropathy. A head-to-head, longer follow up study comparing MP Regimen versus Rituximab is required in terms of duration of remission and side effect profile between the two treatment groups.

Felzartamab in Patients with Anti-Phospholipase A2 Receptor Autoantibody Positive (Anti-PLA2R+) Membranous Nephropathy (MN): Interim Results from the M-PLACE Study

Brad H. Rovin,[1] Sharon G. Adler,[2] Elion Hoxha,[3] Ben Sprangers,[4] Rolf A. Stahl,[3] Jack F. Wetzels,[5] Bettina Schwamb,[6] Rainer Boxhammer,[6] Quynh Nguyen,[6] Stefan Haertle,[6] Pierre M. Ronco.[7,8] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]The Lundquist Institute, Torrance, CA; [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]University Hospitals Leuven, Leuven, Belgium; [5]Radboud Universiteit, Nijmegen, Netherlands; [6]MorphoSys AG, Martinsried, Germany; [7]Sorbonne Universite, Paris, France; [8]INSERM UMRS 1155, Paris, France.*

Background: Primary MN is a rare autoimmune kidney disease. In ~70% of cases, autoantibodies to PLA2R on podocytes form immune complexes that damage the glomerular filtration barrier and typically lead to nephrotic syndrome. Current MN therapies fail to directly target CD20–/CD38+ plasma cells that are the main source of autoantibodies. Depleting plasma cells by targeting CD38 may be an effective strategy for MN, particularly in patients (pts) with high anti-PLA2R Ab titers. Here we report proof-of-mechanism data for felzartamab (MOR202), a fully human anti-CD38 monoclonal antibody (Ab).

Methods: M-PLACE (NCT04145440) is an open-label, multi-national Phase Ib/IIa study of adults with anti-PLA2R+ MN requiring immunosuppressive therapy (IST). Cohort 1 includes de novo and IST-relapsed pts (n=20) and Cohort 2 IST-refractory pts (n=10). Participants receive nine felzartamab infusions (16 mg/kg) over six 28-day cycles (weekly in Cycle 1; monthly thereafter), followed by a 28-week observational follow-up. Concomitant IST use is prohibited. The primary endpoint is the incidence and severity of treatment-emergent adverse events. The key secondary endpoint is the immunologic response rate, as determined by anti-PLA2R Ab reductions. Exploratory endpoints include evaluations of proteinuria and kidney function.

Results: As of April 2021, 12/30 planned pts were enrolled (Cohort 1, n=8; Cohort 2, n=4). Median age was 62.5 years (range 43 to 77 years), 83% were male, and median baseline anti-PLA2R Ab titer was 178 U/mL (18 to 1027 U/mL). Seven pts had received ≥4 weeks of felzartamab therapy. At Week 4, 5/7 pts had a >50% reduction from baseline in anti-PLA2R Ab (Cohort 1, n=3; Cohort 2, n=2); the other 2/7 pts had reductions from baseline of –16.8% and –5.0% (both Cohort 1). Mean % decline in anti-PLA2R Ab from baseline to Week 4 was –53.0% (–92.0% to –5.0%). B-cell counts were not markedly changed from baseline. Felzartamab was well tolerated.

Conclusions: The M-PLACE proof-of-concept study has so far shown that felzartamab rapidly and substantially reduces anti-PLA2R Ab titers in pts with anti-PLA2R+ MN. Longer follow-up is required to assess felzartamab safety and efficacy in this population.

Evaluating the Efficacy of Rituximab in Primary Membranous Nephropathy: An Observational Study from Southern India

Megha Saigal, Swarnalatha Guditi. *Nizam's Institute of Medical Sciences, Hyderabad, India*.

Background: Membranous nephropathy, is an immunological disease. It can occur secondary to infection, malignancy, or SLE. In 70% of patients M-type phospholipase A2 receptor (PLA2R) was positive, and these patients are considered to suffer from primaryMN. In primary MN immunosuppressive therapy is started in patients with progressive disease activity. There have been several studies comparing the efficacy of different immunosuppressive regimens, however the role of rituximab as a primary/ secondary immunosupressive agent in primary MN has not been evaluated among Indian population

Methods: Single centre observational pilot study 20 subjects with histological/ serum Pla2r positive progressive primary membranous nephropathy were recruited. They were then either started on conventional immunosupressve therapy (modified ponticelli regimen) and if no or partial response were initiated on rituximab as a second line agent or in some cases as a primary immunosupressive agent. Rituximab was started as375mg/ m^2 a 4weekly doses. Data regarding urine protein creatinine ratio, serum albumin, serum creatinine, CD 19 count, time to achieve to remission and side-effects were noted.

Results: In our study, males were 65% (13), females contribute to 35% (7). After rituximab therapy 75% (15/20) achieved remission, significant changes were seen in the form of decrease in proteinurea and increase in serum protein and serum albumin levels **p value <0.05**. Time to achieve remission & median no. of doses required was 1.66 ± 0.81 months and 3 respectively. 85% sustained remission attained, with mean duration of followup being 10.16 + 5.96 months.

Conclusions: Therapy with rituximab as a primary/ secondary immunosupressive agent was effective in inducing and maintaining remission in a significant proportion of patients with primary MN.

Intravenous Cyclophosphamide vs. Calcineurin Inhibitors as Treatment in High-Risk Idiopathic Membranous Nephropathy: The Benefit in MAKE Is Preserved in the Presentation IV?

Angela M. Cordoba Hurtado,[1] L. M. Perez-Navarro,[1] Jesus D. Lima-Lucero,[1] Virgilia Soto,[2] Rafael Valdez-Ortiz.[1] [1]*Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico;* [2]*Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico*.

Background: The use of intravenous cyclophosphamide (IV CYC) in high-risk idiopathic membranous nephropathy (IMN) has not been fully evaluated in the MAKE primary endpoints (serum Cr doubling, ERSD, mortality). In our center, the treatment of high-risk IMN is performed with IV CYC or with calcineurin inhibitors (CNI) according to criteria of accessibility and availability of the drug. Our aim was to compare the immunosuppressive treatment scheme with IV CYC vs CNI in primary MAKE events in patients with high-risk IMN.

Methods: Retrospective cohort study. Patients with a diagnosis of IMN diagnosed between January 2012 and January 2020 were included. The patients were treated with IV CYC or CNI. With a minimum follow-up of 12 months and MAKE primary events were recorded in addition to complete, partial, composite response and adverse events at the end of the study.

Results: Thirty-seven patients of which 14 (37.8%) were treated with IV CYC and 23 (62.2%) with CNI. The mean age was 46 ± 15.3 years, 54% male, and 27% hypertensive. Average PrU / CrU 10.43 ± 4.4 gr/gr; mean serum albumin 1.8 ± 0.68 gr/dL; and GFR by CKD EPI of 75ml/min/1.73m^2. With a follow-up of 45.91 ± 23.9 months, no baseline differences were observed between the groups. Table 1

Conclusions: The comparison between IV CYC *vs* CNI for high-risk IMN shows similar outcomes focused on MAKE. However, the comparison in composite and partial response shows a result in favor of the use of CNI. This perspective provides clinical evidence about the use of IV CYC, which is why it is suggested that there are possible differences between our findings and those reported so far with oral CYC. Prospective clinical trials are required to have conclusive results.

An 8-Week Course of Cyclophosphamide and Steroids Is Effective Therapy in Patients with Membranous Nephropathy (MN) and Low PLA2Rab Levels

Coralien Vink- van Setten,[1] Anne-Els van de Logt,[1] Alexander Kühnl,[2] Jack F. Wetzels.[1] [1]*Radboudumc, Nijmegen, Netherlands;* [2]*EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany*.

Background: We introduced individualized therapy in patients with MN and positive anti PLA2R antibodies (aPLA2R) by IIFT test. Treatment (cyclophosphamide combined with steroids) was stopped when the IIFT test (measured at 8, 16, or 24 weeks) became negative. After 8 weeks, 71% of patients were in immunological remission. Unfortunately, 30% of these latter patients needed renewed therapy within 12 months because of immunological and/or clinical relapse. We questioned if quantitative aPLA2R measurement would predict response.

Methods: Available, stored serum samples were retrieved, and aPLA2R levels were measured by ELISA (EUROIMMUN Lübeck, Germany). Good outcome was defined as immunological remission at 8 weeks, followed by clinical remission without clinical relapse nor the need for additional immunosuppressive therapy within 12 months.

Results: Serum samples of 60 patients were available for analysis. Patients were grouped according tertiles of aPLA2R (Table). Higher aPLA2R levels were associated with more severe proteinuria. Patients in the lowest tertile were more likely to develop immunological remission at 8 weeks (95% vs 65% and 50% in the middle and highest tertiles). Moreover, in the subgroup of patients who were treated for 8 weeks only, fewer patients in the lowest tertile of aPLA2R needed renewed immunosuppressive therapy, although not statistically significant (16% vs 43%, p 0.054).

Conclusions: Individualized treatment of MN patients with cyclophosphamide and steroids has been recently introduced. In this study we show that baseline aPLA2R levels predict immunological remission at 8 weeks. Furthermore, patients with low aPLA2R levels at baseline seem to be more likely to have a good overall outcome.

Prospective Cohort Study of Antibody-Guided Therapy in Patients with Membranous Nephropathy

Anne-Els van de Logt, Coralien Vink- van Setten, Jack F. Wetzels. *Radboud Universiteit, Nijmegen, Netherlands.*

Background: Guidelines advise a standard course of 6 months of cyclophosphamide (CP) and steroids in patients with membranous nephropathy (MN). We hypothesized that monitoring of aPLA2R- antibodies (aPLA2R) may enable individualized (and shorter duration of) therapy.

Methods: Patients with MN, with positive aPLA2R and high risk of progression were included. Treatment consisted of CP (1.5 mg/kg/day combined with steroids). aPLA2R were monitored (IFT test) at 8, 16, and 24 weeks after start of treatment. If the IFT test was negative, CP was stopped and prednisone tapered. If the IFT test remained positive at 24 weeks, CP was switched to MMF and therapy continued.

Results: Sixty-five patients (48 males) were included; mean age 61 ± 12 yrs, median serum creatinine 136 [IQR 100-161] µmol/l, serum albumin 21 [IQR 16-26] g/l and UPCR 7.7 [IQR 5.4-11.1] g/10 mmol. Follow-up was 37 [IQR 27-58] months. aPLA2R test was negative in 46 patients after 8 weeks (group A), in 10 patients after 16 weeks (group B1), in 1 patient after 24 weeks (group B2) and in 8 patients aPLA2R remained positive after more than 24 weeks (group B3). In group A no clinical remission (PCR >3.0 g/10 mmol) was observed in 26 % (12 patients) compared to 21 % (4 patients) in group B1-B3 (Log rank p=0.579). Overall 22 patients (34 %) received additional immunosuppressive (IS) therapy because of persistent proteinuria (after aPLA2R disappearance) or clinical relapse. IS free survival was lower in group A compared to group B1-B3. (Figure 1).

Conclusions: Approximately 50% of patients developed long-term clinical remission after 8 weeks of therapy. Our data support aPLA2R-guided therapy. However, in approximately 25% of patients immunological remission was not followed by clinical remission, underlining the need for better biomarkers.

Economic Evaluation of the MENTOR Trial Comparing Rituximab and Cyclosporine for the Treatment of Membranous Nephropathy (MN)

Matthew J. Kadatz,[1,2] Scott Klarenbach,[3] Helen So,[3] Fernando C. Fervenza,[4] Daniel C. Cattran,[5] Sean Barbour.[1] On behalf of the MENTOR trial investigators *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]Vancouver Coastal Health Research Institute, Vancouver, BC, Canada; [3]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [4]Mayo Clinic Minnesota, Rochester, MN; [5]University of Toronto, Toronto, ON, Canada.*

Background: The MENTOR trial (MEmbranous Nephropathy Trial Of Rituximab) showed that rituximab (RTX) was noninferior to cyclosporine (CSA) in inducing complete or partial remission of proteinuria and was superior in maintaining proteinuria remission. However, the cost of RTX is high and it's cost-effectiveness has not been determined.

Methods: A Markov model (Fig 1) was used to determine the incremental cost-effectiveness ratio (ICER) of RTX compared with CSA for the treatment MN from the perspective of a health care payer with a life-time time horizon ($2020 USD). The model outcomes were informed by data from the MENTOR trial and previously published literature. Cost and utility inputs were obtained from the literature.

Results: Based on 1,000 simulations, the mean additional cost of RTX therapy for MN compared with CSA was $168,064 with an improvement in utility of 6.70 QALYs (Fig 2). RTX was cost-effective (assuming a willingness-to-pay threshold of $50,000 / QALY) compared with cyclosporine, with an ICER of $25,071 per additional quality adjusted life year (QALY) over a lifetime time horizon (45 years).

Conclusions: While the initial cost of RTX is high, RTX is a cost-effective option (assuming willingness to pay thresholds of $50,000 or greater) for the treatment of MN when compared with the alternative of CSA. The cost-effectiveness will be further improved with the use of less expensive biosimilars.

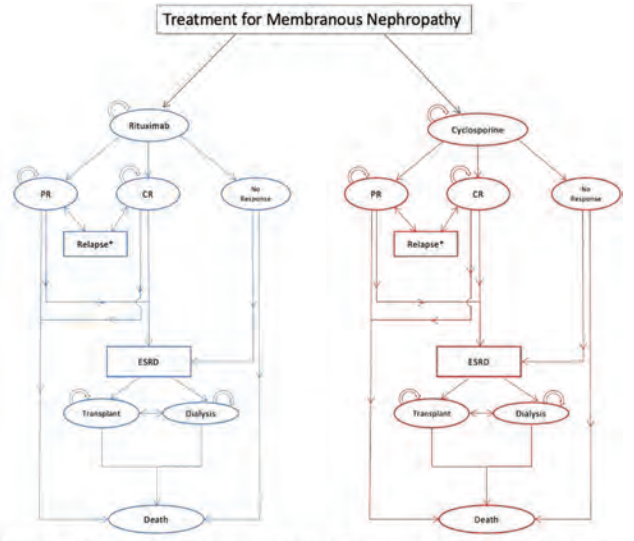

Figure 1: Diagram of health states and possible transitions in the Markov model.

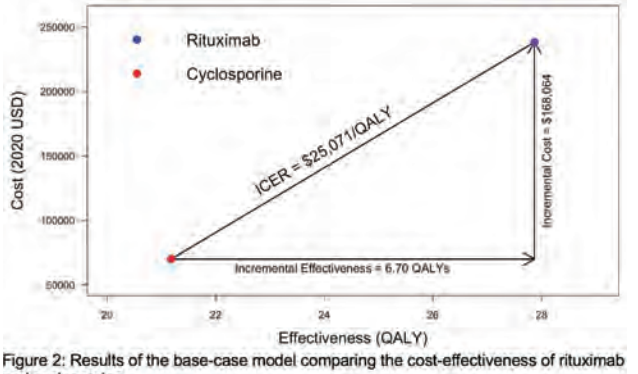

Figure 2: Results of the base-case model comparing the cost-effectiveness of rituximab and cyclosporine.

PO1653

A Multicenter, Prospective, Open-Labeled Study of Acthar Gel Alone or with Tacrolimus to Reduce Urinary Proteinuria in Patients with Idiopathic DNA-JB9-Positive Fibrillary Glomerulopathy

James A. Tumlin,[1] Richard A. Lafayette,[3] Andrew S. Bomback,[2] Amber S. Podoll.[4] FACT Trial Group *[1]Emory University, Atlanta, GA; [2]Columbia University, New York, NY; [3]Stanford University, Stanford, CA; [4]University of Colorado - Anschutz Medical Campus, Aurora, CO.*

Background: Fibrillary Glomerulopathy (FGN) is a rare primary glomerular disease characterized by glomerular accumulation of nonbranching, randomly arranged 10-30 nm in diameter fibrils. The resulting podocyte dysfunction and progressive proteinuria leads to ESRD rates of 50% within 4 years. Herein we present data on 15 patients treated with ACTH or ACTH + Tacrolimus completing 12 months of therapy.

Methods: **Study Design:** Randomized prospective open labeled study of 12 months of SQ ACTH alone or with Tacrolimus in 15 patients with biopsy proven, DNA-B9 + Fibrillary glomerulopathy. **Study Drug Dosing:** ACTH 80 units SQ 2X/ week, Tacrolimus-1.0 mg PO BID. **Primary Endpoint:** Change in UP/Cr ratio (mg/gm) in patients after 12 months of ACTHar gel alone or in combination with Tracrolimus **Definitions:** Responders-Complete-Partial-Clinical response defined at **≤ 300 mg/gm** or ≥ **50% reduction** or ≥ **30% reduction** in UP/Cr from baseline at 12 months.

Results: Of the 15 patients completing 12 months of treatment, **14.3%** acheived complete remission (UP/Cr ratio < 300 mg/gm); **26.0%** acheived a ≥ 75% reduction from baseline, while **60.7%** acheived a ≥ 50% reduction in UP/Cr at 12 months. A total

of **86.6%** acheived a minimum 30% reduction in UP/Cr. The addition of Tacrolimus to ACTH tended to further lower UP/Cr at 12 months (1654.7±317 vs.4449.5±1665) respectively, but did not reach statistical significance

Conclusions: In summary, depo-repository ACTH induced a complete or partial remission in 75% of patients with DNA-JB9 + Fibrillary GN. The addition of Tacrolimus in this population tended to improve complete-partial response rates.

BCX9930, an Oral Factor D Inhibitor in Development for Treatment of Complement-Mediated Diseases, Inhibits Complement Alternative Pathway (AP) Activity in Healthy Subjects

Xilin Chen,[1] Fugang Zhu,[1] Cynthia D. Parker,[1] Melanie Cornpropst,[2] William P. Sheridan,[2] Matthew Davidson,[2] Yarlagadda S. Babu.[1] *[1]BioCryst Pharmaceuticals Inc, Birmingham, AL; [2]Biocryst Pharmaceuticals Inc, Durham, NC.*

Background: Factor D, the rate-limiting enzyme of the AP, is required for the formation of C3 convertase as well as amplification of complement activities initiated by the lectin pathway (LP) and classical pathway (CP). AP amplification is responsible for up to 80% of the LP and CP complement responses (Harboe et al, Clin Exp Immunol 2004). BCX9930 is an orally administered, potent and selective inhibitor of factor D, and has potential for the treatment of complement mediated glomerular diseases including, C3 glomerulopathy, IgA nephropathy, primary membranous nephropathy, and lupus nephritis. This study assessed the effects of oral dosing of BCX9930 on the AP activities in *ex vivo* activated serum in healthy subjects.

Methods: Serum samples from the BCX9930-101 study (NCT04330534) of multiple ascending doses ranging from 50 to 500mg every 12hrs (Q12h) were used to evaluate complement activities with AP-specific Wieslab C5b-9 (AP Wieslab) assay. Levels of complement split products Bb, C3a, C5a and soluble C5b-9 (sC5b-9) in the supernatants from the AP Wieslab assay were further analyzed by multiplex assays.

Results: Oral dosing of BCX9930 resulted in rapid (within ≤1hr) and maximal suppression (median >98% relative to pre-dose levels) of AP Wieslab at all dose levels. The duration of suppression was dose-dependent. At steady state for doses ≥200mg Q12h, maximal suppression persisted for at least 2 dosing intervals (24hrs) following the last dose. Doses of 200, 400 and 500mg Q12h reduced Bb, C5a and C5b-9 levels by >95% through 12hrs post-dose at steady state in the supernatants from AP Wieslab assays. At the highest dose level analyzed, 500mg Q12h, mean inhibition of Bb, C5a, and C5b-9 increased to >98%, and mean inhibition of C3a was 95%.

Conclusions: Oral BCX9930 potently suppressed AP activity in healthy subjects. Suppression ≥95% was achieved through at least 12hrs post-dose across all described assays for the selected clinical dose of 500mg twice daily. As the AP amplification loop also enhances the signal of the CP and LP, BCX9930 has potential to treat diseases mediated by any of the 3 complement pathways. These results support further development of oral BCX9930 for the treatment of complement mediated glomerular diseases.

PO1655

Early Eculizumab Withdrawal in Atypical Hemolytic Uremic Syndrome Is Safe and Cost-Effective

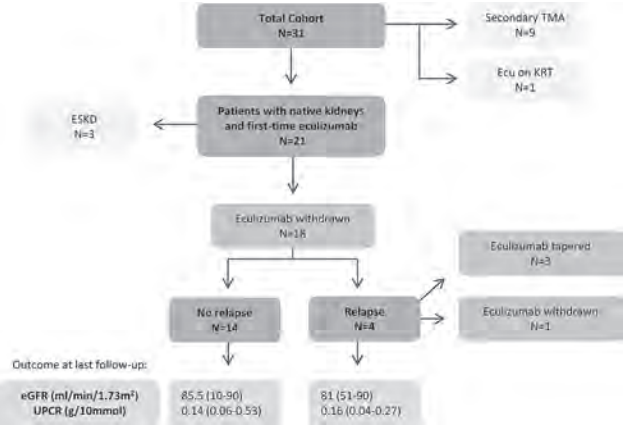
Romy N. Bouwmeester, Caroline Duineveld, Kioa L. Wijnsma, L.P.W.J. Van Den Heuvel, Jack F. Wetzels, Nicole Van De Kar. on behalf of the CUREiHUS study group *Radboudumc, Nijmegen, Netherlands.*

Background: The introduction of eculizumab has improved outcome in patients with atypical hemolytic uremic syndrome (aHUS). The optimal treatment strategy is debated. It is unknown if unbiased withdrawal of eculizumab is a safe strategy. Here we report the results of the CUREiHUS study, a national observational study monitoring eculizumab discontinuation in Dutch aHUS patients after three months of therapy.

Methods: All pediatric and adult aHUS patients with native kidneys and first-time eculizumab treatment (n=21) were evaluated. At last, an extensive cost-effective analysis was conducted.

Results: In the period from January 2016 till October 2020 we included 21 patients. All patients showed full recovery of hematological thrombotic microangiopathy (TMA) parameters after start of eculizumab. A renal response was noted in 18 patients. After a treatment duration of 13.6 weeks (range 2.1-43.9), eculizumab was withdrawn in all patients (Figure 1). During follow-up (80.7 weeks (0.0-236.9)), a relapse occurred in four patients (19.0%). Median time to first relapse was 14.3 weeks (7.1-62.0). Eculizumab was re-initiated within 24 hours in all relapsing patients. At last follow-up, there were no chronic sequelae, i.e. no clinically relevant increase in serum creatinine, proteinuria and/or hypertension, in the relapsing patients. No clinically relevant predictors of relapse (including the presence of a pathogenic mutation) could be determined. The total medical expenses, including costs of among others hospital admission and disease recurrence, of our population were only 33% of the fictive expenses made when patients would have received eculizumab every fortnight.

Conclusions: It is safe and (cost-)effective to discontinue eculizumab after three months of therapy in patients with aHUS in native kidneys. Larger data registries are needed to determine factors to predict relapse(s) and short- and long-term outcomes.



Outcomes of CUREiHUS patients

PO1656

Outcome of Kidney Transplantation in Atypical Hemolytic Uremic Syndrome Without Eculizumab Prophylaxis: A Single-Center Experience

Caroline Duineveld, Romy N. Bouwmeester, Kioa L. Wijnsma, Nicole Van De Kar, Jack F. Wetzels. *Radboudumc, Nijmegen, Netherlands.*

Background: A high risk of aHUS recurrence (60-80%) is reported after kidney transplantation. Therefore, it is suggested to perform kidney transplantation in aHUS patients with eculizumab prophylaxis. In 2017 we reported a favorable outcome after kidney transplantation in aHUS patients without eculizumab prophylaxis, using kidneys from living donors and a transplantation protocol aimed at reduction of endothelial injury. (1) Here, we present the results of our treatment protocol with prolonged follow-up.

Methods: All patients with a previous history of aHUS who received a living or deceased donor kidney transplantation in the Radboud University medical center between 2011 and 2020 were evaluated.

Results: We included 26 aHUS patients (M 9; F 17, median age at transplantation 47y, range 22-69). In 22 patients (85%) 24 genetic variants were found: C3 (N=14), CFH (N=8), CFB (N=2). Recurrence risk was considered high in 18 patients and moderate in 8 patients. Nineteen patients received a graft from a living donor (LD) and 7 patients a graft from a brain-death deceased donor (DBD). All patients were treated with low-dose tacrolimus. Six patients (23%) developed aHUS recurrence (4/19 LD, 2/7 DBD) and were treated with eculizumab. Of note, recurrence occurred >12 months after transplantation in two patients. No patient lost the graft due to aHUS recurrence. One patient lost the graft due to rejection and BK nephropathy, one patient died with a functioning graft due to infections. After a median follow-up of 63.6 months (range 12-116) median eGFR was 53.5 ml/min/1.73m2, and proteinuria was negligible (median urine protein-creatinine ratio 0.12 g/10mmol, range 0.04-0.4).

Conclusions: Kidney transplantation without eculizumab prophylaxis is feasible and safe with a relatively low recurrence rate. Atypical HUS recurrence may present late after kidney transplantation and may not be prevented by short course eculizumab prophylaxis.

Podocytes Soften in Proteinuric CKD: A Potential New Mechanism for Proteinuria?

Luisa Ulloa severino,[1] Xiaolin He,[1] Franziska Lausecker,[2] Rachel Lennon,[2] Mira Krendel,[3] Darren A. Yuen.[1] Yuen Lab *[1]St Michael's Hospital, Toronto, ON, Canada; [2]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [3]State University of New York Upstate Medical University, Syracuse, NY.*

Background: Proteinuria is one of the most common manifestations of glomerular injury, and an important predictor of disease progression. Podocytes are a critical component of the glomerular filtration barrier, and as such podocyte injury is a major cause of proteinuria. Historically, investigators have focused on biochemical changes in podocytes that occur following podocyte injury. In contrast, little is known about the changes in the biophysical properties of these highly specialized epithelial cells.

Methods: 3 different models of proteinuric glomerular disease were studied: (1) Akita$^{+/-}$ Ren$^{+/-}$ mice (a murine model of diabetes and renin-mediated hypertension that we have recently shown develops progressive glomerulosclerosis that mimics human diabetic kidney disease, n = 7), (2) Myo1e$^{-/-}$ mice (a mouse model of genetic FSGS characterized by deficiency of a non-muscle myosin involved in actomyosin contraction, n = 6), and (3) Col4a5$^{-/-}$ mice, a mouse model of Alport's syndrome (n = 12). The stiffness of glomeruli, glomerular basement membrane (GBM), and podocytes was measured using atomic force microscopy (AFM) and associated histology (picrosirius red, silver, and WT1 staining). Similar stiffness measurements were performed in human FSGS and healthy kidney donor biopsies.

Results: AFM measurements revealed that glomerular stiffness increased in Akita$^{+/-}$ Ren$^{+/-}$ and Col4a5$^{-/-}$ mice, a finding that correlated with the degree of glomerulosclerosis. Glomerular stiffness was not increased in Myo1e$^{-/-}$ mice. GBM stiffness was increased in Akita$^{+/-}$ Ren$^{+/-}$ and Myo1e$^{-/-}$ mice, but not in Col4a5$^{-/-}$ Alport's mice. In all 3 mouse models, as well as in human FSGS biopsies, podocytes were softer than in healthy control kidneys.

Conclusions: Taken together, these are the first data demonstrating that podocytes soften in proteinuric glomerular disease. Given the major rearrangements in the actomyosin network that occur in podocytes of proteinuric kidneys, our data suggest that podocyte softening may be a common manifestation of podocyte injury. Further work is ongoing to understand whether this softening is solely a consequence of podocyte injury, or if it also contributes to ongoing podocyte damage.

PO1658

Novel Small Molecule Compounds Protect Podocytes from Injury In Vitro and In Vivo

Richard Helmuth,[1] Manuel Noben,[1] Ha Won Lee,[1] Jean-Michel Saffin,[2] Jochen Reiser,[1] Susanne Heynen-Genel,[2] Vineet Gupta.[1] Gupta lab *[1]Rush University Medical Center, Chicago, IL; [2]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.*

Background: Podocyte dysfunction and loss is a key determinant of proteinuria and glomerular injury. Thus, maintaining healthy podocytes is a therapeutic strategy against kidney disease. We previously developed a high-content imaging-based assay and used it to identify a number of small molecule compounds that show protection of podocytes from injury, suggesting it to be a viable strategy for the discovery and development of novel podocyte-protective agents.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates as previously described (Lee et al. JASN, 2015). Cells were exposed to puromycin aminonucleoside (PAN, podocyte injury inducing agent), with compounds from the screening libraries, or DMSO as control, for 48 hours. Cells were fixed and stained which allowed detection using the Opera High-Content Screening (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. Drosophila based screening assays were used to determine efficacy of selected hits in vivo.

Results: PAN damage resulted in quantitative reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes in the ultra-miniaturized assay system. Screening of a library of chemical compounds identified >28 hits that dose-dependently reduced podocyte damage. A set of 9 compounds showed significant protection in a drosophila model of kidney injury, supporting the findings from the high-throughput screening assay.

Conclusions: Our 1536-well plate-based assay system identified a number of small molecule compounds that dose dependently protected podocytes from damage in vitro. A drosophila model of kidney injury validated most of the in vitro data from the podocyte screening assay. Current in vitro and in vivo mechanistic studies are underway to elucidate new insights into podocyte pathways that are therapeutically targeted by the selected hits. These agents hold promise as novel therapeutics for kidney disease patients with podocyte pathologies.

Characterization of the Direct Effect of Mycophenolic Acid on Murine Podocytes

Seif El Din Abo Zed,[1,2] Agnes Hackl,[1,2] Katrin Bohl,[2,3] Gregor Fink,[1] Eva Nüsken,[1] Kai D. Nüsken,[1] Bernhard Schermer,[2,3] Lutz T. Weber.[1] Nephrologisches Forschungslabor *[1]Children's and Adolescents' Hospital, Faculty of Medicine and University Hospital of Cologne, Cologne, Germany; [2]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; [3]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: Mycophenolic Acid (MPA) is the active component of Mycophenolate Mofetil, a selective, noncompetitive inhibitor of the inosine monophosphate dehydrogenase. Blockade of the de novo purine synthesis depletes the pool of deoxyguanosine triphosphate, leading to a specific suppression of proliferation of B- and T-Lymphocytes. MMF has an established role as a therapeutic agent in childhood nephrotic syndrome, where it currently serves as a second line option for frequent relapsing and steroid dependent cases. Although its immunological functions are well studied, direct effects of MPA on podocytes remain largely unknown. With first preliminary results showing a protective effect in vivo, the present study aims to examine the direct effect of MPA on murine podocytes and its abilities to alter albumin-induced podocyte injury.

Methods: Cultured murine podocytes were exposed to albumin for 48 hours, with one group receiving treatment with MPA for the second 24 hours. Cells were stained with a Synaptopodin antibody and additional markers to visualize components of the cytoskeleton. Currently, we are analyzing apoptosis through a TUNEL assay as well as alterations in intracellular Calcium content with Fluo-4 and fura red. In addition, we study podocyte mobility under injury and with MPA intervention by migration assays. We will also study small GTPases content and activity through a pull-down assay for RhoA and Rac1. In an unbiased approach, podocytes were exposed to either 2 hours of 10 mg/l MPA or an additional 22 hours of 4 mg/l MPA. Total RNA was isolated and subjected to RNASeq anaylses.

Results: Synaptopodin immunofluorescence shows significant alterations of the actin cytoskeleton through albumin exposure. MPA treated cells reveal a restorative ability of the drug, with a recovery of stress fiber formation and a reduction of albumin-induced vacuoles. mRNA expression analyses are in progress.

Conclusions: First results show a promising effect of MPA on stress fiber formation. The additional functional assays will be finished by late summer this year and will give an important insight to MPAs ability to influence pathways, known to be affected during the development of proteinuric diseases. The RNAseq results will provide an objective and detailed picture of the direct effects of MPA on podocytes.

PO1660

Integration of Plasma Proteomics and Metabolomics Revealed Multiple Protein-Metabolite Networks in Steroid-Resistant Nephrotic Pediatric Patients

Sagar Bhayana,[1] Yue Zhao,[4] Michael Merchant,[2] Timothy Cummins,[2] Wimal Pathmasiri,[3] Susan Mcritchie,[3] Susan J. Sumner,[3] Jon B. Klein,[2] William E. Smoyer.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]University of Louisville, Louisville, KY; [3]University of North Carolina System, Chapel Hill, NC; [4]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Nephrotic Syndrome (NS) is a common glomerular disease in children. Glucocorticoids (GC) are the mainstay of NS treatment, but steroid-resistant NS (SRNS) develops in 5-20% of children, dramatically increasing risk for progressive CKD vs. children with steroid sensitive NS (SSNS). There are no validated biomarkers able to predict which children will have SRNS. Here, we used previously published plasma proteomic and metabolomic profiles from children with SSNS and SRNS to test the hypothesis that integrating proteomic + metabolomic data could identify biomarkers and/or targets to define SRNS pathways that were not identified in the individual datasets.

Methods: Proteomic data from 15 paired NS plasma samples (n=7 SSNS; n=8 SRNS) and relative concentrations of metabolites estimated from plasma NMR metabolomics data from the same subjects underwent joint pathway analyses using MetaboAnalyst 5.0. software. Fold change (FC) was calculated as the ratio of pre-treatment to post-treatment for each protein and metabolite, and then log2 transformed. Proteins with $Log_2FC<-10$ or $Log_2FC>10$ and metabolites with $Log_2FC<-1$ or $Log_2FC>1$ were included in the analyses.

Results: Pathway analyses of proteomic data identified "ECM receptor interaction" and "focal adhesion" as the most significantly up- and down-regulated pathways in SRNS vs. SSNS, whereas "Valine, Leucine & Isoleucine biosynthesis", and "Glycosaminoglycan biosynthesis" were the most up- and down-regulated metabolic pathways in SRNS, respectively. Integrated proteomic + metabolomic pathway analyses identified 3 metabolic pathways that were perturbed in SRNS but not in SSNS: 1) "Nicotinate & Nicotinamide" pathway was perturbed in 50% of SRNS subjects (4 SRNS vs. 0 SSNS), 2) "Butanoate" was perturbed in 37.5% of SRNS subjects (3 vs. 0), and 3) "Glycine, Serine & Threonine" metabolism was perturbed in 25% of SRNS subjects (2 vs. 0).

Conclusions: Integrating proteomic + metabolomic data from children with SRNS vs. SSNS have identified multiple pathways and protein-metabolite linkages with potential to become future candidate biomarkers or drug targets of SRNS

PO1661

Spatially Resolved Analysis of Glomerular Structures in Alport Syndrome and FSGS

Laura Perin,[1] Hasmik Soloyan,[1] Paolo Cravedi,[2] Fadi E. Salem,[2] Andrea Angeletti,[3] Sargis Sedrakyan.[1] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Mount Sinai Health System, New York, NY; [3]Universita di Bologna, Bologna, Italy*.

Background: Many transcriptomics studies highlighted the molecular mechanism underlying glomerular diseases, but very little is known about interglomerular heterogeneity and how each glomerular is affected during progressive CKD. Using Spatial transcriptomics, which allows the characterization of the gene expression based on morphological context, we showed important differences between glomeruli of Alport Syndrome (AS) and FSGS patients and defined the interactive gene networks involved in glomerulus damage using healthy glomeruli as reference.

Methods: Using the Nanostring GeoMX Digital Spatial Profiling (DSP, Whole Transcriptomic Atlas) we generated spatial maps of gene expression of human AS (COL4A5 and COL4A$) and FSGS glomeruli (both males and females) and compared them to age-matched healthy controls. A total of 90 regions of interest were selected. After data QC and Q3 normalization, data were analyzed using different platforms and integrated with histopathology assessment.

Results: Data distinguished genes associated with podocyte, glomerular endothelial and mesangial cell phenotype. Unsupervised clustering and dimensionality reduction analysis showed clear differences between not only diseased and normal glomeruli (which presented homogeneous gene expression profile), but also between glomeruli of AS vs FSGS. Though glomeruli of AS and FSGS were histologically similar within each sample, they presented different transcriptomics profiles (for instance, while oxidative phosphorylation, focal adhesions were common to all gloms in AS, Apelin, PI3K-Akt, and Hippo signaling were unique to only a few glomeruli). Marked differences between males and females were observed in both AS and FSGS glomeruli (sheer stress and leukocyte transendothelial migration was more typical in AS male than female, while insulin signaling was only present in AS female. Similar heterogeneity patterns were observed in FSGS). In contrast to FSGS, AS were more enriched for genes associated with TCA cycle, protein processing in the ER, and neurotrophin signaling.

Conclusions: DSP revealed significant interglomerular heterogeneity in AS and FSGS regardless of age and gender leading to the discovery of pathways defining disease phenotypes at single glomerulus level. These preliminary data using DSP may allow the discovery of potential new therapeutic targets for CKD patients.

PO1662

EGR1 Is an Injury Marker in Podocytes

Masahiro Okabe,[1] Nobuo Tsuboi,[1] Taiji Matsusaka,[2] Takashi Yokoo.[1] *[1]Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan*.

Background: There is no good marker that depicts injured podocytes in human histology samples as well as desmin staining in rodent samples. EGR1 (Early Growth Response 1) is a transcriptional factor that regulates cell survival, proliferation, and cell death in response to growth factors, DNA damage, and ischemia. We have reported that injured podocytes express EGR1 protein in the early stages of damage in animal experiments and that EGR1 is expressed on podocytes in human glomeruli. This study aims to explore an association between EGR1 staining in podocytes and podocyte injury in human glomerular diseases.

Methods: Patients who underwent kidney biopsy at Jikei University Hospital, Tokyo, from June 2018 to March 2020 were recruited. Exclusion criteria included age < 20 years, glomeruli < 8, tubulointerstitial diseases, and kidney transplant patients. Blood and urine were collected during the kidney biopsy, and estimated glomerular filtration rate (eGFR), urinary protein to creatinine ratio (UPCR), urinary nephrin mRNA, and urinary podocin mRNA were measured. From the kidney biopsy specimen, the percentage of glomeruli with podocytes expressing EGR1 (%EGR1), the percentage of sclerotic glomeruli (%GS), and the glomerular podocin expression scores were measured. The %EGR1 was compared with these parameters using Spearman's rank correlation coefficient.

Results: Ninety-eight patients were included in this study (male, 58%; median age, 49 [interquartile range, 36–60] years; eGFR, 65 [44–79] mL/min/1.73m^2, UPCR, 0.90 [0.43–2.46] g/g; %EGR1, 26.1 [14.6–41.4]%; IgA nephropathy, n=35; hypertensive nephrosclerosis, n=10; membranous nephropathy, n=6; lupus nephropathy, n=5; minimal change disease (MCD), n=5; and focal segmental nephrosclerosis (FSGS), n=3). The %EGR1 was correlated with UPCR, urinary nephrin mRNA, urinary podocin mRNA, and glomerular podocin expression scores (rho=0.303, 0.378, 0.369, and -0.286; and P=0.0024, <0.001, <0.001, and 0.0043, respectively) but not with eGFR and %GS. In the subgroup with IgA nephropathy, %EGR1 was also correlated with UPCR and urinary podocin mRNA (rho=0.413 and 0.378; and P=0.014 and 0.025, respectively). Interestingly, the %EGR1 was low in MCD (8.33 [0.0–15.4]%), and high in FSGS (40.0 [36.8–46.3]%).

Conclusions: EGR1 expression in podocytes is associated with podocyte injury. EGR1 could be a podocyte injury marker in human glomeruli.

The CLVS1 H310Y Variant Associated with Steroid-Responsive Nephrotic Syndrome Affects Podocyte Function and Glomerular Filtration Barrier Integrity

Brandon M. Lane,[1,2] Megan Chryst-Stangl,[2,3] Mohamed A. Shalaby,[5] Sherif M. El desoky,[5] Guanghong Wu,[2,3] Ricardo Vancini,[3] David N. Howell,[4] Gentzon Hall,[6,2] Jameela A. Kari,[5] Rasheed A. Gbadegesin.[1,2] *[1]Duke University Department of Pediatrics, Durham, NC; [2]Duke Molecular Physiology Institute, Duke University, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]Duke University Department of Pathology, Durham, NC; [5]King Abdulaziz University Hospital, Jeddah, Saudi Arabia; [6]Duke University Hospital, Durham, NC*.

Background: We identified a rare homozygous variant, *p.H310Y*, in the gene encoding clavesin1 *(CLVS1*) as a novel cause of steroid sensitive nephrotic syndrome (SSNS). Knockdown of the orthologous *CLVS1* gene in zebrafish resulted in edema phenotypes that could be rescued with WT *CLVS1* mRNA but not the *H310Y* variant. *CLVS1* knockout in cultured human podocytes decreased endocytosis, increased reactive oxygen species (ROS) accumulation, and increased apoptosis. These aberrant phenotypes were rescued in the presence of glucocorticoids, mimicking the steroid responsive phenotype of *CLVS1 H310Y* patients. Treatment with ROS inhibitors also rescued the reduced viability phenotype in *CLVS1* KO podocytes.

Methods: To better understand the effects of the *CLVS1 H310Y* variant on podocyte homeostasis, we created human podocyte cell lines with CRISPR-Cas9 mediated heterozygous and homozygous *CLVS1 H310Y* knock-in (KI) mutations. We evaluated the KO and KI podocytes through automated live-cell imaging. Additionally, we further evaluated the effects of reduced *CLVS1* function on podocyte function *in vivo* in zebrafish.

Results: Clavesin1 is specifically required for clathrin mediated endocytosis in cultured human podocytes. Additionally, homozygous *H310Y* KI podocytes displayed similar corticosteroid responsive phenotypes to *CLVS1* KO lines, including increased apoptosis that could be rescued with ROS inhibition, while heterozygous KI lines were unaffected. Furthermore, we confirmed that the *H310Y* variant reduces binding to a critical antioxidant transporter, alpha tocopherol transfer protein (p=0.006), likely contributing to the ROS phenotypes. Electron microscopy analysis and quantification of excreted proteins revealed podocyte effacement and decreased glomerular filtration barrier integrity in zebrafish with knockdown of orthologous *CLVS1* when compared to controls (p<0.0001).

Conclusions: Our data further demonstrates the importance of clavesin1 in the maintenance of podocyte viability and GFB integrity. It also suggests that oxidative stress regulation may be compromised in patients carrying pathogenic *CLVS1* variants and highlights the potential for alternative therapies for NS patients that target ROS accumulation in podocytes.

Rare Variants in RCAN1-3 Genes Are Enriched in Patients with CKD

Brandon M. Lane,[1,2] Katherine A. Benson,[4] Susan L. Murray,[6] Megan Chryst-Stangl,[2,6] Guanghong Wu,[2,6] Liming Wang,[5] Elhussein A. Elhassan,[3] David N. Howell,[7] Peter J. Conlon,[3] Robert F. Spurney,[5] Rasheed A. Gbadegesin.[1,2] *[1]Duke University Department of Pediatrics, Durham, NC; [2]Duke Molecular Physiology Institute, Duke University, Durham, NC; [3]Beaumont Hospital, Dublin, Ireland; [4]Royal College of Surgeons in Ireland, Dublin, Ireland; [5]Duke University Hospital, Durham, NC; [6]Duke University School of Medicine, Durham, NC; [7]Duke University Department of Pathology, Durham, NC*.

Background: We recently identified rare variants in the gene encoding Regulator of Calcineurin Type 1 (*RCAN1*) as a novel cause of FSGS/SRNS. Cells expressing mutant *RCAN1* and human podocytes with reduced *RCAN1* displayed increased CN activity that resulted in increased susceptibility to apoptosis compared to WT *RCAN1*. There are two additional proteins in the RCAN family, RCAN2 and RCAN3, both of which are capable of regulating CN activity. To further elucidate the role of pathogenic variants in RCAN genes in the etiology and pathogenesis of chronic kidney disease, we screened patients with CKD for rare variants in *RCAN1-3* genes. In addition, we performed kinase screening to identify compounds that can rescue the phenotype induced by defective RCAN1.

Methods: In collaboration with the Genome England Consortium, we examined associations between potentially pathogenic variants in *RCAN1-3* genes and kidney disease in the large multi-ethnic National Health Service database. We compared the percentage of patients with rare (MAF <0.01), functional *RCAN1-3* variants in patients with CKD (renal and urinary tract disorders) and patients with neurological disorders. We also used target kinase inhibition to examine additional potential RCAN1 regulatory kinases.

Results: Of the 4,153 patients in the UK National Health Service data set with CKD, 39 (0.94%) had rare functional *RCAN 1-3* variants compared to 87 (0.57%) of the 15,141 patients with neurological disorders, revealing a significant enrichment of rare pathogenic variants in *RCAN1-3* genes in patients with kidney disease compared to those without (p=0.0006). Pharmacological inhibition of additional RCAN regulatory kinases including DYRK1A (Harmine) or BMK1 (Ax15836 and XMD8-85) could rescue the elevated CN activity (p =0.4946. 0.3980 and 0.0912 respectively) and reduced viability (p>0.05) in disease causing mutant *RCAN1* expressing cells compared to WT controls.

Conclusions: This data suggests that not only are *RCAN1-3* likely single gene causes of NS/FSGS, but functional variants in the genes may also act as susceptibility or modifier genes that contribute to development of CKD. Our findings also highlight the therapeutic potential of targeting RCAN1 regulatory molecules in the treatment of FSGS.

Spatial Transcriptomic Profiling of Collapsing Glomerulopathy

Shreeram Akilesh,[1] Kammi J. Henriksen,[2] Roberto F. Nicosia,[1] Charles E. Alpers,[1] Kelly D. Smith.[1] *[1]University of Washington, Seattle, WA; [2]University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Collapsing glomerulopathy is a histologically distinct variant of focal and segmental glomerulosclerosis that presents with heavy proteinuria and portends a poor prognosis. Collapsing glomerulopathy can be triggered by viral infections such as HIV and SARS-CoV-2. However, it is not known if distinct molecular mechanisms drive histologically indistinguishable lesions of collapsing glomerulopathy in different clinical contexts.

Methods: Transcriptional profiling of collapsing glomerulopathy lesions is difficult since only a few glomeruli may exhibit this histology within a kidney biopsy. Therefore, we used recently developed spatial transcriptional profiling to quantify 1,852 transcripts in individual glomeruli from HIV and SARS-CoV-2 infected patients with biopsy confirmed collapsing glomerulopathy.

Results: We compared transcriptional signatures on the basis of disease or histology and identified distinct pathways of injury in HIV and SARS-CoV-2 associated collapsing glomerulopathy and thrombotic microangiopathy (Figure). Focused validation using immunohistochemistry and RNA in situ hybridization showed good concordance with spatial transcriptional profiling results.

Conclusions: Spatial transcriptional profiling represents a powerful new method to dissect transcriptional programs of pathologically discernible kidney lesions.

Protein Kinase R Inhibition Ameliorates Mitochondrial Dysfunction in the Tg26 HIV-Associated Nephropathy Mouse Model

Teruhiko Yoshida,[1] Khun Zaw Latt,[1] Avi Z. Rosenberg,[2] Shashi Shrivastav,[1] Jurgen Heymann,[1] Moshe Levi,[3] Cheryl A. Winkler,[4] Jeffrey B. Kopp.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Georgetown University, Washington, DC; [4]Frederick National Laboratory for Cancer Research, Frederick, MD.*

Background: Double-stranded RNA (dsRNA)-activated protein kinase (PKR) is a sensor for dsRNA in response to viral infections, including HIV-1. We previously reported that *APOL1* risk alleles damage podocytes through double-stranded RNA-activated protein kinase (PKR) activation (Okamato, Comm Biol, 2018). Here, we hypothesized that PKR activation could be a mechanistic pathway shared by HIV- and APOL1-mediated nephropathies. Hence, we investigated the effects of PKR inhibition on HIVAN in the well-characterized Tg26 mouse model, which expresses HIV regulatory and accessory genes.

Methods: We evaluated the kidney phenotype of Tg26 mice and wild-type mice treated with the PKR inhibitor (C16) from 6 to 12 weeks of age. We profiled kidney gene expression by RNA-seq and mitochondrial function by the extracellular flux assay using *ex vivo* glomerular tissues.

Results: Kidney disease manifestations, including albuminuria (mean [IQR]) (668 mg/g Cr [60, 1064] vs 2564 [1785, 5646], p=0.03) and global glomerulosclerosis (0.0% [0.0-0.0] vs 8.1 [2.3, 15.8], p=0.008), were reduced in the C16 treated group compared to the vehicle control group. C16 treatment increased mitochondrial gene expression (Fig.A), ameliorated mitochondrial dysfunction, and restored spare respiratory capacity as measured by extracellular flux assay (Fig.B).

Conclusions: PKR inhibition ameliorated mitochondrial dysfunction associated with the HIVAN phenotype observed in Tg26 mice, suggesting that PKR activation contributes to the development of mitochondrial dysfunction in HIVAN.

Recurrent Nephrotic Plasma Activates Pro-Fibrotic Signalling Pathways Downstream of Protease-Activated Receptor 1

Musleeha Chesor,[1,2] Jack P. Tuffin,[1] Carl J. May,[1] Irene Ghobrial,[3] Melissa H. Little,[3,4] Moin Saleem,[1] Gavin I. Welsh.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]Princess of Naradhiwas University, Narathiwat, Thailand; [3]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [4]University of Melbourne, Melbourne, VIC, Australia.*

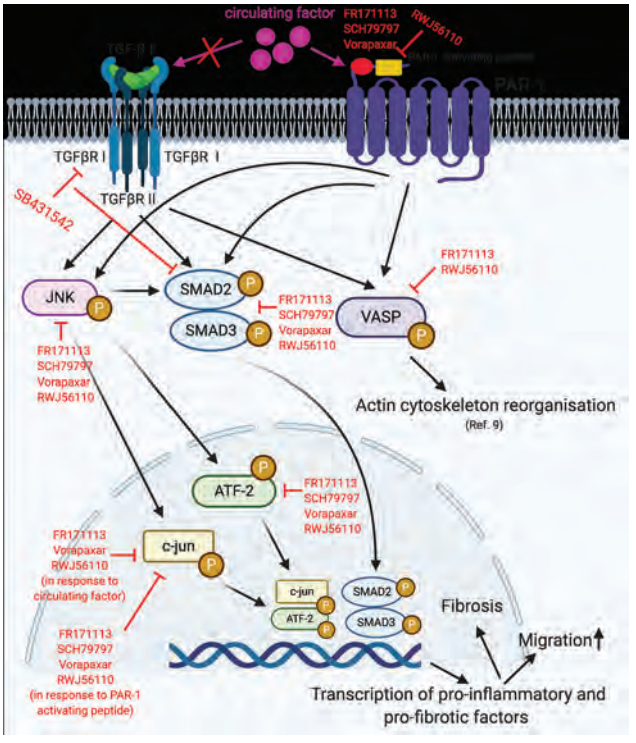
Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to an unknown "circulating factor", the identity of which has so far remained elusive. Our previous work suggests a signaling role for protease-activated receptor-1 (PAR-1), leading to impaired podocyte function. The signaling pathways downstream of PAR-1 in podocytes are unknown and could reveal novel mechanistic insights into the disease.

Methods: Conditionally immortalized human podocytes (ciPods), glomerular-like structure spheroids, and human kidney organoids were treated with PAR-1 agonist peptide or nephrotic plasma (NP), in the absence or presence of four different PAR-1 antagonists.

Results: PAR-1 agonist and patient relapse NP, but not paired remission plasma, induced the phosphorylation of VASP, JNK, and proteins involved in pro-fibrotic pathways. These changes were inhibited by PAR-1 inhibitors, but not by TGF-β1 inhibition. Four PAR-1 inhibitors demonstrated specific antagonistic properties. The phosphorylation of VASP and JNK in a 3D spheroid model and from stem-cell derived kidney organoids corroborated the finding from the 2D model. Functionally, relapse NP induced podocyte motility and podocyte loss from spheroids both of which were also selectively rescued by PAR-1 inhibitors. Treatment of kidney organoids with relapse NP induced the same VASP and pro-fibrotic phosphorylation in podocytes and the loss of podocyte-specific markers.

Conclusions: We propose that the circulating factor acts as a pro-fibrotic effector by activating PAR-1. A greater understanding of these signaling pathways will lead to the identification of novel therapeutic targets for this disease.

Funding: Government Support - Non-U.S.



Proposed mechanism of PAR-1 signaling induced by recurrent SRNS plasma

PO1668

Molecular and Functional Characterization of Human Urinary APOL1 G2/G2 High-Risk Genotype Podocyte

Oyindamola C. Adebayo,[1,2] Pepe M. Ekulu,[2,3] Jean-Paul Decuypere,[2] Mohamed A. Elmonem,[2,4] Agathe B. Nkoy,[2,3] Djalila Mekahli,[2] Benedetta Bussolati,[5] L.P.W.J. Van Den Heuvel,[2,6] Fanny O. Arcolino,[2] Elena N. Levtchenko.[2] *Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium [1]Center for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium; [2]Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; [3]Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); [4]Department of Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt; [5]Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy; [6]Department of Pediatric Nephrology, Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Apolipoprotein L1 (*APOL1*) risk variants, G1 and G2, increase the risk of various non-diabetic kidney diseases in the African population. To date, the precise mechanisms by which *APOL1* risk variants induce injury on podocytes and other kidney cells remain unclear. Trying to unravel these mechanisms, most studies used animal or cell models created by gene editing.

Methods: Conditionally immortalized human podocyte cell lines from urine of a donor carrying *APOL1* high risk genotype, G2/G2 was developed. The *APOL1* G2/G2 cell lines were characterized for podocyte markers at both the mRNA and the protein levels, using real-time quantitative PCR, Western blot and immunofluorescence staining. Following induction of *APOL1* expression by 50 µg/mL polyinosinic-polycytidylic acid (poly(I:C)), we assessed the functional features of APOL1-induced podocyte dysfunction such as cell detachment, cell viability, cell death, autophagy, cytoskeleton organization and podocyte permeability. As control, *APOL1* wild type (G0/G0) podocytes previously generated from a Caucasian donor were used.

Results: We successfully generated human *APOL1* G2/G2 urinary podocyte cell lines. Upon exposure to poly(I:C), G2/G2 and G0/G0 podocytes upregulated *APOL1* expression resulting in podocytes detachment, decreased cells viability and increased apoptosis rate in a genotype-independent manner. G2/G2 podocyte cell lines exhibited altered features, including upregulation of CD2AP, alteration of cytoskeleton, reduction of autophagic flux and increased permeability in an *in vitro* model under continuous perfusion.

Conclusions: The human *APOL1* G2/G2 podocyte cell model is a useful tool for unraveling the mechanisms of APOL1-induced podocyte injury and the cellular functions of APOL1.

PO1669

Topology Mapping of Membrane-Inserted ApoL1

John C. Edwards, Jonathan M. Bruno. *Saint Louis University, Saint Louis, MO.*

Background: ApoL1 inserts into membranes at pH 6 where it has anion permease activity. Titration of the cis compartment to pH 7.5 suppresses the anion permease and activates a cation channel. How ApoL1 is arrayed in the membrane-inserted form at various pH values is unclear.

Methods: Cys was substituted for Ser or Thr at positions throughout ApoL1 and resulting mutants expressed in E. coli. Purified mutants were allowed to insert into phospholipid vesicles at pH 6.0, held at pH 6.0 or titrated to pH 7.5, and reacted with extravesicular membrane-impermeant fluorescent Cys modifying reagent, Alexafluor-568-maleimide. Unreacted reagent was quenched. Non-membrane-inserted protein was removed by chaotropic extraction and Sepharose 4B chromatography. Membrane-associated protein was separated on SDS-PAGE along with ApoL1 standards for quantification. Ratio of fluorescence intensity to mass of ApoL1 protein was normalized to that of protein modified after detergent denaturation to determine relative accessibility of each Cys to the modifying reagent.

Results: Cys substitutions were generated at amino acid positions 40, 80, 149, 173, 186, 200, 204, 226, 247, and 365. We found three patterns of reactivity after membrane insertion. Cys at positions 40, 149, and 365 showed reactivity that was roughly comparable to that in detergent solution with little difference between pH 6.0 and 7.5, consistent with exposure to the aqueous solution on the cis face of the membrane under all conditions. In contrast, Cys at positions 186, 226 and 247 showed decreased reactivity after membrane insertion that was similar at both pH 6.0 and pH 7.5; these positions are not fully accessible from the external solution. Finally, Cys at positions 80, 173, 200, and 204 had decreased reactivity at pH 6.0 with increase in reactivity at pH 7.5, suggesting these positions may be initially buried in the membrane upon insertion at low pH, but titration to neutral pH induces a structural transition that exposes them to the external solution.

Conclusions: Mapping accessibilty of individual amino acid positions in ApoL1 support a model in which a substantial structural transition accompanies the pH shift-induced activation of the cation channel.

Deep Learning-Based Segmentation and Quantification of Podocyte Foot Process Morphology

Linus Butt,[1] David Unnersjö-Jess,[1] Martin Höhne,[1] German Sergei,[2] Annika Wernerson,[3] Anna Witasp,[3] Bernhard Schermer,[1] Kasia Bozek,[2] Thomas Benzing.[1,2] *[1]Uniklinik Koln, Koln, Germany; [2]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [3]Karolinska Institutet Enheten for medicinska njursjukdomar, Huddinge, Sweden.*

Background: The advent of super-resolution light microscopy enabled imaging of the nanoscale dimensions of podocyte foot processes and the slit diaphragm and subsequent quantification of morphological alterations upon glomerular injury. However, these morphological analyses require manual work, which is time-consuming and investigator-dependent.

Methods: We used novel sample preparation protocols and applied super-resolution STED microscopy and conventional confocal microscopy to image podocyte foot processes in murine and human kidney tissue. Deep learning-based segmentation was utilized to automatically segment both the slit diaphragm pattern as well as several thousands of individual foot processes per sample.

Results: Our algorithm, the **a**utomatic **m**orphological **a**nalysis of **p**odocytes (AMAP), segmented the FPs and the SD at high accuracy and more effectively as compared to a previously published semi-automatic dataset. The morphological quantifications show a high agreement with our previous analysis, thereby confirming the correlation of albuminuria with certain morphological alterations of podocytes. In addition, we applied AMAP to human patient tissue and found different patterns of effacement in different disease entities.

Conclusions: The combination of three-dimensional optical imaging and deep-learning segmentation can be used to perform extensive morphological analyses of podocyte in health and disease. It confirms our previous semi-automatically performed analyses in a mouse model of FSGS and can be applied to patient material in order to assess morphological alterations in glomerular disease while eliminating investigator-bias. We believe AMAP can in the future complement the diagnostic algorithms in research and clinical pathology.

Podometrics in Different Cortical Zones and Associations with the Number of Non-Sclerotic Glomeruli

Kotaro Haruhara,[1,2] Go Kanzaki,[2] Takaya Sasaki,[2] Saeko Hatanaka,[2] Yusuke Okabayashi,[2] Akira Shimizu,[3] Luise A. Cullen-McEwen,[1] Nobuo Tsuboi,[2] Takashi Yokoo,[2] John F. Bertram.[1] *[1]Monash University, Clayton, VIC, Australia; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [3]Nihon Ika Daigaku, Bunkyo-ku, Japan*.

Background: Reduced nephron and podocyte number are common features in CKD. While it is well known that glomerular volume and glomerular density (glomerular number per cortical area) differ between cortical zones, zonal differences in podometrics and correlations with nephron number have not previously been explored.

Methods: Non-sclerotic glomerular number per kidney was estimated using the physical disector/fractionator combination. Podocyte density, podocyte number, podocyte volume and volumetric density of podocyte to glomerulus in each cortical zone were estimated using model-based stereology on a single histological section immunostained with two podocyte markers and imaged by confocal microscopy.

Results: Fifty autopsy kidneys were studied. The median age was 68 years ranging from 28 to 85 years. Median eGFR was 74 mL/min/1.73m^2. The median number of non-sclerotic glomeruli per kidney was 421,547 (IQR, 289,095–548,233). Non-sclerotic glomerular number was directly correlated with podocyte number per tuft, podocyte density and volumetric density of podocytes in each cortical zone (Fig). Glomeruli in the superficial cortex were smaller than glomeruli in other zones and had the highest podocyte density and smallest podocyte volume. Podocyte number and volumetric density of podocytes were similar across the cortical zones.

Conclusions: These results demonstrate for the first time that a higher number of non-sclerotic glomeruli is directly associated with three beneficial indices of podocyte and glomerular health. Podocyte number and volumetric density of podocytes were the more reliable indicators of non-sclerotic nephron number, independent of cortical zones.

PO1672

Can Podocyte Number and Density Predict the Response to Therapy in Patients with Primary FSGS?

Natasha de Zoysa,[1] Jonathan E. Ling,[2] Kotaro Haruhara,[1,3] Peter G. Kerr,[2] David J. Nikolic-Paterson,[2] John F. Bertram,[1] Luise A. Cullen-McEwen.[1] *[1]Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; [2]Monash Medical Centre Clayton, Clayton, VIC, Australia; [3]Tokyo Jikeikai Ika Daigaku Igakubu Igakuka, Minato-ku, Japan*.

Background: Podocyte loss is a key event in primary focal segmental glomerulosclerosis (FSGS). Common first-line therapy for patients with primary FSGS involves steroid therapy with or without blood pressure control; however 40-70% of patients achieve no remission. Animal studies have shown that treatment efficacy is achieved partly through preservation of podocyte number, as well as podocyte protective effects. Animal studies have also determined that podocyte number and density are predictive of FSGS severity. Therefore, this study **aimed** to determine if podocyte number and density can predict the response to therapy in patients with primary FSGS.

Methods: A retrospective cohort study of renal biopsies was conducted from 2009-2020 in Melbourne, Australia at a tertiary hospital (Monash Medical Centre). Patients diagnosed with primary FSGS were screened (n=84). Patients were excluded for lack of consent for samples to be used for research purposes (n=38), risks of other forms of FSGS (n=13), insufficient clinical data available (n=2), no biopsy tissue available (n=7) or <6 glomerular profiles available in the biopsy (n=5). Included patients were allocated into groups of treatment responders (n=11) or non-responders (n=8) based on urinary/serum data 6 months following initial diagnosis and commencement of treatment. Biopsies were immunofluorescently stained for podocyte-specific markers. Model-based stereology was used to estimate podometrics. Sections were re-stained with PAS to measure the glomerulosclerotic index (GSI).

Results: Podocyte number per glomerulus in responders (347 (215-606); median (IQR)) was 45% higher than in non-responders (190; 143-263) (P=0.03). Podocyte density in responders (76; 58-142 per $10^6\mu m^3$ of glomerular volume) was similar to non-responders (66; 44-88 per $10^6\mu m^3$ of glomerular volume) (P=0.38). GSI was significantly higher in non-responder patients (1.1; 0.6-2.3) than responders (0.6; 0.2-0.9) (P=0.04), and was significantly and negatively correlated with podocyte number (r = -0.64; P=0.003) and podocyte density (r = -0.48; P=0.04).

Conclusions: Podocyte number per glomerulus in diagnostic renal biopsies could be used as a predictor of treatment response for patients with primary FSGS.

PO1673

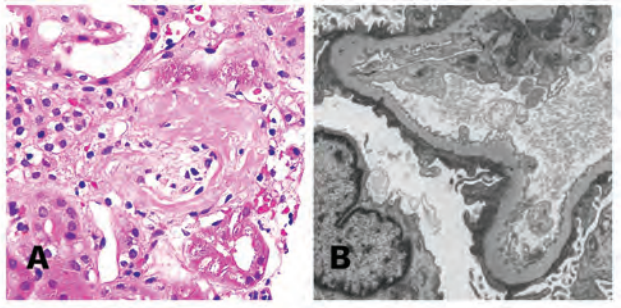
Nephrotic Syndrome in a Patient with Systemic Lupus Erythematous: Is it Lupus Podocytopathy?

Nora H. Hernandez Garcilazo,[1] Mohamed Hassanein,[2] Christopher C. Garces,[1] Si Yuan Khor,[1] Beenu Kaw.[3] *[1]Michigan State University, East Lansing, MI; [2]Cleveland Clinic, Cleveland, OH; [3]Sparrow Health System, Lansing, MI*.

Introduction: Lupus podocytopathy (LP) is a rare form of lupus nephritis (LN) that clinically mimics minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS). We present a case of LP in a patient with systemic lupus erythematosus (SLE).

Case Description: A 73-year-old female with a history of SLE (on Hydroxychloroquine), and nephrolithiasis presented with left flank pain for 2 weeks. Physical exam was notable for peripheral edema and left costovertebral angle tenderness. Labs showed a creatinine 1.02 mg/dL (baseline 0.7), serum albumin 2.6 mg/dL, and urine microalbumin/creatinine (MA/Cr) ratio of 7.5 g/g. Further workup revealed a positive ANA, negative anti-dsDNA antibodies, and normal complements. Kidney biopsy showed FSGS, tip variant, and 100% podocyte foot process effacement (FPE). She was started on high-dose prednisone, simvastatin, ACE inhibitor, and furosemide with potassium supplementation for significant pedal edema. Two months later, her MA/Cr ratio improved to 3 g/g. Prednisone was slowly tapered off over a 7-month period during which symptoms were well-controlled and MA/Cr ratio continued to improve.

Discussion: Nephrotic syndrome in patients with SLE raises suspicion for LP, which represents 1% of LN biopsies. Biopsy findings include diffuse FPE (>70%) on electron microscopy, and absence of immune deposits on light, immunofluorescence, and electron microscopy. LP is divided into MCD or FSGS, with the latter having higher rates of hypertension, acute kidney injury on presentation, and overall worse outcomes. Treatment consists of a short course of high-dose glucocorticoids; however high rates of relapse are observed and tend to coincide with SLE activity.



A. H&E of a glomerulus showing focal segmental glomerulosclerosis, with segmental scars near the tip of the glomerular tuft. There is mild mesangial matrix expansion.

B. Electron microscopy showing diffuse podocyte foot process effacement with no mesangial or glomerular basement membrane immune-type electron-dense deposits identified.

PO1674

Minimal Change Disease as a Sequela of Psoriasis in an Adult

Priya Debnath, Chibuzo C. Okoye, Arham Zia, Samiran Roy Chaudhury, Elena Frolova. *New York City Health and Hospitals Coney Island, Brooklyn, NY.*

Introduction: Minimal change disease (MCD) is usually found in children but can be an uncommon presentation in adults. Relation to psoriasis has not been significantly established even though the latter has been associated with kidney disease such as IgA nephropathy, focal segmental glomerulosclerosis leading to kidney failure. This is an interesting case given that this is a young patient with psoriasis presenting with a flare in the setting of newly diagnosed MCD.

Case Description: A 34-year-old male with history of psoriasis presented with severe body edema after psoriatic flare two weeks prior admission. He was found to have exceptionally low serum albumin of 1.4g/dL, massive proteinuria with spot urine protein creatinine ratio of 7.6 and significant hyperlipidemia. Protein electrophoresis did not show glomerular pathology or spikes in proteins and extensive serological workup was normal. Kidney biopsy reported MCD. Patient improved quickly with steroids of 1mg/kg/day, IV furosemide and albumin infusion. Six months later, the patient was readmitted with new psoriasis flare and again nephrotic syndrome with 7.2g of proteinuria. His symptoms resolved quickly with same treatment used on the first admission. Follow up in clinic one-month post discharge showed normal renal function with proteinuria now at 100mg/day.

Discussion: While there has been evidence of link between psoriasis and kidney disease, finding of MCD is a unique development. The idea can be postulated that since psoriasis is a disease due to dysfunction of T-cells among other causes, a flare can be the initiating event leading to dysregulation of an otherwise stable immune system. This T-cell dysregulation has also been noted in MCD. The underlying cause of MCD is not clear. However, a lot of studies suggest that T-cell dysfunction is one of the implicated agents, known for cell destruction, causing damage to the glomerular membrane leading to the loss of proteins. The rarity of this case belies the complexity of the immunological process leading to the presentation and further research needs to be done to document and establish this as the pathologic process linking the two diseases.

PO1675

Collapsing FSGS from Acquired Nephrin Antibody

Hsiao L. Lai,[1] Abdullah Thayyil,[1] Astrid Weins,[2] Keith H. Keller.[2] *[1]East Carolina University, Greenville, NC; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Deficits in nephrin and other podocyte components are known to result in congenital nephrotic and familial FSGS syndromes. Weins *et. al.* recently described acquired anti-nephrin antibody localizing in glomerular podocytes of patients with minimal change disease.

Case Description: A 16 year old male referred for new onset nephrotic syndrome progressive over 2 weeks was found to have serum albumin 1.2 gm/dL, UPCR 3.1, and elevated lipids with BP 160/100 mm Hg. Hepatitis B/C, HIV, SLE screens were negative. Renal biopsy demonstrated focal collapsing lesions with diffuse podocyte effacement. Immunofluorescence showed punctate IgG, kappa and lambda light chain staining in podocytes, but no albumin. Anti-human IgG colocalized with nephrin in the granular staining. ParvoB19 and COVID-19 titers were negative. Creatinine rose from 0.65 to 1.65 and UPCR to 10.3 but improved rapidly with high dose prednisone and ACEi. Serology for circulating anti-nephrin 2 weeks into treatment was negative, consistent with previous finding that circulating antibody levels quickly drop to low or undetectable with partial clinical remission.

Discussion: This case strengthens evidence that anti-nephrin antibodies cause disruption of the slit pore diaphragm which appears to be readily responsive to immune therapy. Anti-nephrin mediated podocytopathy may present with a spectrum of glomerular histopathology, which on the background of other susceptibility factors, can lead to more severe presentations such as collapsing FSGS.

Anti-Nephrin Autoimmunity in Early Primary FSGS

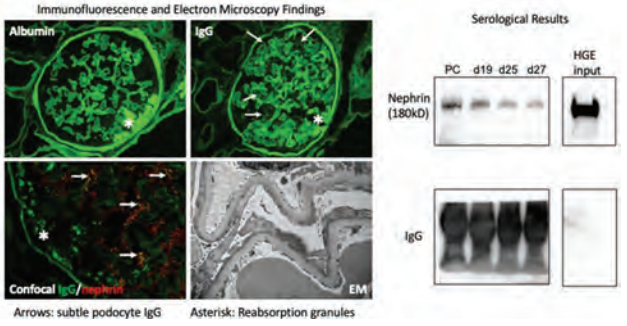
Astrid Weins,[1,2] Walter P. Mutter,[3,2] Keith H. Keller,[1,4] Sujal I. Shah,[1,2] Helmut G. Rennke.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Newton Wellesley Hospital, Newton, MA; [4]Broad Institute, Cambridge, MA.*

Introduction: Minimal change disease (MCD) and primary FSGS are important diagnoses in adults and children with acute nephrotic syndrome (NS). We have reported anti-nephrin-mediated autoimmunity in NS with MCD on kidney biopsy (KBx). Here, we describe a patient with KBx-proven diagnosis of early primary FSGS and persistent anti-nephrin IgG in glomeruli and serum.

Case Description: A 69yo Caucasian man with history of type 2 DM presents with acute kidney injury (sCr 3.49g/dl), anasarca, hyperlipidemia, sAlb1.8g/dl, UPCR 18g/gCr. Serologies including ANA, HIV, anti-PLA2r are negative; FLC ratio is 2.91. A kidney biopsy is ordered; the differential diagnosis includes MCD, membranous nephropathy, FSGS and paraprotein-related diseases. The biopsy contains 52 glomeruli with 12% global sclerosis, and 2 glomeruli with early segmental sclerosis with capillary collapse, epithelial hyperplasia and protein reabsorption granules (PRGs). Diabetic glomerular changes are not seen. Tubular atrophy and interstitial fibrosis are mild, and vascular sclerosis is moderate to severe. Immunofluorescence microscopy (IF) shows trace mesangial IgM and fine granular podocyte IgG with equal kappa/lambda. Electron microscopy reveals diffuse podocyte foot process effacement without deposits and loss of

slit diaphragms. Confocal imaging of IgG/nephrin IF confirms substantial overlap in the fine podocyte granules (arrows), but not in coarse PRGs (asterisks). A diagnosis of early primary FSGS is made. Sera collected on post-biopsy days 19, 25 and 27 are serologically positive for anti-nephrin. The patient was started on oral glucocorticoids, and on d27 was in partial remission (UPCR 2.6g/gCr, SAlb 2.8g/dl). Anti-B cell therapy is considered.

Discussion: Our findings reveal that autoimmune-mediated anti-nephrin podocytopathy can trigger irreversible podocyte injury leading to FSGS, likely in patients with additional predisposing factors. This enhances our understanding of diffuse progressive podocytopathies; accurate and early diagnosis identifies patients who benefit most from B-cell-targeted immunosuppressive therapy.



PO1677

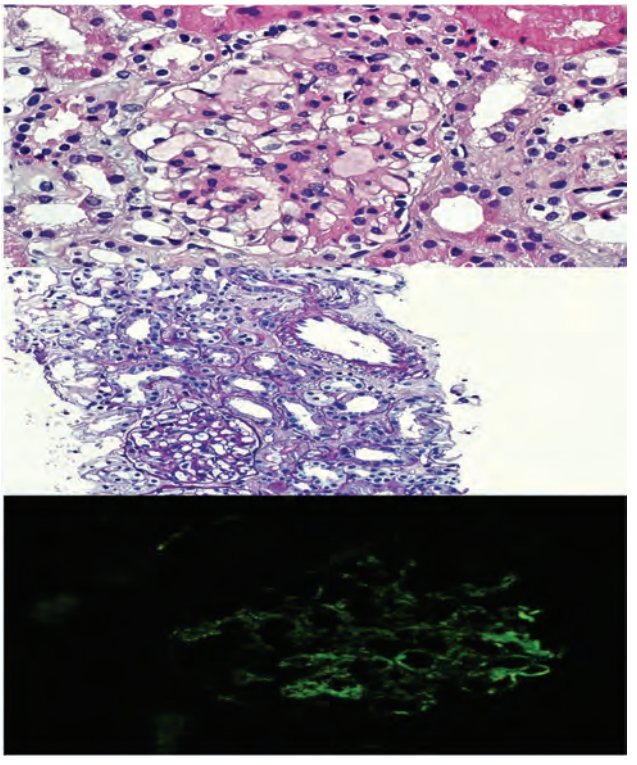
Nephrotic Syndrome Secondary to Minimal Change Disease Following Moderna COVID-19 Vaccine

Shaefiq B. Thappy, Sherin R. Thalappil, Shahem Abbarh, Mohammed Akhtar, Mohamad M. Alkadi. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Minimal Change Disease (MCD) has been reported following vaccines against hepatitis, pneumococcus, influenza and measles. In the COVID-19 era, 3 cases of new-onset MCD and one case of MCD relapse have been reported following the Pfizer-BioNTech COVID-19 vaccine. We herein report a case of MCD after receiving the first dose of Moderna COVID-19 vaccine.

Case Description: A 43-year-old Ethiopian man with no significant past medical history presented with progressive bilateral lower limb edema for two weeks. His symptoms started 7 days after receiving the first dose of COVID-19 vaccine. He then developed dyspnea and scrotal swelling over the following 10-14 days. On physical examination, his blood pressure was 150/92 mm Hg. There was decreased air entry at lung bases, significant bilateral lower limb pitting edema extending to above the knees and scrotal swelling. Lab investigations revelaed hypoalbuminemia, hyperlipidemia and proteinuria of 15 grams. There was no hematuria and his immunologic and serologic work up was negative. Renal biopsy showed minimal change disease with underlying IgA nephropathy. There was no global or segmental glomerulosclerosis, mesangial or endocapillary proliferation. Patient was started on oral prednisolone and furosemide. His edema resolved, serum albumin doubled and proteinuria decreased within the first week of treatment.

Discussion: Symptoms of MCD have been reported 4 days to 16 weeks after vaccination. Although the pathogenesis of MCD is not fully understood, studies suggest that T-cell dysfunction might play a role. More studies are needed to determine the incidence and pathophysiology of this adverse event post COVID-19 vaccine. It is not clear in this case if or when the second dose of the COVID-19 vaccine should be administered.



PO1678

Antiproteinuric and Podocytoprotective Effects of Direct Oral Anticoagulant Therapy in Glomerular Disease

Amanda P. Waller,[1] Katelyn Wolfgang,[1] Eman Abdelghani,[1] Bryce A. Kerlin.[1,2] *[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH.*

Background: Podocyte injury is a key determinant of chronic kidney disease (CKD) progression toward end stage kidney disease. We and others have recently uncovered a putative podocytopathic role for intraglomerular thrombin during proteinuric glomerular disease. Direct oral anticoagulant (DOAC) therapies limit thrombin activity but their ability to improve podocyte health and potentially slow CKD progression remains unknown. Thus, the aim of this study is to determine if DOACs reduce thrombin-mediated podocytopathy during glomerular proteinuria. We hypothesized that DOACs would preserve podocyte health and function in a podocyte-specific model of proteinuric glomerular disease.

Methods: Diphtheria Toxin was used to induce proteinuria in transgenic rats expressing human diphtheria toxin receptor (DTR) in a podocyte-specific manner and was subsequently treated with 1) Dabigatran (20 mg/kg; Dabi), 2) Rivaroxaban (3 mg/kg; Riva), or 3) Sham (saline) and compared to healthy controls (n=7-9/group). Morning spot urine was collected on day 0 and 10 post-DT. Glomeruli were isolated from the kidney, dissociated into single-cell suspensions, and analyzed by flow cytometry after immunofluorescent synaptopodin antibody and TUNEL staining.

Results: Both Dabi and Riva significantly reduced proteinuria (**Fig A**) and terminal podocyte injury (TUNEL positive podocyte fraction; **Fig B**). In addition, there was a trend toward *in situ* podocyte preservation with both DOACs with a significant overall effect of DOAC therapy on podocyte survival **(Fig C)**.

Conclusions: Both Dabi (a direct thrombin inhibitor) and Riva (a direct factor Xa inhibitor) reduce proteinuria and enhance podocyte health in a podocyte-specific model of proteinuric glomerular disease. These data suggest that DOACs may be repurposed as a novel approach to slow or halt proteinuric glomerular disease progression. Because thrombotic disease is a life-threatening co-morbidity of both glomerular disease and CKD, this approach may enable simultaneous thromboprophylaxis and glomerular disease therapy.

Funding: NIDDK Support, Private Foundation Support

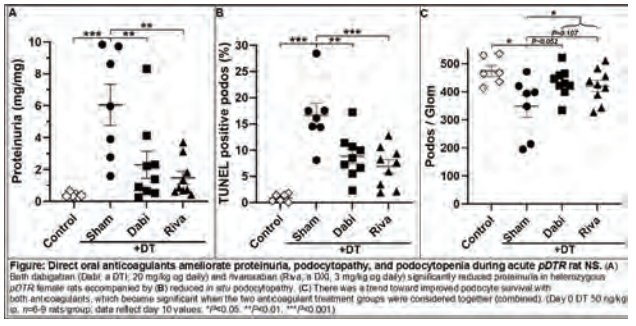


Figure: Direct oral anticoagulants ameliorate proteinuria, podocytopathy, and podocytopenia during acute *pDTR* rat NS. (A) Both dabigatran (Dabi; a DTI; 20 mg/kg qg daily) and rivaroxaban (Riva, a DXI, 3 mg/kg qg daily) significantly reduced proteinuria in heterozygous *pDTR* female rats accompanied by (B) reduced *in situ* podocytopathy. (C) There was a trend toward improved podocyte survival with both anticoagulants, which became significant when the two anticoagulant treatment groups were considered together (combined). (Day 0 DT 50 ng/kg ip, n=6-9 rats/group; data reflect day 10 values; *P<0.05, **P<0.01, ***P<0.001)

PO1679

A Highly Efficient and Reproducible Differentiation Protocol for Induced Pluripotent Stem Cell-Derived Podocytes

Sergii Kyrychenko, Justin A. Gallagher, Timothy A. Norman, Alyssa Fanelli, Xiang Pan, Eva Fast, Rachel Gallagher, Thomas A. Gustafson, Maria Lalioti. *Goldfinch Bio Inc, Cambridge, MA.*

Background: Podocyte processes intertwine to create a slit diaphragm, which, when compromised leads to filtration dysfunction, proteinuria, and eventually to renal failure. It is critical to be able to study the disease and test therapeutic interventions in patient-derived cells, and assess genetic and environmental aspects. Current protocols for differentiation of iPSCs into podocytes (iPodos) suffer from a lack of podocyte maturity or low reproducibility. Our goal was to test and optimize multiple protocols to establish a more translatable, physiologically relevant, and reproducible method.

Methods: We compared two distinct published protocols [Ciampi 2016; Musah 2018]. Additional conditions were tested, including varying the extracellular matrices, media, and length of differentiation. Podocyte signature was evaluated by IF, flow cytometry, and Nanostring analysis. For models of injury, we utilized protamine sulfate (PS) or puromycin aminonucleoside (PAN) treatment. A mouse podocyte cell line was used as a control.

Results: Both protocols generated iPodos with similar efficiency, as measured by synaptopodin, nephrin and podocin staining. iPodos generated from protocol-1 could be maintained in culture up to 14 days but remained relatively immature, based on the expression of collagen α1α2α1(IV) and lack of α3α4α5(IV). Response to PS and PAN treatment was variable compared to mouse podocytes. Altering the matrix from collagen to laminin did not improve reproducibility. iPodos from protocol-2 developed more filopodia and complex cell-cell junctions and appeared more homogeneous, with extended survival up to 4 weeks post-differentiation. PS treatment induced a significant and reproducible dose- and time-dependent decrease in synaptopodin expression, and a more robust accumulation of phalloidin aggregation. Both effects were effectively prevented by cyclosporin A, a calcineurin inhibitor, in a similar manner as in mouse podocytes. iPodos from protocol-2 also showed a more consistent dose-dependent response to PAN injury.

Conclusions: We achieved a more robust and translatable iPodos platform utilizing human iPSCs. Patient-derived iPodos will be an invaluable tool to enable a precision medicine-based approach to validate new therapeutic approaches for podocytopathy-driven kidney disease.

PO1680

Novel Ex Vivo Culture System Reveals Mechanosensitive "Sarcomere-Like Structures" During Early Podocyte Spreading

Shumeng Jiang,[1] Jeffrey H. Miner,[2] Guy M. Genin,[1] Hani Suleiman.[2] *[1]Washington University in St Louis, St Louis, MO; [2]Washington University in St Louis School of Medicine, St Louis, MO.*

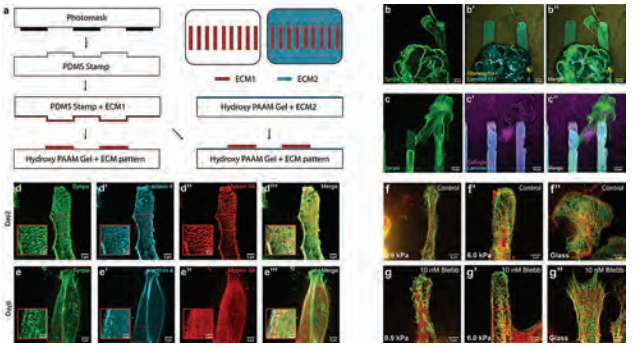
Background: Chronic kidney disease and ESKD are widespread health problems with no cure, in part because the biophysics underlying them are still not clear. A recently discovered feature of injured podocytes includes the de novo assembly of sarcomere-like stress fibers, identified by their alternating myosin and synaptopodin/a-actinin-4. It is not known whether these indicate a transient healing phenotype or are a feature of the cascade leading to foot process effacement.

Methods: To model the early events of podocyte injury, we developed a new in vitro system that enables the study of podocytes outside of their native microenvironment, but with in vivo-like mechanobiological and extracellular matrix (ECM) features. This system includes controllable stiffness, micropatterned substrates for spreading, and the use of primary podocytes as they migrate from freshly isolated glomeruli.

Results: When cultured on micropatterns of physiologically relevant extracellular matrix proteins and appropriate stiffness, myosin- and synaptopodin-positive stress fibers developed over two days of culture, then disappeared after six days, and the appearance of these stress fibers was sensitive to substrate stiffness and could be disrupted by inhibiting actomyosin contraction (blebbistatin), culturing cells with stiffness outside of the physiologic range, or presenting cells with substrates associated with pathology.

Conclusions: These results reveal the role of mechanobiological factors in podocytes represented by the mechanoresponsive sarcomere-like structure and establish a novel system for characterizing this mechanobiology in vitro.

Funding: Private Foundation Support



(a) Protocol for preparing the micropatterns of ECM proteins. (b, c) Primary podocytes prefer surfaces with laminin-521, the normal GBM laminin. (d, e) Sarcomere-like structures were observed at the early stages of podocyte spreading on micropatterns. (f, g) The sarcomere-like structure is mechanosensitive: a soft substrate (0.9 kPa) or myosin inhibition (Blebbistatin) increases the periodicity in the pattern.

PO1681

Primary Cilia in Podocyte Health and Disease

Lindsey A. Fitzsimons,[1,2] Kara M. Button,[2] Jake N. Cho,[3] Michael C. Akom,[3,4] Kerry L. Tucker,[2,1] Ron Korstanje.[5,1] *[1]University of Maine at Orono, Graduate School of Biomedical Science & Engineering, Orono, ME; [2]University of New England College of Osteopathic Medicine, Biddeford, ME; [3]Maine Medical Center, Portland, ME; [4]Tufts University School of Medicine, Boston, MA; [5]The Jackson Laboratory, Bar Harbor, ME.*

Background: Primary cilia are highly specialized elaborations of the plasma membrane that direct many of the signaling cascades critical for pre- and post-natal development and disease. While renal primary cilia are recognized as key genetic and cellular targets in polycystic kidney disease, the presence and function of primary cilia within the renal corpuscle and glomerulus have yet to be fully characterized. The purpose of our study was to perform a focused and quantifiable characterization of primary cilia of glomerular cell populations in health and disease.

Methods: Renal biopsy samples were obtained from patients with Minimal Change Disease (MCD; N=6), Focal Segmental Glomerular Sclerosis (FSGS; N=3), and control renal tissue (CON; N=4). Immunofluorescence analyses (IF) were used to quantify primary cilia number and length, as well as the expression of Sonic Hedgehog (SHH) protein, the ligand component of the Hedgehog signaling pathway and one measure of primary cilia function.

Results: Mean percent ciliation was significantly increased in MCD and FSGS when compared to CON. Analysis of individual glomerular primary cilia revealed increased ciliary length (μm) in both MCD and FSGS when compared to CON. Further analysis comparing primary cilia length in WT-1-positive nuclei (WT-1+; podocytes) also revealed a pronounced increase in cilia length in MCD and FSGS podocyte primary cilia versus CON. Despite increased length of primary cilia, glomerular SHH expression was significantly decreased in both MCD and FSGS when compared to CON. Glomerular diseases MCD and FSGS are therefore associated with an overall increase in podocyte primary cilia length and ciliation, an effect which corresponded to a decrease in SHH expression.

Conclusions: These data provide evidence in support of a role for primary cilia in glomerular disease pathogenesis. Ongoing and future research is needed to establish a mechanistic explanation for these changes observed in glomerular and podocyte cilia number and length. A more thorough understanding of the role(s) of primary cilia in glomerular cells, and specifically in podocytes, remains critical for to both our understanding of disease pathogenesis as well as for the pharmacologic treatment of glomerular chronic kidney disease.

Establishing a Podocyte-PEC Cross-Talk Model Using an Open Microfluidic Co-Culture Device

Yuting Zeng,[1] Jeffrey W. Pippin,[2] Stuart J. Shankland,[2] Ashleigh B. Theberge.[1,3] *[1]University of Washington Department of Chemistry, Seattle, WA; [2]University of Washington Division of Nephrology, Seattle, WA; [3]University of Washington Department of Urology, Seattle, WA.*

Background: Although focal segmental glomerulosclerosis (FSGS) is initially caused by podocyte injuries, their neighboring parietal epithelial cells (PECs) also undergo molecular changes that further damage the glomerulus. The cross-talk between podocytes and PECs is poorly understood, in part due to a lack of appropriate experimental models for study. Our goal is to establish an in vitro coculture model to induce podocyte injury and determine the mediators and responses of PECs.

Methods: Mouse podocytes labeled with EGFP and PECs labeled with tdTomato were cocultured in two neighboring chambers of an open microfluidic device that we engineered. The chambers remain separated until more media is added to overflow the half wall in between. To induce injury, podocytes were exposed to increasing concentrations

of cytotoxic sheep anti-glomerular antibodies (or media alone as control) for 2 hours. The two chambers were then allowed to communicate passively for 1 to 4 days. Diffusion calculations suggested moderate sized (10 kDa) signaling molecules take approximately 2 days to reach the other chamber. Immunocytochemistry characterized podocyte injury and PEC activation and epithelial-mesenchymal transition (EMT).

Results: By day 1, the normal contiguous monolayer of podocytes was disrupted, accompanied by a dose-dependent increase in the de novo expression of the injury marker desmin. In contrast to F-actin staining of the control group exhibiting thick bundles of cortical actin at cell edges, resembling primary processes, the level of F-actin decreased predominantly along the cell borders in injured podocytes, consistent with the destruction of podocyte cytoskeletal structures. By day 4, the percentage of PECs expressing the EMT marker SM22 increased significantly. $SM22^{+}$ PECs were larger and exhibited cellular protrusions, implying enhanced migration and invasion characteristics of the mesenchymal state. The protein expression of CD44, a marker for the activated profibrotic migratory PEC phenotype, was also increased. Levels of SSeCKS remained unchanged in PECs. A time course of bulk RNA seq results from both podocytes and PECs are pending.

Conclusions: This novel in-vitro microfluidic model for coculturing mouse podocytes and PECs has the potential to study many pathways involved in podocyte-PEC crosstalk, glomerular disease mechanisms, and drug screening.

C-Type Lectin-Like Receptor (CLEC) 2, the Ligand of Podoplanin, Induced Dynamic Change of F-Actin Filaments in Podocytes

Keiko Tanaka,[1] Taiji Matsusaka.[2] *[1]Okayama Daigaku, Okayama, Japan; [2]Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan.*

Background: Podoplanin is intensely expressed on podocyte membrane in an evolutionally conserved manner. Podoplanin is connected to F-actins through phosphorylated (p-)ERM in podocytes. CLEC-2, the endogenous ligand of podoplanin, is highly expressed in platelets and also exists in the plasma as a soluble form. Normally, podocytes are sequestered from CLEC-2, but when the glomerular barrier is injured, podocytes can have access to CLEC-2. We studied potential actions of CLEC-2 on podocytes.

Methods: Fc-CLEC-2, a fusion of Fc and human CLEC-2 (51-229), which can bind to mouse podoplanin, was generated in HEK293 cells and purified by Protein A chromatography. The changes of podocytes were evaluated 1 hr after the treatment with Fc or Fc-CLEC-2 (10ug/mL). StrepTagII-FLAG-CLEC-2, a fusion of double-tags and mouse CLEC-2 (51-229), was generated in HEK293 cells and purified by StrepTactin Sepharose column. Kidneys of C57BL/6 mice were perfused with 5 ug/g BW of FLAG-CLEC-2 through the aorta. Kidney samples were collected 1hr after the perfusion.

Results: Cultured podocytes treated with Fc showed an elongated morphology with numerous F-actin filaments, while podocytes with Fc-CLEC-2 showed a round shape with degradation of F-actin. Western blot revealed that pERM/ERM ratio was 0.47-fold decreased in podocytes with Fc-CLEC-2, indicating that CLEC-2 induced dephosphorylation of ERM. Immunostaining depicted abundant moesin, which we found the major ERM in cultured podocytes, around cell protrusions in podocytes with Fc, while moesin staining was reduced in podocytes with Fc-CLEC-2. Next, we evaluated *in vivo* podocytes perfused with FLAG-CLEC-2. In SEM, podocytes perfused with FLAG-CLEC-2 exhibited retraction of foot processes in 18.5% of visual fields. Western blot of glomerular lysate revealed that phosphorylation of Ezrin, the major ERM in *in vivo* podocytes, was 0.50-fold decreased by FLAG-CLEC-2. Double immunostaining of pERM and podocalyxin confirmed dephosphorylation of ERM in podocytes.

Conclusions: These results collectively suggest that CLEC-2 induced dephosphorylation of ERM, which then caused dissociation of podoplanin from F-actin, degradation of F-actin, leading to retraction of foot processes in podocytes. Thus, leakage of CLEC-2 may exaggerate podocyte injury.

A Direct CLIC5A/Ezrin Interaction Accounts for CLIC5A Plasma Membrane Localization and CLIC5A-Stimulated Rac1 Activation in Renal Glomeruli

Md. M. Rahman, Laiji Li, Barbara J. Ballermann. *University of Alberta, Edmonton, AB, Canada.*

Background: CLIC5A is part of the Podocalyxin/Ezrin complex at the apical domain of podocyte foot processes. Ezrin binds membrane phosphatidylinositol-4,5-bisphosphate (PI(4,5)P2) inducing its activation and C-terminal (T567) phosphorylation. Activated Ezrin bridges membrane-spanning proteins to cortical actin, shaping the cellular architecture. We reported that CLIC5A stimulates Rac1-GTP-dependent PI(4,5)P2 generation and Ezrin activation and that CLIC5A deletion disrupts the foot process architecture (J. Cell Sci. 127:5164, 2014 & Kidney Int. 89:833, 2016). Here, we investigated the mechanism by which CLIC5A interacts with Ezrin.

Methods: Direct protein-protein interactions were established by Yeast two-hybrid (Y2H) assay and confirmed by GST pull-down and reciprocal co-immunoprecipitation. Subcellular localization of endogenous proteins was determined by differential detergent fractionation of mouse glomeruli. Ezrin was released from glomerular membranes by stimulating phospholipase C-mediated PI(4,5)P2 hydrolysis with m-3M3FBS.

Results: We found that CLIC5A interacts directly with the Ezrin C-terminal domain, but only if Ezrin was in the activated state. The extreme 16 C-terminal amino acids of Ezrin were necessary for the interaction and Ezrin phosphorylation at T567 increased CLIC5A binding. Expression of a C-terminal ezrin fragment (Ezrin 432-586, phosphomimic T567D), but not C-terminally truncated Ezrin 432-570 effectively blocked CLIC5A-stimulated Ezrin and Rac1 activation. In glomeruli 49 +/- 4 % of endogenous CLIC5A was in the cytoplasmic, 33 +/- 3% in membrane and 18 +/- 1 % in the cytoskeleton-associated fraction. As expected, PI(4,5)P2 hydrolysis reduced Ezrin phosphorylation and shifted Ezrin from membrane and cytoskeletal fractions into the soluble pool. Similarly, PI(4,5) P2 hydrolysis shifted CLIC5A from membrane- and cytoskeletal fractions, increasing the soluble component to 72 +/- 13% ($p = 0.041$, $n= 3$, mean +/- STD).

Conclusions: CLIC5A interacts directly with active Ezrin, and this interaction is required for CLIC5A-dependent Rac1 activation. The release of CLIC5A together with Ezrin from the membrane fraction in response to PI(4,5)P2 hydrolysis suggests that CLIC5A localizes to the plasma membrane because of its direct interaction with Ezrin.

The Mechanosensitive Ion Channel Piezo Activates Rho1 in Drosophila Nephrocytes

Sybille Koehler, Barry Denholm. *Biomedical Scoences, University of Edinburgh, Edinburgh, United Kingdom.*

Background: Podocytes constantly face biomechanical forces such as shear stress and hydrostatic pressure. Increasing forces result in morphological changes, detachment from the glomerular basement membrane and loss into the primary urine. This highlights a requirement for podocytes to sense changes in their physical environment and induce a response to react to increased biomechanical force.

Methods: Here, we investigated the functional role of the mechano-sensitive ion channel Piezo in *Drosophila* nephrocytes.

Results: First, we confirmed Piezo expression and localisation at the nephrocyte diaphragm. Acute activation of the channel with the chemical compound YODA revealed significantly increased Ca^{++} signalling and Rho1 activation, suggesting a functional role of Piezo in nephrocytes and delineating the putative Piezo mechanosensitive pathway. For further analysis, we used knockout flies and observed a filtration phenotype, while morphology and GTPase activation was not altered. In addition, we also studied the impact of elevated Piezo levels and could show, that in line with the YODA effect, Piezo overexpression revealed severely increased Rho1-GTP levels and FITC uptake, while morphology was not changed. Because of this severe pathological phenotype, we tried to rescue the effects of Piezo overexpression with pharmacological inhibition by using tarantula toxin. Intriguingly, treatment with tarantula toxin reversed the elevated Rho1-GTP levels observed upon Piezo overexpression.

Conclusions: Taken together, our data confirms the functional expression of Piezo in nephrocytes, its role in regulating GTPases and the beneficial effect of tarantula toxin to reverse the pathological effects caused by increased Piezo levels.

PO1686

Drosophila Filamin Exhibits a Mechanoprotective Role During Nephrocyte Injury via Hypertrophy

Sybille Koehler, Barry Denholm. *Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.*

Background: Podocytes are constantly exposed to biomechanical forces such as shear stress and hydrostatic pressure. These forces increase during disease like diabetes and hypertension, resulting in adaptive mechanisms such as podocyte hypertrophy. But how do podocytes sense changes in biomechanical forces and how does the molecular response look like?

Methods: To investigate this, we utilized *Drosophila* nephrocytes and studied the functional role of the mechanosensor Cheerio (dFilamin). FilaminB is upregulated in podocyte injury models and upon increased biomechanical stress, therefore serving as an ideal candidate for mediating mechano-protection in response to injury.

Results: Expression of an over-active mechanosensor region variant of Cheerio resulted in a significant hypertrophy phenotype, while morphology and filtration function were only mildly affected. Interestingly, the expression of over-active Cheerio caused a rescue of filtration function after depletion of the nephrocyte diaphragm proteins Duf (dNEPH) and Sns (dNephrin). Additional analysis with human FilaminB confirmed this mechano-protective role and the involvement of the mechanosensor region in the hypertrophy phenotype. To delineate the mechano-protective pathway acting downstream to Cheerio we studied the candidates: TOR, WNT and YAP. Activation of these pathways result in nephrocyte hypertrophy. Interestingly, TOR repression reversed the hypertrophy in over-active Cheerio expressing cells, suggesting TOR to be a novel downstream target of Cheerio and to be responsible for the hypertrophy phenotype.

Conclusions: Although Cheerio and FilaminB mediate a mechano-protective role in the face of injury, their excessive expression resulted in a severe morphological and functional phenotype, emphasizing the need of a tight control of expression levels.

PO1687

Characterization of a Novel FSGS-Associated ACTN4 Mutation in Drosophila melanogaster

Johanna Odenthal, Bodo B. Beck, Bernhard Schermer, Thomas Benzing, Paul T. Brinkkoetter, Malte P. Bartram. *Uniklinik Koln, Koln, Germany.*

Background: Decisive for podocyte morphology and homeostasis during health and disease is a specialized and highly regulated organization of the actin cytoskeleton. In this context, the actin cross-linking protein Alpha-actinin4 (ACTN4) has been shown to play a crucial role in podocyte architecture and function. Mutations in the *ACTN4* gene are associated with focal segmental glomerulosclerosis (FSGS). Here, performing gene panel sequencing in a pediatric patient presenting with steroid resistant nephrotic syndrome and FSGS, a *de novo*, potentially disease causing variant of *ACTN4* was identified, which was previously undescribed and not found in available genome or exome databases. Our aim is to elucidate the pathogenic potential of this variant for podocytes and FSGS progression.

Methods: To elucidate pathogenic effects of the newly identified ACTN4 variant, we employed the genetic toolbox of *Drosophila*. The fly holds podocyte-equivalent cells called nephrocytes, which are responsible for filtration and detoxification of the hemolymph. Cell-specific genetic manipulation enabled us to analyze RNAi-mediated knockdown of Actinin, the single fly homolog, in nephrocytes and its impact on cell morphology and function. Rescue experiments with the novel human ACTN4 variant will now give indication about possible pathogenic consequences of the mutation when compared to wildtype as well as previously described disease-associated variants of ACTN4.

Results: Knockdown of *Drosophila* Actinin in nephrocytes leads to severe functional defects, as filtration capacity is diminished by up to 50%. Morphologically, mislocalization of the ZO-1 homolog Polychaetoid was observed as well as overall reduction of nephrocyte diaphragms. First rescue experiments with wildtype human ACTN4 led to partial rescue of functional and morphological phenotypes observed upon Actinin knockdown.

Conclusions: Our results underline the importance of Actinin for nephrocyte biology. Capacity of wildtype human ACTN4 in rescuing the knockdown associated phenotypes indicates the model's suitability. Further experiments will be performed to elucidate the pathogenicity of the novel ACTN4 variant also in comparison to previously described pathogenic mutations.

PO1688

The Calcium-Sensing Receptor Restores Podocyte Function in Proteinuric Humans and Mice

Anne K. Muehlig,[1,2] Johanna Steingroever,[1] Wiebke Sachs,[3] Catherine Meyer-Schwesinger,[3] Hoon Young Choi,[6] Nicole Endlich,[4] Fabian Braun,[2] Tobias B. Huber,[2] Victor G. Puelles,[2] Claus Peter Schmitt,[5] Jun Oh.[1]
[1]Department of Pediatric Nephrology, University Children's Hospital, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Hamburg, Germany; [3]Center of Experimental Medicine, Institute of Cellular and Integrative Physiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Department of Anatomy and Cell Biology, University of Greifswald, Greifswald, Germany; [5]Department of Pediatrics, Heidelberg University Hospital, Heidelberg, Germany; [6]Yonsei University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

Background: Calcimimetic agents allosterically increase the calcium (Ca^{2+}) sensitivity of the calcium-sensing receptor (CaSR), which suppresses the secretion of parathormone in the parathyroid gland and therefore regulates Ca^{2+}-homeostasis. The CaSR is furthermore expressed in the tubular system and to a lesser extend in podocytes. Activation of CaSR reduces glomerular proteinuria and podocyte damage in animals. However, the precise role of the podocyte CaSR is still unclear.

Methods: A CaSR knockdown (KD) in murine podocytes and podocyte-specific CaSR knockout (KO) in BALB/c mice were generated to study its role in proteinuria.

Results: Podocyte CaSR KD abolished the calcimimetic R-568 mediated Ca^{2+}-influx, reduced the number of actin fibers, cellular attachment and migration velocity in podocytes. In contrast, the activation of the CaSR with R-568 protected the wildtype cells from Adriamycin (ADR)-induced cytoskeletal rearrangement and reduction in adhesion capacity. *In vivo* ADR-induced proteinuria enhanced glomerular CaSR expression in wild type mice (control vs ADR: 33.5±2.0 vs 75.8±7.8 CaSR positive podocytes (%); p=0.0286). In podocyte-specific CaSR KO ADR treatment resulted in a higher albuminuria (control vs KO: 27.9±38.1 vs 85.9±52.7 g/galbumin/creatinine; p=0.023 at day 7), podocyte foot process effacement, podocyte loss (control vs KO: 3504±283.1 vs 2969±547.2 p57+cells/mm^2; p=0.0238 at day 8) and glomerular sclerosis compared to wild type littermates. In addition, four children with nephrotic syndrome, objecting glucocorticoid therapy, were treated with the calcimimetic cinacalcet for 1 to 33 days. Proteinuria declined transiently by up to 96 %, serum albumin increased and edema resolved.

Conclusions: The activation of CaSR regulates key podocyte functions and protects from ADR induced cellular damage *in vitro*. The CaSR reduces toxin induced proteinuria, podocyte loss and glomerular damage in mice. Our findings suggest a major role of CaSR signaling in glomerular disease.

PO1689

Selective PPARγ Modulator with Reduced Adipogenic Potential Ameliorates Experimental Nephrotic Syndrome

Claire Burton,[1] Galen Rask,[1] Amanda P. Waller,[1] Amy Webb,[2] Marina G. da Rocha Pitta,[5] Angélica A. Amato,[3] Rachel Cianciolo,[2] Brian Becknell,[1,2] Bryce A. Kerlin,[1,2] Francisco R. Neves,[3] Alessia Fornoni,[4] Shipra Agrawal.[1,2]
[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]Universidade de Brasilia, Brasilia, Brazil; [4]University of Miami School of Medicine, Miami, FL; [5]Universidade Federal de Pernambuco, Recife, Brazil.

Background: Glomerular disease, often manifesting as nephrotic syndrome (NS) with high proteinuria, can be refractory to standard treatment and is typically associated with hypoalbuminemia, hypercholesterolemia, and hypercoagulopathy. We hypothesized that the nuclear receptor PPARγ can be selectively modulated using a novel partial agonist, GQ-16, to gain therapeutic advantage over traditional PPARγ agonists for NS treatment

Methods: Pio and GQ-16 were administered daily to male Wistar rats with puromycin amino-nucleoside (PAN)-induced nephropathy. Serum and urine chemistries were performed and kidneys, glomeruli, liver, and white adipose tissue (WAT) were harvested for RNA and protein extraction. Blood was collected for determination of thrombin generation parameters.

Results: PAN induced robust proteinuria, which was significantly reduced with Pio to 64% of PAN-value, and robustly with GQ-16 to 81% of PAN, which was comparable to controls. Podocyte hypertrophy also returned to normal with Pio and GQ-16. While both GQ-16 and Pio restored glomerular *Nphs1* and hepatic *Pcsk9* expression and reduced hypercholesterolemia, GQ-16 also restored glomerular *Nrf2*, and reduced disease-associated hypoalbuminemia and hypercoagulopathy. Furthermore, RNA-seq analysis identified both common and distinct glomerular genes altered by Pio and GQ-16 treatments. Moreover, Pio but not GQ-16 significantly induced aP2 (fatty acid binding protein) in adipocytes and in WAT. Both, Pio and GQ-16 induced insulin sensitizing adipokines in WAT with varying degrees

Conclusions: Selective modulation of PPARγ by a partial agonist may be a more beneficial approach than a full PPARg agonist in reducing proteinuria, hypoalbuminemia, and hypercoagulopathy in NS and in decreasing drug-associated side effects such as adipogenesis and weight gain.

Simultaneous Loss of Podocyte Insulin Receptor (IR) and Insulin-Like Growth Factor 1 Receptor (IGF1R) Is Detrimental and Associated with Spliceosome Dysfunction

Jenny Hurcombe,[1] Lusyan Dayalan,[1] Fern Barrington,[1] Lan Ni,[1] Paul T. Brinkkoetter,[2] Martin Holzenberger,[3] Gavin I. Welsh,[1] Richard Coward.[1]
[1]University of Bristol, Bristol, United Kingdom; [2]Uniklinik Koln, Koln, Germany; [3]INSERM, Paris, France.

Background: Insulin signalling to the podocyte via the insulin receptor (IR) is crucial for kidney function. Insulin-like growth factor 1 (IGF1) signalling through the structurally related insulin-like growth factor 1 receptor (IGF1R) is also known to directly affect the podocyte. Since the IR and IGF1R may act redundantly in some contexts, this study sought to elucidate the compound role of the insulin/IGF1 axis in podocyte function using mouse and cell culture models deficient in both receptors.

Methods: To examine the effects of combined receptor loss *in vivo*, a transgenic mouse model with conditional inactivation of podocyte IR and IGF1R was generated. *In vitro*, conditionally immortalised genetic IR knockout, IGF1R knockout and IR/IGF1R dual knockout podocytes were characterised using global proteomic and transcriptomic analysis.

Results: Podocyte specific IR/IGF1R knockout mice developed significant albuminuria and a severe renal phenotype with global sclerosis, renal failure and death occurring between 4 and 24 weeks. >90% loss of IR/IGF1R in cultured mouse podocytes was also detrimental resulting in >50% cell death 7 days after gene knockdown. Enrichment analysis of total proteomic data revealed a striking downregulation of gene ontology terms associated with splicing and RNA processing activity in IR/IGF1R knockout cells. Western blot analysis was used to validate the reduced expression of proteins responsible for spliceosome synthesis and regulation in dual knockout podocytes, including polypyrimidine tract-binding protein 2 (PTBP2), eukaryotic initiation factor 4A (EIF4A) and splicing factor 3B subunit 4 (SF3B4).

Conclusions: This work underlines the critical importance of podocyte insulin/IGF signalling and reveals a novel role for this signalling axis in RNA processing by regulating spliceosome activity.

PO1691

Regression of Severe Preexisting Glomerular Pathology in a Mouse FSGS Model in Response to Treatment with Macula Densa-Derived Biologicals

Georgina Gyarmati, Urvi Nikhil Shroff, Audrey Izuhara, Janos Peti-Peterdi. *University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Macula densa (MD) cells localized at the glomerular vascular pole synthesize and release numerous vasoactive autocoids and newly identified angiogenic (e.g. CCN1) and glomerulotrophic factors that act in a paracrine fashion to maintain high renal/glomerular blood flow and endogenous tissue remodeling. The present study aimed to test the tissue regenerative therapeutic potential of MD-derived biologicals in vivo in a mouse model of focal segmental glomerulosclerosis (FSGS).

Methods: BalbC mice with Adriamycin-induced stable, severe FSGS and albuminuria (albumin/creatinine ratio ACR>10,000mg/g) were randomized into 5 groups and started daily ip injections (150ul each) of either saline (S), human recombinant (hr) CCN1 in low-dose (0.3 ng/mouse) (L), hrCCN1 high-dose (2 ug/mouse) (H), DMEM/F12 control (D), and conditioned culture media of the new MD cell line mMD^{Geo} (MD) for 4 weeks. Transcutaneous GFR (MediBeacon) and ACR were measured weekly. Terminal histological analysis was performed using PAS and Trichrome staining.

Results: Kidney injury was severe at the onset (GFR 1160±51 μL/min/100 g BW, ACR 11219±637) and was sustained throughout the 4 weeks of treatment in control S and D groups (GFR: 1080±143, 992±164; ACR: 10227±5869, 3958±1638, respectively). In contrast, a progressive and significant improvement in kidney function was observed in response to both L, H, and MD treatment (ACR reduced to 1342±573, 921±270, 1113±151, respectively; GFR increased to 1453±100 μL/min/100 g BW in MD group). Similarly, p57+ podocyte number per glomerular area (11±0.4 in L, 12±0.6 in H vs 3.9±0.43 in S;14±0.6 in MD vs 5.5±0.9 in D), GS index (131±2.4 in L, 130±2.3 in H vs 173±3.4 in S; 113±1.9 in MD vs 152±3 in D based on PAS staining) and tissue fibrosis index (67±2 in L, 57±2 in H vs 83±3 in S; 47±2 in MD vs 80±3 in D based on Picrosirius staining density) improved significantly in response to treatment with MD biologicals.

Conclusions: This in vivo preclinical study confirmed that the supplementation of key MD cell-derived factors in the form of injectable biologicals can augment endogenous kidney tissue repair and restores kidney function in a mouse model of FSGS. Targeting MD cell mechanisms is a new potent tissue regenerative therapeutic strategy for kidney diseases.

PO1692

Insulin-Like Growth Factor 1 Receptor (IGF1R) Suppression in the Glomerular Podocyte Has Beneficial and Detrimental Consequences Dependent on the Level of Inhibition

Jenny Hurcombe,[1] Fern Barrington,[1] Virginie M. Betin,[1] Abigail C. Lay,[1] Lusyan Dayalan,[1] Lan Ni,[1] Paul T. Brinkkoetter,[2] Martin Holzenberger,[3] Gavin I. Welsh,[1] Richard Coward.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]Uniklinik Koln, Koln, Germany; [3]INSERM, Paris, France.*

Background: Insulin signalling to the glomerular podocyte via the insulin receptor (IR) is known to be critical for normal kidney function. This study aimed to define the physiological importance of the closely related insulin-like growth factor 1 receptor (IGF1R) in podocytes.

Methods: Transgenic mice with conditional inactivation of podocyte IGF1R were generated to determine the effects of IGF1R suppression *in vivo. In vitro,* conditionally immortalised genetic IGF1R knockout and wild-type podocytes treated with the IGF1R inhibitor picropodophyllin (PPP) were characterised using global proteomic analysis.

Results: Transgenic mice with partial podocyte-specific IGF1R knockout, generated using conventional Cre recombinase, had no apparent basal renal phenotype but unexpectedly, were protected from doxorubicin-induced nephropathy. An additional mouse model using an epigenetically resistant podocyte Cre driver designed to increase receptor knockout efficiency, exhibited mild basal albuminuria by 24 weeks. Our *in vitro* models revealed that the degree of IGF1R inhibition in the podocyte is important. Greater than 90% knockout caused ~50% cell death after 7 days and did not protect against doxorubicin-induced cell death whilst wild-type podocytes treated with PPP (partial inhibition) showed enhanced survival when stressed with doxorubicin. Proteomic analysis revealed that near complete IGF1R suppression results in downregulation of mitochondrial respiratory complex I and DNA damage repair proteins whilst partial IGF1R inhibition promotes expression of respiratory complexes.

Conclusions: Altered mitochondrial function, impairment of DNA damage responses and resistance to oxidative stress in podocytes is dependent on the level of IGF1R suppression and determines whether receptor inhibition is protective or mildly detrimental.

PO1693

Calcium/Calmodulin Kinase 4 Induces FSGS by Promoting Apoptosis While Inhibiting Autophagy in Podocytes

Rhea Bhargava, Kayaho Maeda, Abhigyan Satyam, Isaac E. Stillman, George C. Tsokos. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Podocyte injury and death precede the development of focal segmental glomerulosclerosis(FSGS), but the involved mechanisms remain poorly understood. Calcium/calmodulin kinase 4 (CaMK4), a serine threonine kinase, is increased in podocytes of people with FSGS and in mice models of FSGS.

Methods: B6, B6 *Camk4.fl/fl.podocin*$^{cre-}$ or *Camk4.fl/fl.podocin*$^{cre+}$ mice were created and injected with i.v. adriamycin. Urine was collected on days 0, 3, 7, or 14, and kidney samples were collected on day 7 or 14 after adriamycin injection. Cultured human podocytes in the presence and absence of CAMK4 inhibitor (KN93) were exposed to adriamycin after which immunofluorescence and western blot was performed. Pull down mass-spectrometry and co-immunoprecipitation analysis was performed to identify proteins involved in cell death and those that directly interact with CaMK4 in FSGS.

Results: We found that lack of CaMK4 in podocytes suppressed the development of kidney pathology including the presence of hyaline deposits in glomeruli, podocytopenia and tubulointerstitial damage with intratubular casts in mice injected with adriamycin. Proteinuria in mice lacking CaMK4 in podocytes exposed to adriamycin, was reduced at 7 days and remained low through the 14th day when compared to control mice. Mechanistically we found that CaMK4 phosphorylates 14-3-3, releasing pro-apoptotic protein BAD which in turn binds to the antiapoptotic protein BCL-2, thereby allowing BAX, to aggregate on mitochondria and induce release of cytochrome c through mitochondrial pore formation, followed by caspase activation and apoptosis. In parallel, CaMK4 inhibits autophagy, a process needed for the renewal of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

Conclusions: We demonstrate that mice lacking CaMK4 specifically in podocytes are protected from FSGS-like disease after exposure to adriamycin. These mice also demonstrate markedly reduced proteinuria and podocytopenia. We found that apoptosis leads to cell death while autophagy is protective in FSGS. The characterization of the specific molecular events which lead to podocyte loss and glomerulosclerosis point to putative therapeutic targets and biomarkers for FSGS.

PO1694

A Noncanonical Role for IRE1α in Podocyte Endoplasmic Reticulum (ER)-Phagy

José R. Navarro-Betancourt,[1] Joan Papillon,[1] Julie Guillemette,[1] Takao Iwawaki,[2] Andrey V. Cybulsky.[1] *[1]McGill University, Montreal, QC, Canada; [2]Kanazawa Medical University, Kahoku-gun, Japan.*

Background: Glomerular diseases involving podocyte (glomerular epithelial cell; GEC) injury feature endoplasmic reticulum (ER) stress and activation of the unfolded protein response (UPR). Inositol requiring enzyme-1α (IRE1α), a UPR transducer, mediates chaperone production and autophagy in podocytes during ER stress. Selective autophagy of the ER (ERphagy) is dependent on ER-resident adaptors (e.g. RTN3L) and is stimulated by ER stress. ER-derived coat protein complex II (COPII) vesicles may participate in the delivery of ER cargo to autophagosomes; however, regulation and importance of ERphagy in glomerular disease are not understood.

Methods: We employed mice with podocyte-specific deletion of IRE1α and littermate controls. IRE1α knockout (KO) and control GECs were produced from these mice. GECs were incubated with tunicamycin (TM) to induce ER stress.

Results: Mass spectrometry analysis of TM-stimulated control and IRE1α KO GECs showed that in addition to ER chaperones, proteins in the secretory pathway, including the COPII component Sec23B, were increased in an IRE1α-dependent manner. By immunoblotting, TM enhanced Sec23B and RTN3L expression in control, but not IRE1α KO GECs. By immunofluorescence microscopy, in control GECs, TM increased the biogenesis of LC3 and Sec23B particles, as well as colocalization of Sec23B with LC3 and RTN3L with LC3; increases were attenuated in IRE1α KO GECs. Thus, deletion of IRE1α impaired delivery of COPII vesicles and RTN3L-coated ER fragments to autophagosomes. Knockdown of Sec23B with siRNAs reduced autophagosome formation in TM-treated control GECs. After blocking protein synthesis with cycloheximide, TM stimulated degradation of RTN3L in control GECs, consistent with ERphagy flux, but RTN3L degradation was impaired in IRE1α KO cells. Similarly, TM induced degradation of α3,4,5 collagen IV in control, but not IRE1α KO GECs, suggesting that collagen IV is an IRE1α-dependent ERphagy substrate. In adriamycin nephrosis, where IRE1α activates an adaptive UPR and autophagy, expression of Sec23B and RTN3L was increased in glomeruli of control, but not IRE1α KO mice.

Conclusions: During ER stress, IRE1α redirects a subset of Sec23B-positive COPII vesicles to deliver RTN3L-coated ER fragments to autophagosomes. ERphagy is a novel outcome of the IRE1α pathway in podocytes and may play a cytoprotective role in glomerular diseases.

ACE Inhibition Modulates Insulin-Like Growth Factor 1 (IGF-1) Filtration to Regulate Compensatory Kidney and Glomerular Hypertrophy

Abhijit S. Naik, Su Q. Wang, Mahboob A. Chowdhury, Rajasree Menon, Edgar A. Otto, Jocelyn E. Wiggins, Matthias Kretzler, Markus Bitzer, Roger C. Wiggins. *University of Michigan, Ann Arbor, MI.*

Background: Modeling suggests that preventing glomerular volume (GV) increase could serve as a therapeutic target to mitigate hypertrophy-associated progressive glomerulosclerosis (GS). We, therefore, evaluated how GV is regulated, and how Angiotensin-Converting Enzyme inhibition (ACEi) could reduce compensatory GV increase.

Methods: Uni-nephrectomized (Uni-Nx) wild-type Fischer344 rats were used to model progressive GS triggered by the single kidney state, and the effect of ACEi started either before or after Uni-Nx. Urine IGF ELISA assay, computer-assisted morphometry, single-cell, bulk transcriptomics, immunofluorescence, and human databases were analyzed.

Results: ACEi started *before,* but not *after* Uni-Nx, reduced short (Panel A) and long-term (Panel B) compensatory GV increase, and the associated 8-fold peak of urine IGF-1 post-nephrectomy (Panel C). An IGF-1R inhibitor (picropodophyllin) also reduced compensatory kidney hypertrophy (Panel D). Post-Uni-Nx, a decrease in both serum IGF-1 and glomerular/kidney IGF-1 transcript were noted, and IGFBP3 (the major blood IGFBP) was present in podocyte cytoplasm in the absence of detectable podocyte IGFBP3 transcript, suggesting that IGF-1 and IGF-IGFBP3 complexes had come from blood. A model was developed to predict how IGF-1, IGF-2, and IGF-IGFBP protein complexes would interact with the glomerular filter, and its predictions were confirmed in ERCB database. The importance of hyperfiltered IGF-1 as a driver of glomerular failure in single kidney states was further supported by human kidney allograft half-life analysis.

Conclusions: Hyperfiltered IGF-1 drives compensatory GV increase leading to long-term proteinuria and GS. Timing of ACEi in relation to uni-Nx can reduce both IGF-1 hyperfiltration and GV increase, thereby prolonging single kidney lifespan.

Angiotensin II Induces Oxidative Podocyte Injury via the Upregulation of Nox4

Tae-Sun Ha. *Chungbuk National University, Cheongju, Chungcheongbuk-do, Republic of Korea.*

Background: Angiotensin II (Ang II) induces glomerular and podocyte injury via systemic and local vasoconstrictive or non-hemodynamic effects including oxidative stress. The release of free radicals from podocytes may participate in the development of glomerular injury and proteinuria. We studied the pathophysiologic roles of oxidative stress in Ang II-induced podocyte apoptosis.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times and transfected by Nox4 or AT1R siRNAs or negative control scrambled siRNA for 24 h. The changes of podocyte oxidative stress and apoptosis were observed by confocal imaging, western blotting, realtime PCR, FACS and TUNEL assay according to the presence of Ang II.

Results: Ang II increased the generation of superoxide anions and intracellular reactive oxygen species levels but suppressed superoxide dismutase activity that was reversed by an antioxidant, probucol. Ang II also increased Nox4 protein and expression in podocytes, measured using western blotting and real-time PCR analysis that was also reversed by probucol. Nox4 suppression by small interference RNA (siRNA) reduced the oxidative stress induced by Ang II. These results suggest that Ang II induced oxidative stress via the upregulation of Nox4 protein in a transcriptional mechanism. Ang II promoted podocyte apoptosis that was reduced significantly by probucol and Nox4 siRNA. Ang II-induced podocyte apoptosis were also recovered by Ang II type 1 receptor (AT1R) siRNA.

Conclusions: Our findings suggest that Ang II induced podocyte oxidative stress and apoptosis through AT1R and Nox4. These findings suggest that Ang II promoted podocyte oxidative stress and apoptosis through AT1R and via the upregulation of Nox4, which could be preventive by Nox4 inhibition and/or antagonizing AT1R as well as antioxidants.

Anillin Serves a Protective Function in a Mouse Model of HIV-Associated Nephropathy

Brandon M. Lane,[1,2] Alexis Musick,[4] Guanghong Wu,[2,3] Megan Chryst-Stangl,[2,3] Gentzon Hall,[5,2] David N. Howell,[4] Rasheed A. Gbadegesin.[1,2] *[1]Duke University Department of Pediatrics, Durham, NC; [2]Duke Molecular Physiology Institute, Duke University, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]Duke University Department of Pathology, Durham, NC; [5]Duke University Hospital, Durham, NC.*

Background: HIV associated nephropathy (HIVAN) is characterized by a rapid progression to end stage kidney disease with limited treatment options. We previously demonstrated that mutations in the gene encoding anillin (*ANLN)* can cause FSGS and showed that ANLN is upregulated in the glomerulus of HIVAN patients as well as the HIVAN Tg26 mouse model. ANLN is an F-actin binding protein that affects cell proliferation and survival, two cell processes that are predicted to play a key role in the phenotype associated with HIVAN. We hypothesized that ANLN upregulation is one of the drivers of glomerular disease in HIVAN mice, therefore modulating ANLN expression may present an alternative therapeutic strategy for HIVAN.

Methods: To evaluate the therapeutic potential of reduced functional ANLN in a HIVAN mouse model, we created a mouse line using CRISPR Cas9 mediated gene editing that contains an early stop codon in the *Anln* gene (ANLNx). We then bred heterozygous ANLNx mice with Tg26 HIVAN mice and evaluated proteinuria and mortality over 16 weeks for each genotype. Sclerotic glomeruli from 3 mice in each group were evaluated and quantified at 16 weeks of age by pathologists blinded to genotype.

Results: There was no improvement in glomerular disease phenotype associated with the reduction of functional ANLN in the Tg26 HIVAN model. Urine albumin and creatinine ratio at 8, 12, and 16 weeks were similar between double ANLNx Tg26 heterozygotes compared to Tg26 HIVAN mice (p=1.038, 0.0863. 0.0761 for each time-point). Mice heterozygous for both the ANLNx and Tg26 alleles also did not display any increase in survival compared to mice carrying only the Tg26 allele (p=0.361). Evaluation and scoring of PAS stained kidney sections by independent pathologists revealed similar levels of sclerosis between Tg26 HIVAN mice and mice heterozygous for both the ANLNx and Tg26 alleles.

Conclusions: Genetic ablation of ANLN does not improve kidney disease phenotypes in Tg26 HIVAN mice. ANLN upregulation likely represents a survival mechanism in Tg26 HIVAN mice and not a cause of injury.

The Role of LRP1 in Podocytes

Marwin Groener,[1,2] Patricia Bolanos-Palmieri,[1] Tilman Jobst-Schwan,[1,2] Mario Schiffer.[1,2] *[1]University Hospital Erlangen - Department of Medicine 4 - Nephrology and Hypertension, Erlangen, Germany; [2]Research Center On Rare Kidney Diseases (RECORD), University Hospital Erlangen, Erlangen, Germany.*

Background: Recent studies have demonstrated the importance of endocytosis for podocyte health. However, little is known about the function of the internalized cargo proteins. We investigated the role of the low-density lipoprotein receptor-related protein 1 (LRP1), a large endocytic scavenger receptor, in podocytes *in vitro* and *in vivo*.

Methods: We used immunoblotting and -fluorescence to determine quantity and localization of LRP1 in cultured human podocytes. siRNA knockdown (KD) of LRP1 and an antagonist were used to investigate potential functional importance *in vitro*. We used zebrafish morpholino knockdown models of LRP1 homologs to study the function of LRP1 *in vivo*. LRP1 expression in healthy and diseased human renal tissue was determined by immunohistochemistry.

Results: LRP1 is highly expressed in cultured podocytes where it localizes to the membrane and perinuclear region. It colocalizes with early and late endosomes, in line with its role in endocytic trafficking. Interaction with β1-Integrin (ITB1) was confirmed by immunoprecipitation and colocalization. siRNA KD of LRP1 resulted in a reduction of podocyte number and cell size. Morpholino KD of both Lrp1 isoforms in zebrafish led to pericardial effusion and generalized edema, hinting at a renal phenotype. Interestingly, LRP1 has nearly absent baseline expression in healthy human glomeruli. Glomerular expression is significantly increased in human biopsies of various podocytopathies. However, LRP1 does not colocalize with the podocyte marker nephrin in human tissue.

Conclusions: LRP1 is a highly expressed endocytic receptor in cultured podocytes. Aberrant LRP1 function caused by siRNA KD or pharmacological inhibition resulted in disarrangement of podocyte shape, implicating a crucial role in adhesion and cytoskeletal regulation *in vitro*. Colocalization and immunoprecipitation with ITB1 suggests involvement in integrin trafficking. The importance of LRP1 for kidney function is corroborated by our zebrafish experiments where Lrp1 silencing led to a renal phenotype. Since glomerular LRP1 expression is increased in proteinuric diseases, it could function as a mediating or compensating factor in glomerular injury. However, its absence from podocytes *in vivo* makes its function for podocytes outside of the culture environment unclear. Our findings thus exemplify the difference in podocyte adhesion regulation between podocytes *in vitro* and *in vivo.*

Dach1 Is Essential for Maintaining Normal Podocytes

Keiko Tanaka,[1] Taiji Matsusaka.[2] *[1]Okayama Daigaku Daigakuin Ishiyakugaku Sogo Kenkyuka, Okayama, Japan; [2]Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan.*

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We aimed to elucidate the function of Dach1 in podocytes *in vivo*.

Methods: Because *Dach1* null mice die shortly after birth, kidneys were harvested at P0 and histologically examined. To study the role of Dach1 in mature podocytes, podocyte-specific *Dach1* deleted mice were generated by mating *Dach1*$^{fl/fl}$ mice with *Nphs1*-Cre or *Nphs2*-CreERT2 mice. Eleven *Nphs1*-Cre/*Dach1*$^{fl/fl}$ mice were analyzed at 8-35 weeks of age. 14 *Nphs2*-CreERT2/*Dach1*$^{fl/fl}$ mice were treated with tamoxifen (0.1mg/g BW/day, p.o. 5 days 3 courses) and analyzed 7 days later.

Results: In neonatal wild-type mice, Dach1 is faintly expressed in the cap mesenchyme and increased in the renal vesicles/S-shaped bodies and further intensified and concentrated in mature podocytes. Dach1 is also intensely expressed in the ureteric bud. In *Dach1* null mice, negative Dach1 staining was confirmed. Kidneys of *Dach1* null mice were 14.2 % smaller than those of control mice but showed normal structure. Podocytes in *Dach1* null mice showed normal phenotypes in SEM and TEM with normal slit membrane, and no abnormal leakage of albumin. Immunostaining for WT1, nephrin, podocin, synaptopodin and nestin was normal. Only a small number of podocytes lacked Dach1 staining in *Nphs1*-Cre/*Dach1*$^{fl/fl}$ and *Nphs2*-CreERT2/*Dach1*$^{fl/fl}$ mice, indicating inefficient Cre-mediated recombination. Nevertheless, all *Nphs1*-Cre/*Dach1*$^{fl/fl}$ exhibited abnormal albuminuria (UACR 4.7±1.6 mg/mg vs 0.06±0.007), which increased with age, and seven (63%) mice showed FSGS. Seven (50%) *Nphs2*-CreERT2/*Dach1*$^{fl/fl}$ mice exhibited abnormal albuminuria, and three (21%) mice showed early sclerotic lesions. Immunostaining showed that sclerotic lesions lacked Dach1 as well as WT1, synaptopodin and nephrin. Most of Dach1 negative podocytes in non-sclerotic glomeruli had normal staining for podocyte marker proteins.

Conclusions: These results indicate that Dach1 does not determine the fate of differentiation into podocytes but is indispensable for maintaining normal integrity of mature podocytes.

Funding: Government Support - Non-U.S.

PO1700

TAZ Is Important for Structural and Functional Integrity of Podocytes

Jianchun Chen, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Podocyte is an important component of glomerular filtration barrier (GFB). Maintenance of integrity of slit-diaphragm(SD) structure is critical for normal kidney function. Podocytes lost most epithelial cell tight junction components except for Zonula occludens-1 and -2 (ZO-1 and ZO-2). In podocytes, ZO-1 is an important binding partner of Neph1, and mice with podocyte-specific ZO-1 deletion showed significant growth retardation and severe proteinuria starting at 2 weeks of age, but the regulation of ZO-1 expression in podocytes are not clear. TAZ (transcriptional coactivator with PDZ-binding motif) and its paralog Yes-associated protein (YAP) are two crucial effectors of Hippo signaling pathway. Recent study has shown that podocyte-specific YAP deletion causes FSGS and progressive renal failure, but the potential role of TAZ in podocytes has not been studied.

Methods: Mice with podocyte-TAZ deletion (TAZ^{podKO}) were generated by crossing TAZ$^{flox/flox}$ mice with podocin-Cre recombinase transgenic mice. Urinary albumin excretion and kidney histology and podocyte number per glomerulus were evaluated in TAZ^{podKO} and WT mice. Immunoblotting analysis of isolated glomerulus lysates of TAZ^{podKO} or TAZ^{podWT} mice were performed. In primary cultured mouse podocytes and immortalized mouse podocytes cell morphology and cell lysates were evaluated after silencing TAZ with specific siRNAs.

Results: 41.7% of TAZ^{podKO} mice develop mild proteinuria at age of 3-4 weeks (n=36), with a urine albumin/creatinine ratio of 89.57 ± 12.67 vs 27.86 ± 1.55 (μg/mg, n=7). At 9 weeks of age, compared to TAZ^{podWT} mice, the glomeruli of TAZ^{podKO} mouse kidney had focal sclerosis and significant podocyte loss (WT1+ cells: 13.23 ± 0.699 vs. 17.85 ± 0.608 (n=13). Expression of Bcl2, ZO-1, ZO-2 and synaptopodin were decreased, but expression of cleaved-caspase 3 in the isolated glomeruli from TAZ^{podKO} mice compared with TAZ^{podWT} mice. In cultured podocytes, silencing TAZ by siRNA altered cell morphology and F-actin distribution, and downregulation of Bcl2, ZO-1, ZO-2 and synaptopodin expression and up-regulation of cleaved-caspase 3 expression.

Conclusions: This study demonstrates that TAZ expression plays an important role in regulating podocyte structural protein expression, which cannot be compensated by its paralogue YAP.

PO1701

Neurexin1α Containing Splice Site 4 Interacts with Nephrin and Contributes to Maintenance of the Integrity of Podocyte Slit Diaphragm

Yoshiyasu Fukusumi, Hidenori Yasuda, Ying Zhang, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Neurexins (NRXNs) are synaptic cell adhesion molecules having essential roles in the assembly and maturation of synapses. It is known that NRXN1α contains 6 splicing sites (SS)s, and multiple splicing variants were diffusely expressed in neuronal tissues. We have previously reported that NRXN1α is expressed at slit diaphragm (SD), a cell-cell junction of podocyte, and is downregulated in injured podocytes. The report also showed that NRXN1α expressed in podocytes is a unique variant containing SS1, 3, 4, and 5, which is a rare variant in neural tissues (Am J Physiol, 300:R340, 2011). However, the role of NRXN1α at SD is not well understood yet.

Methods: The interaction of NRXN1α with SD-associated molecules was analyzed by the immunoprecipitation (IP) assay. The function and structure of SD of NRXN1α KO mice were precisely analyzed.

Results: The interaction of NRXN1α with SD molecules such as nephrin and ephrin-B1 was detected by the IP assay with rat glomerular lysates. IP assay with the HEK cell expression systems showed NRXN1α containing SS4 interacted with nephrin, but NRXN1α lacking SS4 did not. The interaction between NRXN1α and nephrin was dissociated, if nephrin was phosphorylated. The interaction of NRXN1α with ephrin-B1 was not detected in the HEK system, suggesting NRXN1α interacts with ephrin-B1 via nephrin. Abnormal proteinuria (92.1 mg/day vs. 23.8 mg/day, $p<0.05$) and clear alterations in the expression of major SD components including nephrin, ephrin-B1 and podocin were detected at the age of 20 weeks of NRXN1α KO mice (IF score; nephrin, 2.68 vs. 3.83, $p<0.05$: ephrin-B1, 2.68 vs. 3.84, $p<0.05$: podocin, 2.78 vs. 3.58, $p<0.05$), although these alterations were not detected at the age of 10 weeks. The phenotypes of the KO mice suggest NRXN1α does not play a major role for formation of SD but contributes to the maintenance of the integrity of SD at an elderly age.

Conclusions: Neurexin1α containing SS4 interacts with nephrin, and is a novel SD component. NRXN1α contributes to maintenance of the function and the molecular integrity of SD. It is conceivable that downregulation of NRXN1α participates in the development of podocyte injury onset at an elderly age.

Possible Role of the Cytosolic RNase Inhibitor in Maintaining the Integrity of the Glomerular Filtration Barrier

Patricia Bolanos-Palmieri, Franz Tiefenböck, Mario Schiffer. *Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.*

Background: The ribonuclease inhibitor (RI) is a cytoplasmic protein encoded by the *RNH1* gene. The RI forms a tight non-covalent bond with members of the RNaseA superfamily and therefore it's considered that its main function is to act as a sentinel for dysregulated RNases. The ratio of RI to substrate has also been shown to vary according to the proliferative and metabolic status of the cell suggesting that the balance in the protein-protein interactions between the RI and its substrates plays a role in maintaining cell homeostasis by impacting processes such as protein synthesis and various signaling pathways. However, the entirety of the biological roles fulfilled by the RI are yet to be described.

Methods: Immunofluorescence staining of human kidney tissue and protein detection by western blot from samples of immortalized podocytes were carried out to confirm the presence of the RI in glomerular cells. As an initial injury model, podocytes were treated with PAN to determine if changes in RI expression occur as a response. RNH1 inhibition was performed in a transgenic zebrafish line that allows for the detection of proteinuria via a GFP-tagged protein in the circulation. At 96hpf the severity of the edema phenotype and the fluorescence levels were recorded.

Results: Our preliminary data shows that the RI is present in human podocytes both in vitro and in vivo, as its expression domain coincides with glomerular cells labelled with synaptopodin. Additionally, the RI is present in cultured podocytes both before and after the temperature shift used to induce quiescence, and it appears to increase after differentiation. There is also expression modulation of RNH1 in response to PAN treatment of podocytes. In our zebrafish model, RNH1 knockdown resulted in up to a 40% increase in mild to severe edema and over 30% decrease in fluorescence suggesting that a reduction in RI might compromise the filtration barrier enough to lead to proteinuria.

Conclusions: Taken together our initial data show a promising avenue for research where the balance between members of the RNaseA superfamily and their cytoplasmic inhibitor may represent a powerful mechanism that allows the cells to modulate the proteome in response to stimuli. An imbalance in this relationship might ultimately affect the integrity of the cells in the kidney.

PO1703

Atypical Caspase 3-Dependent Death in Podocytes

Kazuyoshi Yamamoto,[1,2] Masahiro Okabe,[1,2] Taiji Matsusaka,[2] Takashi Yokoo.[1] *[1]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; [2]Tokai Daigaku, Hiratsuka, Japan.*

Background: Apoptosis of podocytes has been widely reported in many *in vitro* studies, but definitive apoptosis has never been documented *in vivo* podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes *in vitro* and *in vivo*.

Methods: Primary mouse podocytes were transiently transfected with hCD25 and EGFP expression plasmids and treated with a hCD25-targeting immunotoxin, LMB2 (1nM), and observed 1 day later. In some experiments, the cultured podocytes were transfected with Bak1 or Bax siRNA before treatment with LMB2. In *in vivo* experiments, podocyte injury was induced by injecting LMB2 (1.25ng/gBW) into NEP25 mice, which express hCD25 in podocytes, and analyzed 7 days later.

Results: In *in vitro* studies, administration of LMB2 caused loss of co-introduced EGFP in 56.8±13.6%, incorporation of propidium iodide in 13.6±2.5%, activation of caspase 3 (Casp3) in 19.6±2.6% and TUNEL staining in 4.5±1.3% without significant increase in LDH activity in the culture medium. These phenomena were not observed in cells without hCD25 or without LMB2. Ac-DEVD-CHO (10μM), a Casp3 inhibitor, attenuated the loss of EGFP by 38.2%. Inhibition of Bak1 and Bax using siRNAs attenuated EGFP loss by 77.6% and 28.4%, respectively. These indicate that LMB2 induced the typical Casp3 dependent intrinsic apoptosis in podocytes *in vitro*. In *in vivo* studies, kidneys of NEP25 mice contained podocytes positive for cleaved (c) Casp3 and those for cLaminA, a product of Casp3, but no TUNEL+ podocytes. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. The urinary sediments contained podocalyxin-positive podocytes (2.5±0.3/μl). Among these, 39.1±3.7% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. To evaluate the effect of glomerular filtration, NEP25 mice were similarly injected with LMB2 and subjected to UUO 1 day before sacrifice. The obstructed kidney contained significantly more cLaminA+ podocytes than the contralateral kidney. In addition, detaching podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: Thus, due to physical force of glomerular filtration, podocytes doomed to Casp3 dependent death are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. This accounts for the absence of podocyte apoptosis *in vivo*.

PO1704

Mice Deficient in Aminopeptidase A Have Worse Glomerular Injury in Response to Chronic Renal Mass Reduction

Wayne R. Fitzgibbon,[1] Ehtesham Arif,[1] Peifeng Deng,[1] Joshua H. Lipschutz,[1,2] Yusuke Okabayashi,[3] Victor G. Puelles,[3] Jan Wysocki,[4] Daniel Batlle,[4] Juan Carlos Q. Velez.[5] *[1]Medical University of South Carolina, Charleston, SC; [2]VA Medical Center Ralph H Johnson, Charleston, SC; [3]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [4]Northwestern University, Evanston, IL; [5]The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.*

Background: Aminopeptidase A (APA) is a membrane-bound metalloproteinase expressed in podocytes and tubular epithelia. It is a key enzyme in metabolizing angiotensin (Ang) II and diverting Ang I from the formation of Ang II. A recent finding suggests that APA also plays a role in the maintenance of glomerular structure. We have previously shown that global deficiency in APA augmented albuminuria in the early phase of remnant nephropathy. We sought to determine the effect of APA deficiency in a later phase of remnant nephropathy.

Methods: We measured urinary albumin (Alb) and creatinine (Cr) excretion, podocyte morphology and kidney histopathology in 129Sv/C57Bl6 wild type (WT, n=6) and APAKO mice (n=6) subjected to renal mass reduction. Twenty-four hour (24h) urine collections were obtained prior to, and then 2, 4, 6 and 8 weeks following 5/6 nephrectomy. Podocyte density was assessed by immunofluorescence utilizing synaptopodin and Dachshund Family Transcription Factor 1 as podocyte markers.

Results: Baseline median UAlbV was 15 (13-24) and 16 (11-46) μg/24 for the WT and APA mice respectively. Renal mass reduction induced albuminuria in both groups at 2 weeks. However, 24h albumin excretion (UAlbV) was markedly higher for the APAKO compared to the WT mice at all time points post 5/6 nephrectomy ($p = 0.0035$). Median UAlbV at 8 weeks was 104 (33-536) and 1556 (1154-3890) μg/24 ($p=0.0159$) for the WT and APAKO mice. Similar findings were observed when albumin levels were expressed as urine Alb/Cr. The percentage of glomeruli with segmental or global hyalinosis/sclerosis was greater for APAKO mice compared to the WT (36% vs. 4%, $p<0.01$). Further, APAKO mice had a higher level of glomerular collapse (32% vs. 2%, $p<0.005$), parietal epithelial hyperplasia (pseudo-crescents) (28% vs. 2%, $p<0.01$), and a greater degree of tubular injury and microcystic tubular dilatation (45% vs. 5%, $p<0.01$). Affected glomeruli from APAKO mice showed a marked decrease in podocyte number ($p<0.01$). Among glomeruli with preserved architecture, podocyte size was reduced in APAKO mice ($p<0.001$). Neither BUN nor plasma Ang II levels were different between the 2 groups at 8 weeks.

Conclusions: Our findings further support a role for APA in attenuating glomerular injury following 5/6 renal ablation.

Glomerular Endothelial Cell-Derived MicroRNA-192 Regulates Podocyte Nephronectin in Membranous Glomerulonephritis

Janina Müller-Deile, Nina Sopel, Victoria Rose, Christoph Daniel, Kerstin U. Amann, Mario Schiffer. *Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany.*

Background: Autoantibodies binding to podocyte antigens cause idiopathic membranous glomerulonephritis (iMGN). It remains elusive how autoantibodies reach the subepithelial space because the glomerular filtration barrier (GFB) is normally size-selective and impermeable for antibodies.

Methods: Kidney biopsies from patients with iMGN, cell culture, zebrafish and mice models were used to investigate the role of nephronectin (NPNT) regulating microRNAs (miRs) for the GFB.

Results: Glomerular endothelial cell (GEC)-derived miR-192-5p and podocyte-derived miR-378a-3p are upregulated in glomeruli of patients with iMGN whereas NPNT expression is reduced. Overexpression miR-192-5p as well as morpholino-mediated npnt knockdown induced edema, proteinuria and podocyte effacement similar to podocyte-derived miR-378a-3p in zebrafish. Moreover, structural changes of the glomerular basement membrane (GBM) with increased lucidity, slicing and lamellation especially of the lamina rara interna similar to ultrastructural findings seen in advanced stages of iMGN were found (Fig. 1). IgG size nanoparticles accumulated in lucidity areas of the lamina rara interna and lamina densa of the GBM in npnt knockdown zebrafish models. Loss of slit diaphragm proteins and severe structural impairment of the GBM were further confirmed in podocyte-specific Npnt knockout mice. GECs downregulate podocyte NPNT by secretion of miR-192-5p containing exosomes in a paracrine manner.

Conclusions: Podocyte NPNT is important for proper GFB function and GBM structure and is regulated by GEC-derived miR-192-5p and podocyte-derived miR-378a-3p. We hypothesize that loss of NPNT in the GBM is part of the pathophysiology of iMGN and enables subepithelial immune complex deposition in iMGN.

PO1706

Identification of the Mechanism Underlying the Toxicity of Systemically Administered miR-145-5p on Podocytes Based on Podocyte Essential Genes

Zhang Sipan, Junnan Wu, Xiaodong Zhu, Hui Song, Lu Ren, Qiaoli Tang, Xu Xiaodong, Jiong Zhang, Weixin Hu, Zhihong Liu, Shaolin Shi. *Jinling Hospital National Clinical Research Center for Kidney Diseases, Nanjing, China*.

Background: MicroRNAs are emerging as effective therapeutic agents. MiR-145-5p dysregulation has been shown to be involved in kidney injury. To determine whether supplement of miR-145-5p would alleviate kidney injury in mouse models, we first tested the miR-145-5p enriched extracellular vesicles (miR-145-5p EVs) sample for toxicity or side effects on healthy control mice.

Methods: miR-145-5p EVs were injected to mice intravenously every day for a total of 6 days. A group of mice were simultaneously injected with miR-145-5p inhibitor using TransIT®-EE Delivery Solution. Cultured cells were transfected with RNAiMAX or Fugene.

Results: miR-145-5p EVs resulted in proteinuria and podocyte foot process effacement in normal control mice, and this effect was abolished by miR-145-5p inhibitor. We demonstrated that systemically administered miRNA can enter podocytes. miR-145-5p EVs could enter cultured podocytes and cause F-actin loss. miR-145-5p mimic caused a similar reduction of F-actin in the cells. We speculated that miR-145-5p is toxic to podocytes because it is not normally expressed in podocytes and exogenous miR-145-5p can effectively target genes essential for podocytes. By using the concept that genes commonly expressed in all individual podocytes are likely podocyte essential genes, we predicted 611 podocyte essential genes when expression cutoff was set as > 0.1 RPKM. We found that 32 of them are predicted to be targeted by miR-145-5p. Functional annotation of the 32 genes revealed small GTPase mediated signal transduction as the top function. Among genes associated with the small GTPases pathway, Arhgap24 is known to cause podocyte injury and regulate Rac1/Cdc42 activities, and we found miR-145-5p significantly repressed Arhgap24 expression in podocytes *in vivo* and *in vitro*. miR-145-5p- increased activity of both Rac1 and Cdc42.

Conclusions: MiR-145-5p induced podocyte injury through targeting podocyte essential genes associated with small GTPase mediated pathway. Our study provides a novel approach to investigate how a miRNA affects a given cell type, allowing not only identification of the molecular mechanism underlying an observed side effect of a miRNA drug but also prediction of miRNA drug toxicity on various cell types.

Glomerular mRNAs Are Alternatively Spliced and Polyadenylated During Podocyte Injury in Animal Models of Nephrotic Syndrome

Claire Burton,[1] Amy Webb,[2] Rachel Cianciolo,[2] Claire L. Moore,[3] Shipra Agrawal.[1,2] *[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]Tufts University School of Medicine, Boston, MA.*

Background: Glomerular disease, often manifesting as nephrotic syndrome (NS) with high proteinuria, is characterized by podocyte loss and injury. Furthermore, alternative mRNA processing, such as alternative splicing (AS) and alternative polyadenylation (APA) play important roles in physiology, development, and disease; however, there is very limited knowledge of their roles in glomerular disease. We hypothesized that AS and APA events of glomerular RNAs is associated with podocyte injury and proteinuria in NS.

Methods: Glomerular damage characterized by proteinuria was induced by puromycin aminonucleoside (PAN) or adriamycin (ADR) to mimic human minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS), respectively. Urine and serum chemistries, kidney histology and glomerular RNA-seq analyses were performed. APATrap and JunctionSeq bioinformatics analyses software were used to detect APA and AS glomerular events. Correlation of differentially expressed genes (DEGs) was performed with known glomerular disease genes and polyadenylation and splicing factors.

Results: Robust proteinuria was induced in both PAN-MCD and ADR-FSGS models, accompanied by hypoalbuminemia, hypercholesterolemia and histological alterations in the kidneys (protein casts and podocyte hypertrophy). Out of 13,265 genes, MCD model resulted in 1033 and FSGS model in 1308 glomerular DEGs with abs(log2FC)>1 and P_{adj}<0.05. Of 80 analyzed genes with established roles in glomerular disease, 30 were altered in both MCD and FSGS. Significant APA was identified in 71 and 746 genes in MCD and FSGS nephrosis, respectively, and of 173 polyadenylation factors analyzed, 21 were altered in MCD and 24 in FSGS. Significant AS was identified in 136 and 1875 genes in MCD and FSGS models, respectively. In accordance, of 50 splicing factors analyzed, 3 were altered in MCD and 5 in FSGS. Specifically, the identified APA and AS events affected genes of the slit diaphragm complex such as *Nphs1, Nphs2, and Tjp1,* which are critical determinants of podocyte structure and function.

Conclusions: Association of global glomerular mRNA alteration due to AS and APA with podocyte and glomerular injury is a newly recognized phenomenon, with potential implications for therapy and molecular understanding of the disease.

PO1708

Continuous Non-Mutagenic DNA Damage in Podocytes Activates Inflammatory Response and May Accelerate Kidney Aging

Ran Nakamichi, Akihito Hishikawa, Kaori Hayashi, Hiroshi Itoh. *Keio University School of Medicine Department of Internal Medicine, Tokyo, Japan*.

Background: Podocytes are suggested to contribute to kidney aging because of their terminally differentiated features. We have previously reported the association of KAT5-mediated DNA damage repair with altered DNA methylation in podocytes (Cell Rep 2019). However, the role of podocyte DNA damage itself on DNA methylation changes and kidney aging has remained to be adequately elucidated.

Methods: To investigate the significance of DNA double-strand breaks (DSBs) in podocytes, we generated podocyte-specific I-PpoI-expressing mice (podocin-Cre ROSA26-STOP- I-PpoI). I-PpoI is a homing endonuclease which causes non-mutagenic DSBs. RNA-seq and MeDIP-seq analysis were performed using isolated podocytes in I-PpoI mice and wildtype controls.

Results: I-PpoI mice showed severe albuminuria (WT 43±34.4 mg/gCr, Ip-Po1 2224±7.3 mg/gCr, p<0.01) with diffuse foot process effacement in podocytes but glomerulosclerosis and interstitial fibrosis were not observed at 12 weeks of age. Interestingly, infiltration of CD11b-positive cells was shown in I-PpoI mice, which is a similar finding in 2-year-old aged mice. The aged mice showed increased DNA damage and DNA methylation. In I-PpoI mice, rapid deterioration of renal function with glomerulosclerosis and tubulointerstitial fibrosis developed around the age of 20 weeks. RNA-seq analysis revealed that inflammatory-related genes were upregulated in podocytes of I-PpoI mice. Senescent-associated secretory phenotype (SASP)-related gene expression was also increased. MeDIP-seq analysis revealed that 5219 differentially methylated regions (DMRs) were identified in I-PpoI mice compared with controls. Interestingly, there was no significant correlation between the distance from the I-PpoI cutting site and DMRs. DNA methylation was increased in genes containing I-PpoI cutting sites or podocyte epithelial genes such as nephrin and podocin, whereas it was decreased in inflammatory related genes, suggesting gene-specific DNA methylation changes following DNA damage.

Conclusions: The phenotype of the I-PpoI mice may reflect one aspect of accelerated kidney aging. Repeated DNA damage repair in podocytes may cause altered DNA methylation independent of primary DNA damaged sites with promoted inflammation and podocyte morphological changes.

PO1709

Deletion of MCP-1 in Podocytes Does Not Protect Against Glomerular Injury

Corry D. Bondi, Brittney M. Rush, Roderick J. Tan. *University of Pittsburgh Department of Medicine, Pittsburgh, PA.*

Background: Over the past three decades, the global burden of chronic kidney disease (CKD) has nearly doubled straining healthcare budgets. Understanding the role of podocytes in the pathophysiology of proteinuric disease is important for development of novel treatments. Prior studies implicate monocyte chemoattractant protein-1 (MCP-1) in podocyte injury, but the source of MCP-1 has not been definitely identified. Both MCP-1 and its cognate receptor, CCR2, are expressed in podocytes. Therefore, using podocyte-specific MCP-1 knockout mice (PODO-MCP-1$^{-/-}$), we evaluated whether autocrine MCP-1 signaling by podocytes contributes to proteinuric CKD.

Methods: PODO-MCP-1$^{-/-}$ mice were generated by crossing MCP-1 floxed mice with mice harboring Cre recombinase under the control of the podocin promoter. Knockout mice and wild-type littermates were subjected to angiotensin II by osmotic minipumps (Ang II; 1.5mg/kg/day) for 28 days. Weekly spot urines were collected, assessed with ELISA for albuminuria, and results normalized to urinary creatinine. After 28 days, kidneys were harvested and histologic, immunofluorescent, immunoblot, and quantitative PCR analyses were performed. Results are reported as mean ± S.E.M. Threshold for significance was P<.05.

Results: There were no baseline differences in bodyweight, histology, and urinary albumin levels between the two groups. Following 28 days of Ang II infusion, histologic analysis revealed renal pathology particularly glomerulosclerosis. There were no significant differences in bodyweight, albuminuria, renal function, expression of nephrin and WT1, and number of podocytes. *Ccr2* gene expression also revealed no significant difference.

Conclusions: Our results demonstrate that podocyte-specific MCP-1 production is not a major contributor to Ang II-induced glomerular injury as demonstrated by lack of protection in the podocyte-specific MCP-1 knockout mice. Future studies will evaluate other sources of MCP-1 that may impact disease.

Delayed Treatment with a Novel Highly Selective Small-Molecule Agonist of MC5R Attenuates Podocyte Injury and Proteinuria in Puromycin Aminonucleoside Nephrosis

Bohan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. *University of Toledo College of Medicine and Life Sciences, Toledo, OH.*

Background: Clinical studies indicate that the melanocortin peptide ACTH is effective in inducing remission of nephrotic glomerulopathies like MCD and FSGS, even those resistant to steroids, suggesting that a steroid-independent melancortinergic mechanism might contribute. However, the type of melanocortin receptor (MCR) that conveys this beneficial effect as well as the underlying mechanisms remains controversial. Recently, burgeoning evidence suggests that MC5R is likely involved in glomerular pathobiology. This study aims to test the effectiveness of a novel highly selective MC5R agonist (MC5RA) in puromycin aminonucleoside (PAN) nephrosis.

Methods: MC5RA was generated by N-terminal modification of the melanocortin core tetrapeptide His-D-Phe-Arg-Trp-NH2 with an aromatic group, resulting in a triphenylpropionyl melanocortin analog with a 100-fold selective agonistic activity on MC5R. Rats were injured with a tail vein injection of PAN, and 5 days later, were randomized to daily MC5RA or vehicle treatment.

Results: Upon PAN injury, rats developed heavy proteinuria on day 5, entailing an established nephrotic glomerulopathy. Following vehicle treatment, proteinuria continued to progress on day 14 and was sustained till day 21, accompanied by evident histologic signs of podocytopathy, marked by ultrastructural lesions of glomeruli, including extensive effacement of podocyte foot processes and podocyte microvillus transformation, and concomitant with loss of podocyte homeostatic markers, such as synaptopodin and nephrin, and *de novo* expression of podocyte injury marker desmin. Rescue treatment with MC5RA significantly attenuated urine albumin excretion and mitigated the loss of podocyte marker proteins, resulting in improved podocyte ultrastructural changes. *In vitro* in cultured podocytes, MC5RA prevented the PAN-induced disruption of actin cytoskeleton integrity and apoptosis. Mechanistically, MC5RA treatment reinstated inhibitory phosphorylation and thus averted hyperactivity of GSK3β, a convergent point of multiple podocytopathic pathways, in PAN-injured podocytes *in vitro* and *in vivo*.

Conclusions: Pharmacologic targeting of MC5R by using the highly selective small-molecule agonist is likely a promising and feasible therapeutic strategy to improve proteinuria and podocyte injury in glomerular disease.

Tadalafil, a PDE5 inhibitor, Exhibits Renoprotective Effects Preventing Podocyte Damage in an Adriamycin-Induced Nephrotic Syndrome Model

Natsumi Tomita,[1] Yuji Hotta,[1] Aya Naiki-Ito,[2] Tomoya Kataoka,[3] Satoru Takahashi,[2] Kazunori Kimura.[1,3] *[1]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [3]Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.*

Background: Phosphodiesterase (PDE)-5 inhibitor is reportedly a renoprotective compound. Although PDE5 expression is confirmed in the glomeruli, its relationship with renal dysfunction remains elusive. We have previously investigated the renoprotective effects of tadalafil in a CKD model (Tomita N, et al. *Physiol Rep.* 2020), suggesting that such an effect would be related to podocyte damage attenuation. In this study, we investigated how tadalafil, a PDE5 inhibitor, could affect a rat nephrotic syndrome model.

Methods: Wistar ST rats were established as nephrotic syndrome models by administrating adriamycin (ADR) injection. The animals were divided into 3 groups: control (n = 6), ADR (n = 5), and ADR + tadalafil (n = 5). Tadalafil was administered 10 mg/kg daily. After 2 weeks of treatment, the urinary protein and serum albumin levels were evaluated, and the kidney tissue was harvested. WT1-positive cells were identified as podocytes by WT1 immunostaining. Moreover, human renal glomerular epithelial cell damage was induced *in vitro* by ADR supplementation. After 24 h of ADR treatment with or without tadalafil, cell viability was determined using CCK-8.

Results: The ADR injection induced high urinary protein and low serum albumin levels. Two weeks of tadalafil treatment attenuated proteinuria compared to the ADR group ($P<0.01$). ADR reduced the WT1-positive cell number and the tadalafil treatment prevented the reduction ($P<0.05$). Moreover, the ADR treatment resulted in reduced cell viability *in vitro*. The tadalafil treatment improved cell viability compared to the ADR treatment only ($P<0.05$).

Conclusions: This study suggests that the treatment with tadalafil, a PDE5 inhibitor, could effectively prevent podocyte damage in the case of nephrotic syndrome.

PO1712

Targeting mTOR Signaling Improved Kidney Function in APOL1 Risk Variant Mice with Chronic Exposure to Inflammatory Stimuli

Shrijal Shah, Calum Tattersfield, David Demeritt, Olivia Donovan, Lena B. Schaller, Gizelle Mccarthy, Martin R. Pollak, David J. Friedman. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Inheriting two copies of APOL1 risk variants significantly increases the likelihood of developing chronic kidney disease in African Americans. Many different mechanisms of disease have been proposed using cell-based model systems. Here we try to understand risk variant pathophysiology using a transgenic mouse model.

Methods: Transgenic mice with a single copy of human APOL1 G0 and G2 were generated using bacterial artificial chromosome (BAC) on a FVB background. Mice were injected with interferon gamma (IFN-g) plasmid via hydrodynamic tail vein injections to induce APOL1 expression. Since mTOR activation has been frequently observed in podocytes during FSGS, we blocked the pathway using rapamycin to see if it could improve disease outcomes. Mice were injected with 2mg/kg of rapamycin every other day (3 days/week, intraperitoneally) for a total of 2 weeks. Paraffin embedded tissue sections were used for immunohistochemistry and Periodic acid–Schiff (PAS) staining. Glomerular isolations were performed using Dynabeads. APOL1 oligomerization was assessed using blue native PAGE.

Results: 7 Days after IFN-g plasmid injection, the podocytes of G2 mice stained positive for phospho-S6 ribosomal protein indicating mTOR activation accompanied by proteinuria. Blocking mTOR activation using rapamycin reversed ribosomal protein S6 phosphorylation, reduced proteinuria, and improved tissue histology as seen by PAS staining. We hypothesized that rapamycin might be activating autophagy and clearing APOL1 oligomers, but found no evidence for this mechanism of rescue. Instead, we were able to replicate the rescue we had observed with rapamycin using a cell cycle inhibitor, suggesting that rapamycin might be rescuing G2 phenotype by inhibiting podocyte cell cycle entry downstream of risk variant mediated injury.

Conclusions: Persistent expression of APOL1 risk variants pushes podocytes into cell cycle entry. Inhibiting mTOR signaling and subsequent cell cycle entry alleviated injury.

Plin5 Deficiency in Podocyte Negatively Affects the Communication Between Lipid Droplets and Mitochondria in Alport Syndrome

Jin Ju Kim,[1] Sydney S. Wilbon,[4] Judith T. Molina David,[1] Hazel H. Szeto,[3] Jeffrey H. Miner,[2] Flavia Fontanesi,[1] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Washington University in St Louis, St Louis, MO; [3]Social Profit Network, Melno Park, CA; [4]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. We and others have demonstrated pathogenic renal lipid droplets (LD) and triglyceride (TG) accumulation in experimental AS (Col4a3KO mice). Excessive FFA catabolism resulting from excessive lipolysis of TG is a major contributor to cell lipotoxicity. Perilipin 5 (PLIN5) is an LD-related protein that plays a critical role in regulating TG lipase activity and the interactions between LD and mitochondria, where it protects mitochondria from excessive exposure to FFA. Here we test the hypothesis that PLIN5 is expressed in podocytes and that PLIN5 deficiency in AS causes excessive TG breakdown and the loss of LD-mitochondrial contact, thus contributing to kidney failure.

Methods: *In vitro*, Immortalized AS podocytes and WT podocytes were established and characterized in our laboratory by breeding the Col4a3KO mice (Jackson Laboratory) to H-2kb-tsA58 transgenic mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in AS podocytes and kidney cortex in AS mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. LD-Mitochondrial contact was determined by TEM analysis.

Results: PLIN5 deficiency was observed in the kidney cortex of Col4a3KO mice when compared to controls ($p<0.001$). We demonstrate that PLIN5 is expressed in podocytes, and the expression of PLIN5 is significantly decreased in AS podocytes compared to WT podocytes ($p<0.01$). AS podocytes also showed significantly increased rates of TG lipolysis ($p<0.05$), intracellular free fatty acids ($p<0.05$) and apoptosis ($p<0.01$) when compared to WT podocytes. AS podocytes had reduced number of LD-mitochondrial contacts ($P<0.05$), implying that and apoptosis. Moreover, Ezetimibe, which restored LD-Mitochondrial contact *in vitro* ($P<0.05$) and improved kidney function *in vivo*, was found to restore PLIN5 expression *in vitro* and *in vivo (P<0.05)*.

Conclusions: Our study suggests that podocyte PLIN5 deficiency may cause podocyte injury in AS through excessive TG lipolysis and inefficient FA transfer from LD to Mitochondria, leading to mitochondrial dysfunction and contributing to disease progression.

PO1714

UCP2 Regulates Mitochondrial Dynamics and Podocyte Injury by OMA1-Dependent Proteolytic Processing of OPA1

Qianqian Yang, Lingling Xu, Yang Zhou, Lei Jiang, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Podocyte injury and loss are pivotal events in the progression of glomerular diseases, such as diabetic kidney disease (DKD) and focal segmental glomerulosclerosis (FSGS). Disordered mitochondrial dynamics leads to mitochondrial dysfunction, which is extensively involved in podocyte injury. The mitochondrial inner membrane uncoupling protein, UCP2, is involved in the regulation of mitochondrial dynamics, but the specific mechanism is unknown.

Methods: The function and structure of podocyte were detected by electron microscopy, immunofluorescent staining, PAS staining, and urinary albumin. A Seahorse Bioscience XF24 Extracellular Flux Analyzer was used to measure dissolved oxygen in culture medium around adherent cells. Mitochondrial membrane potential was detected using TMRM dye. The content of ATP in cells of each well was determined with an ATP Assay Kit.

Results: We reported that the mitochondrial inner membrane UCP2 expression in podocyte was corelated with proteinuria level in patients. Mice with podocyte-specific *Ucp2* deficiency developed podocytopathy with proteinuria with aging. Furthermore, those mice exhibited increased proteinuria in experimental models evoked by diabetes or adriamycin. Our findings suggest that UCP2 mediates mitochondrial dysfunction by regulating mitochondrial dynamic balance. *Ucp2* deleted podocyte exhibited increased mitochondrial fission and deficient in ATP production. Mechanistically, opacity protein 1 (OPA1), a key protein in fusion of mitochondrial inner membrane, was regulated by UCP2. *Ucp2* deficiency promoted proteolysis of OPA1 by activation OMA1 which belongs to mitochondrial inner membrane zinc metalloprotease. Those finding demonstrate the role of UCP2 in mitochondrial dynamics in podocyte and provide new insights into pathogenesis associated with podocyte injury and proteinuria.

Conclusions: Our findings suggest that UCP2 protects mitochondrial dynamics balance by OMA1-dependent proteolytic processing of OPA1.

L-WNK1 Inhibition Protects from Glomerular Injury in Mice

Cyril Mousseaux,[1,2] Tiffany Migeon,[1,2] Perrine Frère,[1,2] Liliane Louedec,[1,2] Pierre Galichon,[1,2] Juliette Hadchouel.[1,2] *[1]CoRaKID - Inserm UMR_S1155, Paris, France; [2]Sorbonne Universite, Paris, France.*

Background: The With No lysine (K) kinase L-WNK1 plays a key role in the maintenance of cellular homeostasis in response to variations in osmolarity, intracellular chloride concentration or cell volume. We have shown that L-WNK1 activation in the distal nephron results in hypertension. Other studies showed that the inhibition of L-WNK1 could be beneficial in epileptic diseases and to prevent the metastatic process. However, the preclinical study of a L-WNK1 inhibitor was discontinued due to unacceptable side effects. Therefore, L-WNK1 inhibition can be either beneficial or deleterious depending on the pathology and affected tissue. It is necessary to better define the signalling pathways controlled by L-WNK1 in order to develop targeted therapies with limited secondary effects. In that context, we chose to define the roles played by the kinase in the glomerulus, its predominant site of expression within the kidney.

Methods: We used mice carrying an ubiquitous and heterozygous (*L-WNK1*$^{+/-}$) or podocyte-specific homozygous inactivation of L-WNK1 (*NPHS2-Cre;WNK1*$^{lox/lox}$). We characterised their renal function (plasma urea, creatinine, urine albumin/creatinine) and glomerular structure at baseline and in a model of crescentic glomerulonephritis (CGN) induced by the administration of nephrotoxic serum (NTS-CGN).

Results: L-WNK1 inactivation, either global or podocyte-specific, did not impair glomerular function and structure. After induction of NTS-CGN, the renal function of *L-WNK1*$^{+/-}$ mice was improved compared to control ones. We observed a decreased infiltration of macrophages and a lesser stimulation of the expression of fibrotic genes. The same improvement of renal function, associated with a reduced number of glomerular lesions, was observed in *NPHS2-Cre;WNK1*$^{lox/lox}$ mice during NTS-CGN. To uncover the underlying mechanisms, we used the immortalised AB8/13 cell line of human podocytes. Our hypotheses were the stimulation of autophagy, a decreased capacity for proliferation and migration and a reduced stimulation of the TRPC6 calcium channel. We have shown that the pharmacological inhibition of L-WNK1 activity by WNK463 resulted in an increased autophagic flux and a decreased migration/proliferation in a wound-healing assay.

Conclusions: In conclusion L-WNK1 inhibition represents a new target for the protection of the podocytes during CGN.

Protective Role of the Epithelial STAT5 Pathway in Kidney Injury

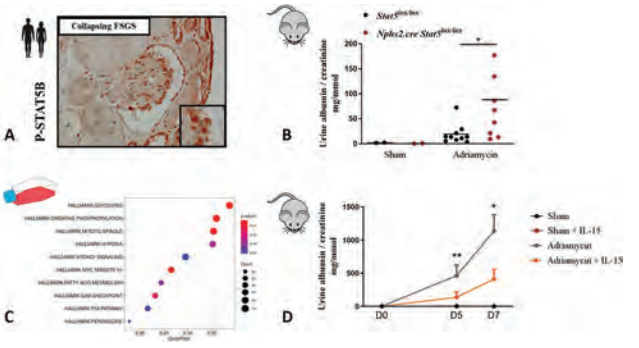
Aïssata Niasse,[1] Kevin Louis,[2] Laurent Mesnard,[3,2] Juliette Hadchouel,[1] Yosu Luque.[3,2] Inserm UMR_S1155 team, Paris, France *[1]INSERM, Paris, France; [2]Assistance Publique - Hopitaux de Paris, Paris, France; [3]Sorbonne Universite, Paris, France.*

Background: During kidney diseases, diverse tissue-specific pathways can regulate kidney injury and prognosis. Thus, therapeutic targeting of these pathways could improve the management and prognosis of chronic kidney diseases. The Janus Kinase/ Signal Transducer and Activator of Transcription (JAK/STAT) pathway, classically described in immune cells, has been recently described in intrinsic kidney cells.

Methods: We 1) analyzed STAT5 activation in kidney biopsies from patients with focal segmental glomerulosclerosis (FSGS) and acute tubular injury (ATI), 2) used experimental models of glomerular and tubular injury in mice with podocyte- or tubular-specific STAT5 deficiency, 3) studied transcriptomic modifications related to *STAT5* deletion in human kidney epithelial cells, 4) explored interleukin-15 mediated STAT5 activation in podocytes and glomerular injury.

Results: Here, we show, for the first time, that STAT5 is activated in both human podocytes (Figure 1A) and tubular cells in FSGS and ATI, respectively. Additionally, STAT5 deficiency in *either* glomerular or tubular epithelium aggravates the functional and structural alterations in a range of experimental models of glomerular (Figure 1B) or tubular disease. STAT5 deficiency in kidney epithelial cells resulted in dysregulation of multiple metabolic pathways, including glycolysis and oxidative phosphorylation (Figure 1C). Interleukin 15 (IL-15), a classical activator of STAT5 in immune cells, increases STAT5 phosphorylation in human podocytes and alleviates glomerular injury *in vivo* (Figure 1D) by activating anti-apoptotic pathways.

Conclusions: In conclusion, activating renal epithelial STAT5 represents a new therapeutic avenue with the potential for a range of beneficial effects in kidney diseases.



A. STAT5B activation in human podocytes in FSGS. B. STAT5 podocyte deficiency aggravates adriamycin-induced proteinuria. C. CRISPR-Cas9 induced deletion of *STAT5B* from human kidney epithelial cells leads to disruption of metabolic pathways. D. IL-15 alleviates adriamycin-induced glomerular injury in mice

PO1717

Shiga Toxin Targets the Podocyte in Haemolytic Uraemic Syndrome (HUS) Resulting in Glomerular Endothelial Cell Complement Dysregulation

Emily E. Bowen, Jenny Hurcombe, Lindsay S. Keir, Fern Barrington, Louise K. Farmer, Abigail C. Lay, Gavin I. Welsh, Eva Larkai, Moin Saleem, Richard Coward. Bristol Renal *University of Bristol Faculty of Health Sciences, Bristol, United Kingdom.*

Background: Haemolytic uraemic syndrome (HUS) is a thrombotic microangiopathy (TMA) that has a predilection to present in the kidney. It is a triad of microangiopathic haemolytic anaemia, thrombocytopenia, and acute kidney injury. In 90% of cases, HUS follows gastroenteritis secondary to infection with Shiga toxin (Stx) producing bacteria such as Escherichia coli. Stx HUS is the leading cause of acute kidney injury in children with a mortality of 5%. However, the precise pathophysiological mechanisms following Stx infection leading to TMA remain poorly understood. Here we show that the podocyte is a key initiator in Shiga toxin HUS, which could explain why the glomerulus is the prime target of systemic Shiga toxin driven infection.

Methods: To demonstrate that the podocyte Shiga toxin receptor (Gb3) is sufficient to trigger the development of HUS, we used conditional gene targeting to engineer human Gb3 expression specifically in the podocytes of adult mice.

Results: Following intraperitoneal Shiga toxin challenge, these mice developed thrombocytopenia, haemolytic anaemia and uraemia (Figure 1) with evidence of glomerular TMA on histology. Interrogation of this model revealed evidence of glomerular endothelial cell complement activation, with loss of local complement factor H protection. Furthermore, C5 inhibition was found to rescue the Shiga toxin HUS phenotype.

Conclusions: Together, these observations provide compelling evidence for the importance of podocyte-glomerular endothelial cell cross-talk within the kidney in the development of Shiga toxin associated HUS and suggest a possible therapeutic role for complement inhibition in patients with this devastating disease.

Funding: Other NIH Support - Charity support - Kidney Research UK

Shiga toxin targets the podocyte in Haemolytic Uraemic Syndrome (HUS) resulting in glomerular endothelial cell complement dysregulation: supporting Figure 1

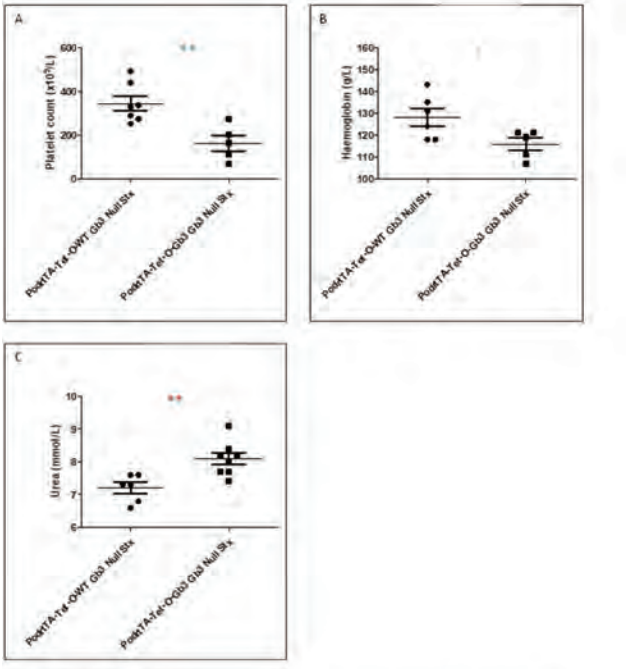


Figure 1: Podocyte Gb3 expressing mice (PodrtTA-Tet-O-Gb3 Gb3 null mice) develop HUS following intraperitoneal Shiga toxin

PodrtTA-Tet-O-Gb3 Gb3 null mice given 10ng/g of IP Shiga toxin show a drop in platelet count (A), drop in haemoglobin (B) and rise in plasma urea (C) vs. age matched control mice (PodrtTA-Tet-O-WT Gb3 null) at Day 10.

These differences were statistically significant A: * Unpaired T test p value 0.004; B: * Unpaired T test p value 0.041; C: **Unpaired T-test p value 0.0052 Note urea results pooled from day 10 to day 16.

Nephronectin Expression Is Controlled by the Non-Canonical TGF-β Pathway in Podocytes

Nina Sopel, Alexandra Ohs, Mario Schiffer, Janina Müller-Deile. *Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany*.

Background: Within the glomerulus, podocytes, glomerular endothelial cells (GEC) and the glomerular basement membrane (GBM) build the glomerular filtration barrier. Extracellular matrix (ECM) of the GBM is mainly composed of proteins synthesized by GECs and podocytes. Our interest focuses on nephronectin (NPNT), an ECM protein mainly produced by podocytes. Recently, it has been described that NPNT expression patterns vary in different glomerular diseases. For example, in focal segmental glomerulosclerosis (FSGS) and membranous glomerulonephropathy (MGN) NPNT expression was decreased compared to healthy controls, while it was increased in diabetic nephropathy (DN). In addition, transforming growth factor beta (TGFβ) is able to down-regulate NPNT on both mRNA and protein level. Our aim is to further analyze this TGFβ-mediated regulation of NPNT in human podocytes.

Methods: Immortalized human podocytes were differentiated for 10 to 12 days at 37°C and pre-incubated with inhibitors for components of the canonical and the non-canonical TGFβ signaling pathway with subsequent culture in the presence or absence of TGFβ. We used cell culture supernatants for ELISA, as well as cell lysates for qPCR and western blot analyses.

Results: While treating differentiated immortalized human podocytes with TGFβ decreased NPNT on both mRNA and protein level, we observed that inhibition of single components of the TGFβ pathway did not alter NPNT mRNA expression and excretion. On protein level, we noted no change after blockade of either Smad2 or Smad3 under baseline conditions. However, TGFβ was still able to decrease NPNT expression when canonical pathway components were inhibited, suggesting a minor role for this pathway in NPNT regulation via TGFβ. If single components of the non-canonical pathway were blocked, we observed an increase in NPNT protein expression, which was not further altered by TGFβ addition.

Conclusions: Taken together, our data suggest that in podocytes NPNT expression is fine-tuned via the non-canonical TGFβ pathway with additional regulation on the post-translational level.

Funding: Government Support - Non-U.S.

Podocyte Damage in Chimeric Kidney Organoids

Taiji Matsusaka,[1] Tomohiro Udagawa,[2] Kenji Osafune,[3] Toshikazu Araoka.[3] *[1]Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; [3]Kyoto Daigaku, Kyoto, Japan*.

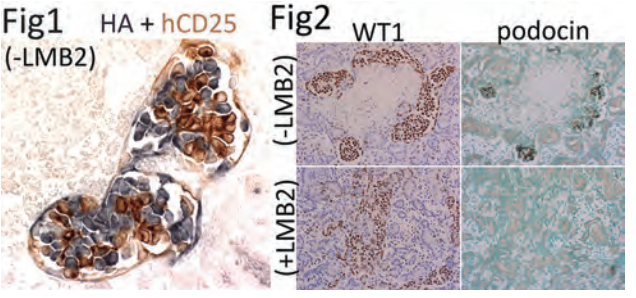
Background: We previously found that when a portion of podocytes are injured, other podocytes are secondarily injured in a mouse model, which may underlie the relentless progression of chronic renal failure. In the present study, we tested whether this phenomenon is observed in kidney organoids.

Methods: Nephron progenitor cells (NPCs) were established by culture-dependent purification (CDP) method from 12.5 dpc NEP25 and RiboTag mouse kidneys (*Cell Stem Cell*. 2016, 19, 516-29). Podocytes of NEP25 mice express hCD25 and can be injured by hCD25-targeted immunotoxin, LMB2. Podocytes of RiboTag mice express hemagglutinin (HA)-tagged ribosomal protein. Kidney organoids were generated by transient stimulation with FGF2 and CHIR99021 of NPC aggregates and subsequent 8-day culture. On day 8, LMB2 (20 nM) was added to induce injury in hCD25+ podocytes.

Results: We confirmed that podocytes in both organoids are stained for nephrin, podocin and WT1. Podocytes derived from NEP25 NPC expressed hCD25 and were injured by LMB2, and those from Ribotag NPC expressed HA and were resistant to LMB2. When two types of NPCs were mixed at 1:1 ratio, organoids showed a chimeric pattern containing hCD25+ and HA+ podocytes (Fig1). 2 days after LMB2 treatment, hCD25 staining completely disappeared accompanied by cleaved (c) lamin A staining, a cell death marker. HA staining was retained, but WT1 was diminished and podocin disappeared (Fig 2). Occasionally, c-lamin A was positive in HA+ cells. RNA of Ribotag podocytes can be obtained by immunoprecipitation with anti-HA antibody. Q-PCR revealed that *Nphs1* (0.31), *Nphs2* (0.04), *Wt1* (0.37) were decreased to the indicated fold by LMB2 and that *Gadd45b* was increased to 4.82-fold.

Conclusions: Thus, podocyte damage damages podocytes in kidney organoids that lack glomerular filtration.

Funding: Government Support - Non-U.S.



PO1720

Increased Old Astrocyte Specifically Induced Substance (OASIS) in Podocytes Leads to the Progression of Nephrotic Syndrome

Yoshiaki Miyake,[1] Masanori Obana,[1] Ayaha Yamamoto,[1] Shunsuke Noda,[1] Koki Tanaka,[1] Shota Tanaka,[1] Makiko Maeda,[1] Katsuhiko Asanuma,[2] Yasushi Fujio.[1] *[1]Osaka Daigaku, Suita, Japan; [2]Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan*.

Background: Old astrocyte specifically induced substance (OASIS) is a transcription factor of the CREB/ATF family. Previously, we found that OASIS was expressed in podocytes in murine kidneys. However, the pathophysiological roles of OASIS in podocytes remain unclear. The aim of this study is to elucidate the role of OASIS in podocytes.

Methods: To assess the relevance of OASIS to renal pathology, the expression of OASIS in glomeruli of lipopolysaccharide (LPS)-treated mice or streptozotocin (STZ)-treated diabetic mice was examined by laser capture microdissection, followed by immunoblotting. To further investigate the functional roles of OASIS in podocytes, podocyte-restricted OASIS overexpressing transgenic (OASIS TG) mice were established. Urinary albumin-creatinine ratio (uACR) was measured. Podocyte injury was assessed by electron microscopy. Tubular injury was evaluated by PAS staining and by measuring *LCN2* mRNA expression. Masson's trichrome staining and quantitative PCR for fibrosis-related genes, *COL1A1* and *FN1*, were performed to analyze tubulointerstitial fibrosis. To explore the effect of OASIS on podocyte actin cytoskeleton in vitro, phalloidin staining was performed on lentivirus-induced OASIS overexpressing murine cultured podocytes.

Results: OASIS expression was increased in glomeruli of both LPS-treated and diabetic mice. uACR was significantly increased in OASIS TG mice (uACR (μg/mg): control; 35.1±24.9, OASIS TG; 8930.0±8461.4, n=9 for control, n=7 for OASIS TG), and electron microscope analysis showed that OASIS overexpression in podocytes caused foot process effacement. In addition, damaged tubules and *LCN2* upregulation were observed in OASIS TG mice. Furthermore, Masson's trichrome staining showed that OASIS overexpression in podocytes evoked kidney fibrosis, and the expression of *COL1A1* and *FN1* were upregulated in OASIS TG mice. Consistent with in vivo study, OASIS overexpressing podocytes showed the reduction in actin stress fiber formation.

Conclusions: The increased OASIS in podocytes contributes to nephrotic progression.

PO1721

Podocyte-Derived RARRES1 Aggravates Kidney Disease Progression by Inducing Both Glomerular and Tubular Injury

Ye Feng,[1,2] Bi-Cheng Liu,[2] Kyung Lee,[1] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; [2]Southeast University Zhongda Hospital, Nanjing, China.*

Background: Our previous study demonstrates that the expression of retinoic acid receptor responder protein 1 (RARRES1) increases in glomeruli of patients with diabetic nephropathy (DN) and focal segmental glomerulosclerosis (FSGS). The glomerular expression of RARRES1 also correlates with eGFR slope and predicts glomerular disease progression. Single-cell RNA-sequencing of the kidney showed that RARRES1 expressed mostly in podocytes within the kidney. Mechanistically, WT-RARRES1 is cleaved into a soluble form which subsequently induces podocyte apoptosis whereas mutant RARRES1 with cleavage defect failed to induce podocyte apoptosis *in vitro*. Here, we further determined whether increased expression of WT-RARRES1 in the podocytes aggravated progression of glomerular disease.

Methods: Mice with podocyte-specific overexpression of human WT- RARRES1 or mutant RARRES1 with cleavage defect were generated and then subjected to aging, adriamycin (ADR) administration or streptozotocin (STZ) injection. To identify the role of podocyte-derived soluble RARRES1 in tubular cells, HK2 cells were treated with soluble RARRES1 obtained from podocyte supernatants.

Results: In vivo, podocyte-specific overexpression of WT-RARRES1 resulted in severe proteinuria and marked glomerular cell injury in mice with aging, adriamycin-induced nephropathy, or STZ-induced diabetic nephropathy as compared to the control mice with overexpression of mutant RARRES1. Interestingly, tubular vacuolation and interstitial injury were also observed in these mice with podocyte-specific overexpression of RARRES1. In addition, we showed that soluble RARRES1 collected from podocyte supernatants was endocytosed in HK2 cells to induce cellular injury. Similarly, cleaved form of human RARRES1 in the mice with podocyte-specific human RARRES1 overexpression was found in the tubular compartments, indicating that soluble RARRES1 generated from podocytes may act on tubular cells through glomeruli-tubule crosstalk.

Conclusions: Our study suggests that RARRES1 is a risk gene for glomerular disease progression through its direct effects in podocytes as well as indirect effects in tubular cells probably via glomeruli to tubules crosstalk.

Podocyte-Specific Extracellular Vesicles Yield Novel Insight into Intercellular Signaling in the Glomerulus

Annika Pape, Kilian Teicher, Inka C. Homeyer, Kian Deheshwar, Anja Obser, Valerie T. Oberüber, Nicola Wanner, Catherine Meyer-Schwesinger, Tobias B. Huber, Fabian Braun. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Extracellular vesicles (EVs) have been identified to play an essential role in basic pathological processes such as priming of the metastatic niche, autoimmunity and propagation of insulin resistance. Nevertheless, knowledge about their role in kidney health and disease remains scarce. A new group of EVs, shed upon apoptosis with the ability to induce a proliferative effect in neighboring cells, was recently identified in cell culture models as well as experimental glomerulonephritis. This study aimed to characterize these medium-sized EVs and the signaling propagated by them in podocyte damage.

Methods: Using differential centrifugation and filtration we established a protocol to separate medium-sized EVs from cell culture supernatants, kidney tissue and urine samples. With Western Blot, immunofluorescence microscopy and image flow cytometry we investigated the release dynamics of podocyte-specific vesicles in different models of murine podocyte damage *in vitro* and *in vivo*. Furthermore, cross culture experiments and life microscopy were used to determine the effect of podocyte-specific medium-sized EVs on parietal epithelial cells.

Results: Podocyte-specific medium-sized EVs were detected in baseline podocyte culture supernatant, untreated murine kidney tissue as well as the urine of healthy human volunteers. Vesicle quantification revealed a drastic increase of vesicle release upon podocyte damage both *in vitro* and *in vivo*. Interestingly, podocyte-specific EVs exerted different effects on the proliferative and migratory behavior of primary parietal epithelial cells.

Conclusions: Our study represents the first investigation of podocyte-specific medium-sized extracellular vesicles, their release dynamics and functional implications in health and disease. Ongoing analyses aim to characterize their proteomic content and effect other renal epithelial cells. As these vesicles can be separated without advanced equipment such as ultracentrifuges, we believe they could also be a valuable source for biomarker research in various nephropathies.

PO1723

Effects of Varying Mild Tubular Injury on Subsequent Glomerular Injury

Janka Babickova,[1,2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Universitetet i Bergen, Bergen, Norway.*

Background: Tubular injury predisposes to CKD, including glomerular injury. We analyzed effects of mild tubular injury on subsequent glomerular injury.

Methods: Double transgenic, Nep25/DTR$^+$ male and female mice (with human CD25 receptor on podocytes and Diphtheria toxin (DT) receptor on proximal tubules) received DT (25, 50, or 100ng/kg; 2x one week apart, n=5/group) to induce tubular injury, or vehicle (VEH). Uninephrectomy was done 4 wks later; 5 wks later glomerular injury was induced by LMB2 toxin (CD25 ligand) and mice were sacrificed 10 days later.

Results: In males, urinary KIM-1 was significantly higher vs VEH with all DT doses on d3 after DT injections, lowest in DT25 and similar with DT50 and DT100. KIM-1 levels were only numerically higher in DT50 and DT100 vs VEH by wk 6. Urinary NGAL was significantly increased at d3 only in DT100 vs VEH. NGAL levels normalized in all DT groups by week 6. In females, KIM-1 levels were increased by d3 with highest level with DT100. KIM-1 levels were only numerically higher vs VEH in a dose-dependent manner by wk 6. Urinary NGAL on day 3 was significantly higher in DT50 and DT100, normalized by wk 6, with numerically highest level in DT100. Males had higher levels of KIM-1 vs females at all timepoints, while NGAL showed similar levels in males and females at DT100 on d3, but higher levels in females at DT100 dose at wk 6. In males, albuminuria at sacrifice after additional podocyte injury showed numerically higher levels by 67% in DT100 vs VEH. In females, albuminuria gradually increased, with levels lower than in males in all groups. Ultrastructural analysis after podocyte injury showed similar significant foot process effacement, glomerular capillary fenestration loss and increased GBM thickness in all groups.

Conclusions: Sex differences in response to tubular injury and albuminuria were observed. Even very mild tubular injury, recovered by assessment of KIM-1 and NGAL-1 led to numerical increase in albuminuria after second hit glomerular injury in both sexes. The sex-dependent differences in KIM-1 and NGAL-1 further support differential susceptibility of nephron segments to injury in females vs males, which may play a role in glomerular sensitization to injury.

Effect of Glomerular Disease on the Podocyte Cell Cycle

Laura Perin,[1] Camille H. Nicolas Frank,[2] Xiaogang Hou,[1] Geremy Clair,[3] Fadi E. Salem,[4] Roger E. De Filippo,[1] Paolo Cravedi,[4] Kevin V. Lemley.[1] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Harvard Medical School, Boston, MA; [3]Pacific Northwest National Laboratory Biological Sciences Division, Richland, WA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Progression of glomerulosclerosis is associated with loss of podocytes and subsequent glomerular tuft instability. A decreased number of podocytes may be able to preserve tuft stability through cell hypertrophy associated with cell cycle re-entry. At the same time, re-entry into the cell cycle can lead to podocyte detachment from the glomerular basement membrane, if podocytes cross the G1/S checkpoint and undergo abortive cytokinesis.

Methods: To study cell cycle dynamics during CKD development, we used a FUCCI mouse model (fluorescence ubiquitination-based cell cycle indicator) affected by X-linked Alport Syndrome (AS). This model has progressive CKD and expresses cell cycle fluorescent reporters exclusively in podocytes. We quantified podocytes cell cycle distribution in WT and AS mice at different ages and collected podocytes in G0 and G1 for proteomics studies.

Results: We showed that with the development of CKD, an increasing fraction of podocytes *in vivo* are in G1 or later cell cycle stages. G1 and G2 podocytes are hypertrophic. Heterozygous female mice, with milder manifestations of CKD, show G1 fraction numbers intermediate between WT and male AS mice. Proteomic analysis showed differences in cytoskeleton re-organization and metabolic processes between podocytes in G0 and G1 in disease vs. WT and indicate alteration of specific proteins also identified in human AS podocytes.

Conclusions: Our data showed that, during progressive CKD, the podocyte cell cycle distribution changes dramatically, suggesting that cell cycle manipulation may have a role in the treatment of various progressive glomerular diseases characterized by podocytopenia.

Glucocorticoid- and Pioglitazone-Induced Proteinuria Reduction Correlates with Glomerular Extracellular Matrix Remodeling in Experimental Nephrotic Syndrome

Sagar Bhayana, Shipra Agrawal, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Peter White, Bryce A. Kerlin, William E. Smoyer. *Nationwide Children's Hospital, Columbus, OH.*

Background: Nephrotic Syndrome (NS) is a common glomerular disease in children. While glucocorticoids (GC) are the mainstay of childhood NS treatment, pioglitazone (Pio; an FDA-approved PPARg agonist to treat type 2 diabetes) has been reported to reduce proteinuria in experimental NS and to directly protect podocytes from injury. Since both GC and Pio activate nuclear receptors (NR3C1 and PPARG, respectively) we hypothesized that their proteinuria-reducing effects result from overlapping glomerular gene transcriptional patterns.

Methods: We performed transcriptome analyses on glomeruli isolated from GC (immunosuppressive)- and Pio (non-immunosuppressive)-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Unsupervised clustering revealed partial reversibility of PAN-associated mRNA dynamics by treatment with either GC or Pio. IPA analyses + web-based bioinformatic platforms identified 29 genes-of-interest common to GC- and Pio-induced proteinuria reduction, which included ECM remodeling, lipid metabolism, DNA-binding and cytoskeletal organization. Based on expression differences using real-time PCR,

29 genes-of-interest were selected for further analysis, which on clinical correlation with a human FSGS database (*Nephroseq*) suggested a direct relevance of glomerular ECM regulation in NS. Also, glomerular cell deconvolution using published single-cell glomerular transcriptome profiles identified podocyte- and mesangial cell-specific perturbations in gene expression during NS and with treatments. Finally, validation of selected genes-of-interest using PAN-induced injury of human podocytes and mesangial cells confirmed significant upregulation of *LGALS3 (primary role in cell adhesion)* and *MMP2/ACTA2 (primary role in ECM degradation/cell motility or integrity)* respectively.

Conclusions: These studies identified podocyte- and mesangial cell-specific transcripts common to both proteinuria-reducing treatments that identify possible targets for future treatment for NS

PO1726

Alteration of Intestinal Microbiota in Patients with ESRD Undergoing Hemodialysis

Takeo Koshida,[1] Tomohito Gohda,[1] Takuya Sugimoto,[2] Takashi Asahara,[2] Masanori Ishizaka,[1] Maki Murakoshi,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Yakult Central Institute, Yakult Honsha Co. Ltd, Tokyo, Japan.*

Background: The alteration in the intestinal microbiota is reported to be associated with various diseases, indicating that the development and progression of end-stage kidney disease also might be associated with dysbiosis.

Methods: The stool samples were collected from patients with hemodialysis (n = 41, HD group) and those with normal renal function (n = 40, NRF group). Both groups are comprised of patients with (HD_DM, n = 20; NRF_DM, n = 19) and without diabetes (HD_non-DM, n = 21; NRF_non-DM, n = 21). We conducted 16S rRNA gene amplicon sequencing using stool samples to analyze the intestinal microbiota.

Results: The reduced abundance of the genera *Megamonas* and *Fusicatenibacter*, and the enriched abundance of the genera Family_XIII_AD3011_group (*Anaerovoracaceae* family), UBA_1819 (*Ruminococcaceae* family), and *Pseudomonas* in the stool samples of HD patients were observed significantly compared with those of NRF patients. Compared with patients with NRF_DM, the relative abundance of the genera *Megamonas* was decreased and that of Family_XIII_AD3011_group was increased significantly in patients with HD_DM, although those relative abundance did not alter between NRF_non-DM and HD_non-DM. The relative abundance of the genera *Suterella* in HD_non-DM was significantly decreased than that in NRF_non-DM, although that relative abundance did not differ between NRF_DM and HD_DM. In the microbial beta diversity, there was no difference between NRF_DM and NRF_non-DM by weighted and unweighted Unifrac analysis, however, there was significant difference between HD_DM and HD_non-DM by unweighted Unifrac analysis ($p = 0.007$). These results suggest that the gut microbiota alters with renal function decline, and varies depending on the presence or absence of diabetes.

Conclusions: The intestinal microbiota might be varied substantially depending on renal function and the presence or absence of diabetes.

PO1727

Nutritional Intervention in Intensive Care Unit Patients Undergoing CRRT

Jihyun Yang, Tae-bum Kim, Hyeon-Jin Min, Young-Bin Son, Jonghyun Lee, Sewon Oh, Myung-Gyu Kim, Won-Yong Cho, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Providing adequate calories and protein constitutes an important part of critical care, and inadequate nutrition for critically ill patients is associated with poor prognosis. Therefore, increased loss of amino acids, electrolytes, and water-soluble vitamins during continuous renal replacement therapy (CRRT) could be a therapeutic target. We evaluated whether enforcing protein, trace elements and vitamin supply could improve the prognosis of CRRT patients.

Methods: A nutritional intervention (100 mg/day of Thiamine, 25–30 kcal/kg of energy, 1.8 g/kg of protein, and 50–100 mcg/day of microelement with selenium) was conducted in patients subject to CRRT from May 2020 to December 2020. The primary outcomes were 28-day mortality, CRRT day, ICU stay, and ventilator-free day, and the outcomes before and after the intervention were compared.

Results: Total 88 patients were included during the study period and compared with 88 patients in the previous year. The average age was 68.05 years old, 56 (63.5%) patients were male. At day 1 APACHE-II score was 35.45±9.2, SAPS3 88.1±16.8, SOFA 10.4±2.7. There were 9 (10.2%) patients with ECMO, 78 (88.6%) using ventilator. There were 19 (21.6%) pneumonia with ARDS patient, 18 (20.5%) cardiac disease, 9 (10.2%) UTI sepsis, 11 (12.5%) gastrointestinal bleeding and sepsis, 6 (6.8%) cerebral hemorrhage, and others. The main reason for CRRT was hemodynamic instability. Baseline characteristics including APACHE-II score, SAPS 3, and SOFA were not significantly different between the nutritional intervention and the non-intervention patients. Nutritional intervention did not induce significant changes in 28-day mortality (36 versus 37, $p = 0.56$) and CRRT days (7.3 ± 6.9 versus 6.3 ± 5.2, $p = 0.29$). However, nutritional intervention showed minimal improvement in ICU stay (22.1 ± 23.9 vs 20.7 ± 22.1, $p = 0.05$) and ventilator-free days (17.8 ± 22.3 vs 12.4 ± 14.4, $p = 0.05$).

Conclusions: This study suggests that support for protein, trace elements, and vitamins may have a positive effect in CRRT patients. Therefore, the nutritional requirements of patients with CRRT should be carefully assessed, individualized, and considered as an important axis of CRRT treatment.

Primary outcome

Variables	Conventional (2019) n=88	Intervention (2020) n=88	p-value
28-day mortality, n (%)	36 (40.9%)	37 (42.0%)	0.56
Duration of CRRT, day (mean±SD)	7.32 ± 6.9	6.34 ± 5.2	0.29
Duration of ventilator, day (mean±SD)	17.84 ± 22.37	12.47 ± 14.43	0.05
Length of stay, day (mean±SD)	22.14 ± 23.9	20.74 ± 22.18	0.05
ICU stay	45.06 ± 40.13	41.3 ± 46.91	0.57
Total hospital stay			

PO1728

Nutritional Phenotypes and Variation in Nutritional Parameter Trajectories Among Non-Dialysis CKD (CKD-ND) Patients Prescribed Oral Nutritional Supplements

Michelle M. Wong,[1,2] Yuyan Zheng,[2] Dani Renouf,[3] Adeera Levin.[1,2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]Providence Health Care, Vancouver, BC, Canada.*

Background: Among CKD-ND patients at risk of undernutrition/protein-energy wasting, the definition of patient subgroups most likely to benefit from ONS treatment is not known. Therefore, our aims were to identify phenotypes of non-dialysis CKD patients prescribed ONS, and to assess nutritional parameter slopes before and after ONS use, by phenotype.

Methods: This longitudinal cohort study included 2543 adult CKD-ND patients who entered multidisciplinary CKD clinics across British Columbia during 2010- 2019, met weight and/or dietary intake criteria for ONS prescription based on dietitian assessment, received ≥1 ONS prescription. Hierarchical cluster analysis was used to identify phenotypes using baseline nutritional parameters. Using linear mixed models, slopes for body mass index (BMI), serum albumin, bicarbonate, phosphate, and neutrophil-to-lymphocyte ratio (NLR), an inflammation marker, were assessed in the 2-year periods before and after the first ONS prescription.

Results: Cluster analysis identified five nutritional phenotypes. Changes in parameter slopes (Δslope = post-ONS slope - pre-ONS slope) varied by cluster (Figure). Cluster 1 (characterized by the highest mean NLR and the lowest mean BMI among clusters) demonstrated statistically significant positive Δslopes for BMI, albumin and bicarbonate, and a negative Δslope for NLR. Cluster 2 (hypoalbuminemia) demonstrated positive Δslopes for BMI, albumin, and phosphate. Cluster 3 (low mean BMI) demonstrated a positive Δslope for BMI, accompanied by negative Δslopes for albumin and bicarbonate, and a positive Δslope for NLR. Cluster 4 (acidosis) demonstrated positive Δslopes for BMI and bicarbonate. In Cluster 5 (highest BMI), a negative Δslope for albumin and a positive Δslope for NLR were observed (no improvement with ONS).

Conclusions: The variation in response to ONS by cluster subgroup lends support to an individualized approach to nutritional management of patients at risk of undernutrition/protein-energy wasting.

PO1729

Association of Muscle Mass and Protein Intake with Risk of ESKD in Patients with CKD

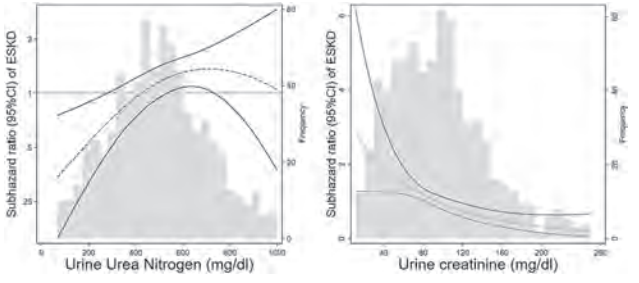
Atif Ibrahim,[1] Neeharika Mettupalli,[1] Waleed Hassan,[1] Yoshitsugu Obi,[1] Mahmoud M. Mohamed,[1] Keiichi Sumida,[1] Miklos Z. Molnar,[2] Barry M. Wall,[1,3] Csaba P. Kovesdy.[1,3] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of Utah Health, Salt Lake City, UT; [3]VA Memphis Medical Center, Memphis, TN.*

Background: Better nutritional status is favorably associated with clinical outcomes, but high protein intake may have deleterious effects on kidney function by virtue of mechanisms unrelated to nutritional status. We hypothesized that dietary protein intake and muscle mass (two markers of nutritional status) have opposite associations with progression of CKD when examined together.

Methods: We examined a cohort of 702 US veterans with stage 3-5 CKD followed at a single institution. We used spot urea nitrogen (UUN) and urine creatinine (UC) and adjusted for urine specific gravity as surrogates of dietary protein intake and muscle mass, respectively. We examined the concomitant association of UUN and UC with ESKD using multivariable adjusted competing-risks regression with adjustment for demographic characteristics, comorbidities, eGFR, proteinuria, smoking status, and body mass index.

Results: Patients were 68±10 years old, 96% were male, 60% were African American and their baseline eGFR was 32±13 mL/min/1.73 m². There were 178 ESKD events (event rate, 72.8/1000 PY; 95%CI, 62.8-84.4) over a median follow-up of 3.5 years. In a multivariable adjusted model including both nutritional markers, higher UUN was associated with a higher risk of ESKD (subhazard ratio [SHR] and 95%CI associated with 100 mg/dl higher UUN: 1.15, 1.00-1.35), while UC was associated with a lower risk of ESKD (SHR and 95%CI associated with one standard deviation higher UC: 0.50, 0.32-0.78) [**Figure**].

Conclusions: Higher protein intake is associated with higher risk of ESKD, while higher muscle mass is associated with a lower risk of ESKD in patients with stage 3-5 CKD. While observational in nature, these results suggest that renoprotection with dietary protein restriction should be pursued with close attention to maintaining optimal nutritional status.



PO1730

The Beneficial Effects of Intradialytic Parenteral Nutrition in Malnourished Hemodialysis Patients: A Randomized Controlled Trial

Athiphat Banjongjit, Kamonchanok Metta, Yingyos Avihingsanon, Somchai Eiam-Ong, Piyawan Kittiskulnam. *Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Intradialytic parenteral nutrition (IDPN) is an intermittently supplemental nutrition support administered during hemodialysis (HD). IDPN has been suggested as a trial option after a failure response to oral nutritional supplements (ONS). However, the extent to which IDPN contributes to improve protein-energy status remains unclear.

Methods: Maintenance HD patients having spontaneous energy and protein intake of ≥ 20 kcal/kg/day and ≥ 0.8 g/kg/day, respectively and intolerance to ONS were randomly assigned 1:1 to receive IDPN or intensive dietary counselling. In IDPN group, 3-in-1, anti-inflammatory omega 3-rich parenteral nutrition was infused during HD for 3 months followed by a treatment-free period of 3 months. The control group received an individualized dietary counselling once a week for 3 months to target the required nutrient intake. The outcomes were changes in serum albumin, muscle parameters and nutritional biomarkers. Serious adverse events were also monitored.

Results: A total of 38 patients were completed the study (age 67±11). Baseline characteristics were not different between groups. After 3 months, serum albumin were significantly higher in the IDPN (n=18) compared with control group (from 3.5±0.3 to 3.8±0.2 *vs* 3.6±0.2 to 3.5±0.3 g/dL, p=0.01, respectively). The infusion volume was 14.2±3.9 ml/kg/HD session. Total energy and protein intake (p=0.04), weight (p=0.01), subjective global assessment (p=0.03), and malnutrition inflammation score (p=0.01) were significantly improved in IDPN group, but not in control group (all p>0.05). Among nondiabetic patients, IDPN significantly reduced serum IL-6 as an inflammatory marker (p=0.03) but unaltered serum acylated ghrelin as an orexigenic hormone (p=0.31). Muscle mass, strength, and serum prealbumin were not different between both groups. Participants in IDPN group reverted to baseline albumin levels after 3-month post-intervention follow-up. Neither volume overload nor uncontrolled hyperglycemia was found throughout the study.

Conclusions: A short-term IDPN supplementation significantly increased serum albumin level, a survival surrogate among HD patients. The impact of IDPN therapy on clinical outcomes may require larger scale with longer period of study.

PO1731

An Itch to Scratch: The Problem with Pruritus

Tucker B. Hurtado, Skylar Malone, Jennifer Robinson. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: Dialysis patients often suffer from some level of associated pruritus and nephrologists generally recognize the condition's impact on patient lives, rating pruritus as a high unmet need for new therapeutic options. However, official diagnosis of CKD-associated pruritus and physician-reported estimates may be highly underestimated.

Methods: Using a HIPAA-compliant, online chart review tool, 177 nephrologists submitted de-identified clinical and non-clinical demographic information for 1,008 dialysis patients in Fall 2020. These data were then merged with physician demographic profiles and attitudinal responses; the full data set was analyzed in SPSS.

Results: When thinking generally, nephrologists estimate that nearly one-half of end-stage renal disease (ESRD) patients on dialysis have some level of pruritus, making it extremely prevalent in this population. However, chart reviews reveal that only 3.2% of dialysis patients are diagnosed with uremic pruritus (3.4% of HD patients and 1.4% of PD patients). On their last visit with their dialysis patients, nephrologists noted that only 4% of patients reported (or they observed) a skin rash, itch, or pruritus (3.7% of HD patients and 5.6% of PD patients). Interestingly, only approximately one-third of those patients were diagnosed with uremic pruritus, indicating there are more patients presenting with a rash or itch who are not actively being diagnosed. Despite the impact on patient lives, nephrologists report that only 25% of HD patients diagnosed with uremic pruritus are pharmacologically treated; this drops to 17% of PD patients with uremic pruritus. Treatments vary wildly and have varying levels of reported success among physicians. Nephrologists do recognize the impact pruritus can have on a patient's quality of life, making this high rate of underdiagnosis especially troubling. On a 1-10 scale rating unmet need for a new therapeutic agent, 62% of nephrologists rated a high unmet need (8-10) for pruritis in dialysis patients.

Conclusions: While many recognize that itching impacts many dialysis patients, actual diagnoses and treatment are rare, driven by a lack of effective treatment options. Elevating awareness among nephrologists will help with patient identification and treatment, especially as new treatment options are available on the market to help patients.

PO1732

Long-Term Safety of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Serum Electrolytes and Albumin

Pablo E. Pergola,[1] Jeanene Fogli,[2] Yang Yang,[2] David M. Spiegel.[2] *[1]Renal Associates PA, San Antonio, TX; [2]Ardelyx Inc, Fremont, CA.*

Background: Tenapanor, an investigational first-in-class phosphate absorption inhibitor (PAI), blocks the paracellular absorption of phosphate in the gastrointestinal tract by local inhibition of the sodium-hydrogen exchanger (NHE3). Tenapanor is being studied as a non-binder approach for the management of hyperphosphatemia in patients on dialysis and it is dosed as one pill (10, 20, or 30 mg) twice daily. Due to its novel mechanism of action, it is important to understand its safety profile, including any potential effects on serum electrolytes and albumin.

Methods: This report evaluates the effects of tenapanor on serum electrolyte and albumin concentrations using data from 3 pivotal trials in which tenapanor met its primary phosphorus-lowering endpoint. Trials included a 12-week monotherapy study (BLOCK), a 52-week monotherapy study (PHREEDOM), and a 4-week tenapanor + phosphate binder combination study (AMPLIFY). Serum electrolytes and albumin were measured per study protocol in central research laboratories.

Results: Tenapanor was generally well tolerated, with diarrhea being the only adverse event reported by >5% of patients. Diarrhea was typically mild to moderate in severity, was transient, and resolved with continued treatment. Data from all 3 trials showed that tenapanor treatment, either alone or in combination with phosphate binders, resulted in no clinically meaningful changes in measured serum electrolytes or albumin at any time point. Data from patients treated with tenapanor continuously for 52 weeks in the longest trial, PHREEDOM, are shown in the table.

Conclusions: In these clinical trials, tenapanor inhibited paracellular absorption of phosphate and decreased serum phosphorus with an acceptable safety profile, with no observed effect on serum electrolytes or albumin in patients on maintenance dialysis with hyperphosphatemia.

Funding: Commercial Support - Ardelyx, Inc.

Laboratory parameter	Baseline (mean ± SD)	Week 26 (mean ± SD)	Week 52 (mean ± SD)
Bicarbonate (mmol/L)	23.6 ± 3.1	24.4 ± 2.9	24.5 ± 3.2
Calcium (mg/dL)	8.2 ± 0.8	8.4 ± 0.8	8.7 ± 0.7
Chloride (mmol/L)	96.9 ± 4.0	97.2 ± 3.7	97.1 ± 3.8

Patient-Reported Experience with Tenapanor in the OPTIMIZE Trial

Susan A. Edelstein, Yang Yang, Brett Stephenson, Suling Zhao, Lynae Pagliaro, Jeanene Fogli. *Ardelyx Inc, Fremont, CA.*

Background: Tenapanor (TEN), a first-in-class phosphate absorption inhibitor (PAI) that works via the paracellular pathway, provides a novel approach for hyperphosphatemia management. The primary goal of this study is to evaluate how to optimize the treatment of hyperphosphatemia in patients with chronic kidney disease (CKD) on dialysis with the use of TEN and its novel mechanism of action.

Methods: Patients with serum phosphorus (sP) >5.5 and ≤10.0 mg/dL during stable phosphate binder (PB) treatment were randomized 1:1 to 2 different treatment cohorts: Cohort 1 (straight switch; n=151) – discontinued current PB and began TEN 30 mg twice daily (BID); or Cohort 2 (50% PB reduction; n=152) – decreased current PB dose by 50% (or more if taking an odd number of PB tablets) and began TEN 30 mg BID. After week 2 investigators could increase PB doses to achieve sP ≤5.5 mg/dL with TEN as the core therapy. Additionally, patients on TEN with sP >5.5 mg/dL could add low dose PB, and patients on TEN and PBs with sP <5.0 mg/dL could reduce PB dose. Participants were monitored for safety and efficacy at weeks 1, 2, 3, 4, 6, 8, and 10. At week 10 or the early termination visit, patients were asked about their experience with their sP management routine during OPTIMIZE compared to before the study. Here we report findings from a selection of questions from the patient experience questionnaires completed by a total of 179 patients (Cohort 1, n=94; Cohort 2, n=85).

Results: When interviewed, 85.1% of patients in Cohort 1 and 83.5% of patients in Cohort 2 reported an improved perception of their sP management routine. Overall,

64.2% of patients (63.8% and 64.8% in Cohort 1 and Cohort 2, respectively) identified an improvement in their sP medication regimen as the top reason for the improved perception, and 30.5% of patients (31.3% and 29.6% in Cohort 1 and Cohort 2, respectively) reported an improved perception of the form or frequency of bowel movements as the top reason for improved perception of their treatment routine.

Conclusions: Patients who were switched to TEN or added TEN to a reduced PB therapy regimen reported improved experience with their sP management. The findings from this analysis show that TEN may improve patient experience with sP management regimens. Further research is needed to elucidate what factors affect a patient's perspective of sP management.

Apparently Paradoxical Relations of Serum Phosphate and Albumin Variability with Outcomes Are Explained by the Directional Change

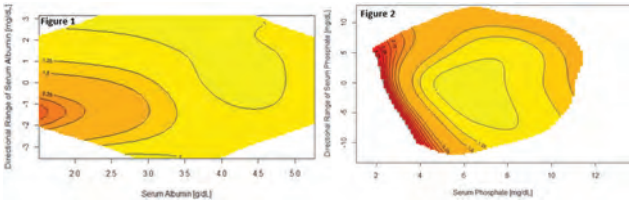
Xiaoling Ye,[1] Karlien J. ter Meulen,[4] Len A. Usvyat,[2] Jeroen Kooman,[4] Peter Kotanko,[1,3] Franklin W. Maddux.[2] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA; [3]Mount Sinai Hospital Mount Sinai Heart, New York, NY; [4]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.*

Background: Evidence indicates that variability of serum phosphate (P) and albumin (Alb) is associated with higher risk of mortality. We aimed to study the variability of P and Alb with all-cause mortality taking into account the interaction with the averaged levels.

Methods: All adult incident HD patients (pts) treated in Fresenius Medical Care NA clinics between 2010&2018 were included. Serum P and Alb levels were averaged from month(mo) 1 to 6 after HD initiation. Variability of P and Alb were described by standard deviation(SD) and directional changes(DR). All-cause mortality was recorded between mo 7 and 18. Cox proportional hazards models with spline terms were applied to explore the association between variability of P & Alb and all-cause mortality. Additionally, tensor product smoothing splines were computed to study the effect of interactions between averaged values of parameters and their variability with outcomes.

Results: We enrolled 353,142 pts. Averaged P was 4.98 mg/dL, median SD and DR were 0.92 and 1.10. Baseline Alb was 3.61 g/dL, median SD and DR were 0.21, and 0.40. Across different levels of P, higher SD of P were associated with higher risk of mortality, especially in those pts with lower averaged P. Contrasting, in pts with low Alb, higher SD was associated with reduced mortality. Regarding Alb, an unidirectional relation between DR and outcome was observed, whereas the relation between DR with outcomes was bidirectional for P (Fig1&2).

Conclusions: The relationship between P variability and mortality was apparent at all levels of P. In well-nourished pts, higher P variability are associated with increased risk of mortality, which is related to the adverse effects of both an increase and a decline of this parameter. In pts with low Alb, the apparently paradoxical association between higher levels Alb variability and better survival due to an improvement of nutritional and inflammatory status, related to a positive DR. Due to possible nonlinear relations between risk factors and outcomes in patients on HD, variability should ideally be explored by various metrics.



PO1735

Restrict Dietary Phosphorus to Decrease Proteinuria and Prevent Decline in Glomerular Filtration Rate in CKD Stages 1 and 2

Anita Saxena. Renal Nutrition Group *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Though dietary phosphorus restriction is therapeutic for disordered phosphorus homeostasis, early restriction of dietary phosphorus is not advised in CKD. Aim: Does early control of dietary phosphorus ameliorates proteinuria, prevent decline in glomerular filtration rate and prevent rise in FGF-23.

Methods: One year longitudinal study on 79 CKD stages 1 and 2 patients. eGFR, serum creatinine, phosphorus, calcium, FGF-23, soluble α-Klotho iPTH FGF 23, blood pressure, were evaluated and compared with 35 controls. 3 days dietary intake was taken using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake: Group 1 (n 42): normal phosphorous intake (<1000mg/day) and Group 2 (n=37): high phosphorous intake (>1000mg/d). Patients in Group 2 were educated on high and low phosphorus foods and counselled to adopt a plant-based diet, for low phosphorus absorption with directed diet plan. Data were analysed using SPSS.

Results: At baseline there was no significant difference in the GFR (group1 85.00±18.64 ml/min vs group 2 82.53±16.30ml/min), serum creatinine between groups. In group2 ; GFR, sKlotho, serum phosphorus and FGF-23 correlated significantly with dietary phosphorus intake. In group 2, FGF-23, serum phosphorus, dietary protein and phosphorus intake were significantly higher and sKlotho was significantly lower than group 1. There was significant difference in serum phosphorus (p 0.000), iPTH, (p 0.004), FGF23 (p0.000), Klotho (p0.000), urinary protein (p0.000), dietary protein (Group 1 37.57±3.40; Group 248.79±5.86 p 0.000) and phosphorus (Group 1868.96±69.99 mg/d and Group 2 1312.26±137.57 mg/d p 0.000) intake and dietary phosphorous to protein ratio (p 0.000) between groups 1 and 2. On dietary intervention in group 2 GFR increased p 0.012 from 80.93±15.34 to 84.11±15.38; and to 87.43±18.27 ml/min at 6 and 12 months respectively, Urinary protein declined to 22.01±3.39 mg/mL. FGF 23 declined from 60.67±6.26 to 58.00±7.07 to 53.29±9.48 pg/mL at 12 months. Dietary phosphorus: protein ratio reduced significantly from 27.16±4.35 to 24.75±4.34 p 0.000 at 12 months ((p<0.000)). Urinary phosphorus excretion increased from 574.37±214.22 to 624.64±137.67 at 12 months.

Conclusions: Restricting dietary phosphorus in stages 1 and 2 can prevent progression of CKD and for control proteinuria.

PO1736

Understanding Obesity Management in CKD Patients

Michael Chiu, Kathy Koyle, Arsh Jain. *London Health Sciences Centre, London, ON, Canada.*

Background: Obesity is a global epidemic that is directly and indirectly linked to progression of chronic kidney disease (CKD). Nephrologists' attitude towards obesity management is not understood.

Methods: We surveyed 14 nephrologists practicing in an academic centre in London, Ontario, Canada to investigate their perception and management of obesity. Then we performed a retrospective chart review of patients in a CKD clinic with obesity (BMI >30kg/m2). Ten follow-up visits were randomly selected for each nephrologist between Jan-Dec 2019. Each chart was assessed for documentation of obesity and a management plan such as lifestyle counselling, pharmacologic intervention, or specialist referral.

Results: There were 13 responses (93%). Responses from a 5-point Likert scale, agree and strongly agree, have been combined. All nephrologists agreed that obesity negatively impacts CKD patients. 92% reported that discussing obesity evokes a negative response and 39% thought patients want to discuss obesity. Interestingly, 0% of nephrologists thought patients know that obesity has effective treatments. 85% of nephrologists talked to their patients about obesity, but 0% felt that they had time to treat it. With regards to management, 54% of nephrologists were comfortable with non-pharmacologic treatment, but only one was comfortable with pharmacologic treatments. 85% of respondents felt that patients should be referred to a specialist. A total of 140 charts were reviewed with a mean age 66 years, weight 105 kg, and BMI 37 kg/m2. Only one chart had obesity as a clinical issue and documented a weight loss discussion using non-pharmacologic strategies.

Conclusions: Our results suggest that obesity is rarely managed despite nephrologists' desire to treat it. This care gap can be addressed using robust Quality Improvement principles. Our centre will improve obesity management by developing a clinical handbook for nephrologists on how to efficiently address obesity with patients as well as a partnership and streamlined referral process to an obesity specialist.

Changes over Time in DASH Diet Accordance by Racial/Ethnic Groups Among US Adults

Tanushree Banerjee,[1] Charles E. Mcculloch,[1] Deidra C. Crews,[2] Nilka Rios Burrows,[3] Alain Koyama,[3] Hal Morgenstern,[4] Rajiv Saran,[4] Neil R. Powe.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Johns Hopkins University, Baltimore, MD; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of Michigan, Ann Arbor, MI.*

Background: Recommendations for healthy dietary patterns may vary for individuals with and without CKD. Racial/ethnic disparities in dietary quality exist, yet there is limited understanding of how dietary patterns have changed over years in different racial/ethnic groups. We examined trends in accordance to a Dietary Approaches to Stop Hypertension (DASH) diet by different racial/ethnic groups in adults with and without CKD.

Methods: We used data from the 2003-2018 NHANES to estimate the prevalence of DASH diet accordance among individuals aged≥20 years with CKD (ACR≥30mg/g or eGFR 15-59 ml/min) and no-CKD by racial/ethnic group. Self-reported race/ethnicity was categorized as non-Hispanic White (NHW), non-Hispanic Black (NHB), Mexican American (MA), or other. Change in diet composition over 16 years was assessed with a DASH diet agreement score with the years collapsed into 2003-06, 2007-10, 2011-14, 2015-18. We calculated the score based on 9 target nutrients by coding each as 1 for met and 0 for not met and summing to a total score of 9. Lowest tertile of the score was considered poor accordance. Prevalence rates were estimated for racial/ethnic groups after age-standardizing to the 2010 US Census data. Time trends in age-adjusted DASH diet prevalence were assessed using logistic regression with time interval as a predictor.

Results: Overall, the prevalence of poor accordance to a DASH diet was 13.5% and 17.5% in adults with CKD and no-CKD. Throughout the period, the age-adjusted prevalence of poor accordance was higher in NHB with CKD (prevalence did not change significantly, Figure) than in NHB with no-CKD. For MA, a significant change in prevalence was noted among no-CKD (ptrend=0.008), but not in those with CKD.

Conclusions: Poor accordance to a DASH diet was greater in adults with no-CKD. However, prevalence of poor accordance did not change in NHB and MA with CKD. Efforts to further improve promotion and accordance to DASH diets may help address CKD progression and health disparities in the US.

Food Purchasing Patterns Among Participants of a Dietary Intervention Trial for African Americans with Hypertension and CKD

Rohin A. Aggarwal, Meghana S. Iragavarapu, Raneitra Grover, Taharat T. Sheikh, Rebecca Brody, Kathryn A. Carson, Chiazam Omenyi, Edgar R. Miller, Deidra C. Crews. Five Plus Nuts and Beans for Kidneys Investigators *Johns Hopkins University, Baltimore, MD.*

Background: Financial resources and the surrounding food environment can impact healthy food purchasing patterns and may play a role in disparities in CKD. We examined predictors of healthy food purchases among control group participants of a clinical trial who were assigned to receive a gift card to a grocer worth $30 per week for 4 months ($480 total) but received no specific guidance on purchases.

Methods: We examined purchasing patterns of 50 participants using receipts linked to a grocer club card. The primary outcome of interest was the number of fresh or frozen fruit or vegetable items purchased, dichotomized at the median to those purchasing <= 6 and > 6 types of fruits/vegetables. Predictors examined included participant sociodemographic factors and food environment factors (i.e. living in a healthy food priority area). Statistical analyses included descriptive statistics and multiple linear regression.

Results: All participants were African American; median age was 63 yrs; 64% were female. Most (78%) were either unemployed or retired; 58% received a H.S. diploma/GED or less. Half had annual income < $25,000. Purchases made included both food and non-food items and many used other funds beyond those from the study. Adjusting for income, women purchased 2.3 more fruit/vegetable items than men (95% CI 0.2-4.5). Those purchasing more fruits/vegetables spent a greater total amount than those purchasing fewer fruits/vegetables.

Conclusions: In a dietary intervention trial for African Americans with CKD, healthy food purchases differed by sex, income level, and dollar amount spent, but not by food security or neighborhood food environment.

Funding: Other NIH Support - NHLBI; NIMHD

Participant Characteristics by Number of Fruits/Vegetables Purchased

	≤ 6 (N=26)	> 6 (N=24)	P value
Age in years, median (IQR)	65 (56-71)	62.5 (55-68)	0.41
Female, %	13 (50)	19 (79)	0.04
Employed full or part time, %	4 (15)	10 (42)	0.06
Income group:	-	-	0.04
< $10,000	6 (29)	2 (11)	
$10,000-24,999	9 (43)	8 (42)	
$25,000-49,999	5 (24)	4 (21)	
$50,000-99,999	1 (5)	3 (16)	
$100,000+	0 (0)	2 (11)	
Lives in Healthy Food Priority Area (limited food access)	8 (31)	4 (17)	0.35
Food insecure (self-reported)	9 (35)	7 (29)	0.77
Total dollars spent, median (IQR)	$355.3 (179.7-467.7)	508.9 (356.5-604.2)	0.003
Dollars spent on fruits/vegetables, median (IQR)	$29.4 (21.5-72.9)	$88.8 (60.2-117.6)	<0.001

PO1739

Experiences of Participants of a Dietary Intervention Trial for African Americans with Hypertension and CKD

Kristal L. Brown, Sophia Lou, Mary Ann C. Stephens, Zehui Zhou, Tahiyat Sheikh, Denise E. Saint-Jean, Chiazam Omenyi, Rebecca Brody, Edgar R. Miller, Deidra C. Crews. Five Plus Nuts and Beans for Kidneys Investigators *Johns Hopkins University, Baltimore, MD.*

Background: African Americans are disproportionately affected by hypertension (HTN) and CKD and evidence suggests dietary modifications towards a more Dietary Approaches to Stop Hypertension (DASH)-accordant diet could improve outcomes for this population. We aimed to explicate barriers and facilitators of healthy eating, and the perceived benefits of the intervention among completed participants of a dietary intervention trial for African Americans with HTN and CKD. Participants were randomized to one of two groups: 1) Self-Shopping DASH (S-DASH) diet group with $30/week grocery allowance for 4 mo. but no specific guidance on purchases, followed by no food allowance for 8 mo.; or 2) Coaching DASH (C-DASH) diet advice group with a $30/week food allowance and assistance in purchasing foods for 4 mo., followed by intermittent coaching without food allowance for 8 mo.

Methods: We performed a content analysis of transcripts from semi-structured interviews with participants who completed the trial (13 C-DASH; 12 S-DASH were randomly selected). Thematic analyses followed 5 stages: 1) reading and rereading all transcripts and utilizing audio recordings as needed for clarity; 2) three coders reading two of the same transcripts, coding them, and comparing codes which were then used to create the initial coding framework; 3) defining codes, coding additional transcripts, discussing/revising the coding framework; 4) formulating initial themes and 5) diagramming relationships among initial themes to merge overlapping themes.

Results: Participants were a mean age of 62 ± 9.3 years, 36% were male. Key themes included healthy diet facilitators (food tracking, motivation, social support, and perception of healthy foods); barriers (transportation, past eating habits, stress and COVID mitigation); and impact of the trial on knowledge and health.

Conclusions: Participants of a dietary intervention trial for African Americans with HTN and CKD identified several facilitators and barriers to healthy eating that could inform future efforts to address disease burden in this population.

Funding: Other NIH Support - NHLBI; NIMHD

Themes	Representative Quotes
Healthy Diet Facilitators	[in reference to materials from the study and grocery allowance] made it easier, I guess, with both phases of it, with giving me all the feedback and stuff like that. You all would give me feedback like doing a good job, keep up the good work, you know, positive reinforcement, whatever you call it. All that made a big difference. (S-DASH) [in reference to support system and ability to eat healthy] Well, like my daughter, she would help, she would go get the foods for me, pick the foods up for me when I couldn't get there. So, she would make sure that, you know, if I couldn't get there, she made sure I would get the foods and get them to me. And she followed me, once I started eating more fruits and vegetables, she started eating more, you know. (C-DASH)
Healthy Diet Barriers	[in reference to things that were difficult to change] … because fresh vegetables are more expensive than canned vegetables. So that was a -- that was another kind of hurdle that I kind of really didn't follow. (S-DASH) [in reference to grocery shopping options and if shopping behaviors changed in the study] And we had a—where I live at now, we had, like, a farmer's market that would come every week as well, but when COVID came, they don't come anymore. (C-DASH)
Impact of Trial on Knowledge and Health	[in reference to how study affected health] Well, it—like I said, it helped me control my pressure a little bit. It's making me more aware and pay attention to my labs plus it's helping me maintain my weight." (C-DASH) [in reference to eating changes since being in the study] And they told me to watch, I started watching my labels as far as the sodium and stuff. (S-DASH)

PO1740

Barriers and Facilitators to DASH Diet Adherence Among Black Adults with CKD: A Qualitative Study

Crystal C. Tyson,[1] Laura P. Svetkey,[1] Isa Granados,[1] Danielle L. Kennedy,[3] Travia K. Dunbar,[1] Pao-Hwa Lin,[1] Gary G. Bennett,[2] Cynthia H. Redd,[1] L. Ebony Boulware,[1] Laura J. Fish.[3] *[1]Duke University School of Medicine, Durham, NC; [2]Duke University, Durham, NC; [3]Duke Cancer Institute, Durham, NC.*

Background: Black individuals are disproportionately burdened by hypertension and chronic kidney disease (CKD). The Dietary Approaches to Stop Hypertension diet (DASH) improves hypertension in Black individuals and is associated with improved CKD outcomes. Yet, adherence to DASH among Black individuals is low. We conducted a qualitative study to assess barriers and facilitators to DASH adherence in Black adults with CKD.

Methods: We conducted focus groups and individual interviews with Black adults with CKD stages 3 or 4 (n=22). Questions included perceptions of CKD and DASH, the cultural-centeredness of DASH, and barriers and facilitators to adopting DASH. Qualitative content analysis was used to analyze interview transcripts.

Results: Among 22 participants (2 focus groups, 8 individual interviews), 13 (59%) had CKD stage 3, 13 (59%) were female, the median age was 61 years, and 19 (90%) had hypertension. Some participants reported having previously heard of DASH, which they perceived as a healthy diet. Participants perceived DASH as culturally-compatible based on 3 emergent themes: 1) Blacks individuals already eat DASH-recommended foods ("*Blacks eat pretty much like this*"); 2) traditional (e.g., southern or soul-food) recipes can be modified into healthy versions ("*you can come up with decent substitutes to make it just as good)*", and 3) diet is not uniform among Black individuals (*"I can't say that I eat traditional"*). Barriers included unfamiliarity or inexperience measuring portion sizes, inadequate cooking skills, unsupportive household members, and high cost of healthy food. Eleven (52%) reported "rarely" or "never" having leftover money to

purchase healthy food after paying monthly bills. Facilitators included having local access to healthy food, living alone or with supportive household members, and having will power and internal/external motivation for change.

Conclusions: Black adults with CKD were interested in adopting DASH and viewed it as a healthy, culturally-compatible diet. Recognizing that diet in Black adults is not uniform, interventions should emphasize person-centered, rather than culture-centered, approaches that minimize barriers and enhance facilitators to adherence.

Funding: Other NIH Support - NHLBI

Priorities for Person-Centered Obesity Management in ESKD

Meera N. Harhay, Brandy-Joe Milliron, Jasmine M. Sweeting, Joanna H. Lee, Sneha S. Hingorany, Jennifer R. Haileselasse, Bengucan Gunen, Ann C. Klassen. *Drexel University, Philadelphia, PA.*

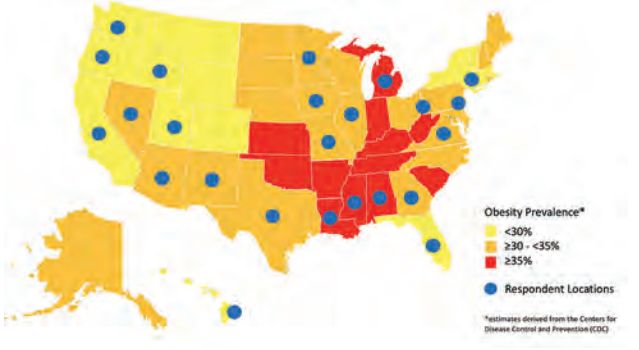
Background: Although obesity is a pervasive kidney transplant barrier, little is known about the social, dietary, and process-of-care challenges to addressing obesity among individuals with ESKD.

Methods: Using purposive sampling we recruited adults with ESKD and obesity (N=40) and ESKD health care professionals (HCPs, N=20) in the United States for semi-structured interviews to elicit perspectives about obesity and barriers and strategies for healthy weight loss. Recorded phone interviews lasting 1.5 hours were transcribed verbatim and analyzed using inductive and deductive thematic analysis.

Results: Median patient age was 55 (interquartile range [IQR] 47,63) years, median dialysis exposure was 5 (IQR 3,10) years, 51% were female, 27% were Black, and median BMI was 37.8 (IQR 33.5, 40.8) kg/m^2. HCPs were renal dietitians, nephrologists, and transplant surgeons. Five themes emerged from patient interviews: 1) obesity-related counseling typically limited to immediate goal (transplant BMI requirements); 2) obesity as a life-long disease or linked to trauma; 3) food choices driven by fatigue and poor sleep quality; 4) existing nutrition programs not transferable to ESKD; 5) absence of culturally-effective nutrition counseling. HCP interviews revealed uncertainty about provider roles and responsibilities for addressing obesity and underscored that poverty and low health literacy are barriers to healthy weight loss.

Conclusions: Obesity-related care for people with ESKD is often limited to addressing BMI limits for transplant. Weight loss interventions for people with ESKD and obesity should be tailored with knowledge of social and financial context and a shift in focus from short-term goals to long-term health.

Funding: NIDDK Support



Geographic distribution of semi-structured interview respondents, including patients with dialysis-dependent kidney disease and obesity, renal dietitians, nephrologists, and transplant surgeons.

PO1742

Association of Nutritional Data and Glycemic Variability in CKD Patients

Nandakishor Kapa, Harshanna Badhesha, Tae Youn Kim, Olivia A. Moss, Chenoa R. Vargas, Seung M. Jin, Henning Langer, Usman Rehman, Jennifer E. Norman, Armin Ahmadi, Thomas Jue, Maryam Afkarian, Baback Roshanravan. *University of California Davis Medical Center, Sacramento, CA.*

Background: Insulin resistance is highly prevalent in chronic kidney disease (CKD) and strongly associated with adverse clinical outcomes. Glycemic variability measured by continuous glucose monitoring (CGM) is a clinical measure of insulin resistance. The association of dietary recalls and healthy eating measures with CGM readings in CKD are unknown.

Methods: We recruited diabetic (n=7) and non-diabetic (n=8) participants with eGFR<60ml/min who had CGM performed over 2 weeks. The ASA24 Dietary Assessment Tool was used to perform dietary recalls on 3 random days over the CGM period. The Healthy Eating Index 2015 (HEI-2015) was used to determine how closely an individual's eating pattern matched Dietary Guidelines for Americans' recommendations. A linear mixed model adjusting for diabetes status was used to determine association of dietary measures from ASA24, HEI-2015 scores, and CGM readings over 3 days.

Results: Participants had a mean age 59±11years, eGFR 35.5±4.6ml/min/1.73m^2 and BMI 32.8±4.6kg/m^2. Greater dietary added sugar, total carbohydrate, and carbohydrate to fiber ratio was associated with higher average daily blood sugar (P<0.001, P<0.001, and P=0.006, respectively). Each 1-point greater HEI score (healthier eating) was inversely associated with average daily blood sugar for fatty acid (-1.09 mg/dL; 95% CI -2.11, -0.07), added sugar (-1.76 mg/dL; CI -3.11, -0.4), vegetable (-2.85 mg/dL; CI -5.5, -0.2), and fruit (-2.63 mg/dL; CI -5.03, -0.22). HEI total score did not show significant association with the CGM readings.

Conclusions: Greater added sugar, saturated fats, and dietary carbohydrate to fiber ratio are strongly associated with greater average daily blood sugar. Sugar, carbohydrates, and saturated fats contribute to glycemic variability. Healthy eating centered on low sugar, low fat, and high vegetable and fruit intake may improve glycemic control in both diabetic and non-diabetic CKD patients.

Funding: NIDDK Support, Commercial Support - Dialysis Clinics Incorporated

HEI-2015 Scores Associated with CGM in Non-Diabetic and Diabetic CKD Patients

	CGM Value (β (95% CI))	
HEI-2015 (n=15)	Average daily blood sugar (mg/dL)	Percent time above target (%)
HEI Fatty Acid	-1.09 (-2.11, -0.07)	-0.34 (-1.19, 0.5)
HEI Added Sugar	-1.76 (-3.11, -0.4)	-1.13 (-2.24, -0.02)
HEI Total Vegetable	-2.85 (-5.5, -0.2)	-1.18 (-3.36, 0.98)
HEI Total Fruit	-2.63 (-5.03, -0.22)	-1.39 (-3.37, 0.59)

PO1743

Late Stage 3 CKD Is an Independent Risk Factor for Sarcopenia, but Not Proteinuria

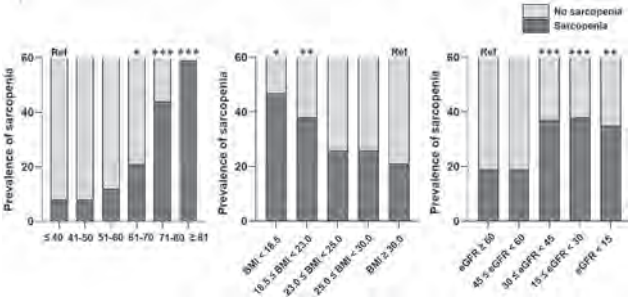
Yong Seon Choi, Jung Nam An, Jwa-kyung Kim, Sung gyun Kim, Young rim Song. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: Most epidemiologic studies assessing the relationship between chronic kidney disease (CKD) and sarcopenia have been performed in dialysis patients. This study aimed to evaluate the relationship between estimated glomerular filtration rate (eGFR), proteinuria, and sarcopenia in patients with non-dialysis-dependent CKD.

Methods: A total of 892 outpatients who did not show any rapid changes in renal function were enrolled in this observational cohort study. We measured the muscle mass using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was found in 28.1% of the patients and its prevalence decreased as body mass index (BMI) increased; however, in patients with BMI ≥ 23 kg/m^2, the prevalence did not increase with BMI. As eGFR decreased, the lean tissue index and HGS significantly decreased. However, the eGFR did not affect the fat tissue index. The risk of sarcopenia increased approximately 1.6 times in patients with eGFR < 45 mL/min/1.73 m^2. However, proteinuria was not associated with sarcopenia. With a decrease in eGFR, the lean muscle mass and muscle strength decreased, and the prevalence of sarcopenia increased.

Conclusions: In patients with late stage 3 CKD, further assessment of body composition and screening for sarcopenia may be needed.



PO1744

Association of Serum Selenium Levels with the Response to Erythropoiesis-Stimulating Agents in Maintenance Hemodialysis Patients

Minoru Yasukawa, Shigeyuki Arai, Michito Nagura, Daigoro Hirohama, Osamu Yamazaki, Yoshifuru Tamura, Yoshihide Fujigaki, Shigeru Shibata. *Teikyo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Itabashi-ku, Japan.*

Background: Reduced response to erythropoiesis-stimulating agent (ESA) has been shown to be associated with poor outcomes in maintenance hemodialysis (MHD) patients. Selenium is a trace element that modulates diverse physiological processes, such as immune responses and cardiovascular function. Previous studies also indicate that selenium and selenoproteins are involved in erythropoiesis. However, its role in the control of anemia in chronic kidney disease patients remains unclear. In this study, we determined serum selenium levels in MHD patients and analyzed their association with hemoglobin levels and the doses of ESA.

Methods: The study included 174 patients who received MHD from four dialysis facilities. We obtained data on demographics, laboratory, comorbidities, hemodialysis prescription and medication by medical record abstraction. Concentration of selenium was measured in serum using ICP-MS.

Results: The mean age was 67.2 years, 77% were male, and 44% of patients received dialysis at least for five years. The average serum selenium concentrations in our cohort were 10.7 ± 2.9 μg/dL, and 88 patients (51%) had a selenium levels of less than 10.5 μg/dL (a lower limit of normal serum selenium levels for adult Japanese population). Patient characteristics, including age, sex, BMI, dialysis vintage, and comorbidities were not significantly different between the low selenium (Low) group and normal selenium (Normal) group. However, the percentage of patients receiving ESA tended to be higher in Low group than in Normal group, whereas hemoglobin levels as well as percentage of patients receiving iron therapy were similar between the groups. In a subgroup analysis involving 146 patients who received ESA, we found a significant negative correlation between serum selenium levels and ESA-resistance index (ERI) (r = -0.25, p = 0.002).

Conclusions: Our study indicates that low levels of serum selenium are associated with poor response to ESA. The relationship between selenium and response to ESA in MHD patients merits further evaluation in larger populations.

PO1745

Serum Irisin and Prediction of Cardiovascular Events in Elderly Patients with CKD Stage 3-5

Teresa Del Mastro, Teresa Arcidiacono, Monica Avino, Arianna Bologna, Nadia Edvige Foligno, Federico Persico, Giuseppe Vezzoli. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Irisin is a circulating myokine released from skeletal muscles after physical exercise. Irisin production decreases during the course of chronic kidney disease (CKD) as a potential consequence of sarcopenia and physical inactivity.

Methods: This observational study explored the relationship of serum irisin with cardiovascular outcome in 79 patients with stage 3-5 CKD.

Results: Serum irisin was significantly higher in healthy subjects (n=20) than CKD patients (7±2 vs 3.1±0.9 μg/ml; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 μg/ml) compared with patients at stage 4 and 5 taken together (n=36, 2.8±0.7 μg/ml, p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)$_2$D levels (21±11 pg/ml) than patients in the middle (30±13 pg/ml; p=0.005) and the highest tertile (27±14 pg/ml; p=0.047). Patients in the highest tertile had lower Kauppila score (10.6±6.9) than patients in the middle (11.8±5.5; p=0.007) and the lowest tertile (6.9±6.8; p=0.043). Twenty patients suffered from cardiovascular events during a 3-year follow-up. A Cox regression model using age, body weight, presence of diabetes mellitus, gender, Kauppila calcification score, serum values of FGF23 (as logarithm), phosphate, sclerostin, albumin and cholesterol, eGFR and serum irisin tertiles as covariates showed that patients in the highest tertile of serum irisin had a lower cardiovascular risk than patients in the middle tertile (B 2.38, OR 10.8, 95%CI 1.65-58.13; p=0.013) or in the lowest tertile (B 1.61, OR 5, 95%CI 1.09-22.83; p=0.038).

Conclusions: These findings suggest that serum irisin may be a marker of cardiovascular outcome in CKD patients.

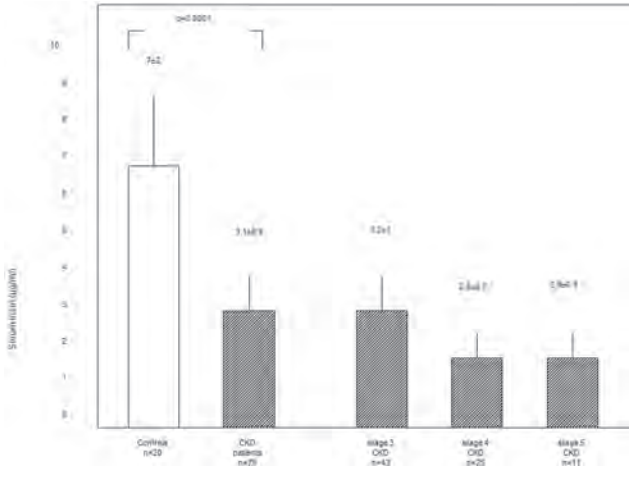


Image 1

	Tertiles of serum irisin		
	The lowest tertile	the middle tertile	the highest tertile
N (M/F)	27(20/7)	25(16/9)	27(17/10)

Deoxycholic Acid (DCA) and Cognitive Impairment and Decline in the Chronic Renal Insufficiency Cohort (CRIC) Study

Kristen L. Nowak,[1] Makoto Miyazaki,[1] Michel Chonchol,[1] Anand Srivastava,[2] Michael J. Fischer,[3] Ana C. Ricardo,[3] Jiang He,[4] Katherine T. Mills,[4] Katherine L. Wolfrum,[5] Amanda H. Anderson,[4] Manjula Kurella Tamura,[6] Harold I. Feldman,[5] Tamara Isakova,[2] Anna Jovanovich.[7] *[1]University of Colorado Health, Aurora, CO; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]University of Illinois at Chicago, Chicago, IL; [4]Tulane University, New Orleans, LA; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]Standford University, Palo Alto, CA; [7]VA Eastern Colorado Health Care System, Aurora, CO.*

Background: Cognitive impairment is common in chronic kidney disease (CKD). The secondary bile acid, DCA, is associated with endothelial dysfunction and oxidative stress, characteristics of cognitive impairment. DCA is also associated with cognitive impairment and risk of Alzheimer's dementia among older adults without CKD. Whether DCA is associated with cognitive impairment in CKD is unknown.

Methods: We used multivariable-adjusted regression models to cross-sectionally and longitudinally evaluate the association between fasting serum DCA levels measured at visit 5 (considered baseline) and cognitive impairment. Among 2836 CRIC Study participants, cognitive impairment was assessed by the Mini-mental State Exam (MMSE). Among 698 participants enrolled in the CRIC Cognitive (COG) Study, cognitive impairment was further assessed by Trails A&B, Category Fluency, Buschke Recall, and Boston Naming tests. Cognitive impairment was defined by a test score >1 standard deviation (SD) worse than the test mean.

Results: Mean age was 59 ± 10 years, 45% were female, and 39% were black. In cross-sectional analyses, there was no association between DCA and cognitive impairment assessed by MMSE in the total cohort after adjustment for demographics and clinical factors (prevalence ratio per 1-SD increase ln DCA: 1.03, 95% CI 0.91-1.17). In longitudinal analyses, DCA was associated with progressive impairment (mean annual % change MMSE per 1-SD increase ln DCA: -0.15, 95% CI -0.34 - -0.02), but not with incident impairment. Among CRIC COG Study participants, in cross-sectional analyses DCA was associated with cognitive impairment based on Category Fluency (prevalence ratio per 1-SD increase ln DCA: 1.36, 95% CI 1.05-1.76) but not with other measures of impairment. In longitudinal analyses among CRIC COG Study participants, DCA was not associated with progressive or incident cognitive impairment.

Conclusions: Among individuals with CKD stages 2-4, higher DCA levels were independently associated with prevalent cognitive impairment in Category Fluency and progressive cognitive impairment assessed by MMSE.

The Association of Sodium Intake and Albuminuria According to Cotinine-Verified Smoking Status: Korean National Health Examination Survey (KoNHES)

Young-Bin Son, Tae-bum Kim, Hyeon-Jin Min, Jonghyun Lee, Jihyun Yang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho, Sewon Oh. Division of Nephrology, Department of Internal Medicine, Korea University Anam Medical Center *Korea University Medical Center, Seoul, Republic of Korea.*

Background: Smoking and high sodium intake are reported about the association with chronic kidney disease. Smoking and sodium intake are modifiable risk factors and the implementation of life style changes in the broad population could have a beneficial effect on public health. We assessed the association of sodium intake and smoking on the presence of albuminuria.

Methods: An observational study from the Korean National Health and Nutrition Examination Survey (2008-2011, 2014-2018) was performed. We included 38,161 adults with eGFR≥60 ml/min/1.73m^2 and had urine cotinine/creatinine ratio (Ucot/Ucrea). Smoking status was assumed by Ucot/Ucrea. 24 hour sodium intake was estimated from spot urine sodium using Kawasaki formula. Albuminuria was defined as urine albumin creatinine ratio ≥ 30mg/g.

Results: Ucot/Ucrea level was significantly higher in current smokers than those in ex-smokers and non-smokers (920.22±9.00, 48.30±2.46, vs. 23.83±1.29 ng/mg, P<0.001). Non-smokers who were exposed to secondhand smoke showed significantly higher Ucot/Ucrea levels than those who were not exposed to secondhand smoke (37.74±3.14 ng/mg vs 16.71±1.13 ng/mg, P<0.001). Ucot/Ucrea level was significantly associated with sodium intake. Sodium intake of 2nd and 3rd Ucot/Ucrea tertile were significantly higher than that of 1st Ucot/Ucrea tertile (4.15±1.31, 4.13±1.43 vs. 3.73±1.15 mg, P <0.001). The quartile groups of sodium intake had a linear relationship with albuminuria (5.2, 5.8, 7.5, and 9.7%, P<0.001). The highest quartile of sodium intake was significantly associated with risk of albuminuria (OR 1.43, 95% CI 1.05-1.93, P=0.022). We evaluated the association of sodium intake with albuminuria according to smoking status estimated by Ucot/Ucrea. In the group with the highest Ucot/Ucrea level, the highest sodium intake quartile indicated significantly higher risk of albuminuria compared to that of lowest quartile (OR: 2.05, 95% CI: 1.20-3.52, P=0.009).

Conclusions: High dietary sodium intake is an independent risk factor for albuminuria and this association was highlighted in high Ucot/Ucrea group. The synergistic effects of cigarette smoking and high salt intake might increase the risk of albuminuria.

PO1748

Interplay Between Serum Thyrotropin, Free Thyroxine, and Thyroid Autoantibody Levels and Survival in a Prospective Hemodialysis Cohort

Amy S. You,[1] Gregory Brent,[2] John J. Sim,[3] Yalitzi Guerrero,[1] Sara S. Kalantar,[4,1] Rebecca Ahdoot,[1] Yoko Narasaki,[1] Matthew D. Nguyen,[1] Csaba P. Kovesdy,[5] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Kaiser Permanente Southern California, Pasadena, CA; [4]University of California Berkeley, Berkeley, CA; [5]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: CKD patients have a high prevalence of hypothyroidism (elevated serum thyrotropin [TSH]) which has been associated with worse survival. In patients with altered protein-hormone binding states (uremia, low/high circulating proteins) among whom routine "indirect" free thyroxine (FT4) assays are not as accurate, little is known about the impact of subclinical (high TSH+normal FT4) and overt (high TSH+low FT4) hypothyroidism and thyroid autoimmune status on hemodialysis (HD) survival.

Methods: In a multicenter prospective cohort of 1117 HD patients from the "Hypothyroidism, Cardiovascular Health, and Survival (HyCARDS)" Study, we conducted protocolized TSH, "direct" FT4 by equilibrium dialysis/tandem mass spectrometry (robust FT4 assessment method in altered protein-hormone binding), and anti-thyroid peroxidase antibody (anti-TPO Ab) assays every 6 months from 2011-19. We examined associations of severity of thyroid dysfunction ascertained by TSH gradations (subclinical vs. overt hypothyroid-range TSH levels) and pairings of TSH+FT4 (subclinical vs. overt hypothyroidism), as well as presence of elevated anti-TPO Abs with mortality using time-varying Cox models.

Results: TSH distributions were higher in those with elevated anti-TPO Abs. In analyses of TSH gradations, elevated TSH was associated with higher mortality (ref: 0.5-<3.0): HRs (95%CI) 1.30 (0.96-1.77) and 1.88 (1.31-2.68) for TSH 3.0-5.0 and >5.0. In analyses of paired TSH+FT4, overt hypothyroidism was associated with higher mortality (aHR [95%CI] 5.11 [1.23-21.28]), while subclinical hypothyroidism trended towards higher mortality (aHR [95%CI] 1.63 [0.98-2.72]). Elevated anti-TPO Abs were not associated with death.

Conclusions: In a prospective cohort of HD patients who underwent rigorous thyroid status assessment, both mild (subclinical) and severe (overt) hypothyroidism were associated with higher mortality. Further studies are needed to determine if correction of thyroid status with thyroid hormone replacement therapy improves survival in this population.

PO1749

Effect of Water Intake and Water Balance on All-Cause and Cardiovascular Mortality Based on a Nationwide Population Study

Seonmi Hwang,[1] Yaerim Kim,[3] Jeonghwan Lee,[2] Jae Yoon Park,[5] Kyung Don Yoo,[4] Yong Chul Kim,[1] Dong Ki Kim,[1] Yon Su Kim,[1] Chun Soo Lim,[2] Jung Pyo Lee.[2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [4]Ulsan University Hospital, Ulsan, Republic of Korea; [5]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: The water balance consists of loss of water and intake of water. Healthy people maintain a good physiological water balance in their daily lives. The aim of this study was to investigate whether fluid intake is independently correlated with all-cause mortality among the general US adult population. In addition, we evaluated the relationship between fluid intake and the participants' hydration status.

Methods: We conducted a prospective cohort study using 1999 to 2015 data from the National Health and Nutrition Examination Survey. A total of 39,039 patients aged over 19 years who had water consumption data using 24-hour dietary recall were enrolled. Participants' hydration status was measured by bioelectical impedance analysis (BIA). The all-cause mortality were calculated using the multivariable Cox model adjusting for comorbidities, body mass index, glomerular filtration rate, serum albumin, and total cholesterol representing nutritional status.

Results: In weighted multivariable Cox models, compared to people with lowest quartile of water intake, the adjusted hazard ratios (aHRs) for all-cause mortality in people with other quartiles 2nd, 3rd, and 4th were 0.83 (95% confidence interval [CI], 0.75-0.91), 0.76 (95% CI, 0.68-0.84) and 0.80 (95% CI, 0.72-0.88), respectively. Restricted cubic spline regression also found a U-shaped relationship between total body water and all-cause mortality. In the correlation analysis, as the water intake increased, the total body water amount measured by BIA increased. Additionally, participants showed lower mortality rates as the total amount of water in the body was higher (1st vs.2nd aHR 0.928 [95% CI, 0.622-1.384] and 1st vs. 3rd aHR 0.542 [95% CI, 0.315-0.933]).

Conclusions: In the general population, which is not in a disease state, too little water in the body and water intake are associated with increased mortality. It is important to maintain adequate hydration status through adequate water consumption.

PO1750

Serum Cystatin C-to-Creatinine Ratio Is a Potential Biomarker for Sarcopenia in Patients with Non-Dialysis-Dependent CKD

Illeon Cho, Yong Seon Choi, Jung Nam An, Sung gyun Kim, Young rim Song. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: Sarcopenia is a prevalent complication in patients with chronic kidney disease (CKD) and linked with quality of life, morbidity and mortality. Sarcopenia is defined as clinical, functional and body compositional parameters, although several candidate biomarkers for this condition have been evaluated. This study aimed to evaluate serum cystatin C to creatinine (Cr) ratio as a potential biomarker for sarcopenia in patients with non-dialysis dependent CKD.

Methods: A total of 517 outpatients were enrolled in this observational cohort study. We measured the muscle mass (lean tissue index, LTI) using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was observed in 25.5% patients. The serum cystatin C/Cr ratio was significantly higher in patients with sarcopenia regardless of age, sex, eGFR, and BMI; and showed a positive correlation with age and pulse pressure, but LTI, HGS, hemoglobin, and serum albumin level showed a negative correlation with serum cystatin C/Cr ratio. Especially in patients with eGFR ≥ 45 mL/min/1.73 m^2, serum cystatin C/Cr ratio showed high negative predictive value in predicting sarcopenia (90.5%) and low LTI (90.4%). As the serum cystatin C/Cr ratio increased by 1, the prevalence risk of sarcopenia and low LTI increased by about 5.8 times and about 9.9 times even after adjusting for sex, age, BMI, underlying disease, albumin, Hb, and eGFR. The association between serum cystatin C/Cr ratio and sarcopenia was maximized in patients with eGFR less than 30, resulting in an increased prevalence risk of about 22.7 times, and in the case of low LTI, an independent association was found in patients with eGFR less than 45, and among them, a 43.9-fold increase in risk was identified. However, there was also no significant result for low HGS.

Conclusions: Serum cystatin C/Cr ratio is inexpensive and easily, quickly, and repeatedly measured; therefore, quick screening and management of sarcopenia will be possible, which will be of great help in the treatment of CKD patients.

PO1751

Prevalence of Inflammation and Associated Healthcare Resource Utilization in Patients with CKD

Rachel Lai,[1] Lynda Szczech,[1] Sarah Clayton,[2] Lewis Harrison,[2] Mollie Lowe,[2] James Jackson.[2] *[1]FibroGen Inc, San Francisco, CA; [2]Adelphi Group Ltd, Bollington, United Kingdom.*

Background: Many patients with chronic kidney disease (CKD) suffer from inflammation, which often increases as CKD progresses. Inflammation is a risk factor for comorbidities and complicates the treatment of anemia, which is common in CKD. Inflammation has been associated with reduced red blood cell and erythropoietin production, as well as increased hepcidin levels, which can lead to functional iron deficiency. Because data on the impact of inflammation on healthcare utilization (HCRU) in patients with CKD are limited, we aimed to assess HCRU in these patients.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme™, a point-in-time survey of physicians and their patients with CKD (stage 3-5D) collected in the United States in 2018. Physician and patient reported HCRU-related information, such as the number of healthcare visits, hospitalizations, and tests conducted to diagnose and monitor patients. Inflammation was defined as C-reactive protein ≥4.9 mg/L, ferritin ≥700 ng/mL, or albumin ≤3.6 g/L. Fisher's exact and t-tests were conducted to assess differences in HCRU between patients with and without inflammation.

Results: There were 227/703 (32%) patients with inflammation; inflammation was present in 136/491 (28%) non-dialysis-dependent, and 91/212 (43%) dialysis-dependent patients. HCRU, including the mean number of healthcare visits, tests conducted, and hospitalizations in the last 12 months, number of pills and injections taken per day, and incidences of requiring a carer were greater in patients with inflammation vs those without (all p<0.05; Table 1).

Conclusions: We found that inflammation was common in patients with CKD and associated with greater HCRU across multiple measures in a real-world setting. Novel treatment approaches in CKD that are effective in patients with inflammation may help to reduce HCRU.

Funding: Commercial Support - FibroGen Inc

Table 1: Comparison of HCRU between patients with and without inflammation

	Patients with inflammation N, Mean (SD)	Patients without inflammation N, Mean (SD)	p-value
Number of healthcare visits in last 12 months for CKD[1]	215, 8.9 (8.4)	467, 6.7 (6.8)	0.0002
Number of tests conducted in last 12 months to monitor CKD[1]	223, 18.4 (7.4)	469, 15.5 (6.5)	<0.0001
Number of hospitalizations in last 12 months for CKD[1]	216, 0.3 (0.6)	469, 0.1 (0.5)	0.0010
Number of pills taken per day for CKD[2]	80, 3.2 (2.5)	197, 2.1 (2.6)	0.0014
Number of injections per day for CKD[2]	56, 0.7 (1.1)	135, 0.4 (0.6)	0.0061

Effects of Home BP-Based Behavioral Guidance on Urinary Albumin Excretion in School Workers with Microalbuminuria-Miyagi Karoshi Prevention Study

Masanori Munakata,[1] Tomomi Hattori,[1] Fumie Kubota-Nakayama,[1] Satoshi Konno,[1] Nobutaka Inoue,[2] Tomohiro Nakamura,[3] Atsushi Hozawa.[3] *[1]Tohoku Rosai Byoin, Sendai, Japan; [2]Kobe Rosai Byoin, Kobe, Japan; [3]Tohoku Medical Megabank Organization, Sendai, Japan.*

Background: Prevention of work-related cardiovascular events, or Karoshi is an important social issue in Japan. This study aimed to examine if home-BP based behavioral guidance is effective to reduce CV event risk in school staffs associated with microalbuminuria, a marker of endothelial damage.

Methods: Subjects were 3868 Miyagi prefectural school workers. Urinary albumin excretion adjusted for creatinine (UAE) and daily sodium intake based on Tanaka method were examined together with usual annual health check-up in 2019. Among them, 169 were diagnosed as having microalbuminuria (30-299.9mg/gCr). Ninety-one subjects agreed to receive the home-BP based health guidance. Guidance was given according to 5 days mean of home BP measurements, or encouraging medical consultation and lifestyle guidance for subjects with ≧135/85mmHg, lifestyle guidance for subjects with 125-134/80-84mmHg and adequate lifestyle guidance for subjects <125/80mmHg if necessary. Outcomes were UAE and frequency of microalbuminuria in the next year. Data were compared between guided and non-guided subjects. Subjects with menstruation were excluded from analysis. Final analysis number was 48 and 43 for guided and non-guided groups.

Results: Guided group demonstrated similar baseline data as compared with non-guided group for age, male gender, body mass index, cardiovascular risk factors and UAE level. Prescription rate for hypertension and diabetes also was similar between them. LogUAE was significantly and similarly decreased in both groups. One year later, microalbuminuria was present in 31.2% for guided group and 30.2% for non-guided group (n.s.). Systolic BP was lowered significantly as compared with baseline in the guided group but not in non-guided group. HbA1C level and daily sodium intake were increased as compared with baseline in guided group but not in non-guided group. Sensitivity analysis excluding treated patients for hypertension or diabetes from baseline demonstrated essentially similar results.

Conclusions: Reduction in UAE did not differ between groups with or without home-BP based behavioral guidance. Our data suggest that notification of microalbuminuria per se have considerable degree of favorable behavioral effects in school workers with microalbuminuria.

PO1753

Weight Changes Following Diabetes Medication: A Population-Based Study

Beini Lyu,[1] Morgan Grams,[2] Lesley A. Inker,[3] Alex R. Chang,[4] Jung-Im Shin.[5] *[1]University of Wisconsin-Madison, Madison, WI; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Tufts Medical Center, Boston, MA; [4]Geisinger Medical Center, Danville, PA; [5]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: The majority of patients with type 2 diabetes are obese, with greater percentages in those with concomitant CKD. Clinical trials suggest that the newer glucose-lowering medications, including sodium-glucose cotransporter-2 inhibitors (SGLT2i) and glucagon-like peptide-1 receptor antagonists (GLP1RA), provide an added benefit of weight loss in people with type 2 diabetes. We evaluated the magnitude of weight change associated with diabetes medication prescription in real-world practice in persons with and without CKD (eGFR <60 vs. ≥60 ml/kg/1.73 m^2).

Methods: We identified patients with diabetes who initiated SGLT2i (n=925), GLP1RA (n=810), dipeptidyl peptidase-4 inhibitors (DPP4i, n=1899), or sulfonylurea (SU, n=3285) between 2015 and 2018 in Geisinger Health System. Outcomes were percent weight change per year among all patients within 1 year after medication initiation and time to first achieving 5% weight loss among patients with overweight/obesity at medication initiation. Inverse probability of treatment weighting (IPTW) based on multinomial propensity scores was used to account for differences in baseline patient characteristics by medication class.

Results: The mean (SD) age of the 6919 patients was 58 (14) years and 3381 (49%) were female. Compared with SU, SGLT2i, GLP1RA, and DPP4i were associated with significant weight loss, with stronger associations for SGLT2i and GLP1RA (**Table**). Similarly, SGLT2i, GLP1RA, and DPP4i users were more likely to achieve 5% weight loss compared with SU (HR [95% CI]: 1.47 [1.28, 1.69] for SGLT2; HR: 1.55 [1.32,1.82] for GLP1; HR: 1.31 [1.19,1.44] for DPP4i). The associations were consistent across CKD status.

Conclusions: In patients with and without CKD, SGLT2i and GLP1RA were associated with significant weight loss compared with SU. These results may further motivate uptake of SGLT2i and GLP1RA, two classes of medications with proven renal benefit, among patients with overweight or obesity.

PO1754

Effects of Caloric Restriction and Aerobic Exercise on Circulating Cell-Free Mitochondrial DNA in Patients with Moderate-to-Severe CKD

Javier Jaramillo Morales,[1] Berfu Korucu,[1] Mindy Pike,[1] Sam A. Headley,[4] Baback Roshanravan,[3] Katherine R. Tuttle,[2] Jonathan Himmelfarb,[2] Cassianne Robinson-Cohen,[1] Talat Alp Ikizler,[1] Jorge Gamboa.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Washington, Seattle, WA; [3]University of California Davis, Davis, CA; [4]Springfield College, Springfield, MA.*

Background: Understanding mechanisms for increased oxidative stress and inflammation in patients with chronic kidney disease (CKD) is vital due to their role in the pathophysiology of this population. Circulating cell-free mitochondrial DNA (ccf-mtDNA) is released to the plasma and believed to promote inflammation by acting as a damaged-associated molecular pattern. Previous studies suggested that in patients with kidney disease, ccf-mtDNA increases and may induce inflammation. Past investigations in patients with CKD have found that aerobic exercise decreases inflammation. We hypothesized that in patients with moderate to severe CKD, aerobic exercise would reduce plasma levels of ccf-mtDNA.

Methods: We performed a post hoc analysis of a multi-center pilot randomized trial of aerobic exercise and caloric restriction (NCT01150851). We measured ccf-mtDNA in plasma at baseline and two and four months after four interventions (aerobic exercise (EX), caloric restriction (CR), EX + CR, usual activity and usual diet). A multivariable model adjusted for age, race, sex, systolic BP, BMI, diabetes, and eGFR was done

Results: Of a cohort of 111 participants who were randomized, 99 had baseline ccf-mtDNA levels, and 92 completed the study. The median age was 57 years old, 44% were female, and 92% had diabetes. Plasma ccf-mtDNA median concentrations at baseline, two, and four months were 3.62, 3.08, 2.78 pM for the usual activity group, and 2.01, 2.20, 2.67 pM for the aerobic exercise group. There was a 16.1% increase per month in ccf-mtDNA in the aerobic exercise group compared to the usual activity group ($p = 0.024$), especially with the combination of aerobic exercise and caloric restriction (29.5% increase per month). After four months of intervention, ccf-mtDNA increased in the aerobic exercise group by 81.6% (95% confidence intervals [CI] 8.2-204.8; $p = 0.024$) compared to the usual activity group, but it was only observed in the aerobic exercise and caloric restriction group (181.7% increase, 95% CI 41.1-462.2; $p = 0.003$)

Conclusions: Our data suggest that aerobic exercise increases plasma ccf-mtDNA levels in patients with CKD stages 3-4, more profoundly in ones with a combination of caloric restriction.

Physical Activity in Patients Undergoing Dialysis: A Pilot Study

Denghui Guo, William F. Fadel, Alissa A. Cranor, Sharon M. Moe, Keith G. Avin, Ranjani N. Moorthi. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients on chronic dialysis have impaired physical function and poor quality of life. Slow gait speed and handgrip strength are indicators of increased all-cause mortality and cardiovascular events in dialysis patients. The relationship between physical activity and gait speed is inconsistent in prior studies. "Cadence", a gait characteristic measured as steps/minute by accelerometer is strongly associated with the intensity of physical activity. We hypothesized that cadence will be lower in dialysis patients compared to healthy adults and that cadence will be correlated with their gait speed.

Methods: Physical activity was measured in N=20 subjects incident to dialysis over 7 days using a validated wrist worn tri-axial accelerometer (ActiGraph). The 7 days included dialysis and non-dialysis days. Average daily cadence (steps/sec) was extrapolated from accelerometer data utilizing a published algorithm. Subject demographics were recorded by self-report or from medical records. Gait speed (meter/sec) was measured over 4 meters. Data on cadence from healthy subjects (N=32) were obtained from a prior study.

Results: Of twenty subjects (4 peritoneal dialysis, 16 hemodialysis), no one recorded any vigorous activity in the entire period, while most (59.4%) of their time was spent in sedentary behavior. Median average daily cadence across subjects was 1.38 [IQR = (1.31 – 1.48)] steps/second. Dialysis subjects had lower average daily cadence than healthy subjects (1.38 vs 1.66 steps/second, p <0.001). When adjusted for age and sex, being "on dialysis" was associated with a 0.24 (95% CI -0.34, -0.14) steps/second lower cadence compared to healthy subjects. For patients on hemodialysis, average daily cadence was not significantly different between HD days and non-HD days, with no significant correlation between 4m speed and cadence (r=-0.28).

Conclusions: In this prospective study, we show that cadence is low in dialysis patients, that dialysis patients are sedentary and cadence does not correlate with gait speed. Thus gait speed alone may not be an accurate representation of intensity of daily physical activity. This pilot study supports the need for detailed studies of gait characteristics in dialysis patients, which will help in the development of personalized exercise and activity programs in patients undergoing dialysis.

PO1756

Physical Activity Scores in Hemodialysis Patients with Thyroid Dysfunction: A Substudy of the NIH THYROID-HD Trial

Yuhei Otobe,[1] Richard Casaburi,[2,3] Harry B. Rossiter,[2] Shlomit Radom-Aizik,[1] Joel D. Kopple,[2,3] Matthew J. Budoff,[2,3] Rachelle Bross,[2] Mackenzie K. Cervantes,[2] Gregory Brent,[4,5] Csaba P. Kovesdy,[6] Yalitzi Guerrero,[1] Yoko Narasaki,[1] Amy S. You,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The Lundquist Institute, Torrance, CA; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [5]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [6]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: Low physical activity is common in hemodialysis (HD) patients and is associated with adverse outcomes in this population (poor health-related quality of life, cardiovascular [CV] disease, death). Prior studies show that hypothyroidism is highly prevalent in HD patients, and is associated with worse self-reported physical function.

Methods: In a substudy of the ongoing multi-center NIH THYROID-HD Trial, we examined baseline physical activity scores determined by the Human Activity Profile (HAP), a validated 94-item instrument assessing daily activities across a wide range of energy expenditures, in HD patients with TSH levels in the high-normal (TSH >3-5 mIU/L) and subclinical hypothyroid range (TSH >5-10 mIU/L). The HAP was used to derive the Maximum Activity Score (MAS) and Adjusted Activity Score (AAS), representing greatest and mean estimated energy expenditures, respectively (range 0-94, segmented to low [<52], moderate [54-73], and high [>74] scores).

Results: Among 57 HD patients who underwent baseline HAP assessment, the mean±SD MAS and AAS scores were 52±21 and 26±27, respectively; median (IQR) MAS and AAS scores were 52 (40, 68) and 22 (0, 49), respectively. In the overall cohort, 79% had low, 14% moderate, and 7% high AAS scores. MAS scores were lower in patients who were older (≥65 yrs), female, White, Hispanic, of longer (>1 yr) vintage, diabetic, or with underlying CV disease. A similar trend was observed for AAS scores.

Conclusions: In this substudy of the NIH THYROID-HD Trial, HAP scores in HD patients with high-normal and subclinical hypothyroid range TSH levels were lower than observed in prior historical dialysis cohorts that did not have underlying thyroid dysfunction. Further research is needed to determine the impact of thyroid hormone replacement on improving physical activity and function in this population.

In Vivo Muscle Mitochondrial Function Is Associated with Exercise Capacity and Efficiency in CKD

Chenoa R. Vargas,[1] Gwenaelle Begue,[3] Usman Rehman,[2] Armin Ahmadi,[2] Tae Youn Kim,[1] Seung M. Jin,[2] Jorge Gamboa,[4] Thomas Jue,[2] Baback Roshanravan.[1] *[1]University of California Davis Department of Internal Medicine, Sacramento, CA; [2]University of California Davis, Davis, CA; [3]California State University Sacramento, Sacramento, CA; [4]Vanderbilt University, Nashville, TN.*

Background: CKD is associated with skeletal muscle dysfunction increasing risk for frailty. Muscle mitochondrial dysfunction may underly impaired physical performance. The associations of in vivo muscle mitochondrial function with exercise capacity and efficiency in CKD is unknown.

Methods: We recruited 8 diabetic and 6 non-diabetic patients with CKD. Leg muscle mitochondrial oxidative capacity was measured by exercise recovery kinetics of [PCr] using ^{31}Phosphorus Magnetic Resonance Spectroscopy (^{31}P MRS). Cardiorespiratory fitness (CRF, VO_2 peak), total work, and work efficiency (total work/VO2peak) were assessed by cycle ergometry. We tested associations of ^{31}P MRS measures with endpoints using Pearson correlations.

Results: Participants had a mean age was 61±10yrs, eGFR of 35±12ml/min with 43% females. Faster PCr recovery rate correlated with VO_2 peak (r=0.58, p=0.03), total work (r=0.70, p=0.03) and work efficiency (r=0.59, p=0.03) (Figure). Associations of PCr recovery with work and work efficiency were independent of age, sex, and weight (both p=0.03).

Conclusions: Muscle mitochondrial oxidative capacity is a major determinant of exercise efficiency and capacity. Therapeutics targeting muscle mitochondria function in CKD may improve physical performance and CRF.

Comparisons of In-Clinic and Free-Living Measures of Physical Function in Predicting Hospitalization in Patients with CKD

Nikita Abraham,[1] Robert E. Boucher,[1] Guo Wei,[1] Jesse Christensen,[2] Sydney E. Hartsell,[1] Judy Carle,[1] Victoria Gonce,[1] Srinivasan Beddhu,[1,2] Kate Lyden.[3] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]University of Massachusetts Amherst, Amherst, MA.*

Background: Physical function is associated with risk of hospitalization; however, comparisons of in-clinic and free-living measures of physical function and their associations with risk of hospitalization has not been well established.

Methods: In this secondary analysis of the Sit Less, Interact, Move More (SLIMM) pilot study, we compared in clinic and free-living measures using accelerometry data. Participants with CKD were randomized to the SLIMM intervention or standard of care and asked to wear a thigh worn accelerometer 7 days before a visit to capture their physical activity. In clinic measures of physical function like 6-minute walk distance were performed during visits. Free-living measures were determined from accelerometry. Free-living 6-minute steps were defined as the number of steps taken during the most active recorded 6-minute period. Free-living measures of physical function were compared to in clinic measures using cox proportional hazards models adjusted for age, sex, smoking, alcohol use, BMI, diabetes, CKD, hypertension, heart failure, and peripheral vascular disease.

Results: 106 participants were randomized, the mean age was 69 ± 12 and 69 ± 14, baseline eGFR was 44 ± 12 and 45 ± 14, and 48% and 37% were female for the standard of care and SLIMM groups respectively. When adjusted for covariates, both in clinic and free-living 6-minute walk distance and steps respectively were associated with hospitalizations (table). In comparisons between in clinic and free-living measures, in clinic measures were not significantly associated with hospitalizations while free-living measures were (table).

Conclusions: Both in clinic and free-living measures of physical function were predictors of hospitalization in patients with CKD.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

Adjusted cox proportional hazard model for hospitalization in in clinic and free-living 6-minute walk

	In clinic alone	Free-living alone	Joint model
In clinic	0.55 (0.34, 0.88)		0.73 (0.45, 1.16)
Free-living		0.49 (0.32, 0.76)	0.58 (0.37, 0.92)

PO1759

Blood Pressure Trends in a Cohort of 9- and 10-Year-Old Children in Iceland: A 10-Year Follow-Up Study

Asdis H. Sigurdardottir,[1,2] Olafur S. Indridason,[3] Sigurdur S. Stephensen,[2] Thordis J. Hrafnkelsdottir,[4,1] Vidar O. Edvardsson.[2,1] *[1]Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland; [2]Children's Medical Center, Landspitali –The National University Hospital of Iceland, Reykjavik, Iceland; [3]Division of Nephrology, Landspitali –The National University Hospital of Iceland, Reykjavik, Iceland; [4]Division of Cardiology, Landspitali–The National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Although there is significant evidence for an association between childhood and adult office blood pressure (BP), data on the correlation of childhood BP and ambulatory BP (ABP) in young adults are missing. The aim of this study was to examine the association between childhood office BP and both ABP and office BP indices in young adults.

Methods: Subjects were recruited from a cohort of 970 young adults aged 20-21-years who participated in a population-based study of BP in 9-10-year-old Icelandic school children. All participants underwent a minimum of 4 resting BP measurements at the childhood BP screening. A total of 121 individuals have completed their participation in the follow-up study, which included office and ambulatory BP measurements. Pearson correlation and linear regression analysis were used to examine the relationship between childhood and follow-up BP.

Results: A significant positive correlation was observed between childhood mean systolic BP (SBP) and systolic office and ambulatory BP at follow-up (r=0.386, p<0.001 and r=0.370, p<0.001, respectively). The correlation between childhood mean systolic office BP and follow-up mean systolic office BP was stronger for males (r=0.580, p<0.001) than for females (r=0.298, p=0.012), and the same applied for mean systolic ABP (r=0.491, p<0.001 and r=0.323, p=0.006, respectively). The correlation of mean childhood diastolic office BP (DBP) with mean DBP indices at follow-up was insignificant for males (office DBP: r=0.244, p>0.05; ABP: r=0.258, p>0.05) but remained significant for females (office DBP: r=0.355, p=0.0026; ABP: r=0.449, p<0.001). In adjusted analysis, childhood mean office SBP significantly associated with mean office SBP at follow-up in both males (beta=0.69, p<0.001) and females (beta=0.26, p<0.001). Each mmHg increment in mean childhood office SBP predicted an increase of mean ambulatory SBP by 0.52 mmHg (p<0.001), unaffected by sex. Childhood DBP did not significantly predict office or ambulatory BP at follow-up in adjusted analysis.

Conclusions: These preliminary results indicate that childhood SBP significantly predicts both systolic office and ambulatory SBP in young adults and these associations are stronger in males.

Preterm Birth and Its Association with Altered Renal Sodium Handling in Response to Mental Stress in Young Adults

Nicholas W. Tully, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Early-life programming events such as preterm birth and very low birth weight (VLBW; <1500 g) contribute to later hypertension development, but the underlying mechanisms are unknown. Experimental data suggest that altered pressure natriuresis and renal sodium handling may be important contributing mechanisms. Adults with primary hypertension exhibit blunted pressure natriuresis in response to sympathetic arousal, but this has not been described in adults born preterm. We investigated renal sodium excretion relative to the change in blood pressure (BP) in response to stress in a cohort of young adults born preterm with VLBW. We hypothesized that young adults born preterm will have a blunted pressure natriuresis response to mental stress compared to those born term with normal birth weight.

Methods: In this long-term prospective cohort of 161 individuals, 129 (80%) born preterm with VLBW and 32 (20%) term-born controls, we measured spot urine sodium/creatinine before and after a 30-min mental stress test and non-invasive continuous BP every 2 min during the stress test. We defined our outcome, pressure natriuresis, as the change in sodium excretion relative to the change in mean arterial pressure (MAP) before and after the stress test with a blunted response being < 0 mg/dL per mmHg. We used generalized linear models to estimate the association between prematurity and the outcome.

Results: The mean age of study participants was 19.8 (SD 0.9) of whom 56% were female. Among those born preterm, median change in sodium excretion relative to change in MAP was 0.022 mg/dL per mmHg [IQR -0.021, 0.12], while the change in term-born counterparts was 0.04 mg/dL per mmHg [-0.005, 0.184]. On unadjusted analyses, the preterm/term difference in pressure natriuresis was B=0.068 mg/dL per mmHg (-0.092 to 0.228), and the relative risk of blunted pressure natriuresis was 1.3 (0.71 to 2.36).

Conclusions: We observed no statistically significant difference in pressure natriuresis response in adults born preterm with VLBW when compared to those born term. Ongoing analyses include investigating other measures of pressure natriuresis in adjusted multivariable models.

The Cardiovascular Risk Analysis According to Different Pediatric Hypertension Guidelines: Data from the Korea National Health and Nutrition Examination Survey, 2016-2018

Jeong Yeon Kim,[1] Sangshin Park,[2] Heeyeon Cho.[1] *[1]Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; [2]University of Seoul, Dongdaemun-gu, Seoul, Republic of Korea.*

Background: Worldwide pediatric hypertension (HTN) prevalence is increasing. Pediatric HTN predicts adulthood HTN, the modifiable leading factor of cardiovascular disease (CVD). Therefore, pediatric HTN is important for CVD risk prevention. There are two well-known pediatric HTN guidelines, the 2017 American Academy of Pediatrics (AAP) and the 2016 European Society for Hypertension (ESH). Also, Korea Center for Disease Control established the blood pressure (BP) classification in 2008 (K-CDC). There is discordance of HTN prevalence in each BP classification. However, no study evaluated the CVD risk according to each BP criteria in the Korean pediatric population. This study evaluated the difference in prevalence and pediatric CVD risk factors according to each BP criteria.

Methods: The data of 2060 children and adolescents aged 10-18 years from the Korea National Health and Nutrition Examination Survey 2016-2018 was reviewed. The BP was classified by AAP, ESH, K-CDC and modified AAP (K-AAP, applying the normal weight Korean children BP reference table in AAP definition). The high BP was defined when BP was above normotension. To analyze the difference in CVD risk, AAP and ESH, AAP and K-AAP, and K-AAP and K-CDC were compared. In each comparison, those newly defined as high BP are compared to those with consistent normotensive - age, sex, height matched. Finally, the BP criteria reflecting more CVD risk was used to analyze data from Korea School Health Examination Survey 2018.

Results: The prevalence of high BP in Korean children and adolescents was generally high in AAP than ESH (19.5% vs 10.6%, p<0.0001). However, there were some differences in prevalence according to age, sex and obesity. AAP reflected more CVD risk factors, including obesity and metabolic risk, than ESH. K-AAP well-screened non-obese children with metabolic risk than AAP and children with obesity and metabolic risks than K-CDC. The prevalence of high BP and HTN in Korean school students with K-AAP was 13.7% and 5.1%, respectively.

Conclusions: The K-AAP classifies Korean children and adolescent with more CVD risk factors as high BP. Therefore, for early CVD risk control, K-AAP could be used to define pediatric HTN in Korea. Further study is warranted for actual CVD association.

Clinical Event Reductions in Hypertension Patients with and Without CKD Treated with Renal Denervation: A Model-Based Estimate Based on Data from the Global SYMPLICITY Registry

Roland E. Schmieder,[1] Felix Mahfoud,[2] Bryan Williams,[3] Giuseppe Mancia,[4] Krzysztof Narkiewicz,[5] Luis M. Ruilope,[6] Markus P. Schlaich,[7] Michael Böhm,[2] Jan B. Pietzsch.[8] *[1]Universitatsklinikum Erlangen, Erlangen, Germany; [2]Universitat des Saarlandes, Saarbrucken, Germany; [3]University College London, London, United Kingdom; [4]Universita degli Studi di Milano-Bicocca, Milano, Italy; [5]Gdanski Uniwersytet Medyczny, Gdansk, Poland; [6]Facultad de Ciencias Medicas 10 de Octubre, La Habana, Cuba; [7]The University of Western Australia, Perth, WA, Australia; [8]Wing Tech, Inc., Menlo Park, CA.*

Background: Estimates of clinical event reductions following renal denervation (RDN) were modelled for patients with and without chronic kidney disease (CKD) based on 3-year follow-up data from the Global SYMPLICITY Registry (GSR).

Methods: CKD (eGFR<60 ml/min/1.73m^2; n=630) and No CKD (eGFR ≥60 ml/min/1.73m^2; n=1,860) cohorts of the GSR were analyzed. Reductions in office systolic blood pressure (oSBP) at 6, 12, 24, and 36 months follow-up were averaged and relative risks (RR) for death, cardiovascular (CV) death, myocardial infarction (MI), stroke, and new-onset end-stage renal disease (ESRD) were obtained from published meta-regression analysis of randomized trials of blood pressure lowering in hypertensive patients. Using the derived RRs, clinical event estimates for maintained baseline oSBP were calculated, facilitating estimation of 36-month absolute event reductions and resulting numbers needed to treat (NNT) for the individual endpoints.

Results: Baseline oSBP and oSBP reductions for the CKD and No CKD cohorts were 163.6 ± 25.7; -11.1 and 166.7 ± 24.6; -15.5 mmHg, respectively. RR ranged from 0.65 for stroke in the No CKD cohort to 0.93 for death in the CKD cohort. There was a numerically higher absolute reduction in major adverse cardiac events (MACE: composite of CV death, MI and stroke) within 3 years of RDN treatment in the CKD vs. No CKD patients (4.0% vs. 3.2%, p=0.12), in part due to higher overall 3-year MACE rates observed in CKD patients (18.8% vs. 11.7%, p<0.001) (Table).

Conclusions: Model-based projections provide a directional estimate of the potential clinical events avoided following RDN treatment and suggest clinically meaningful risk reduction in patients with and without CKD.

Funding: Commercial Support - Medtronic

Achievement of Blood Pressure Target and Risk of Major Adverse Cardiovascular and Cerebrovascular Events in Patients with Metabolic Syndrome

Jimin Lim,[1] Soojin Lee,[4] Jungheon Kwon,[1] Jin hyuk Paek,[1] Woo Yeong Park,[1] Kyubok Jin,[1] Seungyeup Han,[1] Dong Ki Kim,[2,3] Yaerim Kim.[1] *[1]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [3]Kidney Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Eulji University Hospital in Uijeongbu, Uijeongbu-si, Gyeonggi-do, Republic of Korea.*

Background: Metabolic syndrome (MetS) is closely related to adversely cardiovascular morbidities and mortality. Among the components of MetS, controlling the hypertension might provide the highest yield in reducing major cerebro-cardiovascular events (MACCE). Herein, we aimed to investigate the impact of control of hypertension on the development of MACCE and all-cause mortality according to the presence of MetS.

Methods: We performed a nationwide population-based study using the national health insurance database of South Korea. Among 2,998,127 subjects with hypertension who received more than 3 times national health screenings from 2003 to 2011, a total of 1,920,601 subjects were included in the study. The study group was divided by the presence of the MetS and the degree of control of blood pressure (BP), 1) intensive well-controlled (well-C) (SBP <120 and DBP <70), 2) standard well-C (SBP 120-130 and DBP 70-80), 3) uncontrolled subgroup 1(U-S1) (SBP 130-159 or DBP 80-99), and 4) uncontrolled subgroup 2 (U-S2) (SBP ≥160 or DBP ≥100). The main study outcome was all-cause mortality and composite MACCE. The study outcomes were investigated using multivariable Cox-regression analysis after adjusting for clinical variables.

Results: There were 945,243 (49.2%) subjects with 2 or more components of MetS. Among them, 142,991, 179,041, 562,725, and 60,486 subjects were grouped in the well-C intensive, well-C standard, U-S1, and U-S2, respectively. Compared to the well-C standard group, both intensively controlled group (hazard ratio [HR]; 1.123, 95% confidence interval [95% CI]; 1.062-1.186) and uncontrolled group (HR: 1.106; 95% CI 1.061-1.153 in U-S1, and (HR: 1.353; 95% CI 1.265-1.448) in U-S2 group) was associated with increased risk of composite MACCE. In addition, the risk of all-cause mortality in subjects with MetS was increased in well-C intensive group (HR: 1.197; 95% CI 1.143-1.254) and U-S2 group (HR: 1.211; 95% CI 1.211-1.138-1.287), compared to the well-C standard group.

Conclusions: Uncontrolled hypertension increased risk for MACCE and all-cause mortality in patients with or without MetS, whereas intensive control of BP also increased risk. Therefore, proper targeting the blood pressure is important to reduce the risk of major clinical outcomes irrespective of the presence of MetS.

PO1764

Vascular Function Indices Are Strong Predictors of the Severity and Characteristics of Carotid Atherosclerosis

Ashutosh M. Shukla,[1,2] Lina Ly,[1] Malea Joyce,[1,2] Tatiana Orozco,[1] Alfred K. Cheung,[3] Sudhir V. Shah,[4] Mark S. Segal.[1,2] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida, Gainesville, FL; [3]University of Utah Health, Salt Lake City, UT; [4]University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Vascular functional indices strongly predict adverse cardiac outcomes in CKD. However, few have examined the link between vascular function and the severity and characteristics of carotid atherosclerosis in CKD. Management of Cardiovascular disease in cKd(MaCK, NCT03636152) is a randomized controlled study aimed to evaluate the effects of hydroxychloroquine on inflammation, vascular dysfunction and carotid atherosclerosis in Veterans with high-CV risk CKD. Analyzing the baseline parameters of enrollees, we aim to evaluate the predictors of carotid atherosclerosis in CKD patients.

Methods: All randomized participants of MaCK study underwent detailed clinical and laboratory evaluations, including evaluation of inflammation (hsCRP), vascular function (central aortic pressure(CAP), augmentation index(AI) and aortic pulse wave velocity(APWV) by sphygmocore™ XCEL) and detailed evaluation of carotid atherosclerosis 15 mm around bifurcation (total plaque volume (TPV), lipid-rich necrosis, calcification, fibrous cap, and intraplaque hemorrhage by 3T MRI analyzed with Plaquiview™ software).

Results: Initial 17 randomized participants(age 73±4years, all male, 41% with pre-existing CVD and 88% on statins, with eGFR 40±4.7ml/min, microalbumin/creatinine ratio 855±1207mcg/gm, hsCPR 10.6±20.6mg/L total cholesterol 168±40mg/dl, and LDL/HDL ratio 2-1±0.7) with full analyzable MRI were included in the analysis. Significant vascular stiffness was evident at baseline with CAP:98.3±12.6 mm of Hg, Augmentation Index:15.5±7.6 and APWV:9.3±2.4 m/s. Atherosclerotic burden was high, carotid TPV:2207±802mm^3 and Normalized Wall Index:71.7±6, with necrotic core, calcification, fibrous cap, and intraplaque hemorrhage volumes of 357.6±289, 556.2±478, 153.8±122 and 49.6±78 mm^3 respectively. Univariate analysis showed that detailed baseline clinical and laboratory parameters had no significant correlations with TPV or its individual components whereas, vascular functional indices had strong positive correlations with TPV and individual plaque components(p<0.01), especially the CAP, which had among the strongest correlations with lipid-rich necrotic core (p<0.000).

Conclusions: Non-invasively measured central aortic pressure and aortic pulse wave velocity are strong predictors of carotid atherosclerosis and unstable plaques.

PO1765

Relation Between Waist Circumference and Renal Hemodynamic in Healthy Individuals

Agnes Bosch,[1] Dennis Kannenkeril,[1] Christian Ott,[1,2] Robert Pietschner,[1] Kristina Striepe,[1] Mario Schiffer,[1] Roland E. Schmieder.[1] *[1]Department of Nephrology and Hypertension, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Erlangen, Germany; [2]Paracelsus Medical School Nuremberg, Nuremberg, Germany.*

Background: Abdominal adiposity, measured by waist circumference (WC), is associated with increased mortality in individuals with chronic kidney disease. Little is known about the impact of abdominal obesity on the renal perfusion and function in humans. We analyzed whether abdominal adiposity changes renal hemodynamics in 80 healthy, young, male individuals without cardiovascular (CV) disease.

Methods: We analysed the renal hemodynamic using steady state input clearance with infusion of paraaminohippuric acid and inulin, respectively. Intraglomerular pressure and resistances of the afferent (RA) and efferent (RE) arterioles were calculated according to the Gomez equation. The study population was divided in into two groups based on median of WC of the total study population.

Results: The study cohort consisted of male, non-smoking individuals, aged 27 ± 9 years. Mean of WC in the total study cohort was 84.75 ± 9 cm and just 9 patients showed WC > 94 cm (threshold for CV risk according to 2018 hypertension guidelines). Table 1 shows the renal hemodynamic in patients related to mean WC of the total study population. After adjustment for age and mean arterial blood pressure (MAP) using multivariate regression analysis the difference between both WC groups remained significant for the following parameters: RPF (p = 0.006), GFR (p = 0.017), RBF (p = 0.006), RVR (p = 0.006), IP (p = 0.018), RA (p = 0.005).

Conclusions: Increased WC in healthy young, male individuals without cardiovascular disease was associated with reduced GFR and reduced RPF. This effect is likely to be mediated by increased renal vascular resistance, more precisely vasoconstriction of the renal vas afferens.

Renal parameters	Waist circumference (WC)			Waist circumference (WC) / body height		
	≥ median	< median	p-value	≥ median	< median	p-value
Renal plasma flow (ml/min)	620 ± 109	700 ± 104	0.001	630 ± 115	693 ± 103	0.011

Framingham Risk Score and ACC/AHA Pooled Cohort Equation for Prediction of Atherosclerotic Cardiovascular Events in CKD

Benjamin Lidgard,[1] Leila R. Zelnick,[1] Alan S. Go,[2] Kevin D. O'brien,[1] Nisha Bansal.[1] *[1]University of Washington, Seattle, WA; [2]Kaiser Permanente Southern California, Pasadena, CA.*

Background: The Framingham Risk Score and the ACC/AHA Pooled Cohort Equation are used clinically to identify patients at high risk for atherosclerotic cardiovascular disease (ASCVD). The performance of these equations (alone or with clinically available cardiac biomarkers) is unclear in patients with chronic kidney disease (CKD), particularly at more advanced stages. We tested the discrimination of these risk scores and cardiac biomarkers to predict ASCVD in CKD.

Methods: We studied 1027 participants in the Chronic Renal Insufficiency Cohort without ASCVD who were not taking aspirin or statins. Framingham Risk Score, Pooled Cohort Equation, N-terminal pro-brain type natriuretic peptide (NT-proBNP), and high-sensitivity troponin T (hsTnT) were measured at baseline. Outcomes were the composite of fatal and non-fatal myocardial infarction (MI) and cardiac death, with or without stroke, over 10 years. We estimated internally valid C-indices using 10-fold cross validation for each risk score and cardiac risk marker overall, and across categories of eGFR.

Results: Among 1027 participants, the mean age was 52 years, and the mean eGFR was 48 mL/min/1.73 m2. The C-index (95% CI) was 0.74 (0.69, 0.79) for the Framingham Risk Score, and 0.72 (0.67, 0.78) for the Pooled Cohort Equation. Both risk scores had better discrimination for predicting ASCVD at eGFR >60 mL/min/1.73 m2 compared with lower eGFR. HsTnT had comparable discrimination to both risk scores overall. HsTnT alone had comparable discrimination across the spectrum of CKD severity (difference in C-index for lowest vs highest eGFR category for ASCVD -0.04; 95% CI -0.21, 0.14) (**Table**).

Conclusions: The Framingham Risk Score and Pooled Cohort Equation had moderate discrimination for prediction of ASCVD in CKD and performed better at eGFRs >60 versus <60 mL/min/1.73 m2. HsTnT alone had discrimination comparable to each risk score overall, and comparable discrimination across the spectrum of CKD severity. Further work is needed to develop novel risk scores including cardiac biomarkers specifically for use in CKD.

Patients with CKD and Multiple Chronic Conditions Are at Increased Risk of Cardiovascular Events

Michael K. Sullivan, Bhautesh D. Jani, Frances S. Mair, Patrick B. Mark. *University of Glasgow, Glasgow, United Kingdom.*

Background: Major adverse cardiovascular events (MACE) are the leading cause of mortality in chronic kidney disease (CKD). We studied the relationship between the number and type of multiple chronic conditions (MCCs) and the risk of MACE in patients with CKD.

Methods: We retrospectively examined the SAIL Databank: a cohort consisting of the population of Wales, UK (2011-2018). Patients were categorised by the number of MCCs additional to CKD: the primary analysis included all MCCs (e.g. asthma, depression), and a secondary analysis excluded cardiometabolic conditions (hypertension, ischaemic heart disease, cerebrovascular disease, heart failure, atrial fibrillation, peripheral vascular disease, diabetes). The outcome was MACE: myocardial infarction, stroke, heart failure hospitalisation. The risk of MACE associated with number of MCCs was calculated using cox proportional hazards models. Adjustments were made for age, sex, smoking, deprivation, eGFR and cholesterol.

Results: Of the 173,388 patients with CKD, median age was 78 years, 57% were female, 98.6% were of white ethnicity and median eGFR was 51ml/min/1.73m². There was a graded rise in the risk of MACE by MCC count (Figure 1): 1 condition adjusted hazard ratio (aHR) 1.15 (1.02-1.29), 2 MCCs aHR 1.37 (1.22-1.53), 3 MCCs 1.68 (1.50-1.88), ≥4 MCCs 2.61 (2.34-2.92). For non-cardiometabolic conditions, MACE risk was lessened, but the trend persisted: 1 condition aHR 1.16 (1.12-1.20), 2 MCCs aHR 1.30 (1.25-1.35), 3 MCCs 1.43 (1.38-1.49), ≥4 MCCs aHR 1.65 (1.59-1.71).

Conclusions: Patients with CKD and MCCs are at high risk of MACE, even when cardiometabolic conditions are excluded. Cardiovascular risk stratification and preventative strategies in patients with CKD should take into account the number and type of other chronic conditions.

Nondipping Heart Rate in Patients with CKD

Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: A decrease in the nocturnal heart rate (HR) decline, nondipping HR (NHR), was reported to be 14% in the general population and related to cardiovascular events and all-cause mortality, however, the clinicopathologic features of chronic kidney disease (CKD) patients with NHR is still unclear. Previous studies have reported that interstitial and/or tubular atrophy (IF/TA) was significantly associated with both daytime and nighttime hypertension observed with ambulatory blood pressure monitoring (ABPM). We aimed to investigate the clinicopathologic findings associated with NHR status in patients with CKD.

Methods: We retrospectively identified 135 subjects who underwent ABPM and kidney biopsy simultaneously at our institution, from 2016 to 2019. We excluded patients with age <20 years, end-stage kidney disease, less than 5 glomeruli in the kidney biopsy, and patients taking β-blockers. NHR status was defined as (daytime HR – nighttime HR)/ daytime HR <0.1. The percentage of global glomerulosclerosis (GS%), IF/TA, and the severity of arteriosclerosis were scored semi-quantitatively according to the Mayo Clinic/ Renal Pathology Society Chronicity Score (CS).

Results: The median age was 51 years [interquartile range: 35–63], 54.0% of which were male, and the median eGFR was 53.0 [30.0–75.0] mL/min/1.73m². NHR status was found in 39 out of 135 patients (28.9%). Patients with NHR were older and had worse renal function, higher blood pressure, lower hemoglobin level, and a larger amount of urinary protein excretion than patients with dipping HR. In terms of histopathological parameters, patients with NHR had more severe GS%, IF/TA, arteriosclerosis, and higher CS (**Table 1**). In multivariable analysis, GS% was established as an independent determinant of NHR status after its adjustment according to age, sex, and other statistically significant parameters (β = 1.03 [1.00–1.05], *P* = 0.02).

Conclusions: NHR status was observed in 28.9% of CKD patients. This study indicates that GS% is the most relevant histopathological parameter associated with NHR in this population.

Turning the Page on Page Kidney with Dual RAAS Blockade

William J. Assante,[1,2] Jennifer Griffiths,[1,2] Aromma Kapoor.[1,2] *[1]Westchester Medical Center Health Network, Valhalla, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Page kidney is a rare form of secondary hypertension from activation of the renin-angiotensin-aldosterone (RAAS) axis by compression of renal parenchyma. It can occur with blunt abdominal trauma/procedures, but it can occur spontaneously. Initial treatment is an ACE inhibitor (ACE) or angiotensin receptor blocker (ARB). Surgical intervention is pursued if more conservative measures fail. Procedures carry their own intrinsic risk for morbidity and mortality, particularly in the setting of uncontrolled hypertension. This report details the case of a patient with Page kidney responsive to an unconventional conservative management approach: dual RAAS blockade with ACE + ARB after a lack of response with other agents.

Case Description: The patient is a 55M with a history of end stage renal disease (ESRD) on hemodialysis (HD), atrial fibrillation, and type 2 diabetes mellitus admitted for anemia. The patient was dyspneic and weak with right flank pain. He denied hematemesis, melena, or hematuria. Hemoglobin on admission was 4.7 g/dL with INR of 4.8 (on Coumadin for atrial fibrillation). Vitals were normal except a fever to 38.4 C. A CT scan of the abdomen showed a 16.5cm right retroperitoneal hematoma adjacent to the right kidney with anterior dislocation of the kidney. A CT angiogram showed active extravasation within the hematoma. Coumadin was held and a dose of Vitamin K and two units of blood were given. The patient underwent renal artery embolization. Hemoglobin was stable therafter. The patient soon developed hypertensive urgency with blood pressure reaching 190/100 mmHg. The patient's only home medication for blood pressure was Carvedilol. Lisinopril 20mg PO daily was added and increased to maximum dosage, only partially relieving the hypertension. Losartan was added and uptitrated to 100mg PO daily. The patient's blood pressure normalized with average in 120s systolic by discharge. The patient was continued on this regimen as an outpatient. No hyperkalemia was observed.

Discussion: Page kidney is a rare but serious form of secondary hypertension from RAAS activation from renal parenchymal compression. Historically, a trial of either an ACE or ARB is indicated, with refractory cases being managed surgically. In this case, dual RAAS blockade was required for blood pressure control, which allowed surgical interventions, and their associated risk of morbidity and mortality, to be avoided.

PO1770

ESRD Risk Predicting Using Cumulative Hypertension Burden

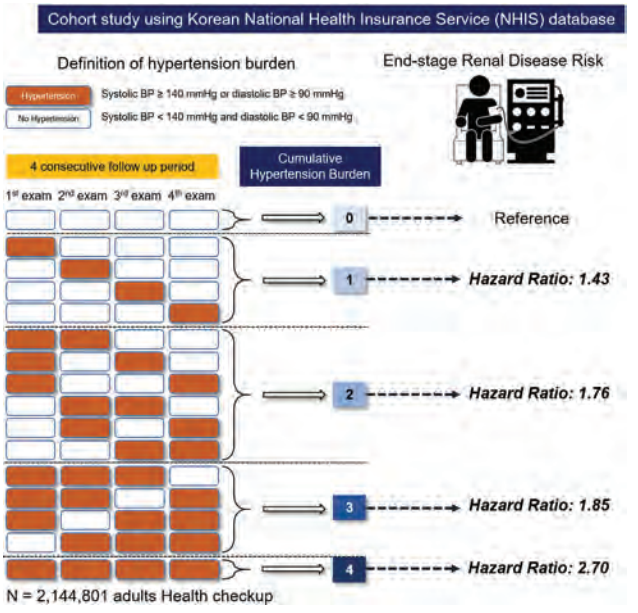
Chang Seong Kim,[1,2] Hong sang Choi,[1] Eun Hui Bae,[1,2] Seong Kwon Ma,[1,2] Soo Wan Kim.[1,2] *[1]Chonnam National University Hospital, Gwangju, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Gwangju, Republic of Korea.*

Background: Hypertension is the leading risk factor for end-stage renal disease (ESRD). However, the association between sustained exposure of increased blood pressure (BP) and ESRD is not well-established. This study investigated whether the cumulative hypertension burden is a substantial risk factor for ESRD.

Methods: The incidence of ESRD among 2,144,801 participants identified from the Korean National Health Insurance Service database, who had documented BP assessments for annual health checkup data between 2006 and 2010, was determined. Over a median follow-up of 7.2 years, ESRD was identified in 1,758 participants. Hypertension burden was defined as the cumulative exposure of hypertension (systolic BP ≥ 140 mmHg or diastolic BP ≥ 90 mmHg) during 4 consecutive follow up period, and scaled 0 to 4.

Results: Hypertension burden was as follows: 0 (n = 1,164,488), 77.6%; 1 (n = 292, 377), 13.6%; 2 (n = 114,397), 5.3%; 3 (n = 52,671), 2.5%; and 4 (n = 20,886), 1.0%. Compared to the hypertension burden of 0, adjusted hazard ratio for ESRD was increased to 1.43, 1.74, 1.85, and 2.70 in hypertension burden of 1, 2, 3, and 4, respectively. A positive dose-dependent relationship between the hypertension burdens and ESRD was found (*P* for interaction < 0.001). This association was maintained for the sustained exposure of both systolic and diastolic hypertension burden. In conclusion, hypertension burden increases the risk of ESRD.

Conclusions: Our study underlines the usefulness of a new assessment of the hypertension burden over a certain period for predicting the risk of ESRD from a large population-based cohort.



PO1771

Hypertension in the US Veterans Health Administration: Updated Prevalence and Risk Factors for Poor Blood Pressure Control

Masaaki Yamada,[1,2] Meenakshi Sambharia,[2] Jason Wachsmuth,[1] Benjamin R. Griffin,[1,2] Melissa L. Swee,[2,3] Saket R. Girotra,[1,2] Heather Reisinger,[1,4] Brian C. Lund,[3] Mary V. Sarrazin,[1,2] Diana I. Jalal.[1,2] *[1]Center for Access & Delivery Research and Evaluation, Iowa City VAMC, Iowa City, IA; [2]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; [3]Iowa City VA Medical Center, Iowa City, IA; [4]Institute for Clinical and Translational Science, Iowa City, IA.*

Background: The Veterans Health Administration (VHA) management guideline recently redefined the blood pressure (BP) cut-off for hypertension diagnosis as ≥130/90 mmHg and recommended a BP goal of <130/90 mmHg for patients with known hypertension. We evaluated the impact of the new definition on the prevalence of hypertension and explored the clinical predictors for uncontrolled BP based on the new treatment goal.

Methods: We retrospectively analyzed data from VHA including Veterans with ≥2 office BP measurements between January 2016 and December 2017. If more than one BP value was available, we used the lowest of the day. Prevalent hypertension was defined as diagnostic codes related to hypertension, prescribed anti-hypertensive drugs, or based on office BP values. We then evaluated the clinical variables associated with uncontrolled BP (mean BP ≥130/90 mmHg) via multivariable logistic regression with risk estimates expressed as relative risk.

Results: Of the 1,959,337 Veterans eligible for inclusion in the analysis, we found that 1,394,230 (71%) and 1,594,093 (81%) met the hypertension diagnosis criteria including ≥140/90 and ≥130/90 mmHg, respectively. Among those who met the diagnosis hypertension criteria including BP ≥130/90 mmHg (n=1,594,093), 34% (n=538,947) had controlled BP (mean BP <130/90 mmHg) and 66% (n=1,054,939) had uncontrolled BP (mean BP ≥130/90 mmHg). Older age, Black race, obesity, kidney disease, and prior cerebrovascular disease (CVD) were associated with increased risk of uncontrolled hypertension (Table 1).

Conclusions: Applying the new 130/90 cut-off to the definition of hypertension increased the prevalence of hypertension by 10% in VHA. Among those with hypertension, 66% of Veterans did not meet the new BP goal of <130/90 mmHg. In addition, our findings indicate the need for targeted interventions in high-risk individuals such as Veterans with obesity, kidney disease, CVD, or of Black race.

Funding: Veterans Affairs Support

Table 1. Clinical Variables Associated with Uncontrolled Hypertension

Variable	Relative Risk of Uncontrolled Hypertension
Age (years)	-
<40	1.0 (REF)
40-49	1.09 (1.08-1.10)
50-59	1.18 (1.17-1.19)
60-69	1.27 (1.26-1.28)
70-79	1.31 (1.29-1.32)

Persistence of Uncontrolled Hypertension Among Older Women Post Implementation of Hypertension Improvement Program

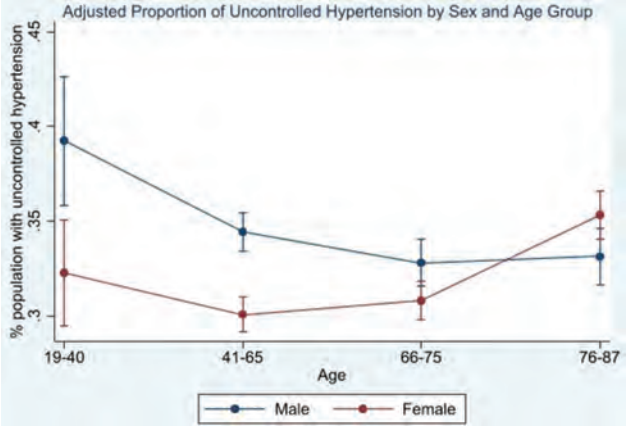
Emily Walsh,[1] Olivia Myers,[2] Talar Markossian,[2] Holly J. Kramer,[2] Katherine Habicht,[3] Beatrice D. Probst.[3] *[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [2]Parkinson School of Health Sciences & Public Health, Loyola University Chicago, Maywood, IL; [3]Loyola University Medical Center, Maywood, IL.*

Background: Age-dependent sex differences in hypertension control have been demonstrated in multiple populations. Four large primary care (PC) practices at Loyola adopted the Target:BP hypertension improvement program in 2018; hypertension control rates increased after adoption. Our study evaluated the impact of the Target:BP program on hypertension control by sex and by age group.

Methods: Analysis used data from 21,864 patients age ≥ 18 years with a hypertension diagnosis and > one outpatient visit in 2019 to a PC clinic enrolled in Target:BP program. Uncontrolled hypertension was defined as blood pressure ≥140/90 mmHg based on last visit. Mixed effects models were used to calculate adjusted odds of uncontrolled hypertension after adjustment for demographics and co-morbidities. Interaction term of sex* age group (≤ 65, 66-75, > 75 years) in fully adjusted mixed effects models was significant (P < 0.001) so adjusted odds of uncontrolled hypertension were calculated by sex and by age group. Adjusted proportion of patients with uncontrolled hypertension by sex and by age group was calculated using marginal effects.

Results: Mean age of patients with hypertension was 64.8 ± 12.7 years; 56.3% were female, 66.6% were White, 21.4% were Black and 11.0% were of Hispanic ethnicity. Among the 5973 (27.3%) with uncontrolled hypertension, 54.7% were female; mean age was 65.2 ± 12.9 years. Adjusted odds of uncontrolled hypertension was significantly higher among women vs. men age 66-75 years (OR 1.33; 95% CI 1.30, 2.28) and age 76+ years (OR 1.73; 95% CI 1.31, 2.28) vs. age ≤ 65 years. Figure 1 shows the adjusted proportion of patients with uncontrolled hypertension by sex and by age group.

Conclusions: Despite implementation of a hypertension improvement program, sex disparities in hypertension control persist among older adults.



PO1773

Influence of Biological Sex on Brachial Cuff Blood Pressure Accuracy

Yasmine Abbaoui,[1] Florence Lamarche,[1] Annie-Claire Nadeau-Fredette,[2] Mohsen Agharazii,[3] Francois Madore,[1] Remi Goupil.[1] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]CHU de Quebec-Universite Laval, Quebec, QC, Canada.*

Background: Females have higher risks of cardiovascular events compared to males with similar BP. Our objective was to assess if the accuracy of brachial cuff and central BP measurements towards intra-aortic BP is influenced by biological sex.

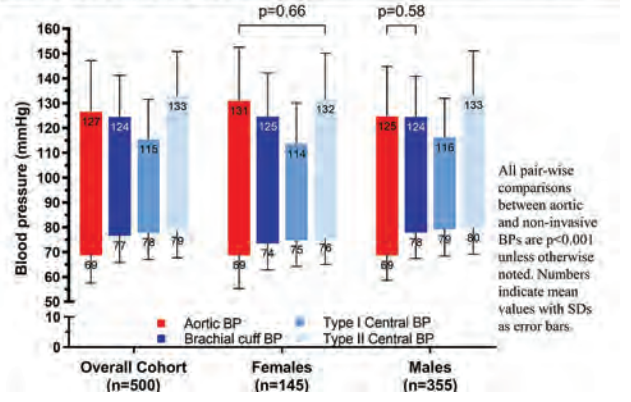
Methods: We enrolled 500 patients undergoing coronary angiography for simultaneous measurements of invasive aortic BP with brachial cuff and central BP (Mobil-o-Graph device). Acceptable accuracy was defined as a mean difference between non-invasive and aortic BPs ≤5 ± ≤8 mmHg. Linear regression and mediation analyses were used to adjust for potential confounders in the relationship between biological sex and BP accuracy.

Results: Of 500 participants, 145 were females. Several characteristics were different in males and females (Table). Brachial cuff systolic BP (SBP) was identical in both groups whereas aortic SBP was 6.2 mmHg higher in females (p<0.001). As such, the brachial cuff appreciably underestimated the aortic SBP in females but not in males. Type II central SBP was the most accurate BP in females, whereas it was brachial cuff SBP in males. In an adjusted linear regression model, only height and pulse pressure were independently associated with the accuracy of brachial cuff SBP. This effect of sex on accuracy was mostly mediated by height (3.5 mmHg; 95% CI 1.4 to 5.6; 57% mediation) to an extent that the direct effect of sex became non-significant (2.9 mmHg; 95% CI -0.3 to 6.2).

Conclusions: Females have higher aortic SBPs than males with identical brachial cuff SBP, which is mostly mediated by a lower height. This could partly explain why females are at higher risk of cardiovascular diseases than males at similar brachial cuff SBP levels.

Clinical characteristics	Female (n=145)	Male (n=355)	p-value
Age	66 ± 11	66 ± 10	0.6
Height (cm)	159 ± 7	174 ± 7	<0.001
Weight (kg)	74 ± 18	86 ± 18	<0.001
BMI (kg/m²)	29 ± 6	28 ± 5	0.3
Active smoking	26%	24%	0.6
Diabetes	26%	29%	0.5
eGFR (mL/min/1.73m²)	79 ± 18	81 ± 17	0.5
Anti-hypertensive medication	76%	81%	0.2
Cuff Brachial SBP (mmHg)	125 ± 18	124 ± 16	1.0
Cuff brachial DBP (mmHg)	74 ± 11	78 ± 11	<0.001
Brachial cuff PP (mmHg)	51 ± 13	47 ± 11	<0.001
Heart rate (bpm)	71 ± 13	66 ± 11	<0.001
Aortic pulse wave velocity (m/s)	9.4 ± 2.1	9.4 ± 1.7	0.9
Augmentation index @ 75 bmp	26 ± 13	17 ± 13	<0.001
Accuracy			
Invasive Aortic SBP	131 ± 22	125 ± 20	<0.001
Difference with Invasive Aortic SBP			
Cuff Brachial SBP	-6.5 ± 12.1	-0.3 ± 11.7	<0.001
Cuff Type I central SBP	-17.3 ± 13.1	-8.8 ± 13.1	<0.001
Cuff Type II central SBP	0.6 ± 15.3	8.3 ± 14.2	<0.001

Mean differences represent the difference between non-invasive BP and aortic BP and are expressed with ± SD. Type I central BP is obtained through calibration with brachial cuff SBP and DBP. Type II central BP is obtained through calibration with brachial cuff mean BP and DBP.



PO1774

Sex-Specific Associations Between Potassium Intake, Blood Pressure, and Cardiovascular Outcomes in the EPIC-Norfolk Cohort Study

Rosa D. Wouda, S.m. Boekholdt, Liffert Vogt. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: High potassium intake is associated with lower blood pressure and lower risk of cardiovascular disease. Whether these associations differ between men and women and whether they depend on daily sodium intake is unknown.

Methods: We performed an analysis in 11,267 men and 13,696 women from the Epic-Norfolk cohort. Daily sodium and potassium consumption was estimated from sodium and potassium concentration in spot urine samples by using the Kawasaki formula. Linear and Cox regression were used to explore the association between potassium intake, systolic blood pressure and cardiovascular events (defined as hospitalization or death due to cardiovascular disease).

Results: After adjustment for cofounders, interaction between potassium intake and sex was significantly associated with systolic blood pressure (p=0.001) and cardiovascular events (p=0.035). In women, but not in men, the inverse slope between potassium intake and systolic blood pressure was steeper in those within the highest quintile compared to the lowest quintile of sodium intake (p<0.001 for interaction). In women within the highest quintile of sodium intake, every 1-gram increase in potassium intake was associated with a 2.9 mmHg lower systolic blood pressure. These associations were paralleled with lower hazards of cardiovascular disease in women (highest vs. lowest potassium intake tertile: HR 0.88, 95% CI 0.93-0.94). Conversely, in men, the inverse association between potassium intake and cardiovascular disease was not statistically significant (highest vs. lowest potassium intake tertile: HR 0.94, 95% CI 0.88-1.01).

Conclusions: We demonstrate that the association between potassium intake and both systolic blood pressure and cardiovascular disease is sex-specific. Our data suggests that particularly women may benefit most from a high potassium intake.

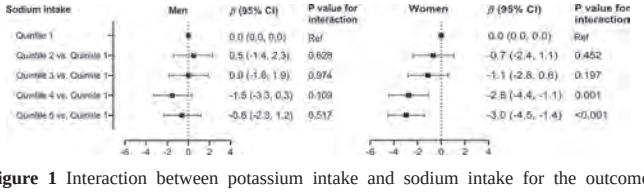


Figure 1 Interaction between potassium intake and sodium intake for the outcome systolic BP in men and women

PO1775

Tryptophan Metabolites Associate with Subclinical and Incident Cardiovascular Disease in CKD

Trista M. Benitez, Elizabeth Vanderwoude, Yun Han, Jaeman Byun, Vetalise K. Cheofor, Brenda W. Gillespie, Rajiv Saran, Anna V. Mathew. *University of Michigan, Ann Arbor, MI.*

Background: Inflammation and oxidative stress contribute to the increased cardiovascular disease (CVD) burden in CKD patients. Altered tryptophan catabolism via the kynurenine pathway associates with CVD, but the ability of these specific metabolites to act as biomarkers of CVD risk in CKD warrants further research.

Methods: We measured tryptophan metabolites using targeted mass spectrometry in moderate to severe CKD patients (n=325; median follow-up 3 years). Vascular calcification at the coronary artery and aorta was measured using a 4-slice LightSpeed QXi and reported as Agatston scores. Incident CVD events included myocardial infarction, coronary revascularization procedures, stroke, transient ischemic attack, new-onset heart failure, sudden cardiac death, and peripheral vascular disease requiring revascularization or amputation. Multiple linear regression and Cox proportional hazard analyses assessed the relationship of tryptophan metabolites to subclinical markers of CVD and CVD events.

Results: We found that lower baseline tryptophan levels predicted increased aortic calcification in a fully adjusted model controlling for demographics, CVD history, traditional risk factors, renal function, CRP, and serum albumin (p=0.006). Higher baseline levels of anthranilic acid and hydroxyanthranilic acid predicted increased coronary calcification and higher total Agatston score, respectively, in the fully adjusted model (p=0.03 and p=0.03). One unit decrease in serum tryptophan at baseline is associated with 70% decrease in time to incident CVD event when adjusting for demographics, CVD history, risk factors, and renal function (HR: 0.31, p = 0.04). Increased anthranilic acid and quinolinic acid independently reduced time to incident CVD event (HR: 1.88, p=0.02; HR: 1.56, p=0.02 respectively), but were not significant in the fully adjusted model.

Conclusions: Lower tryptophan levels are associated with increased aortic calcification and decreased time to incident CVD events. Higher levels of anthranilic acid, hydroxyanthranilic acid, and quinolinic acid are associated with subclinical CVD. Together, these data demonstrate that catabolism of tryptophan via the kynurenine pathway is associated with subclinical CVD and predicts cardiovascular events in CKD.

High Level of Uromodulin Increases the Risk of Hypertension: A Mendelian Randomization Study

Ruilian You,[1] Lanlan Chen,[2] Lubin Xu,[1] Haitao Li,[2] Xiaoxiao Shi,[1] Yali Zheng,[3] Limeng Chen.[1] *[1]Peking Union Medical College Hospital, Dongcheng-qu, China; [2]Jilin University, Changchun, China; [3]Ningxia Medical University, Yinchuan, China.*

Background: The association of uromodulin and hypertension was clinically observed, but not proved as a causal relationship. We conducted a two-sample Mendelian randomization analysis to investigate the causal relationship between uromodulin and blood pressure based on the public datasets.

Methods: We selected two SNPs for the uUMOD exposure from the Genome-Wide Association Studies (GWAS) meta-analysis study(N=10884) and sixteen SNPs for sUMOD based on the open studies in Pubmed(N=4147). Six summary level studies based on the UKbibank and ICBP served as outcomes with the sample of hypertension is 46188, a total sample size of SBP is 1194020, and the DBP is 1194025. We used the Wald ratio to estimate the causal effect of urinary uromodulin(uUMOD) and the inverse variance weighted (IVW) method to combine each SNP's effect. Three methods (IVW, MR-Egger, and Weighted median) were used to access the causal effect of serum uromodulin(sUMOD) on blood pressure. We also adopted Cochran's Q statistic to test the heterogeneity and MR-PRESSO to confirm the horizontal pleiotropy.

Results: MR analysis of the IVW method shows uromodulin could elevate blood pressure and enhance the risk of hypertension. Odds Ratios(OR) of the uUMOD to hypertension (ukb-b-14057 and ukb-b-14177) is 1.04(95% Confidence Interval (CI), 1.03-1.04), while in sUMOD is 1.01(95%CI 1.01-1.02). Both sUMOD and uUMOD can predict the elevation of the SBP and DBP. The effect sizes of the uUMOD to SBP are 1.100 and 0.028 in ieu-b-39 and ukb-b-20175 respectively. The causal relationship between uUMOD and DBP of the ieu-b-39 is 0.88(p-value=4.38E-06) and 0.05 of the ukb-b-7992(p-value=2.13E-10). The β coefficient of sUMOD IVW in ieu-b-38 is 0.371 and 0.011 in ukb-b-20175. For DBP in ieu-b-39 are β=0.313 (SE=0.050) and β=0.018 (SE=0.003)in ukb-b-7992.

Conclusions: Our results solidly indicated that high urinary and serum uromodulin level is a causal risk factor for hypertension.

PO1778

Follistatin Is a Potential Novel Therapeutic Agent for Essential Hypertension

Ann Kuganathan, Marcos S. Leal, Chao Lu, Bo Gao, Jeffrey G. Dickhout, Joan C. Krepinsky. *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

Background: Follistatin (FST) is an inhibitor of several members of the profibrotic TGFb superfamily. It is highly effective at neutralizing activins, without activity against TGFb1 itself. Activins are known to induce inflammation, oxidative stress and fibrosis, all of which contribute to the vascular dysfunction characteristic of hypertension (HTN). We previously showed that FST inhibits kidney fibrosis, improves kidney function and lowers blood pressure (BP) in a hypertensive chronic kidney disease mouse model. While this is a model of secondary HTN, here we seek to analyze the efficacy of FST in improving BP and vascular structure and function in a model of essential HTN.

Methods: Telemeters were implanted in the abdominal aorta of spontaneously hypertensive rats (SHR), a model of essential HTN, and normotensive control Wistar Kyoto (WKY) rats for wireless BP monitoring. Rats were treated with 0.075mg/kg FST or vehicle IP every other day from 12-20 weeks of age (8 weeks). BP was recorded weekly. First branch mesenteric arteries were harvested for analysis of vascular function using myography, assessed for oxidative stress by DHE, or formalin fixed for IHC.

Results: By the end of the study, FST significantly lowered both systolic and diastolic BP in SHRs (200 +/- 9 over 132 +/- 4 mmHg in control and 189 +/- 2 over 123 +/- 2 mmHg in FST-treated SHRs, $P < 0.04$ and $P < 0.03$ respectively). SHR vessels showed increased contractility with the *a*1 adrenergic agonist phenylephrine, which was attenuated by FST. Impaired endothelium-dependent relaxation in SHR vessels was also improved by FST. Structurally, FST-treated vessels had less collagen deposition, assessed by Trichrome, which was accompanied by a reduction in medial thickness. Increased oxidative stress seen in SHR vessels was inhibited by FST.

Conclusions: FST lowers BP in SHR with established HTN, at least in part by reducing vascular oxidative stress and medial thickening. This manifests as improved vascular function, with decreased hypersensitivity to contractile agents and improved endothelial function. Future work will identify the effects of FST on inflammation, and the role of specific activins in essential HTN.

Age and Sex Disparities in Hypertension Treatment Inertia After Implementation of Target: BP

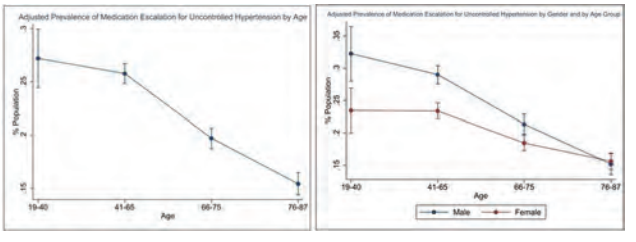
Olivia Myers,[1] Talar Markossian,[1] Beatrice D. Probst,[2] Katherine Habicht,[2] Holly J. Kramer.[1] *[1]Loyola University Chicago, Chicago, IL; [2]Loyola University Health System, Maywood, IL.*

Background: Blood pressure (BP) control decreases with advancing age among women but not men, but reasons for sex disparities remain uncertain. Our institution enrolled four large outpatient primary care clinics in the Target:BP hypertension improvement program in 2018. This hypertension improvement program included audit and feedback of physician prescribing practices of BP lowering medications. We examined the adjusted association of medication escalation, a measure of treatment inertia, with age group among adults with uncontrolled hypertension and determined whether this association is modified by sex. We hypothesized that medication escalation for BP control differs by age group and by sex.

Methods: Adults age ≥ 18 years with uncontrolled hypertension (BP ≥ 140/90 mmHg at last visit) receiving primary care at a clinic enrolled in Target:BP and ≥ 1 primary care visit during 2019 were included. Medication escalation was defined as a change in BP lowering medication class or dose during a visit when hypertension was uncontrolled. Mixed effects models were used to calculate adjusted odds of medication escalation by age group (≤ 65, 66-75, ≥ 76 years) after adjustment for demographics and co-morbidities. Interaction term of sex* age group was then fitted in fully adjusted mixed effects models and was significant ($P < 0.001$). Adjusted odds of medication escalation were then calculated by sex and by age group and adjusted prevalence of medication escalation by age group and by sex was calculated using marginal effects.

Results: Mean age of 5973 adults with uncontrolled hypertension was 65.2 (SD 6.2) years; 54.7% were women; 64.7%% were White, 24.0% were Black and 9.9% were Hispanic ethnicity. Figure (left panel) shows that adjusted prevalence of medication escalation declined with advancing age group among men and women combined. Right panel shows the decline in medication escalation with advancing age group differed by sex until age 76+ years.

Conclusions: Medication escalation for uncontrolled hypertension declines with advancing age and this age associated treatment inertia differs by sex.



PO1780

Oscillometric vs. Auscultatory Blood Pressure Measurements and the Impact of Atrial Fibrillation

Ahmed Aburahma, Christopher B. McFadden. *Cooper University Health Care, Camden, NJ.*

Background: The Hypertension literature recognizes a difference in Oscillometric Blood pressures compared to Auscultatory Blood pressure measurements. Theses differences are small but increased in patients with Atrial fibrillation. This difference varies in previous studies. Again this Difference is larger in subjects with atrial fibrillation. Current Blood pressure measurement guidlines emphasize the use of an Auscultatory method or repeated oscillometric measures to measure blood pressure in patient with arrythmias including atrial fibrillation. This recommendation is not consistently implemented in clinical medicine. We aim to quantify the differences in blood pressure readings between oscillometric and auscultatory method and correlate that to presence or absence of atrial fibrillation.

Methods: This is a retrospective study that involved adult patients seen in the outpatient nephrology clinic by one of the investigators (CM) between january 2016 and january 2020. Data collection included age, sex, BMI, atrial fibrillation (AF), CKD stage, diabetes mellitus, blood pressure readings (by both methods, which were done by the investigator (CM) in all antihypertensive patients) and number of blood pressure medications. Information on a total of 200 patients were collected. 100 of those had hypertension with AF while the other 100 had hypertension but no AF to achieve a power of 80% and P value of 0.05.

Results: After using Unpaired t test, the average difference between two methods in hypertensive patient without atrial fibrillation were around 0.29 mmHg in systolic blood pressure (P value of 0.9 and 95% CI from -5.5 to 6.12) and 5.39 mmhg in diastolic blood pressure (P value of 0.0068 and 95% CI from 1.5 to 9.24). On the other hand, the average difference between two methods in hypertensive patients with atrial fibrillation were 6.8 mmHg in systolic blood pressure (P value of 0.018 and 95% CI from 1.18 to 12.5) and 5.04 mmHg in diastolic blood pressure (P value of 0.002 and 95% CI from 1.87 to 8.21).

Conclusions: This study showed a statistical difference between the two methods in measuring the blood pressure of hypertensive patients with atrial fibrillation. A larger study is needed to show the no difference between the two methods. For now we need to encourage the use of auscultatory method in measuring the Blood pressure in this group of patients.

PO1781

Single-Nephron Salt Excretion and Nighttime Hypertension: A Cross-Sectional Study in Patients with IgA Nephropathy

Nobuo Tsuboi, Hirokazu Marumoto, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Go Kanzaki, Kentaro Koike, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan, Tokyo, Japan.*

Background: Abnormalities in diurnal blood pressure variability and renal salt handling may contribute to poor disease outcomes in patients with IgA nephropathy (IgAN). This study examined the relationships between diurnal blood pressure variability and single-nephron urinary salt excretion (SNUSE) in IgAN patients.

Methods: The subjects were IgAN patients who underwent ambulatory blood pressure (ABP) monitoring and 24-h urine collection during hospitalization for a diagnostic biopsy. In all patients, dietary salt intake was restricted to 6 g/day during hospitalization. Daytime and nighttime hypertension were defined as daytime ABP ≥135/85 mmHg and nighttime ABP ≥120/70 mmHg, respectively. The total nephron number per kidney was estimated by a combined cortical volume assessment of unenhanced computed tomography images and stereology-based measurements of non-sclerotic glomerular density in a biopsy. SNUSE was calculated by dividing urinary salt excretion per day by the total nephron number of both kidneys.

Results: Among the 112 patients (42 years old, 63.4% male, estimated glomerular filtration rate [GFR] 62.4 mL/min/1.73 m^2) included, daytime and nighttime hypertension were noted in 33.0% and 50.9%, respectively. There was no marked difference in the total nephron number or SNUSE in relation to the daytime hypertension. In patients with nighttime hypertension, the total nephron number per kidney was lower (490,000 vs. 796,000/kidney, p = 0.01) and SNUSE was higher (6.53 vs. 4.22 μg/day, p=0.003) than in normotensive patients during nighttime. An increase in SNUSE in patients with nighttime hypertension was associated with advanced tubulointerstitial injury, defined as a T score in the Oxford histopathological classification of IgAN. The single-nephron GFR was comparable among patient groups with and without hypertension both during the daytime and nighttime and was not associated with a T score.

Conclusions: These results provide evidence that salt excretion per nephron is increased in IgAN patients presenting with nighttime hypertension. The difference in SNUSE was identified in relation to the tubulointerstitial injury without producing a difference in single-nephron GFR values among ABP categories, indicating compensatory changes in tubular salt handling at the single-nephron level.

PO1782

Small Changes in eGFR Are Associated with Different Patterns of 24-Hour Ambulatory Blood Pressure Monitoring in the General Population

Sang Youb Han,[1] Sanggon Yoon,[1] Seung Ku Lee,[2] Chol Shin.[2] *[1]Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; [2]Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.*

Background: Alteration of circadian blood pressure (BP) rhythm such as non-dipper and reverse-dipper pattern is associated with cardiovascular diseases and chronic kidney disease (CKD). However, most studies did not control for kidney function even though kidney function is an important risk factor. In this study, we tried to show 24-h ambulatory blood pressure monitoring (ABPM) patterns based on an eGFR in patients without CKD.

Methods: This study was a cross-sectional study from the data of the Korean Genome and Epidemiology Study, which is ongoing prospective cohort study. A total of 1733 participants (60.0±7.00 years, 938 women) who had an eGFR > 60 ml/min/1.73m2 were included. Dipping status was stratified as reverse dipper (<0%), non-dipper (0% to <10%), and dipper (≥10%) based on the night to day ratio of mean BP. They were divided into 4 groups based on quartile of an eGFR (Q4, 128.6-101.6; Q3, 101.5-95.7; Q2, 95.6-87.4; Q1, 87.3-60.5).

Results: The proportion of dipper was progressively decreased from the highest to the lowest eGFR whereas that of reverse dipper and non-dipper significantly increased. (P<0.001). We analyzed the data using logistic regression model in relation to dipper, non-dipper, reverse dipper, and non-dipper plus reverse dipper according to the quartile groups of an eGFR. The highest quartile group (Q4) was fixed as the reference. In univariate analyses, Q1 and Q2 groups were significantly associated with increasing odds ratio (OR) with non-dipper, reverse dipper, and non-dipper plus reverse dipper. After full-adjustment with age, sex, hypertension, diabetes, body mass index, smoking status, exercise, and alcohol consumption, the lowest eGFR group was significantly associated with reverse dippers and non-dipper plus reverse dippers compared to the highest eGFR group (OR=1.689, 95% CI, 1.005-2.840; OR=1.427, 95% CI, 1.027-1.985, respectively). The significant linear trend of non-dipper plus reverse dipper with a decrease in eGFR was confirmed with the test for trend (P=0.024).

Conclusions: Small changes in eGFR are associated with different pattern of 24-h ABPM in general population. ABPM could be useful tool to detect patients with non-dipper in these population.

PO1783

Blood Pressure Control and Undiagnosed Hypertension: A Randomized Diagnostic Study Comparing Clinic, Home, and Kiosk Methods

Yoshio N. Hall,[1] Melissa L. Anderson,[2] Beverly B. Green.[2] *[1]University of Washington, Seattle, WA; [2]Kaiser Permanente Washington Health Research Institute, Seattle, WA.*

Background: Undiagnosed hypertension is common and contributes to CKD and cardiovascular morbidity and mortality. We compared prevalence of blood pressure (BP) control and undiagnosed hypertension at 6 months according to different BP measurement methods.

Methods: BP CHECK was a randomized diagnostic study of 510 adults aged 18-85 without diagnosed hypertension or antihypertensive medications, with elevated BP in clinic and at baseline, conducted 2017-2019 in primary care centers of an integrated healthcare system. Randomization occurred into one of three diagnostic regimens: (1) Clinic BP (usual care), (2) Home BP (twice daily for 5 days), or (3) Kiosk BPs (triplicate BPs on 3 days). All participants completed ABPM at baseline. Primary outcomes were changes in systolic BP and diastolic BP; BP control and receipt of a new hypertension diagnosis at 6 months. We further examined whether changes in patient-reported outcomes relating to physical and psychological well-being and behavior were associated with BP control or a new hypertension diagnosis.

Results: Mean baseline BP was similar across groups (150/88 mmHg). Overall, 93% (472/510) of study participants completed the 6-month visit. All groups experienced a reduction in BP (mean reduction: systolic BP –11.5 mmHg, diastolic BP –5.5 mmHg) with no significant differences by randomization group. Among 323 participants with hypertension based on ABPM, 156 (48%) achieved BP control (<140/90 mmHg) and 130 (40%) had a new hypertension diagnosis recorded in the EHR at 6-months. Participants with undiagnosed hypertension at 6 months experienced significantly lower reductions in both systolic and diastolic BP, compared to individuals with a new hypertension diagnosis (difference in mean change SBP [95% CI], -5.1 mmHg [-7.8,-2.3], P<0.001; DBP -2.4 mmHg [-4.2, -0.5], P=0.01). Changes in patient-reported outcomes from baseline to 6 months were small, with no significant differences in body weight, intake of fruits/vegetables, or measures of physical health according to randomization group or presence of hypertension diagnosis.

Conclusions: Irrespective of BP measuring method, most participants with high BP on screening and ABPM diagnostic testing did not receive a hypertension diagnosis or adequate BP control. New strategies are needed to enhance uptake of BP diagnostic testing into clinical practice.

PO1784

Crit-Line Monitoring Effect on Blood Pressure Control in ESRD Patients Undergoing In-Center Hemodialysis

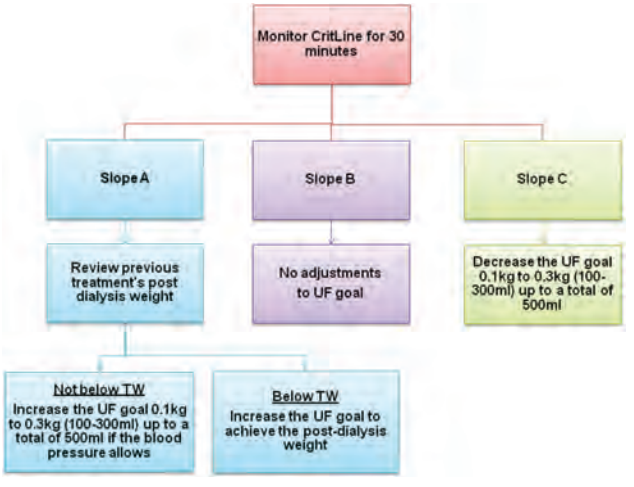
Maggie Meier, Hassaan Iftikhar, Alexandria Y. Li, Frank J. O Brien. *Washington University in St Louis, St Louis, MO.*

Background: Patients with end stage renal disease (ESRD) are admitted to the hospital about twice per year, with a 35% readmission rate. Cardiovascular disease (CVD) makes up 28% of admissions; 38% of patients with CVD admissions have pulmonary edema. Fluid overload in ESRD increases morbidity and mortality. Fluid management improvements have potential to positively impact clinic outcomes in dialysis patients.

Methods: This was a prospective cohort study with adult patients at two outpatient dialysis facilities on the Washington University in St Louis Campus. Our inclusion criteria were patients with consistent 3x weekly in center hemodialysis defined as 80% attendance in the 30 days prior to the study. A critline protocol was implemented by the treatment team (Figure 1).

Results: Among 58 qualified patients, average age was 59. 77% were African American with male predominance (57%). Average BMI was 29. In the Critline cohort, systolic blood pressure trended down (Figure 2). In the initial 25 weeks, average number of antihypertensive medications per patient decreased from 2.6 to 1.8. The number of admissions for fluid overload stayed stable at 10, however readmissions decreased from 4 to 1.

Conclusions: Implementing a Critline protocol trended towards improvements in blood pressure and reduced number of antihypertensives medications. Our findings suggest that a protocolized approach to fluid management using critline will improve our patients outcomes.



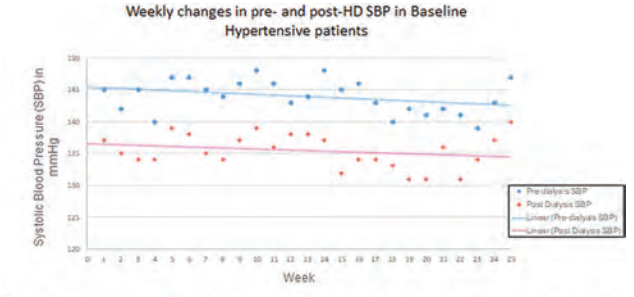


Figure 1. Weekly changes in pre- and post-HD SBP in Baseline Hypertensive patients. Pre- and post-dialysis SBP in hypertensive groups are shown through Week 12. Values given in mmHg. Weekly average post-dialysis SBP is denoted by the filled diamond and the pre-dialysis SBP by the filled circle.

PO1785

Cardiovascular Functional Changes in Transplant Waitlist Dialysis Patients

Peter E. Umukoro,[1] Tzongshi Lu,[2] Sharon M. Moe,[1] Ranjani N. Moorthi,[1] Gordon Mcgregor,[3,4] Thomas F. Hiemstra,[3] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Brigham and Women's Hospital, Boston, MA; [3]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; [4]University of Warwick Warwick Medical School, Coventry, United Kingdom.*

Background: The transition to dialysis is a crucial time in patients with advanced chronic kidney disease (CKD), conferring an increased risk for cardiovascular death. We recently showed that VO_2Peak, an index of cardiovascular functional capacity (CFC) significantly declined in advanced CKD patients following 1-year follow-up in the absence of changes in left ventricular mass index (LVMI). Herein, we hypothesized that initiating dialysis and continuing dialysis could worsen an individual's CFC over time.

Methods: We conducted a cross-sectional study of 241 CKD stage 5 patients from the Cardiopulmonary Exercise Testing in Renal Failure (CAPER) cohort. VO_2Peak (primary endpoint) was assessed by cardiopulmonary exercise testing (CPET) in parallel with transthoracic echocardiography.

Results: Of the 241 patients (mean age [SD] age, 48.9 [14.9] years; 154 [63.9%] male), n=42 patients were pre-dialytic (mean eGFR [SD], 14 [3.4] ml/min/1.73m^2), n=66 were in tertile 1 of dialysis vintage (0-17 months), n=69 in tertile 2 (18-50 months) and n=64 in tertile 3 (≥51 months). Predialysis patients had an impaired VO_2Peak of 22.7 [5.2] ml/min/kg, and this significantly declined to 18.5 [5.5] ml/min/kg in tertile 1 dialysis patients. Compared to the pre-dialysis group, tertile 1 dialysis patients exhibited reduced maximal workload (p=0.003), impaired maximal heart rate (p=0.02), increased LVMI (p<0.001) and markedly elevated FGF23 levels (p=0.01). On assessment of the effects of dialysis vintage, we found an incremental downward trend in VO_2Peak across the groups (19.1 [5.2] tertile 1, 18.0[4.7] tertile 2, 16.9[4.2] ml/min/kg) following exclusion of patients who had prior kidney transplants, however this did not reach statistical significance (p=0.2).

Conclusions: Initiating dialysis in advanced CKD patients is associated with impaired CFC comparable to declines seen in new onset heart failure, making this a critical time for these patients.

PO1786

Major Adverse Limb Events and Mortality After Peripheral Artery Revascularization in Hemodialysis Patients

Ting-yun Lin, Szu-Chun Hung. *Taipei Tzu Chi Hospital, Taipei, Taiwan.*

Background: Revascularization is important for symptom relief and limb salvage in peripheral artery disease, yet limited information exists on the prognosis of hemodialysis patients who receive the procedure. This study sought to determine the incidence and associated factors of major adverse limb events (MALE) after peripheral artery revascularization among hemodialysis patients.

Methods: Hemodialysis patients undergoing peripheral artery revascularization between July 1, 2005, and December 31, 2019, in the Taipei Tzu Chi Hospital were examined for the primary outcome of MALE, defined as severe limb ischemia leading to an intervention or amputation. The secondary outcomes included major adverse cardiovascular events (MACE) and all-cause mortality. Multivariable-adjusted Cox proportional hazards models were used to explore risk factors associated with development of MALE.

Results: A total of 402 hemodialysis patients were included in the final analysis. Overall, the mean age was 68 years, 56.5% (n = 227) were male, 83.3% (n = 335) had diabetes, and 58.0% (n = 233) had coronary artery disease. During a median follow-up of 2.2 years, 54.0% (n = 217) experienced a subsequent MALE, 33.6.0% (n = 136) had a MACE, and 54.5% (n = 219) died. Diabetes, coronary artery disease, current smoking, lower body mass index, and higher platelet count or total cholesterol were significantly associated with increased risk of post-procedure MALE.

Conclusions: A significant proportion of hemodialysis patients undergoing peripheral artery revascularization developed a subsequent MALE and MACE or died. Strategies that address risk factors for MALE should be evaluated to improve the outcomes of revascularized hemodialysis patients.

PO1787

Central Blood Pressure Calibration Method and Cardiovascular Risk Prediction According to Sex

Florence Lamarche,[1] Mohsen Agharazii,[3] Annie-Claire Nadeau-Fredette,[2] Francois Madore,[1] Remi Goupil.[1] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]CHU de Quebec-Universite Laval, Quebec, QC, Canada.*

Background: The accuracy of central BP is improved when calibrated on the mean BP and diastolic BP (C2SBP) compared to calibration on the systolic BP and diastolic BP (C1SBP). Furthermore, preliminary data suggest C2SBP may have the best accuracy in females. We aim to assess whether this enhanced accuracy translates into improved cardiovascular (CV) risk prediction when compared to brachial SBP (bSBP) and C1SBP in the general population and stratified by sex.

Methods: 12,927 participants exempt of known CV disease, with prospective follow-up from administrative databases and central BP measurements were included. The SphygmoCor Px device was used to estimate C1SBP. C2SBP was derived from unprocessed radial pressure waveforms extracted from SphygmoCor output data, which was recalibrated with diastolic BP and 40% form factor derived mean BP. Participants with heart rate <60 were excluded due to incomplete waveforms. Major adverse CV events (MACE) comprised myocardial infarction, stroke, heart failure with hospitalization and CV death. Multivariable Cox regressions, differences in area under the curve, net reclassification index and integrated discrimination index were calculated comparing C2SBP to C1SBP and to bSBP.

Results: Over a median follow-up of 10.1 years (IQR 9.9-10.3), there were 2125 MACE (723/7013 females and 860/5934 males). All BP parameters were significantly associated with MACE, regardless of sex. In the overall cohort, risk prediction metrics marginally favored C2SBP compared to bSBP, but were similar to C1SBP. No significant improvement of CV risk prediction was found in sex-stratified analyses (see Table).

Conclusions: C2SBP marginally improved CV risk prediction when compared to bSBP but not C1SBP in the overall cohort only. All three BP parameters were similarly predictive in both sex, although this analysis possibly lacked power. This may be related to the FF-derived MAP (rather than oscillometric MAP), which is highly dependent on the brachial SBP.

Table 1. Central blood pressure calibration method and cardiovascular risk prediction

Cohort	Calibration method	ΔAUC (95% CI)	NRI (95% CI)	IDI (95% CI)
All	C2SBP vs Brachial SBP model	0.05 (-0.12, 0.12)	0.11 (0.03, 0.17)	0.0002 (-0.0001, 0.0007)
	C2SBP vs C1SBP model	-0.01 (-0.10, 0.07)	-0.01 (-0.10, 0.09)	-0.0004 (-0.0006, 0.0003)
Males	C2SBP vs Brachial SBP model	0.05 (-0.05, 0.13)	0.08 (-0.05, 0.14)	0.0003 (-0.0001, 0.0010)
	C2SBP vs C1SBP model	0.04 (-0.03, 0.11)	-0.03 (-0.11, 0.07)	-0.0001 (-0.0010, 0.0007)
Females	C2SBP vs Brachial SBP model	0.06 (-0.06, 0.18)	0.11 (-0.03, 0.19)	0.0001 (-0.0004, 0.0010)
	C2SBP vs C1SBP model	0.03 (-0.11, 0.17)	0.03 (-0.11, 0.14)	-0.0000 (-0.0007, 0.0009)

Each model includes the relevant BP parameter and age, BMI, smoking status, diabetes, HDL-c, total cholesterol, eGFR, heart rate and use of aspirin, statin, β-blockers, calcium channel blockers, diuretics and renin-angiotensin system blockers. C1SBP, central SBP calibrated on brachial SBP and DBP; C2SBP, central SBP calibrated on brachial SBP and MAP; ΔAUC, difference in area under the receiver operating characteristic curve; NRI, net reclassification index; IDI, integrated discrimination index.

PO1788

Suppressed Renin Activity in CKD: Are We Missing Primary Hyperaldosteronism?

Mohammad A. Sohail,[1] Georges Nakhoul,[2] Susana Arrigain,[2] Jesse D. Schold,[2] Jonathan J. Taliercio,[2] George Thomas,[2] Ali Mehdi.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Background: Primary hyperaldosteronism (PA) is more prevalent than once thought and associated with adverse kidney and cardiovascular outcomes. A prior analysis of the CKD registry at the Cleveland Clinic in patients without a diagnosis of PA showed that the lowest quartile of plasma renin activity (PRA) had more severe hypertension and faster eGFR decline. We hypothesized that some of these patients with suppressed PRA may have undiagnosed PA.

Methods: We reviewed patients in the Cleveland Clinic CKD registry with documented PRA and absolute plasma aldosterone concentration (PAC). Patients in the lowest PRA quartile were identified and stratified by PAC/PRA ratio. A cutoff ratio of ≥20 was considered suggestive of PA regardless of the PAC. Characteristics and outcomes of these two subgroups were compared using t-tests, chi-square tests, Kaplan-Meier analyses and Cox models.

Results: 276 patients were identified for this analysis. Median PRA and PAC were 0.5 ug/L/hr and 8.7 ng/dl respectively. 141 (51%) patients had a PAC/PRA ratio of ≥20 with a median PAC of 14.6 ng/dl in this subgroup. Patients with PAC/PRA of ≥20 vs. <20 had significantly lower eGFR (mean: 50.7 vs. 55.4 mL/min/1.73 m^2; p=0.009), more resistant hypertension (63.1% vs. 48.9%; p=0.044), lower serum potassium values (mean: 3.9 vs. 4.2 mmol/L; p<0.001), and higher serum bicarbonate levels (mean: 26.4 vs. 25.3 mmol/L; p=0.001). With median follow up of 4.2 years, there was no difference in mortality between the two subgroups on adjusted cox model analysis (HR for ≥20 vs.<20: 0.83, 95%CI: 0.47,1.47). No difference in ESKD-free survival at 5 years was noted but the event rate was low (92.6 vs. 91.9 for ≥20 vs.<20; p=0.77).

Conclusions: Our analysis indicates that some CKD patients with suppressed PRA may have underlying PA. More than half of our suppressed PRA cohort had elevated PAC/PRA ratio ≥20 suggestive of PA. The biochemical profile and severe hypertension further supports this diagnosis. We hypothesize that the diagnosis of PA was possibly ruled out because of the "not very high" PAC. Given the limitations of the spot PAC/PRA screen owing to diurnal PAC variations, a suppressed PRA should merit an in-depth evaluation for undiagnosed PA regardless of the PAC. Making this diagnosis is critical since it has significant therapeutic implications.

PO1789

Higher Plasma Renin Activity Level Is Associated with the Severe Intrarenal Arterial Injury in Patients with Hypertensive Emergency

Shu Ushimaru, Sayuri Shirai, Tsutomu Sakurada, Yugo Shibagaki, Daisuke Ichikawa. *Sei Marianna Ika Daigaku Byoin, Kawasaki, Japan.*

Background: It is well known that most patients with hypertensive emergencies have high plasma renin activity (PRA) levels, which indicates the pathophysiology of organ damage. However, the association with intrarenal arterial injury and PRA level has not been well documented.

Methods: We herein investigated this association retrospectively in patients who were diagnosed with hypertensive emergency and were also evaluated the PRA and underwent kidney biopsy between April 2001 and September 2019. The severity of intrarenal arterial injury was classified into stage 0 to stage 3 based on the report by Kohagura et al (Hypertens Res. 2013).

Results: A total of 13 patients (mean age; 39.2±11.2 years, male; 92.3%, BMI; 26.4±3.9 kg/m^2, history of hypertension; 92.3%) were included in this study. All patients had higher systolic blood pressure (≧180 mmHg), and 12 patients had higher diastolic pressure (≧120 mmHg). At admission, 12 patients had kidney injuries, 12 patients had hypertensive retinopathy, 6 patients had acute heart failure, and 1 patient had lacunar infarction. The average PRA levels at admission was 20.0±2.8 ng/mL/ hr. The average duration from diagnosis to kidney biopsy were 14.4 days. The median eGFR on the day of kidney biopsy was 15.3 [IQR 9.1, 21.7] mL/min/1.73m^2. PRA was significantly and positively correlated with severity of intimal edema of intrarenal small arteries (r^2=0.42, p=0.02). However, no association was found between PRA and other histological kidney injury.

Conclusions: Since vascular injury directly leads to organ damage, its presence calls for urgent need for blood pressure lowering with caution for ischemia. Since biopsy is often not available, PRA can be a good substitute to assess vascular injury in the management of those with acute severe hypertension.

Cardiovascular and Renal Outcomes of the New Intensive Blood Pressure Target in a CKD Population in Korea

Kyung hwan Jeong,[1] Soo-Young Yoon,[1] Ji Yoon Kong,[2] Dae Kyu Kim,[1] Jongho Kim,[1] Shinyeong Kang,[1] Jin sug Kim,[1] Hyeon Seok Hwang.[1] *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]Kyung Hee University, Seoul, Republic of Korea.*

Background: Hypertension is one of the most important modifiable risk factors of cardiovascular disease (CVD) including ischemic heart disease (IHD) and stroke. The 2021 Kidney Disease: Improving Global Outcomes (KDIGO) Clinical Practice Guideline for the Management of Blood Pressure (BP) in CKD recommended a target systolic BP (SBP) <120 mmHg regardless of albuminuria, using standardized office BP measurement. We evaluated the prevalence of cardiovascular events and CKD progression to assess the effects of this intensive BP target for CKD patients in Korea.

Methods: The data of 166,397 adults whose baseline estimated glomerular filtration rate (eGFR) <60 mL/min per 1.73 m^2 were extracted from the Korean National Health Insurance Service database between 2009 and 2011. The data were adjusted for multiple factors such as age, sex, smoking, eGFR, and anti-hypertensive medications in multivariate Cox proportional hazards regression models. All participants were divided into four SBP categories (<120 mmHg, 120-129 mmHg, 130-139 mmHg, ≥140 mmHg). The primary outcome was CVD risk, and the secondary outcome was the risk of progression to end-stage renal disease (ESRD), especially in need of intermittent hemodialysis (HD).

Results: The mean ages of the each group of CKD patients were 45.1±15.71 years in SBP <120 mmHg group and 52.13±16.00 years in SBP 120-129 mmHg group. 11.1% in SBP <120 mmHg group and 24.6% in SBP 120-129 mmHg group of the participants were already taking anti-hypertensive medications. 112,012 patients (67.3%) had SBP ≥120 mmHg, and 78,119 patients (46.9%) had SBP ≥130 mmHg. Participants with SBP 120-129 mmHg exhibited a significantly high risk for IHD (hazard ratio (HR), 1.29; 95% confidence interval (CI), 1.03-1.61; P = 0.03) and stroke (HR, 1.57; 95% CI, 1.13-2.18; P <0.001) when compared with the participants with SBP <120 mmHg. Also, the risk of progression to ESRD was also higher (HR, 1.67; 95% CI, 1.46-1.91; P <0.001). Similar statistical findings were observed between the group with SBP <120mmHg and the other groups.

Conclusions: Therefore, the new intensive BP target can be applied to the real clinical practice in CKD population with proper BP monitoring in Korea, and it may eventually reduce the risk of CVD and progression to ESRD in a number of CKD outpatients.

PO1791

Intensive Blood Pressure Control, Age, and All-Cause Mortality in the US Veterans Health Administration

Masaaki Yamada,[1,2] Benjamin R. Griffin,[1,2] Jason Wachsmuth,[2] Meenakshi Sambharia,[1] Melissa L. Swee,[1,3] Saket R. Girotra,[1,2] Heather Reisinger,[2,4] Brian C. Lund,[2] Mary V. Sarrazin,[1,2] Diana I. Jalal.[1,2] *[1]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; [2]Center for Access & Delivery Research and Evaluation, Iowa City VAMC, Iowa City, IA; [3]Iowa City VA Medical Center, Iowa City, IA; [4]Institute for Clinical and Translational Science, Iowa City, IA.*

Background: Intensive blood pressure (BP) control has been shown to improve survival in large clinical trials. It is unknown if intensive BP control is associated with improved outcomes amongst older adults in the real-world setting. We examined the association of intensive BP control with all-cause mortality in U.S. Veterans.

Methods: This retrospective analysis of Veterans Health Administration (VHA) data included Veterans with ≥2 systolic blood pressure (SBP) readings between January 2016 and December 2017 excluding those with mean SBP <100 mmHg to minimize reverse causation. Prevalent hypertension was defined as diagnostic codes related to hypertension, prescribed antihypertensive drugs, or ≥2 office BP of ≥130/90 mmHg. The following SBP categories were examined: <120, 120-129, and ≥130 mmHg (reference). We estimated the potential effect of SBP control on all-cause mortality and evaluated the potential interaction with age using a random-effect Cox regression model.

Results: Of the 1,959,003 Veterans, 18% had SBP <120 mmHg (n=352,684), 26% had SBP 120-129 mmHg (n=507,907), and 56% had SBP ≥130 mmHg (n=1,098,412). Mean SBP <120 and 120-129 mmHg associated significantly with mortality (the adjusted hazard ratio [aHR] was 1.30; 95% confidence interval [CI] 1.28-1.32 for SBP <120 mmHg and 1.03 [95% CI 1.01-1.04] for SBP 120-129 mmHg). There was a significant interaction between SBP category and age (p<0.01). Specifically, we observed a graded association of SBP <120 mmHg with all-cause mortality across increased age categories; this association was significant in the age categories ≥70 years (Figure 1).

Conclusions: Based on the analysis of real-world data of approximately 1.9 million Veterans, intensive BP control (SBP <120 mmHg) was associated with higher mortality specifically among older Veterans. These data have implications for BP management and suggest that intensive control of SBP may be harmful in older adults.

Markers of Kidney Tubular Secretion and Risk of Cardiovascular Disease and Mortality in Persons with CKD in SPRINT

Simon Ascher,[1,2] Ronit Katz,[3] Rebecca Scherzer,[1] Alexander Bullen,[4,7] Stein I. Hallan,[5] Vasantha Jotwani,[1] Rakesh Malhotra,[4] Michelle M. Estrella,[1] Jesse C. Seegmiller,[6] Joachim H. Ix,[4,7] Michael Shlipak,[1] Pranav S. Garimella.[4]
[1]Kidney Health Research Collaborative, Department of Medicine, San Francisco Veterans Affairs Health Care System and University of California San Francisco, San Francisco, CA; [2]University of California Davis, Davis, CA; [3]University of Washington, Seattle, WA; [4]University of California San Diego, University of California San Diego, La Jolla, CA, US, academic, La Jolla, CA; [5]Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; [6]University of Minnesota Academic Health Center, Minneapolis, MN; [7]Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Tubular secretion of organic solutes is essential to the clearance of many drugs, metabolites, and toxins. Whether novel measures of tubular secretion have prognostic value for cardiovascular and mortality risk among hypertensive, nondiabetic persons with CKD is uncertain.

Methods: In 2089 SPRINT (Systolic Blood Pressure Intervention Trial) participants with baseline eGFR <60 ml/min/1.73m2, we created a summary secretion score from 10 tubular secretion biomarkers by averaging across their urine-to-plasma ratios. We used multivariable Cox proportional hazards models to evaluate associations between secretion scores and risk of cardiovascular disease (CVD) and all-cause mortality.

Results: Mean age at baseline was 73 ±9 years and mean eGFR was 46 ±11 ml/min/1.73m2. There were 272 CVD events and 144 deaths during a median follow-up of 3.26 years. In unadjusted analyses, a 1-SD higher secretion score was associated with a lower risk of CVD (hazard ratio [HR] per: 0.87; 95% CI: 0.76, 0.99), but not all-cause mortality (HR: 0.95, 95% CI: 0.80, 1.13) (Table). In multivariable analyses adjusting for baseline eGFR, albuminuria, and CVD risk factors, the association between higher secretion score and CVD risk attenuated and was no longer significant (HR: 0.94, 95% CI: 0.81, 1.08), while higher secretion appeared to be associated with an increased risk of all-cause mortality that did not reach statistical significance (HR: 1.12, 95% CI: 0.95, 1.33).

Conclusions: Among SPRINT participants with CKD, higher tubular secretion was not significantly associated with risk of CVD or mortality after adjustment for eGFR and albuminuria.

Markers of Kidney Tubular Secretion and Risk of Adverse Events in Persons with CKD in SPRINT

Simon Ascher,[1,2] Rebecca Scherzer,[1] Pranav S. Garimella,[3] Ronit Katz,[4] Stein I. Hallan,[5] Vasantha Jotwani,[1] Rakesh Malhotra,[3] Michelle M. Estrella,[1] Jesse C. Seegmiller,[6] Joachim H. Ix,[3,7] Michael Shlipak,[1] Alexander Bullen.[3,7]
[1]Kidney Health Research Collaborative, Department of Medicine, San Francisco Veterans Affairs Health Care System and University of California San Francisco, San Francisco, CA; [2]University of California Davis, Davis, CA; [3]University of California San Diego, La Jolla, CA; [4]University of Washington, Seattle, WA; [5]Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; [6]University of Minnesota Academic Health Center, Minneapolis, MN; [7]Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Tubular secretion is an essential mechanism for the elimination of many drugs, metabolites, and toxins. Impaired tubular secretion may contribute to the high burden of adverse events (AEs) in persons with CKD. Whether novel measures of tubular secretion have prognostic value for AEs during hypertension treatment is unknown.

Methods: In 2089 SPRINT (Systolic Blood Pressure Intervention Trial) participants with baseline eGFR <60 ml/min/1.73m2, we created a summary secretion score from 10 tubular secretion biomarkers by averaging across their urine-to-plasma ratios. Multivariable Cox proportional hazards models were used to evaluate associations between secretion scores and risk of a composite of pre-specified serious AEs (hypotension, syncope, bradycardia, acute kidney injury, electrolyte abnormalities, and injurious falls) and two outpatient AEs (hyperkalemia and hypokalemia).

Results: Mean age was 73 ±9 years and mean eGFR was 46 ±11 ml/min/1.73m2. Overall, 30% of participants experienced at least one AE during a median follow-up of 3.0 years. The association between secretion score and composite AE risk followed a curvilinear pattern. Compared to the lowest secretion score quartile, the highest quartile was associated with reduced risk of the composite AE in analyses adjusting for demographics and clinical characteristics (hazard ratio [HR]: 0.63; 95% CI: 0.44, 0.91) (Table). After additionally adjusting for baseline eGFR and albuminuria, the association attenuated and was no longer significant (HR: 1.01, 95% CI: 0.67, 1.50). In multivariable analyses of the individual AEs, higher secretion was independently associated with higher risk of syncope or hypotension (HR per 1-SD higher secretion score: 1.30, 95% CI: 1.10, 1.54) and lower risk of ambulatory hyperkalemia (HR: 0.71, 95% CI: 0.54, 0.95).

Conclusions: Among SPRINT participants with CKD, higher tubular secretion was associated with lower AE risk, but this association was not independent of eGFR and albuminuria.

Longitudinal Changes in FGF-23 and High-Sensitivity C-Reactive Protein with Incident CKD in the Accord-BP Trial

Wenjin Liu,[1] Yufeng Huang,[1] Robert E. Boucher,[1] Guo Wei,[1] Glenn M. Chertow,[3] Srinivasan Beddhu.[1,2]
[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]Stanford University, Stanford, CA.

Background: In adults over 50 with increased cardiovascular (CV) risk, intensive systolic blood pressure (SBP) lowering reduces the risk of death and major CV events, but increases the risk of incident CKD. Metabolic manifestations of incident CKD related to intensive SBP lowering are unknown. Here we explored the relation between incident CKD and FGF23, an early marker of bone and mineral metabolism, in participants enrolled in the ACCORD-BP trial.

Methods: We included 362 ACCORD BP participants with incident CKD during follow-up along with 359 control participants without any kidney events. Control participants were matched for age, sex, race/ethnicity, SBP intervention and glycemia intervention arms. Incident CKD was defined as a >30% decrease in eGFR to <60 ml/min/1.73m2. Serum concentrations of FGF23 and hs-CRP were measured using Meso Scale Discovery Immunoassay platform at baseline, month 24 and 48/ close-out. Differences from baseline were estimated for the average of month 24 and 48/ close-out using mixed effect models with fixed effects for group and visit.

Results: Mean age was 63±6 yrs, 55% women, and 30% non-white. Baseline duration of diabetes was 11±8 yrs; baseline eGFR, FGF23 and hsCRP in the incident CKD and control groups were 87±17 and 92±19, 76(55,107) and 52(40,76) pg/ml and 3.2 (1.3,7.2) and 3.8(1.3,12.0) μm/ml, respectively. Longitudinal changes in these parameters are summarized in the Table and Figure.

Conclusions: Compared to controls, incident CKD was associated with increase in serum FGF23 and hsCRP levels. The long-term implications of incident CKD with intensive BP control needs further study.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

	Within incident CKD	Within control group	Between groups differences
	Geometric mean change from baseline (95% CI)		
FGF23, pg/ml	1.75 (1.67,1.83)	0.98 (0.93,1.03)	1.79 (1.68,1.91)
hs-CRP, µm/ml	0.97 (0.87,1.09)	0.70 (0.62,0.79)	1.39 (1.20,1.61)

PO1795

Carotid Plaque Characteristics and Incident Cognitive Impairment in Hypertensive Adults

L Parker Gregg,[1,2] Srinivasan Beddhu,[3,4] Robert E. Boucher,[3,4] Manjula Kurella Tamura,[5] Chun Yuan,[6] Jie Sun,[6] Niranjan Balu,[6] Nicholas M. Pajewski,[7] Jeff D. Williamson,[7] Sankar D. Navaneethan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]University of Utah Health, Salt Lake City, UT; [4]VA Salt Lake City Health Care System, Salt Lake City, UT; [5]Stanford Medicine, Stanford, CA; [6]University of Washington, Seattle, WA; [7]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Carotid atherosclerosis is associated with cognitive impairment. We investigated associations of plaque characteristics on carotid magnetic resonance imaging (MRI) with the development of mild cognitive impairment (MCI) or probable dementia.

Methods: In an ancillary study to the Systolic Blood Pressure Intervention Trial (SPRINT), carotid plaque was identified by MRI and characterized as having a lipid-rich necrotic core (NC) or calcification. In the parent study, adjudicated MCI and probable dementia were adjudicated on the basis of neuropsychological testing and proxy reports of cognition-related decline in functional status. We related baseline plaque presence and characteristics of NC or calcification with the incidence of MCI/probable dementia at 3 years of follow-up.

Results: Of 465 participants, 137 (29.5%) had NC plaque. Those with NC plaque were older and more likely to have cardiovascular disease than those without NC plaque. There were 38 MCI/probable dementia outcomes in the entire cohort over 2220 person-years of follow-up. The incidence (95% CI) of a composite outcome of MCI or probable dementia at 3 years was 12.0% (7.5, 18.9) in the NC group and 7.0% (4.6, 10.4) in the no NC group with an absolute risk difference of 5.1% (95% CI -1.2, 11.3, P=0.11). With further adjustment, the absolute risk difference attenuated but the point estimate remained high (Figure). Results for the presence of any plaque or calcified plaque with MCI/probable dementia are also summarized in the Figure.

Conclusions: We observed large differences in risk for MCI/probable dementia associated with the presence vs. absence of NC plaques, but the significance of this finding is uncertain due to the small number of incident cases of cognitive impairment. Nonetheless, our observations indicate the need to study NC plaque as a novel and potentially more relevant marker of vascular health in future studies of cognitive impairment in hypertensive adults.

PO1796

Associations of CKD with Dementia Before and After Transient Ischemic Attack and Stroke in a Population-Based Cohort Study

Dearbhla Kelly, Peter M. Rothwell. The Oxford Vascular Study *University of Oxford Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom.*

Background: Individuals with chronic kidney disease (CKD) appear to have a greater risk of developing cognitive disorders than the general population. Both vascular and neurodegenerative hypotheses have been proposed to underlie this cognitive burden. To explore the vascular hypothesis further, we investigated the association between CKD and dementia before and after transient ischaemic attack (TIA) and stroke.

Methods: In a prospective, population-based cohort study of TIA and stroke (Oxford Vascular Study; 2002-2012), pre-event and new post-event dementia were ascertained through direct patient assessment and follow-up for 5 years, supplemented by review of hospital/primary care records. Associations between pre-dementia and CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73m²) were examined using logistic regression, and between post-event dementia and CKD using both Cox and competing risk regression models, adjusted for age, sex, education, cerebrovascular burden (stroke severity, prior stroke, white matter disease), diabetes mellitus, and dysphasia.

Results: Among 2305 TIA/stroke patients (median [IQR] age, 77 [67-84] years, 1174 [51%] male, 688 [30%] TIA), 1174 (50.9%) had CKD. CKD initially appeared to be associated with both pre-event (odds ratio [OR], 2.04 [95% CI, 1.52–2.72]; P<0.001) and post-event dementia (hazard ratio [HR], 2.01 [95% CI, 1.65–2.44]; P<0.001); however, these associations attenuated and became non-significant after adjustment for the above covariates (OR=0.92 [0.65-1.31]; p=0.65 and HR=1.09 [0.85-1.39]; p=0.50). The results were similar when a competing risk model was used (subdistribution HR [SHR] =1.74 [1.43-2.12; p<0.001, attenuating to 1.01 [0.78-1.33]; p=0.92 with complete adjustment). CKD was more strongly associated with late (>1 year) post-event dementia (SHR=2.32, 1.70-3.17; p<0.001), particularly in the minor events subgroup (SHR=3.08, 2.05-4.64; p<0.001), but not significantly so after complete adjustment (SHR=1.53, 0.90-2.60; p=0.12).

Conclusions: In patients with TIA and stroke, CKD was not independently associated with either pre- or post-event dementia, suggesting that age, sex, education, and cerebrovascular burden may play a more important role in the relationship than renal-specific neurodegenerative mechanisms.

PO1797

Microvascular Endothelial Dysfunction in Women Living with HIV Represents Premature Aging

Dan Wang, Christopher S. Wilcox. *Georgetown University Medical Center, Washington, DC.*

Background: Combined antiretroviral therapy has permitted HIV-infected subjects to survive to old age yet many develop premature cardiovascular disease (CVD) characteristic of small vessel dysfunction though the causes are unclear. We reported that young HIV-infected individuals had endothelial dysfunction in their subcutaneous microarterioles (SMAs) dissected from a gluteal biopsy. We now test the hypothesis that this represents premature microvascular aging due to inflammation and reactive oxygen species (ROS).

Methods: SMAs from young (n=24) and old (n=18) virally-suppressed, HIV-infected and propensity-matched young (n=18) and old (n=16) HIV-negative controls were preconstructed on a myograph and relaxed with acetylcholine (Ach) to assess endothelium-dependent relaxation factor (EDRF*). Circulating IL-6 and urinary* 8-isoprostane $F_{2\alpha}$ were measured to access markers of inflammation and ROS.

Results: Young HIV infected (vs uninfected) subjects had significantly (p< 0.05) reduced EDRF (26±3% vs 39±2%) and significantly (p<0.05) increased circulating IL-6 (13±2 vs 6±2 pg/ml) and urinary 8-isoprostane $F_{2\alpha}$ (2.7±0.5 vs 1.3±0.3 ng/ ml.mg creatinine). Amongst controls, EDRF was reduced significantly (p< 0.05) in old vs young (26±2 % vs 38±3 %), accompanied by increased IL-6 (15±3 vs 6 ± 1 pg/ml) and 8-isoprostane $F_{2\alpha}$ (3.4±0.5 vs 1.3± 0.3 pg/ml). These variables were not significantly different between young and old HIV-infected individuals such that, amongst the old subjects, there was no difference (P=NS) between HIV infected (vs uninfected) subjects for EDRF, IL-6 or 8-isoprostane $F_{2\alpha}$.

Conclusions: Young subjects living with HIV have inflammation and ROS that impair their endothelial function but normal subjects develop age-dependent endothelial dysfunction sufficiently to abolish any difference with subjects who have HIV. Thus, microvascular disease in HIV represents the effects of inflammation and oxidative stress to cause premature aging.

PO1798

Platelet Activity Mediates Enhanced Cardiovascular Risk in Patients with CKD and Peripheral Artery Disease

Qandeel H. Soomro, Lucas Cofer, Yuhe Xia, Elliot S. Luttrell-Williams, Khrystyna Myndzar, David M. Charytan, Jeffrey S. Berger. *New York University, New York, NY.*

Background: Chronic kidney disease (CKD) is common in patients with peripheral artery disease (PAD), and both are associated with poor cardiovascular (CV) outcomes. Platelets drive PAD pathogenesis and mediate atherothrombosis. Platelet function in CKD and the related CV risk is unclear. We investigated relationships between CKD, platelet activity, and incident CV events in a cohort of patients with PAD

Methods: The Platelet Activity and Cardiovascular Events (PACE) study enrolled 289 patients with PAD undergoing lower extremity revascularization (LER). CKD was defined as eGFR<60 mL/min/1.73m^2 by the CKD-EPI equation. We measured platelet activity via light transmission aggregometry (LTA) in response to submaximal ADP, collagen, serotonin, epinephrine, and arachidonic acid (AA) prior to LER, and followed patients for a median of 18 months. The primary clinical endpoints were myocardial infarction (MI) and a composite of major adverse CV events (MACE; MI, stroke, death).

Results: There were 113 (40%) patients with and 172 (60%) without CKD. Patients with CKD (vs. non-CKD) were older and more likely to be female, Hispanic, have diabetes, heart failure, and critical limb ischemia (P<0.05 for each). There were no significant differences in prevalent coronary artery disease or use of antiplatelet therapy between groups. Platelet aggregation in response to submaximal ADP, serotonin, epinephrine, and AA was elevated in the CKD group (**Figure**). After multivariable adjustment, patients with CKD were at greater risk of MI (aHR 2.2 [95% CI: 1.02-4.9]; P=0.045) and MACE (1.9 [1.2-3.3]; P=0.01) than those without CKD. Platelet aggregation in response to submaximal agonist stimulation had a 25% and 12% mediating effect on the association of CKD with MI and MACE, respectively

Conclusions: In patients with PAD, CKD was associated with increased platelet activity and CV events. Heightened platelet activity is an important mechanism underlying increased CV risk in CKD

PO1799

Circulating Vascular Adhesion Protein-1 Level Predicts Risk of Cardiovascular Events and Mortality in Hemodialysis Patients

Dae Kyu Kim,[1] Yu ho Lee,[2] Soo-Young Yoon,[1] Jongho Kim,[1] Jin sug Kim,[1] Yang gyun Kim,[1] So-young Lee,[2] Shin-Young Ahn,[3] Shinyeong Kang,[1] Dong-Young Lee,[4] Kyung hwan Jeong,[1] Ju young Moon,[1] Hyeon Seok Hwang,[1] Sangho Lee.[1] *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [3]Korea University Medical Center, Seoul, Republic of Korea; [4]Korea Veterans Health Service, Seoul, Republic of Korea.*

Background: Vascular adhesion protein-1 (VAP-1) is an oxidative enzyme of primary amines that facilitates the transmigration of inflammatory cells. The oxidative and inflammatory effects of VAP-1 are prominently increased in pathological conditions such as metabolic, atherosclerotic, and cardiac diseases. However, the clinical significance of circulating VAP-1 levels in hemodialysis (HD) patients is unclear.

Methods: A total of 434 HD patients were prospectively enrolled between June 2016 and April 2019 as part of a prospective multicenter cohort study. Plasma VAP-1 levels were measured at the time of study data entry, and the primary endpoint was defined as a composite of cardiovascular (CV) events and cardiac events.

Results: Circulating VAP-1 levels were positively correlated with plasma levels of cardiac remodeling markers, including brain natriuretic peptides, galectin-3, and matrix metalloproteinase-2. Multivariate logistic regression analysis revealed that patients with higher circulating VAP-1 levels were more likely to have left ventricular (LV) diastolic dysfunction (odds ratio, 1.40; 95% confidence interval [CI], 1.04–1.88). The cumulative event rate of the composite of CV events was significantly greater in VAP-1 tertile 3 than in VAP-1 tertiles 1 and 2 (P = 0.009). Patients with VAP-1 levels in tertile 3 were also associated with an increased cumulative event rate of cardiac events (P = 0.015). The VAP-1 tertile 3 was associated with a 2.06-fold higher risk of the composite of CV events (95% CI, 1.10–3.85) and 2.06-fold higher risk of cardiac events (95% CI, 1.03–4.12) after adjustment for multiple variables.

Conclusions: Plasma VAP-1 levels had the positive relationship with circulating levels of cardiac pathology markers and LV diastolic dysfunction. Higher VAP-1 levels were also associated with an increased risk of incident CV events and cardiac events in HD patients. Our results indicate that VAP-1 help clinicians identify those at high risk of CV events

PO1800

Circulating Neprilysin Level Predicts the Risk of Cardiovascular Events in Hemodialysis Patients

Hyeon Seok Hwang,[1] Jin sug Kim,[1] Yang gyun Kim,[1] Yu ho Lee,[2] Dong-Young Lee,[3] Shin-Young Ahn,[4] Ju young Moon,[1] Sangho Lee,[1] Kyung hwan Jeong.[1] *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [3]Korea Veterans Health Service, Seoul, Republic of Korea; [4]Korea University Medical Center, Seoul, Republic of Korea.*

Background: Neprilysin inhibition has demonstrated impressive benefits in heart failure treatment, and is the current focus of interest in cardiovascular (CV) and kidney diseases. However, the role of circulating neprilysin as a biomarker for CV events is unclear in hemodialysis (HD) patients.

Methods: A total of 439 HD patients from the K-cohort were enrolled from June 2016 to April 2019. The plasma neprilysin level and echocardiographic findings at baseline were examined. The patients were prospectively followed up to assess the primary endpoint (composite of CV events and cardiac events).

Results: Plasma neprilysin level was positively correlated with left ventricular (LV) mass index, LV end-systolic volume, and LV end-diastolic volume. Multivariate linear regression analysis revealed that neprilysin level was negatively correlated with LV ejection fraction (β = -2.14; p = 0.013). The cumulative event rate of the composite of CV events was significantly greater in neprilysin tertile 3 (p = 0.049). Neprilysin tertile 3 was also associated with an increased cumulative event rate of cardiac events (p = 0.016). In Cox regression analysis, neprilysin tertile 3 was associated with a 2.61-fold risk for the composite of CV events (95% confidence interval [CI], 1.37–4.97) and a 2.72-fold risk for cardiac events (95% CI, 1.33–5.56) after adjustment for multiple variables.

Conclusions: Higher circulating neprilysin levels independently predicted the composite of CV events and cardiac events in HD patients. The results of this study suggest the importance of future studies on the effect of neprilysin inhibition in reducing CV events.

PO1801

Serum Cathepsin-S Concentration Is Not Related to Arterial Calcification Severity Among Hemodialysis Patients

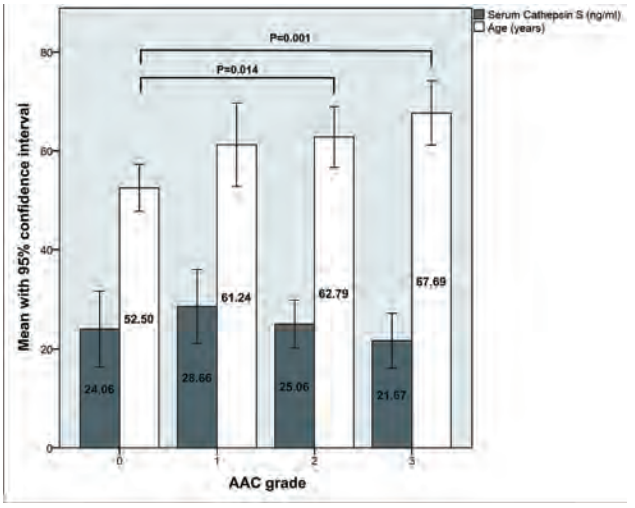
Hao-Wei Ma, Chih-Ching Lin, Szu-Yuan Li. *Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Vascular calcification is prevalent among hemodialysis patients and is strongly correlated to their cardiovascular and total mortality. Cathepsin S, a lysosomal cysteine protease that is elevated in CKD patients, has shown its critical role of vascular calcification in cell culture experiments and in uremic animal model. To validate the relationship of Cathepsin S and vascular calcification in clinical practice, we conducted the current cross sectional study.

Methods: 88 patients on maintenance hemodialysis were enrolled and their serum Cathepsin S and its natural inhibitor Cystatin C were measured. Severity of vascular calcification was semi-quantified by aortic arch calcification (AAC) score on chest X-rays. Patients were divided into groups according to their AAC score, and the serum Cathepsin S level, Cathepsin S / Cystatin C ratio and other factors were compared between groups.

Results: There was no significant difference in the level of Cathepsin S (p=0.778) or Cathepsin S to Cystatin C ratio (p=0.417) between patients with different aortic arch calcification score. Only age was associated with the severity of AAC score (p=0.014). Increasing serum triglyceride level is significantly associated with higher serum Cathepsin S level (Pearson Correlation p=0.001, R square=0.133).

Conclusions: Despite a pre-clinical study supporting the role of Cathepsin S in the development of vascular calcification under uremic and phosphate-rich conditions, serum Cathepsin S was not found to be associated with vascular calcification severity among hemodialysis patients in this study. Serum triglyceride is the strongest predicting factor for higher Cathepsin S levels in these patients. Further study is needed to confirm these findings using a different grading system.



Mean age and serum Cathepsin S with 95% confidence interval between groups of patients, categorized by their Aortic arch calcification (AAC) grade.

Kidney Function Trajectory Following Left Ventricular Assist Device Implantation

Carl P. Walther,[1] Julia Benoit,[2] Harveen Lamba,[1] Sankar D. Navaneethan.[1]
[1]Baylor College of Medicine, Houston, TX; [2]University of Houston, Houston, TX.

Background: LVADs have variable effects on kidney function. Identification of distinctive eGFR trajectory groups after LVAD placement, by applying unsupervised techniques to longitudinal eGFR measures, may enable insights into diverse pathophysiology.

Methods: From a national cohort, we identified persons who underwent isolated, primary continuous flow LVAD implantation in the US, 2016-17. eGFR values from pre-LVAD implantation to 12 months post were used. Latent class mixed models using cubic splines were applied to derivation and validation subsets, and models with 2-9 distinct groups were evaluated to find the optimal number.

Results: In the cohort (3,461 in derivation subset, 1,154 in validation), we identified 5 distinct trajectory groups. The 2 largest groups (1,2) are similar to previously reported cohort averages, with early eGFR increase followed by decline, but differed by baseline eGFR. Three smaller groups (3-5, ~15% of the cohort) demonstrated novel trajectories: group 3 had early worsening with sustained low kidney function; 4 had early and sustained eGFR improvement, and 5 had substantial eGFR variation. These groups differed in baseline factors (groups 3 and 4 had the most pre-LVAD acute dialysis, 4 and 5 the most cardiogenic shock) and outcomes (groups 2 and 4 had the highest survival, 3 and 5 had the lowest).

Conclusions: Novel eGFR trajectories after LVAD implantation were identified in a national cohort. Group 4, with early and sustained increase in eGFR, may reflect type 1 cardiorenal syndrome. Group 3 may reflect chronic kidney disease with early complications, and group 5 may reflect intact kidney parenchyma but post-LVAD right ventricular failure. These results demonstrate the feasibility of identifying previously unobserved heterogeneity in kidney outcomes. The novel trajectory groups may reveal potential for tailored care, in addition to pathophysiologic insights.

Which Loop Is Best? Comparing the Effect of Loop Diuretic Prescribing on Mortality and Heart Failure Readmission

Arti V. Virkud,[1] Abhijit V. Kshirsagar,[2] Patricia Chang,[2] Michele Jonsson Funk,[1] Jessie K. Edwards,[1] Michael R. Kosorok,[1] Emily Gower.[1] *[1]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Loop diuretics are a mainstay of heart failure (HF) management. While furosemide is most commonly prescribed, torsemide and bumetanide are increasingly being prescribed, possibly due to their superior bioavailability. Few trials or real-world evidence studies have compared the effectiveness of prescribing these loop diuretics while adequately addressing critical study design biases.

Methods: We identified beneficiaries initiating the study loop diuretics by using an active comparator, new-user cohort design and Medicare claims data from 2007-2017. We estimated 1-year risks of death and a composite outcome (HF readmission/death) using inverse probability of treatment weighting to adjust for relevant confounders. We calculated a dose equivalency based on furosemide to adjust for disease severity.

Results: We identified 45,310 furosemide, 1,148 torsemide, and 1,630 bumetanide new users. In the total weighted population, 24.3% had a reduced ejection fraction, 27.1% had CKD (> Stage 2), with a mean age of 80.1 years and a mean furosemide dose equivalent of 50.8 mg/mL. The 1-year risk of death across all study loop diuretics was similar (19.9%-20.6%), whereas the risk of the composite outcome was more varied (29.1%-32.0%). The 1-year risk difference (95% CI) of the composite outcome was -2.9% (-6.2, 0.4) for torsemide vs. furosemide and -1.1% (-3.8, 1.6) for bumetanide vs. furosemide.

Conclusions: Among Medicare beneficiaries, the risk of HF readmission/death varies meaningfully with torsemide having a reduced risk compared to other study loop diuretics. This study leverages claims data and causal methodology to generate a less biased and more generalizable estimate than previous studies. While additional trial and real-world evidence studies are needed, this study suggests initial loop diuretic prescription after HF hospitalization may produce long-term differences in risk of death and HF readmission.

Diuretic Resistance in Acute Decompensated Heart Failure with Preserved vs. Reduced Ejection Fraction

Akash Sharma, Rahul Patel, Chakradhar Velagapudi, Shweta Bansal. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Loop diuretic resistance (DR) is one of the common causes of inadequate decongestion in patients hospitalized with acute decompensated heart failure (ADHF). However, DR has not been characterized in patients with HF with preserved ejection fraction (HFpEF).

Methods: In a post hoc analysis of a pilot study which evaluated the role of high-dose spironolactone in hospitalized ADHF patients with DR, we analyzed the prevalence and potential pathophysiologic factors of DR in HFpEF (n=20), and compared those with HF with reduced EF (HFrEF) (n=27). DR was defined as weight loss<1lb/day despite intravenous furosemide>160mg/day (at least one dose of 80mg/day) or no change in dyspnea 48H after admission with usual care.

Results: DR was observed in 10 (50%) of HFpEF subjects as compared to 10 (37%) of HFrEF subjects (p=ns). In general, patients with HFpEF were older, more female and obese, had more diabetes, higher systolic blood pressure and lower brain natriuretic peptide compared to HFrEF (Table 1). There was no difference in clinical presentation, eGFR and pulmonary arterial systolic pressure in DR-HFpEF vs. DR-HFrEF. However, urine sodium/potassium ratio, plasma renin activity and aldosterone were lower in DR-HFpEF as compared to DR-HFrEF, though still higher than diuretic responsive-HFpEF patients (Table 1). Weight loss in response to high-dose spironolactone was similar in DR-HFpEF and HFrEF (14±8.6 vs.14±13 lb).

Conclusions: Although the comparisons were not statistically significant due to small sample size; the results suggest that DR is more prevalent in HFpEF. Despite similar clinical features of congestion and response to high-dose spironolactone, a state of reduced neurohormonal activation points that additional factors might be contributing to DR in HFpEF compared to HFrEF patients.

Renal Outcomes and Safety of Angiotensin Receptor Neprilysin Inhibitors in Patients with Heart Failure: A Meta-Analysis

Rima N. Abou arkoub,[1] Thomas Mavrakanas,[1] Amy Bergeron,[2] Abhinav Sharma,[1] Ahsan Alam.[1] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]McGill University Health Centre Glen Site McConnell Resource Centre Medical Library, Montreal, QC, Canada.*

Background: Angiotensin receptor neprilysin inhibitors (ARNIs) are an effective treatment for heart failure. However, their safety profile compared with angiotensin converting enzyme-inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) with respect to renal outcomes has not been clearly established.

Methods: We conducted a literature search of MEDLINE, Cochrane library, Embase, and clinical trials registries using relevant search terms (last search date May 7, 2021). The primary renal outcome was kidney function decline and the safety outcome was hyperkalemia. Only studies with at least 12 weeks of follow up were included in the renal outcome analysis to better capture CKD.

Results: Ten randomized controlled trials were eligible for inclusion (n=22,174 participants). ARNIs were associated with a lower risk of kidney function decline compared with ACEIs or ARBs: RR 0.65 (95%CI 0.53-0.81). The risk of hyperkalemia was similar in both treatment groups: RR 0.96 (95%CI 0.81-1.13).

Conclusions: ARNI use in patients with heart failure is associated with a lower risk of kidney function decline and a similar risk of hyperkalemia compared to ACEIs or ARBs.

Hydralazine-Isosorbide Dinitrate Associated with Reduced All-Cause and Cardiovascular Mortality in Patients on Dialysis with Heart Failure

Qandeel H. Soomro,[1] Thomas Mavrakanas,[2,3] David M. Charytan.[1,3] *[1]NYU Langone Health, New York, NY; [2]McGill University, Montreal, QC, Canada; [3]Brigham and Women's Hospital, Boston, MA.*

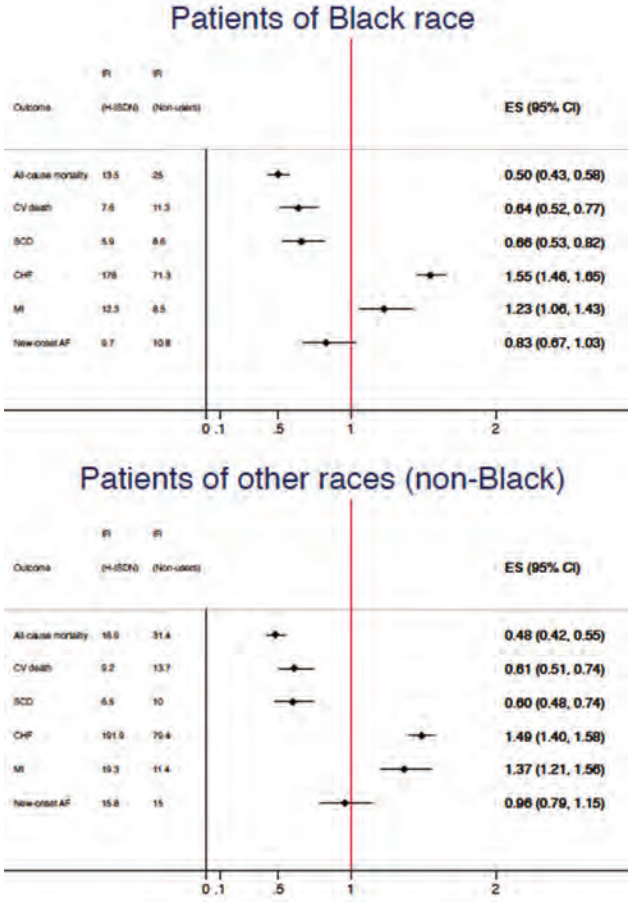
Background: Heart failure (HF) is an important contributor to the increased cardiovascular (CV) mortality incidence in ESKD. Therapies targeting HF's unique pathophysiology in ESKD are lacking. Hydralazine-isosorbide dinitrate (H-ISDN) targets reduced nitric oxide bioavailability and could improve CV mortality in ESKD

Methods: Adult patients with HF on maintenance dialysis between January 2011 and December 31, 2016 were identified using the United States Renal Data System. There were 6306 patients with at least one prescription for H-ISDN and 75,851 non-users. The primary outcome was death from any cause. Secondary outcomes included cardiovascular death and sudden death. Treatment effects were estimated using stabilized inverse probability weights in Cox proportional hazards regression. Because H-ISDN has been shown to improve outcomes in Black HF patients, we investigated effect modification by race

Results: Age was similar in H-ISDN users (66 ± 13 years) and non-users (69 ± 13 years) with 50% and 51% men, respectively. H-ISDN (51%) users were more likely to be of Black race than non-users (27%). Dialysis vintage was longer in H-ISDN (25 months) users compared with non-users (15 months). All characteristics were well balanced in weighted models. Risks of all-cause mortality, cardiovascular death, and sudden death were significantly reduced in H-ISDN users compared to non-users (Table). We did not identify significant effect modification by race (Figure)

Conclusions: To our knowledge, this is the first analysis of the impact of H-ISDN on mortality in ESKD. Our results suggest that combination H-ISDN improves survival in dialysis patients with HF

Outcome	Incidence rate (events)		Weighted HR (95% CI)	p value
	H-ISDN (N=6306)	Non-Users (N=75851)		
All-cause mortality	16.0 (497)	27.9 (34371)	0.48 (0.43-0.54)	<0.001
CV death	8.9 (275)	12.4 (15214)	0.62 (0.53-0.71)	<0.001
SCD	6.7 (207)	9.2 (11292)	0.62 (0.52-0.73)	<0.001
CHF	195.5 (3352)	73.4 (48324)	1.51 (1.44-1.57)	<0.001
MI	18.0 (532)	10.2 (11602)	1.33 (1.20-1.48)	<0.001
New-onset AF	12.5 (257)	13.0 (9789)	0.92 (0.79-1.06)	0.25



PO1807

Long-Term Outcomes After Renal Revascularization for Atherosclerotic Renovascular Disease in the ASTRAL Trial

Philip A. Kalra,[1,2] Darren Green,[1,2] Natalie Ives.[3] The ASTRAL trial investigators *[1]Salford Royal Hospital, Salford, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom; [3]University of Birmingham, Birmingham, United Kingdom.*

Background: The Angioplasty and Stenting for Renal Artery Lesions (ASTRAL) trial recruited 806 patients with atherosclerotic renal artery stenosis (RAS) between 2000-2007, randomised 1:1 to medical therapy with or without renal artery stenting. The initial results were presented in 2009 at median follow-up 34.6 months when no benefit of revascularization to renal functional outcome or cardiovascular events (CVE) were evident. Surviving patients remained under follow up until 2014.

Methods: All available data were analysed to assess whether there was a later impact of revascularization on renal function, CVE and survival, including a composite outcome of renal and CV outcomes and death (as used in the CORAL trial). Pre-specified sub-group analyses of different categories of renal function, renal length, prior rapid deterioration in kidney function, and severity of RAS. Further post-hoc analysis of patients with severe RAS (defined as bilateral 70% or > 70% RAS in a solitary kidney = global renal ischemia), those with/without proteinuria and a per protocol analysis were performed.

Results: The mean age of the entry population was 70.5 years, mean eGFR 40 ml/min/1.73m^2, with mean RAS 76% and blood pressure 150/76 mmHg; 83% of the revascularization group underwent attempted stenting. Median follow-up was 56.4 months with 108 patients lost to follow up or withdrawn; 50% of the evaluable population had died, 14% had received RRT and 40% had suffered a 1st CVE. No benefit of revascularization was observed for any outcome in the intention to treat and per protocol analyses, either in the whole population or the pre-specified sub-groups. In the severe RAS sub-group (163 patients) revascularization was associated with a hazard ratio (HR) of 0.74 (0.54-1.01; p=0.062) for the composite renal and CV outcome and an HR of 0.70 (0.49-1.0) for death (p=0.051).

Conclusions: The long-term follow-up of the ASTRAL trial population showed no overall benefit of renal revascularization to renal and CV outcomes. It has been highlighted that a proportion of the population had lower risk mild-moderate RAS. The long-term outcomes in patients with severe RAS (global renal ischemia) point to a potential benefit of stenting that may be worthy of further study in a more selected population.

PO1808

Revascularization in Atherosclerotic Bilateral Renal Artery Stenosis

Sana J. Shaikh, Bilal Al-Khalil, Ling Chen, Anitha Vijayan. *Washington University in St Louis, St Louis, MO.*

Background: Patients with B/L RAS, if found to have worsening renal failure, refractory HTN or recurrent CHF, are often referred for revascularization despite limited evidence. We hypothesized that revascularization plus medical management prevents adverse outcomes in patients with B/L RAS.

Methods: This was a retrospective single-center cohort study in patients with B/L RAS, RAS in a solitary kidney, U/L RAS with an atrophic or >1cm smaller contralateral kidney or, RAS in a U/L functioning kidney. We excluded patients with non-atherosclerotic RAS, renal artery dissection, atheroembolism and renal transplantation. The primary outcome was Major Adverse Kidney Events (MAKE) at 3 mo. Secondary outcomes were renal events, changes in BP, hospital admissions and all-cause mortality at 1 yr. We used the Chi-square test for the primary outcome and the Chi-square test or two-sample t-tests for the secondary outcomes.

Results: 153 patients were included in the study. There were no differences in the baseline characteristics of the intervention and control groups, except for higher number of smokers in the control cohort (Table 1). There was no difference in MAKE between the 2 groups at 3 mo. At 1 yr, there were fewer admissions for CHF in the intervention group (Table 2). There were no other major differences in secondary outcome measures.

Conclusions: Revascularization for B/L RAS does not improve renal outcomes, BP control or mortality, but may prevent admissions for CHF.

Table 1: Baseline characteristics

Variable	Intervention Group (N=69)	Control Group (N=84)	p value
	no. (%)		
Hypertension	68 (98.6)	81 (96.4)	0.413
Diabetes mellitus	19 (27.5)	22 (26.2)	0.852
CKD stage 3 or more	39 (56.5)	42 (50.0)	0.421
TIA/CVA	11 (15.9)	13 (15.5)	0.937

Hypertension in a Young Female: A Common but an Intriguing Anecdote

Batool Butt,[1] Sohail Sabir.[2] *[1]Foundation University Medical College, Rawalpindi, Pakistan; [2]National University of Medical Sciences, Rawalpindi, Pakistan.*

Introduction: Renal artery stenosis accounts for about 1-10% of the 50 million people with hypertension worldwide. All major trials conducted so far on RAS found no benefit with renal artery stenting. Here we report a case of resistant hypertension in a young female who subsequently found to have bilateral renal artery stenosis and ultimately benefitted from unilateral stenting.

Case Description: A 35 yrs female, married, with no comorbids, presented with 03 months history of intermittent epsiodes of throbbing headache along with dizziness, palpitations, fatigue. Examination revealed BP - 160/100 with no postural drop, and regular pulse with no radio-radial, radio-femoral delays. Her baseline investigations(including blood complete picture, LFTs, RFTs, urine routine examination, PT/PTTK were Normal. Hepatitis B and C serology were negative) USG abdomen showed right shrunken kidney with no renal artery flows on Doppler ultrasound. She was put on four different groups of anti hypertensives including a beta blocker, a calcium channel blocker, thiazide diuretic and an angiotensin receptor blocker but her blood pressure did not settle. Further investigations revealed raised ESR but other tests including autoimmune screening, 2DECHO all negative-CT aortogram revealed a non visualised shrunken right kidney with attenuated right renal artery and a vascular kink in proximal left renal artery. DTPA scan showed estimated GFR of 66.7ml/min with 97% contribution by left kidney and 3% contribution by right kidney. So based on renal imaging findings, a final diagnosis of bilateral renal artery stenosis was made. Percutaneous transluminal angioplasty with stenting to proximal left renal artery was done. She was given dual antiplatelets along with a statin post operatively and advised monthly follow up. Currently she is normotensive without any anti hypertensive medicine.

Discussion: Distinct and new diagnostic and therapeutic innovations for RAS accessible but the best modality for a particular patient remains arduous. Though Renal artery stenting has shown propitious results in few patients but not to the degree many have expected. More RCTs should be contemplated to scrutinize the clinical predictors which will aid in identifying appropriate indications and subgroups of patients that will raise hope of maximum outcome of this intervention and evading gratuitous procedures that wiil not benefit the patient

PO1810

Long-Term Safety and Efficacy of Renal Denervation with the Symplicity Spyral Catheter in the Global SYMPLICITY Registry

Markus P. Schlaich,[1] Felix Mahfoud,[2] Bryan Williams,[3] Luis M. Ruilope,[4] Krzysztof Narkiewicz,[5] Martin Fahy,[7] Giuseppe Mancia,[6] Michael Böhm.[2] *[1]The University of Western Australia, Perth, WA, Australia; [2]Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany; [3]University College London, London, United Kingdom; [4]Hospital Universitario 12 de Octubre, Madrid, Spain; [5]Gdanski Uniwersytet Medyczny, Gdansk, Poland; [6]Universita degli Studi di Milano-Bicocca, Milano, Italy; [7]Medtronic Inc, Minneapolis, MN.*

Background: Catheter-based renal denervation (RDN) therapy targets overactivity of the sympathetic nervous system to treat hypertension. Results from recent randomized sham-controlled clinical trials have demonstrated the safety and efficacy of RDN, but long-term safety and durability of the procedure in real-word patients is also important.

Methods: The Global SYMPLICITY Registry (GSR) is a prospective, international registry of patients who receive radiofrequency RDN treatment due to uncontrolled hypertension or conditions associated with excessive sympathetic nervous system activation. Office and ambulatory blood pressure (BP) levels were measured at baseline, 3, 6, 12, 24, and 36 months per standard of care. Adverse events were collected out to 3 years. In this analysis, we present safety and efficacy data for patients who received RDN with the multi-electrode Symplicity Spyral catheter in GSR.

Results: Currently there are 641 patients treated with the Symplicity Spyral catheter (baseline office BP 168±25 mmHg, 4.6±1.5 prescribed anti-hypertensive medication classes, mean age 60.5 ± 12.5 years, 56.9% male, 42.5% history of cardiac disease, 37.2% type II diabetes mellitus, and 19.1% renal insufficiency with eGFR<60 ml/min/1.73m^2). At 3 years, there were no cases of new renal artery stenosis >70% or renal artery re-intervention. Rates of other adverse events at 3 years included new onset end stage renal disease (2.4%), cardiovascular death (1.6%) and myocardial infarction (0.8%). Mean change in eGFR from baseline to 3 years was -6.5±15.7 mL/min/1.73m^2. Changes in mean 24-hour and office BP from baseline to 6, 12, 24 and 36 months are shown in the **Figure**.

Conclusions: Office and 24-hour BP were significantly reduced from baseline at all follow up time-points after RDN with the Symplicity Spyral catheter, with no instances of renal artery re-intervention.

PO1811

Endovascular Renal Denervation Efficacy in a Five-Year Follow-Up

João Carvão,[1] Patricia Q. Branco,[2] Catarina Mateus,[2] Pedro Gonçalves,[2] Manuel D. Almeida,[2] Maria augusta C. Gaspar.[2] *[1]Servico de Saude da Regiao Autonoma da Madeira, Funchal, Portugal; [2]Centro Hospitalar de Lisboa Ocidental EPE Hospital de Santa Cruz, Carnaxide, Portugal.*

Background: Endovascular renal denervation (ERD) is a minimally invasive procedure that uses radiofrequency ablation to burn the nerves in the renal arteries. Renal sympathetic nerves can modulate sympathetic activity at the whole body level, playing an important role in essential hypertension. This study aim to evaluate ERD efficacy in the treatment of essential hypertension in a five-year follow-up.

Methods: We conducted a prospective study including 41 patients with essential hypertension. ERD was performed using Simplicity Probe or Spyral. Blood pressure (BP) was evaluated using 24hour ambulatory BP monitoring. Echocardiography was performed using HDI 5000. Clinical and biochemical variables were explored.

Results: A total of 41 patients were included. Overall, 53,7% (n=22) were females with a mean age of 63,6 ± 7,5 years, BMI 30,8 ± 5,2 Kg/m^2, 17,1% (n=7) had an estimated glomerular filtration rate (eGFR) < 60ml/min/1,73m^2 and 68,3% (n=28) diabetes. Proteinuria (>300mg/g) was found in 24,4% (n=10) of the patients. A significant reduction in the number of antihypertensive drugs being taken was found after 5 years' follow-up (p<0,001). Despite this reduction, a significant reduction in diastolic blood pressure

(DBP) (p=0,001) was found, but not in systolic blood pressure (SBP) (p=0,08). Also left ventricle mass index (LVMI) reduced significantly (p<0,0001) and a reduction of acute elevation of left ventricle filling pressure (LVFP) was detected using E/e' (p<0,0001). There was a worsening of eGFR (p<0,0001) as expected by the progressive worsening of kidney function. We have found a non significant reduction in proteinuria (p=0,07). In the group with a reduction in proteinuria, it was not associated with BP and LVMI, when using multivariate analysis. In a multivariate analysis, the reduction in the number of antihypertensive drugs, of the LVMI, SBP and DBP were not related with age, gender, body mass index and proteinuria.

Conclusions: In our population, we managed to reduce the number of anti-hypertensive drugs and still reduce patients DBP with RDN. Also RDN showed benefits in reducing LVMI and LVFP. Reduction of proteinuria, when present, was independent of BP anad LVMI. There was a worsening of kidney function as expected in a long term follow-up. RDN has been showed to be an effective mean of treating essential hypertension.

PO1812

Potential Benefits of Asymptomatic Hyperuricemia Treatment: A Systematic Review and Meta-Analysis of Randomized Control Trials

Dhir N. Gala,[1] Kirellos S. Said,[2] Nahla A. El-Shahat,[3] Allison Parrill,[1] Hadeir S. Mohamed,[3] Nada Abdelhalim,[4] Mostafa A. Amin,[5] Hassan S. Abdalshafy,[5] Majd Alahmar,[6] Nguyen Tien Huy,[8] Mohammed Abdel Gawad.[7] *[1]American University of the Caribbean School of Medicine BV, Cupecoy, Sint Maarten (Dutch part); [2]Alexandria University Faculty of Medicine, Alexandria, Egypt; [3]Al-Azhar University Faculty of Medicine, Cairo, Egypt; [4]Istanbul Gelisim Universitesi, Istanbul, Turkey; [5]Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; [6]Mansoura University Faculty of Medicine, Mansoura, Egypt; [7]Gawad Nephrology Clinic, Alexandria, Egypt; [8]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan.*

Background: Asymptomatic hyperuricemia is strongly associated with an increased risk for chronic kidney disease and cardiovascular conditions. However, many current guidelines suggest no medical treatment for patients with asymptomatic hyperuricemia. We aim to systematically analyze randomized control trials with serum uric acid-lowering medication in the treatment of patients with asymptomatic hyperuricemia.

Methods: A literature review of seven medical databases (Scopus, Clinical Gov, Pubmed, Web of Science, Google Scholar, VHL, and GHL) for randomized controlled trials related to the treatment of asymptomatic hyperuricemia was conducted. Bias was evaluated using the Cochrane Risk of Bias 2 tool. Standard differences of means of variables of interest were combined across studies to compare the effects of uric acid lowering treatment versus control. Using the Comprehensive Meta-Analysis program, fixed-effects and random heterogeneity model, forest plots were created for each variable of interest.

Results: Analysis of eleven studies showed significant decreases in creatinine [-0.302 (95% CI: -0.599, -0.005)], systolic blood pressure [-0.277 (95% CI: -0.5, -0.055)], and serum uric acid [-1.972 (95% CI: -2.145, -1.800)] in the treatment versus control group. Furthermore, significant increases in estimated glomerular filtration rate (eGFR) after sensitivity analysis [0.228 (95% CI: 0.027, 0.428)], and high-sensitivity C-reactive protein [0.588 (95% CI: 0.205, 0.971)] were observed in the treatment versus control group. Lastly, non-significant decreases in carotid intima-media thickness test [-0.113 (95% CI: -0.269, 0.042)], and diastolic blood pressure [-0.312 (95% CI: -0.638, 0.013)], while non-significant increases in hemoglobin A1C [0.394 (95% CI: -0.026, 0.813)] and fasting glucose level [0.117 (95% CI: -0.145, 0.380)] were found in the treatment versus control group.

Conclusions: This study showed that uric acid lowering treatment of patients with asymptomatic hyperuricemia may be beneficial in those with elevated creatinine and blood pressure, and decreased eGFR.

PO1813

Urinary Glycogen Synthase Kinase 3β Level Predicts the Progression of Hypertensive Nephrosclerosis

Lingfeng Zeng, Cheuk-Chun Szeto. *Department of Medicine & Therapeutics and Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.*

Background: Hypertensive nephrosclerosis (HTN) is a serious consequence of prolonged hypertension. In the United States, HTN is the second most common cause of end-stage kidney disease. Recently, emerging evidence suggests that glycogen synthase kinase (GSK) 3β is a key factor in the progression of diabetic kidney disease (DKD). However, it remains uncertain whether the role of GSK3β is specific for DKD or a generic mediator of renal damage irrespective to the underlying cause.

Methods: We studied 32 patients with biopsy-proved HTN patients. Their GSK3β level in urinary supernatant was measured by conventional ELISA, and GSK3β mRNA level in urinary sediment was measured by quantitative polymerase chain reaction. The results were compared to the baseline kidney function and the subsequent risk of renal function deterioration.

Results: The average urinary GSK3β level was 212.67 ± 47.74 ng/L by conventional ELISA, which closely correlated with its mRNA level in urinary sediment (r = 0.821, P<0.0001). Urinary GSK3β level significantly correlated with baseline glomerular filtration rate (GFR) (r=-0.451, p=0.010) and the slope of GFR decline (r=-0.397, p=0.033). Patients with a high urinary GSK3β level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSK3β level (log rank test, p=0.028 and p=0.043, respectively). Similarly, urinary GSK3β mRNA level also significantly correlated with baseline GFR (r=-0.582, p<0.0001) and the slope of GFR decline (r=-0.402, p=0.022). Patients with a high urinary GSK3β mRNA level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSK3β level (p=0.022 and p= 0.004, respectively).

Conclusions: These results demonstrated that urinary GSK3β level correlates with the rate of kidney function loss in patients with biopsy-proved HTN, and urinary sediment mRNA level appears to be a more accurate prognostic marker than urinary GSK3β level by ELISA. Our results suggest that GSK3β is a generic mediator for the progression of chronic kidney disease and is not specific for DKD.

Deletion of the Dopamine D2 Receptor in the Renal Proximal Tubule Increases Blood Pressure on Low-Salt Diet and Decreases Blood Pressure on High-Salt Diet: A Case of Inverse Salt Sensitivity

Laureano D. Asico, Shaun C. Moore, Pedro A. Jose, Ines Armando. *The George Washington University School of Medicine and Health Sciences, Washington, DC.*

Background: The dopamine D2 receptor D2 (D2R) in the kidney is important in maintaining normal blood pressure (BP) and preventing inflammation and tissue injury. Global D2R gene (*Drd2*) knockdown i or renal-selective D2R downregulation in the mouse increases BP and results in renal inflammation, tubular injury, and fibrosis. To study the function of D2R in the renal proximal tubule, we generated *Drd2*$^{fl/fl}$, P$_{SGLT2}$::*Cre*+ mice (D2R$^{PT-/-}$) that lack D2R only in the renal proximal tubule and *Drd2*$^{fl/fl}$, P$_{SGLT2}$::*Cre*- (D2R$^{PT+/+}$) mice that do not have the deletion.

Methods: Mice were genotyped for *Drd2*$^{fl/fl}$ and a smaller amplicon representing the Cre deletion mutant. We studied male mice on normal salt (NS; 0.4% NaCl), high (HS; 4% NaCl), and low (LS; <0.08% NaCl) diets.

Results: On NS diet, male D2R$^{PT-/-}$ had slightly higher BP, measured under anesthesia, than male D2R$^{PT+/+}$ mice (106±1 vs 101±2 mmHg, n=15/group; P<0.05). On HS diet D2R$^{PT-/-}$ mice had lower BP than D2R$^{PT+/+}$ (100±3 vs 107±2 mmHg; P<0.04; n=12) but on LS diet D2R$^{PT-/-}$ had higher BP than D2R$^{PT+/+}$ mice (126±5 vs 103±4 mmHg; P<0.01; n=7). Both the decrease in BP on HS diet and the increase in BP on LS diet, relative to BP on NS diet, were confirmed by telemetry in conscious mice. These data indicated that D2R deletion only in the renal proximal tubule impairs the normal responses to changes in salt intake. On NS diet the renal mRNA expressions of NHE3, Na^+/K^+ATPase, and NCC were similar in both groups of mice. On HS diet NHE3 and NCC were lower in D2R$^{PT-/-}$ than D2R$^{PT+/+}$ mice (NHE3: 0.7±0.02 vs 1.0±0.03 fold-change; P<0.05, n=4-5/group; NCC: 0.5±0.1 vs 1.0±0.09 fold-change; P<0.05) while Na^+/K^+ATPase was similar in both groups. On LS diet NHE3, Na^+/K^+ATPase, and NCC expression were higher (P<0.05) in D2R$^{PT-/-}$ than in D2R$^{PT+/+}$ mice.

Conclusions: There are marked differences in the response to changes in dietary salt intake on BP and renal expression of sodium exchanger/transporter/pump in mice lacking D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. There results may have significant clinical implications since in humans, the presence of D2R variants, *DRD2* rs6276 and rs6277, which decrease D2R protein/function, is associated with inverse salt sensitivity.

Renal Proximal Tubule-Specific Alteration of the NKA/Src Receptor Complex in the Mouse: Evidence for Sexual Dimorphism

Shreya T. Mukherji, Lilian Silva, Sandrine V. Pierre. *Marshall Institute for Interdisciplinary Research, Huntington, WV.*

Background: The Na^+/K^+-ATPase (NKA) expressed on the basolateral membrane of renal proximal tubule (RPT) cells serves an anti-natriuretic enzymatic function through its classically recognized ion-pumping properties. There is also pharmacological evidence that, through a Src-mediated mechanism, Na/K-ATPase α1 serves a counteracting natriuretic receptor function that reduces NKA- and NHE3-mediated transport, leading to decreased transepithelial Na^+ flux.

Methods: To test this genetically, we generated RPT cells and mice expressing wild-type (WT) or Src signaling null mutant (Y260A) forms of NKA α1, both with intact ion-transporting functions. In porcine RPT cells (LLC-PK1) expressing NKA α1 ^{Y260A}, a 50% decrease in phosphorylation-mediated inactivation of NHE3 compared to WT NKA α1^{WT}-expressing cells occurred. In mice, a SGLT2-Cre-driven KO and Rosa26 rescue system was used to selectively express WT NKA α1 (RPTα1^{WT}) or NKA α1Y260A (RPTα1^{Y260A}) in the RPT. For all renal phenotyping and biochemical assessments, we studied 4-month adult mice. Basal and renal characterization was conducted by metabolic cages, lithium clearance, and urine analysis.

Results: The RPT-specific rescue was confirmed by immunohistochemistry in kidney cross-sections from RPTα1^{WT} and RPTα1^{Y260A} mice. Kidney size, morphology, and overall structure assessed by periodic acid shift (PAS) staining was unchanged (n=3). In contrast, RPTα1^{Y260A} mice presented with a RPT-mediated hyper-reabsorptive phenotype of 60% decrease in total daily urine output and 40% decrease in absolute sodium output in females but not in males (n=6-11). This sexual dimorphism in urinary phenotype of RPTα1^{Y260A} mice was supported by a 50% increase in membrane abundance of NHE3 in female renal cortex compared to female RPTα1^{WT}, which was not observed in males (n=4-5).

Conclusions: These observations are compatible with a sexual dimorphism in the NKA/Src mechanism of regulation of NHE3 and Na^+ transport in the RPT. This study highlights the importance of improving our understanding of the natriuretic mechanism of NKA signaling in the RPT and its potential impact on sex-based differences in renal physiology and pathophysiology.

Sex-Dependent Regulation of the WNK-NCC Pathway via Ubiquitination in Response to Dietary High Salt Intake in Young Sprague-Dawley Rats

Kiyoung Kim, Mohammed Z. Ferdaus, Richard D. Wainford. *Boston University School of Medicine, Boston, MA.*

Background: The thiazide-sensitive Na^+-Cl^- cotransporter (NCC), located in the apical membrane of distal convoluted tubule, fine-tunes sodium reabsorption and regulates blood pressure. The NCC is downregulated by high salt intake in normotensive salt resistant rats. These studies investigated the potential mechanistic pathways by which NCC is degraded in response to high salt intake in male and female Sprague-Dawley (SD) rats.

Methods: 3-month-old normotensive male and female SD rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days. On day 21, the kidneys were collected and ~200 mg of the renal cortex was used to measure the expression of total NCC, WNK1, WNK4, Nedd4-2, Sortilin, KLHL3, and calcineurin via immunoblotting (N=5~6/group).

Results: A 21-day HS diet evokes the suppression of total NCC protein expression in young normotensive male and female SD rats. A HS diet downregulated WNK1 in male but not female SD rats. A HS diet suppressed the expression of the full-length and short WNK4 variants in female SD rats only. There was a trend for HS to increase Nedd4-2 expression in male SD rats (P=0.06), in contrast female rats downregulated Nedd4-2 in response to HS. The expression of sortilin, KLHL3, and calcineurin was suppressed by a HS diet in female rats only.

Conclusions: These data suggest that in response to a HS diet young female SD rats exhibit greater ubiquitin-dependent proteolytic and lysosomal degradation of the NCC than young male SD rats to regulate sodium homeostasis and blood pressure via a WNK-dependent signaling pathway.

Variables	Male		Female	
	NS	HS	NS	HS
NCC expression (fold change)	1.00 ± 0.12	0.55 ± 0.04*	1.00 ± 0.06	0.43 ± 0.04*
WNK1 expression (fold change)	1.00 ± 0.15	0.48 ± 0.04*	1.00 ± 0.24	1.02 ± 0.23
Full length WNK4 expression (fold change)	1.00 ± 0.16	1.16 ± 0.13	1.00± 0.11	0.26 ± 0.10*

Renal Denervation Improves Renal Afferent Nerve Activity After High Sodium Intake

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Salman Rafii-Tabrizi,[1] Johannes Döllner,[1] Karl F. Hilgers,[1] Peter Linz,[1] Christian Ott,[1,2] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[3] Roland Veelken.[1,2] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat, Nuremberg, Germany; [3]Universitätsklinikum Erlangen, Abteilung für Nephropathologie, Erlangen, Germany.*

Background: Previous work of ours suggests that the sensitivity of renal afferent neurons is decreased under pathological conditions. Here we tested the hypothesis that pathologically decreased sensitivity of renal afferent neurons due to high salt diet is normalized after renal denervation.

Methods: 6 male Sprague Dawley (SD) rats were put on high salt diet (HS; 8% NaCl) for 10 days. In another group of 18 rats on high salt diet (HS) left kidney were deneravated (DNX) 7 days prior to examination. Rats on standard diet with and without DNX (10 and 7 SD rats) were used as controls. Harvested dorsal root ganglion neurons (DRG Th11-L2) with renal afferents were investigated in primary neuronal cell culture using current clamp mode to assess action potential generation during current injection and to characterize neurons as tonic highly active and phasic less active neurons. Results are mean±SEM.

Results: In renal neurons from rats on HS the relation of tonic to phasic neurons shifted towards less active phasic units (62% tonic neurons in control vs. 42% on HS, p<0.05, z-test). Further, neurons from rats on HS exhibited decreased action potential production upon stimulation (controls 14.8+/-0.9 APs/600ms vs. HS 12.1+/-0.8 APs/600ms, p<0.05, t-test). Denervation (DNX) of the left kidney in rats on high salt diet (HS-DNX) led to a recovery of afferent renal DRG neurons. They regained their ability to generate action potentials as in controls (high salt diet 12.1+/-0.8 APs/600ms vs. HS-DNX 14.8+/-0.7 APs/600ms, p<0.05, t-test) and their electrophysiological property of tonic firing (42% tonic neurons in HS vs. 71% HS-DNX, p<0.05, z-test).

Conclusions: In rats on high salt (HS) diet the *in vitro* proportion of highly active tonic neurons with renal afferents decreased at the expense of less active phasic neurons. Furthermore, their firing rate decreased due to HS. These HS effects could be abolished by renal denervation (DNX). Whether DNX in vivo would be able to reduce HS induced sympathetic nerve activity increases remains to be determined.

PO1818

Empagliflozin Prevents Impaired Sensitivity of Afferent Neurons with Renal Axons During a High-Salt Diet

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Laura Wopperer,[1] Karl F. Hilgers,[1] Peter Linz,[1] Nada Cordasic,[1] Christian Ott,[1,2] Mario Schiffer,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[3] Roland Veelken.[1,2] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Erlangen, Germany; [3]Universitätsklinikum Erlangen, Abteilung für Nephropathologie, Erlangen, Germany.*

Background: Afferent renal nerve pathways likely play a role in salt sensitive hypertension. We recently reported that high salt diet (HS) impairs these afferent renal pathways in rats. Now we tested the hypothesis that during HS a decrease in sensitivity of renal afferent neurons is prevented by the SGLT2 inhibitor empagiflozin.

Methods: Respective groups of rats were put on HS containing 8% NaCl or a normal diet. Two groups (HS, controls) received empagiflozin 20 mg/kg BW/day orally. Renal neurons were retrogradely labeled with DiI. In culture, labeled dorsal root ganglion neurons (DRG Th11-L2) with renal afferents were investigated electrophysiologically using current clamp mode to assess action potential generation during current injection (neurons were characterized as tonic highly active (> 5 action potentials, AP) and phasic less active neurons (≤ 5 AP upon stimulation).

Results: In neurons from rats on HS, the relation of tonic highly active neurons to less active phasic neurons shifted consistently towards phasic units (63,8% tonic neurons in controls vs. 42%* on HS, *p<0.05, z-test). However, continuous treatment with empagiflozin preserved the proportion of tonic neurons as in controls (67,9% on HS with concomitant administration of empagiflocin). In controls, empagiflozin did not affect the proportion of tonic to phasic neurons (63,8% tonic neurons in controls vs. 67,9% on HS & empagliflozin, p=0.7, z-test). Blood pressure and heart rate were not altered by HS and or treatment with any chosen dose of empagiflozin.

Conclusions: In rats, chronically elevated sodium intake (8% NaCl) reduced the sensitivity and stimulability of renal afferent DRG neurons. Under these circumstances, concomitant treatment with the SGLT2 inhibitor empagiflozin preserved the function of renal afferent DRG neurons. SGLT 2 inhibitors may help to treat dysfunction of renal innervation in cardiovascular disease.

PO1819

The Role of Histaminergic System Components in Renal Function During Salt-Sensitive Hypertension

Denisha R. Spires,[1,2] Mark Domondon,[2] Ryan Schibalski,[1,2] Samantha M. Perez,[2] Mikhail Fomin,[1,2] Morgan J. Spicer,[1,2] Sergey N. Arkhipov,[3] Callie A. Clarke,[2] Thelma Amoah,[2] Tengis S. Pavlov,[3] Daria Ilatovskaya.[1,2] *[1]Augusta University, Augusta, GA; [2]Medical University of South Carolina, Charleston, SC; [3]Henry Ford Health System, Detroit, MI.*

Background: Up to 50% of hypertensive patients have salt-sensitivity (SS), a condition characterized with an increase in blood pressure in response to salt intake. The abnormal activation of the immune response is a major contributor to SS hypertension and renal injury. Histamine and its receptors (HRs) are a complex system of immunoregulators that have been linked to renal disease development. It is known that the Dahl SS rat fed a high salt diet develops hypertension accompanied with elevated levels of inflammatory factors. We hypothesize that HRs and associated enzymes contribute to renal disease progression during SS hypertension.

Methods: Male Dahl SS rats at 8 weeks of age were placed on either a 0.4% (normal salt; NS, control) or 4% (high salt; HS, hypertensive group) NaCl diet for 21 days to induce SS hypertension. An additional group of animals received 3 injections of ranitidine (RAN; HR2 blocker; 25 mg/kg) or saline (VEH; 2.5 mL/kg) pre- and post- the HS challenge to test the effects of HR2 blockage on renal function.

Results: Using immunohistochemistry, we established the expression of all four HRs as well as histamine-metabolizing and catabolizing enzymes, along the nephron with a pronounced expression in the glomerulus, proximal tubule and the distal tubules. Interestingly, we observed a decrease in histidine decarboxylase, and an increase in histamine N-methyltransferase in the kidney of HS diet fed rats, suggesting a shift in renal histaminergic tone. RAN treatment pre-HS resulted in a significant decrease in urine volume (1.89 ± 0.20 vs 1.60 ± 0.18 mL/100g, p=0.012, in VEH vs RAN groups respectively) and water consumption (14.3 ± 2.25 vs 11.9 ± 1.69 mL), along with elevated Cl^- excretion (728.4 ± 287.4 μM vs 1107.8 ± 416.6 uMol). Post-HS RAN treatment yielded a significant increase in urine osmolality (1313.2 ± 319.7 vs 1659.5 ± 359.2 mOsm).

Conclusions: Thus far, we report a shift in the histaminergic tone toward less histamine production in the Dahl SS rat fed a HS diet. Dahl SS rats acutely treated with H2R blocker exhibit lower water consumption, reduced diuresis, and increased urinary osmolality.

Salt-Induced Blood Pressure Elevation in Females Is Associated with Increased Arachidonic Acid Metabolites

Jeanne A. Ishimwe, Annet Kirabo, Fernando Elijovich, Jane F. Ferguson. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Excess dietary sodium (Na^+) intake is a major risk for salt-sensitive hypertension and cardiovascular disease. Several clinical trials have found that women are more salt-sensitive than men, but the contributing sex-specific mechanisms are poorly understood. Arachidonic acid (AA) and its metabolites play a role in the pathophysiology of hypertension. We hypothesized that women have greater blood pressure (BP) elevation in response to Na^+ intake that is associated with higher AA metabolites than men.

Methods: Plasma AA metabolites were measured via a metabolomics analysis in volunteers who completed a validated 3-day food record to estimate dietary Na^+ intake before the study visit where BP was measured. Based on the recommendations by the American Heart Association, we classified daily Na^+ intake <2.3g as normal salt, and high salt for subjects consuming ≥ 2.3g Na^+. Spearman correlation was used to assess the relationship between Na^+ intake and systolic blood pressure (SBP).

Results: Women (n=81) displayed a stronger relationship between BP and Na^+ intake than men (n=49) (r=0.372; p<0.001 vs. r=0.317; p=0.026). The relationship between Na^+ intake and BP was stronger in white (n=46, r=0.4172; p=0.004) than in black (n=22,r=0.338; p=0.124) women and conversely stronger in black (n=7, r=0.790; p=0.034) than white (n=32, r=0.251; p=0.166) men. We measured plasma levels of palmitate and linoleate, both upstream of AA synthesis, AA, and 12-Hydroxyeicosatetraenoic acid (12-HETE) an AA metabolite. In subjects consuming a high Na^+ diet (women 28, men 25) levels of linoleate (1.211 + 0.330 vs. 0.869 + 0.170; p<0.001), palmitate (1.155+ 0.292 vs. 0.924+ 0.233; p= 0.003), AA (1.119 + 0.242 vs. 0.965 + 0.201; p=0.015) and 12-HETE (1.329+ 0.925 vs. 0.902 + 0.520; p=0.0469) were higher in women. In contrast, no sex differences in any of these parameters were observed between men and women consuming a normal salt diet.

Conclusions: Our findings suggest that AA and its metabolites may account for sex and perhaps also racial differences in salt sensitivity of BP. Further study of AA and its metabolites may shed light on the mechanisms of the sex differences in salt sensitivity.

Gstm1 Genotype Affects Metabolic Response in Hypertension

Yves T. Wang, Nhu Nguyen, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Glutathione S-transferases (GSTs) are a family of enzymes that detoxify electrophiles, including products of oxidative stress. In humans, GST μ-1 (GSTM1) has a common null allele variant, *GSTM1(0)*, which has been linked to elevated oxidative stress in pathophysiological conditions and increased risk and/or accelerated progression of a variety of diseases. Recently, we reported that *Gstm1* knockout (KO) mice had increased oxidative stress and augmented kidney injury in angiotensin II (Ang II)-induced hypertension (HTN).

Methods: Kidney tissue was obtained from 12-20 week old male wild-type (WT) and *Gstm1* knockout (KO) mice at either baseline (no treatment) or following 4 weeks of Ang II-induced HTN via mini-osmotic pump at 1000 ng/kg/min. For each animal, a kidney was excised and snap frozen. For qPCR, mRNA was extracted from an homogenized kidney and used to create cDNA, followed by probing for a panel of 18 *Gst* genes. For metabolomics, frozen tissue was ground to a fine powder and sent to Metabolon (Morrisville, NC) to obtain a global metabolic profile.

Results: Analysis of qPCR results showed no significant alterations in the expression of *Gst* genes between WT and KO mice, except for the expected loss of *Gstm1* in KO mice. Metabolomics analysis yielded data for 926 metabolites, with expected significant differences due to Ang II treatment particularly in inflammatory and oxidative stress pathways. About 10% of detected metabolites (97) showed genotype-based effects and a further 131 (14%) displayed an interaction between genotype and treatment. Comparing Ang II-treated KO and WT mice, there was a significant increase in metabolite abundance in the methionine and glutathione pathways, including the transsulfuration pathway linking them. Furthermore, there was an increase in carnosine and anserine and a decrease in several lipid peroxidation markers.

Conclusions: The loss of GSTM1 in Ang II-induced HTN did not elicit a significant compensatory upregulation of mRNA of other GSTs. It is likely other antioxidant pathways are upregulated based on the altered metabolite abundances. However, based on previous results in treated KO mice, any compensatory mechanism is insufficient to protect against the oxidative stress-induced kidney damage. Further research should be pursued to elucidate the oxidative stress-related specific substrates of GSTM1 that are not detoxified by other pathways.

HMGB-1 Activates Mineralocorticoid Receptor-Dependent Endothelial Cell Injury via Receptor for Advanced Glycation End Products

Tomoyuki Otsuka,[1] Seiji Ueda,[1] Hajime Nagasawa,[1] Teruyuki Okuma,[1] Koji Sato,[1] Takanori Matsui,[3] Sho-ichi Yamagishi,[2] Yusuke Suzuki.[1] *[1]Juntendo University Faculty of Medicine, Bunkyo-ku, Japan; [2]Showa University Faculty of Medicine, Shinagawa-ku, Japan; [3]Kurume University Faculty of Medicine, Kurume-shi, Japan.*

Background: Endothelial dysfunction plays a central role in the pathogenesis of cardio-renal syndrome. High mobility group box-1 (HMGB-1) is a protein with various roles in different cellular compartments, and indirectly regulates the activity of transcription and DNA repair in the nucleus. On the other hand, during tissue damage, it is released into the extracellular environment as damage-associated molecular patterns (DAMPs). HMGB-1 is reported to elevate in CKD patients and be involved in endothelial dysfunction through binding to toll like receptor (TLR) and receptor for advanced glycation end products (RAGE). In addition, we recently demonstrated that RAGE-mediated Rac1 activated mineralocorticoid receptor (MR) and resulted in podocytes damage. In the present study, we hypothesized that crosstalk between HMGB-1/ RAGE and Rac1-MR pathways could contribute to endothelial dysfunction in kidney diseases.

Methods: In the present study, we investigated whether HMGB-1 could activate Rac1-MR axis and induce endothelial injury in cultured human umbilical vein endothelial cells (HUVECs) by assessing expression levels of genes for MCP-1 and cell adhesion factors (ICAM-1, VCAM-1) with or without administration of RAGE aptamer or MR blocker (esaxerenone, 1μM).

Results: HMGB-1 supplementation significantly increased GTP-bound Rac1 and enhanced MR translocation into the nucleus in HUVECs. We also found that RAGE expression was enhanced by HMGB-1 and RAGE aptamer completely abolished Rac1 activation and MR translocation observed in HMGB-1 exposed HUVECs. HMGB-1 also upregulated MCP-1, ICAM-1, and VCAM-1 in HUVECs, all of which were significantly blocked by pretreatment of RAGE aptamer as well as MR blocker.

Conclusions: These results suggest that there may be a close relationship between HMGB-1/ RAGE axis and Rac1/ MR activation, thus contributing endothelial injury. Using RAGE aptamer or MR blocker could be novel therapeutic strategies against endothelial dysfunction in patients with kidney diseases.

PO1823

The Role of Ketogenic Diet on the Development of Salt-Sensitive Hypertension

Daria Golosova,[1] Olha Kravtsova,[1] Vladislav Levchenko,[1] Alexander Staruschenko.[1,2] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Clement J Zablocki VA Medical Center, Milwaukee, WI.*

Background: Hypertension is one of the most important risk factors for cardiovascular disease, which is the leading cause of mortality in the US. Two-thirds of hypertension cases are positively correlated with excessive weight gain. The ketogenic diet (KD) may be useful as part of the treatment of cardiovascular complications especially in obese patients. The KD, a low-carb high-fat diet, triggering the body to burn fat for energy instead of carbohydrates, has gained popularity through the weight loss community. We hypothesized that KD can have protective effects during the development of salt-induced hypertension.

Methods: The Dahl salt-sensitive (SS) rats fed a high salt diet develop hypertension accompanied by kidney injury. The Dahl SS rats were given either 4% NaCl diet (HS; Dyets Inc, 113756) or 4% NaCl modified KD (Harland Tekland, TD 190564) with free access to water for 5 weeks. Blood pressure was monitored with telemetry throughout the study, and urine samples were collected in metabolic cages on days 0, 7, 14, 28, and 35. At the end of the protocol animals were sacrificed and blood and kidney tissues were harvested for the analyses.

Results: Dahl SS rats fed a KD had a lower blood pressure compared to control rats fed a HS diet. Mean arterial pressure was 147 ± 5 mmHg vs 179 ± 9 mmHg (KD vs HS, p<0.05). Reduced renal hypertrophy with decreased kidney to body weight ratio (1.00 ± 0.06 vs 1.25 ± 0.04, p<0.05 compared to HS) and smaller kidneys (3.5 ± 0.1 vs 4.5 ± 0.2 g, p<0.05 compared to HS) were found in the KD group. No differences in glomerular damage scores were detected between the groups. The rats on KD experienced hypoglycemia (282 ± 9 vs 335 ± 14 mg/dL, p<0.05 compared to HS) with reduced glucose urinary excretion (5 ± 1 vs 32 ± 7, glucose to creatinine ratio, p<0.05 compared to HS). Microbiome analyses revealed an increase in the relative abundance of putatively beneficial gut microbiota (*Lactobacillus*) and a reduced level of putatively pro-inflammatory taxa (*Turicibacter*).

Conclusions: Therefore, prolonged KD intervention provides a protective effect on the development of SS hypertension. Our data revealed that KD during HS challenge resulted in decreased blood pressure, reduced kidney hypertrophy, and diminished levels of plasma glucose.

Effect of Tochu Extract and Its Component Geniposidic Acid on Renal Hemodynamics and Hypertensive Renal Damage

Akihiro Tojo, Hiroshi Satonaka, Toshihiko Ishimitsu. *Dokkyo Medical University, Mibu, Japan.*

Background: Aqueous extract of Eucommia ulmoides (Tochu) leaf is used as Tochu tea in Japan and has the effect of lowering blood pressure. We investigated the effects of Tochu extract and its component geniposidic acid on renal hemodynamics and hypertensive renal damage in Dahl salt-sensitive hypertensive rats (DS).

Methods: DS rats received 1% saline solution from 4 weeks of age. After the blood pressure reached 150 mmHg or higher at 9 weeks of age, the rats were treated with 1% saline solution (DSHS), or 1% saline added 0.5% Tochu extract (DSHS + T) or, 1% saline added 0.2% geniposidic acid (DSHS + G) for another 4 weeks. DS rats fed with tap water were used as controls (DSLS). At 13 weeks, renal plasma flow (RPF) was measured by renal clearance study, and immunostaining and PCR of NADPH oxidase, eNOS, sodium transporters and fibrotic factors were performed.

Results: Blood pressure was significantly increased in DSHS rats compared to DSLS rats (196 vs.144 mmHg, $p<0.01$), which was significantly decreased in DSHS + T rats (158 mmHg) and DSHS + G rats (162 mmHg). Vascular resistance of afferent arterioles was significantly increased in DSHS rats compared to DSLS rats, and was decreased in both DSHS + T and DSHS + G rats. RPF was significantly higher in DSHS + T rats than in DSHS rats associated with decreased renal vascular resistance ($p<0.05$). In DSHS rats, NADPH oxidase expression and superoxide production were increased, with increased TGF-beta, procollagen 1, fibronectin and renal fibrosis. These were suppressed in DSHS + T and DSHS + G rats. NO production by eNOS was decreased in DSHS rats, but the treatment groups increased eNOS expression and NO production in the vascular endothelium, resulting in decreased renal vascular resistance and improved renal blood flow. Urinary sodium excretion was significantly higher in DSHS rats than in DSLS rats with decreased sodium chloride co-transporter (NCC). However, there was no further change in NCC or other sodium transporters in the treatment groups, and the high urinary Na excretion in the treatment groups was due to the effect of increased RPF.

Conclusions: Tochu and geniposidic acid suppressed NADPH oxidase and increased eNOS in DS rats, resulting in improved blood pressure, renal hemodynamics and renal damage.

Effect of Uremia on Endothelial Cell Damage Is Mediated by Excessive Neutrophil Extracellular Trap Formation

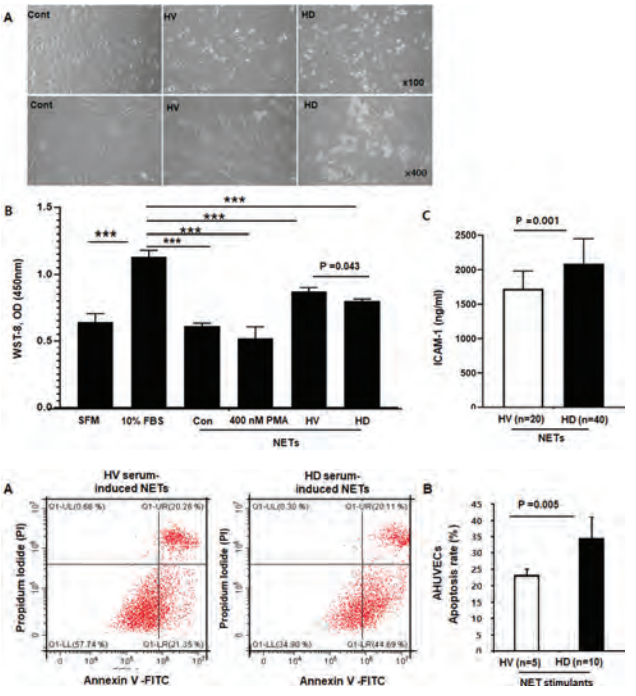
Jwa-kyung Kim, Hoi Woul Lee, Sung gyun Kim. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: Uremia is a clinical syndrome characterized by accumulation of various uremic toxins and associated metabolic abnormalities in chronic kidney disease (CKD). Patients with CKD are at increased risk for cardiovascular (CV) disease and death, and endothelial dysfunction may be a key uremia-specific risk factor. However, the mechanism by which uremia influences endothelial dysfunction is still unclear. We report a role for excessive neutrophil extracellular trap (NET) formation induced by uremic serum on endothelial cell (EC) injury.

Methods: Plasma nucleosome and myeloperoxidase-DNA, representative markers of *in vivo* NETs, and the intracellular adhesion molecule (ICAM)-1 level were measured in incident hemodialysis (HD) patients and healthy volunteer (HV), and their prognostic role was evaluated. For *in vitro* study, we differentiated HL-60 cells into neutrophil-like cells (dHL-60) by applying retinoic acid, and the effect of uremic serum on dHL-60 and ECs were determined.

Results: The amount of *in vivo* NETs were significantly higher in incident HD patients compared to HV, and the markers were strongly associated with ICAM-1 levels. In particular, nucleosome and ICAM-1 levels were independent predictors of a composite endpoint, all-cause mortality or vascular access failure. *In vitro*, uremic serum derived from HD patients showed significantly increased NETs formation from dHL-60, and these NETs significantly decreased EC viability and induced apoptosis. In addition, the ICAM-1 level in HUVEC supernatant was significantly increased by uremic serum-induced NETs compared to control serum-induced NETs.

Conclusions: Dysregulated neutrophil activities in the uremic milieu may play a key role in endothelial damage and vascular inflammatory responses.



PO1826

Contributions of Obesity and Hypertension to Progression of Cardiorenal Syndrome in Non-Diabetic Obese Female ZSF1 Rats

Isabel T. Nguyen, Jaap A. Joles, Marianne C. Verhaar. *Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Obesity and hypertension are highly prevalent in patients with cardiorenal syndrome (CRS). Insight in how these comorbidities individually contribute to disease progression is required to improve treatment strategy. We dissected the separate contribution of obesity and worsening hypertension by deoxycorticosterone acetate (DOCA) plus high salt diet in the obese female ZSF1 rat, a model of metabolic CRS in the absence of diabetes [Nguyen, PLoS One 2020]. We hypothesize that in obese non-diabetic female ZSF1 rats obesity has a profound effect on functional progression of CRS while hypertension mainly affects fibrosis and inflammation.

Methods: Systolic blood pressure (SBP), renal and cardiac function were assessed biweekly in lean and obese female ZSF1 rats from 12 to 26 weeks of age. From 19 weeks, rats were implanted with either a DOCA pellet and fed a high salt (6% w/w) diet or with a placebo pellet and fed a normal salt diet. At 26 weeks of age, glomerular filtration rate (GFR) and effective renal plasma flow (ERPF) were assessed under isoflurane anesthesia. Subsequently, rats were sacrificed and tissues processed for analysis of renal and cardiac damage and inflammation.

Results: Obese versus lean placebo rats showed elevated E/e' ratio from 12 weeks, indicative of diastolic dysfunction. From 24 weeks obese compared to lean placebo rats developed proteinuria with lower GFR at 26 weeks of age. DOCA-salt markedly increased SBP in obese but not lean rats, despite similarly high natriuresis compared to placebo rats. ERPF was increased by DOCA-salt in lean but not obese rats. DOCA-salt worsened proteinuria and glomerulosclerosis in obese rats. Cardiac fibrosis and glomerular hypertrophy, present in obese rats, were not aggravated by DOCA-salt. However, DOCA-salt increased the number of macrophages in heart, but not in glomeruli of obese ZSF1 rats.

Conclusions: Obesity leads to renal and cardiac dysfunction and damage in female ZSF1 rats. Even without worsening of hypertension (DOCA+salt), cardiac dysfunction preceded proteinuria, suggestive of CRS type 2. Our findings suggest that antihypertensive and antiproteinuric treatment at a later stage without initially addressing metabolic risk, even in the absence of diabetes, will not provide adequate functional protection in CRS type 2.

Association Between Kidney Function and Lipid Levels in Older Adults

Shreya Srivastava,[1] Josef Coresh,[1,2] Casey Rebholz,[1] Morgan Grams,[1,2] Kunihiro Matsushita,[1,2] Seth S. Martin,[2] Jung-Im Shin.[1] *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins Medicine, Baltimore, MD.*

Background: The associations between kidney function and lipid levels in older adults have not been well characterized. Moreover, it is unknown whether residual atherosclerotic cardiovascular disease (ASCVD) risk after statin use differs by lipid levels other than total cholesterol (TC) or low-density lipoprotein cholesterol (LDL-C), such as triglyceride (TG).

Methods: We conducted a cross-sectional study of older adults (≥65 years) using visit 5 data (2011-2013) of the Atherosclerosis Risk in Communities study. Multivariable linear and logistic regression was used to examine the eGFR-lipid level associations, stratified by statin use. Among statin users without ASCVD who had LDL-C levels <100 mg/dl, we predicted 10-year ASCVD risk after statin use by TG levels (<150 mg/dl vs. ≥150 mg/dl) across eGFR groups.

Results: The mean age of the study population (n=4965) was 75 (SD 5) years, 58% were female, and 22% were Black. The mean eGFR was 63 (SD 18) ml/min/1.73 m^2 and 52% were on a statin. In both statin users and non-users, there were no associations between eGFR and total TC or LDL-C. Low eGFR was associated with low high-density lipoprotein cholesterol (HDL-C) and high TG (**Figure**). Among statin non-users, eGFR <45 (vs. ≥60) was independently associated with low HDL-C (<50 mg/dl) (prevalence=59% vs. 34%, odds ratio=1.86; 95% CI, 1.38-2.51) and high TG (≥150 mg/dl) (31% vs. 20%, 1.54; 1.13-2.09). The results were similar among statin users. Among statins users with LDL-C <100 mg/dl, the prevalence of high predicted ASCVD risk (risk ≥20%) was greater among those with vs. without high TG across all eGFR categories (eGFR ≥60, 66% vs. 59%; 45-59, 78% vs. 73%; eGFR <45, 90% vs. 79%).

Conclusions: We found that low eGFR was associated with low HDL-C and high TG levels, regardless of statin use. Among statin users who achieved adequate LDL-C control, ASCVD risk was still higher among those with high TG compared to those without high TG.

Nephroprotective Effects of PDE3A Gene Mutations

Anastasiia Sholokh,[1] Tatiana A. Borodina,[1] Daniele Y. Sunaga-Franze,[1] Kerstin Zuehlke,[1] Sylvia Bähring,[2] Michael Bader,[1] Enno Klussmann.[1,3] Anchored Signalling *[1]Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin, Germany; [2]Charite, Experimental and Clinical Research Center, Berlin, Germany; [3]DZHK (German Center for Cardiovascular Research), partner site Berlin, Berlin, Germany.*

Background: Chronic kidney disease (CKD) affects more than 700 million people worldwide. The molecular mechanisms of CKD are poorly understood and the treatment approaches are non-causal and therefore non-selective. Mutations in the gene coding for phosphodiesterase 3A (PDE3A) cause autosomal-dominant hypertension with brachydactyly type E (HTNB). Despite HTNB patients have decade-long hypertension, their kidneys hardly display any hypertension-induced damage. We hypothesize, understanding how PDE3A mutations protect from CKD development will help to uncover the molecular mechanisms of CKD and pave the way to new strategies for CKD prevention and treatment

Methods: CRISPR/Cas9 was applied to introduce mutations in a regulatory or the catalytic domain encoding segment of the *Pde3a* gene of rats to recapitulate the HTNB phenotype (confirmed by radio-telemetry measurements). The inner medulla (IM) and residual kidney (RK) were subjected to Western blot analysis and RNA-sequencing with subsequent validation of the most promising genes-candidates.

Results: In wild-type animals, PDE3A mRNA and protein expression were higher in the IM compared to the RK. In PDE3A mutant animals, the IM PDE3A protein level was decreased. Protein levels of various cAMP signalling pathway components were not changed in PDE3A mutants in both IM and RK. However, the phosphorylation level of cAMP response element-binding protein (CREB) was significantly increased in IM in PDE3A mutants. The mRNA levels of 27 genes were changed upon PDE3A mutation in the regulatory region; some of them clustered as mitochondrial or inflammatory response proteins. The PDE3A mutation in the catalytic domain led to more profound changes in mRNA expression profiles.

Conclusions: In summary, our data show that hypertension-inducing mutations of PDE3A have no profound effects on the expression level of cAMP signaling proteins but change the global transcriptional profiles in the kidney. Alterations of the inflammatory cytokine production or mitochondrial metabolism could be involved in the renoprotective effects of PDE3A mutations.

Cerebrovascular Dysfunction in CKD

Cortney Steele, Ester Oh, Heather Farmer-Bailey, Rachael L. Reddin, Taylor Struemph, Michel Chonchol, Kristen L. Nowak. *University of Colorado - Anschutz Medical Campus, Aurora, CO.*

Background: Cerebrovascular dysfunction, characterized by reduced cerebrovascular reactivity, cerebral hypoperfusion, and increased pulsatile flow within the brain precedes the onset of dementia and is linked to cognitive dysfunction. While large-artery vascular dysfunction is prevalent in chronic kidney disease (CKD), cerebrovascular function has not been well characterized to date in moderate-to-severe CKD.

Methods: Using transcranial Doppler, we compared middle cerebral artery (MCA) blood flow-velocity response to hypercapnia (normalized for blood pressure and end-tidal CO_2; a measure of cerebrovascular reactivity) and MCA pulsatility (a measure of cerebrovascular stiffness) in patients with stage 3-4 CKD vs. age-matched healthy controls using an independent samples t-test. We also administered the trail making test (parts A and B) as an index of processing speed and measured carotid-femoral pulse-wave velocity (CFPWV) as an index of aortic stiffness.

Results: Seven participants with CKD (2F, 68±3 yrs [mean±s.e.m.], estimated glomerular filtration rate [eGFR]: 38±5 ml/min/1.73m^2) were compared to 8 healthy controls (1F, 63±2 yrs, eGFR: 83±5 ml/min/1.73m^2). MCA pulsatility index was greater (1.08±0.10 vs. 0.85±0.04 A.U.; $p<0.05$) and normalized MCA blood flow-velocity response to hypercapnia tended to be lower (-6.3±4.0 vs. 11.6±7.3 %; $p=0.06$) in CKD as compared to healthy controls. Trail making part A time was slower (A: 31.8±3.3 vs. 20.2±1.6 sec; $p<0.01$); part B time tended to be slower (longer time to complete): 71.7±13.6 vs. 42.7±6.7 sec; $p=0.07$) and CFPWV was greater (1122±115 vs. 811±88 cm/sec; $p<0.05$) in CKD vs. control. Greater MCA pulsatility index correlated with worse cerebrovascular reactivity ($r = -0.63$, $p=0.01$), greater CFPWV ($r= 0.65$, $p<0.01$), slower trail making part B time ($r =0.59$, $p<0.05$), and lower eGFR ($r = -0.53$, $p=0.09$).

Conclusions: Impaired cerebrovascular function is evident in patients with moderate-to-severe CKD. Increased cerebrovascular stiffness is associated with reduced kidney function, increased aortic stiffness, impaired processing speed, and worse cerebrovascular reactivity.

PO1830

Circadian Clock Provides Beneficial Effects Against Endothelial Dysfunction by Regulating Heme Synthesis and Heme Oxygenase 1 Expression

Hideyuki Negoro.[1,2] *[1]Harvard Medical School, Boston, MA; [2]The Graduate School of Project Design, Tokyo, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hours variations in gene expression and function to regulate number of physiological functions in humans. Chronic circadian clock disruption is associated with vascular stiffness and dysfunction in endothelial signaling and responses. 5-Aminolevulinic acid (ALA) is the common precursor of heme. The iron ion is inserted into PpIX to form heme in the mitochondria and incorporated into hemoproteins. Heme is a ligand of REV-ERBα and REV-ERBβ which modulate circadian rhythms by binding to the ROR region of CLOCK or BMAL1 to suppress the expression of these genes. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells. To synchronize circadian rhythms, serum stimulations were performed. Cells were also pre-incubated with or without 1 mM ALA and 0.5 mM sodium ferrous citrate (SFC).

Results: In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. ALA/SFC co-incubation affected the oscillation and phase of core clock genes and led to increase of HO-1. HO-1 levels followed a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating Heme synthesis and HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Bradykinin Reduces Long-Lasting TRPV1-Mediated Inward Currents in Afferent Nonfiring Renal Neurons

Kristina Rodionova,[1] Christina Forray-Strauss,[1] Tilmann Ditting,[1,2] Karl F. Hilgers,[1] Nada Cordasic,[1] Peter Linz,[1] Christian Ott,[1,2] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[3] Roland Veelken.[1,2] *[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany; [3]Universitätsklinikum Erlangen, Abteilung für Nephropathologie, Erlangen, Germany*.

Background: Bradykinin had been reported to be sympathoexcitatory via renal afferent nerves. Hence we tested the hypothesis that bradykinin directly stimulates cultivated renal neurons with afferent axons.

Methods: Dorsal root ganglion neurons (Th11-L2) of rats were investigated in voltage clamp mode to assess inward currents and current clamp mode to assess action potential (AP) generation [neurons classified as tonic (high AP generation upon stimulation), phasic (AP ≤ 5 upon stimulation) or no firing]. Stimulation of TRPV1 receptors by protons (pH 6) with and without the addition of bradykinin (1, 10,100 μM). 111 DRG renal neurons retrogradely stained with DiI for investigation.

Results: Bradykinin (BK) alone did not induce inward currents nor APs. Proton stimulation (pH 6) of TRPV1 significantly augmented long-term inward currents (baseline -0.360±0.09nA vs. -1.39±0.34nA, $p<0.05$, mean±SEM) and increased action potential production in tonic neurons (0 APs/10s vs. 9.57±1.89 APs/10s*, $p<0.05$, mean±SEM). However, the co-stimulation of renal neurons with protons and BK had any effect only in one specific subgroup of renal neurons: it significantly decreased long-lasting currents in non firing neurons (ΔI upon stimulation with 100μM BK&pH6: -0.129±0.02nA, 10μM BK&pH6: -0.119±0.03nA, 1μM BK&pH6: -0.063±0.02 nA versus pH 6: -0.312±0.06nA*, *$p<0.05$, mean±SEM).

Conclusions: Bradykinin was only able to reduce long-lasting, TRPV1 dependent inward currents in non-firing renal neurons. Alterations of inward currents are likely involved in the release of neurogenic proinflammatory peptides (SP, CGRP). Hence, bradykinin might impair the release of neuropetides from intrarenal axons of a specific subgroup of renal afferent neurons.

The Impact of rs2254524 LSS Polymorphism on Blood Pressure in a New Mouse Model

Sipontina Faienza,[1] Lorena Citterio,[1] Laura Zagato,[1] Elisabetta Messaggio,[1] Paolo Manunta.[1,2] Genomics of Renal Diseases and Hypertension Unit *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy*.

Background: The blood pressure (BP) response to salt intake is associated with hypertension (HTN) and shows great variability among individuals. Endogenous ouabain (EO) is a steroid hormone previously associated with HTN. To dissect EO and HTN link at genetic level, we identified as a propensity factor the missense variation rs2254524 (Val642Leu; V642: CC variant; L642: AA variant) in the Lanosterol Synthase (LSS), a key enzyme in steroid biosynthesis. In patients, the LSS A variant influences the BP and circulating EO level in response to a low salt diet. Moreover, high EO levels were detected in LSS AA kidneys and are associated with a faster decline in GFR in hypertensives. We hypothesized that LSS affects salt-sensitive HTN by regulation of EO biosynthesis.

Methods: We generated a knock-in mouse model carrying the rs2254524 SNP expression in all tissues. We performed all animal procedures on male mice. The Blood Pressure was measured by the tail-cuff system, on 5 consequent days in conscious mice, after appropriate training.

Results: LSS AA mice were viable, healthy, and undistinguishable phenotypically from LSS CC. The LSS transcript and protein levels were slightly reduced in the Adrenal Gland of LSS AA mice at 3 months of age and in the kidney at 6 months of age. At 3 months of age, EO quantification in LSS AA kidney is about 3.3 pmol/g tissue (SD =1.69) compared to 2.6 pmol/g tissue (SD =1.1) in control. At baseline, LSS AA mice did not affect SBP and kidney function at 3, 6, and 9 months of age. Nevertheless, we observed an increasing trend in SBP upon High Salt (4% NaCl) diet administration in AA mice, compared to that fed with Control Salt Diet (0.5% NaCl), at 3 months (Fig. 1).

Conclusions: Our preliminary results show that the LSS AA variant affects BP upon high-salt diet administration at 3 months, but further studies are necessary to deepen the effect of LSS A variant on salt-sensitivity at different ages.

Funding: Government Support - Non-U.S.

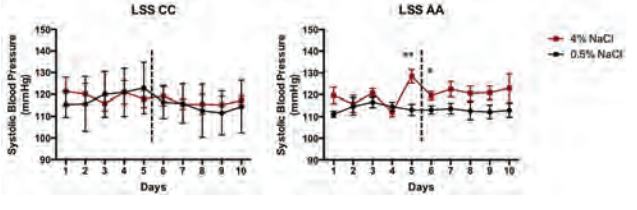

Fig. 1: SBP measurement by the tail-cuff system in LSS CC and LSS AA mice upon 4% and 0.5% NaCl diets administration. The first 5 days are considered as training. Bars indicate average ± SEM. *$P < 0.05$; **$P < 0.01$

PO1833

RNA Sequencing Reveals Induction of Specific Renal Inflammatory Pathways in a Rat Model of Malignant Hypertension

Andrea Hartner, Carlos Menendez-Castro, Nada Cordasic, Mario Schiffer, Roland Veelken, Kerstin U. Amann, Arif Ekici, Christoph Daniel, Karl F. Hilgers. *Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany*.

Background: In malignant hypertension (MH), far more severe kidney injury occurs than in the "benign" form of the disease. The pathogenesis of this peculiar renal injury of malignant hypertension remains incompletely understood. Using a rat model in which some but not all animals develop MH, we performed an unbiased analysis of gene expression by RNA-sequencing to identify transcriptional changes in the kidney specific for malignant hypertension.

Methods: Renovascular hypertension in rats was induced by placing a 0.2 mm clip on the left renal artery (2K1C). Five weeks later, all 2K1C rats had developed hypertension. Rats were then sacrificed, and renal cortical RNA was extracted from the right kidney exposed to high blood pressure. To distinguish MH from non-malignant hypertension (NMH), we considered two factors: weight loss and typical renovascular lesions. Differential gene expression was assessed in three groups: MH, NMH and normotensive, sham operated controls (N=5 per group for RNA sequencing, N between 8 and 14 for other analyses).

Results: Mean blood pressure measured intraarterially was elevated to a similar degree in MH (207±10 mmHg) and NMH (201±4 mmHg) compared to controls (113±3 mmHg, $p<0.05$). 886 genes were exclusively regulated in MH only. Principal component analysis revealed a separated clustering of the three groups. The data pointed to an upregulation of many inflammatory mechanisms in MH including pathways which previously attracted little attention in this setting: Transcripts from all three complement activation pathways were upregulated in MH compared to NMH but not in NMH compared with controls; immunohistochemistry confirmed complement deposition in MH exclusively. The expression of chemokines attracting neutrophil granulocytes as well as actual granulocyte infiltration were increased only in MH rats (CXCL6: 4.1-fold in MH over NMH).

Conclusions: The hypertensive kidney injury in malignant hypertension of 2K1C rats includes a robust expression and deposition of complement components as well as infiltration of neutrophil leukocytes, features which are not observed in the non-malignant course of renovascular hypertension. These pathways may contribute to the specific kidney injury observed in malignant hypertension.

PO1834

Toll-Like Receptor 4 (TLR4) an Effector of Renal Inflammation and Sodium (Na) Transport

Karin C. Oliveira,[1,2] Robert L. Repetti,[1,2] Rajeev Rohatgi.[2,1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Northport VA Medical Center, Northport, NY*.

Background: Na sensitivity of blood pressure (BP) is risk factor for cardiovascular mortality compared to Na resistant subjects. In addition, constrained cholesterol (chol) efflux is novel predictor for future cardiovascular events. Dysregulation of ABCA1, a chol efflux protein, is implicated in hypertension and kidney disease while ABCA1 ablation in macrophages stimulates TLR4 dependent inflammation. We surmised that tubular ABCA1 depletion similarly enhances TLR4 dependent inflammation in a model of Na sensitivity.

Methods: Transgenic mice ($Tg^{PAX8rtTA;tetO\text{-}Cre/+}$), which express CRE in tubular epithelia when fed doxycycline, were bred with mice expressing floxed ABCA1 to generate mice deficient in tubular ABCA1 (FF). Western blotting was performed on whole kidney protein lysate, renal plasma membrane (PM), and mpkCCD cells. Amiloride sensitive short-circuit current (AIsc) was measured in shear and static exposed mpkCCD cells.

Results: FF mice are phenotypically consistent with Na sensitivity (abstract# 3600350). FF and littermate controls (WT) mice fed a chol enriched diet for 6 weeks, a low Na and a high Na diet for 1 week were euthanized and kidneys extracted. Steady-state protein expression of NLRP3 inflammasome increased in ABCA1 deficient (1.5±0.1; n=7 $p<0.05$) vs. WT kidneys (1.0±0.1; n=5); however, TLR4, a receptor that stimulates NLRP3, was unchanged. Western blot of renal PM showed enhanced TLR4 abundance in FF (1.9±0.3; n=3; $p<0.05$) vs. WT (1.0±0.2; n=3) kidneys. Because Na enriched diets augment urine volume, tubular flow, and, thus fluid shear stress (FSS), the role of TLR4 signaling on FSS mediated Na transport was tested in mpkCCD cells. The AIsc in FSS (0.4 dynes/cm^2) exposed cells was greater (40.8±2.1 μA/cm^2;n=20, $p<0.05$) than in static cells (26.7±1.6 μA/cm^2; n=20) and the FSS induced AIsc was reduced (31.5±2.6 μA/cm^2; n=18, $p<0.05$ vs FSS exposed cells) by 10 μM basolateral TAK242, a TLR4 antagonist. FSS (n=9; 1.6±0.2, $p<0.05$) and 5 μM PSC (n=6; 1.7±0.2, $p<0.05$), an ABCA1 inhibitor, also induced NLRP3 protein abundance compared to static cells (n=9; 1.0±0.1) and (n=5, 1.0±0.1), respectively.

Conclusions: ABCA1 tubular deficiency enhances TLR4 PM localization and activation in kidney to induce NLRP3 while a cell model confirms that FSS and reduced ABCA1 stimulate NLRP3 abundance. TLR4 also regulates FSS-induced ENaC-dependent Na transport.

T Lymphocytes in Human Hypertension

Ghazal Z. Quinn,[1] Xin Sheng,[1] Amin Abedini,[1] Lynda Vuong,[2] Briana G. Nixon,[2] Jonathan Hill,[3] Steven S. Pullen,[3] Myung Shin,[4] Ming Li,[2] A. A. Hakimi,[2] Katalin Susztak.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT; [4]Merck & Co Inc, Kenilworth, NJ.*

Background: Mouse models have shown that T lymphocytes are required for hypertension (HTN) development and accumulate in the vasculature and kidneys. The role of immune cells, including T lymphocytes, remains poorly understood in patients with HTN. Here, we analyzed immune cells in human kidney tissue samples in patients with HTN.

Methods: Human kidney tissue was obtained from the unaffected portions of 631 tumor nephrectomies and included clinical, histological and follow up data. Tissue was microdissected into glomerular and tubular compartments for RNA-sequencing. *In silico* deconvolution of each kidney sample was performed using the CIBERSORTx method to enumerate relative cell type fractions. Flow cytometry was used for validation analyses using cell type specific antibodies in another set of 58 human kidney tissue samples. Regression analyses were used to determine the associations of renal immune cells and clinical parameters. Linear mixed modeling was used to assess longitudinal data.

Results: CD4 and CD8 T-cells were increased in patients with HTN ($p<0.05$) while T regulatory cells (Tregs) were decreased (0.4% vs. 0.6%, $p=0.022$). In adjusted models, HTN was associated with older age, Black race, diabetes, decreasing eGFR, dendritic cells (DCs) and Tregs and with increasing CD4 T-cells ($p<0.001$). In samples with CKD stages 1-2, older age, lower Tregs and natural killer T-cells and higher CD4 T-cells were associated with HTN, independent of baseline eGFR or the degree of renal fibrosis ($p<0.001$). In our flow cytometry cohort, HTN was also significantly associated with higher CD4 T-cells, lower Tregs and DCs, but also lower CD8 T-cells, independent of eGFR ($p=0.009$). Longitudinal data were available for 149 subjects for an average of three years and showed that older age, lower baseline eGFR and higher Th17 cells were associated with lower eGFR over time ($p<0.001$).

Conclusions: *In silico* deconvolution resolved a variety of renal immune cells and provided complementary information to flow cytometric analyses in kidney tissue. While multiple T-cell populations were increased in the setting of HTN, Tregs were decreased. These findings were independent of eGFR at CKD stages 1-2. Th17 cell expansion predicted faster eGFR decline. Our results highlight an important association between T-cell populations, HTN, kidney disease and kidney function decline.

Focal Adhesion Kinase: A Major Regulator of Myocardial Failure in CKD

Arvin Halim,[1] Gayatri Narayanan,[1] Takashi Hato,[1] Tzongshi Lu,[2] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Brigham and Women's Hospital, Boston, MA.*

Background: The focal adhesion pathway is essential in signal communication between the extracellular matrix and the cytoskeleton. Failure of this signaling pathway results in cytoskeletal dysfunction and has been shown to be intricately involved in the progression of ischemic cardiomyopathy. Whether this occurs in CKD-associated cardiomyopathy is currently unknown. In this study, our aim was to investigate the role of focal adhesion kinase (FAK), a central component of the focal adhesion pathway in the failing heart in CKD.

Methods: We performed a cross-sectional cohort study of explanted human heart tissues from hemodialysis-dependent (HD, n=19), hypertension with preserved renal function (HTN, n=10), and healthy control (n=21) donors. Left ventricular (LV) tissues were subjected to RNA sequencing, qPCR, and protein analyses. Mechanistic and interference RNA studies using *in vitro* human ventricular cardiac fibroblast models were also conducted.

Results: Hearts from HD donor exhibited significant myocardial fibrosis ($p<0.01$) compared to HTN and control. HD and HTN hearts had higher heart weights ($p<0.01$) and greater LV wall thickness ($p<0.01$) compared to control hearts. RNA-sequencing revealed that the focal adhesion pathway was one of the most perturbed pathways in HD hearts compared to control. FAK mRNA and protein expression was significantly upregulated ($p<0.05$), and major cytoskeletal proteins associated with the focal adhesion pathway, including β-actin ($p<0.01$), β-tubulin ($p<0.01$), vinculin ($p<0.05$), and vimentin ($p<0.01$) were significantly dysregulated in HD hearts compared to control. Uremic mineral stressors (high phosphate and high calcium) decreased FAK expression as well as β-tubulin ($p<0.05$) and vimentin, and promoted cleavage of FAK and vimentin, *in vitro*. Concurrent FAK siRNA transfection and mineral stress significantly decreased both full-length and cleaved FAK expression ($p<0.05$) and further dysregulated vimentin ($p<0.05$) and vinculin ($p<0.05$) expression, *in vitro*.

Conclusions: FAK and the focal adhesion pathway plays a central role in the development of CKD-associated cardiomyopathy and appears to preserve the dynamic formation of the cytoskeleton in HD hearts. These findings suggest a potential therapeutic role for targeting the focal adhesion pathway in the management of cardiac remodeling in CKD.

PO1837

Dual Action of β2AR-Agonism Confers Protection Against Heart Failure and Renal Dysfunction via Inotropic and Lusitropic Effects and Normalized Cholesterol Homeostasis in a Mouse Model of Alport Syndrome

Ahmed Chahdi,[1] Keyvan Yousefi,[1] Jose M. Condor Capcha,[1] Michael Freundlich,[1] Melina Ramic,[1] Guerline Lambert,[1] Serene Shehadeh,[1] Julian C. Dunkley,[1] Yee-Shuan Lee,[1] Aisha Khan,[1] Zane Zeier,[1] Derek Dykxhoorn,[1] Chryso P. Katsoufis,[1] Joshua M. Hare,[1] Mary B. Nabity,[2] Carolina Rivera,[1] Anastasios Lymperopoulos,[3] Keith A. Webster,[1] Camila Irion,[1] Lina Shehadeh.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Texas A&M University, College Station, TX; [3]Nova Southeastern University, Fort Lauderdale, FL.*

Background: *Col4a3*$^{-/-}$Alport mice present a model of heart failure with preserved ejection fraction (HFpEF) secondary to CKD. HFpEF is characteristically unresponsive to pharmacological intervention. Here, we tested the hypothesis that selective β2AR modulation with salbutamol could alleviate symptoms of CKD and simultaneously augment cardiac function. Secondarily, we investigated the mechanism of actions of such β2AR-mediated therapeutics on cardiac and renal functions.

Methods: Alport mice were injected intraperitoneally with salbutamol or DMSO vehicle as a single bolus of 200μg/dose in short-term studies or daily with 100 μg/dose for 2 weeks long-term. Cardiac and renal functions, cAMP levels, *in vivo* renal tubular LDL-C uptake and renal histology were evaluated post-injection.

Results: Short-term, salbutamol improved renal function in parallel with decreased LDLR levels and reduced uptake of LDL-C into renal tubules. Long-term, cardiac diastolic function assessed by isovolumetric relaxation time (IVRT), filling pressures (E/E′), and myocardial performance index, and systolic function reflected by ejection fraction, stroke volume and cardiac output improved significantly in parallel with increased cardiac cAMP. Mechanistically, in the kidney, salbutamol induced IDOL-mediated ubiquitination and subsequent lysosomal degradation of the LDLR via a novel β2AR-mediated, cAMP-independent pathway involving the Rac1/Cdc42 β1PixGEF. β1Pix reversibly sequesters IDOL into a complex with LDLR, thereby blocking the degradation pathway. β2AR stimulation dissipates the complex reactivating IDOL-mediated LDLR degradation thereby re-establishing LDL-C homeostasis and renal function. Using flow cytometry in HEK293T cells, ectopic expression of β1Pix stabilized cell surface LDLR abundance in an IDOL-dependent and PCSK9-independent manner.

Conclusions: β2AR agonism represents a potential treatment strategy to alleviate progression of CKD and heart failure associated with HFpEF phenogroup 3.

PO1838

Phenotyping CKD-Associated Cardiac Fibrosis

Gayatri Narayanan,[1] Arvin Halim,[1] Sharon M. Moe,[1] Tzongshi Lu,[2] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Myocardial fibrosis is a pervasive and progressive complication in CKD patients. Mechanistically, increased collagen cross-linking has been shown to be a critical determinant of tensile strength, stiffness of collagen fibers, and resistance to degradation in ischemic cardiomyopathy, as opposed to increased collagen deposition alone. Whether similar metabolic processes and physiochemical alterations occur in CKD is largely unknown. Herein, we investigated the fibrotic phenotype in CKD-associated cardiomyopathy and the role of disordered mineral stressors.

Methods: Human left ventricular (LV) tissues were collected from hemodialysis (HD; n=13), hypertensive (HTN; n=8), and healthy control (n=12) donors to compare matrix proteins. Mechanistic *in vitro* studies involving treatment of human ventricular cardiac fibroblasts (HCFs) with either 1.8-3.8mM β-glycerophosphate (BGP) or 2.4-5.0mM $CaCl_2$ in media were conducted. Protein expression was assessed by immunoblotting.

Results: We report increased trimeric (400 kDa) collagen I (COL1) in LV tissues from HD and HTN ($p<0.05$) compared to healthy control. Uniquely, monomeric (150 kDa) COL3 was decreased in HD hearts ($p<0.05$) compared to HTN and healthy control. Dimeric (250 kDa) or monomeric COL1 (139 kDa) and other COL3 multimers were not found in any groups. HD and HTN hearts exhibited increased periostin ($p<0.05$) compared to healthy control. There was no significant difference in fibronectin or α-smooth muscle actin (α-SMA) between groups. We next performed dose-dependent studies in HCFs treated with either BGP or $CaCl_2$. 3.8 mM BGP stimulated increased trimeric but not dimeric COL1 ($p<0.05$), and reduced monomeric COL3 ($p<0.01$) synthesis leading to increased total COL1:3 ratio ($p<0.05$), *in vitro*. No other forms of COL1 or COL3 were observed. Additionally, 3.8mM BGP decreased fibronectin expression ($p<0.01$), but did not significantly change periostin or α-SMA expression. At 5 mM $CaCl_2$ treatment, this decreased COL3 ($p<0.01$), fibronectin ($p<0.05$), and periostin ($p<0.05$) expression.

Conclusions: Cardiac fibrosis in hearts from HD patients is characterized by increased trimeric COL1 expression and increased COL1:3 ratio that can be driven by disordered mineral stressors. These changes suggest pathologic cross-linking that can lead to altered mechanical properties and further studies are warranted.

Plasma Proteins Associated with eGFR and Incident Cardiovascular Events in the Cardiovascular Health Study Cohort

Christine P. Limonte,[1] Pranav S. Garimella,[4] Robert Gerszten,[5] Diana I. Jalal,[2] Michelle Odden,[6] Michael Shlipak,[3] Nisha Bansal,[1] Thomas R. Austin,[1] Ian H. de Boer.[1] *[1]University of Washington, Seattle, WA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA; [3]University of California San Francisco, San Francisco, CA; [4]University of California San Diego, La Jolla, CA; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Stanford University, Stanford, CA.*

Background: Proteomics may help identify mechanisms through which low estimated glomerular filtration rate (eGFR) increases risks of heart failure (HF), myocardial infarction (MI), and cardiovascular (CV) death.

Methods: We utilized an aptamer-based assay to measure 1300 proteins among 3185 older adults in the Cardiovascular Health Study. Proteins associated with eGFR were identified using linear regression models. A Bonferroni-corrected p-value less than $7.6x10^{-8}$ was used to account for multiple testing. Proteins significantly associated with eGFR were tested for associations with incident HF, MI, and CV death using Cox-proportional hazard regression adjusting for demographic and clinical variables. We evaluated whether proteins mediated associations between eGFR and incident CV events.

Results: The mean baseline eGFR was 70 ml/min/1.73m^2 and over a follow-up median of 13 years, there were 1033 incident HF, 555 incident MI, and 963 CV death events. 797 proteins were significantly associated with eGFR. Of these, 52, 0, and 22 proteins were associated with incident HF, MI, and CV death, respectively. All proteins associated with HF and CV death significantly mediated the effects between eGFR and incident CHF and CV death, respectively. The 10 proteins most strongly associated with both HF and CV are shown in the **Table**.

Conclusions: eGFR is associated with a large number of plasma proteins. A subset of these proteins are also associated with incident HF and CV death and may reflect mechanisms through which reduced eGFR increases the risk of these outcomes.

Funding: Other NIH Support - NIH - NHLBI

Characterization of Pendrin in Urinary Extracellular Vesicles in a Rat Model of Aldosterone Excess and in Human Primary Aldosteronism

Fumika Ochiai,[1] Emiko Kuribayashi-Okuma,[1] Yuya Tsurutani,[2] Kenichi Ishizawa,[1] Mika Kawagoe,[1] Yoshihiro Tomomitsu,[1] Daigoro Hirohama,[1] Shigeyuki Arai,[1] Osamu Yamazaki,[1] Yoshifuru Tamura,[1] Yoshihide Fujigaki,[1] Tetsuo Nishikawa,[1] Shigeru Shibata.[1] *[1]Teikyo Daigaku Igakubu Daigakuin Igaku Kenkyuka Naikagaku, Itabashi-ku, Japan; [2]Yokohama Rosai Byoin, Yokohama, Japan.*

Background: Pendrin is a Cl/HCO_3 exchanger selectively present in the intercalated cells of the kidney. Although experimental studies demonstrated that pendrin is involved in the fluid volume regulation and acid/base balance, its role in human hypertension is not fully understood. Here, we investigated the changes in pendrin levels in urinary extracellular vesicles (uEVs) isolated from patients with primary aldosteronism (PA) and in a rat model of PA.

Methods: This study included 30 patients who were diagnosed as having PA in Yokohama Rosai Hospital or in Teikyo University Hospital. The protocol was approved by the institutional review board. In animal experiments, SD rats received continuous infusion of aldosterone after uninephrectomy. Isolation of uEV was performed by the ultracentrifugation method in accordance with the previous report (Fernandez-Llama et al. KI 2010).

Results: Western blot analysis revealed that pendrin is detected in dimeric and monomeric forms in uEVs in humans and in rats. In aldosterone-infused rats, pendrin levels in uEVs were highly correlated with the pendrin abundance in the kidney. We also found significant correlation between abundance in uEVs and that in the kidney for Na-Cl cotransporter and epithelial Na channel in this model. In PA patients, pendrin levels in uEVs were reduced by 49% from the baseline by adrenalectomy or pharmacological MR blockade. Correlation analysis revealed that the magnitude of pendrin reduction after treatment significantly correlated with the baseline aldosterone-renin ratio (ARR), and tended to inversely correlate with serum K^+ levels. Furthermore, a cross-sectional analysis in PA patients confirmed a significant correlation between ARR and pendrin levels in uEVs.

Conclusions: These data are consistent with experimental studies demonstrating the role of pendrin in aldosterone-induced hypertension, and suggest that pendrin analysis in uEVs may also be useful to understand the pathophysiology of human hypertension.

PO1841

The Impact of Calcification on Intraplaque Hemorrhage in Coronary Atherosclerosis from Autopsy Samples: The Hisayama Study

Toshiaki Nakano, Hiromasa Kitamura, Yoshinao Oda, Takanari Kitazono, Toshiharu Ninomiya. *Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan.*

Background: Vascular calcification is the specific feature of arterial change and is often seen in coronary arteries among patients with chronic kidney disease (CKD) and older subjects. The information whether vascular calcification is associated with intraplaque hemorrhage is scarce. We aim to examine how much area of calcification is the highest risk on plaque vulnerability.

Methods: We examined 375 coronary arteries obtained from autopsy samples of subjects with CKD stages 0 to 5 in a general Japanese population. Arteries were divided into quintiles based on vascular calcification area. The association of calcification area with the presence of intraplaque hemorrhage in coronary arteries was estimated by using a logistic regression analysis.

Results: Calcification lesions were counted in 149 coronary arteries. All calcification lesions were existed in intima. Subjects in the fourth quartile of calcification area had a significantly higher likelihood of intraplaque hemorrhage than those in the lowest quintile after adjusting for confounders (odd ratio [95% confidence interval], 19.93 [1.48-267.71]), whereas subjects in highest quintile did not (7.86 [0.61-101.70]). The calcification area at highest risk for the presence of intraplaque hemorrhage was 2.02 mm^2, and the risk was constant at greater area than this value in the logistic analysis with restricted cubic spline.

Conclusions: The present study suggests that larger vascular calcification is associated significantly with increased risk for intraplaque hemorrhage, subsequently linking to plaque vulnerability. Above a certain amount of calcification area, these increasing trends may no longer be observed.

PO1842

Radiation Exposure and Coronary Atherosclerosis: Differential Effect of the Radiation Site

Prerna R. Nepali,[1] Mickael Mathieu,[1] Sebastien Monette,[1] Andreas Rimner,[1] Fiona A. Stewart,[2] Adriana Haimovitz-Friedman,[1] Edgar A. Jaimes.[1] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Antoni van Leeuwenhoek Nederlands Kanker Instituut, Amsterdam, Netherlands.*

Background: Accelerated coronary artery atherosclerosis is a common complication of thoracic radiation therapy as result of unintended direct cardiac radiation. It is unclear however whether specific areas of the heart are more susceptible to the effects of radiation. In this study we hypothesize that accelerated development of atherosclerotic lesions post radiation (RT) is dependent upon differential sensitivity of specific areas of the heart to the effects of RT.

Methods: Male Apolipoprotein E knockout mice on a high fat diet received 16Gy cardiac RT targeted to the whole or partial (apical or basal) region of the heart at 9 or 16 weeks of age(n=5 per group). Atherosclerotic lesions in H&E stained slides and inflammatory infiltrates in the hearts by IHC were assessed 8 weeks following radiation and compared to unirradiated controls.

Results: Our studies show that:(1) Subendocardial atherosclerotic lesions at the base of heart in mice irradiated at 9 weeks of age after basal irradiation are comparable to whole heart irradiation. (2) A greater number of atherosclerotic lesions were present in the basal coronary arteries and basal subendocardial vasculature after irradiation of the cardiac base as compared to unirradiated controls in mice irradiated at 16 weeks of age (Table). (3) Apical or whole heart irradiation had no impact on the development of lesions in the basal region of the hearts of 16 week old mice (Table). (4) IL-6 was significantly increased in the serum of mice 6 hours post basal cardiac irradiation (105.10±17.56 pg/ml) when compared to unirradiated controls (29.85±11.63 pg/ml) demonstrating an early inflammatory response. (5) Infiltration of inflammatory cells (CD45 and CD3) and enhanced expression of endothelial adhesion molecules (CD31) were differentially and locally regulated based upon the site of irradiation.

Conclusions: Our results indicate that the base of the heart is more prone to development of RT induced atherosclerotic lesions likely due to acute and delayed inflammatory responses. Avoiding this area from direct radiation exposure may improve the quality of life for cancer patients receiving thoracic RT.

Correlations of Creatinine with Biomarkers of Tubular Injury and Secretory Function in Patients Admitted with Heart Failure

Alexander J. Kula,[1,2] David K. Prince,[2] Kevin D. O'brien,[2] Bryan R. Kestenbaum,[2] Song Li,[2] Nisha Bansal.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: Serum creatinine values during hospitalization for decompensated heart failure (ADHF) may not comprehensively capture kidney function. The aim of this pilot study was to evaluate correlations of traditional markers of filtration (serum creatinine) with novel measures of tubular injury and tubular secretion in patients admitted with ADHF.

Methods: Biospecimens were obtained within 24 hours of admission in 61 patients admitted with ADHF at a University of Washington hospital. We measured serum creatinine, urine tubular injury markers (urine NGAL, KIM-1, Il-18 and TIMP2 standardized to urine creatinine) and proximal tubular secretory function ([urine concentration]/[plasma concentration] normalized to U_{Cr}.). We calculated spearman correlations of each kidney measures with each other and admission serum brain natriuretic peptide (BNP).

Results: Serum creatinine poorly correlated to biomarkers of tubular injury (**Table 1**). Higher serum creatinine was significantly correlated with lower clearance of all secretory biomarkers aside from cinnamoylglycine. Admission BNP did not correlate with serum creatinine or injury biomarkers but had a consistent inverse relationship with secretory biomarkers that did not reach statistical significance.

Conclusions: The results from this pilot study demonstrate that serum creatinine poorly correlates with biomarkers of tubular injury and inversely correlates with tubular secretory clearance in patients admitted for ADHF. More research is needed to understand how filtration, tubular injury, and secretory clearance relate to clinical outcomes and response to treatment in patients with ADHF.

RAAS vs. COVID: Case of an 18-Year-Old with New-Onset Hypertension

Srikanth Thiruvarudsothy,[1] Arsitha Jeyarajasingam,[2] Theesitha Srikanth.[3] *[1]Virtua Health, Marlton, NJ; [2]National Hospital of Sri Lanka, Colombo, Sri Lanka; [3]Sichuan University West China Hospital, Chengdu, China.*

Introduction: It has been increasingly known that SARS-CoV-2 causes an imbalance in the Renin-Angiotensin-Aldosterone System (RAAS). Here we present an interesting case of a young man, who presented with new onset of HTN and elevated renin and aldosterone levels with a h/o COVID-19.

Case Description: An 18-year-old Caucasian man with a remote history of asthma initially presented to his primary care physician with new onset of headaches. He was noted to have an elevated blood pressure, but otherwise a benign physical examination. A workup for secondary HTN revealed an elevated renin (8.7 ng/mL/hr), aldosterone levels (42 ng/dL) and otherwise unremarkable. He was started on Enalapril 5mg daily. A workup including CT and MRI of the brain, were unremarkable. He was referred to nephrology for the new diagnosis of HTN and abnormal renin and aldosterone levels. During the initial renal evaluation, patient was asymptomatic and his BP was well controlled on the Enalapril. Renin and aldosterone levels were repeated, about 8 weeks after the cessation of Enalapril. Patient's blood pressure remained well controlled and didn't require any medications. Since the diagnosis of HTN, the patient maintained a strict low salt diet. He always had good fluid intake. At a follow up visit, patient continued to remain asymptomatic and with good blood pressure control without needing medications. Repeat renin (1.9 ng/mL/hr) and aldosterone (16.8 ng/dL), as well as aldosterone/renin levels were resulted within normal limits. Later patient admitted that he was diagnosed with COVID-19 a month prior to his onset of headaches.

Discussion: SARS-CoV-2, which causes COVID-19, is known to hijack the RAAS cascade and use ACE2 enzyme to make human cell entry. Studies have demonstrated the possible correlation between COVID severity and comorbidities such as HTN (potentially involving the RAAS). Current recommendations are to continue the use of ACE Inhibitors (ACEI) and Angiotensin Receptor Blockers (ARB) in COVID-19 patients. Our case, not only supports the above findings, but also demonstrates how RAAS is vulnerable to SARS-CoV-2, can manifest with new onset HTN and other complications. It is also interesting to see, how ACEIs and ARBs should be utilized as first line agents for BP control and to improve outcomes. To much relief, the effect on RAAS by the SARS-CoV-2 seems to be transient and short lived.

PO1845

Page Kidney: A Case of Spontaneous Subcapsular Hemorrhage Secondary to Anticoagulation

Smit P. Mehta, David Alter, Edgar V. Lerma. *Advocate Christ Medical Center, Oak Lawn, IL.*

Introduction: Page kidney is a rare condition caused by external compression on the renal parenchyma resulting in hypo-perfusion, activation of the renin-angiotensin-aldosterone system, and secondary hypertension. The etiologies of Page kidney include trauma, iatrogenic, spontaneous hematomas, and extrarenal compression.

Case Description: 52-year-old male with a history of polycystic kidney disease (PCKD) on hemodialysis, atrial fibrillation, and aortic stenosis s/p mechanical valve replacement on Warfarin presented to the hospital for acute left flank pain. Pain was described as severe. On exam, the patient was afebrile and hemodynamically stable. Labs were notable for WBC 11.8, Hgb 7.4, and INR 2.4. CTA demonstrated a large hematoma originating from the left kidney measuring 14.3 x 12.7 cm. There were additional findings concerning for active arterial extravasation and compression of renal parenchyma. Patient was transfused 1 unit of PRBC's and admitted to the intensive care unit. While admitted, he became progressively more hypertensive despite escalating antihypertensive therapy. He ultimately underwent angiography and coil embolization to stop the bleed. Following successful coil embolization, his blood pressure normalized and anti-hypertensive medications were titrated off.

Discussion: Our case is unique in that it is the first case of a spontaneous bleed secondary to anticoagulation in the setting of PCKD. The combination of PCKD in a patient with significant need for ongoing anti-coagulation results in a dramatic increase in incidence of Page kidney.

PO1846

Page Kidney and Uncontrolled Hypertension: Rare Complication Post Kidney Biopsy

Naveria Ammad, Marvi M. Bukhari, Blaise W. Abramovitz. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Introduction: Page kidney is a rare phenomenon defined as an external compression of the renal parenchyma that can lead to hypertension and acute kidney injury. Compression of the renal parenchyma can occur from the formation of a subcapsular hematoma of traumatic or non-traumatic origin. This phenomenon can be seen as a rare cause of hypertension related to subcapsular hematoma formation following kidney biopsy. We report a case of a 34-year-old-male with chronic kidney disease who developed abdominal pain and uncontrolled hypertension within 24 hours of kidney biopsy, found to have imaging findings consistent with Page kidney as a complication of the procedure.

Case Description: A 34-year-old male patient with a history of HTN, CAD, and stage 3B CKD presented to the ER with left flank pain and hypertensive urgency with SBP > 200 mmHg one day following a native kidney biopsy. He underwent a kidney biopsy for evaluation of sub-nephrotic range proteinuria and unclear etiology of CKD. CT abdomen/pelvis with contrast demonstrated a new 3.5 cm left kidney subcapsular hematoma with perinephric and retroperitoneal extension. Abdominal pain worsened and repeat imaging showed expansion of the hematoma up to 24.5 cm. Before, during, and after kidney biopsy, the patient had well-controlled HTN with SBP range in the 130-140s mmHg. The day following the biopsy, SBP had risen to over 200 mmHg. Given his recent biopsy, significant HTN, and expansion of subcapsular hematoma on imaging, Page kidney was identified as the culprit leading to uncontrolled HTN. He was admitted to the ICU and started on a nicardipine drip with improvement in BP. Interventional radiology was consulted, and the patient underwent a left renal angiogram showing active extravasation at the hematoma site, which was then embolized. The patient achieved adequate BP control and the nicardipine drip was successfully weaned off. He was then transitioned back to his home oral antihypertensives.

Discussion: Page kidney refers to a condition in which there is an external force compressing the kidney which results in decreased kidney perfusion manifesting in a state of ischemia. This activates the RAAS system leading to secondary hypertension. Although many cases have previously been reported, Page kidney remains an uncommon cause, especially over recent years, of uncontrolled secondary hypertension and acute kidney injury.

PO1847

Nonsuppressed Plasma Renin Activity in Primary Aldosteronism with Hypertensive Kidney Disease

Hazem Ayesh. *University of Toledo - Health Science Campus, Toledo, OH.*

Introduction: Primary aldosteronism (PA) prevalence has been estimated at 4.7–25.5% of all hypertensive patients. Renin aldosterone ratio (ARR) serves as a widely used screening test. Elevated ARR with suppressed plasma renin activity (PRA) is considered a positive screening test which should be followed by confirmatory testing. There are cases when PA is associated with non-suppressed PRA as in our case.

Case Description: A 37-year-old African American female patient with a past medical history of chronic kidney disease stage 4 presented to the hospital with a complaint of severe headache for 2 days associated with nausea and vomiting. Physical exam was remarkable for tachycardia and elevated blood pressure at 190/101 mmHg. Notable labs include low potassium at 3.4 [3.5 – 5.0 mmol/L], elevated creatinine at 4.84 [0.40 – 1.00 mg/dL] with a baseline creatinine of 2.36 mg/dL, urinalysis was positive for proteinuria. Secondary hypertension workup showed unremarkable renal duplex ultrasound, unremarkable thyroid function test, normal free plasma metanephrine, unremarkable urine drug screen. Screening for Cushing's syndrome wasn't performed given there were no supporting clinical manifestations. Plasma aldosterone concentration (PAC) elevated at 64.1 [3.1 – 35.4 ng/dL] with normal PRA at 1.7 ng/mL/hr. Calculated ARR was elevated at 37.7 ng/dL per ng/mL/hour, which raised the suspicion for primary aldosteronism (PA). Saline infusion test (SIT) showed elevated post-infusion PAC at 78.1 ng/dL which confirmed the diagnosis of PA.

Discussion: There are reports in literature that PA is more common than initially thought and has adverse effects on cardiovascular and renal systems independent of hypertension. So early diagnosis and management are highly recommended. The initial finding of non-suppressed PRA despite elevated ARR complicated diagnostic process. Multiple case studies reported non-suppressed PRA in patients with PA, especially when associated with hypertensive kidney disease and arteriosclerosis. In our case, kidney biopsy showed glomerulosclerosis with arteriopathy consistent with hypertensive kidney disease. We suggest focusing on ARR as a reliable screening for PA and not solely depend on the fact that PA is associated with suppressed PRA, especially in these cases. Another important point is to consider lowering ARR cutoff for diagnosis of PA since PRA isn't completely suppressed in these cases.

PO1848

Abiraterone-Induced Mineralocorticoid Excess Despite Concurrent Prednisone in Setting of Drug-Induced Liver Injury(DILI)

Georges Nakhoul, Jessica Nino, Xin Yee Tan, Ali Mehdi, Roman A. Shingarev. *Cleveland Clinic, Cleveland, OH.*

Introduction: Abiraterone, a CYP17A inhibitor used in the treatment of castration-resistant prostate cancer(CRPC), is prescribed with concurrent glucocorticoids(GC) to prevent secondary mineralocorticoid excess(SME). We hereby describe a case of refractory hypokalemia in setting of abiraterone-induced SME despite prophylactic GC.

Case Description: A 70-year-old male with CRPC on abiraterone 1g and prednisone 5mg daily, presented with jaundice, fatigue and hypertension. Workup revealed hyperbilirubinemia, transaminitis and profound hypokalemia.Liver biopsy demonstrated DILI. Abiraterone was thus discontinued. Hypokalemia persisted despite aggressive repletion with up to 320mEq KCl daily. Deoxycorticosterone elevation confirmed abiraterone-induced SME. Increased dosage of prednisone to 40mg daily and addition of eplerenone led to prompt normalization of potassium and blood pressure. Darolutamide was started after DILI resolution for CRPC treatment.

Discussion: Abiraterone's antitumor effect lies in reduction of androgen production by CYP17 inhibition. Excessive deoxycorticosterone/corticosterone accumulation, driven by reactive rise in corticotropin, may manifest as hypokalemia, hypertension or fluid retention. GC coadministration serves to mitigate SME. SME in this case may be explained by:1)Liver injury:Pharmacokinetic studies have shown increased systemic abiraterone exposure in liver impairment up to 3.6 folds, necessitating dose reduction or drug discontinuation. Severe liver impairment causing decreased availability of hepatic 11β-HSD1 may also drive down conversion of prednisone into its active form prednisolone, removing negative feedback to corticotropin.2)Prednisone 5mg BID or dexamethasone 0.5mg daily has shown superiority to prednisone 5mg daily(in this case) for SME prevention, at expense of greater weight gain and insulin resistance. Eplerenone can be used in addition to GC in SME treatment and may be noninferior to GC as steroid sparing preventive option. Spironolactone should be avoided due to its affinity to androgen receptor. It is prudent to monitor for medication adjustment as SME resolves.

Hormones	Reference Values	Results
ACTH *(pg/dl)*	6-76	16 (non-suppressed)
Cortisol *(ng/dl)*	6-23	5.4
Deoxycorticosterone *(ng/dl)*	3.5 – 11.5	42
Renin/Aldosterone *(mcg/dl)*	2- 17	< 2.1
Aldosterone *(ng/dl)*	2-9	8.5
Urine potassium *(mEq)*	< 20	65.6 (**potassium repleted during sampling)*
Urine Creatinine *(mg/dl)*	20 -275	67.6
24 hours urine potassium *(mEq)*	25 – 125	192
Creatinine *(mg/dl)*		0.9 – 1.1 at baseline

PO1849

Characteristics and Outcomes of Cancer Patients with Severe Hyponatremia

Suramath Isaranuwatchai. *Chulabhorn Hospital, Bangkok, Thailand.*

Background: Hyponatremia is the most common electrolyte disorder in cancer patients and associated with poor prognosis in several types of cancer. Severe hyponatremia (serum sodium < 120 mmol/L) is linked to increased hospital length. We conducted this retrospective study to evaluate for clinical and laboratory characteristics of cancer patients with severe hyponatremia.

Methods: Medical records from previous 2 years at Chulabhorn hospital were reviewed. Cancer patients who had serum sodium less than 120 mmol/L were included. Clinical data, including symptoms, causes of hyponatremia, treatments, response to treatments and survival rate, were recorded.

Results: A total of 154 patients with cancer and severe hyponatremia were identified. 147 patients (95.5%) had solid malignancy. Only 7 patients (4.5%) had hematologic malignancy, all of which were lymphoma. The most common solid malignancy was hepatocellular carcinoma (14.9%), followed by lung cancer (14.3%) and pancreatic cancer (10.4%). Interestingly, 36.3% of patients were asymptomatic despite severe hyponatremia. Of 98 patients that were symptomatic, the most common symptom was fatigue (30.5%), followed by nausea/vomiting (26.0%) and alteration of consciousness (19.5%). Seizures were present in only 3 patients (1.9%). The most common cause of hyponatremia was volume depletion (83.8%), which was mostly due to poor intake. Syndrome of inappropriate antidiuresis (SIAD) was the cause of severe hyponatremia in only 7 patients (4.5%). Most of our patients (76.0%) were treated with isotonic saline infusion and 83.8% of which responded with significant improvement in serum sodium level. Hypertonic saline infusion was given in only 27 patients (17.5%). Survival rate at 30 days was 46.1% and survival rate at 90 days was 26.6%.

Conclusions: Our data demonstrated that the most common cause of severe hyponatremia in cancer patients was volume depletion from poor intake, in contrast to SIAD which was suggested by other previous studies. In addition, most patients in our cohort responded to isotonic saline infusion. Fluid restriction and diuretic/aquaretic drug administration, presuming that patients have SIAD, may worsen the serum sodium level in these hypovolemic cancer patients. This study emphasized the importance of clinical evaluation and investigation for cancer patients with severe hyponatremia to achieve the correct diagnosis and provide proper management.

PO1850

Novel Use of Daratumumab for Post-Hematopoietic Cell Transplant Membranous Nephropathy

Stefanie W. Benoit,[1,2] Pooja Khandelwal,[1,2] Michael S. Grimley.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH.*

Introduction: Membranous nephropathy (MN) is the most common cause of glomerulopathy after hematopoietic cell transplantation (HCT), usually seen with graft versus host disease (GVHD). Although remission frequently occurs upon immunosuppression, 20% of patients fail to respond and may progress to end stage renal disease. Here we report the rapid remission of a treatment resistant patient with daratumumab (Dmab).

Case Description: A 16 year old female 1 year post-HCT for beta thalassemia major was started on ruxolitinib for oral GVHD. Three months later, she developed nephrotic syndrome. Renal biopsy showed MN. Serum and renal tissue were negative for PLA2R antibody. Ruxolitinib was changed to ibrutinib in case MN was medication induced. She was treated with tacrolimus (trough 3 – 8 ng/mL), prednisone, losartan, atorvastatin, and 4 weekly rituximab infusions. Eight months into therapy, she failed to meet criteria for even partial remission. The toxicity of additional steroids and/or cyclophosphamide was undesirable. With 0% CD19 cells, rituximab was not indicated. Thus, plasma cell depletion with Dmab was trialed. Dmab was given at weeks 1, 4, and 17. Her nephrotic syndrome resolved and her serum albumin was greater than 3.0 gm/dL by week 10. She weaned off of steroids and tacrolimus by week 16, at which time she had near-complete remission of her renal disease. Trialed off of losartan week 16 – 17, but protein excretion increased, so it was restarted. Time course and biomarkers of MN are in Figure 1.

Discussion: The mechanism of HCT-associated MN is incompletely understood. Its association with GVHD and often successful treatment with rituximab have implicated direct or indirect humoral activation as potential pathogenic mechanisms. The success of CD38 depletion with Dmab may implicate alloantibody production by resident plasma cells as a driver of refractory disease. Dmab may be a novel therapeutic option for HCT patients who are not responsive to traditional MN therapy.

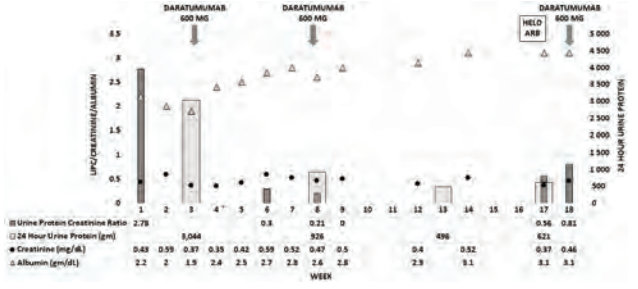

Figure 1: Time course and biomarkers of MN after Dmab. *Urine collection 15 hours

PO1851

M2-Like Macrophages in Injured-Kidney Cortex Promoted Kidney Cancer Progression via the Inhibition of CD8 T Cell Infiltration

Taisuke Ishii, Tetsuhiro Tanaka, Masaomi Nangaku. *Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: Chronic kidney disease (CKD) affects mortality of the cancer patients, especially kidney cancer. However, the biological mechanism remains unknown. Recently, several studies showed that M2-like macrophages had pro-tumor in the tumor effects as well as pro-fibrotic roll in the injured kidney. We aimed to assess the effect of M2-like macrophages in the injured kidney on kidney cancer progression.

Methods: We injected murine kidney cancer cells on renal subcapsule 14 days after unilateral ischemic reperfusion injury (IRI) or aristolochic acid (AA) administration which were used as an injured kidney model. We evaluated cancer progression 20 days after tumor injection and examined macrophage characteristics and intra-tumor T cell population by flow cytometry. To assess the effect of M2-like macrophages on cancer progression and intra-tumor T cell, we used the adoptive transfer of M2-like macrophages collected from the tumor on IRI-treated kidneys and liposomal clodronate (CL) which removed M2-like macrophages from IRI-treated kidneys. We examined whether the inhibition of T cell infiltration contributed to tumor progression in CL-treated IRI kidneys and sham-treated IRI kidneys by using anti-CD8 or anti-CD4 antibodies.

Results: Kidney cancer on IRI kidneys (IRI-KC) was more progressive than that on sham-operated kidneys (Sham-KC). M2-like macrophages accumulated in the IRI-kidney cortex and IRI-KC. Interestingly, the intra-tumor T cell population decreased in IRI-KC compared to Sham-KC. The same phenomenon was observed in the AA model. T cell function and regulatory T cell infiltration were not different between IRI-KC and Sham-KC. Besides, the adoptive transfer experiment showed that kidney cancer co-injected with M2-like macrophages was more progressive than that with Other-type macrophages and intra-tumor T cell decreased in the M2-like macrophage co-injection group. Contrarily, the CL experiment showed that M2-like macrophage depletion from the IRI-kidney cortex inhibited tumor progression and increased tumor infiltrated CD8 T cell. And CD8 T cell removal after M2-like macrophage depletion abrogated this tumor-inhibiting effect, however, CD4 T cell removal didn't affect tumor progression.

Conclusions: M2-like macrophages in injured kidneys promoted kidney cancer progression through the inhibition of CD8 T cell infiltration.

PO1852

Identifying Patients with CKD Risk at the Time of Partial Nephrectomy

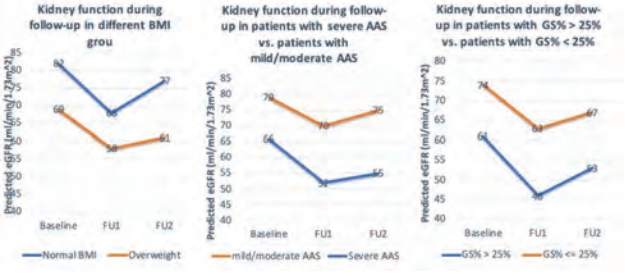
Yihe Yang, Purva D. Sharma, Kenar D. Jhaveri, Vanesa Bijol. *Northwell Health, New Hyde Park, NY.*

Background: The prevalence of chronic kidney disease is high among kidney neoplasm patients because of the overlapping risk factors. We aim to identify risk factors of eGFR decline in kidney cancer survivors post partial nephrectomy (nx).

Methods: All partial nx patients with neoplasm at Northwell Health were included (2018/7-2020/5, n=187). Clinical and histology parameters, including neoplastic and non-neoplastic pathology, were analyzed. Non-neoplastic assessment includes glomerulosclerosis(GS), interstitial fibrosis and tubular atrophy(IFTA), and a semiquantitative estimate of the severity of arterial and arteriolar sclerosis (AAS). Multivariate linear mixed model was performed. Independent variates included age, sex, hypertension, diabetes, baseline eGFR, tumor diagnosis, proteinuria, GS%, IFTA%, and AAS.

Results: The median follow-up time is 147d. In all patients, independent risk factors of post-nx decreased eGFR were female($p=0.02$), age($p=0.01$), overweight($p<0.001$), eGFR<90 at the time of nephrectomy($p<0.001$), severe AAS($p<0.01$), and prolonged follow-up. In the ones with baseline eGFR≥90(n=61), proteinuria($p<0.001$) and BMI($p<0.001$) were independent risk factors of post-nx decreased eGFR. For every 1 kg/m^2 increase in BMI, there is a 3.3, 3.8, and 3.7ml/min/1.73m^2 decline of eGFR at baseline, within 3 mo post-nx, and longer follow-up. For every 100mg/dl increase in urine protein, there is an 11.4, 17.3, and 19.5ml/min/1.73m^2 decline of eGFR at baseline, within 3 mo post-nx, and longer follow-up. In patients with baseline eGFR<90ml/min/1.73m^2(n=126) longer follow-up, severe AAS($p=0.02$), GS%>25%($p=0.02$) and overweight ($p=0.03$) were independent risk factors of decreased post-nx eGFR. eGFR time trend of patients with and without these risk factors is shown in the figure.

Conclusions: We propose a minimum workup for this population to include eGFR, urinalysis, and non-neoplastic pathology evaluation. The time of kidney cancer treatment may be a unique opportunity for these patients to be identified and directed to early interventions, including nephrology consults and patient education on nutrition and weight control.



PO1853

Development of 3D Renal Cell Carcinoma Organoids and Cancer Invasion Assay

Nathan Lee,[1] Shun-Yang Cheng,[1,2] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]University of Southern California, Los Angeles, CA.*

Background: Recent advances in *in vitro* 3D culture technologies, such as organoids derived from hPSCs, have opened new avenues for development of human disease models. Modeling cancer by utilizing cancer organoids provides advantages as they maintain 3D cell-cell interactions, heterogeneity, microenvironment, and drug response of the sample they originate from. Such preclinical models are essential for more efficient translation of cancer research into novel treatment regimens for patients. 5-year survival rate at advanced stage IV RCC is less than 10%, as RCC is also notorious for resistance to chemotherapy and radiation therapy. Therefore, development of effective tools for better understanding and drug screening for RCC are needed. Kidney cancer organoids and novel assays such as cancer invasion assays can be useful tools to personalize potential therapeutics.

Methods: Primary kidney cancer cell lines were generated from patient biopsy samples. 3D kidney cancer organoids and non-cancer kidney organoids for cancer invasion assay were generated from primary kidney cancer cell lines and hPSCs, respectively, by modifications of our laboratory's prior published kidney organoids techniques. Organoids were characterized by immunostaining. Upon maturation, organoids were added onto the non-cancer kidney organoids and incubated together for the invasion assay with or without treatment with drugs. Frozen sections and imaging were utilized to examine the cancer invasion. Kidney cancer organoids were treated with various drugs to investigate efficacy in reduction or inhibition of the invasion.

Results: RCC cancer organoids showed significantly better expression of kidney cancer markers such as KIM-1, HIF-1α, HIF-2α, and CAIX9 compared to 2D primary RCC cells. Addition of the cancer organoids to normal kidney organoids led to invasion of the cancer organoids into the normal kidney organoids within 3 days. Treatment of the cancer organoids by the receptor tyrosine kinase inhibitor, sunitinib or the histone acetyltransferase inhibitor (A-485) showed reduction in efficacy of cancer invasion.

Conclusions: Development and use of cancer invasion assay for renal cell carcinoma utilizing kidney cancer and normal kidney organoids could lead to better understanding of cancer invasion and provide the capability to screen and profile for identification of potential treatment options in renal cell carcinoma.

Multi-Omics Approach to Uncover Underlying Biology of Low-Risk Clear Cell Renal Cell Carcinoma Patients with Progressive Disease

Philipp Strauss,[1] Andreas Scherer,[2] Oystein Eikrem,[1] Hans-Peter Marti.[1] *[1]Universitetet i Bergen, Bergen, Norway; [2]spheromics, Helsinki, Finland.*

Background: Renal Cell Carcinoma (RCC) constitutes approximately 3 % of all cancers and its incidence is rising worldwide, especially in Western countries. In the last two decades, enormous advances have been made in the development and implementation of medical therapies for metastatic ccRCC, however, surgery still represents the only curative option. One of the issues in developing a curative medical therapy lies in the high degree of inter,- and intra tumor heterogeneity. We believe that by applying multi-omics technology to highly specific subgroups and comparing them to closely matched controls we can mitigate the heterogeneity issue and deepen our understanding one step and subgroup at the time.

Methods: We assembled a cohort of ccRCC patients (n=443) and identified all "low-risk" patients which later developed progressing tumours (n=8). Subsequently we performed genome-wide expression profiling, miRNA profiling and proteomics profiling from formalin-fixed samples obtained at initial surgery from these "low-risk" patients and 16 matched patients not progressing to recurrence with metastasis. The patients were matched for Leibovich sore, creatinine, age, sex, tumor size and tumor stage.

Results: Pathway analysis yielded differences between progressive and non-progressive patients in categories such as Molecular Mechanisms of Cancer, B Cell Receptor Signaling in mRNA data and Acute Phase Response Signaling and FXR/RXR Activation in proteomics data. By integrating our three -omics analysis we revealed that acute Phase Response Signaling also plays a role on all three levels. Additionally, we developed a 14-component classifier, drawing from both mRNA, miRNA and protein-based data that reliably differentiated the different subgroups. We further examined the correlations between each of the components and uncovered a dense network of interactions.

Conclusions: Multi-omics methods represent an important tool in furthering our understanding renal cancer biology in the pursuit of medical therapies.

PO1855

TMEM27 Expression and Clinical Characteristics and Survival in Clear Cell Renal Cell Carcinoma

Rickinder Grewal,[1] Hae Yoon Grace Choung,[1] Lisa L. Roberts,[1] Timothy J. Beane,[1] Luojing Chen,[1] Daniel X. Gilroy,[2] Thu H. Le.[1] *[1]University of Rochester School of Medicine and Dentistry, Rochester, NY; [2]Rochester Institute of Technology, Rochester, NY.*

Background: Transmembrane protein 27 (TMEM27/collectrin), a glycoprotein and homolog of angiotensin-converting enzyme 2 (ACE2), is a regulator of renal amino acid uptake in the proximal tubule and may have a protective role in hypertension. Two previous reports have shown that the absence of TMEM27 expression in clear cell renal cell carcinoma (ccRCC) correlates with poorer cancer-related survival. Here we report our findings of TMEM27 expression in ccRCC and clinical outcomes.

Methods: We conducted a retrospective analysis to identify all cases of ccRCC diagnosed between 2010 and 2015 at the University of Rochester Medical Center. The intensity of TMEM27 immunostaining on tumor tissue was semi-quantitatively graded on a scale of 0, 0.5, 1, 1.5, 2, 2.5, and 3 by a single pathologist, and correlated with tumor characteristics and survival.

Results: There were 321 cases of ccRCC. There was evidence of metastasis at time of nephrectomy in 36 (11.2%), and at the latest follow up in 70 (21.8%), and 82 (25.5%) died as of Spring 2021. TMEM27 staining intensity correlated inversely with various tumor characteristics (Table 1). Kaplan-Meier survival analysis showed worse all-cause mortality for tumors without any TMEM27 staining (0) compared to 0.5 or higher, p = 0.02 by log-rank test.

Conclusions: The absence of TMEM27 expression is associated with more aggressive tumor characteristics and poorer all-cause mortality in ccRCC. TMEM27 may be a useful biomarker to assess cancer prognosis. Further studies are needed to better assess if TMEM27 is protective in RCC.

Table 1: Correlation between TMEM27 Staining and Clinical Characteristics

Clinical Characteristic	r value	p-value
Tumor size	-0.191	<0.001
TNM stage (pTx)	-0.145	<0.01
TNM stage (Nx)	-0.152	NS

Sarcomatoid rhabdoid present	-0.073	NS
Large vessel venous invasion	-0.113	<0.05
Lymphatic invasion	-0.072	NS
Metastasis at time of nephrectomy	-0.126	<0.05
Metastasis at follow-up	-0.094	NS
Composite	-0.201	<0.001
Composite with death	-0.202	<0.001

NS: Not Significant, TNM: Tumor, Node, Metastasis

PO1856

Role of miR-23b and miR-133a in Apoptosis Control Induced by TRAIL in Lung Adenocarcinoma and Kidney Carcinoma Cell Lines

Denise Leite, Edgar Maquigussa, Mirian A. Boim. *Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.*

Background: Lung and kidney cancer are often diagnosed as advanced disease and frequently become resistant to systemic therapies. Tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL) binds to TRAIL receptor 1 and 2 (TRAILR1/R2) on the cell surface to stimulate apoptosis, making TRAIL apoptotic pathway a promising target for cancer therapy. Cullin-3 ubiquitination is essential to TRAIL receptors activation. However, resistance to TRAIL is an obstacle to achieve an effective anti-tumoral therapy. One of the mechanisms that lead to TRAIL resistance appears to be dependent on translocation, mediated by clathrin (CLTA), of TRAIL receptors to the nucleus. MicroRNAs (miRs)-23b and -133a may have relevant role in TRAIL resistance.

Methods: A549 and CaKi-2 cell lines and their respective controls (MRC-5 and HK2) were used. mRNA expressions of miR-23b, miR-133a, TRAIL-R1/R2, CUL3, CLTA Apaf-1 and KPNA-1 were estimated by RT-qPCR. MTT assay was used to evaluate the effect of TRAIL-induced cytotoxicity. TRAIL receptors celllular distribution was determined by western blot.

Results: Both cell lines were TRAIL resistant on MTT. TRAIL-R1 and TRAIL-R2 were predominantly located in nuclear compartment of A549 cells. TargetScan showed that miR-23b targets CUL3, Apaf-1 and KPNA-1 and miR-133a targets CLTA. MiR-23b expression was upregulated in A549 and CaKi-2 cells. MiR-23b inhibition upregulated CUL3 expression in A549 cells. In contrast, miR-133a was undetectable in both cell lines. TargetScan was used to determinate potential mRNAs targets for miR-23b and miR-133a.

Conclusions: MiR-23b expression was upregulated in A549 and CaKi-2 cells. However, supposed miR-23a target mRNAs were unchanged suggesting no relationship between miR-23a and those molecules. MiR-23b inhibition upregulated CUL3 expression in A549 cells, which could enhance TRAIL receptors activation and sensivity- this will be investigated in next step. In contrast, miR-133a was undetectable raising the hypothesys of an increased capacity of cells to translocate TRAIL receptors to the nucleus via clathrin and thus be resistant to TRAIL. The possible miR-133a ability to reduce clathrin expression may represent a novel approach for control of TRAIL apoptotic pathway and must be further investigated as a TRAIL sensitizing mechanism.

PO1857

Recapitulating Kidney Angiomyolipoma with Renal Organoids Generated from Tuberous Sclerosis Complex Patient-Derived Induced Pluripotent Stem Cells

Dario R. Lemos.[1,2] Lemos Lab *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Angiomyolipomas (AMLs) constitute 80% of the renal lesions found in patients with Tuberous Sclerosis Complex. AML can cause kidney failure and lead to premature death due to the formation of vascular aneurysms that are prone to spontaneous bleeding. Key aspects of the pathobiology of AMLs, and most remarkably the cell(s) type(s) and developmental mechanisms that give raise to the lesions, remain unknown. Previous efforts to recapitulate AML experimentally using transgenic mice have failed to produce reliable models of AMLs, precluding our ability to study tumor mechanisms and develop novel therapies.

Methods: We directed the nephric differentiation of a series of TSC patient-derived iPSC lines that included a line carrying a heterozygous microdeletion in the *TSC2* locus (*TSC2*$^{+/-}$), a TALEN-engineered isogenic cell line carrying microdeletions in both *TSC2* alleles (*TSC2*$^{-/-}$) and a cell line in which the original mutation present in the patient was corrected using CRISPR-Cas9 (*TSC2*$^{+/+}$).

Results: We derived renal organoids from isogenic TSC2$^{-/-}$, TSC2$^{+/-}$ and TSC2$^{+/+}$ iPSCs. Flow cytometry analysis of kidney organoids derived from TSC2$^{-/-}$ hiPSCs but not from isogenic TSC2$^{+/-}$ or TSC2$^{+/+}$ hiPSCs were enriched in ACTA2^{+} cells, a percentage of which (~24%) co-expressed melanocyte markers including premelanosome protein (PMEL), melanin A (MLANA) and cathepsin K (CTSK) indicative of a myomelanocytic phenotype that is a hallmark of kidney AMLs. Morphologically, ACTA2^{+} cells found in *TSC2*$^{-/-}$ organoids had a plump myoid morphology that matched the well-characterized morphology of kidney AML cells. Whole transcriptome RNA sequencing (RNA-seq) of *TSC2*$^{+/-}$, *TSC2*$^{+/+}$ and *TSC2*$^{-/-}$ organoids identified *MLANA, PMEL, GPNMB, MITF, CTSK* and *ACTA2* as genes that were exclusively upregulated in *TSC2*$^{-/-}$ organoids, confirming the myomelanocytic phenotype of *TSC2*$^{-/-}$ AML organoids. Hallmark gene sets enriched in expression in *TSC2*$^{-/-}$ renal organoids in each comparison included IL6-JAK-STAT3 signaling, adipogenesis, angiogenesis, fatty acid metabolism, KRAS signaling and estrogen response, as major pathways shared with kidney AMLs.

Conclusions: Collectively, our findings support the notion that AMLs originate from cells of the renal lineage and suggest a central role for *TSC2* loss-of-heterozygosity (LOH) genetic mechanisms in the etiology of AML.

PO1858

Characterization of Wilms Tumor and Human Fetal Kidney Using Spatial Transcriptomics

Laura Perin,[1] Astgik Petrosyan,[1] Valentina Villani,[1] Paola Aguiari,[1] Matthew E. Thornton,[2] Shengmei Zhou,[1] Brendan Grubbs,[2] Roger E. De Filippo,[1] Marie Csete,[2] Kevin V. Lemley,[1] Sargis Sedrakyan,[1] Stefano Da Sacco.[1] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Growing evidence links Wilms tumor (WT) to aberrant nephrogenesis. Studies highlighted the genetic complexity of WT, but little is known about the molecular mechanisms that regulate WT development. Using Spatial transcriptomics (ST), which allows analysis of the gene expression based on morphological context, we showed important differences between WT subtypes and defined the interactive gene networks involved in WT development using human fetal kidney (hFK) as reference.

Methods: Using Visium 10x Genomics, we generated spatial maps of gene expression in human fetal kidney (hFK) andfavorable (stage III) and unfavorable (stage I) WTs. Data were analyzed using Space Ranger software v1.0.0, Seurat v3.2, Panther V14, and Loupe Cell Browser and further analyzed against our previously generated bulk/sc-RNA seq data on the same samples.

Results: ST identified specific clusters in hFK that closely recapitulated the developmental stages of normal nephrogenesis (nephrogenic zone, glomeruli, tubules, and stroma). Unfavorable WT and favorable WT clusters showed heterogeneity of the tumor landscape (blastema, epithelium, and stroma and non-renal phenotypes). Blastema in WT favorable vs. WT unfavorable, though histologically identical, presented different transcriptomics profiles. WTs also showed gene expression typical of muscle tissue (or other non-renal phenotypes) rather than mature kidney structures, which correlated with the histologic absence of mature tubules and glomeruli. Comparative RNA-seq analysis identified cells expressing SIX2 and CITED1 as the root cells of the origin of the WT. Unfavorable WT expressed a higher level of CITED1 in blastema foci and higher expression of uncommitted genes and modulation of inductive nephrogenic signals like WNT and FGF. We also identified genes expressed specifically in WT subtypes and performed a preliminary characterization of the immune milieu of WT.

Conclusions: The spatiotemporal mapping combined with different transcriptomic data highlighted the heterogeneity of the WT subtypes confirming uncommitted nephron progenitors as driving the development of WT. We identified genes that may allow for better stratification of WT and potential therapeutic targets for distinct WT subtypes.

Recurrent Renal Cell Carcinoma Post Renal Transplantation

Ivan Rakic,[1] Rujuta R. Patil,[1] Anita K. Patel.[2] *[1]Wayne State University School of Medicine, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI.*

Introduction: Renal Cell Carcinoma (RCC) can occur in renal transplant recipients (RTR). RCC recurrence post nephrectomy occurs in 20-40% of non-transplant(Tx) patients and in less than 15% of RTR. The median survival for patients with metastasis is 6-12 months with 5 year survival less than 10%. We present 3 RTR who developed recurrent RCC post-Tx.

Case Description: RTR1 was 61 years old and received a deceased donor kidney Tx (DDKTx) for IgA nephropathy. He was induced with thymoglobulin. Immunosuppression(IS) included Mycophenolate Mofetil (MMF), Tacrolimus (FK), and steroids (S). 8 years pre-Tx, a 2.5cm RCC lesion was found in the R native kidney, and he underwent nephrectomy. 1 year later, he developed BK viremia, and IS was changed to Everolimus and S. 2 years post-Tx, RCC metastasis was detected only in the pancreas head and tail. Treatment involved tyrosine kinase inhibitors(TKI) and VEGF inhibitors without resolution; he died within 2 years of RCC recurrence with a functioning allograft. RTR2 was 56 years old and received a DDKTx, secondary to ADPKD. IS involved MMF, Cyclosporine, and S. History was significant for L nephrectomy 3 years pre-Tx for RCC. 1 year later, she had a R nephrectomy for RCC. Both lesions were small and renally limited. 10 years post Tx, she presented with recurrent RCC in the pancreas and thyroid. Treatment involved change in IS to Sirolimus and Azathioprine. No other treatment was taken by the patient. She died 4 years later with a functioning allograft. RTR3 is a 54 year-old who received a living, related renal Tx for CKD stage 5. IS included MMF, FK, and S. 8 years post-Tx, he was diagnosed with an 8cm RCC lesion of the L native kidney and underwent nephrectomy. After a 6 year tumor free interval, RCC recurred only in the lungs and lymph nodes. He received IS reduction and TKI with progression of disease to bone metastasis. His current treatment involves TKI with Denosumab, and he still has a functioning allograft.

Discussion: Our cases demonstrate that RCC recurrence occurs at variable time points post-Tx and can present aggressively in RTR with poor outcomes. We suspect that recurrent disease arises from micrometastatic tumor cells that escape immune surveillance. RTR with a history of RCC prior to Tx should be monitored closely for metastatic recurrence post Tx.

PO1860

Impact of ESKD on Overall and Cancer-Specific Mortality in Patients with Localized Prostate Cancer (PCa): A Retrospective Cohort Study of SEER-Medicare

Nagaraju Sarabu. *University Hospitals, Cleveland, OH.*

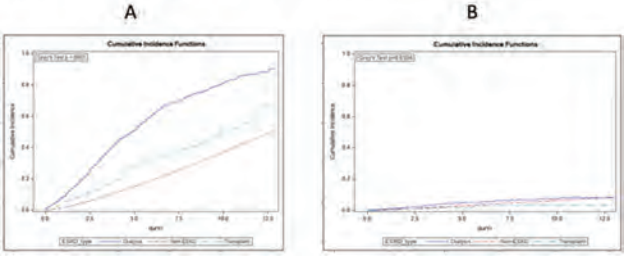
Background: Our objective was to compare overall and PCa specific mortality between ESKD and non-ESKD patients with localized PCa.

Methods: Study participants were male patients, who were diagnosed with localized PCa between January 1st 2004 and September 30, 2015 (last day of International Classification of Diseases-9-Clinical Modification (ICD-9-CM) use) and were 40 years or older at the time of diagnosis. ESKD status, further stratified into dialysis and kidney transplant (KT) was determined using ICD-9-CM codes. Time to death from any cause was modeled using Cox regression and time to PCa specific death using Fine and Gray competing risk model.

Results: At a median follow up of 6.2 years, 3.5 years and 5.0 years for non-ESKD (N=186,482), dialysis (N=970) and KT (N=413), overall mortality rates were 1.8%, 8.5%, and 4.8% at 1-year, 7.7%, 31.5% and 13.5% at 3-years and 15.2%, 50.8% and 27.9% at 5-years respectively (P-Value: <0.001), Figure 1. In multivariate model, dialysis status was associated with 2.9 times higher hazard of death (HR: $_{2.6}2.9_{3.1}$) and transplant status was associated with 2 times higher hazard of death (HR: $_{1.7}2.0_{2.4}$) compared to non-ESKD group. Rates of PCa specific mortality were 0.4%, 1.1%, and 0.7% at 1-year, 1.6%, 3.1%, and 1.5% at 3-years and 3%, 4.8%, and 2.2% at 5-years for non-ESKD, dialysis, and transplant groups respectively (P-value: 0.04). In multivariate model, dialysis status and transplant status were associated with similar risks for PCa specific death to non-ESKD group, Figure 2.

Conclusions: ESKD patients have excess relative overall mortality but similar PCa specific mortality compared to non-ESKD patients with localized PCa.

Figure 1: Cumulative incidences for overall (A) and prostate cancer specific mortality (B), stratified by ESKD status.



Cumulative Incidence Curves

Table 1: Associations of Overall Mortality and Prostate Cancer Specific Mortality with ESKD (dialysis and KT), Localized PCa (2004-2015)

Model	Outcome	Parameter	Hazard Ratio	95% Confidence Interval	P Value
Univariate	Overall Mortality	Dialysis	4.141	3.818, 4.492	<.0001
		Transplant	1.645	1.398, 1.937	<.0001
	Cancer Specific Mortality	Dialysis	1.278	0.978, 1.669	0.0720
		Transplant	0.601	0.333, 1.084	0.0907
Age Adjusted	Overall Mortality	Dialysis	5.020	4.626, 5.448	<.0001
		Transplant	2.249	1.909, 2.648	<.0001
	Cancer Specific Mortality	Dialysis	1.455	1.110, 1.906	0.0066
		Transplant	0.792	0.437, 1.435	0.4416
Multivariate	Overall Mortality	Dialysis	2.851	2.622, 3.099	<.0001
		Transplant	1.995	1.694, 2.351	<.0001
	Cancer Specific Mortality	Dialysis	1.036	0.781, 1.373	0.8066
		Transplant	0.933	0.510, 1.707	0.8215

Hazard Ratios for Mortality

PO1861

Case of Spontaneous Tumor Lysis Syndrome in Metastatic Prostate Cancer

Mohammad Al-Hasan, Mauricio Monrroy. *Albany Medical Center, Albany, NY.*

Introduction: Tumor lysis syndrome has been described in hematological malignancies mainly where there is a large tumor burden that lyse in relatively short period of time causing a large burden of metabolites that causes AKI. In this case, we will present a case of spontaneous tumor lysis syndrome caused by widespread metastatic cancer prostate which is an unusual cancer to cause such syndrome. That metastasis was mainly to the bone marrow causing a picture of pancytopenia, which also raises the possibility that the tumor lysis syndrome could be due to the breakdown of the cells of the bone marrow rather than the lysis of the prostate cancer cells.

Case Description: 65-year-old male patient presented with altered mental status upper GI bleed, hyperkalemia of 6.2, severe acidosis with bicarbonate of 7 and AKI with a creatinine of 7.32 and BUN of 181, calcium 9.3, phosphorus 7.4, uric acid 41.5, bilirubin of 2.9 and LDH was high at 789, alkaline phosphatase was 345, patient had severe anemia with hemoglobin of 2.6, white count 12,600 and thrombocytopenia with platelet count of 6000. urine analysis showed uric acid crystals. flow cytometry analysis of peripheral blood did not reveal a clonal population of cells or expanded population of blasts. CT scan chest abdomen pelvis suggested diffuse osseous lytic and blastic metastatic lesions. Serum immuno-electrophoresis was negative. PSA level of more than 1400.

Discussion: The severe AKI along with the significant elevated serum uric acid level, and presence of uric acid crystals in the urine sediment, made it highly likely the diagnosis of TLS. The presence of diffuse osseous lesions and a PSA above the level that can be measured were consistent with metastatic prostate cancer as the underlying malignancy. No history of treatment was obtained. TLS in solid malignancies is extremely rare, especially without anti-neoplastic therapy. In this case, the presence of severe anemia and thrombocytopenia were highly suspicious for bone marrow invasion, and possible contributor to TLS. Regretfully, a bone marrow biopsy couldn't be obtained before patient expired. Conclusion: TLS can be caused by solid cancers like prostate cancer if it is widely metastasized. Bone marrow extension with lysis of bone marrow cells maybe a contributing factor.

PO1862

Overlooked and Unanticipated: Life-Threatening Hypocalcemia due to Denosumab in a Patient with Prostate Cancer

George Vasquez-Rios, Johnson L. Gomez, Pramodh Chanumolu, Amanda Dijanic, Matthew Abramson. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Denosumab is a monoclonal antibody that inhibits osteoclast-mediated bone resorption by binding to receptor activator of NF-κB ligand, which is upregulated by tumor cells. Despite FDA warning, insidious and severe onset hypocalcemia is a malignant and overlooked complication in patients with advanced CKD.

Case Description: A 77-year-old man with a history of prostate cancer and CKD stage 4 presented to the ED with tremors and numbness in both arms along with perioral dysesthesias. In addition to furosemide and metoprolol, he received his first dose of denosumab 2 weeks prior to presentation, indicated for bone metastasis. Physical examination was remarkable for the Chvostek sign and delayed reflexes in the upper and lower extremities. Lab results were as follows: Na 136 mEq/L, K 4.4 mEq/L, HCO3: 6.4 mEq/L, Cr: 4.8 mg/dL, PO4: 6.1 mg/dL, Ca: 4.8 mg/dL, Mg: 2.6 mg/dL & albumin: 3.5 g/dL. Further studies showed: 25-OH vitamin D: 6.5 (<25 ng/mL), iPTH: 988 (10-55 pg/mL), C-telopeptide: 167 (40-465 pg/mL), ALKP: 243 (44-147 iU/L). Urine calcium-to-creatinine ratio was 0.04, suggestive of minimal calcium excretion. ECG showed prolonged QTc. Given the clinical evidence of severe hypocalcemia and ECG changes, the patient was started on peripheral calcium infusion with hourly iCa2+ measurements to maintain iCa >1 mmol/L and reversal of QTc prolongation. Concomitantly, the patient was treated with calcium carbonate 2500 mg TID, ergocalciferol 50,000 units weekly, and calcitriol 0.5 mcg BID. After 72 hours, his ionized calcium levels stabilized with aggressive oral therapy only. Serum calcium at discharge was 8.2 mg/dL and remained low in the range of 7.5-8.9 for the following 8 weeks.

Discussion: Denosumab has a prolonged elimination half-life (up to 32 days) and therefore, it can induce severe & relapsing hypocalcemia, especially in patients with low vitamin D stores. While patients with creatinine clearance <30 mL/min have been found to be prone to adverse effects, no dose modification has been considered for this therapy. Close monitoring within 14 days after the administration of denosumab and prophylactic therapy with oral calcium and vitamin D could be anticipated in this population.

PO1863

Impact of CKD on the Nutritional Status of Patients with Cancer

Micheline T. Souza,[1] Luiz A. Gil,[1] Thais d. Cardenas,[1] Renato A. Caires,[2] Elerson Costalonga,[1] George B. Coura-Filho,[2] Marcelo T. Sapienza,[1] Lesley A. Inker,[3] Andrew S. Levey,[3] Emmanuel A. Burdmann,[1] Veronica T. Costa e Silva.[2,1] [1]*University of Sao Paulo Medical School, Sao Paulo, Brazil;* [2]*Sao Paulo State Cancer Institute, Sao Paulo, Brazil;* [3]*Tufts Medical Center Cancer Center, Boston, MA.*

Background: Cancer patients routinely live with impaired nutritional status and other comorbidities. There are few prospective data on the impact of chronic kidney disease (CKD) on the nutritional aspects of patients with cancer.

Methods: Patients with solid cancer, admitted for treatment at a cancer hospital in Brazil (Instituto do Câncer do Estado de São Paulo) were prospectively evaluated between April2015 and October2017. Patients underwent a nutritional evaluation including subjective global assessment produced by the patient(PG-SGA), anthropometry(Arm Muscle Area-AMB, weight, height) and electrical bioimpedance(BIA). Sarcopenia was defined as a fat-free mass index(BIA) ≤17.4kg /m² for men and ≤15kg/m² for women. Measurement of the glomerular filtration rate was determined through plasma clearance of ^{51}Cr-EDTA (mGFR). CKD was classified according to the KDIGOguidelines based on mGFR indexed for body surface area.

Results: Six hundred and ninety-six pts were enrolled. Patients were 60(51-67) years, 51.9% male. The most common cancer sites were breast(26.3%), prostate(20%), and gastrointestinal(12.2%). A total of 14.7% had metastatic disease, 94.9% ECOG 0or1. Median mGFR was 81.1(66.7-94.6), with 55.7%, 32.8% and 11.5% presenting mGFR G1, G2 and G3, respectively. When compared to patients with mGFR G1, patients with mGFR G2 and G3 had a higher frequency of malnutrition by PG-SGA and BMI, and a higher proportion of muscle deficit according to AMB. In addition, fat free mass deficit, sarcopenia and lower phase angle values were more frequently observed in mGFR G2 and G3 according to the BIA data(Table1).

Conclusions: In patients with cancer admitted for treatment lower mGFR was associated with worse nutritional status. Therefore, nutritional monitoring in conjunction with the oncology, nephrology and nutritional team is necessary.

Table 1: Association of the Glomerular filtration rate (GRF) according to the KDIGO classification and the clinical oncological and nutritional characteristics

Caracteristics	Overall (696)	G1* (388)	G2** (228)	G3*** (80)	p

The Impact of a Nutritional-Nephrological Combined Approach (NNCA) on the Metabolic Profile and Perceived Quality of Life of CKD Patients

Arianna Bettiga, Federico Di marco, Francesco Fiorio, Riccardo Vago, Umberto Capitanio, Francesco Montorsi, Andrea Salonia, Francesco Trevisani. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Nutritional therapy (NT) based on controlled protein intake represents a cornerstone in the management of CKD. However the international guidelines do not precisely define an adequate protein intake for onco-nephrological patients. Aim of our study is to investigate the impact of a low-normal protein diet on metabolic profile and quality of life in CKD pts affected (CS) or not (CT) by urological non-metastatic malignancies treated with a NNCA.

Methods: 103 pts were enrolled in the Urological Department at San Raffaele hospital between 2018 and 2020, screened for absence of malnutrition and administered a conventional CKD protein-controlled diet (0,7-1 g/Kg/die, 30-35 kcal/ Kg/die) including aproteic foods. Anthropometrical outcomes, lab test exams and clinical variables were examined at baseline and after 6 months. To evaluate the impact of the NNCA on perceived quality of life, a QoL-Short Form36 (SF36) questionnaire were administered to pts.

Results: The combined treatment produced eGFR and urea parameter improvements (49% of pts improved eGFR, 65% uremia) without negatively altering the anthropometrical outcomes. The nutritional status was preserved in both groups and all pts had an improvement in **BMI** (CS: 2.8 kg/h²; CT: 1.3 kg/h²) **PA°** (CS: 2.8%; CT: 1.3%), **BCM/h²** (CS: 1.31; CT: 0.38) and **FFM/h²** (CS: 0.1; CT: 2) and a decrease of **WC** (CS: -1.3cm; CT: -1,65cm), and **ECW/ICW** (CS: 0.02; CT: 0.03). The SF36 questionnaire highlighted a good perceived quality of life in subjects treated with the NNCA, even if social activities were negatively affected.

Conclusions: Our study suggests that low-normal protein high calories diet ameliorates the nephrological scenario, the metabolic complications and the nutritional perspective in uro-oncological CKD pts. Following NNCA, perceived quality of life has been pushed towards high scores and does not appear to be influenced by physical health and emotional status. Harsh clinical monitoring and food choice limitations may have increased the perception of the pathological condition, thereby increasing the sense of responsibility in adhering to the NT. All this improves the physical health, but also demotivates pts and worsens their social attitudes.

PO1865

A Rare Case of Calcitriol-Mediated Hypercalcemia in Metastatic Gastrointestinal Stromal Tumor (GIST)

Iman S. Khan,[1] Victoria Gutgarts,[2] Daniel Kirchhoff,[2] Lakshmi V. Ramanathan,[2] Roman A. Shingarev.[3] [1]*Weill Cornell Medicine, New York, NY;* [2]*Memorial Sloan Kettering Cancer Center, New York, NY;* [3]*Cleveland Clinic, Cleveland, OH.*

Introduction: Hypercalcemia accompanies 10-30% of malignancies. Calcitriol production accounts for <1% cases, usually with lymphoma, but has been reported with solid tumors.

Case Description: A 62 year old male with GIST with liver involvement was admitted for an elevated calcium (Ca) of 13.9 mg/dL & AKI with creatinine (Cr) 2.2 mg/dL. Diagnosed with GIST 3 years prior, he was treated with imatinib & an investigational mitogen-activated protein kinase enzyme inhibitor. Due to disease progression, he was switched to sunitinib 1 week prior to admission and endorsed taking 100,000 IU of OTC vitamin D tablets daily for perceived immunologic benefits. Further workup showed bland urinalysis & fractional sodium excretion of 2.6%. Renal sonogram was normal. AKI was ascribed to hypercalcemia-mediated vasoconstriction & renal blood flow reduction. He had an ionized Calcium 6.6 mg/dL (nl: 4.8-5.3 mg/dL), appropriately low PTH & PTHrP 0.9 pmol/L (nl ≤4.2 pmol/L). The 25(OH) vitamin D was reported at >156 ng/mL, then quantified at 240 ng/mL. Calcitriol was elevated at 71 pg/mL (nl: 18-64 pg/nL). Etiology of hypercalcemia was thought to be from excess vitamin D intake. Cr & Ca improved with hydration, calcitonin & pamidronate. He was readmitted with recurrent hypercalcemia, persistently high 25(OH) vitamin D & calcitriol. Suspected

to be tumor-mediated, prednisone was added to suppress conversion of 25(OH) vitamin D to calcitriol. Over a 3-week prednisone taper, Ca, Cr, 25(OH) vitamin D, calcitriol normalized.

Discussion: In kidneys, 1 alpha hydroxylase converts 25(OH) vitamin D to calcitriol causing Ca retention. This occurs autonomously in lymphomas & granulomatous diseases causing hypercalcemia. Our case is unique as it (a) describes calcitriol mediated hypercalcemia associated with GIST, (b) highlights that hypercalcemia in malignancy can be multifactorial & in our case was from excess vitamin D intake & elevated calcitriol levels.

Kidney Pathology Findings in Patients with AKI Associated with Tyrosine Kinase Inhibitors

Venkata Kishore R. Mukku,[1,2] Omar Mamlouk,[2] William F. Glass,[3] Amanda Tchakarov,[3] Sreedhar A. Mandayam.[2] *[1]The University of Texas Medical Branch at Galveston, Galveston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]The University of Texas Health Science Center at Houston, Houston, TX.*

Background: Tyrosine kinase inhibitors (TKIs) are widely used targeted cancer therapy as they play a critical role in the modulation of growth factor signaling. Nephrotoxicity associated with TKIs can lead to interruption of therapy. However, the literature on the kidney pathology associated with TKIs nephrotoxicity is limited. Here, we present our center observation of tubular and glomerular lesions attributed to possible TKIs.

Methods: We retrospectively reviewed all cancer patients from 2018 to 2020 who we were treated with TKIs and underwent a kidney biopsy at the University of Texas MDACC.

Results: We identified 13 cancer patients treated with Sunitinib, Cabozantinib, Lenvatinib, Regorafenib, Erlotinib, Osimertinib and Ibrutinib between 2018-2020 and developed acute kidney injury (AKI) attributed to possible TKI nephrotoxicity. The median age was 70 (range, 43 to 80) and the median time to develop AKI was 4 months (range, 1 to 58 months) of starting TKI. AKI was severe (stage ≥3) in 6 patients, among which 4 required hemodialysis. Most of the patients had bland urine (7 out of 13) and proteinuria was observed only in 6 patients. Thrombotic microangiopathy (TMA) was the most common pathological finding followed by acute tubular injury (ATI) as they were observed in 5 and 4 patients, respectively. One patient had proliferative glomerulonephritis, one patient had chronic lymphocytic leukemia infiltration, and one patient had no active lesion. TKIs were discontinued in nine patients, and nine patients had partial kidney recovery. Five patients had disease progression and died within 4 months of AKI.

Conclusions: Our case series has demonstrated that kidney limited TMA and ATI were common pathology findings in patients with suspected TKI nephrotoxicity. Nonetheless, half of patients with TMA were on concurrent checkpoint inhibitor therapy with TKI and half of the patients with ATI had associated sepsis diagnosis. The mechanism is likely multifactorial and possibly related to mTOR and VGEF inhibition leading to endothelial injury, and inhibition of the downstream signaling pathway of MAPK/ERK1/2 leading to ATI. Urine analysis was not predictive of the kidney pathology. Treating nephrotoxicity by discontinuation of the offending TKI was associated with partial kidney recovery, however patients had poor overall prognosis.

PO1867

Renal Pathology in Cancer Patients in a New Era of Treatments

Mónica Bolufer,[1] Clara García-Carro,[2] Maria Jose Soler.[1] On behalf of the GLOSEN/ONCONEFROLOGÍA. *[1]Vall Hebron, Barcelona, Spain; [2]Hospital Clinico San Carlos, Madrid, Spain.*

Background: Classically patients with metastatic cancer were not submitted to invasive procedures because of their short life expectancy. Kidney biopsy(KB) is an especially useful diagnostic and prognostic tool in these patients when they develop kidney injury. The aim of our study is to assess clinical and histological characteristics of patients with active solid organ malignancy that underwent KB in a multicenter cohort

Methods: We performed a multicenter collaborative study. Clinical, demographical and histological date from patients with an active neoplasia or in active cancer treatment who underwent KB were collected. We studied the follow-up of the patients in terms of renal function and survival.

Results: 124 patients with cancer who underwent KB during the study period from 11 hospitals were included.63.7% men, mean age 67(SD ±10.28) years old. The indications of KB were acute renal failure (56.6%), proteinuria (20.2%) and exacerbation of CKD (15.3%). At the time of the KB, 30.6% patients presented diabetes and 63.7% high blood pressure. Malignancies: lung (30.6%), intestinal (27.4%), melanoma (7.3%) and genitourinary(17.7%), with 44.3% metastatic cancer Oncoespecific treatment:35.5% received chemotherapy, 31.4% immunotherapy (of which 26.3% received more than 1 checkpoint inhibitor), 24.2% specific therapies and 3.2% conservative treatment Baseline renal function before KB,16.1% presented Cr>1.5mg/dL. At the time of KB, mean Cr 2.54mg/dL ([1,7-3,9 (IQ 25-75)], urine protein/Cr ratio 895mg/g[275-2610(IQ 25-75)] and 53.2% hematuria KB diagnosis:35.5% acute interstitial nephritis (AIN), acute tubular necrosis(8.9%) and IgA nephropathy(8.1%).65% of patients received corticosteroids for an average of 4.8 months[SD ± 3,9].20.2% required kidney replacement therapy and 36.3% presented Cr>1.5mg/dL at 3 months. Average follow-up 16.23[5.5-32,8(IQ 25-75)] months and 37.9% died at the end of follow-up Metastatic cancer at the moment of KB was identified as an independent risk factor for mortality (p=0.012)

Conclusions: Currently, AIN is the first cause of kidney injury in biopsied patients with active cancer. This is followed by thrombotic microangiopathy, membranous nephropathy and IgA among others. KB in this group of patients provides valuable diagnostic and prognostic information. More studies are needed to expand the consensus in the diagnosis and treatment of oncological patients with renal injury

PO1868

Treatment of PLA2R-Negative Membranous Nephropathy in the Setting of Immune Checkpoint Inhibitor and Renal Cell Carcinoma

Vikas D. Reddy,[1] Jaya Kala,[1] Pavlos S. Msaouel,[2] William F. Glass,[1] Omar Mamlouk,[3] Ala Abudayyeh,[3] Jamie S. Lin.[3] *[1]The University of Texas Health Science Center at Houston, Houston, TX; [2]The University of Texas MD Anderson Cancer Center Division of Cancer Medicine, Houston, TX; [3]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Systemic therapy of renal cell cancer (RCC) has undergone major changes over the past decade with the development of targeted therapies such as tyrosine kinase inhibitors (TKIs) and biologic therapies such as immune checkpoint inhibitors (ICIs). Familiarization of the unique nephrotoxicity associated with each treatment is necessary to optimize renal outcomes and cancer care.

Case Description: 57-year-old male with metastatic RCC s/p left nephrectomy progressed after being treated for 16 weeks with the TKI axitinib in combination with pembrolizumab, an ICI targeting PD-1. He subsequently progressed after a 14-week course with second-line cabozatinib (TKI) and was initiated on third-line levatinib (TKI) plus everolimus (mTOR inhibitor) two months prior to presenting with severe diarrhea. Labs were notable for creatinine (Cr) of 2.28 mg/dL (baseline 0.96 mg/dL). CT revealed suspicion for colitis and decreased tumor size of his metastatic disease. Further work-up revealed: 2.87 g on 24 h urine protein, negative anti-GBM and ANCA antibodies, and normal complements. Renal ultrasound showed a hypertrophic right kidney measuring 14 cm in length without obstruction. Due to the broad AKI differential, steroids were empirically started for possible immune-mediated disease, and biopsy was obtained. Pathology revealed membranous nephropathy (MN) with mesangial deposits, PLA2R and THSD7A were negative. With worsening renal function (Cr 3.87 mg/dL) and risk for progression to dialysis, treatment with rituximab (1 g IV D1 and D14) was initiated. Follow-up labs at one month showed Cr 1.50 mg/dL and the patient was restarted on levatinib and everolimus with continued durable response.

Discussion: While TKIs may induce TMA and mTOR inhibitors have been associated with proteinuria and ATN, our patient revealed a unique presentation of secondary MN that was likely induced by his relatively recent ICI therapy. MN can also present as a paraneoplastic lesion, but it is rarely associated with RCC and the presentation did not correlate with his improved CT scan. Given his deteriorating kidney function, treatment with rituximab was fortunately successful and allowed for continued treatment with durable cancer response.

PO1869

Primary Adrenal Insufficiency Secondary to Immune Checkpoint Inhibitors

Joti Bai, Jatinder Kohli. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

Introduction: ICI's are humanized or human immunoglobulin antibodies. Administration of a monoclonal antibody that interrupts the interaction between PD-L1 and PD-L2 and the T-cell PD-1receptor allows tumor-infiltrating lymphocytes (activated T cells) to aggressively identify and destroy cancer cells. However, Use of ICIs can result in toxicity called immune-related adverse events (IrAEs). We present a case of a 55 year old male with history of metastatic malignant melanoma who presented with ICI induced adrenal insufficiency.

Case Description: 55-year-old male PMH of HTN, COPD, Hypothyroidism, metastatic malignant melanoma was recently started Nivolumab presented to the ED with altered mental status and confusion. Laboratory values were notable for hypoglycemic (46mg/dl), hyponatremia (124mmol/l) and borderline High K (5mmol/l), serum osmolality 256 mosm/kg and urine osmolality 538 Mosm/kg. He was initially treated with IV dextrose. Serum cortisol and ACTH were checked to rule out adrenal insufficiency

as etiology for above laboratory abnormalities and history of treatments with ICI (nivolumab). while awaiting these lab results, patient was started on fluid restriction and salt tablets for management of hyponatremia based on available labs at that point which pointed to hypotonic hyponatremia with high urine osmolality pointing to ADH release and goal for correction for sodium level maintained 6-8 Meq for 24hours. Both serum early morning cortisol and ACTH levels were reported to be low with values of 1.4ug/dl and 3.5pg/ml respectively. Patient was subsequently started on IV fluids and IV Hydrocortisone 100 Q8H. Serum sodium level improved at an appropriate rate during the course of hospitalization and serum sodium at the time of discharge was in safe range (136mmol/l). Other peripheral hormones including prolactin, GH, TSH, LH and FSH which were normal. MRI Brain was done to rule out Hypophysitis which revealed normal sella.

Discussion: Long-term follow-up of endocrine irAEs suggests that on occasions thyroid function may recover, but that dysfunction of the corticosteroid and gonadal axis is likely to be permanent. Patients should be informed of the potential adverse events prior to initiation of immune checkpoint inhibitors. Laboratory findings similar to our patient should raise concern for adrenal insufficiency to allow timely diagnosis and management and thus prevent morbidity and mortality.

PO1870

Immune Checkpoint Inhibitors Associated Distal RTA with and Without AKI

David Henderson,[1] Kenar D. Jhaveri,[2] Rimda Wanchoo,[2] Chintan V. Shah.[1] *[1]University of Florida College of Medicine, Gainesville, FL; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: As immune checkpoint inhibitors (ICPI) gain popularity as a widely used anti-cancer therapy, unique immune-related adverse events (irAE) are being associated with their use. Hereby, we present two cases that link ICPI therapy to distal RTA, one with and one without AKI.

Case Description: A 73-year-old male with urothelial cancer on pembrolizumab was evaluated for AKI and acidosis. After 5 doses of ICPI therapy, he was noted to have a serum creatinine of 1.8mg/dl (normal baseline) and a serum CO2 of 20mmol/L. Over the next few days, the serum C02 further decreased to 11mmol/L and serum potassium declined to 3.0mmol/L. Further workup revealed a urine pH of 6.5 with a positive urine anion gap. He was diagnosed with likely ICPI-induced AIN with distal RTA and initiated on sodium bicarbonate, potassium citrate, and prednisone 60mg/day. His ICPI was held. After 2 weeks of treatment, his serum creatinine returned to 1.2mg/dl and serum C02 to 22mmol/L. A 46-year-old female was diagnosed with metastatic lung cancer and squamous cell cancer of the right tonsil for which she was initially treated with Carboplatin/Paclitaxol/Pembrolizumab followed by maintenance Pembrolizumab. Almost 3 months after being initiated on ICPI, she was noted to have normal gap metabolic acidosis that gradually worsened to serum CO2 of 15mmol/L along with serum potassium of 2.4meq/L and serum creatinine of 0.6 mg/dl. Further workup showed a urine anion gap of +26, urine osmolar gap of 80, urine pH of 6.0. 24-hour urine citrate was undetectable. Diagnosis of distal RTA secondary to pembrolizumab was made and therapy was held. Steroids were not initiated, as the kidney biopsy, performed within 2 months of holding the therapy, did not reveal any tubulitis or cellular infiltrates. She is being treated with potassium citrate with normalization of acidosis and hypokalemia.

Discussion: We describe two cases of distal RTA presenting as immune related adverse events associated with use of ICPI. AKI presence is not necessary. Prompt recognition and treatment can lead to quick recovery. It has been postulated that a difference in the expression of PD-L1 among the tubular epithelial cells is responsible for isolated distal RTA

PO1871

Immune Checkpoint Inhibitor-Associated Electrolyte Disorders: Query of the FDA Adverse Event Reporting System

Vipulbhai Sakhiya, Rimda Wanchoo, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Electrolyte disorders with immune checkpoint inhibitors(ICI) therapy are not well characterized. Single center studies have noted hyponatremia as the most common electrolyte disorder associated with ICI.

Methods: We performed a revised more recent query of the FAERS database with a more detailed look at electrolyte disorders only (search terms: hyponatremia, hypernatremia, hypokalemia, hypercalcemia, hypocalcemia, hypophosphatemia, hypomagnesemia, acidosis, hyperphosphatemia and renal tubular acidosis) from 2011-2021.

Results: A total of 2556 cases of electrolytes disorders were reported to the FAERS system. The most commonly reported abnormality is hyponatremia (53.7%), followed by hypokalemia (18.71%), hypercalcemia (9.65%), hyperkalemia (5.56%) and hypocalcemia at 4.68%. The remaining abnormalities were <4%. In all three groups of the agents (CTLA4 inhibitors, PD and PDL1 inhibitors), the trend remained similar. Most events were reported at a median age of 64 in all 3 groups analyzed. Among reported events, proportions of events in male were statistically more significant ($p<0.01$) than females in all 3 drug groups. Nivolumab (n=1130) and ipilumumab (n=684) had the highest number of patients reported with electrolyte disorders. Hyponatremia persisted as the most common abnormality in each specific drug as well. Hypokalemia and hypercalcemia were faily common. Hyperphosphatemia, hypernatremia, hypophosphatemia along with acidosis made up the least number of cases reported.

Conclusions: Electrolyte disorders are an under-recognized cause of ICI therapy. Hyponatremia, hypokalemia and hypercalcemia seem to be the three most commonly reported events with these classes of drugs.

Medication Group	Reaction	Male (N=1461) n (%)	Female (N=921) n (%)	Missing (N=174) n (%)	Overall (N=2556) n (%)

Immune-Checkpoint Inhibitor Use in Patients with ESKD

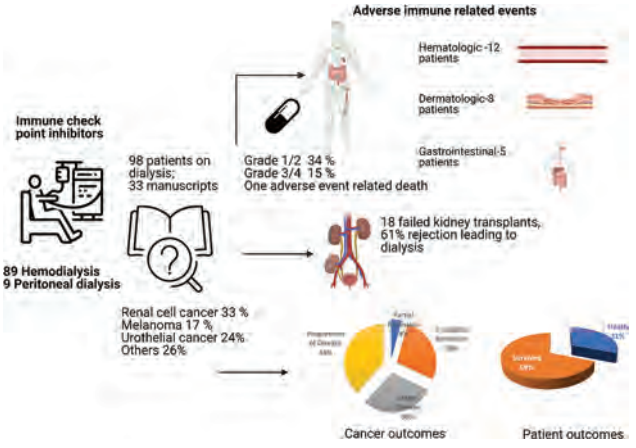
Abhijat Kitchlu,[1] Kenar D. Jhaveri,[2] Ben Sprangers,[4] Motoko Yanagita,[3] Rimda Wanchoo.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]Kyoto Daigaku, Kyoto, Japan; [4]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium.*

Background: As use of immune check point inhibitor(ICI) therapy becomes increasingly widespread across different types of cancer, their use in patients receiving dialysis is likely to increase.

Methods: We performed a structured search of the MEDLINE and EMBASE databases from inception to February 2021. We sought to identify case reports, case series, observational studies and clinical trials which described the use of ICI therapy for cancer in patients receiving dialysis [either hemodialysis (HD) or peritoneal dialysis (PD)]. For each included study, we performed a standardized patient-level data abstraction using pre-specified parameters of interest: patient demographics, cancer diagnosis, ICI treatment characteristics, dialysis modality, immune-related adverse events (irAE), cancer outcomes and survival.

Results: 136 citations for title and abstract screening were noted. Of these 33 met criteria for inclusion. 98 cases with patient-level data were included. Analysis of the reported cases in the literature demonstrates similar incidence of immune-related adverse events in patients with ESKD receiving dialysis as compared to the general population (49%). Grade 3 and 4 adverse events had been seen in fifteen patients (16%). Cancer remission (complete and partial) was seen in close to 30% of patients. Stable disease was seen in 28% and progression of disease in approximately 36% of patients. One-third of the patients died. Urothelial and RCC represented approximately half of all treated cancers, and accounted for approximately 50% of all deaths reported (**Figure**). Eighteen of the reported dialysis patients had prior kidney transplant. Of these, 11 (61%) initiated dialysis after ICI-related rejection of their kidney allograft.

Conclusions: ICI is well tolerated in ESKD patients. Additional data in the dialysis population with use of ICI, and involvement in prospective studies, is needed to better assess outcomes, particularly within specific cancer types.



PO1873

Methotrexate-Induced AKI: Incidence, Risk Factors, and Recovery

Mohit Gupta,[1] I-Hsin Lin,[2] Sheron Latcha.[2] *[1]University of Maryland Medical Center, Baltimore, MD; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Data on short and long term renal outcomes after high dose methotrexate (HD MTX) in large adult cohorts using a standardized definition of AKI is lacking. This is a report on the incidence of AKI after HD MTX, renal outcomes when HD MTX is continued after AKI, and long term renal function in patients who survived beyond 5 years after Risk factors for AKI following HD MTX were also examined.

Methods: In this single center retrospective case control study, all adult patients (>18 years) who had received HD MTX (defined as >1g/m^2) from 2003 – 2013 were analyzed. AKI was identified by a ≥1.5x increase in baseline serum creatinine (Cr) within 4 days after HD MTX. We have collected age at first HD MTX, race, cancer, baseline and all Cr values after HD MTX, and cumulative dose (CD) of MTX. Univariable and multivariable logistic regression models were performed with AKI as the dependent variables. Overall survival for patients that had received HD MTX was presented in a Kalpan-Meier analysis.

Results: In a cohort of 865 patients, 32.1% developed AKI. Patients who developed AKI had a lower baseline Cr (0.7 ±0.2 vs 0.9 ± 0.2; p<0.001), a higher eGFR (95.1 ± 21.8 vs 90.0 ± 22.0; p<0.001) and received a higher CD (25,750 (14100 – 35000) vs 20,000 (9425 – 34,300); p<0.01). There was no statistical difference in overall survival among patients who developed AKI (p=0.13) (Figure 1) and those who continued to receive HD MTX after AKI (p=0.32) (Figure 2). Recovery from AKI to within 20% of baseline Cr was associated with a higher probability of survival (p<0.001).

Conclusions: Despite its relatively common incidence in adult patients receiving HD MTX, AKI does not affect overall survival and should not be a barrier to further administration of chemotherapy.

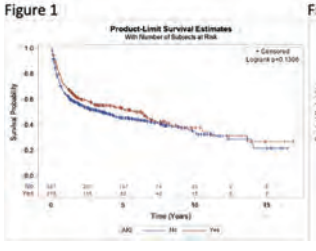

Figure 2

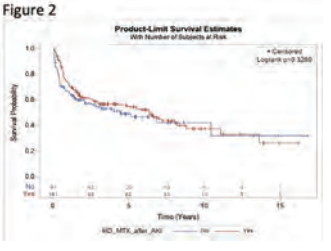

PO1874

Proximal Tubule Dysfunction and Hemophagocytic Lymphohistiocytosis (HLH) Following Use of Novel Immune Checkpoint Inhibitor

David L. Cook, Maura A. Watson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Bintrafusp alfa is a bifunctional fusion protein that inhibits transforming growth factor β (TGF-β) and programmed death ligand 1 (PD-L1) currently being studied for treatment of various cancers. Reported adverse effects include rash and hypothyroidism. We present a patient with renal proximal tubule dysfunction manifested by multiple electrolyte derangements after receiving bintrafusp alfa.

Case Description: A 62 year-old male with squamous cell carcinoma of the head and neck refractory to chemotherapy, radiation and proton therapy was admitted for dysphagia, fever and hypotension two weeks after starting experimental immunotherapy with bintrafusp, NHS/IL-12, and PDS101. He developed hypokalemia requiring high dose supplementation, hypophosphatemia, hyponatremia, hypocalcemia, hypoalbuminemia and non-nephrotic range proteinuria. Other labs showed pancytopenia, elevated transaminases, thyroid stimulating hormone, inflammatory markers and anti-glomerular basement membrane antibodies. Work up showed renal potassium, phosphorus and sodium wasting with glomerular filtration rate (GFR) above 75 mL/min. Respiratory distress and hemoptysis concerning for diffuse alveolar hemorrhage led to ICU transfer. Kidney biopsy showed no glomerular injury, linear basement membrane fluorescence, glomerulosclerosis, interstitial fibrosis or immune complex-deposits. Proximal tubules were focally dilated, suggestive of tubular injury. HLH was subsequently diagnosed and treatment with steroids and intravenous immune globulin was followed by electrolyte normalization and improved clinical status.

Discussion: Immune checkpoint inhibitors are increasingly used for cancer treatment. These medications carry risk of immune-related adverse effects. While secondary HLH has been reported with use of immune checkpoint inhibitors, cases are few and renal involvement even rarer. To date there have been no documented cases of secondary HLH with profound electrolyte derangements but normal GFR after receiving bintrafusp alfa. Awareness of these adverse events is necessary as these medications see more widespread use. *The views expressed are those of the authors and do not necessarily reflect the official policy the Department of Defense or the U.S. government.*

PO1875

Utility of Liquid Chromatography in Monitoring Methotrexate Levels After Glucarpidase for Methotrexate Toxicity

Vishnupriyadevi Parvathareddy,[1] Venkata Kishore R. Mukku,[2] Adnann S. Polani,[1] Sheldon Chen.[3] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas Medical Branch at Galveston, Galveston, TX; [3]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Methotrexate (MTX) is an anti-metabolite with a 1,000-fold affinity for dihydrofolate reductase, competitively inhibiting the reduction of dihydrofolate to tetrahydrofolate that is needed for DNA/RNA and protein synthesis. High-dose MTX is defined as a dose higher than 500 mg/m^2 and results in acute kidney injury in 2-12% of patients. Values above 10 μM at 24 h post-infusion confer a high risk for toxicity.

Case Description: A 61 y/o male with newly diagnosed primary CNS diffuse B cell lymphoma was admitted for De Angelis regimen which included MTX 3,500 mg/m^2. His creatinine increased from 0.9 to 3.1 mg/dL despite concurrent hydration, urinary alkalinization, and leucovorin. MTX level was 89 at 24 h, confirming MTX toxicity. He then received a single dose of glucarpidase 50 U/kg IV. Plasma MTX levels remained high at 44, 41, and 14 on post-glucarpidase days 1, 2, and 3. In contrast, high-performance liquid chromatography (HPLC) measurement of MTX was below 0.05 on post-glucarpidase day 2, showing efficacy of glucarpidase in lowering MTX levels.

Discussion: After high-dose MTX, serum levels must be monitored to determine when to administer leucovorin and glucarpidase, a recombinant carboxypeptidase-G2 that cleaves MTX to inactive metabolites. Intrarenal MTX crystallization can 1) obstruct the tubules, 2) damage the tubular epithelium, and 3) vasoconstrict the afferent arterioles. Because volume depletion and acidic urine are major risk factors for AKI, hyperhydration and urine alkalinization are mandatory during high-dose MTX treatment. Early intervention with the combination of leucovorin and glucarpidase is highly effective in patients who develop kidney dysfunction. A single dose of glucarpidase 50 U/kg IV reduces plasma MTX concentration by >97% within 15 mins. Liquid chromatographic measurement of MTX is recommended within 48 hours of glucarpidase administration, as the MTX metabolites 7-hydroxymethotrexate and 4-deoxy-4-amino N10 methylpteroic acid (DAMPA) cross react with standard immunoassays and falsely elevate the level. In our patient, the serum MTX levels were still elevated by immunoassay, while they were undetectable by liquid chromatography. We recommend using HPLC when available to confirm the lowering of MTX by glucarpidase.

PO1876

Cerebral Salt Wasting Caused by High-Dose Methotrexate

Neda Shahoori,[1,2] Michael M. Samiratedu,[1,2] Efren A. Chavez Morales.[1,2] *[1]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; [2]University of Miami School of Medicine, Miami, FL.*

Introduction: Severe acute hyponatremia is a rare complication of high-dose methotrexate (HDMTX) use.

Case Description: We present an interesting case of a 54 year-old man with relapsed diffuse large B-cell lymphoma with central nervous system (CNS) involvement who received a chemotherapy regimen including HDMTX. He received a single dose of 7.2 g of intravenous HDMTX. Baseline serum sodium (Na) was 140 mmol/L. Within 48 hours serum Na dropped to 120 mmol/L and patient developed mild headache and confusion. Laboratory evaluation revealed a urine Na 245 mmol/L, fractional excretion of sodium (FeNa) 2.5%, urine potassium 47 mmol/L and urine osmolality 561 mOsm/kg. Serum tests showed Na 120 mmol/L, chloride 81 mmol/L, osmolality 245 mOsm/kg, uric acid 2.5 mg/dL, TSH 0.6 uIU/mL, cortisol level 15 microg/dL, creatinine 0.6 mg/dL and a low serum ADH level (<0.8 pg/mL). Rest of serum electrolytes were within normal limits. Patient was polyuric and soon became hypotensive and tachycardic. He was treated with a combination of 3% hypertonic saline and oral loop diuretics with subsequent improvement in symptoms, increase in serum sodium and reduced natriuresis.

Discussion: We hypothesize a case of cerebral salt wasting due to the toxic neurologic effect of HDMTX in a vulnerable patient with an underlying CNS tumor. HDMTX has been associated with toxicity to neurosecretory aspects of the cerebrum which may lead to activation of CNS natriuretic peptides which are thought to be responsible for fluid regulation. There are multiple literature reports about cases of subarachnoid hemorrhage, strokes or seizures who developed hyponatremia originally thought to be due to SIADH, but then attributed to stimulation of CNS natriuretic peptides. We did not measure a serum B-type natriuretic peptide (BNP) in our patient, however serum ADH level was low. BNP was initially called brain natriuretic peptide because it was first found in brain tissue.

However, BNP is produced primarily by myocardial cells of the left ventricle in response to stretch. The primary natriuretic peptides of the CNS are thought to be C-type natriuretic peptide and D-type natriuretic peptide, which have been shown to induce natriuresis leading to hyponatremia and suppressed ADH levels, as was possibly seen in our patient. We report this case to allow clinicians to be aware of this possible occurrence.

PO1877

Cisplatin-Induced AKI Cancer Mouse Model Refinement

Lauren E. Thompson, Courtney D. McGinnis, Charles L. Edelstein, Melanie S. Joy. *University of Colorado Health, Aurora, CO.*

Background: Cisplatin (CIS), a common chemotherapeutic, causes acute kidney injury (AKI) in up to one-third of patients. Traditional mouse models use healthy mice and a single, lethal dose of CIS (20-30 mg/kg). This model does not accurately reflect the clinical use of CIS where cancer patients receive 25-100 mg/m^2 once every 3-4 weeks. There is a need for a multi-dose mouse cancer model of CIS-AKI that more closely reflects CIS clinical use.

Methods: C57BL/6 male mice (8 weeks old; n=45) were injected in the right flank with murine lung cancer cells (CMT167; 0-1,500,00 cells). Subcutaneous solid tumors were allowed to grow for ~2 weeks until digital caliper measurement confirmed they were ≥50 mm^3. Mice were then dosed with CIS (0, 12.5, 15 mg/kg) or vehicle (saline) 1x/week for up to 4 weeks. Mice were evaluated for outcomes of general health (body weight), survival, cancer progression (tumor volume), and kidney injury (SCr, BUN, KIM-1). Assessments were performed ≥1x/week until sacrifice after 1-4 weeks of CIS treatment. Analyses for differences from baseline to sacrifice based on both cancer cells injected and CIS dose were assessed by 2-way ANOVA with a Tukey-Kramer post-hoc test. $p<0.05$ was considered statistically significant.

Results: Groups injected with >1 million CMT167 cells experienced the greatest decline in survival due to rapid tumor growth and ulceration (0% at 8 d). Cancer-free mice treated with CIS also experienced poor survival due to dehydration and weight loss (60% at 15 d). Mice injected with 50,000 CMT167 cells had the best survival (100% at 13 d). Body weight was significantly decreased as CIS dose increased ($p=1.9*10^{-8}$) and increased as number of CMT167 cells increased ($p=5.5*10^{-8}$). Tumor volume was significantly increased as number of CMT167 cells increased ($p=5.1*10^{-5}$) and somewhat decreased as CIS dose increased (p=0.092). CIS dose did not significantly impact BUN or SCr levels but an increase in KIM-1 was somewhat associated with an increased CIS dose (p=0.105; 12.5 vs 15 mg/kg CIS p=0.191). There were no significant differences in body weight, tumor volume, or survival between the 12.5 and 15 mg/kg CIS treated mice.

Conclusions: The results indicate that the ideal CMT167 mouse cancer model of CIS-AKI should use 50,000 CMT167 cells and 15 mg/kg CIS. This model can be used to better understand CIS-AKI and to test potential protective compounds.

Renal Outcomes in High-Dose Cisplatin in Locally Advanced Squamous Cell Carcinoma of the Head and Neck: A New and Interesting Perspective

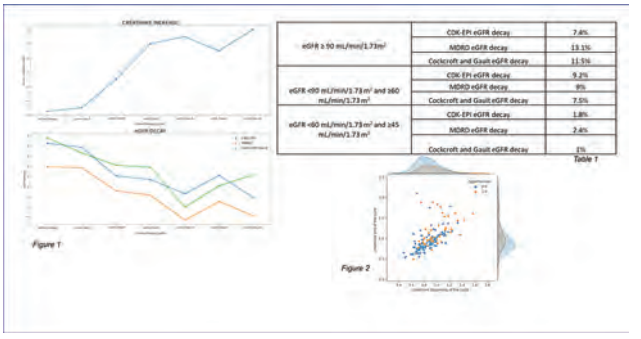
Francesco Trevisani,[1] Giulia Quattrini,[1] Daniele Pugno,[2] Giulia Pegoraro,[2] Alessandra Cinque,[1] Vanesa Gregorc,[1] Aurora Mirabile.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Biorek S.R.L., Milano, Italy.*

Background: Three-weekly high-dose cisplatin (100 mg/m2) concomitant to radiotherapy represents the standard of care with a curative intent in most of locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN). Nevertheless, cisplatin is known as a particularly nephrotoxic drug especially at the cumulative dose of 200 mg/m2 or more. Aim of this study was to investigate the incidence of AKI in patients with LA-SCCHN during and after treatment with high-dose cisplatin-based CRT to identify risk factors for cisplatin-induced AKI.

Methods: A consecutive cohort of 82 patients treated with cisplatin cumulative dose >=200mg/m2 concomitant to radiotherapy, was enrolled in a tertiary single Hospital between 2019 and 2020. Serum creatinine, hemoglobin, lymphocytes and eGFR formulas (CKD-EPI, MDRD, Cockcroft-Gault) were detected at baseline and after each cycle of chemotherapy. AKI and CKD onset were determined according to K-DIGO criteria. Tumor clinical stage as well as comorbidities were also included. Bayesian linear regression was used to evaluate the impact of the clinical and pathological features on eGFR decay through cycles.

Results: At baseline, 57% of pts were CKD I stage, 37% CKD II stage, 6,1 % CKD III stage A-B. Medium decay of eGFR from the baseline to the end of 3 cycle is reported in table 1 showing CKD different stages. The marked decay appears in day 10 during cycle 2 (Figure 1). Performing a bayesian linear regression over cycles, hypertension showed a remarkable impact on the eGFR decay through the therapy over time (Figure 2). However, the AKI incidence was very low in all CKD classes; 2,4% in 1 cycle, 4,8% in 2 cycle and 2,4% in 3 cycle.

Conclusions: Surprisingly, from these data high dose of cisplatin seems feasible in different CKD stages with very low rate of renal toxicity events and AKI-CKD onset.



PO1879

Double Hit: A Case of Chromogranin A-Mediated Proximal Tubulopathy That Progressed to Full-Blown Fanconi Syndrome After Treatment with Everolimus

Adnann S. Polani,[1] Biruh Workeneh.[2] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Hypophosphatemia is an independent risk factor for poor patient outcomes. We present a rare case of hypophosphatemia from a complication of a neuroendocrine tumor (NET) and the treatment for it.

Case Description: A 54-year-old female with metastatic NET presented with dyspnea. Patient had Pneumonia which was treated but a comprehensive electrolyte panel revealed profound hypophosphatemia (phosphorous levels < 1mg /dl). Initial suspicion was that poor nutritional status may be the underlying etiology, however despite aggressive intravenous phosphate supplementation, the hypophosphatemia was resistant. Workup revealed obvious evidence of Fanconi syndrome. Patient had profound glucosuria with normal serum glucose. 24 hours urine phosphorous excretion was markedly elevated at 900 mg. Vitamin D level was borderline low but activated (1,25-vitamin D) levels were markedly low at 1.8 pg/ml. PTH levels were only mildly elevated at 120 pg/ml. A deeper investigation into her course found that patient was diagnosed with a NET 8 months prior to this presentation and had evidence of mild glucosuria with mild-moderate hypophosphatemia at that time. Chromogranin A levels from her NET were substantially elevated at that time. Serial urine analyses during the course of her disease were reviewed, and it was evident that the glucosuria became markedly worse after the patient was started on everolimus therapy. We concluded that hypophosphatemia in this patient is from chromogranin A mediated proximal tubulopathy that developed to full blown Fanconi Syndrome after everolimus. We changed phosphorous supplementation to oral only and recommended holding everolimus provided it was appropriate from an oncological standpoint. Follow up of the patient in 4 weeks off everolimus showed continued improvement in phosphorous levels.

Discussion: Both chromogranin-A and mtor inhibitors have shown to cause acute tubular injury in proximal tubules. Our case is unique in the sense that it presented as severe hypophosphatemia from Fanconi syndrome secondary to two uncommon culprit agents that acted in a sequential manner to worsen the proximal tubulopathy. Based on this case we recommend that in NET patients with high chromogranin A levels, we check for signs of proximal tubulopathy before starting mtor inhibitor therapy.

PO1880

Renal Function Outcomes in Metastatic Non-Small-Cell Lung Carcinoma Patients Treated with First-Line Therapy: An Unexpected Scenario

Francesco Trevisani,[1] Federico Di marco,[1] Antonello Pani,[1] Matteo Floris,[1] Roberto Minnei,[1] Mario Scartozzi,[1] Monica Cattaneo,[3] Michele Ghidini.[2] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Ospedale Luigi Sacco-Polo Universitario, Milano, Italy.*

Background: Immune checkpoint inhibitors (ICIs) and platinum-based chemotherapy (CT) are possible options for the palliative treatment of metastatic non-small cell lung cancer (NSCLC). Recently, CT in combination with immune- checkpoint inhibitors has become the treatment of choice for this setting of patients(pts). Aim of our study was to compare the nephrotoxic effect of both ICIs and CT in a cohort of metastatic NSCLC pts.

Methods: A consecutive cohort of 292 pts treated in first-line for NSLCL with immunotherapy or CT was enrolled in a multicentric trial between 2018-2021. eGFR (using CKD-EPI formula 2009) was detected at baseline and after each cycle of therapy to determine AKI and CKD onset according to K-DIGO criteria. Comparison between numerical variables was performed using linear regressions between groups using Kruskal-Wallis rank sum test for numerical variables and Pearson's Chi square test for categorical variables.

Results: Clinical and pathological characteristics are reported in table 1. In terms of eGFR decay and CKD onset during the treatment cycle, no significative differences were observed (Figure 1). The same behaviour happened with AKI incidence over cycles (p=0.3) (Figure 2). Further analysis including clinical variables lead to the same results, suggesting that the nephrotoxicity of CT and immunotherapy could be considered overlap and not negligible.

Conclusions: Our study surprisingly highlights that both cisplatin/carboplatin-based CT and immunotherapy display a similar incidence of AKI and eGFR decay over time in NSLCC metastatic patients

PO1881

AKI with BRAF and MEK Inhibitors May Not Be a Class Effect

Supriya Gerardine,[1,2] Surya V. Seshan,[1] Ilya Glezerman.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: BRAF tyrosine kinase inhibitors are used in the treatment of BRAF mutant metastatic melanoma. Simultaneous MEK inhibition has been shown to have better response rates and fewer side effects. Renal toxicity has been reported with these agents which can include AIN, ATN and Fanconi syndrome. We report a case of AKI due to biopsy proven AIN from BRAF and MEK inhibitor vemurafenib and cobimetinib

Case Description: This is a 64-year-old woman with diabetes mellitus type 2, stage IV melanoma with BRAF V600E mutation and baseline serum creatinine (SCr) of 0.8 (0.6-1.1) mg/dL. She has been treated with multiple chemotherapy regimens and immunotherapy (last dose of immunotherapy 28 months prior to presentation). Patient received reduced dose dabrafenib and trametinib until 8 months prior to presentation but stopped due to development of fever and AKI (SCr 1.7mg/dL). She was started on vemurafenib 480 mg BID every other day and cobimetinib 40mg every other day 6 ½ months before presentation. Two months later the vemurafenib dose was increased to 960mg BID but patient was noted to have AKI with SCr of 4.5 mg/dl and vemurafenib and cobimetinib were stopped. Her blood pressure was elevated to 154/70 mmHg. Urinalysis showed protein of 100 mg/dL, 0-3 RBC/HPF and 0-6 WBC/HPF. SCr improved to 2.2 mg/dL but remained elevated and renal consult was obtained with subsequent kidney biopsy. It showed active, subacute, and chronic interstitial nephritis with extensive tubular atrophy. Patient was treated with prednisone 50 mg daily and was tapered down to 10 mg daily over two months. Repeat CT scan showed new peritoneal nodules and she was started on a new BRAF/ MEK combination of encorafenib and binimetinib. She is currently tolerating these medications with SCr stable at 1.5mg/dl.

Discussion: BRAF and MEK inhibitors are associated with AKI secondary to ATN and AIN. In the above case, the patient developed AIN with vemurafenib and cobimetinib which were discontinued resulting in significant improvement in kidney function. Due to progression of disease she was started on encorafenib and binimetinib which she is tolerating well. This case demonstrates that renal toxicity from BRAF and MEK inhibitor may not be a class effect and may also be dose dependent. It may be possible to consider a dose reduction or switch to another medication in the same class if renal toxicity is noted.

PO1882

Acute Proteinuric Renal Failure in a Lung Cancer Patient Treated with Poziotinib: First Case Described in the Literature

Laura Cosmai,[1] Marta Pirovano,[2] Giulia V. Re Sartò,[2] Maurizio Gallieni.[1,2] *[1]Aziende Socio Sanitarie Territoriale Fatebenefratelli Sacco, Milano, Italy; [2]Universita degli Studi di Milano Dipartimento di Scienze Biomediche e Cliniche Luigi Sacco, Milano, Italy.*

Introduction: The therapeutic approach to non-small cell lung cancer (NSCLC) has changed significantly in recent years: genomic drivers have enabled the development of new molecularly targeted therapies. The improvements obtained in the survival of these patients, the adverse events related to these novel treatments should not be forgotten. Poziotinib is a new generation tyrosine kinase inhibitor which has been recently registered for the treatment of patients with EGFR/HER2 exon 20 insertion mutation.

Case Description: In 2017, a 58-year-old woman was diagnosed with a pT2, N2, M0, G2 NSCLC for which she was surgically treated with lobectomy and lymphadenectomy, followed by adjuvant CT; and after metastatic relapse, further CT until July 2020. Upon progression, she started Poziotinib. She was referred to us due to the occurrence of hypomagnesemia, hypokalemia and proteinuria (2.8 g/24 h), despite a normal renal function., The objective examination and blood tests were all normal, and the patient did not report any symptom. Due to a quick worsening of renal function (sCr 2 mg/dl), and in particular of proteinuria (3.3 g/24 h), Poziotinib was stopped and dexamethasone 4 mg/day was started. Examinations for glomerulopathies were not diriment; a renal biopsy was performed in order to guide therapeutic decisions. The histological picture showed incomplete glomerular sclerosis (5/15 glomeruli), outbreaks of tubulointerstitial sclero-atrophy, as well as interstitial inflammatory lymphoplasmacytic infiltrate; immunofluorescence was negative for all antisera, while electron microscopy is presently still in progress. Following the discontinuation of Poziotinib, a progressive improvement of AKI and a reduction of proteinuria (1.3 g/24 h) was observed, allowing to hold the drug accountable, in the absence of any other risk factor, for the renal AE observed. From a histological viewpoint, nephroangiosclerosis was documented, but steroidal therapy may have hidden peculiar glomerular lesions. Poziotinib wasn't resumed.

Discussion: This is the very first case of renal toxicity from Poziotinib treatment reported so far. Cases like this highlight the need for both a nephro-oncological evaluation as well as for dedicated paths to perform rapid renal biopsies in order to characterize these events and improve their management.

PO1883

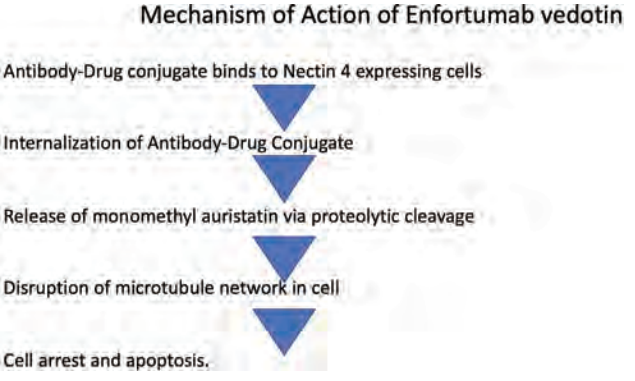
Enfortumab Vedotin-Induced Diabetic Ketoacidosis and AKI: A Case Report

Hassaan Iftikhar, Anitha Vijayan, Charbel C. Khoury. *Washington University in St Louis, St Louis, MO.*

Introduction: Enfortumab vedotin is a novel antineoplastic agent in the management of advanced urolthelial cancers. While hyperglycemia has been reported, diabetic ketoacidosis and AKI are rare.

Case Description: A 69-year-old male with history of metastatic urothelial cancer (treated with carboplatin/gemcitabine and Nivolumab) and CKD who presented to hospital one week after receiving Enfortumab with Diabetic Ketoacidosis (DKA) and AKI with Cr of 3.6mg/dL (Baseline 1.8mg/dL). Urine microscopy revealed granular casts consistent with tubular injury. Patient remained hyperglycemic despite titrating dose of IV regular insulin and subsequently developed shock, toxic epidermal necrolysis, and worsening renal failure with anuria requiring continuous renal replacement therapy. Despite maximal support, patient passed away.

Discussion: Enfortumab vedotin comprises antinectin-4 antibody and a microtubule-disrupting agent monomethyl auristatin E (MMAE). The drug binds to Nectin-4, expressed on tumor cells, with high affinity, which induces the internalization of MMAE and leads to subsequent cell apoptosis through impaired cell division. Dermatologic toxicity occurs from drug binding to Nectin-4 expressed on normal skin cells. AKI was reported in 1% of patients of the phase 2 trial but not in the phase 3 trial. Nectin-4 protein is expressed and can be stained in renal tubular epithelial cells. While DKA may have contributed to our patient's tubular injury, direct tubular toxicity may be possible and requires further research. Physicians prescribing Enfortumab vedotin should be aware of this potential side effect.



PO1884

An Elevated Serum Creatinine in a Patient Receiving Palbociclib

Marco A. Bonilla, Khawaja A. Bashir, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Serum Creatinine (SCr) is the most widely used parameter in clinical practice to estimate glomerular filtration rate (GFR). Various drugs have been reported to cause a reversible and transient elevation in SCr without a true reduction in overall kidney function

Case Description: A 66-year-old woman with a past medical history of metastatic right breast poorly differentiated invasive ductal carcinoma, hormone receptor-positive, and HER2 negative. Who received treatment with fulvestrant and palbociclib, the dose of Palbociclibwas was 100mg orally a day. Presented for evaluation of elevated serum creatinine with decreased eGFR. On initial evaluation sCr was 1.6mg/dl, blood urea nitrogen of 21mg/dl, eGFR of 33ml/min/1.73m^2, her baseline eGFR was ranging from 42 to 52 ml/min/1.73m^2 in the past one year. An estimated glomerular filtration rate by cystatin C was performed and showed a value of 47ml/min with a cystatin-C level of 1.36mg/dl, which was at her baseline kidney function for the past year.

Discussion: Creatinine is freely filtered by the glomerulus and actively secreted by the proximal tubule from the peritubular capillaries, which accounts for 10-40% of creatinine clearance. The organic cation transporter 2 (OTC2), multidrug and toxin extrusion protein (MATE) 1 and MATE2-K, are the solute carrier transporters in the kidney that mediate this active tubular secretion. Clinical studies of abemaciclib, another selective inhibitor of CDK 4/6, have shown a reversible increase in creatinine of about 15-40% over baseline of patients with cancer and healthy subjects. This effect has been seen in about 25% of patients treated with abemaciclib however none of the clinical trials on palbociclib have

reported an increase in serum creatinine. In our case, the difference between eGFR by cystatin C and by serum creatinine demonstrated not a true decrease in kidney function. We have attributed these events to inhibition of the tubular secretion of creatinine by palbociclib and decided to continue treatment with palbociclib. Physicians should be aware that patients undergoing therapy with palbociclib require monitoring of kidney function and an increase in serum creatinine from baseline, might represent an inhibitory effect of the secretion of creatinine and not an actual decrease in kidney function.

PO1885

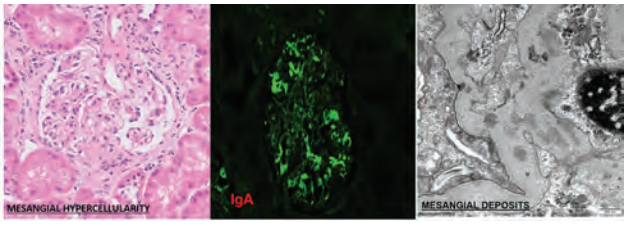
A Case of IgA Nephropathy in the Setting of Sezary Syndrome and Mogamulizumab

Mohankumar Doraiswamy,[1] Sergey V. Brodsky,[1] John C. Reneau,[2] Joshua Leisring.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]The Ohio State University Comprehensive Cancer Center Arthur G James Cancer Hospital and Richard J Solove Research Institute, Columbus, OH.*

Introduction: IgA Nephropathy (IgAN) is an autoimmune disease with complex pathogenesis. Sezary syndrome (SS) is a leukemic subtype of cutaneous T cell lymphoma (CTCL). A rare association has previously been reported between IgAN and CTCL. Mogamulizumab (MG) is a monoclonal antibody drug targeting C-C chemokine receptor type 4 (CCR4) and is used in the treatment of CTCL and SS. MG has been associated with drug eruptions and systemic immune-mediated adverse events.

Case Description: A 63 year-old woman with SS was treated with MG. Her skin symptoms improved and circulating Sezary cells cleared. Due to a cutaneous drug eruption, the frequency of MG administration was reduced to monthly after cycle 7. Labs prior to cycle 19 demonstrated serum creatinine (Cr) 1.77 mg/dL from a prior baseline ~0.9-1.0 mg/dL. She received intravenous fluids but Cr worsened to 3.97 mg/dL. Urinalysis (UA) revealed more than 20 red blood cells (RBCs) per high powered field (HPF). 24 hour urine protein to creatinine ratio (UPCR) was 2.03 g/g. Serologies and complements were normal except double stranded DNA which was 12 IU/mL (normal <4 IU/mL). Kidney biopsy demonstrated mesangial immune complex deposition with IgA, IgG, and C3 predominance consistent with IgAN (Oxford M1E0S1T1C0). Prednisone was initiated at 1 mg/kg/day and tapered over 6 months. MG was stopped. After 6 months Cr had improved to 1.10 mg/dL. UA showed 3-5 RBCs per HPF with UPCR of 0.122 g/g. Her SS remained well controlled without systemic therapy.

Discussion: This case reinforces the association between IgAN and CTCL which has been described in prior case series. In patients with CTCL, altered T cell populations and a dysregulated immune response may contribute to the pathogenesis of IgAN. Complicating this case is the use of MG which can deplete normal CCR4-expressing regulatory T cells by inducing antibody-dependent cellular cytotoxicity. MG is associated with cutaneous granulomatous drug eruptions in which alterations in T cell populations have been implicated. Systemic autoimmune complications outside of the kidneys have also been reported. The possibility that MG could play a role in IgAN should be considered.



PO1886

Filgrastim-Induced Crescentic Glomerulonephritis

Danyi Zheng,[1] William F. Glass,[1] Ala Abudayyeh.[2] *[1]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [2]University of Texas MD Anderson Cancer Center, Housotn, TX.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is caused by deposition of monoclonal immunoglobulins in the glomeruli. It is one of renal disorders included in the spectrum of monoclonal gammopathy of renal significance (MGRS). IgG3 with kappa light chain is the most common type. Autologous stem cell transplantation (SCT) provides a durable remission and better renal outcomes. Granulocyte colony stimulating factor (GCSF) is a recombinant glycoprotein used for mobilization of bone marrow in SCT. GCSF has been implicated as a cause of crescentic transformation of an acute glomerulonephritis in one prior case with a monoclonal deposits in a kidney transplant patient. In this case, we report the clinical and pathologic findings of GCSF induced exacerbation and crescentic transformation of pre-existing PGNMID with successful treatment and SCT.

Case Description: A 48-year-old male with recent diagnosis of MGRS presenting as MPGN and monoclonal IgG Kappa with C3 deposits on biopsy and treated with Velcade, cyclophosphamide and dexamethasone with a plan for SCT. Patient was admitted after acute increase in creatinine from 2.87 m/dl to 6.6mg/dl with hematuria and proteinuria after receiving GCSF during stem cell mobilization. Timing of acute renal injury correlated with increase in WBC after GCSF injections with a peak of 69 K/ul. Repeat kidney biopsy was significant for crescentic membranoproliferative (62% crescents) glomerulonephritis with monoclonal IgG/Kappa deposits. Patient received 5 sessions of plasmapheresis, one dose of renally adjusted IV Cytoxan, and pulse steroids followed with a taper. After a month he undergone an Autologous SCT (creatinine at baseline1.6mg/dl). His kidney function continued to improve and after 16 months post SCT his creatinine is at 1.4mg/dl.

Discussion: GCSF enhances neutrophils activation in large counts and induces its endothelial activation. In the presence of pre-existing renal pathology, MGRS and MPGN with IgG kappa and C3 deposits in this case, the localized immunoglobin and complement deposits in the glomeruli can attract activated neutrophils leading to its infiltration and degranulation in the glomerular microenvironment, and resulting in rupture of glomeruli basement membrane and formation of crescent. Therefore, GCSF induced kidney injury should be suspected due to its potential risk for exacerbating pre-existing glomerulonephritis.

PO1887

Creatinine-Cystatin C Ratio and Mortality in Cancer Patients: A Retrospective Cohort Study

Chan-Young Jung, Keun Hyung Park, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang, Jung Tak Park. *Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea.*

Background: Muscle wasting is prevalent in cancer patients, and early recognition of this phenomenon is important for risk stratification. Recent studies have suggested that the creatinine-cystatin C ratio may correlate with muscle mass in several patient populations. The association between creatinine-cystatin C ratio and survival was assessed in cancer patients.

Methods: A total of 3,060 patients who were evaluated for serum creatinine and cystatin C levels at the time of cancer diagnosis were included. The primary outcome was 6-month mortality. The 1-year mortality, and length of intensive care unit (ICU) and hospital stay were also evaluated.

Results: The mean age was 61.6±13.5 years, and 1,409 patients (46.0%) were female. The median creatinine and cystatin C levels were 0.9 (interquartile range [IQR], 0.6-1.3) mg/dL and 1.0 (IQR, 0.8-1.5) mg/L, respectively, with a creatinine-cystatin C ratio range of 0.12-12.54. In the multivariate Cox analysis, an increase in the creatinine-cystatin C ratio was associated with a significant decrease in the 6-month mortality (per 1 creatinine-cystatin C ratio, hazard ratio [HR] 0.35; 95% confidence interval [CI], 0.28-0.44). When stratified into quartiles, the risk of 6-month mortality was significantly lower in the highest quartile (HR 0.30; 95% CI, 0.24-0.37) than in the lowest quartile. Analysis of 1-year mortality outcomes revealed similar findings. The highest quartile was also associated with shorter length of ICU and hospital stay (both $P<0.001$). These associations were independent of confounding factors.

Conclusions: The creatinine-cystatin C ratio at the time of cancer diagnosis significantly associates with survival and hospitalization in cancer patients.

PO1888

Comparison of Kidney Volume-Based Methodology to Glomerular Filtration Rate Estimating Equations to Predict Measured Glomerular Filtration Rate in Cancer Patients

Regis F. Bezerra,[1,4] Patricia P. Dantas,[1] Filipe d. Freire,[1] Marcelo T. Sapienza,[2] Andrew S. Levey,[3] Lesley A. Inker,[3] Veronica T. Costa e Silva.[1] *[1]ICESP, Sao Paulo, Brazil; [2]Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; [3]Tufts University, Medford, MA; [4]Hospital Sirio-Libanes, Sao Paulo, Brazil.*

Background: Total kidney volume (TKV) has been associated with both measured glomerular filtration rate (mGFR) and with equations recommended to estimate GFR (eGFR) in clinical practice. However, there is scarce data comparing measurement of TKV to eGFR equations as predictors of mGFR, particularly in the oncology setting.

Methods: We enrolled 181 cancer patients treated at an academic tertiary cancer hospital in Brazil (Instituto do Câncer do Estado de São Paulo), who had undergone abdominal imaging and measurement of GFR by plasma clearance of 51Cr-EDTA within 60 days. eGFR was determined based on the CKD-EPI equation using Scr (eGFRcr) and Scr combined with Scys (eGFRcr-cys). eGFR and mGFR were non indexed for body surface area. Total kidney volume (TKV) was measured using a semi-automatic segmentation program, excluding non-functional tissues. The correlations between mGFR and TKV as well as mGFR and eGFR were calculated using the Pearson correlation coefficient. Linear regression models for mGFR having TKV and eGFR equations as predictors were built.

Results: Patients were 55 (14.0) y, 50.3% male. Most common cancer sites were breast (22.7%), male genital (21.8%) and gastrointestinal (20.9%). ECOG levels 0/1 corresponded to 95% of patients. Mean (SD) Body mass index was 27.18 (5.18). Mean (SD) mGFR, eGFRcr and eGFRcr-cys were 84.8(27.23), 90.4 (24.9), and 83.8 (25.9), ml/min, respectively. Mean (SD) TKV for both kidneys was 302.2 (77.9) cm3. PCC for mGFR-TKV, mGFR-eGFRcr and mGFR-eGFRcr-cys were 0.76, 0.78 and 0.85, respectively. TKV improved the coefficient of determination of the linear regression models when added to both eGFRcr and eGFRcr-cys, in overall and assessed subgroups (Table 1).

Conclusions: In conclusion, our results suggest that measurement of TKV is a reliable predictor of mGFR in cancer patients with the potential to be incorporated to the current eGFR equations used in clinical practice.

mGFR is the outcome. eGFRcr, eGFRcr-cys and TKV are the predictors. mGFR: measured glomerular filtration rate; eGFR: estimated glomerular filtration rate is based on CKD-EPI equation, being eGFRcr based on serum creatinine level and eGFRcr-cys being eGFR based on both serum creatinine and serum cystatin C levels. CKD-EPI equation. BSA: body surface area, BMI: body mass index, CKD: chronic kidney disease. TKV: total kidney volume. I: intercept. B1 beta coefficient for eGFR equation. B2: beta coefficient for TKV. R^2: coefficient of determination, represents the proportion of the variance for a dependent variable that's explained by the predictors. eGFR and mGFR were assessed in mL/min/1.73m² values.

Modifications of Renal Function in Cancer Patients Undergoing Repeated and Frequent Administrations of Iodinated Contrast Medium (CM): A Multicentric Retrospective Study from Italy

Laura Cosmai,[1] Marta Pirovano,[4] Giulia V. Re Sartò,[4] Camillo Porta,[2,3] Maurizio Gallieni.[1,4] *[1]Aziende Socio Sanitarie Territoriale Fatebenefratelli Sacco, Milano, Italy; [2]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [3]Azienda Ospedaliero-Universitaria Consorziale Policlinico di Bari, Bari, Italy; [4]Universita degli Studi di Milano Dipartimento di Scienze Biomediche e Cliniche Luigi Sacco, Milano, Italy.*

Background: Contrast-enhanced computed tomography (CECT) is the imaging of choice for the diagnosis, staging, and follow-up of cancer patients, not to take into account its role to evaluate response to oncological treatments; in fact, it has been estimated that 47% of all CECTs are prescribed by Oncologists. Comorbidities, nephrotoxic concomitant medications, as well as chronic dehydration from different causes (nausea and vomiting, diarrhea, etc …) expose cancer patients to a higher risk of developing acute kidney injury (AKI) from CM. Risk factors, definition (PC-AKI vs CI-AKI) and preventive measures have been recently reconsidered, ultimately downsizing the incidence of this adverse event.

Methods: Aim of this study was to retrospectively assess the effects on renal function of repeated CM administrations in 407 oncological patients on active treatment, collected from 5 Italian oncology departments; patients should have undergone at least 3 CECT (on the average 3.5) within a single year (Fig I).

Results: According to our study, neither significant differences in eGFR values (calculated with the CKD-EPI formula) between the baseline and the different post-CECT timepoints, nor AKI cases (defined according to the RIFLE criteria), were recorded.

Conclusions: Repeated CM administrations in cancer patients did not lead to a worsening of renal function, confirming that CI-AKI has a significantly lower incidence than previously thought. Notably, 80% of the patients examined were found to be at low-risk, highlighting some kind of reluctance of Medical Oncologists and Radiologists to perform CECTs in these patients. On the contrary, the administration of CM could, and should, be freely used, in cancer patients, even in those at a higher risk.

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits: Searching for the Underlying Clone

Vincent Javaugue,[1,2] Virginie Pascal,[3] Sébastien Bender,[2] Jean-Michel Goujon,[1] Guy Touchard,[1] Christophe Sirac,[2] Frank Bridoux.[1,2] Centre national de référence amylose AL et autres maladies par dépôts d'Ig monoclonales *[1]Centre Hospitalier Universitaire de Poitiers, Poitiers, France; [2]Centre National de la Recherche Scientifique, Limoges, France; [3]Centre Hospitalier Universitaire de Limoges, Limoges, France*.

Background: The pathophysiological mechanisms of proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) are still largely unknown. Only 30% of PGNMID cases have a detectable circulating monoclonal immunoglobulin (Ig) and a bone marrow corresponding clone.

Methods: We reviewed a French cohort of PGNMID with particular focus on hematological characteristics. A high-throughput sequencing assay from bone marrow and/or blood mRNA encoding immunoglobulins (RACE-RepSeq) was used to detect the underlying clone.

Results: Seventy-one patients (M/F ratio=1.6, median age 59 years) were included. At diagnosis, 73% had renal insufficiency (median serum creatinine=1.7 mg/dL). All patients had proteinuria, with nephrotic syndrome in 59% and microscopic hematuria in 85% of cases. No patient had extra-renal manifestations. By light microscopy, kidney biopsy revealed membranoproliferative glomerulonephritis (74%), mesangial glomerulonephritis (14%) or membranous glomerulonephritis (12%). By immunofluorescence (IF), deposits stained for IgG in 55 cases (mostly IgG3κ), IgM in 7 cases, IgA in 4 cases or light chain (LC) only in 5 cases. Serum and/or urine immunofixation was positive in 26 cases (37%). An underlying clone was found in 21 cases (30%) using bone marrow or blood flow cytometry analysis. The clonal detection rate was particularly low in IgG3κ-PGNMID (9%). The nature of the clone differed with PGNMID subtype: lymphoplasmacytic in IgM-PGNMID, and plasmacytic in IgA/LC-PGNMID. RACE-RepSeq analysis failed to detect a bone marrow or blood clone in 18/26 cases (IgG3κ-PGNMID, n=17; IgGAκ-PGNMID, n=1). IF analysis of kidney samples using anti-Vκ antibodies showed positive staining for Vκ1, Vκ2, Vκ3 and Vκ4 in 3/3 tested IgG3k-PGNMID patients without a detectable clone, whereas deposits stained only for Vκ2 in one IgG1k-PGNMID patient who had a bone marrow Vκ2 clone by RACE-RepSeq analysis.

Conclusions: These results suggest that PGNMID is a heterogeneous medical condition and that some cases might involve oligoclonal production of nephrotoxic Ig restricted to the IgG3k isotype. Such cases should no longer be classified as MGRS.

PO1891

Rituximab-Associated Flare of Cryoglobulinemic Vasculitis

Janina Paula T. Sy-Go, Charat Thongprayoon, Ziad Zoghby, Nelson Leung, Sandhya Manohar. *Mayo Clinic Minnesota, Rochester, MN*.

Background: Patients with cryoglobulinemic vasculitis (CV) can develop disease flare after rituximab administration. The pathogenesis is hypothesized to be from immune complex deposition in the microvasculature, wherein the immune complex consists of the involved cryoglobulin and an antigenic portion of rituximab. Our objective was to describe the prevalence, clinical characteristics, predisposing factors, and outcomes of rituximab-associated flare of CV.

Methods: We conducted a retrospective study in a tertiary referral center. We defined disease flare as any clinical deterioration within two weeks following rituximab administration, including onset of new organ involvement or worsening of the underlying CV not clearly explained by disease progression alone - with or without laboratory evidence.

Results: Among 64 patients with known CV who received rituximab therapy in our center, 14 (22%) developed disease flare. Median age was 67.5 years. Seven patients (50%) had type II CV while the other half had either type I (n=6) or type III (n=1). Twelve patients (86%) had IgM-mediated CV flare. Twelve patients (86%) had an underlying B-cell lymphoproliferative disorder as the cause of their CV. CV flare occurred after a median time of 5.5 days (range: 2-8 days). The organ systems most involved were the skin (n=10), kidneys (n=5), and peripheral nerves (n=3). Nearly all patients received treatment directed against their underlying diseases, including chemotherapy, corticosteroids, and/or plasmapheresis during the flare. Patients who developed flare were more likely to have B-cell lymphoproliferative disorder as the underlying etiology of their CV (p=0.03), had lower creatinine levels prior to rituximab treatment (0.8 vs. 1.05 mg/dL, p=0.01), and eventually received more treatments with plasmapheresis together with rituximab (p=0.03). Eight patients (57%) died after a median time of 27 months.

Conclusions: In our study, the prevalence of rituximab-associated flare of CV is 22%, and it can occur in all types of CV. Flares tend to arise about two days (less than one week) after rituximab administration and are more likely to happen in patients with an underlying B-cell lymphoproliferative disorder. These flares do not indicate failure of response to treatment. Clinicians should be cognizant of its existence and have a high index of suspicion for this phenomenon.

PO1892

Membranous-Like Glomerulopathy with Masked Monoclonal IgG Deposits

Kumail Merchant,[1] Christine B. Sethna,[1] Mala Sachdeva,[2] Vanesa Bijol,[2] Kenar D. Jhaveri.[2] [1]*Steven and Alexandra Cohen Children's Medical Center, New Hyde Park, NY;* [2]*Northwell Health, New Hyde Park, NY.*

Introduction: Membranous-like glomerulopathy with masked monoclonal IgG deposits (MGMID) is a recently described entity characterized by a membranous pattern of injury with monoclonal IgG-kappa restriction, unmasked by pronase digestion on formalin-fixed paraffin-embedded (FFPE) tissue by immunofluorescence microscopy (IF). Retrospective pathology and chart review was performed within a large health system in the USA between 2019-2021 identifying 5 patients.

Case Description: All 5 patients were Caucasian females with median age 17 years (range 12-48). On presentation, 4 patients had elevated urine protein to creatinine ratio (UPC), 3 had microscopic hematuria, and 1 patient had an eGFR <90ml/min/1.73m^2. Of note, 1 patient presented post-partum. Serologic workup revealed positive antinuclear antibody (ANA) in 1 patient (see table) who had a known history of juvenile idiopathic arthritis. Kidney biopsy revealed a membranous pattern of glomerular injury in all patients, with global glomerulosclerosis from 0-31%, segmental glomerulosclerosis from 2-7%, and interstitial fibrosis and tubular atrophy from 2-50%. Electron microscopy revealed subepithelial/intramembranous deposits without substructural organization. Finely granular capillary wall reactivity for C3 was noted on routine IF on frozen sections. On FFPE after pronase digestion, all cases revealed glomerular capillary wall staining for gamma-1 (4 cases) or gamma-3 (1 case) and kappa light chains; lambda light chains were negative. Extensive hematologic workup was negative for monoclonal bands or lymphoproliferative processes. All patients were treated with angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy, and 2 patients were also treated with Rituximab. Four patients had an improvement in UPC. None of the patients required kidney replacement therapy.

Discussion: MGMID is a peculiar entity with monoclonal IgG glomerular deposits primarily affecting young Caucasian females, without obvious correlation to monoclonal lymphoproliferative disorder. Treatment with ACEi or ARB +/- Rituximab improved UPC in most patients in this case series. Better understanding of this entity is important to guide therapy.

Table. Demographics, serologic workup, treatment, and post-treatment results for patient with MGMID

Patient	age	creat	upc	hematuria	ANA	dsDNA	low C3	low C4	ANCA	RF	SFLC	bone marrow	treatment (tx)	post-tx creat	post-tx upc
1	12	0.34	1.17	+	+	-	-	+	-	-	TNP	TNP	ACEi	0.6	0.43
2	17	0.99	1.7	-	-	-	-	-	-	TNP	TNP	TNP	ACEi/ARB	0.85	0.5
3	17	0.77	1.1	+	-	-	-	-	Ind	-	TNP	TNP	ACEi	0.77	0.2
4	26	0.78	5.5	+	-	-	-	-	-	+κ	-		ACEi/Ritux	0.93	2.7
5	48	1.80	0.1	-	-	-	-	-	-	TNP	+κ	-	ACEi/Ritux	1.47	0.6

Abbreviations: creat, serum creatinine; upc, urine protein to creatinine ratio; ANA, antinuclear antibody; dsDNA, anti-double stranded DNA antibody; ANCA, anticytoplasmic nuclear antibody; RF, rheumatoid factor; SFLC, serum free light chains; +, positive; -, negative; Ind, indeterminate; TNP, test not performed; κ, kappa; ACEi, angiotensin converting enzyme inhibitor; ARB, angiotensin receptor blocker; Ritux, rituximab.

PO1893

Thrombotic Microangiopathy, Its Clinical Characteristics, Etiologies, and Outcomes: A Case Series of 33 Patients

Yuriy Khanin, Kenar D. Jhaveri, Vipulbhai Sakhiya, Purva D. Sharma. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Thrombotic Microangiopathy (TMA), is a pathologic pattern of injury that has a variable presentation and etiologies. Here we present a case series of 33 patients from our academic center with biopsy proven TMA, describe their clinical characteristics and compare the differences between drug- induced TMA and other causes of TMA (Table 1)

Methods: We collected data on clinical characteristics, detailed biopsy findings, etiologies and treatment details for 33 patients at our institution with biopsy proven diagnosis of TMA

Results: The average age of the patients who had a kidney biopsy diagnosis of TMA was 49.18 years. 13/33 patients were African-American. Upon initial assessment, 29/33 patients had acute kidney injury, 9/33 had malignant hypertension (BP> 180/120 on presentation), and 15/33 had MAHA. In those in which a cause was able to be determined, 12/33 had drug induced TMA with the most common medication being VEGF inhibitors & Tyrosine kinase inhibitors with anti-VEGF properties (8/12). Three patients had TMA secondary to calcineurin inhibitors and one patient had cocaine induced TMA. 3/33 had complement mediated TMA, diagnosed by confirming activation of the alternative complement cascade. In patients with drug induced TMA, 6/12 patients had improved proteinuria and kidney function after withdrawl of the drug, 3 remained dialysis dependent and 2 were transitioned to home hospice. In the drug induced TMA category, 33% patients were dialysis dependent on discharge from the hospital as opposed to 43% in the non-drug induced TMA category.

Conclusions: Every patient with biopsy proven TMA should undergo a thorough history including medication use and work up, so optimal management can be initiated. In our series, 50% of the patients with drug induced TMA improved after withdrawl of the culprit medication.

PO1894

TAFRO: A New Cause for Thrombotic Microangiopathy Mimicking Atypical Hemolytic Uremic Syndrome Successfully Treated with Anakinra and Eculizumab

Kathryn O'Brien, Daniel L. Landry, Giovanna M. Crisi, Jeffrey Mulhern, Gregory L. Braden. Kidney Care & Transplant Services of New England *UMASS/Baystate, Springfield, MA.*

Introduction: arTAFRO is syndrome of Castleman's disase with : thrombocytopenia, anasarca, myelofibrosis, AKI & organomegaly. We present a 17 yr old girl with abdominal lymph nodes who rapidly developed anasarca, splenomegaly, AKI requiring dialysis, & respiratory failure requiring mechanical ventilation. After a lymph node bx 2 months later showed multicentric Castelman's, plasma cell variant, we realized she early on had TAFRO.

Case Description: She rapidly developed ansarca, an 18 cm spleen, & abdominal nodes to 1.9 cm. Bacterial cultures, spinal tap, viral resp panel, mono, HIV, HVV-8 levels were normal (NL). Hg dropped to 6.7 gm/dl without hemolyisis, platelets 57,000 & WBC,15,500. CRP was 32.5 & sed rate 130. Oliguria ensued & creatinine rose to 3.6 mg/dl. Urinalysis had +1 protein, +3 blood with granular casts. ANA, ASO, streptozyme, myeloperoxidae, proetinase -3, serum immunofixation, anti-phospholipid abs, IgG subclasses, anti-mitochondrial & smooth muscle abs, HLA-B27, ADAMSTS-13 levels & abs were NL. IL-2R levels were markedly high at 12,340 pg/ml as were IL-18, 930 pg/ml, CXCL9 107 pg/ml but Il-6 was only 11.3 pg/ml. Bone marrow showed inceased megakaryocytes & no hemophagocytosis. aHUS testing was negative for all geneitc causes & no abs were found to any complements(C) but both, C3, 65 mg/dl & C4, 4 mg/dl were low & the membrane attack complex C5-C9, markedly elevated at > 50 mg/dl. Renal bx showed endothelial swelling & thrombotic micoangioapathy (TM) confirmed on EM with negative IF. 3 pulses of solumedrol daily, dialysis, 2 plasmaphareses before the aHUS panel returned were started along with 2 doses of Anakinra, an anti-IL-1 drug, 4mg/kg sub q separated by 3 days & 1 dose of Eclizumab, 1200 mg iv. She rapidly improved, was extubated & was discharged off dialysis with a NL creatinine & no edema.

Discussion: We conclude: 1). TAFRO can mimic aHUS & present with markedly elevated IL-2R levels rather than IL-6 levels which can fix complement by the classsic pathway leading to high membrane attack complexes adding to capillary leak, anasarca and TM. 2) An Anti IL-1 drug, Anakinra, & a drug inhibiting C5 cleavage to C5a & C5b, Eclizumab can be combined to successfully treat TAFRO 3) TAFRO must now be added to all reviews and textbooks as a new cause for TM & AKI with classic complement pathway activation.

PO1895

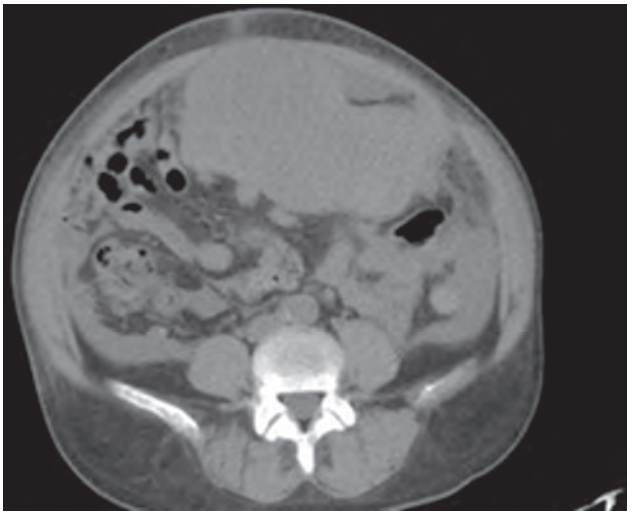
Large Abdominal Mass: An Unusual Presentation of Multiple Myeloma

Naseer Khan,[1,2] Rama Nadella,[1,2] Gregory W. Proctor,[1,2] Paul L. Cespedes,[1,2] Irfan Agha.[1,2] Medical City Dallas Hospital, Dallas, TX *[1]Medical City Dallas Hospital, Dallas, TX; [2]Dallas Renal Group, Dallas, TX.*

Introduction: Extramedullary Soft Tissue Mass (ESTM) is an infrequent presentation of Multiple Myeloma. We present a unique case of Multiple Myeloma with very large bulky tumor masses.

Case Description: A 69 year old AA female presented with severe abdominal distention. CT Scan showed a 17 x 10 x 10 cm mass originating in the retroperitoneal region, a 12.5 cm mass in the pelvis and a 4.3 x 2.7 cm mass in the liver as shown in the image. Further testing showed anemia and renal failure. Biopsy of the mass revealed multiple myeloma, driving a monoclonal IgG lambda clone. FISH panel was positive for 17P/TP53 deletion which is very unfavorable. Patient was treated initially with dexamethasone/cyclophosphamide/Velcade and later with Daratumumab/Carfilzomib/dexamethasone without any response and remained on dialysis ultimately succumbing within 6 weeks of diagnosis.

Discussion: Initial Extramedullary Soft Tissue Mass (ESTM) manifestations in Multiple Myeloma occur in about 3% of the cases. In a large majority (93.5%) these lesions are solitary. Our patient had large, multiple masses with high tumor burden and unfavorable cytogenetic signature. She did not respond to therapy despite utilization of aggressive regimens. This is a very unique presentation of myeloma and with the unfavorable characteristics, had a dismal prognosis despite aggressive therapy.



CT Abd showing ESTM

PO1896

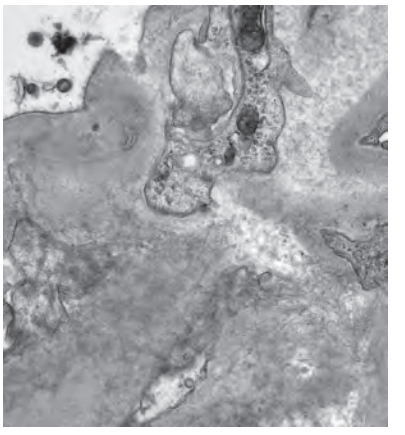
Fibrillary Glomerulonephritis and Graft vs. Host Disease

Omar S. Elbita, Gunjan Garg. *University of Louisville, Louisville, KY.*

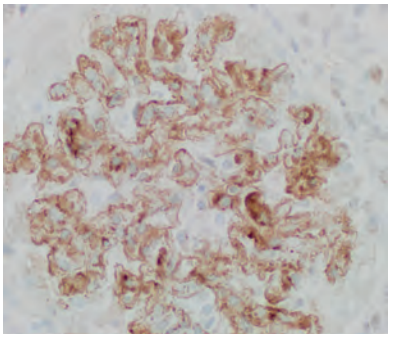
Introduction: Fibrillary Glomerulonephritis (FGN) is rare and seen in 1% of kidney biopsies. Etiology is unkown. It is associated with malignancy, monoclonal gammopathy, autoimmune disorders and infections. There has not been FGN case reported in a pt with Graft Versus Host Disease (GVHD). We present a case AKI sec to FGN with h/o Acute Lymphocytic Leukemia, status post Allogeneic Stem Cell Transplant complicated by Gastrointestinal GVHD.

Case Description: 67 yo African American female with DM, HTN, ALL s/p ASCT in remission, recently diagnosed with GI GVHD, presented with nausea, vomiting & diarrhea. Vitals: BP 140/70, Temp 37°C, HR 109. Exam showed 3+ LEs edema. Labs: Cr 3.5 mg/dL, baseline of 1.1mg/dL. Urinalysis showed hematuria and14.6g/g protein. Histology showed C3 crescentric GN. DNAJB9 stain returned positive and EM findings confirmed FGN. Patient recieved Soulmedrol, followed by Rituximab and then Cyclophosphamide. She was dialysis dependent within 6 mos of diagnosis.

Discussion: FGN may have an undescribed association with GVHD. It is understudied because of rarity. It can present with AKI and kidney Bx is needed for diagnosis and to guide treatment. The trigger to get biopsy was the unexplained protein & blood in urine. Cr stabilized intially. However, earlier diagnosis and treatment could have delayed progression to ESRD.



Fibrils in mesangial matrix



DNAJB9 staining

PO1897

Recurrent Fibrillary Glomerulonephritis Secondary to Chronic Lymphocytic Leukemia: A Rare Case of Treatment Success

Rafeea Shah. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Introduction: Fibrillary GN is a rare form of glomerular disease characterized by the random deposition of small (20nm) fibrils in the mesangium and capillary walls of the glomerulus. There is a recognized association with hepatitis C, malignancy and autoimmune conditions. It is poorly responsive to treatment and up to half of the patients reach ESRD by six years. We present a case of Fibrillary GN secondary to CLL with complete remission after receiving Bendamustine and Rituximab and a subsequent relapse treated with Ibrutinib with good renal recovery.

Case Description: A 69-year-old male presented in 2014 with a pathological spinal fracture and was subsequently found to have CLL. He had normal renal function and no proteinuria at the time of diagnosis and his CLL was managed conservatively. In 2016 he developed nephrotic syndrome (ACR >1000) with a significant decline in renal function to an eGFR of 18ml/min. He underwent a renal biopsy which showed an MPGN pattern of injury with fibrils on electron microscopy suggesting fibrillary glomerulonephritis. He received Bendamustine and Rituximab for CLL and went into complete remission of his nephrotic syndrome and improvement in renal function to eGFR of 57ml/min.

He remained in remission for four years. In 2020 he had relapse of his nephrotic syndrome and eGFR dropped to 17ml/min. Further imaging suggested progression of the CLL. He had a further renal biopsy which again confirmed recurrent Fibrillary GN. He was started on the Tyrosine kinase inhibitor (TKI) Ibrutinib in December 2020 and within 3 months his renal function had improved to an eGFR of 33ml/min and reduction in proteinuria.

Discussion: TKIs have mostly been linked with kidney injury secondary to the potential deleterious effects on the renal endothelium. This is the first reported case of the use of a TKI as a treatment for Fibrillary GN secondary to CLL. In addition, there is scarcity of experience with relapse of Fibrillary GN as it is usually a progressive disease and with little prospect of recovery. This case highlights the following: If there is an identifiable cause driving Fibrillary GN, treatment can be associated with remission of proteinuria and improvement in renal function. Monitoring of the underlying disease is important as recurrence can result in subsequent relapse of nephrotic syndrome. TKIs used with caution can be beneficial in the setting of MGRS.

PO1898

Ruxolitinib for Graft vs. Host Disease-Associated Nephrotic Syndrome: A Case Report

Aman Deep, Vikas Vujjini, Abdallah Sassine Geara. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Graft-versus-host disease (GVHD) is a serious complication of allogenic stem cell transplant in which donor T-cells attack the host antigens. We report a case in which ruxolitinib successfully treated GVHD-related nephrotic syndrome.

Case Description: A 48-years-old male known to have myelodysplastic syndrome (MDS) was referred for evaluation of proteinuria. He was diagnosed with MDS four years prior. Since his disease was persistent with azacitidine, he received allogenic stem cell transplant (SCT) about a year after the MDS diagnosis and he achieved complete remission. However, the post-transplant course was complicated by chronic GVHD which manifested mainly as non-specific interstitial pneumonia (NSIP) about three and a half-year post-transplant. NSIP was treated with high-dose oral steroid therapy, which was tapered down to a maintenance dose of 10 mg daily, and Mycophenolate Mofetil. During his course of GVHD, he had persistent mild proteinuria (UPCR less than 1 g/g of creatinine) without active urine sediment. This proteinuria was noted initially prior to NSIP diagnosis, improved while on high-dose prednisone but progressively worsened after the prednisone was tapered to 10 mg once daily. The proteinuria peaked at 2.4 g/g of creatinine with hypoalbuminemia of 2.6 g/dL at which point it was investigated with a renal biopsy. Renal biopsy showed Membranous Nephropathy with negative staining for anti-PLA2R antibody. The patient was started on ruxolitinib at a dose of 10 mg twice a day. Subsequent follow-up showed drastic reduction in proteinuria. UPCR (g/g of creatinine) of 0.96, 0.4 and 0.09 was noted at 1,2- and 5-months post-therapy initiation respectively.

Discussion: Nephrotic syndrome is a rare manifestation of GVHD with membranous nephropathy histology seen in almost two thirds of patients. Traditionally treated with high-dose steroid with variable efficacy, we decided against it due to the patient-reported adverse effects from prior high-dose steroid therapy. Recent studies such as REACH2 and REACH3 trials have demonstrated that ruxolitinib, a selective Janus Kinase (JAK) 1 and 2 inhibitor, has superior efficacy than other second-line therapy options available. Hence, ruxolitinib can be considered in GVHD-associated Nephrotic syndrome especially if a steroid-sparing approach is needed.

PO1899

Clonal Hematopoiesis of Indeterminate Potential Is Associated with Worse Kidney Function and Anemia in a Cohort of Patients with Advanced CKD

Caitlyn Vlasschaert,[1] Amy J. Mcnaughton,[1] Wilma M. Hopman,[1] Bryan R. Kestenbaum,[2] Cassianne Robinson-Cohen,[3] Sarah M. Moran,[1] Jocelyn S. Garland,[1] Rachel M. Holden,[1] Matthew B. Lanktree,[4] Michael J. Rauh.[1] *[1]Queen's University, Kingston, ON, Canada; [2]University of Washington, Seattle, WA; [3]Vanderbilt University, Nashville, TN; [4]McMaster University, Hamilton, ON, Canada.*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is an inflammatory premalignant disorder resulting from acquired genetic mutations in hematopoietic stem cells. CHIP is common in aging populations and associated with cardiovascular morbidity and overall mortality, but its role in chronic kidney disease (CKD) has not been investigated.

Methods: We performed targeted sequencing to detect CHIP mutations in a cohort of 87 adults with advanced CKD (eGFR < 60 ml/min/1.73m2). Kidney function, hematologic, and mineral bone disease parameters were assessed cross-sectionally at baseline, and a total of 2,091 creatinine measurements and 3,382 hemoglobin measurements were retrospectively collected over the following 12-year period.

Results: At baseline, 20 of 87 (23%) cohort participants had CHIP detected. Those with CHIP had lower baseline eGFR (22.3 ± 2.5 vs. 28.2 ± 1.4 ml/min/1.73 m2, P = 0.04) in age- and sex-adjusted regression models. Individuals with CHIP had a 2.5–fold increased risk of a 50% decline in eGFR or ESKD in a Cox proportional hazard model adjusted for age and sex (95% confidence interval, 1.3–4.7). Further, those with CHIP had lower hemoglobin at baseline (11.6 ± 0.3 vs. 12.8 ± 0.2 g/dL, P = 0.0003) and throughout the follow-up period despite a greater use of erythropoiesis-stimulating agents. Mean cell volume was associated with variant allele fraction, suggesting CHIP may contribute to defective erythropoiesis in CKD.

Conclusions: CHIP was associated with lower eGFR, progression of CKD, and anemia in individuals with advanced CKD. Further assessment of the direction of causality between CHIP and CKD and validation in additional cohorts is required.

PO1900

Case of C3 Glomerulopathy in a Patient with Mesothelioma

Mohammad Al-Hasan, Loay H. Salman, Geovani Faddoul. *Albany Medical Center, Albany, NY.*

Introduction: C3 glomerulopathy has been described in autoimmune diseases and in monoclonal gammopathy caused by plasma cells and B-cell lineage cells malignancies. There have been no reports of C3 glomerulopathy that is associated with mesothelioma. We report here a case of C3 glomerulonephritis was diagnosed in patient with pulmonary mesothelioma.

Case Description: 84-year-old male patient presented with shortness of breath with fluid overload and vasculitic rash in the lower extremities, elevated BUN and creatinine and potassium of 5.7. Patient has been diagnosed with resectable pulmonary mesothelioma two months prior to his presentation and had received only one treatment of immune check inhibitor (Nivolumab plus Ipilimumab) one day prior to admission. Work up was done and showed AKI, proteinuria and hematuria, but negative work up for autoimmune disease or paraproteinemia or an infectious etiology. Decision was made to proceed with kidney biopsy which showed C3-dominant immune-complex mediated glomerulonephritis affecting about 35% of glomeruli with segmental crescent formation in about 5% of the glomeruli, diffuse acute tubular injury and minimal interstitial fibrosis and tubular atrophy.

Discussion: C3 glomerulopathy has been associated with autoimmune diseases and hematological malignancies and is related to uncontrolled activation of the alternative complement pathway, however solid tumors like mesothelioma may also trigger an immune mechanism that would lead to C3 glomerulopathy. We will discuss the possibility that the C3 glomerulopathy was due to or in association with the recent diagnosis of mesothelioma, also I will discuss the possible mechanisms of this association.

PO1901

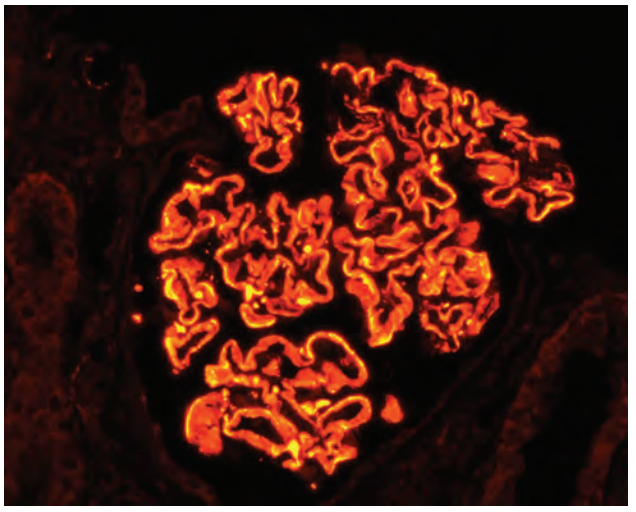
NELL-1 Membranous Nephropathy Associated with Diffuse Reactive Lymphadenopathy

Hatem Elabd,[1] Joel D. Murphy,[2] Tarek Rashid,[3] Hanny Sawaf.[4] *[1]TriHealth, Cincinnati, OH; [2]Arkana Laboratories, Little Rock, AR; [3]Bayonne Medical Center, Bayonne, NJ; [4]Cleveland Clinic, Cleveland, OH.*

Introduction: We present a case of neural epidermal growth factor like-1 (NELL-1) MN associated with diffuse lymphadenopathy without evidence of malignancy or autoimmune disease.

Case Description: A 53-year-old woman with a BRCA 1 mutation presented with nephrotic syndrome. Diffuse lymphadenopathy was found on examination. Laboratory evaluation revealed serum albumin of 1.9 mg/dl, creatinine of 0.4 mg/dl, and UPCR 13.5 g/g. Urine microscopy showed protein (4+), and bland urine sediment. Serum PLA2R antibody was negative. Four excisional lymph node biopsies were performed, all of which revealed reactive hyperplasia without evidence of hematological malignancy. Flow cytometry and a bone marrow biopsy were negative. Serology for ANA, CRP, ESR, C3, C4, EBV, HIV, and Hepatitis B, and C were all negative. Renal pathology revealed diffuse, fine pinholes along the glomerular basement membranes using a Jones sliver stain. By immunofluorescence (IF), glomeruli showed diffuse, global finely granular capillary loop staining for IgG (3+), C3 (1-2+), and stained equally for κ and λ light chains. An IF stain for NELL-1 showed diffuse granular staining capillary loops (3+) while immunohistochemical stains for PLA2R and EXT2 were essentially negative. The ultrastructural evaluation revealed numerous, confluent subepithelial electron-dense deposits along with severe foot process effacement.

Discussion: NELL-1 associated MN was recently discovered as a distinct type of MN. In one series, 33 % of NELL-1 MN associated with malignancies, which is more often than the other known types of MN. The constellation of findings in this case with NELL-1 MN associated with reactive diffuse lymphadenopathy without evidence of malignancy or autoimmune disease is a rare presentation. Therefore, this case adds to the existing literature on NELL-1 associated MN, which helps to raise the awareness of this novel clinical presentation.



NELL-1 granular capillary loops staining

PO1902

Nephrotic Syndrome as a Paraneoplastic Entity

Nancy Daniela Valencia-Morales,[1] Clara García-Carro,[1] Juan León Román,[2] Maria Jose Soler,[2] Arianne Aiffil-Meneses,[1] Maria Dolores Sanchez de la Nieta Garcia,[1] Antolina Rodriguez,[1] Mercedes L. Velo,[1] Elena Valdés-Francí,[1] Ana Sanchez fructuoso.[1] *[1]Hospital Clinico Universitario San Carlos, Madrid, Spain; [2]Vall d'Hebron Hospital Universitari, Barcelona, Spain.*

Background: Association between nephrotic syndrome (NS) and cancer is known but it has been barely studied. Membranous nephropathy (MN) has been identified as a paraneoplastic disease. Incidence of cancer at the time of biopsy of MN is 10-20%. Rates in other glomerulopathies are limited. Concomitant malignancy is associated with poor outcome in NS: cancer therapy is a priority and immunosuppression for NS should be restricted. There is no consensus for cancer screening in patients with NS, with or without known risk factors. Aim: To establish the incidence of cancer in a cohort of patients with NS onset & to analyze clinical & histologic characteristics, type and risk factors for cancer.

Methods: All patients with NS at one hospital in Madrid between 1/2013-12/2019 and all patients with NS at one hospital in Barcelona between 1/2018- 6/2020 were included. Demographical, clinical and laboratory data were recorded. Patients who presented cancer 1 year before or 2 years after NS onset were identified. A logistic regression model was performed to identify risk factors for cancer.

Results: 114 patients presented with NS during the study periods. 57% men, mean age 57.3±17.3. 60% presented high blood pressure, 36% DM2, 7% HIV, and 6% hepatitis C. 44.7% reported smoking, and 13.1% alcohol consumption. More frequent histologic diagnosis: diabetic nephropathy (17.5%), MN (14.9%), minimal change disease (7.9%), membranoproliferative glomerulonephritis (7.9%). 8 patients presented anti phospholipase A2 receptor antibodies. 17.5% patients presented cancer: 12 patients 1 year before the NS onset (10 solid organ, 2 haematological cancer), and 8 patients 2 years after NS onset (3 solid organ, 5 haematological cancer). Patients with cancer were older (72.3±10.3 vs 53.2±17.1, p<0.0001). No differences in smoking, viral infections, renal function, proteinuria or glomerulopathy. Multivariate analysis showed age as the only risk factor for cancer (OR 1.122, IC 95% 1.050-1.1980; p=0.0007).

Conclusions: In our cohort, 17.5 % patients with NS presented also concomitant cancer. Age was the only risk factor for neoplasia. No association between cancer and gender, type of glomerulopathy, or known risk factors for neoplasia as alcohol, tobacco or viral infection was found.

PO1903

Complement Activation in a Mouse Model of Cisplatin-Induced Renal Interstitial Fibrosis

Min Feng,[1] Jianan Su,[1] Honghui Zeng.[2] *[1]Department of Nephrology, Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China; [2]Medical Research Center, Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Cisplatin is widely used for tumor chemotherapy. Renal interstitial fibrosis and chronic renal failure could be induced by periodic use of cisplatin. The mechanism of cisplatin induced renal interstitial fibrosis needs to be clarified.

Methods: In cisplatin group, male C57BL/6 mice were intraperitoneal injected with cisplatin(10mg/kg) on day 0, 7 and 21, and killed on day 28. In control group, mice were intraperitoneal injected with saline and killed at the same timepoint as cisplatin group. The kidney tissue was collected for RNA Illumina high-throughput sequencing, real-time PCR, western blot and masson staining.

Results: Through real-time PCR, western blot and masson staining, successful establishment of a mouse model with cisplatin induced renal interstitial fibrosis was confirmed. Through RNA high-throughput sequencing, 387 long noncoding RNAs(lncRNAs) and 2427 mRNAs were differently expressed between cisplatin group and control group. The expression of lncRNA MSTRG.8677 and lncRNA MSTRG.405 were verified by real-time PCR with the same tendency as RNA sequencing. Complement C3 was found to be at the top among the different expressed mRNAs by RNA sequencing. Several terms related to immunity were found to be within the top 20 terms through GO enrichment analysis of different expressed mRNAs. Systemic lupus erythematous pathway(ko05322,Q=3.4e-17), including the complement cascade pathway, was found to be the top pathway through KEGG enrichment analysis of different expressed mRNAs. The mRNA expression of C3, C1q, C2 and C4 were found to upregulated remarkably in cisplatin group by RNA sequencing and verified by real-time PCR.

Conclusions: Renal interstitial fibrosis could be induced by intraperitoneal injection of cisplatin periodically in mice, with complement cascade pathway activation in the diseased kidney.

PO1904

Changes in Humoral Biomarkers (Klotho) in Patients with Haematological Tumors Undergoing Chemotherapy and Allogeneic Bone Marrow Transplantation Developing AKI

Simone Fontana, Chiara Lanzani, Elisabetta Messaggio, Paolo Manunta. UO nefrologia San Raffaele, UO ematologia San Raffaele *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Acute kidney injury (AKI) is a complication in patients with hematological cancers after chemotherapy (CT) receiving allogeneic bone marrow transplant. It increases the morbidity and mortality rate associated with the procedure. Some urinary/plasma biomarkers (Klotho) have been evaluated as predictors of AKI development after cardiac surgery showing high prognostic value

Methods: Our work is investigating the role and association of these determinants as early markers of susceptibility to AKI during CT, and predictors of CKD. So far, we have enrolled 13 leukemic patients who are candidates for induction CT and subsequent bone marrow transplantation. All the patients carried out sampling for renal function at each

cycle and at the same time plasma and urine were collected. Klotho plasma levels were measured in 4 phases diagnosis (t1); onset of AKI/2 months from diagnosis in patients without damage (t2); 15 days after t2 (t3); bone marrow tx (t4)

Results: We measured Klotho levels in 13 patients. The subjects are respectively 9 M and 4 F, mean age 49 years, all with normal renal function (mean creatinine 0.81 mg/dl) at diagnosis. The mean number of chemotherapy courses was 3.2. 7 patients developed stage I AKI according to AKIN criteria. No differences in anthropometric parameters were observed between the two groups. In subjects with development of renal damage, the average time of development was 2 months from diagnosis. While plasma Kl decreases in a similar way in the first CT in the two groups, in no-AKI group the filtrate return normal before the next cycle. The restoration of normal kidney function is not observed in the Aki group (MANOVA p <0.006)

Conclusions: This trend allows us to hypothesize that Kl is an indication of incomplete recovery of renal (tubular?) function before the next CT cycle, predisposing to the development of kidney disease

PO1905

Systemic Amyloidosis Presenting as Progressive Dysphagia, Hypercalcemia, and Proteinuria

Kennerly C. Patrick, Shreyank D. Tripathi, Nilang G. Patel. *Virginia Commonwealth University Health System, Richmond, VA.*

Introduction: Systemic amyloidosis consists of several disorders whereby amyloid fibrils deposit in the extracellular tissue of multiple organs and as such, is associated with a wide spectrum of disease leading to significant morbidity and mortality. The severity and clinical manifestations of systemic amyloidosis is highly dependent on the site of amyloid fibril deposition.

Case Description: We present a 75-year-old male with no medical history who presented with dysphagia and epigastric abdominal pain. Lab work revealed moderate hypercalcemia and acute kidney injury (AKI) with urinalysis significant for >500mg/dL of protein. He received intravenous fluid resuscitation with improvement in renal function and temporary resolution of hypercalcemia. His AKI and hypercalcemia were attributed to volume depletion and possible milk-alkali syndrome due to consumption of calcium carbonate. After discharge however, he continued to have persistent sub-nephrotic range proteinuria, mild hypercalcemia and progressive renal insufficiency. UPEP and serum free light chain analysis revealed elevated kappa light chains. A kidney biopsy showed glomeruli with mesangial expansion as well as Congo red positive staining of glomeruli, interstitium, and vessels. Electron microscopy showed mesangial deposition of fibrillary material consistent with AL kappa light chain renal amyloidosis. Prior to follow up with Hematology, he was re-hospitalized for AKI, acute liver injury concerning for hepatic amyloidosis and progressive dysphagia likely due to gastrointestinal involvement. Therapy was initiated with bortezomib and dexamethasone; however, no significant kidney recovery was observed, and he remained dependent on dialysis. Due to rapid clinical decline, additional chemotherapy was not offered, and he was transitioned to comfort care.

Discussion: This patient presented with dysphagia, persistent hypercalcemia, renal insufficiency and proteinuria highlighting the clinical variability of systemic amyloidosis. As such, systemic amyloidosis, a rare infiltrative disorder, requires a high level of clinical suspicion in order to reach an early diagnosis and prevent long-term complications and mortality associated with advanced, multi-organ involvement. In addition, it is crucial to exclude coexisting multiple myeloma in patients presenting with hypercalcemia, renal insufficiency and AL amyloidosis.

PO1906

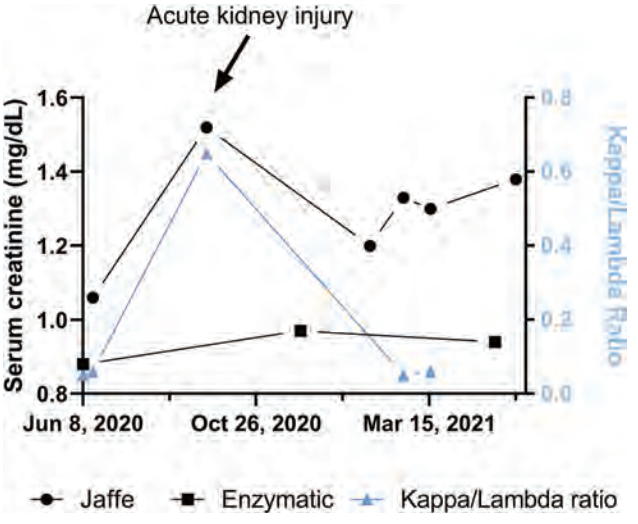
Will the Real Creatinine Please Stand Up? Elevated Creatinine in a Patient with Smoldering Myeloma

Evan Zeitler. *UNC Kidney Center, Chapel Hill, NC.*

Introduction: Monoclonal gammopathies cause altered kidney function by a variety of mechanisms. The assessment of patients with monoclonal proteins is further complicated by non-physiologic alterations in laboratory assays, including the assessment of serum creatinine, as reported in this case of a patient with smoldering myeloma.

Case Description: A 47 yo woman with a history of mixed connective tissue disease, hypertension, and IgG lambda light chain smoldering myeloma was referred for evaluation of creatinine of 1.6 mg/dL. Her medications were acebutolol, furosemide, hydrochlorothiazide and aspirin. Examination revealed BP 129/86, HR 60 without notable physical findings. Her laboratory evaluation was significant for a creatinine of 0.88 mg/dL, BUN of 10 mg/dL, albumin of 4.6 g/dL and total protein of 9.0 g/dL, with an M-spike of 1 g/dL. Her urine protein-creatinine ratio was 0.47 g/g creatinine. Over the next year, creatinine at her primary oncologist ranged from 1.2-1.3 mg/dL (except for a single episode of acute kidney injury), while in the nephrology clinic the creatinine was 0.8-0.9 mg/dL. Further investigation determined that the external lab used a picric acid-based creatinine assay, while creatinine from the nephrology clinic was measured using an enzymatic method.

Discussion: Monoclonal proteins have previously been reported to interfere with creatinine assays, primarily in patients with Waldenstrom's macroglobulinemia. We report here a patient with a monoclonal IgG lambda paraprotein interfering with a Jaffe-based creatinine assay leading to pseudohypercreatininemia. Both nephrologists and oncologists should be aware of this phenomenon in the care of patients with all types of paraproteinemias, so that alternative means of kidney function assessment (such as measurement of cystatin c) can be employed when creatinine assays are unreliable.



Serum creatinine and kappa/lambda free light chain ratios

PO1907

A Unique Case of Light Chain Proximal Tubulopathy

Trevor W. Tobin, John M. Childs, Christina M. Yuan. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Light chain proximal tubulopathy (LCPT), a rare form of monoclonal gammopathy of renal significance (MGRS), is characterized by the accumulation of monotypic light chains within proximal tubular cells. LCPT may present in multiple ways, including acute kidney injury, chronic kidney disease (CKD), Fanconi's syndrome, and proteinuria. We present a case of LCPT, presenting with CKD and non-nephrotic range proteinuria (NNRP).

Case Description: A 62 year old Caucasian male with a past medical history of IgM kappa light chain monoclonal gammopathy of undetermined significance (MGUS) presented for evaluation of CKD. Serum creatinine at the time of initial presentation was 1.4 mg%, which correlated with an estimated GFR of 54. No other electrolyte derangements were present. Urinalysis was negative for glycosuria, pyuria, or hematuria with unremarkable urine microscopy. He had NNRP on spot quantification of approximately 400 mg/g creatinine and 32 mg/g of this proteinuria was albuminuria. There was no history of hypertension or diabetes, and he denied NSAID use. He was taking no medications felt to cause chronic interstitial nephritis. Renal ultrasound was unremarkable, and 24 hour ambulatory blood pressure monitoring documented normal BP levels, on no medications. At follow up, the patient's creatinine fluctuated between 1.4-1.6 mg%, and his proteinuria between 400-600 mg/g creatinine. Renal biopsy was pursued because there was no apparent cause to explain his CKD. Biopsy revealed numerous kappa light chain crystalline structures within proximal tubular epithelial cells by immunofluorescence staining of paraffin sections, after pronase-digestion. There was no other evidence of multiple myeloma or Waldenstrom's macroglobulinemia on prior bone marrow biopsy. He subsequently began therapy with bendamustine and rituximab.

Discussion: We present a case of LCPT manifesting as CKD G3a A1-2. The case was indolent in nature, but was confirmed on renal biopsy using paraffin digestion to prove monoclonality of the crystalline deposits. This led to the diagnosis of a MGRS, and necessitated initiation of chemotherapeutic agents. LCPT is a rare manifestation of MGRS, and might not have been recognized in this case if suspicion had not been high, and biopsy had not been pursued.

PO1908

Deceiving Schistocytes

Catarina A. Gonçalves, Maria Teresa Furtado, Patrícia A. Domingues, Ana D. Piedade, Ana Natario. *Centro Hospitalar de Setubal EPE, Setubal, Portugal*.

Introduction: Myelodysplastic syndrome (MDS) is a clone bone marrow disorder characterized by dyshematopoiesis, which may manifest as cytopenias and non-immune hemolytic anemia. Schistocytes are commonly associated with causes of microangiopathic hemolytic anemia (MAHA), however, schistocytosis with a high reticulocyte count in the peripheral blood smear is a rare and unusual manifestation of MDS.

Case Description: We report the case of a 63-year-old male who presented with complaints of asthenia, fatigue and malaise for the past 3 months. His previous medical history included a past of heavy smoking, arterial hypertension and grade 3 chronic kidney disease (CKD) developed after nephrectomy due to urothelial carcinoma in 2012. He also had in situ papillary urothelial carcinoma of the bladder in 2016, with a course of intra-vesical mitomycin. Vital signs were normal and physical examination was unremarkable. Blood work revealed macrocytic anemia (hemoglobin 7.2g/dL; MGV 101fL) and thrombocytopenia (77.000/μL) and peripheral blood smear demonstrated 16% schistocytes, with normal coagulation tests, lactate dehydrogenase and haptoglobin. Coombs test was negative. Renal function was stable and there was no evidence of hematoproteinuria. Inflammatory markers were negative. A diagnosis of microangiopathic anemia was assumed and the patient was started on daily plasmapheresis and steroids, while further investigation was under way. Folate and cobalamin levels were normal, anti-nuclear antibodies and HIV, hepatitis B and C serologies were negative and full-body CT scan did not show signs of occult malignancy. Levels of C3 and C4 were also within the normal range. ADAMTS-13 activity was 21%. No clinical or analytical improvement was noted after 6 sessions of plasmapheresis (platelet count nadir of 38.000/μL and persistence of schistocytosis). Bone marrow biopsy was performed and a diagnosis of refractory anemia with excess blasts was made.

Discussion: Hemolytic anemia is a common occurrence in patients with hematologic malignancies, particularly acute and chronic myeloid leukemia, but are rarely observed in MDS, with only a few cases reported in the literature. This case highlights the importance of considering a diagnosis of MDS in patients presenting with refractory cytopenias and MAHA.

PO1909

Granulomatous Interstitial Nephritis Secondary to Chronic Lymphocytic Leukemia

Elizabeth C. Kurtz,[1] Maricel Castaner,[2] Sheldon Bastacky,[1] Syeda B. Ahmad.[1] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Allegheny Health Network, Pittsburgh, PA.*

Introduction: Granulomatous interstitial nephritis (GIN) is a rare disorder defined by histological interstitial nephritis and interstitial granulomas. Common association includes medications, sarcoidosis, and infections. We present a less common case of GIN secondary to chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL).

Case Description: A 57 year old male with benign prostatic hypertrophy presented in early 2020 with leukopenia, lymphadenopathy, and sicca symptoms. A lymph node biopsy in March 2020 revealed non caseating granulomatous lymphadenitis diagnosed as sarcoidosis without clear pulmonary involvement and treated with steroids. His creatinine (Cr) was 0.83 mg/dL, calcium 9.5 mg/dL, white blood cell count of 2600, hemoglobin 12.6 g/dL, platelet count of 322,000, lactate dehydrogenase 1094 U/L, uric acid 8.3 mg/dL, negative SS-A/SS-B, negative Epstein Barr Virus, angiotensin converting enzyme 70 U/L, and a normal urinalysis. In August 2020, his Cr rose to 4.24 mg/dL, with urine studies notable for 1+ protein and rare eosinophils. He had negative hepatitis B, hepatitis C, ANA, MPO, and PR3. His free kappa/lambda ratio was 1.89 (normal) and negative serum protein electrophoresis. PET/CT showed non-FDG avid diffuse lymphadenopathy. Renal biopsy revealed mesangial hypercellularity, severe interstitial inflammation, a lymphocyte predominant infiltrate with CD 20 positive B cells and non-caseating granulomas with eosinophils. He was diagnosed with GIN with atypical B cell lymphoid infiltrate. His prednisone dose was increased and he underwent a bone marrow biopsy revealing a CD5+ B cell lymphoproliferative disorder, consistent with Stage 4 CLL/SLL. Cytogenetics revealed trisomy 12 with significant bone marrow involvement, indicating an intermediate prognosis. He is being treated with Obinutuzumab and venetoclax with improvement in his Cr to 2.19 mg/dL.

Discussion: Our case report recapitulates findings from a prior case series in 2015. Search of University of Pittsburgh Pathology database from 2010-2020 yielded no patient with a diagnosis of GIN secondary to CLL. Our patient had partial renal recovery with steroids, obinutuzumab, and venetoclax indicating the efficacy of this regimen compared to rituximab, cyclophosphamide, and steroids. Our case highlights a rare entity of GIN that maybe underdiagnosed in patients with CLL.

PO1910

A Case of Oncogenic Osteomalacia with Urinary Phosphate Wasting Masked by AKI

Terrance Wickman,[1] Swetha Rani Kanduri,[1] Karthik Kovvuru,[1] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Medical Center - New Orleans, New Orleans, LA; [2]The University of Queensland, Saint Lucia, QLD, Australia*.

Introduction: Hypophosphatemia in patients with oncogenic osteomalacia (OO) is due to excess production of fibroblast growth factor 23 (FGF-23) causing urinary phosphate wasting. However, in patients with coexisting acute kidney injury (AKI), hypophosphatemia may normalize as the AKI worsens potentially masking renal phosphate wasting. In-appropriately low or normal phosphorous levels in patients with AKI should prompt further work up to identify potential renal phosphate wasting.

Case Description: 36-year-old morbidly obese woman presented with right-sided abdominal pain and fatigue for 2 weeks. Initial laboratory evaluation revealed AKI (Cr 2.1 mg/dL, baseline 1.2) that failed IV fluid therapy prompting nephrology consultation. Other labs included urine protein creatinine ratio 0.2 g/g, alkaline phosphate (895 U/L), mild hyperbilirubinemia (1.8 mg/dL), mild hypercalcemia (corrected Ca 11 mg/dL), hypophosphatemia (1.8 mg/dL), low vitamin D (28 ng/mL), normal PTH (19 pg/mL), normal PTHrP (2.2 pmol/L) and low normal calcitriol (28 pg/ml). Kidney ultrasound was normal. Liver ultrasound revealed an ill-defined mass not seen in CT scan. FGF-23 levels were sent due to suspicion of OO and returned very high at 12,715 RU/ml. Patient was readmitted to the hospital for accelerated work up to identify the source of FGF-23. Repeat labs on admission showed Cr of 2.2 mg/dL, normal phosphorous 3.2 mg/dL and bilirubin 12 mg/dL. Random liver biopsy showed tumor cells positive for CD56 and Ki-67, with a proliferation rate of 80% indicating high grade metastatic neuro endocrine tumor. Localization of primary tumor was unsuccessful. Oncology was consulted and chemotherapy was entertained, but the patient rapidly deteriorated and opted for comfort measures.

Discussion: Reduced phosphate excretion in patients with AKI leads to hyperphosphatemia, stimulating FGF-23 production to facilitate phosphaturia. However, when AKI is associated with inappropriately low or normal phosphate levels, renal phosphate wasting from other causes should be suspected. Fractional excretion of phosphate might also be falsely low as the decreased eGFR can potentially hinder phosphate excretion. Early detection and accelerated work up could potentially lead to early diagnosis and appropriate treatment.

PO1911

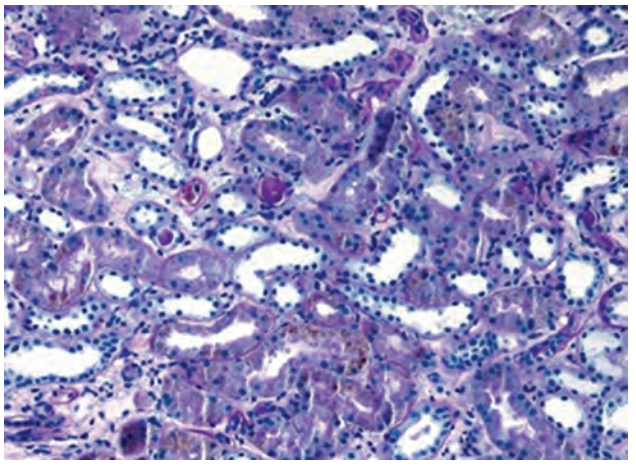
Lysozyme Nephropathy: A Rare Yet Treatable Cause of AKI in Chronic Myelomonocytic Leukemia

Andrew Donati, Anushree C. Shirali. *Yale University School of Medicine, New Haven, CT*.

Introduction: Lysozyme is a small lytic enzyme with bactericidal properties synthesized by monocytes that is freely filtered by the glomerulus. It can be produced in large quantities by neoplastic cells of monocytic lineage resulting in nephrotic range proteinuria (lysozymuria). Lysozyme can accumulate in proximal tubular cells thereby causing toxic injury resulting in tubular cell injury.

Case Description: A 69 year old woman was referred to nephrology clinic for evaluation of elevated serum Cr. Her past medical history included Type-2 Diabetes Mellitus, Hypertension, Hyperlipidemia, JAK2/V617F-positive Polycythemia Vera, Chronic Myelomonocytic Leukemia, bilateral renal angiomyolipomas and gout. Physical exam was unremarkable. Lab data were notable for creatinine (Cr) 1.7 mg/dL (baseline 1.2), Calcium 11.1 mg/dL, Uric acid 7.7 mg/dL, WBC 65.1 x 1000/uL (ANC 40.4; Monocytes 14.3), Hemoglobin 11.6 g/dL and Platelets 141 x 1000/uL. Electrolytes, liver function tests, and viral hepatitis serologies were within normal limits. Urinalysis was unremarkable. Urine albumin/Cr ratio was 79.4 mg/g of creatinine. A kidney biopsy was performed. Light microscopy revealed focal acute tubular injury and PAS-positive cytoplasmic granules. Electron microscopy revealed electron dense aggregates in the cytoplasm of the proximal tubular cells. Serum lysozyme was > 60 mcg/mL (reference range 5-11 mcg/mL). A diagnosis of lysozyme-induced nephropathy (LyN) was made. Repeat bone marrow biopsy revealed myeloid neoplasm with 13% blasts. She started treatment with Decitabine/Cedazuridine and her WBC improved to < 10 1 x 1000/uL and her Cr improved to 1.2 mg/dL.

Discussion: This case demonstrates an uncommon and often under-recognized cause of acute tubular injury in patients with chronic myelomonocytic leukemia. Lysozyme-induced nephropathy can be reversed with targeted therapy.



Light microscopy revealed focal acute tubular injury and PAS-positive cytoplasmic granules (PAS stain).

PO1912

Lymphomatous Infiltration of the Kidney in a Patient with Waldenstrom Macroglobulinemia

Prasanth Ravipati, Lihong Bu, Zohar Sachs, Patrick H. Nachman. *University of Minnesota Twin Cities, Minneapolis, MN.*

Introduction: Kidney disease can be an initial presentation or a chronic manifestation of plasma cell dyscrasias. The aim of this case report is to illuminate a rare presentation of kidney disease driven by lymphomatous infiltration of the kidney in a patient with Waldenstrom's Macroglobulinemia (WM).

Case Description: A 70 year old female with an 8 year history of WM (IgM, kappa) was referred for declining renal function. Four months prior to presentation, she had stable WM disease activity and was without symptoms of worsening disease burden. In November of 2020, she was hospitalized with SARS-CoV-2 infection with respiratory failure and acute kidney injury (AKI). Her serum creatinine (sCr) peaked at 3.7 mg/dL from a baseline of 0.9 mg/dL, but recovered to a sCr of 1.1 mg/dL by the time of discharge. Two months after discharge, her renal function began to decline prompting nephrology referral. Her sCr had risen to 1.9 mg/dL and she had new onset proteinuria of 1.5 g/day. A kidney biopsy showed lymphomatous infiltration of the tubulointerstitium without glomerular involvement. Immunofluorescence microscopy showed strong IgM and kappa stain but minimal lambda stain. Immunohistochemistry showed heavy interstitial staining for CD20 + B cells, and the presence of CD138 + plasma cells. Treatment with rituximab and bendamustine resulted in an improvement in renal function (sCr 1.4 mg/dL).

Discussion: WM is an uncommon hematologic malignancy, and extramedullary involvement is rare. Only 7% of a cohort of patients with WM who underwent kidney biopsy had lymphomatous infiltration of the kidney [Higgins et al., CJASN 2018]. In our case, the differential diagnosis was broad given the patient's modest proteinuria and kidney dysfunction in the context of recent AKI and hospitalization. Considerations included paraprotein related disease, medication related interstitial nephritis, or possibly an undefined sequela of SARS-CoV-2 infection. This case emphasizes the importance of surveillance for kidney dysfunction in patients with plasma cell dyscrasias, even if patients appear to have stable lymphoproliferative disease. Additionally, the effects of SARS-CoV-2 infection in patients with indolent lymphomas is unknown, but it is noteworthy that our patient developed lymphomatous kidney involvement after initial recovery of AKI in the setting of SARS-CoV-2 infection.

PO1913

Beware of the "B": Type B Lactic Acidosis and Atypical Renal Interstitial Infiltrate

Sarah R. Wilson, Prince M. Anand, Kartik Kalra. *Geisinger Medical Center, Danville, PA.*

Introduction: Lactic acid is an endogenous substrate for gluconeogenesis produced by muscle and other tissues. Lactate is the anion of lactic acid and is a source of base though Kreb's cycle. Lactic acid levels can increase due to impaired oxygen delivery (type A) or impaired oxygen utilization by cells (Type B). Here we describe a patient with an unusual presentation of lactic acidosis, and atypical renal interstitial infiltrate.

Case Description: A 32-year-old female with a history of chemotherapy and allogeneic bone marrow transplant in 2018 due to pre-B cell acute lymphoblastic leukemia (ALL) presented with concerns of sepsis due to suspected appendicitis and abnormal labs (pH 7.2, anion gap of 23, bicarbonate level of 10 mmol/L). Her lactate persistently ranged from 10-14 mmol/L despite antibiotics and bicarbonate containing fluids. Additionally, labs were consistent with acute kidney injury (Creatinine (Cr) 1.8 mg/dL from a baseline of 0.8 mg/dL). A kidney biopsy was performed given unexplained rise in Cr and enlarged kidneys (14 cm on renal ultrasound) which was suggestive of significant interstitial nephritis and tubulitis. Further immunohistochemical stains ordered due to suspicion of ALL reoccurrence, showed a mixture of CD3 and CD20-positive lymphocytes as well as CD68-positive cells. The atypical interstitial infiltrate was positive for CD10, CD45, CD79A, TDT, and PAX-5, consistent with B-cell leukemia. Flow cytometry and bone marrow biopsy confirmed the relapse of pre B-cell ALL. The patient was treated with steroids and blinatumomab, resulting in improvement in kidney function and resolution of lactic acidosis.

Discussion: Although our patient had lactic acidosis and AKI in the setting of presumed sepsis, a common clinical presentation, she had a completely different diagnosis. Her persistent lactic acidosis and atypical interstitial infiltrate led to the diagnosis of relapsed ALL with kidney involvement. Malignancy causes Type B lactic acidosis due to increased tumor cells' metabolism, overexpression of cellular glycolytic enzymes, mitochondrial dysfunction, thiamine, and riboflavin deficiency. Tumor cells have a high rate of glucose uptake and preferential production of lactate, even in the presence of oxygen, known as "Warburg effect." Type B lactic acidosis from malignancy overall portends a poor prognosis. The goal of therapy is to target the underlying malignancy.

PO1914

A Case of Hemophagocytic Lymphohistiocytosis (HLH) due to Large B Cell Lymphoma with infiltration in the kidneys

Kinjal Gosalia, Khawaja A. Bashir, Vanesa Bijol, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Secondary HLH is a life-threatening manifestation of certain malignancies and prompt diagnosis is essential in preventing poor outcomes. Kidney involvement in Large B cell lymphoma is under-reported and diagnosis can be challenging in the absence of abnormal kidney function.

Case Description: A 55-year-old male with no significant history was admitted to our facility with worsening mental status. He had 2 prior hospitalizations at an outside facility where he was treated with steroids for a presumed auto-immune CNS syndrome and partial improvement in symptoms. Vitals signs were normal on arrival and he was non-verbal on exam with right sided weakness. Lumbar puncture was negative for infection or malignant cells on analysis. MRI brain showed contrast enhancing lesions. Hospital course was complicated by persistent fevers, a rise in Serum creatinine (Scr) to 1.5md/dl on day 4 of admission in addition to new worsening thrombocytopenia and evidence of ongoing hemolytic anemia. Urinalysis revealed hematuria, no proteinuria, few WBCs but no active sediment. Other lab parameters were relevant for LDH of 3000, Ferritin >3000, TG of 1171 and soluble IL-2 receptor level elevated at >33,000. Patient met clinical criteria for HLH with concerns over a thrombotic microangiopathy (TMA) related to HLH and therefore a kidney biopsy was performed which revealed a diffuse atypical lymphocytic interstitial infiltrate, consistent with large B-cell lymphoma. No evidence of TMA was seen. A bone marrow biopsy performed at the same time, confirmed diffuse large B cell lymphoma with pleomorphic features and extensive involvement. A diagnosis of HLH secondary to Large B-Cell Lymphoma with infiltration to the bone marrow & kidneys was made. The patient's clinical condition deteriorated, and continuous form of renal replacement therapy was started in ICU. Chemotherapy was initiated, however he remained critically ill with worsening lactic acidosis, multi-organ failure and ultimately expired from cardiopulmonary arrest.

Discussion: Malignancy associated HLH is a challenging diagnosis which is often misdiagnosed. Diffuse large B cell lymphoma infiltrating the kidney confers a poor prognosis and this case illustrates the utility of a kidney biopsy in early diagnosis of a diffuse lymphoproliferative disorder which can improve patient outcomes

PO1915

A Unique Case of Paraneoplastic Lupus Nephritis Biopsy Finding in a Patient with Head and Neck Cancer

Swati Jain, Jyotsana Thakkar. *Montefiore Health System, Bronx, NY.*

Introduction: Rheumatic disease can be one of manifestations of paraneoplastic syndrome. We present a case of supraglottic squamous cell carcinoma (SCC) associated nephrotic syndrome and kidney biopsy suggestive of lupus-like changes.

Case Description: 56-year-old male with past medical history of hypertension, opioid abuse (on methadone) and an active smoker was admitted to the hospital for evaluation of painful neck swelling which he first noticed four days prior to admission. Examination was remarkable for lower extremity edema and left neck mass. Nephrology was consulted for evaluation of nephrotic syndrome. Significant laboratory workup revealed spot urine protein/creatinine ratio of 19 grams, serum albumin 2.2 g/dl and a normal serum creatinine 0.9 mg/dl. Serological workup for proteinuria including phospholipase A2 receptor antibody (PLA2R Ab) was negative. Biopsy of the neck mass was suggestive of supraglottic squamous cell carcinoma, subsequently treated with carboplatin and radiotherapy. A kidney biopsy was done for further evaluation. While there were no glomerular changes on light microscopy, immunofluorescence (IF) showed full house capillary staining (IgG, IgM, IgA, C3, C1q, kappa and lambda light chains). Also, enhanced glomerular staining for PLA2R was seen. Electron microscopy revealed sub epithelial deposits. Given lupus like finding on IF, serologies were tested and were negative. Given absence of systemic symptoms of lupus, negative serologies and negative PLA2R Ab, presumed diagnosis of membranous glomerulonephritis secondary from malignancy was made. He was treated conservatively with diuretics, angiotensin convertase inhibitor and anticoagulation for thromboembolism prevention. Proteinuria improved with above treatment, however patient expired due to tumor complications and metastasis.

Discussion: Paraneoplastic systemic lupus erythematous has been reported in patients with solid tumors. Proposed hypothesis is tumor driven breakdown of self-tolerance antigens, which causes generation of auto antibodies. Auto immune disease usually precedes the diagnosis of malignancy and patients develop symptoms later. Our

case is unique, although biopsy was indicative of lupus nephritis, patient had no clinical or laboratory finding for lupus. Nephrologist and oncologist should be aware of this rare clinical association for appropriate diagnosis and management

PO1916

Light Chain Deposition Disease (LCDD) in the Setting of Smoldering Myeloma (SM)

Joel O. Adewuyi, Chintan V. Shah, Dhruv K. Modi. *University of Florida, Gainesville, FL.*

Introduction: Only 50-60% of patients with LCDD meet the criteria for multiple myeloma (MM). SM, a proliferative plasma cell disorder is a precursor for active symptomatic MM. As LCDD is rare, there is limited data for the treatment of LCDD in the setting of SM.

Case Description: A 49-year-old female was found to have proteinuria and microscopic hematuria during a routine workup. Further evaluation showed proteinuria of 4.0 g/day, serum creatinine of 1.3 mg/dL, kappa light chain (KLC) 94.7 mg/dL, lambda light chain (LLC) 1.57 mg/dL, kappa-Lambda ratio (K/L) 60.24, Hemoglobin 12.8 g/d, Calcium 9.26 mg/dl. Kidney biopsy showed nodular mesangial expansion with mild hypercellularity. Moderate tubular atrophy and interstitial fibrosis. Immunofluorescence showed strong kappa staining of mesangium, glomerular, and tubular basement membrane (TBM) with negative lambda staining. Electron microscopy showed the presence of subendothelial, mesangial, and TBM electron dense deposits. Findings were considered to be consistent with kappa associated LCDD. Bone marrow biopsy showed monoclonal plasma cell population in the bone marrow (5% by flow cytometry and 10-15% by CD138 stain) consistent with smoldering myeloma. FISH was abnormal for monosomy of 13 and 11;14 translocation. The skeletal survey was negative for any lytic lesions. She was treated with Bortezomib/Dexamethasone/Cyclophosphamide based regimen weekly for 8 weeks which resulted in a decrease in KLC to 1.45 mg/dl, LLC to 1.0 g/dl, and K/L ratio to 1.45 with negative serum immunofixation. 24-hour urine protein improved to 2.6 g/d. Serum creatinine remained stable at 1.3 mg/dl. Bone marrow biopsy after chemotherapy showed residual plasma cell myeloma involving 5% of the marrow cells. She underwent high dose melphalan followed by Autologous Stem Cell Transplantation (HDM/ASCT). Follow-up labs six years later confirmed successful treatment with serum creatinine improving to 1.02 mg/dl, 24hr-urine protein 484mg/d without microscopic hematuria. SPEP and UPEP remain negative.

Discussion: We report a case of successfully treated LCDD with high dose chemotherapy followed by HDM/ASCT in the setting of smoldering myeloma with six years of follow-up. Patients with LCDD in smoldering myeloma may benefit from high dose chemotherapy along with HDM/ASCT and it should be considered a treatment option.

PO1917

Delayed Thrombotic Microangiopathy Post Bone Marrow Transplant, an Atypical Presentation: A Case Report

Vikas Vujjini, Aman Deep, Matthew Palmer, Abdallah Sassine Geara. *Penn Medicine, Philadelphia, PA.*

Introduction: Thrombotic Microangiopathy (TMA) is a potentially lethal complication of Bone Marrow Transplantation (BMT). We report a case of delayed TMA post-BMT which was successfully treated with Rituximab.

Case Description: A 53-year-old male known to have hepatosplenic gamma-delta T-cell lymphoma (HSTCL) was referred for evaluation of worsening creatinine. He was diagnosed with HSTLC 6 years ago that was refractory to multiple therapies, and ultimately, two years later, he received Double Unit Cord Blood (dUCB) transplantation with good response and minimal residual disease. Despite receiving tacrolimus and mycophenolate mofetil (MMF) for prophylaxis of Graft versus Host Disease (GVHD), he developed mild popular rash consistent with Grade I GHVD skin and recurrent pneumonitis concerning for lung GHVD which responded to steroids. The tacrolimus and MMF were discontinued and steroids were gradually tapered off. Eight months post-transplant, serum creatinine (sCr) started to gradually increase from a baseline of 1.0 mg/dL. We were consulted eighteen months post-dUCB when sCr reached 1.8 mg/dL. Additional evaluation showed mild proteinuria (UPCR 0.77 g/g of creatinine), no active urine sediment, low haptoglobin (< 30 mg/dL) and worsening thrombocytopenia (105 THO/μL). A renal biopsy showed glomeruli with variable capillary wall thickening and double contours, moderate fibrosis of 40-50%, negative immunofluorescence for complement and immunoglobulin, and the electron microscopy showed subendothelial expansion and endothelial swelling. These findings were compatible with chronic TMA lesion concerning for renal GVHD. The patient was treated with weekly Rituximab 375 mg/m^2 for a total of 4 doses with stabilization of sCr and normalization for hemolysis labs, including normalization of platelet count.

Discussion: TMA is a well described complication post-BMT with multifactorial etiology (medication, GVHD, radiation, etc.) with early onset within the first 30-45 days after transplantation, and the mortality rate is approximately 30-80%. Our patient had the unusual delayed presentation post-BMT (after 18 months). Although historically not the first line, several case reports have been published showing use of Rituximab, an anti-CD20 monoclonal antibody, with positive response.

PO1918

A Rare Case of Monoclonal Gammopathy of Renal Significance

Jawad I. Malik, Jonathan A. Bolanos. *University of Maryland Medical Center, Baltimore, MD.*

Introduction: Monoclonal gammapathy of renal significance represents a group of disorders in which monoclonal immunoglobulin secreted by a non malignant or premalignant B cell or plasma cell clone causes renal damage. These disorders do not meet diagnostic criteria for multiple myeloma or lymphoproliferative disorder.

Case Description: 64 year old female with hx of hypertension, presented to ED for worsening lower extremity edema, dyspnea. She was admitted for CHF exaceration. Admission creatnine was 2.0 (prior baseline 1.0). She developed resistence to diuretics with worsening renal failure requriing dialysis. She had 6.0 grams of proteinuria. Kidney biopsy showed ATN, and findings consistent with PGNMIG with IG3k. She had spep/upep/free light chains ratio which were all normal. Bone marrow biopsy was normal. Since no clone had been identified to guide treatment, plan made to treat her with bortexumib, cytoxan and dexamethasone.

Discussion: -PGNMIG is a monclonal gamopathy which resembles immune complex GN - Most comman pattern seen in PGNMIG is IG3k (this is more nephritogenic and has ability to activate compliment cascade causing inflammatory damage. Majority of the patient with PGNMID do not have clone identified. In such patients treatment is empiric with bortexumib/cytoxan/dexamethasone or rituximab.

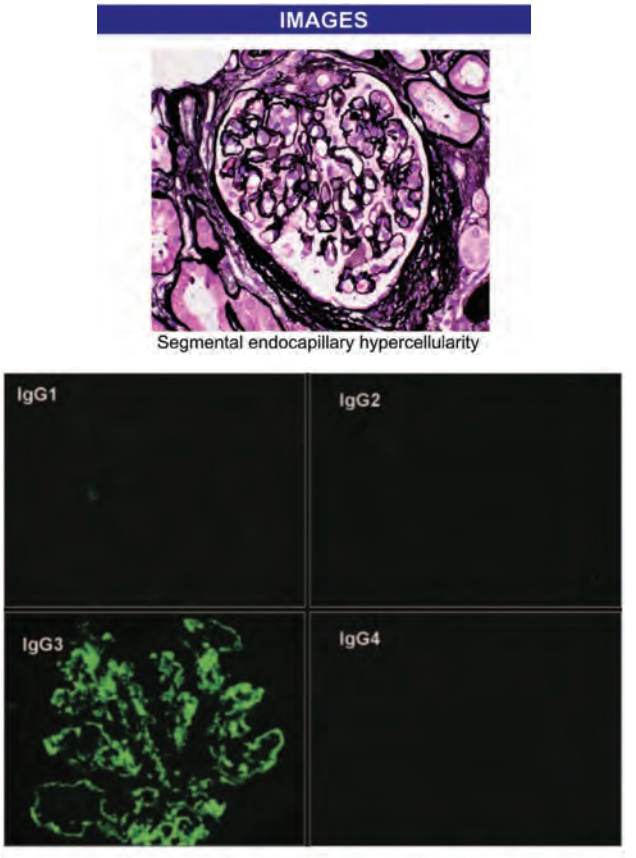


Figure 5. On IF staining for IgG subtypes, there is strong glomerular positivity for IgG3 with negative staining for IgG1, IgG2, and IgG4. Magnification, ×400.

PO1919

Review of Onconephrology Cases: An Insight from the Middle East

Rakesh Madhyastha, Sudeendra S. Gupta, Muriel Ghosn, Fadi A. Hijazi, Nizar M. Attallah. Department of Nephrology, Cleveland Clinic Abu dhabi *Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates.*

Background: Onconephrology is a new subspecialty of nephrology and its data was sparse from the middle east. We have collected data of cancer patients admitted to a tertiary care center and referred to the department of Nephrology to recognize the most common preventable causes of AKI and their outcome in this patient population

Methods: We conducted a retrospective observational study of 39 admitted cancer patients referred to the department of Nephrology between November 2020 and March 2021.

Results: In our study 69% were males, 31% were females. Tumors were;prostate cancer(n=6), bladder cancer (n=5), RCC (n=5), HCC(n=4) and Colon cancer (n=3), breast cancer (n=3), unknown primary (n=2), (n=1) were SCC, tongue, ovary, thyroid, endometrial cancerand laryngeal cancer, additioanlly B cell lymphoma (n=1)and multiple myeloma (n=4). Background history of CKD was present in, 38% (n=15) of the cohort. CKD stage 3 was the most prevalent (n=10). 1 patient had ESRD and maintained on dialysis and 2 patients had undergone a kidney transplant. Recurrent AKIs were most common (n=6), followed by nephrectomy (n=4) and hypertension (n=4), other included diabetes mellitus, urinary tract obstruction, atrophic kidneys, and multiple myeloma. Causes of AKI were Sepsis 30%, hypovolemia 12%, urinary tract infection 10.2%, drug-induced AKI 10% & Hypercalcemia 7.6%.Less common causes were hemorrhagic shock and IV iodinated contrast exposure. Only 33% of the study population was actively receiving oncotherapy at the time of admission. Amongst the cohort, 48% were oliguric and the rest were non-oliguric. A total of 16 patients, received renal replacement therapy during admission; CRRT was done in 10/16 patients, 5/16 patients received conventional hemodialysis and 1 patient received both modalities. Amongst the patients requiring CRRT, the survival rate was 21%, and for patients who received hemodialysis, the survival rate was 50%.41% of the patients died during the admission; 62% of the deaths were deemed secondary to underlying cancer and the remaining 38% were attributed to other causes; the most common being sepsis.

Conclusions: Our study reiterates the importance of prevention of AKI by early recognition and prompt management of risk factors. This study prompts the need for quality improvement initiatives aiming at improving the outcomes of such patients at all tertiary care centers

PO1920

Pseudohyperkalemia Leading to Pseudohyponatremia in Severe Leukocytosis

Hameeda T. Khan,[1] Ilya Glezerman.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Electrolyte abnormalities are common in oncologic malignancies. However spurious derangements are rarer. Here we present a case of coexisting reverse pseudohyperkalemia and pseudohypoanatremia in chronic lymphocytic leukemia.

Case Description: An 84 year old male was diagnosed with chronic lymphocytic leukemia after presenting with weight loss and fevers. Labs showed a WBC of 760 K/mcl, Plasma sodium was 133 Meq/L, plasma potassium 8.8 Meq/L, BUN 15mg/dl, Creatinine 2.8 mg/dl and a GFR of 20 ml/min. Urine analysis showed 100 mg/dl of protein, 300 mg/dl of glucose and small blood. Urine sodium of 82 meq/L and osmolality of 444 mosmol/kg with serum osmolality of 300 mosmol/kg. EKG did not show any hyperkalemic changes. He received insulin, dextrose and kayexalate. Repeat plasma potassium was 10.7 Meq/L. Given high suspicion for reverse pseudohyperkalemia due to leukocytosis, serum labs were sent. Serum potassium was 4.2 Meq/L and serum sodium 134 Meq/L with a concurrent plasma Potassium of >9.0 Meq/L and plasma sodium of 127 Meq/L. The WBC count remained elevated at 693.2 K/mcl. The serum sodium is measured at our institution with direct ion-specific electrode method making derangements from hyperlipidemia and hyperproteinemia unlikely. Treatment was started with methylprednisolone and Rituximab for CLL. The WBC count trended down from 693 to 339.5 K/mcl. Serum potassium remained stable (3.7-4.9) as well as serum sodium (138-141) with concurrent plasma values decreasing in disparity from potassium >9Meq/L to 4.9 Meq/L and sodium 127 Meq/L to 139 Meq/L as the WBC count decreased.

Discussion: This case portrays a challenging case of reverse pseudohyperkalemia and pseudohyponatremia in severe lymphocytosis. While the phenomenon of pseudohyperkalemia in leukemia/lymphomas is established, reverse pseudohyperkalemia where plasma potassium is falsely elevated compared to normal serum levels is lesser known. Furthermore, no mechanism has been established for pseudohyponatremia in plasma samples compared to serum samples in leukocytosis however it was postulated that sodium levels decrease reciprocally to potassium due to potassium release from the leukocytes. Hence in cases of reverse pseudohyperkalemia serum samples are preferred over plasma samples. Parameters need to be established to avoid treatment of spurious electrolyte disorders to avoid treatments resulting in hypokalemia and hypernatremia.

PO1921

Light Chain Proximal Tubulopathy Without Fanconi Syndrome as the Sole Presenting Feature of Multiple Myeloma

Joscelyn E. Hodge,[1] Roberto F. Nicosia,[2] Maurice I. Khayat.[1] *[1]Madigan Army Medical Center, Tacoma, WA; [2]University of Washington, Seattle, WA.*

Introduction: Light chain proximal tubulopathy (LCPT) is a rare pattern of immunoglobulin-related renal injury that occurs in the setting of dysproteinemias. Classic disease associations for LCPT are multiple myeloma, monoclonal gammopathy of renal significance, and other hematolymphoid neoplasms. The key LCPT pathologic feature is the accumulation of monoclonal light chains within the cytoplasm of proximal tubule (PT) cells with resultant clinical PT defects, proteinuria, and renal dysfunction.

Case Description: A 64-year-old male with prostatic adenocarcinoma presented for evaluation of incidentally discovered proteinuria (3.852 g/g creatinine) and stage two chronic kidney disease. Initial evaluation was significant for a kappa/lambda ratio of 474.79, serum M-spike of 0.9 g/dL, and urine M-spike of 1.082 g/dL. Urine immunofixation electrophoresis revealed 94.1% Bence-Jones protein (1.629 g/24h) comprising monoclonal IgG, kappa type. Other laboratory features of myeloma (hypercalcemia, anemia) were absent. Renal biopsy revealed monoclonal kappa light chain crystal inclusions in the cytoplasm of PT epithelial cells. Glomeruli show no significant histologic or ultrastructural abnormalities. Despite the severe histopathologic dysfunction, no clinical features of Fanconi Syndrome were present, including a negative work up for renal tubular acidosis as well as no renal wasting of phosphorous, amino acids, glucose, uric acid, or potassium. PET scan revealed diffuse marrow infiltrating disease with multiple lytic osseous lesions, and the patient was referred to oncology to begin chemotherapy.

Discussion: LCPT continues to be a rare pattern of kidney injury with significant variability in presentation based largely on the composition of the light chains. The toxicity of kappa light chains results from their ability to form crystals, which resist lysosomal proteolysis. Although our patient had extensive crystalline inclusions and significant evidence of tubular injury, no clinical evidence of proximal tubulopathy was evident with proteinuria as the sole presenting feature of diffuse myeloma. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.

PO1922

Monoclonal Gammopathy of Renal Significance: Not Reserved for the Elderly

Suryanarayanan Balakrishnan, Suzanne G. Martin. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) is defined by renal involvement of monoclonal immunoglobulins in the absence of other organ involvement. MGRS includes a wide variety of renal lesions. It is particularly important to distinguish MGRS from monoclonal gammopathy of undetermined significance (MGUS), as early treatment improves renal survival.

Case Description: 36F with a history of pre-eclampsia, stage II chronic kidney disease, and hypertension well-controlled on valsartan 320 mg and metoprolol succinate 100 mg, presented 2 years postpartum with worsening hypertension and proteinuria. Initial urinalysis was positive for 3+ proteinuria and 2+ blood, with dysmorphic RBCs on sediment. Urine protein to creatinine ratio (UPC) was 1574 mg/g Cr. ANA and ANCA were negative, and complements were normal. Her creatinine rose from 1.2mg/dL to 1.8mg/dL over the next two years, and proteinuria rose to 4.7 g/d. Renal biopsy confirmed IgG kappa monoclonal immunoglobulin deposition disease, with large subepithelial deposits and moderate tubular injury, with 20% global and segmental glomerulosclerosis, 10% interstitial fibrosis and tubular atrophy, and moderate vascular sclerosis. Serum and urine immunofixation and serum free light chain ratio were normal. Bone marrow biopsy was also negative, confirming the diagnosis of MGRS. She was treated with dexamethasone and bortezomib for a year, followed by lenalidomide, with stabilization of her renal function and proteinuria for over 3 years. Her creatinine is 2.4mg/dL and UPC is 354mg/g Cr. She has been off therapy for 4 months with no change.

Discussion: There has been historical resistance to treat MGRS, as it does not meet criteria for a proliferative disorder and chemotherapy toxicity is of concern. However, it is associated with progression to CKD/ESRD without treatment. Treatment depends on renal pathology and clone type, and may include proteasome inhibitors, alkylating agents, or immunomodulators. Certain forms of MGRS, such as AL amyloidosis, may benefit from autologous hematopoietic stem cell transplantation due to its high rate of recurrence. Her young age is an unusual feature of MGRS. This case highlights the need for renal biopsy in patients with worsening proteinuria and renal function out of proportion to hypertension, and the role of chemotherapy in MGRS to change the trajectory of disease.

PO1923

Variable Expression of Eighteen Common Housekeeping Genes in Human Non-Cancerous Kidney Biopsies

Philipp Strauss,[1] Håvard Mikkelsen,[1] Jessica Furriol.[2] Renal Research Group of Bergen *[1]Universitetet i Bergen Det medisinsk-odontologiske fakultet, Bergen, Norway; [2]Haukeland Universitetssjukehus, Bergen, Norway.*

Background: Housekeeping, or reference genes (RGs) are, by definition, loci with stable expression profiles that are widely use as internal controls to normalize mRNA levels. However, due to specific events, such as pathological changes, or technical procedures, their expression might be altered, failing to fulfil critical normalization pre-requisites.

Methods: To identify RG genes suitable as internal controls in human non-cancerous kidney tissue, we selected 18 RG candidates based on previous data and screen them in 30 expression datasets (>800 patients), including our own, publicly available or provided by independent groups. Datasets included specimens from patients with hypertensive and diabetic nephropathy, Fabry disease, focal segmental glomerulosclerosis, IgA nephropathy, membranous nephropathy, and minimal change disease. We examined both microdissected and whole section-based datasets. Expression variability of 4 candidate genes (*YWHAZ*, *SLC4A1AP*, and *ACTB*) was further examined by qPCR in biopsies from patients with hypertensive nephropathy (n=11) and healthy controls (n=5).

Results: Only *YWHAZ* gene expression remained stable in all datasets whereas SLC4A1AP was stable in all but one Fabry dataset. All other RGs were differentially expressed in at least 2 datasets, and in 4.5 datasets on average. No differences in *YWHAZ*, *SLC4A1AP*, *RPS13* and *ACTB* gene expression between hypertensive and control biopsies were detected by qPCR.

Conclusions: Although RGs suitable to all techniques and tissues are unlikely to exist, our data suggest that in non-cancerous kidney biopsies expression of *YWHAZ* and *SLC4AIAP* genes is stable and suitable for normalization purposes.

PO1924

Comparison of Proteomic Methods in Evaluating Biomarker-AKI Associations in Cardiac Surgery Patients

Richard X. Liu,[1] Heather Thiessen Philbrook,[1] Vasan S. Ramachandran,[2,3] Josef Coresh,[4,5] Peter Ganz,[6] Joseph V. Bonventre,[7,8] Paul L. Kimmel,[9] Chirag R. Parikh.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Public Health, Boston, MA; [4]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [5]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD; [6]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; [7]Brigham and Women's Hospital, Boston, MA; [8]Harvard Medical School, Boston, MA; [9]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

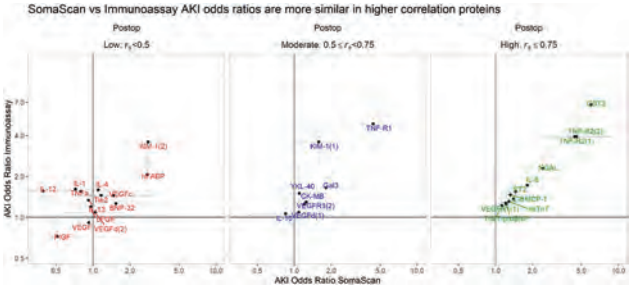
Background: Although immunoassays are the most widely used protein measurement method, aptamer-based methods such as the SomaScan platform can quantify up to 7,000 proteins per sample, creating new opportunities for unbiased discovery.

Methods: In a substudy of the TRIBE-AKI cohort, preop and postop plasma samples from 294 patients with previous immunoassay measurements were analyzed using the SomaScan platform. Inter-platform Spearman correlations (r_s) and AKI associations were compared across 30 preop and 34 postop immunoassay-aptamer pairs. Possible factors contributing to inter-platform differences were tested for association with inter-platform correlation, including target protein, experimental, immunoassay, and aptamer characteristics.

Results: The median r_s was 0.54 (IQR 0.34-0.83) in postop samples and 0.41 (IQR 0.21-0.69) in preop samples. We observed a strong association between r_s and biomarker molarity, with Spearman correlation 0.64 preop and 0.53 postop. No strong associations with other factors were found, including %CVs of both platforms and storage time. We observed significant immunoassay-AKI associations for 13 proteins preop and 24 postop, and SomaScan-AKI associations for 8 proteins preop and 12 postop. All significant AKI associations as measured by SomaScan were also significant as measured by immunoassay. AKI odds ratios were significantly different (P <0.05) between platforms in 4 (14%) pairs, none of which had r_s >0.50.

Conclusions: Although similar AKI associations were observed overall, biomarkers with high physiological concentrations tended to have the best inter-platform operability. Aptamer assays provide unprecedented coverage, excellent precision, and promise for disease associations, but interpretation of results should keep in mind a broad range of correlations with immunoassays.

Funding: NIDDK Support



PO1925

Performance of Creatinine-Based Equations to Estimate Glomerular Filtration Rate in the Context of Drug Dosage Adaptation

Pierre Delanaye,[1] Jonas Björk,[3] Hans Pottel,[2] Ulf Nyman.[3] European Kidney Function Consortium *[1]CHU de Liege - Hopital du Sart Tilman, Liege, Belgium; [2]KULAK, Kortrijk, Belgium; [3]Skanes universitetssjukhus Lund, Lund, Sweden.*

Background: The 1976 Cockcroft-Gault (CG) creatinine-based equation is still used to estimate GFR (eGFR) for dose adaptation of drugs excreted by glomerular filtration although it estimates creatinine clearance. It was developed based on non-standardized creatinine assays and is not recommended by any nephrology guidelines. Incorrect eGFR may lead to hazardous over- or underdosing. We aimed to compare the performance of CG with modern equations based on standardized creatinine assays.

Methods: In a cross-sectional analysis CG was validated against measured GFR (mGFR; using various tracer methods) in 15,479 participants and compared with the Modification-of-Diet-in-Renal-Diseases (MDRD), Chronic-Kidney-Disease-Epidemiology (CKD-EPI), Lund-Malmö-Revised (LMR), and European-Kidney-Function-Consortium (EKFC) equations. Validation focused on bias, imprecision and accuracy (percentage of estimates within ±30% of mGFR, P30), overall and stratified for mGFR, age and body mass index intervals at mGFR <60 mL/min, as well as classification in mGFR stages.

Results: The CG equation performed worse than the other equations, overall and in mGFR, age and BMI subgroups in terms of bias (systematic overestimation), imprecision and accuracy (P30 overall for CG/MDRD/CKD-EPI/LMR/EKFC 73.6%/81.0%/82.4%/87.5%/86.9%) except for patients ≥65 years where bias and P30 were similar to MDRD and CKD-EPI, but worse than LMR and EKFC. At BMI [18.5-25[kg/m^2, all equations performed similarly and at BMI<18.5kg/m^2 CG and LMR had the best results though all equations had poor P30-accuracy (CG/LMR 58.7%/57.2%). At BMI≥25kg/m^2, bias of CG increased with increasing BMI (+19.3mL/min at BMI≥40kg/m^2). The four more recent equations also classified mGFR stages better than CG.

Conclusions: The CG equation exhibited worse performance to estimate GFR overall and in analyses stratified for GFR, age, and BMI. CG was inferior to correctly classify the patients in the mGFR staging compared to more recent creatinine-based equations.

Human Kidney Mimetic Tissue Using Endogenous Lipids and Metabolites as Standards for Quantification and Quality Control

Annapurna Pamreddy, Guanshi Zhang, Hongping Ye. CRPM and KPMP *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Mass spectrometry imagine (MSI) determines the spatial localization of molecular species directly from the sample and has been heralded in tissue analysis. However, majority of studies have not been quantitative and reproducible. The presentation of a quantified tissue distribution has distinct benefits over the common approach of quantifying the tissue homogenate especially if tissue distribution is heterogeneous, making overcoming this limitation a top priority.

Methods: An improved mimetic tissue mold has been developed. Briefly, human kidney tissue was cut into small pieces and spiked with a normalization standard (lyso-PAF), an antioxidant, and a phospholipase A2 (PLA2) inhibitor to protect endogenous lipids and metabolites from the most common degradation. Lipidomic and metabolomic analyses of this mimetic tissue were performed, and the absolute amounts of various compounds were measured and used as standards for side by side MSI analysis of any tissue sample of interest. Since stabilizers are used, the quantitative data of the mimetic tissue are reliable and can be used as quality control (QC) tracers to tissue samples during storage and shipment.

Results: Mimetic tissue molds were prepared by spiking stable isotope labeled compounds at different concentrations layer by layer for validation. Initial validation experiments found that: a) MSI can detect the concentration differences with acceptable linearity, accuracy, and repeatability; b) Spiking of high concentrations affects the endogenous signals; c) It's not practicable to spike each compound for its quantification due to signal suppression, high material and labor consumption; d) Using endogenous amounts as reference standards is a suitable approach. To use the homogenized mimetic tissue as a spatial quantitative and QC standard, the endogenous amounts of lipids and metabolites were measured with bulk omics. More than 200 lipids, 25 amino acids, and numinous organic acids were quantified.

Conclusions: Quantifying endogenous lipids and metabolites using bulk methods as MSI quantification standards is innovative in the field. The similarity of tissue matrix and targeting compounds between mimetic and sample tissues can provide more meaningful and reliable results.

Comparison of Aptamer-Based and Antibody-Based Assays for Protein Quantification in CKD

Carolina Lopez-Silva,[1] Aditya L. Surapaneni,[1] Josef Coresh,[1] Jochen Reiser,[2] Lawrence J. Appel,[1] Chirag R. Parikh,[1] Wassim Obeid,[1] Morgan Grams,[1] Teresa K. Chen.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Rush University, Chicago, IL.*

Background: Novel aptamer-based technologies can identify over 7000 analytes per sample, offering a high-throughput alternative to traditional immunoassays in biomarker discovery. However, the specificity for distinct proteins has not been thoroughly studied in the context of chronic kidney disease (CKD).

Methods: We aimed to validate the use of SOMAscan, an aptamer-based technology, for the quantification of 8 immune activation biomarkers and cystatin C in 498 participants from the African American Study of Kidney Disease and Hypertension (AASK) using immunoassays as the gold standard.

Results: Six biomarkers (IL-8, TNFRSF1B, cystatin C, TNFRSF1A, IL-6 and suPAR) had moderate-to-high correlations (Pearson r=0.22 to 0.94, Spearman r_s=0.30 to 0.98,) between SOMAscan and immunoassay measurements and three (IFN-γ, IL-10 and TNF-α) were uncorrelated (r=-0.03 to 0.10, r_s=-0.03 to 0.06). Of those with moderate-to-high correlations, TNFRSF1B, cystatin C, TNFRSF1A, and suPAR were negatively correlated with iothalamate-measured GFR and associated with higher risk of ESKD. All 6 biomarkers with moderate-to-high correlations were associated with increased risk of mortality. On average, immunoassay measurements were more strongly associated with adverse outcomes than their SOMAscan counterparts (Figure).

Conclusions: SOMAscan is an efficient and relatively reliable technique for the quantification of biomarkers in the setting of CKD and for the detection of potential associations with clinical outcomes. Targeted immunoassays of candidate proteins may provide additional prognostic information.

Figure 1. Analysis Results. Person and Spearman correlation coefficients of protein levels measured via traditional immunoassays vs. SOMAscan. Pearson correlation coefficients of protein levels (as measured by traditional immunoassay vs. SOMAscan) with mGFR. Adjusted hazard ratios (HR) for biomarker levels with incident ESKD and mortality. Models were adjusted for sex, age, and randomized treatment groups. Seemingly unrelated regression (*SUR*) p-values were used to compare the strength of the association between biomarkers measured via immunoassay vs. SOMAscan and ESKD and all-cause mortality. *P-values for the likelihood ratio test (LRT) compare a predictive model using both assays vs. a single assay alone for each protein. In this instance, the LRT P-value for 'immunoassay' indicates whether the additional use of immunoassay provides any additional prognostic information after SOMAscan analysis and vice versa. Statistically significant findings in bold.

Prescribed Sodium Bicarbonate and Incident CKD in US Veterans

Elani Streja,[1,3] Jeffrey A. Kraut,[2] Cachet Wenziger,[1,3] Praveen Kumar Potukuchi,[4] Ankur A. Dashputre,[4] Keiichi Sumida,[4] Csaba P. Kovesdy,[5,4] Kamyar Kalantar-Zadeh.[3,1] *[1]VA Long Beach Healthcare System, Long Beach, CA; [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [3]University of California Irvine, Irvine, CA; [4]The University of Tennessee Health Science Center, Memphis, TN; [5]VA Memphis Medical Center, Memphis, TN.*

Background: Sodium bicarbonate is prescribed for a variety of medical conditions including treatment of hypobicarbonatemia that may happen in the setting of metabolic acidosis or due to other pathologies. Hypobicarbonatemia is usually observed with chronic kidney disease (CKD) when eGFR < 60 mL/min/1/73 m2 and is uncommon without established CKD (eGFR > 60 mL/min.). It is not known whether incident sodium bicarbonate prescription in patients with normal kidney function is associated with adverse outcomes including de novo chronic kidney disease, which we sought to examine in a large national cohort of Veterans.

Methods: In 2,524,842 US Veterans with normal baseline eGFR (≥60 ml/min/1.73m2) and available data on albuminuria in 2004-2006, we examined the association of de novo prescription of bicarbonate medications during the baseline period with incident CKD over 14 years. Associations were examined in hazard models adjusted for demographics, major comorbidities, baseline eGFR, and albuminuria category.

Results: We identified 759 Veterans who were incident bicarbonate users. Overall, patients were a mean 61±14 years old, 7% female, 16% Black, and 5% Hispanic. Bicarbonate users were more likely to be male, Black, smokers, with higher frequencies of comorbidities such as chronic obstructive pulmonary disease, cancer, diabetes, and cardiovascular comorbidities. They also were more likely to have albuminuria. Bicarbonate medication users had a 4.8-fold higher risk of incident CKD (HR: 4.81, 95%CI: 4.38, 5.27).

Conclusions: Veterans with eGFR ≥60 ml/min/1,73m2 who were prescribed sodium bicarbonate exhibited nearly five times greater likelihood of incident CKD. Whether bicarbonate therapy is a surrogate of disease condition with higher risk of CKD or whether it causes CKD directly remains to be examined in additional studies.

LRP2-Facilitated Regulation of Mitochondrial Metabolism by Extracellular Cues: Important Roles for Signal Peptides' Leucines in Protein-Protein Interactions and Signaling

Qingtian Li,[1] Michael Holliday,[1,2] Jenny S. Pan,[1,2] Li Tan,[3,1] Jeffery Li,[1] David Sheikh-Hamad.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]Sichuan University West China Medical Center, Chengdu, China.*

Background: Stanniocalcin 1 (STC1), a mitochondrial intracrine activates mitochondrial anti-oxidant defenses. LRP2/megalin shuttles STC1 to the mitochondria through retrograde early endosome-to-Golgi- and Rab32, and LRP2 KO impairs mitochondrial respiration and glycolysis.

Methods: We determined STC1-LRP2 interaction domains using HA- and FLAG-tagged fragments of STC1 and LRP2, respectively, co-expressed in HEK293T cells.

Results: The trans-membrane domain of LRP2 is required for trafficking to the mitochondria. STC1-FLAG expressed in LRP2 KO cells fails to reach the mitochondria; thus, mitochondrial STC1 is extracellularly-derived via LRP2-mediated trafficking. Tri-leucines L12-14 in LRP2's signal peptide interact with STC1's signal peptide. Mutant LRP2 (L12-L14 -> A12-14) does not bind STC1, while hSTC1 lacking signal peptide or Leucines L8/9/11 does not bind LRP2. Using Seahorse analyzer, STC1 fails to induce

respiration or glycolysis in megalin KO MEF expressing mutant LRP2, while mutant hSTC1 (L8/L9/L11 -> A8/A9/A11) fails to reach the mitochondria or induce respiration and glycolysis in WT MEF.

Conclusions: Our data suggest direct regulation of mitochondrial metabolism by extracellular cues and reveal an important role for signal peptides and their leucines in protein-protein interactions and signaling.

Hypertriglyceridemia-Related Lipid Profiles Affect Glomerulosclerosis in IgA Nephropathy

Wonjung Choi, Yoon-Kyung Chang. *Department of Internal Medicine, Daejeon St. Mary's Hospital, College of Medicine, Daejeon, Republic of Korea.*

Background: Dyslipidemia, is one of the common complications of renal failure. There are many clinical factors that affect IgAN prognosis or histopathology. However, there are only few studies that analysis focused on the histopathologic features between IgA nephropathy with hypertriglyceridemia and related lipid profiles. We evaluate histopathologic features in IgAN between HyperTG group compared to normal TG group

Methods: Study Design This study is a cross-sectional study of a multi-center cohort that underwent kidney biopsy at 8 university hospitals affiliated with the College of Medicine Catholic University between January 2015 and May 2020 were diagnosed with IgAN. A total of 480 patients were enrolled in final cohort. Patient were divided into 2 groups that group 1; <150mg/dL, group 2; ≥150mg/dL. **Statistical Analysis** Logistic regression analyses were performed to estimate the odds ratios (ORs). To define high grade of global and segmental glomerulosclerosis ≥25% define as high grade glomerulosclerosis and <25% define as low grade glomerulosclerosis. Grades 2-4 of MME, MCP were defined as high grade.

Results: Association between serum TG and histopathologic parameters Multivariable linear regression analysis showed that the that percent of GS, SS and CA, MME, MCP scores were positively associated with TG levels. Table 4 shows that HyperTG group showed more higher risk for global and segmental sclerosis after adjusting clinical and labaratory variables.

Conclusions: In conclusion, HyperTG is associated with glomerular sclerosis and mesangial proliferation. Also, HyperTG is independently relevant risk factor for global and segmental sclerosis.

Percutaneous Kidney Biopsy in Outpatient Setting: Can I Go Home Now?

Asheen Zariat,[1] Ameet Kumar,[1] Tyler M. Palombo,[2] Prasanti S. Ravipati,[2] Diane V. Thompson,[1] Khaled Nashar,[1] Swati Arora.[1] *[1]Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA; [2]Drexel University, Philadelphia, PA.*

Background: Kidney biopsies are a key diagnostic tool in renal dysfunction; however, complications ranging from bleeding to hematoma requiring embolization can occur. There is conflicting evidence on how long to keep patients post-biopsy. Some studies show 100% of serious complications occur within 8 hours, while others show that one-third can occur after 8 hours. Shorter observation periods prevent unnecessary testing and help reduce healthcare costs. Our study aims to assess if patients can be safely discharged with a six hour observation period post-biopsy.

Methods: Single-center retrospective Quality Improvement (QI) study of patients undergoing outpatient percutaneous native kidney biopsy over last 5 years (n=177) divided into 2 groups: -Group A: Same-day discharge after -Group B: 23-hour observation after US-guided biopsy by Urology Outcomes compared included timing of hemoglobin (Hb) drop post-procedure, readmission rates, need for transfusions, imaging or interventions.

Results: Of 177 patients, 75 (42.3%) were in Group A and 102 (57.6%) in Group B. Drop in Hb and post-biopsy complications were not significantly different between the groups. Three patients had bleeding complications, two of which required transfusion (Table). All three patients with bleeding complications had >10% Hb drop within first 6 hours post-biopsy. No readmissions related to biopsy occurred.

Conclusions: There were no major complications in either group. This QI study suggests that the majority of asymptomatic patients can be safely discharged at 6 hrs post-biopsy if Hb is stable. This could help reduce healthcare costs and burden to patients. This is a limited single center study: further larger studies are needed to confirm this.

Bleeding Complications Post-Kidney Biopsy									
Patient #	SBP Prior to Biopsy	Hb up to 1 month prior	Hb <6 hrs post-biopsy (% decrease from prior)	Hb 18-20 hrs post-biopsy	Symptoms	Imaging findings	Transfusion (units of pRBC)	Procedures Needed	Length of Stay in days (LOS)

Does Obtaining an Extra Biobank Sample Increase the Risk of Post-Kidney Biopsy Complications? A Single-Center Experience

Sheila Bermejo, Clara García-Carro, Ander Vergara, Irene Agraz, Richard Mast, Juan León Román, Mónica Bolufer, Daniel Serón, Maria Jose Soler. *Vall d'Hebron Hospital Universitari, Barcelona, Spain.*

Background: Kidney biopsy(KB) is the "gold standard" for nephropathies diagnosis and it has a low rate of complications. Obtaining material for KB biobank requires the extraction of extra renal cylinder. The objectives of study are to analyze the characteristics of a cohort of patients with KB, the safety and show whether obtaining extra renal cylinder is associated with an increased risk of complications.

Methods: Observational and prospective study of KBs performed in our center during 2019 and 2020. We started a collection of KB samples to biobank at 2019. In patients who accepted, instead of two cylinders, three cylinders were obtained during the procedure. Clinical and laboratory data of patients were reviewed. Risk factors for complications, including the number of cylinders obtained, was also assessed.

Results: 221 patients in whom we performed a KB at our hospital were included in the biobank. 8 patients(3.6%) underwent trans-jugular renal biopsy, which we have excluded. Of the remaining 213, 126(59.2%) were men, the mean age 56.8(± 16.9) years, 122(57.3%) patients had hypertension, 46(23%) were diabetics, 14(6.5%) were under anticoagulant treatment and 35(16.4%) under antiplatelet treatment. The mean creatinine was 2.22(±1.9) mg/dl, protein/creatinine urine ratio 1119.6[448.3-2957.9]mg/gr, the hemoglobin pre-KB was 12.1(± 2.3) g/dL, 254380(± 8873) platelets, INR 0.98(± 0.09), prothrombin time 11.8(± 1.16) seconds. 69.5%(n=148) of patients 3 renal cylinders were obtained, 27.2%(n=58) 2 cylinders and in 3.3% (=7) one cylinder. Minor complications were observed in 13.6%(n=29) and major complications in 3.3%(n=7). We observed that patients with complications in KB were younger(p=0.034), had less weight(p=0.022), more transfusions(p=0.003), more platelets(p=0.038), a lower PT(p=0.05) and 1 cylinder was obtained in the KB with more frequency(p=0.012). In a multivariate regression logistic analysis PT (OR:1.497,p=0.042), transfusions(OR:5.38,p=0.032) and 1 cylinder obtained(OR:7.258,p=0.032) were identified as a risk factors of KB complications.

Conclusions: KB is a procedure with a low complication rate. Obtaining three KB cylinders for biobank has not shown an increase in the rate of complications, which in concordance with previous published studies remains low.

PO1933

Assessment of Glomerular Number in Fresh Renal Tissue and Renal Pathological Specimens

Kosuke Sonoda, Makoto Harada, Koji Hashimoto, Yuji Kamijo. *Shinshu Daigaku, Matsumoto, Japan.*

Background: On-site evaluation of fresh renal tissue at the time of renal biopsy is useful. However, some cases present poor correlation in glomerular number between fresh renal tissue and renal pathological specimens.

Methods: To examine the usefulness of on-site evaluation, the correlation between glomerular number in fresh renal tissue and renal pathological specimens, and associated factors disturbing the evaluation were investigated via a retrospective cross-sectional observational study.

Results: In the included 129 cases, there was a significant positive correlation between glomerular number in fresh renal tissue and renal pathological specimens. The median ratio of glomerular number (renal pathological specimen/fresh renal tissue) was 0.74 (0.48–0.97). According to this ratio, all cases were divided into three groups: a reasonable estimation group (65 cases), underestimation group (32 cases), and overestimation group (32 cases). Comparing the reasonable estimation group with the underestimation group, significant differences were detected in the extent of interstitial fibrosis and tubular atrophy (IFTA) and in the extent of interstitial inflammation. Logistic regression analyses also demonstrated that IFTA and interstitial inflammation were significantly associated with underestimation.

Conclusions: In conclusion, glomerular number counted by on-site evaluation of fresh renal tissue estimated the actual number of glomeruli in the renal pathological specimen, suggesting clinical benefit. Since tubulointerstitial lesions, such as IFTA and/or interstitial inflammation, may make it difficult to recognize glomeruli in fresh renal tissue, the possibility of underestimation of results for cases with possible severe tubulointerstitial lesions should be considered.

PO1934

Variability in Estimates of Nephron Number from Biopsy

Darya Morozov,[1] Jennifer R. Charlton,[2] Neda Parvin,[1] Gavin T. Oxley,[2] Edwin Baldelomar,[1] Aleksandra Cwiek,[2] Kimberly Deronde,[2] Scott C. Beeman,[3] Kevin M. Bennett.[1] *[1]Washington University in St Louis, St Louis, MO; [2]University of Virginia, Charlottesville, VA; [3]Arizona State University, Tempe, AZ.*

Background: Nephron number may predict kidney health and functional capacity. It is unknown whether biopsies can be used to predict glomerular number (Nglom) in individuals, or how many subjects are required to detect differences between populations. We investigated the accuracy and precision of Nglom measured from biopsy.

Methods: We examined 6 human kidneys, rejected for transplant. We performed 8-10 needle biopsies. We used this and cortical volume to estimate Nglom. We simulated 210-227 "virtual biopsies" (VB) from 3D cationized ferritin- enhanced MRI (CFE-MRI), in 4-5 clusters of 12-18 VBs in bottom, upper, and middle poles (Fig. 1Ai).

Results: Nglom estimated from single needle biopsy had up to 70% error depending upon where it originated (Fig. 1Bi). Nglom estimated from needle and VB varied consistently by ~ 50% (Fig. 1Biv), and there was no preferred biopsy location for accurate estimates of Nglom. The maximum variability in mean Nglom within clusters of closely packed virtual biopsies was 11-56% (Fig. 1Biv). Based on statistical analysis, > 200 physical biopsies are required to be 95% certain the estimated Nglom is within +/- 20% of true Nglom.

Conclusions: A single biopsy is not sufficient to predict Nglom in the individual kidney, but this work provides the required number of subjects required to detect differences in Nglom between populations.

Funding: NIDDK Support

PO1935

Epidemiology of Medical Kidney Disease in the Southwestern United States, 1989-2018

Akira Takahashi,[1,2] Takamasa Miyauchi,[1] Yi Mi Kevin Ren,[1] Toshiki Doi,[2] Takao Masaki,[2] Michifumi Yamashita.[1] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Hiroshima University Hospital, Hiroshima, Japan.*

Background: Kidney biopsy is the main source of epidemiological information for kidney disease. However, large-scale epidemiological studies for glomerular disease (GD) in the US are very limited, and there are no such studies for non-glomerular disease (non-GD). Here, we describe 30-year temporal and demographic trends in GDs and non-GDs in the southwestern US between 1989 and 2018.

Methods: In this retrospective study, all kidney biopsy data at Pathology, Cedars-Sinai Medical Center (CSMC), Los Angeles, CA, between 1989 and 2018 were reviewed. We analyzed the most common 26 GDs and the most common 9 non-GDs. The frequencies of GD and non-GD subtypes and the temporal trends in each disease subtype within demographic subgroup were our primary and secondary outcomes. In addition, the frequency distribution of each disease category was evaluated across age categories stratified by sex and race.

Results: Among 48,068 patients (mean age =50.3 ± 19.3 y.o.; 52.0% men; 55.5% white; 18.4% Latino; 11.1% black; 9.8% Asian; 5.2% others), GD and non-GD composed 83.4% and 16.6% of all biopsies, respectively. In GDs, the frequency of diabetic glomerulosclerosis increased over the three decades (8.4%, 12.2%, and 22.0% of diagnoses; *P* for trend <0.003). The frequency of FSGS, lupus nephritis, immune complex-glomerulonephritis (GN), membranous nephropathy, and minimal change disease declined substantially over time. On the other hand, IgAN and ANCA/pauci-immune GN remained stable. In non-GDs, nephrosclerosis was the most frequent in study period. However, acute tubular necrosis/injury slightly increased over time and became the most common subtype in the latest 10 years. These temporal trends were largely preserved within all demographic subgroups, although cross-sectional frequency distributions differed according to age, sex, and race.

Conclusions: We reported the largest epidemiological study of medical kidney disease in the US. The relative renal biopsy frequencies of many GDs and non-GDs showed significant changes over the three decades in the southwestern US. Temporal

trends were consistently observed within all major demographic groups. We provided evidence that changes in demographics (age, sex, and race) contributed minimally to these findings, suggesting that environmental and lifestyle changes contribute to them.

PO1936

Pathology Core Scoring Parameters and Reproducibility in the CureGN Study

Abigail R. Smith,[1] Matthew Palmer,[11] Virginie Royal,[3] Qian Liu,[1] Nicole K. Andeen,[2] Carmen Avila-Casado,[16] S.M. Bagnasco,[12] Vivette D. D'Agati,[4] Agnes B. Fogo,[5] Joseph Gaut,[15] Rasheed A. Gbadegesin,[6] Larry A. Greenbaum,[14] Jean Hou,[7] Richard A. Lafayette,[8] Helen Liapis,[15] Afshin Parsa,[9] Bruce M. Robinson,[1] Michael B. Stokes,[4] Katherine Twombley,[13] Jarcy Zee,[11] J. Charles Jennette,[10] Cynthia C. Nast.[7] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Oregon Health & Science University School of Medicine, Portland, OR; [3]Universite de Montreal, Montreal, QC, Canada; [4]Columbia University Irving Medical Center, New York, NY; [5]Vanderbilt University Medical Center, Nashville, TN; [6]Duke University School of Medicine, Durham, NC; [7]Cedars-Sinai Medical Center, Los Angeles, CA; [8]Stanford Medicine, Stanford, CA; [9]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [10]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [11]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [12]Johns Hopkins University School of Medicine, Baltimore, MD; [13]Medical University of South Carolina, Charleston, SC; [14]Emory University, Atlanta, GA; [15]Washington University in St Louis School of Medicine, St Louis, MO; [16]University of Toronto, Toronto, ON, Canada.*

Background: CureGN is an NIH-funded multi-center, prospective, observational cohort study of patients with minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), or IgA nephropathy from 66 international sites with 2500 enrolled participants. The large scale of CureGN requires a practical systematic approach to pathologic scoring that can be applied consistently across a large number of cases and multiple scoring pathologists. The method reflects common pathology practices, generating data for assignment to currently used disease classifications and use in future studies utilizing conventional parameters. The objective of this analysis was to determine and evaluate the pathology scoring reproducibility.

Methods: The CureGN Core Scoring Workgroup established definitions of multiple glomerular, tubular, interstitial and vascular lesions evaluated semi-quantitatively, as observed by light, immunofluorescence, and electron microscopy (EM). All cases with complete pathology data as of April 2019 were randomly assigned for scoring of whole slide and EM images to one of eleven pathologists; a random subset of >10% were scored by a second pathologist. Reproducibility was assessed using Gwet's AC1 statistic.

Results: Of 797 biopsy specimens (141 MCD, 186 FSGS, 205 MN, 265 IgA) scored by at least one pathologist, 94 were scored twice (12%). Of 60 pathology features, 46 (77%) demonstrated excellent reproducibility (Gwet's AC1>0.8), and 12 (20%) had good reproducibility (Gwet's AC1>0.6). Mesangial hypercellularity scored as absent, focal or diffuse had moderate reproducibility (AC1=0.58), but scored as absent vs present had AC1=0.71. The percent glomeruli scored as having no lesions had fair reproducibility (AC1=0.34).

Conclusions: The majority of pathologic features scored showed excellent reproducibility, supporting the hypothesis that these features can be scored consistently by multiple pathologists. Future studies will include correlation of these histopathologic features with clinical and demographic characteristics at the time of biopsy and eventually disease biomarkers and clinical outcomes.

PO1937

Dysmorphic Lysosomes, Pathognomonic of Chronic Interstitial Nephritis in Agricultural Communities (CINAC)

Claudia G. Olano,[4] Nehemias A. Guevara,[4] Carlos A. Salinas,[3] Carlos Orantes,[1] Lilly M. Barba,[4] Sami M. Akram.[2] *[1]Ministry of Health of El Salvador, Santa Ana, El Salvador; [2]Loma Linda University, Loma Linda, CA; [3]San Juan de Dios Hospital, nephrology department, Santa Ana, El Salvador; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Background: The etiology and pathogenesis of CINAC are unknown. Two hypotheses have been put forward. Dysmorphic lysosomes (DL) were described as pathognomonic however some argue that DL are non-specific findings. Therefore, we did an observational study of electron microscopic (EM) findings in CINAC comparing to published cases.

Methods: Sixteen patients from Central America, suspected of CINAC clinically underwent kidney biopsy (KB). Demographic characteristics, blood and urine analysis data were collected. Renal histology was studied using light (LM), immunofluorescence (IF), and electron microscopy (EM). We reviewed the literature in PubMed using the following search terms (a). "Chronic Interstitial Nephritis + Electron Microscopy + Kidney" and identified 8 relevant cases (Group A) (b). "Dysmorphic Lysosomes, Electron Microscopy" found 14 cases that described the EM findings (Group C).

Results: Of the 8 patients in group A, who had CIN, only 2had DL on EM. One patient had Calcineurin Inhibitors (CNI) and one patient from Sri Lanka had chronic kidney disease of unknown origin, which is also considered as CINAC. In patient who had CNI, the DL had irregular edges unlike the smooth rounded DL of varying sizes noted in all CINAC patients. In the control group, C, the patients who had DL, were 14 but the DLs were present in organs other than kidneys. The two patients had DL in the kidneys, one was Fabry's disease, and the other was Light chain Proximal tubulopathy (LCPT). In Fabry's disease, the DL were lamellated. In LCPT the DL were rectangular due to the characteristics of the lambda proteins.

Conclusions: Dysmorphic Lysosomes may occur in multiple disorders, however, in young persons with agricultural exposure, non-nephrotic proteinuria, presence of tubular inflammation, presence of smooth rounded clusters of DL are pathognomonic. Morphology of the DL is dictated by the contents of the lysosomes as in the case of LCPT; further, evaluation is recommended.

	CIN-GrA	CINAC-GrB	DL-GrC	Total
DL-Kidney Positive	2	16	2	
DL-Kidney Negative	6	0	12	
	8	16	14	28

The Chi-square statistic is 21.3929. The p-value is 000023.

DL= Dysmorphic Lymphocytes.

GrA: CIN, GrB: CINAC, GrC: Have dysmorphic lymphocytes.

PO1938

Reduction of Globotriaosylceramide Inclusions in Renal Peritubular Capillaries in Patients with Fabry Disease Following Treatment with Pegunigalsidase Alfa

Laura Barisoni,[1] J. Charles Jennette,[2] Myrl D. Holida,[3] Ozlem Goker-Alpan,[4] Gustavo Maegawa,[5] Pilar Giraldo,[6] Derlis E. Gonzalez,[7] Ahmad M. Tuffaha,[8] Sari Alon,[9] Einat Almon,[9] Raul Chertkoff,[9] Derralynn Hughes.[10] *[1]Duke University School of Medicine, Durham, NC; [2]University of North Carolina System, Chapel Hill, NC; [3]The University of Iowa Healthcare, Iowa City, IA; [4]Lysosomal Disorders Research and Treatment Unit, Fairfax, VA; [5]University of Florida, Gainesville, FL; [6]Hospital de Dia Quiron, Zaragoza, Spain; [7]Instituto Privado del Nino y Adolescente, Asuncion, Paraguay; [8]University of Kansas Medical Center, Kansas City, KS; [9]Protalix Biotherapeutics, Carmiel, Israel; [10]Royal Free London NHS Foundation Trust, London, United Kingdom.*

Background: Fabry disease (FD) is a rare genetic disorder characterized by reduced activity of the lysosomal enzyme α-galactosidase A (α-Gal A), leading to accumulation of sphingolipids such as globotriaosylceramide (Gb_3) and globotriaosylsphingosine ($lysoGb_3$), and organ dysfunction. Gb_3 inclusions form in various renal cell types and Gb_3 clearance from renal peritubular capillaries (PTCs) has been used as a surrogate endpoint in trials of approved FD therapies. The objective of this analysis was to quantify the reduced burden of Gb_3 inclusions in PTCs in patients with FD participating in a phase 1/2 trial of pegunigalsidase alfa (recombinant α-Gal A) enzyme replacement therapy.

Methods: In a phase 1/2 dose-ranging study (NCT01678898), 18 adults with FD received 0.2 mg/kg, 1.0 mg/kg, or 2.0 mg/kg of pegunigalsidase alfa by intravenous infusion every 2 weeks for up to 12 months. Kidney biopsies were taken at baseline and after 6 months of treatment. Levels of Gb_3 inclusions in renal PTCs were determined using the Barisoni Lipid Inclusions Scoring System (BLISS) protocol (Barisoni L et al. Arch Pathol Lab Med. 2012;136:816–824).

Results: Of 14 evaluable patients with available kidney biopsies at baseline and 6 months, 12 patients (85.7%) had ≥20% reduction, 11 patients (78.6%) had ≥50% reduction, and 3 patients (21.4%) had ≥90% reduction in Gb_3 inclusions. In the analysis (n=13; excluding 1 male patient due to minimal renal involvement), the mean BLISS score 6 months from baseline was lowered for all doses (reduced by 75.5%, 86.5%, and 39.5% in the 0.2 mg/kg, 1.0 mg/kg, and 2.0 mg/kg treatment groups, respectively). The magnitude of reduction of Gb_3 inclusions was greater in males (n=7; reduction: 85.0%) vs females (n=6; reduction: 47.7%). Overall, mean BLISS score was reduced from 4.23 at baseline to 0.83 at 6 months (67.8% ± 8.9%). Reduction in Gb_3 inclusions at 6 months was correlated with a reduction in plasma $lysoGb_3$ at 12 months (R=0.905).

Conclusions: Results from this phase 1/2 study demonstrated that pegunigalsidase alfa reached the affected tissue and effectively reduced the number of Gb_3 inclusions in renal PTCs at 6 months in adults with FD.

PO1939

Patients with Active Mantle Cell Lymphoma May Present with Monoclonal, Polyclonal, or C3-Dominant Glomerulonephritides, Which Respond to Lymphoma-Directed Therapy

Nicole K. Andeen,[1] Shahad Abdulameer,[4] Vivek Charu,[3] Jonathan E. Zuckerman,[2] Megan L. Troxell,[3] Neeraja Kambham,[3] Charles E. Alpers,[4] Behzad Najafian,[4] Roberto F. Nicosia,[4] Kelly D. Smith,[4] Vanderlene L. Kung,[1] Rupali S. Avasare,[1] Michifumi Yamashita,[5] Mei Lin Bissonnette,[6] Shreeram Akilesh,[4] Jean Hou.[5] *[1]Oregon Health & Science University, Portland, OR; [2]University of California Los Angeles, Los Angeles, CA; [3]Stanford University, Stanford, CA; [4]University of Washington, Seattle, WA; [5]Cedars-Sinai Medical Center, Los Angeles, CA; [6]The University of British Columbia, Vancouver, BC, Canada.*

Background: There are limited reports on kidney biopsy findings in patients with mantle cell lymphoma (MCL).

Methods: We initiated a multi-institutional, retrospective review of kidney biopsy findings from patients with active and treated MCL.

Results: Twenty-nine patients (31 biopsies) with MCL and kidney biopsies were identified, with a median age of 66 (range 48-87), 76% of whom were men. Nineteen patients had active MCL at the time of biopsy, 13 of which (68%) presented with acute kidney injury, proteinuria and/or hematuria, and biopsy findings attributable to lymphoma (Table); 6 (32%) had findings not readily attributable to MCL. Of the former, 10 (77%) had immune complex (IC) disease including proliferative glomerulonephritis with monotypic Ig deposits (PGNMID, 2), C3 dominant GN (3), PLA2R-negative membranous (MN, 3), and/or tubular basement membrane deposits (2). Lymphomatous infiltration was present in 6, 3 with coincident IC lesions. Four with available follow-up were treated for MCL, all with remission of GN (1 PGNMID, 2 C3 dominant GN, 1 MN). Ten patients were biopsied while MCL was in remission; these findings were attributed to various underlying diseases.

Conclusions: In patients with active MCL who undergo kidney biopsy, 68% had kidney biopsy findings attributable to lymphoma. Diverse immune complex diseases were seen in ~50%, including monoclonal, polyclonal, and C3 dominant GN patterns, and nearly 1/3rd had lymphomatous infiltration. Limited follow-up suggests these IC lesions respond to MCL-directed therapy.

Case	Age Sex	Bx indication	Kidney bx diagnosis	Light microscopy	IF	EM deposit location	Follow-up
1	66F	AKI, nephrotic proteinuria, hematuria	PGNMID	MPGN with diffuse crescents	IgG3 kappa (2+), C3 (3+), C1q (2-3+)	Mes, subendo	MCL treated, GN in remission at 5 months
2	65M	AKI, nephrotic syndrome, hematuria	PGNMID	Mesangial, endocapillary proliferative; focal crescents	IgG3 kappa (3+), C3 (3+), C1q (2-3+)	Mes, subendo, rare subepi	Unknown
3	61M	AKI, nephrotic proteinuria, hematuria	C3 dominant GN, lymphoma infiltration	Mesangial proliferative	C3 (4+), IgG (2+), k (2+), l (2+), C1q (1-2+)	Mes	MCL treated, GN in remission at 28 months
4A &B	68M	AKI, proteinuria, hematuria	C3 dominant GN	Mesangial proliferative	C3 (3+), C1q (tr-1+)	Mes, rare subepi	Persisted on repeat bx at 5mo, then MCL treated and GN in remission at 7 years
5	87M	AKI, subnephrotic proteinuria, hematuria	C3 dominant GN, AIN	Mesangial proliferative, mild AIN	C3 (2-3+), C1q (2+), IgG (tr-1+)	Mes, parames	Unknown
6	73M	Progressive CKD subnephrotic proteinuria	MPGN, lymphoma infiltration	MPGN	No gloms available	Mes, subendo, few subepi	Unknown
7	66M	Nephrotic syndrome	Membranous GN, THSD7A+	membranous	IgG (4+), k (2+), l (3+), C3 (3+)	Global subepi, rare mes	Unknown
8	59F	Nephrotic syndrome	Membranous GN, PLA2R-	membranous	IgG (3+), k (2+), l (3+), C3 (3+)	Irregularly distributed subepi	MCL treated, GN in remission at 4.5 years
9	69M	Progressive CKD, subnephrotic proteinuria	Membranous, segmental, TBM deposits, lymphoma infiltration	membranous	IgG (2+), k, l, C3, C1q (all 1-2+), with chunky TBM deposits	Subepi, subend, mes, TBM	Unknown
10	77M	AKI	TBM deposits, ATN	ATN, normal glomeruli	Coarse TBM staining for IgG, k, l, C3	Fine granular TBM	Unknown
11	76M	AKI, hx lupus	Lymphoma infiltration, mild lupus	Mesangial proliferative, duplicated GBM	IgG, IgM, k, l, C3, C1q (all 1+)	Mes, subendo, rare TRI	Unknown
12	72F	AKI	Lymphoma infiltration, arterionephrosclerosis	Normal glomeruli	Negative	Negative	Unknown
13	74M	AKI (autopsy)	Lymphoma infiltration, diabetic nephropathy	Nodular mesangial sclerosis	Not performed	Not performed	(autopsy)

PO1940

Anti-Brush Border Antibody Disease with Nephrotic Syndrome: A Clinicopathologic Analysis of Five Cases

Xiaoye Zhu, Shaojun Liu, Jun Xue, Chuan-Ming Hao. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Anti-brush border antibody(ABBA)disease is a recently described etiology of acute kidney injury and progressive renal tubular injury that mainly affects the older patients. ABBA is characterized by the presence of circulating autoantibodies to the proximal tubular brush border protein LRP2(megalin)and IgG immune complex deposits along the basement membrane of proximal tubules. In the present study, we report 5 cases of ABBA that all presented as nephrotic proteinuria.

Methods: We retrospectively screened for ABBA disease through our renal biopsy cohort from January 2018 to May 2021. The anti-brush border antibody disease was diagnosed based on the presence of ABBA in the serum, showing positive ABBA on a kidney section by indirect immunofluorescence with patient's serum, and kidney histology. Histology of the biopsies and clinical data were analyzed.

Results: Five cases with ABBA disease were identified, out of 0.1% total biopsies. Mean age was 41 years (29-54) with a M:F ratio of 1:4. At biopsy, all had nephrotic syndrome with proteinuria (12.1 g/24h, 3.8-27 g/24h). Only one patient presented with acute kidney injury. Serologies, including ANA, dsDNA, ANCA, anti-GBM were negative. C3 and C4 levels were normal. Neither acute tubular injury nor intensive Interstitial inflammation were found in all these biopsies. Proximal tubular brush border and glomerular basement membranes stained positive for IgG in all cases, and 3 cases also have positive deposits in some segments of TBM. Staining for IgG subclass showed that IgG1 was positive, while IgG2, IgG3 and IgG4 were not detected. Interestingly, we found light chain monotype of lambda in two patients. Electron microscopy showed diffuse podocyte foot process effacement in all cases. All patients received prednisone plus cyclophosphamide therapy and achieved complete recovery after 2 months (range: 1-3) (Table 1).

Conclusions: We report 5 cases of anti-ABBA disease with nephrotic syndrome recovered after treatment with prednisone and cyclophosphamide. The mechanism of podocyte injury in anti-ABBA disease requires additional studies.

Table 1 Clinical characteristics and pathologic findings at presentation

	#1	#2	#3	#4	#5
Age/Sex	29/F	34/F	54/M	34/F	54/F
24h-Urine protein(g/d)	3.8	13.7	11.9	27	4.2

PO1941

Time-Course Kidney Injury in Mice Remnant Kidney Model Fed by High-Protein Diet

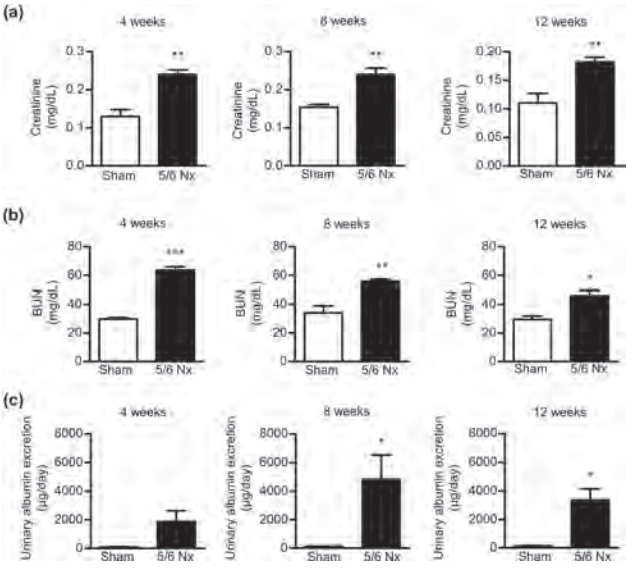
Shohei Tanaka, Hiromichi Wakui, Shingo Urate, Toru Suzuki, Eriko Abe, Shunichiro Tsukamoto, Shinya Taguchi, Kengo Azushima, Kouichi Tamura. *Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan.*

Background: Numerous animal models of CKD have been developed, but mice are relatively resistant to kidney injury. The remnant kidney model mimics progressive renal failure, and widely used in CKD research. The present study was performed to evaluate the effects of combined high-protein diet (HPD) loading and 5/6 nephrectomy (Nx) in a susceptible strain of mice (129/Sv).

Methods: Male 8–11-week-old 129/Sv mice underwent 5/6 Nx or sham surgery, then 2 weeks later were switched to an HPD, and cardiovascular parameters, kidney function, and renal histology were assessed after 4, 8, or 12 weeks.

Results: The 5/6 Nx group showed blood pressure elevation, cardiac hypertrophy, renal function decline, severe albuminuria, and glomerular hypertrophy. However, the glomerulosclerosis by 5/6 Nx was very mild and there was only modest tubulointerstitial inflammation and fibrosis in the 5/6 Nx group, even after 12 weeks of HPD loading. Furthermore, the sham group showed no histological changes.

Conclusions: Thus, an HPD alone is insufficient to cause renal pathology, and a combination of 5/6 Nx and HPD loading induces mild renal pathology.



PO1942

Neutralizing Antibodies in Preventing Polyomavirus Nephropathy: Lessons from the Mouse

Dalton R. Butcher, Bawana D. Thompson, Harsharan K. Singh, Volker Nickeleit. *University of North Carolina at Chapel Hill Department of Pathology and Laboratory Medicine, Chapel Hill, NC.*

Background: Definitive polyomavirus nephropathy (PyVN) affects kidney transplants and impacts allograft function and survival. Data suggest that neutralizing PyV strain specific antibodies can attenuate and possibly even prevent disease. Here we report observations from the mouse on the protective role of anti-PyV antibodies.

Methods: Six breeding mice had been exposed to murine PyV (MUPyV). They had developed a robust IgG response while lacking definitive PyVN and only showing minor qPCR evidence of intra organ MUPyV. Newborns of exposed breeders were split: group 1 (n=23) was injected at birth with MuPyV; group 2 (n=19) was not injected. Group 3 (n=24) was born to unexposed breeders and injected with MUPyV at birth. Tissue, plasma, and urine were analyzed at various time-points (0,1,2,3,6, and 10 weeks) by light microscopy, immunohistochemistry, qPCR, and MuPyV antibody titer testing. The nonparametric Wilcoxon Rank Sums test was used for p-value comparisons

Results: Newborns from exposed breeders had IgG titers between 160-640, no IgM, and only subclinical minor molecular evidence of intra organ MUPyV by qPCR. During 10 weeks of follow up, groups 1 and 2 both cleared MuPyV. By week 10, MUPyV was largely undetectable in the setting of significantly reduced IgG titers (0-40; no IgM). Prior to clearance, both groups displayed a mild transient increase in IgG titers (up to 2560; no IgM) at weeks 2 and 3. MUPyV clearance occurred earlier in group 2 with significantly lower qPCR reads in kidney and spleen noted on week 2 ($P<0.03$). There was no MUPyV induced organ injury. In contrast, group 3 showed persistently high intra organ qPCR reads starting post MUPyV injection on day 0 and lasting through week 10 ($p<0.05$ compared to groups 1/2). Histologically apparent viral tissue injury was first noticeable at week 1 and persisted thereafter. IgG and IgM levels remained undetectable until week 2, when they began to slowly rise. By week 10, IgG titers had risen significantly (up to 20480) while IgM titers had decreased to 0

Conclusions: Preexisting neutralizing antibodies protect from PyVN and facilitate clearance of subclinical MUPyV. In contrast, established MUPyV induced disease/injury is unaffected by neutralizing antibodies. This data can help with developing preventative treatment strategies in man.

PO1943

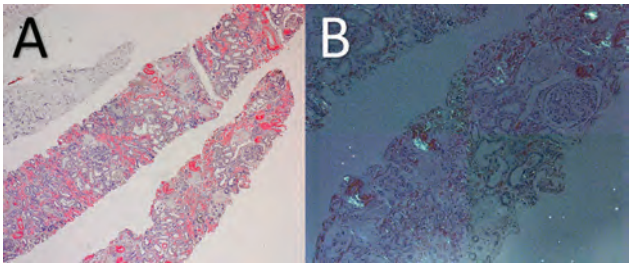
Renal Failure of the Non-Crisis Variety in Scleroderma

Jaime (James) A. Vondenberg, J Pedro Teixeira, Saeed K. Shaffi, Michelle Shieh. *University of New Mexico School of Medicine, Albuquerque, NM.*

Introduction: Renal disease from systemic sclerosis (SS) classically presents as scleroderma renal crisis (SRC). In contrast, amyloidosis in SS is rare.

Case Description: A 73-year-old woman with untreated limited SS for >20 years (with ANA 1:160 centromere pattern, negative Scl-70, sclerodactyly, perioral scleroderma, telangiectasias, Raynaud's, and mild pulmonary hypertension), CKD with baseline creatinine of (Cr) ~1.5 mg/dL, Barrett's esophagus, and recent right below-knee amputation (for chronic wound osteomyelitis and invasive squamous cell carcinoma) is readmitted 2 weeks later for a pseudomonal stump infection. She develops AKI (Cr peak of 6) requiring HD. Renal biopsy reveals amyloidosis [figure]. Immunofluorescence and immunohistochemistry are negative for deposition of kappa, lambda, AA, or leukocyte chemotactic factor 2 (LECT2), but subsequent liquid chromatography-tandem mass spectrometry (LC-TMS) is positive for LECT2.

Discussion: SRC occurs in 5-10% of SS cases but is no longer the primary cause of death in SS with the advent of ACE inhibitors (ACEi). Unlike other autoimmune diseases, amyloidosis, especially renal amyloidosis, is rare in SS. While recovery from dialysis can occur in SRC with ongoing ACEi therapy, AA amyloidosis requiring dialysis carries a poor renal prognosis. LECT2 is a recently discovered amyloid protein that can deposit in multiple organs, with the most significant clinical feature of LECT2 amyloidosis (ALECT2) being slowly progressive renal failure. The pathogenesis is poorly understood. Diagnosis is by renal biopsy, with advanced methods like LC-TMS often needed for LECT2 detection. Though the reason is unclear, ALECT2 seems to have a predilection for Mexican Americans and Native Americans and is likely underdiagnosed in the Southwest U.S. However, it is not usually associated with autoimmune disease, with this being the first known case of ALECT2 occurring in the context of SS.



Biopsy shows amyloid deposits, primarily in the cortical interstitium and vessels, by Congo red stain [A] with green birefringence under polarized light [B], with global sclerosis of 22/35 glomeruli and 50% interstitial fibrosis.

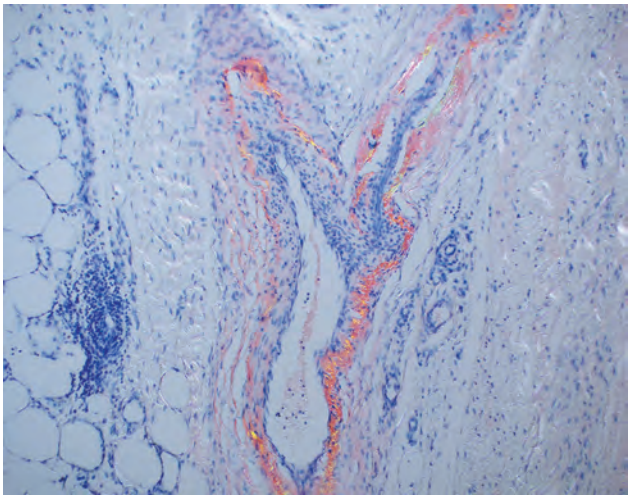
Amyloid of Another Kind: The Unexpected Fat Pad Biopsy

Madeline Kirby,[1] Douglas J. Grider,[1] James S. Cain.[2] *[1]Virginia Tech Carilion School of Medicine, Roanoke, VA; [2]Valley View Nephrology, Roanoke, VA.*

Introduction: Insulin-type amyloidosis is a rare phenomenon in which subcutaneous masses develop at the site of repetitive insulin injections. Here we discuss a patient in which insulin-type amyloid did not present with a subcutaneous mass and instead was diagnosed during the workup for systemic amyloidosis.

Case Description: A 52 year old male with a history of insulin dependent diabetes and stage 3 CKD was evaluated for nephrotic-range proteinuria. He endorsed weight gain, peripheral edema and dyspnea. Physical exam revealed anasarca. He reported a history of amyloidosis in his father. Due to the combination of proteinuria, anasarca and positive family history, a workup for systemic amyloidosis was initiated. Initial serum and urine electrophoresis were non-diagnostic. Urine protein to creatinine ratio was 2610 mg/g. Kappa and lambda ratios were unremarkable. After a rheumatologic workup including ANA, c-ANCA and p-ANCA was negative, an abdominal fat pad biopsy was performed. The fat pad biopsy revealed deep dermal granulomatous vasculitis and vessel damage with extravasated blood. A Congo Red stain showed apple green birefringence on polarization. The site of the fat pad biopsy had no gross abnormalities such as hard masses or skin irregularities. Amyloid typing by liquid chromatography was positive for insulin-type amyloidosis.

Discussion: This case demonstrates a novel clinical and histologic presentation of insulin-type amyloid. By our research, this is the second case report that has discovered insulin type amyloid during the diagnostic workup for systemic amyloid. This finding suggests that a fat pad biopsy be avoided at insulin injection sites. If a patient with insulin dependence has a positive fat pad biopsy we suggest confirmation of the specific amyloid type in order to rule out insulin type amyloidosis.



Congo Red stain showing apple-green birefringence

PO1945

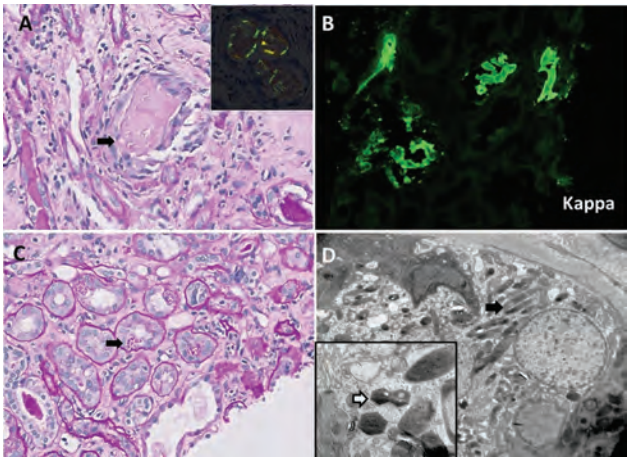
Simultaneous Light-Chain Proximal Tubulopathy (with Crystals), Myeloma Casts Nephropathy, and Intratubular Amyloidosis in a Patient with Monoclonal Gammopathy of Renal Significance

Majd Al Shaarani, Fadi E. Salem. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) is an important complication of monoclonal disease in the kidney with a spectrum of histological changes involving glomerular and tubulointersitial compartments. While MGRS is usually present as a single pathological entity, a combined two or more pathology features in a single patient is rarely reported.

Case Description: A 67 year old male admitted to the hospital for nausea and vomiting in association with AKI (creatinine 9.06 mg/dL), severe anemia (hemoglobin 6.4 g/dL) and hypercalcemia. Urinalysis showed 4-10 RBCs and proteinuria of 30 mg/dL. SPEP detected a monoclonal IgG kappa light chain. The patient received 2 units of blood transfusion pending further study and hematology consult. Kidney biopsy showed a few thick angulated atypical casts in the distal tubules that show positive birefringent apple green staining by Congo red (Fig 1 A&B). By immunofluorescence, the casts are positive for kappa light chain with negative lambda (Fig 1 C&D). In addition, few proximal tubules show rounds or needle-shape intracytoplasmic structures (Fig 2 A&B). Ultrastructural examination demonstrates intracytoplasmic needles, rod, rhomboid or hexagonal crystals (Fig 2 C&D).

Discussion: The pathophysiological features of MGRS are distinctive, yet it can occur simultaneously in one patient. A throughout pathology and clinical assessment is essential in order to guide the treatment.



A. Atypical cast with sharp edges surrounded by epithelial cells of distal tubules (PAS). Congo red-positive intratubular casts (inset)

B. Intratubular casts are positive for Kappa light chain (Direct Immunofluorescent)

C. Renal cortex shows intracytoplasmic magenta-colored structures (arrow) in proximal tubules (PAS)

D. Ultrastructural images of proximal tubular cells show rod and rhomboid intracytoplasmic crystals (black arrow) and hexagonal and oval-shape crystal (white arrow/inset) (transmission EM)

PO1946

Insidious Granulomatous Interstitial Nephritis (GIN) in a Patient with a History of Diffuse Large B Cell Lymphoma (DLBCL)

Yohei Suehiro, Hiroyuki Ueda, Hiroki Nobayashi, Risa Ueda, Yukio Maruyama, Nobuo Tsuboi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Introduction: GIN has diverse etiology as infections, vasculitis, sarcoidosis, and lymphoma. These diseases can occur in the same patient, making diagnosis and treatment decisions challenging. Here, we report a case of GIN with a fever that developed after a long period since the complete remission (CR) of DLBCL.

Case Description: A 46-year-old man was admitted to our hospital with malaise, dyspnea, and severe renal failure (RF). Twenty years before the admission, he was diagnosed with DLBCL. After 4 years of treatments, he achieved CR. Thirteen years after CR, he presented to our hospital with a persistent fever. At this time, impaired renal function (serum [s] Cr 1.8 mg/dL) was noted. FDG-PET CT showed uptake in the enlarged lymph nodes (LN) around the pancreas and in both kidneys. Biopsy of the LN revealed multiple epithelioid granulomas and no evidence of recurrence of DLBCL, and his fever was resolved spontaneously. Two years later, he was admitted due to advanced RF (sCr 11.8 mg/dL), and hemodialysis (HD) was initiated. Both kidneys were atrophic on CT scan, whereas they still showed intense uptake on Ga scintigraphy. The renal biopsy showed diffuse GIN, but recurrence of DLBCL, sarcoidosis, and vasculitis was denied. Examinations for Tuberculosis (TB) were only positive for the interferon-gamma release assays (IGRAs) and negative for renal stains, systemic cultures, and image studies for lung TB. Anti-TB therapy was administered for his persistent fever that recurred after hospitalization. After the initiation of the anti-TB treatment, his fever gradually resolved, and he has been well, although he cannot withdraw HD.

Discussion: The course of our case suggests that the GIN was induced by TB infection, although our patient did not show typical features of systemic TB except for positive IGRAs. There has been an increase in the number of cases of TB infection diagnosed following GIN, which is presented not with the typical features of classical renal TB but with a more insidious form (Oliveria et al., Clin Kidney J 2017). These cases are often diagnosed later and may associate with a poor prognosis. Our case suggests that anti-TB therapy should be considered for patients with IGRAs-positive GIN after excluding other etiologies of GIN, even without the other diagnostic evidence of systemic TB.

PO1947

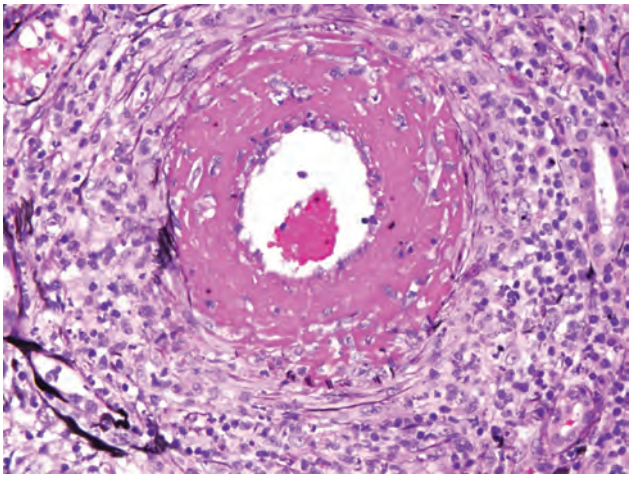
Severe Vasculitis Masquerading as Guillain-Barre Syndrome

Farah Abifaraj, Julia Lewis, Agnes B. Fogo. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Polyarteritis nodosa (PAN) is a rare ANCA-negative, necrotizing arteritis affecting small-medium arteries. Due to rarity of the disease, studies are limited. We present a case of PAN with missed diagnosis at presentation and complicated treatment course.

Case Description: 75-year-old man with hypertension diagnosed 10 months ago presented to outside hospital with bilateral lower extremity ascending numbness and weakness, and arthralgia. Lumbar puncture was inconclusive. He was treated for Guillain-Barre syndrome with IVIG with some improvement. Two months later, he presented to our hospital with localized petechial rash, oliguria, lower extremity edema, right foot drop, marked weakness, and acute kidney injury (creatinine (Cr) 4.09mg/dL). He had hematuria, subnephrotic range proteinuria, high inflammatory markers, and low complements. Renal biopsy revealed necrotizing medium vessel arteritis, consistent with PAN. He was started on steroids and oral cyclophosphamide (CYC) with rapid, dramatic improvement in neurologic symptoms. Unfortunately, a month later, he developed acute hypoxia with worsening multifocal opacities despite adequate diuresis and infectious work-up, including negative bronchoalveolar lavage. Pneumonitis from CYC toxicity was diagnosed. Hypoxia resolved with steroids and replacing CYC with mycophenolate mofetil (MMF). Cr improved to 2.2mg/dL with continued improvement in neuromuscular symptoms.

Discussion: This is a rare presentation of vasculitis causing severe AKI, debilitating peripheral neuropathy and weakness. Neurologic and renal manifestations improved rapidly with treatment. Development of CYC-induced pneumonitis leading to transition to MMF for induction is a rare complication, resulting in rare, but effective treatment. Lastly, development of new onset hypertension in the 8th decade of life warrants work-up for secondary etiologies.



Transmural fibrinoid necrosis of medium-sized renal artery with surrounding inflammatory cells

PO1948

Myoglobin Deposition in the Proximal Tubular Cells in a Patient with Dermatomyositis and Nonglomerular Proteinuria

Dina Hammad,[1,2] Christine E. Loftis,[1,2] Daniel Varela,[1,2] Mourad Alsabbagh,[2] Salil Mangi.[2] *[1]The University of Texas Rio Grande Valley, Edinburg, TX; [2]DHR Health, Edinburg, TX.*

Introduction: Dermatomyositis (DM) is a rare inflammatory myopathy characterized by proximal muscle weakness and skin lesions. Clinical manifestations of DM can involve any organ, including the kidneys. Although renal manifestations are rare, the literature describes cases of DM associated with mesangial proliferative glomerulonephritis, minimal change disease, Ig-A nephropathy, and acute tubular necrosis due to myoglobinuria. We report a rare case of DM with a predominant nonglomerular (NG) proteinuria, with kidney biopsy showing myoglobin deposition in the proximal tubules.

Case Description: A 38-year-old man presented with complaints of gradually worsening proximal muscle weakness and violaceous skin rash. Laboratory studies revealed an elevated creatinine phosphokinase (CPK) level of 8,250 IU/, 3+ hematuria with RBC 0-2, serum creatinine of 0.9 mg/dL, 24-hour urine test showed 1.8 g protein with 343 mg of albumin. The ANA titer was 1:1280, dsDNA was negative. A renal biopsy was done, and it showed acute tubular injury with increased proximal tubular cytoplasmic myoglobin staining with no myoglobin casts. There was no evidence of lupus nephritis. After corticosteroid therapy, Hydroxychloroquine, Mycophenolate Mofetil, and later Rituximab; his CPK level, proteinuria, and clinical symptoms have all steadily improved. This case demonstrates an atypical presentation of DM manifested by NG overflow proteinuria.

Discussion: The main renal manifestations of polymyositis are acute kidney injury related to rhabdomyolysis and glomerulonephritis. Our case highlights a rare presentation of NG proteinuria with preserved renal function. The proteinuria likely resulted from myoglobin and impaired absorption of protein by the proximal tubular cells due to pathologic myoglobin deposition. There was no other evidence of proximal tubule impairment such as hypophosphatemia or glucosuria. In a study at Nephropath, looking at five hundred eighty kidney biopsies with myoglobin stain, most of the cases had myoglobin casts, with only 12 % of them having myoglobin deposition in the proximal tubular cells.

PO1949

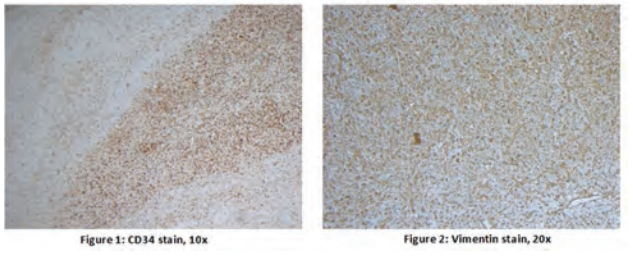
A Case of Asymptomatic Juxtaglomerular Cell Tumor (JGCT)

Arvind K. Garg,[1] Lagu A. Androga.[2] *[1]Mayo Clinic Health System, La Crosse, WI; [2]Mayo Clinic Minnesota, Rochester, MN.*

Introduction: JGCT/ reninoma is an extremely rare benign neoplasm of kidneys typically manifesting as hypertension and hypokalemia secondary to renin secreting tumor cells. We present a case of JGCT presenting as an asymptomatic renal mass.

Case Description: A 61-year-old male of with diabetes mellitus, hypertension (>15 years duration, well-controlled with Losartan 100mg daily) presented with right upper quadrant abdominal pain. Computed tomography scan of abdomen /pelvis with intravenous contrast revealed cholelithiasis without cholecystitis and an incidental 3cm mass at the mid-pole of the left kidney without renal vascular involvement. Kidney ultrasound 5 years prior did not show any renal mass. Spot urinalysis showed no hematuria and proteinuria was 96 mg/g (normal < 150 mg/g). Baseline serum creatinine was 1.3-1.4 mg/dl (normal 0.7-1.3 mg/dl). 24-hour urine creatinine clearance was normal. Given the high suspicion for a malignancy, the patient underwent recommended left radical nephrectomy. Kidney mass biopsy diagnosed JGCT. Light microscopy showed well circumscribed tumor with glomoid appearance with sheets of uniform round- to-polygonal cell with clear to eosinophilic cytoplasm. In addition, there were focal endocrine-like, markedly atypical hyperchromatic nuclei occasionally scattered throughout the tumor. Immunohistochemical stains demonstrated diffuse positivity in tumor cells for CD34 (Figure 1), CD117 and vimentin (Figure 2). Patient sustained a slight rise in creatinine post nephrectomy as expected and he continued to require only one anti-hypertensive medication. Patient remained in remission with stable kidney function without recurrence of tumor at 2 years follow-up.

Discussion: JGCT can present as hypertension and hypokalemia. Our patient had optimal blood pressure control on monotherapy. Losartan may have masked the associated hypokalemia. Nephrectomy (partial or radical) is curative and is the recommended treatment.



CD 34 stain and vimentin stain kidney mass pathology images

PO1950

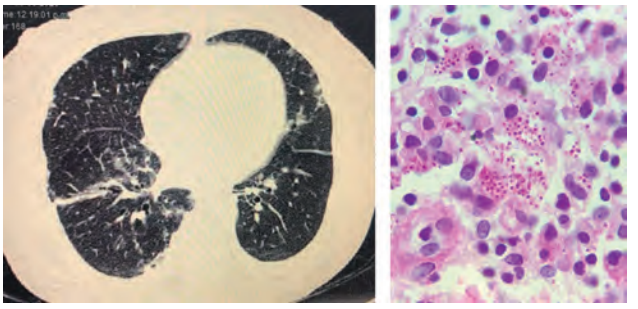
Disseminated Histoplasmosis Mimicking Crohn Disease in Kidney Transplant Recipient

Victor H. Gomez Johnson, Belen Martinez-Vazquez, Octavio R. Garcia-Flores, Francisco Rodríguez. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Introduction: Fungal infections can occur after a kidney transplant due to the use of immunosuppressants. Histoplasmosis is an endemic infection in Mexico and it's pulmonary phase is very common. The risk of complications is high, so an early diagnosis should ideally be made with a biopsy of the affected tissue. We report the case of a kidney transplant recipient with chronic diarrhea associated with disseminated histoplasmosis simulating Chron's disease.

Case Description: A 50-year-old woman with history of CKD of unknown etiology underwent living donor kidney transplant. She received induction with basiliximab and maintenance therapy based on azathioprine, prednisone and cyclosporine. Six years after transplantation, the calcineurin inhibitor was discontinued due to toxicity documented by biopsy and continued with Sirolimus and mycophenolate mofetil. One year after transplantation, she was evaluated for fever and pulmonary nodules, without detecting infectious etiology. One year later, she presented diarrhea and based on the presence of colonic ulcers, Chron's disease was suspected and treatment with mesalazine was started. Due to the persistence of diarrhea, a second colonoscopy was performed establishing the diagnosis of histoplasmosis by means of biopsies of the colonic mucosa and with urinary antigen. Amphotericin B treatment was initiated and 2 weeks later urinary antigen was negative and renal function returned to baseline. Itraconazole-based maintenance therapy was chosen.

Discussion: Acute pulmonary histoplasmosis is caused by inhaling spores and it tends to be a self-limited disease. Disseminated histoplasmosis is common in immunocompromised patients. Gastrointestinal involvement is clinically manifested in 20% of cases, although urinary antigen has a 95% specificity, histopathological identification with PAS(+) and Giemsa(-) stains, remains the ideal test, as they showed submucosal and lamina propia macrophage invasion at the intestinal tissue. Chronic diarrhea can be a manifestation of systemic fungal infection in kidney transplant recipients.



PO1951

Improving the Identification of AKI in the Neonatal ICU: Three Centers' Experiences

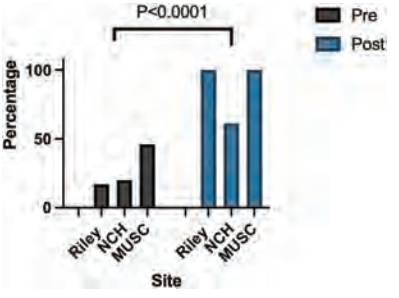
Michelle C. Starr,[1,2] Paulomi Chaudhry,[1,2] Allyson Brock,[1,2] Katherine Vincent,[3] Katherine Twombley,[3] Elizabeth Bonachea,[4] Tahagod Mohamed.[4] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [3]Medical University of South Carolina, Charleston, SC; [4]Nationwide Children's Hospital, Columbus, OH.*

Background: Acute kidney injury (AKI) is common in neonates. Despite its high prevalence, neonatal AKI is diagnosed in <30% of affected neonates. Neonates with AKI are at increased risk for repeated episodes of AKI and CKD. Without an AKI diagnosis, neonates may not be identified for long-term follow up, reducing early identification of CKD and limiting opportunities to slow disease progression.

Methods: In this retrospective cohort study of 3 academic Neonatal Intensive Care Units (NICUs), we evaluated the impact of local standardized approaches implemented to improve neonatal AKI identification. Each center implemented different standardization practices, ranging from automated nephrology consult to neonatology identification based on creatinine. Patients were divided into two groups: 6 months prior to (Cohort 1) and 6 months following (Cohort 2) standardization. We compared AKI incidence and identification, nephrology consultation and nephrology follow-up.

Results: In total, 1887 infants were included. Neonatal AKI identification improved in all three NICUs following protocol implementation (26% to 85%, $p<0.0001$). Each center also saw increases in nephrology consultation (15% to 83%, $p<0.0001$) and nephrology follow-up (7% to 73%, $p<0.0001$). Notably, AKI incidence decreased significantly (21% to 12%, $p<0.0001$).

Conclusions: Multiple strategies can be successfully operationalized to improve neonatal AKI identification. While different in approach, each strategy resulted in increased AKI identification and nephrology involvement. We also report a decrease in AKI rates. This study emphasizes the importance of local standardized approaches to improve AKI identification in the NICU. Further collaborative work by nephrologists and neonatologists is needed to improve identification and follow-up of AKI.



AKI identification rates between Cohorts 1 and 2

PO1952

Diuretic Use, Comorbidity, and Length of Stay in Pediatric AKI

Jessamyn S. Carter,[1,2] Brett Klamer,[2] John D. Spencer,[1] Tahagod Mohamed.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Acute kidney injury (AKI) and fluid overload (FO) both have well known negative effects on morbidity and mortality in many populations. The combination of AKI and FO is associated with synergistically worse outcomes in critically ill children. Diuretic use in management of AKI and FO has been studied in adults with widely varied outcomes ranging from improved mortality to no significant change to increased comorbidity such as prolonged mechanical ventilation. Therefore utility of diuretics remains unclear, and their use in pediatric patients with AKI has not been characterized.

Methods: The Pediatric Hospital Information System (PHIS) database was queried for patients with diagnosis of AKI from January 2015 to December 2019 with admission LOS <15 days. Those <1 or >18 years of age were excluded. ICD codes were used to discern complex chronic conditions (CCCs) as well as acute comorbidities. Daily medication exposure was used to determine diuretic use. LOS in both the ICU and the inpatient floor was assessed. CCCs of interest were chronic kidney disease (CKD), kidney transplant, and heart failure. Measured comorbidities included: shock, mechanical ventilation, hypoxemia, fluid overload, ascites, edema, and oligoanuria. Numeric data were summarized as medians and IQRs and categorical data as frequency and percent. Associations between diuretic use and comorbidity was assessed by Wilcoxon's rank-sum test and Fisher's exact test. Length of stay was then assessed by longitudinal regression.

Results: There were 5490 encounters for analysis with diuretic use in 951. Demographics were similar between groups. Those with CKD or heart failure were more likely to receive diuretics, while those with kidney transplant status were less likely to receive diuretics. LOS was 1.67 days longer in those who received diuretics despite adjustment for age, gender, and illness severity including CCCs. All acute comorbidities were increased in those who received diuretics.

Conclusions: Children with underlying CCCs were more likely to receive diuretics and to have longer LOS. Comorbidities and LOS were also increased in children with AKI who received diuretics regardless of disease severity. This is clinically important as diuretic use may be a corollary for worse outcomes and increased costs. Due to database limitations, temporal association is unknown and further study is needed.

PO1953

The Association of Diuretic Therapy with Fluid Balance and AKI in Hospitalized Preterm Neonates

Mariah L. Wright, Brett Klamer, Elizabeth Bonachea, John D. Spencer, Jonathan L. Slaughter, Tahagod Mohamed. *Nationwide Children's Hospital, Columbus, OH.*

Background: Fluid homeostasis is essential in critically ill preterm neonates because fluid overload is associated with poor outcomes including need for mechanical ventilation, bronchopulmonary dysplasia (BPD) and necrotizing enterocolitis (NEC). Acute kidney injury (AKI) is a common comorbidity in preterm neonates. Diuretics are often used to enhance urinary output (UOP) in AKI- associated oliguria and to achieve negative fluid balance (FB).

Methods: Retrospective study of preterm neonates < 37 weeks gestational age (GA) who received diuretics during the first 14 postnatal days in a single level IV NICU (05/2014- 05/2020). We analyzed FB, UOP, and Scr levels on and off diuretics over first 14 days. We studied prevalence of AKI.

Results: 191 preterm neonates met inclusion criteria. By day 8, 50% of patients were treated with diuretics. After adjusting for birthweight and time after birth, there was a statistically significant decrease in weights while on diuretics with a mean difference of 10g. Peak median FB was +58 mL on postnatal day 8. Mean FB difference on and off diuretic therapy was -35 mL. There was smaller difference in FB between those on or off diuretics in younger GA patients compared to older GA patients (Figure 1). UOP increased by 0.6 mL/kg/h and Scr by 0.2mg/dL while on diuretics compared to no diuretic therapy (Table 1). AKI occurred in 9% and 19% of patients based on an increase in Scr of ≥ 0.3 mg/dL or UOP < 1ml/kg/h for 24 hours respectively. In patients who met AKI criteria, oliguria was noted while off diuretics and increased Scr while on diuretics.

Conclusions: In hospitalized preterm neonates, treatment with diuretics was associated with improved UOP and negative fluid balance. SCr increased while on diuretic therapy. Further studies should analyze the effects of diuretics as mediated by FB and AKI on development of BPD and NEC.

Distribution of weight, FB, UOP and Scr in preterm neonates on and off diuretic therapy

	On diuretics	Off diuretics	Difference on and off diuretics
Weight (g)	1523	1537	-10
Mean FB (mL)	31	66	-35
Mean UOP (mL/kg/h)	3.2	3.8	0.6
Mean Scr (mg/dL)	1.1	0.9	0.2

PO1954

Neonatal AKI Is Associated with Impaired Renal Function at 24 Months of Age

Stephanie C. Krom,[1] Alison Kent,[1,2] Erin Rademacher,[1] Hongyue Wang.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Australian National University, Canberra, ACT, Australia.*

Background: Neonatal acute kidney injury (nAKI) is common, occurring in up to 30% of neonatal intensive care admissions. However, there are currently no guidelines for nephrologic evaluation after the neonatal period. Our objective was to determine the incidence of renal dysfunction at 24-months of age and to identify associated risk factors following nAKI.

Methods: Retrospective single-center cohort study of infants with nAKI (defined as rise in creatinine (Cr) ≥ 0.3, abnormal initial Cr for gestational age, or abnormal rate of Cr decline) seen in pediatric nephrology clinic at 24-months. Abnormal estimated glomerular filtration rate (eGFR) (< 90 ml/min/1.73m^2), hypertension (BP ≥ 95th%ile), proteinuria (TP/Cr > 0.5), and renal length (≥ the 95th or ≤ the 5th %ile) were correlated with high risk NICU events and exposures. Data was obtained by chart review. eGFR was calculated using cystatin C and creatinine separately, using the CKID cystatin C and the revised Schwartz equations, respectively. Data was analyzed using t-tests, Wilcoxon Rank Sum Test, or Chi-square as appropriate.

Results: 36/42 infants with history of nAKI referred to nephrology had a 24-month visit. 20 of 36 subjects (55.5%) had at least one renal abnormality, with 14 (39%) having eGFR < 90 ml/min/1.73m^2 by cystatin C, 7/36 (19.4%) had proteinuria, 3/36 (8.3%) had hypertension, and 4/36 (11.1%) had abnormal renal length. 1/15 subjects with reduced GFR by cystatin C also had a reduced GFR by serum creatinine. Subjects with renal dysfunction at 24 months had a neonatal history of more vasopressors exposure days (mean, 4.5 vs 0.25, p = 0.002), more total diuretic days (mean 122 vs 51 p=0.03), were more likely to be taking a diuretic at discharge (n=11 vs n=3, p= 0.026), or to be of extremely low birth weight (ELBW < 1000 gm) (n=14 vs n=4, p= 0.007) compared to those without renal dysfunction.

Conclusions: The majority of children with nAKI had evidence of renal dysfunction at 24-month of age. Serum Cystatin C was more sensitive at identifying kidney dysfunction than creatinine alone. All children with nAKI should be referred for renal follow-up with a particular focus on children who were ELBW, required vasopressors, or had prolonged diuretic use in the neonatal period.

PO1955

Kidney Outcomes Among Extremely Preterm Born Adolescents with Neonatal AKI

Ryan Lupo,[1] Emily H. Chang,[1] Erica C. Bjornstad,[2] Michael O'Shea,[1] Keia Sanderson.[1] *[1]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Background: Infants born preterm are at increased risk for neonatal acute kidney injury (nAKI). AKI increases the risk for CKD long term however, long term kidney outcomes among preterm born survivors of nAKI are not well known. The aim of the study is to evaluate associations between nAKI and microalbuminuria, elevated blood pressure (BP), and reduced kidney mass in adolescents born extremely preterm.

Methods: We obtained 2 manual BPs, a random urinalysis, and kidney ultrasound on adolecents of the University of North Carolina ELGAN (Extremely Low Gestational Age Newborn) cohort between 2017-2019. We retrospectively obtained serum creatinine (SCr) studies from the initial neonatal intensive care unit hospitalization between 2002-2004. We defined nAKI by neonatal KDIGO guidelines.

Results: Of the 31 participants born <28 weeks gestation, mean age was 15.2 years and 58% were overweight/obese. 32% of adolescents had elevated BP, 13% had reduced kidney mass, and 13% microalbuminuria. 52% of the adolescents had a history of nAKI. 81% experienced Stage 1 AKI, 19% had Stage 2 AKI, and no participants experienced Stage 3 AKI. Those with nAKI had lower birth weight, lower APGAR scores, more mechanical ventilator days, lower urine output, greater vasopressor exposure, greater indomethacin exposure, less methylxanthine exposure, greater # of serum SCr measurements, and more days in the hospital. During adolescence, those with nAKI had lower frequency of elevated BP and microalbuminuria but greater frequency of reduced kidney mass(Table 1).

Conclusions: Adolescents with a history of nAKI were more frequently exposed to nephrotoxic factors and had more indicators of severe illness in early life. However, nAKI was not significantly associated with elevated BP, microalbuminuria, or kidney mass in this sample of adolescents born extremely preterm. Further follow up is needed to better characterize manifestation of CKD in adolescents after nAKI.

Prediction Model of CKD at the Age of One Year Following Prenatal Severe Urinary Tract Dilatation

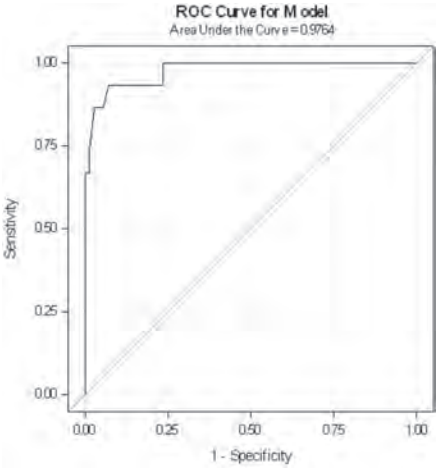
Yael Borovitz,[1] Yossi Geron,[2] Miriam Davidovits,[1,3] Yinon Gilboa,[2,3] Sharon Perlman.[2,3] *[1]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [2]Rabin Medical Center, Petah Tikva, Israel; [3]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: Early childhood chronic kidney disease (CKD) has a wide spectrum of health and developmental implications. Renal replacement therapy may be needed during childhood. Prenatal counselling regarding future renal outcome in cases presenting prenataly with severe urinary tract dilatation (UTD) is challenging. We aimed to create a prenatal ultrasound model for the prediction of early childhood CKD following fetal severe UTD.

Methods: A retrospective cohort study was conducted in a national referral centre. Fetuses diagnosed with severe UTD and maintained follow up comprised the study group. The main outcome was CKD at the age of one year. Logistic regression analysis was used to identify prognostic prenatal ultrasound variables for the renal outcome. Analysis of Maximum Likelihood Estimates was performed to create a multivariable predictive model.

Results: 87 fetuses comprised the study group. 15 cases (17.2%) developed CKD by the age of one year. In all, renal dysfunction and renal dysplasia were diagnosed at birth. Post-natal diagnoses were lower urinary tract obstruction in 5 cases, vesical-ureteral reflux in 10 cases. Bilateral hydronephrosis, abnormal bladder, hydroureter, calyceal dilatation, and abnormal parenchyma, were all significantly related to CKD at the age of one year. A combination of prenatal ultrasound variables yielded a model with a discriminatory ability of c=0.976.

Conclusions: A prediction model incorporating prenatal ultrasound features can discriminate between a normal and an impaired renal outcome at the age of one year. These sonographic features are related to the extent of renal dysplasia and to the remaining functioning nephron mass. Data presented may be used to develop more effective risk assessments and customized parent counseling.



PO1957

Association of Antenatal Corticosteroids with Later Kidney Function in Adolescents Born Preterm with Very Low Birth Weight

Whitney N. Floyd, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Antenatal corticosteroids (ANCS) are given to pregnant women who are at risk of preterm delivery to accelerate fetal lung development. While studies in sheep suggest that ANCS program deleterious effects on renal development leading to higher blood pressure (BP) and worse kidney function, the persistent effects of ANCS exposure on the long-term health of at-risk individuals remains undescribed. We investigated the association of ANCS with BP and kidney function in adolescents born preterm and hypothesized that ANCS are associated with worse BP and kidney function.

Methods: This was a long-term prospective birth cohort of 175 14-year-old adolescents born preterm with very low birth weight (VLBW, <1500 g). We measured manual BP, serum creatinine, and first-morning urine albumin-to-creatinine ratio (ACR), defined high BP as ≥120/80 mmHg and albuminuria as ACR >30 mg/g, and calculated the estimated glomerular filtration rate (eGFR). We used generalized linear models to estimate the association of ANCS with the outcomes.

Results: The cohort consisted of 58% non-Black participants, 55% female participants, and 53% were exposed to ANCS. Among all participants, mean systolic BP was 106.4 mmHg, 13% had high BP, median eGFR was 124.9 ml/min/1.73 m^2 (n=123), and 7% had albuminuria (n=134). In unadjusted analyses, ANCS was not associated with high BP (RR 1.08 mmHg, 95% CI 0.49–2.37), eGFR (β 3.74 ml/min/1.73 m^2, 95% CI -6.74 to 14.22), or albuminuria (RR 1.31, 95% CI 0.34–5.01).

Conclusions: Our research findings indicate that ANCS exposure was not associated with compromised kidney function or worse BP in adolescents born preterm with VLBW. Future analyses will include adjusting for potentially confounding factors in multivariable models and continuing to assess participants' long-term BP and kidney function.

PO1958

Predictors of Renal Function in Pediatric Liver Transplant Recipients

Rim Elchaki, Holly Wilhalme, Robert S. Venick, Marciana Laster. *University of California Los Angeles, Los Angeles, CA.*

Background: Impaired kidney function is a well-recognized complication following liver transplant (LT). In adult LT recipients, the cumulative incidence of renal insufficiency is as high as 10% in 10 years. The burden of kidney dysfunction is thought to be higher in pediatric LT recipients due to longer exposure to nephrotoxic agents & longer lifespan. The aim of this study is to identify predictors of renal function decline in pediatric LT recipients.

Methods: This is a retrospective study of pediatric LT recipients between June 2008 to November 2014. Clinical and biochemical characteristics and eGFR were obtained at baseline, 6, 12, 24, and 60 months. CKD was defined as an eGFR <90 ml/min/1.73 m2 for a least 3 months post-LT. A Multivariable Cox Proportional Hazards model was created to determine predictors of progression to CKD post-LT.

Results: Table 1 shows the baseline characteristics of patients with CKD post-LT compared to those who did not. In bivariate analysis, age, African American race, tumor diagnosis, baseline eGFR, pre-transplant HD and AKI were associated with progression

to CKD (Figure 1). In multivariable analysis, factors associated with increased risk of progression to CKD included: older age at LT (HR 1.012, p<0.001), tumor diagnosis (HR 3.602, p=0.0126) and lower baseline eGFR (HR 0.986, p=0.0014).

Conclusions: In our study we found that risk factors for CKD include: older age at the time of LT, lower baseline eGFR and tumor diagnosis. Further studies are underway to evaluate the role of Tacrolimus in the progression to CKD post LT

Clinical Evaluation of Membrane Therapeutic Plasma Exchange Using Prismaflex Machines and Fresh Frozen Plasma in Pediatric Patients

Siddharth A. Shah. *University of Louisville, Louisville, KY.*

Background: Previous studies have shown that membrane-based therapeutic plasma exchange (m-TPE) can be an effective method. The availability of a TPE 2000 filter membrane set with Prismaflex machines provides added advantage to perform TPE along with continuous renal replacement therapy (CRRT). The extracorporeal volume of this filter at 125 ml is lower than centrifugation-based apheresis systems. There is very little data on the efficacy and complications of this procedure in small children. Fresh frozen plasma (FFP) has a high citrate content (20 mmol/L). There may be the risk of significant hypocalcemia using FFP as replacements.

Methods: We performed a retrospective analysis of children who underwent m-TPE using the TPE 2000 filter membrane set with Prismaflex machines at our center during last year. We included children who required heparin, or bivalirudin as anticoagulation, and FFP as replacements. Given the minimum blood flow requirements of 100 ml/min, we only performed this procedure with children < 10 kg who were on ECMO. To prevent hypocalcemia, we administered calcium chloride drip with starting dose of 20 mg/kg/hour before initiation of TPE. We adjusted the calcium chloride drip based on the ionized calcium monitoring scale. Additional calcium boluses were given for hypocalcemia persisting after drip adjustment to a maximal rate of 50 mg/kg/hr.

Results: We included eight children in the analysis who required both CRRT and TPE. The age range was 23 days-15 years (median: 2 years). On average, we performed 3.1 treatments per patient with a mean treatment time of 175 minutes. In 2/8 patients, bivalirudin was used. Common complications included hypocalcemia requiring additional calcium bolus (2/8), high transmembrane pressure (TMP) (1/8), and hemodynamic instability (1/8). There was no significant correlation between age and dose of calcium drip required (p-value: 0.433); and ECMO and requirement of additional calcium boluses (p-value: 0.107). There was a significant improvement in inflammatory markers (D-dimer, CRP, IL6) and bilirubin level post-pheresis treatment.

Conclusions: The TPE procedure using Prismaflex may be a practical option for children undergoing CRRT, but further studies are required to assess its use in children with weights less than 20 kg. Most children tolerated the procedure well in our study. Hypocalcemia is a critical complication with this procedure.

Comparison of Nafamostat Mesylate and Regional Citrate Anticoagulation in Pediatric CRRT Anticoagulation

Mai J. Miyaji,[1,2] Kelli A. Krallman,[1] Kentaro Ide,[2] Kohei Takashima,[3] Stuart Goldstein.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Kokuritsu Kenkyu Kaihatsu Hojin Kokuritsu Seiiku Iryo Kenkyu Center, Setagaya-ku, Japan; [3]Shiga Ika Daigaku, Otsu, Japan.*

Background: Regional Citrate Anticoagulation (RCA) is the preferred CRRT anticoagulation strategy for children in the US. Nafamostat Mesilate (NM), a synthetic serine protease, has been used widely for CRRT anticoagulation (ACG) in Japan and Korea. While NM is considered safe and effective, there is a paucity of evidence in pediatric CRRT. We compare the safety and efficacy of NM to RCA for pediatric CRRT.

Methods: Using one pediatric hospital in Japan and one in the US, medical records of patients (pts) <21 years of age on CRRT between 2016-2019 were reviewed, excluding pts receiving CRRT with ECMO. Pt demographics, CRRT characteristics, and outcomes were compared between RCA and NM groups. Filter life (FL), defined as the number of hours a single CRRT filter was in use, was the primary outcome. Safety is assessed by bleeding complications.

Results: 76 pts (248 filters) received RCA and 89 pts (226 filters) received NM. Baseline characteristics are shown Table 1. RCA pts were older and received higher Qb. Median FL (hours) did not differ by ACG type (RCA: 35 [16,67] *vs.* NM: 38 [22,68]. The lack of difference in FL between groups persisted when controlling for pt age and CRRT Qb.

Conclusions: RCA and NM are safe and appear to be equally effective ACG for children receiving CRRT. A prospective randomized trial is required to validate these findings.

Patient Demographics/Outcome	RCA(N=76)	NM (N=89)	p-value

NT-ProBNP a Potential Biomarker for Assessing Volume Status of Patients Receiving CRRT

Vimal Chadha, Tara Benton, Bradley A. Warady. *Children's Mercy Hospitals and Clinics, Kansas City, MO.*

Introduction: Fluid overload is a significant risk factor for morbidity and mortality in patients receiving CRRT. Records of fluid balance, clinical signs of fluid overload (weight, peripheral edema), hemodynamic parameters (tachycardia, blood pressure), filling pressure (CVP), bioelectrical impedance, and radiological studies (CXR, IVC diameter) are the clinical tools that are commonly utilized to help assess volume status, each of which has their own limitations. The aminoterminal fragment of B-type natriuretic peptides (NTproBNP), a biologically inert molecule with half-life of 60-120 min produced from left ventricular myocardium, is well established as a good diagnostic and prognostic indicator of heart failure. Our previous observation of a correlation of NTproBNP with volume status in an infant without cardiac disease who received CRRT led us to use NTproBNP as a surrogate marker of volume status in a newborn currently receiving prolonged CRRT.

Case Description: NTproBNP levels were measured at least twice a week in a 4-month-old anephric (status post bilateral nephrectomy for ARPKD) infant receiving CRRT (clearance 30 – 35 mL/kg/hr). NTproBNP levels were correlated with weight (used as surrogate for volume status), and clinical evidence of cardiorespiratory compromise.

Over a period of 47 continuous days on CRRT, 40 NTproBNP values were obtained. The weights ranged from 3.60 kg to 4.88 kg, while the NTproBNP values ranged from 396 to 92,300 pg/mL. There was a significant correlation between patient weight and NTproBNP levels ($r = 0.57$; $p < 0.001$) which helped guide the patient's fluid management. The relationship between patient weight, NTproBNP level and clinical status is shown in the figure.

Discussion: NTproBNP may be able to be used as a reliable complementary marker for volume status in a select (without underlying cardiac disease) group of pediatric patients receiving prolonged CRRT. Further study is required to validate the findings in a cohort of patients.

Prophylactic PD Catheter Placement for Children Undergoing Cardiac Surgery with Cardiopulmonary Bypass: Systematic Review with Meta-Analysis

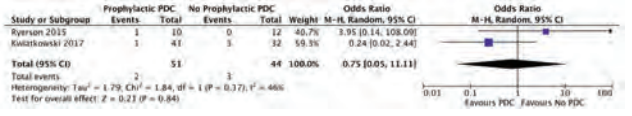
Emma H. Ulrich,[1] Prabhjot K. Bedi,[2] Rashid Alobaidi,[1] Catherine Morgan,[1] Mike Paulden,[3] Michael Zappitelli,[4] Sean M. Bagshaw.[1] *[1]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]The University of Winnipeg, Winnipeg, MB, Canada; [3]University of Alberta, Edmonton, AB, Canada; [4]University of Toronto, Toronto, ON, Canada.*

Background: Infants undergoing cardiopulmonary bypass (CPB) are at high risk of fluid overload, requiring peritoneal dialysis (PD). This systematic review evaluates whether prophylactic PD catheter (PDC) insertion at the time of cardiac surgery improves post-operative outcomes.

Methods: Comprehensive literature search was completed Oct-2020. We identified studies that compared children ≤18 years undergoing cardiac surgery with CPB and receiving prophylactic PDC (inserted intraoperatively *or* ≤24 hours postoperatively) *vs.* children who do not undergo prophylactic PDC placement. Data was extracted on population characteristics; perioperative variables; and short-term postoperative outcomes, including time to negative fluid balance (FB); presence and degree of fluid overload; duration of inotropic support and mechanical ventilation; hospital length of stay; and mortality.

Results: Out of 1067 studies, 208 underwent full-text review for eligibility, and 15 were included: 4 randomized controlled trials; 9 cohort studies; and 2 case-control studies. Intervention was prophylactic PDC insertion with passive peritoneal drainage in 6; PD in 7; and passive peritoneal drainage *or* PD in 2. The comparator group typically received furosemide. Baseline characteristics were heterogeneous for the included studies with respect to age, weight, and illness severity. Surgical procedures performed were also variable within and between studies. Time to negative FB and prevention of fluid overload showed mixed results with some studies favoring prophylactic PDC and others showing no difference. Pooled unadjusted OR for in-hospital mortality was 0.75 (95% CI: 0.05-11.11) (Figure 1). No studies reported serious PDC-related complications. Risk of bias was high in most studies, due to higher illness severity in the intervention groups, small sample size, and observational nature of studies.

Conclusions: Prophylactic PDC insertion is relatively safe in children undergoing cardiac surgery with CPB. Some studies have shown prophylactic PDC improves post-operative outcomes, including time to negative FB and in-hospital mortality; others have shown no difference.



PO1963

Iodine-Induced Hypothyroidism in Pediatric Patients Receiving Peritoneal Dialysis: Is Risk Mitigation Possible?

Sai Sudha Mannemuddhu,[1,2] Heather Morgans,[3] Bradley A. Warady.[3] *[1]East Tennessee Children's Hospital, Knoxville, TN; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Children's Mercy Hospitals and Clinics, Kansas City, MO.*

Background: Children with end-stage kidney disease who receive chronic peritoneal dialysis (PD) are at increased risk for thyroid dysfunction. Iodine-induced hypothyroidism (IIH) from exposure to iodine-containing agents is poorly appreciated, particularly in infants and small children.

Methods: An international survey was conducted to better understand current practices pertaining to iodine exposure and the frequency of IIH in patients receiving PD, and to assess awareness of this issue amongst pediatric nephrologists.

Results: 89 centers responded to the survey. Hypothyroidism in PD patients was diagnosed in 64% of responding centers, although only 1/3 of centers suspected/diagnosed IIH. Etiologies of IIH included exposure to povidone-iodine containing PD caps (53%), cleaning solutions with iodine (37%), and iodinated contrast (10%). While the majority of centers (58%) routinely evaluate thyroid function, only 34% aim to limit iodine exposure by avoidance of iodine-containing cleaning solutions (73%) and contrast agents (33%), monitoring of initial PD drain volume (30%), and use of a non-iodine PD cap (23%). Of centers not routinely evaluating for or utilizing methods to prevent IIH, 81% reported being unaware of the risk.

Conclusions: Hypothyroidism is diagnosed in a substantial percentage of pediatric PD programs. Education pertaining to the risk of IIH associated with iodine exposure may decrease the incidence.

Factors Associated with High-Cost Hospitalizations for Hemodialysis Catheter-Associated Blood Stream Infections in Children

Heather L. Wasik,[1] Alicia Neu,[2] Bradley A. Warady,[3] Brendan Crawford,[5] Troy Richardson,[6] Heidi G. De Souza,[6] Diana Cardwell,[4] Rebecca Ruebner.[2] The Standardized Care to Improve Outcomes in Pediatric End Stage Kidney Disease (SCOPE) collaborative *[1]State University of New York Upstate Medical University, Syracuse, NY; [2]Johns Hopkins University, Baltimore, MD; [3]Children's Mercy Hospitals and Clinics, Kansas City, MO; [4]Children's Health Children's Medical Center Dallas, Dallas, TX; [5]University of Arkansas for Medical Sciences, Little Rock, AR; [6]Children's Hospital Association, Overland Park, KS.*

Background: Hospitalizations of adults for hemodialysis catheter-associated blood stream infections (HD-BSI) lead to high costs. No studies have evaluated hospitalization costs for HD-BSI in children or identified factors associated with high-costs.

Methods: The Standardized Care to Improve Outcomes in Pediatric End-Stage Kidney Disease (SCOPE) collaborative database was used to identify HD-BSI. SCOPE database linked to the Pediatric Health Information Systems (PHIS) database which provided hospitalization billing data. High-cost hospitalization defined as cost above 50th percentile in our study population. Multivariable logistic regression used to assess the relationship between high-cost hospitalization and patient and clinical characteristics.

Results: The median(IQR) LOS for HD-BSI hospitalization was 5(3-10) days. The median(IQR) cost for HD-BSI hospitalization was $18,375($11,584-$36,266). Cost for each service line was higher in high-cost group(p<0.001)(Figure 1). High-cost HD-BSI hospitalization was associated with ICU stay, LOS, need for catheter replacement/rewiring(Table 1). ICU stay (aOR=4.84, 95% CI 1.66-14.08, p=0.004) and need for catheter procedure (aOR 6.29, 95% CI 2.76-14.35, p<0.001) remained associated with high-cost hospitalization in a multivariable model.

Conclusions: Hospitalizations of children for HD-BSI lead to high costs. Efforts to prevent HD-BSI may reduce the costs of caring for children on hemodialysis.

Hemoglobin and Mortality Across Race Among Children Who Transitioned to Dialysis Therapy: An Analysis of CEFDIM and USRDS Data

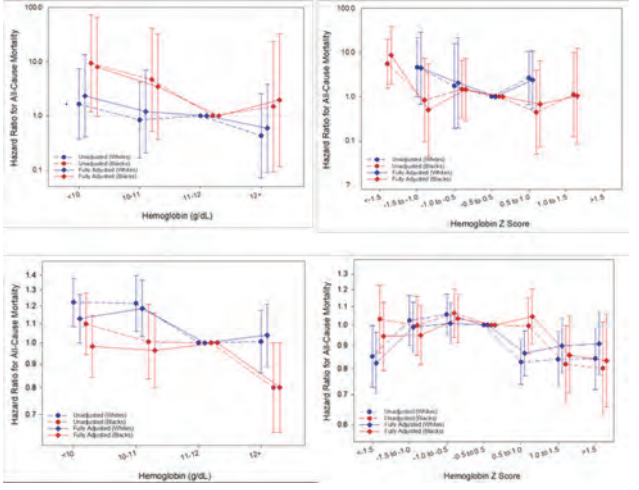
Michael Tronske,[1] Marciana Laster,[2] Jui-Ting Hsiung,[1] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Los Angeles, Los Angeles, CA.*

Background: Low hemoglobin (Hgb) is a strong predictor for mortality in adult dialysis patients, and children on dialysis experience optimal Hgb levels less frequently than adults. Racial disparities have also been identified in pediatric dialysis patients, with Blacks experiencing unfavorable clinical outcomes and poor access compared to Whites. However, there is less literature examining the impact of race on the association of Hgb with mortality among pediatric patients on dialysis.

Methods: We retrospectively studied two cohorts of children (age <21) using data from a large dialysis organization (CEFDIM) and a national data system (USRDS). CEFDIM (n=1069) were followed from 2006-2011, while USRDS (n=26,254) were followed from 1995-2016. The association between Hgb and mortality was observed using Cox regression analyses stratified by race, categorizing Hgb by g/dL as well as z scores (ref: Hgb 11-12g/dL, z scores -0.5 to 0.5). Covariates considered in the models included age, sex, BMI, albumin, comorbidities, and dialysis modality type.

Results: Among Black CEFDIM patients, Hgb <10g/dL was associated with increased mortality (7.9 [0.97,65.27]), as was Hgb z scores <-1.5 (8.62 [1.92,38.77]). Among White CEFDIM patients, these associations were null, and no deaths occurred for z scores <-1.5. Among Black USRDS patients, Hgb above 12 g/dL appears to be protective (0.83 [0.65,1.06]), which was not a protective range for White patients. Meanwhile z scores <-1.5 were significantly protective among White patients (0.82 [0.70,0.96]), but not among Black patients (0.94 [0.79,1.13]).

Conclusions: In children undergoing dialysis, protective Hgb target ranges appear to differ by race, with White children experiencing lower mortality risk from extremely low values and Black children receiving protection from high values.



PO1966

Children on Chronic Hemodialysis Before the First Year of Age: A Three-Year Survival Analysis

Cristina Henriques,[2] Arnaldo Roizenblatt,[1] Maria fernanda C. Carvalho,[2] Fabio A. Takihi,[1] Paulo C. Koch Nogueira.[2] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Hospital Samaritano de Sao Paulo, Sao Paulo, Brazil.*

Background: Peritoneal dialysis is the method of choice for infants who need renal replacement therapy (RRT). However, when it is not possible to perform it or becomes ineffective, hemodialysis is a feasible method in young children. There are few reports on the survival rate of children undergoing hemodialysis in the first year of life. The goal of this study was to determine the mortality rate and its risk factors in children starting hemodialysis during their first year of life.

Methods: We performed a retrospective cohort study, based on data from a reference Dialysis Center in São Paulo city. Data from 47 (8 females) children who underwent chronic hemodialysis before the first year of age were analyzed. Survival was characterized using Kaplan-Meier methods and log-rank tests, followed by a multivariable Cox regression model.

Results: The median weight on the first hemodialysis session was 4.3 Kg (IQR=3.4 to 5.3), while median age was 4.1 months (IQR=2.3 to 6.0), with 21 children younger than 1 month, and only one older than 6 months. Patients were categorized according to the etiology of Chronic Kidney Disease (CKD), congenital anomalies of the kidneys and urinary tract (53.2%) was the most prevalent cause, followed by congenital renal dysplasia (23.4%), autosomal recessive polycystic kidney disease (8.5%), and other etiologies (14.9%). The survival rates were 93%, 75%, and 64% at 1, 2, and 3 years, respectively. Only cardiovascular comorbidity was significantly associated with the

death outcome (HR=5.7, 95%CI=1.7 – 19.6, p=0.006). Anuria had a significant impact on survival only in univariate analysis. Parameters such as gender, age at hemodialysis onset, ethnicity, early dialysis, etiology of CKD had no impact on survival.

Conclusions: Our retrospective cohort gathers an expressive number of children with this rare and severe condition of early onset of hemodialysis, with a uniform follow-up of all individuals We observed satisfactory survival rates among children who started hemodialysis in their first year of life, comparable to the standards of the international pediatric dialysis centers. Hemodialysis became a safe method in young children until the performance of kidney transplantation.

PO1967

The Cost-Effectiveness of Blood Product Irradiation in Pediatric Hemodialysis Patients Awaiting Kidney Transplant

Kyle Merrill. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Pediatric patients diagnosed with end-stage kidney disease often initiate hemodialysis prior to kidney transplantation. Development of anti-HLA antibodies reduces the organ pool for that patient. Blood products are one known cause of allosensitization, or the development of anti-HLA antibodies. Gamma-irradiation of blood products may decrease this possibility. Patients with less anti-HLA antibodies have higher rates of kidney transplantation. Therefore, a cost-effectiveness analysis of whether to irradite blood products for hemodialysis patients and the chance of successful kidney transplantation was performed.

Methods: A Markov model was utilized in this analysis. The model started with the choice to irradiate blood or not prior to entering the Markov. To simplify the model, it was assumed that transfusion with a non-irradiated blood product will result in a cPRA of 30% and irradiation decreased this to 10%. Patients only received one blood product exposure. After kidney transplant, it was asusmed there was no graft failure and return to dialysis. Mortality rates were calculated based on age-specific mortality tables along with the annual excess mortality for each state of the patient.

Results: The irradiate strategy dominates in the base case and is both cheaper at $985,749 (versus $1,049,614) and more effective at 13.00 quality adjusted life years (versus 12.81) when compared to the choice of non-irradiation. A one-way sensitivity analysis was completed on the relative transplant rate and showed that a rate of 1.0006x was the breakpoint where irradiate dominates non-irradiate. A one-way analysis on the cost of blood product irradiation found that even if irradiation costed 100x the base case, it was still the dominating chioce. The last one-way sensitivity analysis noted that as the monthly cost increased from $0 to $10,000 per month, that until the monthly cost was around $3,700, then the more cost-effective choice was to not irradiate, but at any cost higher than $3,750, then the choice to irradiate dominate non-irradiation.

Conclusions: Blood product irradiation was found to be more cost effective. Even with a slight increase in transplant rate, irradiate remained the more cost-effective choice. The cost of irradiation does not affect the choice to irradiate but if hemodialysis were cheaper, the choice to not irradiate was more cost-effective.

PO1968

Partial Extracorporeal Circuit Blood Primes Are Safe and Do Not Decrease Hematocrit in Small Children

Michaela Collins, Xavier French, Kelli A. Krallman, Stuart Goldstein, Jean-Philippe Roy. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Partial blood primes (PBP) for extracorporeal therapies have the potential to decrease unique number of blood unit exposures in children when compared to full blood primes (FBP). Pediatric patients (pts) receive a blood prime when the extracorporeal circuit volume (ECV) exceeds 10-15% of their total blood volume (TBV). FBP use packed red blood cells (PRBC; Hct 60%) for the entire ECV while PBP utilize a standardized approach for less PRBC volume per circuit, allowing the same unit to be used for 3-12 treatments depending on ECV. We aimed to show that PBP does not result in more hemodilution or need for transfusions compared to FBP.

Methods: Data from pts receiving continuous kidney replacement therapy (CKRT) or intermittent therapies (INT), including hemodialysis, plasma exchange and aquapheresis, with FBP were collected retrospectively whereas data from PBP were collected prospectively beginning 8/2019 after a change in local practice. The primary outcomes were 1) pre- and post- treatment hematocrit (Hct) and 2) number of transfusions required between FBP and PBP.

Results: 14 pts (median 8.9kg; IQR 6.6, 12) across 42 CKRT filters and 26 pts (9.3kg; 3.4, 14) with 226 INT between 11/2018 and 1/2021 were analyzed. 11 CKRT filters were PBP (26%) and 11 INT pts received PBP (42%). Although pts receiving PBP had lower pre-procedure HCT (29.4% v 33.1%, p=0.03), there was no difference in change of Hct over time between PBP and FBP (p=0.9). Mean (SD) Hct and percent change are shown in Table 1. PRBC transfusion rate did not differ between PBP and FBP (31.8% vs. 26.1%, p=0.4). We estimate the use of PBP saved 4 PRBC units of exposure in CKRT and 29 units of exposure in INT.

Conclusions: The use of PBP does not result in hemodilution compared to FBP, nor does it result in the need for more transfusions. PBP is a safe alternative to FBP, it improves blood product stewardship and has the potential to reduce sensitization in children with ESKD or at risk for CKD, which may facilitate kidney transplant.

Table 1. Hct Levels and Change by Blood Prime Type (all values mean (SD))

	Pre-Treatment Hct (%)		Post-Treatment Hct (%)		Percent Change		
	FBP	PBP	FBP	PBP	FBP	PBP	p-value

Readmission After Pediatric Kidney Transplantation: A Multicenter Cohort Study

Eric Benz,[1,2] Justin Godown,[3] Douglas E. Schaubel,[2] Cary W. Thurm,[4] Matthew Hall,[4] Sandra Amaral.[1,2] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania Department of Biostatistics and Epidemiology, Philadelphia, PA; [3]Monroe Carell Junior Children's Hospital at Vanderbilt, Nashville, TN; [4]Children's Hospital Association, Overland Park, KS.*

Background: The burden of readmission within one year after pediatric kidney transplant (PKTx) is poorly described, with only one single center study describing rates of readmission as high as 79%. We aimed to examine the epidemiology of readmission after PKTx in a national U.S. cohort.

Methods: We linked the Scientific Registry of Transplant Recipients (SRTR) and the Pediatric Health Information System (PHIS) database, a group of over 50 U.S. pediatric medical centers, to identify PKTx recipients <21 years old who received a kidney-only transplant from 2002-2018 and were discharged from the transplant hospitalization with a functioning graft. We characterized the epidemiology of patient demographic, clinical and transplant factors associated with the initial transplant hospitalization and readmission. We also examined risk factors for readmission within a year using multivariable Cox proportional hazard modeling.

Results: We identified 4,566 patients with a median age of 13 years, 46% had CAKUT and 45% were white, non-Hispanic. Within a year, 3,136 (69%) were readmitted. Factors associated with increased hazard of readmission were age <6 years, black race, public insurance, centers with <15 transplants/year and initial transplant admission >10 days. Transplant admission <5 days was associated with decreased hazard of readmission in the first year.

Conclusions: Over two-thirds PKTx recipients were readmitted within a year post-transplant. Readmission was associated with younger age, black race, public insurance, initial transplant hospitalization and transplant center volume. Future studies to identify modifiable risk factors associated with readmission are planned. Our findings can help improve care models to reduce healthcare utilization and cost.

Encouraging Outcomes from Using a Small-Donor Single Graft in Pediatric Kidney Transplantation

Luciana S. Feltran,[1] Maria fernanda C. Carvalho,[1] Paulo C. Koch Nogueira.[1,2]
[1]Hospital Samaritano de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.

Background: The use of small pediatric kidneys as single for transplantation is controversial, due to the potential risk for graft thrombosis and insufficient nephron mass.

Methods: Aiming to test the benefits of transplanting these kidneys, 375 children who underwent kidney transplantation in a single center were evaluated: 49 (13.1%) received a single graft from a small pediatric donor (≤15Kg, SPD group), 244 (65.1%) from a bigger pediatric donor (>15Kg, BPD group) and 82 (21.9%) from adult living donors (group ALD).

Results: Groups had similar baseline main characteristics. After 5 years of follow-up, children from SPD group were comparable to children from BPD and ALD in patient survival (94, 96, and 98%, p=0.423); graft survival (89, 88, and 93%, p=0.426); the frequency of acute rejection (p=0.998); the incidence of post-transplant lymphoproliferative disease (p=0.671); the rates of vascular thrombosis (p=0.846); and the necessity for post-transplant surgical intervention prior to discharge (p=0.905). The longitudinal evolution of eGFR was not uniform among groups. The 3 groups presented a decrease in the eGFR, but the slope of the curve was steeper in ALD children. At 5 years, the eGFR of ALD group was 10 ml/min/1.73m² inferior to the others. At that time, the eGFR from SPD group was statistically similar to the BPD (p=0.952).

Conclusions: In a specialized transplant center, the use of small single pediatric donor kidneys is as successful as bigger pediatric donors or adult living donors in transplants after 5 years of follow-up.

PO1971

Clinical Characteristics of Recurrent Focal Segmental Glomerulosclerosis (rFSGS) After Kidney Transplant (KTx) Through Computable Phenotypic Algorithm Analyses of Multicenter Data

Vikas R. Dharnidharka,[1] Rebecca R. Scobell,[2] Mahmoud Kallash,[3] Amy Goodwin Davies,[2] Nicole Marchesani,[2] Mitchell Maltenfort,[2] Leslie Walther,[1] Megan Kelton,[4] Margret Bock,[5] Eliza Blanchette,[10] Hillarey Stone,[9] Caroline A. Gluck,[8] Frank E. Hullekes,[7] Leonardo V. Riella,[7] William E. Smoyer,[3] Mark Mitsnefes,[9] Bradley P. Dixon,[5] Joseph T. Flynn,[4] Michael J. Somers,[6] Christopher B. Forrest,[2] Susan L. Furth,[2] Michelle Denburg.[2]
[1]Washington University in St Louis, St Louis, MO; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Nationwide Children's Hospital, Columbus, OH; [4]Seattle Children's Hospital, Seattle, WA; [5]Children's Hospital Colorado, Aurora, CO; [6]Boston Children's Hospital, Boston, MA; [7]Massachusetts General Hospital, Boston, MA; [8]Nemours Biomedical Research Center for Pharmacogenomics and Translational Research, Wilmington, DE; [9]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [10]University of Colorado, Denver, CO.

Background: Primary FSGS, a glomerular disease, has a high rate of progression to end stage kidney failure and varying rates of recurrence after KTx. Treatment effects are hard to determine, requiring both large multicenter populations and granular site level data.

Methods: Using the PEDSnet research network of >11 million records, we refined a published computational phenotype (Denburg et al 2019) for a pediatric nephrotic glomerular disorders cohort to identify patients with evidence of KTx. Standardized chart review was used to identify patients with FSGS and rFSGS (urine protein/creatinine ratio > 2.0 mg/mg post-KTx).

Results: In PEDSnet v4.0 data from 1/2009-11/2020 across 6 centers, 4380 patients met criteria for glomerular disorders and 1994 among those were identified as nephrotic. 220 had evidence for KTx. In charts reviewed to-date for these 220 patients, 89/133 had non-genetic FSGS, and 71 received a KTx after 2009. rFSGS was identified in 29/71 patients, mostly early after KTx (Fig. Panel A). Demographic characteristics of those with FSGS (n=89) and rFSGS (n=29) are shown in the Table. After rFSGS, plasmapheresis (n=26) or rituximab (n=24) were the most common treatments used, remission was complete in 14/29 (48%), and partial in another 6. Allograft loss occurred in 7 patients, not significantly worse than in those without recurrence (Fig. Panel B).

Conclusions: PEDSnet can identify and characterize patients with rare diseases such as rFSGS to create robust databases to compare clinical efficacy of treatments, and for recruitment into clinical trials.

Table:

Characteristic	FSGS (N = 89)	rFSGS (N = 29)
Sex: Female	44 (49.4%)	12 (41.4%)
Race: White	50 (56.2%)	16 (55.2%)
Race: Black or African-American	21 (23.6%)	<11 (<37.9%)
Ethnicity: Hispanic or Latino	11 (12.4%)	<11 (<37.9%)
Follow-up (years)	11.2 (7.3, 14.4)	9.9 (7.9, 15.0)
Age at transplant (years)	13.4 (10.0, 16.8)	13.1 (0.5, 16.7)

All continuous data as median (25th percentile, 75th percentile); categorical data as N (%)

PO1972

Prevalence and Progression of Pediatric CKD in a Large National Cohort

Zubin J. Modi, Jonathan P. Troost, Kevin J. Dombkowski, Debbie S. Gipson.
University of Michigan, Ann Arbor, MI.

Background: National prevalence and disease progression for pre-ESKD chronic kidney disease in children (pCKD) are not well described.

Methods: Data for children <19 years of age were extracted from the IBM MarketScan commercial and Medicaid databases for the years 2009-2018. pCKD prevalence estimates were calculated using stage-specific ICD-CM diagnosis codes (585 and N18) and additional established qualifying pCKD codes. Survival curves were created to estimate the probability of reaching ESKD, stratified by type of CKD code utilized (stage-specific vs other codes).

Results: We identified children <19 years with commercial insurance (n=42,051,432) and Medicaid (n=13,610,450) over the 10-year period. Among these children, we found 197,318 with pCKD among those with commercial insurance (47 per 10,000) and 101,361 among those with Medicaid (74 per 10,000). pCKD stage-specific diagnoses were infrequently reported (commercial insurance:12%; Medicaid: 14%). Among the children with pCKD, 30% with commercial and 35% with Medicaid had multiple years of follow-up. Survival curves over the 10-year study period showed the majority of the progression to ESKD was among those with stage-specific pCKD (Figure).

Conclusions: In a large national cohort, 298,679 children with pCKD were identified over 10 years, with higher period prevalence in Medicaid-insured children. Stage-specific information was available for a small proportion of children, but when present was associated with a higher probability of reaching ESKD. This data suggests that children with conventional, staged CKD codes are more likely to have rapid progression while other codes that qualify for pCKD may capture children with kidney disease that are slower to progress.

Probability of Kidney Survival Stratified by Type of Diagnostic Code

PO1973

Narrow Range of Plant-Protein Intake in the CKiD Cohort Does Not Demonstrate Changes in Estimated GFR

Lokesh N. Shah,[1,5] Matthew Matheson,[2] Susan L. Furth,[3,4] George J. Schwartz,[8] Bradley A. Warady,[6,7] Cynthia Wong.[1,5] *[1]Stanford University School of Medicine, Stanford, CA; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]Lucile Salter Packard Children's Hospital at Stanford, Palo Alto, CA; [6]University of Missouri Kansas City School of Medicine, Kansas City, MO; [7]Children's Mercy Hospitals and Clinics, Kansas City, MO; [8]University of Rochester Medical Center, Rochester, NY.*

Background: Vegetable or plant-based sources of protein may confer health benefits in children with progressive kidney disease. There is currently a knowledge gap in understanding the effect of different proportions of vegetable-based proteins on CKD progression in children.

Methods: The CKiD study is a multicenter, observational cohort of children with CKD. The Child Harvard Service Food Frequency Questionnaire (HSFFQ) was used to assess dietary intake. The proportion of vegetable protein (VP%) was defined as the fraction of plant protein to total protein intake. Statistical analysis used a mixed model with random intercept and slope to determine the effect on log-transformed changes in estimated GFR.

Results: This dataset included 2000 records on 631 subjects with a baseline eGFR from 30 to 90 mL/min/1.73m^2 calculated using CKiD Creatinine–Cystatin C 2012 formula. Across all dichotomized groups of children (sex, African American race, Hispanic ethnicity, etiology of CKD, hypertension, anemia, hyperkalemia, hyperphosphatemia, acidosis, BMI < 95th percentile) the median VP% was 32-35% regardless of group. Longitudinal mixed model analysis did not show any effect on eGFR due to changes in VP%.

Conclusions: Children with chronic kidney disease obtain about a third of their protein intake from plant or vegetable-based sources. More than 90% children in the CKiD cohort had a VP% that was less than 50% of total protein intake. Due to the narrow homogeneity of dietary patterns, there was no effect on the change in eGFR with changes in VP%.

Funding: NIDDK Support, Private Foundation Support

Figure: Distribution of Vegetable Protein Percent in the CKiD Cohort at Baseline

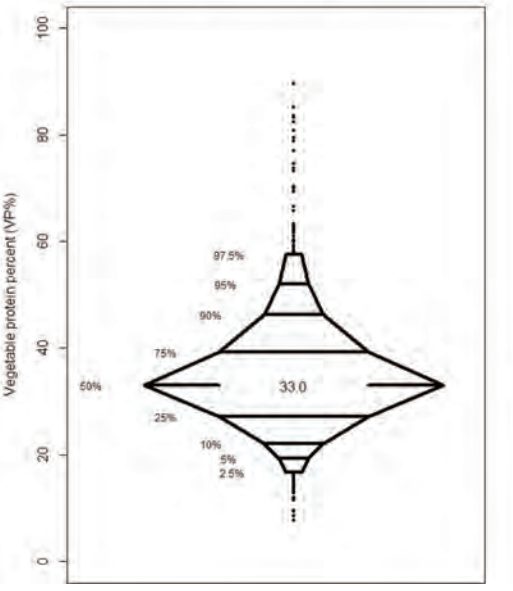

Table 1: Effect of VP% on eGFR

Predictor	Estimate (95% CI) (log scale)	Estimate (95% CI) (% scale)	p-value
VP% at baseline, per 5%	-0.007 (-0.025, 0.011)	-0.7% (-2.4%, +1.1%)	0.44

Diagnosis-Specific Combination of Cystatin C- and Creatinine-Based eGFR

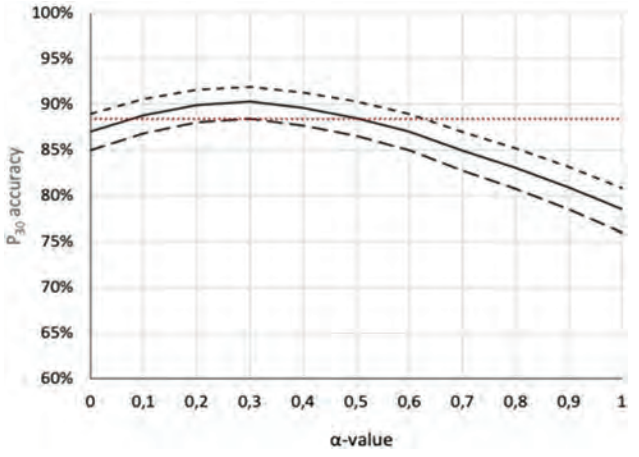
Arend Bokenkamp,[1] Tobias Oostdam,[1] Jonas Björk,[2] Ulf Nyman,[3] Karolien Goffin,[4] Kajsa Åsling Monemi,[5] Magnus D. Hansson,[5] Ulla B. Berg,[5] Karin Littmann,[5] Anders O. Grubb,[2] Hans Pottel,[4] Emil Den bakker.[1] *[1]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; [2]Lunds Universitet, Lund, Sweden; [3]Skanes universitetssjukhus Malmo, Malmo, Sweden; [4]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [5]Karolinska Universitetssjukhuset, Stockholm, Sweden.*

Background: The arithmetic mean of a creatinine- and a cystatin C-based GFR estimation (eGFR) has higher accuracy than either of the two. Smaller studies indicate that the relative contribution of the creatinine- and the cystatin C-based equation should be adapted based on underlying diagnosis.

Methods: Retrospective analysis of 1712 plasma clearance GFR measurements from four pediatric nephrology centers. eGFR was calculated using the height-based Full Age Spectrum equation using creatinine (FAS-creat) and the FAS-cys equation for cystatin C. α describes the contribution of FAS-creat, (1-α) the contribution of FAS-cys. 2/3 of the cohort (mean age 11.8 years, mGFR 93.8 ml/min/1.73m^2) was used to determine the α-values yielding the highest P_{30} accuracy globally (FAS_α) and in diagnosis subgroups. These α-values were validated in the remaining 1/3 of the cohort assessing accuracy, bias and precision.

Results: Globally, the optimal α-value was 0.3 [95% CI 0.2 – 0.4, Figure]. Lower α-values were determined for spina bifida (0), glomerulonephritis (0.2), and liver disease (0.25), while CAKUT, kidney transplantation and tubulointerstitial disease had α-values between 0.35 and 0.55. Accuracy of $FAS_{0.3}$ in the validation cohort was 90.2%, which was significantly higher than accuracy of the arithmetic mean (87.4%, p<0.05). Using the diagnosis-specific α-values rather than $FAS_{0.3}$ improved bias (+2.5 vs +1.3 ml/min/1.73m^2, $p < 0.01$) and precision (14.1 vs 13.8 ml/min/1.73m^2, $p < 0.05$), while accuracy was unchanged. Only in children with spina bifida, a clinically relevant improvement was observed when using the diagnosis-specific α-value.

Conclusions: For calculation of the weighted mean, a fixed mix of 30% FAS-creat and 70% FAS-cys is optimal and yields very high accuracy overall. A disease-specific adaption (i.e. 100% cystatin C eGFR) is clinically relevant only for patients with spina bifida.



PO1975

The Optimal Equation of Estimated Glomerular Filtration Rates for Pediatric CKD Patients in Transition from Adolescent to Adult: Results from KNOW-PedCKD

Seon Hee Lim,[1] Eujin Park,[7] Kyoung Hee Han,[4] Seong heon Kim,[5] Heeyeon Cho,[8] Jae Il Shin,[9] Min Hyun Cho,[10] Joo Hoon Lee,[11] Il-Soo Ha,[2,3] Hee Gyung Kang,[2,3] Peong Gang Park,[6] Yo Han Ahn.[2,3] *[1]Uijeongbu Eulji Medical Center, Uijeongbu-si, Gyeonggi-do, Republic of Korea; [2]Seoul National University College of Medicine Department of Pediatrics, Jongno-gu, Seoul, Republic of Korea; [3]Seoul National University Children's Hospital, Seoul, Republic of Korea; [4]Jeju University Hospital, Jeju, Republic of Korea; [5]Pusan National University Hospital, Busan, Republic of Korea; [6]Ministry of Health and Welfare, Sejong, Republic of Korea; [7]Hallym University Medical Center, Yeongdeongpo-gu, Seoul, Republic of Korea; [8]Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; [9]Severance Hospital, Seodaemun-gu, Seoul, Republic of Korea; [10]Kyungpook National University School of Medicine, Daegu, Daegu, Republic of Korea; [11]Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.*

Background: Estimated glomerular filtration rate (eGFR) is an important value in kidney function evaluation, and it is useful to identify chronic kidney disease (CKD) and its progression. Clinicians use various equations to calculate eGFR which is based on serum creatinine (Cr) or cystatin C (CysC) concentration with other variables such as age, sex, and height. However, there is a lack of consensus on which equation is proper for patients in transition from adolescent to adult. Therefore, we evaluated the reliability of various eGFR calculation methods compared to measured isotope GFR (iGFR) in adolescents and young adults with CKD.

Methods: Seventy-three patients aged from 15 to 23 years were included in the KoreaN cohort study for Outcome in patients With Pediatric Chronic Kidney Disease (KNOW-PedCKD). We compared measured iGFRs with various eGFR calculation equations; the bedside serum Cr based equation ($Schwartz_{Cr}$), the CysC based equation ($Schwartz_{CysC}$), combined Cr and CysC-based Chronic Kidney Disease in Children equation ($CKiD_{Cr\text{-}CysC}$), the Cr-only CKD-EPI ($CKD\text{-}EPI_{Cr}$), and combined Cr and CysC CKD-EPI equation ($CKD\text{-}EPI_{Cr\text{-}CysC}$).

Results: Fifty-two (71.2%) patients were male and 86.3% of patients had non-glomerular causes of CKD. A total of 136 measurements of iGFR was performed at the median age of 17.0 (interquartile range (IQR) 16.0–18.8) years. The mean iGFR was 42.2 ± 29.0 mL/min/1.73m^2. The $Schwartz_{Cr}$ equation had lowest bias (-0.6 mL/min/1.73m^2), high correlation (0.96), and highest accuracy (81.6% within 30% of iGFR) while $Schwartz_{CysC}$, $CKiD_{Cr\text{-}CysC}$, $CKD\text{-}EPI_{Cr}$ and $CKD\text{-}EPI_{Cr\text{-}CysC}$ had an overestimation bias (+1.4, +2.1, +15.5 and +8.9 mL/min/1.73m^2, respectively). In adolescents (n=93) from 15 to 18-year-old, the bias of $Schwartz_{Cr}$ equation was lowest (+0.3 mL/min/1.73m^2) and its accuracy was highest (81.7% within 30% of iGFR). In young adults (n=43) older than 18-year-old, the bias of the $CKiD_{Cr\text{-}CysC}$ equation was lowest (+1.3 mL/min/1.73m^2) and the accuracy of $Schwartz_{Cr}$ was highest (81.4% within 30% of iGFR).

Conclusions: The $Schwartz_{Cr}$ equation may be an optimal method to calculate eGFR in adolescents and young adults with CKD.

PO1976

The Effect of Anemia on Neurocognition in Children with CKD

Joann M. Carlson,[1] Matthew Matheson,[2] Sharon L. Manne,[1] Erin M. Jones,[3] Lyndsay Harshman,[4] Rebecca J. Johnson,[5] Cynthia Wong,[6] Amy Kogon,[7] Judith Jerry-Fluker,[8] Marc Lande,[9] Bradley A. Warady,[10] Susan L. Furth,[7] Stephen R. Hooper.[11] *[1]Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, NJ; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Emory University School of Medicine, Atlanta, GA; [4]The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; [5]University of Missouri Kansas City School of Medicine, Kansas City, MO; [6]Stanford University School of Medicine, Stanford, CA; [7]The Children's Hospital of Philadelphia, Philadelphia, PA; [8]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [9]University of Rochester Medical Center, Rochester, NY; [10]Children's Mercy Hospitals and Clinics, Kansas City, MO; [11]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Chronic kidney disease (CKD) has been shown to affect neurocognitive outcomes. Anemia is associated with CKD and has been associated with a decrease in neurocognition in adults with CKD. Few studies have looked at neurocognitive outcomes in children with both CKD and anemia. This study's purpose is to evaluate the impact of anemia on neurocognition in children with mild to moderate CKD.

Methods: Participants were > 7 y and in the Chronic Kidney Disease in Children Study (CKiD) with NIH Cognitive Toolbox data. Anemia was defined as hemoglobin < 5th percentile for age, sex and race or use of an Erythropoietin-Stimulating Agent. All outcomes were compared between anemic and non-anemic groups descriptively using box plots, t-tests, and the magnitude of differences using Cohen's U_3 statistic for effect size. Inverse probability weighting (IPW) was used to align the non-anemic and anemic groups on sex, estimated GFR level, urine protein/creatinine ratio, disease etiology, seizure history, hypertension and maternal education.

Results: 87 subjects total (25% with anemia) met criteria. Prior to weighting, groups were similar in age (17.9 vs 17.1 y, anemic vs non-anemic) with the anemic group trending towards a higher male percentage (73 vs 52%), and lower baseline eGFR (42 vs 64 ml/min|1.73m2). In the descriptive analysis, box plots displayed that anemic patients had a tendency towards lower scores than non-anemic patients. In the IPW-weighted analysis, subjects who were anemic were found to have worse Picture Vocabulary (U_3=+23), Crystallized Cognition (U_3=+22) and Total Cognition (U_3=+19), but better Pattern Comparison (U_3=-35), Working Memory (U_3=-22) and Fluid Cognition (U_3=-22). However, using the t-test, only Picture Vocabulary (p=0.02) and Crystallized Cognition Composite (p=0.03) were significantly different between the groups, with the anemic group performing more poorly than the non-anemic group.

Conclusions: Children with CKD and anemia had significantly lower scores on Picture Vocabulary and on the Crystallized Cognition Composite compared to non-anemic patients after adjusting for covariates, with moderate to large effect sizes. These results suggest that anemia may be a modifiable determinant of cognitive outcomes in children with CKD.

Adverse Events Following Rituximab Infusion in Children with Nephrotic Syndrome: A Systematic Review

Yuanxin Xue,[1] Cal Robinson,[2] Abdulaziz A. Bamhraz,[3] James Lee,[1] Jason Chung,[6] Lehana Thabane,[7] Joycelyne E. Ewusie,[4] Rajiv Sinha,[5] Rahul Chanchlani.[3] *[1]McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; [2]Division of Nephrology, Department of Pediatrics, The Hospital for Sick Children, Toronto, ON, Canada; [3]Division of Pediatric Nephrology, Department of Pediatrics, McMaster Children's Hospital, Hamilton, ON, Canada; [4]Biostatistics Unit, The Research Institute of St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [5]Department of Pediatric Medicine and Pediatric Nephrology, Institute of Child Health, Kolkata, India; [6]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [7]McMaster University Department of Health Research Methods Evidence and Impact, Hamilton, ON, Canada.*

Background: Rituximab (RTX) is often used off-label in children with various kidney diseases. However, there are limited data on the frequency and severity of adverse events and side effects (AE/SE) observed in children following RTX administration. The aim of this systematic review is to evaluate the AE/SE of RTX in children with nephrotic syndrome (NS).

Methods: Six databases were searched to include literature from 1991-2019 that provided AE/SE data on children (≤18 yrs) receiving RTX. Article screening, data extraction, and quality assessment were independently completed and verified by two reviewers. Primary outcome was the cumulative incidence of AE/SE. Secondary outcomes included the severity (evaluated by the Common Terminology Criteria for Adverse Events), timing, and affected body systems of each AE/SE.

Results: Out of 3364 citations, 40 articles were included and 13% were randomized controlled trials (Table). Most reported AE/SE were infusion-related reactions (22.0%), infections (13.9%), granulocytopenia (3.9%), and hypogammaglobulinemia (2.7%). Reporting of the timing or duration of AE/SE was heterogenous and frequently incomplete. Out of all patients experiencing AE/SE (n=455), 12.7% were severe (grade 3-5), 50.8%

were mild (grade 1-2), and the severity in the rest were indeterminable. Overall, 53/1143 (4.6%) children experienced severe AE/SE.

Conclusions: The majority of children receiving RTX for NS do not experience serious AE/SE and RTX is generally well-tolerated. However, standardized reporting of AE/SE including timing, duration, and severity grade is warranted in future studies.

Type of AE/SE	Description of AE/SE	Proportion of Patients Affected (n=1143)	CTCAE Severity Grading					
			1	2	3	4	5	Unclear
Infusion-related reaction	respiratory distress, bronchospasm, epistaxis, cough/itchy throat, hypotension, hypertension, tachycardia, bradycardia, arrhythmia, nausea, vomiting, chest discomfort, skin rash, itching, facial flushing, abdominal/ankle/pelvic pain, dyspnea, polypnea, pruritus, myalgia, chills, fever, allergic reaction	22.05%	146	43	1	0	0	62

PO1978

Efficacy and Safety of Long-Term Use of Rituximab in Pediatric Patients with Nephrotic Syndrome

Naye Choi,[1,3] Jeesu Min,[1,3] Hyeonju Lee,[1] Ji hyun Kim,[2] Peong Gang Park,[4] Hee Gyung Kang,[1,3] Yo Han Ahn.[1,3] *[1]Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea.*

Background: Rituximab (RTX) is an effective therapeutic agent widely used in children with nephrotic syndrome (NS). However, long-term effects after the B cell depleting treatment remain unclear. We investigated the efficacy and safety of long-term use of RTX in pediatric NS patients.

Methods: We retrospectively reviewed the medical records of 58 patients with steroid-dependent or steroid-resistant NS who had received more than 3 cycles of RTX. Each cycle consisted of one to four infusions of RTX (375 mg/m^2 per dose) until the depletion of B lymphocytes.

Results: The first cycle of RTX was started at the median age of 12.1 (interquartile ranges (IQR) 8.8–14.1) years. Median 5 (IQR 4–8) times of RTX cycles were used during a period of median 4.0 (IQR 2.3-5.9) years. The B lymphocytes recovered to 1% at a median 5.7 (IQR 4.8–6.7) months after the completion of RTX administration. The relapse significantly decreased from median 2.0 (IQR 1.0–3.0) times per year to 0.2 (IQR 0.1–0.5) times per year after long-term RTX treatments (P <0.001). Height growth and hypertension improved significantly compared with prior to the long-term use of RTX. Acute infusion reactions were observed in 21 (36.2%) patients. During long-term RTX treatments, hypogammaglobulinemia developed in 7 (12.1%) patients, and neutropenia was noted in 4 (6.9%) patients. Severe infections which required hospitalization and/or intravenous antibiotic were observed in 6 (10.3%) patients, but no life-threatening infections were identified. No secondary neoplasms or opportunistic infections occurred during the study period.

Conclusions: Long-term therapeutic use of RTX could be effective and relatively safe in pediatric patients with NS. However, impaired immunity should be monitored and carefully followed up during the long-term use of RTX.

PO1979

Rates of Idiopathic Childhood Nephrotic Syndrome Relapse During the COVID-19 Pandemic

Clarkson Crane, Elizabeth G. Ingulli. *University of California San Diego, La Jolla, CA.*

Background: While most children with idiopathic nephrotic syndrome (NS) enter remission after a course of steroid therapy, as many as 60-90% eventually relapse with recurrence of nephrotic-range proteinuria. Infections are thought to be primarily responsible for triggering relapses. The COVID-19 pandemic promoted physical distancing, facial masking, and greater attention to infection prevention measures resulting in decreased transmission of common viral infections. We hypothesize that there will be a decreased rate of NS relapse during this period.

Methods: We conducted a retrospective chart review of children with NS followed at our center. Patients were identified by ICD 9/10 code for proteinuria and included if they had primary steroid-sensitive NS. Numbers of relapses and hospitalizations each year were collected for baseline data, March 1, 2015-March 1, 2020, and for the social distancing period (SDP), March 1, 2020-March 1, 2021.

Results: 137 children with NS were identified. The rate of relapse per year and the rate of hospitalizations per year were lower during the SDP compared with baseline pre-pandemic levels (76 vs 81 relapses per year and 14 vs 19 hospitalizations per year, respectively). Importantly, within a year of NS diagnosis, there was a baseline pre-pandemic average of 1.6 relapses per patient. This was much lower with an average of 0.6 relapses per patient during the SDP (p<0.01). In contrast, there was no difference in new diagnoses of NS comparing SDP vs baseline period (15 vs 14 new cases per year).

Conclusions: Our results support our hypothesis of lower rates of NS relapse and hospitalizations during SDP. Most notably, there were significantly fewer relapses within the year following NS diagnosis during SDP compared with baseline. This is likely attributable to decreased transmission of common infections and greater attention to infection prevention by caregivers. Less hospitalizations during the SDP would suggest decreased severity of relapse, perhaps due to earlier detection, increased caregiver awareness, or fewer infections. Interestingly, the number of new diagnoses was similar. Future analysis will focus on identification of relapse triggers and associations with steroid responsiveness and other demographic characteristics.

PO1980

Sparsentan for Treatment of Pediatric Patients with Selected Proteinuric Glomerular Diseases: Design of the Phase 2 EPPIK Study

Howard Trachtman,[1] Moin Saleem,[2] Rosanna Coppo,[3] Michelle N. Rheault,[4] Ping He,[5] Radko Komers.[5] *[1]NYU School of Medicine, New York, NY; [2]University of Bristol & Bristol Royal Hospital for Children, Bristol, United Kingdom; [3]Fondazione Ricerca Molinette, Regina Margherita Hospital, Turin, Italy; [4]University of Minnesota Medical School Twin Cities, Minneapolis, MN; [5]Travere Therapeutics Inc, San Diego, CA.*

Background: Sparsentan is a novel Dual Endothelin Angiotensin Receptor Antagonist (DEARA) being investigated for focal segmental glomerulosclerosis (FSGS) and IgA nephropathy (IgAN). It is a dual acting, highly selective antagonist of both the endothelin A receptor (ET_AR) and the angiotensin II subtype 1 receptor (AT_1R). The Phase 2 EPPIK study will examine the long-term antiproteinuric and nephroprotective potential and safety of sparsentan in pediatric patients with FSGS, minimal change disease (MCD), IgAN, IgA vasculitis (IgAV), and Alport syndrome (AS).

Methods: The global, open-label, single-arm, multicenter study will evaluate the safety, efficacy, and pharmacokinetics (PK) of sparsentan in ~57 patients (aged ≥1 to <18 years), including ~30 with FSGS and/or MCD (population 1) and ~27 with IgAN, IgAV, or AS (population 2) over 108 weeks (**Figure**). See **Table** for inclusion/exclusion criteria. Sparsentan will be administered in a novel liquid formulation at a dose adjusted to body weight.

Results: Primary endpoints include safety (incidence of treatment-emergent adverse events) and change in urine protein/creatinine ratio (UP/C) from baseline over 108 weeks of sparsentan treatment. Secondary endpoints include PK outcomes, change from baseline over 108 weeks in albumin/creatinine ratio and eGFR, and the proportion of patients with FSGS/MCD who achieve partial remission (UP/C ≤1.5 g/g and >40% reduction in UP/C).

Conclusions: This Phase 2 study will evaluate the long-term safety, antiproteinuric, and nephroprotective effects of sparsentan in pediatric patients.

Table. Key Inclusion and Exclusion Criteria

Inclusion All: eGFR ≥30 mL/min/1.73m^2; mean seated blood pressure 5th to 95th percentile for age, sex, and height
Population 1: Male/female age ≥1 and <18 years; UP/C ≥1.5 g/g at screening despite history or ongoing corticosteroid/immunosuppressive drugs; biopsy-proven FSGS/MCD or FSGS/MCD-associated genetic mutation in a podocyte protein
Population 2: Male/female age ≥2 and <18 years; UP/C ≥1.0 g/g at screening; biopsy-confirmed IgAN/IgAV nephritis or AS-associated genetic mutation
Exclusion All: Weighs <7.3 kg at screening; secondary FSGS/MCD/IgAN/IgAV; significant cardiovascular or hepatic conditions; new immunosuppressive therapy within 6 months of screening or not on stable dose of chronic therapy ≥1 month before screening

Efficacy of New Combination Therapy with Prednisolone, Mizoribine, and Lisinopril for Severe Childhood IgA Nephropathy

Yuko Shima,[1] Hironobu Mukaiyama,[1] Yu Tanaka,[1] Takuzo Wada,[1] Hiroshi Kaito,[2] Ryojiro Tanaka,[2] Kandai Nozu,[3] Kazumoto Iijima,[3] Norishige Yoshikawa,[4] Koichi Nakanishi.[5] *[1]Wakayama Kenritsu Ika Daigaku, Wakayama, Japan; [2]Hyogo Kenritsu Kodomo Byoin, Kobe, Japan; [3]Kobe Daigaku, Kobe, Japan; [4]Shakai Iryo Hojin Aijinkai Takatsuki Byoin, Takatsuki, Japan; [5]Ryukyu Daigaku, Nakagami-gun, Japan.*

Background: Our previous RCT shows that warfarin and dipyridamole added to prednisolone (PSL) and mizoribine (MZB) in the 2-year combination therapy have additional effect for proteinuria remission in severe (diffuse mesangial proliferation, WHO) childhood IgAN compared to that with only PSL and MZB (Pediatr Nephrol 2018;33:2103-12). However, we have to consider avoiding the use of warfarin and dipyridamole due to side effects. Meanwhile, angiotensin-converting enzyme inhibitors such as lisinopril have been widely used for childhood IgAN since the 2000s. Therefore, we intended to examine the effect of new combination therapy including PSL, MZB, and lisinopril.

Methods: This cohort study included 84 patients with severe IgAN enrolled among 546 pediatric IgAN between 1977 and 2017, and divided into 2 groups, 70 patients treated with the previous combination therapy and 14 patients with the new combination therapy. A 1:1 propensity score matching was performed to account for between-group differences and 12 matched pairs were obtained.

Results: Proteinuria remission was significantly more obtained in the new treatment group (100% vs 50.0%, p=0.001). The patients with the new treatment achieved significantly faster proteinuria remission (median 2.4 vs. 12.0 months, p=0.04). The median duration of PSL use was significantly shorter in the new treatment group (13 vs. 24 months, p<0.0001). The median observation period was 4.9 and 4.5 years, and the percentage of patients with normal urine at the latest observation was significantly higher in the new group (66.7% vs. 25.0%, p=0.04).

Conclusions: Our findings suggest the usefulness of the new combination therapy with PSL, MZB, and lisinopril for severe childhood IgAN in achieving early proteinuria remission and shortening PSL use. Further investigations with the larger-scale and long-term outcome will be needed.

PO1982

Renal Activity Index in Lupus (RAIL) Score Distinguishes Responder and Non-Responder in Pediatric Lupus Nephritis

Ellen Cody,[1] Scott E. Wenderfer,[2] Qing Ma,[1] Angela Merritt,[1] Prasad Devarajan,[1] Hermine Brunner.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Baylor College of Medicine, Houston, TX.*

Background: Systemic Lupus Erythematosus (SLE) is a diagnostic and therapeutic challenge, particularly lupus nephritis (LN). We described a composite score, the Renal Activity Index for Lupus (RAIL), consisting of neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), monocyte chemotactic protein 1 (MCP-1), adiponectin, hemopexin and ceruloplasmin, where higher scores reflect more active inflammation on biopsy. We hypothesize that when followed longitudinally during induction therapy, a change in RAIL score distinguishes clinical responders from non-responders.

Methods: Pediatric patients (<18 years) diagnosed with LN were included (IRB #2008-0635). Diagnosis was made according to ACR criteria for SLE with renal biopsy confirmation of LN. Urine was collected at diagnosis and end of induction. Responders were defined by urine protein to creatinine ratio <0.2 mg/mg, absence of hematuria, and normal glomerular filtration rate. Response also defined as improved activity index on follow up biopsy. 15 patients were included, 10 responders, 5 non-responders. Analysis by T-test, as well as sensitivity and specificity for no change in RAIL score.

Results: RAIL score in the responder group pre and post therapy was significantly different, p-value 0.015. T-Test between non-responder and responder difference scores showed trend towards significance, p-value 0.081 (Fig 1). Most responders had a difference of at least 0.5 during induction, whereas most non-responders had no difference or an increase in RAIL score, and a change scoreis >0 identified responders with 90% sensitivity.

Conclusions: A change in RAIL during induction therapy is promising for predicting responders vs non-responders, with average decrease of 1 compared to no change. To further evaluate, more samples are needed, which is on-going.

PO1983

Collapsing FSGS in Siblings with Compound Heterozygous Variants in NUP93 Expand the Spectrum of Kidney Phenotype Associated with NUP93 Mutations

Rachel K. Cason,[1] Anna E. Williams,[1] Megan Chryst-Stangl,[1] Guanghong Wu,[1] Kaye E. Brathwaite,[2] Brandon M. Lane,[1] Vivette D. D'Agati,[3] Rasheed A. Gbadegesin.[1] *[1]Duke University Health System, Durham, NC; [2]Montefiore Health System, Bronx, NY; [3]Columbia University Irving Medical Center, New York, NY.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is a major cause of end stage kidney disease, the collapsing form has the worst prognosis. Study of families with hereditary FSGS has provided insight into disease mechanisms. In this report, we describe a sibling pair with *NUP93* mutations and collapsing FSGS. This is the first report of collapsing FSGS associated with *NUP93* mutations.

Case Description: We identified a Caucasian sibling pair with early onset steroid resistant nephrotic syndrome. Kidney biopsy in both brothers performed at ages 5 and 2 years, respectively, showed collapsing FSGS. Lesions of segmental or global sclerosis with focal collapsing features involved 22/33 and 6/28 glomeruli, respectively. Clinical phenotypes are summarized in Table 1. We obtained DNA from the affected brothers and their unaffected parents and carried out whole genome sequencing on the two affected siblings. We applied our standard filtering algorithm[1] and identified segregating rare compound heterozygous variants 1) C.1772G>T p.G591V, 2) c.2084T>C p.L695S in *NUP93* in the two affected brothers. Both variants are rare with minor allele frequency <0.00015. Both variants are evolutionarily conserved and were predicted to be pathogenic by four *in-silico* tools. 3D modeling revealed that both variants created structural alterations throughout the protein including the amino and the carboxyl terminal residues. These structural alterations are predicted to alter the binding affinity for several NUP93 ligands, likely disrupting the function of the highly organized nuclear pore channel.

Discussion: To the best of our knowledge, this is the first report of collapsing FSGS in patients with *NUP93* mutations. Functional studies to determine the mechanisms by which these variants cause podocytopathy may provide insight into the pathogenesis of the more common idiopathic and virus-mediated forms of collapsing FSGS as well as aid in early disease detection and intervention.

Table 1 - Clinical Phenotypes

Subject	Age at disease onset (yr)	Proteinuria (g)	Age at ESKD (yr)	Kidney Transplant (Y/N)	Recurrence (Y/N)
1	5	25	7	Y	N
2	2	3.6	unknown	Y	N

PO1984

Leukocyte-Derived Human RNase 6 and RNase 3 Provide Resistance to Urinary Tract Infection

Juan de Dios Ruiz-Rosado,[1,2] Hanna H. Cortado,[1] Macie M. Kercsmar,[1] Ashley R. Jackson,[1,2] Birong Li,[1] Brian Becknell.[1,2] *[1]Center for Clinical and Translational Research, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Division of Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH.*

Background: Urinary tract infections (UTIs) account for 7 million office visits and $1.6 billion dollars in health care spending annually in the United States. Uropathogenic *Escherichia coli* (UPEC) is the primary etiological pathogen causing over 80% of UTI. Currently, *there is a critical need for innovative and effective strategies to treat UTI and prevent UTI-associated sequelae.* Antimicrobial peptides (AMPs) are fundamental components of the innate immune system that serve instrumental roles in eliminating pathogenic microbes and thus represent a potential therapeutic tool to limit UTIs. We have identified AMPs within the Ribonuclease (RNase) A Superfamily that promote resistance against uropathogens. In this study, we determined the contribution of human RNase 6 and 3 to bacterial clearance following experimental UTI *in vivo*.

Methods: Humanized *RNASE6* and *RNASE3* transgenic mice (C57BL/6) were generated by integrating human *RNASE6* or *RNASE3* transgene fragments into the mouse genome. Humanized *RNASE6*–expressing or *RNASE3*-expressing transgenic female mice were transurethrally infected with UPEC strain UTI89. Non-transgenic littermates were used as negative controls. Bone marrow-derived macrophages (BMDMs) and BM neutrophils (PMNs) from *RNASE6* and *RNASE3* transgenic mice, respectively, were infected with UPEC *in vitro.* RNASE6 and RNASE3 expression were determined by western blot, flow cytometry and immunofluorescence. Bacterial burden was assessed via quantification of UPEC colony forming units.

Results: *RNASE6* and *RNASE3* transgenic mice showed reduced bacterial burden in the urine and bladder compared to non-transgenic mice following UPEC infection. $F480^+$ macrophages in the infected bladder were identified as the main source of RNASE6, while RNASE3 was predominantly expressed by $Ly6G^+$ neutrophils in the bladder submucosa. We also found that BMDMs from *RNASE6* transgenic mice had reduced intracellular bacteria compared to WT BMDMs after UPEC infection *in vitro*. Decreased extracellular bacterial burden was observed in cell cultures from *RNASE3* transgenic PMNs compared to non-transgenic PMNs.

Conclusions: Our findings indicate that RNASE6 and RNASE3 produced by innate phagocytes have a critical anti-microbial role against UPEC *in vivo* and *in vitro*. These RNases have the potential to effectively limit or prevent UTIs.

PO1985

Human Bladder Tissues Express Gb3 and Are Targeted by Shiga Toxin

Yang Liu,[1,2] Hatim Thaker,[1,2] Songhai Tian,[1,2] Jie Zhang,[1,2] John Manion,[1,2] Siyu Wang,[1,2] Shan Wu,[3] Zhonggao Xu,[4] Min Dong.[1,2] Dong Lab *[1]Boston Children's Hospital Department of Urology, Boston, MA; [2]Harvard Medical School Department of Surgery and Department of Microbiology, Boston, MA; [3]Jilin University, College of Basic Medical Sciences, Department of Pathology, Changchun, China; [4]The First Hospital of Jilin University, Department of Nephrology, Changchun, China.*

Background: Shiga-toxin (Stx) producing *E. coli* associated hemolytic uremic syndrome (STEC-HUS) is the main cause of acute kidney injury (AKI) in children. Glycosphingolipid globotriaosylceramide (Gb3) is the receptor for Stx and determines the tissue specificity of Stx. Previous studies have detected Gb3 in glomeruli, proximal tubules and collecting duct in human kidney, but whether Gb3 is also expressed in other urinary tissues such as bladders remains unknown.

Methods: We first established and validated two complementary detection methods for Gb3 on cultured cells, one with a monoclonal Gb3 antibody and the other detecting Stx bound to cells using an antibody against Stx. Wide-type (WT) and A4GALT (α-1, 4-galactose transferase, Gb3 synthase) knockout (KO) human bladder cancer 5637 cells were utilized as cell models. Using these two approaches, we examined Gb3 expression in the urinary system of human and different animal models. In addition, Stx was administered i.p. in WT and A4GALT KO C57 mice to evaluate the key role of Gb3 in Stx pathogenesis in kidney and bladder tissues. Finally, we examined the impact of Stx on bladder tissues with injection of Stx into the lumen of bladders.

Results: Gb3 is detected on the cell surface of WT 5637 cells, but not on A4GALT KO cells. Consistently, Stx binds to WT 5637 cells, but not A4GALT KO cells. We found that normal human bladder connective tissue and vascular endothelial cells express Gb3, which mediates binding of Stx. Gb3 expression were detected in Yorkshire pig, New Zealand white rabbit, CD1 and C57 mouse, but not in Dolly sheep. Exposure to Stx induced a large amount of inflammatory cells infiltration in the bladder submucosa in C57 mice, and bladder transitional cells necrosis were detected by pathological evaluation; while the transitional cells of A4GALT KO mice showed no corresponding changes.

Conclusions: Here we report the novel finding that Gb3 is expressed within bladder tissues in humans, suggesting that bladder tissues could be a key target of Stx in humans. Furthermore, we found that Gb3 expression varies among different animal models, which will guide the selection of proper animal models for investigating the impact of Stx on urinary tissues. Finally, our study revealed that Gb3 mediate bladder inflammatory cell infiltration and transitional cell necrosis in Stx treated C57 WT mice.

Intercalated Cells Activate Innate Immune Defenses in Response to Uropathogenic Escherichia coli

Sarah C. Linn,[1,2] Laura Schwartz,[1] John D. Spencer.[1,3] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University College of Veterinary Medicine, Columbus, OH; [3]The Ohio State University College of Medicine, Columbus, OH.*

Background: Urinary tract infections (UTI), including pyelonephritis, are common in children. Intercalated cells (IC), positioned in the renal collecting duct, prevent and combat UTI by secreting antimicrobial peptides (AMPs) into the urine. The mechanisms regulating IC AMP production during UTI are unclear. Here, we challenged ICs *in vitro* with uropathogenic *E. coli* (UPEC) or bacterial cell membrane components to define the innate immune responses that control AMP production during UTI.

Methods: ICs (Clone C) were infected with a UPEC pyelonephritis strain (CFT073) or challenged with UPEC cell membrane components including lipopolysaccharide (LPS), muramyl dipeptide (MDP) and γ-D-Glu-mDAP (iE-DAP). Following stimulation, IC lysates were collected, and 87 immune genes were profiled using an antimicrobial response PCR array or targeted qRT-PCR. Western blot was performed to identify which innate immune responses are activated.

Results: In response to UPEC, ICs temporally activate immunomodulatory pathways and AMPs. Analysis of the PCR array data via STRING and Ingenuity Pathway Analysis identified 15 upregulated genes associated with Toll-like receptor (TLR), NOD-like receptor (NLR), and NF-kB signaling 4 hours post infection. Immunoblotting confirmed downstream targets in these pathways are activated in response to UPEC. qRT-PCR identified that AMPs like *Lcn2* are activated while others, including *Rnase8*, are suppressed. Upon stimulation with LPS, qRT-PCR showed upregulation of *Lcn2*, *Defb1*, and *Rnase8* – suggesting that TLR4 activation may regulate the expression of these AMPs. Additionally, qRT-PCR showed *Lcn2* is induced in response to the NOD2 agonist, MDP, while AMP expression did not change with the NOD1 agonist, iE-DAP.

Conclusions: During UPEC infection, TLR, NLR, and NF-kB responses are activated in ICs. Activation of TLR and NLR signaling may induce downstream targets like AMPs. Confirmation studies are needed to determine how these pathways regulate AMP expression and their differential regulatory targets. Identification of these nodes may serve as future targets to increase AMP production as an additional means to treat UTIs in children and adults.

Renal-Derived Alpha-Defensins 1-3 Contribute to Enhanced Urinary Tract Protection in Humanized Mouse Transplant Model Challenged against Uropathogenic Escherichia coli

Jorge J. Canas, Jenaya Hooks, Sam W. Arregui, Andrew L. Schwaderer, David S. Hains. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Alpha-defensins 1-3 are potent antimicrobial peptides expressed from *DEFA1A3* gene locus by human neutrophils and kidneys. Decreased DNA copy numbers of *DEFA1A3* have been associated with UTI susceptibility. Here, we utilize a human *DEFA1* knock-in transgenic mouse (*Defa*$^+$) to study the role of *DEFA1A3* in UTIs. We hypothesized that *DEFA1* protects the murine urinary tract from uropathogenic *E. coli* (UPEC) challenge and renally derived *DEFA1A3* is the protective source.

Methods: Female wild-type (WT) and *Defa*$^+$ mice were infected by transurethral inoculation of UPEC; CFT073, pyelonephritis strain. Bacterial burdens in kidneys and bladders for each group of mice were analyzed at 6 hours post-infection (hpi). We performed transplant isografts of $Defa^{Kidney} \rightarrow WT^{Recipient}$ mice and used $WT^{Kidney} \rightarrow WT^{Recipient}$ as biological controls for UPEC challenges (Figure 1A).

Results: Murine bladder and kidney CFU bacterial burdens results are presented in Figure 1: Comparing the groups at 6 hpi, CFU burden averages were significantly lower in the $Defa^{Kidney} \rightarrow WT^{Recipient}$ infected bladder group, similarly to infected *Defa*$^+$ mice when compared to its WT counterpart (B). Strikingly, kidneys from $Defa^{Kidney} \rightarrow WT^{Recipient}$ were protected against bacterial growth, in contrast to $WT^{Kidney} \rightarrow WT^{Recipient}$ controls, which showed higher titers of CFU burdens per transplanted kidney following pyelonephritis challenge, and recapitulates the protective phenotype observed in the *Defa*$^+$ infected mice when compared to its WT control group (C).

Conclusions: Our findings support the role of renal-derived alpha-defensins 1-3 in not only protecting the transplanted kidney but the entire lower urinary tract from UPEC.

Fate-Mapping Supports a Linear Model of Urothelial Formation and Regeneration

Kelly Grounds, Birong Li, Brian Becknell, Ashley R. Jackson. *Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Urothelium is a highly specialized, slow turnover epithelium that lines the kidney, ureter, bladder and proximal urethra. Bladder urothelium contains several cell types organized into basal (B), intermediate (I) and superficial (S) cell layers. The progenitor responsible for urothelial repair has been the focus of many investigations, with

strong support for both B and I cell contenders. We have previously demonstrated that keratin 5^{+} (K5) urothelial cells (UCs) are context specific progenitors in the kidney. Here, we mapped the fate of K5-UCs across development and following cyclophosphamide (CYC)-induced urothelial injury in the bladder.

Methods: Using tamoxifen (TMX)-inducible *Krt5^{CreERT2};Rosa^{zsGreen}* mice, we permanently labeled K5-UCs with zsGreen (zsGreen^{K5}) across development and evaluated their capacity to form I and S cells during homeostasis or following CYC-induced urothelial injury. Immunofluorescence microscopy was used to determine whether zsGreen^{K5}-UCs were K5^{+}(B-cells), Uroplakin^{+} (Upk; I and S-cells), or K20^{+}(S-cells). Organoid forming assays were used to evaluate progenitor capacity *in vitro*.

Results: Baseline analysis of our Cre;LoxP strategy confirmed that zsGreen^{K5} is specifically expressed in basal K5-UCs 24h after TMX administration at all induction stages. The fate of zsGreen^{K5}-UCs varied, with neonatal (postnatal day [P]1, P7) stages giving rise to adult (P42) I and S cells, the juvenile (P14) stage giving rise to I but not S cells, and adult (P35, P42) stages not escaping the B cell layer. CYC-induced urothelial injury did not engage adult zsGreen^{K5}-UCs for repair, whereas neonatal and juvenile zsGreen^{K5}-UCs gave rise to I and S cells following CYC treatment. Organoid forming assays confirmed that zsGreen^{K5}-UCs could form organoids that express B and I cell markers, and neonatal UCs formed larger organoids than adult UCs.

Conclusions: We show that precise temporal populations of K5-UCs form I cells during homeostasis which in turn are engaged as adults for S cell formation in response to injury. We believe that these findings unite B and I cell progenitor models, by temporally linking a linear progression of B→I→S cell formation. A more complete understanding of the role of discrete urothelial cell populations will enable precise control of urothelial cell differentiation and will inform targeted tissue regeneration strategies.

Urothelial Injury Triggers Adaptive Remodeling That Limits Congenital and Acquired Obstructive Nephropathy

Birong Li, Sudipti Gupta, Christina B. Ching, Ashley R. Jackson, Brian Becknell. Nephrology and Urology Research Affinity Group *Nationwide Children's Hospital, Columbus, OH.*

Background: Congenital urinary tract obstruction (UTO) is the leading cause of chronic kidney disease and end stage renal disease in children. Both congenital and acquired UTO induce renal urothelial cells to remodel and assume a bladder-like morphology, but the mechanisms and significance of these changes remain unclear. We hypothesize that urothelial remodeling occurs as a consequence of injury to Uroplakin (UPK) expressing cells and serves to attenuate obstructive nephropathy.

Methods: Urothelial injury markers were measured by ELISA in children undergoing pyeloplasty for congenital ureteropelvic junction obstruction (UPJO) versus non-obstructed controls. Male and female mice underwent acquired UPJO via unilateral ureteral obstruction (UUO). The fate of Upk+ cells during UUO was traced through the use of Cre/LoxP mapping. The impact of Upk plaque loss on the kidney's response to UUO was assessed through the use of *Upk1b$^{-/-}$* mice. The effects of Upk+ cell depletion during UUO were gauged by administering diphtheria toxin (DT) to *Upk2*iCre(+); *Rosa26$^{DTR/+}$* mice.

Results: Urine from children with congenital UPJO contains elevated urothelial injury markers – including KRT14, UPK2, and KRT20 – compared to unobstructed controls. Mice with UUO exhibit urothelial apoptosis and increased mRNA and protein expression of urothelial injury markers. Lineage analysis of Upk+ cells demonstrates that UUO triggers a sequence of Upk protein downregulation, proliferation, and elaboration of a bladder-like urothelial plaque. When this process is disrupted via *Upk1b* deletion or depletion of Upk^{+} cells, UUO results in augmented tubular injury and interstitial fibrosis.

Conclusions: Urothelial injury is a conserved response to UTO and initiates a series of events that culminate in protective, bladder-like remodeling. The resulting expansion of Upk+ cells and production of urothelial plaque represent an essential adaptation to limit renal parenchymal injury during UTO.

An Ethical Decision-Making Framework for Genomic Testing in Pediatric Kidney Disease

Inez Beadell,[1,2] Ella J. Wilkins,[3,4] Susan M. White,[1,4] Gemma R. Brett,[1,4] Zornitza Stark,[1,4] Michelle Lim,[2] Catherine Quinlan.[1,3] *[1]The University of Melbourne Melbourne Medical School, Melbourne, VIC, Australia; [2]The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; [3]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [4]Victorian Clinical Genetics Services Ltd, Parkville, VIC, Australia.*

Background: Technological advances and increased access have led to genomics expanding beyond the genetics specialty. As a result, non-genetic specialists, including nephrologists, can now order genomic testing for their patients. Consistent decision-making around patient and test selection is required to ensure equitable access while maximizing the utility of genomic testing, from a patient and resource perspective. However, there are currently no frameworks to guide decision-making for genomic testing in pediatric nephrology. We aimed to develop an ethical decision-making framework to guide genomic testing decision-making in pediatric kidney disease.

Methods: A three-stage approach was used: 1) review of the literature on decision-making for genomic testing in nephrology and other disciplines; 2) observation of approaches to genomic testing in the general nephrology clinic and the renal genetics clinic at an Australian pediatric hospital; 3) review and revision of the framework with key stakeholders, including clinical geneticists, genetic counselors, pediatric nephrologists, clinical ethicists, and families from the renal genetics service. The initial framework was modified until consensus from key stakeholders was reached.

Results: A decision-making framework was created. This framework outlines the key decision-making categories and sub-categories for patient selection, with corresponding questions to aid usage. A number of case studies were developed to demonstrate the framework's application. Key factors influencing utilization of the framework were identified, particularly funding pathway, clinical environment, and patient population.

Conclusions: The framework will guide decisions around patient-selection for genomic testing in nephrology at the Australian pediatric hospital of origin as well as other institutions and disciplines. In doing so, it will facilitate consistent approaches to genomic testing, to maximise equity and utility.

PO1991

Genetic Testing and Biomarkers as Predictive Tools for Congenital Anomalies of Kidney and Urinary Tract (CAKUT)

Meredith Harris, Elif Erkan, Kenneth Kaufman. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Cincinnati Children's Hospital is 1 of ~5 centers offering fetal interventions (FI) (amnioinfusions/amnioshunts) & infant hemodialysis (HD) for oligo/anhydramnios (OA), increasing survival from 17 to 50%. As a result of this unique surviving Congenital Anomalies of Kidney & Urinary Tract (CAKUT) population, more investigation into genetics & biomarkers in severe CAKUT needs to be performed, particularly in our growing bilateral multicystic dysplastic kidney (bMCDK) population (fatal at most centers). We hypothesize identification of novel genetic mutations & biomarkers will aid in determination of the clinical course of infants & mechanisms of nephrogenesis.

Methods: Inclusion criteria for severe CAKUT are women undergoing FI for OA or infants starting HD by 1 month of life. We obtained amniotic fluid (AF) during FI and blood from the mother, father, & infant for trios whole exome sequencing (WES). We performed ELISA testing on AF of 4 renal tubular biomarkers produced by fetal kidneys and validated in AF (NGAL, Cystatin c, Uromodulin and ET-1). Controls are 2nd trimester AF from infants without CAKUT.

Results: We enrolled 18 families-6 with bMCDK & obtained 8 AF samples (2 bMCDK). We performed WES on 5 trios (4 bMCDK) & 3 singletons (1 bMCDK). We identified 4 strong candidate genes **(Table).** Biomarker testing included 8 AF samples & 10 controls. All 4 biomarkers are significantly lower in severe CAKUT than controls & are lower in bMCDK than bladder obstruction, likely as the bMCDK population has less renal endowment. Biomarkers are lower in those with intrauterine demise compared to liveborn.

Conclusions: In patients with severe CAKUT, we detected 4 strong candidate genes, 3 implicated in embryo development. This population is enriched for genetic variants, likely due to severity of presentation. We validated 4 biomarkers in AF with correlations to diagnosis & survival. WES & biomarker testing are promising techniques to predict the course of severe CAKUT prenatally. Our goal is to develop a polygenic risk score to predict disease severity in utero based on genetic & biomarker data in this unique population.

Genetic Kidney Disease: The Importance of Variants of Uncertain Significance

Ashley M. Gefen, Laura J. Castellanos, Pamela Singer, Abby M. Basalely, Christine B. Sethna. *Cohen Children's Medical Center, Queens, NY.*

Introduction: Diagnosing genetic kidney disease has become more accessible with the advent of low-cost and rapid genetic testing. The Invitae nephrolithiasis (NL) panel performs next-generation sequencing to evaluate 35 genes associated with NL and nephrocalcinosis (NC).

Case Description: A 7-month-old, ex-full term, white female was referred to pediatric nephrology clinic for recurrent urinary tract infections (UTI). Review of systems was positive for nonbloody diarrhea. She had no allergies or pertinent family history. Vital signs were normal with height at 14th percentile and weight at 6th percentile. Physical exam was unremarkable. Kidney/bladder ultrasound showed bilateral medullary NC. Voiding cystourethrogram was normal. Laboratory evaluation showed hyponatremia

(129 mmol/L), anion-gap metabolic acidosis, hypercalcemia (13.9 mg/dL, ionized calcium 1.52 mmol/L), hypophosphatemia (2.8 mg/dL), hypoparathyroidism (1.45 pg/mL), and hypercalciuria (urine calcium:creatinine 1.3 mg/mg). She was diagnosed with milk protein allergy with diarrhea and electrolyte derangements requiring supplementation. After the diarrhea resolved on milk-free formula, serum electrolytes normalized except for hypercalcemia. Hypercalciuria resolved with hydration and low sodium diet. All supplements were stopped except for potassium citrate. Invitae NL panel was sent and showed 2 heterozygous variants of uncertain significance (VUS) in gene SLC34A1. Mutations in SLC34A1 are associated with autosomal recessive (AR) infantile hypercalcemia 2 (IH2), autosomal dominant hypophosphatemic NL/osteoporosis, and AR Fanconi renotubular syndrome. Parental testing determined the VUS were in a trans-configuration. It was hypothesized that she may be a compound heterozygote for IH2, a disease associated with hypercalcemia, failure to thrive, dehydration, and NC. She was trialed on the treatment of IH2 (phosphorus supplementation) and within 1 week hypercalcemia resolved.

Discussion: Although this patient had VUS in SLC34A1 rather than known pathogenic variants, her clinical presentation was consistent with IH2. Had IH2 treatment not been trialed, this patient would have had continue hypercalcemia with associated morbidity. This case illustrates how genetic testing may change clinical practice by altering treatment strategies, and the importance of taking VUS into consideration.

PO1993

Genetic Causes for Congenital Nephrotic Syndrome: North American Mutations and the Contribution of Regulatory Factors

Shyanne Hefley,[1] Larry A. Greenbaum,[2] Alexandru R. Constantinescu,[3] Tej K. Mattoo,[4] Scott E. Wenderfer,[5] Katherine Twombley,[6] Tetyana L. Vasylyeva.[1] *[1]Texas Tech University Health Sciences Center, Amarillo, TX; [2]Emory University, Atlanta, GA; [3]Joe DiMaggio Children's Hospital, Hollywood, FL; [4]Wayne State University, Detroit, MI; [5]Baylor College of Medicine, Houston, TX; [6]Medical University of South Carolina, Charleston, SC.*

Background: Congenital Nephrotic Syndrome (CNS) is a debilitating disease that affects children within the first few months of life and is characterized by severe proteinuria and loss of kidney function. A majority of CNS cases are caused by mutation of the *NPHS1* gene, particularly in other countries. Our first aim was to determine the specific genetic causes for CNS in North America (NA). Our second aim was to determine the contribution of FOXC1, FOXL1, and GATA3 to *NPHS1* transcription and nephrin production, which could serve as potential drug targets for CNS therapy.

Methods: A retrospective chart review was performed to determine the prevalence of CNS mutations in NA. A survey was administered to members of the Pediatric Nephrology Research Consortium (PNRC) and consisted of 65 questions pertaining to CNS. A questionnaire was developed by a team of pediatric nephrologists and was administered to members of the Pediatric Nephrology Research Consortium (PNRC) via Qualtrics. *In vitro* studies to determine the impact of FOXC1, FOXL1, and GATA3 on *NPHS1* were performed using mouse primary podocytes and siRNA knockdown was performed to determine the effect of these transcription factors on nephrin production.

Results: We found the average age of CNS diagnosis was 2.6 months, with 60.3% of patients being female. Sixty-eight percent of patients underwent genetic testing for their CNS and a majority of patients (65.1%) had *NPHS1* mutations, whereas 11.6% had *NPHS2* mutations. Interestingly, 7.0% had both *NPHS1* and *NPHS2* mutations and 11.6% had only *WT1* mutations. The remaining 4.6% had inconclusive results. We noted that the average age of onset for *NPHS1*-only mutations was 2.1 months, whereas patients with only *NPHS2* mutations had an average age of onset of 4.5 months. Interestingly, patients with either *WT-1* mutations or a combination of *NPHS1* and *NPHS2* mutations had younger ages of onset of 1.35 months and 1.25 months, respectively. In our *in vitro* studies, siRNA knockdown of FOXC1, FOXL1, and GATA3 resulted in alterations in the expression of nephrin.

Conclusions: The results of this study not only demonstrate the distribution of genetic causes for CNS in North America, but also show that transcription factors may play a role in *NPHS1* transcription.

PO1994

Mendelian Causes Are Identified at a Relatively Low Rate and Show a Unique Pattern in Brazilian Pediatric Patients with Steroid-Resistant Nephrotic Syndrome or Focal Segmental Glomerulosclerosis

Andreia Watanabe,[1] Precil D. Neves,[1] Elieser H. Watanabe,[1] Antonio M. Lerario,[3] Denise M. Malheiros,[1] Maria H Vaisbich,[1] Friedhelm Hildebrandt,[2] Matt G. Sampson,[2] Luiz F. Onuchic.[1] *[1]University of Sao Paulo, Sao Paulo, Brazil; [2]Boston Children's Hospital, Boston, MA; [3]University of Michigan, Ann Arbor, MI.*

Background: Genetic and non-genetic factors have been associated with faster progression to chronic kidney failure (CKF) in children with steroid-resistant nephrotic syndrome (SRNS). The contribution profile of such factors in admixed populations, however, is still not well characterized.

Methods: 101 patients/98 families with idiopathic SRNS, age of onset <18yr, were sequenced for 62 NS genes or submitted to whole exome sequencing. Causative variants and *APOL1* risk alleles were confirmed by Sanger sequencing. Clinical data were retrospectively reviewed.

Results: Age of NS onset was 2.9yr (1.5-6.8), 61 (60.4%) were male, 61 (60.4%) self-declared white, 6 (5.9%) had parental consanguinity, and 14 (13.9%) familial disease. Focal segmental glomerulosclerosis (FSGS) was diagnosed in 54/95 (56.8%), minimal change disease (MCD) in 20/95 (21.1%) and collapsing glomerulopathy in 12/95 (12.6%). 43/101 (42.6%) progressed to CKF in 29 months (12.0-61.9) and 9/29 (31%) had recurrence after kidney transplant (KT). *APOL1* high risk genotypes (HRG) were identified in 8/98 (8.2%) and were associated with later NS onset [11.0 (10.0-14.5) *vs* 2.7 (1.4-4.9) yr, p<0.001]. Mendelian causes were found in other 14/98 (14.3%) families: *NPHS1*=4, *NPHS2*=3, *PLCE1*=2, *WT1*=2, *COQ2*=1, and phenocopies in *CUBN*=1 and *COL4A5*=1, all *APOL1* G0/G0. Poorer renal survival was observed in *APOL1* HRG *vs* non-Mendelian/non-*APOL1* HRG (p<0.001), and a trend in Mendelian *vs* non-Mendelian/non-*APOL1* HRG (p=0.06). The *APOL1* or Mendelian cases had no post-KT recurrence. Using Cox regression, age of onset <1yr (OR=6.5, CI:2.3-16.9, p=0.0007) or ≥ 9yr (OR=3.3, CI:1.3-7.9, p=0.015) were associated with reduced renal survival, independently of genetic findings, as well as self-declared non-white (OR=2.6, CI:1.3-5.64, p=0.01) and non-MCD histology (OR=14.2, CI:2.1-948, p=0.002).

Conclusions: Mendelian causes of SRNS/FSGS were identified in 14.3% - a lower rate than in PodoNET, SRNS Study Group and RaDar - and *APOL1* HRG in 8.2% of patients in this admixed population with a low frequency of parental consanguinity. Genetics factors, age of NS onset, ethnicity and biopsy pattern were independently associated with progression to CKF.

PO1995

Genetic Testing in Children with Nephrolithiasis and Nephrocalcinosis

Ashley M. Gefen,[1] Christine B. Sethna,[1] Onur Cil,[5] Farzana Perwad,[5] Meg Schoettler,[4] Louise Amlie-Wolf,[3] Jonathan S. Ellison,[6] Daniel Feig,[7] Joshua Zaritsky.[2] *[1]Cohen Children's Medical Center, Queens, NY; [2]Saint Christopher's Hospital for Children, Philadelphia, PA; [3]Alfred I DuPont Hospital for Children, Wilmington, DE; [4]UCSF Benioff Children's Hospital, San Francisco, CA; [5]University of California San Francisco School of Medicine, San Francisco, CA; [6]Medical College of Wisconsin, Milwaukee, WI; [7]The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Background: Diagnosing genetic kidney disease has become more accessible with the advent of low-cost and rapid genetic testing. The study objective was to determine the sensitivity of genetic testing in diagnosing kidney disease in children with nephrolithiasis (NL) and nephrocalcinosis (NC).

Methods: A retrospective multicenter study was conducted on children ≤21 years with NL/NC that underwent the Invitae sponsored NL panel. Next-generation sequencing evaluated 35 genes. The sensitivity of genetic testing was calculated. Logistic regression examined the association of clinical variables with genetic diagnosis.

Results: Seventy-eight children from 5 centers were included (56 had isolated NL [iNL] and 22 had NC). Sensitivity of genetic testing was 31% (iNl 27%, NC 41%). Of those with genetic diagnoses (Figure 1), 25% had pathogenic mutations alone, 13% carried pathogenic mutations for recessive conditions, 13% carried a pathogenic mutation and variant of uncertain significance (VUS) in the same gene and 50% had VUS alone. Mutations were found in 25 genes, most commonly HOGA and SLC3A1 in iNL and SLC34A3 and CLDN19 in NC. Clinical features are shown in Figure 2. In multivariate analysis, subjects with hypercalciuria were less likely to have a genetic diagnosis (OR 0.35, 95% CI 0.13-0.95, p=0.04).

Conclusions: This study has demonstrated the utility of genetic testing, where explanatory genetic mutations were found in one-third of children with NL/NC. Genetic testing shows promise to improve clinical practice in this population.

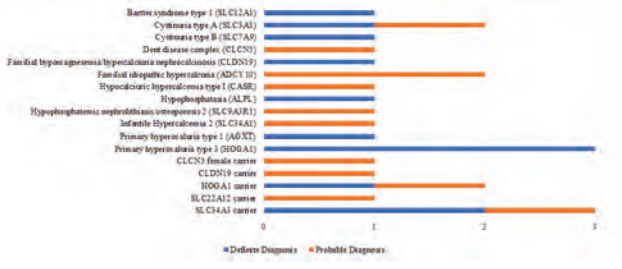

Figure 1: Genetic diagnoses.

Experience from a Single Centre Following a Large Cohort of Children with Cystinuria (1996-2019)

Sergio Camilo Lopez Garcia,[1,2] Naima Smeulders,[1] Wesley N. Hayes,[1] Alexander Cho,[1] Tom A. Watson,[1] Alex Barnacle,[1] Marina J. Easty,[1] Detlef Bockenhauer.[1,2] *[1]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [2]University College London Department of Renal Medicine, London, United Kingdom.*

Background: Cystinuria is a rare monogenic disorder accounting for 5-10% of all paediatric urolithiasis cases. This study reviews epidemiologic, clinical and management data of a large, single centre cohort of cystinuric children.

Methods: Respective data collection from children with cystinuria between June 1996 to April 2019 in our centre.

Results: A total of 52 (54% female) patients were identified with a median (IQR: interquartile range) age at presentation of 6.2 (1.9-10.3) years. 24/52 (46%) had affected family members. Common presenting symptoms were abdominal pain 21/51(41%), urinary tract infection (39%), haematuria (18%); 14/51(28%) cases were diagnosed by family screening or incidentally. 9/52(17%) had cystinuria but did not form a stone. At presentation stone location was upper tract in 30/43(70%), bladder stones were found in 10/43(23%). Estimated GFR was <90ml/min/1.73m^2 in 14/52(27%) at diagnosis. Hyperhydration fluid target was met by 63% and 76% were prescribed alkali, median (IQR) dose was 0.5(0.3-0.7) mEq/kg/day and urine pH 7.0(7.0-8.0). 24/52(46%) patients had 26 treatment periods with cystine-binding thiol drugs (CBTD) for a median (IQR) duration of 34(18-65) months; 7/24(29%) patients on CBTD developed adverse effects leading to discontinuation in 3(13%). Median (IQR) urine cystine was lower (p=0.006) at 0.7 (0.5-0.9) mmol/L after CBTD was started compared to diagnosis at 1.3 (0.7-2.0) mmol/L. Stone removal procedure was performed in 37/43(86%) cases, those treated with CBTD had a higher median (IQR) number of surgical interventions of 4(2-8) vs no CBTD 1(0-2), p<0.001. The annual median (IQR) rate of stone removal procedures/patient was 0.2(0.1-0.4). At the end of follow up eGFR<90 was present in 12/35(34%).

Conclusions: Bladder stones were seen in a 23% of paediatric patients with cystinuria. Median stone removal procedure rate was 0.2/year in our cohort. CBTD significantly decreased free urine cystine levels, but was associated with complications in almost a third. The vast majority underwent a surgical intervention during follow-up, highlighting the burden of disease. Fortunately, eGFR remained stable in most of the patients.

PO1997

Systemic Oxalate Deposition in Patients with Primary Hyperoxaluria Type 3

Bernd Hoppe,[1] Johannes Birtel,[3] Ulrike Herberg,[2] Cristina Martin Higueras.[1] *[1]German Hyperoxaluria Center, Bonn, Germany; [2]Universitatsklinikum Bonn, Bonn, Germany; [3]Oxford Eye Hospital, Oxford, United Kingdom.*

Background: In the contrary to previous reporting we now know, that patients with Primary Hyperoxaluria type 3 (PH3) remain symptomatic in adulthood with recurrent kidney stones. They also are on risk to develop chronic kidney disease (CKD). We therefore consider, that PH3 patients may also develop systemic oxalate deposition.

Methods: We are now examining PH3 patients regularly seen at the German Hyperoxaluria Center (GHC) for systemic depositions by eye exam (by fundus color photography and optical coherence tomography), hand x-rays, bone MRI (3 Tesla of the left knee and proximal tibia) and Speckle tracking echocardiography, which measures changes in global longitudinal strain (GLS), an index of left ventricular contractibility (normal GLS is ≤18%).

Results: At GHC we see 12 pediatric and 4 adult patients on a regular basis, at least twice a year. All 16 patients are in no less than CKD 2. So far the following examinations were performed: an eye exam was performed in 8 patients, it was normal in all. Speckle tracking echocardiography was done in 8 patients, it was abnormal in one (GLS – 17.3% and left ventricular hypertrophy) and borderline in another (GLS – 18.6%) in 2020. During 2021 GLS values returned to normal in both under increased treatment awareness (-23% and -21%, respectively). X-ray left hand was taken in 6 patients, one patient (multiple stone removal procedures, decline in GFR) had tiny sclerosing areas at caput MCP IV and the thumb. MRI of left knee and proximal tibia was performed in 6 patients, clearly visible textural changes as patchy areas of low signal intensity were found in one patient. Two patients had salivary stones in the parotid gland, found in a routine x-ray of the jaw before orthodontic treatment.

Conclusions: Although this is currently only data of a small cohort, systemic oxalate deposition may also occur in PH3. Of course, data in more patients are needed to elucidate the true risk of systemic oxalate deposition and we therefore recommend to screen all known PH3 patients.

PO1998

Temporal Relationship of Transplant, Dialysis, and Medications for Children with Primary Hyperoxaluria

Gregory E. Tasian,[1] Kimberley Dickinson,[4] Hanieh Razzaghi,[4] Levon H. Utidjian,[4] John Karafilidis,[3] Lisa Mucha,[3] Christopher B. Forrest,[4] Christina B. Ching.[2] *[1]Children's Hospital of Philadelphia Division of Urology, Philadelphia, PA; [2]Nationwide Children's Hospital, Columbus, OH; [3]Dicerna Pharmaceuticals Inc, Cambridge, MA; [4]Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Primary hyperoxaluria (PH), a rare inborn error of metabolism resulting in hepatic overproduction of oxalate, causes kidney stones and, for some, end-stage renal disease and systemic oxalosis. Our objective was to determine the timing of dialysis, renal transplant, and use of medications to treat PH manifestations in children relative to their diagnosis.

Methods: A retrospective cohort study was conducted in PEDSnet, a clinical research network of 7 US pediatric health systems. Data from PEDSnet were queried to identify patients <18 years old with a diagnostic code for or related to PH between 2009 – 2020. Outcomes queried were renal transplant, initiation of dialysis, first prescription for medications used to treat end-organ manifestations of PH, and specialty care visits. Outcomes were evaluated relative to cohort entrance date (CED), defined as date of first PH-related diagnostic code.

Results: 341 patients were identified. Median age at CED was 9.4 years (IQR 5.0, 13.0). Median follow-up was 2.9 years (IQR 1.1, 6.0). Median eGFR was 117.33 ml/min (IQR 95.75, 139.79). Most patients with renal transplant were transplanted prior to CED. Similarly, dialysis (n=14) was initiated in the majority before CED and at a younger age than those starting dialysis after CED. Prescription drug therapy before CED was high (29% patients with B6 use; Table). Nephrology was the specialty most commonly responsible for initial PH diagnosis (69% on CED).

Conclusions: In one of the largest cohorts of children in the US with PH, dialysis and renal transplant occurred before diagnosis, suggesting significant morbidity when diagnosis is delayed. Medications for the organs affected by PH were consistently prescribed before diagnosis, suggesting an opportunity for earlier PH identification to enable tailored therapy to potentially delay or prevent need for dialysis and transplant.

Funding: Commercial Support - Dicerna Pharmaceuticals

	Patients (n=341)	Number Pre-CED	Number On or After CED
Medications (*Denotes results where PEDsnet governance prevents reporting numbers <11 to maintain patient privacy)			
Pyridoxine (Vitamin B6)	58 (17%)	17	41
Citrate	146 (43%)	71	75
Thiazides	79 (23%)	38	41
Erythrocyte-stimulating agents	15 (4%)	<11*	<11*
Age in years at first dialysis, median (IQR)	2.31 [0.71, 5.92]	1.15 [0.54, 4.92]	17.45 [11.25, 20.36]

PO1999

Oxalate and Glycolate in Urine and Plasma Related to Kidney Function, Dialysis, or Transplantation in Patients with Primary Hyperoxaluria Type 1

Bernd Hoppe,[1,2] Julia Pick,[3] Cristina Martin Higueras.[1] *[1]German Hyperoxaluria Center, Bonn, Germany; [2]University Hospital Bonn, Center for Rare diseases, Bonn, Germany; [3]Zentrum fur Kinderheilkunde der Universitat Bonn, Bonn, Germany.*

Background: Primary hyperoxaluria type 1 (PH1) is characterized by endogenous oxalate overproduction in the liver, extremely elevated urinary oxalate excretion (Uox), thus recurrent urolithiasis and/or progressive nephrocalcinosis and chronic kidney disease (CKD). It also leads to early renal failure, especially problematic in the young patient (infantile oxalosis). Uox and glycolate (Uglyc) and plasma oxalate (Pox) and glycolate (Pglyc) are used as biochemical markers for diagnosis, treatment and follow up, but also as primary endpoints in studies.

Methods: We retrospectively analyzed these parameters in urine and plasma of 87 genetically confirmed PH1 patients over the last 15 years. All parameters were analyzed by ion-chromatography/mass spectrometry and in the same lab. Correlation and comparative analyses were performed within groups of different renal function (normal,

CKD 1-5; n=48 patients), hemodialysis (HD; n=31), transplantation (Tx; n=32) and related to vitamin B6 medication.

Results: From normal kidney function to CKD3-4 Pox remained stable (median Pox 17 μmol/l), while Pglyc was more markedly elevated (median 90.12 μmol/l). Both were significantly higher in non-B6 versus B6 sensitive patients. Pox and Pglyc did not correlate with kidney function, except for Pox and CKD5. Highest Pox and Pglyc was found in HD (91 and 211 μmol/l, respectively), not related to B6. Uox and Uglyc remained stable at all CKD stages in B6 sensitive, but increased progressively in B6 unsensitive patients. Pox and Uox slowly declined post combined and sequential liver-kidney, but also in isolated kidney Tx, which was performed in adult B6-sensitive patients. In the contrary, PGlyc remained elevated post Tx.

Conclusions: Our findings are in many ways contradictory to previously published observations. Pox or Uox did not correlate to GFR. Pox was surprisingly low until HD and Uox increased until CKD3-4 in non-B6 sensitive patients. PGlyc remained elevated even years after transplantation, but no data are available to compare. Glycolate is widely accepted to be harmless, even at elevated values, but a fundamental proof is missing. So, consequences of this need further investigation.

PO2000

Compassionate Use Treatment with RNAi Medication (Nedosiran) in Two Patients with Primary Hyperoxaluria Type 1 and Maintenance Hemodialysis

Bernd Hoppe,[1] Gesa Schalk,[2] Cristina Martin Higueras.[1] *[1]German Hyperoxaluria Center, Bonn, Germany; [2]Kindernierenzentrum, Bonn, Germany*.

Introduction: The primary hyperoxalurias (PH) are three ultra-rare, autosomal recessive genetic disorders characterized by oxalate overproduction in the liver. Hyperoxaluria induces recurrent kidney stones, nephrocalcinosis, progressive renal impairment, and systemic oxalosis, especially in PH1. Nedosiran is an investigational RNA interference (RNAi) therapeutic administered monthly by subcutaneous injection. It reduces hepatic LDHA protein thereby inhibiting the final step responsible of oxalate production in all types of PH.

Case Description: We report on two PH1 patients, a 40 year old woman (a) on hemodialysis (HD) 6 x 3 hours weekly, and a 6.5 year old boy (b) receiving 5 x 5 hours HD, both homozygous for *AGXT* c.508G>A and treated with pyridoxine. In patient (a), global longitudinal strain (GLS), an index of left ventricular contractibility, was impaired (-13%; normal ≤-18%). Patient (b), has massive oxalate osteopathy, myocardial hypertrophy and cardiac insufficiency (GLS of – 9.98). They received Nedosiran as compassionate use medication for now 6 months. Monthly plasma oxalate (Pox in μmol/l, normal <7.4) was measured, Speckle Echo and/or 3 Tesla bone MRI (left knee) were repeated. Speckle echo improved significantly in both (a: GLS – 23%; b: GLS -16.5%). Bone MRI ameliorated in patient (b) showing a nidus of normal trabecular structure.

Discussion: Clinics improved and Pox declined over the six months of treatment. Pox was influenced in (b) by severe oxalate osteopathy and therefore possibly dissolving oxalate and in (a) when dialysis regimen was reduced to 4 x 3 hours at month 6. We cautiously conclude, that Nedosiran treatment reduces plasma oxalate levels in a way, that liver transplantation may be avoidable in PH1 patients.

Follow up under Nedosiran administration

Patient	Pox Pre RNAi	Pox Month 1	Pox Month 2	Pox Month 3	Pox Month 4	Pox Month 5	Pox Month 6
(a)	64.2-71.6	40.9	60.2	52.8	37.7	23.2	32.4
(b)	73.1-101	96.5	40.6	56.9	48.1	69.7	51.3

PO2001

Functional Analysis of Novel CNNM2 Mutation in Autosomal Dominant Hypomagnesemia with Seizure

Min-hua Tseng. *Chang Gung Medical Foundation, Taoyuan, Taiwan*.

Background: *CNNM2* has been identified to be the responsible gene for patients with hypomagnesemia, seizure, intellectual disability (HSMR) syndrome. The functional impact of mutations in *CNNM2* remains unknown.

Methods: We have identified 1-year-old infant with HSMR featuring severe hypomagnesemia with renal magnesium (Mg^{++}) wasting requiring higher dose of Mg^{++} supplementation. Whole exome sequencing (WES) with direct Sanger sequence was performed to identify the responsible gene. The functional assay of this identified mutants was examined in vitro studies.

Results: With WES, we identified a *de novo* heterozygous mutation c.G1439T (R480L) in CBS domain of *CNNM2* gene without any other gene mutations related to hypomagnesemia. This missense *CNNM2 P480L* mutation was conserved in different species and very pathogenic based on the different software prediction models. This R480L mutation impaired the interaction between CNNM2 and ATP-Mg^{2+} by simulation model. In vitro studies, This CNNM2-R480L protein expression was higher than CNNM2-wild type. Immunocytochemistry images demonstrated the proper localization of CNNM2-R480L and CNNM2-wild type. Mg^{2+} efflux assay revealed significant increase of intracellular Mg^{2+} Green in CNNM2-R480L than CNNM2-WT, indicative of CNNM2-R480L mutation blocking Mg^{2+} efflux.

Conclusions: This novel R480L mutation in CBS domain of *CNNM2* gene diminishes the Mg^{2+} efflux probably through the impaired binding between Mg^{2+}-ATP and CNNM2, accounting for refractory hypomagnesemia.

PO2002

Long-Term Outcome of Bartter Syndrome

Naye Choi,[1,6] Ji hyun Kim,[2] Seong heon Kim,[1] Eun Hui Bae,[3] Joo Hoon Lee,[4] Il-Soo Ha,[6] Yo Han Ahn,[1,6] Hyesun Hyun,[5] Hee Gyung Kang.[1,6] *[1]Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [3]Chonnam National University Hospital, Gwangju, Gwangju, Republic of Korea; [4]Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; [5]Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea*.

Background: Bartter syndrome (BS) is a rare salt-wasting tubulopathy caused by mutations in genes encoding sodium, potassium, or chloride transporters of the thick ascending limb of Henle and/or the distal convoluted tubule of the kidney. BS is characterized by polyuria, failure to thrive, hypokalemia, metabolic alkalosis, hyperreninemia and hyperaldosteronism. Previously, potassium and/or sodium supplements, potassium sparing diuretics and NSAIDS were known as possible treatment options for BS. While presenting symptoms and initial managements of BS are relatively well known, long-term outcomes and treatments are still unclear.

Methods: Through a survey for the members of Genetic Kidney Disease Working Group of the Korean Society of Nephrology, clinically and/or genetically diagnosed 54 Korean BS patients were recruited. We retrospectively reviewed their medical records between 1992-2020 for presenting symptom, laboratory findings, genotype, medication, and their final height and renal function.

Results: There were clinically and/or genetically diagnosed with BS at median age of 5 months old (range 0-271) and their median follow up was 8 years (range 0.5-27). Genetic diagnosis of BS was made in 40 patients; 4 patients with *SLC12A1* gene mutations, 2 patients with *KCNJ1* gene mutations, 33 patients with *CLCNKB* gene mutations, and 1 patient with *BSND* mutation were revealed, respectively. Potassium chloride supplements was administered in 94% of patients and potassium sparing diuretics were administered in 68% of patients. Average dosage of potassium supplementation was equivalent to 4.30 mEq/day/kg (body weight). At the last follow-up of 8 years after the initial diagnosis, 41% had short stature (height less than 3rd percentile) and CKD was observed in six patients (CKD stage 3 in four and stage 5 in two patients).

Conclusions: In conclusion, BS patients need huge amount of potassium supplementation along with potassium sparing agent throughout their lives. Despite of management, growth impairment was observed in significant portion of this population, while CKD was found in 11%.

PO2003

Walking in Patients' Shoes: Novel Approach to Increase Staff Empathy Through Adherence to Dietary Restrictions

Randa Razzouk, Mary Cazzell, Amanda Marroquin, Barrett Brown. *Cook Children's Medical Center, Fort Worth, TX.*

Background: Dietary recommendations for children with end-stage renal disease (ESRD) on dialysis include restrictions in potassium, phosphorus, and sodium. Children must take phosphate binders with meals and snacks. Renal diet compliance can be challenged by adherence difficulties. Patient perceptions of health care professionals' (HCPs) levels of empathy play an important role in improved patient satisfaction. Higher perceived empathy levels lead to improved patient compliance to treatment, diet, and overall positive health. The purpose of this study was to explore the impact of a novel intervention (adherence to a two-week renal diet) on levels of empathy among HCPs directly caring for children with ESRD on dialysis.

Methods: A quasi-experimental comparative interventional study design was utilized with a convenience sample of 37 HCPs who directly cared for children with ESRD on dialysis Through self-assignment, 14 HCPs completed a renal diet education class (control group); 23 completed the class and two-week renal diet and "phosphate binders" intake with logs (experimental group). Pre- and post-intervention levels of empathy were measured using the Jefferson Scale of Empathy. Renal diet logs were reviewed to calculate percentages of two-week compliance and "phosphate binder" use.

Results: Baseline empathy scores for each group were matched (p=0.825). Within the experimental group, post-intervention results showed statistically significant increases in empathy levels after adherence to a two-week renal diet (p=0.004). No significant differences in control group pre- and post-empathy levels were noted. Percentages of compliance to a two-week renal diet were 82% and to "phosphate binders," 83%.

Conclusions: Levels of empathy increased when HCPs followed a two-week renal diet, discovering similar patient adherence issues. HCPs reported less-than-perfect renal diet compliance and use of "phosphate binders." This study can be implemented in various pediatric settings, such as specialty areas treating patients on therapeutic dietary restrictions (e.g. diabetes, celiac disease, epilepsy).

Results from experimental group

Renal Diet Log Items	Renal Diet Class + 2- Week Renal Diet Trial (n=23)
Percentage of Compliance to Renal Diet	Mean(SD): 81.6 (11.39)% Median: 80.5% Range: 64-100%
Percentage of Compliance with Phosphate Binders	Mean(SD):82.75 (15.63)% Median: 86.5% Range: 37-100%
Percentage of Diet Log Record Keeping (out of 14 days)	Mean(SD): 93.25 (20.93)% Median: 100% Range: 7-100%

PO2004

Outcome of a 30-Month Screening, Education, and Treatment Program of Lower Urinary Tract (Dys)Function in Pediatric Kidney Recipients

Liesbeth L. de Wall, Femke Glaap-Roeven, Charlotte M. Bootsma-Robroeks. *Radboudumc, Nijmegen, Netherlands.*

Background: Graft survival of pediatric kidney recipients increased dramatically over the past decades. Lower urinary tract disfunction (LUTD), as one of the factors that might contribute to graft function and survival, is seen in the majority of all recipients despite cause of kidney failure. This study presents the 30 months outcomes of a screening and early intervention program of all pediatric kidney recipients.

Methods: Since June 2018 all pediatric renal recipients underwent an active screening and education for LUTD pre-and post-transplant by our nurse specialist. Personalized education was given to all and urotherapy in case of LUTD. Those without LUTD, received yearly re-evaluation.

Results: A total of 56 recipients are screened thus far, aged 11.8±4.4yrs. Mean±SD time after transplant was 4.4±3.9yrs. After initial screening, LUTD was present in 71% of the patients (Table 1). Maximal bladder capacity exceeded in 59%, abnormal uroflowmetry was present in 58%, and residual voiding was present in 37% of the children. Longitudinal data showed that 16% remained dysfunctional despite urotherapy. In addition, 60% switched between a functional and dysfunctional pattern. Overall, after 30 months, 48% of the children with LUTD developed a persistent functional voiding pattern. Recipients with LUTD significantly needed more health care activities (2-6 times more compared to patients without LUTD). By consequence economic burden rises with €6000,- per patient each year.

Conclusions: LUTD is present in the majority of pediatric kidney recipients, regardless of the cause of kidney failure. Due to LUTD, patients need more health care. Resulting in a significant economic and psycho-social burden. This pro-active screening, treatment and education uro-transplant program was effective in 48% of the children with LUTD in the long term. A longer follow-up time is needed in order to analyze the impact on graft survival and cost-effectiveness.

Funding: Government Support - Non-U.S.

CAUSE OF KIDNEY FAILURE	NEPHROLOGICAL (N = 41)	UROLOGICAL (N = 15)	TOTAL (N = 56)	P-VALUE
Any type of voiding complaint	12%	33%	18%	0.08
Urinary incontinence—daytime	10%	20%	13%	0.31
Urinary incontinence—night-time	32%	20%	29%	0.27
Abnormal sensation of bladder filling	22%	40%	27%	0.18
Toilet behaviour (present > 50%)				
Holding manoeuvres	7%	6%	7%	0.93
Procrastination	46%	40%	45%	0.67
Sensation of incomplete emptying	2%	-	2%	0.54
Sent for voiding	34%	47%	38%	0.39
Rushed voiding	51%	60%	54%	0.56

Machine Learning Can Predict the Individual Risk of Acute Pyelonephritis in Children

Olivier Niel, Pierre François, Claire Sommelette, Michel Kohnen, Chantal Tsobo, Isabel De La Fuente, Armand Biver. *Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg.*

Background: Acute pyelonephritis (AP) is a common infection in children. Timely diagnosis of pediatric AP is necessary, since under-diagnosed AP increase infectious morbidity, whereas over-treatment of AP is responsible for an increase in antibiotic resistance and health costs. However, confirmed AP diagnosis requires validated urine cultures, which can take up to 3 days. Here we propose to use machine learning algorithms to predict the risk of AP in febrile children, using simple parameters available within the first hours of medical care.

Methods: We performed a retrospective study of medical and laboratory files of 102 pediatric patients with a suspected diagnosis of AP, treated between 2014 and 2020 at the pediatric National Reference Hospital of Luxembourg. Based on the results of urine cultures, patients were allocated to the AP or non-AP group. All patients were then randomly split into training and testing batches, used by a Random Forest machine learning algorithm to predict the individual risk of AP, using clinical (age, sex), blood (CRP, white blood cell and neutrophil counts) and urine (red and white blood cell counts) parameters.

Results: Patients' demographic and clinical characteristics were comparable between groups. In particular, sex ratios were not significantly different between AP and non-AP patients (0.86 versus 0.74). Random Forest algorithm mean performance metrics were: accuracy 90.48% [85-99%], sensitivity 91.67% [90-95%], specificity 88.89% [80-90%]. Given a prevalence of AP of 60%, positive predictive value was 92.52% [88-95%], negative predictive value 87.67% [82-89%]; mean AUC-ROC was 0.92. Predictions performed with a neural network or a support vector machine algorithm on the same population obtained comparable performance metrics.

Conclusions: Timely diagnosis of pediatric AP is necessary to minimize infectious morbidity, antibiotic resistance and health costs; however, it requires validated urine cultures, which can take several days. Here we showed that machine learning algorithms can accurately predict the individual risk of AP in pediatric patients within the first hours of medical care, helping pediatricians in daily clinical decision making.

PO2006

Associations Between Clean Intermittent Catheterization, Quality of Life, and Emotional-Behavioral Functioning in Children with CKD

Rebecca J. Johnson,[1,2] Lyndsay Harshman,[3] Matthew Matheson,[4] Amy Kogon,[5] Marc Lande,[6] Susan L. Furth,[5] Bradley A. Warady,[1] Stephen R. Hooper.[7] *[1]Children's Mercy Kansas City, Kansas City, MO; [2]University of Missouri Kansas City School of Medicine, Kansas City, MO; [3]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [4]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Rochester Medical Center, Rochester, NY; [7]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: Need for clean intermittent catheterization (CIC) can affect quality of life (QOL) and emotional functioning in pediatric populations, with some evidence that urethral catheterization is associated with poorer emotional adaptation than use of Mitrofanoff. Little is known about the impact of CIC on QOL and emotional functioning for children with chronic kidney disease (CKD).

Methods: Data from the CKiD study were used to evaluate QOL, emotions/behavior, and CIC in children age 6+ years with mild to moderate CKD (non-glomerular disease). We hypothesized that CIC would be associated with poorer QOL and more internalizing and behavioral symptoms (using ratings from BASC2, PedsQL), and that urethral CIC (versus Mitrofanoff) would predict worse outcomes. Linear mixed models adjusted for sociodemographic and disease-related covariates were used and included predictors for CIC use (vs non-users) as well as for urethral catheterization (vs Mitrofanoff).

Results: The sample included 1484 records (466 CIC non-users, median age 10 years, 66% male, median eGFR 52 ml/min|1.73m^2; 115 CIC users, median age 12 years, 67% male, median eGFR 45, 43% urethral, 48% Mitrofanoff). Median BASC2 scores

were in the average range for both CIC users and non-users. Median PedsQL scores were slightly lower than that of healthy populations for CIC non-users (parent-report 80 [IQR=66,89]; child-report 79 [IQR=70,88]) and even lower for CIC users (parent-report 73 [IQR=59,85]; child-report 76 [IQR=65,85]. CIC predicted higher scores on the BASC2 Internalizing Composite (β=3.33, CI=1.13, 5.54; p=.003), and Behavioral Symptoms Index (β=2.13, CI=0.08, 4.18; p=.04), and lower parent- and child-reported QOL (β=-5.11, CI=-8.46, -1.75; p=.003; β=-3.75, CI=-6.98, -0.52; p=.02). However, urethral CIC predicted lower scores compared to Mitrofanoff on the Internalizing Composite (β=-3.94, CI=-6.65, -1.22; p=.005).

Conclusions: For children with mild to moderate CKD, CIC is associated with poorer QOL and more parent-reported emotional-behavioral symptoms. Urethral CIC (versus Mitrofanoff) is associated with fewer internalizing symptoms. Additional research is needed to determine if other characteristics associated with need for CIC influence emotions and QOL.

PO2007

Pneumococcal Vaccination in High-Risk Pediatric Nephrology Patients

Ashley M. Gefen,[1] Abby M. Basalely,[1] Archana Balamohan,[2] Rachel Frank,[1] Megan Moravec,[1] Jessica Fassano,[1] Sujatha Rajan.[1] *[1]Cohen Children's Medical Center, Queens, NY; [2]Arkansas Children s Hospital, Little Rock, AR.*

Background: Children with nephrotic syndrome (NS), chronic kidney disease (CKD) and immunosuppression (IS) are at high risk of invasive pneumococcal infection but are often under-vaccinated with PCV13 and PPSV23. We aimed to increase vaccination rates in high-risk pediatric nephrology (PN) patients from <10% to 75% by 2022.

Methods: Process measures of vaccine rates (percent of eligible patients monthly that received vaccines) were evaluated over 3 years. Initially, a designated nurse and fellow checked electronic medical records (EMR), Citywide Immunization Registry (CIR) and pediatrician records. PPSV23 was administered in PN clinic. A driver diagram was created to determine sources of improvement and 3 PDSA cycles were completed.

Results: 374 patients (20% up-to-date (UTD), 5% missing PCV13, 32% missing PPSV23, 34% missing both) were identified. Sources of failure to vaccinate with initial interventions were single stakeholder reliance, lack of follow-up and vaccine supply. Primary drivers were patient identification, vaccine administration and rate determination. All physicians and nurses were taught to identify patients, check vaccine history and use a vaccine algorithm. Study of our interventions revealed unanticipated obstacles with monetary cost, vaccine refusal and shared responsibility. To aid monetary issues a new stakeholder (manager) was created. Vaccines were re-offered at subsequent visits if initially refused. Reminders were sent to physicians on the importance of patient identification in clinic. Vaccination increased to >75% and has been sustained for 4 months (Figure 1). Percent UTD increased to 39%.

Conclusions: Incorporating and educating multiple stakeholders and adequate vaccine access improved vaccination rates at our center. Our methods appear successful without excess time expenditure. Further study is underway to ensure sustainability without excess monetary cost.

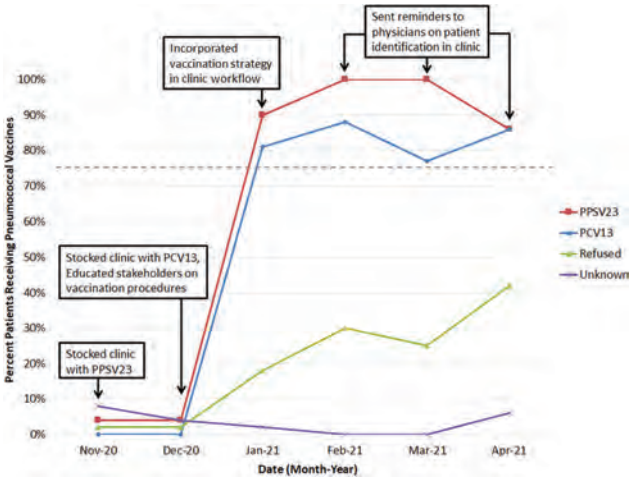

Figure 1: Run chart

PO2008

Psychosis in Adolescence and Young Adulthood with a Kidney Disease Diagnosis in Childhood

Megan Dunleavy,[1,2] Christopher B. McFadden.[1,2] *[1]Rowan University Cooper Medical School, Camden, NJ; [2]Cooper University Health Care, Camden, NJ.*

Background: Advances in medical technology & management continue to improve the lifespan of children with kidney disease; yet, enhanced understanding of this population shows a relative lag. Prior studies examining pediatric kidney disease have repeatedly found neurocognitive deficits in areas of attention, memory, complex cognition, emotion identification and inhibitory control. Such deficits, when considered alongside nervous system injuries resulting from toxin retention and electrolyte aberrations, warrant further investigation. This study seeks to explore for any association among experiences of acute psychosis in adolescence and young adulthood (AYA) and defined history of childhood kidney disease.

Methods: To explore this, a retrospective cohort study using electronic medical records (EMR) was conducted. EMR queries were run to identify & categorize study samples into two groups: ICD-coding defined kidney disease vs healthy peer control. Patient data ranging from July 01, 2012, to February 13, 2021, was then queried for episodes of psychosis in both arms.

Results: Results identified 1192 patients as qualifying for study inclusion. Twenty-one (Prevalence= 1.76%; OR= 0.018) patients qualified for inclusion in the kidney disease group. 1171 (Prevalence= 98.24%; OR= 55.76) patients qualified for inclusion in the control group. Data analysis uncovered ten of 1192 (Prevalence= 0.84%; OR= 0.008) cases experienced acute psychosis throughout AYA. One of these ten cases occurred in CKD sample, representing a 4.76% prevalence (OR= 0.05). The remaining nine cases of AYA psychosis occurred in the control sample, representing a prevalence of 0.77% (OR= 0.008).

Conclusions: Preliminary data demonstrate, those with kidney disease had an increased likelihood of 6.46 (CI= 0.78-54.05) times that seen in control sample for development of acute psychosis in AYA. While unable to rule out the observed effect being due to random chance, acknowledgement of the attributions made by restricted data quantities are held. This pilot study, highlights a novel association deserving of further investigation in a large-scale, multicenter format. Establishing a significant association among childhood kidney disease and psychosis in AYA, would therefore prompt initiation of early education efforts aimed to persuade patient self-awareness, and ignite help-seeking mindsets prior to symptom onset.

PO2009

Pediatric Nephrologists' Perspectives on Palliative Care: A National Survey Study

Taylor R. House,[1,2] Aaron G. Wightman,[1,2] Jodi M. Smith,[1,2] Abby R. Rosenberg.[1,2] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Hospital, Seattle, WA.*

Background: Integration of palliative care (PC) within nephrology practice offers the chance to lessen the burdens experienced by children with chronic kidney disease (CKD) and their families. Yet, little is known about pediatric nephrologists' attitudes regarding engaging in and seeking PC services for children with CKD. We sought to ascertain pediatric nephrologists' perspectives in routine integration of PC for children with CKD.

Methods: A cross-sectional web-based survey was administered to pediatric nephrologists associated with the American Society of Pediatric Nephrology listserv. Three invitations were sent from May 3, 2021 to May 28, 2021. The survey was adapted from a previously validated instrument and pretested by stakeholders; studied areas included institutional and personal experience with PC, training and education, and physician confidence. Data were summarized descriptively.

Results: There were 64 participants (17.7% response rate). Most participants were female (62.5%), Caucasian (64.1%), and practice in urban (76.4%), academic centers (89.1%) with access to subspecialty PC teams (93.8%). Perceived institutional barriers to subspecialty PC consultations were low, and prior consultations were found to be helpful. However, nephrologists expressed concern that consultation may imply to parents that the team is "giving up" on their child. Though 63.6% indicated that consultation should happen at diagnosis for life threatening conditions where cure is feasible but may fail, 59.6% of nephrologists reported that PC is rarely or never consulted for ESKD patients at their center. Confidence in engaging in challenging communication was high, yet only 26.4% and 30.2% of participants, respectively, were comfortable managing pain or psychological distress of children with CKD.

Conclusions: Pediatric nephrologists are receptive to PC consultations for children with CKD, but utilization is low. Parental perception of the implications of consultation are of concern. Among primary PC skills, challenging communication is seen as a strength of pediatric nephrologists, but confidence is low in managing some physical and psychological symptoms. Routine integration of PC will require efforts to assess patient and family impressions of PC and shift that of providers, as well as targeted education to increase skills.

Palliative Care Training in Pediatric Nephrology Fellowship: A Cross-Sectional Survey

Taylor R. House,[1,2] Aaron G. Wightman,[1,2] Jodi M. Smith,[1,2] Abby R. Rosenberg.[1,2] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Hospital, Seattle, WA.*

Background: The integration of primary palliative care (PC) in pediatric nephrology provides an opportunity to address the burdens faced by children with chronic kidney disease (CKD) and their families. Incorporation of PC education in training programs is recommended, but adult nephrology fellows report inadequate preparation to engage in primary PC. Similar experience of pediatric nephrology fellows is unknown. We sought to describe pediatric nephrology fellows' knowledge and confidence in providing primary PC and PC education received during training.

Methods: A cross-sectional web-based survey was administered to pediatric nephrology fellows associated with the American Society of Pediatric Nephrology listserv. Three invitations were sent from May 3, 2021 to May 28, 2021. The survey was adapted from a previously validated instrument and pretested by stakeholders; studied areas related to PC included institutional and personal experience, training and education, and physician confidence. Data were summarized descriptively.

Results: Response rate was 28.7% (29/101). Most respondents were female (79.3%), Caucasian (48.3%), and practiced in an urban setting (85.2%). Only 1 fellow participated in a PC rotation during fellowship, and 46.4% of respondents completed a rotation in medical school or residency. On a scale of 1-5, with 1 being 'no knowledge' and 5 being 'extensive knowledge' of PC principles, fellows reported a mean knowledge of 2.33 ± 1.04. A single fellow had performed over 10 family meetings to elicit goals of care compared to 64.3% of fellows who had performed over 10 kidney biopsies. A quarter of fellows had never led such a meeting. Confidence in ability to discuss goals of care or address psychological distress in a child with CKD or parent were low, with only 30.8% and 26.9%, respectively, feeling moderately or very confident in their ability. Many fellows (44%) felt low confidence in managing pain in a child with CKD. A desire for additional training was prevalent, with 96.2% of fellows indicating that this training should happen during fellowship.

Conclusions: Few pediatric nephrology fellows receive PC education and experiences during training, resulting in low rates of knowledge and confidence across care domains. Fellows indicate a need and desire for improved PC training.

PO2011

Correlation Between Kidney Sodium and Potassium Handling and the Renin-Angiotensin-Aldosterone System in Children with Hypertension

Ella C. Perrin, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Urine sodium and potassium concentrations are used as surrogate markers for dietary sodium and potassium consumption in adults with hypertension, but their association with components of the renin-angiotensin-aldosterone system (RAAS) is incompletely characterized. Some individuals with hypertension may have an abnormal RAAS response to dietary sodium and potassium intake, though this is incompletely described. Our objective was to investigate if plasma renin activity and serum aldosterone are associated with urine sodium and potassium in youth with hypertensive disorders.

Methods: This pilot study was a cross-sectional analysis of baseline data from 44 youth being evaluated for hypertensive disorders in a Hypertension Clinic. We recorded urine sodium and potassium normalized to urine creatinine, plasma renin activity, and serum aldosterone values and calculated the sodium/potassium (UNaK) and aldosterone/renin ratios. We used multivariable generalized linear models to estimate the associations of renin and aldosterone with urine sodium and potassium.

Results: Our cohort was diverse (37% non-Hispanic Black, 14% Hispanic), 66% were male, and median age was 15.3 years; 9% had a secondary etiology and 77% had obesity. Aldosterone was associated inversely with urine sodium/creatinine (β: -0.34, 95% CI -0.62 to -0.06) and UNaK (β: -0.09, 95% CI -0.16 to -0.03), adjusted for estimated glomerular filtration rate and serum potassium.

Conclusions: Higher serum aldosterone levels, but not plasma renin activity, were associated with lower urine sodium and UNaK at baseline in youth referred for hypertensive disorders. Further characterization of the RAAS could help define hypertension phenotypes and guide treatment.

Funding: NIDDK Support, Other NIH Support - National Heart, Lung, and Blood Institute; National Center for Advancing Translational Sciences

PO2012

Aldosterone Producing Adenoma in an Adolescent Black Female

Kristie R. Searcy,[1] Celso E. Gomez-Sanchez,[2] Rohit Ranganath,[1] Radhakrishna Baliga.[1] *[1]LSU Health Shreveport, Shreveport, LA; [2]The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Aldosterone-producing adenoma (APA) is a rare clinical entity in the pediatric population resulting in severe hypertension and/or hypokalemia. Limited number of cases have been reported with somatic KCNJ5 mutation being described in only one case. We have shown that in APAs somatic CACNA1D mutations are more prevalent in the male black patients unlike KCNJ5 which is considered the most frequently mutated gene in black females.

Case Description: A 16-year-old black female was noted to be hypertensive while being evaluated for depression. She was referred to us a year later for recurrent headaches, chronic drug resistant hypertension and persistent hypokalemia. Family history was positive for a maternal uncle with hypertension. On examination, her wt was 98 kg [>99%], ht 178 cms [94%], heart rate 88 per minute and blood pressure 155/94 mmHg [>95%]. Pertinent labs: serum sodium 142, potassium 2.8, chloride 106, and CO2 content 26 mEq/L. Serum creatinine was 0.80, and BUN 10 mg/dL. Plasma aldosterone concentration (PAC) was 27.2 ng/dL and plasma renin activity (PRA) <0.6 ng/mL/h with PAC/PRA ratio of 45 [significant > 20]. Cortisol level was 8.7 [N 1.7-14.1] µg/dl. Timed urine aldosterone for estimated urine creatinine of 1980 mg was 20 µg/d [N <15.6]. Cardiac echocardiogram showed compaction cardiomyopathy. CT abdomen indicated a right adrenal nodule suggesting an adenoma. Robotic right adrenalectomy was performed and pathology was consistent with APA. Blood and right adrenal tissue was sent for germline and somatic mutations. Post-operatively PAC was <3.0 ng/dL. Her headaches resolved, her blood pressure significantly improved to 124/69 mmHg [<90%] with normalization of her serum potassium. One month after right adrenalectomy her blood pressure continues to be well controlled on two antihypertensive medications and her serum potassium levels remain normal.

Discussion: Unilateral APA should be considered in any child who presents with drug resistant hypertension and/or hypokalemia as early diagnosis and prompt adrenalectomy would prevent significant cardiovascular sequelae. The identification of somatic and germline mutations will provide further insight into the mechanisms of APA and assist in tailoring appropriate therapy especially in blacks who have high cardiovascular disease morbidity and mortality.

PO2013

Rare Case of Atypical Hemolytic Uremic Syndrome in a Child

Miranda J. Floen,[1,2] Arwa Nada.[1,2] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]LeBonheur Children's Hospital, Memphis, TN.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is rare with an incidence of 0.26-0.75 cases/million/year for individuals less than 20 years of age. Little is known about the time course of the disease and its clinical episodes. Individuals typically harbor genetic mutations and/or complement autoantibodies.

Case Description: A 7 year-old male presented with 2 weeks history of fatigue, pallor, and emesis. laboratory findings were consistent with HUS; serum creatinine 1.35 mg/dL, hemoglobin 7.5 g/dL, and platelets 86 thou/mcL. Schistocytes were identified on peripheral smear. Stool culture was negative for O157 STEC. Stool PCR was positive for Shigella/Enteroinvasive E. coli. STEC-HUS was diagnosed. Patient was hemodialysis dependent. Given severity of his course and persistent evidence of hemolysis and thrombocytopenia at 5 weeks, Eculizumab was initiated with improvement of hematological parameters. laboratory workup was done at the same time and came back positive for homozygous deletion of CFHR3-CFHR1 and complement factor H (CFH) autoantibodies (2140 AU). Eculizumab was continued for 8 doses with additional 2 doses of Rituximab followed by Mycophenolate Mofetil (MMF) before transition to Ravulizumab which was discontinued after 7 doses. He remained on MMF with no evidence of relapse. He has continued to be off dialysis 11 months after cessation of Ravulizumab at CKD stage III.

Discussion: To our Knowledge, this is the first published pediatric case with CFH-autoantibodies that achieved partial kidney recovery after prolonged dialysis dependent course. aHUS should be considered in children with severe and prolonged course of HUS even if laboratory results are suggestive of STEC-HUS. Aggressive therapy should be considered even if patients are dialysis dependent as this may reverse the course of the disease. There is limited published data on the course and effect of complement blockade therapy (Eculizumab or Ravulizumab) and immunosuppression (Rituximab and MMF) on the course of aHUS due to CFH-autoantibodies. There are variable reports on the efficacy of other therapies, like plasmapheresis, on the course of this specific aHUS entity. Our case highlights the importance of considering these therapies in this population even after prolonged dialysis as this may alter the course of the disease and help kidney recovery.

PO2014

Prenatal Nephrology Consultations and Neonatal Dialysis Survey

Keia Sanderson,[1] Vivian Shih,[2] Bradley A. Warady,[3] Donna J. Claes.[4] *[1]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Children's Mercy Hospitals and Clinics, Kansas City, MO; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Little is known about pediatric nephrology (PN) prenatal consultations for congenital anomalies of the kidney & urinary tract (CAKUT) or possible initiation of kidney replacement therapy (KRT) in neonatal end stage kidney disease (N-ESKD).

The aims were to evaluate PN practice patterns for prenatal counseling of fetal CAKUT & to describe criteria used by PN to offer KRT in N-ESKD.

Methods: A 35 question Qualtrics® survey was distributed via the North American Pediatric Renal Trials and Collaborative Studies email list between 1/1/2021-3/31/2021.

Results: 39 of 108(36%) participating pediatric sites in the US & Canada responded. Median number of faculty (MDs, APPs, APRNS) per center was 7. Median chronic hemodialysis (HD) and peritoneal dialysis (PD) patients per center were 8 & 8, respectively. 38(97%) centers provide prenatal consultation for fetal CAKUT and KRT for N-ESKD. Of those 38 centers, 71% report only a select number of non-trainee workforce members (median 2 per center) participate in prenatal consults. 47% of centers have either written/unwritten criteria for offering KRT in N-ESKD. The most common contraindications to KRT was parental refusal(61%;Table 1). The most common birth weight contraindication was <1500g(52%). 82% of centers reported <5 neonates with ESKD were started on KRT within the past year. 58% of centers use HD therapies as a bridge to PD in N-ESKD(Figure 1); 100% of centers report PD as the primary modality at discharge.

Conclusions: Many PN programs provide prenatal consultations for CAKUT diagnoses by a select group of non-trainee workforce members. Only 50% of centers use written/unwritten criteria for decisions about KRT initiation in N-ESKD. Further multi-center research regarding prenatal consultations and neonatal KRT outcomes is necessary to provide greater evidence based practice.

Table 1: Reported contraindications to dialysis initiation in neonates with ESKD amongst surveyed PN centers (n=38 centers)

Contraindications reported in > 50% of surveyed centers	Contraindications reported in 10-50% of surveyed centers	Contraindications reported in < 10% of surveyed centers
-Parent/Guardian choosing not to pursue dialysis (n=23; 61%) -Born below a minimum birth weight (n=21; 55%) -Surgeon indicates contraindication for dialysis access placement (n=21; 55%)	-Severe pulmonary disorder/respiratory disease (n=15; 39%) -Severe/life threatening genetic abnormality (n=13; 34%) -Severe neurologic impairment (n=7; 18%) -Refractory hypotension (n=7; 18%) -Severe/life threatening cardiac abnormality (n=7; 18%)	-Severe/life threatening liver abnormality (n=3; 8%) -Other severe/life threatening abnormality not already listed (n=3; 8%) -Other contraindication (n=3; 8%) -Below a minimum gestational age (n=2; 5%) -Disagreement between Nephrology and other services regarding the decision to initiate dialysis (n=1; 3%)

Figure 1: Reported use of hemodialysis/CKRT/PIRRT/modified Aquapheresis as a bridge to PD initiation in the neonate with ESKD (n=38 centers)

Postnatal Maturation of Glomerular Filtration Rate in Term Born Neonates: An Individual Patient Data Meta-Analysis

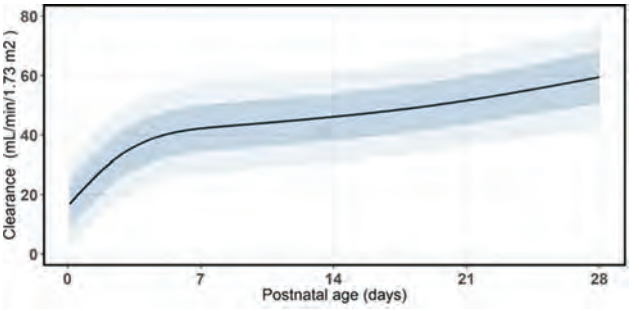
Nori Smeets,[1,2] Joanna IntHout,[1] Maurice J. van der Burgh,[1] George J. Schwartz,[3] Michiel F. Schreuder,[1] Saskia de Wildt.[1,2] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands; [3]University of Rochester, Rochester, NY.*

Background: The evidence from individual studies to support the maturational pattern of measured glomerular filtration rate (GFR) in healthy term born neonates is inconclusive. This hampers the delineation between normal and abnormal kidney development as well as the diagnosis of acute kidney injury (AKI). Thus, we aimed to describe GFR maturation in the first month of life using an individual patient data meta-analysis (IPDMA) of measured GFR data.

Methods: The Pubmed and ClinicalTrials.gov databases were searched to identify studies reporting mGFR as measured by exogenous markers or creatinine clearance (CrCL) in healthy term born neonates. Articles were subsequently reviewed by two individual researchers. The relationship between postnatal age and individual clearance values was investigated using restricted cubic splines with generalized additive linear mixed models on individual data, taking into account clustering by study. Data from aggregated studies were used for sensitivity analyses.

Results: 1521 articles were screened and 50 relevant studies reported mGFR in healthy term born neonates. In total, 1055 measured GFR values from 958 neonates were included. Individual patient data (IPD) were available for 371 neonates and 587 neonates were represented by 46 aggregated datapoints as means/medians per cohort. Mean GFR increases rapidly in the first five days after birth from 16.8 (95% CI 11.2-22.5) ml/min/1.73m^2 at the first day to 39.8 at day 5 (95% CI 35.8-43.7), followed by a more gradual increase to 59.4 (95% CI 45.9-72.9) ml/min/1.73m^2 at end of the fourth week.

Conclusions: These normative values show a clear developmental pattern of GFR maturation in the first weeks of life and indicate a biphasic increase with the largest increase until day 5. Our IPDMA data can therefore serve as a useful baseline for neonatal GFR.



The development of GFR in the first month of life in term born neonates. Black line represents p50, darker blue area indicates p25-p75, lighter blue area indicates p10-p90.

PO2016

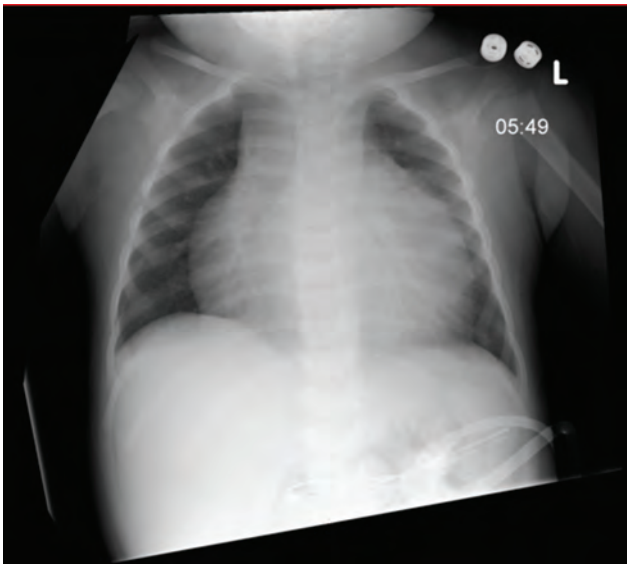
Impending Uremic Cardiac Tamponade in an Infant with ESKD

Cassandra A. Petri, Yalile Perez, Carl H. Cramer, Timothy M. Olson, Nathan Hull, Christian Hanna. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Uremic pericarditis (UP) occurs in patients with advanced chronic kidney disease (CKD) prior to dialysis initiation. The incidence of UP is rare due to advances in CKD management by providing adequate and early dialysis. Additionally, it is extremely rare in children. We present a case of a toddler with advanced CKD presenting with UP and impending cardiac tamponade. Daily intensive hemodialysis resulted in a complete resolution of the pericardial effusion.

Case Description: A 2-year-old female presented with a 3-day history of dry cough and low-grade fever. Her medical history was significant for CKD stage 5 related to branchio-oto-renal dysplasia. Her physical examination was remarkable for increased respiratory rate and the presence of pericardial friction rub. A chest radiograph demonstrated enlargement of the cardiac silhouette **(Figure 1)**. An electrocardiogram (ECG) showed sinus rhythm without ST-segment changes and an echocardiogram demonstrated a large circumferential pericardial effusion. The following day, she developed low oxygen saturation and a repeat echocardiogram demonstrated features of early tamponade physiology. Pericardiocentesis was considered but not performed because the amount of apical fluid was deemed insufficient to safely perform the procedure. Daily intensive hemodialysis was initiated and resulted in a complete resolution of the pericardial effusion within a week.

Discussion: Our case of UP in a pediatric patient is exceptionally rare. The most common presentations of this condition are fever, chest pain, and pericardial friction rub. As seen in this case, a characteristic ECG in UP does not show the diffuse ST and T wave elevations often seen in other forms of pericarditis. UP is an absolute indication for dialysis which usually results in rapid resolution of the pericardial effusion.



PO2017

When Less Is More: Phosphate Homeostasis Insights from a Microvillus Inclusion Disease Patient

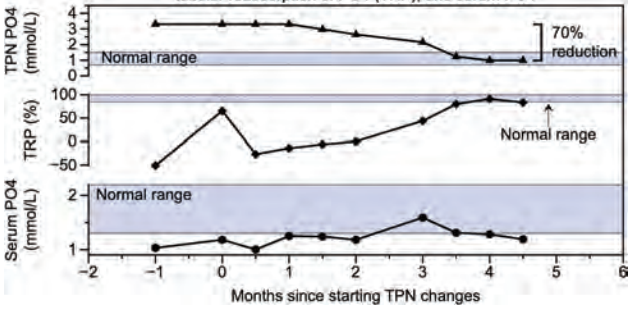
Cal Robinson,[1] Dianna Yanchis,[1,2] Elizabeth M. Garofalo,[1,2] Mathieu Lemaire.[1,2] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]SickKids Research Institute, Toronto, ON, Canada.*

Introduction: Microvillus inclusion disease (MVID) is a rare, severe congenital secretory diarrhea caused by recessive *MYO5B* or *STX3* mutations. Multiple cases of MVID with partial proximal tubule (PT) defects are reported (mostly hyperphosphaturia). While *MYO5B* is expressed in PT cells, MVID patients have normal PT brush border on kidney biopsy, and the PT defect resolves after intestinal transplant. Therefore, it is unlikely that the *MYO5B* genotype is causally related to the proximal tubulopathy.

Case Description: Like all patients diagnosed with *MYO5B*-MVID, our patient required cycled total parenteral nutrition (TPN). She was referred to nephrology at age 2 for persistent hypophosphatemia despite escalating TPN phosphate (PO4) content, and nephrocalcinosis. Urinary PO4 wasting was confirmed given the low (<65%) tubular reabsorption of phosphate (TRP). FGF-23 and PTH were elevated. A 24 hr balance study (on/off TPN) revealed that TRP was lowest and FeNa highest (~2%) while on TPN (these values were improved after 6h without TPN). It also confirmed that the negative PO4 balance was only due to renal losses. We hypothesized that high TPN electrolyte concentrations caused an obligate phosphaturic response. Gradual reductions of TPN sodium (Na^+) (by 13%), then TPN PO4 (by 70%) over 4 mo led to normalization of serum PO4 (Figure), TRP (83-91%) and FeNa (~0.3%).

Discussion: We propose that excessive TPN Na^+ and PO4 promoted a strong phosphaturic response: the combination of several physiologic factors likely explains this unusual phenomenon. Of interest, the intermittently negative TRP suggest that tubular phosphate secretion must have contributed to the massive phosphaturia. A counterintuitive reduction in TPN Na^+ and PO4 reduced renal PO4 wasting without impacting serum Na^+. We surmise that other MVID cases of PO4 wasting were also probably due to unusually high TPN electrolyte concentrations. Detailed balance studies are invaluable tools to assess complex fluid/electrolyte disorders.

Figure. Relationship between TPN PO4, tubular reabsorption of PO4 (TRP), and serum PO4



PO2018

Occurrence of Nephrogenic Systemic Fibrosis with Group II Gadolinium-Based Contrast Agent in a Pediatric Oncology Patient with AKI

Christian Hanna,[1] Amanda Scheuermann,[2] Amanda M. Hopp,[2] Kara Young,[2] John J. Dillon,[1] Scott K. Van Why.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Nephrogenic Systemic Fibrosis (NSF) is a rare systemic disorder occurring in patients with chronic kidney disease (CKD) stage IV or V, end-stage renal disease (ESRD), or acute kidney injury (AKI). It is triggered by gadolinium-based contrast agents (GBCAs) and characterized by sclerodermic skin changes from fibrosis and internal organ damage. Almost all NSF cases are associated with group I GBCAs, and only extremely rare, unconfounded cases are reported with group II agent exposure including none in children. We present a case of a female child with acute myelogenous leukemia (AML) in remission and AKI on hemodialysis who presented with NSF six weeks following a magnetic resonance imaging (MRI) with group II GBCA.

Case Description: A 10-year-old female with intermediate risk AML in remission, complicated by prolonged neutropenia with colitis, invasive fungal sinus and pulmonary infection, and AKI with a renal biopsy-proven acute tubular necrosis on intermittent hemodialysis three times a week presented to the dermatology clinic for evaluation of progressive hardening of her skin. Dermatological examination revealed diffuse, indurated, and compressible plaques involving the lower back, buttocks, posterior thighs, and lateroposterior aspects of the arms. A skin biopsy showed findings consistent with NSF. Six weeks prior to her presentation, she underwent an MRI of the brain and orbits for exotropia evaluation and received intravenous gadobutrol injection, a group II GBCA. Treatment with photopheresis twice weekly over a 2-month period resulted in a gradual improvement of her condition.

Discussion: Our case of group II GBCAs induced NSF is exceptionally rare, with no unconfounded cases in pediatrics from group II GBCAs exposure reported to date. While NSF has been reported rarely in children who received group I GBCAs, the risk of NSF in children exposed to group II or even group III GBCAs is unknown. We strongly recommend that physicians continue kidney function screening prior to group II GBCAs administration in children and carefully evaluate the risk versus benefit of using or withholding group II GBCAs for clinically indicated MRIs in patients with CKD stage IV/V, ESRD, or AKI.

PO2019

Exploring Population Pharmacokinetic Models in Patients Treated with Vancomycin During Continuous Venovenous Hemodiafiltration (CVVHDF) on Different Anticoagulant Modalities

Marcus Kirwan,[1] Mary Coyle,[2] Yvelynne P. Kelly,[2,3] Evelyn Deasy,[2] Maria Donnelly,[2,3] Deirdre M. D'Arcy.[1] *[1]Trinity College Dublin Faculty of Health Sciences, Dublin, Ireland; [2]Tallaght University Hospital, Dublin, Ireland; [3]Trinity College Dublin School of Medicine, Dublin, Ireland.*

Background: Achievement of target concentrations for antibiotics using therapeutic dose monitoring (TDM) is particularly challenging in septic patients requiring renal replacement therapy.

Methods: We conducted an exploratory population pharmacokinetic (PK) analysis in our tertiary level intensive care unit (ICU) on PK of vancomycin following intermittent infusion in critically ill patients receiving continuous venovenous haemodiafiltration (CVVHDF). Clinical, laboratory and dialysis data were extracted from the electronic healthcare record (EHR) using strict inclusion criteria. A population PK analysis was conducted with a one compartment model using the PMetrics population PK modelling package. A base structural model was developed and further analyses were performed with clinical and dialysis-related data, including regional citrate anti-coagulation (RCA) vs non-RCA, to improve model prediction through covariate inclusion. The final selected model simulated patient concentrations using probability of target attainment (PTA) plots to investigate the probability of different dosing regimens achieving target therapeutic concentrations.

Results: 107 vancomycin dosing intervals (155 levels) in 24 patients were examined. An acceptable base model was produced (Plots of observed vs. population predicted concentrations (Obs-Pred) R^2=0.78). No continuous covariates explored resulted in a clear improvement over the base model. Use of anti-coagulation modality and vasopressor use as categorical covariates resulted in similar PK parameter estimates, with a trend towards lower parameter estimate variability both with use of RCA and without vasopressor use. Simulations using PTA plots suggested that a 2 g vancomycin loading dose followed by 750 mg 12 hourly as a maintenance dose, commencing 12 hours after loading, is required to achieve adequate early target trough concentrations of at least 15 mg/L.

Conclusions: Using robust EHR data to construct a base model from a population known to have highly heterogenous antimicrobial PK, simulations based on PTA plots showed that we could achieve acceptable trough vancomycin concentrations early in treatment with a 2 g loading dose and a maintenance dose of 750 mg 12 hourly for ICU patients on CVVHDF.

PO2020

Evaluation of Gabapentinoid Dosing and Adverse Events in Patients with Advanced CKD

Drew A. Wells,[1] Kayla Washington,[1] Brandon Cave,[1] Rongshun Zhu,[2] Lokesh K. Chinthala,[2] Joanna Q. Hudson.[2,1] *[1]Methodist University Hospital, Memphis, TN; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Gabapentinoids (GP, gabapentin and pregabalin) are frequently prescribed in individuals with chronic kidney disease (CKD); however, their exclusive renal elimination warrants dose adjustments to decrease the risk of toxicity. Data to describe prescribing patterns and incidence of adverse events in advanced CKD are limited. This study evaluated prescribing patterns for GPs and whether excessive dosing was associated with increased incidence of gabapentinoid-related adverse events (GRAEs).

Methods: A retrospective analysis of adult patients admitted to the Methodist LeBonheur Healthcare system from January 2014 – October 2020 with CKD stage 4, 5, or end-stage kidney disease (ESKD) receiving GPs prior to admission or during hospitalization for at least two days was conducted. Patients were grouped based on whether the average daily dose prescribed was higher than recommended [inappropriately dosed, (ID)] or as recommended [appropriately dosed (AD)] for CKD stage. The occurrence of GRAEs (altered mental status, respiratory depression, and falls) was compared between groups. Patient characteristics and CKD stage were evaluated to determine any association with GRAEs. Hospital length of stay (LOS) was also evaluated.

Results: The 200 patients included were predominantly female (51%), black (72%), CKD 5/ESKD (84%) with a mean age 61±14 years, and prescribed gabapentin (90%) with 111 (55%) in the AD group and 89 (45%) in the ID group. Baseline characteristics were similar between groups except type 2 diabetes and neuropathy were more common in the ID group. For the primary outcome, there was no statistically significant difference in GRAEs (18% *vs*. 19%, p=0.84). GRAEs were associated with older age (mean age 65±11 years for GRAE *vs.* 60±14 years for no GRAE; p<0.001) and seizure history (14% for GRAE *vs.* 3% for no GRAE, p=0.02), but not with CKD severity. LOS was significantly longer for patients who experienced a GRAE than for those who did not (8.5 vs. 5.3 days; p=0.04).

Conclusions: In patients with advanced CKD, appropriate dosing of gabapentinoids is important to minimize the risk of adverse events, particularly in patients of older age or with a history of seizures. There is a need for prescriber education given the high frequency of inappropriate gabapentinoid dosing in patients with advanced kidney disease.

PO2021

Chronic Dosing of Voclosporin at Clinically Relevant Exposure Levels Does Not Induce Renal Fibrosis Markers in Rats

Linda M. Rehaume, Teresa D. Collins, Jennifer Cross, Robert B. Huizinga. *Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: Although prognosis of lupus nephritis (LN) has improved, the long-term outcome is still poor, with many patients progressing to end-stage renal disease. Calcineurin inhibitors (CNIs) like cyclosporine A (CsA) and tacrolimus have demonstrated benefit in LN; however, prolonged use is associated with renal fibrosis. CsA-induced fibrosis has largely been in the context of high doses required for immunosuppression in transplant patients. Voclosporin (VCS), a potent, novel CNI with a predictable PK/PD profile, is approved for treatment of LN. This study tested the hypothesis that the clinically effective dose of VCS used in LN patients, would not induce fibrosis markers in the chronic dosing rat model compared to CsA and vehicle controls.

Methods: Sprague Dawley rats (n=10/ group) on a low sodium (0.05%) diet were treated by oral gavage (QD) with VCS (4 mg/kg), cyclosporine A control (10 mg/kg) or vehicle control (5 mL/kg) for 3 or 6 weeks. Clinical chemistry was performed on serum and overnight urine. Gene expression (RT-qPCR) and histology were performed on kidneys. Data were analyzed as change from baseline.

Results: There were no significant differences in clinical measures of renal or liver function. There were no significant changes in urine protein/creatinine or fractional excretion. Serum total bilirubin and cholesterol were significantly increased in the CsA treated group compared to vehicle and VCS. At 3 weeks, there was a significant decrease in expression of *Tgfb1* and the epithelial-mesenchymal transition (EMT) marker *Cdh2* (N-cadherin) in VCS treated animals compared to vehicle and CsA, and significant decreases in expression of the EMT regulators, *Snai1* (SNAIL) and *Snai2* (SLUG), and the extracellular matrix components (ECM) *Col1a1*, *Col3a1* and *Vim* in the VCS treated group. At 6 weeks, trends between groups remained, and there were significant decreases in *Tgfb2* and *Col3a1* in the VCS treated group. At 6 weeks, there were no differences in renal histopathology.

Conclusions: This study shows that the clinically relevant dose of voclosporin does not induce renal fibrosis markers in rats, in contrast to the CsA control. Additionally, voclosporin may protect against renal EMT and ECM deposition, which are associated with CsA. Collection of data from a two-year continuation renal biopsy sub-study of AURORA-1 is ongoing.

The Effect on Renal Function of Patients on HIV Pre-Exposure Prophylaxis (PrEP)

Alfredo B. Tiu,[1,2] David J. Looney.[1,2] *[1]VA San Diego Healthcare System, San Diego, CA; [2]University of California San Diego, La Jolla, CA.*

Background: Tenofovir, a nucleotide reverse transcriptase inhibitor, is used in management of hepatitis B and as part of a highly active antiretroviral medication regiments for HIV infected individuals. Tenofovir disoproxil fumarate (TDF) is one of two tenofovir nucleotide analog. The U.S. Food and Drug Administration (FDA) recommended on 16 July 2012 the use of tenofovir-emtricitabine combination medication as pre-exposure prophylaxis (PrEP) against HIV. TDF is cleared through glomerular filtration and tubular secretion. Its nephrotoxicity includes renal tubular acidosis type 2, acute tubular necrosis, and tubulointerstitial disease. Reported data regarding effect of renal function from tenofovir based PrEP are less than 24 months of follow-up. This study evaluates the effect on renal function in patients receiving TDF for PrEP over more than 24 months because it can affect the future of PrEP with more expensive analog of tenofovir (TAF) promoted as less nephrotoxic and other PrEP medications.

Methods: VA San Diego database on adults receiving PrEP is the source for this data. Serum creatinine and estimated glomerular filtration rate (eGFR) are obtained as part of PrEP protocol which started in 2014. The PrEP protocol follows the Centers for Disease Control and Prevention (CDC) recommendations of pre-initiation serum creatinine and eGFR then 3 months after the initiation and annually thereafter. Acute kidney injury is define as an increase in serum creatinine by > 0.3mg/DL within 48 hours or increase in serum creatinine to > 1.5 times baseline based on the Kidney Disease: Improving Global Outcomes (KDIGO) guidelines which is the most recent preferred definition and used more consistently in clinical studies (1,2).

Results: Since 2014, 103 individuals are in the PrEP program. At one year, there are 87 individuals and none meets the criteria for AKI. After 2 years, there are 73 patients and 2 meet the criteria of AKI. Their kidney function returned back to baseline creatinine one month later. 55 individuals completed 3 years on PrEP and none meets the criteria for AKI. 41 individuals completed 4 years of PrEP and none meets criteria for AKI. The average change of eGFR at one year is 7.1%, 7.5% at 2 years, 8.6% at 3 years and 8.1% at 4 years.

Conclusions: Serum creatinine is stable on PrEP and none meet KDIGO AKI definition. The decrease in eGFR is not significant to warrant a change of TDF based PrEP.

Tenofovir Kidney Clearance Predicted by Glomerular and Tubular Secretory Functions

Michael L. Granda, Catherine K. Yeung, David K. Prince, Andrew N. Hoofnagle, Bryan R. Kestenbaum. Kestenbaum *University of Washington, Seattle, WA.*

Background: Proximal tubular secretion is the primary kidney mechanism for eliminating most prescribed medications. Yet, kidney drug dosing is based on estimates of the glomerular filtration rate (GFR). In an empiric pharmacokinetic study, we compared GFR and secreted endogenous solute clearances for predicting the kidney elimination of tenofovir disoproxil fumarate (TDF), a drug with complex kidney handling.

Methods: We recruited 27 adult patients across a wide range of kidney function. Exclusion criteria were use of tenofovir or a secretory antagonist (cimetidine, digoxin, probenecid), dialysis, nephrotic syndrome, or cirrhosis. We administered a single 125mg oral dose of TDF and estimated its kidney clearance from the area under the plasma time concentration curve and urine drug recovery. We measured GFR by iohexol clearance (iGFR) and estimated secretory function from a 10-hour urine collection with mass-spectroscopy measurements of endogenous secretory solutes. We used linear regression, leave one out cross-validation, root mean squared error, and mean percentage error to describe agreement between kidney functions and TDF clearance.

Results: Mean age of the study population was 55 ±15 years, 63% were male, and median iGFR was 78 ml/min/1.73m^2 (IQR 52, 99 ml/min/1.73m^2); ten participants (37%) had an iGFR <60 ml/min/1.73m^2. The mean percentage error (MPE) between observed and iGFR-predicted TDF kidney clearance was 26.7% (Table). The clearances of four endogenous secretory solutes improved the prediction of TDF clearance beyond that of iGFR: cinnamoylglycine, indoxyl sulfate, isovalerylglycine, and tiglylglycine. Combining solute clearance and iGFR results in a lower overall mean percentage error in TDF kidney clearance prediction.

Conclusions: Measurements of secretory solute clearance represent a potential future strategy for improving kidney drug dosing.

Funding: NIDDK Support

Table. Prediction of kidney tenofovir disoproxil fumarate clearance.

Predictor	Root mean squared error (ml/min)	Mean percentage error (%)	Mean percentage error (%) – combined with iGFR[c]
Estimated GFR[a]	68.0	34.5	
Iohexol GFR	60.2	26.7	
Secretory solute clearance[b]			
Cinnamoylglycine	51.9	22.8*	22.4
Indoxylsulfate	43.8	24.0*	22.5
Isovalerylglycine	44.9	32.0*	22.3
Kynurenic acid	76.6	45.0	24.5
P-cresol sulfate	69.8	35.4	23.4
Pyridoxic acid	38.6	22.1	19.6
Tiglylglycine	47.9	30.6*	21.5
Xanthosine	77.4	48.9	24.1

Lower root mean squared errors and mean percentage errors indicate better prediction.

[a] Estimated GFR calculated using the 2009 CKD-EPI equation.

[b] 10-hour timed urine clearance of secretory solutes.

[c] Multiple linear regression including secretory solute AND iGFR as predictors.

**Significantly improves iGFR prediction of kidney tenofovir clearance (p <0.01).*

Subcutaneous VIS649, an APRIL-Neutralizing Antibody: Preliminary Pharmacokinetic (PK) and Pharmacodynamic (PD) Results of VIS649-102, a Phase 1, Single Ascending Dose Study in Healthy Volunteers

Xiaoyan Zhang,[1] Yanlin Wang,[1] Jill Yarbrough,[2] Asher D. Schachter,[2] Susan E. Sloan.[2] *[1]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [2]Visterra, Inc., Waltham, MA.*

Background: Immunoglobulin A (IgA) nephropathy (IgAN) is in part driven by A proliferation-inducing ligand (APRIL). VIS649, a humanized immunoglobulin G (IgG2) monoclonal antibody that blocks APRIL, is currently in Phase 2 clinical development as a potential treatment for IgAN. The preliminary results of VIS649-102, a Phase 1 single ascending dose study of subcutaneously (SC) administered VIS649 in healthy volunteers is reported here.

Methods: VIS649 (200 mg/ mL liquid) was administered as a single dose via the SC route to four cohorts of 12 healthy adult volunteers each. Doses were 200 mg (1x1 mL SC), 400 mg (2x1 mL SC injections), 400 mg (1x2 mL SC injection), and 600 mg (1x2 mL and 1x 1 mL SC injection).

Results: SC-administered VIS649 was well tolerated, with no adverse events that led to study discontinuation, and no injection site reactions. Treatment Emergent AEs (TEAEs) were all mild and all resolved. There was no clinically relevant effect of treatment on laboratory tests, vital signs, or physical examinations. Preliminary PK results show bioavailability of approximately 75% compared to intravenous (IV)-administered VIS649 (Y. Suzuki et al, ERA-EDTA 2021). Single SC doses of either 400 mg or 600 mg suppress total IgA by up to approximately 50-55% from baseline values at 8 weeks post-dose. Single doses of 200 mg SC suppressed IgA by approximately 40% by 6 weeks post-dose. Overall, these preliminary results with SC VIS649 indicate a similar degree and

trajectory of IgA suppression as that achieved by the IV formulation in healthy volunteers, in which the 6 mg/kg single IV dose suppressed IgA by approximately 50% from baseline values at 8 weeks post-dose (Figure 1).

Conclusions: Preliminary results of this Ph1 study of SC-administered VIS649 demonstrated acceptable safety, tolerability, amd bioavailability, and suppressed total IgA by approximately 50-55% from baseline, comparable to IV doses.

Association of Oxypurinol Exposure with Progression of CKD: Pre-Specified Substudy Results from the CKD-FIX Trial

Anushree Tiku,[1] Daniel Wright,[2] Richard O. Day,[3] Sophie Stocker.[4] CKD-FIX Study Group Trial Steering Committee *[1]The George Institute for Global Health, Newtown, NSW, Australia; [2]University of Otago, Dunedin, New Zealand; [3]University of New South Wales, Sydney, NSW, Australia; [4]The University of Sydney, Sydney, NSW, Australia.*

Background: The CKD-FIX trial evaluated the effect of allopurinol on eGFR slope over 104 weeks in patients with chronic kidney disease (CKD) and risk of progression. The aim of this pre-specified substudy was to assess whether exposure to oxypurinol, the active metabolite of allopurinol, predicts change in eGFR.

Methods: Adults with CKD stage 3 or 4 (n=369), no history of gout, and high risk of progression (urinary albumin-to-creatinine ratio ≥265 mg/g or eGFR decrease ≥3.0 mL/min/1.73 m^2 in the preceding year) were randomized to receive allopurinol (n=185) or placebo (n=184). Plasma oxypurinol concentrations were determined at weeks 16, 24, 40, 56, 72, 88 and 104 post-initiation of allopurinol. Non-compartmental pharmacokinetic analysis of oxypurinol concentrations was performed to determine oxypurinol exposure (area under the concentration time curve) using the SimBiology module of MATLAB. The association between eGFR slope and oxypurinol exposure was assessed using least-squares estimates linear regression.

Results: Overall 155 (84%) patients (mean eGFR 31.7 mL/min/1.73 m^2, mean serum urate 8.0 mg/dL) received allopurinol and had ≥1 plasma oxypurinol concentration available. At the end of the 12-week dose-escalation phase, the majority of patents (123; 79%) were prescribed allopurinol 300 mg and the remainder 100 mg (13; 8%) or 200 mg (19; 12%). The mean (standard deviation) eGFR slope and reduction in serum urate concentration were -3.32 (5.02) mL/min/1.73 m^2/year and 2.6 (0.14) mg/dL, respectively. Based on a total of 819 plasma oxypurinol concentrations (median n=6 per patient), there was no correlation between eGFR slope and total oxypurinol exposure (P=0.93), including after adjusting for allopurinol dose (P=0.99). These results were consistent across the three allopurinol dosing regimens. Greater oxypurinol exposure was associated with larger reduction in serum urate concentrations (P<0.0001).

Conclusions: In CKD-FIX participants, exposure to oxypurinol was not associated with change in eGFR. However, reduction in serum urate concentration was dependent on plasma oxypurinol exposure.

Proof-of-Concept Study of Oxalate-Consuming Synthetic Biotic Medicine SYNB8802 in Enteric Hyperoxaluria after Roux-en-Y Surgery

Marja Puurunen,[1] William Denney,[2] Mesaki K. Ndugga-Kabuye,[1] Andrew Marsh,[1] David Lubkowicz,[1] Caroline B. Kurtz,[1] Aoife M. Brennan,[1] Richard Riese.[1] *[1]Synlogic, Cambridge, MA; [2]Human Predictions LLC, Cambridge, MA.*

Background: High urinary oxalate levels (UOx) in patients with enteric hyperoxaluria (EH) can lead to recurrent kidney stones, nephrocalcinosis and chronic kidney disease. SYNB8802 is an engineered *E. coli* Nissle 1917 that contains an oxalate degradation pathway which converts oxalate to formate within the gastrointestinal (GI) tract, thereby reducing urinary oxalate. SYNB8802 is an oral, non-colonizing live biotherapeutic developed for the treatment of EH. SYNB8802 is explored in a Phase 1a/b study in healthy volunteers (HV) and Roux-en-Y (RYGB) patients with hyperoxaluria.
